Document Version Log

Human Health Risk Assessment
Operable Unit 5 Remedial Investigation
Tar Creek Superfund Site, Ottawa County, Oklahoma

Version	Date	Description
1.0	March 2020	This version represents the initial comprehensive submittal of the Human Health Risk Assessment report. This version has been prepared in consultation with the U.S. Environmental Protection Agency (EPA), with input from Tar Creek Superfund Site stakeholder representatives through conference calls, meetings, and interim deliverables.
1.1	May 2020	This version addresses EPA review comments on the initial submittal.

Note: As each new version is published, a description of the changes made will be included in this table.

Acknowledgements

EPA Region 6 and CH2M would like to express their appreciation to a number of organizations and individuals who contributed to the significant efforts of collecting existing site information and data that supported this project, and in the collection of new data. In particular, we would like to thank each American Indian Nation or Tribe within the region of the Tar Creek Superfund Site that helped us with this effort, including:

- Cherokee Nation
- Eastern Shawnee Tribe of Oklahoma
- Miami Tribe of Oklahoma
- Modoc Tribe of Oklahoma
- Ottawa Tribe of Oklahoma
- Peoria Tribe of Indians of Oklahoma
- Quapaw Nation
- Seneca-Cayuga Nation
- Wyandotte Nation

We would also like to thank the following federal, state, local, and other contributing stakeholders:

- Bureau of Indian Affairs
- Dr. F.E. Kirschner, LPG, LPHG, AESE, Inc.
- Dr. Robert Nairn, University of Oklahoma
- Ecological Specialists, Inc.
- Local Environmental Action Demanded Agency
- Paddlefish Research Center/Oklahoma Department of Wildlife Conservation
- The State of Kansas
- The State of Missouri
- The State of Oklahoma
- U. S. Environmental Protection Agency Region 7
- U.S. Fish and Wildlife Service
- U.S. Geological Survey

Executive Summary

This Human Health Risk Assessment (HHRA) was prepared by CH2M HILL, Inc. (CH2M) for the U.S. Environmental Protection Agency (EPA) under EPA Region 6 Remedial Action Contract Number (No.) EP-W-06-021, Task Order 079-RICO-06TS. This HHRA report describes the methods, assumptions, and results of the HHRA performed for Operable Unit 5 (OU5) of the Tar Creek Superfund Site located in Ottawa County, Oklahoma (the site). The site is a former lead and zinc mining area consisting of the Oklahoma portion of the Tri-State Mining District (TSMD), which includes portions of southwestern Missouri, southeastern Kansas, and northeastern Oklahoma. The OU5 study area covers portions of seven watersheds that occur within the TSMD, and as such, extends from northeastern Oklahoma into southwestern Missouri and southeastern Kansas. The study area location is shown on Figure ES-1.

The purpose of the HHRA is to evaluate the potential risks associated with potential exposures to chemicals of potential concern (COPCs) by human receptors identified in the OU5 study area under current and reasonably foreseeable future land use conditions. This HHRA was conducted consistent with EPA Superfund HHRA and other supplemental guidance documents. In addition, input from site stakeholders was considered in the development of the conceptual exposure model and exposure assumptions for characterization of exposures to tribal members and citizens and the general public. EPA's Technical Review Workgroup for Metals and Asbestos Lead Committee was also consulted regarding the approach for lead evaluation for the OU5 study area.

This HHRA evaluates potential exposures to sediment, surface water, mine discharge, and aquatic biota at the site, and estimates potential risk for the following receptors:

- Tribal lifeway (adults and children)
- Aquatic workers (adults only)
- General public (adults and children)

Exposure scenarios evaluated for each exposure medium include the following:

- **Surface water/sediment (rivers and creeks).** Hunting/fishing/gathering and recreational activities (fishing and wading) (incidental ingestion and dermal contact) for tribal lifeway activities, work activities for aquatic workers (for example, hatchery or environmental employees), and recreational activities (swimming/wading/fishing/hunting) for the general public.
- **Surface water (rivers and creeks).** Potable use (ingestion and dermal contact) for tribal lifeway activities and general public recreational activities.
- **Surface water (rivers and creeks).** Use of surface water in a sweat lodge (ingestion, dermal contact, and inhalation of water vapors) as part of tribal lifeway activities.
- **Aquatic biota (fish, shellfish, aquatic plants, amphibians/aquatic reptiles, and semi-aquatic mammals).** Food consumption (ingestion) as part of tribal lifeway activities, food consumption (ingestion - fish only) by the general public, and medicinal use (dermal - aquatic plants only) as part of tribal lifeway activities.

In addition to the above, an evaluation of mine discharge was performed as part of the uncertainty analysis in this HHRA using the surface water scenario for both tribal lifeway and general public receptors. Mine discharge has been found to occur in a few locations in the OU5 watersheds; however, the potential for exposure to mine discharge is expected to be highly limited because of its intermittent occurrence, typical low flow rates, and relatively low accessibility.

Historical analytical metals data (data collected by various investigators and sampling programs before 2017), data obtained during the 2017 remedial investigation (to fill data gaps identified in the Data Gap Summary Report [CH2M, 2017]), and 2017 fish data provided by the Oklahoma Department of Environmental Quality (ODEQ) were combined and used in the HHRA. The combined data for the HHRA were grouped by watershed and exposure medium.

Using the data groupings identified for each watershed and exposure medium, potential exposures to COPCs were quantified based on exposure factors developed using EPA guidance documents, literature describing Native American exposure characteristics, and inputs from the Quapaw Nation and TCTCIT. For metals other than lead, the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) specifies an acceptable site excess lifetime cancer risk (ELCR) range of one in a million to one in ten thousand (1×10^{-6} to 1×10^{-4}). Generally, remedial actions are not warranted for site media with an ELCR of 1×10^{-4} or a hazard index (HI) of 1 or less, although it may be warranted if other site-specific information suggests to risk managers that action is appropriate.

In addition, potential unacceptable risk associated with exposure to lead in environmental media within the OU5 study area was evaluated separately as the standard approach for the evaluation of lead (using biokinetic modeling) is different from other chemicals. Potential lead exposure was evaluated using the Integrated Exposure Uptake Biokinetic (IEUBK) Model for Lead in Children, Windows, Version 1.1, Build 11 (EPA, 2010) and the Adult Lead Methodology (ALM) (EPA, 2017a). The results of the IEUBK and ALM were expressed as follows:

- The IEUBK model results are expressed as the predicted geometric mean (GM) blood lead level (BLL) for children and the percentage of the child population with potential BLLs above the target BLL. Based on the EPA Office of Land and Emergency Management policy (EPA, 1994a), which strives to reduce lead exposure levels so there is no more than a 5 percent probability that children exposed to lead will exceed a BLL of 10 micrograms per deciliter (µg/dL), 10 µg/dL was used as a target BLL and two additional lower target BLLs (5 and 8 µg/dL) were used to provide additional information for comparison.
- The ALM model was used to calculate potential BLLs for the aquatic worker scenario. The model results are expressed as the predicted GM BLL, the corresponding 95th percentile fetal BLLs, and the probability that fetuses exposed to lead will exceed a BLL above the same set of target BLLs (5, 8, and 10 µg/dL) used in the IEUBK model.
- Children (and fetuses) are more sensitive to the effects of lead than adults. Consistent with the standard EPA approach, adult exposures to lead are not evaluated using the ALM when children are evaluated within the same receptor type (i.e., adult tribal lifeway and adult general public exposures to lead were not modeled since child exposures to lead were modeled for these receptor groups).

Based on the risk estimates and output from the lead models, preliminary chemicals of concern (COCs) were identified. Preliminary COCs are chemicals that drive risks based on the exceedance of EPA-acceptable ELCR and/or HI and the lead model output, without regard for background levels or relation to sources associated with historical site activities. The list of preliminary COCs was refined using two additional considerations to identify final COCs: (1) background comparisons, and (2) attribution to mine-related contamination. Final COCs are listed in Table ES-1; specific health endpoints associated with final COCs are summarized in Table ES-2.

The methodologies and assumptions used in an HHRA have inherent as well as site-specific uncertainties. Section 6.6 summarizes uncertainties and their effect on the estimate of potential health outcomes for site-specific scenarios that were of interest to tribal stakeholders. While it is theoretically possible that the HHRA leads to underestimates of potential health outcome, the use of numerous upper-bound assumptions in this HHRA most likely results in conservative estimates.

Table ES-1. Final COCs for Tar Creek OU5

Tar Creek Superfund Site Operable Unit 5 HHRA

Ottawa County, Oklahoma

Final COCs	Sitewide (Biota Only)	Elm Creek	Tar Creek	Neosho River	Beaver Creek	Lost Creek	Lower Spring River
Sediment							
Cadmium		TL	TL, AW		TL		
Lead		TL, AW, GP	TL, AW, GP		TL, GP		TL, GP
Zinc		TL	TL		TL		
Surface Water							
Antimony		TL					
Arsenic			TL, AW, GP				
Barium				TL			
Cadmium		TL, AW, GP	TL, GP		TL		
Cobalt			TL, AW, GP		TL		
Iron			TL, GP	TL			
Lead[a]		TL, GP	TL, GP		TL, GP		
Manganese			TL, AW, GP				
Nickel		TL	TL, AW		TL		
Zinc		TL	TL				
Biota[b]							
Barium	TL						
Cadmium	TL						
Copper	TL						
Lead	TL, GP						
Nickel	TL						
Silver	TL						
Zinc	TL						

Notes:

[a] Lead in surface water was not evaluated for aquatic workers because of the limitations of the ALM.

[b] Final COCs were identified based on sitewide dataset.

Final COCs are identified for the following receptors: TL = Tribal Lifeway, AW = Aquatic Worker, GP = General Public.

ALM = Adult Lead Methodology

COC = chemical of concern

HHRA = human health risk assessment

OU5 = Operable Unit 5

Table ES-2. Summary of Exceedances of EPA-Acceptable Risk by Receptors/Watersheds

Tar Creek Superfund Site Operable Unit 5 HHRA

Ottawa County, Oklahoma

Receptor Scenario	Sitewide (Biota only)	Watershed					
		Elm Creek	Tar Creek	Neosho River	Beaver Creek	Lost Creek	Lower Spring River
Sediment							
Tribal Lifeway (Child) [a]		HI [b] (Cd, Zn) Lead [c]	HI [b] (Cd, Zn) Lead [c]	None	HI [b] (Cd, Zn) Lead [c]	None	Lead [c]
Aquatic Worker		Lead [c]	HI [b] (Cd) Lead [c]	None	None	None	None
General Public (Child) [a]		Lead [c]	Lead [c]	None	Lead [c]	None	Lead [c]
Surface Water							
Tribal Lifeway (Child) [a]		HI [b] (Sb, Cd, Ni, Zn) ELCR [d] (Cd, Ni) Lead [c]	HI [b] (As, Cd, Co, Fe, Mn, Ni, Zn) ELCR [d] (As, Cd, Co, Ni) Lead [c]	HI [b] (Ba, Fe)	HI [b] (Cd, Co, Ni) ELCR [d] (Cd, Co, Ni) Lead [c]	None	None
Aquatic Worker		HI [b] (Cd)	HI [b] (As, Co, Mn, Ni)	None	None	None	None
General Public (Child) [a]		HI [b] (Cd) Lead [c]	HI [b] (As, Cd, Co, Fe, Mn) ELCR [d] (As) Lead [c]	None	Lead [c]	None	None
Biota (Sitewide) [e]							
Tribal Lifeway (Child) [a]	HI [b, e] (Ba, Cd, Cu, Ni, Ag, Zn) Lead [c, e]						
General Public (Child) [a]	Lead [c, e]						

Notes:

[a] Conclusions for target organ HI are based on the results of child receptors because the child exposure scenario yields a higher non-carcinogenic HI than the adult exposure scenario, and child receptors are more sensitive to lead than adult receptors.

[b] Exceedance of EPA-acceptable target organ HI of 1.

[c] Exceedance of target probability of BLL above 5 µg/dL.

[d] Exceedance of EPA-acceptable site ELCR range (1×10^{-6} to 1×10^{-4}).

[e] Biota risk estimates were based on sitewide data.

Chemicals exceeding EPA-acceptable risks are termed "Preliminary Chemicals of Concern" without consideration of background levels or attribution to mining wastes. Background comparison and the nature of mining-related contamination were used to refine the list of preliminary COCs to identify final COCs. Final COCs that exceed EPA-acceptable risk levels are summarized in this table.

µg/dL = microgram(s) per deciliter
BLL = blood lead level
COC = chemical of concern
ELCR = excess lifetime cancer risk
HHRA = human health risk assessment
HI = hazard index
Ag = silver
Ba = barium
Cd = cadmium
Co = cobalt
Cu = copper
Fe = iron
Ni = nickel
Sb = antimony
Zn = zinc

SECTION 1

Introduction

This Human Health Risk Assessment (HHRA) was prepared by CH2M HILL, Inc. (CH2M)[1] for the U.S. Environmental Protection Agency (EPA) under EPA Region 6 Remedial Action Contract Number (No.) EP-W-06-021, Task Order 079-RICO-06TS. This HHRA report describes the methods, assumptions, and results of the HHRA performed for Operable Unit 5 (OU5) of the Tar Creek Superfund Site located in Ottawa County, Oklahoma (the site). The site is a former lead and zinc mining area consisting of the Oklahoma portion of the Tri-State Mining District (TSMD), which includes portions of southwestern Missouri, southeastern Kansas, and northeastern Oklahoma. The OU5 study area covers the watersheds that occur within the TSMD and, as such, extends from northeastern Oklahoma into southwestern Missouri and southeastern Kansas. The study area location is shown on Figure 1-1.

This HHRA supports the remedial investigation (RI) conducted for the Tar Creek Superfund Site and serves as a companion report to the *Remedial Investigation Report, Tar Creek Superfund Site Operable Unit 5, Ottawa County, Oklahoma, Task Order No. 079-RICO-06TS*, which is submitted under separate cover (CH2M, 2020; "the RI report"). Data presented in the RI report are used in this HHRA and referenced herein where needed for background and supporting information.

1.1 Purpose and Overview

This report presents the HHRA for potential exposure to sediment, surface water, mine discharge, and aquatic biota. The purpose of the HHRA is to evaluate the potential risks associated with potential exposures by current and future receptors to chemicals at the site.

The HHRA was conducted in accordance with EPA HHRA guidance. The following are the primary guidance documents used to prepare this HHRA:

- Risk Assessment Guidance for Superfund (RAGS). Volume I, Human Health Evaluation Manual (HHEM) (Part A) (EPA, 1989)
- RAGS. Volume I, HHEM (Part B, Development of Risk-based Preliminary Remediation Goals) (EPA, 1991)
- RAGS. Volume I, HHEM (Part D, Standardized Planning, Reporting and Review of Superfund Risk Assessments) (EPA, 2001)
- RAGS. Volume I, HHEM (Part E, Supplemental Guidance for Dermal Risk Assessment (EPA, 2004)
- RAGS. Volume I, HHEM (Part F, Supplemental Guidance for Inhalation Risk Assessment) (EPA, 2009a)
- Guidance for Risk Characterization (EPA, 1995)
- Guidelines for Carcinogen Risk Assessment (EPA, 2005a)
- Framework for Metals Risk Assessment (EPA, 2007a)
- Exposure Factors Handbook (EFH), 2011 Edition with updates (EPA, 2011)
- HHEM, Supplemental Guidance: Update of Standard Default Exposure Factors (EPA, 2014)

[1] CH2M HILL (CH2M) was acquired by Jacobs Engineering Group Inc. (Jacobs) on December 15, 2017. CH2M is now a wholly owned direct subsidiary of Jacobs.

Additionally, the following lead-specific EPA guidance documents and directives were used in the analysis of lead exposure (Appendix E):

- Office of Solid Waste and Emergency Response (OSWER) Directive: Revised Interim Soil Lead Guidance for Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) Sites and Resource Conservation and Recovery Act (RCRA) Corrective Action Facilities (EPA, 1994a)
- Guidance Manual for the Integrated Exposure Uptake Biokinetic (IEUBK) Model for Lead in Children (EPA, 1994b)
- User's Guide for the IEUBK Model for Lead in Children, Windows (EPA, 2007b)
- Recommendations of the Technical Review Workgroup for Lead for an Approach to Assessing Risks Associated with Adult Exposure to Lead in Soil (EPA, 2003a)
- Assessing Intermittent or Variable Exposures at Lead Sites (EPA, 2003b)
- IEUBK Model for Lead in Children (EPA, 2010)
- Office of Land and Emergency Management (OLEM) Directive 9200.2-167. Memorandum: Updated Scientific Considerations for Lead in Soil Cleanups (EPA, 2016a)
- OLEM Directive 9285.6-56. Memorandum: Update of the Adult Lead Methodology's Default Baseline Blood Lead Concentration and Geometric Standard Deviation Parameters (EPA, 2017b)
- OLEM Directive 9200.2-177. Memorandum: Recommendations for Default Age Range in the IEUBK Model (EPA, 2017c)

Input from site stakeholders was considered in the development of the conceptual exposure model (CEM) and interim deliverables for the HHRA. A full list of meetings and correspondence with stakeholders can be found in Appendix A of the RI report. In addition, EPA's Technical Review Workgroup for Metals and Asbestos Lead Committee was consulted regarding the approach for lead evaluation for the OU5 study area.

In addition to the above EPA guidance documents and stakeholder input, the following reports were used to characterize exposure to media within the OU5 study area by tribal members and citizens of the surrounding communities and general public.

- Quapaw Traditional Lifeways Scenario. Prepared by Barbara Harper, PhD, DABT. AESE, Inc. (Harper, 2008)
- Traditional Tribal Subsistence Exposure Scenario and Risk Assessment Guidance Manual. Report of Grant Number EPA-STAR-J1-R831046 (Harper, 2007)
- The Spokane Tribe's Multipathway Subsistence Exposure Scenario and Screening Level Reasonable Maximum Exposure (RME) (Harper et al., 2002)
- Shoshone-Bannock Exposure Scenario for Use in Risk Assessment: Traditional Subsistence Lifeways. Shoshone-Bannock Tribes Environmental Waste Management Program (S-B EWMP, 2016)
- A longitudinal study of mercury exposure associated with consumption of freshwater fish from a reservoir in rural south central USA (Dong et al., 2015)
- Edible wild plants growing in contaminated floodplains: implications for the issuance of tribal consumption advisories within the Grand Lake watershed of northeastern Oklahoma, USA (Garvin et al., 2017)
- Final Human Health Risk Assessment for the Coeur d' Alene Basin Extending from Harrison to Mullan on the Coeur d' Alene River and Tributaries, Remedial Investigation/Feasibility Study (RI/FS). (TerraGraphics, 2001).

- Zinc and lead poisoning in wild birds in the Tri-State Mining District (Oklahoma, Kansas, and Missouri) (Beyer et al., 2004)
- Pancreatitis in wild zinc-poisoned waterfowl. (Sileo et al., 2003)
- Adverse Health Effects in Canada Geese (*Branta canadensis*) Associated with Waste from Zinc and Lead Mines in the Tri-State Mining District (Kansas, Oklahoma, and Missouri, U.S.A.) (van de Merwe et al., 2011)

1.2 Report Organization

This report is organized as follows:

- **Section 1, Introduction.** Provides an overview of the purpose, regulatory framework, and scope of work for this HHRA.
- **Section 2, Site Characteristics and Potential Receptors.** Discusses site description, site history, demographics, and land use.
- **Section 3, Data Evaluation.** Describes the analytical data used in the HHRA, development of data groupings, and methods and results of the chemical of potential concern (COPC) selection process.
- **Section 4, Exposure Assessment.** Discusses the conceptual site model (CSM) including identification and characterization of potential exposure scenarios, exposure pathways quantified in the HHRA, and quantification of exposure including calculation of exposure point concentrations (EPCs), identification of exposure factors, and estimation of COPC intakes.
- **Section 5, Toxicity Assessment.** Describes sources of quantitative oral and inhalation toxicity values (non-carcinogenic and carcinogenic) and derivation of dermal toxicity values.
- **Section 6, Risk Characterization.** Describes the methods used to characterize non-carcinogenic hazard and carcinogenic risk by integrating information provided in the exposure assessment (Section 4) and toxicity assessment (Section 5). Presents numerical estimation of hazard and risk for the potential exposure scenarios and discusses uncertainties associated with the HHRA outcomes. Analysis of lead was performed separately and is presented in Appendix E.
- **Section 7, References.** Provides a list of references used in preparing the HHRA.
- **Tables and Figures.** Tables and figures are located at the end of the HHRA behind the Tables and Figures dividers.
- **Appendices.** The following appendices, providing supplemental and supporting information, are also included in this report:
  - Appendix A, Response to Comments on Interim HHRA Deliverables
  - Appendix B, RAGS Part D Tables
  - Appendix C, Data Grouping and Sample Lists
  - Appendix D, ProUCL Output
  - Appendix E, Analysis of Lead Exposure
  - Appendix F, Uncertainty Analysis

SECTION 2

Site Characteristics and Potential Receptors

Generally, OU5 is defined by EPA Region 6 as sediments and surface water in perennially flowing creeks, streams, and rivers that may be impacted by historical mining activities within the Oklahoma portion of the TSMD and upstream portions in Kansas and Missouri. The potential exposures addressed under OU5 are associated with the aquatic environment. Terrestrial small game and large game ingestion scenarios were addressed under the OU4 HHRA (EPA, 2006). The definition of OU5 has been further refined by EPA Regions 6 and 7 for the purposes of conducting the RI and HHRA to include the following seven specific watersheds that flow downstream from EPA Region 7 states (Kansas and Missouri) into EPA Region 6 (Oklahoma):

- Fourmile Creek (an upstream background or reference location unaffected by historical mining activities)
- Elm Creek
- Tar Creek (including Lytle Creek)
- Neosho River
- Beaver Creek
- Lost Creek
- Lower Spring River (the portion of Spring River downstream of Empire Lake in Kansas)

Locations of these seven watersheds are illustrated on Figure 2-1. The site description, site history, current/potential future land uses, and current/potential future receptors are summarized in the following subsections.

2.1 Site Description

The Tar Creek Superfund Site itself has no clearly defined boundaries, but consists of areas within Ottawa County, Oklahoma, that have been impacted by historical mining wastes. Historical lead and zinc mining was conducted in an area known as the Picher Field in northern Ottawa County where hazardous substances from mining or milling were stored or disposed. The principal communities within the mining area include Commerce and Quapaw, and the former Oklahoma mining towns of Cardin, Picher, and Hockerville. Similar historical mining and waste disposal practices were performed in southeastern Kansas and southwestern Missouri; these areas combined with the Tar Creek Superfund Site in northeast Oklahoma comprise an area known as the TSMD. The TSMD, the OU5 study area boundary, EPA regional and state boundaries, and the various mining sites are depicted on Figure 2-2.

2.2 Site History

The TSMD consists of an area where widespread historical lead and zinc mining operations were conducted throughout the Tri-State region of Kansas and Missouri (EPA Region 7 states), and Oklahoma (EPA Region 6). The TSMD includes a total of four National Priorities List Superfund Sites in Missouri, Kansas, and Oklahoma as follows: the Cherokee County Site, Cherokee County, Kansas; the Oronogo-Duenweg Mining Belt Site, Jasper County, Missouri; the Newton County Mine Tailings Site, Newton County, Missouri; and the Tar Creek Superfund Site, Ottawa County, Oklahoma (MESL, 2010) as shown on Figure 2-2. Historical information on the TSMD and Tar Creek Superfund Site can be found in Section 2.2 of the RI report.

2.3 Demographics

Table 2-1 presents demographic data for the four counties located within the TSMD (Ottawa County, Oklahoma; Cherokee County, Kansas; Newton County, Missouri; and Jasper County, Missouri). The counties in the OU5 study area and the TSMD are shown on Figure 2-2.

2.4 Land Use and Designated Beneficial Use of Water within the OU5 Study Area

Pastureland, hay, or expanding residential development is the main land use in the OU5 study area, with limited industrial or commercial operations. Nearly all the native prairie and most of the forests are gone, except in riparian areas. Much of the historic Picher Mining District no longer supports vegetation due to extensive tailings remaining on the surface from the mining operations (Woods et al., 2005).

In Ottawa County, agriculture is the primary industry. Agriculture is very diversified in Ottawa County. With an annual rainfall of 40 inches, grain crops are grown with a major portion of the wheat ground double-cropped back to soybeans. Crops grown include soybeans, wheat, milo, corn, and fescue seed. Also produced are blueberries and mushrooms. In livestock production, Ottawa County has cow-calf and stocker operations. They graze mostly on fescue and Bermuda grass pastures, but there are still a few areas of native grasses in the county. Ottawa County also has chicken, turkey, dairy, and hog farming operations (Oklahoma Farm Bureau, 2018). Although it is possible that surface water from watersheds within the OU5 study area may be used for the irrigation of crops or as drinking water for livestock, its use for these purposes is unknown and expected to be unlikely due to the extent of annual rainfall in the area. Since irrigation of crops using surface water is unlikely, it was evaluated qualitatively in the HHRA.

Indigenous subsistence land uses by tribal members and citizens in the OU5 study area include hunting, gathering foods and medicine, and fishing, although these traditional activities have been influenced by modern conveniences (Harper, 2008). Land uses in the OU5 study area by tribal members and citizens include these subsistence activities as well as recreational activities (such as swimming/wading) and traditional uses such as ritual purification (sweat lodge). Potential exposure to media within the OU5 study area through these traditional land uses by tribal members and citizens are evaluated under the tribal lifeway scenario in the HHRA, which represents adults and children living a subsistence lifestyle. Recreational land uses by the general public (including adult and children) in the OU5 study area include fishing, hunting, and swimming/wading. Some other outdoor leisure activities include camping, stream access during wildlife viewing, boating, kayaking, and canoeing. Swimming is not permitted in Wildlife Department Lakes. Species to be caught with a fishing license include bass, crappie, trout, walleye, paddlefish, and alligator Gar. Paddlefish are one of the most unique fish in Oklahoma and are sought out for their fillet and roe (caviar). Additionally, turtles and bullfrogs can be caught with a fishing license. Hunting includes big game, birds, and furbearers.

Watershed-specific land use descriptions, including designated beneficial uses of the water, are summarized in Table 2-2.

2.5 Conceptual Exposure Model

The CEM builds on knowledge obtained from the CSM and conceptual contaminant transport model, and identifies the specific exposure pathways, exposure routes, and receptor populations for each medium evaluated for the OU5 study area, and specifically for the HHRA. The CEM was developed through resource and literature review, as well as observations from the CSM, and most importantly was informed based on input from site stakeholders. Tribal stakeholders, as representatives of tribal members and citizens, recommended the use of the *Quapaw Traditional Lifeways Scenario*

(Harper, 2008) as the primary basis of formulating the CEM, and the CEM relies heavily upon this resource. In addition, tribal stakeholders provided valuable input on specific exposure media that are important from both a cultural and dietary consumption standpoint.

Exposure media in the OU5 study area include sediments, surface water, and aquatic biota. The exposure media are evaluated quantitatively with the exception of irrigated crops, livestock watering, and waterfowl, which are evaluated qualitatively. The CEM is presented on Figure 2-3 (a tabulated form of the CEM is presented in Table 1 of Attachment B).

A summary of exposure scenarios evaluated quantitatively in the HHRA, including potential exposure routes and receptor populations (age group), is provided for each exposure medium below.

- **Surface water/sediment (rivers and creeks).** Hunting/fishing/gathering and recreational activities (fishing and wading) (incidental ingestion and dermal contact) for a tribal lifeway (adult and child), work activities for aquatic workers (for example, hatchery or environmental employees), and recreational activities (swimming/wading/fishing/hunting) for the general public (adult and child).
- **Surface water (rivers and creeks).** Potable use (ingestion and dermal contact) for a tribal lifeway (adult and child) and general public (adult and child).
- **Surface water (rivers and creeks).** Sweat lodge (ingestion, dermal contact, and inhalation of water vapors) for a tribal lifeway (adult and child).
- **Aquatic biota (fish, shellfish, aquatic plants, amphibians/aquatic reptiles, and semi-aquatic mammals).** Food consumption (ingestion) for a tribal lifeway (adult and child), food consumption (ingestion - fish only) for the general public (adult and child), and medicinal use (dermal - aquatic plants only) for a tribal lifeway (adult and child).

In addition to the exposure scenarios listed above, an evaluation of mine discharge was performed using the surface water scenario for both tribal lifeway and general public receptors. Mine discharge has been found to occur in a few locations within OU5 watersheds; however, the potential for exposure is expected to be highly limited because of its intermittent occurrence, typical low flow rates, and relatively low accessibility. Evaluation of this scenario is presented as part of the uncertainty analysis (Section 6.6.2.4 and Appendix F3).

SECTION 3

Data Evaluation

This section summarizes the data and methods used to develop the dataset for the HHRA, including a description of analytical data and the refinement and reduction of the data. Additionally, screening methods used to select COPCs (including specific data groupings), screening levels, and the results for COPCs identified in each data grouping are presented in this section.

3.1 Data Used in the Human Health Risk Assessment

For the RI, site stakeholders identified and contributed information, resources, and analytical data in response to a series of data requests issued by EPA. A key objective of the data acquisition for the RI was to maximize the use of this vast amount of site knowledge, resources, and analytical data to help complete the evaluation. To optimize the use of existing literature and data, the usability of available data and reports was evaluated as part of a data gap assessment (described by the Data Gap Summary Report [CH2M, 2017]). A compilation of historical resources that were assessed is presented in Appendix D of the RI report.

Historical analytical data (data collected by various investigators and sampling programs before 2017), data obtained in a 2017 investigation (performed at the recommendation of the Data Gap Summary Report [CH2M, 2017]), and a 2017 fish analytical dataset provided by Oklahoma Department of Environmental Quality (ODEQ), are combined and used in the HHRA. While the list of historical resources is long (Appendix D of the RI report), only a small number of these resources met data quality objectives and were identified as usable for the RI and HHRA through the data gap analysis process (CH2M, 2017).

The combined data for the HHRA were grouped by watershed and exposure medium for specific exposure scenarios evaluated in the HHRA. A description of the data groupings used in the HHRA and the number of samples for each grouping are discussed by exposure medium in the following subsections and summarized in Table 3-1. More detailed information about the data groups and specific sample lists for each data group are presented in Appendix C. The analytical dataset used in the HHRA is included in Section 6 of the RI report.

For samples with field duplicate analyses, the higher of the two concentrations was used to estimate the EPCs when both values were detects or non-detects. In cases where one result was a detect and the other a non-detect, the detected value was used to estimate the EPCs.

3.1.1 Sediment

The sediment dataset is composed of sediment samples collected from perennially flowing creeks, streams, and rivers within all six watersheds (Elm Creek, Tar Creek, Neosho River, Beaver Creek, Lost Creek, and Lower Spring River) within the OU5 study area from 2004 to 2017. The data presented in this section are in two categories: (1) data collected during the 2017 Data Gap Investigation, and (2) historical data (collected prior to the 2017 Data Gap Investigation). Historical data include samples collected during investigations performed from 2004 to 2017. The 2017 Data Gap Investigation was performed by CH2M, and samples were collected in accordance with the sampling procedures outlined in Section 3 of the RI report. The sediment sample locations are shown on Figure 3-1 of the RI report.

Samples were collected from saturated sediment that is within the defined “wet” banks of each creek/river, meaning the location was perennially under water. Co-located sediment samples were collected after the surface water or biota sample was collected to prevent disturbance of the sediment that may be suspended or deposited on the other media. In some instances, the co-located sediment

samples associated with biota samples were collected at a shallower depth to coincide with the habitat of that specific biota (for example, root zones).

The sediment dataset is composed of unsieved and sieved sediment samples. The unsieved sediment dataset includes 257 samples, which includes historical sediment samples that were screened using a 2.0-millimeter mesh. The sieved sediment dataset includes 206 sieved samples that were screened using a 63-micrometer (µm) or a 250-µm sieve, or in some instances, both sieve sizes. The sample summary in Appendix C, Table 1a includes information on the number of sieved and unsieved samples.

The HHRA evaluated sediment samples collected between 0 and 12 inches below sediment surface (bss). The 0- to 12-inch dataset includes sediment samples collected from the following discrete-depth intervals:

- 0 to 6 inches bss
- 0 to 8 inches bss
- 0 to 12 inches bss

Although deep unsieved sediment samples were collected from an interval of 0 to 18 inches bss, these samples were not included in the dataset used in the HHRA because they were collected at a depth at which contact is not expected to occur and because there was sufficient data coverage with the samples collected from shallower depths where most contact is expected.

Sediment samples collected as part of the 2017 Data Gap Investigation were analyzed for metals including aluminum, antimony, arsenic, barium, beryllium, cadmium, chromium, cobalt, copper, iron, lead, manganese, mercury, nickel, selenium, silver, thallium, vanadium, and zinc. The historical dataset contains samples analyzed for various metals that may be different from the 2017 Data Gap Investigation, including many samples that were analyzed for cadmium, lead, and zinc only.

For the purpose of COPC selection, a “sitewide” sediment dataset composed of both unsieved and sieved samples from all six watersheds was used (a total of 463 samples). In the subsequent exposure estimation and risk characterization section, the watershed-specific maximum of the unsieved and sieved samples for each COPC was selected, yielding six individual sediment datasets and associated risk evaluations (performed on a watershed-specific basis).

3.1.2 Surface Water

The surface water (total metals) dataset consists of 2,207 surface water samples that were collected from perennially flowing creeks, streams, and rivers within all six watersheds (Elm Creek, Tar Creek, Neosho River, Beaver Creek, Lost Creek, and Lower Spring River) in the OU5 study area from 2000 to 2017. Many of these samples were collected over various years from the same sampling location under prescribed sampling programs. The data presented in this section are in two categories: (1) data collected during the 2017 Data Gap Investigation, and (2) historical data (collected prior to the 2017 Data Gap Investigation). Historical data include samples collected during investigations performed from 2000 to 2017. The 2017 Data Gap Investigation was performed by CH2M, and samples were collected in accordance with the sampling procedures outlined in Section 3 of the RI report. The surface water sample locations are shown on Figure 3-2 of the RI report. Surface water samples with co-located biota and sediment sample locations are also shown together on the individual biota figures for fish, mussels, and aquatic plants.

At locations where co-located sediment and/or biota samples were collected, the surface water sample was collected first. Samples were collected from water within the defined “wet” banks of each creek/river and within approximately 2 meters of the actual sediment or biota sample location. If co-located samples could not be collected in real-time (that is, at the same time as biota collection was performed by a volunteer), the team returned to the sample location as soon as reasonably possible to collect the co-located surface water sample. Water samples were collected as close to the centerline

of the water channel as possible. At locations that were not wadable (for example, where a boat would be required to access the centerline of the channel), surface water sampling was not performed.

Surface water (total metals) samples collected as part of the 2017 Data Gap Investigation were analyzed for the following metals: aluminum, antimony, arsenic, barium, beryllium, cadmium, calcium, chromium, cobalt, copper, iron, lead, magnesium, manganese, mercury, molybdenum, nickel, potassium, selenium, silver, sodium, thallium, vanadium, and zinc. The historical dataset contains samples analyzed for various metals that may be different from the 2017 Data Gap Investigation, including many samples that were analyzed for cadmium, lead, and zinc only.

Similar to the sediment dataset, for the purpose of COPC selection, the surface water dataset was composed of "sitewide" surface water (total metals) samples from all six watersheds combined. In the subsequent exposure estimation and risk characterization, the "sitewide" surface water (total metals) dataset was divided by watershed and risk evaluation was performed on a watershed-specific basis. Additionally, as a supplemental evaluation, the exposure estimation and risk characterization of dissolved metals in surface water was performed on a watershed-specific basis in the uncertainty section.

3.1.3 Mine Discharge

In addition to the obvious aboveground mining remnants, mining activities left an extensive network of underground mine workings. In some areas, the roofs of the mines have collapsed into the mine workings, creating subsidence features that extend to the ground surface. When the mines were active, groundwater pumping was required to maintain access to the tunnels. When mining operations ceased, pumping was discontinued. Many mine shafts were also abandoned and left open.

The cessation of pumping resulted in groundwater flow back into the mine workings (CH2M, 2016b). Also, surface water began flowing into the mine workings through numerous inflow points including the subsidence features and abandoned mine shafts (EPA, 2005b). As the mine voids began to flood, chemical weathering products such as acidity, metal ions, iron precipitates, and sulfates began to accumulate in the water (Sutter, 2008). A notable physical attribute of the mine discharge on the surface is the vivid orange-stained stream beds from the precipitation of ferric oxyhydroxide, which is both an aesthetic issue and a toxicity issue with the aquatic ecosystems (Younger et al., 2002).

Direct mine discharge is known to exist in three primary areas of the OU5 study area:

- **Commerce area discharges.** These discharge into an unnamed tributary of Tar Creek; the discharges are currently being treated by passive treatment systems and therefore were not investigated as part of the RI.
- **Tar Creek area discharges.** These are in the vicinity of East 40 Road and the Douthat Bridge over Tar Creek.
- **Beaver Creek area discharges.** These are located on both the north and south sides of East 50 Road along Beaver Creek.

Although potential exposure to mine discharge is expected to be highly limited because of its intermittent occurrence, typical low flow rates, and relatively low accessibility, mine discharge occurs in a few locations within OU5 watersheds. Evaluation of mine discharge was performed using surface water exposure scenarios for both tribal lifeway and general public receptors and is presented in the uncertainty analysis (Section 6.6.2.4 and Appendix F3).

3.1.4 Aquatic Biota

The perennially flowing rivers and creeks of the OU5 study area support a wide variety of biota that currently may be, or in the past have been, exposed to metals in site sediments and surface water.

Potentially exposed aquatic biota include fish, shellfish, aquatic plants, amphibians/aquatic reptiles, and semi-aquatic mammals, and are the focus of the HHRA. Aquatic biota samples were collected from and near the OU5 study area creeks and rivers in various settings. The data presented in this section are in two categories: (1) data collected during the 2017 Data Gap Investigation, and (2) historical data (collected prior to the 2017 Data Gap Investigation). Historical data include samples collected during investigations performed from 2003 to 2017. The 2017 Data Gap Investigation was performed by CH2M, and samples were collected in accordance with the sampling procedures outlined in Section 3 of the RI report.

All samples collected as part of the 2017 Data Gap Investigation were analyzed for the following metals: aluminum, antimony, arsenic, barium, beryllium, cadmium, chromium, cobalt, copper, iron, lead, manganese, mercury, nickel, selenium, silver, thallium, vanadium, and zinc. The historical dataset contains samples analyzed for various metals that may be different from those analyzed in the 2017 Data Gap Investigation.

Because dietary consumption rates are provided on a wet weight basis, all biota datasets used in the HHRA are also presented on a wet weight basis. Some of the historical data (e.g., mussels and aquatic plants) were reported as dry weight, and a dry-weight-to-wet-weight conversion was needed to provide consistent reporting format in the dataset. The conversion from dry weight to wet weight was performed using the moisture content of the samples. EPA guidance provides the equation for the conversion (EPA, 2011). More detailed information about the dry-to-wet-weight conversion is presented in Section 6 (Tables 6-44 and 6-47) of the RI report.

Aquatic biota samples were combined for all six watersheds for each biota category (e.g., fish, shellfish, aquatic plants, amphibians/aquatic reptiles, and semi-aquatic mammals) into a “sitewide” dataset for the purpose of COPC selection as well as the subsequent exposure estimation and risk characterization to account for mobility of tribal lifeway receptors and mobility of animals with an extended home range (e.g., raccoons). Additionally, as a supplemental evaluation of the potential risks associated with biota consumption, the exposure estimation and risk characterization of food consumption pathways was performed on a watershed-specific basis in the uncertainty section.

3.1.4.1 Fish

Tribal members and citizens have indicated that they consume fish in three ways: (1) fillets only, (2) entire head including bones (in soups), and (3) whole fish eviscerated (organs removed) including bones but with the head removed (CH2M, 2016b). Fish were obtained from all OU5 study area watersheds. In some instances, particularly in the Neosho River and Lower Spring River, fish samples from the 2017 Data Gap Investigation were obtained at or near historical fish sampling locations. However, in many instances, fish samples were obtained from Elm Creek, Tar Creek, Beaver Creek, and Lost Creek for the first time (i.e., fish samples from these creeks were not available in the historical dataset). Fish sampling locations are illustrated on Figure 3-4 of the RI report.

Fish were collected from the watersheds with the help of volunteers in the 2017 Data Gap Investigation. Fish collection locations were determined based on input from EPA, ODEQ, Oklahoma Department of Fish and Wildlife, and tribal stakeholders. ODEQ collected fish samples by boat electroshocking. The Paddlefish Research Center also collected game/non-game fish and paddlefish samples by use of rod and reel. Preferentially and as feasible, larger fish were targeted for collection as requested by the Tar Creek Trustee Council Indian Tribes (TCTCIT) (CH2M, 2016b). For game fish, the size limitations and collection of game fish was compliant with the state fishing regulations. Collection of non-game fish is not subject to a size or daily catch limit, and Larry Tippit (Environmental Specialist, Peoria Tribe) suggested sampling non-game fish from 3 to 5 pounds (CH2M, 2016b). Non-game fish samples in this weight size were often not available during the sample collection efforts.

Samples were collected from the following non-game fish and game fish species:

- **Non-game fish.** Freshwater drum, common carp, smallmouth buffalo, and red horse fish species.
- **Game fish.** Largemouth bass, smallmouth bass, green sunfish, white crappie, bluegill, channel catfish, yellow bullhead catfish, black bullhead catfish, longear sunfish, white bass, spotted bass, blue catfish, flathead catfish, and black crappie fish species.

Although the State of Oklahoma considers bluegill, sunfish, yellow and black bullhead catfish, and flathead catfish to be non-game fish (ODWC, 2015), for the purpose of the RI analytical datasets and the HHRA, bluegill, green and hybrid sunfish, and all catfish were included within the game fish category for evaluation of fish consumption by the general public. It is common practice for the general public and tribal members and citizens to consume these fish, regardless of their game or non-game classification, and this adjustment ensures that they are assessed for both the general public and tribal member and citizen exposures.

Each whole fish was subdivided into sample portions consisting of a fillet, head, and carcass, which were weighed and analyzed individually, resulting in three fish tissue samples analyzed for each whole fish. The "total" concentrations of metals in whole fish were calculated based on the weights and concentrations of metals from the three sample portions, as discussed in Section 5.3.3 of the RI report. The estimated "total" concentrations in the 80 whole fish collected in the 2017 Data Gap Investigation were used for the fish consumption under the tribal lifeway exposure scenario because tribal members and citizens consume the entire fish for various dishes (e.g., head soup). Note that an uncertainty analysis was performed to evaluate differences in lead concentration between the whole fish and each fish body part (head, fillet, and carcass) in Section 6.6.1.5.

The data used for the evaluation of fish consumption by the general public were limited to game fish species only, because members of the general public most likely consume game fish species as food. The general public fish data group (game fish fillet) was composed of 101 samples, including 62 game fish fillet samples collected during the 2017 Data Gap Investigation, 33 fish fillet samples collected by ODEQ in 2017 (analyzed for only cadmium, lead, and zinc), and 6 paddlefish fillet samples.

3.1.4.2 Shellfish

Shellfish were collected as part of the RI to support the HHRA. Harper (2008) cites the importance of mussel collection and consumption to tribal subsistence practices. As discussed in the Data Gap Summary Report (CH2M, 2017), Asian clams were anticipated to be used as a surrogate for mussels. However, during the 2017 Data Gap Investigation, CH2M conducted multiple Asian clam surveys within each study area creek/river, and concluded that very limited populations of Asian clams were available for sampling. Therefore, the plans to collect Asian clams were revised, and traditional freshwater mussels were targeted as well. These findings were supported by consultations and field observations shared with the U.S. Geological Survey, U.S. Fish and Wildlife Service (FWS), and input from tribal members and citizens. In particular, no Asian clams or freshwater mussels were observed in any of the study area tributaries that flow into the Neosho or Lower Spring Rivers.

Asian clams were collected from four locations within the Lower Spring River and one location within the Neosho River. The Asian clams that were collected were small in size (less than 1 ounce). Freshwater mussels were only observed in the Neosho and Lower Spring Rivers at locations of historical sample collection. All shellfish collected had smaller body mass, especially the Asian clams, so the samples collected were composite samples of 3 to 15 individual shellfish, depending on local availability and size distributions.

A total of 22 shellfish samples were collected within the OU5 study area in 2003, 2005, and 2017, among which 1 sample was collected from the Neosho River and 21 samples were collected from the Lower Spring River watershed. The shellfish samples collected in 2017 were analyzed based on wet weight,

while the shellfish samples collected in 2003 and 2005 were analyzed based on dry weight. In order to make the analytical results for both sample sets comparable, a dry-weight-to-wet-weight conversion factor was applied to the analytical results for the samples collected in 2003 and 2005 to make the historical analytical results comparable to the 2017 sample results. The shellfish sample locations are shown on Figure 3-5 of the RI report.

3.1.4.3 Aquatic Plants

Aquatic plants are present in OU5 study area watersheds, and some are collected by tribal members and citizens for medicinal use or consumption. Harper (2008) acknowledges the importance of plant collection and consumption to tribal subsistence practices. Tribal stakeholder representatives were consulted and their input was used to select arrowhead and duckweed as two commonly used aquatic plants that are representative plant species from the OU5 study area watersheds (i.e., sediment and surface water located in the wet or saturated areas of perennially flowing creeks, streams, and rivers in the study area).

EPA and CH2M worked with tribal members and citizens and the FWS during the 2017 Data Gap Investigation to identify appropriate sampling areas where the plants are found, and to identify the plant species in the field. After conducting multiple surveys of the study area watershed, and input from site stakeholders, the plant sample quantities collected throughout all watersheds did not meet the data gap minimum target (three samples in each watershed). Heavy rains and flooding that occurred throughout the 2017 sampling program are expected to have limited the growth and availability of the targeted plants. The limited presence of these plants is supported by the following statement made in the presentation by the nine Tribes of Ottawa County: “Tribal members indicated in surveys that they no longer can find some plants that they traditionally gathered for their family’s use” (Garvin, 2005).

The aquatic plant dataset consists of 17 aquatic plant samples collected from five of the six watersheds (Elm Creek, Tar Creek, Neosho River, Lost Creek, and Lower Spring River) within the OU5 study area in 2011 and 2017. The aquatic plant samples collected in 2017 were analyzed based on wet weight, while the aquatic plant samples collected in 2011 were analyzed based on dry weight. In order to make the analytical results for both sample sets comparable, a dry-weight-to-wet-weight conversion factor was applied to the analytical results for the samples collected in 2011 to make the historical analytical results comparable to the 2017 sample results. The aquatic plant sample locations are shown on Figure 3-6 of the RI report. Both arrowhead and duckweed were used for the evaluation of aquatic plant consumption as food, while arrowhead samples were used to evaluate aquatic plants for medicinal purposes (as salve). Additionally, as a supplemental evaluation of the potential risks associated with aquatic plant consumption as food, the exposure estimation and risk characterization of the individual plant parts was performed in the uncertainty section. Because limited data were available for individual plant parts, maximum detected concentrations were used as EPCs for this evaluation.

Arrowhead

The arrowhead plant (*Sagittaria latifolia)* is a horizontal creeper and is most recognizable by its arrowhead-shaped leaves and potato-like tubers. The arrowhead plant is most commonly found in swamps, ditches, ponds, and shallow waters. The arrowhead plant flowers in the summer with three petaled white blossoms, which are arranged in threes. The seeds normally ripen between August and September. The arrowhead tubers are egg shaped and range from 1 to 2 inches in length (USDA-NRCS, 2016). The arrowhead tuber may be consumed much like a potato, and is also used for medicinal purposes (TEMS, 2014).

Tribal members and citizens indicated that they use the arrowhead plant in three ways: (1) consumption of the washed tuber only, (2) medicinal consumption or dermal application of the washed fine roots, and (3) tea consumption from the washed leaves (CH2M, 2016b). In consideration of this, arrowhead

samples were subdivided into tubers, roots, and leaves, as feasible based on plant availability, and each part was submitted for analysis of total metals and mercury.

During the course of sampling, from July 2017 to November 2017, the team identified and tracked the status of the tuber on the arrowhead plants, but saw little development of this portion of the observed plants. The team delayed collecting samples until the final sampling event to allow the tuber time to grow; however, during the collection, some specimens were still lacking tubers, resulting in collection of leaf/stem and root only. The arrowhead plants were located in areas of ponded water along the stream, and not in the main channel.

Arrowhead plants were composited to obtain sufficient sample mass. The plants were rinsed with distilled water, weighed as a whole plant, then divided into leaves, fine roots, and tuber (if available).

Duckweed

Duckweed (*Lemna minor)* grows floating in still or slow-moving fresh water that contains a high supply of mineral nutrients. The duckweed is composed of one or multiple frond chains with one mother root per frond. This mother root decays shortly after the frond is formed, and the duckweed continues to float in water. The duckweed plant has a flattened, oval-shaped plant body, and is typically less than 1 millimeter in length (USDA-NRCS, 2016). Duckweed may be collected and prepared for consumption in soups or eaten raw in salads (TEMS, 2014).

Duckweed collected from the site had very small volume; it was not in thick mats but spread throughout a small ponded area in the stream, and not in the main channel. Duckweed plants were composited to obtain sufficient sample mass. Duckweed was collected into plastic bags, and the team removed other debris and organic matter mixed with the duckweed. The duckweed sample was then placed on a strainer, rinsed with distilled water, and placed into a new resealable plastic bag for delivery to the laboratory.

3.1.4.4 Amphibians and Aquatic Reptiles

Aquatic amphibians were not initially identified as potential exposure media for OU5 study area receptors. However, stakeholder input on this topic indicated that amphibians and aquatic reptiles could be a food source for some tribal members and citizens. To address this potential food source, the bullfrog (*Lithobates catesbeianus*) was identified as a representative species for the HHRA. While they do not spend their entire life in an aquatic environment, bullfrogs were proposed because they are exposed to OU5 study area sediments and surface water, are present within the OU5 study area watersheds, and are consumed by some tribal members and citizens and the general public. Tribal members and citizens also specified that only the rear (hind) legs of bullfrogs were consumed (CH2M, 2016b).

CH2M worked with tribal members and citizens and FWS to identify appropriate sampling areas where bullfrogs are found. Volunteers also helped to identify the bullfrog species and dispatch bullfrogs in the field. Bullfrogs were collected at night, using a flashlight to stun the bullfrogs, and most were speared with a small trident stake, although some were dispatched with a pellet gun[2]. The frogs were rinsed with distilled water, the skin was removed from only the legs, and the legs were then severed from the body of the frog. The leg tissue was not removed from the leg bones. The leg tissue was rinsed again in distilled water, placed in a resealable plastic bag, and then placed into the site freezer.

Both legs from an individual bullfrog were submitted as one sample. Many bullfrog samples collected were too small for shipment as individuals. In these cases, bullfrog legs were composited into one sample. Frog leg tissue samples were submitted to the laboratory still on the bone. The samples,

[2] Lead shot was used in the pellet guns, but because the hind leg samples were collected away from the gunshot area (in the head or main body), this is not expected to have impacted the hind leg samples.

consisting of both tissue and bone, were ground and homogenized by the laboratory prior to analysis. The meat tissue should have been removed from the bone prior to analysis, either in the field during sample preparation, or at the laboratory.

Fourteen bullfrog samples were collected within the OU5 study area. The samples were collected from five of the six watersheds: Tar Creek, Beaver Creek, Neosho River, Lost Creek, and Lower Spring River. All bullfrog samples were collected during the 2017 Data Gap Investigation. The bullfrog sample locations are shown on Figure 3-7 of the RI report.

3.1.4.5 Semi-Aquatic Mammals

According to the tribal members and citizens, semi-aquatic mammals such as raccoons are consumed by some tribal members and citizens and are common and present within all OU5 study area watersheds. Harper (2008) acknowledges the importance of semi-aquatic mammals to tribal subsistence practices. Based on the above rationale, raccoons were selected to represent semi-aquatic mammals consumed in the OU5 study area and were collected as part of the RI program. Tribal members and citizens specified that only the meat (no organs) of a raccoon is eaten (CH2M, 2016a).

Raccoons are opportunistic and adaptable, so their habitat is all of Oklahoma. Raccoons tend to be located in areas with food, water, and a suitable den site. The home range size varies from 3 hectares (7.4 acres) for females in cities, to 5,000 hectares (12,000 acres) for males in prairies. While primarily hunted for their fur, raccoons were also a source of food for tribal members and citizens and early settlers (iNaturalist, 2016).

Raccoons eat hundreds of species of plants and animals, although plants are considered the most important component of the raccoon's diet in most habitats. In the spring, however, raccoons tend to feed more on animals, including crayfish and insects, than plants. Raccoons typically eat 0.5 to 1 pound of food per day, and up to 5 pounds per day as winter approaches. The diet of the omnivorous raccoon, which is usually nocturnal, consists of about 40 percent invertebrates, 33 percent plant foods, and 27 percent vertebrates (iNaturalist, 2016).

Because historical data were not available for raccoons, samples were collected anywhere within a watershed. CH2M worked with tribal members and citizens and FWS to identify appropriate sampling areas where raccoons are found. Volunteers also helped to trap and dispatch raccoons in the field.

Collection of raccoons occurred throughout the year with the support of local licensed tribal member hunters. Both tribal members and CH2M personnel used baited live traps in conspicuously placed locations near water bodies within the watersheds. Captured raccoons were humanely dispatched by sampler volunteers with a gun[3], and the carcass was placed on ice for transportation to the site trailer. The raccoon was then either frozen until processing could be completed or immediately processed by the field team.

The raccoon was processed by collecting tissues from the back leg or haunch. If the raccoon was frozen in the site freezer, the tissue was allowed to thaw just enough to dissect the desired tissues. Care was taken to obtain a tissue sample from a location away from any wound(s). A minimum 4 ounces of tissue was required. The area of incision was rinsed with distilled water. An incision was made through the skin on the back leg. The skin was resected to expose the muscle tissue. Muscle tissue was then removed and rinsed with distilled water prior to placing in a resealable plastic bag.

Nineteen raccoon samples were collected within the OU5 study area. All raccoon samples were collected during the 2017 Data Gap Investigation. The samples were collected from all six watersheds:

[3] Ammunition containing lead may have been used in the rifles and handguns used to dispatch raccoons, but because the back haunch (rump and rear leg) samples were collected away from the gunshot area (typically in the head), this is not expected to have impacted the back haunch samples.

Elm Creek, Tar Creek, Beaver Creek, Neosho River, Lost Creek, and Lower Spring River. The raccoon sample locations are shown on Figure 3-8 of the RI report.

3.2 Identification of Chemicals of Potential Concern

The COPCs are those chemicals that have the greatest potential to cause adverse human health effects if receptors come in contact with exposure media. COPCs were selected using different approaches depending on exposure scenarios, as discussed in the following subsections.

Although a quantitative evaluation of exposure to sediment and surface water was performed on a watershed basis, COPCs were selected per exposure medium (sediment or surface water) for the "sitewide" dataset using combined data from all watersheds (i.e., "sitewide" data groupings). For the identification of sediment COPCs, the dataset consisting of both unsieved and sieved sediment data was used. Total metals (unfiltered) surface water concentrations were used to select surface water COPCs.

Lead is the primary chemical of interest at the site due to strong association with historical mining activities in the TSMD. Therefore, lead was automatically identified as a COPC regardless of receptor type (tribal lifeway, aquatic workers, or general public) or level of detected concentration. The detailed evaluation of potential lead exposure is presented in Appendix E.

3.2.1 COPC Selection for Tribal Lifeway and Aquatic Workers

Because the exposure factor values selected for the tribal lifeway and aquatic worker exposure scenarios are often greater than EPA's default exposure factor values used to develop Regional Screening Levels (RSLs), all detected chemicals in a given dataset regardless of exposure medium (sediment, surface water, and biota) were identified as COPCs for these tribal exposure scenarios, except for essential nutrients and chemicals without quantitative toxicity values (see Section 3.2.3).

3.2.2 COPC Screening Levels for General Public

For general public receptors, EPA's RSLs were used to identify COPCs. Due to the lack of default screening levels for the fish consumption pathway, all detected chemicals in fish datasets were identified as COPCs, with the exception of essential nutrients. The maximum detected concentrations in sediment and surface water were compared to the residential soil and tap water RSLs, respectively. The RSLs based on non-carcinogenic health endpoints were based on a hazard quotient (HQ) of 0.1 to account for the potential presence of multiple chemicals affecting the same target organ, while the RSLs based on carcinogenic health endpoints were based on a target excess lifetime cancer risk (ELCR) of 1×10^{-6}. For those chemicals with more than one RSL (for example, carcinogenic-based RSL and non-carcinogenic-based RSL), the lower value was selected as the final RSL for that chemical.

3.2.3 Chemicals Excluded as COPCs

Chemicals were eliminated as COPCs based on the following criteria:

- Chemicals considered essential nutrients (calcium, magnesium, potassium, and sodium) were not selected as COPCs.
- The chemicals listed below by exposure medium were 100 percent non-detected and were not selected as COPCs for that medium/data grouping.
  - Sediment – uranium
  - Shellfish – antimony, thallium, and vanadium
  - Amphibians/Aquatic Reptiles – antimony, cobalt, and vanadium
  - Semi-Aquatic Mammals – cobalt, silver, and vanadium
  - Aquatic Plants – selenium and thallium

- Chemicals without quantitative toxicity values in EPA's recommended toxicity data sources (see Section 5) were not identified as COPCs. Titanium in sediment was the only chemical excluded as a COPC based on this criterion. Uncertainty associated with elimination of chemicals without quantitative toxicity values as COPCs is discussed in Section 6.5.

3.2.4 COPC Screening Results

Results of the COPC screening process for each receptor group, by exposure scenario, are summarized in Table 3-2. More detailed information about the COPC selection process is presented in Appendix B, RAGS Tables 2.1 through 2.9. The conservative nature of the COPC screening process resulted in the majority of chemicals detected at the site being selected as COPCs, including lead. As indicated earlier, lead was identified as a COPC regardless of receptor type or level of detected concentrations. Further evaluation of COPCs is performed in subsequent sections, with the exception of lead (which is evaluated in Appendix E).

3.2.5 Background Comparison

Although background threshold values (BTVs), based on the 95/95 Upper Tolerance Limit, for sediment and surface water from RI report are shown in Appendix B, RAGS Table 2s, no detected chemicals (including lead) were eliminated as COPCs on a basis of background comparison. The results of background comparisons were used in the selection of final chemicals of concern (COCs) in the risk characterization (Section 6).

SECTION 4

Exposure Assessment

An exposure assessment is a characterization of potential exposures to site media by human receptors under current and anticipated future land use conditions, and identifies potentially complete exposure pathways for further evaluation in the HHRA. EPCs in an exposure medium were estimated and numerical exposure factor values were identified to quantify COPC exposures for the complete exposure pathways identified under each potential exposure scenario.

4.1 Human Health Conceptual Exposure Model

The CEM identifies the means by which humans may be potentially exposed to contaminants in exposure media of the OU5 study area, including the following:

- Primary and secondary sources and mechanisms of COPC release
- Transport media
- Exposure points (points of potential human contact)
- Exposure routes
- Receptor populations

The CEM was defined through resource and literature review, observations from the CSM, and most importantly, input from site stakeholders between 2016 and 2019 (details on stakeholder input and involvement are presented in Appendix A of this HHRA, and in Appendix A of the RI report). Input from tribal members and citizens recommended the use of the *Quapaw Traditional Lifeways Scenario* (Harper, 2008) as the primary basis for formulating the CEM, and the CEM relies heavily upon this resource. In addition, tribal stakeholders provided valuable information and input on exposure media that are important from both a cultural and dietary consumption standpoint.

The CEM also provides an assessment of which exposure pathways are (1) potentially complete, (2) potentially complete but expected to result in insignificant exposure, and (3) incomplete, consistent with EPA (1989) guidance. The CEM is presented on Figure 2-3**.** The CEM in a tabulated format is also presented in Appendix B, RAGS Table 1.

4.1.1 Identification of Potential Receptors

The following three potential receptor scenarios were evaluated in this HHRA:

- **Tribal lifeway scenario**. Traditional lifeway scenario identified for local tribal members and citizens.
- **Aquatic worker scenario**. For example, fish hatchery and environmental employees.
- **General public scenario.** Recreational users.

The HHRA assessed potential exposures and associated risks for two general age groups, child (ages 0 to 6) and adult, under the tribal lifeway and general public scenarios; while only adults were evaluated under the aquatic worker scenario. A brief description of the potential activities and exposure pathways assumed for each receptor scenario is provided in Table 3-1.

4.2 Exposure Pathways Quantified

In accordance with EPA (1989) guidance, only potentially complete exposure pathways were evaluated in the HHRA. To be potentially complete, the four primary elements of an exposure pathway must be present within the OU5 study area:

- Contamination source(s) and mechanism of release
- Transport medium
- Exposure point
- Exposure route to potential receptors

Although some exposure pathways included in Table 3-1 were considered complete but insignificant exposure pathways and are not expected to add appreciable risk relative to other complete exposure pathways, the exposure pathways were included in the quantitative risk estimates to assess potential current or future exposures. An assessment of the exposure pathways is included in the CEM on Figure 2-3. The CEM in a tabulated format is also presented in Appendix B, RAGS Table 1.

The potential exposure pathways quantified in the HHRA for each receptor group are indicated in Table 3-1.

4.3 Quantification of Exposure

To evaluate the potentially complete exposure pathways further, the magnitude, frequency, and duration of exposures were estimated and quantified. EPCs were computed and pathway-specific intakes were estimated. EPA guidance (1989) recommends selecting intake variable values for a given pathway so that the combination of all intake variable values results in an estimate of the RME for that pathway. The RME is the highest exposure that is reasonably expected to occur at a site (EPA, 1989).

4.3.1 Exposure Point Concentrations

Various data groupings were created based on the specific exposure medium and the geographical area (watershed) applicable to each exposure scenario, as summarized in Table 3-1. More detailed information about the data groups is presented in Appendix C, Tables 1a through 1c. The EPCs were calculated for COPCs within each data grouping. For each data grouping, the EPCs were calculated as the upper confidence limit (UCL; often the 95th percentile) of the arithmetic mean concentration. The most current statistical program (ProUCL Version 5.1.002) (EPA, 2016b) and user guide (EPA, 2015) were used to calculate the EPCs. ProUCL provides guidance and a range of parametric and nonparametric methodologies for handling datasets of different distributions. The ProUCL calculation output is presented in Appendix D. The smaller the sample size, the less reliable the UCL estimation becomes. Therefore, for a data group where less than eight samples or less than four detected concentrations were available, the maximum detected concentration was used as the EPC for that data grouping. Additionally, if the UCL of the mean was higher than the maximum detected concentration in the data grouping, the maximum detected concentration for the data grouping was used as the EPC.

4.3.2 Exposure Factors

To assess the daily COPC intake for each receptor group, numerical intake (or exposure) parameter values were selected, in combination with EPCs, to estimate the COPC intake from each complete exposure pathway. The intake factors were selected for an RME, which is the maximum exposure that is reasonably expected to occur within the OU5 study area. The intake parameter values were selected so that the combination of all parameters results in an estimate of the RME for a particular exposure pathway. By design, the estimated RME is higher than that expected to be experienced by most of the exposed population.

Intake parameter values for the RME scenario were developed for potentially complete exposure pathways and receptors (see Appendix B, RAGS Tables 4.1 through Table 4.8). Exposure factor values for tribal lifeway and aquatic worker scenarios were developed based on literature describing Native American exposure characteristics (Garvin et al., 2017; Harper, 2007, 2008; Harper et al., 2002), inputs from the Quapaw Nation and TCTCIT (2018), EPA's risk assessment guidance documents (EPA, 1989, 2004, 2014), and EPA's reports on exposure factor data (EPA, 2011, 2018a, 2018b, 2019b). Exposure factor values for the general public were developed based on EPA's risk assessment guidance documents (EPA, 1989, 2004, 2014), EPA's reports on exposure factor data (EPA, 2011, 2019b), and literature on regional fish analyses (Dong et al., 2015).

Brief descriptions of key exposure parameter values are presented below.

4.3.2.1 Tribal Lifeway (Adult and Child)

- General exposure factors
  - Body weight – 70 kilograms (kg) for adult (based on input from Quapaw Nation) and 15 kg for child receptors (EPA, 2014).
  - Exposure duration – Tribal lifeway receptors were assumed to be exposed to site media for their entire lifetime (70 years): 64 years during adulthood (Harper, 2008) and 6 years during childhood (0 to 6 years old) (EPA, 2014).
- Exposure factors for fishing, hunting, gathering, and recreational activities
  - Incidental ingestion of sediment and surface water – Ingestion rate of sediment is assumed to be the same as the soil ingestion rate (400 milligrams per day [mg/day]) presented in Harper (2008). Incidental water ingestion rate is based on the upper percentile water ingestion rate while swimming (Dufour et al., 2017), as cited in EPA's EFH 2019 update (EPA, 2019b).
  - Exposure frequency (sediment and surface water) – Adult and child receptors were assumed to be exposed to sediment and surface water within the OU5 study area at frequencies of 312 and 234 days per year (days/year), respectively. Adult exposure frequency includes days of exposure through work and non-work activities. An increased exposure frequency of 312 days/year was selected for sediment exposure by child receptors due to additional days of exposure resulting from potential contact with sediment-laden items at their home.
  - Dermal contact (surface water) – Adult and child receptors were assumed to be dermally exposed to sediment and surface water on their whole-body skin surface area for 6 hours per day.
- Exposure factors for drinking water scenario
  - Ingestion of surface water as a drinking water source – Exposure assumptions (ingestion rate, skin surface area, and dermal contact exposure time during bathing/showering) selected for this exposure scenario are consistent with EPA's default values for a residential tap water scenario, except for body weight and exposure duration discussed above and exposure frequency. In addition, an exposure frequency of 365 days/year, rather than the EPA default value of 350 days/year, was selected to account for receptors who do not leave the area during the year.

- Exposure factors for sweat lodge use
  - Ingestion of surface water as a drinking water source during sweat lodge use – Ingestion of water was assumed to be 1 liter per event (Harper, 2008) for both adult and child receptors.
  - Exposure duration – Exposure durations of 64 years for adult receptors (Harper, 2008) and 4 years for child receptors were used, assuming that child tribal members and citizens start using sweat lodges at the age of 2 based on the Quapaw Nation's input.
  - Exposure frequency/exposure time – Adult and child (ages 2 to 6) receptors were assumed to use a sweat lodge for an exposure time of 1 hour per event at a frequency of 1 event per day and 365 events per year. This combined exposure frequency/exposure time (365 events per year for 1 hour per event, or 365 hours per year) was used as a conservative approach to account for a range of exposures by tribal members and citizens. These exposure assumptions are more conservative than input provided by Quapaw Nation and TCTCIT. Based on Quapaw Nation input, children younger than 2 do not use the sweat lodge.
  - Dermal contact – Adult and child receptors were assumed to be dermally exposed to surface water over their entire skin surface area for the durations described above.
- Exposure factors for food consumption
  - Consumption rates – Consumption rates of food items were estimated based on the food ingestion rates (the baseline average Quapaw diet in Oklahoma based on an assumed 2,000 kilocalorie [kcal] daily intake) estimated for various food categories by Harper (2008).
    - Assumes that fish intake accounts for 75 percent of "aquatic and fish" intake.
    - Assumes that shellfish intake accounts for 25 percent of "aquatic and fish" intake.
    - Assumes that aquatic plants account for 100 percent of "roots and bulbs" intake. An alternative (higher) tribal lifeway plant ingestion rate is presented in Appendix F4.
    - Assumes that amphibian intake accounts for 35 percent of "small game" intake. As a very conservative approach, both amphibians/aquatic reptiles (at 35 percent of the "small game" intake rate) and semi-aquatic mammals (at 100 percent of the "small game" intake rate) were assumed to be ingested for the tribal lifeway scenario. This results in evaluation of 135 percent of the "small game" intake rate identified by Harper (2008), which overestimates intake from these aquatic food sources.
    - Assumes that semi-aquatic mammals account for 100 percent of "small game" intake.
    - Assumed child food ingestion rates are 50 percent of adult rates. A review of food consumption data in the EPA EFH (EPA, 2011) and updates (EPA, 2018a, 2018b) suggests that the fraction of child food ingestion rates to adult ingestion rates is 50 percent or less for various food categories (total vegetables, total meat, finfish, and shellfish) (see Appendix B, RAGS Table 4 Supplement C). Therefore, although these food consumption data are based on the general public in the U.S., 50 percent of adult food ingestion is considered a reasonable estimate of child food consumption rates, even for a specific subpopulation such as tribal lifeway receptors, because the specific dietary pattern of subpopulations is accounted for in the adult ingestion rates. Alternative (higher) tribal lifeway food ingestion rates for children (as a percentage of adult rates) are presented in Appendix F4.

- Exposure factors for medicinal use of plants
  - Exposure frequency – Adult and child receptors were assumed to use plant (salve) for medicinal purposes for 312 days/year.
  - Dermal contact – Plant (salve) is assumed to be applied to hands, forearms, face, lower legs, and feet.

4.3.2.2 Aquatic Workers (Adult)

- General exposure factors
  - Body weight – 70 kg for adult (based on input from Quapaw Nation).
  - Exposure frequency and duration – Exposure frequency (250 days/year) and duration (25 years) selected for this exposure scenario are consistent with EPA's default values for an industrial worker scenario (EPA, 2014).
- Exposure factors for work activities (e.g., working at fish hatchery or collecting environmental samples)
  - Incidental ingestion of sediment and surface water – Ingestion rate of sediment is assumed to be the same as soil ingestion rate (400 mg/day) presented in Harper (2008). Incidental water ingestion rate of 0.092 liter per hour is based on the upper percentile water ingestion rate while swimming (Dufour et al., 2017), as cited in EPA's EFH 2019 update (EPA, 2019b).
  - Dermal contact (surface water) – Workers were assumed to be dermally exposed to sediment and surface water through their entire skin surface area for 6 hours per day.

4.3.2.3 General Public (Adult and Child)

- General exposure factors
  - Body weight and exposure duration – Body weight (80 kg for adult) and exposure duration (20 years for adult and 6 years for child, for a total of 26 years) for general public are consistent with EPA's default values for a residential exposure scenario (EPA, 2014).
- Exposure factors for recreational activities (swimming and wading)
  - Incidental ingestion of sediment and surface water – Ingestion rate of sediment is assumed to be the same as EPA's default soil ingestion rates for a residential scenario. Incidental water ingestion rate is based on the upper percentile water ingestion rate while swimming (Dufour, 2017), as cited in EPA's EFH 2019 update (EPA, 2019b).
  - Exposure frequency (surface water and sediment) – Adult and child receptors were assumed to be exposed to sediment and surface water within the OU5 study area at frequencies of one event per day and 28 days/year (1 day/week for the months between April and October but no exposures for November through March).
  - Dermal contact (sediment) – Skin surface area and dermal adherence factors to sediment are assumed to be the same as those of EPA's default residential scenario. Adult receptors were assumed to be dermally exposed to sediment through head, hands, forearms, and lower legs, while child receptors were assumed to be dermally exposed to sediment through head, hands, forearms, lower legs, and feet.
  - Dermal contact (surface water) – Adult and child receptors were assumed to be dermally exposed to surface water through their entire skin surface area for 1 hour per event under a swimming scenario. Under a wading scenario, adult and child receptors were assumed to be

dermally exposed to surface water through the parts of their skin surface area (identified for the sediment dermal exposure above) for 2 hours per event.

- Exposure factors for drinking water scenario
  - Ingestion of surface water as a drinking water source – All of the exposure factors selected for this exposure scenario are consistent with EPA's default values for a residential tap water scenario.
- Exposure factors for fish consumption
  - Consumption rates – The consumption rate of fish was the upper 95th confidence interval of the mean fish consumption rate estimated in a study of self-identified consumers of fish from the Grand Lake watershed, Oklahoma (Dong et al., 2015). The consumption rate of fish used in the HHRA was at the upper end of the range of fish ingestion rates developed by EPA for rivers (Table 10-5 of EPA, 2011). Consistent with the approach used for the tribal lifeway scenario, the child fish consumption rate is 50 percent of the adult fish consumption rate.

4.3.3 Intake Estimate

4.3.3.1 Intake Equations

The amount of a chemical ingested or taken up across the skin is referred to as "intake" or "dose." An average daily intake (DI) of chemical is usually calculated using the following equation for ingestion and dermal contact exposure routes:

$$DI = C \cdot \left(\frac{IR}{BW} \right) \cdot \left(\frac{EF \cdot ED}{AT} \right)$$

In accordance with RAGS Part F (EPA, 2009a), potential risks associated with inhalation exposures were assessed on a concentration basis rather than an intake-based approach. Chemical-specific average exposure concentrations (ECs) were estimated for inhalation exposures by applying appropriate exposure factors and assumptions as shown in the following equation:

$$EC = C \cdot \left(\frac{ET \cdot EF \cdot ED}{AT} \right)$$

Where:

DI = Average daily intake of chemical through ingestion and dermal contact exposure routes (milligrams per kilogram of body weight per day [mg/kg-day]).

EC = Daily average exposure concentration of chemical through inhalation (milligrams per cubic meter [mg/m^3]).

C = Concentration of the chemical in the environmental medium (e.g., sediment, surface water, water vapor, or aquatic biota) to which the receptor is exposed (represented by EPC). The units are milligrams (mg) of chemical per unit of exposure medium (e.g., milligrams per kilogram [mg/kg] for sediment or food items, milligrams per liter [mg/L] for water, and mg/m^3 for water vapor).

IR = Intake rate of the exposure medium. The units are mg/day for sediment, grams per day (g/day) for food, and liters per day for surface water.

BW = Body weight of the exposed person (kg).

ET = Exposure time (hours per day). This describes how many hours a receptor is likely to be exposed to the exposure medium during a day.

EF = Exposure frequency (days/year). This describes how often a person is likely to be exposed to the exposure medium during a typical year.

ED = Exposure duration (years). This describes how long a person is exposed to the exposure medium.

AT = Averaging time (days). This specifies the length of time over which the average dose will be calculated. Usually, two different averaging times are considered: chronic exposure and lifetime exposure. Chronic exposure includes averaging times over the specified exposure duration (e.g., 64 years of exposure for adult tribal lifeway). Chronic exposure averaging times are used when estimating non-cancer hazard, while lifetime exposure uses an averaging time of 70 years when estimating ELCRs.

The last three factors—exposure frequency, exposure duration, and averaging time (and exposure time for inhalation exposure pathway)—combine to yield a factor between zero and one. Values near one indicate that exposure is nearly continuous over the specified averaging period; values near zero indicate that exposure occurs only rarely.

To quantify exposure using the two equations above, each receptor group's exposure must be estimated using exposure factors and the EPCs for the COPCs in the exposure media (e.g., sediment, surface water, or aquatic biota).

4.3.3.2 Estimation of Dermal Intake through Exposure to Water

The method presented in RAGS Part E (EPA, 2004) was used to estimate dermal exposure to COPCs in water for three exposure scenarios: (1) dermal exposure to COPCs in surface water during hunting, fishing, gathering, and recreational activities, and (2) dermal exposure to COPCs in surface water during showering as part of potable use of surface water scenario.

The dermally absorbed dose per event, DA_{event}, was calculated as follows:

$$DAD = \frac{DA_{event} \times EF \times ED \times EV \times SA}{BW \times AT}$$

Where:

DAD	=	Dermal absorption dose (mg/kg-day)
EF	=	Exposure frequency (days/year)
ED	=	Exposure duration (years)
EV	=	Event frequency (events/day)
SA	=	Skin surface area (square centimeter [cm^2])
BW	=	Body weight (kg)
AT	=	Averaging time (days)

$$DA_{event} = K_p \times C_w \times t_{event} \times CF1$$

Where:

DA_{event}	=	Absorbed dose per event (milligrams per square centimeter [mg/cm^2]-event)
Kp	=	Permeability coefficient from water through skin (centimeters per hour)
Cw	=	Concentration of chemical in water (mg/L)
t_{event}	=	Duration of event (hours per event)
CF1	=	Conversion factor (0.001 liter per cubic centimeter)

The calculation of dermally absorbed dose per event is presented in Appendix B, RAGS Table 7 Supplemental tables.

4.3.3.3 Estimation of Dermal Intake through Exposure to Salve

The method developed in RAGS Part E (EPA, 2004) to estimate dermal exposure to chemicals in soil was used to estimate dermal exposure to COPCs in salve under a scenario evaluating medical use of aquatic plants (using arrowhead plant data). Because adherence factor and the salve-to-skin dermal absorption fraction specific to this scenario are not readily available, the soil-to-skin adherence factor and dermal absorption fraction for chemicals in soil were used to estimate dermal absorption dose of COPCs in aquatic plants during their medicinal use.

The dermally absorbed dose was estimated using the following equation:

$$DAD = \frac{C_{plant} \times EF \times ED \times AF \times ABS_d \times SA \times CF2}{BW \times AT}$$

Where:

DAD	=	Dermal absorbed dose (mg/kg-day)
C_{plant}	=	Concentration of COPC in plant (mg/kg)
EF	=	Exposure frequency (days/year)
ED	=	Exposure duration (years)
AF	=	Adherence factor of soil to skin (mg/cm^2-event)
ABS_d	=	Dermal absorption fraction (unitless)
SA	=	Skin surface area (cm^2)
CF2	=	Conversion factor (kilograms per milligram)
BW	=	Body weight (kg)
AT	=	Averaging time (days)

4.3.3.4 Estimation of Inhalation of COPCs in Water Vapor

The EPCs of the COPCs in water vapor were modeled for the evaluation under a sweat lodge exposure scenario in accordance with the methodology presented in Section I of Shoshone-Bannock Exposure Scenario for Use in Risk Assessment (S-B EWMP, 2016). The specific equation and input parameter values are presented in Appendix B, RAGS Table 4.5.

$$C_v = C_{sw} \times \left(\frac{MW_w}{R \times T \times \rho_w}\right) \times EXP\left(18.3036 - \frac{3816.44}{T - 46.13}\right)$$

Where:

C_v	=	COPC concentration in water vapor (mg/m^3)
C_{SW}	=	COPC concentration in surface water (mg/L)
MW_w	=	molecular weight of water (18 grams per mole [g/mol])
R	=	ideal gas law constant (0.06237 millimeters mercury per cubic meter per mole degrees Kelvin [mmHg·m^3]/[mol·K])
T	=	temperature of the sweat lodge (339 degrees Kelvin [or 66 degrees Celsius)
ρ_W	=	density of liquid water (1,000 grams per liter)

4.3.4 Approach for Mutagenic Exposures

COPCs with a mutagenic mode of action (MMOA) require separate exposure estimations for age ranges 0 to <2, 2 to <16, and 16 and older due to toxicity adjustments required for younger age ranges (EPA, 2005b, 2005c). Although speciated chromium data are not available, chromium in surface water was conservatively assumed to be 100 percent in the hexavalent chromium, or Cr (VI), form, which acts through an MMOA. Age-specific toxicity values are not available for Cr (VI); therefore, EPA's default age-dependent adjustment factors (ADAFs) were applied to the cancer slope factor (CSF) and inhalation unit risks (IURs) for Cr (VI) for childhood and early-life exposure to surface water by potential child tribal lifeway and general public receptors.

Tribal lifeway adult/child aggregate exposure (surface water):

$$\text{Aggregated DI} = \sum DI_i \times ADAF_i$$

$$= DI_{(0-<2\ years)} \times 10 + DI_{(2-<6\ years)} \times 3 + DI_{(6-<16\ years)} \times 3 + DI_{(16-<26\ years)} \times 1$$

Where:

DI = *daily intake*
i = *"i"*th age groups as follows.
ADAF = age-dependent adjustment factor, as follows:

Age of Exposure	ADAF
0 to less than 2 years	10
2 to less than 6 years	3
6 to less than 16 years	3
16 and older	1

4.3.5 Approach for Arsenic Speciation

Arsenic exposures through consumption of food were evaluated based on the fraction of arsenic species likely to be present in these food items. The form of arsenic in food items (fish, shellfish, plants, amphibians, and semi-aquatic mammals) was assumed to be 10 percent inorganic arsenic and 90 percent organic arsenic. This assumption of 10 percent of arsenic being in the inorganic form is made based on EPA's technical document, *Technical Summary of Information Available on the Bioaccumulation of Arsenic in Aquatic Organisms* (EPA, 2003c). This document indicates that "The consensus in the literature is that upwards of 85 percent to more than 90 percent of arsenic found in edible portions of marine fish and shellfish is organic arsenic (arsenobetaine, arsenocholine, or dimethylarsinic acid) and that approximately 10 percent is inorganic arsenic" (De Gieter et al., 2002; Goessler et al., 1997; Johnson and Roose, 2002; Ochsenkühn-Petropulu et al., 1997). Therefore, 10 percent of the arsenic concentration in food items was used to estimate carcinogenic risks and non-carcinogenic hazards in the HHRA.

SECTION 5

Toxicity Assessment

This section describes the oral, dermal, and inhalation toxicity values (non-carcinogenic and carcinogenic) used in estimating potential adverse health effects for COPCs at the site.

The oral toxicity values (CSFs and reference doses [RfDs]) and inhalation toxicity values (IURs and reference concentrations [RfCs]) used in the HHRA were obtained from the EPA standard hierarchy of toxicity value sources (EPA, 2003d), as follows:

- Tier 1 Source – Integrated Risk Information System (IRIS) (EPA, 2019c)
- Tier 2 Source – EPA Provisional Peer-Reviewed Toxicity Values (PPRTV)
- Tier 3 Sources – Other peer-reviewed federal and state toxicity values
  - Minimal risk levels identified by the Agency for Toxic Substances and Disease Registry (ATSDR, 2019)
  - California EPA toxicity database (Cal/EPA, 2019)
  - EPA's Health Effects Assessment Summary Tables (EPA, 1997a)

5.1 Non-carcinogenic Toxicity Values

Non-carcinogenic toxicity values (oral RfDs and inhalation RfCs) were used in estimating potential adverse health effects associated with exposure to COPCs. In general, the RfD and RfC are estimates (with uncertainty spanning perhaps an order of magnitude) of daily exposure to the human population (including sensitive subgroups) that are likely to be without an appreciable risk of deleterious effects during a lifetime of exposure (EPA, 1989).

5.1.1 Cadmium

Two oral RfDs are provided in IRIS for cadmium: an oral "water" RfD of $5x10^{-4}$ mg/kg-day and an oral "food" RfD for cadmium of $1x10^{-3}$ mg/kg-day (EPA, 2019c). The oral "food" RfD of $1x10^{-3}$ mg/kg-day was used to quantify potential non-carcinogenic hazard for cadmium associated with sediment ingestion and biota consumption, whereas the oral "water" RfD of $5x10^{-4}$ mg/kg-day was used to quantify potential non-carcinogenic hazard for cadmium associated with surface water ingestion.

5.1.2 Chromium

Trivalent chromium (Cr [III]) is highly insoluble and will not be found in dissolved aqueous phase unless (1) pH is very low (below 4 to 4.5), or (2) the Cr (III) is complexed by a strong bond to an organic molecule that keeps it in solution. These conditions are not observed at Tar Creek. On the other hand, Cr (VI), when stable under oxidizing conditions, is highly soluble and does not form any insoluble salts except under evaporative conditions. Therefore, it is a reasonable assumption that dissolved chromium is essentially 100 percent Cr (VI) over the common pH range. There are cases in which Cr (VI) can be incorporated into freshly precipitating calcite; however, it is not likely a case for Tar Creek.

Based on the above-mentioned characteristics of chromium at different oxidation states, Cr (VI) toxicity values were used for exposure through aqueous media such as surface water, whereas Cr (III) toxicity values were used for exposure through solid media such as sediment and food. The inhalation RfC for chromic acid mists and dissolved Cr (VI) aerosols was used for water vapor.

5.1.3 Manganese

The IRIS oral RfD for manganese (0.14 mg/kg-day) includes manganese from all sources, including diet (EPA, 2019c). Consistent with the RSL User's Guide (EPA, 2019a) and the IRIS assessment for manganese (EPA, 2019c), two separate oral RfDs were used to quantify risks for manganese in the HHRA. An oral RfD for non-diet exposures was calculated by subtracting the dietary contribution from the normal U.S. diet (an upper limit of 5 mg/day) and applying a modifying factor of 3 to address uncertainties associated with non-food manganese exposure sources, resulting in an oral "non-diet" RfD of 0.024 mg/kg-day. The oral "non-diet" RfD was used to estimate potential HQs associated with exposures to sediment and surface water. The oral "diet" RfD of 0.14 mg/kg-day was used to estimate potential risks associated with consumption of biota (fish, shellfish, plants, amphibians, and semi-aquatic mammals).

5.1.4 Mercury

Mercury was assumed to be present as mercuric chloride (and other mercury salts) in sediment and surface water, whereas mercury is assumed to be present as methylmercury in food (animal and plant tissues). Although an RfC is available for elemental mercury, this RfC was not used in the evaluation of inhalation of mercury within the OU5 study area because mercury is expected to be present as mercuric chloride (and other mercury salts) in surface water, not elemental mercury.

5.1.5 Phosphorus

Phosphorus was assumed to be present as adsorbed orthophosphate in the sediment. Although the RSL for white phosphorus was conservatively used in the COPC selection process, the RfC available in IRIS for white phosphorus was not used in the evaluation of ingestion of phosphorus in sediment within the OU5 study area because white phosphorus (which does not occur naturally) is not expected to be found at the site.

5.1.6 Vanadium

The oral RfD for vanadium (0.005 mg/kg-day) used in the HHRA was derived from the oral RfD for vanadium pentoxide (0.009 mg/kg-day). The vanadium oral RfD was calculated by factoring out the molecular weight of the oxide ion. The two atoms of vanadium contribute 56 percent of the molecular weight for vanadium pentoxide. Therefore, the oral RfD for vanadium pentoxide was multiplied by 56 percent to calculate the oral RfD for vanadium (0.005 mg/kg-day). This approach is consistent with the RSL User's Guide (EPA, 2019a).

5.1.7 Silica

The RfC presented on the RSL table is meant to be applied only to particles of crystalline silica (quartz, cristobalite, tridymite) of respirable size; therefore, the silica RfC was not used for the evaluation of silica in water vapor.

5.1.8 Thallium

Thallium was the only COPC with a PPRTV appendix toxicity value. The PPRTV for thallium and compounds document (EPA, 2012) states:

> "It is inappropriate to derive a subchronic or chronic provisional RfD for thallium. However, information is available which, although insufficient to support derivation of a provisional toxicity value, under current guidelines, may be of limited use to risk assessors…Users of screening toxicity values in an appendix to a PPRTV assessment should understand that there is considerably more uncertainty associated with the derivation of a supplemental screening toxicity value than for a value presented in the body of the assessment."

Therefore, the PPRTV appendix value was used for screening purposes only, and a quantitative evaluation of thallium was not conducted.

Non-cancer toxicity values used in the HHRA are presented in Appendix B, RAGS Tables 5.1 and 5.2.

5.2 Carcinogenic Toxicity Values

Carcinogenic toxicity values (CSFs and IURs) were used in evaluating potential carcinogenic effects associated with exposure to known, probable, or possible carcinogens having an EPA weight-of-evidence classification of A, B, or C, respectively. One exception was Cr (VI), which is not considered by EPA to have a weight-of-evidence classification of A, B, or C, but where a CSF was derived by Cal/EPA (2019). CSFs and IURs were used to estimate upper-bound lifetime statistical probabilities of a hypothetical individual developing cancer as a result of exposure to a potential carcinogen.

5.2.1 Chromium

Consistent with EPA's (November 2019) RSL table, the IUR for hexavalent chromium is derived by multiplying the IRIS hexavalent chromium IUR of 1.2×10^{-2} per microgram per cubic meter ($\mu g/m^3$) by 7. This is considered to be a health-protective assumption, and is also consistent with the State of California's interpretation of the Mancuso study that forms the basis of hexavalent chromium's estimated cancer potency.

Cancer toxicity values for COPCs are provided in Appendix B, RAGS Tables 6.1 and 6.2.

5.3 Derivation of Dermal Toxicity Values

Oral RfDs and CSFs were converted to dermal RfDs and CSFs using gastrointestinal absorption factors. The values used for this conversion were obtained from RAGS Part E, Section 4.2, and Exhibit 4-1 (EPA, 2004). Following EPA's recommendation, such a conversion was performed only when a chemical has a gastrointestinal absorption factor of less than 50 percent. If a chemical-specific gastrointestinal absorption factor was not available, gastrointestinal absorption of the chemical was assumed to be greater than 50 percent, and the oral RfD (or oral CSF) was used as the dermal RfD (or dermal CSF) without adjustment.

SECTION 6

Risk Characterization

This section provides a summary of risk characterization at the site. Potential human health risks are discussed separately for carcinogenic and non-carcinogenic health effects due to the different toxicological endpoints, relevant exposure durations, and methods used to estimate risk, with the exception of lead. The standard approach for the evaluation of lead (using multi-media biokinetic modeling) is different from other chemicals, warranting a separate evaluation and discussion; therefore, the detailed evaluation of lead is presented in Appendix E and a summary is provided below.

CERCLA specifies an acceptable site ELCR range of one in a million (1×10^{-6}) to one in ten thousand (1×10^{-4}). Generally, remedial actions are not warranted for site media with an ELCR of 1×10^{-4} or less or a hazard index (HI) of 1 or less, although it may be warranted if other site-specific information suggests to risk managers that action is appropriate. Based on the risk estimates, preliminary COCs were identified. Background comparison and the nature of mining-related contamination was used to refine the list of preliminary COCs to identify final COCs.

Potential lead exposure was evaluated in Appendix E, where a similar refinement process was applied to the results to identify if lead was a final COC. The results of the lead evaluation are incorporated into the risk characterization beginning in Section 6.5.2 (Refinement of Preliminary COCs).

6.1 Approach for Potential Non-carcinogenic Effects

The HHRA evaluated the potential for non-carcinogenic effects by comparing the exposure intakes of each COPC over a specified time period (i.e., chronic) with RfDs derived for a similar exposure period. For the inhalation exposure route, non-carcinogenic effects were evaluated by comparing the ECs of each COPC with the RfC. In EPA methodology, this ratio of exposure to toxicity is referred to as an HQ. The HQ assumes that there is a level of exposure below which it is unlikely for even sensitive populations to experience adverse health effects. If the exposure level exceeds this threshold, there is the potential for non-cancer health effects to occur. The HQ is calculated as follows:

$$HQ = \frac{DI}{RfD} \qquad \text{or} \qquad HQ = \frac{EC}{RfC}$$

Where:

HQ = Hazard quotient
DI = Daily Intake level (mg/kg-day)
RfD = Reference dose (mg/kg-day)
EC = Exposure concentration (mg/m^3)
RfC = Reference concentration (mg/m^3)

Intake and RfD are expressed in the same units (mg/kg-day) and represent the same exposure period. Similarly, ECs and RfCs are expressed in the same units (mg/m^3). An HQ that exceeds 1 (i.e., intake exceeds the RfD or EC exceeds the RfC) indicates that there is a potential for adverse health effects associated with exposure to that COPC.

To assess the potential for non-carcinogenic health effects posed by exposure to multiple COPCs and exposure routes, an HI approach was used (EPA, 1989). This approach assumes that non-carcinogenic hazards associated with exposure to more than one COPC and exposure route are additive. Synergistic or antagonistic interactions between COPCs are not quantified. The HI may exceed 1 even if all of the individual HQs are less than 1.

The HI is equal to the sum of the HQs and is calculated as follows:

$$HI = \frac{DI_1}{RfD_1} + \frac{DI_2}{RfD_2} + \cdots \frac{DI_i}{RfD_i} + \frac{EC_1}{RfC_1} + \frac{EC_2}{RfC_2} + \cdots \frac{EC_j}{RfC_j}$$

Where:

HI = Hazard index
DI = Daily intake level (mg/kg-day)
RfD = Reference dose (mg/kg-day)
I_i = Intake level for the "*i*"th constituent
RfD_i = Reference dose for the "*i*"th constituent
EC = Exposure concentration (mg/m^3)
RfC = Reference concentration (mg/m^3)
EC_j = Exposure concentration for the "*j*"th constituent
$RfCj_i$ = Reference concentration for the "*j*"th constituent

6.2 Approach for Potential Carcinogenic Effects

The potential for carcinogenic effects due to exposure to site media was evaluated by estimating the ELCR. The ELCR is the incremental increase in the probability of developing cancer during one's lifetime (as a result of exposure to site media) above the probability of developing cancer from non-site exposures.

Potential ELCRs associated with exposure to individual carcinogens were calculated using CSFs and chemical intakes for oral and dermal contact exposures, and IURs and ECs for inhalation exposures. The linear low-dose equation was used to estimate the incremental probability of an individual developing cancer over a lifetime as a result of exposure to potential carcinogens. Estimated ELCRs are calculated by multiplying the DI by the CSF or EC by the IUR:

$$ELCR = DI \times CSF \quad \text{or} \quad ELCR = EC \times IUR$$

Where:

ELCR = Excess lifetime cancer risk
DI = Daily intake level (mg/kg-day)
CSF = Cancer slope factor $(mg/kg\text{-}day)^{-1}$
EC = Exposure concentration ($\mu g/m^3$)
IUR = Inhalation unit risk $(\mu g/m^3)^{-1}$

The theoretical probability of developing cancer as a consequence of exposure to two or more COPCs and by two or more exposure pathways was calculated by summing the risk estimates for each COPC in the appropriate scenarios using the following equation:

$$Total\ ELCR = (DI_1 \times CSF_1) + (DI_2 \times CSF_2) + \ldots (DI_i \times CSF_i) +$$

$$(EC_1 \times IUR_1) + (EC_2 \times IUR_2) + \ldots (EC_i \times IUR_i)$$

Where:

ELCR = Excess lifetime cancer risk
DI = Daily intake level (mg/kg-day)

CSF = Cancer slope factor $(mg/kg\text{-}day)^{-1}$
I_i = Intake level for the "*i*"th constituent
CSF_i = Cancer slope factor for the "*i*"th constituent
EC = Exposure concentration $(\mu g/m^3)$
IUR = Inhalation unit risk $(\mu g/m^3)^{-1}$
EC_j = Exposure concentration for the "*j*"th constituent
IUR_j = Inhalation unit risk for the '*j*'th constituent

6.3 Approach for Lead

Potential lead exposure was evaluated using the IEUBK Model for Lead in Children, Windows, Version 1.1, Build 11 (EPA, 2010) and the Adult Lead Methodology (ALM) (EPA, 2017a). Recently updated (but not yet available to the public) default lead intake values for food consumption were used in the IEUBK model (Appendix E, Table 2). The lead analysis is presented in Appendix E.

The IEUBK model provides predictions of blood lead levels (BLLs) for children ages 0 to 7 years old with exposure to lead in various media. The IEUBK model results are expressed as the predicted geometric mean (GM) BLL for children and the percentage of the child population with potential BLLs above the target BLL. Based on EPA OLEM policy (EPA, 1994a), which strives to reduce lead exposure levels so that there is no more than a 5 percent probability that children exposed to lead will exceed a BLL of 10 µg/dL, 10 µg/dL was used as a target BLL. Additionally, the current scientific literature on lead toxicology and epidemiology provides evidence that adverse health effects are associated with BLLs less than 10 µg/dL (EPA, 2016a). Therefore, lead exposure was assessed using two additional, lower target BLLs (5 and 8 µg/dL) to provide additional information for comparison.

The ALM model was used to calculate potential BLLs for the aquatic worker scenario. The model results are expressed as the predicted GM BLL and the corresponding 95th percentile fetal BLLs, and the probability that fetuses exposed to lead will exceed a BLL above the same set of target BLLs (5, 8, and 10 µg/dL) used in the IEUBK model.

6.4 Summary of Risk Estimates

Potential risk associated with exposures to COPCs in the site media were quantified for the RME scenarios identified below:

- **Current/Future Tribal Lifeway.** Sediment (incidental ingestion and dermal contact) and surface water (incidental ingestion and dermal contact) exposure during hunting, fishing, gathering, and recreational activities; surface water as a drinking water source (ingestion and dermal contact); surface water exposure during sweat lodge use (ingestion, dermal contact, and inhalation); food consumption (ingestion of fish, shellfish, aquatic plants, amphibian/aquatic reptiles, and semi-aquatic mammals); and medicinal use of plants (dermal contact).
- **Current/Future Aquatic Workers.** Sediment (incidental ingestion and dermal contact) and surface water (incidental ingestion and dermal contact) exposure during work activities.
- **Current/Future General Public.** Sediment (incidental ingestion and dermal contact) and surface water (incidental ingestion and dermal contact) exposure during recreational activities; surface water as a drinking water source (ingestion and dermal contact); and food consumption (ingestion of fish).

Tables 6-1 through 6-5 summarize the risk estimates for each watershed. Additional detailed information about risk estimates is presented in Appendix B, RAGS Tables 7.1 through 7.42 and 9.1 through 9.42.

6.5 Chemicals of Concern

COCs were identified using a step-wise process, as summarized on Figure 6-1. First, preliminary COCs were identified based on the results of the HHRA. Preliminary COCs are chemicals that drive risks based on the results presented in RAGS Part D Table 9s and the lead model output, without regard for background levels or relation to sources associated with historical site activities. Second, the list of preliminary COCs was refined using two refinement processes (background comparison, and nature of mine-related contamination) to identify the final COCs. Final COCs take background levels and attribution to site sources into account. The following subsections provide detailed information regarding the COC selection and refinement processes.

6.5.1 Identification of Preliminary COCs

Preliminary COCs are identified for a receptor scenario when the potential ELCR or HI exceeds EPA threshold values (a total ELCR of 1×10^{-4} or a target-organ-specific HI of 1), with the exception of lead (which is based on the lead model outputs, as presented in Appendix E). When a target ELCR of 1×10^{-4} is exceeded for an exposure medium for the receptor scenario, the COPCs posing an individual ELCR greater than 1×10^{-6} in the environmental medium were identified as preliminary COCs. When a target-organ-specific HI of 1 is exceeded for an exposure medium for the receptor group, the COPCs posing an HQ greater than 0.1 for that target organ in the environmental medium responsible for the unacceptable HI are identified as preliminary COCs. Because child receptors have higher HI estimates than adult receptors, the preliminary COCs for non-carcinogenic endpoints were identified based on the HHRA results for child receptors under tribal lifeway and general public exposure scenarios. Tables 6-1 through 6-5 summarize preliminary COCs for each receptor scenario by watershed.

6.5.2 Refinement of Preliminary COCs

The lists of preliminary COCs were refined using a two-step refinement process (background comparison, and nature of mine-related contamination). This process is consistent with EPA guidance on HHRA (EPA, 1989, 2002).

- When statistical background comparison (central tendency) indicates concentrations in site sediment are not greater than background, that preliminary COC was not identified as a final COC. The sediment background comparison was performed separately for sieved and unsieved datasets, when sufficient data were available. For preliminary COCs in sediment, when the background comparisons were performed on both sieved and unsieved datasets, if at least one of the datasets indicates that the site concentration is greater than background, the preliminary COC was conservatively retained for further evaluation.
- The surface water comparison to background is based on the total metals (not dissolved metals) surface water datasets for the site and background. The comparison to background is based on total metals because onsite exposures were based on total metals data.
- Preliminary COCs in biota were refined based on background comparisons of sediment data because of the complexity of performing background comparisons on the biota data and relatively small size of background biota datasets. Biological systems are complex; therefore, for instance, the concentrations of chemicals in fish tissue may not be directly compared without considering other factors potentially influencing the chemical concentrations in fish tissue, such as fish species, where they dwell in the water column, part of body sampled, and age (or size). In addition, fish, amphibians/aquatic reptiles, and semi-aquatic mammals are not stationary and may move within or between watersheds. For these reasons, preliminary COCs in biota were refined based on the background comparisons of sediment data. Background comparisons of sediment data were performed by watershed, while preliminary biota COCs were identified based on sitewide data.

Therefore, if at least one of the watershed datasets indicates that the site concentration is greater than background in sediment, the preliminary biota COC was conservatively retained for further evaluation.

For those preliminary COCs that were not eliminated based on background comparisons, further review of the preliminary COCs was performed based on nature of mine-related contamination. Literature review was performed to evaluate the likelihood of the preliminary COC being associated with TSMD ore bodies (Table 7-1 of the RI report). If the preliminary COC is not likely to be associated with TSMD ore bodies, that preliminary COC was not identified as a final COC. The following preliminary COCs were eliminated based on the literature review:

- Molybdenum in sediment
- Aluminum, chromium, and vanadium in surface water
- Mercury in biota

The refinement of preliminary COCs is presented in Tables 6-6 through 6-13. The final list of COCs for the OU5 study area is summarized in Table 6-14; this table also incorporates the identification of lead as a final COC as shown in Appendix E, Table 10. Hazard and cancer risk estimates for the final COCs are summarized in Tables 6-15 through 6-19. More detailed information about COC selection is presented in Appendix B, RAGS Tables 10.1 through 10.19.

6.6 Uncertainty Analysis

The methodologies and assumptions used in any HHRA have inherent uncertainty. This subsection presents a discussion of those uncertainties, as well as their effect on the estimates of potential health outcome (i.e., non-carcinogenic hazard, cancer risk, and lead exposure) in the HHRA. The discussion of their effect is largely qualitative because, in many instances, not enough information exists to quantify the magnitude of these uncertainties. While it is theoretically possible that the HHRA leads to underestimates of potential health outcome, the use of numerous upper-bound assumptions most likely results in conservative estimates.

6.6.1 General Uncertainties

The non-carcinogenic HIs and ELCRs based on RME assumptions presented in Section 6 are estimates of potential upper-bound hazard and risk that are useful in regulatory decision-making. It is improper to consider these estimates as representative of the actual health outcome to potentially exposed individuals because they were estimated by making numerous conservative assumptions (i.e., assumptions that overestimate potential exposure and potential health outcome). Some of the assumptions have a firm scientific basis, while others do not. Various degrees of uncertainty are introduced into the HHRA process every time an assumption is made, including when a default value is used. In the EPA risk assessment process, the methodology dictates that assumptions err on the side of overestimating potential exposure and health outcome. The effect of using numerous assumptions that each overestimate potential health outcome is to exaggerate estimates of potential risk. Such estimates do not provide a realistic estimate of the potential health impacts associated with a site.

General uncertainties associated with standard CERCLA HHRA methodologies and assumptions are summarized in Table 6-20, while specific uncertainties associated with the OU5 HHRA are discussed below.

6.6.2 Uncertainties Associated with OU5 Study Area-Specific Data and Data Usage

6.6.2.1 Use of Historical Data

Historical data[4] used in the HHRA were composed of samples collected by multiple stakeholders and agencies during independent sampling events for various end uses. The data used in the HHRA have been evaluated for usability in the Data Gap Evaluation (CH2M, 2017) and were deemed to be acceptable for use in an HHRA using five general assessment factors: soundness, applicability and utility, clarity and completeness, uncertainty and variability, and evaluation and review. However, as the data were collected by stakeholders and agencies using a variety of collection methods for different investigation objectives, inclusion of these datasets has introduced some degree of uncertainty to the data.

Because of the compilation of analytical datasets from multiple sampling events, the historical dataset contains analytes different from the target analytes that were selected for the 2017 Data Gap Investigation. For example, a subset of historical sediment data includes boron, lithium, phosphorus, strontium, and titanium because samples were collected and analyzed for different investigation objectives. Although these analytes are not likely to be associated with site activities, they were conservatively identified as COPCs and evaluated in the quantitative HHRA.

Additionally, historical data included a range of reporting limits within a data group. Although the range of reporting limits varied for sediment and surface water, the majority of COPCs had a relatively high frequency of detection (greater than 50 percent). Therefore, having a wide range of reporting limits itself is not likely to impact overall HHRA conclusions. However, as is typical with the use of historical datasets in HHRA, the use of compiled historical analytical datasets has introduced some degree of uncertainty to the data used in the HHRA.

6.6.2.2 Use of Sieved and Unsieved Sediment Data

Both sieved and unsieved sediment data were used in the HHRA. Generally, in HHRA, unsieved sediment data are used to evaluate potential exposure to COPCs in sediment, as they are what receptors would be exposed to in the environment during recreational activities in a body of water. Lead is an exception to this, as OLEM 9200.1-128 (EPA, 2016c) recommends sieving soil and dust samples for the assessment of incidental ingestion using the IEUBK model, because dermally adhered soil is largely made up of particle fractions <150 µm.

Soil particle size is directly related to dermal adherence and inversely associated with mobility and bioavailability. These current recommendations concerning use of sieved soil data apply to lead risk assessment but may also be applicable to other metals; however, there is no guidance specific to the use of sieved data for sediment. Based on the review of the unsieved and sieved sediment datasets (see Appendix F1, Figure 1), cadmium, lead, and zinc concentrations in sediment tend to be higher in unsieved data than sieved data, but this observation was not always consistent; therefore, all sediment data were used and the higher EPCs between the unsieved and sieved sediment datasets were selected conservatively as the final EPCs for each watershed in the HHRA (as shown in Appendix B, RAGS Table 3.2 Supplement A). This approach likely overestimates potential health outcomes associated with sediment exposure.

[4] "Historical data" are defined here as data collected prior to 2017 (that is, prior to the 2017 Data Gap Investigation).

6.6.2.3 Use of Total Metals Surface Water Data

Potential exposure associated with COPCs in surface water (exposure during hunting, fishing, gathering, recreational activities, potable use, or sweat lodge use) was evaluated based on total concentrations of metals in surface water in the HHRA. Dissolved concentrations of metals, however, would likely be a better representation of exposure for some of these exposure scenarios.

For instance, inhalation of COPCs in water vapor generated by OU5 study area surface water poured over heated rocks was evaluated based on total concentrations of metals in surface water under a sweat lodge use scenario. However, COPC concentrations in water vapor (water droplets suspended in air) are better represented by dissolved metals surface water data than total metals surface water data. Additionally, surface water could be used as a potable water source with filtration. In this case, dissolved metals surface water data would represent potential exposure better than total metals surface water data.

As part of the uncertainty analysis for the HHRA, an evaluation of potential hazard and risk for potable surface water use and sweat lodge scenarios is performed based on the dissolved metals surface water dataset for the tribal lifeway receptors (Appendix F2, Tables 1 and 2). The EPCs of dissolved metals in surface water were estimated for the final surface water COCs (identified in Tables 6-9 through 6-11) in the same way that EPCs for total metals in surface water were estimated (see Section 4.3.1). The ProUCL output used to calculate EPCs for dissolved metals in surface water is presented in Appendix F2, Tables 3 through 5. Dissolved metal EPCs are comparable to, or up to 45 percent lower than, total metal EPCs. Appendix F2, Tables 1 and 2 show the comparison of risk estimates between dissolved and total metals surface water datasets. Although lower estimations of hazard and risk were observed using the dissolved metals surface water dataset, the results in terms of the level of HI and ELCR estimates and target organ exhibiting unacceptable HI were similar between the two datasets.

6.6.2.4 Mine Discharge

Mine discharge, when it occurs in OU5 watersheds, occurs only intermittently in areas relatively inaccessible to most people (including tribal members and citizens) and typically at low flow rates. Because it does occur in OU5 watersheds, however, the detected chemicals in mine discharge were evaluated as part of the uncertainty analysis for the same exposure scenarios as surface water.

The mine discharge (total metals) dataset consists of 25 samples that were collected in 2007, 2008, and 2017: 5 samples collected from the Tar Creek watershed and 20 samples collected from the Beaver Creek watershed (Appendix F3, Table 1). Mine discharge (total metals) samples collected as part of the 2017 Data Gap Investigation were analyzed for the following metals: aluminum, antimony, arsenic, barium, beryllium, cadmium, calcium, chromium, cobalt, copper, iron, lead, magnesium, manganese, mercury, molybdenum, nickel, potassium, selenium, silver, sodium, thallium, vanadium, and zinc. The historical dataset contains samples analyzed for various metals that may be different from the 2017 Data Gap Investigation, including some samples that were analyzed for cadmium, lead, and zinc only.

All chemicals detected in mine discharge (with the exception of the essential nutrients calcium, magnesium, potassium, and sodium) were identified as COPCs. The EPCs for total metals in mine discharge were estimated in the same way that EPCs for total metals in surface water were estimated (see Section 4.3.1). Total metal EPCs for mine discharge COPCs are summarized in Appendix F3, Table 2. The ProUCL output is presented in Appendix F3, Table 7.

Potential hazard and risk for tribal lifeway exposures to mine discharge were evaluated using the same exposure scenarios (hunting/fishing/gathering and recreational use, potable use, and sweat lodge use) as for surface water (Appendix F3, Tables 3 and 4). Additionally, potential hazards and risks for general public exposures to mine discharge were evaluated using the same exposure scenario (recreational use) and assumptions as the general public wading (dermal only) scenario for surface water (Appendix F3, Tables 5 and 6).

Mine discharge results for Tar Creek and Beaver Creek exceeded acceptable ELCR and HI levels for tribal lifeway but were below acceptable risk levels for the general public. Although Tar Creek mine discharge HI and ELCR estimates were lower than surface water estimates and Beaver Creek mine discharge HI and ELCR estimates were higher than surface water estimates, overall, the results were similar. Therefore, although concentrations (and risk estimates) at mine discharge points were expected to be higher than surface water concentrations (and risk estimates), the results of this comparison indicate otherwise. The potential risks associated with exposures to mine discharge are comparable or even lower than potential risks associated with surface water exposures. Further, it is noted that measured surface water concentrations in the Tar Creek and Beaver Creek watersheds reflect the impacts of mine discharge on surface water.

6.6.2.5 Additional Evaluation for Biota Consumption

An additional evaluation of potential hazard and risk for aquatic biota (animal and plant) ingestion for tribal lifeway receptors was performed (Appendix F4, Table 1) using higher exposure assumptions identified by input from the Quapaw Nation and TCTCIT (2018).

The additional evaluation of potential hazard and risk was performed using the following exposure assumptions:

- Adult aquatic plant ingestion rate of 333 g/day
- Child aquatic biota ingestion rate of 74 percent of the adult ingestion rate

The hazard and risk estimates associated with aquatic biota consumption (as summarized in Table 6-15) are compared to those estimated in this additional evaluation (Appendix F4, Table 1). No carcinogenic final COCs were identified for aquatic biota. Although several additional target organs were identified with unacceptable HIs in the additional evaluation, the overall results were similar to those presented in Table 6-15. Aquatic plant (as food) and shellfish were the only biota categories that exceeded unacceptable hazards in both evaluations.

6.6.2.6 Biota Data Groupings

Potential exposure to COPCs through consumption or medicinal use of biota was evaluated in the HHRA based on the “sitewide” dataset using combined data from all watersheds to account for mobility of tribal lifeway receptors and mobility of animals with an extended home range (e.g., raccoons). As part of this uncertainty analysis, biota-related exposure pathways were evaluated based on watershed-specific biota data (Appendix F5, Tables 1 through 3) to assess potential hazards for tribal lifeway receptors on a watershed by watershed basis.

Fish (estimated whole body eviscerated), shellfish, aquatic plant as food (arrowhead and duckweed), aquatic plant as salve (arrowhead), amphibian/aquatic reptile (frog legs), and semi-aquatic mammal (raccoons) data groups for the final biota COCs (identified in Table 6-12) were created for each of the six watersheds. Note that samples for some biota categories were not available for all watersheds as sampling was limited to the species available at the time of sampling:

- Shellfish tissue data were not available from Tar Creek, Elm Creek, Beaver Creek, and Lost Creek.
- Aquatic plant tissue data (as food) were not available from Beaver Creek.
- Aquatic plant tissue data (as salve) were not available from Neosho River and Beaver Creek.
- Amphibian/aquatic reptile data were not available from Elm Creek.

The ProUCL output used to calculate EPCs for watershed-specific biota datasets is presented in Appendix F5, Tables 4 through 9. Appendix F5, Tables 1 through 3 present HIs for biota-related exposure pathways based on watershed-specific biota datasets and the sitewide dataset.

Noticeable differences in the estimated HI were not observed for fish, shellfish, amphibian/aquatic reptile (frog legs), semi-aquatic mammal (raccoons), and aquatic plant (as salve) between watershed-specific biota datasets and the sitewide dataset. The only incidence where the watershed-specific HI was noticeably greater than the sitewide HI was aquatic plant (as food) in the Elm Creek watershed: the HI is 125 in Elm Creek, whereas the sitewide HI is 91 for the child tribal lifeway scenario.

Also, it should be noted that HIs in Tar Creek, Neosho River, Lost Creek, and Lower Spring River are considerably lower than the sitewide HIs estimated in the HHRA. Therefore, in general, the hazard and risk estimates based on the sitewide dataset in the HHRA were concluded to be an adequate and conservative representation of the estimates based on watershed-specific datasets.

6.6.2.7 Fish Consumption

The potential risk associated with COPC intake through fish consumption was performed based on the estimated "total" concentrations of COPCs in whole fish for tribal lifeway receptors. To provide a practical perspective for those who use different fish body parts in meal preparation, an analysis was performed to evaluate if the estimated "total" concentrations are different from the concentrations in separate body parts (head, fillet, and carcass) and if those who consume a specific body part have higher risk estimates than the estimate based on the "total" concentration in whole fish.

Data

Although various COCs were identified for the biota exposure medium, the total HI associated with exposure to these COCs through fish consumption was less than 1 for both tribal lifeway and general public receptors. Because lead is the primary COC at the Tar Creek Superfund Site, the analysis was performed based on lead data only. To simplify the data analysis, the detected concentrations only were used in this analysis. Among the 80 fish samples included in the data group for the tribal lifeway exposure scenario, 32 samples had no detection of lead in any fish body part; therefore, they were excluded from the dataset. Lead was detected in 40 head, 9 fillet, and 40 carcass samples. For those samples with lead detections, the relative difference in concentration between body part and whole body was calculated for each fish part using the equation below:

$$Relative\ difference = \frac{C_p - C_T}{C_T}$$

Where:

C_p = Lead concentration in a body part (head, fillet, or carcass)
C_T = Estimated "total" lead concentration in whole body

Analysis

Potentially Influential Variables

Various factors may influence the bioaccumulation or partitioning of lead in a fish body. Therefore, the relative difference in lead concentrations was evaluated for the following four variables:

- Fish species (game or non-game species)
- Fish habitat (water column or bottom feeder)
- Fish weight (samples were divided into four groups based on quartile of sample weight):
  - 1st quartile < 56.5 grams (g)
  - 2nd quartile ≥ 56.5 and <110.5 g
  - 3rd quartile ≥ 110.5 and <724.5 g
  - 4th quartile ≥ 724.5 g

- Level of lead exposure; estimated "total" lead concentration in whole fish was used for this variable (samples were divided into four groups based on quartile of estimated "total" lead concentration in whole fish):
  - 1st quartile < 0.29 mg/kg
  - 2nd quartile ≥ 0.29 and < 0.38 mg/kg
  - 3rd quartile ≥ 0.38 and < 0.48 mg/kg
  - 4th quartile ≥ 0.48 mg/kg

To understand the relationship between the categorical variables above, tables presenting the frequency distribution of fish samples were created. As indicated in Appendix F6, Table 1, it was noted that samples of non-game fish species have a tendency for higher body weight and being collected from locations with higher sediment lead concentrations than game fish species. Similarly, bottom feeders have a tendency for higher body weight and were collected from locations with higher sediment lead concentrations than fish inhabiting the water column.

To evaluate if relative differences of lead concentrations vary among the groupings created by the four categories above, a classical "Analysis of Variance" test was performed (Appendix F6, Tables 2 through 4). EPA ProUCL software (Version 5.1.002) (EPA, 2016b) was used for all statistical analysis. No statistically significant differences in relative differences of lead concentrations were observed among the data groupings created by the variables for all three body parts except one. Relative differences in lead concentrations for fish fillet were different between the two data groupings created based on the estimated total "lead" concentration in whole fish[5]. However, regardless of this observed statistically significant difference, all fish fillet samples were used in the analysis because of the small sample size (nine samples were available).

Test of Normality

Using the Shapiro-Wilk test of normality, normality of the data distribution was tested (alpha = 0.05). Quartile-Quartile (Q-Q) plots and the results of normality tests are presented in Appendix F6, Figure 1. Based on the test results, the relative difference of lead concentrations calculated for the three body parts (head, fillet, and carcass) appear to be normally distributed.

Single Sample Hypothesis Test

Single sample hypothesis tests (single sided) were conducted to test if relative difference in lead concentrations was statistically significantly (alpha = 0.05) greater than zero (Appendix F6, Table 5).

The results of the single sample hypothesis test are summarized below.

- Lead concentrations in head of fish are statistically significantly higher than the estimated lead concentrations in whole fish. On average, lead concentrations in head are about 35.6 percent higher than the estimated "total" lead concentrations in whole fish.
- There is no statistically significant increase (alpha = 0.05) in lead concentrations in fish fillet or carcass compared to the estimated "total" lead concentrations in whole fish.

Conclusions

The analysis of detected lead concentrations in fish parts (head, fillet, and carcass) and estimated "total" lead concentrations in whole fish suggest a statistically significantly higher concentration of lead in head than the estimated lead concentration in whole fish. However, no statistically significant increase in lead concentrations was observed in fish fillet or carcass. Therefore, those who eat the head of fish in meals (for example, soup) may experience higher intake of lead than the lead intake based on the estimated "total" lead concentration in whole body in the HHRA.

[5] Because of the small sample counts, the data from the 1st, 2nd, and 3rd quartiles were merged and compared to the 4th quartile dataset.

6.6.2.8 Estimation of Inorganic Arsenic Fraction in Fish Tissue

Arsenic exposures through consumption of fish were evaluated based on the assumption that 10 percent of total arsenic in biota samples is present in a form of inorganic arsenic. As indicated in Section 4.3.5, the broad consensus in the literature suggests that this assumption is reasonable for edible portions of marine fish and shellfish; however, relatively less information is available for the inorganic arsenic fraction in freshwater fish.

Although the results of field studies generally agree with a small fraction of inorganic arsenic (less than 10 percent) observed in marine fish, there are some laboratory-based studies suggesting a higher fraction of inorganic arsenic in freshwater fish (EPA, 1997b). The data from EPA's National Study of Chemical Residues in Lake Fish Tissue (EPA, 2009b) – the first national assessment of freshwater fish contamination in the United States – show a consistent trend of low detection of inorganic arsenic in freshwater fish. Because the study did not analyze fish samples for total arsenic, it is impossible to establish the inorganic arsenic fraction to total arsenic based on these data. However, the data indicate that inorganic arsenic was only detected in a small fraction of samples. Therefore, although field studies generally support the assumption of the small fraction of inorganic arsenic in freshwater fish, consistent with the observation in marine fish used in the HHRA, there is some degree of uncertainty associated with this assumption.

6.6.2.9 Aquatic Plant Parts

Aquatic plant samples (arrowhead and duckweed) were combined to calculate EPCs for plant consumption. Tribal members and citizens may consume different parts of plants (the upper leaf/stem, the tuber, and/or the fine roots of arrowhead). Because concentrations of metals may vary between the different parts of the plants and subsequent metal exposure may depend on patterns of food preparation and consumption of different plant parts, an evaluation of hazard and risks from consumption of separate plant parts (leaf/stem, tuber, fine roots) is performed in Appendix F7.

A comparison of co-located sediment and plant part data for the final biota COCs (identified in Table 6-12[6]) is provided in Appendix F7, Table 1. Concentrations of final COCs in different plant parts were compared and color-coded based on the rank of concentrations. As seen in the table, there was a clear trend of higher concentrations of final COCs in root than leaf, especially when levels of final COCs in sediment are elevated (i.e., greater than their respective BTVs). Elevated concentrations of final COCs are consistent at the co-located sampling point in Elm Creek, Tar Creek, and Lower Spring River, whereas this was not the case for Lost Creek. This observation of higher concentration of metals in root is consistent with the observation in literature (Pullagurala et al., 2018). A sample of tuber was only available from an arrowhead plant collected in Lost Creek. During the course of sampling, from July 2017 to November 2017, the sampling team identified and tracked the status of tubers on the arrowhead plants, but saw little development of this portion of the observed plants. The team delayed collection until the final sampling event to allow the tuber time to grow; however, during the collection, the only specimen that developed a tuber was in Lost Creek. Although it is speculated based on one sample, development of tubers may have something to do with the lower concentrations of final COCs in sediment in Lost Creek compared to those in other watersheds.

Due to the limited number of samples (less than eight), maximum detected concentrations were used as EPCs (see method in Section 4.3.1) to estimate the non-carcinogenic HI, as presented in Appendix F7, Table 2. Roots had the highest estimated HI, followed by leaves. The HIs associated with tubers were below EPA threshold values (a target-organ-specific HI of 1).

[6] No carcinogenic final COCs were identified.

6.6.2.10 Waterfowl

Tribal lifeway and general public receptors may ingest waterfowl caught in the OU5 study area but the risks were not quantified in the HHRA and a discussion of the potential impact on the risk outcome as a result of not including this scenario is discussed here. Waterfowl have a large home range and are expected to be exposed to areas outside the OU5 study area, but when in OU5 study area watersheds may be exposed to metals through ingestion of sediment, surface water, and aquatic biota. Previous investigations show that lead and zinc accumulate in the blood and tissue of waterfowl in the TSMD (van der Merwe, et al., 2011; Beyer et al., 2004). Lead and zinc poisoning has been reported in wild birds in the region (Beyer et al., 2004; Sileo et al., 2004).

As indicated in the Data Gap Evaluation (CH2M, 2017), waterfowl data were not identified during the compilation of existing data. Tribal members and citizens, and members of the general public may hunt and consume waterfowl, but this pathway is not expected to be significant based on TSMD studies that investigated metal tissue concentrations in geese (van der Merwe et al., 2011) and information provided in the Bunker Hill Superfund Site HHRA (TerraGraphics, 2001). Although lead and zinc concentrations were elevated in geese tissue samples collected in the TSMD compared to reference site samples, muscle tissue concentrations from geese (average concentration of lead [0.16 mg/kg] in samples collected in Webb City, Missouri[7]) in these studies were lower than the EPCs for raccoon (0.51 mg/kg) estimated in the HHRA[8]. Because non-carcinogenic HI estimates for the final COCs through consumption of raccoon meat based on an ingestion rate of 69 g/day (roughly equivalent to 4 ounces of meat every other day) were below EPA threshold values (a target-organ-specific HI of 1), risks for waterfowl consumption would not be expected to contribute significantly to sitewide non-carcinogenic hazard estimates.

6.6.2.11 Inhalation of Metals in Water Vapor

Using the method presented in the Shoshone-Bannock risk assessment document (S-B EWMP, 2016), inhalation of COPCs in water vapor (water droplets suspended in air) generated by OU5 study area surface water poured over heated rocks during sweat lodge use was evaluated for tribal lifeway receptors. The equations presented in the Shoshone-Bannock risk assessment calculate air-phase EPCs based on the following assumptions:

- Non-volatile COPCs become airborne as an aerosol as the water they are carried in vaporizes.
- The ideal gas law can be applied to air and water vapor at the temperature and pressure of the sweat lodge.

Based on an assumed sweat lodge temperature of 150 degrees Fahrenheit, or 66 degrees Celsius (S-B EWMP, 2016), a volatilization factor of 0.17 liter of water per cubic meter (L water/m^3) was calculated, and air-phase EPCs were calculated by multiplying surface water EPCs by this volatilization factor.

Although this principle of estimation of COPCs in water vapor during sweat lodge use has been applied in various historical HHRAs with Native American receptor groups (Harris and Harper, 2004; EPA, 2005c; CH2M PRC, 2014), a large degree of uncertainty is associated with the estimated air-phase EPCs calculated using this method.

[7] Canadian geese samples were collected from four areas: Webb City, Missouri; Picher, Oklahoma; and two sites in Galena, Kansas. Lead was not detected in any samples collected in Galena, Kansas (detection limit of 0.024 mg/kg). The average concentration and standard error of concentrations in Webb City, Missouri and Pitcher, Oklahoma are 0.16(±SE 0.16) and 0.03 ((±SE 0.00), respectively.

[8] Sitewide biota consumption for lead is addressed in Appendix E. The addition of waterfowl consumption to the lead evaluation would not change the conclusions.

Because non-volatile contaminants have no vapor pressure, the equations presented in the Shoshone-Bannock risk assessment equations do not have a common physical basis with volatile chemicals. As assumed, it is possible that inhalation of non-volatile COPCs might occur by an alternative physical model, such as respiration of respirable-size aerosols, if such aerosols were formed when water is poured over the hot rocks in a lodge. However, a model of resuspension of non-volatile impurities in aerosol form is inconsistent with other mechanical processes involving steam. For example, EPA does not address this pathway in shower volatilization models (Volatilization Rates from Water to Indoor Air Phase II [EPA, 2000]). It is also inconsistent with the widespread use of steam distillation for commercial water purification. Additionally, compared to EPA's default volatilization factor (0.5 L water/m^3) for various volatile organic compounds during household use of water, the calculated volatilization factor of 0.17 L water/m^3 is expected to highly overestimate concentrations of metals in air.

As presented in Table 6-15, the HI associated with inhalation of water vapor under the sweat lodge scenario is greater than the total HI for the potable use of surface water. In the case of Tar Creek, inhalation of water vapor accounts for more than one-third of the combined HI from all exposure media (sediment, surface water, and biota). Similarly, 100 percent of ELCR from Elm Creek and Beaver Creek and 29 percent of ELCR from Tar Creek were estimated to be associated with inhalation of water vapor under the sweat lodge scenario (Table 6-16). Further, final COCs such as nickel were identified solely based on the hazard/risk estimates associated with inhalation of water vapor under the sweat lodge scenario. Considering that the inhalation hazard/risk estimates under the sweat lodge use scenario are likely to be overestimated, the hazard/risk associated with surface water for tribal lifeway receptors may be considerably less than what was estimated in the HHRA.

Table 2-2. Watershed-Specific Land Use Descriptions and Designated Beneficial Water Uses

Tar Creek Superfund Site Operable Unit 5 HHRA

Ottawa County, Oklahoma

Watershed	Land Use Descriptions	Designated Beneficial Uses of the Waters within Watershed
Elm Creek	No urban areas Primary land use is cultivated crops and hay/pasture[a]	Aesthetic[b] Agriculture[b] Fish and wildlife propagation (warm water aquatic community)[b] Primary body contact recreation[b]
Tar Creek	Contains many urban areas and historical communities Primary land use is cultivated crops and hay/pasture[a]	Habitat limited aquatic community (HLAC)[c, d] Secondary body contact recreation[c]
Neosho River	Mainly rural, but does contain drainage from the urban area of Miami, Oklahoma Primary land use outside of the developed land is hay/pasture and woody wetlands[a]	Public and private water supply (PPWS)[b, e] Not supporting the warm water aquatic community use due to impairment caused by lead[b] Fish consumption designated use[b]
Beaver Creek	Mainly rural, but does contain drainage from the urban area of Quapaw, Oklahoma Primary land use is hay/pasture[a]	Flows through Quapaw Tribal lands that are historically and culturally significant to the tribe, including the tribe's pow-wow grounds. The creek plays an important part in their cultural and religious practices[f] Assigned default beneficial uses of agriculture, aesthetics, fish and wildlife propagation (warm water aquatic community subcategory), and primary body contact recreation[g]
Lost Creek	Mainly rural, but does contain drainage from the urban areas of Wyandotte, Oklahoma, and Seneca and Racine, Missouri Primary land use outside of the developed land is hay/pasture and mixed forest[a]	PPWS[b, e] Cool water aquatic community fully supported[b] Fish consumption designated use not assessed[b]
Lower Spring River	Mainly rural, but does contain drainage from the urban areas of Baxter Springs and Columbus, Kansas Primary land use in the southern portion of the watershed is hay/pasture and mixed forest[a] Primary land use in the northern portion of the watershed is cultivated crops and hay/pasture[a]	PPWS[b, e] Cool water aquatic community[b] Fish consumption not attained due to impairment caused by lead[b]

	Semi-Aquatic Mammal Tissue (Raccoon)	19	1	3	6	3	3	3	• Food consumption		

Notes:

[a] Eviscerated whole fish concentration was estimated based on weighted concentrations of three fish body parts (carcass, fillet, and head).

[b] Sitewide data groupings were used for the selection of COPCs for a given data grouping.

[c] After one set of COPCs was selected per data group, EPCs were estimated based on watershed-specific data groupings for sediment and surface water. Mine discharge is evaluated in Appendix F.

[d] For aquatic biota (animal and plant tissue), EPCs were estimated based on sitewide data groupings to account for movement of animals and receptors.

[e] Whole arrowhead plant (sitewide) was used to estimate EPCs.

COPC = chemical of potential concern

EPC = exposure point concentration

HHRA = human health risk assessment

NA = not available

Notes:

[a] Identification of COPCs was performed on sitewide data of a given exposure medium (sediment, surface water, and each animal/plant tissue data group).
A summary of exposure scenarios/receptor populations for which each data grouping was evaluated is provided in Table 3-1.
Surface water data grouping was evaluated for three exposure scenarios (hunting/fishing/gathering/recreational, potable use, sweat lodge use) for TLW and two exposure scenarios (recreational and potable use) for GP.

[b] Analytes identified as a COPC in at least one data group are presented in this table.
Essential nutrients (calcium, magnesium, potassium, sodium) and analytes with no toxicity information (titanium) were not identified as COPCs in any data groups.

c Because of the lack of readily available screening values for TLW/AW scenarios and their elevated exposure intensity, frequency, and duration more than the EPA's default residential scenario, all the detected analytes (excluding essential nutrients and analytes with no toxicity information) were identified as COPCs.

[d] For the GP scenario, the maximum detected concentrations of the analytes exceeding applicable EPA RSLs were identified as COPCs.
Residential soil and tap water RSLs were used conservatively to identify COPCs in sediment and surface water (recreational scenario).

[e] Because of the lack of readily available screening values for food consumption scenarios, all the detected analytes (excluding essential nutrients and analytes with no toxicity information) were identified as COPCs.

Identification of COPCs:

YES – Analyte was identified as a COPC
TLW/AW – Analyte was identified as COPC because it was detected in at least one sample within the data group.
GP – Analyte was identified as COPC because it was detected in at least one sample within the data group and the maximum detected concentration exceeds applicable EPA RSL.
TLW/AW/GP (Aquatic Animal and Plant Tissue) – Analyte was identified as COPC because it was detected in at least one sample within the data group.

NO, n/d, n/a – Analyte was not identified as a COPC
NO – Analyte was not identified as a COPC because the maximum detected concentration does not exceed applicable EPA RSL.
n/d – Analyte was analyzed but not detected in any samples within the data group.
n/a – not analyzed

Receptor Populations:
AW = aquatic worker receptors
GP = general public receptors
TLW = tribal lifeway receptors

Acronyms:
CAS = Chemical Abstracts Service
COPC = chemical of potential concern
EPA = U.S. Environmental Protection Agency
RAGS = Risk Assessment Guidance for Superfund
RSL = Regional Screening Level

Total (Receptor) [c]			414	648	318	312	258	287

Notes:

[a] Because the child tribal lifeway exposure scenario yields higher non-carcinogenic hazard estimates than the adult exposure scenario, the preliminary COCs for non-carcinogenic endpoints were identified based on the child tribal lifeway exposure scenario.

[b] The target organ-specific total HI is presented for the target organs or target systems whose total HI is greater than 1 in at least one watershed.

[c] When a target organ-specific total HI of 1 is exceeded for an exposure medium (i.e., sediment, surface water, or biota), the COPCs posing an HQ greater than 0.1 for that target organ in the environmental medium responsible for the unacceptable HI are identified as preliminary COCs.

The evaluation of lead exposure was performed in Appendix E. The evaluation of mine discharge was performed in Appendix F.

[d] The non-carcinogenic HI associated with aquatic animal/plant was calculated based on a sitewide dataset. The sitewide non-carcinogenic HI presented under Elm Creek is applicable to all six watersheds for estimating total non-carcinogenic HI for the receptor.

COC = chemical of concern

COPC = chemical of potential concern

HHRA = human health risk assessment

HI = hazard index

HQ = hazard quotient

NA = not available

RME = reasonable maximum exposure

Notes:

[a] When an ELCR of $1x10^{-4}$ is exceeded for an exposure medium (i.e., sediment, surface water, or biota), the COPCs posing an ELCR greater than $1x10^{-6}$ in the environmental medium responsible for the unacceptable ELCR are identified as preliminary COCs.

The lists of preliminary COCs in this table do not include lead. The evaluation of lead exposure was performed in Appendix E. The evaluation of mine discharge was performed in Appendix F.

[b] ELCR associated with aquatic animal/plant was calculated based on sitewide dataset. The sitewide ELCR presented under Elm Creek is applicable to all six watersheds for estimating total ELCR for the receptor.

COC = chemical of concern

COPC = chemical of potential concern

ELCR = excess lifetime cancer risk

HHRA = human health risk assessment

NA = not available

RME = reasonable maximum exposure

Total (Receptor)			14	28	8	9	5	6

Notes:

[a] Because the child exposure scenario yields higher non-carcinogenic hazard estimates than the adult exposure scenario, the preliminary COCs for non-carcinogenic endpoints were identified based on the child exposure scenario.

[b] The target organ-specific total HI is presented for the target organs or target systems whose total HI is greater than 1 in at least one watershed.

[c] When a target organ-specific total HI of 1 is exceeded for an exposure medium (i.e., sediment, surface water, or fish), the COPCs posing an HQ greater than 0.1 for that target organ in the environmental medium responsible for the unacceptable HI are identified as preliminary COCs.

The evaluation of lead exposure was performed in Appendix E. The evaluation of mine discharge was performed in Appendix F.

[d] Non-carcinogenic HI associated with fish consumption was calculated based on sitewide dataset. The sitewide non-carcinogenic HI presented under Elm Creek is applicable to all six watersheds for estimating total non-carcinogenic HI for the receptor.

COC = chemical of concern

COPC = chemical of potential concern

HHRA = human health risk assessment

HI = hazard index

HQ = hazard quotient

NA = not available

RME = reasonable maximum exposure

						Manganese	No (s/us)	Manganese	No (us)		
		Molybdenum	Yes (s)			Molybdenum	Yes (s)				
		Vanadium	No (us)								
Zinc	Yes (s/us)	Zinc	Yes (s/us)			Zinc	Yes (us)				

Notes:

[a] Preliminary sediment COCs were identified for direct exposure (ingestion and dermal contact) through hunting, fishing, gathering, and recreational activities based on hazard estimates for child receptor and ELCR estimates for adult/child aggregate receptor (Tables 6-1 and 6-2).

[b] The evaluation of lead exposure was performed in Appendix E.

[c] Results of background comparisons are presented as follows:

Yes (s/us)	site > bkgd based on both sieved and unsieved data
Yes (s)	site > bkgd based on sieved data only (unsieved data are not available)
No (s/us)	no statistical difference between site and bkgd based on both sieved and unsieved data
No (us)	no statistical difference between site and bkgd based on unsieved data only (sieved data are not available)

Refinement of the preliminary COCs:

To identify the final COCs, the lists of preliminary COCs were refined using a two-step process (see decision flow chart on Figure 6-1):

1. Background comparison, and 2. Nature of mine-related contamination.

1. Background Comparison:

When statistical background comparison (central tendency) indicates concentrations in site sediment are not greater than background (site < bkgd), that preliminary COC was eliminated as a final COC. Statistical background comparisons are presented in Section 6 tables of the RI report. When the background comparison indicates site > bkgd, then further review of that preliminary COC was performed based on nature of mine-related contamination. When the background comparisons were performed on both sieved and unsieved datasets, if at least one of the datasets indicates site > bkgd, the preliminary COC was conservatively retained for further evaluation.

2. Nature of Mine-Related Contamination:

For those preliminary COCs that were not eliminated based on background comparisons, further review of that preliminary COC was performed based on nature of mine-related contamination. Literature review was performed to evaluate likeliness of preliminary COC being associated with TSMD ore bodies (Table 7-1 of the RI report). If preliminary COC is not likely to be associated with TSMD ore bodies, that preliminary COC was eliminated as a final COC.

Based on the literature review, it was concluded that molybdenum is not likely to be associated with TSMD ore bodies; therefore, it was excluded as a final COC.

Final COC.

Bkgd = background

COC = chemical of concern

ELCR = excess lifetime cancer risk

HHRA = human health risk assessment

OU5 = Operable Unit 5

RI = remedial investigation

TSMD = Tri-State Mining District

Table 6-7. Final Sediment COCs for Tar Creek OU5 (Aquatic Worker - Sediment)

Tar Creek Superfund Site Operable Unit 5 HHRA

None		Cadmium	Yes (s/us)	None		None		None		None	
Lead	Yes (s/us)	Lead	Yes (s/us)	None		None		None		None	

Notes:

[a] No preliminary COCs were identified for Elm Creek, Neosho River, Beaver Creek, Lost Creek, and Lower Spring River.

[b] Preliminary sediment COCs were identified for direct exposure (ingestion and dermal contact) through work activities (Table 6-3).

[c] The evaluation of lead exposure was performed in Appendix E.

[d] Results of background comparisons are presented as follow:

Yes (s/us) site > bkgd based on both sieved and unsieved data

Refinement of the preliminary COCs:

To identify the final COCs, the lists of preliminary COCs were refined using a two-step process (see decision flow chart on Figure 6-1):

1. Background comparison, and 2. Nature of mine-related contamination.

1. Background Comparison:

When statistical background comparison (central tendency) indicates concentrations in site sediment are not greater than background (site < bkgd), that preliminary COC was eliminated as a final COC. Statistical background comparisons are presented in Section 6 tables of the RI report. When the background comparison indicates site > bkgd, then further review of that preliminary COC was performed based on nature of mine-related contamination. When the background comparisons were performed on both sieved and unsieved datasets, if at least one of the datasets indicates site > bkgd, the preliminary COC was con fr

2. Nature of Mine-Related Contamination:

For those preliminary COCs that were not eliminated based on background comparisons, further review of that preliminary COC was performed based on nature of mine-related contamination. Literature review was performed to evaluate likeliness of preliminary COC being associated with TSMD ore bodies (Table 7-1 of RI report). If preliminary COC is not likely to be associated with TSMD ore bodies, that preliminary COC was eliminated as a final COC.

No preliminary COC was eliminated based on nature of mine-related contamination.

Final COC.

Bkgd = background

COC = chemical of concern

ELCR = excess lifetime cancer risk

HHRA = human health risk assessment

OU5 = Operable Unit 5

RI = remedial investigation

TSMD = Tri-State Mining District

Nickel	Yes	Nickel	Yes	Nickel	No	Nickel	Yes			Nickel	No
Vanadium	No	Vanadium	Yes	Vanadium	No	Vanadium	No			Vanadium	No
Zinc	Yes	Zinc	Yes								

Notes:

[a] Preliminary surface water COCs were identified for three direct exposure (ingestion and dermal contact) scenarios combined (hunting, fishing, gathering and recreational activities; potable use; sweat lodge use) based on hazard estimates for child receptor and ELCR estimates for adult/child aggregate receptor (Tables 6-1 and 6-2).

[b] The evaluation of lead exposure was performed in Appendix E.

[c] Results of background comparisons are presented as follows:

Yes	site > bkgd; statistically significant increase in site concentrations above background
No	no statistical difference between site and background

[d] No background comparison was performed due to low frequency of detection (2/198 samples). Maximum detected concentrations were lower than the UTL95-95; therefore beryllium was eliminated as final COC.

Refinement of the preliminary COCs:

To identify the final COCs, the lists of preliminary COCs were refined using a two-step process (see decision flow chart on Figure 6-1):

1. Background comparison, and 2. Nature of mine-related contamination.

1. Background Comparison:

When statistical background comparison (central tendency) indicates concentrations in site surface water are not greater than background (site < bkgd), that preliminary COC was eliminated as a final COC. Statistical background comparisons are presented in Section 6 tables of the RI report. When the background comparison indicates site > bkgd, then further review of that preliminary COC was performed based on nature of mine-related contamination.

2. Nature of Mine-Related Contamination:

For those preliminary COCs that were not eliminated based on background comparisons, further review of that preliminary COC was performed based on nature of mine-related contamination. Literature review was performed to evaluate likeliness of preliminary COC being associated with TSMD ore bodies (Table 7-1 of RI report). If preliminary COC is not likely to be associated with TSMD ore bodies, that preliminary COC was eliminated as a final COC.

	Based on the literature review, it was concluded that aluminum, chromium, and vanadium are not likely associated with TSMD ore bodies; therefore they were excluded as final COCs.
COC	Identified as preliminary COC based on the inhalation of water vapor during sweat lodge use only.
	Final COC.

Bkgd = background
COC = chemical of concern
ELCR = excess lifetime cancer risk
HHRA = human health risk assessment
OU5 = Operable Unit 5

		Cobalt	Yes								
		Manganese	Yes								
		Nickel	Yes								

Notes:

[a] Preliminary surface water COCs were identified for direct exposure (ingestion and dermal contact) through work activities (Table 6-3).

[b] Lead in surface water was not evaluated for aquatic workers because of the limitations of the ALM. The evaluation of lead exposure was performed in Appendix E.

[c] No preliminary COCs were identified for Beaver Creek, Lost Creek, and Lower Spring River.

[d] Results of background comparisons are presented as follows:

Yes	site > bkgd; statistically significant increase in site concentrations above background
No	no statistical difference between site and background

Refinement of the preliminary COCs:

To identify the final COCs, the lists of preliminary COCs were refined using a two-step process (see decision flow chart on Figure 6-1):

1. Background comparison, and 2. Nature of mine-related contamination.

1. Background Comparison:

When statistical background comparison (central tendency) indicates concentrations in site surface water are not greater than background (site < bkgd), that preliminary COC was eliminated as a final COC. Statistical background comparisons are presented in Section 6 tables of the RI report. When the background comparison indicates site > bkgd, then further review of that preliminary COC was performed based on nature of mine-related contamination.

2. Nature of Mine-Related Contamination:

For those preliminary COCs that were not eliminated based on background comparisons, further review of that preliminary COC was performed based on nature of mine-related contamination. Literature review was performed to evaluate likeliness of preliminary COC being associated with TSMD ore bodies (Table 7-1 of RI report). If preliminary COC is not likely to be associated with TSMD ore bodies, that preliminary COC was eliminated as a final COC.

Based on the literature review, it was concluded that chromium is not likely to be associated with TSMD ore bodies; therefore, it was excluded as a final COC.

Final COC.

ALM = Adult Lead Methodology
Bkgd = background
COC = chemical of concern
ELCR = excess lifetime cancer risk
HHRA = human health risk assessment
OU5 = Operable Unit 5
RI = remedial investigation
TSMD = Tri-State Mining District

Table 6-11. Final Surface Water COCs for Tar Creek OU5 (General Public - Surface Water)

Tar Creek Superfund Site Operable Unit 5 HHRA

Ottawa County, Oklahoma

Elm Creek		Tar Creek		Neosho River		Beaver Creek		Lost Creek [c]		Lower Spring River [c]

		Arsenic	Yes	Arsenic	No	Arsenic	No				
Cadmium	Yes	Cadmium	Yes					None		None	
		Chromium	Yes	Chromium	No	Chromium	No				
		Cobalt	Yes								
		Iron	Yes								
Lead	Yes	Lead	Yes			Lead	Yes			Lead	No
Manganese	No	Manganese	Yes								

Notes:

[a] Preliminary surface water COCs were identified for two direct exposure (ingestion and dermal contact) scenarios combined (recreational activities and potable use) based on hazard estimates for child receptor and ELCR estimates for adult/child aggregate receptor (Tables 6-4 and 6-5).

[b] The evaluation of lead exposure was performed in Appendix E.

[c] No preliminary COCs were identified for Lost Creek.

[d] Results of background comparisons are presented as follows:

Yes	site > bkgd; statistically significant increase in site concentrations above background
No	no statistical difference between site and background

Refinement of the preliminary COCs:

To identify the final COCs, the lists of preliminary COCs were refined using a two-step process (see decision flow chart on Figure 6-1):

1. Background comparison, and 2. Nature of mine-related contamination.

1. Background Comparison:

When statistical background comparison (central tendency) indicates concentrations in site surface water are not greater than background (site < bkgd), that preliminary COC was eliminated as a final COC. Statistical background comparisons are presented in Section 6 tables of the RI report. When the background comparison indicates site > bkgd, then further review of that preliminary COC was performed based on nature of mine-related contamination.

2. Nature of Mine-Related Contamination:

For those preliminary COCs that were not eliminated based on background comparisons, further review of that preliminary COC was performed based on nature of mine-related contamination. Literature review was performed to evaluate likeliness of preliminary COC being associated with TSMD ore bodies (Table 7-1 of the RI report). If preliminary COC is not likely to be associated with TSMD ore bodies, that preliminary COC was eliminated as a final COC.

Based on the literature review, it was concluded that chromium is not likely to be associated with TSMD ore bodies; therefore, it was excluded as a final COC.

Final COC.

Bkgd = background
COC = chemical of concern
ELCR = excess lifetime cancer risk
HHRA = human health risk assessment

Mercury	Yes (us)	Yes (s/us)	No (us)	No (s/us)	No (us)	No (s/us)	Comment [f]
Nickel	No (us)	Yes (s)**	No (us)	No (s/us)	No (us)	Yes (s)**	Site > Bkgd
Selenium	No (us)	No (s/us)	No (us)	No (s/us)	No (us)	No (s/us)	
Silver	---	Yes (s)**	No (us)	Yes (s)**	---	Yes (s)**	Site > Bkgd
Vanadium	No (us)	No (us)	No (us)	No (us)	No (us)	No (us)	
Zinc	Yes (s/us)	Yes (s/us)	Yes (s)**	Yes (us)	Yes (s)**	Yes (s/us)	Site > Bkgd

Notes:

[a] Preliminary biota COCs were identified for food consumption (ingestion of fish, shellfish, aquatic plants, amphibian/aquatic reptile, and aquatic mammals) and medicinal use (salve) of aquatic plant scenarios combined based on hazard estimates for child receptor and ELCR estimates for adult/child aggregate receptor (Tables 6-1 and 6-2).

[b] Preliminary COCs were identified based on sitewide dataset.

[c] The evaluation of lead exposure was performed in Appendix E.

[d] Results of background comparisons are presented as follows:

Yes (s/us)	site > bkgd based on both sieved and unsieved data
Yes (us)	site > bkgd based on unsieved data (sieved data are not available)
Yes (us)**	site > bkgd based on unsieved data (inconsistent results: sieved data indicate no difference)
Yes (s)**	site > bkgd based on sieved data (inconsistent results: unsieved data indicate no difference)
No (s/us)	no statistical difference between site and bkgd based on both sieved and unsieved data
No (us)	no statistical difference between site and bkgd based on unsieved data (sieved data are not available)
---	no background comparison was performed

[e] Statistical background comparison indicates site concentrations are greater than background only for unsieved data at Lower Spring River. Because of the high frequency of non-detected results (87%) in the Lower Spring River dataset, antimony was excluded as a final COC based on the background comparison.

[f] Excluded as a final COC because it is unlikely to be associated with TSMD ore bodies.

Refinement of the preliminary COCs:

To identify the final COCs, the list of preliminary COCs was refined using a two-step process (see decision flow chart on Figure 6-1):

1. Background comparison, and 2. Nature of mine-related contamination.

1. Background Comparison:

The background comparisons between site and background datasets were performed based on sediment data. See the rationale for use of sediment data for the identification of final COCs in Section 6.4.2.

When statistical background comparison (central tendency) indicates concentrations in site sediment are not greater than background (site < bkgd), that preliminary COC was eliminated as a final COC. Statistical background comparisons are presented in Section 6 tables of the RI report. When the background comparison indicates site > bkgd, then further review of that preliminary COC was performed based on nature of mine-related contamination.

When the background comparisons were performed on both sieved and unsieved datasets, if at least one of the datasets indicates site > bkgd, the preliminary COC was conservatively retained for further evaluation.

Because the background comparison was performed based on watershed-specific datasets, results of comparison are presented by watershed. If site > bkgd was indicated in any of the watershed-specific datasets, the preliminary COC was conservatively retained for the further evaluation (except for antimony). An exception was made for antimony (see the comment below).

Table 6-12. Final Biota COCs for Tar Creek OU5 (Tribal Lifeway - Biota)

Tar Creek Superfund Site Operable Unit 5 HHRA

Ottawa County, Oklahoma

2. Nature of Mine-Related Contamination:

For those preliminary COCs that were not eliminated based on background comparisons, further review of that preliminary COC was performed based on nature of mine-related contamination. Literature review was performed to evaluate likeliness of preliminary COC being associated with TSMD ore bodies (Table 7-1 of RI report). If preliminary COC is not likely to be associated with TSMD ore bodies, that preliminary COC was eliminated as a final COC.

	Based on the literature review, it was concluded that mercury is not likely to be associated with TSMD ore bodies; therefore, it was excluded as a final COC.
	Final COC.

Selenium	No (us)	No (s/us)	No (us)	No (s/us)	No (us)	No (s/us)	

Notes:

[a] Preliminary fish COCs were identified for fish consumption pathway based on hazard estimates for child receptor and ELCR estimates for adult/child aggregate receptor (Tables 6-4 and 6-5).

[b] Preliminary COCs were identified based on sitewide dataset.

[c] The evaluation of lead exposure was performed in Appendix E.

[d] Results of background comparisons are presented as follows:

Yes (s/us)	site > bkgd based on both sieved and unsieved data
Yes (us)	site > bkgd based on unsieved data (sieved data are not available)
Yes (us)**	site > bkgd based on unsieved data (inconsistent results: sieved data indicate no difference)
No (s/us)	no statistical difference between site and bkgd based on both sieved and unsieved data
No (us)	no statistical difference between site and bkgd based on unsieved data (sieved data are not available)

[e] Statistical background comparison indicates site concentrations are greater than background only for unsieved data at Lower Spring River. Because of the high frequency of non-detected results (87%) in the Lower Spring River dataset, antimony was excluded as a final COC based on the background comparison.

[f] Excluded as a final COC because it is unlikely to be associated with TSMD ore bodies

Refinement of the preliminary COCs:

To identify the final COCs, the list of preliminary COCs was refined using a two-step process (see decision flow chart on Figure 6-1): 1. Background comparison, and 2. Nature of mine-related contamination.

1. Background Comparison:

The background comparisons between site and background datasets were performed based on sediment data. See the rationale for use of sediment data for the identification of final COCs in Section 6.4.2.

When statistical background comparison (central tendency) indicates concentrations in site sediment are not greater than background (site < bkgd), that preliminary COC was eliminated as a final COC. Statistical background comparisons are presented in Section 6 tables of the RI report. When the background comparison indicates site > bkgd, then further review of that preliminary COC was performed based on nature of mine-related contamination.

When the background comparisons were performed on both sieved and unsieved datasets, if at least one of the datasets indicates site > bkgd, the preliminary COC was conservatively retained for further evaluation.

Because the background comparison was performed based on watershed-specific datasets, results of comparison are presented by watershed. If site > bkgd was indicated in any of the watershed-specific datasets, the preliminary COC was conservatively retained for further evaluation (except for antimony). An exception was made for antimony (see the comment below).

2. Nature of Mine-Related Contamination:

For those preliminary COCs that were not eliminated based on background comparisons, further review of that preliminary COC was performed based on nature of mine-related contamination. Literature review was performed to evaluate likeliness of preliminary COC being associated with TSMD ore bodies (Table 7-1 of the RI report). If preliminary COC is not likely to be associated with TSMD ore bodies, that preliminary COC was eliminated as a final COC.

	Because of the high frequency of non-detected results (87%) in the Lower Spring River dataset, antimony was excluded as a final COC based on the background comparison.
	Based on the literature review, it was concluded that mercury is not likely to be associated with TSMD ore bodies; therefore, it was excluded as a final COC.
	No Final COC was identified.

Bkgd = background

Notes:

[a] Because the child exposure scenario yields a higher non-carcinogenic HI than the adult exposure scenario, a summary of non-carcinogenic HI for the final COCs is presented for child exposure scenario.

[b] The lists of final COCs in this table do not include lead. The evaluation of lead exposure was performed in Appendix E. The evaluation of mine discharge was performed in Appendix F.

[c] The non-carcinogenic HI associated with aquatic biota (animal/plant) was calculated based on the sitewide dataset. The sitewide non-carcinogenic HI presented under Elm Creek is applicable to all six watersheds for estimating total non-carcinogenic HI for the receptor.

[d] Percent (%) contribution for each exposure route and total (exposure medium) is calculated as percentage of total (receptor) HI. Percent contribution for final COC is calculated on an exposure medium basis as percentage of total (exposure medium).

COC = chemical of concern

HHRA = human health risk assessment

HI = hazard index

NA = not applicable; target organ is not associated with the final COCs

RME = reasonable maximum exposure

RME = reasonable maximum exposure

Table 6-19. Summary of Receptor Risks for Final COCs - General Public Adult/Child Aggregate

Tar Creek Superfund Site Operable Unit 5 HHRA

Ottawa County, Oklahoma

Exposure Medium	Exposure Point	Exposure Route	Tar Creek (TABLE 10.13.RME)	% [b] contribution
Excess Lifetime Carcinogenic Risk [a]				
Surface Water (Rivers & Creeks)	Recreational Activities	Ingestion	4.E-06	0.6%
		Dermal	4.E-07	0.1%
		Total	4.E-06	0.7%
	Potable Use	Ingestion	7.E-04	98.8%
		Dermal	3.E-06	0.5%
		Total	7.E-04	99.3%
	Total (Surface Water)		7.E-04	100%
	Final Surface Water COCs [a]		Arsenic	100%
Total (Receptor) [b]			**7.E-04**	**100%**

Notes:

[a] The list of final COCs in this table does not include lead. The evaluation of lead exposure was performed in Appendix E. The evaluation of mine discharge was performed in Appendix F.

[b] Percent (%) contribution is calculated as percentage of total (receptor) ELCR.

COC = chemical of concern

ELCR = excess lifetime cancer risk

HHRA = human health risk assessment

RME = reasonable maximum exposure

Table 6-20. General Uncertainties in the Human Health Risk Assessment

Tar Creek Superfund Site Operable Unit 5 HHRA

Ottawa County, Oklahoma

HHRA Report Section	Assessment	Topic	Methodology	Probable Effect on Site-Related Risk Estimates
Section 3	Data Evaluation	Selection of COPCs	When a chemical was 100% non-detected in an exposure medium, it was assumed to be not present in the medium.	No significant impact
			Chemicals with maximum detected concentrations above screening levels were retained as COPCs even if they may be within background levels.	Overestimates site-related risks
Section 4	Exposure Assessment	Use of the EPC in estimation of COPC intake	Receptors are assumed to be exposed to the EPCs (conservative estimation of average concentrations based on UCL of the mean or maximum detected concentration) for the entire exposure duration.	Likely overestimates risks
		Use of the conservative, high-end exposure assumptions in estimation of COPC intake	Numerical exposure factors (e.g., ingestion rate, exposure frequency, exposure duration) used in the estimation of COPC intake are selected conservatively.	Likely overestimates risks
Section 5	Toxicity Assessment	Toxicity values derived from animal studies	Extrapolation from animal to human toxicity may introduce error because of differences in pharmacokinetics, target organs, and population variability.	Under- or overestimates risks
		Toxicity values derived primarily from high doses (whereas most environmental exposures occur at low doses)	This assumes linearity at low doses.	Likely overestimates risks
		Lack of dermal toxicity values	Dermal toxicity values are not available; therefore, adjusted oral value toxicity values were used.	May under- or overestimate risk
		Speciated chromium data are not available	Cr (VI) toxicity values were used for exposure through aqueous media such as surface water and mine discharge, whereas Cr (III) toxicity values were used for exposure through solid media such as sediment and food.	Under- or overestimates risks
		Missing toxicity values	Oral RfD (phosphorus, silica, and thallium) and inhalation RfC (antimony, copper, iron, lithium, mercury, molybdenum, phosphorus, silica, silver, thallium, and zinc) are not available.	Underestimates risk

Table 6-20. General Uncertainties in the Human Health Risk Assessment

Tar Creek Superfund Site Operable Unit 5 HHRA

Ottawa County, Oklahoma

HHRA Report Section	Assessment	Topic	Methodology	Probable Effect on Site-Related Risk Estimates
Section 6	Risk Characterization	Risk from multiple chemicals	Assumes additivity of risks from multiple chemicals; chemical mixtures may actually have synergistic, potentiating, or antagonistic effects.	May under- or overestimate risks
		Combination of several upper-bound assumptions	The result of combining several upper-bound assumptions is that the final estimate of potential exposure or potential risk is conservative.	May overestimate risks

Notes:

COPC = chemical of potential concern

EPC = exposure point concentration

HHRA = human health risk assessment

RfC = reference concentration

RfD = reference dose

UCL = upper confidence limit

Notes:

[1] Evaluation of site media is performed separately for each watershed.

[2] Sediment (0 to 12 inches deep) from saturated zones of perennial rivers or creeks.

[3] The use of surface water for the irrigation of crops or as drinking water for livestock is unknown and expected to be unlikely due to the extent of annual rainfall in the area.

[4] Terrestrial small game (birds, rabbits) and large game (deer, elk) were addressed under Operable Unit 4 (Source Material, Transition Zone Soil, Rural Residential Yards, and Wells).

[5] Aquatic plants growing in the wet bank-to-bank section of perennial flowing rivers and creeks.

[6] Potential risk associated with fish consumption by the Tribal lifeway receptors is evaluated using two datasets: (1) whole body eviscerated, and (2) head with bones.

[7] Potential risk associated with fish consumption by the general public is evaluated using the fish filet dataset.

[8] Potential risk associated with shellfish consumption is evaluated using the Asian clam and limited mussel samples.

[9] Amphibians and aquatic reptiles living in the wet bank-to-bank section of perennial flowing rivers and creeks.

[10] Potential risk associated with amphibian/aquatic reptile consumption is evaluated using the frog leg samples.

[11] Semi-aquatic mammals (raccoon, beaver, mink, muskrat, otter) living in the wet bank-to-bank section of perennial flowing rivers and creeks.

[12] Potential risk associated with semi-aquatic mammal consumption is evaluated using the raccoon samples.

[13] Potential risk associated with waterfowl consumption is evaluated qualitatively.

[14] Potential risk associated with aquatic plant consumption is evaluated using the arrowhead and duckweed samples.

[15] Potential risk associated with medical use of aquatic plants is evaluated using the arrowhead samples.

[16] Mine discharge evaluated using the same exposure assumptions as surface water in Appendix F.

Figure 2-3.
Conceptual Exposure Model

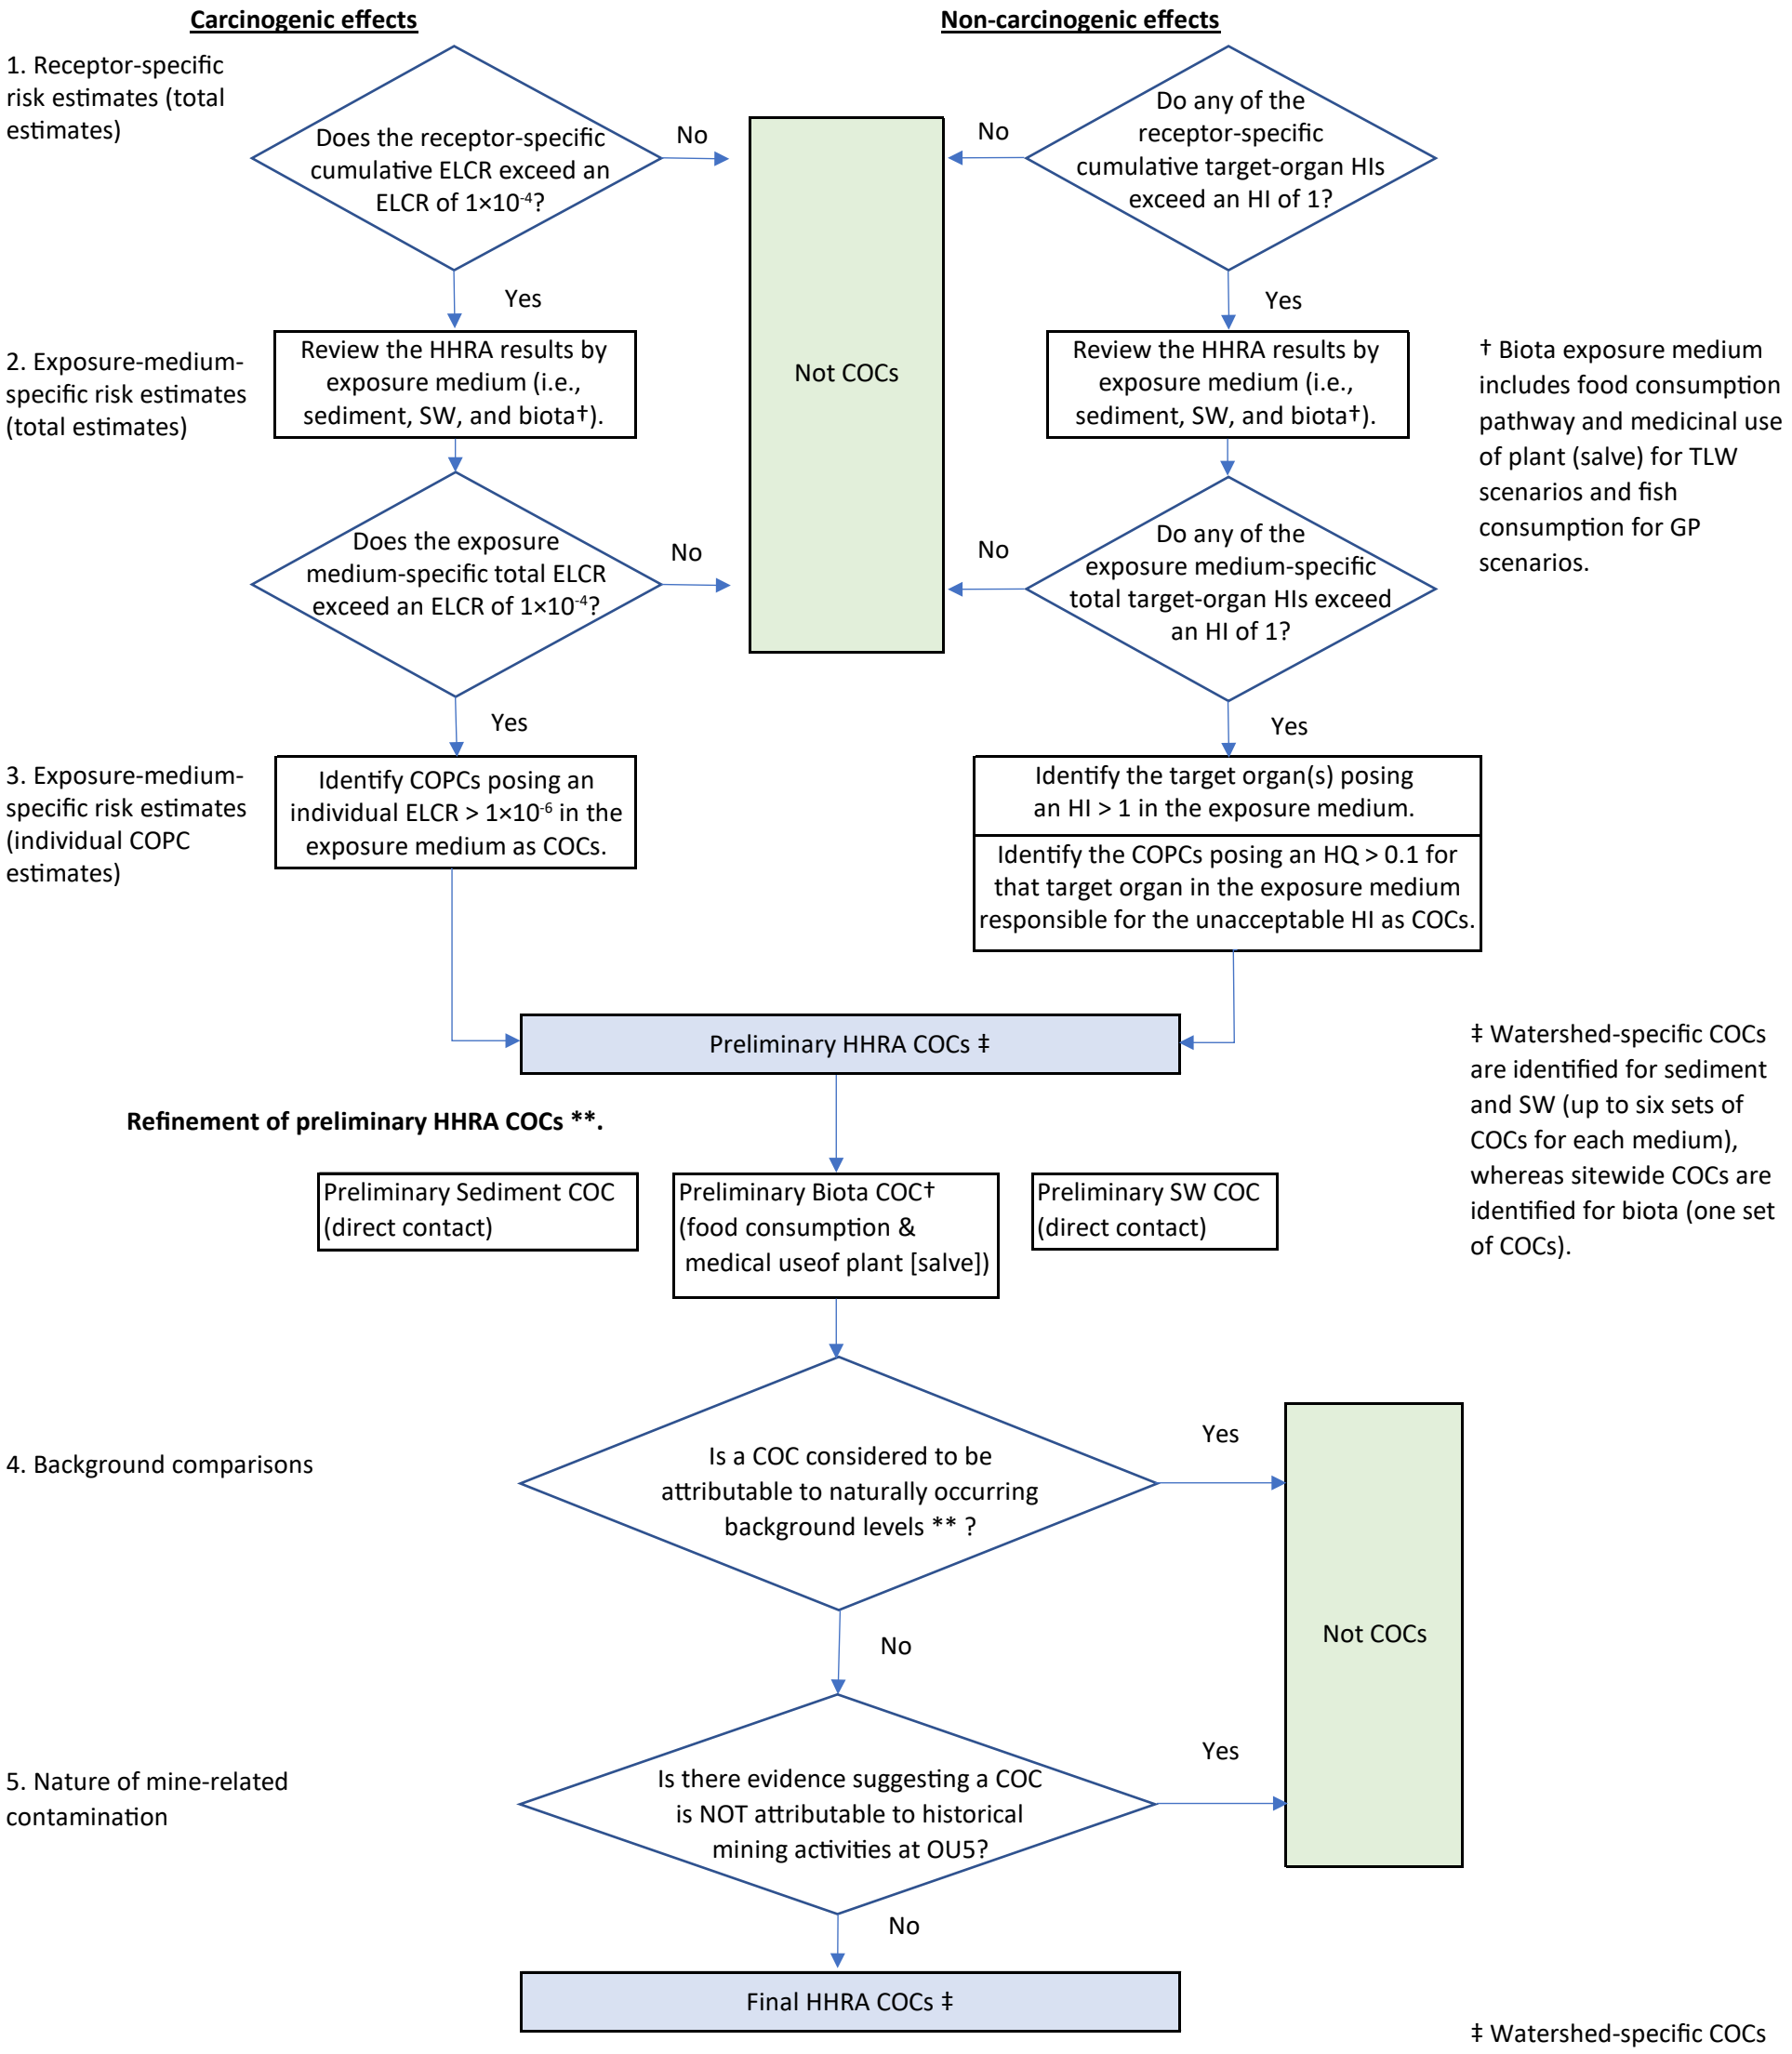
Identification of HHRA COCs for the TLW and GP exposure scenarios



† Biota exposure medium includes food consumption pathway and medicinal use of plant (salve) for TLW scenarios and fish consumption for GP scenarios.

‡ Watershed-specific COCs are identified for sediment and SW (up to six sets of COCs for each medium), whereas sitewide COCs are identified for biota (one set of COCs).

Acronyms:
COC = Chemical of Concern; COPC = Chemical of Potential Concern;
HHRA = Human Health Risk Assessment; SW = Surface water;
TLW = tribal lifeway; GP = general public

**** General rules to ascertain site is attributable to naturally occurring background levels.**

COCs are NOT considered to be attributable to naturally occurring background levels.

Sediment and biota:	Site > background for both sieved and unsieved datasets.
	Site > background for at least one of the two datasets (sieved or unsieved). Analysis may be performed on the only one of two datasets due to small sample size.
SW:	Site > background (based on total metal dataset).

COCs are considered to be attributable to naturally occurring background levels.

Sediment and biota:	Site is comparable to background for both sieved and unsieved datasets.
	Site is comparable to background for the dataset on which the analysis is performed. Analysis is not performed on the other dataset due to small sample size.
SW:	Site is comparable to background (based on total metal dataset).

Appendix A
Response to Comments on Interim HHRA Deliverables

Appendix A. Response to Comments on Interim HHRA Deliverables

Introduction

This response to comments (RTC) document addresses comments related to Human Health Risk Assessment (HHRA) for both Tar Creek Operable Unit 5 (OU5) and Tar Creek Operable Unit 4 (OU4). The RTC is a compilation of comments and responses related to three technical documents that have been produced from 2017 to 2019 and issued to interested parties for review and comment prior to submittal of the current draft HHRA report.

The following list identifies each document that was produced, when it was submitted, the parties that provided written comments, and corresponding RTC tables within this appendix.

- **Document No. 1 –** ***Remedial Investigation Report, Version 1.1, Tar Creek Superfund Site Operable Unit 5, Ottawa County, Oklahoma, Task Order No. 079-RICO-06TS, Document Control No. 0079-02013.*** **June 2019.** Submitted to interested parties by EPA via email on July 1, 2019.

  The following parties provided HHRA-related written comments on this document:

  – Abt Associates on behalf of Tar Creek Trustee Council Indian Tribes (TCTCIT) on October 8, 2019 (Table 1a)
  – AESE, Inc., on behalf of Quapaw Nation on October 17, 2019 (Table 1b)
  – Oklahoma Department of Environmental Quality (ODEQ) on October 18, 2019 (Table 1c)

- **Document No. 2 –** ***Technical Memorandum, Human Health Risk Assessment Process, Objectives, and Tribal Lifeways Scenarios Developed for Operable Unit 5, Version 1.2.*** **May 11, 2018.** Submitted to interested parties by EPA via email on May 11, 2018.

  The following parties provided HHRA-related written comments on this document:

  – TCTCIT on June 15, 2018 (Table 2a)
  – AESE, Inc., on behalf of Quapaw Nation on June 18, 2018 (Table 2b[1])
  – ODEQ on July 11, 2018 (Table 2c)

- **Document No. 3 –** ***Draft RAGS Part D Tables (Tables 1-6) for Human Health Risk.*** **Submitted to interested parties by EPA via email. November 14, 2017.**

  The following parties provided HHRA-related written comments on this document:

  – TCTCIT on January 24, 2018 (provided proposed revisions in the Excel file, no written comments)
  – AESE, Inc., on behalf of Quapaw Nation on January 8, 2018 (Table 2b[1])
  – ODEQ on January 8, 2018 (Table 3a)
  – Bureau of Indian Affairs (BIA) on December 13, 2017 (Table 3b)
  – Earl Hatley on January 17, 2018 (Table 3c)
  – LEAD Agency on January 17, 2018 (Table 3d)
  – Larry Tippit/Peoria Tribe of Indians of Oklahoma on January 18, 2018 (Table 3e)

[1] Table 2b contains comments from AESE, Inc., on behalf of Quapaw Nation, for both Documents No. 2 and No. 3.

This page intentionally left blank.

Item	Section	Page	Comment	Response
2			It is difficult to interpret the data gap investigation when the complete RIR is not presented: This draft of the RIR does not include the HHRA; however, the RIR presents conclusions and generalizations about the HHRA. For example, in Section 3.6 the RIR states: *Despite the challenges meeting the data gap objectives for aquatic biota, there are sufficient quantities of samples to support the HHRA.* (p. 3-14) This statement is difficult to verify without being able to review the HHRA. What analyses has EPA done to support this statement regarding the adequacy of sample size for aquatic biota for the HHRA?	A goal of the RI sampling was to collect supplemental data so that the final dataset provided representative concentrations of aquatic biota that people consume. During the RI, over many field events and various months, it was difficult to find mussels, duckweed, and arrowhead plants to sample due to very limited populations. Tribal input was used to identify potential locations of aquatic plants for sampling. The final datasets are representative of the biota populations present at the time of sampling and are therefore adequate for use in the HHRA.
3			The RIR incorrectly indicates that the scope, conceptual exposure model (CEM), and other aspects of the RIR were "agreed upon" or decided by "consensus" with site stakeholders. a, The RIR states, for example: *The OU5 CEM was defined and agreed upon through resource and literature review, observations from the OU5 CSM, and most importantly, a series of consultations with site stakeholders. Tribal members and citizens input in particular recommended the use of the Quapaw Traditional Lifeways Scenario (Harper, 2008) as the primary basis of formulating the CEM, and the CEM relies heavily upon this resource. In addition, Tribal stakeholders provided valuable input on particular exposure media that are important from both a cultural and dietary consumption standpoint.* (p. 1-2). While it is accurate that the TCTCIT recommended the Quapaw Traditional Lifeways Scenario for use in the CEM, it is not accurate that the TCTCIT agree with EPA's CEM overall. The TCTCIT provided extensive comments on EPA's CEM for OU5 (Abt Associates, 2018), and have yet to receive any response to the comments from EPA. See also comment #4 below regarding inaccurate representations of "consensus" decisions.	Beginning in 2015, input was solicited various times from tribal members and citizens (through AESE/Quapaw Nation and TCTCIT) and the input was used to guide development of the CEM, identify representative biota for sampling, and develop exposure factor values. See Appendix A of the RI report, which summarizes stakeholder engagement activities.

Table 1a. Response to Comments Provided by Abt Associates on behalf of TCTCIT on Document No. 1

Item	Section	Page	Comment	Response
4			Several statements in Section 3.4.3 (Aquatic Plants) are inconsistent with previous TCTCIT comments and recommendations: a, The RIR states: *…consensus was reached on selection of arrowhead root and duckweed as to commonly used aquatic plants that are representative plant species from the seven OU5 watersheds.* (p. 3-8) Although duckweed and arrowhead root are aquatic plant species in the area, analyses in the RIR should not be limited to these species. For example, watercress is another aquatic plant species for which there are available data that could be included in the RIR. Further, we agree that the TCTCIT did previously communicate to EPA that arrowhead root and duckweed are commonly used plants. However, the TCTCIT has never agreed to the notion of limiting data used in the RIR to two aquatic plants. While we understand that EPA was only able to sample a limited number of species due to cost constraints, the TCTCIT believes that all available data, including previously collected data, should be included in the RIR analyses.	Duckweed and arrowhead plants were sampled based on input from the Quapaw Nation and TCTCIT. Both plants are included in the HHRA dataset and are used to represent edible aquatic vegetation in OU5, consistent with discussions held with stakeholders during the HHRA planning stage. The whole arrowhead plant was used to evaluate the salve exposure scenario and ingestion.
5			Some deviations from the field sampling scope during the collection of arrowhead root samples could impact interpretation of the data: Tribal members and citizens consume the upper leaf/stem, the tuber, and the fine roots of arrowhead root. Therefore, EPA intended to collect all three sections of these plants and submit them for analysis. Some specimens were lacking tubers; in these instances, EPA collected the upper leaf/stem and the fine roots. In plants that absorb and hyperaccumulate metal contaminants, the concentrations of the heavy metals may vary between the different parts of the plant. Often, concentrations of contaminants in the roots are greater than concentrations in the leaves (Pullagurala et al., 2018). Tubers also accumulate heavy metals such as lead (Musilova et al., 2015). Plants with tubers present may uptake contaminants at different rates than plants without them; therefore, it may not be appropriate to compare arrowhead root plants with tubers to plants without tubers. This is a concern because it could lead to inaccurate estimates of exposure for locations where plant samples without tubers were collected.	The aquatic plant data were separated by plant part (leaf/stem, tuber, fine roots); metal concentrations in different plant parts are compared and discussed in the uncertainty analysis.

Table 1a. Response to Comments Provided by Abt Associates on behalf of TCTCIT on Document No. 1

Item	Section	Page	Comment	Response
6			EPA was unable to perform moisture content analyses on the 2017 biota samples – all of the tissue data are expressed on a wet-weight (ww) basis: Although ww data are appropriate for analyzing exposure for the HHRA, information regarding the samples' moisture content can help support some analytical decisions. For example, due to limited sampling, EPA is evaluating the plant results as a whole, rather than by plant species. It is important to understand the typical moisture content of each plant species; if the moisture content varies significantly, it is not appropriate to group these species. For example, a plant with a higher moisture content would have a higher dry weight of the contaminant. This is a concern because by grouping the small sample size of plant species that vary greatly in moisture content, EPA could be inconsistently estimating risk across sites.	Metal concentrations in biota samples may differ based on various sample characteristics (not only moisture content but also species, age, sex, and body part, which may be a more important determinant of metal concentrations), but the collected samples were used as a representative of the range of biota that may be consumed over the long-term exposure duration assumed in the HHRA. A discussion of potential impacts on the risk estimates related to use of different parts of biota during food preparation (for fish and aquatic plant) is provided in the uncertainty analysis.
10			Because there is only a small amount of aquatic plant data available in OU5, EPA evaluated the aquatic results as a whole instead of by plant species. How does EPA intend to use these data? Depending on how the EPA plans to use these data, this approach may not be not be satisfactory. As we mentioned above (see comment #9), different plant species uptake contaminants at different rates (Pullagurala et al., 2018). Additionally, the architecture and physiology of duckweed and arrowhead root are very different and may lead to significant differences in concentrations of these species. For example, duckweed plants are simple free-floating plants that lack an obvious stem or leaves, while arrowhead root is more complex with roots, tubers, and well-defined leaves. Duckweed plants were analyzed as a whole, while the leaves, roots, and tubers of the arrowhead root plants were analyzed separately. It is important for us to understand how these data will be used for us to evaluate if EPA's proposed approach is robust. For example, if EPA relies upon average metal concentrations across all plant parts and species for the HHRA, they may underestimate risk to a Tribal member or citizen who consumes mostly roots because, compared to leaves, roots typically contain elevated concentrations of metals.	The aquatic plant data were separated by plant part (leaf/stem, tuber, fine roots) in Appendix F7 and are compared and discussed in the uncertainty analysis.

Table 1b. Response to Comments Provided by AESE, Inc., on behalf of Quapaw Nation, on Document No. 1

Item	Section	Page	Comment	Response
1	Figure 7-3		ARD source omitted. Ingestion, dermal, inhalation needs to be evaluated. Also need irrigation of plants with groundwater/surface water that is mine affected. Plant to cattle to human is omitted. Water to cattle to human is omitted. This CSM needs a major revision.	Acid rock drainage (ARD), in the form of mine discharge, was added as a source to surface water on the CEM. Mine discharge is accessible for contact at two locations, which are conservatively addressed in Appendix F3 using the same exposure assumptions as surface water. Locations where mine discharge enters and mixes with surface water were sampled. Irrigation of plants with surface water that is affected by the mine was added as a potential exposure route on the CEM and is discussed in the HHRA. Plants (arrowhead and duckweed) growing in surface water (which is more exposure than irrigation) were sampled during the RI and associated exposures are addressed in the HHRA. Vegetation (and incidental soil) exposures by grazing cattle (and subsequent human consumption of meat and milk) are terrestrial exposures addressed under Tar Creek OU4 and were further evaluated in the memorandum titled, *Tar Creek Source Material Operable Unit 4 Remedial Action: Results of Bioaccumulation Study of Chemicals of Concern in Row Crop and Pasture Grasses,* prepared by CH2M, dated November 12, 2019; risks were within EPA's acceptable risk levels.

Table 1c. Response to Comments Provided by the ODEQ on Document No. 1

Item	Section	Page	Comment	Response
1			Does EPA plan to use sieved or un-sieved sediment sample data in its risk models. Does EPA plan to use total or dissolved surface water sample data in its risk models?	Both unsieved and sieved sediment data were used in the HHRA. Total metals surface water data were used in the quantitative risk estimates. An evaluation of potential risk based on dissolved metals surface water data is included in the uncertainty analysis of the HHRA.
2			DEQ has concerns about using only one aquatic plant sample as the background reference sample for all aquatic plants in the entire study area and using a dry weight to wet weight conversion factor on this one sample. DEQ would prefer that additional sampling be conducted to increase the sample size for background reference and that those samples be analyzed appropriately so that a conversion factor is not required. This data could be evaluated in the Feasibility Study (FS) stage of the Super-fund Process. In lieu of conducting additional sampling, DEQ requests that EPA include a reference document into the Rl for using the dry to wet weight conversion factor and provide guidance stating that one sample is adequate for background reference.	The background reference concentration in the aquatic plant sample was not used to eliminate COPCs in the HHRA. After the risk estimates were calculated, sediment background comparisons were considered when identifying preliminary COCs in aquatic plants. Because dietary consumption rates are provided on a wet weight basis, all biota datasets used in the HHRA are presented on a wet weight basis. Some of the historical data (e.g., mussels and aquatic plants) were reported as dry weight, and a dry-weight-to-wet-weight conversion was needed to provide consistent reporting format in the dataset. The conversion from dry weight to wet weight was performed using the moisture content of the samples. Chapter 11 of EPA's Exposure Factors Handbook (2011) provides the equation for the conversion.

Table 1c. Response to Comments Provided by the ODEQ on Document No. 1

Item	Section	Page	Comment	Response
3			It appears as if there are different approaches to determining how chemicals of potential concern (COPC) are carried forward in a risk assessment. Although not yet released, the human health risk assessment appears as if it will use BTV (discussed in Section 5 of RI) while the BERA appears to use toxicity threshold values. Is this accurate? If so, why use different approaches?	The background threshold values (BTVs) were not used to identify COPCs. Rather, COPCs for general public direct contact exposure pathways were identified by comparison to EPA's Regional Screening Levels. However, for biota consumption pathways and Tribal Lifeway exposure scenarios, all detected chemicals in a given dataset were conservatively identified as COPCs.

Table 2a. Response to Comments Provided by TCTCIT on Document No. 2

Item	Section	Page	Comment	Response
1	Topic #1a: Consultation process – TCTCIT participation in the consultation process should not be construed as an "endorsement" of EPA's HHRA approach for OU5.	2	The HHRA memo (CH2M HILL, 2018) indicates that EPA has consulted with the nine Tribes in the ongoing HHRA, including, for example, providing documents such as the Remedial Investigation Data Gap Summary Report (CH2M HILL, 2016) for the Tribes for review. We agree that EPA has provided such HHRA work products to the Tribes, in addition to holding periodic check-in teleconferences/meetings, during which EPA has provided general updates to the Tribes on the status of EPA's ongoing HHRA. The TCTCIT appreciate that EPA undertakes these check-ins, consistent with EPA's Indian Policy (Ruckelshaus, 1984; McCarthy, 2014) and trust responsibilities. However, the TCTCIT's participation should not be construed as a blanket "endorsement" of EPA's proposed HHRA approach, and EPA's eventual HHRA results. This is particularly true since some of the main overarching comments and concerns raised by the TCTCIT on the HHRA throughout this government-to-government consultation process have yet to be addressed by EPA (see Topic #4 below).	Comment noted; the exposure scenarios and exposure factor values (and ranges) included in the draft OU5 HHRA prepared by TCTCIT's consultant (Abt Associates) in June 2019 were taken into consideration when developing this HHRA.
2a	Topic #1b: Consultation process – the process should inform, but not be a substitute for, EPA conducting the work needed to delineate RME values.	2	As a part of the HHRA consultation process, EPA has requested information on exposure pathways and levels, and some of the information provided by the TCTCIT has been incorporated into the RME tables in the HHRA memo. In particular, EPA provided the Tribes with draft RME tables via email on November 7, 2017, and requested that the Tribes confirm/review some of the proposed exposure parameters, such as number of days per year and hours per day that Tribal adults and children are exposed to surface water and sediment in OU5. In an effort to facilitate the HHRA process, the TCTCIT technical representatives provided feedback on these values, to the best of their ability and knowledge. However, as communicated to EPA by the TCTCIT in subsequent conversations, including a conference call held on March 16, 2018, the TCTCIT technical representatives do not formally gather, nor do they have access to data on Tribal population exposure metrics, as a part of their respective Tribal departmental duties. Therefore, the provided information should be viewed as estimates that may inform, but should not be a substitute for, whatever process EPA may need to complete to formally and accurately delineate these parameters. This might include consulting with other governmental entities that may gather relevant information, or conducting Tribal population surveys, if needed. For example, EPA guidance on exposure assessment states that site-specific exposure factors can be developed by collecting behavior and activity patterns through surveys, which can be implemented via several methods, including activity diaries and questionnaires (EPA 1992).	Comment noted; the exposure scenarios and exposure factor values (and ranges) included in the draft OU5 HHRA prepared by TCTCIT's consultant (Abt Associates) in June 2019 were taken into consideration when developing this HHRA.

Table 2a. Response to Comments Provided by TCTCIT on Document No. 2

Item	Section	Page	Comment	Response
2b	Topic #1b: Consultation process – the process should inform, but not be a substitute for, EPA conducting the work needed to delineate RME values.	3	We further note that EPA appears to be using values provided by the TCTCIT as inputs for all exposed Tribes. This may not be appropriate, as the TCTCIT includes only seven of the nine Tribes in OU5, and TCTCIT exposure values may not be representative, even as estimates, for the other two Tribes. Finally, in numerous instances, EPA is incorrectly citing the TCTCIT for exposure values in the HHRA memo and accompanying RME tables (see Topic #1c below for further discussion of this topic). EPA should remove reference to the TCTCIT in instances where they are incorrectly cited as the source of information (see Topic #1c), and EPA should complete the work needed to comprehensively delineate exposure parameters, rather than solely relying upon TCTCIT estimates.	Comment noted; the exposure scenarios and exposure factor values (and ranges) included in the draft OU5 HHRA prepared by TCTCIT's consultant (Abt Associates) in June 2019 were taken into consideration when developing this HHRA. Input from the Quapaw Nation and ODEQ was also considered, and the final HHRA exposure scenarios and exposure factor values reflect input from all sources. The reference for each final exposure factor value indicates the source of the value.
3a	Topic 1c: Consultation process – in many instances, EPA's incorporation of information provided by the TCTCIT is inaccurate and EPA incorrectly cites the TCTCIT as the source of numerous exposure parameters.	3	As noted above, EPA circulated draft RME tables via email on November 7, 2017, and requested the Tribes' input on a number of parameters. Also noted above, the TCTCIT do not formally compile the type of requested information (such as the number of days per year that Tribal members and citizens are exposed to surface water and sediment in OU5). However, in an effort to facilitate the HHRA process, the TCTCIT provided EPA with some estimates, based on their existing knowledge of Tribal activities. These values were provided to EPA via email by the TCTCIT on January 24, 2018. It appears that some of this information has been used by EPA in the HHRA memo in a manner that is inconsistent with the TCTCIT's original intent. In other instances, EPA is incorrectly citing the TCTCIT as the source of exposure parameters that the TCTCIT did not provide, or for which the TCTCIT provided a different value. For example:	Comment noted; the exposure scenarios and exposure factor values (and ranges) included in the draft OU5 HHRA prepared by TCTCIT's consultant (Abt Associates) in June 2019 were taken into consideration when developing this HHRA. Input from the Quapaw Nation and ODEQ was also considered, and the final HHRA exposure scenarios and exposure factor values reflect input from all sources. The reference for each final exposure factor value indicates the source of the value.

Table 2a. Response to Comments Provided by TCTCIT on Document No. 2

Item	Section	Page	Comment	Response
3b	Topic 1c: Consultation process – in many instances, EPA's incorporation of information provided by the TCTCIT is inaccurate and EPA incorrectly cites the TCTCIT as the source of numerous exposure parameters.	3, Bullet 1	"Tribal Lifeway" vs "Tribal Worker" scenarios – the TCTCIT estimated that many Tribal adults are exposed to surface water and sediment 312 days/year, through a combination of all activities involving contact with OU5 streams and creeks. This includes fishing, hunting, gathering, ceremonial and other cultural practices, recreating, and work (e.g., hatchery employees who are exposed to OU5 stream water as a part of their daily work duties, or staff from environmental departments who are exposed when collecting environmental samples). The TCTCIT provided this value of 312 days/year to EPA in their January 24, 2018 response to EPA's request. In the HHRA memo, EPA now describes separate "Tribal Lifeway" and "Tribal Worker" exposure scenarios (these separate scenarios did not exist in the November 7, 2017 version of the RME tables). The value of 312 days/year provided by the TCTCIT has been assigned to the "Tribal Lifeway" exposure scenario for the surface water and sediment exposure frequency (see Table 4.2 and page 4/26 of the HHRA memo), and a separate value of 250 days/year is assigned for the "Tribal worker" exposure frequency. The latter value is based on EPA standard exposure factors (see Table 4.3 and page 5/26 of the HHRA memo). This approach raises at least two questions of concern to the TCTCIT: Is EPA intentionally incorporating work-related exposure into both scenarios? Why is a separate "Tribal Worker" scenario needed, if work-related exposure is already incorporated into the "Tribal Lifeway" exposure scenario?	The final exposure frequency for surface water and sediment exposures by Tribal Adults is 312 days/year in this HHRA; this exposure frequency is intended to cover members who (1) work and perform other activities in surface water and sediment outside of work, and (2) do not "work" in surface water but who conduct other Tribal Lifeway activities in or using surface water and sediment. A separate Aquatic Worker scenario is provided to address surface water and sediment exposures by tribal members and citizens who may have minimal surface water or sediment exposure outside of their work exposure. This scenario was also described and emphasized as an important scenario by a TCTCIT entity.
3c	Topic 1c: Consultation process – in many instances, EPA's incorporation of information provided by the TCTCIT is inaccurate and EPA incorrectly cites the TCTCIT as the source of numerous exposure parameters.	4, Bullet 1	Tribal children exposure frequency for surface water and sediment – the TCTCIT estimated that children are exposed to surface water 234 days/year and to sediment 312 days/year in their January 24, 2018 response to EPA. In the HHRA memo RME tables, the exposure frequency for children is set to 244 days/year for both sediment and surface water, and EPA incorrectly sites the TCTCIT for this value (see Tables 4.2 and 4.5, and pages 4/26 and 6/26). Further, EPA states on page 6/26 of the HHRA memo that it is not possible for children to be more exposed to sediment than to surface water because "sediments are below surface water" (page 6/216 of the HHRA memo). The TCTCIT understand that sediments are generally located below surface water. However, the TCTCIT believe it is possible for sediment exposure to be greater than surface water exposure, and would like to clarify that the estimate of 312 days/year includes exposure to sediment that does not involve contact with water. This includes, for example, through contact with sediment-laden clothing and footwear of children's parents, or other sediment-laden items, such as aquatic plants, mussels, etc., collected by family or other members of the community. EPA should remove the TCTCIT as the source for their 244 days/year exposure value in Tables 4.2 and 4.5. We request that EPA reconsider their assertion regarding the impossibility of sediment exposure being higher than surface water exposure for children.	For tribal children, exposure frequencies of 312 days/year (sediment) and 234 days/year (surface water) are used in the HHRA. These exposure frequencies are in addition to evaluation of surface water for potable use and surface water in sweat lodges.

Item	Section	Page	Comment	Response
3d	Topic 1c: Consultation process – in many instances, EPA's incorporation of information provided by the TCTCIT is inaccurate and EPA incorrectly cites the TCTCIT as the source of numerous exposure parameters.	4, Bullet 2	Tribal children swimming and wading event time for surface water and sediment – the TCTCIT estimated that children swim for 6 hours/day and wade for 6 hours/day in their January 24, 2018 reply to EPA. These event times have been set to 1 hour/day and 5 hours/day, respectively, in the HHRA memo (see Table 4.2 and page 4/26 in the HHRA memo). Again, the HHRA memo incorrectly cites the TCTCIT as the source of these values and EPA should remove the TCTCIT as the source for these values. Further, we are concerned that one hour/day does not accurately reflect the duration of children's time swimming (particularly in warmer months, when TCTCIT representatives report that children swim many hours per day each day). However, we acknowledge that we do not have quantitative data on childhood time spent swimming and wading. EPA may therefore need to conduct additional data collection efforts to determine a value for these parameters.	For tribal children, an event time of 6 hours is assumed for a combination of swimming and wading in the HHRA; as a conservative approach, exposure factor values for a swimming scenario are used in the risk estimates to account for a child swimming 6 hours per event.

Table 2a. Response to Comments Provided by TCTCIT on Document No. 2

Item	Section	Page	Comment	Response
3e	Topic 1c: Consultation process – in many instances, EPA's incorporation of information provided by the TCTCIT is inaccurate and EPA incorrectly cites the TCTCIT as the source of numerous exposure parameters.	4, Bullet 3	Exposure to mine discharge – the TCTCIT estimated that adults spend 6 hours/day, 156 days/year; and children spend 1 hour/day, 48 days/year in contact with mine discharge in the information they provided to EPA on January 24, 2018. The HHRA memo states that these exposure times and frequencies were not incorporated into exposure scenarios because EPA believes the TCTCIT was providing estimates of contact with "water bodies that have received mine discharge, rather than direct contact with the shallow mine discharges in the two areas, prior to entering water bodies" (page 8/26 of the HHRA memo). (We note that page 7 of the HHRA memo describes three mine discharge areas, and so we assume the reference to two areas in the quoted text is a typographical error). The TCTCIT would like to affirm that they understand the definition of the term "mine discharge," and the estimates provided by the TCTCIT indeed reflect their estimates for adult and child exposure to the mine drainage areas described in the HHRA memo. These include (1) the area in Commerce, Oklahoma where discharges led to the eventual inclusion of the Tar Creek Superfund Site on the National Priorities List; (2) the area by East 40 Road, where Tar Creek and the old creek bed of Lytle Creek converge; and (3) the area on Beaver Creek, immediately north and south of East 50 Road. However, we acknowledge that these are best estimates, and not quantitative data. EPA may therefore need to conduct additional data collection efforts to determine the value of these parameters.	The mine discharges sampled are representative of those that people could contact outside of creeks, rivers, and tributaries. Mine discharges in one area of the Tar Creek watershed (in Commerce) are currently being treated by passive treatment systems at the point of discharge. The mine discharges within the remaining two areas occur intermittently, have a typically low flow rate, flow over very short distances before reaching a creek, are not wide or deep (typically shallow flow of less than 3 to 5 feet across), and are not easily accessible or are restricted by physical structures such as fences or heavy overgrowth. Although exposure is expected to be infrequent, mine discharge was conservatively evaluated for tribal lifeway hunting/ fishing/gathering and recreational activities (incidental ingestion and dermal contact), tribal lifeway potable use (ingestion and dermal contact), tribal lifeway sweat lodge (ingestion, dermal contact, and inhalation of water vapors), and general public wading (dermal contact) using the same exposure assumptions as surface water in Appendix F3.

Table 2a. Response to Comments Provided by TCTCIT on Document No. 2

Item	Section	Page	Comment	Response
3f	Topic 1c: Consultation process – in many instances, EPA's incorporation of information provided by the TCTCIT is inaccurate and EPA incorrectly cites the TCTCIT as the source of numerous exposure parameters.	5, Bullet 1	The TCTCIT did not provide the ingestion rates for turtles/frogs and for aquatic mammals in Table 4.7 (and discussed on page 7/26 of the HHRA memo), and thus EPA should remove the TCTCIT as the cited source for this information. The TCTCIT did provide the value of 133 g/day for the arrowhead root consumption rate listed in Table 4.7. However, this value is directly derived from the value provided in Harper (2008) for the daily consumption rate for "roots and bulbs." EPA should therefore cite Harper (2008) and not the TCTCIT for this value. Further, when originally providing this value, the TCTCIT did not fully understand the context in which it was to be used. This value represents only a fraction of the total daily plant intake in the Tribal diet described by Harper (2008). In a risk assessment, it is typical to conservatively assume that the total intake of dietary items is from the contaminated source area (see, for example, the HHRA EPA (URS, 2005) conducted for the Midnite Mine Superfund Site). In which case, the daily intake value for plants reported in the HHRA memo and RME tables should be the total plant intake from Harper (2008) of 558 g/day (consisting of legumes, squash and other vegetables, roots and bulbs, greens, and sweets).	The reference for the adult ingestion rate for turtles/frogs, semi-aquatic mammals, and aquatic plants was changed to Harper (2008). This HHRA addresses exposures from the aquatic environment (OU5) only, and not terrestrial sources (OU4). Therefore, the total plant intake from Harper (2008) of 558 g/day (which includes both terrestrial and aquatic sources) is not applicable to OU5.
4	Topic #1d: Consultation process – many of the Tribes are incorrectly identified in the HHRA memo.	5	In general, please correctly refer to the Tribes in communications, and specifically for the HHRA memo, please make the following corrections on page 1/26: • Miami Tribe of Oklahoma (not Miami Nation of Oklahoma) • Seneca-Cayuga Nation (not Seneca-Cayuga Tribe of Oklahoma) • Wyandotte Nation (not Wyandotte Nation of Oklahoma).	The names of the Tribes have been corrected to those indicated in the comment.
5a	Topic #2a: Tribal Lifeways characterization – the characterization of Tribal exposure scenarios in the HHRA memo is confusing and inconsistent across the memorandum and attachments.	5	The HHRA memo describes "Tribal Lifeway," "Worker," and "Sweat Lodge" exposures. However, the relationship between the three is inconsistently described, and it is therefore unclear how the "combined risk" mentioned in the memorandum will be calculated by EPA.	Potential risks associated with each exposure pathway (e.g., ingestion of fish, ingestion of aquatic plants, potable use of surface water) are presented separately. Potential risks associated with aquatic worker exposures are also presented separately. However, cumulative risks from sediment (ingestion and dermal contact), surface water (incidental ingestion, dermal contact, potable use, sweat lodge ingestion, sweat lodge dermal contact, and sweat lodge inhalation), aquatic animal (ingestion), and aquatic plants (ingestion and dermal) exposures are presented to provide a combined risk estimate for OU5 media.

Table 2a. Response to Comments Provided by TCTCIT on Document No. 2

Item	Section	Page	Comment	Response
5b	Topic #2a: Tribal Lifeways characterization – the characterization of Tribal exposure scenarios in the HHRA memo is confusing and inconsistent across the memorandum and attachments.	5, Bullet 1	Section 3 of the HHRA memo (page 3/26) provides a narrative description of the exposure scenarios and is titled "Tribal Lifeway Exposure Scenarios." This section is divided by media and within each media is further subdivided into "Tribal Lifeways Exposures," "Worker Exposures," and "Sweat Lodge Exposure." This structural organization would imply that worker exposure and sweat lodge exposure are subcategories of an overall "Tribal Lifeways Exposure" receptor population.	As presented in the HHRA, a complete "Tribal Lifeway Exposure Scenario" for OU5 consists of potential exposures to sediment (ingestion and dermal contact), surface water (incidental ingestion, dermal contact, potable use, sweat lodge water ingestion, sweat lodge water dermal contact, and sweat lodge water inhalation), aquatic animals (ingestion), and aquatic plants (ingestion and dermal). The adult exposure frequency (312 days/ year) used for sediment and surface water exposures is high enough to account for exposures that may occur at work or while performing Tribal Lifeway activities. A separate "Aquatic Worker" scenario is also presented in the HHRA to address people who work in surface water and sediment (250 days/year) but do not participate in other Tribal Lifeway scenarios.
5c	Topic #2a: Tribal Lifeways characterization – the characterization of Tribal exposure scenarios in the HHRA memo is confusing and inconsistent across the memorandum and attachments.	5, Bullet 2	However, the CEM presented in Attachment one (page 11/26 of the HHRA memo) only shows two Tribal "potential receptor" groups ("Tribal Lifeway" and "Tribal Worker"), and sweat lodges are depicted as an "Exposure Point" (not a receptor). The RME tables in Attachment two (beginning on page 15 of the HHRA memo) similarly list "Tribal Lifeway" and "Tribal Worker" as "Receptor Populations," and sweat lodges as an "Exposure Point."	In the HHRA, sweat lodge exposures are included as part of the Tribal Lifeway scenarios, and include surface water exposures during sweat lodge use (water ingestion, dermal contact with water, and inhalation of steam).

Table 2a. Response to Comments Provided by TCTCIT on Document No. 2

Item	Section	Page	Comment	Response
5d	Topic #2a: Tribal Lifeways characterization – the characterization of Tribal exposure scenarios in the HHRA memo is confusing and inconsistent across the memorandum and attachments.	6	The TCTCIT recommends that EPA clarify what are considered receptor populations vs exposure points in the HHRA. Further, EPA should clarify the relationship among these exposure populations and, specifically, how EPA intends to determine the "combined risk" (page 3/6 and 11/26 of the HHRA memo), for these exposure groups. Without such changes, the TCTCIT question, for example, how will EPA assess the "combined risk" for a Tribal member or citizen who practices traditional lifeways and also has work-related exposures?	The receptor populations addressed in the HHRA are presented in RAGS Table 1: Tribal Lifeway (adults and children) and General Public (adults and children). Exposure points are indicated in RAGS Table 1 for all media. Potential risks from sediment (ingestion and dermal contact), surface water (incidental ingestion, dermal contact, potable use, sweat lodge ingestion, sweat lodge dermal contact, and sweat lodge inhalation), aquatic animal (ingestion), and aquatic plants (ingestion and dermal) exposures are presented in the HHRA separately and combined to provide a cumulative risk estimate for exposure to OU5 media. Aquatic workers are presented separately to address people who work in surface water and sediment (250 days/year) but may not participate in other Tribal Lifeway scenarios. For those tribal members or citizens who practice traditional lifeways and have work-related exposures, their potential risks are addressed in the Tribal Lifeway scenario.

Table 2a. Response to Comments Provided by TCTCIT on Document No. 2

Item	Section	Page	Comment	Response
6	Topic #2b: Tribal Lifeways characterization – EPA's characterization of Tribal wading and swimming exposure routes is confusing and potentially misleading/inaccurate	6, Para. 1 to 3	The HHRA memo makes statements (page 4/26) regarding the relative frequencies of exposure of Tribal members and citizens engaged in different Tribal Lifeways activities: *Exposure to surface water while wading and swimming consists of both dermal exposure and incidental ingestion. For the purpose of the risk assessment, these exposures for a tribal lifeways scenario with surface water will be evaluated by assessing exposure during wading and swimming activities. Wading and swimming may also occur as a recreational or ceremonial activity, but these exposures are expected to occur at a lower frequency than during hunting and gathering activities, and are therefore addressed by this more conservative exposure scenario. (page 4/26)* Statements are also made in the HHRA memo on pages 5/26 and 6/26 regarding relative frequencies of surface water and sediment exposure during Tribal Lifeway activities: *The tribal lifeways scenario associated with surface water is a conservative representation of many other surface water [sediment] exposures that tribal members and citizens may encounter on a frequent or occasional basis, such as when Entering cold surface water during challenges…Occasional visitors contact surface water during tribal festivals or ceremonies, or recreational activities such as swimming, fishing, or hunting. (page 5/26 and 6/26)* These statements are confusing and the intended significance to the Tribal Lifeways exposure scenario is unclear. We recommend removing the language and replacing with "Tribal members are exposed to surface water and sediment when wading and swimming, which may take place during hunting, fishing, gigging, gathering, ceremonial, and recreational activities that are part of typical cultural practices." Also, EPA should explain or provide sources for the basis of their statements regarding relative frequencies for the different listed Tribal activities. If sources cannot be provided, then these assertions should be removed from the HHRA memo and not incorporated into the OU5 HHRA.	The language referencing these activities has been modified for the HHRA. The HHRA text states that tribal members are exposed to surface water and sediment when wading and swimming, which may take place during hunting, fishing, gigging, gathering, ceremonial, and recreational activities that are part of typical cultural practices.

Table 2a. Response to Comments Provided by TCTCIT on Document No. 2

Item	Section	Page	Comment	Response
7	Topic #2c: Tribal Lifeways characterization – EPA's characterization of Tribal use of plants is confusing and potentially misleading/inaccurate.	7	The HHRA memo states that: *Aquatic plants may also be used for ceremonial practices involving dermal contact or ingestion, but assessment of medicinal use on skin, and direct ingestion of plants as discussed further below, address ceremonial use of plants. (page 6/26)* The HHRA memo then states: *The tribal lifeway scenario associated with aquatic plants is a conservative representation of other aquatic plant ingestion exposures that tribal members and citizens encounter on an occasional basis, such as when ingesting aquatic plants for medicinal purposes. (page 7/26)* Ceremonial and medicinal use of plants should be considered in addition to (not subsumed within) consuming plants as a part of the Tribal diet. EPA should provide the basis (i.e., cite sources) for their statement regarding the "occasional basis" of ingesting aquatic plants for medicinal purposes, and implied relative consumption rates of plants for dietary vs medicinal/ceremonial purposes. If EPA cannot provide a source, these statements should be removed from the HHRA memo and not incorporated into the OU5 HHRA.	Ceremonial and medicinal use of aquatic plants was considered, and potential risks from medicinal use of plants as salve (based on total arrowhead plant data) are included in the HHRA based on the knowledge of use of arrowhead for this purpose. Regarding the statements in the HHRA memo, they will not be included in the OU5 HHRA without sufficient evidence to support the argument.
8	Topic #2d: Tribal Lifeways characterization – EPA's exposure route assumptions for sweat lodge participation should be re-evaluated and adjusted.	7	The HHRA memo states that: *Adults may use a sweat lodge for ceremonial purposes, and the water used in this ceremony comes from surface water, leading to a dermal exposure to surface water. (page 5/26)* Exposure during a sweat lodge ceremony includes inhalation or oral ingestion of water as steam, in addition to dermal contact. In a sweat lodge, water is turned to steam and the participants sit in a steam bath, during which time they are breathing and potentially talking, which means that exposure could be through inhalation or ingestion, in addition to dermal contact. There may also be exposure to sediment during sweat lodge use. EPA should re-evaluate their exposure assumptions and adjust accordingly.	Inhalation, ingestion (1 L/day by adults and children), and dermal contact exposures (whole body) to surface water are included in the HHRA for sweat lodge use.
9	Topic #2e: Tribal Lifeways characterization – the exposure scenarios described in the HHRA memo do not include Tribal use of groundwater springs.	7	Many Tribal members and citizens visit groundwater springs within OU5 to gather plants for consumption (e.g., watercress) and to engage in cultural practices. During these visits, they are exposed via ingestion and dermal contact with the water and sediment. Exposure at groundwater springs should be included in the HHRA.	Groundwater is not a medium addressed under OU5. However, while water from groundwater springs are not specifically addressed in the HHRA, exposures to direct mine discharge are evaluated as a worst-case scenario in Appendix F3.

Table 2a. Response to Comments Provided by TCTCIT on Document No. 2

Item	Section	Page	Comment	Response
10a	Additional details – EPA's body surface area exposure parameter values may underestimate the exposure for both adult workers and children.	8, Bullet 1	Worker skin surface area exposed to surface water and sediment – the HHRA memo states that only the hands and forearms of workers come into contact with surface water and sediment (see pages 5/26 and 6/26 of the HHRA memo). The TCTCIT understand from conversations with Tribal workers that this is not necessarily true. Tribal workers normally wear protective gear when in contact with surface water and sediment, but the nature of the work can be variable and it is common to have contact with water and sediment on the face, legs, and sometimes body as a result of normal work conditions in the field. Figure 1 provides an illustration of this point, showing Tribal hatchery workers directly exposed up to their chests to surface water and sediments pumped from the Spring River. Therefore, it would be appropriate to expand the exposed skin surface area for workers to ensure that the HHRA estimates are protective of all Tribal community members. This would affect the "skin surface area available for contact" parameter in Tables 4.3 and 4.6.	It is conservatively assumed in the HHRA that an aquatic worker has their entire body exposed to surface water and sediment every work day (250 days/year) for 25 years.
10b	Additional details – EPA's body surface area exposure parameter values may underestimate the exposure for both adult workers and children.	8, Bullet 2	Child skin surface area exposed to surface water and sediment when wading – the HHRA memo assumes that when wading, children's hands, forearms, lower legs, and feet are exposed to surface water and sediment. This may be an underestimate of the portions of the body that get wet and come into contact with sediment, particularly for young children (up to 6 years). It may be appropriate to expand the exposed skin surface area to the "total skin area" used for swimming for this age group. This would affect the "skin surface area available for contact" parameter in Tables 4.2 and 4.5.	It is conservatively assumed in the HHRA that a tribal child has their entire body exposed to surface water and sediment during every swimming/wading event.
11a	Topic #3b: Additional details – there are minor unexplained numerical discrepancies between the HHRA memo and the November 7, 2018 version of the RME tables.	8, Bullet 1	Text on page 15/26, Table 4.1: Adult dermal contact is identified as 0.72 hours/event. This value is slightly different than the value in an earlier version of the RME tables that EPA shared with the TCTCIT via email on November 7, 2017 (previous estimate was 0.71 hours/event). What is the reason for this slight difference?	The HHRA uses a water dermal contact event time of 0.71 hour/event for adults, which is the default value provided by EPA for daily potable water dermal contact.
11b	Topic #3b: Additional details – there are minor unexplained numerical discrepancies between the HHRA memo and the November 7, 2018 version of the RME tables.	8, Bullet 2	Text on page 16/26, Table 4.1: Child dermal contact is identified as 0.53 hours/event. This value is slightly different than the value in an earlier version of the RME tables that EPA shared with the TCTCIT via email on November 7, 2017 (previous estimate was 0.54 hours/event). What is the reason for this slight difference?	The HHRA uses a water dermal contact event time of 0.54 hour/event for children, which is the default value provided by EPA for daily potable water dermal contact.

Table 2a. Response to Comments Provided by TCTCIT on Document No. 2

Item	Section	Page	Comment	Response
12	Topic #3c: Additional details – incorrect spelling of Tribal activities.	8	On pages 5/26 and 6/26, under "Applicability of Evaluated Exposure Scenarios to Other Surface Water (Sediment) Scenarios," the HHRA memo lists "*Jigging or spearing fish….*" We believe this is a typographical error that should be corrected to "*Gigging or spearing fish….*"	The spelling of "gigging" is correct in the HHRA.
13	Topic #4a: Overall nature and extent – the HHRA may underestimate the risk if cumulative effects across multiple exposure pathways and multiple contaminants are not adequately characterized.	10	The HHRA memo indicates, "The HHRA will present exposure and risk estimates for each sampled medium separately and will also provide risk estimates for all exposure media (surface water, sediments and aquatic biota) and pathways combined at OU5" (page 11/26 of the HHRA memo). However, EPA does not describe how they intend to assess risk from all pathways combined. Further, EPA does not describe how the HHRA will address the combined risk associated with the multiple metal contaminants that are present within OU5. It is therefore difficult for the TCTCIT to evaluate the adequacy of EPA's "combined" approach for all exposure media and pathways, and whether EPA intends to assess cumulative risk. EPA (U.S. EPA, 2003) defines cumulative risk as the combined risks from aggregate exposures to multiple agents or stressors, and further states that: *this definition requires that the risks from multiple agents or stressors be combined. This does not necessarily mean that the risks should be "added," but rather that some analysis should be conducted to determine how the risks from the various agents or stressors interact. It also means that an assessment that covers a number of chemicals or other stressors but that merely lists each chemical with a corresponding risk without consideration of the other chemicals present is not an assessment of cumulative risk. (U.S. EPA, 2003, p.17)* The description of EPA's HHRA approach for OU5 is incomplete because it does not adequately describe how cumulative risk will be determined, particularly given the multiple contaminants present at this site.	The HHRA provides cumulative risk estimates assuming additivity for chemicals with the same target organ. The HHRA presents cumulative risk estimates for each exposure scenario, based on risks from surface water and sediment in each waterway separately and combined watershed-wide risks from biota consumption. To understand potential vulnerability of communities around Tar Creek Superfund Site, a discussion of demographic data (as indicators of additional stressors) in these communities will be included in the HHRA.
14	Topic #4b: Overall nature and extent – underestimation of risk – the HHRA may underestimate risk due to the inadequate consideration of "background" contaminant exposure levels.	10-11	The TCTCIT has previously commented on this topic [see, for example, Abt Associates (2016)]. The HHRA is focused on OU5, which consists of surface water and sediment located downstream of mined areas. Because of this focus, EPA is only considering exposure to contaminants through dermal contact and ingestion of surface water, sediments, and aquatic biota within OU5. However, members and citizens of the TCTCIT are not only exposed to metal contaminants of the Tar Creek Superfund Site through these exposure pathways. TCTCIT members and citizens also engage in other activities that may expose them to these metals. For example, they may be exposed while gathering and ingesting terrestrial plants, and while hunting and ingesting big game in other parts of the Tar Creek Superfund Site. By not taking into account these other "background" contaminant exposure pathways and levels, EPA may over-estimate levels that are considered "safe" within OU5, which may ultimately lead to cleanup levels that are not protective of human health.	EPA's *Guidance for Conducting Remedial Investigations and Feasibility Studies Under CERCLA* (EPA, 1988) indicates that when a site is divided into operable units (OUs), a risk assessment should be performed for each unit separately. During the remedial alternatives process, the alternatives should be evaluated to ensure that they protect human health and the environment from each potential pathway of concern at the site or those areas of the site being addressed as part of an OU.

Table 2a. Response to Comments Provided by TCTCIT on Document No. 2

Item	Section	Page	Comment	Response
			Disregarding other sources of contaminant exposure and contaminant background levels when assessing risk and setting "safe" exposure levels is at direct odds with EPA's own risk assessment guidance. For example: EPA guidance for metals risk assessment, children's risk assessment, and for setting safe consumption limits indicate that, to properly address the risk of a contaminant to human health, assessors need to consider all exposure sources in their assessments (U.S. EPA, 2000a, 2000b, 2007). EPA's *Framework for Metals Risk Assessment* states: *In Exposure Assessment, the risk assessor quantifies the total exposure to a toxic agent in the environment based on amount taken into the body, including any combination of the oral, inhalation, and dermal routes of exposure* (U.S. EPA, 2007, p. 4-1). EPA guidance is clear that when establishing safe consumption levels, a comprehensive evaluation of all sources of exposure should be conducted (U.S. EPA, 2000a). For example, when setting fish consumption advisories (FCAs), EPA states that it is important to consider all exposure routes because even though exposure through the consumption of fish alone may be safe, the total exposure to a contaminant, when including sources other than the fish, may cause an individual to exceed a safe exposure level, thus requiring issuance of an FCA (U.S. EPA, 2000a). EPA's guidance for deriving ambient water quality criteria (AWQC) also recommends considering all sources of exposure when assessing risk, by applying a relative source contribution (RSC; U.S. EPA, 2000b). The 2015 AWQC update recommends the inclusion of an RSC ranging from 20% to 80%, to account for contaminant exposure from other sources, including food consumption (e.g., meats, poultry, fruits, vegetables, grains), dermal exposure, and respiratory exposure (U.S. EPA, 2015). While the AWQC is obviously focused on water criteria, the guidance includes broader statements about EPA-wide policy on characterizing exposure and human health risk. Throughout this guidance, EPA stresses that assessors should consider all sources of contaminant exposure when evaluating human health risk, and states that this approach is an Agency-wide priority: *The policy of considering multiple sources of exposure when deriving health-based criteria has become common in EPA's program office risk characterizations and criteria and standard-setting actions. Numerous EPA workgroups have evaluated the appropriateness of factoring in such exposures, and the Agency concludes that it is important for adequately protecting human health* (U.S. EPA, 2000b, p. 4-4). Even if risk assessors focus on a particular exposure scenario, EPA guidance is clear that assessors need to characterize all "background" exposure values and include them in the assessment (U.S. EPA, 2003, 2007). Within this context, EPA defines "background" as all existing metal sources other than the targeted source. Therefore, even if EPA is focusing their HHRA on aquatic exposure pathways within OU5, they still need to consider other "background" sources of exposure, which for Tribal members and citizens in OU5	If separate alternatives have been developed for different areas or media of the site, it is recommended that they be combined during the detailed analysis phase to present comprehensive options addressing all potential threats posed by the site or that area being addressed by the OU. EPA's *Risk Assessment Guidance for Superfund (RAGS) Part A* (EPA, 1989) states: "The human health evaluation should focus on the subject of the RI/FS [remedial investigation/feasibility study], whether that is an operable unit or the site as a whole. The baseline risk assessment and other risk information gathered will provide the justification for taking the action for the operable unit. At the same time, personnel involved in conducting the human health evaluation for a focused RI/FS must be mindful of other potential exposure pathways, and other actions that are being contemplated for the site to address other potential exposures. Risk analysts should foresee that exposure pathways outside the scope of the focused RI/FS may ultimately be combined with exposure pathways that are directly addressed by the focused RI/FS. Considering risks from all related operable units should prevent the unexpected discovery of high multiple pathway risks during the human health evaluation for the last operable unit." The HHRA risk estimates address potential exposures to media within OU5 only. The risk estimates associated with terrestrial exposures were presented in the HHRA for OU4.

Table 2a. Response to Comments Provided by TCTCIT on Document No. 2

Item	Section	Page	Comment	Response
			include, for example, contaminated air and soil, large game, small game, and terrestrial plants in other parts of the Tar Creek Superfund Site. If EPA does not consider these sources, EPA may underestimate the risk and set exposure and cleanup levels that are in fact not protective of human health.	The approach for development of preliminary remediation goals (PRGs) and target levels for various health endpoints (e.g., cancer risk, hazard index, blood lead level), including considerations for other OUs, have not yet been established and will be developed after the HHRA for OU5.

Table 2b. Response to Comments Provided by AESE, Inc., on Behalf of Quapaw Nation on Document No. 2 and No. 3

Item	Section	Page	Comment	Response
1	Introduction	1 Para. 2 and 3	The Quapaw Tribe of Oklahoma (QTO) provided comments on an earlier supporting document (Attachment No 1). The majority of concerns raised in this previous review still are unresolved. The QTO believes it would be much more expeditious and cost-effective for EPA to respond to these previous concerns (Attachment No. 1) as well as additional concerns provided herein before proceeding any further. The QTO reiterates that OU4-specific cleanup standards/goals have been developed without considering risk associated with the use of the other OUs. Remediation/removal in OU4 has proceeded relying on these values. Having this concern in 2015, made the Tribe realize that in order to save time and resources, we needed to develop a Reasonable Maximal Exposure Scenario (RME) for each OU as soon as possible.[1] As demonstrated below, the information contained in this technical memorandum falls far short. [1] In early 2016 the Tribe proposed to EPA to develop RME's for each OU type; however, funding was not received.	The HHRA risk estimates address potential exposures to media within OU5 only; the RME exposure scenarios and assumptions are based on input received from the QTO and TCTCIT. The risk estimates associated with terrestrial exposures were presented in the HHRA for OU4. The approach for development of PRGs and target levels for various health endpoints (e.g., cancer risk, hazard index, blood lead level) have not yet been established.
2	General Comments (in addition to those raised in Attachment No. 1)	2, Bullet 1	Aquatic-based and terrestrial-based variants of the RME for the QTO need to be developed as soon as possible (see Attachment No. 1)	The HHRA risk estimates address potential exposures to media within OU5 only; the RME exposure scenarios and assumptions are based on input received from the QTO and TCTCIT. The risk estimates associated with terrestrial exposures were presented in the HHRA for OU4.
3	General Comments (in addition to those raised in Attachment No. 1)	2, Bullet 2	From data presented in the Tech Memo, it is clear that the Tribes of the Tar Creek Trustee council (TCTC) rely on resources at much lower consumption rates, frequencies, and durations. Therefore the QTO is greatest exposed hedonistic receptor in the area. This means that tribes of the TCTCIT are much lower risk populations and should not be the subject of development of RMEs, since the QTO RME (terrestrial and aquatic variants) is protective of the TCTCIT Tribes. This also means that PRGs/RAOs and ultimately selection of the preferred alternative must be based on the QTO RME and not RME based on the TCTCIT tribes.	The final biota consumption rates used in the HHRA were obtained from Harper (2008) (see RAGS Table 4.6). The approach for development of PRGs and target levels for various health endpoints (e.g., cancer risk, hazard index, blood lead level) have not yet been established.

Table 2b. Response to Comments Provided by AESE, Inc., on Behalf of Quapaw Nation on Document No. 2 and No. 3

Item	Section	Page	Comment	Response
4	General Comments (in addition to those raised in Attachment No. 1)	2, Bullet 3	The General Objectives of the Tar Creek OU5 HHRA (Section 2.0) is misleading: *The objectives of the HHRA are two-fold: first, to estimate the level of risk to human health associated with concentrations of environmental contaminants detected in OU5 media (surface water, sediments, biota, and mine discharge);* At this stage of the RI/FS, estimating PRGs/RAOs is the objective, followed by quantification of residual risk associated with each proposed alternative in the FS. The Hazard Ranking Score (HRS) has already demonstrated that Risk is excessive, even to the general public. Risk is clearly much greater for the QTO who "live close to the land". *Risks are estimated **for current exposures to OU5** media as well as reasonably foreseeable future uses. All contaminated media within OU5 are considered (such as sediment and surface water) if individuals are likely to be exposed to the media. All relevant **routes of exposure for OU5 are considered**, including direct contact (ingestion and dermal exposure) and indirect contact (exposure to food items that have accumulated contaminants through sediments).* [Emphasis added] EPA cannot discount risk associated with the other OUs. In other words EPA needs to assess risk allocation from all OUs, from all COCs released, from all media, along all pathways to the QTO.	EPA's *Role of the Baseline Risk Assessment in Superfund Remedy Selection Decisions* (EPA, 1991) indicates that the primary purpose of the baseline risk assessment is to provide risk managers with an understanding of the actual and potential risks to human health and the environment posed by the site and any uncertainties associated with the assessment. The approach for development of PRGs and target levels for various health endpoints (e.g., cancer risk, hazard index, blood lead level) have not yet been established.
5	General Comments (in addition to those raised in Attachment No. 1)	3, Bullet 4	Sweatlodge usage was intentionally left ambiguous in the original QTO HHRA Scenario. The Traditional QTO frequency of sweatlodge use requires more research. This was included in the aforementioned proposal mentioned in Attachment No. 1. The downriver tribes may use a sweat lodge less than once per month, but research may reveal that the QTO use it at a higher frequency. This is important because the QTO reservation encompasses the most contaminated lands of all OUs.[2,3] The QTO are the population representing the RME, and sweatlodge use is likely an important risk-driving activity. This means that PRGs/RAOs and subsequent remedies will be based on remedies that are protective for the Quapaw Tribe. [2] The Tribe also has the right to hunt fish and gather in areas downstream of their reservation. [3] Many of the QTO members are dual citizens or have relatives of the downstream tribes that would result in the QTO to be exposed via diet during hunting, fishing, and gathering or via trade of contaminated resources.	A sweat lodge exposure frequency of 365 days/year, exposure time of 1 hour/event, and exposure duration of 64 years is used for adults in the HHRA based on *Shoshone-Bannock Exposure Scenario for Use in Risk Assessment: Traditional Subsistence Lifeways*. (S-B EWMP, 2016). These exposure assumptions are more conservative than input provided by Quapaw and TCTCIT. A sweat lodge exposure frequency of 365 days/year, exposure time of 1 hour/event, and exposure duration of 4 years (children ages 2 to 6) is used for children in the HHRA based on input from QTO since TCTCIT indicated that children do not use the sweat lodge.

Table 2b. Response to Comments Provided by AESE, Inc., on Behalf of Quapaw Nation on Document No. 2 and No. 3

Item	Section	Page	Comment	Response
6	General Comments (in addition to those raised in Attachment No. 1)	3, Bullet 5	The distinction between ordinary surface water and mine discharge surface water is not clear. *"Mine discharge occurs in three known locations of the Tar Creek Superfund Site in Ottawa County, Oklahoma"* It is not clear why there is any distinction at all, since any mine discharge becomes diluted with other water, and at some magical undefined point becomes ordinary surface water. The standard RME should be applied to these locations just as with any other location. This approach should save on risk calculation costs as well. Also, water quality standards are not dependent on the depth of the water (Section 3.4). The mine water media also needs to be connected to Surface Water in the wire-frame CSM.	The mine discharges sampled are representative of those that people could contact outside of creeks, rivers, and tributaries. Mine discharges in one area of the Tar Creek Watershed (in Commerce) are currently being treated by passive treatment systems at the point of discharge. The mine discharges within the remaining two areas occur intermittently, have a typically low flow rate, and are not easily accessible. Although exposure is expected to be infrequent, mine discharge was conservatively evaluated using the same exposure scenarios and assumptions as surface water in Appendix F3. Mine discharge media is connected to surface water in the conceptual site model (CSM) figure provided in the HHRA.
7	Specific Comments	4, Bullet 1	Section 1.0(1). While there is a logic to start by collecting all available data and then filling data gaps, a more complete process would be to: (Step 1) develop a whole-site human usage map and exposure scenario (the "exposome"), (Step 2) develop DQOs with detection limits based on total exposure and on background , (Step 3) review existing data for data usability according to EPA guidelines, (Step 4) develop a data gap report, (Step 5) collect new data, (Step 6) determine how to allocate risk among OUs and develop RMEs for as many OUs or sub-site areas as needed, and (Step 7) evaluate exposure and risk. These earlier documents cannot exist, since the RME(s) have not been developed and they are necessary to developing OU-specific DQOs and subsequently determine data usability. The allocation of risk among OUs means that the total allowable human risk (e.g., 1E-6 and HI = 1) will need to be subdivided among OUs so that individual OUs do not usurp the entire risk budget. Risk targets for individual OUs will need to be fractions of the total allowable risk. This comment is expanded in the next comment.	This HHRA addresses potential exposures to media within OU5 only. The risk estimates associated with terrestrial exposures were presented in the HHRA for OU4 and residential exposures in the HHRA for OU2. The preliminary CSM was developed at the beginning of the OU5 study in 2016 and continued to be refined with input from QTO and TCTCIT, and has informed the OU5 HHRA. Step 1 is not necessary as each OU has allocated risk (Step 6) and each OU has completed Steps 2 through Step 7. The RME for OU5 scenarios and exposure assumptions were identified through input from TCTCIT and QTO. The approach for development of PRGs and target levels for various health endpoints (e.g., cancer risk, hazard index, blood lead level) have not yet been established.

Table 2b. Response to Comments Provided by AESE, Inc., on Behalf of Quapaw Nation on Document No. 2 and No. 3

Item	Section	Page	Comment	Response
8	Specific Comments	4, Bullet 2	The "Overview of the Superfund HHRA Process" is incorrect. *1. The first step focuses on data collection and analysis to evaluate the characteristics of the site and support identification of the chemicals of potential concern (COPCs) in site media.* This step is performed prior to listing in HRS and only identifies gross COPCs detrimental to the general public. The HHRAS/RME is required to determine necessary detection limits of COPCs. However, since Tribal populations use are the greatest exposed hedonistic receptor in the area, generally for mine sites, all EPA Target Analyte List (plus molybdenum) are COCs and the list of TAL+Mo cannot be screened-down. Regardless, COCs, necessary detection limits, and geographic scope are determined near Step 4. Data gaps cannot be determined until EPA knows what data are needed (DQOs) and if the exiting data meet these DQOs. A later step is developing the SAP/FSP (or similar document(s)) that provides statistical design-level rationale for sampling biotic and abiotic media identified by EPA to be lacking from the historic database at the proper risk-based detection levels. This lacking information is termed data gaps. In order to determine what data are missing, EPA must first know what data they need to perform the BHHRA. The BHHRA is based on the reasonably anticipated future land use (RAFLU) of the target population. Note that land use is determined by the land owner first, and then the area is cleaned up to make that use safe, rather than forcing land use to be limited if the cleanup is not sufficient to reduce risk enough based on the RAFLU (i.e., if institutional controls are needed). At TC, since these are Tribal lands, the QTO is the target of the BHHRA. Once the RAFLU and the target population have been identified, a plan is developed that specifies the data needs for the BHHRA. This is done in the HHRA work plan by using the conceptual site model as a visual accounting tool to derive the list of data that are needed. Next, the quality and quantity of those data are defined in a similar manner while the data quality objectives are being prepared. Once the DQOs have been prepared, the DQOs are used as a screening tool to evaluate the historical data. Data that meet the DQOs are retained for the BHHRA. Data that do not meet the DQO's are rejected and the data gap is recorded. Finally, a SAP and a FSP are developed using the DQOs and the HHRA WP to fill the gaps. This approach is detailed in the NCP.	The first step of the baseline HHRA process, as presented in EPA's RAGS Part A, is Data Evaluation, which includes screening site data for chemicals exceeding risk-based concentrations. The chemicals exceeding screening levels are termed chemicals of potential concern (COPCs), and those that are risk drivers based on the HHRA results are termed chemicals of concern (COCs). The data usability evaluation that was conducted on the existing dataset in 2016 is documented in the Data Gap Summary Report (CH2M, 2016). The data that were concluded to be usable for the HHRA have been incorporated into the HHRA dataset. Significant historical studies and associated datasets have focused on only cadmium, lead, and zinc. New data gap samples were analyzed for all metals, not an abbreviated list. The analyte list and the detection limits needed from a risk-based standpoint were identified in the Quality Assurance Project Plan (2017), which included the data quality objectives (DQOs). The HHRA evaluates a Tribal Lifeway scenario in OU5. The preliminary CSM was developed at the beginning of the OU5 study in 2016 and continued to be refined with input from QTO and TCTCIT. The exposure scenarios and assumptions were identified with input from QTO and TCTCIT.

Table 2b. Response to Comments Provided by AESE, Inc., on Behalf of Quapaw Nation on Document No. 2 and No. 3

Item	Section	Page	Comment	Response
9	Specific Comments	5, Bullet 3	Exposure parameters do not have "conservative safety factors" (Section 1.0(2)). *….These assumptions, or default values, are assumed to be representative of a population, although they often include a conservative safety factor. These parameters include things such as time spent contacting surface water.* Exposure factors for the general population are based on actual data and statistical analysis, aiming at central tendency or upper percentiles, depending on the exposure pathway. For unstudied populations, the exposure parameters are extrapolated from actual data with professional judgment. A "reasonable maximum" is exactly that, reasonable.	The specific section of the Technical Memorandum cited in the comment was a general discussion of the Superfund HHRA process. In the HHRA for OU5, the exposure scenarios and assumptions for the Tribal Lifeway scenarios were identified with input from the Quapaw Nation and TCTCIT.
10	Specific Comments	5, Bullet 4	An ecological determination of water body types (and therefore the specific boundaries of OU5) will probably be needed, because the sampling locations appear to include wetlands, streams, rivers, lakes, and springs. Perhaps the boundary of OU5 is a high water mark for a lake, but how is the boundary determined for a wetland or floodplain with seasonal discharges?	OU5 is defined as the wet-bank-to-wet-bank boundaries of perennial flowing streams. Wetlands and riparian areas were included in OU4. All samples used in the OU5 HHRA were collected within the OU5 study area and specifically within the wet-bank-to-wet-bank boundaries of the perennial flowing creeks, with limited exception to select biota such as frogs and raccoons.
11	Specific Comments	5, Bullet 5	The relation between OU5 and the other OUs or other exposure areas is not clear. The floodplains are not included in the OU5 consideration. This is a systemic problem with the approach of subdividing a superfund site into OUs. While remedies may occur as separate engineering actions (e.g., pump and treat groundwater, excavate soil, cap sediments), the human body integrates all media, pathways, and contaminants into one cumulative set of doses with one single physiological response. A truly cumulative approach does not set a remedy for one medium at a time, or one OU at a time unless the contributions from ALL OTHER media, pathways, chemicals, and OUs is treated as background exposures (the RSC or relative source contribution approach). Otherwise, 100% of exposure and risk must be assumed to be derived from each individual OU, and no exposure can occur from other OUs. As currently envisioned, for OU5 100% of time and exposure and food must come from OU5. The only alternative to this is to allocate risk among OUs, such as allowing OU5 to contribute only 20% of the total risk, thus requiring, for instance, the total hazard index (summation of HQ's) from all COCs to be 0.2, not 1.0.	EPA's *Guidance for Conducting Remedial Investigations and Feasibility Studies Under CERCLA* (EPA, 1988) indicates that when a site is divided into OUs, a risk assessment should be performed for each unit separately. During the remedial alternatives process, the alternatives should be evaluated to ensure that they protect human health and the environment from each potential pathway of concern at the site or those areas of the site being addressed as part of an OU. If separate alternatives have been developed for different areas or media of the site, it is recommended that they be combined during the detailed analysis phase to present comprehensive options addressing all potential threats posed by the site or that area being addressed by the OU.

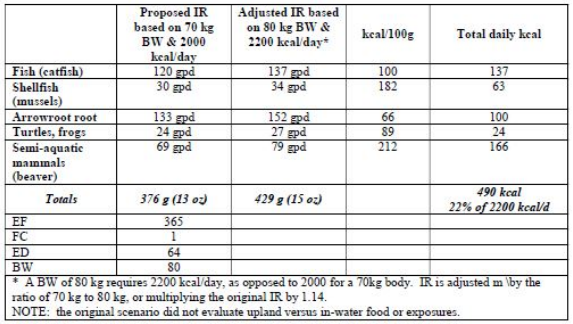
Table 2b. Response to Comments Provided by AESE, Inc., on Behalf of Quapaw Nation on Document No. 2 and No. 3

Item	Section	Page	Comment	Response
				EPA's *Risk Assessment Guidance for Superfund (RAGS) Part A* (EPA, 1989) states: "The human health evaluation should focus on the subject of the RI/FS, whether that is an operable unit or the site as a whole. The baseline risk assessment and other risk information gathered will provide the justification for taking the action for the operable unit. At the same time, personnel involved in conducting the human health evaluation for a focused RI/FS must be mindful of other potential exposure pathways, and other actions that are being contemplated for the site to address other potential exposures. Risk analysts should foresee that exposure pathways outside the scope of the focused RI/FS may ultimately be combined with exposure pathways that are directly addressed by the focused RI/FS. Considering risks from all related operable units should prevent the unexpected discovery of high multiple pathway risks during the human health evaluation for the last operable unit." The HHRA risk estimates address potential exposures to media within OU5 only; floodplains were addressed as riparian areas in the OU4 HHRA. In the OU5 HHRA, the following is assumed: • All sediment and surface water exposures occur within OU5. • All drinking water and sweat lodge water is obtained from surface water in OU5. • All fish and shellfish food (100% of the "aquatic and fish" food category in Harper [2008]) is from OU5.

Table 2b. Response to Comments Provided by AESE, Inc., on Behalf of Quapaw Nation on Document No. 2 and No. 3

Item	Section	Page	Comment	Response
				• All small game food (135% of the "small game" food category in Harper [2008]) is from OU5. • All roots and bulbs food (100% of the "roots & bulbs" food category in Harper [2008]) is from OU5. • All plants used for salve (45 days/year) are from OU5. The approach for development of PRGs and target levels for various health endpoints (e.g., cancer risk, hazard index, blood lead level) have not yet been established.
12	Specific Comments	6, Bullet 6	The body weight of 80 kg is acceptable only if all the dietary intake values are adjusted upward (See General Comment 3, Attachment No. 1). There are several ways to calculate this. A simple way is to multiply body weight (pounds) by 15-16 kcal/pound to maintain body weight.[4] The Harris-Benedict formula is based on total body weight, height, age, and sex and is a more accurate way to calculate basal metabolic rate. Men: BMR = 66 + (13.7 x wt in kg) + (5 x ht in cm) - (6.8 x age in years), Women: BMR = 655 + (9.6 x wt in kg) + (1.8 x ht in cm) - (4.7 x age in years). The BMR is then multiplied by a factor that considers the activity level of the person:·Sedentary = BMR x 1.2 (little or no exercise, desk job), Lightly active = BMR x 1.375 (light exercise/ sports 1-3 days/week). Moderately active = BMR x 1.55 (moderate exercise/ sports 6-7 days/week). Very active = BMR x 1.725 (hard exercise every day, or exercising 2 xs/day). Extra active = BMR x 1.9 (hard exercise 2 or more times per day, or training for marathon, or triathlon, etc. A similar approach is taken by the University of Maryland.[5] Men who are moderately active should multiply their weight in pounds by 15; women multiply by 12. The resulting number is the total calories per day needed to maintain weight. Relatively inactive men should multiply their weight by 13 and women, by 10. A moderately active woman who weighs 150 lbs. would need 1,800 calories per day to maintain her weight. The US Department of Health and Human Services provides age-specific guidelines in their publication, "Dietary Guidelines for Americans, 2015-2020, 8th edition. [6] For use in this RME, a single simplified value of 2200 kcal/day will be used, for a lightly active to moderately active lifestyle. Note again that, based on the original QTO scenario, the aquatic ecosystem provides only 22% of total food. If OU5 is allowed to contribute 100% of allowable exposure and risk, then none of the other food can come from any other OU, and the person or family cannot live in those OUs and come into contact with them.	A body weight of 70 kg for Tribal Lifeway adults is used in the HHRA, consistent with the *Quapaw Traditional Lifeways Scenario* (Harper, 2008).

Table 2b. Response to Comments Provided by AESE, Inc., on Behalf of Quapaw Nation on Document No. 2 and No. 3

Item	Section	Page	Comment	Response
				


13	Specific Comment	7, Bullet 7	The rationale for the values in the separate document TCTC_RAGS_Table 4 from 2016 are not clear from the footnotes. For example, the Tribes proposed a shellfish IR of 30 gpd, while the proposed value was 12 gpd (not converted to g/kg-d), and the Tribes' IR for plants is 133 gpd while the proposed value was 40 gpd. The rates in the TCOU5RI (the current document under review) no longer have the lower proposed values, so please verify that the older RAGS_Table 4 table is no longer the operative table. Again, the QTO is the RME in which PRGs/RAOs must be based. Comments provided by the TCTC demonstrate that that Tribes belonging to this entity are less likely to be exposed, even in the downstream areas than the QTO7 (Also See Comment No. 5 Attachment No. 1).	The final values for biota ingestion rates are presented in RAGS Table 4.6; as shown, the shellfish ingestion rate is 30 g/day for adults. The final values for plant ingestion rates are presented in RAGS Table 4.7; as shown, the ingestion rate is 133 g/day for adults.
14	Specific Comment	8, Bullet 8	The tribal worker scenario is not a useful scenario for two reasons. First, the tribal worker is assumed to spend fewer days per year (250 days) than the resident (312 days), and a shorter exposure duration (25 versus 70 years). It is not clear why the tribal worker's exposure is less than the ordinary resident. The only difference is that the skin surface might be reduced if the worker wears waders, but this difference alone seems unnecessary. Second, if the tribal worker's allowable risk is set at 1e-6 and HI=1, then this worker must live somewhere else, retire somewhere else, he cannot eat fish from the lake with his family members, and he cannot use the sweatlodge. It is more realistic that a regular tribal resident also works on the remedy, which does not change the total exposure in the scenario as described now.	Aquatic workers are presented separately to address people who work in surface water and sediment (250 days/year) but do not participate in other Tribal Lifeway scenarios (i.e., they may not practice in sweat lodge ceremonies or other Tribal Lifeway scenarios, thus their RME comes from being an aquatic worker exposed to surface water and sediment while working).
15	Specific Comment	8, Bullet 9	Please remove the term "conservative" throughout the document and substitute the work "reasonable". The RME is reasonable, not a conservative worst case. For example, Section 3.1.4 says both that the RME does not include special high-contact water events but implies that it still over-estimates total reasonable exposures. It would be more appropriate to say that the reasonable maximum may not include certain high-contact events; those events might not need to be addressed in a risk assessment, but special advice to members depending on exposure point concentrations might be warranted.	The wording in the HHRA indicates that the RME scenario may not include certain high-contact events.

	Proposed IR based on 70 kg BW & 2000 kcal/day	Adjusted IR based on 80 kg BW & 2200 kcal/day*	kcal/100g	Total daily kcal
Fish (catfish)	120 gpd	137 gpd	100	137
Shellfish (mussels)	30 gpd	34 gpd	182	63
Arrowroot root	133 gpd	152 gpd	66	100
Turtles, frogs	24 gpd	27 gpd	89	24
Semi-aquatic mammals (beaver)	69 gpd	79 gpd	212	166
Totals	*376 g (13 oz)*	*429 g (15 oz)*		*490 kcal 22% of 2200 kcal/d*
EF	365			
FC	1			
ED	64			
BW	80			

* A BW of 80 kg requires 2200 kcal/day, as opposed to 2000 for a 70kg body. IR is adjusted m \by the ratio of 70 kg to 80 kg, or multiplying the original IR by 1.14.
NOTE: the original scenario did not evaluate upland versus in-water food or exposures.

Table 2b. Response to Comments Provided by AESE, Inc., on Behalf of Quapaw Nation on Document No. 2 and No. 3

Item	Section	Page	Comment	Response
16	Specific Comment	8, Bullet 10	Section 3.1.1 The consideration of salve is good. It is not clear if any other aquatic plants will be sampled, or whether arrowroot represents all edible aquatic vegetation.	Duckweed and arrowhead plants were sampled based on input from QTO and TCTCIT. Both plants are included in the HHRA dataset and are used to represent edible aquatic vegetation. All parts of the arrowhead plant were used to evaluate the salve and ingestion exposure scenarios.
17	Specific Comment	8, Bullet 11	Section 3.3.2, Fish and shellfish ingestion. See comment on adjusting the intake rate. When the actual risk assessment is done, more attention to the method of preparation of various species may be needed, such as a crayfish boil, fish served skin on or off, and so on. A similar comment pertains to aquatic plants and how much sediment might remain on them (relevant to collection and sampling methods as well as to risk estimation).	A body weight of 70 kg was used for Tribal Lifeway adults in the HHRA, so no adjustment was needed for the intake rate. Based on input from QTO and TCTCIT, three types of fish samples were analyzed: head only, fillet only, and eviscerated carcass (the eviscerated whole body was calculated based on these separate parts). The HHRA estimates risk based on calculated whole body concentrations. Differences in concentrations between the estimated whole body concentrations and specific body parts (e.g., head only, fillet only) are discussed in the uncertainty analysis. The sediment ingestion rate (400 mg/day) used in the HHRA incorporates incidental ingestion of residual sediments potentially adhered to unwashed aquatic plants (Harper, 2008). A discussion of potential impacts on the risk estimates related to use of different parts of biota during food preparation (for fish and aquatic plant) is provided in the uncertainty analysis.

Table 2b. Response to Comments Provided by AESE, Inc., on Behalf of Quapaw Nation on Document No. 2 and No. 3

Item	Section	Page	Comment	Response
18	Specific Comment	8, Bullet 12	From a public health perspective, past exposures (e.g., in the town of Picher) are relevant to providing appropriate biomedical intervention and specific health advice to individuals. While this is not part of a risk assessment document, it will be relevant when preparing advice based on sampling results, especially if institutional controls are part of the remedy. In point of fact, people who have had past exposures in Picher may already be carrying a high lead burden even if their blood lead levels are now below 5 ug/dl, and some consideration should be made of those past exposures. Remedies are developed for future people who start with no pre-existing body burden and no past exposures, so protecting the health of current tribal members who already have an exposure history should be considered.	Comment noted.
19	Attachment No. 1, December 13, 2017 on the Review of HHRA RAGS Part D Table 4 Review - Introduction Memo to Tim Kent, QTO Environmental Program Director and RPM General Comments	1 and 2	This memo constitutes a review of the aforementioned document. Tim Kent has directed us to send this directly to you. In preparing these comments, the Tribe has attempted to focus on issues that could make a difference in the RI/FS and ultimately selection of the remedy in the Proposed Plan. The OU4-specific cleanup standards/goals have been developed without considering risk associated with the use of the other OUs. Remediation/removal in OU4 has proceeded relying on these values. Having this concern in 2015, made the Tribe realize that in order to save time and resources, we needed to develop a Reasonable Maximal Exposure Scenario (RME) for each OU as soon as possible.[1] Because the RMEs were not developed, a piecemeal approach is resulting in a requirement for perpetual institutional controls and 5-year reviews, as well as an inability to reuse the lands and resources for their intended uses.[2] Like the proposed plan and ROD, development of the OU5 RME should be a cooperative effort including EPA and the State, and needs to proceed without further delay. Ideally this will result in a cleanup where institutional controls and land use controls are not needed, and UU/UE can be achieved.[3]	The HHRA addresses potential exposures to media within OU5 only. The RME exposure scenarios and assumptions were identified with input from QTO and TCTCIT. The approach for development of PRGs and target levels for various health endpoints (e.g., cancer risk, hazard index, blood lead level) have not yet been established.

Table 2b. Response to Comments Provided by AESE, Inc., on Behalf of Quapaw Nation on Document No. 2 and No. 3

Item	Section	Page	Comment	Response
20	Attachment No. 1, December 13, 2017 on the Review of HHRA RAGS Part D Table 4 Review - General Comment 1	2	The QTO Traditional Scenario was developed to represent the general or average Traditional QTO citizen who relies on both aquatic AND terrestrial resources—it is not a Reasonable Maximal Exposure (RME) for a given OU.[4] The RME should be a comprehensive site-wide exposure scenario, not an OU-specific exposure. As long as terrestrial and aquatic OUs are separated, the true OU-specific RME is one that describes individuals using either terrestrial OR aquatic OUs. The latter would be an RME for 100% time and 100% sustenance from each OU. For example, the RME for a person who is more reliant on aquatic resources would require a greater aquatic diet, water from surface water or mine discharge (whichever is higher) and more aquatic area exposure time. As presented by EPA, the OU5 user is recreational, which is by definition not comprehensive. Further, limiting OU5 use to recreational use is inconsistent with the Tribes' plans for land use, and is in effect an institutional control. It also prevents a multi-OU cumulative exposure assessment. The options are to either (1) develop an RME for 100% of time and diet in OU5 and another for 100% OU4, or (2) develop a combined OU4/OU5 RME that uses resources from both areas simultaneously (in effect assuming a relative source contribution from each OU). As currently devised, the OU4 user cannot use resources from OU5 because his/her risk allocation has already been filled, and vice versa.	The HHRA addresses potential exposures to aquatic resources within OU5 only. The RME exposure scenarios and assumptions for the Tribal Lifeway scenario – which includes surface water and sediment exposures from fishing, hunting, gathering, recreational activities, and sweat lodge use; potable use of surface water; consumption of aquatic biota and plants; and medicinal use of plants as salve – were identified with input from QTO and TCTCIT. Potential exposures to terrestrial resources (including soil contact, terrestrial small game and large game ingestion scenarios, and plant consumption) were addressed in the OU4 HHRA. The approach for development of PRGs and target levels for various health endpoints (e.g., cancer risk, hazard index, blood lead level) have not yet been established.
21	Attachment No 1, December 13, 2017 on the Review of HHRA RAGS Part D Table 4 Review - General Comment 2	2	Based solely on the approach used to build the RAGS Table 4, the Tribe still foresees major problems associated with the HHRA for the future traditional resident. These problems are overarching and associated with balkanizing the site into OUs without reintegrating risk across the OUs to enable a comprehensive assessment of site risk as required by CERCLA. This concern has been raised by the Tribe previously and is clearly nothing new. The Tribe warned EPA on these issues as far back as 2004 and reiterated these concerns in no less than five memoranda. An early example first is General Comment 3, November 22, 2005	The approach for development of PRGs and target levels for various health endpoints (e.g., cancer risk, hazard index, blood lead level) have not yet been established.

<table>
<tr><th>Item</th><th>Section</th><th>Page</th><th>Comment</th><th>Response</th></tr>
<tr><td>22</td><td>Attachment No. 1, December 13, 2017 on the Review of HHRA RAGS Part D Table 4 Review - General Comment 3</td><td>3</td><td>The PRGs/RAOs do not consider the exposure that ecological or human receptors receive from the Surface water pathway as well as riparian resources. This is a major error and omission on the part of both the ecological and the Human Health Risk Assessments (this will be discussed in greater detail in comments on those reports). The residual exposure to humans from drinking surface water and using surface water in sweatlodge ceremonies alone exceed allowable risk. This risk is real and cannot be assumed away or managed via institutional controls such as signage or education— people are using these resources today. This means that that the allowable risk to Tribal members who use resources for traditional cultural practices will be exceeded even if the uplands are returned to background conditions.

The concept of an Operable Unit was developed to partition remedial actions into workable or manageable units—not to balkanize risk assessments. The NCP requires protection of human health and the environment for the reasonably foreseeable land use of the site—not of an OU. In summary, as long as the residual risk from OU1 is measurable, the allowable risk from other OUs must be reduced by an amount so that the cumulative site-wide risk does not exceed the threshold criteria. In this instance, the risk allocated for all other OUs has been usurped by OU1. Therefore, the PRG for all media (e.g. surface water, ground water, soils, floodplain sediments, and air) must be pre-release baseline (background). The following table is included as another early example (excerpted from Attachment No. 2). Pay particular attention to footnote No. 2 to the table.

Tribal Exposure Areas on Tribal lands
<table><tr><th>General Activity</th><th>Source Areas: Chat Piles/Bases/Flotation Tailings Ponds</th><th>Transition Zones</th><th>Wetlands/Streams [2]</th></tr><tr><td>Relative Potential for Tribal Residential Use</td><td>High</td><td>High</td><td>High</td></tr><tr><td>Relative Potential for Tribal Subsistence Fishing Use</td><td>NA</td><td>NA</td><td>High</td></tr><tr><td>Relative Potential for Tribal Gathering Use (Aquatic)</td><td>NA</td><td>NA</td><td>High</td></tr><tr><td>Relative Potential for Tribal Gathering Use (Terrestrial)</td><td>High</td><td>High</td><td>NA</td></tr><tr><td>Relative Potential for Tribal Hunting Use</td><td>High</td><td>High</td><td>High</td></tr><tr><td>Relative Potential for Tribal Recreational Use</td><td>High</td><td>High</td><td>High</td></tr><tr><td colspan="4">General Population Exposure on Tribal lands [1]</td></tr><tr><td>Relative Potential for General Public Sportfishing Use</td><td>NA</td><td>NA</td><td>Moderate-Low</td></tr><tr><td>Relative Potential for General Public Bathing Use</td><td>NA</td><td>NA</td><td>Moderate-Low</td></tr></table>NA = Not Applicable
[1] If members of the General Public (GP) reside on Tribal Lands, the residential recreational doses for the GP must also be determined.

[2] although this EA is not officially part of OU4, the dose from these areas must be considered in the Risk Assessment. If the Dose allocation from this EA equals or exceeds Risk Criteria defined by the NCP, then all other EAs must be cleaned-up to pre-release background conditions.</td><td>The approach for development of PRGs and target levels for various health endpoints (e.g., cancer risk, hazard index, blood lead level) have not yet been established.</td></tr>

Item	Section	Page	Comment	Response
23	Attachment No. 1, December 13, 2017 on the Review of HHRA RAGS Part D Table 4 Review - General Comment 3	4	Conversion to g/kg-d. This seems to be a systemic problem. An example for fish from Table 3-1 is that the fish daily ingestion rate = 120 g/d; (mistakenly converted to 15 g/kg-d by EPA). This is simply a dilution of the 120 g/d estimate by a 70 kg person into an 80 kg person because EPA assumes that the same amount is eaten by both a 70 kg person and an 80 kg person. (120 g/d)/70 kg = 1.714 g/kg/d, not 1.5 g/kd-d. EPA's value of 1.5 g/kg-d comes from dividing the 120 g/d by 80 kg, which means that the larger person is eating less per body weight than the original 70 kg person. 2000 kcal (1526 g/d) is not enough to sustain an 80 kg person, as shown below (See Attachment). We do not dispute that the average American is now 80 kg. But this means that everyone is eating more. If EPA wants to assume that people are heavier today, then they also have to recognize that they eat more, i.e., every intake factor needs to be multiplied by 1.145. The goal for Tribes is to recapture its old lifestyle that leads to non-supersized people. The Traditional Scenario was developed for when people were a traditional size. If EPA wants to adjust to new super-sized people to assess risk for current conditions, they must scale all of the aforementioned exposure factors. However, the goal of the Tribe goal is for our future citizens to reach 70 kg once again. This means that the future traditional Tribal resident needs to be assessed assuming a traditional body weight of 70 kg, or alternately that the 80 kg person eats proportionally more. *We recommend that EPA also examines the total caloric intake for the whole diet and compare it to the caloric needs per kg of body weight, rather than simply diluting a 70-kg diet into an 80-kg body.*	A body weight of 70 kg was used for Tribal Lifeway adults in the HHRA, so no adjustment was needed for food intake rates.
24	Attachment No. 1, December 13, 2017 on the Review of HHRA RAGS Part D Table 4 Review - General Comment 4	5	Use of two Canadian studies for reducing the soil ingestion rate. These two fecal tracer studies were conducted with the Nemiah Band, a traditional community; all food was provided to the participants by the investigators in the Davis et al. (2012) study, and participants were engaged in fisheries activities. A similar study of the same community was conducted by the same investigators (Irvine et al., 2014), with participants engaged in traditional activities; all food was provided to the participants by the investigators. As explained in Attachment No. 4: Soil Ingestion for Oklahoma," these two studies are not considered to be applicable to the Quapaw exposure scenario. QTO believes that decades of previous work with multiple lines of evidence is not invalidated by these two studies. The approved Quapaw scenario uses a soil/sediment ingestion of 400 mg/d; the attachment presents the rationale for reducing the soil ingestion rate for another Tribe that behaves differently to 330 mg/d if the other Tribe(s) so desire.	A sediment ingestion rate of 400 mg/day was used in the HHRA for Tribal Lifeway adults and children.

Item	Section	Page	Comment	Response
25	Attachment No. 1, December 13, 2017 on the Review of HHRA RAGS Part D Table 4 Review - General Comment 5	5	Geographic scope of OU5 needs to be revised. We see several problems: a. We cannot ascertain the geographic scope from the provided information. Does OU5 extend all the way to Grand Lake. Or is it solely within the OU4 boundary? b. It is not clear whether riparian and flood-plain soils are included and whether the nature and extent of contamination has been characterized downstream of the source area on the QTO reservation. c. Downstream Tribes who are not using the source area uplands should perhaps have a separate OU and subsequent RME based on that OU. That RME would include the floodplains where residences occur.	a. The geographic scope of OU5 is shown on Figure 1-1 of the HHRA. b. Riparian and floodplain soils were included in the HHRA for OU4. c. The RME for the Tribal Lifeway scenario in OU5 was based on input from both QTO and TCTCIT, with the more conservative input used where input differed. Floodplains are addressed in OU4.
26	Attachment No. 1, December 13, 2017 on the Review of HHRA RAGS Part D Table 4 Review - General Comment 6	6	Frequency of sweat lodge use. The Quapaw scenario includes daily use of a sweatlodge. We note that asking one tribal member about a lower rate does not invalidate the value used in the officially approved scenario. However, if the downriver tribes wish to use a lower frequency, they may do so.	A sweat lodge exposure frequency of 365 days/year, exposure time of 1 hour/event, and exposure duration of 64 years is used for adults in the HHRA. These exposure assumptions are more conservative than input provided by Quapaw and TCTCIT. A sweat lodge exposure frequency of 365 days/year, exposure time of 1 hour/event, and exposure duration of 4 years (children ages 2 to 6) is used for children in the HHRA based on input from QTO since TCTCIT indicated that children do not use the sweat lodge.

Item	Section	Page	Comment	Response
27	Attachment No. 1, December 13, 2017 on the Review of HHRA RAGS Part D Table 4 Review - Specific Comments	6, Table 3-1	• Does waterfowl data already exist (so it is not a data gap)? • Cell 8j: "Two plant types (duckweed and arrowhead root); duckweed = washed whole plant; arrowhead = washed tuber only, washed fine roots only, and washed leaves/stalk only." (OK, but duckweed is not listed in Table 4-1.) • Cell 11j: What grain size will be used in sieving? As EPA knows, more contaminants are adsorbed as the surface area increases with smaller grain sizes, and stream silt would have smaller grain sizes. Additionally, the sand- silt cutoff (63 um) is the point at which grittiness is detected and spit out. See the Soil Ingestion attachment for a longer discussion	As indicated in the Data Gap Summary Report (2017), site-specific waterfowl (duck) breast meat/tissue data were not identified during the compilation of existing data. However, based on information provided in the Bunker Hill Superfund Site HHRA (TerraGraphics, 2001) and additional literature (van der Merwe et al., 2011), waterfowl tissue are qualitatively assessed in the uncertainty analysis, so there is not a data gap. Duckweed and arrowhead plant are included in the HHRA dataset for aquatic plant consumption. The available dataset for sediment includes both sieved and unsieved samples; the sieved samples were sieved using various sieve sizes ranging from 2 mm to 63 µm.

Item	Section	Page	Comment	Response
28	Attachment No. 1, December 13, 2017 on the Review of HHRA RAGS Part D Table 4 Review - Specific Comments	6, Table 4-1 Food	Footnote 3 – 10% of aquatic food is shellfish, which is reasonable, but what % of the total diet is aquatic?	The percentage of the total diet that is aquatic is not identified in the HHRA but is presented in Figure 9 of the *Quapaw Traditional Lifeways Scenario* (Harper, 2008). In this figure, the following food categories are shown as percentages of daily grams and are incorporated into the OU5 HHRA: • Aquatic and Fish 8% – 100% of the category is assumed to be OU5 fish and shellfish. • Small game 4% – 100% of the category is assumed to be OU5 semi-aquatic mammals (represented by raccoon samples). An additional 35% of the category is assumed to be OU5 amphibians and reptiles (represented by frog leg samples). • Roots and Bulbs 9% – 100% of the category is assumed to be OU5 aquatic plants (represented by duckweed and arrowhead samples). Based on the addition of these categories (8 + 4 + 9), approximately 21% of the diet is aquatic. An alternative (higher) Tribal Lifeway plant ingestion rate is presented in Appendix F4.
29	Attachment No. 1, December 13, 2017 on the Review of HHRA RAGS Part D Table 4 Review - Specific Comments	6, Table 4-1 Food	Footnote 4 – 20% of aquatic food is amphibian and reptile; 20% is plants. This leaves 50% for fish if small mammals are kept separate; again, what % of the total diet is comprised of aquatic-sourced foods, and what assumption are made about where the rest of the food comes from? It cannot come from OU4, because OU4 has already filled the entire risk allocation.	Approximately 21% of the total diet is aquatic. The rest of the food comes from terrestrial sources, consistent with Figure 9 of the *Quapaw Traditional Lifeways Scenario* (Harper, 2008). Terrestrial food items were addressed in the HHRA for OU4.

Table 2b. Response to Comments Provided by AESE, Inc., on Behalf of Quapaw Nation on Document No. 2 and No. 3

Item	Section	Page	Comment	Response
30	Attachment No. 1, December 13, 2017 on the Review of HHRA RAGS Part D Table 4 Review - Specific Comments	6, Table 4-1 Food	It is not clear whether EPA intends to use a fish ingestion rate of 120 g/d plus shellfish (12 g/d), aquatic tubers (40 g/d), plus herps (24 g/d). or whether EPA intends to divide 120 g/d into different fractions.	As indicated in RAGS Tables 4.6 and 4.7 (RAGS tables are presented in Appendix B of the HHRA), the following ingestion rates are used for adults: fish = 90 g/day, shellfish = 30 g/day, frog = 24 g/day, raccoon = 69 g/day, and aquatic plants = 133 g/day.
31	Attachment No. 1, December 13, 2017 on the Review of HHRA RAGS Part D Table 4 Review - Specific Comments	6, Table 4-1 Food	Aquatic tubers = 40 g/d (no duckweed?)	As indicated in RAGS Table 4.7 of the HHRA, an aquatic plant ingestion rate of 133 g/day was used for adults; this ingestion rate is applied to the aquatic plant dataset consisting of duckweed and all arrowhead plant data.
32	Attachment No. 1, December 13, 2017 on the Review of HHRA RAGS Part D Table 4 Review - Specific Comments	6, Table 4-1 Food	Again, EPA should not convert a 70kg person diet into an 80kg person unless the values are raised to account for a larger person eating more.	A body weight of 70 kg was used for Tribal Lifeway adults in the HHRA, so no adjustment was needed for the intake rate.
33	Attachment No. 1, December 13, 2017 on the Review of HHRA RAGS Part D Table 4 Review - Specific Comments	6, Table 4-2 Sediment	The exposure frequency of 126 days per year is reasonable for recreational use, but the QTO has not agreed that OU4 is solely recreational or that it is off-limits to users of other OUs (due to unacceptable cumulative risk).	A sediment exposure frequency of 312 days/year is used for the Tribal Lifeway scenario in the HHRA, as indicated in RAGS Table 4.1.

Table 2b. Response to Comments Provided by AESE, Inc., on Behalf of Quapaw Nation on Document No. 2 and No. 3

Item	Section	Page	Comment	Response
34	Attachment No. 1, December 13, 2017 on the Review of HHRA RAGS Part D Table 4 Review - Specific Comment	7, Table 4.3 SW Potable (surface water in creeks) and Table 4-4 SW (also in surface water creeks	It is not clear how these two tables are different. If the difference is expected to be related to exposure point concentration, then it would seem that a single set of exposure assumption should be used with several different exposure point concentrations (the creek, the mine drainage, the river, and groundwater).	The differences in the tables are based on exposure assumptions. Four RAGS tables present the exposure assumptions used in the HHRA for various Tribal Lifeway scenarios in surface water: • Table 4.2 – Water contacted during swimming and wading activities for 6 hrs/day (312 days/year for adults and 234 days/year for children) • Table 4.3 – Water used as a daily drinking water source (2.5 L/day for adults and 0.78 L/day for children) • Table 4.4 – Water as a drinking water source when using a sweat lodge (an additional 1 L/day for adults and children) • Table 4.5 – Water inhaled while in a sweat lodge Mine discharge is evaluated using the same exposure scenarios and assumptions as surface water in Appendix F3. Separate exposure point concentrations (EPCs) are used for each watershed.

Table 2b. Response to Comments Provided by AESE, Inc., on Behalf of Quapaw Nation on Document No. 2 and No. 3

Item	Section	Page	Comment	Response
35	Attachment No. 1, December 13, 2017 on the Review of HHRA RAGS Part D Table 4 Review - Specific Comment	7, Table 4.3 SW Potable (surface water in creeks) and Table 4-4 SW (also in surface water creeks	The drinking/swimming/sweatlodge RME should use maximum concentration of whatever resource is more contaminated. This will provide the upper bound of risk. Then, several mixes of the various sources would provide a more central tendency of risks (e.g., 50:50 GW and SW for 365 days/year, plus swimming during 126 days/year).	The exposure scenarios evaluated in the risk assessment are for chronic exposure durations (64 years for adults and 6 years for children for the Tribal Lifeway scenarios). Consistent with EPA guidance presented in *Calculating Upper Confidence Limits for Exposure Point Concentrations at Hazardous Waste Sites* (EPA, 2002), EPCs are based on 95% upper confidence limit (UCL) of the arithmetic mean concentrations (or mean concentrations for lead) rather than maximum detected concentrations. This approach is appropriate since chronic exposures would not occur to maximum detected concentrations. Groundwater was addressed in OU1 and is not addressed in the OU5 HHRA.
36	Attachment No. 1, December 13, 2017 on the Review of HHRA RAGS Part D Table 4 Review - Specific Comment	7, Table 4-5 SW sweat lodge	Infants (0-24 months) have no sweat lodge use (OK). See note above about frequency	Children below the age of 2 were not included as sweat lodge receptors in the HHRA.
37	Attachment No. 1, December 13, 2017 on the Review of HHRA RAGS Part D Table 4 Review - Specific Comment	7, Table 4-6 Arrowhead -medical salve (in addition to ingestion in Table 4-1	Includes dermal while digging, 12 d/yr x 64 yrs (adult) or 6 yrs (child). This is OK, but the same exposure is received when gathering for food use	The sediment ingestion rate (400 mg/day) used in the HHRA incorporates a variety of soil exposure pathways and activities such as wild foods harvesting and/or gathering, as indicated in Harper (2008).

Table 2b. Response to Comments Provided by AESE, Inc., on Behalf of Quapaw Nation on Document No. 2 and No. 3

Item	Section	Page	Comment	Response
38	Attachment No. 1, December 13, 2017 on the Review of HHRA RAGS Part D Table 4 Review - Specific Comment	7, Table 4-7 Discharge	Dermal exposure 1 hr/event (washing) x 10 events/yr. – adult and child. The exposure frequency should be the same as for the other water bodies, even if the drainage is intermittent.	The mine discharges occur intermittently, have a typically low flow rate, and are not easily accessible. Although the mine discharges are only intermittent and the discharges are not easily accessible, mine discharge was conservatively evaluated for the same exposure scenarios and assumptions as surface water in Appendix F3.
39	Attachment No. 1, December 13, 2017 on the Review of HHRA RAGS Part D Table 4 Review - Specific Comment	7, Table 4-7 Discharge	The RME should use the maximum concentration from whatever resource is more contaminated. Thus, this is a question of exposure point concentration, not exposure frequency	If at least eight sample results and four detections of a chemical are available in the dataset, EPCs are based on 95% UCL of the arithmetic mean concentrations (or mean concentrations for lead) rather than maximum detected concentrations. The use of 95% UCL of the arithmetic mean concentrations is consistent with EPA guidance presented in *Calculating Upper Confidence Limits for Exposure Point Concentrations at Hazardous Waste Sites* (EPA, 2002), This approach is appropriate since chronic exposures would not occur to maximum detected concentrations. Mine discharge was evaluated in Appendix F3.

Table 2c. Response to Comments Provided by ODEQ on Document No. 2

Item	Section	Page	Comment	Response
1	Cover Letter		As you will see, most of our comments are focused on requesting additional documentation and justification of the Reasonable Maximum Exposure (RME) input parameters. Without this documentation, DEQ may not be in a position to support the conclusions drawn from the Human Health Risk Assessment.	Comment noted.
2	General Concerns	1, Bullet 1	Per Oklahoma Department of Environmental Quality (DEQ) policy, any deviations from Risk Assessment Guidance for Superfund (RAGS) or default input parameters in the Human Health Risk Assessment (HHRA) process require approval from DEQ. Given that the authority for this HHRA is under EPA, DEQ requests to see any data or information available that will adequately justify some of the large deviations between defaults and the site specific inputs. Please see section 3.2, 3.3, and 3.4 for more specifics.	Comment noted.
3	General Concerns	1, Bullet 2	DEQ is concerned that several of the exposure scenarios presented in the Technical Memorandum reviewed and commented on in this document will result in remedial goals that are close to background concentrations.	Comment noted. However, the exposure scenarios addressed in the HHRA were identified through input from AESE/Quapaw Nation and TCTCIT.
4	2.0 General Objectives for the Tar Creek OU5 HHRA	1, Bullet 1	Is the focus of this HHRA to address current exposure scenarios or traditional exposure scenarios? For example, Harper, 2008 explicitly states “This report describes traditional uses. The purpose of this report is not to describe contemporary uses that are suppressed or distorted by lack of access, resource degradation, or knowledge of contamination.” However, the Tribal Lifeways Technical Memorandum (TM) states “Risks are estimated for current exposures to OU5 media as well as reasonably foreseeable future uses.” Currently, the HHRA uses both Traditional Quapaw Scenarios provided in the multiple Harper documents (Harper, 2007, 2008, and Harper et al. 2012) and current exposure scenarios provided by Tar Creek Trustee Council Indian Tribes (TCTCIT). DEQ requests that EPA provide clarification regarding this subject.	The focus is on Tribal Lifeway scenarios and General Public scenarios. Based on input from AESE/Quapaw Nation and TCTCIT, there are some tribal members and citizens who currently practice one or more aspects of the Tribal Lifeway scenario. Therefore, the exposure-scenario-specific and cumulative scenario risk estimates presented in the HHRA are applicable to the range of potential exposures for current and future site uses.

Table 2c. Response to Comments Provided by ODEQ on Document No. 2

Item	Section	Page	Comment	Response
5	2.0 General Objectives for the Tar Creek OU5 HHRA	2, Bullet 1	Are the goals of the exposure scenarios to have both traditional and current input parameters go into the Chronic Daily Intake models? For example, the sediment exposure scenario includes inputs derived from both Harper (2008) and TCTCIT.	The focus is on Tribal Lifeway scenarios and General Public scenarios. Based on input from AESE/Quapaw Nation and TCTCIT, there are some tribal members and citizens who currently practice one or more aspects of the Tribal Lifeway scenario. Therefore, the exposure-scenario-specific and cumulative scenario risk estimates presented in the HHRA are applicable to the range of potential exposures for current and future site uses. The final exposure assumptions for the Tribal Lifeway scenarios are presented in RAGS Tables 4.1 through 4.8.
6	2.0 General Objectives for the Tar Creek OU5 HHRA	2, Bullet 2	Can EPA provide documentation where mixed traditional/current lifeways have gone into the same risk scenarios at other Superfund Sites?	Based on input from AESE/Quapaw Nation and TCTCIT, there are some tribal members and citizens who currently practice one or more aspects of the Tribal Lifeway scenario. Therefore, the exposure-scenario-specific and cumulative scenario risk estimates presented in the HHRA are applicable to the range of potential exposures for current and future site uses. The Coeur d'Alene Basin HHRA (TerraGraphics, 2001) addresses both Traditional Tribal Subsistence Lifestyle and Current Subsistence Lifestyle scenarios.
7	2.0 General Objectives for the Tar Creek OU5 HHRA	2, Bullet 3	Are the exposure scenario assumptions provided more appropriate for restoration endpoints rather than remediation endpoints?	The RME exposure scenarios and assumptions are based on input received from AESE/Quapaw Nation and TCTCIT.

Table 2c. Response to Comments Provided by ODEQ on Document No. 2

Item	Section	Page	Comment	Response
8	2.0 General Objectives for the Tar Creek OU5 HHRA	2, Bullet 4	DEQ requests that EPA consider conducting surveys within Tribal Communities in order to have data supported input parameters for determining reasonable maximum exposure.	Based on input from AESE/Quapaw Nation and TCTCIT, some tribal members and citizens currently practice one or more aspects of the Tribal Lifeway scenario. Because there is a wide range in current use of resources within OU5, as well as many tribal members and citizens, the time needed to develop and administer a survey of current resource use would be lengthy and not practical. AESE/Quapaw Nation and TCTCIT have also indicated that there is limited value in surveys since current exposures may be suppressed due to tribal members' and citizens' knowledge of impacted media within the study area, and therefore do not reflect future use following site cleanup.
9	3.1 Surface Water Exposure Scenarios Potable Surface Water (Ingestion and Dermal) - Referencing Table 4.1 in CH2M (2018) and RAGS Part D Tables (November 2017)	2, Bullet 1	The Ingestion Rate (IR) for Tribal Adults is proposed to be 2.0 L/day. The IR for General Public Adults is 2.5 L/day. Are these differences intentional or accidental? DEQ proposes that the values be identical unless otherwise justifiable.	The HHRA uses a potable water ingestion rate of 2.5 L/day for both Tribal Lifeway adults and General Public adults, as indicated in RAGS Table 4.3. This final water ingestion rate (2.5 L/day) was updated to be higher than the value presented in Harper (2008) but is justifiable since Harper (2008) was based on EPA's default water ingestion rate available at the time it was written, but has since been updated (EPA, 2014).

Table 2c. Response to Comments Provided by ODEQ on Document No. 2

Item	Section	Page	Comment	Response
10	3.1 Surface Water Exposure Scenarios Potable Surface Water (Ingestion and Dermal) - Referencing Table 4.1 in CH2M (2018) and RAGS Part D Tables (November 2017)	2, Bullet 2	The Exposure Duration (ED) for Tribal Adults is 64 years, while the ED for General Public Adults is 20 years. Can EPA please explain the discrepancy?	The Tribal Lifeway scenario is assumed to occur within OU5 for a lifetime of 70 years (EPA's default value; EPA, 2014) – 64 years as an adult and 6 years as a child. However, the general public is assumed to live in the same place for 26 years (EPA's default residential exposure duration; EPA, 2014) – 20 years as an adult and 6 years as a child.
11	3.1 Surface Water Exposure Scenarios Potable Surface Water (Ingestion and Dermal) - Referencing Table 4.1 in CH2M (2018) and RAGS Part D Tables (November 2017)	2, Bullet 3	The Event Time (ET) for dermal exposure is different between Tribal Children (0.53 hr/event) and General Public Children (1 hr/event) with the longer time favoring the General Public. However, the ET for dermal exposure favors Tribal Adults (0.72 hr/event) versus General Public Adults (0.58 hr/event). This discrepancy does not make sense to DEQ, especially since the inputs appear to be coming from standard defaults listed (EPA, 2014) and (EPA, 2004) and are not times proposed by TCTCIT. Can EPA please elaborate and justify why these differences occur?	The final ET used in the HHRA was changed to 0.54 hour/event for dermal exposure for Tribal Lifeway children and General Public children, as shown in RAGS Table 4.3 of the HHRA.
12	3.1 Surface Water Exposure Scenarios Wading and Swimming Exposures (Ingestion and Dermal) - Referencing Table 4.2 in CH2M (2018) and RAGS Part D Tables (November 2017)	3, Bullet 1	DEQ has compared the exposure times and exposure frequencies of Tribal Adult and Tribal Child to default input parameters and find them to be well outside the norm. DEQ requests to review any data/information available to justify the proposed inputs. Are these exposure times based on traditional or contemporary exposure scenarios?	The swimming/wading exposure times for Tribal Lifeway are much higher than those for General Public adults and children. However, the Tribal Lifeway exposure times and exposure frequencies were based on input from TCTCIT and AESE/Quapaw Nation. Based on their input, an exposure time of 6 hrs/event is representative of both current and future exposure scenarios for some tribal members and citizens.

Table 2c. Response to Comments Provided by ODEQ on Document No. 2

Item	Section	Page	Comment	Response
13	3.1 Surface Water Exposure Scenarios Wading and Swimming Exposures (Ingestion and Dermal) - Referencing Table 4.2 in CH2M (2018) and RAGS Part D Tables (November 2017)	3, Bullet 2	There appears to be no ingestion rate for wading in the General Public scenario. This is not explicitly stated in the CH2M (2018) document but was part of the RAGS Part D Tables.	Agreed; wading by the general public is not expected to result in water ingestion exposures since only splashing would occur. Rather, incidental water ingestion exposures are associated with the swimming scenario and are included as indicated in RAGS Table 4.2.
14	3.13 Sweat Lodge Exposure Tribal Member	3, Bullet 1	DEQ has no disagreement with the inputs. However, we are confused about the actual exposure scenario regarding sweat lodges and metals. Our understanding of how sweat lodges work are that water is boiled or poured onto hot rocks, that in turn create steam or vapor. Heavy metal boiling points are all well over 1000° F. Almost certainly, sweat lodges do not reach 1000° F, therefore, heavy metals would precipitate out or stay in solution instead of volatilizing in the steam or vapor. A sweat lodge essentially works like a distillery except that instead of collecting the steam/vapor and condensing it back into water, the steam/vapor is allowed to escape. However, even if it is assumed that metals do stay in vapor, the exposure point would be the dermal adherence of vapor and not dermal adherence of the actual surface water. DEQ requests that EPA and TCTCIT reconsider the exposure scenario or attempt to measure the metal concentration in vapor to determine the actual exposure point concentration to skin.	The exposure assumptions for sweat lodge use are presented in RAGS Tables 4.4 and 4.5. Water exposures may occur by drinking, pouring on the skin, or inhaling water vapors. The approach used for quantifying inhalation exposures was based on that presented in the *Shoshone-Bannock Exposure Scenario for Use in Risk Assessment: Traditional Subsistence Lifeways* (S-B EWMP, 2016).
15	3.2 Sediment Exposures 3.2.1 Sediment Exposure (Ingestion and Dermal) - Referencing Table 4.2 in CH2M (2018) and RAGS Part D Tables (November 2017)	3, Bullet 1	Ingestion rate of Tribal Adults (400 mg/day) are nearly quadruple that of the General Public (100 mg/day). DEQ requests documentation or data that justify the deviations.	A sediment ingestion rate of 400 mg/day was used for Tribal Lifeway adults, consistent with the *Quapaw Traditional Lifeways Scenario* (Harper, 2008).

Table 2c. Response to Comments Provided by ODEQ on Document No. 2

Item	Section	Page	Comment	Response
16	3.2 Sediment Exposures 3.2.1 Sediment Exposure (Ingestion and Dermal) - Referencing Table 4.2 in CH2M (2018) and RAGS Part D Tables (November 2017)	4, Bullet 1	Ingestion rate of tribal children (400 mg/day) is nearly double that of general public children (200 mg/day). DEQ requests documentation or data that justify the deviations.	A sediment ingestion rate of 400 mg/day was used for Tribal Lifeway children, consistent with the *Quapaw Traditional Lifeways Scenario* (Harper, 2008).
17	3.2 Sediment Exposures 3.2.1 Sediment Exposure (Ingestion and Dermal) - Referencing Table 4.2 in CH2M (2018) and RAGS Part D Tables (November 2017)	4, Bullet 2	DEQ has compared the exposure times and exposure frequencies of Tribal Adult and Tribal Child to default input parameters and find them to be well outside the norm. DEQ requests documentation or data that justify the deviations.	Agreed that the exposure frequencies for Tribal Lifeway are much higher than those for General Public adults and children. However, the Tribal Lifeway exposure frequencies were based on input from TCTCIT and AESE/Quapaw Nation. The exposure frequency reflects a variety of exposure pathways and frequencies such as cooking, wild food harvesting and/or gathering, residual sediment on foods and clothing, and holding natural materials in the mouth while processing or using the materials.
18	3.2 Sediment Exposures 3.2.1 Sediment Exposure (Ingestion and Dermal) - Referencing Table 4.2 in CH2M (2018) and RAGS Part D Tables (November 2017)	4, Bullet 3	Soil to Skin Adherence Factor (SSAF) for tribal members (0.1 mg/cm2-day) is greater than the SSAF for the general public (0.07 mg/cm2-day). Are there physiological differences in dermal properties of tribal skin versus that of the general public? DEQ requests documentation or data that justify the deviations.	A SSAF of 0.1 was used for Tribal Lifeway adults and children for consistency with the *Quapaw Traditional Lifeways Scenario* (Harper, 2008). This value is recommended in the document to account for averaging among outdoor activities with moderate to high dermal adherence and indoor activities with a lower adherence rate. There are no known physiological differences in dermal properties of skin between tribal members and the general public, but the types of sediment contact conducted by the two groups may warrant the higher SSAF.

Table 2c. Response to Comments Provided by ODEQ on Document No. 2

Item	Section	Page	Comment	Response
19	3.3 Aquatic Biota Exposure Scenarios 3.3.2 Aquatic Food Ingestion Exposure Scenarios	4, Bullets 1 & 2	DEQ encourages EPA to review the following study conducted by University of Oklahoma and Harvard University http://grandlakemercurystudy.org/images/GrandLakeWatershedMercuryStudy_FinalReport_Sept2014.pdf and visit the website http://www.grandlakemercurystudy.org/Fish_Consumption.html The above referenced study has data for fish consumption rates, percent of native and non-native fish consumed, what type of fish are typically consumed, and where people frequently fish. The study is based on a sample size of n=150. DEQ requests this data be represented in the HHRA considering it is the only data available regarding these type of inputs.	The study was reviewed, and the fish ingestion rate published in *A longitudinal study of mercury exposure associated with consumption of freshwater fish from a reservoir in rural south central USA* (Dong et al., 2015) was used in the HHRA for General Public adults, as indicated in RAGS Table 4.6.
20	3.4 Mine Discharge	4, Bullet 1	DEQ questions whether the inputs (EF = 10 days/year, 1 hour event time) provided are representative of Reasonable Maximum Exposure. DEQ knows of four main areas were mine discharge comes to the surface: (1) Douthat Bridge (2) Mayer Ranch (3) SE Commerce, and (4) Holder Private Property. Two of these areas are currently being addressed with Passive Treatment Systems. While DEQ understands that it has no data to support its concern in regard to the Holder Private Property mine discharge, DEQ has never observed people in the mine discharge waters at Douthat Bridge.	There are three primary historical mine discharge areas: two in the Tar Creek watershed, and one in the Beaver Creek watershed. The two noted in the Tar Creek watershed are those associated with discharges in the Douthat area and the discharges in the Commerce area (Mayer Ranch and SE Commerce). The mine discharges sampled are representative of those that people could contact outside of creeks, rivers, and tributaries. Mine discharges in one area of the Tar Creek Watershed (in Commerce) are currently being treated by passive treatment systems at the point of discharge. Although the mine discharges within the remaining two areas occur intermittently, have a typically low flow rate, and are not easily accessible, mine discharge was conservatively evaluated for the same exposure scenarios and assumptions as surface water in Appendix F3.

Table 3a. Response to Comments Provided by ODEQ on January 8, 2018 on Document No. 3

Item	Section	Page	Comment	Response
1	Table 4.1 General Public		General Public Receptor (fish): No comment- values proposed seem reasonable	No action required.
2	Table 4.1 Tribal Members		Tribal Member Receptor (fish and friends): Are there any more recent data for ingestion of fish for tribal members? The value used for ingestion rate is described by the author as a traditional Quapaw/sustenance ingestion rate	As indicated in RAGS Table 4.6 of the HHRA, the following ingestion rate is used for Tribal Lifeway adults: fish = 90 g/day. The RME exposure assumptions are based on input received from AESE/Quapaw Nation and TCTCIT.
3	Total Daily Kcal Table - Tribal Members		Total Daily Kcal Table (Supporting Information): Please review the 1:1 ratio of Kcal to grams for fish (i.e 100 Kcal per 100g). On the USDA food composition database (https://ndb.nal.usda.gov/ndb/search/list) I was able to find at least five reports documenting nutrient composition for fish that are likely to be caught and eaten in the exposure points of the watersheds of Tar Creek. All values reported are above EPA's current assumption. • #15187, Bass, cooked, dry heat; 146 kcal per 100g • #15223, Catfish, cooked, dry heat; 105 Kcal per 100g • #15218, Sunfish, cooked, dry heat; 114 Kcal per 100g • #15195, Drum, cooked, dry heat; 153 Kcal per 100g • #15011, Catfish, breaded and fried; 229 Kcal per 100g	The values presented in the Total Daily Kilocalorie (Kcal) Table were a rough estimate of Kcal based on ingestion of resident fish and other aquatic resources (Harper, 2008). As indicated in RAGS Table 4.6 of the HHRA, the following ingestion rates are used in the HHRA for Tribal Lifeway adults: fish = 90 g/day (assuming that 75% of the Harper [2008] "Aquatic and Fish" category is fish).
4	Table 4.1 General Public		Fish Ingestion Rate Comparison: In table using EPA (2011) child and adult values for g/kg BW-day, the value for the adult has been miscalculated. It should be (0.88 g/kg BW-day} X (70 kg)= 61.6 g/day not 13.1 g/day.	As indicated in RAGS Table 4.6 of the HHRA, the following ingestion rate is used for General Public adults: fish = 67 g/day. The fish ingestion rate is based on a longitudinal study of mercury exposure associated with consumption of freshwater fish from a reservoir in rural south-central USA (Dong et al., 2015).

Table 3a. Response to Comments Provided by ODEQ on January 8, 2018 on Document No. 3

Item	Section	Page	Comment	Response
5	Table 4.2 General Public		General Public Receptor (Sediment): Why not use the SRC (2016) value for Exposure Frequency? The citation for the value seems more vetted than Professional Judgement. DEQ proposes using the SRC (2016) value unless there is clear justification for not using it.	The General Public exposure frequency of 28 days/year assumes 1 day/week for the months of April through October but no exposures for November through March, as indicated in RAGS Table 4.1 of the HHRA. Based on discussions with EPA Region 7, the SRC (2016) Streamlined HHRA was intentionally conservative. The exposure assumptions for General Public in OU5 are expected to be reasonable.
6	Table 4.2 Tribal Member		Tribal Member Receptor (Sediment): Why is the EPA (2004) Soil-to-Skin Adherence Factor of 0.2 mg/ cm 2 not being used for Tribal Member Receptor as it is being used for the General Public Receptor? The Harper (2008) manuscript suggests using the 0.1 adherence factor as a means to account for both indoor and outdoor activities which would have lower and higher adherence factors, respectively. It does not appear to endorse the adherence factor as a mechanism to describe the nature of skin. DEQ does not follow the logic for using the two different values, especially considering the increased Exposure Frequency value being proposed for the Tribal Member Receptor. DEQ proposes using the EPA (2004) adherence factor for both Tribal Member and General Public Receptors. However, if an alternate value is to be used, DEQ requests that the same adherence factor be used for both Tribal Member and General Public Receptors regardless of the value used in the final calculations.	A SSAF of 0.1 was used for Tribal Lifeway adults and children for consistency with the *Quapaw Traditional Lifeways Scenario* (Harper, 2008). This value is recommended in the document to account for averaging among outdoor activities with moderate to high dermal adherence and indoor activities with a lower adherence rate. There are no known physiological differences in dermal properties of skin between tribal members and the general public, but the types of sediment contact conducted by the two groups may warrant the higher SSAF.
7	Table 4.3 General Public		General Public Receptor (Surface Water- Swimming): Why not use the SRC (2016) value for Exposure Frequency? The citation for the value seems more vetted than Professional Judgement. DEQ proposes using the SRC (2016) value unless there is clear justification for not using it. Exposure time/duration for swimming and wading should be re-evaluated. DEQ feels like swimming and wading events are likely to last longer than one hour.	The General Public exposure frequency of 28 days/year assumes 1 hour/day, 1 day/week for the months of April through October but no exposures for November through March, as indicated in RAGS Table 4.2 of the HHRA. Based on discussions with EPA Region 7, the SRC (2016) Streamlined HHRA was intentionally conservative. The exposure assumptions for General Public in OU5 are expected to be reasonable.

Table 3a. Response to Comments Provided by ODEQ on January 8, 2018 on Document No. 3

Item	Section	Page	Comment	Response
8	Table 4.4 Tribal Member		Tribal Member Receptor (Surface Water - Swimming): Exposure time/duration for swimming and wading should be re-evaluated. DEQ feels like swimming and wading events are likely to last longer than one hour. Beyond what is explained in the footnotes, DEQ does not follow the logic behind differing Exposure Frequencies for swimming and wading (65 days/year vs 61 days/year). DEQ proposes that the values be equivalent, as they are in the general public receptor.	As indicated in RAGS Table 4.2 of the HHRA, the exposure time for swimming/ wading for Tribal Lifeway is 6 hours/day and the exposure frequency is 312 days/ year. The RME exposure assumptions are based on input received from TCTCIT.
9	Table 4.4 General Public		General Public Receptor {Surface Water - Potable): No comment -values proposed seem reasonable	No action required.
10	Table 4.3 Tribal Member		Tribal Member Receptor (Surface Water- Potable): No comment - values proposed seem reasonable Is it possible to adjust future tables 4.3 and 4.4 so that the same Exposure Scenario is being evaluated in each table? As it is now, there is some table dyslexia; which may cause some undue confusion.	No action required. Exposure factors are presented by media. Sediment is presented in RAGS Table 4.1 and surface water is presented in RAGS Table 4.2 of the HHRA.
11	Table 4.5 General Public		General Public Receptor (Mine Discharge): Exposure Frequency seems high to DEQ. Would support a lower value if decided to be used.	Although the mine discharges occur intermittently, have a typically low flow rate, and are not easily accessible, mine discharge was conservatively evaluated for the same exposure scenarios and assumptions as surface water in Appendix F3.
12	Table 4.7 Tribal Member		Tribal Member Receptor (Mine Discharge): Exposure Frequency seems high to DEQ. Would support a lower value if decided to be used. Is it possible to change this table to 4.5 so that the same Exposure Scenario is being evaluated in each table? As it is now, there is some table dyslexia; which may cause some undue confusion.	Although the mine discharges occur intermittently, have a typically low flow rate, and are not easily accessible, mine discharge was conservatively evaluated for the same exposure scenarios and assumptions as surface water in Appendix F3.

Table 3a. Response to Comments Provided by ODEQ on January 8, 2018 on Document No. 3

Item	Section	Page	Comment	Response
13	Table 4.5 Tribal Member		Tribal Member Receptor (Sweat Lodge): Ultimately, DEQ will support any value proposed by Tribal Stakeholders but it is DEQ's understanding that the current value for exposure frequency is too high. Sweat Lodge practice in Oklahoma appears to be a more spiritual/ceremonial experience rather than a daily experience.	The RME exposure assumptions are based on input received from AESE/Quapaw Nation and TCTCIT. A sweat lodge exposure frequency of 365 days/year, exposure time of 1 hour/event, and exposure duration of 64 years is used for adults in the HHRA. A sweat lodge exposure frequency of 365 days/year, exposure time of 1 hour/ event, and exposure duration of 4 years (children ages 2 to 6) is used for children in the HHRA based on input from QTO since TCTCIT indicated that children do not use the sweat lodge.
14	Table Unlisted		(Aquatic plants): No comment. DEQ will rely on Tribal Stakeholders for Exposure Frequency values.	No action required.

Table 3c. Response to Comments Provided by Earl Hatley on January 17, 2018 on Document No. 3

Item	Section	Page	Comment	Response
1			Non-Food Exposure Assumptions It is assumed that tribal peoples are using surface water as potable water for drinking, cooking, etc. and non-tribal peoples are not, but will in the future. Question: Where does this assumption come from? Comment: Grand Lake is a primary drinking water source for many communities and rural water districts in the area, serving ALL customers (tribal and non-tribal). I am drinking this water through my tap via my rural water district, which obtains this water from the City of Vinita. Vinita obtains this water which they treat for drinking from Grand Lake. If the mine water and runoff from the Superfund Site area continue for years, unabated, then it could very well be that none of us will be able to use the area surface water as potable water the stated purposes in the Risk Assessment's assumptions.	Comment noted and considered in the HHRA framework.
2			Non-Food Exposure Assumptions Members of the public are assumed not to come in contact with sediments. Question: Given the assumption below this one that non-tribal peoples swim or wade in creeks or streams, how can they not be in contact with sediments? Comment: I like to fish. I also like to boat in the water. It is impossible not to be in contact with sediments doing these activities on the streams or along the shore of the Grand Lake. Another assumption is that non-Tribal do not hunt for mussels or shell fish. I know this is not true from personal observation. How do they harvest these with being in contact with sediments? Most people I know, including myself, love watercress and other water plants. It is assumed that non-tribal people aren't interested. My non-tribal friends are.	Comment noted and considered in the HHRA framework.

Table 3d. Response to Comments Provided by LEAD Agency on January 17, 2018 on Document No. 3

Item	Section	Page	Comment	Response
1			Comments received on LEAD website: I know that people eat more local caught fish than the EPA represents in their risk assessment, and would certainly eat more if they knew the fish were safe. I also know that most people are not swimming in the watershed because of the look of the water and fear of pollution. If we knew the water was safe, most people would be swimming in the waters and boating like they use to. SO, PLEASE TELL THIS TO EPA!! Please let them know how much fish you would like to eat if you knew they were safe and how much you would love to swim if you knew the water was safe. We all need to be involved. LEAD can't do it all. After all, YOU ARE LEAD! I am relatively new to this area. I moved here in August 2016. Tar Creek Superfund site has been in the news for many years, but seeing it and living in the direct path of the contamination is another matter. More-so, I have a child at home and I worry for her exposure. People here know about Tar Creek and the environmental pollution of heavy metals. People here use great caution and unfortunately, due to the contamination and danger of exposure, the creek is not used like it was prior to the realization of the contamination. If not for Tar Creek's contamination, I would fish in the creek at least 1 to 2 times a month, or 12-24 times per year. I would eat the fish I catch, which would total 2-4 fish per trip. This is 24 to 96 fish per year that my family would eat, including my child. My grave concern is that Tar Creek is a tributary to the Grand River and ultimately to the Grand Lake 'O The Cherokees. Grand Lake is a major residential lake and a thriving recreational lake. Fishing and water sports and boating are wide-spread in Grand Lake. Tar Creek is polluting Grand Lake in Oklahoma and people are generally unaware of this threat to their health, life and safety. Please clean up Tar Creek and warn people not to eat the fish, nor animals in the creeks' pathway/region, nor the native wild fruit and vegetables. Ottawa County enjoys a densely populated Native American demographic group, as there are 10 sovereign Tribes in the County. Many of these Native people have grown up for generations using Tar Creek and its environs for hunting, fishing, foraging, growing crops and raising animals. This is certainly the same for all demographic groups in this area, but there is a cultural tie to these lands from the Tribes and their people. We are a rural community. Many people hunt and fish and live off the land. Tar Creek's contamination is adversely affecting all of these people.	Comments noted and considered in the HHRA framework.

Table 3d. Response to Comments Provided by LEAD Agency on January 17, 2018 on Document No. 3

Item	Section	Page	Comment	Response
2			LEAD Agency conducted the Grand Lake Mercury Study which was a research project with the Harvard School of Public Health and OU Health Sciences Center in which 150 fishermen and women participated. The majority of the fish, etc. caught and eaten by these participants came from the upper Grand Lake and the Neosho River. From them we learned that they were fishing but fishing less than they wanted to, consuming fewer fish than they wanted due for the most part that they feared the quality and safety of the fish, turtles, frogs and crawdads caught locally. http://www.grandlakemercurystudy.org/Fish_Consumption.html People are fishing in Lytle Creek and when asked they will not say they eat them. But there are no warning signs up advising them NOT to eat them. There are no warning signs anywhere along any of the streams, rivers or upper Grand Lake with any advisory. The reason fewer people recreate in and around our impacted streams is because they know something is wrong with doing so. There is an often unspoken fear and concern also for the cattle and deer and other wildlife that consume water from these impacted waters and that are then consumed by the public. It is hard to separate the contaminated water from the land as the contaminated water flows over and through the land to the sediments and the concerned streams that flow. All those then flow to the rivers that fill the Grand Lake o' the Cherokees. The combined items on plates of food eaten by tribal and non-tribal residents need to be considered, not just the fish, but also freshwater mussels, frogs, turtles, wild onions found along the streams, the serving sizes and numbers of re-fills taken by each person. Also the dust on the plates, the dust breathed in, and the dust landing on the outdoor cooked foods adds to the loading of metals eaten. As we have learned from the Harvard School of Public Health research done at this site, we must remember there are impacts on our people from the multiple metals that are in these contaminated soils, sediment, dust and the foods we consume grown in the waters and in the soils. The metal contaminant exposures are linked to poor birth outcomes and impaired neurodevelopment. The multiple metals lead to more toxic effects on the brain than an individual metal. Living near this superfund site is bad for our health and we have probably been underestimating the impacts on our health and wellbeing for decades. Babies are born pre-polluted and impacted by their contaminated environments even before they are walking or talking, exposed by what the mother has consumed or breathed in from her environment.	Comments noted and considered in the HHRA framework.

Table 3d. Response to Comments Provided by LEAD Agency on January 17, 2018 on Document No. 3

Item	Section	Page	Comment	Response
			Our wish is for tribal and non-tribal persons to be able to use our perennially flowing creeks, streams, rivers within the Oklahoma portion of the Tri-State Mining District more fully as a resource for food and recreation, for drinking and for as the Cherokees, "to go to water" for our spiritual needs. As a member of the Cherokee Nation, one of the downstream tribes affected by the Tar Creek Superfund site, the contaminants continue finding new ways to effect both the environment and those who rely upon it. These residual metals end up in the Grand Lake o' the Cherokees, my only daily drinking water source, and certainly the source for the many fish eaten at the "fish frys" I and others attend throughout the year.	

Table 3e. Response to Comments Provided by Larry Tippit/Peoria Tribe of Indians of Oklahoma on January 18, 2018 on Document No. 3

Item	Section	Page	Comment	Response
1			Although the "Technical Assistance Service for Communities -- Tar Creek Superfund Site Fact Sheet - January 2018" and the attached tables questionnaire may be "specific /exact science", I believe they leave much to be desired in the way of actuality/real - life, and common sense. For example: Where the study tables are averaged out in daily average grams consumptions, most hunters / gatherers take fish and game and plant resources, " in season" when they are available, lawful, and /or most readily harvested. This means that a person or family may consume many pounds ("gorge" when plentiful) of a subsistence resource in season (maybe several weeks) and then stretch out their intake (by canning or other means of preserving) throughout the rest of the year, depending on when their stores are exhausted. Also, in my experience, many "children," young kids, with their exuberant activities, eat or consume more that their adult parents. Therefore, assuming that an adult may eat 120 grams of fish a day while a child (depending on the age, size, and activity) eats only 40 grams in the same period, is not a hard and fast or reliable fact. So it is not only possible, but also probable that the tables, as presented, do not and cannot present an accurate representation of the consumption of the resources, whether fish, mammal, or plant.	Exposure by hunter/gatherers is addressed by the Tribal Lifeway scenario. Additionally, an alternative (higher) percentage (of the adult ingestion rate) for children is presented in Appendix F4. Overall, the risk assessment process and assumptions account for short times when consumption of aquatic food items is higher and longer periods when consumption is lower.
2			Another point I wish to highlight is that in the way of aquatic exposure, many more people besides Tribal and Ottawa County residents are exposed to water, sediments, fish, game, and plant contaminants. There are many sportsmen and families that come from out of state to Ottawa County, particularly the Twin Bridges area and Miami City park, to fish and recreate. The Twin Bridges park is a regular site for out of state fishermen to come, put in their boats, and motor up both Spring and Neosho Rivers to fish for several different species of fish, including rough fish and paddle fish, as well as local game fish. This is especially evident during different spawning and fish "run" seasons, not counting the heated docks for fishing that are in use in spring and fall seasons and on not only the Spring and Neosho rivers, but Grand Lake also. Duck and goose hunter travel, in season, from other in-state areas and from out-of-state to hunt the Spring River / Neosho River / Grand Lake area, thereby being exposed to water, sediments, and possibly contaminated harvests of waterfowl. And this doesn't take into account the number of families that come to camp for days and weekends to swim, wade, and play in the parks and rivers and lake.	Sportsmen (including waterfowl hunters) and families who come from out-of-state to fish and recreate in specific watersheds are addressed by the General Public exposure scenarios for recreational exposures to surface water and sediment (28 days/year), which are presented by watershed in Tables 6-4 and 6-5. In addition, their consumption of fish (game and non-game) from specific watersheds is addressed by the Tribal Lifeway evaluation presented in Appendix F3. Consumption of waterfowl is discussed in Section 6.6.2.7, and as indicated, potential risks are not expected to be significant.

Table 3e. Response to Comments Provided by Larry Tippit/Peoria Tribe of Indians of Oklahoma on January 18, 2018 on Document No. 3

Item	Section	Page	Comment	Response
3			There is no way of having a realistic number of individuals that are impacted by the contamination from the mine wastes, sediments, and impacted waters in the Tri-State Mining District / Tar Creek Superfund site. Besides hunters, fishermen, and recreation, there are many farmers, ranchers, and other types of employments that come into contact with mining wastes and heavy metal impacted waters daily through their jobs. These too should somehow be figured in the picture or tables. Farmers and ranchers irrigate their crops and pastures from these water sources, thus a pathway. Gravel haulers obtain river gravel and sediments from river bottoms and floodplains for fill dirt that goes into someone's yard or house foundation pad, another pathway. State, Federal, and private fish and wildlife folks, game rangers and biologists are in constant contact with these waters and sediments. NRCS employees involved with conservation projects, stream bank stabilization, etc., deal regularly with aquatic resources, sediments and such. Tribal Environmental employees from all the different Tribes in Ottawa County are particularly exposed to waters and sediments and mine discharges. Peoria Aquatic Facility workers daily work with fish, aquatic organisms, wade in water and sediments, and monthly take surface and pore water and sediment samples, all from mining injured waters; and the list goes on.	Comment noted and considered in the HHRA framework.
4			Another issue dealing with cleanup has to do with the aesthetics of Ottawa County and the local cities. The documents presents the conclusion that the Tar Creek Superfund site will only be addressed for cleanup if the "cancer health risk " is between 1 in 10,000 and 1 in a million, and that on a site-by-site basis. The city of Miami is in a condition of deterioration. In spite of a growing Northeastern A & M Junior College, the city is in a state of decline. With no industry moving in, the City government has touted Miami as a "retirement" community. But who wants to move into a Superfund Contamination site, with so much visible contamination, much less the threat of contamination from air, soil, and water.	Comment noted and considered in the HHRA framework.
5			Not many employees of the Peoria Tribe have much to do with the taking of raccoons. But my research shows that there are four different "coon hunting clubs" in the area, each fielding between 30 to 60 members. Each club has regular seasonal hunts, besides contest or field trial invitational hunts (which may bring in hundreds of hunters, dogs, and spectators. There is no way of estimating the number of raccoons that are taken and / or consumed from these events.	Raccoon samples were collected and evaluated in the HHRA.

Appendix B
Risk Assessment Guidance for Superfund (RAGS) Part D Tables

TABLE 1

SELECTION OF EXPOSURE PATHWAYS

Tar Creek Superfund Site Operable Unit 5 Remedial Investigation

Ottawa County, Oklahoma

Scenario Timeframe	Medium	Exposure Medium	Exposure Point[1]	Receptor Population	Receptor Age	Exposure Route	Type of Analysis	Rationale for Selection of Exposure Pathway
Current/ Future	Sediment (Rivers and Creeks)	Sediment (Rivers and Creeks)	Sediment (0 to 12 inches deep)[2]	Tribal Lifeway	Adult/Child	Incidental ingestion, dermal	Quant	Surface sediment may be contacted during hunting/fishing/gathering and recreational activities (swimming, wading)
				Aquatic Worker	Adult	Incidental ingestion, dermal		Surface sediment may be contacted during work
				General Public (Recreator)	Adult/Child	Incidental ingestion, dermal		Surface sediment may be contacted during recreational activities (swimming, wading, fishing, hunting)
	Surface Water (Rivers and Creeks) [3]	Surface Water (Rivers and Creeks)	Surface Water (Rivers & Creeks)	Tribal Lifeway	Adult/Child	Incidental ingestion, dermal		Surface water may be contacted during hunting/fishing/gathering and recreational use (swimming, wading)
				Aquatic Worker	Adult	Incidental ingestion, dermal		Surface water may be contacted during work
				General Public (Recreator)	Adult/Child	Incidental ingestion, dermal		Surface water may be contacted during recreational use (swimming, wading, fishing, hunting)
			Surface Water (Potable Use)	Tribal Lifeway	Adult/Child	Ingestion,dermal		Surface water may be used as a potable source (drinking and bathing)
				General Public	Adult/Child	Ingestion, dermal		Surface water may be used as a potable source (drinking and bathing)
			Surface Water (Sweat Lodge)	Tribal Lifeway	Adult/Child	Ingestion, dermal		Surface water may be contacted during sweat lodge use
			Water Vapor (Sweat Lodge)	Tribal Lifeway	Adult/Child	Inhalation		Water vapor in Sweat Lodge may be inhaled.
	Sediment/ Surface Water (Rivers and Creeks)	Aquatic Biota (Animal[4] and Plant[5] Tissue)	Fish Tissue	Tribal Lifeway	Adult/Child	Ingestion		Fish may be consumed for food[10]
				General Public (Fisher)	Adult/Child	Ingestion		Fish may be consumed for food[11]
			Shellfish Tissue	Tribal Lifeway	Adult/Child	Ingestion		Shellfish may be consumed for food[12]
			Aquatic Plant (as Food)	Tribal Lifeway	Adult/Child	Ingestion		Aquatic plants may be consumed for food[13]
			Aquatic Plant (as Salve)	Tribal Lifeway	Adult/Child	Dermal		Aquatic plants may be used for medicinal purposes[14]
			Amphibian/Aquatic Reptile[6] Tissue	Tribal Lifeway	Adult/Child	Ingestion		Frogs and turtles may be consumed for food[15]
			Semi-Aquatic Mammals[7] Tissue	Tribal Lifeway	Adult/Child	Ingestion		Semi-aquatic mammals may be consumed for food[16]

TABLE 1

SELECTION OF EXPOSURE PATHWAYS

Tar Creek Superfund Site Operable Unit 5 Remedial Investigation

Ottawa County, Oklahoma

Scenario Timeframe	Medium	Exposure Medium	Exposure Point[1]	Receptor Population	Receptor Age	Exposure Route	Type of Analysis	Rationale for Selection of Exposure Pathway
			Waterfowl Tissue[8]	Tribal Lifeway	Adult/Child	Ingestion	Qual	Waterfowl (ducks and geese) may be consumed for food
				General Public (Hunter)	Adult/Child	Ingestion		
			Irrigated Crops (as Food)[9]	Crop Consumers	Adult/Child	Ingestion	N/A [9]	Irrigated crops may be consumed for food (expected to be unlikely)
			Livestock (Meat)[9]	Livestock (Meat) Consumers	Adult/Child	Ingestion	N/A [9]	Livestock (meat) may be consumed for food (expected to be unlikely)

Notes:

(1) Evaluation of site media is performed separately for each watershed. Chemicals of potential concern (COPCs) are selected by media based on aggregated data. Exposure point concentrations (EPCs) are calculated per watershed for sediment, surface water, and mine discharge. EPCs for biota COPCs are calculated based on aggregated data.

(2) Sediment (0 to 12 inches deep) from saturated zones of perennial rivers or creeks.

(3) Mine discharge evaluated using the same exposure assumptions as surface water in Appendix F.

(4) Terrestrial small game (birds, rabbits) and large game (deer, elk) were addressed under Operable Unit 4 (Source Material, Transition Zone Soil, Rural Residential Yards and Wells).

(5) Aquatic plants growing in the wet bank-to-bank section of perennial flowing rivers and creeks.

(6) Amphibians and aquatic reptiles living in the wet bank-to-bank section of perennial flowing rivers and creeks.

(7) Semi-aquatic mammals (raccoon, beaver, mink, muskrat, otter) living in the wet bank-to-bank section of perennial flowing rivers and creeks.

(8) Potential risk associated with waterfowl consumption is evaluated qualitatively.

(9) The use of surface water for the irrigation of crops or as drinking water for livestock is unknown and expected to be unlikely due to the extent of annual rainfall in the area.

(10) Potential risk associated with fish consumption by the Tribal lifeway receptors is evaluated using two datasets: (1) whole body eviscerated and (2) head with bones.

(11) Potential risk associated with fish consumption by the general public is evaluated using the fish filet dataset.

(12) Potential risk associated with shellfish consumption is evaluated using the Asian clam and mussel samples.

(13) Potential risk associated with aquatic plant consumption is evaluated using the arrowhead and duckweed samples.

(14) Potential risk associated with medical use of aquatic plants is evaluated using the arrowhead samples.

(15) Potential risk associated with amphibian/aquatic reptile consumption is evaluated using the frog leg samples.

(16) Potential risk associated with semi-aquatic mammal consumption is evaluated using the raccoon samples.

Types of Analysis:

N/A = not applicable
Quant = quantitative analysis
Qual = qualitative analysis

TABLE 2.1a
OCCURRENCE, DISTRIBUTION AND SELECTION OF CHEMICALS OF POTENTIAL CONCERN
Tar Creek Superfund Site Operable Unit 5 Remedial Investigation
Ottawa County, Oklahoma

Scenario Timeframe: Current/Future
Medium: Sediment (Rivers and Creeks)
Exposure Medium: Sediment (Rivers and Creeks) - Tribal Lifeway and Aquatic Workers

Notes:
(1) Background values are the 95/95 Upper Tolerance Limit (UTL) for sediment from *Tar Creek Superfund Site Operable Unit 5 Ottawa County, Oklahoma Remedial Investigation Report* (April, 2019).
(2) Rationale Codes:
Deletion Reason: No Toxicity Information (NTX)
Essential Nutrient (NUT)

Definitions:
ARAR/TBC = Applicable or Relevant and Appropriate Requirement/To Be Considered
COPC = Chemical of Potential Concern
J = compound was detected below the reporting limit in the sample
LJ = result is estimated (low)
mg/kg = milligram per kilogram
NA = not available

Notes:
(1) Maximum concentration is used for screening.
(2) Background values are the 95/95 Upper Tolerance Limit (UTL) for sediment from *Tar Creek Superfund Site Operable Unit 5 Ottawa County, Oklahoma Remedial Investigation Report* (April, 2019).
(3) EPA RSL for residential soil (November 2019) based on a target cancer risk of 1×10^{-6} and a non-cancer hazard quotient (HQ) of 0.1.
The RSL for Chromium(VI) was used for Chromium, total.
The RSL for Mercuric Chloride was used for Mercury.
(4) Rationale Codes:
Selection Reason: Above Screening Levels (ASL)
Deletion Reason: No Toxicity Information (NTX)
Below Screening Level (BSL)
Essential Nutrient (NUT)

Definitions:
ARAR/TBC = Applicable or Relevant and Appropriate Requirement/To Be Considered
c = carcinogenic
COPC = Chemical of Potential Concern
G = Lead screening level based on blood lead modeling, as cited in Section 5.2 of RSL User's Guide
J = compound was detected below the reporting limit in the sample
LJ = result is estimated (low)
mg/kg = milligram per kilogram
n = non-carcinogenic
NA = not available
R = Relative bioavailability absorption was applied
RSL = Regional Screening Level

Notes:
(1) Background values are the 95/95 Upper Tolerance Limit (UTL) for surface water from *Tar Creek Superfund Site Operable Unit 5 Ottawa County, Oklahoma Remedial Investigation Report* (April, 2019); values are for "total" metals.
(2) Rationale Codes:
Deletion Reason: Essential Nutrient (NUT)

Definitions:
ARAR/TBC = Applicable or Relevant and Appropriate Requirement/To Be Considered
COPC = Chemical of Potential Concern
J = compound was detected below the reporting limit in the sample
LJ = result is estimated (low)
mg/L = milligram per liter
NA = not available

Notes:
(1) Maximum concentration is used for screening.
(2) Background values are the 95/95 Upper Tolerance Limit (UTL) for surface water from *Tar Creek Superfund Site Operable Unit 5 Ottawa County, Oklahoma Remedial Investigation Report* (April, 2019); values are for "total" metals.
(3) EPA RSL for tap water (November 2019) based on a target cancer risk of $1x10^{-6}$ and a non-cancer hazard quotient (HQ) of 0.1.
The RSL for Chromium(VI) was used for Chromium, total.
The RSL for Mercuric Chloride was used for Mercury.
(4) Rationale Codes:
Selection Reason: Above Screening Levels (ASL)
Deletion Reason: No Toxicity Information (NTX)
Below Screening Level (BSL)
Essential Nutrient (NUT)

Definitions:
ARAR/TBC = Applicable or Relevant and Appropriate Requirement/To Be Considered
COPC = Chemical of Potential Concern
G = Lead screening level based on blood lead modeling, as cited in Section 5.2 of RSL User's Guide
J = compound was detected below the reporting limit in the sample
LJ = result is estimated (low)
mg/L = milligram per liter
n = non-carcinogenic
NA = not available
RSL = Regional Screening Level

TABLE 2.3

Notes:
(1) Eviscerated whole fish concentration was estimated based on weighted concentrations of three fish body parts (carcass, filet, and head).
(2) Although fish samples were collected from the background reference area, background values were not established due to the limited number of background samples.

Definitions:
ARAR/TBC = Applicable or Relevant and Appropriate Requirement/To Be Considered
COPC = Chemical of Potential Concern
J = compound was detected below the reporting limit in the sample
mg/kg (w) = milligrams per kilogram (based on wet weight)
NA = not available

TABLE 3.1.RME
MEDIUM-SPECIFIC EXPOSURE POINT CONCENTRATION SUMMARY
REASONABLE MAXIMUM EXPOSURE
Tar Creek Superfund Site Operable Unit 5 Remedial Investigation
Ottawa County, Oklahoma

Scenario Timeframe: Current/Future
Medium: Sediment (Rivers and Creeks)
Exposure Medium: Sediment (Rivers and Creeks)

Exposure Point	Chemical of Potential Concern	Units	Arithmetic Mean	95% UCL (Distribution)	Maximum Concentration (Qualifier)	Exposure Point Concentration			
						Value	Units	Statistic	Rationale

Notes:

Statistics: Maximum - Maximum detected value
Adjusted Gamma - UCL adjusted for level significance assuming gamma distribution
Chebyshev (mean, Sd) - nonparametric UCL using sample mean and standard deviation based on the Chebyshev inequality
GROS Approximate Gamma - UCL approximation based on the regression on order statistics (ROS) method for a gamma distribution
Hall's Bootstrap - nonparametric UCL
H-UCL - UCL based upon Land's H-statistic assuming lognormal distribution
KM (BCA) - nonparametric UCL based upon Kaplan-Meier estimates using the bias-corrected accelerated bootstrap method
KM (Chebyshev) - nonparametric UCL based upon Kaplan-Meier estimates using the Chebyshev inequality
KM (t) - UCL based upon Kaplan-Meier estimates using the Student's t-distribution critical value
KM Adjusted Gamma - UCL based upon Kaplan-Meier estimates, adjusted for level significance assuming gamma distribution
KM Approximate Gamma - UCL based upon Kaplan-Meier estimates, calculated using chi-square approximation assuming gamma distribution
KM H-UCL - UCL based upon Kaplan-Meier estimates using Land's H-statistic assuming lognormal distribution
Modified-t - nonparametric UCL adjusted for skewness
Student's-t - UCL based on Student's t statistic assuming normal distribution

(1) Shapiro-Wilk W/Lilliefors Test indicates data are log-normally distributed.
(2) Shapiro-Wilk W/Lilliefors Test indicates data are normally distributed.
(3) Anderson-Darling and/or Kolmogorov-Smirnov Tests indicate data are gamma distributed.
(4) Distribution tests are inconclusive; therefore, the nonparametric UCL was used as the EPC.
(5) The maximum detected concentration was used as the EPC because there were less than 8 samples or 4 detected concentrations.
(6) The maximum detected concentration was used as the EPC because the UCL exceeded the maximum detected concentration.
(7) The arithmetic mean concentration was used as the EPC for lead.

EPC = Exposure Point Concentration
G = gamma distribution
J = result is estimated
L = Log-normal distribution
mg/kg = milligram per kilogram
N = normal distribution
NA = not available
RME = Reasonable Maximum Exposure
UCL = Upper Confidence Limit

TABLE 3.2.RME
MEDIUM-SPECIFIC EXPOSURE POINT CONCENTRATION SUMMARY
REASONABLE MAXIMUM EXPOSURE
Tar Creek Superfund Site Operable Unit 5 Remedial Investigation
Ottawa County, Oklahoma

Scenario Timeframe: Current/Future
Medium: Sediment (Rivers and Creeks)
Exposure Medium: Sediment (Rivers and Creeks)

Exposure Point	Chemical of Potential Concern	Units	Arithmetic Mean	95% UCL (Distribution)	Maximum Concentration (Qualifier)	Exposure Point Concentration			
						Value	Units	Statistic	Rationale

Notes:

Statistics: Maximum - Maximum detected value
Adjusted Gamma - UCL adjusted for level significance assuming gamma distribution
Approximate Gamma - UCL calculated using chi-square approximation assuming gamma distribution
Chebyshev (mean, Sd) - nonparametric UCL using sample mean and standard deviation based on the Chebyshev inequality
GROS Adjusted Gamma - UCL based on the regression on order statistics (ROS) method, adjusted for level significance assuming gamma distribution
GROS Approximate Gamma - UCL approximation based on the regression on order statistics (ROS) method for a gamma distribution
H-UCL - UCL based upon Land's H-statistic assuming lognormal distribution
KM (BCA) - nonparametric UCL based upon Kaplan-Meier estimates using the bias-corrected accelerated bootstrap method
KM (Chebyshev) - nonparametric UCL based upon Kaplan-Meier estimates using the Chebyshev inequality
KM (t) - UCL based upon Kaplan-Meier estimates using the Student's t-distribution critical value
KM Adjusted Gamma - UCL based upon Kaplan-Meier estimates, adjusted for level significance assuming gamma distribution
KM Approximate Gamma - UCL based upon Kaplan-Meier estimates, calculated using chi-square approximation assuming gamma distribution
KM H-UCL - UCL based upon Kaplan-Meier estimates using Land's H-statistic assuming lognormal distribution
Modified-t - nonparametric UCL adjusted for skewness
Student's-t - UCL based on Student's t statistic assuming normal distribution

(1) Shapiro-Wilk W/Lilliefors Test indicates data are log-normally distributed.
(2) Shapiro-Wilk W/Lilliefors Test indicates data are normally distributed.
(3) Anderson-Darling and/or Kolmogorov-Smirnov Tests indicate data are gamma distributed.
(4) Distribution tests are inconclusive; therefore, the nonparametric UCL was used as the EPC.
(5) The maximum detected concentration was used as the EPC because there were less than 8 samples or 4 detected concentrations.
(6) The maximum detected concentration was used as the EPC because the UCL exceeded the maximum detected concentration.
(7) The arithmetic mean concentration was used as the EPC for lead.

EPC = Exposure Point Concentration
G = gamma distribution
J = result is estimated
J^ = result is estimated (high)
L = log-normal distribution
LJ = result is estimated (low)
mg/kg = milligram per kilogram
N = normal distribution
NA = not available
RME = Reasonable Maximum Exposure
UCL = Upper Confidence Limit

Notes:

EPC = Exposure Point Concentration

TABLE 3.2.RME Supplement A
MEDIUM-SPECIFIC EXPOSURE POINT CONCENTRATION SUMMARY
REASONABLE MAXIMUM EXPOSURE
Tar Creek Superfund Site Operable Unit 5 Remedial Investigation
Ottawa County, Oklahoma

Scenario Timeframe: Current/Future
Medium: Sediment (Rivers and Creeks)
Exposure Medium: Sediment (Rivers and Creeks)

			Sieved Sediment EPC		Unsieved Sediment EPC		Maximum EPC of Sieved or Unsieved Sediment	
Exposure Point	Chemical of Potential Concern	Units	Value	Statistic	Value	Statistic	Value	Soil Depth

mg/kg = milligram per kilogram

NA = not available or not applicable

UCL = Upper Confidence Limit

Statistics: Maximum = Maximum detected value
Adjusted Gamma = UCL adjusted for level significance assuming gamma distribution
Approximate Gamma = UCL calculated using chi-square approximation assuming gamma distribution
Chebyshev (mean, Sd) = nonparametric UCL using sample mean and standard deviation based on the Chebyshev inequality
GROS Adjusted Gamma = UCL based on the regression on order statistics (ROS) method, adjusted for level significance assuming gamma distribution
GROS Approximate Gamma = UCL approximation based on the regression on order statistics (ROS) method for a gamma distribution
H-UCL = UCL based upon Land's H-statistic assuming lognormal distribution
KM (BCA) = nonparametric UCL based upon Kaplan-Meier estimates using the bias-corrected accelerated bootstrap method
KM (Chebyshev) = nonparametric UCL based upon Kaplan-Meier estimates using the Chebyshev inequality
KM (t) = UCL based upon Kaplan-Meier estimates using the Student's t-distribution critical value
KM Adjusted Gamma = UCL based upon Kaplan-Meier estimates, adjusted for level significance assuming gamma distribution
KM Approximate Gamma = UCL based upon Kaplan-Meier estimates, calculated using chi-square approximation assuming gamma distribution
KM H-UCL = UCL based upon Kaplan-Meier estimates using Land's H-statistic assuming lognormal distribution
Modified-t = nonparametric UCL adjusted for skewness
Student's-t = UCL based on Student's t statistic assuming normal distribution

TABLE 3.3.RME
MEDIUM-SPECIFIC EXPOSURE POINT CONCENTRATION SUMMARY
REASONABLE MAXIMUM EXPOSURE
Tar Creek Superfund Site Operable Unit 5 Remedial Investigation
Ottawa County, Oklahoma

Scenario Timeframe: Current/Future
Medium: Surface Water (Rivers and Creeks)
Exposure Medium: Surface Water (Rivers and Creeks)

Exposure Point	Chemical of Potential Concern	Units	Arithmetic Mean	95% UCL (Distribution)	Maximum Concentration (Qualifier)	Exposure Point Concentration			
						Value	Units	Statistic	Rationale

Notes:

Statistics: Maximum - Maximum detected value
Adjusted Gamma - UCL adjusted for level significance assuming gamma distribution
GROS Approximate Gamma - UCL approximation based on the regression on order statistics (ROS) method for a gamma distribution
KM (BCA) - nonparametric UCL based upon Kaplan-Meier estimates using the bias-corrected accelerated bootstrap method
KM (Chebyshev) - nonparametric UCL based upon Kaplan-Meier estimates using the Chebyshev inequality
KM (t) - UCL based upon Kaplan-Meier estimates using the Student's t-distribution critical value
KM Adjusted Gamma - UCL based upon Kaplan-Meier estimates, adjusted for level significance assuming gamma distribution
KM Approximate Gamma - UCL based upon Kaplan-Meier estimates, calculated using chi-square approximation assuming gamma distribution
KM H-UCL - UCL based upon Kaplan-Meier estimates using Land's H-statistic assuming lognormal distribution

(1) Shapiro-Wilk W/Lilliefors Test indicates data are log-normally distributed.
(2) Shapiro-Wilk W/Lilliefors Test indicates data are normally distributed.
(3) Anderson-Darling and/or Kolmogorov-Smirnov Tests indicate data are gamma distributed.
(4) Distribution tests are inconclusive; therefore, the nonparametric UCL was used as the EPC.
(5) The maximum detected concentration was used as the EPC because there were less than 8 samples or 4 detected concentrations.
(6) The maximum detected concentration was used as the EPC because the UCL exceeded the maximum detected concentration.
(7) The arithmetic mean concentration was used as the EPC for lead.

EPC = Exposure Point Concentration
G = gamma distribution
J = result is estimated
L = log-normal distribution
LJ = result is estimated (low)
mg/L = milligram per liter
N = normal distribution
NA = not available
RME = Reasonable Maximum Exposure
UCL = Upper Confidence Limit

TABLE 3.3.RME Supplement A
MEDIUM-SPECIFIC EXPOSURE POINT CONCENTRATION SUMMARY
REASONABLE MAXIMUM EXPOSURE
Tar Creek Superfund Site Operable Unit 5 Remedial Investigation
Ottawa County, Oklahoma

Scenario Timeframe: Current/Future
Medium: Surface Water (Rivers and Creeks)
Exposure Medium: Surface Water (Rivers and Creeks)

Exposure Point	Chemical of Potential Concern	Exposure Point Concentration in Surface Water[1]		Exposure Point Concentration in Water Vapor[2]	
		Value	Units	Value	Units

Notes:

(1) Selection of surface water EPCs presented on Table 3.3.RME.

(2) Water vapor

RME = Reasonable Maximum Exposure

mg/m^3 = milligrams per cubic meter

mg/L = milligram per liter

$$C_{vapor} = C_{sw} \times (MW / (R \times T \times \rho w)) \times Exp\ (18.3036 - (3816.44/ (T - 46.13))$$

** Adapted the equation in the S-B EMWP (2016).

Chemical Concentration in Surface Water (C_{sw})

Chemical Concentration in Water Vapor (C_{vapor})

Molecular Weight of Water (MW) = 18 g/mole

Ideal Gas Law Constant (R) = 0.06237 mmHg-m^3/mole-K

Temperature of Sweat Lodge (T) = 339 K

Density of Liquid Water (ρw) = 1,000 g/L

Shoshone-Bannock Exposure Scenario for Use in Risk Assessment: Traditional Subsistence Lifeways. Shoshone-Bannock Tribes Environmental Waste Management Program (S-B EMWP). February 2016.

TABLE 3.4.RME
MEDIUM-SPECIFIC EXPOSURE POINT CONCENTRATION SUMMARY
REASONABLE MAXIMUM EXPOSURE
Tar Creek Superfund Site Operable Unit 5 Remedial Investigation
Ottawa County, Oklahoma

Scenario Timeframe: Current/Future
Medium: Sediment/Surface Water (Rivers and Creeks)
Exposure Medium: Aquatic Biota (Animal Tissue)

Exposure Point	Chemical of Potential Concern	Units	Arithmetic Mean	95% UCL (Distribution)	Maximum Concentration (Qualifier)	Exposure Point Concentration			
						Value	Units	Statistic	Rationale

Notes:
[1] Eviscerated whole fish concentration was estimated based on weighted concentrations of three fish body parts (carcass, fillet, and head).

Statistics: Maximum - Maximum detected value
Approximate Gamma - UCL calculated using chi-square approximation assuming gamma distribution
H-UCL - UCL based upon Land's H-statistic assuming lognormal distribution
KM (BCA) - nonparametric UCL based upon Kaplan-Meier estimates using the bias-corrected accelerated bootstrap method
KM (Chebyshev) - nonparametric UCL based upon Kaplan-Meier estimates using the Chebyshev inequality
KM (t) - UCL based upon Kaplan-Meier estimates using the Student's t-distribution critical value
KM Approximate Gamma - UCL based upon Kaplan-Meier estimates, calculated using chi-square approximation assuming gamma distribution
Modified-t - nonparametric UCL adjusted for skewness

(1) Shapiro-Wilk W/Lilliefors Test indicates data are log-normally distributed.
(2) Shapiro-Wilk W/Lilliefors Test indicates data are normally distributed.
(3) Anderson-Darling and/or Kolmogorov-Smirnov Tests indicate data are gamma distributed.
(4) Distribution tests are inconclusive; therefore, the nonparametric UCL was used as the EPC.
(5) The arithmetic mean concentration was used as the EPC for lead.

EPC = Exposure Point Concentration
G = gamma distribution
J = result is estimated
L = log-normal distribution
mg/kg (w) = milligrams per kilogram (based on wet weight)
N = normal distribution
NA = not available
RME = Reasonable Maximum Exposure
UCL = Upper Confidence Limit

KM Bootstrap t - nonparametric UCL based upon Kaplan-Meier estimates using the bootstrap-t method
KM H-UCL - UCL based upon Kaplan-Meier estimates using Land's H-statistic assuming lognormal distribution
Student's-t - UCL based on Student's t statistic assuming normal distribution

(1) Shapiro-Wilk W/Lilliefors Test indicates data are log-normally distributed.
(2) Shapiro-Wilk W/Lilliefors Test indicates data are normally distributed.
(3) Anderson-Darling and/or Kolmogorov-Smirnov Tests indicate data are gamma distributed.
(4) Distribution tests are inconclusive; therefore, the nonparametric UCL was used as the EPC.
(5) The maximum detected concentration was used as the EPC because there were less than 8 samples or 4 detected concentrations.
(6) The arithmetic mean concentration was used as the EPC for lead.

EPC = Exposure Point Concentration
G = gamma distribution
J = result is estimated
L = log-normal distribution
mg/kg (w) = milligrams per kilogram (based on wet weight)
N = normal distribution
NA = not available
RME = Reasonable Maximum Exposure
UCL = Upper Confidence Limit

TABLE 3.8.RME
MEDIUM-SPECIFIC EXPOSURE POINT CONCENTRATION SUMMARY
REASONABLE MAXIMUM EXPOSURE
Tar Creek Superfund Site Operable Unit 5 Remedial Investigation
Ottawa County, Oklahoma

Scenario Timeframe: Current/Future
Medium: Sediment/Surface Water (Rivers and Creeks)
Exposure Medium: Aquatic Biota (Plant Tissue)

Exposure Point	Chemical of Potential Concern	Units	Arithmetic Mean	95% UCL (Distribution)	Maximum Concentration (Qualifier)	Exposure Point Concentration			
						Value	Units	Statistic	Rationale

Notes:
Statistics: Maximum - Maximum detected value
Adjusted Gamma - UCL adjusted for level significance assuming gamma distribution
KM (t) - UCL based upon Kaplan-Meier estimates using the Student's t-distribution critical value
KM Bootstrap t - nonparametric UCL based upon Kaplan-Meier estimates using the bootstrap-t method
Student's-t - UCL based on Student's t statistic assuming normal distribution

(1) Shapiro-Wilk W/Lilliefors Test indicates data are normally distributed.
(2) Anderson-Darling and/or Kolmogorov-Smirnov Tests indicate data are gamma distributed.
(3) Distribution tests are inconclusive; therefore, the nonparametric UCL was used as the EPC.
(4) The maximum detected concentration was used as the EPC because there were less than 8 samples or 4 detected concentrations.
(5) The arithmetic mean concentration was used as the EPC for lead.
(6) The maximum detected concentration was used as the EPC because the UCL exceeded the maximum detected concentration.

EPC = Exposure Point Concentration
G = gamma distribution
J = result is estimated
mg/kg (w) = milligrams per kilogram (based on wet weight)
N = normal distribution
NA = not available
RME = Reasonable Maximum Exposure
UCL = Upper Confidence Limit

		Adult/Child	Fish Tissue	C_{Fish}	Chemical Concentration in Fish	EPC	mg/kg	Calculated	CDI (mg/kg-day) =
				IR-F-Adj	Ingestion Rate of Fish, Age-adjusted	11,005	g/kg	Calculated	C_{Fish} x IR-F-Adj x FI x CF5 x 1/AT
				EF	Exposure Frequency	365	days/year	--	IR-F-Adj (g/kg) =
				FI	Fraction Ingested from Contaminated Source	1	unitless	(8)	(ED-C x EF-C x IR-F-C / BW-C) + (ED-A x EF-A x IR-F-A / BW-A)
				AT-C	Averaging Time (Cancer)	25,550	days	(2)	
				CF5	Conversion Factor 5	0.001	kg/g	- -	

Notes:

(†) EPC and chemical intake will be calculated for each of four aquatic animal categories separately.

(1) Calculated as the product of ED (years) x 365 days/year.

(2) Calculated as the product of 70 years assumed human lifetime x 365 days/year.

(3) Assumes that 75'% of Harper (2008) "Aquatic & Fish" category is fish.

(4) Assumes that 25% of Harper (2008) "Aquatic & Fish" category is shellfish.

(5) Assumes that 35% of Harper (2008) "Small game" category is turtles and frogs.

(6) Assumes that 100% of Harper (2008) "Small game" category is semi-aquatic mammals.

(7) Based on a comparison of adult and child food consumption rates in the EPA Exposure Factor Handbook (2011) and Updates (2018), child consumption rate is assumed to be 50% of adult ingestion rate (see Table 4 Supplement C).

(8) Conservatively assumed that 100% of aquatic food items come from Operable Unit 5.

(9) Upper 95th confidence interval of mean fish consumption rate.

TABLE 4 SUPPLEMENT A

Skin Surface Area for Adult

REASONABLE MAXIMUM EXPOSURE

Tar Creek Superfund Site Operable Unit 5 Remedial Investigation

Ottawa County, Oklahoma

Age Group	Skin Surface Area (m^2)								Exposed Skin Surface (m^2) (Face, Hands, Lower Arms, Lower Legs, and Feet)	Exposed Skin Surface (m^2) (Hands and Feet)
	Head	Face [2]	Arms	Hands	Feet	Forearms/ Arms Ratio	Forearms [3]	Lower Legs	Sum	Sum
Adult Male [1]	0.136	0.045	0.314	0.107	0.137	0.4713	0.148	0.268	0.705	0.244
Adult Female [1]	0.114	0.038	0.237	0.089	0.122	0.4713	0.112	0.233	0.594	0.211
					Average (m^2)				0.650	0.228
					Average (cm^2)				6,495	2,275

Notes:

(1) Based on Table 7-12 Recommended Mean Surface Area for Adult (Aged 21+ years) (EPA, 2011).

(2) Skin surface area for face is assumed to be 1/3 of head skin surface area.

(3) Forearms to arms skin area ratio was assumed to be 47%, based on ratio of forearms to arms ratio for males in Table 7-12 (EPA, 2011).

20 to < 50 years	0.15	10.5		0.08	5.6	
Median Based Data[e]						

Notes:

[a] Information about age-specific body weight and food consumption rates were obtained from EPA Exposure Factors Handbook (EFH) and its updates.

[b] Body weight adjusted food consumption rates (in g/kg-day) in the EFH are converted to consumption rates in grams per day by multiplying by age-specific body weight.

[c] Child/Adult fractions were calculated by dividing child food consumption rate by adult food consumption rate.

[d] Adult body weight of 70 kg was used.

[e] Because of the small % consuming (less than 50%), the estimates based on median are not presented.

[f] Body weight of child (0 to < 1 year old) is time weighted average.

[g] Because of lack of measurable ingestion rate for child (0 to <1 year old), TWA ingestion rate was estimated child (1 to <6 years old).

TABLE 5.1
NON-CANCER TOXICITY DATA -- ORAL/DERMAL
Tar Creek Superfund Site Operable Unit 5 Remedial Investigation
Ottawa County, Oklahoma

Chemical of Potential Concern	Chronic/ Subchronic	Oral RfD		Oral Absorption Efficiency for Dermal (1)	Absorbed RfD for Dermal (2)		Primary Target Organ(s)	Combined Uncertainty/Modifying Factors	RfD:Target Organ(s)	
		Value	Units		Value	Units			Source(s)	Date(s) (MM/DD/YYYY)

Notes:

(1) Source: Risk Assessment Guidance for Superfund (RAGS). Volume 1: Human Health Evaluation Manual (Part E, Supplemental Guidance for Dermal Risk Assessment) Final. Section 4.2 and Exhibit 4-1. EPA recommends that the oral RfD should not be adjusted to estimate the absorbed dose for compounds when the absorption efficiency is greater than 50%. Constituents that do not have oral absorption efficiencies reported on this table were assumed to have an oral absorption efficiency of 100%.
(2) Adjusted based on RAGS Part E.
(3) Toxicity values used for exposure through media other than water (sediment, plant, fish, meat).
(4) Chromium (hexavalent) toxicity values used for exposure through aqueous media such as surface water, whereas chromium (trivalent) toxicity values used for exposure through solid media such as food.
(5) The RfD for manganese is based on non-diet sources. The RfD (0.14 mg/kg-day) presented in IRIS includes manganese from all sources, including diet. This RfD was adjusted by subtracting the dietary contribution from the normal U.S. diet (an upper limit of 5 mg/day) and applying a modifying factor of 3 to address uncertainties associated with non-food manganese exposure sources.
(6) Mercury is assumed to be present as mercuric chloride (and other Mercury salts) in sediment and surface water. whereas mercury is assumed to be present as methylmercury in food (animal meat and plants).
(7) No toxicity values were available for the form of phosphorus (adsorbed orthophosphate) expected to be found at the site.
(8) Due to increased uncertainty, PPRTV Appendix toxicity value was not used in the quantitative evaluation of non-carcinogenic hazard.
(9) Consistent with EPA's (November 2019) RSL table, the RfD for vanadium was derived from the IRIS oral RfD for vanadium pentoxide by factoring out the molecular weight of the oxide ion. Vanadium pentoxide has a molecular weight (MW) of 181.88. The two atoms of vanadium contribute 56% of the MW. Vanadium pentoxide's oral RfD of 9E-03 mg/kg-day multiplied by 56% gives a vanadium oral RfD of 5.04E-03 mg/kg-day.
(9) Primary target organs and critical effects for lithium are not specified in the PPRTV document. Studies presented in the PPRTV document indicate lithium exposure is associated with adverse effects on the following target organs/systems: urinary, nervous, endocrine, reproductive, hematological, and developmental.

Definitions:

EPA = U.S. Environmental Protection Agency
HEAST = Health Effects Summary Tables

Notes:

(1) RfC for chromic acid mists and dissolved Cr(VI) aerosols was used.
(2) Although an RfC is available for elemental mercury, this RfC was not used in the evaluation of mercury at OU 5 because it is assumed that mercury is present as mercuric chloride (and other mercury salts) in sediment and surface water and is present as methylmercury in food (animal meat and plants).
(3) The RfC presented on the RSL table is meant to be applied only to particles of crystalline silica (quartz, cristobalite, tridymite), of respirable size; therefore, no RfC value is identified for silica in water vapor.

TABLE 6.1
CANCER TOXICITY DATA -- ORAL/DERMAL
Tar Creek Superfund Site Operable Unit 5 Remedial Investigation
Ottawa County, Oklahoma

Chemical of Potential Concern	Oral Cancer Slope Factor		Oral Absorption Efficiency for Dermal -1	Absorbed Cancer Slope Factor for Dermal (2)		Weight of Evidence/ Cancer Guideline Description	Oral CSF	
	Value	Units		Value	Units		Source(s)	Date(s) (MM/DD/YYYY)

Notes:

(1) Source: Risk Assessment Guidance for Superfund (RAGS). Volume 1: Human Health Evaluation Manual (Part E, Supplemental Guidance for Dermal Risk Assessment) Final. Section 4.2 and Exhibit 4-1. EPA recommends that the oral slope factor should not be adjusted to estimate the absorbed dose for compounds when the absorption efficiency is greater than 50%. Constituents that do not have oral absorption efficiencies reported on this table were assumed to have an oral absorption efficiency of 100%.

(2) Adjusted based on RAGS Part E.

(3) Mercury is assumed to be present as mercuric chloride (and other Mercury salts) in sediment and surface water. whereas mercury is assumed to be present as methylmercury in food (animal meat and plants).

Definitions:

Cal/EPA = California Environmental Protection Agency
CSF = Cancer Slope Factor
IRIS = Integrated Risk Information System
NA = Not Available
mg/kg-day = milligram per kilogram per day

Weight of Evidence definitions:

Group A chemicals (known human carcinogens) are agents for which there is sufficient evidence to support the causal association between exposure to the agents in humans and cancer.
Group C chemicals (possible human carcinogens) are agents for which there is limited evidence of carcinogenicity in animals and inadequate or a lack of human data.
Group D chemicals (not classifiable as to human carcinogenicity) are agents with inadequate human and animal evidence of carcinogenicity or for which no data are available.

TABLE 6.2
CANCER TOXICITY DATA -- INHALATION
Tar Creek Superfund Site Operable Unit 5 Remedial Investigation
Ottawa County, Oklahoma

Chemical of Potential Concern	Unit Risk		Weight of Evidence/ Cancer Guideline Description	Unit Risk	
	Value	Units		Source(s)	Date(s) (MM/DD/YYYY)

Notes:

(1) Consistent with EPA's (November 2019) RSL table, the unit risk for hexavalent chromium is derived by multiplying the IRIS hexavalent chromium value by 7. This is considered to be a health-protective assumption, and is also consistent with the State of California's interpretation of the Mancuso study that forms the basis of hexavalent chromium's estimated cancer potency.

Weight of Evidence definitions:

Group A chemicals (known human carcinogens) are agents for which there is sufficient evidence to support the causal association between exposure to the agents in humans and cancer.
Group B1 chemicals (probable human carcinogens) are agents for which there is limited evidence of possible carcinogenicity in humans.
Group C chemicals (possible human carcinogens) are agents for which there is limited evidence of carcinogenicity in animals and inadequate or a lack of human data.
Group D chemicals (not classifiable as to human carcinogenicity) are agents with inadequate human and animal evidence of carcinogenicity or for which no data are available.

Definitions:

EPA = Environmental Protection Agency
Cal/EPA = California Environmental Protection Agency
IRIS = Integrated Risk Information System
NA = Not Available
PPRTV = Provisional Peer-Reviewed Toxicity Value
RSL = Regional Screening Level
$\mu g/m^3$ = microgram per cubic meter

Notes:
CSF = Cancer slope factor
EPC = Exposure point concentration
NA = Not applicable/Not available
RfC = Reference concentration
RfD = Reference dose
µg/L = microgram per liter
mg/m^3= milligram per cubic meter
mg/kg = milligram per kilogram
mg/kg/day = milligram per kilogram per day
mg/L = milligram per liter

CALCULATION OF DAEVENT
REASONABLE MAXIMUM EXPOSURE
Elm Creek Watershed
Tar Creek Superfund Site Operable Unit 5 Remedial Investigation
Ottawa County, Oklahoma

Scenario Timeframe: Current/Future
Receptor Population: Aquatic Worker
Exposure Scenario: Work Activities

Chemical of Potential Concern	Groundwater Concentration (CW) (mg/L)	Permeability Coefficient (Kp) (cm/hr)	Duration of Event (t_{event}) (hr/event)	DA_{event} (mg/cm^2-event)
Aluminum	7.2E-01	1.0E-03	6.0	4.3E-06
Antimony	2.2E-03	1.0E-03	6.0	1.3E-08
Arsenic	3.1E-03	1.0E-03	6.0	1.9E-08
Barium	7.1E-02	1.0E-03	6.0	4.3E-07
Cadmium (water)	3.9E-02	1.0E-03	6.0	2.3E-07
Chromium (hexavalent)	2.8E-03	2.0E-03	6.0	3.3E-08
Cobalt	7.8E-03	4.0E-04	6.0	1.9E-08
Copper	1.4E-02	1.0E-03	6.0	8.6E-08
Iron	9.4E-01	1.0E-03	6.0	5.6E-06
Lead	6.4E-02	1.0E-04	6.0	3.8E-08
Manganese (non-diet)	6.6E-01	1.0E-03	6.0	3.9E-06
Nickel	1.9E-02	2.0E-04	6.0	2.3E-08
Selenium	5.0E-04	1.0E-03	6.0	3.0E-09
Vanadium	2.2E-03	1.0E-03	6.0	1.3E-08
Zinc	6.7E+00	6.0E-04	6.0	2.4E-05

Equations:

$$DA_{event} = Kp \times CW \times t_{event} \times 0.001\ L/cm^3$$

Notes:
Values for permeability constant (Kp) are from EPA Regional Screening Level Parameter Table (2019)
cm/hr = centimeter per hour
hr = hour
L/cm^3 = liter per cubic centimeter
mg/cm^2-event =milligram per square centimeter per event
mg/L = milligram per liter

Notes:
ADAF = Age-dependent adjustment factor
bgs = below ground surface
CSF = Cancer slope factor
EPC = Exposure point concentration
mg/kg = milligram per kilogram
mg/kg/day = milligram per kilogram per day
mg/L = milligram per liter

Zinc	6.3E+00	6.0E-04	6.0	2.3E-05	6.0	2.3E-05	1.4E+02

Equations:

$$DA_{event} = Kp \times CW \times t_{event} \times 0.001\ L/cm^3$$

$$DA_{event}\text{-}Adj = (DA_{event}\text{-}A \times SA\text{-}A \times EV\text{-}A \times EF\text{-}A \times ED\text{-}A) / BW\text{-}A + (DA_{event}\text{-}C \times SA\text{-}C \times EV\text{-}C \times EF\text{-}C \times ED\text{-}C) / BW\text{-}C$$

Notes:
Values for permeability constant (Kp) are from EPA Regional Screening Level Parameter Table (2019)
cm/hr = centimeter per hour
hr = hour
L/cm^3 = liter per cubic centimeter
mg/cm^2-event = milligram per square centimeter per event
mg/L = milligram per liter
mg/kg = milligram per kilogram

Equations:

$$DA_{event} = Kp \times CW \times t_{event} \times 0.001\ L/cm^3$$

$$DA_{event}\text{-}Adj = (DA_{event}\text{-}A \times SA\text{-}A \times EV\text{-}A \times EF\text{-}A \times ED\text{-}A) / BW\text{-}A + (DA_{event}\text{-}C \times SA\text{-}C \times EV\text{-}C \times EF\text{-}C \times ED\text{-}C) / BW\text{-}C$$

Notes:
Values for permeability constant (Kp) are from EPA Regional Screening Level Parameter Table (2019)
cm/hr = centimeter per hour
hr = hour
L/cm^3 = liter per cubic centimeter
mg/cm^2-event = milligram per square centimeter per event
mg/L = milligram per liter
mg/kg = milligram per kilogram

Zinc	6.3E+00	6.0E-04	1.0	3.8E-06	1.0	3.8E-06	7.9E-01

Equations:

$$DA_{event} = Kp \times CW \times t_{event} \times 0.001\ L/cm^3$$

$$DA_{event}\text{-}Adj = (DA_{event}\text{-}A \times SA\text{-}A \times EV\text{-}A \times EF\text{-}A \times ED\text{-}A) / BW\text{-}A + (DA_{event}\text{-}C \times SA\text{-}C \times EV\text{-}C \times EF\text{-}C \times ED\text{-}C) / BW\text{-}C$$

Notes:
Values for permeability constant (Kp) are from EPA Regional Screening Level Parameter Table (2019)
cm/hr = centimeter per hour
hr = hour
L/cm^3 = liter per cubic centimeter
mg/cm^2-event = milligram per square centimeter per event
mg/L = milligram per liter
mg/kg = milligram per kilogram

CALCULATION OF DAEVENT
REASONABLE MAXIMUM EXPOSURE
Tar Creek Watershed
Tar Creek Superfund Site Operable Unit 5 Remedial Investigation
Ottawa County, Oklahoma

Scenario Timeframe: Current/Future
Receptor Population: General Public
Exposure Scenario: Wading

Exposure Factors	Parameter Code	Units	Adult	Child
Skin Surface Area Available for Contact	SA	cm^2	6,032	2,373
Event Frequency	EV	events/day	1	1
Exposure Frequency	EF	days/year	28	28
Exposure Duration	ED	years	20	6
Body Weight	BW	kg	80	15

Chemical of Potential Concern	Groundwater Concentration (CW) (mg/L)	Permeability Coefficient (Kp) (cm/hr)	Duration of Event (t_{event}) (hr/event)	DA_{event} (mg/cm^2-event)	Duration of Event (t_{event}) (hr)	DA_{event} (mg/cm^2-event)	DA_{event}-Adj (mg/kg)
Aluminum	4.7E-01	1.0E-03	2.0	9.4E-07	2.0	9.4E-07	6.5E-02
Antimony	5.7E-04	1.0E-03	2.0	1.1E-09	2.0	1.1E-09	7.8E-05
Arsenic	3.4E-02	1.0E-03	2.0	6.8E-08	2.0	6.8E-08	4.7E-03
Barium	5.0E-02	1.0E-03	2.0	1.0E-07	2.0	1.0E-07	6.9E-03
Beryllium	2.8E-04	1.0E-03	2.0	5.6E-10	2.0	5.6E-10	3.9E-05
Cadmium (water)	1.6E-02	1.0E-03	2.0	3.3E-08	2.0	3.3E-08	2.2E-03
Chromium (hexavalent)	3.7E-03	2.0E-03	2.0	1.5E-08	2.0	1.5E-08	1.0E-03
Cobalt	3.2E-02	4.0E-04	2.0	2.5E-08	2.0	2.5E-08	1.7E-03
Copper	6.1E-03	1.0E-03	2.0	1.2E-08	2.0	1.2E-08	8.4E-04
Iron	5.1E+01	1.0E-03	2.0	1.0E-04	2.0	1.0E-04	7.1E+00
Lead	3.7E-02	1.0E-04	2.0	7.4E-09	2.0	7.4E-09	5.1E-04
Manganese (non-diet)	1.6E+00	1.0E-03	2.0	3.2E-06	2.0	3.2E-06	2.2E-01
Mercury (HgCl)	5.8E-05	1.0E-03	2.0	1.2E-10	2.0	1.2E-10	7.9E-06
Molybdenum	1.0E-02	1.0E-03	2.0	2.0E-08	2.0	2.0E-08	1.4E-03
Nickel	3.3E-01	2.0E-04	2.0	1.3E-07	2.0	1.3E-07	9.2E-03
Selenium	8.1E-04	1.0E-03	2.0	1.6E-09	2.0	1.6E-09	1.1E-04
Silica (as SIO2)	1.6E+01	1.0E-03	2.0	3.1E-05	2.0	3.1E-05	2.1E+00
Silver	2.2E-04	6.0E-04	2.0	2.7E-10	2.0	2.7E-10	1.8E-05
Thallium	2.3E-04	1.0E-03	2.0	4.5E-10	2.0	4.5E-10	3.1E-05
Vanadium	8.2E-03	1.0E-03	2.0	1.6E-08	2.0	1.6E-08	1.1E-03
Zinc	6.3E+00	6.0E-04	2.0	7.6E-06	2.0	7.6E-06	5.2E-01

Equations:

$$DA_{event} = Kp \times CW \times t_{event} \times 0.001\ L/cm^3$$

$$DA_{event}\text{-}Adj = (DA_{event}\text{-}A \times SA\text{-}A \times EV\text{-}A \times EF\text{-}A \times ED\text{-}A) / BW\text{-}A + (DA_{event}\text{-}C \times SA\text{-}C \times EV\text{-}C \times EF\text{-}C \times ED\text{-}C) / BW\text{-}C$$

Notes:
Values for permeability constant (Kp) are from EPA Regional Screening Level Parameter Table (2019)
cm/hr = centimeter per hour
hr = hour
L/cm^3 = liter per cubic centimeter
mg/cm^2-event = milligram per square centimeter per event
mg/L = milligram per liter
mg/kg = milligram per kilogram

Receptor Total (Sediment + Swimming + Potable Use + Sweat Lodge + Aquatic Biota)											NA					3E+02

Notes:
CSF = Cancer slope factor
EPC = Exposure point concentration
NA = Not applicable/Not available
RfC = Reference concentration
RfD = Reference dose
µg/L = microgram per liter
mg/m^3= milligram per cubic meter
mg/kg = milligram per kilogram
mg/kg/day = milligram per kilogram per day
mg/L = milligram per liter

Medium Total											1.1E-03					NA
Receptor Total (Sediment + Swimming + Potable Use + Sweat Lodge + Aquatic Biota)											7E-03					NA

Notes:
CSF = Cancer slope factor
EPC = Exposure point concentration
NA = Not applicable/Not available
RfC = Reference concentration
RfD = Reference dose
µg/L = microgram per liter
mg/m^3= milligram per cubic meter
mg/kg = milligram per kilogram
mg/kg/day = milligram per kilogram per day
mg/L = milligram per liter

TABLE 7.17.RME SUPPLEMENT A

CALCULATION OF CHEMICAL CANCER RISKS FOR COPC WITH MUTAGENIC MODE OF ACTION

REASONABLE MAXIMUM EXPOSURE

Neosho River Watershed

Tar Creek Superfund Site Operable Unit 5 Remedial Investigation

Ottawa County, Oklahoma

Scenario Timeframe: Current/Future
Receptor Population: Tribal Lifeway
Receptor Age: Adult/Child Aggregate

Medium	Exposure Medium	Exposure Point	Exposure Route	COPC	EPC		Cancer Risk Calculations										
							Intake					CSF/Unit Risk

Cobalt	4.6E-03	4.0E-04	6.0	1.1E-08
Copper	1.3E-02	1.0E-03	6.0	7.7E-08
Iron	6.9E+00	1.0E-03	6.0	4.2E-05
Lead	4.5E-03	1.0E-04	6.0	2.7E-09
Manganese (non-diet)	2.5E-01	1.0E-03	6.0	1.5E-06
Molybdenum	8.0E-04	1.0E-03	6.0	4.8E-09
Nickel	9.4E-03	2.0E-04	6.0	1.1E-08
Selenium	5.0E-04	1.0E-03	6.0	3.0E-09
Vanadium	5.1E-03	1.0E-03	6.0	3.1E-08
Zinc	7.6E-02	6.0E-04	6.0	2.7E-07

Equations:

$$DA_{event} = Kp \times CW \times t_{event} \times 0.001\ L/cm^3$$

Notes:
Values for permeability constant (Kp) are from EPA Regional Screening Level Parameter Table (2019)
cm/hr = centimeter per hour
hr = hour
L/cm^3 = liter per cubic centimeter
mg/cm^2-event = milligram per square centimeter per event
mg/L = milligram per liter

	Exposure Medium Total										NA					2.1E+02
Medium Total											NA					2.3E+02
Receptor Total (Sediment + Swimming + Potable Use + Sweat Lodge + Aquatic Biota)											NA					3E+02

Notes:
CSF = Cancer slope factor
EPC = Exposure point concentration
NA = Not applicable/Not available
RfC = Reference concentration
RfD = Reference dose
µg/L = microgram per liter
mg/m^3= milligram per cubic meter
mg/kg = milligram per kilogram
mg/kg/day = milligram per kilogram per day
mg/L = milligram per liter

Medium Total											8.7E-05					1.0E+00
Receptor Total (Sediment + Surface Water)											1E-04					3E+00

Notes:
CSF = Cancer slope factor
EPC = Exposure point concentration
NA = Not applicable/Not available
RfC = Reference concentration
RfD = Reference dose
mg/kg = milligram per kilogram
mg/kg/day = milligram per kilogram per day
mg/L = milligram per liter

TABLE 7.25.RME SUPPLEMENT A
CALCULATION OF DAEVENT
REASONABLE MAXIMUM EXPOSURE
Elm Creek Watershed
Tar Creek Superfund Site Operable Unit 5 Remedial Investigation
Ottawa County, Oklahoma

Scenario Timeframe: Current/Future
Receptor Population: Aquatic Worker
Exposure Scenario: Work Activities

Chemical of Potential Concern	Groundwater Concentration (CW) (mg/L)	Permeability Coefficient (Kp) (cm/hr)	Duration of Event (t_{event}) (hr/event)	DA_{event} (mg/cm^2-event)
Aluminum	1.4E+00	1.0E-03	6.0	8.4E-06
Arsenic	8.4E-03	1.0E-03	6.0	5.1E-08
Barium	7.5E-02	1.0E-03	6.0	4.5E-07
Cadmium (water)	1.8E-03	1.0E-03	6.0	1.1E-08
Chromium (hexavalent)	3.3E-03	2.0E-03	6.0	3.9E-08
Cobalt	7.9E-03	4.0E-04	6.0	1.9E-08
Copper	6.4E-03	1.0E-03	6.0	3.8E-08
Iron	1.8E+00	1.0E-03	6.0	1.1E-05
Lead	1.1E-02	1.0E-04	6.0	6.4E-09
Manganese (non-diet)	2.3E-01	1.0E-03	6.0	1.4E-06
Nickel	1.5E-02	2.0E-04	6.0	1.7E-08
Selenium	2.0E-03	1.0E-03	6.0	1.2E-08
Silica (as SIO2)	1.5E+01	1.0E-03	6.0	9.3E-05
Silver	3.4E-04	6.0E-04	6.0	1.2E-09
Thallium	4.1E-04	1.0E-03	6.0	2.5E-09
Vanadium	7.4E-03	1.0E-03	6.0	4.4E-08
Zinc	5.9E-01	6.0E-04	6.0	2.1E-06

Equations:

$$DA_{event} = Kp \times CW \times t_{event} \times 0.001\ L/cm^3$$

Notes:
Values for permeability constant (Kp) are from EPA Regional Screening Level Parameter Table (2019)
cm/hr = centimeter per hour
hr = hour
L/cm^3 = liter per cubic centimeter
mg/cm^2-event =milligram per square centimeter per event
mg/L = milligram per liter

Notes:
CSF = Cancer slope factor
EPC = Exposure point concentration
NA = Not applicable/Not available
RfC = Reference concentration
RfD = Reference dose
µg/L = microgram per liter
mg/kg = milligram per kilogram
mg/kg/day = milligram per kilogram per day
mg/L = milligrams per liter

Receptor Total (Sediment + Surface Water)											1E-05					1E+00

Notes:

CSF = Cancer slope factor
EPC = Exposure point concentration
NA = Not applicable/Not available
RfC = Reference concentration
RfD = Reference dose
mg/kg = milligram per kilogram
mg/kg/day = milligram per kilogram per day
mg/L = milligram per liter

TABLE 7.32.RME SUPPLEMENT A
CALCULATION OF DAEVENT
REASONABLE MAXIMUM EXPOSURE
Lost Creek Watershed
Tar Creek Superfund Site Operable Unit 5 Remedial Investigation
Ottawa County, Oklahoma

Scenario Timeframe: Current/Future
Receptor Population: Aquatic Worker
Exposure Scenario: Work Activities

Chemical of Potential Concern	Groundwater Concentration (CW) (mg/L)	Permeability Coefficient (Kp) (cm/hr)	Duration of Event (t_{event}) (hr/event)	DA_{event} (mg/cm^2-event)
Aluminum	3.6E-01	1.0E-03	6.0	2.1E-06
Barium	7.2E-02	1.0E-03	6.0	4.3E-07
Cadmium (water)	3.7E-05	1.0E-03	6.0	2.2E-10
Copper	5.0E-02	1.0E-03	6.0	3.0E-07
Iron	3.2E-01	1.0E-03	6.0	1.9E-06
Lead	1.2E-01	1.0E-04	6.0	7.1E-08
Manganese (non-diet)	1.2E-01	1.0E-03	6.0	7.3E-07
Nickel	1.8E-03	2.0E-04	6.0	2.2E-09
Vanadium	4.0E-04	1.0E-03	6.0	2.4E-09
Zinc	4.6E-02	6.0E-04	6.0	1.6E-07

Equations:

$$DA_{event} = Kp \times CW \times t_{event} \times 0.001\ L/cm^3$$

Notes:
Values for permeability constant (Kp) are from EPA Regional Screening Level Parameter Table (2019)
cm/hr = centimeter per hour
hr = hour
L/cm^3 = liter per cubic centimeter
mg/cm^2-event =milligram per square centimeter per event
mg/L = milligram per liter

Notes:
CSF = Cancer slope factor
EPC = Exposure point concentration
NA = Not applicable/Not available
RfC = Reference concentration
RfD = Reference dose
µg/L = microgram per liter
mg/kg = milligram per kilogram
mg/kg/day = milligram per kilogram per day
mg/L = milligrams per liter

	Exposure Medium Total										2.1E-05					NA
Medium Total											2.1E-05					NA
Receptor Total (Sediment + Swimming + Potable Use + Fish)											2E-05					NA
Receptor Total (Sediment + Wading + Potable Use + Fish)											2E-05					NA

Notes:
CSF = Cancer slope factor
EPC = Exposure point concentration
NA = Not applicable/Not available
RfC = Reference concentration
RfD = Reference dose
µg/L = microgram per liter
mg/kg = milligram per kilogram
mg/kg/day = milligram per kilogram per day
mg/L = milligrams per liter

Zinc	2.5E-01	6.0E-04	6.0	9.1E-07	6.0	9.1E-07	5.6E+00

Equations:

$$DA_{event} = Kp \times CW \times t_{event} \times 0.001\ L/cm^3$$

$$DA_{event}\text{-}Adj = (DA_{event}\text{-}A \times SA\text{-}A \times EV\text{-}A \times EF\text{-}A \times ED\text{-}A) / BW\text{-}A + (DA_{event}\text{-}C \times SA\text{-}C \times EV\text{-}C \times EF\text{-}C \times ED\text{-}C) / BW\text{-}C$$

Notes:
Values for permeability constant (Kp) are from EPA Regional Screening Level Parameter Table (2019)
cm/hr = centimeter per hour
hr = hour
L/cm^3 = liter per cubic centimeter
mg/cm^2-event = milligram per square centimeter per event
µg/L = microgram per liter
mg/kg = milligram per kilogram

Selenium	4.7E-04	1.0E-03	0.71	3.4E-10	0.54	2.6E-10	2.4E-03
Silica (as SIO2)	1.5E+01	1.0E-03	0.71	1.1E-05	0.54	8.2E-06	7.8E+01
Thallium	8.0E-04	1.0E-03	0.71	5.7E-10	0.54	4.3E-10	4.1E-03
Vanadium	2.2E-03	1.0E-03	0.71	1.5E-09	0.54	1.2E-09	1.1E-02
Zinc	2.5E-01	6.0E-04	0.71	1.1E-07	0.54	8.2E-08	7.8E-01

Equations:

$$DA_{event} = Kp \times CW \times t_{event} \times 0.001\ L/cm^3$$

$$DA_{event}\text{-}Adj = (DA_{event}\text{-}A \times SA\text{-}A \times EV\text{-}A \times EF\text{-}A \times ED\text{-}A) / BW\text{-}A + (DA_{event}\text{-}C \times SA\text{-}C \times EV\text{-}C \times EF\text{-}C \times ED\text{-}C) / BW\text{-}C$$

Notes:
Values for permeability constant (Kp) are from EPA Regional Screening Level Parameter Table (2019)
cm/hr = centimeter per hour
hr = hour
L/cm^3 = liter per cubic centimeter
mg/cm^2-event = milligram per square centimeter per event
µg/L = microgram per liter
mg/kg = milligram per kilogram

Molybdenum	3.9E-03	1.0E-03	6.0	2.3E-08
Nickel	9.5E-03	2.0E-04	6.0	1.1E-08
Selenium	4.7E-04	1.0E-03	6.0	2.8E-09
Silica (as SIO2)	1.5E+01	1.0E-03	6.0	9.1E-05
Thallium	8.0E-04	1.0E-03	6.0	4.8E-09
Vanadium	2.2E-03	1.0E-03	6.0	1.3E-08
Zinc	2.5E-01	6.0E-04	6.0	9.1E-07

Equations:

$$DA_{event} = Kp \times CW \times t_{event} \times 0.001\ L/cm^3$$

Notes:
Values for permeability constant (Kp) are from EPA Regional Screening Level Parameter Table (2019)
cm/hr = centimeter per hour
hr = hour
L/cm^3 = liter per cubic centimeter
mg/cm^2-event =milligram per square centimeter per event
mg/L = milligram per liter

Thallium	8.0E-04	1.0E-03	0.71	5.7E-10	0.54	4.3E-10	1.4E-03
Vanadium	2.2E-03	1.0E-03	0.71	1.5E-09	0.54	1.2E-09	3.7E-03
Zinc	2.5E-01	6.0E-04	0.71	1.1E-07	0.54	8.2E-08	2.6E-01

Equations:

$$DA_{event} = Kp \times CW \times t_{event} \times 0.001\ L/cm^3$$

$$DA_{event}\text{-}Adj = (DA_{event}\text{-}A \times SA\text{-}A \times EV\text{-}A \times EF\text{-}A \times ED\text{-}A) / BW\text{-}A + (DA_{event}\text{-}C \times SA\text{-}C \times EV\text{-}C \times EF\text{-}C \times ED\text{-}C) / BW\text{-}C$$

Notes:
Values for permeability constant (Kp) are from EPA Regional Screening Level Parameter Table (2019)
cm/hr = centimeter per hour
hr = hour
L/cm^3 = liter per cubic centimeter
mg/cm^2-event = milligram per square centimeter per event
µg/L = microgram per liter
mg/kg = milligram per kilogram

Notes:
CSF = Cancer slope factor
EPC = Exposure point concentration
NA = Not applicable/Not available
RfC = Reference concentration
RfD = Reference dose
µg/L = microgram per liter
mg/kg = milligram per kilogram
mg/kg/day = milligram per kilogram per day
mg/L = milligrams per liter

TABLE 9.24.RME
SUMMARY OF RECEPTOR RISKS AND HAZARDS FOR COPCs
REASONABLE MAXIMUM EXPOSURE
Beaver Creek Watershed
Tar Creek Superfund Site Operable Unit 5 Remedial Investigation
Ottawa County, Oklahoma

Scenario Timeframe: Current/Future
Receptor Population: Tribal Lifeway
Receptor Age: Adult/Child Aggregate

Medium	Exposure Medium	Exposure Point	Chemical of Potential Concern	Carcinogenic Risk				Non-Carcinogenic Hazard Quotient
