Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

ProUCL computes and outputs H-statistic based UCLs for historical reasons only.
H-statistic often results in unstable (both high and low) values of UCL95 as shown in examples in the Technical Guide.
It is therefore recommended to avoid the use of H-statistic based 95% UCLs.
Use of nonparametric methods are preferred to compute UCL95 for skewed data sets which do not follow a gamma distribution.

Suggested UCL to Use

95% KM Approximate Gamma UCL	0.386	95% GROS Approximate Gamma UCL	0.27

When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test
When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)
For such situations, GROS method may yield incorrect values of UCLs and BTVs
This is especially true when the sample size is small.
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)
For such situations, GROS method may yield incorrect values of UCLs and BTVs
This is especially true when the sample size is small.
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)
For such situations, GROS method may yield incorrect values of UCLs and BTVs
This is especially true when the sample size is small.
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Suggested UCL to Use

95% KM (t) UCL 140.5

When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test
When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Nonparametric Distribution Free UCL Statistics

Detected Data appear Approximate Normal Distributed at 5% Significance Level

Suggested UCL to Use

95% KM (t) UCL 3.107

When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test
When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Gamma Statistics on Detected Data Only

k hat (MLE)	0.6	k star (bias corrected MLE)	0.541
Theta hat (MLE)	3.335	Theta star (bias corrected MLE)	3.703
nu hat (MLE)	22.82	nu star (bias corrected)	20.55
Mean (detects)	2.002		

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Minimum	0.01	Mean	1.73
Maximum	20.8	Median	0.55
SD	4.519	CV	2.612
k hat (MLE)	0.442	k star (bias corrected MLE)	0.412
Theta hat (MLE)	3.916	Theta star (bias corrected MLE)	4.201

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)
For such situations, GROS method may yield incorrect values of UCLs and BTVs
This is especially true when the sample size is small.
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Minimum	0.01	Mean	0.933

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)
For such situations, GROS method may yield incorrect values of UCLs and BTVs
This is especially true when the sample size is small.
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Maximum Detect	4.31	Maximum Non-Detect	0.06
Variance Detects	1.919	Percent Non-Detects	11.11%
Mean Detects	1.136	SD Detects	1.385
Median Detects	0.66	CV Detects	1.219
Skewness Detects	2.136	Kurtosis Detects	4.769
Mean of Logged Detects	-0.449	SD of Logged Detects	1.194

Note: Sample size is small (e.g., <10), if data are collected using ISM approach, you should use
guidance provided in ITRC Tech Reg Guide on ISM (ITRC, 2012) to compute statistics of interest.
For example, you may want to use Chebyshev UCL to estimate EPC (ITRC, 2012).
Chebyshev UCL can be computed using the Nonparametric and All UCL Options of ProUCL 5.1

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)
For such situations, GROS method may yield incorrect values of UCLs and BTVs
This is especially true when the sample size is small.
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

k hat (MLE)	1.835	k star (bias corrected MLE)	1.297
Theta hat (MLE)	2.188	Theta star (bias corrected MLE)	3.095
nu hat (MLE)	33.03	nu star (bias corrected)	23.35
Mean (detects)	4.016		

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)
For such situations, GROS method may yield incorrect values of UCLs and BTVs
This is especially true when the sample size is small.
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)
For such situations, GROS method may yield incorrect values of UCLs and BTVs
This is especially true when the sample size is small.
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)
For such situations, GROS method may yield incorrect values of UCLs and BTVs
This is especially true when the sample size is small.
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

95% KM (BCA) UCL	N/A		

Warning: One or more Recommended UCL(s) not available!

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

nu hat (MLE)	62.45	nu star (bias corrected)	52.76
Mean (detects)	3.095		

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)
For such situations, GROS method may yield incorrect values of UCLs and BTVs
This is especially true when the sample size is small.
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Minimum	0.01	Mean	2.771
Maximum	14	Median	1.77
SD	3.067	CV	1.107
k hat (MLE)	0.785	k star (bias corrected MLE)	0.696

Nonparametric Distribution Free UCL Statistics

Detected Data appear Approximate Normal Distributed at 5% Significance Level

Suggested UCL to Use

95% KM (t) UCL 0.0468

When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test
When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)
For such situations, GROS method may yield incorrect values of UCLs and BTVs
This is especially true when the sample size is small.
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Mean (detects)	0.307		

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)
For such situations, GROS method may yield incorrect values of UCLs and BTVs
This is especially true when the sample size is small.
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Appendix E
Analysis of Lead Exposure

APPENDIX E

Analysis of Lead Exposure

E.1 Introduction

This appendix presents the approach, assumptions, and results of the assessment of lead exposure in the human health risk assessment (HHRA) for Tar Creek Superfund Site Operable Unit 5 (OU5). The approach was discussed with the U.S. Environmental Protection Agency (EPA) on August 29, 2019. EPA's Technical Review Workgroup Lead Committee was consulted regarding the approach for lead evaluation for the OU5 study area. The TRW review comments and responses provided on December 17, 2019 (EPA, 2019), are presented in Attachment A of this appendix.

The purpose of the lead analysis is to identify potential unacceptable risk associated with exposure to lead in environmental media within the OU5 study area. Given the elevated concentrations of lead in OU5 study area media that are already known, a conscious effort was made to evaluate potential lead exposures efficiently and effectively without expending considerable effort in identifying specific exposure parameter values characterizing unique OU5 study area exposure scenarios. This approach results in identifying exposure media associated with the potential for elevated blood lead levels (BLLs).

E.2 Approach for Evaluation of Lead Exposure

E.2.1 Integrated Exposure Uptake Biokinetic Model

The potential risks associated with child exposures to lead (tribal lifeway and general public) were evaluated using the Integrated Exposure Uptake Biokinetic (IEUBK) Model for Lead in Children, Windows, Version 1.1, Build 11 (EPA, 2010). The IEUBK model provides predictions of BLLs for children from ages 0 to 7 years with exposure to lead in various media. This model addresses three components of risk assessments: the multi-media nature of exposures to lead, lead pharmacokinetics, and significant variability in exposure and risk, through estimation of probability distributions of BLLs for children exposed to similar environmental concentrations. The IEUBK model is a probabilistic model designed to predict the cumulative distribution of BLLs based on central tendency exposure (CTE) parameter values. Therefore, the arithmetic mean values of the lead concentrations in sediment[1] and surface water[2] (as shown in Table 1 of this appendix, and as presented in the Risk Assessment Guidance for Superfund [RAGS] Table 3 series in Appendix B of the HHRA) were used as soil and drinking water exposure point concentrations (EPCs), respectively, in the analysis.[3] All the other default input parameter values in the IEUBK model (Table 2) were used for the initial analysis, except for the mother's BLL at childbirth, which was updated to 0.6 micrograms per deciliter (µg/dL) based on the recommendation by EPA (EPA, 2017a). Additionally, recently updated default lead intake values through food consumption were used in the model (Table 3). Further, following current EPA guidance (EPA, 2017b), the default age range of 0 to 84 months was modified to 12 to 72 months based on the U.S. Centers for Disease Control and Prevention's recommendation. Tables 2 and 3 summarize the general and age-specific IEUBK input parameter values used in the analysis.

[1] The higher EPC between unsieved and sieved sediment data is used as the final EPC.

[2] The "total" (rather than "dissolved") lead concentration is used as the EPC.

[3] The IEUBK model does not address sediment and surface water specifically but does address soil and drinking water. Therefore, sediment was addressed as soil and surface water was addressed as drinking water in the model.

The IEUBK model results are expressed as the predicted geometric mean (GM) BLL for children and the percentage of the child population with potential BLLs above the target BLL. Based on the EPA Office of Land and Emergency Management (OLEM) policy (EPA, 1994), which strives to reduce lead exposure levels so that there is no more than a 5 percent probability that children exposed to lead will exceed a BLL of 10 µg/dL, 10 µg/dL was used as a target BLL. Additionally, the current scientific literature on lead toxicology and epidemiology provides evidence that adverse health effects are associated with BLLs less than 10 µg/dL (EPA, 2016). Therefore, lead exposure was assessed using two additional, lower target BLLs (5 and 8 µg/dL) based on consultation with EPA Region 6.

IEUBK output is presented in Attachment B.

E.2.2 Adult Lead Methodology

An interim approach to assessing potential risks associated with adult exposures to lead was developed by EPA's TRW for Lead (EPA, 2003a) and updated in 2017 (EPA, 2017c). This methodology is a variation of the IEUBK model. The Adult Lead Methodology (ALM) model is used to evaluate potential risks to fetuses of women exposed to lead in non-residential settings. The model estimates fetal BLLs in pregnant women exposed to lead in soil (EPA, 2003a).[4]

Because the ALM is a probabilistic model, the arithmetic mean lead concentration was used as the EPC, consistent with EPA guidance (EPA, 2003a). Additionally, central tendency values for ingestion rate and exposure frequency were estimated and used in the ALM model. Without specific information regarding sediment ingestion rate for aquatic workers, an ingestion rate of 100 milligrams per day (mg/day), equal to EPA's default adult reasonable maximum exposure (RME) residential soil ingestion rate (EPA, 2014), was used as a conservative CTE ingestion rate. Additionally, an exposure frequency of 219 days per year (days/year) was assumed for the aquatic worker, as recommended in the ALM frequently asked questions[5]. This value is a CTE estimate for non-residential exposure scenarios (i.e., both commercial and industrial), and corresponds to the average time spent at work by both full- and part-time workers engaged in non-contact-intensive activities. The geometric standard deviation (GSD) and baseline BLLs from the most recent 6 years (2009 to 2014) of data from the National Health and Nutrition Examination Survey, as recommended by EPA (2017a), were used in the ALM model.

The ALM model was used to calculate potential BLLs for the aquatic worker scenario. The model results are expressed as the predicted GM BLL, the corresponding 95th percentile fetal BLLs, and the probability that fetuses exposed to lead will exceed a BLL above the same set of target BLLs (5, 8, and 10 µg/dL) used in the IEUBK model.

ALM output is presented in Attachment C.

E.3 Risk Characterization

E.3.1 Results of Evaluation

E.3.1.1 IEUBK

The estimated probabilities that children exposed to lead will exceed a target BLL of 5 µg/dL, as summarized in Table 4, were greater than 5 percent for all watersheds except Neosho River and Lost Creek. Note that statistical tests (central tendency tests) indicate that both sediment and surface water concentrations in Neosho River and Lost Creek are comparable to background (CH2M, 2020).

[4] The ALM model does not address sediment specifically, but does address soil. Therefore, sediment was addressed as soil in the model.

[5] https://www.epa.gov/superfund/lead-superfund-sites-frequent-questions-risk-assessors-adult-lead-methodology#industrial%20worker

The estimated probabilities that children exposed to lead will exceed target BLLs of 8 and 10 µg/dL were less than 5 percent for two additional watersheds (Beaver Creek and Lower Spring River).

E.3.1.2 ALM

The estimated probabilities that fetuses exposed to lead will exceed target BLLs of 5 and 8 µg/dL, as summarized in Table 4, were greater than 5 percent for two watersheds (Elm Creek and Tar Creek). Of these two watersheds, the estimated probability that fetuses exposed to lead will exceed a target BLL of 10 µg/dL was less than 5 percent for Tar Creek. The estimated probabilities that fetuses exposed to lead will exceed target BLLs of 5, 8, and 10 µg/dL were less than 5 percent for the other four watersheds (Neosho River, Beaver Creek, Lost Creek, and Lower Spring River).

E.3.2 Conclusion

Based on the initial IEUBK (using the default IEUBK input parameter values for children) and ALM (using a conservatively estimated CTE sediment ingestion rate and exposure frequency for aquatic workers) analyses of lead exposure, lead was identified as a preliminary chemical of concern (COC) in the following watersheds:

- Tribal lifeway child – Elm Creek, Tar Creek, Beaver Creek, and Lower Spring River (further analysis of lead was performed in the uncertainty analysis below)
- General public child – Elm Creek, Tar Creek, Beaver Creek, and Lower Spring River
- Aquatic worker – Elm Creek and Tar Creek

E.4 Uncertainty Analysis

E.4.1 Additional Analysis for Tribal Lifeway Children Based on RME Values

An additional analysis of potential lead exposure was performed using RME input parameter values. RME values were used in this additional analysis as high-end exposure estimates to avoid the extensive effort to develop CTE values representative of specific tribal lifeway exposure scenarios. It is acknowledged that there are considerable uncertainties associated with the use of these RME parameter values in the IEUBK model since the model is designed to predict the cumulative distribution of BLLs based on CTE parameter values. However, this additional analysis was performed so that, in combination with the results of the initial analysis, a range of potential lead exposure and risk outcomes could be evaluated.

E.4.1.1 Approach

For the additional analysis using the IEUBK model for tribal lifeway children, the focus was on three key exposure pathways (sediment ingestion, drinking water ingestion, and food consumption [i.e., dietary intake]) considered to be the most significant exposure pathways for the tribal lifeway exposure scenario and the most influential on model output. Consistent with the RME values identified in the HHRA (Appendix B, RAGS Table 4 series), the following RME input parameter values were used in the additional analysis:

- Soil/dust (sediment) – RME sediment ingestion rate of 400 mg/day (adapted from Harper, 2008).
- Drinking water – RME drinking water ingestion rate of 0.78 liter per day (EPA, 2014).
- Diet – Lead intake from consumption of aquatic food obtained from the OU5 study area was estimated based on adult ingestion rates (Harper, 2008) and EPA's Exposure Factors Handbook and updates (EPA, 2011, 2018a, 2018b). The detailed approach and assumptions used in the calculation of lead intake through food consumption are presented in Table 5.

Table 3 summarizes the RME values used in the additional analysis in comparison to the default IEUBK model values used in the initial analysis. The additional analysis was performed using the same sediment and surface water EPCs used in the initial analysis and a target BLL of 5 µg/dL.

E.4.1.2 Results

The IEUBK model predicted a geometric mean BLL above 30 µg/dL (which is above the level that can be analyzed by the IEUBK model) for all six watersheds, as well as Fourmile Creek which was selected as a background or reference location (Table 6). The IEUBK model is not validated at levels above a geometric mean BLL of 30 µg/dL, however, and the results should be evaluated with caution. The results do not reflect the actual magnitude of the risk. That is, a higher intake rate does not mean a higher BLL. Observational data indicates that there is a non-linear relationship (curvilinear relationship) between intake rate (micrograms per day) and BLL. Although there is a considerable degree of uncertainty associated with the conservative nature of RME assumptions used in this additional analysis, lead cannot be excluded as a preliminary COC based on the results of the additional analysis. Therefore, lead was identified as a preliminary COC for all six watersheds.

E.4.2 Time-Weighted Average Analysis of Lead Exposure for General Public Children

General public children were assumed to contact sediment and surface water at an exposure frequency of 28 days/year under a recreational user scenario (in comparison to the tribal lifeway exposure frequency of 312 days/year). Because of this low frequency of exposure, an evaluation of lead EPCs based on time-weighted average (TWA) concentrations accounting for exposure outside of the OU5 study area (i.e., at residential yards) was conducted to estimate potential impacts on IEUBK model results.

E.4.2.1 Approach

First, an attempt was made to estimate acceptable lead concentrations in soil/sediment for each watershed using the IEUBK model. The acceptable lead concentrations in soil/sediment, corresponding to the probability that 5 percent of exposed children will exceed the target BLL of 5 µg/dL, were estimated for each watershed based on its surface water EPC[6] (as the drinking water EPC) and default IEUBK input parameter values.

Second, while the sediment EPC for each watershed was kept as a fixed value, TWA concentrations were estimated for various combinations of the three variables below:

- Exposure time spent at an OU5 study area water body: 0.5 and 1 hour
- Exposure frequency to visit an OU5 study area water body: 1 and 2 days/week
- Lead concentration in residential yard: 50, 120, 250, and 400 milligrams per kilogram (mg/kg)

Lastly, each TWA concentration was compared to the modeled acceptable soil/sediment lead concentration to identify which combinations of the three variables achieve the acceptable lead concentrations.

The TRW has recommended that the IEUBK model and the ALM be applied to exposures that exceed a minimum frequency of 1 day per week (day/week) and a duration of 3 consecutive months (EPA, 2003b). As discussed in Appendix B, RAGS Table 4.1, the exposure frequency of 28 days/year was selected for general public receptors, assuming 1 day/week of exposure during the 7 months between April and October. Based on the TRW's recommendation, two exposure frequencies were used to

[6] Although as lead concentrations in soil/sediment decrease, lead concentrations in surface water are expected to decrease proportionally, current surface water EPCs were used as drinking water EPCs without an established correlation between sediment and surface water lead concentrations.

calculate TWA concentrations (1 day/week and 2 days/week). An exposure frequency higher than 2 days/week was not used because assuming even the shortest exposure duration of 3 months (or roughly 13 weeks), an exposure frequency of 3 days/week (corresponding to an annual exposure frequency of 39 days/year) would exceed the RME exposure frequency of 28 days/year.

E.4.2.2 Results

Due to elevated lead concentrations in surface water, no acceptable soil/sediment concentrations were established for Elm Creek and Tar Creek; lead intake through drinking water alone exceeds the acceptable level. For Beaver Creek and Lower Spring River, 59 mg/kg and 123 mg/kg, respectively, were calculated as acceptable soil/sediment concentrations based on their respective surface water EPCs and default IEUBK input parameter values (Table 7). Evaluation of TWA was not performed for Neosho River and Lost Creek because the results of the initial analysis already indicate that concentrations of lead in sediment and surface water in these two watersheds are acceptable.

TWA concentrations calculated based on various combinations of the three variables indicated that the range of exposure time and exposure frequency values has little impact on the calculated TWA concentrations (Table 8). Because of the short exposure time and infrequent exposure to sediment at the OU5 study area, soil concentrations in residential yards control the TWA concentrations. Therefore, the lead concentration in OU5 study area sediment has little impact on TWA concentrations. EPCs based on TWA concentrations accounting for exposure outside of the OU5 study area (i.e., residential yards) could result in lower BLLs only when lead concentrations in residential yards are approximately the same as the calculated acceptable lead concentration in soil/sediment.

E.4.3 Analysis of Dissolved Lead Concentrations in Surface Water

Dissolved lead concentrations in surface water were noticeably lower than total lead concentrations. Statistical comparisons of site data with background levels indicated that dissolved lead concentrations in surface water in all watersheds except Tar Creek are comparable to background (Table 1). Therefore, if receptors used a water treatment system on their drinking water supply (assumed to be surface water in the HHRA), their lead exposure through potable use of surface water would be lower than that predicted based on total lead concentrations in surface water.

E.4.4 Limitations of IEUBK/ALM Model Exposure Scenarios

Various potentially complete exposure pathways and scenarios were identified and evaluated in the HHRA for the receptors identified at the OU5 study area. However, all pathways and scenarios were not addressed in the lead exposure analysis using the IEUBK or ALM models presented in this appendix due to limitations associated with the models. For instance, although lead exposure through dermal contact was not evaluated in either model, this exposure route is not considered to be the primary route of exposure for lead. Additionally, potential additional lead exposure during sweat lodge use for tribal lifeway children (ingestion, dermal contact, and inhalation) and through incidental ingestion and dermal contact to surface water during hunting/fishing/gathering and recreational activities was not included in the analysis. Table 9 summarizes the exposure pathways and scenarios addressed in the lead exposure analysis and qualitative assessment of potential impact from not including some of the exposure pathways and scenarios. Although there are limitations associated with the lead exposure analysis performed using the IEUBK and ALM models, lead is identified as a preliminary COC for all watersheds, including those with lead in sediment and surface water at levels comparable to background levels. Therefore, the purpose of the lead analysis (i.e., to identify potential unacceptable risk associated with exposure to lead in environmental media within the OU5 study area) was adequately achieved.

E.5 Conclusions

Based on the results of the initial and additional lead exposure analysis, lead was conservatively identified as a preliminary COC in sediment and surface water for all six watersheds under the tribal lifeway child scenario. Based on the results of the initial lead exposure analysis, lead was identified as a preliminary COC in sediment for two watersheds (Elm Creek and Tar Creek) under the aquatic worker scenario. Lead was also identified as a preliminary COC in sediment and surface water in two additional watersheds (Beaver Creek and Lower Spring River) under the general public child scenario. Please note that sediment and surface water EPCs in these two watersheds are below the screening levels identified in Section 3.2 of the HHRA; however, lead was conservatively identified as a preliminary COC for these watersheds under the general public child scenario.

Consistent with Section 6.4 of the HHRA, a refinement of lead as a final COC was conducted based on the results of background comparisons. Although COC refinement was performed for other metals using a two-step process, the second step of the refinement process (i.e., elimination of preliminary COCs based on the nature of mine-related contamination) was not performed for lead because lead is a primary COC at the OU5 study area. Based on the results of background comparisons, lead was eliminated as a final COC from Neosho River and Lost Creek because statistical background comparisons (central tendency) indicate that lead concentrations in sediment and surface water at these watersheds are not greater than background. The list of watersheds where lead is identified as a final COC is summarized in Table 10.

As stated in Section E.1, the purpose of this lead analysis is to identify potential unacceptable risk associated with exposure to lead in OU5 environmental media. The biokinetic models were run as a tool to determine if lead poses unacceptable risk to potential human receptors at OU5 rather than to characterize the magnitude of potential exposure. The streamlined approach was taken because of limitations of the IEUBK model in assessing specific tribal exposure scenarios and the goal of efficiently determining whether lead is a preliminary COC without expending considerable effort in identifying specific exposure parameter values characterizing unique OU5 study area exposure scenarios. The objective was reviewed by EPA's Technical Review Workgroup Lead Committee. Although a considerable degree of uncertainty associated with use of high-end exposure assumptions (e.g., food and sediment ingestion rates that are far above CTE values) and the conservative approach taken in the analyses was acknowledged, the primary objective of the lead analysis at this stage of the investigation was accomplished. The preliminary remediation goal for lead, which is a risk-based concentration accounting for the magnitude of potential exposure, will be identified in the feasibility study stage of the project.

Notes:

Units for concentrations in sediment are presented in mg/kg and concentrations in surface water are presented in mg/L.

[a] Matrix: SED - sediment; SW - surface water

[b] Average concentrations were used as EPCs. When lead was not detected, one-half the reporting limit was used in the calculation.

[c] UTLs were calculated as 95% upper confidence bounds of the 95th percentiles of the background data (presented in Section 6 tables from the RI report). UTLs calculated without a definitive distributional assumption of the data (i.e., normal, gamma, or lognormal) have a coverage probability less than 95%.

[d] Comparisons of individual site sample concentrations to background threshold values were conducted assuming one-half the reporting limit for non-detects.

[e] Additional statistical analysis indicates that site and background concentrations are comparable.

[f] Eliminated three high non-detected results from the calculation of EPC.

-- = not available/not applicable

Acronyms:

BTV = background threshold value

EPC = exposure point concentration

RI = remedial investigation

RL = reporting limit

SL = screening level

UTL = upper tolerance limit

UTL95-95 = 95% upper tolerance limit with 95% coverage

Units:

mg/L = milligrams per liter

mg/kg = milligrams per kilogram

Appendix E, Table 2. Summary of General IEUBK Input Parameter Values Used in the Analyses

Tar Creek Superfund Site Operable Unit 5 Remedial Investigation

Ottawa County, Oklahoma

Parameter	Value	Basis
Soil concentration (mg/kg)	Site-specific	EPC sediment concentration (mean concentrations)
Dust concentration (mg/kg)	0.7 x (soil concentration) + (air concentration x 100)	IEUBK Default. Indoor dust lead is derived using multiple source analysis
Outdoor air concentration (µg/m^3)	0.1	IEUBK Default (EPA, 1994b, 2007)
Indoor air concentration (µg/m^3)	30% of outdoor air concentration	IEUBK Default (EPA, 1994b)
Drinking water concentration (µg/L)	Site-specific	EPC surface water concentration (mean concentrations)
Maternal BLL at birth (µg/dL)[a]	0.6	Based on National Health and Nutrition Examination Survey (NHANES) update (2009-2014) (EPA, 2017)
Absorption fractions at low intakes:		IEUBK Default (EPA, 1994b)
Air (lung absorption)	32%	
Soil/dust	30%	
Water	50%	
Diet	50%	
Soil/dust ingestion weighting factor (percent soil)	45%	EPA, 1994b
Geometric standard deviation	1.6	EPA, 1994b
Target BLL (µg/dL)	5, 8, and 10	10 µg/dL is based on EPA, 2016. The lower target BLLs (5 and 8 µg/dL) also evaluated for comparison.

Note:

[a] Maternal BLL at birth does not impact results for the 12- to 72-month age range.

Acronyms:

BLL = blood lead level

EPA = U.S. Environmental Protection Agency

EPC = exposure point concentration

IEUBK = Integrated Exposure Uptake Biokinetic

OLEM = Office of Land and Emergency Management

OSWER = Office of Solid Waste and Emergency Response

Units:

µg/dL = micrograms per deciliter

µg/L = micrograms per liter

µg/m^3 = micrograms per cubic meter

mg/kg = milligrams per kilogram

Notes:

[a] Analysis of lead exposure was performed for child receptors using the IEUBK model based on the site-specific sediment and surface water EPCs.

Sediment EPCs were used as soil EPCs, while surface water EPCs were used as drinking water EPCs.

Default values were used for the other IEUBK input parameter values.

[b] Analysis of lead exposure was performed for aquatic workers using the ALM model based on the site-specific sediment EPCs.

A central tendency soil (sediment) ingestion rate of 100 mg/day and exposure frequency of 219 days/year were used for the aquatic worker.

The GSD and baseline BLL from the most recent 6 years (2009-2014) of blood lead data from the NHANES were used in the ALM model.

[c] Average concentrations were used as EPCs.

[d] Sediment EPCs were calculated for unsieved and sieved datasets separately and the higher of the two was used as the final EPC.

[e] Total metal data were used.

[f] Eliminated three high non-detected results from the calculation of EPC.

† No statistically significant difference from background.

* Greater than the target probability of 5%.

Acronyms:

ALM = Adult Lead Methodology

BLL = blood lead level

EPC = exposure point concentration

GM = geometric mean

GSD = geometric standard deviation

IEUBK = Integrated Exposure Uptake Biokinetic

NHANES = National Health and Nutrition Examination Survey

Units:

µg/dL = micrograms per deciliter

µg/L = micrograms per liter

mg/kg = milligrams per kilogram

Notes:

[a] Information about age-specific body weight and food consumption rates was obtained from EPA Exposure Factors Handbook.

[b] Body weight adjusted food consumption rates (in g/kg-day) in the EFH are converted to consumption rates in grams per day by multiplying by age-specific body weight.

[c] Child/Adult fractions were calculated by dividing child food consumption rate by adult food consumption rate.

[d] Summary of Child/Adult fractions used to estimate age-specific child food consumption rates.

Fish - Child/Adult fractions based on finfish data.

Shellfish and Frog - Child/Adult fractions based on shellfish data.

Mammal - Child/Adult fractions based on total meat data.

Plant - Child/Adult fractions based on total vegetable data.

[e] RME food ingestion rates established for tribal lifeway adult based on Harper (2008). See Tables 4.6 and 4.7 RME.

[f] Food consumption rates for child were calculated by multiplying adult food consumption rate by Child/Adult fraction.

[g] Lead EPC (average concentrations) are presented in Tables 3.5 through 3.11 RME.

[h] Lead intake through food consumption was estimated by multiplying food consumption rates by lead EPC.

Acronyms:

EPA = U.S. Environmental Protection Agency

EPC = exposure point concentration

EFH = Exposure Factors Handbook

RME = reasonable maximum exposure

Units:

µg/day = micrograms per day

µg/g = micrograms per gram

g/day = grams per day

g/kg-day = grams per kilogram per day

mg/kg = milligrams per kilogram

Appendix E, Table 6. Summary of Additional Lead Exposure Analysis for Tribal Lifeway Child Using IEUBK Model

Tar Creek Superfund Site Operable Unit 5 Remedial Investigation

Ottawa County, Oklahoma

Receptor	Model	Parameter Value	Watershed						
			Fourmile Creek (reference)	Elm Creek	Tar Creek	Neosho River	Beaver Creek	Lost Creek	Lower Spring River
Tribal Lifeway Child	IEUBK[a,b]	Sediment EPC (mg/kg)[c,d]	27.1	4281	1095	37.8 †	275	168 †	146
		Surface Water EPC (µg/L)[c,e]	2.4	63.6	36.8	4.5 †	10.6	2.7 †,[f]	6.2 †
		GM BLL (µg/dL)	126 **	142 **	131 **	126 **	128 **	127 **	127 **

Notes:

[a] Analysis of lead exposure was performed for child receptors using the IEUBK model based on the site-specific sediment and surface water EPCs.

Sediment EPCs were used as soil EPCs, while surface water EPCs were used as drinking water EPCs.

[b] RME values (presented for Additional Analysis in Appendix E Table 3) were used for the soil ingestion, drinking water, and food consumption exposure pathways.

[c] Average concentrations were used as EPCs.

[d] Sediment EPCs were calculated for unsieved and sieved datasets separately and the higher of the two was used as the final EPC.

[e] Total metal data were used.

[f] Eliminated three high non-detected results from the calculation of EPC.

† No statistically significant difference from background.

** Greater than the IEUBK Model BLL limit of 30 µg/dL. It should be noted that the IEUBK model is not validated at levels above GM BLL of 30 µg/dL and should be evaluated with caution. The results do not reflect the actual magnitude of the risk. That is, the higher intake rate does not mean higher BLL. Observational data indicate that there is a non-linear relationship (curvilinear relationship) between intake rate (µg/day) and BLL.

Acronyms:

BLL = blood lead level

EPC = exposure point concentration

GM = geometric mean

IEUBK = Integrated Exposure Uptake Biokinetic

RME = reasonable maximum exposure

Units:

µg/dL = micrograms per deciliter

µg/L = micrograms per liter

mg/kg = milligrams per kilogram

Appendix E, Table 7. Summary of Estimated Acceptable Soil/Sediment Concentrations

Tar Creek Superfund Site Operable Unit 5 Remedial Investigation

Ottawa County, Oklahoma

Receptor	Model	Parameter Value	Watershed[e]						
			Fourmile Creek (reference)	Elm Creek	Tar Creek	Neosho River	Beaver Creek	Lost Creek	Lower Spring River
General Public	IEUBK[a]	Surface Water EPC (µg/L)[b,c]	2.4	63.6	36.8	4.5 †	10.6	2.7 †, [f]	6.2 †
Child		Acceptable Soil/Sediment (mg/kg)	176	too high[d]	too high[d]	146 [e]	59	173 [e]	123
Presented for reference		Sediment EPC (mg/kg)	27.1	4,281	1,095	37.8 †	275	168 †	146

Notes:

[a] The acceptable soil/sediment concentrations corresponding to 5% of population exceeding BLL of 5 µg/dL were estimated using the IEUBK model. Although as lead concentrations in soil/sediment decrease, lead concentrations in surface water are expected to decrease proportionally, surface water EPCs were retained to be used as drinking water EPCs, while default values were used for the other input parameters in the IEUBK Model.

[b] Average concentrations were used as EPCs.

[c] Total metal data were used.

[d] No acceptable soil/sediment concentration can be achieved due to high concentration of lead in drinking water (surface water). Lead intake from drinking water (surface water) pathway is too high to achieve the lead exposure goal.

[e] Sediment concentrations in Neosho River and Lost Creek are already lower than the acceptable soil/sediment concentrations without using time-weighted average.

† No statistically significant difference from background.

Acronyms:

µg/L = micrograms per liter

BLL = blood lead level

EPC = exposure point concentration

IEUBK = Integrated Exposure Uptake Biokinetic

mg/kg = milligrams per kilogram

1	0.25	0.75	0.14	0.86	0.29	0.71
1	0.25	0.75	0.14	0.86	0.29	0.71
1	0.25	0.75	0.14	0.86	0.29	0.71
1	0.25	0.75	0.14	0.86	0.29	0.71
IEUBK default time spent outdoor			4	hr/day		

Notes:

Equation[1]: PbS_w = EF_site x [(F_site x PbS_site) + (F_yard x PbS_yard)] + (EF_yard x PbS_yard)

Where:

EF_site = Fraction of year (exposure frequency) at which a child visits the site (days/week).

EF_yard = Fraction of year (exposure frequency) child does not visit the site (EF_yard = 1 - EF_site) (unitless).

F_site = Fraction of daily outdoor time spent at OU5 site. The IEUBK lead model default value for total time spent by a child 0 to 6 years old playing outdoors is limited to 4 hours (unitless).

F_yard = Fraction of outdoor time a child spends in their yard (F_yard = 1 - F_site) (unitless).

PbS_site = Average sediment lead concentration at the site (mg/kg).

PbS_w = TWA soil lead concentration (mg/kg).

PbS_yard = Average soil concentration in their yard (mg/kg).

Exceed Exceeds acceptable Soil/Sediment Concentration

It was simply assumed that when the receptor is not spending time at OU5, they spend their time at their residential yard.

hr/day = hours per day

mg/kg = milligrams per kilogram

Appendix E, Table 9. Exposure Scenarios Addressed by the Analyses using the IEUBK and ALM Models

Tar Creek Superfund Site Operable Unit 5 Remedial Investigation

Ottawa County, Oklahoma

Exposure Medium	Exposure Scenario/Receptor Population									
	Tribal Lifeway	Exposure Pathway	IEUBK (initial)	IEUBK (additional)	Aquatic Worker	Exposure Pathway	ALM	General Public	Exposure Pathway	IEUBK (initial)
Sediment	Hunting/fishing/gathering and recreational activities	Incidental Ingestion	√(+,-)[b]	√(++)	Work activities	Incidental Ingestion	√	Recreational activities	Incidental Ingestion	√(+)[b]
		Dermal Contact [a]	(-)			Dermal Contact [a]	(-)		Dermal Contact [a]	(-)
Surface Water	Hunting/fishing/gathering and recreational activities	Incidental Ingestion	√ (-) [c]	√ [c]	Work activities	Incidental Ingestion	(-)	Recreational activities	Incidental Ingestion	√ (-) [c]
		Dermal Contact [a]	(-)			Dermal Contact [a]	(-)		Dermal Contact [a]	(-)
	Potable source	Ingestion	√	√(++)				Potable source	Ingestion	√
		Dermal Contact [a]	(-)					Dermal Contact	Dermal Contact [a]	(-)
	Sweat lodge use	Ingestion	√ (-) [c]	√ [c]						
		Dermal Contact [a]	(-)							
		Inhalation (water vapor)	(-)							
Fish	Food consumption	Ingestion	√(+,-) [d]	√(++) [d]				Fish consumption		√(+,-) [d]
Shellfish	Food consumption	Ingestion	√(+,-) [d]	√(++) [d]						
Aquatic Plant as Food	Food consumption	Ingestion	√(+,-) [d]	√(++) [d]						
Aquatic Plant as Salve	Medicinal use	Dermal Contact [a]	(-)							
Amphibian/Aquatic Reptile	Food consumption	Ingestion	√(+,-) [d]	√(++) [d]						
Semi-Aquatic mammal	Food consumption	Ingestion	√(+,-) [d]	√(++) [d]						

Notes:

[a] IEUBK/ALM does not evaluate lead exposure through dermal contact.

[b] Lead exposure through incidental ingestion of sediment was evaluated based on residential exposure assumptions.

[c] Ingestion of surface water as potable source was assumed to include exposure from other scenarios.

[d] Ingestion of OU5 food items was evaluated as part of regular U.S. diet for the initial analysis. The dietary intake of lead was calculated conservatively based on ingestion rates in Harper (2008), EPA EFH and updates (EPA, 2011, 2018a, 2018b), and site-specific data in the additional analysis (Appendix E Table 5).

√ - The exposure pathway was evaluated in the analysis.

Qualitative evaluation of potential impact on overall risk assessment conclusion:

(++) - Analysis using the RME exposure assumptions likely overestimates potential lead exposure for Tribal Lifeway child.

(+) - Analysis using the IEUBK default input parameter values likely overestimates potential lead exposure occurring during recreational activities.

(+,-) Although analysis using the IEUBK default input parameter values are considered an appropriate representation of potential lead exposure, it may over- or underestimate lead exposure through exposure media within OU5.

(-) - Analysis does not include potential lead exposure through the specific exposure pathway; therefore, it likely underestimates potential lead exposure.

Acronyms:

ALM = Adult Lead Methodology

IEUBK = Integrated Exposure Uptake Biokinetic

Tribal Lifeway (child) [b]	Lead	Yes (s/us)	Lead	Yes (s/us)	Lead	No (s/us)	Lead	Yes (s/us)	Lead	No (s/us)	Lead	Yes (s/us)
General Public (child) [b]	Lead	Yes (s/us)	Lead	Yes (s/us)			Lead	Yes (s/us)			Lead	Yes (s/us)

Notes:

[a] Results of background comparisons are presented as follows:

Yes (s/us)	site > bkgd based on both sieved and unsieved data
No (s/us)	no statistical difference between site and bkgd based on both sieved and unsieved data
Yes	site > bkgd; statistically significant increase in site concentrations above bkgd
No	no statistical difference between site and bkgd

[b] Conclusions are based on the results of child receptors using the IEUBK model, which addresses multi-media nature of exposure to lead. Child receptors are more sensitive to lead than adult receptors.

Refinement of lead as the final COC.

To select lead as a final COC, the results of background comparison were reviewed.
When statistical background comparison (central tendency) indicates lead concentrations in site medium are not greater than background, lead was eliminated as a final COC. When the background comparison indicates site > bkgd, lead was identified as a final COC.

Because lead has been identified as a primary contaminant of concern, no further evaluation of lead was performed based on the nature of mine-related contamination.

Lead Final COC

Acronyms:

Bkgd = background

COC = chemical of concern

Attachment A
Memorandum, TRW Lead Committee Consultation: Review of OU5 Tar Creek Superfund Site

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY
WASHINGTON, D.C. 20460

Technical Review Workgroup Lead Committee

An interoffice workgroup convened by Office of Superfund Remediation and Technology Innovation

MEMORANDUM

Date: December 17, 2019

Subject: TRW Lead Committee Consultation: Review of OU5 Tar Creek Superfund Site

From: Michele Burgess, Todd Phillips, and James Brown
Co-Chairpersons of the Technical Review Workgroup Lead Committee

To: Katrina Coltrain, US EPA Region 6
Ghassan Khoury, US EPA Region 6

The Technical Review Workgroup (TRW) Lead Committee prepared this memorandum in response to your request on November 7, 2019 for review of Tar Creek (OU5) Superfund Site in Region 6.

During the teleconference with TRW Lead Committee on November 14, you presented information on the site that informed the following comments.

- While the memo acknowledges that using sediment and surface water Exposure Point Concentrations (EPCs) as soil and drinking water inputs for the risk calculations is an overestimate of exposure, they do not quantify the magnitude of the overestimate. It is recommended that a time-weighted analysis using site-specific or reasonable estimates of exposure to these site media along with appropriate residential media concentrations be included in the Human Health Risk Assessment (HHRA) to inform risk management.
- For Model Run 2, the selected ingestion rate of 400 mg/day for sediment seems very high compared to what is typically used for children (generally 100 mg/day or less). Central tendency estimates are recommended for risk assessment.

- For the assessment of tribal lifeways that include intake of alternative media (like plants), one approach would be to calculate the intake (in µg of Pb per day) for each medium or species comprising that medium (e.g., plant type) and to evaluate whether the intake is greater than 1 µg Pb/day. Those below 1 µg Pb/day may be considered to contribute minimally to risk (this is analogous to P5 soil exposures differing by < 20 ppm). Given that all the alternate media intakes exceed 1 µg Pb/day media, those media may be candidates for risk management consideration. Are public health entities developing local food intake recommendations for other biota (e.g., https://www.deq.ok.gov/state-environmental-laboratory-services/environmental-public-health-information/healthy-fish-consumption-in-oklahoma/tar-creek/)?
- Exposure to metal contaminants in river water through sweat lodge use may be a complete pathway; however, the lead (dissolved or suspended in particulates) would not be vaporized (only the water) so the inhalation and dermal exposures to lead during sweat lodge use are likely to be negligible relative to intakes from using that water as a source of drinking water.
- Because some of the exposure inputs (exposure point concentrations and inputs) result in IEUBK model predictions that exceed 30 µg/dL, these suggest that exposure is unacceptable. That the IEUBK model has not been validated for such high exposures is not an issue; the objective of modeling is to determine whether there is unacceptable risk rather than precisely quantifying the level of that risk exceedance.
- Development of PRGs is typically a risk management activity and is generally based on exposure to those exposure media within EPA's authority for this site (commonly soil, sediment, and surface water). For the risk assessment (which generally precedes the development of PRGs), consideration of other media (such as local or home-grown produce or game) may be appropriate as determined by the conceptual site model.

From File	Tar Creek OU5 RI Surface Water Dissolved Metals ProUCL Input.xls
Full Precision	OFF
Confidence Coefficient	95%
Number of Bootstrap Operations	2000

Antimony, dissolved (mg/L)

General Statistics

Total Number of Observations	8	Number of Distinct Observations	3
Number of Detects	0	Number of Non-Detects	8
Number of Distinct Detects	0	Number of Distinct Non-Detects	3

Warning: All observations are Non-Detects (NDs), therefore all statistics and estimates should also be NDs!
Specifically, sample mean, UCLs, UPLs, and other statistics are also NDs lying below the largest detection limit!
The Project Team may decide to use alternative site specific values to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable Antimony, dissolved (mg/L) was not processed!

Cadmium, dissolved (mg/L)

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Minimum	6.0000E-5	Mean	0.0131
Maximum	0.0876	Median	0.01

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Mean (detects)	8.0000E-4		

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Appendix F3, Table 2. Mine Discharge Exposure Point Concentration Summary

Tar Creek Superfund Site Operable Unit 5 Remedial Investigation
Ottawa County, Oklahoma

Notes:

[a] ProUCL Version 5.1.002 (EPA, 2016) and user guide (EPA, 2015) were used to calculate the EPCs.
[b] The arithmetic mean values, calculated using 1/2 the detection limit for non-detected values, were used as the lead EPCs.

Statistics: Maximum - Maximum detected value
Adjusted Gamma - UCL adjusted for level significance assuming gamma distribution
KM (t) - UCL based upon Kaplan-Meier estimates using the Student's t-distribution critical value
KM Adjusted Gamma - UCL based upon Kaplan-Meier estimates, adjusted for level significance assuming gamma distribution
Student's-t - UCL based on Student's t statistic assuming normal distribution

(1) Shapiro-Wilk W/Lilliefors Test indicates data are normally distributed.
(2) Anderson-Darling and/or Kolmogorov-Smirnov Tests indicate data are gamma distributed.
(3) The maximum detected concentration was used as the EPC because there were less than 8 samples or 4 detected concentrations.
(4) The arithmetic mean concentration was used as the EPC for lead.

µg/L = micrograms per liter
EPC = exposure point concentration
J = result is estimated
NA = not available
UCL = upper confidence limit

EPA. 2015. ProUCL Version 5.1 User Guide. Statistical Software for Environmental Applications for Data Sets with and without Nondetect Observations. EPA/600/R-07/041. October.

Notes:

[a] Surface water hazard quotients for chemicals detected in mine discharge as presented in Appendix B RAGS Part D Table 9.9 (child TLW receptor at Tar Creek) and 9.23 (child TLW receptor at Beaver Creek).

[b] Mine discharge hazard quotients calculated based on the same exposure factors as surface water.

EPC = exposure point concentration

HI = hazard index

MD = mine discharge

mg/L = milligrams per liter

NA = not applicable

SW = surface water

TLW = tribal lifeway

Appendix F3, Table 4. Comparison of ELCR Estimates between Surface Water and Mine Discharge Data (Tribal Lifeway)

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Minimum	0.01	Mean	31.2
Maximum	85.81	Median	27.74
SD	21.56	CV	0.691

Nonparametric Distribution Free UCL Statistics

Detected Data appear Approximate Normal Distributed at 5% Significance Level

Suggested UCL to Use

95% KM (t) UCL 40.51

When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test
When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Arsenic (µg/L)

General Statistics

Total Number of Observations	4	Number of Distinct Observations	4
		Number of Missing Observations	0
Minimum	8.8	Mean	24.82
Maximum	50.86	Median	19.81
SD	19.29	Std. Error of Mean	9.645
Coefficient of Variation	0.777	Skewness	1.052

Note: Sample size is small (e.g., <10), if data are collected using ISM approach, you should use guidance provided in ITRC Tech Reg Guide on ISM (ITRC, 2012) to compute statistics of interest.
For example, you may want to use Chebyshev UCL to estimate EPC (ITRC, 2012).
Chebyshev UCL can be computed using the Nonparametric and All UCL Options of ProUCL 5.1

Normal GOF Test

Shapiro Wilk Test Statistic	0.896	**Shapiro Wilk GOF Test**
5% Shapiro Wilk Critical Value	0.748	Data appear Normal at 5% Significance Level

Barium (µg/L)

General Statistics

Total Number of Observations	2	Number of Distinct Observations	2
		Number of Missing Observations	0
Minimum	15.3	Mean	16.1
Maximum	16.9	Median	16.1

Warning: This data set only has 2 observations!
Data set is too small to compute reliable and meaningful statistics and estimates!
The data set for variable Barium (µg/L) was not processed!

It is suggested to collect at least 8 to 10 observations before using these statistical methods!
If possible, compute and collect Data Quality Objectives (DQO) based sample size and analytical results.

95% KM Adjusted Gamma UCL	2.842	95% GROS Adjusted Gamma UCL	2.717

When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test
When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Chromium (µg/L)

General Statistics

Total Number of Observations	3	Number of Distinct Observations	3
Number of Detects	1	Number of Non-Detects	2
Number of Distinct Detects	1	Number of Distinct Non-Detects	2

Warning: Only one distinct data value was detected! ProUCL (or any other software) should not be used on such a data set!
suggested to use alternative site specific values determined by the Project Team to estimate environmental parameters (e.g., EPC, BT

The data set for variable Chromium (µg/L) was not processed!

Warning: Data set has only 3 Detected Values.
This is not enough to compute meaningful or reliable statistics and estimates.

Note: Sample size is small (e.g., <10), if data are collected using ISM approach, you should use guidance provided in ITRC Tech Reg Guide on ISM (ITRC, 2012) to compute statistics of interest.
For example, you may want to use Chebyshev UCL to estimate EPC (ITRC, 2012).
Chebyshev UCL can be computed using the Nonparametric and All UCL Options of ProUCL 5.1

Suggested UCL to Use

95% Student's-t UCL 204

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Molybdenum (µg/L)

General Statistics

Total Number of Observations	1	Number of Distinct Observations	1
		Number of Missing Observations	0
Minimum	5.5	Mean	5.5
Maximum	5.5	Median	5.5

Warning: This data set only has 1 observations!
Data set is too small to compute reliable and meaningful statistics and estimates!
The data set for variable Molybdenum (µg/L) was not processed!

It is suggested to collect at least 8 to 10 observations before using these statistical methods!
If possible, compute and collect Data Quality Objectives (DQO) based sample size and analytical results.

Nickel (µg/L)

General Statistics

Total Number of Observations	20	Number of Distinct Observations	20
		Number of Missing Observations	0
Minimum	20.27	Mean	27.5
Maximum	36.79	Median	27.75
SD	5.281	Std. Error of Mean	1.181
Coefficient of Variation	0.192	Skewness	0.219

Appendix F5, Table 3. Summary of Receptor Hazards for Final Watershed Specific Biota COCs - Tribal Lifeway Child [a]

Tar Creek Superfund Site Operable Unit 5 Remedial Investigation

Ottawa County, Oklahoma

Exposure Medium	Exposure Point	Exposure Route	Elm Creek	% [c] contribution	Tar Creek	% [c] contribution	Lower Spring River	% [c] contribution
Non-Carcinogenic Hazard Index [b]								
Aquatic Biota Animal/Plant	Shellfish	Ingestion	NA		NA		3	15%
	Aquatic Plant (food)	Ingestion	124	100%	37	100%	16	85%
	Total (Biota) [c]		124	100%	37	100%	19	100%
	Target Organ-Specific Total HI	Dermal	NA		NA		≤ 1	
		Gastrointestinal	3		≤ 1		≤ 1	
		Hematologic	27		12		7	
		Immune	27		12		7	
		Urinary	94		24		11	
		Whole Body	NA		≤ 1		≤ 1	
	Final Biota COCs [b]		Cadmium	76%	Cadmium	66%	Barium	5.1%
			Copper	2.0%	Copper	0.1%	Cadmium	53%
			Zinc	22%	Nickel	0.4%	Copper	1.6%
					Silver	NA	Nickel	2.8%
					Zinc	33%	Silver	0.8%
							Zinc	37%
Total (Receptor) [c]			124	100%	37	100%	19	100%

Notes:

[a] Because the child exposure scenario yields higher non-carcinogenic HI than the adult exposure scenario, a summary of non-carcinogenic HI for the final COCs is presented for child exposure scenario.

[b] The lists of final COCs on this table do not include lead. The evaluation of lead exposure was performed in Appendix E. Final COCs for each watershed are based on Table 5-12. Although Neosho River has HI>1 for shellfish and Lost Creek has HI>1 for aquatic plants, when considering only the final COCs for these watersheds, the HIs are less than 1 for all target organs.

[c] Percent (%) contribution for each exposure route and total (exposure medium) is calculated as percentage of total (receptor) HI. Percent contribution for final COC is calculated on an exposure medium basis as percentage of total (exposure medium).

Acronyms:

COC = chemical of concern

HI = hazard index

NA = not applicable; target organ is not associated with the final COCs

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)
For such situations, GROS method may yield incorrect values of UCLs and BTVs
This is especially true when the sample size is small.
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Suggested UCL to Use

95% KM (t) UCL	0.0796

When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test
When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)
For such situations, GROS method may yield incorrect values of UCLs and BTVs
This is especially true when the sample size is small.
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Nonparametric Distribution Free UCL Statistics

Detected Data appear Approximate Normal Distributed at 5% Significance Level

Suggested UCL to Use

95% KM (t) UCL	0.0877

When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test
When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL

Appendix F5, Table 5. ProUCL Output - Whole Fish Tissue (Tar Creek)
Tar Creek Superfund Site Operable Unit 5 Remedial Investigation
Ottawa County, Oklahoma

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Suggested UCL to Use

95% KM (t) UCL	0.428

When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test
When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

ProUCL computes and outputs H-statistic based UCLs for historical reasons only.
H-statistic often results in unstable (both high and low) values of UCL95 as shown in examples in the Technical Guide.
It is therefore recommended to avoid the use of H-statistic based 95% UCLs.
Use of nonparametric methods are preferred to compute UCL95 for skewed data sets which do not follow a gamma distribution.

Suggested UCL to Use

95% H-UCL	59.43

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

ProUCL computes and outputs H-statistic based UCLs for historical reasons only.
H-statistic often results in unstable (both high and low) values of UCL95 as shown in examples in the Technical Guide.
It is therefore recommended to avoid the use of H-statistic based 95% UCLs.
Use of nonparametric methods are preferred to compute UCL95 for skewed data sets which do not follow a gamma distribution.

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)
For such situations, GROS method may yield incorrect values of UCLs and BTVs
This is especially true when the sample size is small.
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)
For such situations, GROS method may yield incorrect values of UCLs and BTVs
This is especially true when the sample size is small.
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Nonparametric Distribution Free UCL Statistics

Detected Data appear Approximate Normal Distributed at 5% Significance Level

Suggested UCL to Use

95% KM (t) UCL	0.237

When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test
When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL

Appendix F5, Table 6. ProUCL Output - Whole Fish Tissue (Neosho River)
Tar Creek Superfund Site Operable Unit 5 Remedial Investigation
Ottawa County, Oklahoma

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

ProUCL computes and outputs H-statistic based UCLs for historical reasons only.
H-statistic often results in unstable (both high and low) values of UCL95 as shown in examples in the Technical Guide.
It is therefore recommended to avoid the use of H-statistic based 95% UCLs.
Use of nonparametric methods are preferred to compute UCL95 for skewed data sets which do not follow a gamma distribution.

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)
For such situations, GROS method may yield incorrect values of UCLs and BTVs
This is especially true when the sample size is small.
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Minimum	0.01	Mean	0.0516
Maximum	0.168	Median	0.0462

Nonparametric Distribution Free UCL Statistics

Detected Data appear Approximate Gamma Distributed at 5% Significance Level

Suggested UCL to Use

95% KM Adjusted Gamma UCL	0.0807	95% GROS Adjusted Gamma UCL	0.0796

When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test
When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL

Appendix F5, Table 7. ProUCL Output - Whole Fish Tissue (Lower Spring River)
Tar Creek Superfund Site Operable Unit 5 Remedial Investigation
Ottawa County, Oklahoma

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Suggested UCL to Use

95% Student's-t UCL	0.47

When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test
When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Note: For highly negatively-skewed data, confidence limits (e.g., Chen, Johnson, Lognormal, and Gamma) may not be reliable. Chen's and Johnson's methods provide adjustments for positvely skewed data sets.

Suggested UCL to Use

95% Student's-t UCL	32.15	or 95% Modified-t UCL	32.71
or 95% H-UCL	30.99		

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

ProUCL computes and outputs H-statistic based UCLs for historical reasons only.
H-statistic often results in unstable (both high and low) values of UCL95 as shown in examples in the Technical Guide.
It is therefore recommended to avoid the use of H-statistic based 95% UCLs.
Use of nonparametric methods are preferred to compute UCL95 for skewed data sets which do not follow a gamma distribution.

Nonparametric Distribution Free UCL Statistics

Detected Data appear Approximate Normal Distributed at 5% Significance Level

Suggested UCL to Use

95% KM (t) UCL 3.179

When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test
When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)
For such situations, GROS method may yield incorrect values of UCLs and BTVs
This is especially true when the sample size is small.
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Suggested UCL to Use

95% Student's-t UCL	38.29

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

P-Value > Alpha (0.05)

Notes:

Data were analyzed using EPA ProUCL software (Version 5.1.002) (2016).

[a] Interpretation of the results: Lead concentrations in the head of fish are statistically significantly higher (alpha = 0.05) than the estimated "total" lead concentrations in whole fish.

On average, lead concentrations in the head are about 35.6% higher than the estimated "total" lead concentrations in whole fish.

[b] Interpretation of the results: There is no statistically significant increase (alpha = 0.05) in lead concentrations in the fish fillet or carcass compared to the estimated "total" lead concentrations in whole fish.

Nickel	Whole Body	1.7E+00	3.8E-01	1.4E+00	3.1E-01	3.6E+00	7.9E-01	5.4E-01	1.2E-01
Zinc	Immune, Hematologic	1.4E+03	2.1E+01	7.9E+02	1.2E+01	1.8E+03	2.7E+01	1.8E+01	2.6E-01
Exposure Route Total			91		43		125		0.9
Exposure Scenario Total			91		43		125		0.9
Target Organ-Specific HI	Total Gastrointestinal HI =		2		1		3		0.2
	Total Immune HI =		21		12		27		0.3
	Total Hematologic HI =		21		12		27		0.3
	Total Urinary HI =		67		30		95		0.3
	Total Whole Body HI =		0.4		0.3		0.8		0.1

Notes:

[a] Total Plant HQ from RAGS Part D Table 9s.

[b] Leaves, Roots, and Tubers HQs are calculated using a risk ratio:
(Total Plant HQ/Total Plant EPC) x Leaves, Roots, or Tubers EPC

COPC = chemical of potential concern

EPC = exposure point concentration

HI = hazard index

HQ = hazard quotient

mg/kg = milligrams per kilogram

NA = not applicable/available

ND = not detected
