# Executive Summary

The Sherwin-Williams Company (Sherwin-Williams) is conducting a Remedial Investigation/ Feasibility Study (RI/FS) pursuant to Administrative Order on Consent (AOC) Index No. II CERCLA-02-99-2035 (US EPA Region II, 1999). This report presents the results of a Human Health Risk Assessment (HHRA) that was conducted for the Former Manufacturing Plant (FMP) in Gibbsboro, New Jersey.

The HHRA characterized the risk to human health from exposure to soil, sediment, and surface water at the FMP. The FMP was divided into four exposure areas: North of Foster Avenue (NFA), South of Foster Avenue (SFA), the Undeveloped Area (UNDV), and East of United States Avenue (EUSA). A section of Upper Hilliards Creek (UHC) is evaluated together with the UNDV for some receptors. The receptors evaluated in this HHRA included a Construction Worker, Utility Worker, and Outdoor Worker; child and adult Recreator; and adult and child Resident. Soil exposure pathways included incidental ingestion of soil, dermal contact with soil, and inhalation of vapors and particulates potentially emitted from soil. Soil was evaluated in the 0- to 10-foot (ft) or 0- to 2-ft depth interval, depending on the receptor. Sediment exposure pathways included incidental ingestion and dermal contact. Surface water exposure pathways included dermal contact while wading.

Chemicals of potential concern (COPCs) were determined for each exposure area and medium. COPCs in soil and sediment were determined by comparing the detected concentrations to conservative risk-based screening criteria (the lower of the United States Environmental Protection Agency [EPA] residential Regional Screening Level [RSL] or the New Jersey Residential Direct Contact Soil Remediation Standards [NJ RDCSRS]). COPCs in surface water were determined by comparing to EPA RSLs for tap water. In the absence of an RSL, the lower of the New Jersey surface water quality standard and federal Ambient water quality standard was used for surface water. Soil COPCs included metals, cyanide, polycyclic aromatic hydrocarbon (PAH) compounds, polychlorinated biphenyl (PCB) compounds, pesticides, semi-volatile organic compounds (SVOCs), volatile organic compounds (VOCs), and tentatively identified compounds (TICs). Sediment COPCs included metals, cyanide, PCB compounds, PAH compounds, and a TIC. Surface water COPCs included metals, cyanide, PAH compounds and VOCs. It should be noted that the COPCs in each medium were not necessarily COPCs in every exposure area.

Cancer risks and non-cancer hazards were evaluated following EPA guidance, using conservative estimates of exposure that tend to overestimate rather than underestimate, risk. An example of this conservatism is the assumption that a future Resident would live on the site for 26 years. Cancer risks are characterized as the incremental probability that an individual will develop cancer over a lifetime due to site-related exposures under the specific exposure scenarios evaluated. EPA's target cancer risk range is 1 in 1 million ($1 \times 10^{-6}$) to 1 in 10,000 ($1 \times 10^{-4}$). Non-cancer hazards are expressed as a total hazard index (HI) and EPA uses a target HI of 1. An HI less than or equal to 1 indicates that adverse non-cancer health effects are not expected, even in susceptible populations. An HI greater than 1 does not mean that adverse health effects will occur, only that further evaluation is warranted. Risk from exposure to lead was evaluated using blood lead models, pursuant to EPA guidance. At EPA's direction, lead risks are reported as the

probability of having a blood lead level (BLL) greater than 5 µg/dL.[1] EPA considers lead risks to exceed the target risk threshold if the probability of having a BLL greater than the blood lead target is greater than EPA's goal of 5%.

Chromium was detected in soil in all exposure areas evaluated and in sediment from UHC. In soil, chromium risks were calculated using Cr(VI) data. At the direction of EPA, chromium risks were calculated two ways in sediment, assuming that Cr(VI) is either 5% or 100% of the total chromium concentration. The 5% value is based on the ratio developed from the FMP soil data, while 100% was selected by EPA as a worst-case assumption.

Cancer risks for the Utility, Construction, and Outdoor Workers were within or below EPA's target risk range in all four exposure areas. Non-cancer hazards for the Utility and Outdoor Workers were below EPA's target HI in all four exposure areas. For the Construction Worker, non-cancer hazards exceeded EPA's target HI in the NFA and UNDV.

Cancer risks for the adult and child Resident exceeded EPA's target risk range in the NFA, SFA, and UNDV. Non-cancer hazards for the child Resident exceeded EPA's target HI in the NFA, SFA, and UNDV. Non-cancer hazards for the adult Resident exceeded EPA's target HI in the UNDV, but not the other three exposure areas.

*Assuming 5% Cr(VI) in sediment:* Cancer risks for the adolescent Recreator were within EPA's target risk range in the UNDV, which includes exposure to UHC. Risks for the child and adult Recreators and hazards for all Recreator receptors exceeded EPA's target risk range and HI. For the Recreators, exposure to sediment was the major contributor to cancer risk and non-cancer hazard.

*Assuming 100% Cr(VI) in sediment:* Cancer risks exceeded EPA's target risk range for all Recreators in the UNDV. Non-cancer hazards for all Recreators exceeded EPA's target HI. Exposure to sediment was the major contributor to cancer risk and non-cancer hazard.

The analytes with the greatest contribution to risk or hazard varied by exposure area and receptor, but generally included the following COPCs:

- **Soil:** Arsenic, antimony, hexavalent chromium, cyanide, benzo(a)pyrene, Aroclor 1260, and 1,2,4-trimethylbenzene (TIC)
- **Sediment:** Arsenic and chromium (evaluated as Cr(VI))[2]

Lead risks were evaluated for exposure to soil for a child Resident; a child, adolescent, and adult Recreator; a Utility Worker; a Construction Worker; and an Outdoor Worker. Lead risks exceeded EPA's target of 5% for the child Resident in the NFA, SFA, and UNDV; for the Construction and Outdoor Worker in the SFA; and the Construction Worker in the UNDV. Lead risks exceeded EPA's target of 5% in the UNDV+UHC for the child Recreator, largely due to exposure to sediment in UHC.

[1] EPA's May 2017 comment letter (US EPA Region II, 2017) directed that a target BLL of 5 µg/dL rather than 10 µg/dL be used in this HHRA for both adults and children, "consistent with recommendations provided by the EPA Lead Technical Review Workgroup for other Region 2 Superfund Sites" (no citation provided). EPA's OLEM Directive 9200.2-167 (US EPA, 2016a) indicates that evidence provided by current scientific literature supports the use of a target blood lead level less than 10 µg/dL.

[2] Cr(VI) is a risk driver in sediment only for the assumption that Cr(VI) is 100% of the total chromium concentration.

Risks to commercial workers from vapor intrusion were evaluated separately for eight buildings (1 Foster Avenue, 2 Foster Avenue, 4 Foster Avenue, 5 Foster Avenue, 7 Foster Avenue, 10 Foster Avenue, former 6 East Clementon Road, 3 US Avenue). The sub-slab and indoor air data were screened against health-based values that are protective of commercial worker exposures. Overall, the exceedances of criteria for the indoor air data indicate a potential risk to commercial workers. The VI risks may be underestimated, due to elevated detection limits for non-detected VOCs in sub-slab soil gas data, and VOCs without screening criteria that were detected at elevated concentrations in sub-slab soil gas and/or indoor air. Based on site observations and background sources (*i.e.*, non-site related indoor sources) of VOCs, many of the indoor air exceedances may be a result of contaminant sources unrelated to sub-slab vapor. However, it is not known whether VOCs detected in indoor air could have been present in sub-slab soil gas at levels below the detection limit, and thus whether the presence of these compounds in indoor air could be related to vapor intrusion.

# 1 Introduction

The Sherwin-Williams Company (Sherwin-Williams) is conducting a Remedial Investigation/ Feasibility Study (RI/FS) pursuant to Administrative Order on Consent (AOC) Index No. II CERCLA-02-99-2035 (US EPA Region II, 1999). RI activities are being conducted at the Sherwin-Williams/Hilliards Creek Site (Hilliards Creek Site), which includes the Former Manufacturing Plant Area (FMP Area) and Kirkwood Lake, located in Gibbsboro and portions of Voorhees, New Jersey. This report presents the results of a Human Health Risk Assessment (HHRA) that was conducted for the FMP Area in Gibbsboro, New Jersey.

This HHRA presents the risk assessment methodology and results for the evaluation of cancer risk and non-cancer hazard for the FMP Area (Figure 1). This HHRA is conducted in accordance with United States Environmental Protection Agency (EPA) guidance, the Pathways Analysis Report (PAR) submitted to EPA in September 2016 (Gradient, 2016), the comments received from the Agency on the PAR in December 2016 (US EPA Region II, 2016), and the comments received from the Agency on the draft HHRA in May 2017 (US EPA Region II, 2017).

## 1.1 Site Description

The Site Characterization Summary Report (SCSR) for the FMP presents the site description, site history, summary of previous investigations and the RI, and a summary of results (Weston, 2016). The general areas evaluated as part of the HHRA for the FMP are discussed below and shown on Figure 2. The zoning is shown on Figure 3.

- **Former Manufacturing Plant (FMP).** The FMP consists of 23.4 acres, and the extent is outlined on Figure 2. The areas within this boundary are considered as "onsite" for the purposes of this report. The northern section of the FMP is bounded by Clementon Road to the west, United States Avenue to the east, Foster Avenue to the south, and to the north by Silver Lake and commercial property. The southern section is bounded by Foster Avenue to the north, residential properties along West Clementon Road to the west, and United States Avenue to the east. The property to the south of the FMP includes vacant land and a cemetery. (Silver Lake and the portions of Hilliards Creek southwest of Clementon Road will be evaluated under a separate HHRA.) The FMP property, and the properties to the north of the FMP, are zoned as Office/Technical Park (OTP) (Figure 3). The former plant site is currently utilized as an office and light industrial park and is owned by Brandywine Realty Trust.

Several off-site areas were evaluated (Figure 2):

- The section of United States Avenue that contains soil borings and the Former Service Station/Tavern (FSST) at the corner of United States Avenue and Berlin Road. The street appears to lie within the area zoned as OTP, while the FSST is currently vacant and is zoned as Professional Office (PO).

- The off-site undeveloped areas to the south of the FMP on both sides of Hilliards Creek. This area is zoned as Office/Residential (OR). This area includes a cemetery, a portion of Hilliards Creek, and a wooded area north of Bridgewood Lake.
- **Upper Hilliards Creek (UHC).** Hilliards Creek originates at Silver Lake, flows through a culvert under a paved portion of the FMP in a southeasterly direction, daylights south of Foster Avenue, and flows through a culvert under West Clementon Road. UHC is the portion of HC between Foster Avenue and West Clementon Road, a distance of approximately 0.2 mile. The land adjacent to the portion of UHC that flows through the FMP is zoned as OTP. South of the FMP property boundary, the land adjacent to UHC is zoned as OR.

## 1.2 Future Site Uses

The FMP is zoned as OTP (Figure 3). This area is currently used as an office and industrial park, and the likely future use will be for commercial/industrial purposes. The FSST is zoned as PO and it is assumed that it will be used for commercial purposes. The off-site area to the south of the FMP is zoned as OR; thus, it could potentially be developed for either commercial office or residential use, but the likely future use includes the existing cemetery and undeveloped land.

## 1.3 Report Organization

This report is organized into the following sections that detail the exposure pathways and analysis methods incorporated into the HHRA:

- **Section 2. Exposure Areas** – This section defines each of the exposure areas that were evaluated in the HHRA.
- **Section 3. Potential Receptors and Exposure Pathways** – This section presents potentially complete routes of exposure and potentially exposed populations evaluated in the HHRA.
- **Section 4. Data Summary** – This section provides an overview of the available data and the data handling procedures applied in the HHRA.
- **Section 5. Selection of Chemicals of Potential Concern** – This section presents a preliminary screening level analysis to identify chemicals of potential concern (COPCs) for each environmental medium and exposure area.
- **Section 6. Exposure Point Concentrations** – This section describes the methods used to develop exposure point concentrations (EPCs) for the HHRA.
- **Section 7. Exposure Assessment** – The quantitative exposure assessment methods and exposure parameter assumptions are defined in this section for each receptor population evaluated in the HHRA.
- **Section 8. Toxicity Assessment** – This section provides the sources for identification of non-cancer and cancer toxicity values used in the risk characterization of the HHRA.
- **Section 9. Risk Characterization** – This section presents the results of the risk evaluation.

- **Section 10. Uncertainties** – This section discusses the inherent uncertainties associated with the assumptions used to calculate risks.
- **Section 11. Conclusions** – This section presents the overall conclusions of the risk assessment.

# 2 Exposure Areas

The FMP was divided into four exposure areas for the HHRA. The exposure areas are geographic designations created for the risk assessment in order to define areas with similar anticipated use (based on zoning and other considerations) or similar levels of contamination. The exposure areas are shown on Figure 2 and discussed below.

- **North of Foster Avenue (NFA).** This includes the area of the FMP located north of Foster Avenue, and comprises approximately 10.5 acres. It includes the areas around the former building at 6 East Clementon Road, the buildings at 2, 4, and 10 Foster Avenue and 3 United States Avenue, and Lakeside Manor. The former building at 6 East Clementon Road has been removed and only the building slab currently remains. The building at 10 Foster Avenue is used for commercial office space. The buildings at 2 and 4 Foster Avenue and 3 United States Avenue are currently used as warehouse and office space. Most of this area consists of paved parking lots with small landscaped areas. Lakeside Manor includes a function hall (near Silver Lake) called "Lakeside Manor," and the building slab of a former barn near United States Avenue. Workers and delivery persons may enter the property from United States Avenue. Function attendees access the property by driving from Foster Avenue. The area between the function hall and the lake is landscaped. The portion between the building and United States Avenue is unpaved.
- **South of Foster Avenue (SFA).** This is a developed area of the FMP south of Foster Avenue (approximately 5.2 acres). Most of this area is covered by buildings or paved/unpaved parking lots, except for the grassy area adjacent to Hilliards Creek. There are buildings used for office space at 1, 5, and 7 Foster Avenue.
- **Undeveloped Area (UNDV).** This area includes approximately 14 acres of undeveloped land in the southern portion of the FMP and south of the FMP. The portion within the FMP includes an area associated with the former waste water settling lagoons that were used during site operations and areas in the Hilliards Creek floodplain. The portion south of the FMP includes a cemetery, a wooded area north of Bridgewood Lake, and UHC and the associated floodplain. UHC is the portion of Hilliards Creek between Foster Avenue and West Clementon Road, a distance of approximately 0.2 mile. For the purpose of this report, UHC is evaluated together with the UNDV.
- **East of United States Avenue (EUSA).** This exposure area includes the area of United States Avenue that has soil borings, plus a 0.5-acre FSST parcel at the corner of United States Avenue and Berlin Road. The service station/tavern previously located on the parcel has been removed.

# 3 Potential Receptors and Exposure Pathways

The potential receptors, exposure media, and exposure pathways evaluated in the HHRA are discussed below by exposure area. Table 1 summarizes the receptors evaluated in each exposure area, as well as current land use and zoning. A conceptual site model (CSM) is presented in Figure 4. The CSM provides information regarding potential chemical sources, potentially affected environmental media, contaminant exposure pathways, and potential receptors located in the various exposure areas. For the potential exposure pathways, the CSM identifies those that are complete, complete but insignificant, or incomplete. Insignificant pathways are those that are possible but expected to have a negligible contribution to overall exposure. Insignificant and incomplete pathways are eliminated from further consideration in the risk assessment.

## 3.1 North of Foster Avenue

The NFA is currently an office industrial park (Figure 3). The receptors evaluated in the NFA include a Utility Worker, a Construction Worker, and an Outdoor Worker. Risks for individuals who currently work at or visit the site (*e.g.,* office workers and visitors to Lakeside Manor) were not evaluated, because their risk would be lower than the risk for an Outdoor Worker.

A current/future Utility Worker may conduct maintenance on subsurface utilities under current conditions or if the area is redeveloped. This worker was assumed to be exposed to surface and subsurface soil (0-10 ft) *via* incidental ingestion, dermal contact, and inhalation of particulates and volatiles emitted from soil. The exposure frequency is 10 days/year, and the exposure duration is 25 years.

A future Construction Worker was evaluated to account for exposures during potential future redevelopment. The construction project is assumed to last 1 year; thus, the exposure duration is 1 year, and the exposure frequency is 250 days/year. The Construction Worker is assumed to be exposed to surface and subsurface soil (0-10 ft) *via* incidental ingestion, dermal contact, and inhalation of particulates/volatiles from soil.

A future Outdoor Worker may be exposed to surface soil (0-2 ft) *via* incidental ingestion, dermal contact, and inhalation of particulates/volatiles from soil while working outdoors at the site. The Outdoor Worker is assumed to have an exposure frequency of 225 days/year and an exposure duration of 25 years.

Although the NFA is not zoned as residential, a hypothetical future adult and child Resident were evaluated to account for potential redevelopment for mixed use residential/commercial purposes. The hypothetical future Resident may be exposed to surface soil (0-2 ft) *via* incidental ingestion, dermal contact, and inhalation of particulates/volatiles generated from soil. The hypothetical future Resident is assumed to have an exposure frequency of 350 days/year, and an exposure duration of 6 years as a child and 20 years as an adult, for a total exposure of 26 years (US EPA, 2014).

## 3.2 South of Foster Avenue

The SFA is currently used as an office industrial park, and is zoned as an Office Technical Park (Figure 3). The receptors evaluated in the SFA include a Utility Worker, a Construction Worker, an Outdoor Worker, and a hypothetical future adult and child Resident. The exposures for these receptors are assumed to be the same as those in the NFA. Although the SFA is not zoned as residential, a hypothetical future adult and child Resident were evaluated to account for potential redevelopment for mixed use residential/commercial purposes.

## 3.3 East of United States Avenue

The EUSA includes the area of United States Avenue with soil borings, and the FSST. The FSST is zoned as Professional Office (PO), and it is assumed that it will be used for commercial purposes (Figure 3). Receptors evaluated in the EUSA include a current/future Utility Worker, a future Construction Worker, a future Outdoor Worker, and a hypothetical future adult and child Resident. The exposures for these receptors are assumed to be the same as those in the NFA. Although the EUSA is not zoned as residential, a hypothetical future adult and child Resident were evaluated to account for potential redevelopment for mixed use residential/commercial purposes.

Note that a total of 11 soil borings were installed in United States Avenue for delineation purposes. Four of the eleven borings had samples from depths of less than 10 ft, and these data were used in the HHRA. The other seven borings included samples only from depths of greater than 10 ft, and these data were not used in the HHRA.

## 3.4 Undeveloped Area

The UNDV encompasses undeveloped areas within and south of the FMP, including UHC, and is evaluated as a single exposure area. The receptors evaluated in the UNDV include a future Utility Worker, a future Construction Worker, a future Outdoor Worker, and a future adult, adolescent (6-16 years old), and child (0-6 years old) Recreator. A current/future adult and child Resident were also evaluated, because the area south of the FMP is zoned as OR (Figure 3). All receptors are exposed to soil *via* incidental ingestion, dermal contact, and inhalation of particulates/volatiles generated from soil. The Utility and Construction Workers are exposed to soil 0-10 ft. The Outdoor Worker, Recreator, and Resident are exposed to soil 0-2 ft. The workers and the Resident have the same exposure duration and frequency as those described above for the NFA.

The Recreator is assumed to represent an individual visiting the site while engaging in passive recreation.[3] The Recreator is assumed to visit the site 150 days/year (3 days/week for 50 weeks/year). The exposure durations are 6 years for the child Recreator (0-6 years old), 10 years for the adolescent Recreator (6-16 years old), and 26 years for the adult Recreator. The Recreator is assumed to be exposed to surface soil (0-2 ft) *via* incidental ingestion, dermal contact, and inhalation of particulates/volatiles generated from soil. The Recreator is also

[3] This Recreator could be either a hypothetical future Resident of the UNDV or an individual who resides near the Site. Thus, exposure to UHC was not evaluated for a Resident separately from a Recreator, because the exposure scenario would be the same.

assumed to contact sediment and surface water two days per week during the five warmest months of the year (May through September) (44 days/year) while potentially wading in UHC. Due to the shallow nature of UHC (approximately 6 inches [in] deep) it is assumed that swimming will not occur. The Recreator is assumed to be exposed to sediment *via* incidental ingestion and dermal contact, and surface water via dermal contact for 44 days/year, for 6 years as a child, 10 years as an adolescent, and 26 years as an adult. It was assumed that no significant ingestion of surface water will occur during a wading scenario.

## 3.5 FMP Buildings

Several of the commercial buildings at the FMP have been evaluated for the potential for vapor intrusion through the collection of sub-slab soil gas and indoor air data (Lockheed Martin, 2009; Sherwin-Williams, 2016a). Sub-slab data were collected in five sampling rounds from 2008-2015, at one or more of eight buildings (1 Foster Avenue, 2 Foster Avenue, 4 Foster Avenue, 5 Foster Avenue, 7 Foster Avenue, 10 Foster Avenue, former 6 East Clementon Road, 3 US Avenue). Indoor air data were collected at three buildings (2 Foster Avenue, 4 Foster Avenue, and 3 US Avenue) in four sampling rounds (August 2015, twice in December 2015, and October 2016). Samples were collected from various locations throughout the buildings (office spaces/cubicles, reception areas, hallways, warehouse), including the raised crawl space in 3 US Avenue. Samples were collected during the evening when tenants were not present, with ventilation systems running normally. The sub-slab and indoor air data were screened to evaluate the potential for risks to commercial workers *via* vapor intrusion.

# 4 Data Summary

This section summarizes the available data for the site and provides the rationale for the data used in the HHRA. The data used in the HHRA includes the RI site characterization data and the historical data collected by Sherwin-Williams and EPA. The RI data are from 2005-2015, while the historical data used are from 1991-2003. Additional soil data were collected in September and October 2016 and analyzed for chromium, as hexavalent chromium [Cr(VI)]), and/or New Jersey extractable petroleum hydrocarbons (NJ EPH) to better characterize the FMP (Sherwin-Williams, 2016b).

The data used include the following:

- **Soil.** RI data: 1,048 samples (including 64 field duplicates) collected from 332 soil borings. Historical data: 203 samples (including 14 field duplicates) collected from 141 soil borings. Total: 1,251 soil samples (including 78 field duplicates) from 476 locations.
- **Sediment.** RI data: 13 samples (including one field duplicate). Historical data: 4 samples. Total: 17 sediment samples from 15 locations.
- **Surface Water.** RI data: 10 samples (no field duplicates). Historical data: 7 samples. Total: 17 surface water samples from 11 locations.

Table 2 lists the number of soil, sediment, and surface water sample locations by exposure area included in the HHRA. Appendix A lists the soil sample locations, and the individual samples, included in the HHRA. Appendix B presents the data used in the HHRA. Sample locations are shown on Figures 5 through 8, which correspond to different exposure areas: NFA; SFA and EUSA; UNDV; and UHC, respectively.

Samples were analyzed for Target Compound List (TCL) volatile organic compounds (VOCs), semi-volatile organic compounds (SVOCs), pesticides/polychlorinated biphenyls (PCBs), Target Analyte List (TAL) metals plus cyanide, and petroleum hydrocarbons, although not all samples were analyzed for all analyte groups.

In addition, sub-slab and indoor air data were collected in multiple years (2008, 2009, 2014, 2015, and 2016) from several buildings at the FMP to characterize the vapor intrusion (VI) pathway. These samples were analyzed for VOCs, air-phase petroleum hydrocarbons (APH), methane, and/or hydrogen sulfide.

## 4.1 General Data Considerations

Several sets of field duplicate samples were collected for quality control and quality assurance. The field duplicate samples were averaged with their parent sample to obtain one result per sample. At sediment and surface water locations that were sampled more than once, the HHRA included both samples as independent data points.

The site sampling data include the results from the field X-ray fluorescence (XRF) screening conducted during sampling activities, which were utilized to make field decisions on additional step-out sampling to aid in delineating the extent of contamination. The XRF data were not used in the HHRA because these screening data are not as accurate as laboratory data, and the existing laboratory data are adequate to describe site conditions and support the calculation of EPCs for the risk assessment.

In soil, xylenes were analyzed either as total xylenes or as individual isomers (o-xylene, m/p-xylene), depending on the sampling date. In soil 0-10 ft, a total of 320 samples were analyzed for individual xylenes, and 169 samples were analyzed for total xylenes. To avoid double counting risks from xylenes, risks for soils were evaluated only for total xylenes. The results for individual xylenes were summed to generate a value for total xylenes for each sample. The total xylenes concentrations were used in the Appendix C, Table 2 series screening tables for soil. The total xylenes concentration was calculated as follows:

- The total xylene concentration is the sum of the detected concentrations for all isomers (o-xylene, m+p-xylene).
- If the xylene isomers are not detected, the total xylene is not detected, then the minimum detection limit of the xylene isomers is used.

In sediment and surface water, xylenes were reported consistently within each exposure area; therefore, risks were evaluated for xylenes as they are reported in the Appendix C tables.

Chromium was analyzed as total chromium in FMP soil, sediment, and surface water during the RI. Due to the higher human toxicity of Cr(VI) and in order to properly evaluate the human health risks at the site, Sherwin-Williams collected additional soil samples in the Fall of 2016 throughout the FMP and analyzed them for both total chromium and Cr(VI) (Sherwin-Williams, 2016b). The range of total chromium concentrations in the 2016 dataset (146 samples, 2.4-4,040 milligrams per kilogram [mg/kg]) was similar to that in the previous combined RI/historical dataset (1,051 samples, 0.92-4,040 mg/kg; sampled 1991-2015).

The petroleum present in the subsurface at the FMP is a light mineral spirit containing low concentrations of target compounds (Weston, 2016). A total of 225 samples were analyzed for total petroleum hydrocarbons (TPH) by EPA Method 418.1. A total of 97 samples (in 0- to 10-ft depth interval) were analyzed by the New Jersey Department of Environmental Protection (NJDEP) EPH method, which reports results by carbon-range fraction. The soil data analyzed for TPH were not used in the HHRA due to the more detailed information provided by the carbon-range fractions in the EPH analysis.

Tentatively identified compounds (TICs) were reported with the analytical data, however, only those with published toxicity factors were included in the HHRA. The methodology used to select the TICs included in the HHRA is discussed in Section 5.

## 4.2 Soil

Soil samples collected from depths of 0-2 ft below ground surface (bgs) were used to assess exposure to surface soil for the adult, adolescent, and child Recreators; adult and child Residents; and Outdoor Workers. Soil samples from 0-0.5 ft bgs were used to evaluate lead risks to child

Residents. EPA's "Superfund Lead-Contaminated Residential Site Handbook" (US EPA, 2003a) recommends that child Resident risks evaluated with the Integrated Exposure and Uptake Biokinetic (IEUBK) Model be based on soil samples from a depth of 0-1 in. The shallowest soil sampling available for this Site is from a depth of 0-0.5 ft, and this depth interval was used to calculate lead EPCs for the child Resident. For the child Recreator, soil samples collected from 0-2 ft bgs were selected at the direction of EPA because mean lead concentrations were higher in the 0-2 ft interval than the 0-0.5 ft interval in the UNDV. Soil samples collected from depths of 0-10 ft bgs were used to assess exposure to surface and subsurface soil for a Construction Worker and Utility Worker. The available data are adequate to describe site conditions and support the calculation of EPCs for the risk assessment.

## 4.3 Sediment

Sediment samples collected from a depth of 0-0.5 ft bgs were used in the HHRA, because Recreators are likely exposed only to the surface sediments. All 17 sediment samples collected from UHC were used in the HHRA. The available data are adequate to describe site conditions and support the calculation of EPCs for the risk assessment.

## 4.4 Surface Water

Surface water samples from all depths were used in the HHRA. The metals concentrations from unfiltered samples were used to evaluate surface water exposure because it is assumed that dermal contact occurs with unfiltered surface water. All 17 surface water samples collected from UHC were used in the HHRA. The available data are adequate to describe site conditions and support the calculation of EPCs for the risk assessment.

## 4.5 Sub-slab and Indoor Air Data

Sub-slab data from 2008, 2009, 2014, and 2015, and indoor air from 2015 and 2016 were used in the screening evaluation, to evaluate the potential for risks to commercial workers *via* vapor intrusion. Sub-slab samples were analyzed for VOCs, APH, methane, and hydrogen sulfide. Indoor air samples were analyzed for VOCs and methane.

# 5 Selection of Chemicals of Potential Concern

## 5.1 Data Used and Screening Criteria

A screening-level analysis was conducted to identify the COPCs to be evaluated in the quantitative risk assessment. The maximum detected soil and sediment concentrations were screened against risk-based screening criteria for soil. The soil screening criteria were the lower of either the EPA Regional Screening Levels (RSLs) for residential soil or the New Jersey Residential Direct Contact Soil Remediation Standards (NJ RDCSRS) (US EPA, 2016b; NJDEP, 2011a). The EPA RSLs used for screening were those where non-cancer hazards are calculated with a target hazard quotient (HQ) of 0.1 and cancer risks are calculated with a target risk of 1 x $10^{-6}$ (US EPA, 2016b). The maximum detected surface water concentrations were screened against the EPA RSL for tap water (US EPA, 2016b). In the absence of an RSL, the lower of the New Jersey surface water quality standard and the federal ambient water quality standard was used (NJDEP, 2011b; US EPA, 2015a).

For several compounds with no published screening criteria, a screening value for a suitable surrogate compound was used (Table 3). For acenaphthylene and phenanthrene, structurally related polycyclic aromatic hydrocarbons (PAHs) (acenaphthene and anthracene, respectively) were used as surrogate compounds (US EPA, 2010a; US FDA, 2010; FLDOH, 2010). For benzo(g,h,i)perylene, pyrene was used as a surrogate because it was the most chemically similar PAH with the lowest reference dose (RfD) within Group 2 PAHs (US EPA, 2010a). For 4-nitrophenol, 2,4-dinitrophenol was used as a surrogate compound based on a comparative toxicity study that indicates a higher toxicity for 2,4-dinitrophenol (Koizumi *et al*., 2001). For the remaining compounds, surrogates were chosen based on compounds with similar structures that were expected to be toxicologically similar.

For several compounds, the EPA RSL table offers soil criteria for multiple species or forms of a given compound. In most cases, little information is available about the specific form of a compound present at the site because the results are reported only as the total analyte (*e.g.*, total thallium). For analytes that have screening criteria for multiple forms, either the most conservative value (lowest RSL) or the criterion for the most generic or widely applicable form (*e.g.*, thallium soluble salts) was selected (Table 4).

As per NJDEP guidance (2010a), total EPH concentrations were calculated as the sum of the detects in the individual hydrocarbon fractions. The total EPH was first screened against the screening criterion of 1,700 mg/kg established for petroleum hydrocarbons other than No. 2 fuel oil and/or diesel fuel. Samples with an exceedance were then screened against sample-specific Soil Remediation Criteria (SRC) calculated using the NJDEP EPH calculator (NJDEP, 2010b). The sample-specific SRCs were based on residential exposure to be conservative.

Chromium was analyzed as total chromium in the FMP sediment and surface water. Total chromium concentrations were screened against the RSL for Cr(VI), and chromium was retained as a COPC in sediment and surface water. Total chromium does not exceed the RSL for Cr(III)

in any exposure area or medium, thus risks were not evaluated for Cr(III). The assumptions used for the chromium data are discussed in Section 5.4.

As noted in Section 4, field duplicate samples were averaged with their parent sample to obtain one result per sample. Note that this approach sometimes resulted in cases where the maximum value used for screening is actually an average of two samples.

Soil screening was done separately for each of the depth intervals used for receptors in the exposure area (*i.e.*, 0-0.5 ft, 0-2 ft, and 0-10 ft). The screening to determine COPCs was conducted using all the data from the list of TCL/TAL compounds (*i.e.*, compounds on the standard analyte list of VOCs, SVOCs, metals, inorganics, pesticide/PCBs).

## 5.2 Screening Results

The results of the screening evaluation and the identification of COPCs for each medium and exposure area are summarized in Table 5; only analytes that are COPCs in at least one exposure area are listed. Detailed screening results by exposure area and medium are presented in Appendix C[4] (Tables 2.1-2.14). Analytes with maximum concentrations above the risk-based screening criteria were retained as COPCs for the risk assessment. Compounds were not eliminated as COPCs based on background concentrations.

The COPCs retained for the HHRA include a total of 43 COPCs (Table 5). Soil COPCs retained in one or more exposure areas include 15 metals, cyanide, 2 pesticides, 3 PCBs (Aroclors), 9 PAHs, 4 SVOCs, and 5 VOCs. Sediment and surface water COPCs include 12 metals, cyanide, 2 PCBs (Aroclors), 8 PAHs, and 4 VOCs.

As per NJDEP guidance (2010a), total EPH concentrations were first screened against the screening criterion of 1,700 mg/kg established for petroleum hydrocarbons other than No. 2 fuel oil and/or diesel fuel. A total of 38 of 97 samples had detected EPH, and, of these, 6 samples had a total EPH concentration above 1,700 mg/kg (Appendix D). The EPH concentrations for these 6 samples were then entered into the NJDEP EPH calculator to calculate sample specific, health-based SRC (Appendix D). All six samples had total EPH below their respective sample-specific SRC (Appendix D).[5] Therefore, the EPH hydrocarbon fractions were not retained as COPCs.

Four analytes (calcium, magnesium, potassium, and sodium) were not retained as COPCs because they are essential human nutrients, present at low concentrations, and toxic at only very high doses (US EPA, 1989).

EPA guidance notes that a chemical can be excluded from a quantitative risk assessment if it is detected infrequently and is not detected in other media or at high concentrations (US EPA, 1989). Analytes with exceedances of screening criteria in only one exposure area and that had a low detection frequency (generally less than 5%), were not retained as COPCs (US EPA, 1989).

[4] Appendix C includes the EPA Risk Assessment Guidance for Superfund (RAGS) Part D Planning Tables. The RAGS Planning Tables use a numbering system and a format that is determined by EPA.

[5] Sample MPSB0308-SS-AE-AF included a parent and field duplicate sample, which were averaged to be consistent with how all other data were treated. The average of the parent and field duplicate samples (4,427 mg/kg) was below its screening criterion (5,100 mg/kg) (Appendix E, Table 2). It is noted that parent sample MPSB0308-SS-AE-AF-0 had a EPH concentration (5,450 mg/kg) above its sample-specific SRC (5,000 mg/kg), while its field duplicate (MPSB0308-SS-AE-AF-1) had an EPH concentration (3,404 mg/kg) below its sample-specific SRC (5,300 mg/kg).

These analytes are indicated with "LDF" on the Appendix C Table 2 series screening tables. Several analytes were eliminated as COPCs due to low detection frequency in soil, but none were eliminated in sediment or surface water. The rationale for the elimination of these soil compounds is discussed below, and the data for these compounds are summarized in Table 6.

- Aroclor 1248 was detected in seven samples site-wide, all from the NFA. Only one sample (MPS0019, 1.5-2 ft bgs) had a concentration (0.44 mg/kg) above the screening criterion of 0.2 mg/kg. The detection frequency was 2.5% for soil 0-10 ft, and 6.7% for soil 0-2 ft. Aroclor 1248 is not a COPC in any other exposure area. Based on the detection frequencies, Aroclor 1248 was retained as a COPC in soils 0-2 ft, and eliminated as a COPC in soils 0-10 ft.
- 1,2,4,5-Tetrachlorobenzene was detected in five samples from the NFA with a detection frequency of 1.6% in soil 0-10 ft and 2.7% in soil 0-2 ft. Only one subsurface soil sample (MPSB0143, 4.5-5 ft bgs) had a detected concentration (4.4 mg/kg) above the screening criterion of 2.3 mg/kg. 1,2,4,5-Tetrachlorobenzene is not a COPC in any other exposure area.
- 2,6-Dinitrotoluene was detected in one sample from the NFA, at a detection frequency of 0.3% in soil 0-10 ft. The sample (TB-38, 8-9.6 ft) had a concentration of 1.2 mg/kg, above the screening criterion of 0.36 mg/kg. 2,6-Dinitrotoluene is not a COPC in any other exposure area.
- 2-Hexanone was detected in the NFA (MPSB0151, 1.5-2 ft) at 860 mg/kg, above the screening criterion of 20 mg/kg. The detection frequency in the NFA was 0.5% in soil 0-10 ft, and 1.6% in soil 0-2 ft. 2-Hexanone is not a COPC in any other exposure area.
- Bromomethane was detected in three samples site-wide, two in the NFA, and one in the EUSA. One sample in the NFA (MPSB0150 4.5-5 ft bgs) had a concentration of 1.5 mg/kg, above the screening criterion of 0.68 mg/kg. In the NFA, the detection frequency was 1% in soil 0-10 ft. Bromomethane is not a COPC in any other exposure area.

EPA recommends conducting risk assessments for "the most important chemicals (*e.g.*, those contributing 99 percent of the risk)" (US EPA, 1989). The analytes discussed above had exceedances in only one exposure area, a low detection frequency, and are not COPCs in other exposure areas; therefore, these analytes were eliminated as COPCs.

## 5.3 Screening for Tentatively Identified Compounds

An evaluation was conducted for TICs reported by the laboratory in samples being used in the HHRA. The laboratory does not run calibration standards for the TICs. TICs are identified by the laboratory instrumentation based on a comparison between the sample spectra and the spectra stored in an electronic library. Since the laboratory does not run calibration standards for the TICs, the compound identification is not certain, and all TIC concentrations are considered estimated (J) values. The TIC data have not been validated.

Appendix E, Table 1 presents a list of the TICs detected in soil (0-10 ft), sediment (0-0.5 ft), and surface water, the number of samples where each TIC was detected, and the range of concentrations reported for each TIC. The soil depths were limited to 0-10 ft, as 10 ft is the deepest depth used in the HHRA. Similarly, sediment depths were limited to 0.5 ft, which is the

deepest depth used in the HHRA. Surface water samples from all depths were included in the dataset. Many TIC names are similar, *i.e.*, the same compound is reported with different suffix values, or with a slightly different spelling (different commas, dashes, or spaces); thus, in Appendix E, Table 1, the suffix values have been removed in order to consolidate the list of TICs. Since the same TIC may be detected at multiple retention times in the same sample, the TIC concentrations are based on the maximum detection of each TIC per sample and analysis.

The list of TICs was reviewed to determine those that have toxicity factors and screening values published by EPA. The search was conducted using EPA's RSL Table (US EPA, 2016b), which lists toxicity factors for over 800 analytes from the following sources: EPA's Integrated Risk Information System (IRIS), EPA's Provisional Peer-Reviewed Toxicity Values (PPRTVs), EPA's Health Effects Assessment Summary Tables (HEAST), the Agency for Toxic Substances and Disease Registry (ATSDR), and the California Environmental Protection Agency (CalEPA). RSLs were identified for a total of 25 TICs in soil and sediment. No RSLs were identified for any TICs detected in surface water. The TICs were screened against the EPA RSLs, by medium, exposure area, and depth interval (soil 0-10 ft and 0-2 ft, sediment 0-0.5 ft) (Appendix E, Tables 2, 3, and 4). The TICs are grouped by analysis (VOC *vs.* SVOC) in Appendix E, Table 1, but not in Appendix E, Tables 2, 3, and 4 in order to consolidate results for each TIC.

TICs with exceedances of screening criteria were evaluated for detection frequency to be consistent with the screening for the target analytes. In general, TICs with exceedances that had a detection frequency of less than 5% (within an exposure area and soil depth interval) were eliminated as COPCs. However, to be conservative, TICs with exceedances with a detection frequency less than 5% were retained as COPCs in the SFA if they were COPCs in the NFA, and *vice versa*, within a given soil depth interval (0-10 ft or 0-2 ft). Thus, the three trimethylbenzene TICs in the NFA and SFA 0-10 ft soil, and the benzo(j)fluoranthene TIC in the NFA and SFA 0-2 ft soil, were retained as COPCs. The following TICs were eliminated as COPCs in all exposure areas due to low detection frequency: 2,3,3,4,4,5-hexachloro-1,1-biphenyl; 2,3,3,4,4-pentachloro-1,1-biphenyl; 2,3,4,4,5-pentachloro-1,1-biphenyl; 3,3,4,4,5,5-hexachloro-1,1-biphenyl; 7,12-dimethylbenz[a]anthracene; and 1,2,3-trichlorobenzene (see Appendix E). The TICs retained as COPCs, for the exposure areas where they have exceedances, include 4 TICs in 0-10 ft soil, 2 TICs in 0-2 ft soil, and 1 TIC in sediment (Table 7).

## 5.4 Chromium Data

The soil dataset included a total of 146 soil samples (from 46 borings) that were analyzed for both total chromium and, in the case of soil samples collected in September and October 2016, for hexavalent chromium [Cr(VI)]. These data were used to examine the relationship between Cr(VI) and total Cr (Sherwin-Williams, 2016b). The ratio of Cr(VI) to total Cr was calculated for each sample, using the detection limit for samples with non-detected Cr(VI). For the entire dataset, the Cr(VI) ratio ranged from 0.01% to 30%, with an average Cr(VI) ratio of 5%. It should be noted, however, that the maximum value of 30% was determined to be an outlier[6] and is not considered representative of the overall dataset (Sherwin-Williams, 2016b).

In sediment, data collected from UHC were analyzed for total chromium, but not hexavalent chromium. At the direction of EPA, this HHRA evaluated the risk from Cr(VI) in sediment using two different assumptions for the Cr(VI)/Cr ratio. Cr(VI) was assumed to be either 5% or 100% of the total chromium concentration for UHC sediment. The 5% is based on the average ratio

[6] This sample was collected from a location under the slab of a former building, in an area containing fill materials.

from the soil data, since the percent Cr(VI) in UHC sediment is likely to be no higher than in FMP soil. The 100% was selected by EPA as a worst-case assumption. Since surface water was not analyzed for Cr(VI), the HHRA used the conservative assumption that the Cr(VI) concentration is equivalent to the total Cr concentration, to be consistent with the previous HHRAs for the other Sherwin-Williams sites in this area.

## 5.5 Vapor Intrusion Screening

Sub-slab and indoor air samples were screened against screening criteria calculated using the US EPA Vapor Intrusion Screening Level (VISL) calculator (Version 3.5.1) (US EPA, 2016c). Screening criteria were calculated separately for indoor air and sub-slab soil gas using the default exposure assumptions for the commercial worker scenario based on a target HQ of 1 and a target cancer risk of 1 x $10^{-6}$ (US EPA, 2016c). Several compounds detected in one or more indoor air samples did not have screening criteria (Appendix F).

The sub-slab data indicated that all detected concentrations from samples collected from 1 Foster Avenue, 10 Foster Avenue, 5 Foster Avenue, 6 Clementon Road (same as former 6 East Clementon Road), and 7 Foster Avenue were below the sub-slab screening criteria (Appendix F). Exceedances of sub-slab screening criteria were observed in samples collected from 2 Foster Avenue, 3 US Avenue, and 4 Foster Avenue. A total of 12 VOCs were detected at concentrations above the sub-slab screening criteria in at least one sample, including 1,2,3-trimethylbenzene, 1,2,4-trimethylbenzene, benzene, cyclohexane, ethylbenzene, m,p-xylenes, n-hexane, n-nonane, o-xylene, tetrachloroethene, trichloroethene, and vinyl chloride (VC) (Appendix F, Table 2). The high detected concentrations of aliphatic and aromatic compounds, benzene, ethylbenzene, xylene, toluene, and 1,2,4-trimethylbenzene, resulted in elevated detection limits for other VOCs in sub-slab data. In some cases, the detection limits for non-detected VOCs exceeded their respective sub-slab screening criterion. In addition, sub-slab criteria were not available for several VOCs. The uncertainties associated with elevated detection limits and VOCs with no screening criteria are discussed in Section 10.

In the indoor air data, a total of 10 VOCs were detected at concentrations above the EPA indoor air screening criteria in at least one sample, including acrolein, benzene, benzyl chloride, bromodichloromethane, chloroform, 1,2-dichloroethane, ethylbenzene, naphthalene, 1,1,2,2-tetrachloroethane, and trichloroethene (Appendix F, Table 6). The compounds with exceedances were generally similar between sampling rounds. Indoor air data were also screened against NJDEP Vapor Intrusion Non-Residential Indoor Air Screening Levels (NJDEP, 2013). A total of six VOCs (1,2-dichloroethane, benzene, chloroform, ethylbenzene, naphthalene and trichloroethylene) were detected at concentrations above NJDEP Non-Residential Indoor Air Screening Levels (Appendix F, Table 6). Several detected VOCs have no indoor air screening criteria. The uncertainties associated with detected VOCs with no indoor air criteria are discussed in Section 10.

Overall the exceedances of criteria for the indoor air data indicate a potential risk to commercial workers. However, the extent to which sub-slab soil gas contributes to the detected VOCs in indoor air has not been determined. Benzene and ethylbenzene were the only analytes with exceedances of criteria in both sub-slab and indoor air at 2 Foster Avenue and 3 US Avenue, and benzene was the only analyte with exceedances in both sub-slab and indoor air at 4 Foster Avenue. It should be noted that several VOCs were detected in indoor air above screening criteria. These VOCs were not detected in sub-slab soil gas, but their detection limits were above

the sub-slab criteria. Therefore, it is uncertain whether these VOCs have exceedances in sub-slab soil gas as well as indoor air.

While the number of indoor air exceedances increased in 2016 from 2015, this may be a result of contaminant sources unrelated to sub-slab vapor. The buildings underwent renovations that could have contributed to the detected concentrations. Based on a site visit performed by Weston, multiple potential sources of background VOCs (*i.e.*, non-site related indoor sources) were identified (*e.g.*, evidence of paint, cleaning products, adhesives, aerosol lubricants, solvents, detergents, brake fluid, smoking) (Sherwin-Williams, 2016a).

As discussed in Section 10.5, there are several uncertainties associated with the evaluation of VOCs in indoor air. The VI risks estimated from sub-slab data may be biased low due to elevated detection limits in the sub-slab data. The detection limits for 27 non-detected VOCs in sub-slab soil gas exceeded their respective screening criterion, but risk was not evaluated for non-detects. In addition, it is not known whether VOCs detected in indoor air could have been present in sub-slab soil gas at levels below the detection limit, and thus whether the presence of these compounds in indoor air could be related to vapor intrusion. Also, several compounds detected in sub-slab soil gas and/or indoor air (and the TICs reported in indoor air) did not have screening criteria. Several of these compounds were detected at high concentrations, however, risks from these compounds were not assessed due to the absence of screening criteria. Therefore, VI risks based on sub-slab soil gas and/or indoor air data may be underestimated.

# 6 Exposure Point Concentrations

In a risk assessment, an EPC represents the concentration of a chemical in an environmental medium to which an individual is exposed. Soil and sediment EPCs were calculated by exposure area using the data from the depth range appropriate for each receptor. EPCs for the non-lead COPCs were calculated as the 95% upper confidence limit on the mean (UCLM), or the maximum value, whichever is lower (EPCs for lead are discussed below). The individual results from all samples within the appropriate depth interval were used to calculate the soil EPC. The 95% UCLM values were calculated using EPA's ProUCL software Version 5.1 (US EPA, 2016d; Outputs provided in Appendix G) using the option that specifies whether a value is a non-detect. If the 95% UCLM is higher than the maximum detected value, or if it cannot be calculated due to too few data points or too few detects, the maximum detected concentration within the exposure area was used as the EPC. EPCs for TICs were calculated using the detected concentrations only, and were calculated as the 95% UCLM, or the maximum value, whichever is lower. The ProUCL output files are presented in Appendix G.

Lead risks from incidental soil and sediment ingestion were evaluated using EPA's blood lead model known as the Adult Lead Model (ALM) (US EPA, 2003b) for non-residential adult receptors (Recreators, Construction Workers, and Utility Workers), and EPA's blood lead model known as the IEUBK model (US EPA, 1994a, 2010b) for the child Recreator and Resident (Appendix H). Both models estimate a central tendency (geometric mean [GM]) BLL on the basis of average or typical exposure parameter values. Therefore, for lead, EPCs for soil were the arithmetic mean of all the samples within the exposure area from the appropriate depth interval (0-0.5 ft for child Residents,[7] 0-2 ft for adult Recreators and Outdoor Workers, and 0-10 ft for Construction and Utility Workers). For the child Recreator, soil samples collected from 0-2 ft bgs were selected at the direction of EPA because lead concentrations were higher in the 0-2 ft interval (mean concentration of 665 mg/kg) than the 0-0.5 ft depth (mean concentration of 339 mg/kg). The arithmetic mean is used as the EPC consistent with EPA guidance (US EPA, 2003b).

Chromium is a COPC in UHC sediment. As previously discussed, risks were evaluated in two ways, assuming that the Cr(VI) in sediment is either 5% or 100% of the of the total chromium concentration. The 5% evaluation was done by multiplying the chromium EPCs in soil and sediment by 5%. The risk calculations for the 5% Cr(VI) assumption are presented in Appendix C-1, and the risk calculations for the 100% Cr(VI) assumption are presented in Appendix C-2.[8]

[7] EPA's Superfund Lead-Contaminated Residential Site Handbook (US EPA, 2003a) recommends that child Resident risks be evaluated based on soil samples from a depth of 0-1 in. The shallowest soil sampling available for this Site is from a depth of 0-0.5 ft; therefore, this depth interval was used to calculate lead EPCs for the child Resident.
[8] Please note that Appendix C-2 includes only the tables that pertain to the recreator risks for the UNDV+UHC.

# 7 Exposure Assessment

## 7.1 Quantification of Exposure

This section discusses the basis for calculating human intake levels resulting from exposures to COPCs other than lead and describes each input parameter (lead risk inputs are discussed in Section 7.2). Exposure estimates represent the daily dose of a chemical taken into the body, averaged over the appropriate exposure period, expressed in the units of mg of chemical per kg of human body weight per day. The primary source for the exposure equations used in the HHRA is the EPA's Risk Assessment Guidance for Superfund (RAGS) (US EPA, 1989).[9] The generalized equation for calculating chemical intakes is shown below:

$$I = \frac{EPC \times CR \times EF \times ED}{BW \times AT}$$

where:

| | | |
|---|---|---|
| I | = | Intake,[10] the amount of chemical at the exchange boundary (mg/kg body weight-day) |
| EPC | = | Exposure Point Concentration, the chemical concentration contacted over the exposure period at the exposure point (*e.g.*, mg/kg in soil) |
| CR | = | Contact Rate, the amount of contaminated medium contacted per unit time or event (*e.g.*, soil ingestion rate [mg/day]) |
| EF | = | Exposure Frequency, how often exposure occurs (days/year) |
| ED | = | Exposure Duration, how long exposure occurs (years) |
| BW | = | Body Weight, the average body weight over the exposure period (kg) |
| AT | = | Averaging Time, period over which exposure is averaged (days) |

Exposure factors (*e.g.*, contact or ingestion rate, exposure frequency, exposure duration, body weight) are the parameters that are used to calculate a receptor's exposure for a given exposure scenario. The values used for each exposure factor are summarized in Appendix C (Table 4.1) and are discussed in detail below. The exposure factor input values are consistent with current EPA guidance. When appropriate, exposure parameters were based on site-specific considerations and professional judgment.

Several COPCs (identified in Appendix C, Table 6.1) are considered carcinogens with mutagenic modes of action to account for potentially increased susceptibility to mutagenic carcinogens for early life exposures (US EPA, 2005). Cancer risks for the Resident and Recreator were calculated separately for carcinogens with mutagenic modes of action to account for potentially increased susceptibility to mutagenic carcinogens for early life exposures (US EPA, 2005). For the mutagens, intakes were calculated separately for the following age groups: 0-2 years old, 2-6

[9] Note that this approach is not used to evaluate lead. Consistent with EPA guidance, lead risk is evaluated using blood lead models.
[10] Expressed as a Dose for dermal contact and Concentration for inhalation exposure.

years old, 6-16 years old, and 16-26 years old, with exposure durations of 2, 4, 10, and 10 years, respectively.

### 7.1.1 Incidental Ingestion of Soil

For the incidental soil ingestion pathway, intake was calculated as:

$$Intake\left(\frac{mg}{kg \cdot day}\right) = \frac{C_{soil}\left(\frac{mg}{kg}\right) \times B \times IR_{soil}\left(\frac{mg}{day}\right) \times FS \times EF\left(\frac{days}{yr}\right) \times ED(yrs) \times 10^{-6}\ \frac{kg}{mg}}{BW(kg) \times AT(days)}$$

where:

| | | |
|---|---|---|
| $C_{soil}$ | = | Concentration of the Chemical in Soil (mg/kg) |
| B | = | Relative Bioavailability, the relative oral absorption fraction (unitless) |
| $IR_{soil}$ | = | Soil Ingestion Rate (mg/day) |
| FS | = | Fraction of Soil from the site (unitless) |
| EF | = | Exposure Frequency (days/year) |
| ED | = | Exposure Duration (years) |
| BW | = | Body Weight (kg) |
| AT | = | Averaging Time (days) |

Conservative EPA-recommended values were used for each of the input parameters. The basis for each value used is detailed below.

*Soil Concentrations ($C_{soil}$).* The lower of either the 95% UCLM or the maximum detected concentration in soil was used as the EPC.

*Relative Bioavailability (B).* To accurately quantify potential exposures from incidental ingestion of soil, it is important to consider the amount of a chemical that is solubilized in gastrointestinal (GI) fluids and absorbed across the GI tract into the bloodstream. A chemical present in soil may be absorbed less completely than the same dose of the chemical administered in toxicity studies used to evaluate safe dose levels. A relative bioavailability estimate for a specific compound represents the absorption fraction from soil (the exposure route of concern) relative to the absorption fraction from food or water (in most toxicity studies, chemical doses are administered in food or water).

It is widely recognized that bioavailability of many metals and organics from soil tends to be considerably lower than bioavailability from food or water. EPA guidance recognized the need to make adjustments for the reduced bioavailability of compounds in soil. In Appendix A of EPA's RAGS (US EPA, 1989, p. A-3), EPA noted:

> If the medium of exposure in the site exposure assessment differs from the medium of exposure assumed by the toxicity value (e.g., RfD [Reference Dose] values usually are based on or have been adjusted to reflect exposure via drinking water, while the site medium of concern may be soil), an absorption adjustment may, on occasion, be appropriate. For example, a substance might be more completely absorbed following exposure to contaminated drinking water than

following exposure to contaminated food or soil (*e.g.*, if the substance does not desorb from soil in the GI tract).

For arsenic in soil, EPA's default relative oral bioavailability of 0.6 (60%) was used (US EPA, 2012a). For COPCs other than arsenic (and lead; see Section 7.2), relative oral bioavailability information is not readily available; therefore, a relative bioavailability of 100% was used (Appendix C, Table 5.1).

*Soil Ingestion Rate ($IR_{soil}$).* EPA's default daily soil ingestion rate of 100 mg/day for an adult resident was used for the adult Resident, adult Recreator, and adolescent (6-16 years old) Recreator (US EPA, 2014). EPA's default daily soil ingestion rate of 200 mg/day was used for the child Recreator and Resident (US EPA, 2014). These rates represent the upper-bound value for soil and dust ingestion (US EPA, 2014). EPA's default adult soil ingestion rate of 100 mg/day was used for the Outdoor Worker (US EPA, 2014). A soil ingestion rate of 330 mg/day was used for the Construction Worker and Utility Worker, as recommended by EPA (2002). This value is based on the 95$^{th}$ percentile value for adult soil intake rates reported in a soil ingestion mass-balance study (Stanek *et al*., 1997). For assessment of mutagenic compounds, a soil ingestion rate of 200 mg/day is used for the 0-2 years old and 2-6 years old age groups, and a rate of 100 mg/day is used for the 6-16 years old and 16-26 years old age groups.

*Fraction of Soil From the Site (FS)*. While it is likely that only a portion of an individual's daily incidental soil ingestion occurs at the site, to be conservative, an assumption that 100% of the individual's daily soil exposure occurs at the site was used for all receptors.

*Exposure Frequency (EF) and Exposure Duration (ED)*.

- For the Utility Worker, the exposure duration is 25 years based on the 95$^{th}$ percentile duration that an individual stays at any one workplace (US EPA, 2014). This assumption overestimates exposures for most workers because the median occupational tenure of the working population has been estimated to be 7.9 years for men and 5.4 years for women (US EPA, 2011a). The exposure frequency for the Utility Worker is assumed as 10 days/year, based on professional judgment.
- For the Construction Worker, the exposure frequency is 250 days/year, and the exposure duration is 1 year as it is assumed that a potential construction project could take up to 1 year (US EPA, 2014).
- For the Outdoor Worker, the exposure frequency is 225 days/year, and the exposure duration is 25 years based on EPA's recommended values for an outdoor worker (US EPA, 2014).
- For the Recreator, the exposure frequency is 150 days/year, based on 3 days/week for 50 weeks/year. The exposure duration is 6 years for the child Recreator, 10 years for the adolescent Recreator (6-16 years old), and 26 years for the adult Recreator.
- For the future Resident, an exposure duration of 6 years for a child and 20 years for an adult were used, for a total exposure of 26 years (US EPA, 2014). The exposure frequency is 350 days/year, accounting for 15 days/year spent away from home (US EPA, 2014). For assessment of mutagenic compounds, exposure durations of 2, 4, 10, and 10 years were used for the 0-2 years old, 2-6 years old, 6-16 years old, and 16-26 years old age groups, respectively.

*Body Weight (BW).* Based on EPA guidance (US EPA, 2014), a mean adult body weight of 80 kg (US EPA, 2011a, Table 8.3) was used for adult receptors in the HHRA. For the adolescent Recreator, the age-weighted mean body weight of 44 kg for an adolescent aged 6-16 years is used (US EPA, 2011a). For child receptors, the age-weighted mean body weight of 15 kg for a child aged 1-6 years was used (US EPA, 1991a). For assessment of mutagenic compounds, the body weight is the age-weighted average body weight for each age group (US EPA, 2011a): 9 kg (0-2 years old), 17 kg (2-6 years old), 44 kg (6-16 years old) and 76 kg (16-26 years old) (Appendix C, Table 4.5).

*Averaging Time (AT)*. For non-cancer hazards, the averaging time is equal to the exposure duration multiplied by 365 days/year. For cancer risks, exposures are averaged over a 70-year (25,550 days) average lifetime consistent with EPA guidance (US EPA, 2014).

## Mutagenic Compounds

For Residents and Recreators, cancer risks were calculated separately for carcinogens with mutagenic modes of action to account for potentially increased susceptibility to mutagenic carcinogens for early life exposures (US EPA, 2005). Based on EPA guidance, a 10-fold adjustment was made for exposures during the first 2 years of life (0-2 years old age group), a 3-fold adjustment was made for the 2-6 years old and 6-16 years old age groups, and no adjustment was made for exposure in the 16-26 years old age group (US EPA, 2005). Intakes were calculated using exposure parameters specific to each age group (0-2 years old, 2-6 years old, 6-16 years old, and 16-26 years old). The age-adjusted exposure factors for chemicals with mutagenic modes of action are presented in Appendix C, Table 4.5.

For the incidental soil ingestion pathway, intake for mutagens was calculated as:

$$Intake\left(\frac{mg}{kg \cdot day}\right) = \frac{C_{soil}\left(\frac{mg}{kg}\right) \times IFSM_{adj}\left(\frac{mg \cdot yr}{kg \cdot day}\right) \times B \times FS \times EF\left(\frac{days}{yr}\right) \times 10^{-6}\,\frac{kg}{mg}}{AT\left(days\right)}$$

where $C_{soil}$, B, FS, EF, and AT are as defined above, and where the age-adjusted mutagenic soil ingestion rate ($IFSM_{adj}$) is given by:

$$IFSM_{adj}\left(\frac{mg \cdot yr}{kg \cdot day}\right) = \left(\frac{ED_{0-2} \times IRS_c \times 10}{BW_{0-2}}\right) + \left(\frac{ED_{2-6} \times IRS_c \times 3}{BW_{2-6}}\right) + \left(\frac{ED_{6-16} \times IRS_a \times 3}{BW_{6-16}}\right) + \left(\frac{ED_{16-26} \times IRS_a \times 1}{BW_{16-26}}\right)$$

where:

| | | |
|---|---|---|
| $IFSM_{adj}$ | = | Age-adjusted Mutagenic Soil Ingestion Rate (mg-year/kg-day) |
| $IRS_c$ | = | Child Soil Ingestion Rate (mg/day) |
| $IRS_a$ | = | Adult Soil Ingestion Rate (mg/day) |
| $ED_{(age)}$ | = | Exposure Duration (years) |
| $BW_{(age)}$ | = | Average Body Weight for the age group (kg) |

To calculate cancer risks for trichloroethylene, which was detected in NFA soil, the standard cancer and mutagen equations were combined. Intakes for the Resident cancer risk were calculated using the following equation (US EPA, 2016e):

$$Intake_{TCE}\left(\frac{mg}{kg \cdot day}\right)=\frac{C_{soil}\left(\frac{mg}{kg}\right)\times\left[\left(CAF_o\times\left(IF_{child}+IF_{adult}\right)\right)+\left(MAF_o\times IFSM_{adj}\right)\right]\times B\times FS\times EF\left(\frac{days}{yr}\right)\times 10^{-6}\,\frac{kg}{mg}}{AT\left(days\right)}$$

The parameters $C_{soil}$, B, FS, EF, AT, and $IFSM_{adj}$ are as defined above. The additional parameters are defined as:

| | | |
|---|---|---|
| $IF_{child}$ | = | Intake factor for a child 0-6 (mg-year/kg-day) |
| $IF_{adult}$ | = | Intake factor for an adult (mg-year/kg-day) |
| $CAF_o$ | = | Toxicity adjustment factor for carcinogens – oral slope factor (unitless) |
| $MAF_o$ | = | Toxicity adjustment factor for mutagens – oral slope factor (unitless) |

The cancer toxicity adjustment factor ($CAF_o$) and mutagen toxicity adjustment factor ($MAF_o$) are calculated based on the different toxicity values (oral cancer slope factors [CSFs]) for TCE, as follows (US EPA, 2016e 216-3867):

$$CAF_o(0.804)=\frac{NHL{+}Liver\ CSF_o\left(3.7\times 10^{-2}\left(\frac{mg}{kg\text{-}day}\right)^{-1}\right)}{Adult\text{-}based\ CSF_o\left(4.6\times 10^{-2}\left(\frac{mg}{kg\text{-}day}\right)^{-1}\right)}$$

$$MAF_o(0.202)=\frac{Kidney\ CSF_o\left(9.3\times 10^{-3}\left(\frac{mg}{kg\text{-}day}\right)^{-1}\right)}{Adult\text{-}based\ CSF_o\left(4.6\times 10^{-2}\left(\frac{mg}{kg\text{-}day}\right)^{-1}\right)}$$

The intake factors for the child ($IF_{child}$) and adult ($IF_{adult}$) are calculated with the following equation, where IRS, ED, and BW are defined as above:

$$IF=\frac{IRS\times ED}{BW}$$

### 7.1.2 Dermal Contact with Soil

For dermal exposure to contaminants in soil, a dermal intake (the amount absorbed into the body) is calculated as (US EPA, 2004a):

$$DAD\left(\frac{mg}{kg\cdot day}\right)=\frac{C_{soil}\left(\frac{mg}{kg}\right)\times ABS\times AF\left(\frac{mg}{cm^2}\right)\times SA\left(\frac{cm^2}{event}\right)\times EF\left(\frac{events}{yr}\right)\times ED\left(yrs\right)\times 10^{-6}\,\frac{kg}{mg}}{BW\left(kg\right)\times AT\left(days\right)}$$

where:

| | | |
|---|---|---|
| DAD | = | Dermal Absorbed Dose (mg/kg-day) |
| $C_{soil}$ | = | Concentration of the Chemical in Soil (mg/kg) |
| ABS | = | Dermal Absorption fraction (unitless) |
| AF | = | Soil to Skin Adherence Factor (milligrams per square centimeter [mg/cm$^2$]) |
| SA | = | Skin Surface Area Exposed (cm$^2$/exposure event) |
| EF | = | Exposure Frequency (exposure events/year) |
| ED | = | Exposure Duration (years) |
| BW | = | Body Weight (kg) |
| AT | = | Averaging Time (days) |

The three parameters unique to the dermal exposure equation – the dermal absorption fraction (ABS), the soil to skin adherence factor (AF), and the skin surface area (SA) – are discussed in this section. The values used for other parameters are the same as discussed in Section 7.1.1.

*Dermal Absorption Fraction (ABS).* The dermal absorption fraction represents the amount of a chemical in contact with skin that is absorbed through the skin and into the bloodstream. The dermal absorption values were obtained from EPA's dermal risk assessment guidance (US EPA, 2004a, Exhibit 3.4). For arsenic, the dermal absorption fraction is 0.03; for cadmium, the dermal absorption fraction is 0.001; for PAH compounds and TICs based on PAHs, the dermal absorption fraction is 0.13; for dibenzofuran, the dermal absorption fraction is 0.03; for other SVOCs and dieldrin the dermal absorption fraction is 0.1; for Aroclors 1248/1254/1260 and the biphenyl TIC, the dermal absorption fraction is 0.14; for pentachlorophenol, the dermal absorption fraction is 0.25 (Appendix C, Table 5.1). Dermal absorption values are not available for the other COPCs; therefore, dermal exposures were not calculated for these constituents in the HHRA.

*Soil to Skin Adherence Factor (AF).* The adherence factor represents the amount of soil that adheres to the skin per unit of surface area (US EPA, 2004a). Adherence factors vary depending on the properties of the soil, the part of the body, and the type of activity. EPA's recommended soil to skin adherence factor for an adult resident (0.07 mg/cm$^2$) was used to calculate dermal absorption for adult Resident, adult Recreator, and adolescent Recreator exposed to soil (US EPA, 2014). EPA's recommended soil-to-skin adherence factor of 0.3 mg/cm$^2$ for the Construction Worker (US EPA, 2002, 2016e) was used for the Construction Worker and Utility Worker (US EPA, 2014). EPA's recommended soil to skin adherence factor for a worker (0.12 mg/cm$^2$) was used for the Outdoor Worker (US EPA, 2014). EPA's recommended soil to skin adherence factor for the child Resident (0.2 mg/cm$^2$) is based on children playing in wet soil and is used to represent contact with soil and used for the child Resident and Recreator. For assessment of mutagenic compounds, the child soil to skin adherence factor of 0.2 mg/cm$^2$ was used for the 0-2 years old and 2-6 years old age groups, while the adult soil to skin adherence factor of 0.07 mg/cm$^2$ was used for the 6-16 years old and 16-26 years old age groups. These factors were used because soil to skin adherence factors are not available for specific ages.

*Skin Surface Area Exposed (SA).* This parameter reflects the amount of skin that is available for exposure to soil. The skin surface area was 6,032 cm$^2$ for the adult Resident and Recreator, based on EPA's recommended value for an adult Resident with exposed skin surface limited to the head, hands, forearms, lower legs, and feet (US EPA, 2014). The age-weighted mean skin surface area of 4,639 cm$^2$ was used for the adolescent Recreator based on EPA's values for an adolescent (6-16 years old) with exposed skin limited to the head, hands, forearms, lower legs,

and feet (US EPA, 2011a).[11] For a Recreator exposure to soil, this likely overestimates exposure, because it is likely that the Recreator would wear shoes when walking on the site. The SA of 2,373 $cm^2$ was used for the child Resident and Recreator, based on EPA's recommended value for a child Resident (<1 to <6 years old) with exposed skin limited to the head, hands, forearms, lower legs, and feet (US EPA, 2014).

For assessment of mutagenic compounds, the following skin surface areas were used (Appendix C, Table 4.5): 1,954 $cm^2$ (0-2 years old), 2,591 $cm^2$ (2-6 years old), 4,639 $cm^2$ (6-16 years old), and 6,709 $cm^2$ (16-26 years old). The skin surface area was 3,527 $cm^2$ for the Outdoor Worker, Construction Worker, and Utility Worker based on EPA's recommended value for an industrial worker with exposure to the face, hands, and forearms (US EPA, 2014).

EPA assumes that VOCs in soil will volatilize before penetrating the skin. Thus, EPA does not provide default dermal absorption fraction values for VOCs (US EPA, 2004a). Therefore, dermal contact with VOCs in soil is not evaluated in the risk assessment.

## Mutagenic Compounds

For the dermal contact pathway, intake for mutagens was calculated as:

$$DAD\left(\frac{mg}{kg \cdot day}\right) = \frac{C_{soil}\left(\frac{mg}{kg}\right) \times ABS \times DFSM_{adj}\left(\frac{mg-year}{kg-day}\right) \times EF\left(\frac{events}{yr}\right) \times 10^{-6}\ \frac{kg}{mg}}{AT(days)}$$

where DAD, $C_{soil}$, ABS, EF, and AT are as defined above, and where the age-adjusted mutagenic soil dermal contact factor ($DFSM_{adj}$) is given by:

$$DFSM_{adj}\left(\frac{mg-year}{kg-day}\right) = \left(\frac{ED_{0-2} \times AF_c \times SA_{0-2} \times 10}{BW_{0-2}}\right) + \left(\frac{ED_{2-6} \times AF_c \times SA_{2-6} \times 3}{BW_{2-6}}\right) + \left(\frac{ED_{6-16} \times AF_a \times SA_{6-16} \times 3}{BW_{6-16}}\right) + \left(\frac{ED_{16-26} \times AF_a \times SA_{16-26} \times 1}{BW_{16-26}}\right)$$

where:

| | | |
|---|---|---|
| $DFSM_{adj}$ | = | Age-adjusted Mutagenic Soil Dermal Contact Factor (mg-year/kg-day) |
| $AF_c$ | = | Child Soil to Skin Adherence Factor (mg/$cm^2$) |
| $AF_a$ | = | Adult Soil to Skin Adherence Factor (mg/$cm^2$) |
| $SA_{(age)}$ | = | Skin Surface Area Exposed to Soil for age range ($cm^2$/day) |
| $ED_{(age)}$ | = | Exposure Duration (years) |
| $BW_{(age)}$ | = | Body Weight for age range (kg) |

For the mutagen trichloroethylene, which was detected in NFA soil, calculation of cancer risks for the Resident are done as follows (US EPA, 2016e):

[11] Pursuant to EPA guidance (US EPA, 2004a), the assumption of forearms representing 45% of the arms and lower legs representing 40% of the legs was used.

$$DAD_{TCE}\left(\frac{mg}{kg\cdot day}\right)=\frac{C_{soil}\left(\frac{mg}{kg}\right)\times ABS\times\left[\left(CAF_o\times\left(DF_{child}+DF_{adult}\right)\right)+\left(MAF_o\times DFSM_{adj}\right)\right]\times EF\left(\frac{days}{yr}\right)\times 10^{-6}\,\frac{kg}{mg}}{AT\left(days\right)}$$

where DAD, $C_{soil}$, ABS, EF, AT, and $DFSM_{adj}$ are as defined above, and where the dermal contact factors for child ($DF_{child}$) and adult ($DF_{adult}$) are calculated by:

$$DF=\frac{SA\times AF\times ED}{BW}$$

where SA, AF, ED, and BW are defined as above, and where:

| | | |
|---|---|---|
| $DF_{child}$ | = | Intake factor for a child 0-6 (mg-year/kg-day) |
| $DF_{adult}$ | = | Intake factor for an adult (mg-year/kg-day) |
| $CAF_o$ | = | Toxicity adjustment factor for carcinogens – oral slope factor (unitless) |
| $MAF_o$ | = | Toxicity adjustment factor for mutagens – oral slope factor (unitless) |

The derivation of the $CAF_o$ and $MAF_o$ are presented in Section 7.1.1.

### 7.1.3 Inhalation of Particulates and VOCs from Soil

For inhalation of particulates and VOCs generated from soil, an average daily exposure was calculated as (US EPA, 2002, 2009a):

$$EC\left(\frac{mg}{m^3}\right)=\frac{C_{air}\left(\frac{mg}{m^3}\right)\times ET\left(\frac{hr}{d}\right)\times EF\left(\frac{d}{yr}\right)\times ED\left(yr\right)\times\frac{1d}{24hr}}{AT\left(d\right)}$$

where:

| | | |
|---|---|---|
| EC | = | Exposure Concentration (milligrams per cubic meter [$mg/m^3$]) |
| $C_{air}$ | = | Concentration of Chemical in Air ($mg/m^3$) |
| ET | = | Exposure Time (hours/day) |
| EF | = | Exposure Frequency (days/year) |
| ED | = | Exposure Duration (years) |
| AT | = | Averaging Time (days) |

The parameters unique to the inhalation exposure equation, concentration of chemical in air ($C_{air}$) and exposure time (ET), are discussed in this section. The values for other parameters are the same as discussed in Section 7.1.1.

*Concentration of Chemical in Air ($C_{air}$).* The concentration of a substance in air was determined with the volatilization factor (VF) and the particulate emissions factor (PEF) using the following equation:

$$C_{air} = C_{soil} \times \left( \frac{1}{VF} + \frac{1}{PEF} \right)$$

where:

| | | |
|---|---|---|
| $C_{air}$ | = | Concentration of Chemical in Air (mg/m$^3$) |
| $C_{soil}$ | = | Concentration of the Chemical in Soil (mg/kg) |
| VF | = | Volatilization Factor (m$^3$ air/kg soil) |
| PEF | = | Particulate Emissions Factor (m$^3$ air/kg soil) |

The chemical-specific VFs for Philadelphia, Pennsylvania were calculated using the equations described in the RSL User Guide (US EPA, 2016e) and the same assumptions as the PEF calculations discussed below. The chemical-specific VFs used in the air concentration calculations are presented in Appendix C, Tables 3.6 and 3.7.

The EPA default PEF of 3.2 x 10$^9$ m$^3$ air/kg soil for Philadelphia, Pennsylvania, was selected as the most representative of conditions in the Gibbsboro area (US EPA, 1996, 2015b). The derivation of the PEF is presented below. The PEF was calculated based on meteorological conditions within Climatic Zone VIII, which includes the state of New Jersey (US EPA, 1996). Of the three cities with specific meteorological information available within Climatic Zone VIII, Philadelphia, Pennsylvania, was selected as the most representative of conditions in the Gibbsboro/Voorhees, New Jersey, area (US EPA, 1996).

The PEF was calculated using the following equations:

$$PEF\left(\frac{m^3}{kg}\right) = Q/C \times \frac{3{,}600\,\text{sec}/hr}{0.036 \times (1-V) \times (U_m/U_t)^3 \times F(x)}$$

$$Q/C = A \times \exp\left[\frac{(\ln A_s - B)^2}{C}\right]$$

where:

| | | |
|---|---|---|
| Q/C | = | Dispersion Factor for fugitive dusts emitted from soils |
| V | = | Fraction of Vegetative Cover (unitless) |
| $U_m$ | = | Mean Annual Windspeed (meters per second [m/s]) |
| $U_t$ | = | Equivalent Threshold Value of Windspeed at 7 m (m/s) |
| F(x) | = | Function Dependent on $U_m/U_t$ (unitless) |
| $A_s$ | = | Area of Site (acre) |
| A | = | PEF Dispersion Constant A (unitless) |
| B | = | PEF Dispersion Constant B (unitless) |
| C | = | PEF Dispersion Constant C (unitless) |

*Dispersion Factor (Q/C).* Calculated using Equation D-1 from EPA (2002) (87.36898 grams per square meters per second [g/m$^2$-s] per kg/m$^3$).

*Fraction of Vegetative Cover (V).* The PEF was calculated using the default vegetation coverage of 50% or 0.5.

*Mean Annual Windspeed ($U_m$)*, *Threshold Value of Windspeed ($U_t$)*, *Function Dependent on* $U_m/U_t$. The mean annual windspeed (4.29 m/s), the equivalent threshold value of windspeed (11.32 m/s), and the function dependent on $U_m/U_t$ (0.0993) were selected based on values listed for Philadelphia, Pennsylvania (US EPA, 1996, Table 2).

*Area of Site (acre).* Area is the default of 0.5 acre.

*PEF Dispersion Constants (A*, *B*, *C).* These constants were derived using dispersion modeling and meteorological data for each of the 29 cities representing the various climatic zones across the United States (US EPA, 2002). The dispersion constants (A = 14.0111, B = 19.6154, and C = 225.3397) for Philadelphia, Pennsylvania, were selected as the most representative geographic location (US EPA, 2002, Exhibit D-2).

*Exposure Time (ET).* Exposure time is the amount of time a receptor is exposed to soil particulates/volatiles in the air. Construction, Utility, and Outdoor Workers are assumed to be exposed to soil particulate/volatiles throughout an 8-hour work day (US EPA, 2014). Residents are conservatively assumed to be exposed to soil particulates/volatiles throughout the entire day (US EPA, 2014). Recreators (adult, adolescent, and child) are conservatively assumed to be exposed to soil particulates/volatiles while on site for 8 hours/day based on professional judgment.

## Mutagenic Compounds

For the inhalation pathway, the exposure concentration for mutagens is calculated as:

$$EC = C_{air} \times IF_{adj}$$

where the age-adjusted intake factor ($IF_{adj}$, unitless) is given by:

$$IF_{adj} = \frac{EF \times ET}{AT} \times \left[(ED_{0-2} \times 10) + (ED_{2-6} \times 3) + (ED_{6-16} \times 3) + (ED_{16-26} \times 1)\right]$$

For the mutagen trichloroethylene, which was detected in NFA soil, calculation of cancer risks for the Resident are done as follows (US EPA, 2016e):

$$EC_{TCE} = C_{air} \times \left[\left(CAF_i \times \left(IF_{child} + IF_{adult}\right)\right) + \left(MAF_i \times IF_{adj}\right)\right]$$

where EC, $C_{air}$, and $IF_{adj}$ are as defined above, and where the intake factors for child ($IF_{child}$) and adult ($IF_{adult}$) are calculated by:

$$IF = \frac{ET \times EF \times ED}{AT}$$

where ET, EF, ED, and AT are defined as above, and where:

$IF_{child}$ = Intake factor for a child 0-6 (unitless)
$IF_{adult}$ = Intake factor for an adult (unitless)
$CAF_i$ = Toxicity adjustment factor for carcinogens – inhalation unit risk (unitless)
$MAF_i$ = Toxicity adjustment factor for mutagens – inhalation unit risk (unitless)

The $CAF_i$ and $MAF_i$ are calculated based on the different toxicity values (inhalation unit risks [IURs]) for TCE, as follows (US EPA, 2016e):

$$CAF_i(0.756) = \frac{NHL{+}Liver\ IUR\left(3.1 \times 10^{-6}\left(\frac{\mu g}{m^3}\right)^{-1}\right)}{Adult\text{-}based\ IUR\left(4.1 \times 10^{-6}\left(\frac{\mu g}{m^3}\right)^{-1}\right)}$$

$$MAF_i(0.244) = \frac{Kidney\ IUR\left(1.0 \times 10^{-6}\left(\frac{\mu g}{m^3}\right)^{-1}\right)}{Adult\text{-}based\ IUR\left(4.1 \times 10^{-6}\left(\frac{\mu g}{m^3}\right)^{-1}\right)}$$

### 7.1.4 Incidental Ingestion and Dermal Contact with Sediment

For the sediment incidental ingestion and dermal exposure pathways, intake was calculated using the same equation and parameters used to calculate soil incidental ingestion (Section 7.1.1) and dermal exposure (Section 7.1.2). Several parameters used in these equations have different assumptions from those used to determine soil exposure: sediment concentration ($C_{sediment}$), bioavailability (B), sediment to skin adherence factors (AF), and the exposure frequency (EF), as discussed below.

*Sediment Concentration ($C_{sediment}$).* The lower of either the 95% UCLM or the maximum detected concentration in sediment was used as the EPC.

*Relative Bioavailability (B).* Sediment-specific relative bioavailability values are not available. The soil bioavailability values were used for sediment.

*Sediment to Skin Adherence Factor (AF).* EPA's recommended soil to skin adherence factor for a child resident (0.2 mg/cm$^2$) is based on children playing in wet soil (US EPA, 2014). This value was used to represent contact with sediment for the adult/adolescent/child Recreator. For assessment of mutagenic compounds, the child soil to skin adherence factor of 0.2 mg/cm$^2$ was used for all the age groups (0-2 years old, 2-6 years old, 6-16 years old, and 16-26 years old age groups). These factors were used because adherence factors are not available for specific ages.

*Exposure Frequency (EF)*. Recreators are assumed to contact sediment at the site 2 days/week during the five warmest months of the year (May through September), for a total of 44 days/year.

All other exposure assumptions (skin surface area exposed, exposure duration, and body weight) were the same as the soil assumptions for dermal contact and discussed above.

### 7.1.5 Dermal Contact with Surface Water

For dermal exposure to contaminants in surface water, a dermal absorbed dose was calculated according to the recommended equations in EPA's Supplemental Guidance for Dermal Risk Assessment (US EPA, 2004a).

$$DAD\left(\frac{mg}{kg \cdot day}\right) = \frac{DA_{event}\left(\frac{mg}{cm^2 - event}\right) \times SA\left(cm^2\right) \times EV\left(\frac{event}{day}\right) \times EF\left(\frac{days}{yr}\right) \times ED\left(yrs\right)}{BW\left(kg\right) \times AT\left(days\right)}$$

where:

| | | |
|---|---|---|
| DAD | = | Dermal Absorbed Dose (mg/kg-d) |
| $DA_{event}$ | = | Absorbed Dose per event (mg/cm$^2$-event) |
| EV | = | Event Frequency (events/day) |
| SA | = | Skin Surface Area Exposed (cm$^2$) |
| EF | = | Exposure Frequency (exposure events/year) |
| ED | = | Exposure Duration (years) |
| BW | = | Body Weight (kg) |
| AT | = | Averaging Time (days) |

The absorbed dose per event ($DA_{event}$) from surface water dermal contact was calculated using the EPA equations (US EPA, 2004a) presented below. For inorganics in water, the $DA_{event}$ is calculated using the dermal permeability coefficient of a compound in water (Kp) accounting for the event duration ($t_{event}$). For organics in water, EPA uses a mathematical model to predict absorption from exposures to water. Compounds for which there are sufficient data to predict dermal absorption with acceptable confidence are said to be within the model's "effective predictive domain" (EPD). There is significant uncertainty associated with evaluation of dermal absorption for highly lipophilic chemicals that fall outside the EPD. Three compounds identified as COPCs in surface water (benzo(a)pyrene, benzo(b)fluoranthene, and indeno(1,2,3-cd)pyrene) fall outside the EPD. EPA provides guidance on quantification of dermal risk from chemicals in water that fall outside the EPD (US EPA, 2004a). Therefore, although there is low confidence in the dermal permeability coefficient values for chemicals outside the EPD, these values were used to calculate dermal risk for the three COPCs that are outside the EPD (US EPA, 2016e). One of the parameters in the absorbed dose per event calculation is the event duration (hour/event), which is the amount of time spent in dermal contact with water. For the event duration, it is assumed that the adult/adolescent/child Recreator is exposed to surface water for 1 hour each day they visit the site.

Vinyl chloride (VC), which is a mutagen, was detected in surface water. Cancer risks for VC are calculated using a different equation to account for increased susceptibility from early life exposures, as per EPA guidance (US EPA, 2016e, 2000). The DAD for VC is calculated for the child Recreator using the following equation:

$$DAD\left(\frac{mg}{kg \cdot day}\right) = DA_{event}\left(\frac{mg}{cm^2 - event}\right) \times \left[IF_{child} + \left(\frac{EV_{child} \times SA_{child}}{BW_{child}}\right)\right]$$

where $DA_{event}$, EV, SA, and BW are defined as above, and the child-specific intake factor (IF) is calculated as follows:

$$IF_{child} = \frac{SA_{child} \times EV_{child} \times EF \times ED_{child}}{BW_{child} \times AT}$$

The same adjustment is performed for the adolescent Recreator using appropriate age-adjusted parameters.

## Calculation of Absorbed Dose Per Event ($DA_{event}$)

### Inorganics

$$DA_{event}\left(\frac{mg}{cm^2 \cdot event}\right) = C_{sw}\left(\frac{mg}{L}\right) \times Kp\left(\frac{cm}{hr}\right) \times t_{event}\left(\frac{hr}{event}\right) \times 0.001\frac{L}{cm^3}$$

where:

| | | |
|---|---|---|
| $C_{sw}$ | = | Concentration of Chemical in Surface Water (mg/L) |
| Kp | = | Dermal Permeability Coefficient of Compound in Water (centimeter [cm]/hour) |
| $t_{event}$ | = | Event Duration (hours/event) |

The exposure parameters that are specific to surface water dermal pathway are discussed below.

*Surface Water Concentrations ($C_W$).* The lower of either the 95% UCLM or the maximum detected concentration in surface water was used as the EPC.

*Skin Surface Area Exposed (SA).* This parameter reflects the amount of skin that is available for exposure to surface water. For the wading scenarios, to be consistent with sediment exposure, the skin surface area is 6,032 $cm^2$ for the adult Recreator, 5,340 $cm^2$ for the adolescent Recreator, and 2,373 $cm^2$ for the child Recreator. For assessment of mutagenic compounds, the following values were used (Appendix C, Table 4.5): 1,954 $cm^2$ (0-2 years old), 2,591 $cm^2$ (2-6 years old), 4,639 $cm^2$ (6-16 years old), and 6,709 $cm^2$ (16-26 years old).

*Event Duration ($t_{event}$).* Recreators were assumed to wade for 1 hour per day based on professional judgment.

*Exposure Frequency (EF)*. Recreators were assumed to contact surface water at the site 2 days/week during the five warmest months of the year (May through September). This yields an exposure frequency of 44 days/year.

### Organics

For organics, the absorbed dose per event calculation depends on whether the chemical reaches steady state within the event duration, as presented in the equations below.

**Non-steady State ($t_{event} \leq t^*$)**

Where the event duration ($t_{event}$) is less than or equal to the time to reach steady state (t*):

$$DA_{event}\left(\frac{mg}{cm^2 \cdot event}\right) = 2 \times FA \times C_{sw}\left(\frac{mg}{L}\right) \times Kp\left(\frac{cm}{hr}\right) \times \sqrt{\left(\frac{6 \times \tau_{event}\left(\frac{hr}{event}\right) \times t_{event}\left(\frac{hr}{event}\right)}{\pi}\right)}$$

**Steady State ($t_{event} > t^*$)**

Where the event duration ($t_{event}$) is greater than the time to reach steady state (t*):

$$DA_{event}\left(\frac{mg}{cm^2 \cdot event}\right) = FA \times C_{sw}\left(\frac{mg}{L}\right) \times Kp\left(\frac{cm}{hr}\right) \times \left[\left(\frac{t_{event}\left(\frac{hr}{event}\right)}{(1+B)}\right) + 2 \times \tau_{event}\left(\frac{hr}{event}\right) \times \left(\frac{1+3B+3B^2}{(1+B)^2}\right)\right]$$

where:

| | | |
|---|---|---|
| FA | = | Fraction Absorbed (unitless) |
| $C_{sw}$ | = | Concentration of Chemical in Surface Water (mg/L) |
| Kp | = | Dermal Permeability Coefficient of Compound in Water (cm/hour) |
| $\tau$ event | = | Lag Time (hour/event) |
| $t_{event}$ | = | Event Duration (hours/event) |
| B | = | Ratio of permeability of chemical in stratum corneum to permeability in viable epidermis (unitless) |

The fraction absorbed and dermal permeability coefficient values were obtained from the chemical-specific parameters used to calculate the EPA RSLs (US EPA, 2016f).

The other various factors were calculated with the following equations.

**Permeability Factor (B)**

$$B = Kp\left(\frac{cm}{hr}\right) \times \left(\frac{MW\left(\frac{g}{mole}\right)^{1/2}}{2.6}\right)$$

**Steady State Time Constant (t*)**

If B ≤ 0.6:

$$t^*(hr) = 2.4 \times \tau_{event}\left(\frac{hr}{event}\right)$$

If B > 0.6:

$$t^*(hr) = \sqrt{b-(b^2-c^2)} \times \left(\frac{l_{sc}^2\,(cm)}{D_{sc}\left(\frac{cm^2}{hr}\right)}\right)$$

**Factors "c" and "b"**

$$c = \left(\frac{1+3B+3B^2}{3(1+B)}\right)$$

$$b = \left(\frac{2(1+B)^2}{\pi}\right) - c$$

**Lag Time ($\tau$ event)**

$$\tau_{event}\left(\frac{hr}{event}\right) = \frac{l_{sc}^2(cm)}{6D_{sc}\left(\frac{cm^2}{hr}\right)}$$

**Effective Diffusivity (Dsc)**

$$D_{sc}\left(\frac{cm^2}{hr}\right) = 10^{-2.8-(0.0056MW\left(\frac{g}{mole}\right))} \times l_{sc}(cm)$$

where:

| | | |
|---|---|---|
| $\tau$ event | = | Lag time (hours/event) |
| t* | = | Time to reach steady state (hour) |
| B | = | Ratio of permeability of chemical in stratum corneum to permeability in viable epidermis (unitless) |
| b,c | = | Correlation coefficients, which have been fitted to the Flynn data (unitless) |
| $l_{sc}$ | = | Skin thickness (cm) |

| | | |
|---|---|---|
| MW | = | Molecular weight (g/mole) |
| $D_{sc}$ | = | Effective diffusion coefficient for chemical transfer through the stratum corneum ($cm^2$/hour) |

The surface water absorbed dose per event are presented in Appendix C, Table 4.5.

## Mutagenic Compounds

For the dermal contact pathway, the dermal absorbed dose for mutagens was calculated as:

$$DAD\left(\frac{mg}{kg \cdot day}\right) = \frac{DA_{event}\left(\frac{mg}{cm^2 - event}\right) \times DFWM_{adj}\left(\frac{events \cdot cm^2}{kg}\right)}{AT(days)}$$

where the age-adjusted mutagenic surface water dermal contact factor ($DFWM_{adj}$) is given by:

$$DFWM_{adj}\left(\frac{events \cdot cm^2}{kg}\right) = \left(\frac{EV_{0-2} \times EF_{0-2} \times ED_{0-2} \times SA_{0-2} \times 10}{BW_{0-2}}\right) + \left(\frac{EV_{2-6} \times EF_{2-6} \times ED_{2-6} \times SA_{2-6} \times 3}{BW_{2-6}}\right) + \left(\frac{EV_{6-16} \times EF_{6-16} \times ED_{6-16} \times SA_{6-16} \times 3}{BW_{6-16}}\right) + \left(\frac{EV_{6-16} \times EF_{6-16} \times ED_{16-30} \times SA_{16-26} \times 1}{BW_{16-26}}\right)$$

where:

| | | |
|---|---|---|
| $DFWM_{adj}$ | = | Age-adjusted Mutagenic Surface Water Dermal Contact Factor (events-$cm^2$/ kg) |
| $EV_{(age)}$ | = | Event Frequency (events/day) |
| $EF_{(age)}$ | = | Exposure Frequency (days/year) |
| $ED_{(age)}$ | = | Exposure Duration (years) |
| $SA_{(age)}$ | = | Skin Surface Area Exposed to Surface for age range ($cm^2$/day) |
| $BW_{(age)}$ | = | Body Weight for age range (kg) |

The $DA_{event}$ is calculated using the equations for COPCs without a mutagenic mode of action, but adjusting the event duration ($t_{event}$) for the Resident accordingly.

$$t_{event-adj}\left(\frac{hr}{event}\right) = \left(\frac{t_{event(0-2)} \times ED_{(0-2)} + t_{event(2-6)} \times ED_{(2-6)} + t_{event(6-16)} \times ED_{(6-16)} + t_{event(16-26)} \times ED_{(16-26)}}{ED_{(0-2)} + ED_{(2-6)} + ED_{(6-16)} + ED_{(16-26)}}\right)$$

where:

| | | |
|---|---|---|
| $t_{event-adj}$ | = | Age-adjusted Mutagenic Surface Water Event Duration (hours/event) |
| $t_{event(age)}$ | = | Event Duration (hours/event) |
| $ED_{(age)}$ | = | Exposure Duration (years) |

## 7.2 Adult Lead Model

Current knowledge of lead pharmacokinetics indicates that risk values derived by the standard risk methodology would not provide an accurate indication of potential risk; therefore, EPA has not yet established toxicity criteria for lead (US EPA, 2004b). Consequently, lead risks were evaluated using blood lead models, which predict BLLs based on the total lead intake from various environmental media. Lead risks for non-residential adults were assessed using EPA's ALM (US EPA, 2003b, 2009b, 2017b). The ALM predicts a median BLL estimate for an adult as a function of the baseline BLL plus an increment that is attributable to exposure to site soil (US EPA, 2003b). This increment is a function of the biokinetic slope factor (BKSF), the concentration of lead in soil, the soil ingestion rate, the fraction of lead in soil that is absorbed, and the exposure frequency. EPA guidance sets a target BLL for an adult female in order to protect a developing fetus, with the goal that the fetus should have no more than a 5% probability of exceeding the target BLL (US EPA, 2003b). The age of the adult receptor is different for lead than for other non-lead COPCs. For evaluation of lead, EPA considers the appropriate adult receptor to be a woman of child-bearing age (US EPA, 2003b).

The basic form of the equation for the ALM is as follows:

$$BLL_{adult} = PbB + \frac{(EF \times AbsF \times PbS \times IR \times BKSF)}{AT}$$

where:

| | | |
|---|---|---|
| BLL | = | Blood Lead Level predicted by model (µg/dL) |
| PbB | = | GM Baseline BLL (µg/dL) for adult females (aged 18-45 years) |
| EF | = | Exposure Frequency (days/year) |
| AbsF | = | Absorption Fraction (dimensionless) |
| PbS | = | Soil Lead concentration (µg/g) |
| IR | = | Soil Ingestion Rate (g/day) |
| BKSF | = | Biokinetic Slope Factor (µg/dL per µg/day) |
| AT | = | Averaging Time (days/year) |

The input values used in the model are summarized in Table 8 and described below. First, an average baseline lead concentration in blood ($PbB_{base}$) for adults is identified to account for continuing exposure to background levels of lead in food, soil, and dust, and pre-existing body burdens due to prior lead exposures. Baseline BLLs were obtained from EPA (US EPA, 2017b) and are based on the most recent data from National Health and Nutrition Examination Surveys (NHANES) from 2009-2014. For adults, the GM and geometric standard deviation (GSD) BLLs for women of childbearing age (ages 18-45), where the GM is 0.6 µg/dL and the GSD is 1.8, were used to reflect the most current data. To this baseline, the model adds the incremental increase in blood lead due to the lead source of interest (in this case, exposure to lead *via* incidental ingestion of soil or sediment).

Since the ALM is used to assess lead risks for non-residential scenarios (US EPA, 2017b), lead risks were calculated for the Construction Worker, Utility Worker, Outdoor Worker, and adult Recreator. The concentration of lead in soil (PbS) was the arithmetic mean lead concentration (*i.e.*, EPC) in each exposure area. Lead uptake on a daily basis is calculated by multiplying the

concentration of lead in soil by the soil ingestion rate (IR) and the absorption fraction (AbsF) for lead in soil. The absorption fraction is the amount of lead that is absorbed into the bloodstream from the GI tract. The exposure frequency (EF) varies by receptor and exposure area. To evaluate lead risk, exposure frequencies were 219 days/year for the Outdoor Worker and Construction Worker, 150 days/year for the Recreator, and 10 days/year for the Utility Worker. The value of 219 days/year is recommended by EPA (US EPA, 2003b) and is based on the average time spent at work by both full-time and part-time workers.[12] For all receptors with exposure frequencies other than 219 days/year, the exposure frequency is identical to that used to evaluate risk for the non-lead COPCs. The averaging time (AT) for chronic exposure to lead in soil is assumed to be 1 year (*i.e.*, 365 days) for all receptors. The BKSF relates the incremental lead uptake into the body to an incremental increase in BLL in adults. EPA's default value of 0.4 was used for the BKSF.

The soil and sediment ingestion rates for the adult Recreator and Outdoor Worker were assumed to be 0.05 g/day to reflect central tendency estimates. The soil ingestion rate for the Construction Worker and Utility Worker was 0.1 g/day. The exposure inputs used in a lead risk assessment should be central tendency estimates, not upper-bound estimates, because the blood lead model predicts a GM BLL and the GSD is used to calculate the upper-bound estimated (95$^{th}$ percentile) BLL. This is the reason that the values for some exposure parameters differ for non-lead COPC and lead risk assessments.

Lead was identified as a COPC in UNDV soil and UHC sediment. Recreators were assumed to be exposed to sediment as well as soil for 44 days out of the 150 days/year they visit the site. Therefore, the EPC used in the lead model was a weighted mean concentration of UNDV soil and UHC sediment.[13] For all other exposure areas, the lead EPC was the mean soil concentration.

For lead, EPA recommends an oral absorption factor for adults of 0.12 for ingestion of lead in soil based on 20% absorption of soluble lead, and a relative bioavailability of 60% for lead in soil (*i.e.*, 0.12 = 0.2 x 0.6) (US EPA, 2003b). The recommended EPA absorption factor of 0.12 was used to evaluate ingestion of lead from soil or sediment.

Total BLLs for adults are predicted by adding the estimated incremental increase in blood lead to the average baseline BLL. A GSD appropriate for adults was used to estimate the probable range of BLLs around the predicted GM adult BLL from the model. For this evaluation, EPA's recommended baseline BLL of 0.6 µg/dL and a GSD of 1.8 were used (US EPA, 2017b).

BLLs estimated using the ALM were evaluated based on a comparison to the EPA's risk management criterion for lead. EPA's health protection goal is for a developing fetus to have no more than a 5% probability of exceeding the target BLL (US EPA, 2003b). The adult and adolescent lead risks were expressed as the probability of having a fetal blood lead above 5 µg/dL with a probability goal of less than or equal to 5%. This goal is based on protecting the fetus of a pregnant receptor.

[12] Note that the exposure frequency recommended for adults in the ALM is a central tendency value and is lower than that used for the non-lead risk assessment.
[13] The weighted mean concentration is calculated as [(soil EPC x soil EF) + (sediment EPC x sediment EF)]/(soil EF).

## 7.3 IEUBK Model

Lead risks for children were assessed using an EPA blood lead model known as the IEUBK model (US EPA, 1994a, 2010b). The IEUBK model is a computer-based model that estimates the blood lead concentration in children resulting from their exposure to lead in soil, dust, drinking water, diet, and air. Specifically, the model estimates the intake and uptake of lead into the body and then uses biokinetic modeling to predict BLLs. Because of variations in behavior and physiology among individual children, different children will have different BLLs, even if they are exposed to the same environment. The IEUBK model addresses this by treating its central estimate of blood lead concentration (averaged over childhood from ages 0-7 years)[14] as a GM of a lognormal distribution among similarly exposed children. EPA's default GSD of 1.6 is used to calculate the proportion of children in the variable population with BLLs falling above 10 µg/dL. Child lead risks are presented as the probability of having a blood lead above 5 µg/dL, consistent with the target BLL used for the ALM and at EPA's direction.

The input values used in the IEUBK model are presented in Table 9. Certain parameters have input values that vary with age; these are listed as a range in Table 9. The IEUBK model assumes that an individual's total daily soil ingestion is based on 45% soil and 55% house dust. EPA's recommended weighting factors of 45% soil and 55% dust were used for the child Resident and child Recreator. In the absence of site-specific air concentrations, dietary lead intake, drinking water concentration, water consumption rate, and soil ingestion rate, default assumptions were used (Table 9). US EPA's recommended maternal blood concentration of 0.6 µg/dL was used (US EPA, 2017b). For the IEUBK model, soluble lead is estimated to be 50% bioavailable in food and water and 30% bioavailable in soil and dust (US EPA, 2007a).

The lead EPCs are presented in Appendix C, Table 3.3. For receptors with exposure to both soil and sediment, the lead EPC was a weighted mean concentration. The child Recreator is assumed to be exposed to UNDV soils 150 days/year, and UHC sediment for 44 of the 150 days they visit the site. Therefore, the EPC used in the lead model was a weighted mean concentration of UNDV soil and UHC sediment.[15]

It should be noted that the dermal exposure route for lead in soil is not evaluated because this exposure route is typically insignificant when compared to ingestion. The IEUBK model makes no provision for assessing dermal exposures.

[14] Note that the age of the child receptor for evaluation of lead risk is different than for the non-lead COPCs; the IEUBK model uses a child aged 0-7 years, while the non-lead risks use 0-6 years for the child.
[15] The weighted mean concentration is calculated as [(soil EPC x soil EF) + (sediment EPC x sediment EF)]/(soil EF).

# 8 Toxicity Assessment

## 8.1 Overview of Toxicity Values

Potential cancer risk and non-cancer hazard are evaluated using dose-response relationships for carcinogenicity (oral cancer slope factors [CSFs]) and systemic toxicity (oral RfDs). The primary source of toxicity values is EPA's IRIS. Toxicity values in IRIS undergo a rigorous peer review process and are generally considered to be of high quality. Additional toxicity values were obtained from the EPA RSL Table (US EPA, 2016b) which obtained some values from the PPRTV or the HEAST.

In most cases, little information is available about the form of a compound present in environmental media at the site. Therefore, in cases where toxicity values are available for multiple forms or species of a compound, the toxicity value for the form that is either the most widely applicable or that results in the most conservative estimates of risk was selected. Toxicity factors are summarized in Appendix C (Tables 5.1, 5.2, 6.1, and 6.2) which also includes the source of the toxicity values and the form of the compound they are based on.

Cancer risks were calculated separately for carcinogens with mutagenic modes of action to account for potentially increased susceptibility to mutagenic carcinogens for early life exposures (US EPA, 2005). For the mutagens, EPA recommends weighting the CSFs by the following toxicity adjustment factors: 10-fold adjustment for the 0-2 years old age group, 3-fold adjustment for the 2-6 years old and 6-16 years old age groups, and no adjustment for the 16-26 years old age group (US EPA, 2005).[16]

### Oral Reference Doses

An RfD is an estimate of daily exposure that a sensitive population can experience over a lifetime with a negligible risk of systemic health effects. EPA derives RfDs by first identifying the highest dose level that does not cause observable adverse effects (*i.e.*, the no observed adverse effect level [NOAEL]; US EPA, 1993a). If a NOAEL was not identified, a lowest observed adverse effect level (LOAEL) may be used. This dose level is then divided by uncertainty factors to calculate an RfD. An uncertainty factor of 100 is often used to account for interspecies differences (if animal studies were used) and sensitive human subpopulations (*e.g.*, children and the elderly; US EPA, 1993a). Additional uncertainty factors may be used depending on the quality of the toxicological data. The oral toxicity factors used to evaluate potential non-cancer hazards are presented in Appendix C, Table 5.1. EPA published new RfDs for trimethylbenzenes in September 2016 and benzo(a)pyrene in January 2017, which were used in this HHRA (US EPA, 2016g, 2017a).

[16] For the risk assessment, the toxicity adjustment factors were included in the exposure assessment equations for convenience. Mathematically the cancer risks results are the same, regardless of where the toxicity adjustment factor is applied.

## Oral Cancer Slope Factors

The CSF is an upper-bound estimate of carcinogenic potency used to calculate risk from exposure to carcinogens by relating estimates of lifetime average chemical intake to the incremental risk of an individual developing cancer over their lifetime (US EPA, 1992a). The CSFs recommended by EPA are conservative, upper-bound estimates, which means that EPA is reasonably confident that the "true" cancer risk does not exceed the estimated risk calculated using the CSF, and may be as low as zero.

For VC, which was detected in surface water, EPA's IRIS database presents two CSF values based on the linearized multistage (LMS) method.[17] The CSF for continuous lifetime exposure during adulthood is 0.72 $(mg/kg\text{-}day)^{-1}$, and the CSF for continuous lifetime exposure from birth is 1.4 $(mg/kg\text{-}day)^{-1}$ (US EPA, 2003c). Based on EPA guidance, the CSF for adulthood exposure is used in this HHRA (US EPA, 2016h).

In January 2017, EPA released an updated Toxicological Review of benzo(a)pyrene, with a revised CSF of 1 $(mg/kg\text{-}day)^{-1}$ (US EPA, 2017a), which was used in this HHRA. For the other carcinogenic PAH compounds, the CSF was estimated using a toxic equivalency factor (TEF), which relates the cancer potency of that compound to that of benzo(a)pyrene, the most well-characterized PAH with respect to carcinogenicity. For benzo(a)anthracene, benzo(b)fluoranthene, benzo(k)-fluoranthene, chrysene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene, the CSF is based on the TEF recommended by EPA (US EPA, 1993b).

The oral toxicity factors used to evaluate potential cancer risks are presented in Appendix C, Table 6.1.

## Dermal Reference Doses and Dermal Cancer Slope Factors

There are no EPA-derived toxicity values based specifically on toxicity studies involving dermal exposures. In the absence of dermal-specific RfDs or CSFs, oral toxicity factors are used, assuming that once a chemical is absorbed into the blood stream, the health effects are similar regardless of whether the route of exposure is oral or dermal. However, since oral toxicity criteria are based on the amount of a chemical *administered* per unit time and body weight (chemical intake), they were adjusted to be applicable to *absorbed* doses (dermal exposures are expressed as absorbed intake levels) (US EPA, 1989, 1992b, 2004a).

Since most RfDs are based on studies where a chemical is administered in food or water, this adjustment is made using the oral absorption efficiency for that chemical. If oral absorption is very high (almost 100%), then the absorbed dose is virtually the same as the administered dose, and no adjustment of the toxicity factor is necessary. If oral absorption is very low (*e.g.*, 5%), the absorbed dose is much smaller than the administered dose, and an adjustment of the toxicity criteria is necessary. For any given chemical, EPA recommends adjusting the oral toxicity factor for use in evaluating dermal risks only when the oral absorption for that chemical is less than 50%, to "obviate the need to make comparatively small adjustments in the toxicity value that would otherwise impart on the process a level of accuracy that is not supported by the scientific literature" (US EPA, 2004a).

[17] EPA guidance recommends using values from the LMS method (US EPA, 2003c).

For non-cancer effects, this adjustment is made by multiplying the oral RfD (for applied doses) by the oral absorption efficiency (*i.e.*, $RfD_{oral} \times ABS_{oral} = RfD_{dermal}$). For antimony, barium, cadmium, Cr(VI), manganese, mercury, and vanadium, adjustments of the $RfD_{dermal}$ were performed as recommended by EPA (Appendix C, Table 5.1). For the other COPCs, the dermal RfDs are the same as the oral RfDs.

For cancer, this adjustment is made by dividing the oral CSF (for applied doses) by the oral absorption efficiency (*i.e.*, $CSF_{oral} / ABS_{oral} = CSF_{dermal}$) if the oral absorption efficiency is less than 50%. For Cr(VI), the oral absorption value is 2.5%; therefore, the $CSF_{dermal}$ was adjusted to 20 $(mg/kg\text{-}day)^{-1}$ ($CSF_{oral}$ divided by the oral absorption value) (Appendix C, Table 6.1). No other COPCs with CSFs have oral absorption efficiencies less than 50%; thus, no other adjustments were required.

### Inhalation Reference Concentrations

Inhalation reference concentrations (RfCs) are used to evaluate systemic toxicity *via* inhalation exposure as per EPA (US EPA, 2009a). An inhalation RfC is "an estimate…of a continuous inhalation exposure to the human population (including sensitive subgroups) that is likely to be without appreciable risk of deleterious effects during a lifetime" (US EPA, 2011b). The RfC values are given in units of $mg/m^3$ and are presented in Appendix C, Table 5.2. EPA published new RfCs for trimethylbenzenes in September 2016 and benzo(a)pyrene in January 2017, which were used in this HHRA (US EPA, 2016g, 2017a).

### Inhalation Unit Risk

Inhalation unit risk (IUR) values are used to evaluate inhalation carcinogenicity as recommended by EPA (US EPA, 2009a). An IUR is the "upper-bound excess lifetime cancer risk estimated to result from continuous exposure to an agent at a concentration of 1 $\mu g/m^3$ in air" (US EPA, 2011b).

In January 2017, EPA released an updated Toxicological Review of benzo(a)pyrene, with a revised IUR of $6 \times 10^{-4}$ $(\mu g/m^3)^{-1}$ (US EPA, 2017a), which was used in this HHRA. For the other carcinogenic PAH compounds [benzo(a)anthracene, benzo(b)fluoranthene, benzo(k)-fluoranthene, chrysene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene] the IUR was estimated using TEF approach described above (US EPA, 1993b).

The IUR values used in this HHRA are given in units of $(\mu g/m^3)^{-1}$ and are presented in Appendix C, Table 6.2.

## 8.2 Lead

Current knowledge of lead pharmacokinetics indicates that risk values derived by the standard risk methodology would not provide an accurate indication of potential risk; therefore, EPA has not yet established toxicity criteria (RfD, CSF) for lead (US EPA, 2004b). Instead, lead risks were evaluated by modeling BLLs. Lead risks for adolescents and adults were evaluated using EPA's ALM (US EPA, 2003b) as discussed in Section 7.2. Lead risks for children were evaluated using EPA's IEUBK model (US EPA, 1994a, 2010b) as discussed in Section 7.3.

EPA has assigned lead a weight-of-evidence classification for human carcinogenicity of "B2" ("probable human carcinogen") based on sufficient animal evidence but inadequate human

evidence (US EPA, 2004b). Even though the weight of evidence for lead carcinogenicity is B2, EPA does not evaluate lead cancer risk using a CSF, having concluded that neurological effects in young children are the most relevant endpoint. Adult risks were assessed based on BLLs, with a goal of protecting against this effect in the unborn children of pregnant women.

# 9 Risk Characterization

The HHRA evaluated the cancer risk and non-cancer hazard for all receptors exposed to the various media in each exposure area. The total risk for each receptor is the sum of the risks over all COPCs and all exposure pathways.

## 9.1 Calculation of Cancer Risk

Cancer risks are characterized as the incremental probability that an individual will develop cancer during his or her lifetime due to chemical exposure to contaminants at the site under the specific exposure scenarios evaluated. The risks are calculated with the inputs for the exposure parameters that were described earlier in this report. The term "incremental" implies the risk above the background cancer risk experienced by all individuals in the course of daily life. According to the American Cancer Society, the lifetime probability of developing cancer (*i.e.*, background cancer risk) is slightly less than 1 in 2 (42%) for men and slightly more than 1 in 3 (38%) for women (ACS, 2016). The incremental risk above the background cancer risk is termed the "excess lifetime cancer risk" (ELCR). Cancer risks are expressed as a unitless probability (*e.g.*, 1 in 1 million, or 1 x $10^{-6}$) of an individual developing cancer over a lifetime, above background risk, as a result of site-related exposures. EPA has established a target cancer risk range of 1 x $10^{-6}$ to 1 x $10^{-4}$ (US EPA, 1990, 1991b).

Excess (incremental) cancer risks for the ingestion and dermal exposure pathways were calculated using intake estimates (lifetime average daily doses, calculated as part of the exposure assessment) and CSFs (summarized as part of the toxicity assessment) as follows (US EPA, 1989):

$$CancerRisk = Intake\left(\frac{mg}{kg \cdot day}\right) \times SF\left(\frac{mg}{kg \cdot day}\right)^{-1}$$

For the inhalation pathway, the cancer risk was calculated as the inhalation exposure concentration (in µg/$m^3$) multiplied by the IUR:

$$CancerRisk = EC\left(\frac{\mu g}{m^3}\right) \times IUR\left(\frac{\mu g}{m^3}\right)^{-1}$$

Cancer risks were calculated for each exposure pathway and COPC according to EPA guidance (US EPA, 1989). The total ELCR was the sum of the cancer risks across all COPCs and exposure pathways for each exposure area. Pursuant to EPA guidance (US EPA, 1989), the total cancer risks were rounded to one significant digit for presentation.[18]

[18] The use of significant figures in reporting risk results was presented in EPA (1989), p. 8-8 for non-cancer hazard and p. 8-12 for cancer risk.

## 9.2 Calculation of Non-cancer Hazard

Risks from non-carcinogenic effects are expressed as HQs rather than probabilities. An HQ compares the calculated intakes and exposures (average daily doses or exposures, calculated as part of the exposure assessment in Section 7) to RfDs or concentrations derived by EPA (RfDs and RfCs) (summarized as part of the toxicity assessment in Section 8).

For soil ingestion, oral intake estimates (expressed as applied or administered doses) were divided by the oral RfD (applicable to applied or administered doses). For dermal exposures to soil, dermal intake estimates (expressed as an absorbed dose) were divided by an adjusted oral RfD (adjusted to apply to absorbed doses) (US EPA, 2004a). The HQ for oral and dermal intakes was calculated based on the RfD as shown in EPA (1989):

$$HazardQuotient = \frac{Intake\left(\frac{mg}{kg \cdot day}\right)}{RfD\left(\frac{mg}{kg \cdot day}\right)}$$

For the inhalation pathway, the HQ was calculated as the inhalation exposure concentration (in mg/m$^3$) divided by the inhalation RfC:

$$HazardQuotient = \frac{EC\left(\frac{mg}{m^3}\right)}{RfC\left(\frac{mg}{m^3}\right)}$$

HQs were calculated for each receptor, exposure pathway, and COPC according to EPA guidance (US EPA, 1989). For each exposure route, HQs were summed across all COPCs to calculate a hazard index (HI). As per EPA guidance, HIs were rounded to one significant figure, and HIs for the individual exposure pathways were rounded to two significant figures (US EPA, 1989).

EPA considers an HI greater than 1 to exceed the target risk threshold. Because an HQ is simply a ratio of site exposures to reference exposure levels (RfDs, RfCs, *etc.*), HIs do not represent the probability that an adverse health effect will occur. An HI less than 1 suggests that exposures are likely to be without an appreciable risk of non-cancer effects during a lifetime. An HI greater than 1 indicates only that a potential may exist for adverse health effects. Unlike cancer risks, non-cancer HIs are not additive across different age groups for a resident. Typically, because child exposures are higher than adult exposures, the HI for a child Resident represents the greatest HI experienced by that receptor during his or her lifetime.

Summing HQs for different COPCs represents a conservative approach that may overestimate actual Site risks, because the RfD or RfC for a COPC is calculated based on a specific toxicological endpoint (*e.g.*, liver or kidney effects). As recognized by EPA (1989), summations are most valid for chemicals that are associated with similar toxicological endpoints (*i.e.,* they affect the same target organ or operate *via* similar mechanisms of action). Based on EPA guidance, major effects categories for target organs or systems include neurotoxicity,

developmental toxicity, reproductive toxicity, immunotoxicity, and adverse effects by target organ (*i.e.*, hepatic, renal, respiratory, cardiovascular, GI, hematological, musculoskeletal, and dermal/ocular effect) (US EPA, 1989). The following target organs or systems were identified: developmental, endocrine, GI, hematological, hepatic, immunological, nervous system, renal, reproductive, respiratory, and skin. The target system was assigned as "systemic" when the critical effect was identified as decreased body weight, or when the effect was of unclear biological significance (*e.g.*, decreased hair cystine). In order to provide an accurate estimate of potential non-cancer health risks, the risk tables in Appendix C present the HIs summed by toxicological endpoint (Appendix C, Tables 9.1-9.6).

## 9.3 Risk Characterization for Lead

As described in Section 7.2, lead risks were assessed using EPA's IEUBK model for children, and EPA's ALM for adults. At EPA's direction, lead risk for children is reported as the probability of having a BLL greater than 5 µg/dL (rather than 10 µg/dL), based on EPA's OLEM Directive 9200.2-167 (US EPA, 2016a), which summarizes current toxicological evidence. Lead risk for adults is reported as the probability that the fetal blood lead exceeds 5 µg/dL. EPA's target protection level for children is that a child should not have greater than a 5% probability of having a BLL greater than 10 µg/dL (US EPA, 1998, 2016a). However, at EPA's direction, a target BLL of 5 µg/dL rather than 10 µg/dL was used in this HHRA. EPA considers lead risks to exceed the target risk threshold if the probability of having a BLL greater than the blood lead target is greater than EPA's goal of 5%. This risk target is the same for the fetus of an adult receptor.

## 9.4 Risk Results

The estimated cancer risks and non-cancer hazards are discussed below by exposure area and receptor. The total risk for each receptor is the sum of the risks over all COPCs and exposure pathways. The total HI for each receptor is the sum of the HIs for each exposure route. As noted in Section 9.2, non-cancer HIs were not added across different age groups for a Resident (*i.e.*, child and adult risks for the Resident are not added). Pursuant to EPA guidance (US EPA, 1989), the total HIs were rounded to one significant figure; HIs for the individual exposure pathways were rounded to two significant figures.[19] Cancer risks were reported with one significant figure (US EPA, 1989).

The cancer risks and non-cancer hazards for all properties are summarized in Table 10. Appendix C, Tables 7.1-7.12 present the detailed risk calculations, and Appendix C, Tables 9.1 to 9.7 present the summary of cancer risk and non-cancer hazard by receptor as well as the non-cancer hazards by target organ.[20] Appendix C, Table 11 presents a summary of the cancer risks and non-cancer hazards. Appendix C, Table 12 presents a summary of risk by pathway and includes the percent contribution of each exposure pathway to the total risk and the COPC contributing the majority of the risk for each pathway. Appendix C, Table 13 presents a summary of risk by media for each receptor. Appendix C, Tables 14.1 (cancer) and 14.2 (non-cancer) provide risks or HIs by medium and analyte for each receptor and exposure area to allow the

[19] The use of significant figures in reporting risk results is presented in EPA (1989), p. 8-8 for non-cancer hazard and p. 8-12 for cancer risk.
[20] EPA RAGS Table 8 is not applicable to this risk assessment and is not presented. EPA RAGS Table 10 is not presented, because this information is already included in Appendix C, Table 9.1.

determination of the major risk drivers. (The risk calculations assuming 5% Cr(VI) in sediment are presented in Appendix C-1, and those assuming 100% Cr(VI) in sediment are presented in Appendix C-2. The table numbers are the same in both Appendix C-1 and C-2.)

EPA has established a target cancer risk range of $1 \times 10^{-6}$ to $1 \times 10^{-4}$ (US EPA, 1990, 1991b). If the cancer risk is greater than $1 \times 10^{-4}$, there may be a concern for possible health effects. As noted in Section 9.2, EPA considers an HI greater than 1 to exceed the target risk threshold.

The risks from exposure to lead are summarized in report Table 11. The output from the blood lead modeling is presented in Appendix H.

### 9.4.1 North of Foster Avenue

Cancer risks and non-cancer hazards were calculated for the Utility Worker, Construction Worker, Outdoor Worker, and adult and child Resident exposed to soil in the NFA.

Cancer risks for the Utility Worker and Construction Worker were both $5 \times 10^{-6}$, which is within EPA's target risk range. Incidental ingestion of soil contributed 76% of the total cancer risk for both receptors, with Aroclor 1260 contributing 54% of soil ingestion risk, followed by arsenic (23%). Cancer risk for the Outdoor Worker was $2 \times 10^{-5}$, within EPA's target risk range. Incidental ingestion of soil contributed 72% of the total cancer risk for the Outdoor Worker. Arsenic contributed 60% of the ingestion risk, followed by 2,3,4,4,5,5-hexachlorobiphenyl (TIC) at 13% (Appendix C, Table 12).

For the child and adult Resident, the cancer risk was $2 \times 10^{-4}$, which is above EPA's target risk range. Ingestion of soil contributed 82% of the total cancer risk, with arsenic contributing 40% of the soil ingestion risk, followed by hexavalent chromium (25%).

Non-cancer hazards for the Utility Worker, Outdoor Worker, and adult Resident were 0.3, 0.5, and 0.9, respectively, below EPA's target HI of 1. The non-cancer hazard for the Construction Worker was 6, above EPA's target HI of 1. Incidental ingestion of soil contributed 66% of the total HI, followed by dermal contact (26%), with Aroclor 1260 as the major contributor (86-98%) to the hazard for both pathways. The HIs by target organ for the Construction Worker were 5 for the immune system and less than 1 for all other target organs (Appendix C, Table 9.2).

The non-cancer hazard for the child Resident was 7, which is above EPA's target HI of 1. Incidental ingestion of soil contributed 79% of the total HI, with Aroclor 1260 (37%), 2,3,4,4,5,5-hexachlorobiphenyl (TIC) (22%), and arsenic (20%) as the major contributors. The HIs by target organ for the child Resident were 3 for the immune system, 2 for the reproductive system, 2 for the skin, and less than 1 for all other target organs (Appendix C, Table 9.4).

It should be noted that the elevated levels of PCBs in soil were limited to the Silver Lake conveyance and beneath the parking lot northwest of the Silver Lake conveyance.

The predicted GM BLLs for the Utility Worker, Construction Worker, Outdoor Worker and child Resident were 0.6, 1.5, 1.0, and 3.0 µg/dL, respectively. The probabilities of fetal BLL exceeding 5 µg/dL for the Utility Worker (0.01%), Construction Worker (1%), and Outdoor Worker (0.2%) were all below EPA's goal of 5%. The probability of BLL exceeding 5 µg/L for the child Resident (14%) exceeded EPA's goal of 5%.

### 9.4.2 South of Foster Avenue

Cancer risks and non-cancer hazards were calculated for the Utility Worker, Construction Worker, Outdoor Worker, and adult and child Resident exposed to soil in the SFA.

Cancer risks for the Utility Worker and Construction Worker were both 1 x $10^{-6}$, within EPA's target risk range. Incidental ingestion of soil contributed 82% of the total cancer risk for both receptors, with arsenic as the major contributor to ingestion risk (79%). Cancer risk for the Outdoor Worker was 2 x $10^{-5}$, also within EPA's target risk range. Incidental ingestion of soil contributed 73% of the total cancer risk, with arsenic (58%) and benzo(a)pyrene (26%) as the major risk contributors (Appendix C, Table 12).

For the child and adult Resident, the cancer risk was 3 x $10^{-4}$, above EPA's target risk range. Ingestion of soil contributed 79% of the total cancer risk, with benzo(a)pyrene contributing 53% of the soil ingestion risk, followed by arsenic (19%).

Non-cancer hazards for the Utility Worker, Outdoor Worker, and adult Resident were 0.06, 0.5, and 0.9, respectively, below EPA's target HI of 1. The non-cancer hazard for the Construction Worker was 1, at EPA's target HI of 1. Incidental ingestion of soil contributed 72% of the total HI, followed by inhalation of particulates/volatiles (25%). Incidental ingestion risks were driven by a combination of antimony (36%), arsenic (14%), thallium (13%), and 1,2,4-trimethylbenzene (TIC) (13%). 1,2,4-Trimethylbenzene (TIC) was the major (52%) contributor to the inhalation hazard, followed by 1,3,5-trimethylbenzene (TIC) (24%). The HIs by target organ for the Construction Worker were less than 1 for all target organs (Appendix C, Table 9.2).

The non-cancer hazard for the child Resident was 7, which is above EPA's target HI of 1. Incidental ingestion of soil contributed 92% of the total HI, with antimony as the major contributor (61%), followed by arsenic (12%). The HIs by target organ for the child Resident were 4 for the hematological system, 1 for the skin, and less than 1 for all other target organs (Appendix C, Table 9.4).

The predicted GM BLLs for the Utility Worker, Construction Worker, Outdoor Worker, and child Resident were 0.7, 3.2, 3.3, and 19 µg/dL, respectively. The probability of fetal BLL exceeding 5 µg/dL for the Utility Worker (0.03%) was below EPA's goal of 5%. The probability of fetal BLL exceeding 5 µg/L for the Construction Worker (18%) Outdoor Worker (19%), and child Resident (99.8%) were all above EPA's goal of 5%.

### 9.4.3 East of United States Avenue

Cancer risks and non-cancer hazards were calculated for the Utility Worker, Construction Worker, Outdoor Worker, and adult and child Resident exposed to soil in the EUSA.

Cancer risks for the Utility Worker, Construction Worker, Outdoor Worker, and adult and child Resident were 1 x $10^{-7}$, 1 x $10^{-7}$, 9 x $10^{-7}$, and 8 x $10^{-6}$, respectively, all below EPA's target risk range. Incidental ingestion of soil contributed 83-90% of the total cancer risk. For the Workers, arsenic was the major (83-85%) contributor to soil ingestion risk (Appendix C, Table 12). For the adult and child Resident, arsenic contributed 47% of the soil ingestion risk, followed by hexavalent chromium (41%).

Non-cancer hazards for the Utility Worker, Construction Worker, Outdoor Worker, adult Resident, and child Resident were 0.007, 0.2, 0.05, 0.07, and 0.8, respectively, all below EPA's target HI of 1. Incidental ingestion of soil contributed 98-99% of the total HI, with thallium accounting for 57% of soil ingestion risk for all receptors, followed by cobalt and iron (16-18% each).

Lead was not a COPC in EUSA soil; therefore, lead risk was not calculated for the EUSA.

### 9.4.4 Undeveloped Area

Cancer risks and non-cancer hazards were calculated for the Utility Worker, Construction Worker, Outdoor Worker, and adult and child Resident exposed to soils in the UNDV.

Cancer risks for the Utility Worker, Construction Worker, and Outdoor Worker were $8 \times 10^{-6}$, $8 \times 10^{-6}$, and $4 \times 10^{-5}$, respectively, all within EPA's target risk range. Incidental ingestion of soil contributed 81-83% of the total cancer risk for these receptors, with arsenic accounting for over 90% of soil ingestion risk (Appendix C, Table 12).

For the child and adult Resident, the cancer risk was $3 \times 10^{-4}$, above EPA's target risk range. Ingestion of soil contributed 85% of the total cancer risk, with arsenic contributing 75% of the soil ingestion risk, followed by benzo(a)pyrene (16%).

Non-cancer hazards for the Utility Worker and Outdoor Worker were 0.08 and 0.8, respectively, which are below EPA's target HI of 1. The non-cancer hazard for the Construction Worker was 2, which exceeds EPA's target HI of 1. Incidental ingestion of soil contributed 81% of the total HI, with arsenic contributing 60% of the soil ingestion hazard and other COPCs each contributing less than 10%. The HIs by target organ for the Construction Worker were 1.3 for skin and less than 1 for all other target organs (Appendix C, Table 9.2).

Non-cancer hazards for the child and adult Residents were 10 and 2, respectively, which exceeded EPA's target HI of 1. For the child Resident, incidental ingestion of soil contributed 80% of the total HI, with arsenic (42%) and cyanide (25%) as the major contributors. The HIs by target organ for the child Resident were 4 for skin, 2 for endocrine, 2 for the reproductive system, and less than 1 for all other target organs. For the adult Resident, inhalation of particulates/volatiles from soil contributed 64% of the total HI, with cyanide contributing nearly 100% of the inhalation hazard. Incidental ingestion of soil accounted for 32% of the non-cancer hazard for the adult Resident, with arsenic (42%) and cyanide (25%) as the major contributors. The HIs by target organ for the adult Resident were 1.4 for endocrine and less than 1 for all other target organs (Appendix C, Table 9.4).

The predicted GM BLLs for the Utility Worker, Construction Worker, Outdoor Worker, and child Resident were 0.7, 2.6, 1.6, and 3.9 µg/dL, respectively. The probability of fetal BLL exceeding 5 µg/dL for the Utility Worker (0.02%) and Outdoor Worker (2%) are below EPA's goal of 5%. The probability of fetal BLL exceeding 5 µg/L for the Construction Worker (9%) and the probability of BLL exceeding 5 µg/L for the child Resident (31%) are both above EPA's goal of 5%.

### 9.4.5 Undeveloped Area and Upper Hilliards Creek

Cancer risks and non-cancer hazards were calculated for the adult, adolescent, and child Recreators exposed to UNDV soil, and sediment and surface water in UHC. In the risk results

presented below, the results using the assumption of 5% Cr(VI) are presented first, and the results using the assumption of 100% Cr(VI) are presented second.

Cancer risk for the adolescent Recreator was 1 x $10^{-4}$, which is within EPA's target risk range. Cancer risks for the child Recreator and adult Recreator were 1 x $10^{-3}$ and 2 x $10^{-4}$, respectively, which are above EPA's target risk range. For all three Recreator receptors, the primary pathway contributing to cancer risk is incidental ingestion of sediment (47-73%). For the adolescent and adult Recreators, dermal contact with sediment also contributed significantly (21-28%) to the total cancer risk. For all three Recreators, arsenic was the primary contributor (79-98%) to all sediment exposure pathways.

The non-cancer HIs for the child, adolescent, and adult Recreators are 12, 3, and 2, respectively, all of which exceed EPA's target HI of 1. Incidental ingestion of sediment contributed 43% to 63% of the total HIs, followed by incidental ingestion of soil (18-26%). For all three receptors, arsenic is the main contributor (70%) to sediment ingestion hazard, followed by cyanide (22%). In soil, arsenic and cyanide contribute 42% and 25% of the soil ingestion hazard, respectively, for all three Recreator receptors. The HIs by target organ for the child Recreator were 8 for skin, 3 for the reproductive system, and less than 1 for all other target organs (Appendix C, Table 9.5). The HIs by target organ for the adolescent Recreator were 2 for skin and less than 1 for all other target organs (Appendix C, Table 9.6). The HIs by target organ for the adult Recreator were 1 or less for all target organs (Appendix C, Table 9.7).

Using the assumption of 100% Cr(VI) for UHC sediment increased the cancer risks for the child and adolescent Recreators and the non-cancer hazard for the child Recreator. The cancer risk for the adolescent Recreator increased from 1 x $10^{-4}$ to 2 x $10^{-4}$, which is above EPA's target risk range. For the child, the cancer risk increased from 1 x $10^{-3}$ to 4 x $10^{-3}$ and remains above the EPA target risk range. Sediment ingestion remained the primary pathway contributing to total cancer risk for both receptors, and Cr(VI) was the major contributor (64-81%) for this pathway. The non-cancer hazard for the child Recreator increased from 12 to 13, but the relative contributions of the different pathways remained the same, and arsenic remained the primary contributor to hazards.

The predicted GM BLL for the adult Recreator was 1.8 µg/dL and the predicted probability of a BLL exceeding 5 µg/dL was 3%, below EPA's goal of 5%. For the child Recreator exposed to UNDV soil and UHC sediment, the GM BLL was 10 µg/dL and the predicted probability of a BLL exceeding 5 µg/dL was estimated as 93%, above EPA's goal of 5%.

# 10 Uncertainty

The HHRA process involves multiple steps and assumptions, which contribute inherent uncertainties that affect the final risk estimates. Uncertainties may exist in numerous areas, including sample collection, laboratory analysis, derivation of toxicity values, and estimation of potential site exposures. EPA's approach to human health risk assessment involves the concept of "reasonable maximum exposure" (RME), which is defined as "the highest exposure that is reasonably expected to occur at a site but that is still within the range of possible exposures" (US EPA, 2004a). EPA states that "intent of the RME is to estimate a conservative exposure case (*i.e.*, well above the average case) that is still within the range of possible exposures" (US EPA, 1989). EPA also notes that this high-end exposure "is the highest dose estimated to be experienced by some individuals, commonly stated as approximately equal to the 90th percentile exposure category for individuals" (US EPA, 2015c). Thus, most individuals will have lower exposures that those presented in this risk assessment. The most important contributors to uncertainty in this risk assessment are discussed below.

## 10.1 Uncertainties in Exposure Assumptions

### 10.1.1 Exposure Pathways

Several pathways are incomplete and were not quantitatively evaluated in the HHRA. Due to the shallow nature of UHC (approximately 6 in), it was assumed that no significant ingestion of surface water would occur during a wading scenario. Any incidental ingestion of surface water while wading would be expected to be very small and have a negligible contribution to risk; thus, the exclusion of this pathway is not expected to change the overall conclusions of the risk assessment.

### 10.1.2 Exposure Point Concentrations

Historic data (pre-2005) were included in the HHRA for completeness and to add sample coverage. In order to estimate the potential impact on EPCs from inclusion of the pre-2005 data, the mean concentrations from datasets that include or exclude the pre-2005 data were compared, for the COPCs in each media. The mean concentrations from the datasets that include or exclude the pre-2005 data are generally within 20% of each other. When they differ by more than 20%, the higher mean is from the dataset that includes the pre-2005 data (used in this report). Thus, while inclusion of the pre-2005 data may tend to overestimate risk, removal of these data is unlikely to change the conclusions of the risk assessment, as the EPCs are likely to be of similar magnitude.

In some cases, the maximum concentration was used as the EPC, because the calculated 95% UCLM was greater than the maximum detected value. This may occur when there are very few detects or the concentration distribution is highly skewed. In the 0-10 ft soils, the EPC was equal to the maximum concentration in the following areas: 3 COPC in the EUSA, 1 COPC in the NFA, and 2 TICs in the SFA. In the 0-2 ft soils, the EPC was equal to the maximum concentration in

the following areas: 4 COPCs in the EUSA, and 1 TIC in the SFA. One COPC (cyanide) and one TIC (benzo(j)fluoranthene) in sediment, and 7 COPCs (antimony, benzo(a)pyrene, benzo(b)fluoranthene, indeno(1,2,3-cd)pyrene, naphthalene, 1,4-dichlorobenzene and VC) in surface water used maximum concentrations as the EPCs. The use of the maximum concentration as the EPC likely results in an overestimate of risk, because the maximum is not representative of an individual's average exposure over a long period of time.

Cyanide is a risk driver for several receptors in the UNDV (Appendix C, Table 12). Cyanide was conservatively assumed to be in the form of cyanide ion (CN-) or hydrogen cyanide (HCN) (US EPA, 2016e). However, the form of cyanide present at the site is not known. Thus, risks from cyanide may be overestimated if the cyanide is in a form that does not produce HCN (*e.g.*, an iron-cyanide complex like the pigment Prussian blue, which is composed of ferric ferrocyanide). Furthermore, the cyanide concentration in air is estimated from the soil concentration using a VF, however if the cyanide is present in a non-volatile form such as an iron-cyanide complex then risks would be lower.

The EPC for Cr(VI) in the NFA soil may be biased high and thus may overestimate risk. The EPC includes two samples (MPSB0289 and MPSB0288) with elevated Cr(VI) concentrations (293 and 40.7 mg/kg). A statistical test for outliers (Rosner test) in the Cr(VI) dataset was performed using EPA's ProUCL Version 5.1. The test indicated that these two values are outliers at the 1% significance level (Sherwin-Williams, 2016b). Excluding the two outliers would result in lower EPCs (0.82 *vs* 7.5 mg/kg for 0-2 ft; 1.5 *vs* 35 mg/kg for 0-10 ft), and thus result in a lower cancer risk and non-cancer hazard. However, because Cr(VI) contributes 4-20% of the total cancer risk and <1% of the non-cancer hazard for the receptors in the NFA, this would not change the conclusions for the NFA.

The surficial soil dataset used in this HHRA includes 124 soil samples that were composited over a depth interval of more than 0.5 ft, the majority of which were from the 0-2 ft depth interval. Composite samples were collected from the NFA, SFA, and UNDV. In the NFA, most of the composite samples (35/44) are from the RI dataset. In contrast, most of the composite samples in the SFA (10/15) and UNDV (59/65) are from the historic dataset (*i.e.*, data collected prior to initiation of the RI in 2005). Compositing a sample across a wider depth interval could potentially dilute contamination that is present within a narrower depth interval. Therefore, the inclusion of composite samples in the HHRA may have resulted in an underestimation of risk for surface soils.

In the absence of Cr(VI) sediment data, the HHRA evaluated Cr(VI) sediment risk in two ways, assuming Cr(VI) was either 5% or 100% of the total chromium concentration. Based on an evaluation of the 2016 FMP soil data, Cr(VI) was on average 5% of total chromium (Sherwin-Williams, 2016b). Since the percent Cr(VI) in UHC sediment is likely to be no higher than in FMP soil, the assumption that total chromium is 100% Cr(VI) in sediment likely overestimates risk.

The HHRA used the conservative assumption that total chromium detected in surface water was 100% Cr(VI). This assumption likely overestimates risk because chromium speciation is a function of pH and Eh (redox potential) and previous geochemical modeling indicated that Cr(VI) would be less than 1% of the total chromium concentration (Sherwin-Williams, 2015). However, surface water accounts for less than 10% of the total cancer risks and non-cancer hazards for the Recreator receptors, and chromium contributes only 2-3% to the surface water cancer risks and <1% to the surface water non-cancer hazards. Therefore, this uncertainty is unlikely to impact the overall risk and hazard estimates for the Recreator receptors.

### 10.1.3 Exposure Frequency and Duration

Outdoor Workers and Residents were assumed to have exposure to soil for 225 and 350 days/year, respectively. This exposure frequency does not account for grass, leaf, and snow covering (during the colder months), which could potentially limit soil exposures. Therefore, the risks may be lower than those estimated in this report. The assumption that a Recreator would wade in UHC for 44 days/year is likely an overestimate, as this area is not attractive for wading. Thus, risks from contact with surface water and sediment are likely to be lower than estimated here.

For the Utility Worker and Outdoor Worker, the exposure duration was 25 years, based on the 95$^{th}$ percentile duration that an individual stays at any one workplace (US EPA, 1991a, 2014). This assumption overestimates exposures for most workers, because the median occupational tenure of the working population has been estimated to be 7.9 years for men and 5.4 years for women (US EPA, 2011a).

As noted previously, an exposure frequency of 150 days/year for a Recreator is conservative and, thus, may overestimate risk. EPA's Supplemental Guidance for Inhalation Risk Assessment notes "an example trespasser/recreational scenario could consist of an exposure… for 100 days per year or less" (US EPA, 2009a). The Risk Assessment Information System (RAIS) Risk Calculator developed under the United States Department of Energy (DOE) Oak Ridge National Laboratory (ORNL) recommends an exposure frequency of 74 days for a Recreator (US DOE, 2013). The selected value of 150 days/year is higher than both of these values and, thus, may overstate risk.

The residential exposure scenario assumes that the Resident will live in a given exposure area for 26 years, including 6 years as a child and 20 years as an adult. It assumes that the Resident will ingest or touch soil, and inhale dust from soil, for 350 days/year for 26 years regardless of weather conditions.

### 10.1.4 Soil and Sediment Ingestion Rates

The exposure factors used in the risk assessment generally represent high-end "upper percentile" (*e.g.*, 90$^{th}$ or 95$^{th}$ percentile) exposure factors. High-end ingestion rates (100 and 200 mg/day, the 90$^{th}$ percentile) were applied for year-round exposure (350 days/year), however soil ingestion rates will likely be lower in winter months when people spend less time outdoors. Data analyzed by EPA indicate that soil intake decreases by 6-55% on poor weather days when children are more likely to stay inside, compared with good weather days (US EPA, 1994a). Data regarding hand-to-mouth events, which are a primary mechanism by which soil is ingested, indicate that hand-to-mouth frequency is significantly greater indoors than outdoors (US EPA, 2012c). Therefore, risks evaluated with the high-end soil ingestion rates for year-round exposure may over-estimate risks. For example, a recent reanalysis of previous soil ingestion studies estimated a mean of 26 mg/day for children, with a 95$^{th}$ percentile estimated as 79 mg/day (Stanek *et al*., 2012a,b).

Construction and Utility Workers were assumed to incidentally ingest 330 mg/day. EPA recommended the ingestion rate of 330 mg/day for a Construction Worker for their soil screening level guidance (US EPA, 2002) based on a study by Stanek *et al*. (1997), who noted that the 95$^{th}$ percentile soil ingestion rate of 330 mg/day is substantially uncertain. The most current Exposure Factors Handbook (US EPA, 2011a) did not acknowledge this study as a key or secondary study

for soil and dust ingestion rates. Therefore, use of this high-end ingestion rate may over-estimate risks for Construction and Utility Workers.

### 10.1.5 Skin Surface Area Exposed to Sediment

Although absorption could occur through dermal contact with sediment while wading, the exposed skin surface area may be limited to the feet, rather than the head, hands, forearms, lower legs, and feet, as assumed in the risk assessment. In addition, the time that the skin would contact sediment would likely be very short, as the sediment would wash off in the surface water. Therefore, the risk from dermal contact with sediment is likely to be overestimated in this report.

## 10.2 Uncertainty in COPCs

### 10.2.1 COPC Selection

Chemicals were eliminated as COPCs during the screening evaluation (Appendix C, Table 2s). Maximum detected concentrations were compared against generic health based screening criteria (*e.g.,* RSLs). Chemicals with concentrations below their respective screening criterion do not warrant further evaluation. EPA (1989) uses a screening evaluation to reduce the number of COPCs carried through the risk assessment, because in many cases risks are driven by a handful of chemicals. Chemicals that were not identified as COPCs are not expected to be major risk contributors, and the exclusion of these chemicals is not anticipated to change the conclusions of the risk assessment.

Historic data (pre-2005) were included in the HHRA for completeness and to add sample coverage. However, there is uncertainty as to how well the historic data represent current conditions, particularly for VOCs and SVOCs which have the potential to break down over time. Using the same screening process performed in Appendix C, a total of 13 compounds would be eliminated as COPCs in various exposure areas if the pre-2005 data were not used in the HHRA, including 5 metals, 4 SVOCs, and 4 VOCs (report Table 12). Thus, inclusion of the pre-2005 data may tend to overestimate risk. However, these compounds were not risk drivers; thus, removal of the pre-2005 data is unlikely to change the conclusions of the risk assessment. The TICs included as COPCs would not change if the pre-2005 data were removed.

Several compounds were reported with elevated detection limits, some of which exceeded the maximum detected concentration, and/or the screening criteria. Depending on the exposure area and soil depth interval, the number of compounds for which the maximum detection limit is above the screening criterion but the compound is not a COPC (*i.e*., the maximum detected concentration is below the screening criterion) ranges from 4-22 compounds (mostly VOCs and SVOCs). This situation also occurs for one compound in sediment and nine compounds in surface water. Thus, the elevated detection limits could have resulted in an underestimate of the number of COPCs, which could have resulted in an underestimation of risk.

### 10.2.2 Tentatively Identified Compounds

A total of 2,391 TICs were reported in samples from the FMP (Appendix E, Table 1). A total of 25 TICs with published toxicity factors were included in the screening to identify COPCs (Appendix E). The remaining TICs were not evaluated in the HHRA due to a lack of published

toxicity factors. If the unevaluated TICs contribute to risk, then the risks presented in the HHRA could be underestimated.

The EPCs for the TICs were calculated using only the detected concentrations, because if TICs are not detected, they are not reported. For this reason, the EPCs for TICs are likely to be biased high and overestimate risk.

The TIC 1,2,4-trimethylbenzene was identified as a significant contributor to non-cancer hazard for the Utility and Construction Workers (23% for both receptors) in the SFA *via* the inhalation pathway. Due to the uncertainty in compound identification and quantitation associated with TICs, there is also uncertainty associated with the risk contributed by this compound.

## 10.3 Uncertainties in Dermal Absorption

A dermal absorption value of 3% for arsenic in soil was used in this report (US EPA, 2004a). Lowney *et al*. (2007) measured dermal bioavailability of arsenic in soil, in monkeys, and found that dermal absorption of arsenic was less than 1%. Therefore, the dermal absorption value of 3% used for arsenic likely overestimates dermal risks.

Dermal absorption factors were not available for a number of metal COPCs in soil (aluminum, antimony, barium, Cr(VI), cobalt, copper, iron, manganese, thallium, vanadium, zinc, and cyanide). Although dermal risks from these metals were not calculated, dermal absorption of these metals is not a primary route of metal exposure (US EPA, 2007b); thus, this pathway would provide an insignificant contribution to risk.

In addition, default soil absorption values were used for sediment, in the absence of sediment specific values. The dermal absorption of metals in soil and sediment is dependent on chemical, physical, and biological factors (US EPA, 2004a). Therefore, the use of dermal soil absorption values to evaluate sediment exposures may over- or underestimate dermal risks from sediment exposure.

The dermal exposure route for lead in soil was not evaluated because this exposure route is typically insignificant when compared to ingestion (ATSDR, 2007). EPA's ALM and IEUBK Model do not include dermal exposures.

Dermal risks were calculated for three COPCs in UHC surface water that are outside the EPD based on EPA's mathematical model for calculating absorbed dose; these include benzo(a)pyrene, benzo(b)fluoranthene, and indeno(1,2,3-cd)pyrene. EPA (2004a) noted that chemicals outside the EPD may not be absorbed before desquamation (or shedding) of the skin, which would reduce the amount of chemical available for absorption and would, therefore, reduce risks from dermal contact. Dermal risks from UHC surface water contributed roughly 20-40% of the total cancer risk for the adult, adolescent, and child Recreators with 78% of the dermal risk from benzo(a)pyrene, which is outside the EPD. Due to the uncertainty associated with chemicals outside the EPD, the dermal risks may be overestimated.

## 10.4 Uncertainties in Toxicity Reference Values

In the absence of toxicity reference values for thallium, dibenzofuran, and 1,2,3-trichlorobenzene, PPRTV screening toxicity values were used for the RfDs. A PPRTV screening value was also

used for the 1,1'-biphenyl RfC. Although the RfD and RfC are derived using current EPA methodology, the available information does not provide enough support to derive a PPRTV toxicity value. Consequently, this PPRTV screening toxicity value has considerably more uncertainty associated with it than other toxicity values from EPA IRIS and PPRTV.

## 10.5 Uncertainties Associated with Indoor Air Exposures

Risks to commercial workers exposed to VOCs in indoor air may be biased low due to elevated detection limits. The high detected concentrations of aliphatic and aromatic compounds, benzene, ethylbenzene, xylene, toluene, and 1,2,4-trimethylbenzene, resulted in elevated detection limits for other VOCs in several sub-slab soil gas samples. The detection limits for 27 non-detected VOCs in sub-slab soil gas exceeded their respective screening criterion. Four of these VOCs were detected in indoor air above their screening criterion (1,1,2,2-tetrachloroethane, acrolein, benzyl chloride and bromodichloromethane). Therefore, it is not known whether these compounds could have been present in sub-slab soil gas at levels below the detection limit, and thus whether the presence of these compounds in indoor air could be related to vapor intrusion. Regardless, the VI risks estimated from sub-slab data may be biased low.

Several compounds detected in sub-slab soil gas and/or indoor air did not have screening criteria; thus, risks from these compounds were not evaluated. Several of these compounds were detected at high concentrations; for example, petroleum hydrocarbons (C5-C8 aliphatics, C9-C10 Aromatics, C9-C12 Aliphatics) were detected at concentrations ranging from 870-69,000,000 $\mu g/m^3$ in sub-slab soil gas samples collected from 2 Foster Avenue, 3 US Avenue, and 4 Foster Avenue, as well as indoor air samples collected in August 2015 at these properties.[21] Also, the TICs reported in indoor air did not have screening criteria (Appendix F Table 5). Risks from these compounds were not assessed due to the absence of screening criteria; therefore, VI risks based on sub-slab soil gas and/or indoor air data may be underestimated.

## 10.6 Uncertainties in Setting a Target Lead Risk

EPA's guidance for assessing lead at Superfund sites currently uses a target BLL of 10 µg/dL for children, a value recommended by the Centers for Disease Control and Prevention (CDC) in 1991 (US EPA, 1994b). The basis of the CDC's 1991 recommended BLL was protection against decreased IQ and impaired neurobehavioral development (CDC, 1991). EPA's risk reduction goal for impacted sites is to limit the probability of a child's BLL exceeding 10 µg/dL to 5% or less (US EPA, 2012b). In 2012, CDC revised its recommendations regarding childhood blood lead screening based on their conclusion that there is no safe BLL, and, therefore, it is not appropriate to identify a BLL of concern (CDC, 2012). Instead, CDC has replaced the "level of concern" concept for lead (*i.e.*, conclusions regarding exposure levels associated with specific adverse health effects) with a "reference level" based on the statistical distribution of blood lead concentrations in the US population. CDC selected a reference level of 5 µg/dL, which represents the 97.5$^{th}$ percentile of the distribution of BLLs for 1- to 5-year-old children in the US, based on the NHANES surveys conducted in 2005-2006 and 2007-2008 (CDC, 2012). EPA guidance states that "the current scientific literature on lead toxicology and epidemiology provides evidence that adverse health effects are associated with blood lead levels less than 10 µg/dL" (US EPA,

[21] The indoor air data report unadjusted and adjusted petroleum fractions, as denoted by "unadj." and "APH," respectively (Appendix F, Table 3). The adjusted concentrations account for the subtraction of individual analyte concentrations (*e.g.*, benzene) from the petroleum fraction reported.

2016a). At the direction of EPA this HHRA used a target BLL of 5 µg/dL for evaluation of both adult and child lead risks (US EPA Region II, 2017). It has not yet been established whether EPA will continue to use a 5% probability of exceeding any revised target as the definition of unacceptable risk. Thus, there is uncertainty associated with whether lead risks should be characterized as unacceptable if they exceed a probability of 5%.

# 11 Conclusions

This risk assessment characterized the risk to human health from exposure to soil, sediment, and surface water at the FMP. The FMP was divided into four exposure areas: North of Foster Avenue, South of Foster Avenue, East of United States Avenue, and Undeveloped Area. The receptors evaluated in this HHRA included a Construction Worker; Utility Worker; Outdoor Worker; adult, adolescent, and child Recreator; and adult and child Resident. Soil exposure pathways included incidental ingestion of soil, dermal contact with soil, and inhalation of particulates/volatiles potentially emitted from soil. Soil was evaluated in the 0-10 ft, 0-2 ft, or 0-0.5 ft depth interval depending on the receptor and COPC. Recreators were evaluated for exposure to surface water and sediment in Upper Hilliards Creek. Sediment exposure pathways included incidental ingestion and dermal contact. Surface water exposure pathways included dermal contact while wading.

COPCs for soil and sediment were determined by comparing the detected concentrations to conservative risk-based screening criteria (the lower of the EPA RSL or the NJ RDCSRS). COPCs for surface water were determined by comparing the detected concentrations EPA RSLs for tap water. Soil COPCs included metals, cyanide, PAH compounds, PCB compounds, pesticides, SVOCs, VOCs, and TICs. Sediment COPCs included metals, cyanide, PCB compounds, PAH compounds, and a TIC. Surface water COPCs included metals, cyanide, PAH compounds and VOCs. It should be noted that the COPCs in each medium were not necessarily COPCs in every exposure area.

Risks were evaluated for both cancer and non-cancer effects following EPA guidance, using conservative estimates of exposure that tend to overestimate, rather than underestimate, risk. Risk from exposure to lead in soil was evaluated using blood lead models, as per EPA guidance. Cancer risks are characterized as the incremental probability that an individual will develop cancer over a lifetime due to site-related exposures under the specific exposure scenarios evaluated. EPA's target risk range is given as one in a million ($1 \times 10^{-6}$) to one in ten thousand ($1 \times 10^{-4}$). Non-cancer hazard is expressed as a total HI, and EPA uses a target HI of 1. An HI less than or equal to 1 indicates that adverse non-cancer health effects are not expected, even in susceptible populations. An HI greater than 1 does not mean that adverse health effects will occur, only that further evaluation is warranted. Risk from exposure to lead was evaluated using blood lead models. At the direction of EPA, lead risks are reported as the probability of having a BLL greater than 5 µg/dL. EPA considers lead risks to exceed the target risk threshold if the probability of having a BLL greater than the blood lead target is greater than EPA's goal of 5%.

Chromium was detected in soil from all exposure areas evaluated and in sediment from UHC. In soil, chromium risks were calculated using Cr(VI) data. At the direction of EPA, chromium risks were calculated two ways for UHC sediment, assuming that Cr(VI) is either 5% or 100% of the total chromium concentration.

Cancer risks for the Utility, Construction, and Outdoor Workers were within or below EPA's target risk range in all four exposure areas. Non-cancer hazards for the Utility and Outdoor Workers were below EPA's target HI in all four exposure areas. For the Construction Worker, non-cancer hazards exceeded EPA's target HI in the NFA (6) and UNDV (2).

Cancer risks for the adult and child Resident exceeded EPA's target risk range in the NFA, SFA, and UNDV. Non-cancer hazards for the child Resident exceeded EPA's target HI in the NFA, SFA, and UNDV. Non-cancer hazards for the adult Resident exceeded EPA's target HI in the UNDV, but not the other three exposure areas.

*Assuming 5% Cr(VI) in sediment:* Cancer risks for the adolescent Recreator were within EPA's target risk range in the UNDV, which includes exposure to UHC. Risks for the child and adult Recreators, and hazards for all three Recreators, exceeded EPA's target risk range or HI. For the Recreators, exposure to sediment was the major contributor to cancer risk and non-cancer hazard.

*Assuming 100% Cr(VI) in sediment:* Cancer risks and non-cancer hazards exceeded EPA's target risk range or HI for all three Recreators in the UNDV.

The analytes with the greatest contribution to risk or hazard varied by exposure area and receptor, but generally included the following COPCs:

- **Soil:** Arsenic, antimony, hexavalent chromium, cyanide, benzo(a)pyrene, Aroclor 1260, and 1,2,4-trimethylbenzene (TIC)
- **Sediment:** Arsenic and chromium (evaluated as Cr(VI))[22]

Lead risks were evaluated for exposure to soil for a child Resident; a child, adolescent, and adult Recreator; a Utility Worker; a Construction Worker; and an Outdoor Worker. Lead risks exceeded EPA's target of 5% for the child resident in the NFA, SFA, and UNDV; for the Construction and Outdoor Worker in the SFA; and the Construction Worker in the UNDV. Lead risks exceeded EPA's target of 5% in the UNDV+UHC for the child Recreator, largely due to exposure to sediment in UHC.

Risks to commercial workers from vapor intrusion were evaluated separately for eight buildings (1 Foster Avenue, 2 Foster Avenue, 4 Foster Avenue, 5 Foster Avenue, 7 Foster Avenue, 10 Foster Avenue, former 6 East Clementon Road, 3 US Avenue). The sub-slab and indoor air data were screened against health-based values that are protective of commercial worker exposures. Overall, the exceedances of criteria for the indoor air data indicate a potential risk to commercial workers. The vapor intrusion risks may be underestimated, due to elevated detection limits for non-detected VOCs in sub-slab soil gas data, and VOCs without screening criteria that were detected at elevated concentrations in sub-slab soil gas and/or indoor air. Based on site observations and background sources (*i.e.*, non-site related indoor sources) of VOCs, many of the indoor air exceedances may be a result of contaminant sources unrelated to sub-slab vapor. However, it is not known whether VOCs detected in indoor air could have been present in sub-slab soil gas at levels below the detection limit, and thus whether the presence of these compounds in indoor air could be related to vapor intrusion.

[22] Cr(VI) is a risk driver in sediment only for the assumption that Cr(VI) is 100% of the total chromium concentration.

Notes:

For borings with co-locations, only the original co-location is labeled on the figures.

For example, MPSB0330 is not shown on the figures, but MPSB0050 is.
