Results of X-Ray Fluorescence Study

Calibration and Usability Assessment of Field Portable X-Ray Fluorescence Data From the August 1998 Sampling in the Coeur d'Alene Drainage, Idaho - DRAFT

PREPARED FOR: Dan Winstanley/SEA

COPIES:

DATE: October 20, 1999

1.0 Introduction

Pursuant to United States Environmental Protection Agency (EPA) Region 10 Work Assignment No. 54-50-OC2Q (URS Greiner, Inc. (URSG) in conjunction with Work Assignment No. 31-81-OC2Q (CH2M HILL, Inc.), aerial photogrammetry and hyperspectral imaging (HI) of selected portions of the Coeur d'Alene basin was conducted as part of the Coeur d'Alene Basin RI/FS. A Spectrace 9000 field portable x-ray fluorescence (FPXRF) instrument was used to analyze multimedia samples in the field at selected locations in the Coeur d'Alene Basin, Idaho, during August of 1998. This work was the ground-truthing portion of the hyperspectral imaging data collection task that is described in the *Field Sampling Plan and Quality Assurance Project Plan Addenda for the Bunker Hill Basin-Wide RI/FS: Addendum 09, Delineation of Contaminant Source Areas in the Coeur d'Alene Basin using Survey and Hyperspectral Imaging Techniques* (URS Greiner and CH2M HILL September 25, 1998).

The primary purpose for collecting the FPXRF field measurements was to obtain spectra and XRF measurements for background and mining-related materials (i.e., bedrock, vegetation, waste rock, tailings, and precipitates) within the same areas that were flown for HI analysis. The collected FPXRF data will ultimately be used to correlate the actual element concentrations to the HI spectral signature for the same materials. Once the HI/FPXRF correlation is established, the HI results can be extrapolated to other locations with limited or no conventional sampling information.

The purpose of this memorandum was to evaluate the FPXRF data quality for quantitative usability (i.e., do they met screening level or higher data quality criteria) and to calibrate the FPXRF field measurements using contract laboratory program (CLP) validated laboratory data. This memorandum is not intended to serve as a data presentation report. To achieve the objectives, the following activities were performed and described below.

- Review the FPXRF field data set for precision and reduce database by eliminating outliers that do not meet 99 percent confidence limit.

- Assess the degree of correlation between the reduced FPXRF field measurements and analytical data obtained by standard EPA methods (CLP) using the linear least squares fit (LLSF) method. Also, assess the degree of correlation between the reduced FPXRF field measurements and analytical data obtained by nonstandard methods.
- Develop a calibration curve for the FPXRF field measurements using standard method data (CLP) and the LLSF equation for selected elements (lead, and zinc). Derive a "calculated" FPXRF value from the field measured FPXRF concentration using the LLSF calibration equation (derived values are contained in Attachment A). Perform this same step using the larger nonstandard method data set for selected elements (cadmium, lead, zinc, and iron)
- Evaluate the improvement in the calculated FPXRF concentrations by comparing the laboratory / field FPXRF percent difference (PD) to the laboratory / calculated FPXRF percent difference and assess usability of data (screening or quantitative).

This technical memorandum addresses the quality assurance of the FPXRF data consistent with the EPA Method 6200 generic protocol for the *Field Portable X-Ray Fluorescence Spectrometry For The Determination Of Elemental Concentrations In Soil And Sediment*. The Spectrace FPXRF instrument is included in the method detection limits, precision and accuracy tables for typical analytical results from FPXRF instruments as "TN 9000" instrument in the EPA Method 6200 document.

2.0 Available Data

In addition to FPXRF field measurements on 725 samples, sample splits or archived samples were sent to four commercial laboratories for metals analysis. The participating laboratories and their roles are summarized below.

- Columbia Analytical Services, Inc. (CAS), Kelso, Washington, analyzed a subset of archived soil samples in August, 1999, using the EPA-CLP RAS total metals method. This work was intended to validate the results of the FPXRF measurements as well as the two non-CLP laboratories noted below.
- Mineral Exploration, Carson City, Nevada, and Chemex Labs, Inc., Reno, Nevada (referred to collectively as Chemex laboratories, or simply Chemex) analyzed soil and vegetation samples in early February 1998. Chemex used analytical methods comparable to, but more rigorous than, the EPA Standard Method used by the Columbia Analytical Services (CAS) laboratory.
- The Mineral Lab, Inc., Lakewood, Colorado, analyzed soil samples in late January, 1998 using x-ray fluorescence total metals analysis.

Table 1 summarizes the project data sets and purpose for their collection. Details on the number of samples analyzed and the analytical methods used by each laboratory are presented below.

2.1 Columbia Analytical Services, Inc. (CAS) (EPA Standard Method)

A total of 12 splits/duplicates (10 original and two splits/duplicates) of archived samples from the August 1998 samples analyzed by the Chemex Laboratory were sent to Columbia Analytical Services, Inc. laboratory. These samples were analyzed for 23 elements (analytical data are presented in Attachment B) using standard EPA-CLP RAS total metals methods to be compare with, and thereby determine the relative validity of, most of the earlier chemical results from the other laboratories. The samples included two tailings and eight soils.

The CAS analytical results were validated by Luce and Associates, Midway Park, North Carolina. Their validation designation for each reported analytical concentration is the handwritten alpha characters on the attached analytical data results from CAS (Attachment D). Only the selenium concentrations were rejected.

2.2 Chemex Laboratories (Nonstandard Aggressive Digestion Method)

Samples were sent to Chemex Laboratories to be digested by methods more aggressive than standard EPA methods. These data are expected to provide measurements closer to the "total" values measured by XRF.

A total of 40 "soil" samples (35 original and five splits/duplicates) and 14 vegetation samples were sent Chemex Laboratories for preparation and chemical analysis. The samples included three known tailings and two known aqueous precipitates within the soil data set that contained various amounts of organic matter (typical of the forest litter samples collected in the field). The 35 soil samples were pulverized in a tungsten carbide equipped mill. The tungsten carbide contributes 30 to 300 milligrams per kilogram (mg/kg, equivalent to parts per million) tungsten and 10 to 100 mg/kg cobalt (see Attachment B). Tungsten was equal to and generally much less than 80 mg/kg and cobalt equal to or less than 20 mg/kg in the attached analytical results.

The 14 vegetation samples were floated and washed to remove as much as possible of the inorganic particulates present in the samples. The organic samples were then microwaved dry, macerated and ashed for chemical analysis. Inorganic particulates were present in minor amounts and archived for future analytical work, if necessary.

The pulverized soil and ashed vegetation samples were digested in two stages, the first using pure nitric acid followed by aqua-regia. The nitric acid facilitates the digestion of both sulfide minerals and destruction of organic matter (Chemex website: www.chemex.com). This digestion is reported to generally produce data that are fractionally higher than a digestion that uses only an aqua-regia digestion (3:1 HCl:HNO3). However it, similar to aqua-regia digestion alone, is still a partial digestion and does not completely dissolve a sample. Aluminum, barium, titanium, sodium and potassium are rarely fully dissolved so that their concentrations will probably not match data generated by stronger digestions or true total metals analytical techniques like x-ray fluorescence (XRF).

Chemex analyzed metals in all the soil samples and most of the metals in the ashed vegetation samples using inductively coupled plasma (ICP) in their G32 package designed for soils, silts, lake and stream sediments. This package includes 32 elements as listed with their detection limits on the cover sheets of the attached analytical results (Attachment C).

Chemex used a combination ICP-MS (Mass Spectroscopy) to increase the accuracy and precision of selected elements present in the ashed samples. The concentrations of antimony, arsenic, cadmium, copper, mercury, silver and several other metals (see Attachment B, the cover sheet on the attached analytical data set for the ashed vegetation samples) in these organic phases were totally unknown prior to analysis so this method was used for their analysis. This was shown to be necessary for mercury, where only four of the 14 samples equaled or exceeded one mg/kg in the ashed samples.

Conversely, 10 of the 14 ashed vegetation samples contained more than one- percent (10,000 mg/kg) manganese and 13 of the 14 ashed samples contained more than 15 percent calcium. Both lead and zinc exceeded one percent in two of the ashed vegetation samples that contained detectable mercury (sample REP 04 at 1 mg/kg and REP 05, the highest detected mercury, at 4 mg/kg). Concentrations for the two samples are 3.42 and 2.12 percent lead, respectively and 1.18 and 1.19 percent zinc, respectively. These ashed vegetation concentrations must be multiplied by the average six percent ash to convert the concentrations back to a dry weight concentration in the original samples.

2.3 The Mineral Lab, Inc. (laboratory XRF)

A total of 10 splits/duplicates of the 35 samples analyzed by Chemex and six of the same samples analyzed by CAS were analyzed by the Mineral Lab (see Attachment D). This laboratory used x-ray fluorescence (XRF) to analyze 31 major, minor and trace elements. This analytical method is a true total metals analysis in which preparation includes only air-drying and pulverization; eliminating the partial digestion necessary by AA, ICP and ICP-MS analytical analysis of the other two laboratories. As such, the analytical data from this laboratory is expected to equal or exceed the partial to near complete digestion results of the other two laboratories. Later text demonstrates that XRF data essentially equals arsenic concentrations but generally exceeds iron, manganese, copper, lead and zinc concentrations reported by the other two laboratories.

As stated in the cover letter of the attached analytical data report from the Mineral Laboratory (Attachment D), a 5 to 10 percent relative precision/accuracy is expected for the major-minor elements (reported in percent) and 10 to 15 percent for the trace elements (reported in mg/kg) in "samples of average geologic composition." The subsequent text indicates that these are reasonable expectations.

3.0 Data Review/ Reduction of FPXRF Spectrace 9000 Measurements

The precision of the FPXRF data is monitored by replicate measurements. The standard deviation of the mean sample is used to assess method precision. Three times the standard deviation is used to establish the confidence level. Data points associated with lower confidence levels than the project's criteria (99 percent) were eliminated from use to provide a higher precision database (Attachment A).

A total of 725 field measurements were recorded for the August, 1998 use of the Spectrace 9000 field portable x-ray fluorescence (FPXRF) instrument. The instrument was use to analyze 25 elements. After averaging duplicate measurements the total number drops to

662 measurements. Average values are identifiable by the blanks (no values) in the time column of the working database (Attachment A).

The FPXRF instrument uses the common radioactive isotopes to activate the individual elements, a mercury iodide crystal detector provides replicate measurements, and a fundamental parameter model computes element concentrations and standard deviation for each value for each of the 25 elements as an integral part of the analysis. Table 2 lists the average standard deviation for each of the elements analyzed in the 35-sample soil data set and the 14-sample vegetation data set shared with the above laboratories. There is a direct relationship between the elemental concentrations and the standard deviation resulting from the FPXRF measurement. In other words, the standard deviation increases with increasing concentration. FPXRF field measurements less than three times the associated standard deviation have been eliminated from the working database (Attachment A).

In addition, the initially reported FPXRF negative values have been eliminated from the working database. The FPXRF fundamental parameter (and other models) computation results in both positive and negative values. Positive values represent elemental concentrations that are above both the detection limit and interference from other elements. Negative values are those in which the element concentration in the sample is either below the detection limit for the element and/or an interfering element is significantly higher than the sample calibration. In this case, the lead concentration is very high in many of the samples and since lead interferes with the arsenic determination, the relatively low but still ordinarily detectable arsenic concentrations are computed as negative values. The highest arsenic concentration in the Chemex 35 sample data set is only 102 mg/kg compared with the lead concentrations commonly near 10,000 mg/kg.

Eliminating each element concentration that is less than three times the standard deviation results in a significant decrease in useful elements in the FPXRF data set. Table 3 lists the number of original values in the initial data set and the remaining values after these procedures were performed. Chromium is computed in two ways to eliminate iron interference in the fundamental parameter computation. In this case, high chromium is eliminated and low chromium is relatively common. As shown in Table 3, it is apparent that several elements are not present in sufficient concentrations to be statistically useful. Table 3 shows that 10 elements (cobalt, nickel, selenium molybdenum, mercury, cadmium, tin, silver, uranium and thorium) have 11 or less values remaining after three standard deviations and negative values are subtracted. The elimination of these values results in a higher precision working database that is presented in Attachment A.

4.0 Data Comparability

4.1 Methodology

The data sets from the different laboratories were compared to assess their degree of correlation to the EPA standard method results. Comparability refers to the confidence with which one data set can be compared to another. In this case, FPXRF data generated from the TN 9000 instrument were compared to a validated EPA CLP data set and a larger nonstandard method data set. An evaluation of comparability was conducted by using linear regression analysis. Three factors were determined using the linear regression. These factors were the y-intercept, the slope of the line, and the coefficient of determination (r^2).

In order to compare the data sets, nondetect results were assigned half the reporting limit. Values with a greater than concentration were assigned the greater than value with the exception of manganese in the Chemex ashed-vegetation samples. Manganese greater than one percent were not included because only three of the values were less than one percent. Duplicates of all four data sets (Chemex, CAS, Mineral Lab, and FPXRF) are averaged with the mean value used in all computations.

4.2 Findings

Pulverization was common to all three laboratories. No specific instructions were given to any of the three laboratories on how a representative sample was to be taken for pulverization, prepared or analyzed (except for selection of the ICP and ICP-MS packages at Chemex). This is not a usual condition as most soil and sediment submittals include specific instructions to the laboratory not only to homogenize a sample prior to taking the sample for pulverization but also the appropriate procedure to homogenize the sample. Most good laboratories have a reasonably reliable homogenization step but it is important to assure that this is done well. Larger lighter density particles tend to concentrate at the top of a transported sample while finer-grained and denser particles tend to settle to the bottom. Experience has shown that some laboratories just pour a subset of the sample as received generally resulting in a preponderance of lower concentration data. Other laboratories forego most to all of the pulverization by pulling a sample directly from the finer-grained sample at the bottom of the received sample generally resulting in higher concentrations of metals.

The digestion procedure of the Chemex and CAS laboratories makes these results somewhat different, particularly compared with the Mineral Laboratory where there is no digestion procedure necessary in the sample preparation. As discussed above, the Chemex laboratories impose a more rigorous digestion than CAS that should result in slightly higher recovery of elements from the samples. Both the Chemex and CAS laboratory results are anticipated to be less than those of the Mineral Lab because the XRF analytical method used by the Mineral Lab is a true total metals analysis rather than a relatively rigorous partial sample digestion procedure (independent of mineralogy).

Table 4 lists linear least-square fit (LLSF) equations between reported analytical data for iron, manganese, copper, lead, zinc and arsenic. This suite of elements was selected from the FPXRF database because these elements are important in the ores/tailings of Coeur d'Alene district and were among the elements with the most samples above their respective method detection limits. This suite of elements (plus cadmium, antimony and mercury) is strongly intercorrelated.

The LLSF results indicate that analytical results from one laboratory can be very reliably converted to analytical results of the other two but the assumption that the individual element concentrations are interchangeable without a calibration curve is seriously flawed. In other words, single element concentrations are not the same between laboratories (with the near exception of arsenic concentrations) but single element concentrations can be very reliably converted to comparable analytical results from any of the other laboratories.

4.2.1 Nonstandard Method (Chemex Laboratories) versus Standard EPA Method (CAS)

As shown in Table 4, the correlation coefficients for the 10 samples indicate an almost perfect correlation between the analytical results reported by both laboratories with 92 to 100 percent of the variance accounted for in the correlation. However, both the intercepts and the slopes of individual elements are generally significantly different.

The 10 arsenic concentrations have an almost perfect equivalence with an intercept near the perfect value of zero and a slope very near that of 1.000. The zinc concentrations are also very close to the ideal fit with a higher intercept of 11 mg/kg compared to the Chemex results and a slope of 1.067 when 9 of the 10 samples are considered. The tenth sample that was removed from this set is the unoxidized tailings sample from the area of Tamarack tailings removal. If this tenth sample is included, the zinc results more clearly correlate with most of the other elements. This relationship illustrates the ability of a single high concentration to strongly affect LLSF equations. Single high concentrations also affect mean values. As in this and other element comparisons, removal of the single very high concentration did not affect the correlation coefficient (see copper in Table 4 also), but strongly affects both the intercept and slope of the calibration curve used to convert, in this case, CAS zinc results to comparable Chemex zinc results.

With the exception of the manganese, the slope values indicate that even though the analytical results are comparable and consistent, higher concentrations of these elements are extracted using the more rigorous digestion of the Chemex laboratory. Copper has the lowest extraction by CAS resulting in a slope of 1.479 for 9 or the 10 samples (tailings sample removed) and 2.449 for all 10 samples but the correlation is still excellent.

The Chemex laboratory results for iron, manganese, copper, lead, zinc and arsenic are quantitatively comparable to the validated CAS data.

4.2.2 Nonstandard Method (Chemex) versus Laboratory XRF (the Mineral Lab)

Similar to the Chemex versus CAS, there is excellent correlation for all elements but a somewhat lower correlation coefficient (0.94) for manganese. With the exception of manganese, the correlation accounts for 97 to 100 percent of the total variance, and it accounts for 88 percent even for manganese.

Arsenic concentrations are almost equivalent between the two samples with an intercept of only -8.7 and a slope of 0.9967. All other elements indicate lower slopes for the Chemex digestion than the total metals analysis by XRF in The Mineral Lab. This is probably a result of the digestion, which although rigorous, does not totally digest the sample. Copper, similar to that of the Chemex-CAS combination has the lowest slope (0.54). This supports the conclusion that digestion is probably responsible for the decrease. However, the samples probably involve similar mineralogies because the digestion gives sufficiently consistent results that the correlation for copper still accounts for 98 percent of the variance.

The Mineral Lab results for iron, manganese, copper, lead, zinc and arsenic are quantitatively comparable to the Chemex data.

4.2.3 Standard EPA Method (CAS) versus Laboratory XRF (The Mineral Lab)

The CAS comparison with the Mineral Lab analytical results shows excellent correlation. Similar to the Chemex results, manganese has the poorest correlation but still has a

correlation of 0.95 accounting for 91 percent of the variance. Except for manganese, the correlation between the two analytical results from the two laboratories is greater than 0.98, accounting for more than 96 percent of the variance.

As anticipated, the slopes are fractionally lower for the CAS data using the lesser aggressive digestion procedure than for the Chemex results when compared to the XRF method used by The Mineral Lab.

The Mineral Lab results for iron, manganese, copper, lead, zinc and arsenic are quantitatively comparable to the validated CAS data.

5.0 FPXRF Data Calibration/ Recalculation

5.1 Methodology

The FPXRF results were calibrated following field sample measurement and the data reduction described above using methodology equivalent to “empirical calibration “ per method 6200 as follows. In an empirical calibration, one must apply the goals of the project and relevant criteria for the analytes of interest. It is within these criteria that the FPXRF instrument should be calibrated most accurately. For this project, the CLP results meet project criteria; thus, FPXRF field measurements are calibrated against CLP results.

An empirical calibration using site specific calibration standards (SSCS) involves analysis of SSCS by the FPXRF instruments and by a conventional analytical method such as ICP or AA. A total acid digestion procedure should be used by the laboratory for sample preparation. Generally, a minimum of 10 and a maximum of 30 well characterized SSCS site typical standards are required to perform an adequate empirical calibration. The number of required standards depends on the number of analytes of interest and interfering elements. Theoretically, an empirical calibration with SSCS should provide the most accurate data for a site because the calibration compensates for site-specific matrix effects. For the following FPXRF calibrations, 10 CLP measurements were used. These measurements are representative of site conditions in terms of concentration ranges and location distribution.

The calibration equation is developed using a least squares fit regression analysis. After the regression terms to be used in the equation are defined, a mathematical equation can be developed to calculate the analyte concentration in an unknown sample. In some FPXRF instruments, the software of the instrument calculates the regression equation. In this case, the regression equations were calculated independent of the FPXRF instrument using SYSTAT software. The software uses calculated intercept and slope values to form a multiterm equation.

It is possible to define up to six linear or nonlinear terms in the regression equation. Terms can be added and deleted to optimize the equation. The goal is to produce an equation with the smallest regression error and the highest correlation coefficient. The software automatically computes these values as the regression terms are added, deleted, or modified. It is also possible to delete data points from the regression line if these points are significant outliers or if they are heavily weighing the data. Once the regression equation has been selected for an analyte, the equation can be entered into the software for quantitation of analytes in subsequent samples. For an empirical calibration to be

acceptable, the regression equation for a specific analyte should have a correlation coefficient of 0.98 or greater or meet the goals of the project.

5.2 Findings

Lead, zinc and cadmium are elements of particular interest and their concentrations in the environment are largely controlled by iron and manganese. This relationship is demonstrated by the high correlation between iron, manganese, copper, lead, zinc, cadmium, antimony and silver in all data sets. The FPXRF concentrations of lead has the highest correlation with the nonstandard laboratory data set at r=0.98 (where r is the correlation coefficient); zinc is second at 0.95; manganese follows at 0.94; copper at 0.93; and iron at 0.86. These correlation have been performed for both standard (CLP) and nonstandard (Chemex) results and are discussed below.

With the exception of cadmium (r=-.62), the correlation between the FPXRF and Chemex is above and significantly exceeds the r-squared value of 0.7 (70 percent of the variance accounted for) necessary to qualify the data as screening level (EPA Method 6200 Protocol). In fact, both lead and zinc could potentially meet definitive data level data criteria of 0.9 or greater and both manganese and copper are close to meeting this specification. Cadmium has a typically strong correlation with zinc both in the Coeur d'Alene area and in most mineral deposits around the world in which zinc is a major constituent. Cadmium is calculated from the zinc concentration in soils, forest litter and vegetation by LLSF equations as described in the following section on cadmium.

Iron has a slightly low correlation partly because iron concentrations are typically above a percent and in some cases above 10 percent. The calibration of the fundamental parameter model becomes increasingly nonlinear above several percent. One method of dealing with this potential problem is to recalculate a calibration model using LLSF equations. Although not discernable using correlation coefficients, zinc concentrations above about 3,000 mg/kg apparently become nonlinear with the concentrations less than 3,000 mg/kg so a separate LLSF equation is used for the two concentration ranges.

The following discussions outline the construction of a new calibration curve for lead, zinc and iron using LLSF equation. The relative improvement is judged by the percent difference between the standard (C_s, in this case, the CAS or Chemex concentration) and the measured concentration (C_m, in this case the FPXRF concentration):

$$Percent\ Difference\,(PD) = ((C_s - C_m)/(C_m)\,x100$$

As described in the EPA Method 6200 Protocol. The acceptance range for the calibration is plus or minus 20 percent.

5.2.1 Lead

The LLSF equation relating the validated 10 CAS lead concentrations with their respective FPXRF measurements is:

$$Calculated\ Lead = 1.724\ x\ FPXRF - 316$$

The average PD resulting from this equation is –13 percent with a median PD of 0.33 percent (half of the samples are above this concentration and half are below). This equation is used to calculate the lead concentrations CPBCAS listed in Attachment A.

Given the small number of validated analytical data and the excellent correlation between the validated data and the larger analytical data set from the Chemex laboratory, a more definitive correlation is expected from using this larger data set. The average PD between the field measured FPXRF and Chemex lead concentrations is 78 percent and between the FPXRF and CAS, 56 percent. A LLSF calibration results in the following equation:

$$Calculated\ Lead\ (CPB) = 44.3 + 1.752\ x\ FPXRF\ Lead\ Concentration$$

Table 5 shows the results along with the other parameters relative to the lead concentration in the 35-sample data set. The results have an average PD of 19 percent (median of 0.0 percent) between the Chemex and the calculated FPXRF field data from the individual PD values on Table 4 (column PDPB). This indicates that the calculated lead concentrations for all 35 samples are within the definitive level criteria. However, when the single high PD of 309 percent (GEM06S) is removed, the average PD drops to 10 percent (median of 0.0 percent). In addition to the above qualifying parameters (three standard deviations above the method detection limit and over 90 percent of the variance accounted for), this PD is well within the range of acceptable data for definitive level data quality criteria (above screening level).

The above equation was used to calculate a lead concentration for all samples and the results are included in the working database included as Attachment A.

5.2.2 Zinc

The LLSF equation relating the 10 validated CAS zinc concentrations with their respective FPXRF measurements is:

$$Calculated\ Zinc = 2.058\ x\ FPXRFZN - 0.006\ x\ FPXRFFE - 456$$

Although there are 10 validated analytical concentrations, there are only 9 FPXRF zinc concentrations that pair with these 10 because one FPXRF value is below the method detection limit. The average PD resulting from this equation is 12 percent with a median PD of –0.2 percent. The iron concentration in the soils is high enough that it partially affects the zinc concentration of this small data set.

Similar to the above lead calibration, the LLSF between the larger Chemex data set is expected to more accurately reflect the zinc concentrations. The average PD between the field measured FPXRF and Chemex zinc concentrations is 91 percent. A LLSF calibration results in two equations to account for nonlinearity in the zinc concentration range:

Less than 3,000 mg / kg FPXRF (ZNS)

$$Calculated\ Zinc\,(CZN) = -11.2 + 1.1284\,x\,FPXRF\ Zinc\ Concentration$$

Greater than 3,000 mg / kg FPXRF (ZNS)

$$Calculated\ Zinc\,(CZN) = -1163 + 2.676\,x\,FPXRF\ Zinc\ Concentration$$

The results of these calculations and other zinc parameters are listed on Table 6. The calibration considerably decreased the average PD for the Chemex-FPXRF comparison to 53 percent (median of 12 percent) and the CAS-FPXRF comparison to a much more acceptable 18 percent. Removing the single high PD of 946 percent, the average PD drops to 27 percent (median of 12 percent). This suggests that there is considerable heterogeneity probably involving zinc mineralogy and more complicated elemental interference in the samples that are affecting the zinc much more than the lead concentration. However, given the acceptable CAS comparison (validated data, albeit with fewer samples) and the results after removing the single high PD, the zinc data are acceptable at the screening level and may be acceptable at the definitive level.

The above equations were used to calculate a zinc concentration for all samples and the results are included in the working database included as Attachment A.

5.2.3 Iron

The average PD between Chemex and the field measured FPXRF iron concentrations is an acceptable 14 percent (median of 3 percent) but a calibration was performed to ascertain if the calculated iron concentrations would remove potential interference in the measured zinc and manganese concentrations. The resulting LLSF equation is:

$$Calculated\ Iron\,(CFE) = 2730 + 1.494\,x\,FES - 5.1818\,x\,TIS + 0.5091\,x\,KS$$

Where FES, TIS and KS are the field measured FPXRF iron, titanium and potassium measurements for each sample. The results from this calculation and the other parameters for iron are listed on Table 7. The average PD for iron in the Chemex-FPXRF data sets drops to -2 percent (median of –1 percent). Unfortunately, the calculated iron concentration did not add sufficiently to the PD of either zinc or manganese to be useful. The iron concentration data are acceptable at the screening level.

The above equation was used to calculate an iron concentration for all samples and the results are included in the working database included as Attachment A.

5.2.4 Manganese

Table 8 lists the manganese comparison between Chemex and FPXRF data and other manganese data. The percent difference for manganese could not be improved so it is used as an example of the variability created by heterogeneity in the sample coupled with the apparently minimal differences in precision and accuracy of the commercial laboratories. The average PD between Chemex and the FPXRF is 4.9 percent (median of 0.0) but between the CAS and FPXRF, an acceptable 1.4 percent. The variability in the FPXRF manganese concentrations could also be a nonlinear interference between manganese and iron. The manganese concentration is considered acceptable at the screening level based on the PD comparison with the validated CAS laboratory data.

5.2.5 Cadmium

The measured cadmium FPXRF values are not useful even at the screening level because they are generally too low (generally much less than the method detection limit) but the consistency between the zinc and cadmium concentrations allows the cadmium concentration to be estimated from the zinc concentration. The cadmium to zinc ratio of the Chemex 35 sample data set has a median of 0.0067. Using this simple ratio to calculate cadmium from the measured FPXRF zinc (ZNS) and the calculated zinc concentration (CZN):

$$Calculated\ \ Cadmium = 0.0067\ xZinc$$

The results are shown on Table 9. The average cadmium PD for the Chemex versus the measured FPXRF zinc data is 90 percent and for the Chemex versus the calculated FPXRF zinc concentration, and improved PD of 53 percent.

Calculating a LLSF equation for the data and eliminating the two precipitates (REXPREC and HECLAM) results in the following equation:

$$Calculated\ Cadmium\,(CCD) = 4.2 + 0.01\,x\ FPXRF\ Zinc\ Concentration$$

This equation gives an average cadmium PD of only –8.4 percent (median of –14) allowing the calculated FPXRF cadmium data to be accepted at the screening level for soils.

The cadmium to zinc ratio for vegetation, as anticipated, is different from that of soil. The forest litter contains a small but apparently measurable mixture of soil and organics that complicates the end members. Two LLSF equations were developed from the data to represent vegetation and forest litter:

$$Forest\ Litter - Calculated\ Cadmium\,(CCD) = -30 + 0.3414\,x\ FPXRF\ Zinc\ Concentration$$

$$Vegetation - Calculated\ Cadmium\,(CCD) = -5 + 0.2862\ x\ FPXRF\ Zinc\ Concentration$$

These give an average PD of -23 percent for the forest litter and -10 percent for the Chemex versus calculated FPXRF ashed vegetation zinc concentrations. These PDs indicate that the equations can be used to estimate the cadmium concentration at a level that may be acceptable at the screening level.

The above equations were used, and where appropriate coupled with the average 0.06 factor to convert from an ashed value to a dry weight vegetation concentration, to calculate a cadmium concentration for all samples. The results are included in the working database included at Attachment A.

6.0 Summary

The Spectrace 9000 field portable x-ray fluorescence (FPXRF) data for lead, zinc, iron, manganese and cadmium have been evaluated to ascertain that the field measurements met screening level or higher data quality criteria. The Columbia Analytical Services Laboratory results, using EPA standard methods (CLP), were validated and compared to Chemex Laboratory data that used a slightly more aggressive acid digestion and The Mineral Lab x-ray fluorescence data (true total metals data). The correlation between the data for these three laboratories was excellent indicating the data from all three commercial laboratories are comparable.

The samples analyzed by the laboratories were randomly selected on the basis of representing the spatial distribution (all areas sampled), media (soils, forest litter, precipitates and tailings) and concentration ranges (particularly lead and zinc).

The levels for acceptance at either a screening level or definitive level are described in the EPA Method 6200 Protocol for FPXRF measurements. A correlation based r-squared value of 0.7 or better is needed for the data to meet screening level and greater than 0.9 at a 99 percent confidence level is needed for the definitive level data criteria.

Calibrating the FPXRF field measurements, against the results of the EPA standard and nonstandard methods, using linear-least-square fit equations indicates that lead and zinc are both above screening level and may be definitive level data based on the plus or minus 20 percent difference criteria. Iron, manganese and estimated cadmium are screening level data. Given the broad characteristics of the sample media and concentrations coupled with both the heterogeneity of the samples and the precision / accuracy of three laboratories plus a field instrument, this is excellent.

Attachment A presents the final working FPXRF database. This database was created from the original FPXRF field data set by systematically following data processing procedures to: (1) develop a single estimator for each value; (2) eliminate all values that were less than the method detection limit (three standard deviations); and (3) using calculated lead, zinc, iron and cadmium concentrations for all the samples based on the equations developed from the comparison between the FPXRF and the commercial laboratory.

Table 1
Project Data Sets

Data Set/Method	Quantity	Collection Purpose
Hyperspectral Imaging	Very Large Number of Spectral Signatures	The product of the HI process is a map generated by continuous sample coverage at an average five-meter grid within selected areas (virtually impossible to accomplish with conventional sampling techniques). **These data are not discussed in this memorandum.**
Field XRF (Spectral 9000 FPXRF measurements)	725 Soil and Vegetation Samples	Portable instrumentation was used to collect spectra and XRF measurements at key features (waste rock, tailings, precipitates, vegetation, etc.) within the areas to be flown for HI. Collected data (contained in Attachment A) will be used to correlate the actual element concentrations to the HI spectral signature for the same materials.
Non Standard Method Using Aggressive Digestion (Chemex Laboratories)	35 Soil Samples 14 Vegetation Samples	This data set (from a subset of the FPXRF samples) was compared to the EPA standard method CLP values. With a high correlation established between the standard and nonstandard methods, this larger data set (collected at lower cost) was also used to calibrate the FPXRF field measurements.
EPA Standard Method (CLP) (CAS Laboratory)	10 Soil Samples	This data set (from a subset of the FPXRF samples) was used to empirically calibrate, or requantify, the FPXRF field measurements and assess the suitability (quality) of the aggressive digestion data for use in calibrating the field XRF measurements.
Laboratory XRF (The Mineral Lab)	10 Soil Samples	This data set (from a subset of the FPXRF samples) was compared to field XRF data.

Table 2
Average Standard Deviations for
Spectrace 9000 FPXRF (mg/kg)

Parameter	Average std. Dev. (mg/kg)	
	Soils	Vegetation
Chromium-high (CRH)	286.0	191.0

OVERALL ASSESSMENT OF THE DATA

____ The data are **acceptable** according to the criteria referenced above, with no qualifiers assigned by the reviewer.

_X_ The data are **acceptable with the qualifications noted and appended** to the data by the reviewer. These qualifiers modify the usefulness of the individual values to which they are assigned. (For definitions of the qualifiers used, see the end of the data validation worksheet).

____ The data are **unacceptable** according to the criteria referenced above, and have been rejected by the reviewer.

The conclusions presented in the attached narrative(s) and worksheet(s) were drawn based on the reviewer's professional judgement. The qualifiers assigned to the accompanying data (if any) were assigned based on the validation criteria referenced above and the reviewer's professional judgement. The signature below authorizes the release of the attached materials.

NARRATIVE - METALS (IN-CLP)

I. HOLDING TIMES

The holding times specified in *Functional Guidelines* were met. Holding times were calculated using the dates presented in the table below. The analysis of mercury must be performed within 28 days of sample collection. All other metals must be analyzed within six months of sample collection. Although holding time criteria have only been established for water samples, the criteria were applied to soil samples for the purposes of this data validation.

Sample Number	Matrix	Sampling Date	ICP Analysis	AA Analysis	Mercury Analysis
51001	Soil	before 02/19/99	*08/19/99*	*by 08/19/99*	*08/20/99*
51002	Soil	before 02/19/99	*08/19/99*	*by 08/19/99*	*08/20/99*
51003	Soil	before 02/19/99	*08/19/99*	*by 08/19/99*	*08/20/99*
51004	Soil	before 02/19/99	*08/19/99*	*by 08/19/99*	*08/20/99*

51015	Soil	08/13/99	08/19/99	by 08/19/99	08/20/99

In the table above, the dates marked with asterisks indicate those analyses that were not performed within the required holding time. Listed below are the data affected because analyses were not performed within holding times. The qualifiers shown have been assigned by the reviewer based on the recommendations in *Functional Guidelines*.

Sample	Analyte	Qualifier Assigned
51001	Mercury	J
51002	Mercury	J
51003	Mercury	J
51004	Mercury	J
51005	Mercury	J
51006	Mercury	J
51007	Mercury	J
51008	Mercury	J
51009	Mercury	J
51010	Mercury	J
51011	Mercury	J
51012	Mercury	J
51001	All other metals	Positive results received J qualifiers; negative results received UJ qualifiers.
51002	All other metals	Positive results received J qualifiers; negative results received UJ qualifiers.

Sample	Analyte	Qualifier Assigned
51003	All other metals	Positive results received J qualifiers; negative results received UJ qualifiers.
51004	All other metals	Positive results received J qualifiers; negative results received UJ qualifiers.
51005	All other metals	Positive results received J qualifiers; negative results received UJ qualifiers.
51006	All other metals	Positive results received J qualifiers; negative results received UJ qualifiers.
51007	All other metals	Positive results received J qualifiers; negative results received UJ qualifiers.
51008	All other metals	Positive results received J qualifiers; negative results received UJ qualifiers.
51009	All other metals	Positive results received J qualifiers; negative results received UJ qualifiers.
51010	All other metals	Positive results received J qualifiers; negative results received UJ qualifiers.
51011	All other metals	Positive results received J qualifiers; negative results received UJ qualifiers.
51012	All other metals	Positive results received J qualifiers; negative results received UJ qualifiers.

II. CALIBRATION

All initial calibrations were performed as specified in the Statement of Work. The initial calibration verification (ICV) and continuing calibration verification (CCV) standards were analyzed as required and had recoveries within specified control limits.

The contract required detection limit (CRDL) check standards were analyzed at the frequency specified and for the required analytes. The recoveries for the ICP and GFAA CRDL check standards were consistent with acceptable instrument linearity in the lower range of the calibration curve.

III. BLANKS

The initial calibration blanks (ICB) and continuing calibration blanks (CCB) were analyzed at the frequency specified in the Statement of Work. Listed below are the sample data affected by calibration blanks that contained analytes at concentrations with absolute values equal to or greater than the IDL. The qualifiers shown have been assigned by the reviewer based on the recommendations in *Functional Guidelines*. Note that in the table below, the values in the column labeled "Blank Result" are in units of µg/L, and reflect the raw data taken from the instrument. The results in the column labeled "Reported Sample Results" are in the reporting units appropriate to the sample matrix. The calculations necessary to directly compare blank results with sample results were performed by the reviewer before any qualifiers were assigned.

Sample	Analyte	Time of Blank Analysis	Blank Result	Reported Sample Result	Action Taken
51008	Beryllium	08/19/99 19:20	0.2 µg/L	0.15 mg/Kg	0.15 U
51010	Beryllium	08/19/99 19:20	0.2 µg/L	0.16 mg/Kg	0.16 U
51011	Beryllium	08/19/99 19:20	0.2 µg/L	0.16 mg/Kg	0.16 U

Sample	Analyte	Time of Blank Analysis	Blank Result	Reported Sample Result	Action Taken
51010	Sodium	08/19/99 19:20	17.8 µg/L	18.3 mg/Kg	18.3 U
51013	Selenium	08/19/99 15:32	2.0 µg/L	0.47 mg/Kg	0.47 U

Preparation blanks were analyzed as required. Listed below are the sample data affected by preparation blanks that contained analytes at concentrations with absolute values equal to or greater than the IDL. The qualifiers shown have been assigned by the reviewer based on the recommendations in *Functional Guidelines*.

Sample	Analyte	Blank ID	Blank Result	Reported Sample Result	Action Taken
51001	Mercury	PBS	0.07 mg/Kg	0.15 mg/Kg	0.15 U
51005	Mercury	PBS	0.07 mg/Kg	0.16 mg/Kg	0.16 U
51006	Mercury	PBS	0.07 mg/Kg	0.16 mg/Kg	0.16 U

No evidence of trip blanks, field blanks, or equipment blanks was found.

IV. ICP INTERFERENCE CHECK SAMPLES (ICS)

The ICP ICS was analyzed for the required analytes and at the required frequency. The percentage recoveries for the ICS analytes fell within specified control limits. Listed below are the sample data affected by potential interference effects. The qualifiers shown have been assigned by the reviewer based on the recommendations in *Functional Guidelines*.

Sample	Analyte	Interferent	Qualifier Assigned
51008	Antimony	Iron	J
51008	Cadmium	Iron	J
51009	Antimony	Iron	J
51009	Cadmium	Iron	J
51010	Antimony	Iron	J
51010	Cadmium	Iron	J
51011	Antimony	Iron	J
51011	Cadmium	Iron	J
51012	Antimony	Iron	J
51012	Cadmium	Iron	J
51013	Antimony	Iron	J
51013	Cadmium	Iron	J
51015	Antimony	Iron	J
51015	Cadmium	Iron	J

V. LABORATORY CONTROL SAMPLE (LCS)

The LCS was analyzed as required. The recoveries for the LCS analytes fell within specified control limits.

VI. DUPLICATE SAMPLE ANALYSIS

Laboratory duplicates were analyzed as required, and results fell within specified control limits.

VII. MATRIX SPIKE SAMPLE ANALYSIS

Matrix (pre-digestion) spikes for soil/sediment samples were analyzed as required. Listed below are the sample data affected by matrix spike recoveries that did not meet specified control limits. The qualifiers shown have been assigned by the reviewer based on the recommendations in *Functional Guidelines*.

Spike Sample	Matrix	Analyte	Percent Recovery	Control Limits (%)	Samples Affected	Qualifier Assigned
51001S	Soil	Antimony	56.2	75-125	51001	J
51001S	Soil	Antimony	56.2	75-125	51002	J
51001S	Soil	Antimony	56.2	75-125	51003	J
51001S	Soil	Antimony	56.2	75-125	51004	J
51001S	Soil	Antimony	56.2	75-125	51005	J
51001S	Soil	Antimony	56.2	75-125	51006	UJ
51001S	Soil	Antimony	56.2	75-125	51007	J
51001S	Soil	Antimony	56.2	75-125	51008	J
51001S	Soil	Antimony	56.2	75-125	51009	J
51001S	Soil	Antimony	56.2	75-125	51010	J
51001S	Soil	Antimony	56.2	75-125	51011	J
51001S	Soil	Antimony	56.2	75-125	51012	J
51001S	Soil	Antimony	56.2	75-125	51013	J
51001S	Soil	Antimony	56.2	75-125	51014	J
51001S	Soil	Antimony	56.2	75-125	51015	J
51001S	Soil	Selenium	24.0	75-125	51001	R
51001S	Soil	Selenium	24.0	75-125	51002	R
51001S	Soil	Selenium	24.0	75-125	51003	R
51001S	Soil	Selenium	24.0	75-125	51004	R
51001S	Soil	Selenium	24.0	75-125	51005	R
51001S	Soil	Selenium	24.0	75-125	51006	R
51001S	Soil	Selenium	24.0	75-125	51007	R
51001S	Soil	Selenium	24.0	75-125	51008	R
51001S	Soil	Selenium	24.0	75-125	51009	R
51001S	Soil	Selenium	24.0	75-125	51010	R
51001S	Soil	Selenium	24.0	75-125	51011	R
51001S	Soil	Selenium	24.0	75-125	51012	R
51001S	Soil	Selenium	24.0	75-125	51013	J
51001S	Soil	Selenium	24.0	75-125	51014	R
51001S	Soil	Selenium	24.0	75-125	51015	R

VIII. FURNACE ATOMIC ABSORPTION QC

For all GFAA analyses, duplicate injections were made as required. For analytes with concentrations greater than the CRDL, the results from the duplicate injections agreed within 20% relative standard deviation (%RSD).

Post-digestion spikes (analytical spikes) were performed on all required samples analyzed by GFAA. All initial spike recoveries were greater than 40%. Listed below are the sample data affected by recoveries from post-digestion spikes that did not meet specified control limits. The qualifiers shown have been assigned by the reviewer based on the recommendations in *Functional Guidelines*. The absorbance of the analyte listed for each of these samples was less than 50% of the "spike absorbance", so no method of standard additions (MSA) analyses were required for these samples. Any samples that required MSA analysis are discussed in a later section below.

Spike Sample	Matrix	Analyte	Percent Recovery	Control Limits (%)	Samples Affected	Qualifier Assigned
51008A	Soil	Thallium	45.0	85-115	51008	J
51009A	Soil	Thallium	75.0	85-115	51009	J
51010A	Soil	Thallium	80.0	85-115	51010	UJ
51011A	Soil	Thallium	75.0	85-115	51011	J
51012A	Soil	Thallium	65.0	85-115	51012	UJ
51015A	Soil	Thallium	75.0	85-115	51015	J
51013A	Soil	Selenium	71.0	85-115	51013	UJ

The Method of Standard Additions (MSA) was used to determine the concentration of arsenic in samples 51001, 51004, 51005, 51006, and 51007.

IX. ICP SERIAL DILUTION

Serial dilutions were analyzed at the frequency required. For analytes with sufficiently high concentrations (minimally a factor of 50 times greater than the IDL), the results of the serial dilution fell within the specified control limits.

X. SAMPLE RESULT VERIFICATION

Concentration calculations were verified for ten percent of the analytes in each sample. All were found to be correct. All of the others were therefore assumed to be correct. All sample results were within the linear range of the ICP or within the calibrated range of the instrument being used. All results met the contract required detection limits.

Ten percent or more of the calculations and data transcriptions related to the parameters discussed in Sections II through IX above were checked and verified. No transcription or data reduction errors were found.

XI. FIELD DUPLICATES

Field duplicate samples were not identifiable from documentation in the data package.

XII. OVERALL ASSESSMENT OF THE DATA

The data are **acceptable with the qualifications noted and appended** to the data by the reviewer. These qualifiers modify the usefulness of the individual values to which they are assigned. (For definitions of the qualifiers used, see the end of the data validation worksheet).

Subject: Metals data qualifiers
Mime-Version: 1.0
Content-type: text/plain; charset=us-ascii
Content-Disposition: inline

Dick,

Steve Hughes tells me that you have some questions regarding the qualifiers on the laboratory forms from the HI confirmation sampling.

Using the EPA CLP reporting criteria there should be four discreet columns of qualifiers. The first three are from the laboratory and the final column is handwritten by the validator.

The laboratory qualifier columns are 'C' - concentration, 'Q' - quality assurance, and 'M' - methodology. The only columns that are important to you are the laboratory 'C' column and the data validation (handwritten) column.

It is important to note, that in every case if there is a data validation qualifier provided then it overrides the laboratory's concentration qualifier.

The valid validation qualifiers are 'U' - undetected, 'UJ' - undetected at an estimated detection limit, 'J' - estimated positive result, and 'R' - rejected from use. If there is no data validation qualifier then the laboratory concentration qualifier stands as the final qualifier.

The valid laboratory 'C' column qualifiers are 'U' - undetected, 'B' - detected below the CLP Contract Required Detection Limit (CRDL) but above the instument detection limit (IDL), and a blank which signifies a positive result.

This should help clarify the information you are looking at. If you have any other questions please call me at (206) 674-1843 or reply to this e-mail.

Todd Goins

Project:
P.O. # : SE 00030

Samples submitted to our lab in Vancouver, BC.
This report was printed on 18-FEB-1999.

SAMPLE PREPARATION

CHEMEX CODE	NUMBER SAMPLES	DESCRIPTION
1646	40	Tung. Carb. Ring approx 150 mesh
220	40	Transferring charge
229	40	ICP - AQ Digestion charge

* NOTE 1:

The 32 element ICP package is suitable for trace metals in soil and rock samples. Elements for which the nitric-aqua regia digestion is possibly incomplete are: Al, Ba, Be, Ca, Cr, Ga, K, La, Mg, Na, Sr, Ti, Tl, W.

ANALYTICAL PROCEDURES

The results of this assay were based solely upon the content of the sample submitted. Any decision to invest should be made only after the potential investment value of the claim or deposit has been determined based on the results of assays of multiple samples of geologic materials collected by the prospective investor or by a qualified person selected by him/her and based on an evaluation of all engineering data which is available concerning any proposed project Statement required by Nevada State Law NRS 519

CERTIFICATE A9911163

(QVR) - SHEA CLARK SMITH

Project:
P.O. # : SE 00030

Samples submitted to our lab in Vancouver, BC.
This report was printed on 18-FEB-1999.

SAMPLE PREPARATION

CHEMEX CODE	NUMBER SAMPLES	DESCRIPTION
225	15	Run as received

* NOTE 1:

The 32 element ICP package is suitable for trace metals in soil and rock samples. Elements for which the nitric-aqua regia digestion is possibly incomplete are: Al, Ba, Be, Ca, Cr, Ga, K, La, Mg, Na, Sr, Ti, Tl, W.

ANALYTICAL PROCEDURES

CHEMEX CODE	NUMBER SAMPLES	DESCRIPTION	METHOD	DETECTION LIMIT	UPPER LIMIT
9201	15	Al %: ICP + ICP-MS package	ICP	0.01	15.00
9202	15	Sb ppm: ICP + ICP-MS package	ICP-MS/ICP	0.1	10000
9203	15	As ppm: ICP + ICP-MS package	ICP-MS/ICP	0.2	10000
9204	15	Ba ppm: ICP + ICP-MS package	ICP	10	10000
9205	15	Be ppm: ICP + ICP-MS package	ICP	0.5	100.0
9206	15	Bi ppm: ICP + ICP-MS package	ICP-MS/ICP	0.02	10000
9207	15	Cd ppm: ICP + ICP-MS package	ICP-MS/ICP	0.1	500
9208	15	Ca %: ICP + ICP-MS package	ICP	0.01	15.00
9209	15	Cr ppm: ICP + ICP-MS package	ICP	1	10000
9210	15	Co ppm: ICP + ICP-MS package	ICP	1	10000
9211	15	Cu ppm: ICP + ICP-MS package	ICP-MS/ICP	0.2	10000
9212	15	Ga ppm: ICP + ICP-MS package	ICP-MS/ICP	0.1	10000
9213	15	Ge ppm: ICP + ICP-MS package	ICP-MS	0.1	500
9214	15	Fe %: ICP + ICP-MS package	ICP	0.01	15.00
9215	15	La ppm: ICP + ICP-MS package	ICP	10	10000
9216	15	Pb ppm: ICP + ICP-MS package	ICP	2	10000
9217	15	Mg %: ICP + ICP-MS package	ICP	0.01	15.00
9218	15	Mn ppm: ICP + ICP-MS package	ICP	5	10000
9219	15	Hg ppm: ICP + ICP-MS package	ICP-MS/ICP	0.01	10000
9220	15	Mo ppm: ICP + ICP-MS package	ICP-MS/ICP	0.2	10000
9221	15	Ni ppm: ICP + ICP-MS package	ICP	1	10000
9222	15	P ppm: ICP + ICP-MS package	ICP	10	10000
9223	15	K %: ICP + ICP-MS package	ICP	0.01	10.00
9224	15	Sc ppm: ICP + ICP-MS package	ICP	1	10000
9225	15	Ag ppm: ICP + ICP-MS package	ICP-MS/ICP	0.02	100.0
9226	15	Na %: ICP + ICP-MS package	ICP	0.01	10.00
9227	15	Sr ppm: ICP + ICP-MS package	ICP	1	10000
9228	15	Te ppm: ICP + ICP-MS package	ICP-MS	0.1	500
9229	15	Tl ppm: ICP + ICP-MS package	ICP-MS/ICP	0.1	10000

9233	15	V ppm: ICP + ICP-MS package	ICP	1	10000
9234	15	Zn ppm: ICP + ICP-MS package	ICP	2	10000

The results of this assay were based solely upon the content of the sample submitted. Any decision to invest should be made only after the potential investment value of the claim or deposit has been determined based on the results of assays of multiple samples of geologic materials collected by the prospective investor or by a qualified person selected by him/her and based on an evaluation of all engineering data which is available concerning any proposed project

Lab no. 990024

Mr. Dick Glanzman
CH2M Hill
P.O. Box 241325
Denver, Colorado 80224

Dear Mr. Glanzman:

Enclosed are the x-ray fluorescence (XRF) analytical results for the ten URS Greiner samples submitted last week with URS Greiner PO no. SE00029. Please give me a call if you would like this report mailed and/or faxed directly to URS Greiner in Washington. The invoice will ben sent directly to URS Greiner at the end of January.

The samples were air-dried before grinding and analysis. A representative portion of each sample was ground to approximately -400 mesh in a steel swing mill and then analyzed by our standard "XRF-powder" procedure for 31 major, minor and trace elements. The relative precision/accuracy for this procedure is ~5-10% for major–minor elements and ~10–15% for trace elements (those elements listed in ppm) at levels greater than twice the detection limit in samples of average geologic composition. A replicate sample and a standard reference material ("SY3", a Canadian standard rock) were analyzed with the samples to demonstrate analytical reproducibility for your samples and analytical accuracy for a geologic standard, respectively. The accepted ("known") values for the standard are listed with the XRF results.

Thank you for the opportunity to be of service.

Sincerely,

Peggy Dalheim
