SECTION 1 - INTRODUCTION

1.01 Background

O'Brien & Gere Engineers, Inc. (O'Brien & Gere) conducted field studies on the upper Hudson River. This work was prompted by the PCB Reassessment Remedial Investigation and Feasibility Study (RRI/FS) being performed on the upper Hudson River by the U.S. Environmental Protection Agency (USEPA). The work being performed by USEPA in conjunction with the Hudson River RRI/FS is described in their Phase 1 Report (USEPA, 1991b) and the Final Phase 2 Work Plan and Sampling Plan (USEPA, 1992).

The study area for this project was the forty-mile stretch of the upper Hudson River between Fort Edward, N.Y. (river mile 194.5), and the Federal Dam at Troy (river mile 153.4). The upper Hudson River flows south from Fort Edward over a series of dams and canal locks to Troy where it becomes tidal. There are seven river reaches, or intervals between dams, within the study area. Figure 1 is a site map which depicts the upper Hudson River and denotes the location of the seven dams and associated reaches within the study area.

Between 1976 and 1978, NYSDEC conducted several sediment sampling surveys in the Hudson River to estimate the extent of PCB in the river bed (Tofflemire and Quinn, 1979). Total PCB concentrations were reported as the sum of Aroclors 1016, 1221, and 1254 using packed column gas chromatography (GC). Based on the results of the survey, NYSDEC identified forty PCB "hot-spots" (sediment areas containing more than 50 parts per million [ppm] total PCB), most

of which were located in the Thompson Island Pool (TIP), between river mile 188.5 and river mile 194.

In 1984, NYSDEC conducted another sediment survey which focused on previously delineated "hot spots" within the TIP (Brown *et. al.*, 1988). The objective of the 1984 survey was to confirm the results of the 1976-1978 survey and to further define areas for possible dredging. NYSDEC collected and analyzed 674 grab and 408 core samples from the TIP. PCB analyses were again performed using packed column GC methodologies. Results were reported as PCB Aroclors 1242, 1254, and 1260 using the method of Webb and McCall (Webb and McCall, 1973). Although total PCB concentrations were reported, no mention was made of the method used to calculate the totals.

Following the completion of a Feasibility Study conducted in 1984 to evaluate remedial alternatives (NUS, 1984), USEPA issued a Record of Decision (ROD) for the upper Hudson River PCB Superfund Site (USEPA, 1984). The ROD recommended containment of exposed remnant deposits along the shoreline upstream of the former dam location at Fort Edward and an evaluation of domestic water quality at Waterford, N.Y. The USEPA also recommended that no action be undertaken to remediate sediment-bound PCBs in the upper Hudson River below Fort Edward.

In 1989, USEPA announced it would reassess its 1984 No Action decision concerning PCB-contaminated sediments in the upper Hudson River by performing a Reassessment RI/FS. This reassessment involves a number of sediment sampling tasks (USEPA, 1992).

During the Summer and Fall of 1991, O'Brien & Gere performed a survey of PCB in sediment of the upper Hudson River. This report presents a summary of the

1991 Sediment Sampling and Analysis Program (SSP). Additional details of the work are presented in the Quality Assurance Project Plan (QAPP; O'Brien & Gere, 1993) developed for the Hudson River Project.

1.02 Program Scope and Objectives

The principal objective of the investigation was to provide sufficient data to calculate mean concentrations of PCB in sediment and pore water over one to two mile intervals of the upper Hudson River. This included collecting and analyzing sediment samples composited over one to two mile river reaches at specific depth intervals. Congener specific analytical methods were utilized for PCB quantification in environmental samples so that physicochemical changes in PCB sample composition (e.g., due to biodegradation and phase partitioning) and fate and transport mechanisms could be evaluated.

The project consisted of the following field and laboratory tasks:

- collection of approximately 520 sediment samples, including core and grab samples, from Reach 8 (TIP) and approximately 480 from Reaches 1 through 7,
- compositing sediment core segments according to river reach, sediment type, and depth below the sediment/water interface,
- extracting interstitial pore water from sediment cores and compositing based on river reach, sediment type, and depth,
- analyzing sediment and pore water for congener specific PCB, total organic carbon (TOC), bulk density, and moisture content, and
- archiving discrete sediment core samples.

SECTION 2 - METHODS

2.01 Sediment Sampling Locations

The sediment study involved the collection and processing of more than one-thousand sediment cores and grab samples from the upper Hudson River. Approximately one-half of these samples were collected from Reach 8 (TIP) while the remaining were collected from Reaches 1 through 7.

2.01.1 Thompson Island Pool

To facilitate sample documentation, the TIP was divided into six sub-reaches, designated 8A through 8F. Locations of samples collected in the TIP are shown in Figures 2 through 7 and approximate river mile delineations are contained in Table 1. The approach to selecting target locations for sampling in the TIP was based on an evaluation of the 1984 NYSDEC data (Brown *et al.*, 1988). The 1984 NYSDEC survey found that the variability in PCB concentrations in fine-grained sediment was higher than the variability observed in coarse-grained material. Therefore, to account for this variability when estimating mean PCB concentrations in sediments, a greater number of samples were collected from regions of the river containing fine-grained sediments than from regions of coarse-grained sediments. A total of 520 sediment samples (cores and grabs) were collected in the TIP with an average sample collection density of eighty-seven samples per river mile.

Figures 2 through 7 indicate the discrete samples composited by sediment type and date of collection. Twenty samples out of 520 were not

composited, due to sediment type or holding time constraints, and were archived only. These sample locations are indicated by an asterisk.

2.01.2 River Reaches 1 through 7

Historically, sediment PCB concentrations and PCB concentration variability are lower in Reaches 1 through 7 than in sediments collected from Reach 8 (Tofflemire and Quinn, 1979). This means that fewer sample analyses were necessary to account for the variability in sediment PCB concentrations in these reaches than in Reach 8 when estimating means. Within Reaches 1 through 7, approximately thirty sediment samples were collected per mile. Similar to Reach 8, a greater number of samples were collected from regions of the river containing fine-grained sediment than from regions containing coarse-grained sediments.

Reaches 1 through 7 were divided into approximately two-mile subreaches to facilitate sample collection and compositing. Table 1 contains the approximate river mile delineations for these subreaches. Twenty-four fine and eight coarse sediment samples were targeted in each two-mile river segment resulting in approximately two to three fine composites and one coarse composite per segment. Figures 8 through 25 depict sample locations in Reaches 1 through 7 and indicate the samples composited according to sediment type.

2.01.3 Tributaries

Additional sampling was conducted in four tributaries to the upper Hudson River: the Hoosic River, the Batten Kill, Fish Creek, and the Snook Kill (Figure 1). Typically, four core samples were collected from each tributary approximately one-hundred yards upstream of its confluence with the Hudson River. The Hoosic River enters the Hudson River from the east at approximate river mile 167.6, the Snook Kill joins the Hudson River at approximate river mile 191.7, Fish Creek at river mile 181.2, and the Batten Kill at river mile 182.2. Figures 26 through 29 depict the locations of core samples collected from these tributaries.

2.02 Sample Collection Procedures

Sediment sample collection procedures generally followed the standard operating procedures described in the QAPP (O'Brien & Gere, 1993). The vessel employed for the SSP was a 24-foot pontoon boat powered by a 50 HP outboard motor and equipped with a 15-foot high tripod used for coring. The following sections detail the sampling procedures used during the sediment program.

2.02.1 Vessel Positioning

The boat was positioned at predetermined sampling locations using a IMC Hydro I automated range-azimuth positioning system, which provided positional accuracy of ± 0.6 meters. Once positioned, front and rear anchoring spuds were lowered into the sediment to maintain the vessel in a stationary position for coring.

Prior to sampling, approximately 140 horizontal control points were surveyed along the river. Coordinates are New York State Plane Coordinates in the Transverse Mercator projection (East Zone) specified in feet relative to the 1927 datum along the north (northings) and east (eastings) axes. Coordinates for each control point are presented in Appendix G.

Vessel positioning was accomplished by directing a laser beam, generated by the Hydro I unit, at a prism attached to the tripod aboard the boat. The time required for the beam to travel to the boat and back to the land-based unit was automatically converted to a distance and used to calculate the position of the boat relative to known control points. These coordinates were transmitted to the onboard computer and provided real-time display of the boat's position.

2.02.2 Sediment Coring

The core collection procedure employed during the SSP generally consisted of pushing an aluminum core tube into the sediment through a hole in the floor of the pontoon boat until no further penetration of the sediment was manually achievable, pulling the core tube partially out of the water, and capping the bottom of the core with a plastic cap. Specific core collection procedures were as follows:

- 1) the depth to the sediment/water interface was determined manually and recorded in the field notebook, along with other pertinent observations such as sample coordinates, and the date and time of sample collection,

- 2) the core barrel was manually pushed into the sediment through a hole in the center of the vessel decking (in dense sediment, a portable vibracorer was used to collect core samples),
- 3) the bottom of the core was sealed as soon as the core barrel was removed from the water with a plastic cap and duct tape,
- 4) the length of the core was measured and the water above the sediment/water interface removed by cutting a slot in the aluminum core liner with a decontaminated hacksaw, and
- 5) the top of the core was capped and taped, then stored vertically on the sampling vessel until it was delivered to the field laboratory at the end of the day's activities (typically within 4 to 6 hours).

2.02.3 Grab Sampling

Where insufficient sediment was present to enable a core sample to be obtained, a grab sample was collected. The grab sampling procedure consisted of the following steps:

- 1) a decontaminated metal scoop, attached to a 20-foot extension handle, was maneuvered along the river bottom to gather sample material,
- 2) the grab sample was retrieved and transferred directly to an appropriate sample container, and
- 3) the sample was placed in a sample cooler and delivered to the field laboratory at the end of the day's activities.

2.03 Sediment Sample Processing Procedure

Sample processing involved sediment type classification, core segmentation, compositing, and sample preparation. The following sections describe the procedures employed for sediment core and grab sample processing.

2.03.1 Sediment Type Classification

Before processing, sediment samples were classified as either coarse or fine, based on texture and bulk density measurements, then frozen. A bulk density value of 1.44 g/ml was established as a cut-off between coarse and fine sediment based on bulk density measurements of fifty sediment grab samples collected during the initial phases of the sampling program and covering a range of sediment textures. The procedures used to classify sediment are described below:

- A subsample of surficial sediment was removed from the core tube at the field laboratory and inspected. Sediment which consisted primarily of clay was classified as fine; coarse sand and gravel samples were classified as coarse.
- Sediment types other than those described above were classified based on bulk density measurements. Bulk density measurements (gram : wet sediment/ml wet sediment) were made by filling a small crucible of known weight and volume with sediment and determining the weight of crucible and sediment. Sediments with a bulk density greater than 1.44 g/ml were classified as coarse and sediments with a bulk density less than 1.44 g/ml were classified as fine.

2.03.2 Core Segmentation

Following sediment type classification, cores were frozen overnight in a vertical position to maintain the sediment stratigraphy and to facilitate core sectioning the next day. Core segmentation involved vertically segmenting the frozen sediment cores at 5, 10, and 25 cm below the sediment/water interface. The following standard operating procedures were used for core segmentation:

- 1) the frozen cores to be composited were removed from the freezer, uncapped, and placed horizontally in a vice,
- 2) ice at the top of the core was chipped away until the sediment/water interface was exposed,
- 3) the total length of the core was measured in centimeters,
- 4) the aluminum core tube was sectioned at five, ten, and twenty-five centimeter depths from the sediment/water interface using a pipe cutter and the segments were separated using a chisel and rubber mallet, and
- 5) discrete segments were placed into stainless steel beakers and allowed to thaw at room temperature for approximately two hours.

2.03.3 Sediment Sample Compositing and Grain Size Determination

The resulting 0-5, 5-10, and 10-25 cm core segments, in addition to grab samples, were composited based on sediment type, location, and date of collection. The greater than 25 cm core segments were archived frozen at Northeast Analytical Laboratories, Inc. in Schenectady, N.Y. Subsamples of

discrete and composite sediment samples were also archived frozen at Northeast Analytical Laboratories, Inc.

Typically, eight to twelve sediment samples from the same river reach and sediment type were composited. Due to uncertainties regarding the precision of grab sampling techniques and the penetration depth, grab samples were composited separate from core samples. Specific sediment sample compositing procedures were as described below.

- 1) Thawed sediment samples were mixed thoroughly with an electric mixer and then composited. Fifty-gram subsamples from each core section were transferred to stainless steel trays and mixed. Sediment remaining in the stainless steel beakers was further processed to obtain pore water samples (see Section 2.04).
- 2) Fifty-gram subsamples of each composite were transferred to 250-ml glass jars which were then sealed in plastic bags, labeled, and stored in coolers prior to transport to the analytical laboratory.

Grain size of surficial sediments was estimated according to the following procedure. Fifty-gram subsamples from the 0-5 cm composites were sieved through a $63 \mu\text{m}$ (230 mesh) stainless steel sieve to separate the sand and silt/clay fractions. These two fractions were dried and weighed to the nearest 0.1 gram. These data provided an estimate of the percent sand and percent silt/clay in the samples.

2.04 Pore Water Extraction Procedure

Pore water extraction involved centrifugation of discrete sediment core sections, filtration of the supernatant, and compositing of filtered pore water. Sediment pore water was not extracted from grab samples or samples consisting primarily of clay. Samples consisting of clay do not yield sufficient amounts of pore water for congener specific PCB analysis and are difficult to process due to compaction during centrifugation. Specific sediment pore water extraction procedures consisted of the following standard operating procedures:

- 1) stainless steel beakers containing discrete sediment samples were placed into a bench-top centrifuge (Beckman Model GS-6) and spun at 3500 rpm for approximately twenty minute,
- 2) approximately 10 ml of extracted pore water was pipetted from each beaker and pressure-filtered through a clean 0.5 micron pore size nylon membrane filter, housed in a 750-ml stainless steel pressure filter holder, using pressurized high purity nitrogen gas, and
- 3) composite pore water samples were collected in 250-ml or 500-ml sample jars and placed into coolers prior to transport to the analytical laboratory.

2.05 Laboratory Analysis

Sediment and pore water samples collected during the sediment sampling program were analyzed according to procedures presented in the following table. Details of the analytical procedures are presented in the QAPP (O'Brien & Gere, 1993).

Parameter	Sediment	Pore Water (3)
Total Organic Carbon	EPA 9060/415.1	EPA 9060
Congener Specific PCB	NEA-608CAP (1)	NEA-608CAP (1)
Bulk Density	(2)	N/A
Moisture Content	(2)	N/A
Grain Size	ASTM Method D422	N/A

Notes:

N/A = not applicable

- (1) Standard Operating Procedure for Laboratory Method NEA-608CAP, Congener Specific PCB Analysis. Northeast Analytical, Inc., August 1989.
- (2) Methods of Soil Analysis, Part 1 - Physical and Mineralogical Methods, Second Edition, A. Klute, ed., Madison, WI, 1986.
- (3) Pore water samples consisting of 200 ml or more of filtrate were analyzed for PCB and TOC. Samples consisting of less than 200 ml were analyzed for TOC only.

Northeast Analytical, Inc. (NEA) performed congener specific PCB analysis on sediment and pore water samples. Total organic carbon, bulk density, and moisture content analyses were subcontracted to Hudson Environmental Services (HES) by NEA. HES was also subcontracted to conduct grain size distribution tests on coarse composite sediment samples collected from the TIP. Ten percent of the SSP analyses were performed by OBG Laboratories, Inc. (OBG Laboratories) for inter-laboratory comparison.

2.06 Quality Assurance/Quality Control

Quality assurance/quality control (QA/QC) samples were collected in accordance with the QAPP (O'Brien & Gere, 1993). These samples included matrix spike, blind duplicate, field duplicate, and equipment blank samples. Matrix spike samples were laboratory duplicate samples which were split and prepared by the laboratory. The laboratory spiked the samples with a known quantity of analyte, then analyzed the sample and recorded the percent recovery. Blind duplicate samples were submitted to the laboratory without indication of where the samples were collected. Field duplicate samples were prepared by processing sediment samples in duplicate. Appropriate sediment core sections were split and processed side-by-side, then submitted for analysis. Equipment blank samples were prepared at the field laboratory by decontaminating the sampling equipment, filling four six-inch core liners with swimming pool filter sand and organic free water, freezing the cores overnight, then processing the blank samples according to the procedures used for processing environmental samples. Raw data results of QA/QC sample analyses are included in Appendices B through E, as described in Section 4.

Congener specific PCB sediment and pore water data generated by NEA was submitted to a data validation process. This process involved an evaluation of data quality based on criteria, developed by O'Brien & Gere, that reflect current methodologies and protocols for data validation (USEPA, 1987; USEPA 1991a). These criteria included documentation completeness, holding times, instrument performance, calibration, blank analysis, surrogate recovery matrix spike analysis, duplicate analysis, compound identification, and overall data assessment. Results of

the evaluation will be presented in separate data validation reports for sediment and pore water which are in preparation.

In addition to standard QA/QC analyses, the validity of the sediment compositing procedure was tested by submitting two sets of discrete sediment samples for PCB and conventional parameter analyses along with the corresponding composite samples.

SECTION 3 - DATA PRODUCTION AND REPORTING

3.01 Northeast Analytical, Inc.

NEA was responsible for congener specific PCB and conventional parameter (TOC, bulk density, moisture content, and grain size) testing of 375 sediment samples and 86 pore water samples for the SSP. NEA performed the congener specific analyses and subcontracted the conventional parameter analyses to HES.

Upon completion of the analyses, NEA and HES generated a series of data reports which have been reproduced as Appendices D and E. These data reports were prepared consistent with New York State Department of Environmental Conservation (NYSDEC) Analytical Services Protocol (ASP) Category B reporting requirements. Since a specific NYSDEC ASP reporting protocol does not exist for congener specific PCB analysis, a reporting package and quality control program was developed by NEA which adheres to guidelines set forth in the NYSDEC ASP Superfund PCB/pesticide requirements. The PCB data reporting packages generated by NEA contain the following components:

- title page,
- sign-off sheet,
- table of contents,
- case narrative,
- sample result forms,
- chain of custody forms,
- sample log-in sheet,
- internal sample control record (internal sample tracking sheet),

- matrix spike summary table,
- duplicate summary table,
- method blank summary table,
- sample raw data,
- analyst sample injection log, and
- standards/QC sample (blanks, matrix spikes, duplicates) raw data.

3.02 OBG Laboratories, Inc.

OBG Laboratories was responsible for the analysis of approximately thirty sediment and thirty pore water samples. Sediment samples were analyzed for TOC, bulk density, moisture content, and congener specific PCB. Pore water samples were analyzed for congener specific PCB and TOC. TOC analyses were subcontracted to HES while bulk density, moisture content, and PCB quantification was performed by OBG Laboratories.

Upon completion of the analyses, OBG Laboratories generated a series of data reports reproduced in Appendices B and C. These data reports were prepared consistent with NYSDEC ASP Category B reporting requirements. Since a specific NYSDEC ASP reporting protocol does not exist for congener specific PCB analysis, a reporting package and quality control program was developed which adheres to guidelines set forth in the NYSDEC ASP Superfund PCB/pesticide requirements.

The PCB data reporting packages generated by OBG Laboratories contain the following components:

- title page,
- sign-off sheet,

- table of contents,
- sample cross reference table,
- case narrative,
- laboratory report (sample result) forms,
- chain of custody forms,
- case file forms,
- sample log-in sheet,
- sample control record (internal sample tracking sheet),
- quality control summary table,
- sample raw data, and
- analyst sample injection log.

SECTION 4 - SAMPLING AND ANALYSIS RESULTS

4.01 Sediment Sampling Program Results

The sediment sampling and analysis program involved the collection of over 1000 discrete sediment cores and the analysis of 375 composite sediment samples and 86 composite pore water samples from locations along a 40 mile stretch of the upper Hudson River from Fort Edward to Troy, N.Y. Analysis of these samples provided data for several parameters including congener specific PCB, TOC, bulk density, moisture content, and grain size distribution. These data are summarized in the following tables (with the exception of eleven sediment sample PCB results which were rejected based on failure to meet data validation criteria):

Table 2 - Field Data Summary,

Table 3 - Composite Sample Identification and Classification,

Table 4 - Sediment Sample Cross-Reference Table,

Table 5 - Sediment Conventional Parameter Testing Results,

Table 6 - Sediment PCB Testing Results,

Table 7 - Pore Water PCB Testing Results, and

Table 8 - Tributary PCB Testing Results.

Field sampling data were recorded during sediment sample collection and processing and are presented in Table 2. Discrete core and grab samples were assigned sample identification numbers corresponding to the location and sequence of sample collection. Sample locations are given in feet (northing and eastings) based on New York State Plane Coordinates in the Transverse Mercator projection (East Zone) using the 1927 datum. Other field data summarized in Table 2 include

the sample collection method employed (core or grab), length of core sample retrieved, and sediment sample classification (coarse or fine) based on field laboratory measurements and observations.

Table 3 presents a summary of composite sample identification numbers, identities of discrete samples comprising each composite, visual classifications assigned to each sample, and results of particle size fractionation conducted in the field laboratory.

Table 4 is provided as a sample cross-reference table to facilitate the comparison of sample identification numbers and results obtained from the three analytical laboratories.

Conventional parameter testing results for sediment samples are summarized in Table 5 which gives bulk density, moisture content, and TOC data for each composite sample analyzed.

Table 6 is a summary of sediment PCB testing results. PCB data is presented as total PCBs (mg/kg-dry weight) and as a percentage by weight of the total concentration for each PCB homolog group (homolog distribution). The degree of chlorination in each sample is indicated by the mean total number of chlorine atoms per biphenyl molecule (Total Cl/Bp). Chlorine position is indicated by the mean number of chlorines in the ortho position per biphenyl molecule (Ortho Cl/Bp) and the mean number of chlorine atoms in the meta and para positions per biphenyl (Meta+Para Cl/Bp).

Pore water PCB and TOC testing results are presented in Table 7. TOC concentrations are given in mg/L; total PCB concentrations are given in μ g/L. The PCB homolog distributions shown represent the weight percentage of each homolog

present in the sample. Chlorine content and position on the PCB molecule are indicated by the mean total number of chlorines per biphenyl molecule (Total Cl/Bp), the mean number of chlorine atoms substituted in the ortho position on each biphenyl (Ortho Cl/Bp), and the number of chlorines atoms substituted in the meta and para positions per biphenyl molecule (Meta + Para Cl/Bp).

Table 8 presents PCB testing results of composite sediment samples collected from four tributaries to the Hudson River; the Hoosic River, Fish Creek, the Batten Kill, and the Snook Kill. Total PCB, PCB homolog distributions, and average chlorine content and substitution position are presented.

4.02 Data Validation and Composite Verification Results

Data validation indicates that the data met the validation criteria developed by O'Brien & Gere to the extent that over 97% of the sediment data and 100% of the pore water data were usable for the quantitative evaluation of PCBs in the upper Hudson River. Data quality criteria were not met in forty-six sediment samples, the majority of which were the result of compound identification errors. Compound identification errors resulted in the rejection of eleven sediment samples. Rejected sediment sample results have not been included in the data summary tables generated for this report. A total of seventy-three pore water samples did not meet data quality criteria. The majority of these excursions were the result of field blank contamination and thus, received a designation of "U". This designation raises the detection limit of the affected samples to the level at which the associated field blanks were detected the analytical laboratory. No pore water samples were rejected,

however. The results of data validation will be presented in a separate data validation report.

Results of two composite sample verification tests are summarized in Table 9. PCB concentrations detected in fifty-nine discrete sediment samples, comprising two sets of composite samples, were averaged and compared to the corresponding PCB concentrations detected in the composite samples in order to verify the correctness of the compositing scheme.

Field notes and laboratory data, including supporting documentation, have been assembled into Appendices A through E to this report. Appendix F is a directory of archived samples currently being stored at NEA. Appendix G describes the horizontal and vertical control points used during sample location and collection.

HUDSON RIVER REACH DESIGNATIONS

Reach Designation	Reach Number *	Approximate River Mile Delineation **	Bordering Townships ***	Figure Number
1AB	1	157.7 - 159.7	Schagticoke/Waterford	23
1CD	1	155.7 - 157.7	Troy/Waterford	24
1EF	1	154.3 - 155.7	Troy/Waterford	25
2AB	2	161.6 - 163.6	Schagticoke/Halfmoon	21
2CD	2	159.7 - 161.6	Schagticoke/Halfmoon	22
3ABC	3	163.6 - 166.0	Schagticoke/Halfmoon	20
4AB	4	166.0 - 168.0	Schagticoke/Stillwater	19
5AB	5	181.5 - 183.4	Easton/Saratoga	11
5CD	5	179.5 - 181.5	Easton/Saratoga	12
5EF	5	177.5 - 179.5	Easton/Saratoga	13
5GH	5	175.5 - 177.5	Easton/Saratoga	14
5IJ	5	173.5 - 175.5	Easton/Saratoga	15
5KL	5	171.5 - 173.5	Easton/Stillwater	16
5MN	5	169.5 - 171.5	Easton/Stillwater	17
5OP	5	168.0 - 169.5	Schagticoke/Stillwater	18
6A	6	184.8 - 186.3	Greenwich/Northumberland	9
6B	6	183.4 - 184.8	Greenwich/Northumberland	10
7A	7	187.5 - 188.5	Fort Edward/Northumberland	8
7B	7	186.3 - 187.5	Fort Edward/Northumberland	8
8A	8	193.5 - 194.5	Fort Edward/Moreau	2
8B	8	192.5 - 193.5	Fort Edward/Moreau	3
8C	8	191.5 - 192.5	Fort Edward/Moreau	4
8D	8	190.5 - 191.5	Fort Edward/Moreau	5
8E	8	189.5 - 190.5	Fort Edward/Northumberland	6
8F	8	188.5 - 189.5	Fort Edward/Northumberland	7
HOOSIC R.	4	167.6	Schagticoke	26
BATTEN KILL	5	182.2	Easton	29
SNOOK KILL	8	191.7	Moreau	28
FISH CREEK	5	181.2	Saratoga	27

Notes:

* Refer to Figure 1

** Tributary river mile designations are at the approximate river mile confluence with the Hudson River.

*** Towns bordering Hudson River on east/west shores.

Note:

- * xyy-zz (x designates reach, yy designates subreach, zz designates core #).
- ** aa/bb-cc,dd (aa designates primary constituent, bb [if shown] designates secondary constituent, cc, dd, etc. indicate materials present in small fractions)
- Notation: CS = coarse sand; ST = silt; FS = fine sand; CL = clay; MS = medium sand; PD = plant debris; WC = wood chips; R = rocks; G = gravel
- *** grain size results based on dry weight of sand fraction from subsample of 0-5 cm composite retained on 230 mesh sieve. Percent silt represents the silt and clay fraction passing through the sieve.

- = indicated composite depth interval not collected or processed.

ND = no data collected.

Notes:

* = Cl/Bp represents chlorine atoms per biphenyl molecule; Total Cl/Bp is the mean total number of chlorines per biphenyl, Ortho Cl/Bp is the mean number of chlorines in the ortho position on the biphenyl molecule, and Meta+Para Cl/Bp is the mean sum of chlorines in the meta and para positions on the biphenyl molecule.

Notes:

* = Cl/Bp represents chlorine atoms per biphenyl molecule; Total Cl/Bp is the mean total number of chlorines per biphenyl, Ortho Cl/Bp is the mean number of chlorines in the ortho position on the biphenyl molecule, and Meta+Para Cl/Bp is the mean sum of chlorines in the meta and para positions on the biphenyl molecule.

Notes:

* = Cl/Bp represents chlorine atoms per biphenyl molecule; Total Cl/Bp is the mean total number of chlorines per biphenyl, Ortho Cl/Bp is the mean number of chlorines in the ortho position on the biphenyl molecule, and Meta+Para Cl/Bp is the mean sum of chlorines in the meta and para positions on the biphenyl molecule.
