Remedial Investigation Report – Operable Unit 2

PMC Groundwater Site, Petoskey, Michigan
WA No. 243-RICO-0554/Contract No. EP-S5-06-01

Prepared for

July 2019

ch2m.

Executive Summary

This remedial investigation (RI) report was prepared for the U.S. Environmental Protection Agency (EPA) Region 5. It presents the results of the RI activities of Operable Unit 2 (OU2) completed at the Petoskey Manufacturing Company (PMC) Groundwater Superfund Site in Petoskey, Michigan (site) to assess the potential vapor intrusion (VI) risks from site-related contaminants. Contamination at the site was first discovered in September 1981 when water samples collected from a municipal water supply well (Ingalls Street Well) showed detections of trichloroethene (TCE), cis 1,2-dichloroethene (DCE), and trihalomethanes. Two records of decision (RODs) were signed by EPA to address contamination in soil and groundwater. Components of the final 1998 ROD include soil excavation, soil vapor extraction, establishment of institutional controls, and long-term monitoring of groundwater. During the third five-year review for the site in 2014, VI was identified as a potential issue. OU2 was established by EPA in 2017. OU2 includes VI risks at the site as well as the surrounding residential and commercial properties (study area).

This report has been prepared for Work Assignment No. 243-RICO-0554, under Contract No. EP-S5-06-01 in accordance with the Quality Assurance Project Plan (QAPP) (CH2M 2018a). The objectives of the RI are to characterize the source area for VI, update the VI conceptual site model, and provide information to support a remedial alternatives assessment. The primary objective of this RI is to characterize the VI pathway.

Conceptual Site Model

TCE at the site is present in vadose zone and saturated intervals of weathered limestone and sand/gravel deposits overlying more competent limestone bedrock. TCE was historically released from the former PMC property and was identified in a municipal supply well located to the northwest of the site near the shore of the Traverse Bay of Lake Michigan. The TCE plume originates beneath the former PMC site and is present in both shallow and deep groundwater. Groundwater elevations at the site are flat, and gradient reversals are caused by fluctuations in the stage of Lake Michigan. This results in virtually no net advective flow.

Natural attenuation of the plume appears to be limited. The presence of cis-1,2-DCE and vinyl chloride was seen in only a few wells historically, and they were not detected in 2018. The aquifer is generally aerobic; therefore, intrinsic bioremediation via reductive dechlorination is very limited. An evaluation of the time-series trends of TCE indicate that TCE concentrations are generally stable, although some wells show decreasing trends. Attenuation is primarily occurring through volatilization and dispersion. As a result, the plume is generally at quasi-equilibrium. The presence of TCE in vadose and the saturated zone is acting as an ongoing source to groundwater, contributing to the slow attenuation and persistence of the plume.

Because TCE is attenuating via volatilization, some of these vapors have migrated under buildings (subslab) and in some cases into those buildings. Both vadose-zone soil and groundwater have been identified as contributors to soil vapor concentrations. However, groundwater is the primary source, in particular, at downgradient and adjacent properties where contaminant vapors have been identified. Subslab depressurization systems have been installed by EPA to mitigate these vapors at some of the properties.

Summary of Remedial Investigation Activities

RI field activities and previous VI investigation activities were conducted in the study area in October 2016 through November 2018 with several rounds of exterior soil vapor, sewer gas, subslab soil vapor,

and indoor air sampling. There are properties where sampling was recommended but access has not been granted. The field activities summarized below were completed following the procedures and quality assurance requirements documented in the 2018 QAPP (CH2M):

- Subslab soil vapor samples and sewer samples were collected in January 2017. Near-slab and/or subslab soil vapor, crawlspace air, indoor air, and outdoor air samples were also collected in May through July 2017 and February 2018. These property-specific VI assessment activities are described in more detail in appendix B.
- Fifteen borings were advanced in May 2018 to provide lithologic information to support the CSM, collect soil samples, collect groundwater grab samples, and select vapor probe locations, as follows:
  - Soil samples were collected from 10 of the borings for analysis of VOCs to support the RI, and percent moisture, permanganate natural oxidant demand, and total organic carbon to support the focused feasibility study.
  - Groundwater grab samples were collected from nine of the borings and analyzed for VOCs.
  - Fifteen multi-depth (up to three depth intervals) soil vapor probes were installed throughout the study area and sampled for VOCs.
- Two monitoring wells were installed using rotosonic drilling methods in May 2018 to delineate groundwater within the former PMC property boundary due to a data gap caused by two wells that were removed in 2004 during building demolition. Vertical profile groundwater grab samples were collected at four intervals (15 to 20 feet below ground surface [bgs], 20 to 25 feet bgs, 40 to 45 feet bgs, and 45 to 50 feet bgs) from one of the borings and analyzed for VOCs.
- Sewer gas samples were collected at nine locations (five from sanitary sewers and four from storm sewers) in June 2018.
- Twenty-five existing and new monitoring wells were gauged and sampled in June 2018 and analyzed for VOCs. In addition, six wells were selected for analysis of perfluorinated compounds to address a request from the Michigan Department of Environment, Great Lakes, and Energy (EGLE).[1]
- Two rounds of instantaneous differential pressure readings were collected at 15 exterior soil vapor probes in June and July, and October and November 2018, as well as long-term differential pressure readings from June to July 2018 at five select exterior soil vapor probe locations.
- Exterior soil vapor samples were collected at 15 locations in October and November 2018.
- Concurrent indoor air, outdoor air, crawlspace air, and subslab soil vapor samples were collected from 15 residential properties in October and November 2018.
- Sewer gas samples were collected at 12 locations (6 from sanitary sewers and 6 from storm sewers) in October 2018.

Although data collection was focused on investigating the nature and extent of TCE impacts, EPA requested that samples be analyzed for the Target Compound List of VOCs using EPA Method SW-846 8260B for both groundwater and soil. Vapor samples were analyzed for VOCs via method TO-15. Perfluorinated compounds were analyzed by HPLC-MS-MS.

[1] Effective April 22, 2019, the Michigan Department of Environmental Quality (MDEQ) reorganized into the Michigan Department of Environment, Great Lakes, and Energy (EGLE). Historical references to MDEQ occur throughout this document.

Summary of Remedial Investigation Results

Physical Characteristics of the Site

The study area rests on fill underlain by permeable, friable limestone with unconsolidated lacustrine gravel (including boulder and cobble size) and sand. A beach face or foreshore depositional regressive sequence, identified by a top-to-bottom sequence of varying grain-size deposits, including sand and shale, is also identified under the limestone within the former PMC property boundary. The thickness of the friable limestone and unconsolidated deposits ranges from 20 to approximately 40 feet bgs overlying more competent limestone.

The more competent limestone bedrock that underlies the weathered limestone is generally described on the boring logs as consisting of or containing clay, interbedded with thin shale layers and slightly fossiliferous (Charlevoix Limestone). Fractures are described as containing fine to medium sand with some silt. However, the distinction of the interfaces between the friable limestone, unconsolidated deposits, and Charlevoix Limestone is difficult to determine.

The unconsolidated surficial deposits and shallow limestone bedrock underlying the site compose a single unconfined water table aquifer. Hydraulic conductivity based on historical slug testing ranges from 7.67 x 10^{-4} centimeters per second (2.16 feet per day) to 2.11 x 10^{-3} centimeters per second (5.98 feet per day). The groundwater seepage velocity calculated using the June 2018 groundwater surface elevation map and range of hydraulic conductivity was estimated between 0.0002 to 0.0006 feet per day. Vertical hydraulic gradients calculated for five well pairs indicate that there is virtually no vertical gradient, and only a slight upward vertical gradient was noted at one well pair.

Water levels in the study area range from 5 to 19 feet bgs (June 2018) with the shallowest groundwater levels closer to Lake Michigan in the vicinity of Bayview Park and the [redacted] However, the hydraulic gradient across the site is virtually flat and reversals in gradient caused by fluctuations in lake stage indicate that there is no net advective flow across the site. However, for the purposes of conservative assessment of these environmental investigation results, groundwater flow within this evaluation is interpreted to be generally towards Lake Michigan. The local reversals of the groundwater flow direction in the nearshore area noted in previous hydraulic studies likely enhance dispersion and volatilization of the plume. Seasonal temperatures are moderated by Lake Michigan (Appendix A).

Nature and Extent of Contamination

Development of Site-Specific Contaminants of Concern

Chloroform was only detected in one groundwater sample and is a common by-product that forms when chlorine or other disinfectants are added to drinking water; it is not listed as a chemical of potential concern (COPC) for OU1 in the 1998 ROD, nor is it considered site-related for OU2.

Groundwater Investigation Results

Only two VOCs were detected above SLs in groundwater—TCE and chloroform. TCE was detected above the EPA Residential Groundwater vapor intrusion screening level (VISL), and the Michigan Department of Environmental Quality (MDEQ) Residential Volatilization to Indoor Air Criteria (VIAC). The highest concentrations of TCE were detected in groundwater within the footprint of the former PMC facility, and concentrations above SLs were detected extending from the former facility to the northwest towards the lake.

Time-series concentration trends of TCE indicate stable trends in five of the wells evaluated and decreasing trends in three of the wells. Trends in the source area wells were stable, although TCE was

not detected in deep well PS-104 during the last two events, and concentrations in this well historically have been less than 10 micrograms per liter. Near the shoreline, trends are decreasing in the shallow well evaluated (PS-11) and increasing in nearby deeper well (PS-106), indicating a slight change in plume shape over time. No TCE degradation products were detected in 2018, indicating that intrinsic bioremediation via reductive dechlorination is not occurring. Attenuation of TCE thus appears limited and localized. Volatilization and dispersion are expected to be the primary attenuation mechanisms at the site.

Perfluorinated compounds were detected in four of the six wells sampled. None of the concentrations exceeded respective SLs.

Soil Investigation Results

TCE, benzene, ethylbenzene, and tetrachloroethene (PCE) were each detected above SLs. TCE was detected above the VIAC in most of the samples. The highest concentrations of TCE were detected in soil in the western portion of the footprint of the former PMC property both above and below the water table.

Benzene and ethylbenzene were detected above their respective VIAC SLs also primarily along the western half of the former PMC property. This area is where the highest concentrations of TCE are noted, and where historical releases likely occurred. These chemicals were identified in collocated soil vapor samples but were not identified in groundwater above SLs.

One metal, arsenic, was detected above the EPA Residential Soil Regional Screening Level. Exceedances were detected outside of and within the site boundary, below the water table, and at similar concentrations.

Sewer Gas Investigation Results

Sewer gas analytical results from January 2017, June 2018, and October 2018 indicated that TCE exceeded the EPA Residential Soil Vapor VISL at three sanitary sewer locations during one or both sampling events. These locations are within the footprint of the TCE soil vapor impacts. Current results of sewer gas sampling indicate that concentrations in sewer gas do not generally exceed the adjacent soil vapor concentrations.

Three other VOCs (acrolein, bromodichloromethane, and chloroform) exceeded EPA and MDEQ screening levels (SLs) in sewer gas. However, none of these chemicals are considered site-related. Both bromodichloromethane and chloroform are considered present due to drinking water and/or use of bleach in cleaning agents. Acrolein is ubiquitous in the environment from cooked foods and is widely found in human urine.

Exterior Soil Vapor Investigation Results

TCE was detected in 59 of the 62 soil vapor samples and exceeded SLs (EPA Residential Soil Vapor VISL [Target Cancer Risk = 1 x 10-6 and Target Hazard Quotient =1]) in 35 of the samples. Detections of TCE were similar in concentrations from June to October/November 2018, but were generally slightly more elevated during the June 2018 sampling event. Although TCE was detected in most samples, concentrations exceeding SLs were located within or adjacent to the shallow TCE groundwater plume footprint, suggesting the groundwater plume as the source of the vapor concentrations beyond the PMC site. This conclusion is supported by results of the mass partitioning analysis. The analysis evaluated the extent that TCE mass in the saturated and unsaturated zones contributes to soil vapor concentrations. The evaluation concluded that although both vadose zone soil and groundwater contribute to TCE in soil vapor at the former PMC property, the TCE source strength appears greater from groundwater both beneath the former property and in the study area.

Benzene was detected above SLs in 11 samples from nine locations. At the location with the highest benzene concentration (PMC-SVB-09-06), chemicals were detected that suggest a release of solvents,

including petroleum-based solvents. Based on these data and location of the detections, these chemicals are potentially present due to a site-related release. Benzene and ethylbenzene appear to be observed primarily within the boundary of the former PMC property and associated with those locations where TCE was noted. As a result, benzene and ethylbenzene have been considered in the human health risk assessment (HHRA) as potential site-related compounds and will be evaluated further for potential risk.

PCE was detected above soil vapor SLs in four samples collected from three locations. The highest concentration was detected at the deepest sample interval in boring SVB-10. Two borings indicated concentrations increasing with depth and two indicated concentrations decreasing with depth. No samples collected from or near these locations presented concentrations of PCE above SLs in soil or groundwater. The presence of PCE in the study area is sporadic, which could suggest multiple small releases or reworking of the soils during redevelopment.

Fate and Transport

TCE released from a former aboveground storage tank and waste-handling practices at the site migrated from soil to groundwater. Once dissolved, aqueous-phase TCE migrated toward the former municipal supply well during active pumping, resulting in the plume extending to Lake Michigan. When the Ingalls Municipal well was abandoned, flow conditions returned to non-pumping conditions. Advective migration of TCE in groundwater is very low due to the flat hydraulic gradient and flow reversals caused by fluctuations in lake stage. However, these conditions likely enhance dispersion and volatilization of the plume.

TCE is attenuating primarily through volatilization and dispersion, as degradation products were not identified. However, aqueous TCE concentration trends indicate that attenuation processes are likely matched by back diffusion from the matrix; most of the wells evaluated show stable trends. Soil vapor results indicate that groundwater is the primary source of TCE vapor concentrations, although residual TCE in vadose zone soil also contribute to vapor concentrations at the former PMC property.

Attenuation of vapors is noted as a decrease in vapor concentrations away from the source. Beneath the former PMC property, some soil vapor concentrations were higher in shallow samples than near the groundwater table. This indicates that concentrations in both groundwater and soil are contributing to the concentrations observed in soil vapor. Downgradient of the former PMC property and at adjacent properties, higher concentrations were generally noted in deeper samples closer to the water table, indicating groundwater as the primary source of vapor concentrations.

Once in soil vapor, TCE diffuses toward the surface through the porous media beneath the site and potentially migrates into buildings through advection caused by differences in temperatures inside and outside of the building or through operation of fans that can create driving forces for soil vapor entry, for example. Fluctuations in groundwater levels due to changes in lake stage also likely enhances volatilization. Potential vapor migration into buildings is discussed in more detail in Appendix B which includes a detailed evaluation of sewer gas samples collected in June and October 2018. The results indicate the presence of VOCs at relatively low concentrations, that are either below or comparable to concentrations observed in multi-level soil vapor samples collected at the site. Utility lines can potentially play a role in transport across the building envelope. However, as presented within this RI and in the attached VI technical memorandum, there is no evidence that the sewer network is currently acting as a preferential pathway to surrounding buildings.

Risk Assessment Results

The HHRA evaluated the potential current and future risks to human health posed by detected chemicals at the site. Indoor air, crawlspace air, subslab and exterior soil vapor, and soil were evaluated, where applicable, at properties included in the RI investigation. Groundwater data was not used in the quantitative risk assessment of the VI pathway since an extensive network of soil vapor sampling

locations is available for the site and is more extensive than the groundwater monitoring network. Groundwater as a source of mass storage and transport for VI is considered in the conceptual site model and in the nature and extent sections of the RI, and in the upcoming feasibility study.

- Potential current indoor air risk estimates based on indoor air/crawlspace air were within EPA-acceptable levels (target risk range of 1×10^{-6} to 1×10^{-4} and noncancer threshold of 1) at the residential properties that have not yet been mitigated.
- Potential current/future indoor air risk estimates based on exterior soil vapor (migrating to indoor air) were within EPA-acceptable levels at residential properties.
- Potential future indoor air risk estimates based on subslab soil vapor (migrating to indoor air) were:
  - Within EPA-acceptable levels for six residential properties.
  - Within EPA's acceptable target risk range at four residential properties.
  - Above EPA's noncancer threshold at four residential properties; the primary risk driver is TCE. Therefore, TCE was identified as a chemical of concern (COC) for inhalation of indoor air (based on subslab soil vapor data).

Residential and commercial properties with existing operational subslab depressurization systems or other vapor intrusion mitigation systems (VIMS) were not evaluated in the HHRA. Operation of the SSD systems and other VIMS components are currently operated and maintained by EGLE. The systems are expected to remain in place and operational until site remediation is achieved.

The ecological risk assessment was prepared following EPA guidance for Superfund sites (EPA 1997, EPA 1998). Habitat in the study area was identified as landscaped yards and public spaces with maintained lawns and small to medium trees and shrubs and Bay Front Park West that includes the Lake Michigan shoreline. Groundwater mixing with the water of Lake Michigan constitutes Groundwater to Surface Water Interaction and is part of the conceptual site model. The TCE plume is well below water quality criteria next to Lake Michigan; therefore, there is no significant pathway to aquatic receptors from groundwater. The soil vapor exposure pathway to ecological receptors is considered complete but insignificant due to the lack of habitat.

The evaluation of per- and polyfluoroalkyl substances (PFAS) in groundwater was conducted in accordance with the MDEQ-approved QAPP, and the results indicate that PFAS are not COCs at the PMC site and therefore do not impact remedy selection. As shown in Table 4-1 of the RI report, there were no exceedances of the EPA Tap Water RSLs, MDEQ residential drinking water criteria or MDEQ groundwater/surface water interface in the collected groundwater samples. Therefore, no further investigation of PFAS is proposed for OU2. Confirmatory PFAS sampling can be requested as part of the OU1 five-year review.

Conclusions

TCE is widespread in shallow soils at the site. PCE, benzene, and ethylbenzene are present in localized areas on the site. A groundwater TCE plume is present at the site due to releases at the former PMC property and has migrated primarily through historical operation of a municipal supply well toward Lake Michigan. TCE concentrations are relatively stable in groundwater, as documented during the third five-year review (2014) and confirmed by the lack of degradation products and mostly stable concentration trends. However, TCE is attenuating through volatilization, diffusion, and dispersion. Therefore, concentrations of TCE in soil vapor resulted in the creation of OU2 and investigation of VI potential. In addition to groundwater, residual soil mass beneath the former PMC property is contributing to soil vapor concentrations. The utilities in the soil source area can contribute to migration into buildings overlying the impacted soil vapor, but do not appear to be significantly expanding the area

of impacted soil vapor or transporting soil vapors to off-site properties. Downgradient and adjacent to the former PMC property, groundwater is the primary source of TCE in soil vapor.

VI has been observed in some buildings on or near the former PMC property and is being addressed in some cases with mitigation systems. Since EPA's Final VI Guidance (2015) requires that mitigation only be used as an interim step, remedial options to remove the source material causing this VI must be considered.

CH2M recommends that the following tasks be accomplished:

- Develop Remedial Action Objectives.
- Conduct a feasibility study to select an appropriate remedy.
- Install preemptive mitigation in a limited number of additional structures with elevated subslab concentrations.
- Continue to attempt to obtain access to properties that have not yet provided access for interior VI sampling (subslab soil vapor, crawlspace air, and/or indoor air).

SECTION 1

Introduction

CH2M HILL, Inc. (CH2M) has conducted a remedial investigation (RI) of Operable Unit 2 (OU2) at the Petoskey Manufacturing Company (PMC) Groundwater Superfund Site in Petoskey, Michigan (site) to assess the potential vapor intrusion (VI) risks from site-related contaminants. This data will be used to develop and evaluate remedial alternatives, and to prepare a focused feasibility study to be submitted after this RI report. The RI activities included herein are based on the recommendations presented in the *Technical Memorandum-Proposed Approach to Complete Nature and Extent Delineation of the PMC Groundwater Site, Emmet County, Michigan* (CH2M 2017a), the *Quality Assurance Project Plan, PMC Groundwater Superfund Site, Operable Unit 2* (CH2M 2018a), and additional correspondence and teleconferences between the U.S. Environmental Protection Agency (EPA) Work Assignment Manager, Michigan Department of Environment, Great Lakes, and Energy (EGLE),[2] and CH2M.

OU2 was established by EPA in 2017 to determine the nature and extent of vapor migration from the former PMC manufacturing facility through an analysis of historical data and subsurface investigations. OU2 includes VI risks at the site as well as the surrounding residential and commercial properties (study area). OU2 geographically overlays the earlier OU1 for which the primary risk pathway was groundwater ingestion that has proceeded through a Record of Decision (ROD).

This RI report summarizes the soil, groundwater, sewer gas, indoor air, crawlspace air, outdoor air, subslab soil vapor, near-slab soil vapor, and exterior soil vapor data collected by CH2M within the study area in from October 2016 to November 2018 and thus incorporates historical data from before the RI to define the nature and extent of contamination and refine the conceptual site model (CSM). This RI also presents a human health and ecological risk assessment (ERA) and an evaluation of mass partitioning and storage between vadose and saturated zones.

1.1 Background

The former Petoskey Manufacturing Company was located at 200 West Lake Street, Petoskey, Emmet County, Michigan (Figure 1-1). The site has been redeveloped as a condominium complex (Water Street Condominiums) and is located approximately 500 feet south of Little Traverse Bay of Lake Michigan. It is bordered to the north by another condominium complex, to the east and south by residential structures, and to the west by the Bay Front Park access easement and a parking lot associated with a commercial structure. Additional single-family residential structures lie to the west and south (Figure 1-2). Bear River, which drains into Little Traverse Bay, is located approximately 500 feet east of the site. Immediately south of Lake Street (behind a row of homes) is a steep bluff running approximately parallel to the shoreline.

1.1.1 Objectives

To establish the RI objectives, CH2M completed a Quality Assurance Project Plan (QAPP) (2018a) that presents information regarding site setting; methods used in evaluating the nature and extent of contamination, and fate and transport of site-related chemicals; and the approach to evaluate risk to

[2] Effective April 22, 2019, the Michigan Department of Environmental Quality (MDEQ) reorganized into the Michigan Department of Environment, Great Lakes, and Energy (EGLE). Historical references to MDEQ occur throughout this document.

human health and the environment. This information is presented in Worksheets #10 and #11 of the Uniform Federal Policy (UFP)-QAPP and briefly described as follows:

- Refinement of the source area delineation for VI OU2:
  - Saturated zone: further define spatially and temporally the volatile organic compound (VOC) concentrations in groundwater to evaluate current and future VI pathways and in support of the remedy evaluation.
  - Vadose zone: further delineate VOCs in exterior soil vapor horizontally and vertically.
- Update of the VI CSM:
  - Refine the CSM to better understand the predominant transport mechanisms for VOCs in the subsurface, evaluate VOC mass storage, and evaluate remedial alternatives.
- Provide information in support of a remedial alternatives assessment that will include both vadose and saturated zones:
  - Provide physical and chemical characterization of the site soil to understand how it may be storing VOCs and transmitting them toward structures.

1.2 Approach

Activities performed during the RI were conducted in accordance with the UFP-QAPP. Evaluations in this report are based on data collected during the investigation and applicable data from previous investigations.

The following methods were used to evaluate the investigation results:

- Assembly and review of data
- Evaluation of the nature and extent of contamination
- Evaluation of the fate and transport of contamination
- Assessment of human health risk
- Assessment of ecological risk

Following evaluation of the results, the report presents recommendations for a path forward.

1.3 Pre-OU2 Remedial Investigations

The former PMC facility was a small fabricating operation that was active from 1946 to 2000. Activities included die casting, plating, and painting small automotive trim parts. The facility used trichloroethene (TCE) and xylene as solvents; TCE was stored in a 1,000-gallon aboveground storage tank (Figure 1-3), which was determined to have leaked while the plant was active (Environmental Consultants & Services Inc. [EC&S] 2001). There were likely multiple points of discharge at the facility as observed during a 2001 site inspection (EC&S 2001) and summarized as follows:

- The concrete floor had cracks, and some areas were covered with oil and metal chips.
- There was a paint and drum storage room off the northwestern part of the building.
- Casting machines, finishing machines, and paint operations were onsite.
- A concrete pit that housed the municipal water connections was observed with floor sweepings, but the integrity of the bottom was not discernable.

- Several drains and trenches that potentially discharged to the city sewer were noted, including the following:
  - An open trench that ran the length of the eastern part of the plant to divert cooling water and water-soluble quenching liquids
  - A truck well drain
  - A former trench with concrete bottom and sides that went to a clean out pit before discharging
  - Two additional floor drains
- Patched concrete floors were noted where a roto-finish machine was located.
- Spent soap solution was reportedly emptied into a drain in the floor.

ECS (2001) also describes the existence of a 1,000-gallon TCE aboveground storage tank that the Michigan Department of Environmental Quality (MDEQ) determined had leaked.

1.3.1 Subsurface Contamination Discovery and Listing on the National Priorities List (1980–1983)

Contamination at the site was first discovered in September 1981 when analytical data from water samples collected from a municipal water supply well (Ingalls Street Well) showed detections of TCE, cis-1,2-dichloroethene (DCE), and trihalomethanes. The City of Petoskey requested assistance from the Michigan Department of Natural Resources to conduct a hydrogeological investigation to identify the source of the contamination and to aid in identifying responsible parties.

Results from the MDEQ soil and groundwater sampling indicated elevated concentrations of several VOCs, including xylene, toluene, TCE, and ethylbenzene near the site, which was attributed to PMC. MDEQ subsequently asked PMC to determine the extent of the contaminated soil, and to remove and dispose of the impacted material. In 1982, PMC, under the direction of MDEQ, completed a partial soil removal from the west side of the building to a depth ranging from 2 to 5 feet. Subsequently, the site was proposed for the National Priorities List and listed in 1983.

1.3.2 Site Investigation Activities and Records of Decision (1984–2000)

In 1984, EPA negotiated a removal administrative order on consent by PMC. This order required PMC to conduct further hydrogeological studies. PMC completed the work under the direction of EPA and MDEQ. In 1987, EPA and PMC signed another administrative order on consent agreeing to conduct a full RI and feasibility study to determine the nature and extent of contamination and investigate appropriate remedial alternatives to address the contamination. In 1990, EPA relieved PMC of conducting further RI and feasibility study work, and entered into the State Cooperative Agreement with MDEQ, with the state agreeing to perform the RI and feasibility study with funding provided by EPA.

In 1992, MDEQ retained first EDER Associates and then Malcom-Pirnie, Inc. to complete site investigation activities. Concurrently with the state-led RI, EPA began a focused feasibility study to examine the impact of site-related contamination on the Ingalls Well.

The first ROD document was signed in 1995, which called for air stripping of water from the Ingalls Street well. In addition, pilot testing of a soil vapor extraction system was performed in September 1995. TCE concentrations ranged from 2 to 9 parts per billion (ppb) and decreased throughout the first test. Concentrations decreased to near nondetectable concentrations during the second test. In 1997, the State of Michigan and the EPA provided funding for an alternative remedy that consisted of removing the Ingalls Street well and constructing an alternative municipal supply well.

A second ROD was signed in 1998 to address the remaining soil and groundwater contamination. The major components of the selected remedy as described in the 1998 ROD included the following:

- **Soil Excavation.** In November 1999, a total of 2,740 tons of contaminated soil was excavated in the areas shown on Figure 1-3 and disposed of offsite. Soil was excavated from the northern portion of the site to a depth of up to 15 feet below ground surface (bgs). Deeper contaminated soil was left in place, to a depth of approximately 17 feet below grade.
- **Soil Vapor Extraction.** The second soil vapor extraction system, located at the northwest corner of the PMC building, operated intermittently in 1999 and 2000, and removed in 2000. Overall operation of the soil vapor extraction system removed 753 grams of TCE from the subsurface.
- **Monitored Natural Attenuation of the Groundwater.** This included the development of a groundwater monitoring plan, followed by installation of a monitoring well network, and an initial 3-year period of monitoring, followed by long-term monitoring.
- **Establishment deed restrictions** on and around the former PMC property that restrict excavation and the use of groundwater. A restrictive covenant on the former PMC parcel has been in place since 2005. The Petoskey Groundwater Protection ordinance applies to the entire area of the site and is reproduced as Attachment 6 to the 2009 five-year review for this site. It prohibits obtaining any water service other than that provided by the city without a permit from the city or MDEQ (now EGLE).
- **Establishment of a Contingency Plan** in the Long-Term Monitoring Plan that will be implemented if natural attenuation is not occurring sufficiently or at an acceptable rate. Potential contingency remedies were considered in the *Memorandum Technical Impracticability of Groundwater Restoration Petoskey Manufacturing Company Superfund Site* (CH2M 2013) and will be further developed in the groundwater portion of the feasibility study for OU2, currently in preparation.

1.3.3 Additional Site Investigation Activities and Sale of the PMC Facility (2001–2009)

A soil removal was conducted in fall 2000 to remove an 8-foot by 10-foot area of soil stained from hydraulic fluid leaking from a compressor in the northwest corner of the building. Soil samples were collected in November 2001 through the floor of the facility at depths of 1 to 6 feet. TCE was detected in about half of the samples analyzed above the method detection limit of 50 micrograms per kilogram (µg/kg); the maximum concentration detected was 1,300 µg/kg.

The former PMC facility was sold in April 2003 to a developer, and the PMC building was demolished in July 2004. Additional rounds of soil samples were collected as the slab was removed, and additional soil excavation was completed in 2004 in conjunction with construction activities. The construction of the residential condominium complex started in September 2004, and by 2008, 10 of the planned 16 residences were completed. In fall 2009, the property was in foreclosure because the developer went bankrupt. Construction for the remaining six units was completed by 2014 by a subsequent developer.

It is reported that a barrier consisting of a polyvinyl chloride membrane was placed beneath a portion of the complex in five of the units (EC&S 2004), which left 12 units either partially or completely without an engineered barrier; however, a final report was not issued on this work due to lack of payment. A polyvinyl chloride membrane in this western half of the property “to prevent storm water infiltration and storm water contact with impacted soils” was reported as observed by EPA in the September 21, 2004, site inspection report (EPA 2005). The incomplete installation likely limits the barrier’s effectiveness. A piece of thick black plastic was encountered at 4 feet below ground surface (bgs) when drilling at SVB-10 that could be evidence for the continued existence of this barrier over part of the site. This barrier is not believed to provide effective protection from VI but could affect the flow of liquids or gasses during remedy implementation.

EPA finalized a groundwater monitoring plan in 2006 and began quarterly monitoring. However, groundwater monitoring ceased in 2007 for 1 year until wells damaged during a park reconstruction project in 2005 were replaced or repaired by the City of Petoskey. The groundwater monitoring required by the 1998 ROD was then conducted in 2009, and the results were presented in the second five-year review, which was signed on December 23, 2009. Additional long-term groundwater monitoring activities were later completed as discussed in the following sections.

1.3.4 Groundwater and Vapor Intrusion Investigation Activities by CH2M (2011–2018)

Sampling activities were initiated by CH2M in 2011 to support the long-term groundwater monitoring as described in the ROD for the groundwater OU1.

1.3.4.1 July 2011 Monitoring Well Sampling

In July 2011, groundwater samples were collected for analysis of VOCs from 20 monitoring wells. Groundwater samples were also collected for total and dissolved zinc from three wells to determine if galvanized steel casings contributed to historically detected zinc concentrations. Details of this sampling event are presented in *Technical Memorandum Groundwater Monitoring Report for Long-Term Monitoring Activities – July 2011* (CH2M 2011a).

EPA completed the third five-year review in 2014. VI was identified as a potential issue at the former PMC source area.

1.3.4.2 Pre-OU2 Remedial Investigation Activities

In 2016, CH2M prepared a QAPP (CH2M 2016a) for soil, groundwater, and VI screening sampling. Following agency discussions and review of the QAPP, an agreement was reached between the agencies to implement the QAPP and to include recommendations as presented in *Revised Sampling Approach Technical Memorandum-PMC Groundwater Superfund Site, Petoskey, Michigan* (CH2M 2016b), including adding metals, dissolved gases, and 1,4-dioxane to the groundwater analytical parameters.

In October 2016, groundwater samples were collected for analysis of VOCs, general chemistry, dissolved gases, total and dissolved metals, and 1,4-dioxane from 21 monitoring wells. The general chemistry and dissolved gas analyses were used to support an evaluation of monitored natural attenuation. Metals analysis was used to evaluate whether well construction materials are contributing to elevated concentrations of metals in groundwater. 1,4-Dioxane analysis was added because of its status as an emerging contaminant and potential chemical of concern (COC). Details of this sampling event are presented in *Long-Term Groundwater Monitoring Activities, PMC Groundwater Superfund Site* (CH2M 2017b). MDEQ requested that future groundwater sampling at the site include analysis of per- and polyfluoroalkyl substances (PFAS) because of the potential for historical activities at the site to have used these chemicals.

In 2016, CH2M installed subslab soil vapor sample probes in garages at the Water Street Condominiums (most of the living space of the condominiums directly overlies the garages) and attempted to complete the installation of multidepth subsurface soil vapor probes. However, the subsurface lithology prevented the use of the planned drilling method (direct-push) for the multidepth soil vapor probes due to refusal from what is interpreted as large boulders or blocks of weathered bedrock. In January 2017, samples were collected from the 22 subslab soil vapor probes at the Water Street Condominiums for VOC analysis. Analytical results demonstrated that TCE concentrations exceeded the EPA VI screening level (VISL). Based on these results, EPA's Removal Program initiated rapid response activities, including additional subslab soil vapor probe installation, subslab soil vapor and indoor air sampling, and installation of subslab depressurization (SSD) systems to mitigate the VI pathway in 11 of the 17 units of the Water Street Condominiums. Results of these response activities are presented as an appendix to

the *Technical Memorandum Vapor Intrusion Investigation – PMC Groundwater Site, Emmet County, Michigan* (CH2M 2018b).

Also, in January 2017, sewer gas samples were collected from one sanitary sewer and two storm sewer lines. Analytical results demonstrated that only one storm sewer sample had a chloroform exceedance. Chloroform is considered to be a common by-product that forms when chlorine or other disinfectants are added to drinking water.

While response activities were being conducted, CH2M implemented a VI assessment at a commercial building and residences surrounding the Water Street Condominiums. These activities were completed in May, June, and July 2017, and February 2018, and included subslab, near-slab, and exterior soil vapor probe installation and sampling, and indoor air sampling. The data collected by CH2M is presented in *Technical Memorandum Vapor Intrusion Investigation – PMC Groundwater Site, Emmet County, Michigan* (CH2M 2018b).

1.4 OU2 Remedial Investigation

In 2017, EPA established a new VI OU, OU2. The scope of investigation for OU2 was defined in the *Quality Assurance Project Plan, PMC Groundwater Superfund Site, Operable Unit 2* (CH2M 2018a). In May and June 2018, soil and groundwater samples were collected, sewer gas samples were collected, and exterior soil vapor probes and monitoring wells were installed and sampled. In October and November 2018, the soil vapor probes were sampled, and additional residential indoor air, crawlspace air, outdoor air, sewer gas, and soil vapor sampling was completed. Results for the property specific VI investigations from October 2016 to November 2018 are summarized in this RI and discussed in further detail in the VI Technical Memorandum, included as Appendix B to this report.

1.5 Report Organization

This report is organized as follows:

- **Section 1 – Introduction.** Presents a discussion of the objectives of this RI, the site setting, a summarized site history, and a summary of the document organization.
- **Section 2 – Remedial Investigation Activities.** Describes RI activities at the site and study area performed during Event 1, completed in May and June 2018, and Event 2, completed in October and November 2018.
- **Section 3 – Site Geology and Hydrology.** Summarizes subsurface conditions at the site and study area based on observations made during RI activities and historical investigations.
- **Section 4 – Nature and Extent of Contamination.** Presents the nature and extent of contamination observed at the site as a result of data collected during Event 1, conducted in May and June, and Event 2, conducted in October and November 2018
- **Section 5 – Conceptual Site Model.** Provides contaminant fate and transport, routes of migration, and a CSM.
- **Section 6 – Baseline Risk Assessment.** Presents the approach, results, and conclusions of the human health and ERAs.
- **Section 7 – Summary and Conclusions.** Provides a summary and conclusions for the RI conducted of OU2 at the former PMC site and study area.
- **Section 8 – References.** Lists references used in preparation of this document.

SECTION 2

Remedial Investigation Activities

This report primarily details the RI activities at PMC that were performed over two sampling events. Event 1 was completed in May and June 2018. Event 2 was completed in October and November 2018. Details on previous investigation activities conducted in 2011, 2016, 2017, and 2018 can be found in the following documents:

- *Long-Term Groundwater Monitoring Plan, PMC Groundwater Site, Emmet County, MI* (CH2M 2011b)
- *Uniform Federal Policy–Quality Assurance Project Plan, PMC Groundwater Site, Emmet County, MI* (CH2M 2016a)
- *Technical Memorandum Groundwater Monitoring Report for Long-Term Monitoring Activities – July 2011* (CH2M 2011a)
- *Long-Term Groundwater Monitoring Activities, PMC Groundwater Superfund Site* (CH2M 2017b)
- *Technical Memorandum Vapor Intrusion Investigation – PMC Groundwater Site, Emmet County, Michigan* (CH2M 2018b); The portions of this document covering the field activities and building specific sampling activities have been updated and are presented as Appendix B of the current report under the revised title "Individual Property Vapor Intrusion Investigations PMC Groundwater Site, Emmet County, Michigan".
- *Quality Assurance Project Plan, PMC Groundwater Superfund Site, Operable Unit 2, Petoskey, Michigan* (CH2M 2018a)

Previously collected data were evaluated and used to design the 2018 sampling approach. Those data are used in this report to evaluate the nature and extent of contamination, and for human health and environmental risk assessments.

RI activities conducted at PMC included:

- Event 1, May and June 2018: drilling and installation of monitoring wells, surface and subsurface soil sampling, exterior soil vapor probe installation and sampling, groundwater sampling, collection of instant and long-term differential pressure data at exterior soil vapor probes, and sewer gas sampling
- Event 2, October and November 2018: installation and sampling of subslab soil vapor probes, indoor air and crawlspace air sampling, sewer gas sampling, collection of instant and long-term differential pressure data at exterior soil vapor probes, and exterior soil vapor probe sampling

Details of each sampling event are described in the following subsections. The investigation included other associated field activities, such as investigation-derived waste characterization, transport, and disposal. Figure 2-1 shows the investigation sampling locations. Appendix B contains details of five field events conducted for evaluation of VI at individual properties. Appendix C contains site photographs taken during the site reconnaissance and investigation activities.

2.1 Site Reconnaissance

Site reconnaissance was conducted before intrusive activities to assess the accessibility and proximity of proposed sample locations to the desired site features to be evaluated. Proposed monitoring wells, subslab soil vapor, and exterior soil vapor sample locations were marked in the field with a pin flag or spray paint (exterior locations) or non-permanent chalk/markers (interior locations) to assist in identifying the sample location during the utility locate clearance. The exterior soil vapor locations were

used for collecting soil samples, grab groundwater samples, and exterior soil vapor samples from multiple depths. Borings were located and adjusted, if needed, because of utilities and obstructions. During the May 2018 installation activities, there were four deviations greater than 10 feet from the proposed locations presented in the UFP-QAPP due to the presence of subsurface utilities (SVB-01, SVB-03, SVB-04, and SVB-13). One location (SVB-13) was not installed in the offset location due to the property owner revoking access.

During the October/November 2018 activities, installation of proposed basement soil vapor probes at three residential properties was not completed for various reasons, including the inability to access enough ground surface to complete a thorough utility locate survey, inability to penetrate the soil greater than 5 feet bgs based on groundwater infiltration, and/or refusal. At these locations, indoor air samples were deployed near the ground surface in attempts to capture potential vapors penetrating the exposed basement ground.

2.2 Utility Clearance

The Michigan one-call service (MISS DIG) was contacted to mark out public utilities around the proposed drilling locations. Additionally, a private utility locator (GPRS, Inc.) was subcontracted to identify and mark out underground utilities where monitoring wells and exterior soil vapor probes would be installed, and within the buildings where subslab soil vapor probes would be installed. GPRS, Inc. used ground-penetrating radar, electromagnetics, and a magnetometer as necessary to verify and mark the presence of underground utilities or other potential subsurface objects that could be damaged by intrusive work. GPRS also identified and marked out rebar and other anomalies within and under the building slabs. Four proposed drilling locations were adjusted in May 2018 due to subsurface utilities. Two proposed drilling locations were unable to be scanned in October 2018 as the ground surface encountered at these residences was inaccessible due to storage maintained in the basements that could not be readily rearranged.

2.3 Soil, Groundwater Grab, and Exterior Soil Vapor Sampling

In May 2018, soil borings were advanced with a rotosonic drill rig to just below the water table (approximately 12 to 16 feet bgs) at 15 of the 16 planned locations (Figure 2-1); SVB-13 was not completed because access to the boring location was revoked. Groundwater grab and soil samples were collected, and then permanent exterior multidepth soil vapor probes were installed (Table 2-1). Groundwater grab samples could only be collected at 9 of the 15 locations because the drill encountered refusal before groundwater.

Attempts were made to install triple-depth soil vapor probes at each location with screens set at approximately 5, 10, and 15 feet bgs. However, the actual number of screens and the screen depths were adjusted at each location depending on the soil types and depth to groundwater and/or saturated soils observed in the soil borings; 31 screens were installed across 15 boreholes (Table 2-1; Appendix D).

The soil vapor probe screens were placed in the more porous soils observed in the soil borings if possible. The bottom of the deepest probe screen was placed at least 1 foot above observed saturated soils. The top of the shallowest probe screen was placed at least 5 feet bgs, unless it was beneath an impervious layer (i.e., asphalt), in which case, it may be 4 feet bgs. There is at least 2.5 feet between the screen intervals to avoid crossover of the volumes sampled (that is, the assumed sphere of influence around the screen where the soil vapor sample is collected). The following subsections presents additional details for each of these activities.

2.3.1 Soil Sampling

Fifteen borings were advanced in May 2018 where permanent soil vapor probes were to be installed (Figure 2-1). Soil cores were continuously logged and screened by a CH2M geologist in accordance with the QAPP (CH2M 2018a) to provide lithologic information to support the CSM and to guide soil vapor probe installation depth. Soil cores were screened using a photoionization detector (PID) and inspected for discoloration, staining, and odors.

Soil samples were collected from 10 of the 15 borings for VOCs, percent moisture, permanganate natural oxidant demand, and total organic carbon analysis (Table 2-1). Samples were not collected from all borings because excessive heating of the soil occurred while advancing some borings due to the rotosonic drilling method (discussed in more detail in Section 4). Samples were shipped to the analytical laboratory under chain of custody and temperature control for overnight delivery. Nondisposable sample tooling and equipment were decontaminated between sample intervals.

2.3.2 Grab Groundwater Sampling

Grab groundwater sampling was completed in May 2018 at 9 of the 15 soil boring locations, where water was encountered (Table 2-1). Appendix D presents the grab groundwater sampling forms. The grab samples were collected at the groundwater table, where the boring encountered groundwater, after installation of a temporary 1-inch-diameter polyvinyl chloride well with 5-foot-long slotted screens. Depth to water was collected prior to grab groundwater sampling. Groundwater was purged using a peristaltic pump and collected in accordance with Field Operating Procedure #8, included in the UFP-QAPP (CH2M 2018a). Water quality parameters (including temperature, conductivity, dissolved oxygen [DO], pH, oxidation-reduction potential [ORP], and turbidity) were recorded. Grab groundwater samples were shipped to the analytical laboratory under chain of custody for VOC analysis and temperature control for overnight delivery. Nondisposable sample equipment was decontaminated between wells. After collection of the grab samples, the borehole was then completed as soil vapor sampling location.

Grab groundwater samples were also collected to vertically profile groundwater prior to installation of monitoring well CMW-01. Grab groundwater samples were collected for analysis of TCE using the techniques described above from four 5-foot intervals, as determined in the field based on the presence of groundwater observed in the soil logs: 15 to 20, 20 to 25, 40 to 45, and 45 to 50 feet bgs. The TCE results were used to determine the screened depth for this well. Soils between 25 and 35 feet were described as dry to damp. Grab groundwater samples were shipped to the analytical laboratory under chain of custody for TCE analysis and temperature control for overnight delivery.

2.3.3 Exterior Soil Vapor Probe Installation

In May 2018, after soil and groundwater grab sampling was completed in each of the 15 soil borings, permanent exterior multi-depth soil vapor probes were installed. The soil vapor probe installation diagrams are presented in Appendix D.

After determining the target depths of the soil vapor probe screens at each location, dry bentonite and/or sand was added to the boring to bring the depth up to the appropriate location and absorb any residual groundwater if necessary. The soil vapor probe, consisting of a 6-inch-long, 0.5-inch-outer-diameter stainless-steel wire mesh screen attached to 0.25-inch-outer-diameter Teflon tubing extending to ground surface, was placed with a sand pack to 4 to 6 inches above the screen. Approximately 6 inches of dry granular bentonite were then placed above the filter sand, and the borehole was filled with granular bentonite hydrated in lifts until the bottom depth of the next shallower probe screen was reached. Subsequent shallower probe screens were then installed in a similar manner, and the borehole was filled with granular bentonite hydrated in lifts to the ground surface. Approximately 2 inches of sand was placed on top of the bentonite before installing shallower interval screens to prevent the bentonite

from clogging the screens. The probes were completed with 6-inch-diameter locking traffic-rated flush-mount covers that are secured within a cement pad.

2.3.4 Exterior Soil Vapor Sampling

Exterior soil vapor sampling was performed at the 15 multidepth probes in June 2018 and October/November 2018 (Table 2-1). Appendix D contains the soil vapor sampling logs. The subsurface at each exterior soil vapor probe was allowed to equilibrate for at least 2 weeks after installation was completed in May 2018 prior to purging, leak-checking, and sample collection. A helium-leak check was performed on each probe by placing a shroud flooded with helium gas around the surface of the probe to confirm it was installed correctly such that ambient air would not be drawn into the sample. A vacuum air pump and sampling manifold (consisting of stainless-steel Swagelok gas-tight valves and fittings) was used to purge 3 dead volumes (volume within the probe screen, sand pack, and probe tubing) of soil vapor into a Tedlar bag at a rate of 200 milliliters per minute (mL/min).

Helium concentrations in the shroud and the purged soil vapor were measured with a Dielectric MGD-2002 Helium Detector. The soil vapor probe passed the leak check if the helium concentration in the purged soil vapor was less than 5 percent of the concentration present in the shroud. Each of the soil vapor probes passed the helium-leak check prior to soil vapor sample collection. The Tedlar bags were also screened using a ppbRAE PID for total VOCs and a LandTec GEM Landfill Gas Meter for oxygen, carbon dioxide, and methane. The measurements were recorded on the sampling logs provided in Appendix D.

Soil vapor samples were collected in 1-liter bottle vacs equipped with flow controllers set to 200 mL/min for a 5-minute sample time. A digital vacuum gauge was used to measure the vacuum in the bottle vac before and after sampling. The samples were shipped under chain of custody to the analytical laboratory for VOC analysis by EPA Method TO-15.

2.4 Monitoring Well Installation and Sampling

Two monitoring wells were installed in May 2018 to further delineate groundwater impacts. Wells CMW-01 and CMW-02 were installed within the former PMC property boundary to address a data gap where wells were removed during building demolition in 2004 (Figure 2-1). The wells were installed using rotosonic drilling methods within the shallow interval of the aquifer. Wells were completed with 2-inch-inner-diameter polyvinyl chloride riser and 5 feet of 0.01-slot screen with a #1 sand filter pack. Appendix C contains the well completion logs.

Following the well installation, the newly installed and existing monitoring wells were sampled in June 2018 (Table 2-2). Prior to monitoring well sampling activities, depth to water was measured from the monitoring wells. In addition, surface water elevation was measured from the established point at Petoskey City Marina. Groundwater samples were then collected for VOCs from 25 monitoring wells using a peristaltic pump and low-flow techniques. Six wells were also sampled for PFAS analysis at the request of MDEQ for OU1 but were not included in this sampling effort for efficiency. Additional precautions and procedures were followed when collecting samples for PFAS analysis in accordance with the UFP-QAPP FOP #12, Groundwater Sampling for Perfluorinated Compounds (PFCs) (CH2M 2018a). This FOP provides specifics of what materials may and may not be used when sampling for PFCs.

For all analyses except PFCs, groundwater samples were collected from monitoring wells using a peristaltic pump with clean disposable tubing. Water quality parameters (including temperature, conductivity, DO, pH, ORP, and turbidity) were recorded. Samples were shipped to the analytical laboratory under chain of custody and temperature control for overnight delivery. Nondisposable sample equipment was decontaminated between wells. PFCs were collected using approved equipment and material, as outlined in the FOP. Field personnel were instructed to avoid bringing certain items

onsite, including weather-proof log books, Teflon tubing, and new clothing. Samples were collected under similar low-flow conditions as the other analytes, but caution was exercised with regard to equipment used and kept onsite during the time of sampling. Appendix C contains the well sampling forms.

An obstruction was encountered that prevented sampling well PS-105D.

2.5 Sewer Gas Sampling

Sewer gas samples were collected in January 2017 (pre-OU2 RI) and June and October 2018, as follows:

- January 2017: One sanitary sewer sample and two storm sewer samples
- June 2018: Five sanitary sewer samples and four storm sewer samples
- October 2018: Six sanitary sewer samples and six storm sewer samples

Appendix D contains the sewer gas sampling logs. The depth to water, flow direction, approximate depth of water, and approximate sizes and locations of connecting pipes within the sewer manholes were recorded on the sampling logs.

The January 2017 sewer gas samples were collected using slightly different procedures from those used in June and October 2018. The manhole covers were removed, and the opening was covered with plastic sheeting secured to the ground. This was left in place for at least 30 minutes to allow the sewer conditions to equilibrate before field readings and samples were collected. Tubing was lowered into the manhole through the plastic sheeting; this tubing was used for field screening and sample collection. Field screening of the sewer gas was performed using a MultiRAE for total VOCs, hydrogen sulfide, oxygen, carbon monoxide and lower explosive limit, and a LandTec GEM Landfill Gas Meter for oxygen, carbon dioxide, and methane. The sewer gas samples were collected in 6-liter evacuated canisters equipped with flow controllers set to 200 mL/min for a 30-minute sample time. A digital vacuum gauge was used to measure the vacuum in the canister before and after sampling. The samples were shipped under chain of custody to the analytical laboratory for VOC analysis by EPA Method TO-15.

The June and October 2018 sewer gas samples were collected by removing the manhole cover, collecting field readings, and then placing an evacuated canister into the sewer to collect for 24 hours. Field screening of the sewer gas was performed using a LandTec GEM Landfill Gas Meter for oxygen, carbon dioxide, and methane attached to the end of Teflon tubing that was lowered into the manhole. Immediately after screening, sewer gas samples were collected by lowering a 6-liter evacuated canister into the sewer manhole and securing it with rope so that the sample inlet was several feet above the observed water surface. The manhole was then replaced, and the samples collected for 24 hours. After retrieval, samples were shipped to the analytical laboratory under chain of custody. A digital vacuum gauge was used to measure the vacuum in the canister before and after sampling. The samples were shipped under chain of custody to the analytical laboratory for VOC analysis by EPA method TO-15 SIM.

2.6 Vapor Intrusion Investigation

The VI investigation was completed across five sampling events in 2017 and 2018. A total of 25 properties was sampled, which included two properties with multiple residences, one commercial property, and 22 residential properties with single-family or duplex houses. Field investigation activities consisted of collecting indoor, crawlspace, and outdoor air samples and subslab or near-slab soil vapor samples at the individual properties. Appendix B contains details of this investigation.

2.7 Investigation-Derived Waste

The waste generated during a field investigation is known as investigation-derived waste. Investigation-derived waste includes soil cuttings from soil boring activities and decontamination water from

decontamination of drilling equipment. Solid wastes described above were containerized in clean 55-gallon drums, labeled appropriately with waterproof labels, and temporarily stored in a staging area located in the parking lot of the commercial property west of the site. Appendix D contains the manifest and associated documentation.

2.8 Sample Analysis

The various media samples were collected and sent to an analytical laboratory to be analyzed for the following:

- Groundwater:
  - Target Compound List (TCL) VOCs via method SW-846 8260B
  - Perfluorooctanoic acid (PFOA)/perfluorooctanesulfonic acid (PFOS) via method perfluoroalkyl substances by HPLC-MS-MS
- Soil:
  - TCL VOCs via method SW-846 8260B
  - Total organic carbon via method Walkley Black
  - Target Analyte List metals (minus cyanide) via methods SW-846 6010C, 6020A, and 7471B
  - Permanganate natural oxidant demand via method permanganate natural oxidant demand
- Exterior Soil Vapor and Sewer Gas:
  - Exterior Soil Vapor: VOCs via method TO-15
  - Sewer Gas: VOCs via method TO-15 and TO-15 SIM
- Indoor air, crawlspace air, outdoor air, and subslab soil vapor:
  - VOCs via method TO-15 and TO-15 SIM
- Investigation-Derived Waste, Soil:
  - Toxicity Characteristic Leaching Procedure (TCLP) VOCs via method SW-846 5035A and SW-846 8260B
  - TCLP semivolatile organic compounds and total polychlorinated biphenyls via methods SW-846 3510C, 3546, 8270C, and 8082
  - TCLP metals (including mercury) via methods SW-846 5035A, 6010C, 6020A, and 7471A
- Investigation-Derived Waste, Aqueous:
  - Total VOCs via method SW-846 8260B
  - Total semivolatile organic compounds via methods SW-846 3510C and 8270C
  - Total polychlorinated biphenyls via methods SW-846 3511 and 8082
  - Total Resource Conservation and Recovery Act metals (including mercury) via methods SW-846 3005A, 6010C, 6020A, and 7470A

Appendix E contains laboratory data packages.

2.9 Quality Assurance/Quality Control Sampling

Field quality assurance/quality control (QC) samples were collected according to the following:

- Matrix spike (MS)/matrix spike duplicates (MSD)—An MS/MSD sampling set was collected for at least every 20 field samples collected per matrix (groundwater and soil) per parameter.
- Field duplicates—A field duplicate sample was collected for at least every 10 samples collected per matrix.
- Equipment Blanks—Equipment blanks associated with groundwater and soil samples were collected of laboratory-grade deionized water certified to be free of PFOA/PFOS poured into, over, or pumped through sampling equipment when nondisposable equipment was used.
- Trip blanks—A trip blank accompanied each cooler, including groundwater or soil samples shipped for VOC analyses.

  QA/QC results are discussed in Appendix F. Results of individual QA/QC samples are available in Appendix E; cross reference information between field and laboratory sample numbers are in the database submitted to EPA.

2.10 Data Quality Assessment

CH2M performed data review, verification, and validation as described in the UFP-QAPP for the samples collected for the RI. The data analytical result quality was assessed from soil and surface water collected during the field investigation. The following data quality indicators were reviewed:

- Data set narrative, to identify issues that the lab reported in the data deliverable
- Sample integrity (sample collection, preservation, and holding times)
- Basic QC measurements used to assess the accuracy, precision, and representativeness of data, including QC blanks, laboratory control samples, MS/MSDs, internal standard and surrogate recoveries, when applicable, and field or laboratory duplicate results
- Sample results, TCLs, and detection limits, to verify that project analytical requirements are met
- Initial and continuing calibration data
- Precision between the two columns or detectors for methods that employ second column detector confirmation
- Initiation of corrective actions, as necessary, based on data review findings

Analytical results were evaluated using precision, accuracy, representativeness, comparability, and completeness (PARCC) criteria. The PARCC evaluation determined that the data can be used for project decisions, while considering the validation flags applied to some samples to reflect data usability limitations. Data review, verification, and validation efforts are documented in the data quality evaluation report (Appendix F).

SECTION 3

Site Geology and Hydrogeology

3.1 Surface Features

The study area of this RI includes the footprint of the former PMC facility and the surrounding neighborhood. Built on the same property as the former PMC facility is the 200 West Lake Street Condominiums (aka Water Street Condominiums), which consist of four buildings, each housing a total of 16 single-family condominium units and one commercial property, none of which have basements. The surrounding neighborhood consists of multiple single-family residences (with a few duplexes and small apartments) and one commercial property, most of which have stone foundations, and a crawlspace-turned-basement ("Michigan-style" basement) with or without concrete poured flooring.

North of the former PMC facility is [redacted], [redacted] Northeast and northwest of the former PMC facility, surrounding the [redacted], are park spaces, connected by a bike path. These park spaces front the Little Traverse Bay of Lake Michigan.

Northwest of the former PMC facility is a [redacted] property with a finished basement and poured concrete foundation. This facility is occupied primarily during standard daytime business hours.

3.2 Climate

Seasonal temperatures are moderated by Lake Michigan. The average annual temperature in Petoskey is 44 degrees Fahrenheit (°F). The warmest month, on average, is July, with an average temperature of 66.4°F. The coolest month, on average, is January, with an average temperature of 20.0°F. Historically recorded maximum and minimum temperatures are 99°F and –25°F, respectively.

The average amount of precipitation is 33 inches per year. There is an average of 158 days of precipitation per year and 123 inches of snow, with the most snow occurring in December and January. Appendix A contains weather data for the city of Petoskey.

Based on data from the nearby city of Charlevoix, winds are expected to be primarily westerly to northwesterly with a substantial frequency of winds over 10 miles per hour. This suggests the potential for somewhat higher than typical differential pressure and air exchange rate variation (Song, et al. 2014 and 2018).

3.3 Topography

Generally, the topography of the city of Petoskey rises away from the lake towards the south and southeast. The topography is divided in two by Bear River, which is oriented approximately northeast-southwest, and drains into the Little Traverse Bay. The elevation to the south peaks at around 900 feet above sea level (asl), and the elevation to the southeast peaks around 800 feet asl.

Topography within the study area also increases away from the lake from approximately 578 feet asl along the waterfront to approximately 595 feet asl along West Lake Street (Figure 1-2). Roughly parallel to the waterfront, the elevation increases approximately 25 feet at a bluff between West Lake Street and West Jefferson Street.[3]

[3] Contour map data obtained from http://contourmapcreator.urgr8.ch/. Accessed October 31, 2018.

3.4 Regional Geology

Surficial geology of the Petoskey, Michigan, area consists of coarse-grained glacial till, glacial outwash sand and gravel, postglacial alluvium, and lacustrine sand and gravel underlain by the Devonian-age Traverse Group (Michigan Geological Survey 2018). Although these unconsolidated lacustrine deposits are reported of various thicknesses (5 to 200 feet) overlying weathered bedrock (Seller, et al. 2018), based on outcrops located close to the site, this layer is very thin within the study area (Kesling, Segal and Sorensen 1974). The glacial lithologies cannot be regionally correlated in the subsurface due to the lateral and vertical heterogeneity that resulted from a complex depositional history (USGS 2007). Although the thickness of the of most of the glacial deposits in Emmet County range from 201 to 800 feet thick, they have been noted as not present or thin to the north (Western Michigan University, Department of Geology 1981).

The Traverse Group, present beneath the lacustrine sand and gravel, consists of five formations: the Gravel Point Formation, overlain by the Charlevoix Limestone, overlain by the Petoskey Formation, overlain by the Whiskey Creek Formation, overlain by the Jordan River Formation. Near Petoskey, Michigan, the Gravel Point Formation, Charlevoix Limestone, and the Petoskey Formation are exposed (Milstein 1987). The Gravel Point Formation consists of "a grey to brown, fine to cryptocrystalline, dense, lithographic limestone" containing shale beds up to 2 feet thick, and "zones of chert nodules and petroliferous biohermal masses." The Charlevoix Limestone consists of a "grey to brown, fine to coarsely crystalline, slightly argillaceous, shaley limestone, commonly interbedded with coquina." The Petoskey Formation overlays the Charlevoix Limestone and is a "pale buff to greyish brown, fine-grained, arenaceous limestone, containing zones of porous, friable limestone with a strong petroliferous odor." The Traverse Group exhibits extensive fossils, and the state stone, the Petoskey Stone (consisting of fossilized coral colonies) originates from the Petoskey Formation. Within the PMC study area, the Charlevoix and Petoskey Formations are present (Milstein 1987).

3.4.1 Surface Water Hydrology

The two main surface water bodies near the site are Lake Michigan (Little Traverse Bay) located approximately 400 feet north of the site, and Bear River, which runs north-south approximately 500 feet east of the site.

3.4.2 Regional Hydrogeology

In southern Emmet County, Michigan, Traverse Group forms the bedrock surface. The Traverse Group is a regional saline aquifer, underlain by the Bell shale, which serves as a confining unit separating the Traverse Group from lower aquifers (Ellis 2013). In some areas of Emmet County, the Traverse Group has been highly fractured leading to localized areas of very high permeability within the group (U.S. Geological Survey 2007).

3.5 Site-specific Geology

To evaluate the site-specific geology, three cross-sections were developed at the locations shown in Figure 3-1. The cross-sections, presented in Figures 3-2 through 3-4, incorporate historical well installation logs, as well as recent well installation and boring logs. The study area rests on dark brown to black fill that ranges from 3 to 5 feet in thickness, composed of fine-grained sand with gravel and occasional trace clay. The fill beneath the approximate footprint of former PMC building, currently the Water Street Condominiums, is underlain by friable limestone with unconsolidated lacustrine gravel (including boulder and cobble size) and sand. Additionally, within the friable limestone layers, locally discontinuous layers of gravel, silt sand with gravel, and gravelly silty clay are seen at CMW-01 (Figure 3-2). These layers are similar to beach face or foreshore deposits (Schuster & Nutz 2018); in particular, they indicate a regressive

sequence (coarsing upward) likely associated with post-glacial deposition caused by changes in historical Lake Michigan stage levels.

During the construction of mitigation systems in the Water Street Condominiums [redacted], cavities were hand dug beneath the slab and vacuum excavated. The materials removed were described as “foundation sand and a little bit of gravel” (Posavatz 2018).

The friable limestone and unconsolidated deposits are present over the more competent fractured limestone bedrock described as shaley and slightly argillaceous (Charlevoix Limestone). The friable limestone and unconsolidated deposits are typically identified to approximately 40 feet bgs (see PS-2 and PS-106 on the cross-sections) overlying the more competent Charlevoix Limestone. However, at some borings, such as CMW-01 (Figure 3-2), the Charlevoix Limestone was not identified (Appendix C). Because of poor recovery during drilling, the strata over the Charlevoix Limestone is not well defined; therefore, the interface between the layers are generalized in each cross-section.

The Charlevoix Limestone bedrock that underlies the unconsolidated deposits is generally described as interbedded with thin shale layers and slightly fossiliferous. Fractures are described as containing fine to medium sand with some silt. Due to the presence of boulders and limestone that impacted drilling recovery, logs frequently describe the pieces of the rock that are brought to the surface making distinction of the interface between the unconsolidated lacustrine and limestone deposits, and Charlevoix Limestone difficult to determine.

3.6 Site-specific Hydrogeology

The unconsolidated surficial deposits and shallow limestone bedrock underlying the site compose a single unconfined table aquifer. Water levels in the study area range from 5 to 19 feet bgs in June 2018 (Table 3-1). Depth to water at the former PMC property averages about 13 feet bgs. Specifically, upgradient of the site along Lake Street, depth to water averages about 15 feet bgs, downgradient of the site near the commercial property, the average depth to water is about 12 feet bgs. Groundwater is shallower near the shore as noted at well PS-10A, at [redacted] where depth to water averages 9 feet bgs.

An evaluation of the hydrogeologic characteristics of the site were presented in the *Technical Memorandum Technical Impracticability of Groundwater Restoration Petoskey Manufacturing Company Superfund Site, Petoskey, Michigan* (CH2M 2013) and are summarized in this section. Historical RIs and groundwater elevation monitoring are included to help understand the dynamics of groundwater movement at the site. Conclusions of past hydrogeologic studies indicate the following:

- There is a lag time in aquifer response to changes in the lake water elevations (lake stage) resulting in local reversals of the groundwater flow direction nearshore, i.e., when lake elevation is low, groundwater flow is towards the lake; when lake elevation rises, groundwater flow is towards the site (away from the lake), resulting in highly variable flow direction based on frequent short-term changes in lake stage.
- Slug and pump test results indicated that the hydraulic conductivities (k) at the site range from 7.67×10^{-4} centimeters per second (2.16 feet per day) at well MW-105D to 2.11×10^{-3} centimeters per second (5.98 feet per day) at well MW-201S. Pumping tests indicated that Lake Michigan exerts a high degree of influence on the water levels; groundwater elevations in observation wells rose and fell throughout the pump test even though a constant pumping rate was maintained (Malcolm Pirnie 1998).
- Equilibrium hydrogeologic conditions, the basis for static water level measurement and potentiometric maps, do not exist near the lake; therefore, developing accurate groundwater flow maps is challenging for the site.

- Continuous water level measurements collected every 30 minutes over 3 months in 2004 concluded the following (MDEQ 2005):
  - The horizontal hydraulic gradient is generally flat across the site.
  - There is a high degree of hydraulic connection vertically within the aquifer.
  - When lake stage is higher than the groundwater elevations, the head differential between the lake and the groundwater causes the normally (continually) flowing groundwater to back up (mound) until an equilibrium was reached.
  - Groundwater flow was to the north/northwest for most of the study period.

Figure 3-5 shows the groundwater elevation map generated from groundwater elevations measured during the June 1, 2018, sampling event and provides a snapshot of the groundwater conditions on that day. This figure indicates that some of the groundwater anomalies described above are present, as noted by the flat hydraulic gradient. Groundwater elevations, with one exception (MW-105S), vary by less than 0.5 foot across the study area. Because there is not enough elevation change, contours are not presented on the figure. Although net advective flow is not a condition at the site, for the purposes of conservative assessment of these environmental investigation results, groundwater flow within this evaluation is interpreted to be generally towards Lake Michigan.

To estimate the seepage velocity at the site, the June 1, 2018, groundwater surface elevation map and the following equation from Darcy's Law, was used:

$$V = ki/n_e$$

Where:

V = Groundwater seepage velocity (feet per day)
k = Hydraulic conductivity (feet per day)
i = Groundwater hydraulic gradient (feet per feet)
n_e = Effective porosity (estimated as 0.3)

The effective porosity value used here is the same as has been previously used at this site (CH2M 2013) and is well within the ranges widely stated for limestone formations (USGS 1963, Duffield 2018). The hydraulic conductivity values used (2.16 to 5.98 feet per day) represent the range of values reported in the Phase II RI The hydraulic gradient of 0.00003 was calculated between CMW-1 and COP-3 (Figure 3-5), and an assumed effective porosity of 0.3 was used. The groundwater flow velocity calculated using June 1, 2018, groundwater elevation data was between 0.0002 to 0.0006 foot per day or 0.08 to 0.22 foot per year.

To evaluate how groundwater migrates vertically at the site, vertical hydraulic gradients were calculated for five well pairs (Table 3-2). Virtually no vertical gradient was noted at four of the five pairs. Although, the deeper wells at three of these pairs had a slightly higher head value (0.01 to 0.09 feet) than the shallower wells, indicating an upward vertical gradient. At the PS-105S/PS-105D pair, a downward vertical gradient of 0.12 (unitless) was noted.

SECTION 4

Nature and Extent of Contamination

This section discusses the nature and extent of contamination observed in the study area from samples collected in 2018. The discussion is broken into soil, groundwater, and soil vapor results. Appendix B contains additional property-specific VI investigation results. Appendix E contains the analytical data packages for the data discussed in this section. Appendix F contains the associated data quality evaluation report.

4.1 Screening Levels

To define the nature and extent of contamination at the site, conservative screening levels (SLs) for VI were selected using state and federal guidance documents and media described in the following subsections.

4.1.1 Groundwater Screening Levels

SLs for groundwater samples are presented in Worksheets #15-3 and #15-4 of the UFP-QAPP (CH2M 2018a), and are summarized as follows:

- The EPA tap water regional screening levels (RSLs; EPA, November 2017) are based on a Target Cancer Risk (TCR) of 1×10^{-6} and a Target Hazard Quotient (THQ) of 1.
- The EPA residential groundwater VISLs were developed from the EPA VISL calculator using the November 2017 EPA RSLs. The VISLs were calculated based on a TCR of 1×10^{-6} and a THQ of 1.
- For chemicals without published RSLs, appropriate surrogate chemicals with RSLs were identified and their RSLs used. Appropriate surrogates were identified based on similar chemical and toxicological properties and include the following:

Compound	Surrogate
Methylcyclohexane	Cyclohexane
trans-1,3-Dichloropropene	1,3-Dichloropropene
m&p-Xylene	Total xylenes
o-Xylene	

- The MDEQ Residential Volatilization To Indoor Air Criteria (VIAC) are unrestricted site-specific criteria that apply to a residential house with a basement located in Emmet County, site-specific depth to groundwater of 13 feet, and U.S. Department of Agriculture (USDA) soil type of sand.

4.1.2 Soil Screening Levels

SLs for soil samples are presented in Worksheets #15-1 and #15-2 of the UFP-QAPP (CH2M 2018a), and are summarized as follows:

- The EPA Residential Soil RSLs (EPA, November 2017) are based on a TCR of 1 × 10-6 and a THQ of 1.
- The MDEQ Residential VIAC are unrestricted site-specific criteria that apply to a residential house with a basement located in Emmet County, site-specific depth to groundwater of 13 feet, and USDA soil type of sand. Site-specific criterion may be below target detection limits (TDL). In accordance when the TDL for a hazardous substance is greater than the developed cleanup criterion, the criterion is the TDL. The use of the TDL in lieu of the VIAC is applicable for benzene, ethylbenzene, TCE, and PCE (MDEQ 2018).

4.1.3 Subslab Soil Vapor, Soil Vapor, and Sewer Gas Screening Levels

SLs for subslab soil vapor, soil vapor, and sewer gas samples are presented in Worksheets #15-5 and #15-6 of the UFP-QAPP (CH2M 2018a) and summarized as follows:

- The EPA residential soil vapor VISLs were developed from the EPA VISL Calculator using the November 2017 EPA RSLs. The VISLs were calculated based on a TCR of 1 x 10^{-6} and a THQ of 1.
  - The EPA default soil-vapor-to-indoor-air attenuation factor of 0.3 is used to calculate the soil vapor VISLs. Use of an attenuation factor of 0.03 for screening sewer gas is a default in the absence of established guidance and is based on the assumption that similar ratio of soil vapor entry rate (Qsoil) versus overall building ventilation rate (QB) would hold similarly for sewer gas and for subslab soil vapor.
  - These EPA VISLs differ from those used in the VI technical memorandum (Appendix B) because EPA elected to use VISLs based on a TCR of 1 x 10^{-5} and a THQ of 1 for risk management decisions at the site.
- The EPA residential soil vapor removal management levels (RMLs) were developed from the EPA VISL Calculator using the November 2017 EPA RSLs. The RMLs were calculated based on a TCR of 1 x 10^{-4} and a THQ of 3, except for TCE, where a THQ of 1 was used.
- The MDEQ Residential VIAC are unrestricted site-specific criteria that apply to a residential house with a basement located in Emmet County, site-specific depth to groundwater of 13 feet, and USDA soil type of sand. Within Appendix B, the VIACs were not utilized, as they were either identical to or less stringent when compared to the RIASL for soil vapor contaminants of concern at this site. As a result, the VI technical memorandum does not screen against the VIACs.

4.1.4 Indoor Air and Crawlspace Screening Levels

VISLs for indoor air and crawlspace air samples are presented in Worksheets #15-5 and #15-6 of the UFP-QAPP (CH2M 2018a) and summarized as follows. Outdoor air was not screened against any criteria, as this data set was used as a screening tool in the MLE to be included with the human health risk assessment (HHRA) in the final RI:

- The EPA residential indoor air VISLs were developed from the EPA VISL Calculator using the November 2017 EPA regional SLs. The VISLs were calculated based on a TCR = 1 x 10^{-6} and a THQ = 1. These EPA VISLs differ from those used in the VI technical memorandum (Appendix B) because EPA elected to use VISLs based on a TCR of 1 x 10^{-5} and a THQ of 1 for risk management decisions at the site.
- The EPA residential indoor air RMLs were developed from the EPA VISL Calculator using the November 2017 EPA RSLs. The RMLs were calculated based on a TCR = 1 x 10^{-4} and a THQ = 3, except for TCE where a THQ = 1 was used.
- The MDEQ residential indoor air media-specific volatilization to indoor air interim action SLs (August 2017), otherwise known as the recommended interim action SLs.

The MDEQ time-sensitive residential indoor air media-specific volatilization to indoor air interim action SLs (August 2017), otherwise known at the time-sensitive recommended interim action SLs.

4.1.5 Development of Site-Specific Contaminants of Potential Concern Based on Multiple Lines of Evidence

The volatile site-specific constituents of potential concern were defined in the 1998 ROD for OU1 as:

- Acetone
- 1,2-DCE (total)
- Ethylbenzene
- Methylene Chloride
- Tetrachloroethene (PCE)
- Toluene
- TCE
- Vinyl Chloride
- Xylenes (total)

A formal evaluation of chemicals of potential concern (COPCs) for OU2 is presented in Section 6.1 and associated tables. That evaluation begins with the indoor air detections above SLs, and then evaluates on a building-specific basis whether there is evidence for indoor or subsurface sources. The following VOCs were considered COPCs in one or more units or exposure scenarios:

- TCE
- Benzene
- Naphthalene
- 1,3-Dichlorobenzene

Several other constituents were evaluated in this process and not selected as COPCs for the following reasons. Additional VOCs were detected in soil and/or groundwater samples but did not exceed the VI screening criteria. Two VOCs not listed on the COPC list (acrolein and bromodichloromethane) exceeded EPA and MDEQ SLs in sewer gas. However, none of these chemicals is considered site-related.

- Acrolein
  - Acrolein is ubiquitous in the environment from cooked foods and is widely found in human urine (Stevens and Maier 2008). Thus, the appearance of acrolein in sewer gas is to be expected.
- Bromodichloromethane
  - Bromodichloromethane is considered present in part due to disinfected drinking water and is also found in most cleaning products where bleach is an ingredient and, thus, is highly likely to be discharged to sewers (Odabasi 2008 and 2014).
- Chloroform
  - Chloroform was only detected in one groundwater sample and is a common by-product that forms when chlorine or other disinfectants are added to drinking water. Chloroform is not listed as a COPC for OU1 in the 1998 ROD.
  - Chloroform exceeded the SL of 10^{-5}, hazard quotient (HQ)=1 used in the building-specific data evaluation in several of the indoor air samples collected at three residential properties in June 2017 and one residential property in February 2018. The chloroform concentrations observed in indoor air are within the 95th percentile range observed at other U.S. residences where VI is not suspected (The sole exception is one sample in a [redacted] building [redacted] that slightly exceeds the reported 95th percentile [EPA 2011]).
  - The most common source of chloroform in indoor air is shower water (Nuckols, et al. 2005) in which chloroform is present as a by-product of the disinfection process. The group of chemicals

for which chloroform is the most common representative (total trihalomethanes) is known to be present at low levels in the City of Petoskey drinking water (City of Petoskey 2015). Chloroform is also found in very high concentrations in numerous household cleaners that contain bleach as an ingredient (Odabasi 2008 and 2014). It is highly likely to be discharged to sewers (Odabasi 2008 and 2014). Very substantial discharges of chloroform to municipal systems have been reported from residential washing machines (Shephard 1996).

- Only one residential building had a subslab soil vapor result with chloroform exceeding the 10^{-5}, HQ=1 SL. That distribution is not consistent with the location of the major solvent-using activities of the former PMC facility (Figure 1-3).
- McHugh and Beckley (2018) sampled 103 manholes and stated that the frequency of detection of chloroform in sewer gas at locations not expected to be impacted by environmental sites is 82 percent, with a median concentration of 26 micrograms per cubic meter (µg/m^3) and a 90th percentile of 360 µg/m^3. The concentrations observed in sewer gas samples at the site (median 67.5 µg/m^3; maximum 150 µg/m^3) are well within this range.

In addition, trihalomethane was observed in sewer gas samples. However, the exceedances were only observed in sanitary sewer samples, which is consistent with the attribution to drinking water or household cleaning.

4.2 Groundwater Results

Groundwater sampling results presented in this section include the site monitoring wells and grab groundwater samples. Tables 4-1 and 4-2 summarize the results of the monitoring well and grab samples, respectively. An obstruction was encountered that prevented sampling of well PS-105D.

4.2.1 Groundwater Sampling

Two VOCs were detected above SLs—TCE and chloroform. TCE was detected in 11 of the 25 monitoring wells sampled and 9 of the 13 grab samples collected from 10 locations. Detections of TCE in monitoring wells exceeded the EPA Tap Water RSL and the EPA Residential Groundwater VISL at 11 of 25 locations, and exceeded the MDEQ site-specific VIAC at 5 locations. Detections of TCE in monitoring wells exceeded the EPA Tap Water RSL and the EPA Residential Groundwater VISL at 11 of 25 locations and exceeded the MDEQ site-specific VIAC at 5 locations. Detections of TCE in grab groundwater samples exceeded EPA Tap Water RSL and the EPA Residential Groundwater VISL in 8 of 13 samples collected from seven locations and exceeded the MDEQ site-specific VIAC in one sample. The highest concentration of TCE (36 micrograms per liter [µg/L]) was detected at monitoring well PS-4 (Figure 4-1). The highest concentrations of TCE were detected in groundwater near the footprint of the former PMC facility, and concentrations above SLs were detected extending from the former facility to the northwest towards the lake.

Table 4-3 summarizes the field parameter data. There were a few locations where the recorded ORP and DO do not appear to be in agreement or equilibrium, including CMW1, MW205D-R, MW402D, and PS104. The field instruments were calibrated daily. It is well known that in samples that have not fully reached biogeochemical equilibrium that ORP measurements can not agree with other indicators of biogeochemical conditions. It is also understood that interferences or errors can effect an ampermetric DO sensor in the field in a way that would not necessarily be revealed by normal calibration procedures (USGS 2013).

PFAS were sampled from six wells and detected in four of these wells. PFAS results were compared to the criteria in the approved QAPP (Table 15-4; CH2M 2018a): EPA tap water RSLs, MDEQ residential drinking water criteria, and state groundwater/surface water interface criteria (MDEQ 2018). Three PFCs

(perfluorobutanoate, PFOS, and perfluorooctyl sulfonate) were detected at CMW-01, and one of these compounds (perfluorobutanoate) was also detected in CMW-02; however, none of the compounds were detected in downgradient well pair PS-4/PS-104. Further downgradient, perfluorobutanesulfonic acid was identified at MW-402S. Perfluorooctyl sulfonate was detected at PS-BS. None of the PFC concentrations exceeded respective SLs.

4.2.2 Natural Attenuation Evaluation

The selected remedy for groundwater based on the 1998 ROD is monitored natural attenuation. To evaluate whether natural attenuation is acting to reduce plume concentrations, TCE time-series trend charts were prepared for selected wells with a minimum of four sampling events. Figure 4-2A shows trends at source area wells PS-4 and PS-104. Figure 4-2B shows trends at wells located downgradient but near the source area, and Figure 4-2C shows trends at downgradient wells. Section 5.3 discusses mechanisms that act to naturally attenuate TCE in groundwater. A review of the trend charts indicates that concentrations of TCE in the source area wells are generally stable (Figure 4-2A). Although the last two samples collected from PS-104 (deep well) did not detect TCE, TCE concentrations in this well historically have been less than 10 µg/L, indicating a lack of vertical migration near the source area. Trends at near-source wells PS-CD and MW-402S are generally decreasing, but PS-CS and COP-5R are generally stable (Figure 4-2B). Trends in downgradient well PS-106 initially increased but are stable since approximately 2008, but trends in PS-11 are decreasing (Figure 4-2C). These data indicate that trends are localized and stable to decreasing.

In addition to time-series trends, the presence of degradation products of TCE, cis-1,2-DCE, trans-1,2-DCE, and vinyl chloride are used to evaluate whether reductive dechlorination is occurring. This is the primary degradation pathway of chlorinated VOCs, such as TCE, that occurs under reducing conditions. Based on the DO and ORP values recorded during June 2018 groundwater sampling (Table 4-3), the aquifer is generally aerobic. In addition, no degradation products were identified in groundwater in 2018, indicating little to no reductive dechlorination of TCE.

4.3 Soil Results

Table 4-4 summarizes the soil sampling results for detected chemicals. The EPA views bulk soil sampling for VI as a supporting line of evidence that can be used to establish potential locations of source zones, but which cannot be used to rule out VI because it is subject to false negatives (EPA 2015). At this site, the soil samples were frequently hot (> 212 ◦F) due the difficult drilling and thus are expected to underestimate actual VOC concentrations. The hottest temperature samples were those collected from the vadose zone below the first encounter with the crushed rock/rock fragments which is noted as “hard drilling” or “hot, hard drilling” on some of the boring logs. Samples collected below the water table were somewhat cooler than those in the “hard drilling” portions of the vadose zone.

4.3.1 Soil Sample Results

TCE was detected above the MDEQ site-specific VIAC TDL of 50 µg/kg and/or the EPA Residential Soil RSL of 940 µg/kg in 7 samples collected from 4 soil borings at concentrations ranging from 110 µg/kg at SVB-7 (4 to 5 feet bgs) to 2,700 µg/kg at SVB-10 (19 to 20 feet bgs). Concentrations of TCE in soil found above SLs appear to fall primarily within the western portion of the former PMC property. The highest concentrations of TCE were detected in soil in the western portion of the footprint of the former PMC property both above (SVB-12 1.5 to 2.5 feet bgs at 1,100 µg/kg; SVB-10 3 to 4 feet bgs at 200 µg/kg) and below (SVB-12 14 to 15 feet bgs at 1,600 µg/kg; SVB-10 19.5 to 20 feet bgs at 2,700 µg/kg) the water table (Figure 4-3). Although these data suggest that mass is present in both the vadose and saturated zones, it may not reflect an accurate profile of mass with depth because samples were not collected from every proposed location.

Benzene and ethylbenzene (associated with gasoline and other lighter hydrocarbon-derived products) were detected above the TDL of the MDEQ site-specific VIAC (but not EPA Residential Soil RSL) in one location in the western half of the former PMC property (SVB-07), where the highest concentrations of TCE are noted and where historical releases likely occurred; these chemicals were identified in collocated soil vapor samples (as discussed in Section 4.4.3); however, these chemicals were not identified in groundwater above SLs. Figure 4-4 shows the distribution of these data. Other VOCs were detected, but concentrations did not exceed SLs.

One metal, arsenic, was detected above the EPA Residential Soil RSL (0.68 µg/kg) in samples collected from SVB-05 (14.5 to 15 feet bgs) at 1.2 µg/kg and CMW-02 (29 to 30 feet bgs) at 1.1 µg/kg. These exceedances were detected outside of and within the site boundary, respectively, both below the water table, and at similar concentrations. Given that arsenic is a naturally occurring metal, was not detected in associated shallow sample at SVB-05, and concentrations are similar at both locations, these exceedances are not considered site-related contamination. Figure 4-5 shows the distribution of these data.

Total organic carbon is an indicator of the capacity of the soils natural organic matter to sorb VOCs. The total organic concentrations in sampled soils were generally low (<0.5 percent by weight), with the exception of the shallow samples at SVB-05, SVB-12, and SVB-15 where concentrations were between 1 and 4 percent by weight (Table 4-4).

4.4 Sewer Gas, Exterior Soil Vapor, and Subslab Soil Vapor Results

This section presents the results of the sewer gas, exterior soil vapor, and subslab soil vapor sampling and analysis conducted as part of this RI. A more detailed evaluation of the structure specific VI activities completed at the site is included in the VI technical memorandum (Appendix B).

4.4.1 Sewer Gas Sampling

Sewer gas was sampled in January 2017 as part of the pre-OU2 RI VI investigation activities reported in Appendix B and again in June and October 2018 as part of the RI. Sewer gas sampling methods were described in Section 2.5.1. Additional information about the construction and condition of the sewers at the site was obtained from records provided by the City of Petoskey.

Sewer gas analytical results during the RI can be summarized as follows:

- For the June 2018 sampling event, TCE was observed above the EPA Residential Soil Vapor VISL of 16 µg/m^3 at sanitary sewer locations SA-07 (55 µg/m^3) and SA-03 (19 µg/m^3)[4] (Table 4-5).
- For the October 2018 sampling event, TCE was observed above the EPA Residential Soil Vapor VISL at sanitary sewer locations SA-07 (39 µg/m^3) and SA-01 (19 µg/m^3) (Table 4-5).

TCE was detected in seven sewer gas samples located within the plume extent; two of these are located on the former PMC property. The remaining samples collected within the footprint of the TCE plume did not present elevated levels of TCE. The concentrations of sewer gas do not exceed the adjacent soil vapor concentrations (presented in Section 4.4.2). Sewer gas analytical results were screened against EPA Residential Soil Vapor VISL, EPA Residential Soil Vapor RML, and MDEQ site-specific VIAC.

Other VOCs were observed in the samples collected but did not exceed the SLs.

[4] This sample was initially inadvertently reported as storm sewer sample ST-04; however, review of the June 2018 sampling records indicates that this sample was actually collected at sanitary sewer location SA-03 (with the SA-03 results corresponding to sample ST-04). This review is further supported by the presence of trihalomethanes in the actual sample for SA-03 (which would not generally be expected in a storm water sample) and its consistency with the October 2018 sampling data.

Section 5.2.3 provides additional discussion of the importance of utilities in the CSM.

4.4.2 Exterior Soil Vapor Investigation

The following subsections summarize the exterior soil vapor investigation activities.

4.4.2.1 May and June 2018

TCE was detected in all but one soil vapor sample during sampling of all 15 exterior soil vapor locations. TCE exceeded SLs in 22 of the samples collected from 12 of 15 locations. The highest concentration was detected at 7,500 µg/m^3 at SVB-12 (5 feet bgs) (Figure 4-8). Spatially, TCE above SLs was identified within or adjacent to the shallow groundwater TCE plume, with the highest concentrations of TCE in soil vapor occurring within the western and northern portion of the footprint of the former PMC facility. Concentrations are higher in shallow soil vapor compared to deeper samples collected within the former PMC property boundary (Figure 4-8), indicating the presence of residual mass in soil that may be acting as a source to soil vapor (as well as groundwater). Exceedances of the EPA Residential Soil Vapor RML and the MDEQ site-specific VIAC, occur in all but two locations (SVB-02 and SVB-03). However locations SVB-02 and SVB-03 have exceedances for other VOCs such as benzene and ethylbenzene.

4.4.2.2 October and November 2018

Thirty-one exterior soil vapor samples were collected from 16 soil vapor probes (SVB-01 through SVB-12, and SVB-14 through SVB-16). TCE was detected in all but one sample (SG-50). Of the samples with detections, TCE exceeded VISLs in 19. The highest concentration was detected at 15,000 µg/m^3 at SVB-12 (5 feet bgs), which is higher than the concentration detected in May and June 2018 (Figure 4-8). This increased detection could be due in part to the heavy rains and/or snow received prior to sample collection, elevating the shallow groundwater and displacing the vapors upward.

Spatially, TCE above VISLs was identified in a similar pattern when compared to the May and June 2018 results, where detections were within or adjacent to the shallow groundwater TCE plume, with the highest concentrations of TCE in soil vapor occurring within the western portion of the footprint of the former PMC facility. Concentrations continued to be higher in shallow soil vapor when compared to deeper samples collected within the former PMC property boundary (Figure 4-8), indicating the presence of residual mass in soil that may be acting as a source to soil vapor (as well as groundwater). TCE exceedances of the EPA Residential Soil Vapor RML (70 µg/m^3) and the MDEQ site-specific VIAC (67 µg/m^3), occur in nine soil vapor probe locations.

4.4.2.3 Summary of 2018 Soil Vapor Results

The distribution of TCE in shallow soil vapor beyond the former PMC property boundary is consistent with historical exterior soil vapor sample results which showed the greatest offsite extension north of Lake Street and west of the former PMC manufacturing site (CH2M 2018b). Concentrations are presented in Table 4-6 and shown in Figures 4-8 and 4-9. Exterior soil vapor with the highest concentrations of TCE were located along the western and northern portions of the former PMC property and near sanitary sewer lines on East Lake Street (SVB-01 at 13.5-14 feet bgs; SVB-04 at 5.5-6, 8.5-9, and 12-12.5 feet bgs; SVB-07 at 5-5.5, 11.5-12; SVB-08 at 6.5-7; and SVB-09 at 5.5-6, 9.5-10). However, as the depth of the sanitary sewer near these samples is approximately 5 to 6.5 feet, and the TCE concentrations within sanitary sewer samples collected in this area (Table 4-5) were orders of magnitude lower than concentrations in the exterior soil vapor, it is unlikely that the sanitary sewer is currently acting as a preferential pathway for offsite transport.

Six additional VOCs (1,3-butadiene, benzene, bromodichloromethane, chloroform, ethylbenzene, and PCE) were detected above SLs in soil vapor (Table 4-6). 1,3-Butadiene and bromodichloromethane were each detected above their respective SL at only one location each (SVB-09 and SVB-11, respectively), as presented in Figure 4-9. Chloroform was detected above SLs in at least one sample at SVB-09, SVB-10,

and SVB-12. All these locations are close either to a water line, sanitary sewer line, or both (Figure 4-9). The maximum chloroform concentration observed was 8.5 µg/m^3. The presence of chloroform and bromodichloromethane and not considering these constituents as site-related COCs is discussed in more detail in Section 4.5.

Benzene and ethylbenzene are both typical of gasoline and other lighter hydrocarbon-derived products and were observed during Events 1 and 2 with the following trends in exterior soil vapor samples:

- May and June 2018: Benzene was detected above SLs in 10 exterior soil vapor locations, with the highest concentration (250 µg/m^3) detected at SVB-09 at 6 feet bgs. Of those 10 locations where benzene was noted, six were identified to be within the former PMC property. Ethylbenzene was detected above SLs at three locations; two within the western portion of the former PMC facility and 1 west of the commercial property, with the highest concentration of ethylbenzene detected near the commercial property (60 µg/m^3) at SVB-02 at 6 feet bgs. Ethylbenzene exceedances were co-located with benzene exceedances (Figure 4-9).
- October and November 2018: Benzene detections were observed in eight exterior soil vapor locations, with one exceedance noted at SVB-12 (27 J µg/m^3), a location within the former PMC property. At SVB-12, ethylbenzene was not detected in the October 2018 sample. However, the highest exterior soil vapor detection of TCE (15,000 µg/m^3) was observed in the same sample.

Based on these data and location of the detections, these chemicals are potentially present due to a site-related release. Benzene and ethylbenzene appear to be observed primarily within the boundary of the former PMC property and associated with those locations where TCE was noted. As a result, benzene and ethylbenzene have been considered in the HHRA and associated MLE table as potential site-related compounds and will be evaluated further for potential risk. Benzene concentrations were generally lower in October and November 2018 then in June 2018, suggesting a seasonal effect.

PCE was detected above SLs in four May and June samples collected from three locations (SVB-10 through 12), and three October and November samples collected from two locations (SVB-10 and SVB-12), with the highest concentration (990 µg/m^3) detected at SVB-10 at 10 feet bgs in October 2018. Three samples were collected at SVB-10, and concentrations increased with depth during the May and June sampling, but were similar concentrations at the 10- and 15.6-foot-bgs depths in October 2018. An increasing trend of PCE with depth was noted at SVB-04 and SVB-12 (Table 4-7 and Figure 4-9). Differences in the depth pattern of TCE and PCE could reflect mass storage of PCE in the groundwater and partial dichlorination in the vadose zone.

PCE detections above SLs in soil vapor fall within the western portion of the footprint of the former PMC facility. No samples collected from these locations or nearby locations presented concentrations of PCE above SLs in soil or groundwater. The presence of PCE in the study area is sporadic and does not appear to have an obvious source, although two of the highest concentrations are near the drum storage area as shown in Figure 1-3.

4.5 Specific Building Vapor Intrusion Investigation

A detailed VI technical memorandum has been prepared for all property-specific VI investigation activities that have been conducted at the site to date and is intended to supplement the RI investigation information presented herein (Appendix B).

4.6 Mass Partitioning Analysis

To evaluate the extent that TCE mass in the saturated and unsaturated zones contributes to soil vapor concentrations in the study area, an equilibrium partitioning analysis, or mass partitioning analysis, was conducted. The analysis used Henry's law equilibrium to estimate partitioning from VOCs in

groundwater and a 3-phase equilibrium partitioning model to estimate potential soil vapor concentrations from VOCs in soil. Calculated concentrations were then compared to measured concentrations. Appendix F contains the technical memorandum documenting the evaluation process, calculations, and quantitative results.

The evaluation concluded that although both vadose-zone soil and groundwater contribute to TCE in soil vapor at the former PMC property, the TCE source strength appears greater from groundwater. A strong groundwater contribution is also noted downgradient of the former PMC property near the [redacted] property. However, both the saturated and unsaturated zones at this site contain sufficient mass of TCE to each independently produce subslab soil vapor concentrations that are elevated above VI SLs. This suggests that alternatives to rapidly remediate the site would need to address both media.

In addition, TCE vapor transport from groundwater appears to be more attenuated in the vadose zone than indicated by agency default attenuation factors. The EPA (2015) default attenuation factor for subslab soil vapor and "near-source" exterior soil vapor is identical; therefore, the default attenuation factors do not rely on attenuation in the soil column observed here. Although this conclusion is uncertain, it is supported by data collected for this investigation and reported in the literature (Provoost, et al. 2011). As a result, a cleanup level protective of VI using the EPA default attenuation factor is likely to be conservative.

4.7 Differential Pressure Measurement

The differential pressure between shallow soil vapor and ambient air was recorded on four dates during the RI investigation (Figure 4-10). In many cases, multiple measurements were taken to estimate temporal variability. As expected, low vacuums or low positive pressures were observed at soil vapor locations distant from any known SSD systems. Consistent vacuums stronger than 0.015 inches of water (3.7 Pascals) were interpreted as probable evidence of an extended vacuum field extension influence from the mitigation systems at the Water Street Condominiums or the [redacted] building. These measurements were made to provide qualitative insights to how vacuum fields extend in the shallow soils at the site, in support of the upcoming feasibility study.

4.8 Deviations from the QAPP

During the implementation of the RI field activities, deviations from the QAPP occurred. The tasks and deviation notes are summarized in the following table.

Task	Deviation Notes
Permanent monitoring well sampling	An obstruction was noted in monitoring well PS-105D at the time of groundwater sampling. The obstruction was unable to be freed, and tubing could not be deployed. As a result, sampling of this monitoring well could not be completed.
Soil vapor probe installation location	SV-03 and SV-13 could not be installed in the originally proposed locations due to the presence of underground utilities. When attempting to relocate these probes, the adjacent property declined access and ultimately would not allow installation of SV-13.
Soil vapor probe installation sampling	Soil vapor probes were proposed to be installed within the capillary fringe of groundwater plume at PMC. Due to difficult subsurface conditions encountered (i.e., refusal, high water table, etc.), probes were installed to the deepest possible depths when installation could achieve a minimum of 2 feet bgs. If 2 feet or greater could not be achieved, a proposed probe was not installed. The depths of the soil vapor probes were determined by the water table/capillary fringe. If it was less than 15 feet bgs, then 3 depths of soil vapor probes would not be installed. The number and depth of soil vapor probe screens was ultimately based on the observed soil types and depth to groundwater. Attempts were made to place three screen intervals at each location.

Task	Deviation Notes
Grab soil sampling	Material encountered in the subsurface prevented sample collection at select proposed locations (including gravel/cobbles and no recovery of material while drilling).
Grab groundwater sampling	The QAPP proposed grab groundwater samples every 10 feet during logging of the two newly installed monitoring wells. This activity was completed successfully at CMW-1. However, this task was not completed at CMW-2. MDEQ expressed concern over potentially impacting the deeper aquifer through vertical contamination and requested that this activity not be completed.

SECTION 5

Conceptual Site Model

The CSM was updated to include soil, groundwater, sewer gas, and soil vapor sampling data collected in 2018. The area where groundwater concentrations of TCE are detected extends from the site to approximately 700 feet northwest towards the City of Petoskey's former Ingalls municipal water supply well and Lake Michigan. TCE continues to be detected in this area above the EPA Residential Groundwater VISL, as well as the MDEQ site-specific VIAC. TCE in groundwater appears to be the primary source of TCE in soil vapor off the former PMC property; the highest concentrations were located within or adjacent to the aqueous TCE plume. Migration and mass storage also may have occurred in the vadose zone, for example in the eastern part of the Water Street Condominiums and in the area north of West Lake Street and west of the site. However, shallow vadose-zone sources are likely also present and are important contributors to soil vapor concentrations within the former PMC property boundary.

5.1 Contaminant Fate and Transport

This section summarizes the physical properties of TCE, the chemical released from the former PMC property that is present over the largest aerial extent and in highest concentrations in groundwater and soil vapor. TCE was also identified as a primary target for remediation in the OU1 ROD. These physical properties are used to assess the movement and partitioning of TCE in the environment. They can estimate the potential TCE to migrate through a medium and how long TCE will remain in the environment.

Notable physical properties of TCE include the following:

- Density greater than water at 1.4642 grams per cubic centimeter.
- Solubility of 1,280 milligrams per liter (mg/L).
- High volatility based on vapor pressure (69 millimeters of mercury) and Henry's Law Constant (0.00985 atmosphere-cubic meters per mole); volatilization is ongoing based on soil vapor sampling results.

5.2 Routes of Migration

To evaluate potential routes of migration, this section summarizes an assessment of the release of TCE to groundwater and subsequent aqueous and vapor-phase transport. Transport occurs via advection, volatilization, dispersion, and retardation once VOCs have dissolved in groundwater and via advection and diffusion once volatilized. Transport of volatiles in the vadose zone can also occur through diffusion or advection; either in the bulk soils or in preferential flow pathways such as utilities.

5.2.1 Release Mechanisms

The presence of TCE at the site is attributed to releases from primarily the western portion of the former PMC property, where the former aboveground storage tank was located (Figure 1-3) and historical waste handling occurred. TCE, when initially released from the storage tank or disposed of on the ground, would have likely been present as dense nonaqueous phase liquid (DNAPL) that may have migrated primarily vertically, as governed by bedding planes and fractures, through the vadose zone to groundwater (Figure 5-1). However, additional releases may have occurred as dissolved-phase TCE from washwater or other diluted mixtures. Figure 1-3 shows potential locations of solvent release such as a former drum storage area, a former paint storage area, and process water trench. As DNAPL, TCE is

denser than groundwater, enhancing vertical migration until TCE dissolved. Once dissolved, chemical transport and volatilization occurred as described in the following sections.

During migration, DNAPL can become trapped in the unsaturated zone as "disconnected blobs and ganglia of organic liquid" (Kueper 2003). Those trapped DNAPL elements will continue to both volatilize into soil vapor and dissolve into groundwater during infiltration events (Kueper 2003). In fractured rock, there is a higher probability of DNAPL becoming entrained. Soil and aqueous concentration data at this site suggest that DNAPL is not currently present at this site, rather TCE is only present in groundwater and sorbed to soil. The presence of residual mass makes plumes like that at the site difficult to remediate (Kueper 2003).

Additional releases of TCE in dissolved form, for example as washwater, or even mixed in with a petroleum-based solvent as a light nonaqueous phase liquid could possibly have occurred based on the limited information available about site operations. Historical soil data (shown in Figure 5 in CH2M 2018a) suggest that TCE, and in some cases PCE, was released to shallow soils in eastern and southern parts of the site. Not all of the areas with these soil releases were excavated; some were assumed to be capped by the foundations, and others passed the standards that prevailed at the time. Historical bulk soil standards would not be considered to be protective of the VI pathway today.

5.2.2 Dissolution

Aqueous solubility is defined as the concentration of a chemical dissolved in water when the pure chemical (DNAPL in the case of TCE) is in contact and in equilibrium with water. To evaluate whether TCE is potentially present as residual DNAPL, the maximum concentration is compared to its solubility (1,280 mg/L) with a typical rule of thumb being DNAPL indicated at 1 percent of solubility. The highest concentration of TCE in groundwater, 0.055 mg/L, is several orders of magnitude below this value, indicating that residual DNAPL is not present in the saturated zone.

A similar rule of thumb suggests that DNAPL is likely present if organic vapor concentrations in soil vapor exceed 100 to 1,000 parts per million. One-hundred parts per million of TCE is 537,000 $\mu g/m^3$ (EPA 1994). The maximum possible vapor-phase nonaqueous phase liquid concentration for TCE is 4.9×10^8 $\mu g/m^3$ (EPA 2014). The highest historically observed TCE concentrations at the site was approximately 15,000 $\mu g/m^3$ in subslab soil vapor (CH2M 2018b). This suggests that residual DNAPL is no longer present as a separate phase in the vadose zone. The mass present in the vadose zone is typically composed of a combination of mass diffused into the particle matrix, mass in soil vapor, and mass partitioned into the moisture layers on vadose zone soil particles (EPA 2014). The fraction in the moisture layer is often the largest (Carr, et al. 2017).

5.2.3 Volatility and Vapor Migration Routes

The partitioning of a molecule from aqueous phase to the vapor phase is termed volatilization. Depending on the Henry's Law Constant (a partitioning coefficient between adjacent water and air bodies), VOCs in groundwater can volatilize at the water table into the overlying soil. TCE easily partitions into the vapor phase, where it can migrate through air-filled soil pores via primarily diffusion along a concentration gradient. Volatilization is enhanced by changes in water levels, as are known to occur frequently at the PMC site (Ilangasekare, et al. 2013). A similar partitioning process occurs in the vadose zone between the soil vapor and the vadose-zone soil moisture.

In the standard VI CSM, diffusive transport dominates in the deeper portions of the vadose zone, and pressure-driven advective transport dominates in a zone within approximately 5 feet of the foundation (EPA 2012). The advective transport in VI is generally attributed to the stack effect in structures that couples to soil vapor; however, rising water tables can also force soil vapor upwards in a piston like effect (EPA 2012).

Diffusion through concrete slabs also occurs, which is driven by concentration differentials not pressure differentials (EPA 2012). Although advection is generally assumed to be the dominant process moving vapors through the building envelope, there are reportedly situations where diffusion across the building envelope becomes predominant. One such case was reported in two buildings directly over PCE source material in Fairbanks, Alaska (Barnes and McRae 2017).

The exterior soil vapor map indicates that TCE in soil vapor is primarily present where it is also present in groundwater and where TCE was identified in soil. However, the depth profiles show that the concentrations onsite typically decrease with depth while those offsite typically increase with depth. This supports the conclusion in Section 4.5 that the TCE source mass on the former PMC manufacturing facility appears to be stored in both the vadose and saturated zone. Downgradient, the VOC mass appears to be predominantly stored in the groundwater.

Vapors also can migrate via advection (and diffusion) along preferential subsurface pathways, such as a utility corridor or more porous zones of soil or rock, or beneath surface barriers that limit the direction(s) of vapor migration, such as frozen ground or asphalt. Current results of sewer gas sampling suggest that concentrations in sewer gas do not generally exceed the adjacent soil vapor concentrations.

Sewer gas samples were collected from the sanitary (SA) and storm (ST) sewers (Figure 2-1). The samples were collected during three separate events in January 2017, June 2018, and November 2018. The results, which are presented in Table 4-5, indicate the presence of VOCs at relatively low concentrations, that are either below or comparable to concentrations observed in multi-level soil vapor samples collected around the site. There is no evidence that either sewer network is currently acting as a preferential pathway to buildings beyond the site. However, a role for sewers in transporting gasses across the building envelope of individual structures within the area of impacted soil vapor cannot be ruled out.

Information obtained from the City of Petoskey and reviewed as part of the sewer pathway assessment also indicates that the sewer network is unlikely to currently act as a major preferential pathway to properties distant from the site due to the following:

- The depth of the catch basins and manholes where sewer gas samples were collected ranges from approximately 3.25 to 6.4 feet bgs, indicating that both storm and sanitary sewer utilities are at least 1.5 feet above the water table in the investigation area and that VOC-containing groundwater is therefore unlikely to directly infiltrate into either sewer network (since the capillary fringe is expected to be thin in this coarse material); and
- Based on information provided by the City of Petoskey, most of the sanitary and storm sewer network within the investigation area appears to have been removed and replaced with new piping, manholes, and catch basins circa 2005 as part of utility improvements (Northwest Design Group Consulting Engineers, 2005). The former PMC facility was sold to a developer in 2003 and was demolished in 2004. Thus, potential solvent discharge to the sewers as part of historical manufacturing activities would not be expected to directly contribute residual VOCs to the new sewer systems.

Review of utility information provided by the City of Petoskey also indicates the presence of a 14-inch-diameter sanitary sewer force main installed prior to 2005 (Northwest Design Group Consulting Engineers 2005). This line is approximately 7 feet deep and generally runs from west to east with sections found along the western and northern sides of the Water Street Condominiums. This utility line is not readily accessible through manholes and was not sampled; however, because it is located above the groundwater table and, as a force main, is not directly connected to surrounding properties, it is not expected to act as a preferential pathway for VI. Since force mains operate under positive pressure, flow would be expected to be outwards from the sewer rather than inwards as is common with gravity sewers. Also, given the positive pressurization, leaks in a force main should be readily identified by odor.

5.2.4 Advection

Advection occurs in both the aqueous and vapor phase. In the aqueous phase, advection refers to the movement of dissolved-phase contaminants caused by the flow of groundwater. Physical migration of TCE in groundwater is slowed by the flat hydraulic gradient at the site as noted by the low seepage velocity estimated to range from 0.08 to 0.22 foot per year and flow reversals caused by changes in lake stage. Historical migration resulted from pumping at the former municipal supply well. The shape of the TCE plume shown in Figure 4-1 confirms that dissolved-phase contamination is present in both the shallow and deeper portions of the aquifer and has migrated toward the lake. As discussed above the plume shape has recently shifted toward PS-106.

The combination of the very low seepage velocity with the observed periodic groundwater flow reversals inland of the shoreline contribute to slow advection of the TCE plume. However, there is expected to be an enhancement of dispersion processes at this site due to the cyclic effects of lake stage on the aquifer (Boutt and Fleming 2009).

The soil vapor data set suggest that the plume has migrated along the north side of West Lake Street, west of the site. Cross section A'-A (Figure 3-2) shows a layer of sand and gravel, primarily weathered limestone, at or below the water table running along this axis.

In the vapor phase, advection occurs in the vadose zone when bulk movement is induced by spatial differences in soil vapor pressure. The direction of advective vapor transport is always toward the direction of lower air pressure. Near the surface of the earth, vapor transport is, in part cyclic, due to barometric pumping. Near buildings, advection is generally expected to occur due to differences in temperature between the building interior and the subsurface environment or the operation of combustion units or fans that can create driving forces for soil vapor entry (stack effect). Advection may be hindered where extensive surface barriers, such as asphalt, concrete, or frozen soil are present (EPA 2015).

5.2.5 Dispersion and Diffusion in the Saturated Zone

Hydrodynamic dispersion is the process that spreads out a contaminant plume in three dimensions: parallel to the direction of migration (longitudinal), laterally (transverse), and vertically. The underlying processes are mechanical dispersion and molecular diffusion. Similar to advection, the magnitude of mechanical dispersion is generally proportional to instantaneous groundwater velocity. The result is spreading and mixing at the plume edges. This results in reduced concentration of the molecules in groundwater at the downgradient and lateral edges of the plume as at PMC, where concentrations are highest beneath the former PMC site and decrease downgradient. Based on the multidirectional flow of groundwater due to impacts of the lake, contaminants may disperse along the shoreline where they interact with porewater from the lake. Bout and Fleming describe the enhanced dispersion processes that occur in similar situations where the stage of a surface water body influences the groundwater as,

> "*Time-dependent variations in surface water stage in both fresh and salt water environments are acknowledged to strongly influence local groundwater flow….Variations in surface water stage can arise from many natural and anthropogenic sources including: precipitation and flood events, tidal oscillation, wave induced displacement, dam releases, and associated reservoir drawdown... Yim and Mohsen [1992] developed a 1-D numerical model to simulate mass transport from a contaminant plume to a tidal estuary. They compare models with and without tidal fluctuation and find that although concentrations near the interface are less in the simulation with tidal fluctuations, the velocity gradients are much greater, and allow more mass exchange from the aquifer to the estuary"* (Bout and Fleming 2009)

Because vapor-phase diffusion coefficients are about 10,000 times greater than water diffusion coefficients, vapor diffusion through the air-filled pores of the soil matrix is usually the dominant diffusion transport mechanism for VOCs in the unsaturated zone. However, the tendency for vapor-

phase VOCs to diffuse through soil depends on the chemical and physical properties (diffusion coefficients in air and water), soil porosity (higher porosity encourages diffusion), and the soil moisture content (high moisture content may provide a barrier to vapor diffusion) (EPA 2015). Soil porosity at the site is expected to be high in the unconsolidated materials given the high percentage of gravel and sand. In addition, the weathered limestone is fractured and interlayered with the sand and gravel creating pathways through the weathered limestone, although these pathways may not always be vertical and are likely circuitous.

5.2.6 Retardation

Retardation in groundwater flow primarily occurs in finer-grained units, because of dual-phase porosity and total organic carbon is usually higher in these intervals, resulting in higher sorption of chemicals onto soil particles. However, the aquifer in the study area is primarily characterized by coarser-grained sand and gravel or limestone boulders/blocks; therefore, retardation is limited. Locally discontinuous layers of gravel, silt sand with gravel, and gravelly silty clay are seen, for example at CMW-01 below 40 feet, which could provide some local retardation. This is also supported by the small amount of organic carbon present (average of 0.29 mg/kg; Table 4-4).

5.3 Fate of Chemicals

In addition to the volatilization of TCE from groundwater to soil vapor, attenuation processes act to reduce contaminant concentrations in groundwater. These include a variety of physical, chemical, or biological processes that, under favorable conditions, act without human intervention to reduce the mass, toxicity, mobility, volume, or concentration of contaminants in soil or groundwater. These in situ processes include degradation, dispersion, dilution, sorption, volatilization, and chemical or biological stabilization, transformation, or destruction of contaminants.

An evaluation of historical groundwater trends indicates that TCE in groundwater is not attenuating significantly; only three of the eight wells evaluated reported decreasing concentration trends. Degradation products are also generally not present in groundwater, indicating that reductive dechlorination is not occurring. Because weathered limestone is a porous medium, some sorption of TCE into the limestone matrix has likely occurred as indicated by the presence of TCE in vadose-zone samples collected from the western portion of the former PMC property. Some sorption to the overlying fill layer, which is a fine-grained sand with gravel and occasional trace clay is also likely, although that layer is so thin that only a few of the shallowest soil vapor probes are installed in it (for example at SVB-11, SVB-15, and SVB-08). Residual mass in soil may continue to be a source of TCE to shallow groundwater through infiltration of precipitation, and to VI through volatilization. However, the mass equilibrium evaluation concluded that groundwater was likely a greater overall contributor to vapor concentrations than soil. The presence of TCE in soil vapor indicates that volatilization is occurring, although the stable trends noted in Section 4.2.3 indicate that this is not occurring at a rate that would effectively reduce contaminant concentration in the groundwater.

Regardless of source type, soil vapor concentrations emanating from a subsurface vapor source generally attenuate, or decrease, as the volatile chemicals move from the source through the soil to outdoor or indoor air. When this is not the case, other sources are indicated. This was noted during the mass partitioning evaluation beneath the former PMC property where higher concentrations in soil vapor were identified in shallower samples further from the groundwater table but where TCE is present in soil. The evaluation concluded that TCE in both soil and groundwater are contributing to VOC mass in soil vapor beneath the former PMC property. Downgradient of the former PMC property and at adjacent properties, groundwater appears to be the primary source of soil vapor, where the highest concentrations were in the deeper samples closest to the groundwater table.

5.4 Conceptual Site Model

Figure 5-1 graphically presents the CSM for the site. The site is in a primarily residential area. TCE at the site is present in vadose zone soil, soil vapor, and saturated intervals of permeable weathered limestone and sand and gravel deposits that overlie more competent limestone. TCE was historically released from the former PMC property and identified in a municipal supply well located to the northwest of the site near the shore of the Traverse Bay of Lake Michigan. The TCE plume originates beneath the former PMC site and is present in both shallow and deep groundwater. The TCE has volatilized from residual soil mass and groundwater to soil vapor that was identified within or near the source area and plume extent. Because of the influence of Lake Michigan onsite groundwater, there is virtually no current net advective flow. Historical plume movement was likely caused by the operation of the former supply well.

Based on historical TCE trends presented in Section 4.2.3, the plume is generally stable (at quasi-equilibrium). Stable trends were noted based on the time-series evaluation of TCE concentrations, although some wells show decreasing trends. The presence of TCE in the vadose and saturated zone is acting as an ongoing source to groundwater, as well as soil vapor, contributing to the persistence of the plume and soil vapor concentrations. Intrinsic bioremediation via reductive dechlorination of the plume appears to be limited. The presence of cis-1,2-DCE and vinyl chloride were present in only a few wells historically and were not detected in 2018. The TCE in groundwater is primarily attenuating through volatilization.

Both vadose-zone soil and groundwater have been identified as contributors to soil vapor concentrations, although groundwater is the primary source. In particular, groundwater is the primary source to vapor concentrations downgradient and adjacent to the site where contaminant vapors have been identified. These vapors have the potential to migrate under buildings (subslab) and in some cases into those buildings (Figure 5-1). Given the coarse lithology beneath the site, including sand, gravel, and weathered limestone, vapors are expected to diffuse readily and transport readily by advection when a driving force is present. However, vapor migration beneath a building is impacted by the lithology beneath it. Vapors will migrate differently through weathered bedrock compared to a fill that is primarily sand and gravel. The continuous extent of weathered bedrock beneath any one building is difficult to discern as it is comprised of highly weathered limestone.

VOC mass is stored in the vadose zone beneath and in groundwater both beneath and beyond the site. It is likely that, given the age of the release, a quasi-equilibrium has been reached, where the rate of diffusion out of the solid matrix and volatilization from the aqueous phases is balanced by dispersion at the horizontal edges of the plume and volatilization from the plume.

SECTION 6

Baseline Risk Assessment

6.1 Human Health Risk Assessment Summary

This section summarizes the HHRA for OU2 of the PMC Groundwater Superfund Site. Appendix H contains the complete HHRA.

The HHRA provides an evaluation of the potential current and future risks to human health posed by detected chemicals at the site, in accordance with EPA guidance for conducting HHRAs (EPA 1989, 2001, 2004, 2009). The HHRA consists of the following components:

- Data collection and evaluation, including identification of COPCs
- Exposure assessment
- Toxicity assessment
- Risk characterization

Condominium units and buildings with existing operational SSD systems or other vapor intrusion mitigation systems (VIMS) were not evaluated in the HHRA. SSD systems are installed at 12 residential properties. The systems are currently operated and maintained by EGLE and are expected to be in service until the site achieves remediation.

6.1.1 Conceptual Exposure Model

A human health conceptual exposure model (CEM) was developed that describes the contaminant sources, migration pathways, potential exposure media, receptors, and exposure routes. The CEM is presented graphically in Appendix H, Attachment H-1, Figure 1 and in Attachment H-2, Table 1.

Based on current and reasonably foreseeable future site conditions, the following potential current and future human receptors were identified and evaluated in the HHRA:

6.1.1.1 Current Exposure Scenarios

- Residents—Adults and children currently living in residential properties (apartment units, condominium units, houses) who may contact COPCs in indoor air and crawlspace air (that may be impacted by VOCs migrating from the subsurface).
  - Soil exposures to residents outside the site were not evaluated since soil contamination investigations at the site and immediate vicinity were conducted in the 1990s; a ROD was issued in 1995.
  - Soil contamination was found beneath the site after it was demolished in 2004. Exposures to soil beneath the facility were not evaluated in previous reports; however, soil exposures by residents at the Water Street Condominiums on the site are expected to be insignificant because residents will not have significant contact with soil due to the lack (or small size) of gardens in a condominium setting. Disturbance of soils at the site is also governed by an existing restrictive covenant agreement.
- Industrial/Commercial Workers—Two commercial units are present in the study area, and both have SSD systems. Therefore, industrial/commercial workers were not further evaluated in the HHRA.

6.1.1.2 Reasonably Foreseeable Future Exposure Scenarios

- Residents—Adults and children living in residential properties (apartment units, condominium units, houses) who may contact COPCs in indoor air (that may be impacted by VOCs migrating from the

subsurface). Soil exposures by residents at the condominium units are expected to be insignificant because residents will not have significant contact with soil due to the lack (or small size) of gardens in a condominium setting. Disturbance of soils at the site is also governed by an existing restrictive covenant agreement.

- Construction Workers—Construction workers who may contact COPCs in soil (via direct contact and air emissions from soil) while conducting intrusive soil activities such as building construction or utility maintenance in soil beneath the former PMC facility. Exposures to soil beneath the facility were not evaluated in previous reports; therefore, soil within the site was addressed in this HHRA.

6.1.2 Analytical Data

Indoor air, crawlspace air, subslab soil vapor, exterior soil vapor, and soil samples collected by CH2M in 2017 and 2018 were used in the HHRA. In addition, data collected in 2017 and 2018 by The Mannik & Smith Group, Inc. at the Water Street Condominiums and one additional residential property were used in the HHRA. Information regarding the Mannik & Smith data is presented in the VI investigation technical memorandum (Appendix B). Section 2 describes the data-collection activities for samples used in the HHRA. Groundwater data were not used in the quantitative risk assessment of the VI pathway, since an extensive network of soil vapor sampling locations is available for the site and is more extensive than the groundwater monitoring network. Groundwater as a source of mass storage and transport for VI is considered in the CSM and Section 4 of this RI, as well as in the upcoming feasibility study. For the properties with no indoor air, crawlspace air, or subslab data, indoor air risks were estimated using the nearest exterior soil vapor point to the associated property.

6.1.2.1 Indoor Air and Crawlspace Air

Indoor air samples collected in March through July, September, and November 2017, and January, February, and November 2018 were used in the HHRA. Crawlspace air samples collected in June 2017 and February and November 2018 were used in the HHRA. Indoor air samples were collected from 27 condominium units and 22 residential properties; crawlspace air samples were collected from 7 condominium units and 2 residential properties (Appendix H-3, Table 1); indoor air and crawlspace air data sets were evaluated separately for each property.

Under current conditions, residents could be exposed to COPCs in indoor air and crawlspace air.

6.1.2.2 Subslab Soil Vapor

Subslab soil vapor samples collected in January, April, July, September, and November 2017, and January, February, and November 2018 were used in the HHRA. The subslab soil vapor data were collected from 6 condominium units and 8 detached residential properties (Appendix H-3, Table 1); subslab soil vapor data sets were evaluated separately for each property.

Under future exposure scenarios, residents could be exposed to COPCs in subslab soil vapor if COPCs migrate to indoor air.

6.1.2.3 Exterior Soil Vapor

Exterior soil vapor samples collected in May, June, and July 2017, and February and June 2018 were used in the HHRA. The closest exterior soil vapor samples collected near the residential properties where no indoor air, crawlspace air, and/or subslab soil vapor samples were collected were used to evaluate the VI pathway. The exterior soil vapor data were used for the [redacted] (Appendix H-3, Table 1); exterior soil vapor data sets were evaluated separately for each property.

Under future exposure scenarios, residents could be exposed to COPCs in exterior soil vapor if COPCs migrate to indoor air. Exterior soil vapor data from one residential property was used to evaluate current conditions because indoor air and subslab soil vapor data were not collected at this property.

6.1.2.4 Soil

Soil samples collected from 1 to 10 feet bgs in May 2018 were used in the HHRA to evaluate direct-contact exposures to soil. The soil data were collected during the installation of 10 of 15 soil vapor probes adjacent to the Water Street Condominium units and were grouped into one exposure unit (Appendix H-3, Table 1). Samples were not collected from all borings because excessive heating of the soil occurred while advancing some borings as a result of the rotosonic drilling method. The data limitations of the samples that were collected are discussed in Section 7.2.1.

Under future exposure scenarios, construction workers could be exposed to COPCs in soil (1 to 10 feet bgs) via direct contact and emissions from soil in excavations. Soil exposures by residents at the condominium units are expected to be insignificant because residents will not extensively work in gardens or have significant soil exposure in a condominium setting.

6.1.3 Chemicals of Potential Concern

The COPCs are those chemicals that have the potential to cause adverse human health effects if receptors contact site media. The maximum detected concentration of each chemical in a data grouping was compared to its respective SL. If the maximum detected concentration exceeded its SL, it was retained as a COPC for the HHRA. Chemicals that were undetected in all samples within a medium/data grouping were not selected as COPCs for that medium.

The SLs used in the HHRA for indoor air and crawlspace air exposure via inhalation were the residential air *Regional Screening Levels (RSLs) for Chemical Contaminants at Superfund Sites* (EPA 2019a).

Subslab and exterior soil vapor were evaluated for the potential VI pathway to indoor air. The SLs for soil vapor were calculated using the EPA *Vapor Intrusion Screening Level (VISL) Calculator* (EPA 2019b).

For indoor air, crawlspace air, and subslab and exterior soil vapor, a multiple lines of evidence evaluation was performed if the maximum detected concentration exceeded its VISL to evaluate whether the chemical is related to VI or potentially present because of background sources. If a chemical is related to VI, it was selected as a VI COPC.

The SLs used in the HHRA for soil exposure via direct contact and emissions from soil are the EPA industrial soil RSLs (EPA 2019a).

6.1.4 Exposure Evaluation

The potential exposure pathways for the site are identified graphically in Attachment H-1, Figure 1 and Attachment H-2, Table 1. The potentially complete exposure pathways quantified for each receptor group and the exposure media are presented in the table below. Indoor air exposure estimates were calculated only for the exposure pathways and properties with COPCs.

Table 6-1. Potentially Complete Exposure Pathways

Medium	Current Scenario - Residents (Condominiums)	Current Scenario - Residents (Residential Properties)	Current/Future Scenarios - Residents (Residential Properties)	Future Scenario - Residents (Condominiums)
Indoor air	X	X		
Crawlspace air				
Subslab soil vapor				X
Exterior soil vapor			X	

Because no COPCs were identified for soil, potential soil exposures were not quantified in the HHRA.

The exposure point concentrations (EPCs) are the concentrations of COPCs in a medium to which a receptor could be exposed at a specific location (the "exposure point"). The following is an overview of the EPCs used for each exposure medium:

- **Measured EPCs:**
  - Current Indoor Air/Crawlspace Air EPCs—The maximum detected indoor air/crawlspace air concentrations (where available) were used as the EPCs for current exposure scenarios.
- **Modeled EPCs:**
  - Current Indoor Air EPCs—Exterior soil vapor data were used to model indoor air EPCs for current exposure scenarios where indoor air/crawlspace air and/or subslab soil vapor data were not available. The maximum detected concentrations of COPCs in each exterior soil vapor data grouping were used in the model to calculate indoor air EPCs.
  - Future Indoor Air EPCs—Subslab soil vapor data (where available) were used to model indoor air EPCs for future exposure scenarios; where subslab soil vapor data were not available, exterior soil vapor data were used. The maximum detected concentrations of COPCs in each subslab soil vapor or exterior soil vapor data grouping were used in the model to calculate indoor air EPCs.

An RME scenario was quantified for potential receptors under current and future exposure scenarios (EPA 1989). The primary references for exposure factor values are the standard default exposure factors presented in the *Human Health Evaluation Manual, Update of Standard Default Exposure Factors* (EPA 2014).

6.1.5 Toxicity Assessment

Toxicity values were used in the HHRA to estimate potential health effects for COPCs. Health effects are divided into two broad groups: noncarcinogenic and carcinogenic. Toxicity values used in the HHRA were obtained from the EPA standard hierarchy of toxicity value sources (EPA 2003), as follows:

- Tier 1 Source—Integrated Risk Information System (EPA 2019c)
- Tier 2 Source—EPA Provisional Peer-Reviewed Toxicity Values
- Tier 3 Sources—Other peer-reviewed federal and state toxicity values
  - California EPA toxicity database (2019)

6.1.6 Risk Characterization

EPA's target range for carcinogenic risk associated with Superfund sites is one-in-ten thousand (1×10^{-4}) to one-in-a-million (1×10^{-6}). That is, the risk associated with the site should not exceed this target range. The threshold (acceptable) noncancer hazard index (HI) is 1 or less per target organ. HIs were calculated in a phased approach: (1) screening His were calculated by summing all HQs for a receptor, and (2) final HIs were calculated for each potential receptor by target organ (or critical effect or target system). Risk estimates were calculated for potential receptors and exposure pathways using conservative assumptions for exposure factors and EPCs.

Potential risks associated with exposures to COPCs in site media were quantified for RME scenarios. The estimated ELCRs are presented in Tables 7.1 through 7.15 in Appendix H, Attachment H-2 and summarized in Appendix H, Attachment H-2, Tables 9.1 through 9.15. Indoor air risk estimates were calculated on a building-specific basis where COPCs were identified. Soil risk estimates were not calculated since COPCs were not identified in soil.

6.1.7 Summary of Chemicals of Concern

Generally, remedial actions are not warranted for site media with an ELCR of 1 x 10^{-4} or below, or a HI of 1 or less, although it may be warranted if other EPA policies or site-specific information suggests to EPA risk managers that action is appropriate.

In general, COCs are identified when the potential ELCR or HI for a receptor group exceeds EPA threshold values (a total ELCR of 1 x 10^{-4} or a target organ-specific HI of 1) and concentrations are site-related. When a potential ELCR of 1 x 10^{-4} is exceeded for an exposure medium for a receptor group, the COPCs posing an individual ELCR greater than 1 x 10^{-6} in the environmental medium responsible for the unacceptable risks are identified as COCs. When a potential target organ-specific HI exceeds 1 for an exposure medium for a receptor group, the COPCs posing a HQ greater than 0.1 for that target organ in the environmental medium responsible for the unacceptable HI are identified as COCs. Factors such as nature of contamination source, laboratory contamination, and background levels are typically considered when identifying COCs.

COCs for site media and receptors are summarized in Table 6-2. The estimated ELCRs and HIs for the COCs for site media and receptors are presented in Tables 10.1 through 10.4 of Appendix H, Attachment H-2.

Table 6-2. Summary of Media/Receptor COCs

Location	ELCR COCs	Adult Target-Organ-Specific HI COCs	Child Target-Organ-Specific HI COCs
Resident—Future Indoor Air Exposures (from Subslab Soil Vapor)			
[redacted]	None	TCE (HIs = 6)	TCE (HIs = 6)
[redacted]	None	TCE (HIs = 4)	TCE (HIs = 4)
[redacted]	None	TCE (HIs = 2)	TCE (HIs = 2)
[redacted]	None	TCE (HIs = 4)	TCE (HIs = 4)

NA – not applicable

6.1.8 HHRA Summary and Conclusions

The HHRA was performed to evaluate potential current and future risks associated with detected constituents at OU2 of the PMC Groundwater Superfund Site. For the purposes of the HHRA, indoor air, crawlspace air, subslab and exterior soil vapor, and soil were evaluated.

Potential risks at the site were evaluated for the following potential exposure pathways:

- Current Exposure Scenarios
  - Indoor Air (Condominiums and Residential Properties)—Inhalation of COPCs in indoor air and crawlspace air.
- Current/Future Exposure Scenarios
  - Exterior Soil Vapor (Residential Properties)—Inhalation of COPCs in exterior soil vapor that potentially migrates to indoor air.
- Future Exposure Scenarios
  - Subslab Soil Vapor and Exterior Soil Vapor (Condominiums and Residential Properties)—Inhalation of COPCs in soil vapor that potentially migrates to indoor air.

Indoor air risk estimates were less than or within EPA's target risk range and HI threshold for current exposures at the condominiums and residential properties that have not yet been mitigated. That is, the

potential ELCRs for these exposure points were less than or within the target ELCR range of 1×10^{-6} to 1×10^{-4}, and the estimated target-organ-specific HIs did not exceed the threshold of 1.

Exterior soil vapor (migrating to indoor air) risk estimates for current/future exposures were less than or within EPA's target risk range and HI threshold at residential properties.

Subslab soil vapor (migrating to indoor air) risk estimates for potential future exposures were less than or within EPA's target risk range and HI threshold for six residential properties. Although risk estimates for potential future exposures at four of the properties were within EPA's acceptable ELCR range, the noncancer HI estimates exceed the HI threshold of 1, with TCE being the risk driver for the properties. Therefore, TCE was identified as a COC for inhalation of indoor air (based on subslab soil vapor migrating to indoor air). The estimated ELCRs and HIs for this COC (i.e., TCE) for the applicable properties are presented in Tables 10.1 through 10.4 of Appendix H-2.

The 12 residential properties with existing operational SSD systems or other VIMS were not evaluated in the HHRA.

6.2 Environmental Evaluation

The ERA was prepared for the study area site and was conducted consistent with the following guidance:

- *Ecological Risk Assessment Guidance for Superfund: Process for Designing and Conducting Ecological Risk Assessments* (EPA 1997)
- *Guidelines for Ecological Risk Assessment* (EPA 1998)

EPA guidance recommends an iterative approach that uses screening steps to focus the ERA on media, pathways, and receptors with the greatest potential to drive unacceptable risk. The area assessed consists of terrestrial area of the former PMC site and aquatic areas of Lake Michigan adjacent to the site. Ecological issues relevant to the soil and groundwater contamination of the site are discussed in the ROD and five-year review reports for OU1.

6.2.1 Screening Level Problem Formulation

The first step of the ERA process is the problem formulation for the site, which establishes the goals, scope, and focus of the screening-level ecological risk assessment (SLERA). It summarizes the site history and ecological setting of the site in terms of the habitats and biota known or likely to be present and the types of chemicals present in ecologically relevant media. The CEM provides an understanding of chemical sources, transport pathways, exposure media, exposure pathways and routes, and ecological receptors. If complete exposure pathways exist, then assessment endpoints are developed to identify receptors for which complete exposure pathways exist and to summarize methods that will be used to evaluate potential risks to those receptors.

6.2.2 Ecological Setting and Habitats

The study area includes the footprint of the former PMC facility (site), which includes the Water Street Condominiums consisting of four buildings, each housing three-story condominiums, and the surrounding neighborhood. North of the former PMC facility is a second condominium complex, consisting of two buildings of multiple three-story condominiums each, none of which have basements. Northeast and northwest of the former PMC facility are park spaces connected by a bike path. These park spaces front the Little Traverse Bay of Lake Michigan. The rest of the surrounding neighborhood consists of multiple single-family residences.

The site habitat includes landscaped yards and public spaces. These areas contain maintained lawns and small to medium trees and shrubs. The nearby Bay Front Park West is adjacent to Lake Michigan, with shoreline consisting of a mix of sand and riprap. No significant natural habitat areas are present.

6.2.3 Conceptual Ecological Exposure Model

The CEM relates potentially exposed receptor populations with potential source areas based on physical site characteristics and completed exposure pathways. Important components of the CEM are the identification of potential source areas, transport pathways, exposure media, exposure pathways and routes, and receptor groups. Actual or potential exposures of ecological receptors associated with a site are determined by identifying the most likely and relevant pathways of contaminant release and transport. A complete exposure pathway has the following three components: (1) a source of contaminants that results in a release to the environment, (2) a pathway of contaminant transport through an environmental medium, and (3) an exposure or contact point for an ecological receptor. The main objective of the CEM is to identify any complete and critical exposure pathways that may be present at the site. Figure 6-1 illustrates a diagrammatic CEM for the site. Key components of the CEM are discussed in the following subsections.

6.2.3.1 Source Areas

The former PMC facility was a small fabricating operation that was active from 1946 to 2000. Activities included die casting, plating, and painting small automotive trim parts. The facility used TCE and xylene as solvents; TCE was stored in a 1,000-gallon aboveground storage tank, which was determined to have leaked while the plant was active. Other releases of TCE, PCE, and potentially benzene are believed to have occurred.

6.2.3.2 Transport Pathways and Exposure Media

A transport pathway describes mechanisms by which site-related constituents, once released, might be transported from a source to ecologically relevant media (soil, sediment, surface water, and groundwater), where exposures might occur to ecological receptors. Figure 6-1 shows the transport pathways. Potential transport pathways can contribute to the spread of contamination from the site. Volatilization and exposure can occur via soil vapor. Constituents can be released from soil through infiltration and reach groundwater.

Section 3.5 details the hydraulic connection between surface water in Lake Michigan and the groundwater system. Groundwater sampling analytical results indicate the presence of a TCE plume with the highest concentration (which is only 36 µg/L) in the northwest corner of the former facility footprint, extending to the northwest to parking areas associated with the commercial property west of the site. The detections of TCE are observed migrating offsite to the northwest; however, further plume migration is mitigated by the periodic reversals in groundwater direction.

6.2.3.3 Exposure Pathways and Routes

An exposure pathway links a source with one or more receptors by one or more media and exposure routes. Exposure, and thus potential adverse effects, can occur only if a complete exposure pathway exists. Figure 6-1 shows the potentially complete exposure pathways to ecological receptors that are evaluated in this SLERA.

Groundwater does not act as a direct exposure media to terrestrial receptors. Therefore, there is no complete pathway. Discharge of groundwater to surface water can act as an exposure pathway to aquatic receptors. However, as discussed above, plume migration in shallow groundwater is mitigated by Lake Michigan, and both deep and shallow groundwater concentrations of TCE are well below water quality criteria (i.e., 200 µg/L). Therefore, surface water of Lake Michigan is not an exposure pathway. While the soil vapor exposure pathway is theoretically complete, the lack of habitat suggests that the

potential exposure to wildlife species is limited; therefore, the soil vapor exposure pathway is considered complete but insignificant.

6.2.3.4 Receptors and Assessment and Measurement Endpoints

Ecological risk endpoints define ecological attributes that are to be protected (assessment endpoints) and measurable characteristics of those attributes (measurement endpoints) that can be used to gauge the degree of impact that has occurred or could occur. Assessment endpoints most often relate to attributes of biological populations or communities and focus the risk assessment on components of the ecosystem that could be adversely affected by contaminants from a site (EPA 1997). Since no significant exposure pathway was identified for terrestrial receptors, assessment endpoints were not developed.

6.2.4 Scientific Management Decision Point

The CEM shows that no significant exposure pathways to ecological receptors are present at the former PMC site; therefore, no further risk analysis is warranted.

SECTION 7

Summary and Conclusions

7.1 Summary

The RI for OU2 at the PMC Groundwater Superfund Site in Petoskey, Michigan, was initiated to assess the potential VI pathway and associated risks from site-related contaminants. OU2 was established by EPA in 2017 to determine the extent of vapor migration from the former PMC manufacturing facility through an analysis of historical VI data, and subsurface and indoor air investigations. OU2 includes VI risks at the site and at the surrounding residential and commercial properties. OU2 geographically overlays the earlier OU1 for which the primary risk pathway was groundwater ingestion that has proceeded through a ROD.

RI activities included installation and sampling of borings for soil and grab groundwater, and installation and sampling of soil vapor probes. Two monitoring wells were installed. Groundwater samples were also collected from the new and existing monitoring wells. Sewer gas samples were collected from sanitary and storm sewers. Vapor, sewer gas, and groundwater grab samples were analyzed for VOCs. Monitoring well samples were analyzed for VOCs and PFCs. Soil was analyzed for VOCs, general chemistry, and metals.

Although other VOCs were detected at the site and are considered potential site-related compounds, TCE is the primary COC as indicated in the ROD and is present over the largest magnitude and extent of the site. TCE was identified in the vadose zone and saturated intervals of weathered limestone and permeable deposits that overlay more competent limestone. TCE was historically released from the former PMC property and was identified in a former municipal supply well located to the northwest of the site near the shore of the Traverse Bay of Lake Michigan, where plume migration was caused by active pumping. The TCE plume originates beneath the former PMC site and is present in both shallow and deep groundwater. Because of the influence of Lake Michigan, site groundwater flow gradient is low and impacted by gradient reversals that result in virtually no net advective flow across the site.

TCE was detected above SLs in soil vapor, sewer gas, groundwater, and soil. The extent of TCE above SLs has been delineated in groundwater, and there appears to be residual source mass in soil beneath the site contributing to both soil vapor and groundwater concentrations. The sewers do not appear to be a source of current vapor migration beyond the PMC facility. However, utilities can play a role in the intrusion of VOCs into individual structures. Human health risk estimates will also be summarized in the final RI after the analysis of the additional samples.

Data from pre-RI investigations and the historical data collected per the ROD and previous RIs were incorporated to formulate the conclusions presented in this report. TCE above SLs has been vertically and horizontally delineated in soil vapor and site groundwater. There are chemical concentrations in soil that are a potential ongoing source to groundwater and soil vapor. It is recommended that a feasibility study be prepared for this site to evaluate remedial alternatives. The VI risk and threat to groundwater from VOCs should both be considered when evaluating remedial alternatives since the spatial extent of the VOCs of concern largely overlaps.

7.1.1 Nature and Extent of Contamination

Although other VOCs were identified in site media, TCE is the primary COC as indicated in the ROD and is present over the largest magnitude and extent of the site where TCE was detected above the EPA Residential Groundwater VISL and the MDEQ site-specific VIAC. The highest concentrations of TCE were detected in groundwater within the footprint of the former PMC facility, and concentrations above SLs were detected extending from the former facility to the northwest towards the lake.

Time-series concentration trends of TCE indicate stable trends in five of the wells evaluated and decreasing trends in three of the wells. Trends in the source area wells were stable, although TCE was not detected in deep well PS-104 during the last two events, and concentrations in this well historically have been less than 10 µg/L. Near the shoreline, trends are decreasing in the shallow well evaluated (PS-11) and stable in the deeper well (PS-104) (Figure 4-2A). No TCE degradation products were detected in 2018. Attenuation of TCE appears limited and localized.

In soil, TCE was detected above the residential VIAC in most of the samples (Figure 4-3). The highest concentrations of TCE were detected in soil in the western portion of the footprint of the former PMC property both above and below the water table.

Sewer gas samples collected from the sanitary and storm sewers indicate the presence of VOCs at relatively low concentrations, that are either below or comparable to concentrations observed in multi-level soil vapor samples collected at the site (Figure 4-6). There is no evidence that either sewer network is currently acting as a preferential pathway to surrounding buildings beyond the former PMC manufacturing property. Information obtained from the City of Petoskey and reviewed as part of the sewer pathway assessment also indicates that the current sewer network is unlikely to act as a preferential pathway taking VOCs beyond the site based on the lack of contact with sitewide VOC-containing groundwater, and the apparent removal and replacement of most sanitary and sewer systems on the site (lines were replaced with new piping, manholes, and catch basins circa 2005 as part of utility improvements). The historical sewers were marked as “removed” as opposed to “abandon” in the engineering drawings for the 2005 project (Northwest Design Group 2005). As a result of the replacement of the systems, potential solvent discharge to the sewers as part of historical manufacturing activities would not be expected to directly contribute residual VOCs to the new sewer systems. In addition, the review of utility information provided by the City of Petoskey also indicates the presence of a sanitary sewer force main installed prior to 2005 running generally from west to east with sections found along the western and northern sides of the Water Street Condominiums. This utility line is not readily accessible through manholes and was not sampled; however, because it is located above the groundwater table and, as a force main, is not directly connected to surrounding properties, it is not expected to act as a preferential pathway for VI.

TCE vapor source strength[5] is found both in the vadose zone and in groundwater at the historical source area (Water Street Condominiums), though TCE source strength appears to be greater from groundwater (Appendix F). This conclusion is supported by the mass portioning analysis conducted. The analysis evaluated the extent that TCE mass in the saturated and unsaturated zones contributes to soil vapor concentrations. The evaluation concluded that although both vadose zone soil and groundwater contribute to TCE in soil vapor at the former PMC property, the TCE source strength appears greater from groundwater both beneath the former property and in the study area.
PCE concentrations are coincident with TCE in a limited area on the western side of the former PMC property. There is little evidence of PCE migration off the former PMC property.

Benzene and ethylbenzene were detected above their respective VIAC SLs in soil at one location along the western portion of the former PMC property. These chemicals were also identified in co-located soil vapor samples and several soil vapor samples to the west along East Lake Street. Based on the spatial pattern, the benzene and ethylbenzene concentrations observed are probably related at least in part to operations at the former PMC facility. Benzene and ethylbenzene were not identified in groundwater above SLs.

[5] The term “vapor source strength” here is used to refer to the capacity of an environmental media to produce and maintain elevated concentrations in soil vapor through equilibrium. In essence the vapor source strength of the groundwater is the deep soil vapor concentration that would be expected if there was no mass storage associated with the vadose zone soil particles. The vapor source strength of the vadose zone soil is measured by the soil vapor concentration that would be observed if there was no groundwater contamination.

7.1.2 Fate and Transport

TCE released from a former aboveground storage tank and various other locations migrated to groundwater. Once dissolved, aqueous-phase TCE migrated toward the former municipal supply well during active pumping, resulting in the plume extending to Lake Michigan. Advective migration of TCE in groundwater is virtually nonexistent currently due to the flat hydraulic gradient and flow reversals caused by fluctuations in lake stage. TCE migration in the vadose zone has probably occurred over short distances. Migration of TCE in the historical sewer lines that were removed in 2005 cannot be ruled out. However, these conditions likely enhance dispersion and volatilization of the plume.

TCE is attenuating primarily through volatilization and dispersion, as degradation products were not identified. However, aqueous TCE concentration trends indicate that this process is not rapidly reducing concentrations; most of the wells evaluated show stable trends. This suggests that back diffusion from the matrix largely balances the volatilization and dispersion loss mechanisms, thus the site is in a state of quasi-equilibrium. The mass balance evaluation indicates groundwater as the primary source of TCE vapor concentrations, although residual TCE in vadose-zone soil also contributes to vapor concentrations at the former PMC property.

Attenuation of vapors is noted as a decrease in vapor concentrations away from the source. Beneath the former PMC property, some soil vapor concentrations were higher in shallower samples further from the groundwater table and where TCE is present in soil. This indicates that concentrations in both groundwater and soil are contributing to the observed concentrations in shallow soil vapor. Downgradient of the former PMC property and at adjacent properties, higher soil vapor concentrations were generally noted in deeper samples closer to the water table indicating groundwater as the primary source of vapor concentrations.

Once in soil vapor, TCE diffuses toward the surface through the porous media beneath site and can migrate into buildings through advection caused by differences in temperatures inside and outside of the building or through operation of fans that can create driving forces for soil vapor entry, for example (a conventional VI pathway). Advective entry through the building envelope often occurs through preferential pathways, including those associated with utilities. Fluctuations in groundwater levels due to changes in lake stage also likely enhances volatilization.

7.1.3 Risk Assessment

The HHRA identified TCE as the only site-related COC at select residential and condominium properties. The HHRA included as Appendix H details the full assessment.

The ERA identified habitat in the study area as landscaped yards and public spaces with maintained lawns and small to medium trees and shrubs, and Bay Front Park, including the Lake Michigan shoreline. No significant natural areas were identified. Because groundwater is not a direct exposure pathway to receptors at this time, and the lake acts as a hydraulic barrier mitigating plume migration, there is no significant pathway to ecological receptors from groundwater. The soil vapor exposure pathway is considered complete but insignificant for ecological receptors due to the lack of habitat. Because no significant exposure pathways to ecological receptors are present, no further risk analysis is warranted.

7.2 Conclusions

TCE is widespread in shallow soil at the site. PCE, benzene, and ethylbenzene are present in localized areas and are not considered COCs. A groundwater TCE plume is present due to releases at the former PMC property and has migrated primarily through historical operation of a municipal supply well toward Lake Michigan. TCE concentrations are relatively stable, as documented during the third five-year review (2014) and confirmed by the lack of degradation products and mostly stable concentration trends presented in this report. TCE is attenuating through volatilization and dispersion.

Therefore, concentrations of TCE in soil vapor resulted in the creation of OU2 and investigation of VI potential. In addition to groundwater, residual soil mass beneath the former PMC property is contributing to soil vapor concentrations. Downgradient and adjacent to the former site, groundwater is the primary source of TCE in soil vapor.

7.2.1 Data Limitations

The following are the principle limitations of the data reported in this document:

- Heating of the soil occurred while advancing rotosonic borings due to the drilling method that was used. The rotosonic cores were advanced without the introduction of drilling fluids (water) to ensure that the soil vapor samples were not impacted by the introduction of fluids. This excessive heating may have reduced concentrations of VOCs observable in soil samples, or caused transport of VOCs within the cores. However, bulk soil samples are considered only a secondary line of evidence for VI. Time was allowed for the heat to dissipate before soil samples were collected so that the samples could be handled. Rotosonic cores were heated in excess of 212 °F. Long periods of time separated the drilling from the collection of soil vapor samples that would minimize the effect of this local heating on soil vapor data.
- Neither deep soil vapor borings nor groundwater wells were installed through the foundations of the existing Water Street Condominiums units. However, information is available on the concentrations beneath the foundation from the subslab samples reported in Appendix B.
- The shallow soils at the site have been partially excavated and most soils reworked during condominium construction and historical soil removals. Information collected from many of the 11 borings collected at the site are shown on the cross sections A-A’ and B-B’ (Figures 3-2 and 3-3). The sand and gravel fill and friable limestone with lacustrine sand and gravel depicted on the cross-sections are broadly consistent with the materials observed during construction of the mitigation systems and the pressure field extension observed from those mitigation systems.
- The ability of EPA to install monitoring wells or soil vapor probes in some areas, such as directly south of the Water Street Condominiums was limited by roads, utility corridors, and/or private property owners not providing access.

7.2.2 Recommendations for Future Work

CH2M recommends that the following tasks be completed:

- Develop remedial action objectives.
- Address data gaps that are relevant to the selected remedy either during remedy design or a staged remedy implementation.
- Conduct a feasibility study.
- Conduct preemptive interim mitigation on several properties.
- Continue to attempt to obtain access to properties that have not yet provided access for interior VI sampling (subslab soil vapor, crawlspace air, and/or indoor air) and obtain additional samples at certain additional properties as recommended in Appendix B.

Table 4-1. Monitoring Well Analytical Results - Detections Summary June 2018
PMC Groundwater Superfund Site, Emmet County, Petoskey, Michigan

Notes:
µg/L = micrograms per liter
ng/L = nanograms per liter
mg/L = micrograms per liter
-- = no value available
EPA = U.S. Environmental Protection Agency
MDEQ = Michigan Department of Environmental Quality
NA = compound not reported by the laboratory
RL = reporting limit
MDL = method detection limit
J = The result is an estimated quantity. The associated numerical value is the approximate concentration of the analyte in the sample.
U = The analyte was analyzed for, but was not detected above the reported sample quantitation limit.
UJ = The analyte was not detected above the reported sample quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the action limit of quantitation necessary to accurately and precisely measure the analyte in the sample.
R = The data are unusable. The sample results are rejected due to serious deficiencies in meeting Quality Control (QC) criteria. The analyte may or may not be present in the sample.
[a] The EPA tap water regional screening levels (RSLs; EPA, November 2017) are based on a TCR of 1 × 10-6 and a THQ of 1. Exceedances of this criteria are bold and underlined.
[b] The EPA residential groundwater vapor intrusion screening levels (VISLs) were developed from the EPA VISL calculator using the November 2017 EPA RSLs. The VISLs were calculated based on a TCR of 1 × 10-6 and a THQ of 1. Exceedances of this criteria are shaded grey.
[c] The MDEQ residential shallow groundwater media-specific volatilization to indoor air recommended interim action screening levels (RIASLs; MDEQ, August 2017). Exceedances of this criteria are bold boxed.
* Where screened interval is not known, total depth of well is presented

Table 4-5. Sewer Gas Analytical Results—Detections Summary 2018
PMC Groundwater Superfund Site, Emmet County, Petoskey, Michigan

Notes:

µg/m^3 = micrograms per cubic meter
-- = no value available
EPA = U.S. Environmental Protection Agency
MDEQ = Michigan Department of Environmental Quality
MDL = method detection limit
RL = reporting limit
J = The result is an estimated quantity. The associated numerical value is the approximate concentration of the analyte in the sample.
U = The analyte was analyzed for, but was not detected above the reported sample quantitation limit.
UJ = The analyte was not detected above the reported sample quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the action limit of quantitation necessary to accurately and precisely measure the analyte in the sample.
R = The data are unusable. The sample results are rejected due to serious deficiencies in meeting Quality Control (QC) criteria. The analyte may or may not be present in the sample.

[a] The EPA residential soil vapor vapor intrusion screening levels (VISLs) were developed from the EPA VISL Calculator using the November 2018 EPA regional screening levels. The VISLs were calculated based on a TCR = 1 x 10-6 and a THQ = 1. Use of an attenuation factor of 0.03 for screening sewer gas is a default in the absence of established guidance, and is based on the assumption that similar ratio of soil vapor entry rate (Qsoil) vs. overall building ventilation rate (QB) would hold similarly for sewer gas and for subslab soil vapor. Exceedances of this criteria are bold and underlined

[b] The EPA residential soil vapor removal management levels (RMLs) were developed from the EPA VISL Calculator using the November 2018 EPA Regional Screening Levels. The RMLs were calculated based on a TCR = 1 x 10-4 and a THQ = 3, except for TCE where a THQ =1 was used. Use of an attenuation factor of 0.03 for screening sewer gas is a default in the absence of established guidance, and is based on the assumption that similar ratio of soil vapor entry rate (Qsoil) vs. overall building ventilation rate (QB) would hold similarly for sewer gas and for subslab soil vapor. Exceedances of this criteria are shaded grey.

[c] The MDEQ residential soil vapor media-specific volatilization to indoor air interim action screening levels (August 2017), otherwise known at the recommended interim action screening levels (RIASLs). Exceedances of this criteria are bold boxed.

[d] The MDEQ time-sensitive residential soil vapor media-specific volatilization to indoor air interim action screening levels (August 2017), otherwise known at the time-sensitive recommended interim action screening levels (TSRIASLs). Exceedances of this criteria are italicized.

[e] The criteria for 1,3-dichloropropene was used.

[f] The criteria for total xylenes was used

Notes:

µg/m3 = micrograms per cubic meter

-- = no value available

EPA = U.S. Environmental Protection Agency

MDEQ = Michigan Department of Environmental Quality

MDL = method detection limit

RL = reporting limit

J = The result is an estimated quantity. The associated numerical value is the approximate concentration of the analyte in the sample.

U = The analyte was analyzed for, but was not detected above the reported sample quantitation limit.

UJ = The analyte was not detected above the reported sample quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the action limit of quantitation necessary to accurately and precisely measure the analyte in the sample.

R = The data are unusable. The sample results are rejected due to serious deficiencies in meeting Quality Control (QC) criteria. The analyte may or may not be present in the sample.

[a] The EPA residential soil vapor vapor intrusion screening levels (VISLs) were developed from the EPA VISL Calculator using the November 2017 EPA regional screening levels. The VISLs were calculated based on a TCR = 1 x 10-6 and a THQ = 1. Use of an attenuation factor of 0.03 for screening sewer gas is a default in the absence of established guidance, and is based on the assumption that similar ratio of soil vapor entry rate (Qsoil) vs. overall building ventilation rate (QB) would hold similarly for sewer gas and for subslab soil vapor. Exceedances of this criteria are bold and underlined

[b] The EPA residential soil vapor removal management levels (RMLs) were developed from the EPA VISL Calculator using the November 2017 EPA Regional Screening Levels. The RMLs were calculated based on a TCR = 1 x 10-4 and a THQ = 3, except for TCE where a THQ =1 was used. Use of an attenuation factor of 0.03 for screening sewer gas is a default in the absence of established guidance, and is based on the assumption that similar ratio of soil vapor entry rate (Qsoil) vs. overall building ventilation rate (QB) would hold similarly for sewer gas and for subslab soil vapor. Exceedances of this criteria are shaded grey.

[c] The MDEQ residential soil vapor media-specific volatilization to indoor air interim action screening levels (August 2017), otherwise known at the recommended interim action screening levels (RIASLs). Exceedances of this criteria are bold boxed.

[d] The MDEQ time-sensitive residential soil vapor media-specific volatilization to indoor air interim action screening levels (August 2017), otherwise known at the time-sensitive recommended interim action screening levels (TSRIASLs). Exceedances of this criteria are italicized.

[e] The criteria for 1,3-dichloropropene was used.

[f] The criteria for total xylenes was used

Notes:

µg/m3 = micrograms per cubic meter

-- = no value available

EPA = U.S. Environmental Protection Agency

MDEQ = Michigan Department of Environmental Quality

MDL = method detection limit

RL = reporting limit

J = The result is an estimated quantity. The associated numerical value is the approximate concentration of the analyte in the sample.

U = The analyte was analyzed for, but was not detected above the reported sample quantitation limit.

UJ = The analyte was not detected above the reported sample quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the action limit of quantitation necessary to accurately and precisely measure the analyte in the sample.

R = The data are unusable. The sample results are rejected due to serious deficiencies in meeting Quality Control (QC) criteria. The analyte may or may not be present in the sample.

[a] The EPA residential soil vapor vapor intrusion screening levels (VISLs) were developed from the EPA VISL Calculator using the November 2017 EPA regional screening levels. The VISLs were calculated based on a TCR = 1 x 10-6 and a THQ = 1. Use of an attenuation factor of 0.03 for screening sewer gas is a default in the absence of established guidance, and is based on the assumption that similar ratio of soil vapor entry rate (Qsoil) vs. overall building ventilation rate (QB) would hold similarly for sewer gas and for subslab soil vapor. Exceedances of this criteria are bold and underlined

[b] The EPA residential soil vapor removal management levels (RMLs) were developed from the EPA VISL Calculator using the November 2017 EPA Regional Screening Levels. The RMLs were calculated based on a TCR = 1 x 10-4 and a THQ = 3, except for TCE where a THQ =1 was used. Use of an attenuation factor of 0.03 for screening sewer gas is a default in the absence of established guidance, and is based on the assumption that similar ratio of soil vapor entry rate (Qsoil) vs. overall building ventilation rate (QB) would hold similarly for sewer gas and for subslab soil vapor. Exceedances of this criteria are shaded grey.

[c] The MDEQ residential soil vapor media-specific volatilization to indoor air interim action screening levels (August 2017), otherwise known at the recommended interim action screening levels (RIASLs). Exceedances of this criteria are bold boxed.

[d] The MDEQ time-sensitive residential soil vapor media-specific volatilization to indoor air interim action screening levels (August 2017), otherwise known at the time-sensitive recommended interim action screening levels (TSRIASLs). Exceedances of this criteria are italicized.

[e] The criteria for 1,3-dichloropropene was used.

[f] The criteria for total xylenes was used

Notes:

µg/m3 = micrograms per cubic meter

-- = no value available

EPA = U.S. Environmental Protection Agency

MDEQ = Michigan Department of Environmental Quality

MDL = method detection limit

RL = reporting limit

J = The result is an estimated quantity. The associated numerical value is the approximate concentration of the analyte in the sample.

U = The analyte was analyzed for, but was not detected above the reported sample quantitation limit.

UJ = The analyte was not detected above the reported sample quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the action limit of quantitation necessary to accurately and precisely measure the analyte in the sample.

R = The data are unusable. The sample results are rejected due to serious deficiencies in meeting Quality Control (QC) criteria. The analyte may or may not be present in the sample.

[a] The EPA residential soil vapor vapor intrusion screening levels (VISLs) were developed from the EPA VISL Calculator using the November 2017 EPA regional screening levels. The VISLs were calculated based on a TCR = 1 x 10-6 and a THQ = 1. Use of an attenuation factor of 0.03 for screening sewer gas is a default in the absence of established guidance, and is based on the assumption that similar ratio of soil vapor entry rate (Qsoil) vs. overall building ventilation rate (QB) would hold similarly for sewer gas and for subslab soil vapor. Exceedances of this criteria are bold and underlined

[b] The EPA residential soil vapor removal management levels (RMLs) were developed from the EPA VISL Calculator using the November 2017 EPA Regional Screening Levels. The RMLs were calculated based on a TCR = 1 x 10-4 and a THQ = 3, except for TCE where a THQ =1 was used. Use of an attenuation factor of 0.03 for screening sewer gas is a default in the absence of established guidance, and is based on the assumption that similar ratio of soil vapor entry rate (Qsoil) vs. overall building ventilation rate (QB) would hold similarly for sewer gas and for subslab soil vapor. Exceedances of this criteria are shaded grey.

[c] The MDEQ residential soil vapor media-specific volatilization to indoor air interim action screening levels (August 2017), otherwise known at the recommended interim action screening levels (RIASLs). Exceedances of this criteria are bold boxed.

[d] The MDEQ time-sensitive residential soil vapor media-specific volatilization to indoor air interim action screening levels (August 2017), otherwise known at the time-sensitive recommended interim action screening levels (TSRIASLs). Exceedances of this criteria are italicized.

[e] The criteria for 1,3-dichloropropene was used.

[f] The criteria for total xylenes was used

Notes:

µg/m3 = micrograms per cubic meter

-- = no value available

EPA = U.S. Environmental Protection Agency

MDEQ = Michigan Department of Environmental Quality

MDL = method detection limit

RL = reporting limit

J = The result is an estimated quantity. The associated numerical value is the approximate concentration of the analyte in the sample.

U = The analyte was analyzed for, but was not detected above the reported sample quantitation limit.

UJ = The analyte was not detected above the reported sample quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the action limit of quantitation necessary to accurately and precisely measure the analyte in the sample.

R = The data are unusable. The sample results are rejected due to serious deficiencies in meeting Quality Control (QC) criteria. The analyte may or may not be present in the sample.

[a] The EPA residential soil vapor vapor intrusion screening levels (VISLs) were developed from the EPA VISL Calculator using the November 2017 EPA regional screening levels. The VISLs were calculated based on a TCR = 1 x 10-6 and a THQ = 1. Use of an attenuation factor of 0.03 for screening sewer gas is a default in the absence of established guidance, and is based on the assumption that similar ratio of soil vapor entry rate (Qsoil) vs. overall building ventilation rate (QB) would hold similarly for sewer gas and for subslab soil vapor. Exceedances of this criteria are bold and underlined

[b] The EPA residential soil vapor removal management levels (RMLs) were developed from the EPA VISL Calculator using the November 2017 EPA Regional Screening Levels. The RMLs were calculated based on a TCR = 1 x 10-4 and a THQ = 3, except for TCE where a THQ =1 was used. Use of an attenuation factor of 0.03 for screening sewer gas is a default in the absence of established guidance, and is based on the assumption that similar ratio of soil vapor entry rate (Qsoil) vs. overall building ventilation rate (QB) would hold similarly for sewer gas and for subslab soil vapor. Exceedances of this criteria are shaded grey.

[c] The MDEQ residential soil vapor media-specific volatilization to indoor air interim action screening levels (August 2017), otherwise known at the recommended interim action screening levels (RIASLs). Exceedances of this criteria are bold boxed.

[d] The MDEQ time-sensitive residential soil vapor media-specific volatilization to indoor air interim action screening levels (August 2017), otherwise known at the time-sensitive recommended interim action screening levels (TSRIASLs). Exceedances of this criteria are italicized.

[e] The criteria for 1,3-dichloropropene was used.

[f] The criteria for total xylenes was used

Clean Harbor WPS – Soil and Water Disposal – RI 2018

WASTE MATERIAL PROFILE SHEET

Clean Harbors Profile No. CH1684506

A. GENERAL INFORMATION

GENERATOR EPA ID #/REGISTRATION # *NONEREQUIRED* GENERATOR NAME: *USEPA*

GENERATOR CODE (Assigned by Clean Harbors) *US31534* CITY *Petoskey* STATE/PROVINCE *MI* ZIP/POSTAL CODE *49770*

ADDRESS *200 West Lake Street* PHONE: (720) 286-4107

CUSTOMER CODE (Assigned by Clean Harbors) *CA59174* CUSTOMER NAME: *Cascade Drilling*

ADDRESS *22722 29th Drive SE, Suite 228* CITY *Bothell* STATE/PROVINCE *WA* ZIP/POSTAL CODE *98021*

B. WASTE DESCRIPTION

WASTE DESCRIPTION: *Non-Hazardous Waste Solid (Soil)*

PROCESS GENERATING WASTE: **Investigation Derived Waste from Soil Gas Probe and Monitoring Well Installations at former Petoskey Manufacturing Comp.**

IS THIS WASTE CONTAINED IN SMALL PACKAGING CONTAINED WITHIN A LARGER SHIPPING CONTAINER ? **No**

C. PHYSICAL PROPERTIES (at 25C or 77F)

PHYSICAL STATE
- [x] SOLID WITHOUT FREE LIQUID
- [ ] POWDER
- [ ] MONOLITHIC SOLID
- [ ] LIQUID WITH NO SOLIDS
- [ ] LIQUID/SOLID MIXTURE
- [ ] % FREE LIQUID
- [ ] % SETTLED SOLID
- [ ] % TOTAL SUSPENDED SOLID
- [ ] SLUDGE
- [ ] GAS/AEROSOL

NUMBER OF PHASES/LAYERS: 1 2 3

% BY VOLUME (Approx.)
- TOP *0.00*
- MIDDLE *0.00*
- BOTTOM *0.00*

VISCOSITY (If liquid present)
- [ ] 1 - 100 (e.g. Water)
- [ ] 101 - 500 (e.g. Motor Oil)
- [ ] 501 - 10,000 (e.g. Molasses)
- [ ] > 10,000

COLOR: *Brown*

ODOR
- [x] NONE
- [ ] MILD
- [ ] STRONG

Describe:

BOILING POINT °F (°C)
- [ ] <= 95 (<=35)
- [ ] 95 - 100 (35-38)
- [ ] 101 - 129 (38-54)
- [ ] >= 130 (>54)

MELTING POINT °F (°C)
- [ ] < 140 (<60)
- [ ] 140-200 (60-93)
- [x] > 200 (>93)

TOTAL ORGANIC CARBON
- [x] <= 1%
- [ ] 1-9%
- [ ] >= 10%

FLASH POINT °F (°C)
- [ ] < 73 (<23)
- [ ] 73 - 100 (23-38)
- [ ] 101 -140 (38-60)
- [ ] 141 -200 (60-93)
- [ ] > 200 (>93)

pH
- [ ] <= 2
- [ ] 2.1 - 6.9
- [x] 7 (Neutral)
- [ ] 7.1 - 12.4
- [ ] >= 12.5

SPECIFIC GRAVITY
- [ ] < 0.8 (e.g. Gasoline)
- [ ] 0.8-1.0 (e.g. Ethanol)
- [ ] 1.0 (e.g. Water)
- [ ] 1.0-1.2 (e.g. Antifreeze)

DOES THIS WASTE CONTAIN ANY HEAVY GAUGE METAL DEBRIS OR OTHER LARGE OBJECTS (EX., METAL PLATE OR PIPING >1/4" THICK OR >12" LONG, METAL REINFORCED HOSE >12" LONG, METAL WIRE >12" LONG, METAL VALVES, PIPE FITTINGS, CONCRETE REINFORCING BAR OR PIECES OF CONCRETE >3")? YES [ ] NO [x]

If yes, describe, including dimensions:

DOES THIS WASTE CONTAIN ANY METALS IN POWDERED OR OTHER FINELY DIVIDED FORM? YES [ ] NO [x]

DOES THIS WASTE CONTAIN OR HAS IT CONTACTED ANY OF THE FOLLOWING; ANIMAL WASTES, HUMAN BLOOD, BLOOD PRODUCTS, BODY FLUIDS, MICROBIOLOGICAL WASTE, PATHOLOGICAL WASTE, HUMAN OR ANIMAL DERIVED SERUMS OR PROTEINS OR ANY OTHER POTENTIALLY INFECTIOUS MATERIAL? YES [ ] NO [x]

I acknowledge that this waste material is neither infectious nor does it contain any organism known to be a threat to human health. This certification is based on my knowledge of the material. Select the answer below that applies:

The waste was never exposed to potentially infectious material. YES NO

Chemical disinfection or some other form of sterilization has been applied to the waste. YES NO

I ACKNOWLEDGE THAT THIS PROFILE MEETS THE CLEAN HARBORS BATTERY PACKAGING REQUIREMENTS. YES NO

I ACKNOWLEDGE THAT MY FRIABLE ASBESTOS WASTE IS DOUBLE BAGGED AND WETTED. YES NO

SPECIFY THE SOURCE CODE ASSOCIATED WITH THE WASTE. *G43* SPECIFY THE FORM CODE ASSOCIATED WITH THE WASTE. *W301*

E. CONSTITUENTS

Are these values based on testing or knowledge? Knowledge ☑ Testing

If constituent concentrations are based on analytical testing, analysis must be provided. Please attach document(s) using the link on the Submit tab.

Please indicate which constituents below apply. Concentrations must be entered when applicable to assist in accurate review and expedited approval of your waste profile. Please note that the total regulated metals and other constituents sections require answers.

WASTE MATERIAL PROFILE SHEET

Clean Harbors Profile No. CH1684523

A. GENERAL INFORMATION

GENERATOR EPA ID #/REGISTRATION # *NONEREQUIRED* GENERATOR NAME: *USEPA*

GENERATOR CODE (Assigned by Clean Harbors) *US31534* CITY *Petoskey* STATE/PROVINCE *MI* ZIP/POSTAL CODE *49770*

ADDRESS *200 West Lake Street* PHONE: *(720) 286-4107*

CUSTOMER CODE (Assigned by Clean Harbors) *CA59174* CUSTOMER NAME: *Cascade Drilling*

ADDRESS *22722 29th Drive SE, Suite 228* CITY *Bothell* STATE/PROVINCE *WA* ZIP/POSTAL CODE *98021*

B. WASTE DESCRIPTION

WASTE DESCRIPTION: *Non-Hazardous Waste Liquid (Groundwater)*

PROCESS GENERATING WASTE: **Investigation Derived Waste from soil gas probe and monitoring well installations at former Petoskey Manufacturing Comp**

IS THIS WASTE CONTAINED IN SMALL PACKAGING CONTAINED WITHIN A LARGER SHIPPING CONTAINER ? **No**

C. PHYSICAL PROPERTIES (at 25C or 77F)

PHYSICAL STATE
- SOLID WITHOUT FREE LIQUID
- POWDER
- MONOLITHIC SOLID
- [x] LIQUID WITH NO SOLIDS
- LIQUID/SOLID MIXTURE
  - % FREE LIQUID *90.00 - 100.00*
  - % SETTLED SOLID *0.00 - 10.00*
  - % TOTAL SUSPENDED SOLID
- SLUDGE
- GAS/AEROSOL

NUMBER OF PHASES/LAYERS: 1 [x] 2 3

% BY VOLUME (Approx.): TOP *90.00*; MIDDLE *0.00*; BOTTOM *10.00*

VISCOSITY (If liquid present)
- [x] 1 - 100 (e.g. Water)
- 101 - 500 (e.g. Motor Oil)
- 501 - 10,000 (e.g. Molasses)

Groundwater Site Survey Report 2018

Jacobs

PMC Groundwater Site, Petoskey - Surveying Services

Surveyor's Report

Project Understanding

Establish Horizontal Coordinates and Vertical Elevations on three monitor wells and 15 soil vapor probes as directed by Jacobs. Verify horizontal and vertical control points on site as previously established. Create a report detailing the field and office work completed, provide coordinates and elevations of the wells and provide quality control measures taken.

Methodology

With the base at both CP #1 and CP#2 observations were taken at all monitor wells. Control points were observed multiple times with RTK GPS. Once we received the OPUS solution for each control point, we adjusted all data to the Michigan State Plane Coordinate System, Central Zone based on the North American Datum of 1983 (2011). The redundancy at each monitor well allowed us to validate the locations of all monitor wells and control points. For elevations on site, we collected static data at CP #1 and sent that data to OPUS. A second OPUS solution was obtained at CP #2 as a redundant check. We ran a closed level loop from CP #1 through all control points and top of casings. We were able to validate the elevations of the monitor wells and control points by means of a closed level loop. A least squares adjustment report of all level loops is included.

Initial Project Control

Horizontal Datum

All coordinates for this project are on the Michigan State Plane Coordinate System, Central Zone based on the North American Datum of 1983 (2011) from control points 1, 2 and 3 that were established in 2016 on this site. These three points were recovered in good condition and their locations and elevations were verified. An analysis of the horizontal accuracies attained is attached.

Control Monuments Established – Horizontal and Vertical Control:

- CP #1 - Set 5/8" x 3' long rebar w/Spicer Traverse cap

Northing:	751310.8760	Standard Deviation 0.024 at 95% confidence level
Easting:	19531323.1660	Standard Deviation 0.020 at 95% confidence level
Elevation:	594.432	Standard Deviation 0.023 at 95% confidence level

Witnesses:

South 13'	Northerly edge of E-W sidewalk
East 22'	4" Ornamental tree
S42°E 17.5'	Garbage can mount
N47°W 37'	Light Pole

- CP #2 - Set 5/8" x 3' long rebar w/Spicer Traverse cap

Northing:	751381.0750	Standard Deviation 0.008 at 95% confidence level
Easting:	19531418.0710	Standard Deviation 0.029 at 95% confidence level
Elevation:	591.001	Standard Deviation 0.010 at 95% confidence level

Witnesses

South 5'	Northerly edge of sidewalk
South 27'	4" Maple
S60°E 20'	Light Pole
S49°W 54'	Light Pole

- CP #3 - Set 5/8" x 3' long rebar w/Spicer Traverse cap

Northing:	751313.5250	Standard Deviation 0.012 at 95% confidence level
Easting:	19531208.7930	Standard Deviation 0.011 at 95% confidence level
Elevation:	593.480	Standard Deviation 0.001 at 95% confidence level

Witnesses:

South 15'	Northerly edge of E-W sidewalk
S64°W 16'	Bayfront Park West Sign (Center of Sign)
S38°E 20'	Garbage can mount
N13°E 20.5'	4" Maple

Vertical Datum

All elevations for this project are based on NAVD'88 from control points 1, 2 & 3 as established on site in 2016. All three points were included in the level loop that was run this year and the elevations previously established were confirmed. A least squares adjustment of the level loop is included in the project deliverables.

Equipment Used

For this project we used three different Surveying instruments. We used a Leica GS14 GNSS base/rover RTK system to collect horizontal positions for the project. The same Leica GS14 base was used to collect static GPS data at Control Point #1 and #2 that was later processed through OPUS. We also used a Leica DNA 10 digital level to establish elevations for all project monitoring wells. Finally, we used a Leica TS15 robotic total station to locate the building corners of the condominium complex. All of Spicer Group's digital levels and total stations are calibrated on an annual basis so that no instrument is ever more than 11 months out of calibration

Deliverables

Spreadsheet for Monitoring Wells & Soil Vapor Probes:
A spreadsheet containing the X, Y and Z coordinates of each monitoring well, including a ground elevation and top of inner casing elevation as well as each soil vapor probe including the elevation at the top of the metal.

Finished Floor elevations and spot grades:
The locations and elevations of the garage floors at the condominium units were surveyed as part of this project and are included in the ASCII file of all points included in this survey.

Miscellaneous Files:
Least squares adjustment report, horizontal control point assessment, and project field notes.

Certification

I hereby certify, as a Professional Surveyor Licensed in Michigan, that all surveying work performed has been performed in accordance with the specifications listed in the Scope of Work, and that all accuracies referenced in said Scope of Work have been achieved.

Vapor Intrusion Best Practices
Sewer Gas Sampling Log - Canister Method

Project Info

Project Name: PMC **Project #:** 699973

Sampler Name: R. Sleeper / S. Chumney **Date:** 10/9/18

Structure

Identification: SA-07

Manhole or Cleanout Location:

Sewer Gas Sampling Log

Sample location		SA-07
Sample Identification		PMC-SA-07-101018
Set up Information	Manhole removal time	1247
	Field Analysis time (If applicable - 30 min equilibration period)	—
Optional Field Analysis MultiRae PID	O2 (%)	
	CO (ppm)	
	H2S (ppm)	
	LEL (%)	
	Total VOCs (ppmv)	
Optional Field Analysis LandTec GEM	O2 (%)	20.3
	CO2 (%)	6.3
	CH4 (%)	0.2
	CH4 (%) with carbon filter	—

Canister Sampling	Canister ID	AS00260
	Flow controller ID	FCR00319
	Sampling rate or period (mL/min)	24hr
	Sample start date and time	10/9/18 - 1248
	Initial canister pressure (" Hg)	-29.66
	Sample completion date and time	10/10/18 - 1225
	Final canister pressure (" Hg)	-6.36
Passive Sampling	Sample device type or ID	
	Sample start date and time	~~10/9/18~~ 1248
	Sample end date and time	

Weather conditions during sampling: Sunny partly cloudy 65°

Observations and Comments: DTW / ~~sewage~~ Sewage ≈ 2.8' Below grade

Soil Vapor Probe Diagrams June 2018

PROJECT NUMBER	PROBE NUMBER SVB-01
699973.FI.01	SHEET 1 OF 1 DATE: 5/16/2018

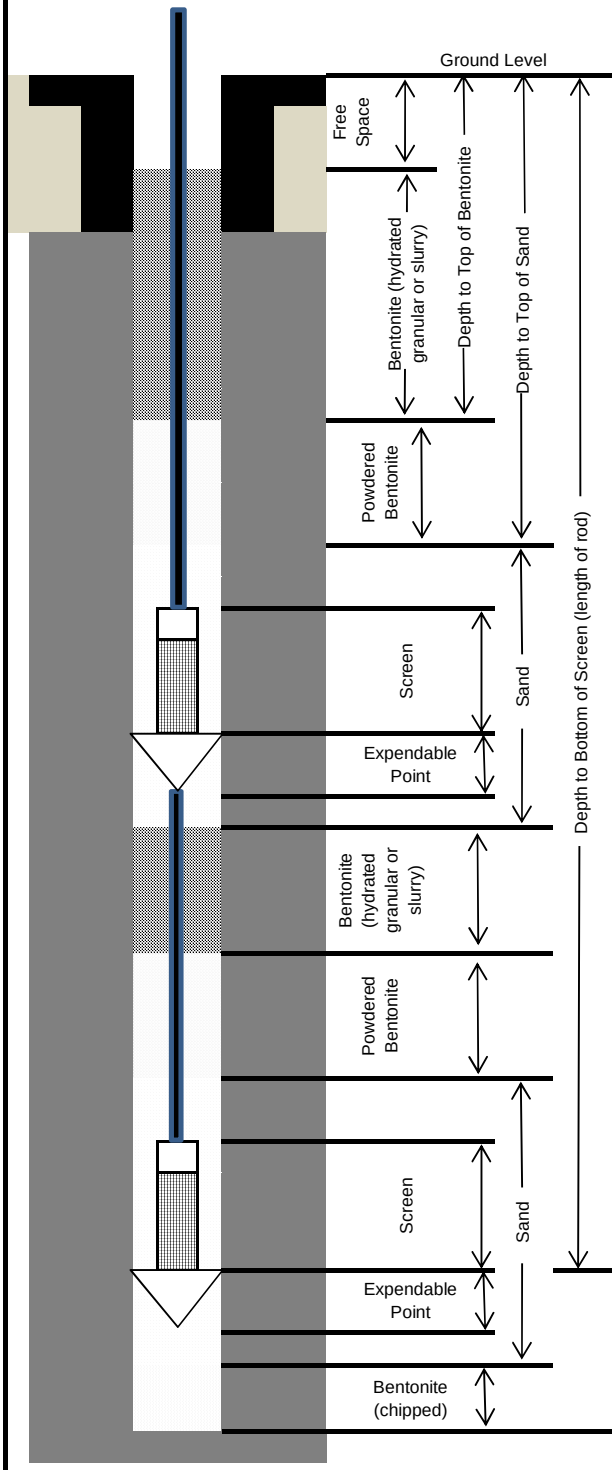
Soil Vapor Probe Diagram

PROJECT : EPA Region 5 PMC LOCATION : Petoskey, MI

DRILLING CONTRACTOR : Mateco

DRILLING METHOD AND EQUIPMENT USEI Rotosonic drilling with 4.5-inch OD single core barrel - Geoprobe 8140DT

START : 5/16/2018 END 5/30/2018 Installer :



Outer Diameter of Rod (in.)	4.5 in
Depth to Bottom of Screens (ft)	5.83 ft, 14 ft
Length of Expendable Points (in.)	2 in
Screen Diameter (in.) / Length (in.)	.05 in/6 in
Screen Mesh (in.)	0.006 in
Teflon Tubing Outer Diameter (in.)	0.25 in
Length of Sand Packs (ft.)	1.5 ft, 2 ft
Depth to Top of Sand (ft)	4.83 ft, 13 ft
Length of Powdered Bentonite Seal (in.)	6 in, 6 in
Depth to Top of Powdered Bentonite (ft)	4.33 ft, 12.5 ft
Length of Bentonite (ft)	3.33 ft, 4 ft
Depth to Top of Bentonite (ft)	1 ft, 6.33 ft
Length of Free Space (in.)	
Flush Mount Diameter.	

Specifications (Type)

Sand: K&E Well Gravel (silica sand)

Bentonite: All types were Haliburton brand.

Three types used: powdered, granular, and chipped.

Three types used: powdered, granular, and chipped.

Soil Vapor Sampling Forms June 2018

Soil Vapor Sampling Log

ch2m:

Project: EPA RS PMC Petoskey MI

Sampler: Jenn Simms

Sample Location Information

Property ID/Address: [redacted]

Condition of ground in the surrounding area: grass

Location ID: SVB-01-5.8 Sample ID: PMC-SVB-01-5.8-062918

Sample Location Description: North side of W. Lake St (btwn sidewalk & street)

Soil Vapor Probe Leak Checking and Sampling Log

Manifold Leak Check

Manifold leak check (procedure: ensure manifold holds pressure at -10 "Hg for 30 seconds). If using a pelican-case pump, open the lid during leak check to ensure all interior pieces are intact. 12:06	Pass	Fail
	X	

Describe corrective measures taken to pass the manifold leak test: None

Soil Vapor Probe Helium Leak Check and Purge Results

Purge rate (mL/Min): 200 Helium Conc. in the Purged Vapor: 0

Start Time: 12:07 Calculated leak percentage: 0%

Purge Vacuum ("Hg): 0 Probe Leak Check Result*: (Pass) Fail

Avg. Helium Conc. in the Enclosure: 33.7%, 34.3%, 20.4%, 35.8% = 31.1%

End Time: 12:34

*The soil vapor probe passes the leak test if the helium concentration in the purged soil vapor is less than 5% of what it was in the helium enclosure during purging. For example, if the helium concentration in the purged soil vapor is 2,300 ppm that is 0.23%, and the average helium concentration in the enclosure was 35%, then the percentage leak is 0.66% (0.23/35*100 = 0.66%)). Do NOT collect a soil vapor sample if the leak check fails.

1 dead volume is 1.5L, so purge 4.5L

Field Analysis (required readings are determined on a project-specific basis. Fill in all that are necessary):

(MiniRAE) or MultiRAE Photoionization Detector

Total VOCs (ppm): 29.5 O_2 (%):

H_2S (ppm): LEL (%):

CO (ppm):

Soil Vapor Probe Leak Checking and Sampling Log

Manifold Leak Check

Manifold leak check (procedure: ensure manifold holds pressure at -10 "Hg for 30 seconds). If using a pelican-case pump, open the lid during leak check to ensure all interior pieces are intact. 09:52

Pass	Fail
X	

Describe corrective measures taken to pass the manifold leak test: None

Soil Vapor Probe Helium Leak Check and Purge Results

Purge rate (mL/Min): 200

Start Time: 09:56

Purge Vacuum ("Hg): 0

Helium Conc. in the Purged Vapor: 0ppm

Calculated leak percentage: 0%

Probe Leak Check Result*: (Pass) Fail

Avg. Helium Conc. in the Enclosure: 35.8%, 53.2%, 34.7%, 41.2%, 31.3%, 27.2 = 37.2%

End Time: 10:43

*The soil vapor probe passes the leak test if the helium concentration in the purged soil vapor is less than 5% of what it was in the helium enclosure during purging. For example, if the helium concentration in the purged soil vapor is 2,300 ppm that is 0.23%, and the average helium concentration in the enclosure was 35%, then the percentage leak is 0.66% (0.23/35*100 = 0.66%)). Do NOT collect a soil vapor sample if the leak check fails.

1 dead volume is 3.1 L, so purge 9.3 L

End Time: 10:58

*The soil vapor probe passes the leak test if the helium concentration in the purged soil vapor is less than 5% of what it was in the helium enclosure during purging. For example, if the helium concentration in the purged soil vapor is 2,300 ppm that is 0.23%, and the average helium concentration in the enclosure was 35%, then the percentage leak is 0.66% [0.23/35*100 = 0.66%]. Do NOT collect a soil vapor sample if the leak check fails.

Sample Location Description: [redacted]

Soil Vapor Probe Leak Checking and Sampling Log

Manifold Leak Check

Manifold leak check (procedure: ensure manifold holds pressure at -10 "Hg for 30 seconds). If using a pelican-case pump, open the lid during leak check to ensure all interior pieces are intact. 1807	Pass	Fail
	X	

Describe corrective measures taken to pass the manifold leak test: NA

Soil Vapor Probe Helium Leak Check and Purge Results

Purge rate (mL/Min): 200 mL/min

Start Time: 1809

Purge Vacuum ("Hg): 0

Avg. Helium Conc. in the Enclosure: 23.1, 34.1, 21.9, 20.1, 21.2 Avg = 24.2 %

End Time: 1839

Helium Conc. in the Purged Vapor: 0

Calculated leak percentage: 0

Probe Leak Check Result*: (Pass) Fail

*The soil vapor probe passes the leak test if the helium concentration in the purged soil vapor is less than 5% of what it was in the helium enclosure during purging. For example, if the helium concentration in the purged soil vapor is 2,300 ppm that is 0.23%, and the average helium concentration in the enclosure was 35%, then the percentage leak is 0.66% (0.23/35*100 = 0.66%)]. Do NOT collect a soil vapor sample if the leak check fails.

1 dead Volume = 1.2

So Purge 3.6L

Field Analysis (required readings are determined on a project-specific basis. Fill in all that are necessary):

MiniRAE or MultiRAE Photoionization Detector				LandTec GEM Landfill Gas Meter

Soil Vapor Probe Leak Checking and Sampling Log

Manifold Leak Check

Manifold leak check (procedure: ensure manifold holds pressure at -10 "Hg for 30 seconds). If using a pelican-case pump, open the lid during leak check to ensure all interior pieces are intact.	Pass	Fail
	X	

Describe corrective measures taken to pass the manifold leak test: NA

Soil Vapor Probe Helium Leak Check and Purge Results

Purge rate (mL/Min): 200

Start Time: 1236

Purge Vacuum ("Hg): Ø

Helium Conc. in the Purged Vapor: 0,0,0,0,0

Calculated leak percentage:

Probe Leak Check Result*: (Pass) Fail

Avg. Helium Conc. in the Enclosure: 27%, 18%, 18%, 22%, 24% → Ave = 22%

End Time: 1259

*The soil vapor probe passes the leak test if the helium concentration in the purged soil vapor is less than 5% of what it was in the helium enclosure during purging. For example, if the helium concentration in the purged soil vapor is 2,300 ppm that is 0.23%, and the average helium concentration in the enclosure was 35%, then the percentage leak is 0.66% [0.23/35*100 = 0.66%]). Do NOT collect a soil vapor sample if the leak check fails.

Field Analysis (required readings are determined on a project-specific basis. Fill in all that are necessary):

MiniRAE or MultiRAE Photoionization Detector				LandTec GEM Landfill Gas Meter	
Total VOCs (ppm):	0.2	O_2 (%):	✓	O2 (%):	20.0

Avg. Helium Conc. in the Enclosure: 23%, 38%

End Time: 1731

Helium Conc. in the Purged Vapor: 0,0,0,0

Calculated leak percentage:

Probe Leak Check Result*: (Pass) Fail

*The soil vapor probe passes the leak test if the helium concentration in the purged soil vapor is less than 5% of what it was in the helium enclosure during purging. For example, if the helium concentration in the purged soil vapor is 2,300 ppm that is 0.23%, and the average helium concentration in the enclosure was 35%, then the percentage leak is 0.66% [0.23/35*100 = 0.66%]). Do NOT collect a soil vapor sample if the leak check fails.

Field Analysis (required readings are determined on a project-specific basis. Fill in all that are necessary):

Soil Vapor Probe Leak Checking and Sampling Log

Manifold Leak Check

Manifold leak check (procedure: ensure manifold holds pressure at -10 "Hg for 30 seconds). If using a pelican-case pump, open the lid during leak check to ensure all interior pieces are in-tact. (Pass) Fail

Describe corrective measures taken to pass the manifold leak test: NA

Soil Vapor Probe Helium Leak Check and Purge Results

Purge rate (mL/Min): 200 mL/min

Start and End Times: 1407 - 1430

Purge Vacuum ("Hg): 0"

Avg. Helium Conc. in the Enclosure: 18.6 %

Total Volume Purged (L): ~5L

Helium Conc. in the Purged Vapor: 0%

Calculated leak percentage: NA

Probe Leak Check Result*: (Pass) Fail

*The soil vapor probe passes the leak test if the helium concentration in the purged soil vapor is less than 5% of what it was in the helium enclosure during purging. For example, if the helium concentration in the purged soil vapor is 2,300 ppm that is 0.23%, and the average helium concentration in the enclosure was 35%, then the percentage leak is 0.66% [0.23/35*100 = 0.66%]). Do NOT collect a soil vapor sample if the leak check fails

Field Analysis (required readings are determined on a project-specific basis. Fill in all that are necessary):

Sample Location Description: [redacted]

Soil Vapor Probe Leak Checking and Sampling Log

Manifold Leak Check

Manifold leak check (procedure: ensure manifold holds pressure at -10 "Hg for 30 seconds). If using a pelican-case pump, open the lid during leak check to ensure all interior pieces are intact.	Pass	Fail
	X	

Describe corrective measures taken to pass the manifold leak test: NA

Soil Vapor Probe Helium Leak Check and Purge Results

Purge rate (mL/Min): 200

Start Time: 1356

Purge Vacuum ("Hg): Ø

Avg. Helium Conc. in the Enclosure: 27%

End Time: 1429

Helium Conc. in the Purged Vapor: Ø

Calculated leak percentage: Ø

Probe Leak Check Result*: (Pass) Fail

*The soil vapor probe passes the leak test if the helium concentration in the purged soil vapor is less than 5% of what it was in the helium enclosure during purging. For example, if the helium concentration in the purged soil vapor is 2,300 ppm that is 0.23%, and the average helium concentration in the enclosure was 35%, then the percentage leak is 0.66% [0.23/35*100 = 0.66%]). Do NOT collect a soil vapor sample if the leak check fails.

Field Analysis (required readings are determined on a project-specific basis. Fill in all that are necessary):

MiniRAE or MultiRAE Photoionization Detector

Total VOCs (ppm): 0.1 O_2 (%): 19.6

H_2S (ppm): / LEL (%): /

CO (ppm): /

Soil Vapor Probe Leak Checking and Sampling Log

Manifold Leak Check

Manifold leak check (procedure: ensure manifold holds pressure at -10 "Hg for 30 seconds). If using a pelican-case pump, open the lid during leak check to ensure all interior pieces are in-tact. (Pass) Fail

Describe corrective measures taken to pass the manifold leak test: NA

Soil Vapor Probe Helium Leak Check and Purge Results

Purge rate (mL/Min): 200 mL/min

Start and End Times: 927 - 932

Purge Vacuum ("Hg): 0

Avg. Helium Conc. in the Enclosure: 31.3 %

Total Volume Purged (L): 1L

Helium Conc. in the Purged Vapor: 0

Calculated leak percentage: NA

Probe Leak Check Result*: (Pass) Fail

*The soil vapor probe passes the leak test if the helium concentration in the purged soil vapor is less than 5% of what it was in the helium enclosure during purging. For example, if the helium concentration in the purged soil vapor is 2,300 ppm that is 0.23%, and the average helium concentration in the enclosure was 35%, then the percentage leak is 0.66% [0.23/35*100 = 0.66%]). Do NOT collect a soil vapor sample if the leak check fails.

Field Analysis (required readings are determined on a project-specific basis. Fill in all that are necessary):

MiniRAE or MultiRAE Photoionization Detector				LandTec GEM Landfill Gas Meter	
Total VOCs (ppm):	0	O_2 (%):	20.9%	O2 (%):	22.2%
H_2S (ppm):	0	LEL (%):	0 %	CO2 (%):	0.3%
CO (ppm):	0			CH4 (%):	0 %

Project: PMC Petaluma

Sampler: S. Chumney & R. Sleeper

Sample Location Information

Property ID/Address: [redacted]

Condition of ground in the surrounding area: Concrete slab

Location ID: PMC-09-SSO2 Sample ID: PMC-09-SSO2-101018

Sample Location Description: [redacted]

Soil Vapor Probe Leak Checking and Sampling Log

Manifold Leak Check

Manifold leak check (procedure: ensure manifold holds pressure at -10 "Hg for 30 seconds). If using a pelican-case pump, open the lid during leak check to ensure all interior pieces are intact.	*Pass*	*Fail*
	X	

Describe corrective measures taken to pass the manifold leak test: NA

Soil Vapor Probe Helium Leak Check and Purge Results

Purge rate (mL/Min): 200

Start Time: 1520

Purge Vacuum ("Hg): Ø

Avg. Helium Conc. in the Enclosure: 24%, 22%

End Time: 1525

Helium Conc. in the Purged Vapor: 225 ppm

Calculated leak percentage:

Probe Leak Check Result*: (Pass) *Fail*

*The soil vapor probe passes the leak test if the helium concentration in the purged soil vapor is less than 5% of what it was in the helium enclosure during purging. For example, if the helium concentration in the purged soil vapor is 2,300 ppm that is 0.23%, and the average helium concentration in the enclosure was 35%, then the percentage leak is 0.66% (0.23/35*100 = 0.66%)). Do NOT collect a soil vapor sample if the leak check fails.

Field Analysis (required readings are determined on a project-specific basis. Fill in all that are necessary):

~~MiniRAE or MultiRAE Photoionization~~ Detector PPB RAE			LandTec GEM Landfill Gas Meter	
Total VOCs (ppm): .791	O_2 (%): —		O2 (%):	20.9
H_2S (ppm): ✓	LEL (%): ✓		CO2 (%):	0.0
CO (ppm):			CH4 (%):	.2

Case Narrative

Samples for the above noted Work Order were received on 06/01/2018. The attached "Sample Receipt Checklist" documents the status of custody seals, container integrity, preservation, and temperature compliance.

Samples were analyzed according to the analytical methodology previously transmitted in the "Work Order Acknowledgement". Methodologies are also documented in the "Analytical Result" section for each sample. Quality control results are listed in the "QC Report" section. Sample association for the reported quality control is located at the end of each batch summary. If applicable, results are appropriately qualified in the Analytical Result and QC Report sections. The "Qualifiers" section documents the various qualifiers, units, and acronyms utilized in reporting. A copy of the laboratory's scope of accreditation is available upon request.

With the following exceptions, all sample analyses achieved analytical criteria.

Re: **PMC** Work Order: **1806126**

Dear Heather,

ALS Environmental received 5 samples on 01-Jun-2018 10:00 AM for the analyses presented in the following report.

The analytical data provided relates directly to the samples received by ALS Environmental - Holland and for only the analyses requested.

Sample results are compliant with industry accepted practices and Quality Control results achieved laboratory specifications. Any exceptions are noted in the Case Narrative, or noted with qualifiers in the report or QC batch information. Should this laboratory report need to be reproduced, it should be reproduced in full unless written approval has been obtained from ALS Environmental. Samples will be disposed in 30 days unless storage arrangements are made.

The total number of pages in this report is 33.

If you have any questions regarding this report, please feel free to contact me:

ADDRESS: 3352 128th Avenue, Holland, MI, USA

Case Narrative

Samples for the above noted Work Order were received on 06/01/2018. The attached "Sample Receipt Checklist" documents the status of custody seals, container integrity, preservation, and temperature compliance.

Samples were analyzed according to the analytical methodology previously transmitted in the "Work Order Acknowledgement". Methodologies are also documented in the "Analytical Result" section for each sample. Quality control results are listed in the "QC Report" section. Sample association for the reported quality control is located at the end of each batch summary. If applicable, results are appropriately qualified in the Analytical Result and QC Report sections. The "Qualifiers" section documents the various qualifiers, units, and acronyms utilized in reporting. A copy of the laboratory's scope of accreditation is available upon request.

With the following exceptions, all sample analyses achieved analytical criteria.

QUALIFIERS, ACRONYMS, UNITS

Qualifier	Description
*	Value exceeds Regulatory Limit
**	Estimated Value
a	Analyte is non-accredited
B	Analyte detected in the associated Method Blank above the Reporting Limit
E	Value above quantitation range
H	Analyzed outside of Holding Time
J	Analyte is present at an estimated concentration between the MDL and Report Limit
ND	Not Detected at the Reporting Limit
O	Sample amount is > 4 times amount spiked
P	Dual Column results percent difference > 40%
R	RPD above laboratory control limit
S	Spike Recovery outside laboratory control limits
U	Analyzed but not detected above the MDL
X	Analyte was detected in the Method Blank between the MDL and Reporting Limit, sample results may exhibit background or reagent contamination at the observed level.

Acronym	Description
DUP	Method Duplicate
LCS	Laboratory Control Sample
LCSD	Laboratory Control Sample Duplicate
LOD	Limit of Detection (see MDL)
LOQ	Limit of Quantitation (see PQL)
MBLK	Method Blank
MDL	Method Detection Limit
MS	Matrix Spike
MSD	Matrix Spike Duplicate
PQL	Practical Quantitation Limit
RPD	Relative Percent Difference
TDL	Target Detection Limit
TNTC	Too Numerous To Count
A	APHA Standard Methods
D	ASTM
E	EPA
SW	SW-846 Update III

Units Reported	Description
% of sample	Percent of Sample
µg/Kg-dry	Micrograms per Kilogram Dry Weight
µg/L	Micrograms per Liter
mg/L	Milligrams per Liter

Case Narrative

Samples for the above noted Work Order were received on 05/18/2018. The attached "Sample Receipt Checklist" documents the status of custody seals, container integrity, preservation, and temperature compliance.

Samples were analyzed according to the analytical methodology previously transmitted in the "Work Order Acknowledgement". Methodologies are also documented in the "Analytical Result" section for each sample. Quality control results are listed in the "QC Report" section. Sample association for the reported quality control is located at the end of each batch summary. If applicable, results are appropriately qualified in the Analytical Result and QC Report sections. The "Qualifiers" section documents the various qualifiers, units, and acronyms utilized in reporting. A copy of the laboratory's scope of accreditation is available upon request.

With the following exceptions, all sample analyses achieved analytical criteria.

Wet Chemistry:

Batch 118941, Method OXDMD_KMNO4_S, Samples 18051328-02C DUP2, -14C DUP3, and -16C DUP3: The RPDs between the samples and their duplicates were out of control. The corresponding sample result should be considered estimated.

Checklist completed by Keith Wierenga (eSignature) 19-May-18 (Date) Reviewed by: Chad Whelton (eSignature) 20-May-18 (Date)

Matrices: Soil & Water

Carrier name: FedEx

Shipping container/cooler in good condition?	Yes ☑	No ☐	Not Present ☐
Custody seals intact on shipping container/cooler?	Yes ☐	No ☐	Not Present ☑
Custody seals intact on sample bottles?	Yes ☐	No ☐	Not Present ☑
Chain of custody present?	Yes ☑	No ☐	
Chain of custody signed when relinquished and received?	Yes ☑	No ☐	
Chain of custody agrees with sample labels?	Yes ☑	No ☐	
Samples in proper container/bottle?	Yes ☑	No ☐	
Sample containers intact?	Yes ☑	No ☐	
Sufficient sample volume for indicated test?	Yes ☑	No ☐	
All samples received within holding time?	Yes ☑	No ☐	
Container/Temp Blank temperature in compliance?	Yes ☑	No ☐	
Sample(s) received on ice?	Yes ☑	No ☐	
Temperature(s)/Thermometer(s):	4.0/4.0 C	SR2	
Cooler(s)/Kit(s):			
Date/Time sample(s) sent to storage:	5/19/2018 9:06:09 AM		
Water - VOA vials have zero headspace?	Yes ☑	No ☐	No VOA vials submitted ☐
Water - pH acceptable upon receipt?	Yes ☑	No ☐	N/A ☐
pH adjusted?	Yes ☐	No ☑	N/A ☐
pH adjusted by:

System Monitoring Compounds							
42) Dibromofluoromethane	4.648	111	182632	19.90	ug/L		0.00
Spiked Amount 20.000	Range 85 - 115		Recovery = 99.50%				
45) 1,2-Dichloroethane-d4	5.171	65	177885	20.20	ug/L		0.00
Spiked Amount 20.000	Range 75 - 120		Recovery = 101.00%				
64) Toluene-d8	7.671	98	615517	20.26	ug/L		0.00
Spiked Amount 20.000	Range 85 - 110		Recovery = 101.30%				
85) Bromofluorobenzene	9.433	95	221934	20.54	ug/L		0.00
Spiked Amount 20.000	Range 80 - 110		Recovery = 102.70%				
Target Compounds							Qvalue
2) Dichlorodifluoromethane	1.167	85	31607	3.74	ug/L		99
3) Chloromethane	1.282	50	48735	2.99	ug/L		90
4) Vinyl chloride	1.353	62	37796	3.31	ug/L	#	38
5) Bromomethane	1.568	96	16036	1.39	ug/L		90
6) Chloroethane	1.640	64	39671	1.21	ug/L	#	61
7) Trichlorofluoromethane	1.812	101	38338	3.31	ug/L		97
8) Ethyl ether	2.019	59	27155	3.86	ug/L		97
9) Acrolein	2.127	56	37040	31.38	ug/L		92
10) 1,1-Dichloroethene	2.199	61	41216	4.28	ug/L		98
11) 1,1,2-Trichlorotrifluo...	2.206	151	23118	4.27	ug/L		98
12) Methyl iodide	2.327	142	28724	3.45	ug/L		95
13) Acetone	2.234	43	18409	2.60	ug/L		95
14) Chloroprene	3.373	53	45447	4.31	ug/L		99
15) Carbon disulfide	2.392	76	90839	4.44	ug/L		98
16) Allyl chloride	2.499	41	48925	3.88	ug/L		87
17) Methyl acetate	2.485	43	46105	3.19	ug/L	#	95
18) Acetonitrile	2.499	41	48925	3.88	ug/L		89
19) Methylene chloride	2.607	49	43239	3.55	ug/L		92
20) trans-1,2-Dichloroethene	2.858	61	45556	4.21	ug/L		97
21) t-Butanol	2.729	59	48671	16.82	ug/L	#	76
22) Acrylonitrile	2.822	53	21858	3.87	ug/L		91
23) Methyl tert-butyl ether	2.850	73	92128	3.64	ug/L		97
24) Hexane	3.130	57	32991	4.41	ug/L		94
25) 1,1-Dichloroethane	3.294	63	62323	4.33	ug/L		96
26) Diisopropyl ether	3.337	45	94027	3.38	ug/L	#	23
27) Vinyl acetate	3.302	86	5659	7.82	ug/L	#	1
28) Ethyl tert butyl ether	3.753	59	91455	3.59	ug/L		96
29) 2,2-Dichloropropane	3.961	77	44197	4.66	ug/L		97
30) cis-1,2-Dichloroethene	3.953	61	53356	3.87	ug/L		99
31) 2-Butanone	3.953	43	35378	3.71	ug/L		90
32) Ethyl Acetate	4.011	43	56163	3.33	ug/L	#	94
33) Methyl acrylate	4.068	55	49635	3.94	ug/L		96
34) Propionitrile	4.741	54	4584	5.47	ug/L	#	81

Quantitation Report (QT Reviewed)

Data Path : D:\msdchem\1\DATA\8V180515\
Data File : 15MAY38.D
Acq On : 15 May 2018 8:18 pm
Operator : EMR
Sample : 4PPB
Misc : IS/SS 200-20081
ALS Vial : 27 Sample Multiplier: 1

Quant Time: May 16 10:31:33 2018
