Tribal Allotment Beach	1	27				8.5%			
All soil	154	21	0.5	1,015	214	14%	1.2%	102%	44%
All beach sediment	24	30	4.3	2,099	1125	11%	3.3%	78%	68%
All DUs	178	22	0.5	2,099	214	14%	1.2%	102%	47%

N = number of DUs

Margin of error (ME) is the half-width of the confidence interval (assuming a normal distribution of means): (upper confidence limit [UCL]-lower confidence limit [LCL])/2, in units of concentration (ppm).

Relative error (RE) is the ME divided by the estimate of the mean, expressed as a percentage.

Table 6-2. IVBA Measured in Soil as part of the 2014 Upland Soils Study

Locations	Analyte	N	Average (%)	Standard Deviation	Minimum (%)	Maximum (%)
ADAs	Aluminum	20	20.2	5.7	9.4	30.6

	Zinc	3	46.5	5.7	42.7	53.0

Table 6-3. Lowest and Highest COPC Concentrations Measured in Fish

COPC	Minimum (mg/kg ww)	Maximum (mg/kg ww)	Species, Low	Species, High
Mercury	0.0753	0.585	Kokanee	Sucker
TEQ	3.66×10^{-8}	1.15×10^{-6}	Burbot	Whitefish
PCB Aroclors	0.0031	0.217	Burbot	Sucker
Lead	0.02	0.775	Northern pike	Sucker
Thallium	0.0042	0.0739	Sturgeon	Walleye

Table 6-4. Recommended Dietary Allowances and Reference Doses for Iron, Manganese, and Cobalt

COPC	RDA, Adults		AI/ADI, Adults		TUIL[a]	RfD (mg/kg-day)	RfD[b] (mg/day)
	Male	Female	Male	Female			
Cobalt	NA	NA	5-8 µg/day[c]	5-8 µg/day[c]	NA	3.0E-04	0.024
Iron	8 mg/day	18 mg/day	NA	NA	45 mg/day	7.0E-01	56
Manganese	NA	NA	2.3 mg/day[d]	1.8 mg/day[d]	11 mg/day	0.140	11.20

NA = not available

[a]The TUIL is the highest level of daily nutrient intake that it likely to pose no risk of adverse health effects in almost all individuals)

[b]RfD is an estimate (with uncertainty spanning perhaps an order of magnitude) of a daily oral exposure to the human population (including sensitive subgroups) that is likely to be without an appreciable risk of deleterious effects during a lifetime. Unit conversion done using default adult body weight of 80 kg (EPA, 2014a)

[c]Average adult daily intake.

[d]Adequate intake

Sources: EPA (2019a) (RfD); NAP (2001) (RDA, AI, TUIL).

Table 6-5. Thallium in Sediment, Surface Water, and Fish from the UCR. Sampling Results by Reach.

Reach	Analyte	Sediment					Surface Water, Disturbed, Total					Fish				
		Number Detects / Number of Samples			Detection Frequency (%)	Mean Concentration (ND=1/2DL) (mg/kg)	Number Detects / Number of Samples			Detection Frequency (%)	Mean Detected Concentration (µg/L)	Number Detects / Number of Samples			Detection Frequency (%)	Mean Detected Concentration (mg/kg ww)

95%: 95% estimated using ProUCL

95UTL95; non-parametric 95% upper tolerance limit for the 95%.

mean = arithmetic mean for COPCs without non-detects; Kaplan Meier mean for COPCs with non-detects

Residential Screening Level calculated using Hazard quotient = 1, Cancer risk = 10^{-4}

[A] Antimony data not included in NURE data set. Value is 95UTL90 by unspecified method of bootstrapping from ECY 2019.

[B] Residential screening levels for lead are approximately 50 mg/kg when the lead risk benchmark is P3; 200 mg/kg when the lead risk benchmark is P5; and 400 mg/kg when the lead risk benchmark is P8

ECY. (2019). Upland Regional Soil Background Characterization in Northeast Washington Watersheds. Washington State Department of Ecology. Publication No. 19-03-014. https://fortress.wa.gov/ecy/publications/SummaryPages/1903014 html.

Table 7-1. Summary of Residential Soil Exposure Areas that Exceeded Risk Benchmarks for Both Lead and Non-Lead COPCs for the Current Residential (Non-Beach DUs) Child Population when Risks are Summed Across Pathways

	Total # of DUs with HI >1 (non-lead analysis)	**# of Exposure Areas > P3 (~50 ppm Pb in soil)**	**# of Exposure Areas > P5 (~200 ppm Pb in soil)**	**# of Exposure Areas > P8 (~400 ppm Pb in soil)**
Lead (not including fish consumption)[a]	Not applicable	389 of 588 residential DUs	87 of 588 residential DUs	12 of 588 residential DUs
			# of DUs that Exceed both Lead and Non-Lead Benchmarks	
COPCs other than Lead (burbot consumption, RME)	• 588 of 588 (developmental and nervous systems) • 43 of 588 (skin/hair/nails system)	• 389 (developmental and nervous systems) • 42 (skin/hair/nails system)	• 87 (developmental and nervous systems) • 39 (skin/hair/nails system)	• 12 (developmental and nervous systems) • 12 (skin/hair/nails system)
COPCs other than lead (kokanee consumption, RME)	• 219 of 588 (nervous system) • 588 of 588 (skin/hair/nails system)	• 176 (nervous system) • 389 (skin/hair/nails system)	• 44 (nervous system) • 87 (skin/hair/nails system)	• 7 (nervous system) • 12 (skin/hair/nails system)
COPCs other than lead (northern pike consumption, RME)	• 588 of 588 (nervous and skin/hair/nails systems)	• 389 (nervous and skin/hair/nails systems)	• 87 (nervous and skin/hair/nails systems)	• 12 (nervous and skin/hair/nails systems)
COPCs other than lead (rainbow trout consumption, RME)	• 577 of 588 (nervous system) • 588 of 588 (skin/hair/nails system)	• 383 (nervous system) • 389 (skin/hair/nails system)	• 83 (nervous system) • 87 (skin/hair/nails system)	• 12 (nervous system) • 12 (skin/hair/nails system)
COPCs other than lead (smallmouth bass consumption, RME)	• 588 of 588 (developmental, nervous, and skin/hair/nails systems)	• 389 (developmental, nervous, and skin/hair/nails systems)	• 87 (developmental, nervous, and skin/hair/nails systems)	• 12 (developmental, nervous, and skin/hair/nails systems)
COPCs other than lead (sturgeon consumption, RME)	• 588 of 588 (nervous system) • 18 of 588 (skin/hair/nails system)	• 389 (nervous system) • 17 (skin/hair/nails system)	• 87 (nervous system) • 17 (skin/hair/nails system)	• 12 (nervous system) • 11 (skin/hair/nails system)

Table 7-1. Summary of Residential Soil Exposure Areas that Exceeded Risk Benchmarks for Both Lead and Non-Lead COPCs for the Current Residential (Non-Beach DUs) Child Population when Risks are Summed Across Pathways

	Total # of DUs with HI >1 (non-lead analysis)	**# of Exposure Areas > P3 (~50 ppm Pb in soil)**	**# of Exposure Areas > P5 (~200 ppm Pb in soil)**	**# of Exposure Areas > P8 (~400 ppm Pb in soil)**
COPCs other than lead (sucker consumption, RME)	• 588 of 588 (developmental, nervous, and reproductive systems) • 578 of 588 (skin/hair/nails system)	• 389 (developmental, nervous, and reproductive systems) • 389 (skin/hair/nails system)	• 87 (developmental, nervous, and reproductive systems) • 87 (skin/hair/nails system)	• 12 (developmental, nervous, and reproductive systems) • 12 (skin/hair/nails system)
COPCs other than lead (walleye consumption, RME)	• 2 of 588 (cardiovascular system) • 588 of 588 (developmental, nervous, and skin/hair/nails systems) • 9 of 588 (endocrine system)	• 2 (cardiovascular system) • 389 (developmental, nervous, and skin/hair/nails systems) • 5 (endocrine system)	• 2 (cardiovascular system) • 87 (developmental, nervous, and skin/hair/nails systems) • 1 (endocrine system)	• 2 (cardiovascular system) • 12 (developmental, nervous, and skin/hair/nails systems)
COPCs other than lead (whitefish consumption, RME)	• 588 of 588 (nervous, reproductive, and skin/hair/nails systems)	• 389 (nervous, reproductive, and skin/hair/nails systems)	• 87 (nervous, reproductive, and skin/hair/nails systems)	• 12 (nervous, reproductive, and skin/hair/nails systems)

[a]Estimates of lead results by fish species are shown in Appendix 5.

Table 7-2. Summary of Residential Beach Exposure Areas that Exceeded Risk Benchmarks for Both Lead and Non-Lead COPCs for the Current Residential (Beach DUs) Child Population, not Including Fish Consumption[a]

	# of Exposure Areas > P3	**# of Exposure Areas > P5**	**# of Exposure Areas > P8**
Lead	19 of 21 residential beach DUs	5 of 21 residential beach DUs	None
COPCs other than Lead (RME)	None	None	None

[a]Estimates of lead results by fish species are shown in Appendix 5.

Table 7-3. Summary of Upland Soil Exposure Areas that Exceeded Risk Benchmarks for Both Lead and Non-Lead COPCs for the Future Residential Child Population when Risks are Summed Across Pathways

	Total # of ADAs with HI >1 (non-lead analysis)	**# of Exposure Areas > P3 (~50 ppm Pb in soil)**	**# of Exposure Areas > P5 (~200 ppm Pb in soil)**	**# of Exposure Areas > P8 (~400 ppm Pb in soil)**
Lead (not including fish consumption)[a]	Not applicable	139 of 142 upland ADAs	68 of 142 upland ADAs	15 of 142 upland ADAs
		# of ADAs that Exceed both Lead and Non-Lead Benchmarks		
COPCs other than Lead (burbot consumption, RME)	• 142 of 142 (developmental and nervous systems) • 55 of 142 (skin/hair/nails system)	• 139 (developmental and nervous systems) • 55 (skin/hair/nails system)	• 68 (developmental and nervous systems) • 51 (skin/hair/nails system)	• 15 (developmental and nervous systems) • 15 (skin/hair/nails system)

COPCs other than lead (northern pike consumption, RME)	• 142 of 142 (nervous and skin/hair/nails systems)	• 139 (nervous and skin/hair/nails systems)	• 68 (nervous and skin/hair/nails systems)	• 15 (nervous and skin/hair/nails systems)
COPCs other than lead (rainbow trout consumption, RME)	• 142 of 142 (nervous and skin/hair/nails systems)	• 139 (nervous and skin/hair/nails systems)	• 68 (nervous and skin/hair/nails systems)	• 15 (nervous and skin/hair/nails systems)
COPCs other than lead (smallmouth bass consumption, RME)	• 142 of 142 (developmental, nervous, and skin/hair/nails systems)	• 139 (developmental, nervous, and skin/hair/nails systems)	• 68 (developmental, nervous, and skin/hair/nails systems)	• 15 (developmental, nervous, and skin/hair/nails systems)
COPCs other than lead (sturgeon consumption, RME)	• 142 of 142 (nervous system) • 21 of 142 (skin/hair/nails system)	• 139 (nervous system) • 21 (skin/hair/nails system)	• 68 (nervous system) • 21 (skin/hair/nails system)	• 15 (nervous system) • 13 (skin/hair/nails system)

Table 7-3. Summary of Upland Soil Exposure Areas that Exceeded Risk Benchmarks for Both Lead and Non-Lead COPCs for the Future Residential Child Population when Risks are Summed Across Pathways

	Total # of ADAs with HI >1 (non-lead analysis)	**# of Exposure Areas > P3 (~50 ppm Pb in soil)**	**# of Exposure Areas > P5 (~200 ppm Pb in soil)**	**# of Exposure Areas > P8 (~400 ppm Pb in soil)**
COPCs other than lead (sucker consumption, RME)	• 142 of 142 (developmental, nervous, reproductive, and skin/hair/nails systems)	• 139 (developmental, nervous, reproductive, and skin/hair/nails systems)	• 68 (developmental, nervous, reproductive, and skin/hair/nails systems)	• 15 (developmental, nervous, reproductive, and skin/hair/nails systems)
COPCs other than lead (walleye consumption, RME)	• 1 of 142 (cardiovascular system) • 142 of 142 (developmental, nervous, and skin/hair/nails systems) • 3 of 142 (endocrine system)	• 1 (cardiovascular system) • 139 (developmental, nervous, and skin/hair/nails systems) • 3 (endocrine system)	• 1 (cardiovascular system) • 68 (developmental, nervous, and skin/hair/nails systems)	• 1 (cardiovascular system) • 15 (developmental, nervous, and skin/hair/nails systems)
COPCs other than lead (whitefish consumption, RME)	• 142 of 142 (nervous, reproductive, and skin/hair/nails systems)	• 139 (nervous, reproductive, and skin/hair/nails systems)	• 68 (nervous, reproductive, and skin/hair/nails systems)	• 15 (nervous, reproductive, and skin/hair/nails systems)

[a]Estimates of lead risk by fish species are shown in Appendix 5.

Table 7-4. Summary of Residential Lead Results, not Including Fish Consumption

	Current Child Resident Population (No Beach on Property)			Future Child Resident Population		
	> P3 (~50 ppm Pb in soil)	**> P5 (~200 ppm Pb in soil)**	**> P8 (~400 ppm Pb in soil)**	**> P3 (~50 ppm Pb in soil)**	**> P5 (~200 ppm Pb in soil)**	**> P8 (~400 ppm Pb in soil)**
# DUs or ADAs*	389** of 588	87 of 588	12 of 588	139 of 142	68 of 142	15 of 142
# Current play areas	12 of 18	6 of 18	2 of 18	NA	NA	NA
# Current houses	137 of 202	28 of 202	2 of 202	NA	NA	NA
# Current gardens	77 of 145	8 of 145	0 of 145	NA	NA	NA

Note: Fish consumption is not included in the above counts.

*Assuming full-time residential land use at residential soil non-house DUs and ADAs without residences is likely to overestimate risk.

**Not all DU types are included in Table 7-4; therefore, the number of play areas, house and gardens do not equal the total number of DUs that are shown for the current child resident population. For example, in the column for P3 for current child resident population, $12+137+77 \neq 389$ and $18+202+145 \neq 588$.

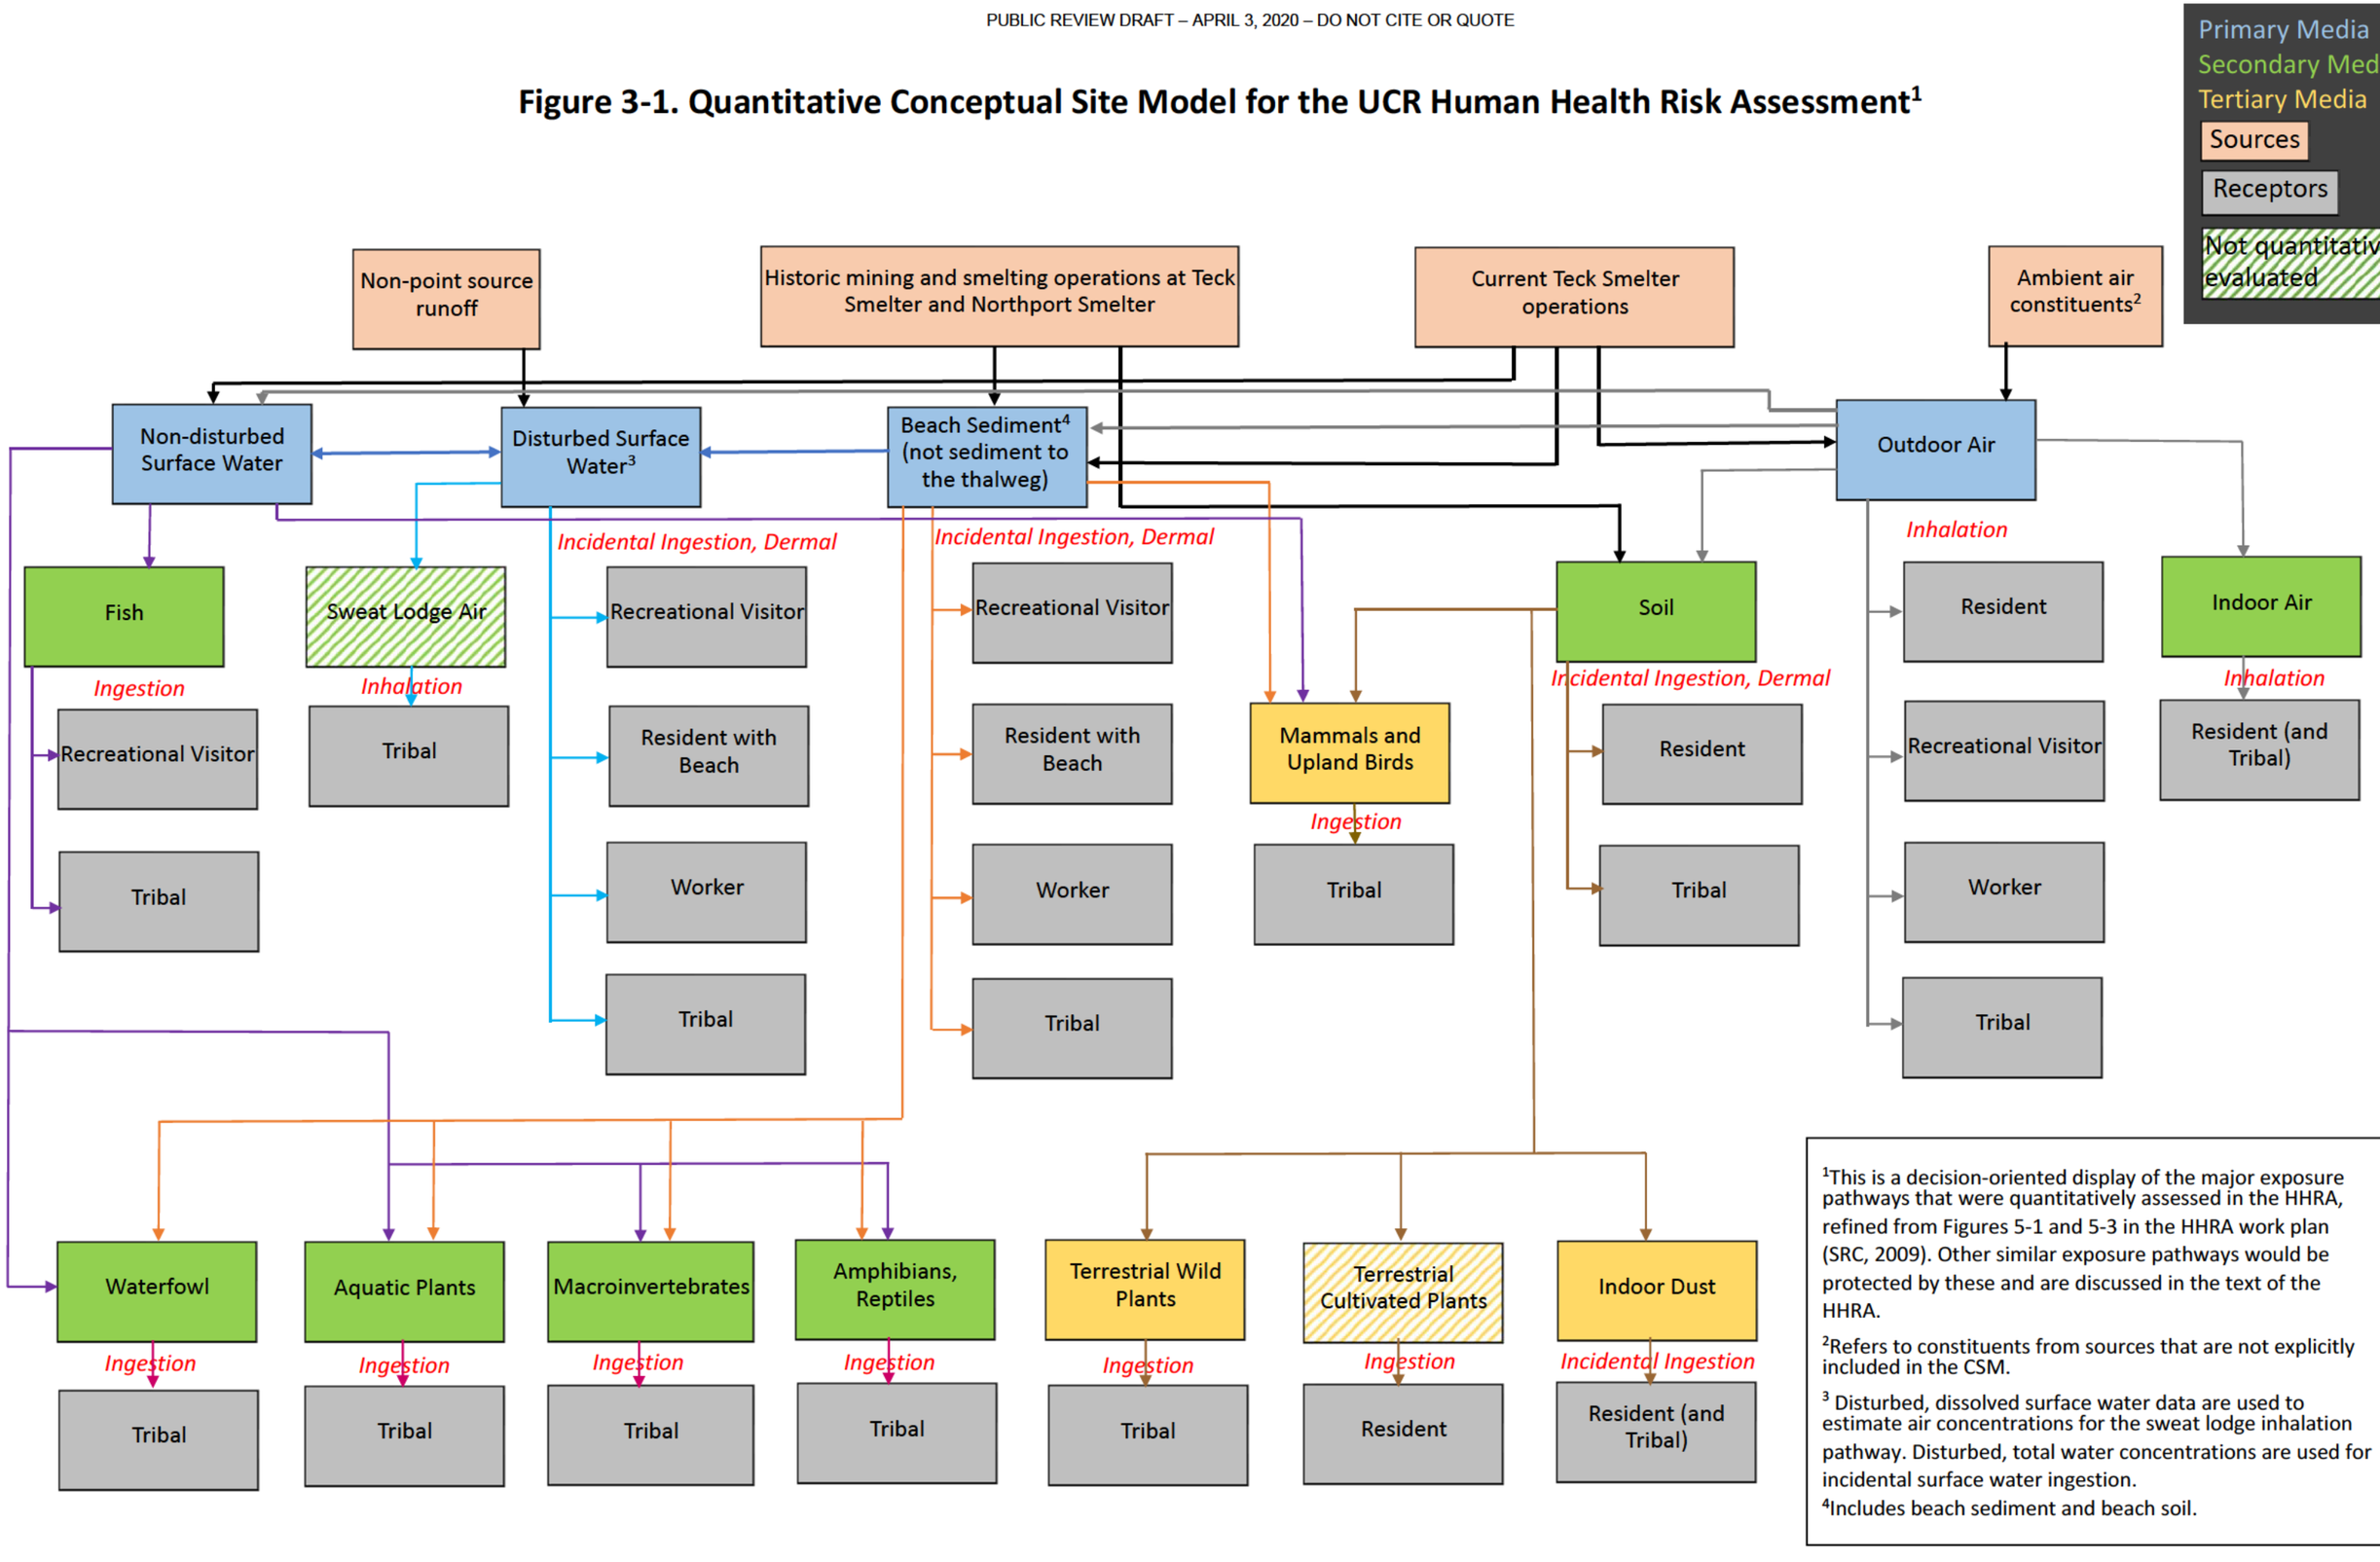
Figure 3-1. Quantitative Conceptual Site Model for the UCR Human Health Risk Assessment[1]



[1]This is a decision-oriented display of the major exposure pathways that were quantitatively assessed in the HHRA, refined from Figures 5-1 and 5-3 in the HHRA work plan (SRC, 2009). Other similar exposure pathways would be protected by these and are discussed in the text of the HHRA.

[2]Refers to constituents from sources that are not explicitly included in the CSM.

[3] Disturbed, dissolved surface water data are used to estimate air concentrations for the sweat lodge inhalation pathway. Disturbed, total water concentrations are used for incidental surface water ingestion.

[4]Includes beach sediment and beach soil.

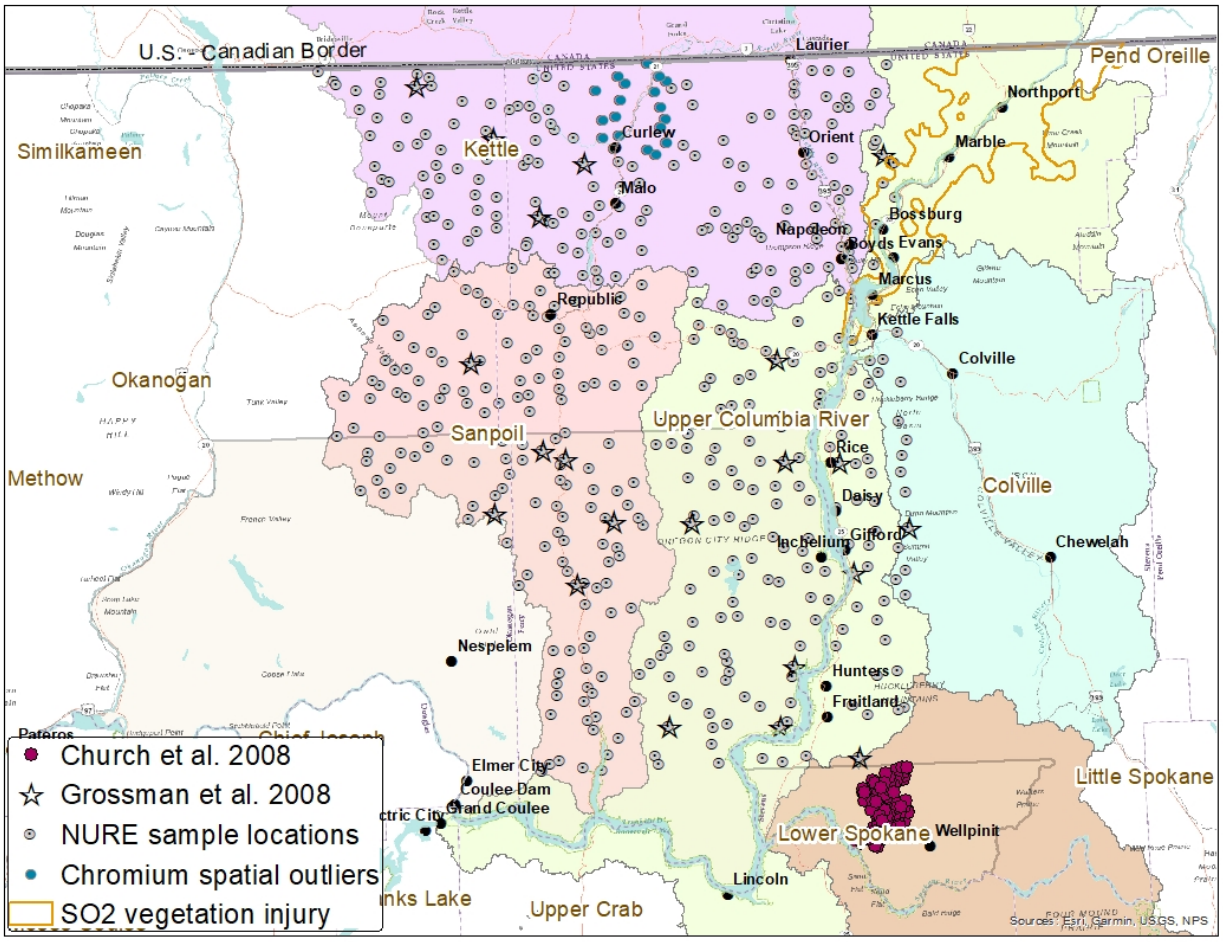

Figure 6-2. Comparison of Lead Concentrations Measured in Site Residential Soil to Lead Risk Benchmarks and Estimated Background used in this HHRA.

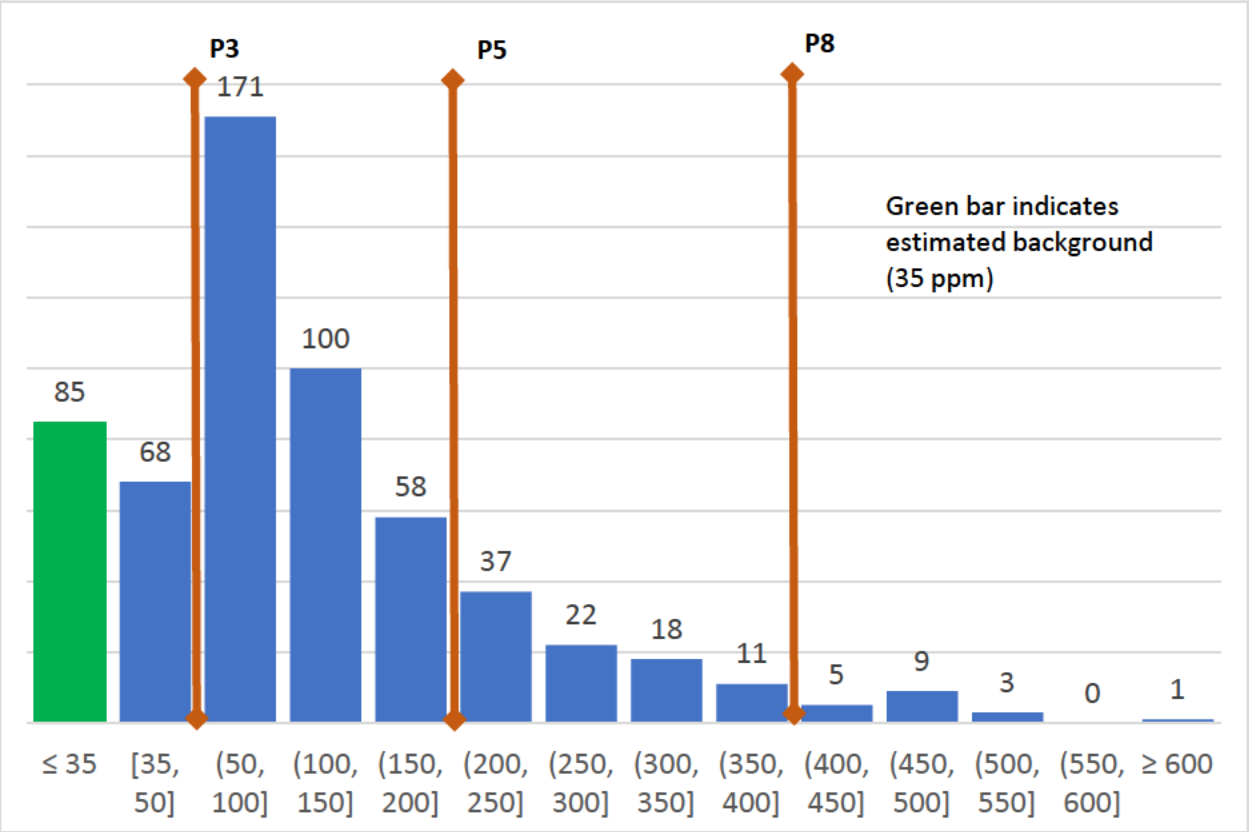
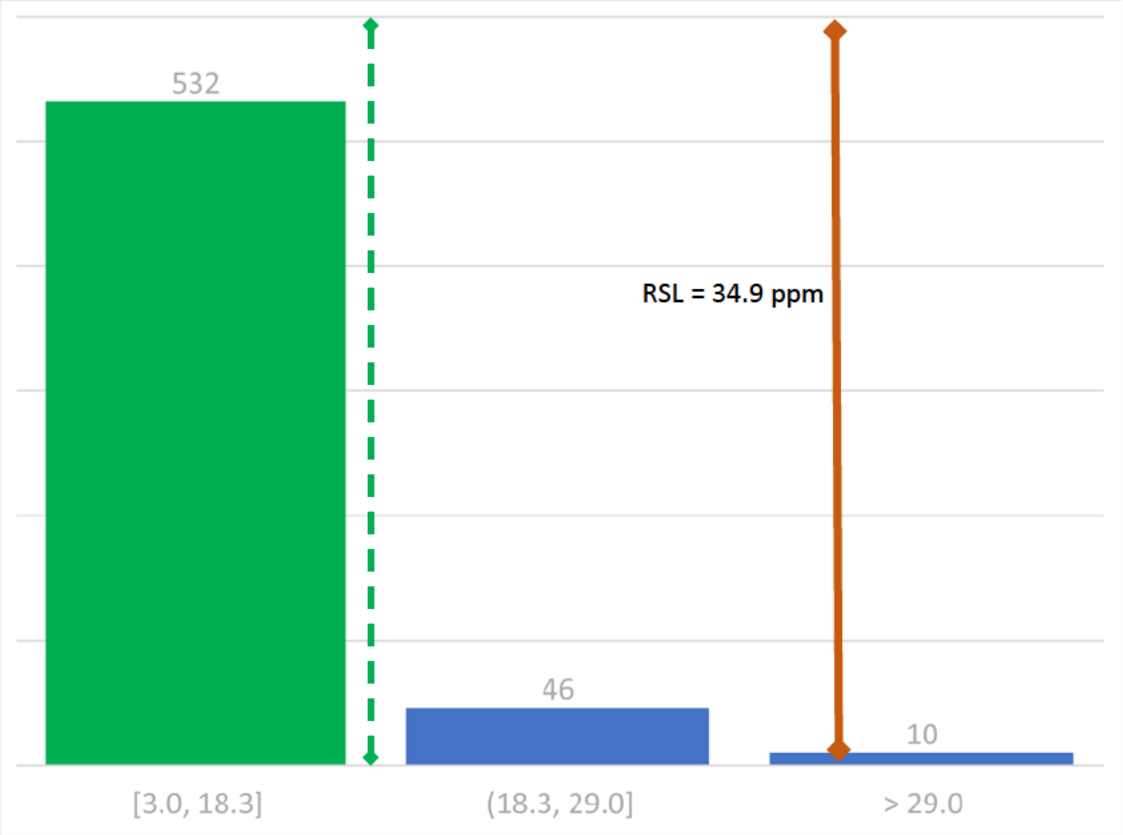


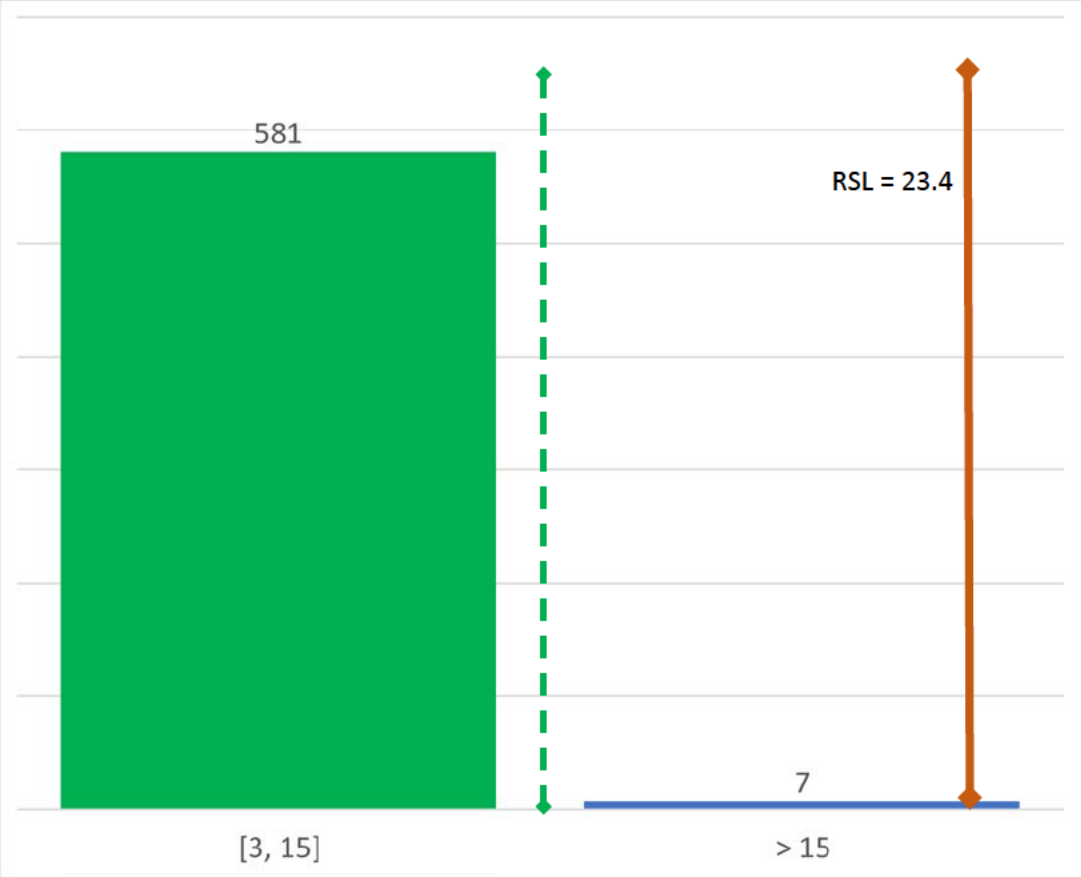
Ranges of concentration ('bins') are shown on the x-axis. The number of DUs in each of the bins appears at the top of each bar. With the exception of the first and last bins, each bin includes the concentration at the lower limit and excludes the concentration at the upper limit. For example, the bin labeled '(400-450]' includes DUs with lead concentrations equal to 400 but does not include DUs with lead concentrations equal to 450 ppm. The orange vertical lines are located at soil lead concentrations that correspond to the IEUBK model's prediction of a probability of 5% or more that a child's blood lead concentration would equal or exceed 3 µg/dL (***P3***), 5 µg/dL (***P5***) and 8 µg/dL (***P8***). See Section 3.4.1 for more details on the IEUBK model.

Figure 6-3. Comparison of Arsenic Concentrations Measured in Site Residential Soil to Site-specific Background Data



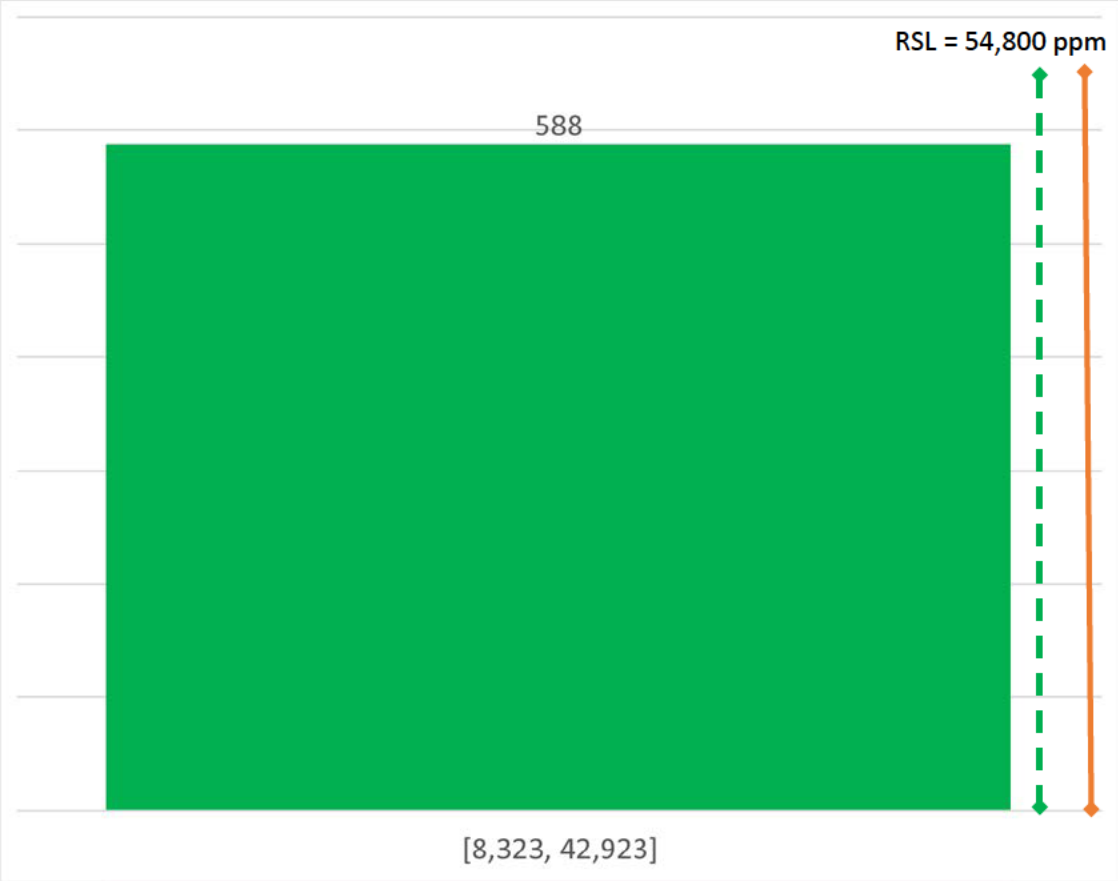
Ranges of concentration ('bins') are shown on the x-axis. The number of DUs in each of the bins appears at the top of each bar. With the exception of the first and last bins, each bin includes the concentration at the lower limit and excludes the concentration at the upper limit. For example, the bin labeled '(18.3, 29.0]' includes DUs with arsenic concentrations equal to 18.3 but does not include DUs with arsenic concentrations equal to 29.0 ppm. The green dashed vertical line is located at the estimated background concentration of arsenic in soil (18.3 ppm). The orange vertical line is located at the estimated Residential Screening Level (RSL). See Appendix 4 for more details on the estimation of background concentration.

Figure 6-4. Comparison of Cobalt Concentrations Measured in Site Residential Soil to Site-specific Background Data



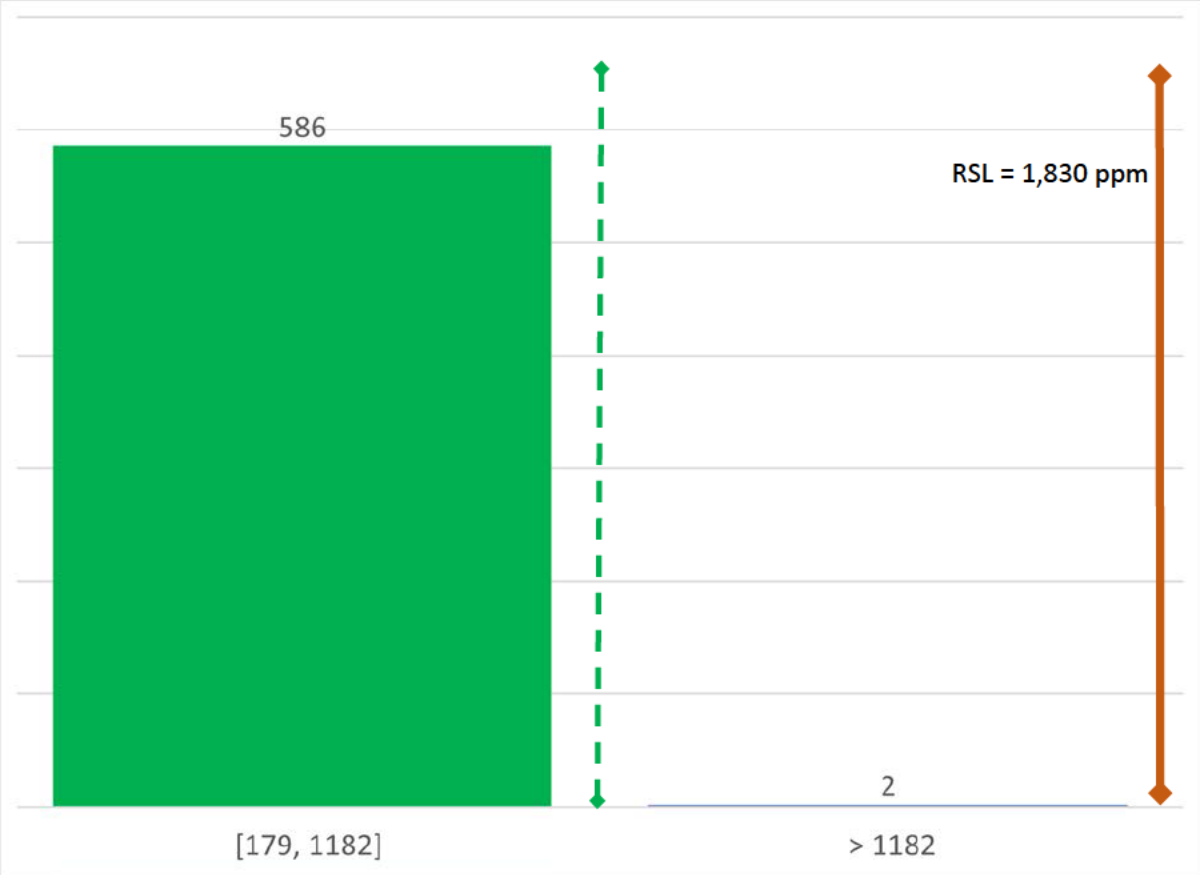
Ranges of concentration ('bins') are shown on the x-axis. The number of DUs in each of the bins appears at the top of each bar. Each bin includes the concentration at the lower limit and excludes the concentration at the upper limit. For example, the bin labeled '(3, 15]' includes DUs with cobalt concentrations equal to 3 but does not include DUs with cobalt concentrations equal to 15 ppm. The green dashed vertical line is located at the estimated background concentration of cobalt in soil (15 ppm). The orange vertical line is located at the estimated Residential Screening Level (RSL). See Appendix 4 for more details on the estimation of background concentration.

Figure 6-5. Comparison of Iron Concentrations Measured in Site Residential Soil to Site-specific Background Data



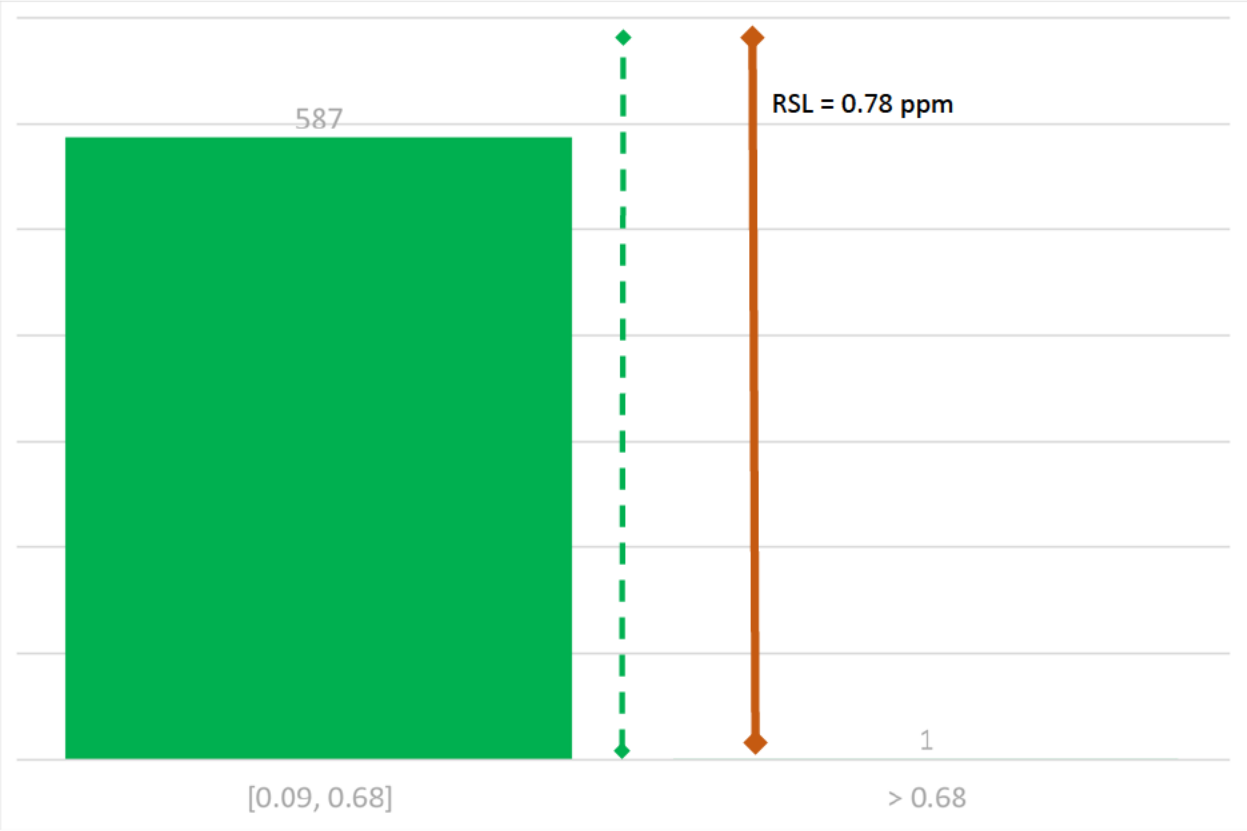
Ranges of concentration ('bins') are shown on the x-axis. The number of DUs in the bin appears at the top of each bar. The bin includes the concentrations at the lower and upper limit. All of these data are below the background concentration of iron (51,690 ppm), represented by the green dotted vertical line, and the estimated Residential Screening Level (RSL), represented by the orange vertical line. See Appendix 4 for more details on the estimation of background concentration.

Figure 6-6. Comparison of Manganese Concentrations Measured in Site Residential Soil to Site-specific Background Data



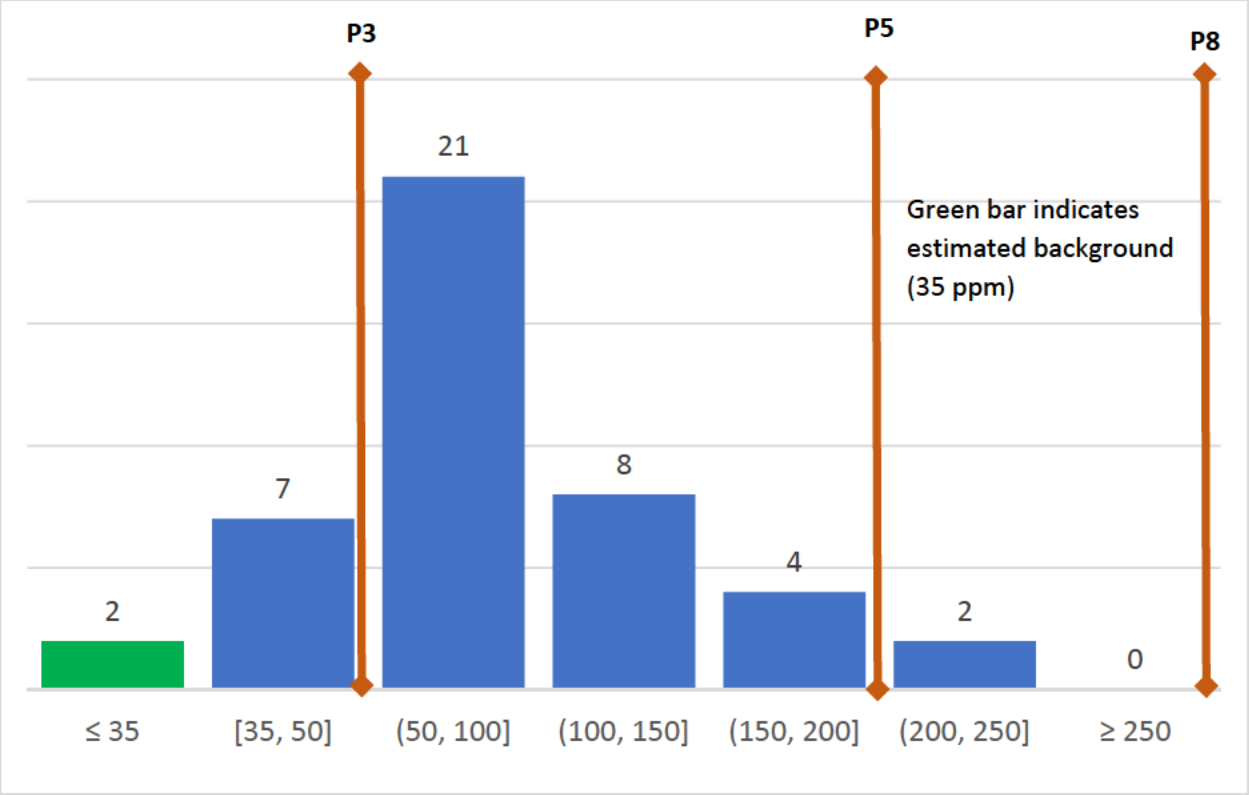
Ranges of concentration ('bins') are shown on the x-axis. The number of DUs in each of the bins appears at the top of each bar. Each bin includes the concentration at the lower limit and excludes the concentration at the upper limit. The green dashed vertical line is located at the estimated background concentration of manganese in soil (1,182 ppm). The orange vertical line is located at the estimated Residential Screening Level (RSL). See Appendix 4 for more details on the estimation of background concentration.

Figure 6-7. Comparison of Thallium Concentrations Measured in Site Residential Soil to Site-specific Background Data



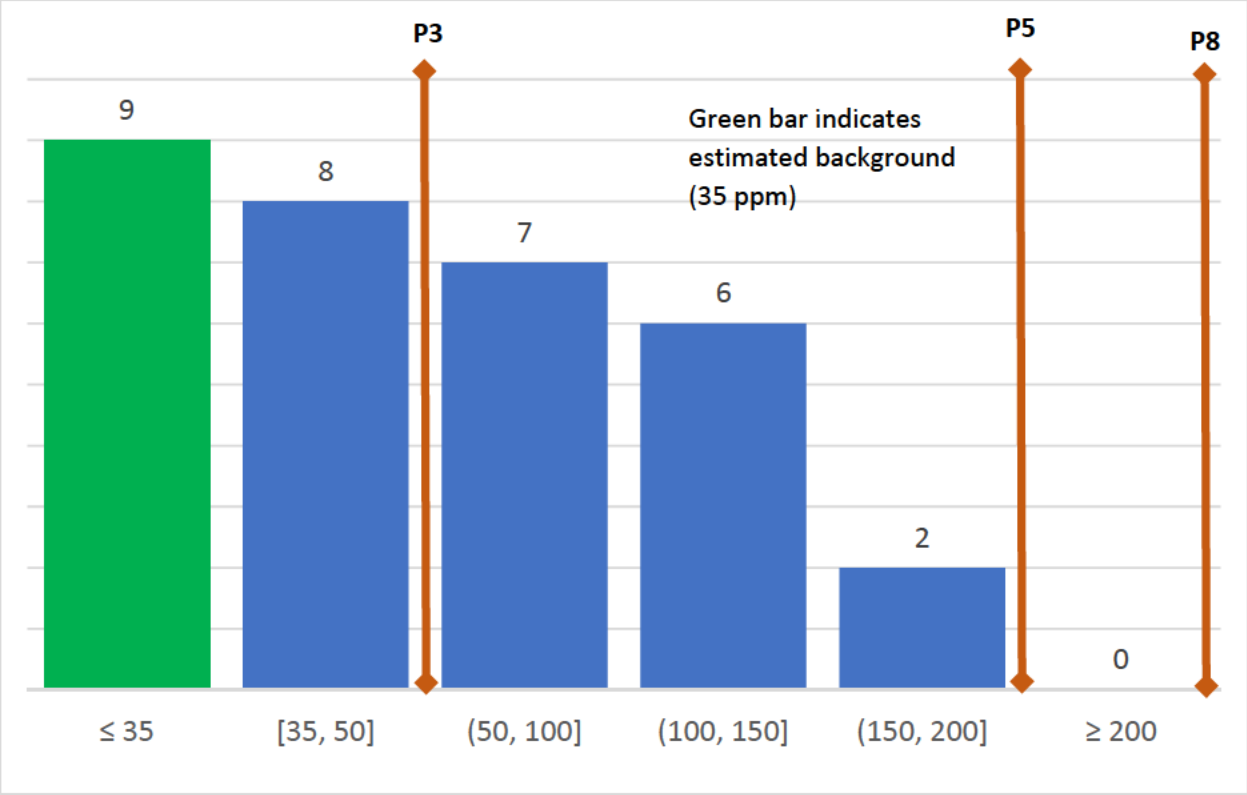
Ranges of concentration ('bins') are shown on the x-axis. The number of DUs in each of the bins appears at the top of each bar. Each bin includes the concentration at the lower limit and the concentration at the upper limit. For example, the bin labeled '(0.09, 0.68]' includes DUs with thallium concentrations between 0.09 and 0.68 ppm. The green dashed vertical line is located at the estimated background concentration of thallium in soil (0.68 ppm). The orange vertical line is located at the estimated Residential Screening Level (RSL). See Appendix 4 for more details on the estimation of background concentration.

Figure 6-8. Comparison of Lead Concentrations Measured in Agricultural Soil DUs to Lead Risk Benchmarks and Estimated Background used in this HHRA.



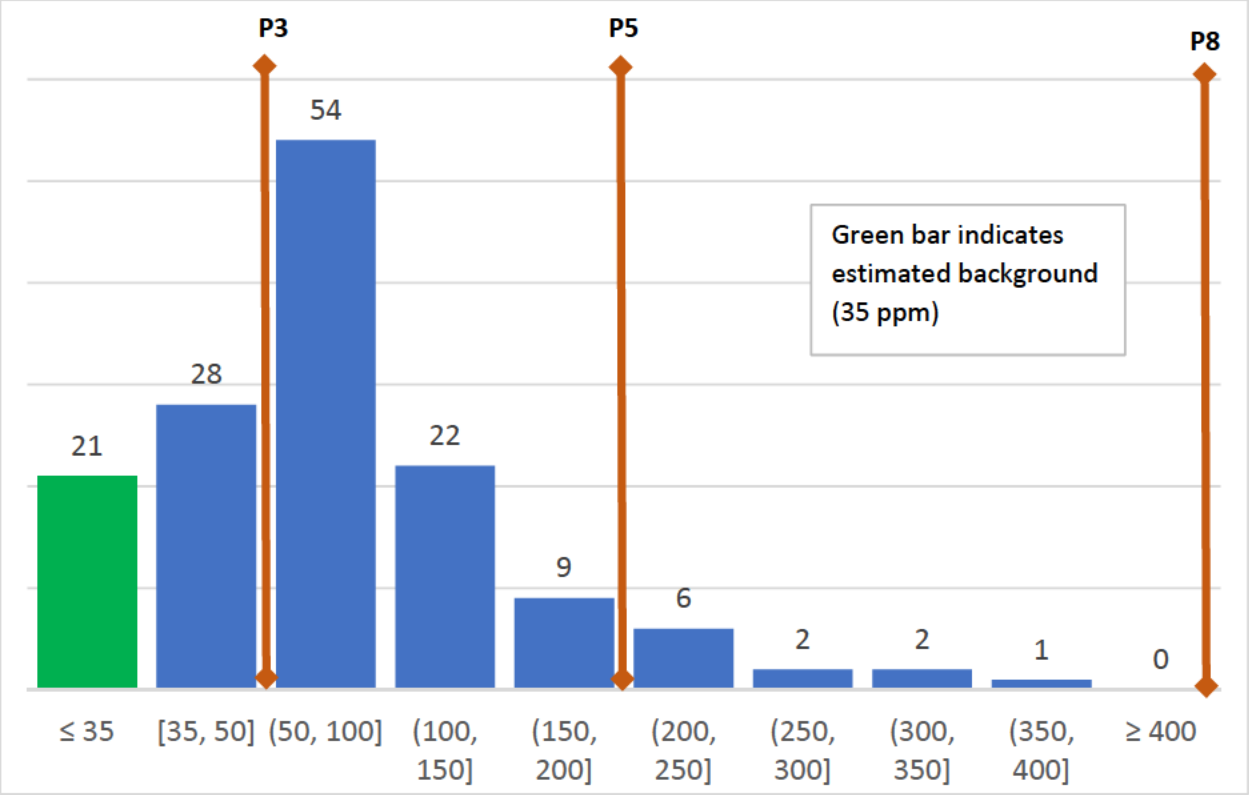
Ranges of concentration ('bins') are shown on the x-axis. The number of DUs in each of the bins appears at the top of each bar. With the exception of the first and last bins, each bin includes the concentration at the lower limit and excludes the concentration at the upper limit. For example, the bin labeled '(50, 100]' includes DUs with lead concentrations equal to 50 but does not include DUs with lead concentrations equal to 100 ppm. The orange vertical lines are located at soil lead concentrations that correspond to the IEUBK model's prediction of a probability of 5% or more that a child's blood lead concentration would equal or exceed 3 µg/dL (***P3***), 5 µg/dL (***P5***) and 8 µg/dL (***P8***). See section 3.4.1 for more details on the IEUBK model.

Figure 6-9. Comparison of Lead Concentrations Measured in Animal Activity Area Soil DUs to Lead Risk Benchmarks and Estimated Background used in this HHRA.



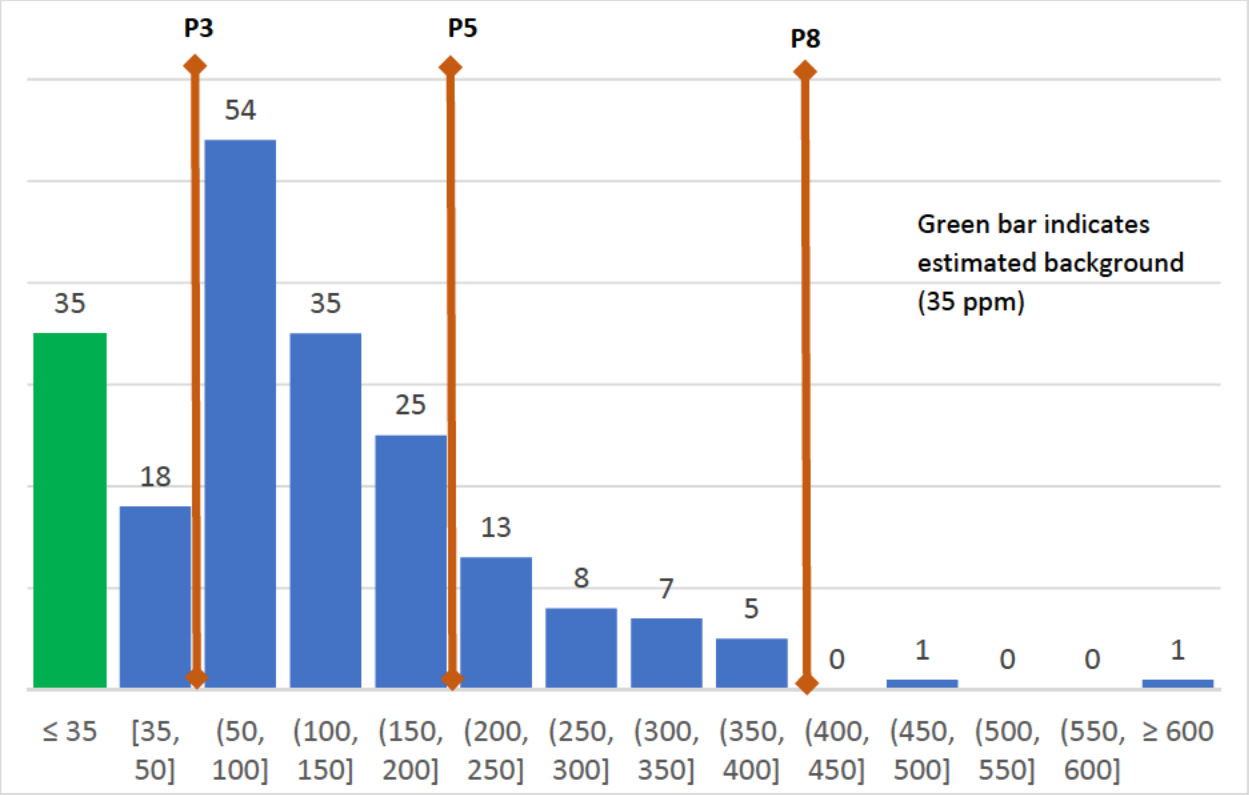
Ranges of concentration ('bins') are shown on the x-axis. The number of DUs in each of the bins appears at the top of each bar. With the exception of the first and last bins, each bin includes the concentration at the lower limit and excludes the concentration at the upper limit. For example, the bin labeled '(50, 100]' includes DUs with lead concentrations equal to 50 but does not include DUs with lead concentrations equal to 100 ppm. The orange vertical lines are located at soil lead concentrations that correspond to the IEUBK model's prediction of a probability of 5% or more that a child's blood lead concentration would equal or exceed 3 µg/dL (***P3***), 5 µg/dL (***P5***) and 8 µg/dL (***P8***). See section 3.4.1 for more details on the IEUBK model.

Figure 6-10. Comparison of Lead Concentrations Measured in Garden Soil DUs to Lead Risk Benchmarks and Estimated Background used in this HHRA.



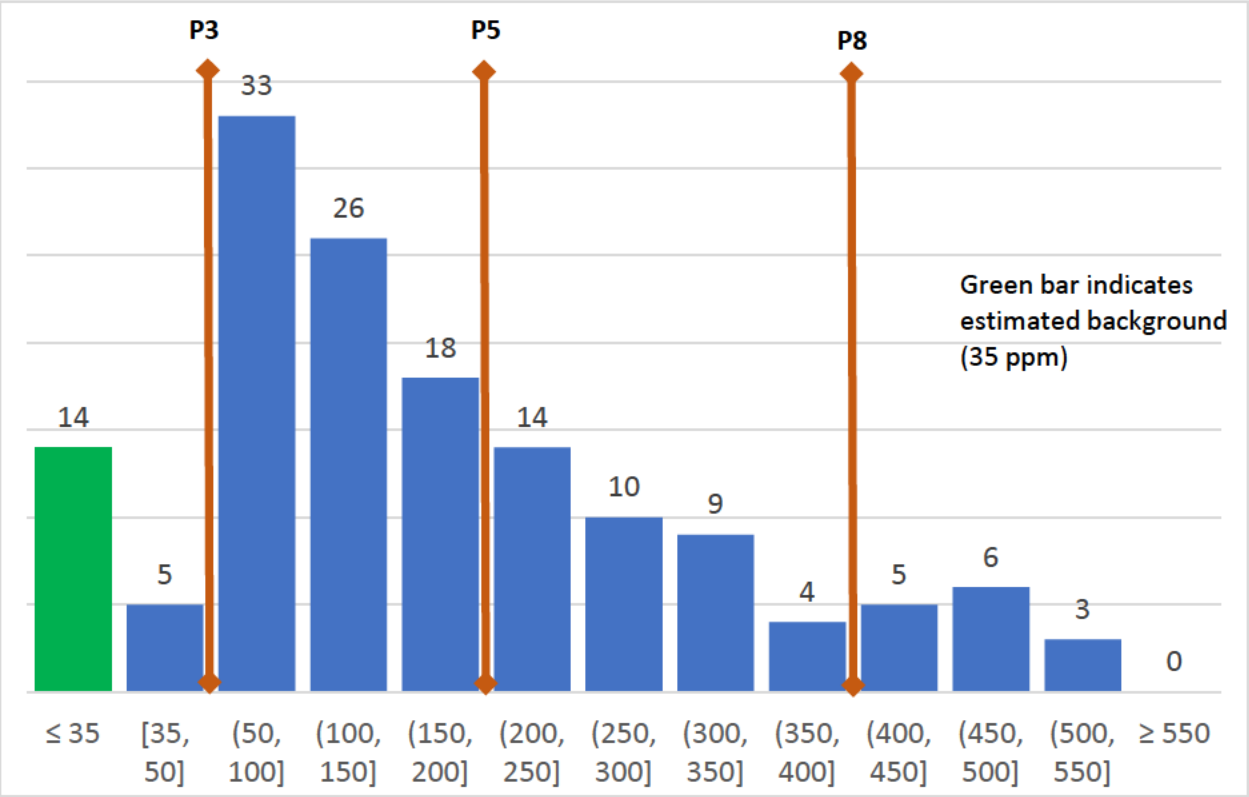
Ranges of concentration ('bins') are shown on the x-axis. The number of DUs in each of the bins appears at the top of each bar. With the exception of the first and last bins, each bin includes the concentration at the lower limit and excludes the concentration at the upper limit. For example, the bin labeled '(50, 100]' includes DUs with lead concentrations equal to 50 but does not include DUs with lead concentrations equal to 100 ppm. The orange vertical lines are located at soil lead concentrations that correspond to the IEUBK model's prediction of a probability of 5% or more that a child's blood lead concentration would equal or exceed 3 µg/dL (***P3***), 5 µg/dL (***P5***) and 8 µg/dL (***P8***). See section 3.4.1 for more details on the IEUBK model.

Figure 6-11. Comparison of Lead Concentrations Measured in House Soil DUs to Lead Risk Benchmarks and Estimated Background used in this HHRA.



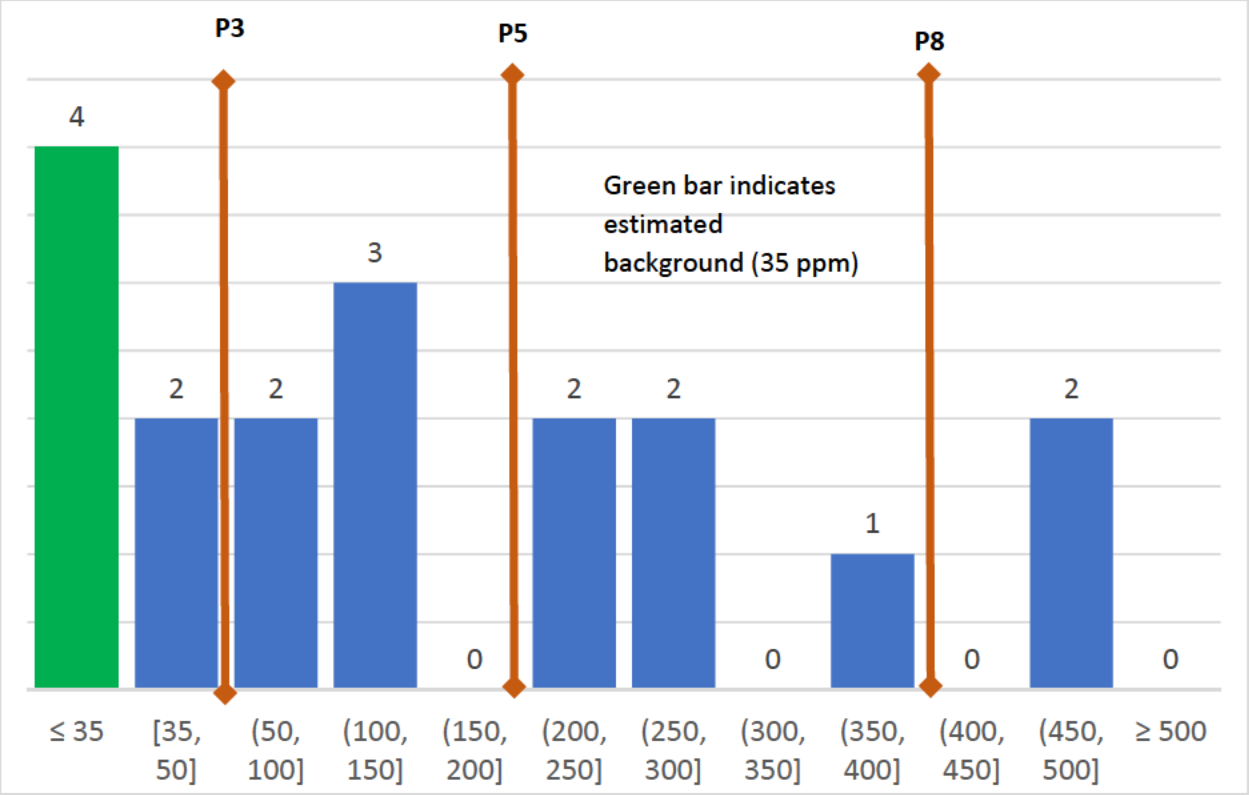
Ranges of concentration ('bins') are shown on the x-axis. The number of DUs in each of the bins appears at the top of each bar. With the exception of the first and last bins, each bin includes the concentration at the lower limit and excludes the concentration at the upper limit. For example, the bin labeled '(50, 100]' includes DUs with lead concentrations equal to 50 but does not include DUs with lead concentrations equal to 100 ppm. The orange vertical lines are located at soil lead concentrations that correspond to the IEUBK model's prediction of a probability of 5% or more that a child's blood lead concentration would equal or exceed 3 µg/dL (***P3***), 5 µg/dL (***P5***) and 8 µg/dL (***P8***). See section 3.4.1 for more details on the IEUBK model.

Figure 6-12. Comparison of Lead Concentrations Measured in Other Not Specified Soil DUs to Lead Risk Benchmarks and Estimated Background used in this HHRA.



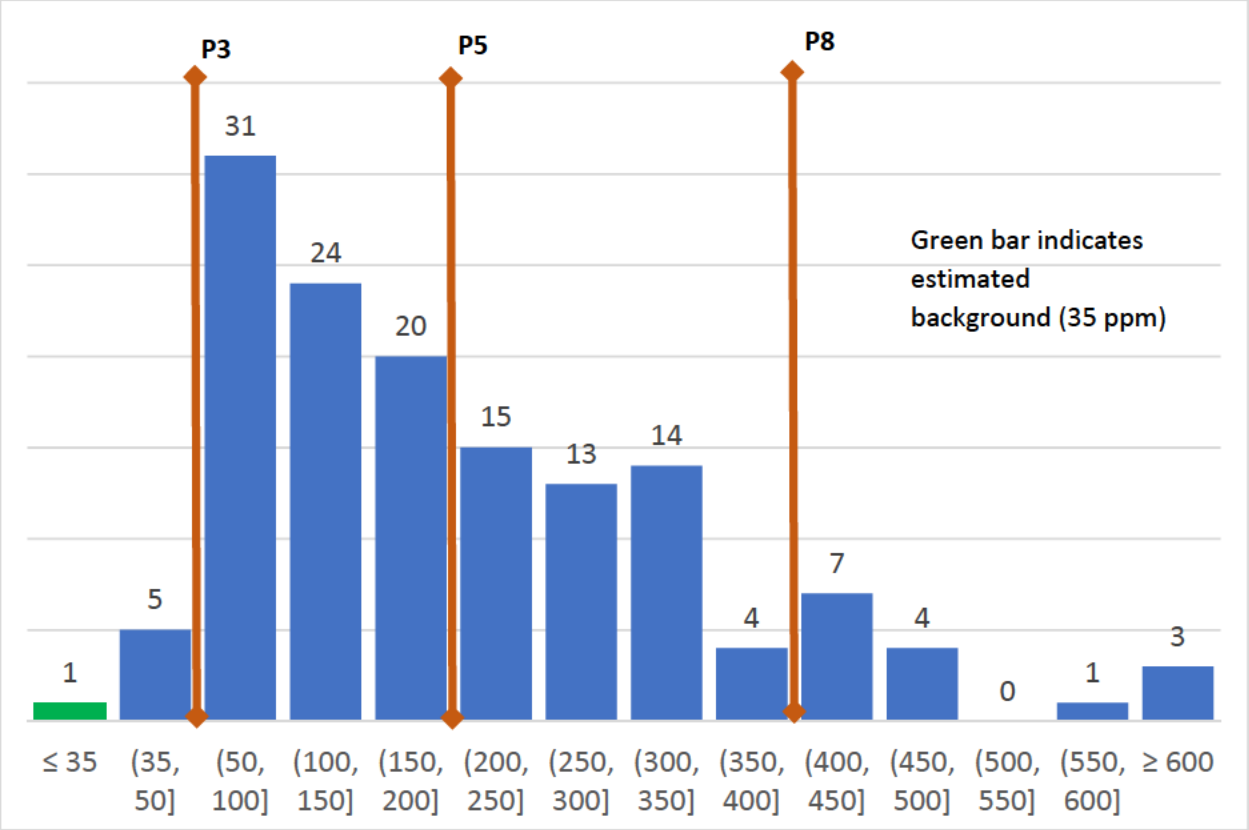
Ranges of concentration ('bins') are shown on the x-axis. The number of DUs in each of the bins appears at the top of each bar. With the exception of the first and last bins, each bin includes the concentration at the lower limit and excludes the concentration at the upper limit. For example, the bin labeled '(50-100]' includes DUs with lead concentrations equal to 50 but does not include DUs with lead concentrations equal to 100 ppm. The orange vertical lines are located at soil lead concentrations that correspond to the IEUBK model's prediction of a probability of 5% or more that a child's blood lead concentration would equal or exceed 3 µg/dL (***P3***), 5 µg/dL (***P5***) and 8 µg/dL (***P8***). See Section 3.4.1 for more details on the IEUBK model.

Figure 6-13. Comparison of Lead Concentrations Measured in Play Area Soil DUs to Lead Risk Benchmarks and Estimated Background used in this HHRA.



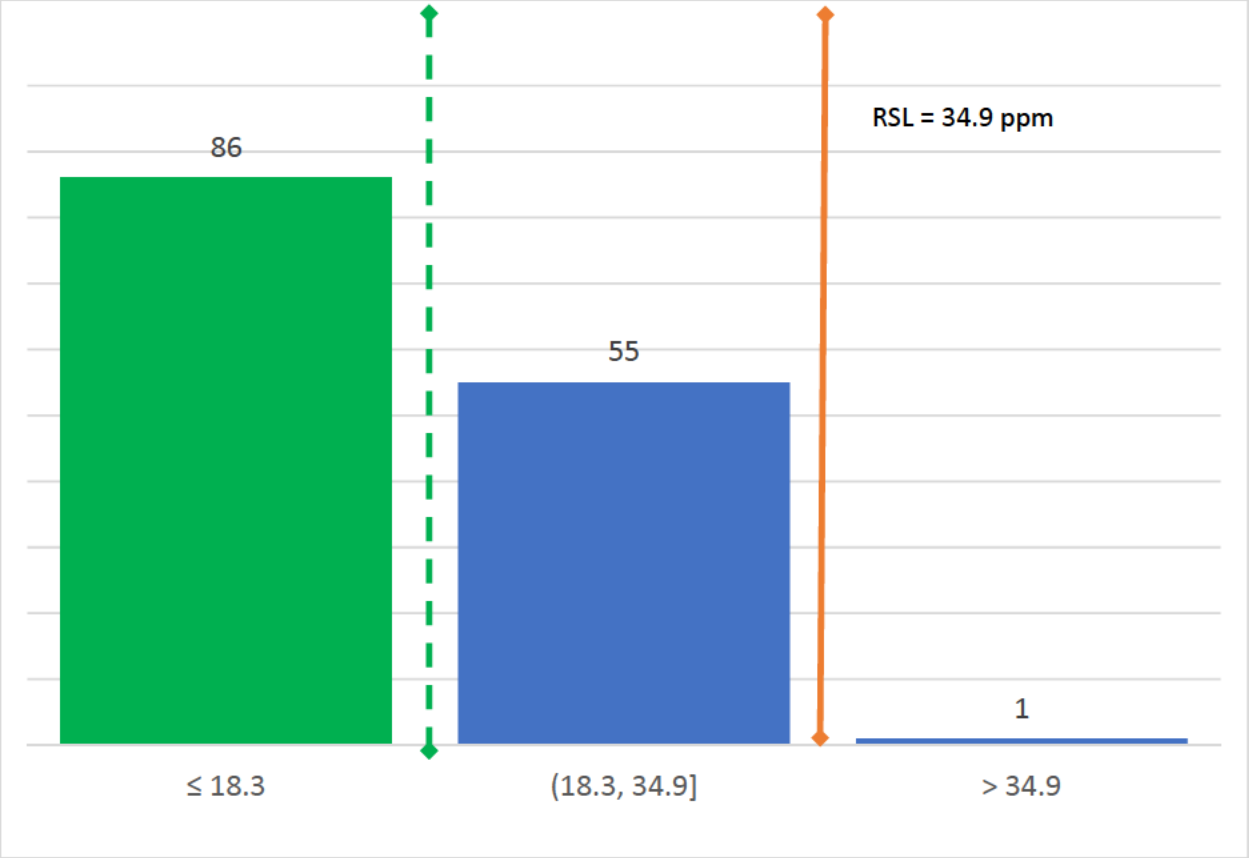
Ranges of concentration ('bins') are shown on the x-axis. The number of DUs in each of the bins appears at the top of each bar. With the exception of the first and last bins, each bin includes the concentration at the lower limit and excludes the concentration at the upper limit. For example, the bin labeled '(50, 100]' includes DUs with lead concentrations equal to 50 but does not include DUs with lead concentrations equal to 100 ppm. The orange vertical lines are located at soil lead concentrations that correspond to the IEUBK model's prediction of a probability of 5% or more that a child's blood lead concentration would equal or exceed 3 µg/dL (***P3***), 5 µg/dL (***P5***) and 8 µg/dL (***P8***). See section 3.4.1 for more details on the IEUBK model.

Figure 6-14. Comparison of Lead Concentrations Measured in Upland Soil ADAs to Lead Risk Benchmarks and Estimated Background used in this HHRA.



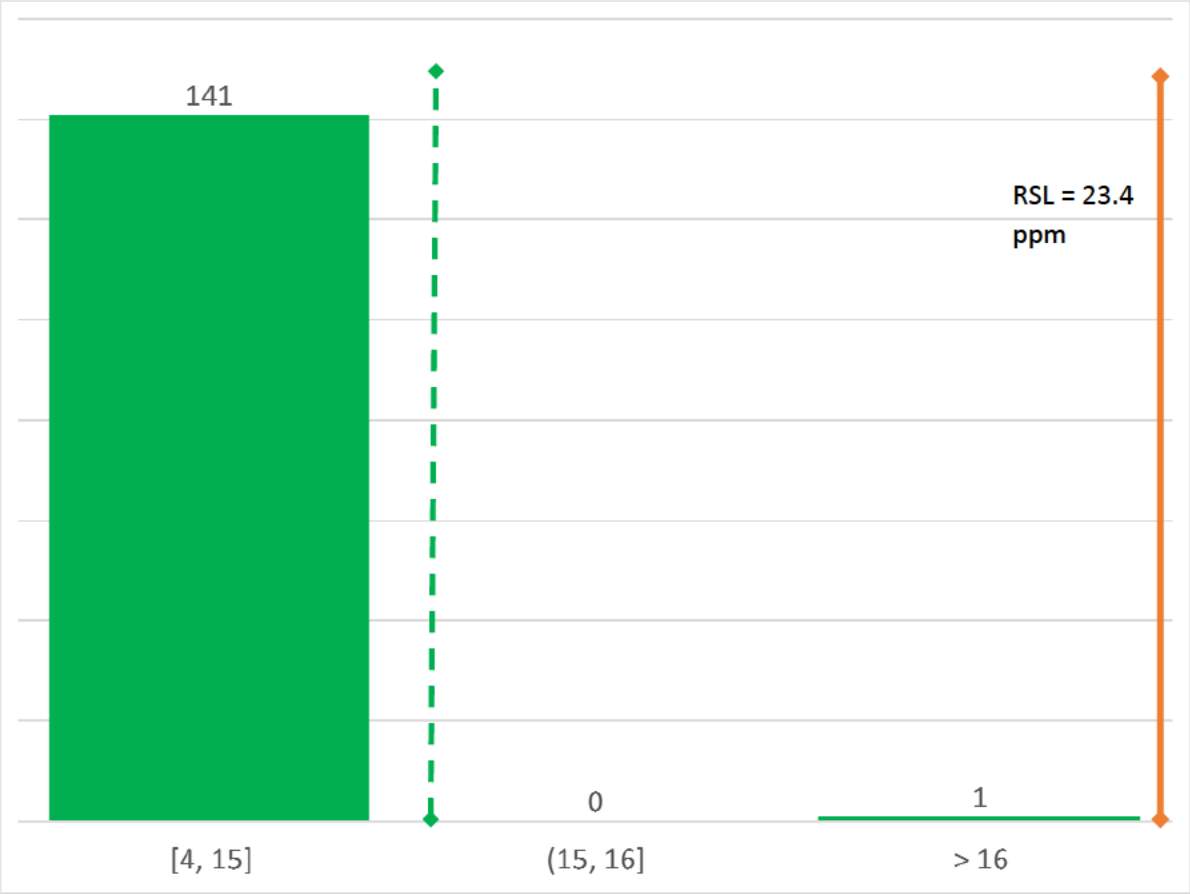
Ranges of concentration ('bins') are shown on the x-axis. The number of DUs in each of the bins appears at the top of each bar. With the exception of the first and last bins, each bin includes the concentration at the lower limit and excludes the concentration at the upper limit. For example, the bin labeled '(50, 100]' includes DUs with lead concentrations equal to 50 but does not include DUs with lead concentrations equal to 100 ppm. The orange vertical lines are located at soil lead concentrations that correspond to the IEUBK model's prediction of a probability of 5% or more that a child's blood lead concentration would equal or exceed 3 µg/dL (***P3***), 5 µg/dL (***P5***) and 8 µg/dL (***P8***). See section 3.4.1 for more details on the IEUBK model.

Figure 6-15. Comparison of Arsenic Concentrations Measured in Upland Soil to Site-specific Background Data



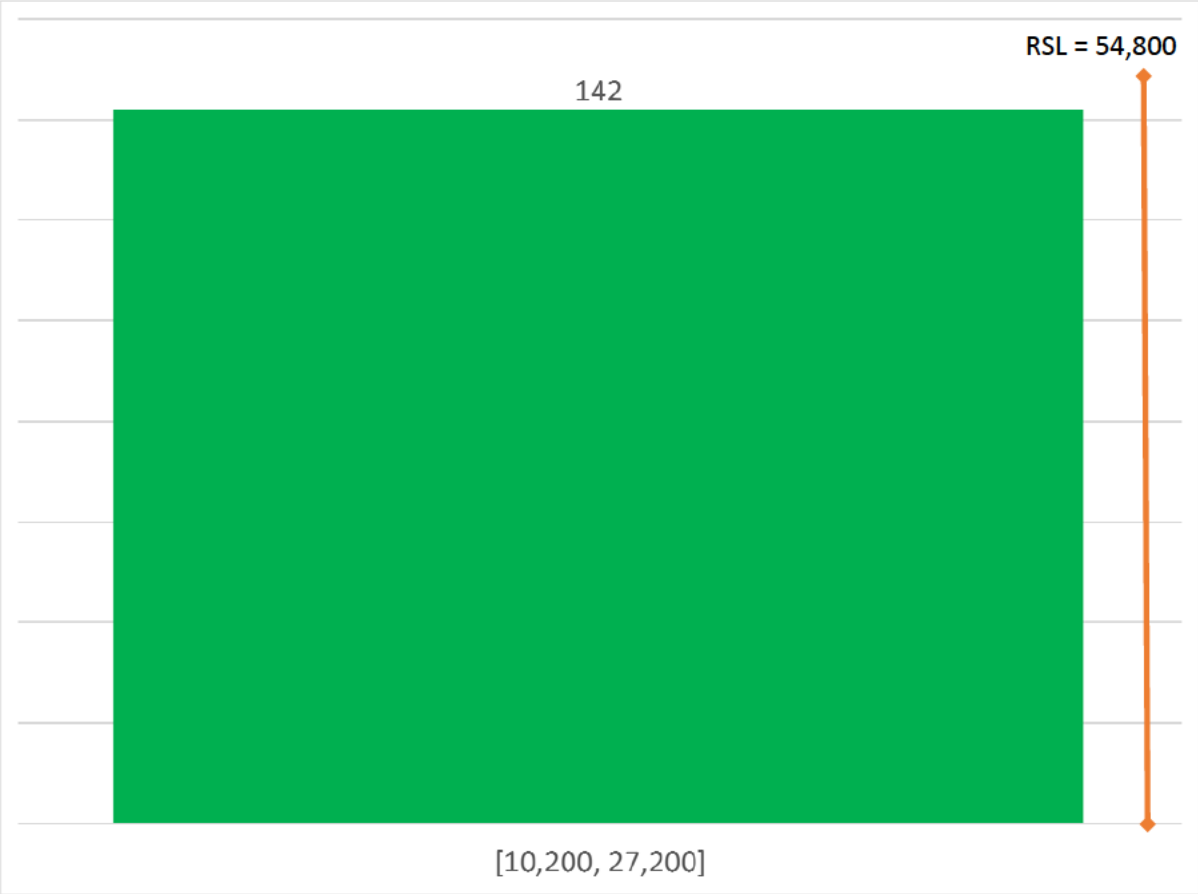
Ranges of concentration ('bins') are shown on the x-axis. The number of ADAs in each of the bins appears at the top of each bar. With the exception of the first and last bins, each bin includes the concentration at the lower limit and excludes the concentration at the upper limit. For example, the bin labeled '(18.3, 34.9]' includes ADAs with arsenic concentrations equal to 18.3 but does not include ADAs with arsenic concentrations equal to 34.9 ppm. The green dotted vertical line is located at the estimated background concentration of arsenic in soil (18.3 ppm). The orange vertical line is located at the estimated Residential Screening Level (RSL). See Appendix 4 for more details on the estimation of background concentration.

Figure 6-16. Comparison of Cobalt Concentrations Measured in Upland Soil to Site-specific Background Data



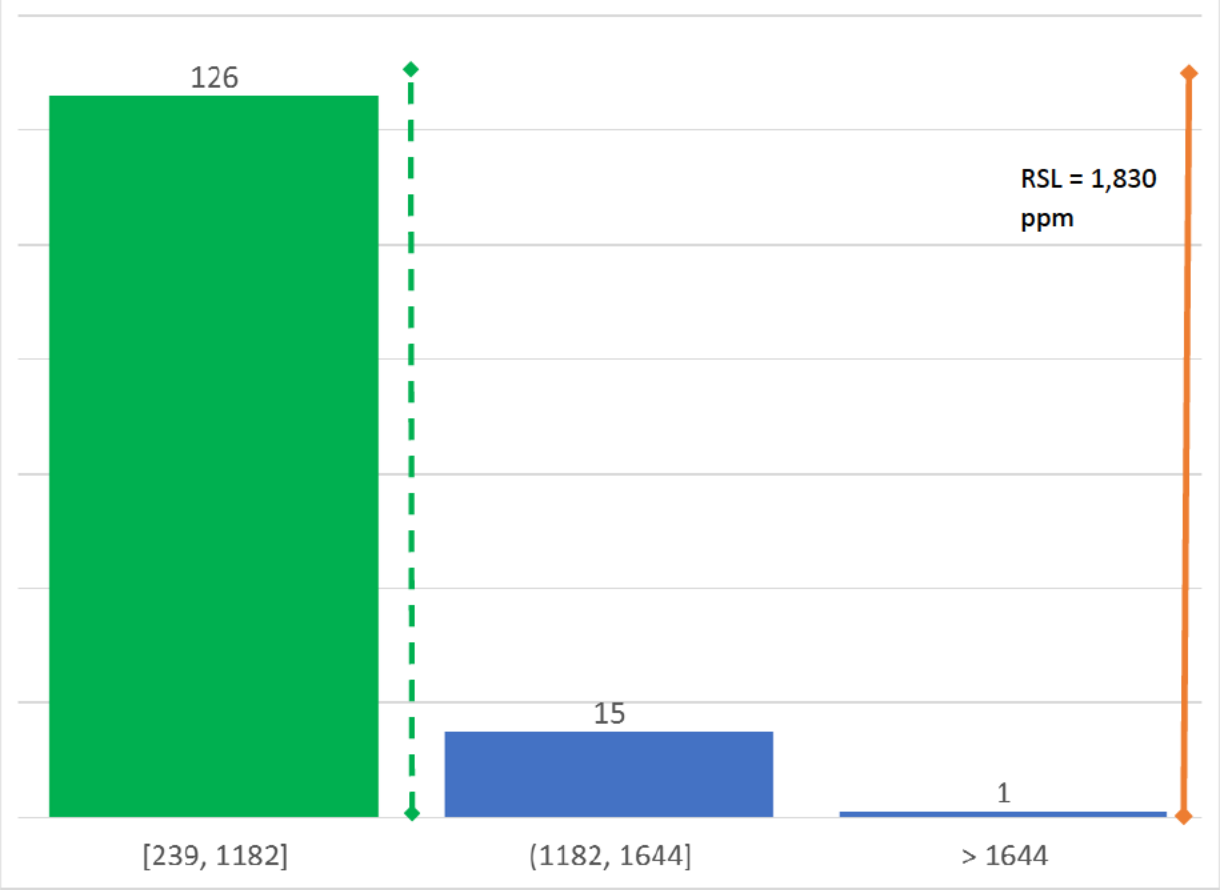
Ranges of concentration ('bins') are shown on the x-axis. The number of ADAs in each of the bins appears at the top of each bar. With the exception of the first and last bins, each bin includes the concentration at the lower limit and excludes the concentration at the upper limit. For example, the bin labeled '(15,16]' includes ADAs with cobalt concentrations equal to 15 but does not include ADAs with cobalt concentrations equal to 16 ppm. The green dotted vertical line is located at the estimated background concentration of cobalt in soil (15 ppm). The orange vertical line is located at the estimated Residential Screening Level (RSL). See Appendix 4 for more details on the estimation of background concentration.

Figure 6-17. Comparison of Iron Concentrations Measured in Site Upland Soil to Site-specific Background Data



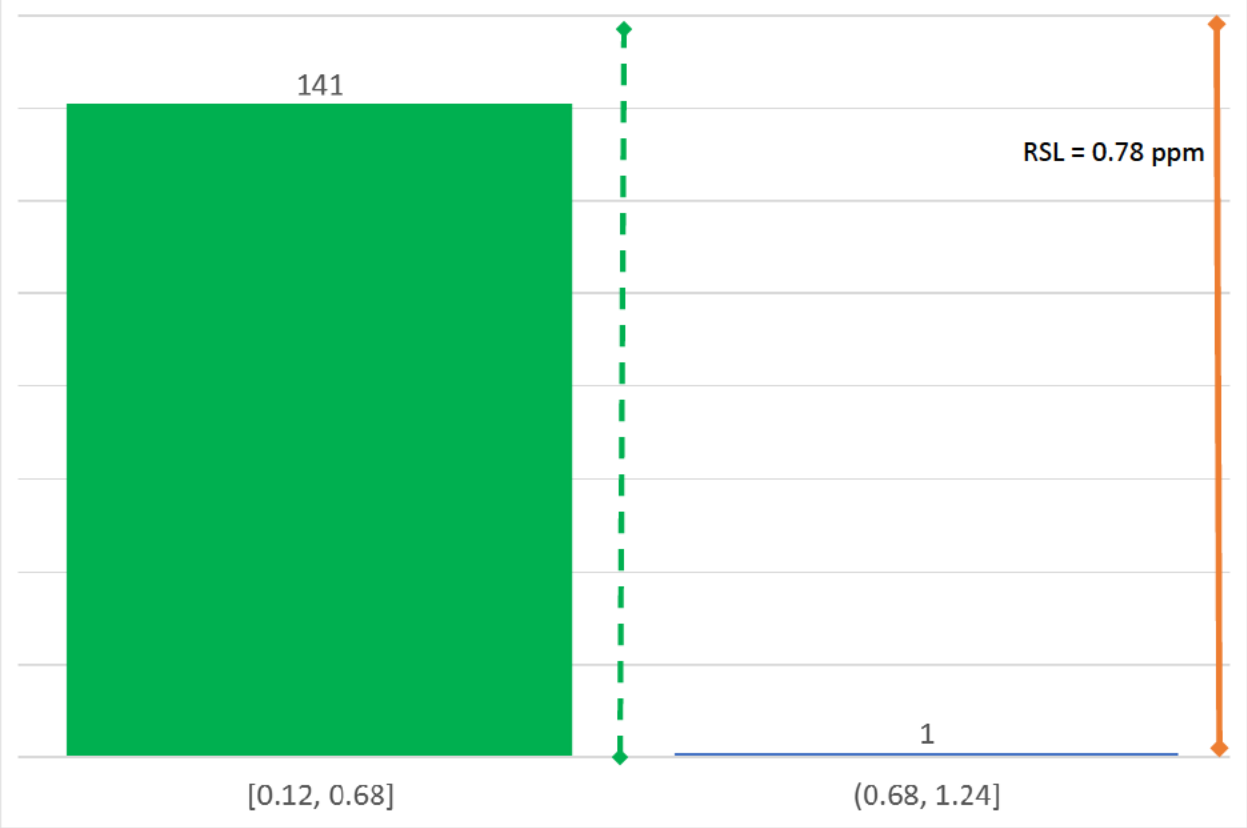
Ranges of concentration ('bins') are shown on the x-axis. The number of ADAs in each of the bins appears at the top of each bar. The bin includes the concentration at the lower limit and the concentration at the upper limit. All of these data are below the background concentration of iron (51,690 ppm). The orange vertical line is located at the estimated Residential Screening Level (RSL). See Appendix 4 for more details on the estimation of background concentration.

Figure 6-18. Comparison of Manganese Concentrations Measured in Site Upland Soil to Site-specific Background Data



Ranges of concentration ('bins') are shown on the x-axis. The number of ADAs in each of the bins appears at the top of each bar. With the exception of the first and last bins, each bin includes the concentration at the lower limit and excludes the concentration at the upper limit. For example, the bin labeled '(1182,1644]' includes ADAs with manganese concentrations equal to 1182 but does not include ADAs with manganese concentrations equal to 1644 ppm. The green dotted vertical line is located at the estimated background concentration of manganese in soil (1,182 ppm). The orange vertical line is located at the estimated Residential Screening Level (RSL). See Appendix 4 for more details on the estimation of background concentration.

Figure 6-19. Comparison of Thallium Concentrations Measured in Site Upland Soil to Site-specific Background Data



Ranges of concentration ('bins') are shown on the x-axis. The number of ADAs in each of the bins appears at the top of each bar. With the exception of the first and last bins, each bin includes the concentration at the lower limit and excludes the concentration at the upper limit. For example, the bin labeled '(0.68, 1.24]' includes ADAs with thallium concentrations equal to 0.68 but does not include ADAs with thallium concentrations equal to 1.24 ppm. The green dotted vertical line is located at the estimated background concentration of thallium in soil (0.68 ppm). The orange vertical line is located at the estimated Residential Screening Level (RSL). See Appendix 4 for more details on the estimation of background concentration.

Appendix 1. Upper Columbia River: Draft Site-Wide Human Health Risk Assessment (HHRA) for the Colville High Intensity Resource User (CHIRU) population

1 Introduction

The Upper Columbia River (UCR) Site ("the Site") is in the northeast portion of the State of Washington and includes approximately 150 river miles of the Columbia River, extending from the United States (U.S.) – Canada border south and west to the Grand Coulee Dam. A remedial investigation and feasibility study (RI/FS) is currently underway in response to concerns regarding historical discharges of hazardous substances into the Columbia River from smelting processes and facility operations by Teck Resources Limited ("Teck") and its affiliated predecessors at the Trail facility located in Trail, British Columbia (B.C.). In accordance with a Settlement Agreement signed by the U.S. and Teck American Incorporated (TAI; U.S. Environmental Protection Agency [EPA], 2006), TAI will complete the RI/FS and baseline ecological risk assessment (BERA), and EPA will complete the human health risk assessment (HHRA).

The purpose of the HHRA is to assess the potential risks to humans, both under current conditions and in the future, from exposure to Site-related contaminants present in environmental media associated with the UCR, assuming no steps are taken to remediate the environment or to reduce human contact with contaminated environmental media.[1] The results of the HHRA are intended to help inform risk managers and the public about potential human risks attributable to exposure to Site-related contaminants and to help determine if there is a need for action at the Site (EPA, 1989). The methods used to evaluate risks in this HHRA are consistent with current EPA guidelines for HHRA at Superfund sites (e.g., EPA, 1989, 1992, 2001, 2004a, 2004b, 2011, 2014).

The conceptual site model (CSM) for the UCR Site, as first defined in the HHRA Work Plan (SRC, 2009), identifies residential, recreational, occupational, and tribal populations as potential receptors exposed to Site-related contamination. Two Native American populations with reservations in the vicinity of the Site are the Confederated Tribes of the Colville Reservation (CCT) and the Spokane Tribe of Indians (STI). This appendix contains the HHRA for the Colville High Intensity Resource User (CHIRU) population. This population represents members of the Colville tribal community, including residents of the Colville Reservation and potential residents of tribal allotments along the UCR, who obtain some of their food by fishing, hunting, and gathering at the UCR Site, or who participate in traditional activities such as basket-weaving and sweat lodges. Calculations for the CHIRU population utilized exposure parameters derived from the Tribal Consumption and Resource Use Survey (Tribal Survey; Westat, Inc., 2012), which captured information from residents of the Colville Reservation, and recommendations of the Natural Resources Committee of the CCT (Water Quality Standards Act [WQSA], 2014). The HHRA for the STI is presented in Appendix 2 of the Site-wide HHRA.

[1] Subsequent to the collection of residential soil data (including tribal allotments) from the Site in 2014 and 2016, a Time Critical Removal Action (TCRA) and/or Voluntary Removal Action (VRA) was conducted on tribal allotment decision unit (DU) 412. This DU was included in this appendix using post-removal soil concentrations from 2015.

HHRAs typically contain the following sections: Introduction, Site Characterization, Exposure Assessment, Toxicity Assessment, Risk Characterization, Uncertainty Assessment, and Summary/Conclusion. Given that the CHIRU HHRA in this appendix is part of the broader HHRA for the UCR Site, only sections pertaining specifically to the CHIRU are included here for the sake of brevity. The Site Characterization, which includes descriptions of UCR Site history and usage, physical characteristics, and ecological resources, as well as summaries of all Site-related data collected to date, is presented in Section 2 of the Site-wide HHRA to which this document is appended and is not repeated here. Similarly, the Toxicity Assessment, which identifies potential adverse human health effects from a chemical and how those effects depend on exposure level (i.e., "dose-response"), as well as how toxic effects of a chemical depend on the route of exposure (oral, inhalation, dermal) and duration of exposure (subchronic, chronic, or lifetime), is presented in Section 4 of the Site-wide HHRA and is not repeated here. This appendix primarily focuses on the Exposure Assessment and Risk Characterization of the UCR HHRA for the CHIRU population and contains portions of the Uncertainty Analysis pertinent to tribal-specific risk assessment.

2 Exposure Assessment

Exposure is the process by which receptors (representing hypothetical populations)[2] contact chemicals in the environment. Receptors can be exposed to chemicals in soil, dust, sediment, water, air, or food, and these exposures can occur through several pathways: ingestion (intentional or incidental), dermal contact, and inhalation. This section summarizes the environmental media and chemicals of potential concern (COPCs) evaluated in this Appendix, identifies complete exposure pathways for the CHIRU population, and describes the methods used to quantify exposure from each pathway.

2.1 Conceptual Site Model (CSM)

Figure 1 presents the CSM that summarizes the current understanding of how chemical contaminants that have been released to the environment at the Site might result in the exposure of receptors. The environmental media evaluated in this appendix include soil/dust and sediment on tribal allotments, UCR disturbed surface water,[3] air, and biota (fish, mussels, crayfish, amphibians/reptiles, waterfowl, wild/cultural plants, upland birds, and wild game [mammals]). Sweat lodge air was not quantitatively evaluated in this HHRA and is expected to make a negligible contribution to risk (see Appendix 3 of the Site-wide HHRA for further discussion).

2.1.1 Exposure Areas

An exposure area (also referred to as an exposure unit) is an area where a receptor population may be exposed to one or more environmental media. Within the exposure area, contact with each medium is assumed to be random when considered on the time scale of the exposure scenario being evaluated (usually many years). Selection of the bounds of an exposure area is based mainly on consideration of the likely activity patterns of the exposed receptor populations but also must consider the spatial extent of data that are available to estimate exposure

[2] Please see the Note to Readers in the Site-wide HHRA for a more detailed explanation of "receptor" and other risk assessment terminology used in this appendix.

[3] "Disturbed" surface water samples were collected after kicking up the sediments on the riverbed, consistent with wading or swimming.

parameters and exposure concentrations. The Tribal Survey (Westat, Inc., 2012) collected information on Local Area[4] resource use by residents of the Colville Reservation. Merging the survey data with the data collected from the various environmental media (e.g., fish, macroinvertebrate [mussels and crayfish], and plant tissue; disturbed surface water and beach sediment; soil and outdoor air) or modeled using Site-specific data (e.g., tissue concentrations in birds and mammals) required consideration of the differences in the spatial scales the data represent. Table 1 presents the exposure areas defined for evaluation in this HHRA appendix by medium. The rationale for these exposure areas follows.

2.1.1.1 Soil, Indoor Dust, and Sediment

The CHIRU population was assumed to be exposed to soil, indoor dust, and surface sediment on the tribal allotments sampled as part of the 2014 and 2016 Residential Soil Studies (Figure 2; CH2MHill, 2016; TAI, 2017a). The tribal allotment DUs were sampled to assess potential risks to CCT members from exposure to metals in the surface soil on the allotments, and in the surface sediment of the tribal allotment with a beach. Prior to sampling, the DUs were delineated to include the areas of the allotments that were used most often (SRC, 2014); therefore, the size of the exposure area was assumed to be the same as the DU sampled. Indoor dust, which would be associated with any current building or buildings added to the allotments in the future, was also assumed to have been impacted by contaminants in an exposure area equal to the size of the DU sampled.

2.1.1.2 Disturbed Surface Water

The exposure area for surface water was identified as UCR Reaches 1-6, from the U.S. – Canadian border downstream to River Mile 597 in the Lower Reservoir of Lake Roosevelt (Figure 2-4 of the Site-wide HHRA). The rationale for combining surface water data to estimate one exposure point concentration (EPC) for the Site was based on the number of samples that were available for each reach of the UCR (TAI, 2013a), as discussed in Section 2.6.1 of the Site-wide HHRA.

2.1.1.3 Air

Outdoor air samples were collected from one location near Northport, Washington, by TAI (see Figure 2-12 in the Site-wide HHRA; Washington State Department of Ecology [ECY], 2017). The exposure area for air was identified as the entire Site.

2.1.1.4 Aquatic Biota

The measured concentrations of COPCs in fish, mussel, and crayfish tissue collected from all six river reaches were used to calculate EPCs for these media (CH2MHill, 2007; Exponent, 2013a; TAI, 2013b; Windward Environmental LLC [Windward], 2017a; TAI, 2018; TAI, 2017b; see Figures 2-14 through 2-17 in the Site-wide HHRA). The exposure area for fish was UCR Reaches 1-6. The rationale for combining the fish tissue data across reaches was an assumption that at least some of the fish species have home ranges that span more than one river reach, resulting in exposures throughout the river. More detail can be found in Section 3.1.1.3 of the Site-wide HHRA. The exposure area for ingestion of mussels and crayfish collected on-Site was

[4] The *Local Area* includes the UCR and the land located within the geographic extent of the CCT Resource Zones (see Figure 1 of the Tribal Survey DAR [SRC, 2019a]). The geographic extent of the UCR Site has not been determined yet (see first sentence of Section 1.1, SRC, 2019a).

UCR Reaches 1-6 as well. Limited information was available on locations where CCT members may collect shellfish for consumption, and the Recreational Consumption and Resource Use (RecUse) Survey (IEc, 2012) did not include questions on collection of shellfish. Therefore, the shellfish data were evaluated on a Site-wide basis. In addition to collection of mussels and crayfish from the UCR, they were also collected from two reference areas (the Sanpoil River and Buffalo Lake; Figure 2-17 of the Site-wide HHRA) (Windward, 2017b). Risk calculations were also run on macroinvertebrates collected from the reference areas, which were considered a single exposure area. Given that crayfish tissue data were used as a surrogate for amphibians and reptiles, the exposure area for consumption of amphibians and reptiles was UCR Reaches 1-6 as well.

2.1.1.5 Waterfowl

Waterfowl have large home ranges and feeding territories (much larger than the Site) and may be exposed to UCR surface water and surface sediment along the entire length of the Site. Waterfowl tissue EPCs were derived using an uptake model that required inputs for surface water and sediment. Estimated waterfowl tissue concentrations were calculated using UCR Reaches 1-6 EPCs for total disturbed surface water, and in most cases, the less than (<) 2 millimeters (mm) surface sediment fraction EPCs calculated for the upper, middle, and lower reaches of the UCR Site defined in the RecUse Survey (IEc, 2012). Sediment data are described in greater detail in Section 2.6 of the Site-wide HHRA. Because the feeding territory for waterfowl is large and many species are migratory, modeling the tissue concentrations of COPCs from Site media was preferred to measuring the concentrations in harvested birds due to uncertainty regarding whether the exposure history of the birds sampled represents exposure to media on-Site or elsewhere.

2.1.1.6 Wild/Cultural Plants

Wild/cultural plants were collected from 12 sampling areas (SAs), including 9 tribal allotments and 1 upland aerial deposition area (ADA), in 2018 as described in TAI (2019) and shown in Figure 3. Fourteen plant species were collected across these SAs, though not all plants were present in each of the SAs. Table 2 lists the plant species collected, time of collection, and SAs in which they were found.

2.1.1.7 Upland Birds and Wild Game (Mammals)

Upland birds (e.g., turkey) and wild game (e.g., deer) have large feeding territories, and may be exposed to UCR surface soil and surface water along the entire length of the Site. As such, the exposure area identified for exposure of upland birds and wild game to soil and surface water was the entire Site. Estimated bird and mammal tissue concentrations were calculated using UCR Reaches 1-6 EPCs for COPCs in total disturbed surface water and EPCs for COPCs in surface soil samples collected at a depth of 0-3 inches that were co-located with the wild/cultural plant samples. Given that turkey and deer feed primarily on terrestrial vegetation (versus aquatic vegetation), and that the incidental ingestion of soil will occur while feeding on terrestrial vegetation, the uptake model used to estimate EPCs in upland birds and game focused on COPC concentrations in soil and in surface water rather than in surface sediment. Because the feeding territory for upland birds and game is large, modeling the tissue concentrations of COPCs from Site media was preferred to measuring the concentrations in organisms that are harvested (due to uncertainty of whether the exposure history for these organisms represents Site exposures).

2.1.2 Exposed Population

The receptor population of concern addressed in this appendix to the Site-wide HHRA is the CHIRU population. This population obtains food and other resources (e.g., medicines, clothing, etc.) from the Local Area (SRC, 2019a). The CHIRU population was assumed to conduct activities on tribal allotments north of the Colville Reservation, and may have direct contact with surface soil or sediment in allotments. The evaluation in this appendix conservatively assumed full-time residential exposure to soil on tribal allotments, which is more applicable to potential future use than current use. CHIRU adults and children may be exposed to COPCs while breathing air on tribal allotments, as well as air and dust inside any current or potential future structures on allotments. Given the lack of indoor air data and activity data regarding time spent indoors versus outdoors for the CHIRU population, the exposure pathway for inhalation of air was not evaluated separately for indoor and outdoor air. Rather, exposure to air was assumed to be 24 hours/day.[5] The CHIRU population may be exposed to COPCs via consumption of terrestrial wild/cultural plants, waterfowl, upland birds, and wild game (mammals) harvested from the Site. The CHIRU population was assumed to contact surface water and surface sediment on the tribal allotment beach, and to consume fish and other aquatic biota (crayfish, mussels, amphibians and reptiles) harvested from the Site.

Many residents of the Colville Reservation participated in the Tribal Survey to characterize activities that may differ from national averages. Approximately 89% of the households agreed to participate in the enumeration stage of the survey (Westat, 2012). Of the 4,783 Colville Reservation residents enumerated at the beginning of the Tribal Survey, 2,645 residents were selected for participation in the survey in accordance with the sampling plan (Westat, 2010), and 1,165 (44%) completed the survey (i.e., completed two or more Automated Multiple Pass Method [AMPM] dietary recall interviews and the Food Questionnaire [FQ]; SRC, 2019a). As described in Westat (2012), sample weights for each participant and household were developed for use in analyzing the survey data to account for differences in sampling and response rates. In other words, the sample weights were calculated for people who responded to the survey to represent non-respondents as well, so that the weighted estimates represented all expected eligible households and people in the population. The Tribal Survey results were used to establish many of the exposure factors representative of the CHIRU population.

EPA (1989) recommends evaluating exposure and risk to individuals using intake parameter values (e.g., soil ingestion rate) that are near the upper end of the range (e.g., the 95th percentile [P95]), and "average," near the central portion of the range. These exposure scenarios are referred to as the Reasonable Maximum Exposure (RME) scenario when the intake parameters are from the upper end of the range, and the Central Tendency Exposure (CTE) scenario when average values are used.

2.1.3 Exposure Pathways

As described above, several types of media may be contaminated at the Site, including sediment, surface water, air, soil/dust, and biota. Figure 1 presents the likely routes by which the CHIRU population might contact contaminants in the environment. As shown, receptors may be exposed to contaminants in primary, secondary, or tertiary media by ingestion, inhalation, and dermal

[5] COPC concentrations in indoor air were assumed equal to concentrations in outdoor air.

contact. Those terms (i.e., primary, secondary, and tertiary) refer to how many steps the exposure medium is from the source of contamination. "Primary" refers to the original source (e.g., the discharge point) of a chemical constituent, while "secondary" and "tertiary" sources are environmental media (abiotic or biotic) that receive chemical inputs from a primary (or secondary) source. For example, air is a primary source of contaminants from a smokestack, while soil is a secondary source (contaminants are first in the air, then deposited on soil). The terms do not convey any prioritization of importance, but rather refer to transport steps in the CSM. Only exposure pathways considered complete (known with certainty to occur) and for which data were available were carried through the remainder of this Appendix. Only exposure pathways considered complete and for which data were available were carried through the HHRA, including this appendix.

Exposure pathways evaluated for the CHIRU population included:

- Incidental ingestion of surface soil and indoor dust at all tribal allotments except the one bordering the UCR[6]
- Dermal contact with surface soil at all tribal allotments except the one bordering the UCR
- Incidental ingestion of surface sediment at the tribal allotment bordering the UCR
- Dermal contact with surface sediment at the tribal allotment bordering the UCR
- Incidental ingestion of disturbed surface water
- Dermal contact with disturbed surface water
- Inhalation of air
- Consumption of fish (each species evaluated individually)
- Consumption of mussels
- Consumption of crayfish
- Consumption of amphibians and reptiles
- Consumption of waterfowl
- Incidental ingestion of aquatic wild/cultural plants[7]
- Consumption of terrestrial wild/cultural plants
- Consumption of upland birds, and
- Consumption of wild game (mammals).

2.2 Selection of Chemicals of Potential Concern (COPCs)

The HHRA Work Plan for the UCR Site (SRC, 2009) presented a list of initial contaminants of interest (COIs) developed using information about known and potential sources of contamination

[6] Section 3.3.10 of the Site-wide HHRA describes the procedure used to evaluate incidental ingestion of indoor dust in combination with incidental ingestion of surface soil.
[7] While basket-weaving

and data obtained during investigations and monitoring events near or at the Site. The COI list included metals and metalloids, pesticides, semi-volatile organic compounds (SVOCs), polycyclic aromatic hydrocarbons (PAHs), polychlorinated biphenyls (PCBs), dioxins/furans, polybrominated diphenyl ethers (PBDEs), and radionuclides associated with the uranium-238 decay chain. COIs were evaluated in a risk-based screen described in detail in Section 3.2 of the Site-wide HHRA to identify COPCs. The list of COIs analyzed differed by each medium depending on the Site-specific data collected during RI sampling events.

2.2.1 Surface Water COPCs

The surface water COI screen is presented in detail in Section 3.2.3 of the Site-wide HHRA. Surface water COPCs that have toxicity values and had measured concentrations (TAI, 2013a) that exceeded risk-based screening levels (RBSLs) and were evaluated quantitatively in this HHRA are:

- Aluminum
- Antimony
- Arsenic/inorganic arsenic
- Barium
- Beryllium
- Chromium
- Cobalt
- Iron
- Lead
- Manganese
- Thallium
- Uranium
- Vanadium

2.2.2 Surface Sediment COPCs

Surface sediment data evaluated in this appendix were those data collected from the tribal allotment beach as part of the 2014 Residential Soil Study (CH2MHill, 2016). The COI screen is described in detail in Section 3.2.4.5 of the Site-wide HHRA. Tribal allotment beach sediment COPCs that have toxicity values and measured concentrations that exceeded RBSLs and were evaluated quantitatively are:

- Antimony
- Arsenic
- Chromium

- Cobalt
- Iron
- Lead
- Manganese
- Thallium

2.2.3 Air COPCs

The air COI screen is presented in detail in Section 3.2.5 of the Site-wide HHRA. In the HHRA, the air COI screen is presented as "outdoor air" and "indoor air." However, in this appendix, exposure to air by the CHIRU population was assumed to be 24 hours/day. Air COPCs that have toxicity values and measured concentrations (CH2MHill, 2015; ECY, 2017) that exceeded RBSLs and were evaluated quantitatively are:

- Arsenic
- Cadmium
- Lead

2.2.4 Surface Soil and Indoor Dust COPCs

Surface soil samples at the Site were collected in multiple sampling events from 2014 through 2016, as described in Section 2.6 of the Site-wide HHRA. Surface soil data evaluated in this appendix were those data collected from tribal allotments as part of the 2014 and 2016 Residential Soil Studies (CH2MHill, 2016; TAI, 2017a). The soil COI screen is described in detail in section 3.2.6.1 of the Site-wide HHRA. Surface soil COPCs that have toxicity values and measured concentrations that exceeded RBSLs and were evaluated quantitatively are:

- Aluminum
- Antimony
- Arsenic
- Cadmium
- Chromium
- Cobalt
- Iron
- Lead
- Manganese
- Nickel
- Thallium
- Vanadium

In the absence of Site-specific data, indoor dust was evaluated based on residential soil data. Therefore, COPCs identified for surface soil were the COPCs identified for indoor dust.

2.2.5 Fish COPCs

The fish COI screen is described in detail in Section 3.2.6.2 of the Site-wide HHRA. Fish COPCs that have toxicity values and measured concentrations (CH2MHill, 2007; Exponent, 2013a; TAI, 2013b; Windward, 2017a; TAI, 2018) that exceeded RBSLs and were evaluated quantitatively are:

- 4,4'-DDE
- Aluminum
- Antimony
- Inorganic arsenic
- Bis(2-ethylhexyl)phthalate
- Chromium
- Dieldrin
- Heptachlor epoxide
- Hexachlorobenzene
- Lead
- Mercury
- PBDE congener 47
- Selenium
- Toxic equivalent (TEQ) (dioxin-like PCBs and dioxins/furans)
- Thallium
- Total PCBs
- Zirconium

2.2.6 Crayfish and Amphibian/Reptile COPCs

Crayfish were collected from the UCR in 2016 (TAI, 2016; TAI, 2017b), as described in Section 2.6 of the Site-wide HHRA. For the crayfish COI screen, the data for "whole body, no stomach carapace" were screened. These data were evaluated using the 4-step approach detailed for fish in Section 3.2.6.2 of the Site-wide HHRA. The crayfish COI screen is shown in Table 3. Crayfish COPCs that have toxicity values, measured concentrations that exceed RBSLs, and were therefore evaluated quantitatively are:

- Arsenic/inorganic arsenic
- Barium

- Cadmium
- Chromium
- Cobalt
- Copper
- Lead
- Mercury
- Methylmercury
- TEQ dioxins/furans
- Thallium
- Total PCBs

In the absence of Site-specific data on concentrations of COIs in amphibians and reptile tissue, COPCs for crayfish were assumed to be an appropriate surrogate for the COPCs for amphibians and reptiles. Data from crayfish, insectivorous fish (kokanee, whitefish), and all fish were initially considered as potential surrogates for amphibian and reptiles. Crayfish (using signal crayfish as a surrogate) are opportunistic feeders; their diet shifts from aquatic insects as juveniles to more plant-based as adults (U.S. Fish and Wildlife Service [USFWS], 2015). Kokanee and whitefish feed on zooplankton and aquatic insects. EPCs were calculated for the two insectivorous fish species collected in the 2009 sampling event. Measured Site-specific concentrations of TEQ and mercury were higher in fish, while inorganics other than mercury tended to be higher in crayfish. Frogs (using the northern leopard frog as a surrogate species) are herbivorous as tadpoles and feed on insects as frogs (Dewey, 1999). Literature-based studies that reported COPC concentrations measured in both frog and fish tissue were also reviewed (Hothem et al., 2015; Unrine et al., 2007); frog tissue metal concentrations were similar to or higher than fish tissue concentrations, excepting mercury and selenium. Because a similar pattern was observed in the Site-specific crayfish and fish tissue data, and because metals are the primary COPCs of concern at this Site, crayfish were determined to be an acceptable surrogate for amphibians and reptiles. The crayfish COPCs were quantitatively evaluated as the COPCs for amphibians and reptiles.

2.2.7 Mussel COPCs

Mussels were collected from the UCR in 2016 (TAI, 2016; TAI, 2017b), as described in Section 2.6 of the Site-wide HHRA. These data were evaluated using the 4-step approach detailed for fish in Section 3.2.6.2 of the Site-wide HHRA. The mussel COI screen is shown in Table 4. Mussel COPCs that have toxicity values, measured concentrations that exceed RBSLs, and were therefore evaluated quantitatively are:

- Antimony
- Arsenic/inorganic arsenic
- Barium

- Cadmium
- Chromium
- Cobalt
- Iron
- Lead
- Manganese
- TEQ (dioxin-like PCBs and dioxins/furans)
- Thallium
- Total PCBs

2.2.8 Wild/Cultural Plant COPCs

Aquatic and terrestrial wild/cultural plants are secondary and tertiary media at the Site, respectively. Contaminants in UCR surface water and surface sediment can be taken up into aquatic plant tissue via bioaccumulation and bioconcentration. Terrestrial plants may absorb contaminants from the soil, and soil particles may adhere to plant surfaces. The CHIRU population may consume and otherwise utilize plants collected within the Site (Westat, Inc., 2012). Wild/cultural aquatic and terrestrial plants were collected in 2018 from selected areas within tribal allotments (from the 2014 and 2016 residential soil studies) and one ADA (from the 2014 upland soil study) located in the northern half of the Site for laboratory analysis of COIs (Figure 3; TAI, 2019). Given that contaminants found in surface sediment or soil are likely those found in aquatic and terrestrial plants, respectively, aquatic and terrestrial plant COPCs were assumed equal to surface sediment and surface soil COPCs.

COPCs that have toxicity values and were quantitatively evaluated as the COPCs for aquatic wild/cultural plants are the surface sediment COPCs:

- Antimony
- Arsenic
- Chromium
- Cobalt
- Iron
- Lead
- Manganese
- Thallium

COPCs that have toxicity values and were quantitatively evaluated as the COPCs for terrestrial wild/cultural plants are the surface soil COPCs:

- Aluminum
- Antimony
- Arsenic
- Cadmium
- Chromium
- Cobalt
- Iron
- Lead
- Manganese
- Nickel
- Thallium
- Vanadium

2.2.9 Waterfowl COPCs

Waterfowl are secondary exposure media at the Site. Contaminants in sediment and surface water can be taken up into the tissues of waterfowl via bioaccumulation. COPCs in surface water, surface sediment, and aquatic plants, along with any detected bioaccumulative COIs investigated in those media, are the COPCs for waterfowl. COIs were determined to be bioaccumulative based on a review of the EPA *Framework for Metals Risk Assessment* (EPA, 2007). In addition, cadmium is a Site-related COI (Johnson et al., 2013) that has been shown to bioaccumulate (Brown et al., 1996). COPCs for waterfowl that have toxicity values are listed in Table 5. The only COPCs that were evaluated quantitatively in the HHRA were those for which defensible uptake models could be found to estimate waterfowl tissue concentrations[8] (see the shaded COPCs in Table 5).

2.2.10 Upland Bird COPCs

Upland birds are tertiary exposure media at the Site; contaminants in soil and surface water can bioaccumulate in avian tissue. COPCs in tribal allotment surface soil and surface water, along with any detected bioaccumulative COIs investigated in those media, are the COPCs for upland birds. COIs were determined to be bioaccumulative as described in the waterfowl COPC screen above. COPCs for upland birds that have toxicity values are listed in Table 6. The only COPCs that were evaluated quantitatively in the HHRA were those for which defensible uptake models could be found to estimate upland bird tissue concentrations (see the shaded COPCs in Table 6).

2.2.11 Wild Game (Mammal) COPCs

Wild game are tertiary exposure media at the Site; contaminants in soil and surface water can bioaccumulate in upland mammal tissue. COPCs for tribal allotment surface soil and surface water are the COPCs for wild game, along with any detected bioaccumulative COIs measured in

[8] Beryllium and mercury were not evaluated quantitatively for waterfowl as no defensible aquatic plant uptake models were found.

upland and residential soil and surface water. COIs were determined to be bioaccumulative as described in the waterfowl COPC screen above. COPCs for wild game (mammals) that have toxicity values are listed in Table 7. The only COPCs that were evaluated quantitatively in the HHRA were those for which defensible uptake models could be found to estimate upland game tissue concentrations (see the shaded COPCs in Table 7).

2.3 Exposure Point Concentrations (EPCs)

An EPC is an estimate of the concentration of a COPC in a site medium, averaged over the area to which a receptor is exposed (i.e., exposure area). EPA (1992) recommends that the 95% upper confidence limit of the arithmetic mean (95UCL) be used as the EPC for quantifying exposure and risk to individuals under both the RME and the CTE scenarios. Both the Integrated Exposure Uptake Biokinetic Model for Lead in Children (IEUBK model) and the Adult Lead Methodology (ALM) require the EPC for lead to be an arithmetic mean or average value (see Section 2.4.3.1 for more information). The approaches used to calculate EPCs for lead and other COPCs in soil/dust, sediment, surface water, air, and fish are described in detail in Section 3.3 and Appendix 10 of the Site-wide HHRA.

EPCs for surface water, air, and fish are the 95UCL for non-lead COPCs and the KM mean (when non-detect samples were present in the data set) or arithmetic mean (when all samples were detected for lead in the data set) for lead and are presented in Tables 8 through 10. EPCs for tribal allotment soil/dust and sediment are shown in Table 11, along with the rationale for selecting the EPC (see footnotes b and c of Table 11). Calculations of EPCs for other media that are evaluated for the CHIRU population and not in the Site-wide HHRA are described below.

2.3.1 Crayfish and Amphibian/Reptile EPCs

For crayfish, the whole body minus the carapace and stomach,[9] and the stomach/carapace were submitted separately for analysis for crayfish collected from areas 2, 5, and 6 and the reference areas (Sanpoil River and Buffalo Lake) (TAI, 2017b). Only whole body crayfish were collected in Reaches 3 and 4. No crayfish samples were collected from Reach 1.[10] The data from the whole body minus the carapace and stomach (the part of the crayfish consumed by humans) for crayfish collected from Reaches 2, 5, and 6 and the reference areas were used to calculate EPCs for crayfish tissue. Target analyte list (TAL) metals, methylmercury, inorganic arsenic, PCB congeners, and dioxins/furans were analyzed in crayfish samples from Reaches 2, 5, and 6 and reference locations. As discussed in Section 2.2.6, the crayfish EPCs were used as surrogate EPCs for amphibians and reptiles. The crayfish and amphibian/reptile EPCs are shown in Table 12.

2.3.2 Mussel EPCs

Mussels were collected in six reaches of the UCR and in one reference area (Sanpoil River; TAI, 2017b). The soft tissue of the mussel (including any liquid inside the shell) was collected and submitted for analysis. Similar tissue was collected for mussel samples from all reaches; therefore, mussel data from Reaches 1-6 were used to calculate the EPCs. TAL metals were

[9] Whole body minus the carapace and stomach leaves the head, claws, abdomen, tail and shell around the claws and tail.

[10] Only one crayfish was collected by hand from Reach 1. This specimen was immobile, appeared to have a hole in its carapace, and was not retained for analysis.

analyzed in mussel samples from all 6 Reaches. Samples collected from Reaches 2, 5, 6, and the Sanpoil River (the reference location) were also analyzed for methylmercury, inorganic arsenic, PCB congeners, and dioxins/furans. Total arsenic was detected in all mussel samples collected from Reaches 2, 5 and 6 and the reference area, and inorganic arsenic was detected in 15 of those mussel samples. A value equal to the method detection limit was used as the sampling result value for samples that were non-detect. The Site-specific mean percent of arsenic present as inorganic arsenic in mussels was 7.7%. For samples from reaches that were not analyzed for inorganic arsenic (Reaches 1, 3 and 4), the Site-specific estimate for mussels of the percent of total arsenic present as inorganic arsenic (7.7%) was used to estimate the inorganic arsenic concentration in mussels. The mussel tissue EPCs are shown in Table 13.

2.3.3 Wild/Cultural Plant EPCs

Terrestrial and aquatic wild/cultural plants were collected in the Spring and Summer of 2018 from 12 SAs, including 9 tribal allotments and 1 upland ADA, as described in TAI (2019). Fourteen plant species were collected across these SAs, though not all plants were present in each of the 12 SAs (Table 2). COPC concentrations were reported by the laboratory on a dry weight basis. Dry weight tissue concentrations were converted to wet weight using sample specific percent solids and the equation: wet weight (ww) concentration (mg/kg) = dry weight (dw) concentration (mg/kg) × fraction solids. EPCs were calculated separately for each plant species across all plant SAs. Separate EPCs were generated for rose hips and rose stems/leaves (Table 14).

While the plants were not collected with an objective of random distribution across the region or across tribal allotments, this analysis assumes that the samples collected represent a reasonable proxy for plants collected across the area. In most cases, plants were collected from areas representing a range of soil metal concentrations as shown by the results of co-located soil sample analysis (TAI, 2019).

2.3.4 Waterfowl EPCs

Waterfowl tissue concentrations were estimated using the equations for estimating concentrations of COPCs in animal products and animal transfer coefficients (TCos) for inorganic chemicals to chicken meat from the California EPA Office of Environmental Health Hazard Assessment (OEHHA, 2012, 2015). The mallard duck (*Anas platyrhynchos*) was selected as the surrogate receptor representative of waterfowl for this model.

The uptake equation (OEHHA, 2015) is:

$$Conc_{waterfowl} = (Dose_{water} + Dose_{plants} + Dose_{sediment}) \times TCo$$

Where:

$Conc_{waterfowl}$	=	EPC in waterfowl meat (µg/kg ww)
$Dose_{water}$	=	Ingestion rate (liters per day [L/day]) × Conc in surface water (micrograms per liter [µg/L])
$Dose_{plants}$	=	Ingestion rate (kilograms per day [kg/day]) × Conc in plants (micrograms per kilogram [µg/kg] dw)
$Dose_{sediment/soil}$	=	Ingestion rate (kg/day) × Conc in surface sediment/soil (µg/kg dw)

TCo = Transfer coefficient (day/kg)

Variables needed for the model are ingestion rates of surface water, sediment, and aquatic plants for waterfowl; TCos for chicken meat for each COPC; and COPC concentrations in surface water, aquatic plants, and surface sediment. Food, water, and incidental sediment ingestion rates for the mallard were obtained from the scientific literature and are summarized in Table 15.

TCos for the bird uptake equation (chicken [OEHHA, 2015]) are as follows:

- Arsenic: 0.03 day per kg (day/kg)
- Cadmium: 0.5 day/kg
- Lead: 0.13 day/kg
- Selenium: 0.9 day/kg

The TCo for lead to chicken meat cited in OEHHA (2015) is 0.4. After review of the studies the TCo value was derived from and additional information on the TCo derivation calculations received from OEHHA (OEHHA, 2020), the lead TCo was re-calculated using the data reported in the original derivation studies (Latta and Donaldson, 1986a, 1986b) for the exposure group fed a methionine adequate diet;[11] a TCo of 0.13 was used to estimate uptake of lead into bird tissue.

Surface water and surface sediment concentrations used in the model are shown in Table 16. Sediment/soil EPCs were Site-specific 95UCL concentrations for non-lead COPCs and Kaplan Meier (KM) mean lead concentrations in surface sediment (public beach sediment [<2 mm], relict floodplain soil [<2 mm], and residential beach sediment [<250 µm]) collected from the Upper, Middle, and Lower regions of the UCR. Surface water EPCs were 95UCL concentrations for non-lead COPCs and the KM mean lead concentrations in total disturbed surface water samples collected in UCR Reaches 1 through 6. Aquatic plant concentrations for the model were estimated because aquatic plant parts collected from the Site in 2018 are not representative of the plant parts consumed by waterfowl. Concentrations of contaminants in aquatic plants were estimated using sediment to water potato regression models (Campbell et al., 1999), if available for a given COPC (Table B-3 of SRC, 2009). If not, the uptake model for metals (Jackson, 1998; Table B-4 of SRC, 2009) was used to estimate aquatic plant COPC concentrations. The equations used to estimate uptake of COPCs by aquatic plants are listed in Table 17.

Animal TCos and plant uptake models were available for arsenic, cadmium, lead and selenium. Waterfowl EPCs for these COPCs are shown in Table 16, along with the surface water, surface sediment/soil, and estimated plant concentrations for each COPC.

2.3.5 Upland Bird EPCs

EPCs in upland bird tissue were derived using an uptake model based on Site-specific EPCs for surface soil, surface water, and terrestrial plants following the same approach described above for waterfowl. Site-specific soil EPCs used in the uptake equation were mean or KM mean concentrations for both non-lead COPCs and lead in soil samples collected from a depth of 0-3

[11] The TCo cited in OEHHA (2015) was derived using data from the exposure group fed a methionine-deficient diet.

inches, sieved to <149 µm, and co-located with the wild/cultural plant samples. Site-specific surface water EPCs were 95UCL concentrations of non-lead COPCs and KM mean lead concentrations in total disturbed surface water samples collected in UCR Reaches 1 through 6. These EPCs are presented in Table 18. Soil arsenic and lead concentrations were not adjusted for relative bioavailability (RBA) in birds, as RBA methods developed for humans (based on data from IVBA and juvenile swine) cannot be used to make RBA adjustments for birds.

The Washington State turkey management plan (Washington Department of Fish and Wildlife, 2005) states that turkeys consume a diet comprised of 75% plant material and 25% invertebrates. Measured COPC concentrations in plant parts (sampled in 2018) likely to be consumed by upland birds (nuts and fruit;[12] Sample and LaTier [2019]) were used to calculate the EPC (KM mean for lead and 95UCL for non-lead COPCs) for the plant portion of the diet. Invertebrate concentrations were modelled using literature-based bioaccumulation models for terrestrial arthropods (Beyer and Sample 2017, Supplemental PowerPoint Slideshow S2) and measured soil concentrations. Invertebrate uptake models were only available for arsenic, cadmium and lead. The turkey diet was assumed to be 100% plants for beryllium, mercury, nickel, and selenium.

TCos were available for arsenic, beryllium, cadmium, lead, mercury, nickel and selenium (Table 18). The TCo for lead to chicken meat cited in OEHHA (2015) is 0.4. After review of the studies the TCo value was derived from and additional information on the TCo derivation calculations received from OEHHA (OEHHA, 2020), the lead TCo was re-calculated using the data reported in the original derivation studies (Latta and Donaldson, 1986a, 1986b) for the exposure group fed a methionine adequate diet; a TCo of 0.13 was used to estimate uptake of lead into bird tissue.

The bird uptake equation (OEHHA, 2015) is:

$$Conc_{uplandbird} = (Dose_{water} + Dose_{food} + Dose_{soil}) \times TCo$$

Where:

$Conc_{uplandbird}$	=	EPC in upland bird meat (µg/kg ww)
$Dose_{water}$	=	Ingestion rate (L/day) × Conc in surface water (µg/L)
$Dose_{food}$	=	Ingestion rate (kg/day) × ((Conc in plants [µg/kg dw] × 0.75) + (Conc in inverts [µg/kg dw] × 0.25))[13]
$Dose_{soil}$	=	Ingestion rate (kg/day) × Conc in surface soil (µg/kg)
TCo	=	Transfer coefficient (day/kg)

Variables needed for the model are ingestion rates of surface water, soil, and plants for upland birds; TCos for chicken meat for each COPC (Table 18); and concentrations in surface water, plants, invertebrates, and surface soil (Table 18). Food, water, and incidental soil ingestion rates for the wild turkey (*Meleagris gallopavo*), selected as the surrogate receptor representative of upland birds, were obtained from the scientific literature and are summarized in Table 19.

[12] Nuts = hazelnuts and Ponderosa pine nuts; fruits = sarvisberries, rose hips, huckleberries, and chokecherries

[13] Invertebrate uptake models were only available for arsenic, cadmium and lead. The turkey diet was assumed to be 100% plants for beryllium, mercury, nickel, and selenium.

Upland bird EPCs are shown in Table 20.

2.3.6 Wild Game (Mammal) EPCs

Wild game tissue concentrations were estimated using the equations for estimating concentrations of COPCs in animal products and animal TCos for inorganic chemicals to cattle meat from the California EPA OEHHA (OEHHA, 2015). The Site-specific COPC concentrations measured in surface (0-3") soil samples (<149 µm) that were co-located with the wild/cultural plant samples, total disturbed surface water, and measured plant concentrations used in the uptake model are summarized in Table 21. White-tailed deer (*Odocoileus virginianus*) was selected as the surrogate receptor representative of upland game mammals. Deer are primarily browsers, but will also consume berries, nuts, fungi and herbaceous vegetation (Korschgen, 1952; Dahlberg and Guettinger, 1956; Harlow and Jones, 1965; Sotola and Kirkpatrick, 1973). To calculate the plant EPC, it was assumed that the deer diet was 50% browse (willow and rose stems/leaves), 15% herbaceous plants (mint and kinninkinnick leaves), 15% nuts (hazelnuts and pine nuts), 5% fungi (black tree lichen), 10% fruit (chokecherries, huckleberries, sarvisberries and rose hips), and 5% tule leaves. Food, water and incidental soil ingestion rates used for white-tailed deer are summarized in Table 22.

TCos (Table 21) were available for arsenic, beryllium, cadmium, lead, mercury, nickel and selenium. Calculated deer tissue COPC concentrations are summarized in Table 21.

2.4 Exposure Evaluation

Details of the methods used to evaluate exposure to lead and non-lead COPCs are provided in Sections 3.4 and 3.5 of the Site-wide HHRA and are only summarized briefly below.

2.4.1 Methodology of Lead Exposure Evaluation

The primary population of concern for risk from exposure to lead in this appendix is CHIRU children younger than age six. For the assessment of lead, EPA recommends the use of the IEUBK model to evaluate exposures of children to lead-contaminated media in a residential setting (EPA, 1994a, 1994b, 1998, 2016). The IEUBK model predicts the probability distribution of blood lead concentrations (PbBs) in a population of young children (12-72 month age range was used in this HHRA per EPA, 2017a) exposed to a user-specified set of environmental lead levels (EPA, 1994a, 1998, 2016). This model allows users to input data on the levels of lead in soil, dust, water, air, diet, and other (user-defined intakes) for a specific location, as well as data on the amounts of these media ingested or inhaled by a child living at that location. All inputs to the IEUBK model are central tendency point estimates (EPA, 1994a, 1994b). These point estimates are then integrated to calculate an estimate of the central tendency (the geometric mean) of the distribution of PbBs that might occur in a population of children exposed to the specified conditions. Assuming the distribution is lognormal and given (as input) an estimate of the variability in PbBs (this is specified by the geometric standard deviation [GSD]), the model calculates the expected distribution of PbBs for a population of similarly exposed children, as well as an estimate of the probability of PbB exceeding the target risk level specified by the user.

For some activities, exposure of children to Site media is unlikely while adult exposure may occur (specifically the basket weaving exposure scenario[14]). When adults are exposed to media where lead is a COPC (and there is no exposure to young children), the ALM is recommended (EPA, 2003). The ALM is designed to assess non-residential (i.e., workplace or commercial) exposure to lead-contaminated soil by adults. The receptor evaluated in the ALM is the fetus (the most sensitive endpoint being the developing nervous system); risk estimates based on the ALM are considered to be protective of other adverse health effects in adults related to lead exposure.

For this Appendix to the Site-wide HHRA, the risk evaluation benchmarks selected for evaluation of lead risk were defined as >5% probability of exceeding a PbB of 3, 5, and 8 micrograms per deciliter (µg/dL; referred to as "P3," "P5," and "P8," respectively). These benchmarks are within the risk range of child PbBs associated with adverse health effects (2 to 8 µg/dL) cited in the 2016 Office of Land and Emergency Management (OLEM) Soil Lead Directive (EPA, 2016). The IEUBK model cannot be used to assess Site-related risk at the risk benchmark of P2 because with default parameter values and assuming zero lead in soil, the IEUBK model will calculate more than 5% probability that PbB will be >2 µg/dL (that is to say that the P2 risk goal is exceeded if soil lead concentration is 0 ppm). The estimated background soil lead concentration at the Site is approximately 35 parts per million (ppm; Appendix 4 of the Site-wide HHRA). P3 was selected as a lead risk benchmark to evaluate the low end of the risk range of child PbBs associated with adverse health effects. For this HHRA Appendix, the results for P3, P5, and P8 were assessed quantitatively.

The IEUBK model (V1.1, build 11 with inputs shown in Table 23) was used to derive PRGs for residential soil lead exposures for each of these risk benchmarks as follows:

- Utilizing the IEUBK model, a 5% probability of exceeding a blood lead level of 3 µg/dL was associated with a concentration of approximately 50 ppm lead in soil.
- Utilizing the IEUBK model, a 5% probability of exceeding a blood lead level of 5 µg/dL was associated with a concentration of approximately 200 ppm lead in soil.
- Utilizing the IEUBK model, a 5% probability of exceeding a blood lead level of 8 µg/dL was associated with a concentration of approximately 400 ppm lead in soil.

The PRGs associated with each of these risk benchmarks is based on an assumed default RBA of 60% for lead. Site-specific IVBA information was used to derive RBA-adjusted lead concentrations, which allows direct comparison with these PRGs.

In general, the IEUBK model predicts that lead intakes of at least 1 µg/day (at 30% absolute bioavailability [ABA]) are needed to decrease the soil PRG by approximately 20 ppm for a target risk goal of 5% exceeding a PbB of 5 µg/dL (P5). For example, the PRG decreases from 200 ppm to 180 ppm when lead intake increases 1 µg/day (i.e., the alternate exposure pathway in the IEUBK model). In this Site-wide HHRA, exposures that were predicted to contribute <1 µg Pb/day were classified as minimal.

[14] Stifelman (2019)

2.4.2 Methodology of Non-Lead Exposure Evaluation

The amount of a chemical that is ingested, inhaled, or absorbed through the skin is referred to as "intake" or "dose." Chemical intakes estimated for specific averaging times (e.g., lifetime) are referred to as average daily intakes (ADI). For non-lead chemicals, exposure is quantified using equations that include variables such as the EPC, the intake rate of the chemical, the body weight of the exposed person, the exposure frequency (EF; how often a person is likely to be exposed to the contaminated medium over the course of a typical year), and the exposure duration (ED; how long a person is likely to be exposed during his or her lifetime). Aside from the EPC, variables in the equations used to calculate chemical intakes are referred to as "exposure parameters" and are specific for the population being evaluated. The specific equations used to quantify the amount of non-lead COPCs ingested, absorbed through the skin, or inhaled are given in Section 3.5.1 of the Site-wide HHRA. The exposure parameters derived for the CHIRU receptor population are described in the next sections. When the same individual may be exposed to a chemical beginning as a child and extending into adulthood, exposure was calculated as the time weighted average (TWA) lifetime exposure for evaluating cancer risks. For non-cancer hazards, children and adults were evaluated separately.

2.4.3 Exposure Parameters

For every exposure scenario of potential concern, it is expected that there will be variability among individuals in the level of exposure at a specific location due to differences in intake rates, body weights, exposure frequencies, and exposure durations. Thus, there is normally a wide range of ADIs among different members of an exposed population. Because of this, all daily intake calculations must specify what part of the range of doses is being estimated. Typically, attention is focused on ADIs that are near the upper end of the range (e.g., P95; RME), and on ADIs that are "average" or otherwise near the central portion of the range (e.g., mean; CTE). Both RME and CTE scenarios were evaluated for receptors in this HHRA Appendix for non-lead COPCs.

Table 24 presents the exposure parameters used to generate human intake factor (HIF) values for the RME and CTE exposure scenario (for ingestion and dermal pathways) and time weighting factor (TWF) values (for inhalation pathways) for the CHIRU receptor population. Several general exposure parameters, such as body weight, exposure duration, and skin surface area, were taken from standard EPA guidance documents (e.g., EPA, 1989, 2011, 2014). Others were derived from the Tribal Survey (SRC, 2019a), communications with the CCT (e.g., Fraser, 2019a, 2019b, 2019c, 2019d, 2019e, 2019f, 2019g; Fraser, 2017; Stifelman, 2019; WQSA, 2014), or based on professional judgement. Detailed information on exposure parameters specific to this receptor population is provided in the remainder of this section.

2.4.3.1 Exposure Parameters Specific to Lead Risk Assessment

Exposure parameters used in the IEUBK model were CTEs (EPA, 1994a). Default parameter values were used when representative Site-specific information was not available. These defaults were modified to incorporate Site-specific information from the UCR Site when appropriate. Tables 23 and 25 present the input parameters used for evaluating lead exposures to CHIRU children using the IEUBK model for selected pathways at the UCR Site. Table 23 shows IEUBK model values with defaults as recommended by EPA and the Site-specific information. Table 25 provides the values for the age-specific parameters for the IEUBK model.

2.4.3.2 Exposure Parameters for Non-Lead Risk Assessment

Soil/Sediment Ingestion Rate

Soil and sediment ingestion rates (assumed to be equal) for the CHIRU population were taken from EPA (2017c, 2017d). For adults, for exposure to non-lead COPCs, the RME value was assumed to be 240 mg/day, which is the P95 adult daily soil ingestion rate determined for tribal subsistence/high contact populations (EPA, 2017d). The CTE soil ingestion value of 50 mg/day was the mean adult daily soil ingestion rate from EPA (2017d). The child RME and CTE soil ingestion rates of 200 and 80 mg/day, respectively, were taken from the update to Chapter 5 ("Soil and Dust Ingestion") of the EPA *Exposure Factors Handbook* (2017c; Table 24).

Contact Rates with Soil, Sediment and Surface Water

One major objective of the Tribal Survey (Westat, Inc., 2012) was to determine long-term average contact with and daily consumption rates (DCRs) of environmental media during activities that include hunting, fishing, gathering, and utilization of environmental resources from the UCR Site. Approximately 3,100 CCT residents spent on average 355 hours annually engaged in these activities on land located within the Local Area (SRC, 2019a). To evaluate exposure of the CHIRU population during activities on beaches, the EF of time spent engaged in activities "on land" was derived from the Tribal Survey (SRC, 2019a). The RME and CTE values of 62 and 18 days/year, respectively, were the P95 and mean values of time spent on land; this value is representative of all ages. For generic residential exposures of this population to soil in their yards (assuming year-round residence on tribal allotments), EPA default EFs were used (Table 24).

Approximately 3,100 CCT residents engage in activities in waters located within the Local Area (SRC, 2019a). To evaluate exposure of the CHIRU population during activities that take place in water, the EF was derived from the Tribal Survey for the RME and CTE scenarios. Values did not vary significantly by age or sex; the estimated RME EF was 91 days/year (P95), and the CTE EF was the estimated mean value of 34 days/year. The ET (hours/day spent in the water) was also derived for all ages and sex combined; the estimated ETs for the RME and CTE scenarios were 10 and 3.6 hours/day, respectively (Table 24).

Wild/Cultural Plant Consumption Rates

Species-specific plant DCRs were derived using information from the Tribal Survey Data Analysis Report (DAR) (SRC, 2019a), the UCR Plant Tissue Study Data Summary Report (DSR; Ramboll, 2019, TAI, 2019), and communications with the CCT (Fraser, 2017; Fraser, 2019a, 2019b, 2019c, 2019d, 2019e, 2019f, 2019g; Turner, 1997). Adult RME and CTE DCRs were derived for chokecherry, huckleberry, sarvisberry, black tree lichen, rose hips, kinnikinnick, rose stems and leaves, wild mint, hazelnut, pine nuts, lomatium, camas, and spring beauty/Indian potato. DCRs, expressed as g/day, were calculated as the product of consumption frequency (days/year) and the mean mass of the plants consumed on the days they were consumed (grams [g]; "meal size"). Information used to calculate these DCRs is found in Table 26.

For items that are mouthed (e.g., during preparation of plant material for weaving), exposure was estimated as if that plant part was ingested. Given the lack of more specific data on this

behavior, this HHRA appendix assumed that 50% of the plant material was consumed while mouthing (RME scenario for tule and willow). Risk calculations were also conducted assuming 5% of plant material was consumed while mouthing (CTE scenario for tule and willow). The selected percentages of ingestion associated with mouthing willow saplings and tule are uncertain. The range of 5-50% was used as a reasonable assumption to estimate ingestion associated with processing weaving materials as CTE and RME estimates, respectively.

Child DCRs were not available for consumption of wild plants. Therefore, to perform exposure calculations for the CHIRU child population for this exposure pathway, the child DCR for each terrestrial plant species was estimated by multiplying the adult DCR by a ratio of child-to-adult estimated energy requirements (EER). Values for EER were calculated based on regression models reported in Institute of Medicine (IOM, 2005). This methodology is described in detail in SRC (2019b) and in Appendix 14 to the Site-wide HHRA. Exposure to aquatic plants that are mouthed (e.g., during preparation of plant material for weaving) is not a complete exposure pathway for children (Stifelman, 2019); therefore, a child DCR was not calculated for aquatic plants (tule and willow).

Fish Consumption Rate

The fish DCR of 400 g/day utilized by the CCT in determining human health criteria for their surface water quality standards (WQSA, 2014) was the adult RME. The value is based on the subsistence consumption rate adopted by the CCT (WQSA, 2014). The adult CTE fish DCR of 80 g/day was derived by the CCT using the median frequency of ingestion by regular fish consumers and a 90th percentile meal size (Fraser, 2019b, 2019c).

To perform exposure calculations for the CHIRU child population, the child DCR for fish was estimated by multiplying the adult DCR by a ratio of child-to-adult EER as described above. This was done separately to derive the RME and CTE child DCRs for fish of 200 g/day and 40 g/day, respectively (Fraser, 2019c; Table 24).

Crayfish, Mussel, and Amphibian/Reptile Consumption Rates

DCRs estimated for crayfish, mussels, amphibians and reptiles (e.g., frogs, turtles, snakes) were based on data derived from the Tribal Survey (SRC, 2019a). DCRs were calculated as the product of consumption frequency (days/year) and the mass of the food items consumed on the days they were consumed (grams; "meal size"). The FQ was designed to collect information on long-term average intake frequencies of specified food items and their source and location. The FQ provided data for the daily frequency of crayfish, mussels, and amphibians/reptiles from the Local Area and from all areas (Local and non-Local). For crayfish, consumption frequency estimates were based on Local Area data (n=80; P95 of 30 days/year and mean of 13 days/year). Based on the sample size available for the Local Area, mussel consumption frequency estimates were based on Local and non-Local data (n=71; P95 of 30 days/year and mean of 9 days/year). Amphibian and reptile consumption frequency estimates were calculated from 5 people who reported eating these organisms from the Local Area (P95 of 30 days/year and mean of 22 days/year). No survey participants reported consuming amphibians and reptiles from non-local sources.

The 24-hour dietary recall interviews (AMPMs) were intended to characterize the types and amounts of food ingested by survey respondents on up to 4 different days (each representing a different season of the year). During the Tribal Survey, due to resource constraints, interviewers made the decision to focus on getting as many respondents to complete 2 AMPMs rather than having fewer respondents who complete all 4 AMPMs (Westat, 2012). The recall interviews did not capture the intake of shellfish sourced from the Local Area. However, the AMPM provided data for the meal size of market shellfish (clams, crab and shrimp). AMPM estimates were used for the meal size of locally-sourced shellfish, amphibians and reptiles. For crayfish, mussels, and amphibians and reptiles, the mean meal size used to derive DCRs was 70.1 g.

For these organisms, the number of children reported in the Tribal Survey was not sufficient to produce reliable estimates of long-term DCRs. The child DCR for crayfish, mussels, and amphibians and reptiles was estimated by multiplying the adult DCR by a ratio of child-to-adult EER as described above. RME and CTE DCRs are shown in Table 23.

Waterfowl Consumption Rate

The DCR for waterfowl was estimated based on data from the Tribal Survey (SRC, 2019a). As described above, the DCR was calculated as the product of consumption frequency (days/year) and the mass of the food items consumed on the days they were consumed (grams; "meal size"). The FQ provided data for the daily frequency of consuming waterfowl sourced from the Local Area and the percentage of waterfowl sourced from the Local Area (n=13; P95 of 6 days/year and mean of 5 days/year). The AMPMs did not capture meals that included waterfowl. As explained in more detail in the Tribal Survey DAR (SRC, 2019a), the adult mean meal size for chicken obtained from the AMPMs (100 g) was used as a surrogate for the adult mean meal size for waterfowl.

The data available from the Tribal Survey for children consuming waterfowl was very limited (n=3). Therefore, the child DCR for waterfowl was estimated by multiplying the adult DCR by a ratio of child-to-adult EER as described above. RME and CTE DCRs for waterfowl are shown in Table 23.

Upland Bird Consumption Rate

The DCR for upland birds was estimated based on data from the Tribal Survey (SRC, 2019a). As described above, the DCR was calculated as the product of consumption frequency (days/year) and the mass of the food items consumed on the days they were consumed (grams; "meal size"). Approximately 19% of Tribal Survey participants who completed the FQ reported eating wild upland birds. The FQ provided data for the daily frequency with which upland bird meat was consumed and the percentage of upland birds sourced from the Local Area. As shown in Table 13 of the Tribal Survey DAR (SRC, 2019a), the daily frequency of consumption by adults was 24.7 days/yr (P95) or 11.6 days/yr (mean). The 24-hour recall interviews did not capture meals that included upland birds, though they did contain many reports for consumption of chicken and turkey. As described in the Tribal Survey DAR (SRC, 2019a), the adult mean meal size for chicken obtained from the AMPMs (100 g) was used as a surrogate for the adult mean meal size for upland birds.

Given the small sample size available to estimate meal size and consumption frequency for children consuming upland birds, the child DCR was estimated by multiplying the adult DCR by a ratio of child-to-adult EER as described above. This was done separately for the RME and CTE child DCRs as shown in Table 23.

Wild Game (Mammal) Consumption Rate

The Tribal Survey (Westat, Inc., 2012) did not capture many respondents who reported consuming wild game other than deer/venison. The few survey participants who reported consuming bear, elk, and moose are shown in Table 10 of the Tribal Survey DAR (SRC, 2019a). The wild game (mammal) DCR was estimated using the National Cancer Institute (NCI) method and venison consumption data obtained in the Tribal Survey (Westat, Inc., 2012; SRC, 2019a). A total of 916 Tribal Survey participants reported deer consumption on the FQ or on one or more AMPM interviews. Using the NCI models, described in SRC (2019a), the mean and P95 adult DCRs for venison were estimated to be 12 and 42 g/day, respectively (i.e., the CTE and RME). The daily frequency of consuming venison from the Local Area by adults was approximately 10% (i.e., on average once every 9 days); approximately 88% of all venison consumed by adults was sourced from the Local Area.

Child DCRs for wild game (i.e., venison) were estimated using the adult DCRs and the ratio of the average meal sizes for children and adults from the Tribal Survey. The average meal size for children was 48 grams, and the average meal size for adults was 151 grams; the resulting ratio was 0.32 (SRC, 2019a). This ratio was applied to the adult DCRs to estimate the CTE and RME child DCRs as shown in Table 23.

3 Risk Characterization

3.1 Lead Risk Calculations

The IEUBK model was used for all analyses involving lead exposure for children and the ALM was used for analyses of lead exposures that did not involve children, as described in detail in the Site-wide HHRA to which this document is appended. Lead risk was quantitatively assessed in terms of whether the exposure exceeded the risk benchmark. For this HHRA, the selected benchmarks for quantitative risk evaluation were “does the exposure result in more than 5% probability of exceeding PbB of 3, 5, or 8 µg/dL;” P3, P5, and P8, respectively. For media other than residential soil, lead risk may also be presented in terms of how exposure to the medium contributes to overall risk given a selected concentration of lead in residential soil. When lead intake from the subject medium was less than or equal to (≤) 1 µg of lead per day, then that intake contributed minimally to lead risk. Below, lead risk results are presented by exposure pathway.

3.1.1 Incidental Ingestion of Surface Soil and Indoor Dust at Tribal Allotments

Methodology: The receptor population includes CHIRU children who may reside on a tribal allotment in the future. Arithmetic mean values for triplicate IC samples, or the sample result if a single IC sample was collected at each DU, were used as the soil lead EPC for the batch mode calculation. The soil lead EPC was the RBA-adjusted lead result to allow the default RBA for soil to be retained in the IEUBK model batch mode analysis. Dust lead concentration was calculated as the mass fraction of soil in indoor dust (MSD)-based result from the RBA-adjusted

soil lead EPC for the same reason (the MSD approach included the contribution from outdoor air lead). Outdoor air lead concentration was based on Site-specific information as described in Table 23. The results for the 32-month-old child were used as a surrogate for hypothetical children 12-72 months old per EPA guidance.

Results: The results of the IEUBK model are shown in Table 27. The results in Table 27 indicate that of the 35 tribal allotment DUs assessed (not including the tribal allotment beach DU which was assessed separately in Section 3.1.2), incidental ingestion of soil and soil-derived dust at the following tribal allotment DUs exceeded risk benchmarks for lead:

- 21 tribal allotment DUs had more than a 5% probability of exceeding a PbB of 3 µg/dL (P3 benchmark).
- 17 tribal allotment DUs had more than a 5% probability of exceeding a PbB of 5 µg/dL (P5 benchmark).
- 6 tribal allotment DUs had more than a 5% probability of exceeding a PbB of 8 µg/dL (P8 benchmark).

3.1.2 Incidental ingestion of Surface Sediment at Tribal Allotment Beach

Methodology: This exposure pathway was analyzed using the IEUBK model to assess risk from Site air and a time-weighted combination of tribal allotment DU soil and tribal allotment beach DU sediment for solid media exposure. Because the tribal allotment beach (DU 411) is not associated with a house DU and the IEUBK model requires a residential soil concentration, a surrogate was used based on the average soil lead concentration for other DUs on that tribal allotment (DU 410, DU 412 [using the post-removal action concentration as shown in Table 3-12 of the Site-wide HHRA], and DU 413). The time weighting of solid media intake used an assumed beach exposure of 2 days per week (adjusted from the RecUse Survey data beach visits assuming beach use during weekends; SRC 2019c). As discussed in the Uncertainty section of the Site-wide HHRA, this adjustment is unlikely to significantly impact predicted PbB and is likely to overestimate actual exposures. Because residential beaches were assumed to be relatively close to the residence, track-in of sediment from the beach was assumed and the MSD-dust lead concentration was derived from the time-weighted soil and sediment concentration.

Results: Table 28 shows the results for this exposure pathway for the P3, P5, and P8 benchmarks. As shown, incidental ingestion of sediment at the tribal allotment beach exceeded the P3 and P5 risk benchmark. Incidental ingestion of sediment did not exceed the P8 risk benchmark at the tribal allotment beach.

3.1.3 Incidental Ingestion of UCR Surface Water at Tribal Allotment Beach

Methodology: This exposure pathway was analyzed using the IEUBK model to assess risk from Site air, Site surface water, and a time-weighted combination of tribal allotment DU soil and tribal allotment beach DU sediment for solid media exposure. Because the tribal allotment beach (DU 411) is not associated with a house DU, a surrogate soil concentration was derived from the average soil lead concentration for other DUs on that tribal allotment (DU 410, DU 412 [using the post-removal action concentration as shown in Table 3-12 of the Site-wide HHRA], and DU 413). The time weighting of solid intake used an assumed surface water exposure of 1 day per

week (adjusted from the RecUse Survey data for swimming during beach visits; SRC, 2019c). As discussed in the Uncertainty section of the Site-wide HHRA, this adjustment is unlikely to significantly impact predicted PbB and is likely to overestimate actual exposures. Because the tribal allotment beach was assumed to be close to any associated residence, track-in of sediment from the beach was assumed and the MSD-dust lead concentration was derived from the time-weighted soil and sediment concentration.

Incidental ingestion of surface water during activities in surface water at a tribal allotment beach was added as an additional intake to the IEUBK model (where the average Site-wide concentration of lead in surface water was multiplied by the number of hours spent in water per day from the RecUse Survey and volume of water consumed while swimming per hour to derive an intake of lead per day; Table 23; SRC, 2019a, 2019c). An absorption fraction of 50% was used for the additional intake of lead (lead in surface water ingested incidentally during activities in surface water at the tribal allotment beach). Incidental intake of surface water was not subtracted from drinking water intake. Because the volume of incidental water intake is small compared to daily drinking water consumption and occurs only during an active event, it is unlikely to impact average drinking water intake.

Results: Table 29 shows the results for this exposure pathway for the P3, P5, and P8 benchmarks. As shown, incidental ingestion of surface water during activities in surface water at the Tribal Allotment beach exceeded the P3 and P5 risk benchmarks. Incidental ingestion of surface water during activities at the tribal allotment beach did not exceed the P8 risk benchmark.

3.1.4 Inhalation of Air

As discussed in the footnote to Table 23, the concentration of lead in UCR air (CH2MHill, 2015) is an order of magnitude lower than the default air lead concentration in the IEUBK model and is not likely to influence the results. Additionally, EPA evaluated air lead concentration data measured at the Sheep Creek monitoring station near Northport, WA. EPA has analyzed numerous studies that compared air lead concentration to PbBs in children.[15] The analysis indicates that the air-associated exposure from inhalation or ingestion of lead in house dust and surface soil can lead to a PbB that is 5 to 10 times the value in air. Based on air results at the Sheep Creek monitoring station during the 1999-2009 monitoring period, the lead concentration is 0.0242 µg/m^3 in air. This could lead to a 0.12 to 0.24 µg/dL level of lead in blood, which is low risk (EPA, 2018). The EPC value used in this HHRA appendix, for lead in air measured at Sheep Creek from 2002-2009, was 0.023 µg/m^3 (Table 23).

For lead, the air concentration from the Sheep Creek monitoring station is well below the levels expected to pose significant human health risks based on current understanding of relationships between air lead concentrations and PbBs resulting from direct and indirect exposures to air lead (Appendix 8 of the Site-wide HHRA). As such, risk from lead in air was included in the risk calculations as an input to the IEUBK model for all evaluations; however, this pathway was not evaluated as a separate exposure for lead.

[15] Integrated Science Assessment (ISA) for Lead (https://www.epa.gov/isa/integrated-science-assessment-isa-lead); April 2017.

3.1.5 Consumption of Site Biota

Methodology: Analysis of Site-related biota consumption using the IEUBK model is not necessarily informative because the average soil lead concentrations in tribal allotment DUs are >200 ppm (see Table 11). As noted earlier (see Section 3.1.1), this means that soil lead exposure alone would thereby exceed both P3 and P5 risk benchmarks without adding consumption of Site biota. To provide information to the CCT and other Site residents who engage in these activities, an approach was used to evaluate relative risk of consuming these biota (as discrete intakes) with focus on those that resulted in an average daily lead intake in excess of 1 µg Pb/day. An ADI of 1 µg Pb per day, in the absence of other lead exposures, would correspond to a predicted PbB of approximately 0.10-0.17 µg/dL depending on the assumed bioavailability of lead in the medium (from 30-50% ABA, respectively). See the Summary section (5) for more information.

Results: The biota-specific EPC was multiplied by the biota-specific DCR to derive a biota-specific ADI of lead. The following sections discuss the results for consumption of plants and other Site biota.

Table 30 shows the results for plants, where the mean or KM mean lead concentration for each plant species sampled was multiplied by the plant-specific DCRs to calculate lead intake. Those that exceeded 1 µg Pb/day are in bold text. Note that children do not engage in basket weaving (SRC, 2019a; Stifelman, 2019), so exposure to lead while basket weaving was calculated based on assumed incidental plant intakes for adults only. The lead intakes for adults while basket weaving were much lower than 1 µg Pb/day (0.003 and 0.016 for tule and willow, respectively; Table 31).

This same evaluation of lead intake was performed for the assessment of risk from the consumption of other Site biota. Tables 32 and 33 present the calculated lead intakes associated with consumption of fish, mussels, crayfish, amphibians and reptiles, waterfowl, upland birds, and wild game (mammals) harvested from the vicinity of the UCR. Those that exceeded 1 µg Pb/day are shown in bold text. Note that the intake of lead via consumption of mussels and crayfish collected from reference area sampling is presented for informational purposes.

3.2 Non-Lead Risk Calculations

3.2.1 Non-Cancer Hazard Summary

Risk of non-cancer effects is evaluated by comparing the estimated exposure concentration over a specified time period to a toxicity reference value (threshold) that represents the exposure below which it is unlikely for sensitive populations to experience adverse health effects (EPA, 1989). This ratio of exposure to toxicity is called a hazard quotient (HQ). To assess the overall potential for non-cancer effects posed by more than one chemical, or if exposure to a COPC occurs by more than one route, HQs are summed to yield a Hazard Index (HI). Within an exposure pathway (e.g., incidental ingestion of soil), HQs were summed across COPCs to derive an HI. HQs were also summed across pathways of the same media (e.g., incidental ingestion and dermal contact with soil) to derive an HI.

Non-cancer hazards were assessed against risk benchmarks. Risk benchmarks are risk levels that EPA uses to distinguish risks that are a potential concern from risks that are below the level of

concern. The benchmark for non-cancer hazards used in this assessment was an HQ >1. If the HQ for a chemical is ≤1, there is no appreciable risk (e.g., the probability is close to zero) that non-cancer health effects will occur. If an HQ is >1, then there is some possibility that an adverse non-cancer effect may occur (e.g., the probability is >0, but is likely not close to 1). This is because of the margin of safety inherent in the derivation of all toxicity values (see Section 4.3 of the Site-wide HHRA). However, the larger the HQ value, the more likely it is that an adverse effect may occur. When an HI is calculated, the risk benchmark is also HI >1. The HI can exceed one even if no single chemical exposure exceeds its reference dose/reference concentration (RfD/RfC; EPA, 1989). This is likely to overestimate actual exposures.

The assumption of dose additivity in the HI approach is most relevant to chemicals that induce the same effect by the same mode of action. If an HI >1 because of summing several HQs, then the chemicals can be segregated by effect and mode of action, and an HI can be calculated for each target organ group (EPA, 1989). Target organs were assigned to each COPC as shown in Table 4-2 of the Site-wide HHRA, based on data in EPA (2019b). Target organ group HI calculation results are discussed below for receptors with total HI >1.

In this assessment, the following terminology is used to categorize non-cancer hazard based on the HQ or HI. Risks are considered to be below non-cancer hazard benchmarks used by the Comprehensive Environmental Response, Compensation and Liability Act (CERCLA) if the HQ or HI is ≤1; if the HQ or HI is >1, there is a possibility that non-cancer health effects may occur (EPA, 1989, 1997; EPA and Clay, 1991). Detailed methodology for estimating non-cancer hazards is provided in Section 5.2.1 of the Site-wide HHRA. The results of the non-cancer evaluation for each exposure pathway are summarized below.

3.2.1.1 Surface Soil/Indoor Dust Exposure at Tribal Allotments

Risks for incidental ingestion of surface soil and indoor dust, and dermal contact with soil, are presented separately.

Incidental Ingestion of Surface Soil and Indoor Dust

Current and future CHIRU adults and children were assumed to be exposed to non-lead COPCs in soil and indoor dust via incidental ingestion at all tribal allotment DUs sampled in the 2014 and 2016 residential soil studies (except at the one tribal allotment beach DU). For the adult CHIRU population, all total soil/dust ingestion non-cancer hazards (summed across COPCs for each DU) were below 1 under both the RME and CTE scenarios (Tables 34 through 103). Total soil/dust ingestion non-cancer hazards for the child CHIRU population (summed across COPCs) were >1 at 29 of the 35 tribal allotment DUs under the RME scenario. For the child CHIRU population under the CTE scenario, no tribal allotment DUs exceeded 1, not considering target organ effects. No COPCs had individual HQs >1 using either RME or CTE exposure assumptions.

Dermal Contact with Surface Soil

Current and potential future CHIRU adults and children were assumed to be exposed to non-lead COPCs in soil via dermal exposure at all 35 tribal allotment DUs sampled in the 2014 and 2016 residential soil studies that are not beaches. For both CHIRU adults and children, all total soil

dermal non-cancer hazards (summed across COPCs for each DU) were <1 under both the RME and CTE scenarios (Tables 34 through 103).

Total Exposure to Surface Soil and Indoor Dust
When exposure to non-lead COPCs in tribal allotment soil was summed across pathways (incidental ingestion of soil/dust and dermal contact with soil), total non-cancer HIs ranged from 0.3 to 1 for adults and 1 to 5 for children under the RME scenario (Tables 34 through 103). When these HIs for children were aggregated by target organ, 2 tribal allotment DUs had HIs >1 for the skin/hair/nails system under RME assumptions. Under the CTE scenario, total non-cancer HIs ranged from 0.04 to 0.2 for adults and 0.3 to 1 for children. No target organ systems had HIs >1 for the CTE scenario. Based on HIs being >1 when evaluated by target organ system at the RME, there is potential for non-cancer health effects from exposure to non-lead COPCs through the total exposure to surface soil and indoor dust pathway.

3.2.1.2 Sediment Exposure at Tribal Allotment Beach

Tribal allotment DU 411 borders the UCR; beach sediment was sampled as part of the 2014 Residential Soil Study. The CHIRU population was assumed to be exposed to non-lead COPCs in tribal allotment beach sediment while participating in activities near the river. Under the RME exposure scenario, the HI for incidental sediment ingestion was 0.1 for adults and 0.4 for children; the HI for dermal contact with sediment was 0.002 for adults and 0.009 for children (Table 104). Summed across exposure pathways (incidental ingestion and dermal contact with sediment), total HIs were 0.1 for adults and 0.4 for children at the RME. No target organ HIs were >1 under the RME scenario. As no HIs exceeded 1 for the RME scenario, no HIs exceeded 1 for the CTE scenario (Table 105). Based on the HI not exceeding 1, risks of non-cancer health effects from exposure to non-lead COPCs through this pathway are below non-cancer hazard benchmarks used by CERCLA (EPA, 1989, 1997; EPA and Clay, 1991).

3.2.1.3 Surface Water Exposure at Tribal Allotment Beach

The CHIRU population was assumed to be exposed to non-lead COPCs in unfiltered, disturbed UCR surface water via incidental ingestion and dermal contact while participating in activities in the UCR. For adults, under both the RME and CTE scenarios, HIs (summed across COPCs) for incidental ingestion and dermal contact were <1 (Tables 106 and 107). Total (ingestion + dermal) non-cancer hazards for surface water were 0.2 (RME) and 0.02 (CTE) for adults. For children, HIs for incidental ingestion and dermal contact did not exceed 1 for the RME and CTE scenarios. Total non-cancer HIs for children were 0.6 under the RME scenario and 0.06 under the CTE scenario. Aggregated by target organ, HIs for no target organ system exceeded 1 under either the RME or CTE scenario. Based on the HI not exceeding 1, risks of non-cancer health effects from exposure to non-lead COPCs through this pathway are below non-cancer hazard benchmarks used by CERCLA (EPA, 1989, 1997; EPA and Clay, 1991).

3.2.1.4 Air Exposure at Tribal Allotments

The CHIRU population was assumed to be exposed to non-lead COPCs (arsenic and cadmium) in air for 24 hours/day on tribal allotments. For adults and children, total non-cancer HIs were <1 (summed across COPCs) under both RME and CTE scenarios (Tables 108a and 108b). HIs for air were 0.4 for the CTE scenario and 0.6 for the RME scenario for both adults and children. HIs grouped by target organ did not exceed 1 as well. Based on the HI not exceeding 1, risks of non-

cancer health effects from exposure to non-lead COPCs through this pathway are below non-cancer hazard benchmarks used by CERCLA (EPA, 1989, 1997; EPA and Clay, 1991).

3.2.1.5 Exposure to Non-Lead COPCs from Consumption of Fish from the UCR

The CHIRU population (adults and children) was assumed to be exposed to non-lead COPCs in fish caught from the UCR and consumed. Risks for fish were estimated by consumption of individual species. Exposure to non-lead COPCs from consumption of fish was evaluated using EPCs calculated using all data for an individual fish species collected from UCR Reaches 1 to 6, to inform whether there is variability in risk based on preferential consumption of a particular species (Tables 109 through 126). For the RME CHIRU population, risk was highest from consumption of walleye fillets (child and adult HIs of 100 and 40, respectively; Table 116), followed by consumption of suckers (child and adult HIs of 90 and 30, respectively; Table 115) and smallmouth bass (child and adult HIs of 80 and 30, respectively; Table 113). HIs for all individual species evaluated were >1 at the RME for adults and children. COPCs contributing the most to non-cancer risk were mercury, thallium, and TEQ, which had HQs >1 for each species under RME exposure assumptions.[16] Target organ HIs >1 for the child and adult CHIRU population at the RME are as follows (Tables 109-117):

- Cardiovascular system[17]: HI >1 for walleye (adult and child) and whitefish (child)
- Developmental system: HI >1 all individual fish species (adult and child)
- Endocrine system[18]: HI >1 for walleye (adult and child) and whitefish (child)
- Gastrointestinal system[19]: HI >1 for sucker (child)
- Hematologic system: HI >1 for burbot (child), northern pike (child), smallmouth bass (child), and sturgeon (child)
- Nervous system: HI >1 for all individual fish species (adult and child)
- Reproductive system: HI >1 for all individual fish species (adult and child) except northern pike[20]
- Skin/hair/nails system: HI >1 for all individual fish species (adult and child)

Using CTE exposure parameters, all HIs for adults and children in the CHIRU population were >1 (adult HIs ranged from 2 to 7; child HIs ranged from 6 to 20; Tables 118 through 126). Target organ HIs >1 for the child and adult CHIRU population at the CTE are as follows:

- Cardiovascular system: HI >1 for walleye (child)
- Developmental system: HI >1 for burbot (adult and child), kokanee (child), northern pike (child), rainbow trout (child), smallmouth bass (adult and child), sturgeon (child), sucker (adult and child), walleye (adult and child) and whitefish (child)
- Endocrine system[21]: HI >1 for walleye (child)

[16] Note that northern pike were not analyzed for TEQ.
[17] COPCs that affect the cardiovascular system were not detected/not analyzed in northern pike.
[18] Note that northern pike and sturgeon were not analyzed for COPCs that affect the endocrine system.
[19] Note that northern pike and sturgeon were not analyzed for COPCs that affect the gastrointestinal system.
[20] Northern pike were not analyzed for COPCs that affect the reproductive system.
[21] Note that northern pike and sturgeon were not analyzed for COPCs that affect the endocrine system.

- Nervous system: HI >1 for burbot (adult and child), kokanee (child), northern pike (child), rainbow trout (child), smallmouth bass (adult and child), sturgeon (child), sucker (adult and child), walleye (adult and child) and whitefish (child)
- Reproductive system[22]: HI >1 for burbot (child), kokanee (child), rainbow trout (child), smallmouth bass (adult and child), sturgeon (child), sucker (adult and child), walleye (child) and whitefish (adult and child)
- Skin/hair/nails system: HI >1 for burbot (child), kokanee (adult and child), northern pike (child), rainbow trout (adult and child), smallmouth bass (adult and child), sturgeon (child), sucker (child), walleye (adult and child) and whitefish (adult and child)

Based on target organ HIs being >1, there is potential for non-cancer health effects from exposure to non-lead COPCs through fish consumption.

3.2.1.6 Exposure to Non-Lead COPCs from Consumption of Mussels from the UCR

CHIRU adults and children were assumed to be exposed to non-lead COPCs through the consumption of mussels from the UCR. As shown in Tables 127 and 128, adult and child HIs (summed across COPCs) under RME and CTE scenarios were not >1 from consuming mussels from Site locations. Adult and child HIs from consuming mussels from the reference location were also not >1 for RME and CTE scenarios (Tables 129 and 130). Because no HIs were >1 when aggregated by target organ system for adults or children at the RME or CTE scenarios, risks of non-cancer health effects from exposure to non-lead COPCs through consumption of mussels are considered below non-cancer hazard benchmarks used by CERCLA (EPA, 1989, 1997; EPA and Clay, 1991).

3.2.1.7 Exposure to Non-Lead COPCs from Consumption of Crayfish from the UCR

CHIRU adults and children were assumed to be exposed to non-lead COPCs through the consumption of crayfish from the UCR. As shown in Tables 131 through 134, HIs for children and adults at the RME and CTE, summed across COPCs, did not exceed 1 for crayfish collected in Site and reference locations. HIs grouped by target organ did not exceed 1 as well. Because no target organ HIs exceeded 1, risks of non-cancer health effects from exposure to non-lead COPCs through consumption of crayfish are below non-cancer hazard benchmarks used by CERCLA (EPA, 1989, 1997; EPA and Clay, 1991).

3.2.1.8 Exposure to Non-Lead COPCs from Consumption of Amphibians and Reptiles from the UCR

CHIRU adults and children were assumed to be exposed to non-lead COPCs through the consumption of amphibians and reptiles from the UCR. As shown in Tables 135 and 136, HIs for children and adults at the RME and CTE, summed across COPCs, were not >1 due to consuming amphibians and reptiles from Site locations. HIs grouped by target organ were also not >1. Based on the target organ HI not being >1, risks of non-cancer health effects from exposure to non-lead COPCs through this pathway are below non-cancer hazard benchmarks used by CERCLA (EPA, 1989, 1997; EPA and Clay, 1991).

[22] Northern pike were not analyzed for COPCs that affect the reproductive system.

3.2.1.9 Exposure to Non-Lead COPCs from Consumption of Waterfowl

The CHIRU population was assumed to be exposed to non-lead COPCs (arsenic, cadmium, and selenium) in waterfowl harvested from the Upper, Middle, and Lower Regions of the UCR and consumed. For adults and children, total non-cancer HIs did not exceed 1 (summed across COPCs) under either RME or CTE scenarios (Tables 137 and 138). HIs grouped by target organ also did not exceed 1. Based on the HI not exceeding 1, risks of non-cancer health effects from exposure to non-lead COPCs through this pathway are below non-cancer hazard benchmarks used by CERCLA (EPA, 1989, 1997; EPA and Clay, 1991).

3.2.1.10 Exposure to Non-Lead COPCs from Consumption of Wild/Cultural Plants

CHIRU adults and children were assumed to be exposed to non-lead COPCs in plants consumed from the UCR Site. Aquatic plants evaluated (tule and willow) were assumed to be incidentally ingested while basket-weaving (mouthing) and other similar activities; this exposure pathway was assumed to only be complete for adults. HIs for adults exposed to aquatic plants were <1 (summed across COPCs) under both RME and CTE scenarios (Tables 139 through 142). HIs grouped by target organ were <1 as well.

For terrestrial plants, which were assumed to be consumed by adults and children at rates shown in Table 24, non-cancer HIs were calculated by plant species. Table 143 summarizes the total plant risk results for the RME and CTE scenarios. Species-specific tables (Tables 139-142, RME; Tables 144-169, CTE) show non-cancer risk results for the Site exposure area. For chokecherry, huckleberry, sarvisberry, black tree lichen, rose hips, kinnikinnick, rose stems/leaves, wild mint, hazelnut, pine nut, and camas, adult and child HIs for the RME and CTE scenario did not exceed 1 (summed across COPCs); target organ HIs also did not exceed 1 (Tables 144 through 163, Tables 166-167).

For lomatium, the adult HI (summed across COPCs) did not exceed 1 at the RME and CTE, but the child HI at the RME was >1 (Tables 154 and 167). Child total HI did not exceed 1 at the CTE for lomatium. No target organ HIs were >1 for consumption of lomatium under RME exposure assumptions.

Adult HIs from consumption of spring beauty/Indian potato did not exceed 1 at the RME and CTE (Tables 143, 156 and 169). For children assumed to consume spring beauty/Indian potato, HIs summed across COPCs were >1 for the RME and CTE exposure scenarios. Target organ HIs were >1 for the child for both the RME and CTE scenarios for the skin/hair/nails system (Tables 143, 156, and 169).

Based on target organ HIs being >1 for consumption of spring beauty/Indian potato, there is potential for non-cancer health effects from exposure to non-lead COPCs through consumption of this species.

3.2.1.11 Exposure to Non-Lead COPCs from Consumption of Upland Birds

The CHIRU population was assumed to be exposed to non-lead COPCs in upland birds harvested from the UCR Site and consumed. For adults and children, total non-cancer HIs did not exceed 1 (summed across COPCs) under both RME and CTE scenarios (Tables 170 and 171). HIs grouped by target organ also did not exceed 1. Based on the HI not exceeding 1, risks

of non-cancer health effects from exposure to non-lead COPCs through this pathway are below non-cancer hazard benchmarks used by CERCLA (EPA, 1989, 1997; EPA and Clay, 1991).

3.2.1.12 Exposure to Non-Lead COPCs from Consumption of Wild Game (Mammals)

The CHIRU population was assumed to be exposed to non-lead COPCs in wild game (mammals) harvested from upland portions of the UCR Site and consumed. For adults and children, total non-cancer HIs did not exceed 1 (summed across COPCs) under both RME and CTE scenarios (Tables 172 and 173). HIs grouped by target organ also did not exceed 1. Based on the HI not exceeding 1, risks of non-cancer health effects from exposure to non-lead COPCs through this pathway are below non-cancer hazard benchmarks used by CERCLA (EPA, 1989, 1997; EPA and Clay, 1991).

3.2.2 Cancer Summary

The excess risk of cancer from exposure to a chemical is described in terms of the probability of developing cancer because of that exposure. Cancer risks are summed across all carcinogenic chemicals and all exposure pathways that contribute to exposure for a given population. If there is exposure to the same chemical in more than one medium, the total risk from that chemical is the sum of the risks across each medium. If exposure is to more than one chemical, the total cancer risk is estimated by summing the chemical-specific risks across all carcinogenic chemicals.

In general, EPA considers excess cancer risks below 10^{-6} to be negligible, and risks above 10^{-4} to warrant action.[23] Excess cancer risks that range between 10^{-6} and 10^{-4} are generally considered to be acceptable (EPA, 1989; EPA and Clay, 1991), although this is evaluated on a case-by-case basis. In this assessment, the following terminology was used to categorize cancer risks. Cancer risks that are $\leq 10^{-4}$ are within an acceptable range and risks above 10^{-4} are unacceptable (National Contingency Plan [NCP], 1990). As recommended in EPA's *An Examination of EPA Risk Assessment Principles and Practices* (EPA, 2004a), calculated cancer risks retained more than one significant figure and are presented in summary tables shown to one significant figure.

Cancer risks for each chemical were calculated as described in Section 5.2.2 of the Site-wide HHRA. Total excess cancer risks for each COPC, receptor, and exposure pathway are described separately by exposure pathway below.

3.2.2.1 Surface Soil/Indoor Dust Exposure at Tribal Allotments

Because arsenic is the only non-lead COPC in tribal allotment soil that has both a slope factor and a dermal absorption fraction, cancer risk from exposure to soil was solely attributable to arsenic. Current and potential future CHIRU adults and children were evaluated for exposure to arsenic in tribal allotment soil and dust via incidental ingestion, and dermal contact with soil, for receptors exposed under both RME and CTE scenarios. Total excess cancer risks from soil/dust ingestion, and from dermal contact with soil, were below 10^{-4} (Tables 34 through 103) for both children and adults. When ingestion and dermal contact risks were summed, total excess cancer risks ranged from 3×10^{-6} to 8×10^{-5} at the RME and from 2×10^{-7} to 6×10^{-6} at the CTE,

[23] Note that excess cancer risk can be expressed in several formats. A cancer risk of 10^{-6} is equivalent to 1 in 1,000,000 and can be expressed in scientific notation format as 1E-06. Similarly, a cancer risk of 10^{-4} is equivalent to 1 in 10,000 or 1E-04. For the purposes of this document, all cancer risks are presented as 10^{-4}, 10^{-6}, etc.

depending on the tribal allotment. These risks are within the acceptable cancer risk range used by CERCLA (EPA and Clay, 1991; EPA, 1997).

3.2.2.2 Surface Sediment Exposure at Tribal Allotment Beach

Current and potential future CHIRU adults and children were evaluated for exposure to arsenic in tribal allotment beach sediment via incidental ingestion and dermal contact for receptors exposed under both RME and CTE scenarios. Total excess cancer risks from sediment ingestion and dermal contact were below 10^{-4} (Tables 104 and 105) for both children and adults. When ingestion and dermal contact risks were summed, the total excess cancer risk was 3×10^{-6} at the RME and 9×10^{-8} at the CTE. These risks are within the acceptable cancer risk range used by CERCLA (EPA and Clay, 1991; EPA, 1997).

3.2.2.3 Surface Water Exposure at Tribal Allotment Beach

Current and potential future CHIRU adults and children were evaluated for exposure to arsenic in UCR surface water at the tribal allotment beach via incidental ingestion and dermal contact for receptors exposed under both RME and CTE scenarios. Total excess cancer risks from surface water ingestion and dermal contact were below 10^{-4} (Tables 106 and 107) for both children and adults. When ingestion and dermal contact risks were summed, the total excess cancer risk was 3×10^{-7} at the RME and 8×10^{-9} at the CTE. These risks are within the acceptable cancer risk range used by CERCLA (EPA and Clay, 1991; EPA, 1997).

3.2.2.4 Air Exposure at Tribal Allotments

The CHIRU population were assumed to be exposed to arsenic in air via inhalation 24 hours/day. Total excess cancer risks were 1×10^{-5} at the RME and 3×10^{-6} at the CTE (Tables 108a and 108b). These risks are within the acceptable cancer risk range used by CERCLA (EPA and Clay, 1991; EPA, 1997).

3.2.2.5 Exposure to Non-Lead COPCs from Consumption of Fish from the UCR

Total excess cancer risks for the consumption of fish exceeded 10^{-4} at the RME for each individual species evaluated except for northern pike, which did not have any detected COPCs having cancer slope factors (Tables 109 through 117). TWA cancer risks ranged from 1×10^{-4} for sturgeon to 6×10^{-4} for sucker and whitefish. At the CTE, total excess cancer risk did not exceed 10^{-4} for individual species (Tables 118 through 126; TWA cancer risk ranged from 1×10^{-5} for sturgeon to 4×10^{-5} for sucker and whitefish). RME risks for fish consumption by the CHIRU population exceeded the acceptable cancer risk range used by CERCLA (EPA and Clay, 1991; EPA, 1997).

3.2.2.6 Exposure to Non-Lead COPCs from Consumption of Mussels from the UCR

CHIRU adults and children were assumed to be exposed to non-lead COPCs in mussels harvested from the UCR (Site and reference locations) and consumed. Total excess cancer risks (summed across COPCs) for adults and children were 6×10^{-6} (RME) and 6×10^{-7} (CTE) for Site locations, and 4×10^{-6} (RME) and 4×10^{-7} (CTE) for reference locations (Tables 127 through 130). These risks are within the acceptable cancer risk range used by CERCLA (EPA and Clay, 1991; EPA, 1997).

3.2.2.7 Exposure to Non-Lead COPCs from Consumption of Crayfish from the UCR

CHIRU adults and children were assumed to be exposed to non-lead COPCs in crayfish caught from the UCR (Site and reference locations) and consumed. Total excess cancer risks (summed across COPCs) for adults and children were 6×10^{-6} (RME) and 1×10^{-6} (CTE) for Site locations and 3×10^{-6} (RME) and 5×10^{-7} (CTE) for reference locations (Tables 131 through 134). These risks are within the acceptable cancer risk range used by CERCLA (EPA and Clay, 1991; EPA, 1997).

3.2.2.8 Exposure to Non-Lead COPCs from Consumption of Amphibians and Reptiles from the UCR

CHIRU adults and children were assumed to be exposed to non-lead COPCs in amphibians and reptiles caught from the UCR and consumed. Total excess cancer risks (summed across COPCs) for adults and children were 6×10^{-6} (RME) and 2×10^{-6} (CTE) for Site locations (Tables 135 and 136). These risks are within the acceptable cancer risk range used by CERCLA (EPA and Clay, 1991; EPA, 1997).

3.2.2.9 Exposure to Non-Lead COPCs from Consumption of Waterfowl

CHIRU adults and children were assumed to be exposed to arsenic in waterfowl harvested in the vicinity of the UCR and consumed. Total excess cancer risks for the RME ranged from 1×10^{-7} (Middle Region) to 4×10^{-7} (Upper Region), and for the CTE ranged from 5×10^{-8} (Middle Region) to 1×10^{-7} (Upper Region) (Tables 137 and 138). These risks are within the acceptable cancer risk range used by CERCLA (EPA and Clay, 1991; EPA, 1997).

3.2.2.10 Exposure to Non-Lead COPCs from Consumption of Wild/Cultural Plants

CHIRU adults were assumed to be exposed to arsenic in aquatic plants (tule and willow) harvested from the UCR and assumed to be incidentally ingested while being mouthed during basket-weaving. Total excess cancer risks for tule (9×10^{-8} and 3×10^{-9}) and willow (2×10^{-7} and 9×10^{-9}) at the RME and CTE, respectively, were below 10^{-4} (Tables 139 through 142). These risks are within the acceptable cancer risk range used by CERCLA (EPA and Clay, 1991; EPA, 1997).

CHIRU adults and children were assumed to be exposed to arsenic in terrestrial plants harvested from the vicinity of the UCR and consumed. For all terrestrial plants, total excess cancer risks at the RME and CTE were below 10^{-4} (Tables 143 through 169). These risks were within the acceptable cancer risk range used by CERCLA (EPA and Clay, 1991; EPA, 1997).

3.2.2.11 Exposure to Non-Lead COPCs from Consumption of Upland Birds

CHIRU adults and children were assumed to be exposed to arsenic in upland birds harvested in the vicinity of the UCR and consumed. Total excess cancer risks for adults and children were 2×10^{-6} for the RME scenario and 3×10^{-7} for the CTE scenario (Tables 170 and 171, respectively). These risks are within the acceptable cancer risk range used by CERCLA (EPA and Clay, 1991; EPA, 1997).

3.2.2.12 Exposure to Non-Lead COPCs from Consumption of Wild Game (Mammals)

CHIRU adults and children were assumed to be exposed to arsenic in wild game (mammals) harvested in the vicinity of the UCR and consumed. Total excess cancer risks for adults and

children were 5×10^{-7} for the RME scenario and 6×10^{-8} for the CTE scenario (Tables 172 and 173, respectively). These risks are within the acceptable cancer risk range used by CERCLA (EPA and Clay, 1991; EPA, 1997).

4 Uncertainty

Risk estimates such as those reported in this appendix are derived from combining exposure and toxicity estimates for cancer and non-cancer effects. Uncertainty is generally accounted for in HHRA calculations by making health-protective assumptions in estimating the parameters used in risk calculations. Section 6 of the Site-wide HHRA contains a detailed discussion of uncertainty in lead and non-lead risk assessment. This section discusses the uncertainty associated with exposures specific to this Appendix.

4.1 Assumptions Regarding Site Use

Tribal members regularly engaging in tribal lifestyles and activities, represented herein by the CHIRU receptor population, may contact environmental media (air, soil/dust, sediment, and water) as well as consume soil- and sediment- impacted biota to a greater extent than other residents in the area of the Site. Exposure of the CHIRU population to soil and indoor dust on tribal allotments was assessed assuming full-time residential exposure, even though there are currently no occupied houses or full-time residences on these properties. This exposure scenario would be representative of potential future use and is a conservative approach when evaluating current use. Because of this, the results are more likely to overestimate than to underestimate exposure to soil and dust and therefore risk from exposure to Site-related COPCs during current uses of these tribal allotments.

Some activities that Tribal Survey respondents engaged in on the banks of the UCR may have been incorrectly recorded during the Tribal Survey as taking place within one of the UCR river reaches (CCT, 2019), possibly introducing either a low bias in the estimates of EF for contact with soil/sediment and a high bias in estimates of EF for contact with UCR water, or a high bias in the estimates of EF for contact with soil/sediment and a low bias in estimates of EF for contact with UCR water. A small percentage (<5%, n=29) of Tribal Survey participants' responses to questions about the frequency of their on-land activities were identified as potential statistical outliers. A sensitivity analysis that evaluated the effect of these participants' responses on the EF estimates reported estimates for the CTE that were approximately 4.6-11% lower than the original estimate and estimates for the RME that were 12-27% lower than the original estimate. Responses provided by 16 participants (<3% of sample) to questions about the frequency of their activities in water were identified as potential statistical outliers. The estimated EFs for in-water activities were not sensitive to potential outliers; a sensitivity analysis found the effect of these participants' responses on the CTE EF estimate was no more than 6% and the effect on the RME EF estimate was approximately 1% (SRC, 2019a). Thus, these sources of uncertainty are unlikely to substantially influence risk calculations.

4.2 Double-Counting of Intakes for Lead Risk Assessment

Double-counting lead intakes for specific exposure media occurs if the IEUBK model default values for consumption are not adjusted to account for consumption at the Site (for example, downward adjustment of default dietary intakes of lead to account for consumption of lead in locally harvested fish). Double counting of media consumption can result in an overestimation of

lead intake. In general, if amounts consumed at the Site and frequencies of consumption are low, double-counting is unlikely to substantially influence risk-based decisions. These exposure pathways were assessed separately from other media (soil, sediment, and surface water) and presented as discrete intakes.

4.3 Estimation of EPCs in Food Items

While measured COPC concentrations were available for the majority of Site-related media evaluated in this appendix (i.e., soil, sediment, surface water, air, fish, crayfish, mussels, and plants), EPC concentrations in other media were estimated using surrogate data (amphibians and reptiles) or uptake modeling into tissue (waterfowl, upland birds and wild game [mammals]).

4.3.1 Uncertainty Associated with Available Data

In all exposure calculations, the desired input parameter is the true mean concentration of a contaminant within a medium, averaged over the area where random exposure is assumed to occur. However, because the true mean cannot be calculated based on a limited set of measurements, EPA (1989, 1992) recommends that the exposure estimate be based on the 95UCL. When data are plentiful and inter-sample variability is not large, the 95UCL may be only slightly higher than the mean of the data. However, when data are sparse or highly variable, the 95UCL may be substantially greater than the mean of the available data. Using the 95UCL as the EPC is a health-protective assumption for risk calculations. Uncertainties associated with data and EPCs calculated for soil, sediment, surface water, air, and fish are discussed in the Site-wide HHRA.

The Quality Assurance Project Plan (QAPP) for the Macroinvertebrate Tissue Study (TAI, 2016) specified collection of six composite samples of mussels from different locations within each UCR River reach. Six mussel beds were not located in any of the reaches, resulting in more than one sample being collected from an individual bed. Measured metal concentrations from mussel samples collected within a bed were more similar than measured metal concentrations in mussel samples collected within a reach. There is uncertainty regarding whether the spatial distribution of composite samples from each area is equally representative of the collection from all locations.

The availability of mussels in the UCR for collection and consumption is also uncertain. Macroinvertebrate sampling was targeted to be conducted during the time period when the reservoir water level is typically at its lowest and mussels would be most accessible. During the spring 2016 sampling event, water levels were higher than anticipated, and the number of mussels targeted for collection was not achieved. The collection of a sufficient number of mussels for chemical tissue analysis required scuba diving in the majority of the sampling areas (A1 and A3-A6) in the fall (TAI, 2017b). Insufficient availability of mussels as a resource for consumption would result in an overestimate of risk assuming daily exposure (which is the methodology used to assess risk in this HHRA).

In the absence of Site-specific tissue concentration data for amphibians and reptiles, the EPCs calculated for crayfish were used to evaluate risk from consumption of these organisms (see Section 2.2.9 for the rationale). The uncertainty in the risk estimate related to selection of these EPCs is unknown in both direction and magnitude.

4.3.2 Uncertainty Associated with Uptake Modeling

While soil and surface water concentrations are typically measured at sites, plant and biota concentrations are sometimes estimated using uptake models. In a study conducted to evaluate the predictive utility of uptake models, it was determined that the three general estimation methods used overestimated measured plant concentrations for over 50% of soil concentrations (Bechtel Jacobs Co., 1998). For this risk assessment, wild/cultural plants were collected to measure COPC concentrations in the plant parts consumed by the CHIRU receptor population and to reduce uncertainty in the risk estimates. For most plants, estimated plant concentrations (using the mean soil concentration from the plant SAs) overestimated the measured plant concentrations (Table 174). Measured concentrations tended to exceed estimated plant tissue concentrations for black tree lichen (arsenic, cadmium, lead) and for the underground plant parts (camas, lomatium, and spring beauty) that were collected (arsenic, cadmium, lead and nickel).

Consumption of black tree lichen, camas, lomatium and spring beauty resulted in estimated lead intakes >1 µg/day, and in a non-cancer target organ HI >1 for the skin/hair/nails system for consumption of spring beauty by children under RME exposure assumptions. Collection of site-specific plant data reduced the uncertainty associated with these risk estimates.

For this risk assessment, uptake models were used to predict tissue concentrations for waterfowl, upland birds, and game mammals (see Sections 2.1.1.5 and 2.1.1.7). As noted above, Site-specific factors that affect COPC bioavailability and uptake may lead to under- or overestimation of modeled food concentrations.

4.4 Uncertainty in Dietary Estimates

Consumption rates of biota (macroinvertebrates, plants, birds, game) were derived when possible from the Tribal Survey (SRC, 2019a).[24] As described in the Tribal Survey DAR (SRC, 2019a), there are uncertainties associated with the 24-hour dietary recalls, as well as the FQ. The 24-hour dietary recalls provided detailed records of food items consumed during the recall periods, but 24-hour recalls tend to under-estimate the frequency for foods that are consumed infrequently and over-estimate the variability in daily consumption rates within a population (Dodd et al., 2006). The FQ was developed specifically for the Tribal Survey, based on a validated food frequency questionnaire that had been used in many large surveys (Westat, Inc., 2010). A draft version of the FQ was also tested with members of the survey population. An advantage of FQs in general is they are more likely to capture food items that are consumed infrequently, while a disadvantage is that participants tend to have difficulty accurately recalling the frequency of eating particular food items (Dodd et al., 2006).

4.4.1 Shellfish and Amphibian/Reptile DCRs

The mussel and crayfish DCRs were calculated using the frequency of consumption (obtained from the FQ in the Tribal Survey) and the meal size of market shellfish (obtained from the 24-hour dietary recalls in the Tribal Survey). The FQ data for mussels sourced from the Local Area was provided by 10 participants (Table 9 of SRC, 2019a; the sample weights of these participants summed to 54). An additional 61 participants provided data on the FQ for mussels that were not sourced from the Local Area (Table 9 of SRC, 2019a; the sample weights of these

[24] Uncertainty associated with the fish DCR, obtained from the CCT, is not discussed in this appendix.

participants summed to 418); including these participants' responses, the average daily frequency of consumption was approximately 2.4% (approximately 8.8 days per year). The estimates for the frequency of consuming crayfish sourced from the Local Area are based on a much larger number of participants (n = 80). However, these are still relatively small sample sizes upon which to base estimates of consumption frequency for the UCR.

The 24-hour recalls did not capture consumption of locally sourced shellfish. The AMPM data includes meal size information for commercial sources of shellfish. As a result, the meal size estimates for mussels and crayfish were based on the meal size data for all commercial shellfish (i.e., mollusks and crustaceans) that were reported on the 24-hour recalls. Most meals captured in the 24-hour recalls included shrimp (49/89) or clams (26/89), with a few crabs (6/89) and oysters (5/89), 1 lobster, and 2 "seafood." By using the commercial shellfish as a surrogate to estimate meal size for locally sourced mussels and crayfish, the DCRs, and therefore exposures, are potentially overestimated; however, the magnitude of the overestimate is unknown.

The consumption rates (meal size and consumption frequency) of amphibians and reptiles are very uncertain due to minimal or no data. Five participants out of 1,165 respondents reported consuming amphibians/reptiles ("aquatic organisms") sourced from the Local Area on the Tribal Survey FQ. The average frequency of consumption was approximately 6% (22 days/year). There were no reports of consumption of amphibians or reptiles in any of the Tribal Survey 24-hour diet recalls. Therefore, as with mussels and crayfish, the meal size estimates were taken from 24-hour recall data for all mollusks and crustaceans.

4.4.2 Plant DCRs

Adult DCRs for plants were derived using a combination of consumption frequency and meal size data from the Tribal Survey, and information provided directly by the CCT. The Tribal Survey collected age-specific information on consumption of wild plants harvested from the Local Area. The exposure factor estimated for the consumption of wild plants (consumption rate in grams of aquatic and terrestrial wild plants consumed per day) is based on Tribal Survey respondents who reported consumption of wild plants ("consumers only") harvested from the Local Area. For most of the plant species collected during the Plant Study, survey responses were only sufficient to derive an estimate of consumption frequency (number of days per year a particular plant is consumed) for wild/cultural plant species of interest. Based on the available sample sizes for consumers, the only meal size data sufficient to fully derive DCRs based on the Tribal Survey was the grams per day estimate for huckleberries. Additional information on the meal sizes for wild plants based on recipes provided by the CCT or from Turner (1997) was utilized to develop DCRs for other wild plant species. For plant species utilized for weaving, it was assumed that either 50% (RME) or 5% (CTE) of the material mouthed while weaving was incidentally ingested. The magnitude and direction of uncertainty resulting from assumptions made to derive the DCR estimates is unknown, except for plants utilized for weaving. The assumption that 5-50% of the mouthed material is ingested is more likely to overestimate than underestimate intake.

4.4.3 Waterfowl and Upland Bird DCRs

The Tribal Survey 24-hour recalls did not capture consumption of wild upland birds or waterfowl. DCRs for adults were estimated using meal size data from the Tribal Survey for

chicken. There is some uncertainty related to using the average domestic poultry meal size as a surrogate for the average meal size for wild upland birds. Burger and Gochfeld (2002) reported both meal sizes and DCRs for market chicken exceed the meal sizes and DCRs for wild game (including dove, duck, quail, and wild turkey). However, the average chicken meal size for adults reported on the AMPM (100 grams) was approximately half the average chicken meal size estimated in Burger and Gochfeld (2002; ranged from 245 to 255 grams). It is within the range of meal sizes reported in Burger and Gochfeld (2002) for duck, wild-caught quail, and wild turkey (24 to 127 grams). Furthermore, the average meal size of 100 grams based on the AMPM data is within the range of meal sizes reported in the literature for wild game (38–183 grams; Section 5.2.4.2 of SRC, 2019a). This indicates that using the daily meal size of chicken reported on the AMPMs is a reasonable surrogate for estimating meal size for upland birds.

The FQ provided data for waterfowl sourced from the Local Area for 16 survey participants. An additional 7 adults provided data for waterfowl that were not sourced from the Local Area. The small sample size available from the FQ for waterfowl is a source of substantial uncertainty. For upland birds, the FQ data include a few participants whose responses may be considered statistical outliers. Three participants (all adults) reported eating wild upland game birds much more frequently than the rest of the participants. They also reported sourcing all the game birds from the Local Area. Two of the participants reported daily frequencies equivalent to approximately 4 days per week (daily frequency = 0.5704) and one participant reported eating wild upland bird meat every day. The next highest daily frequency (0.1429, or approximately once per week) was reported by four participants. However, most participants who reported eating wild upland birds (n = 208) reported eating them approximately 6 times per year (daily frequency = 0.0167). The effect of the potential outliers on the estimates is small. The estimates of the mean and P95 decrease by approximately 3 days per year with the three largest responses omitted from the dataset.

4.4.4 Wild Game (Mammal) DCRs

As described in the Tribal Survey (SRC, 2019a), the FQ and 24-hour recalls provided few data on the consumption of wild game such as bear, elk, and moose. However, venison consumption was reported on at least one 24-hour recall by 202 survey participants (179 adults and 23 children), and 30 participants reported consumption on more than one dietary recall. These data were used to calculate an adult DCR for wild game (mammals). Child DCRs for venison were estimated using the adult DCRs and the ratio of average meal sizes for children and adults from the Tribal Survey. A detailed discussion of the uncertainty in the modeling approach used to derive the adult DCR used for wild game (mammals) is provided in the Tribal Survey DAR (SRC, 2019a).

4.4.5 Estimation of Child DCRs

For the majority of food items evaluated in this appendix, data were not available to derive DCRs for children. Therefore, child DCRs were estimated by multiplying the adult DCR by a ratio of child-to-adult estimated energy requirements (EER). The EER ratio was based on EERs estimated from regression models applied to data from doubly labeled water studies (IOM, 2005; SRC, 2019b; Appendix 14 of the Site-wide HHRA). The regression models predicted EER based on age, body weight and height, and physical activity. The EER ratio was calculated for the average of EERs estimated for three physical activity (PA) levels that ranged from low to highly

active, for males and females combined (SRC, 2019b, Table 2). While these data were considered the best available data for estimating child and adult EER (IOM, 2005), the data were not provided by a random sample and how well they represent the variability in the target population is not known. Sources of uncertainty in the EER ratio include the uncertainty in the predicted average EERs for children and adults due to variability in age, height and weight among the population; differences in EER between males and females; differences in the PA level of the population; and, possibly, other physiological variables that may affect EER in the target population that were not represented in the population from which the EERs were derived. The application of a single EER ratio to estimate DCRs for specific foods assumes that amounts of individual foods consumed by children and adults scale with EER.

5 Summary

Exposure to COPCs in surface soil, indoor dust, air, surface water, surface sediment, fish, plants, mussels, crayfish, amphibians/reptiles, birds (waterfowl and upland birds), and game (mammals) were evaluated for the CHIRU adult and child receptor populations. Risks from exposure to lead were assessed using the ALM and the IEUBK model, for adults and children, respectively. Risks from exposure to other COPCs were estimated using standard equation and exposure pathways and parameters based on EPA guidance, the Tribal Survey (Westat, 2012; SRC, 2019a), and personal communication with the CCT.

The risk evaluation benchmarks selected for quantitative evaluation of lead risk were defined as >5% probability of exceeding each of these target PbBs: >5% probability of exceeding 3 µg/dL (referred to as "P3"), >5% probability of exceeding 5 µg/dL (referred to as "P5"), or >5% probability of exceeding 8 µg/dL (referred to as "P8"). Each of these risk benchmarks for lead was evaluated separately in this Appendix to the Site-wide HHRA. For other COPCs, risk was estimated for RME and CTE exposure scenarios. Risk benchmarks used herein for COPCs other than lead were either a non-cancer HQ or HI >1 or a TWA excess cancer risk $>10^{-4}$.

Lead risks at 35 tribal allotment DUs (not including the tribal allotment beach DU) exceeded risk benchmarks as follows:

- 21 tribal allotment DUs had more than a 5% probability of exceeding a PbB of 3 µg/dL (P3 benchmark).
- 17 tribal allotment DUs had more than a 5% probability of exceeding a PbB of 5 µg/dL (P5 benchmark).
- 6 tribal allotment DUs had more than a 5% probability of exceeding a PbB of 8 µg/dL (P8 benchmark).

Lead risk at the tribal allotment beach exceeded the P3 and P5 risk benchmarks due to incidental ingestion of sediment and surface water during activities on the beach.

Lead risk due to consumption of Site-related biota was evaluated as relative risk, with a focus on those intakes in excess of 1 µg Pb/day. The following pathways resulted in lead intake >1 µg/day:

- Consumption of sarvisberries by children
- Consumption of black tree lichen by children
- Consumption of lomatium by children
- Consumption of camas by children
- Consumption of spring beauty/Indian potato by children
- Consumption of amphibians and reptiles by children from UCR Reaches 2, 5, and Reaches 1-6 combined
- Consumption of fish (sucker and walleye) by children (consumption of other fish species resulted in <1 µg lead per day intake)
- Consumption of upland birds by children

Tribal members engaging in tribal lifestyles and cultural practices may contact environmental media (soil, sediment, and water) as well as soil- and sediment- impacted biota to a greater extent than other residents. Some tribal allotment DUs had fairly high soil lead concentrations (>200 ppm, which is the soil lead concentration associated with the P5 risk benchmark); therefore, soil lead is likely to be the major contributor to lead risk at these locations.

Table 175 presents average daily lead intakes via consumption of biota harvested or collected from the UCR Site. Table 175 indicates that some of the exposures resulted in intakes that exceeded 1 µg Pb per day intake due to high lead concentration in the biota tissue and/or high biota consumption rate.

For the following recommendations, readers should bear in mind the confidence in the results. For example, lead intakes that are based on survey data and measured tissue concentrations are more confident than those where intakes or tissue concentrations are estimated from other species or modeled. In general, those exposures shown in Table 175 that result in intakes <1 µg Pb/day are unlikely to present unacceptable risk from lead exposure, whereas those that exceed 1 µg Pb/day may warrant consideration of risk management alternatives.

For those biota where the concentration of lead in the tissue is high (such as camas and other underground plants), it may be advisable to seek an alternative source (that is, one not impacted by the Site or other lead sources) or to remove the biota tissue that is most likely to be high in lead before consuming (such as peeling root vegetables to remove the part that contacts the soil). For those biota where the lead concentration was generally low, but intake is high (such as fish), it may be advisable to reduce consumption from the Site and replace with biota that are less contaminated. For those biota where both intake and lead concentration are high, it may be advisable to consider both reducing consumption and finding a less contaminated non-Site source.

For non-lead COPCs, total non-cancer HIs were >1 for exposure of the CHIRU receptor populations via the following pathways:

- Exposure of CHIRU children to soil/indoor dust (ingestion and dermal pathways combined) on 29 tribal allotments at the RME
- Consumption of fish from the UCR for both children and adults at the RME and CTE
- Consumption of lomatium by children under RME exposure assumptions
- Consumption of spring beauty/Indian potato by children under RME and CTE exposure assumptions

Because the total HI is >1 for the pathways discussed above, non-cancer risks were aggregated by target organ effects (Tables 176 through 179). Risks from exposure to non-lead COPCs exceeded non-cancer risk benchmarks (i.e., target organ HIs >1) for the following exposure pathways:

- Exposure to soil/indoor dust by CHIRU children at 2 tribal allotments under RME exposure assumptions
- Consumption of fish by CHIRU adults and children under both RME and CTE exposure assumptions (adults under CTE scenario do not have target organ HIs >1 for consumption of northern pike or sturgeon)
- Consumption of spring beauty/Indian potato by children under RME and CTE exposure assumptions

Risks from exposure to non-lead COPCs exceeded cancer risk benchmarks (i.e., total excess cancer risk $>10^{-4}$) for the following exposure pathways:

- Consumption of fish by the CHIRU population under RME exposure assumptions (Tables 109 through 117), except for northern pike, which did not have any detected COPCs having cancer slope factors (Table 111)

For additional consideration, in its *Upper Columbia River Freshwater Mussel and Crayfish Evaluation (2018 Results)*, Washington State Department of Health (WDOH) evaluated the mussel data collected from the UCR (WDOH, 2019). Meal restrictions were recommended to the general public and high consumers for both the Site and reference areas due to manganese concentrations in freshwater mussels. Regardless of evaluation of the UCR mussel tissue concentration data, the Department of Fish and Wildlife prohibits the harvest of freshwater clams and mussels from all Washington freshwater sources because they do not consider them safe to eat due to potential bacterial contamination.[25] WDOH evaluated the crayfish data collected from the UCR and did not recommend restriction of crayfish consumption for the general public (WDOH, 2019). For high consumers (those that consume up to 23 meals per month of fish and shellfish), WDOH recommends consuming no more than 10 meals per month of crayfish from the UCR due to levels of inorganic arsenic.

Table 1. Exposure Areas by Environmental Medium

Medium	Exposure Area
Soil and indoor dust	Individual tribal allotment decision unit (DU)
Surface sediment	Individual tribal allotment beach DU
Surface water	UCR reaches 1-6 combined
Air	Entire Site
Fish	UCR reaches 1-6 combined
Mussels	UCR reaches 1-6 combined
Crayfish	UCR reaches 1-6 combined
Amphibians/reptiles	UCR reaches 1-6 combined
Waterfowl	UCR River region (Upper, Middle and Lower regions as defined in IEc [2012])
Wild/cultural plants (evaluated as individual species)	All plant sampling areas (SAs) combined (see TAI, 2019)
Upland birds	Entire Site
Wild game (mammals)	Entire Site

Table 2. Wild/Cultural Plants Collected from the UCR Site

Plant Species	Date of Collection	Sampling Area(s)
Black tree lichen (*Bryoria fremontii*)	Spring (April 25-May 2, 2018)	SA01, SA05, SA08
Camas (*Camassia quamash*)	Spring (April 25-May 2, 2018)	SA01, SA03, SA05, SA07
Chokecherry (*Prunus virginiana*)	Late Summer (August 20-28, 2018)	SA01, SA03, SA07, SA09
Hazelnut (*Corylus cornuta var. californica*)	Late Summer (August 20-28, 2018)	SA02, SA03, SA04, SA06, SA09
Huckleberry (*Vaccinium cespitosum*)	Early Summer (June 18-20, 2018)	SA04
Kinnikinnick (*Arctostaphylos uva-ursi*)	Spring (April 25-May 2, 2018)	SA02, SA03, SA04, SA06
Lomatium (*Lomatium triternatum*)	Spring (April 25-May 2, 2018)	SA02, SA03, SA05, SA08
Lomatium (*Lomatium triternatum*)	Early Summer (June 18-20, 2018)	SA03
Ponderosa pine (*Pinus ponderosa*)	Late Summer (August 20-28, 2018)	SA01, SA02, SA03, SA04, SA07
Sarvisberry (*Amelanchier alnifolia*)	Late Summer (August 20-28, 2018)	SA01, SA03, SA07, SA08, SA14
Spring beauty/Indian potato (*Claytonia lanceolate*)	Spring (April 25-May 2, 2018)	SA01, SA02, SA03, SA04, SA05, SA08
Tule (*Schoenoplectus acutus*)	Late Summer (August 20-28, 2018)	SA14
Wild mint (*Mentha arvensis*)	Late Summer (August 20-28, 2018)	SA14
Wild rose (*Rosa gymnocarpa, R. nutkana,* and *R. woodsi*) stems and leaves	Early Summer (June 18-20, 2018)	SA01, SA03, SA04, SA06
Wild rose (*Rosa gymnocarpa, R. nutkana,* and *R. woodsi*) hips	Late Summer (August 20-28, 2018)	SA06, SA09, SA14
Willow (*Salix exigua*)	Spring (April 25-May 2, 2018)	SA16
Willow (*Salix exigua*)	Late Summer (August 20-28, 2018)	SA15

RBSL = risk-based screening level; DF = detection frequency; COPC = chemical of potential concern

Table 5. COPCs for Waterfowl

COPC[a]	Basis for Selection
2,4'-DDD	Detected bioaccumulator in surface sediment
2,4'-DDE	Detected bioaccumulator in surface sediment
2,4'-DDT	Detected bioaccumulator in surface sediment
4,4'-DDD	Detected bioaccumulator in surface water and surface sediment
4,4'-DDE	Detected bioaccumulator in surface sediment
4,4'-DDT	Detected bioaccumulator in surface sediment
Aldrin	Detected bioaccumulator in surface water
Alpha-chlordane	Detected bioaccumulator in surface water and surface sediment
Aluminum	Surface water COPC
Antimony	Surface water, surface sediment and aquatic plant COPC
Arsenic	Surface water, surface sediment and aquatic plant COPC
Barium	Surface water COPC
Benzo(a)anthracene	Detected bioaccumulator in surface sediment
Benzo(a)pyrene	Detected bioaccumulator in surface sediment
Benzo(b)fluoranthene	Detected bioaccumulator in surface water and surface sediment
Benzo(k)fluoranthene	Detected bioaccumulator in surface sediment
Beryllium	Surface water COPC
Bis(2-ethylhexyl)phthalate	Detected bioaccumulator in surface water and surface sediment
Cadmium	Detected bioaccumulator in surface water, and surface sediment
Chromium	Surface water, surface sediment and aquatic plant COPC
Chrysene	Detected bioaccumulator in surface water and surface sediment
Cobalt	Surface water and aquatic plant COPC
Dibenzo(a,h)anthracene	Detected bioaccumulator in surface sediment
Fluoranthene	Detected bioaccumulator in surface sediment
Hexachlorobenzene	Detected bioaccumulator in surface water and surface sediment
Indeno(1,2,3-cd)pyrene	Detected bioaccumulator in surface water and surface sediment
Inorganic arsenic	Surface water COPC
Iron	Surface water, surface sediment and aquatic plant COPC
Lead	Surface water, surface sediment and aquatic plant COPC
Manganese	Surface water and aquatic plant COPC
Mercury	Detected bioaccumulator in surface water and surface sediment
Selenium	Detected bioaccumulator in surface water and surface sediment
TEQ (dioxin-like PCBs and dioxins/furans)	Detected bioaccumulator in surface water and surface sediment
Thallium	Surface water and aquatic plant COPC
Total PCBs (non-dioxin-like congeners or aroclors)	Detected bioaccumulator in surface water and surface sediment
Uranium	Surface water COPC
Vanadium	Surface water COPC

[a]Shaded COPCs are those evaluated quantitatively in the HHRA.

Table 6. COPCs for Upland Birds

COPC[a]	Basis for Selection
4,4'-DDD	Detected bioaccumulator in surface water
Aldrin	Detected bioaccumulator in surface water
Alpha-chlordane	Detected bioaccumulator in surface water
Aluminum	Surface water and surface soil COPC
Antimony	Surface water and surface soil COPC
Arsenic	Surface water and surface soil COPC
Barium	Surface water COPC
Benzo(b)fluoranthene	Detected bioaccumulator in surface water
Beryllium	Surface water COPC
Bis(2-ethylhexyl)phthalate	Detected bioaccumulator in surface water
Cadmium	Detected bioaccumulator in surface water and surface soil
Chromium	Surface water and surface soil COPC
Chrysene	Detected bioaccumulator in surface water
Cobalt	Surface water and surface soil COPC
Hexachlorobenzene	Detected bioaccumulator in surface water
Indeno(1,2,3-cd)pyrene	Detected bioaccumulator in surface water
Inorganic arsenic	Surface water COPC
Iron	Surface water and surface soil COPC
Lead	Surface water and surface soil COPC
Manganese	Surface water and surface soil COPC
Mercury[b]	Detected bioaccumulator in surface water
Nickel	Surface soil COPC
Selenium	Detected bioaccumulator in surface water and surface soil
TEQ (dioxin-like PCBs and dioxins/furans)	Detected bioaccumulator in surface water
Thallium	Surface water and surface soil COPC
Total PCBs (non-dioxin-like congeners or aroclors)	Detected bioaccumulator in surface water
Uranium	Surface water COPC
Vanadium	Surface water and surface soil COPC

[a]Shaded COPCs are those evaluated quantitatively in the HHRA.

[b]Total mercury was analyzed in surface water. As there is no toxicity value for inorganic mercury, risk calculations were done with the assumption that 100% of the measured mercury is methylmercury.

Table 7. COPCs for Wild Game (Mammals)

COPC[a]	Basis for Selection
4,4'-DDD	Detected bioaccumulator in surface water
Aldrin	Detected bioaccumulator in surface water
Alpha-chlordane	Detected bioaccumulator in surface water
Aluminum	Surface water and surface soil COPC
Antimony	Surface water and surface soil COPC
Arsenic	Surface water and surface soil COPC
Barium	Surface water COPC
Benzo(b)fluoranthene	Detected bioaccumulator in surface water
Beryllium	Surface water COPC
Bis(2-ethylhexyl)phthalate	Detected bioaccumulator in surface water
Cadmium	Detected bioaccumulator in surface water and surface soil
Chromium	Surface water and surface soil COPC
Chrysene	Detected bioaccumulator in surface water
Cobalt	Surface water and surface soil COPC
Hexachlorobenzene	Detected bioaccumulator in surface water
Indeno(1,2,3-cd)pyrene	Detected bioaccumulator in surface water
Inorganic arsenic	Surface water COPC
Iron	Surface water and surface soil COPC
Lead	Surface water and surface soil COPC
Manganese	Surface water and surface soil COPC
Mercury[b]	Detected bioaccumulator in surface water
Nickel	Surface soil COPC
Selenium	Detected bioaccumulator in surface water and surface soil
TEQ (dioxin-like PCBs and dioxins/furans)	Detected bioaccumulator in surface water
Thallium	Surface water and surface soil COPC
Total PCBs (non-dioxin-like congeners or aroclors)	Detected bioaccumulator in surface water
Uranium	Surface water COPC
Vanadium	Surface water and surface soil COPC

[a]Shaded COPCs are those evaluated quantitatively in the HHRA.

[b]Total mercury was analyzed in surface water. As there is no toxicity value for inorganic mercury, risk calculations were done with the assumption that 100% of the measured mercury is methylmercury.

Table 8. Disturbed, Unfiltered Surface Water EPCs

Analyte	Number of Detects / Number of Samples	Maximum Detected Concentration (µg/L)	Arithmetic Mean Detected Concentration (µg/L)	Standard Deviation (µg/L)	95% UCL[a] (µg/L)	UCL Statistic[a]	Selected Exposure Point Concentration for both RME and CTE risks

N/A = not applicable; ND = not detected; UCL = Upper confidence limit; UCL-P = Parametric UCL; UCL-NP = Nonparametric UCL

[a] Based on recommendations from ProUCL, version 5 1 00 software (EPA 2015); includes non-detects treated per recommendations for each statistical method:
Adjusted Gamma UCL assumes approximate gamma distribution
Approximate Gamma UCL assumes approximate gamma distribution
Chebyshev (Mean, Sd) UCL obtained using classical sample mean and standard deviation
GROS Adjusted Gamma UCL based on the ROS method for a gamma distribution
GROS Approximate Gamma UCL based on the ROS method for a gamma distribution
H-UCL based on Land's H-statistic; assumes lognormality
KM (Chebyshev) UCL based on Kaplan-Meier method using the Chebyshev inequality
KM (t) UCL based on Kaplan-Meier method using the t-distribution cutoff value
KM Adjusted Gamma UCL based on Kaplan-Meier method adjusted for level significance
KM Approximate Gamma UCL based on Kaplan-Meier method using chi-square approximation
KM H-UCL based on Kaplan-Meier method and Land's H-Statistic
KM Student's t based on Kaplan-Meier method using Student's t-distribution
Modified-t UCL modified for skewness
Student's t UCL based on Student's t-distribution

[b] Mean calculated using KM method

[c] Some samples were not analyzed for inorganic arsenic For these samples, a calculated inorganic arsenic result was generated by multiplying the total arsenic result by the site-specific fraction (5 5%) of inorganic arsenic to total arsenic

Table 11. Tribal Allotment Soil and Sediment EPCs

DU	SRC_DU_ID	DU Type	Media	analyte	Number of Detects / Number of Samples[a]	Maximum Detected Concentration (mg/kg)	Arithmetic Mean Detected Concentration (mg/kg)	Standard Deviation	T-statistic UCL or CF*result[b]	Selected EPC for both RME and CTE risks		
										Ingestion[c] (mg/kg)	Dermal (mg/kg)	Rationale

[a]Field replicates treated as individual samples.

[b]T-statistic 95UCL = mean concentration across replicates + (2.92 * standard deviation / √(3)). EPCs from a single incremental composite sample (ICS) when ≥3 ICS composite samples were not available for estimating the 95UCL were estimated by applying a site-specific confidence factor (CF; 1.2) to the soil concentration measured in the single ICS composite sample (See Appendix 12 to the Site-wide HHRA).

[c] With the exception of RBA Adjusted Lead, an adjustment factor of 0.7 was applied to the soil concentration to generate an indoor dust concentration (where indoor EPC = outdoor EPC *0.7). A combined Soil/Dust EPC was generated for use in Ingestion pathway risk calculations [combined soil/dust EPC = (outdoor soil EPC * 0.45) + ((outdoor soil EPC * 0.7) * 0.55)]. The lead EPC was adjusted for dust within the IEUBK model.

[d] TCRA or VRA taken at this DU. The maximum backfill concentration from the 2015 TCRA Final Completion Report was used as the soil EPC.

[e]Sediment not evaluated for dust exposure.

[a]No amphibian or reptile samples were collected at the site. Crayfish tissue Site data were used as a surrogate.

[b] Based on recommendations from ProUCL, version 5.1.00 software (EPA, 2015); includes non-detects treated per recommendations for each statistical method:

UCL = Upper confidence limit; UCL-P = Parametric UCL; UCL-NP = Nonparametric UCL

KM H-UCL = UCL based on Kaplan-Meier method and Land's H-Statistic

95% KM (t) UCL = UCL based on Kaplan-Meier method using the t-distribution cutoff value

95% Chebyshev (Mean, Sd) UCL = UCL obtained using classical sample mean and standard deviation

95% Adjusted Gamma UCL = UCL adjusted for level of significance

95% Student's t = UCL based on Student's t-distribution

[c]Mean calculated using KM method

Selenium	0.915	0.352	0.122	0.04	0.00888

Table 22. Intake Parameters for White-Tailed Deer

Parameter	Value	Reference
FIR [a] (kg ww/day)	3.194	French et al., 1955; Magruder et al., 1958; Ozoga and Verme, 1970; Ullrey et al., 1969; Ullrey et al., 1970; Bateman, 1949
FIR (kg dw/day)	1.692	Sample et al., 1997 (assumes 53% dry matter in food)
Water Ingestion Rate (L/day)	3.61	Lautier et al., 1988
Soil Ingestion Rate (kg dw/day)	0.0161	Arthur and Alldredge, 1979

[a] Food ingestion rate is the midpoint of adult food ingestion rates cited

Table 23. IEUBK Input Parameters Based on EPA (2016) and Site-Specific Information

Parameter	Value	Basis
Soil concentration (mg/kg)	C_{soil}	EPC soil concentration, which was the RBA-adjusted arithmetic mean for each DU (the average of the 3 incremental composite [IC] sample results, if replicates were collected, for that DU or the single sample result if only 1 IC sample was collected; discrete core samples were not included). See Section 3.3.1 and Appendix 11 of the Site-wide HHRA for more information.
Dust concentration (mg/kg)	$C_{dust} = 0.7 \bullet C_{soil(weighted)} +$ (air conc • 100)	Indoor dust lead was derived from residential soil data as described in Sections 2.6.2 and 3.3.6 of the Site-wide HHRA (all non-beach tribal allotment DUs were considered potential future house DUs) and air based on Site-specific data (EPA, 1994a, 1994b).
Outdoor air concentration (µg per cubic meter [µg/m^3])	0.023‡	ProUCL (the KM mean; EPA, 2015) based on Sheep Creek 2002-2009 monitoring data.
Indoor air concentration (µg/m^3)	30% of outdoor air concentration	IEUBK Default (EPA, 1994a, 1994b)
Drinking water concentration (µg/L)	0.9	EPA (2016)
Maternal PbB at birth (µg/dL)*	0.6	Based on National Health and Nutrition Examination Survey (NHANES) update (2009-2014) (EPA, 2017b)
Absorption Fractions (AF†) at low intakes: Air Diet Water Soil/dust Sediment	 32% 50% 50% DU-specific DU-specific	 IEUBK Default (EPA, 1994a, 1994b) IEUBK Default (EPA, 1994a, 1994b) IEUBK Default (EPA, 1994a, 1994b) SRC (2017). See Appendix 11 of Site-wide HHRA. SRC (2017). See Appendix 11 of Site-wide HHRA.
RBA (soil/dust)	DU-specific RBA %	SRC (2017). See Appendix 11 of Site-wide HHRA.
Fraction soil	45%	IEUBK Default (EPA, 1994a, 1994b)
GSD	1.6	IEUBK Default (EPA, 1994a, 1994b)
Target PbB	3, 5, and 8 µg/dL	Within the risk range of child PbBs associated with adverse health effects from EPA (2016)

*Maternal PbB at birth does not impact results for the 12-72 month age range.
† AF% = RBA% * 0.5.
‡ Note that the concentration of lead in UCR air (CH2MHill, 2015) is an order of magnitude lower than the default air lead concentration in the IEUBK model (0.1 µg/m^3) and is not likely to influence the results.

TABLE 24
EXPOSURE PARAMETERS FOR COLVILLE HIGH INTENSITY RESOURCE USER POPULATION

Exposure Pathway	Exposure Parameter	Units	RME Value and Source				CTE Value and Source			
			Adult		Child		Adult		Child	
General	Body weight	kg	80	EPA, 2011a, 2014a [a]	15	EPA, 2011a, 2014a [a]	80	EPA, 2011a, 2014a [a]	15	EPA, 2011a, 2014a [a]

Notes:
[a] Table 8-3 of EPA (2011a): weighted mean values for adults 21-78 years old. Table 8-1 of EPA (2011a): weighted average of mean body weights (birth to <6 years)
[b] Table 16-5 of EPA (2011a): mean value for residential occupancy = 12 years. Dividing that into adult and child portions using the same ratio as for the RME (e.g., 6/27) yields ~9 years for the adult and ~3 years for the child.
[c] 95th percentile value of time spent in a residence is equivalent to 100% of the time; EPA (2011a) Table 16-16. 350 days/yr assumes 2 weeks' vacation away from home.

TABLE 24
EXPOSURE PARAMETERS FOR COLVILLE HIGH INTENSITY RESOURCE USER POPULATION

Exposure Pathway	Exposure Parameter	Units	RME Value and Source		CTE Value and Source	
			Adult	Child	Adult	Child

[d] Based on an estimate of 70% of time spent at home (EPA, 2011a, Table 16-16, mean time spent at home in all rooms, doers only; 1001.4 minutes/1440 minutes = 70%). 70% x 365 days = 256 days.
[e] Upper percentile, general population children, soil + dust
[f] Central tendency, general population children 1<6 years, soil + dust
[g] 95th percentile value of time spent on the land (days/yr); age/sex combined (no significant difference between gender when all ages are combined).
[h] Mean value of time spent on the land (days/yr); age/sex combined (no significant difference between gender when all ages are combined).
[i] Time weighted mean of head, hands, forearms, lower legs, and feet (male and female, age 21+ years).
[j] 95th percentile value of time spent in the water (days/yr); age/sex combined (no significant difference between gender when all ages are combined).
[k] Mean value of time spent in the water (days/yr); age/sex combined (no significant difference between gender when all ages are combined).
[l] 95th percentile value of time spent in the water (hours/day); age/sex combined (no significant difference between gender when all ages are combined).
[m] Mean value of time spent in the water (hours/day); age/sex combined (no significant difference between gender when all ages are combined).
[n] Mean recommended value for water ingestion while swimming. Water-related activities evaluated in this exposure pathway (e.g., gathering plants, fishing) are assumed to have lower ingestion rates than swimming (Table 3-93 in EPA (2011a) shows that water ingestion rates while fishing are less than half the average ingestion rate while swimming)
[o] CTE ingestion rate assumed to be half that of the RME receptor.
[p] Intake rates for plant and animal tissue are representative of a daily intake (g/day) averaged across a year; therefore, the exposure frequency is set to 365 days/yr.
[q] P95 consumption frequency = 30 days/year; Mean consumption frequency = 15 days/year (SRC, 2019b). Meal size = 1 cup (Fraser, 2017). Weight = 160 g (Fraser, 2019d).
[r] Child DCRs were derived by multiplying the adult DCR by a ratio of children-to-adult dietary intake which was estimated using energy requirements for children and adults based on regression models presented in IOM (2005) (see Appendix 14 of the Site-wide HHRA).
[s] P95 consumption frequency = 52 days/year; Mean consumption frequency = 15 days/year (SRC, 2019b). Mean meal size = 46 g (SRC, 2019b).
[t] P95 consumption frequency = 25 days/year; Mean consumption frequency = 16 days/year (SRC, 2019b). Meal size = 1 cup (Fraser, 2017). Weight = 170 g (Primolicious, 2019).
[u] P95 consumption frequency = 12 days/year; Mean consumption frequency = 10 days/year (Fraser, 2017). Meal size = 1/2 cup (Fraser, 2017; SRC, 2019b). Weight = 53 g (2 5 cups fresh lichen); volume is reduced to 20-25% of original through cooking. So this serving would start out as 2 or 2.5 cups fresh (Turner, 1997; Fraser, 2019b).
[v] P95 consumption frequency = 64 days/year; Mean consumption frequency = 23 days/year (SRC, 2019b). Meal size = 27g (handful [10 hips] Fraser, 2019f).
[w] Assumed RME DCR to be equal to CTE DCR.
[x] Mean consumption frequency = 6 days/year (Fraser, 2017). Assumed RME consumption frequency is equal to CTE consumption frequency. Meal size = handful of leaves per 1.5 quarts water (Fraser, 2017). Weight = 5 g fresh (direct measure; Fraser, 2019a).
[y] P95 consumption frequency = 64 days/year; Mean consumption frequency = 23 days/year (SRC, 2019b). Meal size = 1 foot total leaves/branches/hips per 1.5 quarts water (Fraser, 2017). Weight = For all samples collected, mean is 0.103 g/cm ww; 3.1 g/foot (Ramboll, 2019a [Appendix F of Appendix A]; Ramboll, 2019b).
[z] P95 consumption frequency = 30 days/year; Mean consumption frequency = 30 days/year (SRC, 2019b). Meal size = a bundle 4" x 1.5" per 1.5 quarts of water (Fraser, 2017). Weight = a bundle of 4" length and 1.5" diameter is 30 g fresh (direct measure; Fraser, 2019a).
[aa] P95 consumption frequency = 25 days/year; Mean consumption frequency = 10 days/year (SRC, 2019b). Meal size = 28.35 g (1 ounce; Fraser, 2017; USDA, 2018). Weight = 28.35 g (USDA, 2018).
[ab] P95 consumption frequency = 40 days/year; Mean consumption frequency = 15 days/year (SRC, 2019b). Meal size = 28.35 g (1 ounce; Fraser, 2017; USDA, 2018). Weight = 28.35 g (USDA, 2018).
[ac] P95 consumption frequency = 26 days/year; Mean consumption frequency = 14 days/year (SRC, 2019b). Mean meal size estimate for bitter root and lomatium = 66.8 g (Table 18,SRC, 2019b).
[ad] P95 consumption frequency = 26 days/year; Mean consumption frequency = 14 days/year (SRC, 2019b). Mean meal size estimate for bitter root and lomatium = 66.8 g (Table 18,SRC, 2019b).
[ae] P95 consumption frequency = 12 days/year; Mean consumption frequency = 12 days/year (SRC, 2019b). Mean meal size estimate for bitter root and lomatium = 66.8 g (Table 18,SRC, 2019b).
[af] CTE consumption frequency = 39.85 hours per year weaving/carving (Fraser, 2017). Meal size = 170cm per hour (Fraser, 2019a). Weight = For all samples collected, mean is 0.117 g/cm ww (Ramboll 2019a, 2019b). The RME DCR assumes 50% of the mean mouthed weight is ingested (Fraser, 2019a). The CTE DCR assumes 5% of mean mouthed weight is ingested (Fraser, 2019a).
[ag] Exposure pathway is incomplete for 0-6 age group (personal communication with Marc Stifelman during 7-9-19 meeting).
[ah] CTE consumption frequency = 92.72 hours per year weaving/carving (Fraser, 2017). Meal size = 30cm per hour (Fraser, 2019a). Weight = For all samples collected, mean is 0.282 g/cm ww (Ramboll 2019a and 2019b). The RME DCR assumes 50% of the mean mouthed weight is ingested (Fraser, 2019a). The CTE DCR assumes 5% of mean mouthed weight is ingested (Fraser, 2019a).
[ai] Adult CTE and RME ingestion rates for wild game (venison) were estimated using a two-part regression model developed by the National Cancer Institute (NCI; Tooze et al., 2006), with data provided by the Tribal Survey 24-hour dietary recall interviews. Child estimates were calculated by multiplying the DCR estimates for adults (by NCI method) to the ratio of the average meal size for children to the average meal size for adults. Meal size estimates did not use sample weights due to the small sample size for children.
[aj] The P95 adult DCR for waterfowl is the product of the mean meal size for chicken and P95 daily consumption frequency for waterfowl.
[ak] The mean adult DCR for waterfowl is the product of the mean meal size for chicken and mean daily consumption frequency for waterfowl.

TABLE 24
EXPOSURE PARAMETERS FOR COLVILLE HIGH INTENSITY RESOURCE USER POPULATION

Exposure Pathway	Exposure Parameter	Units	RME Value and Source		CTE Value and Source	
			Adult	Child	Adult	Child

[al] The CTE for ingestion rate is the product of the mean daily frequency of consuming upland birds sourced from the Local Area (11.6 days/year) and the mean consumption amounts (on consumption days) for chicken (100 grams). The RME for ingestion rate for upland birds was estimated using the 95th percentile for daily frequency of consuming upland birds from the Local Area (24.7 days/year) and the mean consumption amounts (on consumption days) for chicken (100 grams).

[am] The RME value of 400 g/day recommended by the Natural Resources Committee and approved by the Colville Business Council as the fish consumption rate used for the purpose of deriving new water quality standards to protect the use of reservation waters for a subsistence fishery.

[an] The CCT did not provide child DCRs. Therefore, to complete this exposure pathway child DCRs were derived by mulltiplying the adult DCR by a ratio of children-to-adult dietary intake which was estimated using energy requirements for children and adults based on regression models presented in IOM (2005) (see Appendix X).

[ao] Value is based on a median frequency of ingestion by regular fish eaters and a 90th percentile meal size.

[ap] 0.0833 1/day * 70.1 g/day. Frequency estimates for mussels include all (local and not local) sources (P95= 30 days/year). Total grams of intake on consumption days (meal size) = 70.1 grams (mean). Meal size totals are based on Tribal survey AMPM data for all mollusks and crustaceans.

[aq] 0.0240 1/day * 70.1 g/day. Frequency estimates for mussels include all (local and not local) sources (mean = 9 days/year). Total grams of intake on consumption days (meal size) = 70.1 grams (mean). Meal size totals are based on Tribal survey AMPM data for all mollusks and crustaceans.

[ar] 0.0833 1/day * 70.1 g/day. Frequency estimates for crayfish are based on local area only (P95= 30 days/year). Total grams of intake on consumption days (meal size) = 70.1 grams (mean). Meal size totals are based on Tribal survey AMPM data for all mollusks and crustaceans.

[as] 0.0362 1/day * 70.1 g/day. Frequency estimates for crayfish are based on local area only (mean = 13 days/year). Total grams of intake on consumption days (meal size) = 70.1 grams (mean). Meal size totals are based on Tribal survey AMPM data for all mollusks and crustaceans.

[at] 0.0833 1/day * 70.1 g/day. Frequency estimates for aquatic organisms were reported only for local area (95%=30 days/year). Total grams of intake on consumption days = 70.1 grams (mean). Daily ingestion totals are based on Tribal survey AMPM data for all mollusks and crustaceans.

[au] 0.0600 1/day * 70.1 g/day. Frequency estimates for aquatic organisms were reported only for local area (mean=22 days/year). Total grams of intake on consumption days = 70.1 grams (mean). Daily ingestion totals are based on Tribal survey AMPM data for all mollusks and crustaceans.

Table 25. Age-dependent Inputs to the IEUBK Model Based on TRW Lead Committee Recommendations (EPA, 2016, 2017a)

Age[1] (months)	Air		Diet[3]	Water[4]	Soil-Dust[5]
	Time Outdoors (hours)	Ventilation Rate[2] (cubic meters per day [m^3/day])	Dietary Intake (μg/day)	Intake (L/day)	Intake IR_{SD} (milligrams per day [mg/day])[6]
0 to <12	1.0	3.22	2.66	0.4	86
12 to <24	2.0	4.97	5.03	0.43	94
24 to <36	3.0	6.09	5.21	0.51	67
36 to <48	4.0	6.95	5.38	0.54	63
48 to <60	4.0	7.68	5.64	0.57	67
60 to <72	4.0	8.32	6.04	0.6	52

[1]The recommended age range for Superfund sites using the IEUBK model is 12-72 months (EPA, 2017a).
[2]The values shown are the midpoint of the age range. This version of the IEUBK model (version 1.1, build 11) uses the midpoint values of the regression equation used to calculate inhalation rate as a continuous non-linear function of age (EPA, 2016).
[3]TRW Lead Committee analysis (EPA, 2016) of Dietary Pb Concentration 1995-2005 (FDA, 2010); Dietary intake 2003-06 NHANES What We Eat in America (WWEIA) (CDC, 2010a, 2010b); Methodology National Cancer Institute (NCI) Method (Parsons et al., 2009; Tooze et al, 2006)
[4]TRW Lead Committee analysis (EPA, 2016) of Office of Water Six-Year data (EPA, 2010a, 2010b)
[5]Soil-dust ingestion rate in the IEUBK model is apportioned as follows: 45% intake is soil and 55% intake is dust
[6]TRW Lead Committee analysis (EPA, 2016) of age-specific values derived from structural equations modeling of children from Bunker Hill Superfund Site assuming 50% dust, 25% yard soil, 10% neighborhood soil, and 15% community soil (von Lindern et al., 2016)

Table 26. Estimation of Adult DCRs for Wild/Cultural Plants

Species	Consumption (Use) Frequency (days/year)		Meal Size	Mean Meal Size (g)	Adult DCR (g/day)		Notes/Source
	RME	CTE			RME	CTE	
Chokecherry	30	15	1 cup	160	13.2	6.6	Freq: SRC, 2019a; Meal size: Fraser, 2017; Fraser, 2019e
Huckleberry	52	15	Mean for adults: 46 g	46	6.6	1.9	SRC, 2019a
Sarvisberry	25	16	1 cup (6 ounces; 170 g)[1]	170	11.6	7.5	Freq: SRC, 2019a; Meal size: Fraser, 2017; Primolicious LLC, 2019
Black tree lichen	12	10	½ cup; volume reduced to 20-25% through cooking, so ½ cup cooked = 2.5 cups fresh (53 g)	53	1.7	1.5	Freq: Fraser, 2017; Meal size: Fraser, 2019f; Turner, 1997
Wild rose (hips)	64	23	27 g fresh rose hips used to make tea	27	4.7	1.7	Freq: SRC, 2019a; Meal size: Fraser, 2019g
Kinnikinnick	6[2]	6	Handful of leaves per 1.5 quarts (qts) water (5 g fresh)	5	0.08	0.08	Freq: Fraser, 2017; Meal size: Fraser, 2019e and direct measure
Wild rose (stems, leaves)	64	23	1 ft leaves/stems/ hips per 1.5 qts water. For all samples, mean = 0.103 grams per centimeter (g/cm) ww; 3.1 grams per foot (g/ft)	3.1	0.5	0.2	Freq: SRC, 2019a; Meal size: Fraser, 2017; TAI, 2019; Ramboll, 2019
Wild mint	30	30	1 bundle (4” long × 1.5” diameter) per 1.5 qts water; = 30 g fresh	30	2.5	2.5	Freq: SRC, 2019a; Meal size: Fraser, 2017; Fraser, 2019e and direct measure
Hazelnut	25	10	1 ounce (28.35 g)	28.35	1.9	0.8	Freq: SRC, 2019a; Meal size: Fraser, 2017; USDA, 2018
Ponderosa pine nut	40	15	1 ounce (28.35 g)	28.35	3.1	1.2	Freq: SRC, 2019a; Meal size: Fraser, 2017; USDA, 2018
Lomatium (root)	26	14	Mean meal size for bitter root and lomatium	66.8	4.8	2.6	SRC, 2019a
Camas (bulb)	26	14	Mean meal size for bitter root and lomatium	66.8	4.8	2.6	SRC, 2019a
Spring beauty/Indian potato (corm)	12	12	Mean meal size for bitter root and lomatium	66.8	2.2	2.2	SRC, 2019a
Tule	NA	39.85 hr/yr	170 centimeters per hour (cm/hr); for all samples	0.117	1.1	0.1	Freq: Fraser, 2017; Processing

Table 26. Estimation of Adult DCRs for Wild/Cultural Plants

Species	Consumption (Use) Frequency (days/year)		Meal Size	Mean Meal Size (g)	Adult DCR (g/day)		Notes/Source
	RME	CTE			RME	CTE	
			collected, mean weight is 0.117 g/cm ww				info: Fraser, 2019a; Assumed meal size[3]
Willow	NA	92.72 hr/yr	30 cm/hr; Overall mean is 0.282 g/cm ww	0.282	1.1	0.1	Freq: Fraser, 2017; Processing info: Fraser, 2019a; assumed meal size[3]

[1]Meal size determined using online produce converter for blueberries (www.howmuchisin.com)
[2]No RME frequency available; assumed RME = CTE frequency (Fraser, 2017)
[3]RME assumes 50% ingested during mouthing per use; CTE assumes 5% ingested during mouthing per use. The selected percentages of ingestion associated with mouthing willow samplings are uncertain. The range of 5/50% was used as a reasonable assumption to estimate ingestion associated with processing waving materials as CTE and RME estimates, respectively.

Table 27. Results of Exposure to Lead in Soil and Indoor Dust at Tribal Allotments[a]

Tribal Allotment DU	Predicted Geometric Mean PbB (µg/dL)	Probability of Exceeding 3 µg/dL	Probability of Exceeding 5 µg/dL	Probability of Exceeding 8 µg/dL

aValues in bold exceed risk benchmarks for lead.
bThis DU underwent a removal action; maximum backfill concentrations are used as the soil EPC.

Table 28. Results of IEUBK Model for Exposure to Sediment at Tribal Allotment Beach

Receptor	Predicted Geometric Mean PbB (µg/dL)	Probability of Exceeding 3 µg/dL	Probability of Exceeding 5 µg/dL	Probability of Exceeding 8 µg/dL
CHIRU child	2.9	**47.8%**	**12.7%**	1.6%

Bold values exceed lead risk benchmark.

Table 29. Results of IEUBK Model for Exposure to Surface Water at Tribal Allotment Beach

Receptor	Predicted Geometric Mean PbB (µg/dL)	Probability of Exceeding 3 µg/dL	Probability of Exceeding 5 µg/dL	Probability of Exceeding 8 µg/dL
CHIRU child	2.96	**48.8%**	**13.2%**	1.7%

Bold values exceed lead risk benchmarks.

Table 30. Lead Intakes by Plant Type for Children

Plant Species	Plant Part	Mean Lead Conc in Plant (µg/g ww)	Plant DCR (g/day)	Lead Intake (µg Pb/day)
Chokecherry	Berry	0.014	3.3	<0.1
Huckleberry	Berry	0.013	0.95	<0.1
Sarvisberry	Berry	1.68	3.75	**6.3**
Black Tree Lichen	Entire	33.4	0.75	**25.0**
Rose hips	Hips	0.0499	0.85	<0.1
Kinnikinnick	Leaves	0.621	0.04	<0.1
Rose stems/leaves	Leaves	0.59	0.1	0.1
Wild mint	Leaves	0.091	1.25	0.1
Hazelnut	Nut	0.004	0.4	<0.1
Ponderosa pine	Nut	0.477	0.6	0.3
Lomatium	Root	10.5	1.3	**13.7**
Camas	Root/bulb	12.1	1.3	**15.7**
Spring beauty/Indian potato	Root/Corm	15.4	1.1	**17.0**

Note: Tule and Willow are not included in this table because children are assumed to not engage in basket-weaving (Stifelman, 2019). See Table 31.

Table 31. Lead Intakes During Basket Weaving by Plant Type for Adults

Species	Plant Part	Concentration of Lead in Plant (µg/g ww)	DCR[1] (g/day)	Intake of Lead (µg Pb/day)
Tule	Root/culm	0.031	0.1	<0.1
Willow	Stem	0.155	0.1	<0.1

[1]Assumes 5% ingested during mouthing per use.

Table 32. Lead Intakes from Fish, by Species, for the CHIRU Child

Fish DCR (g/day)	Lead Intake Burbot (µg Pb/day)	Lead Intake Kokanee (µg Pb/day)	Lead Intake Northern Pike (µg Pb/day)	Lead Intake Rainbow Trout (µg Pb/day)	Lead Intake SM Bass (µg Pb/day)	Lead Intake Sturgeon (µg Pb/day)	Lead Intake Sucker (µg Pb/day)	Lead Intake Walleye (µg Pb/day)	Lead Intake Whitefish (µg Pb/day)
40	0.9	0.2	0.1	0.9	0.7	0.2	**5.4**	**1.0**	0.4

Table 33. Lead Intakes from Site-associated Biota other than Plants

Species	UCR Reach	Concentration of Lead in Organism (µg/g ww)	DCR (g/day)	Intake of Lead (µg Pb/day)
Mussels	1	0.690	0.85	0.6
	2	0.498	0.85	0.4
	3	0.454	0.85	0.4

-- = no toxicity value available ND = not detected NA = not analyzed

(a) Some samples were not analyzed for inorganic arsenic For these samples, a calculated inorganic arsenic result was generated by multiplying the total arsenic result by the site-specific fraction (5 5%) of inorganic arsenic to total arsenic

(b) Based on toxicity values for Chromium (VI)

(c) Assumes chemical form of mercury in tissue is methylmercury

(d) Non-dioxin-like component evaluated based on Aroclor

(e) Non-dioxin-like component evaluated based on sum of non-dioxin-like congeners

(f) When calculating total HQs from PCBs, the HQ was set equal to max of the Aroclor HQ or PCB congener sum HQ

(g) When calculating total cancer risks from non-dioxin-like PCBs, the non-dioxin-like risk was set equal to max of the Aroclor risk or congener sum risk

(h) oRfD based on Aroclor-1254; oSF based on high risk and persistence tier (see Tables 4-2 and 4-4)

-- = no toxicity value available ND = not detected NA = not analyzed

(a) Some samples were not analyzed for inorganic arsenic For these samples, a calculated inorganic arsenic result was generated by multiplying the total arsenic result by the site-specific fraction (5 5%) of inorganic arsenic to total arsenic

(b) Based on toxicity values for Chromium (VI)

(c) Assumes chemical form of mercury in tissue is methylmercury

(d) Non-dioxin-like component evaluated based on Aroclor

(e) Non-dioxin-like component evaluated based on sum of non-dioxin-like congeners

(f) When calculating total HQs from PCBs, the HQ was set equal to max of the Aroclor HQ or PCB congener sum HQ

(g) When calculating total cancer risks from non-dioxin-like PCBs, the non-dioxin-like risk was set equal to max of the Aroclor risk or congener sum risk

(h) oRfD based on Aroclor-1254; oSF based on high risk and persistence tier (see Tables 4-2 and 4-4)

-- = no toxicity value available ND = not detected NA = not analyzed

(a) Some samples were not analyzed for inorganic arsenic For these samples, a calculated inorganic arsenic result was generated by multiplying the total arsenic result by the site-specific fraction (5 5%) of inorganic arsenic to total arsenic

(b) Based on toxicity values for Chromium (VI)

(c) Assumes chemical form of mercury in tissue is methylmercury

(d) Non-dioxin-like component evaluated based on Aroclor

(e) Non-dioxin-like component evaluated based on sum of non-dioxin-like congeners

(f) When calculating total HQs from PCBs, the HQ was set equal to max of the Aroclor HQ or PCB congener sum HQ

(g) When calculating total cancer risks from non-dioxin-like PCBs, the non-dioxin-like risk was set equal to max of the Aroclor risk or congener sum risk

(h) oRfD based on Aroclor-1254; oSF based on high risk and persistence tier (see Tables 4-2 and 4-4)

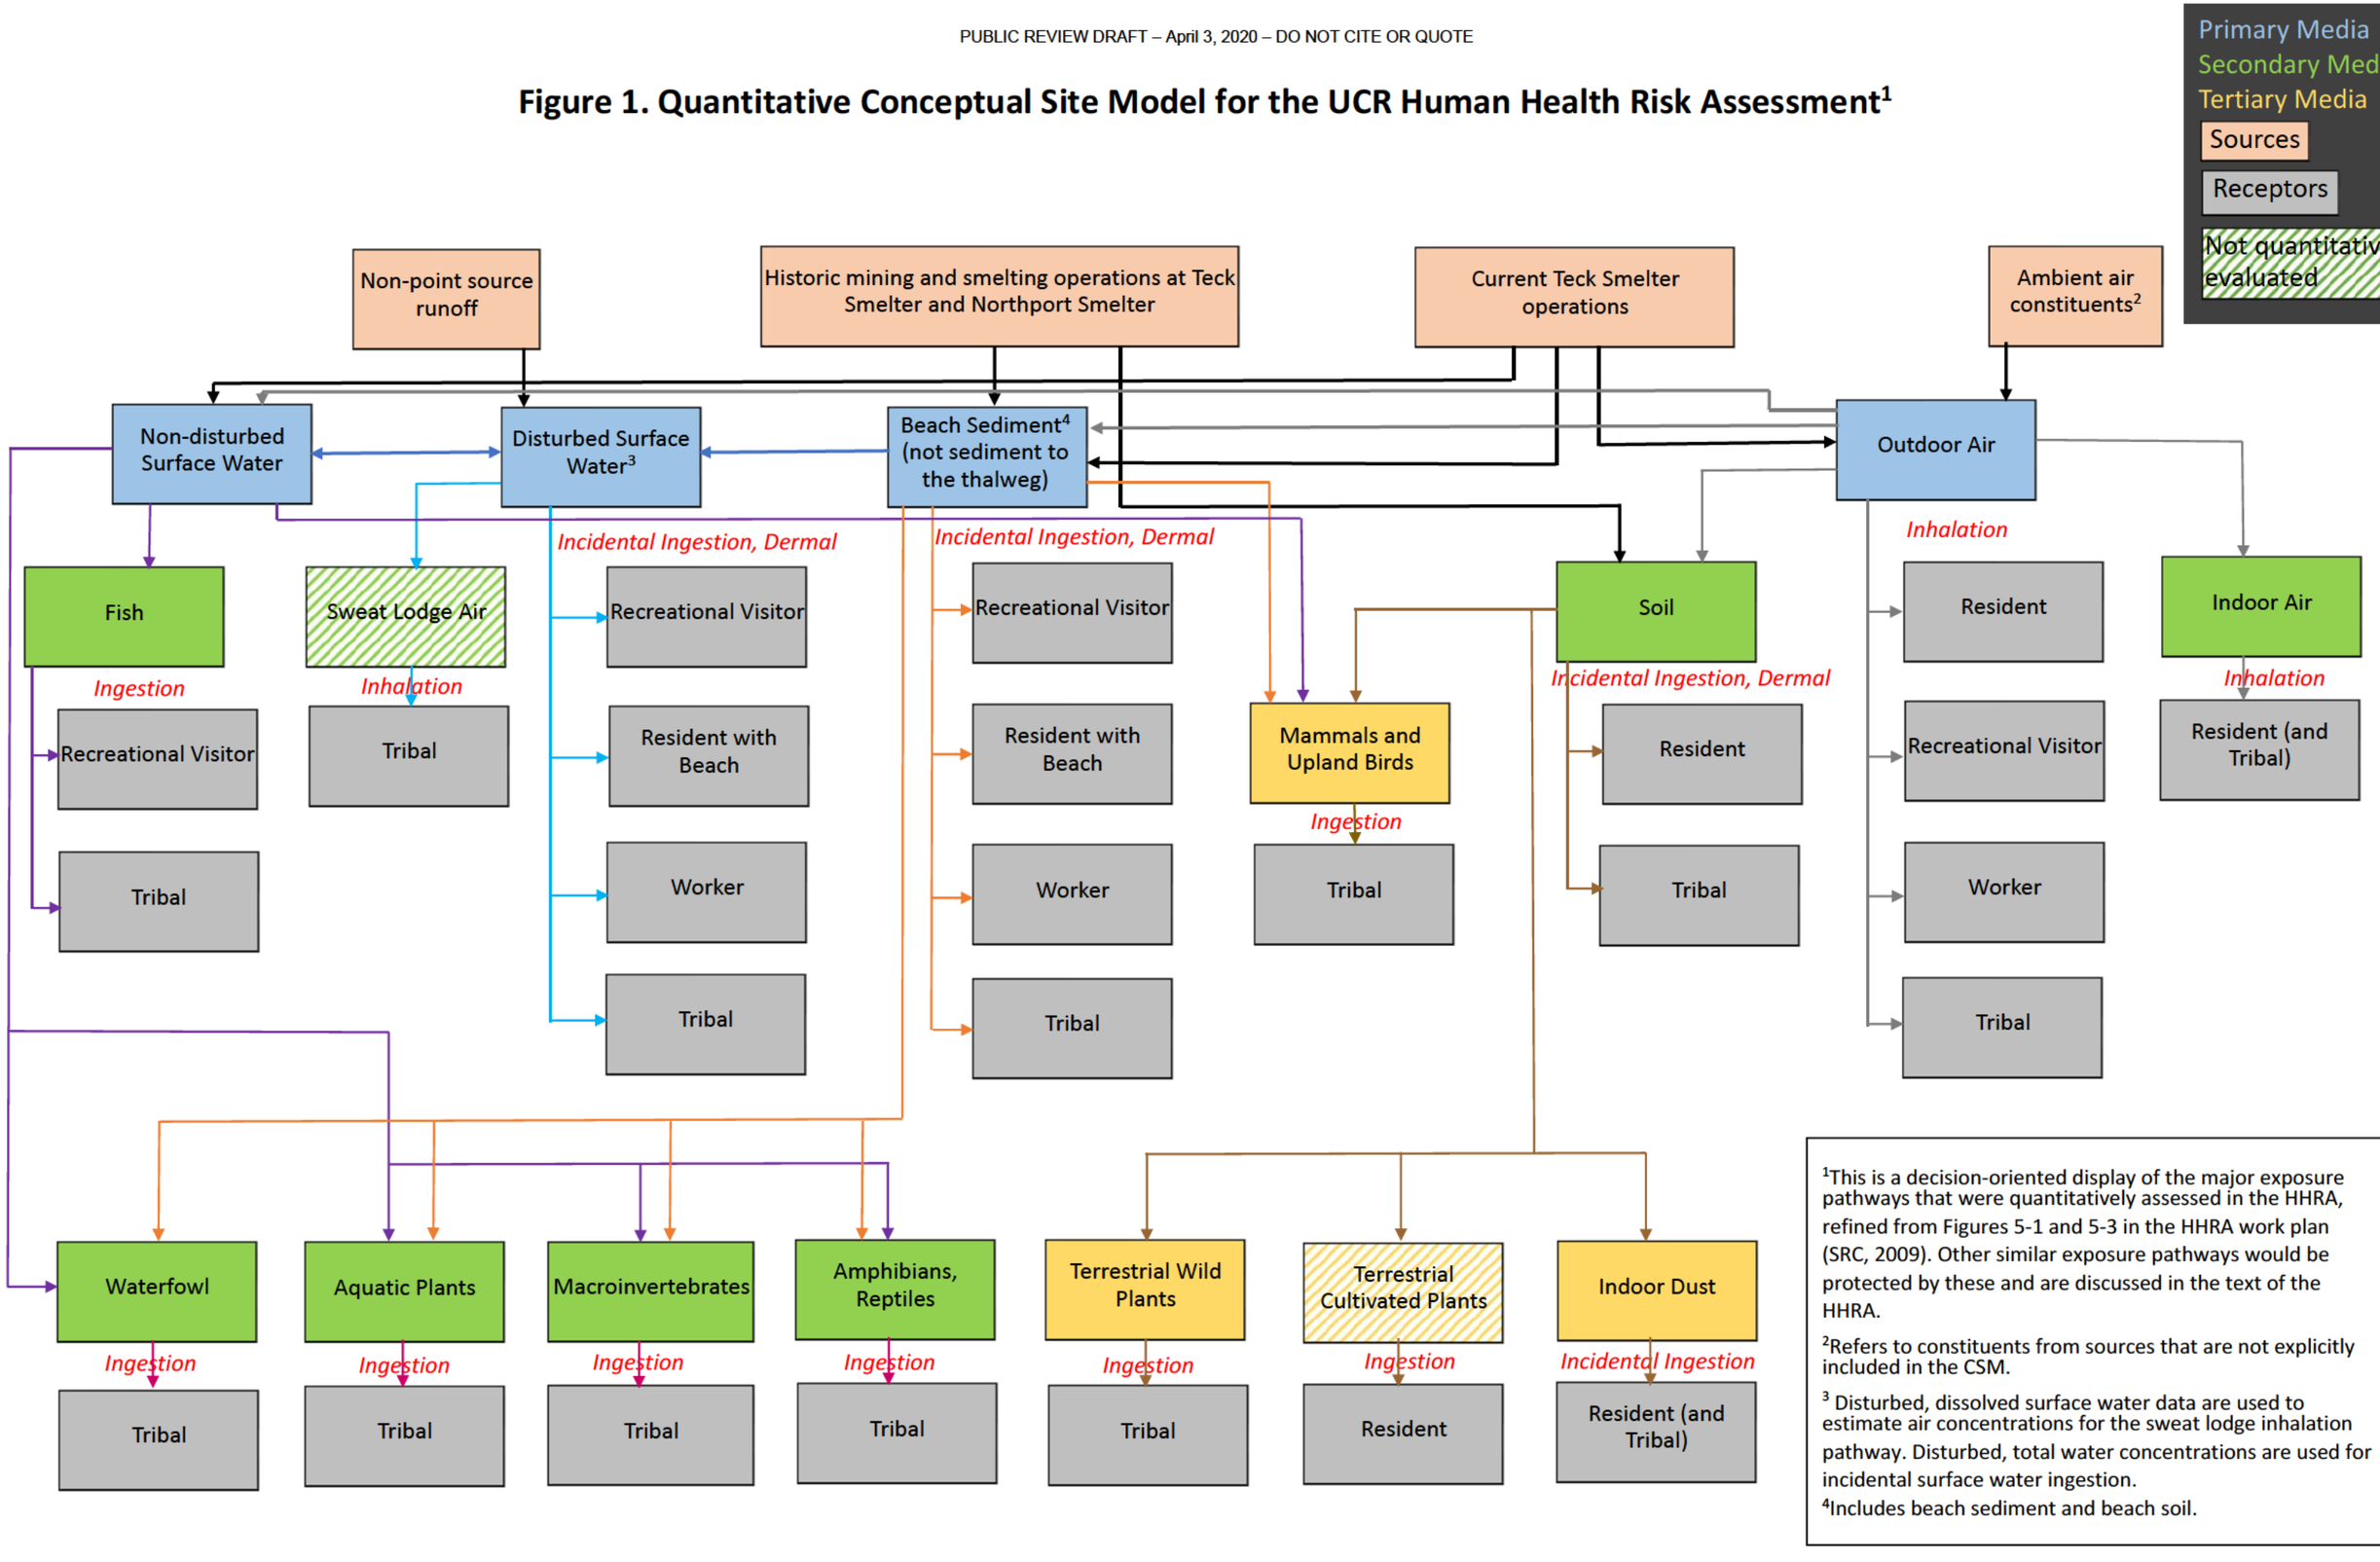
Figure 1. Quantitative Conceptual Site Model for the UCR Human Health Risk Assessment[1]



[1]This is a decision-oriented display of the major exposure pathways that were quantitatively assessed in the HHRA, refined from Figures 5-1 and 5-3 in the HHRA work plan (SRC, 2009). Other similar exposure pathways would be protected by these and are discussed in the text of the HHRA.

[2]Refers to constituents from sources that are not explicitly included in the CSM.

[3] Disturbed, dissolved surface water data are used to estimate air concentrations for the sweat lodge inhalation pathway. Disturbed, total water concentrations are used for incidental surface water ingestion.

[4]Includes beach sediment and beach soil.

Appendix 3. Sweat Lodge Air Exposure Pathway for Metals in Surface Water at UCR Site

TO: Marc Stifelman, Monica Tonel, EPA Region 10
FROM: Gary Diamond, SRC
DATE: 05/25/18
RE: Sweat lodge air exposure pathway for metals in surface water at UCR site

SRC has reviewed the sweat lodge air pathway in the UCR HHRA. We recommend that potential exposure to airborne low-volatile COPC metals in UCR surface water during sweat lodge not be quantitatively assessed in the HHRA because:

- Non-volatile metals will not vaporize at sweat lodge temperatures
- Intake of non-volatile metals in surface water in a sweat lodge will be limited to ingestion of metals in water droplets formed from contact with heated rocks (the relatively large diameter of the spray droplets would result in deposition in the upper airway and transport to the esophagus and gastrointestinal tract)
- Ingestion of dissolved contaminants in a sweat lodge is a negligible contributor to risk, relative to ingestion of unfiltered disturbed surface water from direct contact during other water activities such as swimming and wading

We also recommend that no further data collection to evaluate this pathway is warranted since such efforts are unlikely to improve confidence in characterization of human health risk at the site. This memorandum provides the basis for these recommendations.

Inhaled/Ingested Metals in Water Spray – Insignificant Pathway

Formation of spray in a sweat lodge would involve recoil of surface water from the heated rocks into the air. Were it to occur in the sweat lodge, recoil alone (e.g., without an aerosolizer) would result in relatively large airborne droplets that would quickly be removed from air by gravitational settling. If inhaled, these large droplets would be preferentially deposited in the upper airways and transferred to the gastrointestinal tract, rather than being absorbed across the alveolar region of the lung (ICRP, 1994). Even in highly aerosolized sprays (e.g., bathing showers), aerosol droplet sizes are sufficiently large (> 5 µm) to predict preferential deposition in the upper airway (Zhou et al., 2007). If a sweat lodge were to produce aerosols of the magnitude produced in a hot bath shower (e.g., delivering 9 L water/minute), the water ingestion rate in the sweat lodge would be approximately 72 mL (12 mL/10 minutes × 60 minutes/hour; based on Zhou et al., 2007). As most of the water applied to rocks in sweat lodges is expected to evaporate (Harris and Harper, 1997), this ingestion rate is likely to be a substantial overestimate of the water droplet ingestion rate in the sweat lodge. In comparison, rates of incidental ingestion of surface water while engaged in water related activities are considerably higher than the rate predicted for a 10-minute hot shower (12 mL). For recreational visitors who ingest water while swimming, the estimated ingestion is 213 mL during a beach trip (71 mL/hour × 3 hours/day; Table 3-31 in the river-associated HHRA), and for residents with subsistence lifestyles who ingest water during water-related activities, the estimated ingestion rate is 210 mL (21 mL/hour × 10 hours/day; Table 3-32 in the river-associated HHRA).

Volatilization of Metals in Steam – Incomplete Pathway

Metals identified as surface water COPCs have very low vapor pressures at the assumed temperature of the sweat lodge (150° F; Harper et al. 2002; Harris and Harper, 1997) and, as a

result, the steam produced from heating surface water on the rocks should not have appreciable concentrations of metals (see further discussion below).

Uncertainties related to Midnite Mine model for calculating sweat lodge air concentrations of low volatility metals. EPA (2005c) described an approach for calculating concentrations of chemicals, including metals, in sweat lodge air from volatilization transfer of chemicals from water to water vapor. The calculation is based on the following assumptions: (1) water vapor (steam) is produced in the sweat lodge from pouring surface water over heated rocks; (2) the sweat lodge is heated to a temperature of 150° F (Harper et al. 2002; Harper et al. 2002; Harris and Harper, 1997); (3) the sweat lodge atmosphere achieves a saturating water concentration (0.15 L/m^3 [Lide, 2002]); (4) chemicals in the surface water applied to the rocks are transferred to water vapor; (5) this transfer results in concentrations in the saturating water vapor that are the same as the concentrations in the surface water (i.e., 1 µg metal/L surface water produces a concentration of 0.15 $\mu g/m^3$ water vapor). Although applicable to volatile chemicals, the Midnite Mine model does not specify or simulate a plausible mechanism for transfer of COPC metals from surface water to water vapor. For the following reasons, the above Midnite Mine model will grossly overestimate air concentrations of COPC metals in sweat lodge air and, therefore, is not being used to estimate air pathway exposures in sweat lodges at the UCR site.

To illustrate the extent to which the Midnite Mine model overestimates concentrations of metals in sweat lodge air, the model was implemented as a pseudo-screen for COPC metals in surface water. Metals identified as COPCs in this pseudo-screen have very low vapor pressures at the assumed temperature of sweat lodges (150° F; Harper et al. 2002; Harris and Harper, 1997) and, as a result, the vapor produced from heating surface water on the rocks should not have appreciable concentrations of metals. For example, at 150° F, the vapor pressure of barium would be approximately 1×10^{-17} Pascals (Pa) (5×10^{-22} atmospheres), compared to approximately 2.5×10^4 Pa (0.25 atmospheres) for water. The corresponding air concentration for barium would be approximately 5×10^{-12} µg Ba/m^3, which is a factor of 10^{-12} lower than the concentration predicted from the assumptions in the Midnite Mine model (5 $\mu g/m^3$). These estimates are for elemental barium; however, vapor pressure would not be expected to be substantially higher for barium compounds. Vapor pressures for other COPCs identified in the pseudo-screen ranged from 10^{-32} Pa (manganese) to 10^{-70} Pa (uranium).[1] Therefore, vaporization should result in air concentrations of COPC metals that are far lower than the concentrations predicted from the model.

A possible exception to this would be elemental mercury (Hg^0) or methylmercury (MeHg); both forms of this metal would have appreciable vapor pressures at ambient temperatures (ATSDR, 1999; Huber et al., 2006; Lindqvist and Rodhe, 1985). Total mercury was measured in non-disturbed and disturbed surface water and in public beach sediment. Mercury in these samples was not speciated, therefore, the concentrations of Hg^0 or MeHg relative to total mercury concentration in these media is unknown. However, the dominant form present in any well-oxygenated medium is likely to be inorganic mercuric salts (ATSDR, 1999).

[1] Vapor pressures of the elements (data page). (2017, August 26). In Wikipedia, The Free Encyclopedia. Retrieved 19:26, January 19, 2018, from https://en.wikipedia.org/w/index.php?title=Vapor_pressures_of_the_elements_(data_page)&oldid=797289367

The maximum concentrations of total mercury measured in disturbed water at the UCR site were 6.8E-04 micrograms per liter (µg/L) (dissolved) and 1.15E-01 µg/L total (including suspended sediment). Worst-case scenarios can be calculated for the concentration of elemental Hg (Hg^0) or MeHg in sweat lodge air, based on these maximum surface water concentrations.

Worst-case assumptions for exposure to Hg^0 or MeHg in sweat lodge air:

- 100% of the mercury measured in surface water was either Hg^0 (highly unlikely because at least some if not most of any elemental Hg^0 in surface water would be oxidized) or MeHg (highly unlikely to find complete conversion of mercury in water or sediment to MeHg, ATSDR, 1999)
- 4 L of water were brought into the sweat lodge and poured over the heated rocks (Harper et al., 2002)
- sweat lodge volume is 2.1 cubic meters (m^3) (based on sweat lodge dimensions reported in Harper et al., 2002)
- all Hg^0 or MeHg in water applied to rocks is transferred to air (it is possible for this to occur if the amount of Hg transferred to heated rocks is less than the amount required to achieve saturation equilibrium in sweat lodge air; 3.6E+03 µg/m^3 for Hg^0 at 150° F based on Huber et al., 2006)

Based on these worst-case assumptions, surface water concentrations for Hg^0 or MeHg of 6.8E-04 µg/L (dissolved) or 1.15E-01 µg/L (total) would correspond to 2.7E-04 µg and 4.6E-01 µg transferred to the sweat lodge rocks from surface water, and corresponding concentrations in air within the sweat lodge of 1.3E-03 µg/m^3 or 2.2E-01 µg/m^3, respectively. Both worst-case sweat lodge air concentrations are below the current EPA chronic inhalation reference concentration (RfC) for Hg^0 (3E-01 µg/m^3, U.S. EPA 2018). There are no reference values for MeHg in air. This worst-case scenario is more health protective than the Midnite Mine model because it assumes complete transfer of mercury to sweat lodge air rather than transfer only with water vapor.

Alternative models for predicting concentrations of metals in sweat lodge air. The CCT circulated a draft report (Cohen & Associates, 2012). This report summarizes many of the same limitations of the Midnite Mine model, including criticisms from ATSDR, DOE and WADOH (see text beginning on page 3-42). An alternative to the Midnite Mine approach is described based on data for radionuclides in air after sudden decompression of superheated water (i.e., reactor accident that is likely to have produced at least some spray). Based on these data, the fraction released was estimated to be 0.006. The report also cites a NUREG-1140 report in which the release fraction for nonvolatiles was assigned a value of 0.001. The corresponding transfer coefficient in the Midnite Mine model is 1 (which results in a ratio of 0.15 for concentrations in sweat lodge air/surface water). Neither of the above release fractions is relevant to transfers of metals from water to air ambient pressures and temperatures of sweat lodges.

Conclusion. Transfer of low-volatile metal COPCs to sweat lodge air is likely to be negligible. Vaporization will not occur to any significant extent because of the low vapor pressures of these metals at sweat lodge temperatures. Water spray would be ingested post-inhalation rather than absorbed across the lung. Risks from ingestion of UCR surface water are addressed in the HHRA in the assessment of incidental ingestion of disturbed water while swimming or wading,

and the addition of the small amount of dissolved metals ingested during sweat lodge activities will not result in a change to the risk estimate. Given the above considerations, we recommend that inhalation exposure in sweat lodges be considered in the risk assessment as an ingestion pathway and that this ingestion pathway be considered negligible and not addressed quantitatively in the HHRA; and that further efforts to collect data to assess air pathway exposures to metals in sweat lodges are not needed to support the HHRA.

Appendix 4. Estimates for Background Concentrations of COPCs in Soil

This appendix presents estimates of background concentrations for soil chemicals of potential concern (COPCs) for use in the baseline Human Health Risk Assessment (HHRA) for the Upper Columbia River (UCR) Site. Site-specific background estimates are being developed as part of the Remedial Investigation and Feasibility Study (RI/FS) for this Site but are not available yet; therefore, interim background estimates were developed for use in the HHRA. Stream sediment and soil samples collected within the UCR drainage basin as part of the National Uranium Resource Evaluation (NURE) program (Smith, 2006; Smith et al., 2013) were used as the basis for the soil background estimates presented in Table 1. The background concentrations are upper confidence limits on estimates of the 95th percentile; as such, we would expect the majority of Site-specific soil data that do not reflect Site-related contamination to be below the background estimates presented in Table 1.

The data used to estimate the soil background concentrations for COPCs in this Appendix were derived from stream sediment and soil samples collected by the NURE program in the Colville River, Kettle River, Lower Spokane, Sanpoil River, and UCR sub-basins of the Columbia River drainage basin.[1] The NURE samples were sieved to <149 µm fraction (Smith et al., 2013). The majority of the COPC results in the background dataset were determined by the Savannah River Laboratory (SRL) using neutron activation analysis (Al, Fe, Mn and V) and atomic absorption (Co, Cr, Ni, and Pb) as part of the original NURE program analysis. The SRL data for 21 sample locations located within the 5 sub-basins were replaced with data available from a reanalysis of NURE archived samples undertaken as part of the U.S. Geological Survey (USGS) National Geochemical Survey (NGS) (Grossman et al., 2008). The NGS program used inductively-coupled plasma – atomic emission spectroscopy (ICP-AES) to measure the COPCs listed in Table 1 except arsenic, which was analyzed by hydride generation-atomic absorption spectrophotometry (HG-AAS; Hageman, 2002). Church et al. (2008) reanalyzed archived NURE samples for locations within the Lower Spokane sub-basin by ICP-mass spectrometry (MS) following digestion by Environmental Protection Agency (EPA) Method 3050B. The archived material analyzed by Church et al. (2008) corresponded to sample locations that SRL had not previously analyzed. Smith et al. (2013) provides a good overview of the NURE and USGS NGS data (as well as other national geochemical datasets).

The NURE data included some errors in the arsenic data for sample locations in the Kettle River, Sanpoil River and UCB sub-basins (Church, 2010a, 2010b); these data were replaced with data provided by Smith (2007). One record (rec_no = 5184673) was removed from the background dataset because the sample was located within the 100-year floodplain of the UCR. Two records (rec_no = 5185476 and 5185477) were removed because the NURE data indicated they were potentially affected by mining activities (field [contamc] contained the word *mining*). Another record (rec_no = 5184696) was removed because the NURE database indicated the

[1] The five sub-basins correspond to hydrologic unit code (HUC) 8-digit hydrologic units, while the Columbia River Drainage Basin is a HUC-4 or subregion level unit. The five sub-basins correspond to the Washington State Water Resource Inventory Areas (WRIAs) hydrologic units.

sampled material may have contained mine tailings [field [samptyp] = 99). Seven sample locations, all located south of the community of Marble, are within the area that had exhibited effects of SO_2 emissions on vegetation (Scheffer and Hedgcock, 1955). These data were retained in the background analysis dataset because they had no effect on the estimates of the UTL95-95.

The background dataset includes 571 sample locations. The majority of the sample locations are west of the UCR (Figure 1). The number of samples ranges widely among the sub-basins: Colville River (n=14), Lower Spokane (n=56), UCR (n=156), Kettle River (n=161) and Sanpoil River (n=184). The sample sizes exceed 500 for each COPC with the exception of cadmium and thallium (n=56 each) and arsenic (n=443) (Table 1). The only results available for thallium and cadmium in the background dataset were provided by the reanalysis of NURE archived samples from the Lower Spokane sub-basin by Church et al. (2008). Thallium was not previously measured in NURE samples. While cadmium was measured by SRL, the detection limit for SRL's analysis of NURE samples collected exceeds the maximum concentration measured in the Lower Spokane by Church et al. (2008). The background dataset does not include any results for antimony.

The data were checked for outliers using the *MM* method (Yohai, 1987). The background estimates were calculated with all data included and compared to the estimates obtained after removing the records that were flagged as possible outliers. The potential outliers had no discernable effect on the background estimates, likely due to the large sample sizes that were available. The data were also checked for spatial outliers using the local Moran I statistic (Anselin, 1995). A group of 19 sample locations with high chromium concentrations was identified in the Kettle River sub-basin. The mean and standard deviation of the chromium concentration for the 19 locations were 467 and 441 ppm, respectively, while the mean and standard deviation for the rest of the chromium data were 47 and 46 ppm, respectively. The 19 sample locations were removed prior to estimating the background concentration for chromium.

An estimate of the 95% upper tolerance limit for the 95^{th} percentile of the population (95UTL95) was used to define the background concentration for each COPC in soil. The UTL95-95 was estimated using ProUCL version 5.1 (EPA, 2015). Goodness-of-fit tests indicated the normal, gamma and lognormal distributions did not provide a good fit for the COPCs. The UTL95-95s were estimated using a nonparametric method based on the binomial distribution (EPA, 2015, Equation 3-10). Non-parametric estimates of the 95% of the population distribution are also presented in Table 1. The 95% were estimated using the ranks (*order statistics*) of the sample data, with interpolation when needed (EPA, 2015, Equation 3-1). Antimony data were not available from the NURE database; Table 1 includes a background estimate reported by Washington State Department of Ecology (ECY, 2019) for antimony of 2.15 mg/kg (this value is a UTL90-95).

For comparison purposes, the background soil concentration estimates were compared with residential soil screening levels (RSLs) calculated for a target hazard quotient (HQ) of 1.0 and a cancer risk of 10^{-4} (Table 1). The same toxicity values used in the COI screen were used for this calculation except for chromium. Toxicity values for hexavalent chromium were used in the

COI screen, but toxicity values for trivalent chromium were used in these RSL calculations, as the medium of interest is soil and the expected form of chromium in soil is likely trivalent (ATSDR, 2012). RSLs were the residential RSLs from EPA (2019), with the exception of inorganic arsenic. The inorganic arsenic RSL was the non-carcinogenic screening level for a resident child, calculated using the RSL Calculator tool (EPA, 2019). All calculated HQs are less than (<) 1. Based on the HQ being <1, the risk of non-cancer health effects from exposure to non-lead COPCs at estimated background soil concentrations is below the non-cancer hazard benchmarks used by CERCLA (EPA, 1989, 1997; EPA and Clay, 1991).

LEAD BATCH MODE OUTPUT FILE
Model Version: 1.1 Build11

User Name: SRC
Date: 2/20/2020
Site Name: UCR
Operable Unit: Current Resident, Kokanee
Run Mode: Research

* : signify default values used in place of missing input data.
# : signify surrogate values entered (determined) by user.
---: signify missing input data.
PBB & PRED are the observed and predicted blood Pb levels in µg/dL.

Percent exceedance was calculated using values of GSD and PbB Cutoff as follows:
GSD = 1.6
PbB Cutoff (C) = 3, 5, or 8 µg/dL

Input File: RES KOK_02`20`20.dat

LEAD BATCH MODE OUTPUT FILE
Model Version: 1.1 Build11

User Name: SRC
Date: 2/20/2020
Site Name: UCR
Operable Unit: Current Resident, Northern Pike
Run Mode: Research

* : signify default values used in place of missing input data.
# : signify surrogate values entered (determined) by user.
---: signify missing input data.
PBB & PRED are the observed and predicted blood Pb levels in µg/dL.

Percent exceedance was calculated using values of GSD and PbB Cutoff as follows:
GSD = 1.6
PbB Cutoff (C) = 3, 5, or 8 µg/dL

Input File: newNOr.dat

LEAD BATCH MODE OUTPUT FILE
Model Version: 1.1 Build11

User Name: SRC
Date: 2/20/2020
Site Name: UCR
Operable Unit: Current Resident, Rainbow Trout
Run Mode: Research

* : signify default values used in place of missing input data.
# : signify surrogate values entered (determined) by user.
---: signify missing input data.
PBB & PRED are the observed and predicted blood Pb levels in µg/dL.

Percent exceedance was calculated using values of GSD and PbB Cutoff as follows:
GSD = 1.6
PbB Cutoff (C) = 3, 5, or 8 µg/dL

Input File: RES RAI_02`20`20.dat

LEAD BATCH MODE OUTPUT FILE
Model Version: 1.1 Build11

User Name: SRC
Date: 2/20/2020
Site Name: UCR
Operable Unit: Current Resident, Smallmouth Bass
Run Mode: Research

* : signify default values used in place of missing input data.
# : signify surrogate values entered (determined) by user.
---: signify missing input data.
PBB & PRED are the observed and predicted blood Pb levels in µg/dL.

Percent exceedance was calculated using values of GSD and PbB Cutoff as follows:
GSD = 1.6
PbB Cutoff (C) = 3, 5, or 8 µg/dL

Input File: RES SMB_02`20`20.dat

LEAD BATCH MODE OUTPUT FILE
Model Version: 1.1 Build11

User Name: SRC
Date: 2/20/2020
Site Name: UCR
Operable Unit: Current Resident, Sturgeon
Run Mode: Research

* : signify default values used in place of missing input data.
# : signify surrogate values entered (determined) by user.
---: signify missing input data.
PBB & PRED are the observed and predicted blood Pb levels in µg/dL.

Percent exceedance was calculated using values of GSD and PbB Cutoff as follows:
GSD = 1.6
PbB Cutoff (C) = 3, 5, or 8 µg/dL

Input File: RES STU_02`20`20.dat

LEAD BATCH MODE OUTPUT FILE
Model Version: 1.1 Build11

User Name: SRC
Date: 2/20/2020
Site Name: UCR
Operable Unit: Current Resident, Sucker
Run Mode: Research

* : signify default values used in place of missing input data.
# : signify surrogate values entered (determined) by user.
---: signify missing input data.
PBB & PRED are the observed and predicted blood Pb levels in µg/dL.

Percent exceedance was calculated using values of GSD and PbB Cutoff as follows:
GSD = 1.6
PbB Cutoff (C) = 3, 5, or 8 µg/dL

Input File: RES SUC_02`20`20.dat

LEAD BATCH MODE OUTPUT FILE
Model Version: 1.1 Build11

User Name: SRC
Date: 2/20/2020
Site Name: UCR
Operable Unit: Current Resident, Walleye
Run Mode: Research

* : signify default values used in place of missing input data.
# : signify surrogate values entered (determined) by user.
---: signify missing input data.
PBB & PRED are the observed and predicted blood Pb levels in µg/dL.

Percent exceedance was calculated using values of GSD and PbB Cutoff as follows:
GSD = 1.6
PbB Cutoff (C) = 3, 5, or 8 µg/dL

Input File: RES WAL_02`20`20.dat

LEAD BATCH MODE OUTPUT FILE
Model Version: 1.1 Build11

User Name: SRC
Date: 2/20/2020
Site Name: UCR
Operable Unit: Current Resident, Whitefish
Run Mode: Research

* : signify default values used in place of missing input data.
# : signify surrogate values entered (determined) by user.
---: signify missing input data.
PBB & PRED are the observed and predicted blood Pb levels in µg/dL.

Percent exceedance was calculated using values of GSD and PbB Cutoff as follows:
GSD = 1.6
PbB Cutoff (C) = 3, 5, or 8 µg/dL

Input File: RES WHI_02`20`20.dat

LEAD BATCH MODE OUTPUT FILE
Model Version: 1.1 Build11

User Name: SRC
Date: 2/22/2020
Site Name: UCR
Operable Unit: Current Resident, No Fish Consumption
Run Mode: Research

* : signify default values used in place of missing input data.
# : signify surrogate values entered (determined) by user.
---: signify missing input data.
PBB & PRED are the observed and predicted blood Pb levels in µg/dL.

Percent exceedance was calculated using values of GSD and PbB Cutoff as follows:
GSD = 1.6
PbB Cutoff (C) = 3, 5 or 8 µg/dL

Input File: 02222020_Res no bch no fish.dat

LEAD BATCH MODE OUTPUT FILE
Model Version: 1.1 Build11

User Name: SRC
Date: 3/6/2020
Site Name: UCR
Operable Unit: Future Resident, Burbot
Run Mode: Research

* : signify default values used in place of missing input data.
# : signify surrogate values entered (determined) by user.
---: signify missing input data.
PBB & PRED are the observed and predicted blood Pb levels in µg/dL.

Percent exceedance was calculated using values of GSD and PbB Cutoff as follows:
GSD = 1.6
PbB Cutoff (C) = 3, 5, or 8 µg/dL

Input File: 03`06`2020 BUR.dat

LEAD BATCH MODE OUTPUT FILE
Model Version: 1.1 Build11

User Name: SRC
Date: 3/6/2020
Site Name: UCR
Operable Unit: Future Resident, Kokanee
Run Mode: Research

* : signify default values used in place of missing input data.
# : signify surrogate values entered (determined) by user.
---: signify missing input data.
PBB & PRED are the observed and predicted blood Pb levels in µg/dL.

Percent exceedance was calculated using values of GSD and PbB Cutoff as follows:
GSD = 1.6
PbB Cutoff (C) = 3, 5, or 8 µg/dL

Input File: 03`06`2020 KOK.dat

LEAD BATCH MODE OUTPUT FILE
Model Version: 1.1 Build11

User Name: SRC
Date: 3/6/2020
Site Name: UCR
Operable Unit: Future Resident, Northern Pike
Run Mode: Research

* : signify default values used in place of missing input data.
# : signify surrogate values entered (determined) by user.
---: signify missing input data.
PBB & PRED are the observed and predicted blood Pb levels in µg/dL.

Percent exceedance was calculated using values of GSD and PbB Cutoff as follows:
GSD = 1.6
PbB Cutoff (C) = 3, 5, or 8 µg/dL

Input File: 03`06`2020 NOR.dat

LEAD BATCH MODE OUTPUT FILE
Model Version: 1.1 Build11

User Name: SRC
Date: 3/6/2020
Site Name: UCR
Operable Unit: Future Resident, Rainbow Trout
Run Mode: Research

* : signify default values used in place of missing input data.
# : signify surrogate values entered (determined) by user.
---: signify missing input data.
PBB & PRED are the observed and predicted blood Pb levels in µg/dL.

Percent exceedance was calculated using values of GSD and PbB Cutoff as follows:
GSD = 1.6
PbB Cutoff (C) = 3, 5, or 8 µg/dL

Input File: 03`06`2020 RAI.dat

LEAD BATCH MODE OUTPUT FILE
Model Version: 1.1 Build11

User Name: SRC
Date: 3/6/2020
Site Name: UCR
Operable Unit: Future Resident, Smallmouth Bass
Run Mode: Research

* : signify default values used in place of missing input data.
# : signify surrogate values entered (determined) by user.
---: signify missing input data.
PBB & PRED are the observed and predicted blood Pb levels in µg/dL.

Percent exceedance was calculated using values of GSD and PbB Cutoff as follows:
GSD = 1.6
PbB Cutoff (C) = 3, 5, or 8 µg/dL

Input File: 03`06`2020 SMB.dat

LEAD BATCH MODE OUTPUT FILE
Model Version: 1.1 Build11

User Name: SRC
Date: 3/6/2020
Site Name: UCR
Operable Unit: Future Resident, Sturgeon
Run Mode: Research

* : signify default values used in place of missing input data.
# : signify surrogate values entered (determined) by user.
---: signify missing input data.
PBB & PRED are the observed and predicted blood Pb levels in µg/dL.

Percent exceedance was calculated using values of GSD and PbB Cutoff as follows:
GSD = 1.6
PbB Cutoff (C) = 3, 5, or 8 µg/dL

Input File: 03`06`2020 STU.dat

LEAD BATCH MODE OUTPUT FILE
Model Version: 1.1 Build11

User Name: SRC
Date: 3/6/2020
Site Name: UCR
Operable Unit: Future Resident, Sucker
Run Mode: Research

* : signify default values used in place of missing input data.
# : signify surrogate values entered (determined) by user.
---: signify missing input data.
PBB & PRED are the observed and predicted blood Pb levels in µg/dL.

Percent exceedance was calculated using values of GSD and PbB Cutoff as follows:
GSD = 1.6
PbB Cutoff (C) = 3, 5, or 8 µg/dL

Input File: 03`06`2020 SUC.dat

ID	FAM	BLK	AGE (mon)	SOIL (µg/g)	DUST (µg/g)	WATER (µg/L)	AIR (µg/m³)	Other (µg/day)	PBB (µg/dL)	PRED (µg/dL)	P(PbB>3) (%)	P(PbB>5) (%)	P(PbB>8) (%)

LEAD BATCH MODE OUTPUT FILE
Model Version: 1.1 Build11

User Name: SRC
Date: 3/6/2020
Site Name: UCR
Operable Unit: Future Resident, Walleye
Run Mode: Research

* : signify default values used in place of missing input data.
# : signify surrogate values entered (determined) by user.
---: signify missing input data.
PBB & PRED are the observed and predicted blood Pb levels in µg/dL.

Percent exceedance was calculated using values of GSD and PbB Cutoff as follows:
GSD = 1.6
PbB Cutoff (C) = 3, 5, or 8 µg/dL

Input File: 03`06`2020 WAL.dat

LEAD BATCH MODE OUTPUT FILE
Model Version: 1.1 Build11

User Name: SRC
Date: 3/6/2020
Site Name: UCR
Operable Unit: Future Resident, Whitefish
Run Mode: Research

* : signify default values used in place of missing input data.
# : signify surrogate values entered (determined) by user.
---: signify missing input data.
PBB & PRED are the observed and predicted blood Pb levels in µg/dL.

Percent exceedance was calculated using values of GSD and PbB Cutoff as follows:
GSD = 1.6
PbB Cutoff (C) = 3, 5, or 8 µg/dL

Input File: 03`06`2020 WHI.dat

LEAD BATCH MODE OUTPUT FILE
Model Version: 1.1 Build11

User Name: SRC
Date: 2/28/2020
Site Name: UCR
Operable Unit: Future Resident, No Fish Consumption
Run Mode: Research

* : signify default values used in place of missing input data.
# : signify surrogate values entered (determined) by user.
---: signify missing input data.
PBB & PRED are the observed and predicted blood Pb levels in µg/dL.

Percent exceedance was calculated using values of GSD and PbB Cutoff as follows:
GSD = 1.6
PbB Cutoff (C) = 3, 5 or 8 µg/dL

Input File: ADA 02`28`2020 NO Fish.dat

Run Mode: Research

* : signify default values used in place of missing input data.
# : signify surrogate values entered (determined) by user.
---: signify missing input data.
PBB & PRED are the observed and predicted blood Pb levels in µg/dL.

Percent exceedance was calculated using values of GSD and PbB Cutoff as follows:
GSD = 1.6
PbB Cutoff (C) = 3 µg/dL, 5 µg/dL, or 8 µg/dL

Input File: 08272019 Public Beach Sediment SW While Swim Beach Fish.dat

LEAD BATCH MODE OUTPUT FILE
Model Version: 1.1 Build11

User Name: SRC
Date: 8/28/2019
Site Name: UCR
Operable Unit: Recreational Visitor, Boat Trips to Public Beaches, With and Without Fish Consumption
Run Mode: Research

* : signify default values used in place of missing input data.
# : signify surrogate values entered (determined) by user.
---: signify missing input data.
PBB & PRED are the observed and predicted blood Pb levels in µg/dL.

Percent exceedance was calculated using values of GSD and PbB Cutoff as follows:
GSD = 1.6
PbB Cutoff (C) = 3 µg/dL, 5 µg/dL, 8 µg/dL

Input File: Aug 28 2019 Pub Bch Sed SW Fish Boat.dat

LEAD BATCH MODE OUTPUT FILE
Model Version: 1.1 Build11

User Name: SRC
Date: 8/28/2019
Site Name: UCR
Operable Unit: Recreational Visitor, Camping Trips to Public Beaches, With and Without Fish Consumption
Run Mode: Research

* : signify default values used in place of missing input data.
# : signify surrogate values entered (determined) by user.
---: signify missing input data.
PBB & PRED are the observed and predicted blood Pb levels in µg/dL.

Percent exceedance was calculated using values of GSD and PbB Cutoff as follows:
GSD = 1.6
PbB Cutoff (C) = 3 µg/dL, 5 µg/dL, 8 µg/dL

Input File: 28 Aug 2019 Pub Bch Sed SW Fish Campers.dat

LEAD BATCH MODE OUTPUT FILE
Model Version: 1.1 Build11

User Name: SRC
Date: 2/24/2020
Site Name: UCR
Operable Unit: Recreational Visitor, Beach Trips to Bossburg Flat Beach UDUs, With and Without Fish Consumption
Run Mode: Research

* : signify default values used in place of missing input data.
# : signify surrogate values entered (determined) by user.
---: signify missing input data.
PBB & PRED are the observed and predicted blood Pb levels in µg/dL.

Percent exceedance was calculated using values of GSD and PbB Cutoff as follows:
GSD = 1.6
PbB Cutoff (C) = 3 µg/dL, 5 µg/dL, 8 µg/dL

Input File: UDU Beachgoers SED SWIM FISH MHF_08`28`2019.dat

LEAD BATCH MODE OUTPUT FILE
Model Version: 1.1 Build11

User Name: SRC
Date: 2/24/2020
Site Name: UCR
Operable Unit: Recreational Visitor, Boat Trips to Bossburg Flat Beach UDUs, With and Without Fish Consumption
Run Mode: Research

* : signify default values used in place of missing input data.
# : signify surrogate values entered (determined) by user.
---: signify missing input data.
PBB & PRED are the observed and predicted blood Pb levels in µg/dL.

Percent exceedance was calculated using values of GSD and PbB Cutoff as follows:
GSD = 1.6
PbB Cutoff (C) = 3 µg/dL, 5 µg/dL, 8 µg/dL

Input File: 08`29`2019 boat 2015BeachSoil_SummaryStats_UDU SED SW FISH.dat

LEAD BATCH MODE OUTPUT FILE
Model Version: 1.1 Build11

User Name: SRC
Date: 2/24/2020
Site Name: UCR
Operable Unit: Recreational Visitor, Camping Trips to Bossburg Flat Beach UDUs, With and Without Fish Consumption
Run Mode: Research

* : signify default values used in place of missing input data.
# : signify surrogate values entered (determined) by user.
---: signify missing input data.
PBB & PRED are the observed and predicted blood Pb levels in µg/dL.

Percent exceedance was calculated using values of GSD and PbB Cutoff as follows:
GSD = 1.6
PbB Cutoff (C) = 3 µg/dL, 5 µg/dL, 8 µg/dL

Input File: 08`29`2019 Campers UDU SED SW FISH.dat

ID		FAM	BLK	AGE (mon)	SOIL (µg/g)	DUST (µg/g)	WATER (µg/L)	AIR (µg/m³)	Other (µg/day)	PBB (µg/dL)	PRED (µg/dL)	P(PbB>3) (%)	P(PbB>5) (%)	P(PbB>8) (%)

LEAD BATCH MODE OUTPUT FILE
Model Version: 1.1 Build11

User Name: SRC
Date: 8/29/2019
Site Name: UCR
Operable Unit: Recreational Visitor, Beach Visits to Relict Floodplains, With and Without Fish Consumption
Run Mode: Research

* : signify default values used in place of missing input data.
# : signify surrogate values entered (determined) by user.
---: signify missing input data.
PBB & PRED are the observed and predicted blood Pb levels in µg/dL.

Percent exceedance was calculated using values of GSD and PbB Cutoff as follows:
GSD = 1.6
PbB Cutoff (C) = 3 µg/dL, 5 µg/dL, 8 µg/dL

Input File: RF Beach UPSOIL_SED SW FISH MHF_08`29`2019.dat

LEAD BATCH MODE OUTPUT FILE
Model Version: 1.1 Build11

User Name: SRC
Date: 8/29/2019
Site Name: UCR
Operable Unit: Recreational Visitor, Boat Trips to Relict Floodplains, With and Without Fish Consumption
Run Mode: Research

* : signify default values used in place of missing input data.
# : signify surrogate values entered (determined) by user.
---: signify missing input data.
PBB & PRED are the observed and predicted blood Pb levels in µg/dL.

Percent exceedance was calculated using values of GSD and PbB Cutoff as follows:
GSD = 1.6
PbB Cutoff (C) = 3 µg/dL, 5 µg/dL, 8 µg/dL

Input File: RF Boaters UPSOIL_RF149UM_EPCS SED SW FISH MHF_08`29`2019.dat

LEAD BATCH MODE OUTPUT FILE
Model Version: 1.1 Build11

User Name: SRC
Date: 2/25/2020
Site Name: UCR
Operable Unit: Recreational Visitor, Camping Trips to Relict Floodplains, With and Without Fish Consumption
Run Mode: Research

* : signify default values used in place of missing input data.
# : signify surrogate values entered (determined) by user.
---: signify missing input data.
PBB & PRED are the observed and predicted blood Pb levels in µg/dL.

Percent exceedance was calculated using values of GSD and PbB Cutoff as follows:
GSD = 1.6
PbB Cutoff (C) = 3 µg/dL, 5 µg/dL, 8 µg/dL

Input File: Campers UPSOIL_RF149UM_SED SW FISH.dat

Appendix 6. EPA Action Memorandum for the Upper Columbia River Site Residential Properties Soil Removal near Northport, Stevens County, Washington

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY
REGION 10
1200 Sixth Avenue, Suite 900
Seattle, WA 98101-3140

OFFICE OF
ENVIRONMENTAL CLEANUP

August 6, 2015

SUBJECT: Action Memorandum for the Upper Columbia River Site Residential Properties Soil Removal near Northport, Stevens County, Washington

FROM: Jeffrey Fowlow, Federal On-Scene Coordinator
Emergency Preparedness and Prevention Unit

THRU: Wally Moon, Unit Manager
Emergency Preparedness and Prevention Unit

TO: Chris D. Field, Manager
Emergency Management Program

I. PURPOSE

The purpose of this Action Memorandum is to document approval of the time-critical removal action ("TCRA") described herein for the Upper Columbia River Site Residential Properties Soil Removal near Northport, Stevens County, Washington (Site).

The Upper Columbia River Site is currently the subject of a remedial investigation / feasibility study (RI/FS) to investigate contamination along the Upper Columbia River from the Grand Coulee Dam to the United States (U.S.)-Canada border related to historical smelting operations. As a part of field sampling activities for the RI/FS, the U.S. Environmental Protection Agency ("EPA") identified several residential properties and tribal allotments[1] in the Columbia River valley north of the town of Northport, Washington, which contained lead and/or arsenic at elevated levels. The residential properties are the focus of the time-critical removal action described herein. Any future time-critical removal actions taken on the tribal allotments will be addressed as a separate action. The residential properties and tribal allotments are located on land that is historically and culturally significant to both the Confederated Tribes of the Colville Reservation (Colville Confederated Tribes) and the Spokane Tribe of Indians.

Teck Metals, Limited (TML), a potentially responsible party ("PRP") at the Site, is currently negotiating a Settlement Agreement and Order on Consent ("Settlement Agreement") with EPA in accordance with the Comprehensive Environmental Response, Compensation, and Liability Act ("CERCLA") for the funding and performance of the removal action. Under that Settlement Agreement, Teck American

[1] For the purpose of this Action Memo, the term "allotment" refers to parcels of land outside the borders of an established Indian reservation that are owned by private tribal members.

Incorporated (TAI) would be the party performing the work, though both TAI and TML will be held jointly and severally responsible for the work, and herein referred to as "Teck".

II. SITE CONDITIONS AND BACKGROUND

The Superfund Enterprise Management System (formerly CERCLIS) ID Number for the Upper Columbia River Site is WASFN1002171 and the Site/Spill ID is 10NZ.

A. Site Description

1. Removal site evaluation

EPA is performing an RI/FS along the Upper Columbia River. The Upper Columbia River consists of the areal extent of hazardous substances contamination within the U.S. in or adjacent to the Upper Columbia River, including the Franklin D. Roosevelt Lake ("Lake Roosevelt"), from the border between the U.S. and Canada downstream to the Grand Coulee Dam.

A smelter owned by Teck located in Trail, British Columbia, on the Columbia River approximately 10 miles north of the U.S./Canada border has discharged metals-laden slag and liquid wastes into the Columbia River, as well as discharges from the smelter to the properties and allotments that are the subject of this removal action. Under the RI/FS, which is being funded by Teck, sampling has been conducted to determine levels of contamination in fish, river sediment, beach sediment, river water, and soil to support human health and ecological risk assessments.

As part of the RI/FS, in 2014 EPA collected and analyzed soil samples from residential properties in the Columbia River valley north of Northport, WA to the U.S.-Canada border to investigate potential airborne metals contamination from the Trail smelter and the former LeRoi Smelter that had historically operated in Northport. A total of 74 properties along both sides of the river were sampled. At each property, EPA identified representative decision units that had high human contact with soil (i.e., yards, gardens, play areas, etc.). Once the sampling areas were identified, EPA used an incremental composite (IC) sampling approach to collect IC samples from each decision unit ("DU"). A DU is an identified area within a property that is distinguishable from other areas by factors such as location or use and include areas within a property with a high likelihood of exposure to humans from contaminated soil. Examples of decision units are play areas, gardens, or lawns. Most DUs had three IC samples collected. Each IC sample was collected from shallow surface soil (usually 0-1" deep), except gardens which went to tilling depth (usually 0-12" deep). A total of 237 DUs were sampled.

The action level (i.e., the level at which action is triggered) for lead ("Pb") is 700 milligrams per kilogram ("mg/kg"), and the removal action will result in achieving a cleanup level of 250 mg/kg or less, based on a project-specific determination by EPA

(Memorandum from Richard Albright to Mr. Pendowski et al *"Dispute Decision Regarding Upper Columbia River Action Levels for Time-Critical Removal Action Dispute, Upper Columbia River Superfund Site",* April 21, 2015). The cleanup level for arsenic (As) is 20 mg/kg, based on the Washington State Model Toxics Control Act Method A Unrestricted use concentration. The results of the RI/FS sampling effort identified 17 properties, including 14 residential properties and three tribal allotments, which contained lead at concentrations near or above the Site action level.

In May 2015, the EPA Region 10 Removal Program conducted a removal site evaluation. During this removal site evaluation, EPA prepared for the proposed removal action by documenting the condition and layout of each property designated for cleanup and coordinating with each of the property owners. At some of the properties, EPA either extended the size of some DUs, or added new DUs, based on additional observations of property use and interviews with the landowners that indicated areas of the property with a high likelihood of exposure to humans from contaminated soil. EPA also collected and analyzed soil samples from the original DUs to better delineate the horizontal and vertical extent of contamination and to assist in removal planning (i.e., measuring quantities and depths of contaminated soil for logistics, disposal, and cost estimating).

Sampling conducted in 2014 and 2015 also identified tribal allotments where lead and arsenic concentrations exceed action levels; however, this removal action does not include those tribal allotments because the benefits of alternative removal or remedial techniques are being further evaluated for potential future cleanup actions.

2. Physical location

The community of Northport (population 295) is located along the eastern shoreline of the Upper Columbia River, approximately six miles south of the border with Canada and 35 miles north of Colville, Washington. Surrounding land use is primarily forestry and agricultural, with a number of rural residential properties.

The area has a humid continental climate characterized by cold winters and hot summers. The average annual precipitation is 19.5 inches, and the average annual snowfall is 53.7 inches. Average maximum temperatures are as high as 88.4 degrees Fahrenheit (°F) in the summer (July) and average minimum temperatures are as cold as 19.8 °F in winter (January).

3. Site characteristics

The area within the Site in which the removal actions will be conducted consists of 14 residential properties within the Columbia River valley near Northport, Washington (Figure 1). Specific property details including property owner names and locations are included in the confidential enforcement addendum.

Each residential property has one or more DUs designated for removal activities. Each residential property DU is located in an area of the property likely to be used by the residents and/or visitors and so poses an increased exposure risk to the elevated arsenic and lead in the soil. Specifically, most of the DUs at the properties are areas of the residential yard where the residents or visitors are likely to perform recreational, gardening, and/or yard maintenance activities that would likely expose them to the contaminated soil.

4. Release or threatened release into the environment of a hazardous substance or pollutant or contaminant

The primary contaminants of concern (COCs) are lead and arsenic. These contaminants are hazardous substances or pollutants or contaminants as defined by sections 101(14) & (33) of CERCLA, 42 U.S.C. § 9601(14) and (33).

The primary source of the lead and arsenic contamination at each of these properties is believed to be emissions from the Teck smelter in nearby Trail, British Columbia.

Numerous studies have been performed at the Site since 2000 as part of the Upper Columbia River site assessment process and RI/FS. Sampling efforts relevant to the current residential soil removal action are discussed below.

2014 Residential Soil Sampling

In 2014, EPA sampled soil at multiple residential properties and tribal allotments in the Columbia River valley between Northport and the U.S./Canada border that may have elevated metals as a result of regional smelter operations. Property owners volunteered to have their property sampled, and the sampling was conducted between August and October 2014.

The results of this investigation indicated that 14 properties and three tribal allotments contained at least one area (i.e., a decision unit) with concentrations of lead over or near the TCRA action level of 700 mg/kg. The average lead concentration from the IC sampling approach for these properties was 985 mg/kg, which is approximately 4 times higher than the cleanup level of 250 mg/kg. The maximum IC sample lead concentration was 1,936 mg/kg, which is approximately 8 times higher than the cleanup level. The average and maximum IC sample concentrations for arsenic were 52.4 and 103 mg/kg, respectively, which are 2.5 and 5 times the cleanup level for arsenic of 20 mg/kg. Each IC sample was collected from shallow surface soil (usually 0-1” deep), except gardens samples from which were collected from tilling depth (usually 0-12” deep).

2015 Removal Sampling

During EPA's site visit in May 2015, EPA reviewed the DUs from the 2014 sampling event. At certain properties, EPA either extended the boundaries of the DUs, or added new DUs, to ensure that high-risk property areas (i.e., yards or gardens with an elevated risk of potential human contact) were included. From these DUs, EPA

collected and analyzed additional samples to further characterize the vertical and horizontal extent of contamination. At each DU sampled in 2014, EPA assumed that the soil at depths from 0 to 6 inches below ground surface (bgs) was contaminated, and new grab samples were collected at depths from 6 to 12 inches bgs. At new DUs, EPA collected grab samples at intervals of 0 to 6 inches and 6 to 12 inches bgs. The samples were analyzed in the field using field-portable X-ray fluorescence (XRF) instruments, with a subset of the samples analyzed at an off-site laboratory.

During the May 2015 sampling event, a total of approximately 480 grab samples were collected and analyzed in the field by XRF, and 100 of these samples were submitted to an off-site laboratory for metals analysis. The results indicated that 80 of the samples exceeded the site cleanup level for either lead or arsenic based on the laboratory data or XRF field screening data if laboratory data was not available. For the laboratory data, lead was detected as high as 1,590 mg/kg, which is 6 times the cleanup level of 250 mg/kg, and arsenic was detected as high as 89 mg/kg, which is 4.5 times the cleanup level of 20 mg/kg.

EPA also submitted five of the samples for toxicity characteristic leaching procedure (TCLP) lead and arsenic analyses at the off-site laboratory to determine if the contaminated site soil was a characteristic hazardous waste. The samples selected for TCLP analyses included those with the highest total lead and arsenic concentrations as determined by XRF. All of the samples were well below the applicable TCLP limits for lead and arsenic, indicating that the site soil can likely be disposed of as non-hazardous waste.

5. NPL Status

Although the Upper Columbia River Site is not currently on the National Priorities List (NPL), it is being investigated through an RI/FS conducted by TAI (formerly Teck Cominco American Incorporated) subject to EPA oversight.

6. Maps, pictures, and other graphic representations

Figure 1 indicates the location of the Site, including the general area on both sides of the Columbia River between Northport and the U.S./Canadian Border where the 14 residential properties and several tribal allotments are located. For specific details including maps of each individual property, please refer to the confidential enforcement addendum.

B. Other Actions to Date

1. Previous actions

In 2004, EPA performed a time-critical removal action at the LeRoi Smelter Site in the town of Northport. The site included a 20-acre smelter operations complex and a 10-acre adjacent lumber mill complex which was formerly part of the original smelter

complex. The smelter operated intermittently from 1896 to 1921 and processed copper, gold, silver, and lead ores from nearby mines in Washington State and British Columbia. The primary contaminants of concern for the removal action were lead and arsenic.

In addition to cleanup of the smelter site itself, the scope of the removal action included the removal of lead and arsenic contaminated soil from 29 residential and common-use properties within or near the town limits of Northport, followed by backfill with clean top soil and property restoration. The removal action was performed to address lead and arsenic contamination associated with nearby and distant smelting operations, mine-waste disposal practices, and construction practices using mine-waste contaminated materials.

2. Current actions

There are no government or known private cleanup activities that are currently being performed at the Site that have not been previously described.

C. State and Local Authorities' Roles

1. State and local actions to date

The Washington State Department of Ecology (Ecology) has been involved in the RI/FS at the Site. Teck American Incorporated entered into a voluntary agreement with Ecology to remove contaminated sediment from Black Sand Beach in the Fall of 2010. The beach is located about three miles south of the Canadian border near Northport, WA and is located within the Site.

2. Potential for continued State/local response

Ecology is expected to remain involved in the RI/FS and in any future remedial cleanup actions.

D. Tribal Government Coordination

Staff-to-staff level coordination has occurred between EPA and the Colville Confederated Tribes regarding the proposed TCRA. EPA offered formal government-to-government consultation to the Chairman of the Confederated Tribes of the Colville Indian Reservation and the Spokane Tribe of Indians on May 27, 2015. On July 7, 2015, the Colville Tribe Business Council ("Council") accepted the offer of consultation and a meeting between EPA and Council occurred on July 21, 2015, in Nespelem, Washington. Prominent topics discussed in the consultation include the Council's desire to be informed of and participate in any ongoing and future negotiations between EPA and Teck at this tribal site where tribal lands and resources are affected. Also discussed was the Council's desire for a long-term cleanup plan for the overall Upper Columbia River Site in general and long term plans for the tribal allotments beyond removal actions in 2015 to include multiple possible options available which have yet to be fully

explored and discussed. In addition, the Council emphasized the requirement of Tribal Cultural Resource Monitors where any soil disturbing actions are undertaken.

III. THREATS TO PUBLIC HEALTH OR WELFARE OR THE ENVIRONMENT

The current conditions at this Site meet the following factors which indicate that the Site may pose an unacceptable risk to the public health or welfare or the environment and a removal action is appropriate under the National Oil and Hazardous Substances Pollution Contingency Plan (NCP), 40 C.F.R. § 300.415(b)(2).

A. Actual or potential exposure to nearby human populations, animals, or the food chain from hazardous substances or pollutants or contaminants [300.415(b)(2)(i)]

The data from previous environmental investigations shows that surface soil at the properties is contaminated with elevated concentrations of lead and arsenic, and that the primary source of the elevated concentrations of metals is from releases from Teck's smelting operations in nearby Trail, British Columbia.

Potential human exposure routes include direct contact with and ingestion of contaminated soil and inhalation of windblown dust. Human receptors include residents, visitors, trespassers, and passers-by. The potential for exposure is increased by the fact that the majority of these properties are residential with full-time residents.

At each property, the portion of the property subject to investigation and subsequently designated for removal action (i.e., the DUs) were selected based on their proximity to the residences and likelihood that the decision units would be used frequently by residents or visitors. The DUs include lawn and garden areas used by residents for property access, recreation, lawn and house maintenance, and gardening, and therefore represent an increased risk of exposure to the elevated levels of lead and As in the soil.

The effects of exposure to the contaminants of concern on organ systems is influenced by several factors, including dose, duration of exposure, and route of exposure, as well as the age and health of the receptor exposed. Lead is known to be toxic to humans. Children are most susceptible to the effects of lead and even low levels of lead in the blood of children can result in behavior and learning problems, lower IQ and hyperactivity, slowed growth, hearing problems, anemia, and in rare cases, ingestion of lead can cause seizures, coma and even death. Pregnant women are also particularly vulnerable to the effects of lead contamination and exposure to lead can result in serious effects to the mother and her developing fetus, including reduced growth of the fetus and premature birth.

B. High levels of hazardous substances or pollutants or contaminants in soils largely at or near the surface that may migrate (40 C.F.R. § 300.415[b][2][iv])

Portions of the DUs on the properties are only partially vegetated. Lead and arsenic are present at elevated concentrations in shallow surface soil (i.e., 0-6 inches bgs), which create the likelihood of exposure from residential and recreational use, and the soils are susceptible to migration within and off of the properties because of water- and wind-borne and mechanical influences.

C. Weather conditions that may cause hazardous substances or pollutants or contaminants to migrate or be released (40 C.F.R. § 300.415(b)(2)(v))

The climate in the region of the site includes cold, freezing winters with a large amount of snow and hot, often dry summers. These weather conditions can increase the likelihood that the contaminants in shallow surface soil are susceptible to dispersion (e.g., snow melt and rains in the spring may disperse contaminants in surface water runoff, and the dry and hot conditions in summer and early fall may cause contaminants to disperse by wind, especially in areas that are not protected by a vegetated cover).

D. The availability of other appropriate federal or state response mechanisms to respond to the release (40 C.F.R. § 300.415(b)(2)(vii))

The proposed TCRA is expected to be conducted by Teck in accordance with CERCLA and with oversight by EPA. There are no known other appropriate federal or state response mechanisms capable of providing the appropriate resources in the prompt manner needed to address the potential human health and ecological risks associated with the hazardous substances described herein.

IV. ENDANGERMENT DETERMINATION

Actual or threatened releases of hazardous substances from this Site may present an imminent and substantial endangerment to the public health, or welfare, or the environment.

V. PROPOSED ACTIONS AND ESTIMATED COSTS

A. Proposed Actions

The proposed action is intended to mitigate the potential human health threats posed by exposure to lead and arsenic, including direct contact, ingestion, and inhalation pathways.

1. Proposed action description

Soil in each DU above cleanup levels (250 mg/kg for lead and/or 20 mg/kg for arsenic) will be excavated to a maximum depth of 12 inches (24 inches for gardens) for off-Site disposal in an appropriate landfill (selected consistent with the off-site rule) followed by backfill and restoration. The Site consists of 14 residential properties. The general approach to be used at all locations is described below.

Property Preparation

Property-Specific Work Plans are being developed based on interviews with the affected property owner and EPA observations made during site reconnaissance activities. The pre-removal condition of the property (e.g., the house or any other structure, driveways, paved parking areas, fences, utilities, trees or other vegetated areas, gardens, etc.) will be documented. The presence (or evidence) of any children, pets, and/or livestock will also be noted. Items that cannot be temporarily relocated during removal activities will be identified and protected from damage. Removal activities will be conducted in a way that considers property features and uses. The removal activities will be coordinated with the property owner and performed in such a manner as to minimize impacts to the property and the residents.

If necessary, access roads and driveways to the property and DUs will be improved to allow access for equipment and vehicles. Work areas and roads for site traffic will be established in project work plans. Any residential items or personal belongings in the work zone (i.e., DU and support zones) will be temporarily relocated or marked and protected. The location of any underground or aboveground utilities will be identified and marked.

Excavation

In each DU where soil excavation occurs, the contaminated soil will be excavated to an initial depth of 6 inches bgs. In most areas, excavation will primarily be with mechanical equipment (e.g., excavators, skid steers, and loaders), while in some sensitive locations (i.e., near houses, buried utilities, or trees/vegetation), excavation will be performed by hand using shovels and other hand tools.

At the bottom of the initial 6-inch excavation, the soil will be screened using XRF to determine whether additional excavation is required. Screening samples will be located in a grid pattern at a frequency of at least one sample every 400 square feet. If analysis of samples from any location indicates that the soil at the bottom of the excavation contains either lead or arsenic above the cleanup levels, excavation will continue at that location to a maximum depth of 12 inches bgs. The lateral extent of any additional excavation will be determined by soil sampling and analysis to ensure all soil with concentrations exceeding the lead or arsenic cleanup levels is removed. At the bottom of any 12-inch excavation area, the soil will be screened by XRF to determine whether the soil is still above lead or arsenic cleanup levels. If soil at the 12-inch depth is below

both lead and arsenic cleanup levels, backfilling can proceed. If soil is above cleanup levels for lead or arsenic, a geotextile fabric or similar material will be laid down at the bottom of the excavation area before backfilling as a visual indicator between contaminated soil and clean backfill.

Around mature trees, excavation will be performed by hand and will only extend to approximately 2 inches bgs within the tree's root radius to avoid damage to the tree.

Field screening with the XRF will be supported by a site-specific sampling plan (SSSP) and quality assurance project plan (QAPP) and will include the collection of confirmation samples and analysis at an off-site laboratory to validate the precision and accuracy of the field XRF screening. The SSSP/QAPP will be reviewed and approved by EPA prior to removal activities.

Personnel and equipment exiting work areas will be decontaminated to avoid the spread of contaminants.

Waste Management and Disposal

Excavated soil should be managed within the confines of each DU and then will be loaded directly into haul trucks to minimize short-term cleanup impacts to the property. The haul trucks will then transport the contaminated soil to a centrally located stockpile area or, if necessary and/or feasible, directly to a disposal facility consistent with the off-site rule. If needed, the specific locations of any stockpile will be determined on a case-by-case basis. At the stockpile location, contaminated soil from each property will be loaded on to trucks for transport to an appropriate landfill consistent with the off-site rule.

Based on the results of EPA's sampling in May 2014, the soil may be able to be disposed of as non-hazardous waste in a Subtitle D landfill, although this is subject to verification and final waste profiling by the intended disposal facility.

Property Backfill and Restoration

Following the excavation of the contaminated soil at each DU, the excavated area will be backfilled to the original grade with pit run gravel and/or top soil, depending on the property. Additionally, as appropriate grass seed can be added to areas backfilled with clean top soil.

Sources of pit run gravel and top soil will be screened by XRF in accordance with the SSSP/QAPP to ensure that the backfill material does not contain lead or arsenic at concentrations greater than the site cleanup levels.

Following backfill, the property will be restored to a condition comparable to its pre-removal condition, based on pre-removal documentation. If the removal activities require the removal of fencing or shrubs/vegetation, they will be repaired or replaced.

Best Management Practices

Best Management Practices (BMPs) will be implemented during removal activities to protect workers, residents, the community, and the environment from short-term construction impacts such as erosion, sedimentation, fugitive dust, noise, and other similar potential impacts. Removal activities on residential properties will be closely coordinated with the property owners and residents to minimize disruption and impacts to the residents and property.

Greener Cleanup Best Management Practices

Appropriate and practicable greener cleanup BMPs will be implemented during cleanup activities, including, but not limited to, minimizing energy consumption (e.g., using new and well-maintained equipment), minimizing generation and transport of fugitive dust (e.g., implementation of construction BMPs), minimizing waste generation through reuse and recycling, minimizing impacts to water resources (e.g., implementation of construction storm water and surface water BMPs), minimizing areas requiring activity or use limitations (e.g., source removal), minimizing unnecessary soil and habitat disturbance, and minimizing lighting and noise disturbance (e.g., implementation of construction BMPs).

Post-Removal Site Controls

If soil contamination in excess of the cleanup level is detected below 12 inches, a geotextile fabric or other similar visual marker will be installed to act as a warning to current or future property owners regarding the contaminated soil below. Following the removal action, a report detailing the removal activities will be provided to each property owner that will document the location of known areas above lead and arsenic cleanup levels. EPA expects that any necessary additional post-removal site controls will be addressed through the anticipated future remedial action.

On properties where sod, grass seed, and/or plants have been installed, a maintenance plan will be provided to each property owner so that the new plantings establish roots and survive.

2. Contribution to remedial performance

The proposed removal action will not impede future actions based upon available information. The proposed removal action may be the first and only action or one of a series of actions depending on post-removal activities such as those necessary to maintain the protectiveness of the cleanup.

The proposed removal action has been and will continue to be closely coordinated with the Remedial Program to ensure that the action will contribute to the efficient

performance of any long-term remedial action with respect to the release or threatened release concerned.

3. Engineering Evaluation/Cost Analysis

An Engineering Evaluation/Cost Analysis is not required because this is a TCRA.

4. Applicable or relevant and appropriate requirements

The NCP requires that removal actions attain Applicable or Relevant and Appropriate Requirements (ARARs) under federal or state environment or facility siting laws, to the extent practicable. (40 C.F.R. § 300.415(j)) In determining whether compliance with ARARs is practicable, EPA may consider the scope of the removal action and the urgency of the situation. (40 C.F.R. § 415(j)) The scope of the removal action proposed in this Action Memorandum is limited.

Endangered Species Act [16 U.S.C. §§ 1531 – 1544; 50 C.F.R. Parts 17, 402]. The Endangered Species Act (ESA) protects species of fish, wildlife, and plants that are listed as threatened or endangered with extinction. It also protects designated critical habitat for listed species. The ESA outlines procedures for federal agencies to follow when taking actions that may jeopardize listed species, including consultation with resource agencies. The requirements of the ESA are potentially applicable to the Site since listed threatened or endangered species habitat areas will or could be impacted by response action. Consistent with ESA Section 7, if any federally designated threatened or endangered species are identified in the vicinity of removal work and the action may affect such species and/or their habitat, EPA will consult with USFWS to ensure that response actions are conducted in a manner to avoid adverse habitat modification and jeopardy to the continued existence of such species.

National Historic Preservation Act [16 U.S.C. § 470f; 36 C.F.R. Parts 60, 63, 800]. Section 106 of the National Historic Preservation Act (NHPA) requires federal agencies to take into account the effects of their undertakings on historic properties and seek ways to avoid, minimize or mitigate any adverse effects on those properties. This includes archaeological sites, historic sites and traditional cultural properties that are eligible to the National Register of Historic Places.

The Section 106 process seeks to accommodate historic preservation concerns with the needs of federal undertakings through consultation among the agency official and the affected parties, commencing at the early stages of project planning. The EPA is the lead Agency responsible for ensuring that all work is conducted in compliance with Section 106 of the National Historic Preservation Act. EPA will consult with other parties that have an interest in the effects of the planned undertaking and provide them a reasonable opportunity to comment on such undertakings. These parties include, but

are not limited to, the State Historic Preservation Officer and the concerned Tribal Historic Preservation Officers (THPOs).

On June 16, 2015, EPA representatives met with the Colville Confederated Tribes THPO and staff archaeologist regarding the planned soil removal work and discussed the field protocol to be followed by the work crews in coordination with the cultural monitors. A detailed description of the agreed upon field coordination/communication protocol is contained in the Statement of Work (Appendix C to the Administrative Settlement Agreement and Order on Consent for the performance of a removal action by TAI). This protocol will also be included in the Cultural Resources Coordination Plan to be completed by TAI. All field personnel are expected to be familiar with the cultural resources coordination plan and the field coordination/communication protocol to be followed on all properties. As contained in the protocol, the cultural monitors will have stop work authority if a suspected archaeological object or archaeological resource is encountered. Additionally, EPA personnel on-site will have stop work authority if there is any deviation from the coordination/communication protocol without prior approval by EPA. EPA has provided a copy of the field protocol to the Washington State Department of Archaeology and Historic Preservation Office which serves as the State Historic Preservation Office (SHPO) and provides continued updates regarding the planned work and its coordination efforts with the Colville Confederated Tribes.

On July 20, 2015, representatives for EPA, TAI and the CCT History/Archaeology Program discussed TAI's preliminary start date for conducting soil removal work so that the CCT can arrange for the availability of cultural monitors.

The performance of the removal action are expected to achieve the standards set forth under Washington State's MTCA (Chapter 173-340 of the Washington Administrative Code [WAC]) to address potential threats to public health and welfare and the environment from a release or threat of release of hazardous substances. As discussed above, soil cleanup levels for the removal action are based on MTCA Method A cleanup levels and the Work will achieve these levels. The State of Washington's solid waste and dangerous management regulations, found at WAC 173-300 *et seq*., are potentially applicable to solid waste generation and management at the Site.

Clean Water Act. The removal action shall comply with substantive stormwater requirements for construction activities, including erosion and sediment controls. (90.48 RCW, 33 U.S.C. §1251 *et seq*.)

5. Project schedule

The removal action activities are expected to start in August 2015 and the residential properties are expected to be completed by October 2015. The project is expected to last approximately eight to twelve weeks. Excavation is expected to be completed before winter weather arrives (usually November) before snowfall covers the planned

excavation areas and because the access roads/driveways to some of the properties will become impassable.

B. Estimated Costs

Teck is expected to pay for past costs and the cost of the removal action, including EPA's oversight costs. If EPA were to undertake implementation of the work described in this Action Memorandum, an Amendment will be written.

VI. EXPECTED CHANGE IN THE SITUATION SHOULD ACTION BE DELAYED OR NOT TAKEN

A delay in action or no action at the Site would increase the actual or potential threats to the public health and/or the environment associated with exposure to Site contaminants and would allow Site contaminants to continue to migrate from surface soils.

VII. OUTSTANDING POLICY ISSUES

None.

VIII. ENFORCEMENT ADDENDUM

Refer to attached confidential enforcement addendum.

IX. RECOMMENDATION

This decision document sets forth the recommended removal action for the Site that has been developed in accordance with CERCLA, and is consistent with the NCP. The recommended removal action is based on the administrative record for the Site.

Conditions at the Site meet the NCP 40 C.F.R. § 300.415(b) criteria for a removal action, and I request your approval of the recommended removal action. The recommended removal action is expected to be funded and conducted by Teck with oversight provided by EPA. However, if Teck is unwilling or unable to fund or conduct the recommended removal action, and EPA must undertake all removal action work, the total project ceiling is currently estimated to be $5,291,850.

X. APPROVAL/DISAPPROVAL

By the approval which appears below, EPA selects the removal action for the Site as set forth in the recommendations contained in this Action Memorandum.

Re: Dispute Decision Regarding Upper Columbia River Action Levels for Time-Critical Removal Action Dispute, Upper Columbia River Superfund Site

Dear Mr. Pendowski, Mr. Kieffer, Mr. Passmore, and Ms. Lehnertz:

This letter sets forth my determination with respect to the Washington Department of Ecology's February 13, 2015, request for dispute resolution, the Spokane Tribe of Indians' February 19, 2015, notification of participation in the dispute resolution process and subsequent submittal, the Confederated Tribes of the Colville Reservation's February 20, 2015 request for dispute resolution and subsequent submittal, and the U.S. Department of the Interior's March 19, 2015 comments via telephone on the dispute, regarding EPA's proposal of a lead action level for a Time-Critical Removal Action for various residential properties within the Upper Columbia River Superfund Site ("Site"). In summary, I hereby determine:

1. The lead action level for the Time-Critical Removal Action at residential properties at the Site must be determined through CERCLA removal action procedures and tribal consultation policies and will be documented in an Action Memorandum and the associated administrative record;

2. EPA intends to select an action level for the Time-Critical Removal Action for lead of 700 parts per million which will result in a cleanup level of less than 250 parts per million; and
3. EPA will continue to follow all appropriate CERCLA remedial action procedures, including the Memorandum of Agreement, and tribal consultation policies, for determining final cleanup levels for lead for the Remedial Action at the Site.

I. Background

On June 2, 2006, EPA and Teck Cominco Metals, Ltd. and Teck Cominco American Incorporated (collectively "Teck Cominco") entered into a settlement agreement for the performance of a CERCLA Remedial Investigation and Feasibility Study ("RI/FS") at the Site. On May 18, 2007, five governmental parties ("Participating Parties") entered into the Intergovernmental Memorandum of Agreement for the Upper Columbia River Superfund Site ("MOA").[1] The MOA provides a framework for coordination and cooperation among the Participating Parties to address the RI/FS process at the Site. While the governmental parties, except for EPA, are not parties to the settlement agreement with Teck Cominco, they have statutory and regulatory mandates applicable to the RI/FS and are active government oversight participants in Teck Cominco's performance of the RI/FS. The current dispute is raised under Section VII of the MOA.

In December 2014, EPA began the process of considering action levels for a potential Time-Critical Removal Action at the Site to address lead contamination in soils at residential properties, pursuant to Section 104(a) of CERCLA, 42 U.S.C. § 9604(a), and 40 C.F.R. § 300.415, that pose an immediate threat to human health. EPA initiated conversations with the Washington Department of Ecology on December 16, 2014, and with the Confederated Tribes of the Colville Reservation on December 18, 2014, regarding a potential Time-Critical Removal Action at residential properties with lead levels over 1,000 ppm, and for children's play areas with lead levels over 700 ppm. At that time, EPA expressed that complete data regarding lead levels in soils at the Site were not expected until January 29, 2015, and therefore the discussions regarding an action level range of 700 ppm to 1,000 ppm were preliminary and were not meant to convey a final agency decision on the action level. Throughout December 2014, January 2015, and February 2015, EPA conducted weekly telephone calls with the Participating Parties and was in regular communication with Teck Cominco. On March 11, 2015, following the official commencement of this dispute, EPA met with the parties to the dispute in Spokane, Washington. At that meeting, the concerns of the parties to the dispute were discussed, and EPA presented the perspective of its technical team regarding the proposed action level for the Time-Critical Removal Action. The conversations that occurred over the past few months were intended to provide for open communication among all parties regarding a Time-Critical Removal Action from residential properties at the Site, and were not intended to convey or determine an action level. To date, EPA has not made a determination of the action level for the Time-Critical Removal Action for residential properties at the Site.

II. The Issues

In its request for dispute resolution, the Washington Department of Ecology contends that applying the same action levels developed for the Bunker Hill Superfund Site is inappropriate because it is

[1] The signatories to the MOA, referred to as the Participating Parties, are the United States Environmental Protection Agency, the Washington Department of Ecology, the Confederated Tribes of the Colville Reservation, the Spokane Tribe of Indians, and the United States Department of the Interior.

inconsistent with EPA policy, with current scientific consensus on health risks associated with lead exposure, with more recent bioavailability studies, with Washington's policies, and with other EPA actions.

In its request for participation in the dispute resolution process, the Spokane Tribe of Indians did not initially raise any specific issues, but requested to participate in the process, as provided for in the MOA. In follow up written communication dated March 12, 2015, Dr. F. E. Kirschner of AESE, Inc., on behalf of the Spokane Tribe of Indians, contends that the proposed use of action levels at the Site that were developed for the Bunker Hill Superfund Site are inappropriate, and that the proposed action level would provide disproportionate protection of human health at the Site than is provided for under Washington State policy.

In its request for dispute resolution, the Confederated Tribes of the Colville Reservation contends that EPA did not coordinate with the Confederated Tribes of the Colville Reservation prior to communicating EPA's cleanup intent and proposed cleanup levels to Teck Cominco, and gave no meaningful consideration to Tribal cleanup standards. Additionally, the Confederated Tribes of the Colville Reservation contends that it shares the Washington Department of Ecology's concerns regarding application of cleanup levels from the Bunker Hill Superfund Site.

In its comments via telephone regarding the current dispute, the U.S. Department of the Interior expressed its support for EPA's proposed action level for the Time-Critical Removal Action and the technical basis used to reach the proposal.

A. Removal Action Authority and Procedures

In the present action level determination process, EPA must follow the procedures of its removal action authority, as laid out in CERCLA, 42 U.S.C. §§ 9601, *et seq.*, the National Oil and Hazardous Substances Pollution Contingency Plan ("NCP"), 40 C.F.R. Part 300, and relevant EPA guidance documents. Section 104(a)(1) of CERCLA, 42 U.S.C. § 9604(a)(1), grants EPA the authority to act, consistent with the NCP, to remove a hazardous substance, pollutant, or contaminant, whenever there is a release or a threat of such a release into the environment. Additionally, pursuant to Section 104(a)(2) of CERCLA, 42 U.S.C. § 9604(a)(2), any removal action taken should, to the extent practicable, contribute to the efficient performance of any long term remedial action with respect to the release or threatened release concerned. Therefore decisions made regarding action levels or cleanup levels of a removal action do not constitute final remedial actions, but rather should contribute to final remedial actions. Conducting the Time-Critical Removal Action for residential properties at the Site is intended to address the immediate threat to human health from lead exposure, and will contribute to the long term cleanup of the Site through the remedial action process.

The removal program is in the final stages of the site evaluation and has determined that a Time-Critical Removal Action is appropriate to address immediate threats to human health due to lead contaminated soils. Factors EPA must consider when making this determination include, but are not limited to, actual or potential exposure to humans, actual or potential contamination of drinking water, and threat of fire or explosion.[2] Since EPA has not completed the required process for starting a Time-Critical Removal Action, EPA is now in the final stages of determining action levels, cleanup levels, and the scope of this

[2] 40 C.F.R. § 300.415(b)(2).

Time-Critical Removal Action for residential properties at the Site. Pursuant to 40 C.F.R § 300.415(j), when conducting a removal action, EPA shall, to the extent practicable considering the urgency of the situation and the scope of the removal, attain applicable or relevant and appropriate requirements under federal or state environmental laws ("ARARs"). EPA recognizes that many of the concerns raised in this dispute address ARARs and EPA will consider those issues, in addition to the urgency of the situation and the scope of the removal, as it determines whether the Time-Critical Removal Action will attain ARARs. As noted above on page 2, removal activities conducted by EPA with an action level of 700 ppm will result in a cleanup level of 250 ppm, which is consistent with the State of Washington's cleanup standard for lead.

When a final determination is made to implement a Time-Critical Removal Action, EPA prepares an Action Memorandum in accordance with EPA guidance which provides a concise written record of the removal decision.[3] The Action Memorandum authorizes the initiation of on-site activities, pursuant to Section 104(a) of CERCLA, 42 U.S.C. § 9604(a). There is no opportunity for official public comment regarding selection of a Time-Critical Removal Action prior to initiation of on-site activities because of the time-critical element of such actions. Pursuant to 40 C.F.R. § 300.415(n)(2)(i), within 60 days of initiation of on-site removal activity, EPA will publish an administrative record providing supporting documentation of EPA's decision to conduct the Time-Critical Removal Action. Pursuant to 40 C.F.R. § 300.415(n)(2)(ii), EPA will then provide for a public comment period, as appropriate, for a period of not less than 30 days. That public comment period, which follows determination of removal action levels and initiation of on-site removal activity, is the mechanism for official public comment regarding Time-Critical Removal Actions. Tribal consultation regarding Time-Critical Removal Actions will be addressed in Section II.D, below.

EPA understands the importance of public participation in its decision-making process and recognizes the specific interests of the parties involved in the present dispute in determining final remedial cleanup levels. However the very nature of, and legal procedures for, Time-Critical Removal Actions require rapid decision-making to address immediate threats to human health.

B. Remedial Action Authority and Procedures – Including the RI/FS and MOA

While the removal action procedures described above authorize the determination of the action levels for a Time-Critical Removal Action, remedial action procedures, including the RI/FS process and the MOA, govern the determination of the long term remedial cleanup levels at the Site. Remedial action authority and the selection of cleanup standards are authorized under Sections 104 and 121 of CERCLA, 42 U.S.C. §§ 9604 and 9621. Following a preliminary assessment and site inspection, 40 C.F.R. § 300.430 authorizes the RI/FS. As mentioned in Section I above, EPA and Teck Cominco entered into a settlement agreement under which Teck Cominco agreed to conduct the RI/FS, consistent with EPA guidance and the NCP. The purpose of an RI/FS is to assess site conditions and evaluate alternatives to the extent necessary to select a remedy and includes project scoping, data collection, risk assessment, treatability studies, and analysis of alternatives.[4] The MOA, under which the current dispute was raised, is "intended to assist the Participating Parties in achieving enhanced communication, coordination and

[3] EPA *Superfund Removal Guidance for Preparing Action Memoranda, Final Guidance, September 2009*, available at http://www2.epa.gov/sites/production/files/2014-02/documents/superfund_removal_guide_for_preparing_action_memo.pdf.
[4] 40 C.F.R. § 300.430(a)(2).

efficiencies during the RI/FS process."[5] Therefore the MOA and its dispute resolution procedures apply only to the RI/FS process (not to determinations made by EPA pursuant to its removal authority). EPA is committed to adhering to the letter and spirit of the MOA and will take into account comments and critiques raised by the Participating Parties regarding the RI/FS process.

Following completion of the RI/FS process, EPA will follow legal requirements in CERCLA and the NCP, specifically 40 C.F.R. § 300.430(f), to select a remedial action. Remedial actions involve long-term actions designed to provide a permanent solution to threats posed by hazardous substances, pollutants, or contaminants. Cleanup levels and remediation goals for selected remedial actions must address ARARs, and the site-specific evaluation of ARARs is based on a number of factors in the NCP.[6] The comments and issues raised in the current dispute, such as using data from the Bunker Hill Site, using IEUBK modelling, not attaining cleanup standards from Washington state law and policies, not applying ATSDR and CDC standards, and not mirroring cleanup levels selected at other Superfund sites, are issues that will be relevant to the discussion surrounding ARARs and the applicability of ARARs to the remedy. Additionally, pursuant to 40 C.F.R. § 300.430(f)(3), EPA will provide for a public comment period on the proposed remedy prior to making a final decision. EPA encourages input and participation from state and tribal partners, as well as other members of the public, in selecting the appropriate remedy for the Site.

C. Removal Action Level for Lead

In December 2014, EPA proposed an action level for lead for a potential Time-Critical Removal Action for residential properties at the Site of 700-1,000 ppm. That action level was proposed based on EPA's concern that a number of residential soil samples had lead levels above 1,000 ppm. EPA proposed the lower action level of 700 ppm for children's play areas where children's risk for exposure to lead would be higher. That proposal, and subsequent conversations, led to the initiation of the current dispute in February 2015. That initial proposal was not a decision under the remedial program procedures. As described in Section II.A above, the decision to conduct a Time-Critical Removal Action and the proposal of certain action levels was made pursuant to removal action authorities and procedures, which falls outside the purview of the dispute resolution mechanism of the MOA. EPA does not have the legal authority to make a decision regarding a Time-Critical Removal Action in a response to a dispute raised under the MOA. However, the MOA dispute resolution process has provided a valuable mechanism for the exchange of information regarding lead action levels and EPA is taking the opportunity to use the MOA dispute resolution process to provide the Participating Parties with information on EPA's intended action level for the upcoming Time-Critical Removal Action for residential properties at the Site.

As mentioned above, EPA is currently in the process of determining the scope and action level of the Time-Critical Removal Action. While I am not in a position to make a final decision regarding action levels or cleanup levels for lead in this dispute resolution decision letter, EPA intends to select an action level for lead of 700 ppm for the Time-Critical Removal Action. Therefore, residential soils that are above 700 ppm of lead would undergo a removal action and would be cleaned up to less than 250 ppm of lead. The Time-Critical Removal Action will be focused on immediate threats to human health and there will be additional assessment, through the RI/FS process which provides for input from the Participating Parties under the MOA, and additional opportunity for public comment on the proposed

[5] MOA, page 1.
[6] 40 C.F.R. § 300.400(g).

remedy, to determine a final remedial cleanup level. During that remedial process, EPA will address possible changes in acceptable modelling methods, potential expansion of the sampling area, ARARs, and other relevant issues.

EPA's project team considered a number of factors in proposing the action level for the Time-Critical Removal Action for residential properties, including results of site-specific bioavailability data gathered through the RI/FS process, and other studies regarding bioavailability, lead ingestion rates, and blood lead levels. The project team also reviewed blood lead level and bioavailability data from the Bunker Hill Superfund Site, as well as studies conducted as recently as 2013 and 2014, to propose in December 2014 that removal of soils from residential properties with lead levels of 700 ppm to 1,000 ppm or higher would adequately address the immediate threat to human health.[7] Following bioavailability and blood lead level studies, and calculation of the lead ingestion rate for the Bunker Hill Superfund Site, the project team used that data to estimate the lead ingestion rate at the Upper Columbia River Superfund Site. The project team used this data in its risk evaluation for the Upper Columbia River Superfund Site for purposes of proposing the action level for the Time-Critical Removal Action because the bioavailability data at the two sites is comparable. Additionally, the data and studies from the Bunker Hill Superfund Site have been reviewed extensively by EPA and a distinguished panel from the National Academy of Sciences who published their supportive findings.[8] The current proposal of a blanket action level of 700 ppm (as opposed to an action level of 700 ppm for residential properties where children live and an action level of 1,000 ppm for residential properties where children do not live) was proposed because the demographics of residents can and does change over time, and a property without children present currently may have children present at the property in the future.

In the past EPA has approved different lead cleanup levels at other sites based on site-specific analyses. For example, at the Tar Creek Superfund Site, Ottawa County, Oklahoma, EPA conducted a Time-Critical Removal Action to address lead contaminated soil in 1995 and 1996. The removal in 1995 focused only on areas where children tend to congregate such as schools, playgrounds, and parks and set an action level of 500 milligrams per kilogram ("mg/kg").[9] The removal in 1996 focused on residential properties, and an action level of 500-1,500 mg/kg was selected. For residential properties where children less than 72 months of age resided who had blood lead levels higher than or equal to 10 µg/dL and soil lead concentrations were identified as a significant contributor to that level, the action level was 500 mg/kg. For residential properties that did not meet those criteria, the action level was 1,500 mg/kg. Additionally, the Action Memorandum, dated March 21, 1996, specifically states "the final remediation goal for lead and all other contaminants will be established in the Record of Decision for the Site."[10] Ultimately, the cleanup level selected through the remedial program in the Record of Decision was 500 mg/kg.

At the Jefferson County Mining Site, Jefferson County, Missouri, EPA initiated a Time-Critical Removal Action in 2007 to address lead contaminated soil. The action level ranged from 400-1,200

---

[7] Large scale reviews and integration of data from tracer, mechanistic, validation modeling/measurement, and empirical relations (biomonitoring/environmental concentration) studies have found that mean ingestion rates in children were less than 100 milligrams per day and may be as low as 40-80 milligrams per day. Estimating Children's Soil and Dust Ingestion Rates Using Blood Lead Biomonitoring at the Bunker Hill Superfund Site in the Silver Valley of Idaho.

[8] Superfund and Mining Megasites: Lessons from the Coeur d'Alene River Basin, available at http://www.nap.edu/catalog/11359/superfund-and-mining-megasites-lessons-from-the-coeur-dalene-river.

[9] 1 mg/kg = 1 ppm.

[10] Action Memorandum for Tar Creek Superfund Site, dated March 21, 1996, page 7.

mg/kg. For properties that were high-use areas for children 84 months of age or younger, or residential properties where children resided who had blood lead levels greater than 10 µg/dL, the action level was 400 mg/kg. For other properties that did not meet those criteria, the action level was 1,200 ppm. While EPA selected different cleanup levels for the removal actions at the Tar Creek Superfund Site and the Jefferson County Mining Site than it has proposed for the Time-Critical Removal Action at the Upper Columbia River Superfund Site, EPA has always applied a site-specific analysis. EPA has also been clear that cleanup levels selected for removal actions are not the final remedial action cleanup levels.

D. Meaningful Tribal Consultation

EPA's policy is to consult on a government-to-government basis with tribal governments when EPA actions and decisions may affect tribal interests.[11] EPA is committed to engaging in consultation with the Confederated Tribes of the Colville Reservation and the Spokane Tribe of Indians throughout the removal and remedial actions at the Site, pursuant to EPA policy and the MOA, as applicable. Specifically regarding Time-Critical Removal Actions in Region 10, "EPA should offer formal consultation directly to Tribal leadership prior to approval of the Action Memorandum, whenever time allows."[12]

I apologize for any miscommunications or misunderstandings regarding consultation that occurred as a result of communications between EPA, the Confederated Tribes of the Colville Reservation, and the Spokane Tribe of Indians in December 2014 through the present on the matter of EPA's proposed action level of 700-1,000 ppm for lead for a Time-Critical Removal Action at the Site. The communications between EPA and these parties were meant to serve as initial informal consultation to discuss the potential action level for the Time-Critical Removal Action. EPA should have been clearer in those early discussions that a decision had not yet been made, and should have ensured that proper procedures for meaningful formal tribal consultation were followed. EPA fully intends to consult with the Confederated Tribes of the Colville Reservation and the Spokane Tribe of Indians prior to approval of the Action Memorandum for the Time-Critical Removal Action at the Site. In the near future, EPA will initiate formal consultation regarding the Time-Critical Removal Action.

As EPA and the Confederated Tribes of the Colville Reservation and the Spokane Tribe of Indians proceed with formal consultation, EPA will take into consideration the issues raised regarding action levels during this dispute, and welcomes any additional input from the Tribes.

III. Decision

The dispute raised by the Washington Department of Ecology, the Spokane Tribe of Indians, and the Confederated Tribes of the Colville Reservation, is resolved as of the date of this letter. EPA's proposal to conduct a Time-Critical Removal Action for residential properties at the Site with an action level of 700 ppm for lead are governed by the authorities and requirements of CERCLA and the NCP regarding removal actions. The MOA and its dispute resolution procedures address the RI/FS process of the remedial action for the Site.

[11] EPA Region 10 Tribal Consultation and Coordination Procedures, page 1.
[12] EPA Region 10 Tribal Consultation and Coordination Procedures, Appendix A.

Accordingly:

1. The lead action level for the Time-Critical Removal Action at residential properties at the Site must be determined through CERCLA removal action procedures and tribal consultation policies and will be documented in an Action Memorandum and the associated administrative record;
2. EPA intends to select an action level for the Time-Critical Removal Action for lead of 700 parts per million which will result in a cleanup level of less than 250 parts per million; and
3. EPA will continue to follow all appropriate CERCLA remedial action procedures, including the Memorandum of Agreement, and tribal consultation policies, for determining final cleanup levels for lead for the Remedial Action at the Site.

IV. Administrative Record

An administrative record includes the documents that provide the basis for an EPA decision. The administrative record for the Time-Critical Removal Action for the Site will include documents that were used in reaching the decisions detailed in the Action Memorandum. Pursuant to 40 C.F.R. § 300.415(n)(2), EPA will publish the administrative record within 60 days of initiation of on-site removal activity.

EPA acknowledges the importance of the critical issues brought up through this dispute resolution process and will work with the Participating Parties to address those concerns through the proper procedures. EPA is committed to continuing dialog with the Participating Parties throughout the RI/FS process, in accordance with the MOA, and into the selection of the remedy to ensure a long-term solution to contamination at the Site.

Sincerely,

Richard Albright, Director
Office of Environmental Cleanup

Appendix 7. EPA Letter to K. McCaig, Teck American Incorporated, dated June 14, 2017

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY
REGION 10
HANFORD/INL PROJECT OFFICE
825 Jadwin Avenue, Suite 210
Richland, Washington 99352

June 14, 2017

Kris McCaig
Project Manager
Teck American Incorporated
501 North Riverpoint Boulevard, Suite 300
Spokane, Washington 99202

Dear Ms. McCaig,

On February 17, 2017 Teck American, Inc. (TAI) initiated the dispute resolution process in the Settlement Agreement for Implementation of Remedial Investigation and Feasibility Study at the Upper Columbia River Site (Settlement Agreement). TAI raised two separate disputes through two separate letters initiating the disputes. In one letter, TAI disputed EPA's December 8, 2016 directive to TAI to fund EPA to conduct terrestrial plant sampling and tissue analysis. In a separate letter TAI disputed EPA's July 22, 2016 Level of Effort (LOE) for Assessment and Estimations of Upland Soils (background study). We have reached agreement on a resolution of the disputes.

EPA and TAI agree that a delineation study will be conducted within the RI/FS. The delineation study will consist of a combined analysis of empirical data (soil measurements), geospatial and geostatistical analyses, air modeling, and lead isotope ratio data.

TAI will agree to conduct the plant tissue sampling prior to the completion of a delineation study and agrees to:

a. Conduct the plant tissue sampling, rather than fund EPA to conduct the sampling.
b. Hold a technical meeting with EPA and CCT to refine data quality objectives and determine efficiencies that may be gained by limiting the quality assurance project plan to what can be done this fall (tentatively planned for June 22).
c. Draft the Quality Assurance Project Plan (QAPP) and submit to EPA for review and approval this summer. EPA and TAI will work toward a fall 2017 sampling program. It is likely sampling during two seasons will be necessary because the types of plants and plant parts that need to be gathered differ in different seasons.
d. Conduct a study that will primarily be focused on collection of plant tissue from the three Tribal allotments sampled in the 2014 Residential Soil Study that had concentrations of lead in soil above the TCRA action level (700 ppm) plus a reference area.

TAI agrees to prepare a technical assessment in response to EPA's LOE for Assessment and Estimations of Upland Soils (Background). This is to be completed independently of the delineation study. EPA agrees to consider new information resulting from the delineation study that may change the background soil numbers from the background assessment.

While not directly related to the dispute, as discussed during the informal dispute resolution, TAI has also voluntarily agreed to conduct removal actions at four upland residential properties, sampled in 2016, that have measured lead concentrations above 600 ppm.

Sincerely,

Laura C. Buelow
Project Manager

Appendix 8. EPA Response to December 2017 Petition re: A Comprehensive Air Monitoring Program from Northport to the U.S. – Canada Border, April 18, 2018

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY
REGION 10
1200 Sixth Avenue
Seattle, WA 98101

April 18, 2018

Dear Petitioners:

Thank you for your petition of December 2017 to the U.S. Environmental Protection Agency requesting that EPA and the Washington Department of Ecology plan and institute a comprehensive air monitoring program from Northport to the U.S./Canada border. We have carefully considered your request. Based on our analysis of existing data we have decided we will not conduct additional air monitoring.

From our evaluation of data collected in 1999 – 2009, we believe that the risk to you from the outdoor air in Northport is low. Based on our analysis of Ecology's report[1] and operational improvements at the Trail facility, we expect current-day concentrations to be even lower.

Below is a technical description of our analysis of the existing data which we have used to make this decision:

EPA evaluated air data measured at a monitoring station near Northport (at Sheep Creek) for the period January 1999 to February 2009. Concentrations today are likely to be lower than those at the Sheep Creek station during that period, because of operational improvements at the Teck facility. EPA has analyzed numerous studies that compared air lead concentration to blood lead concentrations in children[2]. The analysis indicates that the air-associated exposure from inhalation or ingestion of lead in house dust and surface soil can lead to a blood lead level that is 5 to 10 times the value in air. Based on air results at the Sheep Creek monitoring station during the 1999-2009 monitoring period, we see 0.0242 $\mu g/m^3$ in air. This could lead to a 0.12 to 0.24 $\mu g/dL$ level of lead in blood, which is low risk.

In summary:

- For lead, the air concentration from the Sheep Creek monitoring is 0.0242 $\mu g/m^3$, which is well below the levels expected to pose significant human health risks based on current understanding of relationships between air lead concentrations and blood lead concentrations resulting from direct and indirect exposures to air lead.

[1] *Upper Columbia River Valley: Preliminary Review and Evaluation of Available Air Quality Monitoring Data and Consideration of Potential Present-Day Health Risks* (https://fortress.wa.gov/ecy/publications/SummaryPages/1702003.html); Ecology, March 2017

[2] Integrated Science Assessment (ISA) for Lead (https://www.epa.gov/isa/integrated-science-assessment-isa-lead); April 2017.

- For arsenic, the air concentration from the Sheep Creek monitoring is 0.00421 $\mu g/m^3$. This level corresponds to a cancer risk of $2x10^{-5}$ (an increased risk of cancer of two in one hundred thousand for a lifetime exposure). For comparison, this is same level of risk from naturally occurring arsenic in soil.

- For cadmium, the air concentration from the Sheep Creek monitoring is 0.00136 $\mu g/m^3$. This level corresponds to a cancer risk of $2x10^{-6}$ (an increased risk of cancer of 2 in one million for a lifetime exposure).

- For zinc, the air concentration from the Sheep Creek monitoring is 0.0514 $\mu g/m^3$. This level is well below all risk based screening levels.

The existing air data is sufficient to conduct the human health risk assessment for the Upper Columbia River Site and, therefore, EPA will not be collecting additional air monitoring data as part of the remedial investigation and feasibility study for the Site. EPA believes that our evaluation of the potential risk to people from outdoor air, using existing air data, is technically sound.

Again, we appreciate your concern for local air quality and share your commitment to protecting public health in the Northport area. If you have any further questions, please contact me at (206) 553-8696, or Monica Tonel of my staff at (206) 553-0323.

Sincerely,

Cami Grandinetti

Appendix 9. Beach-by-Beach Comparison of the Concentration of COPCs in 0 to 15 cm (Surface Sediment) Versus 0 to 45 cm (Subsurface Sediment) Core Samples for the Less than 2 mm Particle Size Fraction

The table below shows the mean concentration of COPCs in the surface (0-15cm) and subsurface (0-45cm) horizons by public beach. Shaded cells indicate where the subsurface COPC concentration exceeded the surface concentration by more than 10%. The frequency is tallied in the right-most column for each COPC in the table. As shown the subsurface concentration of COPCs was generally no greater than the surface concentration, the exceptions being Barnaby Island Campground and Bradbury. For all other beaches, risk management decisions for surface sediment would be protective of subsurface exposures. For Barnaby Island Campground and Bradbury, additional consideration may be warranted.

Appendix 10
CH2M Groundwater Memorandum

TECHNICAL MEMORANDUM - FINAL

Groundwater Exposure Assessment - Upper Columbia River Site

PREPARED FOR:	Monica Tonel/EPA Marc Stifelman/EPA
PREPARED BY:	Marilyn Gauthier LPG
DATE:	March 6, 2018
PROJECT NUMBER:	670274

The purpose of this technical memorandum is to summarizes the occurrence of groundwater in the Upper Columbia River (UCR) Site and evaluate the potential for groundwater to be or become impacted by releases of metals from Teck's Trail Smelter and/or other sources. This evaluation is needed to determine whether groundwater exposure should be evaluated as a complete pathway in the human health risk assessment for the UCR Site. This memorandum was prepared as an update to the Human Health Risk Assessment Work Plan (EPA 2009), which acknowledged the potential for groundwater to be impacted from releases at the Site, but did not include any data or evaluation findings.

Summary of Geology and Hydrogeology

As shown in Figure 1, surface geology along the shore of the UCR north of the Kettle River consists primarily of gravel, sand and clay deposited by glacial streams adjacent to or downstream from temporary ice fronts related to glaciation during the Pleistocene. The UCR is located within the footprint of the ancestral glacial Lake Columbia, which formed at least three times during the Pleistocene glacial period. The glacial lake and its tributaries deposited coarser materials interbedded with silt and clay, forming deltas between bedrock ridges and outcrops. In certain areas, such as the international border, Little Dalles, and Kettle Falls, glacio-fluvial sediments are absent and the river runs over and between bedrock outcrops (typically metasedimentary rocks, limestone, and quartzite). A similar pattern of glacio-fluvial sediments interspersed with bedrock outcrops is found along the Columbia River between Trail and the border (Figure 2). The surface geology south of the Kettle River consists of basalt, and, in some places along the south shore of the Lake Roosevelt reservoir, the basalt cliffs rise nearly 1,000 feet above the lake.

Discontinuous local aquifers are present in permeable glacial alluvial deposits and in permeable sedimentary rocks (sandstones and limestones) (Whitehead 1994) along the Columbia River. Yields of wells completed in these aquifers are in the tens to hundreds of gallons per minute, depending upon the aquifer extent and groundwater recharge (Whitehead 1994). The aquifer that provides the water supply for the City of Northport is an example of a permeable glacial deposit that contains useable quantities of groundwater. The sand and gravel deposits that comprise this aquifer extend from ground surface to depths greater than 200 feet, with static water levels on the order of 75 feet below ground surface (Weston Solutions, Inc. [Weston] 2004). Maximum pumping rates from these wells range from 20 to 100 gallons per minute (Weston 2004).

Groundwater in the project area occurs in interconnected pore spaces between granular particles of unconsolidated aquifers and in fractures or voids of bedrock aquifers. These aquifers receive recharge

from percolation of precipitation into the ground and leakage from surface water bodies (Whitehead 1994). Groundwater flows from higher-elevation recharge areas to lower elevations in the project area, where it discharges into streams, lakes, or rivers, or is pumped from the ground for various uses.

Shallow perched groundwater has been observed at elevations up to 160 feet above the full pool level of the Lake Roosevelt reservoir (Riedel et al. 1997). A study by Thompson (1977), using thermal infrared imagery, identified broad areas of bank seepage, spring discharge, stream inflow, and subsurface discharge into Lake Roosevelt. Observations of bank seepage and groundwater discharge correlated with the presence of unconsolidated glacial sediments rather than bedrock. Shallow groundwater seepage into the reservoir has been identified as a contributor to soil instability and landslides (Jones et al. 1961).

Movement of water between the Lake Roosevelt reservoir and the adjacent geologic strata depends upon several factors, including reservoir stage, bank storage and discharge during various reservoir stages, elevation and gradients of adjacent shallow aquifers, and regional discharge of groundwater into the reservoir from deeper aquifers (Thompson 1977).

Groundwater in the Columbia Plateau basalts aquifer discharges to Lake Roosevelt at the northern edge of the south-sloping Columbia basalts (Whitehead 1994). Lower reaches of the Columbia River farther to the south (and outside of the UCR study area) subsequently receive discharge from this extensive basalt aquifer. Groundwater in the basalt units may flow upward or downward among the units, depending upon local water level, groundwater gradients, and pumping conditions (Whitehead 1994). Depths to groundwater measured in water wells on properties nearest the river range from 60 to 110 feet below grade

Groundwater Use

Groundwater from wells and springs located within the UCR Site is used for public and domestic potable water supply, irrigation, power generation, and industry. There are 139 public water systems that utilize groundwater located within 5 miles of the UCR and Lake Roosevelt shoreline (Table 1). 3,312 water wells, 12 water supply springs, and 131 public water systems that utilize groundwater located within 5 miles of the UCR and Lake Roosevelt shoreline. Area residents may also have their own wells or may be served by a community well. In the northern portion of the Site, where potential impacts from smelter emissions and/or slag deposits along the river are of concern, there are 1,940 registered active water supply wells. Based on available records for water supply wells in the area[1], wells located nearest the river and reservoir are generally completed in local glacio-fluvial aquifers. Where glacio-fluvial sediments are absent or thin, wells are completed in fractured bedrock.

Chemical Sources

Potential sources of chemicals that could reach and impact groundwater at the UCR Site include current and historic mining and smelting operations. Teck's Trail Smelter, located approximately 10 river miles north of the border, is considered a source of metals found in soil, sediment, and other media at the UCR Site. However, other sources such as current/historic mines, mills, and smelters in the area that have been operated by other companies may also have contributed metals and other chemicals. Known and suspected releases from the Trail facility and other sources that have relevance to the UCR Site are depicted on the left side of Figure 3. These sources include, but are not limited to:

- Atmospheric emissions (stack and fugitive)
- Disposal of slag, tailings, liquid and solid waste to the Columbia River

[1] https://fortress.wa.gov/ecy/waterresources/map/WCLSWebMap/WellConstructionMapSearch.aspx

- Discharge of process wastewater and accidental spills and releases to the Columbia River

Another potential concern could be groundwater migration from upland source areas.

Groundwater Exposure Assessment

The following sections describe the release and transport mechanisms that could link chemical releases from the Trail Smelter and other sources to human exposure to impacted groundwater.

Aerial Emissions

Lead and arsenic potentially related to atmospheric emissions from the Trail Smelter may be present in surface soil at some locations in the northern portion of the UCR Site. As indicated in Figure 3, where present, metals have the potential to dissolve and leach into the underlying soil and groundwater. However, lead is strongly adsorbed to soil and is generally retained in the upper layers of soil and does not leach appreciably into the subsoil and groundwater (ATSDR 2007). Arsenic behaves similarly, but may leach to subsurface soil and groundwater under reducing conditions (Ecology 2006). Soil pH measurements from the upland soil study conducted in 2014 (TAI 2015) show that surface soil in the UCR aerial deposition study area is generally acidic or neutral (pHs between 5 and 7) so there is limited potential for leaching of lead and arsenic to subsurface soil or groundwater accessed by a water supply well. Therefore, given that depths to groundwater measured in water wells on properties nearest the river are in the range of 60 feet below grade and deeper, the groundwater exposure pathway for this source/release combination is incomplete, as shown in Figure 3.

Disposal of Slag to Columbia River

Approximately 10 million tons of granulated slag were discharged into the Columbia River from the Trail Smelter until 1995. The slag was transported as suspended and bed load during periods of high flow and was deposited further downstream when flow rates diminished. Slag-impacted sediments are commonly observed in depositional features (banks, bars) in the upper reaches of the UCR Site between Marcus and the international border. Slag has also been observed in sediment cores taken from the former river channel (thalweg) portion of Lake Roosevelt, indicating that the river carried slag further south prior to its impoundment behind Grand Coulee Dam.

Metals present in the slag have potential to leach to interstitial water between sediment grains (sediment porewater). However, at locations where slag may be present in sediments in or adjacent to a stream channel and bank, the daily and seasonal ranges of river stage and lake levels at the Site make it impractical to construct or use water supply wells in such areas. Additionally, except for local surface water influx into sediment/soil adjacent to the river during periods of high water (bank storage), groundwater flow is toward the river so migration of potentially impacted porewater or groundwater from where slag may be present in sediment to areas where water supply wells are located, typically several hundred feet away from and upgradient of the river, is unlikely. Therefore, the groundwater exposure pathway for this source/release combination is incomplete, as shown in Figure 3.

Liquid Effluent, Spills, and Other Aqueous Releases to Columbia River

Liquid effluent has been discharged to the Columbia River since the early days of smelter operations. Dissolved metal concentrations in the effluent and the number of spills and other aqueous release have decreased over time. Recent rounds of surface water sampling in the river have not identified water quality issues. All samples were below drinking water standards, except samples designed to retain suspended sediments. However, based on sediment quality data from the lower reaches of the Site where finer grained sediments are present, metals from earlier releases may have become attached to flocculated particles that settled out as sediment in the reservoir (TAI 2011). The impacted fine-grained sediments are primarily within Lake Roosevelt and water supply wells are not completed in this material. As with slag-enriched deposits in the upper reaches of the Site, groundwater flow is from upland areas

toward the reservoir so migration of potentially impacted porewater or groundwater from potentially affected sediments is unlikely. Therefore, the groundwater exposure pathway for this source/release combination is incomplete, as shown in Figure 3.

Groundwater Migration from Upland Source Areas

Water wells located downgradient of upland source areas have the potential to be impacted by leaching and dissolution of contaminants into the underlying groundwater and subsequent migration of the contaminant plume. Based on sampling at 39 mines and mills within the UCR Site (EPA 2002 and 2003) and the removal actions at Northport (Weston 2005) and Young America Mine (TechLaw 2012), there is no evidence that groundwater is contaminated by metals within or downgradient of known source areas within the UCR Site. For example, during the removal action at Young America Mine, groundwater samples were collected from a private water supply well installed through the former tailings impoundment and from a seep within a mine adit. Concentrations of metals in both samples were below EPA maximum contaminant levels (MCLs). Therefore, the groundwater exposure pathway for this source/release combination is incomplete, as shown in Figure 3.

Concerns have been expressed about possible migration of known groundwater contamination related to Teck's operations in Trail, British Columbia. The following bullets summarize conditions in the area and provide the basis for concluding that the plume will not affect groundwater within the UCR Site:

- The impacted groundwater is broadly characterized as an ammonium sulphate plume and contains elevated concentrations of nitrogen, sulphate, fluoride, total dissolved solids, and various metals (e.g., arsenic, cadmium, iron, lead, manganese, and zinc) (Teck 2012).
- Surface and subsurface geology in the vicinity of Trail consist of fine sands, silty fine sands, and sandy silts, which are consistent with a glacio-fluvial or glacio-lacustrine origin. In addition to the finer-grained material, a zone of higher permeability sediments (sand and gravel) is present under Teck's Trail facility. The gravel-rich zone appears to extend under the Columbia River and beneath East Trail. The zone appears to provide a pathway for groundwater flow and plume migration. The shallow portion of the plume discharges to the river just downgradient of the facility, but the deeper portion of the plume crosses under the Columbia River in the gravel-rich strata and flows into the East Trail Aquifer, eventually discharging back to the Columbia River through river bed sediments and into the river itself approximately 600 hundred feet downstream (Teck 2012). The approximate extent of the plume is shown in yellow on Figure 4.
- Teck installed a hydraulic containment system within the footprint of the plume near, but upgradient of, the point of initial discharge to the Columbia River. The recovered groundwater is routed to a recently constructed water treatment plant located on the bench above the river at the Trail facility. The goal of the remedial action is to "provide sufficient plume capture to eliminate or reduce the discharge of deleterious substances to fish-frequented waters." (Teck 2012). The recovery and treatment system was expected to be fully operational by summer of 2017 (Teck 2017).
- An ecological risk assessment was performed to determine if active remediation would be required to address plume re-entry to the Columbia River downstream of East Trail. The assessment found that unacceptable risks were unlikely and that no remedial intervention was required (Teck 2012). However, follow-up monitoring was planned to confirm that conditions in the area remain similar to those used in the risk assessment (Teck 2015).
- As indicated in Figure 4, the ammonium sulphate groundwater plume has been delineated. The impacted aquifers do not extend into the UCR project area. Consequently, groundwater in the UCR project area cannot be impacted by the ammonium sulfate plume and the groundwater exposure pathway for this source/release combination is incomplete.

Groundwater Data

As part of the research effort for this memorandum, CH2M reviewed Washington Department of Health (DOH) pre-treatment water quality monitoring records for all public water systems located in the northern portion of the Site where potential impacts from smelter emissions and/or slag deposits along the river are of concern. Data for a total of 65 public water systems (4 spring-sourced systems and 61 well-sourced systems) were reviewed. The results of the data reviews are listed by water system in Table 1. More information about each water system can be found at the link below:

https://fortress.wa.gov/doh/eh/portal/odw/si/FindWaterSystem.aspx

For the most part, the water provided by public water systems in the upper portion of the UCR Site meets drinking water standards. Exceptions include infrequent exceedances of the criteria for total coliform, e. coli, and fecal coliform, along with occasional exceedances of the criteria for iron and manganese. Such contaminants are not related to releases from the Teck smelter. Sporadic exceedances of the arsenic criterion were reported in a cluster of systems near Hunters, WA (Hunters Water District, Hunters Campground, and Columbia School District) and the system for Union Gospel Mission Camp near Wellpinit, WA (which is not part of the UCR Site). The elevated concentrations of arsenic in these systems are not thought to be related to releases from the Trail smelter because the sources for these systems are located in upland areas considerably outside of the estimated footprints for higher smelter emissions soil impacts and well past the area of slag impacts in the river/reservoir.

LEGEND

CENOZOIC

TERTIARY

Tr — rhyolite dikes

Ti — hornblende–feldspar and hornblende porphyries

MIDDLE EOCENE

mEc — CORYELL INTRUSIONS: biotite monzonite, biotite – augite monzonite; mEm–syenite; mEg–granitic; gr–gneissic

mEs — SHEPPARD INTRUSIONS: granite, rhyolite dikes

mEm — MARRON FORMATION: andesite flows; minor lapilli tuff, tuffaceous sandstone and tuffaceous conglomerate

EOCENE – PALEOCENE

PEg — leucocratic biotite quartz monzonite, granite

PALEOCENE

Pgn — K–feldspar megacrystic biotite–hornblende quartz monzonite

MESOZOIC

LATE CRETACEOUS

uKsm — SOPHIE MTN FORMATION: coarse conglomerate with quartzite and/or siltstone clasts, minor argillite

EARLY CRETACEOUS

lKg — granite, quartz porphyry, granitic gneiss; kg–Kinnaird pluton; Kinnaird gneiss

MIDDLE TO EARLY JURASSIC

mJp — NELSON INTRUSIONS: includes Nelson, Bonnington (mJb), Trail (mJt), and Mackie (mJm) plutons: porphyritic granite, granodiorite, quartz monzonite, tonalite; minor diorite, porphyry and breccia

EARLY TO MIDDLE JURASSIC

mJrm — ROSSLAND MONZONITE: biotite/biotite–augite monzonite, monzodiorite

mJsk — SILVER KING INTRUSIONS: plagioclase porphyry (leucodiorite)

Jec — EAGLE CREEK PLUTONIC COMPLEX: diorite, gabbro, meta–diorite, pyroxenite, monzonite

Jm — monzogabbro; monzonite, diorite

EARLY JURASSIC

lJr — ROSSLAND GROUP: mafic to intermediate flows and tuffs, tuffites, argillaceous siltstone, turbidite siltstone and wacke, minor pebble conglomerate and subvolcanic intrusions

lJh — HALL FORMATION: argillite, carbonaceous siltstone; minor pebble conglomerate and carbonate

lJe — ELISE FORMATION: mafic flows, pyroclastic breccia; mafic to intermediate tuffs, turbites

lJes — Elise sedimentary rock: argillaceous siltstone

lJeu — Upper Elise Formation: basaltic to andesitic lapilli, crystal and fine tuff, mafic flows, tuffaceous siltstone and conglomerate; lJem–mafic flows

lJel — Lower Elise Formation: basaltic flows and flow breccias, basaltic pyroclastic breccia, minor basaltic to andesitic crystal and fine tuff

lJa — ARCHIBALD FORMATION: argillite, turbidite siltstone, conglomerate and minor maroon siltstone

EARLY JURASSIC AND LATE TRIASSIC (?)

lJy — YMIR GROUP: argillite, siltstone, grit, impure limestone; minor chert, wacke; generally rusty–weathering

DEVONIAN TO EOCENE (?)

tg — TRAIL GNEISS: amphibolite and biotite gneiss, hornblende gneiss, minor schist, pegmatite and aplite

PENNSYLVANIAN (?)

cg — CASTLEGAR GNEISS COMPLEX: heterogeneous hornblende ±biotite quartz–feldspar paragneiss, amphibolite, calc–silicate gneiss, orthogneiss

DEVONIAN

Dj — JOHNSON CREEK PLUTON: trondhjemite

Note: System Name and Use entries are shown as provided by DOH (https://fortress.wa.gov/doh/eh/portal/odw/si/FindWaterSystem.aspx).
Emergency = Any source that is approved by the department for emergency purposes only, is not used for routine or seasonal water demands, is physically disconnected, and is identified in the purveyor's emergency response
Seasonal = A public water system source used on a regular basis, that is not a permanent or emergency source.
Permanent = A public water system supply source that is used regularly each year, and based on expected operational requirements of the system, will be used more than three consecutive months in any twelve-month period.
Public water systems are defined as all systems serving more than one single-family residence or more than five residences on the same farm, and are classified as either Group A or Group B depending on the number of people served and the number of residential connections
* System is located outside of upland and/or near-river areas thought to be impacted by Teck smelter releases

Appendix 11: Approach Used to Adjust Soil and Sediment Arsenic and Lead Concentrations Based on Relative Bioavailability

Note: Table 1 in the following memorandum, dated 9/20/17, contained an errata based on a misclassification of one DU. The following table is corrected and utilized in the UCR Site-wide HHRA.

Re: Approach that will be used to adjust soil arsenic and lead concentrations in residential soils based on relative bioavailability (RBA) in the Upper Columbia River (UCR) Human Health Risk Assessment (HHRA)

The Residential Soil Study sampled residential soils in 2014 and 2016 (Figures 1 and 2). The study included measurements of soil arsenic and lead concentrations in each Decision Unit (DU) and measurement of arsenic and lead in vitro bioaccessibility (IVBA) from soil in a subset of DUs (SRC 2014, Ramboll Environ 2016). The IVBA measurements will be used to calculate RBA-adjusted soil concentrations for DUs included in the study. This memorandum describes how the IVBA data collected in 2014 and 2016 will be used to adjust the lead and arsenic soil concentrations for RBA, as discussed during the meeting in Spokane on May 11, 2017. RBA-adjusted lead and arsenic concentrations for properties that were sampled in 2014 were provided to landowners in 2015 (U.S. EPA 2015). This memorandum briefly describes how the IVBA data were used to adjust the 2014 arsenic and lead concentrations as well.

RBA Adjustments of Arsenic and Lead Concentrations of Residential Soils Collected in 2014

For each DU with IVBA data, an RBA-adjusted soil lead concentration was calculated using the following equations (U.S. EPA 2006, 2009):

$$RBA = (0.878 \times IVBA - 0.028) \quad \text{Equation 1}$$

$$\text{RBA-adjusted Pb concentration} = RBA/0.6 \times \text{measured Pb concentration} \quad \text{Equation 2}$$

where IVBA is in decimal format (i.e., not as a percentage), 0.6 is the default soil RBA in the Integrated Exposure Uptake Biokinetic (IEUBK) Model for Lead in Children (0.6 = 0.3/0.5), and the measured Pb concentration is based on the IC soil sample result (or average, if replicate IC samples were collected).

Soil lead concentrations measured in DUs without IVBA data were adjusted using one of two RBAs, depending on whether the DU was a beach (CM2M Hill 2016). RBAs for beaches were estimated using Equation 1 with the average IVBA for all beach DUs. RBAs for all other types of DUs were estimated using Equation 1 with the average IVBA for all DUs except beaches.

Arsenic concentrations collected from residential soils in 2014 were adjusted for RBA using the national default value of 60% for soil arsenic (Equation 3; U.S. EPA 2012), as EPA had not completed validation of a method for predicting arsenic RBA from arsenic IVBA at the time the Residential Soil Study results for 2014 were provided to property owners.

$$\text{RBA-adjusted As concentration} = 0.6 \times \text{measured As concentration} \quad \text{Equation 3}$$

Where the measured As concentration is based on the IC soil sample result (or average, if replicate IC samples were collected).

RBA Adjustments of Arsenic and Lead Concentrations of Residential Soils Collected in 2014 and 2016

The RBA means for DUs sampled in 2016 are significantly lower for both lead and arsenic than the means for DUs sampled in 2014 (t-test, $p<0.001$). The mean difference between the 2014 and 2016 arsenic RBA was 11.6 (95% CI: 9, 14); and the mean difference in lead RBA was 12.6 (8, 17).

Several factors may have contributed to the differences in the RBA means from the 2014 and 2016 sampling events, including chemical form of arsenic or lead in the soil as well as physical chemical characteristics of arsenic- or lead-bearing soil particles in soils. Given that the above factors may have contributed to spatial variability in RBA, and given that the 2016 samples were collected, in general, further south than the 2014 samples, RBA adjustments of soil arsenic and lead concentrations will be based on the RBAs estimated for soils within or outside of the 2014 soil study boundary (Figures 1 and 2). The following approach will be used to adjust arsenic and lead concentrations for RBA:

Lead:

- For each non-beach DU in which lead IVBA was measured: Assign RBA calculated from Equation 1. Calculate the RBA-adjusted soil concentration using Equation 2.
- For each non-beach DU within the 2014 study boundary and in which lead IVBA was not measured: Using the average of the IVBA data for all non-beach DUs located within the 2014 boundary, calculate the RBA for the DU using Equation 1. Calculate RBA-adjusted soil concentration using Equation 2.
- For each non-beach DU located outside the 2014 study boundary and in which lead IVBA was not measured: Using the average of the IVBA data for all non-beach DUs located outside the 2014 boundary, calculate the RBA for the DU using Equation 1. Calculate RBA-adjusted soil concentration using Equation 2.
- For each beach DU in which lead IVBA was measured: Assign RBA calculated from Equation 1. Calculate adjusted soil concentration using Equation 2.
- For each beach DU located within the 2014 study boundary and in which lead IVBA was not measured: Using the average of the IVBA data for all beach DUs located within the 2014 boundary[1], calculate the RBA for the DU using Equation 1. Calculate RBA-adjusted soil concentration using Equation 2.
- For each beach DU located outside the 2014 study boundary and in which lead IVBA was not measured: Using the average of the IVBA data for all beach DUs located outside the 2014

[1] As described in SRC (2017), this includes 7 beaches sampled between 2009-2011 (Integral, 2014) as well as beach DUs that were sampled as part of the 2014 and 2016 Residential Soil Studies (CH2M Hill, 2016; Ramboll Environ, 2017). Four of the 7 beaches sampled between 2009-2011 are located within the 2014 residential soil study boundary; IVBA data for the four beaches were included in the data that were used to estimate the average IVBA for beaches located within the 2014 residential soil study boundary. Three of the 7 beaches sampled between 2009-2011 are located outside the 2014 residential soil study boundary; IVBA data for the three beaches were included in the data that were used to estimate the average IVBA for beaches located outside the 2014 residential soil study boundary. Two of these 7 beaches (Flat Creek and Swimming Hole) were reanalyzed in 2013 for IVBA of the <250µm fraction; those data are used in place of the values from the 2009-2011 analysis.

boundary[1], calculate the RBA for the DU using Equation 1. Calculate RBA-adjusted soil concentration using Equation 2.

Arsenic:

EPA recently validated a method for using IVBA to predict RBA of arsenic in soil (U.S. EPA 2017). Soil arsenic concentrations will be adjusted for RBA using the following equations:

$$RBA = (0.79 \times IVBA + 0.03) \quad \text{Equation 4}$$

where IVBA is in decimal format (i.e., not as a percentage)

$$\text{RBA-adjusted As concentration} = RBA \times \text{measured As concentration} \quad \text{Equation 5}$$

the measured As concentration is based on the IC soil sample result (or average, if replicate IC samples were collected).

The same approach described above for lead will be used to adjust arsenic soil concentrations for RBA:

- For each non-beach DU in which arsenic IVBA was measured: Assign RBA calculated from Equation 4. Calculate the RBA-adjusted soil concentration using Equation 5.
- For each non-beach DU within the 2014 study boundary and in which arsenic IVBA was not measured: Using the average of the IVBA data for all non-beach DUs located within the 2014 boundary, calculate the RBA for the DU using Equation 4. Calculate RBA-adjusted soil concentration using Equation 5.
- For each non-beach DU located outside the 2014 study boundary and in which arsenic IVBA was not measured: Using the average of the IVBA data for all non-beach DUs located outside the 2014 boundary, calculate the RBA for the DU using Equation 4. Calculate RBA-adjusted soil concentration using Equation 5.
- For each beach DU in which arsenic IVBA was measured: Assign RBA calculated from Equation 4. Calculate adjusted soil concentration using Equation 5.
- For each beach DU located within the 2014 study boundary and in which arsenic IVBA was not measured: Using the average of the IVBA data for all beach DUs located within the 2014 boundary[1], calculate the RBA for the DU using Equation 4. Calculate RBA-adjusted soil concentration using Equation 5.
- For each beach DU located outside the 2014 study boundary and in which arsenic IVBA was not measured: Using the average of the IVBA data for all beach DUs located outside the 2014 boundary[1], calculate the RBA for the DU using Equation 4. Calculate RBA-adjusted soil concentration using Equation 5.

The mean RBAs for arsenic and lead that will be applied to the soils not evaluated for IVBA are presented in Tables 1 and 2. The approach for adjusting arsenic and lead concentrations for DUs that were not evaluated for IVBA requires the DU to be categorized as to being located within or outside the 2014 residential soil study area and assigned the corresponding RBA mean from Table 1 (non-beach DUs) or Table 2 (beach DUs). Two of these 7 beaches were included in the beach reanalysis effort; those data are used in place of the 2009-2011 calculated results.

RE: Estimation of Exposure Point Concentrations (EPCs) at the Upper Columbia River (UCR) site from Single Incremental Composite Samples (ICS)

In a previous memorandum dated July 17, 2019 (Attachment A), a method was proposed for estimating exposure point concentrations (EPCs) from a single incremental composite sample (ICS) when ≥3 ICS composite samples were not available for estimating the 95% upper confidence limit on the mean (95UCL). The July 17 memorandum provided a statistical rationale for deriving a confidence factor (CF) to be applied to the soil concentration measured in the single ICS composite sample. The CF was based on the 95UCL/mean ratio estimated for decision units (DUs) with 3 composite samples. The 95th percentile of 95UCL/mean ratio was selected as the CF to ensure that the probability of a false negative error was ≤5% (i.e., concluding that the population mean at the DU is below a level of concern when it actually equals or exceeds the level of concern). This report describes the approach used to derive a value for the CF that was used at the Upper Columbia River (UCR) site.

Central to application of the CF method is the requirement to derive a robust estimate of a CF that can be applied broadly across DUs and, preferably, across contaminants. This was accomplished at the UCR site by examining estimates of the 95th percentile of the 95UCL/mean ratio derived from various groupings of DU types. Table 1 presents the results for two groupings: (1) all residential soil DUs and; (2) all DUs (e.g., residential soils, beaches, upland soils). CFs based on the residential soils provide the strongest basis for the CF because this group comprises the largest set of observations (n=259) which were obtained by application of a uniform sampling methodology (depth, ICS plan, sieving). The "all DU" grouping includes a variety of DU types (soils, beaches, relict floodplains) for which numbers of DUs of each type (with the exception of residential soils) were too small to reliably estimate a CF (<20 DUs). The various DU types are likely to have been impacted by different sources of contamination (e.g., aerial deposition, deposition of sediments) which could contribute to different degrees of spatial heterogeneity. The resulting CFs were nearly identical for the two DU groupings. The mean CF was 1.2 for both DU groupings and the mean relative percent difference (RPD) was negligible for individual metals (1.4%; range: -0.1 - 5.3%).

Based this analysis, a CF value of 1.2 was selected for calculating the EPC for DUs at which a single ICS composite sample was available. This CF was applied to all contaminant of potential concern (COPC) metals. EPC was calculated as follows:

$$\text{EPC} = \text{concentration in single ICS composite sample} \times 1.2$$

Table 1.

Re: Proposed approach to derive an exposure point concentration (EPC) for soil concentrations derived from a single incremental composite sample (ICS) in the Upper Columbia River (UCR) Human Health Risk Assessment (HHRA)

Derivation of an Exposure Point Concentration (EPC) for soil concentrations derived from a single Incremental Composite Sample (ICS)

Adequacy of data from decision units (DUs) sampled with 1 ICS composite: The data quality objective (DQO) established for residential soils was to estimate the EPC for non-lead chemicals of potential concern (COPCs) as the 95% upper confidence limit on the mean (95UCL) of 3 ICS composite samples. It is not possible to satisfy the DQO for DUs that were sampled with 1 composite because the 95UCL cannot be calculated for a single composite sample. Although data for DUs that had 1 composite fail the DQO requirement, the data are still useful for human health risk assessment (HHRA) in that each single composite represents the mean of 30 randomly positioned increments collected from the DU and, therefore, provide an estimate of the DU mean. Since an estimate of confidence in the mean from a single composite cannot be directly calculated, an alternative approach was taken in which the single composite mean was adjusted by multiplying by a confidence factor (CF). The CF was derived from estimates of confidence in the mean for DUs from which 3 ICS composite sample were collected. The CF was based on the 95UCL/mean ratio estimated for DUs with 3 composite samples. This report describes a general procedure for deriving CFs and provides a rationale for using an upper percentile (specifically the 95th percentile) of 95UCL/mean ratio as the basis for the CF. The actual values for the CFs used in the Upper Columbia River HHRA are presented in Appendices to the HHRA.

False negative probability for uncertainty adjustment: In the context of HHRA, a false negative error corresponds to concluding that the true mean concentration (the population mean at the DU) is below a level of concern (risk-based concentration, RBC) when it actually equals or exceeds the RBC. The CF adjustment serves to control the probability of a false negative error (i.e., type 1 error, where the null hypothesis is population mean ≥ RBC).

A false negative error will occur if we conclude that the adjusted mean (i.e., measured concentration from a single composite x CF) is less than the RBC when it is actually greater than or equal to the RBC. The observed standard deviation (SD) of residential soil arsenic concentrations, for example, is approximately 0.61 x the mean (11.8 ppm ± 7.19, n=1139). If it is assumed that soil arsenic concentrations are lognormally distributed, we can expect concentrations obtained from random single composite samples to have a probability distribution similar to that shown in Figure 1 (in the simulation the true mean was assumed to be equal to the RBC, 20 ppm). The mean 95UCL/mean ratio for arsenic in residential soils at DUs where 3 ICS composite samples were obtained is 1.09 (95UCL ratio: 1.08, 1.10; 95th percentile ratio: 1.21; n=219). If the concentration obtained from a single composite sample were to be adjusted with a CF equal to the mean of the 95UCL/mean ratios (adjusted mean = measured mean x 1.09), the probability

of a false negative error can be expected to be 24% (Figure 2). Typically, we would like the false negative error to be ≤5%. This can be achieved for DUs with a single ICS composite sample if the CF is the observed 95th percentile of the 95UCL/mean ratios (adjusted mean = measured mean x 1.21; Figure 3). A false negative error of ≤5% will be satisfied for all COPC metals if the single composite mean is adjusted by the 95th percentile of the 95UCL/mean ratios (Table 1).

Method used to estimate EPC for single composite DUs in the HHRA: If the DU mean was based on a single composite, the mean was adjusted by the 95th percentile of the 95UCL/mean ratios estimated for DUs in which 3 ICS composite samples were used to estimate the DU mean. The 95UCLs for the 3-composite DUs were based on the t statistic for n=3 composites. The values for the 95th percentile of 95UCL/mean ratio were estimated for specific types of DUs (e.g., residential soil DUs, upland soil ADAs, beaches) based on triplicate ICS composite samples for DUs that were considered most similar to the specific DU type.

Table 1. Predicted False Negative Error for Mean Concentration Adjusted with the 95th Percentile of the Ratio 95UCL/Mean

Metal	95th Percentile of 95UCL/Mean Ratio[a]	CV for Concentration (SD/mean)[b]	False Negative Error for DU with Single ICS Composite
Arsenic	1.21	0.61	4.7%
Cobalt	1.14	0.36	2.3%
Iron	1.08	0.23	3.5%
Manganese	1.15	0.38	2.5%
Thallium	1.25	0.50	0.9%

[a]Estimated from residential soil DUs (excluding beaches and drip lines) in which there were 3 composites (N=259).
[b]Estimated from residential soil samples (N=1139)
CV, coefficient of variation

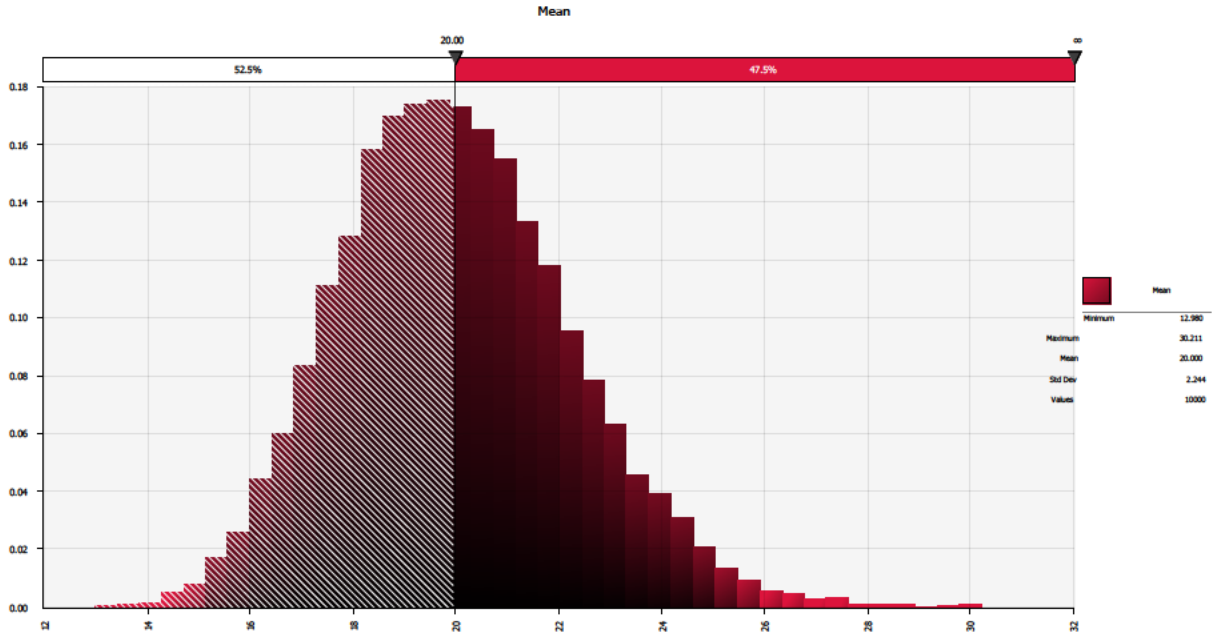

Figure 1. Monte Carlo simulation of arsenic concentrations estimated from a single composite sample consisting of 30 increments. Shown is the probability density for means from 10,000 random composites drawn from a lognormal distribution of arsenic concentration (mean=20, SD=0.61 x mean). Arsenic concentration is shown on the x-axis and probability on the y-axis. If the RBC is 20 (=mean), then approximately half of the single composites are below the RBC (false negative) and half are above the RBC (false positive).

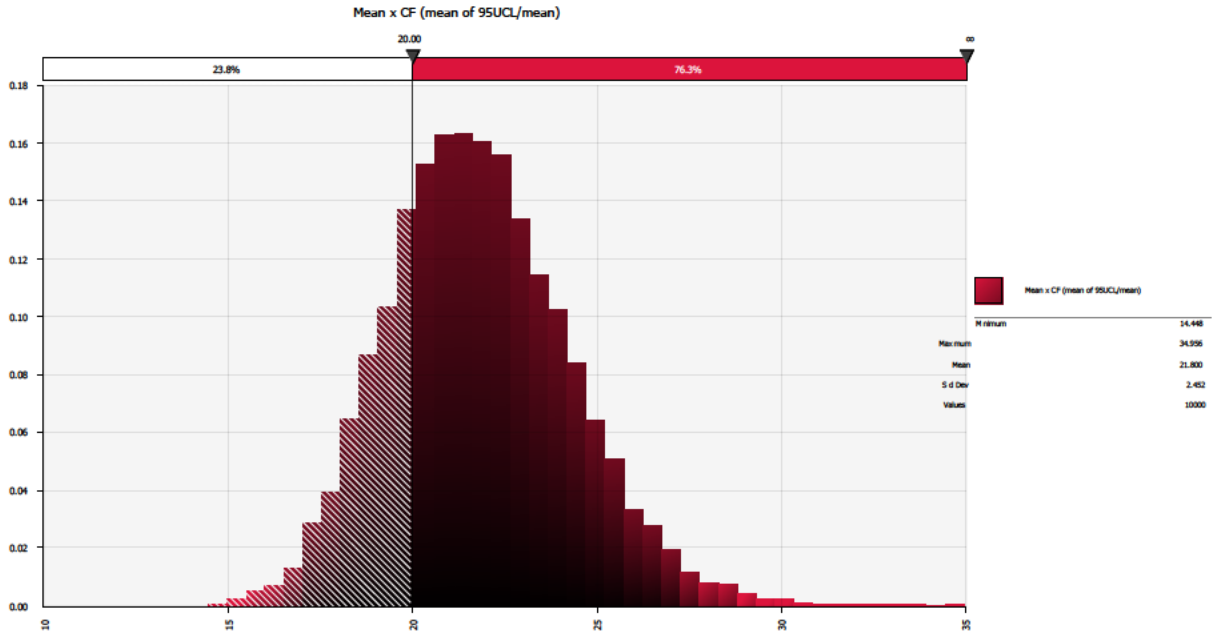

Figure 2. Probability density of CF-adjusted arsenic concentration (mean X CF), when the CF is the mean ratio 95UCL/mean (=1.09) of residential soils DUs where 3 ICS composite samples were collected. Approximately 24% of the single composites are below the RBC (false negative).

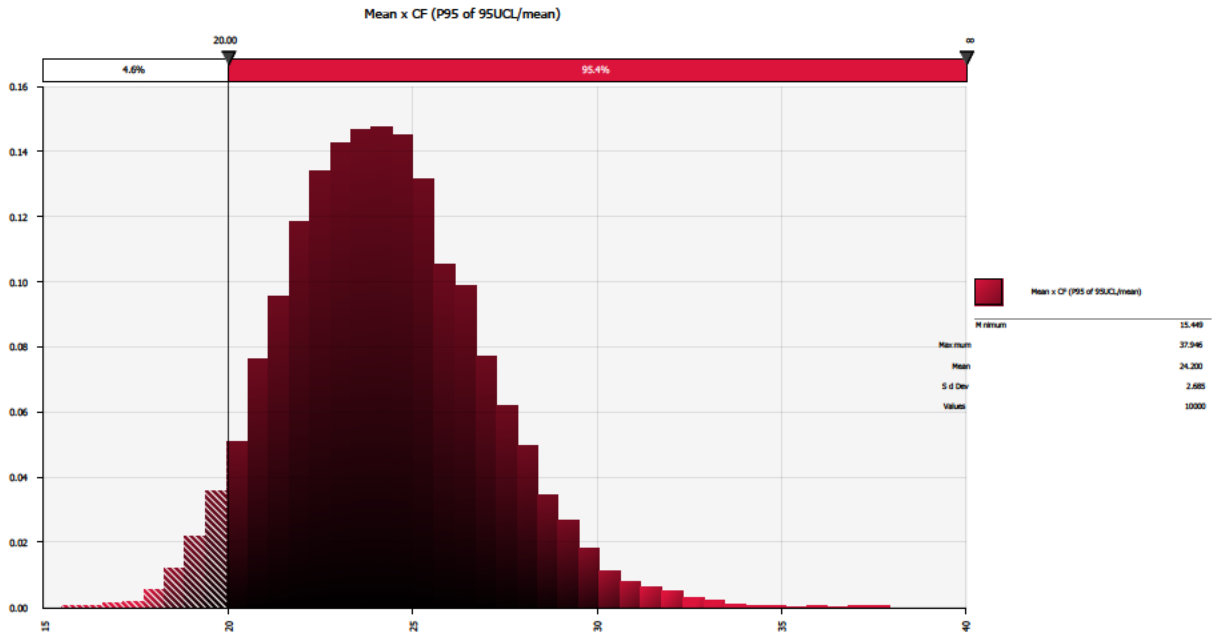

Figure 3. Probability density of uncertainty-adjusted arsenic concentration (mean X CF), when the CF is the 95th percentile ratio 95UCL/mean (=1.21) of residential soils DUs where 3 ICS composite samples were collected. Approximately 4.7% of the single composites are below the RBC (false negative).

Re: Proposed approach to calculate food consumption rates in children from adult consumption rates in the Upper Columbia River (UCR) Human Health Risk Assessment (HHRA)

Calculation of Food Consumption Rates in Children from Adult Consumption Rates

Food consumption rates for the Confederated Tribes of the Colville Reservation (CCT) exposure scenario in the Upper Columbia River (UCR) Human Health Risk Assessment (HHRA) were derived from a survey of CCT residents (the "Tribal Survey;" Westat, 2012). The survey included a 24-hour dietary recall and a food frequency questionnaire and was intended to yield estimates of consumption for children (ages 0-6 years) and other ages. For most foods, a sufficient number of adult subjects reported eating the food to provide a reliable estimate of adult consumption rates. However, for some foods, the number of children who consumed the food was insufficient for estimating consumption rates for children.

In the HHRA, if a rate of consumption of a specific food could not be estimated for children from the Tribal Survey (or other credible sources), consumption rates for children were calculated from the adult consumption rate using the following equation (Equation 1):

$$CR_{child} = CR_{adult} \cdot \frac{EER_{child}}{EER_{adult}} \qquad \text{Eq. (1)}$$

where CR is the consumption rate (grams [g]/day) for children or adults, and EER is the Estimated Energy Requirement for children and adults. Values for EER were calculated based on regression models for EER reported in IOM (2005). Based on the EERs calculated from IOM (2005), a value of 0.5 was used in Equation 1 to represent the EER_{child}/EER_{adult} ratio. The basis for this child/adult ratio of 0.5 is described below.

Calculation of Estimated Energy Requirement (EER) for children and adults:

Estimates of EER reported in IOM (2005) were based on clinical studies of clearance of doubly labeled water. Measurement of clearance of doubly labeled water provides an estimate of the metabolic production of carbon dioxide, from which estimates of oxygen consumption and energy expenditure can be derived. IOM (2005) reports values for the EER, which is the sum of basal energy expenditure, thermal effect of food (energy expended as a result of consumption of food), and energy expenditures from physical activity, thermal regulation and growth of tissue including pregnancy and production of milk (energy deposition). Doubly labeled water studies are cross-sectional measurements of energy expenditure and, therefore, do not measure energy deposition. Values for energy deposition reported in IOM (2005) were based on estimates of the energy content of protein and adipose added to body mass during growth. Energy deposition varies with age; being highest during infancy 175 kilocalories [kcal]/day at age ≤3 months) and decreasing to 20 kcal/day at age ≥13 months). After cessation of growth, total energy expenditure and EER converge (energy balance).

Values for EER for specific ages were estimated from regression equations reported in IOM (2005) that related EER to body size (body mass and length). The regression equations used to calculate EER within specific age ranges are described below.

EER for ages 1 – 35 months (Equation 2):

$$\mathrm{EER} = (89 \cdot \mathrm{BW} - 100) + \mathrm{ED} \qquad \text{Eq. (2)}$$

where EER is expressed in units of kcal/day, BW is body weight (kilograms [kg]) and ED is energy deposition (kcal/day). Age-range values for ED were as follows:

ED 0–3 months: 175 kcal

ED 4–6 months: 56 kcal

ED 7–12 months: 22 kcal

ED 13–36 months: 20 kcal

EER for ages 3-18 years (Equations 3 and 4):

$$\mathrm{EER(male)} = 88.5 - (61.9 \cdot \mathrm{age}) + \mathrm{PA} \cdot (26.7 \cdot \mathrm{BW} + 903 \cdot \mathrm{HT}) + \mathrm{ED} \qquad \text{Eq. (3)}$$

$$\mathrm{EER(female)} = 135.3 - (30.8 \cdot \mathrm{age}) + \mathrm{PA} \cdot (10.0 \cdot \mathrm{BW} + 934 \cdot \mathrm{HT}) + \mathrm{ED} \qquad \text{Eq. (4)}$$

where age is in years, PA is a physical activity coefficient and HT is body height (meters [m]). Age range values for ED were as follows:

ED ages 3-8 years: 20 kcal/day

ED for ages 9-18 years: 25 kcal/day

Values for PA used in the regression equations were as follows:

PA Level	Males	Females
sedentary	1.00	1.00
low active	1.13	1.16
active	1.26	1.31
very active	1.42	1.56

The bases for physical activity coefficients of children are described in detail in IOM (2005). Physical activity levels in children are approximately equivalent exertion from the following activities:

sedentary: lying awake, sitting

low active: walking at a pace of 2.5 miles/hour for 2 hours

active: walking at a pace of 2.5 miles/hour for 4 hours

very active: walking at a pace of 2.5 miles/hour for 6 hours

EER for ages 19 years and older (Equations 5 and 6):

$$\mathrm{EER(male)} = 662 - (9.53 \cdot \mathrm{age}) + \mathrm{PA} \cdot (15.91 \cdot \mathrm{BW} + 539.6 \cdot \mathrm{HT}) \qquad \text{Eq. (5)}$$

$$\mathrm{EER(female)} = 354 - (6.91 \cdot \mathrm{age}) + \mathrm{PA} \cdot (9.36 \cdot \mathrm{BW} + 726 \cdot \mathrm{HT}) \qquad \text{Eq. (6)}$$

Values for PA used in the adult regression equations were as follows:

PA Level	Males	Females
sedentary	1.00	1.00
low active	1.11	1.12
active	1.25	1.27
very active	1.48	1.45

The bases for physical activity coefficients for adults are described in detail in (IOM, 2005). Physical activity levels in adults are approximately equivalent to exertion from the following activities:

sedentary: physical activities required for independent living

low active: walking 2.2 miles/day at a rate of 3-4 miles/hour

active: walking 7 miles/day at a rate of 3-4 miles/hour

very active: walking 17 miles/day at a rate of 3-4 miles/hour

The above regression equations require values for body height and/or weight. Reference values for body weight and height used in the regression equations are presented in Table 1 (IOM, 2005).

Estimates of energy requirement in children and adults:

Figure 1 shows EERs calculated from regression equations and reference body weights and heights for children and adults. The EERs shown in Figure 1 are the average values for three physical activity categories: low active, active or very active (sedentary was not included in the average). The discontinuities in the age profiles shown in Figure 1 result from three different regression models for subjects in specific age ranges (i.e., 1-35 months, 3-18 years, ≥19 years). Table 2 summarizes EER estimates for adults and children (HHRA age range category 0-6 years) for the four physical activity levels represented in the IOM (2005) regression equations. Child/adult ratios (male female average) for EER ranged from 0.48 (very active) to 0.53 (sedentary). The average for the non-sedentary activity levels was 0.50. This value was selected for use in Equation 1 for calculating food consumption rates for children from adult consumption rates.

Appendix 15: All Ages Lead Model Analysis

TO: Monica Tonel, Marc Stifelman, and David Charters (US EPA)

FROM: Gary Diamond and Mark Follansbee (SRC)

DATE: June 5, 2019

RE: Comparison of IEUBK Model (IEUBKM) and All Ages Lead Model (AALM) simulations of blood lead levels (BLLs) resulting from visits to hypothetical public beaches at the UCR site.

The AALM.CSL (v4.3_122118) was used to simulate repeated single day exposures to public beach sediments in combination with a baseline exposure.

The baseline simulation was constructed as age-specific Pb intakes (ug/day) that predicted BLLs similar to the age-year BLLs predicted from the IEUBKM for combined exposures to Pb in air, food, drinking water, and residential soil and dust. Figure 1 compares the AALM and IEUBKM baseline simulations. The Pb intakes used in the AALM were as follows:

Age (year)	Age (day)	Pb Intake (ug/day)
0.0	0	0
0.2	90	9
1	365	10
2	730	8.5
3	1095	8.5
4	1460	10
5	1825	12
6	2190	12
7	2555	11
8	2920	11
9	3285	11
10	3650	11

Beach exposures were simulated as 6 single-day beach visits over a 3-month period, each year. The interval between events was 15 days. The exposure was to beach sediment at the mean RBA-adjusted concentration measured at hypothetical public beaches with high-end concentration of lead in beach sediment (within the range observed at the UCR site). Using higher exposure point concentrations for the beach (relative to the residence) would tend to magnify the difference in BLL predicted by the IEUBKM and AALM for acute exposure scenarios. When the child was not at the beach, the child was assumed to be at the residence; for these comparisons, the residential soil lead concentration was 129 ppm (based on site-specific information). The indoor dust lead concentration was based on the residential soil lead concentration of 129 ppm using the MSA analysis in the IEUBKM (using UCR measured air data), because the residence was assumed to be not located close to the beach. Soil, dust, and sediment ingestion rates were assumed to be the age-year IEUBKM defaults for soil plus dust (IR_{SD}). See SRC 2018 for a complete list of inputs to the IEUBKM.

Figure 2 shows the BLLs predicted from the AALM for combined baseline exposures (air, food, drinking water, and residential and indoor dust) and exposures to beach A sediment during a single 3-month season of beach visits occurring between the first year and second year. The AALM simulates each exposure at the beach as a single-day event. This results in a BLL spike associated with each beach visit, representing uptake of Pb during the exposure followed by the elimination of Pb from blood and a return towards the baseline BLL.

Figure 3 shows BLLs predicted from the AALM for repeated seasons of beach A visits each age year. Overlaid on the AALM simulation are the age-year BLLs predicted from the IEUBKM for the same scenario, along with the average BLL predicted for ages 12 – 72 months. The 12 to 72-month average is the IEUBKM prediction used in the risk assessment for this scenario. The age-year BLLs predicted from the IEUBKM are within the range of the discrete BLL spikes predicted from the AALM. This reflects the time-weighting calculation used in the IEUBKM which adjusts the exposure concentration by for the frequency of beach visits within the season rather than within the year (e.g., the exposure concentration is adjusted by the 1/7, the weekly frequency, rather than by 1/7 x 3/12). This approach ensures that average BLLs are not underestimated for the season by averaging with BLLs out of season (U.S. EPA 2003; Lorenzana et al., 2005). The 12 to 72-month average BLL predicted by the IEUBKM is 1.95 µg/dL. The corresponding average for the same age range predicted by the AALM is 1.87 µg/dL.

Figure 4 shows the corresponding AALM simulation of visits to beach B. The higher sediment concentration at beach B results in larger BLL spikes than beach A. The 12 to 72-month average BLL predicted by the IEUBKM is 2.5 µg/dL. The corresponding average for the same age range predicted by the AALM is 2.12 µg/dL.

Recommendation: Because the difference between the IEUBKM and AALM for these hypothetical public beach exposures is small (the IEUBKM prediction falls within the range of BLLs predicted by the AALM), the IEBUKM results should be included in the risk characterization section of the site-wide baseline HHRA and the information in this memorandum should be included in the uncertainty section of the site-wide baseline HHRA.

$PbB_{fetal,\ 0.95}$	95th percentile PbB among fetuses of adult workers	µg/dL	1.7	5.0	5.0	5.0
PbB_t	Target PbB level of concern (e.g., 2-8 ug/dL)	µg/dL	**8.0**	**5.0**	**5.0**	**5.0**
$P(PbB_{fetal} > PbB_t)$	**Probability that fetal PbB exceeds target PbB_t assuming lognormal distribution**	**%**	**0.0%**	**5.0%**	**5.0%**	**5.0%**

UDU-06

Calculations of Blood Lead Concentrations (PbBs) and Risk in Nonresidential Areas
U.S. EPA Technical Review Workgroup for Lead
Version date 06/14/2017

Edit Red Cells

Variable	Description of Variable	Units	GSDi and PbBo from Analysis of NHANES 2009-2014	GSDi and PbBo from Analysis of NHANES 2007-2010	GSDi and PbBo from Analysis of NHANES 2004-2007	GSDi and PbBo from Analysis of NHANES III (Phases 1&2)
PbS	Soil lead concentration	µg/g or ppm	33.3	1129	776	100
$R_{fetal/maternal}$	Fetal/maternal PbB ratio	--	0.9	0.9	0.9	0.9
BKSF	Biokinetic Slope Factor	µg/dL per µg/day	0.4	0.4	0.4	0.4
GSD_i	Geometric standard deviation PbB	--	1.8	1.7	1.8	2.1
PbB_0	Baseline PbB	µg/dL	0.6	0.7	1.0	1.5
IR_S	Soil ingestion rate (including soil-derived indoor dust)	g/day	0.050	0.050	0.050	0.050
IR_{S+D}	Total ingestion rate of outdoor soil and indoor dust	g/day	--	--	--	--
W_S	Weighting factor; fraction of IR_{S+D} ingested as outdoor soil	--	--	--	--	--
K_{SD}	Mass fraction of soil in dust	--	--	--	--	--
$AF_{S,D}$	Absorption fraction (same for soil and dust)	--	0.12	0.12	0.12	0.12
$EF_{S,O}$	Exposure frequency (same for soil and dust)	days/yr	219	219	219	219
$AT_{S,O}$	Averaging time (same for soil and dust)	days/yr	365	365	365	365
PbB_{adult}	PbB of adult worker, geometric mean	µg/dL	0.6	2.3	2.1	1.6
$PbB_{fetal,\ 0.95}$	95th percentile PbB among fetuses of adult workers	µg/dL	1.5	5.0	5.0	5.0
PbB_t	Target PbB level of concern (e.g., 2-8 ug/dL)	µg/dL	**8.0**	**5.0**	**5.0**	**5.0**
$P(PbB_{fetal} > PbB_t)$	**Probability that fetal PbB exceeds target PbB_t assuming lognormal distribution**	**%**	**0.0%**	**5.0%**	**5.0%**	**5.0%**
