1.0 INTRODUCTION

This report presents a human health risk assessment (HHRA) update conducted for the shoreline sediment, groundwater in shallow piezometers, and shellfish tissue at Site 09 Allen Harbor Landfill (site), located at the Former Naval Construction Battalion Center (NCBC) Davisville, in North Kingstown, Rhode Island. This HHRA update was performed in support of the Site 09 Five Year Event Long-Term Monitoring (LTM) Report and will ultimately be used in the Fourth Five Year Review as part of the evaluation of compliance with the Remedial Action Objectives (RAOs) identified in the Record of Decision (ROD) (EA, 1997). The RAOs and selected remedial alternatives for Site 09 are described in the ROD. The selected remedial alternatives include:

- the construction of a multimedia cap (including a gas venting system), a stone shoreline revetment, an offshore breakwater, and the construction of inter-tidal wetlands;
- LTM of landfill gas, groundwater, sediment, and shellfish to evaluate the effectiveness of the remedy; and
- implementation of land-use controls, including a deed restriction on site use to maintain the integrity of the cap, a deed restriction on the installation or use of groundwater wells for drinking water or showering purposes, and warning signs to inform the public of the Rhode Island Department of Environmental Management (RIDEM) ban on shellfishing in the harbor.

A summary of the Site 09 history is provided in the Draft Tier II Sampling and Analysis Plan, Long Term Monitoring Site 07 Calf Pasture Point and Site 09 Allen Harbor Landfill (Resolution, 2016) and is, therefore, not included in this HHRA update. However, the previously conducted HHRAs are briefly summarized in the following section.

1.1 Previous HHRAs

As part of the March 2013 Third Five-Year Review Report (Tetra Tech, 2013), a limited screening-level human health risk evaluation was conducted for the primary chemicals detected in Site 09 sediment samples collected in 2005 to 2012 as part of the LTM program. The results of this limited evaluation concluded that the potential risks associated with potential exposure to sediment exceeded United States Environmental Protection Agency (USEPA) and RIDEM target levels based on a residential exposure scenario; and exceeded RIDEM target levels but were within USEPA target levels based on a recreational exposure scenario. Potentially carcinogenic polycyclic aromatic hydrocarbons (cPAHs) at location SED09-10 were the major contributors to the estimated potential cancer risks. The potential noncancer hazard index (HI) did not exceed USEPA/RIDEM's target level of 1 per target organ.

As part of the August 2015 Long-Term Monitoring Data Summary and Optimization Recommendations Report (Tetra Tech, 2015), an HHRA was conducted to evaluate potential risk/hazard to recreational users from ingestion of shellfish, direct contact exposure to sediment based on a swimming/wading and clamming scenario, and shallow groundwater (piezometer water) based on a clamming scenario. This HHRA considered data collected from 2007 to 2012. This HHRA is referred to as the "2013 HHRA" throughout this report given that this is the year in which the HHRA presented in the August 2015 LTM Report was conducted.

The 2013 HHRA conclusions indicated that the potential cancer risks associated with ingestion of shellfish tissue estimated for an adolescent, adult, and/or lifelong recreational user exceeded RIDEM's target cumulative cancer risk level of $1x10^{-5}$, but were within USEPA's target risk range of 10^{-6} to 10^{-4}. Risk drivers (i.e., chemicals that are the primary contributors to the exceedance of the target risk level) were arsenic, polychlorinated biphenyls (PCBs), and pesticides in shellfish tissue. The potential noncancer HIs for an adolescent and adult recreational user ingesting shellfish did not exceed USEPA/RIDEM's target HI of 1 per target organ.

The 2013 HHRA conducted as part of the 2015 LTM report also concluded that concentrations of primary contaminants in shellfish generally did not change during the 2007 to 2012 timeframe. The range of PCB concentrations detected in the Site 09 shellfish tissue samples collected in 2012 were within the range of concentrations detected in samples collected through the National Oceanic and Atmospheric Administration (NOAA) Mussel Watch Program. This suggests that it is possible that some of the PCB contamination noted in the Site 09 samples may reflect regional conditions.

Potential risks for adolescent, adult, and lifelong recreational users exceeded RIDEM's target cumulative cancer risk level of $1x10^{-5}$ in several cases evaluated in the 2013 HHRA due to exposure to shallow sediment (0 to 0.5 feet below ground surface [bgs]) and piezometer water. Primary risk drivers for exposure to shallow sediment were arsenic and cPAHs. Primary risk drivers for exposure to piezometer water (using maximum concentrations) were arsenic and vinyl chloride. However, using refined exposure assumptions to more accurately represent Site 09-specific exposure conditions, potential cancer risks were less than RIDEM's target risk level of $1x10^{-5}$ for exposure to shallow sediment. Potential cancer risks estimated using 95 percent (%) upper confidence limits on the arithmetic mean concentration (UCLs) as the exposure point concentrations (EPCs) instead of maximum concentrations for piezometer water were also less than RIDEM's target risk level of $1x10^{-5}$. The 95% UCLs are likely to be more representative of actual exposure conditions. The potential noncancer HIs for an adolescent and adult recreational user exposed to sediment and piezometer water did not exceed USEPA/RIDEM's target HI of 1 per target organ.

Comparison of regional cPAH sediment data to Site 09 shallow sediment data for several cPAHs suggests that concentrations of cPAHs detected in shallow sediment at location SED09-10 are

elevated compared to the regional dataset as well as when compared to the other Site 09 shallow sediment samples. Site 09 shallow sediment samples for the other sampling locations are within the range of or slightly exceed (i.e., are within one order of magnitude of) detected concentrations in the regional sediment dataset.

1.2 Objectives

The objective of this HHRA update (referred to herein as the 2017 HHRA update) is to determine whether there have been any changes and/or updates to USEPA HHRA guidance or site-specific conditions since the 2013 HHRA was conducted that would result in a change of the conclusions of the 2013 HHRA. The 2017 HHRA update includes the following:

- Calculation of summary statistics for analytical sediment, shallow groundwater (piezometer water), and shellfish tissue data collected along the Site 09 shoreline as part of the LTM, which are considered representative of current conditions (i.e., 2017 HHRA update dataset);
- Update of screening levels and chemical of potential concern (COPC) selection for shoreline sediment, shallow groundwater (piezometer water), and shellfish tissue;
- Update of human receptor exposure assumptions/parameters;
- Calculation of EPCs for COPCs within each medium based on the 2017 HHRA update dataset;
- Update of toxicity values for COPCs identified based on the 2017 HHRA update dataset.

In accordance with the approach discussed and agreed upon by the Davisville Base Realignment and Closure (BRAC) Cleanup Team (BCT) during the January 12, 2017 teleconference, a quantitative evaluation was performed to determine whether updates to the 2013 HHRA would result in changes to the overall conclusions of the 2013 HHRA, or whether the conclusions of the 2013 HHRA remain valid. Revised risk/hazard calculations were performed as part of this 2017 HHRA update to estimate the cumulative potential cancer risk and/or noncancer hazard associated with a recreational user exposure scenario, determine whether risk/hazard estimates exceed USEPA and/or RIDEM target risk/hazard levels, and identify whether the current institutional controls in place at Site 09 are still needed.

The following USEPA risk assessment guidance was utilized in this 2017 HHRA update. Guidance documentation includes, but is not limited to, the following:

- *Navy Policy for Conducting Human Health Risk Assessments Under the Environmental Restoration Program* (DON, 2001)
- *U.S. Navy Human Health Risk Assessment Guidance* (DON, 2008)

- *Risk Assessment Guidance for Superfund, Volume I, Human Health Evaluation Manual* (Parts A, B, E) (USEPA, 1989a; 1991a; 1991b; 2004)
- *Human Health Toxicity Values in Superfund Risk Assessments* (USEPA, 2003)
- *Guidelines for Carcinogenic Risk Assessment* (USEPA, 2005a and b)
- *Exposure Factors Handbook* (USEPA, 2011)
- *Human Health Evaluation Manual, Supplemental Guidance: Update of Standard Default Exposure Factors* (USEPA, 2014a)

The remainder of this report is organized into the following sections, consistent with USEPA's four-step paradigm for HHRA (USEPA, 1989a):

- Data Evaluation/Hazard Identification (Section 3.0)
- Exposure Assessment (Section 4.0)
- Toxicity Assessment (Section 5.0)
- Risk Characterization (Section 6.0)

Section 7.0 presents the summary and conclusions, and Section 8.0 presents the references cited in this report. Tables and figures, numbered sequentially as referenced in this report, are presented at the end of the text.

This page intentionally left blank.

2.0 CONCEPTUAL SITE MODEL

Site 09 is an approximate 15-acre, grassy, wooded area formerly used by the Navy as a landfill. The site is located within a 100-year floodplain and is bounded to the east by Allen Harbor, to the west by a bicycle path, and to the north and south by vegetated wetlands (Figure 1). Allen Harbor is used for recreational boating and is supported by two marinas. In 1984, RIDEM closed Allen Harbor to shellfishing due to suspected contamination by several sources, including Site 09.

As part of the selected remedy for Site 09 identified in the ROD (EA, 1997), the landfill has been capped and is currently covered with grass with small shrubs. A revetment wall and constructed wetland is located along the southern and eastern boundary of the landfill with a stone breakwater structure separating the wetland from the harbor.

Waste materials such as municipal-type waste, construction debris, rubble, preservatives, paint thinners, degreasers (e.g., solvents), PCBs, oil, asbestos, ash, sewage sludge, and waste fuel oil were disposed of in the landfill. Dredged sediment was used to construct the created wetland and contaminants potentially present within the dredged sediment may have entered media within the created wetland through leaching.

Constituents found in shoreline sediment immediately adjacent to Site 09 are most likely due to historical erosion of the landfill face and overland runoff prior to remedy implementation. This conclusion is supported by the historical presence of landfill debris along the Site 09 shoreline (e.g., asphalt, metal debris, glass fragments) prior to capping the landfill. Most of the constituents historically associated with quantifiable human health and ecological risk in near-shore sediment [polychlorinated aromatic hydrocarbons (PAHs), PCBs, and metals] are not detected, or are detected at low concentrations or frequency, in groundwater at the landfill.

Contaminants from the landfill and dredged sediment used to construct the created wetland may have entered sediment, sediment pore water, and surface water at Site 09 through leaching, and may have accumulated in shellfish living at the site.

Current Site Use

Site 09 was transferred as Parcel 10 from the Navy to the Town of North Kingstown via the U.S. Department of the Interior on May 10, 2004. The Town's current and future planned use of the property is as open space/conservation land. The property will not be used for residential purposes in the future due to environmental land use restrictions placed on the property as required by the ROD (EA, 1997). Groundwater at the site is classified by RIDEM as GB (i.e., not suitable for public or private drinking water use without treatment). However, Rhode Island does not have an USEPA-approved Comprehensive State Groundwater Protection Program; therefore, this classification is not recognized by USEPA. There are no groundwater production wells located on or downgradient of

Site 09. Institutional controls on the site include a restriction on the installation or use of groundwater wells for drinking water or showering purposes, and warning signs to inform the public of the RIDEM ban on shellfishing in the harbor.

This HHRA update evaluates potential exposure to shoreline sediment, piezometer water (which is assumed to be a mixture of shallow groundwater and surface water), and shellfish tissue based on recreational use of the Site 09 shoreline.

The potentially exposed receptors and exposure pathways for the Site 09 shoreline are summarized in Table 1.

3.0 DATA EVALUATION

This section summarizes the shoreline sediment, shallow groundwater (piezometer water), and shellfish tissue data evaluated in the HHRA update, and also provides a revised COPC selection to identify chemicals for further evaluation. A discussion of the sampling details associated with the data collection is provided in the LTM Report, and is not included in this HHRA update.

3.1 Summary of the Shoreline Dataset

The datasets for evaluation in the HHRA update are discussed by media in this section. Figure 2 identifies the shoreline sample locations.

3.1.1 Sediment

Shallow sediment samples were collected between 0 to 0.5 feet bgs from twelve locations along the Site 09 shoreline during three sampling events conducted in September 2014, September 2015, and September 2016. Due to a miscommunication, deep sediment samples were collected from 2 to 3 feet bgs instead of 0 to 0.5 feet bgs from the twelve locations in October 2013. Sediment samples were analyzed for metals, PCB Aroclors, pesticides, semivolatile organic compounds (SVOCs), and volatile organic compounds (VOCs). Appendix A presents a summary of sediment samples and individual analytical sediment sample results.

The 2013 sediment samples were collected from 2 to 3 feet bgs as specified in the Final Quality Assurance Project Plan for Long Term Monitoring of Site 09 (EA, 2001). However, it had been subsequently agreed to by the Davisville BCT to collect shallow sediment samples which are more representative for potential human contact. Contact with deeper sediment (2 to 3 ft bgs) is not considered a complete exposure pathway for recreational users. Rather than exclude the deep sediment from this HHRA update completely, shallow and deep sediment samples were summarized separately and included in a screening-level evaluation in this HHRA update for informational purposes. However, the deep sediment samples were not evaluated in the HHRA beyond the screening-level evaluation.

3.1.2 Shallow Groundwater (Piezometer Water)

Shallow groundwater samples were collected during four sampling events conducted in October 2013, September 2014, September 2015, and September 2016 from twelve piezometers located along the Site 09 shoreline. The piezometer water is assumed to be a mixture of groundwater and surface water, but is referred to in this HHRA update as shallow groundwater (piezometer water). The screened interval for the piezometers is approximately two to three feet bgs. Shallow groundwater samples were analyzed for total (unfiltered) metals, dissolved (filtered) metals, PCB Aroclors, pesticides, SVOCs, and VOCs. Appendix A presents a summary of shallow groundwater (piezometer water) samples and individual analytical sample results.

3.1.3 Shellfish Tissue

Shellfish tissue samples were collected during four sampling events conducted in October 2013, September 2014, September 2015, and December 2016 from ten locations along the Site 09 shoreline. Shellfish tissue samples were analyzed for metals, PCB homologs, pesticides, and SVOCs. Shellfish data from the initial 2016 sampling event (September 2016) were not included due to data quality issues, per agreement with the BCT. Shellfish analytical results were reported and evaluated on a wet weight basis. Appendix A presents a summary of shellfish tissue samples and individual analytical shellfish tissue sample results.

3.2 Data Treatment

Analytical data were evaluated, validated, and qualified prior to use in the HHRA update. Data evaluation and validation included a comparison of the site data to corresponding blank (laboratory, field, equipment, and trip) concentration data. Data validation reports are presented as Attachment B of the LTM report. Data rejected during data validation ("R" qualified) were not used in the HHRA. Estimated values ("J" qualified) were used in the HHRA without modification. If the value was flagged with "U" or "UJ," the result was considered a non-detect value.

For each medium, data were compiled into summary statistics. For each chemical detected at least once within a medium, the summary statistics include frequency of detection, range of detection limits, range of detected concentrations, and location of maximum detected result. Note that due to the exclusion of "R" qualified groundwater results for certain analytes, the frequency of detection may vary within a medium.

For sample locations in which a duplicate sample was also collected, the duplicate sample results for each chemical/medium combination were processed for use in the calculation of summary statistics. Duplicates were resolved as follows: (1) where both the sample and the duplicate results are not detected, the resulting value is the average of the limits of detection; (2) where both the sample and the duplicate results are detected, the resulting value is the average of the detected results; and (3) where one of the pair is reported as not detected and the other is detected, the detected concentration is used.

Appendix B presents comparisons of the summary statistics for chemicals detected in the 2017 HHRA update shallow sediment and groundwater (piezometer water) datasets to the summary statistics for COPCs identified in the 2013 HHRA. The summary statistics comparisons indicate that the maximum detected shallow sediment concentrations have increased for about half of the metals and decreased for the other half. The majority of the maximum detected shallow sediment concentrations for the pesticides, PAHs, and VOCs have decreased. The maximum detected shallow groundwater concentrations for the majority of the metals, pesticides, PAHs, and VOCs have decreased.

A trend analysis of shellfish tissue concentrations was performed as part of the LTM Report. This analysis indicates an upward concentration trend for several metals, specifically in sample locations at the north and south ends of the Site 09 shoreline. Downward concentration trends were identified for several PAHs and PCB homologs in these areas.

3.3 Identification of Sediment and Groundwater COPCs

The identification of sediment and shallow groundwater COPCs was performed per medium based on a comparison of the maximum detected concentrations of detected chemicals to the screening or regulatory values discussed below. Chemicals detected at concentrations above the screening or regulatory values were identified as COPCs for further evaluation in the HHRA update. Chemicals that were not detected in a particular medium or were detected at concentrations below the screening or regulatory values were eliminated from being COPCs and were not evaluated further.

The COPC selection for sediment and shallow groundwater (piezometer water) are presented in Tables 2.1 and 2.2, respectively. For analytes lacking a chemical-specific screening level, a conservative surrogate chemical was selected and its screening level was used for COPC screening. Specific instances where surrogate assignments were made are identified in footnotes in the COPC selection tables. Screening levels and regulatory criteria were used to select sediment and groundwater COPCs as discussed per media below.

3.3.1 Sediment

Published human health screening levels for sediment are not available. Therefore, sediment COPCs were conservatively selected using the USEPA residential soil Regional Screening Levels (RSLs) (USEPA, 2016a) based on a target excess lifetime cancer risk (ELCR) of 10^{-6} and a target hazard quotient (HQ) of 0.1 (to account for potential cumulative effects of multiple chemicals acting on the same target organ), and the RIDEM Method 1 Direct Contact Exposure Criteria for soil (RIDEM, 2011). The residential screening levels are overly conservative for a recreational sediment scenario as they are based on a 350 day per year exposure frequency, which is unlikely for sediment exposure. A chemical was selected as a sediment COPC if the maximum detected concentration exceeded either of the screening levels. The comparison to screening levels was performed separately for shallow and deep sediment.

RIDEM soil criteria have not changed since the 2013 HHRA was performed. However, the USEPA RSLs are typically updated twice per year. Changes to the RSLs associated with each update are documented on USEPA's RSL website (https://www.epa.gov/risk/regional-screening-levels-rsls-whats-new-may-2016).

In January 2017, USEPA released the final Integrated Risk Information System (IRIS) assessment of benzo(a)pyrene (USEPA, 2017a). This assessment includes revised cancer toxicity values as well

as new noncancer toxicity values for benzo(a)pyrene and also affects the cancer toxicity values for other cPAHs, which are derived by application of an equivalency factor to the cancer toxicity values for benzo(a)pyrene (USEPA, 1993). The most current version of the RSL table (May 2016) pre-dates the benzo(a)pyrene update. Therefore, USEPA RSLs for PAHs were calculated using the RSL calculator (USEPA, 2017b) to reflect the most current toxicity values.

Table 2.1 presents the COPC selection for sediment. Table 2.3 presents a comparison of the COPCs identified in the 2013 HHRA and those identified as a result of the updated COPC selection performed in this 2017 HHRA update. This comparison shows that the 2017 HHRA update did not identify any additional COPCs in shallow sediment. Three PAHs identified as COPCs in the 2013 HHRA are no longer identified as COPCs based on the updated dataset.

The list of COPCs identified in deep sediment is shorter than in shallow sediment. Three chemicals (aluminum, manganese, and Total PCBs), which were not previously identified as COPCs in deep sediment, were identified as COPCs based on the updated dataset. However, these chemicals were identified as COPCs in shallow sediment in both the 2013 HHRA and are also identified as COPCs in shallow sediment based on the updated dataset. One PAH identified as a COPC in the 2013 HHRA is no longer identified as a COPC based on the updated dataset.

3.3.2 Groundwater

Groundwater screening levels include the USEPA Maximum Contaminant Levels (MCLs) for drinking water (USEPA, 2017c), USEPA tapwater Regional Screening Levels (RSLs) (USEPA, 2016a) based on a target excess lifetime cancer risk (ELCR) of 10^{-6} and a target hazard quotient (HQ) of 0.1 (to account for potential cumulative effects of multiple chemicals acting on the same target organ), and RIDEM GA Groundwater Objectives (RIDEM, 2011). A chemical was selected as a groundwater COPC if the maximum detected concentration exceeded any of the groundwater screening levels.

USEPA MCLs and RIDEM GA Groundwater Objectives have not changed since the 2013 HHRA was performed. However, the USEPA RSLs are typically updated twice per year. Changes to the RSLs associated with each update are documented on USEPA's RSL website (https://www.epa.gov/risk/regional-screening-levels-rsls-whats-new-may-2016).

As discussed for sediment in Section 3.3.1, USEPA RSLs for PAHs were calculated using the RSL calculator (USEPA, 2017b) to reflect the most current toxicity values.

Table 2.2 presents the COPC selection for shallow groundwater. Table 2.3 presents a comparison of the COPCs identified in the 2013 HHRA and those identified as a result of the updated COPC selection performed in this 2017 HHRA update. This comparison shows that the list of total metals identified as shallow groundwater COPCs has not changed. Three dissolved metals, two PAHs, and four VOCs identified as COPCs in the 2013 HHRA are no longer identified as COPCs based on the

updated dataset. Two PAHs, which were not previously identified as COPCs in shallow groundwater, were identified as COPCs based on the updated dataset.

3.4 Development of Shellfish Tissue Screening Levels

The quantification of potential risk/hazard associated with exposure to shellfish tissue was performed for all chemicals detected in shellfish tissue; therefore, a COPC selection step was not performed for this medium. In accordance with the approach used in the 2013 HHRA, risk-based concentrations for shellfish tissue were derived for use in the estimation of potential risk/hazard using a "risk-ratio" approach, which is further discussed in Section 6.2. Risk-based concentrations for shellfish tissue were developed using the USEPA RSL Calculator (USEPA, 2017b). Default exposure inputs provided in the calculator for a residential exposure scenario [i.e., exposure frequency of 350 days per year, exposure duration of 26 years, and body weight of 80 kilogram (kg)], were used in conjunction with a shellfish ingestion rate of 12,800 milligrams per day (mg/day). The shellfish ingestion rate is equal to the 95th percentile uncooked weight per capita of shellfish consumption for the U.S. population (USEPA, 2011) and was recommended for use by USEPA Region 1 (Tetra Tech, 2013). The shellfish tissue RSLs were developed based on a target ELCR of 10^{-6} and a target HQ 1. (Note: Given that the risk-based concentrations are not used to exclude chemicals from further evaluation, use of a target HQ less than 1 is not necessary).

Shellfish tissue RSLs are not available for lead. Therefore, the screening level for lead in shellfish tissue is equal to the U.S. Food and Drug Administration (USFDA) action level for lead in crustaceans (USFDA, 2007).

4.0 EXPOSURE ASSESSMENT

The purpose of the exposure assessment is the quantification of the extent, frequency, and duration of actual or potential exposure to chemicals by pathways relevant to the site and activities of the potential receptors.

4.1 Determination of Exposure Point Concentrations

Exposure points are the locations where potential receptors may contact COPCs at or from a site. The exposure points (or exposure areas) were defined based on the anticipated receptor activity and the spatial distribution of COPC concentrations. EPCs are the concentrations of COPCs in the environmental medium that receptors may contact, which are estimated in order to determine the magnitude of potential exposure. EPCs for evaluation of the reasonable maximum exposure (RME) scenario were calculated as described below.

Sediment

Sediment EPCs were calculated based on shallow sediment samples collected between 0 and 0.5 feet bgs from all locations along the shoreline (SED09-01, SED09-02A, SED09-03A, SED09-04A, SED09-05A, SED09-06B, SED09-07B, SED09-08B, SED09-09, SED09-10, SED09-11B, and SED09-12B).

The 2013 HHRA developed sediment EPCs for multiple scenarios, as follows:

- 95% UCL for shallow sediment data collected from 2010 through 2012;
- 95% UCL for shallow sediment data collected from 2010 through 2012 assuming sample location SED09-10 (which had detections of PAHs at least an order of magnitude greater than those detected at other locations) represents 10% of the exposure unit and remaining locations represent 90% of the exposure unit for select PAHs (i.e., an “area weighted” UCL case);
- 95% UCL for shallow sediment data collected in 2012;
- 95% UCL for shallow sediment data collected in 2012 assuming SED09-10 represents 10% of the exposure unit and remaining locations represent 90% of the exposure unit for select PAHs (i.e., an “area weighted” UCL case); and
- Maximum concentration for deep sediment data collected in 2010.

In this 2017 HHRA update, EPCs were calculated based only on the shallow sediment dataset. Deep sediment data (collected from 2 to 3 feet bgs) are not considered to be available for direct contact by recreational users. The combined 2014 through 2016 shallow sediment dataset was evaluated because no discernable concentration pattern was identified within this timeframe. All sediment sampling locations were weighted equally.

Shallow Groundwater

Shallow groundwater EPCs were calculated based on piezometer water samples collected from all locations along the shoreline (P09-01, P09-02A, P09-03A, P09-04A, P09-05A, P09-06B, P09-07B, P09-08B, P09-09, P09-10, P09-11B, and P09-12B).

The 2013 HHRA developed shallow groundwater EPCs for multiple scenarios, as follows:

- Maximum concentration for piezometer water data collected from 2010 through 2012 using total metals results;
- 95% UCL for piezometer water data collected from 2010 through 2012 using total metals results;
- 95% UCL for piezometer water data collected from 2010 through 2012 using dissolved metals results.

In this 2017 HHRA update, the combined 2013 through 2016 dataset was evaluated because no discernable concentration pattern was identified within this timeframe. Shallow groundwater (piezometer water) EPCs are equal to the UCL or the maximum concentration, whichever is lower (USEPA, 2002). The 2017 HHRA update derived EPCs for metals based on the total (unfiltered) results. Dissolved (filtered) metals data were not evaluated beyond a comparison to screening levels because it is common HHRA practice to use total results to evaluate human exposure to chemicals in water as the total fraction represents the fraction available for ingestion. While dissolved concentrations are applicable to the dermal contact pathway, the dermal contact pathway is conservatively evaluated using totals data.

Shellfish Tissue

Shellfish tissue EPCs were calculated based on shellfish tissue samples collected from all locations along the shoreline (ET09-03, ET09-04, ET09-05, ET09-06, ET09-07, ET09-08, ET09-09, ET09-10, ET09-11, and ET09-12).

The 2013 HHRA developed shellfish tissue EPCs for multiple scenarios, as follows:

- Maximum detected concentration for 2012 dataset;
- 95% UCL concentration for 2012 dataset;
- Maximum detected concentration in the 2010 through 2012 datasets;
- 95% UCL for 2010 through 2012 datasets; and
- 95% UCL for 2007 through 2012 datasets.

In this 2017 HHRA update, shellfish tissue EPCs were calculated based on the combined 2013 through 2016 shellfish tissue dataset because no discernable concentration pattern was identified within this timeframe.

For all media evaluated in the 2017 HHRA update, EPCs are equal to the UCL or the maximum concentration, whichever is lower (USEPA, 2002). USEPA's ProUCL Version 5.1.002 software (USEPA, 2016b) was used to calculate the ProUCL recommended UCL. Based on information presented in the ProUCL guidance (USEPA, 2015) regarding minimum sample size and frequency detection, UCLs were calculated where at least 10 samples and at least 6 detects are available. Appendix C presents the ProUCL input and output sheets.

When the minimum sample size and number of detects were not met for a dataset, or if the UCL was greater than the maximum detected concentration, the maximum detected concentration was used as the EPC.

The EPCs for COPCs in shallow sediment, shallow groundwater (piezometer water), and shellfish tissue evaluated in the 2017 HHRA update are presented in Tables 3.1, 3.2, and 3.3, respectively. Tables 3.1 through 3.3 also show a comparison of the updated EPCs to those evaluated in the 2013 HHRA. The EPCs equal to the 95% UCL scenario from the 2013 HHRA were utilized in the comparison. The results of the comparison are discussed by media as follows.

The shallow sediment EPCs based on all sample locations (i.e., unweighted and weighted EPCs) developed in the 2013 HHRA have slightly increased (less than 2 times higher) for metals and PCBs. The shallow sediment EPCs for the cPAHs have decreased in comparison to the 2013 unweighted EPCs and have increased (with the exception of one cPAH) (less than 2 times higher) in comparison to the 2013 weighted EPCs.

The updated shallow groundwater EPCs for several COPCs have increased (between 1 to 23 times higher) in comparison to the EPCs calculated in the 2013 HHRA. However, the maximum detected shallow groundwater concentrations for the majority of the metals, pesticides, cPAHs, and VOCs have decreased. The increase in EPCs is likely due to a smaller sample size and higher reporting limits used for non-detect results utilized in the calculation of the UCL.

The majority of the updated shellfish tissue EPCs for PCBs, pesticides, and SVOCs have decreased in comparison to the EPCs calculated in the 2013 HHRA. The EPCs for several metals have increased.

4.2 Receptors and Exposure Pathways

The receptors and exposure pathways evaluated in the 2013 HHRA based on current and potential future land use remain appropriate for evaluation in the 2017 HHRA update and are summarized in Table 1 and as follows:

- Current/future recreational users (adolescent [age 7 through 16 years] and adult) may be exposed to shoreline shallow sediment via incidental ingestion and dermal contact while swimming, wading or harvesting shellfish (clamming); shallow groundwater (piezometer water) along the shoreline via direct contact while clamming; and to shellfish tissue via ingestion.

There are no formal recreational facilities (e.g., public swimming areas) currently located along the Site 09 shoreline and there are no known plans for development of formal recreational facilities in the future. Therefore, it is unlikely that a young child would be routinely exposed to the environmental media along the Site 09 shoreline. Therefore, exposure to Site 09 media by young children (birth through 6 years) was not evaluated in this 2017 HHRA update. The recreational user exposure scenarios evaluated in the HHRAs are also protective of occasional trespassers to the shoreline.

The quantitative exposure assumptions used for evaluation in the 2013 HHRA were updated based on current USEPA guidance (USEPA, 2004, 2011 and 2014) and an RME scenario, as appropriate. Table 4 presents a comparison of the exposure assumptions utilized in the 2013 HHRA in comparison to the updated exposure assumptions. Parameters that have changed based on the update are highlighted. Several exposure parameters were updated based on revisions to USEPA's recommended default exposure assumptions, including body weight, exposure duration, skin surface area, and sediment adherence factor. Site-specific assumptions used in the 2013 HHRA were not changed based on professional judgment, including the assumed exposure frequency of 80 days per year and event frequency of 1 event per day. The exposure frequency for recreational users is based on exposure to shoreline shallow sediment and groundwater for three days a week over the course of the warmer weather months (April through October). Assumptions based on the percentages of the total body surface area exposed to shallow groundwater used in the 2013 HHRA were also not changed. However, the total skin surface area values were revised based on application of the percentages to the revised total body surface areas identified based on USEPA guidance (2011 and 2014). The 2013 HHRA used a default soil ingestion rate of 100 mg/day. There is considerable debate in the scientific community regarding incidental soil ingestion, and research to better characterize soil ingestion rates continues. USEPA acknowledges in the *Exposure Factors Handbook* that studies of adult soil ingestion are extremely limited (USEPA, 2011). USEPA (2011) identifies a central tendency soil ingestion rate for adults of 50 milligrams per day (mg/day). The ingestion rate is based on the average soil ingestion rate identified by Davis and Mirick (2006) and

includes both soil and dust. USEPA (2014) recommends an upper-bound soil (RME) ingestion rate of 100 mg/day for adults. The source of the 100 mg/day recommendation dates back to 1989 and was the recommended value in 1991 (USEPA, 1989b, 1991a). The soil ingestion rate represents the total daily intake of soil integrated over a variety of activities and sources, both indoors and outdoors. The use of the upper-bound soil ingestion rate of 100 mg/day is not considered to be appropriate for the evaluation of sediment ingestion under a recreational scenario for the following reasons: (1) Other locations contribute to the total daily soil intake, particularly given the less than 24 hours of exposure anticipated for the recreational receptor; and (2) the 100 mg/day rate is based on outdated studies of soil ingestion (USEPA, 1989b). More recently published studies incorporate improvements in study design and analysis and address some of the issues and uncertainties associated with the earlier studies (Stanek et al., 1997; Stanek et al.; 1999, Stanek and Calabrese, 2000). These newer data suggest that the upper-bound estimate of long-term soil ingestion for adults is approximately half of the 100 mg/day older estimate, and the central tendency estimate is approximately one-fifth of the older mean value of 50 mg/day. Therefore, based on the newer data, an upper-bound estimate of adult soil ingestion is 50 mg/day, and a central tendency estimate of soil ingestion is 10 mg/day. The upper-bound value of 50 mg/day is therefore used in this 2017 HHRA update.

4.3 Calculation of Unit Intakes

In the 2013 HHRA, chronic daily intake values for the incidental ingestion and dermal contact pathways of exposure to sediment and groundwater were calculated in accordance with USEPA guidance (1989a and 2004). Equations in these documents are used for calculating a lifetime average daily dose (LADD) relevant to cancer risk (i.e., cancer intake) or for calculating an average daily dose (ADD) relevant to noncancer hazard (i.e., noncancer intake). The medium-specific equations used for the calculation of cancer and noncancer intakes of the COPCs (presented in the 2013 HHRA, Attachment 2) are still valid and appropriate for use, and are presented below.

Unit intake estimates were calculated based on the updated exposure assumptions discussed in Section 4.2, consistent with the equations utilized in the 2013 HHRA. The equations for calculation of unit intake are as follows:

<u>Sediment:</u>

- Incidental ingestion Intake [(mg/kg-day)(kg/mg)]= [Ingestion Rate (mg/day) x conversion factor (1E-6 kg/mg) x exposure frequency (days/year) x exposure duration (years) x fraction from contaminated source (unitless)] / [body weight (kg) x averaging time (days)]

- Dermal Intake [(mg/kg-day)/(kg/mg)]= [surface area (square centimeters [cm^2]) x adherence factor (mg/cm^2-event) x event frequency (events/day) x exposure frequency (days/year) x exposure duration (years) x conversion factor (1E-6 kg/mg)] / [body weight (kg) x averaging time (days)]

Groundwater:

- Dermal Intake [(cm^2-event)/(kg-day)]= [surface area (cm^2) x event frequency (events/day) x exposure frequency (days/year) x exposure duration (years)] / [body weight (kg) x averaging time (days)]

Chemical-specific parameters, including concentration, sediment absorption factors, and water dermal absorption parameters are not included in the unit intakes.

5.0 TOXICITY ASSESSMENT

The toxicity assessment was conducted in accordance with USEPA guidance and considers chronic (long-term) exposures for carcinogenic and noncarcinogenic COPCs. The USEPA's guidance regarding the hierarchy of sources of human health dose-response values in risk assessment was followed (USEPA, 2003) and is presented below:

- *Tier 1*: USEPA's IRIS (USEPA, 2017d)
- *Tier 2*: Provisional Peer-Reviewed Toxicity Values obtained from USEPA via the USEPA National Center for Environmental Assessment in Cincinnati, Ohio (USEPA, 2017e)
- *Tier 3*: Other sources of dose-response values including, but not limited to, California EPA's Office of Environmental Health and Hazard Assessment Toxicity Criteria Database (CalEPA, 2016), minimal risk levels published by the Agency for Toxic Substances and Disease Registry (ATSDR, 2016), and the Health Effects Assessment Summary Tables (USEPA, 1997)

Where published dose-response values were not available for a chemical, dose-response values based on surrogate chemicals (i.e., chemicals with structural similarities) were identified. The chosen surrogate is referenced in the summary table(s) of dose-response values.

No noncancer reference doses (RfDs) or cancer slope factors (CSFs) are available for evaluating dermal exposure. Therefore, cancer risks and noncancer hazards associated with dermal exposure may be evaluated using an oral CSF or RfD adjusted such that the toxicity value is appropriate for the dermal pathway. As detailed by USEPA (2004), for purposes of evaluating dermal exposure, it is generally necessary to adjust an oral toxicity factor (i.e., RfD or CSF) from an administered (i.e., applied) dose to an absorbed (i.e., internal) dose. Because the toxicity values for the COPCs at the site are expressed as orally administered doses (i.e., applied or intake-based), it is necessary to

adjust both the RfDs and CSFs for these substances in estimating exposure on an absorbed-dose basis when assessing dermal exposure.

Table 5 summarizes the oral and dermal noncancer toxicity values (i.e., RfDs) and the corresponding critical effects for Site 09 shallow sediment and groundwater COPCs. Table 6 summarizes the oral and dermal CSFs and the corresponding weight-of-evidence classifications for Site 09 shallow sediment and groundwater COPCs.

In the 2013 HHRA, the quantitative evaluation of potential risks for carcinogenic COPCs with a mutagenic mode of action followed the USEPA guidance titled *Supplemental Guidance for Assessing Susceptibility from Early-Life Exposure to Carcinogens* (USEPA, 2005a). Specifically, the quantification of cancer risks for child receptors involves the use of age-dependent adjustment factors (ADAFs), as follows:

- an ADAF of 10 was used for exposures occurring less than 2 years of age
- an ADAF of 3 was used for exposures occurring between 2 and less than 16 years of age
- an ADAF of 1 was used for exposures occurring after 16 years of age

The Site 09 COPCs considered to be mutagenic, for which application of ADAFs is necessary, are benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, chrysene, and dibenz(a,h)anthracene. Vinyl chloride is a mutagenic COPC. However, cancer toxicity values for vinyl chloride account for mutagenic action, such that ADAFs are not applied to the cancer risks for vinyl chloride.

6.0 RISK CHARACTERIZATION

Risk characterization combines estimates of exposure with toxicity data to develop estimates of the probability that an adverse effect will occur under the specified conditions of exposure. The risk characterization was divided into three phases: (1) risk estimation, (2) risk description, and (3) uncertainty analysis.

Risk estimation is undertaken by combining the toxicity factors and exposure assessment equations to calculate estimates of risks. Noncancer hazards are reported as pathway-specific HIs (hazard indices), which are the sum of individual COPC HQs for that pathway. A total HI is calculated, as well as HQs from COPCs that affect the same target organ. Estimates of cancer risks are reported as ELCRs. Current practice considers cancer risks to be additive when assessing exposure to a mixture of hazardous substances. The significance of the risk estimates are relative to risk management criteria set forth in USEPA policy. The uncertainty analysis describes the impact of data uncertainty and variability, exposure assumptions, and toxicity values on estimates of potential risk.

The potential cancer risk for each receptor is estimated for each medium by means of an ELCR. The ELCR represents the incremental upper-bound probability that an individual could develop cancer over his or her lifetime due to exposure to potential carcinogens under the conditions specified in the exposure scenario. For example, cancer risk levels of 10^{-6} and 10^{-4} represent an incremental chance of one-in-one-million and one-in-ten-thousand, respectively, that an individual could contract cancer over a lifetime.

USEPA (1991b) states that where the cumulative incremental current or future potential ELCR to an individual is less than 10^{-4}, action generally is not warranted unless there are adverse environmental impacts. RIDEM uses a target ELCR of 10^{-5} (RIDEM, 2011). The potential ELCR for each pathway (i.e.., the shallow sediment incidental ingestion pathway, the shallow groundwater pathway or the shellfish ingestion pathway) was calculated by summing the potential ELCRs from each COPC within the pathway, while receptor risks for each medium were calculated by summing ELCRs for each pathway within the medium (e.g., the shallow sediment incidental ingestion and dermal contact pathways).

The sum of the HQs for all chemicals within a pathway that have the same target organ or type of toxicity is termed the pathway HI. The HI is useful as a reference point for gauging potential effects of environmental exposures to complex mixtures. In general, HIs that are less than 1 are not of regulatory concern; however, an HI of greater than 1 does not automatically indicate that an adverse effect will occur and should not automatically be interpreted as posing an unacceptable risk to the exposed population. The magnitude of the HQ cannot be directly equated to a probability or effect level.

The total pathway HI for each exposure point was calculated by summing the HQs for all COPCs. Total HIs for each receptor by medium were calculated by summing the total HIs across pathways within the media (e.g., summing dermal and incidental ingestion shallow sediment risk estimates). As a first approximation, all COPCs are assumed to have additive effects. If the total HI for all COPCs does not exceed USEPA or RIDEM's target HI, then the total HI per target organ would also not exceed USEPA/RIDEM's target HI. Therefore, calculation of target HIs per target endpoint is not performed when the total HI is equal to or below 1. Both USEPA and RIDEM use a target HI per target organ of 1 (USEPA, 1991b; RIDEM, 2011).

For each associated exposure scenario with a potential cumulative ELCR/HI above USEPA or RIDEM target levels, risk drivers were identified as COPCs with an individual ELCR > 10^{-6} or target organ HI > 1, at one significant figure. Chemicals of concern (COCs) were identified as risk drivers that cause an exceedance of USEPA or RIDEM target ELCR or HI levels.

The following sections discuss the methods used for estimating the potential ELCR and HI.

6.1 Estimation of Potential ELCR and HI Associated with Exposure to Shallow Sediment and Groundwater (Piezometer Water)

In accordance with USEPA HHRA guidance (1989a, 2004, 2005a and b), potential ELCR and noncancer HQs associated with exposure to shallow sediment and groundwater (piezometer water) were estimated for the associated COPCs within each medium using the following equations. These equations include combination of the revised EPCs, pathway-specific unit intakes, chemical-specific toxicity values, and other chemical-specific factors (i.e., sediment ingestion and dermal-water absorption factors).

Sediment:

- Potential ELCR = EPC [milligram per kilogram mg/kg)] x unit intake [(mg/kg-day)(kg/mg)] x CSF $(mg/kg\text{-}day)^{-1}$ x sediment ABS (unitless) x ADAF (as applicable)
- Potential HQ = EPC (mg/kg) x unit intake [(mg/kg-day)(kg/mg)] x {1 / [RfD (mg/kg-day)]} x sediment ABS (unitless)

Groundwater:

- Potential ELCR = EPC (ug/L) x unit intake $[(cm^2\text{-event})/(kg\text{-day})]$ x CSF $(mg/kg\text{-}day)^{-1}$ x dermal factor ("Z") $(L/cm^2\text{-event})$ x 0.001 mg/ug) x ADAF (as applicable)
- Potential HQ = EPC (ug/L) x unit intake $[(cm^2\text{-event})/(kg\text{-day})]$ x {1 / [RfD (mg/kg-day)]} x dermal factor ("Z") $(L/cm^2\text{-event})$ x 0.001 mg/ug

Chemical-specific parameters including oral and dermal sediment absorption factors and dermal water parameters used in the calculation of oral and/or dermal dose in the 2013 HHRA were updated, as necessary, and are presented in Tables 7 and 8, respectively. These chemical-specific parameters are discussed further in Section 6.1.1 and 6.1.2.

Potential ELCR and HI estimates were estimated individually for adolescent and adult recreational users based on exposure to shallow sediment and groundwater (piezometer water). Since potentially carcinogenic effects are averaged over a receptor's lifetime, potential ELCR estimates were also estimated for a "Lifelong" scenario by summing the associated estimates for the adolescent and adult age groups. A lifelong scenario is not appropriate for evaluating noncancer HI because noncancer exposures are averaged over the period of exposure for each receptor. The estimation of potential ELCR/HI for a current/future recreational user exposed to shoreline shallow sediment and shallow groundwater (piezometer water) is presented on Table 9.1 (assuming exposure to sediment occurs while swimming/wading) and Table 9.2 (assuming exposure to sediment occurs while clamming). The potential ELCR and HI results are discussed in Section 6.3.

6.1.1 Sediment Absorption Factors

USEPA guidance (USEPA, 2012) recommends the use of site-specific bioavailability data to adjust exposure estimates in site-specific HHRAs when the medium of exposure in the exposure assessment differs from the medium of exposure associated with the toxicity value (i.e., CSF and RfD). In the absence of reliable site-specific data, the default assumption is that the bioavailability of a chemical is the same in an exposure medium at a site (e.g., sediment, water, etc.) as it is in the exposure medium used to derive the toxicity value. For arsenic, published toxicity values in USEPA's IRIS database are based upon exposure to arsenic in water (USEPA, 2017d). Therefore, use of these toxicity factors without adjustment assumes that the bioavailability of arsenic in soil or sediment is the same as the bioavailability of arsenic in water (relative bioavailability (RBA) of 100%). However, bioavailability studies conducted in animal models show that bioavailability of arsenic in soil is typically less than that of highly water soluble forms of arsenic (USEPA, 2012). Therefore, assuming an RBA of 100% for evaluation of arsenic in soil/sediment will result in an overestimation of risk. As a result of this recent research, USEPA released guidance recommending a default RBA for arsenic in soils of 60% be used where site-specific arsenic bioavailability assessment is not feasible (USEPA, 2012b). A RBA of 60% (0.6) was applied to arsenic in sediment in this HHRA in accordance with USEPA's guidance for soil by setting the oral absorption adjustment factor for arsenic in sediment to 0.6, as shown in Table 7.

Dermal absorption adjustment fractions for sediment COPCs were identified consistent with USEPA (2004) guidance.

6.1.2 Dermal Water Parameters

The dermal factor ("Z") represents the dose absorbed per unit area per event (DA_{event}) term (USEPA, 2004) with the water concentration (i.e., EPC) removed. The combination of the EPC (µg/L), "Z" (L/cm^2-event), and conversion factor of 0.001 mg/ug equal DA_{event} (mg/cm^2-event), making the groundwater equations for estimation of potential ELCR and HQ associated with dermal exposure presented in Section 6.1 consistent with those recommended in USEPA's dermal HHRA guidance (USEPA, 2004; Equations 3.2, 3.3, and 3.4). The parameters used in the calculation of the dermal factor ("Z") are presented in Table 8.

The quantification of potential noncancer hazards and cancer risks associated with the surface water pathway followed Exhibit 1-2 in the USEPA RAGS Part E guidance (2004). Specifically, if dermal assessment was not recommended in USEPA RAGS Part E (2004), no further evaluation of the dermal pathway was conducted for that COPC. Dermal assessment is not recommended for chemicals with a very large or very small octanol-water partition coefficient (K_{ow}) value, including benzo(a)anthracene, benzo(a)pyrene, and benzo(b)fluoranthene. These chemicals are considered to be outside of the "Effective Prediction Domain (EPD)", which means that an appropriate dermal permeability constant (K_p) value cannot be predicted by the statistical model (USEPA, 2004).

6.2 Estimation of Potential ELCR and HQ Associated with Shellfish Ingestion

Consistent with the approach used in the 2013 HHRA, in this 2017 HHRA update, risk-based shellfish tissue concentrations were derived for use in the estimation of potential ELCR and HI associated with the shellfish tissue ingestion pathway using a "risk-ratio" approach. This type of approach is presented in the USEPA RSL User's Guide (USEPA, 2016a). Risk-based concentrations (i.e., RSLs) for shellfish tissue were developed based on cancer effects using a target ELCR of 1E-6 and noncancer effects using a target HQ of 1, as described in Section 3.4. Potential ELCR and noncancer HQ estimates were developed for each chemical detected in shellfish tissue using the following equations:

Estimation of potential ELCR:

$$\frac{RSL_{cancer}\,(mg/kg)}{Target\ ELCR\ of\ 1E-6} = \frac{Tissue\ EPC\ (mg/kg)}{Potential\ ELCR}$$

$$Potential ELCR = \frac{Tissue\ EPC\ (mg/kg) \times 1E-6}{RSL_{cancer}\,(mg/kg)}$$

Estimation of potential HQ:

$$\frac{\text{RSL}_{\text{noncancer}}\,(\text{mg/kg})}{\text{Target HQ} = 1} = \frac{\text{Tissue EPC (mg/kg)}}{\text{Potential HQ}}$$

$$\text{Potential HQ} = \frac{\text{Tissue EPC (mg/kg)} \times 1}{\text{RSL}_{\text{noncancer}}\,(\text{mg/kg})}$$

The cumulative potential ELCR and total HI associated with the shellfish ingestion pathway was estimated by summing the potential ELCR and HQs for all of the detected chemicals. Because the comparison of site data to reference area data indicated that site arsenic concentrations may be consistent with reference area concentrations, the potential cumulative ELCR and total HI was also estimated excluding arsenic. This approach is consistent with the approach utilized in the 2013 HHRA. The estimation of potential ELCR/HI for a current/future recreational user exposed to shellfish tissue via ingestion is presented on Table 9.3.

6.3 Risk Characterization Results

The potential cancer risk and noncancer hazard results are discussed in this section. To evaluate the potential cumulative ELCR and HI for a recreational user who swims or wades, clams, and ingests shellfish from the Site 09 shoreline, the ELCR/HIs associated with sediment/groundwater exposure were added to those associated with shellfish tissue exposure. Exposure to shallow sediment was evaluated for both a swimming/wading and clamming exposure scenario. The potential ELCR/HI associated with exposure to shallow sediment via swimming/wading was included in the cumulative ELCR/HI estimate because the swimming/wading scenario represents a higher level of sediment exposure and higher level of risk/hazard than the clamming scenario. The potential cumulative ELCRs and HIs estimated based on exposure to all three media are presented in Table 10. Table 10 also summarizes the cumulative potential ELCRs and HIs associated with the scenarios considered to be the most representative of exposure estimated in the 2013 HHRA.

The cumulative potential ELCR associated with a lifetime recreational user exposure to shallow sediment (assuming a swimming/wading scenario), groundwater (piezometer water), and shellfish is 3×10^{-4}, which is greater than USEPA's target risk range of 10^{-6} to 10^{-4} and RIDEM's target risk level of 10^{-5}. Arsenic in shellfish tissue contributes the majority of the risk with an individual potential ELCR of 2.9×10^{-4}. The cumulative potential ELCR excluding arsenic is 2×10^{-5}, which is within USEPA's target risk range of 10^{-6} to 10^{-4} and greater than RIDEM's target risk level of 10^{-5}. PCBs and aldrin in shellfish tissue contribute the majority of the risk if arsenic is excluded, with a combined potential ELCR of 7.8×10^{-6}.

The total potential HI associated with an adolescent recreational user exposure to shallow sediment (assuming a swimming/wading scenario), groundwater (piezometer water), and shellfish is 2.7,

which is greater than USEPA and RIDEM's target HI of 1. Arsenic in shellfish tissue contributes the majority of the hazard with an individual potential HQ of 1.7. The total potential HI excluding arsenic is 1, which is equal to USEPA and RIDEM's target HI of 1. Given the total potential HI for all detected chemicals excluding arsenic is 1, the total potential HI per target organ would also not exceed the target HI of 1.

These results indicate that the overall conclusions of the 2013 HHRA, which are that ingestion of shellfish tissue obtained from the Site 09 shoreline by a current/future recreational user poses a potential cancer risk or noncancer hazard above RIDEM target levels due to arsenic, PCBs, and pesticides (specifically aldrin), remain valid. The 2017 HHRA update also concluded that the potential cancer risk due to ingestion of shellfish has increased to above USEPA's target risk range of 10^{-6} to 10^{-4} due to arsenic (which may be regionally influenced). Based on this conclusion, the current institutional control prohibiting ingestion of shellfish continues to be necessary to protect public health.

The potential ELCRs and HIs associated with exposure to shallow sediment and groundwater (piezometer water) estimated in the 2017 HHRA update are less than or approximately equal to the potential ELCRs and HIs estimated in the 2013 HHRA. Excluding arsenic concentrations, the potential ELCR and HI associated with shellfish ingestion estimated in the 2017 HHRA update is less than and equal to, respectively, the potential ELCR and HI estimated in the 2013 HHRA. However, the potential ELCR and HQ associated with arsenic concentrations in shellfish have increased based on the current shellfish tissue dataset. The shellfish tissue EPC for arsenic of 3.4 mg/kg (Table 3.3) is within the range of arsenic concentrations detected in reference tissue samples collected from the shoreline of Prudence Island (ET09-01) and from Fishing Cove in Wickford, Rhode Island (ET09-02) between 2007 and 2011. These results indicate that concentrations of arsenic in site shellfish tissue samples evaluated in the 2017 HHRA update may be due to background conditions, rather than Site 09.

The shellfish tissue EPC (i.e., maximum concentration) for aldrin of 0.0056 mg/kg is less than the range of aldrin concentrations detected in reference tissue samples from the shoreline of Prudence Island (ET09-01) and from Fishing Cove in Wickford, Rhode Island (ET09-02) between 2007 and 2011. These results indicate that concentrations of aldrin in site shellfish tissue samples evaluated in the 2017 HHRA update may be due to background conditions, rather than Site 09.

If both arsenic and aldrin concentrations in shellfish tissue are excluded from the 2017 HHRA update, the cumulative potential ELCR associated with a lifetime recreational user exposure to shallow sediment (assuming a swimming/wading scenario), groundwater (piezometer water), and shellfish is $1x10^{-5}$. This potential ELCR is within USEPA's target risk range of 10^{-6} to 10^{-4} and equal to RIDEM's target risk level of 10^{-5}.

In addition, the shellfish tissue EPC (i.e., 95% UCL) for PCBs of 0.0203 mg/kg is less than the range of PCB concentrations detected in samples collected in 2011 (the most currently available dataset) through the NOAA Mussel Watch Program (https://products.coastalscience.noaa.gov/nsandt_data/data.aspx) (i.e., 0.027 to 0.085 mg/kg). This suggests that it is possible that some of the PCB contamination noted in the Site 09 samples may reflect regional conditions.

6.4 Description of Uncertainties

Estimation of potential risks to human health that may result from exposure to chemicals in the environment is a complex process that often requires the combined efforts of multiple disciplines. Each assumption, whether regarding the toxicity value to use for a particular chemical or the value of a parameter in an exposure equation, has a degree of variability and uncertainty associated with it. In each step of the HHRA process, beginning with the data collection and analysis and continuing through the toxicity assessment, exposure assessment, and risk characterization, conservative assumptions are made that are intended to be protective of human health and to ensure that risks are not underestimated. There is a probability of overestimating health risks or hazards for a number of reasons. The following subsections provide a discussion of the key uncertainties that may affect the final estimates of human health risk in this HHRA. Uncertainties are arranged by topic.

6.4.1 Environmental Sampling and Analysis

The process of environmental sampling and analysis results in uncertainties from several sources, including errors inherent in sampling procedures or analytical methods. One area of uncertainty is sampling procedures. Since it is not possible to sample the entire area of interest at a given site, several samples are taken from each medium within a site, and the results are considered representative of the chemicals present throughout the site. This assumption may overestimate or underestimate risk.

Uncertainty is also associated with analytical methods. Due to uncertainty of quantification, individual chemicals were sometimes listed as detected but with the value qualified as estimated by laboratory qualification or validation procedures. The estimated value was used in the HHRA. This uncertainty may either overestimate or underestimate risk depending on how close the estimated value is to the true value.

Shallow groundwater (piezometer) data from all LTM sampling events conducted following the 2013 HHRA, occurring between October 2013 and September 2016, were included in the HHRA update. Given the lack any discernable concentration pattern indicating a consistent increase or decrease in concentration over time, inclusion of the data from all rounds provides for a robust dataset.

The HHRA utilizes the total (unfiltered) groundwater data for oral exposure pathways, consistent with the recommendation in USEPA (2004). However, as indicated in USEPA (2014):

> "….particulate-bound chemicals in an aqueous medium (e.g., suspended sediment particles) would be considered to be much less bioavailable for dermal absorption, due to inefficient adsorption of suspended particles onto the skin surface and a slower rate of absorption into the skin. The uncertainty in the estimation of the dermal dose from a water sample with high turbidity is directly proportional to the magnitude of the difference in the concentration between an unfiltered and filtered sample. The actual bioavailable concentration is likely to lie somewhere between the unfiltered and filtered sample concentrations."

Therefore, the use of the unfiltered groundwater data for quantitative evaluation of the dermal contact pathway is conservative.

6.4.2 COPC Selection

A comparison of maximum detected chemical concentrations to USEPA RSLs and RIDEM criteria was conducted as part of the COPC selection process for sediment and groundwater. RSLs are conservative risk-based values that are used when selecting COPCs so as not to omit a chemical that might contribute significantly to risk. Chemicals whose maximum concentrations were below their respective screening value were not identified as COPCs or further evaluated to quantify potential risk/hazard. It is unlikely that this risk-based screening excluded chemicals that would be of concern, based on the conservative exposure assumptions and conservatively derived toxicity criteria that are the basis of the screening level. Although following this methodology does not provide a quantitative risk estimate for all chemicals, it focuses the assessment on the chemicals accounting for the greatest risks (i.e., chemicals whose maximum concentrations exceeded their respective screening level). Although the overall potential risk estimates are uncertain, it is not expected that actual risks will be significantly greater than estimated risks given that a reasonable effort was made to characterize current and future potential health risks given current knowledge.

The sediment and shallow groundwater (piezometer water) datasets contains some non-detect results with levels of detection (LODs) greater than USEPA residential soil and tapwater RSLs (2016a), respectively, for several analytes. These elevated LODs introduce some level of uncertainty into the COPC selection and calculation of EPCs. The use of USEPA tapwater RSLs (which are protective of a drinking water ingestion scenario) to select COPCs for evaluation of incidental ingestion by recreational users for a clamming scenario is overly conservative. Similarly, the use of USEPA residential soil RSLs to select sediment COPCs for evaluation of incidental ingestion and dermal contact by recreational users for a swimming/wading/clamming scenario is overly conservative. For piezometer water, for a subset of analytes for which the LODs are greater than the tapwater RSLs, the LODs are less than the RIDEM GA groundwater objectives (RIDEM,

2011) and/or USEPA MCLs (USEPA, 2017c). Additionally, several of the analytes with elevated LODs were identified as shallow groundwater COPCs based on detected concentrations in other samples.

The presence of elevated LODs for chemicals selected as COPCs for further evaluation in the HHRA update may result in calculation of a higher EPC for that COPC, resulting in a higher estimated potential risk/hazard. Therefore, the presence of LODs above the tapwater and residential soil RSLs for a subset of sediment and piezometer water samples, respectively, is not considered to alter the conclusions of the HHRA update.

6.4.3 Toxicological Data

Uncertainty is associated with the toxicity values and toxicity information available to assess potential adverse effects.

One of the major contributors to uncertainty is the accuracy of the toxicity values used. A cancer potency value is a mathematical extrapolation of the slope of the dose-response curve from high doses administered to animals (or the exposures observed in epidemiological studies) to the low doses commonly experienced in the environment. The USEPA has developed potency values for chemicals classified as carcinogens, based on the premise that there is no threshold (i.e., there is no level of exposure below which there is no risk of a carcinogenic effect). USEPA's *Guidelines for Carcinogen Risk Assessment* (USEPA, 2005b) acknowledges that the mode of action of a carcinogen may involve both threshold and non-threshold mechanisms. To the extent that the approach used to develop the potency estimate is incorrect, the extrapolated risks may be overestimations or underestimations. However, in the derivation of toxicity values, conservative assumptions are employed. Therefore, toxicity values tend to be biased toward overestimating potential risk.

For dermal exposure pathways, the absence of dermal toxicity criteria necessitated the use of oral toxicity data. To calculate potential risk estimates for the dermal pathway, absolute oral bioavailability factors that reflect the toxicity study conditions were used to modify the oral toxicity criteria. For the chemicals with oral absorption exceeding 50%, a default oral absorption factor of 100% was used. The potential risk estimates for the dermal pathways may be overestimated or underestimated depending on how closely these values reflect the difference between the oral and dermal routes.

<u>Chromium</u>

Many metals can exist in different oxidation states; for some metals, the oxidation state can have different toxicities. This is the case for chromium. Chromium exists in two common oxidation states: trivalent chromium (chromium-3, Cr[III], or Cr+3) and hexavalent chromium (chromium-6, Cr[VI], or Cr+6). Trivalent chromium is essentially nontoxic as evidenced by its residential soil RSL of

120,000 mg/kg (USEPA, 2016a). It can be bought over-the-counter as a supplement and is included in most vitamins.

Chromium is most commonly present in the environment in the trivalent state because typical conditions in the environment favor the reduction of chromium from the hexavalent to the trivalent state. Hexavalent chromium in soil is expected to be reduced to trivalent chromium by organic matter, which is facilitated by low pH (ATSDR, 2012). In addition, if hexavalent chromium is ingested, it is rapidly converted to the trivalent form after entering the stomach, and is therefore not considered by USEPA to pose a cancer risk via the ingestion route of exposure (USEPA, 2013).

Total chromium results in Site 09 media were evaluated as trivalent chromium in the HHRA update, consistent with the approach in the 2013 HHRA. Chromium was not identified as a COPC in sediment based on evaluation as trivalent chromium, but was identified as a COPC based on evaluation as trivalent chromium in piezometer water.

The chromium species present in shellfish tissue is presumed to be trivalent due to the greater chemical stability of trivalent chromium as compared to hexavalent chromium, the general reducing conditions in foods, and the greater oxidizing potential of hexavalent chromium that causes its irreversible reduction to trivalent chromium in living organisms (USFDA, 1993; IOM, 2001). Hexavalent chromium is rapidly converted to the trivalent form after entering the stomach, and is therefore not considered by USEPA to pose a cancer risk via the ingestion route of exposure (USEPA, 2013). The USFDA Guidance for Chromium in Shellfish considers all chromium reported in shellfish as trivalent chromium and derives levels of concern for chromium in shellfish based on safe dietary intake levels rather than an adverse health effect endpoint (USFDA, 1993). Due to the likelihood that all chromium present in food and living organisms is present as trivalent chromium and the USFDA guidance assuming all chromium is trivalent chromium in shellfish, the HHRA evaluated total chromium concentrations in shellfish tissue as trivalent chromium.

6.4.4 Exposure Assessment

The primary areas of uncertainty affecting exposure parameter estimation involve the assumptions regarding exposure pathways, the estimation of EPCs, and the parameters used to estimate chemical doses. The uncertainties associated with these various sources are discussed below.

6.4.4.1 EPCs

With respect to determining EPCs for this evaluation, one assumption was that the concentrations of chemicals in the medium evaluated would remain constant over the exposure time. Depending on the properties of the chemical and the medium in which it was detected, this assumption may overestimate risks, depending on the degree of chemical degradation to less toxic species or transport to other media. Conversely, environmental bioactivation of chemicals to more toxic

chemicals was also not considered. Therefore, this assumption may underestimate risk if bioactivation mechanisms are significant.

The majority of the maximum detected piezometer water concentrations in the updated dataset are lower than those calculated in the 2013 HHRA. However, the updated shallow groundwater EPCs for several COPCs have increased (between 1 to 23 times higher) in comparison to the EPCs calculated in the 2013 HHRA. The increase in EPCs, despite the decrease in overall concentrations, is likely due in part to a smaller sample size and higher reporting limits used for non-detect results utilized in the calculation of the UCL selected as the EPC.

6.4.4.2 Exposure Assumptions

The parameter values used to describe the extent, frequency, and duration of exposure are associated with some uncertainty. Actual risks for some individuals within an exposed population may vary from those predicted depending on the actual exposure durations, intake rates (e.g., ingestion rates), or body weights.

There are no formal recreational facilities (e.g., public swimming areas) currently located along the Site 09 shoreline and there are no known plans for development of formal recreational facilities in the future. Therefore, it is unlikely that a young child would be routinely exposed to the environmental media along this shoreline. However, some uncertainty is introduced by the exclusion of a young child receptor. This uncertainty is not considered to change the conclusions of the 2017 HHRA update, which are generally consistent with those from the 2013 HHRA.

The exposure assumptions were generally selected to produce a reasonable upper-bound estimate of exposure in accordance with USEPA guidelines, although in some cases the combination of the various assumptions may lead to greater than an upper bound estimate. Therefore, exposures and estimated potential risks for the evaluated receptors are likely to be representative of reasonable upper-bound exposures, but in some cases may exceed reasonable upper-bound exposures.

7.0 SUMMARY AND CONCLUSIONS

This HHRA update was performed in support of the Site 09 Five Year Event LTM Report and will ultimately be used as part of the evaluation in the Fourth Five Year Review to confirm compliance with the RAOs identified in the ROD (EA, 1997). The objective of this HHRA update is to determine whether there have been any changes and/or updates to USEPA HHRA guidance or site-specific conditions since the 2013 HHRA was conducted that would result in a change of the conclusions of the 2013 HHRA or whether the conclusions of the 2013 HHRA remain valid. Revised risk/hazard calculations were performed as part of this 2017 HHRA update to estimate the cumulative potential cancer risk and/or noncancer hazard associated with a recreational user exposure scenario, determine whether risk/hazard estimates exceed USEPA and/or RIDEM target risk/hazard levels, and identify whether the current institutional controls in place at Site 09 are still needed. The receptors and exposure pathways evaluated in the HHRA update are consistent with those evaluated in the 2013 HHRA based on current and potential future land use, including recreational users exposed to shoreline media while swimming, wading, and clamming/harvesting shellfish.

The overall conclusion of this HHRA update is that the conclusions of the 2013 HHRA remain valid and ingestion of shellfish tissue obtained from the Site 09 shoreline by a current/future recreational user poses a potential cancer risk or noncancer hazard above RIDEM target levels due to arsenic, PCBs, and pesticides (specifically aldrin). Based on this conclusion, the current institutional control prohibiting ingestion of shellfish continues to be necessary to protect public health. The shellfish tissue EPCs for arsenic and aldrin are within the range of concentrations detected in reference tissue samples collected from the shoreline of Prudence Island and from Fishing Cove in Wickford, Rhode Island between 2007 and 2011. These results indicate that concentrations of arsenic and aldrin in site shellfish tissue samples evaluated in the 2017 HHRA update may be due to background conditions, rather than Site 09. In addition, the shellfish tissue EPC for PCBs is less than the range of PCB concentrations detected in samples collected in 2011 (the most currently available dataset) through the NOAA Mussel Watch Program. This suggests that some of the PCB contamination noted in the Site 09 samples may reflect regional conditions.

If both arsenic and aldrin concentrations in shellfish tissue are excluded from the 2017 HHRA update, the cumulative potential ELCR associated with a lifetime recreational user exposure to shallow sediment (assuming a swimming/wading scenario), groundwater (piezometer water), and shellfish is $1x10^{-5}$. This potential ELCR is within USEPA's target risk range of 10^{-6} to 10^{-4} and equal to RIDEM's target risk level of 10^{-5}. The associated total potential noncancer HI (conservatively based on all target endpoints combined) does not exceed USEPA or RIDEM's target level. Therefore, no site-related COCs are identified as a result of the 2017 HHRA update.

Notes:

Refer to Appendix A for samples included in data set.

Shallow sediment is defined as sediment samples collected from within the 0 to 0.5 ft bgs depth interval.

Deep sediment is defined as sediment samples collected from within the 1.5 to 3 ft bgs depth interval.

Totals for use in risk assessment are calculated as discussed in the report text and have a CAS number beginning with "RA-".

ARAR/TBC = Applicable or Relevant and Appropriate Requirements/To be Considered.

C = Cancer. Screening value is based on the screening level protective of carcinogenic effects.

CAS = Chemical Abstracts Service.

COPC = Chemical of Potential Concern.

ft = feet.

ft bgs = feet below ground surface.

in = Inches.

L = Lead screening level developed by USEPA using blood-lead modeling based on target blood lead concentrations (USEPA Regional Screening Level (RSL) Table User's Guide, May 2016).

mg/kg = milligrams per kilogram.

N/A = Not Applicable or Not Available.

NC = Noncancer. Screening value is based on the screening level protective of noncarcinogenic effects.

PCBs = Polychlorinated biphenyls.

SVOCs = Semivolatile organic compounds.

USEPA = United States Environmental Protection Agency.

VOCs = Volatile organic compounds.

(1) Minimum/maximum detected concentration and associated data flags.
EB = Equipment blank contamination.
J = The chemical was positively identified; however, the associated numerical value is an estimated concentration.
J+ = The chemical was positively identified; however, the associated numerical value is a high estimated concentration.
J- = The chemical was positively identified; however, the associated numerical value is a low estimated concentration.

(2) Range of Laboratory Reporting Limits (RLs).

(3) Maximum detected concentration used for screening.

(4) Background values were not used for COPC screening purposes, although applicable background values may be considered in the risk characterization portion of the risk assessment update, if available.

(5) Sediment screening levels include the following:
- USEPA Regional Screening Level (RSL) for residential soil based on a target risk level of 1E-6 for carcinogens and a target hazard quotient of 0.1 for noncarcinogens (May 2016).
The screening value for trivalent chromium was used for total chromium.
The screening value for endrin was used for endrin aldehyde.
The screening value for manganese (non-diet) was used for manganese.
The screening value for acenaphthene was used for acenaphthylene.
The screening value for mercuric chloride was used for mercury.
The screening value for pyrene was used for benzo(g,h,i)perylene.
The screening value for Aroclor 1254 was used for total PCBs.
The screening value for anthracene was used for phenanthrene.
USEPA RSLs were updated for carcinogenic polycyclic aromatic hydrocarbons (PAHs) (i.e., benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, chrysene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene) to reflect USEPA's final Integrated Risk Information System (IRIS) assessment of benzo(a)pyrene (USEPA. IRIS Toxicological Review of Benzo[a]pyrene (Final Report). U.S. Environmental Protection Agency, Washington, DC, EPA/635/R-17/003F, 2017).
- RIDEM Residential Direct Exposure Criteria - RIDEM Rules and Regulations for the Investigation and Remediation of Hazardous Material Releases, DEM-DSR-01-93. November 2011.
The screening value for trivalent chromium was used for total chromium.

(6) Rationale Codes:
Selection Reason: Above Screening Level (ASL)
Deletion Reason: Below Screening Level (BSL)

Notes:

Refer to Appendix A for samples included in the data set. The groundwater data evaluated in the HHRA Update includes piezometer water samples collected along the Site 09 shoreline, which represent both groundwater and surface water.

ARAR/TBC = Applicable or Relevant and Appropriate Requirements/To be Considered.

C = Cancer. Screening value is based on the screening level protective of carcinogenic effects.

CAS = Chemical Abstracts Service.

COPC = Chemical of Potential Concern.

MCL = Maximum Contaminant Level.

N/A = Not Applicable or Not Available.

NC = Noncancer. Screening value is based on the screening level protective of noncarcinogenic effects.

RIDEM = Rhode Island Department of Environmental Management.

SVOCs = Semivolatile organic compounds.

ug/L = micrograms per liter.

USEPA = United States Environmental Protection Agency.

VOCs = Volatile organic compounds.

(1) Minimum/maximum detected concentration and associated data flags.

J = The chemical was positively identified; however, the associated numerical value is an estimated concentration.

J- = The chemical was positively identified; however, the associated numerical value is a low estimated concentration.

(2) Range of Laboratory Reporting Limits (RLs).

(3) Maximum detected concentration used for screening.

(4) Background values were not used for COPC screening purposes, although applicable background values may be considered in the risk characterization portion of the risk assessment update, if available.

(5) Groundwater screening levels include the following:

- USEPA Maximum Contaminant Levels (MCLs) for drinking water. Accessed April 2017. https://www.epa.gov/ground-water-and-drinking-water/table-regulated-drinking-water-contaminants.

- USEPA Regional Screening Level (RSL) for tapwater based on a target risk level of 1E-6 for carcinogens and a target hazard quotient of 0.1 for noncarcinogens (May 2016).

The screening value for trivalent chromium was used for total chromium.

The screening value for manganese (non-diet) was used for manganese.

The screening value for mercuric chloride was used for mercury.

The screening value for pyrene was used for benzo(g,h,i)perylene.

The screening value for anthracene was used for phenanthrene.

USEPA RSLs were updated for carcinogenic polycyclic aromatic hydrocarbons (PAHs) (i.e., benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, chrysene, and indeno(1,2,3-cd)pyrene) to reflect USEPA's final Integrated Risk Information System (IRIS) assessment of benzo(a)pyrene (USEPA. IRIS Toxicological Review of Benzo[a]pyrene (Final Report). U.S. Environmental Protection Agency, Washington, DC, EPA/635/R-17/003F, 2017).

- RIDEM GA Groundwater Objectives - RIDEM Rules and Regulations for the Investigation and Remediation of Hazardous Material Releases, DEM-DSR-01-93. November 2011.

(6) Rationale Codes:

Selection Reason: Above Screening Level (ASL)

Deletion Reason: Below Screening Levels (BSL)

Notes:

Shading indicates a difference between the COPC lists identified in the 2013 HHRA (a) and based on the current dataset (as defined in the text).

CAS = Chemical Abstracts Service.

COPC = Chemical of Potential Concern.

HHRA = Human Health Risk Assessment.

PCBs = Polychlorinated biphenyls.

SVOCs = Semivolatile organic compounds.

VOCs = Volatile organic compounds.

(a) 2013 HHRA presented in Appendix F of the Long-Term Monitoring Data Summary and Optimization Recommendations Report (Tetra Tech; August 2015).

(b) Selected in Tables 2.1 and 2.2 based on data set described in the text and as presented in Appendix A.

Notes:

CAS = Chemical Abstracts Service.

EPC = Exposure point concentration.

HHRA = Human health risk assessment.

mg/kg = milligrams per kilogram.

PCBs = Polychlorinated biphenyls.

RME = Reasonable Maximum Exposure.

SVOCs = Semivolatile organic compounds.

UCL = Upper confidence limit.

USEPA = United States Environmental Protection Agency.

(1) Kaplan-Meier (KM) mean calculated using USEPA's ProUCL software version 5.1.002 (May 2016).

(a) KM method mean only calculated for datasets of sufficient sample size containing non-detects. Arithmetic means were used if KM method mean was not calculated.

(2) UCL calculations were performed using USEPA's ProUCL software version 5.1.002 (May 2016). For data sets with multiple detection limits for non-detects, the use of the Kaplan Meier non-parametric test procedure is recommended and used to calculate an appropriate UCL. For the Kaplan Meier test procedure, the type of data distribution was determined using a series of tests (Shapiro-Wilk, Kolmogorov-Smirnov, Anderson-Darling) for normal, lognormal, or gamma data distributions. The results of these distribution tests determined which UCL calculation was performed. The UCL suggested by ProUCL is used, unless otherwise noted. In cases where more than one UCL is suggested, the higher UCL is used, unless otherwise noted.
NP = Non-parametric; N = Normal; LN = Lognormal; G = Gamma; NC = Not calculated.

(3) Equal to the maximum detected concentration.
J = The chemical was positively identified; however, the associated numerical value is an estimated concentration only.
J+ = The chemical was positively identified; however, the associated numerical value is a high estimated concentration.

(4) Indicates the statistic on which the exposure point concentration is based.

TABLE 3.1
EXPOSURE POINT CONCENTRATION SUMMARY AND COMPARISON
REASONABLE MAXIMUM EXPOSURE
HUMAN HEALTH RISK ASSESSMENT UPDATE
SITE 09 - ALLEN HARBOR LANDFILL
FORMER NAVAL CONSTRUCTION BATTALION CENTER DAVISVILLE
NORTH KINGSTOWN, RHODE ISLAND

Scenario Timeframe:	Current/Future
Medium:	Shallow Sediment
Exposure Medium:	Shallow Sediment

Exposure Point	Chemical of Potential Concern	CAS Number	Units	Mean (1)	UCL (Distribution) (2)	Maximum Concentration (Qualifier) (3)	Exposure Point Concentration - 2017 HHRA Update				Exposure Point Concentration - 2013 HHRA	
							Value	Units	Statistic (4)	Rationale (5)	Value	
											Unweighted (6)	Weighted (7)

95% Adjusted Gamma UCL = Calculated using Adjusted Gamma distribution procedure.

95% KM (Chebyshev) UCL = Calculated using 95% Kaplan Meier (Chebyshev inequality) non-parametric procedure.

95% KM (t) UCL = Calculated using 95% Kaplan Meier (Student's t approximation) non-parametric procedure.

95% Modified-t UCL = Calculated using a modified t approximation procedure.

95% Student's-t UCL = Calculated using a normal Student's t approximation procedure.

(5) The UCL recommended by ProUCL is used (where multiple values are recommended, the higher is used).

(b) ProUCL computes and outputs the H-statistic based UCLs for historic reasons only as it often results in unstable (both low and high) values (USEPA, 2010).

As such, the 95% Modified-t UCL UCL was used to estimate the 95% UCL for this data set.

(6) EPCs presented in Table F-2.3 of the 2013 HHRA. These EPCs were calculated as the 95% UCL (or maximum detected concentration if a sufficient number of samples were not available to calculate a UCL) based on 2012 sediment data.

(7) EPCs presented in Tables F-2.4 and F-2.5 of the 2013 HHRA. These EPCs were calculated as the 95% UCL (or maximum detected concentration if a sufficient number of samples were not available to calculate a UCL) based on 2012 sediment data, weighted to account for elevated carcinogenic polycyclic aromatic hydrocarbon concentrations at location SED09-10.

Notes:
CAS = Chemical Abstracts Service.
EPC = Exposure point concentration.
HHRA = Human health risk assessment.
N/A = Not available.
RME = Reasonable Maximum Exposure.
SVOCs = Semivolatile organic compounds.
UCL = Upper confidence limit.
ug/L = micrograms per liter.

EXPOSURE POINT CONCENTRATION SUMMARY AND COMPARISON
REASONABLE MAXIMUM EXPOSURE
HUMAN HEALTH RISK ASSESSMENT UPDATE
SITE 09 - ALLEN HARBOR LANDFILL
FORMER NAVAL CONSTRUCTION BATTALION CENTER DAVISVILLE
NORTH KINGSTOWN, RHODE ISLAND

Scenario Timeframe:	Current/Future
Medium:	Groundwater
Exposure Medium:	Shallow Groundwater (Piezometer Water)

Exposure Point	Chemical of Potential Concern	CAS Number	Units	Mean (1)	UCL (Distribution) (2)	Maximum Concentration (Qualifier) (3)	Exposure Point Concentration - 2017 HHRA Update				Exposure Point Concentration - 2013 HHRA
							Value	Units	Statistic (4)	Rationale (5)	Value (6)

USEPA = United States Environmental Protection Agency.

VOCs = Volatile organic compounds.

(1) Kaplan-Meier (KM) mean calculated using USEPA's ProUCL software version 5.1.002 (May 2016).

(a) KM method mean only calculated for datasets of sufficient sample size containing non-detects. Arithmetic means were used if KM method mean was not calculated.

(2) UCL calculations were performed using USEPA's ProUCL software version 5.1.002 (May 2016). For data sets with multiple detection limits for non-detects, the use of the Kaplan Meier non-parametric test procedure is recommended and used to calculate an appropriate UCL. For the Kaplan Meier test procedure, the type of data distribution was determined using a series of tests (Shapiro-Wilk, Kolmogorov-Smirnov, Anderson-Darling) for normal, lognormal, or gamma data distributions. The results of these distribution tests determined which UCL calculation was performed. The UCL suggested by ProUCL is used, unless otherwise noted. In cases where more than one UCL is suggested, the higher UCL is used, unless otherwise noted.
NP = Non-parametric; N = Normal; LN = Lognormal; G = Gamma; NC = Not calculated.

(3) Equal to the maximum detected concentration.
J = The chemical was positively identified; however, the associated numerical value is an estimated concentration only.
J- = The chemical was positively identified; however, the associated numerical value is a low estimated concentration.

(4) Indicates the statistic on which the exposure point concentration is based.
Maximum = Maximum detected concentration.
95% Chebyshev (Mean, Sd) UCL = Calculated using Chebyshev inequality non-parametric procedure.
95% Gamma Adjusted KM-UCL = Calculated using Kaplan Meier Adjusted Gamma distribution procedure.
95% KM (Chebyshev) UCL = Calculated using 95% Kaplan Meier (Chebyshev inequality) non-parametric procedure.
95% KM (t) UCL = Calculated using 95% Kaplan Meier (Student's t approximation) non-parametric procedure.
97.5% KM (Chebyshev) UCL = Calculated using 97.5% Kaplan Meier (Chebyshev inequality) non-parametric procedure.

(5) The UCL recommended by ProUCL is used (where multiple values are recommended, the higher is used).
(b) Maximum detected concentration used for EPC due to the low number of detections or small sample size.

(6) EPCs presented in Tables F-2.9 (includes total metals) and F-2.10 (includes dissolved metals) of the 2013 HHRA. These EPCs were calculated as the 95% UCL (or maximum detected concentration if a sufficient number of samples were not available to calculate a UCL) based on 2010 through 2012 piezometer water data.

Notes:
CAS = Chemical Abstracts Service.
EPC = Exposure point concentration.
HHRA = Human health risk assessment.
mg/kg = milligrams per kilogram.
N/A = Not applicable.
PCBs = Polychlorinated biphenyls.
RME = Reasonable Maximum Exposure.
SVOCs = Semivolatile organic compounds.
UCL = Upper confidence limit.

TABLE 3.3
EXPOSURE POINT CONCENTRATION SUMMARY AND COMPARISON
REASONABLE MAXIMUM EXPOSURE
HUMAN HEALTH RISK ASSESSMENT UPDATE
SITE 09 - ALLEN HARBOR LANDFILL
FORMER NAVAL CONSTRUCTION BATTALION CENTER DAVISVILLE
NORTH KINGSTOWN, RHODE ISLAND

Scenario Timeframe:	Current/Future
Medium:	Shellfish tissue
Exposure Medium:	Shellfish tissue

Exposure Point	Chemical of Potential Concern (1)	CAS Number	Units	Mean (2)	UCL (Distribution) (3)	Maximum Concentration (Qualifier) (4)	Exposure Point Concentration - 2017 HHRA Update				Exposure Point Concentration - 2013 HHRA
							Value	Units	Statistic (5)	Rationale (6)	Value (7)

USEPA = United States Environmental Protection Agency.

VOCs = Volatile organic compounds.

(1) All compounds detected in fish tissue between 2013 - 2016 are included.

(2) Kaplan-Meier (KM) mean calculated using USEPA's ProUCL software version 5.1.002 (May 2016).

(a) KM method mean only calculated for datasets of sufficient sample size containing non-detects. Arithmetic means were used if KM method mean was not calculated.

(3) UCL calculations were performed using USEPA's ProUCL software version 5.1.002 (May 2016). For data sets with multiple detection limits for non-detects, the use of the Kaplan Meier non-parametric test procedure is recommended and used to calculate an appropriate UCL. For the Kaplan Meier test procedure, the type of data distribution was determined using a series of tests (Shapiro-Wilk, Kolmogorov-Smirnov, Anderson-Darling) for normal, lognormal, or gamma data distributions. The results of these distribution tests determined which UCL calculation was performed. The UCL suggested by ProUCL is used, unless otherwise noted. In cases where more than one UCL is suggested, the higher UCL is used, unless otherwise noted.
NP = Non-parametric; N = Normal; LN = Lognormal; G = Gamma; NC = Not calculated.

(4) Equal to the maximum detected concentration.
J = The chemical was positively identified; however, the associated numerical value is an estimated concentration only.

(5) Indicates the statistic on which the exposure point concentration is based.
Maximum = Maximum detected concentration.
95% Adjusted Gamma UCL = Calculated using Adjusted Gamma distribution procedure.
95% Chebyshev (Mean, Sd) UCL = Calculated using Chebyshev inequality non-parametric procedure.
95% Gamma Adjusted KM-UCL = Calculated using Kaplan Meier Adjusted Gamma distribution procedure.
95% GROS Adjusted Gamma UCL = Calculated using adjusted gamma regression on order statistics procedure.
95% KM (Chebyshev) UCL = Calculated using 95% Kaplan Meier (Chebyshev inequality) non-parametric procedure.
95% KM (t) UCL = Calculated using 95% Kaplan Meier (Student's t approximation) non-parametric procedure.
95% KM H-UCL = Calculated using 95% Kaplan Meier (Land's H-stat) lognormal procedure.
95% Student's-t UCL = Calculated using a normal Student's t approximation procedure.
KM Student's-t UCL = Calculated using a Kaplan Meier (Student's t approximation) lognormal procedure.

(6) The UCL recommended by ProUCL is used (where multiple values are recommended, the higher is used).
(b) Maximum detected concentration used for EPC due to the low number of detections or small sample size.
(c) 95% UCL exceeds maximum detected concentration. Therefore, maximum concentration used for EPC
(d) ProUCL computes and outputs the H-statistic based UCLs for historic reasons only as it often results in unstable (both low and high) values (USEPA, 2010).
As such, the 95% Chebyshev (Mean, Sd) UCL was used to estimate the 95% UCL for this data set.

(7) EPCs presented in Table F-1.7 of the 2013 HHRA. These EPCs were calculated as the 95% UCL (or maximum detected concentration if a sufficient number of samples were not available to calculate a UCL) based on May 2010 through 2012 shellfish data.

NORTH KINGSTOWN, RHODE ISLAND

				Adolescent Recreator			Adult Recreator		
Exposure Media/ Scenario	Exposure Route(s)	Parameter	Units	2013 HHRA	Current Value	Current Source	2013 HHRA	Current Value	Current Source

Notes:

Shading indicates a difference between exposure assumptions/unit intakes utilized in the 2013 HHRA in comparison to current exposure assumptions/unit intakes.

BPJ = best professional judgement.

cm^2 = square centimeters.

HHRA = Human Health Risk Assessment.

kg = kilograms.

mg = milligrams.

USEPA = United States Environmental Protection Agency.

(1) Recommended mean body weight. Weighted average of recommended mean body weight for the associated age range (USEPA, 2011; Table 8-3).

(2) Equal to the central tendency ingestion rate for soil and dust by the general population (Table 5-1). Central tendency value used given the application of a default soil and dust ingestion rate to sediment is conservative.

(3) Assumes three days a week from April through October based on best professional judgement.

(4) The exposure duration for an adolescent reflects the 10 years from ages 7 to 16 years old.

(5) The exposure duration for the adult recreator was conservatively selected such that the combined exposure duration of the adolescent and adult recreator equals the default residential exposure duration (i.e., 26 years; USEPA, 2014), consistent with the approach used in the 2013 HHRA.

(6) Represents weighted mean surface area for males and females, including hands, forearms, lower legs, and feet, for ages 7 to 16 years old.

(7) Represents weighted mean surface area for adult males and females, including hands, lower legs and feet.

(8) BPJ; Represents a more conservative adherence factor than the recommended value for children playing in tidal flat sediment for all body areas except feet (USEPA, 2011; Table 7-4).

(9) Represents the weighted geometric mean adherence factor for adult reed gatherers (forearms, hands, lower legs, and feet) (USEPA, 2004; Exhibit C-2).

(10) Assumes 33 percent of total body skin surface area (i.e., 13,350 cm^2; weighted average of recommended mean surface area for the associated age [USEPA, 2011; Table 7-1]) is exposed.

(11) Represents weighted mean surface area for adult males and females, including hands, forearms, lower legs and feet.

(12) Assumes 10 percent of total body skin surface area (i.e., 13,350 cm^2; weighted average of recommended mean surface area for the associated age [USEPA, 2011; Table 7-1]) is exposed.

(13) Assumes 10 percent of total body skin surface area of an adult resident (i.e., 19,652 cm^2 [USEPA, 2014]).

(14) Unit Intakes for sediment exposure were calculated as follows, consistent with the equations utilized in the 2013 HHRA (Attachment 2) to calculate the Risk-Based Concentrations:

Incidental ingestion Intake [(mg/kg-day)(kg/mg)] =

[Ingestion Rate (mg/day) x conversion factor (1E-6 kg/mg) x exposure frequency (days/year) x exposure duration (years) x Fraction from contaminated source (unitless)] / [body weight (kg) x averaging time (days)]

Dermal Intake [(mg/kg-day)/(kg/mg)] =

[surface area (cm^2) x adherence factor (mg/cm^2-event) x event frequency (events/day) x exposure frequency (days/year) x exposure duration (years) x conversion factor (1E-6 kg/mg)] / [body weight (kg) x averaging time (days)]

(15) Unit Intakes for water exposure were calculated as follows, consistent with the equations utilized in the 2013 HHRA (Attachment 2) to calculate the Risk-Based Concentrations:

Dermal Intake [(cm^2-event)/(kg-day)] = [surface area (cm^2) x event frequency (events/day) x exposure frequency (days/year) x exposure duration (years)] / [body weight (kg) x averaging time (days)]

(16) Value for the "refined adherence factor" scenario used.

Notes:

CAS = Chemical Abstracts Service.

HHRA = Human Health Risk Assessment.

N/A = Not Applicable/Not Available.

mg/kg-day = milligrams per kilogram per day.

PCBs = Polychlorinated biphenyls.

RfD = Reference Dose.

SVOCs = Semivolatile organic compounds.

USEPA = United States Environmental Protection Agency.

VOCs = Volatile organic compounds.

Shading indicates a difference between toxicity information utilized in the 2013 HHRA in comparison to current toxicity information obtained in accordance with USEPA's recommended hierarchy discussed in the report text.

(1) The following surrogates were used for chemicals without available toxicity values or with multiple forms:

Value for trivalent chromium was used for total chromium.

Value for manganese (non-diet) was used for manganese.

Value for mercuric chloride was used for mercury.

Value for Aroclor 1254 was used for total PCBs.

(2) Oral Absorption Efficiencies from Exhibit 4-1 (USEPA, 2004. Risk Assessment Guidance for Superfund, Part E).

(3) Calculated as: (oral RfD) x (oral to dermal adjustment factor).

(4) Toxicity data obtained from the following sources:

TABLE 5

COMPARISON OF NON-CANCER TOXICITY DATA -- ORAL/DERMAL

Chemical of Potential Concern (1)	CAS Number	Chronic/ Subchronic	Oral RfD			Oral Absorption Efficiency For Dermal (2)	Absorbed RfD for Dermal (3)			Primary Target Organ(s)		Combined Uncertainty/Modifying Factors (Current)	RfD:Target Organ(s) (4)			
			Value		Units		Value		Units				2013 HHRA		Current	
			2013 HHRA	Current			2013 HHRA	Current		2013 HHRA	Current		Source(s)	Date(s)	Source(s)	Date(s)

H - USEPA Health Effects Assessment Summary Table [https://epa-heast.ornl.gov/]

I - USEPA Integrated Risk Information System [https://www.epa.gov/iris].

P - USEPA Provisional Peer Reviewed Toxicity Values Appendix [https://hhpprtv.ornl.gov/].

(5) Oral absorption efficiency exceeds 50%. Therefore, no adjustment of the oral RfD is necessary (USEPA, 2004. Exhibit 4-1).

(6) An absorbed RfD of 4.0E-4 mg/kg-day was used in the 2013 HHRA for evaluation of the sediment - adolescent and adult recreational user - swimming/wading scenarios. The use of this alternate absorbed RfD, which is equaivalent to the oral RfD without adjusting per USEPA RAGS Part E, appears to have been used in error.

Notes:

CAS = Chemical Abstracts Service.

CSF = Cancer Slope Factor.

HHRA = Human Health Risk Assessment.

N/A = Not Applicable/Not Available.

mg/kg-day = Milligrams per kilogram per day.

PCBs = Polychlorinated biphenyls.

SVOCs = Semivolatile organic compounds.

USEPA = United States Environmental Protection Agency.

VOCs = Volatile organic compounds.

Shading indicates a difference between toxicity information utilized in the 2013 HHRA in comparison to current toxicity information obtained in accordance with USEPA's recommended hierarchy discussed in the report text.

Weight of Evidence Characterization/USEPA Group:

A - Human carcinogen

B1 - Probable human carcinogen - indicates that limited human data are available

B2 - Probable human carcinogen - indicates sufficient evidence in animals and inadequate or no evidence in humans

C - Possible human carcinogen

D - Not classifiable as a human carcinogen (by the oral route)

LIKELY - Likely to be carcinogenic to humans.

INADEQUATE - Inadequate information to assess carcinogenic potential.

TABLE 6

COMPARISON OF CANCER TOXICITY DATA -- ORAL/DERMAL

HUMAN HEALTH RISK ASSESSMENT UPDATE

SITE 09 - ALLEN HARBOR LANDFILL

FORMER NCBC DAVISVILLE

Chemical of Potential Concern (1)	CAS Number	Oral Cancer Slope Factor			Oral Absorption Efficiency for Dermal (2)	Absorbed Cancer Slope Factor for Dermal (3)			Weight of Evidence/ Cancer Guideline Description (USEPA Group)	Oral CSF (4)				Mutagen?
		Value		Units		Value		Units		Source(s) 2013 HHRA	Date(s) (MM/YYYY)	Source(s) Current	Date(s) (MM/YYYY)	
		2013 HHRA	Current			2013 HHRA	Current							

(1) The following surrogates were used for chemicals without available screening levels or with multiple forms:

Value for Aroclor 1254 was used for total PCBs.

(2) Oral Absorption Efficiencies from Exhibit 4-1 (USEPA, 2004. Risk Assessment Guidance for Superfund, Part E).

(3) Calculated as: (oral slope factor) / (oral to dermal adjustment factor)

(4) Toxicity data obtained from the following sources:

E - USEPA Regional Screening Levels for Chemical Contaminants at Superfund Sites User's Guide Section 2.3.5

I - USEPA Integrated Risk Information System [https://www.epa.gov/iris].

S - USEPA Regional Screening Levels for Chemical Contaminants at Superfund Sites User's Guide Section 5

(5) Oral absorption efficiency exceeds 50%. Therefore, no adjustment of the oral RfD is necessary (USEPA, 2004. Exhibit 4-1).

(6) Values for carcinogenic polycyclic aromatic hydrocarbons (cPAHs) calculated by application of the appropriate relative potency factor (USEPA, 1993) to the slope factor for benzo(a)pyrene.

(7) Cancer toxicity values for vinyl chloride account for mutagenic action, such that age-dependent adjustment factors (ADAFs) are not applied for vinyl chloride.

Notes:

CAS = Chemical Abstracts Service.

N/A = Not Applicable. Chemical is not assessed via this pathway.

SVOC = Semi-volatile organic compound.

VOC = Volatile organic compound.

USEPA, 2004. Risk Assessment Guidance for Superfund. Vol. 1, Part E. July, 2004.

(a) USEPA, 2004. Exhibit B-3 (Organics).

(b) USEPA, 2004. Exhibit 3-1. (Inorganics)

(c) Default for all other inorganics.

(d) Value is calculated as follows:

Z (inorganics) (L/cm^2-event) = Kp (cm/hr) x tevent (hr/event) x 0.001 L/cm^3

Z (organics) (L/cm^2-event): If tevent < t*, Then Z = 2 FA x Kp [square root (6 x t x tevent/p)] x 0.001 L/cm^3

Z (organics) (L/cm^2-event): If tevent > t*, Then Z = FA x Kp [(tevent/1 + B) + 2 t ((1 + 3 B + 3 B^2)/(1 + B)^2)] x 0.001 L/cm^3

Value is equal to Daevent (USEPA, 2004; Equations 3.2, 3.3, and 3.4) without the water concentration included.

(e) Equation A-4. Default value.

(f) Exhibit B-2.

(g) Value for trivalent chromium used.

(h) Dermal pathway is considered to be negligible, therefore, the dermal exposure pathway is not quantitatively evaluated, as discussed in the report text.

Definitions:

B - Relative Contribution of Permeability Coefficient.

DAevent - Absorbed dose per event.

Dsc - Effective diffusion coefficient through stratum corneum.

FA - Fraction Absorbed.

Kow - Octanol-Water Partition Coefficient.

Kp - Dermal Permeability Coefficient.

lsc - Apparent thickness of stratum corneum.

MW - Molecular Weight.

t - lag time (hr/event).

t* - Time to reach steady state.

TABLE 9.1
POTENTIAL CANCER RISKS AND NONCANCER HAZARD QUOTIENTS - RECREATIONAL USER - SWIMMING/WADING
HUMAN HEALTH RISK ASSESSMENT UPDATE
SITE 09 - ALLEN HARBOR LANDFILL
FORMER NCBC DAVISVILLE
NORTH KINGSTOWN, RHODE ISLAND

Scenario Timeframe: Current/Future
Receptor Population: Recreational Users - Swimming/Wading
Exposure Point: Site 09 - Shoreline

Medium	Receptor Age	Exposure Route	COPC	CAS	EPC (a)		Unit Intake - Cancer (b)		Unit Intake - Noncancer (b)		Cancer Toxicity Value - Cancer Slope Factor (c)		Noncancer Toxicity Value - Reference Dose (c)		ADAF	Sediment ABS (d)	Dermal Factor (Z) (L/cm^2-event) (d)	Potential Cancer Risk (e)	Potential Noncancer Hazard Quotient (e)
					Value	Units	Value	Units	Value	Units	Value	Units	Value	Units					

Notes:
ABS = Absorption factor.
ADAF = Age-Adjusted Absorption fraction.
CAS = Chemical Abstracts Service.
COPC = Chemical of potential concern.
EPC = Exposure point concentration.
HHRA = Human Health Risk Assessment.
mg/kg = milligram per kilogram.
N/A = Not applicable/available.
PCB = Polychlorinated Biphenyl.
SVOC - Semivolatile organic compound.
VOC - Volatile organic compound.
(a) Presented on EPC comparison Table 3.2.
(b) Calculated on Table 4.
(c) Noncancer and cancer toxicity values are presented on Tables 5 and 6, respectively.
(d) Sediment oral and dermal absorption factors from Table 7. Dermal factor (Z) calculated in Table 8.
(e) Potential cancer risks and noncancer hazard quotients were calculated per exposure route using the following equations. Potential risks and hazard quotients were then summed for all exposure routes per receptor age group.
Potential cancer risk:
Sediment: EPC x Unit Intake x Cancer Toxicity Value x Sediment ABS x ADAF
Groundwater: EPC x Unit Intake x Cancer Toxicity Value x ADAF x Dermal Factor (Z) x 0.001 mg/ug
Potential hazard quotient [HQ] =
Sediment: EPC x Unit Intake x (1/Noncancer Toxicity Value) x Sediment ABS
Groundwater: EPC x Unit Intake x (1/Noncancer Toxicity Value) x Dermal Factor (Z) x 0.001 mg/ug
(f) Potential cancer risk estimates for the lifelong scenario were calculated by summing the associated estimates for the adolescent and adult. Potential noncancer hazard quotients for the lifelong scenario are the associated estimates for the adolescent.

Scenario Timeframe: Current/Future
Receptor Population: Recreational Users - Clamming
Exposure Point: Site 09 - Shoreline

Medium	Receptor Age	Exposure Route	COPC	CAS	EPC (a)		Unit Intake - Cancer (b)		Unit Intake - Noncancer (b)		Cancer Toxicity Value - Cancer Slope Factor (c)		Noncancer Toxicity Value - Reference Dose (c)		ADAF	Sediment ABS (d)	Dermal Factor (Z) (L/cm^2-event) (d)	Potential Cancer Risk (e)	Potential Noncancer Hazard Quotient (e)
					Value	Units	Value	Units	Value	Units	Value	Units	Value	Units					

Notes:
ABS = Absorption factor.
ADAF = Age-Adjusted Absorption fraction.
CAS = Chemical Abstracts Service.
COPC = Chemical of potential concern.
EPC = Exposure point concentration.
HHRA = Human Health Risk Assessment.
mg/kg = milligram per kilogram.
N/A = Not applicable/available.
PCB = Polychlorinated Biphenyl.
SVOC - Semivolatile organic compound.
VOC - Volatile organic compound.
(a) Presented on EPC comparison Table 3.2.
(b) Calculated on Table 4.
(c) Noncancer and cancer toxicity values are presented on Tables 5 and 6, respectively.
(d) Sediment oral and dermal absorption factors from Table 7. Dermal factor (Z) calculated in Table 8.
(e) Potential cancer risks and noncancer hazard quotients were calculated per exposure route using the following equations. Potential risks and hazard quotients were then summed for all exposure routes per receptor age group.
Potential cancer risk:
Sediment: EPC x Unit Intake x Cancer Toxicity Value x Sediment ADAF x ABS
Groundwater: EPC x Unit Intake x Cancer Toxicity Value x ADAF x Dermal Factor (Z) x 0.001 mg/ug
Potential hazard quotient [HQ] =
Sediment: EPC x Unit Intake x (1/Noncancer Toxicity Value) x Sediment ADAF x ABS
Groundwater: EPC x Unit Intake x (1/Noncancer Toxicity Value) x ADAF x Dermal Factor (Z) x 0.001 mg/ug
(f) Potential cancer risk estimates for the lifelong scenario were calculated by summing the associated estimates for the adolescent and adult. Potential noncancer hazard quotients for the lifelong scenario are the associated estimates for the adolescent.

Potential Cumulative Cancer Risk / Total Hazard Index (q)					**3E-04**	**2.5**
Potential Cumulative Cancer Risk / Total Hazard Index - Calculated without Arsenic (r)					**1E-05**	**0.8**

Notes:
CAS = Chemical Abstracts Service.
EPC = Exposure point concentration.
mg/kg = milligram per kilogram.
N/A = Not applicable/available.
NC = Not calculated.
PCBs = Polychlorinated biphenyls.
SVOCs = Semivolatile organic compounds.
USEPA = United States Environmental Protection Agency.
(a) Calculated using the USEPA Regional Screening Level (RSL) calculator for fish consumption (accessed April 2017). Screening levels are based on a shellfish ingestion rate of 12.8 g/day (95th percentile per capita intake rate for freshwater/estuarine fish [USEPA, 2011]), and a target cancer risk level of 1E-6 and a target hazard quotient of 1.
(b) For potential carcinogens, the potential cancer risk is estimated as follows:

$$\frac{[EPC]}{\text{(fish screening level based on cancer endpoint)} \times 1E\text{-}6}$$

(c) For potential noncarcinogens, the hazard quotient (HQ) is estimated as follows:

$$\frac{[EPC]}{\text{(fish screening level based on noncancer endpoint)} \times 1}$$

(d) The screening value for cadmium (diet) was used.
(e) The screening value for trivalent chromium was used.
(f) The Food and Drug Administration (FDA) action level for lead in crustacea (FDA, 2007. National Shellfish Sanitation Program. Guide for the Control of Molluscan Shellfish. 2007) was used for lead (1.5 mg/kg). Cancer risk and noncancer hazard quotients were not calculated.
(g) The screening value for manganese (diet) was used.
(h) The screening value for methyl mercury was used.
(i) The screening value for Aroclor 1254 was used.
(j) The screening value for chlordane was used.
(k) The screening value for alpha-BHC was used.
(l) The screening value for endosulfan was used.
(m) The screening value for endrin was used.
(n) The screening value for acenaphthene was used.
(o) The screening value for pyrene was used.
(p) The screening value for anthracene was used.
(q) Potential cumulative cancer risk is estimated by summing the potential risk for the individual chemicals. Total potential hazard index (HI) is estimated by summing the potential hazard quotient for the individual chemicals. The total HIs presented are overly conservative because they are based on additivity of hazard quotients for all selected constituents regardless of the target endpoint.
(r) Potential cumulative cancer risk and total potential HI, as described in (q), for all chemicals, excluding arsenic.
(s) Includes all chemicals detected at least once in shellfish tissue.
Shading indicates an exceedance of Rhode Island Department of Environmental Management's (RIDEM) target cumulative cancer risk level of 1E-5 or a target hazard quotient of 1.

Notes:
EPC = Exposure point concentration.
HHRA = Human health risk assessment.
PCBs = Polychlorinated biphenyls.
RIDEM = Rhode Island Department of Environmental Management.
UCL = Upper confidence limit on the arithmetic mean concentration.
USEPA = United States Environmental Protection Agency.
(a) The potential risk/hazard estimates from the 2013 HHRA are based on the following scenarios:
Incidental ingestion and dermal contact with shallow sediment while swimming/wading using the refined exposure assumptions and EPCs equal to the 95% UCL based on the 2012 dataset, including weighted EPCs for location SED09-10 for select carcinogenic polycyclic aromatic hydrocarbons (cPAHs) (Table F-2.5);
Incidental ingestion and dermal contact with shallow sediment while clamming using EPCs equal to the 95% UCL based on the 2012 dataset (Table F-2.6);
Dermal contact with piezometer water while clamming using EPCs equal to the 95% UCL based on the 2010 through 2012 dataset, including dissolved metals (Table F-2.10);
(Note: the potential cancer risk and noncancer hazard index estimates including the total metals (instead of the dissolved metals) dataset are 1E-6 and 0.09, respectively.)
Ingestion of shellfish using EPCs equal to the 95% UCL based on the 2010 through 2012 dataset (Table F-1.7).
(b) Potential cancer risk for lifetime recreational user (adolescent + adult).
(c) Potential noncancer hazard associated with sediment and groundwater presented for the adolescent recreational user.
(d) Risk drivers were identified as chemicals with an individual potential cancer risk greater than 1E-6, when the medium-specific total potential cancer risk for the receptor exceeds RIDEM's target cumulative risk level of 1E-5, and chemicals causing an exceedance of RIDEM's total noncancer hazard index of 1 per target endpoint.
(e) For informational purposes, and consistent with the 2013 HHRA, risk/hazard estimates are also provided excluding arsenic.
(f) The cumulative potential risk/hazard index estimates were calculated by summing the potential risk/hazard estimates for all exposure media. Potential risk/hazard estimates for shallow sediment for the swimming/wading scenario (instead of the clamming scenario) were utilized in the calculation of the cumulative risk/hazard estimates because it is the activity with the higher sediment exposure.
Green shading indicates an exceedance of RIDEM's cumulative target cancer risk level of 1E-5.
Yellow shading indicates an exceedance of RIDEM's cumulative target cancer risk level of 1E-5 and USEPA's cumulative target cancer risk range of 1E-6 to 1E-4, or an exceedance of RIDEM and USEPA's target hazard index of 1 per target endpoint.

Analyte Group	**Compound**	**CAS**	**Units**								

Notes:

< = Result not detected above laboratory reporting limit.

CAS = Chemical Abstracts Service.

EB = Equipment blank contamination.

FD = Field duplicate.

ft = feet.

in = inches.

J = Estimated value.

J+ = The chemical was positively identified; however, the associated numerical value is a high estimated concentration.

J- = The chemical was positively identified; however, the associated numerical value is a low estimated concentration.

mg/kg = milligram per kilogram.

N = Normal sample.

PCBs = Polychlorinated biphenyls.

SVOC = Semivolatile organic compound.

U = Not detected.

UJ = The analyte was not detected; and the reporting limit is approximate.

VOC = Volatile organic compound.

(a) Total concentrations were calculated per sample by summing only the detected individual compounds (i.e., Aroclor) concentrations. For samples without any detections of individual compounds (i.e., Aroclor), the maximum reporting detection limit within the sample is presented as a non-detect value.

Analyte Group	**Compound**	**CAS**	**Units**								

Notes:

< = Result not detected above laboratory reporting limit.

CAS = Chemical Abstracts Service.

EB = Equipment blank contamination.

FD = Field duplicate.

ft = feet.

in = inches.

J = Estimated value.

J+ = The chemical was positively identified; however, the associated numerical value is a high estimated concentration.

J- = The chemical was positively identified; however, the associated numerical value is a low estimated concentration.

mg/kg = milligram per kilogram.

N = Normal sample.

PCBs = Polychlorinated biphenyls.

SVOC = Semivolatile organic compound.

U = Not detected.

UJ = The analyte was not detected; and the reporting limit is approximate.

VOC = Volatile organic compound.

(a) Total concentrations were calculated per sample by summing only the detected individual compounds (i.e., Aroclor) concentrations. For samples without any detections of individual compounds (i.e., Aroclor), the maximum reporting detection limit within the sample is presented as a non-detect value.

Analyte Group	**Compound**	**CAS**	**Units**								

Notes:

< = Result not detected above laboratory reporting limit.

CAS = Chemical Abstracts Service.

EB = Equipment blank contamination.

FD = Field duplicate.

ft = feet.

in = inches.

J = Estimated value.

J+ = The chemical was positively identified; however, the associated numerical value is a high estimated concentration.

J- = The chemical was positively identified; however, the associated numerical value is a low estimated concentration.

mg/kg = milligram per kilogram.

N = Normal sample.

PCBs = Polychlorinated biphenyls.

SVOC = Semivolatile organic compound.

U = Not detected.

UJ = The analyte was not detected; and the reporting limit is approximate.

VOC = Volatile organic compound.

(a) Total concentrations were calculated per sample by summing only the detected individual compounds (i.e., Aroclor) concentrations. For samples without any detections of individual compounds (i.e., Aroclor), the maximum reporting detection limit within the sample is presented as a non-detect value.

Analyte Group	**Compound**	**CAS**	**Units**								

Notes:

< = Result not detected above laboratory reporting limit.

CAS = Chemical Abstracts Service.

EB = Equipment blank contamination.

FD = Field duplicate.

ft = feet.

in = inches.

J = Estimated value.

J+ = The chemical was positively identified; however, the associated numerical value is a high estimated concentration.

J- = The chemical was positively identified; however, the associated numerical value is a low estimated concentration.

mg/kg = milligram per kilogram.

N = Normal sample.

PCBs = Polychlorinated biphenyls.

SVOC = Semivolatile organic compound.

U = Not detected.

UJ = The analyte was not detected; and the reporting limit is approximate.

VOC = Volatile organic compound.

(a) Total concentrations were calculated per sample by summing only the detected individual compounds (i.e., Aroclor) concentrations. For samples without any detections of individual compounds (i.e., Aroclor), the maximum reporting detection limit within the sample is presented as a non-detect value.

Analyte Group	**Compound**	**CAS**	**Units**								

Notes:

< = Result not detected above laboratory reporting limit.

CAS = Chemical Abstracts Service.

EB = Equipment blank contamination.

FD = Field duplicate.

ft = feet.

in = inches.

J = Estimated value.

J+ = The chemical was positively identified; however, the associated numerical value is a high estimated concentration.

J- = The chemical was positively identified; however, the associated numerical value is a low estimated concentration.

mg/kg = milligram per kilogram.

N = Normal sample.

PCBs = Polychlorinated biphenyls.

SVOC = Semivolatile organic compound.

U = Not detected.

UJ = The analyte was not detected; and the reporting limit is approximate.

VOC = Volatile organic compound.

(a) Total concentrations were calculated per sample by summing only the detected individual compounds (i.e., Aroclor) concentrations. For samples without any detections of individual compounds (i.e., Aroclor), the maximum reporting detection limit within the sample is presented as a non-detect value.

Analyte Group	**Compound**	**CAS**	**Units**								

Notes:

< = Result not detected above laboratory reporting limit.

CAS = Chemical Abstracts Service.

EB = Equipment blank contamination.

FD = Field duplicate.

ft = feet.

in = inches.

J = Estimated value.

J+ = The chemical was positively identified; however, the associated numerical value is a high estimated concentration.

J- = The chemical was positively identified; however, the associated numerical value is a low estimated concentration.

mg/kg = milligram per kilogram.

N = Normal sample.

PCBs = Polychlorinated biphenyls.

SVOC = Semivolatile organic compound.

U = Not detected.

UJ = The analyte was not detected; and the reporting limit is approximate.

VOC = Volatile organic compound.

(a) Total concentrations were calculated per sample by summing only the detected individual compounds (i.e., Aroclor) concentrations. For samples without any detections of individual compounds (i.e., Aroclor), the maximum reporting detection limit within the sample is presented as a non-detect value.

Notes:

< = Result not detected above laboratory reporting limit.

CAS = Chemical Abstracts Service.

F = Filtered sample.

FD = Field duplicate.

FF = Field filtered sample.

J = Estimated value.

J+ = The chemical was positively identified; however, the associated numerical value is a high estimated concentration.

J- = The chemical was positively identified; however, the associated numerical value is a low estimated concentration.

N = Normal sample.

PCBs = Polychlorinated biphenyls.

SVOC = Semivolatile organic compound.

U = Not detected.

ug/L - microgram per liter.

UJ = The analyte was not detected; and the reporting limit is approximate.

VOC = Volatile organic compound.

(a) Total concentrations were calculated per sample by summing only the detected individual compounds (i.e., Aroclor) concentrations. For samples without any detections of individual compounds (i.e., Aroclor), the maximum reporting detection limit within the sample is presented as a non-detect value.

Notes:

< = Result not detected above laboratory reporting limit.

CAS = Chemical Abstracts Service.

F = Filtered sample.

FD = Field duplicate.

FF = Field filtered sample.

J = Estimated value.

J+ = The chemical was positively identified; however, the associated numerical value is a high estimated concentration.

J- = The chemical was positively identified; however, the associated numerical value is a low estimated concentration.

N = Normal sample.

PCBs = Polychlorinated biphenyls.

SVOC = Semivolatile organic compound.

U = Not detected.

ug/L - microgram per liter.

UJ = The analyte was not detected; and the reporting limit is approximate.

VOC = Volatile organic compound.

(a) Total concentrations were calculated per sample by summing only the detected individual compounds (i.e., Aroclor) concentrations. For samples without any detections of individual compounds (i.e., Aroclor), the maximum reporting detection limit within the sample is presented as a non-detect value.

Notes:

< = Result not detected above laboratory reporting limit.

CAS = Chemical Abstracts Service.

F = Filtered sample.

FD = Field duplicate.

FF = Field filtered sample.

J = Estimated value.

J+ = The chemical was positively identified; however, the associated numerical value is a high estimated concentration.

J- = The chemical was positively identified; however, the associated numerical value is a low estimated concentration.

N = Normal sample.

PCBs = Polychlorinated biphenyls.

SVOC = Semivolatile organic compound.

U = Not detected.

ug/L - microgram per liter.

UJ = The analyte was not detected; and the reporting limit is approximate.

VOC = Volatile organic compound.

(a) Total concentrations were calculated per sample by summing only the detected individual compounds (i.e., Aroclor) concentrations. For samples without any detections of individual compounds (i.e., Aroclor), the maximum reporting detection limit within the sample is presented as a non-detect value.

Notes:

< = Result not detected above laboratory reporting limit.

CAS = Chemical Abstracts Service.

F = Filtered sample.

FD = Field duplicate.

FF = Field filtered sample.

J = Estimated value.

J+ = The chemical was positively identified; however, the associated numerical value is a high estimated concentration.

J- = The chemical was positively identified; however, the associated numerical value is a low estimated concentration.

N = Normal sample.

PCBs = Polychlorinated biphenyls.

SVOC = Semivolatile organic compound.

U = Not detected.

ug/L - microgram per liter.

UJ = The analyte was not detected; and the reporting limit is approximate.

VOC = Volatile organic compound.

(a) Total concentrations were calculated per sample by summing only the detected individual compounds (i.e., Aroclor) concentrations. For samples without any detections of individual compounds (i.e., Aroclor), the maximum reporting detection limit within the sample is presented as a non-detect value.

Notes:

< = Result not detected above laboratory reporting limit.

CAS = Chemical Abstracts Service.

F = Filtered sample.

FD = Field duplicate.

FF = Field filtered sample.

J = Estimated value.

J+ = The chemical was positively identified; however, the associated numerical value is a high estimated concentration.

J- = The chemical was positively identified; however, the associated numerical value is a low estimated concentration.

N = Normal sample.

PCBs = Polychlorinated biphenyls.

SVOC = Semivolatile organic compound.

U = Not detected.

ug/L - microgram per liter.

UJ = The analyte was not detected; and the reporting limit is approximate.

VOC = Volatile organic compound.

(a) Total concentrations were calculated per sample by summing only the detected individual compounds (i.e., Aroclor) concentrations. For samples without any detections of individual compounds (i.e., Aroclor), the maximum reporting detection limit within the sample is presented as a non-detect value.

Notes:

< = Result not detected above laboratory reporting limit.

CAS = Chemical Abstracts Service.

F = Filtered sample.

FD = Field duplicate.

FF = Field filtered sample.

J = Estimated value.

J+ = The chemical was positively identified; however, the associated numerical value is a high estimated concentration.

J- = The chemical was positively identified; however, the associated numerical value is a low estimated concentration.

N = Normal sample.

PCBs = Polychlorinated biphenyls.

SVOC = Semivolatile organic compound.

U = Not detected.

ug/L - microgram per liter.

UJ = The analyte was not detected; and the reporting limit is approximate.

VOC = Volatile organic compound.

(a) Total concentrations were calculated per sample by summing only the detected individual compounds (i.e., Aroclor) concentrations. For samples without any detections of individual compounds (i.e., Aroclor), the maximum reporting detection limit within the sample is presented as a non-detect value.

Notes:

< = Result not detected above laboratory reporting limit.

CAS = Chemical Abstracts Service.

F = Filtered sample.

FD = Field duplicate.

FF = Field filtered sample.

J = Estimated value.

J+ = The chemical was positively identified; however, the associated numerical value is a high estimated concentration.

J- = The chemical was positively identified; however, the associated numerical value is a low estimated concentration.

N = Normal sample.

PCBs = Polychlorinated biphenyls.

SVOC = Semivolatile organic compound.

U = Not detected.

ug/L - microgram per liter.

UJ = The analyte was not detected; and the reporting limit is approximate.

VOC = Volatile organic compound.

(a) Total concentrations were calculated per sample by summing only the detected individual compounds (i.e., Aroclor) concentrations. For samples without any detections of individual compounds (i.e., Aroclor), the maximum reporting detection limit within the sample is presented as a non-detect value.

Notes:

< = Result not detected above laboratory reporting limit.

CAS = Chemical Abstracts Service.

F = Filtered sample.

FD = Field duplicate.

FF = Field filtered sample.

J = Estimated value.

J+ = The chemical was positively identified; however, the associated numerical value is a high estimated concentration.

J- = The chemical was positively identified; however, the associated numerical value is a low estimated concentration.

N = Normal sample.

PCBs = Polychlorinated biphenyls.

SVOC = Semivolatile organic compound.

U = Not detected.

ug/L - microgram per liter.

UJ = The analyte was not detected; and the reporting limit is approximate.

VOC = Volatile organic compound.

(a) Total concentrations were calculated per sample by summing only the detected individual compounds (i.e., Aroclor) concentrations. For samples without any detections of individual compounds (i.e., Aroclor), the maximum reporting detection limit within the sample is presented as a non-detect value.

Notes:

< = Result not detected above laboratory reporting limit.

CAS = Chemical Abstracts Service.

F = Filtered sample.

FD = Field duplicate.

FF = Field filtered sample.

J = Estimated value.

J+ = The chemical was positively identified; however, the associated numerical value is a high estimated concentration.

J- = The chemical was positively identified; however, the associated numerical value is a low estimated concentration.

N = Normal sample.

PCBs = Polychlorinated biphenyls.

SVOC = Semivolatile organic compound.

U = Not detected.

ug/L - microgram per liter.

UJ = The analyte was not detected; and the reporting limit is approximate.

VOC = Volatile organic compound.

(a) Total concentrations were calculated per sample by summing only the detected individual compounds (i.e., Aroclor) concentrations. For samples without any detections of individual compounds (i.e., Aroclor), the maximum reporting detection limit within the sample is presented as a non-detect value.

VOCs	N	XYLENES, TOTAL	1330-20-7	ug/L		< 1.0 U	< 1.0 U		< 1.0 U	

Notes:

< = Result not detected above laboratory reporting limit.

CAS = Chemical Abstracts Service.

F = Filtered sample.

FD = Field duplicate.

FF = Field filtered sample.

J = Estimated value.

J+ = The chemical was positively identified; however, the associated numerical value is a high estimated concentration.

J- = The chemical was positively identified; however, the associated numerical value is a low estimated concentration.

N = Normal sample.

PCBs = Polychlorinated biphenyls.

SVOC = Semivolatile organic compound.

U = Not detected.

ug/L - microgram per liter.

UJ = The analyte was not detected; and the reporting limit is approximate.

VOC = Volatile organic compound.

(a) Total concentrations were calculated per sample by summing only the detected individual compounds (i.e., Aroclor) concentrations. For samples without any detections of individual compounds (i.e., Aroclor), the maximum reporting detection limit within the sample is presented as a non-detect value.

Notes:

< = Result not detected above laboratory reporting limit.

CAS = Chemical Abstracts Service.

FD = Field duplicate.

J = Estimated value.

J- = The chemical was positively identified; however, the associated numerical value is a low estimated concentration.

mg/kg = milligram per kilogram.

N = Normal sample.

PCBs = Polychlorinated biphenyls.

R = Rejected.

SVOC = Semivolatile organic compound.

U = Not detected.

UJ = The analyte was not detected; and the reporting limit is approximate.

VOC = Volatile organic compound.

(a) Total concentrations were calculated per sample by summing only the detected individual compounds (i.e., homolog) concentrations. For samples without any detections of individual compounds (i.e., homolog) the maximum reporting detection limit within the sample is presented as a non-detect value.

(b) Lab calculated value; Not used. Totals for use in risk assessment are calculated as discussed in the report text.

Notes:

< = Result not detected above laboratory reporting limit.

CAS = Chemical Abstracts Service.

FD = Field duplicate.

J = Estimated value.

J- = The chemical was positively identified; however, the associated numerical value is a low estimated concentration.

mg/kg = milligram per kilogram.

N = Normal sample.

PCBs = Polychlorinated biphenyls.

R = Rejected.

SVOC = Semivolatile organic compound.

U = Not detected.

UJ = The analyte was not detected; and the reporting limit is approximate.

VOC = Volatile organic compound.

(a) Total concentrations were calculated per sample by summing only the detected individual compounds (i.e., homolog) concentrations. For samples without any detections of individual compounds (i.e., homolog) the maximum reporting detection limit within the sample is presented as a non-detect value.

(b) Lab calculated value; Not used. Totals for use in risk assessment are calculated as discussed in the report text.

Notes:

< = Result not detected above laboratory reporting limit.

CAS = Chemical Abstracts Service.

FD = Field duplicate.

J = Estimated value.

J- = The chemical was positively identified; however, the associated numerical value is a low estimated concentration.

mg/kg = milligram per kilogram.

N = Normal sample.

PCBs = Polychlorinated biphenyls.

R = Rejected.

SVOC = Semivolatile organic compound.

U = Not detected.

UJ = The analyte was not detected; and the reporting limit is approximate.

VOC = Volatile organic compound.

(a) Total concentrations were calculated per sample by summing only the detected individual compounds (i.e., homolog) concentrations. For samples without any detections of individual compounds (i.e., homolog) the maximum reporting detection limit within the sample is presented as a non-detect value.

(b) Lab calculated value; Not used. Totals for use in risk assessment are calculated as discussed in the report text.

Notes:

< = Result not detected above laboratory reporting limit.

CAS = Chemical Abstracts Service.

FD = Field duplicate.

J = Estimated value.

J- = The chemical was positively identified; however, the associated numerical value is a low estimated concentration.

mg/kg = milligram per kilogram.

N = Normal sample.

PCBs = Polychlorinated biphenyls.

R = Rejected.

SVOC = Semivolatile organic compound.

U = Not detected.

UJ = The analyte was not detected; and the reporting limit is approximate.

VOC = Volatile organic compound.

(a) Total concentrations were calculated per sample by summing only the detected individual compounds (i.e., homolog) concentrations. For samples without any detections of individual compounds (i.e., homolog) the maximum reporting detection limit within the sample is presented as a non-detect value.

(b) Lab calculated value; Not used. Totals for use in risk assessment are calculated as discussed in the report text.

Notes:

< = Result not detected above laboratory reporting limit.

CAS = Chemical Abstracts Service.

FD = Field duplicate.

J = Estimated value.

J- = The chemical was positively identified; however, the associated numerical value is a low estimated concentration.

mg/kg = milligram per kilogram.

N = Normal sample.

PCBs = Polychlorinated biphenyls.

R = Rejected.

SVOC = Semivolatile organic compound.

U = Not detected.

UJ = The analyte was not detected; and the reporting limit is approximate.

VOC = Volatile organic compound.

(a) Total concentrations were calculated per sample by summing only the detected individual compounds (i.e., homolog) concentrations. For samples without any detections of individual compounds (i.e., homolog) the maximum reporting detection limit within the sample is presented as a non-detect value.

(b) Lab calculated value; Not used. Totals for use in risk assessment are calculated as discussed in the report text.

Notes:

Refer to the 2013 HHRA presented as Appendix F of the Long-Term Monitoring Data Summary and Optimization Recommendations Report for samples (Tetra Tech; August 2015) included in 2013 HHRA data set. Refer to Appendix A for samples included in the 2017 HHRA Update data set.

Shallow sediment is defined as sediment samples collected from within the 0 to 0.5 ft bgs depth interval.

Deep sediment is defined as sediment samples collected from within the 1.5 to 3 ft bgs depth interval.

Totals for use in risk assessment are calculated as discussed in the report text and have a CAS number beginning with "RA-".

CAS = Chemical Abstracts Service.

COPC = Chemical of Potential Concern.

HHRA = Human Health Risk Assessment.

ft = feet.

ft bgs = feet below ground surface.

in = Inches.

mg/kg = milligrams per kilogram.

N/A = Not Applicable or Not Available.

PCBs = Polychlorinated biphenyls.

SVOCs = Semivolatile organic compounds.

VOCs = Volatile organic compounds.

(1) Minimum/maximum detected concentration and associated data flags.

EB = Equipment blank contamination.

J = The chemical was positively identified; however, the associated numerical value is an estimated concentration.

J+ = The chemical was positively identified; however, the associated numerical value is a high estimated concentration.

J- = The chemical was positively identified; however, the associated numerical value is a low estimated concentration.

(2) Range of Reporting Detection Limits (RDLs).

(3) Chemicals presented on this table include the shoreline sediment COPCs identified in the 2013 HHRA and chemicals detected in the 2017 HHRA shoreline sediment dataset (as defined in the text and Appendix A). Chemicals not identified as COPCs in the 2013 HHRA that were also not detected in the 2017 HHRA dataset are not included.

(4) An indicator of whether the associated chemical was identified as a COPC in the 2013 HHRA or 2017 HHRA update is provided for informational purposes.

Notes:

Refer to the 2013 HHRA presented as Appendix F of the Long-Term Monitoring Data Summary and Optimization Recommendations Report for samples (Tetra Tech; August 2015) included in 2013 HHRA data set. Refer to Appendix A for samples included in the 2017 HHRA Update data set.

CAS = Chemical Abstracts Service.

COPC = Chemical of Potential Concern.

HHRA = Human Health Risk Assessment.

N/A = Not Applicable or Not Available.

ND = Not detected.

PCBs = Polychlorinated biphenyls.

ug/L = micrograms per liter.

SVOCs = Semivolatile organic compounds.

VOCs = Volatile organic compounds.

(1) Minimum/maximum detected concentration and associated data flags.

J = The chemical was positively identified; however, the associated numerical value is an estimated concentration.

J- = The chemical was positively identified; however, the associated numerical value is a low estimated concentration.

(2) Range of Reporting Detection Limits (RDLs).

(3) Chemicals presented on this table include the shoreline groundwater COPCs identified in the 2013 HHRA and chemicals detected in the 2017 HHRA shoreline groundwater dataset (as defined in the text and Appendix A). Chemicals not identified as COPCs in the 2013 HHRA that were also not detected in the 2017 HHRA dataset are not included.

(4) An indicator of whether the associated chemical was identified as a COPC in the 2013 HHRA or 2017 HHRA update is provided for informational purposes.

General Statistics

Total Number of Observations	9	Number of Distinct Observations	8
		Number of Missing Observations	13
Number of Detects	7	Number of Non-Detects	2
Number of Distinct Detects	6	Number of Distinct Non-Detects	2
Minimum Detect	6.9000E-4	Minimum Non-Detect	0.0093
Maximum Detect	0.18	Maximum Non-Detect	0.011
Variance Detects	0.00415	Percent Non-Detects	22.22%
Mean Detects	0.089	SD Detects	0.0644
Median Detects	0.074	CV Detects	0.724
Skewness Detects	0.46	Kurtosis Detects	-0.647
Mean of Logged Detects	-3.083	SD of Logged Detects	1.911

Note: Sample size is small (e.g., <10), if data are collected using ISM approach, you should use guidance provided in ITRC Tech Reg Guide on ISM (ITRC, 2012) to compute statistics of interest. For example, you may want to use Chebyshev UCL to estimate EPC (ITRC, 2012). Chebyshev UCL can be computed using the Nonparametric and All UCL Options of ProUCL 5.1

Normal GOF Test on Detects Only

Shapiro Wilk Test Statistic	0.887	**Shapiro Wilk GOF Test**
5% Shapiro Wilk Critical Value	0.803	Detected Data appear Normal at 5% Significance Level
Lilliefors Test Statistic	0.3	**Lilliefors GOF Test**
5% Lilliefors Critical Value	0.304	Detected Data appear Normal at 5% Significance Level

Detected Data appear Normal at 5% Significance Level

Kaplan-Meier (KM) Statistics using Normal Critical Values and other Nonparametric UCLs

KM Mean	0.0693	KM Standard Error of Mean	0.0231

97.5% KM Chebyshev UCL	0.214	99% KM Chebyshev UCL	0.299

Gamma GOF Tests on Detected Observations Only

A-D Test Statistic	0.773	**Anderson-Darling GOF Test**
5% A-D Critical Value	0.732	Detected Data Not Gamma Distributed at 5% Significance Level
K-S Test Statistic	0.302	**Kolmogorov-Smirnov GOF**
5% K-S Critical Value	0.321	Detected data appear Gamma Distributed at 5% Significance Level

Detected data follow Appr. Gamma Distribution at 5% Significance Level

Gamma Statistics on Detected Data Only

k hat (MLE)	0.884	k star (bias corrected MLE)	0.6
Theta hat (MLE)	0.101	Theta star (bias corrected MLE)	0.148
nu hat (MLE)	12.37	nu star (bias corrected)	8.402
Mean (detects)	0.089		

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Minimum	6.9000E-4	Mean	0.0723
Maximum	0.18	Median	0.074
SD	0.0649	CV	0.897

95% t UCL (Assumes normality)	0.112	95% H-Stat UCL	7.402

DL/2 is not a recommended method, provided for comparisons and historical reasons

Nonparametric Distribution Free UCL Statistics

Detected Data appear Normal Distributed at 5% Significance Level

Suggested UCL to Use

95% KM (t) UCL	0.112

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.

Recommendations are based upon data size, data distribution, and skewness.

These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Suggested UCL to Use

95% Adjusted Gamma UCL 16777

When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test
When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

97.5% Chebyshev(Mean, Sd) UCL	187.1	99% Chebyshev(Mean, Sd) UCL	235.3

Suggested UCL to Use

95% Student's-t UCL	128.6	or 95% Modified-t UCL	129.6
or 95% H-UCL	130.3		

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

ProUCL computes and outputs H-statistic based UCLs for historical reasons only.
H-statistic often results in unstable (both high and low) values of UCL95 as shown in examples in the Technical Guide.
It is therefore recommended to avoid the use of H-statistic based 95% UCLs.
Use of nonparametric methods are preferred to compute UCL95 for skewed data sets which do not follow a gamma distribution.

Gamma Statistics on Detected Data Only

k hat (MLE)	0.598	k star (bias corrected MLE)	0.549
Theta hat (MLE)	3961	Theta star (bias corrected MLE)	4315
nu hat (MLE)	27.5	nu star (bias corrected)	25.25
Mean (detects)	2368		

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Minimum	0.01	Mean	1786
Maximum	14800	Median	357
SD	3127	CV	1.751
k hat (MLE)	0.259	k star (bias corrected MLE)	0.255

Nonparametric Distribution Free UCL Statistics

Detected Data appear Approximate Normal Distributed at 5% Significance Level

Suggested UCL to Use

95% KM (t) UCL	8.228

When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test

When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.

Recommendations are based upon data size, data distribution, and skewness.

These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).

However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Theta hat (MLE)	2525	Theta star (bias corrected MLE)	2671
nu hat (MLE)	23.65	nu star (bias corrected)	22.36
Mean (detects)	1106		

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Minimum	0.01	Mean	963.2
Maximum	17300	Median	200

DL/2 is not a recommended method, provided for comparisons and historical reasons

Nonparametric Distribution Free UCL Statistics

Detected Data appear Lognormal Distributed at 5% Significance Level

Suggested UCL to Use

95% KM (Chebyshev) UCL	3380

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Nonparametric Distribution Free UCL Statistics

Detected Data appear Approximate Normal Distributed at 5% Significance Level

Suggested UCL to Use

95% KM (t) UCL	8.228

When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test

When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.

Recommendations are based upon data size, data distribution, and skewness.

These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).

However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

5% Lilliefors Critical Value	0.167	Detected Data appear Lognormal at 5% Significance Level	

Detected Data appear Lognormal at 5% Significance Level

Lognormal ROS Statistics Using Imputed Non-Detects

Mean in Original Scale	966.1	Mean in Log Scale	5.194
SD in Original Scale	3074	SD in Log Scale	1.905
95% t UCL (assumes normality of ROS data)	1903	95% Percentile Bootstrap UCL	2049
95% BCA Bootstrap UCL	2679	95% Bootstrap t UCL	5550
95% H-UCL (Log ROS)	3958		

Statistics using KM estimates on Logged Data and Assuming Lognormal Distribution

KM Mean (logged)	5.185	KM Geo Mean	178.6
KM SD (logged)	1.924	95% Critical H Value (KM-Log)	3.696
KM Standard Error of Mean (logged)	0.369	95% H-UCL (KM -Log)	4159
KM SD (logged)	1.924	95% Critical H Value (KM-Log)	3.696
KM Standard Error of Mean (logged)	0.369		

DL/2 Statistics

DL/2 Normal		**DL/2 Log-Transformed**	
Mean in Original Scale	968	Mean in Log Scale	5.282
SD in Original Scale	3073	SD in Log Scale	1.794
95% t UCL (Assumes normality)	1905	95% H-Stat UCL	3100

DL/2 is not a recommended method, provided for comparisons and historical reasons

Nonparametric Distribution Free UCL Statistics

Detected Data appear Lognormal Distributed at 5% Significance Level

Suggested UCL to Use

95% KM (Chebyshev) UCL	3380

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

5% A-D Critical Value	0.859	Detected Data Not Gamma Distributed at 5% Significance Level
K-S Test Statistic	0.311	**Kolmogorov-Smirnov GOF**
5% K-S Critical Value	0.18	Detected Data Not Gamma Distributed at 5% Significance Level

Detected Data Not Gamma Distributed at 5% Significance Level

Gamma Statistics on Detected Data Only

k hat (MLE)	0.29	k star (bias corrected MLE)	0.282
Theta hat (MLE)	1802	Theta star (bias corrected MLE)	1849
nu hat (MLE)	16.22	nu star (bias corrected)	15.82
Mean (detects)	522.2		

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Minimum	0.01	Mean	471.7
Maximum	12500	Median	29.2
SD	2235	CV	4.738
k hat (MLE)	0.231	k star (bias corrected MLE)	0.23
Theta hat (MLE)	2040	Theta star (bias corrected MLE)	2048
nu hat (MLE)	14.33	nu star (bias corrected)	14.28
Adjusted Level of Significance (β)	0.0413		
Approximate Chi Square Value (14.28, α)	6.762	Adjusted Chi Square Value (14.28, β)	6.475

95% BCA Bootstrap UCL	210.5		
90% Chebyshev(Mean, Sd) UCL	189.1	95% Chebyshev(Mean, Sd) UCL	240
97.5% Chebyshev(Mean, Sd) UCL	310.6	99% Chebyshev(Mean, Sd) UCL	449.4

Suggested UCL to Use

95% H-UCL	105.7

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.

Recommendations are based upon data size, data distribution, and skewness.

These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).

However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

ProUCL computes and outputs H-statistic based UCLs for historical reasons only.

H-statistic often results in unstable (both high and low) values of UCL95 as shown in examples in the Technical Guide.

It is therefore recommended to avoid the use of H-statistic based 95% UCLs.

Use of nonparametric methods are preferred to compute UCL95 for skewed data sets which do not follow a gamma distribution.

ANTIMONY

General Statistics

Total Number of Observations	36	Number of Distinct Observations	29

Mean (detects)	0.389		

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Minimum	0.23	Mean	0.373

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Suggested UCL to Use

95% KM (t) UCL 0.00953

When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test
When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.

Recommendations are based upon data size, data distribution, and skewness.

These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).

However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

ProUCL computes and outputs H-statistic based UCLs for historical reasons only.

H-statistic often results in unstable (both high and low) values of UCL95 as shown in examples in the Technical Guide.

It is therefore recommended to avoid the use of H-statistic based 95% UCLs.

Use of nonparametric methods are preferred to compute UCL95 for skewed data sets which do not follow a gamma distribution.

Detected Data appear Approximate Gamma Distributed at 5% Significance Level

Suggested UCL to Use

95% KM Adjusted Gamma UCL	0.001	95% GROS Adjusted Gamma UCL	0.0101

Warning: Recommended UCL exceeds the maximum observation

When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test

When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.

Recommendations are based upon data size, data distribution, and skewness.

These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).

However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Nonparametric Distribution Free UCL Statistics

Detected Data appear Approximate Normal Distributed at 5% Significance Level

Suggested UCL to Use

95% KM (t) UCL 8.39E-04

When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test

When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.

Recommendations are based upon data size, data distribution, and skewness.

These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).

However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Nonparametric Distribution Free UCL Statistics

Detected Data appear Approximate Normal Distributed at 5% Significance Level

Suggested UCL to Use

95% KM (t) UCL 7.46E-04

When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test

When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.

Recommendations are based upon data size, data distribution, and skewness.

These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).

However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Nonparametric Distribution Free UCL Statistics

Detected Data appear Approximate Gamma Distributed at 5% Significance Level

Suggested UCL to Use

95% KM Adjusted Gamma UCL	0.0108	95% GROS Adjusted Gamma UCL	0.0131

When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test

When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.

Recommendations are based upon data size, data distribution, and skewness.

These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).

However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Detected Data appear Approximate Gamma Distributed at 5% Significance Level

Suggested UCL to Use

95% KM Adjusted Gamma UCL	0.175	95% GROS Adjusted Gamma UCL	0.143

When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test

When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.

Recommendations are based upon data size, data distribution, and skewness.

These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).

However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

1.0 INTRODUCTION

This report presents an ecological risk assessment (ERA) update conducted for shoreline exposures to sediment, sediment porewater, surface water, and shellfish at Site 09 (Allen Harbor Landfill) (site), located at the Former Naval Construction Battalion Center (NCBC) Davisville, in North Kingstown, Rhode Island (Figure 1). This ERA update was performed in support of the Site 09 Five Year Event Long-Term Monitoring (LTM) Report and will ultimately be used as part of the evaluation of compliance with the Remedial Action Objectives (RAOs) identified in the Record of Decision (ROD) (EA, 1997) in the Fourth Five Year Review Report. The RAOs and selected remedial alternatives for Site 09 are described in the LTM Report.

A summary of the Site 09 history is provided in the Draft Tier II Sampling and Analysis Plan, Long Term Monitoring Site 07 Calf Pasture Point and Site 09 Allen Harbor Landfill (Resolution, 2016) and is, therefore, not included in this ERA update. However, the previously conducted ERAs are briefly summarized in the following section.

1.1 Previous ERAs

As summarized in the Third Five-Year Review Report (Tetra Tech, 2015), the Marine Ecological Risk Assessment (EA, 1996) indicated that ecological risks to marine organisms in Allen Harbor were reported to be "moderate'' to "slight." Moderate risk to marine organisms was reported to be limited to the narrow inter-tidal zone to the north and south of the site. Risks to terrestrial ecological receptors were reported to be moderate to high within the Allen Harbor Watershed (an area in which the Allen Harbor Landfill was one of the contributors to elevated risk). The ERA identified elevated risks to several terrestrial receptors, resulting from exposure to contaminants. Elevated concentrations of polycyclic aromatic hydrocarbons (PAHs), pesticides, polychlorinated biphenyls (PCBs), and metals in surface soil and sediment were the primary sources of ecological risk to terrestrial receptors. Sediment samples collected from Allen Harbor had concentrations of PAHs, pesticides, PCBs, and metals in excess of benchmark screening values. A benthic community structure analysis showed no obvious toxicological effects relative to reference stations; however, the elevated concentrations of contaminants were identified in the risk assessment as "flags" of potential ecological risk (EA, 1996).

An ERA was conducted in 2015 in support of the Third Five-Year Review Report for Site 09 (Tetra Tech, 2015) using recently collected (e.g., 2010 to 2012) sediment, shallow piezometer water (representing brackish sediment porewater; assumed to be mixture of groundwater and surface water), seep water (representing surface water), and shellfish data. The 2015 ERA identified no unacceptable risks to ecological receptors exposed to sediment, sediment pore water or surface water.

1.2 Objectives

The objective of this ERA update (referred to herein as the 2017 ERA update) is to determine whether there have been any changes and/or updates to USEPA ERA guidance or site-specific conditions since the 2015 ERA was conducted that would result in a change of the conclusions of the 2015 ERA. The 2017 ERA update includes the following:

- Calculation of summary statistics for analytical shallow sediment, piezometer water, seep water, and shellfish data collected along the Site 09 shoreline as part of the LTM, which are considered representative of current conditions (i.e., 2017 ERA update data set);
- Review and update of screening levels and chemical of potential concern (COPC) selection for shoreline shallow sediment, piezometer water (representing sediment porewater), seep water (representing surface water);
- Review and update of food web modeling evaluating birds and mammals exposed to shoreline sediment and shellfish.

Revised quantitative risk calculations were not required to be conducted for this update per the Davisville Base Realignment and Closure (BRAC) Cleanup Team (BCT) January 12, 2017 teleconference. However, given the relatively simple nature of the 2015 ERA and the addition of some new detected chemicals, the 2015 ERA risk screenings and food web calculations were updated to reflect the current data set. These updated evaluations and a comparison of exposure point concentrations (EPCs) between the 2015 ERA and this 2017 ERA update are used to assess whether the conclusions of the 2015 ERA remain valid.

1.3 Approach for the ERA Update

The approach for this ERA update is consistent with the approach used in the 2015 ERA. The following risk assessment guidance was utilized in this 2017 ERA update. Guidance documentation includes, but is not limited to, the following:

- *Navy Policy for Conducting Ecological Risk Assessments (DON, 1999a)*
- *Navy Guidance for Conducting Ecological Risk Assessments (DON, 1999b)*
- *Ecological Risk Assessment Guidance for Superfund: Process for Designing and Conducting Ecological Risk Assessments, Interim Final (USEPA, 1997).*
- *Guidelines for Ecological Risk Assessment (USEPA, 1998)*
- *The Role of Screening-Level Risk Assessments and Refining Contaminants of Concern in Baseline Ecological Risk Assessments (USEPA, 2001)*

Consistent with the 2015 ERA, this ERA update consisted of Steps 1, 2, and 3a of the eight-step ecological risk evaluation process discussed in USEPA guidance (USEPA, 1997) and the Navy Policy

for Conducting ERAs (1999). Steps 1 and 2 comprise the screening-level ERA and corresponds with Tier 1 of the Navy Policy to include comparisons of conservative exposure estimates to screening-level and threshold toxicity values. Step 3a is the first step of a baseline ERA and consists of refining the Tier 1 assumptions to further focus the ERA process on the chemicals of greatest concern at the site. Step 3a corresponds with the first part of Tier 2 of the Navy Policy.

2.0 DATA USED IN THE ECOLOGICAL RISK ASSESSMENT UPDATE

This section summarizes the shoreline shallow sediment, shallow piezometer water (representing sediment porewater), seep water (representing surface water), and shellfish data evaluated in this ERA update. A discussion of the sampling details associated with collection of the shoreline data is provided in the LTM Report, and is not included in this ERA update.

2.1 Summary of the Shoreline Data Set

The data sets for evaluation in the 2017 ERA update are discussed by media in this section. Figure 2 identifies the shoreline sample locations. Analytical results for samples used in the ERA are presented in Appendix A.

2.1.1 Shallow Sediment

Shallow sediment samples were collected from within the top 6 inches below ground surface (bgs) during sampling events in September of 2014, 2015, and 2016. A total of 33 shallow sediment samples (including 7 field duplicates) were collected as part of the three sampling events. Samples were collected from 12 locations in 2016, from 11 locations in 2015, and from the 3 locations in 2014. Samples were analyzed for metals, volatile organic compounds (VOCs), semi-volatile organic compounds (SVOCs), pesticides, and PCBs as Aroclors.

Sediment samples were also collected in 2013. However, these samples were collected from 2 to 3 feet bgs as specified in the Final Quality Assurance Project Plan for Long Term Monitoring of Site 09 (EA, 2001) and not as shallow sediment samples as had subsequently been agreed to by the Davisville BCT. These samples were not included in this ERA update since the sample depth is not representative of ecologically active zone for marine sediment.

Shallow sediment data for detected chemicals are summarized in Table 1. The summary table provides the frequency of detection (FOD), range of detected concentrations, mean of detected concentrations and location of maximum detected result for each detected chemical.

2.1.2 Shallow Piezometer Water

Shallow piezometer water samples were collected during sampling events in 2013, 2014, 2015, and 2016. The piezometers were grouped into two areas: adjacent to the stone revetment (P09-01, P09-02A, P09-3A, P09-4A, P09-05A, P09-09, P09-10) and beyond the breakwater structure (P09-06B, P09-07B, P09-08B, P09-11B, P09-12B). Samples were collected from all 12 locations in 2013 and 2015, from 11 locations in 2016 (P09-05A was not sampled due to lack of water), and from the 5 beyond the breakwater locations in 2014. Samples were analyzed for metals (total and dissolved), VOCs, SVOCs, pesticides, and PCBs as Aroclors. In addition, field water quality parameters were

collect during each sampling event. Measurements of salinity averaged approximately 20 parts per thousand indicating brackish water.

Shallow piezometer data for detected chemicals from adjacent to the stone revetment and beyond the breakwater structure are summarized in Tables 2 and 3, respectively. The summary table provides the FOD, range of detected concentrations, mean of detected concentrations and location of maximum detected result for each detected chemical. PCBs and pesticides were not detected in any of the collected piezometer samples.

2.1.3 Seep Water

Seep water samples were collected during sampling events in 2013, 2014, 2015, and 2016. Samples were collected from two locations in 2013 and from three locations in 2014, 2015, and 2016 and were analyzed for VOCs. In addition to the VOC samples, field water quality parameters were collect during each sampling event. Measurements of salinity averaged approximately 27 parts per thousand indicating brackish water that was more saline than the piezometer water.

Seep water data for detected chemicals are summarized in Table 4. The summary table provides the FOD, range of detected concentrations, mean of detected concentrations and location of maximum detected result for each detected chemical.

2.1.4 Shellfish

Shellfish tissue samples were collected during sampling events in 2014, 2015, and 2016. In 2016, shellfish were collected in September and December. The initial September 2016 sampling results were not included in the ERA update due to data quality issues, per agreement with the BCT; instead, the data from the December 2016 re-sampling were used.

A total of 46 shellfish tissue samples (including six field duplicates) were collected from ten locations. Shellfish samples were analyzed for metals, SVOCs, pesticides, PCBs as homologs, and lipids. In addition, shellfish measurements (e.g., shell length, weight) were made during each sampling event.

Shellfish data are presented in Appendix A and the maximum and average concentrations considered in the food web model update are provided in Table 5.

2.2 Data Treatment

Analytical data were evaluated, validated, and qualified prior to use in the 2017 ERA update. Data evaluation and validation included a comparison of the site data to corresponding blank (laboratory, field, equipment, and trip) concentration data. Data validation reports are presented as Appendix B of the LTM report. Data rejected by the evaluation ("R" qualified) were not used in the ERA.

Estimated values ("J" qualified) were used in the ERA without modification. If the value was flagged with "U" or "UJ," the result was considered a non-detect value.

For each medium, data were compiled into summary statistics. For each chemical detected at least once within a medium, the summary statistics include frequency of detection, range of detection limits, range of detected concentrations, and location of maximum detected result.

For sample locations in which a duplicate sample was also collected, the duplicate sample results for each chemical/medium combination were processed for use in the calculation of summary statistics. Duplicates were resolved as follows: (1) where both the sample and the duplicate results are not detected, the resulting value is the average of the limits of detection; (2) where both the sample and the duplicate results are detected, the resulting value is the average of the detected results; and (3) where one of the pair is reported as not detected and the other is detected, the detected concentration is used.

2.3 Data Evaluation Approach for 2017 ERA Update

Summary statistics for the recent shoreline data sets are provided in Tables 1, 2, 3, 4 and 5 and the maximum detected concentrations were used to update the screening-level evaluations presented in the 2015 ERA. As needed, the average concentrations (conservatively represented by the average of the detected concentrations) were used to refine the screening level results. In addition, the maximum and average concentrations for all media types considered in the 2015 ERA are provided in the tables to support a qualitative discussion of the recently collected data relative to the findings of the 2015 ERA.

3.0 TIER 1 ECOLOGICAL SCREENING RISK ASSESSMENT

The primary objective for a Tier 1 screening risk assessment (SRA) is to determine which, if any, exposure pathways and COPCs warrant further evaluation in a more refined ERA. The Navy Tier 1 ecological SRA process can be described in two steps. Step 1 is equivalent to Step 1 of the USEPA (1997) ERA process and includes a site description, pathway identification/problem formulation, and toxicity evaluation. The goals of this step are to describe the ecological setting of the site and determine whether ecological exposure pathways are potentially complete. Step 2 of the Navy Tier 1 ecological SRA process is equivalent to Step 2 of the USEPA (1997) ERA process. First, potential exposure is evaluated based on conservative assumptions. Then, risk is estimated by comparing the chemical concentrations detected in each medium of concern to conservative, screening-level, medium-specific benchmark criteria.

After Step 2 in the risk assessment process, a Scientific/Management Decision Point (SMDP) is normally reached to determine whether exit criteria for Tier 1, Step 2 have been met. The approach used in this 2017 ERA update is consistent with the 2015 ERA.

3.1 Ecological Setting

The ecological setting for Site 09 is consistent with that described in the 2015 ERA. Site 09 is located within the former NCBC Davisville facility and encompasses approximately 15 acres. It is located along Allen Harbor with a shoreline approximately 2000 feet in length above the 100-year flood plain elevation. The site was used as a landfill but is currently capped with an impermeable geosynthetic liner and is currently covered with grass with small shrubs. The terrain is gently sloping, with a topographic high in the center of the landfill. The Site is bounded to the east by Allen Harbor, to the west by a bicycle path, and to the north and south by vegetated wetlands (Figure 1).

A revetment wall and constructed wetland are located along the southern and eastern boundary of the landfill with a stone breakwater structure separating the wetland from the harbor.

Fiddler crabs, snails, quahogs, and ribbed mussels have been observed within in the wetlands. Vegetation within the created wetland includes smooth cordgrass (*Spartina alterniflora*) and sea lavender (*Limonium carolinianum*). The surrounding shoreline area also includes the invasive common reed (*Phragmites*).

3.2 Potential Exposure Pathways and Receptors

Ecological receptors within the wetland may be exposed to contaminants in sediment, sediment pore water, surface water, and prey tissue (i.e., shellfish) at the Site. The potentially exposed receptors and exposure pathways for the Site 09 shoreline evaluated in the 2015 ERA remain appropriate and are summarized as follows:

- Benthic invertebrates exposed to shallow sediment;
- Aquatic organisms exposed to sediment pore water (represented by piezometer water) and surface water (represented by seep water);
- Terrestrial plants exposed to surface water (represented by seep water); and
- Birds and mammals exposed to shallow sediment and shellfish via ingestion pathways.

3.3 Assessment and Measurement Endpoints

Assessment endpoints describe the characteristics of an ecosystem that have an intrinsic environmental value that is to be protected (e.g., protection of warm-water fish community). Typically, assessment endpoints and receptors are selected for their potential exposure, ecological significance, economic importance, and/or societal relevance. Because assessment endpoints often cannot be measured directly, measurement endpoints are a set of surrogate endpoints used to provide a quantitative metric for evaluating potential effects of chemicals on the ecosystem components potentially at risk. Measurement endpoints provide the actual measurements used to evaluate ecological risk and are selected to represent mechanisms of toxicity and exposure pathways.

The assessment endpoints and measurement endpoints for the Site 09 shoreline evaluated in the 2015 ERA remain appropriate and are summarized as follows:

- Benthic invertebrate assessment endpoint- Adverse effects on the survival, reproduction, and/or growth of sediment invertebrates
    - Measurement endpoint – Comparison of measured concentrations of chemicals in shallow sediment to sediment screening levels protective of benthic invertebrates.
- Aquatic organism assessment endpoint- Adverse effects on the survival, reproduction, and/or growth of aquatic organisms
    - Measurement endpoint – Comparison of measured concentrations of chemicals in sediment pore water to surface water screening levels protective of aquatic organisms.
    - Measurement endpoint – Comparison of measured concentrations of chemicals in surface water to surface water screening levels protective of aquatic organisms.
- Terrestrial plant assessment endpoint- Adverse effects on the survival, reproduction, and/or growth of terrestrial plants
    - Measurement endpoint – Comparison of measured concentrations of chemicals in surface water to plant-based surface water screening levels.

- Bird and mammal assessment endpoint- Adverse effects on the survival, reproduction, and/or growth of birds and mammals
    - Measurement endpoint – Comparison of estimated ingested dose of chemicals in the sediment and shellfish to No Observed Adverse Effects Levels (NOAELs) and Lowest Observed Adverse Effects Levels (LOAELs) for surrogate wildlife species. Raccoon and green heron were selected as the surrogate species (consistent with the 2015 ERA).

3.4 Conceptual Site Model

Contamination may be present at Site 09 from use of the Site as a landfill. Waste materials such as municipal-type waste, construction debris, rubble, preservatives, paint thinners, degreasers (e.g., solvents), PCBs, oil, asbestos, ash, sewage sludge, and waste fuel oil were disposed of in the landfill. Dredged sediment was used to construct the created wetland and contaminants potentially present within the dredged sediment may have entered media within the created wetland through leaching.

Constituents found in shoreline sediment immediately adjacent to Site 09 are most likely due to historical erosion of the landfill face and overland runoff prior to remedy implementation. This conclusion is supported by the historical presence of landfill debris along the Site 09 shoreline (e.g., asphalt, metal debris, glass fragments) prior to capping the landfill. Most of the constituents historically associated with quantifiable human health and ecological risk in near-shore sediment (PAH, PCB, and metals) are not detected, or are detected at low concentrations or frequency, in groundwater at the landfill.

Contaminants from the landfill and from the dredged sediment used to construct the created wetland may have entered sediment, sediment pore water, and surface water at Site 09 through leaching, and may have accumulated in shellfish living along the shoreline at Site 09. Ecological receptors within the wetland may be exposed to contaminants in sediment, sediment pore water, and surface water.

3.5 Ecological Effects Evaluation

The ecological effects evaluation consists of identification of screening ecotoxicity values (SEVs) for sediment and surface water, and toxicity reference values (TRVs) for the food web pathways. These values are expressed as concentrations (in milligram/kilogram [mg/kg] on a dry weight basis for sediment or in micrograms per liter [ug/L] for water) or dosage (in mg/kg of body weight per day [mg/kg-day] for wildlife) of a chemical believed to have little or no effect on the long-term health of the representative species of concern.

The SEVs and TRVs used in the 2015 ERA remain appropriate and sources are summarized as follows:

- Sediment
    - Effects Range - Low (ER-L) values (Long, et al., 1995; Long and Morgan, 1991);
    - USEPA Region 3 Biological Technical Assistance Group (BTAG) sediment screening levels (USEPA, 2006a, 2006b); and
    - National Oceanic and Atmospheric Administration (NOAA) Screening Quick Reference Table (SQuiRT) sediment benchmarks (Buchman, 2008).
- Surface water and sediment pore water (aquatic organisms)
    - National Recommended Water Quality Criteria (NRWQC) (USEPA, 2013)
    - Rhode Island Department of Environmental Management (RIDEM) Ambient Water Quality Criteria (RIDEM, 2009)
    - USEPA Region 3 BTAG screening levels (USEPA, 2006c, 2006d),
    - NOAA SQuiRT surface water benchmarks (Buchman, 2008).
- Surface water (plants)
    - Oak Ridge National Laboratory (ORNL) toxicological benchmarks for plants (Efroymson, et al., 1997).

For both sediment and surface water, marine values were preferentially selected, but freshwater values were used if marine values were not available.

Risks to mammals and birds from exposure to chemicals in sediment were determined using food web models to estimate the total daily dose (TDD) which was compared to chemical-specific TRVs representing acceptable daily doses in mg/kg-day. The TRVs were developed from NOAELs and LOAELs obtained from wildlife studies. The majority of the TRVs were obtained from the ORNL Toxicological Benchmarks for Wildlife (Sample et al., 1996) and USEPA Eco-SSL documents and were supplemented with other toxicity information when necessary. Refer to Attachment 1 of the 2015 ERA report for a detailed presentation of the TRVs and sources.

3.6 Exposure Estimation

Mechanisms for exposure of a representative species to chemicals depend on the physical and behavioral characteristics of the organism. Most exposure for sediment invertebrates, aquatic invertebrates, and plants can be loosely termed “direct contact.” Sediment and aquatic invertebrates have in common the ability to absorb chemicals from sediment or water through

external body surfaces or by intake of food, sediment, or water. Plants may absorb chemical in sediment or water through the roots. Wildlife species may be exposed to chemicals in sediment through direct incidental ingestion of sediment or indirectly by ingestion of contaminated food items.

Consistent with the 2015 ERA, it is anticipated that ecological receptors may come in contact with surface sediment, sediment pore water (piezometer water), and surface water through direct contact or incidentally during ingestion of prey items. Information used to estimate the exposure includes EPCs (i.e., maximum and average detected concentrations), species-specific exposure factors, chemical-specific exposure factors, and exposure equations. The approaches used to estimate exposures in this 2017 ERA update are consistent with the approaches used in the 2015 ERA.

Exposure Point Concentrations

Exposure was estimated using analytical data for shallow sediment, piezometer water, seep water, and shellfish presented in Attachment A. Maximum values were used as the EPCs in the screening to select COPCs in Tables 1 through 4 and in food web modeling presented in Tables 6 and 7.

Species-Specific Exposure Factors

Attachment 1 of the 2015 ERA presented the exposure factors for the mammalian (raccoon) and avian (green heron) receptors evaluated in the food web model. These assumptions are still valid and were used in this ERA update.

Chemical concentrations of shellfish tissue collected in 2014, 2015, and 2016 from Site 09 were used in the food chain model to estimate the dose incurred from ingestion of food items. Recent shellfish analytical results were reported on a wet weight basis (Appendix A); however, the ingestion rates used in the 2015 ERA were expressed on a dry weight basis. Percent moisture data were not reported in the current tissue data set, so the percent moisture results for the 2009 to 2012 shellfish data (average of 86.6% moisture; 13.4% solids)[1] were used to complete the wet weight to dry weight conversion of the shellfish data to be consistent with the food web modeling approach used in the 2015 ERA.

Conservative food chain model inputs were used to evaluate the COPCs. These included the following:

- Assumed sediment and shellfish COPC concentrations are represented by the maximum concentrations in the sediment and shellfish data sets.

[1] dry weight tissue = (wet weight tissue / fraction solids)

- Assumed representative species weight is the low-end of the range and food intake is estimated at the high-end of the range.
- Assumed 100 percent bioavailability of COPCs.
- Assumed species is present year-round.
- Assumed that receptors obtain all of their daily dietary requirements from within the site.

Exposure Equations

To estimate potential dietary exposure, a TDD was estimated for the raccoon and green heron. The TDD calculation considers concentrations of the COPCs in the food items (i.e., shellfish), estimated amounts of abiotic media (i.e., sediment) that it would incidentally ingest, the relative amount of different food items in its diet, body weight, species-specific home range factor, and food ingestion rates.

A home range factor accounts for how much of the receptor's diet comes from the site based on the ratio of the area of receptor's home range to the available habitat area on-site. In the screening level evaluation it was conservatively assumed that 100% of the receptor's diet comes from the given exposure area and there is no seasonal migration out of the exposure area. These assumptions are conservative for receptors that may migrate off-site during parts of the year.

The following generalized equation was used to evaluate the TDD from all sources (i.e., food or prey item, drinking water, incidental ingestion) for each COPC:

$$TDD = \frac{\Sigma([IR_f \times C_f] + [IR_s \times C_s] + [IR_w \times C_w]) \times H}{\text{Body Weight}}$$

Where:

IR_f = Ingestion rate of food (kg/day)

IR_s = Incidental ingestion rate of sediment (kg/day)

IR_w = Ingestion rate of water (L/day)

C_f = Concentration of COPC in food (mg/kg)

C_s= Concentration of COPC in sediment (mg/kg)

C_w = Concentration of COPC in water (mg/kg)

H = Home range factor (ratio of the receptor's home range to the size of exposure area)

The sum of the doses from the various sources represents the full TDD from each COPC that a receptor may be exposed through as a result of foraging within an exposure area. This generalized equation was modified for each representative species. The surface water in Allen Harbor is saline, so is not used as a drinking water source for birds or mammals in the food chain model (C_w is assumed to be zero in the TDD calculations).

3.7 Risk Calculations

The integration of toxicity and exposure information is used to predict possible adverse effects to ecological receptors. The hazard quotient (HQ) method is used to screen sites when potential adverse effects to ecological receptors occur.

To estimate risks to benthic invertebrates, aquatic organisms, and plants, screening level HQs were calculated by comparing the maximum detected concentration for each chemical in each medium (i.e., an estimate of exposure) to the appropriate SEV (i.e., an estimate of effects) using the following formula:

$$HQ = \text{Maximum detected concentration}/SEV$$

For higher trophic level wildlife receptors, the risk estimate is also based on the HQ, defined as the ingested dose divided by the species-specific TRV:

$$HQ = TDD/TRV$$

Due to the consistently applied conservative assumptions implicit in a Tier 1 SRA the presence of HQs above 1 does not necessarily constitute ecological risk; only that additional consideration is warranted.

Analytes which exceed their respective screening benchmarks (i.e., HQs > 1) and analytes without screening benchmarks were retained as COPCs.

3.8 Risk Characterization

The COPCs and receptors with HQs greater than 1 in the updated Tier 1 ecological SRA risk assessment are summarized below.

Risk to Benthic Invertebrates Exposed to Shallow Sediment

The maximum detected concentrations for shallow sediment were compared against direct contact sediment SEVs identified for marine benthic invertebrates. The resulting HQs are presented in Table 1.

Twenty nine COPCs (representing analytes and analyte groups) had HQs above 1 when maximum detected sediment concentrations were compared against the benthic invertebrate SEVs. These HQs ranged from 1.1 for nickel to 145 for dieldrin (detected once above the SEV). Four COPCs lacked benthic invertebrate SEVs (beryllium, 2-butanone, acetone, and methylene chloride). Consistent with the 2015 ERA, total chlorinated VOCs were determined, but are not retained as a COPC; instead, the VOCs are evaluated individually.

In comparison to the 2015 ERA, eight chemicals that had been considered COPCs previously did not have HQs above 1 based on the current data set. Five chemicals that were not detected in the 2015 ERA data set were detected in the current data set and two (gamma-BHC and Aroclor-1254) were identified as COPCs.

Risk to Aquatic Organisms Exposed to Sediment Porewater – Piezometers Adjacent to Revetment Wall

The maximum detected concentrations for piezometer water collected from adjacent to the revetment wall were compared to surface water SEVs designed to be protective of aquatic life. The resulting HQs are presented in Table 2.

Thirteen COPCs (representing analytes and analyte groups) had HQs above 1 when maximum detected sediment concentrations were compared against the surface water SEVs (nine COPCs were identified in both dissolved and total phases). These HQs ranged from 1.1 for total PAHs to 2,200 for iron. Two compounds (BTEX and total chlorinated VOCs) were presented in the screen, but not selected as COPCs because risks were considered by evaluating individual VOCs. Eleven metals were identified as COPCs in the total recoverable phase and nine were retained in the dissolved phase.

In comparison to the 2015 ERA, two new COPCs were selected (total PAHs and total mercury) and the dissolved phases of four metals (arsenic, chromium, lead, zinc) were also identified as COPCs in the current data set, but not the 2015 ERA. There were no pesticides or PCBs detected in the current data set. Several PAHs and two phthalates were detected in the current data set but were not previously detected in the 2015 ERA. These chemicals were not identified as COPCs.

Risk to Aquatic Organisms Exposed to Sediment Porewater – Piezometers Beyond Breakwater Structure

The maximum detected concentrations for piezometer water collected from beyond the breakwater structure were compared to surface water SEVs designed to be protective of aquatic life. The resulting HQs are presented in Table 3.

Thirteen COPCs (representing analytes and analyte groups) had HQs above 1 when maximum detected sediment concentrations were compared against the surface water SEVs (eight COPCs were identified in both dissolved and total phases). These HQs ranged from 1.5 for total carbon disulfide to 7,149 for total recoverable aluminum. Eleven metals were identified as COPCs in the total recoverable phase and eight were retained in the dissolved phase.

In comparison to the 2015 ERA, two new COPCs were selected (2-butanone and carbon disulfide) and the dissolved phases of four metals (chromium, copper, lead, and zinc) were also identified as COPCs in the current data set, but not the 2015 ERA. There were no pesticides or PCBs detected in the current data set. Several PAHs, 2,4,5-trichlorophenol, 2-butanone, toluene, total xylenes, and several metals (predominantly in the dissolved phase) were detected in the current data set but were not previously detected in the 2015 ERA. Of these chemicals, 2-butanone, and dissolved phase copper, lead, and zinc were identified as COPCs.

Risk to Aquatic Organisms and Plants Exposed to Surface Water

The maximum detected concentrations for seep water were compared to surface water SEVs designed to be protective of aquatic life and to SEVs designed to be protective of plants. The resulting HQs are presented in Table 4.

Seep samples were only analyzed for VOCs. Four VOCs were detected and there were no HQs above 1. However, two VOCs (cis-1,2-dichloroethene and trans-1,2-dichloroethene) were selected as COPCs because plant SEVs were not available. Total chlorinated VOCs was presented in the screen, but not selected as a COPC because risks were considered by evaluating individual VOCs.

In comparison to the 2015 ERA, COPC selection was similar with both cis-1,2-dichloroethene and trans-1,2-dichloroethene retained based on a lack of plant SEVs. In the 2015 ERA, total 1,2-dichloroethene and vinyl chloride were also retained as COPCs based on a lack of plant SEVs.

Risk to Birds and Mammals

Risks to mammals and birds were assessed using conservative food web models and assumptions presented previously in the 2015 ERA. Table 5 presents the sediment and shellfish data considered in the 2017 ERA update of the models and Tables 6 and 7 present the conservative exposure food web models and HQs for the raccoon and green heron, respectively.

NOAEL-based HQs for the raccoon were above 1 for aluminum, antimony, arsenic, chromium, iron, and nickel (Table 6) and NOAEL-based HQs for the green heron were above 1 for aluminum, arsenic, chromium, copper, iron, lead, and mercury (Table 7). Therefore, these chemicals were identified as COPCs for wildlife. Aluminum, iron, and mercury were previously identified as COPCs for wildlife in the screening-level food web evaluation in the 2015 ERA, but antimony, arsenic, chromium, copper, lead, and nickel were not. However, it appears that food web risks were underestimated in the 2015 ERA because wet weight shellfish data were not converted to dry weight before inclusion in the food web model.

3.9 Tier 1 Conclusions

In this update of the Tier 1 portion of the ERA, it was determined that complete exposure pathways exist from the shallow sediment, groundwater (piezometer water), and surface water (seep water) at Site 09 to benthic invertebrates, aquatic organisms, plants and wildlife receptors. This evaluation indicated that certain COPCs warrant additional evaluation to assess the potential for risks to ecological receptors exposed to these media.

4.0 TIER 2, STEP 3A COPC REFINEMENT

The purpose of Tier 2, Step 3a is to reevaluate COPCs that were retained in Tier 1 for further evaluation in a Tier 2 BERA, and to identify and eliminate from further consideration those COPCs that were retained because of the use of very conservative exposure scenarios. Using less conservative, more realistic, Tier 2, Step 3a assumptions, the Tier 1 ecological SRA risk estimates were recalculated for the pathways and COPCs retained at the end of the Tier 1 SRA. These recalculated risk estimates were used to refine the list of COPCs identified in the Tier 1 ecological SRA.

Consistent with the 2015 ERA, the following factors were evaluated, as appropriate, to determine if the risks are great enough to warrant additional evaluations:

- Magnitude of criterion exceedance
- Frequency of chemical detection and spatial distribution
- Alternate benchmarks
- Food chain modeling assumptions

4.1 COPC Refinement – Benthic Invertebrates Exposed to Shallow Sediment

As indicated in Table 1, six metals slightly exceeded an HQ of 1, with HQs ranging from 1.1 (nickel) to 2.7 (copper) using the screening-level SEVs. However, when compared to the higher effect benchmarks there were no exceedances. When average concentrations were compared to the screening-level SEVs only copper slightly exceeded the SEV (34 mg/kg) with a concentration of 38 mg/kg. Beryllium was selected as a COPC because a screening value was not available. Beryllium was detected in 15 of 16 samples and concentrations ranged from 0.15 to 1.4 mg/kg. Based on the relatively low concentrations of beryllium no impacts are expected. Because the metals concentrations only slightly exceed the screening-level SEVs and no higher effects benchmarks are exceeded, it is it expected that metals risks to benthic invertebrates is minimal. This finding is consistent with the 2015 ERA.

Ten individual PAHs had HQs above 1 using the screening-level SEVs, with HQs ranging from 2 to 23. The toxicity of PAHs is assumed to be additive, so evaluating combined PAHs is useful in examining the potential risks. When evaluated as total PAHs the maximum HQ based on the screening-level SEV was 4.7, for high molecular weight (HMW) PAHs the maximum HQ was 8.2, and for low molecular weight (LMW) PAHs it was 9.4. The concentrations of total PAHs ranged from 0.011 to 19 mg/kg, and only two samples exceeded the screening-level SEV of 4.02 mg/kg. When

total PAH concentrations were compared to the higher effects benchmark there were no exceedances.

The concentrations of HMW PAHs ranged from 0.011 to 14 mg/kg, and three of the 19 samples exceeded the screening-level SEV of 1.7 mg/kg. When concentrations of HMW PAHs were compared to the higher effects benchmark, only one sample that exceeded the benchmark. The concentrations of LMW PAHs ranged from 0.005 to 5.2 mg/kg, and two samples exceeded the screening-level SEV of 0.55 mg/kg. When concentrations of LMW PAHs were compared to the higher effects benchmark there was only one sample that exceeded the benchmark. In general, only a few of the 19 samples exceeded the screening-level SEV, and fewer exceeded the higher effects benchmark. In addition, when the average concentrations were compared to screening values there were no exceedances of the screening-level SEV. Therefore, PAHs are not considered a risk to benthic invertebrates. This finding is consistent with the 2015 ERA.

Carbon disulfide was the only VOC retained as a COPC for benthic invertebrates due to exceedance of the screening level-SEV. No higher effects benchmark was identified for carbon disulfide. As indicated in the 2015 ERA, VOCs are typically not very toxic to invertebrates. Although carbon disulfide was detected more frequently in the current data set than in the 2015 ERA, the maximum and average detected concentrations were lower in the current data set. Therefore, consistent with the 2015 ERA, carbon disulfide is not considered a risk to benthic invertebrates.

Six pesticides had HQs above 1 using the screening-level SEVs, with HQs ranging from 1.2 to 145. All of the pesticides had a low frequency of detection with one to three detected concentrations out of nine samples. 4,4-DDE, endrin aldehyde, and heptachlor epoxide had HQs below 2, only slightly exceeding the screening-level SEVs with no exceedances of the higher effects benchmarks. 4,4-DDT was detected in three samples with concentrations ranging from 0.0046 to 0.0093 mg/kg, all samples exceed the screening-level SEV of 0.00158 mg/kg, but none exceeded the higher effects benchmark. Dieldrin was only detected in one sample at 0.0029 mg/kg which exceeded the screening-level SEV of 0.00002 mg/kg, but not the higher effects benchmark. Gamma-BHC (lindane) was detected in two samples at concentrations of 0.003 and 0.0021 mg/kg, which exceeded the screening-level SEV of 0.00032 mg/kg and the higher effects benchmark of 0.00099 mg/kg. All of the pesticides were detected infrequently and a relatively low concentrations that are not indicative of disposal activities. Therefore, risks to benthic invertebrates due to pesticides are expected to be minimal and not related to site activities. This finding is consistent with the 2015 ERA.

Aroclor-1254, Aroclor-1260, and total PCBs were also retained as COPCs with screening-level HQs ranging from 3.9 to 7.9 based on comparisons to the total PCB screening-level SEV. SEVs are not available for the individual Aroclors, so evaluating total PCBs is most appropriate in this refinement

step. Total PCBs exceeded the screening-level SEV of 0.0227 mg/kg in six of the seven detected samples with a range of concentrations of 0.049 to 0.18 mg/kg. When the PCBs were compared to the higher effects benchmarks, there were no exceedances. Because the concentrations of PCBs were relatively low, and there were no exceedances when compared to the higher effects benchmarks, potential risks from PCBs are expected to be minimal. This finding is consistent with the 2015 ERA, which showed slightly higher levels of Aroclor-1260 but reached the same conclusion.

A review of the average detected concentrations in the current data set and the average EPCs considered in the 2015 ERA indicates that, in general the average concentrations were similar. Some chemicals were higher in the current data set (most metals, some HMW PAHs, most pesticides, and total PCBs) and others were lower (aluminum, manganese, most PAHs, VOCs). The increases or decreases were relatively small with the largest differences found for pesticides where dieldrin and endrin aldehyde averages were approximately four times higher in the current data set than the 2015 ERA data set. However, given the infrequent detection of these COPCs, this does not necessarily indicate a trend and all detected concentrations considered in the 2017 ERA update were below the higher effects benchmarks.

Although there are several exceedances of the screening-level SEVs, the exceedances of the higher effects benchmarks are infrequent and relatively low (maximum HQ of 3). As indicated in Section 3.4, dredged material was used to construct the created wetland and likely serves as a potential source of COPCs. COPCs concentrations in surface sediment may reflect contributions from both the dredged materials and the landfill. Therefore, consistent with the 2015 ERA, no chemicals in sediment are retained as COPCs for benthic invertebrates.

4.2 COPC Refinement – Aquatic Organisms Exposed to Sediment Pore Water

Piezometers Adjacent to Revetment Wall

As indicated in Table 2, total PAHs slightly exceeded the screening-level SEV with an HQ of 1.1 based on a detected concentration in one of three samples. One VOC, carbon disulfide, exceeded the screening-level SEV of 0.92 ug/L in two samples with a range of detected concentrations of 0.4 to 5.3 ug/L. Carbon disulfide had a low frequency of detection and was only detected in 4 of the 12 samples. Based on the infrequent detections and exceedances of the screening-level SEVs, concentrations of total PAHs and carbon disulfide are not expected to adversely impact aquatic organisms at the Site and both chemicals are eliminated as COPCs for aquatic organisms.

Eleven metals had HQs above 1 based on comparisons to screening-level SEVs; however, beryllium and mercury were only COPCs in the total recoverable, not dissolved phase. The bioavailable fraction of metals is more closely represented by dissolved metals in the water column. Therefore,

only COPCs selected in dissolved metals are further evaluated. Concentrations of aluminum, arsenic, chromium, copper, iron, lead, manganese, nickel, and zinc exceeded screening-level SEVs in the dissolved phase.

Piezometer water is being used to represent exposure to sediment porewater that might occur for aquatic organisms. Aquatic receptors within the sediment are typically exposed to pore water in the upper 0 to 6 inches of sediment within the biologically active zone. However, the piezometer water was collected at a depth of 2 to 3 feet bgs which is likely deeper than most aquatic organisms would be found. Groundwater at this depth will be diluted as it moves upward towards the biologically active zone. Therefore, the actual concentrations of pore water in the biologically active zone would likely be lower than what is present in groundwater or piezometer water, and exceedances of piezometer water do not necessarily indicate unacceptable risk to the aquatic community.

A dilution factor has not been determined at this site, but if a dilution factor of 10 was used all concentrations of zinc would be below the screening-level SEV. Average concentrations of arsenic, chromium, lead, manganese and nickel would also be below the screening-level SEVs with a 10-fold dilution. Average concentrations of aluminum, copper, and iron exceeded the screening-level SEVs with a 10-fold dilution applied.

When considered on a sample-by-sample basis, the following COPCs exceed the screening-level SEVs with the 10-fold dilution applied –one sample each for arsenic and lead, two samples each for chromium, copper, manganese, and nickel, six samples for aluminum, and seven samples for iron. In general, these exceedances are limited to the northern (P09-01, P09-02A) and southern (P09-09, P09-10) portions of the site.

A review of dissolved and total recoverable phase metals data from nearby shallow (or intermediate depth if nearby shallow groundwater was not available) groundwater monitoring wells was conducted to qualitatively assess whether the monitoring well data corresponded with elevated concentrations in nearby piezometer water.

Monitoring wells MW09-25S and MW09-11S are located within the northern portion of the site in the vicinity of piezometers P09-01 and P09-02A which had exceedances of the screening level SEVs for aluminum, chromium, copper, iron, lead, manganese, and nickel with the 10-fold dilution applied. Concentrations of these COPCs in the groundwater data are much lower than the piezometer water concentrations indicating that groundwater is not likely the source of the COPCs in piezometer water.

Monitoring well MW09-21S is located within the southern portion of the site in the vicinity of piezometers P09-09 and P09-10 which had exceedances of the screening level SEVs for aluminum,

iron, and manganese with the 10-fold dilution applied. As noted for the northern wells, concentrations of these COPCs in the groundwater data are much lower than the piezometer water concentrations indicating that groundwater is not likely the source of the COPCs in piezometer water.

Arsenic in piezometer water from one location (P09-05A) was elevated above the screening level SEV with the 10-fold dilution factor applied, so data from groundwater well MW09-17I were reviewed. While arsenic in the piezometer was detected at 666 ug/L, the highest concentration in the groundwater was 0.58 ug/L. Therefore, groundwater is not expected to be the source of the elevated arsenic at P09-05A.

Based on this review of the groundwater data, it does not appear that the piezometer water concentrations of metals above the screening-level SEVs are related to groundwater discharge from the site. Therefore, metals are eliminated as COPCs for aquatic organisms.

These findings are consistent with the 2015 ERA. Concentrations of metals in the piezometer water are higher than observed in the 2015 ERA data set; however, consistent with the 2015 ERA, the review of the groundwater data indicates that groundwater from the site does not appear to be the source of COPC in piezometer water.

Piezometers Beyond Breakwater Structure

As indicated in Table 3, only two VOCs were selected as COPCs and each was detected only three times in 20 samples. As indicated in the 2015 ERA, VOCs are typically not very toxic to invertebrates. Carbon disulfide had a maximum concentration of 1.4 ug/L which only slightly exceeded the screening value of 0.92 ug/L and the maximum concentration of 2-butanone (43 ug/L) resulted in a maximum HQ of 14. Based on the relatively low levels of these VOCs and the infrequent detections, concentrations of carbon disulfide and 2-butanone are not expected to adversely impact aquatic organisms at the Site and both chemicals are eliminated as COPCs for aquatic organisms.

Eleven metals had HQs above 1 based on comparisons to screening-level SEVs; however, arsenic, beryllium, and mercury were only COPCs in the total recoverable, not dissolved phase. As stated previously, the dissolved metals in the water column represent the bioavailable fraction, so only COPCs selected in dissolved metals are further evaluated. Concentrations of aluminum, chromium, copper, iron, lead, manganese, nickel, and zinc in the dissolved phase exceeded screening-level SEVs.

As indicated previously, concentrations of pore water in the biologically active zone would likely be lower than what is present in groundwater or piezometer water, and exceedances of piezometer

water do not necessarily indicate unacceptable risk to the aquatic community. Therefore, a 10-fold dilution factor was applied to further evaluate COPCs in piezometer water.

With a dilution factor of 10 considered, concentrations of chromium, lead, and zinc would all be below the screening-level SEVs. Average concentrations of chromium, lead, and zinc would also be below the screening-level SEVs with a 10-fold dilution. Average concentrations of aluminum, copper, iron, manganese, and nickel exceeded the screening-level SEVs with a 10-fold dilution applied.

When considered on a sample-by-sample basis, the following COPCs exceed the screening-level SEVs with the 10-fold dilution applied – two samples for copper, three samples for manganese, five samples each for aluminum and nickel, and six samples for iron. These exceedances occur in all five of the outside the breakwater piezometer locations with P09-08B and P09-012B, located in the southeastern potion of the site, showing the most frequent exceedances.

As described above, shallow (or intermediate depth) groundwater data for dissolved and total recoverable phase metals from nearby monitoring wells were reviewed to qualitatively assess whether the monitoring well data corresponded with elevated concentrations in nearby piezometer water.

Monitoring wells MW09-08S, MW-09-20I, and MW09-09S are located within the southeastern portion of the site in the vicinity of piezometers P09-06B, P09-07B, P09-08B, and P09-12B which had exceedances of the screening level SEVs for aluminum, copper, iron, manganese, and nickel with the 10-fold dilution applied. Similar to the observations noted for the piezometers adjacent to the revetment wall, the concentrations of these COPCs in the groundwater data are much lower than the piezometer water concentrations indicating that groundwater is not likely the source of the COPCs in piezometer water.

Monitoring wells MW-09-10S and MW09-23S are located in the vicinity of piezometers P09-11B which had exceedances of the screening level SEVs for aluminum and copper with the 10-fold dilution applied. Aluminum and copper were detected infrequently in the groundwater from MW-09-10S and MW09-23S and the detected concentrations are well below the maximum aluminum and copper concentrations in P09-11B (3,680 and 88.6 ug/L, respectively).

Based on this review of the groundwater data, it does not appear that the piezometer water concentrations of metals above the screening-level SEVs are related to groundwater discharge from the site. Therefore, metals are eliminated as COPCs for aquatic organisms.

These findings are consistent with the 2015 ERA. Some dissolved phase metals that were not previously detected in the 2015 ERA data set are detected in the current data set (copper, lead,

zinc) and dissolved phase concentrations are generally higher in the current data set. However, consistent with the 2015 ERA, the review of the groundwater data indicates that groundwater from the site does not appear to be the source of COPC in piezometer water.

4.3 COPC Refinement – Aquatic Organisms Exposed to Surface Water

Two VOCs were selected as COPCs due to a lack of available plant screening values (cis-1,2-dichloroethene, and trans-1,2-dichloroethene). These VOC were both detected at low frequencies (two detects out of 11 samples) and concentrations were well below plant-based screening values for other VOCs identified by Efroymson, et al. (1997; values for VOCs range from 1,000 to 100,000 ug/L). No impacts to plants are expected from exposure to VOCs in surface water.

The VOC concentrations detected in seep water in the current data set are lower than the concentrations evaluated in the 2015 ERA and the findings of this update are consistent with the 2015 ERA.

4.4 COPC Refinement – Birds and Mammals

A refined food web model was used to assess the potential for risks to mammals and birds. Alternative average exposure factors and average detected concentrations were used to refine the conservative evaluation presented in the screening-level food webs presented in Tables 6 and 7. The alternative exposure factors used were consistent with those used in the 2015 ERA.

Although the screening-level food webs assumed that the receptors obtained all of their diet from the shoreline area surrounding the site (i.e., where shallow sediment and shellfish were collected), it is more likely that they also forage elsewhere. The home range of the raccoon was reported as 386 acres (USEPA, 1993 as cited in Tetra Tech, 2015), which is larger than the shoreline area surrounding the site (0.9 acres). Therefore, a home range factor of 0.00233 was calculated by dividing the approximate shoreline area (0.9 acres) by the home range (386 acres). The home range for the green heron was reported as 0.355 kilometers (km) of shoreline, which is smaller than the shoreline of the site (approximately 0.6 km). Because the home range was smaller than the site shoreline, the home range factor for the green heron remained the same (H=1) as in the conservative food web model.

In addition, the average sediment and shellfish concentrations were used in the refined food web model calculations. The resulting TDD was divided by the NOAEL- and LOAEL-based TRVs to estimate the potential for adverse effects to ecological receptors over the range of toxicity levels.

Table 8 presents the refined food web model calculations for the raccoon for the six COPCs with NOAEL-based HQs above 1 in the conservative food web model. The results of the refined evaluation indicate that no chemicals exceeded a HQ of 1 for the raccoon.

Table 9 presents the refined food web model calculations for the green heron for the seven COPCs with NOAEL-based HQs above 1 in the conservative food web model. The results of the refined evaluation indicate that five COPCs had HQs above 1 (HQs ranging from 1.1 to 3.4) using the NOAEL-based TRV. However, none of the HQs were above 1 when the LOAEL-based TRV was used.

While all of the TDDs are dominated by the shellfish contribution, the aluminum and iron TDDs for the green heron also contain a significant contribution (27% to 30%) from the incidental ingestion of sediment during foraging. The sediment ingestion rate of 5% was selected based on best professional judgement due to a lack of data for the green heron and is likely to be an overestimate. Even a slight reduction in the sediment ingestion rate would bring the NOAEL-based HQ for aluminum below 1 and would reduce the iron HQ. The heron food web model also assumes that the heron obtains all of their diet from the shoreline of the Site. This is likely an overestimate and a reduction of the home range factor from 1 to 0.75 would bring the NOAEL-based HQs for aluminum and chromium below 1 and would reduce the NOAEL-based HQs for arsenic, iron, and mercury to 1.1, 2.6, and1.2, respectively.

Based on the low NOAEL-based HQs, the lack of LOAEL-based HQs above 1, and the conservative nature of the sediment ingestion rate and the home range factor, risks to the green heron due to exposure to sediment and shellfish are expected to be minimal.

As described in Section 4.1, average sediment concentrations varied, but not substantially or consistently up or down, between the current data set and the data set considered in the 2015 ERA. For the shellfish, most metals and approximately half of the organic constituents had higher average concentrations in the current data set than in the previous dataset. The greatest difference in shellfish concentration was for chromium with an average concentration of 2.8 mg/kg_{ww} in the current data set and 0.18 mg/kg_{ww} in the previous data set. Although many of the shellfish concentrations were higher in the current data set than in the 2015 ERA, the overall findings of minimal risks to wildlife are consistent with the previous ERA.

5.0 ECOLOGICAL RISK UNCERTAINTY ANALYSIS

ERA results depend primarily on the use of multiple lines of evidence supporting particular conclusions, and each line of evidence is subject to varying degrees of uncertainty. Because of the complexity of ecosystems and the associated mechanisms that cause ecological stress, uncertainty in environmental risk characterization is inevitable. Uncertainty could be attributable to a number of sources, including but not limited to the following:

- Sampling and statistical variability
- Difficulty of extrapolating from laboratory data to field data
- Problems in evaluating environmental responses to mixtures of contaminants
- Range of conditions for which models or HQs are applicable

Additional sources of uncertainty associated with this evaluation are described below. In general, the assumptions made in multiple points in the ERA tend to err on the side of over-estimating risks. The cumulative impact of multiple conservative assumptions is more likely to over-estimate, than under-estimate, potential risks to ecological receptors.

Uncertainty in Ecological Effects Data

Sediment SEVs were not available for a beryllium, 2-butanone, acetone, and methylene chloride which were detected in sediment. Mammalian TRVs were not available for 2-butanone or tetrachloroethene and avian TRVs were not available for antimony beryllium, four VOCs, and heptachlor epoxide so these chemicals could not be evaluated in the food web models. These chemicals were selected as COPCs because, with no SEV or TRV, it cannot be stated with certainty that those COPCs do not pose an ecological risk. However, VOCs are typically not toxic to invertebrates and they do not tend to bioaccumulate in the food chain.

Several of the screening-level SEVs are very conservative, and are based on laboratory studies using chemical forms that are more bioavailable than chemicals found in the environment.

The community-level screening benchmarks and wildlife TRVs used do not generally account for possible synergistic, antagonistic, or additive effects of COPC mixtures in environmental media. These factors may result in an under-estimate or over-estimate of potential risk. Assessing potential risks due to exposures to chemical mixtures is challenging since chemicals within the mixture may not be equally bioavailable and may not act on the receptor with the same toxic mechanism.

The TRVs used in the food web model are based on species other than the endpoint species (e.g., rats, mice). Uncertainty exists in the application of toxicity data across species because the

contaminant may be more or less toxic to the endpoint species than it was to the test study species.

Uncertainties in Ecological Exposure Estimation

In general, the sampling activities targeted areas with the potential to have been impacted by historic site activities. However, these areas may not represent ecological habitats or areas likely to be frequented by ecological receptors. Therefore, ecological exposures represented by some samples may be limited or receptors may forage in other portions of the Site. This type of sampling is expected to bias results high.

Shellfish data used in the 2017 ERA update were reported on a wet weight basis and percent moisture data were not reported. Therefore, the percent moisture results for the 2009 to 2012 shellfish data were used to convert the wet weight data to dry weight to be consistent with the food web modeling approach used in the 2015 ERA. The lack of sample specific percent moisture results represents a source of uncertainty in the food web evaluation where the shellfish represent the prey item for the raccoon and the shrew. The average percent moisture of 86.6% from the 2009 to 2012 shellfish data is slightly higher than the average for bivalves listed in USEPA guidance (82% moisture; USEPA, 1993). However, even a slight decrease in the percent moisture would lower the dry weight tissue concentrations and the associated wildlife HQs.

As stated previously, the piezometer water was collected at a depth of 2 to 3 ft bgs, which is deeper than the biologically active zone (typically 0 to 6 inches). Therefore, the comparison of those data to surface water SEVs is very conservative and likely to over-estimate risks to aquatic receptors.

The average concentrations evaluated in the 2017 ERA update are based on the detected concentrations. An average concentration that included non-detect values would be lower; therefore, the evaluation of the average of the detected concentrations in the COPC refinement may over-estimate risks throughout the exposure area and for mobile receptors.

The TDD in the food web model is based on an equation that incorporates ingestion rates, body weights, and other exposure factors. These exposure factors were obtained from literature studies or predicted using various equations. Ingestion rates and body weights vary among species, especially among species inhabiting different habitats and species present on-site could be somewhat different from those models in the food web model.

6.0 ECOLOGICAL RISK SUMMARY AND CONCLUSIONS

This 2017 ERA update was performed in support of the Site 09 Five Year Event LTM Report and will ultimately be used as part of the evaluation to confirm compliance with the RAOs identified in the ROD. The objective of this ERA update is to determine whether there have been any changes and/or updates to ERA guidance or site-specific conditions since the 2015 ERA was conducted that would result in a change of the conclusions of the 2015 ERA or whether the conclusions of the 2015 ERA remain valid.

The receptors and exposure pathways evaluated in the ERA update are consistent with those evaluated in the 2015 ERA. These included the following:

- Benthic invertebrates exposed to shallow sediment;
- Aquatic organisms exposed to sediment pore water (represented by piezometer water) and surface water (represented by seep water);
- Terrestrial plants exposed to surface water (represented by seep water); and
- Birds and mammals exposed to shallow sediment and shellfish via ingestion pathways

Toxicity values and exposure assumptions used in the 2017 ERA update are consistent with those used in the 2015 ERA. Updated analytical data from all media were used to update the benchmark screens and food web models and to qualitatively identify differences between the current data set and the data set evaluated in the 2015 ERA.

The overall conclusion of this 2017 ERA update is that the conclusions of the 2015 ERA remain valid and exposure to shallow sediment, pore water, surface water, and shellfish along the Site 09 shoreline does not pose a site-related risk to ecological receptors. Concentrations of several metals were elevated in piezometer water, but it does not appear that these concentrations are related to groundwater at the site.

Notes:
Only detected chemicals are presented. See Appendix A for all analytical results.
All concentrations reported in micrograms per kilograms (mg/kg).
COPC - Chemical of Potential Concern.
HQ - Hazard Quotient (Maximum detected concentration/SEV).
J+ - The chemical was positively identified; however, the associated numerical value is a high estimated concentration.
J - Estimated concentration.
J- -The chemical was positively identified; however, the associated numerical value is a low estimated concentration.
NA - Not available or Not applicable.
ND - Not detected.
No SEV - Analyte was detected but SEV was not identified (analyte is retained as a COPC).
SEV - Screening Ecotoxicity Value.

1 - Concentrations presented in Table F-3.2 in the Long-Term Monitoring Data Summary and Optimization Recommendations Report for Site 09 (Tetra Tech, 2015).
2 - Value for endrin.
3 - Risks considered by evaluating individual volatile organic compounds (VOCs).

Screening Level Sources (in Order of Preference):
ER-L 1995 - Effects Range - Low (ER-L) values (Long, et al., 1995)
ER-L 1991 - ER-L values (Long and Morgan, 1991)
Region 3 - USEPA Region 3 Biological Technical Assistance Group (BTAG) sediment screening benchmarks (USEPA, 2006, 2006)
NOAA - NOAA SQuiRT sediment benchmarks (Buchman, 2008)
Freshwater values (FW) were only selected if no marine values were available.

Higher Effect Benchmark Sources (in Order of Preference):
ER-M 1995 - Effects Range - Median (ER-M) values (Long, et al., 1995)
ER-M 1991 - ER-M values (Long and Morgan, 1991)
NOAA - NOAA SQuiRT sediment benchmarks (Buchman, 2008)

Notes:
Only detected chemicals are presented. See Appendix A for all analytical results.
All concentrations reported in micrograms per liter (ug/L).
COPC - Chemical of Potential Concern.
HQ - Hazard Quotient (Maximum detected concentration/SEV).
J+ - The chemical was positively identified; however, the associated numerical value is a high estimated concentration.
J - Estimated concentration.
J- -The chemical was positively identified; however, the associated numerical value is a low estimated concentration.
NA - Not available or Not applicable.
ND - Not detected in dataset evaluated in the 2015 ecological risk assessment [ERA]).
SEV - Screening Ecotoxicity Value.
1 - Concentrations presented in Table F-3.3 in the Long-Term Monitoring Data Summary and Optimization Recommendations Report for Site 09 (Tetra Tech, 2015).
2 - Chronic value not available. Value calculated by multiplying acute LOAEL value by 0.01 to estimate chronic NOAEL.
3 - Risks considered by evaluating individual volatile organic compounds (VOCs).
SEV Sources (in Order of Preference):
NRWQC - National Recommended Water Quality Criteria (USEPA, 2013).
RIDEM - RIDEM Saltwater Ambient Water Quality Criteria (AWQC) (RIDEM, 2009).
Region 3 - USEPA Region 3 marine screening benchmarks (USEPA, 2006c).
NOAA - National Oceanic and Atmospheric Adminstration chronic marine surface water values (Buchman, 2008).
RIDEM FW - RIDEM Freshwater AWQC (RIDEM, 2009).
Region 3 FW - USEPA Region 3 freshwater screening benchmarks (USEPA, 2006d).

Notes:
Only detected chemicals are presented. See Appendix A for all analytical results.
All concentrations reported in micrograms per liter (ug/L).
COPC - Chemical of Potential Concern.
HQ - Hazard Quotient (Maximum detected concentration/SEV).
J - Estimated concentration.
J- -The chemical was positively identified; however, the associated numerical value is a low estimated concentration.
ND - Not detected in dataset evaluated in the 2015 ecological risk assessment [ERA]).
SEV - Screening Ecotoxicity Value.
1 - Concentrations presented in Table F-3.4 in the Long-Term Monitoring Data Summary and Optimization Recommendations Report for Site 09 (Tetra Tech, 2015).
2 - Chronic value not available. Value calculated by multiplying acute LOAEL value by 0.01 to estimate chronic NOAEL.
SEV Sources (in Order of Preference):
NRWQC - National Recommended Water Quality Criteria (USEPA, 2013).
RIDEM - RIDEM Saltwater Ambient Water Quality Criteria (AWQC) (RIDEM, 2009).
Region 3 - USEPA Region 3 marine screening benchmarks (USEPA, 2006c).
NOAA - National Oceanic and Atmospheric Adminstration chronic marine surface water values (Buchman, 2008)
RIDEM FW - RIDEM Freshwater AWQC (RIDEM, 2009).
Region 3 FW - USEPA Region 3 freshwater screening benchmarks (USEPA, 2006d).

Notes:

Only detected chemicals are presented. See Appendix A for all analytical results.
All concentrations reported in micrograms per liter (ug/L).
1 - Risks considered by evaluating individual volatile organic compounds (VOCs).
2 - Concentrations presented in Table F-3.5 in the Long-Term Monitoring Data Summary and Optimization Recommendations Report for Site 09 (Tetra Tech, 2015).
COPC - Chemical of Potential Concern.
HQ - Hazard Quotient (Maximum detected concentration/SEV).
J - Estimated concentration.
NA - Not available or Not applicable.
No SEV - Analyte was detected but SEV was not identified (analyte is retained as a COPC).
SEV - Screening Ecotoxicity Value.
SEV Sources:
ORNL - Oak Ridge National Laboratory (Efroymson, et al., 1997).
Region 3 - USEPA Region 3 marine screening benchmarks (USEPA, 2006c).

Notes
All concentrations reported in micrograms per kilograms (mg/kg).
ND - Not detected.
NV - No value available.
dw - Dry Weight.
ww - Wet Weight.
1 - VOCs were not analyzed for in shellfish samples; only incidental ingestion of soil sediment was evaluated for VOCs.
2 - PCBs in sediment are reported on an Aroclor basis. PCBs in shellfish tissue are reported as total PCB homologs.
3 - Shellfish data converted from wet weight to dry weight assuming 13.4% solids (dry weight tissue = [wet weight tissue / fraction solids]). This solids value is based on the average percent moisture obtained from Site 09 shellfish tissue data from 2009 through 2012.
4 - Concentrations presented in Appendix F-3, Attachment 1, Table 6 in the Long-Term Monitoring Data Summary and Optimization Recommendations Report for Site 09 (Tetra Tech, 2015).

Exposure Parameters: [4]

Body Weight = (BW)	0.2	kg
Shellfish Ingestion Rate = (Ii)	0.031	kg/day
Sediment Ingestion Rate = (Is)	0.0016	kg/day
Home Range = (HR)	Assume 100% on site	
Contaminated Area = (CA)	Assume equal to home range	
Home Range Factor = (H)	1	unitless

Dose (sediment) = (Cs * Is)(H)/BW
Dose (Shellfish) = (Ci * Ii)(H)/BW
Ci = Contaminant concentration in Shellfish
Cs = Contaminant concentration in sediment
Total Dose = Dose (sediment) + Dose (Shellfish)
H=CA/HR (Assume = to 1)

LOAEL = Lowest Observed Adverse Effects Level
NOAEL = No Observed Adverse Effects Level
NV = No value available

Cells are shaded if the hazard quotient is greater than 1.0

1 - VOCs were not analyzed for in shellfish samples; only incidental ingestion of soil sediment was evaluated for VOCs.
2 - PCBs in sediment are reported on an Aroclor basis. PCBs in shellfish tissue are reported as total PCB homologs.
3 - Toxicity reference values presented in Appendix F-3, Attachment 1, Table 3, in the Long-Term Monitoring Data Summary and Optimization Recommendations Report for Site 09 (Tetra Tech, 2015).
Acetone values are from Sample et.al., 1996.
4 - Exposure parameters presented in Appendix F-3, Attachment 1, Tables 1 and 2 (Tetra Tech, 2015).

Notes:
Results reported on a wet weight basis.
< = Result not detected above laboratory reporting limit.
CAS = Chemical Abstracts Service.
FD = Field duplicate.
J = Estimated value.
J- = The chemical was positively identified; however, the associated numerical value is a low estimated concentration.
mg/kg = milligram per kilogram.
N = Normal sample.
PCBs = Polychlorinated biphenyls.
R = Rejected.
SVOC = Semivolatile organic compound.
U = Not detected.
UJ = The analyte was not detected; and the reporting limit is approximate.
VOC = Volatile organic compound.
(a) Total concentrations were calculated per sample by summing only the detected individual compounds (i.e., homolog) concentrations. For samples without any detections of individual compounds (i.e., homolog) the maximum reporting detection limit within the sample is presented as a non-detect value.
(b) Lab calculated value; Not used. Totals for use in risk assessment are calculated as discussed in the report text.

Notes:
Results reported on a wet weight basis.
< = Result not detected above laboratory reporting limit.
CAS = Chemical Abstracts Service.
FD = Field duplicate.
J = Estimated value.
J- = The chemical was positively identified; however, the associated numerical value is a low estimated concentration.
mg/kg = milligram per kilogram.
N = Normal sample.
PCBs = Polychlorinated biphenyls.
R = Rejected.
SVOC = Semivolatile organic compound.
U = Not detected.
UJ = The analyte was not detected; and the reporting limit is approximate.
VOC = Volatile organic compound.
(a) Total concentrations were calculated per sample by summing only the detected individual compounds (i.e., homolog) concentrations. For samples without any detections of individual compounds (i.e., homolog) the maximum reporting detection limit within the sample is presented as a non-detect value.
(b) Lab calculated value; Not used. Totals for use in risk assessment are calculated as discussed in the report text.

Notes:
Results reported on a wet weight basis.
< = Result not detected above laboratory reporting limit.
CAS = Chemical Abstracts Service.
FD = Field duplicate.
J = Estimated value.
J- = The chemical was positively identified; however, the associated numerical value is a low estimated concentration.
mg/kg = milligram per kilogram.
N = Normal sample.
PCBs = Polychlorinated biphenyls.
R = Rejected.
SVOC = Semivolatile organic compound.
U = Not detected.
UJ = The analyte was not detected; and the reporting limit is approximate.
VOC = Volatile organic compound.
(a) Total concentrations were calculated per sample by summing only the detected individual compounds (i.e., homolog) concentrations. For samples without any detections of individual compounds (i.e., homolog) the maximum reporting detection limit within the sample is presented as a non-detect value.
(b) Lab calculated value; Not used. Totals for use in risk assessment are calculated as discussed in the report text.

Notes:
< = Result not detected above laboratory reporting limit.
CAS = Chemical Abstracts Service.
EB = Equipment blank contamination.
FD = Field duplicate.
J = Estimated value.
J+ = The chemical was positively identified; however, the associated numerical value is a high estimated concentration.
J- = The chemical was positively identified; however, the associated numerical value is a low estimated concentration.
mg/kg = milligram per kilogram.
N = Normal sample.
PCBs = Polychlorinated biphenyls.
SVOC = Semivolatile organic compound.
U = Not detected.
UJ = The analyte was not detected; and the reporting limit is approximate.
VOC = Volatile organic compound.
(a) Total concentrations were calculated per sample by summing only the detected individual compounds (i.e., Aroclor) concentrations. For samples without any detections of individual compounds (i.e., Aroclor), the maximum reporting detection limit within the sample is presented as a non-detect value.

Notes:
< = Result not detected above laboratory reporting limit.
CAS = Chemical Abstracts Service.
EB = Equipment blank contamination.
FD = Field duplicate.
J = Estimated value.
J+ = The chemical was positively identified; however, the associated numerical value is a high estimated concentration.
J- = The chemical was positively identified; however, the associated numerical value is a low estimated concentration.
mg/kg = milligram per kilogram.
N = Normal sample.
PCBs = Polychlorinated biphenyls.
SVOC = Semivolatile organic compound.
U = Not detected.
UJ = The analyte was not detected; and the reporting limit is approximate.
VOC = Volatile organic compound.
(a) Total concentrations were calculated per sample by summing only the detected individual compou (i.e., Aroclor) concentrations. For samples without any detections of individual compounds (i.e., Ar the maximum reporting detection limit within the sample is presented as a non-detect value.

Notes:

< = Result not detected above laboratory reporting limit.

CAS = Chemical Abstracts Service.

EB = Equipment blank contamination.

FD = Field duplicate.

J = Estimated value.

J+ = The chemical was positively identified; however, the associated numerical value is a high estimated concentration.

J- = The chemical was positively identified; however, the associated numerical value is a low estimated concentration.

mg/kg = milligram per kilogram.

N = Normal sample.

PCBs = Polychlorinated biphenyls.

SVOC = Semivolatile organic compound.

U = Not detected.

UJ = The analyte was not detected; and the reporting limit is approximate.

VOC = Volatile organic compound.

(a) Total concentrations were calculated per sample by summing only the detected individual compou
(i.e., Aroclor) concentrations. For samples without any detections of individual compounds (i.e., Ar
the maximum reporting detection limit within the sample is presented as a non-detect value.

Notes:
< = Result not detected above laboratory reporting limit.
CAS = Chemical Abstracts Service.
F = Filtered sample.
FD = Field duplicate.
FF = Field filtered sample.
J = Estimated value.
J+ = The chemical was positively identified; however, the associated numerical value is a high estimated concentration.
J- = The chemical was positively identified; however, the associated numerical value is a low estimated concentration.
N = Normal sample.
PCBs = Polychlorinated biphenyls.
SVOC = Semivolatile organic compound.
U = Not detected.
ug/L - microgram per liter.
UJ = The analyte was not detected; and the reporting limit is approximate.
VOC = Volatile organic compound.
(a) Total concentrations were calculated per sample by summing only the detected individual compounds (i.e., Aroclor) concentrations. For samples without any detections of individual compounds (i.e., Aroclor), the maximum reporting detection limit within the sample is presented as a non-detect value.

Notes:
< = Result not detected above laboratory reporting limit.
CAS = Chemical Abstracts Service.
F = Filtered sample.
FD = Field duplicate.
FF = Field filtered sample.
J = Estimated value.
J+ = The chemical was positively identified; however, the associated numerical value is a high estimated concentration.
J- = The chemical was positively identified; however, the associated numerical value is a low estimated concentration.
N = Normal sample.
PCBs = Polychlorinated biphenyls.
SVOC = Semivolatile organic compound.
U = Not detected.
ug/L - microgram per liter.
UJ = The analyte was not detected; and the reporting limit is approximate.
VOC = Volatile organic compound.
(a) Total concentrations were calculated per sample by summing only the detected individual compounds (i.e., Aroclor) concentrations. For samples without any detections of individual compounds (i.e., Aroclor), the maximum reporting detection limit within the sample is presented as a non-detect value.

Notes:
< = Result not detected above laboratory reporting limit.
CAS = Chemical Abstracts Service.
F = Filtered sample.
FD = Field duplicate.
FF = Field filtered sample.
J = Estimated value.
J+ = The chemical was positively identified; however, the associated numerical value is a high estimated concentration.
J- = The chemical was positively identified; however, the associated numerical value is a low estimated concentration.
N = Normal sample.
PCBs = Polychlorinated biphenyls.
SVOC = Semivolatile organic compound.
U = Not detected.
ug/L - microgram per liter.
UJ = The analyte was not detected; and the reporting limit is approximate.
VOC = Volatile organic compound.
(a) Total concentrations were calculated per sample by summing only the detected individual compounds (i.e., Aroclor) concentrations. For samples without any detections of individual compounds (i.e., Aroclor), the maximum reporting detection limit within the sample is presented as a non-detect value.

Notes:
< = Result not detected above laboratory reporting limit.
CAS = Chemical Abstracts Service.
F = Filtered sample.
FD = Field duplicate.
FF = Field filtered sample.
J = Estimated value.
J+ = The chemical was positively identified; however, the associated numerical value is a high estimated concentration.
J- = The chemical was positively identified; however, the associated numerical value is a low estimated concentration.
N = Normal sample.
PCBs = Polychlorinated biphenyls.
SVOC = Semivolatile organic compound.
U = Not detected.
ug/L - microgram per liter.
UJ = The analyte was not detected; and the reporting limit is approximate.
VOC = Volatile organic compound.
(a) Total concentrations were calculated per sample by summing only the detected individual compounds (i.e., Aroclor) concentrations. For samples without any detections of individual compounds (i.e., Aroclor), the maximum reporting detection limit within the sample is presented as a non-detect value.

VOCs	N	XYLENES, TOTAL	1330-20-7	ug/L		< 1.0 U		< 1.5 U		

Notes:
< = Result not detected above laboratory reporting limit.
CAS = Chemical Abstracts Service.
F = Filtered sample.
FD = Field duplicate.
FF = Field filtered sample.
J = Estimated value.
J+ = The chemical was positively identified; however, the associated numerical value is a high estimated concentration.
J- = The chemical was positively identified; however, the associated numerical value is a low estimated concentration.
N = Normal sample.
PCBs = Polychlorinated biphenyls.
SVOC = Semivolatile organic compound.
U = Not detected.
ug/L - microgram per liter.
UJ = The analyte was not detected; and the reporting limit is approximate.
VOC = Volatile organic compound.
(a) Total concentrations were calculated per sample by summing only the detected individual compounds (i.e., Aroclor) concentrations. For samples without any detections of individual compounds (i.e., Aroclor), the maximum reporting detection limit within the sample is presented as a non-detect value.

Notes:

< = Result not detected above laboratory reporting limit.

CAS = Chemical Abstracts Service.

F = Filtered sample.

FD = Field duplicate.

FF = Field filtered sample.

J = Estimated value.

J+ = The chemical was positively identified; however, the associated numerical value is a high estimated concentration.

J- = The chemical was positively identified; however, the associated numerical value is a low estimated concentration.

N = Normal sample.

PCBs = Polychlorinated biphenyls.

SVOC = Semivolatile organic compound.

U = Not detected.

ug/L - microgram per liter.

UJ = The analyte was not detected; and the reporting limit is approximate.

VOC = Volatile organic compound.

(a) Total concentrations were calculated per sample by summing only the detected individual compounds (i.e., Aroclor) concentrations. For samples without any detections of individual compounds (i.e., Aroclor), the maximum reporting detection limit within the sample is presented as a non-detect value.

Notes:
< = Result not detected above laboratory reporting limit.
CAS = Chemical Abstracts Service.
F = Filtered sample.
FD = Field duplicate.
FF = Field filtered sample.
J = Estimated value.
J+ = The chemical was positively identified; however, the associated numerical value is a high estimated concentration.
J- = The chemical was positively identified; however, the associated numerical value is a low estimated concentration.
N = Normal sample.
PCBs = Polychlorinated biphenyls.
SVOC = Semivolatile organic compound.
U = Not detected.
ug/L - microgram per liter.
UJ = The analyte was not detected; and the reporting limit is approximate.
VOC = Volatile organic compound.
(a) Total concentrations were calculated per sample by summing only the detected individual compounds (i.e., Aroclor) concentrations. For samples without any detections of individual compounds (i.e., Aroclor), the maximum reporting detection limit within the sample is presented as a non-detect value.

Laboratory Audit Report

Project:	Former NCBC Davisville, Site 09 Allen Harbor Landfill LTM	
Laboratory:	Eurofins Spectrum Analytical, Inc., North Kingstown, RI	
Project Number:	60273164.LT.FI2	
Prepared by:	Waverly Braunstein	Date: 1/11/2017

SUMMARY/BACKGROUND

A focused laboratory audit was conducted at the Eurofins Spectrum Analytical Inc., (Eurofins) facility in North Kingston, RI, on December 15, 2016. This audit was conducted in response to recent laboratory performance issues which resulted in the rejection of the Fall 2016 Site 9 shellfish data and subsequent shellfish resampling.

Shellfish samples were collected September 13-16, 2016 and submitted to Eurofins for analysis for PCB homologues, organochlorine pesticides, semivolatile organics (SVOCs), polynuclear aromatic hydrocarbons (PAHs), and metals. The samples were appropriately logged and placed in a freezer for storage prior to preparation. After analyses were completed, it was determined that surrogate standard recoveries were less than 10 percent in approximately half of the samples analyzed for pesticides, SVOCs, and PAHs. These nonconformances were sufficiently severe that all non-detect results in these samples would be rejected and considered unusable for decision making purposes.

When the severity of these nonconformances became known, the laboratory intended to re-extract and reanalyze the affected samples. It was expected that this could be done without any concern with respect to holding times, since holding times are suspended when tissue samples are frozen. However, when laboratory personnel went to retrieve the samples, it was discovered that the unused portions had been returned to a cooler in the walk-in refrigerator rather than the freezer. This resulted in the pesticide, SVOC, and PAH holding times being grossly exceeded and the samples were unusable. As a result, it was necessary to recollect the shellfish samples.

The sections below detail the items reviewed during the audit with a focus on anything noted which may have contributed to the nonconformances noted above. Suggested corrective actions are noted where appropriate.

REVIEW ELEMENTS

The audit consisted of a laboratory tour, document review, observation of procedures, and discussions with laboratory personnel focusing on the following areas:

- ✓ Sample receiving and log-in
- ✓ Internal chain of custody/sample tracking
- ✓ Project management/communication
- ✓ Sample preparation standard operating procedures (SOPs)
- ✓ Personnel training/qualification
- ✓ Sample preparation documentation
- ✓ Spiking technique

These areas were selected since the primary purpose of the audit was to determine why the unused portion of the sample was not frozen, and why the surrogate recoveries were so poor.

In general, laboratory policies and procedures were found to be acceptable, and laboratory staff were aware of all applicable documents.

The laboratory has procedures in place to document proper storage procedures and to note project specific requirements. If the initial surrogate recoveries had been acceptable, the current procedures would have been sufficient to ensure sample integrity. However, these procedures were not robust enough to ensure that sample integrity is maintained in the instance when samples require re-extraction and re-analysis. Possible improvements to these procedures are discussed in detail in the appropriate sections below.

No obvious deficiencies were observed that suggest improper laboratory procedures led to low the surrogate recoveries. However, possible changes to the laboratory spiking procedures were discussed that may lead to improved recoveries. These changes are discussed in more detail below.

Discussion

Sample Receiving and Log-in

No deficiencies were noted in sample receiving. The space was clean, well-organized, and of sufficient size to handle expected sample capacity. Procedures were in place for documentation and resolution of sample receipt issues relating to sample integrity (i.e., temperature, headspace, preservation, etc.), and discrepancies between sample containers and chain of custody documents. It was clearly noted on the laboratory Work Order that tissue samples were to be stored in freezers until sample preparation, and this was done.

Internal Chain of Custody/Sample Tracking

Samples are appropriately signed in and out of sample storage. A bar code system is used; the record is stored electronically, and is readily accessible for review. However, there was nothing in the system that would have alerted the last sample technician that all required aliquots had been removed and the remaining sample volume should be returned to the freezer.

Suggested corrective action: The system could be modified to track the aliquots needed by each department and to alert the preparation technician taking the last aliquot to return the unused sample to the freezer. Alternatively, the estimated sample size needed to complete all analyses could be removed from the original container prior to any preparations and stored in the refrigerator, while all remaining volume could be returned to the freezer.

Project Management/Communication

The project manager was aware of the need to store the shellfish samples frozen prior to preparation, and communicated this to the staff. The samples were stored properly prior to sample preparation. However, at the time the samples underwent preparation, the project manager was out of the office and was therefore unable to provide the oversight necessary to ensure that samples were returned to the freezer.

Sample Preparation SOPs

The laboratory has an SOP (No. 110.0060, Rev. 2) dedicated to the preparation of tissue samples. The procedure is an adaptation of soil and sediment preparation procedures, and is used in conjunction with

that SOP (No. 50.0053, Rev. 4). The technicians interviewed were aware of the SOPs and verified that samples were prepared in accordance with these procedures.

The SOP clearly indicates that tissue samples are stored in the freezer until the day before preparation, and that freezing suspends the holding time indefinitely. However, it does not contain procedures for determining when all required aliquots have been obtained, nor does it explicitly instruct the technician to return the samples to the freezer once the last aliquot has been removed for analysis.

Suggested corrective action: Provide procedures in the SOP for each technician to determine if the necessary sample aliquots have been collected and to return the unused sample portion to the freezer following removal of the last required aliquot.

Personnel Training/Qualifications

Training files were reviewed and found to be acceptable. Each technician must successfully complete an initial demonstration of capability through completion of a spiking study, and performance is monitored on an ongoing basis thereafter through the use of control charts. However, as noted above, these studies are not conducted on tissue samples due to the limited number of shellfish samples analyzed annually. Proficiency is monitored using soil and sediment samples.

Sample Preparation Documentation

Sample preparation and extraction logs were reviewed and found to be comprehensive and complete. The technician performing each step is identified and spiking procedures are documented. No deficiencies were noted.

Spiking Technique

The procedure states that appropriately dried samples are transferred to filter paper, wrapped “burrito style,” and then placed in the soxhlet apparatus. The samples are spiked with surrogate solution after placing the sample in the soxhlet apparatus. The SOP does not go into additional detail, but discussions with the technician indicated that the spike is injected on the filter paper; no attempt is made to insert the needle of the syringe into the wrapped sample due to concerns with cross-contamination. It is possible that this procedure does not allow the spiking solutions the necessary contact/incorporation with the sample, thereby leading to volatilization of the spiking solutions prior to sealing the soxhlet apparatus.

An alternate procedure was discussed whereby the sample would be placed on the coffee filter, but before the sample was wrapped, the analyst would create a small depression in the sample, add the spiking solution, cover it with more sample, then proceed to wrap the sample as usual. The laboratory agreed to try this procedure with the recollected samples. The revised spiking procedure did produce acceptable surrogate recoveries in the tissue samples, but did not work well for the method blank and laboratory control sample (LCS); the spiking solution did not incorporate well into these quality control (QC) samples and yielded poor surrogate recoveries. Therefore, the samples were re-prepped using the original spiking procedure and acceptable surrogate recoveries were achieved for both the tissue and QC samples.

CONCLUSIONS

The cause of the initial poor surrogate recoveries could not be definitively determined. Tissue samples are a complex matrix and there is no readily available guidance for the preparation of this type of sample, nor could studies of expected surrogate recoveries be found. The laboratory tried modifications to its surrogate spiking procedure that were discussed during this audit. These modifications yielded acceptable surrogate recoveries for the tissue samples but not for the LCS and method blank. Therefore the samples were re-extracted and reanalyzed using the original spiking technique and acceptable

surrogate recoveries were achieved for both the tissue samples and QC samples. Based on these results, it appears that the cause of the poor surrogate recoveries in the shellfish samples collected in September 2016 was not related to the spiking technique; the source of the error is of indeterminate cause.

The failure to return unused sample aliquot to the freezer to suspend holding time was due to the fact that the last technician who removed an aliquot did not know that no further aliquots were needed. Changes to laboratory tracking procedures should be made to prevent this from happening in the future. Since the ability to suspend holding times via freezing is applicable primarily to tissue samples, and since the laboratory receives so few of these samples annually, it is important to incorporate this into written procedures rather than rely on the memory of the technicians and the oversight of the project manager.

EUROFINS SPECTRUM ANALYTICAL, INC. RI

STANDARD OPERATING PROCEDURE

for

Organic Preparation of Soil Samples by Soxhlet (Method 3540C)
Rev 4

1. Scope and Application

This Standard Operating Procedure (SOP) pertains to the preparation of soil and sediment samples for analysis by EPA SW846 methods SW8081, SW8015, SW8082 and SW8270. Discussions include sample extraction, sample cleanup references, sample concentration technique and the preparation of standard spiking solutions for the analysis of semivolatile, Total Petroleum Hydrocarbons (TPH), Diesel Range Organics (DRO), or pesticide/PCB organic compounds in soil samples.

2. Personnel Qualifications and Responsibilities

This method is restricted to use by or under the supervision of trained analysts in the Organic Preparation Laboratory (OPREP). Each analyst must demonstrate the ability to generate acceptable results with this method. Refer to the training requirements for analysts before performing this extraction method.

3. Summary of Procedure

A 30-gram sample is mixed with anhydrous sodium sulfate to form a free-flowing mixture. This is solvent extracted overnight using soxhlet extraction. The extract is dried through powdered and granular anhydrous sodium sulfate and is ready for cleanup and/or analysis following concentration using a Caliper TurboVap or Kuderna-Danish (KD) apparatus followed by nitrogen blow down.

4. Sample Preservation, Containers, Handling, and Storage

4.1 The sample holding times are as follows:

- Sample must be extracted within 14 days from the time of sample collection
- Sample extracts must be analyzed within 40 days of sample extraction

4.2 Sediment/Soil samples – Decant and discard any water layer on the sediment sample. Mix sample thoroughly, especially composited samples. Discard any foreign objects such as sticks, leaves and rocks. Refer to SOP No. 110.0039 for more detail on sub

sampling techniques.

4.3 Waste samples consisting of multiple phases must be prepared by separating the phases and performing the appropriate extraction technique on the phase(s) of interest.

5. Interferences and Potential Problems

5.1 Solvents, reagents, glassware and other sample processing hardware can yield interferences during sample preparation; therefore, these materials must be demonstrated to be free of interferences under the conditions of the analysis by analyzing method blanks.

5.2 Interferences may be co-extracted from the sample. Additional cleanup steps may be necessary to give improved results of analysis of the analytes of interest.

5.3 Phthalate esters can contaminate sample extracts, as many products found in the laboratory contain these esters. Plastics must be avoided during the preparation steps to minimize interferences from these compounds.

6. Equipment and Apparatus

6.1 Beakers – 400ml.

6.2 Flat bottomed 250ml Boiling flasks.

6.3 Soxhlet extractor.

6.4 Condensers, 55/50.

6.5 Balance capable of weighing +/- 0.1 gram.

6.6 Glass syringes for delivering spike and surrogate solutions – 0.25ml, 0.5ml, and 1.0ml.

6.7 Volumetric flasks for making up surrogate and matrix spike solutions – 50ml, 250ml.

6.8 Aluminum Foil (Industrial Grade)

6.9 Hotplates (option instead of mantles)

6.10 Food grade paper coffee filters

7. Standards and Reagents

Reagent grade chemicals shall be used in all tests. Other grades may be used provided the reagent is first verified to be of sufficiently high purity to permit use without lessening the accuracy of the test. The following chemicals including solvents and standards are extensively used in the lab:

7.1 Methylene chloride: pesticide quality or equivalent, to be used for glassware rinsing.

7.2 Acetone: pesticide quality or equivalent, to be used for rinsing glassware.

7.3 1:1 v/v methylene chloride/acetone mixture, to be use for sample extraction.

7.4 Surrogate Standards: *Please note that standards from other vendors could be used as long as the standards are of high purity (> 96%) and traceable to reference materials*.

- Semivolatiles Full Scan: Restek BN Surrogate mix (Cat. No. 31086) at 5000µg/mL in Methylene Chloride; Restek Acid surrogate mix (Cat. No. 31087) at 10,000µg/mL in Methanol.
- Semivolatiles SIM: Cambridge Benzo (e)pyrene d-12 surrogate (Cat. No. DLM-257-S) at 200µg/mL.
- Diesel Range Organics (DRO)/TPH: o-Terphenyl at 10,000µg/mL (Made from neat source (Aldrich).
- Pesticides/PCB: Ultra Decachlorobiphenyl (DCB)(Cat. No. PPS-150) at 1000 µg/mL in Toluene, and Ultra 2,4,5,6-Tetrachloro-m-xylene (TCX)(Cat. No. IST-440) at 2000µg/mL in Acetone.

7.5 Lab Control Sample and Matrix Spike: *Please note that standards from other vendors could be used as long as the standards are of high purity (> 96%) and traceable to reference materials*.

- Semivolatile: Restek 8270 MegaMix (Cat. No. 31850) at 1000µg/mL in Methylene Chloride; Restek 3, 3’ Dichlorobenzidine (Cat. No. 31026) at 2000µg/mL in Methanol, and 8270 add-on compounds from neat. An 8270 add-on Intermediate standard is prepared for the following compounds at 1000µg/mL in Methanol: Benzaldehyde, 1, 1’ Biphenyl, Caprolactam, Acetophenone, Atrazine.
- Pesticides: Restek Single/Dual Column Organochlorine Pesticides Mix AB#2 (Cat. No. 32292) at 8- 80µg/mL.
- PCB: Restek Aroclor 1016/1260 (Cat. No. 32039) at 1000µg/mL in Hexane.
- TPH/DRO: LCS uses Diesel/gasoline.

7.9. Anhydrous sodium sulfate: granular for drying the samples and sample extracts. Baked at 400°C for four hours.

8. Procedure

8.1 Standards Preparation: All standards for the Organic Preparation Laboratory (OPREP) are prepared in the associated Instrumentation Laboratory (GC or GC/MS). The GC or GC/MS Laboratory analyzes the standards at dilution for quality control purposes prior to relinquishing the standards to OPREP. When more than one bottle is prepared, only one bottle is transferred at a time to OPREP. The OPREP technician will notify the GC or GC/MS Laboratory Analyst when new standard is needed, or the last bottle is being taken.

8.1.1 All primary standards received from vendors are logged into the LIMS Standard Logbooks. These include standards for surrogates, LCS and matrix spikes.

The standards are labeled ZPyymmddX,
where:
Z = S for Semivolatile or TPH/DRO, P for Pesticides or PCB
P= Primary standard
yymmdd = date standard is received, and
X = the order the standard is logged into the logbook on that date, in increasing alphabetical order.

The expiration date for ampulated solutions shall not exceed the manufacturer's expiration date or one year from the date of receipt, whichever comes first.

8.1.2 Preparation of Surrogate standard:

8.1.2.1. Semivolatile Full Scan: The Semivolatile working surrogate standard is prepared by combining 2.5ml of the Base/Neutral primary standard in and 2.5ml of the Acid primary standard and diluting to 250ml using methanol.

The working standard contains the following compounds:

Compound	Concentration (µg/ml)
1,2-Dichlorobenzene-d_4	50
2-Fluorobiphenyl	50
Nitrobenzene-d_5	50
p-terphenyl-d14	50
2-Chlorophenol-d_4	75
2-Fluorophenol	75
Phenol-d_6	75
2, 4, 6-Tribromophenol	75

Semivolatile SIM surrogate standard is prepared by diluting 1.25mL of the 200ug/mL primary standard in **Section 7.7** to 50mL in methanol. The resulting concentration is 5ug/mL of Benzo (e) pyrene d-12.

The working surrogate spike standard is labeled ZWyymmddX
where:
Z = S for Semivolatile or TPH/DRO, P for Pesticides or PCB
W=Working Standard
yymmdd = date working standard is prepared,
X = the order that the working standard is prepared on that date, in increasing alphabetical order.

8.1.2.2. The working Pesticide/PCB surrogate standard is prepared by combining 1.2mL of the DCB mix and 0.3mL of the TCX mix and diluting to 1000mL using acetone. The working standard contains the following compounds with the following concentrations:

Compound	Concentration (µg/mL)
Decachlorobiphenyl	1.2
2,4,5,6-Tetrachloro-m-xylene	0.6

8.1.2.3. The TPH/DRO working surrogate standard is prepared by taking 1mL of the o-Terphenyl primary standard and diluting to 200 mL using methanol. The working standard contains 50 µg/mL of o-Terphenyl.

A smaller or larger amount may be used to prepare the surrogate. The final volume of the surrogate solution will be adjusted accordingly.

The expiration date for the surrogate standard is six months from the date of preparation.

8.1.3 Preparation of Lab Control Sample (LCS) and Matrix Spike (MS) Standard:

8.1.3.1. The Semivolatile Full Scan working LCS/MS Standard is prepared by combining 2.5ml of Base/Neutral Composite Set primary standard, 2.5ml of Acid Composite Mix primary standard and 2.5ml of Composite Mix #3 primary standard and diluting to 100ml using methanol. The working Semivolatile SIM LCS/MS Standard is prepared by a further 10 times dilution of the above standard.

8.1.3.2 The working Pesticide LCS/MS Standard is prepared by taking 1.25mL of the Pest Mix AB#2, and diluting it to 50 mL in methanol. The working standard contains the full list of SW8081 individual response compounds at 2-20 µg/mL. See **Attachment 1** for a list of the individual

compounds and their concentrations.

8.1.3.3 The working PCB LCS/MS Standard is prepared by taking 0.8mL of Aroclor 1016/1260 mix and diluting it to 200mL in acetone. The working standard contains the following compounds with the following concentrations:

Compounds	Concentration(µg/mL)
Aroclor 1016	4.0
Aroclor 1260	4.0

8.1.3.4 The TPH/DRO working LCS/MS Standard is prepared by first preparing an intermediate standard and making a dilution of it.

On an analytical balance, weigh out 5.00g of diesel fuel into a 10ml Class A volumetric flask and bring to volume with Methanol.

The intermediate spike standard is labeled SIyymmddX
where:
SI = Semivolatile intermediate standard
yymmdd = date intermediate standard is prepared,
X = the order that the intermediate standard is prepared on that date, in increasing alphabetical order.

The working LCS/MS Standard is prepared by taking 1ml of the intermediate standard above, and diluting to 100ml using Methanol. The working LCS/MS Standard contains the following:

Compounds	Concentration (µg/ml)
Diesel fuel	5000

The LCS/MS Standard is labeled using the same approach discussed in **Section 8.1.2.1**.

A smaller or larger amount may be used to prepare the LCS/MS Standard. The final volume will be adjusted accordingly.

The standard solution is placed in amber bottles and stored in the freezer in the GC or GC/MS lab at –10 to –20°C. One bottle is transferred to the OPREP Lab and stored in the refrigerator at 4± 2°C. The bottles are stored in a separate location from samples or sample extracts to make sure that there is no cross contamination.

All of the appropriate standard preparation information is to be recorded in the LIMS Standard Logbook.

NOTE: All standards prepared from a primary standard expire on or before the primary standard's expiration date.

8.2 Sample Extraction Procedure:

Before starting:

- The soxhlet extractor must be inspected periodically to ensure that the glassware does not have any cracks.
- Remove the surrogate and LCS/MS spiking standards from the refrigerator and allow them to reach room temperature.

8.2.1 Pour 150mL of 1:1 v/v methylene chloride/acetone into each round bottom flask and add about 3 boiling stones.

8.2.2 The sample is mixed to ensure sample homogeneity. A representative portion of the sample is measured into a pre-weighed 400ml glass beaker. A 30 gram ± 0.5 gram sample is transferred into the beaker using a clean stainless steel scoopula. The weight measurement is recorded to the nearest 0.1 gram. Smaller portions of samples may be used. Adjust the final volume accordingly to maintain the same ratios for reporting purposes.

8.2.3 Add enough anhydrous sodium sulfate to the sample, but not more than 1:1 w/w of the sample. When mixed with the anhydrous sodium sulfate, the solid material must be a free flowing; however, it should not contain an excessive amount of anhydrous sodium sulfate. If a sample matrix presents difficulty, discuss the issue with the OPREP Supervisor or Lab Director before proceeding.

8.2.4 Pour the soil sample and anhydrous sodium sulfate mixture into the paper coffee filter and wrap up similar to how a burrito is folded. Once done, place the "burrito" into the labeled soxhlet extractor.

8.2.5 Place the soxhlet extractor vessel onto its boiling flask. Be careful not to knock the extractor over and also be sure not to get any soil into the boiling flask.

8.2.6 According to the test method being used, add the following spikes to the samples already in soxhlets.

- Use a syringe to add 1.0mL of the surrogate standard to the Blank, LCS, all samples and any MS/MSD sample.
- Use a syringe to add 1.0 mL of the LCS/MS standard to the LCS and any

MS/MSD samples.

8.2.6 The boiling flask is now placed on hotplate. The soxhlet is chained so it will not tip over. The condenser is placed on top of the extractor. Start the water running through the condensers. Turn on the hotplates to a set point of 215 degrees F. This is the setting that produces a heating surface temperature we have found to be sufficient for proper cycling. Measure the cycle/hour rate and record this in the extraction logbook. Allow the sample to extract for a **minimum of 16 hours**.

8.2.7 At the end of the extraction, turn off the hotplates. Allow the samples to cool to room temperature. Take the soxhlet out, drain the extraction solvent into the boiling flask and dump the soil mixture into solid waste container. Cover the boiling flask with aluminum foil.

8.2.8 Record all extraction information, including the Date and Time the soxhlet extraction began and ended, in the appropriate Prep Batch Logbook (**Figures 1 and 2**).

8.3 The sample extract is now ready for filtration and concentration. These procedures are found in SOP No. 50.0054, Extract Filtration and Concentration.

8.4. After concentration the extract may require cleanup. The following is a list of Cleanup Procedures**:**

8.4.1. **Sulfur cleanup** is mandatory for all Pesticide/PCB sample extracts containing sulfur. All QC samples including blanks, lab control samples, matrix spikes and duplicate matrix spikes must be subjected to the same cleanup as the field samples. Sulfur cleanup will be performed using activated copper powder. Refer to SOP No. 50.0036 Method 3660B Sulfur Cleanup, for details on activating copper and using it in a sample extract.

8.4.2. **Acid cleanup (PCB extract only)** is mandatory for all PCB sample extracts. Refer to SOP No. 50.0031 Method 3665A Sulfuric Acid Cleanup, for details on using the acid cleanup in a PCB sample extract.

8.4.3. **GPC cleanup** is useful for both Pesticide and semivolatile samples. Refer to SOP No. 50.0032 Method 3640A GPC Cleanup, for details on the procedure for cleanup and quality control criteria for GPC.

8.4.4. Other cleanup methods may be found in SOP numbers 50.0033(Florisil) and 50.0034 (Silica Gel).

8.5 The extracts are transferred to the Semivolatile lab. The extracts are stored in the refrigerator at 4^{o}C until analysis. The storage location is recorded electronically by the analyst during LIMS batch transfer.

8.6 Sample and Extract Disposal:

All samples and sample extracts are disposed of in a way in accordance with applicable OSHA and state regulations.

8.6.1 Samples – All unused portions of samples are returned to the respective storage area. Such portions are kept for 60 days after data submission. After such period, the remainder of the samples is disposed of by the Sample Custodian or his/her designee.

8.6.2 Sample Extracts – All sample extracts are kept for at least 60 days after the submittal of data for the last sample. After such period, the sample extracts are disposed of by the GC or GC/MS labs.

9. Data Reduction and Calculations

Data reduction for calculation of standard preparation:

$$\text{Concentration of working standard} = \frac{(\text{Concentration of ampule})(\text{amount used})}{\text{Final Volume}}$$

10. Quality Assurance/Quality Control

Quality assurance and quality control (QA/QC) procedures are implemented to ensure generation of data of known and documented quality. QA/QC procedures associated with the Organic Preparation Laboratory include preparation of Method Blanks, surrogate spikes, lab control sample, matrix spikes and balance checks. To trace spiking standards, the original manufacturer's list of standard compounds and concentrations are filed and the manufacturer's reference number is documented in the standard preparation log book.

10.1. Method Blank – A method blank is a weight of a clean reference matrix (granular sodium sulfate) that is carried through the entire analytical procedure.

10.1.1 Frequency of Method Blank:

A Method Blank is extracted once for the following, whichever is more frequent:

- Each SDG analysis (not to exceed 20 samples), or
- Each matrix within an SDG, or
- Each extraction procedure within an SDG, or
- Whenever samples are extracted.

10.1.2 Procedure for Method Blank:

- The Method Blank is prepared in identical fashion to the associated samples.
- The Method Blank is subjected to similar extraction, cleanup, concentration and analysis procedures.
- The Method Blank is labeled **MB** and is given a sequential number for every batch of twenty samples or less.

10.2 Lab Control Sample (LCS) – A Lab Control Sample is a weight of a clean reference matrix (granular sodium sulfate) that is spiked with all appropriate target analytes and surrogate spikes, and carried through the entire analytical procedure.

10.2.1 Frequency of LCS:

A LCS is extracted once for the following, whichever is more frequent:

- Each SDG analysis (not to exceed 20 samples), or
- Each matrix within a SDG, or
- Each extraction procedure within a SDG, or
- Whenever samples are extracted.

10.2.2 Procedure for LCS:

- The LCS is prepared in identical fashion as the associated samples; and in addition:
- 1.0mL of the surrogate solution prepared in **Section 8.1.2** and 1.0 mL of the lab control sample prepared in **Section 8.1.3** is added to the LCS sample.
- The LCS is subjected to similar extraction, cleanup, concentration and analysis procedures.
- The LCS is labeled **LCS** and is given the same numerical value as the corresponding method blank.

10.3 Duplicate Matrix Spikes – Matrix spikes and matrix spike duplicates are performed to evaluate the accuracy and precision associated with the sample batch of similar matrix.

For samples that are known to contain target analytes, the laboratory should perform one matrix spike and duplicate. For clean samples and those without documented history, a duplicate set of matrix spikes is performed. Since the majority of the samples received do not have any documented history, the lab will perform matrix spike and matrix spike duplicate.

10.3.1 Frequency of duplicate matrix spikes:

A duplicate set of matrix spikes is extracted once for the following, whichever is more frequent:

- Each SDG analysis (not to exceed 20 samples), or
- Each matrix within a SDG, or
- Each extraction procedure within a SDG.

10.3.2 Procedures for Duplicate Matrix Spikes:

- The duplicate matrix spikes are prepared in identical fashion as the associated samples; in addition
- 1.0 ml of the surrogate solution prepared in **Section 8.1.2** and 1.0 ml of lab control sample prepared in **Section 8.1.3** are added to the duplicate matrix spike samples.
- The duplicate matrix spikes are subjected to similar extraction, cleanup, concentration and analysis procedures.

11. Data Validation and Reporting

11.1 Data generated in the organic preparation laboratory will be reviewed by the supervisor. These data consist of, but are not limited to, extraction/preparation logbook entries, balance calibration logbooks, weights for soil samples, volumes and lot numbers of solvent used. The Quality Control Officer will perform periodic and unscheduled reviews.

12. Corrective Action Procedures

Corrective actions are to be taken if the QA/QC as outlined in this SOP are not adhered to:

12.1 Method Blank Analysis:

All samples that are prepared with a non-compliant Method Blank will be re-extracted and re-analyzed. The re-extracted samples will be labeled with the suffix RE. The analysis laboratory will inform the Organic Preparatory Laboratory when method blank contamination has occurred.

12.2 Surrogate Recovery:

All samples with surrogate recoveries outside of the control limits will be re-extracted and re-analyzed. The re-extracted sample is labeled with the suffix RE. If the re-extracted sample exhibits similar behavior, both data sets will be submitted to demonstrate matrix effects. The analysis laboratory will inform the Organic Preparatory Laboratory when surrogate recoveries have not met accepted criteria, and require re-extraction.

12.3 LCS Recovery:

All samples that are associated with the non-compliant LCS will be re-extracted and re-analyzed. The re-extracted samples will be labeled with the suffix RE. The analysis laboratory will instruct the Organic Preparatory Laboratory when LCS recoveries have not met accepted criteria, and require re-extraction.

12.4 Matrix Spike Recovery and RPD:

These are used as advisory limits and do not trigger sample re-extraction.

13. Health and Safety

Health and safety hazards in the Organic Prep Lab include exposure to analytical standards and solvents. Always work in under a well-ventilated hood. Lab coats, gloves and safety glasses must be worn in the lab at all times.

14. Pollution Prevention, Waste Management, Definitions and Acronyms

See sections 19.0 (Waste Management) and 20.0 (Definitions, Acronyms, and Abbreviations) of the current Quality Assurance Plan.

SPECTRUM ANALYTICAL, INC

STANDARD OPERATING PROCEDURE

for

Tissue Sample Preparation
Rev. 2

1. Scope and Application

This SOP described procedures for the preparation of tissue samples for analysis by the common EPA SW-846 analysis methods. The sample preparation steps have been modified to address the increased fat concentration in the samples compared to other environmental matrices. The prepared sample extracts/digestates are analyzed according to the instrumental conditions detailed in the EPA analysis methods. These methods have not been validated by the lab for biological tissue matrices. These methods are used when requested by a customer desiring protocols as similar as possible to standard EPA environmental analysis techniques. Alternative methods published by the US FDA, NYSDEC and others may be more appropriate for certain classes of compounds or for research studies on biological tissue matrices.

2. Personnel Qualifications and Responsibilities

This method is restricted to use by or under the supervision of trained analysts. Each analyst must demonstrate the ability to generate acceptable results with this method. Refer to the lab's training requirements for analysts before performing this extraction method.

3. Summary of Procedure

Tissue samples are stored frozen until just prior to preparation. Samples are reduced in size using a blender or tissue homogenizer and subsequently further prepared for analysis. Percent Lipid Determination is covered in a separate SOP (50.0102).

4. Sample Preservation, Containers, Handling, and Storage

Fish samples are stored in a freezer until the day before preparation. Tissue samples may be frozen indefinitely, holding time only advances while tissue is unfrozen.

If freeze drying is required, see NYS Department of Environmental Conservation Prep Lab SOP4 (5/28/14) Hale Creek Field Station Sections V for Freeze Drying, as well as Special Operation

Procedure (SpOP) for Freeze Drying High Moisture Solid-Matrix Samples. The SpOP details the use of our Labconco Freezone Freeze Dry System (EIA-PESFRZ1.MOD Freeze Dry, 1/00).

5. Interferences and Potential Problems

See the individual analytical methods. This preparation SOP is designed to address the matrix interferences from elevated lipid/fat content of tissue samples.

6. Equipment and Apparatus

Waring-type blender with stainless steel container and blades, or Tissue homogenizer

7. Standards and Reagents

See the individual analytical SOPs

8. Procedure

8.1 Initial Preparation:

- Fish samples are stored in freezer until the day before preparation. Tissue samples may be frozen indefinitely, holding time only advances while tissue is unfrozen.

- Thaw fish in refrigerator the day before preparation.

- Sample is homogenized in stainless steel Waring blender or tissue homogenizer. Typically the entire fish sample is homogenized. If only a portion of the sample is to be analyzed (fillet, liver, etc.) this must be identified by the Project Manager. When required, refer to NYS Department of Environmental Conservation Prep Lab SOP4 (5/28/14) Hale Creek Field Station Sections III and IV for more in depth guidance on sample dissection and homogenization. This document details several ways to filet fish prior to homogenization and specifies using the left side of the fish. This is not a routine method for preparing the filet but may be required for some projects.

- If volatile organics analysis is required, homogenization should occur in a laboratory free of volatile organic solvents. Please note that the homogenization process is likely to cause significant loss of volatile organic constituents.

- Homogenized sample is split into portions for analysis. Samples are typically retained in 4oz wide mouth glass jars with Teflon cap liners. Method holding times are applied from the time sample is thawed until analysis. If sample is refrozen, the holding time “clock” is halted at that time.

- If volatile organics analysis is required, an approximately 1 gram portion of the sample is weighed into tared pre-preserved VOC sample bottles containing 5ml sodium bisulfate solution. Two separate preserved aliquots per sample should be weighed-out so that extra sample is available if needed. A third aliquot of approximately 1 gram is also weighed into a tared methanol preserved VOC vial. The 14 day VOC holding time is applied beginning from sample thawing until the time of analysis.

8.2 Extractable Organics Preparation:

- Weigh out an approximately 10 gram wet weight aliquot for extraction.

- Aliquot is dried with diatomaceous earth to a free-flowing mixture. Anhydrous sodium sulfate may be used, but due to the additional volume required, diatomaceous earth is preferable.

- Dried sample aliquot is spiked with the appropriate volume of surrogate standard solution.

- Sample aliquot is extracted overnight (18hours +/- 2 hours) in a soxhlet extraction apparatus using 1:1 methylene chloride / hexane solvent. Alternatively sample may be extracted using a pressurized fluid extraction apparatus using the current method SW3545 with 1:1 methylene chloride / hexane solvent.

- Sample extract is filtered and dried through anhydrous sodium sulfate and concentrated using a kuderna-danish apparatus.

- For semivolatile organics the final volume is 10ml prior to GPC clean-up and 0.5ml after GPC clean-up.

- For pesticides/PCBs the final extract volume is brought to 10ml in methylene chloride prior to GPC clean-up.

8.3 Semivolatile Organics Analysis:

- The extract is cleaned using GPC.

- The extract is analyzed using a GC/MS system calibrated to the requirements of the current method SW8270. Based on past experience, samples for semivolatile organic analysis may require two injections to demonstrate matrix interference with polar surrogate recoveries.

- Reporting limits are elevated by approximately a factor of 3 from a typical soil sample due to the 10g sample size. Results are reported without correction for percent moisture, on a wet-weight basis.

8.4 PCB Only Analysis:

- 5ml of the pesticide/PCB extract is cleaned using GPC, exchanged into hexane and concentrated to 2.5ml using dry nitrogen

- The extract is cleaned using silica gel, and sulfuric acid. If necessary the extract is further cleaned using GPC.

- The cleaned extract is analyzed using GC a "Y" splitter with two dissimilar columns connected to electron capture detectors following the current method SW8082.

- Reporting limits are elevated by approximately a factor of 3 from a typical soil sample due to the 10g sample size. Results are reported without correction for percent moisture, on a wet-weight basis.

8.5 Pesticide and PCB Analysis:

- 5ml of the pesticide/PCB extract is cleaned using GPC, exchanged into hexane and concentrated to 2.5ml using dry nitrogen

- if necessary the extract is further cleaned using florisil.

- The cleaned extract is analyzed using GC a "Y" splitter with two dissimilar columns connected to electron capture detectors following the current methods SW8081 and SW8082.

- Reporting limits are elevated by approximately a factor of 3 from a typical soil sample due to the 10gram sample size. Results are reported without correction for percent moisture, on a wet-weight basis.

8.6 Volatile Organics Prep/Analysis:

- A 1 gram sample aliquot preserved in sodium bisulfate solution is analyzed by the current method SW5035 followed by the SW8260 analysis method. The sample aliquot is reduced from 5 grams to 1 gram to reduce sample foaming which will prevent future analyses until the system is decontaminated.

- If foaming is observed using the current method SW5035 – sodium bisulfate preserved sample aliquot, the analysis is immediately stopped to avoid instrument contamination. The methanol preserved aliquot is used following standard procedures.

- Reporting limits are elevated by approximately a factor of 5 due to the reduced sample size. Results are reported without correction for percent moisture, on a wet weight basis. Please note that initial homogenization of the sample could result in significant loss of volatile constituents.

8.7 Metals Analysis:

- ICP digestion uses EPA Method 200.11 modified as follows:

- Samples are pretreated prior to ICP digestion by weighing 1-2 grams of homogenized tissue into a polyethylene tube, adding approximately 5ml concentrated HNO3 to cover the tissue, covering the tube with a watch glass, and allowing to sit in a ventilated hood for approximately 24 hours.

- Place tubes in a heating block at 95 degrees C. for 30 minutes, cool.

- Add 2 ml concentrated HNO3 and heat in the heating block at 95 degrees C for another 30 minutes, cool.

- Repeat the addition of concentrated HNO3 and heating until the tissue fibers are visibly broken-down.

- Add 5 ml concentrated HCl and heat and heat in the heating block at 95 degrees for 15 minutes.

- Cool, bring to 50 ml volume with DI water, centrifuge at 3000 rpm for 2 –3 minutes.

- Digestates are decanted and analyzed by ICP following the current method SW6010 analysis method.

- Results are reported without correction for percent moisture, on a wet weight basis.

8.7 Mercury Analysis:

- Mercury analysis uses Method 245.6 modified as follows.

- Samples for mercury analysis are pretreated by placing approximately 0.20 – 0.75gram in a BOD bottle, adding approximately 4ml concentrated H2SO4 and 1ml concentrated HNO3 to cover the tissue, heat in a water bath at 80 degrees C for 30 minutes, cool sample.

- Add 15ml KmnO4 and 8ml K2S2O8 solution.

- Heat at 80 degrees C for 90 minutes.

- Calibration standards are prepared using the same procedure.

- Analyze using the cold vapor technique by the current analysis Method SW7471.

- Results are reported without correction for percent moisture, on a wet weight basis.

8.8 Cyanide Analysis:

- Sample size is reduced to 0.5g to prevent clogging of the purging apparatus during distillation.

- Distillation proceeds as typical for a soil sample using 50% sulfuric acid, magnesium chloride and sulfamic acid.

- Sample distillate is analyzed colorimetrically by current method SW9012 following standard procedures. Reporting limit is elevated by a factor of 2 from a soil sample due to reduced sample size. Results are reported without correction for percent moisture, on a wet-weight basis.

9. Data Reduction and Calculations

Percent Lipids = (A * B) / (C * D * 10,
where:

A = Residue weight following evaporation to dryness
B = Final extract volume (typically 10mL)
C = Portion of extract used for lipids determination (typically 2.5mL)
D = Tissue weight extracted (typically approx. 10g)

10. Quality Assurance/Quality Control

Quality assurance and quality control (QA/QC) procedures are implemented to ensure generation of data of known and documented quality. QA/QC procedures associated with the Organic Preparation Laboratory include preparation of Method Blanks, surrogate spikes, lab control sample, matrix spikes and balance checks.

For specific details, see the individual analytical SOPs

11. Data Validation and Reporting

N/A

12. Data Management and Records Management

Electronic data generated from tissue sample preparation is saved and managed per SOP No. 110.0029 Electronic Data Management.

13. Corrective Action Procedures

See Corrective Action Procedures for the individual analytical SOPs.

14. Health and Safety

Health and safety hazards in the Preparation Laboratories include exposure to acids, bases, analytical standards and solvents. Always work in under a well-ventilated hood. Lab coats, gloves and safety glasses must be worn in the lab at all times.

15. Pollution Prevention, Waste Management, Definitions and Acronyms

See Sections 19.0 (Waste Management) and 20.0 (Definitions, Acronyms, and Abbreviations) of the current Quality Assurance Plan

To	Bob Shoemaker
Subject	2016 Shellfish Tissue Comparisons and Statistical Analyses
From	Maryann Welsch
Date	March 9, 2017

This memorandum presents the results of an evaluation of metal and total PCB concentrations in shellfish tissue collected along the shoreline of the Allen Harbor Landfill in September 2016 and December 2016. The September 2016 analytical data were collected as part of a long-term monitoring program. Due to analytical data quality issues, additional shellfish tissue samples were collected in December 2016 at the same locations as the September 2016 samples. The purpose of this evaluation is to determine if the December 2016 analytical results are representative of September 2016 analytical results for future comparisons conducted as part of the monitoring program.

Paired-sample tests were conducted on the shellfish tissue analytical data for metals and PCBs from samples collected in September 2016 and December 2016 to determine whether there is a statistically significant difference in shellfish concentrations measured at each location between the two dates. The pairs were defined based on the ten locations, e.g., aluminum concentrations detected in tissue samples collected at location ET09-03 in September 2016 and December 2016 are considered one pair of samples.

Table 1 presents the analytical data for metals and PCBs for shellfish samples collected at each location in September and December 2016. The same species of shellfish were collected at each location on both dates with the exception of two locations. At location ET09-04, quahog tissue was collected in September, whereas ribbed mussel tissue was collected in December. At ET09-06, ribbed mussel tissue was collected in September whereas quahog tissue was collected in December. For the purposes of this evaluation, the two different species were treated as paired samples at these locations.

Table 2 presents the summary statistics and the results of the paired-sample tests conducted for each parameter. The paired-sample test was selected based on the distribution of the September and December datasets for each parameter. If both the September and December datasets per parameter are normally distributed, then a paired t-test was used to determine if the mean concentrations of September and December datasets are statistically different. If one or both datasets are not normal or lack a distribution, then the nonparametric Wilcoxon signed-rank (WSR) test was used to determine if the median concentrations are statistically different between September and December datasets. The null hypothesis (H_O) and alternative hypothesis (H_A) of these tests are:

H_O = Mean/Median of September Concentrations = December Concentrations

H_A = Mean/Median of September Concentrations ≠ December Concentrations

For both tests, a p-value of less than 0.05 indicates that the null hypothesis is rejected and the alternative is accepted with 95% confidence. A p-value of greater than 0.05 indicates that the null hypothesis is not rejected and the mean/median concentrations measured in September and December are equal. In addition, the data for each parameter were plotted into two graphs, a Quartile-Quartile (Q-Q) plot and a boxplot, to illustrate the range and distribution of the September and December datasets (**Attachment A**).

Results of Metals Comparisons

Most metals were detected in all samples collected in September and December 2016 with the exception of cobalt and sodium, which were not detected in September 2016 samples. Therefore, comparisons were not made for these two metals. Total chromium and copper were detected at low frequencies (less than 5 samples) in both September and December, and as a result, statistical comparisons were not conducted for these two metals, but Q-Q plots illustrate how detected and non-detected (reporting values were used for non-detects) concentrations compare (**Attachment A**). Selenium was detected in at least five samples in both September and December, but not at the same locations (detected in both months in samples from only three locations). Therefore, due to the low frequency of detection of paired samples, statistical comparisons were not conducted for selenium.

The following metals were normally distributed with 100% detection for both September and December datasets: aluminum, arsenic, nickel, and potassium. A paired-sample t-test was conducted for these four metals. The following metals were not normally distributed and/or with less than 100% detection in one or both months: cadmium, calcium, iron, lead, magnesium, manganese, mercury, silver, and zinc. The WSR test was conducted for these metals.

The results of these tests indicate that:

- Mean or median concentrations of all but four metals are equal in September and December datasets.
- Calcium, mercury, potassium, and silver were found to be significantly different between paired samples in September and December.
- These statistical test results are supported by the Q-Q plots and boxplots, which illustrate significant overlap in the central tendencies and ranges of concentrations for most metals except for the four metals mentioned above.
- In addition, Q-Q plots and boxplot (selenium only) illustrate that detected concentrations of total chromium, copper, and selenium are similar and overlap in both September and December datasets.

Results of PCB Comparisons

The total PCB concentrations in September and December were not normally distributed. Therefore, a WSR test was conducted for this comparison. The results of the WSR test indicate that the median concentrations of total PCBs in paired samples in September and December are equal. This is supported by the Q-Q and box plots, which illustrate significant overlap in the central tendencies and ranges of concentrations of total PCBs in September and December.

Results of Physical Parameter Comparisons

Comparisons of physical parameters including lipids, shell length, and width were also conducted to determine the similarity of specimen size and lipid content in paired samples collected in September and December. Lipids were not normally distributed, and therefore, a WSR test was conducted.

Shell length and width data were normally distributed in both months, so a paired-sample t-test was conducted on both of these parameters. The results of the WSR and paired t-tests indicate that:

- Median lipids measured in paired samples collected in September and December are equal
- Mean lengths and widths measured in paired samples collected in September and December are equal.
- These findings are supported by the Q-Q and box plots, which illustrate significant overlap in the central tendencies and ranges of these parameters in September and December.

Conclusions

The results of this evaluation indicate that, with the exception of four metals (calcium, mercury, potassium, and silver), the December shellfish tissue dataset is equivalent to the September tissue dataset and can be used to represent the Fall 2016 tissue conditions in future comparisons at each location to support the long-term monitoring program.

Notes:

NC - Not calculated.

ND - Not detected.

WSR - Wilcoxon Signed-Rank test.

The paired-sample test was selected based on the distribution of the September and December datasets. If both are normally distributed with 100% detection, a paired t-test was selected. If one or both datasets were not normal and/or with less than 100% detection, the nonparametric Wilcoxon signed-rank test was selected.

The paired-sample test null hypothesis is the true mean/median difference is equal to zero. The alternative hypothesis (two-tailed) is that the true mean/median difference is not equal to zero.

A p-value of less than 0.05 indicates statistical significance (approximately 95% confidence).

If the p-value of the paired-sample test is > 0.05, then the null hypothesis is not rejected and the September and December mean/median concentrations are considered equal.

If the p-value of the paired-sample test is < 0.05, then the null hypothesis is rejected and the alternative hypothesis is accepted, which is that the September and December mean/median concentrations are not equal.

Attachment I

Allowable Air Toxic Emission Rate Development and Gas Vent Emissions Comparison

ATTACHMENT I

Developing Allowable Air Toxic Emission Rates for Allen Harbor Landfill Gas Vents

Resolution Consultants (Resolution) back-calculated allowable air toxic gram per second (g/s) emission rates for the landfill vents using Rhode Island Department of Environmental Management (RIDEM) acceptable ambient levels (AALs) and AERSCREEN. AERSCREEN[1] is the United States Environmental Protection Agency (USEPA) recommended screening-level air quality model based on the AERMOD[2] modeling system. The AERSCREEN model consists of two main components: 1) the MAKEMET program which generates a site-specific matrix of screening-level meteorological conditions for input to the AERMOD model; and 2) the AERSCREEN command-prompt interface program. AERSCREEN interfaces with MAKEMET for generating the meteorological matrix, with AERMAP the terrain processor, and AERMOD dispersion model itself. For this application AERSCREEN was applied using model defaults for a screening level model.

Each vent was simulated in the model as a point source with a 1 g/s emission rate and 4-foot release height with no buoyancy or momentum out of the vent. This conservatism is included in the model since the vents do not release vertically to the atmosphere. Modeled concentrations were estimated by AERSCREEN at the nearest ambient boundary point determined to represent an approximate "worst case". For this application that point was determined to be almost due east of Vent GV09-05 at a distance of approximately 40 meters (see Figure 1). A total worst-case concentration from all five vents was then calculated based on the downwind distance from each vent to the point due east of GV09-05. This corresponds to a wind from the southwest which could cause overlap of the five plumes at this point. Each vent was modeled separately and the results were summed up to represent the total concentration at the worst case point as shown below.

Vent	Distance (m)	AERSCREEN 1-hour Result (ug/m3)
GV09-05	40	31,760
GV09-04	65	25,215
GV09-03	115	17,480
GV09-02	150	14,885
GV09-01	225	11,751
	Total	101,091

The AERSCREEN model provided results for the 1-hour averaging period. Scaling ratios from the AERSCREEN User's Guide were used to determine the 24-hour and annual averaging period using values of 0.6 and 0.1, respectively.

1 AERSCREEN User's Guide. USEPA-454/B-16-004 (December 2016). Office of Air Quality Planning and Standards, Research Triangle Park, North Carolina.

2 User's Guide for the AMS/EPA Regulatory Model (AERMOD). USEPA-454/B-16-011 (December 2016). Office of Air Quality Planning and Standards, Research Triangle Park, North Carolina.

3 State of Rhode Island and Providence Plantations Department of Environmental Management Office of Air Resources, Air Pollution Control Regulation No. 22, Air Toxics. October 9, 2008.

The AERSCREEN results in micrograms per cubic meter (ug/m3) were divided by the AAL for each air toxic compound. This was performed for each applicable averaging period: 1-hour, 24-hour, and annual. The AALs are taken from RIDEM Air Regulation 22[3], Table 1. Since the AERSCREEN model was used with a 1 g/s emission rate, the equation below results in the allowable emission rate in g/s which corresponds to the RIDEM AAL for each air toxic.

$$Allowable\ emission\ rate\ \left(\frac{g}{s}\right) = AERSCREEN\ 1\frac{g}{s} * \frac{RIDEM\ AAL\ \frac{ug}{m3}}{AERSCREEN\ \frac{ug}{m3}}$$

The minimum allowable g/s emission rate was chosen in instances where an air toxic has multiple AALs based on different averaging periods. All of the calculated g/s values from the five vents were added together and compared against the AAL based allowable emission rates for each compound as shown in Table 1. As a conservative measure, when adding the calculated g/s values from the five vents, the reporting limits for the nondetect results were used in the summation, and a total sum of the nondetect reporting limits and detected results (if any) for each compound was used for comparison against the AAL-based calculated allowable emission rates. For the field duplicate pair, the highest of the detected result or reporting limit was chosen for the summation. None of the summed calculated air toxic emission rates are above the AAL-based calculated allowable emission rate.

Notes
1 : Calculated g/s values are RIDEM Aceptable Ambient Level (AAL) divided by the screening model result
2: NA - There is no established AAL for this time period.
3 : Allowable calculated g/s based on minimum calculated g/s for the 1-hour, 24-hour, and annual modeling time periods
4 : 2-HEXANONE / Methyl Butyl Ketone not found in Regulation 22 Table I
5 : Used non-specific 1,3-Dichloropropene because CAS 10061015 specific to cis-, not in Regulation 22 Table I
6 : METHANE not found in Regulation 22 Table I
7 : Used non-specific 1,3-Dichloropropene because CAS 10061026 specific to trans-, not in Regulation 22 Table I
8 : For nondetect results, the reporting limits were used in the summation of the five gas vent results
9: NC - Not Calculated
Units
ug/m3 - Microgram per cubic meter
g/s - Gram per second
