Five-Year Review Summary Form

SITE IDENTIFICATION		
Site name: Former Naval Construction Battalion Center Davisville		
EPA ID: RI6170022036		
Region: 1	**State:** RI	**City/County:** Washington
SITE STATUS		
NPL status: Final		
Remediation status: Operating		
Multiple OUs? Yes	**Construction completion date:**	
Has site been put into reuse? Yes		
REVIEW STATUS		
Lead agency: U.S. Department of the Navy		
Author name: Prepared by Tetra Tech under contract to the Navy		
Author title:	**Author affiliation:**	
EPA's Review period: January 2013 to December 2017		
Date(s) of site inspection: June 22, 2017		
Type of review: Post-SARA		
Review number: 4 (Fourth)		
Triggering action: Third Five-Year Review – March 28, 2013		
Triggering action date *(from WasteLAN)*: 03/28/2013		
Due date *(five years after triggering action date):* 03/28/2018		

Five-Year Review Summary Form, cont'd.

Issues:

Site 07 – Calf Pasture Point

1. Surface water and sediment should continue to be monitored to ensure ongoing protectiveness for recreational swimmers/waders, shell fisherman, and ecological receptors.
2. Site contaminants in the groundwater plume are migrating toward surface water in the southern, western, and eastern shores; however, it is unknown how long it will take for concentrations to reach levels at these exposure areas that may pose a risk to human health or the environment.

Site 09 – Allen Harbor Landfill

No issues affecting the protectiveness of the remedy were identified during this review.

Site 16 – Creosote Dip Tank Area, Fire-Fighting Training Area and Former Building 41

The Environmental Land Use Restriction (ELUR) for recording on the deed for Parcel 8, Zone 4 (area south of Davisville Road and the eastern Pier area were previously transferred) has not been completed. Coordination with current property owner(s) will be required.

Recommendations and Follow-Up Actions:

Site 07 - Calf Pasture Point

1. The Long-Term Monitoring Plan (LTMP) should be updated to include surface water and sediment monitoring and risk evaluations and/or assessments, as needed, to support future five-year reviews and to ensure ongoing protectiveness. The LTMP should also be revised to state that surface water and sediment monitoring will continue until such time that levels of site contaminants allow for unlimited use and unrestricted exposure.
2. Based on the results of a discussion concerning the CSM and analysis approach, an analysis should be conducted to evaluate the estimated amount of time (if ever) that it will take for the concentrations of site contaminants to reach levels in surface water and sediment that pose a risk to human health and the environment.

Site 09 - Allen Harbor Landfill

None.

Site 16 – Creosote Dip Tank Area, Fire-Fighting Training Area and Former Building 41

In coordination with current property owner(s), submit ELUR for recording on deed for Parcel 8, Zone 4 (area south of Davisville Road and the eastern Pier area were previously transferred).

Five-Year Review Summary Form, cont'd.

Protectiveness Statements:

Site 07 - Calf Pasture Point

The remedy at Calf Pasture Point is protective of human health and the environment in the short-term. Exposure pathways that could result in unacceptable risks from groundwater are being addressed through institutional controls. These controls are effectively preventing exposure to site-related contaminants in groundwater. A risk screening evaluation indicates that there is no unacceptable risk to recreational swimmers/waders, shell fisherman, or ecological receptors from site-related contaminants in surface water and sediment. However, to ensure that the remedy remains protective in the long term, the following actions will be taken: (1) Surface water and sediment monitoring results will continue to be compared to risk screening numbers to ensure ongoing protectiveness and (2) Based on the results of a discussion concerning the conceptual Site Model (CSM) and analysis approach, an analysis should be conducted to evaluate the estimated amount of time (if ever) for the concentrations of site contaminants to reach levels in surface water and sediment that pose a risk to human health and the environment.

Site 09 - Allen Harbor Landfill

The remedy at Allen Harbor Landfill is protective of human health and the environment. Exposure pathways that could result in unacceptable risks are being addressed through remedy-related institutional controls and a state-enforced prohibition of shellfishing in Allen Harbor. These controls are effectively preventing exposure to site-related contaminants.

Site 16 – Creosote Dip Tank Area, Fire-Fighting Training Area and Former Building 41

The remedy at Site 16 is currently protective of human health and the environment. The soil removal portion of the remedy was successful in removing soil with contaminant of concern (COC) concentrations exceeding industrial/commercial Direct Exposure Criteria (DECs) from the site, and the 0 to 2 feet of backfill used to restore the excavated areas prevents exposure to COCs at greater depths. Groundwater treatment was successful in reducing concentrations of tricholorethene (TCE) to levels that allowed for a transition to monitored natural attenuation (MNA). The results of future Long-Term Monitoring (LTM) will be used to evaluate the effectiveness of the remedy, including confirmation of the lack of migration of subsurface soil COCs to other media beyond the compliance boundary and by evaluating trends in groundwater COC concentrations. Implementation of Land Use Controls (LUCs) via the Land Use Control Implementation Plan (LUCIP) in the North Central Area (NCA) portion of the site will provide protection by prohibiting residential exposure to surface and subsurface soil and by preventing human exposure to groundwater. Although LUCs have not been formally implemented in the non-NCA portion of the site, inspections have confirmed that no activities that could facilitate human exposure to groundwater or to volatile organic compound (VOC) vapors migrating into buildings have been conducted at the site (i.e., no well installation and no building construction). Attempts by the Navy to implement the required LUCs via addition to the deed associated with previous transfer of the property are underway.

Based on the information available to date and the activities that are completed and ongoing, the Site 16 remedy is currently protective. Exposure pathways that could result in unacceptable risks are being addressed through implemented LUCs or by the confirmed lack of unacceptable site uses (i.e., no well installation or building construction) and therefore exposure to site-related contaminants in soil and groundwater is currently being prevented. To ensure the future protectiveness of the remedy, the Navy is coordinating with the current site owner to allow incorporation of an ELUR documenting the LUCs required by the Record of Decision (ROD) for the non-NCA portion of Site 16 into the deed for previous transfer of the property.

Executive Summary

This report presents the results of the fourth Five-Year Review for the former Naval Construction Battalion Center (NCBC) Davisville, located in North Kingstown, Rhode Island. The Installation Restoration (IR) Program for the former NCBC Davisville includes 13 sites and 3 Study Areas. At three of the sites, Site 07 – Calf Pasture Point, Site 09 – Allen Harbor Landfill, and Site 16 – Creosote Dip Tank Area, Fire-Fighting Training Area (FFTA), and former Building 41, hazardous substances, pollutants, or contaminants remain after remedy implementation in excess of levels that allow for unlimited use and unrestricted exposure. These sites are therefore subject to the statutory requirement under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) to review their remedies at least once every 5 years to assure that they continue to be protective of human health and the environment. The triggering action for this review is the completion of the Third Five-Year Review Report.

At Site 07 - Calf Pasture Point, the remedy includes institutional controls (CERCLA and non-CERCLA deed restrictions) and Long-Term Monitoring (LTM) of groundwater and sediment. Non-CERCLA Deed restrictions include a prohibition on the construction of buildings for residential or commercial use; CERCLA prohibition on the construction of any building, structure, or facility without adequate ventilation; and prohibition on the installation of water supply wells and use of groundwater for any purpose other than sampling or remediation. Compliance with deed restrictions is documented annually via land use controls (LUC) inspections in accordance with the land use control implementation plan (LUCIP) for NCBC Davisville.

Based on the data review and technical assessment performed for this Five-Year Review, the remedy at Calf Pasture Point is protective of human health and the environment in the short-term because exposure pathways that could result in unacceptable risks are being addressed through institutional controls that prevent exposure to contaminants in site groundwater and because a risk screening evaluation indicates there is no unacceptable risk to recreational swimmers/waders, shell fishermen, or ecological receptors from site-related contaminants in surface water and sediment. Supplemental risk assessment and monitoring program optimization will continue during the LTM program to verify the protectiveness of the remedy and to ensure that reasonable potential exposure pathways are being adequately monitored.

At Site 09 - Allen Harbor Landfill, the remedy includes a multimedia cap (including a passive gas venting system); stone shoreline revetment; an offshore breakwater structure; the construction of an inter-tidal wetland; institutional controls (deed

restrictions) and maintain warning signs to inform the public of the State ban on shellfishing in the harbor; and LTM of groundwater, sediment, shellfish, and landfill gas. Compliance with deed restrictions is documented annually via LUC inspections in accordance with the LUCIP.

Based on the data review and technical assessment performed for this Five-Year Review, the remedy at Site 09 is protective of human health and the environment. Exposure pathways that could result in unacceptable risks are being addressed through remedy-related institutional controls and a state-enforced prohibition on shellfishing in Allen Harbor. These controls are effectively preventing exposure to site-related contaminants. Supplemental risk assessment and monitoring program optimization will continue during the LTM program to verify the protectiveness of the remedy and to ensure that reasonable potential exposure pathways are being adequately monitored.

At Site 16 – Creosote Dip Tank Area, FFTA, and former Building 41, the remedy includes excavation and off-site disposal of surface soils (to a depth of 2 feet below ground surface [bgs]) in the north central area (NCA) of Site 16 with contaminant concentrations greater than Rhode Island Department of Environmental Management (RIDEM) industrial/commercial (I/C) direct exposure criterions (DECs); excavation and off-site disposal of surface soils (to a depth of 2 feet bgs) near the marina building (Building E-107) with backfilling and restoration; focused in-situ treatment of groundwater at the eastern end of former Building 41; Monitored Natural Attenuation (MNA) of the residual VOC-contaminated groundwater plume; and LTM of groundwater (and surface water and sediments, as necessary) after active groundwater treatment until groundwater standards are achieved. Deed restrictions include the establishment of a waste management area (WMA) in the NCA/marina to ensure that future use of the NCA is limited to non-residential activities (which also excludes recreational use as defined by RIDEM). A soil management plan is being implemented to address any disturbance to the soils and covers. Recreational use currently occurs at the marina (Quonset Davisville Navy Yacht Club).

Based on the data review and technical assessment performed for this Five-Year Review, the remedy at Site 16 is currently protective of human health and the environment. Exposure pathways that could result in unacceptable risks are being addressed through long-term maintenance and monitoring of the ROD remedies and implemented LUCs and by the confirmed acceptable site uses (i.e., no well installation or building construction) and therefore exposure to site-related contaminants in soil and groundwater is currently being prevented. To ensure the future protectiveness of the remedy, the Navy is coordinating with the current site owner to allow incorporation of an Environmental Land Use Restriction (ELUR) documenting the LUCs required by the

Record of Decision (ROD) for the non-NCA portion of Site 16 into the deed for previous transfer of the property. Supplemental risk assessment and monitoring program optimization will be used during the LTM program to verify the protectiveness of the remedy and to ensure that reasonable potential exposure pathways are being adequately monitored.

1.0 Introduction

1.1 Overview of the Five-Year Review Process

The purpose of the Five-Year Review is to determine whether the remedies implemented at former Naval Construction Battalion Center (NCBC) are protective of human health and the environment. The methods, findings, and conclusions of the Five-Year Review for the former NCBC Davisville are documented in this Five-Year Review Report. In addition, this report presents issues identified during the review and provides recommendations to address them.

The following is a summary of the requirements for Five-Year Reviews:

- The statutory requirement for a Five-Year Review was added to the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) as part of the Superfund Amendments and Reauthorization Act (SARA) of 1986. A Five-Year Review is required when both of the following conditions are met, whether the site is on the National Priorities List (NPL) or not:

  1) Upon completion of the remedial actions at a site, hazardous substances, pollutants, or contaminants remain in excess of levels that allow for unlimited use and unrestricted exposure. For example, if a site is restricted to industrial use because hazardous substances, pollutants, or contaminants remain in excess of levels that allow for unlimited use and unrestricted exposure, Five-Year Reviews must be conducted.

  2) The ROD or Decision Document (DD) for the site was signed on or after October 17, 1986 (the effective date of SARA).

- CERCLA §121(c), as amended, states:

  "If the President selects a remedial action that results in any hazardous substances, pollutants, or contaminants remaining at the site, the President shall review such remedial action no less often than each five years after the initiation of such remedial action to assure that human health and the environment are being protected by the remedial action being implemented. In addition, if upon such review it is the judgment of the President that action is appropriate at such site in accordance with section [104] or [106], the President shall take or require such action. The President shall report to the Congress a list of facilities for which such review is required, the results of all such reviews, and any actions taken as a result of such reviews."

- The National Contingency Plan (NCP), 40 Code of Federal Regulations (C.F.R.) Part 300.430(f)(4)(ii), states:

  If a remedial action is selected that results in hazardous substances, pollutants, or contaminants remaining at the site above levels that allow for unlimited, and unrestricted exposure, the lead agency shall review such action no less often than every five years after initiation of the selected remedial action.

This is the fourth Five-Year Review for the former NCBC Davisville. The triggering action for this statutory review was the completion of the Third Five-Year Review Report on March 28, 2013.

This Five-Year Review Report has been prepared in accordance with the United States Environmental Protection Agency (EPA) *Comprehensive Five-Year Review Guidance*, dated June 2001, and United States Department of the Navy *Policy for Conducting Five-Year Reviews Under the CERCLA Program* (2004). Additionally, the EPA memorandum dated September 13, 2012, with the subject *Clarifying the Use of Protectiveness Determinations for Comprehensive Environmental Response, Compensation, and Liability Act Five-Year Reviews* was considered during the preparation of this report.

1.1.1 Public Notification

To initiate the Five-Year Review for NCBC Davisville, discussions occurred between the Navy and regulators [EPA and Rhode Island Department of Environmental Management (RIDEM)] during the Base Realignment and Closure (BRAC) Cleanup Team (BCT) meeting on June 22, 2017. Additionally, on the same day, the Navy gave a presentation at the Restoration Advisory Board (RAB) meeting summarizing the results of the third Five-Year Review and outlining the work to be completed during the fourth Five-Year Review.

The completed Fourth Five-Year Review Report will be available at the Information Repository maintained by Quonset Development Corporation in the Annex Building at 95 Cripe Street, North Kingstown, Rhode Island. A public notice will be published announcing the completion of the Five-Year Review and its availability at the Information Repository.

1.2 Roles and Responsibilities

In accordance with CERCLA, the Navy is the lead agency responsible for implementation and maintenance of the selected remedies for the affected sites as outlined in Section 1.1. The review team for this document includes EPA and RIDEM. The Navy is the responsible party and will issue the final Five-Year Review Report after revising this draft based on EPA and RIDEM comments. After EPA's review of this draft, EPA is expected to approve the Final Five-Year Review Report upon resolution and integration of EPA's comments. After RIDEM's review of this draft, RIDEM is expected to concur on the Final Five-Year Review Report upon resolution and integration of the State's comments.

1.3 Scope of the Five-Year Review

This fourth Five-Year Review addresses Navy Installation Restoration (IR) Site 07 [EPA Operable Unit (OU) 8], Calf Pasture Point; Navy IR Site 09 (EPA OU1), Allen Harbor Landfill; and Creosote Dip Tank Area, Fire Fighting Training Area (FFTA), and former Building 41, Navy IR Site 16 (EPA OU9). This is the first Five-Year Review for Site 16 because the ROD for this site was signed in 2014, after the finalization of the Third Five-Year Review Report. The locations of the IR sites are provided on Figure 1-1. Section 1 discusses the purpose of this report, and Sections 2 through 4 summarize the results of the Five-Year Review process for Sites 07, 09, and 16, respectively. Appendix A presents summaries of interview results, Appendix B presents photologs of site inspections performed in 2017, Appendix C presents updated risk tables, and Appendix D contains the Five Year Data Summary reports, which present the results of the comprehensive five-year monitoring event used to complete the Five-Year Reviews of Sites 07 and Site 09.

1.4 Status of Other CERCLA Sites at NCBC Davisville

Table 1-1 provides a summary of the status of other CERCLA sites at NCBC Davisville.

1.5 Next Review

The next Five-Year Review for the former NCBC Davisville is required by March 2023, 5 years from the date of this review.

Table 1-1: Summary of CERCLA Sites at NCBC Davisville

Site	OU	Site Description	Current Status	Phase	Date Completed
01*	7	Construction Equipment Department Drum Storage Area	RI	Under Investigation	Ongoing
02	7	Construction Equipment Department Battery Acid Disposal Area	RI	Under Investigation	Ongoing

15*	00	Building 56	NFA DD	RA, AR, UU	May 1998
16	9	Creosote Dip Tank and Fire Training Area	LTM	RA, ROD Requirement	Ongoing

* = Study Area
RI = Remedial Investigation
NFA ROD = No Further Action Record of Decision
NFA ESD = No Further Action Explanation of Significant Differences
NFA DD = No Further Action Decision Document
LTM = Long-Term Monitoring
AR = Acceptable Risks (human health and ecological risks within acceptable ranges)
UU = Suitable for Unrestricted Use (Five-Year Reviews not required)
RA = Removal Action performed to achieve condition of no unacceptable risks
Rem. Action = Remedial Actions performed to achieve condition of no unacceptable risks

Note
1 The ROD for Site 05 is for soils only, there is no ROD for groundwater at the site. There is, however, a soils and groundwater ROD at Sites 06, 11 and 13, which are in close proximity to Site 05

2.0 Site 07 – Calf Pasture Point

This section presents the findings of the Five-Year Review for the remedy implemented at Navy IR Site 07 (Calf Pasture Point) at the former NCBC Davisville.

2.1 Calf Pasture Point Summarized Site Chronology

A list of important Site 07 historical events and relevant dates in the site chronology are shown below. The identified events are illustrative, not comprehensive.

Event	Date
A trench was reportedly filled with containers of Decontaminating Agent Non-Corrosive (DANC) solution (1,1,2,2-tetrachloroethane [PCA] and oxidizing agents that readily break down to release chlorine when contacted by water).	1968 to 1974
Completion of the Initial Assessment Study (IAS) of the former NCBC Davisville facility (Hart, 1984).	9/1984
Completion of the Verification Step – Confirmation Study of the former NCBC Davisville facility (TRC, 1987).	2/1987
EPA's Hazard Ranking Scoring Package for the former NCBC Davisville facility.	1989
NCBC Davisville facility placed on the CERCLA NPL.	11/21/1989
Federal Facility Agreement (FFA) signed by the Navy, EPA, and State of Rhode Island.	3/1992
Munitions bunker, Building 339, demolished by the Navy (FWENC, 1997).	2/1997
RI completed (Three Phases I, II, and III) (EA, 1998a).	9/11/1998
ROD signed.	9/30/1999
Class I survey of Parcel 9 completed and annotated with references to the deed for groundwater use and land use restrictions.	2/2000
Final *Conceptual Long-Term Monitoring Plan* (LTMP), which included establishment of performance standards (NewFields, 2000a).	3/7/2000
Finding of Suitability to Transfer (FOST) to transfer the property (Parcel 9) to the United States Department of Interior for transfer to the Town of North Kingstown, Rhode Island (Navy, 2000a). The FOST cites the ROD requirement to record Environmental Land Use Restrictions (ELURs) to establish environmental restrictions on the property's title.	5/2000

Event	Date
Munitions bunker, Buildings 59 and 60, demolished by the Navy (FWENC, 2000a).	9/2000
Final Quality Assurance Project Plan (QAPP) for LTM of Site 07.	7/2001
LTM program Monitoring Event (ME) 01 for Site 07 completed, including 16 wells and 10 piezometers.	8/2001
Parcel 9 received by the Town of North Kingstown and the deed recorded (ELUR was not recorded with deed).	10/2001
Signature date of the *First Five-Year Review Report* for NCBC Davisville (EA, 2003c).	3/28/2003
Nine monitoring wells installed at Site 07 (MW07-27S, MW07-35D, MW07-37S/D, MW07-38S/D, and MW07-39S/I/D) as recommended in the *First Five-Year Review Report*	3/2004 - 4/2004
Signature date of the *Second Five-Year Review Report* for NCBC Davisville (Tetra tech, 2008b).	3/28/2008
Three additional groundwater monitoring wells added, MW07-24S, MW07-32D, MW07-32R.	5/2008
ELUR was recorded by Town of North Kingstown	5/2009
Draft Final Sampling and Analysis (SAP) for Source Area Investigation submitted (Tetra Tech, 2011a).	2/2011
Source Area Investigation conducted, including installation of eight new groundwater monitoring wells and tidal study.	4/2011 through 6/2012
Source Area Removal of trench filled with DANC cans conducted.	6 to 9/2011
Signature date of the *Third Five-Year Review Report* for the NCBC Davisville (Tetra Tech, 2013b).	3/28/2013
Final Source Area Investigation and Long-Term Monitoring Data Summary Report submitted, including investigative work conducted in 2010, 2011, and 2012 (Tetra Tech, 2015a).	7/31/2015
Draft Tier II SAP for LTM at Site 07 Calf Pasture Point and Site 09 Allen Harbor Landfill submitted (Resolution, 2016d).	6/24/2016
Draft Final Fall 2016 Five-Year Event Monitoring Report, Site 07 submitted (Resolution, 2018a).	2/8/2018

2.2 Calf Pasture Point Background Information

In this section, background information for Calf Pasture Point, such as physical characteristics, current and former land use, and a history of environmental actions is presented.

2.2.1 Physical Characteristics

Calf Pasture Point is a peninsula located in the northeastern portion of the Former NCBC Davisville facility (Figure 1-1). An existing tidal estuary was filled with dredged material during World War II to form the current peninsula. Site 07 is located in the southern portion of Calf Pasture Point (Parcel 9) on the northeastern edge of Allen Harbor (Figures 1-1 and 2-1). Narragansett Bay, the harbor Entrance Channel, and the harbor itself form the eastern, southern, and southwestern shorelines of Site 07, respectively.

A bedrock outcrop in the center of the peninsula, north of well MW07-07S, forms a prominent hill with a maximum elevation of approximately 55 feet above mean sea level (msl) (Figure 2-2).

2.2.2 Land and Resource Use

Currently, the site is undeveloped property with forest and grass cover. Site 07 will not be used for residential purposes in the future because Calf Pasture Point has been transferred to the Town of North Kingstown via Public Benefit Conveyance for use as an open space/conservation area. Acquisition in this manner restricts the transferee to use of the property as a park or for other recreational purposes in perpetuity, with no opportunity for residential or commercial development. The site is currently used for limited recreational activities such as walking, hiking and open space for dog walking. Several cut-grass style paths are annually maintained throughout the site, but no recreational building or other structures have been built at the site.

Groundwater underlying Calf Pasture Point has been classified by RIDEM as GA (i.e., presumed to be suitable for public or private drinking water use without treatment). No groundwater production wells or potable water supply wells are located on or downgradient of Site 07. Any potential future water needs would be met via municipal water available from the Town of North Kingstown.

Allen Harbor is used for recreational boating and contains two marinas. In 1984, RIDEM closed much of Allen Harbor to shellfishing due to suspected bacterial contamination. Subsequently, an additional basis for closure was due to surface runoff from Allen Harbor Landfill and other source areas. In 2004, the remainder of the harbor (the Entrance Channel) was closed to shellfishing.

Allen Harbor is classified by RIDEM as SA {b}. Class SA waters are designated for shellfish harvesting, contact recreational activities, and fish and wildlife habitat; the {b} designation indicates a “partial uses" status (that can affect the application of criteria)

for waters in the vicinity of marinas and/or mooring fields where seasonal shellfishing closures are likely.

2.2.3 History of Contamination

From the early 1940s until the mid-1970s, Site 07 was used for training of Naval Seabees (construction battalions) in the use of heavy construction equipment. Calf Pasture Point formerly contained three munitions bunkers (Buildings 59, 60, and 339) located along Magazine Road, which formerly traversed the site from north to south between Sanford Road/Finn Street and the southern tip of Calf Pasture Point. The bunkers were earthen covered and were located in the middle of Calf Pasture Point, to the north, east, and south of the bedrock outcrop. The bunkers were demolished by the Navy in February 1997 (Building 339) and September 2000 (Buildings 59 and 60). IR Site 07 is composed of the forest- and grass-covered area of Calf Pasture Point, south of the former munitions bunkers (i.e., south of the bedrock outcrop) to the Allen Harbor and Narragansett Bay shorelines.

Sometime between 1968 and 1974, in the area south of the former munitions bunkers, a trench was filled with cans that contained DANC solution. This trench (with cans of DANC) was located during the Source Area Investigation conducted in 2011. The chemicals buried in the trench are the source of a dissolved chlorinated volatile organic compound (CVOC) plume identified in groundwater at Site 07. The DANC cans (and impacted soils) in the trench were removed in 2011 as documented in the *Removal Action Completion Report* (Shaw, 2012).

2.2.4 Initial Response and Basis for Taking Action

Potential human health risks associated with exposure to the COCs at Site 07 were estimated through the evaluation of several potential exposure scenarios. These scenarios were developed to reflect the potential for exposure to COCs based on current land use, potential future land uses, and the location of the site. The Human Health Risk Assessment (HHRA) was prepared in accordance with CERCLA guidance using Phase I, II, and III RI data (TRC, 1991 and 1994; EA, 1998a).

The Base Re-Use Plan for Calf Pasture Point specifies that future use of the site will be for open space/conservation, which may include recreational activities. Accordingly, the Navy evaluated exposure pathways for hypothetical future recreational users and consumers of locally caught non-depurated shellfish. For purposes of completeness, the Navy also evaluated future construction/remediation workers and hypothetical future residents. The future recreational scenario assumed that a showering facility may be constructed using groundwater from the site; however, it is expected that any future

showering facility at Calf Pasture Point would use municipal water available in the area from the Town of North Kingstown. The following exposure pathways were considered to represent potentially complete pathways for receptor exposure to COCs in soil, groundwater, air, offshore sediment, shellfish, and/or surface water and were evaluated in the HHRA for Site 07:

- ***Exposures via Soil***
  - Incidental ingestion of total soil (surface and subsurface) by future construction workers.
  - Incidental ingestion of surface soil by recreational users.
- ***Exposure via Sediment***
  - Incidental ingestion of sediment by recreational users.
- ***Exposures via Groundwater***
  - Incidental ingestion of shallow groundwater by future construction workers.
  - Consumption of deep/bedrock groundwater by hypothetical future residents.
  - Inhalation of volatile organic compounds (VOCs) from deep/bedrock groundwater by recreational users while showering.
  - Dermal contact with deep/bedrock groundwater by recreational users while showering.
- ***Exposures via Surface Water***
  - Incidental ingestion of surface water by recreational child/adult users while swimming.
  - Dermal contact with surface water by recreational child/adult users while swimming.
- ***Exposure via Shellfish***
  - Ingestion of shellfish collected from Allen Harbor adjacent to Site 07.

Risk estimates for the following human exposure pathways were identified as unacceptable based on the Site 07 HHRA:

- Ingestion of deep and bedrock groundwater by residential populations (due to elevated concentrations of VOCs and several inorganics).
- Inhalation of VOCs in deep and bedrock groundwater by recreational populations while showering.

- Dermal contact with VOCs in deep and bedrock groundwater by recreational populations while showering.

CVOCs, predominantly 1,1,2,2-PCA and TCE in groundwater, were identified as the primary COCs for Site 07. Risk estimates for the following COCs exceeded a Hazard Index (HI) of 1 (i.e., an indication of the potential for adverse non-carcinogenic health effects) or the EPA target cancer risk range of 10^{-4} to 10^{-6}:

- Aluminum
- Arsenic
- Beryllium
- Chromium
- Manganese
- Chloroform
- Benzene
- Vinyl chloride
- 1,1-Dichloroethene (DCE)
- 1,2-DCE (total)
- 1,1,2-Trichloroethane (1,1,2-TCA)
- TCE
- 1,1,2,2-PCA
- Tetrachloroethene (PCE)

The marine Ecological Risk Assessment (ERA) (SAIC, 1996) evaluated risks to the environment using data from offshore sediment and shellfish samples collected along the western and southern shorelines of Calf Pasture Point. Inorganics and VOCs (the COCs at Site 07) were not identified as a concern in either the shoreline sediment or shellfish samples. No significant terrestrial ecological risks were identified at Site 07.

2.3 Remedial Actions

This section discusses the remedy selection and implementation history for Calf Pasture Point, along with a discussion of the LTM program currently in place at Site 07.

2.3.1 Remedy Selection

The ROD for Site 07 was signed on September 30, 1999. The selected remedy was deed restrictions with LTM. As stated in the ROD, the Remedial Action Objectives (RAOs) for Site 07 are to prevent human exposure to COCs in deep and bedrock groundwater and to ensure that the discharge of groundwater to wetlands and offshore areas continues to pose no unacceptable risks from COCs. The selected remedial alternative includes the following components:

- A deed restriction prohibiting the use of groundwater to prevent human contact with, or use of, impacted groundwater from the site (e.g., for drinking or

showering purposes) maintained for as long as the site groundwater conditions may pose an unacceptable risk to human health or the environment.

- No use of groundwater for any purpose (including showering, drinking, and irrigation) will be available onsite.

- In addition, any design, construction or development of any building, structure, facility, or other improvement within the southern portion of the property (Figure 2-2) shall include adequate ventilation, as approved by the Navy, EPA, and RIDEM.

- The Grantee under the deed shall be required to submit a yearly certification to the Navy, EPA, and RIDEM of compliance with the deed restrictions. The groundwater and land use restrictions contained in the deed shall be incorporated into an ELUR, which shall be filed and recorded by the Navy or disposal agency in the land records of the Town of North Kingstown, Rhode Island, in accordance with state and local law.

- LTM of the groundwater plume to ensure that the site continues to pose no unacceptable risks to human health or the environment. Other media such as sediment from the shoreline or interior wetlands are also sampled, based on trends identified from groundwater data.

- Five-Year Reviews of the remedy for the site by the Navy, EPA, and RIDEM to ensure the continued protection of human health and the environment (EA, 1999b).

Additionally, the ROD stated that signature of the ROD constituted final documentation that the three former munitions bunkers were closed appropriately, as described in the Foster Wheeler Environmental Corporation (FWENC) Closeout Report (1997).

2.3.2 Remedy Implementation

As summarized in the previous section, land use controls (LUCs) and LTM were the primary components of the selected remedy. LUC inspections were initiated in May 23, 2001, the deed was recorded on October 17, 2001, and the ELUR was recorded on May 8, 2009. LTM was initiated in August 2001.

2.3.2.1 LUCs

In accordance with the ROD (EA, 1999b) and as outlined in the LUCIP (EA, 2002b), Parcel 9 includes the following ELUR:

- No construction or development of any building, structure, facility, or other improvement without adequate ventilation, as approved by the Navy, EPA, and RIDEM, within the portion of land south of the east-west line shown on Figure 2-2. This restriction will be required for as long as site conditions may pose an unacceptable risk to human health and the environment.

- For the entire parcel, water supply wells will not be installed nor will groundwater be utilized, except for sampling or other remedial purposes.

Although not a requirement under the CERCLA remedy, for the entire parcel, no construction of buildings for residential or commercial use is mandated as part of the deed restrictions on the transfer of the property from the Navy (Department of the Interior) to the Town of North Kingstown.

These environmental land use restrictions apply to use of the contaminated site, as delineated on Figure 2-1 (land use restriction boundary).

LUC inspections of Parcel 9 are performed in conjunction with each Site 07 LTM event, no less frequently than annually, to document that there has been no variance from the environmental land use restrictions stated above and that there has been no interference with the implemented remedy.

At least once per year (usually more frequently), compliance with these controls is verified through a review of town records to ensure that no permits have been issued that would change the use of the site or allow the installation of groundwater supply wells. An updated LUCIP was submitted as draft on November 2016, and the final LUCIP is currently being prepared. Significant changes include a more comprehensive site-related questionnaire on updated land use and includes signature requirements for current tenant, not just land owner. The draft Annual LUCIP for 2016 report was submitted for review on February 9, 2018.

2.3.2.2 LTM

The objective of the monitoring component of the remedy is to obtain the data necessary to assess the long-term effectiveness of the remedy and to ensure that the groundwater plume continues to pose no unacceptable risks to human health and the environment. LTM was initiated in August 2001. A detailed summary of the LTM

performed between initiation in August 2001 (ME 01) and March 2013 (ME16, date of last Five-Year Review) is included in the Final Third Five Year Review Report (Tetra Tech, 2013b). A site map with long-term monitoring locations is provided on Figure 2-2.

Through ME16, the only approved LTMP for Site 07 was the 2001 QAPP for LTM at Site 07 (EA, 2001a). As summarized in this document, LTM consisted of sampling at 9-month intervals from a network of 16 wells and 10 shoreline piezometers, and sampling at 27-month intervals from an expanded list of 26 wells and 24 piezometers. These well lists do not include new wells installed since the inception of the plan.

The *Draft Source Area Investigation and Long-Term Monitoring Data Summary Report for Site 07: Calf Pasture Point* was submitted in February 2013. Based on the results of the Source Area Investigation and updated conceptual site model (CSM), changes to the LTM program were proposed, including decreasing the sampling frequency to annual. During subsequent monthly meetings, annual LTM beginning in 2013 was proposed and agreed by the BCT. The *Draft Source Area Investigation and Long-Term Monitoring Data Summary Report for Site 07: Calf Pasture Point* was completed in July 2015, and the approved changes to the LTM program are documented in the June 2016 *Draft Tier II Sampling and Analysis Plan, Long Term Monitoring, Site 07 Calf Pasture Point and Site 09 Allen Harbor Landfill.* This draft document is currently being finalized based on regulator comments.

2.4 Progress Since the Last Review

The previous Five-Year Review concluded that the remedy at Calf Pasture Point was protective of human health and the environment and that exposure pathways that could result in unacceptable risks are being addressed through institutional controls that prevent exposure to contaminants in site groundwater.

This section presents the concerns not related to remedy protectiveness that were included in the *Third Five-Year Review Report*, with a brief description of the actions taken by the Navy since the last review:

- Concern 1: Implement EPA Region 1 request to complete an ESD to document the removal action (excavation and off-site removal) of the source area that was not a component of the 1999 Site 07 ROD.

- Concern 2: LTM program needs to be reviewed/updated, including updating Project Action Limits (PALs) based on new Maximum Contaminant Levels (MCLs) or EPA Regional Screening Levels (RSLs) (as appropriate).

- Concern 3: LTM ME data reporting and LTM comprehensive reviews of site data need to be reviewed/updated to ensure appropriate data is shared with BCT in a timely manner to ensure continued protectiveness.

To address Concern 1, the *Third Five-Year Review Report* included a recommendation to prepare ESD to document the 2011 removal action. The *Draft Explanation of Significant Differences (ESD) OU8 Calf Pasture Point Solvent Disposal Area (Site 7)* was submitted in July 2013. Comments on the draft document were received from Region 1 EPA on August 22, 2013. Based on Navy attorney review of Region 1 EPA comments, it was determined that the removal action was a "self-contained event" that did not affect the ROD, thereby not requiring an ESD. This determination was presented to the BCT during the December 12, 2013, monthly teleconference. It was further agreed by the BCT that documentation of the removal action in the *Removal Action Completion Report* would confirm completion of the removal action and be adequate for the project record. The Final *Removal Action Completion Report* was submitted on October 1, 2012. The Navy sent a letter to EPA Region 1 and RIDEM on February 7, 2014, formally retracting the ESD for Site 7 removal action.

To address Concern 2, the Third Five-Year Review Report included recommendations to schedule a DQO meeting to discuss optimization of the LTMP and establish the objectives and scope of the LTMP and to prepare a revised SAP for LTM at Site 07. A scoping meeting was held on April 30, 2013, to discuss optimization of the LTMP and establish objectives of the LTMP. Further discussions on LTM optimization and objectives occurred during monthly BCT teleconferences following this scoping meeting. Based on the scoping meeting and subsequent teleconferences, agreements on optimization and objectives of the LTMP were achieved. As a result of the formal scoping meeting and subsequent teleconferences, a Draft *Tier II Sampling and Analysis Plan, Long Term Monitoring, Site 07 Calf Pasture Point and Site 09 Allen Harbor Landfill* was prepared and submitted on June 24, 2016. Currently, a final version of the document is being prepared based on regulator comments and Navy responses.

To address Concern 3, the *Third Five-Year Review Report* included a recommendation to schedule a DQO meeting to discuss reporting requirements for data reports and schedule for comprehensive data reviews. A scoping meeting was held on September 5, 2013, to discuss reporting requirements of the LTMP and frequency of reporting. Further discussions on the reporting requirements and frequency of reporting occurred during monthly BCT teleconferences following this scoping meeting. Reporting requirements and frequency of reporting are provided in the Draft *Tier II Sampling and Analysis Plan, Long Term Monitoring, Site 07 Calf Pasture Point and Site 09 Allen Harbor Landfill* submitted on June 24, 2016.

No significant activities or fieldwork efforts have occurred at the site since the last Five-Year Review.

2.5 Five-Year-Review Process

In this section, a description of the Five-Year Review process specific to Calf Pasture Point, including the document review, data review, and site inspection, is provided.

2.5.1 Document Review

Documents reviewed as part of this Five-Year Review are referenced throughout the text and are included in the reference section. Information in this subsection summarizes the results of LTM and are based on LTM reports.

A review of all of the Calf Pasture Point LTM data, along with data collected from investigative activities to supplement the LTM program, was performed as part of the Five-Year Review.

2.5.2 Data Review

As required by the ROD for Site 7, LTM (ME17 through ME20) was performed between 2013 and 2016, in accordance with the updated LTM scope and protocols documented in the Draft *Tier II Sampling and Analysis Plan, Long Term Monitoring, Site 07 Calf Pasture Point and Site 09 Allen Harbor Landfill (Resolution, 2016d).* Results of these LTM events were summarized in annual data reports, with the contents of these reports following the guidance outlined in the Draft Tier II SAP.

The following general conclusions are presented based on the comprehensive evaluation of site data as summarized from the *Draft Final Monitoring Event 20, Fall 2016 Five Year Event Monitoring Report* (Resolution, 2018a), which evaluates all LTM to date with a focus on the past 5 years (Figures 2-3 through 2-7 present spatial distributions of TCE, VC, cis-DCE, trans-DCE and PCE for ME20, taken from the draft final report):

- Analysis of Mann-Kendall trend test data indicates that groundwater concentration trends are generally consistent and stable throughout the site since 2012 (evaluations performed in the *Final Source Area Investigation and Long-Term Monitoring Data Summary Report* [Tetra Tech, 2015a]) and over the long term (since 2001).

- The primary plume migration pathways described in the *Final Source Area Investigation and Long-Term Monitoring Data Summary Report* (Tetra Tech, 2015a) remain consistent (i.e., no significant changes in plume migration patterns). The plumes appear generally stable (in both overall size and concentrations), with some localized increasing trends likely due to plume redistribution/equilibration (see Figures 2-3 through 2-7).

- Along the western portion of Site 07, contamination does not appear to be migrating upward through the silt layer to the shoreline, as evidenced by the lack of VOC detections in shallow zone wells MW07-04S, MW07-38S, and MW07-33S during ME20 (see Figures 2-3 through 2-7). VOC concentrations in the deep zone in the western portion of Site 07 are generally much lower compared to concentrations in other portions of the plume.

- Along the eastern portion of Site 07, contamination does not appear to be migrating up to the shallow zone along the eastern shoreline of Site 07 (see Figures 2-3 through 2-7). Low concentrations or non-detect results in MW07-18S and MW07-20S support the conclusion discussed in the *Final Source Area Investigation and Long-Term Monitoring Data Summary Report* (Tetra Tech, 2015a) that the silt and clay layers along the eastern shoreline are acting as a confining layer.

- Based on very low or non-detect concentrations in the sediment and surface water data, the current sampling schedule of once every 5 years is sufficient for these media.

- The *Final Source Area Investigation and Long-Term Monitoring Data Summary Report* (Tetra Tech, 2015a) concluded that sampling in different seasons does not appear to impact contaminant concentrations at any groundwater or piezometer locations with the possible exception of MW07-21S, P07-05, and P07-24. This conclusion is confirmed in the *Draft Final Monitoring Event 20, Fall 2016 Five Year Event Monitoring Report* (Resolution, 2018a) as well.

- The overall conclusion of the 2017 HHRA update included in the *Fall 2016 Five Year Event Monitoring Report* is that the conclusions of the 2012 HHRA remain valid and that exposure to shallow groundwater, surface water, and sediment along the Site 07 shoreline by recreational users does not result in a potential excess lifetime cancer risk (ELCR) or noncancer HI in excess of EPA or RIDEM target levels.

Based on concentrations of CVOCs observed through ME20, the relative stability of the plume, the degradation of the plume, and the overall conclusion of the 2017 HHRA update, the LTM component of the Site 07 remedy continues to be protective of human health and the environment.

2.5.3 Site Inspection

This section summarizes the routine LTM program site inspection activities, as well as the site inspection activities performed specifically for this fourth Five-Year Review.

2.5.3.1 LTM Program Site Inspections

Site inspections are conducted at Calf Pasture Point in conjunction with each LTM event. During the inspections, each monitoring well is checked to ensure that it is locked, labeled, and in good condition. Observations are noted on monitoring well inspection forms that are included in the appendices of the LTM reports. The site inspection also includes an on-site verification of the effectiveness of LUCs by observing land use conditions (presence of buildings and level of recreational use at the site) and evidence of groundwater extraction wells.

LUC inspections performed during the LTM program have not detected any evidence of newly installed groundwater wells or new construction at Site 07.

2.5.3.2 Five-Year Review Site Inspection

Tetra Tech performed a site inspection on September 20, 2017, as part of the fourth Five-Year Review. The inspection include a site walkover, including along the Narragansett Bay shoreline, and annotation of conditions. Photographs from the 2017 site inspections are included in Appendix B.

The site was observed to consist of a mix of forested, grassy, and sandy areas. The inspection began at Sanford Road, west of the site, and proceeded to the east along a gravel road and then south until reaching monitoring well MW07-23S. The inspection then proceeded toward the east along the southern shoreline of Calf Pasture Point, and monitoring wells MW07-21 and MW07-24 were observed. The portion of the site adjacent to Narragansett Bay was then observed.

Overall, the site was found to be in good conditions. All wells encountered along the western and southern shorelines of the site appeared in good condition, and the well casings were locked. Additionally, wells located within the site were also found to be in good conditions, and the well casings were locked. Piezometers within the Entrance Channel were observed to be in generally good condition, though piezometers along the

western shoreline were leaning and/or in various states of dis-repair. These will need to be replaced prior to sampling during a LTM event.

2.5.3.3 Interviews

The Navy holds annual RAB meetings for former NCBC Davisville to discuss the process of the cleanup program and ongoing investigations and/or site status. Comments and/or information received during these meetings are recorded and addressed by Navy, Region 1 EPA, and RIDEM representatives during these annual meetings. The RAB meeting notes are available to all attendees and are placed in the Administration Record.

The following individuals were interviewed as part of the fourth Five-Year Review for former NCBC Davisville.

Interviewee	Title/Affiliation
Nicole LaFontaine	North Kingstown Director of Planning and Development
Steven King	Quonset Development Corporation, Chief Operating Officer
Susan Licardi	North Kingstown Director of Water Department/Supply
Phil Bergeron	North Kingstown Director of Public Works
Chelsey Dumas	North Kingstown Department of Recreation
Ralph Mollis	North Kingstown Town Manager

The types of questions that were asked of interviewees are provided on the Typical Interview Questions from the June 22, 2017 RAB presentation, included in Appendix A. Steven King of Quonset Development Corporation was interviewed on September 21, 2017, and Susan Licardi of North Kingstown Water Department was interviewed on September 22, 2017. On Friday, September 23, 2017, Susan Licardi spoke with several other North Kingstown managers, with her questions focused on town-owned Sites 07 and 09. Appendix A includes a summary of information gathered during these interviews. The Typical Interview Questions from the June 22, 2017 RAB presentation were also provided to the Quonset Davisville Navy Yacht Club. However, no responses were received.

2.6 Technical Assessment

2.6.1 Question A: Is the remedy functioning as intended by the decision documents?

Based on the document review, data review, and site inspections, the remedy at Calf Pasture Point is functioning as intended by the ROD. Groundwater samples are collected from monitoring wells screened in the overburden (shallow and deep) and bedrock zones throughout the interior portions of Calf Pasture Point and from shallow piezometers along the western and southern shorelines of Calf Pasture Point (sampling was performed once in 2010 along the eastern shoreline with Narragansett Bay).

As demonstrated by the results of supplemental monitoring, investigations, and risk assessments discussed above, the remedy at Calf Pasture Point is meeting the RAO stated in the ROD, to "ensure that the discharge of groundwater to wetlands and offshore areas continues to pose no unacceptable risks from COCs." The current sampling network is adequate to evaluate the protectiveness of the remedy. The current network includes piezometers placed at a spacing of approximately 50 feet along the entire length of the eastern and southern Calf Pasture Point shorelines to monitor COC concentrations at the most likely points of human exposure where impacted groundwater may discharge. Temporary piezometers were sampled for COCs along the eastern shoreline (Narragansett Bay) in 2010 by Region 1 United States Environmental Protection Agency; no COCs were detected. Shallow and intermediate groundwater wells are routinely sampled at the eastern shoreline and evaluated as a component of the remedy; therefore, piezometer sampling at the eastern shoreline is not required to ensure protectiveness.

The other RAO identified in the ROD for Calf Pasture Point is to "prevent human exposure to COCs in deep and bedrock groundwater." To achieve this objective, the remedy includes environmental land use restrictions that: (a) prohibit the construction or development of any building, structure, facility, or other improvement without adequate ventilation and (b) prohibit the installation of water supply wells or the use of groundwater for any purpose, except for sampling or remediation. At least once per year (usually more frequently), compliance with these controls is verified through a review of town records to ensure that no permits have been issued that would change the use of the site, allow the construction of residential or commercial units, or allow the installation of groundwater supply wells. An on-site inspection is also conducted to verify that no buildings or water supply wells are installed on the site.

2.6.2 Question B: Are the exposure assumptions, toxicity data, cleanup levels, and RAOs used at the time of the remedy selection still valid?

There have been no changes in the physical conditions of the site that would affect the protectiveness of the remedy.

The HHRA for Site 07 was updated as part of the *Monitoring Event 20, Fall 2016 Five Year Monitoring Report, Site 07: Calf Pasture Point* (Resolution, 2017a and 2018a) (Appendix F). The objective of the updated HHRA was to determine whether there have been any changes and/or updates to EPA HHRA guidance or site-specific conditions since the 2012 HHRA performed in support of the *Third Five-Year Review Report* (Tetra Tech, 2013b) that would result in a change of the conclusions of the 2012 HHRA. The 2017 HHRA update included the following:

- Summary statistics calculations for 2016 LTM sediment, surface water, and shallow groundwater analytical data collected along the Site 07 shoreline (referred to as the 2017 HHRA update data set).

- Update of screening levels and contaminant of potential concern (COPC) selection for shoreline sediment, surface water, and shallow groundwater.

- Update of human receptor exposure assumptions/parameters.

- Calculation of exposure point concentrations (EPCs) for COPCs in each medium based on the 2017 HHRA update data set.

- Update of toxicity values for COPCs identified based on the 2017 HHRA update data set.

The receptors and exposure pathways evaluated in the 2012 HHRA are still relevant for the 2017 HHRA update based on current and potential future land use. These receptors and pathways include recreational users exposed to shoreline media while swimming, wading, or clamming/harvesting shellfish. Revised formal risk/hazard calculations were not performed as part of the 2017 HHRA update; however, a quantitative evaluation of the potential exposure to Site 07 shoreline shallow groundwater, surface water, and/or sediment by recreational users was conducted to determine whether updates to the 2012 HHRA would result in cumulative potential cancer risks and/or noncancer hazards greater than EPA and RIDEM target risk/hazard levels.

The overall conclusion of the updated HHRA was that the conclusions of the 2012 HHRA remain valid. There have been no changes in exposure assumptions, toxicity criteria, or contaminant characteristics that have affected the protectiveness of the selected remedy. Therefore, the RAOs are still valid, and applicable state and federal standards have not changed since the ROD was signed in September 1999.

The marine ERA (SAIC, 1996) evaluated risks to the environment using data for offshore sediment and shellfish samples collected along the western and southern shorelines of Calf Pasture Point. VOCs (the COCs at Site 07) were not identified as a concern in either the shoreline sediment or shellfish samples. No significant terrestrial ecological risks were identified at Site 07.

Ecological receptors may also be exposed to Site 07 shoreline shallow groundwater; this exposure pathway was not previously evaluated. Data evaluated in the 2017 HHRA update were compared to ecological screening criteria (Appendix C). Data evaluated include 2013 to 2016 shallow groundwater data from piezometers and 2016 surface and sediment data.

Shallow groundwater results were compared to surface water ecological criteria. After considering a minimal dilution factor of 10 to account for exposure to shallow sediment porewater after underlying groundwater mixes with overlying surface water, no chemicals were selected as COPCs for groundwater from piezometers. No chemical concentrations in surface water or sediment exceeded their applicable screening levels, so no chemicals were selected as COPCs for surface water or sediment. Therefore, unacceptable risks are not expected for ecological receptors exposed to Site 07 groundwater, surface water, or sediment.

2.6.3 Question C: Has any other information come to light that could call into question the protectiveness of the remedy?

No additional human health or ecological risks have been identified and no weather-related events have affected the protectiveness of the remedy.

The rationale for remedy selection at Site 07 was based in part on the assumption that the extent of the plume was stable or decreasing. Based on an evaluation of CVOC plume configuration from 2012 to 2016 compared to 1995/96, some plume expansion has occurred to the east/southeast of the source area and previously unidentified migration pathways through MW07-11D toward Narragansett Bay and along an eastern migration pathway toward the DPT07-18/MW07-18D and DPT07-16/MW07-16 well clusters. The location of the center of mass in 2012 to 2016 is different from that observed in 1995/96 because the center of mass has moved from the source area to

the south and is currently located near the center of the site. This could be due in part to depletion of source material adsorbed to the aquifer material close to the release area.

With the exception of the migration pathway from the source area through MW07-11D toward Narragansett Bay and along an eastern migration pathway toward the DPT07-18/MW07-18D and DPT07-16/MW07-16 well clusters, there have been no changes regarding understanding of the extents of the leading edges of the plumes, although long-term trends are increasing at several locations along certain migration pathways (MW07-11D, -19D, -34D, and DPT07-16I).

Of particular note, contamination in areas where migration may be occurring (MW07-11D, -19D, -34D, and DPT07-16I) is all within the deep overburden groundwater aquifer (even though DPT07-16I is designated an "I" well) (see Figures 2-3 through 2-7). Along two of these pathways, MW07-19D (along cross-section A-A' of the *Monitoring Event 20, Fall 2016 Five Year Monitoring Report, Site 07: Calf Pasture Point* [Resolution, 2018a]) and MW07-34D (in the eastern portion of cross-section B-B' of the *Monitoring Event 20, Fall 2016 Five Year Monitoring Report, Site 07: Calf Pasture Point* [Resolution, 2018a]), contamination has already been detected beyond these locations, demonstrating that although the extent of contamination is not changing, the distribution along the migration pathways may be changing. The only identified migration pathways where the overall extent is changing is the pathway from the source area through MW07-11D and along the eastern migration arm to toward the DPT07-18/MW07-18D and DPT07-16/MW07-16 well clusters, where the plume is getting closer to Narragansett Bay over time. However, as determined through the tidal study, upward gradients in this area are infrequent (only occurring over short periods of time under certain low tides). Additionally, as determined from soil borings and well installations, a laterally extensive confining silt layer is present and typically is at least 10 to 15 feet thick. The silt layer is nearly 30 feet thick near the DPT07-18/MW07-18D and DPT07-16/MW07-16 well clusters. Consequently, the connection and discharge of deep groundwater to the shoreline environment are very complicated and limited. CVOC contamination may eventually reach the Narragansett Bay shoreline (likely nearly there based on fall 2016 results at DPT07-16I); however, the contaminant migration rate toward the shoreline is likely to be very slow as a consequence of both the gradient and laterally extensive silt layer. Also, the same groundwater/surface water interactions observed along the Entrance Channel are likely to impact both groundwater flow and contaminant discharge along the Narragansett Bay shoreline.

2.6.4 Technical Assessment Summary

Based on the data reviewed and the site inspection, the remedy is functioning as intended by the ROD. Supplemental data collection and risk assessments have been conducted during LTM to monitor the protectiveness of the remedy. There have been no changes in physical conditions at the site, toxicity factors, or to the standardized risk assessment methodology that would affect the protectiveness of the remedy. There is no other information at this time that calls into question the protectiveness of the remedy.

2.7 Issues

Although no deficiencies were identified during this five-year review for Site 07, and no issues related to site operations (LUCs and LTM), conditions or activities prevent the remedy from being protective in the short term, the following issues are identified to ensure future protectiveness -

Issue	Affects Current Protectiveness (Y/N)	Affects Future Protectiveness (Y/N)
Surface water and sediment should continue to be monitored to ensure ongoing protectiveness for recreational swimmers/waders, shell fisherman, and ecological receptors.	N	Y
Site contaminants in the groundwater plume are migrating toward surface water in the southern, western, and eastern shores; however, it is unknown how long it will take for concentrations to reach levels at these exposure areas that may pose a risk to human health or the environment.	N	Y

2.8 Recommendations and Follow-Up Actions

Issue	Recommendations/ Follow-Up Actions	Party Responsible	Oversight Agency	Milestone Date	Affects Protectiveness (Y/N)	
					Current	Future
1	The LTMP should be updated to include surface water and sediment monitoring and risk evaluations and/or assessments, as needed, to support future five-year reviews and to ensure ongoing protectiveness. The LTMP should also be revised to state that surface water and sediment monitoring will continue until such time that levels of site contaminants allow for unlimited use and unrestricted exposure.	Navy	EPA/ RIDEM	8/1/18	N	Y
2	Based on the results of a discussion concerning the CSM and analysis approach, an analysis should be conducted to evaluate the estimated amount of time (if ever) that it will take for the concentrations of site contaminants to reach levels in surface water and sediment that pose a risk to human health and the environment.	Navy	EPA/ RIDEM	6/1/22	N	Y

Although not associated with the protectiveness of the remedy and based on comments received on the Draft *Fall 2016 Five Year Event Monitoring Report, Site 07 Monitoring Event 20 (*Resolution, 2017a) and Navy responses on July 12, 2017, the following three

concerns remain to be addressed with respect to long-term analysis of site data and contaminant fate and transport:

- Evaluation of mass balance and natural attenuation mechanisms for CVOC plumes identified at the site.

- Evaluation of tidal influence on contamination migration at the site.

- Evaluation of contaminant migration to the eastern shoreline with emphasis on increases observed at DPT06-16I between 2012 and 2016.

Mass Balance and Natural Attenuation Mechanisms

A quantitative mass balance and natural attenuation mechanism evaluation will be performed based on data from 2011, 2012, 2014 and 2016. Only data from these time frames will be used because a better understanding of the residual contamination and CSM was realized upon completion of the *Final Source Area Investigation and Long-Term Monitoring Data Summary Report* (Tetra Tech, 2015a). The evaluation will be completed as a technical memorandum separate from the Five-Year Review (included as concern at end of section).

Tidal Influence on Contaminant Migration

Most wells at Site 07 are tidally influenced, which also adds to the complexity of fate and transport at the site. The tidal cycles may influence contaminant concentrations observed in nearshore groundwater by introducing greater variability in contaminant concentrations during mid- and high tide conditions due to exchange of fresh and saline groundwater. However, during low tide, the plume is not prevented from discharging into surface waters. Tidal cycles do not prevent or block the plume from discharging into surface waters.

Tidal influence on contaminant migration (as well as other contributing factors) is discussed in Section 3.2.3 (Transport and Fate Analysis) of the Final *Source Area Investigation and Long-Term Monitoring Data Summary Report* (Tetra Tech, 2015a). Because tidal influences have not changed since the last Five-Year Review, the discussions and conclusions presented are still valid.

Evaluation of Contaminant Migration to Eastern Shoreline

Several comments from Region I EPA concerning migration of contamination to the eastern shoreline were received on the *Draft Fall 2016 Five Year Event Monitoring Report, Site 07 Monitoring Event 20* (Resolution, 2017a). A concern was raised about

the recent occurrence of elevated contamination at DPT07-16I (TCE at 83 µg/L, cis-1,2-DCE at 120 µg/L, and vinyl chloride at 5.2 µg/L) and its potential impact on the migration of contamination toward Narragansett Bay. The following text evaluates the migration of contamination toward the eastern shoreline based on all available site data and the CSM updated based on the results of various investigations performed between 2010 and 2012.

Contaminant migration from the central portion of the site toward the eastern shoreline (Narragansett Bay) was evaluated based on both groundwater and soil CVOC concentrations in the Final *Source Area Investigation and Long-Term Monitoring Data Summary Report* (Tetra Tech, 2015a). Sections 3.1 and 3.2 of this report present cross-sections and spatial analyses of CVOCs in groundwater, and Appendix E presents cross-sections and spatial analyses of CVOC results in soil (both fixed-based laboratory and Color-Tec results). As shown on Figures 3-8 and 3-11 of Tetra Tech (2015a), low-level CVOC concentrations were detected at MW07-18I (1,2-dichloroethane [DCA] at 3.3 µg/L in fall 2011) and DPT07-16I (TCE at 0.7 µg/L in summer 2012). TCE was also detected at DPT07-16S at 0.69 µg/L during summer 2012 sampling. Figures 3-9 and 3-12 show that a spatially expansive CVOC plume occurs throughout the site in the deep zone, which is vertically consistent with the well screen interval at DPT07-16I (monitoring sandy zones below vertically thick silt with clays), including migration toward Narragansett Bay. As shown on Figure E-1 of Tetra Tech (2015), two cross-sections are presented from the central portion of the site to the eastern shoreline. Both diverge at MW07-34D, with cross-section 4-4' projecting through well cluster DPT07-18/MW07-18D, and cross-section 5-5' projecting through well clusters DPT07-29/34 and DPT07-16/MW07-16. Although the DPT07-16/MW07-16 well cluster is not labeled in the southern portion of cross-section 5-5', the lithologies presented are based on the well log at MW07-16D, which exhibits a thick silt layer with some clay from approximately 17 to 44 feet below ground surface (bgs) (27 feet thick). Figures E-7 through E-19 present total CVOC isoconcentrations for soil at sequentially deeper elevations. Generally, migration toward the eastern shoreline is observed from approximately 35 to 60 feet bgs. Further, Figure E-24 shows elevated CVOC concentrations at SB-202 at a depth below the thick silt with clay layer at approximately -50 feet bgs, with an easterly component beyond SB-217. Based on results from 2016 at DPT07-16I, the extent of CVOC below the thick silt with clay layer extends to near the eastern shoreline, now to the DPT07-16/MW07-16 well cluster.

Concentrations and number of parameters detected at DPT07-16I increased in fall 2016 compared to summer 2012. In fall 2016, TCE was detected at 83 µg/L, cis-1,2-DCE at 120 µg/L, and vinyl chloride at 5.2 µg/L (see Figures 2-3 through 2-7). In summer 2012, only TCE was detected at 0.7 µg/L. Although these changes appear significant, no

CVOCs were detected at DPT07-16S in fall 2016, signifying that the advancement of CVOC contamination is restricted to the zone underlying the thick silt with clay unit. Further, it is important to continue to monitor the potential continued advancement of the CVOC plume underlying the thick silt with clay unit, based on the evaluation of data from 2012 to 2016, the conclusion of the CSM that elevated CVOC concentrations are restricted to below the thick silt with clay layer are still valid. Further, even if CVOCs were detected in DPT07-16S (they currently are not), this well is located approximately 100 feet from a potential surface water discharge point (assumed to be near the low-tide levels during typical low tides). Based on the conclusions that a low risk, within the risk range, occurs from piezometers that have elevated CVOC concentrations in the entrance channel, it can be concluded that a low or no risk occurs along the Bay shoreline.

The objective of the remedy was to "ensure that the discharge of groundwater to wetlands and offshore areas continues to pose no unacceptable risks from COCs." Although the extent of CVOC contamination may continue to increase along the MW07-11D pathway and toward the DPT07-18/MW07-18D and DPT07-16/MW07-16 pathways (i.e., towards Narragansett Bay), the protectiveness of the remedy is unaffected. Contaminant concentrations are at least an order of magnitude greater at MW07-21 (near the Entrance Channel) compared to those detected at MW07-11D (near Narragansett Bay) and DPT07-16I. Unacceptable risks are not predicted for CVOC concentrations in environmental media at the Entrance Channel. Based on the distribution of contamination observed during 2016, it is also unlikely that concentrations at MW07-11D or DPT07-16I will ever increase to the levels observed at MW07-21, and as a consequence, unacceptable human health risks would not be predicted as a consequence of potential discharge of CVOCs to the shoreline area downgradient of MW07-11D or DPT07-16I. Therefore, future risks are not predicted to occur along the Narragansett Bay shoreline or in the bay based on contaminant migration trends thick silt with clay layer impeding upward migration of elevated CVOC concentrations. However, LTM will continue to observe and evaluate the extent of the CVOC plume over time.

Although not associated with the protectiveness of the remedy, two concerns are identified that related to LTM and evaluation of LTM data. These concerns are:

- Finalize the UFP-SAP for Long-Term Monitoring at Site 07 (Draft is dated June 2016). A tentative submittal date is August 2018.

- Prepare and submit Technical Memorandum on mass balance and natural attenuation mechanisms for CVOC plume from 2012 to 2016. A tentative submittal date is October 2018.

2.9 Protectiveness Statement

The remedy at Calf Pasture Point is protective of human health and the environment in the short-term. Exposure pathways that could result in unacceptable risks from groundwater are being addressed through institutional controls. These controls are effectively preventing exposure to site-related contaminants in groundwater. A risk screening evaluation indicates that there is no unacceptable risk to recreational swimmers/waders, shell fisherman, or ecological receptors from site-related contaminants in surface water and sediment. However, to ensure that the remedy remains protective in the long term, the following actions will be taken: (1) Surface water and sediment monitoring results will continue to be compared to risk screening numbers to ensure ongoing protectiveness and (2) Based on the results of a discussion concerning the CSM and analysis approach, an analysis should be conducted to evaluate the estimated amount of time (if ever) for the concentrations of site contaminants to reach levels in surface water and sediment that pose a risk to human health and the environment.

3.0 Site 09 - Allen Harbor Landfill

This section presents the findings of the Five-Year Review for the remedy that was implemented at Navy IR Site 09 (Allen Harbor Landfill) at the former NCBC Davisville.

3.1 Allen Harbor Landfill Summarized Site Chronology

A list of important Site 09 historical events and relevant dates in the site chronology are shown below. The identified events are illustrative, not comprehensive.

Event	Date
Allen Harbor Landfill was used for the disposal of waste material generated by the former NCBC Davisville facility and NAS Quonset Point.	1946 to 1972
After landfilling operations ceased, the landfill was closed by placing a discontinuous 2-foot soil cover over the fill materials.	1972
Completion of the NCBC Davisville IAS (Hart, 1984).	9/1984
Completion of the *Verification Step - Confirmation Study of the former NCBC Davisville Facility* (TRC, 1987).	2/1987
EPA's Hazard Ranking Scoring Package for the former NCBC Davisville facility.	1989
NCBC Davisville facility placed on the CERCLA NPL.	11/21/1989
FFA signed by the Navy, EPA, and State of Rhode Island.	3/1992
RI for Allen Harbor Landfill completed.	12/1996
ROD signed.	9/29/1997
Submittal of Final *Design Analysis Report For Closure of the Allen Harbor Landfill* (EA, 1998b). Construction of landfill cap begins.	3/31/1998
Construction of landfill cap completed and ESD submitted for polychlorinated biphenyl (PCB)-contaminated soil removal and extension of the soil cap and revetment (EA, 1999a).	8/1999
Initiation of landfill inspections and settlement surveys.	12/29/1999
Final *Remedial Action Report for Site 09-Allen Harbor Landfill Cap* (FWENC, 2000b).	6/2000
FOST to transfer Parcel 10 to the U.S. Department of Interior for transfer to the Town of North Kingstown, Rhode Island (Navy, 2000b).	12/14/2000
Final *Conceptual Long-Term Monitoring Plan (CLTMP)* which included establishment of performance standards (Newfields, 2000b).	12/22/2000

Event	Date
Final *Remedial Action Operations and Long-Term Management Plan for Allen Harbor Landfill* (FWENC, 2001a).	5/2001
Final Landscape Plan for Allen Harbor Landfill (Beckman-Weremay, 2001).	10/2001
Final QAPP for LTM of Site 09 (EA, 2001b).	11/2001
LTM program initiated with ME 01.	11/30/2001
Final *Revision 1: Quality Assurance Project Plan for Long-Term Monitoring of Site 09 (Allen Harbor Landfill)* (EA, 2003b).	2/2003
Signature date of the *First Five-Year Review Report* for the NCBC Davisville facility.	3/30/2003
Parcel 10 transferred.	5/10/2004
Parcel 10 ELUR recorded.	6/8/2004
Revisions to QAPP for Long-Term Monitoring at Site 09 Allen Harbor Landfill (Tetra Tech, 2007r).	11/2007
Signature date of the *Second Five-Year Review Report* for the NCBC Davisville facility.	3/28/2008
Installation of replacement wells MW09-08DA, MW09-09DA, and MW09-14IA and landfill liner repairs (from installation of wells).	6/2009
Revision 2 to the LTM Program at Site 09 Allen Harbor Landfill, movement of sediment sampling zone from 2 to 3 feet bgs to 2 to 6 inches bgs (via BCT agreements).	12/2009 and 1/2010
Piezometers within the created wetland moved from the center of the created wetland to the base of the stone revetment based on EPA request.	9/2010
Proposed Revisions for Landfill Gas Monitoring Program for Site 09 Allen Harbor Landfill. RIDEM approval for reduced monitoring received April/May.	3 and 4/2012
Signature date of the *Third Five-Year Review Report* for the NCBC Davisville.	3/28/2013
Navy submits Final *Long-Term Monitoring Data Summary and Optimization Recommendations Report* (Tetra Tech, 2015b).	8/27/2015
Navy submits Draft *Tier II Sampling and Analysis Plan, Long Term Monitoring, Site 07 Calf Pasture Point and Site 09 Allen Harbor Landfill*	6/24/2016
Navy submits Draft Final F*all 2016 Five Year Event Monitoring Report, Site 09, Monitoring Event 45*	10/30/2017

3.2 Allen Harbor Landfill Background Information

In this section, background information for Allen Harbor Landfill such as physical characteristics, current and former land use, and a history of environmental actions is presented.

3.2.1 Physical Characteristics

Allen Harbor Landfill is located in the Main Center of the former NCBC Davisville facility, within Parcel 10, as shown on Figure 1-1 and 3-1. Allen Harbor Landfill is an approximately 15-acre grassy area formerly used by the Navy as a landfill. The site is located within a 100-year floodplain and is bounded to the north and south by vegetated wetlands, to the east by Allen Harbor, and to the west by Sanford Road. Allen Harbor is used for recreational boating and is supported by two marinas. In 1984, RIDEM closed Allen Harbor to shellfishing due to suspected contamination from several sources, including Site 09. The shellfishing ban is still in place.

The site was closed in accordance with the ROD (September 1997) including capping with an impermeable geosynthetic liner (a multimedia landfill cap) and is covered with grass and small shrubs. A revetment wall and constructed wetland are located along the southern and eastern boundaries of the landfill. A stone breakwater structure separates the wetland from the harbor (Figure 3-1). The site terrain is gently sloping, with a topographic high in the center of the landfill.

3.2.2 Land Resource Use

Parcel 10, which includes Site 09, is currently owned by the Town of North Kingstown after being transferred from the Navy via the U.S. Department of the Interior. In the future, Allen Harbor Landfill will not be used for residential purposes due to ELURs placed on the property, as required by the ROD. Currently and in the foreseeable future, the town's planned use of the property is as open space/conservation land. No formal land use currently occurs as there are no paths for limited reactional activities to occur.

Groundwater at the site is classified by RIDEM as GB (i.e., presumed to be not suitable for public or private drinking water use without treatment). No groundwater production wells or potable supply wells are located on or downgradient of the site. Any potential future water needs would be met via municipal water available from the Town of North Kingstown.

Allen Harbor is used for recreational boating and contains two marinas. In 1984, RIDEM closed much of Allen Harbor to shellfishing due to suspected bacterial contamination. Subsequently, an additional basis for closure was due to surface runoff from Allen Harbor Landfill and other source areas. In 2004, the remainder of the harbor (the Entrance Channel) was closed to shellfishing.

Allen Harbor is classified by RIDEM as SA {b}. Class SA waters are designated for shellfish harvesting, contact recreational activities, and fish and wildlife habitat; the {b} designation indicates a “partial uses" status (that can affect the application of criteria) for waters in the vicinity of marinas and/or mooring fields where seasonal shellfishing closures are likely.

3.2.3 History of Contamination

A 1939 aerial photograph of the Allen Harbor area depicts the landfill as an undeveloped open grass field lined with shrubs and bushes. From 1946 to 1972, the Allen Harbor Landfill was used for the disposal of waste materials including municipal-type waste, construction debris, rubble, preservatives, paint thinners, degreasers (e.g., solvents), PCB oil, asbestos, ash, sewage sludge, and waste fuel oil. Disposal activities usually included burning the waste and covering it with soil. In 1972, after landfilling operations had ceased, the landfill was closed by placing a discontinuous 2-foot soil cover over the fill materials.

3.2.4 Initial Response and Basis for Taking Action

Groundwater data from the RI indicated the presence of elevated concentrations of VOCs and low-level concentrations of polynuclear aromatic hydrocarbons (PAHs), pesticides, and metals. Elevated concentrations of PAHs, pesticides, PCBs, and metals were detected in surface and subsurface soil samples. Semivolatile organic compounds (SVOCs), pesticides, PCBs, and metals were detected in sediment samples throughout Allen Harbor.

According to the HHRA that was completed during the RI, contaminants with a cancer risk greater than 10^{-4} and/or HI greater than 1.0 included the following:

- Arsenic, manganese, bis(2-chloroethyl)ether, 1,2-DCE, 1,2-DCE (total), 1,2-dichloropropane, TCE, and vinyl chloride in groundwater.
- Heavy metals, PAHs, and PCBs in sediment.
- Arsenic, copper, zinc, Aroclor-1254, and Aroclor-1260 in shellfish.

The human health risks that exceeded risk management goals at Site 09 were associated with the following exposure scenarios:

- Ingestion of deep groundwater by future residents.
- Use of site groundwater for showering in a potential recreational facility.
- Dermal contact with or incidental ingestion of site surface soil by recreational users of the site.
- Incidental ingestion of shoreline sediment by recreational users of the site.
- Consumption of shellfish from the site shoreline.

Potential health risks to site workers during remedial activities were associated with the incidental ingestion of soil (EA, 1996c).

Ecological risks to marine organisms in Allen Harbor were reported to be "moderate" to "slight." Moderate risk to marine organisms was reported to be limited to the narrow inter-tidal zone to the north and south of the site. Risks to terrestrial ecological receptors were reported to be moderate to high within the Allen Harbor Watershed, within which the Allen Harbor Landfill was one of the contributors to elevated risk (EA, 1996c). Elevated concentrations of PAHs, pesticides, PCBs, and metals in surface soil and sediment were the primary sources of ecological risk to terrestrial receptors. Sediment samples collected from Allen Harbor had concentrations of PAHs, pesticides, PCBs, and metals in excess of benchmark screening values. A benthic community structure analysis showed no obvious toxicological effects relative to reference stations; however, the elevated concentrations of contaminants were identified in the risk assessment as "flags" of potential ecological risk (EA, 1996c).

3.3 Remedial Actions

This section discusses the remedy selection and implementation history for Site 09, along with a discussion of the LTM program currently in place at the site.

3.3.1 Remedy Selection

The ROD for Site 09, signed on September 29, 1997, documented selection of a remedy including construction of a multimedia cap (including a gas venting system), stone shoreline revetment, offshore breakwater, and inter-tidal wetlands, LTM, and LUCs. RIDEM concurred with the remedy on September 25, 1997.

As stated in the ROD, the RAOs for Allen Harbor Landfill are as follows:

Surface Soil

- Prevent human and terrestrial animal exposure to COCs in surface soil.
- Prevent off-site migration of surface soil and surface soil contaminants through overland runoff.

Subsurface Soil

- Reduce leachate generation.
- Reduce or eliminate surface erosion and exposure of fill materials along landfill shoreline.

Groundwater

- Prevent human exposure to COCs in deep groundwater.

Sediment

- Minimize risks from marine ecological exposure to COCs in sediment.
- Control potential future sediment contamination from landfill constituents (COCs).

Wetlands

- Control potential future contamination of wetlands from landfill constituents (COCs).
- Improve quality of existing wetlands and create new wetlands on site along the shoreline.

Shellfish

- Control potential future contamination of shellfish from landfill constituents
- Prevent or minimize human ingestion of shellfish from the landfill shoreline containing COCs in excess of health advisory concentrations.

Based on the results of the RI/Feasibility Study (FS) and the community response to the Proposed Plan, the selected remedy for Site 09 was Alternative 3 - Multimedia Cap. A complete description of the selected alternative is presented in Section VIII of the ROD (EA, 1997) and in the August 1999 ESD (EA, 1999a).

EPA's *Presumptive Remedy for CERCLA Municipal Landfill Sites* (OSWER Directive 9355.0-49FS) states that containment technologies are the preferred remedies for municipal-type landfill waste. Accordingly, cleanup goals (i.e., treatment goals) were not developed as part of the Site 09 remedy. The components of the selected alternative address the identified risk pathways and RAOs identified for Site 09. The

LTM program established as part of the selected alternative was designed to ensure the protection of human health and the environment over time. The selected remedy includes the following components:

- Construction of a multimedia cap above the 100-year storm elevation (14 feet above msl) that consists of multiple soil layers and two impermeable layers and a soil cap in the area below 14 feet msl to comply with current federal and state laws. This component of the remedy addressed the RAOs for surface and subsurface soil.

- Construction of a passive gas venting system as part of the cap system. Landfill gases collected within the gas vent layer are passively vented to the atmosphere via five vents at the landfill. The points of discharge (vents) were fenced to protect potential site visitors.

- Removal and/or covering of landfill debris from the landfill shoreline. This addressed the RAOs for surface soil, sediment, and shellfish.

- Construction of a stone revetment along the shoreline of Site 09 to protect the landfill face from wave action (e.g., tidal forces and storm events). This stabilization of the landfill face addressed the RAOs for surface soil, sediment, and shellfish.

- Construction of a breakwater structure just east of a majority of the revetment wall along with construction of a wetland area between the revetment wall and breakwater structure, which together act to trip waves and reduce energy reaching the revetment. Construction of this wetland area along the shoreline of the site also serves as a natural resources/habitat improvement. Material dredged from the Entrance Channel to Allen Harbor was used in the construction of the wetlands. The progression of wetland development is being monitored over time to verify its sustainability. This addressed the RAOs for sediment, shellfish, and wetlands.

- Establishment of institutional controls, as follows (addressing the RAO for groundwater):

    - Implementation of land use restrictions that include deed restrictions regarding site and groundwater use.
    - Implementation of appropriate land use restrictions (i.e., no use of motorized vehicles, no digging, no deep-rooted vegetation) to protect

human health and the environment through limiting site development to maintain the integrity of the cap.
- Prevention of the installation or use of groundwater wells that would be used for drinking water or showering purposes.

- Conduct LTM of landfill gas, groundwater, sediment, and shellfish quality to evaluate the effectiveness of the remedy.

- Five-year reviews of the decision for the site by the Navy, EPA, and RIDEM.

A Rhode Island prohibition on the collection of shellfish from Allen Harbor addresses human health risks associated with the ingestion of shellfish from the landfill shoreline. As part of the remedy for Allen Harbor Landfill, the Navy maintains signage along the landfill shoreline to warn the public about the shellfishing ban.

The Navy and EPA signed the ROD in September 1997, which declared that the selected remedy is protective of human health and the environment, complies with current federal and state applicable or relevant and appropriate requirements (ARARs), and is cost effective (EA, 1997).

3.3.2 Remedy Implementation

On March 31, 1998, the Final: *Design Analysis Report for Closure of the Allen Harbor Landfill* (EA, 1998b) was submitted, and the capping activity commenced. FWENC completed the remedial action in August 1999 (FWENC, 2000b). In addition to the remediation activities outlined in the ROD, a removal action was performed by FWENC in spring 1999, when PCB-contaminated soil was discovered at the northern end of the landfill. To document the addition of the PCB removal and a northerly extension of the soil cap and the revetment to the remedy for this site, an ESD was submitted in August 1999. The ESD did not fundamentally alter the remedy at the site.

3.3.2.1 Remedy Operations and Maintenance

On March 30, 2000, quarterly physical inspections of the landfill were initiated and were continued on a quarterly basis for 2 years. From 2002 to 2012, inspections were conducted semi-annually in accordance with the Final *Remedial Action Operations and Long-Term Management Plan for Allen Harbor Landfill* (FWENC, 2001a). Beginning in 2013, inspections have been conducted annually (biennially for landfill settlement surveys).

Maintenance and repairs are performed on an as-needed basis based on the findings of the inspections. Prior to 2008, most maintenance/repairs were performed annually,

typically in the fall (generally, August, September and October). From 2008 to 2012, most repairs are completed concurrent with quarterly LTM activities (or semi-annually, in 2012).

O&M or post-closure care at the Allen Harbor Landfill must be performed after the landfill closure, in accordance with Resource Conservation and Recovery Act (RCRA) requirements in 40 C.F.R 264 Subpart N; the Rhode Island Hazardous Waste Regulations, Section 8; and the ROD. Five-year reviews must be conducted as long as contamination remains at the site in excess of levels that allow for unlimited use and unrestricted exposure.

Landfill settlement surveys were conducted annually until 2012 at each monitoring well, each gas vent, and at six locations each on the revetment and breakwater to monitor subsidence in the landfill and along the shoreline. Currently, settlement surveys are conducted biennially. Settlement survey data are reviewed to determine if subsidence has exceeded the acceptable range of 6 inches over any 100-linear-foot area of the landfill cap.

Based on the landfill inspections conducted from 2000 through 2017, it appears that, overall, the cap, revetment slope, and breakwater structure portions of the site remedy are in good condition and functioning according to design. Based on settlement survey results, there has been minor subsidence in a few areas, but this has not exceeded the acceptable range. Additional details regarding the maintenance activities that have occurred are provided in Section 3.5.

3.3.2.2 LUCs

In accordance with the ROD (EA, 1997), deed, ELUR, and LUCIP (EA, 2002b), Parcel 10 (Site 09) includes the following:

- For the entire parcel, no residential or commercial use, as stated in the ROD (park/recreational uses are permitted).

- For the entire parcel, water supply wells shall not be installed nor shall groundwater be utilized, except for sampling or other remedial purposes

- For the contaminated site, as delineated on Figure 3-1 (land use restriction boundary), use by the Grantee, its successors, and assigns, will be for pedestrian traffic only. Restrictions include, but are not limited to: digging, use of motorized vehicles, or other activities that may damage the remedy components

(multimedia cap, gas vents, monitoring wells, stone revetment, etc.) or otherwise allow direct exposure to hazardous waste under the cap.

- The warning signs to inform the public of the State ban on shellfishing in Allen Harbor will be maintained.

On November 30, 2001, LUC inspections were initiated during ME 01. LUC inspections are performed in accordance with the QAPP for LTM at Site 09 (EA, 2001b and 2003b) and LUCIP (EA, 2002b). LUC inspections have been performed during each ME at Allen Harbor Landfill to verify compliance with the land use restrictions established as part of the site remedy (Section 3.3.1). Copies of the institutional controls inspection checklists are included in each of the ME reports and/or data reports. Compliance with LUCs is documented annually in LUCIP Annual Letter Reports.

Based on the Site 09 LUC inspections completed during ME 01 through ME 45 and the LUCIP Annual Letter Reports, there was compliance with the institutional controls stated in the ROD and LUCIP.

An updated LUCIP was submitted as draft on November 2016, and the final LUCIP is currently being prepared. The draft Annual LUCIP report for 2016 was submitted for review on February 9, 2018.

3.3.2.3 LTM

The objective of the monitoring component of the remedy is to obtain the data necessary to assess the long-term effectiveness of the remedy. LTM at Allen Harbor Landfill began in December 2001. Since the first ME, there have been four LTM scopes performed (as approved by the BCT) for LTM events at Site 09. The changes have generally been related to relocation of sampling locations (e.g., relocation of piezometers closer to revetment wall). The following presents a brief summary of the LTM scopes and/or changes since ME 01:

- Between December 2001 and December 2010, quarterly monitoring occurred.

- Beginning in January/February 2008, quarterly monitoring was revised to two semi-annual large events (26 wells) and two semi-annual small events (14 wells).

- Beginning in December 2009, the sampling depth of sediments was adjusted from 2 to 3 feet bgs to 2 to 6 inches bgs.

- In September 2012, at the request of EPA, the piezometers within the created wetland were moved to the base of the stone revetment wall.

- In March 2012, soil gas and vent monitoring and sampling was changed to monitoring annually, with fixed-base sampling once every 5 years, and sampling of piezometers and shellfish beyond the breakwater into Allen Harbor was initiated.

A detailed summary of the LTM performed between initiation in December 2001 (ME 01) and September/October 2012 (ME40, date of last Five-Year Review) is included in the Final *Third Five Year Review Report* (Tetra Tech, 2013b). A site map and long-term monitoring locations is provided as Figures 3-2 and 3-3.

The *Draft Long-Term Monitoring Data Summary and Optimization Recommendations Report for Site 09: Allen Harbor Landfill* was submitted in December 2013. Based on the results of the data summary and updated CSM, recommendations to the LTMP were proposed, including annual sampling. The recommendation for annual sampling was agreed to by the BCT and implemented beginning in 2013, although the report was not finalized until August 2015. The revised LTM program based on the approved report recommendations was documented in the June 2016 *Draft Tier II Sampling and Analysis Plan, Long Term Monitoring, Site 07 Calf Pasture Point and Site 09 Allen Harbor Landfill.* This draft document is currently being finalized based on regulator comments.

3.4 Progress Since the Last Review

The previous Five-Year Review concluded that the remedy at Allen Harbor Landfill was protective of human health and the environment, and exposure pathways that could result in unacceptable risks were being addressed through remedy-related institutional controls and a state-enforced prohibition on shellfishing in Allen Harbor. These controls were effectively preventing exposure to site-related contaminants.

This section presents the concerns not related to remedy protectiveness that were included in the *Third Five-Year Review Report*, with a brief description of the actions taken by the Navy since the last review:

- Concern 1: LTM program needs to be reviewed/updated, including updating PALs based on new MCLs or EPA RSLs (as appropriate).

- Concern 2: LTM ME data reporting and LTM comprehensive reviews of site data need to be reviewed/updated to ensure appropriate data is shared with BCT in a timely manner to ensure continued protectiveness.

- Concern 3: Evaluation of area downgradient and offshore (beyond breakwater) of MW09-20I needs to be completed.

To address the issue of reviewing and updating the LTM program (Concern 1), the following recommendations were made:

- *Schedule a DQO meeting to discuss optimization of the LTM program and establish the objectives and scope of the LTM program.*

- *Prepare a revised Work Plan/SAP for LTM at Site 09.*

A scoping meeting was held on August 20, 2014, to discuss optimization of the LTM and establish objectives of the LTM. Further discussions on the optimization and objectives occurred during monthly BCT teleconferences following this scoping meeting. Based on the scoping meeting and subsequent teleconferences, agreements on optimization and objectives of the LTM were achieved.

As a result of the formal scoping meeting and subsequent teleconferences, a Draft *Tier II Sampling and Analysis Plan, Long Term Monitoring, Site 07 Calf Pasture Point and Site 09 Allen Harbor Landfill* was prepared and submitted on June 24, 2016. Currently, a final version of the document is being prepared based on regulator comments and Navy responses. To address the issue of LTM reporting and comprehensive reviews of site data and sharing with the BCT in a timely manner (Concern 2), it was recommended that *a* DQO meeting be scheduled to discuss reporting requirements for data reports and to schedule for comprehensive data reviews.

A scoping meeting was held on September 5, 2013, to discuss reporting requirements of the LTM program and frequency of reporting. Further discussions on the reporting requirements and frequency of reporting occurred during monthly BCT teleconferences following this scoping meeting.

Reporting requirements and frequency of reporting are provided in the Draft *Tier II Sampling and Analysis Plan, Long Term Monitoring, Site 07 Calf Pasture Point and Site 09 Allen Harbor Landfill* currently being finalized.

To address the issue of evaluating the area downgradient and offshore (beyond breakwater) (Concern 3), the area downgradient and offshore of the landfill (beyond the breakwater) was investigated in 2012 as part of ME 40. The work performed and results of the investigation and associated interpretations are presented in Sections 2 and 3, respectively, with incorporation of these results in the CSM in Section 5, of the Final *Long-Term Monitoring Data Summary and Optimization Recommendations Report for Site 09: Allen Harbor Landfill* (Tetra Tech, 2015b). As summarized from Section 3.9 of the Final report, Color-Tec® field screening indicated the presence of low concentration (likely less than 10 µg/L) CVOC at five sediment sample locations along the revetment wall within the constructed wetland area and no positive field screening detections within the center of the constructed wetland. Further, Color-Tec® field screening was also performed in the sediment of the offshore beyond the breakwater and no positive results were identified at any field screening location (samples were collected approximately 10, 25 and 50 feet from the breakwater structure, between piezometers P09-07 to P09-08 to P09-12).

3.5 Five-Year Review Process

This section provides a description of the Five-Year Review process specific to Site 09 including the document review, data review, and site inspection.

3.5.1 Document Review

Documents reviewed as part of this Five-Year Review are referenced throughout the text and are included in the reference section. Information in this subsection summarizes the results of LTM and are based on LTM reports.

A review of documents relevant to the remedial actions and LTM activities conducted at Allen Harbor Landfill was undertaken as part of the Five-Year Review.

3.5.2 Data Review

A review of LTM data was performed as part of the Five-Year Review. Data from 45 rounds of sampling are included in the review. In the data review, all parameters detected in an environmental medium are evaluated, not just those parameters for which PALs have been established (as is typical in the LTM Data Summary Reports). Comprehensive evaluations of site-wide data from all environmental media were performed as part of the Final *Long-Term Data Summary and Recommendations Report for Site 09: Allen Harbor Landfill* (Tetra Tech, 2015b) and Draft Final *Fall 2016 Five Year Monitoring Report, Site 09 Monitoring Event 45* (Resolution, 2017c).

The following general conclusions are presented based on the comprehensive evaluation of site data presented in the Draft Final *Fall 2016 Five Year Monitoring Report, Site 09 Monitoring Event 45* (Figures 3-4 and 3-5 present spatial distributions of TCE and VC, and cis-DCE and trans-DCE, respectively for ME45, taken from the draft final report):

Hydrogeology

- The hydrogeology at Site 09 is stable, consistent, and well understood after 45 MEs. The hydrogeology data collected during ME 41 through ME 45 is consistent with previous events and the conclusions in the Site 09 LTM Data Summary and Optimization Recommendations Report.

Groundwater Beneath the Landfill

- Concentrations of CVOCs in groundwater beneath the landfill appear to be stable or possibly decreasing (see Figures 3-4 and 3-5). The combined TCE, cis-1,2-DCE, trans-1,2-DCE, and VC data indicate that anaerobic reduction dechlorination is occurring. The overall size, shape, and concentration profile of the CVOCs in groundwater beneath the landfill is consistent with those in the Site 09 LTM Data Summary and Optimization Recommendations Report.

- Benzene continues to be the only other VOC consistently detected at concentrations exceeding the PAL in groundwater beneath the landfill. The concentrations observed appear to be stable and limited to a few areas, consistent with previous MEs.

- Periodic PAL exceedances of other VOCs such as 1,1,2-TCA, 1,1-DCE, 1,2-DCE, methylene chloride, and chlorobenzene were observed, and these occurrences are consistent with previous MEs. The results during ME 41 through ME 45 were generally lower than historical averages.

- Detections of SVOCs and PAHs remain sporadic and infrequent. However, benzo(a)pyrene was detected in excess of the PAL (0.2 µg/l) for the first time during ME 45 at MW09-09S (0.21 µg/L) and MW09-20I (0.43 µg/L).

- Aroclor-1260 was only one PCB detected between ME 41 and ME 45, at MW09-11S (0.45 µg/L) during ME 41. The only two pesticide detections between ME 41 and ME 45 were beta-BHC at MW09-07S (0.020 µg/L) and MW09-24S (0.016 µg/L) during ME 44.

- Arsenic continues to be the only metal consistently detected in excess of the PAL in the groundwater beneath the landfill. Although arsenic concentrations exceed the PAL, the concentrations of arsenic in groundwater beneath the landfill are significantly less than those observed in the piezometers, and arsenic is naturally occurring in soil and groundwater.

Piezometers

- Only one CVOC was detected in piezometers during ME 42 through ME 45, vinyl chloride at P09-10 (1.1 µg/L) during ME 42.

- Benzene was only detected once in piezometers during ME 42 through ME 45 at P09-10 (1.3 µg/L) during ME 42.

- Arsenic copper, nickel, mercury, lead, chromium, and zinc have been frequently detected in excess of their PALs in piezometer samples during ME 42 through ME 45. However, the elevated concentrations appear to be largely the result of suspended solids in the samples because dissolved results for these metals are generally much less than total concentrations. The high suspended solids (i.e., turbidity) are due to poor groundwater recharge at these locations because groundwater does not significantly discharge along the shoreline of Site 09, which prevents collection of samples from piezometers via low-flow sampling. Furthermore, concentrations of these metals in monitoring wells (i.e., groundwater beneath the landfill) are much lower, further indicating that the elevated metals concentrations are not due to migration of groundwater beneath the landfill to the shoreline. It is possible that the elevated arsenic results are due to isobaric interferences from the metals ICP-MS analysis.

- Besides the metals listed above, there have been no PAL exceedances in groundwater since ME 42, and the vast majority of VOC, SVOC, PAH, pesticide, and PCB results have been non-detect.

Sediment

- VOCs, PAHs, pesticides, and PCBs were sporadically detected in sediment during ME 43 through ME 45. Mann-Kendall trend analyses indicate either no trend or downward trends. Zinc, 4,4'-DDT, phenanthrene, and pyrene were the only analytes with PAL exceedances during ME 43 through ME 45.

- Zinc was detected in excess of its PAL (219 mg/kg) at SED09-09 (263 mg/kg) during ME 44. The zinc concentration at this location decreased to 172 mg/kg during ME 45, less than the PAL.

- 4,4'-DDT was detected in excess of its PAL (6 µg/kg) at SED09-01 (8 µg/kg) during ME 43 and SED09-09 (9.3 µg/kg) during ME 44. 4,4'-DDT was not detected at either location during the following ME, with both reporting limits significantly less than the PAL.

- Phenanthrene was detected in excess of its PAL (1,500 µg/kg) at SED09-10 (3,300 µg/kg) during ME 44. The phenanthrene concentration decreased to 960 µg/kg during ME 45, less than the PAL.

- Pyrene was detected in excess of its PAL (2,600 µg/kg) at SED09-10 (2,700 µg/kg) during ME 44. The pyrene concentration decreased to 890 µg/kg during ME 45, less than the PAL.

Shellfish

- The 2013 through 2016 shellfish samples had concentrations of metals, PCBs, and PAHs greater than the maximum concentrations reported in reference samples collected from 2007 through 2011. However, a comparison to pre-remedy data indicates that site concentrations are significantly less than in samples collected from the same areas of the site in 1995, prior to installation of the cap.

- Overall, the trend analyses reported statistically significant upward trends for some metals including arsenic at ET09-03, ET09-04, ET09-05, and ET09-06 and for anthracene at ET09-04. However, comparison to landfill groundwater data indicates that these upward trends are not site related. In addition, Mann-Kendall trend analysis performed on arsenic at reference locations ET09-01 and ET09-02 in the Site 09 LTM and Optimization Recommendations Report indicated increasing trends for arsenic at these reference locations (Tetra Tech, 2015b), suggesting that arsenic in shellfish may be related to background conditions or other anthropogenic sources.

- The shellfish population appears to be more abundant and more diverse than observed during previous MEs. Quahogs, which were not frequently present during previous MEs, have become more common. Many parts of the stone

revetment and breakwater structure have become covered with shellfish shells from birds capturing and eating shellfish, indicating that the shellfish population is abundant enough to support the feeding habits of marine predatory birds.

Landfill Gas

- Laboratory VOC results were converted to emission rates and compared to newly calculated allowable emission rates based on updated RIDEM air toxic regulations in RIDEM Air Pollution Control Regulation No. 22 (RIDEM, 2008). There were no VOC exceedances of the new calculated allowable emission rates. The laboratory methane result was also converted to an emission rate. The methane emission rate was less than the calculated emission rate of 0.525 gram per second, which is based on the RIDEM maximum allowable emission of 100 pounds per day.

- Soil gas screening results from ME 41 through ME 45 indicate that the landfill cap has not been compromised and is functioning as designed.

Risk Assessment Updates

- The overall conclusion of this 2017 HHRA update is that the conclusions of the 2013 HHRA remain valid and that ingestion of shellfish tissue obtained from the Site 09 shoreline by a current/future recreational user poses a potential cancer risk or noncancer hazard exceeding RIDEM target levels due to arsenic, PCBs, and pesticides (specifically aldrin). Based on this conclusion, the current institutional control prohibiting ingestion of shellfish continues to be necessary to protect public health. However, the shellfish tissue EPCs for arsenic and aldrin are within the range of concentrations detected in reference tissue samples collected from the shoreline of Prudence Island and from Fishing Cove in Wickford, Rhode Island, between 2007 and 2011. These results indicate that concentrations of arsenic and aldrin in site shellfish tissue samples evaluated in the 2017 HHRA update may be due to background conditions rather than Site 09. In addition, the shellfish tissue EPC for PCBs is less than the range of PCB concentrations detected in samples collected in 2011 (the most currently available data set) through the National Oceanic and Atmospheric Administration Mussel Watch Program (https://products.coastalscience.noaa.gov/nsandt_data/data.aspx). This suggests that some of the PCB contamination detected in the Site 09 samples may reflect regional conditions.

The overall conclusion of the 2017 ERA update is that the conclusions of the 2015 ERA remain valid and that exposure to shallow sediment, pore water, surface water, and

shellfish along the Site 09 shoreline does not pose unacceptable site-related risk to ecological receptors. Concentrations of several metals were elevated in piezometer water, but it does not appear that these concentrations are related to groundwater at Site 09, as discussed above.

The data collected to date during the LTM program support the conclusions of the RI/FS that formed the basis for the ROD signed in 1997 by the Navy and EPA and concurred with by RIDEM. The LTM data indicate that groundwater continues to pose an unacceptable risk to human health if used for drinking or showering. Shallow groundwater data from the shoreline piezometers indicate that the VOC plume in shallow groundwater at the site extends into the offshore area south of the landfill (likely near the Allen Harbor side of the breakwater structure) but that groundwater does not transport significant concentrations of landfill constituents into near-shore sediments. The analysis of landfill gas samples indicates that VOCs, SVOCs, petroleum hydrocarbons, and methane are being released from the landfill at rates that are less than state criteria.

3.5.3 Site Inspection

This section summarizes the routine LTM program site inspection activities, as well as the site inspection activities performed specifically for this fourth Five-Year Review.

3.5.3.1 LTM Program Site Inspections

Site inspections are conducted annually at Allen Harbor Landfill in conjunction with each LTM event. During the inspection, each monitoring well is checked to ensure that it is locked, labeled, and in good condition. The site inspection also includes an on-site verification of the effectiveness of LUCs by observing land use conditions (presence of buildings and level of recreational use at the site) and evidence of groundwater extraction wells.

Review of site inspection forms completed during the LTM program indicates that all wells are locked and properly labeled. LUC inspections performed during the LTM program have not detected any evidence of water supply wells or new construction at the site.

3.5.3.2 Five-Year Review Site Inspection

Tetra Tech performed a site inspection on September 20, 2017, as part of the Five-Year Review. The inspection include a site walkover and annotation of conditions. Photographs from the 2017 site inspections are included in Appendix B.

The site inspections began at the southwestern corner of the landfill near the southern drainage swale and then proceeds along the exterior perimeter of the landfill. Groundwater monitoring wells and passive landfill gas vents are inspected as they were encountered.

Overall, the site was found to be in good conditions. All wells appeared in good condition, and the well casings were locked. Piezometers were observed to be in generally good condition. The stone revetment wall and break water structure also appears to be in good shape (no areas of settlement, missing rocks, etc. was observed). There were no barren portions (devoid of vegetation) in the created wetland. There were numerous ribbed mussels noted within the rocks of the breakwater structures along nearly the entire length of the structure. The warning signs to inform the public of the State ban on shellfishing in Allen Harbor were observed to be present and in good shape.

3.5.3.3 Interviews

The Navy holds annual RAB meetings for former NCBC Davisville to discuss the process of the cleanup program and ongoing investigations and/or site status. Comments and/or information received during these meetings are recorded and addressed by Navy, Region 1 EPA, and RIDEM representatives during these annual meetings. The RAB meeting notes are available to all attendees and are placed in the Administration Record.

The following individuals were interviewed as part of the fourth Five-Year Review for former NCBC Davisville.

Interviewee	Title/Affiliation
Nicole LaFontaine	North Kingstown Director of Planning and Development
Steven King	Quonset Development Corporation, Chief Operating Officer
Susan Licardi	North Kingstown Director of Water Department/Supply
Phil Bergeron	North Kingstown Director of Public Works
Chelsey Dumas	North Kingstown Department of Recreation
Ralph Mollis	North Kingstown Town Manager

The types of questions that were asked of interviewees are provided on the Typical Interview Questions from the June 22, 2017 RAB presentation, included in Appendix A. Steven King of Quonset Development Corporation was interviewed on September 21,

2017, and Susan Licardi of North Kingstown Water Department was interviewed on September 22, 2017. On Friday, September 23, 2017, Susan Licardi spoke with several other North Kingstown managers, with her questions focused on town-owned Sites 07 and 09. Appendix A includes a summary of information gathered during these interviews. The Typical Interview Questions from the June 22, 2017 RAB presentation were also provided to the Quonset Davisville Navy Yacht Club. However, no responses were received.

3.6 Technical Assessment

3.6.1 Question A: Is the remedy functioning as intended by the decision documents?

The review of LTM data, risk assumptions, site inspections, LUC inspections, and ARARs indicates that the remedy is functioning as intended by the ROD. The evaluation presented in this section includes a discussion of the performance of the remedy with respect to the objectives stated in the ROD.

Surface Soil. The RAOs stated in the ROD for surface soil include: (a) prevention of human and terrestrial animal exposure to contaminants in surface soil and (b) prevention of off-site migration of surface soil and surface soil constituents through overland runoff. The remedial actions taken to address these objectives were the construction of the RCRA cap and soil cap over the landfill surface and construction of the shoreline revetment. These actions prevent exposure to surface soils by human and terrestrial ecological receptors and prevent erosion of landfill materials into the shoreline environment, respectively. These site features are inspected by the Navy semi-annually or annually, as required by the ROD, to ensure their continued integrity and effectiveness. Although minor issues such as surface rutting and intrusive vegetation have been identified during inspections, they have been remedied and have not impacted the integrity of the landfill cap, drainage swales, or revetment.

Subsurface Soil. The RAOs stated in the ROD for subsurface soil include: (a) reduction in leachate generation and (b) reduction or elimination in surface erosion and exposure of fill materials along landfill shoreline.

The evaluation of water level data collected during LTM suggests that the cap is impeding the infiltration of rainwater through the unsaturated zone, which reduces the generation of leachate (Tetra Tech, 2015b; Resolution, 2017b). A qualitative comparison of on-site groundwater levels to those observed at the nearest United States Geological Survey monitoring well suggests water levels in monitoring wells located outside of the capped area (i.e., MW09-02S, MW09-24S, and MW09-25S)

correlate more closely to the off-site well than water levels measured in wells located within the capped area, indicating that water levels within the cap respond differently to seasonal variations in precipitation than wells located beyond the limits of the cap. These data, along with the evaluation of landfill survey data indicating the integrity of the cap is intact, provide evidence to support a reduction in leachate generation since construction of the remedy.

Erosion of and exposure to fill materials located along the landfill shoreline have been mitigated by the removal of debris and construction of the stone revetment. Semi-annual or annual inspections of the revetment have indicated only minor displacement of stones, occasional vegetative growth (which has been removed), and minimal erosion at the toe of the slope presumably resulting from a concentrated runoff from the edge of the landfill cap. None of these issues has negatively impacted the integrity or effectiveness of the revetment.

Groundwater. The RAO stated in the ROD for groundwater is to prevent human exposure to contaminants in deep groundwater. The Navy has performed LUC inspections at least annually at Allen Harbor Landfill to verify that no water supply wells are constructed on the site. Based on the findings of these inspections, there is no exposure to contaminated groundwater.

Sediment. The RAOs stated for sediment in the ROD include: (a) minimizing risks from marine ecological exposure to contaminants in sediment and (b) controlling potential future sediment contamination from landfill constituents. To evaluate risks along the shoreline associated with site contamination, sediment sampling results are compared to site-specific Shoreline Risk Monitoring and Remediation Goal (RG) Values that were developed for the protection of aquatic, terrestrial, and human health exposure pathways. Site-specific RG Values were developed for zinc, total Aroclors, and 4,4'-DDE based on the conclusions of a harbor-wide study presented in a report titled *Preliminary Remediation Goals (PRGs) for NCBC Allen Harbor Landfill (Site 09)* (SAIC, 1998). These site-specific values, together with Effect Range Median values, represent the PALs for sediment along the Allen Harbor Landfill shoreline.

The evaluation of LTM data collected during the first 45 events of monitoring indicates that exceedances of PALs in sediment samples are infrequent, with the exception of PCBs at SED09-01.

Remedial actions along the shoreline (i.e., sediment removal and wetland construction) have reduced contaminant levels to less than PALs at all locations except SED09-01, and sediments are not being recontaminated by landfill constituents.

Wetlands. The RAOs stated in the ROD for wetlands include (a) controlling potential future contamination of wetlands from landfill constituents and (b) improving the quality of existing wetlands and creating new wetlands along the landfill shoreline.

The evaluation of piezometer and sediment sampling data indicates that, in general, the remedial action is controlling the migration of landfill contaminants into the wetlands. The principle VOCs detected in water samples collected from piezometers are daughter product CVOCs (cis-1,2-DCE, trans-1,2-DCE, and vinyl chloride) and benzene in monitoring wells located along the southern shoreline of the landfill (P09-08 and P09-10). Over the past several years, concentrations in piezometer samples have decreased at or near long-term lows, and there are no increasing trends for any CVOCs. Additionally, changes in the sampling locations of the piezometers with respect to the landfill did not result in changes in concentrations or trends. Exceedances of PALs in sediment samples collected from the constructed wetland (SED09-02 through SED09-08) are infrequent.

Wetland inspections have been conducted semi-annually/annually as part of the LTM program for Allen Harbor Landfill. Inspections include an evaluation of the enhanced wetland areas located north of the site and the constructed wetland east of the landfill. With few exceptions, these wetland areas are populated with abundant vegetation and are minimally impacted by invasive species.

During wetland inspections, several ospreys (*Pandion haliaetus*) and double-crested cormorants (*Phalacrocorax auritus*) were observed on poles near the constructed wetland. Two American egrets (*Casmerodius albus*) were observed in the natural marsh south of the constructed wetland. A belted kingfisher (*Megaceryle alcyon*) was observed on a pole near the enhanced wetland. All are predators of fish and/or shellfish and appear to be benefiting from the food sources provided by Allen Harbor, the constructed wetland, enhanced wetland, and other tidal marshes fringing Allen Harbor (Tetra Tech, 2007p).

Shellfish. The RAOs stated in the ROD for shellfish include: (a) controlling potential future contamination of shellfish from landfill constituents and (b) preventing or minimizing human ingestion of shellfish from the landfill shoreline containing site-related contaminants in excess of health advisory concentrations.

The comparison of shellfish sampling data collected from 2007 to 2016 to reference sample results (from the same species) collected during the RI in 1995 from similar locations indicates that the remedy is controlling contamination of shellfish from landfill constituents. There are three signs present along the landfill shoreline notifying

trespassers and the public of the state-imposed shellfishing ban that is in place for Allen Harbor. All three signs are in good condition.

3.6.2 Question B. Are the exposure assumptions, toxicity data, cleanup levels, and RAOs used at the time of the remedy selection still valid?

The HHRA for Site 09 was updated as part of the *Draft Final Fall 2016 Five Year Monitoring Report, Site 09, Monitoring Event 45* (Resolution, 2017c) (Appendix G-1). The objective of the updated HHRA was to determine whether there have been any changes and/or updates to EPA HHRA guidance or site-specific conditions since the 2013 HHRA performed in support of the *Long-Term Monitoring Data Summary and Optimization Recommendations Report* (Tetra Tech, 2015b) that would result in a change of the conclusions of the 2013 HHRA, or whether the conclusions of the 2013 HHRA remain valid. Revised risk/hazard calculations were performed as part of the 2017 HHRA update to estimate the cumulative potential cancer risk and/or noncancer hazard associated with a recreational user exposure scenario, to determine whether risk/hazard estimates exceed EPA and/or RIDEM target risk/hazard levels, and to identify whether the current institutional controls in place at Site 09 are still needed.

The receptors and exposure pathways evaluated in the 2017 HHRA update are consistent with those evaluated in the 2013 HHRA. These receptors and pathways include recreational users exposed to shoreline media while swimming, wading, or clamming/harvesting shellfish. There have been no changes in exposure assumptions, toxicity criteria, or contaminant characteristics that have affected the protectiveness of the selected remedy or monitoring activities. Therefore, the 2017 HHRA update supports that the conclusions of the 2013 HHRA remain valid. The RAOs are still valid, and applicable state and federal standards have not changed since the ROD was signed in September 1997. It still appears that ingestion of shellfish tissue obtained from the Site 09 shoreline by a current/future recreational user poses a potential cancer risk or noncancer hazard exceeding RIDEM target levels due to arsenic, PCBs, and aldrin. Based on this conclusion, the remedy is functioning as intended in that the current institutional control prohibiting ingestion of shellfish continues to be necessary to protect public health.

An ERA was conducted in 2015 for Site 09 in support of the *Third Five-Year Review Report* (Tetra Tech, 2015b) using recently collected (e.g., 2010 to 2012) sediment, shallow piezometer water (representing brackish sediment porewater, assumed to be a mixture of groundwater and surface water), seep water (representing surface water),

and shellfish data. The 2015 ERA identified no unacceptable risks to ecological receptors exposed to sediment, sediment pore water, or surface water.

An ERA update was conducted in 2017 (Resolution Consultants, 2017b) in support of the Site 09 Five Year Event LTM Report. The objective of the ERA update was to determine whether there have been any changes and/or updates to EPA ERA guidance or site-specific conditions since the 2015 ERA was conducted that would result in a change of the conclusions of the 2015 ERA. The 2017 ERA update presented updated risk screenings and food-web modeling evaluating birds and mammals exposed to shoreline sediment and shellfish. Toxicity values and exposure assumptions used in the 2017 ERA update are consistent with those used in the 2015 ERA. The overall conclusion of this 2017 ERA update is that the conclusions of the 2015 ERA remain valid and that exposure to shallow sediment, pore water, surface water, and shellfish along the Site 09 shoreline does not pose a site-related risk to ecological receptors. Concentrations of several metals were elevated in piezometer water, but it does not appear that these concentrations are related to groundwater at the site, as discussed above.

3.6.3 Question C: Has any other information come to light that could call into question the protectiveness of the remedy?

No weather-related events have affected the protectiveness of the remedy, and there is no other information that calls into question the protectiveness of the remedy.

3.6.4 Technical Assessment Summary

Based on the LTM data reviewed and LUC inspections, the remedy at Allen Harbor Landfill is functioning as intended by the ROD. Regular monitoring of groundwater, sediment, and landfill gas is occurring at the locations where exposures to these media are most likely to occur. Shellfish sampling along the landfill shoreline commenced in 2007. Landfill inspections are being performed and documented to verify the integrity of the landfill cap, monitoring wells, gas vents, revetment, wetlands, breakwater, and other remedy features.

LUCs are effectively preventing exposure to groundwater contaminated with VOCs, SVOCs, and metals. The landfill cap components prevent contact with contaminants in surface and subsurface soils. Sediment sampling data indicate that contaminant levels in sediment are within acceptable ranges and that sediments are not being recontaminated by landfill constituents. Landfill gas sampling data indicate that emission rates from gas vents are within acceptable ranges. Shellfish sampling data

indicate that the remedy is controlling the contamination of shellfish by landfill constituents.

There have been no changes in physical conditions at the site, toxicity factors, or to the standardized risk assessment methodology that would affect the protectiveness of the remedy. There is no other information at this time that calls into question the protectiveness of the remedy.

3.7 Issues

No deficiencies were identified during this Five-Year Review for Allen Harbor Landfill, and no issues related to site operations (performance of LUCs and LTM), conditions, or activities prevent the remedy from being protective at this time or in the future.

3.8 Recommendations and Follow-Up Actions

Because no issues affecting the protectiveness of the remedy were identified, there are no recommendations for Site 09 Allen Harbor Landfill and no follow-up actions are required.

Although not associated with the protectiveness of the remedy and based on comments received on the Draft Final *Fall 2016 Five Year Monitoring Report, Site 09, Monitoring Event 45* (Resolution, 2017c) and Navy responses on August 9, 2017, there are three remaining concerns to be addressed with respect to long-term analysis of site data and contaminant fate and transport. These three concerns are:

- Evaluation of the whether organic or inorganic arsenic analysis for shellfish would be beneficial to the LTM evaluation and determination of remedy effectiveness.

- Evaluation of the recommendations for LTM optimization summarized in the *Draft Final Monitoring Event 45, Fall 2016 Five Year Monitoring Report.*

- Evaluation of the Conceptual Site Model for Groundwater with emphasis on the monitoring network of groundwater wells and shoreline piezometers used during LTM for determination of long-term effectiveness of the enacted remedy.

Evaluation of organic or inorganic arsenic analysis for shellfish tissue sampling

It is possible that the elevated arsenic results are due to isobaric interferences from the metals ICP-MS analysis. Further, current toxicity criteria are based on inorganic

arsenic. Therefore, an evaluation of organic arsenic would not yield usable data for evaluation of remedy protectiveness.

Evaluation of recommendations for LTM optimization

Based on the data review completed, the Navy feels that the modest recommendations for further optimization made in the *Draft Final Fall 2016 Five Year Monitoring Report, Site 09, Monitoring Event 45* deserve to be enacted in future LTM sampling.

Evaluation of Conceptual Site Model for Groundwater

Although the Navy addressed all of the comments pertaining to the CSM for groundwater in the August 9, 2017, response letter, this concern has been frequently and consistently raised by Region 1 EPA over the past several years. Additionally, this topic was a concern (Concern 3) for Site 09 in the *Third Five Year Review Report* (Tetra Tech, 2013b). As such, a technical meeting is needed to discuss the Conceptual Site Model for Groundwater to evaluate whether modifications to the monitoring network of groundwater wells and shoreline piezometers are necessary.

Although not associated with the protectiveness of the remedy, the following concerns are identified that related to LTM and evaluation of LTM data:

- UFP-SAP for Long-Term Monitoring at Site 09 needs to be finalized (Draft is dated June 2016). A tentative submittal date is August 2018.

- A technical meeting is needed to discuss the CSM for groundwater to evaluate whether modifications to the monitoring network of groundwater wells and shoreline piezometers are necessary. A tentative meeting date is March 2019.

- To evaluate isobaric interferences from the metals ICP-MS analysis, a subset of groundwater samples will be collected during the 2018 LTM event and analyzed by both ICP-MS and atomic absorption spectroscopy. A tentative submittal date for proposal of groundwater subset sampling is August 2018.

3.9 Protectiveness Statement

The remedy at Allen Harbor Landfill is protective of human health and the environment. Exposure pathways that could result in unacceptable risks are being addressed through remedy-related institutional controls and a state-enforced prohibition of shellfishing in Allen Harbor. These controls are effectively preventing exposure to site-related contaminants.

4.0 Site 16 – Creosote Dip Tank Area, Fire-Fighting Training Area and Former Building 41

This section presents the findings of the Five-Year Review for the remedy that was implemented at Navy IR Site 16 (Creosote Dip Tank Area, FFTA, and former Building 41) at the former NCBC Davisville.

4.1 Creosote Dip Tank Area, Fire-Fighting Training Area, and Former Building 41 Summarized Site Chronology

Event	Date
Creosote dipping of wood pilings and general fire-fighting operations performed in the north-central portion of the site	1960s–1990s
Completion of the *Initial Site Assessment of the former NCBC Davisville* (Hart, 1984).	9/1984
Completion of the *Verification Step - Confirmation Study of the former NCBC Davisville Facility* (TRC, 1987).	2/1987
EPA's Hazard Ranking Scoring Package for the former NCBC Davisville facility.	1989
NCBC Davisville facility placed on the CERCLA NPL.	11/21/1989
FFA signed by the Navy, EPA, and State of Rhode Island.	3/1992
Soil Removal Action performed around upended creosote dip tank.	1992
Basewide Environmental Baseline Survey (EBS) for NCBC Davisville performed.	1995
Phase II EBS – Initial Field Program performed (soil samples and test pits near Building E-107).	1996
Phase II EBS Follow-on Investigation (soil and groundwater sampling at creosote dip tank area, FFTA, etc.)	1997
Phase II EBS Follow-on Addendum Investigation (sampling near former Building 41).	1998
Phase I RI, Stage 1 (field investigation including membrane interface probe study in NCA).	1999-2001
Phase I RI, Stage 2 (site-wide field investigation).	1999-2001
Phase II RI (site-wide field investigation including well installation and sampling).	2002
Phase II Screening Level Ecological Risk Assessment (SLERA)	2004

Event	Date
Supplemental Phase II Hydrogeologic Investigation/Hydrogen Release Compound (HRC) Injection Pilot Study	2004
1,4-Dioxane Groundwater Study	2004/2006
Phase III RI (site-wide field investigation including (direct-push technology [DPT] and real-time field screening of CVOC concentrations).	2007-2008
FS Support Field Investigation (additional field data collection including test pitting and soil gas and offshore CVOC delineation).	2010
Perfluorooctanic Acid/Perfluorooctane Sulfonate Groundwater Study	2011
Draft RI Report for the Nike PR-58 Site (USACE)	2007-2011
FS (identified cleanup levels and RAOs)	2012
FS Addendum	2013
ROD for Site 16 signed	June 2014
Remedial Actions for soil and groundwater performed at Site 16.	2015-2016
Navy submits Draft Final *Tier II Sampling and Analysis Plan, Long Term Monitoring, Creosote Dip Tank Area, Fire-Fighting Training Area, and Former Building 41* (Resolution Consultant, 2017d)	November 2017
LTM program initiated with ME 01.	December 2017

4.2 Creosote Dip Tank Area, Fire-Fighting Training Area, and Former Building 41 Background Information

In this section, background information for Site 16 such as physical characteristics, current and former land use, and a history of environmental actions is presented.

4.2.1 Physical Characteristics

Site 16 is an irregularly shaped area bounded on the west by Thompson Road and to the south by railroad tracks (Figures 1-1 and 4-1); Site 16 also extends north to Allen Harbor and east to Narragansett Bay. The terrain at Site 16 is relatively flat to gently sloping towards the adjoining surface water bodies (Figure 4-1). Ground surface elevations range from approximately 10 to 33 feet above msl. Surface water runoff flows north to Allen Harbor and east to Narragansett Bay and is facilitated by the extensive pavement south and east of the NCA but mitigated by the significant vegetative cover that currently exists within the NCA. There are no freshwater streams within Site 16; however, an extensive stormwater drainage system exists in the area. In

addition to receiving surface water runoff from the surrounding environs, Allen Harbor and Narragansett Bay are also the discharge areas for groundwater underlying Site 16 and much of NCBC Davisville. Approximately 20 percent of the NCA is within the 100-year floodplain, and most of the NCA is within the 500-year floodplain.

4.2.2 Land and Resource Use

Most of Site 16 south of Davisville Road consists of parking areas and buildings. The developed portions of the site include mostly paved acreage south of Davisville Road and east of Allen Harbor Road, which is now primarily used for the temporary storage of cars delivered by ships and trains pending delivery to dealers. Most of the developed portion of Site 16 was transferred to the Quonset Development Corporation (QDC) as part of the Navy's 1998 MARAD property transfer. The portion of the site east of Allen Harbor Road and north of Davisville Road (the extreme eastern portion of the site) was part of the Naval Construction Battalion Center and was transferred along with the former Quonset Naval Air Station between 1975 and 1980 to the Town of North Kingstown, Rhode Island, Port Authority (now QDC) and the State of Rhode Island. The remaining area of the site is heavily wooded vacant land currently leased to QDC and will likely be the last parcel of the former NCBC Davisville property transferred by the Navy through the BRAC process. The NCA (the northern portion of Site 16 directly south of Allen Harbor) lies north of Davisville Road and is bounded by Allen Harbor to the north, Westcott Road to the west, Davisville Road to the south, and Allen Harbor Road to the east. Site 16 includes the area between former Building 41 and Narragansett Bay. There are no historical or archeological areas of importance at Site 16.

Allen Harbor (to the north) and Narragansett Bay (to the east) are the discharge areas for groundwater underlying Site 16. Three ponds (the Davol Pond system) located immediately southwest of the developed portion of Site 16 are not significant discharge points for groundwater underlying the site, but the ponds do appear to be a discharge area for groundwater in the NCBC area. An extensive storm water drainage system exists within the Site 16 site boundary. Much of the surface/storm water in the undeveloped and developed portions of the site drains to Allen Harbor and Narragansett Bay, respectively. Most buildings historically associated with Site 16 have been demolished. Building E-107 is at the northern boundary of the site near the southwestern corner of Allen Harbor. Buildings 39, 318, and E-319 are large commercial/industrial warehouse-type buildings located south of Davisville Road. The former Building 41 and several other smaller former buildings that previously existed within the site boundary have been demolished.

NCBC Davisville was decommissioned in March 1994 and closed on April 1, 1994, under the BRAC Program. The NCA portion of Site 16 is currently forested and shrub land. The small portion of Site 16 immediately north of the NCA and in the immediate vicinity of Building E-107 is used for marina (i.e., recreational) purposes. These areas of Site 16 are still owned by the Navy and are currently leased to QDC, which has sub-leased the marina area to the Allen Harbor Boating Association.

Prior to contamination being identified in this area, the remainder of Site 16 was previously transferred and includes mostly paved areas primarily used by the North Atlantic Distribution, Inc. (NORAD), a commercial automotive company, for the storage of cars delivered by ships and trains pending delivery to automotive dealers. Seafreeze Ltd., a commercial fish processing enterprise, is located at the eastern edge of Site 16 at the Narragansett Bay shoreline. The anticipated future land use for most of Site 16 (including the NCA) is commercial/industrial; however, it is anticipated that the area in the immediate vicinity of Building E-107 (the marina building) will continue to be used for marina (recreational) purposes.

Groundwater at the site is classified by RIDEM as GB (i.e., presumed to be not suitable for public or private drinking water use without treatment). However, per EPA groundwater remediation guidance, in states without an EPA-approved Comprehensive State Groundwater Protection Program (CSGWPP) such as Rhode Island, CERCLA groundwater remediation must meet federal drinking water standards *(i.e.,* MCLs and non-zero Maximum Contaminant Level Goals [MCLGs]) and risk-based standards, or more stringent state groundwater standards (unless the water is non-potable) based on the EPA classification of the groundwater, which is Class IIB in this area. No groundwater production wells are located on or downgradient of the site. Any potential future water needs would be met via municipal water available from the Town of North Kingstown.

4.2.3 History of Contamination

Creosote dipping of wood pilings occurred during the late 1960s in the western portion of the NCA of the Site 16 investigation area. The wood pilings were dipped into tanks containing creosote and staged in the area to dry before being loaded onto ships. In the early 1990s, an upended creosote dip tank was identified in the western portion of the site adjacent to the asphalt-paved road. A former FFTA was reportedly located in an asphalt-paved area east of the former Creosote Dip Tank Area. Reportedly, structures were constructed, doused with flammable materials, set on fire, and extinguished as part of fire-fighting training exercises during the late 1960s. Building 41 was a preservation and packing shop and construction equipment and automotive parts

storage building. Preservation and degreasing operations occurred within the building. Based on past activities, it is likely that petroleum products and solvents were used and stored within Building 41.

4.2.4 Initial Response and Basis for Taking Action

In the early 1990s, an upended creosote dip tank was identified in the western portion of the site adjacent to the asphalt-paved road. The location where the tank was found is the "original" Creosote Dip Tank Area and was first addressed by a removal action conducted by the Navy in 1992 (Halliburton NUS Corporation, 1994) and then further investigated during the Phase II EBS. During the EBS investigations, the reported underground storage tank (UST) located near the southeastern corner of Building E-107 was identified as two septic tanks (buried and interconnected pontoon tanks). They were excavated and removed along with the related total petroleum hydrocarbon (TPH)-impacted soil. NFA was recommended in the closure report prepared by FWENC for the septic tanks (1998).

Unacceptable risks to human health were identified for current and future site exposure scenarios. The results of the HHRA indicated that potential unacceptable risks were associated with (1) exposure to surface soil in the NCA by hypothetical future residents (due to PAHs, dioxins/furans, arsenic, and lead); (2) exposure to subsurface soil in the NCA by industrial workers, recreational users, and hypothetical future residents (due to PAHs, dioxins/furans, arsenic, and lead); (3) potable use of groundwater by hypothetical future residents (due to VOCs, naphthalene, and metals); and (4) exposures to the indoor air of a building constructed over the VOC groundwater plume by industrial workers and hypothetical future residents (due to TCE).

Soil COCs

Concentrations of the following chemicals exceeding threshold values for the industrial and residential exposure scenario or leachability concerns in either surface or subsurface soil were selected as risk-based COCs for soil:

- Carcinogenic PAHs, arsenic, lead, naphthalene, dioxins/furans, and benzene.

In addition to these risk-based COCs identified in the HHRA as the primary risk drivers, the following chemicals were also identified as COCs based on exceedances of chemical-specific ARARs (i.e., RIDEM's residential DEC and/or GA leachability criteria):

- Antimony, manganese, benzo(g,h,i)perylene, fluoranthene, fluorene, 2-methylnaphthalene, 1,1-DCE, 1,1-biphenyl, pyrene, vinyl chloride, TCE, and PCE.

Although TPH is not a contaminant under CERCLA, TPH concentrations at several locations exceeded the RIDEM residential DEC and leachability criteria. The TPH contamination in the Site 16 soils is generally collocated with PAH contamination.

Groundwater COCs

The following chemicals were selected as risk-based COCs for groundwater:

- Benzene, cis-1,2-DCE, PCE, TCE, vinyl chloride, and naphthalene.

In addition to these risk-based COCs identified in the HHRA as the primary risk drivers the following chemicals were also identified as COCs primarily based on their exceedances of chemical-specific ARARs (i.e., EPA MCLs or RIDEM GA groundwater objectives):

- 1,1-DCE, 1,1,2-TCA, bis(2-ethylhexyl) phthalate, methylene chloride, antimony, arsenic, barium, beryllium, cadmium, chromium, cobalt, lead, nickel, nitrate, nitrite, selenium, and thallium.

Three ERAs were performed at Site 16, Phase I and II SLERAs in 2004 and an updated SLERA in 2009. The Phase I SLERA was conducted to evaluate risks to terrestrial ecological receptors exposed to chemicals in surface soil and aquatic ecological receptors exposed to chemicals in groundwater seeps and sediment collected in association with the groundwater seeps in Allen Harbor, located adjacent to Site 16. The Phase II SLERA evaluated ecological risks to benthic invertebrates and wildlife exposed to COPCs in sediment at Allen Harbor based on the sediment samples results evaluated in the Phase I SLERA, as well as additional sediment samples collected as part of the Phase II RI. An updated SLERA was conducted in 2009, using data from all sampling events, to evaluate the ecological risks to terrestrial plants, soil invertebrates, and wildlife exposed to COPCs in surface soil at Site 16 as part of the Phase III RI. The 2009 SLERA focused on surface soil in the NCA portion of Site 16. The developed area of Site 16 was not evaluated in the ERAs because it is largely paved, and viable habitat is very limited in this area.

Exposure pathways for ecological receptors included direct contact with contaminated soil, sediment, and surface water; incidental ingestion of contaminated soil and sediment; and ingestion of contaminated food items.

Based on the SLERA, there are no unacceptable ecological risks identified that are solely and definitely attributable to releases from Site 16.

4.3 Remedial Actions

This section discusses the remedy selection and implementation history for Site 16.

4.3.1 Remedy Selection

The ROD for Site 16, signed June 2014, documented selection of the remedy that included excavation and off-site disposal of surface soils, backfilling and restoration of excavated areas, focused in-situ treatment of groundwater at the eastern end of former Building 41, monitored natural attenuation of residual VOC-contaminated groundwater, and LUCs including the establishment of a waste management area (WMA).

As stated in the ROD, the RAOs for Site 16 are as follows:

Soil RAOs for the Northwestern Portion of the NCA, Excluding the Benzene Sub-Area

- No.1: Prevent industrial worker (including construction worker) exposure to subsurface soil containing concentrations of COCs (PAHs, arsenic, and lead) that cause unacceptable risk.

- No. 2: Ensure/verify that surface and subsurface soil contaminants (e.g., naphthalene) do not migrate to groundwater, surface water, and sediment causing the groundwater, surface water, and sediment to have associated unacceptable risk.

- No. 3: Prevent hypothetical future residential exposure to surface and subsurface soil contaminants (PAHs, arsenic, lead, and dioxins/furans) that cause unacceptable risk.

Soil RAOs for the Benzene Sub-Area (BTEX hot spot area)

- No.4: Prevent industrial worker (including construction worker) exposure to subsurface soil (in the benzene sub-area) containing concentrations of COCs (PAHs, arsenic, lead) that cause unacceptable risk.

- No. 5: Ensure/verify that surface and subsurface soil contaminants (e.g., benzene and naphthalene in the benzene sub-area) do not migrate to groundwater, surface water, and sediment causing the groundwater, surface water, and sediment to have associated unacceptable risk.

- No. 6: Prevent future residential exposure to surface and subsurface soil (in the benzene sub-area) containing concentrations of COCs (PAHs, arsenic, lead, and dioxins/furans) that cause unacceptable risk.

Soil RAO Specific to Soils in the Vicinity of the Marina Building

- No. 7: Prevent recreational user exposure to soil in the vicinity of the marina building containing concentrations of COCs (PAHs) that cause unacceptable risk.

Groundwater RAOs

- No. 1: Prevent human exposure (including drinking, showering, and irrigation) to groundwater containing COCs that cause unacceptable risk and does not meet the selected cleanup levels.

- No. 2: Verify that groundwater discharging to Allen Harbor and Narragansett Bay continues to pose no unacceptable risks.

- No. 3: Prevent unacceptable risks to industrial workers and hypothetical future residents that could result from exposure to VOC vapors migrating into buildings.

- No. 4: Restore groundwater quality to beneficial use.

The Selected Remedy for Site 16 includes selective excavation and off-site disposal of shallow soil (to a depth of 0-2 feet bgs), maintaining and monitoring the protective cover, establishment of a WMA at the NCA/marina, limited in-situ chemical oxidation of groundwater at the eastern end of former Building 41, MNA, and LUCs. This combination of alternatives was selected because it provides the best balance with respect to the nine evaluation criteria and will be least disruptive to continued industrial use of the property. The remedy will also allow for the continued recreational use of the area in the immediate vicinity of the marina.

4.3.2 Remedy Implementation

The Site 16 remedy included soil excavation and installation of soil covers over excavated areas, in-site groundwater treatment, LUCs, and LTM, as summarized below.

4.3.2.1 Soil Excavation and Protective Cover

As summarized in the previous section, the soil component of the remedy for Site 16 included selective excavation and off-site disposal of shallow soil (to a depth of 0-2 feet bgs) and maintaining and monitoring the protective cover. This work began in

November 2015. Initially, site clearing was performed to facilitate soil sampling and excavation activities. Vegetative material was chipped and left on-site. Soil sampling was performed to verify delineation of excavations and characterize the soils for disposal. A total of approximately 4,800 tons of impacted soils was removed and disposed of off-site at an approved facility. Since the impacted soils were fully delineated, no confirmation sampling was performed. After excavation was completed, backfilling was performed and the site was restored to match the existing conditions and grade. Backfill material was verified to be clean (few positive detections for various analytes – mostly metals - were well below applicable RIDEM Residential and Industrial DECs). Additional details and summary of work performed are included in the Final *Remedial Action Completion Report, Soil Remedial Action at Site 16* dated August 2016.

4.3.2.2 In-situ Groundwater Treatment

As summarized in the previous section, the initial groundwater component of the remedy for Site 16 included limited in-situ chemical oxidation of the groundwater at the eastern end of former Building 41. Groundwater remediation began in September 2015, which included initial site set-up and removal off all automobiles from the area. Prior to in-situ chemical oxidation, a baseline groundwater sampling event occurred, which included a focused synoptic groundwater event. Sampling was completed at 54 Site 16 groundwater monitoring wells. Upon completion of the baseline groundwater sampling, the 12 injection wells were re-developed by pumping groundwater out of each well for approximately 3 hours from August 26 to 28, 2016. From September 11 to 25, a total of 39,500 pounds of 100% permanganate (delivered as 99,567 pounds of 40% permanganate) was injected into the injection wells. After the injection phase was complete and permanganate concentrations returned to less than 1 part per million (ppm), four rounds of groundwater monitoring occurred. Sampling was performed at 25 Site 16 groundwater monitoring wells. Additional details and summary of the work completed are included in the Final *Remedial Action Completion Report, Groundwater Remedial Action at Site 16* dated April 2017.

Since groundwater remedial goals were not meet upon completion of the four rounds of groundwater monitoring as part of the groundwater remedial action (summarized in the Final *Remedial Action Completion Report, Groundwater Remedial Action at Site 16* report), an additional round of groundwater sampling was performed. Details and summary of the work completed are included in the Final *Groundwater Sampling Report, Groundwater Remedial Action at Site 16* dated October 2017. The following summarizes key interpretations of this additional sampling round:

- In almost all evaluation wells, TCE concentrations were less than in the final monitoring round compared to the baseline event.

- There was a significant decline in TCE concentrations from the baseline event to the first post-injection event (monitoring round 1) and a slight increase in concentrations have occurred since this first post-injection event.

Table 4-1 summarizes the groundwater sampling results as part of the Site 16 groundwater Remedy Implementation.

4.3.2.3 LUCs

As documented in the ROD, the LUC performance objectives for the LUCs at Site 16 are as follows:

- Allow recreational uses within the existing Allen Harbor Boating Association (AHBA) marina that are consistent with marina activities and will not disturb components of the remedy (e.g., soil cover, monitoring wells).

- Prohibit expansion of residential use (which also excludes recreational use as defined by RIDEM) within the NCA. Prohibited residential uses shall include, but are not limited to, any form of housing, child-care facilities, pre-schools, elementary schools, secondary schools, playgrounds, convalescent, or nursing care facilities.

- Establish a WMA to control excavation/disturbance of contaminated surface and subsurface soil by requiring all soil disturbance and excavation activities be conducted according to a health and safety plan and soil management plan approved in advance by the FFA signatories.

- Prohibit disturbance of the cover on the NCA and marina, within Site 16 boundaries, without approval from Navy, USEPA, and RIDEM.

- Prohibit any use of groundwater, unless authorized in advance by the FFA signatories, except for purposes of environmental monitoring or remediation.

- Prohibit construction and occupation of any future buildings unless (1) an investigation, concurred upon by FFA signatories, shows that risks to human health from vapor intrusion are within acceptable limits or (2) the FFA signatories

concur on the design of a vapor mitigation system for the building, and the vapor mitigation system is installed and operating properly and successfully.

- Maintain the integrity of any existing or future monitoring or remediation system(s).

The ROD included the following implementation actions for LUCs at Site 16:

- Modify the existing LUCIP to describe these LUCs.

- Incorporate these restrictions into any real estate property documents (i.e., deeds or leases) associated with future sale or lease of the site.

- Conduct annual inspections to ensure that there are no violations of these restrictions. The Navy will provide annual certifications of the inspections to EPA and RIDEM.

- If a violation of the restrictions occurs, report to EPA and RIDEM a description of the violation and the corrective actions to be taken to restore protectiveness.

- Establish restrictions, enforceable by the Navy, on properties that the Navy has already transferred to other parties.

The NCA portion of Site 16, north of Davisville Road, is owned by the Navy, and the LUCs required by the ROD for this area of the site are being implemented in accordance with the LUCIP (draft submitted in November 2016; final in preparation). Prior to the signing of the 2014 ROD, the area had prior deed restrictions which restricted use to activities consistent with a port facility (therefore, prohibiting residential/recreational development). Inspections of the NCA have been performed since 2002 in conjunction with CERCLA inspections of Sites 07 and 09 called for in a 2002 LUCIP. The LUCIP update will incorporate the LUCs required by the Site 16 ROD for both the NCA portion of Parcel 7 and the groundwater plume on previously transferred property.

The area of Site 16 south of Davisville Road was transferred out of Navy ownership, as part of Parcel 8, prior to the discovery of groundwater contamination in this area, and no environmental land use restrictions were imposed as part of the property transfer. Implementation of the ROD for this area will required coordination with/approval of the current property owner. Previous inspections of the NCA portion of Site 16 also included visual inspection of this area to confirm that no activities that

violate the LUCs are being conducted, and this process will continue during future inspections. The draft Annual LUCIP for 2016 report was submitted for review on February 9, 2018.

4.3.2.4 LTM

The *Draft Final Tier II Sampling and Analysis Plan, Long Term Monitoring, Creosote Dip Tank Area, Fire-Fighting Training Area, and Former Building 41 (Site 16)* report was submitted on November 20, 2017. The LTM component of the selected remedy for Site 16 began in December 2017. A site map with groundwater monitoring wells is provided as Figure 4-2.

4.4 Progress Since the Last Review

This is the first occurrence of Site 16 in a Five-Year Review because the ROD was signed in June 2014, after submission of the *Third Five-Year Review Report* on March 28, 2013.

4.5 Five-Year Review Process

This section provides a description of the Five-Year Review process specific to Site 16, including the document review, data review, and site inspection.

4.5.1 Document Review

Documents reviewed as part of this Five-Year Review are referenced throughout the text and are included in the reference section.

A review of documents relevant to the remedial actions activities conducted at Site 16 was undertaken as part of the Five-Year Review. The documents reviewed to complete the review included RI Reports and risk assessments, the FS, Proposed Plan, ROD, Remedial Action Completion Reports for soil and groundwater, and draft/draft final LTM work plans. For a complete list of documents that were reviewed during this Five-Year Review, please refer to the references section of this report.

4.5.2 Data Review

A review of data collected during the soil and groundwater remedial actions was performed as part of the Five-Year Review. The data collected for the soil remedial action consisted of confirmatory (either pre- or post-removal) sampling to verify that the remedial actions have been adequately performed. The data collected for the groundwater remedial action (focused in-situ chemical oxidation) included the collection

of a baseline and four post injection groundwater sampling events (a synoptic groundwater level event also occurred with each sampling round). The data collected during the completion of the soil and groundwater remedies at Site 16 support the conclusions of the RI/FS that formed the basis for the ROD signed in June 2014 by the Navy and EPA and concurred with by RIDEM. The Draft Final UFP-SAP for LTMP at Site 16 was submitted on November 20, 2017 and the Year 1 baseline groundwater sampling event occurred in December 2017. Preliminary results of this sampling event were shared with EPA and RIDEM on February 13, 2018. Figure 4-3 presents the spatial distribution of TCE based on previous investigations, prior to initiation of the remedy and LTMP.

4.5.3 Site Inspection

This section summarizes site inspection activities performed as part of annual LUCIP monitoring and the site inspection performed specifically for this Five-Year Review.

4.5.3.1 LTM Program Site Inspections

Site inspections will be conducted in a similar manner as those with Sites 07 and 09 once the LTM program is enacted.

4.5.3.2 Five-Year Review Site Inspection

Tetra Tech performed a site inspection on September 21, 2017, as part of the Five-Year Review. The inspection includes a site walkover and annotation of conditions. Photographs from the 2017 site inspections are included in Appendix B.

The site inspection began at the southwestern corner of Davisville and Marine Road and progresses eastward. Key observations recorded during the site inspections include:

- Condition of the soil cover and stone revetment wall by Building E-107
- Condition of the NCA
- Condition of the asphalt parking lots south and east of Davisville Road
- Any other adverse conditions encountered.

Overall, the site appears to be in good shape. No deficiencies were noted.

4.5.3.3 Interviews

The Navy holds annual RAB meetings for former NCBC Davisville to discuss the process of the cleanup program and ongoing investigations and/or site status. Comments and/or information received during these meetings are recorded and

addressed by Navy, Region 1 EPA, and RIDEM representatives during these annual meetings. The RAB meeting notes are available to all attendees and are placed in the Administration Record.

The following individuals were interviewed as part of the fourth Five-Year Review for former NCBC Davisville.

Interviewee	Title/Affiliation
Nicole LaFontaine	North Kingstown Director of Planning and Development
Steven King	Quonset Development Corporation, Chief Operating Officer
Susan Licardi	North Kingstown Director of Water Department/Supply
Phil Bergeron	North Kingstown Director of Public Works
Chelsey Dumas	North Kingstown Department of Recreation
Ralph Mollis	North Kingstown Town Manager

The types of questions that were asked of interviewees are provided on the Typical Interview Questions from the June 22, 2017 RAB presentation, included in Appendix A. Steven King of Quonset Development Corporation was interviewed on September 21, 2017, and Susan Licardi of North Kingstown Water Department was interviewed on September 22, 2017. On Friday, September 23, 2017, Susan Licardi spoke with several other North Kingstown managers, with her questions focused on town-owned Sites 07 and 09. Appendix A includes a summary of information gathered during these interviews. The Typical Interview Questions from the June 22, 2017 RAB presentation were also provided to the Quonset Davisville Navy Yacht Club. However, no responses were received.

4.6 Technical Assessment

4.6.1 Question A: Is the remedy functioning as intended by the decision documents?

The review of data collected during the soil and groundwater remedial actions performed between 2014 and 2017 and the results of site inspections indicate that the remedy is currently functioning as intended by the ROD. Although the LUCs required for the non-NCA portion of Site 16 have not been formally implemented (because the property was transferred prior to the identification of contamination), the current use of the site and results of visual inspections of the area confirm that activities that could

violate the LUCs are not taking place at the site. There is no evidence of the installation of wells for groundwater extraction or construction of buildings that could allow vapor intrusion.

4.6.2 Question B. Are the exposure assumptions, toxicity data, cleanup levels, and RAOs used at the time of the remedy selection still valid?

The *Remedial Investigation and Baseline Risk Assessment at Site 16* (Tetra Tech, 2009i) indicated the presence of soil and groundwater contamination from past operating practices that posed potentially unacceptable risk to current and possible future human receptors. There were no unacceptable ecological risks identified in the ecological risk assessment of the Remedial Investigation of Site 16 soil (Tetra Tech, 2009) or for surface water and sediment associated with Site 16 (Tetra Tech, 2004). Therefore, the RAOs in the FS and ROD included preventing exposure to industrial, recreational, and hypothetical future residential receptors to COCs in soil and groundwater and eliminating the potential for migration of soil COCs to groundwater. The implemented remedies address these RAOs.

There have been changes in some HHRA guidance and toxicity factors and changes in ecological screening levels since the preparation of the HHRA and SLERA (Tetra Tech, 2009i) and SLERAs for surface water and sediment (EA, 2004j and 2004k). Sections 4.6.2.1 and 4.6.2.2 summarize changes in factors or guidance for the HHRA and SLERA, respectively. Appendix C provides tables that show the factors that have changed compared to those used in the original risk assessments for Site 16 media. There have been no significant changes to ARARs that would affect cleanup levels developed for the site (Section 4.6.2.3).

The conclusion of the analysis of these changes in the sections that follow is that the RAOs are still valid and that the remedies for Site 16 are still protective.

4.6.2.1 Human Health Risk Assessment

Some changes have occurred in EPA Risk Assessment Guidance for Superfund (RAGS) since 2008 when the Site 16 HHRA was prepared. These include default exposure factors, toxicity criteria, and EPA RSLs. However, these result generally in lower risk estimates for the COCs that were remediated in soil (benzo(a)pyrene equivalents, arsenic, and lead). Therefore, in spite of changes in risk assessment methods, toxicity values, and cleanup targets, the remedy remains currently protective.

The changes in HHRA methods and values are organized below in the order of the steps of risk assessment (Hazard Identification, Exposure Assessment, and Toxicity Assessment) and then related to the RAOs and selected remedies.

Hazard Assessment (Identifying Chemicals of Potential Concern)

New Contaminants and/or Contaminant Sources: With the exception of pre- and post-confirmatory based sampling for the soil removal remedy, there has been no new soil sampling since the ROD was signed, and no new contaminants detected at the site since the groundwater remedy was implemented, and no new contaminant sources have been identified (LTM was initiated in December 2017).

Changes in Screening Criteria: The HHRA was prepared using the July 2008 RSLs and RIDEM DECs. Tables C-5 to C-7 (of Appendix C) present comparisons of the screening levels used in the HHRA to current values. There have been changes to the RSLs since 2008 due mainly to changes in toxicity criteria and exposure assumptions. The most significant change is that the July 2008 RSLs for tap water only considered exposures to ingestion of water and inhalation of volatiles, but the current RSLs also consider dermal exposures to water. In general, the current RSLs for soil are higher for most chemicals than those used in the HHRA, and the current RSLs for tap water and protection of groundwater are lower than those used in the HHRA. However, a review of the COPC selection tables for the chemicals with changes indicates that the list of COPCs would not significantly change if the current screening levels were used. In addition, the changes in screening criteria do not affect the protectiveness of the remedy for soil or groundwater because the same major COPCs would have been retained for evaluation in the HHRA.

Exposure Assessment

A key factor in Exposure Assessment that could impact the protectiveness of the remedy is if there were a change in land use designation for Site 16. However, current and reasonably anticipated future land use for Site 16 is the same as that considered in the signed ROD, which is commercial/industrial in all areas except the area in the immediate vicinity of Building E-107, which is used for marina (recreational) purposes. Therefore, the remedy remains protective since the anticipated land uses at the site have not changed.

The following changes in EPA risk assessment methodology related to exposure assessment have occurred since the HHRA and FS were finalized:

- In 2014, EPA updated standard exposure factors for human health. Tables C-8 to C-10 (of Appendix C) present a comparison of current exposure assumptions to those used in the HHRA. Tables C-11 and C-12 (of Appendix C) present a

comparison of the cancer intakes and noncancer intakes calculated using the exposure assumptions used in the HHRA and those based on the current exposure assumptions. For all exposure pathways with the exception of incidental ingestion of surface water and the noncancer intake for ingestion of groundwater by an adult resident, the intakes calculated with the current exposure assumptions are slightly less than those calculated using the exposure assumptions used in the HHRA. Consequently, the cancer risks and hazard indices would be slightly lower if they were calculated with the current exposure assumptions although cancer risks and hazard indices would still be unacceptable. Therefore, the conclusions of the HHRA and the remedy for Site 16 would not change.

- EPCs in the HHRA were calculated using EPA's ProUCL Version 4.00.02. There have been several updates to ProUCL since the HHRA was prepared, with the current version being Version 5.1.002. Some of the EPCs might change (increase or decrease) if they were calculated using the current version of ProUCL. However, the changes are not expected to be significant enough to result in major changes to the estimated cancer risks and hazard indices, and the overall conclusions of the HHRA and the remedy for Site 16 would not change.

Toxicity Assessment

Changes in Toxicity and Other Contaminant Characteristics: There have been no changes in human health toxicity criteria that would impact the protectiveness of the remedy. The toxicity factors [i.e., Cancer Slope Factors (CSFs) and Reference Doses (RfDs)] used in the HHRA for Site 16 were obtained primarily from Integrated Risk Information System (IRIS) or other sources. A comparison of toxicity criteria used in the HHRA to current toxicity criteria is provided in Tables C-1 through C-4 of Appendix C. Although the toxicity criteria for several chemicals have changed, the changes do not affect the protectiveness of the remedy. Carcinogenic PAHs, dioxins/furans, and arsenic were the major COCs identified in soil. The CSF and inhalation unit risk (IUR) for benzo(a)pyrene have decreased, but the criteria for dioxins/furans and arsenic have not changed. Therefore, the cancer risks for exposures to soil would decrease although risks would still exceed acceptable levels. However, these changes do not affect the protectiveness of the remedy for soil, which was - soil removal and off-site disposal, cover with clean fill, and LUCs. The soil removal areas were based on RIDEM DECs and these values have not changed, therefore the remedy for soil would not change.

Benzene, cis-1,2-DCE, PCE, TCE, vinyl chloride, and naphthalene were the major COCs identified in groundwater (Figure 4-3 presents the spatial distribution of TCE). Toxicity criteria for benzene, vinyl chloride, and naphthalene have not changed. The

current CSF and IUR for PCE are indicate lower toxicity than the values used in the HHRA, and the current CSF and IUR for TCE indicate higher toxicity than the values used in the HHRA. The RfDs and Reference Concentrations (RfCs) for PCE and TCE indicate that they are now considered more toxic than they were at the time of HHRA preparation. In addition, there is now an RfD available for cis-1,2-DCE. As a result, the cancer risks and HIs would be different than those presented in the HHRA. However, these changes do not affect the remedy for groundwater since the groundwater cleanup levels are based on MCLs, which have not changed- . Also, these changes do not affect the monitoring criteria for groundwater, which are also based on MCLs.

There have been updates to several of the input assumptions to EPA's Integrated Exposure Uptake Biokinetic model and Adult Lead Methodology (ALM) since the HHRA was prepared. In addition, the acceptable blood-lead level in the ALM has been lowered from 10 µg/dL to 5 µg/dL. The acceptable blood-lead level target change does not affect the soil cleanup levels because the RIDEM DEC was used as the cleanup goal for soil. The RIDEM DEC for lead has not changed and would still be lower than levels based on the updated ALM.

4.6.2.2 Ecological Risk Assessment

The EPA ERA guidance used to prepare the 2004 SLERA of Allen Harbor surface water and sediment potentially impacted by Site 16 and the 2009 SLERA of Site 16 remains the most current guidance. Toxicity reference values (TRVs) that were used to evaluate risks to wildlife from chemicals in sediment have been updated since preparation of the 2004 SLERA. The sediment TRVs were derived in the EPA Ecological Soil Screening Level (Eco SSL) guidance for several metals and a few organic chemicals (primarily DDTs and PAHs). The majority of the more recent TRVs are either similar to or greater than the TRVs used in the 2004 SLERA, although some TRVs are now lower. Therefore, the hazard quotients (HQs) would not change significantly for most chemicals based on the new TRVs and it is likely that a similar overall conclusion of acceptable ecological risk for sediment would be reached. The TRVs used in the 2009 SLERA to evaluate risks to wildlife from surface soil are the most recent TRVs; therefore, conclusions of acceptable ecological risk with soil would not change.

The 2004 SLERAs evaluated ecological risks to aquatic ecological receptors exposed to groundwater seeps and sediment associated with the seeps in Allen Harbor and evaluated risks to benthic invertebrates and wildlife exposed to sediment in Allen Harbor adjacent to Site 16. The SLERA included comparisons of seep water concentrations to EPA National Recommended Water Quality Criteria, which are periodically updated. The current EPA Water Quality Criteria are similar to the screening levels used in the 2004 evaluation, so the list of preliminary COPCs would not likely be expanded based

on updated criteria. The SLERA included comparisons of sediment chemistry to effects range low and effects range median benchmarks from Long and Morgan (1990) and Long et al. (1995). These sediment criteria have not been updated; therefore, the list of preliminary COPCs would not change. Risks to wildlife were based on food-chain modeling and as discussed above, changes in the TRVs would not result in significant changes to the risk conclusions.

A SLERA evaluating ecological risks to terrestrial plants, soil invertebrates, and wildlife exposed to COPCs in surface soil at Site 16 was conducted in 2009. Soil chemical concentrations were compared to EPA Eco SSLs supplemented with Canadian Soil Guidelines, Oak Ridge National Laboratory plant and invertebrate benchmarks, and Dutch Target Values, when necessary. These criteria have not been updated; therefore, the list of preliminary COPCs would not change. Risks to wildlife were based on food-chain modeling, and as discussed above, changes in the TRVs would not result in significant changes to the risk conclusions.

Several refinement factors were also considered when evaluating the results of the SLERAs and determining that chemical concentrations in soil do not present a risk to ecological receptors exposed to seep water, sediment, and/or surface soil. These factors, such as frequency of detection, comparison to background values, bioavailability, and comparison to alternate benchmarks would not be affected by any changes to screening criteria.

4.6.2.3 ARARs and TBCs

ARARs and TBCs considered during the preparation of the ROD were reviewed to determine changes since the ROD was signed. There have been no changes in ARARs or TBCs that would affect the protectiveness of the remedy. Toxicity values are TBCs per the Final FS Report for Site (Tetra Tech, 2012d), and there is an updated EPA toxicity assessment for benzo(a)pyrene (USEPA, 2017), which is a soil COC addressed in the soil remedies. The most significant change in benzo(a)pyrene toxicity is an oral CSF that is approximately seven times lower than the previous slope factor (resulting in EPA RSLs that are approximately 10 times higher than those calculated with the previous benzo(a)pyrene toxicity value). However, the PRGs for benzo(a)pyrene equivalents in soil were based on the RIDEM DEC, and these have not been updated to reflect the new benzo(a)pyrene toxicity assessment. Therefore, this TBC does not affect the specific remedial target for soil, but the updated benzo(a)pyrene toxicity assessment does support that the remedy remains protective.

One potential ARAR that developed after the ROD was signed is the listing of the northern long-eared bat as a threatened status by United States Fish and Wildlife

Service (USFWS). Therefore, a Phase 1 habitat assessment and consultation with the United States Fish and Wildlife Service (USFWS) and Rhode Island Fish and Wildlife Service was conducted by Resolution Consultants prior to mobilization for implementation of the soil removal portion of the remedy. The Phase I Habitat Assessment findings stated that potentially suitable northern long-eared bat summer habitat was not confirmed in the Site 16 NCA. Occurrence records for the bat are not reported by RIDEM, no known roost trees are present and suitable trees with exfoliating bark, crevices, cracks and cavities in the NCA are not present, and no water resources are present at the NCA. Additionally, no winter hibernacula are present in the vicinity of the NCA according to information received from RIDEM. USFWS issued a letter dated August 12, 2015, agreeing with the conclusion that northern long-eared bat summer habitat is not confirmed for Site 16.

4.6.3 Question C: Has any other information come to light that could call into question the protectiveness of the remedy?

No weather-related events have affected the protectiveness of the remedy, and there is no other information that calls into question the protectiveness of the remedy.

4.6.4 Technical Assessment Summary

Based on the data reviewed and the site inspections, the remedy is currently functioning as intended by the ROD. There have been no changes in physical conditions at the site, toxicity factors, changes to ARARs or TBC guidance, or to the standardized risk assessment methodology that would affect the protectiveness of the remedy. No other information has been discovered that calls into question the protectiveness of the remedy.

4.7 Issues

As summarized in Section 4.3.3.2, a portion of Site 16 was previously transferred without the LUCs subsequently required by the Site 16 ROD. In accordance with the lease for Parcel 7, annual inspections are conducted to verify compliance with the lease restrictions and include formerly owned lands (Parcel 8). Although there have been no non-compliance issues to date, without an ELUR recorded on the deed for this portion of the property, future remedy protectiveness cannot be ensured. Implementation of the ELURs will require necessary coordination with the current property owner(s). The Navy has begun the process of coordinating with the current property owner to accept the required restrictions on their property.

Issue	Affects Current Protectiveness (Y/N)	Affects Future Protectiveness (Y/N)
The ELUR for recording on the deed for Parcel 8, Zone 4 (area south of Davisville Road and the eastern Pier area were previously transferred) has not been completed. Coordination with current property owner(s) will be required.	N	Y

4.8 Recommendations and Follow-Up Actions

Issue	Recommendations/ Follow-Up Actions	Party Responsible	Oversight Agency	Milestone Date	Affects Protectiveness (Y/N)	
					Current	Future
1	In coordination with current property owner(s), submit ELUR for recording on deed for Parcel 8, Zone 4 (area south of Davisville Road and the eastern Pier area were previously transferred).	Navy	EPA/ RIDEM	9/1/18	N	Y

4.9 Protectiveness Statement

The remedy at Site 16 is currently protective of human health and the environment. The soil removal portion of the remedy was successful in removing soil with COC concentrations exceeding industrial/commercial DECs from the site, and the 0 to 2 feet of backfill used to restore the excavated areas prevents exposure to COCs at greater depths. Groundwater treatment was successful in reducing concentrations of TCE to levels that allowed for a transition to MNA. The results of future LTM will be used to evaluate the effectiveness of the remedy, including confirmation of the lack of migration of subsurface soil COCs to other media beyond the compliance boundary and by evaluating trends in groundwater COC concentrations. Implementation of LUCs via the LUCIP in the NCA portion of the site will provide protection by prohibiting residential exposure to surface and subsurface soil and by preventing human exposure to groundwater. Although LUCs have not been formally implemented in the non-NCA portion of the site, inspections have confirmed that no activities that could facilitate

human exposure to groundwater or to VOC vapors migrating into buildings have been conducted at the site (i.e., no well installation and no building construction). Attempts by the Navy to implement the required LUCs via addition to the deed associated with previous transfer of the property are underway.

Based on the information available to date and the activities that are completed and ongoing, the Site 16 remedy is currently protective. Exposure pathways that could result in unacceptable risks are being addressed through implemented LUCs or by the confirmed lack of unacceptable site uses (i.e., no well installation or building construction) and therefore exposure to site-related contaminants in soil and groundwater is currently being prevented. To ensure the future protectiveness of the remedy, the Navy is coordinating with the current site owner to allow incorporation of an ELUR documenting the LUCs required by the ROD for the non-NCA portion of Site 16 into the deed for previous transfer of the property.

APPENDIX A
INTERVIEW SUMMARIES

This page intentionally left blank

Typical Interview Questions

1. What is your overall impression of the project?
2. Are you aware of any community concerns regarding either of these sites?
3. Are you aware of any problems, concerns associated with on-going monitoring and maintenance activities?
4. Do you feel that the land-use controls at these sites are adequately communicated to the public?
5. Do you feel well informed about the long-term monitoring activities?
6. Do you have any comments, suggestions, or recommendations regarding the management of the sites?

Fourth Five Year Review Interview

September 20, 2017

Steve King, Quonset Development Corporation, Chief Operating Officer

Answer to Question 1 –

For Sites 07 and 09, projects are going well. The land is being used and serving the intended purposes. For Site 16, the overall impression is that the process is moving too slowly. The main goal of QDC is to develop the properties and put them into productive use for the State. The goal is develop future business. In general, the process to complete the environmental work at Site 16 is going too slow and is impacting future business. However, we are excited about the cleanup at the North Central Area and hope to put the land into development soon for productive use.

Answer to Question 2 –

For Sites 07 and 09, there are no known community concerns. There are no community concerns for Site 16. However, upgradient of Site 16, at the adjacent Nike PR-58 site, there is concern about the newly constructed athletic parks. There are continued questions from the community about whether the fields are safe to use. A town council member refers to the plume that underlies the site as toxic, which raises concerns to the public. People also did not like that trees were cut down around the property (some clearing at Site 16).

Answer to Question 3 –

No concerns were raised for Sites 07 and 09. Two main concerns occur for Site 16 – business interruptions due to groundwater sampling and other activities and maintenance of flush mount wells in asphalt areas and stickups in areas that are cut/maintained. While QDC understands that sampling and maintaining wells need to occur, the hope is that interruptions and maintenance can be minimized.

Answer to Question 4 and 5 –

Yes, communication is good.

Answer to Question 6 –

For all sites, especially Site 16, get in and out quickly to minimize disturbances to the existing businesses and finish other sites quickly so that the land can be developed for commercial use.

Fourth Five Year Review Interview

September 21, 2017

Susan E. Licardi, North Kingstown Director of Water Supply

Answer to Questions 1 to 6 –

In general, the town's impressions of the projects is that all is going well and there are no outstanding problems or concerns. Additionally, communication with town and residents is very good.

On September 22, 2017, Susan spoke with several town leaders to see if they had anything to add as well. There were no concerns or problems identified.

Anderson, Scott

From: Sue Licardi <SLicardi@northkingstown.org>
Sent: Friday, September 22, 2017 10:18 AM
To: Anderson, Scott
Subject: RE: NCBC Davisville 5 Year Review Interview/Questions

Scott:
I have spoken to the Town Planner (Nicole LaFontaine), Public Works Director (Phil Bergeron), Rec. Dept. (Chelsey Dumas) and the Town Manager (Ralph Mollis) and none of them were aware of any problems or concerns regarding maintenance or monitoring associated with NCBC Davisville. The only property that came up was the Quonset site that is being used for soccer fields and questions about the contamination and land use restrictions. Let me know if you have any questions or need additional information.

Cc: TownManager
Subject: NCBC Davisville 5 Year Review Interview/Questions

Hi Susan, Steve, Ms. LaFontaine and Mr. Mollis,

As some of you may know, Tetra Tech has been contracted by the Navy to perform a Five Year Review of NCBC Davisville for Site 9 (Allen Harbor Landfill), Site 7 (Calf Pasture Point) and Site 16 (Former Building 41 and North Central Area). Tetra Tech was the main contractor from about 2007 to 2012, though I had funding which extended my participation through 2015 and early 2016 (though I wasn't involved too much from fall 2015 onward). I received my new funding end of July/early August and I have been setting up the job to get various tasks moving again.

I know/see that Steve King and Susan Licardi are cc'd on various NCBC Davisville documents and I believe that John Reiner is no longer with the town. I've been kept in the loop enough to see that the RAB meetings have decreased in attendance and even frequency, many times only consisting of a single meeting per year with only Steve King and a representative from the town beyond the Navy, EPA and State members.

Since I've been off the job a short while and getting the job re-established, I was wondering if I could call you sometime this week for a brief interview/questionnaire to get your opinions on those sites related to the Five Year Report. I've attached the interview questions.

If it is more convenient for you, you can also just respond to my email. I wasn't sure who to include from the town and don't believe I need all three of you to respond (Susan, Nicole, Ralph). I was trying to limit the interview/questions to

those who are familiar with the site and would have an opinion on how work and interactions between Navy and QDC/Town of North Kingstown has been proceeding.

I am out the rest of today, but in all day tomorrow, Thursday and Friday. I'm in around lunch time on Wednesday and the rest of the day. Feel free to email me a time to talk as I don't want to be an inconvenience to your busy schedules.

Thank you for your time.

Thank you,

Scott R. Anderson, PG | **Senior Hydrogeologist/Project Manager**

Only detected chemicals are presented. All concentrations reported in micrograms per liter (µg/L).
COPC - Chemical of Potential Concern
HQ - Hazard Quotient (maximum detected concentration/screening value)
J - Estimated concentration
J- - Estimated concentration, biased low

Screening Level Sources:
Region 3 - USEPA Region 3 marine screening benchmarks (USEPA, 2006c).
Region 3 FW - USEPA Region 3 freshwater screening benchmarks (USEPA, 2006d).

Notes:
1 - U.S. EPA, 2004: Risk Assessment Guidance for Superfund (Part E, Supplemental Guidance for Dermal Risk Assessment) Interim. EPA/540/R/99/005.
2 - Adjusted dermal RfD = Oral RfD x Oral Absorption Efficiency for Dermal.
3 - Values are for pyrene.
4 - Values are for cadmium - water.
5 - Values are for hexavalent chromium.
6 - Values used in the 2009 risk assessment were IRIS values adjusted following USEPA Region I Risk Update Number 4, November 1996 which specified different adjustments for soil and water.

Indicates current toxicity criteria is less toxic than previous value.
Indicates current toxicity value is more toxic than previous value.
Indicates target organs have changed.

Notes:
1 - USEPA, 2004: Risk Assessment Guidance for Superfund (Part E, Supplemental Guidance for Dermal Risk Assessment) Interim. EPA/540/R/99/005.
2 - Adjusted cancer slope factor for dermal = Oral cancer slope factor / Oral Absorption Efficiency for Dermal.
3 - Trichloroethene, carcinogenic PAHs, and hexavalent chromium are considered to act via the mutagenic mode of action. These chemicals are evaluated in accordance with USEPA's Supplemental Guidance for Assessing Susceptibility from Early-Life Exposure to Carcinogens (2005).
4 - Air Toxics Hot Spots Program Technical Support Document for Cancer Potencies. Appendix B.
5 - Public Health Goals for Chemicals in Drinking Water; Hexavalent Chromium (Cr VI).
6 - OSWER Directive No.9285.7-75.
7 - USEPA, PCBs: Cancer Dose-Response Assessment and Applications to Environmental Mixtures, September 1996, EPA/600/P-96/001F.
8 - Values are for hexavalent chromium.
Indicates current toxicity criteria is less toxic than previous value.
Indicates current toxicity value is more toxic than previous value.

Notes:

1 - Air Toxics Hot Spots Program Technical Support Document for Cancer Potencies. Appendix B.

2 - OSWER Directive No.9285.7-75.

3 - Trichloroethene, carcinogenic PAHs, and hexavalent chromium are considered to act via the mutagenic mode of action. These chemicals are evaluated in accordance with USEPA's Supplemental Guidance for Assessing Susceptibility from Early-Life Exposure to Carcinogens (2005).

4 - USEPA, PCBs: Cancer Dose-Response Assessment and Applications to Environmental Mixtures, September 1996, EPA/600/P-96/001F.

5 - Values are for hexavalent chromium.

6 - IRIS presents a value of 1.2E-02 $(ug/m^3)^{-1}$ for hexavalent chromium and assumes a trivalent chromium to hexavalent chromium ration of 6:1. The IRIS value is multiplied by 7 as recommended in the RSL user guide.

Indicates current toxicity criteria is less toxic than previous value.

Indicates current toxicity value is more toxic than previous value.

57-12-5	Cyanide	160 N	2.3 N	200	200

Notes

1 - USEPA Regional Screening Levels for Chemical Contaminants at Superfund Sites. Values used in the 2009 risk assessment are from the June 2008 RSL table. Current values are from the June 2017 RSL table. Values correspond to a cancer risk of 1E-06 for carcinogens and hazard index of 0.1 for noncarcinogens.
2 - RIDEM values are from Rules and Regulations for the Investigation and Remediation of Hazardous Waste Materials Releases, DEM-DSR-01-93, March 31, 1993. Values used in the 2009 risk assessment were from the February 2004 amended version of the regulations. The current values are from the November 2011 amended version of the regulations.
3 - Value is derived by dividing criteria for 2,3,7,8-TCDD by World Health Organization Toxicity Equivalent Factor.
4 - Value is for m-xylenes.
5 - The value for cis-1,2-dichloroethene has been used as a surrogate for total 1,2-dichloroethene.
6 - The value for acenaphthene was used as a surrogate for acenaphthylene.
7 - The value for pyrene is used as a surrogate for benzo(g,h,i)perylene and phenanthrene.
8 - The value for chlordane was used as a surrogate for alpha- and gamma-chlordane.
9 - The value for alpha-BHC has been used as a surrogate for delta-BHC.
10 - The value for endosulfan has been used as a surrogate for endosulfan II and endosulfan sulfate.
11 - The value for endrin has been used as a surrogate for endrin aldehyde and endrin ketone.
12 - The value for total PCB congeners (Aroclors) is presented.
13 - The values for chromium VI are presented.
14 - Value is for mercuric chloride.

Indicates current screening level is greater than value used in 2009 risk assessment.
Indicates current screening level is less than value used in 2009 risk assessment.

Qualifiers:
C - Carcinogen.
HI - Hazard index
N - Non-carcinogen.

Acronyms:
USEPA - United States Environmental Protection Agency
NA - No criteria available.
PCB - Polychlorinated biphenyl
RIDEM - Rhode Island Department of Environmental Management

Footnotes:

1 - USEPA Regional Screening Levels for Chemical Contaminants at Superfund Sites, July 7, 2008. Values used in the 2009 risk assessment are from the June 2008 RSL table. Current values are from the June 2017 RSL table. Values correspond to a cancer risk of 1E-06 for carcinogens and hazard index of 0.1 for noncarcinogens.

2 -Values used in the 2009 risk assessment are from the 2006 Edition of the Drinking Water Standards and Health Advisories, EPA 822-B-06-013. Current values are from the 2012 Edition of the Drinking Water Standards and Health Advisories, EPA 822-S-12-001.

3 - RIDEM values are from Rules and Regulations for the Investigation and Remediation of Hazardous Waste Materials Releases, DEM-DSR-01-93, March 31, 1993. Values used in the 2009 risk assessment were from the February 2004 amended version of the regulations. The current values are from the November 2011 amended version of the regulations.

4 - The value for cis-1,2-dichloroethene was used as a surrogate for total 1,2-dichloroethene.

5 - Value is for total xylenes

6 - The value for acenaphthene is used as a surrogate for acenaphthylene.

7 - The value for pyrene is used as a surrogate for benzo(g,h,i)perylene and phenanthrene.

8 - The value for chlordane is used as a surrogate for alpha- and gamma-chlordane.

9 - The value for total PCB congeners (Aroclors) is presented.

10 - The value for alpha-BHC is used as a surrogate for delta-BHC.

11 - The value for endosulfan is used as a surrogate for endosulfan II and endosulfan sulfate.

12 - The value for endrin is used as a surrogate for endrin aldehyde and endrin ketone.

TABLE C-6

COMPARISON OF HUMAN HEALTH SCREENING CRITERIA FOR GROUNDWATER/SURFACE WATER/SEEPS
FORMER NCBC DAVISVILLE, NORTH KINGSTOWN, RHODE ISLAND

CAS No.	Parameter	USEPA Regional Screening Levels for Tap Water[1]		USEPA Maximum Contaminant Levels[2]		RIDEM GA Groundwater Objective[3]		RIDEM GB Groundwater Objective[3]	
		2009 HHRA	Current/June 2017	2009 HHRA	Current	2009 HHRA	Current/2011	2009 HHRA	Current/2011

13 - The value for chromium VI is presented.
14 - Value for cobalt is from the September 12, 2008 RSL table.
15 - The MCL for this parameter is actually a treatment technique. The SDWA action level (at the tap) has been presented.
16 - Value is for mercuric chloride.
Indicates current screening level is greater than value used in 2009 risk assessment.
Indicates current screening level is less than value used in 2009 risk assessment.

Qualifiers:
C - Carcinogenic.
N - Noncarcinogenic.

Notes:
1 - Protection of groundwater SSLs used in the 2009 risk assessment was calculated using the USEPA Soil Screening Levels calculator. This Internet site no longer exists and has been replaced with the RSL calculator.
2 - USEPA Regional Screening Level Table, June 2017. Values are adjusted for a dilution attenuation factor of 20.
3 - RIDEM values are from Rules and Regulations for the Investigation and Remediation of Hazardous Waste Materials Releases, DEM-DSR-01-93, March 31, 1993. Values used in the 2009 risk assessment were from the February 2004 amended version of the regulations. The current values are from the November 2011 amended version of the regulations.
4 - Value is derived by multiplying criteria for 2,3,7,8-TCDD by World Health Organization Toxicity Equivalent Factor.
5 - The value for chlordane was used as a surrogate for alpha- and gamma-chlordane.
6 - The value for endosulfan has been used as a surrogate for endosulfan II and endosulfan sulfate.
7 - The value for chromium VI is presented.
8 - Leachability criteria for inorganics are based on SPLP/TCLP analysis.
9 - Value is MCL based soil screening level.
Indicates current screening level is greater than value used in 2009 risk assessment.
Indicates current screening level is less than value used in 2009 risk assessment.

Qualifiers:
C - Carcinogen.
N - Noncarcinogen.
MCL - Maximum Contaminant Level.

Acronyms:
NA = No criteria available
PCB = Polychlorinated biphenyl
RIDEM = Rhode Island Department of Environmental Management
SPLP = Synthetic Precipitation Leaching Procedure
SSL = Soil Screening Level
TCLP = Toxicity Characteristics Leaching Procedure
USEPA = United States Environmental Protection Agency

Vapor Intrusion					
EF	Exposure Frequency (days/year)	NA	NA	250[2]	250[4]

Notes:
1 - Assumes a 30 week construction project over a course of one year. Exposure to groundwater occurs only for 6 weeks.
2 - USEPA, 2002: Supplemental Guidance for Developing Soil Screening Levels for Superfund Sites. OSWER 9365.4-24.
3 - USEPA, 1989: Risk Assessment Guidance for Superfund. Vol 1: Human Health Evaluation Manual, Part A.
4 - USEPA, 2014: Human Health Evaluation Manual, Supplemental Guidance: Update of Standard Default Exposure Assumptions.
5 - USEPA, 2004: Risk Assessment Guidance for Superfund (Part E, Supplemental Guidance for Dermal Risk Assessment) Final. PA/540/R/99/005.
6 - Assume an 8-hour work shift.
7 - USEPA, 2008: Soil Screening Guidance calculation Internet site at http://risk.lsd.ornl.gov/calc_start.htm.
Site-specific values for Hartford, Connecticut (This Internet site is no longer active).
8 - USEPA, 2017: Regional Screening Levels Calculator Internet site at https://epa-prgs.ornl.gov/cgi-bin/chemicals/csl_search.
Site-specific values for Hartford, Connecticut.
9 - Professional judgment.

Value is less conservative than value used in 2009 risk assessment.
Value is more conservative than value used in 2009 risk assessment.

TABLE C-9

SUMMARY OF EXPOSURE INPUT PARAMETERS - REASONABLE MAXIMUM EXPOSURES
TRESPASSERS AND RECREATIONAL USERS
FORMER NCBC DAVISVILLE, NORTH KINGSTOWN, RHODE ISLAND

CF	Conversion Factor (kg/mg)	NA	NA	1E-06	1E-06	1E-06	1E-06

Notes:
1 - Adolescents ages 7 to 16 years old.
2 - USEPA, 1989: Risk Assessment Guidance for Superfund. Vol 1: Human Health Evaluation Manual, Part A.
3 - USEPA, 2014: Human Health Evaluation Manual, Supplemental Guidance: Update of Standard Default Exposure Assumptions.
4 - USEPA, 2011: 2011 Exposures Factor Handbook, Table 3.5.
5 - USEPA, 1991: Human Health Evaluation Manual, Supplemental Guidance: Standard Default Exposure Factors. OSWER Directive 9285.6-03.
6 - Assume one day a week in warm weather months.
7 - Assume four days a week in warm weather months.
8 - Child and adult recreational users are assumed to be at the site only a portion of the day.
9 - Assume that head, forearms, hands, lower legs, and feet are exposed, USEPA, 1997a.
10 - Assume that head, forearms, hands, lower legs, and feet are exposed, USEPA, 2011.
11 - USEPA, 2004: Risk Assessment Guidance for Superfund (Part E, Supplemental Guidance for Dermal Risk Assessment) Final. PA/540/R/99/005.
12 - Professional judgment.
13 - USEPA, 2008: Soil Screening Guidance calculation Internet site at http://risk.lsd.ornl.gov/calc_start.htm. Site-specific values for Hartford, Connecticut.
14 - USEPA, 2017: Regional Screening Levels Calculator Internet site at https://epa-prgs.ornl.gov/cgi-bin/chemicals/csl_search. Site-specific values for Hartford, Connecticut.
15 - USEPA Region 4, 2000: Supplement Guidance to RAGS: Region 4 Bulletins.
16 - Assume two days a week in warm weather months for reasonable maximum exposure and one day a week for central tendency exposure.
17 - USEPA, 1993: Superfund's Standard Default Exposure Factors for the Central Tendency and Reasonable Maximum Exposure.
18 - USEPA, 2004, 95th percentile for a child playing in wet soil, Exhibit 3-3.
19 - Shoaf et. Al. 2005: Child Dermal Sediment Loads Following Olay in Tide Flat, Journal of Exposure Analysis and Environmental Epidemiology 15, 407-412.

Value is less conservative than value used in 2009 risk assessment.
Value is more conservative than value used in 2009 risk assessment.

RE: Draft Final Fall 2016 Five Year Event Monitoring Report, Site 07 Monitoring Event 20, Former NCBC Davisville, North Kingstown, Rhode Island

Dear Ms. Williams and Mr. Gottlieb:

On behalf of the Naval Facilities Engineering Command (NAVFAC), Mid-Atlantic (MIDLANT), Resolution Consultants is submitting the Draft Final Fall 2016 Five Year Event Monitoring Report for Site 07 Monitoring Event 20. If you have any questions regarding this deliverable, please contact the Navy RPM Mr. Todd Bober or myself.

Sincerely,

Resolution Consultants
Robert Shoemaker

1.0 PROJECT BACKGROUND

1.1 Introduction

The results from Monitoring Event (ME) 20, conducted in August and September 2016, December 2016, and January 2017 as part of the Long-Term Monitoring Program (LTMP) at Installation Restoration Program (IRP) Site 07 Calf Pasture Point (see Figure 1), Former Naval Construction Battalion Center (NCBC) Davisville, North Kingstown, Rhode Island (hereafter referred to as Site 07) are provided in this Five Year Event Monitoring Report. ME 20 was conducted in accordance with the Draft Tier II Sampling And Analysis Plan Long Term Monitoring Site 07 Calf Pasture Point and Site 09 Allen Harbor Landfill (Tier II LTM SAP) dated June 24, 2016 (Resolution, 2016). A detailed discussion of the site history and conceptual site model can be found in Worksheet 10-1 of the Tier II LTM SAP.

Field and laboratory analytical data collected during ME 20 are summarized in tables and figures attached to this report. In order to facilitate a broader discussion of plume migration in the Discussion of Contaminant Transport Pathways (Section 3.2), plume maps and isoconcentration figures were also generated for ME 18. Data and backup for the tables and figures are provided as Attachments to this report: Field sampling forms are provided in Attachment A, data validation reports are provided in Attachment B, the land-use control implementation plan (LUCIP) checklist is provided as Attachment C, statistical data including Mann Kendall results, Frequency of Detection tables, Trend Plots, and Summary of Detected Analyte tables can be found in Attachment D, and a Tabular Evaluation of Long-Term Trends is provided in Attachment E.

2.0 FIVE YEAR EVENT MONITORING ACTIVITIES

Pre-field tasks (e.g., path clearing), sediment sampling, and surface water sampling were conducted from August 15, 2016 through August 26, 2016. The groundwater and piezometer sampling were conducted from September 07, 2016 through September 28, 2016. Synoptic water level measurements were performed on September 22, 2016. During the synoptic water level measurements, it was discovered that monitoring well MW07-20D was damaged to point that it could not be sampled. Therefore this well along with the corresponding shallow well MW07-20S were abandoned and reinstalled from December 12, 2016 through December 15, 2016 and redeveloped on December 27, 2016. See Section 2.2 for more detail. Newly installed MW07-20DA was sampled on January 13, 2017. The ME 20 sampling activities were conducted in conjunction with IRP Site 09 Allen Harbor Landfill ME 45. A summary of activities performed during ME 20 is summarized below:

- Groundwater samples were collected from 73 monitoring wells
- 20 piezometers were sampled in the intertidal zone along the southern and western shores of Calf Pasture Point.
- Outgoing mid-tide synoptic water level measurements were taken at 55 wells on Calf Pasture Point and the staff gauge in Allen Harbor
- Surface water samples were collected from transects that originate at piezometer locations P07-02, P07-04, P07-06 through P07-10, P07-20, P07-24, and the MW07-43 well cluster (EPA Line C). These samples were collected on August 16, 2016.
- Six surficial sediment samples were collected co-located with piezometers P07-05 through P07-10. These samples were collected on August 15, 2016.

All groundwater, piezometer, sediment and surface water samples were analyzed for the site specific list of volatile organic compounds (VOCs) according to SW-846 Method 8260: benzene, chloroform, 1,2-dichloroethane (1,2-DCA), 1,1-dichloroethene (1,1-DCE), cis-1,2-dichloroethene (cis-1,2-DCE), trans-1,2-dichloroethene (trans-1,2-DCE), 1,1,2,2-tetrachloroethane (1,1,2,2-PCA), tetrachloroethene (PCE), 1,1,2-trichloroethane (1,1,2-TCA), trichloroethene (TCE), and vinyl chloride (VC). The monitoring wells and piezometers sampled during ME 20 consist of the Site 07 Five Year Event suite of sampling locations. These sampling locations, along with the sampling rationale, are presented in Table 1.

Sampling locations are depicted on Figure 2. Detected VOCs in the shallow/intermediate overburden wells, deep overburden wells, bedrock wells, piezometers, sediment samples and surface water samples are depicted in Figures 3 through 8. Results are discussed is Section 3.

Synoptic water level measurements were collected from 55 on-site monitoring wells and the staff gauge in Allen Harbor during outgoing mid-tide conditions on September 22, 2016. Monitoring well casing elevations were utilized to calculate groundwater elevations in each well. Depth to groundwater measured in each well and calculated groundwater elevations are summarized in Table 2. These groundwater elevations were used to create shallow and intermediate overburden, deep overburden, and bedrock potentiometric contour maps, presented as Figures 9, 10, and 11, respectively. Groundwater Flow Net diagrams were also produced along cross sections A-A' and B-B' as shown in Figures 12 and 13. Groundwater conditions at Calf Pasture Point are further discussed in Section 3.3.

Field sampling forms completed during ME 20 are provided in Attachment A.

2.1 Monitoring Procedures

Groundwater samples were collected and analyzed for the site specific short list of VOCs from monitoring wells and piezometers using the Environmental Protection Agency (EPA) Region I Low Stress (Low Flow) methodology (EPA, 2010). In cases where a sampling point did not provide sufficient recharge to enable stabilization of the water level, the sampling point was evacuated of standing water and allowed to recharge prior to the collection of water quality data and the groundwater sample. This occurred at the following piezometers during ME 20: P07-15, P07-20, P07-21, and P07-22. All monitoring wells produced sufficient recharge for low-flow sampling. Consistent with EPA methodology, prior to the collection of sample aliquots for laboratory analysis water quality parameters including temperature, pH, specific conductivity, dissolved oxygen, oxidation-reduction potential, salinity and turbidity were measured (where sufficient water was available) and recorded with electronic data collection software. A summary of field measurements recorded during monitoring well and piezometer groundwater sample collection activities is provided on Tables 3 and 4, respectively. Analytical results for the monitoring wells and piezometers are provided in Tables 5 and 6, respectively.

In accordance with the procedures and standard operating procedures (SOPs) outlined in the Sampling and Analysis Plan (SAP), six surficial sediment samples co-located with piezometers P07-05, P07-06, P07-07, P07-08, P07-09, and P07-10 were collected as discreet undisturbed samples and analyzed for the site specific short list of VOCs. Sediment samples were collected at low tide from 0 - 6 inches below ground surface (bgs), immediately adjacent to piezometer locations. A

disposable plastic trowel was used to dig a hole six inches deep. A new, disposable trowel was used for each soil sample location. A photoionization detector (PID) was used to screen the hole for any elevated readings. During ME 20, no elevated PID readings were observed at any sediment location. Therefore, the samples were collected as a discreet sample using a dedicated coring device (i.e., Terra Core® Sampler) directly from the bottom of the sample hole (i.e., 6 inches bgs). Sediment sample locations are shown on Figure 2. Analytical results are provided in Table 7.

As a part of the Five Year Event, surface water samples were collected within a four hour window of two hours before and two hours after low tide along transects that originate at piezometer locations P07-02, P07-04, P07-06 through P07-10, P07-20, P07-24, and the MW07-43 well cluster (EPA Line C). These samples were collected and analyzed for the site specific short list of VOCs in accordance with the SOPs and procedures outlined in the SAP. For each transect, samples were collected at three distinct sampling depths as follows:

- Depth 1: At the harbor floor where water is approximately 6 inches deep (Identified in the sample ID as "FLOOR01");
- Depth 2: At the harbor floor where the water is 3 feet deep (Identified in the sample ID as "FLOOR02");
- Depth 3: At the mid-point of the water column where the water is 3 feet deep (Identified in the sample ID as "MID01")

Surface water transect locations are shown on Figure 2. Analytical results are provided in Table 8.

2.2 Deviations from Planned Monitoring Activities

Chicago Bridge and Iron (CB&I) has been conducting an Environmental Security Technology Certification Program (ESTCP) Rapid Assessment of Remedial Effectiveness and Rebound in Fractured Bedrock demonstration in the immediate vicinity of the MW07-05 well cluster since March 2015. As part of this research project, CB&I began injecting potable water in bedrock well MW07-05R in August 2016 and this continued through October 2016. As a result, the groundwater in this well was not representative of the bedrock aquifer at the time of the ME 20 event. Therefore, during the August 17, 2016 Base Realignment and Closure (BRAC) Cleanup Team (BCT) teleconference, the BCT agreed to skip the sampling of bedrock well MW07-05R during ME 20.

Monitoring well MW07-16D could not be located during the 2016 sampling event. Based on discussions with Tetra Tech, it is believed that this well was destroyed by a storm sometime around 2011 or 2012. The remnants of the well have never been found, so it is assumed that the protective casing was pulled off the well and swept away and the polyvinyl chloride (PVC) riser

snapped off. This well is not deemed critical for the LTM, as the shallow (DPT07-16S), intermediate (DPT07-16I), and bedrock (MW07-16R) wells for this cluster are still intact. As such, this well has been removed from Table 1 and Figure 2.

During the synoptic water level measurements, it was discovered that the well casing for monitoring well MW07-20D had corroded to the point that it had become detached from the well, there was no longer an expansion cap on the well riser, and the well was obstructed at approximately 26 feet bgs. The obstruction appeared to be the result of the well riser being plugged with sand at that depth. The well is 74.5 feet deep and Resolution was unable to determine whether the well riser was completely full of sand from the bottom of the well to the depth of the obstruction or if there was something else obstructing the well and the sand was on top of that obstruction. Regardless, Resolution was unable to clear the obstruction and the well was not able to be used for synoptic water level measurement or sampling. The BCT was notified of this situation via email on September 23, 2016. Following a site visit on September 30, 2016, it was proposed via email that both wells of the MW07-20 well pair (i.e., MW07-20D and MW07-20S) be abandoned and reinstalled approximately 25-30 feet inland of their current location to reduce their exposure to the shoreline elements and potential vandalism from beachgoers. The BCT agreed to this proposal via email on October 4, 2016. The MW07-20 well pair was abandoned and reinstalled as MW07-20SA and MW07-20DA from December 12, 2016 through December 15, 2016 according to the procedures in the Technical Memorandum included as Attachment G of this report. Boring logs and well construction details are also included in Attachment G. The replacement wells were redeveloped on December 27, 2016 and newly installed monitoring well MW07-20DA was sampled on January 13, 2017. Newly installed shallow well MW07-20SA was not sampled, as the original well MW07-20S had been sampled on September 22, 2016.

No other deviations from the planned monitoring activities occurred during ME 20. Synoptic water level measurements and sample collection was performed in accordance with the methodologies established in the Tier II LTM SAP (Resolution, 2016). The land-use control inspection was completed in accordance with the Final Land Use Control Implementation Plan (EA, 2002).

3.0 SUMMARY AND EVALUATION OF DATA

3.1 Analytical Results and discussion

This section discusses chlorinated volatile organic compounds (CVOCs) that were detected in monitoring well, piezometer, sediment, and surface water samples during ME 20 at concentrations exceeding the project action limits (PALs) (where applicable). The PALs for groundwater are established in the SAP (Resolution, 2016). Additional discussion of individual constituents (e.g., 1,1,2,2-PCA) is provided, as appropriate. Sample locations are shown on Figure 2.

Appendix D provides detected results summary tables for groundwater, piezometer, sediment and surface water samples for ME 1 through 20. Additional tables in Appendix D present summary statistics, including frequency of detection, and the mean and maximum of detected concentrations. These tables provide a summary of those contaminants which were detected in groundwater, piezometer and sediment samples, which represent the majority of constituents and are of greatest potential concern. Summary statistics were not performed on surface water data, as there are not enough comparable rounds of data collected to calculate statistics.

Analytical data were also evaluated to identify trends of increasing or decreasing concentrations. Trend graphs for all positively identified CVOCs in all media are provided in Appendix D. Statistical analysis of the data was also performed using the Mann-Kendall Trend Test. A summary of the Mann-Kendall analysis of trends for samples from groundwater monitoring wells and piezometers and for sediment samples are provided in Appendix D. Mann Kendall tests were not performed on surface water data, as there are not enough comparable rounds of data collected to perform the tests.

In order to spatially examine the distribution and temporal trends of selected constituents exceeding the PALs (or spatially and temporally extensive source contaminants), key constituent (i.e., 1,1,2,2-PCA, TCE, cis-1,2-DCE, trans-1,2-DCE and VC) plume maps were generated for ME 18 (Fall 2014 Biennial Event) and ME 20 (Fall 2016 Five Year Event). These plume maps are included as Figures 14 through 33 and discussed in detail in Section 3.2. Plume maps were not generated for ME 17 (Fall 2013 Annual Event) and ME 19 (Fall 2015 Annual Event), as these events reflect smaller sampling events and plume maps generated for these events would not be comparable to those of the larger ME 18 and ME 20 events. As stated in the Source Area Investigation Report (Tetra Tech, 2015), while other contaminants exceeding the PALs are observed at Site 07, these five constituents represent persistent concentrations above the PALs and are spatially extensive and temporally consistent.

To further evaluate the spatial and temporal trends of these selected compounds, isocontours were illustrated on cross-sections A-A' and B-B' for ME 18 and ME 20. These isocontour figures are provided as Figures 34 through 53 and discussed in detail in Section 3.2. Plume maps and isocontour figures were drawn according to the data set from that particular monitoring event. For the purposes of the plume maps the shallow zone was considered 0-30 feet bgs while the deep zone was considered 30 feet bgs and deeper. ME 18 represented the Biennial Event list of sampling locations, while ME 20 represented the Five Year Event list of sampling locations. Therefore, the isocontours and plumes were drawn with the data for that particular ME and may not accurately reflect the distribution of contamination in areas which were not sampled as part of that ME.

An extensive spatial and temporal analysis was performed using the available data. The analysis will assist in understanding current conditions and will allow for the estimation of future contaminant migration, where applicable, to ensure the selected remedy remains protective as mandated by the Record of Decision (ROD).

3.1.1 Volatile Organic Compounds in Groundwater Samples from Monitoring Wells

Consistent with previous monitoring reports and the Source Area Investigation Report (Tetra Tech, 2015), VOCs which have been detected in Site 07 groundwater samples collected from monitoring wells during ME 20 at concentrations greater than the PALs include the CVOCs TCE, 1,1,2-TCA, 1,1-DCE, 1,2-DCA, cis-1,2-DCE, trans-1,2-DCE, PCE, VC, and the non-chlorinated VOC benzene. The VOCs, 1,1,2,2-PCA, and chloroform were also detected, but these compounds have no associated PAL. The principle CVOCs discussed in this report include the parent constituent, 1,1,2,2-PCA, degradation product TCE, and TCE daughter products cis-1,2-DCE, trans-1,2-DCE and VC.

1,1,2,2-Tetrachloroethane. No PAL has been established for 1,1,2,2-PCA in the groundwater at Site 07; however, this is a commonly detected compound at NCBC Davisville and a known component of Decontaminating Agent, Non-Corrosive (DANC), and was therefore included in the statistical analysis and discussion.

Consistent with previous MEs, 1,1,2,2-PCA has been detected in shallow / intermediate zone groundwater samples collected from the central portion of the Site and near the entrance channel. The highest concentration of 1,1,2,2-PCA during ME 20 in the shallow / intermediate groundwater zone occurred at MW07-39S (1,650 ug/L). The maximum detected concentrations in the shallow groundwater zone have historically occurred at MW07-19S and MW07-39S. However, statistically-significant downward trends continue to be present at MW07-19S and MW07-39S (see Attachment D).

Detected concentrations of 1,1,2,2-PCA have occurred across much of the Site in the deep groundwater zone. Currently, the highest concentrations of 1,1,2,2-PCA are found in the central portion of the site between MW07-17D and MW07-39-03D with the highest concentration observed during ME 20 at DPT07-39-04D (10,000 ug/L). These wells (where detections greater than 5,000 ug/L occur) are in the central portion of the Site, immediately downgradient from the former source area. In general, 1,1,2,2-PCA concentrations at these wells have fluctuated slightly over time and all exhibit either statistically-significant decreasing trends or no trends.

Between the central portion of the Site and the shorelines, either statistically-significant downward trends or no trends are generally observed. This suggests that, overall, the 1,1,2,2-PCA plume in the deep zone is degrading in some areas and remaining relatively stable in other areas. One exception is MW07-11D, located in the eastern portion of the Site (i.e., toward Narragansett Bay), where an upward trend is observed. However, concentrations for 1,1,2,2-PCA have been 60 ug/L, 57 ug/L, 56 ug/L, and 44 ug/L over the past three monitoring events, respectively. More data is needed to determine if this represents a leveling off or perhaps even a decline in the 1,1,2,2-PCA concentration trend at MW07-11D. For the remainder of the site, concentrations of 1,1,2,2-PCA appear to be either stable or decreasing for the most part.

Trichloroethene. Consistent with previous MEs, TCE has been detected within the shallow / intermediate groundwater zone at concentrations exceeding the PAL (5 ug/L) across the central portion of the Site, from the Entrance Channel near monitoring well MW07-21S north to MW07-41I. The highest concentration in the shallow / intermediate zone observed during ME 20 was at MW07-39S (13,800 ug/L)

In the deep overburden zone, elevated levels of TCE (exceeding the PAL) have been detected across the Site. Values greater than 5,000 ug/L were observed along the primary migration pathway from MW07-15D in the northern central part of the site down to MW07-21D near the entrance channel, with the highest concentration in the deep zone observed at DPT07-39-04D (73,000 ug/L).

Statistically-significant upward trends are observed for TCE concentrations in monitoring wells MW07-09R, MW07-11D, MW07-12D, MW07-19D, MW07-21D, MW07-21R, MW07-24DUT, and MW07-34D. These observations are consistent with the trends observed in the Site Investigation Report (Tetra Tech, 2015) and all these wells except MW07-12D are already sampled annually (MW07-12D is sampled biennially). The recent data from these wells suggests that TCE concentrations may be leveling off. MW07-12D and MW07-24DUT have seen only minor TCE concentrations fluctuations since ME 18. While MW07-21D and MW07-21R saw their highest TCE

concentration during ME 18, TCE concentrations at both wells have decreased since that event. Similarly, MW07-11D and MW07-19D saw their highest TCE concentrations during ME 19, but their TCE concentrations decreased during ME 20. The lowest concentration in five years was observed in MW07-34D during ME 20. These wells with statistically significant upward trends are within the TCE plume boundaries, and these trends along with the recent data indicate that, while the overall plume extents are relatively unchanged, some dissolution, redistribution, and degradation of mass is occurring within the plume. Statistically significant downward trending TCE concentrations are observed at twenty eight monitoring wells sampled during ME 20. No trends were observed for the remaining wells sampled during ME 20 that had enough data to run the Mann Kendall trend test.

cis-1,2-Dichloroethene. cis-1,2-DCE is a degradation product of TCE, and was observed at elevated concentrations throughout the shallow and deep groundwater zones with a spatial distribution similar to TCE. Concentrations of cis-1,2-DCE have exceeded the PAL of 70 ug/L in the shallow / intermediate groundwater zone across the central portion of the Site, at monitoring well locations MW07-19S, MW07-21S, MW07-39I, MW07-39S, MW07-41I, MW07-42I. The highest concentration detected in the shallow / intermediate zone during ME 20 was at MW07-42I (6,100 ug/L).

PAL exceedances of cis-1,2-DCE were also observed in the deep groundwater zone across much of the site during ME 20 at monitoring wells MW07-09D, MW07-11D, MW07-17D,MW07-19D, MW07-21D, MW07-23D, MW07-24D, MW07-27D, MW07-34D, MW07-39D, MW07-40D, MW07-45D, DPT07-39-03D/I, DPT07-09-27D, DPT07-16I and DPT07-39-4D. The highest concentration detected in the deep zone during ME 20 was at DPT07-39-03I (2,990 ug/L).

Eight monitoring wells (MW07-09R, MW07-11D, MW07-19D, MW07-21D, MW07-23D, MW07-24DUT, MW07-27D, MW07-34D) had statistically significant upward trends for cis-1,2-DCE during ME 20. Four of these locations (MW07-19D, MW07-21D, MW07-23D, MW07-27D) saw their highest cis-1,2-DCE concentration during ME 18 and have shown decreasing concentrations since that event. MW07-24DUT has shown very stable concentrations over the past 5 years. MW07-09R has been decreasing in concentration over the past five years, with its lowest concentrations in five years during ME 20. MW07-11D and MW07-34D had their highest cis-1,2-DCE concentrations during ME 19, but their concentrations decreased significantly during ME 20. As mentioned above cis-1,2-DCE is a degradation product of TCE and similar to TCE these trends and recent data indicate that, while the overall plume extents are relatively unchanged, some dissolution, redistribution, and degradation of mass is occurring within the plume. There were 18 statistically significant downward trends for cis-1,2-DCE during ME 20 and the majority of sampled locations (27) had either no observable or no significant trend in concentrations.

trans-1,2-Dichloroethene. During ME 20, concentrations of trans-1,2-DCE exceeded the PAL of 100 ug/L in the shallow / intermediate groundwater zone at four monitoring well locations (MW07-19S, MW07-39I, MW07-39S, MW07-42I) in the central portion of the Site. The highest concentration detected in the shallow/intermediate zone during ME 20 was at MW07-39I (635 ug/L).

PAL exceedances of trans-1,2-DCE were observed in the deep groundwater zone along the primary migration pathway from the center of the site towards the entrance channel at monitoring wells MW07-09D, MW07-17D, MW07-21D, MW07-27D, MW07-39D, DPT07-09-27, DPT07-39-03I and DPT07-39-03D. The highest concentration detected in the deep zone during ME 20 was at MW07-17D (630 ug/L). trans-1,2-DCE is also a degradation product of TCE, and is also observed throughout the shallow and deep groundwater zones.

The concentration trends observed for trans-1,2-DCE are primarily no or not significant trends (35 locations) and decreasing trends (13 locations), compared to only 4 increasing trends (MW07-09R, MW07-11D, MW07-19D, and MW07-34D). Of the four wells with increasing trends, MW07-09R, MW07-19D, and MW07-34D showed the lowest concentration in the past five years during ME 20.

Vinyl Chloride. VC exceeded the PAL of 2 ug/L in groundwater from the shallow / intermediate zone during ME 20 at only three wells (MW07-41I, MW07-42I, MW07-21S) from the central portion of the Site to the shoreline. The highest concentration observed in the shallow / intermediate zone was 140 ug/L at MW07-42I.

In the deep zone, VC was detected above its PAL value at six locations (DPT07-39-04D, DPT07-39-03D, DPT07-39-03I, MW07-39D, MW07-27D and MW07-19D) across the central portion of the site down to the entrance channel, and at low levels below 10 μg/L at two locations on the western shoreline (DPT07-16I, and DPT07-24D).

Similar to trans-1,2-DCE, the concentration trends observed for VC are primarily no or not significant trends (35 locations) or decreasing trends (12 locations) compared to only 7 increasing trends (MW07-09R, MW07-11D, MW07-19D, MW07-27D, MW07-21D, MW07-39S and MW07-34D). Vinyl chloride is the final chlorinated VOC degradation product of TCE and most of the monitoring wells with increasing trends also show increasing trends for TCE and cis-1,2-DCE, indicating that biodegradation of TCE is occurring within the plume.

Other VOCs. The Site 07 VOC list also includes 1,1,2-TCA, chloroform, PCE, benzene, 1,2-DCA, and 1,1-DCE. A statistical summary of these compounds is provided Appendix D.

3.1.2 Volatile Organic Compounds in Groundwater Samples from Piezometers

This section summarizes the VOCs detected at concentrations exceeding PALs in aqueous samples from piezometers sampled during the ME 20 event. The principal VOCs which have been detected in groundwater at concentrations greater than the PALs include the parent compound 1,1,2,2-PCA and its degradation products TCE and VC.

1,1,2,2-Tetrachloroethene. During ME 20 1,1,2,2-PCA was detected at concentrations greater than the PAL of 13.9 ug/L in piezometers P07-07, P07-08, P07-09, and P07-10. These piezometers are located downgradient of the former source area and along the shoreline of the Entrance Channel, and these locations and concentrations are consistent with previous MEs. Concentrations at these shoreline piezometers have fluctuated over time and show either downward or no statistically-significant trend.

Trichloroethene. During ME 20, TCE was detected at concentrations greater than the PAL of 184 ug/L at piezometers P07-08 and P07-09. These locations are along the Entrance Channel shoreline downgradient of the former source area, as noted above, and TCE concentrations at these locations have fluctuated over time and show no statistically-significant trends.

Vinyl Chloride. During ME 20 VC exceeded the PAL of 3.78 ug/L at piezometers P07-05, P07-06, P07-09, and P07-20. VC concentrations at these piezometer locations along the shoreline and downgradient of the former source area have fluctuated over time, with statistically-significant upward trends at P07-05 and P07-06, consistent with previous MEs.

Other VOCs. Additional VOCs that have been detected in piezometers include 1,1,2-TCA, 1,1-DCE, 1,2-DCE, benzene, cis-1,2-DCE and trans-1,2-DCE. A statistical summary of these compounds is provided in Appendix D.

3.1.3 Volatile Organic Compounds in Sediments

The only compound detected in sediment during ME 20 was PCE, detected at a concentration of 12 ug/kg at locations SED07-05 and SED07-10. Consistent with previous reports, since sediment samples are collocated with piezometer samples where elevated detections are found, no further analysis is provided for these limited detections. A statistical summary of detected compounds in sediment is provided in Appendix D. The sediment data was also used as part of a shoreline human health risk assessment (HHRA) update at Site 07. A summary can be found in Section 3.4, the HHRA update in its entirety can be found in Attachment F.

3.1.4 Volatile Organic Compounds in Surface Water

Low detections of CVOCs were observed during the ME 20 event in surface water samples collected at transects beginning at P07-08 and P07-24. The CVOCs 1,2-DCA, cis-1,2-DCE, TCE, and VC were detected along transect P07-24 and cis-1,2-DCE was detected along transect P07-08. All detections were below 10 ug/L. Appendix D contains trend plots and summary tables comparing surface water data collected during ME 20 to the previous surface water sampling event in 2012. As there are only two comparable data points for this media, no further statistical analysis was performed. The surface water data was also used as part of a shoreline HHRA update at Site 07. A summary can be found in Section 3.4, the HHRA update in its entirety can be found in Attachment F.

3.2 Discussion of Contaminant Transport Pathways

In order to facilitate a greater understanding of the extent of groundwater contamination at Site 07, and to provide information to support the upcoming Fourth Five Year Review, updated plume maps and isocontour figures were prepared for TCE, cis-DCE, trans-DCE, 1,1,2,2-DCA, and VC. Plume maps were generated for the shallow and deep overburden zones, and isocontour figures were generated for cross sections A-A' and B-B'. One set of figures was produced using data collected during ME 20, and one set was produced using data collected during ME 18. These maps and figures are presented as Figures 14 through 53. Based on analysis of these updated maps and figures, along with review of the previous conclusions drawn in the Source Area Investigation and Long-Term Monitoring Data Summary Report (Tetra Tech, 2015), the following general conclusions have been made for the ME 20 Five Year Event Monitoring Report:

CVOC contamination in the shallow and intermediate groundwater zones occurs in the central portion of the site and the Entrance Channel.

- Highest concentrations of CVOCs in the shallow / intermediate groundwater zone are observed in wells MW07-42I, MW07-39S/I, MW07-41I and MW07-19S.
- Low level contamination extends to the shoreline piezometers (assumed to contain a mixture of groundwater and surface water).
- Very low or no detections were observed in the shallow/intermediate zone in the north, west, or eastern areas of Site 07.

The highest and most widespread concentrations of CVOCs at Calf Pasture Point are occurring in the deep overburden and shallow bedrock aquifers.

- Highest concentrations site wide occur in approximately the central portion of the Site near the former source area, between MW07-17D and DPT07-39-03.
- Three primary migration pathways are evident from the former source area as concluded in the Source area Investigation Report (Tetra Tech, 2015.) One toward Allen Harbor, one toward the Entrance Channel and one toward Narragansett Bay.
- The flow towards Narragansett Bay has two components, one heading to the east, and one heading towards the south east.
- The largest mass of CVOC contamination is following the primary pathway towards the entrance channel, consistent with the Source Area investigation Report. (Tetra Tech, 2015.)

Along cross-section A-A', CVOC concentrations are highest at the former source area between MW07-17D and DPT07-39-03. Contamination is migrating to the offshore environment through two main vertical pathways. Migration is observed from MW07-39I/S to MW07-42I to MW07-19S to MW07-21S in the shallow zone, and within the deep overburden and shallow bedrock toward MW07-21R in the deep zone.

- The highest concentrations appear to be moving in the deep overburden and shallow bedrock zones towards MW07-21R.
- Lower, but still elevated concentrations are migrating upward through MW07-39I/S, MW07-42I, MW07-19S, MW07-21S, and appear to be discharging near P07-09.

Consistent with previous MEs, contamination along cross section B-B' does not appear to be effectively migrating upward at the Narraganset Bay and Allen Harbor shorelines, likely due to increased silt thickness that limits upward migration on the eastern and western boundaries of Calf Pasture Point.

- Along the western portion of cross-section B-B' contamination does not appear to be migrating upward through the silt layer to the shoreline, as evidenced by the nondetect VOC results in shallow zone wells MW07-04S, MW07-38S, and MW07-33S during ME 20. Concentrations observed in the deep zone of the western portion of cross section B-B' are generally much lower compared to other portions of the plume.
- Along the eastern portion of cross section B-B', contamination does not appear to be reaching the eastern shoreline of Site 07. Low concentration or nondetect results in the MW07-18 cluster and MW07-20 cluster support the conclusion discussed in the Site Investigation Report

(Tetra Tech, 2015) that the silt and clay layers along the eastern shoreline are acting as a confining layer.

These observations are generally consistent with the conclusions reached in the Source Area Investigation Report (Tetra Tech, 2015). However, during ME 20 TCE, cis-1,2-DCE, and VC were detected above their PALs for the first time at well DPT07-16I, suggesting that migration along a new deep zone pathway may be occurring along the northeastern side of the Site. Migration along this pathway is limited to the deep zone, as evidenced by the absence of detected results in DPT07-16S. Therefore, migration along this new pathway does not pose risk to the eastern Narragansett Bay shoreline. In addition, the lateral extent of the pathway appears limited, as evidenced by the nondetect or detected results below the PALs at wells DPT07-09-28D, DPT07-29-34I, MW07-29D, DPT07-18I, MW07-18D, DPT07-30I, and MW07-30D.

The contaminant migration pathways are generally complex, with contaminants moving within different groundwater zones at different locations across the Site. Several wells on Site 07 are tidally influenced, which also adds to the complexity of fate and transport on the site. The tidal cycles may influence contaminant concentrations observed in nearshore groundwater by introducing greater variability in the contaminant concentrations during mid and high tide conditions due to the exchange of fresh and saline groundwater. During low tide the plume is not prevented from discharging into Narragansett Bay. However, discharge at the down gradient shoreline sample locations DPT07-016S and MW07-20S has not been observed, as evidenced by the consistent nondetect VOC results at these locations. In addition, EPA installed and sampled 31 piezometers along the Narragansett Bay shoreline in 2010 and did not detect any TCE. A detailed tidal study was conducted by Tetra Tech from March 21, 2012 through June 11, 2012; the findings of this study are described in the Source Area Investigation Report (Tetra Tech, 2015).

Consistent with previous monitoring events, the location of the highest contamination is near the central portion of the Site, downgradient from the former source area. From a migration perspective, the Entrance Channel appears to be the only shoreline location being effectively reached by contamination. However, low-level contamination also reaches Allen Harbor along the western portion of cross-section B-B', but this is generally confined to the deep overburden and shallow bedrock zones.

Mass balance calculations and specific detailed assessments of attenuation mechanisms for the CVOC plume were not performed as part of the ME 20 Five Year Event Monitoring Report. An analysis of mass balance and natural attenuation mechanisms will be provided in the upcoming Fourth Five Year Review.

3.3 Evaluation of long-term groundwater flow conditions

The hydrogeology for the Site was analyzed with two different methods in order to comprehensively understand how groundwater flows in the subsurface between the former source area and shorelines. Synoptic water level measurements were collected during each ME to provide hydraulic head data for the development of potentiometric maps for the evaluation of groundwater flow directions and estimation of hydraulic gradients. During each ME, a synoptic round of groundwater level measurements was collected from 55 monitoring wells and a staff gauge in Allen Harbor within a time frame of 45 minutes at mid-tide conditions. Since tides significantly impact the Site, a long-term tidal study was performed over several months in 2012 and data analyzed in order to determine transient flow and gradients. A summary of this event is provided in the Source Area Investigation Report (Tetra Tech, 2015). This section provides a discussion of hydrogeological interpretations made based on the synoptic water level data collected during ME 20 and since 1995.

3.3.1 Synoptic Groundwater Flow

Synoptic groundwater measurements were recorded on September 22, 2016 in 53 monitoring wells at Site 07. Measurements were not taken at MW07-05R due to an ongoing bedrock study by CB&I, and measurements were not taken at MW07-20D due to damage to the well (see Section 2.2). These groundwater measurements and the corresponding groundwater elevations from ME 20 are summarized on Table 2. A surface water level reading was also recorded from the Allen Harbor Staff Gauge as part of the synoptic water level measurements. Groundwater measurements were recorded during outgoing mid-tide within a 45 minute window to minimize the transient effects tide has on groundwater levels (and flow) at Site 07. Groundwater potentiometric contours were created using a kriging algorithm in Surfer® 9 modeling software for three distinct units of the aquifer at the Site: shallow and intermediate overburden, deep overburden, and bedrock. Potentiometric contour maps are presented for each depth interval as Figures 9, 10, and 11, respectively.

In general, groundwater flow directions at Site 07 are similar for the shallow and deep zones and are similar between monitoring events. Groundwater elevations are not expected to vary significantly based on the control elevation of the surrounding surface water. The following sections present a more detailed groundwater flow analysis for each groundwater zone.

Groundwater contours were also developed to show vertical groundwater flow along two transects trending approximately north to south (Transect A-A',Figure 12) and west to east (Transect B-B', Figure 13) across Site 07. The locations of these transects are presented on Figure 2. The associated cross sections incorporate all vertical depth intervals (i.e., shallow and intermediate

overburden, deep overburden, bedrock) to produce vertical head distributions. Vertical flow shown on cross sections A-A' and B-B' during ME 20 indicate slightly different flow patterns in the northern area of the site to previous year's maps due to lack of data at MW07-05R. The comparatively high groundwater elevation at this well observed in ME 17 through 19 as well as previous MEs creates a zone of upwelling in the northern area of Site 07 which is not reflected during ME 20 in Figures 12 and 13. It is assumed this area of upwelling is still present, however as Figures 12 and 13 were created using only data available from ME 20, these features are not observed.

3.3.2 Groundwater Flow Zones

The following sections describe groundwater flow by zone at Site 07.

Shallow Intermediate (Overburden) Zone

The shallow and intermediate overburden potentiometric surface is presented on Figure 9. Based on the groundwater elevation contours, groundwater generally flows from north to south across Site 07, with localized deviations. On the northwestern portion of Site 07, groundwater flows northeast to southwest, toward Allen Harbor. In central portions of Site 07, groundwater flows from northwest to southeast toward the Allen Harbor entrance channel and Narragansett Bay. Based on the groundwater contours, groundwater flow along the eastern portions of Site 07 is from north to south with a portion of the groundwater turning southwest toward the Allen Harbor entrance channel and a portion flowing toward Narragansett Bay, which is consistent with previous monitoring events. Based on groundwater contour maps, groundwater flow from the majority of the Site appears to be focused toward the Allen Harbor entrance channel.

Generally, the gradients are fairly uniform throughout the Site, especially from the vicinity of the bedrock outcrop in the northern portion of the site toward the shoreline of Allen Harbor and the Entrance Channel. Gradients are gentler (i.e., flatter) between the vicinity of the bedrock outcrop toward Narragansett Bay.

Deep (Overburden) Zone

The deep overburden potentiometric surface is presented on Figure 10. Based on the groundwater elevation contours, groundwater flows radially from the northwestern portions of the Site. In the western portion of the Site, groundwater flows northeast to southwest toward Allen Harbor. In eastern portions of the Site, groundwater generally flows from north to south, with components flowing northwest to southeast. The lowest observed groundwater elevation occurred at MW07-11D, upgradient of Narragansett Bay. It should be noted that historically, the lowest groundwater elevation is observed at MW07-20D, but as mentioned in Section 3.3.1 MW07-20D was not

available for the ME 20 synoptic water level measurements. The highest groundwater elevations are consistently in the vicinity of the bedrock outcrop. Water level elevations were approximately 3 to 4 feet above MSL in the vicinity of the bedrock outcrop and approximately 0.5 to 3 feet above MSL along the shorelines. Ultimately, deep groundwater would flow towards and beneath Narragansett Bay, but discharge to the shoreline is unlikely due to laterally extensive silt.

Bedrock Zone

The bedrock potentiometric surface is presented on Figure 11. Based on limited bedrock groundwater elevation data, groundwater flows radially from the Site 07 former source area southwest toward Allen Harbor, south toward the Allen Harbor entrance channel, and southeast toward Narragansett Bay. The lack of a synoptic water level measurement from MW07-05R (see Section 3.3.1) did not change the interpretation of bedrock groundwater flow as compared to previous MEs.

Overall, the gradient appears to be fairly uniform throughout the Site from the vicinity of the bedrock outcrop and central portions of the Site to the shorelines. Approximately 0.5 feet of elevation change occurs over this distance (highest elevations of Site to shoreline). As such, gradients are higher toward Allen Harbor and the Entrance Channel compared to Narragansett Bay since the total travel distance is shorter and potentiometric elevation along the shorelines is similar.

Cross Section – Vertical Flow

Cross section A-A' is located in the central portion of Site 07 and trends north to south originating in the former source area at Site 07 and ending in the Allen Harbor entrance channel (see Figure 2). The cross section A-A' groundwater contours are presented on Figure 12. As indicated by the groundwater contours, groundwater flows vertically downward with a component flowing horizontally from the north to south at the start of the cross section. In central to downgradient portions of the cross section, groundwater flow is horizontal to the south, with a slight upward vertical component in the south.

Cross section B-B' trends west to east from Allen Harbor to Narragansett Bay (see Figure 2). The cross section B-B' groundwater contours are presented on Figure 13. As shown on the cross section, in western portions of the cross section, groundwater flows vertically upwards and then downward from the west. In eastern portions of the cross section, flow is trending slightly upward and horizontally to the east.

3.3.3 Comparison with Previous Events

The hydrogelogy and groundwater flow observed during ME 20 is consistent with the previous three MEs. Groundwater elevations may vary from event to event, but overall groundwater flow pathways are generally uniform over the course of time. The highest groundwater elevations are consistently observed in the northern portion of the Site, near the bedrock outcrop, and the lowest are observed along the shoreline. Overall, groundwater flow is radial from the bedrock outcrop toward the eastern, southern and western shorelines of Calf Pasture Point. No significant changes in groundwater flow interpretation have been noted since the conclusions drawn in the Source Area Investigation Report (Tetra Tech, 2015).

3.4 Updated Human Health Risk Assessment Update

A HHRA update was conducted for the shoreline surface water, sediment, and groundwater in shallow piezometers at Site 07. An ecological risk assessment (ERA) update was not performed as part of the ME 20 Five Year Event Monitoring Report but will be performed as part of the upcoming Fourth Five Year Review. The objective of this HHRA update (also referred to as the 2017 HHRA update) is to determine whether there have been any changes and/or updates to USEPA HHRA guidance or site-specific conditions since the 2012 HHRA performed in support of the Third Five-Year Review Report (Tetra Tech, 2013) that would result in a change of the conclusions of the 2012 HHRA, or whether the conclusions of the 2012 HHRA remain valid. This section provides a summary of the HHRA update. The full HHRA update is provided as **Attachment F**.

Revised formal risk/hazard calculations were not performed as part of this 2017 HHRA update. However, a quantitative evaluation of the potential exposure to Site 07 shoreline shallow groundwater, surface water, and/or sediment by recreational users was conducted to determine whether updates to the 2012 HHRA would result in cumulative potential cancer risk and/or noncancer hazard above USEPA and RIDEM target risk/hazard levels.

The 2012 HHRA (Tetra Tech, 2013) concluded that the potential risks associated with potential human exposure to surface water, sediment, and shallow groundwater did not exceed United States Environmental Protection Agency (USEPA) or Rhode Island Department of Environmental Management (RIDEM) target levels. Potential risk associated with the consumption of shellfish obtained off the shoreline of Allen Harbor was identified above USEPA and RIDEM target levels for arsenic, mercury, and polychlorinated biphenyls (PCBs), however, these chemicals were determined not to be related to Site 07 activities.

Data evaluated in the 2017 HHRA update were selected to be representative of current conditions, and include shallow groundwater samples collected from the twenty shoreline piezometers located

on the southern and western boundaries of Site 07 between October 2013 and September 2016; surface water samples collected from three depths along ten transects located along the southern boundary of Site 07; and sediment samples collected in August 2016 from six locations along the southern boundary of Site 07.

The receptors and exposure pathways evaluated in the 2017 HHRA update are consistent with those evaluated in the 2012 HHRA based on current and potential future land use, including recreational users exposed to shoreline media while swimming, wading, or clamming/harvesting shellfish.

The overall conclusion of this 2017 HHRA update is that the conclusions of the 2012 HHRA remain valid and exposure to shallow groundwater, surface water, and sediment along the Site 07 shoreline by recreational users does not result in a potential excess lifetime cancer risk (ELCR) or noncancer hazard index (HI) above USEPA or RIDEM target levels. The potential cancer risk and noncancer HI results are summarized by receptor, as follows:

3.4.1 Current/Future Recreational Users – Swimming and Wading Scenarios

Child, adolescent, adult, and lifelong recreational users were evaluated for exposure to shoreline surface water and sediment via incidental ingestion and dermal contact while swimming or wading. No sediment chemicals of potential concern (COPCs) were identified (i.e., sediment concentrations are less than risk-based screening levels). This exposure scenario was evaluated based on surface water samples collected at low tide at the harbor floor and mid-point of the water column. Samples collected in surface water approximately three feet deep (i.e., Depths 2 and 3/Case 1) were utilized for evaluation of the swimming scenario. Samples collected in surface water approximately six inches deep (i.e., Depth 1/Case 3) were utilized for evaluation of the wading scenario.

The potential cumulative ELCRs associated with a recreational user wading scenario are less than USEPA's target risk range of 10^{-6} to 10^{-4} and RIDEM's target risk level of 10^{-5}. The total HI is less than USEPA/RIDEM's target HI of 1.

The potential cumulative ELCRs and HI associated with a recreational user wading scenario are less than or within USEPA's target risk range of 10^{-6} to 10^{-4}, and less than USEPA/RIDEM's target HI of 1, respectively. However, the potential cumulative ELCR associated with the child and lifelong recreational user wading scenario is slightly higher than RIDEM's target risk level of 10^{-5}. VC in surface water (incidental ingestion exposure route) was identified as the risk driver causing the exceedance of RIDEM's target risk level based on the exposure point concentration (EPC) equal to the one detected concentration. Due to the low frequency of detection (approximately 0.03

percent), VC is not identified as a surface water chemical of concern (COC). The total potential cumulative ELCRs for the child and lifelong recreational user wading scenario are less than 10^{-5} if vinyl chloride is excluded as a COPC.

These results indicate that the conclusions of the 2012 HHRA, which indicated that potential exposures to sediment and surface water along the Site 07 shoreline by recreational users while swimming or wading do not pose a cancer risk or noncancer hazard above USEPA or RIDEM target levels. As a result, adverse health effects are not anticipated for this receptor.

3.4.2 Current/Future Recreational Users – Shell Fisherman

Adolescent and adult recreational users were evaluated for exposure to shallow groundwater along the shoreline via dermal contact; and exposure to shoreline surface water and sediment via incidental ingestion and dermal contact while clamming/harvesting shellfish. No sediment COPCs were identified (i.e., sediment concentrations are less than risk-based screening levels). This exposure scenario was evaluated based on surface water samples collected at low tide at the harbor floor and mid-point of the water column where water is approximately six inches deep (i.e., Depths 1 and 2/Case 3), and shallow groundwater samples within each of the groundwater exposure points (Southern Boundary, Shoreline, Western Boundary, Mid-Southern Boundary).

The potential cumulative ELCRs associated with a recreational user – shell fisherman scenario are less than USEPA's target risk range of 10^{-6} to 10^{-4} and RIDEM's target risk level of 10^{-5}. The total HI is less than USEPA/RIDEM's target HI of 1. These results indicate that the conclusions of the 2012 HHRA, which indicated that potential exposures to shallow groundwater, sediment, and surface water along the Site 07 shoreline by recreational users while clamming/harvesting shellfish do not pose a cancer risk or noncancer hazard above USEPA or RIDEM target levels, remain valid. As a result, adverse health effects are not anticipated for this receptor.

4.0 QUALITY ASSURANCE/QUALITY CONTROL

The data obtained during ME 20 were determined to be of sufficient quality to be used to evaluate the long-term effectiveness of the remedial action (i.e., long-term monitoring and 5-year reviews). Quality assurance/quality control (QA/QC) samples collected during this sampling event included matrix spike/matrix spike duplicate (MS/MSD) samples, field duplicate samples, and trip blanks. Select non-compliances for accuracy, precision, and sensitivity are discussed in the data validation reports but are not expected to impact the overall usability of the data. Laboratory result data was 98.7% complete, with the following exceptions:

- The non-detected result for 1,1,2,2-tetrachloroethane in sediment sample SED07-10-ME20-1 was rejected (R) due to low internal standard areas. The affected result is not usable for project decisions.
- A total of twenty (20) non-detected results were rejected (R) in groundwater samples MW07-13S-ME20-1 and MW07-13D-ME20-1 due to holding time exceedances. The affected results are not usable for project decisions.

The analytical results from samples collected during ME 20 were subject to Tier I Plus (stage 2B manual) validation in accordance with the Draft Tier II LTM SAP (Resolution, 2016); *Region I, EPA New England Environmental Data Review Program Guidance (April 2013); EPA New England Environmental Data Review Supplement for Regional Data Review Elements and Superfund Guidance/Procedures (April 2013);* and *National Functional Guidelines for Evaluation Organic Data Review* (September 2016). Standard EPA data qualifiers were assigned to the data during validation to assess data quality. These qualifiers include “J”, “UJ”, “U”, and “R” are defined in the data validation memoranda presented in Attachment B. The validated analytical data are presented in Tables 5 and 6.

5.0 SITE INSPECTION ACTIVITIES

Site inspection activities at Site 07 were completed on September 23, 2016 in accordance with the Final Land-Use Control Implementation Plan (EA, 2002). The on-site monitoring wells were observed to be capped, labeled, locked, and in good condition, with the exception of MW07-20D, which was found to be inundated with sand at the time of inspection. Weathered padlocks were replaced on select wells as needed during the ME 20 field activities. A copy of the LUCIP checklist is provided in Appendix C.

The MW07-20 well pair was abandoned and re-installed by Resolution Consultants in December 2016 (see Section 2.1). During the MW07-20 well pair installation activities on December 12, 2016, Resolution observed that the Town of North Kingstown had excavated soils from the access road at Calf Pasture Point. The excavated area was approximately 20 feet wide by 100 feet long and 1 to 2 feet deep. The soil was transported inland and staged along the side of the access road. The excavated area was backfilled with sand from unknown origin.

6.0 CONCLUSIONS

As required by the ROD for Site 07, LTM was performed between 2013 and 2016, in accordance with the updated LTM scope and protocols that are currently being memorialized in the Draft Tier II LTM SAP (Resolution, 2016). Recommendations in the Source Are Investigation Report (Tetra Tech, 2015) have been implemented and the conclusions drawn in that report have been updated and evaluated based on new site data collected during ME 17 through ME 20. The following general conclusions are presented based on the comprehensive evaluation of site data:

- Analysis of Mann Kendall trend test data indicates that groundwater concentration trends are generally consistent and stable throughout the site since the Source Area Investigation (Tetra Tech, 2015). Therefore, the current reporting schedule of performing Mann Kendall trend tests once every five years is sufficient.
- The primary plume migration pathways described in the Source Area Investigation Report (Tetra Tech, 2015) remain consistent. The plumes appear generally stable with some localized increasing trends likely due to localized plume redistribution. These wells with statistically significant upward trends are within the TCE plume boundaries, and these trends along with the recent data indicate that, while the overall plume extents are relatively unchanged, some dissolution, redistribution, and degradation of mass is occurring within the plume.
- Along the western portion of Site 07, contamination does not appear to be migrating upward through the silt layer to the shoreline, as evidenced by the nondetect VOC results in shallow zone wells MW07-04S, MW07-38S, and MW07-33S during ME 20. Concentrations observed in the deep zone of the western portion of Site 07 are generally much lower compared to other portions of the plume.
- During ME 20 TCE, cis-1,2-DCE, and VC were detected above their PALs for the first time at well DPT07-16I, suggesting that migration along a new deep zone pathway may be occurring along the northeastern side of the Site. However, along the eastern portion of Site 07, contamination does not appear to be migrating up to the shallow zone along the eastern shoreline of Site 07. Low concentration or nondetect results in monitoring wells MW07-18S and MW07-20S support the conclusion discussed in the Site Investigation Report (Tetra Tech, 2015) that the silt and clay layers along the eastern shoreline are acting as a confining layer.
- Based on very low or nondetect concentrations in the sediment and surface water data, the current sampling schedule of once every five years is sufficient for these media.
- The Source Area Investigation Report (Tetra Tech 2015) concluded that sampling in different seasons does not appear to impact contaminant concentrations at any groundwater or

piezometer locations with the possible exception of MW07-21S, P07-05 and P07-24. Monitoring events since 2012 have been conducted annually in the fall, therefore no further evaluation of seasonality have been performed.

- The overall conclusion of this 2017 HHRA update is that the conclusions of the 2012 HHRA remain valid and exposure to shallow groundwater, surface water, and sediment along the Site 07 shoreline by recreational users does not result in a potential ELCR or noncancer HI above USEPA or RIDEM target levels.

Based on concentrations of CVOCs observed through ME 20, the relative stability and/or degradation of the plume that is interpreted to be occurring, and the overall conclusion of the 2017 HHRA update, the remedy continues to be protective of human health and the environment. However, since TCE, cis-1,2-DCE, and VC were detected above their PALs for the first time at well DPT07-16I during ME 20, the upcoming Fourth Five Year Review should consider increasing the sample frequency of DPT07-16I to monitor these changes. The upcoming Fourth Five Year Review should also consider increasing the sample frequency of DPT07-16S to monitor any potential upward migration of COCs from DPT07-16I.

7.0 SCHEDULE OF FUTURE FIELD ACTIVITIES

Monitoring Event 21 at Calf Pasture Point is scheduled to occur in September/October 2017. This will include the annual suite of monitoring wells and piezometers (see Table 1).

MW07-32R			X	Bladder	Site 16	Evaluate GW beyond Spink Neck

Notes:

(1) Sediment sample will be collected co-located with piezometer
(2) A surface water sampling transect will originate at this location and run perpendicular to the shore. Three samples per transect will be collected as decribed in Worksheet 17-1.
Analytical for site specific list of VOCs
(3) The MW07-20 well pair was abandoned and reinstalled in December 2016. The reinstalled wells were named MW07-20SA and MW07DA. See the Site 07 ME20 Five Year Event Report for details.

GROUNDWATER SAMPLE LOG SHEET

Event: ME 20
Site Name: NCBC DAVISVILLE IRP SITE 07
Project No: 60273164 LT.F1

Sample ID: DPT07-30I-ME20-1
Well ID: DPT07-30I
QC Duplicate ID: NA
Sampler: Tom Croft
Well Type: Monitoring Well
MS/MSD: NA

Well Information

Well Diameter (in.):	1.5	Static Water Level (ft-BTOR):	5.23
Top of Screen (ft-BTOR):	45	H/S PID Monitor Reading (ppm):	0.0
Bottom of Screen (ft-BTOR):	55	Purge Method:	Low Flow - peristaltic
		Sample Method:	Low Flow - peristaltic

Purge Information

Date	Time	Level (ft-BTOR)	Rate (ml/min)	Color	ODOR	pH (S.U. units)	S.C. (uS/cm)	DO (mg/l)	Turbidity (NTUs)	Temp (C)	ORP (mV)	Salinity (ppt)

TB-081616-1	Trip Blank

Data validation activities were conducted with reference to

- *DoD Quality Systems Manual (QSM) for Environmental Laboratories, version 5.0* (July 2013);
- *Test Methods for Evaluating Solid Waste, Physical/Chemical Methods SW846, specifically SW-846 Method 8260C, Volatile Organic Compounds by Gas Chromatography/Mass Spectrometry* (USEPA, 2006);
- *EPA New England Environmental Data Review Program Guidance* (April 2013);
- *EPA New England Environmental Data Review Supplement for Regional Data Review Elements and Superfund Specific Guidance/Procedures* (April 2013);
- *USEPA National Functional Guidelines for Superfund Organic Methods Data Review* (September 2016);
- laboratory quality control (QC) limits, as applicable.

The USEPA Region 1 and National Data Validation Functional Guidelines were modified to accommodate the non-CLP methodologies. In the absence of method-specific information, laboratory quality control (QC) limits, DoD QSM 5.0, or project-specific requirements, Resolution Consultants professional judgment was used as appropriate.

REVIEW ELEMENTS

The data were evaluated based on the following review elements (where applicable to the method):

✓	Data completeness (chain-of-custody [COC])/sample integrity
✓	Holding times and sample preservation
✓	GC/MS performance checks
✗	Initial calibration/continuing calibration verification
✓	Laboratory blanks/trip blanks/equipment blanks
✓	Surrogate spike recoveries
✓	Matrix spike (MS) and/or matrix spike duplicate (MSD) results
✓	Laboratory control sample (LCS)/laboratory control sample duplicate (LCSD) results
NA	Field duplicates
✓	Internal standards
✓	Sample results/reporting issues

The symbol (✓) indicates that no validation qualifiers were applied based on this parameter. NA indicates that the parameter was not included as part of this data set or was not applicable to this validation and therefore not reviewed. The symbol (✗) indicates that a QC nonconformance resulted in the qualification of data. Any QC nonconformance that resulted in the qualification of data is discussed below. In addition, nonconformances or other issues that were noted during validation, but did not result in qualification of data, may be discussed for informational purposes only.

The data appear valid as reported and may be used for decision making purposes. Selected data points were qualified as estimated due to nonconformances of certain QC criteria (see discussion below). Qualified sample results are presented in Table 1.

RESULTS

Data Completeness (COC)/Sample Integrity

The data package was reviewed and found to meet acceptance criteria for completeness:

- The COCs were reviewed for completeness of information relevant to the samples and requested analyses, and for signatures indicating transfer of sample custody.
- The laboratory sample login sheet(s) were reviewed for issues potentially affecting sample integrity, including the condition of sample containers upon receipt at the laboratory.
- Completeness of analyses was verified by comparing the reported results to the COC requests.

Holding Times and Sample Preservation

Sample preservation and preparation/analysis holding times were reviewed for conformance with the QC acceptance criteria. The QC acceptance criteria were met.

GC/MS Performance Checks

The data were reviewed to ensure that the 4-bromofluorobenzene (BFB) tuning was performed at the correct frequency and that the method acceptance criteria were met. All samples were analyzed within 12 hours of the BFB tunes.

Initial Calibration/Continuing Calibration Verification

Calibration data were reviewed for conformance with the QC acceptance criteria to ensure that:

- the initial calibration (ICAL) percent relative standard deviation (%RSD), correlation coefficient (r)/coefficient of determination (r2), and/or response factor (RF) method acceptance criteria were met;
- the initial calibration verification standard (ICV) percent recovery acceptance criteria were met;
- the continuing calibration verification standard (CCV) method percent difference or percent drift (%Ds) and RF acceptance criteria were met; and
- the retention time method acceptance criteria were met.

Nonconformances are summarized in Attachment A in Table A-1. Data qualification to the analytes associated with the specific ICAL and/or CCV was as follows:

ICAL and CCV Response Factor Nonconformances

Criteria	Actions	
	Detected Results	Nondetected Results[2]
RF<minimum RF (Table 4 method 8260C)	J	R[1]
[1]Resolution Consultants professional judgment may be used to either raise reporting level or to estimate reporting limit if low standard response is adequate.		
[2]Sample results qualified as not detected (U) due to blank contamination are not rejected, but estimated (UJ).		

ICAL Linearity Nonconformances

Criteria	Actions	
	Detected Results	Nondetected
%RSD > 15% and quantitation based on mean RF	J	UJ
r or r^2 < 0.99 and quantitation based on linear regression	J*	UJ*
* No guidance in NFG, thus Resolution Consultants professional judgment was used		

ICV Recovery Nonconformances

Criteria	Actions*	
	Detected Results	Nondetected Results
Recovery > 120%	J+	No qualification
Recovery < 80%	J-	UJ
* No guidance in NFG, thus Resolution Consultants professional judgment was used		

CCV Linearity Nonconformances

Criteria		Actions	
		Detected Results	Nondetected Results
Opening CCV	Closing CCV		
%D > 20%	%D > 50%	J	UJ
%Drift >20%	%Drift >50%	J*	UJ*
* No guidance in NFG, thus Resolution Consultants professional judgment was used			

Qualified sample results are shown in Table 1.

Laboratory Blanks/Trip Blanks/Equipment Blanks

Laboratory method blanks and trip blanks were evaluated as to whether there were contaminants detected above the detection limit (DL). Equipment rinsate blanks were not collected for surface water samples.

Data validation qualifications for individual samples are based on the maximum contaminant concentration detected in all associated blanks.

Detected results in blanks are not discussed in this data validation report if the associated results were nondetect or if qualification of sample results was not required.

The QC acceptance criteria were met and/or qualification of the sample results was not required. There were no detected target analytes reported in trip blank sample TB-081616-1.

Surrogate Spike Recoveries

The surrogate recoveries (%Rs) were reviewed for conformance with the QC acceptance criteria. All QC acceptance criteria were met.

MS and/or MSD Results

The MS/MSD %Rs and relative percent differences (RPDs) were reviewed for conformance with the QC acceptance criteria. The QC acceptance criteria were met and/or qualification of the sample results was not required.

LCS/LCSD Results

The LCS/LCSD %Rs and/or RPDs were reviewed for conformance with the QC acceptance criteria. All QC acceptance criteria were met.

Field Duplicates

There were no field duplicate samples submitted with this data set. No validation actions were taken on this basis.

Internal Standards

The internal standard (IS) recoveries were reviewed for conformance with the QC acceptance criteria. All QC acceptance criteria were met.

Sample Results/Reporting Issues

All compounds detected at concentrations less than the limit of quantitation (LOQ) but greater than the DL were qualified by the laboratory as estimated (J). This "J" qualifier was retained during data validation.

The LOQs for vinyl chloride and 1,1-dichloroethene are greater than the Project Action Limit (PAL). The limit of detection (LOD) and the DL are less than the PAL. Results are usable for project objectives.

QUALIFICATION ACTIONS

Sample results qualified as a result of validation actions are summarized in Table 1. All actions are described above.

Attachment B

Qualifier Codes and Explanations

Qualifier	Explanation
J	The analyte was positively identified; the associated numerical value is the approximate concentration of the analyte in the sample.
J+	The analyte was positively identified; the associated numerical value is the approximate concentration of the analyte in the sample and is potentially biased high.
J-	The analyte was positively identified; the associated numerical value is the approximate concentration of the analyte in the sample and is potentially biased low.
JN	The analyte was tentatively identified; the associated numerical value is the approximate concentration of the analyte in the sample.
UJ	The analyte was not detected above the reported sample quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the actual quantitation limit necessary to accurately and precisely measure the analyte in the sample.
U	The analyte was analyzed for, but was not detected above the reported sample quantitation limit.
R	The sample results are rejected due to serious deficiencies in the ability to analyze the sample and meet quality control criteria. The presence or absence of the analyte cannot be verified.

Attachment C

Reason Codes and Explanations

Reason Code	Explanation
be	Equipment blank contamination
bf	Field blank contamination
bl	Laboratory blank contamination
bt	Trip blank contamination
c	Calibration issue
d	Reporting limit raised due to chromatographic interference
fd	Field duplicate RPDs
h	Holding times
i	Internal standard areas
k	Estimated Maximum Possible Concentration (EMPC)
l	LCS or OPR recoveries
lc	Labeled compound recovery
ld	Laboratory duplicate RPDs
lp	Laboratory control sample/laboratory control sample duplicate RPDs
m	Matrix spike recovery
md	Matrix spike/matrix spike duplicate RPDs
nb	Negative laboratory blank contamination
p	Chemical preservation issue
r	Dual column RPD
q	Quantitation issue
s	Surrogate recovery
su	Ion suppression
t	Temperature preservation issue
x	Percent solids
y	Serial dilution results
z	ICS results

Reviewed by:	Lori Herberich/Resolution Consultants	File Name: R0762_VOC

SUMMARY

The samples listed below were collected by Resolution Consultants from the Site 07 Calf Pasture Point LTM, Former NCBC Davisville site on August 16, 2016.

Sample ID	Matrix/Sample Type
SW07-02-FLOOR01-ME20-1	Surface water
SW07-02-FLOOR01-ME20-2	Field Duplicate of SW07-02-FLOOR01-ME20-1
SW07-02-FLOOR02-ME20-1	Surface water
SW07-04-FLOOR02-ME20-2	Field Duplicate of SW07-02-FLOOR02-ME20-1
SW07-02-MID01-ME20-1	Surface water
SW07-20-FLOOR01-ME20-1	Surface water
SW07-20-FLOOR02-ME20-1	Surface water
SW07-20-FLOOR02-ME20-2	Field Duplicate of SW07-20-FLOOR02-ME20-1
SW07-20-MID01-ME20-1	Surface water
SW07-24-FLOOR01-ME20-1	Surface water
SW07-24-FLOOR02-ME20-1	Surface water
SW07-24-MID01-ME20-1	Surface water
SW07-43S/D-FLOOR01-ME20-1	Surface water
SW07-43S/D-FLOOR02-ME20-1	Surface water
SW07-43S/D-MID01-ME20-1	Surface water

Data validation activities were conducted with reference to

- *DoD Quality Systems Manual (QSM) for Environmental Laboratories, version 5.0* (July 2013);
- *Test Methods for Evaluating Solid Waste, Physical/Chemical Methods SW-846, specifically SW-846 Method 8260C, Volatile Organic Compounds by Gas Chromatography/Mass Spectrometry* (USEPA, 2006);
- *EPA New England Environmental Data Review Program Guidance* (April 2013);

- *EPA New England Environmental Data Review Supplement for Regional Data Review Elements and Superfund Specific Guidance/Procedures* (April 2013);
- *USEPA National Functional Guidelines for Superfund Organic Methods Data Review* (September 2016);
- laboratory quality control (QC) limits, as applicable.

The USEPA Region 1 and National Data Validation Functional Guidelines were modified to accommodate the non-CLP methodologies. In the absence of method-specific information, laboratory quality control (QC) limits, DoD QSM 5.0, or project-specific requirements, Resolution Consultants professional judgment was used as appropriate.

REVIEW ELEMENTS

The data were evaluated based on the following review elements (where applicable to the method):

✓	Data completeness (chain-of-custody [COC])/sample integrity
✓	Holding times and sample preservation
✓	GC/MS performance checks
✗	Initial calibration/continuing calibration verification
✓	Laboratory blanks/trip blanks/equipment blanks
✓	Surrogate spike recoveries
✗	Matrix spike (MS) and/or matrix spike duplicate (MSD) results
✓	Laboratory control sample (LCS)/laboratory control sample duplicate (LCSD) results
✓	Field duplicates
✓	Internal standards
✓	Sample results/reporting issues

The symbol (✓) indicates that no validation qualifiers were applied based on this parameter. NA indicates that the parameter was not included as part of this data set or was not applicable to this validation and therefore not reviewed. The symbol (✗) indicates that a QC nonconformance resulted in the qualification of data. Any QC nonconformance that resulted in the qualification of data is discussed below. In addition, nonconformances or other issues that were noted during validation, but did not result in qualification of data, may be discussed for informational purposes only.

The data appear valid as reported and may be used for decision making purposes. Selected data points were qualified as estimated due to nonconformances of certain QC criteria (see discussion below). Qualified sample results are presented in Table 1.

RESULTS

Data Completeness (COC)/Sample Integrity

The data package was reviewed and found to meet acceptance criteria for completeness:

- The COCs were reviewed for completeness of information relevant to the samples and requested analyses, and for signatures indicating transfer of sample custody.
- The laboratory sample login sheet(s) were reviewed for issues potentially affecting sample integrity, including the condition of sample containers upon receipt at the laboratory.

- Completeness of analyses was verified by comparing the reported results to the COC requests.

Holding Times and Sample Preservation

Sample preservation and preparation/analysis holding times were reviewed for conformance with the QC acceptance criteria. The QC acceptance criteria were met.

GC/MS Performance Checks

The data were reviewed to ensure that the 4-bromofluorobenzene (BFB) tuning was performed at the correct frequency and that the method acceptance criteria were met. All samples were analyzed within 12 hours of the BFB tunes.

Initial Calibration/Continuing Calibration Verification

Calibration data were reviewed for conformance with the QC acceptance criteria to ensure that:

- the initial calibration (ICAL) percent relative standard deviation (%RSD), correlation coefficient (r)/coefficient of determination (r2), and/or response factor (RF) method acceptance criteria were met;
- the initial calibration verification standard (ICV) percent recovery acceptance criteria were met;
- the continuing calibration verification standard (CCV) method percent difference or percent drift (%Ds) and RF acceptance criteria were met; and
- the retention time method acceptance criteria were met.

Nonconformances are summarized in Attachment A in Table A-1 and A-2. Data qualification to the analytes associated with the specific ICAL and/or CCV was as follows:

ICAL and CCV Response Factor Nonconformances

Criteria	Actions	
	Detected Results	Nondetected Results[2]
RF<minimum RF (Table 4 method 8260C)	J	R[1]
[1]Resolution Consultants professional judgment may be used to either raise reporting level or to estimate reporting limit if low standard response is adequate.		
[2]Sample results qualified as not detected (U) due to blank contamination are not rejected, but estimated (UJ).		

ICAL Linearity Nonconformances

Criteria	Actions	
	Detected Results	Nondetected
%RSD > 15% and quantitation based on mean RF	J	UJ
r or r^2 < 0.99 and quantitation based on linear regression	J*	UJ*
* No guidance in NFG, thus Resolution Consultants professional judgment was used		

ICV Recovery Nonconformances

Criteria	Actions*	
	Detected Results	Nondetected Results
Recovery > 120%	J+	No qualification
Recovery < 80%	J-	UJ
* No guidance in NFG, thus Resolution Consultants professional judgment was used		

CCV Linearity Nonconformances

Criteria		Actions	
		Detected Results	Nondetected Results
Opening CCV	Closing CCV		
%D > 20%	%D > 50%	J	UJ
%Drift >20%	%Drift >50%	J*	UJ*
* No guidance in NFG, thus Resolution Consultants professional judgment was used			

Qualified sample results are shown in Table 1.

The RF for tetrachloroethene did not meet the method 8260C requirements for continuing calibrations as required by the QSM. The nonconformances are summarized in Table A-2. The RF results for tetrachloroethene met the National Functional Guidelines requirements. Professional judgement was used to qualify the affected results for tetrachloroethene as estimated (UJ).

Laboratory Blanks/Trip Blanks/Equipment Blanks

Laboratory method blanks and trip blanks were evaluated as to whether there were contaminants detected above the detection limit (DL). Equipment rinsate blanks were not collected with surface water samples.

Data validation qualifications for individual samples are based on the maximum contaminant concentration detected in all associated blanks.

Detected results in blanks are not discussed in this data validation report if the associated results were nondetect or if qualification of sample results was not required.

The QC acceptance criteria were met and/or qualification of the sample results was not required.

Surrogate Spike Recoveries

The surrogate recoveries (%Rs) were reviewed for conformance with the QC acceptance criteria. All QC acceptance criteria were met.

MS and/or MSD Results

The MS/MSD %Rs and relative percent differences (RPDs) were reviewed for conformance with the QC acceptance criteria.

Nonconformances are summarized in Attachment A in Table A-3. Data qualification to the analytes associated with the specific MS/MSD nonconformances was as follows:

Criteria	Action	
	Detected Compounds	Nondetected Compounds
%R>UL	J+	No qualification
20% ≤ %R < LL	J-	UJ
%R <20% (see note 1)	J-	R*
RPD >UL	J	No qualification
Note: Actions are applied to the native unspiked sample only (see note 2) *When the native sample concentration is >4X the concentration of the spike added (based on Region I criteria), evaluate the MS, MSD, and native sample with regards to %RSD rather than %R (Resolution Consultants professional judgment).		

1. Based on NFG 2016 VOC guidance, Resolution Consultants professional judgment is used to reject (R) non-detects in associated samples for any analyte with < 20% recovery. Also, Resolution Consultants professional judgment is used to estimate (UJ) rather the reject (R) sample results previously negated (U) on the basis of blank contamination.
2. If a field duplicate sample was also collected for the native sample chosen for MS/MSD analysis, professional judgment is used to apply MS/MSD actions to the corresponding field duplicate sample as well as the native sample.

Qualified sample results are shown in Table 1.

LCS/LCSD Results

The LCS/LCSD %Rs and/or RPDs were reviewed for conformance with the QC acceptance criteria. All QC acceptance criteria were met.

Field Duplicates

Field duplicate RPDs were reviewed for conformance with the Resolution Consultants QC criteria of ≤50% for solid matrices and ≤30% for aqueous matrices. These criteria apply if both results were greater than two times the limit of quantitation (LOQ). All QC acceptance criteria were met.

Internal Standards

The internal standard (IS) recoveries were reviewed for conformance with the QC acceptance criteria. All QC acceptance criteria were met.

Sample Results/Reporting Issues

All compounds detected at concentrations less than the LOQ but greater than the DL were qualified by the laboratory as estimated (J). This "J" qualifier was retained during data validation.

The LOQs for vinyl chloride and 1,1-dichloroethene are greater than the Project Action Limit (PAL). The limit of detection (LOD) and the DL are less than the PAL. Results are usable for project objectives.

QUALIFICATION ACTIONS

Sample results qualified as a result of validation actions are summarized in Table 1. All actions are described above.

Qualifier Codes and Explanations

Qualifier	Explanation
J	The analyte was positively identified; the associated numerical value is the approximate concentration of the analyte in the sample.
J+	The analyte was positively identified; the associated numerical value is the approximate concentration of the analyte in the sample and is potentially biased high.
J-	The analyte was positively identified; the associated numerical value is the approximate concentration of the analyte in the sample and is potentially biased low.
JN	The analyte was tentatively identified; the associated numerical value is the approximate concentration of the analyte in the sample.
UJ	The analyte was not detected above the reported sample quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the actual quantitation limit necessary to accurately and precisely measure the analyte in the sample.
U	The analyte was analyzed for, but was not detected above the reported sample quantitation limit.
R	The sample results are rejected due to serious deficiencies in the ability to analyze the sample and meet quality control criteria. The presence or absence of the analyte cannot be verified.

MW07-45S-ME20-1	Ground water
MW07-ME20-TB02	Trip Blank
P07-08-ME20-1	Ground water

Sample ID	Matrix/Sample Type
P07-09-ME20-1	Ground water
P07-10-ME20-1	Ground water
P07-24-ME20-1	Ground water

Data validation activities were conducted with reference to

- *DoD Quality Systems Manual (QSM) for Environmental Laboratories, version 5.0* (July 2013);
- *Test Methods for Evaluating Solid Waste, Physical/Chemical Methods SW-846, specifically SW-846 Method 8260C, Volatile Organic Compounds by Gas Chromatography/Mass Spectrometry* (USEPA, 2006);
- *EPA New England Environmental Data Review Program Guidance* (April 2013);
- *EPA New England Environmental Data Review Supplement for Regional Data Review Elements and Superfund Specific Guidance/Procedures* (April 2013);
- *USEPA National Functional Guidelines for Superfund Organic Methods Data Review* (September 2016);
- laboratory quality control (QC) limits, as applicable.

The USEPA Region 1 and National Data Validation Functional Guidelines were modified to accommodate the non-CLP methodologies. In the absence of method-specific information, laboratory quality control (QC) limits, DoD QSM 5.0, or project-specific requirements, Resolution Consultants professional judgment was used as appropriate.

REVIEW ELEMENTS

The data were evaluated based on the following review elements (where applicable to the method):

✓	Data completeness (chain-of-custody [COC])/sample integrity
✓	Holding times and sample preservation
✓	GC/MS performance checks
✗	Initial calibration/continuing calibration verification
✓	Laboratory blanks/trip blanks/equipment blanks
✓	Surrogate spike recoveries
✗	Matrix spike (MS) and/or matrix spike duplicate (MSD) results
✗	Laboratory control sample (LCS)/laboratory control sample duplicate (LCSD) results
✓	Field duplicates
✓	Internal standards
✓	Sample results/reporting issues

The symbol (✓) indicates that no validation qualifiers were applied based on this parameter. NA indicates that the parameter was not included as part of this data set or was not applicable to this validation and therefore not reviewed. The symbol (✗) indicates that a QC nonconformance resulted in the qualification of data. Any QC nonconformance that resulted in the qualification of data is discussed below. In addition, nonconformances or other issues that were noted during validation, but did not result in qualification of data, may be discussed for informational purposes only.

The data appear valid as reported and may be used for decision making purposes. Selected data points were qualified as estimated, due to nonconformances of certain QC criteria (see discussion below). Qualified sample results are presented in Table 1.

RESULTS

Data Completeness (COC)/Sample Integrity

The data package was reviewed and found to meet acceptance criteria for completeness:

- The COCs were reviewed for completeness of information relevant to the samples and requested analyses, and for signatures indicating transfer of sample custody.
- The laboratory sample login sheet(s) were reviewed for issues potentially affecting sample integrity, including the condition of sample containers upon receipt at the laboratory.
- Completeness of analyses was verified by comparing the reported results to the COC requests.

The COC recorded samples R0864-17 as MW09-17D-ME20-1 and R0864-19 as MW07-27D-ME20-1 which were later changed to MW07-17D-ME20-1 and DPT07-09-27D-ME20-1 through email correspondence between Resolution Consultants and the laboratory.

Holding Times and Sample Preservation

Sample preservation and preparation/analysis holding times were reviewed for conformance with the QC acceptance criteria. The QC acceptance criteria were met.

GC/MS Performance Checks

The data were reviewed to ensure that the 4-bromofluorobenzene (BFB) tuning was performed at the correct frequency and that the method acceptance criteria were met. All samples were analyzed within 12 hours of the BFB tunes.

Initial Calibration/Continuing Calibration Verification

Calibration data were reviewed for conformance with the QC acceptance criteria to ensure that:

- the initial calibration (ICAL) percent relative standard deviation (%RSD), correlation coefficient (r)/coefficient of determination (r2), and/or response factor (RF) method acceptance criteria were met;
- the initial calibration verification standard (ICV) percent recovery acceptance criteria were met;
- the continuing calibration verification standard (CCV) method percent difference or percent drift (%Ds) and RF acceptance criteria were met; and
- the retention time method acceptance criteria were met.

Nonconformances are summarized in Attachment A in Table A-1. Data qualification to the analytes associated with the specific ICAL and/or CCV was as follows:

ICAL and CCV Response Factor Nonconformances

Criteria	Actions	
	Detected Results	Nondetected Results[2]
RF<minimum RF (Table 4 method 8260C)	J	R[1]
[1]Resolution Consultants professional judgment may be used to either raise reporting level or to estimate reporting limit if low standard response is adequate.		
[2]Sample results qualified as not detected (U) due to blank contamination are not rejected, but estimated (UJ).		

ICAL Linearity Nonconformances

Criteria	Actions	
	Detected Results	Nondetected
%RSD > 15% and quantitation based on mean RF	J	UJ
r or r^2 < 0.99 and quantitation based on linear regression	J*	UJ*
* No guidance in NFG, thus Resolution Consultants professional judgment was used		

ICV Recovery Nonconformances

Criteria	Actions*	
	Detected Results	Nondetected Results
Recovery > 120%	J+	No qualification
Recovery < 80%	J-	UJ
* No guidance in NFG, thus Resolution Consultants professional judgment was used		

CCV Linearity Nonconformances

Criteria		Actions	
		Detected Results	Nondetected Results
Opening CCV	Closing CCV		
%D > 20%	%D > 50%	J	UJ
%Drift >20%	%Drift >50%	J*	UJ*
* No guidance in NFG, thus Resolution Consultants professional judgment was used			

Qualified sample results are shown in Table 1.

Laboratory Blanks/Trip Blanks/Equipment Blanks

Laboratory method blanks and trip blanks were evaluated as to whether there were contaminants detected above the detection limit (DL). Equipment blanks were not collected with ground water samples.

Data validation qualifications for individual samples are based on the maximum contaminant concentration detected in all associated blanks.

Detected results in blanks are not discussed in this data validation report if the associated results were nondetect or if qualification of sample results was not required.

The QC acceptance criteria were met and/or qualification of the sample results was not required. There were no detected target analytes reported in trip blank sample MW07-ME20-TB02.

Surrogate Spike Recoveries

The surrogate recoveries (%Rs) were reviewed for conformance with the QC acceptance criteria. All QC acceptance criteria were met.

MS and/or MSD Results

The MS/MSD %Rs and relative percent differences (RPDs) were reviewed for conformance with the QC acceptance criteria.

Nonconformances are summarized in Attachment A in Table A-2. Data qualification to the analytes associated with the specific MS/MSD nonconformances was as follows:

Criteria	Action	
	Detected Compounds	Nondetected Compounds
%R>UL	J+	No qualification
20% ≤ %R < LL	J-	UJ
%R <20% (see note 1)	J-	R*
RPD >UL	J	No qualification
Note: Actions are applied to the native unspiked sample only (see note 2) *When the native sample concentration is >4X the concentration of the spike added (based on Region I criteria), evaluate the MS, MSD, and native sample with regards to %RSD rather than %R (Resolution Consultants professional judgment).		

1. Based on NFG 2016 VOC guidance, Resolution Consultants professional judgment is used to reject (R) non-detects in associated samples for any analyte with < 20% recovery. Also, Resolution Consultants professional judgment is used to estimate (UJ) rather the reject (R) sample results previously negated (U) on the basis of blank contamination.
2. If a field duplicate sample was also collected for the native sample chosen for MS/MSD analysis, professional judgment is used to apply MS/MSD actions to the corresponding field duplicate sample as well as the native sample.

Qualified sample results are shown in Table 1.

LCS/LCSD Results

The LCS/LCSD %Rs and/or RPDs were reviewed for conformance with the QC acceptance criteria.

Nonconformances are summarized in Attachment A in Table A-3. Data qualification to the analytes associated with the specific LCS %Rs or RPDs was as follows:

Criteria[1]	Action	
	Detected Compounds	Nondetected Compounds
%R > UL	J+	No qualification
%R < LL	J-	UJ
%R < 20% (see note 1)	J-	R
%RPD > UL	J	No qualification
(LL = lower limit, UL = upper limit)		
[1]Professional judgment was applied to use MS/MSD RPD actions in the absence of NFG or Region 1 actions.		

Qualified sample results are shown in Table 1.

Field Duplicates

Field duplicate RPDs were reviewed for conformance with the Resolution Consultants QC criteria of ≤50% for solid matrices and ≤30% for aqueous matrices. These criteria apply if both results were greater than two times the limit of quantitation (LOQ). All QC acceptance criteria were met.

Internal Standards

The internal standard (IS) recoveries were reviewed for conformance with the QC acceptance criteria. All QC acceptance criteria were met.

Sample Results/Reporting Issues

All compounds detected at concentrations less than the LOQ but greater than the DL were qualified by the laboratory as estimated (J). This "J" qualifier was retained during data validation.

Any sample that was analyzed at a dilution because of high concentrations of target or non-targets was checked to confirm that the results and/or sample-specific LOQs and limits of detection (LODs) were adjusted accordingly by the laboratory.

The LOQs for vinyl chloride and 1,1-dichloroethene are greater than the Project Action Limit (PAL). The LOD and the DL are less than the PAL Results are usable for project objectives.

QUALIFICATION ACTIONS

Sample results qualified as a result of validation actions are summarized in Table 1. All actions are described above.

Data validation activities were conducted with reference to

- *DoD Quality Systems Manual (QSM) for Environmental Laboratories, version 5.0* (July 2013);
- *Test Methods for Evaluating Solid Waste, Physical/Chemical Methods SW-846, specifically SW-846 Method 8260C, Volatile Organic Compounds by Gas Chromatography/Mass Spectrometry* (USEPA, 2006);
- *EPA New England Environmental Data Review Program Guidance* (April 2013);
- *EPA New England Environmental Data Review Supplement for Regional Data Review Elements and Superfund Specific Guidance/Procedures* (April 2013);
- *USEPA National Functional Guidelines for Superfund Organic Methods Data Review* (September 2016);
- laboratory quality control (QC) limits, as applicable.

The USEPA Region 1 and National Data Validation Functional Guidelines were modified to accommodate the non-CLP methodologies. In the absence of method-specific information, laboratory quality control (QC) limits, DoD QSM 5.0, or project-specific requirements, Resolution Consultants professional judgment was used as appropriate.

REVIEW ELEMENTS

The data were evaluated based on the following review elements (where applicable to the method):

✓	Data completeness (chain-of-custody [COC])/sample integrity
✓	Holding times and sample preservation
✓	GC/MS performance checks
✗	Initial calibration/continuing calibration verification
✓	Laboratory blanks/trip blanks/equipment blanks
✓	Surrogate spike recoveries
✗	Matrix spike (MS) and/or matrix spike duplicate (MSD) results
✗	Laboratory control sample (LCS)/laboratory control sample duplicate (LCSD) results
✓	Field duplicates
✓	Internal standards
✓	Sample results/reporting issues

The symbol (✓) indicates that no validation qualifiers were applied based on this parameter. NA indicates that the parameter was not included as part of this data set or was not applicable to this validation and therefore not reviewed. The symbol (✗) indicates that a QC nonconformance resulted in the qualification of data. Any QC nonconformance that resulted in the qualification of data is discussed below. In addition, nonconformances or other issues that were noted during validation, but did not result in qualification of data, may be discussed for informational purposes only.

The data appear valid as reported and may be used for decision making purposes. Selected data points were qualified as estimated due to nonconformances of certain QC criteria (see discussion below). Qualified sample results are presented in Table 1.

RESULTS

Data Completeness (COC)/Sample Integrity

The data package was reviewed and found to meet acceptance criteria for completeness:

- The COCs were reviewed for completeness of information relevant to the samples and requested analyses, and for signatures indicating transfer of sample custody.
- The laboratory sample login sheet(s) were reviewed for issues potentially affecting sample integrity, including the condition of sample containers upon receipt at the laboratory.
- Completeness of analyses was verified by comparing the reported results to the COC requests.

Sample R0868-19 (MW09-18D-ME20-1) was incorrectly listed on the COC and subsequently the laboratory report. The sample corresponds to location MW07-18D-ME20-1 and is referenced in the database and report as MW07-18D-ME20-1.

Holding Times and Sample Preservation

Sample preservation and preparation/analysis holding times were reviewed for conformance with the QC acceptance criteria. The QC acceptance criteria were met.

GC/MS Performance Checks

The data were reviewed to ensure that the 4-bromofluorobenzene (BFB) tuning was performed at the correct frequency and that the method acceptance criteria were met. All samples were analyzed within 12 hours of the BFB tunes.

Initial Calibration/Continuing Calibration Verification

Calibration data were reviewed for conformance with the QC acceptance criteria to ensure that:

- the initial calibration (ICAL) percent relative standard deviation (%RSD), correlation coefficient (r)/coefficient of determination (r2), and/or response factor (RF) method acceptance criteria were met;
- the initial calibration verification standard (ICV) percent recovery acceptance criteria were met;
- the continuing calibration verification standard (CCV) method percent difference or percent drift (%Ds) and RF acceptance criteria were met; and
- the retention time method acceptance criteria were met.

Nonconformances are summarized in Attachment A in Table A-1. Data qualification to the analytes associated with the specific ICAL and/or CCV was as follows:

ICAL and CCV Response Factor Nonconformances

Criteria	Actions	
	Detected Results	Nondetected Results[2]
RF<minimum RF (Table 4 method 8260C)	J	R[1]
[1]Resolution Consultants professional judgment may be used to either raise reporting level or to estimate reporting limit if low standard response is adequate.		
[2]Sample results qualified as not detected (U) due to blank contamination are not rejected, but estimated (UJ).		

ICAL Linearity Nonconformances

Criteria	Actions	
	Detected Results	Nondetected
%RSD > 15% and quantitation based on mean RF	J	UJ
r or r^2 < 0.99 and quantitation based on linear regression	J*	UJ*
* No guidance in NFG, thus Resolution Consultants professional judgment was used		

ICV Recovery Nonconformances

Criteria	Actions*	
	Detected Results	Nondetected Results
Recovery > 120%	J+	No qualification
Recovery < 80%	J-	UJ
* No guidance in NFG, thus Resolution Consultants professional judgment was used		

CCV Linearity Nonconformances

Criteria		Actions	
		Detected Results	Nondetected Results
Opening CCV	Closing CCV		
%D > 20%	%D > 50%	J	UJ
%Drift >20%	%Drift >50%	J*	UJ*
* No guidance in NFG, thus Resolution Consultants professional judgment was used			

Qualified sample results are shown in Table 1.

Laboratory Blanks/Trip Blanks/Equipment Blanks

Laboratory method blanks and trip blanks were evaluated as to whether there were contaminants detected above the detection limit (DL). Equipment blanks were not collected with ground water samples.

Data validation qualifications for individual samples are based on the maximum contaminant concentration detected in all associated blanks.

Detected results in blanks are not discussed in this data validation report if the associated results were nondetect or if qualification of sample results was not required. The QC acceptance criteria were met and/or qualification of the sample results was not required.

Surrogate Spike Recoveries

The surrogate recoveries (%Rs) were reviewed for conformance with the QC acceptance criteria. All QC acceptance criteria were met.

MS and/or MSD Results

The MS/MSD %Rs and relative percent differences (RPDs) were reviewed for conformance with the QC acceptance criteria.

Nonconformances are summarized in Attachment A in Table A-2. Data qualification to the analytes associated with the specific MS/MSD nonconformances was as follows:

Criteria	Action	
	Detected Compounds	Nondetected Compounds
%R>UL	J+	No qualification
20% ≤ %R < LL	J-	UJ
%R <20% (see note 1)	J-	R*
RPD >UL	J	No qualification
Note: Actions are applied to the native unspiked sample only (see note 2) *When the native sample concentration is >4X the concentration of the spike added (based on Region I criteria), evaluate the MS, MSD, and native sample with regards to %RSD rather than %R (Resolution Consultants professional judgment).		

1. Based on NFG 2016 VOC guidance, Resolution Consultants professional judgment is used to reject (R) non-detects in associated samples for any analyte with < 20% recovery. Also, Resolution Consultants professional judgment is used to estimate (UJ) rather the reject (R) sample results previously negated (U) on the basis of blank contamination.
2. If a field duplicate sample was also collected for the native sample chosen for MS/MSD analysis, professional judgment is used to apply MS/MSD actions to the corresponding field duplicate sample as well as the native sample.

Qualified sample results are shown in Table 1.

LCS/LCSD Results

The LCS/LCSD %Rs and/or RPDs were reviewed for conformance with the QC acceptance criteria.

Nonconformances are summarized in Attachment A in Table A-3. Data qualification to the analytes associated with the specific LCS %Rs or RPDs was as follows:

Criteria[1]	Action	
	Detected Compounds	Nondetected Compounds
%R > UL	J+	No qualification
%R < LL	J-	UJ
%R < 20% (see note 1)	J-	R
%RPD > UL	J	No qualification
(LL = lower limit, UL = upper limit)		
[1]Professional judgment was applied to use MS/MSD RPD actions in the absence of NFG or Region 1 actions.		

Qualified sample results are shown in Table 1.

Field Duplicates

Field duplicate RPDs were reviewed for conformance with the Resolution Consultants QC criteria of ≤50% for solid matrices and ≤30% for aqueous matrices. These criteria apply if both results were greater than two times the limit of quantitation (LOQ). All QC acceptance criteria were met.

Internal Standards

The internal standard (IS) recoveries were reviewed for conformance with the QC acceptance criteria. All QC acceptance criteria were met.

Sample Results/Reporting Issues

All compounds detected at concentrations less than the LOQ but greater than the DL were qualified by the laboratory as estimated (J). This "J" qualifier was retained during data validation.

Any sample that was analyzed at a dilution because of high concentrations of target or non-targets was checked to confirm that the results and/or sample-specific LOQs and limits of detection (LODs) were adjusted accordingly by the laboratory.

The LOQs for vinyl chloride and 1,1-dichloroethene are greater than the Project Action Limit (PAL). The LOD and the DL are less than the PAL. Results are usable for project objectives.

QUALIFICATION ACTIONS

Sample results qualified as a result of validation actions are summarized in Table 1. All actions are described above.

Attachment B

Qualifier Codes and Explanations

Qualifier	Explanation
J	The analyte was positively identified; the associated numerical value is the approximate concentration of the analyte in the sample.
J+	The analyte was positively identified; the associated numerical value is the approximate concentration of the analyte in the sample and is potentially biased high.
J-	The analyte was positively identified; the associated numerical value is the approximate concentration of the analyte in the sample and is potentially biased low.
JN	The analyte was tentatively identified; the associated numerical value is the approximate concentration of the analyte in the sample.
UJ	The analyte was not detected above the reported sample quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the actual quantitation limit necessary to accurately and precisely measure the analyte in the sample.
U	The analyte was analyzed for, but was not detected above the reported sample quantitation limit.
R	The sample results are rejected due to serious deficiencies in the ability to analyze the sample and meet quality control criteria. The presence or absence of the analyte cannot be verified.

Attachment C

Reason Codes and Explanations

Reason Code	Explanation
be	Equipment blank contamination
bf	Field blank contamination
bl	Laboratory blank contamination
bt	Trip blank contamination
c	Calibration issue
d	Reporting limit raised due to chromatographic interference
fd	Field duplicate RPDs
h	Holding times
i	Internal standard areas
k	Estimated Maximum Possible Concentration (EMPC)
l	LCS or OPR recoveries
lc	Labeled compound recovery
ld	Laboratory duplicate RPDs
lp	Laboratory control sample/laboratory control sample duplicate RPDs
m	Matrix spike recovery
md	Matrix spike/matrix spike duplicate RPDs
nb	Negative laboratory blank contamination
p	Chemical preservation issue
r	Dual column RPD
q	Quantitation issue
s	Surrogate recovery
su	Ion suppression
t	Temperature preservation issue
x	Percent solids
y	Serial dilution results
z	ICS results

Data validation activities were conducted with reference to:

- *DoD Quality Systems Manual (QSM) for Environmental Laboratories, version 5.0* (July 2013);
- *Test Methods for Evaluating Solid Waste, Physical/Chemical Methods SW-846, specifically SW-846 Method 8260C, Volatile Organic Compounds by Gas Chromatography/Mass Spectrometry* (USEPA, 2006);
- *EPA New England Environmental Data Review Program Guidance* (April 2013);
- *EPA New England Environmental Data Review Supplement for Regional Data Review Elements and Superfund Specific Guidance/Procedures* (April 2013);
- *USEPA National Functional Guidelines for Superfund Organic Methods Data Review* (September 2016);
- laboratory quality control (QC) limits, as applicable.

The USEPA Region 1 and National Data Validation Functional Guidelines were modified to accommodate the non-CLP methodologies. In the absence of method-specific information, laboratory quality control (QC) limits, DoD QSM 5.0, or project-specific requirements, Resolution Consultants professional judgment was used as appropriate.

REVIEW ELEMENTS

The data were evaluated based on the following review elements (where applicable to the method):

✓	Data completeness (chain-of-custody [COC])/sample integrity
✗	Holding times and sample preservation
✓	GC/MS performance checks
✗	Initial calibration/continuing calibration verification
✓	Laboratory blanks/trip blanks/equipment blanks
✗	Surrogate spike recoveries
✗	Matrix spike (MS) and/or matrix spike duplicate (MSD) results
✗	Laboratory control sample (LCS)/laboratory control sample duplicate (LCSD) results
✓	Field duplicates
✓	Internal standards
✓	Sample results/reporting issues

The symbol (✓) indicates that no validation qualifiers were applied based on this parameter. NA indicates that the parameter was not included as part of this data set or was not applicable to this validation and therefore not reviewed. The symbol (✗) indicates that a QC nonconformance resulted in the qualification of data. Any QC nonconformance that resulted in the qualification of data is discussed below. In addition, nonconformances or other issues that were noted during validation, but did not result in qualification of data, may be discussed for informational purposes only.

The data appear valid as reported and may be used for decision making purposes. Selected data points were qualified as estimated and/or rejected due to nonconformances of certain QC criteria (see discussion below). Qualified sample results are presented in Table 1.

RESULTS

Data Completeness (COC)/Sample Integrity

The data package was reviewed and found to meet acceptance criteria for completeness:

- The COCs were reviewed for completeness of information relevant to the samples and requested analyses, and for signatures indicating transfer of sample custody.
- The laboratory sample login sheet(s) were reviewed for issues potentially affecting sample integrity, including the condition of sample containers upon receipt at the laboratory.
- Completeness of analyses was verified by comparing the reported results to the COC requests.

Holding Times and Sample Preservation

Sample preservation and preparation/analysis holding times were reviewed for conformance with the QC acceptance criteria.

Nonconformances are summarized in Attachment A in Table A-1.

Criteria	Detect	Non-detect
Sample temperature > 6°C but ≤ 10°C upon receipt at the laboratory	Use professional judgment	Use professional judgment
Sample temperature > 10°C upon receipt at the laboratory	Use professional judgment J-	Use professional judgment R
Aqueous sample properly preserved but analyzed outside the 14-day technical holding time	J*	R
Holding times grossly exceeded	J-	R

* The true direction of any bias may be unknown in this case. Use professional judgment based on knowledge of the chemistry of the analytes in the sample, or do not assign a direction to the bias.

Qualified sample results are shown in Table 1.

GC/MS Performance Checks

The data were reviewed to ensure that the 4-bromofluorobenzene (BFB) tuning was performed at the correct frequency and that the method acceptance criteria were met. All samples were analyzed within 12 hours of the BFB tunes.

Initial Calibration/Continuing Calibration Verification

Calibration data were reviewed for conformance with the QC acceptance criteria to ensure that:

- the initial calibration (ICAL) percent relative standard deviation (%RSD), correlation coefficient (r)/coefficient of determination (r2), and/or response factor (RF) method acceptance criteria were met;
- the initial calibration verification standard (ICV) percent recovery acceptance criteria were met;

- the continuing calibration verification standard (CCV) method percent difference or percent drift (%Ds) and RF acceptance criteria were met; and the retention time method acceptance criteria were met.

Nonconformances are summarized in Attachment A in Table A-2. Data qualification to the analytes associated with the specific ICAL and/or CCV was as follows:

ICAL and CCV Response Factor Nonconformances

Criteria	Actions	
	Detected Results	Nondetected Results[2]
RF<minimum RF (Table 4 method 8260C)	J	R[1]
[1]Resolution Consultants professional judgment may be used to either raise reporting level or to estimate reporting limit if low standard response is adequate.		
[2]Sample results qualified as not detected (U) due to blank contamination are not rejected, but estimated (UJ).		

ICAL Linearity Nonconformances

Criteria	Actions	
	Detected Results	Nondetected
%RSD > 15% and quantitation based on mean RF	J	UJ
r or r^2 < 0.99 and quantitation based on linear regression	J*	UJ*
* No guidance in NFG, thus Resolution Consultants professional judgment was used		

ICV Recovery Nonconformances

Criteria	Actions*	
	Detected Results	Nondetected Results
Recovery > 120%	J+	No qualification
Recovery < 80%	J-	UJ
* No guidance in NFG, thus Resolution Consultants professional judgment was used		

CCV Linearity Nonconformances

Criteria		Actions	
		Detected Results	Nondetected Results
Opening CCV	Closing CCV		
%D > 20%	%D > 50%	J	UJ
%Drift >20%	%Drift >50%	J*	UJ*
* No guidance in NFG, thus Resolution Consultants professional judgment was used			

Qualified sample results are shown in Table 1.

Laboratory Blanks/Trip Blanks/Equipment Blanks

Laboratory method blanks and trip blanks were evaluated as to whether there were contaminants detected above the detection limit (DL). Equipment rinsate blanks were not collected with ground water samples.

Data validation qualifications for individual samples are based on the maximum contaminant concentration detected in all associated blanks.

Detected results in blanks are not discussed in this data validation report if the associated results were nondetect or if qualification of sample results was not required.

The QC acceptance criteria were met and/or qualification of the sample results was not required. There were no detected target analytes reported in trip blank sample MW07-ME20-TB06.

Surrogate Spike Recoveries

Nonconformances are summarized in Attachment A in Table A-3. Data qualification on the basis of surrogate recovery nonconformances was as follows:

Criteria	Action	
	Detected Compounds	Nondetected Compounds
%R > Upper Limit (UL)	J+	No qualification
20% ≤%R < Lower Limit (LL)	J-	UJ
%R < 20%	J-	R

Qualified sample results are shown in Table 1.

MS and/or MSD Results

The MS/MSD %Rs and relative percent differences (RPDs) were reviewed for conformance with the QC acceptance criteria.

Nonconformances are summarized in Attachment A in Table A-4. Data qualification to the analytes associated with the specific MS/MSD nonconformances was as follows:

Criteria	Action	
	Detected Compounds	Nondetected Compounds
%R>UL	J+	No qualification
20% ≤ %R < LL	J-	UJ
%R <20% (see note 1)	J-	R*
RPD >UL	J	No qualification
Note: Actions are applied to the native unspiked sample only (see note 2) *When the native sample concentration is >4X the concentration of the spike added (based on Region I criteria), evaluate the MS, MSD, and native sample with regards to %RSD rather than %R (Resolution Consultants professional judgment).		

1. Based on NFG 2016 VOC guidance, Resolution Consultants professional judgment is used to reject (R) non-detects in associated samples for any analyte with < 20% recovery. Also, Resolution Consultants professional judgment is used to estimate (UJ) rather the reject (R) sample results previously negated (U) on the basis of blank contamination.
2. If a field duplicate sample was also collected for the native sample chosen for MS/MSD analysis, professional judgment is used to apply MS/MSD actions to the corresponding field duplicate sample as well as the native sample.

Qualified sample results are shown in Table 1.

LCS/LCSD Results

The LCS/LCSD %Rs and/or RPDs were reviewed for conformance with the QC acceptance criteria.

Nonconformances are summarized in Attachment A in Table A-5. Data qualification to the analytes associated with the specific LCS %Rs or RPDs was as follows:

Criteria[1]	Action	
	Detected Compounds	Nondetected Compounds
%R > UL	J+	No qualification
%R < LL	J-	UJ
%R < 20% (see note 1)	J-	R
%RPD > UL	J	No qualification
(LL = lower limit, UL = upper limit)		
[1]Professional judgment was applied to use MS/MSD RPD actions in the absence of NFG or Region 1 actions.		

Qualified sample results are shown in Table 1.

Field Duplicates

Field duplicate RPDs were reviewed for conformance with the Resolution Consultants QC criteria of ≤50% for solid matrices and ≤30% for aqueous matrices. These criteria apply if both results were greater than two times the limit of quantitation (LOQ). All QC acceptance criteria were met.

Internal Standards

The internal standard (IS) recoveries were reviewed for conformance with the QC acceptance criteria. All QC acceptance criteria were met.

Sample Results/Reporting Issues

All compounds detected at concentrations less than the LOQ but greater than the DL were qualified by the laboratory as estimated (J). This "J" qualifier was retained during data validation.

Any sample that was analyzed at a dilution because of high concentrations of target or non-targets was checked to confirm that the results and/or sample-specific LOQs and limits of detection (LODs) were adjusted accordingly by the laboratory. Samples requiring dilutions have not met all project action limits (PALs) due to the high concentration of target or non-target results.

The LOQs for vinyl chloride and 1, 1-dichloroethene in samples DPT07-18S-ME20-1 and DPT07-16I-ME20-1 are greater than the PAL. The LODs and the DLs are less than the PAL. Results are usable for project objectives.

Eurofins Spectrum Analytical in North Kingstown, RI analyzed samples DPT07-18S-ME20-1 and DPT07-16I-ME20-1. Eurofins Spectrum Analytical in Agawam, MA analyzed all other samples in the data package.

QUALIFICATION ACTIONS

Sample results qualified as a result of validation actions are summarized in Table 1. All actions are described above.

Attachment B

Qualifier Codes and Explanations

Qualifier	Explanation
J	The analyte was positively identified; the associated numerical value is the approximate concentration of the analyte in the sample.
J+	The analyte was positively identified; the associated numerical value is the approximate concentration of the analyte in the sample and is potentially biased high.
J-	The analyte was positively identified; the associated numerical value is the approximate concentration of the analyte in the sample and is potentially biased low.
JN	The analyte was tentatively identified; the associated numerical value is the approximate concentration of the analyte in the sample.
UJ	The analyte was not detected above the reported sample quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the actual quantitation limit necessary to accurately and precisely measure the analyte in the sample.
U	The analyte was analyzed for, but was not detected above the reported sample quantitation limit.
R	The sample results are rejected due to serious deficiencies in the ability to analyze the sample and meet quality control criteria. The presence or absence of the analyte cannot be verified.

Attachment C

Reason Codes and Explanations

Reason Code	Explanation
be	Equipment blank contamination
bf	Field blank contamination
bl	Laboratory blank contamination
bt	Trip blank contamination
c	Calibration issue
d	Reporting limit raised due to chromatographic interference
fd	Field duplicate RPDs
h	Holding times
i	Internal standard areas
k	Estimated Maximum Possible Concentration (EMPC)
l	LCS or OPR recoveries
lc	Labeled compound recovery
ld	Laboratory duplicate RPDs
lp	Laboratory control sample/laboratory control sample duplicate RPDs
m	Matrix spike recovery
md	Matrix spike/matrix spike duplicate RPDs
nb	Negative laboratory blank contamination
p	Chemical preservation issue
r	Dual column RPD
q	Quantitation issue
s	Surrogate recovery
su	Ion suppression
t	Temperature preservation issue
x	Percent solids
y	Serial dilution results

Data Validation Report

Project:	Site 07 Calf Pasture Point LTM, Former NCBC Davisville
Laboratory:	EUROFINS SPECTRUM ANALYTICAL
Service Request:	R0887
Analyses/Method:	EPA SW-846 Method 8260C for VOCs (GC/MS) / 8260C
Validation Level:	Tier 1 Plus
Resolution Consultants Project Number:	60273164.SA.DM
Prepared by:	Elissa McDonagh/Resolution Consultants — Completed on: 11/12/2016
Reviewed by:	Lori Herberich/Resolution Consultants — File Name: R0887_VOC

SUMMARY

The samples listed below were collected by Resolution Consultants from the Site 07 Calf Pasture Point LTM, Former NCBC Davisville site on September 23, 26 and 27, 2016.

Sample ID	Matrix/Sample Type
MW07-12D-ME20-1	Ground water
MW07-15D-ME20-1	Ground water
MW07-24D-ME20-1	Ground water
MW07-24DUT-ME20-1	Ground water
MW07-ME20-FD08	Field Duplicate of MW07-24DUT-ME20-1
MW07-37D-ME20-1	Ground water
MW07-37S-ME20-1	Ground water
MW07-39I-ME20-1	Ground water
MW07-ME20-FD07	Field Duplicate of MW07-39I-ME20-1
MW07-43S-ME20-1	Ground water
MW07-ME20-TB07	Trip Blank
P07-02-ME20-1	Ground water
P07-03-ME20-1	Ground water
P07-04-ME20-1	Ground water
P07-05-ME20-1	Ground water
P07-06-ME20-1	Ground water
P07-14-ME20-1	Ground water
P07-15-ME20-1	Ground water
P07-21-ME20-1	Ground water
P07-22-ME20-1	Ground water
P07-28-ME20-1	Ground water

Data validation activities were conducted with reference to

- *DoD Quality Systems Manual (QSM) for Environmental Laboratories, version 5.0* (July 2013);
- *Test Methods for Evaluating Solid Waste, Physical/Chemical Methods SW-846, specifically SW-846 Method 8260C, Volatile Organic Compounds by Gas Chromatography/Mass Spectrometry* (USEPA, 2006);
- *EPA New England Environmental Data Review Program Guidance* (April 2013);
- *EPA New England Environmental Data Review Supplement for Regional Data Review Elements and Superfund Specific Guidance/Procedures* (April 2013);
- *USEPA National Functional Guidelines for Superfund Organic Methods Data Review* (September 2016);
- laboratory quality control (QC) limits, as applicable.

The USEPA Region 1 and National Data Validation Functional Guidelines were modified to accommodate the non-CLP methodologies. In the absence of method-specific information, laboratory quality control (QC) limits, DoD QSM 5.0, or project-specific requirements, Resolution Consultants professional judgment was used as appropriate.

REVIEW ELEMENTS

The data were evaluated based on the following review elements (where applicable to the method):

✓	Data completeness (chain-of-custody [COC])/sample integrity
✓	Holding times and sample preservation
✓	GC/MS performance checks
✗	Initial calibration/continuing calibration verification
✓	Laboratory blanks/trip blanks/equipment blanks
✗	Surrogate spike recoveries
✓	Matrix spike (MS) and/or matrix spike duplicate (MSD) results
✗	Laboratory control sample (LCS)/laboratory control sample duplicate (LCSD) results
✓	Field duplicates
✓	Internal standards
✓	Sample results/reporting issues

The symbol (✓) indicates that no validation qualifiers were applied based on this parameter. NA indicates that the parameter was not included as part of this data set or was not applicable to this validation and therefore not reviewed. The symbol (✗) indicates that a QC nonconformance resulted in the qualification of data. Any QC nonconformance that resulted in the qualification of data is discussed below. In addition, nonconformances or other issues that were noted during validation, but did not result in qualification of data, may be discussed for informational purposes only.

The data appear valid as reported and may be used for decision making purposes. Selected data points were qualified as estimated due to nonconformances of certain QC criteria (see discussion below). Qualified sample results are presented in Table 1.

RESULTS

Data Completeness (COC)/Sample Integrity

The data package was reviewed and found to meet acceptance criteria for completeness:

- The COCs were reviewed for completeness of information relevant to the samples and requested analyses, and for signatures indicating transfer of sample custody.
- The laboratory sample login sheet(s) were reviewed for issues potentially affecting sample integrity, including the condition of sample containers upon receipt at the laboratory.
- Completeness of analyses was verified by comparing the reported results to the COC requests.

Holding Times and Sample Preservation

Sample preservation and preparation/analysis holding times were reviewed for conformance with the QC acceptance criteria. The QC acceptance criteria were met.

GC/MS Performance Checks

The data were reviewed to ensure that the 4-bromofluorobenzene (BFB) tuning was performed at the correct frequency and that the method acceptance criteria were met. All samples were analyzed within 12 hours of the BFB tunes.

Initial Calibration/Continuing Calibration Verification

Calibration data were reviewed for conformance with the QC acceptance criteria to ensure that:

- the initial calibration (ICAL) percent relative standard deviation (%RSD), correlation coefficient (r)/coefficient of determination (r2), and/or response factor (RF) method acceptance criteria were met;
- the initial calibration verification standard (ICV) percent recovery acceptance criteria were met;
- the continuing calibration verification standard (CCV) method percent difference or percent drift (%Ds) and RF acceptance criteria were met; and
- the retention time method acceptance criteria were met.

Nonconformances are summarized in Attachment A in Table A-1, A-2 and A-3. Data qualification to the analytes associated with the specific ICAL and/or CCV was as follows:

ICAL and CCV Response Factor Nonconformances

Criteria	Actions	
	Detected Results	Nondetected Results[2]
RF<minimum RF (Table 4 method 8260C)	J	R[1]
[1]Resolution Consultants professional judgment may be used to either raise reporting level or to estimate reporting limit if low standard response is adequate.		
[2]Sample results qualified as not detected (U) due to blank contamination are not rejected, but estimated (UJ).		

ICAL Linearity Nonconformances

Criteria	Actions	
	Detected Results	Nondetected
%RSD > 15% and quantitation based on mean RF	J	UJ
r or r^2 < 0.99 and quantitation based on linear regression	J*	UJ*
* No guidance in NFG, thus Resolution Consultants professional judgment was used		

ICV Recovery Nonconformances

Criteria	Actions*	
	Detected Results	Nondetected Results
Recovery > 120%	J+	No qualification
Recovery < 80%	J-	UJ
* No guidance in NFG, thus Resolution Consultants professional judgment was used		

CCV Linearity Nonconformances

Criteria		Actions	
		Detected Results	Nondetected Results
Opening CCV	Closing CCV		
%D > 20%	%D > 50%	J	UJ
%Drift >20%	%Drift >50%	J*	UJ*
* No guidance in NFG, thus Resolution Consultants professional judgment was used			

Qualified sample results are shown in Table 1.

The RF for tetrachloroethene did not meet the method 8260C requirements for initial and/or continuing calibrations as required by the QSM. The nonconformances are summarized in Table A-1 and A-3. The RF results for tetrachloroethene met the National Functional Guidelines requirements. Professional judgement was used to qualify the affected results for tetrachloroethene as estimated (UJ).

Laboratory Blanks/Trip Blanks/Equipment Blanks

Laboratory method blanks and trip blanks were evaluated as to whether there were contaminants detected above the detection limit (DL). Equipment rinsate blanks were not collected with ground water samples.

Data validation qualifications for individual samples are based on the maximum contaminant concentration detected in all associated blanks.

Detected results in blanks are not discussed in this data validation report if the associated results were nondetect or if qualification of sample results was not required.

The QC acceptance criteria were met and/or qualification of the sample results was not required. There were no detected target analytes reported in trip blank sample MW07-ME20-TB07.

Surrogate Spike Recoveries

The surrogate recoveries (%Rs) were reviewed for conformance with the QC acceptance criteria.

Nonconformances are summarized in Attachment A in Table A-4. Data qualification on the basis of surrogate recovery nonconformances was as follows:

Criteria	Action	
	Detected Compounds	Nondetected Compounds
%R > Upper Limit (UL)	J+	No qualification
20% ≤%R < Lower Limit (LL)	J-	UJ
%R < 20%	J-	R

Qualified sample results are shown in Table 1.

MS and/or MSD Results

The MS/MSD %Rs and relative percent differences (RPDs) were reviewed for conformance with the QC acceptance criteria. Qualifications were not required based on MS/MSD nonconformances.

LCS/LCSD Results

The LCS/LCSD %Rs and/or RPDs were reviewed for conformance with the QC acceptance criteria.

Nonconformances are summarized in Attachment A in Table A-5. Data qualification to the analytes associated with the specific LCS %Rs or RPDs was as follows:

Criteria[1]	Action	
	Detected Compounds	Nondetected Compounds
%R > UL	J+	No qualification
%R < LL	J-	UJ
%R < 20% (see note 1)	J-	R
%RPD > UL	J	No qualification
(LL = lower limit, UL = upper limit)		

Notes:

1. Based on NFG 2016 VOC guidance, Resolution Consultants professional judgment is used to reject (R) non-detects in all associated samples for any analyte with < 20% recovery. Also, Resolution Consultants professional judgment is used to estimate (UJ) rather reject sample results previously negated (U) on the basis of blank contamination.

Qualified sample results are shown in Table 1.

Field Duplicates

Field duplicate RPDs were reviewed for conformance with the Resolution Consultants QC criteria of ≤50% for solid matrices and ≤30% for aqueous matrices. These criteria apply if both results were greater than two times the limit of quantitation (LOQ). All QC acceptance criteria were met.

Internal Standards

The internal standard (IS) recoveries were reviewed for conformance with the QC acceptance criteria. All QC acceptance criteria were met.

Sample Results/Reporting Issues

All compounds detected at concentrations less than the LOQ but greater than the DL were qualified by the laboratory as estimated (J). This "J" qualifier was retained during data validation.

Any sample that was analyzed at a dilution because of high concentrations of target or non-targets was checked to confirm that the results and/or sample-specific LOQs and limits of detection (LODs) were adjusted accordingly by the laboratory. Samples requiring dilutions have not met all Project Action Limits (PALs) due to the high concentration of target or non-target results.

QUALIFICATION ACTIONS

Sample results qualified as a result of validation actions are summarized in Table 1. All actions are described above.

Attachment B

Qualifier Codes and Explanations

Qualifier	Explanation
J	The analyte was positively identified; the associated numerical value is the approximate concentration of the analyte in the sample.
J+	The analyte was positively identified; the associated numerical value is the approximate concentration of the analyte in the sample and is potentially biased high.
J-	The analyte was positively identified; the associated numerical value is the approximate concentration of the analyte in the sample and is potentially biased low.
JN	The analyte was tentatively identified; the associated numerical value is the approximate concentration of the analyte in the sample.
UJ	The analyte was not detected above the reported sample quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the actual quantitation limit necessary to accurately and precisely measure the analyte in the sample.
U	The analyte was analyzed for, but was not detected above the reported sample quantitation limit.
R	The sample results are rejected due to serious deficiencies in the ability to analyze the sample and meet quality control criteria. The presence or absence of the analyte cannot be verified.

Attachment C

Reason Codes and Explanations

Reason Code	Explanation
be	Equipment blank contamination
bf	Field blank contamination
bl	Laboratory blank contamination
bt	Trip blank contamination
c	Calibration issue
d	Reporting limit raised due to chromatographic interference
fd	Field duplicate RPDs
h	Holding times
i	Internal standard areas
k	Estimated Maximum Possible Concentration (EMPC)
l	LCS or OPR recoveries
lc	Labeled compound recovery
ld	Laboratory duplicate RPDs
lp	Laboratory control sample/laboratory control sample duplicate RPDs
m	Matrix spike recovery
md	Matrix spike/matrix spike duplicate RPDs

Data Validation Report

Project:	Site 07 Calf Pasture Point LTM, Former NCBC Davisville
Laboratory:	EUROFINS SPECTRUM ANALYTICAL
Service Request:	R0928
Analyses/Method:	EPA SW-846 Method 8260C for VOCs (GC/MS) / 8260C
Validation Level:	Tier 1 Plus
Resolution Consultants Project Number:	60273164.SA.DM
Prepared by:	Elissa McDonagh/Resolution Consultants Completed on: 11/21/2016
Reviewed by:	Kristin Rutherford/Resolution Consultants File Name: R0928_VOC

SUMMARY

The samples listed below were collected by Resolution Consultants from the Site 07 Calf Pasture Point LTM, Former NCBC Davisville site on September 27 and 28, 2016.

Sample ID	Matrix/Sample Type
DPT07-09-28D-ME20-1	Ground water

P07-23-ME20-1	Ground water
P07-29-ME20-1	Ground water

Data validation activities were conducted with reference to

- *DoD Quality Systems Manual (QSM) for Environmental Laboratories, version 5.0* (July 2013);
- *Test Methods for Evaluating Solid Waste, Physical/Chemical Methods SW846, specifically SW-846 Method 8260C, Volatile Organic Compounds by Gas Chromatography/Mass Spectrometry* (USEPA, 2006);
- *EPA New England Environmental Data Review Program Guidance* (April 2013);
- *EPA New England Environmental Data Review Supplement for Regional Data Review Elements and Superfund Specific Guidance/Procedures* (April 2013);
- *USEPA National Functional Guidelines for Superfund Organic Methods Data Review* (September 2016);
- laboratory quality control (QC) limits, as applicable.

The USEPA Region 1 and National Data Validation Functional Guidelines were modified to accommodate the non-CLP methodologies. In the absence of method-specific information, laboratory quality control (QC) limits, DoD QSM 5.0, or project-specific requirements, Resolution Consultants professional judgment was used as appropriate.

REVIEW ELEMENTS

The data were evaluated based on the following review elements (where applicable to the method):

✓	Data completeness (chain-of-custody [COC])/sample integrity
✓	Holding times and sample preservation
✓	GC/MS performance checks
✗	Initial calibration/continuing calibration verification
✓	Laboratory blanks/trip blanks/equipment blanks
✗	Surrogate spike recoveries
✗	Matrix spike (MS) and/or matrix spike duplicate (MSD) results
✓	Laboratory control sample (LCS)/laboratory control sample duplicate (LCSD) results
✓	Field duplicates
✓	Internal standards
✓	Sample results/reporting issues

The symbol (✓) indicates that no validation qualifiers were applied based on this parameter. NA indicates that the parameter was not included as part of this data set or was not applicable to this validation and therefore not reviewed. The symbol (✗) indicates that a QC nonconformance resulted in the qualification of data. Any QC nonconformance that resulted in the qualification of data is discussed below. In addition, nonconformances or other issues that were noted during validation, but did not result in qualification of data, may be discussed for informational purposes only.

The data appear valid as reported and may be used for decision making purposes. Selected data points were qualified as estimated, due to nonconformances of certain QC criteria (see discussion below). Qualified sample results are presented in Table 1.

RESULTS

Data Completeness (COC)/Sample Integrity

The data package was reviewed and found to meet acceptance criteria for completeness:

- The COCs were reviewed for completeness of information relevant to the samples and requested analyses, and for signatures indicating transfer of sample custody.
- The laboratory sample login sheet(s) were reviewed for issues potentially affecting sample integrity, including the condition of sample containers upon receipt at the laboratory.
- Completeness of analyses was verified by comparing the reported results to the COC requests.

Holding Times and Sample Preservation

Sample preservation and preparation/analysis holding times were reviewed for conformance with the QC acceptance criteria. The QC acceptance criteria were met.

GC/MS Performance Checks

The data were reviewed to ensure that the 4-bromofluorobenzene (BFB) tuning was performed at the correct frequency and that the method acceptance criteria were met. All samples were analyzed within 12 hours of the BFB tunes.

Initial Calibration/Continuing Calibration Verification

Calibration data were reviewed for conformance with the QC acceptance criteria to ensure that:

- the initial calibration (ICAL) percent relative standard deviation (%RSD), correlation coefficient (r)/coefficient of determination (r2), and/or response factor (RF) method acceptance criteria were met;
- the initial calibration verification standard (ICV) percent recovery acceptance criteria were met;
- the continuing calibration verification standard (CCV) method percent difference or percent drift (%Ds) and RF acceptance criteria were met; and
- the retention time method acceptance criteria were met.

Nonconformances are summarized in Attachment A in Table A-1, A-2, A-3, and A-4. Data qualification to the analytes associated with the specific ICAL and/or CCV was as follows:

ICAL and CCV Response Factor Nonconformances

Criteria	Actions	
	Detected Results	Nondetected Results[2]
RF<minimum RF (Table 4 method 8260C)	J	R[1]
[1]Resolution Consultants professional judgment may be used to either raise reporting level or to estimate reporting limit if low standard response is adequate.		
[2]Sample results qualified as not detected (U) due to blank contamination are not rejected, but estimated (UJ).		

ICAL Linearity Nonconformances

Criteria	Actions	
	Detected Results	Nondetected
%RSD > 15% and quantitation based on mean RF	J	UJ
r or r^2 < 0.99 and quantitation based on linear regression	J*	UJ*
* No guidance in NFG, thus Resolution Consultants professional judgment was used		

ICV Recovery Nonconformances

Criteria	Actions*	
	Detected Results	Nondetected Results
Recovery > 120%	J+	No qualification
Recovery < 80%	J-	UJ
* No guidance in NFG, thus Resolution Consultants professional judgment was used		

CCV Linearity Nonconformances

Criteria		Actions	
		Detected Results	Nondetected Results
Opening CCV	Closing CCV		
%D > 20%	%D > 50%	J	UJ
%Drift >20%	%Drift >50%	J*	UJ*
* No guidance in NFG, thus Resolution Consultants professional judgment was used			

Qualified sample results are shown in Table 1.

The response factor (RF) for tetrachloroethene did not meet the method 8260C requirements for initial and/or continuing calibrations as required by the QSM. The nonconformances are summarized in Tables A-1 and A-3. The RF results for tetrachloroethene met the National Functional Guidelines requirements. Professional judgement was used to qualify the affected results for tetrachloroethene as estimated (UJ).

Laboratory Blanks/Trip Blanks/Equipment Blanks

Laboratory method blanks and trip blanks were evaluated as to whether there were contaminants detected above the detection limit (DL). Equipment rinsate blanks were not collected for ground water samples.

Data validation qualifications for individual samples are based on the maximum contaminant concentration detected in all associated blanks.

Detected results in blanks are not discussed in this data validation report if the associated results were nondetect or if qualification of sample results was not required.

The QC acceptance criteria were met and/or qualification of the sample results was not required. There were no detected target analytes reported in trip blank sample MW07-ME20-TB08.

Surrogate Spike Recoveries

The surrogate recoveries (%Rs) were reviewed for conformance with the QC acceptance criteria.

Nonconformances are summarized in Attachment A in Table A-5. Data qualification on the basis of surrogate recovery nonconformances was as follows:

Criteria	Action	
	Detected Compounds	Nondetected Compounds
%R > Upper Limit (UL)	J+	No qualification
20% ≤%R < Lower Limit (LL)	J-	UJ
%R < 20%	J-	R

Qualified sample results are shown in Table 1.

MS and/or MSD Results

The MS/MSD %Rs and relative percent differences (RPDs) were reviewed for conformance with the QC acceptance criteria.

Nonconformances are summarized in Attachment A in Table A-6. Data qualification to the analytes associated with the specific MS/MSD nonconformances was as follows:

Criteria	Action	
	Detected Compounds	Nondetected Compounds
%R>UL	J+	No qualification
20% ≤ %R < LL	J-	UJ
%R <20% (see note 1)	J-	R*
RPD >UL	J	No qualification
Note: Actions are applied to the native unspiked sample only (see note 2) *When the native sample concentration is >4X the concentration of the spike added (based on Region I criteria), evaluate the MS, MSD, and native sample with regards to %RSD rather than %R (Resolution Consultants professional judgment).		

1. Based on NFG 2016 VOC guidance, Resolution Consultants professional judgment is used to reject (R) non-detects in associated samples for any analyte with < 20% recovery. Also, Resolution Consultants professional judgment is used to estimate (UJ) rather the reject (R) sample results previously negated (U) on the basis of blank contamination.
2. If a field duplicate sample was also collected for the native sample chosen for MS/MSD analysis, professional judgment is used to apply MS/MSD actions to the corresponding field duplicate sample as well as the native sample.

Qualified sample results are shown in Table 1.

LCS/LCSD Results

The LCS/LCSD %Rs and/or RPDs were reviewed for conformance with the QC acceptance criteria. All QC acceptance criteria were met.

Field Duplicates

Field duplicate RPDs were reviewed for conformance with the Resolution Consultants QC criteria of ≤50% for solid matrices and ≤30% for aqueous matrices. These criteria apply if both results were greater than two times the limit of quantitation (LOQ). All QC acceptance criteria were met.

Internal Standards

The internal standard (IS) recoveries were reviewed for conformance with the QC acceptance criteria. All QC acceptance criteria were met.

Sample Results/Reporting Issues

All compounds detected at concentrations less than the LOQ but greater than the DL were qualified by the laboratory as estimated (J). This "J" qualifier was retained during data validation.

Any sample that was analyzed at a dilution because of high concentrations of target or non-targets was checked to confirm that the results and/or sample-specific LOQs and LODs were adjusted accordingly by the laboratory. Samples requiring dilutions have not met all Project Action Limits (PALs) due to the high concentration of target or non-target results.

QUALIFICATION ACTIONS

Sample results qualified as a result of validation actions are summarized in Table 1. All actions are described above.

Qualifier Codes and Explanations

Qualifier	Explanation
J	The analyte was positively identified; the associated numerical value is the approximate concentration of the analyte in the sample.
J+	The analyte was positively identified; the associated numerical value is the approximate concentration of the analyte in the sample and is potentially biased high.
J-	The analyte was positively identified; the associated numerical value is the approximate concentration of the analyte in the sample and is potentially biased low.
JN	The analyte was tentatively identified; the associated numerical value is the approximate concentration of the analyte in the sample.
UJ	The analyte was not detected above the reported sample quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the actual quantitation limit necessary to accurately and precisely measure the analyte in the sample.
U	The analyte was analyzed for, but was not detected above the reported sample quantitation limit.
R	The sample results are rejected due to serious deficiencies in the ability to analyze the sample and meet quality control criteria. The presence or absence of the analyte cannot be verified.

Data Validation Report

Project:	Site 07 Calf Pasture Point LTM, Former NCBC Davisville
Laboratory:	EUROFINS SPECTRUM ANALYTICAL
Service Request:	S0037
Analyses/Method:	EPA SW-846 Method 8260C for VOCs (GC/MS) / 8260C
Validation Level:	Tier 1 Plus
Resolution Consultants Project Number:	60273164.SA.DM
Prepared by:	Elissa McDonagh/Resolution Consultants Completed on: 01/26/2017
Reviewed by:	Kristin Rutherford/Resolution Consultants File Name: S0037_VOC

SUMMARY

The samples listed below were collected by Resolution Consultants from the Site 07 Calf Pasture Point LTM, Former NCBC Davisville site on January 13, 2017.

Sample ID	Matrix/Sample Type
GW07-TB01	Trip Blank
MW07-20DA-ME20-1	Ground water
MW07-ME20-FD11	Field Duplicate of MW07-20DA-ME20-1

Data validation activities were conducted with reference to

- *DoD Quality Systems Manual (QSM) for Environmental Laboratories, version 5.0* (July 2013);
- *Test Methods for Evaluating Solid Waste, Physical/Chemical Methods SW846, specifically SW-846 Method 8260C, Volatile Organic Compounds by Gas Chromatography/Mass Spectrometry* (USEPA, 2006);
- *EPA New England Environmental Data Review Program Guidance* (April 2013);
- *EPA New England Environmental Data Review Supplement for Regional Data Review Elements and Superfund Specific Guidance/Procedures* (April 2013);
- *USEPA National Functional Guidelines for Superfund Organic Methods Data Review* (September 2016);
- laboratory quality control (QC) limits, as applicable.

The USEPA Region 1 and National Data Validation Functional Guidelines were modified to accommodate the non-CLP methodologies. In the absence of method-specific information, laboratory quality control (QC) limits, DoD QSM 5.0, or project-specific requirements, Resolution Consultants professional judgment was used as appropriate.

REVIEW ELEMENTS

The data were evaluated based on the following review elements (where applicable to the method):

✓	Data completeness (chain-of-custody [COC]/sample integrity
✓	Holding times and sample preservation
✓	GC/MS performance checks
✗	Initial calibration/continuing calibration verification
✓	Laboratory blanks/trip blanks/equipment blanks
✓	Surrogate spike recoveries
✓	Matrix spike (MS) and/or matrix spike duplicate (MSD) results
✓	Laboratory control sample (LCS)/laboratory control sample duplicate (LCSD) results
✓	Field duplicate results
✓	Internal standards
✓	Sample results/reporting issues

The symbol (✓) indicates that no validation qualifiers were applied based on this parameter. NA indicates that the parameter was not included as part of this data set or was not applicable to this validation and therefore not reviewed. The symbol (✗) indicates that a QC nonconformance resulted in the qualification of data. Any QC nonconformance that resulted in the qualification of data is discussed below. In addition, nonconformances or other issues that were noted during validation, but did not result in qualification of data, may be discussed for informational purposes only.

The data appear valid as reported and may be used for decision making purposes. No data were rejected. Selected data points were qualified as estimated due to nonconformances of certain QC criteria (see discussion below). Qualified sample results are presented in Table 1.

RESULTS

Data Completeness (COC)/Sample Integrity

The data package was reviewed and found to meet acceptance criteria for completeness:

- The COCs were reviewed for completeness of information relevant to the samples and requested analyses, and for signatures indicating transfer of sample custody.
- The laboratory sample login sheet(s) were reviewed for issues potentially affecting sample integrity, including the condition of sample containers upon receipt at the laboratory.
- Completeness of analyses was verified by comparing the reported results to the COC requests.

Holding Times and Sample Preservation

Sample preservation and preparation/analysis holding times were reviewed for conformance with the QC acceptance criteria. The QC acceptance criteria were met.

GC/MS Performance Checks

The data were reviewed to ensure that the 4-bromofluorobenzene (BFB) tuning was performed at the correct frequency and that the method acceptance criteria were met. All samples were analyzed within 12 hours of the BFB tunes.

Initial Calibration/Continuing Calibration Verification

Calibration data were reviewed for conformance with the QC acceptance criteria to ensure that:

- the initial calibration (ICAL) percent relative standard deviation (%RSD), correlation coefficient (r)/coefficient of determination (r2), and/or response factor (RF) method acceptance criteria were met;
- the initial calibration verification standard (ICV) percent recovery acceptance criteria were met;
- the continuing calibration verification standard (CCV) method percent difference or percent drift (%Ds) and RF acceptance criteria were met; and
- the retention time method acceptance criteria were met.

Nonconformances are summarized in Attachment A in Table A-1. Data qualification to the analytes associated with the specific ICAL and/or CCV was as follows:

ICAL and CCV Response Factor Nonconformances

Criteria	Actions	
	Detected Results	Nondetected Results[2]
RF<minimum RF (Table 4 method 8260C)	J	R[1]
[1]Resolution Consultants professional judgment may be used to either raise reporting level or to estimate reporting limit if low standard response is adequate.		
[2]Sample results qualified as not detected (U) due to blank contamination are not rejected, but estimated (UJ).		

ICAL Linearity Nonconformances

Criteria	Actions	
	Detected Results	Nondetected
%RSD > 15% and quantitation based on mean RF	J	UJ
r or r^2 < 0.99 and quantitation based on linear regression	J*	UJ*
* No guidance in NFG, thus Resolution Consultants professional judgment was used		

ICV Recovery Nonconformances

Criteria	Actions*	
	Detected Results	Nondetected Results
Recovery > 120%	J+	No qualification
Recovery < 80%	J-	UJ
* No guidance in NFG, thus Resolution Consultants professional judgment was used		

CCV Linearity Nonconformances

Criteria		Actions	
		Detected Results	Nondetected Results
Opening CCV	Closing CCV		
%D > 20% opening CCV	%D > 50%	J	UJ
%Drift >20% opening CCV	%Drift >50%	J*	UJ*
* No guidance in NFG, thus Resolution Consultants professional judgment was used			

Qualified sample results are shown in Table 1.

Laboratory Blanks/Trip Blanks/Equipment Blanks

Laboratory method blanks and trip blanks were evaluated as to whether there were contaminants detected above the method detection limit (DL).

Data validation qualifications for individual samples are based on the maximum contaminant concentration detected in all associated blanks.

Detected results in blanks are not discussed in this data validation report if the associated results were nondetect or if qualification of sample results was not required.

The QC acceptance criteria were met and/or qualification of the sample results was not required. There were no detected target analytes reported in trip blank sample GW07-TB01.

Surrogate Spike Recoveries

The surrogate recoveries (%Rs) were reviewed for conformance with the QC acceptance criteria. All QC acceptance criteria were met.

MS and/or MSD Results

The MS/MSD %Rs and relative percent differences (RPDs) were reviewed for conformance with the QC acceptance criteria. All QC acceptance criteria were met.

LCS/LCSD Results

The LCS/LCSD %Rs and/or RPDs were reviewed for conformance with the QC acceptance criteria. All QC acceptance criteria were met.

Field Duplicate Results

Field duplicate RPDs were reviewed for conformance with the Resolution Consultants QC criteria of ≤50% for solid matrices and ≤30% for aqueous matrices. These criteria apply if both results were greater than two times the limit of quantitation (LOQ). All QC acceptance criteria were met.

Internal Standards

The internal standard (IS) recoveries were reviewed for conformance with the QC acceptance criteria. All QC acceptance criteria were met.

Sample Results/Reporting Issues

All criteria were met.

QUALIFICATION ACTIONS

Sample results qualified as a result of validation actions are summarized in Table 1. All actions are described above.

REVIEW ELEMENTS

The data were evaluated based on the following review elements (where applicable to the method):

✓	Data completeness (chain-of-custody [COC])/sample integrity
✓	Holding times and sample preservation
✓	GC/MS performance checks
✓	Initial calibration/continuing calibration verification
✓	Laboratory blanks/trip blanks/equipment blanks
✓	Surrogate spike recoveries
✗	Matrix spike (MS) and/or matrix spike duplicate (MSD) results
✓	Laboratory control sample (LCS)/laboratory control sample duplicate (LCSD) results
✓	Field duplicates
✗	Internal standards
✓	Sample results/reporting issues

The symbol (✓) indicates that no validation qualifiers were applied based on this parameter. NA indicates that the parameter was not included as part of this data set or was not applicable to this validation and therefore not reviewed. The symbol (✗) indicates that a QC nonconformance resulted in the qualification of data. Any QC nonconformance that resulted in the qualification of data is discussed below. In addition, nonconformances or other issues that were noted during validation, but did not result in qualification of data, may be discussed for informational purposes only.

The data appear valid as reported and may be used for decision making purposes. Selected data points were qualified as estimated and rejected due to nonconformances of certain QC criteria (see discussion below). Qualified sample results are presented in Table 1.

RESULTS

Data Completeness (COC)/Sample Integrity

The data package was reviewed and found to meet acceptance criteria for completeness:

- The COCs were reviewed for completeness of information relevant to the samples and requested analyses, and for signatures indicating transfer of sample custody.
- The laboratory sample login sheet(s) were reviewed for issues potentially affecting sample integrity, including the condition of sample containers upon receipt at the laboratory.
- Completeness of analyses was verified by comparing the reported results to the COC requests.

Holding Times and Sample Preservation

Sample preservation and preparation/analysis holding times were reviewed for conformance with the QC acceptance criteria. The QC acceptance criteria were met.

GC/MS Performance Checks

The data were reviewed to ensure that the 4-bromofluorobenzene (BFB) tuning was performed at the correct frequency and that the method acceptance criteria were met. All samples were analyzed within 12 hours of the BFB tunes.

Initial Calibration/Continuing Calibration Verification

Calibration data were reviewed for conformance with the QC acceptance criteria to ensure that:

- the initial calibration (ICAL) percent relative standard deviation (%RSD), correlation coefficient (r)/coefficient of determination (r2), and/or response factor (RF) method acceptance criteria were met;
- the initial calibration verification standard (ICV) percent recovery acceptance criteria were met;
- the continuing calibration verification standard (CCV) method percent difference or percent drift (%Ds) and RF acceptance criteria were met; and
- the retention time method acceptance criteria were met.

The QC acceptance criteria were met.

Laboratory Blanks/Trip Blanks/Equipment Blanks

Laboratory method blanks, trip blanks, and equipment rinsate blanks were evaluated as to whether there were contaminants detected above the detection limit (DL).

Data validation qualifications for individual samples are based on the maximum contaminant concentration detected in all associated blanks.

Detected results in blanks are not discussed in this data validation report if the associated results were nondetect or if qualification of sample results was not required.

The QC acceptance criteria were met and/or qualification of the sample results was not required. There were no detected target analytes reported in trip blank sample TB-081516-1.

Surrogate Spike Recoveries

The surrogate recoveries (%Rs) were reviewed for conformance with the QC acceptance criteria. All QC acceptance criteria were met.

MS and/or MSD Results

The MS/MSD %Rs and relative percent differences (RPDs) were reviewed for conformance with the QC acceptance criteria.

Nonconformances are summarized in Attachment A in Table A-1. Data qualification to the analytes associated with the specific MS/MSD nonconformances was as follows:

Criteria	Action	
	Detected Compounds	Nondetected Compounds
%R>UL	J+	No qualification
20% ≤ %R < LL	J-	UJ
%R <20% (see note 1)	J-	R*
RPD >UL	J	No qualification
Note: Actions are applied to the native unspiked sample only (see note 2) *When the native sample concentration is >4X the concentration of the spike added (based on Region I criteria), evaluate the MS, MSD, and native sample with regards to %RSD rather than %R (Resolution Consultants professional judgment).		

1. Based on NFG 2016 VOC guidance, Resolution Consultants professional judgment is used to reject (R) non-detects in associated samples for any analyte with < 20% recovery. Also, Resolution Consultants professional judgment is used to estimate (UJ) rather the reject (R) sample results previously negated (U) on the basis of blank contamination.
2. If a field duplicate sample was also collected for the native sample chosen for MS/MSD analysis, professional judgment is used to apply MS/MSD actions to the corresponding field duplicate sample as well as the native sample.

Qualified sample results are shown in Table 1.

LCS/LCSD Results

The LCS/LCSD %Rs and/or RPDs were reviewed for conformance with the QC acceptance criteria. All QC acceptance criteria were met.

Field Duplicates

Field duplicate RPDs were reviewed for conformance with the Resolution Consultants QC criteria of ≤50% for solid matrices and ≤30% for aqueous matrices. These criteria apply if both results were greater than two times the limit of quantitation (LOQ). All QC acceptance criteria were met.

Internal Standards

The internal standard (IS) recoveries were reviewed for conformance with the QC acceptance criteria.

Nonconformances are summarized in Attachment A in Table A-2. Data qualification to the analytes associated with the specific IS on the basis of IS recoveries were as follows:

Sample IS area compared to CCV and CCV IS area compared to ICAL*		
Qualify results	Detect	Nondetect
Area response <20% of the opening CCV or mid-point standard from the ICAL	J+	R
20% ≤ Area response < 50% of the opening CCV or midpoint standard from the ICAL	J+	UJ
Area response > 200% of the opening CCV or mid-point standard from ICAL	J-	No qualification
RT shift between sample/blank and opening CCV or mid-point standard from ICAL > 10.0 seconds	R	R
* Per the DoD QSM v5.0, the laboratory may use the IS area of the CCV in place of the ICV. If an IS area fails with respect to the ICAL, but passes with respect to the CCV, then use professional judgment to evaluate the sensitivity and linearity of the analysis before applying validation actions. (Resolution Consultants professional judgment)		

Qualified sample results are shown in Table 1.

Sample Results/Reporting Issues

All compounds detected at concentrations less than the LOQ but greater than the DL were qualified by the laboratory as estimated (J). This "J" qualifier was retained during data validation.

The percent solids data were reviewed to ensure that NFG 2016 specified criteria were met.

All percent solids criteria were met.

Samples SED07-10-ME20-1 and SED07-05-ME20-1 were reanalyzed due to internal standard nonconformances. There were internal standard nonconformances and surrogate nonconformances in the reanalyses. The original analyses were reported and were qualified for internal standard nonconformances.

QUALIFICATION ACTIONS

Sample results qualified as a result of validation actions are summarized in Table 1. All actions are described above.

Compounds associated with Internal Standards:

Fluorobenzene – vinyl chloride, 1,1-dichloroethene, trans-1,2-dichloroethene, cis-1,2-dichloroethene, chloroform, benzene, trichloroethene, 1,1,2-trichloroethane

Chlorobenzene-d5 – tetrachloroethene

1,4-Dichlorobenzene-d4 – 1,1,2,2-tetrachloroethane

Attachment B

Qualifier Codes and Explanations

Qualifier	Explanation
J	The analyte was positively identified; the associated numerical value is the approximate concentration of the analyte in the sample.
J+	The analyte was positively identified; the associated numerical value is the approximate concentration of the analyte in the sample and is potentially biased high.
J-	The analyte was positively identified; the associated numerical value is the approximate concentration of the analyte in the sample and is potentially biased low.
JN	The analyte was tentatively identified; the associated numerical value is the approximate concentration of the analyte in the sample.
UJ	The analyte was not detected above the reported sample quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the actual quantitation limit necessary to accurately and precisely measure the analyte in the sample.
U	The analyte was analyzed for, but was not detected above the reported sample quantitation limit.
R	The sample results are rejected due to serious deficiencies in the ability to analyze the sample and meet quality control criteria. The presence or absence of the analyte cannot be verified.

Attachment C

Reason Codes and Explanations

Reason Code	Explanation
be	Equipment blank contamination
bf	Field blank contamination
bl	Laboratory blank contamination
bt	Trip blank contamination
c	Calibration issue
d	Reporting limit raised due to chromatographic interference
fd	Field duplicate RPDs
h	Holding times
i	Internal standard areas
k	Estimated Maximum Possible Concentration (EMPC)
l	LCS or OPR recoveries
lc	Labeled compound recovery
ld	Laboratory duplicate RPDs
lp	Laboratory control sample/laboratory control sample duplicate RPDs
m	Matrix spike recovery
md	Matrix spike/matrix spike duplicate RPDs
nb	Negative laboratory blank contamination
p	Chemical preservation issue
r	Dual column RPD
q	Quantitation issue
s	Surrogate recovery
su	Ion suppression
t	Temperature preservation issue
x	Percent solids
y	Serial dilution results
z	ICS results

Attachment C

Institutional Control Checklist

INSTITUTIONAL CONTROL INSPECTION CHECKLIST
for LAND USE CONTROL AND IMPLEMENTATION PLAN
Parcel 9, Zone 3
(Includes OU8, Site 07)

A. Annual Certification:

Name: THOMAS J. MULLIGAN

Affiliation: TOWN MANAGER, TOWN OF NORTH KINGSTOWN

Signature: Thomas J Mulligan

Date: 12/27/2016

B. Documentation Inspection:

Inspect documentation to ensure no permits have been issued to change the use of the Site, build residential or commercial units, or install ground-water supply wells, including the following:

	ITEM	CHECK ONE	COMMENTS*
1.	Any related notice(s) filed with the Town of North Kingstown, RIDEM, or CRMC?	☐ Yes ☑ No	
2.	Any related building permits found?	☐ Yes ☑ No	
3.	Any related Department of Public Works Permits found?	☐ Yes ☑ No	
4.	Any related Zoning permits or variances found?	☐ Yes ☑ No	
5.	Any related Conservation Commission findings, proposals, or notices of intent found?	☐ Yes ☑ No	

C. Physical On-Site Inspection:

Name: Rachel MacPhee

Affiliation: Resolution Consultants

Signature:

Date: 09/23/16

	ITEM	CHECK ONE	COMMENTS*
1.	Land-Use Condition; i.e. Buildings Present? If yes, is there evidence of damage to the remedy?	☐ Yes ☒ No ☐ Yes ☒ No	
2.	Evidence of any ground-water supply wells? If yes, is there evidence of damage to the remedy?	☐ Yes ☒ No ☐ Yes ☒ No	
3.	Weather Conditions?	--	Sunny ~85°F

*If the answer to a question is 'Yes', use the 'Comments' column to explain, e.g. list type(s) and names(s) of notices, permits, variances, notices of intent found; describe the type and location of where a building or ground-water supply well was observed.

INSTITUTIONAL CONTROL INSPECTION CHECKLIST
for LAND USE CONTROL AND IMPLEMENTATION PLAN
Parcel 9, Zone 3
(Includes OU8, Site 07)

October 14

D. Additional Comments

The Town of North Kingstown excavated soils from the access road at Calf Pasture Point on 12-12-16. The excavated area was ~20 ft wide by ~100 ft long and ~1-2 ft deep. The soil was transported inland and staged along the side of the access road. The excavated area was backfilled with sand from unknown origin.

Notes:

U = Not Detected; UJ = Detection Limit Approximate; J = Quantitation Approximate; R = Rejected

(1) If sample was not detected, one half of detection limit was used in calculation of average concentration.

Maximum value presented when original and duplicate samples were analyzed

Notes:
U = Not Detected; UJ = Detection Limit Approximate; J = Quantitation Approximate; R = Rejected
(1) If sample was not detected, one half of detection limit was used in calculation of average concentration.
Maximum value presented when original and duplicate samples were analyzed

Notes:

Datasets presented for all analytes detected in at least one location since ME-01.

Field duplicates assigned the maximum value.

A significance level of 95% was used to interpret results.

* - When N > 10, the Normal approximation is used and calculated per box 4-9 in Data Quality Assessment: Statistical Methods for Practitioners.

EPA QA/G-9S. When the normal approximation is used, the critical value is the standard normal distribution.

When S is 0, no critical value is calculated and a conclusion of no trend is made.

NA = The Mann-Kendall Trend Test was not computed because there were not at least 4 samples, or there were less than 3 detected concentrations.

Notes:

Datasets presented for all analytes detected in at least one location since ME-01.

Field duplicates assigned the maximum value.

A significance level of 95% was used to interpret results.

* - When N > 10, the Normal approximation is used and calculated per box 4-9 in Data Quality Assessment: Statistical Methods for Practitioners.

EPA QA/G-9S. When the normal approximation is used, the critical value is the standard normal distribution.

When S is 0, no critical value is calculated and a conclusion of no trend is made.

NA = The Mann-Kendall Trend Test was not computed because there were not at least 4 samples, or there were less than 3 detected concentrations.

Notes:
1) U or < = Non-detect at laboratory detection limit
2) J = Estimated Value, J+ = biased high, J- = biased low, R = rejected
3) All units are in micrograms per liter (ug/l)
4) NE = not established
5) Criteria exceedances are bolded and highlighted

P07-24	1.4	0.39	0.87	< 1.0 U

Notes:
1) U or < = Non-detect at laboratory detection limit
2) R = Result was rejected during data validation
3) All units are in micrograms per liter (ug/l)
4) Red shading indicates September 2016 results are higher than the averge value
5) For field duplicate results in 2016, the higher of the two results was chosen

1.0 INTRODUCTION

This report presents a human health risk assessment (HHRA) update conducted for the shoreline surface water, sediment, and groundwater in shallow piezometers at Site 07 (Calf Pasture Point) (site), located at the Former Naval Construction Battalion Center (NCBC) Davisville, in North Kingstown, Rhode Island. This HHRA update was performed in support of the Site 07 Five Year Event Long-Term Monitoring (LTM) Report and will ultimately be used as part of the evaluation of compliance with the Remedial Action Objectives (RAOs) identified in the Record of Decision (ROD) (EA, 1999) in the Fourth Five Year Review Report. The RAOs for Site 07 are to prevent human exposure to chemicals of concern (COCs) in deep and bedrock groundwater and to ensure that the discharge of groundwater to wetlands and offshore areas continue to pose no unacceptable risk from COCs. Therefore, the selected remedial alternatives included: (1) a deed restriction on groundwater and land use; (2) LTM of the groundwater plume (as well as sampling of other media such as shoreline sediment, as warranted based upon trends identified from the groundwater data) to ensure that the site continues to pose no unacceptable risks to human health and the environment.; and (3) Five-year reviews.

A summary of the Site 07 history is provided in the main text of the LTM Report and is, therefore, not included in this HHRA update. However, the previously conducted HHRAs are briefly summarized in the following section.

1.1 Previous HHRAs

In 2007, an HHRA was conducted to evaluate the shoreline surface water, sediment, and piezometer groundwater data collected during the LTM and other sampling performed to date. The objective of the HHRA was to evaluate the human health risks associated with potential human exposure to surface water, sediment, and shallow groundwater located along the Site 07 (Calf Pasture Point) shoreline (Tetra Tech, 2007). The 2007 HHRA concluded that the potential risks associated with potential human exposure to surface water, sediment, and shallow groundwater did not exceed United States Environmental Protection Agency (USEPA) or Rhode Island Department of Environmental Management (RIDEM) target levels. Potential risk associated with the consumption of shellfish obtained off the shoreline of Allen Harbor was identified above USEPA and RIDEM target levels for arsenic, mercury, and polychlorinated biphenyls (PCBs), however, these chemicals were determined not to be related to Site 07 activities.

In 2012, the 2007 shoreline HHRA was updated in support of the Third Five-Year Review Report for Site 07 (Tetra Tech, 2013) using newer surface water, sediment, and shallow groundwater data collected since the 2007 HHRA was conducted. The 2012 HHRA conclusions indicated that the conclusions of the 2007 HHRA (i.e., potential risk/hazard associated with potential human exposure

to surface water, sediment, and shallow groundwater did not exceed USEPA or RIDEM target levels) remained valid.

1.2 Objectives

The objective of this HHRA update (referred to herein as the 2017 HHRA update) is to determine whether there have been any changes and/or updates to USEPA HHRA guidance or site-specific conditions since the 2012 HHRA was conducted that would result in a change of the conclusions of the 2012 HHRA. The 2017 HHRA update includes the following:

- Calculation of summary statistics for analytical sediment, surface water, and shallow groundwater data collected along the Site 07 shoreline as part of the LTM, which are considered representative of current conditions (i.e., 2017 HHRA update dataset);
- Update of screening levels and chemical of potential concern (COPC) selection for shoreline sediment, surface water, and shallow groundwater;
- Update of human receptor exposure assumptions/parameters;
- Calculation of exposure point concentrations (EPCs) for COPCs within each medium based on the 2017 HHRA update dataset;
- Update of toxicity values for COPCs identified based on the 2017 HHRA update dataset.

In accordance with the approach discussed and agreed upon by the Davisville Base Realignment and Closure (BRAC) Cleanup Team (BCT) during the January 12, 2017 teleconference, revised formal risk/hazard calculations were not performed as part of this 2017 HHRA update. However, a quantitative evaluation was performed to determine whether updates to the 2012 HHRA would result in cumulative potential cancer risk and/or noncancer hazard estimates above USEPA and RIDEM target risk/hazard levels, changing the overall conclusions of the 2012 HHRA, or whether the conclusions of the 2012 HHRA remain valid.

The following USEPA risk assessment guidance was utilized in this 2017 HHRA update. Guidance documentation includes, but is not limited to, the following:

- *Navy Policy for Conducting Human Health Risk Assessments Under the Environmental Restoration Program* (DON, 2001)
- *U.S. Navy Human Health Risk Assessment Guidance* (DON, 2008)
- *Risk Assessment Guidance for Superfund, Volume I, Human Health Evaluation Manual* (Parts A, B, E) (USEPA, 1989; 1991; 2004)
- *Human Health Toxicity Values in Superfund Risk Assessments* (USEPA, 2003)
- *Guidelines for Carcinogenic Risk Assessment* (USEPA, 2005a and b)

- *Exposure Factors Handbook* (USEPA, 2011)
- *Human Health Evaluation Manual, Supplemental Guidance: Update of Standard Default Exposure Factors* (USEPA, 2014a)

The remainder of this report is organized into the following sections, consistent with USEPA's four-step paradigm for HHRA (USEPA, 1989):

- Data Evaluation/Hazard Identification
- Exposure Assessment
- Toxicity Assessment
- Risk Characterization

2.0 CONCEPTUAL SITE MODEL

A detailed conceptual site model (CSM) is presented in Worksheet 10-1 of LTM Sampling and Analysis Plan (SAP) (Resolution, 2016). A brief summary of the CSM related to the HHRA is included in this section. Calf Pasture Point is a peninsula located on the northeastern portion of the Former NCBC Davisville facility. Site 07 is located on the southern portion of Calf Pasture Point. Site 07 is forested and grass covered and extends to the Allen Harbor and Narragansett Bay shorelines. Narragansett Bay, the Allen Harbor entrance channel, and Allen Harbor itself form the eastern, southern, and western shorelines of Site 07, respectively (**Figure 1**).

Current Site Use

Calf Pasture Point, including Site 07, was transferred to the Town of North Kingstown, Rhode Island for use as an open space/conservation area in November 2001. The acquisition restricts the transferee to use the property as a park and for recreational purposes, in perpetuity, with no opportunity for residential or commercial development. Additionally, under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), land use restrictions with compliance monitoring have been placed on the property to ensure that future use will not conflict with the remedy. As a result, Calf Pasture Point is currently used for passive recreational purposes only and installation of water supply wells and/or use of Site 07 groundwater for any purpose (other than sampling or other remedial purposes), including drinking, showering, and irrigation, is prohibited. In addition, any structure constructed on Site 07 must have adequate ventilation to mitigate any potential vapor intrusion pathway.

This HHRA update evaluates potential exposure to shoreline groundwater, surface water, and sediment based on recreational use of the Site 07 shoreline.

Target Chemicals

Historical investigations and risk assessments identified chlorinated volatile organic compounds (VOCs) in groundwater as the primary COCs for Site 07, with some metals also contributing potential risk/hazard. The list of target chemicals selected for analysis during the LTM has since been reduced to only the site-specific list of VOCs (i.e., benzene, chloroform, 1,2-dichloroethane, 1,1-dichloroethene, cis-1,2-dichloroethene, trans-1,2-dichloroethene, 1,1,2,2-tetrachloroethane, tetrachloroethane, 1,1,2-trichloroethene, trichloroethene [TCE], and vinyl chloride). This is because Site 07 is a VOC release site only; metals present in Site 07 media are considered to be representative of natural conditions, due to the hydraulic fill, or have mobilized by reducing conditions caused by the chlorinated VOC plume. In addition, metals in sediment did not contribute significantly to risk in the 2012 shoreline HHRA. Furthermore, the ROD does not address sediment

beyond to state that they will be sampled as part of the LTM program. Therefore, this HHRA update evaluates potential exposure to the target VOCs only.

The potentially exposed receptors and exposure pathways for the Site 07 shoreline are summarized in **Table 1**.

3.0 DATA EVALUATION

This section summarizes the shoreline groundwater, surface water, and sediment data evaluated in the HHRA update, and also provides a revised COPC selection to identify chemicals for further evaluation. A discussion of the sampling details associated with collection of the shoreline groundwater, surface water, and sediment data is provided in the LTM Report, and is not included in this HHRA update.

3.1 Summary of the Shoreline Dataset

The datasets for evaluation in the HHRA update are discussed by media in this section. **Figure 2** identifies the shoreline sample locations.

3.1.1 Groundwater

Shallow groundwater samples were collected during multiple sampling events conducted between October 2013 and September 2016 from twenty piezometers located along the northern bank of the entrance channel separating Narragansett Bay from Allen Harbor (i.e., the southern boundary of Site 07) and along the Allen Harbor shoreline on the western boundary of Site 07. The screened interval for the groundwater piezometers is approximately two to three feet below ground surface (bgs). Shallow (unfiltered) groundwater samples were analyzed for the target VOCs identified in Section 2. **Appendix A** presents a summary of shallow groundwater samples and individual analytical groundwater sample results.

3.1.2 Surface Water

Surface water samples were collected during one sampling event in August 2016 from three depths along ten transects along the northern bank of the entrance channel separating Narragansett Bay from Allen Harbor (i.e., the southern boundary of Site 07). Samples were collected from three different depths at low tide, as follows:

- Depth 1: At the harbor floor where water is approximately six inches deep (for evaluation of a recreational wading scenario);
- Depth 2: At the harbor floor where water is approximately three feet deep (for evaluation of a recreational swimming scenario); and
- Depth 3: At the mid-point of the water column where the water is approximately three feet deep (for evaluation of a recreational swimming scenario).

Surface water samples were analyzed for the target VOCs identified in Section 2. **Appendix A** presents a summary of surface water samples and individual analytical surface water sample results.

3.1.3 Sediment

Sediment samples were collected during one sampling event in August 2016 from six locations along the northern bank of the entrance channel separating Narragansett Bay from Allen Harbor (i.e., the southern boundary of Site 07). Sediment samples were analyzed for the target VOCs identified in Section 2. **Appendix A** presents a summary of sediment samples and individual analytical sediment sample results.

3.2 Data Treatment

Analytical data were evaluated, validated, and qualified prior to use in the HHRA update. Data evaluation and validation included a comparison of the site data to corresponding blank (laboratory, field, equipment, and trip) concentration data. Data validation reports are presented as Attachment B of the LTM report. Data rejected by the evaluation ("R" qualified) were not used in the HHRA. Estimated values ("J" qualified) were used in the HHRA without modification. If the value was flagged with "U" or "UJ," the result was considered a non-detect value.

For each medium, data were compiled into summary statistics. For each chemical detected at least once within a medium, the summary statistics include frequency of detection, range of detection limits, range of detected concentrations, and location of maximum detected result. Note that due to the exclusion of "R" qualified groundwater results for certain analytes, the frequency of detection may vary within a medium.

For sample locations in which a duplicate sample was also collected, the duplicate sample results for each chemical/medium combination were processed for use in the calculation of summary statistics. Duplicates were resolved as follows: (1) where both the sample and the duplicate results are not detected, the resulting value is the average of the limits of detection; (2) where both the sample and the duplicate results are detected, the resulting value is the average of the detected results; and (3) where one of the pair is reported as not detected and the other is detected, the detected concentration is used.

Appendix B presents comparisons of the summary statistics for target VOCs detected in the 2017 HHRA shoreline dataset to the summary statistics for COPCs identified in the 2012 HHRA. The summary statistics comparisons indicate that the maximum detected concentrations of all target VOCs identified as COPCs in shallow groundwater and sediment in the 2012 HHRA have decreased. With the exception of vinyl chloride, the maximum detected concentrations of all target VOCs identified as COPCs in surface water in the 2012 HHRA have also decreased. Vinyl chloride was detected in one out of thirty surface water samples in the updated dataset. However, the detected value is J-flagged, so it is considered an estimated value.

3.3 Identification of COPCs

The identification of COPCs was performed per medium based on a comparison of the maximum detected concentrations of detected chemicals to the screening or regulatory values discussed below. Chemicals detected at concentrations above the screening or regulatory values were identified as COPCs for further evaluation in the HHRA update. Chemicals that were not detected in a particular medium or were detected at concentrations below the screening or regulatory values were eliminated from being COPCs and were not evaluated further.

The COPC selection for groundwater, surface water, and sediment are presented in **Tables 2.1 through 2.3**, respectively. For analytes lacking a chemical-specific screening level, a conservative surrogate chemical was selected and its screening level was used for COPC screening. Specific instances where surrogate assignments were made are identified in footnotes in the COPC selection tables.

Screening levels and regulatory criteria were used to select COPCs as discussed per media below.

3.3.1 Groundwater

Groundwater screening levels include the USEPA tapwater Regional Screening Levels (RSLs) (USEPA, 2016a) based on a target excess lifetime cancer risk (ELCR) of 10^{-6} and a target hazard quotient (HQ) of 0.1 (to account for potential cumulative effects of multiple chemicals acting on the same target organ) and RIDEM GA Groundwater Objectives (RIDEM, 2011). A chemical was selected as a groundwater COPC if the maximum detected concentration exceeded either of the groundwater screening levels.

RIDEM GA Groundwater Objectives have not changed since the 2012 HHRA was performed. However, the USEPA RSLs are updated approximately twice per year. Changes to the RSLs associated with each update are documented on USEPA's RSL website (https://www.epa.gov/risk/regional-screening-levels-rsls-whats-new-may-2016).

Table 2.1 presents the COPC selection for groundwater. **Table 2.4** presents a comparison of the COPCs identified in the 2012 HHRA and those identified as a result of the updated COPC selection performed in this 2017 HHRA update. This comparison shows that the list of groundwater COPCs has not changed.

3.3.2 Surface Water

Consistent with the 2012 HHRA, surface water COPCs were conservatively selected using groundwater screening levels. Therefore, the surface water screening levels used in this 2017 HHRA update include the USEPA tapwater RSLs (USEPA, 2016a) based on a target ELCR of 10^{-6} and a target HQ of 0.1 (to account for potential cumulative effects of multiple chemicals acting on the

same target organ) and RIDEM GA Groundwater Objectives (RIDEM, 2011). A chemical was selected as a surface water COPC if the maximum detected concentration exceeded either of the surface water screening levels.

As discussed above, RIDEM GA Groundwater Objectives have not changed since the 2012 HHRA was performed. However, the USEPA RSLs are updated approximately twice per year. Changes to the RSLs associated with each update are documented on USEPA's RSL website (https://www.epa.gov/risk/regional-screening-levels-rsls-whats-new-may-2016).

Table 2.2 presents the COPC selection for surface water. **Table 2.4** presents a comparison of the COPCs identified in the 2012 HHRA and those identified as a result of the updated COPC selection performed in this 2017 HHRA update. This comparison shows that 1,2-dichloroethane is added as a surface water COPC based on one J-flagged detection equal to the limit of detection (LOD). The use of groundwater screening levels (which are protective of a drinking water ingestion scenario) to select surface water COPCs is conservative. The 1,2-dichloroethane detection of 1.0 J ug/L is less than the risk-based screening level derived based on a recreational surface water exposure scenario.

3.3.3 Sediment

Sediment COPCs were conservatively selected using the USEPA residential soil RSLs (USEPA, 2016a) based on a target ELCR of 10^{-6} and a target HQ of 0.1 (to account for potential cumulative effects of multiple chemicals acting on the same target organ) and the RIDEM Method 1 Direct Contact Exposure Criteria for soil (RIDEM, 2011). A chemical was selected as a sediment COPC if the maximum detected concentration exceeded either of the screening levels.

RIDEM soil criteria have not changed since the 2012 HHRA was performed. However, the USEPA RSLs are updated approximately twice per year. Changes to the RSLs associated with each update are documented on USEPA's RSL website (https://www.epa.gov/risk/regional-screening-levels-rsls-whats-new-may-2016).

As shown in **Table 2.4**, one sediment COPC was identified in the 2012 HHRA. No sediment COPCs were identified based on the updated screening level comparison. Therefore, exposure to sediment is not evaluated further in this HHRA update.

4.0 EXPOSURE ASSESSMENT

The purpose of the exposure assessment is the quantification of the extent, frequency, and duration of actual or potential exposure to chemicals by pathways relevant to the site and activities of the potential receptors.

4.1 Determination of Exposure Point Concentrations

Exposure points are the locations where potential receptors may contact COPCs at or from a site. The exposure points (or exposure areas) were defined based on the anticipated receptor activity and the spatial distribution of COPC concentrations. EPCs (exposure point concentrations) are the concentrations of COPCs in the environmental medium that receptors may contact, which are estimated in order to determine the magnitude of potential exposure. EPCs for evaluation of the reasonable maximum exposure (RME) scenario were calculated as described below.

The following exposure points were evaluated within the Site 07 shoreline:

Shallow groundwater

- *Southern Boundary* – includes shallow groundwater locations P07-02 through P07-10, and P07-20 through P07-24. The 2012 HHRA evaluated two data sets within the Southern Boundary Area due to a change in concentration over the LTM data evaluated in the 2012 HHRA. These datasets were referred to as "Case 1" and "Case 2". This 2017 HHRA update evaluated the combined 2013 through 2016 dataset as one exposure point because no discernable concentration pattern was identified within this timeframe.
- *Shoreline* – includes all shallow groundwater locations. This scenario is referred to as "Case 3" in the 2012 HHRA.
- *Western Boundary* – includes shallow groundwater locations P07-14 through P07-17, P07-28, and P07-29. This scenario is referred to as "Case 4" in the 2012 HHRA.
- *Mid-Southern Boundary* – includes shallow groundwater locations P07-05 through P07-10. USEPA guidance indicates that groundwater EPCs should be derived based on monitoring wells within the center or core of the plume (USEPA, 2014b). Therefore, shallow groundwater piezometers located within the center of the Southern Boundary, in which detected concentrations of COPCs are higher in comparison with other areas, were evaluated as a separate exposure point to evaluate a worst-case exposure scenario. This exposure point was not evaluated in the 2012 HHRA.

Surface Water

- Depth 1: At the harbor floor where water is approximately six inches deep (for evaluation of a recreational wading scenario). This scenario corresponds to "Case 3" (low tide) and "Case 4" (low/mid/high tide) evaluated in the 2012 HHRA.

- Depths 2 and 3: Includes surface water samples collected at the harbor floor (Depth 2) and at the mid-point of the water column (Depth 3) where water is approximately three feet deep (for evaluation of a recreational swimming scenario). This scenario corresponds to "Case 1" (low tide) and "Case 2" (low/mid/high tide) evaluated in the 2012 HHRA.

Groundwater EPCs are equal to the upper confidence limit (UCL) or the maximum concentration, whichever is lower (USEPA, 2002b). USEPA's ProUCL Version 5.1 software (USEPA, 2016h) was used to calculate the ProUCL recommended UCL. Based on information presented in the ProUCL guidance (USEPA, 2015) regarding minimum sample size and frequency detection, UCLs were calculated where at least 10 samples and at least 6 detects are available. **Appendix C** presents the ProUCL input and output sheets.

When the minimum sample size and number of detects were not met for a dataset, or if the UCL was greater than the maximum detected concentration, the maximum detected concentration was used as the EPC. Due to the low frequency of detection of surface water COPCs, surface water EPCs are equal to the maximum detected concentration.

The EPCs for COPCs in shallow groundwater and surface water evaluated in the 2017 HHRA update are presented in **Tables 3.1 and 3.2**, respectively. Tables 3.1 and 3.2 also show a comparison of the updated EPCs to those evaluated in the 2012 HHRA. The results of the comparison are discussed by media as follows.

The majority of the updated shallow groundwater EPCs are between one and three times higher than the EPCs calculated in the 2012 HHRA. However, the majority of the maximum detected concentrations in the updated dataset are lower than those calculated in the 2012 HHRA. Several of the shallow groundwater COPCs evaluated along the western boundary in the 2012 HHRA were not detected in the updated dataset, therefore, the COPC list for the western boundary has decreased.

The updated surface water EPCs associated with the low tide wading scenario (Depth 1) increased in comparison to the associated EPCs evaluated in the 2012 HHRA (Case 3). However, the Kaplan Meier mean and maximum detected concentrations have decreased. The increase in EPCs for this scenario is due to the smaller sample sizes available for EPC calculations in the 2017 HHRA update, resulting in use of the maximum detected concentration as the EPC, instead of the 95% UCL used in the 2012 HHRA.

The surface water COPCs identified for the low tide swimming scenario in the 2012 HHRA (Case 1) (i.e., cis-1,2-dichloroethene, TCE, and vinyl chloride) were not detected in the associated dataset in the 2017 HHRA update (Depths 2 and 3). However, one additional COPC (1,2-dichloroethane) was identified in the 2017 HHRA update.

4.2 Receptors and Exposure Pathways

The receptors and exposure pathways evaluated in the 2012 HHRA based on current and potential future land use remain appropriate and are summarized in **Table 1** and as follows:

- *Current/Future Recreational User – Swimmer/Wader (child, adolescent, adult)* - Exposure to shoreline surface water and sediment via incidental ingestion and dermal contact while swimming or wading;
- *Current/Future Recreational User* – Shell Fisherman (adolescent, adult) – Exposure to shallow groundwater along the shoreline via dermal contact; and exposure to shoreline surface water and sediment via incidental ingestion and dermal contact while clamming/harvesting shellfish.

As indicated in Section 3.3.3, no sediment COPCs were identified based on the updated screening level comparison. Therefore, exposure to sediment was not evaluated further beyond screening.

Young child (age 2 through 6 years), adolescent (age 7 through 16 years), and adult recreational users were evaluated for swimming and wading scenarios. Young children are not likely to harvest shellfish, therefore, adolescent and adult recreational users were evaluated for the clamming/shellfish harvesting scenario.

There are no formal recreational facilities (e.g., public swimming areas) currently located along the Site 07 shoreline and there are no known plans for development of formal recreational facilities in the future. Therefore, it is unlikely that a young child would be routinely exposed to the environmental media along this shoreline. However, exposures by a young child were conservatively evaluated. The recreational user exposure scenarios are also protective of occasional trespassers to the shoreline.

The quantitative exposure assumptions used for evaluation in the 2012 HHRA were updated based on current USEPA guidance (USEPA, 2011, 2014a, and 2014c) and an RME scenario. Table 4 presents a comparison of the exposure assumptions utilized in the 2012 HHRA in comparison to the updated exposure assumptions. Parameters that have changed based on the update are highlighted. Several exposure parameters were updated based on revisions to USEPA's recommended default exposure assumptions, including body weight, exposure duration, noncancer averaging time (resulting from revised exposure duration), skin surface area, and surface water ingestion rate. Site-specific assumptions used in the 2012 HHRA based on professional judgment were not changed, including the assumed exposure time of 2 hours per event and exposure frequency of 80 events per year. The exposure frequency for recreational users is based on exposure to shoreline shallow groundwater and surface water for three days a week over the course of the warmer weather months (April through October). Assumptions based on the percentages of the total body surface area exposed to shallow groundwater and surface water used

in the 2012 HHRA were also not changed. However, the total skin surface area values were revised based on application of the percentages to the revised total body surface areas identified based on USEPA guidance (2011 and 2014a).

4.3 Calculation of Unit Intakes

In the 2012 HHRA, chronic daily intake values for the incidental ingestion and dermal contact pathways of exposure were calculated in accordance with USEPA guidance (1989 and 2004). Equations in these documents are used for calculating a lifetime average daily dose (LADD) relevant to cancer risk (i.e., cancer intake) or for calculating an average daily dose (ADD) relevant to noncancer hazard (i.e., noncancer intake). The medium-specific equations used for the calculation of cancer and noncancer intakes of the COPCs (presented in the 2012 HHRA Table 4s) are still valid and appropriate for use. Absorption factors and other parameters used in the calculation of oral and dermal dose in the 2012 HHRA are also still valid.

Unit intake estimates were calculated based on the updated exposure assumptions discussed in Section 4.2, consistent with the equations utilized in the 2012 HHRA Table 4s. The equations for calculation of unit intake are as follows:

- Incidental ingestion Intake [(mg/kg-day)(L/ug)]= [Ingestion Rate (L/hour) x conversion factor (0.001 mg/ug) x exposure time (hours/event) x exposure frequency (events/year) x exposure duration (years)] / [body weight (kg) x averaging time (days)]

- Dermal Intake [(cm^2-event)/(kg-day)]= [surface area (cm^2) x event frequency (events/day) x exposure frequency (days/year) x exposure duration (years)] / [body weight (kg) x averaging time (days)]

Chemical-specific parameters, including concentration, are not included in the unit intakes.

5.0 TOXICITY ASSESSMENT

The toxicity assessment was conducted in accordance with USEPA guidance and considers chronic (long-term) exposures for carcinogenic and noncarcinogenic COPCs. The USEPA's guidance regarding the hierarchy of sources of human health dose-response values in risk assessment was followed (USEPA, 2003) and is presented below:

- *Tier 1*: USEPA's Integrated Risk Information System (IRIS) (USEPA, 2017a)
- *Tier 2*: Provisional Peer-Reviewed Toxicity Values obtained from USEPA via the USEPA National Center for Environmental Assessment in Cincinnati, Ohio (USEPA, 2017b)
- *Tier 3*: Other sources of dose-response values including, but not limited to, California EPA's Office of Environmental Health and Hazard Assessment Toxicity Criteria Database (CalEPA, 2016), minimal risk levels published by the Agency for Toxic Substances and Disease Registry (ATSDR, 2016), and the Health Effects Assessment Summary Tables (USEPA, 1997)

Where published dose-response values were not available for a chemical, dose-response values based on surrogate chemicals (i.e., chemicals with structural similarities) were identified. The chosen surrogate is referenced in the summary table(s) of dose-response values.

No noncancer reference doses (RfDs) or cancer slope factors (CSFs) are available for evaluating dermal exposure. Therefore, cancer risks and noncancer hazards associated with dermal exposure may be evaluated using an oral CSF or RfD adjusted such that the toxicity value is appropriate for the dermal pathway. As detailed by USEPA (2004), for purposes of evaluating dermal exposure, it is generally necessary to adjust an oral toxicity factor (i.e., RfD or CSF) from an administered (i.e., applied) dose to an absorbed (i.e., internal) dose. Because the toxicity values for the COPCs at the site are expressed as orally administered doses (i.e., applied or intake-based), it is necessary to adjust both the RfDs and CSFs for these substances in estimating exposure on an absorbed-dose basis when assessing dermal exposure. For the Site 07 COPCs, no adjustment was necessary. Therefore, the dermal RfD and CSF are equal to the oral RfD and CSF, respectively.

Table 5 summarizes the oral and dermal noncancer toxicity values (i.e., RfDs) and the corresponding critical effects for Site 07 COPCs. **Table 6** summarizes the oral and dermal CSFs and the corresponding weight-of-evidence classifications.

In the 2012 HHRA, the quantitative evaluation of potential risks for carcinogenic COPCs with a mutagenic mode of action followed the USEPA guidance titled *Supplemental Guidance for Assessing Susceptibility from Early-Life Exposure to Carcinogens* (USEPA, 2005a). Specifically, the quantification of cancer risks for child receptors involves the use of age-dependent adjustment factors (ADAFs), as follows:

- an ADAF of 10 was used for exposures occurring less than 2 years of age
- an ADAF of 3 was used for exposures occurring between 2 and less than 16 years of age
- an ADAF of 1 was used for exposures occurring after 16 years of age

Application of the ADAFs was performed using the same method used in the development of the USEPA RSLs (USEPA, 2016a). The only Site 07 COPC considered to be mutagenic, for which application of ADAFs is necessary, is TCE. The USEPA characterizes TCE as "carcinogenic to humans" based on human epidemiological studies on kidney and liver tumors and non-Hodgkin's lymphoma (NHL). USEPA classifies TCE as "carcinogenic by a mutagenic mode of action" for the induction of kidney tumors only. Therefore, ADAFs are applied to the TCE CSF associated with kidney tumors. No ADAFs are applies to the TCE CSF associated with liver tumors and NHL (USEPA, 2017a).

Vinyl chloride is a mutagenic COPC. However, cancer toxicity values for vinyl chloride account for mutagenic action, such that ADAFs are not applied to the cancer risks for vinyl chloride. Toxicological studies in animals have shown an increased sensitivity to vinyl chloride induced carcinogenesis in early-life and prenatal exposure. The effects of early-life exposure are qualitatively and quantitatively different from those of later exposures. Therefore, it would not be appropriate to prorate early-life exposures as if they were received at a proportionately lesser rate over a full lifetime. Therefore, estimating risks from birth (e.g., child from ages 0 to 6), requires summing a non-prorated "early-life risk" and a prorated "later-life risk" over a life span of 70 years. In cases where the receptor is not being exposed from birth, there is no early-life component. The later-life component is prorated as the defined exposure duration over an assumed life span of 70 years. Therefore, in the 2012 HHRA, potential cancer risks to vinyl chloride were calculated in a chemical-specific manner, consistent with the approach used in the development of the USEPA RSLs (USEPA, 2016a).

No changes to the approaches for evaluation of TCE and vinyl chloride used in the 2012 HHRA were made in the 2017 HHRA update.

6.0 RISK CHARACTERIZATION

Risk characterization combines estimates of exposure with toxicity data to develop estimates of the probability that an adverse effect will occur under the specified conditions of exposure. The risk characterization was divided into three phases: (1) risk estimation, (2) risk description, and (3) uncertainty analysis.

Risk estimation is undertaken by combining the toxicity factors and exposure assessment equations to calculate estimates of risks. Noncancer hazards are reported as pathway-specific hazard indices (HIs), which are the sum of individual COPC HQs for that pathway. A total HI is calculated, as well as HQs from COPCs that affect the same target organ. Estimates of cancer risks are reported as ELCRs. Current practice considers cancer risks to be additive when assessing exposure to a mixture of hazardous substances. The significance of the risk estimates are relative to risk management criteria set forth in USEPA policy. The uncertainty analysis describes the impact of data uncertainty and variability, exposure assumptions, and toxicity values on estimates of potential risk.

The methods for estimating cancer risks and noncancer HIs in the 2012 HHRA are consistent with current USEPA guidance (1989, 2001, 2004, 2005a and b). Therefore, revised formal risk/hazard calculations were not performed as part of this 2017 HHRA update. However, a quantitative evaluation was performed to determine whether updates to the 2012 HHRA would result in cumulative potential risk and/or noncancer hazard estimates above USEPA and/or RIDEM target risk/hazard levels, changing the overall conclusions of the 2012 HHRA, or whether the conclusions of the 2012 HHRA remain valid. Potential cancer risk and noncancer HIs were calculated by scaling the 2012 HHRA ELCR and HQ results per medium, exposure point, exposure route/pathway, and COPC based on the revised EPCs, pathway-specific unit intakes, and chemical-specific toxicity values, using the following equations:

- Updated potential ELCR = 2012 HHRA risk estimate x (current EPC / 2012 EPC) x (current unit intake / 2012 unit intake) x (current CSF / 2012 CSF)
- Updated potential HQ = 2012 HHRA HQ estimate x (current EPC / 2012 EPC) x (current unit intake / 2012 unit intake) x (2012 RfD / current RfD)

The sum of the HQs for all chemicals within an exposure point and pathway that have the same target organ or type of toxicity is termed the pathway HI. The HI is useful as a reference point for gauging potential effects of environmental exposures to complex mixtures. In general, HIs that are less than 1 are not of regulatory concern; however, a HI of greater than 1 does not automatically indicate that an adverse effect will occur and should not automatically be interpreted as posing an unacceptable risk to the exposed population. The magnitude of the HQ cannot be directly equated to a probability or effect level.

The total pathway HI for each exposure point was calculated by summing the HQs for all COPCs. Total HIs for each receptor by medium were calculated by summing the total HIs across pathways within the media (e.g., summing dermal and incidental ingestion surface water risk estimates). As a first approximation, all COPCs are assumed to have additive effects. If the total HI for all COPCs does not exceed USEPA or RIDEM's target HI, then the total HI per target organ would also not exceed USEPA/RIDEM's target HI. Therefore, calculation of target HIs per target endpoint is not performed. Both USEPA and RIDEM use a target HI per target organ of 1 (USEPA, 1991; RIDEM, 2011).

The potential cancer risk for each receptor is estimated for each medium by means of an ELCR. The ELCR represents the incremental upper-bound probability that an individual could develop cancer over his or her lifetime due to exposure to potential carcinogens under the conditions specified in the exposure scenario. For example, cancer risk levels of 10^{-6} and 10^{-4} represent an incremental chance of one-in-one-million and one-in-ten-thousand, respectively, that an individual could contract cancer over a lifetime.

USEPA (1991) states that where the cumulative incremental current or future potential ELCR to an individual is less than 10^{-4}, action generally is not warranted unless there are adverse environmental impacts. RIDEM uses a target ELCR of 10^{-5} (RIDEM, 2011). The potential ELCR for each pathway (e.g., the surface water incidental ingestion pathway) was calculated by summing the potential ELCRs from each COPC at each exposure point within the pathway, while receptor risks for each medium were calculated by summing ELCRs for each pathway within the medium (e.g., the surface water incidental ingestion and dermal contact pathways).

Potential ELCR and HI estimates were calculated individually for the child, adolescent, and adult recreational users. Potential ELCR estimates were also calculated for a "Lifelong" scenario by summing the associated estimates for the child, adolescent, and adult age groups, as applicable. A lifelong scenario is not appropriate for evaluating noncancer HI.

For each associated exposure scenario with a potential cumulative ELCR/HI above USEPA or RIDEM target levels, COCs were defined as COPCs with an individual ELCR > 10^{-6} or target organ HI > 1, at one significant figure.

6.1 Risk Characterization Results

The potential cancer risk and noncancer hazard results are discussed in this section for each of the receptors evaluated.

6.1.1 Current/Future Recreational Users – Wading Scenario

Child, adolescent, and adult recreational users were evaluated for exposure to shoreline surface water and sediment via incidental ingestion and dermal contact while wading. No sediment COPCs were identified (i.e., sediment concentrations are less than risk-based screening levels). This exposure scenario was evaluated based on surface water samples collected at low tide at the harbor floor where water is approximately six inches deep (i.e., Depth 1/Case 3).

Table 7.1 presents the scaling table in which potential ELCRs and HIs were calculated for the Recreational User wading scenario. Potential ELCR estimates for the lifelong scenario were calculated by summing the associated estimates for the child, adolescent, and adult age groups.

As shown in Table 7.1, the potential ELCRs associated with the adolescent and adult recreational user wading scenario are less than USEPA's target risk range of 10^{-6} to 10^{-4}, and less than RIDEM's target risk level of 10^{-5}. The potential ELCRs associated with the child and lifelong recreational user wading scenario is 2×10^{-5}, which is at the low end of USEPA's target risk range of 10^{-6} to 10^{-4}, and slightly higher than RIDEM's target risk level of 10^{-5}. The risk driver causing the cumulative potential ELCR to exceed RIDEM's target risk level is vinyl chloride in surface water (incidental ingestion exposure route). The surface water EPC for vinyl chloride of 3.7 J ug/L is the maximum detected concentration based on one detected concentration out of 30 samples. Due to the low frequency of detection (approximately 0.03 percent), vinyl chloride is not identified as a surface water COC. The total potential cumulative ELCRs for the child and lifelong recreational user wading scenario are less than 10^{-5} if vinyl chloride is excluded as a COPC.

The potential HIs associated with the child, adolescent, and adult recreational user wading scenario are less than USEPA/RIDEM's target HI of 1.

These results indicate that the conclusions of the 2012 HHRA, which indicated that potential exposures to sediment and surface water along the Site 07 shoreline by recreational users while wading do not pose a cancer risk or noncancer hazard above USEPA target levels, remain valid. As a result, adverse health effects are not anticipated for this receptor.

6.1.2 Current/Future Recreational Users – Swimming Scenario

Child, adolescent, and adult recreational users were evaluated for exposure to shoreline surface water and sediment via incidental ingestion and dermal contact while swimming. No sediment COPCs were identified (i.e., sediment concentrations are less than risk-based screening levels). This exposure scenario was evaluated based on surface water samples collected at low tide at the harbor floor and at the mid-point of the water column where water is approximately three feet deep (i.e., Depths 2 and 3/Case 1).

1,2-Dichloroethane is the only surface water COPC identified for further evaluation of a swimming scenario based on the Depths 2 and 3/Case 1 surface water dataset. However, 1,2-dichloroethane was not a COPC evaluated in the 2012 HHRA, so a potential noncancer HQ could not be scaled based on the 2012 HHRA results. The EPC for 1,2-dichloroethane is 1 ug/L (Table 3.2). The tapwater RSL for 1,2-dichloroethane is 0.17 ug/L based on a target risk level of 10^{-6}, and 13 ug/L based on target HQ of 1. Therefore, 1 ug/L of 1,2-dichloroethane corresponds to a risk level of 6×10^{-6} and a HQ of 0.08, which are within USEPA's target risk range of 10^{-6} to 10^{-4}, below RIDEM's target risk level of 10^{-5}, and below USEPA/RIDEM's target HI of 1.

These results indicate that the conclusions of the 2012 HHRA, which indicated that potential exposures to sediment and surface water along the Site 07 shoreline by recreational users while swimming do not pose a cancer risk or noncancer hazard above USEPA or RIDEM target levels, remain valid. As a result, adverse health effects are not anticipated for this receptor.

6.1.3 Current/Future Recreational Users – Shell Fisherman

Adolescent and adult recreational users were evaluated for exposure to shallow groundwater along the shoreline via dermal contact; and exposure to shoreline surface water and sediment via incidental ingestion and dermal contact while clamming/harvesting shellfish. No sediment COPCs were identified (i.e., sediment concentrations are less than risk-based screening levels).

This exposure scenario was evaluated based on surface water samples collected at low tide at the harbor floor where water is approximately six inches deep (i.e., Depth 1/Case 3), and shallow groundwater samples within each of the groundwater exposure points (Southern Boundary, Shoreline, Western Boundary, Mid-Southern Boundary).

Tables 7.2 and 7.3 presents the scaling tables in which potential ELCRs and HIs were calculated for the Shell Fisherman scenario within the Southern Boundary and Mid-Southern Boundary, respectively. Total potential ELCRs and HIs were calculated by summing the potential ELCRs/HIs associated with surface water exposure to the potential ELCRs/HIs associated with shallow groundwater exposure. Potential ELCR estimates for the lifelong scenario were calculated by summing the associated estimates for the adolescent and adult age groups. The child receptor is not considered to perform shellfishing.

One shallow groundwater COPC, 1,2-dichloroethane, did not have an available noncancer toxicity value (i.e., RfD) when evaluated in the 2012 HHRA, so a potential noncancer HQ could not be scaled based on the 2012 HHRA results. Therefore, a potential noncancer HQ value equal to that for 1,1,2-trichloroethane was used. 1,1,2-Trichloroethane has a slightly higher (less toxic) reference dose as compared to 1,2-dichloroethane, making the use of this potential HQ conservative for application to 1,2-dichloroethane.

As shown in Tables 7.2 and 7.3, the potential ELCRs associated with the adolescent, adult, and lifelong shell fisherman scenario are less than or at the low end of USEPA's target risk range of 10^{-6} to 10^{-4}, and less than RIDEM's target risk level of 10^{-5}. The potential HIs associated with the adolescent and adult shell fisherman scenario are less than USEPA/RIDEM's target HI of 1.

The highest concentrations of shallow groundwater COPCs are within the Southern Boundary, specifically in the Mid-Southern boundary, resulting in the shallow groundwater EPCs being higher in these areas in comparison with the EPCs associated with the Western Boundary (Case 4) and the EPCs associated with the Shoreline (combined Southern and Western Boundaries) (Case 3). Therefore, the potential ELCRs and HIs associated with the Shoreline and Western Boundary exposure points are less than those estimated for the Southern Boundary.

These results indicate that the conclusions of the 2012 HHRA, which indicated that potential exposures to shallow groundwater, sediment, and surface water along the Site 07 shoreline do not pose a cancer risk or noncancer hazard above USEPA or RIDEM target levels, remain valid. As a result, adverse health effects are not anticipated for this receptor.

6.2 Description of Uncertainties

Estimation of potential risks to human health that may result from exposure to chemicals in the environment is a complex process that often requires the combined efforts of multiple disciplines. Each assumption, whether regarding the toxicity value to use for a particular chemical or the value of a parameter in an exposure equation, has a degree of variability and uncertainty associated with it. In each step of the HHRA process, beginning with the data collection and analysis and continuing through the toxicity assessment, exposure assessment, and risk characterization, conservative assumptions are made that are intended to be protective of human health and to ensure that risks are not underestimated. There is a probability of overestimating health risks or hazards for a number of reasons. The following subsections provide a discussion of the key uncertainties that may affect the final estimates of human health risk in this HHRA. Uncertainties are arranged by topic.

6.2.1 Environmental Sampling and Analysis

The process of environmental sampling and analysis results in uncertainties from several sources, including errors inherent in sampling procedures or analytical methods. One area of uncertainty is sampling procedures. Since it is not possible to sample the entire area of interest at a given site, several samples are taken from each medium within a site, and the results are considered representative of the chemicals present throughout the site. This assumption may overestimate or underestimate risk.

Analytical methods also involved uncertainties. Due to uncertainty of quantification, individual chemicals were sometimes listed as detected but with the value qualified as estimated by laboratory qualification or validation procedures. The estimated value was used in the HHRA. This uncertainty may either overestimate or underestimate risk depending on how close the estimated value is to the true value.

Shallow groundwater (piezometer) data from all LTM sampling events conducted following the 2012 HHRA, occurring between 2013 and 2016, were included in the HHRA update. None of the sampling events were excluded from the HHRA due to their not being any discernable concentration pattern indicating a consistent increase or decrease in concentration over time. This assumption may result in an over-estimate of potential risk associated with exposure to shallow groundwater given that it is likely that concentrations of certain chemicals may have decreased over time.

The HHRA utilizes the total (unfiltered) groundwater and surface water data for oral exposure pathways, consistent with the recommendation in USEPA (2004). However, as indicated in USEPA (2014a):

> "....particulate-bound chemicals in an aqueous medium (e.g., suspended sediment particles) would be considered to be much less bioavailable for dermal absorption, due to inefficient adsorption of suspended particles onto the skin surface and a slower rate of absorption into the skin. The uncertainty in the estimation of the dermal dose from a water sample with high turbidity is directly proportional to the magnitude of the difference in the concentration between an unfiltered and filtered sample. The actual bioavailable concentration is likely to lie somewhere between the unfiltered and filtered sample concentrations."

Therefore, the use of the unfiltered groundwater and surface water data for the dermal contact pathway is conservative.

6.2.2 COPC Selection

A comparison of maximum detected chemical concentrations to USEPA RSLs and RIDEM criteria was conducted as part of the COPC selection process. RSLs are conservative risk-based values that are used when selecting COPCs so as not to omit a chemical that might contribute significantly to risk. Chemicals whose maximum concentrations were below their respective screening value were not identified as COPCs or further evaluated to quantify potential risk/hazard. It is unlikely that this risk-based screening excluded chemicals that would be of concern, based on the conservative exposure assumptions and conservatively derived toxicity criteria that are the basis of the screening level. Although following this methodology does not provide a quantitative risk estimate for all chemicals, it focuses the assessment on the chemicals accounting for the greatest risks (i.e., chemicals whose maximum concentrations exceeded their respective screening level).

Although the overall potential risk estimates are uncertain, it is not expected that actual risks will be significantly greater than estimated risks given that a reasonable effort was made to characterize current and future potential health risks given current knowledge.

The shallow groundwater and surface water datasets contain non-detect results with LODs greater than USEPA tapwater RSLs (2016a) for several target VOCs. These elevated LODs introduce some level of uncertainty into the COPC selection and calculation of EPCs. The use of USEPA tapwater RSLs (which are protective of a drinking water ingestion scenario) to select surface water COPCs is conservative. The LODs associated with all surface water results are less than the associated risk-based screening level derived using the USEPA RSL calculator (2016a) based on a recreational surface water exposure scenario (using the exposure assumptions presented in Table 4). Therefore, although the LODs for surface water are greater than the tapwater RSLs used for selecting surface water COPCs in this HHRA update, the COPC selection results in this HHRA update are conservative and the conclusions of the HHRA update would not change if surface water LODs were less than the tapwater RSLs.

The LODs associated with the majority of the groundwater results are less than RIDEM GA groundwater objectives (RIDEM, 2011). Additionally, groundwater COPCs identified in the HHRA update are the same as those identified in the 2012 HHRA. Therefore, the presence of LODs above the tapwater RSLs are not considered to result in the exclusion of any target VOCs that would alter the conclusions of the HHRA update.

6.2.3 Toxicological Data

Uncertainty is associated with the toxicity values and toxicity information available to assess potential adverse effects.

One of the major contributors to uncertainty is the accuracy of the toxicity values used. A cancer potency value is a mathematical extrapolation of the slope of the dose-response curve from high doses administered to animals (or the exposures observed in epidemiological studies) to the low doses commonly experienced in the environment. The USEPA has developed potency values for chemicals classified as carcinogens, based on the premise that there is no threshold (i.e., there is no level of exposure below which there is no risk of a carcinogenic effect). USEPA's *Guidelines for Carcinogen Risk Assessment* (USEPA, 2005b) acknowledges that the mode of action of a carcinogen may involve both threshold and non-threshold mechanisms. To the extent that the approach used to develop the potency estimate is incorrect, the extrapolated risks may be overestimations or underestimations. However, in the derivation of toxicity values, conservative assumptions are employed. Therefore, toxicity values tend to be biased toward overestimating potential risk.

For dermal exposure pathways, the absence of dermal toxicity criteria necessitated the use of oral toxicity data. To calculate potential risk estimates for the dermal pathway, absolute oral bioavailability factors that reflect the toxicity study conditions were used to modify the oral toxicity criteria. For the chemicals with oral absorption exceeding 50%, a default oral absorption factor of 100% was used. The potential risk estimates for the dermal pathways may be overestimated or underestimated depending on how closely these values reflect the difference between the oral and dermal routes. These estimates are uncertain and may result in either an overestimation or underestimation of risk.

6.2.4 Exposure Assessment

The primary areas of uncertainty affecting exposure parameter estimation involve the assumptions regarding exposure pathways, the estimation of EPCs, and the parameters used to estimate chemical doses. The uncertainties associated with these various sources are discussed below.

6.2.4.1 EPCs

With respect to determining EPCs for this evaluation, one assumption was that the concentrations of chemicals in the medium evaluated would remain constant over the exposure time. Depending on the properties of the chemical and the medium in which it was detected, this assumption may overestimate risks, depending on the degree of chemical degradation to less toxic species or transport to other media. Conversely, environmental bioactivation of chemicals to more toxic chemicals was also not considered. Therefore, this assumption may underestimate risk if bioactivation mechanisms are significant.

The majority of the maximum detected concentrations in the updated dataset are lower than those calculated in the 2012 HHRA. However, the majority of the updated shallow groundwater EPCs are between one and three times higher than the EPCs calculated in the 2012 HHRA. The increase in EPCs, despite the decrease in overall concentrations, is due in part to a smaller sample size, resulting in the selection of the maximum detected concentration as the EPC for some scenarios.

6.2.4.2 Exposure Assumptions

The parameter values used to describe the extent, frequency, and duration of exposure are associated with some uncertainty. Actual risks for some individuals within an exposed population may vary from those predicted depending on the actual exposure durations, intake rates (e.g., surface water ingestion rates), or body weights.

There are no formal recreational facilities (e.g., public swimming areas) currently located along the Site 07 shoreline and there are no known plans for development of formal recreational facilities in the future. Therefore, it is unlikely that a young child would be routinely exposed to the

environmental media along this shoreline. However, exposures by a young child were conservatively evaluated.

The exposure assumptions were generally selected to produce a reasonable upper-bound estimate of exposure in accordance with USEPA guidelines, although in some cases the combination of the various assumptions may lead to greater than an upper bound estimate. Therefore, exposures and estimated potential risks for the evaluated receptors are likely to be representative of reasonable upper-bound exposures, but in some cases may exceed reasonable upper-bound exposures.

7.0 SUMMARY AND CONCLUSIONS

This HHRA update was performed in support of the Site 07 Five Year Event LTM Report and will ultimately be used as part of the evaluation to confirm compliance with the RAOs identified in the ROD (EA, 1999) in the Fourth Five Year Review Report. The objective of this HHRA update is to determine whether there have been any changes and/or updates to USEPA HHRA guidance or site-specific conditions since the 2012 HHRA was conducted that would result in a change of the conclusions of the 2012 HHRA or whether the conclusions of the 2012 HHRA remain valid. Revised formal risk/hazard calculations were not performed as part of this 2017 HHRA update. However, a quantitative evaluation of the potential exposure to Site 07 shoreline shallow groundwater, surface water, and/or sediment by recreational users was conducted to determine whether updates to the 2012 HHRA would result in cumulative potential cancer risk and/or noncancer hazard above USEPA and RIDEM target risk/hazard levels.

The receptors and exposure pathways evaluated in the HHRA update are consistent with those evaluated in the 2012 HHRA based on current and potential future land use, including recreational users exposed to shoreline media while swimming, wading, or clamming/harvesting shellfish.

The overall conclusion of this HHRA update is that the conclusions of the 2012 HHRA remain valid and exposure to shallow groundwater, surface water, and sediment along the Site 07 shoreline by recreational users does not result in a potential cancer risk or noncancer hazard above USEPA or RIDEM target levels. The potential cancer risk and noncancer HI results are summarized by receptor, as follows:

7.1 Current/Future Recreational Users – Swimming and Wading Scenarios

Child, adolescent, adult, and lifelong recreational users were evaluated for exposure to shoreline surface water and sediment via incidental ingestion and dermal contact while swimming or wading. No sediment COPCs were identified (i.e., sediment concentrations are less than risk-based screening levels). This exposure scenario was evaluated based on surface water samples collected at low tide at the harbor floor and mid-point of the water column. Samples collected in surface water approximately three feet deep (i.e., Depths 2 and 3/Case 1) were utilized for evaluation of the swimming scenario. Samples collected in surface water approximately six inches deep (i.e., Depth 1/Case 3) were utilized for evaluation of the wading scenario.

The potential cumulative ELCRs associated with a recreational user wading scenario are less than USEPA's target risk range of 10^{-6} to 10^{-4} and RIDEM's target risk level of 10^{-5}. The total HI is less than USEPA/RIDEM's target HI of 1.

The potential cumulative ELCRs and HI associated with a recreational user wading scenario are less than or within USEPA's target risk range of 10^{-6} to 10^{-4}, and less than USEPA/RIDEM's target HI of

1, respectively. However, the potential cumulative ELCR associated with the child and lifelong recreational user wading scenario is slightly higher than RIDEM's target risk level of 10^{-5}. Vinyl chloride in surface water (incidental ingestion exposure route) was identified as the risk driver causing the exceedance of RIDEM's target risk level based on the EPC equal to the one detected concentration. Due to the low frequency of detection (approximately 0.03 percent), vinyl chloride is not identified as a surface water COC. The total potential cumulative ELCRs for the child and lifelong recreational user wading scenario are less than 10^{-5} if vinyl chloride is excluded as a COPC.

These results indicate that the conclusions of the 2012 HHRA, which indicated that potential exposures to sediment and surface water along the Site 07 shoreline by recreational users while swimming or wading do not pose a cancer risk or noncancer hazard above USEPA or RIDEM target levels. As a result, adverse health effects are not anticipated for this receptor.

7.2 Current/Future Recreational Users – Shell Fisherman

Adolescent and adult recreational users were evaluated for exposure to shallow groundwater along the shoreline via dermal contact; and exposure to shoreline surface water and sediment via incidental ingestion and dermal contact while clamming/harvesting shellfish. No sediment COPCs were identified (i.e., sediment concentrations are less than risk-based screening levels). This exposure scenario was evaluated based on surface water samples collected at low tide at the harbor floor and mid-point of the water column where water is approximately six inches deep (i.e., Depths 1 and 2/Case 3), and shallow groundwater samples within each of the groundwater exposure points (Southern Boundary, Shoreline, Western Boundary, Mid-Southern Boundary).

The potential cumulative ELCRs associated with a recreational user – shell fisherman scenario are less than USEPA's target risk range of 10^{-6} to 10^{-4} and RIDEM's target risk level of 10^{-5}. The total HI is less than USEPA/RIDEM's target HI of 1. These results indicate that the conclusions of the 2012 HHRA, which indicated that potential exposures to shallow groundwater, sediment, and surface water along the Site 07 shoreline by recreational users while clamming/harvesting shellfish do not pose a cancer risk or noncancer hazard above USEPA or RIDEM target levels, remain valid. As a result, adverse health effects are not anticipated for this receptor.

Notes:

Refer to Appendix A for samples included in data set.

ARAR/TBC = Applicable or Relevant and Appropriate Requirements/To be Considered.

C = Cancer. Screening value is based on the screening level protective of carcinogenic effects.

CAS = Chemical Abstracts Service.

COPC = Chemical of Potential Concern.

ug/L = micrograms per liter.

N/A = Not Applicable or Not Available.

NC = Noncancer. Screening value is based on the screening level protective of noncarcinogenic effects.

RIDEM = Rhode Island Department of Environmental Management.

USEPA = United States Environmental Protection Agency.

VOCs = Volatile organic compounds.

(1) Minimum/maximum detected concentration and associated data flags.

J = The chemical was positively identified; however, the associated numerical value is an estimated concentration.

J- = The chemical was positively identified; however, the associated numerical value is a low estimated concentration.

(2) Range of Reporting Detection Limits (RDLs).

(3) Maximum detected concentration used for screening.

(4) Background values were not used for COPC screening purposes, although applicable background values may be considered in the risk characterization portion of the risk assessment, if available.

(5) Groundwater screening levels include the following:

- USEPA Regional Screening Level (RSL) for tapwater based on a target risk level of 1E-6 for carcinogens and a target hazard quotient of 0.1 for noncarcinogens (May 2016).

- RIDEM GA Groundwater Objectives - RIDEM Rules and Regulations for the Investigation and Remediation of Hazardous Material Releases, DEM-DSR-01-93. November 2011.

The following surrogates were used for chemicals without available screening levels:

The value for 1,1-Dichloroethene was used for cis-1,2-Dichloroethene and trans-1,2-Dichloroethene.

(6) Rationale Codes:

Selection Reason: Above Screening Level (ASL)

Deletion Reason: Below Screening Levels (BSL); Essential Nutrient (NUT)

TABLE 3.1
EXPOSURE POINT CONCENTRATION SUMMARY AND COMPARISON
REASONABLE MAXIMUM EXPOSURE
HUMAN HEALTH RISK ASSESSMENT UPDATE
SITE 07 - CALF PASTURE POINT
FORMER NAVAL CONSTRUCTION BATTALION CENTER DAVISVILLE
NORTH KINGSTOWN, RHODE ISLAND

Scenario Timeframe:	Current/Future
Medium:	Groundwater
Exposure Medium:	Shallow Groundwater

Notes:

CAS = Chemical Abstracts Service.

EPC = Exposure point concentration.

HHRA = Human health risk assessment.

N/A = Not applicable.

RME = Reasonable Maximum Exposure.

ug/L = micrograms per liter.

UCL = Upper confidence limit.

USEPA = United States Environmental Protection Agency.

VOCs = Volatile organic compounds.

(1) Site 07 – Southern Boundary (corresponds to the 2012 HHRA Cases 1 and 2) includes groundwater locations P07-02, P07-03, P07-04, P07-05, P07-06, P07-07, P07-08, P07-09, P07-10, P07-20, P07-21, P07-22, P07-23, and P07-24 sampled between 2013 and 2016 as part of the long-term monitoring program.

Site 07 – Shoreline (corresponds to the 2012 HHRA Case 3) includes groundwater locations in both the Southern Boundary and the Western Boundary sampled between 2013 and 2016 as part of the long-term monitoring program.

Site 07 – Western Boundary (corresponds to the 2012 HHRA Case 4) includes groundwater locations P07-14, P07-15, P07-16, P07-17, P07-28, and P07-29 located outside of the Southern Boundary sampled between 2013 and 2016 as part of the long-term monitoring program.

Site 07 - Mid-southern Boundary includes locations P07-05, P07-06, P07-07, P07-08, P07-09, and P07-10 sampled between 2013 and 2016 as part of the long-term monitoring program, which represent an area of higher concentrations within the Southern Boundary.

(2) Kaplan-Meier (KM) mean calculated using USEPA's ProUCL software version 5.1.002 (May 2016).

(b) Arithmetic means of detected concentrations used since KM mean was not calculated.

(3) UCL calculations were performed using USEPA's ProUCL software version 5.1.002. For data sets with multiple detection limits for non-detects, the use of the Kaplan Meier non-parametric test procedure is recommended and used to calculate an appropriate UCL. For the Kaplan Meier test procedure, the type of data distribution was determined using a series of tests (Shapiro-Wilk, Kolmogorov-Smirnov, Anderson-Darling) for normal, lognormal, or gamma data distributions. The results of these distribution tests determined which UCL calculation was performed.
The UCL suggested by ProUCL is used, unless otherwise noted. In cases where more than one UCL is suggested, the higher UCL is used, unless otherwise noted.
NP = Non-parametric; N = Normal; LN = Lognormal; G = Gamma; NC = Not calculated.

(4) Equal to the maximum detected concentration.
J = The chemical was positively identified; however, the associated numerical value is an estimated concentration only.
J- = The chemical was positively identified; however, the associated numerical value is a low estimated concentration.

(5) Indicates the statistic on which the exposure point concentration is based.
Maximum = Maximum detected concentration.
95% Approx. Gamma UCL = Calculated using an Approximate Gamma distribution procedure.
95% Gamma Adjusted UCL = Calculated using Adjusted Gamma distribution procedure.
95% Gamma Adjusted KM-UCL = Calculated using Kaplan Meier Adjusted Gamma distribution procedure.
95% KM (t) UCL = Calculated using 95% Kaplan Meier (Student's t approximation) non-parametric procedure.
95% KM H-UCL = Calculated using 95% Kaplan Meier (Land's H-stat) lognormal procedure.
95% KM (Chebyshev) UCL = Calculated using 95% Kaplan Meier (Chebyshev inequality) non-parametric procedure.
97.5% KM (Chebyshev) UCL = Calculated using 97.5% Kaplan Meier (Chebyshev inequality) non-parametric procedure.

(6) The UCL recommended by ProUCL is used (where multiple values are recommended, the higher is used).
(a) Maximum detected concentration used for EPC due to the low number of detections or small sample size.

(7) EPCs presented in Table 3.2.RME of the 2012 HHRA for Site 7 Case 2 Post-2010 South Boundary.

(8) EPCs presented in Table 3.3.RME of the 2012 HHRA for Site 7 Case 3.

(9) EPCs presented in Table 3.4.RME of the 2012 HHRA for Site 7 Case 4.

ug/L = micrograms per liter.

UCL = Upper confidence limit.

VOCs = Volatile organic compounds.

(1) Site 07 – Low Tide – Depth 1 (corresponds to the 2012 HHRA Case 3) includes all surface water locations sampled in 2016 as part of the long-term monitoring program; including samples collected at the harbor floor where surface water is 6 inches deep. Utilized in evaluation of a wading and clamming scenario.

Site 07 – Low Tide – Depth 2 (corresponds to the 2012 HHRA Case 1) includes all surface water locations sampled in 2016 as part of the long-term monitoring program; including samples collected at the harbor floor where surface water is 3 feet deep. Utilized in evaluation of a swimming scenario.

Site 07 – Low Tide – Depth 3 (corresponds to the 2012 HHRA Case 1) includes all surface water locations sampled in 2016 as part of the long-term monitoring program; including samples collected at the mid-point of the water column where surface water is 3 feet deep. Utilized in evaluation of a swimming scenario.

(2) Kaplan-Meier (KM) mean calculated using USEPA's ProUCL software version 5.1.002 (May 2016).

(3) Equal to the maximum detected concentration.

J = The chemical was positively identified; however, the associated numerical value is an estimated concentration only.

(4) Indicates the statistic on which the exposure point concentration is based.

Maximum = Maximum detected concentration.

(5) Maximum detected concentration used for EPC due to the low number of detections or small sample size.

(6) EPCs presented in Table 3.7.RME of the 2012 HHRA for the Site 7 - Location 1 - Low Tide scenario (Case 3). These EPCs for the low tide scenario are higher than those for the low, middle & high tide scenario (Case 4).

COMPARISON OF EXPOSURE ASSUMPTIONS

HUMAN HEALTH RISK ASSESSMENT UPDATE

SITE 07 - CALF PASTURE POINT

FORMER NAVAL CONSTRUCTION BATTALION CENTER DAVISVILLE

NORTH KINGSTOWN, RHODE ISLAND

				Child Recreator			Adolescent Recreator			Adult Recreator		
Exposure Media/ Scenario	Exposure Route(s)	Parameter	Units	2012 HHRA	Current Value	Current Source	2012 HHRA	Current Value	Current Source	2012 HHRA	Current Value	Source

Notes:

Shading indicates a difference between exposure assumptions/unit intakes utilized in the 2012 HHRA in comparison to current exposure assumptions/unit intakes.

BPJ = best professional judgement.

cm^2 = square centimeters.

HHRA = Human Health Risk Assessment.

kg = kilograms.

L/hour = liters per hour.

N/A = Not applicable/available.

USEPA = United States Environmental Protection Agency.

(1) Assumes 2 hours per event based on best professional judgement.

(2) Assumes three days a week from April through October based on best professional judgement.

(3) Assumes exposure occurs from ages 2 to 6 years old.

(4) Assumes 25 percent of total body skin surface area (evaluated in the swimming scenario) is exposed.

(5) The exposure duration for an adolescent reflects the 10 years from ages 7 to 16 years old.

(6) Assumes 33 percent of total body skin surface area (evaluated in the swimming scenario) is exposed.

(7) Assumes 10 percent of total body skin surface area (evaluated in the swimming scenario) is exposed.

(8) Recommended mean body weight. Weighted average of recommended mean body weight for the associated age range (USEPA, 2011; Table 8-3).

(9) Recommended total body surface area. Weighted average of recommended mean body weight for the associated age range (USEPA, 2011; Table 7-1).

(10) Unit Intakes were calculated as follows, consistent with the equations utilized in the 2012 HHRA, Risk Assessment Guidance for Superfund (RAGS) Part D Table 4s:

Ingestion Intake = (Ingestion Rate x conversion factor (0.001 mg/ug) x exposure time x exposure frequency x exposure duration)/(body weight x averaging time)

Dermal Intake = (surface area x event frequency x exposure frequency x exposure duration)/(body weight x averaging time)

Notes:

CAS = Chemical Abstracts Service.

HHRA = Human Health Risk Assessment.

N/A = Not Applicable/Not Available.

N/E = Not evaluated.

mg/kg=day = milligrams per kilogram per day.

RfD = Reference Dose.

USEPA = United States Environmental Protection Agency.

VOCs = Volatile organic compounds.

Shading indicates a difference between toxicity information utilized in the 2012 HHRA in comparison to current toxicity information obtained in accordance with USEPA's recommended hierarchy discussed in the report text.

(1) Oral absorption efficiency exceeds 50%. Therefore, no adjustment of the oral slope factor is necessary (USEPA, 2004. Exhibit 4-1).

(2) Oral Absorption Efficiencies from Exhibit 4-1 (USEPA, 2004. Risk Assessment Guidance for Superfund, Part E).

(3) Calculated as: (oral RfD) x (oral to dermal adjustment factor).

(4) Toxicity data obtained from the following sources:

I - USEPA Integrated Risk Information System [https://www.epa.gov/iris].

P - USEPA Provisional Peer Reviewed Toxicity Values Appendix [https://hhpprtv.ornl.gov/].

Notes:

CAS = Chemical Abstracts Service.

CSF = Cancer Slope Factor.

HHRA = Human Health Risk Assessment.

N/A = Not Applicable/Not Available.

N/E = Not evaluated.

mg/kg=day = milligrams per kilogram per day.

USEPA = United States Environmental Protection Agency.

VOCs = Volatile organic compounds.

Shading indicates a difference between toxicity information utilized in the 2012 HHRA in comparison to current toxicity information obtained in accordance with USEPA's recommended hierarchy discussed in the report text.

(1) Oral absorption efficiency exceeds 50%. Therefore, no adjustment of the oral slope factor is necessary (USEPA, 2004. Exhibit 4-1).

(2) Calculated as: (oral slope factor) / (oral to dermal adjustment factor)

(3) Toxicity data obtained from the following sources:

I - USEPA Integrated Risk Information System [https://www.epa.gov/iris].

C - California Environmental Protection Agency Office of Environmental Health Hazard Assessment Toxicity Criteria Database [https://oehha.ca.gov/chemicals]

(4) CSF associated with Non-Hodgkins Lymphona and liver effects.

(5) CSF associated with kidney effects.

(6) Cancer toxicity values for vinyl chloride account for mutagenic action, such that age-dependent adjustment factors (ADAFs) are not applied for vinyl chloride.

Weight of Evidence Characterization/USEPA Group:

A - Human carcinogen

B1 - Probable human carcinogen - indicates that limited human data are available

B2 - Probable human carcinogen - indicates sufficient evidence in animals and inadequate or no evidence in humans

C - Possible human carcinogen

D - Not classifiable as a human carcinogen (by the oral route)

CARC - Carcinogenic to humans.

LIKELY - Likely to be carcinogenic to humans.

INADEQUATE - Inadequate information to assess carcinogenic potential.

TABLE 7.1
POTENTIAL CANCER RISKS AND NONCANCER HAZARD QUOTIENTS - SCALING TABLES - RECREATIONAL USER - WADER
HUMAN HEALTH RISK ASSESSMENT UPDATE
SITE 07 - CALF PASTURE POINT
FORMER NCBC DAVISVILLE
NORTH KINGSTOWN, RHODE ISLAND

Scenario Timeframe: Current/Future
Receptor Population: Recreational Users - Wader
Exposure Point: Site 07 - Low Tide (Case 3)

Medium	Receptor Age	Exposure Route	COPC	CAS	EPC (ug/L) (a)			Unit Intake - Cancer (b)			Unit Intake - Noncancer (b)			Cancer Toxicity Value - Cancer Slope Factor (c)			Noncancer Toxicity Value - Reference Dose (c)			Potential Cancer Risk (d)		Potential Noncancer Hazard Quotient (e)	
					2012 HHRA	Current	Ratio	2012 HHRA	Current	Ratio	2012 HHRA	Current	Ratio	2012 HHRA	Current	Ratio	2012 HHRA	Current	Ratio	2012 HHRA	Current	2012 HHRA	Current

Notes:
CAS = Chemical Abstracts Service.
COPC = Chemical of potential concern.
EPC = Exposure point concentration.
HHRA = Human Health Risk Assessment.
N/A = Not applicable/available.
Ratio = Equals the associated current value divided by the associated 2012 value, with the exception of the noncancer toxicity value, which is the associated 2012 value divided by the associated current value.
(a) Presented on EPC comparison Table 3.2.
(b) Calculated on Table 4.
(c) Noncancer and cancer toxicity values are presented on Tables 5 and 6, respectively.
(d) Potential cancer risks and noncancer hazard quotients for the 2012 HHRA presented in Risk Assessment Guidance for Superfund (RAGS) Part D Table 9s in the 2012 HHRA report. Updated potential cancer risks and noncancer hazard quotients estimated by scaling the risk and hazard quotient estimates calculated in the 2012 HHRA based on the changes in EPCs, exposure assumptions (used to calculate the unit intake), and toxicity values using the following equations:
Updated potential risk = 2012 HHRA risk estimate x (current EPC / 2012 EPC) x (current unit intake / 2012 unit intake) x (current cancer slope factor [CSF] / 2012 CSF)
Updated potential hazard quotient [HQ] = 2012 HHRA HQ estimate x (current EPC / 2012 EPC) x (current unit intake / 2012 unit intake) x (2012 reference dose [RfD] / current RfD)
(e) Potential cancer risk estimates for the lifelong scenario were calculated by summing the associated estimates for the child, adolescent, and adult age groups.
Shading indicates an exceedance of Rhode Island Department of Environmental Management's (RIDEM) target cumulative cancer risk level of 1E-5 due to incidental ingestion of vinyl chloride in surface water. The maximum detected concentration of vinyl chloride in surface water was selected as the surface water EPC because only one of the 30 vinyl chloride surface water results were detected. Due to the low frequency of detection (approximately 0.03 percent), vinyl chloride is not identified as a surface water chemical of concern. The total potential cumulative cancer risk estimate is less than 1E-5 when vinyl chloride is excluded.

TABLE 7.2
POTENTIAL CANCER RISKS AND NONCANCER HAZARD QUOTIENTS - SCALING TABLES - RECREATIONAL USER - SHELL FISHERMAN
HUMAN HEALTH RISK ASSESSMENT UPDATE
SITE 07 - CALF PASTURE POINT
FORMER NCBC DAVISVILLE
NORTH KINGSTOWN, RHODE ISLAND

Scenario Timeframe: Current/Future
Receptor Population: Recreational Users - Shell Fisherman
Exposure Point: Site 07 Surface Water + Groundwater (Southern Boundary)

Medium	Exposure Point	Receptor Age	Exposure Route	COPC	CAS	EPC (ug/L) (a)			Unit Intake - Cancer (b)			Unit Intake - Noncancer (b)			Cancer Toxicity Value - Cancer Slope Factor (c)			Noncancer Toxicity Value - Reference Dose (c)			Potential Cancer Risk (d)		Potential Noncancer Hazard Quotient (e)	
						2012 HHRA	Current	Ratio	2012 HHRA	Current	Ratio	2012 HHRA	Current	Ratio	2012 HHRA	Current	Ratio	2012 HHRA	Current	Ratio	2012 HHRA	Current	2012 HHRA	Current

Notes:
CAS = Chemical Abstracts Service.
COPC = Chemical of potential concern.
EPC = Exposure point concentration.
HHRA = Human Health Risk Assessment.
N/A = Not applicable/available.
Ratio = Equals the associated current value divided by the associated 2012 value, with the exception of the noncancer toxicity value, which is the associated 2012 value divided by the associated current value.
(a) Presented on groundwater and surface water EPC comparison Tables 3.1 and 3.2, respectively.
(b) Calculated on Table 4.
(c) Noncancer and cancer toxicity values are presented on Tables 5 and 6, respectively.
(d) Potential cancer risks and noncancer hazard quotients for the 2012 HHRA presented in Risk Assessment Guidance for Superfund (RAGS) Part D Table 9s in the 2012 HHRA report. Updated potential cancer risks and noncancer hazard quotients estimated by scaling the risk and hazard quotient estimates calculated in the 2012 HHRA based on the changes in EPCs, exposure assumptions (used to calculate the unit intake), and toxicity values using the following equations:
Updated potential risk = 2012 HHRA risk estimate x (current EPC / 2012 EPC) x (current unit intake / 2012 unit intake) x (current cancer slope factor [CSF] / 2012 CSF)
Updated potential hazard quotient [HQ] = 2012 HHRA HQ estimate x (current EPC / 2012 EPC) x (current unit intake / 2012 unit intake) x (2012 reference dose [RfD] / current RfD)
(e) Potential cancer risk estimates for the lifelong scenario were calculated by summing the associated estimates for the adolescent and adult age groups. The child receptor is not considered to perform shellfishing.
(f) A RfD was not available for 1,2-dichloroethane when evaluated in the 2012 HHRA, therefore, a potential noncancer hazard quotient could not be scaled based on the 2012 HHRA results. Therefore, a potential noncancer hazard quotient value equal to that for 1,1,2-trichloroethane was used. 1,1,2-Trichloroethane has a slightly higher (less toxic) reference dose as compared to 1,2-dichloroethane, making the use of this potential hazard quotient conservative for application to 1,2-dichloroethane.

TABLE 7.3
POTENTIAL CANCER RISKS AND NONCANCER HAZARD QUOTIENTS - SCALING TABLES - RECREATIONAL USER - SHELL FISHERMAN
HUMAN HEALTH RISK ASSESSMENT UPDATE
SITE 07 - CALF PASTURE POINT
FORMER NCBC DAVISVILLE
NORTH KINGSTOWN, RHODE ISLAND

Scenario Timeframe: Current/Future
Receptor Population: Recreational Users - Shell Fisherman
Exposure Point: Site 07 Surface Water + Groundwater (Mid-Southern Boundary)

Medium	Exposure Point	Receptor Age	Exposure Route	COPC	CAS	EPC (ug/L) (a)			Unit Intake - Cancer (b)			Unit Intake - Noncancer (b)			Cancer Toxicity Value - Cancer Slope Factor (c)			Noncancer Toxicity Value - Reference Dose (c)			Potential Cancer Risk (d)		Potential Noncancer Hazard Quotient (e)	
						2012 HHRA	Current	Ratio	2012 HHRA	Current	Ratio	2012 HHRA	Current	Ratio	2012 HHRA	Current	Ratio	2012 HHRA	Current	Ratio	2012 HHRA	Current	2012 HHRA	Current

Notes:
CAS = Chemical Abstracts Service.
COPC = Chemical of potential concern.
EPC = Exposure point concentration.
HHRA = Human Health Risk Assessment.
N/A = Not applicable/available.
Ratio = Equals the associated current value divided by the associated 2012 value, with the exception of the noncancer toxicity value, which is the associated 2012 value divided by the associated current value.
(a) Presented on groundwater and surface water EPC comparison Tables 3.1 and 3.2, respectively.
(b) Calculated on Table 4.
(c) Noncancer and cancer toxicity values are presented on Tables 5 and 6, respectively.
(d) Potential cancer risks and noncancer hazard quotients for the 2012 HHRA presented in Risk Assessment Guidance for Superfund (RAGS) Part D Table 9s in the 2012 HHRA report. Updated potential cancer risks and noncancer hazard quotients estimated by scaling the risk and hazard quotient estimates calculated in the 2012 HHRA based on the changes in EPCs, exposure assumptions (used to calculate the unit intake), and toxicity values using the following equations:
Updated potential risk = 2012 HHRA risk estimate x (current EPC / 2012 EPC) x (current unit intake / 2012 unit intake) x (current cancer slope factor [CSF] / 2012 CSF)
Updated potential hazard quotient [HQ] = 2012 HHRA HQ estimate x (current EPC / 2012 EPC) x (current unit intake / 2012 unit intake) x (2012 reference dose [RfD] / current RfD)
(e) Potential cancer risk estimates for the lifelong scenario were calculated by summing the associated estimates for the adolescent and adult age groups. The child receptor is not considered to perform shellfishing.
(f) A RfD was not available for 1,2-dichloroethane when evaluated in the 2012 HHRA, therefore, a potential noncancer hazard quotient could not be scaled based on the 2012 HHRA results. Therefore, a potential noncancer hazard quotient value equal to that for 1,1,2-trichloroethane was used. 1,1,2-Trichloroethane has a slightly higher (less toxic) reference dose as compared to 1,2-dichloroethane, making the use of this potential hazard quotient conservative for application to 1,2-dichloroethane.

Notes:

EPC = Exposure point concentration.

FD = Field duplicate.

HHRA = Human health risk assessment.

N = Normal sample.

(a) Southern Boundary (corresponds to the 2012 HHRA Cases 1 and 2) includes groundwater locations along the southern boundary sampled between 2013 and 2016 as part of the long-term monitoring program.

Shoreline (corresponds to the 2012 HHRA Case 3) includes groundwater locations in both the Southern Boundary and the Western Boundary sampled between 2013 and 2016 as part of the long-term monitoring program.

Western Boundary (corresponds to the 2012 HHRA Case 4) includes groundwater locations along the western boundary sampled between 2013 and 2016 as part of the long-term monitoring program.

Mid-Southern Boundary includes groundwater locations along the southern boundary sampled between 2013 and 2016 as part of the long-term monitoring program, which represents an area of higher concentrations within the Southern Boundary.

Notes:

EPC = Exposure point concentration.

FD = Field duplicate.

HHRA = Human health risk assessment.

N = Normal sample.

(a) Low Tide – Depth 1 (corresponds to the 2012 HHRA Case 3) includes all surface water locations sampled in 2016 as part of the long-term monitoring program; including samples collected at the harbor floor where surface water is 6 inches deep. Utilized in evaluation of a wading and clamming scenario.

Low Tide – Depth 2 (corresponds to the 2012 HHRA Case 1) includes all surface water locations sampled in 2016 as part of the long-term monitoring program; including samples collected at the harbor floor where surface water is 3 feet deep. Utilized in evaluation of a swimming scenario.

Low Tide – Depth 3 (corresponds to the 2012 HHRA Case 1) includes all surface water locations sampled in 2016 as part of the long-term monitoring program; including samples collected at the mid-point of the water column where surface water is 3 feet deep. Utilized in evaluation of a swimming scenario.

Notes:

Refer to the 2012 HHRA presented as Appendix F of the Third Five-Year Review Report (Tetra Tech; March 2013) for samples included in 2012 HHRA data set. Refer to Appendix A for samples included in the 2017 HHRA Update data set.

CAS = Chemical Abstracts Service.

COPC = Chemical of Potential Concern.

HHRA = Human Health Risk Assessment.

ug/L = micrograms per liter.

VOCs = Volatile organic compounds.

(1) Minimum/maximum detected concentration and associated data flags.

J = The chemical was positively identified; however, the associated numerical value is an estimated concentration.

J- = The chemical was positively identified; however, the associated numerical value is a low estimated concentration.

(2) Range of Reporting Detection Limits (RDLs).

(3) Chemicals presented on this table include the shoreline groundwater COPCs identified in the 2012 HHRA and chemicals detected in the 2017 HHRA shoreline groundwater dataset (as defined in the text and Appendix A). Chemicals not identified as COPCs in the 2012 HHRA that were also not detected in the 2017 HHRA dataset are not included.

UCL Statistics for Data Sets with Non-Detects

User Selected Options	
Date/Time of Computation	ProUCL 5.13/7/2017 1:09:03 PM
From File	ProUCL GW South_West Input.xls
Full Precision	OFF
Confidence Coefficient	95%
Number of Bootstrap Operations	2000

1,1,2,2-TETRACHLOROETHANE

General Statistics

Total Number of Observations	45	Number of Distinct Observations	28
Number of Detects	26	Number of Non-Detects	19
Number of Distinct Detects	25	Number of Distinct Non-Detects	3
Minimum Detect	0.55	Minimum Non-Detect	0.3
Maximum Detect	180	Maximum Non-Detect	1
Variance Detects	2758	Percent Non-Detects	42.22%
Mean Detects	37.2	SD Detects	52.52
Median Detects	8.35	CV Detects	1.412
Skewness Detects	1.628	Kurtosis Detects	1.92
Mean of Logged Detects	2.275	SD of Logged Detects	1.903

Normal GOF Test on Detects Only

Shapiro Wilk Test Statistic	0.728	**Shapiro Wilk GOF Test**
5% Shapiro Wilk Critical Value	0.92	Detected Data Not Normal at 5% Significance Level
Lilliefors Test Statistic	0.297	**Lilliefors GOF Test**
5% Lilliefors Critical Value	0.17	Detected Data Not Normal at 5% Significance Level

Detected Data Not Normal at 5% Significance Level

Kaplan-Meier (KM) Statistics using Normal Critical Values and other Nonparametric UCLs

KM Mean	21.62	KM Standard Error of Mean	6.564
KM SD	43.18	95% KM (BCA) UCL	34.04
95% KM (t) UCL	32.65	95% KM (Percentile Bootstrap) UCL	32.83
95% KM (z) UCL	32.42	95% KM Bootstrap t UCL	37.66
90% KM Chebyshev UCL	41.31	95% KM Chebyshev UCL	50.23
97.5% KM Chebyshev UCL	62.62	99% KM Chebyshev UCL	86.93

Gamma GOF Tests on Detected Observations Only

A-D Test Statistic	0.819	**Anderson-Darling GOF Test**
5% A-D Critical Value	0.813	Detected Data Not Gamma Distributed at 5% Significance Level
K-S Test Statistic	0.16	**Kolmogorov-Smirnov GOF**
5% K-S Critical Value	0.182	Detected data appear Gamma Distributed at 5% Significance Level

Detected data follow Appr. Gamma Distribution at 5% Significance Level

Gamma Statistics on Detected Data Only

k hat (MLE)	0.477	k star (bias corrected MLE)	0.448
Theta hat (MLE)	77.96	Theta star (bias corrected MLE)	83.09
nu hat (MLE)	24.81	nu star (bias corrected)	23.28
Mean (detects)	37.2		

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Minimum	0.01	Mean	21.5

Suggested UCL to Use

a Adjusted KM-UCL (use when k<=1 and 15 < n < 50 but k<=1) 39.08

When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test
When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

UCL Statistics for Data Sets with Non-Detects

User Selected Options	
Date/Time of Computation	ProUCL 5.13/7/2017 12:46:08 PM
From File	ProUCL GW SiteWide Input.xls
Full Precision	OFF
Confidence Coefficient	95%
Number of Bootstrap Operations	2000

1,1,2,2-TETRACHLOROETHANE

General Statistics

Total Number of Observations	54	Number of Distinct Observations	28
		Number of Missing Observations	333
Number of Detects	26	Number of Non-Detects	28
Number of Distinct Detects	25	Number of Distinct Non-Detects	3
Minimum Detect	0.55	Minimum Non-Detect	0.3
Maximum Detect	180	Maximum Non-Detect	1
Variance Detects	2758	Percent Non-Detects	51.85%
Mean Detects	37.2	SD Detects	52.52
Median Detects	8.35	CV Detects	1.412
Skewness Detects	1.628	Kurtosis Detects	1.92
Mean of Logged Detects	2.275	SD of Logged Detects	1.903

Normal GOF Test on Detects Only

Shapiro Wilk Test Statistic	0.728	**Shapiro Wilk GOF Test**
5% Shapiro Wilk Critical Value	0.92	Detected Data Not Normal at 5% Significance Level
Lilliefors Test Statistic	0.297	**Lilliefors GOF Test**
5% Lilliefors Critical Value	0.17	Detected Data Not Normal at 5% Significance Level

Detected Data Not Normal at 5% Significance Level

Kaplan-Meier (KM) Statistics using Normal Critical Values and other Nonparametric UCLs

KM Mean	18.07	KM Standard Error of Mean	5.58
KM SD	40.21	95% KM (BCA) UCL	27.61
95% KM (t) UCL	27.41	95% KM (Percentile Bootstrap) UCL	27.75
95% KM (z) UCL	27.25	95% KM Bootstrap t UCL	31.41
90% KM Chebyshev UCL	34.81	95% KM Chebyshev UCL	42.39
97.5% KM Chebyshev UCL	52.92	99% KM Chebyshev UCL	73.59

Gamma GOF Tests on Detected Observations Only

A-D Test Statistic	0.819	**Anderson-Darling GOF Test**
5% A-D Critical Value	0.813	Detected Data Not Gamma Distributed at 5% Significance Level
K-S Test Statistic	0.16	**Kolmogorov-Smirnov GOF**
5% K-S Critical Value	0.182	Detected data appear Gamma Distributed at 5% Significance Level

Detected data follow Appr. Gamma Distribution at 5% Significance Level

Gamma Statistics on Detected Data Only

nu hat (MLE)	24.81	nu star (bias corrected)	23.28
Mean (detects)	37.2		

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Minimum	0.01	Mean	17.92

Nonparametric Distribution Free UCL Statistics

Detected Data appear Approximate Gamma Distributed at 5% Significance Level

Suggested UCL to Use

95% KM Approximate Gamma UCL	32.25

When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test
When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Nonparametric Distribution Free UCL Statistics

Detected Data appear Approximate Gamma Distributed at 5% Significance Level

Suggested UCL to Use

95% KM Approximate Gamma UCL	250.3

When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test
When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

nu hat (MLE)	26.13	nu star (bias corrected)	22.85
Mean (detects)	55.78		

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Minimum	0.01	Mean	39.51
Maximum	180	Median	11.75
SD	54.13	CV	1.37
k hat (MLE)	0.259	k star (bias corrected MLE)	0.255

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Technical Memorandum
Abandonment and Reinstallation of the MW07-20 Well Pair
Site 07 Calf Pasture Point Long Term Monitoring
Former Naval Construction Battalion Center Davisville
North Kingstown, Rhode Island
December 5, 2016

1.0 INTRODUCTION

While performing the Fall 2016 long term monitoring (LTM) at Installation Restoration Program (IRP) Site 07, Resolution Consultants (Resolution) discovered that the well casing for monitoring well MW07-20D had corroded to the point that it had become detached from the well (see Photo 1 in Attachment A), there was no longer an expansion cap on the well riser (see Photo 2 in Attachment A), and the well was obstructed at approximately 26 feet below ground surface (bgs). The obstruction appeared to be the result of the well riser being plugged with sand at that depth. The well is 74.5 feet deep and Resolution was unable to determine whether the well riser was completely full of sand from the bottom of the well to the depth of the obstruction or if there was something else obstructing the well and the sand was on top of that obstruction. Regardless, Resolution was unable to clear the obstruction and it was determined that monitoring well MW07-20D would need to be abandoned and a replacement well installed approximately 25 to 30 feet inland of the current location in order to reduce exposure to storm surge, sea spray, and accidental damage or vandalism by recreational users of the Calf Pasture Point beach (as described below).

After further discussion, the Navy is proposing to also abandon the corresponding shallow well, MW07-20S, and install a replacement adjacent to the proposed new location of monitoring well MW07-20D to maintain the shallow deep well pairing. During the Fall 2014 LTM at IRP Site 07, Resolution discovered the shallow well had been vandalized (see Photos 3 through 6 in Attachment A). Resolution was able to repair the well (see Photo 7 in Attachment A), and collect samples during subsequent monitoring events, including the Fall 2016 LTM at IRP Site 07, and no additional vandalism has been observed. Nevertheless, moving this well inland would reduce potential damage from the natural elements described above, as well as from vandalism. The location of the existing wells and proposed location of the replacement wells are shown on Figure 1.

The United States Environmental Protection Agency (EPA) and Rhode Island Department of Environmental Management provided concurrence on the new location of the MW07-20 well pair during the October 27, 2016 Base Realignment and Closure (BRAC) Cleanup Team (BCT) teleconference. At the request of EPA and RIDEM, this Technical Memorandum has been drafted to provide details on the abandonment and re-installation procedures.

2.0 ABANDONMENT OF EXISTING WELLS MW07-20S AND MW07-20D

Well construction diagrams and boring logs for monitoring wells MW07-20S and MW07-20D are provided in Attachment B. For both wells, abandonment will be performed in accordance with the RIDEM Groundwater Quality Rules, Appendix 1 (RIDEM, 2010) to the greatest extent possible.

For monitoring well MW07-20S, an attempt will be made to pull the well out since it is only 15 feet deep and only the upper 3 feet of the well was grouted when originally installed. If successfully pulled, the remaining borehole will be tremie grouted with neat cement or neat cement grout up to 4 feet bgs, and the upper 4 feet will be restored with sand. It is possible that upon pulling of the well, some or all of the remaining borehole will collapse since the upper 12 feet of the borehole is comprised of mostly sand (see Boring Log in Attachment B). If this occurs the borehole will be tremie grouted from the point of collapse up to 4 feet bgs, and the upper 4 feet will be restored with sand. If the well is not able to be pulled, the well riser will be tremie grouted from the bottom of the well to 4 feet bgs. The upper 4 feet of well material will be removed, and the upper 4 feet will be restored with sand.

Monitoring well MW07-20D is 74.5 feet deep and is grouted to 61 feet bgs. Therefore pulling the well or overdrilling is not practical. Monitoring well MW07-20D will be abandoned by tremie grouting the well riser from the depth of the obstruction (i.e., approximately 26 feet bgs) to 4 feet bgs. The upper 4 feet of well material will be removed, and the upper 4 feet will be restored with sand.

3.0 REINSTALLATION OF MONITORING WELLS MW07-20S AND MW07-20D

Prior to reinstallation, a ticket with Rhode Island Call Before You Dig will be opened and utility clearance of the well locations will be performed by a subcontractor in accordance with Standard Operating Procedure (SOP) 3-01 *Utility Clearance* (see Attachment C). Reinstallation of the MW07-20 well pair will be performed according to SOP 3-12 *Monitoring Well Installation*

(see Attachment C) and the specific details in this Technical Memorandum. The wells will be installed using a hollow stem auger (HSA) drill rig. Drilling tools and equipment will be decontaminated in accordance with SOP 3-06 *Equipment Decontamination* (see Attachment C). Soils will be logged during installation of the deep well according to SOP 3-16 *Soil and Rock Classification* and headspace screening for volatile organic compounds (VOCs) will be performed according to SOP 3-19 *Headspace Screening for Total VOCs* using a photoionization detector calibrated in accordance with SOP 3-20 *Operation and Calibration of a Photoionization Detector* (see Attachment C). If elevated headspace readings are observed (i.e., greater than 25 parts per million [PPM]), a soil sample will be collected according to the VOC sampling procedures in Section 7.6.1 of SOP 3-21 *Surface and Subsurface Soil Sampling Procedures* (see Attachment C) and submitted for laboratory analysis of site-specific list of VOCs according to SW-846 Method 8260B. The VOC analysis will be performed according to the requirements of the Draft *Tier II Sampling and Analysis Plan, Long Term Monitoring, Site 07 Calf Pasture Point and Site 09 Allen Harbor Landfill* (Resolution, 2016).

Monitoring well MW07-20D will be reinstalled with a 10 foot screened interval starting from the top of bedrock. The HSA drill rig will be used to drill through the overburden, and once refusal is encountered, a rollerbit will be advanced 1 to 3 feet to confirm the top of bedrock. After the top of bedrock has been confirmed, the portion of bedrock that was drilled with the rollerbit will be plugged with bentonite and the well will be constructed above. The existing MW07-20D well is screened with a 6-slot screen; the slot size for the replacement well will be determined in the field based on the amount of fine sediment observed in the screened interval and is expected to either be 10-slot, 6-slot, or 7-slot based on historical data. The well screen and riser will be 2 inch polyvinyl chloride (PVC). Inert silica sand will be used for the filter pack; grade 0 silica sand will be used for a 10-slot screen and grade 00 silica sand will be used for 6-slot or 7-slot screens. The well will be completed with a lockable above ground steel protective casing, and will be outfitted with a padlock that is keyed the same as the other NCBC Davisville wells. The replacement well will be identified as MW07-20DA in order to distinguish it from the original well.

Monitoring well MW07-20S will be reinstalled with a 10 foot screened interval that intercepts the water table with approximately 7 feet of screen below the water table and three feet of screen above to account for seasonal variations in water table elevation. The existing MW07-20S well is screened with a 10-slot screen; the slot size for the replacement well will be determined in the field based on the amount of fine sediment observed in the screened interval, and it is

expected to either be 10-slot, 6-slot, or 7-slot based on historical data. The well screen and riser will be 2 inch PVC. The filter pack and well completion will be the same described for MW07-20DA above. The replacement well will be identified as MW07-20SA in order to distinguish it from the original well.

A Rhode Island-licensed surveyor will be contracted to survey the horizontal location and the vertical elevation of the measuring point for each replacement well. A notch or other indelible mark will be made on the riser of each replacement well to identify the measuring point. The elevation of the measuring points will be surveyed to the North American Vertical Datum of 1988 (NAVD 88).

4.0 WELL DEVELOPMENT AND SAMPLING

Once each replacement well has been installed and allowed to set for 24 hours, the well will be developed according to the procedures in SOP 3-13 *Monitoring Well Development* (see Attachment C). After the well pair has equilibrated for a minimum of 14 days from development, monitoring well MW07-20DA will be sampled. Monitoring well MW07-20SA will not be sampled since the original MW07-20S well was successfully sampled in September 2016.

5.0 INVESTIGATION DERIVED WASTE MANAGEMENT

Investigation derived waste (IDW) will consist of soil cuttings, equipment decontamination water, and development water, and will be managed according to the procedures in SOP 3-05 *Investigation Derived Waste Management* (see Attachment C). The drilling subcontractor will setup a temporary IDW staging area on IRP Site 07. Once well installation and development is complete, the drilling subcontractor will transport the IDW to the fenced in IDW staging area next to the trailer. A skid steer or similar piece of equipment will be used for IDW transport to the temporary and fenced in IDW staging areas. The IDW will be characterized along with the existing IDW from the Fall 2016 LTM event and properly disposed of at a Navy approved disposal facility. The IDW will also be handled in accordance with RIDEM Policy Memo 95-01 *Guidelines for the Management of Investigative Derived Wastes* and all disposal facilities will be per-approved by EPA Region I in accordance with the Off-Site Rule 40 CFR 300.440. Well materials that are removed from the existing well pair (i.e., upper 4 feet of well material) will be disposed of as construction and demolition debris.

6.0 REPORTING

The details of the abandonment and reinstallation of the MW07-20 well pair, along with the sample results for MW07-20DA will be included on the Site 07 Calf Pasture Point Fall 2016 Five Year Event Monitoring Report.

Resolution Standard Operating Procedures

Utility Clearance

Procedure 3-01

1.0 Purpose and Scope

1.1 This standard operating procedure (SOP) describes the process for determining the presence of subsurface utilities and other cultural features at locations where planned site activities involve the physical disturbance of subsurface materials.

1.2 This procedure is the Program-approved professional guidance for work performed by Resolution Consultants under the Comprehensive Long-Term Environmental Action Navy (CLEAN) contract (Contract Number N62470-11-D-8013).

1.3 The procedure applies to the following activities: soil gas surveying, excavating, trenching, drilling of borings and installation of monitoring and extraction wells, use of soil recovery or slide-hammer hand augers, and all other intrusive sampling activities.

1.4 The primary purpose of the procedure is to minimize the potential for damage to underground utilities and other subsurface features, which could result in physical injury, disruption of utility service, or disturbance of other subsurface cultural features.

1.5 If there are procedures, whether it be from Resolution Consultants, state, and/or federal, that are not addressed in this SOP and are applicable to utility clearance, those procedures should be added as an appendix to the project specific SAP.

1.6 As guidance for specific activities, this procedure does not obviate the need for professional judgment. Deviations from this procedure while planning or executing planned activities must be approved in accordance with Program requirements for technical planning and review.

2.0 Safety

2.1 Field and subcontractor personnel shall adhere to a site-specific health and safety plan (HASP).

3.0 Terms and Definitions

3.1 **Utility**

For the proposes of this SOP, a utility is defined as a manmade underground line or conduit, cable, pipe, vault or tank that is, or was, used for the transmission of material or energy (e.g., gas, electrical, telephone, steam, water or sewage, product transfer lines, or underground storage tanks).

3.2 **As-Built Plans**

As-built plans are plans or blueprints depicting the locations of structures and associated utilities on a property.

3.3 **One-Call**

The Utility Notification Center is the one-call agency for nationwide call before you dig. The Utility Notification Center is open 24 hours a day, and accepts calls from anyone planning to dig. The phone number 811 is the designated call before you dig phone number that directly connects you to your local one-call center. Additional information can be found at www.call811.com.

PRINTED COPIES ARE UNCONTROLLED. CONTROLLED COPY IS AVAILABLE ON COMPANY INTRANET.

Calling before you dig ensures that any publicly owned underground lines will be marked so that you can dig around them safely. Having the utility lines marked not only prevents accidental damage to the lines, but prevents property damage and personal injuries that could result in breaking a line.

The following information will need to be provided when a call is placed to One-Call:

- Your name, phone number, company name (if applicable), and mailing address.
- What type or work is being done.
- Who the work is being done for.
- The county and city the work is taking place in.
- The address or the street where the work is taking place.
- Marking instructions, (specific instructions as to where the work is taking place).

Under normal circumstances it takes between 2 to 5 days from the time you call (not counting weekends or holidays) to have the underground lines marked. Because these laws vary from state to state, exactly how long it will take depends on where your worksite is located. You will be given an exact start time and date when your locate request is completed, which will comply with the laws in your area.

In the event of an emergency (any situation causing damage to life or property, or a service outage), lines can be marked sooner than the original given time if requested.

3.4 **Toning**

Toning is the process of surveying an area utilizing one or more surface geophysical methods to determine the presence or absence of underground utilities. Typically, toning is conducted after identifying the general location of utilities and carefully examining all available site utility plans. Each location is marked according to the type of utility being identified. In addition, areas cleared by toning are flagged or staked to indicate that all identified utilities in a given area have been toned.

4.0 Training and Qualifications

4.1 The **Contract Task Order (CTO) Manager** is responsible for verifying that these utility locating procedures are performed prior to the initiation of active subsurface exploration.

4.2 The **Program Quality Manager** is responsible for ensuring overall compliance with this procedure.

4.3 The **Field Manager** is responsible for ensuring that all utility locating activities are performed in accordance with this procedure.

4.4 All **Field Personnel** are responsible for the implementation of this procedure.

5.0 Equipment and Supplies

5.1 Equipment and supplies necessary for locating subsurface utilities will be provided by the subcontractor; however, the project **Field Manager/Field Personnel** will provide any additional equipment and supplies as needed as well as maintain information regarding the utility clearance activities in the field logbook.

6.0 Procedure

Proceed wtih the following steps where subsurface exploration will include excavations, drilling, or any other subsurface investigative method that could damage utilities at a site. In addition to the steps outlined below, always exercise caution while conducting subsurface exploratory work.

6.1 Prepare Preliminary Site Plan

- Prepare a preliminary, scaled site plan depicting the proposed exploratory locations as part of the project specific Sampling and Analysis Plan (SAP) or Work Plan. Include as many of the cultural and natural features as practical in this plan.

6.2 Review Background Information

- Search existing plan files to review the as-built plans to identify the known location of utilities at the site. Plot the locations of utilities identified onto a preliminary, scaled site plan. Inform the CTO Manager if utilities lie within close proximity to a proposed exploration or excavation location. The CTO Manager will determine if it is necessary to relocate proposed sampling or excavation locations.
- Include the utility location information gathered during previous investigations (e.g., remedial investigation or remedial site evaluation) in the project design documents for removal or remedial actions. In this manner, information regarding utility locations collected during implementation of a CTO can be shared with the subcontractor during implementation of a particular task order. In many instances, this will help to reduce the amount of additional geophysical surveying work the subcontractor may have to perform.
- Conduct interviews with onsite and facility personnel familiar with the site to obtain additional information regarding the known and suspected locations of underground utilities. In addition, if appropriate, contact shall be made with local utility companies to request their help in locating underground lines. Pencil in the dimensions, orientation, and depth of utilities, other than those identified on the as-built plans, at their approximate locations on the preliminary plans. Enter the type of utility, the personnel who provided the information, and the date the information was provided into the field log.
- During the pre-field work interviewing process, the interviewer will determine which site personnel should be notified in the event of an incident involving damage to existing utilities. Record this information in the field logbook with the corresponding telephone numbers and addresses.

6.3 Site Visit/Locate Utilities/Toning

- Prior to the initiation of field activities, the Field Task Manager or similarly qualified field personnel shall visit the site and note existing structures and evidence of associated utilities, such as fire hydrants, irrigation systems, manhole and vault box covers, standpipes, telephone switch boxes, free-standing light poles, gas or electric meters, pavement cuts, and linear depression. Compare notes of the actual site configuration to the preliminary site plan. Note deviations in the field logbook and on the preliminary site plan. Accurately locate or survey and clearly mark with stakes, pins, flags, paint, or other suitable devices all areas where subsurface exploration is proposed. These areas shall correspond with the locations drawn on the preliminary site plan.
- Following the initial site visit by the Field Task Manager, a trained utility locating subcontractor will locate, identify, and tone all utilities depicted on the preliminary site plan. The Field Task Manager or similarly qualified field personnel shall visit the site and identify the areas of subsurface disturbance with white spray paint, chalk, white pin flags or some other easily identifiable marking. The utility locator should utilize appropriate sensing equipment to attempt to locate utilities that might not have appeared on the as-built plans. At a minimum, the utility subcontractor should utilize a metal detector and/or magnetometer; however, it is important to consider the possibility that non-metallic utilities or tanks might be present at the site. Use other appropriate surface geophysical methods such as Ground Penetrating Radar, Radiodetection, etc. as appropriate. Clear proposed exploration areas of all utilities in the immediate area where subsurface exploration is proposed. Clearly tone all anomalous areas. Clearly identify all toned areas on the preliminary site plan. All utilities near the area of subsurface disturbance should also be marked out by the utility subcontractor using the universal colors for subsurface utilities (i.e., red – electric; blue – water; green – sewer; yellow – gas; etc.). After toning the site and plotting all known or suspected buried utilities on the preliminary site plan, the utility locator shall provide the Field Task Manager with a copy of the completed preliminary

site plan. Alternatively, the Field Task Manager or designee shall document the results of the survey on the preliminary site plan.

- Report to the Field Task Manager anomalous areas detected and toned that are in close proximity to the exploration or excavation areas. The Field Task Manager shall determine the safe distance to maintain from the known or suspected utility. It may be necessary to relocate the proposed exploration or excavation areas. If this is required, the Field Task Manager or designee shall relocate them and clearly mark them using the methods described above. Completely remove the markings at the prior location. Plot the new locations on the site plan and delete the prior locations from the plan. In some instances, such as in areas extremely congested with subsurface utilities, it may be necessary to dig by hand or use techniques such as air knife to determine the location of the utilities.

6.4 **Prepare Site Plan**

- Prior to the initiation of field activities, draft a final site plan that indicates the location of subsurface exploration areas and all known or suspected utilities present at the site. Provide copies of this site plan to the Navy Technical Representative (NTR), the CTO Manager, and the subcontractor who is to conduct the subsurface exploration/excavation work. Review the site plan with the NTR to verify its accuracy prior to initiating subsurface sampling activities.

7.0 Quality Control and Assurance

7.1 Utility locating must incorporate quality control measures to ensure conformance to these and the project requirements.

8.0 Records, Data Analysis, Calculations

8.1 A bound field logbook will be kept detailing all activities conducted during the utility locating procedure.

8.2 The logbook will describe any changes and modifications made to the original exploration plan. The trained utility locator shall prepare a report and keep it in the project file. Also, a copy of the final site plan will be kept in the project file.

Investigation Derived Waste Management

Procedure 3-05

1.0 Purpose and Scope

This standard operating procedure (SOP) describes activities and responsibilities of the United States (U.S.) Navy Environmental Restoration (ER) Program, Naval Facilities Engineering Command, Atlantic (NAVFAC Atlantic) with regard to management of investigation-derived waste (IDW). The purpose of this procedure is to provide guidance for the minimization, handling, labelling, temporary storage, inventory, classification, and disposal of IDW generated under the ER Program. This procedure will also apply to personal protective equipment (PPE), sampling equipment, decontamination fluids, non-IDW trash, non-indigenous IDW, and hazardous waste generated during implementation of removal or remedial actions. The information presented will be used to prepare and implement work plans (WPs) for IDW-related field activities. The results from implementation of WPs will then be used to develop and implement final IDW disposal plans.

If there are procedures whether it be from Resolution Consultants, state and/or federal that are not addressed in this SOP and are applicable to IDW then those procedures may be added as an appendix to the project specific SAP.

This procedure applies to all Navy ER projects performed in the NAVFAC Atlantic Area of Responsibility.

This procedure shall serve as management-approved professional guidance for the ER Program and is consistent with protocol in the Uniform Federal Policy-Quality Assurance Project Plan (DoD 2005). As professional guidance for specific activities, this procedure is not intended to obviate the need for professional judgment during unforeseen circumstances. Deviations from this procedure while planning or executing planned activities must be approved by both the Contract Task Order (CTO) Manager and the Quality Assurance (QA) Manager or Technical Director, and documented.

This procedure was developed to serve as management-approved professional guidance for the management of IDW generated under the ER Program. It focuses on the requirements for minimizing, segregating, handling, labeling, storing, and inventorying IDW in the field. Certain drum inventory requirements related to the screening, sampling, classification, and disposal of IDW are also noted in this procedure.

2.0 Safety

The health and safety considerations for the work associated with this SOP, including both potential physical and chemical hazards, will be addressed in the project Health and Safety Plan (HASP). In the absence of a HASP, work will be conducted according to the CTO WP and/or direction from the **Site Safety Officer (SSO)**.

All **Field Personnel** responsible for IDW management must adhere to the HASP and must wear the PPE specified in the site-specific HASP. Generally, this includes, at a minimum, steel-toed boots or steel-toed rubber boots, safety glasses, American National Standards Institute-standard hard hats, and hearing protection (if heavy equipment is in operation). If safe alternatives are not achievable, discontinue site activities immediately.

3.0 Terms and Definitions

None.

PRINTED COPIES ARE UNCONTROLLED. CONTROLLED COPY IS AVAILABLE ON COMPANY INTRANET.

4.0 Training and Qualifications

4.1 The **CTO Manager** is responsible for ensuring that IDW management activities comply with this procedure. The **CTO Manager** is responsible for ensuring that all personnel involved in IDW management shall have the appropriate education, experience, and training to perform their assigned tasks.

4.2 The **Program Quality Manager** is responsible for ensuring overall compliance with this procedure.

4.3 The **Field Manager** is responsible for ensuring that all IDW is managed according to this procedure.

4.4 All **Field Personnel** are responsible for the implementation of this procedure.

5.0 Equipment and Supplies

The equipment and supplies required for implementation of this SOP include the following:

- Containers for waste (e.g., [U.S. Department of Transportation] DOT approved 55-gallon open and closed top drums) and material to cover waste to protect from weather (e.g., plastic covering);
- Hazardous /non-hazardous waste drum labels (weatherproof);
- Permanent marking pens;
- Inventory forms for project file;
- Plastic garbage bags, zip lock storage bags, roll of plastic sheeting; and
- Steel-toed boots, chemical resistant gloves, coveralls, safety glasses, and any other PPE required in the HASP.

6.0 Procedure

The following procedures are used to handle the IDW.

6.1 Drum Handling

6.1.1 IDW shall be containerized using DOT approved drums. The drums shall be made of steel or plastic, have a 55-gallon capacity, be completely painted or opaque, and have removable lids (i.e., United Nations Code 1A2 or 1H2). Typically 55-gallon drums are used, however small drums may be used depending on the amount of waste generated. New steel drums are preferred over recycled drums.

6.1.2 Recycled drums should not be used for hazardous waste, PCBs or other regulated shipments. For short-term storage of liquid IDW prior to discharge, double-walled bulk steel or plastic storage tanks may be used. For this scenario, consider the scheduling and cost-effectiveness of this type of bulk storage, treatment, and discharge system versus longer-term drum storage.

6.1.3 For long-term IDW storage at other project locations, the DOT approved drums with removable lids are recommended. Verify the integrity of the foam or rubber sealing ring located on the underside of some drum lids prior to sealing drums containing IDW liquids.

6.1.4 If the ring is only partially attached to the drum lid, or if a portion of the ring is missing, select another drum lid with a sealing ring that is in sound condition.

6.1.5 To prepare IDW drums for labeling, wipe clean the outer wall surfaces and drum lids of all material that might prevent legible and permanent labeling. If potentially contaminated material adheres to the outer surface of a drum, wipe that material from the drum, and segregate the paper towel or rag used to remove the material with visibly soiled PPE and

disposable sampling equipment. Label all IDW drums and place them on pallets prior to storage.

6.2 Labelling

6.2.1 Containers used to store IDW must be properly labelled. Two general conditions exist: 1) from previous studies or on-site data, waste characteristics are known to be either hazardous or nonhazardous; or 2) waste characteristics are unknown until additional data are obtained.

6.2.2 For situations where the waste characteristics are known, the waste containers should be packaged and labelled in accordance with state regulations and any federal regulations that may govern the labelling of waste.

6.2.3 The following information shall be placed on all non-hazardous waste labels:

- Description of waste (i.e., purge water, soil cuttings);
- Contact information (i.e., contact name and telephone number);
- Date when the waste was first accumulated.

6.2.4 The following information shall be placed on all hazardous waste labels:

- Description of waste (i.e., purge water, soil cuttings);
- Generator information (i.e., name, address, contact telephone number);
- EPA identification number (supplied by on-site client representative);
- Date when the waste was first accumulated.

6.2.5 When the final characterization of a waste is unknown, a notification label should be placed on the drum with the words “waste characterization pending analysis” and the following information included on the label:

- Description of waste (i.e., purge water, soil cuttings);
- Contact information (i.e., contact name and telephone number);
- Date when the waste was first accumulated.

6.2.6 Once the waste has been characterized, the label should be changed as appropriate for a nonhazardous or hazardous waste.

6.2.7 Waste labels should be constructed of a weatherproof material and filled out with a permanent marker to prevent being washed off or becoming faded by sunlight. It is recommended that waste labels be placed on the side of the container, since the top is more subject to weathering. However, when multiple containers are accumulated together, it also may be helpful to include labels on the top of the containers to facilitate organization and disposal.

6.2.8 Each container of waste generated shall be recorded in the field notebook used by the person responsible for labelling the waste. After the waste is disposed of, either by transportation off-site or disposal on-site in an approved disposal area, an appropriate record shall be made in the same field notebook to document proper disposition of IDW.

PRINTED COPIES ARE UNCONTROLLED. CONTROLLED COPY IS AVAILABLE ON COMPANY INTRANET.

6.3 Types of Site Investigation Waste

Several types of waste are generated during site investigations that may require special handling. These include solid, liquid, and used PPE, as discussed further below.

Solid Waste

Soil cuttings from boreholes will typically be placed in containers unless site specific requirements allow for soil cuttings to be placed back into the borehole after drilling is complete. Drilling mud generated during investigation activities shall be collected in containers. Covers should be included on the containers and must be secured at all times and only open during filling activities. The containers shall be labelled in accordance with this SOP. An inventory containing the source, volume, and description of material put in the containers shall be logged on prescribed forms and kept in the project file.

Non-hazardous solid waste can be disposed on-site in the designated site landfill or in a designated evaporation pond if it is liquefied. Hazardous wastes must be disposed off-site at an approved hazardous waste landfill.

Liquid Waste

Groundwater generated during monitoring well development, purging, and sampling can be collected in truck-mounted containers and/or other transportable containers (i.e., 55-gallon drums). Lids or bungs on drums must be secured at all times and only open during filling or pumping activities. The containers shall be labelled in accordance with this SOP. Non-hazardous liquid waste can be disposed of in one of the designated lined evaporation ponds on-site. Hazardous wastes must be handled separately and disposed off-site at an approved hazardous waste facility.

Personal Protective Equipment

PPE that is generated throughout investigation activities shall be placed in plastic garbage bags. If the solid or liquid waste that was being handled is characterized as hazardous waste, then the corresponding PPE should also be disposed as hazardous waste. If not, all PPE should be disposed as non-hazardous waste in the designated on-site landfill. Trash that is generated as part of field activities may be disposed of in the landfill as long as the trash was not exposed to hazardous media.

6.4 Waste Accumulation On-Site

6.4.1 Solid, liquid, or PPE waste generated during investigation activities that are classified as nonhazardous or “characterization pending analysis” should be disposed of as soon as possible. Until disposal, such containers should be inventoried, stored as securely as possible, and inspected regularly, as a general good practice.

6.4.2 Solid, liquid, or PPE waste generated during investigation activities that are classified as hazardous shall not be accumulated on-site longer than 90 days. All hazardous waste containers shall be stored in a secured storage area. The following requirements for the hazardous waste storage area must be implemented:

- Proper hazardous waste signs shall be posted as required by any state or federal statutes that may govern the labelling of waste;
- Secondary containment to contain spills;
- Spill containment equipment must be available;
- Fire extinguisher;
- Adequate aisle space for unobstructed movement of personnel.

6.4.3 Weekly storage area inspections shall be performed and documented to ensure compliance with these requirements. Throughout the project, an inventory shall be maintained to itemize the type and quantity of the waste generated.

6.5 Waste Disposal

6.5.1 Solid, liquid, and PPE waste will be characterized for disposal through the use of client knowledge, laboratory analytical data created from soil or groundwater samples gathered during the field activities, and/or composite samples from individual containers.

6.5.2 All waste generated during field activities will be stored, transported, and disposed of according to applicable state, federal, and local regulations. All wastes classified as hazardous will be disposed of at a licensed treatment storage and disposal facility or managed in other approved manners.

6.5.3 In general, waste disposal should be carefully coordinated with the facility receiving the waste. Facilities receiving waste have specific requirements that vary even for non-hazardous waste, so characterization should be conducted to support both applicable regulations and facility requirements.

6.6 Regulatory Requirements

The following federal and state regulations shall be used as resources for determining waste characteristics and requirements for waste storage, transportation, and disposal:

- Code of Federal Regulations (CFR), Title 40, Part 261;
- CFR, Title 49, Parts 172, 173, 178, and 179.

6.7 Waste Transport

A state-certified hazardous waste hauler shall transport all wastes classified as hazardous. Typically, the facility receiving any waste can coordinate a hauler to transport the waste. Shipped hazardous waste shall be disposed of in accordance with all RCRA/USEPA requirements. All waste manifests or bills of lading will be signed either by the client or the client's designee.

7.0 Quality Control and Assurance

7.1 Management of IDW must incorporate quality control measures to ensure conformance to these and the project requirements.

8.0 Records, Data Analysis, Calculations

8.1 Maintain records as required by implanting the procedures in this SOP.

8.2 Deviations from this procedure or the sampling and analysis plan shall be documented in field records. Significant changes shall be approved by the **Program Quality Manager**.

Equipment Decontamination

Procedure 3-06

1.0 Purpose and Scope

1.1 This standard operating procedure (SOP) describes methods of equipment decontamination, to be used for activities where samples for chemical analysis are collected or where equipment will need to be cleaned before leaving the site or before use in subsequent activities.

1.2 As guidance for specific activities, this procedure does not obviate the need for professional judgment. Deviations from this procedure while planning or executing planned activities must be approved in accordance with Program requirements for technical planning and review.

2.0 Safety

It is the responsibility of the **Site Safety Officer (SSO)** to set up the site zones (i.e., exclusion, transition, and clean) and decontamination areas. Generally the decontamination area is located within the transition zone, upwind of intrusive activities, and serves as the washing area for both personnel and equipment to minimize the spread of contamination into the clean zone. Typically, for equipment, a series of buckets are set up on a visqueen-lined bermed area. Separate spray bottles containing cleaning solvents as described in this procedure or the Contract Task Order (CTO) Work Plan (WP) and distilled water are used for final rinsing of equipment. Depending on the nature of the hazards and the site location, decontamination of heavy equipment, such as augers, pump drop pipe, and vehicles, may be accomplished using a variety of techniques.

All **Field Personnel** responsible for equipment decontamination must adhere to the site-specific health and safety plan (HSP) and must wear the personal protective equipment (PPE) specified in the site-specific HSP. Generally this includes, at a minimum, Tyvek® coveralls, steel-toed boots with boot covers or steel-toed rubber boots, safety glasses, American National Standards Institute-standard hard hats, and hearing protection (if heavy equipment is in operation). Air monitoring by the **SSO** may result in an upgrade to the use of respirators and cartridges in the decontamination area; therefore, this equipment must be available on site. If safe alternatives are not achievable, discontinue site activities immediately.

In addition to the aforementioned precautions, the following sections describe safe work practices that will be employed.

2.1 **Chemical Hazards associated with Equipment Decontamination**

- Avoid skin contact with and/or incidental ingestion of decontamination solutions and water.
- Utilize PPE as specified in the site-specific HSP to maximize splash protection.
- Refer to material safety data sheets, safety personnel, and/or consult sampling personnel regarding appropriate safety measures (i.e., handling, PPE including skin and respiratory).
- Take the necessary precautions when handling detergents and reagents.

2.2 **Physical Hazards associated with Equipment Decontamination**

- To avoid possible back strain, it is recommended to raise the decontamination area 1 to 2 feet above ground level.
- To avoid heat stress, over exertion, and exhaustion, it is recommended to rotate equipment decontamination among all site personnel.

PRINTED COPIES ARE UNCONTROLLED. CONTROLLED COPY IS AVAILABLE ON COMPANY INTRANET.

- Take necessary precautions when handling field sampling equipment.

3.0 Terms and Definitions

None.

4.0 Training and Qualifications

4.1 The **CTO Manager** is responsible for ensuring that decontamination activities comply with this procedure. The **CTO Manager** is responsible for ensuring that all personnel involved in equipment decontamination shall have the appropriate education, experience, and training to perform their assigned tasks.

4.2 The **Program Quality Manager** is responsible for ensuring overall compliance with this procedure.

4.3 The **Field Manager** is responsible for ensuring that all field equipment is decontaminated according to this procedure.

4.4 All **Field Personnel** are responsible for the implementation of this procedure.

5.0 Procedure

Decontamination of equipment used in soil/sediment sampling, groundwater monitoring, well drilling and well development, as well as equipment used to sample groundwater, surface water, sediment, waste, wipe, asbestos, and unsaturated zone, is necessary to prevent cross-contamination and to maintain the highest integrity possible in collected samples. Planning a decontamination program requires consideration of the following factors:

- Location where the decontamination procedures will be conducted
- Types of equipment requiring decontamination
- Frequency of equipment decontamination
- Cleaning technique and types of cleaning solutions appropriate to the contaminants of concern
- Method for containing the residual contaminants and wash water from the decontamination process
- Use of a quality control measure to determine the effectiveness of the decontamination procedure

The following subsections describe standards for decontamination, including the frequency of decontamination, cleaning solutions and techniques, containment of residual contaminants and cleaning solutions, and effectiveness.

5.1 Decontamination Area

Select an appropriate location for the decontamination area at a site based on the ability to control access to the area, the ability to control residual material removed from equipment, the need to store clean equipment, and the ability to restrict access to the area being investigated. Locate the decontamination area an adequate distance away and upwind from potential contaminant sources to avoid contamination of clean equipment.

5.2 Types of Equipment

Drilling equipment that must be decontaminated includes drill bits, auger sections, drill-string tools, drill rods, split barrel samplers, tremie pipes, clamps, hand tools, and steel cable. Decontamination of monitoring well development and groundwater sampling equipment includes submersible pumps, bailers, interface probes, water level meters, bladder pumps, airlift pumps, peristaltic pumps, and lysimeters. Other sampling equipment that requires decontamination includes, but is not limited to, hand trowels,

hand augers, slide hammer samplers, shovels, stainless-steel spoons and bowls, soil sample liners and caps, wipe sampling templates, composite liquid waste samplers, and dippers. Equipment with a porous surface, such as rope, cloth hoses, and wooden blocks, cannot be thoroughly decontaminated and shall be properly disposed of after one use.

5.3 Frequency of Equipment Decontamination

Decontaminate down-hole drilling equipment and equipment used in monitoring well development and purging prior to initial use and between each borehole or well. Down-hole drilling equipment, however, may require more frequent cleaning to prevent cross-contamination between vertical zones within a single borehole. When drilling through a shallow contaminated zone and installing a surface casing to seal off the contaminated zone, decontaminate the drilling tools prior to drilling deeper. Initiate groundwater sampling by sampling groundwater from the monitoring well where the least contamination is suspected. Decontaminate groundwater, surface water, and soil sampling devices prior to initial use and between collection of each sample to prevent the possible introduction of contaminants into successive samples.

5.4 Cleaning Solutions and Techniques

Decontamination can be accomplished using a variety of techniques and fluids. The preferred method of decontaminating major equipment, such as drill bits, augers, drill string, and pump drop-pipe, is steam cleaning. To steam clean, use a portable, high-pressure steam cleaner equipped with a pressure hose and fittings. For this method, thoroughly steam wash equipment and rinse it with potable tap water to remove particulates and contaminants.

A rinse decontamination procedure is acceptable for equipment such as bailers, water level meters, new and re-used soil sample liners, and hand tools. The decontamination procedure shall consist of the following: (1) wash with a non-phosphate detergent (Alconox®, Liquinox®, or other suitable detergent) and potable water solution; (2) rinse with potable water; (3) spray with laboratory-grade isopropyl alcohol; (4) rinse with deionized or distilled water; and (5) spray with deionized or distilled water. If possible, disassemble equipment prior to cleaning. Add a second wash at the beginning of the process if equipment is very soiled.

Decontaminating submersible pumps requires additional effort because internal surfaces become contaminated during usage. Decontaminate these pumps by washing and rinsing the outside surfaces using the procedure described for small equipment or by steam cleaning. Decontaminate the internal surfaces by recirculating fluids through the pump while it is operating. This recirculation may be done using a relatively long (typically 4 feet) large-diameter pipe (4-inch or greater) equipped with a bottom cap. Fill the pipe with the decontamination fluids, place the pump within the capped pipe, and operate the pump while recirculating the fluids back into the pipe. The decontamination sequence shall include: (1) detergent and potable water; (2) potable water rinse; (3) potable water rinse; and (4) deionized water rinse. Change the decontamination fluids after each decontamination cycle.

Solvents other than isopropyl alcohol may be used, depending upon the contaminants involved. For example, if polychlorinated biphenyls or chlorinated pesticides are contaminants of concern, hexane may be used as the decontamination solvent; however, if samples are also to be analyzed for volatile organics, hexane shall not be used. In addition, some decontamination solvents have health effects that must be considered. Decontamination water shall consist of distilled or deionized water. Steam-distilled water shall not be used in the decontamination process as this type of water usually contains elevated concentrations of metals. Decontamination solvents to be used during field activities will be specified in the CTO WP.

Rinse equipment used for measuring field parameters, such as pH (indicates the hydrogen ion concentration – acidity or basicity), temperature, specific conductivity, and turbidity with deionized or distilled water after each measurement. Also wash new, unused soil sample liners and caps with a fresh

detergent solution and rinse them with potable water followed by distilled or deionized water to remove any dirt or cutting oils that might be on them prior to use.

5.5 **Containment of Residual Contaminants and Cleaning Solutions**

A decontamination program for equipment exposed to potentially hazardous materials requires a provision for catchment and disposal of the contaminated material, cleaning solution, and wash water.

When contaminated material and cleaning fluids must be contained from heavy equipment, such as drill rigs and support vehicles, the area must be properly floored, preferably with a concrete pad that slopes toward a sump pit. If a concrete pad is impractical, planking can be used to construct solid flooring that is then covered by a nonporous surface and sloped toward a collection sump. If the decontamination area lacks a collection sump, use plastic sheeting and blocks or other objects to create a bermed area for collection of equipment decontamination water. Situate items, such as auger flights, which can be placed on metal stands or other similar equipment, on this equipment during decontamination to prevent contact with fluids generated by previous equipment decontamination. Store clean equipment in a separate location to prevent recontamination. Collect decontamination fluids contained within the bermed area and store them in secured containers as described below.

Use wash buckets or tubs to catch fluids from the decontamination of lighter-weight drilling equipment and hand-held sampling devices. Collect the decontamination fluids and store them on site in secured containers, such as U.S. Department of Transportation-approved drums, until their disposition is determined by laboratory analytical results. Label containers in accordance with Procedure 3-05, *IDW Management*.

6.0 Quality Control and Assurance

A decontamination program must incorporate quality control measures to determine the effectiveness of cleaning methods. Quality control measures typically include collection of equipment blank samples or wipe testing. Equipment blanks consist of analyte-free water that has been poured over or through the sample collection equipment after its final decontamination rinse. Wipe testing is performed by wiping a cloth over the surface of the equipment after cleaning. These quality control measures provide "after-the fact" information that may be useful in determining whether or not cleaning methods were effective in removing the contaminants of concern.

7.0 Records, Data Analysis, Calculations

Any project where sampling and analysis is performed shall be executed in accordance with an approved sampling and analysis plan. This procedure may be incorporated by reference or may be incorporated with modifications described in the plan.

Deviations from this procedure or the sampling and analysis plan shall be documented in field records. Significant changes shall be approved by the **Program Quality Manager**.

Monitoring Well Installation

Procedure 3-12

1.0 Purpose and Scope

1.1 This standard operating procedure (SOP) describes the methods to be used during the installation of groundwater monitoring wells. It describes the components of monitoring well design and installation and sets forth the rationale for use of various well installation techniques in specific situations.

1.2 As guidance for specific activities, this procedure does not obviate the need for professional judgment. Deviations from this procedure while planning or executing planned activities must be approved in accordance with Program requirements for technical planning and review.

2.0 Safety

2.1 The health and safety considerations for the work associated with this SOP, including both potential physical and chemical hazards, will be addressed in the project Health and Safety Plan (HASP). In the absence of a HASP, work will be conducted according to the Contract Task Order (CTO) Work Plan (WP) and/or direction from the **Site Safety Officer (SSO)**.

2.2 Before well installation commences, appropriate entities (e.g. DigSafe, local public works departments, company facilities) must be contacted to assure the anticipated well locations are marked for utilities, including electrical, telecommunications, water, sewer, and gas.

2.3 Physical Hazards Associated with Well Installation

- Stay clear of all moving equipment and avoid wearing loose fitting clothing.
- When using an approved retractable-blade knife, always cut away from one self and make sure there are no other people in the cutting path or the retractable-blade knife.
- To avoid slip/trip/fall conditions during drilling activities, keep the area clear of excess soil cuttings and groundwater. Use textured boots/boot cover bottoms in muddy areas.
- To avoid heat/cold stress as a result of exposure to extreme temperatures and personal protective equipment (PPE), drink electrolyte replacement fluids (1 to 2 cups per hour is recommended) and, in cases of extreme cold, wear fitted insulating clothing.
- To avoid hazards associated with subsurface utilities, ensure all sampling locations have been properly surveyed as described in SOP 3-01, Utility Clearance.
- Be aware of restricted mobility caused by PPE.

PRINTED COPIES ARE UNCONTROLLED. CONTROLLED COPY IS AVAILABLE ON COMPANY INTRANET.

3.0 Terms and Definitions

3.1 **Annulus:** The annulus is the down-hole space between the borehole wall and the well casing and screen.

3.2 **Bridge:** A bridge is an obstruction in the drill hole or annulus. A bridge is usually formed by caving of the wall of the well bore, by the intrusion of a large boulder, or by the placement of filter pack materials during well completion. Bridging can also occur in the formation during well development.

3.3 **Filter Pack:** Filter pack is sand or gravel that is smooth, uniform, clean, well-rounded, and siliceous. It is placed in the annulus of the well between the borehole wall and the well screen to prevent formation materials from entering the well and to stabilize the adjacent formation.

3.4 **Grout:** Grout is a fluid mixture of cement and water that can be forced through a tremie pipe and emplaced in the annular space between the borehole and casing to form an impermeable seal. Various additives, such as sand, bentonite, and polymers, may be included in the mixture to meet certain requirements.

3.5 **Heaving (Running) Sands:** Loose sands in a confined water-bearing zone or aquifer which tend to rise up into the drill stem when the confining unit is breached by the drill bit. Heaving sands occur when the water in the aquifer has a pressure head great enough to cause upward flow into the drill stem with enough velocity to overcome the weight of the sand.

3.6 **Sieve Analysis:** Sieve analysis is the evaluation of the particle-size distribution of a soil, sediment, or rock by measuring the percentage of the particles that will pass through standard sieves of various sizes.

4.0 Interferences

4.1 Heaving sands may be problematic in unconsolidated sands encountered below the water table.

4.2 Rotary drilling methods requiring bentonite-based drilling fluids should be used with caution to drill boreholes that will be used for monitoring well installation. The bentonite mud builds up on the borehole walls as a filter cake and permeates the adjacent formation, potentially reducing the permeability of the material adjacent to the well screen.

4.3 If water or other drilling fluids have been introduced into the boring during drilling or well installation, samples of these fluids should be obtained and analyzed for chemical constituents that may be of interest at the site. In addition, an attempt should be made to recover the quantity of fluid or water that was introduced, either by flushing the borehole prior to well installation and/or by overpumping the well during development.

4.4 Track-mounted drill rigs are suitable for travelling on many types of landscapes that truck-mounted units cannot access, but may have limitations on extremely uneven or soft terrain.

4.5 Care should be taken to prevent cross-contamination between well locations. All drilling equipment coming in contact with potentially contaminated soil and/or groundwater will be decontaminated by the drilling subcontractor prior to initial drilling activities and between drilling locations in accordance with SOP 3-06, Equipment Decontamination.

5.0 Training and Qualifications

5.1 **Qualifications and Training**

The individual executing these procedures must have read, and be familiar with, the requirements of this SOP.

PRINTED COPIES ARE UNCONTROLLED. CONTROLLED COPY IS AVAILABLE ON COMPANY INTRANET.

5.2 **Responsibilities**

5.2.1 **Contract Task Order (CTO) Managers** are responsible for issuing sampling and analysis plans (SAPs) that reflect the procedures and specifications presented in this procedure. Individual municipalities, county agencies, and possibly state regulatory agencies enforce regulations that may include well construction and installation requirements. The **CTO Manager** shall be familiar with current local and state regulations, and ensure that these regulations are followed. The **CTO Manager** is responsible for ensuring that all personnel involved in monitoring well installation shall have the appropriate education, experience, and training to perform their assigned tasks.

5.2.2 The **Program Quality Manager** is responsible for ensuring overall compliance with this procedure.

5.2.3 The **Field Manager** is responsible for direct supervision of the installation of monitoring wells and ensuring that procedures and specifications are implemented in the field in accordance with the approved SAP and well installation permits. The qualifications for the **Field Manager** must be in accordance with local jurisdictions with authority over the operations conducted.

5.2.4 All field personnel are responsible for the implementation of this procedure.

5.2.5 The on-site hydrogeologist/engineer is expected to obtain a description of the lithologic samples obtained during the excavation and construction of a monitoring well. These data are often required to provide guidance regarding the installation of specific components of the monitoring well. Guidance for lithologic sample collection and sample description is contained within SOP 3-16, Soil and Rock Classification.

6.0 Equipment and Supplies

6.1 Materials provided by the drilling contractor may include:

- Drill rig, drill rods, hollow stem augers, etc.
- Decontamination equipment (e.g., steam cleaner, high-pressure washer, brushes, etc.)
- Decontamination pad materials
- Well screen/riser pipe with flush-threaded couplings including riser and bottom caps
- Clean, filter sand
- Bentonite chips or pellets
- Cement grout and tremie pipe
- Portland cement for well pad completion
- Steel protective riser covers and locking caps
- Weighted calibrated tape
- Split-spoon samplers
- 55-gallon drums or containers for drill cuttings, decontamination fluids, etc.

6.2 In addition to those materials provided by the drilling contractor, equipment and materials required by the project geologist/engineer may include, but is not limited to, the following:

- Photoionization Detector (PID)
- Spill kit, including at a minimum sorbent pads and shovel (if not provided by subcontractor)

PRINTED COPIES ARE UNCONTROLLED. CONTROLLED COPY IS AVAILABLE ON COMPANY INTRANET.

- Plastic sheeting
- Teaspoon or spatula
- Resealable plastic bags
- Boring Log Records
- Decontamination materials (per SOP No. 3-06 - Equipment Decontamination)
- Weighted measuring tape for depth measurement
- Soil logging materials (e.g. USCS classification field card, millimeter rule, hand lens, etc.)
- Survey lathes or pin flags
- Digital camera
- PPE as required by the HASP
- Planning documents including the site-specific HASP and SAP
- Large indelible ink or paint pen
- Field logbook/field forms/site maps (water proof)

7.0 Procedure

7.1 General Procedures

- Specific drilling, sampling, and installation equipment and methodology will be dictated by the type of well to be installed (e.g., single case (Type II), double case (Type III), bedrock, etc.), geologic characteristics of the site, the type of contaminants being monitored, and local and state regulations.
- For access to locations when travelling over difficult terrain, an appropriate line should be chosen before mobilizing the drill rig or other support vehicles. If clearing of trees or ground cover is required, perform these activities in advance to avoid down time. Avoid wet or soft areas where possible or use ground mats and/or timbers to aid in supporting the rig as it travels. If drilling on soft material, place geomatting and ground mats under the rig tracks or stabilizers prior to drilling.
- A utility locate must be conducted to identify all underground utilities at the site prior to drilling (refer to SOP 3-01, Utility Clearance*)*. Proper clearance procedures for aboveground/overhead utilities must also be followed as specified in the HASP.
- Although new well materials (well screen and riser pipe) generally arrive at the site boxed and sealed within plastic bags, it is sometimes necessary to decontaminate the materials prior to their use. Well materials should be inspected by the project geologist/engineer upon delivery to check for cleanliness. If the well materials appear dirty, or if local or regional regulatory guidance requires decontamination, then well material decontamination should be performed by the drilling subcontractor in accordance with SOP 3-06, Equipment Decontamination.
- The diameter of the borehole must be a minimum of 2 inches greater than the outside diameter of the well screen or riser pipe used to construct the well. This is necessary so that sufficient annular space is available to install filter packs, bentonite seals, and grout seals, and allow the passage of tremie pipe where grouting at depth is required. Bedrock wells may require reaming after coring in order to provide a large enough borehole diameter for well installation.
- When soil sampling is required (refer to the SAP), soil samples will be collected for visual logging by advancing split-spoon samplers through the augers. The soil will be visually logged by a field geologist and include lithologic characteristics (i.e., soil type, color, density, moisture content, etc.) using the the

PRINTED COPIES ARE UNCONTROLLED. CONTROLLED COPY IS AVAILABLE ON COMPANY INTRANET.

methods described in SOP 3-16, Soil and Rock Classification. This information will be recorded on a boring/well log form, along with well construction details.

7.2 Drilling Techniques

Drilling of monitoring well boreholes may be accomplished by a variety of methods as described below. Preferred methods include those that temporarily case the borehole during drilling (i.e., hollow stem auger and sonic methods) using an override system. Other methods can be used where specific subsurface conditions or well design criteria dictate.

- Hollow stem auger (HSA) – Borings are advanced by rotating steel hollow stem augers with an attached cutting head. Soil cuttings are displaced by the cutting head and transported to the surface via continuous spiral flights attached to each auger stem. This method is widely used for unconsolidated soils that have a tendency to collapse within the boring. A bottom plug can be placed in the bottom auger to prevent soils from entering and clogging the auger, especially in the case of heaving sands. However, a bottom plug cannot be used when soil samples are to be collected through the augers. Soil plugs that accumulate in the bottom of the auger must be removed or knocked out prior to sampling or well installation.
- Solid stem auger – This type of drilling method is similar to HSA drilling using a solid stem or sealed hollow stem auger flights to advance the boring. Solid stem, continuous flight auger use is limited to semi-consolidated sediments or to cohesive or semi-cohesive unconsolidated sediments that don't have a tendency to collapse when disturbed.
- Sonic methods – Sonic drilling consists of advancing concentric hollow drill casings (inner and outer) using rotation in conjunction with axial vibration of the drill casing. Once the casings are advanced to the appropriate depth, the inner string is removed with a core of drill cuttings while the outer casing remains in place to keep the borehole open. Cuttings are removed from the inner casing relatively intact for logging or sampling purposes. This drilling method is used for a variety of soil types, from heaving sands to consolidated or indurated formations. Smearing of the formation along the borehole walls is minimal since moderate vibration and rotation techniques are used to advance the casings. Since the total borehole diameter in sonic drilling is only incrementally larger than the inner casing diameter, care should be taken during installation of the monitoring well to ensure the well is centered and adequate space is available for annular materials.
- Rotary methods (water or mud) – Rotary drilling methods consist of drill rods coupled to a drill bit that rotates and cuts through the soils to advance the borehole. Water or drilling fluid ("mud") is forced through the hollow drill rods and drill bit as the rods are rotated. The soil cuttings are forced up the borehole with the drilling fluids to the surface and the fluids recirculated. The drilling fluid provides a hydrostatic pressure that reduces or prevents the borehole from collapsing. Clean, potable water must be used for water-rotary drilling to prevent introducing trace contaminants. A sample of the potable water should be collected during the course of well installation for analysis of the same parameters defined for the groundwater samples. If mud-rotary is used to advance boreholes, potable water and bentonite drilling mud should only be used. No chemical additives shall be mixed in the drilling fluid to alter viscosity or lubricating properties. Adequate well development is essential for removal of drilling mud and fluids from the formation materials and ensure collection of representative groundwater samples.
- Rotary methods (Air) – Air rotary methods are similar to water rotary but use high air velocities in place of drilling fluids to rotate the drill bit and carry the soil cuttings up the borehole to the surface. Care must be taken to ensure that contaminants are not introduced into the air stream from compressor oils, etc. Most compressor systems are compatible with a coalescing filter system. Cuttings exiting the borehole under pressure must be controlled, especially when drilling in a zone of potential contamination. This can be accomplished by using an air diverter with hose or pipe to carry the cuttings to a waste container. Letting the cuttings blow uncontrolled from the borehole is not acceptable.

PRINTED COPIES ARE UNCONTROLLED. CONTROLLED COPY IS AVAILABLE ON COMPANY INTRANET.

7.3 Well Construction and Installation

- If rotary drilling techniques are used, the borehole should be flushed or blown free of material prior to well installation. If hollow stem augers are used, the soil or bottom plug should be removed and the augers raised approximately six inches above the bottom of the borehole, while slowly rotating the augers to remove cuttings from the bottom of the boring. The depth of the borehole should be confirmed with a weighted, calibrated tape.
- The riser pipe and screen should be connected with flush-threaded joints and assembled wearing clean, disposable gloves. No solvent or anti-seize compound should be used on the connections. The full length of the slotted portion of the well screen and unslotted riser pipe should be measured and these measurements recorded on a well construction form (Attachment 1).
- If placed in an open borehole, the assembled well should be carefully lowered and centered in the borehole so that the well is true, straight, and vertical throughout. Centering can also be accomplished with the use of centralizers, if necessary. However, centralizers should be placed so that they do not inhibit the installation of filter sand, bentonite seal, and annular grout. Wells less than 50 deep generally do not require centralizers.
- If hollow stem augers are used, the well should be lowered through the augers and each auger flight removed incrementally as the filter sand, bentonite seal, and grout are tremmied or poured into the annular space of the well. The well should be temporarily capped before filter sand and other annular materials are installed.
- Clean, silica sand should be placed around the well screen to at least 1 foot above the top of the screen. The filter sand should be appropriately graded and compatible with the selected screen size and surrounding formation materials. In general, the filter pack should not extend more than 3 feet above the top of the screen to limit the thickness of the monitoring zone. As the filter pack is placed, a weighted tape should be lowered in the annular space to verify the depth to the top of the layer. This measurement will be recorded on the well construction form (Attachment 1). If necessary, to eliminate possible bridging or creation of voids, placement of the sand pack may require the use of a tremie pipe. Tremie pipe sandpack installations are generally suggested for deeper wells and for wells which are screened some distance beneath the water table.
- A minimum 2-foot thick layer of bentonite pellets or slurry seal will be installed immediately above the filter sand to prevent vertical flow within the boring from affecting the screened interval. Bentonite chips/pellets must be hydrated if place above the water table prior to grouting. If bridging is of concern as in the case of deep wells, powdered bentonite may be mixed with water into a very thick slurry and a tremie pipe used to place the seal to the desired depth. Placement of the bentonite seal in the borehole will be recorded on the well construction form (Attachment 1).
- The remaining annular space around the well will be grouted from the top of the bentonite seal to the surface with a grout composed of neat cement, a bentonite cement mixture, or high solids sodium bentonite grout.
- Each well riser will be secured with an expandable, locking cap (vented if possible). Optionally, a hole can be drilled in the upper portion of the riser to allow venting of the well.
- The well will be completed within a concrete well pad consisting of a Portland cement/sand mixture. Well pads are generally 3 feet by 3 feet square but may be larger or smaller depending on site conditions and state-specific well construction standards. Round concrete well pads are also acceptable. A minimum of 1 inch of the finished pad should be below grade to prevent washing and undermining by soil erosion.
- If completed as a flush-mount well, the well riser will be cut off approximately 4 to 6 inches below ground surface and an expandable, locking cap placed on the well riser. The area around the riser is dug out and a steel well vault or manhole cover placed over the riser and set almost flush to the ground

PRINTED COPIES ARE UNCONTROLLED. CONTROLLED COPY IS AVAILABLE ON COMPANY INTRANET.

to protect the well. The manhole cover should be water-tight and secured with bolts to prevent casual access. The well pad will then be constructed around the well vault and slightly mounded at the center and sloping away to prevent surface water from accumulating in the well vault.

- If completed as a stick-up well, the well riser is cut approximately 2.5 to 3 feet above the ground surface and an expandable, locking cap placed on the well riser. A steel guard pipe with hinged, locking cap is placed over the well riser as a protective casing. The bottom of the guard pipe will be set approximately 2 feet below ground surface and sealed by pouring concrete from the top of the annular grout around the pipe to grade. The concrete well pad should be completed at the same time. Weep holes will be drilled in the base of the guard pipe to facilitate draining of rainwater or purge water from inside the guard pipe.
- Bumper posts or bollards may be necessary for additional well protection, especially in high traffic areas. The bumper posts should be placed around the well pad in a configuration that provides maximum protection to the well and extend a minimum of 3 feet above the ground.

7.4 Double Cased Wells

Under certain site conditions, the use of a double-cased or telescoping (Type III) well may be necessary. Installation of double-cased wells may be required to prevent the interconnection of two separate aquifers, seal off a perched aquifer without creating a vertical hydraulic conduit, prevent cross-contamination during construction of wells in deeper aquifers hydro-stratigraphically below impacted aquifers, or case off highly impacted soils present above the aquifer to prevent potential “dragging down” of contaminants.

Similar to conventional wells, construction of double-cased wells can be accomplished using a varety of drilling methods. Well construction is initiated by “keying” a large diameter, outer casing into a stratigraphic zone of low permeability (clay layer or bedrock). The size of the outer casing should be a minimum of 2 inches greater than the outside diameter of the inner casing to allow installation of annular seal materials during well completion. A pilot borehole should be drilled through the overburden soil and/or contaminated zone into a clay confining layer or bedrock. The borehole for the outer casing should be of sufficient size to contain the outer casing with a minimum of 2 inches around the outside diameter to allow sufficient annular space for tremie or pressure grouting. The boring should extend a minimum of 2 feet into a clay layer and a minimum of 1 foot into bedrock, if possible, to ensure an adequate seal. The boring should never breach a confining layer or keyed zone under any circumstances.

Once the boring is completed, the outer casing can be set in the borehole and sealed with grout. The outer casing can be set two ways, with or without a bottom cap. If no bottom cap is applied, the casing is usually driven approximately 6 inches into the clay confining unit. A grout plug is generally placed in the bottom of the casing and once set, standing water in the casing is evacuated prior to drilling below the casing. As an alternative, a cap can be placed on the bottom of the casing and if set below the water table, the casing can be filled with clean, potable water to hold down the casing in the boring. Grouting should be conducted using tremie-grouting or pressure-grouting methods by pumping grout into the annular space between the outer casing and the borehole wall from the bottom of the casing to the ground surface. Grout around the casing should be allowed to cure at least 24 hours before attempting to drill through the bottom.

Once the grout is cured, a smaller diameter drill pipe/bit is used to bore through the grout plug or bottom cap to the desired well depth. The well is then constructed as described in Section 7.3 above.

7.5 Post Installation Procedures

- Wells should be permanently labelled or marked for identification. Well tags can be used to record the site name, well number, total depth, installation date, etc. At a minimum, the well number will be written in indelible marker or paint on both the outside of the protective casing and inside beneath the casing lid, as well as on the riser pipe.

PRINTED COPIES ARE UNCONTROLLED. CONTROLLED COPY IS AVAILABLE ON COMPANY INTRANET.

- A measuring point will be marked on the top of the riser pipe for taking water level measurements. The measuring point can be notched using a knife or saw or can be marked with a waterproof marker or paint. The measuring point will also be the point which will be surveyed for vertical elevation data.
- Upon completion, the following measurements will be taken by the field geologist/engineer and recorded on the well construction diagram.
    - Depth to static water level
    - Depth of non-aqueous phase liquid (NAPL), if present
    - Total depth of well measured from top of casing (TOC)
    - Height of well casing above ground surface
    - Height of protective casing above ground surface
- All monitoring wells will be surveyed for horizontal and vertical control by a licensed surveyor.
- Investigation-derived waste (IDW) including drill cuttings, spent materials (e.g., PPE), and decontamination water should be properly managed in accordance with SOP 3-05, IDW Management.

8.0 Quality Control and Assurance

8.1 Field personnel will follow specific quality assurance (QA) guidelines as outlined in the SAP. Certain quality control (QC) measures should be taken to ensure proper well installation and construction in accordance with this SOP, project specific SAP, and applicable well standards.

8.2 The borehole will be checked for total open depth, and extended by further drilling or shortened by backfilling, as required before installation of the well materials.

8.3 Water level and NAPL presence will be checked during well installation to ensure that the positions of well screen, filter sand, and seals relative to water level conform to project requirements

8.4 The depth to top of each layer of annular materials (i.e., filter sand, bentonite, grout) will be verified and adjusted as necessary for proper placement.

9.0 Records, Data Analysis, Calculations

All field information will be recorded in the field logbook and/or standardized field forms by field personnel. Field data recorded will include drilling contractor information, drilling methods, well material and construction information provided on the boring logs and well construction forms, observations or problems encountered during drilling, fluid level data, and any deviations from the procedures in this SOP and other project plans. Well Construction Forms (Attachment 1) will provide visual and descriptive information the monitoring well and are often the most critical form of documentation generated during the installation of a monitoring well. The field logbook is kept as a general log of activities and should not be used in place of the boring log.

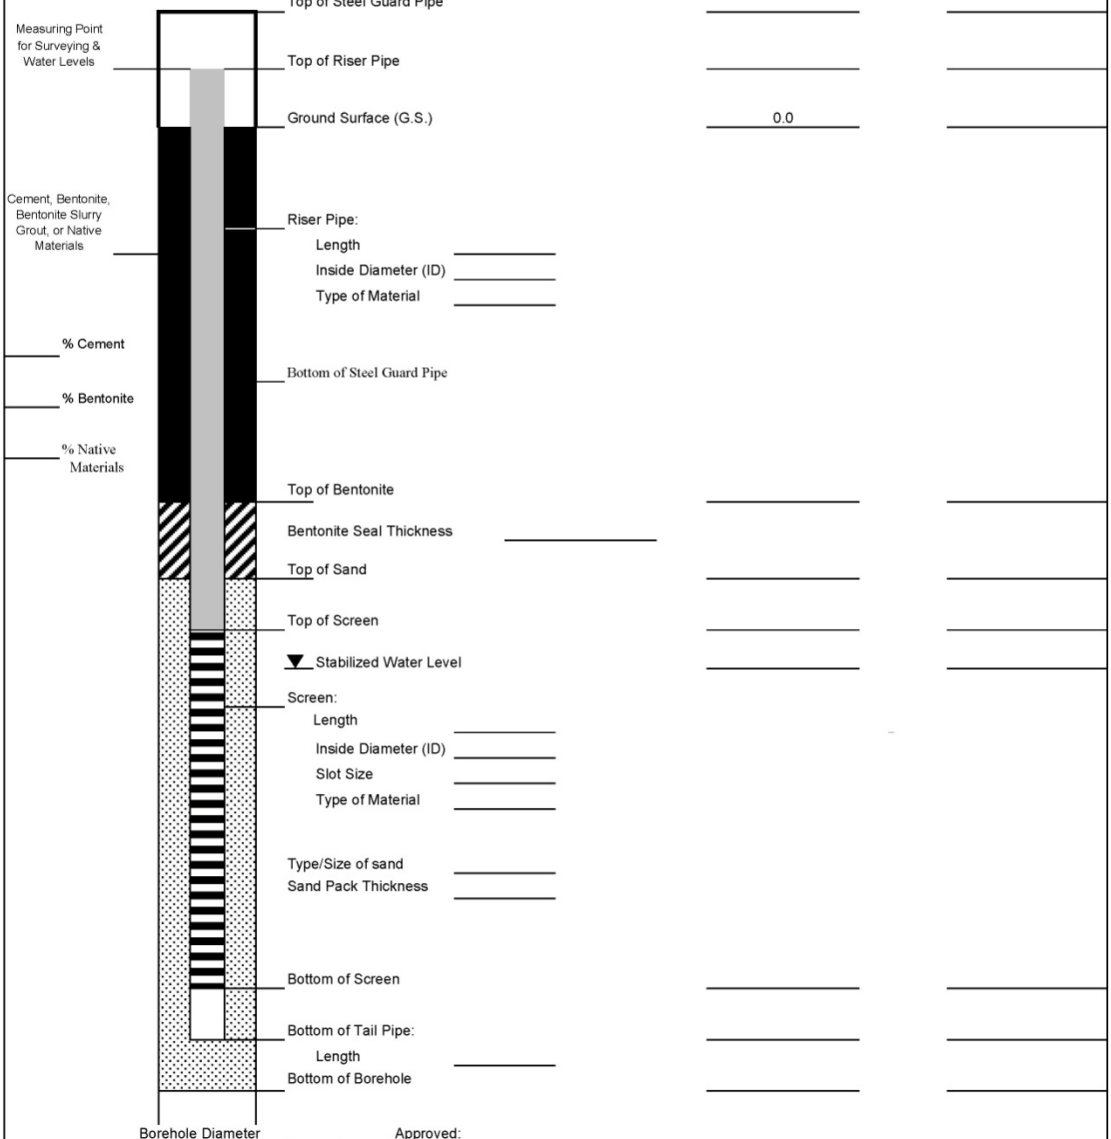
MONITORING WELL CONSTRUCTION DETAIL



PRINTED COPIES ARE UNCONTROLLED. CONTROLLED COPY IS AVAILABLE ON COMPANY INTRANET.

Monitoring Well Development

Procedure 3-13

1.0 Purpose and Scope

1.1 This standard operating procedure (SOP) describes the procedures used for developing newly installed monitoring wells and/or redeveloping existing wells.

1.2 The purpose of well development is to remove interferences from a well to provide better connection between the well and the formation, to improve pumping performance of the well, and to be able to collect more representative information from the well (e.g., samples, test results, etc.). Proper well development will:

- Remove drilling residuals (e.g., water, mud) from the borehole and surrounding formations;
- Improve or restore hydraulic conductivity of the surrounding formations which may have been disturbed during the drilling process;
- Remove residual fines from the well screen and sand pack (filter pack) materials, thus reducing turbidity of groundwater and permitting the collection of more representative groundwater samples.

1.3 There may be circumstances where well development is not desirable, for example, in the presence of non-aqueous phase liquids (NAPL) or other significant contamination if development could worsen the contaminant impact. If NAPL begins to intrude during development, the development process will be halted. This situation will be considered a cause for sample modification requiring approval by the CTO Manager and other stakeholders, as applicable.

1.4 The applicable well development procedures for a particular site may be subject to State or local regulatory requirements. In all cases, the project team should consult their local regulatory requirements and document the selected well development procedure in the project-specific Sampling and Analysis Plan (SAP). For project-specific information refer to the SAP, which takes precedence over these procedures.

1.5 This procedure is the Program-approved professional guidance for work performed by Resolution Consultants under the Comprehensive Long-Term Environmental Action Navy (CLEAN) contract (Contract Number N62470-11-D-8013).

1.6 As guidance for specific activities, this procedure does not obviate the need for professional judgment. Deviations from this procedure while planning or executing planned activities must be approved in accordance with Program requirements for technical planning and review.

2.0 Safety

2.1 The health and safety considerations for the work associated with this SOP, including both potential physical and chemical hazards, will be addressed in the project Health and Safety Plan (HASP). In the absence of a HASP, work will be conducted according to the Contract Task Order (CTO) SAP and/or direction from the Site Safety Officer (SSO).

2.2 Monitoring well development may involve chemical hazards associated with potential contaminants in the soil or aquifer being characterized and may involve physical hazards associated with use of well development equipment.

3.0 Terms and Definitions

None.

PRINTED COPIES ARE UNCONTROLLED. CONTROLLED COPY IS AVAILABLE ON COMPANY INTRANET.

4.0 Interferences

4.1 Equipment/materials used for development may react with the groundwater during development. Appropriate development equipment has been selected for the anticipated condition of the groundwater.

4.2 Appropriate development methods such as using a surge-block to flush suspended fines in the groundwater in and out of the well screen can improve the yield of wells and improve their potential to be developed successfully. However, the effectiveness of development can be significantly reduced in wells that do not yield sufficient water to allow this flushing to take place.

4.3 For formations with a significant content of fine-grained materials (silts and clays), or wells with improperly sized screens, it may not be possible to reduce turbidity to commonly acceptable levels. Possible solutions may include collecting a sample even if excessively turbid, or installing a replacement well.

4.4 Development itself disturbs the surrounding formation and disrupts equilibrium conditions within the well. Groundwater samples will not be collected until a minimum of 24 hours after a well is developed to allow conditions to stabilize. For sites with fine-grained formations (silts and clays) and highly sorptive contamination, a longer time period between development and sampling should be considered.

5.0 Training and Qualifications

5.1 Qualifications and Training

The individual executing these procedures must have read, and be familiar with, the requirements of this SOP.

5.2 Responsibilities

5.2.1 The **CTO Manager** is responsible for ensuring that well development activities comply with this procedure. The **CTO Manager** is responsible for ensuring that all personnel involved in well development shall have the appropriate education, experience, and training to perform their assigned tasks.

5.2.2 The **Program Quality Manager** is responsible for ensuring overall compliance with this procedure.

5.2.3 The **Field Manager** is responsible for ensuring that all well development activities are conducted according to the either this procedure or the applicable procedure presented in the project-specific SAP.

5.2.4 **Field sampling personnel** are responsible for the implementation of this procedure.

5.2.5 The field sampler and/or task manager is responsible for directly supervising the well development procedures to ensure that they are conducted according to this procedure and for recording all pertinent data collected during sampling.

6.0 Equipment and Supplies

6.1 This equipment list was developed to aid in field organization and should be used in planning and preparation. Depending on the site-specific requirements and the development method selected, additional or alternative material and equipment may be necessary. In addition, for sites where groundwater is expected to be contaminated, the materials to be placed down the well and in contact with groundwater should be evaluated so that they are compatible with the chemical conditions expected in the well.

6.2 Equipment and materials used for well development may include, but is not limited to:

Well development equipment

- Surge block

PRINTED COPIES ARE UNCONTROLLED. CONTROLLED COPY IS AVAILABLE ON COMPANY INTRANET.

- Disposable Teflon bailers, appropriate to the diameter of the well(s): 1-inch to 1.5-inch for 2-inch inside diameter (ID) monitoring wells.
- Watterra® footvalve
- Electric submersible pump
- 12-volt power source for electric pump
- High density polyethylene (HDPE) tubing appropriately sized for Watterra® footvalve and/or electric submersible pump
- Drums or containers for storage of purge water
- Nephelometer to measure turbidity
- Multi-parameter water quality meter(s) to measure temperature, pH, conductivity, dissolved oxygen (DO), oxidation reduction potential (ORP)
- Instrument calibration solutions
- Water level meter
- Oil/water interface probe

General equipment

- Project-specific plans including the site-specific HASP and SAP
- Field notebook/field forms/site maps
- Indelible markers/pens
- 5-gallon buckets

Equipment decontamination supplies (refer to SOP 3-06, Equipment Decontamination)

- Health and safety supplies, including personal protective equipment (PPE)
- Appropriate hand tools
- Keys or combinations to access monitoring wells
- Distilled/deionized water supply
- Disposable bailer string (polypropylene)
- Plastic trash bags

7.0 Procedure

Development generally consists of removing water and entrained sediment from the well until the water is clear (to the extent feasible) and the turbidity is reduced, which indicates the well is in good hydraulic connection with the surrounding formation. In addition to simply removing water, development can be improved when flushing through the well screen and gravel pack takes place in both directions, that is, both into the well and into the formation. This action breaks down sediment bridges that can occur in the formation or sand pack, which reduce the connection between the well and the formation

7.1 General Preparation

- All down-well equipment should be decontaminated prior to use and between well locations in accordance with SOP 3-06, Equipment Decontamination
- Although equipment is decontaminated between well locations, if wells are known or suspected to be contaminated based on observations during well installation, it is recommended that well development be conducted in order from the least contaminated to the most contaminated well to minimize the chances of cross-contamination.
- Management of investigation-derived waste (IDW), including development purge water and miscellaneous expendable materials generated during the development process, will be conducted in accordance with SOP 3-05, IDW Management.

PRINTED COPIES ARE UNCONTROLLED. CONTROLLED COPY IS AVAILABLE ON COMPANY INTRANET.

- Prior to accessing the well, the wellhead should be cleared of debris and/or standing water. Nothing from the ground surface should be allowed to enter the well.
- The depth to water and total well depth should be measured with a water level meter and recorded in the field logbook or on a Well Development Record (Attachment 1). This information will be used to calculate the volume of standing water (i.e., the well volume) within the well, and plan the specific details of the well development. If wells are suspected to contain NAPL, an oil/water interface probe should be used to measure liquid levels and depth to bottom of the well.
- Permanent monitoring wells will be developed no sooner than 24 hours after well installation is completed in order to allow well completion materials to set properly.

7.2 Monitoring Well Development Procedures

Generally, development will begin by gently surging the well with a surge block or bailer as described in Sections 7.2.1 and 7.2.2, respectively. Surging can become more vigorous as development progresses but initially the well must be gently surged to allow material blocking the screen to become suspended without damaging the well. Next, a bailer can be used to remove the sediment settled at the base of the well. A bailer, Watterra® pump, or electric submersible pump will then be used to purge the well, per Sections 7.2.2, 7.2.3, or 7.2.4, respectively. The well will be purged until the removed water becomes less turbid or per the requirements of the project-specific SAP, or State or local requirements. At this point the well will be surged again with a surge block or bailer. The well can be surged more vigorously at this point. After surging, the well will be purged again until the turbidity once again decreases. The surge/purge cycle should be completed at least three times during the development process. After the last surge, the well will be purged until the development completion criteria outlined in 7.3.2 or per the project-specific SAP are met.

7.2.1 Surge Block

The default method of well development is the use of a surge block in conjunction with pumping or bailing to remove sediment-laden water.

- The construction of the surge block must be appropriate for the diameter of the well. The surge block must be mounted on rods or other stiff materials to extend it to the appropriate depths and to allow for the surge block to be moved up and down in the well.
- Insert the surge block into the well and lower it slowly to the screened or open interval below the static water level. Start the surge action by slowly and gently moving the surge block up and down in the well. A slow initial surging, using plunger strokes of approximately 1 meter or 3 feet, will allow material which is blocking the screen to separate and become suspended.
- After 5 to 10 plunger strokes, remove water from the well using a separate bailer (Section 7.2.2) or pumping techniques (Sections 7.2.3 or 7.2.4). The returned water should be heavily laden with suspended fines. The water will be discharged to 5-gallon buckets or 55-gallon drums to be managed per the requirements presented in the project-specific SAP.
- In some cases, the bailer or Watterra® foot valve can act as a surge block, flushing water in and out of the well screen as groundwater is removed.
- Repeat the process of surging and pumping/bailing. As development continues, slowly increase the depth of surging to the bottom of the well screen. Surging within the riser portion of the well is neither necessary nor effective.

7.2.2 Bailer

- Tie a string or other cable securely to the bailer. Lower it to the screened or open interval of the monitoring well below the static water level.
- The bailer may be raised and lowered repeatedly within the screened interval to attempt to simulate the action of a surge block by pulling fines through the well screen, and pushing water out into the formation to break down bridging.

- With the bailer full of water, remove it from the well and discharge the water into 5-gallon buckets or 55-gallon drums to be managed per the requirements presented in the project-specific SAP.
- The Watterra® system (Section 7.2.3) or electric submersible pump (Section 7.2.4) may be used as a complementary development method to the bailer, especially when removal of additional water at a faster rate is beneficial.
- Continue alternately surging and bailing, monitoring the purge water periodically (Section 7.3.1) until development completion criteria are met (Section 7.3.2).

7.2.3 Watterra® system

- Attach high-density polyethylene (HDPE) tubing to the decontaminated Watterra® pump foot valve
- Lower the foot valve and tubing assembly near the bottom of the well.
- Lift and lower the tubing to allow water to enter the Watterra® foot valve and travel up the tubing and discharge the water into 5-gallon buckets or 55-gallon drums to be managed per the requirements presented in the project-specific SAP.
- The lifting and lowering action of the Watterra® sysem will cause some surging action to aid in breaking up fine material in the surrounding formation.
- A bailer (Section 7.2.2) may be used as a complementary development method to the Watterra® system, especially during the initial stages of development when a high volume of sediment may be required to be removed.
- An electric submersible pump (Section 7.2.4) may also be used as a complementary development method to the Watterra® system, especially when more volume of water is desired to be pumped or the turbidity criteria cannot be met due to the surging action of the Watterra® system.
- Continue alternately surging and pumping, monitoring the purge water periodically (Section 7.3.1) until well development completion criteria are met (Section 7.3.2).

7.2.4 Electric Submersible Pump

- Attach HDPE tubing to the decontaminated electric submersible pump.
- Lower the pump and tubing assembly near the bottom of the well, at least a few inches above the well total depth.
- Begin pumping, discharging the water into 5-gallon buckets or 55-gallon drums to be managed per the requirements presented in the project-specific SAP.
- Continue alternately surging and pumping, monitoring the purge water discharge periodically (Section 7.3.1) until well development completion criteria are met (Section 7.3.2).

7.3 Discharge Monitoring

7.3.1 Monitoring the Progress of Development

The progress of the development is evaluated through visual observation of the suspended sediment load and measurement of the turbidity and other parameters in the purged diischarge water. As development progresses, the water should become clearer, measured turbidity should decrease, and specific capacity (pumping rate divided by drawdown) should stabilize. Water quality parameters, including DO, conductivity, ORP, pH, temperature, and turbidity may be measured and recorded periodically to determine the progress of development using the criteria outlined in Section 7.3.2 or per the project-specific SAP. Water quality parameters should be measured on each well volume removed.

7.3.2 Completion of Development

The well will be considered developed when the following criteria are met or per the criteria set forth in the project-specific SAP:

- A minimum of three times the standing water volume in a well (to include the well screen and casing plus saturated annulus, assuming 30 percent porosity) is removed.

PRINTED COPIES ARE UNCONTROLLED. CONTROLLED COPY IS AVAILABLE ON COMPANY INTRANET.

- Groundwater parameters for three consecutive standing water volumes are within the following:
    - pH – within ± 0.2 units
    - Specific conductivity – within ± 3%
    - ORP – within ± 10 mV
    - Temperature – within ±1 degree Celsius
    - Turbidity – at or below 10 nephelometric turbidity units (NTU) or within ± 10% if above 10 NTU.
- The sediment thickness remaining within the well is less than 1 percent of the screen length or less than 30 millimeters (0.1 ft) for screens equal to or less than 10 feet long.

Dissolved oxygen (DO) readings may be recorded but DO readings will not be used as development completion criteria because DO may not stabilize.

If the well has slow groundwater recharge and is purged dry, the well will be considered developed when bailed or pumped dry three times in succession and the turbidity has decreased, or per the requirements set forth in the project-specific SAP. Water quality parameters may be recorded if feasible using the flow-through cell.

If any water is added to the well's borehole during development or drilling, three times the volume of water added will also be removed during well development, or per the requirements set forth in the project-specific SAP.

7.4 Development of Wells with Low Yield

Water is the primary mechanism to remove fines and flush water through the gravel pack for effective development. Therefore, development can be a challenge in wells that do not yield sufficient water to recharge when water is removed. However, often these wells are the most in need of development to improve their performance as they are typically installed in low permeability formations with a high content of fines. Development of these wells can improve their yield.

The surging portion of the development can be successfully performed in a well with standing water regardless of its yield. It is the subsequent removal of fine materials that is hindered when insufficient water is recharged to the well. When wells go dry or drawdown significantly during development, development can be performed intermittently, allowing sufficient water to recharge prior conducting the next stage of surging. These intermittent procedures can take place hours or even days apart, depending on project-specific time constraints.

7.5 Wells containing NAPL

Additional care should be taken when planning development of wells that contain NAPL. If the NAPL is flammable, there are health and safety as well as handling issues to consider. If NAPL in excess of a persistent sheen is noted, the recharge rate will be evaluated through hand bailing. In most cases, it is generally preferable to remove NAPL by bailing to the extent practical prior to performing development. Groundwater parameters, excluding turbidity, will not be collected during well development if NAPL or excessive sheen is noticed in the purged water during development to ensure the meter probes are not fouled or destroyed. Well development will be halted.

Development by surging or pumping the well dry can result in the spreading of NAPL vertically in the soil column around the well. These methods can be used, if information exists describing the vertical thickness of the NAPL smear zone around the well, and if the methods do not result in mounding or drawdown that exceeds this thickness. Alternate methods such as bailing may also be used, but any method should not allow the well to be pumped dry or result in significant drawdown that would spread the NAPL vertically.

PRINTED COPIES ARE UNCONTROLLED. CONTROLLED COPY IS AVAILABLE ON COMPANY INTRANET.

7.6 Temporary Well Points

For certain projects, temporary well points (TWPs) may be installed to collect groundwater samples at a site. Since no sand pack, bentonite chips, or bentonite grout are generally used in the construction of the TWPs, development can proceed as soon as sufficient water has entered the well to static conditions. Due to the small diameter of these wells, generally ¾-inch to 1-inch ID, development will be performed using either a small diameter (0.5-inch) bailer and/or a peristaltic pump with dedicated tubing. The TWPs will have minimal water column and may purge dry during development. However, attempts will be made to remove fines from the well prior to sampling. Purging and sampling may occur as soon as approximately 80% of the static water has re-entered the TWP, or per the requirements set forth in the project-specific SAP.

8.0 Quality Control and Assurance

8.1 Field personnel will follow specific quality assurance (QA) guidelines as outlined in the project-specific SAP.

8.2 Quality control (QC) requirements are dependent on project-specific sampling objectives. The project-specific SAP will provide requirements for equipment decontamination (frequency and materials) and IDW handling.

9.0 Records, Data Analysis, Calculations

9.1 All data and information (e.g., development method used) must be documented on field data sheets (Attachment 1) or within site logbooks with permanent ink. Data recorded may include the following:

- Well Location
- Weather conditions
- Date and Time
- Purge Method
- Reading/measurements obtained

Soil and Rock Classification

Procedure 3-16

1.0 Purpose and Scope

1.1 The purpose of this document is to define the standard operating procedure (SOP) to thoroughly describe the physical characteristics of the sample and classify it according to the Unified Soil Classification System (USCS).

1.2 This procedure is the Program-approved professional guidance for work performed by Resolution Consultants under the Comprehensive Long-Term Environmental Action Navy (CLEAN) contract (Contract Number N62470-11-D-8013).

1.3 As guidance for specific activities, this procedure does not obviate the need for professional judgment. Deviations from this procedure while planning or executing planned activities must be approved in accordance with Program requirements for technical planning and review. If there are procedures whether it be from Resolution Consultants, state and/or federal that are not addressed in this SOP and are applicable to surface water sampling then those procedures may be added as an appendix to the project specific SAP.

1.4 It is fully expected that the procedures outlined in this SOP will be followed. Procedural modifications may be warranted depending upon field conditions, equipment limitations, or limitations imposed by the procedure. Substantive modification to this SOP will be approved in advance by the Program Quality Manager. Deviations to this SOP will be documented in the field records.

2.0 Safety

2.1 Depending upon the site-specific contaminants, various protective programs must be implemented prior to sampling. All **field sampling personnel** responsible for sampling activities must review the project-specific health and safety plan (HASP) paying particular attention to the control measures planned for the sampling tasks. Conduct preliminary area monitoring to determine the potential hazard to field sampling personnel. If significant contamination is observed, minimize contact with potential contaminants in both the vapor and liquid phase through the use of respirators and disposable clothing.

2.2 In addition, observe standard health and safety practices according to the project-specific HASP. Suggested minimum protection during well sampling activities includes inner disposable vinyl gloves, outer chemical-protective nitrile gloves, rubberized steel-toed boots, and an American National Standards Institute-standard hard hat. Half-face respirators and cartridges and Tyvek® suits may be necessary depending on the contaminant concentrations, and shall always be available on site.

2.3 Daily safety briefs will be conducted at the start of each working day before any work commences. These daily briefs will be facilitated by the **Site Safety Officer (SSO)** or designee to discuss the day's events and any potential health risk areas covering every aspect of the work to be completed. Weather conditions are often part of these discussions. As detailed in the HASP, everyone on the field team has the authority to stop work if an unsafe condition is perceived until the conditions are fully remedied to the satisfaction of the SSO.

2.4 The health and safety considerations for the work associated with soil classification include:

- At no time during classification activities are personnel to reach for debris near machinery that is in operation, place any samples in their mouth, or come in contact with the soils/rocks without the use of gloves.
- Stay clear of all moving equipment and be aware of pinch points on machinery. Avoid wearing loose fitting clothing.
- When using cutting tools, cut away from yourself. The use of appropriate, task specific cutting tools is recommended.
- To avoid heat/cold stress as a results of exposure to extreme temperatures and PPE, drink electrolyte replacement fluids (1 to 2 cups per hour is recommended) and in case of extreme cold, wear insulating clothing.

3.0 Terms and Definitions

None.

4.0 Interference

None.

5.0 Training and Qualifications

5.1 The **Contract Task Order (CTO) Manager** is responsible for ensuring that the soil and rock classification procedures comply with this procedure. The **CTO Manager** is responsible for ensuring that all personnel involved in soil and rock classification shall have the appropriate education, experience, and training to perform their assigned tasks.

5.2 The **Program Quality Manager** is responsible for ensuring overall compliance with this procedure.

5.3 The **Field Manager** is responsible for ensuring that all project **field personnel** follow these procedures.

5.4 Field personnel are responsible for the implementation of this procedure. Minimum qualifications for **field sampling personnel** require that one individual on the field team shall have a minimum of 6 months of experience with soil and rock classification.

5.5 The **project geologist** and/or **task manager** is responsible for directly supervising the soil and rock classification procedures to ensure that they are conducted according to this procedure, and for recording all pertinent data collected. If deviations from the procedure are required because of anomalous field conditions, they must first be approved by the **Program Quality Manager** and then documented in the field logbook and associated report or equivalent document.

6.0 Equipment and Supplies

6.1 The following equipment list contains materials which may be needed in carrying out the procedures outlined in this SOP. Not all equipment listed below may be necessary for a specific activity. Additional equipment may be required, pending field conditions.

- Personal protective equipment (PPE) and other safety equipment, as required by the HASP
- Field log book and pen with indelible ink
- Boring log

- Munsell Soil Color Chart
- Scoopula, spatula, and/or other small hand tools
- California Sampler
- Hand-held penetrometer

7.0 Calibration or Standardization

None.

8.0 Procedure

8.1 Soil Classification

The basic purpose of the classification of soil is to thoroughly describe the physical characteristics of the sample and to classify it according to an appropriate soil classification system. The USCS was developed so that soils could be described on a common basis by different investigators and serve as a "shorthand" description of soil. A classification of a soil in accordance with the USCS includes not only a group symbol and name, but also a complete word description.

Describing soil on a common basis is essential so that soil described by different site qualified personnel is comparable. Site individuals describing soil as part of site activities *must* use the classification system described herein to provide the most useful geologic database for all present and future subsurface investigations and remedial activities.

The site geologist or other qualified individual shall describe the soil and record the description in a boring log, logbook, and/or electronic field data collection device. The essential items in any written soil description are as follows:

- Classification group name (e.g., silty sand)
- Color, moisture, and odor
- Range of particle sizes and maximum particle size
- Approximate percentage of boulders, cobbles, gravel, sand, and fines
- Plasticity characteristics of the fines
- In-place conditions, such as consistency, density, and structure
- USCS classification symbol

The USCS serves as ”shorthand“ for classifying soil into 15 basic groups:

GW[1] Well graded (poorly sorted) gravel (>50 percent gravel, <5percent fines)

GP[1] Poorly graded (well sorted) gravel (>50percent gravel, <5percent fines)

GM[1] Silty gravel (>50 percent gravel, >15 percent silt)

GC[1] Clayey gravel (>50 percent gravel, >15 percent clay)

SW[1] Well graded (poorly sorted) sand (>50 percent sand, <5 percent fines)

SP[1] Poorly graded (well sorted) sand (>50 percent sand, <5 percent fines)

[1] If percentage of fine is 5 percent to 15 percent, a dual identification shall be given (e.g., a soil with more than 50 percent poorly sorted gravel and 10 percent clay is designated GW-GC.

SM[1] Silty sand (>50 percent sand, >15 percent silt)

SC[1] Clayey sand (>50 percent sand, >15 percent clay)

ML[2] Inorganic, low plasticity silt (slow to rapid dilatancy, low toughness, and plasticity)

CL[2] Inorganic, low plasticity (lean) clay (no or slow dilatancy, medium toughness and plasticity)

MH[2] Inorganic elastic silt (no to slow dilatancy, low to medium toughness and plasticity)

CH[2] Inorganic, high plasticity (fat) clay (no dilatancy, high toughness, and plasticity)

OL Organic low plasticity silt or organic silty clay

OH Organic high plasticity clay or silt

PT Peat and other highly organic soil

Figure8-1 defines the terminology of the USCS. Flow charts presented in Figure 8-2 and indicate the process for describing soil. The particle size distribution and the plasticity of the fines are the two properties of soil used for classification. In some cases, it may be appropriate to use a borderline classification (e.g., SC/CL) if the soil has been identified as having properties that do not distinctly place the soil into one group.

8.1.1 Estimation of Particle Size Distribution

One of the most important factors in classifying a soil is the estimated percentage of soil constituents in each particle size range. Being proficient in estimating this factor requires extensive practice and frequent checking. The steps involved in determining particle size distribution are listed below:

1. Select a representative sample (approximately 1/2 of a 6-inch long by 2.5-inch diameter sample liner).
2. Remove all particles larger than 3 inches from the sample. Estimate and record the percent by volume of these particles. Only the fraction of the sample smaller than 3 inches is classified.
3. Estimate and record the percentage of dry mass of gravel (less than 3 inches and greater than 1/4 inch).
4. Considering the rest of the sample, estimate, and record the percentage of dry mass of sand particles (about the smallest particle visible to the unaided eye).
5. Estimate and record the percentage of dry mass of fines in the sample (do not attempt to separate silts from clays).
6. Estimate percentages to the nearest 5 percent. If one of the components is present in a quantity considered less than 5 percent, indicate its presence by the term “trace”.
7. The percentages of gravel, sand, and fines must add up to 100 percent. “Trace” is not included in the 100 percent total.

8.1.2 Soil Dilatancy, Toughness, and Plasticity

8.1.2.1 Dilatancy

To evaluate dilatancy, follow these procedures:

[2] If the soil is estimated to have 15 percent to 25 percent sand or gravel, or both, the words “with sand” or “with gravel” (whichever predominates) shall be added to the group name (e.g., clay with sand, CL; or silt with gravel, ML). If the soil is estimated to have 30 percent or more sand or gravel, or both, the words “sandy” or “gravely” (whichever predominates) shall be added to the group name (e.g., sandy clay, CL). If the percentage of sand is equal to the percent gravel, use “sandy.”

PRINTED COPIES ARE UNCONTROLLED. CONTROLLED COPY IS AVAILABLE ON COMPANY INTRANET.

1. From the specimen, select enough material to mold into a ball about 1/2 inch (12 millimeters [mm]) in diameter. Mold the material, adding water if necessary, until it has a soft, but not sticky, consistency.
2. Smooth the soil ball in the palm of one hand with the blade of a knife or small spatula. Shake horizontally, striking the side of the hand vigorously against the other hand several times. Note the reaction of water appearing on the surface of the soil. Squeeze the sample by closing the hand or pinching the soil between the fingers, and note the reaction as none, slow, or rapid in accordance with the criteria in Table 8-1. The reaction is the speed with which water appears while shaking, and disappears while squeezing.

Table 8-1: Criteria for Describing Dilatancy

Description	Criteria
None	No visible change in specimen.
Slow	Water appears slowly on the surface of the specimen during shaking and does not disappear or disappears slowly upon squeezing.
Rapid	Water appears quickly on the surface of the specimen during shaking and disappears quickly upon squeezing.

8.1.2.2 Toughness

Following the completion of the dilatancy test, shape the test specimen into an elongated pat and roll it by hand on a smooth surface or between the palms into a thread about 1/8 inch (3 mm) in diameter. (If the sample is too wet to roll easily, spread it into a thin layer and allow it to lose some water by evaporation.) Fold the sample threads and re-roll repeatedly until the thread crumbles at a diameter of about 1/8 inch. The thread will crumble at a diameter of 1/8 inch when the soil is near the plastic limit. Note the pressure required to roll the thread near the plastic limit. Also, note the strength of the thread. After the thread crumbles, lump the pieces together and knead it until the lump crumbles. Note the toughness of the material during kneading. Describe the toughness of the thread and lump as low, medium, or high in accordance with the criteria in Table 8-2.

Table 8-2: Criteria for Describing Toughness

Description	Criteria
Low	Only slight pressure is required to roll the thread near the plastic limit. The thread and the lump are weak and soft.
Medium	Medium pressure is required to roll the thread near the plastic limit. The thread and the lump have medium stiffness.
High	Considerable pressure is required to roll the thread near the plastic limit. The thread and the lump have very high stiffness.

DEFINITION OF TERMS

MAJOR DIVISIONS			SYMBOLS	TYPICAL DESCRIPTIONS
COARSE GRAINED SOILS More Than Half of Material is Larger Than No. 200 Sieve Size	GRAVELS More Than Half of Coarse Fraction is Smaller Than No. 4 Sieve	CLEAN GRAVELS (Less than 6% Fines)	GW	Well graded gravels, gravel-sand mixtures, little or no fines
			GP	Poorly graded gravels, gravel-sand mixtures, little or no fines
		GRAVELS With Fines	GM	Silty gravels, gravel-sand-silt mixtures, non-plastic fines
			GC	Clayey gravels, gravel-sand-clay mixtures, plastic fines
	SANDS More Than Half of Coarse Fraction is Smaller Than No. 4 Sieve	CLEAN SANDS (Less than 6% Fines)	SW	Well graded sands, gravelly sands, little or no fines
			SP	Poorly graded sands, gravelly sands, little or no fines
		SANDS With Fines	SM	Silty sands, sand-silt mixtures, non-plastic fines
			SC	Clayey sands, sand-clay mixtures, plastic fines
FINE GRAINED SOILS More Than Half of Material is Smaller Than No. 200 Sieve Size	SILTS AND CLAYS Liquid Limit is Less Than 50%		ML	Inorganic silts, rock flour, fine sandy silts or clays, and clayey silts with non- or slightly-plastic fines
			CL	Inorganic clays of low to medium plasticity, gravelly clays, silty clays, sandy clays, lean clays
			OL	Organic silts and organic silty clays of low plasticity
	SILTS AND CLAYS Liquid Limit is Greater Than 50%		MH	Inorganic silts, micaceous or diatomaceous fine sandy or silty soils, elastic silts, clayey silt
			CH	inorganic clays of high plasticity, fat clays
			OH	Organic clays of medium to high plasticity, organic silts
HIGHLY ORGANIC SOILS			PT	Peat and other highly organic soils

8.1.2.3 Plasticity

The plasticity of a soil is defined by the ability of the soil to deform without cracking, the range of moisture content over which the soil remains in a plastic state, and the degree of cohesiveness at the plastic limit. The plasticity characteristic of clays and other cohesive materials is defined by the liquid limit and plastic limit. The liquid limit is defined as the soil moisture content at which soil passes from the liquid to the plastic state as moisture is removed. The test for the liquid limit is a laboratory, not a field, analysis.

The plastic limit is the soil moisture content at which a soil passes from the plastic to the semi-solid state as moisture is removed. The plastic limit test can be performed in the field and is indicated by the ability to roll a 1/8-inch (0.125-inch) diameter thread of fines, the time required to roll the thread, and the number of times the thread can be re-rolled when approaching the plastic limit.

The plasticity tests are not based on natural soil moisture content, but on soil that has been thoroughly mixed with water. If a soil sample is too dry in the field, add water prior to performing classification. If a soil sample is too sticky, spread the sample thin and allow it to lose some soil moisture.

Table 8-3 presents the criteria for describing plasticity in the field using the rolled thread method.

Table 8-3: Criteria for Describing Plasticity

Description	Criteria
Non-Plastic	A 1/8-inch thread cannot be rolled.
Low Plasticity	The thread can barely be rolled.
Medium Plasticity	The thread is easy to roll and not much time is required to reach the plastic limit.
High Plasticity	It takes considerable time rolling the thread to reach the plastic limit.

8.1.3 **Angularity**

The following criteria describe the angularity of the coarse sand and gravel particles:

- **Rounded** particles have smoothly-curved sides and no edges.
- **Subrounded** particles have nearly plane sides, but have well-rounded corners and edges.
- **Subangular** particles are similar to angular, but have somewhat rounded or smooth edges.
- **Angular** particles have sharp edges and relatively plane sides with unpolished surfaces. Freshly broken or crushed rock would be described as angular.

8.1.4 **Color, Moisture, and Odor**

The natural moisture content of soil is very important. Table **8-4** shows the terms for describing the moisture condition and the criteria for each.

Table 8-4: Soil Moisture Content Qualifiers

Qualifier	Criteria
Dry	Absence of moisture, dry to the touch
Moist	Damp but no visible water
Wet	Visible water, usually soil is below water table

Color is described by hue and chroma using the Munsell Soil Color Chart (Munsell 2000). For uniformity, all site geologists shall utilize this chart for soil classification. Doing so will facilitate correlation of geologic units between boreholes logged by different geologists. The Munsell Color Chart is a small booklet of numbered color chips with names like “5YR 5/6, yellowish-red.” Note mottling or banding of colors. It is particularly important to note and describe staining because it may indicate contamination.

PRINTED COPIES ARE UNCONTROLLED. CONTROLLED COPY IS AVAILABLE ON COMPANY INTRANET.

In general, wear a respirator if strong organic odors are present. If odors are noted, describe them if they are unusual or suspected to result from contamination. An organic odor may have the distinctive smell of decaying vegetation. Unusual odors may be related to hydrocarbons, solvents, or other chemicals in the subsurface. An organic vapor analyzer may be used to detect the presence of volatile organic contaminants.

8.1.5 In-Place Conditions

Describe the conditions of undisturbed soil samples in terms of their density/consistency (i.e., compactness), cementation, and structure utilizing the following guidelines:

8.1.5.1 Density/Consistency

Density and consistency describe a physical property that reflects the relative resistance of a soil to penetration. The term “density” is commonly applied to coarse to medium-grained sediments (i.e., gravels, sands), whereas the term “consistency” is normally applied to fine-grained sediments (i.e., silts, clays). There are separate standards of measure for both density and consistency that are used to describe the properties of a soil.

The density or consistency of a soil is determined by observing the number of blows required to drive a 1 3/8-inch (35 mm) diameter split barrel sampler 18 inches using a drive hammer weighing 140 lbs (63.5 kilograms [kg]) dropped over a distance of 30 inches (0.76 meters). Record the number of blows required to penetrate each 6 inches of soil in the field boring log during sampling. The first 6 inches of penetration is considered to be a seating drive; therefore, the blow count associated with this seating drive is recorded, but not used in determining the soil density/consistency. The sum of the number of blows required for the second and third 6 inches of penetration is termed the “standard penetration resistance,” or the “N-value.” The observed number of blow counts must be corrected by an appropriate factor if a different type of sampling device (e.g., Modified California Sampler with liners) is used. For a 2 3/8-inch inner diameter (I.D.) Modified California Sampler equipped with brass or stainless steel liners and penetrating a cohesionless soil (sand/gravel), the N-value from the Modified California Sampler must be divided by 1.43 to provide data that can be compared to the 1 3/8-inch diameter sampler data.

For a cohesive soil (silt/clay), the N-value for the Modified California Sampler should be divided by a factor of 1.13 for comparison with 1 3/8-inch diameter sampler data.

Drive the sampler and record blow counts for each 6-inch increment of penetration until one of the following occurs:

- A total of 50 blows have been applied during any one of the three 6-inch increments; a 50-blow count occurrence shall be termed “refusal” and noted as such on the boring log.
- A total of 150 blows have been applied.
- The sampler is advanced the complete 18 inches without the limiting blow counts occurring, as described above.

If the sampler is driven less than 18 inches, record the number of blows per partial increment on the boring log. If refusal occurs during the first 6 inches of penetration, the number of blows will represent the N-value for this sampling interval. Table 8-5 and Table 8-6 present representative descriptions of soil density/consistency vs. N-values.

PRINTED COPIES ARE UNCONTROLLED. CONTROLLED COPY IS AVAILABLE ON COMPANY INTRANET.

Table 8-5: Measuring Soil Density with a California Sampler – Relative Density (Sands, Gravels)

Description	Field Criteria (N-Value)	
	1 3/8 in. ID Sampler	2 in. ID Sampler using 1.43 factor
Very Loose	0–4	0–6
Loose	4–10	6–14
Medium Dense	10–30	14–43
Dense	30–50	43–71
Very Dense	> 50	> 71

Table 8-6: Measuring Soil Density with a California Sampler – Fine Grained Cohesive Soil

Description	Field Criteria (N-Value)	
	1 3/8 in. ID Sampler	2 in. ID Sampler using 1.13 factor
Very Soft	0–2	0–2
Soft	2–4	2–4
Medium Stiff	4–8	4–9
Stiff	8–16	9–18
Very Stiff	16–32	18–36
Hard	> 32	> 36

For undisturbed fine-grained soil samples, it is also possible to measure consistency with a hand-held penetrometer. The measurement is made by placing the tip of the penetrometer against the surface of the soil contained within the sampling liner or shelby tube, pushing the penetrometer into the soil a distance specified by the penetrometer manufacturer, and recording the pressure resistance reading in pounds per square foot (psf). The values are as follows (Table 8-7):

Table 8-7: Measuring Soil Consistency with a Hand-Held Penetrometer

Description	Pocket Penetrometer Reading (psf)
Very Soft	0–250
Soft	250–500
Medium Stiff	500–1000
Stiff	1000–2000
Very Stiff	2000–4000
Hard	>4000

Consistency can also be estimated using thumb pressure using Table 8-8.

Table 8-8: Measuring Soil Consistency Using Thumb Pressure

Description	Criteria
Very Soft	Thumb will penetrate soil more than 1 inch (25 mm)
Soft	Thumb will penetrate soil about 1 inch (25 mm)
Firm	Thumb will penetrate soil about 1/4 inch (6 mm)
Hard	Thumb will not indent soil but readily indented with thumbnail
Very Hard	Thumbnail will not indent soil

PRINTED COPIES ARE UNCONTROLLED. CONTROLLED COPY IS AVAILABLE ON COMPANY INTRANET.

8.1.5.2 *Cementation*

Cementation is used to describe the friability of a soil. Cements are chemical precipitates that provide important information as to conditions that prevailed at the time of deposition, or conversely, diagenetic effects that occurred following deposition. Seven types of chemical cements are recognized by Folk (1980). They are as follows:

- Quartz – siliceous
- Chert – chert-cemented or chalcedonic
- Opal – opaline
- Carbonate – calcitic, dolomitic, sideritic (if in doubt, calcareous should be used)
- Iron oxides – hematitic, limonitic (if in doubt, ferruginous should be used)
- Clay minerals – if the clay minerals are detrital or have formed by recrystallization of a previous clay matrix, they are not considered to be a cement. Only if they are chemical precipitates, filling previous pore space (usually in the form of accordion-like stacks or fringing radial crusts) should they be included as “kaolin-cemented,” “chlorite-cemented,” etc.
- Miscellaneous minerals – pyritic, collophane-cemented, glauconite-cemented, gypsiferous, anhydrite-cemented, baritic, feldspar-cemented, etc.

The degree of cementation of a soil is determined qualitatively by utilizing finger pressure on the soil in one of the sample liners to disrupt the gross soil fabric. The three cementation descriptors are as follows:

- Weak – friable; crumbles or breaks with handling or slight finger pressure
- Moderate – friable; crumbles or breaks with considerable finger pressure
- Strong – not friable; will not crumble or break with finger pressure

8.1.5.3 *Structure*

This variable is used to qualitatively describe physical characteristics of soil that are important to incorporate into hydrogeological and/or geotechnical descriptions of soil at a site. Appropriate soil structure descriptors are as follows:

- Granular – spherically shaped aggregates with faces that do not accommodate adjoining faces
- Stratified – alternating layers of varying material or color with layers at least 6 mm (1/4 inch) thick; note thickness
- Laminated – alternating layers of varying material or color with layers less than 6 mm (1/4 inch) thick; note thickness
- Blocky – cohesive soil that can be broken down into small angular or subangular lumps that resist further breakdown
- Lensed – inclusion of a small pocket of different soil, such as small lenses of sand, should be described as homogeneous if it is not stratified, laminated, fissured, or blocky. If lenses of different soil are present, the soil being described can be termed homogeneous if the description of the lenses is included
- Prismatic or Columnar – particles arranged about a vertical line, ped is bounded by planar, vertical faces that accommodate adjoining faces; prismatic has a flat top; columnar has a rounded top
- Platy – particles are arranged about a horizontal plane

PRINTED COPIES ARE UNCONTROLLED. CONTROLLED COPY IS AVAILABLE ON COMPANY INTRANET.

8.1.5.4 Other Features

- Mottled – soil that appears to consist of material of two or more colors in blotchy distribution
- Fissured – breaks along definite planes of fracture with little resistance to fracturing (determined by applying moderate pressure to sample using thumb and index finger)
- Slickensided – fracture planes appear polished or glossy, sometimes striated (parallel grooves or scratches)

8.1.6 **Development of Soil Description**

Develop standard soil descriptions according to the following examples. There are three principal categories under which all soil can be classified. They are described below.

8.1.6.1 Coarse-grained Soil

Coarse-grained soil is divided into sands and gravels. A soil is classified as a sand if over 50 percent of the coarse fraction is "sand-sized." It is classified as a gravel if over 50 percent of the coarse fraction is composed of "gravel-sized" particles.

The written description of a coarse-grained soil shall contain, in order of appearance: Typical name including the second highest percentage constituent as an adjective, if applicable (underlined); grain size of coarse fraction; Munsell color and color number; moisture content; relative density; sorting; angularity; other features, such as stratification (sedimentary structures) and cementation, possible formational name, primary USCS classification, secondary USCS classification (when necessary), and approximate percentages of minor constituents (i.e., sand, gravel, shell fragments, rip-up clasts) in parentheses.

Example: POORLY-SORTED SAND WITH SILT, medium- to coarse-grained, light olive gray, 5Y 6/2, saturated, loose, poorly sorted, subrounded clasts, SW/SM (minor silt with approximately 20 percent coarse-grained sand-sized shell fragments, and 80 percent medium-grained quartz sand, and 5 percent to 15 percent ML).

8.1.6.2 Fine-grained Soil

Fine-grained soil is further subdivided into clays and silts according to its plasticity. Clays are rather plastic, while silts have little or no plasticity.

The written description of a fine-grained soil should contain, in order of appearance: Typical name including the second highest percentage constituent as an adjective, if applicable (underlined); Munsell color; moisture content; consistency; plasticity; other features, such as stratification, possible formation name, primary USCS classification, secondary USCS classification (when necessary), and the percentage of minor constituents in parentheses.

Example: SANDY LEAN CLAY, dusky red, 2.5 YR 3/2, moist, firm, moderately plastic, thinly laminated, CL (70 percent fines, 30 percent sand, with minor amounts of disarticulated bivalves [about 5 percent]).

8.1.6.3 Organic Soil

For highly organic soil, describe the types of organic materials present as well as the type of soil constituents present using the methods described above. Identify the soil as an organic soil, OL/OH, if the soil contains enough organic particles to influence the soil properties. Organic soil usually has a dark brown to black color and may have an organic odor. Often, organic soils will change color, (e.g., from black to brown) when exposed to air. Some organic soils will lighten in color significantly when air-dried. Organic soils normally will not have a high toughness or plasticity. The thread for the toughness test will be spongy.

8.2 Example: ORGANIC CLAY, black, 2.5Y, 2.5/1, wet, soft, low plasticity, organic odor, OL (100 percent fines), weak reaction to HCl.

8.3 Rock Classification

The purpose of rock classification is to thoroughly describe the physical and mineralogical characteristics of a specimen and to classify it according to an established system. The generalized rock classification system described below was developed because, unlike the USCS for soils, there is no universally accepted rock classification system. In some instances, a more detailed and thorough rock classification system may be appropriate. Any modifications to this classification system, or the use of an alternate classification system should be considered during preparation of the site work plan. Both the CTO Manager and the QA Manager or Technical Director must approve any modifications to this classification system, or the use of another classification system.

Describing rock specimens on a common basis is essential so that rocks described by different site geologists are comparable. Site geologists describing rock specimens as a part of investigative activities must use the classification system described herein, or if necessary, another more detailed classification system. Use of a common classification system provides the most useful geologic database for all present and future subsurface investigations and remedial activities.

In order to provide a more consistent rock classification between geologists, a rock classification template has been designated as shown in **Error! Reference source not found.**. The template includes classification of rocks by origin and mineralogical composition. When classifying rocks, all site geologists shall use this template.

The site geologist shall describe the rock specimen and record the description in a boring log or logbook. The items essential for classification include (i.e., metamorphic foliated):

- Classification Name (i.e., schist)
- Color
- Mineralogical composition and percent
- Texture/Grain size (i.e., fine-grained, pegmatitic, aphlitic, glassy)
- Structure (i.e., foliated, fractured, lenticular)
- Rock Quality Designation (sum of all core pieces greater than two times the diameter of the core divided by the total length of the core run, expressed as a percentage)
- Classification symbol (i.e., MF)

Example: Metamorphic foliated schist: Olive gray, 5Y, 3/2, Garnet 25 percent, Quartz 45 percent, Chlorite 15 percent, Tourmaline 15 percent, Fine-grained with Pegmatite garnet, highly foliated, slightly wavy, MF.

9.0 Quality Control and Assurance

None

DEFINITION OF TERMS					
PRIMARY DIVISIONS			SYMBOLS		SECONDARY DIVISIONS
SEDIMENTARY ROCKS	Clastic Sediments	CONGLOMERATE		CG	Coarse-grained Clastic Sedimentary Rock types including: Conglomerates and Breccias
		SANDSTONE		SS	Clastic Sedimentary Rock types including: Sandstone, Arkose and Greywacke
		SHALE		SH	Fine-grained Clastic Sedimentary Rock types including: Shale, Siltstone, Mudstone and Claystone
	Chemical Precipitates	CARBONATES		LS	Chemical Precipitates including: Limestone, Crystalline Limestone, Fossiliferous Limestone Micrite and Dolomite
		EVAPORITES		EV	Evaporites including: Anhydrite, Gypsum, Halite, Travertine and Caliche
IGNEOUS ROCKS		EXTRUSIVE (Volcanic)		IE	Volcanic Rock types including: Basalt, Andesite, Rhyolite, Volcanic Tuff, and Volcanic Breccia
		INTRUSIVE (Plutonic)		II	Plutonic Rock types including: Granite, Diorite and Gabbro
METAMORPHIC ROCKS		FOLIATED		MF	Foliated Rock types including: Slate, Phyllite, Schist and Gneiss
		NON-FOLIATED		MN	Non-foliated Rock types including: Metaconglomerate, Quartzite and Marble

PRINTED COPIES ARE UNCONTROLLED. CONTROLLED COPY IS AVAILABLE ON COMPANY INTRANET.

10.0 Data and Records Management

10.1 Document soil classification information collected during soil sampling onto the field boring logs, field trench logs, and into the field notebook. Copies of this information shall be sent to the **CTO Manager** for the project files.

10.2 Field notes will be kept during coring activities in accordance with SOP 3-03 – Recordkeeping, Sample Labeling, and Chain of Custody. The information pertinent to soil classification activities includes chronology of events, sample locations (x,y,z), time/date, sampler name, methods (including type of core liner/barrel, if applicable), sampler penetration and acceptability, sample observations, and the times and type of equipment decontamination. Deviations to the procedures detailed in the SOP should be recorded in the field logbook.

Headspace Screening for Total VOCs

Procedure 3-19

1.0 Purpose and Scope

1.1 This standard operating procedure (SOP) describes the basic techniques for using headspace analysis to screen for volatile organics in contaminated soils using a portable Photo Ionization Detector (PID) or Flame Ionization Detector (FID).

1.2 As guidance for specific activities, this procedure does not obviate the need for professional judgment. Deviations from this procedure while planning or executing planned activities must be approved in accordance with Program requirements for technical planning and review.

2.0 Safety

2.1 The health and safety considerations for the work associated with this SOP will be addressed in the project Health and Safety Plan (HASP). In the absence of a HASP, work will be conducted according to the Contract Task Order (CTO) Work Plan (WP) and/or direction from the **Site Safety Officer (SSO)**. Note that headspace screening usually requires Level D personal protection unless there is a potential for airborne exposure to site contaminants. Under circumstances where potential airborne exposure is possible respiratory protective equipment may be required based on personal air monitoring results. Upgrades to Level C will be coordinated with the Site Safety Officer (SSO) or **CTO Manager**.

2.2 Health and safety hazards and corresponding precautions include, but are not limited to, the following:

2.2.1 Dermal contact with contaminated soil. Personnel should treat all soil as potentially contaminated and wear chemically impervious gloves. Minimize skin contact with soil by using sampling instruments such as stainless steel spades or spoons. Do not touch any exposed skin with contaminated gloves.

2.2.2 Inhalation hazards. Appropriate air monitoring should be conducted to ensure that organic vapor concentrations in the breathing zone do not exceed action levels as specified in the Site-Specific HASP. When ambient temperatures are low enough to require warming samples using the vehicle heater, the vehicle's windows should be opened enough to prevent the build-up of any organic vapors. Use the PID or FID to verify the airborne concentrations in the vehicle remain below applicable action levels. Note that many volatile organic compounds (VOCs) are flammable and all precautions must be observed to eliminate any potential ignition sources.

2.2.3 Shipping limitations. Follow applicable regulations when shipping FID/PID equipment. When shipping an FID by air, the hydrogen tank must be bled dry. Calibration gas canisters are considered dangerous goods and must be shipped according to IATA and DOT regulations. Consult your EHS Coordinator and check with your shipping company to determine the correct shipping procedures

3.0 Terms and Definitions

None.

4.0 Interferences

4.1 Regardless of which gas is used for calibration, the instrument will respond to all analytes present in the sample that can be detected by the type of lamp used in the PID.

4.2 Moisture will generate a positive interference in the concentration measured for a PID and is characterized by a slow increase in the reading as the measurement is made. Care must be taken to

PRINTED COPIES ARE UNCONTROLLED. CONTROLLED COPY IS AVAILABLE ON COMPANY INTRANET.

minimize uptake of moisture to the extent possible. Refer to the manufacturers' instructions for care, cleaning, and maintenance.

4.3 Uptake of soil into the PID must be avoided as it will compromise instrument performance by blocking the probe, causing a positive interference, or dirtying the PID lamp. Refer to the manufacturers' instructions for care, cleaning, and maintenance.

4.4 The user should listen to the pitch of the sampling pump. Any changes in pitch may indicate a blockage and corrective action should be initiated.

5.0 Training and Qualifications

5.1 **Qualifications and Training**

The individual executing these procedures must have read, and be familiar with, the requirements of this SOP.

5.2 **Responsibilities**

5.2.1 The CTO Manager is responsible for ensuring that the collection of headspace readings comply with this procedure. The CTO Manager is responsible for ensuring that all personnel involved in the collection of headspace readings shall have the appropriate education, experience, and training to perform their assigned tasks.

5.2.2 The Program Quality Manager is responsible for ensuring overall compliance with this procedure.

5.2.3 The Field Manager is responsible for ensuring that all headspace readings are conducted according to this procedure as well as verifying that the PID/FID is in proper operating condition prior to use and for implementing the calibration.

5.2.4 All Field Personnel are responsible for the implementation of this procedure.

6.0 Equipment and Supplies

6.1 The following materials must be on hand in good operating condition and/or in sufficient quantity to ensure that proper field analysis procedures may be followed:

- Calibrated PID/FID instrument;
- Top-sealing "Zip-Loc" type plastic bags – or – 16 ounces of soil or "mason-" type glass jars and aluminum foil;
- Project field book and/or boring logs;
- Personal Protective Equipment (PPE) as specified in the project HASP; and
- Material Safety Data Sheets (MSDSs) for any chemicals or site-specific contaminants.

7.0 Procedure

7.1 **Preparation**

Review available project information to determine the types of organic vapors that will likely be encountered to select the right instrument. The two basic types of instruments are FIDs and PIDs.

FIDs work well with organic compounds that have relatively lightweight molecules, but may have problems detecting halogenated compounds or heavier organic compounds; FIDs can detect methane for example. Since the FID uses a flame to measure organic compounds, ensure that work is conducted in an atmosphere, which is free of combustible vapors. If ambient temperatures are below 40°F, the flame of the FID may be difficult to light.

PRINTED COPIES ARE UNCONTROLLED. CONTROLLED COPY IS AVAILABLE ON COMPANY INTRANET.

When using a PID, select an instrument that can measure the ionization potential of the anticipated contaminants of concern. PIDs work well with a range of organic compounds and can detect some halogenated hydrocarbons; PIDs cannot detect methane. The correct ultraviolet (UV) light bulb must be selected according to the types of organic vapors that will likely be encountered. The energy of the UV light must equal or exceed the ionization potential of the organic molecules that the PID will measure. The NIOSH Pocket Guide to Chemical Hazards is one source for determining ionization potentials for different chemicals. Bulbs available for PIDs include 9.4 eV, 10.6 (or 10.2) eV, and 11.7 eV bulbs. The 10.6 eV bulb is most commonly used as it detects a fairly large range of organic molecules and does not burn out as easily as the 11.7 eV bulb. The 9.4 eV bulb is the most rugged, but detects only a limited range of compounds. Under very humid or very cold ambient conditions, the window covering the UV light may fog up, causing inaccurate readings. Ask the **SSO** about correction factors when high humidity conditions exist.

After selecting the correct instrument, calibrate the PID/FID according to the manufacturer's instructions. Record background/ambient levels of organic vapors measured on the PID/FID after calibration and make sure to subtract the background concentration (if any) from your readings. Check the PID/FID readings against the calibration standard every 20 readings or at any time when readings are suspected to be inaccurate, and recalibrate, if necessary. Be aware that, after measuring highly contaminated soil samples, the PID/FID may give artificially high readings for a time.

7.2 Top-Sealing Plastic Bag

Place a quantity of soil in a top-sealing plastic bag and seal the bag immediately. The volume of soil to be used should be determined by the **CTO Manager** or **Field Manager**. The volume of soil may vary between projects but should be consistent for all samples collected for one project. Ideally, the bag should be at least 1/10th-filled with soil and no more than half-filled with soil. Once the bag is sealed, shake the bag to distribute the soil evenly. If the soil is hard or clumpy, use your fingers to gently work the soil (through the bag) to break up the clumps. Do not use a sampling instrument or a rock hammer since this may create small holes in the plastic bag and allow organic vapors to escape. Alternatively, the sample may be broken up before it is placed in the bag. Use a permanent marker to record the following information on the outside of the bag:

- Site identification information (i.e., borehole number);
- Depth interval; and
- Time the sample was collected. For example: "SS-12, 2-4 ft, @1425".

Headspace should be allowed to develop before organic vapors are measured with a PID/FID. The amount of time required for sufficient headspace development will be determined by the project-specific sampling plan and the ambient temperature. Equilibration time should be the same for all samples to allow an accurate comparison of organic vapor levels between samples. However, adjustments to equilibration times may be necessary when there are large variations in ambient temperature from day to day. When ambient temperatures are below 32°F, headspace development should be within a heated building or vehicle. When heating samples, be sure there is adequate ventilation to prevent the build-up or organic vapors above action levels.

Following headspace development, open a small opening in the seal of the plastic bag. Insert the probe of a PID/FID and seal the bag back up around the probe as tightly as possible. Alternatively, the probe can be inserted through the bag to avoid loss of volatiles. Since PIDs and FIDs are sensitive to moisture, avoid touching the probe to the soil or any condensation that has accumulated inside of the bag. Since the PID/FID consumes organic vapors, gently agitate the soil sample during the reading to release fresh organic vapors from the sample. Erratic meter response may occur at high organic vapor concentrations or conditions of elevated headspace moisture, in which case, headspace data should be discounted. Record the highest reading on the field form or in the field notebook as described in Section 9.

PRINTED COPIES ARE UNCONTROLLED. CONTROLLED COPY IS AVAILABLE ON COMPANY INTRANET.

7.3 **Jar and Aluminum Foil (Alternate Method)**

Half-fill a clean glass jar with the soil sample to be screened. Quickly cover the jar's opening with one to two sheets of clean aluminum foil and apply the screw cap to tightly seal the jar. Allow headspace development for at least ten minutes. Vigorously shake the jar for 15 seconds, both at the beginning and at the end of the headspace development period. Where ambient temperatures are below 32°F (0°C), headspace development should be within a heated area. When heating samples, be sure there is adequate ventilation to prevent the build-up of organic vapors above action levels.

Subsequent to headspace development, remove the jar lid and expose the foil seal. Quickly puncture the foil seal with the instrument sampling probe, to a point about one-half of the headspace depth. Exercise care to avoid uptake of water droplets or soil particulates. As an alternative, use a syringe to withdraw a headspace sample, and then inject the sample into the instrument probe or septum-fitted inlet. This method is acceptable contingent upon verification of methodology accuracy using a test gas standard. Following probe insertion through the foil seal or sample injection to probe, record the highest meter response on the field form or in the field notebook. Using foil seal/probe insertion method, maximum response should occur between two and five seconds. Erratic meter response may occur at high organic vapor concentrations or conditions of elevated headspace moisture, in which case, headspace data should be discounted.

8.0 Quality Control and Assurance

Quality Assurance/Quality Control (QA/QC) will include the collection of duplicate samples. In general, one duplicate will be collected per 20 samples. Organic vapor concentrations measured in the primary and duplicate samples should be similar within plus or minus 20 percent. The frequency of headspace duplicate collection will be determined by the project manager/task manager. The PID/FID instrument must be calibrated according to the manufacturer's instructions before beginning screening, and checked or recalibrated every 20 analyses or when readings are suspected to be inaccurate. Record ambient organic vapor levels in the field notebook and on the field form. Periodically check ambient organic vapor levels. If ambient levels have changed more than 20 percent, recalibrate the PID/FID. Make sure readings are not collected near a vehicle exhaust or downwind of a drill rig exhaust. If grossly contaminated soil is encountered, decontaminate sampling instruments between samples and/or change contaminated gloves to avoid cross contaminating less contaminated samples.

9.0 Records, Data Analysis, Calculations

9.1 All data generated (results and duplicate comparisons) will be recorded in the field notebook and/or on the field form. Any deviation from the outlined procedure will also be noted. Field conditions (ambient temperature, wind, etc.) should also be recorded in the field notebook.

9.2 Readings may be recorded in a field notebook, on a boring log, or on an appropriate form specific to the project. The form should include the following information:

- When the PID/FID was calibrated (date/time) and calibration standard used;
- Background/ambient concentrations measured after PID/FID calibration;
- Location of sample (i.e., bore-hole number);
- Depth interval of sample measured;
- Lithology of material measured; and
- PID/FID reading and units of measure.

PRINTED COPIES ARE UNCONTROLLED. CONTROLLED COPY IS AVAILABLE ON COMPANY INTRANET.

9.3 Note that if PID/FID measurements are recorded on a boring log, it is not necessary to duplicate information in the column where the PID/FID readings are recorded (e.g., borehole number, depth interval, lithology type).

9.4 All documentation will be stored in the project files and retained following completion of the project.

SOP 3-20 Operation and Calibration of a Photoionization Detector

Author	Reviewer	Revisions (Technical or Editorial)
Robert Shoemaker Senior Scientist	Chris Barr Program Quality Manager	Rev 0 – Initial Issue (May 2012)

PRINTED COPIES ARE UNCONTROLLED. CONTROLLED COPY IS AVAILABLE ON COMPANY INTRANET.

Operation and Calibration of a Photoionization Detector

Procedure 3-20

1.0 Purpose and Scope

1.1 Purpose and Applicability

1.1.1 This standard operating procedure (SOP) describes the procedures that will be followed by field staff for operation and calibration of a photoionization detector (PID). The PID is primarily used by AECOM personnel for safety and survey monitoring of ambient air, determining the presence of volatiles in soil and water, and detecting leakage of volatiles.

1.1.2 PIDs routinely used by field personnel include the Photovac Microtip, Thermoelectron 580EZ, and MiniRAE 2000. Personnel responsible for using the PID should first read and thoroughly familiarize themselves with the instrument instruction manual.

1.2 Principle of Operation

1.2.1 The PID is a non-specific vapor/gas detector. The unit generally consists of a hand-held probe that houses a PID, consisting of an ultraviolet (UV) lamp, two electrodes, and a small fan which pulls ambient air into the probe inlet tube. The probe is connected to a readout/control box that consists of electronic control circuits, a readout display, and the system battery. Units are available with UV lamps having an energy from 9.5 electron volts (eV) to 11.7 eV.

1.2.2 The PID analyzer measures the concentration of trace gas present in the atmosphere by photoionization. Photoionization occurs when an atom or molecule absorbs a photon of sufficient energy to release an electron and become a positive ion. This will occur when the ionization potential of the molecule (in electron volts (eV)) is less than the energy of the photon. The source of photons is an ultraviolet lamp in the probe unit. Lamps are available with energies ranging from 9.5 eV to 11.7 eV. All organic and inorganic vapor/gas compounds having ionization potentials lower than the energy output of the UV lamp are ionized and the resulting potentiometric change is seen as a positive reading on the unit. The reading is proportional to the concentration of organics and/or inorganics in the vapor.

1.2.3 Sample gases enter the probe through the inlet tube and enter the ion chamber where they are exposed to the photons emanating from the UV lamp. Ionization occurs for those molecules having ionization potentials near to or less than that of the lamp. A positive- biased polarizing electrode causes these positive ions to travel to a collector electrode in the chamber. Thus the ions create an electrical current which is amplified and displayed on the meter. This current is proportional to the concentration of trace gas present in the ion chamber and to the sensitivity of that gas to photoionization.

1.2.4 In service, the analyzer is first calibrated with a gas of known composition equal to, close to, or representative of that to be measured. Gases with ionization potentials near to or less than the energy of the lamp will be ionized. These gases will thus be detected and measured by the analyzer. Gases with ionization potentials greater than the energy of the lamp will not be detected. The ionization potentials of the major components of air, i.e., oxygen, nitrogen, and carbon dioxide, range from about 12.0 eV to 15.6 eV and are not ionized by any of the lamps available. Gases with ionization potentials near to or slightly higher than the lamp are partially ionized, with low sensitivity.

1.3 Specifications

1.3.1 Refer to the manufacturer's instructions for the technical specifications of the instrument being used. The operating concentration range is typically 0.1 to 2,000 ppm isobutylene equivalent.

PRINTED COPIES ARE UNCONTROLLED. CONTROLLED COPY IS AVAILABLE ON COMPANY INTRANET.

2.0 Safety

2.1 The health and safety considerations for the work associated with this SOP, including both potential physical and chemical hazards, will be addressed in the project Health and Safety Plan (HASP). In the absence of a HASP, work will be conducted according to the Contract Task Order (CTO) Work Plan (WP) and/or direction from the **Site Safety Officer (SSO)**.

2.2 Only PIDs stamped Division I Class I may be used in explosive atmospheres. Refer to the project HASP for instructions pertaining to instrument use in explosive atmospheres.

3.0 Terms and Definitions

None.

4.0 Interferences

4.1 Regardless of which gas is used for calibration, the instrument will respond to all analytes present in the sample that can be detected by the type of lamp used in the PID.

4.2 Moisture will generate a positive interference in the concentration measured for a PID and is characterized by a slow increase in the reading as the measurement is made. Care must be taken to minimize uptake of moisture to the extent possible. Refer to the manufacturers' instructions for care, cleaning, and maintenance.

4.3 Uptake of soil into the PID must be avoided as it will compromise instrument performance by blocking the probe, causing a positive interference, or dirtying the PID lamp. Refer to the manufacturers' instructions for care, cleaning, and maintenance.

4.4 The user should listen to the pitch of the sampling pump. Any changes in pitch may indicate a blockage and corrective action should be initiated.

5.0 Training and Qualifications

5.1 **Qualifications and Training**

The individual executing these procedures must have read, and be familiar with, the requirements of this SOP.

5.2 **Responsibilities**

5.2.1 The CTO Manager is responsible for ensuring that the operation and calibration activities comply with this procedure. The CTO Manager is responsible for ensuring that all personnel involved in the operation and calibration shall have the appropriate education, experience, and training to perform their assigned tasks.

5.2.2 The Program Quality Manager is responsible for ensuring overall compliance with this procedure.

5.2.3 The Field Manager is responsible for ensuring that all operation and calibration activities are conducted according to this procedure.

5.2.4 All Field Personnel are responsible for the implementation of this procedure.

6.0 Equipment and Supplies

- Calibration Gas: Compressed gas cylinder of isobutylene in air or similar stable gas mixture of known concentration. The selected gas should have an ionization potential similar to that of the vapors to be monitored, if known. The concentration should be at 50-75% of the range in which the instrument is to be calibrated;

PRINTED COPIES ARE UNCONTROLLED. CONTROLLED COPY IS AVAILABLE ON COMPANY INTRANET.

- Regulator for calibration gas cylinder;
- Approximately 6 inches of Teflon® tubing;
- Tedlar bag (optional);
- Commercially-supplied zero grade air (optional);
- "Magic Marker" or “Sharpie” or other waterproof marker;
- Battery charger;
- Moisture traps;
- Spare lamps;
- Manufacturer’s instructions; and
- Field data sheets or logbook/pen.

7.0 Procedure

7.1 Preliminary Steps

7.1.1 Preliminary steps (battery charging, check-out, calibration, maintenance) should be conducted in a controlled or non-hazardous environment.

7.2 Calibration

7.2.1 The PID must be calibrated in order to display concentrations in units equivalent to ppm. First a supply of zero air (ambient air or from a supplied source), containing no ionizable gases or vapors is used to set the zero point. A span gas, containing a known concentration of a photoionizable gas or vapor, is then used to set the sensitivity.

7.2.2 Calibrate the instrument according to the manufacturer’s instructions. Record the instrument model and identification number, the initial and adjusted meter readings, the calibration gas composition and concentration, and the date and the time in the field records.

7.2.3 If the calibration cannot be achieved or if the span setting resulting from calibration is 0.0, then the lamp must be cleaned (Section 7.4).

7.3 Operation

7.3.1 Turn on the unit and allow it to warm up (minimum of 5 minutes). Check to see if the intake fan is functioning; if so, the probe will vibrate slightly and a distinct sound will be audible when holding the probe casing next to the ear. Also, verify on the readout display that the UV lamp is lit.

7.3.2 Calibrate the instrument as described in Section 7.2, following the manufacturer’s instructions. Record the calibration information in the field records.

7.3.3 The instrument is now operational. Readings should be recorded in the field records.

7.3.4 When the PID is not being used or between monitoring intervals, the unit may be switched off to conserve battery power and UV lamp life; however, a “bump” test should be performed each time the unit is turned on and prior to taking additional measurements. To perform a bump test, connect the outlet tubing from a Tedlar bag containing a small amount of span gas to the inlet tubing on the unit and record the reading. If the reading is not within the tolerance specified in the project plan, the unit must be recalibrated.

7.3.5 At the end of each day, recheck the calibration. The check will follow the same procedures as the initial calibration (Section 7.2) except that no adjustment will be made to the instrument. Record the information in the field records.

PRINTED COPIES ARE UNCONTROLLED. CONTROLLED COPY IS AVAILABLE ON COMPANY INTRANET.

7.3.6 Recharge the battery after each use (Section 7.4).

7.3.7 When transporting, ensure that the instrument is packed in its stored condition in order to prevent damage.

7.4 **Routine Maintenance**

7.4.1 Routine maintenance associated with the use of the PID includes charging the battery, cleaning the lamp window, replacing the detector UV lamp, replacing the inlet filter, and replacing the sample pump. Refer to the manufacturer's instructions for procedures and frequency.

7.4.2 All routine maintenance should be performed in a non-hazardous environment.

7.5 **Troubleshooting Tips**

7.5.1 One convenient method for periodically confirming instrument response is to hold the sensor probe next to the tip of a magic marker. A significant reading should readily be observed.

7.5.2 Air currents or drafts in the vicinity of the probe tip may cause fluctuations in readings.

7.5.3 A fogged or dirty lamp, due to operation in a humid or dusty environment, may cause erratic or fluctuating readings. The PID should never be operated without the moisture trap in place.

7.5.4 Moving the instrument from a cool or air-conditioned area to a warmer area may cause moisture to condense on the UV lamp and produce unstable readings.

7.5.5 A zero reading on the meter should not necessarily be interpreted as an absence of air contaminants. The detection capabilities of the PID are limited to those compounds that will be ionized by the particular probe used.

7.5.6 Many volatile compounds have a low odor threshold. A lack of meter response in the presence of odors does not necessarily indicate instrument failure.

7.5.7 When high vapor concentrations enter the ionization chamber in the PID the unit can become saturated or "flooded". Remove the unit to a fresh air environment to allow the vapors to be completely ionized and purged from the unit.

8.0 Quality Control and Assurance

8.1 The end use of the data will determine the quality assurance requirements that are necessary to produce data of acceptable quality. These quality assurance requirements will be defined in the site-specific workplan or Sampling and Analysis Plan (SAP), hereafter referred to as the project plan.

8.2 Calibration of the PID will be conducted at the frequency specified in the project plan. In the absence of project-specific guidance, calibration will be performed at the beginning of each day of sampling and will be checked at the end of the sampling day or whenever instrument operation is suspect. The PID will sample a calibration gas of known concentration. The instrument must agree with the calibration gas within ±10%. If the instrument responds outside this tolerance, it must be recalibrated.

8.3 Checks of the instrument response (Section 7.5) should be conducted periodically and documented in the field records.

9.0 Records, Data Analysis, Calculations

Safety and survey monitoring with the PID will be documented in a bound field logbook, or on standardized forms, and retained in the project files. The following information is to be recorded:

- Project name and number;
- Instrument manufacturer, model, and identification number;

PRINTED COPIES ARE UNCONTROLLED. CONTROLLED COPY IS AVAILABLE ON COMPANY INTRANET.

- Operator's signature;
- Date and time of operation;
- Calibration gas used;
- Calibration check at beginning and end of day (meter readings before adjustment);
- Span setting after calibration adjustment;
- Meter readings (monitoring data obtained);
- Instances of erratic or questionable meter readings and corrective actions taken; and
- Instrument checks and response verifications – e.g., battery check, magic marker response (Section 7.5) or similar test.

Surface and Subsurface Soil Sampling Procedures

Procedure 3-21

1.0 Purpose and Scope

1.1 This standard operating procedure (SOP) describes the procedures for soil sampling. The procedure includes surface and subsurface sampling by various methods using hand auguring, test pit, direct-push, and split-spoon equipment.

1.2 The procedure includes soil sampling for volatile organic compounds (VOCs). For project specific information (e.g. sampling depths, equipment to be used, and frequency of sampling), refer to the Sampling and Analysis Plan (SAP), which takes precedence over these procedures. Surface soil sampling, typically considered to be up to two feet below ground surface by EPA standards, is typically accomplished using hand tools such as shovels or hand augers. Test pit samples are considered subsurface samples, although normally collected via hand tools similar to surface soil sampling or by excavation machinery. Direct-push and split-spoon sampling offer the benefit of collecting soil samples from a discrete or isolated subsurface interval, without the need of extracting excess material above the target depth. These methods dramatically reduce time and cost associated with disposal of material from soil cuttings when compared to test pit sampling. In addition, direct-push and split-spoon sampling methods can obtain samples at targeted intervals greater than 15 feet in depth, allowing for discrete depth soil sampling while speeding up the sampling process. Direct-push methods work best in medium to fine-grained cohesive materials such as medium to fine sands, silts, and silty clay soils. Split-spoon sampling works well in all types of soil, but is somewhat slower than direct-push methods. Samples are composited so that each sample contains a homogenized representative portion of the sample interval. Due to potential loss of analytes, samples for volatile analysis are not composited. Samples for chemical analysis can be collected by any of the above-mentioned sampling methods, as disturbed soil samples. Undisturbed samples are collected, sealed, and sent directly to the laboratory for analysis. For undisturbed samples, the samples are not homogenized.

2.0 Safety

2.1 The health and safety considerations for the work associated with this SOP, including both potential physical and chemical hazards, will be addressed in the project Health and Safety Plan (HASP). In the absence of a HASP, work will be conducted according to the Contract Task Order (CTO) Work Plan (WP) and/or direction from the **Site Safety Officer (SSO)**.

2.2 Before soil sampling commences, appropriate entities (e.g. DigSafe, local public works departments, company facilities) must be contacted to assure the anticipated soil sampling locations are marked for utilities, including electrical, telecommunications, water, sewer, and gas.

3.0 Terms and Definitions

None.

4.0 Interferences

4.1 Low recovery of soil from sampling equipment will prevent an adequate representation of the soil profile and sufficient amount of soil sample. If low recovery is a problem, the hole may be offset and re-advanced, terminated, or continued using a larger diameter sampler.

PRINTED COPIES ARE UNCONTROLLED. CONTROLLED COPY IS AVAILABLE ON COMPANY INTRANET.

4.2 Asphalt in soil samples can cause false positive results for hydrocarbons. To ensure samples are free of asphalt, do not collect samples that may contain asphalt. If the collection of samples potentially containing asphalt is unavoidable, note the sampling depths at which the presence of asphalt are suspected.

4.3 Instrumentation interferences addressed in SOPs for Calibration of the Photoionization Detector (PID), Headspace Screening for Total Volatile Organics, and Equipment Decontamination must also be considered.

4.4 Cross contamination from sampling equipment must be prevented by using sampling equipment constructed of stainless steel that is adequately decontaminated between samples.

5.0 Training and Qualifications

5.1 **Qualifications and Training**

The individual executing these procedures must have read, and be familiar with, the requirements of this SOP.

5.2 **Responsibilities**

5.2.1 The CTO Manager is responsible for ensuring that soil sampling activities comply with this procedure. The CTO Manager is responsible for ensuring that all personnel involved in soil sampling shall have the appropriate education, experience, and training to perform their assigned tasks.

5.2.2 The Program Quality Manager is responsible for ensuring overall compliance with this procedure.

5.2.3 The Field Manager is responsible for ensuring that all soil sampling activities are conducted according to this procedure.

5.2.4 All Field Personnel are responsible for the implementation of this procedure.

6.0 Equipment and Supplies

The depth at which samples will be collected and the anticipated method of sample collection (direct-push, split-spoon, hand auger, shovel, or test pits) will be presented in the SAP. The following details equipment typically needed for soil sampling, based on the various methods. See the SAP for specific detail of equipment and supply needs.

6.1 Depending on the nature of suspected contamination, field screening instrumentation may be used for direct sampling. Appropriate instrumentation and calibration standards should be available. If volatile organic contaminants are suspected and a PID will be used, refer to the equipment and instrumentation listed in SOP 3-20 Operation and Calibration of a Photoionization Detector. Equipment in this SOP includes but is not limited to:

- PID/FID;
- Calibration gas; and
- Tedlar® gas bags (for calibration).

6.2 If field screening methods include jar headspace screening for volatile organics, refer to the equipment and procedure in SOP 3-19 Headspace Screening for Total VOCs. Equipment in this SOP includes but is not limited to:

- Clean soil (“drillers jars”) jars; and
- Aluminium foil.

PRINTED COPIES ARE UNCONTROLLED. CONTROLLED COPY IS AVAILABLE ON COMPANY INTRANET.

6.3 Appropriate decontamination procedures must be followed for sampling equipment. Refer to SOP 3-06 Equipment Decontamination. Equipment in this SOP includes but is not limited to:

- Phosphate-free detergent;
- Isopropyl Alcohol;
- Tap water;
- Deionized Ultra-Filtered (DIUF) Water;
- Plastic buckets or washbasins;
- Brushes; and
- Polyethylene sheeting.

6.4 The following general equipment is needed for all soil sampling, regardless of method:

- Stainless steel bowls;
- Stainless steel trowels;
- Appropriate sample containers for laboratory analysis;
- Personal Protective Equipment (PPE);
- Logbook;
- Cooler and ice for preservation; and
- Stakes and flagging to document sampling location.

6.5 The following additional equipment is needed for volatile organic sampling:

- Electronic pan scale and weights for calibration; and
- Syringes or other discrete soil core samplers.

6.6 The following additional equipment may be needed for surface and test pit soil sampling:

- Hand Auger

6.7 The following additional equipment may be needed for soil sampling from direct push and/or split-spoon equipment:

- Tape measure or folding carpenter's rule for recording the length of soil recovered.

Note: All subsurface drilling equipment will be provided and maintained by the subcontractor.

7.0 Procedure

7.1 **General Soil Sampling Procedure for All Soil Sampling Methods**

7.1.1 Record the weather conditions and other relevant on-site conditions.

7.1.2 Select the soil sampling location, clear vegetation if necessary, and record the sampling location identification number and pertinent location details.

7.1.3 Verify that the sampling equipment is properly decontaminated, in working order, and situated at the intended sampling location.

7.1.4 Place polyethylene sheeting on the ground and assemble all necessary sampling equipment on top of it. Cover surfaces onto which soils or sampling equipment will be placed (i.e. tables with polyethylene sheeting).

7.1.5 Follow the appropriate procedures listed below for either surface, split-spoon, direct push, or test pit sample collection (7.2, 7.3, 7.4, and 7.5 respectively).

7.1.6 Collect soil samples according to procedures listed in Section 7.6 depending on project specific analyses.

7.1.7 Record date/time, sample ID, and sample descriptions in the field logbook or field form. A sketch or description of the location may also be recorded so the sample location can be re-constructed, especially if the location will not be recorded using global positioning satellite (GPS) equipment.

7.1.8 Immediately label the sample containers and place them on ice, if required for preservation. Complete the chain-of-custody form(s) as soon as possible.

7.1.9 Dispose of all excess excavated soil in accordance with the SAP.

7.1.10 If required, mark the sample location with a clearly labelled wooden stake or pin flag. If the location is on a paved surface, the location may be marked with spray paint.

7.1.11 Decontaminate the sampling equipment according to SOP 3-06 Equipment Decontamination.

7.2 Surface Sampling

7.2.1 The criteria used for selecting surface soil locations for sampling may include the following:

- Visual observations (soil staining, fill materials);
- Other relevant soil characteristics;
- Site features;
- Screening results;
- Predetermined sampling approach (i.e. grid or random); and
- Sampling objectives as provided in the SAP.

7.2.2 The following procedures are to be used to collect surface soil samples. Surface soils are considered to be soils that are up to two feet below ground surface, though state regulations and project objectives may define surface soils differently; therefore, the SAP should be consulted for direction on the depth from which to collect the surface soil samples. Sampling and other pertinent data and information will be recorded in the field logbook and/or on field forms. Photographs may be taken as needed or as specified in the SAP.

1. Gently scrape any vegetative covering until soil is exposed. Completely remove any pavement.
2. Remove soil from the exposed sampling area with a trowel, hand auger, or shovel. Put soils within the sampling interval in a stainless steel bowl for homogenizing. Monitor the breathing zone and sampling area as required in the HASP.
3. For VOC analyses, collect representative soil samples directly from the recently-exposed soil using a syringe or other soil coring device (e.g., TerraCore®, EnCore®). Follow procedures in Section 7.6.1 for VOC sampling.
4. Collect sufficient soil to fill all remaining sample jars into a stainless steel bowl. Homogenize the soil samples to obtain a uniform soil composition which is representative of the total soil sample collected according to the following procedure:

    a) Remove all rocks and non-soil objects using a stainless steel spoon or scoop.

b) Form a cone shaped mound with the sample material, then flatten the cone and split the sample into quarters.

c) Use the stainless steel spoon/scoop to mix the quarter samples that are opposite.

d) After mixing the opposite quarters, reform the cone shaped mound.

e) Repeat this procedure a minimum of five (5) times, removing any non-soil objects and breaking apart any clumps.

7.3 Split-Spoon Sampling

7.3.1 At each boring location, the frequency and depth of split-spoon samples will be determined from the SAP. Split-spoon samples may be collected continuously, intermittently, or from predetermined depths.

7.3.2 Split-spoon samplers shall be driven into undisturbed soil by driving the spoon ahead of the drill augers/casing. In cohesive soils, or soils where the borehole remains open (does not collapse), two split-spoon samples may be taken prior to advancing the augers/casing.

7.3.3 After split-spoons are retrieved, open the split-spoon and measure the recovery of soil. If a PID will be used for screening, immediately scan the recovered sample for VOCs using the PID. Scan the recovered soil boring by making a hole in the soil with a decontaminated trowel and placing the PID inlet very close to the hole. Be very careful not to get soil on the tip of the PID. Take PID readings every 6 inches along the split-spoon and/or in any areas of stained or disturbed soil. Record the highest PID reading and the depth at which it was observed along with all other pertinent observations. If required in the SAP, VOC and headspace samples should be collected (see Section 7.6.1) prior to logging the sample.

7.3.4 If headspace screening for VOCs is required in the SAP, collect a soil sample (as defined in the SAP) and perform headspace screening according to SOP 3-19 Headspace Screening for Total VOCs.

7.3.5 Soils collected using the split-spoon sampler will be logged by the field representative using the procedure required in the SAP.

7.3.6 Collect the remainder of the sample volume required into a stainless steel bowl. Homogenize the soil so the material is uniform in composition and representative of the total soil sample collected. Follow homogenizing techniques as described in Section 7.2.

7.3.7 The SAP may specify that intervals to be sent to the laboratory be determined by visual observation and/or highest PID screening or headspace results, which can only be determined once the boring is complete. In this instance, a VOC sample should be collected at each interval. The remainder of the soil from that interval will be set aside in a clearly labelled stainless steel bowl covered with aluminium foil. Once the boring has been completed and the sample interval has been determined, the remainder of the soil can be homogenized according to Section 7.2 and submitted for laboratory analysis.

7.3.8 Once a boring is complete and all required samples have been collected, the boring must be completed as specified in the SAP (e.g., completed as a monitoring well, backfilled with bentonite, etc).

7.4 Direct Push Sampling

At each boring location, the frequency of direct-push samples will be determined from the SAP. Typically, samples with direct-push equipment are collected in 4 foot (ft) intervals, but smaller (e.g., 2 ft) and larger (e.g., 5 ft) intervals are also possible.

1. Sample using Macro-Core samplers with acetate liners to obtain discrete soil samples at the depths specified in the SAP.

2. Cut open the acetate liner. If required in the SAP, immediately scan the recovered soil boring for VOCs using a PID by making a hole in the soil with a decontaminated trowel and placing the PID inlet very close to the hole. Be very careful not to get soil on the tip of the PID. Take PID readings every 6 inches along the split-spoon and/or in any areas of stained or disturbed soil. Record the

highest PID reading and the depth at which it was observed along with all other pertinent observations. VOC and headspace samples, if required in the SAP should be collected (see Section 7.6.1) prior to logging the sample.

3. If required in the SAP, collect a soil sample (as defined in the SAP) and perform headspace screening according to SOP 3-19 Headspace Screening for Total VOCs.

4. Soils collected using the direct-push sampler will be logged by the by the field representative using the procedure required in the SAP.

5. Collect the remainder of the sample into a stainless steel bowl. Homogenize the soil collected so that the material is uniform in composition and representative of the total soil sample collected. Follow homogenizing techniques as described in Section 7.2.

6. Once a boring is complete and all required samples have been collected, the boring must be completed as specified in the SAP (e.g., completed as a monitoring well, backfilled with bentonite, etc).

7.5 Test Pit Sampling

7.5.1 Excavate the test pit to the desired depth.

7.5.2 Using the excavator bucket, collect soil samples as specified in the SAP. Collect a sample and perform screening analyses as required by the SAP. If VOCs contamination is suspected, perform headspace screening according to SOP 3-19 Headspace Screening for Total VOCs.

7.5.3 Collect the sample from center of the bucket to avoid potential contamination from the bucket.

7.5.4 VOC samples should also be collected from an undisturbed section soil in the excavator bucket. The top layer of exposed soil should be scraped away just prior to collecting the VOC samples.

7.5.5 Collect the remainder of the sample volume required into a stainless steel bowl. Homogenize the soil so the material is uniform in composition and representative of the total soil sample collected. Follow homogenizing techniques as described in Section 7.2.

7.5.6 Dispose of all excavated soil according to the SAP.

7.6 Sample Collection Methods

7.6.1 Volatile Organics Sampling

For soils collected for analyses of volatile organics, including Volatile Petroleum Hydrocarbons (VPH) or other purgable compounds, a closed system is maintained. From collection through analysis, the sample bottles are not opened. The bottle kit for a routine field sample for these analyses will typically include three 40-mL VOA vials and one soil jar. Two 40-mL VOA vials will contain either 5 mL reagent water or 5 mL sodium bisulfate and magnetic stir bars (i.e., low level vials). The third VOA vial will contain 15 mL methanol with no magnetic stir bar (i.e., high level vial). These vials are usually provided by the laboratory and are pre-weighed, with the tare weight recorded on the affixed sample label. No additional sample labels are affixed to the VOA vials, as addition of a label would alter the vial weight. All information is recorded directly on the sample label using an indelible marker. The soil jar is provided for percent solids determination. For VOC or VPH analyses, samples are collected prior to sample homogenization. Collect the VOC sample in accordance with the procedure described below.

1. Determine the soil volume necessary for the required sample weight, typically 5 grams:

   a) Prepare a 5 mL sampling corer (e.g., Terra Core®) or cut-off plastic syringe.

   b) Tare the sampler by placing it on the scale, and zeroing the scale.

   c) Draw back the plunger to the 5 gram mark or 5mL (5cc) mark on cut-off syringe, and insert the open end of the sampler into an undisturbed area of soil with a twisting motion, filling the

PRINTED COPIES ARE UNCONTROLLED. CONTROLLED COPY IS AVAILABLE ON COMPANY INTRANET.

sampler with soil. Note the location of the plunger with respect to the milliliter (cc) or other graduation printed on the sampler.

d) Weigh the filled sampler, and remove or add soil until the desired weight is obtained. Note the location of the plunger which corresponds to this weight. Do not use this sample for laboratory analysis.

2. Once the required soil volume has been determined, pull the plunger back to this mark and hold it there while filling the syringe for each sample.

3. Collect 5 grams of soil using the cut-off syringe or Terra Core® sample device. Extrude the 5-grams of soil into one of the low level 40-mL VOA vials. Quickly wipe any soil from the threads of the VOA vial with a clean Kimwipe® and immediately close the vial. It is imperative that the threads be free from soil or other debris prior to replacing the cap on the vial in order to maintain the closed system necessary for the analysis.

4. Gently swirl the vial so that all of the soil is fully wetted with the preservative.

5. Fill the other low level 40 mL VOA vial in this manner.

6. Repeat the process for the high level VOA vials, only for the high level VOA vial three 5 gram aliquots (i.e., 15 grams total) should be extruded into the high level VOA vial.

   NOTE: Depending on the laboratory, some high level VOA vials only contain 5 mL or 10 mL of methanol. If this is the case, either 5 grams total or 10 grams total, respectively, should be extruded into the high level VOA vial. In other words, the mass of soil in grams should be identical to the volume of methanol in mL (i.e., 1:1 ratio of soil to methanol).

7. Collect any additional QC sample collected (e.g., field duplicate, MS, and MSD) in the same manner as above.

8. Fill the 4-oz glass jar with soil from the same area for percent moisture determination.

7.6.2 Soil Sampling Method (All other analyses except VOC/VPH)

When all the required soil for a sampling location has been obtained, the soil can be homogenized as described in section 7.2. Collect sufficient volume to fill all of the remaining sample containers at least ¾ full for all other analyses. Homogenize the soil in a decontaminated stainless steel bowl, removing rocks, sticks, or other non-soil objects and breaking apart any lumps of soil prior to filling the remaining sample containers.

NOTE: Soil samples must contain greater than 30% solids for the data to be considered valid.

8.0 Quality Control and Assurance

8.1 Sampling personnel should follow specific quality assurance guidelines as outlined in the SAP. Proper quality assurance requirements should be provided which will allow for collection of representative samples from representative sampling points. Quality assurance requirements outlined in the SAP typically suggest the collection of a sufficient quantity of field duplicate, field blank, and other samples.

8.2 Quality control requirements are dependent on project-specific sampling objectives. The SAP will provide requirements for equipment decontamination (frequency and materials), sample preservation and holding times, sample container types, sample packaging and shipment, as well as requirements for the collection of various quality assurance samples such as trip blanks, field blanks, equipment blanks, and field duplicate samples.

PRINTED COPIES ARE UNCONTROLLED. CONTROLLED COPY IS AVAILABLE ON COMPANY INTRANET.

9.0 Records, Data Analysis, Calculations

All data and information (e.g., sample collection method used) must be documented on field data sheets, boring logs, or within site logbooks with permanent ink. Data recorded may include the following:

- Weather conditions;
- Arrival and departure time of persons on site;
- Instrument type, lamp (PID), make, model and serial number;
- Calibration gas used;
- Date, time and results of instrument calibration and calibration checks;
- Sampling date and time;
- Sampling location;
- Samples collected;
- Sampling depth and soil type;
- Deviations from the procedure as written; and
- Readings obtained.

RE: Draft Final Fall 2016 Five Year Event Monitoring Report, Site 09 Monitoring Event 45, Former NCBC Davisville, North Kingstown, Rhode Island

Dear Ms. Williams and Mr. Gottlieb:

On behalf of the Naval Facilities Engineering Command (NAVFAC), Mid-Atlantic (MIDLANT), Resolution Consultants is submitting the Draft Final Fall 2016 Five Year Event Monitoring Report for Site 09 Monitoring Event 45. If you have any questions regarding this deliverable, please contact the Navy RPM Mr. Todd Bober or myself.

Sincerely,

Resolution Consultants

1.0 PROJECT BACKGROUND

1.1 Introduction

The results from Monitoring Event (ME) 45, conducted in September and December 2016, as part of the Long-Term Monitoring (LTM) Program at Allen Harbor Landfill (Site 09, see Figure 1), Former Naval Construction Battalion Center (NCBC) Davisville, are provided in this report. ME 45 was conducted in accordance with the Draft Tier II Sampling and Analysis Plan Long Term Monitoring Site 07 Calf Pasture Point and Site 09 Allen Harbor Landfill (Tier II LTM SAP) dated June 24, 2016 (Resolution, 2016b). A detailed discussion of the site history and conceptual site model can be found in Worksheet 10-1 of the Tier II LTM SAP.

ME 45 was a Five Year Event (see Table 1). In addition to presenting the data from ME 45, comparisons to recent historical data and evaluation of long term trends are also included. The human health and ecological risk assessments for Site 09 have also been updated with data since the last risk assessments.

Field and laboratory analytical data collected during ME 45 are summarized in tables and figures attached to this report. Data and backup for the data presented in tables and figures are provided as Attachments to this report: Field sampling forms are provided in Attachment A, data validation reports are provided in Attachment B, the land-use control implementation plan (LUCIP) checklist is provided as Attachment C, the site inspection report and photographs are provided in Attachment D, summary of detected analytes tables are included in Attachment E. Statistical analysis data including frequency of detection (FOD) tables, Mann Kendall trend analyses, and trend plots are located in Attachment F. Updated Risk Assessments are provided in Attachment G. Results of a laboratory audit performed for the shellfish resampling and statistical comparisons of the September 2016 and December 2016 shellfish samples are provided in Appendix H. Appendix I contains updated allowable air toxic emission rates and comparison to the Site 09 landfill gas vent emissions.

2.0 FIVE YEAR MONITORING EVENT ACTIVITIES

The Site 09 landfill maintenance activities were conducted from August 15, 2016 through August 24, 2016. The Site 09 sampling was initially conducted from September 6, 2016 through September 30, 2016 in conjunction with the Calf Pasture Point (Site 07) ME 20. Sampling locations are presented on Figure 2 and Figure 3. The shellfish data collected during the initial sampling were not usable for project objectives (see Section 2.2 for more detail). Therefore, the shellfish samples were recollected from December 12, 2016 through December 14, 2016. A complete summary of activities performed during ME 45 is summarized below:

- Groundwater samples were collected from 26 monitoring wells
- Four shellfish tissue samples were collected from outside the created wetland breakwater structure, two were collected south of the landfill, two were collected north of the landfill, and two were collected within the created wetland. Details on the type of shellfish collected at each location are presented in Section 2.1. Shellfish samples were co-located with piezometers with the exception of the two wetland sample locations ET09-07 and ET09-08. Shellfish data collected during the September sampling event was deemed unusable during data evaluation. Therefore, a re-sampling event for all ten shellfish tissue sample locations was conducted in December 2016 (see Section 2.2).
- Piezometer samples were collected from 11 locations. P09-05A was found to be dry after several attempts to sample; therefore no samples were collected from this location (see Section 2.2). Samples were collected from beyond the breakwater in 5 locations (P09-06B, P09-07B, P09-08B, P09-11B, and P09-12B), and from inside the wetland in four locations (P09-02, P09-03, and P09-04A). One sample was collected from north of the landfill (P09-01), and two from south of the landfill (P9-09, and P09-10).
- Synoptic water level measurements were recorded during outgoing mid-tide, low tide and high tide at 27 monitoring wells and the staff gauge in Allen Harbor.
- 20 soil gas points around the perimeter of the landfill cap were screened with a photoionization detector (PID) and landfill gas meter.
- 5 gas vents were sampled with SUMMA canisters for laboratory analysis of Volatile Organic Compounds (VOCs) and methane. The gas vents were also screened with a PID and landfill gas meter.
- Three seep samples were collected.

- 12 sediment samples were collected from 0-6 inches below ground surface (bgs), co-located with the piezometers P09-01, P09-2A, P09-3A, P09-4A, P09-5A, P09-6B, P09-7B, P09-8B, P09-09, and P09-10.
- One surface water sample was collected from Allen Harbor.
- Landfill inspection and landfill maintenance activities were performed.

Groundwater samples collected from monitoring wells and piezometers were analyzed for one or more of the following parameters: VOCs, semivolatile organic compounds (SVOCs), polycyclic aromatic hydrocarbons (PAHs), pesticides, sulfide, polychlorinated biphenyls (PCBs), metals (dissolved and total), and salinity. Sediment samples were analyzed for one or more of the following: VOCs, PAHs, pesticides, PCBs, and metals. Shellfish tissue samples were analyzed for SVOCs, PAHs, pesticides, PCB homologs, metals, and percent lipids. Landfill gas samples were analyzed for VOCs and methane. Sampling locations, analyses, and sampling rationale are presented on Table 1.

Field sampling forms completed during ME 45 are provided in Attachment A.

2.1 Monitoring Procedures

Synoptic groundwater measurements; sample collection; and soil gas point and gas vent screening were performed in accordance with the Draft Tier II LTM SAP (Resolution, 2016b). The land-use control inspection and site inspections were completed in accordance with the Final Quality Assurance Project Plan (QAPP) (EA, 2001) and the Final Land Use Control Implementation Plan (EA, 2002).

Groundwater samples were collected from monitoring wells and piezometers using the Environmental Protection Agency (EPA) Region I Low Stress (Low Flow) methodology (EPA, 2010). Piezometer samples were collected at low tide. In cases where a sampling point did not provide sufficient recharge to enable stabilization of the water level, the sampling point was evacuated of standing water and allowed to recharge prior to the collection of the water quality data and the piezometer sample. Consistent with EPA methodology, prior to the collection of sample aliquots for laboratory analysis, water quality parameters including temperature, pH, specific conductivity, dissolved oxygen, oxidation-reduction potential, and turbidity were measured (where sufficient water was available) and recorded with an electronic data collection device. A summary of field measurements recorded during monitoring well and piezometer groundwater sample collection activities is provided on Tables 4 and 5 of this report, respectively.

Sediment samples were collected at low tide from 0-6 inches bgs, immediately adjacent to piezometer locations, using a clean, disposable trowel for each location. A PID was used to screen the hole for any elevated readings. During ME 45, no elevated readings were observed at any of the sediment locations. Therefore, the sediment sample aliquot for VOC analysis was collected as a discreet sample using a dedicated coring device (i.e., Terra Core® Sampler) directly from the bottom of the sample hole (i.e., 6 inches bgs). For the non-VOC samples, sediments from the targeted depth interval were homogenized in a decontaminated stainless steel bowl then transferred into the appropriate containers for laboratory analysis. Sediment samples were co-located with piezometers, and where applicable, shellfish tissue sample collection locations.

Two types of shellfish were collected during ME 45 as follows: Quahogs were collected at locations ET09-05, ET09-06, ET09-09, ET09-10, and ET09-12, and Ribbed Mussels were collected at locations ET09-03, ET09-04, ET09-07, ET09-08, and ET09-11. Quahogs were collected anywhere from 0.5 – 2 feet bgs depending on where they could be located. With the exception of location ET09-07, Ribbed Mussels were collected from the surface of the breakwater structure, so the sample depth was zero feet. At wetland location ET09-07, Ribbed Mussels were collected anywhere from 0 – 0.5 feet bgs, where they were located embedded in the wetland sediment. Shellfish tissue sampling locations are shown on Figure 2. Samples were placed in Ziplock® bags and sent to the laboratory on ice whole for preparation and analysis. See Section 2.2 for details on the shellfish resampling.

Landfill Gas Vent samples were collected at five gas vent locations, GV09-01 – GV09-05. Screening parameters were collected with a PID and landfill gas meter at each gas vent prior to sample collection. The samples were collected using laboratory-provided SUMMA Canisters.

Three seep samples were collected during ME 45 from the southeastern side of the landfill where erosion channels have formed in the created wetland due to the flow of surface water from the revetment wall during receding tide. Two of the seep samples are adjacent to piezometers P09-07 and P09-08, respectively; the third is in the area south of the MW09-08 well cluster. The seep samples were collected during ebb (i.e., receding) tide when flow through the seep channels was at its low point but still high enough to collect a sample. A clean unpreserved glass bottle was dipped directly into the top 1 inch of flow and then this bottle was used to fill the sulfide and salinity samples. VOC samples were collected by directly filling the VOC vials from the seep. Seep samples were collected for VOCs, Sulfide, and Salinity analysis.

The annual landfill inspection was conducted on September 28, 2016 (Attachment D).

2.2 Deviations from Planned Monitoring Activities

On November 17, 2016, the laboratory notified Resolution that the shellfish samples collected in September 2016 had extremely low or no surrogate recoveries for the SVOC, PAH, and pesticides analyses. The Project Chemist reviewed the data and determined that the majority of the results would be rejected during data validation and any results not rejected would be estimated and biased extremely low. Resolution requested that the laboratory re-extract and re-analyze the samples for these analyses, but due to laboratory error, the shellfish samples had not be placed back in the freezer following the initial sample preparation; they were placed in the refrigerator instead. Therefore, the holding time for the analyses had been grossly exceeded and re-extraction and reanalysis was not possible. The PCB homolog and metals data were not affected by this data quality issue.

The Base Realignment and Closure (BRAC) Cleanup Team (BCT) was notified of the shellfish sample data quality issue on November 18, 2016. The data quality issue and a resampling proposal were discussed during the December 1, 2016 BCT conference call. The BCT agreed to resample the shellfish and analyze the samples for the full suite of analyses, validate the September 2016 PCB homolog and metals data, and compare these data to the validated December 2016 PCB homolog and metals data to assess whether the data can be considered to be from the same population and the same season (Resolution, 2016c). Details on the comparison of the September 2016 and December 2016 PCB homolog and metals data are discussed in Section 4.3.

Resolution recollected the shellfish samples from December 12, 2016 through December 14, 2016. Resolution sent a chemist to audit the laboratory on December 15, 2016. Details on the laboratory audit can be found in Section 4.2.

During the ME 45 piezometer sampling, several piezometers were found to have little to no recharge. These occurrences are consistent with previous monitoring events since the inception of the LTM program and reflect the very limited discharge of groundwater around the landfill shoreline. Multiple attempts were made to increase productivity in these piezometers, including removing the piezometers and cleaning the screens at location P09-05A, and installing additional new piezometers at locations P09-02, P09-03A, and P09-05A. Low recharge piezometers were also visited over multiple days to try and fill the required sample volume. Despite these efforts, the full sample set was unable to be collected at several piezometer locations during ME 45. Location P09-05A experienced zero recharge over several days and no groundwater samples were collected at this location. Locations P09-02A, P09-03A, P09-07B, and P09-08B experienced low recharge. As a result, pesticides/PCBs at P09-02A, SVOC/PAHs and total and dissolved metals at P09-03A,

SVOC/PAHs, dissolved metals, and salinity at P09-07B, and salinity at P09-08B were unable to be collected during ME 45.

During the Fall 2013 ME 42 sampling event, sediment samples were collected from seven locations (SED09-01, SED09-02A, SED09-03A, SED09-04A, SED09-05A, SED09-09, SED09-10, and SED09-11B) at a target depth of 24-36 inches bgs as specified in the Final Quality Assurance Project Plan for Long Term Monitoring of Site 09 (EA, 2001) and not from 0-6 inches bgs as had subsequently been agreed to by the BCT. Samples were not re-collected for this event. Therefore, the ME 42 sediment samples are not included in historic sediment data comparisons, statistical analyses, and trend plots. They are included in the human health risk assessment update however. Sediment samples in Monitoring Events 43 through 45 were collected from 0-6 inches bgs.

3.0 SUMMARY OF LONG TERM MONITORING RESULTS

This section presents and discusses the hydrogeology and analytical results for ME 45.

A number of figures were prepared for this report using data collected during ME 45. Data figures presented in this report include:

- Tag Maps of all positively identified VOCs, SVOCs, PAHs, Pesticides, PCBs, and Metals for all sampled media.
- Spatial Analysis Maps for trichloroethene (TCE), vinyl chloride (VC), cis-1,2-dichloroethene (cis-1,2-DCE), and trans-1,2-dichloroethene (trans-1,2-DCE) in the Shallow and Deep flow zones.
- Updated Isoconcentration Figures for TCE, cis-1,2-DCE, trans-1,2-DCE, and VC along Groundwater Cross-Sections A-A', B-B', C-C' and D-D'.
- Trend data figures presenting the Mann Kendall trend analysis results for TCE, cis-1,2-DCE, trans-1,2-DCE, VC, other VOCs, benzene/toluene/ethylbenzene/xylene (BTEX), and metals in the Shallow and Deep flow zones.

3.1 Hydrogeology

This section provides a summary of the hydrogeological interpretations based on the groundwater level measurements collected during ME 45. Three rounds of synoptic water level measurements were recorded on September 20, 2016 in 27 monitoring wells and the Allen Harbor Staff Gauge. Gauging rounds were conducted during high, outgoing mid, and low tides. Groundwater elevations were calculated based on the most current annual settlement survey results, as appropriate; by adjusting top-of-riser elevations to reflect the October 2016 landfill settlement survey. Each round of groundwater measurements were recorded within 45 minutes to minimize the transient effects tide has on groundwater levels and flow. Groundwater potentiometric contours were created for the shallow/intermediate overburden and deep overburden flow zones for each round of synoptic water level data. The contours were created using a kriging algorithm in Surfer® 9 modeling software. The potentiometric contour maps are presented for each flow zone as Figures 5 and 6 (low tide), 8 and 9 (outgoing mid tide), and 11 and 12 (high tide).

The synoptic water level data was also used to show vertical groundwater flow along Transect B-B' which extends approximately east to west across Allen Harbor Landfill. The location of this transect is presented on Figure 4, and the cross section with the groundwater contours is presented on Figures 7, 10, and 13 for low, outgoing mid, and high tide conditions respectively. The cross

section incorporates all vertical depth intervals (i.e., shallow overburden, deep overburden, bedrock) to produce vertical head distributions. A summary of vertical hydraulic gradients for all data to present is provided in Table 3.

The following sections describe groundwater flow at Site 09.

Shallow / Intermediate Overburden

During outgoing mid tide conditions, consistent with previous monitoring events, groundwater flow across the Site in the shallow/intermediate zone during ME 45 was generally southeasterly from the bike path in the northern portions of the site, becoming more easterly approaching the Allen Harbor shoreline. Components of southerly flow can be seen in the southern end of the landfill near wells MW09-05S and MW09-21S, and a small north-easterly flow component is found on the northern tip of the site near well MW09-25S. A localized high point at MW09-17I causes southeastern, eastern, and northeastern radial flow components in the east center portion of the landfill. The outgoing mid tide shallow/intermediate overburden potentiometric map is presented as Figure 8.

Low tide conditions at the landfill mirror the outgoing mid tide conditions with some minor changes due to tidal influence. Flow in the northern portion of the site remains generally southeasterly from the bike path with a minor north-easterly component near the shoreline. Along the majority of the landfill edge in the central and southern portions of the site, shallow/intermediate groundwater discharges to Allen Harbor nearly parallel to the stone revetment/landfill boundary. Due to a localized low point at MW09-27S a west/northwesterly flow component is seen in the west central portion of the site. The low tide shallow/intermediate overburden potentiometric map is presented as Figure 5.

At high tide, the groundwater flow conditions mirror conditions observed during outgoing mid tide. A localized high at MW09-17I causes radial flow to the northeast, east, and south east, the northern portion of the site experiences general southeasterly flow with a northeasterly flow component near MW09-25S, and the southern portion of the site shows general southeasterly flow towards Allen Harbor. The high tide shallow/intermediate overburden potentiometric map is presented as Figure 11.

Deep Overburden

In general, groundwater flow in the deep zone during ME 45 was similar to that in the shallow/intermediate zone at each tidal stage. All three tidal stages show southeasterly groundwater flow in the northern half of the landfill. During outgoing mid tide, southeasterly flow is

seen across the whole site in the deep overburden zone. A high point at MW09-23D causes additional minor flow paths to the south and east in the central portion of the site. At low tide, groundwater discharges to Allen Harbor nearly parallel to the stone revetment/landfill boundary along the central and southern portions of the site, with a northwest/west flow component created by a localized low point at MW09-27D. During high tide a mounding effect is seen through the central portion of the site, causing radial flow to the east, west, and south from the center of the landfill. Deep overburden maps for low, mid and high tide can be found in Figures 6, 9, and 12 respectively.

Cross Section – Vertical Flow

During outgoing mid tide, a gently sloping downward gradient is observed from the bike path to Allen Harbor in cross section B-B'. At low tide, flow is more horizontal in the western portion of the site, with a steeper downward flow component in the middle and eastern portions of the site. High tide shows upward gradients discharging to Allen Harbor on the far east end of the transect. These flow conditions are consistent with previous monitoring events. Cross section B-B' vertical flow is presented as Figure 7 (low tide), Figure 10 (mid tide) and Figure 13 (high tide).

Long-Term Groundwater Trends

A detailed analysis of long term groundwater flow conditions and vertical gradients from ME 01 through ME 40 can be found in the Site 09 LTM and Optimization Recommendations Report (Tetra Tech, 2015). No significant changes in the overall groundwater flow conditions were observed during the past five monitoring events. The hydrogeology data show that flow conditions at Site 09 are stable and consistent with previous reporting.

A summary of vertical hydraulic gradients in several well pairs across the site, updated with outgoing mid–tide synoptic water level data through ME 45, is provided in Table 3. An evaluation of long term trends in the vertical hydraulic gradient data through ME 40 can be found in the Site 09 LTM and Optimization Recommendations Report (Tetra Tech, 2015). No significant changes in vertical gradients or site-wide groundwater trends have been observed since ME 40.

3.2 Analytical Results of Monitoring Data

Data validation memoranda are provided in Attachment B. Plots depicting concentration trends are presented in Attachment F for all locations sampled during ME 45, any analyte, in all media, with at least two results. Also included in Attachment F are FOD tables and Mann Kendall trend analyses for all data to date. Mann Kendall trend analyses were performed for all media, all locations sampled during ME 45, and all detected analytes where there were at least 4 sampling rounds and

3 rounds in which concentrations were detected. Attachment E contains Summary Tables for all analytes detected since ME 01. As mentioned in Section 2.2, the ME 42 sediment samples are not included in historic sediment data comparisons, statistical analyses, and trend plots since these samples were not collected as surface sediment samples.

3.2.1 Monitoring Well Sampling Results

The project action limits (PALs) for groundwater samples collected from monitoring wells are the federal Maximum Contaminant Levels (MCLs), unless the Rhode Island Department of Environmental Management (RIDEM) GA groundwater quality objectives are more stringent. The PALs for groundwater are listed in Worksheet 15 of the Draft Tier II LTM SAP (Resolution, 2016b). Table 8 provides analytical results for groundwater samples collected from monitoring wells during ME 45 compared against the PALs for groundwater. Groundwater analytical data (detected results, with exceedances of PALs identified in red) are also presented on Figures 14 through 18.

This section discusses compounds detected in groundwater samples at concentrations exceeding the PALs established in the Draft Tier II LTM SAP (Resolution, 2016b). For select compounds without PALs, a brief discussion of detections in groundwater is also included. The discussion is presented according to analytical group (e.g., VOCs, metals, etc.). Groundwater sample locations are shown on Figure 2. Attachment E provides summary tables of all groundwater analytes, including contaminants detected and non-detected compounds and associated PALs for comparison from ME 01 to ME 45.

Volatile Organic Compounds in Groundwater Monitoring Wells

The principal VOCs that have been detected in groundwater at concentrations greater than PALs include chlorinated VOCs (CVOCs) and benzene. The primary CVOCs include the parent compound TCE and its daughter products cis-1,2-DCE and VC, and other CVOCs 1,1-DCE, trans-1,2-Dichloroethene (trans-1,2-DCE) and 1,1,2-Trichloroethane. Other CVOCs and non-CVOCs detected at concentrations exceeding PALs are also discussed in this section.

Trichloroethene. Since ME 41, TCE has been detected at concentrations exceeding the PAL of 5 µg/L in MW09-20I, MW09-21D, and MW09-03D. TCE was detected above the PAL in MW09-14IA during ME 44, but was not detected during ME 41, ME 42, ME 43, and ME 45. TCE has also been detected at MW09-08DA, MW09-09DA, MW09-14D, MW09-20D, MW09-24D, and MW09-25S but at concentrations less than the PAL, with no observable trends.

MW-09-20I has shown increasing TCE concentrations since ME 42, increasing from 140,000 ug/L during ME 42 to 490,000 µg/L during ME 45. These concentrations, while increasing, are still below

the historical high of 1,200,000 µg/L during March 2009 (ME 28). The ME 42 TCE concentration was a historic low and a decrease from the ME 41 concentration of 430,000 ug/L. Based on these concentrations, it is possible that dense non-aqueous-phase liquid (DNAPL) is present at or near this location. The Mann Kendall trend analysis indicates an overall downward trend in TCE concentrations at this location since ME 01.

For the two other wells where TCE exceeds the PAL (MW09-21D and MW09-03D), the TCE concentrations are significantly less than those at MW09-20I. At MW09-21D, TCE concentrations since ME 41 have ranged from 47 to 110 µg/L, well below the historic high concentration of 500 ug/L (ME 01) and below the average concentration of 162 ug/L. The Mann Kendall trend analysis also indicates an overall downward trend at this location. At MW09-03D, TCE concentrations have historically (since ME 01) been near the PAL, with a maximum concentration of 7.3 µg/L and an average concentration of 5.5 ug/L. Since ME 41, concentrations have barely exceeded the PAL, ranging from 0.82 to 6.3 ug/L. The Mann Kendall trend analysis also indicates an overall downward trend at this location.

Figures 57 and 58 present a spatial analysis of TCE during ME 45. For simplicity, only the PAL concentration contour is provided (i.e., the figure is not an isoconcentration map). Additionally, maximum spatial extent is assumed via linear interpolation. As observed on Figure 57, because TCE was detected only at MW09-20I, the overall extent of TCE in the shallow zone remains unchanged since observations made in the Site 09 LTM and Optimization Recommendations Report (Tetra Tech, 2015). Figure 58 presents TCE in the deep zone and, similar to the shallow zone, the extent of TCE is essentially unchanged in the vicinity of MW09-03D and MW09-21D since the last plume analysis in the Site 09 LTM and Optimization Recommendations Report (Tetra Tech, 2015). Overall, based on Figures 57 and 58, there is no evidence of spatially extensive TCE plumes in either groundwater zone at the Site. TCE is not shown to extend into Allen Harbor because there are no data to confirm its presence offshore, although it is likely that TCE may occur at depth offshore (see below).

Further spatial analysis of TCE is provided on Figures 41, 45, 49, and 53, which present ME 45 TCE isoconcentrations along cross-sections A-A', B-B', C-C', and D-D', respectively. Figures 41 and 45 present TCE isoconcentrations along cross-sections A-A' and B-B' (parallel to groundwater flow, from onshore to offshore), respectively. Because TCE has exceeded the PAL only at MW09-20I and MW09-21D, the overall size and shape of the TCE extent appear relatively consistent with previous monitoring events. Based on the isoconcentrations presented in Figure 45 and flow nets presented on Figures 7, 10, and 13, it is possible that TCE may occur at depth beyond the breakwater structure (shown in cross-section B-B'). This observation is consistent with previous monitoring

events. Figures 49 and 53 present TCE isoconcentrations along cross-sections C-C' and D-D', respectively. Consistent with previous events, only limited areas of TCE are interpolated around wells MW09-03D and MW09-24D (Figure 49), and MW09-21D, MW09-14IA, and MW09-25S (Figure 53).

Overall, the size, shape, and concentration profile of the TCE extent remain stable and are consistent with those in the Site 09 LTM and Optimization Recommendations Report (Tetra Tech, 2015).

Vinyl Chloride. VC has been frequently detected at concentrations greater than the PAL of 2 µg/L at the following wells: shallow wells MW09-08S, and MW09-09S, intermediate wells MW09-20I and MW09-14IA, and deep wells MW09-03D, MW09-08DA, MW09-09DA, and MW09-21D.

At MW09-08S, VC concentrations have exceeded the PAL but have been decreasing since the ME 41 concentration of 10 µg/L. The Mann Kendall trend analysis also indicates an overall downward trend at this location.

At MW09-09S, VC concentrations have ranged from 1,100 to 450 ug/L since ME 41. The Mann Kendall trend analysis indicates an overall upward trend at this location. The lack of significant concentrations of TCE at this location over time suggests that TCE once present has been reduced to cis-1,2-DCE and VC. Although the overall trend for VC is upward, concentrations since ME 41 have been steadily decreasing, as have concentrations of cis-1,2-DCE. This suggests that overall CVOC mass at this location may have recently begun to slowly decrease over time.

At MW09-20I, VC concentrations have ranged between 14,000 and 4,500 µg/L since ME 41. The Mann Kendall trend analysis indicates an overall upward trend at this location. The overall upward trend for VC coupled with the overall downward trend for TCE is indicative of anaerobic reductive dechlorination occurring at this location.

At MW09-14IA, the VC PAL was exceeded during ME 41 (11 ug/L), ME 43 (16 ug/L) and ME 45 (3.4 J ug/L), however, these concentrations are much lower than concentrations previously observed and the Mann Kendall trend analysis indicates an overall downward trend.

At MW09-03D, VC concentrations have ranged from 2.2 to 21 µg/L since ME 41. The Mann Kendall trend analysis indicates an overall downward trend at this location.

At MW09-08DA, VC was only detected above its PAL during ME 42 at a concentration of 27 ug/L. VC was either nondetect or detected below its PAL during the other MEs since ME 41. The Mann Kendall trend analysis indicates there is no overall trend at this location.

At MW09-09DA, VC was detected above the PAL during ME 42 (4.1 ug/L), ME 43 (4.6 ug/L), and ME 44 (2.9 ug/L). VC was not detected during ME 45. The Mann Kendall trend analysis indicates there is no overall trend at this location.

At MW09-21D, VC has been consistently detected in excess of the PAL, at concentrations ranging from 73 to 140 µg/L since ME 41. Consistent with previous monitoring events, the Mann Kendall trend analysis indicates an overall upward trend at this location. Similar to location MW09-20I, the overall upward trend for VC coupled with the overall downward trend for TCE is indicative of anaerobic reductive dechlorination occurring at this location.

At MW09-20D, VC was detected above the PAL during ME 41 (2.4 J ug/L). Concentrations during ME 42 through ME 44 ranged from 1.1 to 1.4 ug/L and the VC result during ME 45 was rejected during data validation. These concentrations are consistent with previous results and the Mann Kendall trend analysis indicates no overall trend at this location.

Figures 57 and 58 present a spatial analysis of VC during ME 45. For simplicity, only the PAL concentration contour is provided (i.e., the figure is not an isoconcentration map). Additionally, maximum spatial extent is assumed (i.e., linear distribution of concentrations are assumed). As observed on Figure 57, the overall extent of VC in the shallow and intermediate zones has remained essentially unchanged since observations made in the Site 09 LTM and Optimization Recommendations Report (Tetra Tech, 2015). VC is detected in monitoring wells MW09-08S, MW09-20I, and MW09-09S along the southeastern perimeter of the landfill. An isolated detection at MW09-14IA (3.4 ug/L) also creates a small plume in the center of the landfill. For the deep groundwater zone shown on Figure 58, the overall extent of VC is shown to mirror TCE (described above) with small plumes around MW09-03D and MW09-21D. The extent of VC in these two small plumes is essentially unchanged since observations made in the Site 09 LTM and Optimization Recommendations Report (Tetra Tech, 2015).

Further spatial analysis of VC is provided on Figures 42, 46, 50, and 54 which presents isoconcentrations along cross sections A-A', B-B', C-C', and D-D', respectively, during ME 45. Overall, plumes shown on these figures are consistent with historical figures. Along cross sections A-A' and B-B' (Figures 42 and 46), the plume is centered on high concentrations at MW09-20I. Cross sections B-B' and C-C' (Figures 46 and 50) also show a small plume centered on the detection of 21 ug/L at MW09-03D. Along cross section D-D' (Figure 54) a plume is shown originating from the detection of 73 ug/L at MW09-21D.

Similar to TCE, the overall, the size, shape, and concentration profile of the VC extent remain stable and are consistent with those in the Site 09 LTM and Optimization Recommendations Report (Tetra Tech, 2015).

cis-1,2-Dichloroethene. Since ME 41, cis-1,2-DCE has been detected at concentrations exceeding the PAL of 70 µg/L in five monitoring wells: MW09-20I, MW09-21D, MW09-03D, MW09-08DA, and MW09-09S.

At MW09-20I, cis-1,2-DCE concentrations ranged between 22,000 (ME 45) to 53,000 µg/L (ME 42) since ME 41. The Mann Kendall trend analysis indicates no overall trend at this location. The concentrations observed since ME 41 are consistent with the average concentration of 41,800 ug/L and well below the historic high of 150,000 ug/L (ME 36). The overall consistent concentrations in this well (i.e., no trend) coupled with overall downward trends for TCE and overall upward trends for VC indicate that anaerobic reductive dechlorination is occurring in this well.

At MW09-09S, concentrations of cis-1,2-DCE since ME 41 have ranged from 1,300 to 470 ug/L. The Mann Kendall trend analysis indicates an overall upward trend at this location. The lack of significant concentrations of TCE at this location over time suggests that TCE once present has been reduced to cis-1,2-DCE and VC. Although the overall trend for cis-1,2-DCE is upward, concentrations since ME 41 have been steadily decreasing, as have concentrations of VC. This suggests that overall CVOC mass at this location may have recently begun to slowly decrease over time.

At MW09-03D, cis-1,2-DCE concentrations have mostly been around the PAL of 70 ug/L since ME 41, with concentrations ranging between 65 ug/L to 80 ug/L. There was also one anomalous result of 7.7 ug/L during ME 44. The Mann Kendall trend analysis indicates an overall downward trend at this location. TCE and VC also have overall downward trends at this location indicating that anaerobic reductive dechlorination is occurring and the overall CVOC mass is decreasing at this location.

At MW09-21D, cis-1,2-DCE concentrations have ranged from 290 ug/L to 420 ug/L since ME 41. The Mann Kendall trend analysis indicates an overall downward trend is occurring at this location. TCE (downward trend) and VC (upward trend) are also present in this well indicating that anaerobic reductive dechlorination is occurring.

At MW09-08DA cis-1,2-DCE concentrations have mostly been detected below the PAL since ME 41 with concentrations ranging from nondetect (1.0 U) to 2.4 ug/L. However, there was one anomalous result above the PAL at 84 ug/L during ME 42. The Mann Kendall trend analysis

indicates no trend at this location. The ME 42 result of 84 ug/L appears to be truly an anomaly, as the average concentration prior to ME 42 was 2.2 ug/L and the concentrations after ME 42 were consistent with that average. However, with the ME 42 result included, the historic average is now 7.6 ug/L.

Cis-1,2-DCE has also been detected in wells MW09-08S, MW09-09DA, MW09-14IA and MW09-27D since ME 41, but below the PAL. The Mann Kendall trend analysis indicates overall downward or no trend at these locations.

Spatial analysis of cis-1,2-DCE in the shallow and deep groundwater during ME 45 is provided in Figures 59 and 60. Similar to the TCE and VC plume figures, only the PAL concentration contour is provided on these figures. Cis-1,2-DCE concentrations exceeding the PAL of 70 µg/L were detected in groundwater samples collected from two shallow/intermediate wells (MW09-09S and MW09-20I) and two deep wells (MW09-21D, and MW07-03D) during ME 45. Consistent with previous monitoring events, the plume remains stable with one lobe in the shallow groundwater zone around MW09-20I and MW09-09S, and two lobes in the deep groundwater zone around MW09-21D and MW09-03D. Cis-1,2,-DCE isoconcentrations during ME 45 are also presented on cross-sections A-A', B-B', C-C', and D-D' in Figures 43, 47, 51, and 55. The plumes presented in these cross section figures are consistent with previous monitoring events.

trans-1,2-Dichloroethene. Since ME 41, trans-1,2-DCE has been consistently detected at concentrations exceeding the PAL of 100 µg/L in well MW09-20I only. This is consistent with all previous MEs. Concentrations ranged from 13,000 to 21,000 ug/L. These concentrations are well below the historic high of 140,000 ug/L (ME 36) and slightly less than the historic average of 21,200 ug/L. The Mann Kendall trend analysis indicates no significant trend at this location.

Spatial analysis of trans-1,2-DCE in the shallow and deep groundwater units is provided along with cis-1,2-DCE in Figure 59 but not Figure 60 since trans-1,2-DCE was not detected above the PAL in in the deep zone during ME 45. Consistent with previous monitoring events, the plume remains stable with one lobe in the shallow groundwater zone around MW09-20I. Trans-1,2,-DCE isoconcentrations during ME 45 are presented on cross-sections A-A', B-B', C-C', and D-D' in Figures 44, 48, 52, and 56. The plumes presented in these cross sections are consistent to previous monitoring events.

Benzene. The aromatic hydrocarbon, benzene, while present within various zones, is primarily in the shallow/intermediate groundwater zone. Since ME 41 the PAL for benzene (5 µg/L) has been consistently exceeded in shallow monitoring wells MW09-21S and MW09-25S. Shallow wells MW09-07S and MW09-09S exceeded the PAL in all MEs since ME 41 with the exception of ME 45, when

the benzene was nondetect for both wells. For well MW09-09S, the nondetect reporting limit (10 ug/L) was elevated due to dilution during ME 45. Benzene also exceeded the PAL in MW09-11S during ME 44 for the second time since the inception of the LTM program. The Mann Kendall trend analysis indicates overall downward trends for MW09-07S and MW09-21S and no trend for MW09-25S. An overall upward trend is indicated in MW09-09S although concentrations since the inception of the LTM program have only ranged from 4.3 to 11 ug/L. Benzene concentrations have also exceeded the PAL in intermediate wells MW09-14IA (ranging from 25 to 34 µg/L), MW09-17I (ranging from 15 to 18 µg/L), and MW09-20I (ranging from 5.5 to 7.3 ug/L). Overall downward trends were observed at MW09-14IA and MW09-17I, and no trend was observed at MW09-20I.

At deep well, MW09-09DA, benzene slightly exceeded the PAL during ME 45 with a concentration of 5.7 ug/L. At shallow well MW09-11S the benzene concentration slightly exceeded the PAL during ME 44 (7.0 ug/L). The Mann Kendall trend analysis indicates no trend for either well.

At wells MW09-08S, MW09-10S, MW09-11S, MW09-14D, MW09-21D and MW09-24D, benzene has also been frequently detected, although concentrations have not exceeded the PAL and typically range from 1 to 3 µg/L. Overall decreasing concentration trends were observed at MW09-08S, MW09-21D and MW09-24D. No trends were observed for MW09-10S, MW09-11S, and MW09-14D.

Other VOCs. The following compounds were detected above the PAL at MW09-20I: 1,1,2-trichloroethane (PAL: 5 ug/L) and 1,1-dichloroethene (PAL: 7 ug/L) during ME 41 through ME 45; tetrachloroethene (PAL: 5 ug/L) during ME 41, ME 42, and ME 45; 1,2-dichloroethane (PAL: 5 ug/L) and methylene chloride (PAL: 5 ug/L) during ME 43 and ME 45. These occurrences are consistent with previous MEs, and the detected results during ME 41 through ME 45 were generally lower than the historic averages.

Chlorobenzene was detected above the PAL of 100 ug/L in MW09-11S (170 ug/L) during ME 44. Chlorobenzene has been periodically detected above the PAL during previous MEs and the Mann Kendall trend analysis indicates an overall downward trend.

PAHs. Benzo(a)pyrene was detected above the PAL of 0.2 ug/L in MW09-09S (0.21 ug/L) and MW09-20I (0.43 ug/L) during ME 45 for the first time since the inception of the LTM program. However, these concentrations were just slightly above the PAL.

Metals in Groundwater Monitoring Wells

Arsenic is the only metal which has been detected consistently above the PAL since ME 41. Arsenic has been consistently above the PAL of 10 µg/L at monitoring wells MW09-07S, MW09-10S, MW09-

14IA, MW09-23S, and MW09-24D. Consistent detections under the PAL have also occurred at wells MW09-08DA, MW09-08S, MW09-09DA, MW09-20D, MW09-20I, and MW09-24S. Results of the Mann Kendall trend analysis indicate overall upward trends at MW09-14IA, MW09-20D and MW09-24D, and overall downward trends at MW09-07S and MW09-20I. No trends were indicated at MW09-08DA, MW09-08S, MW09-09DA, MW09-10S, MW09-23S, and MW09-24S.

Several other metals have been detected consistently during ME 41 through ME 45, but either the concentrations have been below the PAL or no PAL is established.

3.2.2 Piezometer Sampling Results

This section discusses the analytes that exceeded PALs in piezometer samples during ME 45 along with comparison to results since ME 42 (piezometers were not sampled during ME 41) and overall trends. Piezometer samples were collected from 12 locations during ME 45 as shown on Figure 2. Sample locations and analyses along with sample rationale are presented on Table 1. Section 2.2 of this report details deviations from the planned sampling presented in Table 1.

The sampling results discussion below is organized according to analyte group (e.g., VOCs, metals, etc.). The PALs for piezometers are listed in Worksheet 15 of the Draft Tier II LTM SAP (Resolution, 2016b). Piezometer analytical results are presented on Table 9 and Figures 19 through 23. Attachment E provides summary tables of all analytes, including detected and non-detected results, and associated PALs for comparison from ME 01 to ME 45.

Volatile Organic Compounds in Piezometers

There are no PALs for VOCs in piezometers. The primary VOCs of concern at Site 09 are TCE and its daughter products (cis-1,2-DCE, trans-1,2-DCE, and VC) and benzene. Benzene and VC have been detected once each since ME 42; during ME 42 at P09-10 at concentrations of 1.3 ug/L and 1.1 ug/L, respectively. There have not been any other detections of TCE, its daughter products, or benzene in piezometers since ME 42.

Metals in Piezometers

Since ME 42, arsenic copper, nickel, mercury, lead, chromium, and zinc have been detected in piezometer samples at concentrations exceeding PALs.

Arsenic. Since ME 42, total arsenic has been detected above the PAL of 36 ug/L one or more times in P09-01, P09-07B, P09-08B, P09-09, P09-10, and P09-12B. The Mann Kendall trend analysis indicates overall upward trends at locations P09-01, P09-09, and P09-10, an overall downward

trend at P09-12B, and no trend at P09-07B and P09-08B. For all these locations, the turbidity is high during sampling due to the poor production of groundwater (i.e., samples are not able to collected via low flow). In addition, the dissolved concentrations of arsenic at these locations are much lower; the only dissolved arsenic concentration above the PAL was at P09-07B during ME 44 at a concentration of 37.6 ug/L, just above the PAL. Therefore, the elevated arsenic results appear to be related to the suspended solids present in the samples and not from impacts to groundwater beneath the landfill. Furthermore, total arsenic concentrations in landfill groundwater samples are much lower than those of the piezometers.

Copper. Since ME 42, copper has been detected above the PAL of 2.9 µg/L one or more times in P09-01, P09-02A, P09-03A, P09-04A, P09-06B, P09-07B, P09-08B, P09-09, P09-10, and P09-12B. The Mann Kendall trend analysis indicates an overall upward trend at P09-09, overall downward trend at P09-06B and P09-12B, and no trend at P09-01, P09-02A, P09-03A, P09-04A, P09-07B, P09-08B, P09-10. Similar to arsenic, the elevated copper results appear to be related to suspended solids in the samples, as the dissolved concentrations are much lower. In addition, copper concentrations in landfill groundwater are largely nondetect or low.

Nickel. Since ME 42, nickel has been detected above the PAL of 8.3 µg/L in all piezometers during all the MEs. This is consistent with previous MEs, nickel is almost always detected above the PAL. The Mann Kendall trend analysis indicated an overall upward trend at P09-09, and no trend at all the other locations. Similar to arsenic and copper, the elevated nickel results appear to be related to suspended solids in the samples, as the dissolved concentrations are much lower. The landfill groundwater nickel concentrations are also largely nondetect or low and beneath the PAL.

Mercury. Since ME 42, mercury has been detected above the PAL of 0.08 µg/L at least one time in P09-01, P09-02A, P09-06A, P09-07B, P09-09, P09-10, and P09-12. The Mann Kendall trend analysis indicates no trend at these locations. As with the other metals, dissolved concentrations are much lower. The landfill groundwater mercury results since ME42 are almost all nondetect and all detected results were below the PAL.

Lead. Since ME 42, lead has been detected above the PAL of 8.1 µg/L at least one time in P09-01, P09-02A, P09-04A, P09-06B, P09-07B, P09-08B, P09-09, P09-10, and P09-12B. The Mann Kendall trend analysis indicates an overall upward trend at P09-08 and P09-09 and no trend at the other locations. As with the other metals, dissolved concentrations are much lower. The landfill groundwater lead concentrations since ME42 are also largely nondetect or low and below the PAL.

Chromium. Since ME 42, chromium has been detected above the PAL of 50 µg/L at least one time in all piezometers, with chromium exceeding the PAL in almost all results since ME 42. The Mann

Kendall trend analysis indicates overall upward trends at P009-09 and P09-10 and no trend at the other locations. As with the other metals, the dissolved concentrations are much lower. The landfill groundwater chromium concentrations since ME42 are also largely nondetect or low and below the PAL.

Zinc. Since ME 42, zinc has been detected above the PAL of 81 µg/L at least one time in all piezometers. The Mann Kendall trend analysis indicates overall upward trends at P09-08 and P09-09, an overall downward trend at P09-12, and no trend at the other locations. As with the other metals, dissolved concentrations are much lower. Zinc is detected in landfill groundwater more frequently that the other metals discussed, however the concentrations are significantly lower than those observed in the piezometers.

Other Parameters Detected in Piezometers

Besides the metals listed above, there have been no PAL exceedances since ME 42 and the vast majority of VOC, SVOC, PAH, pesticide, and PCB results have been nondetect.

3.2.3 Surface Water Seep Results

During ME 45, surface water seeps were collected from the southeastern side of the landfill where erosion channels have formed in the created wetland due to the flow of surface water from the revetment wall during receding tide. Two of the seep samples are adjacent to piezometers P09-07 and P09-08, respectively; the third is in the area south of the MW09-08 well cluster. The seep samples were collected during ebb (i.e., receding) tide when flow through the seep channels was at its low point but still high enough to collect a sample. Seep samples were submitted for VOCs, sulfide, and salinity analysis. The VOCs and sulfide results were all nondetect, which is consistent with previous MEs. The salinity results indicate that the seeps are largely seawater.

3.2.4 Sediment Sampling Results

During ME 45, twelve locations were sampled for VOCs, PAHs, and metals, four locations were sampled for pesticides/PCBs, and five locations were sampled for sulfide as shown on Table 1 and Figure 2. A total of 3 VOCs, 17 PAHs, 11 metals, 1 PCB, and 3 pesticides were detected. No detections exceeded their PAL values. The PALs for sediment samples are the Effects Range, Median (ERM), September 1999, unless otherwise noted, as specified in Worksheet 15 of the Draft Tier II LTM SAP. Table 10 provides analytical results for sediment samples collected during ME 45. Analytical data from sediment samples (detected results) are also presented on Figures 24 through 28.

Man Kendall trend tests were performed on shallow sediment data only (i.e., only on the data for the sediment samples collected from 0-6 inches bgs). All results were either not significant or downward trending.

3.2.5 Shellfish Sampling Results

During ME 45, shellfish samples were collected from 10 locations as shown on Figure 2. All shellfish tissue samples were analyzed for metals, SVOCs/PAHs, pesticides, PCB homologs, and total lipids during ME 45. Sample locations and analyses along with sample rationale are presented on Table 1. There are no PALs established for the shellfish tissue samples. Table 11a provides the wet weight shellfish sampling results. Table 11b provides the lipid-normalized shellfish sampling results for the hydrophobic organic analyses. Metals results were not lipid-normalized and not included in Table 11b. Analytical data from shellfish tissue samples (detected results) are also presented on Figures 29 through 31. Metals and PCB homologs were detected in shellfish samples from all 10 locations. PAHs were only detected in shellfish samples ET09-03, ET09-04, and ET09-07. No pesticides were detected in the shellfish samples. A total of 6 PAHs, 18 metals, and 7 PCB homologs were detected in one or more shellfish sample. ME 45 was the tenth shellfish tissue sampling round conducted since the inception of the LTM.

Comparison of Shellfish Data to Historical Results

Shellfish samples have been collected at locations ET09-03 through ET09-08 to evaluate potential impacts of site-related contamination on the shellfish along the landfill shoreline since December 2007, after sufficient quantities and sizes of shellfish were established. Shellfish sampling was conducted at locations ET09-07 and ET09-08 in 2010; however, insufficient size and quantity shellfish were found at these locations in subsequent attempts. Shellfish of sufficient size and quantity were found in 2015 (ME 44) and 2016 (ME 45) at these two locations and were subsequently sampled. Sampling at ET09-09 through ET09-12 began in 2012 as these samples were positioned beyond the breakwater structure to further evaluate potential off-shore contaminant migration to Allen Harbor.

Reference samples ET09-01 and ET09-02 were collected from 2007 through 2011 from the Fishing Cove in Wickford, Rhode Island and from the shoreline of Prudence Island in Narragansett Bay to evaluate the anthropogenic background levels of contamination present in similar marshy areas within or adjacent to Narragansett Bay.

Results presented in the Third Five-Year Review indicated that for samples collected during 2007 through 2011, SVOCs, pesticides, and metals were present in ribbed mussels at concentrations

generally comparable to the two reference stations. Concentrations of PAHs and PCBs exceeded the levels detected in reference samples, most notably in ET09-03 and ET09-06. The 2011 samples reported concentrations of PAHs similar to reference concentrations; however, PCB concentrations were greater than reference sample concentrations (Tetra Tech, 2013). A comparison of the 2007 through 2011 PAH and PCB shellfish data to shellfish data to that of the pre-remedy marine ERA revealed that concentrations in the 2007 through 2011 shellfish were generally lower than pre-remedy concentrations.

Shellfish sample results collected from 2013 through 2016 are presented in Table 11c. No PALs have been established for shellfish tissue samples collected at Site 09; therefore, the shellfish tissue results were compared to the results from the two reference samples collected in 2007 through 2011. The maximum detected concentration or maximum reporting limit in the case of nondetect results is provided for comparison. Results of this comparison are provided in Table 11d.

For metals, PCB homologs, pesticides, and PAHs, samples from Site 09 had one or more detected concentrations greater than the maximum reference sample concentration. Therefore, metals, PCBs homologs, and PAHs were subject to additional evaluation below. No SVOCs were reported with detected concentrations greater than the maximum reference samples and the majority of the nondetect reporting limits were similar or below those of the reference samples. Therefore, SVOCs were eliminated from further evaluation. For pesticides, trans-chlordane was detected in four shellfish samples in 2013 at concentrations slightly greater than the maximum reference concentration at locations ET09-03, ET09-04, ET09-06, and ET09-11. Since the trans-chlordane detections were mostly limited to samples collected in 2013 and no subsequent concentrations were reported over the maximum reference concentration, trans-chlordane was eliminated from further evaluation. The remaining pesticide results were at concentrations below those of the reference samples or nondetect with reporting limits similar to those of the reference samples. Therefore, pesticides as a whole were eliminated from further evaluation and only metals, PCB homologs, and PAHs were subject to additional evaluation.

The 1996 Marine Ecological Risk Assessment (ERA) (EA, 1996) reported percent lipid and contaminant concentrations in shellfish samples collected at locations AHW1RMND, AHW2RMND, AHW3RMND, and AHW6RMND which correspond to current LTM locations ET09-03, ET09-04, ET09-05, and ET09-06, respectively.

Lipophilic contaminants accumulate in proportion to tissue lipids. Lipid content may vary based on seasonality as an organisms fat reserves change based on migration, hibernation, or reproduction. Lipid content also varies between species. Lipid normalization is a standard practice for many

organic contaminants and is intended to reduce observed variability in tissue contaminant concentrations. Concentrations of organic contaminants are normalized to percentages of tissue lipids to account for differences in the lipid content between species and sites, which is known to affect the partitioning and accumulation of organic constituents. Percent lipids were reported for ribbed mussel samples in Table A1-2.6 of the 1996 ERA. Total PCBs were reported for ribbed mussel samples in Table A1-2.1D of the 1996 ERA. Low- and high-molecular weight and total PAH concentrations for ribbed mussels were reported in Table A1-2.2D of the 1996 ERA. The 1996 ERA shellfish samples from locations AHW1RMND, AHW2RMND, AHW3RMND, and AHW6RMND were compared to 2013 through 2016 ribbed mussel and quahog samples from locations ET09-03, ET09-04, ET09-05, and ET09-06 in Table 11e. Comparisons were made for the mean, minimum, and maximum with both non-lipid normalized and lipid normalized data. The 1996 ERA metals shellfish data from locations AHW1RMND, AHW2RMND, AHW3RMND, and AHW6RMND located in Table A1-2.5D were also compared to the 2013 through 2016 shellfish data from locations ET09-03, ET09-04, ET09-05, and ET09-06 in Table 11e, however the metals data were not lipid normalized.

Lipid-normalized ratios were calculated for low- and high-molecular weight PAHs, total PAHs, and total PCBs using the following calculation:

Lipid-normalized concentration = laboratory reported result / percent lipids

The 2013 through 2016 PCBs and PAHs concentrations were generally significantly lower than the sample results reported in the ERA. Non-normalized concentrations of PCBs and PAHs were significantly lower than those reported in the ERA. The mean concentration of total PCBs in the 1996 ERA was 600 µg/kg with a maximum concentration of 1,267 µg/kg, while the 2013 through 2016 mean total PCB concentration was 10.23 µg/kg with a maximum concentration of 110 µg/kg. The mean total PAH concentration in the 1996 ERA was 3,772 µg/kg with a maximum concentration of 5,871 µg/kg, while the 2013 through 2016 mean total PAH concentration was 59.8 µg/kg with a maximum concentration of 260 µg/kg. The lipid-normalized PCB and PAH results display a similar trend with the 2013 through 2016 concentrations being much lower than the 1996 ERA concentrations. Though samples were collected from different species at some locations (i.e., quahogs were collected at some locations during 2013 through 2016), normalization to lipid content of the organism facilitates inter-species comparisons. The metals data, which were not normalized, displayed a similar trend with the 2013 through 2016 data being lower than the data from the 1996 ERA, although not to the extent of the PCBs and PAHs.

Shellfish data since the inception of the LTM program were evaluated to identify potential increasing or decreasing concentration trends on a location-by-location basis. Trend graphs for the contaminants are presented in Attachment F. Statistical analysis of the data was also performed

using the Mann Kendall trend analyses. A summary of the Mann Kendall trend analyses is also presented in Attachment F.

Though statistical analyses were performed on all datasets, the discussion herein is limited to contaminants reporting at least four detected values. Results are discussed on a location-by-location basis below.

ET09-03: statistically significant upward trends were reported for aluminum, arsenic, iron, and manganese. A statistically significant downward trend was reported for naphthalene.

ET09-04: statistically significant upward trends were reported for aluminum, arsenic, chromium, cobalt, copper, iron, magnesium, vanadium, zinc and anthracene. A statistically significant downward trend was reported for trichlorobiphenyl.

ET09-05: statistically significant upward trends were reported for aluminum, arsenic, calcium, copper, magnesium, and zinc. Statistically significant downward trends were reported for silver, heptachlorobiphenyl, hexachlorobiphenyl, pentachlorobiphenyl, tetrachlorobiphenyl, 2-methylnaphthalene, delta-BHC, phenanthrene, acenaphthene, fluoranthene, naphthalene, and pyrene.

ET09-06: statistically significant upward trends were reported for aluminum, arsenic, copper, and zinc. Statistically significant downward trends were reported for fluoranthene and naphthalene.

ET09-07: no statistically significant trends were reported.

ET09-08: no statistically significant trends were reported.

ET09-09: a statistically significant downward trend was reported for mercury.

ET09-10: no statistically significant trends were reported.

ET09-11: a statistically significant downward trend was reported for mercury.

ET09-12: a statistically significant downward trend was reported for potassium.

Overall, the trend analyses reported statistically significant upward trends for some metals including arsenic at ET09-03, ET09-04, ET09-05, and ET09-06 and for anthracene at ET09-04. Trends reported in the Site 09 LTM and Optimization Report included statistically significant upward trends for arsenic at ET09-01 through ET09-06, which includes reference locations ET09-01 and ET09-02 (Tetra Tech, 2015). This upward trend for reference and site samples suggests that concentrations

of arsenic in shellfish tissue may be related to background or other anthropogenic sources rather than site-related contamination.

The 2013 through 2016 shellfish samples had detected concentrations of metals, PCBs, and PAHs greater than the maximum concentrations reported in reference samples collected from 2007 through 2011. However, a comparison to pre-remedy data indicates that site concentrations are significantly lower than those collected from the same areas of the site in 1995, prior to the completion of the remedy. Statistically significant upward trends for some metals including arsenic occur at some shellfish sampling locations. However, comparison to the landfill groundwater data indicates that these are not site-related. In addition, Mann Kendall trend analysis performed on arsenic at reference locations ET09-01 and ET09-02 in the Site 09 LTM and Optimization Report indicated increasing trends for arsenic at these locations (Tetra Tech, 2015), suggesting that arsenic in shellfish may be related to background conditions or other anthropogenic sources. Overall, the comparison of the 2013 through 2016 shellfish data to the historical shellfish data indicates that the current remedy is protective of shellfish within the constructed wetland and is controlling the migration of landfill contaminants, such that there is no further degradation of the shellfish population inhabiting the landfill shoreline.

3.2.6 Harbor Sample Results

One surface water sample was collected from Allen Harbor in the area where the entrance channel meets Allen Harbor during ME 45 and analyzed for VOCs, metals, PAHs, and salinity in order to provide background information for these analytes in Allen Harbor. The sample was collected during slack tide (i.e., the period between the tides when there is no net movement of water in either direction from the tides) using a peristaltic pump and lowering tubing to the midpoint of the water column. Ethylbenzene and total chromium were the only analytes detected. Significant dilutions were necessary for the metals analyses due to the high concentrations of major cations. The laboratory results are included with groundwater samples in Table 8. The location of the harbor sample and the detected results are shown in Figure 32.

3.2.7 Gas Vent Sampling Results

Gas vent samples were collected using SUMMA canisters for laboratory analysis of VOCs and methane. Gas vent locations are shown on Figure 2 and the laboratory results are presented in Table 13a. The laboratory results were used along with air flow measurements, temperature, barometric pressure, and molecular weights to calculate emission rates for each compound in grams per second (g/s) as shown on Table 13b. The Third Five Year review (Tetra Tech, 2013) pointed out that the RIDEM air toxics regulations were updated in the RIDEM Air Pollution Control

Regulation No. 22 (RIDEM, 2008). Therefore, new allowable air toxic emission rates in g/s were calculated using the acceptable ambient levels (AALs) found in Table 1 of RIDEM Air Pollution Control Regulation No. 22 (RIDEM, 2008) and the AERSCREEN air quality modelling software. These new allowable emission rates were used for comparison to the gas vent calculated emission rates for VOCs. When comparing the gas vent emission rates to the new allowable emission rates, the gas vent emission rates were summed for each VOC and compared to the new allowable emission rates. The new allowable emission rates represent a worst case scenario at the nearest ambient boundary point of the landfill. The calculated gas vent emission rates and comparison to the new allowable emission rates is presented on Table 13b. There were no VOC exceedances of the new allowable emission rates. Specific details on the derivation of the allowable emission rates and comparison to the new allowable emission rates can be found in Attachment I.

For methane, the RIDEM maximum allowable emission from landfill gas vents of 100 pounds per day was used for comparison since methane is not an air toxic and not included in RIDEM Air Pollution Control Regulation No. 22. The maximum allowable methane emission of 100 pounds per day was converted to a calculated emission rate of 0.525 g/s and compared to the sum of the methane emission rates from all five gas vents on Table 13a. The sum of the gas vent methane emissions was below the calculated emission rate of 0.525 g/s.

3.2.8 Gas Probe Monitoring Results

Monitoring of gas probes has been performed to evaluate whether landfill gases are migrating laterally beneath the landfill cap and are present in soil gas outside of the capped area. A total of 20 perimeter gas probes were monitored annually from 2013 - 2016, located as shown on Figure 2. The gas probes consist of temporary drive points that are installed outside the limits of the landfill cap; the gas probes are screened using a LandTec GEM-2000 landfill gas screening instrument. Field measurements of percent methane, percent carbon dioxide, percent oxygen, and hydrogen sulfide are collected at gas probe locations during each LTM event. The data collected during ME 45 is presented on Table 7. No readings exceeding 0.1 percent were recorded for methane in the gas probes during ME 45, which is consistent with previous MEs.

4.0 QUALITY ASSURANCE/QUALITY CONTROL

4.1 Data Validation and Usability

The data obtained during ME 45 were determined to be of sufficient quality to be used to evaluate the long-term effectiveness of the remedial action (i.e., landfill cap with deed restrictions, long-term monitoring, and 5-year reviews). Quality assurance/quality control (QA/QC) samples collected during this sampling event included matrix spike/matrix spike duplicate (MS/MSD) samples and field duplicate samples. Other QA/QC samples included trip blanks and equipment blanks. Non-compliances with select project data quality objectives for accuracy, precision, and sensitivity are discussed in the data validation reports, but have a minor impact on the overall usability of the data. Laboratory result data (not including the original Shellfish data, see Section 2.2) was 98.2% complete, with the following exceptions:

- The non-detect VOC results in five groundwater samples (MW-09-27D-ME45-1, MW09-ME45-FD01, MW09-14D-ME45-1, MW09-20D-ME45-1, and MW09-ME45-FD03) were rejected due to holding time exceedances. The affected results are not usable for project decisions.
- Eight non-detect SVOC results in shellfish sample ET09-10-ME45R-1 were rejected due to low matrix spike recovery. The affected results are not usable for project decisions.
- Three non-detect mercury results (both filtered and unfiltered results for P09-10-ME45-1, and the total result for P09-09-ME45-1) were rejected due to holding time exceedances. The affected results are not usable for project decisions.

The analytical results from samples collected during ME 45 were subject to Tier 1 Plus validation in accordance with the draft QAPP (RC, 2016), *DoD Quality Systems Manual, version 5.0* (DoD, 2013), *EPA New England; Environmental Data Review Program Guidance* (EPA, 2013a), EPA New England; Environmental Data Review Supplement for Regional Date Review Elements and Superfund Specific Guidance/Procedures (EPA, 2013b) *National Functional Guidelines for Inorganic Data Review* (EPA, 2016a), and *National Functional Guidelines for Evaluation Organic Data Review* (EPA, 2016b). Standard EPA Region I data qualifiers were assigned to the data during validation to assess data quality. These qualifiers include “J”, “UJ”, “U”, and “R” are defined in the data validation memoranda presented in Attachment B. The analytical data are summarized in Tables 8 through 13a and shown on Figures 14 through 32 include the qualifiers added as a result of the validation process.

4.2 Laboratory Audit of Eurofins Spectrum Analytical Incorporated

As mentioned in Section 2.2, the September 2016 SVOC, PAH, and pesticide shellfish data had extremely low surrogate recoveries that would have led to rejected results. As a result, the shellfish samples were recollected analyzed for all analyses on December 12, 2016 through December 14, 2016. A Resolution chemist performed a laboratory audit at Eurofins Spectrum Analytical Incorporated in North Kingstown, Rhode Island on December 15, 2016 such that the laboratory login and preparations procedures for the December 2016 shellfish samples could be observed and audited. The laboratory audit focused on the following:

- Sample receiving and login
- Internal chain of custody/sample tracking
- Project management/communication
- Sample preparation standard operating procedures
- Personnel training/qualification
- Sample preparation documentation
- Spiking technique

No major deficiencies were found for the sample receiving and login, personnel training/ qualification, and sample preparation documentation. Suggested areas of improvement/ corrective actions were noted for internal chain of custody/sample tracking, project management/ communication, and sample preparation standard operating procedures. In addition, modifications to the spiking procedure were suggested and implemented by the laboratory. However, these modifications were subsequently found to be not totally effective. Therefore the original spiking technique was used for the December 2016 shellfish analyses. The conclusion of the audit and follow up communications with the laboratory was that the cause of the poor surrogate recoveries in the September 2016 was not related to the spiking technique and was of indeterminate cause. Deficiencies in the laboratory tracking procedures and communication resulted in the September 2016 sample aliquots not being returned to the freezer as specified in the SOP, which resulted in the gross hold time exceedance that prevented re-preparation and reanalysis of the September 2016 samples. A Technical Memorandum summarizing the laboratory audit is included in Attachment H-1.

4.3 Statistical Comparison of September 2016 and December 2016 Shellfish Data

A statistical comparison of the September 2016 and December 2016 total PCBs and metals shellfish data was performed to evaluate whether the December 2016 shellfish data can be considered to be of the same population as that of the September 2016 shellfish data. The comparison was limited to total PCBs and metals, as these were the only two analyses that were not affected by data quality issues described in Section 2.2. The September 2016 PCB homolog and metals data were validated prior to use in the statistical comparison. Physical parameters such as lipids, shell length, and width were also evaluated.

Paired-sample tests were conducted on the shellfish tissue analytical data for metals and PCBs from samples collected in September 2016 and December 2016 to determine whether there is a statistically significant difference in shellfish concentrations measured at each location between the two dates. The pairs were defined based on the ten locations (e.g., aluminum concentrations detected in tissue samples collected at location ET09-03 in September 2016 and December 2016 are considered one pair of samples). A stepwise approach was implemented for the statistical analysis. First, the distribution of each analyte/date dataset was determined. If both datasets (i.e., September 2016 and December 2016) were normally distributed per analysis (i.e., total PCBs and metals), then a paired t-test was used to determine if the mean concentrations of the two datasets were statistically different. If one or both datasets were not normal or lack a distribution, then the nonparametric Wilcoxon signed-rank (WSR) test was used to determine if the median concentrations are statistically different between the datasets. In addition, the data for each analysis were plotted into Quartile-Quartile (Q-Q) plots and boxplots to illustrate the range and distribution of the two datasets.

The results of the statistical evaluation indicated that, with the exception of four metals (calcium, mercury, potassium, and silver), the detected shellfish tissue concentrations and the physical parameters measured in the December 2016 dataset are equivalent to those in September 2016. Because the majority of analyte data are considered equivalent, the December 2016 shellfish tissue dataset is representative of Fall 2016 shellfish tissue concentrations. As a result, the December 2016 shellfish data for all analyses were used for evaluation in this Five Year Event Monitoring Report. Further details on the statistical comparison, including tables, Q-Q plots, and boxplots can be found in the Technical Memorandum included as Attachment H-2.

5.0 LANDFILL SETTLEMENT SURVEYS

From 1999 to 2011, settlement surveys were conducted annually at Allen Harbor Landfill. The frequency was decreased to biennially in 2014. As outlined in the O&M Plan (Foster Wheeler, 2001), the objectives of the survey are to evaluate the degree to which the landfill cap, revetment, constructed wetlands, and breakwater have settled since the construction of the remedy, and to maintain accurate well elevations so that groundwater elevations that support the LTM are accurate. The surveyed locations for the settlement survey conducted in October 2016 are shown on Figure 1 of the Annual Landfill Inspection Report for 2016, provided as Attachment D.

The October 2016 settlement survey was completed by Louis Federici Associates on October 31, 2016. A total of 51 locations were surveyed, including the top of each polyvinyl chloride (PVC) riser, top of each steel casing, and adjacent ground surface for the 28 on-site monitoring wells; 5 gas vent risers, and 18 survey markers located on the breakwater, revetment, and constructed wetland (six markers at each area).

A comparison of the 2016 survey results to the previous survey data (1999 to present) is provided in Table 14. Three comparisons are provided in the table for the 2016 survey: elevation change from the previous survey; elevation change between the 2016 survey and the initial (1999) survey, and maximum elevation change (maximum elevation minus minimum elevation) between the initial (1999) and the 2016 survey. Positive numbers indicate increasing elevations while negative numbers indicate decreasing elevations from the initial survey elevations (1999). All values are in feet (1 inch = 0.083 feet).

5.1 2016 Landfill Settlement Survey

Between November 2014 and October 2016, with the exception of monitoring well MW09-02S (PVC riser elevation), MW09-03D (PVC riser and steel casing elevation), MW09-10S (PVC riser elevation), MW09-27D (PVC riser elevation), Gas Vent GV09-01, revetment markers RMP-50, RMP-51, RMP-52, RMP-60 and RMP-61, wetland survey markers MMP-10, MMP-11, MMP-12, MMP-13, and MMP-15, and breakwater markers BMP-1833, and BMP-1835, elevation changes of less than 0.30 feet (approximately 3.6 inches) were observed at all surveyed points. It is of note that for all locations, with the exception of one breakwater location (BMP-1833), the changes occur as increased elevations. Three locations show increases in elevation greater than 0.5 feet, and the maximum increase is observed to be 0.70 feet (approximately 8.4 inches) at MMP-15.

Changes in elevations during the period between October 1999 and October 2016 are summarized below:

- Monitoring wells, PVC riser elevations – 12 wells had elevation changes of 0.10 feet or greater and 2 wells had elevation changes greater than 0.20 feet. The maximum elevation change was 0.22 feet (approximately 2.6 inches) at MW09-11S. Elevations were increasing or showed no change at all but 6 wells.
- Monitoring wells, top of steel casings – 8 of the 27 monitoring wells had elevations changes of 0.10 feet or greater. The greatest elevation change was 0.17 feet (approximately 2.0 inches) at MW09-27S and MW09-27D, while the least amount of change observed was 0 feet at MW09-09DA, MW09-10S, and MW09-21D. Elevations decreased at 8 wells, increased at 16 wells, and showed no change in 3 wells.
- Gas vents – All five vents had elevation changes of less than 0.10 feet. The maximum elevation change observed was 0.05 feet (approximately 0.6 inches) at GV09-05.
- Breakwater –The maximum change observed was 0.81 feet (approximately 9.7 inches) at BMP-1833. The minimum change observed was 0.02 feet (approximately 0.24 inches) at BMP-1831. All locations had decreasing elevations.
- Revetment – A 0.43 foot (approximately 5.2 inch) elevation change was observed at RMP-68, which is the highest change observed in this data set. A 0.02 (approximately 0.24 inch) elevation change was observed at RMP-51, the lowest change in the data set.
- Wetland – All six wetland locations showed changes greater than 0.2 inches. The maximum change observed was 0.42 feet (approximately 5.0 inches) at MMP-10. The minimum change observed was 0.20 feet (approximately 2.4 inch) at MMP-14. All locations had increasing elevations.

5.2 Landfill Settlement Survey Conclusions

Generally, elevation changes are not consistently either increasing or decreasing over time at any of the surveyed locations, suggesting that heaving due to long-term freeze/thaw conditions is the primary factor controlling changes in elevations. Generally, the largest changes in elevations site-wide occur at the wetland locations, and the smallest changes site-wide are observed in the monitoring wells, both the PVC monitoring points and the top of steel casing monitoring points.

In the Draft ME 44 Biennial Report (Resolution, 2016a) it was noted that that some settling may be occurring along the revetment and breakwater, due to observed changes in excess of 0.5 feet in several locations since 1999. During the 2016 survey only one location (BMP-1833) showed a change greater than 0.5 feet. It was noted in the ME 44 report that the increase in revetment and breakwater elevation changes observed between the surveys performed by Crossman Engineering

(i.e., 1999-2001) and the surveys performed by Diprete Engineering in 2013 and 2014 are likely due to Diprete Engineering using measuring points that were not in the exact same locations as those used by Crossman Engineering. The 2016 survey was performed by a different contractor, Louis Federici Associates. It is likely that the breakwater, revetment, and wetland locations surveyed by Louis Federici Associates were closer to the original locations surveyed by Crossman Engineering, and therefore the changes are significantly lower than the 2013 and 2014 surveys.

The results of the survey indicate that no action is warranted at this time to address landfill settlement at Site 09. The changes in elevation at each gas vent were evaluated to determine the extent to which settling is occurring within the capped portion of the landfill: no settlement measurements were in excess of the O&M Plan benchmark of 6 inches per 100 feet.

6.0 UPDATED RISK ASSESSMENT

6.1 Human Health Risk Assessment Update

A human health risk assessment (HHRA) update was conducted for the shoreline sediment, groundwater in shallow piezometers, and shellfish tissue at Site 09. The objective of this HHRA update (also referred to as the 2017 HHRA update) is to determine whether there have been any changes and/or updates to USEPA HHRA guidance or site-specific conditions since the 2013 HHRA, performed by Tetra Tech, Inc. in support of the August 2015 Long-Term Monitoring Data Summary and Optimization Recommendations Report (Tetra Tech, 2015), was conducted that would result in a change of the conclusions of the 2013 HHRA, or whether the conclusions of the 2013 HHRA remain valid. This section provides a summary of the HHRA update. The full HHRA update is provided as Attachment G-1.

Revised risk/hazard calculations were performed as part of this 2017 HHRA update to estimate the cumulative potential cancer risk and/or noncancer hazard associated with a recreational user exposure scenario, determine whether risk/hazard estimates exceed USEPA and/or RIDEM target risk/hazard levels, and identify whether the current institutional controls in place at Site 09 are still needed.

The 2013 HHRA conducted as part of the 2015 LTM report concluded that the potential cancer risks associated with ingestion of shellfish tissue estimated for a recreational user exceeded RIDEM's target cumulative cancer risk level of $1x10^{-5}$, but were within USEPA's target risk range of 10^{-6} to 10^{-4}. Risk drivers (i.e., chemicals that are the primary contributors to the exceedance of the target risk level) were arsenic, PCBs, and pesticides in shellfish tissue. The potential noncancer HIs for an adolescent and adult recreational user ingesting shellfish did not exceed USEPA/RIDEM's target HI of 1 per target organ. The 2013 HHRA also concluded that the range of PCB concentrations detected in the Site 09 shellfish tissue samples collected in 2012 were within the range of concentrations detected in samples collected through the National Oceanic and Atmospheric Administration (NOAA) Mussel Watch Program. This suggests that it is possible that some of the PCB contamination noted in the Site 09 samples may reflect regional conditions.

Potential risks for recreational users exceeded RIDEM's target cumulative cancer risk level of $1x10^{-5}$ in several cases evaluated in the 2013 HHRA due to exposure to shallow sediment (0 to 0.5 feet [bgs) and piezometer water. Primary risk drivers for exposure to shallow sediment were arsenic and cPAHs. Primary risk drivers for exposure to piezometer water (using maximum concentrations) were arsenic and VC. However, using refined exposure assumptions to more accurately represent Site 09-specific exposure conditions, potential cancer risks were less than RIDEM's target risk level of

$1x10^{-5}$ for exposure to shallow sediment. Potential cancer risks estimated using 95 percent (%) upper confidence limits (UCLs) on the arithmetic mean concentration as the exposure point concentrations (EPCs) instead of maximum concentrations for piezometer water were also less than RIDEM's target risk level of $1x10^{-5}$. The 95% UCLs are likely to be more representative of actual exposure conditions. The potential noncancer HIs for an adolescent and adult recreational user exposed to sediment and piezometer water did not exceed USEPA/RIDEM's target HI of 1 per target organ.

Comparison of regional cPAH sediment data to Site 09 shallow sediment data for several cPAHs suggests that concentrations of cPAHs detected in shallow sediment at location SED09-10 are elevated compared to the regional dataset as well as when compared to the other Site 09 shallow sediment samples. Site 09 shallow sediment samples for the other sampling locations are within the range of or slightly exceed (i.e., are within one order of magnitude of) detected concentrations in the regional sediment dataset.

Data evaluated in the 2017 HHRA update were selected to be representative of current conditions, and include shallow sediment samples collected between 0 to 0.5 feet bgs from twelve locations along the Site 09 shoreline during three sampling events conducted in September 2014, September 2015, and September 2016; shallow groundwater samples collected during four sampling events conducted in October 2013, September 2014, September 2015, and September 2016 from twelve piezometers located along the Site 09 shoreline (assumed to be a mixture of groundwater and surface water); and shellfish tissue samples collected during four sampling events conducted in October 2013, September 2014, September 2015, and December 2016 from ten locations along the Site 09 shoreline.

The receptors and exposure pathways evaluated in the 2017 HHRA update are consistent with those evaluated in the 2013 HHRA based on current and potential future land use, including recreational users exposed to shoreline media while swimming, wading, or clamming/harvesting shellfish.

The overall conclusion of this 2017 HHRA update is that the conclusions of the 2013 HHRA remain valid and ingestion of shellfish tissue obtained from the Site 09 shoreline by a current/future recreational user poses a potential cancer risk or noncancer hazard above RIDEM target levels due to arsenic, PCBs, and pesticides (specifically aldrin). Based on this conclusion, the current institutional control prohibiting ingestion of shellfish continues to be necessary to protect public health. However, the shellfish tissue EPCs for arsenic and aldrin are within the range of concentrations detected in reference tissue samples collected from the shoreline of Prudence Island

and from Fishing Cove in Wickford, Rhode Island between 2007 and 2011. These results indicate that concentrations of arsenic and aldrin in site shellfish tissue samples evaluated in the 2017 HHRA update may be due to background conditions, rather than Site 09. In addition, the shellfish tissue EPC for PCBs is less than the range of PCB concentrations detected in samples collected in 2011 (the most currently available dataset) through the NOAA Mussel Watch Program (https://products.coastalscience.noaa.gov/nsandt_data/data.aspx). This suggests that some of the PCB contamination noted in the Site 09 samples may reflect regional conditions.

If both arsenic and aldrin concentrations in shellfish tissue are excluded from the 2017 HHRA update, the cumulative potential ELCR associated with a lifetime recreational user exposure to shallow sediment (assuming a swimming/wading scenario), groundwater (piezometer water), and shellfish is within USEPA's target risk range of 10^{-6} to 10^{-4} and does not exceed RIDEM's target risk level of 10^{-5}. The associated total potential noncancer HI (conservatively based on all target endpoints combined) does not exceed USEPA or RIDEM's target level. Therefore, no site-related chemicals of concern (COCs) are identified as a result of the 2017 HHRA update.

6.2 Ecological Risk Assessment Update

An ERA update was conducted for shoreline exposures to sediment, sediment porewater, surface water, and shellfish at Site 09. The objective of this ERA update is to determine whether there have been any changes and/or updates to ERA guidance or site-specific conditions since the 2015 ERA was conducted by Tetra Tech, Inc. (Tetra Tech, 2015), that would result in a change of the conclusions of the 2015 ERA, or whether the conclusions of the 2015 ERA remain valid. This section provides a summary of the ERA update. The full ERA update is provided as Attachment G-2.

The 2017 ERA update includes the following:

- Calculation of summary statistics for analytical shallow sediment, piezometer water, seep water, and shellfish data collected along the Site 09 shoreline between 2013 and 2016, which are considered representative of current conditions;
- Review and update of screening levels and chemicals of potential concern (COPC) selection for shoreline shallow sediment, piezometer water (representing sediment porewater), seep water (representing surface water); and
- Review and update of food web modeling evaluating birds and mammals exposed to shoreline sediment and shellfish.

Although revised quantitative risk calculations were not required to be conducted for this ERA update per the Davisville BCT January 12, 2017 teleconference, given the relatively simple nature of the 2015 ERA and the addition of some new detected chemicals, the 2015 ERA risk screenings and food web calculations were updated to reflect the current data set. These updated evaluations and a comparison of EPCs between the 2015 ERA and the 2017 ERA update are used to assess whether the conclusions of the 2015 ERA remain valid.

The potentially exposed ecological receptors and exposure pathways for the Site 09 shoreline evaluated in the 2015 ERA remain appropriate and are summarized as follows:

- Benthic invertebrates exposed to shallow sediment;
- Aquatic organisms exposed to sediment pore water (represented by piezometer water) and surface water (represented by seep water);
- Terrestrial plants exposed to surface water (represented by seep water); and
- Birds and mammals exposed to shallow sediment and shellfish via ingestion pathways.

Toxicity values and exposure assumptions used in the 2017 ERA update are consistent with those used in the 2015 ERA. Updated analytical data from all media were used to update the benchmark screens and food web models and to qualitatively identify differences between the current data set and the data set evaluated in the 2015 ERA. Consistent with the 2015 ERA, the ERA update included two tiers of evaluation: a screening level evaluation using the maximum detected concentrations to identify COPCs and a COPC refinement evaluation using the average detected concentrations to further evaluate the potential for ecological risk.

The overall conclusion of the 2017 ERA update is that the conclusions of the 2015 ERA remain valid and exposure to shallow sediment, pore water, surface water, and shellfish along the Site 09 shoreline does not pose a site-related risk to ecological receptors. Concentrations of several metals were elevated in piezometer water, but it does not appear that these concentrations are related to groundwater at Site 09.

7.0 SITE INSPECTION ACTIVITIES

Site inspection was completed at Allen Harbor Landfill on September 28, 2016. Recreational use including walking and jogging observed. No new building or groundwater supply wells were present. The Site Inspection Report is provided as Attachment D.

8.0 CONCLUSIONS AND RECOMMENDATIONS

As required by record of decision (ROD) for Site 09, LTM was performed between 2013 (ME 41) and 2016 (ME 45) in accordance with the updated LTM scope and protocols in the Draft Tier II SAP (Resolution, 2016b). As previously mentioned, piezometers, sediment, and shellfish were not sampled during ME 41 and sediment samples were not collected as surface sediment samples during ME 42.

8.1 Conclusions

The following general conclusions are presented based on the comprehensive evaluation of site data between ME 41 and ME 45:

Hydrogeology

- The hydrogeology at Site 09 is stable, consistent, and well understood after 45 MEs. The hydrogeology data collected during ME 41 through ME 45 is consistent with previous events and the conclusions in the Site 09 LTM and Optimization Recommendations Report (Tetra Tech, 2015).

Groundwater Beneath the Landfill

- The CVOCs in groundwater beneath the landfill appear to be stable or possibly decreasing. The combined TCE, cis-1,2-DCE, trans-1,2-DCE, and VC data indicate that anaerobic reduction dechlorination is occurring. The overall size, shape, and concentration profile of the CVOCs in groundwater beneath the landfill is consistent with those in the Site 09 LTM and Optimization Recommendations Report (Tetra Tech, 2015).
- Benzene continues to be the only other VOC consistently detected above the PAL in groundwater beneath the landfill. The concentrations observed appear to be stable and limited to a few areas, consistent with previous MEs.
- Periodic PAL exceedances of other VOCs such as 1,1,2-trichloroethane, 1,1-dichloroethene, 1,2-dichloroethene, methylene chloride, and chlorobenzene were observed and these occurrences are consistent with previous MEs. The detected results during ME 41 through ME 45 were generally lower than historic averages.
- Detections of SVOCs and PAHs remain sporadic and infrequent. However, benzo(a)pyrene was detected above the PAL (0.2 ug/l) for the first time during ME 45 at MW09-09S (0.21 ug/L) and MW09-20I (0.43 ug/L).

- There was only one PCB detected between ME 41 and ME 45: Aroclor 1260 at MW09-11S (0.45 ug/L) during ME 41. There were only two pesticide detections between ME 41 and ME 45: Beta-BHC at MW09-07S (0.020 ug/L) and MW09-24S (0.016 ug/L) during ME 44.
- Arsenic continues to be the only metal consistently detected above the PAL in the groundwater beneath the landfill. It should be noted that although above the PAL, the concentrations of arsenic in groundwater beneath the landfill are significantly lower than those observed in the piezometers. It should also be noted that arsenic is naturally occurring in soil and groundwater.

Piezometers

- There was only one CVOC detected in the piezometers during ME 42 through ME 45: VC at P09-10 (1.1 ug/L) during ME 42.
- Benzene was only detected once in piezometers during ME 42 through ME 45: P09-10 (1.3 ug/L) during ME 42.
- Arsenic copper, nickel, mercury, lead, chromium, and zinc have been frequently detected above their PALs in piezometer samples during ME 42 through ME 45. However, these appear to be largely the result of suspended solids in the sample, as the dissolved results for these metals are generally much lower than the totals. The high suspended solids (i.e., turbidity) is due to the poor groundwater recharge at these locations due to groundwater not significantly discharging along the shoreline of Site 09. This results in the inability to collect the samples via low-flow sampling. Furthermore, the concentrations of these metals in the monitoring wells (i.e., groundwater beneath the landfill) are much lower, further indicating the elevated metals concentration are not due to migration of landfill groundwater to the shoreline. It is possible that the elevated arsenic results are due to isobaric interferences from the metals ICP-MS analysis (see Section 8.2 below).
- Besides the metals listed above, there have been no PAL exceedances since ME 42 and the vast majority of VOC, SVOC, PAH, pesticide, and PCB results have been nondetect.

Sediment

- VOCs, PAHs, pesticides, and PCBs have been sporadically detected during ME 43 through ME 45. Mann Kendall trend analyses indicate either no trend or downward trends. Zinc, 4,4'-DDT, phenanthrene, and pyrene were the only analytes with PAL exceedances during ME 43 through ME 45.

- Zinc was detected above its PAL (219 mg/kg) at SED09-09 (263 mg/kg) during ME 44. The zinc concentration at this location decreased to 172 mg/kg during ME 45, below the PAL.
- 4,4'-DDT was detected above its PAL (6 ug/kg) at SED09-01 (8 ug/kg) during ME 43 and SED09-09 (9.3 ug/kg) during ME 44. 4,4'-DDT was not detected at either location during the following ME, with both reporting limits being well below the PAL.
- Phenanthrene was detected above its PAL (1,500 ug/kg) at SED09-10 (3,300 ug/kg) during ME 44. The phenanthrene concentration decreased to 960 ug/kg during ME 45, below the PAL.
- Pyrene was detected above its PAL (2,600 ug/kg) at SED09-10 (2,700 ug/kg) during ME 44. The pyrene concentration decreased to 890 ug/kg during ME 45, below the PAL.

Shellfish

- The 2013 through 2016 shellfish samples had detected concentrations of metals, PCBs, and PAHs greater than the maximum concentrations reported in reference samples collected from 2007 through 2011. However, a comparison to pre-remedy data indicates that site concentrations are significantly lower than those collected from the same areas of the site in 1995, prior to the completion of the remedy.
- Overall, the trend analyses reported statistically significant upward trends for some metals including arsenic at ET09-03, ET09-04, ET09-05, and ET09-06 and for anthracene at ET09-04. However, comparison to the landfill groundwater data indicates that these are not site-related. In addition, Mann Kendall trend analysis performed on arsenic at reference locations ET09-01 and ET09-02 in the Site 09 LTM and Optimization Recommendations Report indicated increasing trends for arsenic at these reference locations (Tetra Tech, 2015), suggesting that arsenic in shellfish may be related to background conditions or other anthropogenic sources.
- The shellfish population appears to be more abundant and more diverse than observed during previous MEs. Quahogs, which were not frequently present during previous MEs, have become more common. Many parts of the stone revetment and breakwater structure have become covered with shellfish shells (see Photolog in Attachment D) from birds capturing and eating shellfish, indicating that the shellfish population is abundant enough to support the feeding habits of marine predatory birds.

Landfill Gas

- Laboratory VOC results were converted to emission rates and compared to newly calculated allowable emission rates based on the updated RIDEM air toxic regulations in RIDEM Air Pollution Control Regulation No. 22 (RIDEM, 2008). There were no VOC exceedances of the new calculated allowable emission rates. The laboratory methane result was also converted to an emission rate. The methane emission rate was below the calculated emission rate of 0.525 g/s, which is based on the RIDEM maximum allowable emission of 100 pounds per day.
- Soil gas screening results measured during ME 41 through ME 45 indicate that the landfill cap has not been compromised and is functioning as designed.

Risk Assessment Updates
