ATTACHMENT D

Aquatic Plant Tissue Exposure Point Concentration Calculations

For polycyclic aromatic hydrocarbons (PAHs), aquatic plant tissue exposure point concentrations (EPCs) were estimated from sediment using an approach that incorporated the uptake differences between low molecular weight (LMW) and high molecular weight (HMW) PAH compounds. Due to the lack of sediment-to-plant uptake information in the scientific literature, the aquatic plant uptake was assumed to be identical uptake into terrestrial plants from soil. Therefore, the bioaccumulation approach from the PAH-specific ecological soil screening levels (Eco-SSL) document (USEPA, 2007) was used to estimate the total PAH (TPAH) concentration in aquatic plants using site-specific sediment PAH data.

The 17 PAH compounds analyzed in sediment, are categorized as follows:

LMW PAHs:

- 2-methylnaphthalene
- Acenaphthene
- Acenaphthylene
- Anthracene
- Fluorene
- Naphthalene
- Phenanthrene

HMW PAHs:

- Benzo(a)anthracene
- Benzo(a)pyrene
- Benzo(b)fluoranthene
- Benzo(g,h,i)perylene
- Benzo(k)fluoranthene
- Chrysene
- Dibenz(a,h)anthracene
- Fluoranthene
- Indeno(1,2,3-c,d)pyrene
- Pyrene

The following steps in the EPC calculation approach were used (all steps are reflected in Table E-1):

1. Calculate LMW and HMW TPAH concentrations in sediment – LWM and HWM TPAH concentrations were calculated for each sediment sample (including all field duplicates) by summing the concentration of detected PAHs in each category.
2. Estimate (model) LMW and HMW TPAH concentrations in plants – On a sample-specific basis, the LMW and HMW TPAH sediment concentrations calculated during Step 1 were used to estimate plant concentrations. For LMW TPAHs, the sediment

concentrations were multiplied by a BCF of 2.09 (Table 6.3 from USEPA, 2007). For HMW TPAHs, the sediment concentrations were calculated using the following regression model (Table 6.4 from USEPA, 2007):

$$\ln(Tissue_{aquatic\ plant}) = 0.9469 \times \ln(Sediment_{MW}) - 1.7026$$

Where:

ln = log normal
$Tissue_{aquatic\ plant}$ = concentration in aquatic plant tissue
$Sediment_{MW}$ = Step 1 molecular weight-specific TPAH concentration

3. Calculate TPAH concentration in aquatic plants – the LWM and HMW TPAH plant tissue concentrations were summed to calculate the overall TPAH concentration in aquatic plants from sediment samples.

4. Calculate EPC – First, the higher of the normal and corresponding field duplicate concentrations were selected for samples 308A, 314, 315 and 324 (the minimum concentration was ignored). Second, the 95 percent (%) upper confidence limit (UCL) of the mean (i.e., 95% UCL) was calculated for all 27 sample-specific aquatic plant tissue concentrations from Step 3 using USEPA's ProUCL version 4.00.05. This value was used as the TPAH EPC for aquatic plants in the food web assessment.

2-1 Conceptual Exposure Model for Human Health Risk Assessment

SECTION 1

Introduction

1.1 Introduction

This baseline human health risk assessment (HHRA) for the Gowanus Canal Superfund Site is Appendix L to the remedial investigation (RI) report. The baseline HHRA was conducted to assess the nature, magnitude, and probability of potential harm to public health posed by environmental media containing hazardous substances released to the Gowanus Canal by past activities along the canal—specifically, the potential human health risks associated with direct contact with sediment and surface water in the canal, with ingestion of fish and crabs caught in the canal, with direct contact of sediment and surface water that overtops the canal during significant rainfall events, and with inhalation of emissions from the canal into the ambient air near the canal. The data evaluated in the HHRA are presented in Appendix I to the RI report and discussed in Section 4 of the RI report.

1.2 Site Background

The Gowanus Canal is located in Brooklyn, New York, a borough of New York City. The canal is connected to the Gowanus Bay in the Upper New York Bay and borders the neighborhoods of Red Hook, Cobble Hill, Carroll Gardens, and Park Slope. The waterfront adjacent to the canal is primarily commercial and industrial and currently consists of concrete plants, warehouses, and parking lots. There are five bridge crossings over the canal, at Union Street, Carroll Street, Third Street, Ninth Street, and Hamilton Avenue (Figure 1-1 of the RI). The Gowanus Expressway and the New York Subway also cross over the canal.

The Gowanus Canal, completed in the 1860s, was built to allow water access for industrial needs by bulkheading and dredging a tidal creek and wetland that was previously fished for oysters. The canal quickly became one of the nation's busiest industrial waterways and was home to heavy industry such as gas works, coal yards, manufacturers of cement, manufacturers of soap, tanneries, paint and ink factories, machine shops, chemical plants, and oil refineries. It was also used as a repository of untreated industrial wastes, raw sewage, and surface water runoff for many decades. Although much of the industrial activity along the canal has stopped, high contaminant levels remain in the sediments. Despite ongoing pollution problems, some local residents use the Gowanus Canal for recreational purposes such as canoeing and swimming/diving, while others catch and eat fish and crabs.

The City built a "flushing tunnel" in 1911 to replace stagnant canal water with fresh, oxygen-rich water to improve water quality. The tunnel was in operation until the 1960s, when a mechanical failure caused it to shut down and the canal water became stagnant and thus polluted once again. The flushing tunnel was rehabilitated and reactivated in 1999 by the City's Department of Environmental Protection (NYCDEP) to pump water from Buttermilk Channel to the Gowanus Canal using the 1911 technology. The flushing tunnel

was shut down by NYCDEP on July 19, 2010, for an extended period of facility improvements to modernize the technology and improve operations. In early 2010, an aeration pipe was installed within the canal to circulate superoxygenated water while the flushing tunnel is shut down. The aeration pipe began operation in early July 2010, and repairs were started on the flushing tunnel. The completion date is anticipated to be September 2014.

The canal is part of the New York-New Jersey Estuary, which the U.S. Environmental Protection Agency (USEPA) has designated an Estuary of National Significance under the Clean Water Act Section 320 and USEPA's National Estuary Program.

SECTION 2

Conceptual Site Model

The conceptual site model (CSM) for human receptors presents an overview of site conditions, potential contaminant migration pathways, and potential exposure pathways to potential receptors. Figure 2-1 presents the preliminary CSM developed for the Gowanus Canal. Table 1 in the Attachment summarizes the potential exposure pathways and scenarios that were evaluated as part of the risk assessment.

There have been many sources of contamination to the canal, as discussed in Section 1. Although much of the industrial activity along the canal has stopped, high contaminant levels remain in the sediments.

The watershed drainage area of the Gowanus Canal is 1,758 acres, and the canal waterfront, or riparian area (defined as all blocks wholly or partially within ¼ mile of the canal), is occupied by commercial and industrial properties. The waterfront properties include concrete plants, warehouses, and parking lots. The riparian areas are classified as 18 percent residential, 6 percent park, and 76 percent mixed use. The entire watershed is 53 percent residential, 2 percent park, and 45 percent mixed use (NYCDEP, 2008).

Combined sewers (i.e., sewers that receive both sewage and stormwater flows) serve 92 percent of the Gowanus Canal watershed, while storm sewers serve 2 percent (NYCDEP, 2008). Direct runoff drains 6 percent of the watershed. Three stormwater outfalls also discharge to the canal. During significant rainfall events, the Gowanus Canal receives untreated discharges of combined sewage that exceed the capacity of the Red Hook and Owls Head wastewater pollution control plants (WPCPs); during such events, the canal has overflowed onto neighboring properties and streets. The area surrounding the canal is within a 100-year flood zone, indicating that there is a 1 percent annual chance of flooding in this area (FEMA, 2007).

Currently, the New York State Department of Health (NYSDOH) has fish-consumption advisories for the Upper Bay of the New York Harbor (north of the Verrazano Narrows Bridge), including the Gowanus Canal (NYSDOH, 2010). There are no warning signs concerning the fish-consumption advisories posted along the canal; however, New York City has posted caution signs at locations of combined sewer outfall (CSO) discharges that state during wet weather the CSOs may discharge harmful bacteria to the canal and people should not swim, boat, or fish during these periods. A fishing license is not required to fish in the Gowanus Canal. The main contaminants of concern identified in the NYSDOH health advisories for the waters of the Upper Bay of New York Harbor are polychlorinated biphenyls (PCBs) and dioxin in fish, and cadmium, dioxin, and PCBs in crab and lobster. The NYSDOH advisories include the following advice:

- For women under 50 years and children under 15 years: Do not eat any fish from these waters, eat no more than a few meals per year of crab meat from these waters, and avoid eating the crab tomalley (hepatopancras) and cooking liquid.

- For all others: Do not eat gizzard shad, white perch, or crab and lobster tomalley (hepatopancreas) and cooking liquid; eat only one meal per month of Atlantic needlefish, bluefish, rainbow smelt, and striped bass; eat no more than four meals per month of all other fish species and blue crab meat.

Potential current and future receptors at the Gowanus Canal may include recreational users, anglers, local residents, and nearby industrial workers. The recreational receptors may contact surface water and sediment through incidental ingestion and dermal absorption and inhale ambient air (volatile and particulate emissions from the surface water and sediment) at canal level while boating, fishing, and crabbing in the canal and potentially, although less common and less likely, while swimming/diving in the canal.

Swimming/diving in the canal, although it does occur (Gowanus Dredgers Canoe Club, 2010; New York Times, 2007; The Gowanus Lounge, 2007), is rare due to the general conditions of the canal, which are largely associated with CSO discharges to the canal. The anglers may also ingest fish or crabs caught in the canal, and share the fish and crabs with family members, including young children and adolescents. Residents and industrial workers may inhale ambient air (associated with volatile and particulate emissions from the canal) at street level. Also, it has been noted that during significant rainfall events the canal may overflow (about two to three times per year), and these residents and industrial workers may contact surface water and sediment (that has overtopped the canal) through incidental ingestion and dermal contact. If any of the sediment that has overtopped the canal is not washed away with rain, it is usually swept up by the local residents or workers and does not accumulate.

Future use of the area surrounding the canal is most likely to remain the same as current use (industrial and residential), with the potential for construction of new housing, which would result in additional residential populations living close to the canal.

SECTION 3

Scope of Human Health Risk Assessment

The primary objective of the baseline HHRA is to assess the potential current and future health risks from the contamination associated with the Gowanus Canal, in the absence of any remedial action. The risk assessment evaluates potential carcinogenic risks and noncarcinogenic hazards for a reasonable maximum exposure (RME) scenario consistent with the National Contingency Plan (NCP) (USEPA, 1994a) and Risk Assessment Guidance for Superfund (RAGS) guidance documents (USEPA, 1989, 1991, 2001a, 2004, 2009). The RME is the highest exposure that is reasonably expected to occur at a site (USEPA, 1989). The risk assessment comprises the following components:

- **Hazard Assessment/Identification of Chemicals of Potential Concern**—Identification of the contaminants found in the canal media and selection of the chemicals of potential concern (COPCs). COPCs represent that subset of the chemicals found at the canal that is expected to contribute the most to the risk estimates for the canal.
- **Exposure Assessment**—Identification of the potential pathways of human exposure and estimation of the magnitude, frequency, and duration of these exposures.
- **Toxicity Assessment**—Assessment of the potential adverse effects of the COPCs and compilation of the noncarcinogenic and carcinogenic toxicity values used for developing numerical risk estimates.
- **Risk Characterization**—Integration of the results of the hazard, exposure, and toxicity assessments to develop numerical estimates of health risks and characterize the potential health risks associated with potential exposure to site-related contamination.
- **Uncertainty Assessment**—Identification and discussion of sources of uncertainty in the risk assessment.

Page Intentionally Left Blank

SECTION 4

Hazard Assessment/Identification of COPCs

The identification of COPCs includes data collection, data evaluation, and data screening to identify those chemicals which would contribute the most to the total risk estimates associated with the site.

The data collection and evaluation involve gathering and reviewing the available site information and compiling a set of data for the purpose of conducting the baseline HHRA. Once the data collection and evaluation are completed, the established data set is further screened to focus the risk assessment efforts on the contaminants that need to be evaluated quantitatively in the risk assessment (data screening).

4.1 Data Summary

The purpose of this investigation is to evaluate the potential human health risks associated with contamination in surface sediment and surface water in the Gowanus Canal, in fish and crab caught in the canal, and in air from emissions from the canal media. Surface water and sediment samples collected from the canal, fish and crab tissue samples collected from the canal, and air samples collected at canal level and street level adjacent to the canal were evaluated in the baseline HHRA. Samples for all media have also been collected from reference areas. All of the data are included in Appendix I to the RI report. The samples evaluated in the baseline HHRA and the laboratory analysis performed for these samples are identified in Table 4-1. All data used in the risk assessment were validated in accordance with USEPA Region 2 Data Validation SOPs (USEPA Region 2, 1992, 2001b).

4.1.1 Surface Sediment

Surface sediment sampling activities were conducted within the Gowanus Canal and New York Harbor between June 17 and July 1, 2010. Surface sediment samples were collected over the length of the canal from 0 to 6 inches below the top of soft sediment. Some of the surface sediment samples were collected at locations where sediments are exposed at low-tide. Figures 2-3a through 2-3c in the RI report identify the locations where the surface sediment samples were collected. A total of 27 surface sediment samples were collected from the canal. Twelve of the samples were collected from "exposed" locations. All sediment samples were analyzed for Target Compound List (TCL) organics and Target Analyte List (TAL) metals (including mercury and cyanide), and these data were evaluated in the HHRA. Additionally, 19 sediment samples were analyzed for PCB congeners. These 19 locations were selected to provide data for areas with the greatest potential for human exposure (e.g., the canoe launch), to provide data in areas where high PCB concentrations were previously measured in sediment, and to provide spatial coverage throughout the canal. The PCB concentrations and risks were calculated based on total PCBs derived from congener data. Aroclor data were not used in the risk calculations. Ten surface sediment samples were also collected from the Gowanus Bay and Upper New York Bay, outside the mouth of the canal, to provide information for offsite conditions. Figure 2-4 of the RI identifies the reference surface sediment locations.

Two data groupings of surface sediment were evaluated in the HHRA. All of the surface sediment data were included in the data set to evaluate overflow sediment. Only the surface sediment samples collected from "exposed" locations were included in the data set used to evaluate contact with sediment during recreational use of the canal.

4.1.2 Surface Water

Surface water samples were collected from the length of Gowanus Canal during two sampling events representing dry-weather (June 19, 2010; 27 samples) and wet-weather (July 13, 2010; 26 samples) conditions. Figures 2-5a through 2-5c in the RI identify the locations where the surface water samples were collected. Ten offsite surface water samples were collected from the New York Harbor and Buttermilk Channel. Figure 2-6 identifies the offsite surface water sample locations. The surface water samples were collected from approximately 6 inches below the water surface. Surface water samples from all locations were analyzed for TCL organics and TAL metals (total and dissolved including mercury and cyanide). The total metals data were evaluated to estimate risks associated with metals in the HHRA, as the receptors would come in direct contact with total (rather than dissolved) concentrations in surface water.

4.1.3 Ambient Air

Air-sampling activities were conducted along the Gowanus Canal and at background locations during two sampling events. Air samples were collected between July 7 and 9, 2010, prior to the start of the canal oxygenation system. A second round of air sampling was conducted July 28 and 29, 2010, following the start-up of the oxygenation system. Air samples were collected at 10 locations along the length of the canal with two samples collected at each location, one at canal level and one at street level. Air samples were also collected at three background locations, with one sample at street level at each location. Figure 2-9 in the RI shows the locations of the air samples. Air samples along the canal were analyzed for VOCs and PAHs. Location 506 at the street level was also analyzed for PCBs during the first sampling event.

4.1.4 Fish Tissue

Fish and crab samples were collected in the Gowanus Canal and reference locations in Gowanus Bay and Upper New York Bay from June 21 through July 9, 2010. Fish and shellfish were collected in six reaches of the canal and in three reference areas (Figures 2-7 and 2-8 of the RI). Species targeted for sampling and evaluation in the HHRA included blue crab, striped bass, and white perch. Additional species caught and evaluated in the HHRA included American eel. These species were targeted on the basis of previous catch records for the canal, since they are typically consumed by humans, and because they represent different levels within the food web and have potentially different exposure within the ecosystem. These species were selected as the target fish/crab species for the canal in consultation with USEPA.

Both top-level predator (striped bass) and middle-level predator (white perch) fish tissue samples were collected and evaluated in the HHRA. The top-level predators represent species reflecting high-end bioaccumulation due to their position in the food web and are occasionally harvested and consumed by anglers. However, these fish tend to have a relatively large home range, and thus lower site fidelity, and a greater chance of

accumulating contaminants from offsite sources. The midlevel predator represents species most frequently harvested and consumed by anglers and likely retains greater site fidelity. However, the midlevel predator may not reflect maximum bioaccumulation due to its position in the food web. Additionally, because eel were caught during the sampling, and eel are consumed by humans, the eel were evaluated in the HHRA and represent bottom feeders.

Section 2.5 of the RI details the fish sampling, tissue preparation and grouping, and the preparation of fish samples for laboratory analysis. Twelve composite samples of blue crab, six composite samples of eel, five composite samples of striped bass, and two composite samples of white perch were included for quantitative evaluation in the HHRA.

Edible tissue (filet only) samples were analyzed to assess potential human health risks associated with ingestion of striped bass, white perch, and eel. For blue crab, edible portion samples and hepatopancreas samples were analyzed separately and combined to estimate human health risks. The hepatopancreas is a main component of a crab's digestive system. It functions as both the liver and pancreas for the crab, and is involved in producing digestive enzymes and is responsible for filtering impurities from the crab's blood. Some chemicals, such as PCBs and mercury, accumulate in the hepatopancreas. May and Burger (1996) reported that most crabbers in the Newark Bay Complex eat only cleaned crabs, and discard the hepatopancreas, with fewer than 3 percent of those surveyed eating the whole crab. The New Jersey Department of Environmental Protection (NJDEP) (2002) reported that 15 percent of the population surveyed in the Newark Bay Complex ate the hepatopancreas. It is possible that an individual may be exposed to the hepatopancreas during cooking unless actions are taken to remove the hepatopancreas from the crab prior to cooking. Based on the NJDEP report (NJDEP, 2002) and the potential for the hepatopancreas to be released during cooking, an individual may be exposed to both crab edible tissue and hepatopancreas. Therefore, the risk evaluation considered exposures to both the edible tissue and the hepatopancreas as the RME scenario. Risks from ingestion of the edible tissue only are discussed in the Uncertainty Assessment.

4.2 Data Evaluation

All of the data included in the risk assessment were evaluated to assess their reliability for use in the quantitative risk assessment. The following criteria were used to assess data usability:

- Estimated values flagged with a J or NJ qualifier were treated as unqualified detected concentrations.
- Data qualified with an R (rejected) were not used in the risk assessment.
- Data qualified with a B (blank contamination) were used in the risk assessment as if the constituents were not detected.
- For duplicate samples, the maximum concentration between the two samples was used as the sample concentration.

- Only the detected congeners were used to calculate the total PCB concentrations for each sample. Undetected congeners and congeners qualified with a B were not included in the calculations (see Section 5.3.1).
- Nondetected values (for all analytes except PCBs) were included in the risk assessment and exposure concentration calculation at the detection limit using ProUCL (USEPA, 2010a).

4.3 Selection of COPCs

The identification of COPCs is shown in Tables 2.1 through 2.13 in the Attachment. The methodology used to select the COPCs for quantitative evaluation in the baseline HHRA is outlined below:

- Sediment data were compared to the USEPA Regional Screening Levels (RSLs) for residential exposure to soil (USEPA, 2010b). RSLs that are based on the chemical's noncarcinogenic effects (noted with an ''"N" next to the screening toxicity value on the COPC screening table) were divided by 10 to account for potential exposure to multiple constituents. RSLs that are based on carcinogenic effects (noted with a "C"'' next to the screening toxicity value on the COPC screening table) were used without adjustment because the target carcinogenic risk used in the RSL calculations is based on a 1 × 10–6 risk level. Constituents whose maximum detected concentration is below the screening level were not retained as COPCs. As discussed in Section 4.1.1, sediment samples were analyzed for both Aroclors and PCB congeners. Only the PCB congener data were evaluated in the risk assessment so that the risks associated with PCBs would not be double-counted in the HHRA. In accordance with EPA guidance (USEPA, 1996) for PCB congener analysis, the "dioxin-like" PCB toxicity equivalent (TEQ) concentration, the "non-dioxin-like" total PCB concentration, and the total PCB concentration were calculated for each sample using the methods discussed in Section 5.3.1. The dioxin-like PCB TEQ concentration was screened against the 2,3,7,8-TCDD RSL (which was re-calculated from the value on the RSL table using the 2,3,7,8-TCDD oral cancer slope factor from USEPA, 1995), the non-dioxin-like PCB concentration was screened against the Aroclor-1260 RSL, and the total PCB concentration was screened against the Aroclor-1254 RSL.
- Surface water data were compared to the USEPA tap water RSLs (USEPA, 2010b). RSLs that are based on the chemical's noncarcinogenic effects were divided by 10 to account for potential exposure to multiple constituents. RSLs that are based on carcinogenic effects were used without adjustment because the target carcinogenic risk used in the RSL calculations is based on a 1 ×10–6 risk level. Constituents whose maximum detected concentration is below the screening value were not retained as COPCs.
- Fish tissue and crab sample data were compared to the USEPA Region 3 fish ingestion RSLs (USEPA Region 3, 2010c). RSLs that are based on noncarcinogenic effects were divided by 10 to account for exposure to multiple constituents. RSLs that are based on carcinogenic effects were used without adjustment. Constituents whose maximum detected concentrations are below the screening level were not retained as COPCs. In accordance with USEPA guidance (USEPA, 1996) for PCB congener analysis, the "dioxin-like" PCB TEQ concentration, the "non-dioxin-like" total PCB concentration,

and the total PCB concentration were calculated for each sample using the methods discussed in Section 5.3.1. The dioxin-like PCB TEQ concentration was screened against the 2,3,7,8-TCDD RSL (which was re-calculated from the value on the RSL table using the 2,3,7,8-TCDD oral cancer slope factor from USEPA, 1995), the non-dioxin-like PCB concentration was screened against the Aroclor-1260 RSL, and the total PCB concentration was screened against the Aroclor-1254 RSL.

- Air data were compared to the USEPA resident air RSLs (USEPA, 2010b). RSLs that are based on noncarcinogenic effects were divided by 10 to account for exposure to multiple constituents. RSLs that are based on carcinogenic effects were used without adjustment. Constituents whose maximum detected concentrations are below the screening level were not retained as COPCs.
- Essential human nutrients (calcium, magnesium, potassium, and sodium) that are toxic at concentrations significantly higher than those found in canal media, and whose concentrations in canal media are only slightly higher than the concentrations at which they occur naturally, were not retained as COPCs.
- Lead concentrations less than 0.015 mg/L in surface water (the Safe Drinking Water Act action level for lead in potable water) and less than 400 mg/kg in sediment (USEPA, 1994b) are considered adequately protective of human health under residential land-use conditions. Lead was retained as a COPC when exceeding these values. Lead was not detected in fish tissue.
- Constituents that were detected in less than 5 percent of the samples were not retained as COPCs (USEPA, 1989).
- Detected constituents classified as USEPA Class A carcinogens (known human carcinogens) were retained as COPCs for evaluation regardless of the comparison of the concentration to the screening level (USEPA, 1989).
- For constituents detected in canal samples that do not have established USEPA RSLs, the RSL values for surrogate constituents were selected based on guidance from the Superfund Technical Support Center and used in the COPC screening process.

4.4 Constituents of Potential Concern

Table 4-2 lists the chemicals that were identified as COPCs for site media:

- Surface sediment (exposed and near-shore)—11 PAHs [acenaphthene, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, chrysene, dibenz(a,h)anthracene, fluoranthene, indeno(1,2,3-cd)pyrene, naphthalene, and pyrene], one additional SVOC [bis(2-ethylhexyl)phthalate], PCBs, and 10 metals (aluminum, arsenic, cadmium, chromium, cobalt, copper, iron, lead, manganese, and vanadium).
- Surface sediment (overflow scenario)—the chemicals indicated above (exposed and near-shore) plus one additional PAH (fluorene).
- Surface water (dry event)—one VOC (benzene), four PAHs [benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene , and indeno(1,2,3-cd)pyrene], one additional

SVOC [bis(2-ethylhexyl)phthalate], and four metals (arsenic, chromium, copper, and selenium).

- Surface water (wet event and overflow)—the chemicals indicated above (dry event) plus four additional VOCs (1,4-dichlorobenzene, chloroform, ethylbenzene, and tetrachloroethene), two additional PAHs [dibenz(a,h)anthracene and naphthalene] , two additional metals (cobalt and lead), and one less metal (copper).
- Ambient air (street level)—benzene, chloroform, ethylbenzene and naphthalene.
- Ambient air (canal level)—the chemicals indicated above (street level) plus xylene.
- Fish tissue (striped bass)—two pesticides (p,p'-DDE and p,p'-DDT), PCBs, and three metals (arsenic, mercury, and selenium).
- Fish tissue (white perch)—PCBs and two metals (mercury and selenium)
- Fish tissue (eel)—six pesticides (alpha-chlordane, gamma-chlordane, dieldrin, p,p'-DDD, p,p'-DDE, and p,p'-DDT), PCBs, and six metals (arsenic, chromium, copper, cyanide. mercury, and selenium).
- Blue crab—five PAHs (benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, dibenz(a,h)anthracene, and indeno(1,2,3-cd)pyrene), PCBs, and three metals (arsenic, copper, and mercury).

SECTION 5

Exposure Assessment

Exposure assessment is the estimation of the likelihood, magnitude, frequency, duration, and routes of potential exposure to a chemical. Exposure refers to the potential contact of an individual (or receptor) with a chemical. Exposure can occur when contaminants migrate from a source to an exposure point, or when a receptor comes into direct contact with contaminated media.

The components of exposure assessment include the following:

- Characterization of exposure setting
- Identification of exposure pathways, and evaluation of whether they are complete
- Quantification of exposure

5.1 Characterization of Exposure Setting

Characterization of exposure setting consists of two parts: (1) characterization of the site with respect to its physical characteristics and (2) characterization of the site with respect to human populations at or near the site.

5.1.1 Physical Setting

The physical setting is described in the Section 2, the CSM. The Gowanus Canal is a 1.8-mile-long canal located in the New York City borough of Brooklyn, Kings County, New York. The canal borders several residential neighborhoods including Red Hook, Cobble Hill, Carroll Gardens, and Park Slope. The waterfront properties abutting the canal are primarily commercial and industrial.

The Gowanus Canal is a tidally influenced dead-end channel that opens to Gowanus Bay and Upper New York Bay. The canal experiences a semidiurnal tidal cycle (i.e., two high tides and two low tides each tidal day). The entire canal is classified as a saline tributary to Upper New York Bay, and the reach between the head of the canal and 22nd Street is classified as a "minor river, tidal tributary," according to Title 6 of the New York Code of Rules and Regulations, Chapter X, Part 890. The only freshwater inflows to the canal are wet-weather CSO and stormwater discharges. Because of its narrow width, limited freshwater input, and enclosed upper end, the canal has low current speeds and limited tidal exchange with Gowanus Bay, though these are enhanced by additional circulation from the flushing tunnel when it is operating (NYCDEP, 2008).

5.1.2 Potentially Exposed Populations

As discussed above, the area around the Gowanus Canal consists of industrial, commercial, and residential properties. The Gowanus Canal itself may be used for recreational activities such as boating, swimming/diving, fishing, and crabbing (Gowanus Dredgers Canoe Club, 2010; New York Times, 2007; The Gowanus Lounge, 2007). Despite current fish advisories for the Upper New York Bay, which includes the Gowanus Canal, there have been observations of fishing/crabbing along the canal (The Gowanus Lounge, 2007). Although

most properties abutting the canal are commercial and industrial, there are residential neighborhoods within a few blocks of the canal. Therefore, potential current receptors for the surface water, sediment, air, and/or fish and crabs include recreationalists, anglers (and their families), local residents, and industrial workers. Table 1 in the Attachment identifies the potential receptors.

Future use of the canal and use of the surrounding area will likely remain the same as current use. Additionally, there have been discussions concerning construction of residential housing complexes adjacent to the canal. Therefore, the future potentially exposed populations are assumed to be the same as the current potentially exposed populations.

5.2 Identification of Exposure Pathways

An exposure pathway may be described as the physical course that a COPC takes from the point of release to a receptor. To be complete, an exposure pathway must have all of the following components present:

- A source
- A mechanism of a chemical release and transport
- An environmental transport medium
- An exposure point (receptor location)
- An exposure route (inhalation, dermal absorption, ingestion)
- A receptor or exposed population

In the absence of any one of these components, an exposure pathway is considered incomplete and, by definition, there is no risk or hazard. In some cases, a receptor may contact a source directly, eliminating the release and transport pathway.

The potential exposure pathways for Gowanus Canal are identified in the preliminary CSM (Figure 2-1) and Table 1 in the Attachment.

5.2.1 Contaminant Sources

The potential contaminant sources are identified in the preliminary CSM, in Section 2, and include past use of the areas abutting the canal by gas works, coal yards, manufacturers of cement, manufacturers of soap, tanneries, paint and ink factories, machine shops, chemical plants, and oil refineries. The canal was also used as a repository of untreated industrial wastes, raw sewage, and surface water runoff for many decades.

5.2.2 Release and Transport Mechanisms

The primary contaminant release and transport mechanism at the Gowanus Canal site appears to be the discharge from past industrial activities into the canal surface water, accumulation in the sediment, and bioaccumulation into fish and crabs. The transport pathway from emissions from surface water and sediment to ambient air will be evaluated in the risk assessment using the ambient air data collected along the canal. Additionally, the canal has been known to overflow during heavy precipitation events, resulting in transport of surface water and sediment out of the canal onto properties and streets adjacent to the canal. The surface water and sediment remains on the properties and streets adjacent to the canal only for short periods of time during the overflow and flooding events.

5.2.3 Exposure Points and Exposure Routes

Potential exposure points include the surface water and sediment within the canal, surface water and sediment temporarily deposited on properties adjacent to the canal when the canal overflows its banks during heavy precipitation events, ambient air at canal level and street level adjacent to the canal, and fish and crab caught in the canal. Table 1 in the Attachment lists all of the potential exposure pathways that were considered for evaluation in the risk assessment.

5.2.4 Summary of Potential Exposure Pathways

In summary, the potential pathways that were evaluated under the current/future land use scenario include the following:

- Adult, adolescent (12–18 years old), and child (1–6 years old) recreational: incidental ingestion and dermal contact with canal surface water (during both wet- and dry-sampling events); incidental ingestion and dermal contact with exposed and near-shore sediment in the canal; inhalation of ambient air at canal level (both before and during aeration system operation).
- Adult and adolescent (12–18 years old) angler and child (1–6 years old) of angler: ingestion of fish (striped bass, white perch, and eel) and crab caught in the canal.
- Adult and child (1–6 years) residents: inhalation of ambient air at street level (both before and during aeration system operation); incidental ingestion and dermal contact with canal overflow surface water (using surface water collected during wet events); incidental ingestion and dermal contact with sediment deposited adjacent to the canal (using surface sediment data) during canal overflow events.
- Adult industrial worker: inhalation of ambient air at street level (both before and during aeration system operation); incidental ingestion and dermal contact with canal overflow surface water (using surface water collected during wet events); incidental ingestion and dermal contact with sediment deposited adjacent to the canal (using surface sediment data) during canal overflow events.

5.3 Quantification of Exposure

Quantification of exposure involves estimating the exposure point concentration (EPC) and chemical intake.

5.3.1 Exposure Concentrations

The EPC is the estimated concentration at the point of contact. EPCs may be measured directly (i.e., surface water concentration) or calculated using fate and transport models. No fate and transport modeling was conducted for the Gowanus Canal risk assessment since data were collected at potential exposure points.

The EPCs for each COPC were calculated as the 95 percent upper confidence limit (UCL) of the mean concentration. The maximum detected concentration was used in place of the UCL as the EPC when the calculated UCL was greater than the maximum detected value or less than eight samples were available for the data grouping.

ProUCL, Version 4.00.05 (USEPA, 2010a), was used to calculate the UCLs and determine the data distribution. The data distribution identified was used to compute the most appropriate UCL for that specific data set. The recommendations in the ProUCL output file and outlined in the ProUCL model documentation were used to select the appropriate UCL.

In accordance with USEPA guidance (USEPA, 1996), EPCs were calculated separately for each medium (sediment and fish tissue) and data groupings for which PCB congeners were analyzed for (1) "dioxin-like" PCB TEQ concentrations, (2) "non-dioxin-like" total PCB concentrations, and (3) total PCB concentrations. These three concentrations were calculated for each sample using the methods discussed below. The concentrations were calculated using only the detected PCB congeners in each sample. Nondetected congeners and B-flagged congeners were not included in the individual sample sums. The calculations are included in Tables 2.8 Supplement A, 2.11 Supplement A, and 2.12 Supplement A in the Attachment for fish and crab, and for sediment, respectively. Detection limits are not shown on these tables for all of the dioxin congeners. The reporting limits are unreliable because during data validation the reporting limits were not provided correctly if the sample was reanalyzed or diluted. Appendix H presents the data quality evaluation. The uncertainties associated with the EPC calculation approach for PCBs are discussed in Section 8.

TEQ concentrations for "dioxin-like" PCBs were calculated for each sample in accordance with the World Health Organization (WHO) toxicity equivalency factor (TEF) approach (USEPA, 2010d). The purpose of using the WHO TEF approach is to adjust the relative carcinogenic potency of specific dioxin-like PCB congeners relative to 2,3,7,8-tetrachlorodibenzo-p-dioxin (2,3,7,8-TCDD), the most potent dioxin congener. TEFs are published by WHO for mammals (including humans), fish, and wildlife. PCB TEQs were calculated using the mammal TEFs. Using the measured concentration values for each congener and the TEF for that congener, the TEQ for a mixture of PCB congeners in a specific sample is calculated as follows:

$$TEQ = \Sigma\ (TEFi \times Ci)$$

where:

TEFi = Toxicity equivalency factor for congener *i*
Ci = Concentration of congener *i*

Risks from the calculated dioxin-like PCB TEQ are therefore based on the toxicity factors for 2,3,7,8-TCDD. The TEFs used to calculate the dioxin-like PCB TEQ concentrations are provided in Table 5-1. Although there are also noncancer toxicity factors for 2,3,7,8-TCDD, there is greater uncertainty associated with evaluating the noncancer risk for the dioxin-like PCB TEQ concentrations using these values. Therefore, the evaluation of noncancer hazards associated with the dioxin-like PCB TEQ concentrations is presented in the uncertainty evaluation (Section 8).

The non-dioxin-like PCB concentrations (the sum of all detected non-dioxin-like PCB congeners) were also calculated and evaluated for carcinogenic risks using carcinogenic toxicity factors for total PCBs. The total PCB concentrations (the sum of all detected PCB congeners, not adjusted using TEFs) were also calculated for each sample and were used to evaluate noncarcinogenic effects.

Most arsenic present in fish and crab tissue is present in the organic form of arsenic (organoarsenical compounds), which is relatively nontoxic to humans and is excreted rapidly and unchanged in urine (U.S. Food and Drug Administration [FDA], 1993; ATSDR, 2007). Some regulatory agencies (for example, FDA) regulate arsenic in fish based on a default but conservative assumption that 10 percent of the total arsenic in fish tissue is potentially in the toxic (carcinogenic) form. Therefore, for this HHRA, it was assumed that 10 percent of the measured total arsenic in fish and crab tissue was in the inorganic form of arsenic. To account for this adjustment, the EPCs for arsenic used in the intake calculations are 10 percent of the total measured arsenic concentrations. The total measured arsenic concentrations are shown in Tables 3.8 through 3.11 in the Attachment, while 10 percent of the total measured values are shown in the Tables 7.8.RME through 7.10.RME and 7.7.CTE through 7.9.CTE in the Attachment.

5.3.2 Estimation of Chemical Intakes

The quantification of exposure is based on an estimate of the chronic daily intake (CDI), the average amount of the chemical contaminant entering the receptor's body per day. Chemical intake estimates for the ingestion and dermal exposure pathways are generally expressed as follows:

$$CDI = \frac{C \times CR \times EF \times ED}{BW \times AT}$$

Where:

CDI = chronic daily intake (mg/kg-day)
C = chemical concentration (mg/L, mg/kg)
CR = contact rate (L/day, mg/day)
EF = exposure frequency (days/year)
ED = exposure duration (years)
BW = body weight (kg)
AT = averaging time (days)

For the dermal pathway, the contact rate usually incorporates the skin surface area in contact with the exposure medium (water or sediment), and an absorption factor. The intake equation for the dermal exposure pathway is shown in the Attachment, Tables 4.1 (RME and CTE) and 4.5 (RME and CTE) for sediment and Tables 4.2 (RME and CTE) and 4.6 (RME and CTE) for surface water.

Chemical exposure estimates for the inhalation pathway are generally expressed as follows:

$$EC = \frac{Ca \times ET \times EF \times ED \times CF}{AT}$$

Where:

EC = exposure concentration (mg/m^3)
Ca = chemical concentration in air (mg/m^3)
ET = exposure time (hours/day)
EF = exposure frequency (days/year)
ED = exposure duration (years)
CF = conversion factor (day/24 hours)
AT = averaging time (days)

The intake and exposure equations require exposure parameters that are specific to each exposure pathway. Many of the exposure parameters have default values, which were used for this assessment. These assumptions, based on estimates of body weights, media intake levels, and exposure frequencies and duration, are provided in USEPA guidance. Other assumptions (e.g., for the recreational scenarios) require consideration of location-specific information and were determined using professional judgment. Tables 4.1.RME through 4.6.RME in the Attachment present the exposure parameters that were used for the exposure scenarios that were evaluated in the risk assessment. RME scenario exposure parameters were compiled for all scenarios; central tendency exposure (CTE) parameters were compiled only for scenarios where the RME risk for an environmental medium is greater than 'USEPA's noncarcinogenic hazard or carcinogenic risk target levels (target organ-specific hazard index (HI) >1.0, and excess lifetime cancer risk (ELCR) >1 × 10^{-4}). The exposure parameters selected for each receptor are discussed below.

For the fish consumption evaluation, the fish ingestion rate for each of the species of fish evaluated was adjusted to a percentage of the total fish ingestion rate assumed, as reported in literature for the State of New York. The percentage of ingestion of each fish type was obtained from the 1991 New York State Angler Report (Connelly et al., 1992). It was assumed that eel represent bottom feeders with 44 percent of the total fish consumption, striped bass represent the intermediate level with 47 percent consumption, and white perch represent the remaining 9 percent. A 100 percent crab ingestion rate was assumed for blue crab. Burger (2002) found that individuals typically consumed either fish or crabs, and that those who did consume both fish and crabs had lower consumptions of each. Therefore, the total noncarcinogenic hazards and carcinogenic risks were not combined for consumption of both fish and crabs.

For the fish and crab ingestion scenarios, an additional exposure parameter was used in the CDI calculation (USEPA, 2000) for the CTE scenario. During cooking and fish preparation, concentrations of some lipophilic contaminants decrease. Therefore, if appropriate for the COPC, a preparation/cooking loss factor (PCF) was applied to the equation for the CTE assessment.

Appendix C of USEPA's *Guidance for Assessment Chemical Contaminant Data for Use in Fish Advisories, Volume 2: Risk Assessment and Consumption Limits* (USEPA, 2000) summarizes many of the studies that have evaluated loss of PCBs and pesticides from fish during food preparation and cooking. A review of the available literature found the results range considerably, both between various cooking methods and within the same method. Cooking losses, expressed as percent loss based on total PCB mass before and after cooking, as high as 74 percent were reported in one study (Skea et al., 1979). Other studies reported net gains of PCBs (Moya et al., 1998; Armbruster et al., 1987). PCB losses from cooking may be a function of the cooking method (baking, frying, broiling, etc.), cooking duration, temperature during cooking, preparation techniques (i.e., trimmed vs. untrimmed, with or without skin), lipid content of the fish, the fish species, magnitude of the PCB contamination in the raw fish, the extent to which lipids separated during cooking are consumed, reporting method, and/or the experimental study design. Personal preferences for various preparation and cooking methods and other related habits (such as consuming pan drippings) may result in consumption of PCBs "lost" from the fish upon cooking.

A review of literature found that PCB cooking losses may range from 0 to 74 percent. Despite the wide range of cooking loss estimates, most PCB losses were between 10 and 40 percent. A value of 20 percent (midpoint of 0 – 40 percent) was selected as the CTE estimate for cooking loss. For the RME, a cooking loss factor was not used to include the possibility that pan drippings are consumed along with the fish. Table 5-2 identifies the PCFs used for the CTE evaluation.

Recreational Adult, Adolescent, and Child

The recreational adult, adolescent (ages 12–18), and child (ages 1–6) are individuals who may use the canal for boating, fishing, crabbing, or—although unlikely—swimming/diving and be exposed to the surface water, sediment, and air at canal level. It is assumed that the RME recreational user would engage in recreational activities in the canal for 1 day per week for one-half of the year, from May through October (26 days/year). For estimating the exposure to the surface water and sediment during recreational activities, swimming was assumed. It was assumed that the RME recreational user would be exposed to surface water and sediment for 2.6 hours during each exposure, the national average time spent swimming per swimming event (USEPA, 1989). It was assumed that the RME ingestion rate of sediment during swimming would be 50 percent of the resident ingestion rate of soil (50 mg/day for adults and adolescents and 100 mg/day for children [USEPA, 1991]). The RME ingestion rate of surface water was assumed to equal 0.05 L/day, the surface water ingestion rate for swimming activities (USEPA, 1989). For dermal exposure to sediment, it was assumed that the head, hands, forearms, lower legs, and feet could come into contact with the sediment (i.e., skin surface areas of 6,925 cm^2 [adult], 10,470 cm^2 [adolescent; includes full arms and legs since information was not available for this age group for forearms and lower legs alone], and 2,800 cm^2 [child] [USEPA, 2004]). A sediment-to-skin adherence factor of 0.3 cm^2, the average adherence factor for reed gatherers (USEPA, 2004), was selected for the adult, and a sediment-to-skin adherence factor of 0.2 cm^2, the average adherence factor for children in wet soil (USEPA, 2004), was selected for the adolescent and child. For surface water, it was assumed the full body (18,000 cm^2 [adult], 15,758 cm^2 [adolescent], and 6,600 cm^2 [child] [USEPA, 2004]) would be exposed. The default exposure durations of 24 years (adult), 6 years (adolescent ages 12–18), and 6 years (child ages 1–6) and default body weights of 70 kg (adult), 57 kg (mean body weight of girls and boys ages 12–18), and 15 kg (child ages 1–6) were used for exposure to all media.

For the CTE scenarios, the exposure frequency was assumed to be one-half of the RME exposure frequency (or 1 day every other week for one-half of the year). It was assumed that the CTE recreational user would be exposed to the surface water and sediment for one-half of the RME exposure time, or 1.3 hours during each exposure. It was also assumed that the ingestion rates of sediment and surface water would be half the RME values, or 25 mg/day for adults and adolescents and 50 mg/day for children for sediment, and 0.025 L/day for all recreational receptors for surface water. The CTE skin surface areas for exposure to surface water and sediment, and the sediment-to-skin adherence factors were assumed to be the same as the RME values. The total CTE exposure duration for the recreational receptor was assumed to be 9 years (USEPA, 1997), the 50th percentile value for living at one residence, therefore, for each of the receptors (adult, adolescent, and child) the exposure duration was assumed to be 3years. The default body weights of 70 kg (adult), 57 kg (mean body weight

of girls and boys from 12–18), and 15 kg (child ages 1–6) were used to evaluate CTE exposure to all media.

Adult Angler

It was assumed the adult angler would ingest the fish or crabs they catch in the canal. There is not a lot of published literature concerning ingestion rates of self-caught crabs. Burger (2002) reported results of an angler study for fish and crabs in the Newark Bay Complex, and has estimated a yearly consumption rate for self-caught crab by multiplying the number of crab meals eaten per month by the number of crabs eaten at each meal by the number of months per year crabs are caught. Burger assumed the average size of one crab is 70 g. In the Burger (2002) study, it was noted that most of the people interviewed mainly fished or mainly crabbed, and that more than 30 percent of the people who fished and crabbed in the Newark Bay Complex did not eat their catch. People reported crabbing for only 3 months of the year, which is why data from only the 3-month period were used to calculate the annual ingestion rate. This may underestimate the risks and hazards associated with crab ingestion if crabs are actually caught in the canal and eaten for longer than 3 months a year. The yearly consumption rate of self-caught crab estimated from Burger (2002) is 5,760 grams (g), or 16 g/day. A 95% UCL of the yearly consumption value was estimated on the basis of this to be 23 g/day, and an average yearly consumption value was estimated to be 16 g/day. The 95% UCL value was used for the RME scenario for crab ingestion, and the average value was used for the CTE scenario.

Burger (2002) also presented a yearly consumption rate of self-caught fish (based on the Newark Bay Complex study) of 8,210 g, or 22 g/day. This is similar to the value of 26 g/day, the 95th percentile recreational freshwater angler's fish ingestion rate, in the *Exposure Factors Handbook* (USEPA, 1997) and is also similar to the 1991 New York State Angler Survey derived rate of 31.9 g/day (Connelly et al., 1992). The fish ingestion rate of 26 g/day (USEPA, 1997) was used for an RME adult. The mean recreational freshwater angler's fish ingestion rate of 8 g/day (USEPA, 1997) was used for the CTE adult angler.

Adolescent Angler

It was assumed that the adolescent angler, ages 12–18 years, would fish or crab in the canal and ingest the fish and crabs caught in the canal. In addition to eating the fish or crab caught by an adult family member, several studies have found that children begin fishing at approximately 10 years of age (Connelly et al., 1992). There is not a lot of published literature concerning ingestion rates of self-caught crabs by adults, and even less for children. Therefore, the fish ingestion rate for the adolescent was estimated assuming that the intake for an adolescent is about two-thirds of that of an adult. This approach yields ingestion rates generally consistent with the limited information provided in USEPA's *Exposure Factors Handbook* (USEPA, 1997). For adolescents ages 10-19 years, the 95th percentile intake is 26.8 g/day (USEPA, 1997), which is comparable with the 17 g/day used in the HHRA for adolescents ages 12-18 years. The RME ingestion rate of crabs by adolescents was assumed to be 15 g/day (two-thirds the adult rate).. Similarly, the CTE ingestion rate of fish by adolescents was assumed to be 5.3 g/day, and the CTE ingestion rate of crabs by adolescents was assumed to be 10.7 g/day.

Child of Angler

It was assumed that the child (ages 1–6 years) of an angler would ingest the fish and crabs caught by a parent/relative in the canal. There is not a lot of published literature concerning ingestion rates of self-caught crabs by adults, and even less for children. However, based on information presented in USEPA's *Exposure Factors Handbook* (USEPA, 1997) for fish ingestion rates for children, children ingest about one-third the amount of fish that adults ingest. This approach yields ingestion rates generally consistent with the limited information provided in USEPA *Exposure Factors Handbook* (USEPA, 1997). According to Table 10-1 of the *Exposure Factors Handbook* (USEPA, 1997), the 95th percentile intake for children ages 0-9 years is 16.5 g/day, compared to the RME value used in the HHRA of 9 g/day for children ages 1-6 years. The RME ingestion rate of crabs by children was assumed to be 8 g/day. Similarly, the CTE ingestion rate of fish by children was assumed to be 2.7 g/day and the CTE ingestion rate of crabs by children was assumed to be 5.3 g/day.

Industrial Adult

The industrial adult is an individual who works near the canal and may be exposed to ambient air (collected at street-level stations) 250 days/year, 8 hours/day. This industrial adult may also be exposed to canal overflow surface water and sediment. It was conservatively assumed that the canal overflows three times per year and remains in overflow conditions 3 days during each overflow event, for a total of 9 days per year of exposure to the overflowed surface water and surface sediment. It is assumed that the adult industrial worker could be exposed to the overflow water and sediment 8 hours/day during these 9 days. It was assumed that the ingestion rate of the canal overflow sediment would be equal to the adult industrial worker ingestion rate of soil, or 100 mg/day (USEPA, 2002). The ingestion rate of surface water was conservatively assumed to equal 0.05 L/day, the ingestion rate of surface water for swimming activities (USEPA, 1989). For dermal exposure to sediment, it was assumed that the head, hands, and forearms could come into contact with the sediment, for a surface area of 3,300 cm^2 (USEPA, 2004). For dermal exposure to surface water, it was assumed the head, hands, forearms, and lower legs could come into contact with the surface water, for a surface area of 5,700 cm^2 (USEPA, 2004). A sediment-to-skin adherence factor of 0.2 cm^2, the soil adherence factor for industrial workers (Exhibit 3-5 in USEPA, 2004), was selected. The default exposure duration of 25 years for an adult industrial worker and default body weight of 70 kg were used for exposure to media.

Residential Adult and Child

The residential adult and child are individuals who live near the canal and may be exposed to ambient air (collected at street-level stations) 350 days/year, 24 hours/day (RME scenario). This resident may also be exposed to canal overflow surface water and sediment. It was conservatively assumed that the canal overflows three times per year and remains in overflow conditions 3 days during each overflow event, for a total of 9 days per year of exposure to the overflowed surface water and surface sediment. It was assumed the RME ingestion rate of the canal overflow sediment would be equal to the resident ingestion rates of soil (100 mg/day [adult] and 200 mg/day [child] [USEPA, 2002]). The RME ingestion rate of surface water was assumed to equal 0.05 L/day, the surface water ingestion rate for exposure scenarios involving swimming activities (USEPA, 1989), and the RME exposure time for exposure to the surface water was assumed to equal 2.6 hours during each exposure, the national average time spent swimming per swimming event (USEPA, 1989).

For dermal exposure to sediment and the surface water, it was assumed that the head, hands, forearms, and lower legs could come into contact with the sediment, for a surface area of 5,700 cm^2 (adult) and 2,800 cm^2 (child, including feet) (USEPA, 2004). A sediment-to-skin adherence factor of 0.2 cm^2, the average adherence factor for children in wet soil (USEPA, 2004), was selected. Default exposure durations of 24 years (adult) and 6 years (child) and default body weights of 70 kg (adult) and 15 kg (child) were used for exposure to all media.

For the CTE scenario, it was assumed the residential receptors would be exposed to ambient air 234 days/year (USEPA, 1993). It was assumed that the CTE resident would be exposed to the surface water for one-half of the RME exposure time, or 1.3 hours during each exposure. It was also assumed that the ingestion rates of sediment and surface water would be one-half the RME value, or 50 mg/day for adults 100 mg/day for children for sediment, and 0.025 L/day for both adults and children for surface water. The CTE skin surface areas for exposure to surface water and sediment and the sediment-to-skin adherence factors were assumed to be the same as the RME values. The CTE exposure duration for the residential receptor was assumed to be 9 years (USEPA, 1997), the 50^{th} percentile value for living at one residence; therefore, the CTE exposure duration for the adult was assumed to be 3 years and the CTE exposure duration for the child was assumed to be 6 years, for a total residential exposure duration of 9 years. The default body weights of 70 kg (adult), and 15 kg (child ages 1–6) were used to evaluate CTE exposure to all media.

SECTION 6

Toxicity Assessment

Toxicity assessment defines the relationship between the magnitude of exposure and possible severity of adverse effects, and it weighs the quality of available toxicological evidence. Toxicity assessment generally consists of two steps: hazard identification and dose-response assessment. Hazard identification is the process of determining the potential adverse effects from exposure to the chemical and the type of health effect involved. Dose-response assessment is the process of quantitatively evaluating the toxicity information and characterizing the relationship between the dose of the constituent administered or received and the incidence of adverse health effects in the exposed population. Toxicity criteria (e.g., reference doses [RfDs], inhalation reference concentrations [RfCs], cancer slope factors [CSFs], and inhalation unit risk factors [IURs]) are derived from the dose-response relationship.

USEPA recommends that a tiered approach be used to obtain the toxicity values (RfDs, RfCs, CSFs, and IURs) that are used to estimate noncarcinogenic and carcinogenic risks (USEPA, 2003a). The hierarchy of toxicity value sources is the following:

1. Integrated Risk Information System (IRIS) (USEPA, 2010e)
2. Provisional Peer-Reviewed Toxicity Values (PPRTV)
3. Other USEPA and non-USEPA sources, including the National Center for Environmental Assessment (NCEA), Agency for Toxic Substances and Disease Registry (ATSDR), Health Effects Assessment Summary Tables (HEAST), California EPA (Cal EPA), and USEPA's Office of Water

The use in an HHRA of toxicity values from sources other than IRIS increases the uncertainty of the quantitative risk estimates. Some of the COPCs elicit both systemic (noncarcinogenic) toxic effects and cancer (carcinogenic) effects. Because of this, these constituents are evaluated as both noncarcinogens and carcinogens. The health risks for carcinogenic and noncarcinogenic effects were estimated separately based on different toxicity values.

Chromium is a COPC for sediment, surface water, and fish tissue (eel). It was assumed that all of the chromium detected in these media is hexavalent chromium, or Cr(VI), both for determining if chromium was a COPC (comparing the total chromium concentrations to the Cr(VI) RSLs) and for calculating the risks associated with exposure to chromium in these media. Cr(VI) is unstable in the body (in biological tissues) and is ultimately reduced to trivalent chromium, or Cr(III), by a variety of reducing agents, including ascorbate and glutathione (ATSDR, 2008; USEPA, 2010e). Cr(VI) exerts toxicity through direct contact mechanisms rather than bioaccumulation to a critical concentration in tissue. Therefore, all of the chromium detected in fish tissue samples is most likely Cr(III). However, the Cr(VI) toxicity values were used to evaluate the risks associated with chromium in fish tissue and all media. An RfD and RfC for Cr(VI) are available in IRIS; however, IRIS does not include a

CSF or IUR for CR(VI). The CSF for CR(VI) used in the HHRA is the same one included on the RSL Table (USEPA, 2010b) from NJDEP.

6.1 Toxicity Information for Noncarcinogenic Effects

Noncarcinogenic health effects include a variety of toxic effects on body systems, ranging from toxicity to the kidneys to central nervous system disorders. The toxicity of a chemical is assessed through a review of toxic effects noted in short-term (acute) animal studies, long-term (chronic) animal studies, and epidemiological investigations.

USEPA (1989) defines the chronic RfD as a dose that is likely to be without appreciable risk of deleterious effects during a lifetime of exposure. Chronic RfDs are specifically developed to be protective for long-term exposure to a chemical or compound (for example, 7 years to a lifetime), and consider uncertainty in the toxicological database and sensitive receptors. Chronic RfDs were used to evaluate noncarcinogenic risks to all receptors evaluated in the risk assessment.

In the development of RfDs, all available studies examining the toxicity of a chemical following exposure are considered on the basis of scientific merit. The lowest dose level at which an observed toxic effect occurs is identified as the lowest observed adverse effect level (LOAEL), and the dose at which no effect is observed is identified as the no observed adverse effect level (NOAEL). Several uncertainty factors (UFs) may be applied to account for uncertainties such as limited data, extrapolation of data from animal studies to human exposures, or the use of subchronic studies to develop chronic criteria. These UFs range from 10 to 10,000, and are based on professional judgment. Consequently, there are varying degrees of uncertainty in the toxicity criteria, which range from 1 to 3,000 for the COPCs identified for this site.

USEPA-derived oral RfDs and inhalation RfCs, and associated UF and modifying factor (MF) values, available for the COPCs are presented in Tables 5.1 and 5.2 in the Attachment. The RfD for Aroclor 1254 was used to estimate the noncarcinogenic effects associated with exposure to total PCBs.

Per USEPA guidance, oral RfDs were adjusted from administered dose (oral) to absorbed dose (dermal) to evaluate dermal toxicity. When appropriate, the RfDs were adjusted using oral absorption factors (USEPA, 2004). This adjustment is shown in Table 5.1 in the Attachment.

6.2 Toxicity Information for Carcinogenic Effects

Potential carcinogenic effects are quantified as CSFs or IURs that convert estimated exposures directly to incremental lifetime carcinogenic risks.

CSFs and IURs may be derived from the results of chronic animal bioassays, human epidemiological studies, or both. Animal bioassays are usually conducted at dose levels that are much higher than are likely to be encountered in the environment. This design detects possible adverse effects in the relatively small test populations used in the studies. The actual risks from exposure to a potential carcinogen are not likely to exceed the estimated risks and are probably much lower or even zero. USEPA-derived CSFs and IURs are presented in the Attachment, Tables 6.1 and 6.2. The CSF for 2,3,7,8-TCDD (dioxin) was

used to estimate the carcinogenic risks associated with the dioxin-like PCBs and the CSF for total PCBs was used to estimate the carcinogenic risks associated with the non-dioxin-like PCBs.As was done for oral RfDs, oral CSFs were adjusted from administered dose (oral) to absorbed dose (dermal) to evaluate dermal toxicity. When appropriate, the CSFs were adjusted using oral absorption factors (USEPA, 2004). This adjustment is shown in Table 6.1 in the Attachment. The IRIS toxicity profile for PCBs (USEPA, 2010e) presents a tiered approach for evaluating carcinogenic risks associated with exposure to PCBs. IRIS recommends that the first tier upper-bound CSF of 2.0 $(mg/kg\text{-}day)^{-1}$ be used to evaluate upper-bound risks estimates for exposures to PCBs through ingestion of fish and sediment, and dermal contact with sediment, and that the central-estimate of 1.0 $(mg/kg/day)^{-1}$ be used to evaluate cancer risks for the CTE estimate.

6.3 Approach for Potential Mutagenic Effects

For COPCs that act via a mutagenic mode of action (MMOA), cancer risks were estimated using age-dependent adjustment factors (ADAFs), as is consistent with cancer guidelines and supplemental guidance (USEPA, 2005a, b). Consistent with the Superfund guidance on MMOA (http://www.epa.gov/oswer/riskassessment/sghandbook/chemicals.htm), the carcinogenic PAHs are considered to act via a MMOA. Additionally, chromium is also categorized as a chemical with a MMOA (McCarrol, et al., 2010). The calculation of cancer risk using ADAFs is presented in Tables 7s of the Attachment. As chemical-specific data are not available for the carcinogenic PAHs or chromium, default ADAFs, as included in the USEPA Region 3 memorandum *Derivation of RBCs for Carcinogens That Act via a Mutagenic Mode of Action and Incorporate Default ADAFs* (USEPA, 2006), were used for the MMOA evaluation. The default ADAFs used to adjust the CSFs are 10 for 0-2 year olds, 3 for 2-6 year olds, 3 used for 6-12 year olds, and 1 for 16-30 year olds. The CSF was multiplied by the appropriate ADAF to derive the age-specific CSF for a receptor to calculate the total carcinogenic risk. Additionally, the exposure factors for children 0–2 years old and 2–6 years old were assumed to be the same as the parameters for a child 0–6 years old, with the exception of the exposure duration, which was instead 2 years and 4 years, respectively. The exposure factors for the adult residential receptor were used for residents 6–16 years old and 16–30 years old, with the exception of the exposure durations, which were 10 years and 14 years, respectively. For the adolescent receptors, the exposure factors for the adolescents 12-16 years old and 16-18 years old were assumed to be the same as the parameters for an adolescent 12-18 years old, with the exception of the exposure duration, which was 4 years and 2 years, respectively.

SECTION 7

Risk Characterization

Risk characterization combines the results of the previous elements of the risk assessment to evaluate the potential health risks associated with exposure to the COPCs. The risk characterization is then used as an integral component in risk management decision-making.

7.1 Methods for Estimating Risks

Potential human health risks are discussed independently for carcinogenic and noncarcinogenic effects because of the different toxicological endpoints, relevant exposure duration, and methods used to characterize risk. The methodology used to estimate noncarcinogenic hazards and carcinogenic risks are described below.

7.1.1 Noncarcinogenic Hazard Estimation

Noncarcinogenic health risks are estimated by comparing the calculated exposures to RfDs (or RfCs). The calculated intake divided by the RfD (or exposure concentration divided by the RfC) is equal to the hazard quotient (HQ):

$$HQ = Intake / RfD \text{ or } Exposure\ Concentration / RfC$$

The intake and RfD (or exposure concentration and RfC) represent the same exposure route (i.e., oral intakes are divided by oral RfDs, inhalation exposure concentrations are divided by inhalation RfCs). An HQ that exceeds 1.0 (i.e., intake exceeds the RfD) indicates that there is a potential for adverse health effects associated with exposure to that constituent.

To assess the potential for noncarcinogenic health effects posed by exposure to multiple constituents, an HI approach is used (USEPA, 1986). This approach assumes that noncarcinogenic hazards associated with exposure to more than one constituent are additive (HI = sum of the HQs). Synergistic or antagonistic interactions between constituents are not considered. The HI may exceed 1.0 even if all of the individual HQs are less than 1. HIs may be added across exposure routes to estimate the total noncarcinogenic health effects to a receptor posed by exposure through multiple routes. If the HI is greater than 1, separate HIs are estimated for each target organ to assess whether the HI for a specific target organ is greater than 1. A target-organ-specific HI greater than 1 indicates that there is some potential for adverse noncarcinogenic health effects associated with exposure to the COPCs, possibly warranting remedial action. If the HI for each target organ does not exceed 1, noncarcinogenic hazards are not expected.

7.1.2 Carcinogenic Risk Estimation

The potential for carcinogenic effects due to exposure to site-related constituents is evaluated by estimating the ELCR, which is the incremental increase in the probability of developing cancer during one's lifetime in addition to the probability of getting cancer associated with exposure to all non-site-related sources of carcinogens.

Carcinogenic risk is calculated by multiplying the intake by the CSF (or exposure concentration by the IUR).

$$ELCR = Intake \times CSF \quad \text{or} \quad Exposure\ Concentration \times IUR$$

The combined risk from exposure to multiple constituents was evaluated by adding the risks from individual constituents. Risks were also added across the exposure routes if an individual would be exposed through multiple routes.

As required under the NCP (USEPA, 1994a) "[f]or known or suspected carcinogens, acceptable exposure levels are generally concentration levels that represent an excess upper bound lifetime cancer risk to an individual of between 10^{-4} to 10^{-6} using information on the relationship between dose and response." When a cumulative carcinogenic risk to a receptor under the assumed RME exposure conditions exceeds 1 in 10 thousand (i.e., 10^{-4} ELCR), the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) generally requires remedial action to reduce risks at the site.

7.1.3 Lead

Lead concentrations less than 0.015 mg/L in surface water (the Safe Drinking Water Act action level for lead in potable water) and less than 400 mg/kg in sediment (USEPA, 1994b) are considered adequately protective of human health under residential land-use conditions. Lead concentrations less than 800 mg/kg in sediment are considered adequately protective of human health under industrial land-use conditions. Lead was retained as a COPC when exceeding the residential values. Lead was identified as a COPC for exposed and near-shore surface sediment, surface sediment for the overflow scenario, and surface water during the wet event. Lead does not have available published toxicity factors, and therefore potential risks associated with lead are evaluated differently than the other COPCs. The toxicity of lead is evaluated by USEPA based on blood-lead uptake using a physiologically based pharmacokinetic model called the Integrated Exposure Uptake Biokinetic (IEUBK) model.

The IEUBK model is used to evaluate lead exposure to children. An interim approach to assessing risks associated with adult exposures to lead was developed by USEPA's Technical Review Workgroup for Lead (USEPA, 2003b) and updated in 2005. This methodology is a variation of the IEUBK model. The adult lead methodology (ALM) is used to evaluate risks associated with nonresidential adult exposures to lead in soil (or sediment for this assessment). The model focuses on estimating fetal blood concentrations in women exposed to lead in soil (USEPA, 2003b). It was used in this risk evaluation to be protective of potentially sensitive receptors within the industrial worker population and recreational population that may be exposed to overflow sediment. Because the lead model is a probabilistic model, several of the USEPA default parameters are based on central tendency (i.e., average) values (USEPA, 2003b). Therefore, the arithmetic means for sediment concentration served as the input value for the soil (sediment) concentrations.

The exposure parameters used in the ALM for ingestion and exposure frequency are the same as those that were used to evaluate direct contact with overflow sediment by the industrial worker and direct contact with exposed and near-shore sediment by the recreational adult. The sediment ingestion rate of 100 mg/day and exposure frequency of 9 days/year was assumed for the adult industrial worker. For the recreational adult, a

sediment ingestion rate of 50 mg/day and an exposure frequency of 26 days/year were used.

The ALM uses different sets of geometric standard deviations (GSDs) and baseline blood lead levels based on different studies. The GSD is a measure of the inter-individual variability in blood lead concentrations in a population whose members are exposed to the same nonresidential environmental lead levels. The baseline blood lead concentration is intended to represent the best estimate of a reasonable central value of blood lead concentrations in women of child-bearing age that are not exposed to lead-contaminated nonresidential soil (sediment) or dust at the site (USEPA, 2003b, c). In this analysis, geometric means were used.

ALM spreadsheets provided by USEPA (version date June 21, 2009) were used to calculate blood lead concentrations for the industrial worker. The model results are expressed as the predicted geometric mean blood lead level for adults (that is, women of child-bearing age) and the corresponding 95th percentile fetal blood lead concentrations and the percent of the population potentially experiencing concentrations above 10 micrograms per deciliter (µg/dL), below which adverse manifestations are not expected.

The potential risks associated with residential/recreational exposures to lead are addressed using the IEUBK Lead Model for Windows, Version 1.1, Build 11 (USEPA, 1994c, 2010f). The IEUBK model was designed to provide predictions of the probability of elevated blood lead levels for children. This model addresses three components of environmental risk assessments: the multimedia nature of exposures to lead, lead pharmacokinetics, and significant variability in exposure and risk, through estimation of probability distributions of blood lead levels for children exposed to similar environmental concentrations. Although use of the IEUBK model to evaluate exposure to lead in the sediment and surface water for recreational and residential receptors is extremely conservative, there is currently no better method available. The arithmetic mean of the lead concentration in sediment and surface water was used with the default input parameters to represent site-specific exposures to lead.

7.2 Risk Assessment Results

The results of the risk characterization are presented below by receptor group. The risk estimates are calculated in the Attachment, Tables 7.1.RME through 7.10.RME and 7.1.CTE through 7.9.CTE, and summarized in the Attachment, Tables 9.1.RME through 9.10.RME and 9.1.CTE through 9.9.CTE. A summary of the RME results is shown in Table 7-1, and a summary of the CTE results is shown in Table7-2. CTE risks were calculated when the total RME HI to a receptor group exceeded 1.0 and/or the total RME ELCR exceeded 1×10^{-4}. The risk estimates for each receptor group are summarized below and compared to USEPA's target HI of 1 and target ELCR range of 1×10^{-6} to 1×10^{-4}. Noncarcinogenic hazards less than 1 are below USEPA's noncarcinogenic goal of protection of an HI of 1. Carcinogenic risks between or below 1×10^{-6} to 1×10^{-4} are within USEPA's acceptable carcinogenic risk levels.

Noncarcinogenic hazards and carcinogenic risks are calculated for each of the receptors. However, carcinogenic risks are combined for the adult, adolescent, and child to estimate the carcinogenic risks to the recreational user, angler, and resident.

7.2.1 Recreational Adults

Tables 9.1.RME and 9.1.CTE in the Attachment summarize the HIs (and ELCRs, which are discussed in Section 7.2.4) for recreational adult exposure to Gowanus Canal exposed and near-shore surface sediment, Gowanus Canal surface water, and air at canal level. The higher of the risks and hazards estimated for the two surface water scenarios and the two ambient air scenarios were included in the total estimated risks and hazards for the receptor group.

- Total HI (RME) = 0.2, below USEPA's target.
- Total HI (CTE) = 0.08, below USEPA's target.
- Lead was identified as a COPC for sediment and surface water (wet-weather event only). Exposure to lead in sediment was evaluated using the adult lead model. The model results are presented in Table 11.1 (Attachment). The mean sediment lead concentration of 660 mg/kg results in geometric mean blood levels ranging from 1.1 to 1.6 microgram per deciliter (µg/dL) for women of child-bearing age. The corresponding 95th percentile fetal blood lead levels range from 2.6 to 4.9 µg/dL. The probabilities that the fetal blood lead levels exceed 10 µg/dL range from 0.005 to 0.5 percent. These values are less than the blood lead goal as described in the 1994 OSWER Directive (USEPA, 1994b) of no more than 5 percent of children (fetuses of exposed women) exceeding 10 µg/dL blood lead.

7.2.2 Recreational Adolescents

Table 9.2.RME in the Attachment summarizes the HIs (and ELCRs, which are discussed in Section 7.2.4) for recreational adolescent exposure to Gowanus Canal exposed and near-shore surface sediment, Gowanus Canal surface water, and air at canal level. The higher of the risks and hazards estimated for the two surface water scenarios and the two ambient air scenarios were included in the total estimated risks and hazards for the receptor group.

- Total HI (RME) = 0.2, below USEPA's target.
- Total HI (CTE) = 0.1, below USEPA's target.
- Lead was identified as a COPC for sediment and surface water (wet-weather event only). Exposure to lead in sediment was evaluated using the adult lead model, as discussed for the recreational adults. The probabilities that the fetal blood lead levels exceed 10 µg/DL range from 0.005 to 0.5 percent, which is less than the blood lead goal as described in the 1994 OSWER Directive (USEPA, 1994b) of no more than 5 percent of children (fetuses of exposed women) exceeding 10 µg/dL blood lead.

7.2.3 Recreational Children

Tables 9.3.RME and 9.3.CTE in the Attachment summarize the HIs (and ELCRs, which are discussed in Section 7.2.4) for recreational child exposure to Gowanus Canal exposed and near-shore surface sediment, Gowanus Canal surface water, and air at canal level. The higher of the risks and hazards estimated for the two surface water scenarios and the two ambient air scenarios were included in the total estimated risks and hazards for the receptor group.

- Total HI (RME) = 0.5, below USEPA's target.
- Total HI (CTE) = 0.2, below USEPA's target.
- Lead was identified as a COPC for sediment and surface water (wet-weather event only). Site-specific lead exposures were evaluated for recreational children using the IEUBK model. This calculation was based on the site-specific arithmetic mean concentration of lead detected in the sediment (660 mg/kg) and surface water (13 mg/L). The results of the model, along with the probability distribution plot are presented in Table 11.2 in the Attachment. The predicted geometric mean blood lead level for a young child was 7.1 µg/dL, with 23 percent of the population potentially experiencing concentrations exceeding 10 µg/dL, below which adverse manifestations are not expected. These results indicate that if a child was exposed to the sediment and surface water at levels consistent with residential exposure to soil and potable use of surface water, the percent of the exposed population with a blood lead level exceeding 10 µg/dL would be above the 5 percent level that USEPA considers being protective of human health. However, it is unlikely that a child recreational receptor would be exposed to the sediment and surface water at the levels estimated in the IEUBK model, and it is more likely there would be no adverse effects associated with exposure to the lead.

7.2.4 Recreational Receptors – Lifetime Carcinogenic Risks

Carcinogenic risks were estimated for the combined lifetime (young child/ adolescent/adult) recreational receptor, following USEPA risk assessment methodology. The total carcinogenic risk to a recreational receptor was calculated by adding the risks calculated for the young child, adolescent, and adult. The RME carcinogenic risks are summarized in Table 7-4, the CTE carcinogenic risks are summarized in Table 7-5, and the risks are discussed below. The higher of the risks estimated for the two surface water scenarios and the two ambient air scenarios were included in the total estimated risks.

- Total ELCR (RME) = 1×10^{-3}, above USEPA's target risk range. The risk is associated primarily with exposure to surface water (7×10^{-4}) and sediment (7×10^{-4}), and the risk drivers are carcinogenic PAHs. The carcinogenic PAHs were highest in the surface water samples collected at sampling locations 319 and 325 during the dry-weather sampling event and locations 309 and 319 during the wet-weather sampling event. The carcinogenic PAHs were highest (10 times higher than the next highest detection) in sediment sample 314, at the head of the 6th Street basin (see Figure 2-3a in the RI), and were therefore associated primarily with this location. The concentrations of the PAHs in the canal surface water during both dry- and wet-weather events and in the sediment were statistically significantly greater than in the reference area (see Sections 4.3.2 and 4.4.5 of the RI)
- Exposed and Near Shore Sediment ELCR (RME) = 7×10^{-4}, above USEPA's target risk range
- Surface water, dry weather event ELCR (RME) = 6×10^{-4}, above USEPA's target risk range

- Surface water, wet weather event ELCR (RME) = 5×10^{-4}, above USEPA's target risk range
- Air at canal level, prior to aeration system operation ELCR (RME) = 4×10^{-7}, below USEPA's target risk range
- Air at canal level, after to aeration system operation started ELCR (RME) = 4×10^{-7}, below USEPA's target risk range
- Total ELCR (CTE) = 3×10^{-4}, above USEPA's target risk range
- Exposed and Near Shore Sediment ELCR (CTE) = 1×10^{-4}, above USEPA's target risk range
- Surface water, dry weather event ELCR (CTE) = 1×10^{-4}, above USEPA's target risk range
- Surface water, wet weather event ELCR (CTE) = 9×10^{-5}, within USEPA's target risk range

7.2.5 Industrial Workers

Table 9.4.RME in the Attachment summarizes the HIs and ELCRs for industrial worker exposures to ambient air at street level and surface water and sediment associated with canal overflow. The higher of the risks and hazards estimated for the two ambient air scenarios were included in the total estimated risks and hazards for the receptor group.

- Total HI (RME) = 0.8, below USEPA's target HI.
- Total ELCR (RME) = 8×10^{-5}, within USEPA's target risk range.
- Lead was identified as a COPC for sediment and surface water. Exposure to lead in sediment was evaluated using the adult lead model. The model results are presented in Table 11.3 of the Attachment. The mean sediment lead concentration of 533 mg/kg results in geometric mean blood levels ranging from 1.1 to 1.6 ug/dL for women of child-bearing age. The corresponding 95th percentile fetal blood lead levels range from 2.5 to 4.8 µg/dL. The probabilities that the fetal blood lead levels exceed 10 µg/DL range from 0.003 to 0.4 percent. These values are less than the blood lead goal as described in the 1994 OSWER Directive (USEPA, 1994b) of no more than 5 percent of children (fetuses of exposed women) exceeding 10 µg/dL blood lead.

7.2.6 Adult Residents

Tables 9.5.RME and 9.4.CTE, in the Attachment summarize the HIs for adult resident exposures to ambient air at street level and surface water and sediment associated with canal overflow. The higher of the hazards estimated for the two ambient air scenarios were included in the total estimated risks and hazards for the receptor group.

- Total HI (RME) = 1 (calculated HI value is 1.1), equals USEPA's target of HI of 1. The HI is associated with inhalation of ambient air. The HIs for all target organs are below USEPA's target, and therefore, the hazard is within USEPA acceptable levels.
- Surface water and sediment HIs (RME) are below 0.1, below USEPA's target.

- Total HI (CTE) = 0.7, below USEPA's target.
- Lead was identified as a COPC for sediment and surface water. Exposure to lead in sediment was evaluated using the adult lead model. The model results are presented in Table 11.3 in the Attachment. The mean sediment lead concentration of 533 mg/kg results in geometric mean blood levels ranging from 1.1 to 1.6 µg/dL for women of child-bearing age. The corresponding 95th percentile fetal blood lead levels range from 2.5 to 4.8 ug/dL. The probabilities that the fetal blood lead levels exceed 10 µg/DL range from 0.003 to 0.4 percent. These values are less than the blood lead goal as described in the 1994 OSWER Directive (USEPA, 1994b) of no more than 5 percent of children (fetuses of exposed women) exceeding 10 µg/dL blood lead.

7.2.7 Child Residents

Tables 9.6.RME and 9.5.CTE in the Attachment summarize the HIs for child resident exposures to ambient air at street level and surface water and sediment associated with canal overflow. The higher of the hazards estimated for the two ambient air scenarios were included in the total estimated risks and hazards for the receptor group.

- Total HI (RME) = 1 (calculated HI value is 1.3), equals USEPA's target HI of 1. The HI is associated with inhalation of ambient air. The HIs for all target organs are below USEPA's target.
- Surface water and sediment HIs (RME) are below 0.3, below USEPA's target.
- Total HI (CTE) = 0.8, below USEPA's target.
- Lead was identified as a COPC for overflow sediment and surface water. Site-specific lead exposures were evaluated for recreational children using the IEUBK model. This calculation was based on the site-specific arithmetic mean concentration of lead detected in the sediment (533 mg/kg) and surface water (13 mg/L). The results of the model, along with the probability distribution plot are presented in Table 11.2 in the Attachment. The predicted geometric mean blood lead level for a young child was 6.1 µg/dL, with 14.9 percent of the population potentially experiencing concentrations exceeding 10 µg/dL, below which adverse manifestations are not expected. These results indicate that if a child was exposed to the sediment and surface water at levels consistent with residential exposure to soil and potable use of surface water, the percent of the exposed population with a blood lead level exceeding 10 µg/dL would be above the 5 percent level that USEPA considers to be protective of human health. However, it is unlikely that a child recreational receptor would be exposed to the sediment and surface water at the levels estimated in the IEUBK model, and it is more likely there would be no adverse effects associated with exposure to the lead.

7.2.8 Child/Adult (Lifetime) Residents

Carcinogenic risks were estimated for the combined lifetime (child/adult) resident, following USEPA risk assessment methodology. Tables 9.7.RME and 9.6.CTE in the Attachment summarize the ELCRs for lifetime resident exposures to ambient air at street level and surface water and sediment associated with canal overflow. The higher of the risks

estimated for the two ambient air scenarios were included in the total estimated risks and hazards for the receptor group.

- Total ELCR (RME) = 3×10^{-4}, above USEPA's target risk range. The ELCR is associated primarily with exposure to overflow sediment (2×10^{-4}), with smaller contributions from exposure to overflow surface water (6×10^{-5}) and ambient air after the aeration system started operating (4×10^{-5}). The sediment risk drivers are carcinogenic PAHs, with highest concentrations in samples 314, at the head of the 6th Street basin, and 315, at the mouth of the 7th Street turning basin (see Figure 2-3a in the RI). PAH concentrations were variable in the reference area sediment, but concentrations observed in the canal were generally higher than those in the reference area (see discussion in Section 4.3.2 of the RI). Additionally, the statistical comparison of the PAH data from the canal and the reference area surface sediment indicated concentrations in the canal were statistically significantly greater than the reference area.
- Total ELCR (CTE) = 8×10^{-5}, within USEPA's target risk range.

7.2.9 Adult Anglers

Tables 9.8.RME and 9.7.CTE in the Attachment summarize the HIs (and ELCRs, which are discussed in Section 7.2.12) for angler adults who ingest fish and crab caught from the canal. Striped bass are representative of upper level predator fish, white perch are representative of middle level predator fish, and eel are representative of bottom feeders.

- Total Fish HI (RME) = 17, above USEPA's target HI. The HIs for ingestion of striped bass and eel exceed USEPA's target HI. The hazard is associated with PCBs, with smaller contributions (below 1) from mercury. About 70 percent of the total HI is contributed by assumed consumption of American eel. The average concentration of total PCBs in the eel from the canal is about two times higher than the average concentration of total PCBs in the reference samples (see Table 7-3 for average concentrations in canal and reference fish tissue samples). The average concentration of mercury in the eel from the canal samples is slightly lower than the average concentration in the eel from the reference samples.
- Total Crab HI (RME) = 3, above USEPA's target HI. The hazard is associated with PCBs, with smaller contributions (below 1) from arsenic and mercury. The average concentration of PCBs in blue crab from the canal is almost twice the average concentration of PCBs in blue crab from the reference samples (Table 7-3); however, the average concentrations of arsenic and mercury in blue crab from the reference samples are slightly higher than the average concentrations in the canal samples.
- White perch HI (RME) is below USEPA's target.
- Total Fish HI (CTE) = 2, above USEPA's target HI. The hazard is primarily associated with PCBs in fish (mainly eel).
- Total Crab HI (CTE) = 2, above USEPA's target HI. The hazard is primarily associated with PCBs.

7.2.10 Adolescent Anglers

Tables 9.9.RME and 9.8.CTE in the Attachment summarize the HIs (and ELCRs, which are discussed in Section 7.2.12) for adolescent anglers who ingest fish and crab caught from the canal. Striped bass are representative of upper level predator fish, white perch are representative of middle level predator fish, and eel are representative of bottom feeders.

- Total Fish HI (RME) = 13, above USEPA's target HI. The hazard is associated with PCBs, with smaller contributions (below 1) from mercury (in striped bass and eel). The HIs for ingestion of striped bass and eel exceed USEPA's target HI. About 74 percent of the total HI is contributed by assumed consumption of American eel. The average concentration of total PCBs in the eel from the canal is about two times higher than the average concentration of total PCBs in the reference samples (see Table 7-3 for average concentrations in canal and reference fish and crab tissue samples). The average concentration of mercury in the eel from the canal samples is slightly lower than the average concentration in the eel from the reference samples.
- Total Crab HI (RME) = 3, above USEPA's target HI. The hazard is associated with PCBs, with smaller contributions (below 1) from arsenic and mercury. The average concentration of PCBs in blue crab from the canal is almost twice the average concentration of PCBs in blue crab from the reference samples. The average concentrations of arsenic and mercury in the blue crab from the reference samples are slightly higher than the average concentrations in the canal samples.
- White perch HI (RME) is below USEPA's target.
- Total Fish HI (CTE) = 1 (calculated HI value is 1.3), equals USEPA's target HI.

Total Crab HI (CTE) = 0.6, below USEPA's target HI.

7.2.11 Children of Anglers

Tables 9.10.RME and 9.9.CTE in the Attachment summarize the HIs (and ELCRs, which are discussed in Section 7.2.12)for children of anglers who ingest fish and crab caught from the canal. Striped bass are representative of upper level predator fish, white perch are representative of middle level predator fish, and eel are representative of bottom feeders.

- Total Fish HI (RME) = 27, above USEPA's target HI. The hazard is associated with PCBs, with smaller contributions (below 1) from mercury (in striped bass and eel). About 70 percent of the total HI is contributed by assumed consumption of American eel. The average concentration of total PCBs in the eel from the canal is about two times higher than the average concentration of total PCBs in the reference samples (see Table 7-3 for average concentrations in canal and reference fish and crab tissue samples). The average concentration of mercury in the eel from the canal samples is slightly lower than the average concentration in the eel from the reference samples.
- Total Crab HI (RME) = 5, above USEPA's target HI. The hazard is associated with PCBs, with smaller contributions (below 1) from arsenic and mercury. The average concentration of PCBs in blue crab from the canal is almost twice the average concentration of PCBs in blue crab from the reference samples. The average

concentrations of arsenic and mercury in the blue crab from the reference samples are slightly higher than the average concentrations in the canal samples.

- Total Fish HI (CTE) = 3, above USEPA's target HI, primarily associated with PCBs in eel.
- Total Crab HI (CTE) = 4, above USEPA's target HI, primarily associated with PCBs.

7.2.12 Anglers – Lifetime Carcinogenic Risks

Carcinogenic risks were estimated for the combined lifetime (child/adolescent/adult) angler, following USEPA risk assessment methodology. The total carcinogenic risk to a angler was calculated by adding the risks calculated for the young child, adolescent, and adult. The RME carcinogenic risks are summarized in Table 7-4 and the CTE carcinogenic risks are summarized in Table 7-5, and are presented below. Striped bass are representative of upper level predator fish, white perch are representative of middle level predator fish, and eel are representative of bottom feeders.

- Total Fish ELCR (RME) = 7×10^{-4}, above USEPA's target risk range. The risk from ingestion of eel (bottom feeders) and striped bass (top level predators) exceed USEPA's target risk range. The risk is associated primarily with ingestion of eel (74 percent). The risk drivers are PCBs. The dioxin-like PCBs and nondioxin-like PCBs contributed to the risk at similar risk levels. The average concentration of non-dioxin-like PCBs and dioxin-like PCB TEQs in the eel from the canal is almost two times higher than the average concentrations in the reference samples (see Table 7-3 for average concentrations in canal and reference fish and crab tissue samples).
- Total white perch (middle level predators) ELCR (RME) is within the target risk range .
- Total Crab ELCR (RME) = 3×10^{-4}, above USEPA's target risk range. The risk drivers are PCBs. The average concentration of non-dioxin-like PCBs and dioxin-like PCB TEQs in blue crab from the canal (see Table 7-3 for average concentrations in canal and reference fish and crab tissue samples) is almost twice the average concentration of PCBs in blue crab from the reference samples.
- Total Fish ELCR (CTE) = 2×10^{-5}, within USEPA's target risk range.
- Total Crab ELCR (CTE) = 6×10^{-5}, within USEPA's target risk range.

SECTION 8

Uncertainty Assessment

The risk measures used in HHRAs are not fully probabilistic estimates of risk, but are conditional estimates given that a set of assumptions about exposure and toxicity are realized. Thus, it is important to specify the assumptions and uncertainties inherent in the risk assessment to place the risk estimates in proper perspective (USEPA, 1989).

8.1 Uncertainty in Data Evaluation and COPC Identification

The sampling conducted along the canal for use in the HHRA focused on areas where contact with the canal is most likely to occur (shallow and exposed sediment and surface water and air samples collected from similar locations) to estimate the most realistic exposure and risk to potential receptors. Additional surface water and surface sediment samples were collected from locations where historic operations and discharges to the canal have most likely occurred. Only the surface sediment samples from the exposed and shallow areas were used to evaluate the recreational exposure risks, as this is the sediment that these receptors are most likely to contact. All of the surface water samples were included in the recreational scenario evaluations since the receptors could be exposed to the water throughout the canal while boating. All of the surface water and surface sediment samples were used to evaluate risks to the residential and industrial worker receptors associated with exposure to canal overflow water and sediment. Therefore, the available data were evaluated in the HHRA in data groupings for each receptor group to estimate the reasonable maximum exposures and risks.

The uncertainty associated with the data analysis is minimal, and all of the data were validated prior to being used in the HHRA. A data quality evaluation was performed on all analytical data evaluated in the HHRA, as discussed in Section 4.1 of the RI.

A few constituents (mainly pesticides) were not detected in any of the fish or crab tissue samples but had detection limits above the human health risk-based screening level. This may result in slightly underestimating the risk associated with ingestion of fish and crab. However, it should be noted that risks above acceptable levels were identified for the fish and/or crab tissue and risks were primarily associated with the PCBs detected in the fish and crab tissue. The pesticides detected in the fish and crab tissue did not contribute significantly to the risk.

A comparison of data collected from the canal to data collected from the reference locations was not used to identify the COPCs for the canal media. This may result in including COPCs related to background conditions in the risk estimates.

All of the canal data were screened against residential screening levels to select the COPCs. The use of residential screening levels is conservative, as not all the scenarios evaluated in the HHRA are residential (i.e., the industrial worker scenario). This may result in including COPCs with small contributions to overall risk estimates.

8.2 Uncertainty Associated with Exposure Assessment

The exposure factors used for quantifying exposure were conservative and reflect upper-bound assumptions. The reliability of the values chosen for the exposure factors also contributes substantially to the uncertainty of the resulting risk estimates. Because most of the exposure factors are upper-bound assumptions, the resulting risks are likely overestimates.

The most conservative recreational scenario (swimming) was used to evaluate potential exposure and risks for recreational adults, adolescents, and children. Based on the current conditions of the canal, it is likely that this is an overestimate of actual exposure to recreational receptors. Although possible, it is highly unlikely that a recreational receptor would swim in the canal for 26 days per year for 2.6 hours per day. Although the RME scenario indicated a slight risk above USEPA target levels, the CTE scenario (using more realistic but conservative assumptions of an exposure frequency of 13 days per year and an exposure time of 1.3 hours per day) indicated a risk within USEPA acceptable risk levels.

For the purposes of this risk assessment, the angler population is defined as those individuals who consume self-caught fish from the Gowanus Canal at least once per year, in the absence of a fishing ban or fish consumption advisories. Sources of uncertainty in the PCB concentrations in fish used in the assessment include the fact that concentrations were averaged over location, and weighted by species. The weighting of species intake in order to derive an average EPC in fish is a source of uncertainty because there are limited site-specific data available to estimate the species ingestion preferences (e.g., weighting factors).

Cancer risks and noncancer health hazards were not specifically quantified for subsistence anglers, or other subpopulations of anglers who may be highly exposed. Although there are no known distinct subpopulations that may be highly exposed, there is some degree of uncertainty as to whether these subpopulations have been adequately addressed in this risk assessment.

As described in Section 5.3.2, reported cooking losses vary considerably among the numerous studies reviewed. However, little information is available to quantify personal preferences among anglers for various preparation and cooking methods and other related habits (such as consumption of pan drippings). The assumption that there is no loss of PCBs during cooking or preparation, used in the RME cancer risk and noncarcinogenic hazard calculations, is conservative and could overestimate cancer risks and noncarcinogenic hazards.

The sediment/skin adherence factor represents the amount of sediment that adheres to skin and is available for dermal exposure. Because this value is likely to vary based on one's activity, the values used for this parameter, which are estimates from single activities, are somewhat uncertain. For dermal contact with canal sediments, published adherence factors for adults gathering reeds and for children playing in wet soils were used as a surrogate for recreational children and adults and children. Although it is somewhat uncertain whether these scenarios are representative of contact with canal sediments, they appear to be a reasonable use of available data.

Commercial PCB mixtures tested in laboratory animals were not subject to prior selective retention of persistent congeners through the food chain, so there is a potential that

carcinogenic risks and noncarcinogenic hazards have been underestimated. However, since the CSFs are based on animal exposures to a group of PCB mixtures (i.e., Aroclor 1260, 1254, 1242, and 1016) that contain overlapping groups of congeners spanning the range of congeners most often found in environmental mixtures, this source of potential uncertainty is unlikely to have a significant impact.

The fact that any previous exposures (either background, or past consumption of contaminated fish) may still be reflected in an individual's body burden today is an additional source of uncertainty, and may result in an underestimate of noncarcinogenic health hazards.

The risk assessment assumed that people would consume both the combined muscle (edible portion) and hepatopancreas from blue crab. This may result in an overestimation of risk, as many crabbers do not consume the hepatopancreas, and some chemicals, such as PCBs and mercury, accumulate in the hepatopancreas. However, the hepatopancreas is small compared to the edible portion of the fish, and therefore, although concentrations may be higher in the hepatopancreas, it contributes a small amount of the total amount of crab consumed by the receptor. Therefore, it would not significantly change the total amount of contaminants consumed.

Dioxin-like PCB TEQ concentrations, non-dioxin-like PCB concentrations, and total PCB concentrations were calculated for each sample using detected PCB congeners only. In general, if the nondetected dioxin congeners were included in the sample concentration calculations, the non-dioxin-like PCB concentrations and the total PCB concentrations would be similar to those used in the risk assessment and the resulting risks would not differ significantly. The dioxin-like PCB TEQ concentrations would not always be similar, since if the most toxic congener (3,3',4,4',5-Pentachlorobiphenyl [126]) was not detected in a sample, inclusion of this congener at the detection limit times the TEF would contribute significantly to the dioxin-like PCB TEQ, even if it was not detected. Therefore, this may result in an underestimation of actual risk if this congener was present in the sample at a concentration below the reporting limit. However, when this congener was detected in a sample, it was generally J flagged as detected below the reporting limit, so it is unlikely that it would be present in the samples at concentrations similar to reporting limits, and it would likely be present at much lower concentrations and not contribute significantly to the dioxin-like PCB TEQ concentration for the sample. Additionally, congeners that were B qualified, indicating they were detected in a laboratory or field blank at a concentration similar to that in the sample, were not included in the concentration calculation. There were a number of samples with B-qualified congeners, which may result in an underestimation of risk if these congeners are present in the samples at a concentration below the blank contamination level. However, the B-qualified concentrations were generally below the reporting limits.

There are inherent limitations and uncertainties associated with estimating health risks on the basis of fish and crab consumption that should be considered when interpreting the results of this HHRA. Factors contributing to these uncertainties include the following:

- Game fish and blue crab ranges are not limited to the canal, but reflect cumulative uptake from all areas they traverse. Blue crab and some of the game fish species kept by anglers have relatively large home ranges, and those caught within the canal are likely, at least in part, to have inhabited areas outside the canal and therefore to have been

potentially exposed to contaminants not related to the canal. However, differences between canal and reference concentrations of PCBs in fish and crab tissue and sediment were identified, with canal media having higher concentrations.

Assumptions regarding fishing/crabbing frequency and fish/crab consumption rates are variable and affect the estimates of exposure and associated risk.

8.3 Uncertainty Associated with Toxicity Assessment

Uncertainty associated with the noncarcinogenic toxicity factors is included in Table 5.1 in the Attachment. The USEPA applies several UFs to extrapolate doses from animal studies to humans. The UFs for the COPCs range from 1 to 3,000. Therefore, there is a high degree of uncertainty in the noncarcinogenic toxicity criteria based on the available scientific data. The noncarcinogenic toxicity factors used in the HHRA are expected to be overestimates of actual toxicity.

CSFs and IURs developed by USEPA represent upper-bound estimates. Carcinogenic risks generated in this assessment should be regarded as an upper-bound estimate on the potential carcinogenic risks. The true ELCR is likely to be less than the predicted value (USEPA, 1989).

Use of provisional or withdrawn toxicity factors increases the uncertainty of the quantitative hazard and risk estimates. Provisional toxicity values (from Cal EPA, PPRTV, ATSDR, and NCEA) were used in the HHRA. The provisional values were used to provide a quantitative estimate rather than a merely qualitative risk discussion; however, USEPA has not fully promulgated these toxicity values.

The TEFs used to adjust the concentrations of the dioxin-like PCB congeners to TEQ of dioxin for the sediment and fish/crab also results in uncertainty in the risk assessment. In particular, although the TEF scheme and TEQ methodology is intended primarily for estimating exposure and risk through ingestion (primarily dietary intakes; USEPA, 2010c), it was also used to estimate exposure and risk through dermal contact. Additionally, not using the dioxin-like PCB congener TEQ to evaluate noncarcinogenic risks may underestimate the noncarcinogenic hazard associated with exposure to the PCBs. However, there is a lot of uncertainty with use of this process, and even more uncertainty with use of it for noncarcinogenic hazards since the TEFs are based on the relationship of the PCB congeners to the carcinogenic risks associated with dioxin. Although, there is a large degree of uncertainty associated with use of this method for noncarcinogenic-hazard evaluation, noncarcinogenic hazards were estimated as part of the uncertainty evaluation.

Noncarcinogenic hazards were calculated for the dioxin-like PCB TEQ concentrations for sediment and fish/crab using the RfD for 2,3,7,8-TCDD from the 1998 dioxin ATSDR toxicity profile. It should be noted that use of this RfD in itself presents a source of uncertainty, as the ATSDR toxicity profiles are a Tier 3 source of toxicity information. Noncarcinogenic hazards were calculated for the non-dioxin-like PCB concentrations using the RfD for Aroclor 1254. The sum of the noncarcinogenic hazards associated with the dioxin-like PCB TEQ concentrations and the non-dioxin-like PCB concentrations for all receptors for sediment and fish/crab are below 1 and in most cases are less than the noncarcinogenic hazards associated with the total PCB concentration, which were estimated using the total PCB concentrations and the RfD for Aroclor 1254. Therefore, evaluation of

the noncarcinogenic hazards for the dioxin-like PCB TEQ concentrations does not change the conclusions of the HHRA.

SECTION 9

Human Health Risk Summary

The risk assessment was conducted to evaluate the potential human health risks associated with direct contact with sediment and surface water in the Gowanus Canal, with ingestion of fish and crabs from the canal, with direct contact of sediment and surface water that overtops the canal during significant rainfall events, and with inhalation of emissions from the canal into the ambient air near the canal.

Table 5 and Tables 9.1.RME through 9.10.RME in the Attachment summarize the RME ELCRs and HIs. Table 6 and Tables 9.1.CTE through 9.9CTE in the Attachment summarize the CTE ELCRs and HIs. Estimated HIs and ELCRs associated with exposure to canal-related media indicate the potential for unacceptable risks based on exposure to some media by some receptor groups. Risk estimates are summarized below:

- Recreational receptors (adult, adolescent, and child)
  - Exposures are to surface water and surface sediment (from exposed and near-shore locations) in the canal and to ambient air at canal level while swimming in the canal for 26 days per year for 2.6 hours each day (very conservative assumptions given the nature of the canal and current CSO discharges).
  - HIs and ELCRs (RME) for inhalation of canal level air are within USEPA acceptable levels.
  - Total HI (RME) (all media combined) for all recreational receptors is within acceptable risk levels.
  - Total ELCR (RME) for recreational receptor (1×10^{-3}) exceeds USEPA's target risk range, primarily because of carcinogenic PAHs in surface water and sediment above background levels (see Sections 4.3.2 and 4.4.5 of the RI).
  - Total HI (CTE) for all recreational receptors are below USEPA's target level.
  - Total ELCR (CTE) for recreational receptor (3×10^{-4}) exceeds USEPA's target levels and ranges; the CTE scenario may be more representative of likely exposure (although still conservative, at an assumed swimming frequency of 13 days per year for 1.3 hours per day). The risk is primarily associated with exposure to the young child (67 percent of the risk).
  - Exposure to lead in sediment by adult and adolescent recreational receptors was demonstrated not to be a concern using the adult lead model. The IEUBK model indicated potential adverse effects for children exposed to lead in sediment and surface water; however, the model is based on residential exposure to these media, including using the surface water as a potable water supply. Therefore, it is unlikely, based on a more-realistic recreational exposure, that there would be any adverse effects based on exposure to recreational children.
- Industrial workers and residential receptors (adult and child)

- Exposures are to ambient air at street level and surface water and sediment associated with canal overflow.
- Total HI and ELCR (RME) for industrial workers are below or within USEPA's target levels.
- Total HIs (RME) for residential adults (Total HI equals 1, calculated value is 1.1) and for children (Total HI equals 1, calculated value is 1.3) do not exceed USEPA's target level of 1. Inhalation of ambient air at street level contributes over 75 percent of the hazard. No target organ HIs exceed USEPA's target levels.
- HIs (RME) for exposure to surface water and sediment are within USEPA acceptable levels.
- ELCRs (RME) for inhalation of street level air are within USEPA acceptable levels.
- ELCR (RME) for lifetime (child/adult) resident (3×10^{-4}) exceeds USEPA's acceptable level primarily associated with carcinogenic PAHs in sediment (with a smaller contribution from surface water below 1×10^{-4}) that were above background levels (see Sections 4.3.2 and 4.4.5 of the RI).
- Exposure to lead in sediment by industrial workers was demonstrated not to be a concern using the adult lead model. The IEUBK model indicated potential adverse effects for children exposed to lead in sediment and surface water; however, the model is based on residential exposure to these media, including using the surface water as a potable water supply. Therefore, it is unlikely, on the basis of a more realistic exposure, that there would be any adverse effects based on recreational children's exposure to lead.

- Anglers (adult, adolescent, and child)
  - Exposure is from ingestion of fish (striped bass [representative of top level predators], white perch [representative of middle level predators], and eel [representative of bottom feeders]) and crab caught in the Gowanus Canal. Assuming that fishing/crabbing and ingestion of fish/crab from the Gowanus Canal occur at typical recreational angler fish consumption rates is very conservative given the nature of the canal and current CSO discharges to the canal.
  - Total Fish HIs (RME) (all fish types) for adults (17), adolescents (13), and children (27) exceed acceptable risk levels, primarily because of PCBs. The ingestion of striped bass and eel contributed higher HIs than ingestion of white perch (which for the child only did contribute to HI above 1). Additionally, mercury contributed to the HIs, at HIs above 0.1 but below 1.
  - Total Crab HIs (RME) for adults (37), adolescents (3), and children (5) exceed acceptable risk levels, primarily because of PCBs. Additionally, mercury and arsenic contributed to the HIs, at HIs above 0.1 but below 1.0.
  - Average PCB concentrations in canal samples are about twice the average PCB concentrations in reference samples; however, concentrations of PCBs in reference samples would also result in HIs and ELCRs above acceptable risk levels.

- Total Fish ELCR (RME) for angler (7×10^{-4}) exceeds USEPA's target risk range, primarily because of PCBs.
- Total Crab ELCR (RME) for angler (3×10^{-4}) exceeds USEPA's target risk range, primarily because of PCBs.
- Total Fish HIs (CTE) for adults (2.0), adolescents (1.7), and children (3.2) exceed USEPA's target level; these are associated with PCBs in fish and crab.
- Total Crab HIs (CTE) for adults (2) and children (3) exceed USEPA's target level; these are associated with PCBs. Total HI (CTE) for adolescents (Total HI equals 1, calculated as 1.3) does not exceed USEPA's target level.
- Total Fish ELCR (CTE) for angler receptor is within USEPA's target range; the CTE scenario may be more representative of consumption of fish for the Gowanus Canal (although still conservative).
- Total Crab ELCR (CTE) for angler receptor is within USEPA's target range; the CTE scenario may be more representative of consumption of crab for the Gowanus Canal (although still conservative).
- A primary contributor to fish consumption risk is PCBs in tissues of fish caught from the canal. This conclusion is supported by NYDOH's decision to issue fish consumption advisories for the Upper Bay of the New York Harbor (north of the Verrazano Narrows Bridge), including the Gowanus Canal (NYSDOH, 2010) in part on the basis of PCB concentrations present in fish. Reference area average PCB fish concentrations are about one half the average concentrations identified in canal fish. However, these would also result in risks above acceptable risk levels.

1. Duplicate sample.
2. Sediment sample used in recreational scenario for exposure to exposed and near shore surface sediment. All sediment samples used for overflow scenario.
3. Sample not used, volume not available to calculate $\mu g/m^3$.
4. Edible tissue sample.
5. Hepatopancreas sample.

TABLE 4-2

Chemicals of Potential Concern

Gowanus Canal Remedial Investigation, Brooklyn, New York

Surface Sediment (Exposed and Near-Shore Sediment in Gowanus Canal)	Surface Sediment	Surface Water (Gowanus Canal)	Ambient Air	Fish
	Canal overflow scenario	**Dry-weather event**	**Canal level, pre-aeration system**	**Striped bass**
Acenaphthene	Acenaphthene	Benzene	Benzene	p,p'-DDE
Benzo(a)anthracene	Benzo(a)anthracene	Benzo(a)anthracene	Chloroform	p,p'-DDT
Benzo(a)pyrene	Benzo(a)pyrene	Benzo(a)pyrene	Ethylbenzene	Dioxin-like PCB TEQ
Benzo(b)fluoranthene	Benzo(b)fluoranthene	Benzo(b)fluoranthene	Xylene, total	Nondioxin-like PCB
Benzo(k)fluoranthene	Benzo(k)fluoranthene	Bis(2-ethylhexyl) phthalate	Naphthalene	Total PCB
Bis(2-ethylhexyl) phthalate	Bis(2-ethylhexyl) phthalate	Indeno(1,2,3-c,d)pyrene		Arsenic
Chrysene	Chrysene	Arsenic	**Canal level, during aeration**	Mercury
Dibenz(a,h)anthracene	Dibenz(a,h)anthracene	Chromium	**system operation**	Selenium
Fluoranthene	Fluoranthene	Copper	Benzene	**White perch**
Indeno(1,2,3-c,d)pyrene	Fluorene	Selenium	Chloroform	Dioxin-like PCB TEQ
Naphthalene	Indeno(1,2,3-c,d)pyrene		Ethylbenzene	Nondioxin-like PCB
Pyrene	Naphthalene	**Wet-weather event**	Xylene, total	Total PCB
Dioxin-Like PCB TEQ	Pyrene	**(and surface water overflow)**	Naphthalene	Mercury
Nondioxin-Like PCB	Dioxin-Like PCB TEQ	1,4-Dichlorobenzene		Selenium
Total PCB	Nondioxin-Like PCB	Benzene	**Street level, pre-aeration system**	**Eel**
Aluminum	Total PCB	Chloroform	Benzene	alpha-Chlordane
Arsenic	Aluminum	Ethylbenzene	Chloroform	Dieldrin
Cadmium	Arsenic	Tetrachloroethylene(PCE)	Ethylbenzene	gamma-Chlordane
Chromium	Cadmium	Benzo(a)anthracene	Naphthalene	p,p'-DDD
Cobalt	Chromium	Benzo(a)pyrene		p,p'-DDE
Copper	Cobalt	Benzo(b)fluoranthene	**Street level, during aeration**	p,p'-DDT
Iron	Copper	Dibenz(a,h)anthracene	**system operation**	Dioxin-like PCB TEQ
Lead	Iron	Indeno(1,2,3-c,d)pyrene	Benzene	Nondioxin-like
Manganese	Lead	Naphthalene	Chloroform	Total PCB
Vanadium	Manganese	Arsenic	Ethylbenzene	Arsenic
	Vanadium	Chromium	Naphthalene	Chromium
		Cobalt		Copper
		Lead		Cyanide, total
		Selenium		Mercury
				Selenium
				Blue crab
				Benzo(a)anthracene
				Benzo(a)pyrene
				Benzo(b)fluoranthene
				Dibenz(a,h)anthracene
				Indeno(1,2,3-cd)pyrene
				Dioxin-like PCB TEQ
				Nondioxin-like
				Total PCB
				Arsenic
				Copper
				Mercury

TABLE 5-1
WHO Dioxin-like PCB TEFs
Gowanus Canal Remedial Investigation, Brooklyn, New York

PCB Congener	WHO TEF[a,b]
3,3',4,4'-Tetrachlorobiphenyl (77)	0.0001
3,4,4',5-Tetrachlorobiphenyl (81)	0.0003
2,3,3',4,4'-Pentachlorobiphenyl (105)	0.00003
2,3,4,4',5-Pentachlorobiphenyl (114)	0.00003
2,3',4,4',5-Pentachlorobiphenyl (118)	0.00003
2,3',4,4',5'-Pentachlorobiphenyl (123)	0.00003
3,3',4,4',5-Pentachlorobiphenyl (126)	0.1
Congeners (156/157)	0.00003
2,3',4,4',5,5'-Hexachlorobiphenyl (167)	0.00003
3,3',4,4',5,5'-Hexachlorobiphenyl (169)	0.03
2,3,3',4,4',5,5'-Heptachlorobiphenyl (189)	0.00003

	Fish Total Risk		2E-04				27	
	Crab Total Risk		9E-05				5.5	

NA—Not applicable, pathway incomplete.
Receptor Total risks and hazards for recreational receptors includes sum of exposed and near-shore sediment, maximum of dry event and wet event surface water, and maximum of air prior to aeration system operation and after aeration system started.
Receptor Total risks and hazards for residential and industrial receptors includes maximum between air prior to and after aeration system operation, and surface water, and sediment.

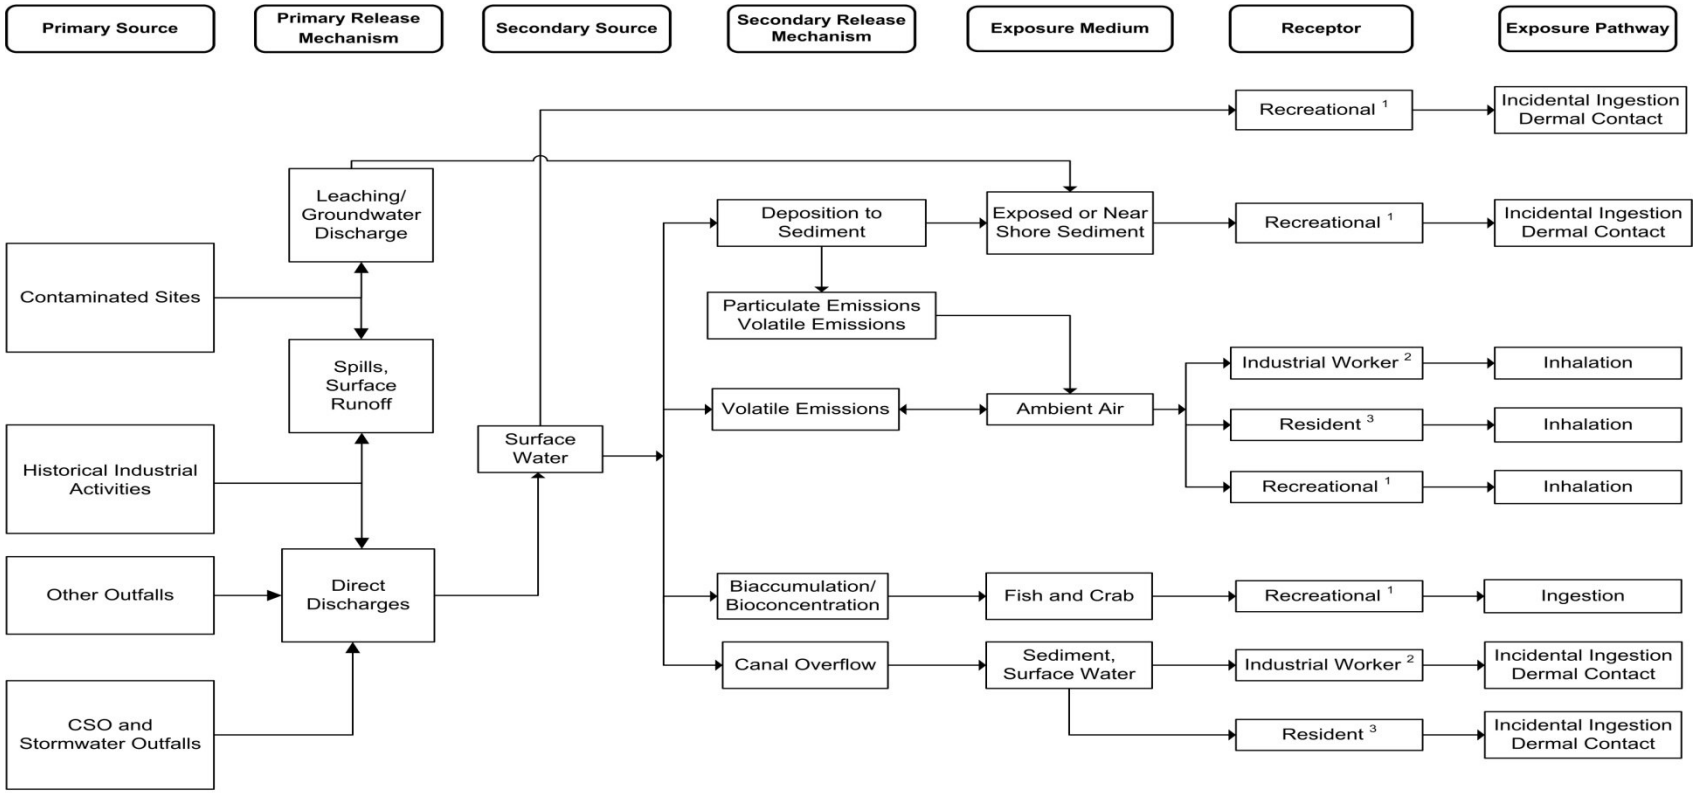
	Fish Total Risk		9E-06				2.7	
	Crab Total Risk		3E-05				3.6	

NA—Not applicable, pathway incomplete.
Receptor Total risks and hazards for recreational receptors includes sum of exposed and near-shore sediment, maximum of dry event and wet event surface water, and maximum of air prior to aeration system operation and after aeration system started.
Receptor Total risks and hazards for residential and industrial receptors includes maximum between air prior to and after aeration system operation, and surface water, and sediment.

TABLE 7-4
Summary of Total RME Cancer Risks for Recreational User and Angler
Gowanus Canal Remedial Investigation, Brooklyn, New York



Media	Exposure Pathway	Receptor			
		Recreational adult Cancer Risk	Recreational Adolescent Cancer Risk	Recreational Child Cancer Risk	Total Recreational Cancer Risk

TABLE 1

SELECTION OF EXPOSURE PATHWAYS

Gowanus Canal Remedial Investigation, Brooklyn, New York

Scenario Timeframe	Medium	Exposure Medium	Exposure Point	Receptor Population	Receptor Age	Exposure Route	Type of Analysis	Rationale for Selection or Exclusion of Exposure Pathway
Current/Future	Sediment	Surface Sediment	Exposed and near shore sediment in Gowanus Canal	Recreational	Adult	Ingestion	Quant	People have been observed boating and fishing/crabbing in the canal. These receptors may be exposed to surface sediment at boat launch locations, bridge crossing locations, and at locations with exposed sediment, or sediment covered by shallow water.
						Dermal	Quant	
					Adolescent	Ingestion	Quant	
						Dermal	Quant	
					Child	Ingestion	Quant	
						Dermal	Quant	
	Surface Water	Surface Water	Gowanus Canal	Recreational	Adult	Ingestion	Quant	People have been observed boating and fishing/crabbing in the canal. These receptors may be exposed to surface water throughout the canal during these activities.
						Dermal	Quant	
					Adolescent	Ingestion	Quant	
						Dermal	Quant	
					Child	Ingestion	Quant	
						Dermal	Quant	
	Air	Air	Ambient air at canal level	Recreational	Adult	Inhalation	Quant	People have been observed boating and fishing in the canal. These receptors may inhale ambient air from particulate and volatile emissions from exposed sediment and volatile emissions from surface water throughout the canal during these activities.
					Adolescent	Inhalation	Quant	
					Child	Inhalation	Quant	
			Ambient air at street level	Industrial Worker	Adult	Inhalation	Quant	Workers at the businesses surrounding the canal may inhale ambient air from particulate and volatile emissions from exposed sediment and volatile emissions from surface water during the workday.
				Resident	Adult	Inhalation	Quant	People live within a few blocks of the canal, and may inhale ambient air from particulate and volatile emissions from exposed sediment and volatile emissions from surface water at their residences and the surrounding areas.
					Child	Inhalation	Quant	
					Child/Adult	Inhalation	Quant	
	Surface Water/Sediment	Fish and Crab Tissue	Striped Bass in Gowanus Canal	Angler	Adult	Ingestion	Quant	People have been observed fishing in the canal. These receptors may eat the fish they catch from the canal. Striped bass are representative of top-level predator fish.
					Adolescent	Ingestion	Quant	
					Child	Ingestion	Quant	
			White Perch in Gowanus Canal	Angler	Adult	Ingestion	Quant	People have been observed fishing in the canal. These receptors may eat the fish they catch from the canal. White perch are representative of middle-level predator fish.
					Adolescent	Ingestion	Quant	
					Child	Ingestion	Quant	
			Eel in Gowanus Canal	Angler	Adult	Ingestion	Quant	People have been observed fishing in the canal. These receptors may eat the fish they catch from the canal. American eel are representative of bottom feeders.
					Adolescent	Ingestion	Quant	
					Child	Ingestion	Quant	

TABLE 1

SELECTION OF EXPOSURE PATHWAYS

Gowanus Canal Remedial Investigation, Brooklyn, New York

Scenario Timeframe	Medium	Exposure Medium	Exposure Point	Receptor Population	Receptor Age	Exposure Route	Type of Analysis	Rationale for Selection or Exclusion of Exposure Pathway
Curren/tFuture	Surface Water/Sediment	Fish and Crab Tissue	Crab in Gowanus Canal	Angler	Adult	Ingestion	Quant	People have been observed crabbing in the canal. These receptors may eat the crab they catch from the canal.
					Adolescent	Ingestion	Quant	
					Child	Ingestion	Quant	
	Sediment	Overflow Surface Sediment	Sediment deposited in areas adjacent to Gowanus Canal associated with canal overflow	Industrial Worker	Adult	Ingestion	Quant	Workers at businesses surrounding the canal may be exposed to sediment that gets deposited near the canal when the canal overflows, prior to being washed away with rain.
						Dermal	Quant	
				Residential	Adult	Ingestion	Quant	People live within a few blocks of the canal. These receptors may be exposed to surface sediment that gets deposited outside of the canal when the canal overflows prior to being wahsed away with rain.
						Dermal	Quant	
					Child	Ingestion	Quant	
						Dermal	Quant	
					Child/Adult	Ingestion	Quant	
						Dermal	Quant	
		Air	Particulate and volatile emissions from sediment deposited in areas adjacent to Gowanus Canal associated with canal overflow	Industrial Worker	Adult	Inhalation	None	Emissions from deposited sediment associated with canal overflow is not expected to be a significant exposure pathway.
				Residential	Adult	Inhalation	None	
					Child	Inhalation	None	
					Child/Adult	Inhalation	None	
	Surface Water	Overflow Surface Water	Canal Overflow - Surface Water (surface water data from wet event)	Industrial Worker	Adult	Ingestion	Quant	Workers at businesses surrounding the canal may be exposed to canal surface water when the canal overflows.
						Dermal	Quant	
				Residential	Adult	Ingestion	Quant	People live within a few blocks of the canal. These receptors may be exposed to surface water outside of the canal when the canal overflows.
						Dermal	Quant	
					Child	Ingestion	Quant	
						Dermal	Quant	
					Child/Adult	Ingestion	Quant	
						Dermal	Quant	
		Air	Volatile emissions from overflow surface water in areas adjacent to Gowanus Canal	Industrial Worker	Adult	Inhalation	None	Emissions from surface water associated with canal overflow is not expected to be a significant exposure pathway.
				Residential	Adult	Inhalation	None	
					Child	Inhalation	None	
					Child/Adult	Inhalation	None	

Quant: will be quantitatively evaluated.

Qual: will be qualitatively evaluated.

None: Not considered to be a significant exposure pathway, and therefore not evaluated.

Notes for Tables 2.1 through 2.12
Selection of Chemicals of Potential Concern
Gowanus Canal Remedial Investigation, Brooklyn, New York

Screening Toxicity Values from USEPA Regional Screening Level (RSL) Table, November 2010.

sediment - screening toxicity value is residential RSL
surface water - screening toxicity value is tap water RSL
air - screening toxicity value is ambient air RSL
fish - screening toxicity value is fish tissue RSL from EPA Region III Website

Footnotes/Definitions

ARAR/TBC = Applicable or Relevant and Appropriate Requirement/ To Be Considered
C = Carcinogenic
COPC = Chemical of Potential Concern
J = Estimated Value
N = Noncarcinogenic
N/A = Not available or not applicable
NJ = Qualitative identification questionable due to poor resolution. Presumptively present at approximate quantity
NRWQC = U.S. Environmental Protection Agency (USEPA). 2009. National Recommended Water Quality Criteria for Human Health for Consumption of Organism only from EPA's National Recommended Water Quality Criteria, Office of Water, Office of Science and Technology, 2009.
NYSDEC = New York State DEC, Chapter X, Division of Water, Part 703: Surface Water and Groundwater Quality Standards and Groundwater Effluent Limitations . Values correspond to classification of canal (SD) and classification of Bay (I) and are the standards for Health - fish consumption and recreation.

Surrogates used for those Chemicals without a Screening Toxicity Value (RSL)

1,3-dichlorobenzene - used 1,2-dichlorobenzene as surrogate
acenaphthylene - used acenaphthalene as surrogate
benzo(g,h,i)perylene - used pyrene as surrogate
chromoium - used hexavalent chromium
dimethyl phthalate - calculated based on PPRTV toxicity value form PPRTV profile dated 9/25/2007
PCB dioxin - used 2,3,7,8-TCDD, however, did not use 2,3,7,8-TCDD RSL, but updated the RSL using the cancer slope factor for 2,3,7,8-TCDD from USEPA, 2005, Health Assessment Document for Polychlorinated Dibenzo-p-Dioxins, EPA 600/8-84-014F.
PCB non-dioxin - used Total PCBs
phenanthrene - used anthracene as surrogate

TABLE H-3.1
Exposed Sediment in Canal - Exposure Point Concentration
Gowanus Canal Remedial Investigation
Brooklyn, New York

Scenario Timeframe:	Current/Future
Medium:	Sediment
Exposure Medium:	Surface Sediment

Exposure Point	Chemical of Potential Concern	Units	Arithmetic Mean	95 % UCL Distribution	Maximum Detected Value	Exposure Point Concentration

Notes:
(1) Assumed sediment ingestion rate is equal to 1/2 of the incidental soil ingestion rate.
(2) Professional judgement, conservatively assumed recreational use of the canal would occur 1 day per week for one-half the year.
(3) SA includes head, hands, forearms, lower legs, and feet.
(4) Average adherence factor for children in wet soil.
(5) Professional Judgement assuming adolescents from 12 to 18 years of age.
(6) Body weight is average of the mean values for boys and girls for the ages 12 through 18.
(7) SA includes head, hands, arms, legs, and feet.
(8) Average adherence factor for reed gatherers (from Exhibit 3-3 of EPA, 2004).

				CF1	Conversion Factor 1	1/24	day/hr	- -	
				AT-C	Averaging Time (Cancer)	25,550	days	EPA, 1989	

Notes:
(1) National average time spent swimming per swimming event.
(2) Professional judgement, conservatively assumed recreational use of the canal would occur 1 day per week for one-half the year.
(3) Professional Judgement assuming adolescents from 12 to 18 years of age.

Notes:
(1) 95th percentile recreational freshwater anglers fish ingestion rate.
(2) Ingestion rate assumed to be 2/3 the adult ingestion rate.
(3) There are no recreational fish ingestion values or crab ingestion values for children. Therefore, ingestion rate assumed to be 1/3 the adult ingestion rate.
(4) Bottom feeders percent consumption (44%) used to for eel, intermediate level percent consumption (47%) used for striped bass, and remaining percent (4%) used for white perch.

				CF2	Conversion Factor 2	0.001	l/cm^3	- -	

Notes:
(1) Assumed ingestion rate for canal overflow water would be 1/2 of mean water ingestion rate for adults for exposure scenarios involving swimming activities.
(2) Professional judgement, conservatively assumes industrial receptors will contact overflow ponded surface water 8 hours per day.
(3) Professional judgement, conservatively assumes residential receptor will contact overflow surface water for the same exposure time as the national average time spent swimming per swimming event.
(4) SA includes head, hands, forearms, lower legs, and feet (for child only).
(5) Professional judgement, conservatively assumes canal overflows 3 times a year, and remains on surface 3 days per each overflow event.

				CF1	Conversion Factor 1	1/24	day/hr	- -	
				AT-C	Averaging Time (Cancer)	25,550	days	EPA, 1989	

Notes:
(1) Professional judgement, assuming 1/2 the RME value, or 1/2 the ingestion rate of surface water for swimming.
(2) Professional judgement, conservatively assumed recreational use of the canal would occur 1 day per week for one-half the year.
(3) Professional Judgement assuming adolescents from 12 to 18 years of age.

Notes:
(1) Mean recreational freshwater anglers fish ingestion rate.
(2) Ingestion rate assumed to be 2/3 the adult ingestion rate.
(3) There are no recreational fish ingestion values or crab ingestion values for children. Therefore, ingestion rate assumed to be 1/3 the adult ingestion rate.
(4) Bottom feeders percent consumption (44%) used to for eel, intermediate level percent consumption (47%) used for striped bass, and remaining percent (4%) used for white perch.
(5) Average yearly crab ingestion rate.
(6) Based on 9 years, the 50th percentile of time at a single residence, divided into three years for each receptor age range.

				CF1	Conversion Factor 1	0.001	mg/µg	- -	
				CF2	Conversion Factor 2	0.001	l/cm^3	- -	

Notes:
(1) Professional judgement, assuming 1/2 the RME value, or 1/2 the ingestion rate of surface water for swimming.
(2) 1/2 the RME value, equal to 1/2 the national average time spent swimming per swimming event.
(3) SA includes head, hands, forearms, lower legs, and feet (for child only).
(4) Professional judgement, assumed equal to 1/2 RME value.

NA = Not Applicable or Not Available.

(1) Source: Risk Assessment Guidance for Superfund. Volume 1: Human Health Evaluation Manual, Part E, Supplemental Guidance for Dermal Risk Assessment (Final).
Section 4.2 and Exhibit 4-1. USEPA recommends that the oral RfD should not be adjusted to estimate the absorbed dose for compounds when the absorption efficiency is greater than 50%.
Constituents with oral absorption efficiencies greater than 50%, or without reported oral absorption efficiencies, are shown with an oral absorption efficiency of 100%.

(2) Adjusted Dermal RfD = RfD (oral) x Oral to Dermal Adjustment Factor

N/A-Not available

(1) Source: Risk Assessment Guidance for Superfund. Volume 1: Human Health Evaluation Manual, Part E, Supplemental Guidance for Dermal Risk Assessment (Final). Section 4.2 and Exhibit 4-1. USEPA recommends that the oral RfD should not be adjusted to estimate the absorbed dose for compounds when the absorption efficiency is greater than 50% Constituents with oral absorption efficiencies greater than 50%, or without reported oral absorption efficiencies, are shown with an oral absorption efficiency of 100%.

(2) Adjusted Dermal CSF = CSF (oral) / Oral to Dermal Adjustment Factor

(3) EPA Carcinogen Group:

A - Human carcinogen

B1 - Probable human carcinogen - indicates that limited human data are available

B2 - Probable human carcinogen - indicates sufficient evidence in animals and inadequate or no evidence in humans

C - Possible human carcinogen

D - Not classifiable as a human carcinogen

E - Evidence of noncarcinogenicity

IARC Carcinogen Group:

2A: The agent is probably carcinogenic to humans

2B: The agent is possibly carcinogenic to humans

TABLE 6.1

CANCER TOXICITY DATA -- ORAL/DERMAL

Gowanus Canal Remedial Investigation, Brooklyn, New York

Chemical of Potential Concern	Oral Cancer Slope Factor	Oral to Dermal Adjustment Factor (1)	Adjusted Dermal Cancer Slope Factor (2)	Units	EPA Carcinogen Group (3)	Source (4)	Date (5) (MM/DD/YY)

(4) CalEPA = California EPA

EPA-D = EPA, 1985. Health Assessment Document for Polychlorinated Dibenzo-p-Dioxins. U.S. Environmental Protection Agency, Office of Health and Environmental Assessment, Environmental Criteria and Assessment Office. Cincinnati, OH. EPA 600/8-84-014F.

IRIS = Integrated Risk Information System

NCEA = National Center for Environmental Assessment

NJ = New Jersey DEP

(5) For CalEPA values, the date CalEPA toxicity database was searched.

For IRIS values, the date IRIS was searched.

For NCEA values, the date of the NCEA document.

For New Jersey values, the date New Jersey DEP toxicity database was searched.

(6) 2,3,7,8-TCDD toxicity values will be used for dioxin-like PCBs.

Total PCBs toxicity values used for non-dioxin like PCBs.

(7) Chemical acts via a mutaganic mode of action. Age-dependent adjustment factor (ADAF) of 10 used for 0-2 year old, ADAF of 3 used for 2-6 year old, and ADAF of 3 used for 6-12 year old. Oral cancer slope factor multiplied by appropriate ADAF to derive age-specific oral cancer slope factor for receptor.

Notes-

NA = Not available / Not applicable.

DAevent for surface water from dry event calculated on Table 7.1.RME Supplement A.

DAevent for surface water from wet event calculated on Table 7.1.RME Supplement B.

Total includes sum of exposed and near shore sediment, maximum of dry event and wet event surface water, and maximum of air prior to areation system operation and after aeration system started

TABLE 7.1.RME Supplement A
Calculation of Daevent Dry Event
Recreational Scenario
Gowanus Canal Remedial Investigation, Brooklyn, New York

Chemical of Potential Concern	Water Concentration (CW) (µg/L)	Permeability Coefficient (K_p) (cm/hr)	B (dimensionless)	Lag Time (τ_{event}) (hr)	t* (hr)	Fraction Absorbed Water (FA) (dimensionless)	Duration of Event (t_{event}) (hr)	DA_{event} (mg/cm^2-event)	Eq

Selenium	4.1E+01	1.0E-03	NA	NA	NA	NA	2.6	1.1E-07	1

Inorganics: DA_{event} (mg/cm^2-event) =

$K_p \times CW \times t_{event} \times 0.001$ mg/µg $\times 0.001$ l/cm^3 (eq 1)

Organics: DA_{event} (mg/cm^2-event) =

If $t_{event} < t^*$, then DA_{event} =

$2 \times FA \times K_p \times CW \times (\text{sqrt}((6 \times \tau_{event} \times t_{event})/\pi)) \times 0.001$ mg/µg $\times 0.001$ l/cm^3 (eq 2)

If $t_{event} > t^*$, then DA_{event} =

$FA \times K_p \times CW \times (t_{event}/(1+B) + 2 \times \tau_{event} \times ((1 + 3xB + 3xB^2)/(1+B)^2) \times 0.001$ mg/µg $\times 0.001$ l/cm^3 (eq 3)

Notes:

NA - Not applicable

Permeability constants and other input parameter values from EPA 2004, *Risk Assessment Guidance for Superfund Volume I: Human Health Evaluation Manual (Part E, Supplemental Guidance for Dermal Risk Assessment - Final).* EPA/540/R/99/005. The default value of 0.001 was assigned to inorganics not listed in this document.

B - Dimensionless ratio of the permeability coefficient of a compound through the stratum corneum relative to its permeability coefficient across the viable epidermis (dimensionless).

t* - Time to reach steady-state

Inorganics: DA_{event} (mg/cm^2-event) =
K_p x CW x t_{event} x 0.001 mg/µg x 0.001 l/cm^3 (eq 1)

Organics: DA_{event} (mg/cm^2-event) =
If $t_{event}<t^*$, then DA_{event} =
2 x FA x K_p x CW x (sqrt((6 x τ_{event} x t_{event})/π)) x 0.001 mg/µg x 0.001 l/cm^3 (eq 2)

If $t_{event}>t^*$, then DA_{event} =
FA x K_p x CW x (t_{event}/(1+B) + 2 x τ_{event} x ((1 + 3xB + 3xB^2)/(1+B)^2) x 0.001 mg/µg x 0.001 l/cm^3 (eq 3)

Ethylbenzene
Notes:
NA - Not applicable
Permeability constants and other input parameter values from EPA 2004, *Risk Assessment Guidance for Superfund Volume I: Human Health Evaluation Manual (Part E, Supplemental Guidance for Dermal Risk Assessment - Final).* EPA/540/R/99/005. The default value of 0.001 was assigned to inorganics not listed in this document.
B - Dimensionless ratio of the permeability coefficient of a compound through the stratum corneum relative to its permeability coefficient across the viable epidermis (dimensionless).
t* - Time to reach steady-state

Total										Total of Receptor Risks Across All Media	2.1E-04				Total of Receptor Hazards Across All Media	2.5E-01

Notes-

NA = Not available / Not applicable.

* Constituent acts via a mutagenic mode of action (MMOA). ADAF of 3 used to adjust CSF for 12-16 year old for exposure duration of 4 years, ADAF of 1 used to adjust CSF for 16-18 year old for exposure duration of 2 years.
Non-cancer calculations shown under 12-16 year old only, as non-cancer calculations are not adjusted for MMOA.

DAevent for surface water from dry event calculated on Table 7.1.RME Supplement A.

DAevent for surface water from wet event calculated on Table 7.1.RME Supplement B.

Total includes sum of exposed and near shore sediment, maximum of dry event and wet event surface water, and maximum of air prior to areation system operation and after aeration system started.

Total										Total of Receptor Risks Across All Media	8.5E-04				Total of Receptor Hazards Across All Media	5.3E-01

Notes-

NA = Not available / Not applicable.

* Constituent acts via a mutagenic mode of action (MMOA). ADAF of 10 used to adjust CSF for 0-2 year old for exposure duration of 2 years, ADAF of 3 used to adjust CSF for 2-6 year old for exposure duration of 4 years.
Non-cancer calculations shown under 0-2 year old only, as non-cancer calculations are not adjusted for MMOA.

DAevent for surface water from dry event calculated on Table 7.1.RME Supplement A.

DAevent for surface water from wet event calculated on Table 7.1.RME Supplement B.

Total includes sum of exposed and near shore sediment, maximum of dry event and wet event surface water, and maximum of air prior to areation system operation and after aeration system started

Inorganics: DA_{event} (mg/cm^2-event) =
$K_p \times CW \times t_{event} \times 0.001\ mg/\mu g \times 0.001\ l/cm^3$ (eq 1)

Organics: DA_{event} (mg/cm^2-event) =
If $t_{event} < t^*$, then DA_{event} =
$2 \times FA \times K_p \times CW \times (\sqrt{((6 \times \tau_{event} \times t_{event})/\pi)}) \times 0.001\ mg/\mu g \times 0.001\ l/cm^3$ (eq 2)

If $t_{event} > t^*$, then DA_{event} =
$FA \times K_p \times CW \times (t_{event}/(1+B) + 2 \times \tau_{event} \times ((1 + 3xB + 3xB^2)/(1+B)^2) \times 0.001\ mg/\mu g \times 0.001\ l/cm^3$ (eq 3)

Notes:
NA - Not applicable
Permeability constants and other input parameter values from EPA 2004, *Risk Assessment Guidance for Superfund Volume I: Human Health Evaluation Manual (Part E, Supplemental Guidance for Dermal Risk Assessment - Final).* EPA/540/R/99/005. The default value of 0.001 was assigned to inorganics not listed in this document.
B - Dimensionless ratio of the permeability coefficient of a compound through the stratum corneum relative to its permeability coefficient across the viable epidermis (dimensionless).
t* - Time to reach steady-state

Inorganics: DA_{event} (mg/cm^2-event) =
$K_p \times CW \times t_{event} \times 0.001$ mg/µg $\times 0.001$ l/cm^3 (eq 1)

Organics: DA_{event} (mg/cm^2-event) =
If $t_{event} < t^*$, then DA_{event} =
$2 \times FA \times K_p \times CW \times (\text{sqrt}((6 \times \tau_{event} \times t_{event})/\pi)) \times 0.001$ mg/µg $\times 0.001$ l/cm^3 (eq 2)

If $t_{event} > t^*$, then DA_{event} =
$FA \times K_p \times CW \times (t_{event}/(1+B) + 2 \times \tau_{event} \times ((1 + 3xB + 3xB^2)/(1+B)^2) \times 0.001$ mg/µg $\times 0.001$ l/cm^3 (eq 3)

Notes:
NA - Not applicable
Permeability constants and other input parameter values from EPA 2004, *Risk Assessment Guidance for Superfund Volume I: Human Health Evaluation Manual (Part E, Supplemental Guidance for Dermal Risk Assessment - Final).* EPA/540/R/99/005. The default value of 0.001 was assigned to inorganics not listed in this document.
B - Dimensionless ratio of the permeability coefficient of a compound through the stratum corneum relative to its permeability coefficient across the viable epidermis (dimensionless).
t* - Time to reach steady-state

Overflow Surface Water Total											6.3E-05					
Total											3.0E-04	Total of Receptor Hazards Across All Media				

Notes-

NA = Not available / Not applicable.

DAevent for surface water calculated on Table 7.5.RME Supplement A.

Total includes maximum between air prior to and after aeration system operations, and surface water, and sediment.

1. See Table 7.7.RME Supplement A for calculation of intake and cancer risk following MMOA method.

TABLE 7.7.RME Supplement A

NA - Not applicable

Permeability constants and other input parameter values from EPA 2004, *Risk Assessment Guidance for Superfund Volume I: Human Health Evaluation Manual (Part E, Supplemental Guidance for Dermal Risk Assessment - Final).* EPA/540/R/99/005. The default value of 0.001 was assigned to inorganics not listed in this document.

B - Dimensionless ratio of the permeability coefficient of a compound through the stratum corneum relative to its permeability coefficient across the viable epidermis (dimensionless).

t* - Time to reach steady-state

TABLE 7.1.CTE Supplement B

Surface Water Total - Wet Event											1.6E-05					7.9E-03
Total										Total of Receptor Risks Across All Media	5.4E-05				Total of Receptor Hazards Across All Media	9.9E-02

Notes-

NA = Not available / Not applicable.

* Constituent acts via a mutagenic mode of action (MMOA). ADAF of 3 used to adjust CSF for 12-15 year old for exposure duration of 3 years, the CTE exposure duration for an adolescent.

DAevent for surface water from dry event calculated on Table 7.1.CTE Supplement A.

DAevent for surface water from wet event calculated on Table 7.1.CTE Supplement B.

Total includes sum of exposed and near shore sediment, and maximum of dry event and wet event surface water

Total										Total of Receptor Risks Across All Media	2.1E-04			Total of Receptor Hazards Across All Media		1.7E-01

Notes-

NA = Not available / Not applicable.

* Constituent acts via a mutagenic mode of action (MMOA). ADAF of 10 used to adjust CSF for 0-2 year old for exposure duration of 2 years, ADAF of 3 used to adjust CSF for 2-3 year old for exposure duration of 1 year, for a total CTE exposure duration of 3 years.
Non-cancer calculations shown under 0-2 year old only, as non-cancer calculations are not adjusted for MMOA.

DAevent for surface water from dry event calculated on Table 7.1.CTE Supplement A.

DAevent for surface water from wet event calculated on Table 7.1.CTE Supplement B.

Total includes sum of exposed and near shore sediment, and maximum of dry event and wet event surface water

Organics: DA_{event} (mg/cm^2-event) =

If $t_{event}<t^*$, then DA_{event} =

$2 \times FA \times K_p \times CW \times (sqrt((6 \times \tau_{event} \times t_{event})/\pi))$ x 0.001 mg/µg x 0.001 l/cm^3 (eq 2)

If $t_{event}>t^*$, then DA_{event} =

$FA \times K_p \times CW \times (t_{event}/(1+B) + 2 \times \tau_{event} \times ((1 + 3xB + 3xB^2)/(1+B)^2)$ x 0.001 mg/µg x 0.001 l/cm^3 (eq 3)

Notes:

NA - Not applicable

Permeability constants and other input parameter values from EPA 2004, *Risk Assessment Guidance for Superfund Volume I: Human Health Evaluation Manual (Part E, Supplemental Guidance for Dermal Risk Assessment - Final).* EPA/540/R/99/005. The default value of 0.001 was assigned to inorganics not listed in this document.

B - Dimensionless ratio of the permeability coefficient of a compound through the stratum corneum relative to its permeability coefficient across the viable epidermis (dimensionless).

t* - Time to reach steady-state

Total										Total of Receptor Risks Across All Media	7.5E-05				Total of Receptor Hazards Across All Media	

Notes-

NA = Not available / Not applicable.

DAevent for surface water calculated on Table 7.4.CTE Supplement A.

Total includes maximum between air prior to and after aeration system operations, and surface water, and sediment.

1. See Table 7.6.CTE Supplement A for calculation of intake and cancer risk following MMOA method.

TABLE 7.6.CTE Supplement A

Medium	Exposure Medium	Exposure Point	Chemical of Potential Concern	Carcinogenic Risk				Non-Carcinogenic Hazard Quotient				
				Ingestion	Inhalation	Dermal	Exposure Routes Total	Primary Target Organ(s)	Ingestion	Inhalation	Dermal	Exposure Routes Total

HI - Hazard Index

CNS - Central Nervous System

Receptor Total and target organ total includes sum of exposed and near shore sediment, maximum of dry event and wet event surface water, and maximum of air prior to areation system operation and after aeration system started

* Constituent acts via a mutagenic mode of action (MMOA). ADAF of 3 used to adjust CSF for 12-16 year old for exposure duration of 4 years, ADAF of 1 used to adjust CSF for 16-18 year old for exposure duration of 2 years. Non-cancer calculations shown under 12-16 year old only, as non-cancer calculations are not adjusted for MMOA.

Medium	Exposure Medium	Exposure Point	Chemical of Potential Concern	Carcinogenic Risk				Non-Carcinogenic Hazard Quotient				
				Ingestion	Inhalation	Dermal	Exposure Routes Total	Primary Target Organ(s)	Ingestion	Inhalation	Dermal	Exposure Routes Total

HI - Hazard Index

CNS - Central Nervous System

Receptor Total and target organ total includes sum of exposed and near shore sediment, maximum of dry event and wet event surface water, and maximum of air prior to areation system operation and after aeration system started

* Constituent acts via a mutagenic mode of action (MMOA). ADAF of 10 used to adjust CSF for 0-2 year old for exposure duration of 2 years, ADAF of 3 used to adjust CSF for 2-6 year old for exposure duration of 4 years. Non-cancer calculations shown under 0-2 year old only, as non-cancer calculations are not adjusted for MMOA. as non-cancer calculations are not adjusted for MMOA.

SUMMARY OF RECEPTOR RISKS AND HAZARDS FOR COPCs

REASONABLE MAXIMUM EXPOSURE

Gowanus Canal Remedial Investigation, Brooklyn, New York

Scenario Timeframe: Current/Future
Receptor Population: Angler
Receptor Age: Child

Medium	Exposure Medium	Exposure Point	Chemical of Potential Concern	Carcinogenic Risk				Non-Carcinogenic Hazard Quotient				
				Ingestion	Inhalation	Dermal	Exposure Routes Total	Primary Target Organ(s)	Ingestion	Inhalation	Dermal	Exposure Routes Total

HI - Hazard Index

* Constituent acts via a mutagenic mode of action (MMOA). ADAF of 10 used to adjust CSF for 0-2 year old for exposure duration of 2 years, ADAF of 3 used to adjust CSF for 2-6 year old for exposure duration of 4 years. Non-cancer calculations shown under 0-2 year old only, as non-cancer calculations are not adjusted for MMOA.

Target organ totals for Fish

Total Body Weight HI Across All Media =	4.1E-02
Total Developmental HI Across All Media =	1.4E+00

Receptor Total											Receptor HI Total	1.1E+00

HI - Hazard Index

CNS - Central Nervous System

Receptor Total and target organ totals includes maximum between air prior to and after aeration system operation, and sediment.

Total Finger and Toe Nails HI Across All Media =	1.5E-01
Total Nasal HI Across All Media =	9.7E-01
Total Ocular HI Across All Media =	1.5E-01
Total Respiratory HI Across All Media =	9.7E-01

1.0 TYPOLOGY OF BULKHEAD CONSTRUCTION

The purposes of this document are to identify the types of bulkheads that line the Gowanus Canal in Brooklyn, New York (Figure 1), to evaluate the historic significance and integrity of each of these types of bulkheads, and to recommend possible treatment strategies for historically significant bulkheads. The study was carried out in compliance with Section 106 of the National Register Preservation Act in conjunction with this EPA directed CERCLA (Superfund) action. In the case that repair of deteriorated bulkheads appears infeasible, mitigation recommendations have been made. As specified in the scope of work for this investigation, little original research was conducted. Instead, most of the information in this document was gathered from information in two previous studies: Hunter Research, Inc. (HRI)'s *National Register of Historic Places Eligibility Evaluation and Cultural Resources Assessment for the Gowanus Canal* (HRI 2004) and Adam Brown's *Gowanus Canal: Bulkhead Inventory Survey* (Brown 2000).

1.1 DEFINITION OF A BULKHEAD

In general terms, a bulkhead is a structure erected to prevent the bank of a waterway from collapsing into the waterway. As indicated in the *Design of Coastal Revetments, Seawalls and Bulkheads*, issued by the U.S. Army Corps of Engineers:

> The terms *bulkhead* and *seawall* are often used interchangeably. However, a bulkhead is primarily intended to retain or prevent sliding of the land, while protecting the upland area against wave action is of secondary importance. Seawalls, on the other hand, are more massive structures whose primary purpose is interception of waves. Bulkheads may be either cantilevered or anchored (like sheetpiling) or gravity structures (such as rock-filled timber cribs). Their use is limited to those areas where wave action can be resisted by such materials (USACE 1995:1-1).

Over time, a variety of materials and construction techniques have been employed for river and canal bulkheads including timber cribs, timber piles, wood sheet piling, and steel sheet piling.

1.2 HISTORY OF BULKHEAD CONSTRUCTION ON THE GOWANUS CANAL

Although precise information about bulkhead planning and installation on the Gowanus Canal is minimal, HRI was able to assemble significant amounts of information concerning the sequence of bulkhead construction in their 2004 report.

The Gowanus Canal, as initially planned in the 1840s, was viewed as a possible solution to the lack of adequate drainage for sewage and stormwater of the rapidly growing city. In addition, the filling of the Gowanus marshes would provide additional available land for development. The initial plans for the canal were developed by Major David B. Douglass, a West Point-trained engineer who had earlier worked on New Jersey's Morris Canal.

A year after Douglass made his proposals, Daniel Richards, one of the city's most prominent landowners and real estate developers, presented a plan to City Council which would drain the Gowanus meadows and allow them to be filled. Developed in collaboration with the City Surveyor, Willard Dey, Richards's plan called for a 5,400-foot-long, 100-foot-canal, approximately 14 feet deep excavated to five feet below mean water with walls at four feet above mean high water.

Page Intentionally Left Blank

In order to avoid the expense of cribwork, Richards apparently proposed timber sheet piling to retain the vertical canal banks. When initial construction had been completed in 1854, the waterway lacked finished walls in most places or was lined with timber sheet piling unable to withstand stormwater washing mud into the canal (HRI 2004:40).

The initial major improvements for the canal took place between 1866 and 1870 under the auspices of the Gowanus Canal Improvement Commission. HRI described the types of bulkhead construction employed:

> At least inshore of Hamilton Avenue, the commission built canal walls where none existed previously or were not being built by private interests. Some landowners such as Edwin Litchfield built cribwork walls along their own frontages, often using these walls to fill extensive areas away from the canal....Existing conditions strongly suggest that the commission walls built 1866-1870 were also cribwork, based in part on the poor performance of sheet pile structure in the marsh environment (HRI 2004:42).

1.3 TYPES OF BULKHEADS ON THE GOWANUS CANAL

Three major types of bulkheads are present along the Gowanus Canal:

- Timber cribwork. In many areas the upper section is deteriorated, replaced with concrete and/or covered with rip-rap.
- Concrete bulkheads or relieving platforms, including five bridge abutments.
- Sheet piling of timber or steel.

1.3.1 Timber Crib Bulkheads

The earliest examples of this type consisted of a few rough logs laid along the water's edge with earth and sand filling behind them. Later cribs were constructed of rough logs, notched at the junction to form a rectangular framing, weighted with stones to sink it to the bottom, the filling being rock, earth and sand. As the crib sank in the subsoil additional logs were placed, building it up to the proper height.

HRI described a standardized mid-nineteenth century timber crib bulkhead:

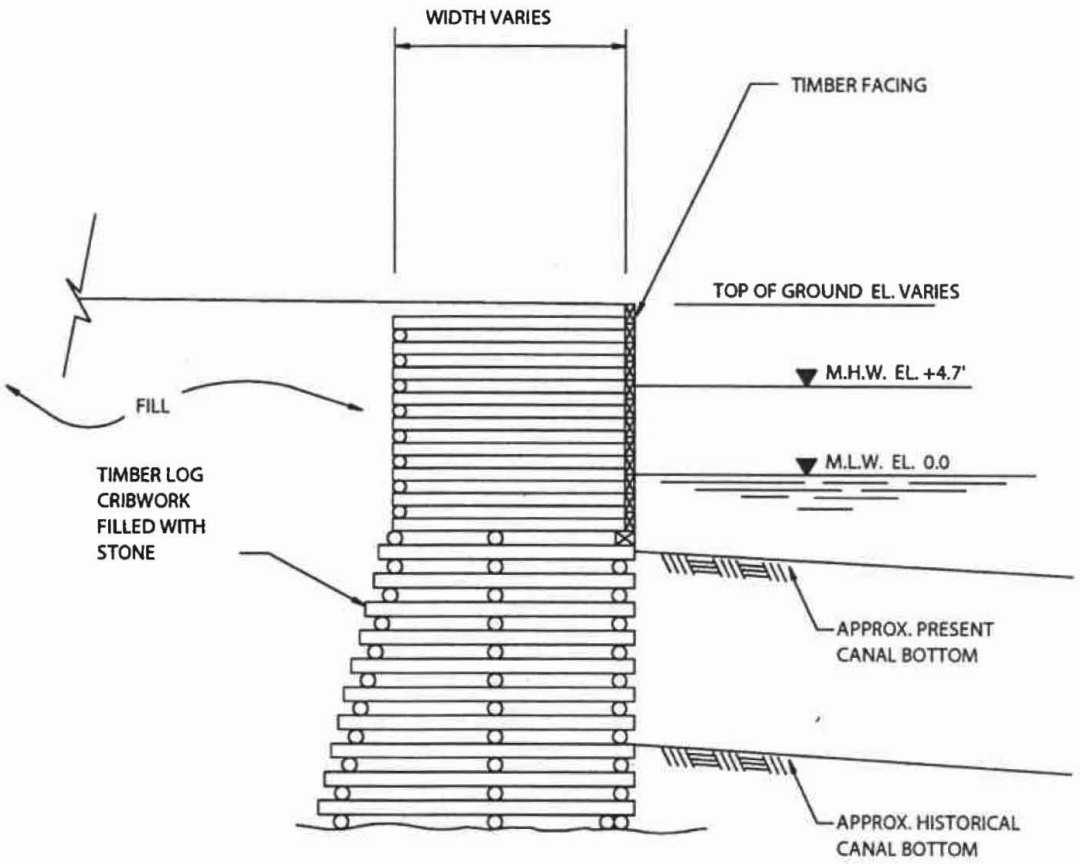
> Cribwork construction of the mid-nineteenth century and later involved spiking together logs in alternating perpendicular rows forming square or rectangular cells. Arranged in lines or grids, these cells commonly measured five to eight feet on a side, and from about seven to eight feet in height. Empty cribwork units could be floated into place and sunk as fill was added. Some cells, probably at the bottom of cell units, had plank flooring to hold enough material to sink the structure; builders added more fill once the cells were in place to form a solid bulkhead. Cribwork often reached to between 20 and 25 feet below mean low water, and extended to about 10 feet above this elevation. In section, cribs below mean low water typically extended to widths of 20 to 25 feet, sometimes tapering in the exterior or both faces as they rose. Above mean low water, crib widths in section narrowed to about fifteen feet....Square timbers, spiked or bolted together in a smooth, continuous face and fitted into notch cribwork logs, formed the outer face of the bulkhead above mean low water in most cases….The upper horizontal surface of the bulkhead varied from packed earth to timber to stone (HRI 2004:72).

The turn-of-the-twentieth century crib was made of squared timbers, halved together at the corners and splices, the successive corners held together with drift bolts. Mooring piles and string pieces were provided and a deck of six-inch planks was usually added.

The timber crib bulkhead was recommended where timber was cheap and a hard clay or gravel bottom could be found at a reasonable depth. The estimated lifespan of crib bulkheads was 50 to 75 years (Orrock 1910:161). According to a 1905 report, the Department of Docks of the City of New York had constructed about 17,550 linear feet of crib bulkhead (Hoag 1905:107).

By the early twentieth century, opinion at the New York Dock Department had turned against the timber crib:

> Of all the structures with which the Department has had to deal, the most uncertain and unsatisfactory are crib bulkheads. No one can afford to predict their behavior; they may bulge on the face; they may retain a constant profile but bulge for line; they may even show an inshore movement at times; they may settle and they may not (Hoag 1905:105).



Based upon his field investigations, marine diver Adam Brown subdivided the types of timber crib bulkheads found on the Gowanus Canal: general timber crib (Type 1; Figure 2); crib with mass concrete for the upper three to five feet (Type 2; Figure 3); crib with concrete blocks for the upper three to five feet (Type 3; Figure 4); crib with vertical timber facing (Type 4; Figure 5); crib with fender piles along face (Type 5; Figure 6); crib with steel strap tiebacks (Type 6; Figure 7); and crib with concrete bulkhead wall (Type 7; Figure 8).

By far the most common of these types observed by Adam Brown was the general timber crib which, in 2000, represented 44.5 percent of the total bulkhead length. Second most common was the crib with mass concrete for the upper three to five feet (Type 2) which accounted for 18.2 percent of the total bulkhead length. The remaining types represented from 0.6 to 5.6 percent of the total bulkhead length. Many of the types of timber crib bulkheads may represent attempts to maintain deteriorating bulkheads. For example, the mass concrete or concrete blocks may have been employed to either cover or replace the original, then deteriorated timber superstructure, as may be the use of vertical timber facing or fender piles. Steel strap tiebacks may have been used, as they are with sheetpile walls, to anchor the wall to the adjacent bank to prevent shifting.

HRI indicated that in the early twentieth century, concrete bulkheads were appended to older cribwork and that the new work generally extended beyond the old a distance of about 20 feet (HRI 2004:74).

1.3.2 Timber Pile Bulkheads

Timber crib bulkheads were appropriate where there was a firm surface upon which the crib could be set. Where, as in many locations in the former Gowanus marshes, the waterway bottom was sandy or silty or bedrock or clay were located more than 25 feet below mean low water, timber pile-driven bulkheads were the norm.

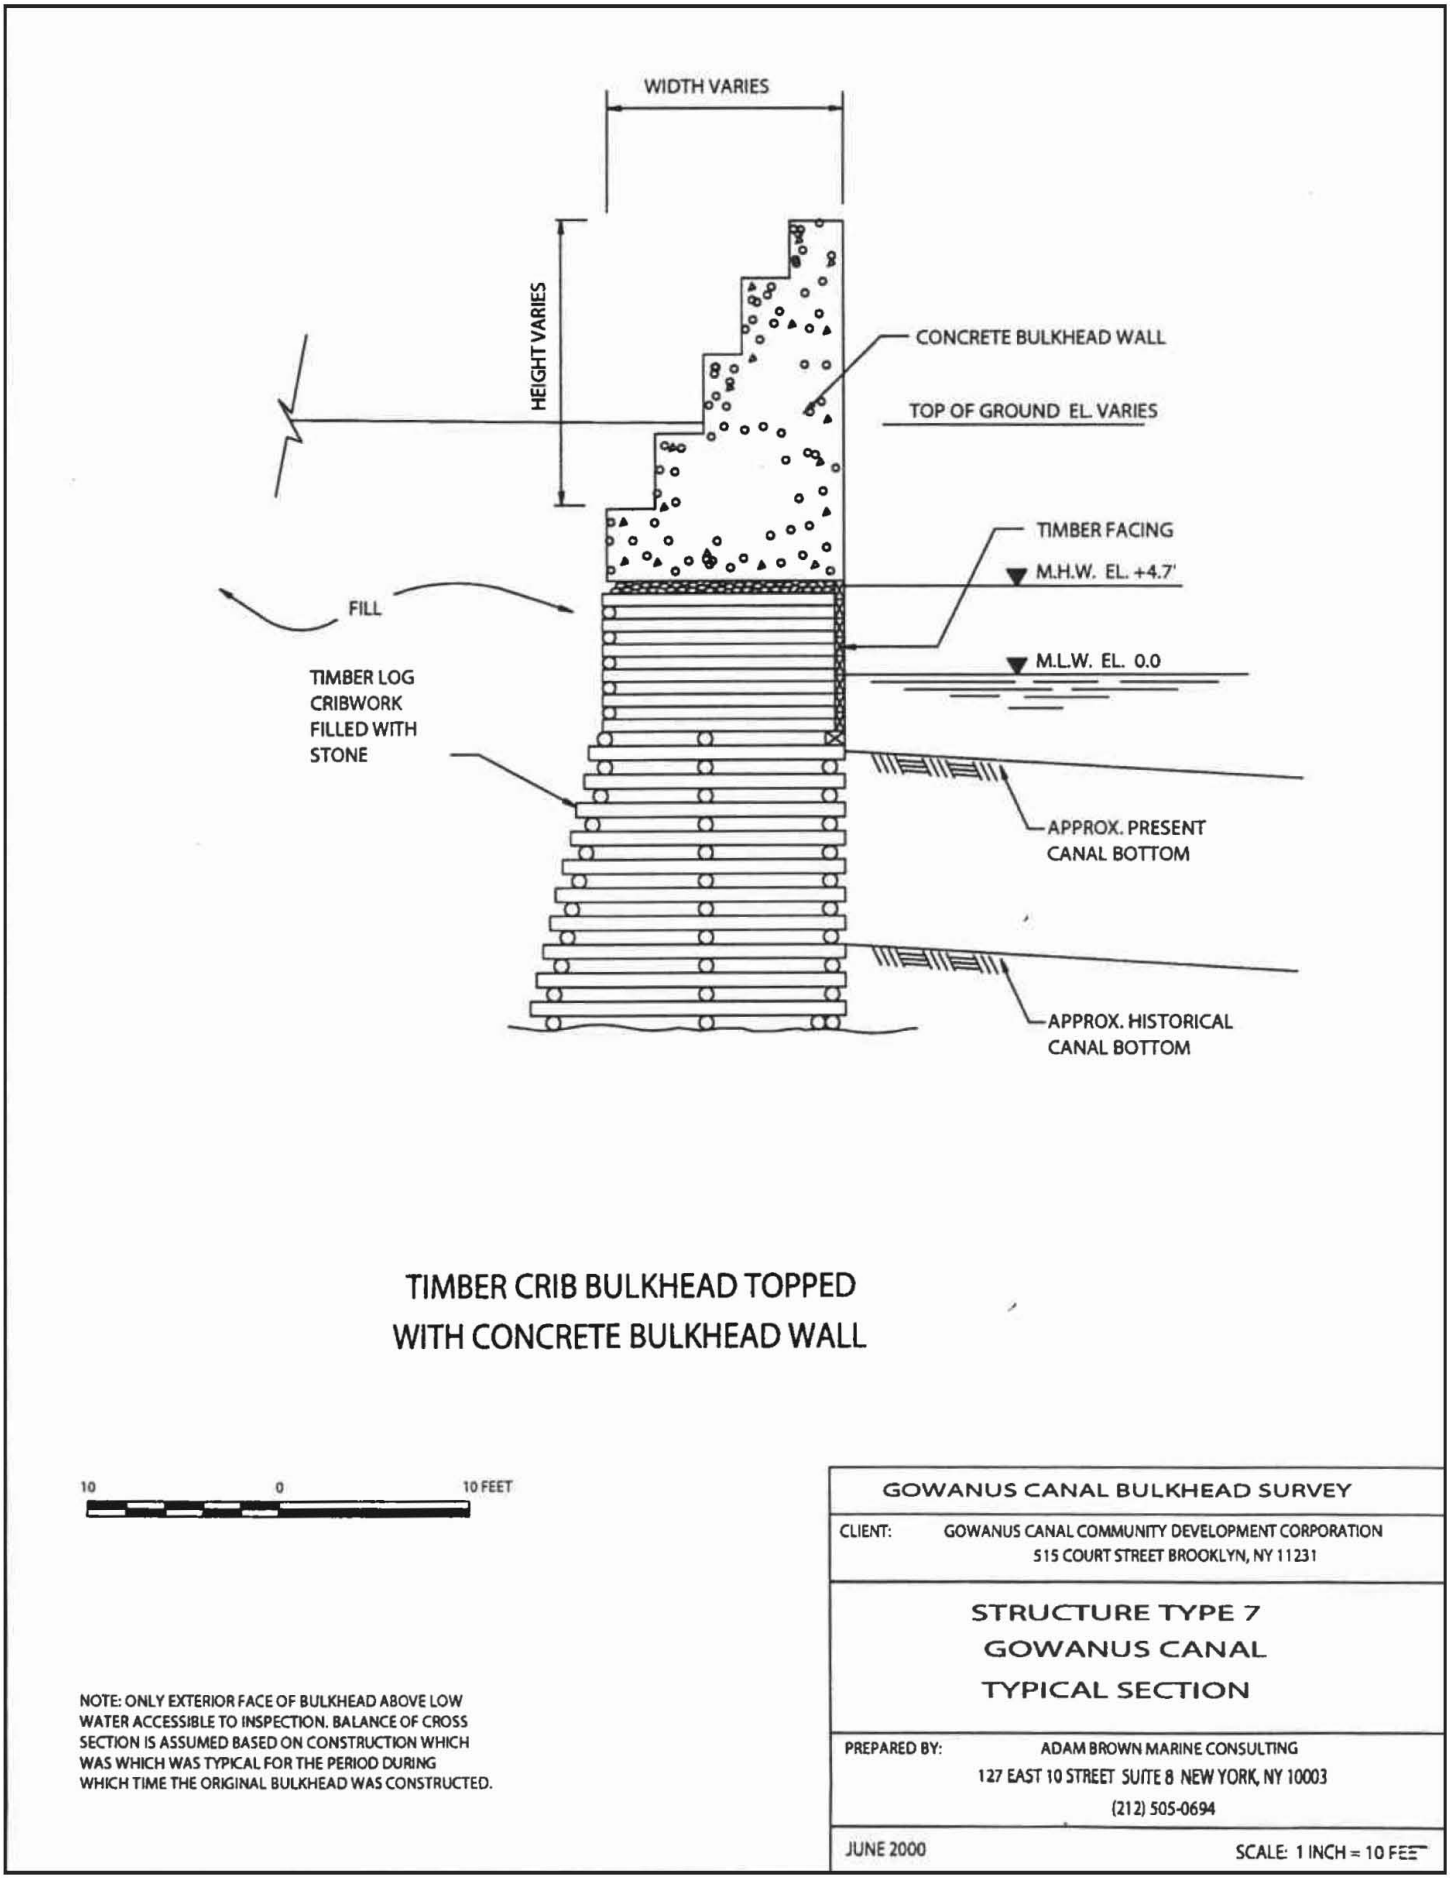

Figure 8. Typical section of timber crib bulkhead topped with concrete bulkhead wall (Brown 2000). Used by permission.

As J.F. Springer indicated in his history of steel sheet piling prepared for *Cassier's Magazine*, the earliest sheet-pile was an unhewn timber. This raw timber was succeeded by squared timber and tongue-and-groove timber. Springer viewed the culmination of the development of wood sheet piling as the Wakefield sheeting developed in the latter portion of the nineteenth century which he described, as follows:

> Each consists of three planks identical in width and thickness. These are bolted and nailed together to form a unit-pile, having a face equal to that of a single plank and a tongue and groove of the depth of one-half the width of a plank.

Springer indicated that this type of piling was often quite successful (Springer 1910:160). However, there could also be difficulties with this material. One was its limited ability to withstand lateral pressure. A second is the inevitable deterioration of the interlock points, while a third was the difficulty of driving sheeting through hard soils (Springer 1910:162).

Adam Brown indicated that the following types of closely spaced timber pile bulkheads are present on the Gowanus Canal: closely spaced timber piles (Type 8; Figure 9), representing 0.9 percent of the total bulkhead length; piles topper with concrete base and concrete blocks (Type 9; Figure 10), representing 0.2 percent of the total bulkhead length; piles with timber waler (Type 10; Figure 11), representing 0.7 percent of the total bulkhead length; piles with horizontal timber facing (Type 11; Figure 12), representing 0.2 percent of the total bulkhead length; and piles with vertical facing over horizontal facing (Type 12; Figure 13).

1.3.3 Wood Sheet Pile Bulkheads

Although steel sheet pile bulkheads began being used in the late nineteenth century in some areas of the country, available evidence suggests that they were first used on the Gowanus Canal in the second quarter of the twentieth century. Initially the sheet pile was employed behind new timber piles to add stability to the construction but after World War II, steel piling tended to replace the timber pile supports and subdecks completely (HRI 2004:74).

Adam Brown described the construction of the steel sheet pile bulkhead (Figures 14 and 15):

> A steel sheet pile bulkhead consists of a flexible wall formed of steel sheets with interlocking joints and cap of concrete construction. The bulkhead is restrained from outward movement by an anchorage system placed above the low water level. The anchorage system is made up of tie rods and anchors (deadmen), of either concrete blocks, sheet piles, or A-frames of batter piles (Brown 2000).

According to Adam Brown, approximately 16.6 percent of the total bulkhead length was, as of 2000, constructed of sheet pile.

1.3.4. Steel Sheet Pile Bulkheads

According to HRI, most concrete bulkheads in the New York City area were relieving platform designs (Figure 16), introduced shortly after 1900 by some of the region's railroads. In his bulkhead study, Adam Brown defines a "relieving platform":

> A relieving platform is a deck of timber or concrete supported on piles, generally of timber, at an elevation sufficiently above mean low water to eliminate underwater

> construction and low enough to keep timber piles permanently wet. A masonry gravity wall is located at the outshore face of the platform to retain the fill which extends from the deck up to finished grade. Upland or onshore fill is retained by an embankment of rip rap, or rip rap protected earth, beneath the deck, and a curtain wall located at the inshore end of the deck. Batter piles are provided to resist the lateral thrust from live load surcharges, from the earth placed above the deck and from the fill acting on the unsupported length of the curtain wall. The objective of this type of structure is to relieve or reduce the lateral thrust which would act on a wall with a vertical face extending from canal bottom to finished grade (Brown 2000).

According to Adam Brown, as of 2000, approximately 2.9 percent of the total bulkhead length consisted of relieving platforms.

junction with the platform, where the thickness of riprap, through which the filling passed, was a minimum. This could have been prevented by careful grading of the riprap to make it sufficiently tight to hold the filling, by depositing a bed of selected dry filling over the riprap, or by placing a vertical sheeting at the rear edge of the platform.

It is important to make the dredged trench of sufficient

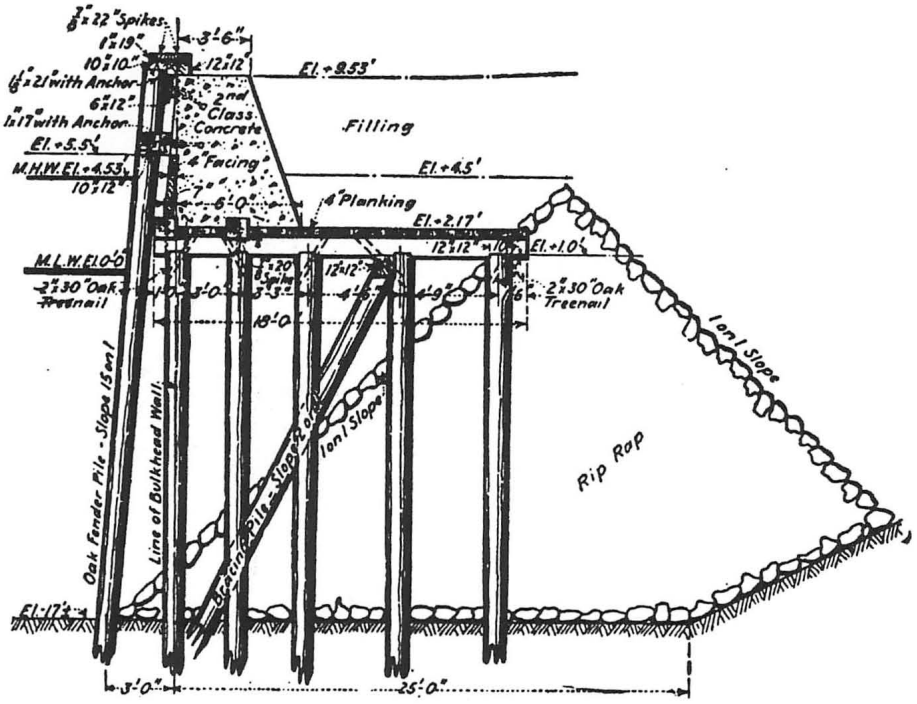

Fig. 31. Platform Wall, Gowanus Bay, Brooklyn, N. Y.

width, in the rear of such a wall, to prevent the riprap from sliding and pushing the piles out of plumb. Where such a wall encloses a large tidal area to be filled by pumping, special attention must be paid to the management of the filling and to the openings for controlling the effluent of the pumps and the flow of the tide through the wall, in order to prevent the washing of the dredged material through the riprap.

This wall was designed for a live load of 500 pounds per square foot and required piles to be placed 4 feet longi-

Figure 16. Example of platform wall construction (Greene 1917).

2.0 NATIONAL REGISTER SIGNIFICANCE AND INTEGRITY REQUIREMENTS FOR BULKHEADS

Considered in its entirety, the Gowanus Canal bulkhead system, as other surveyed bulkhead systems in New York (for example, the Hudson River Bulkhead), is representative of the evolution of bulkhead technology in the region. As noted, the earliest portions of the bulkhead may date from the 1850s or 1860s, while the dates of the most recent sections are not known, but probably post-date 1960.

The earliest portions of the bulkheads are of timber crib construction. Historian Michael Raber, in his evaluation of the Hudson River bulkheads, discusses significance and integrity issues related to timber crib bulkheads:

> When timber was relatively inexpensive, cribwork was a cheap form of bulkhead requiring only hand tools after any dredging phases. Disappearance of marine borers from the harbor beginning about 1850 made most bulkhead components permanent. Periodic replacement of all components subject to decay above mean low water complicates any identification of extant cribwork bulkheads with particular decades, and minimizes the significance of these upper elements. Cribwork bottoms are the least documented and probably most varied elements in timber bulkheads throughout the port, however, and tend to remain well preserved under water. The bottoms…could include important information on once-widespread vernacular engineering practice (Raber 2000:5).

As noted, the condition of portions of the bulkhead varies as does its date of construction or alteration. While concrete may usually be indicative of twentieth century construction, it may represent alterations to a nineteenth century bulkhead whose timber crib substructure remains intact. Steel sheet pile bulkheads may have replaced original bulkhead construction but may contribute to the significance of the resource as evidence of the evolution of bulkhead construction. Additional research should be focused on, among other topics, the dates of construction of the later portions of the bulkhead.

JMA recommends that all portions of the bulkhead that can be dated to before 1960 be considered eligible for the National Register under Criterion A. In addition, it is recommended that the timber crib portions of the bulkhead also be considered eligible under Criterion C as exemplifying the characteristics of nineteenth century timber crib construction and under Criterion D as having the potential to yield information about mid-to-late nineteenth century, timber crib construction practice.

3.0 PRESERVATION TREATMENT AND MITIGATION STRATEGIES FOR BULKHEADS

3.1 CASE STUDIES OF OTHER FEDERALLY-FUNDED OR PERMITTED UNDERTAKINGS INVOLVING BULKHEADS

The following represent easily accessible information on federal undertakings in which historic bulkheads are affected. This information may not be representative, and it is recommended that further information be sought in one or more state historic preservation office research collections.

Hudson River Park

Character of the Bulkhead

The Hudson River Park, planned to extend along the west shore of Manhattan from its tip to the Clinton neighborhood, includes within its APE the Hudson River Bulkhead. The bulkhead and its associated structural systems were constructed between 1871 and 1936 by the New York City Department of Docks. The EIS for the undertaking described the bulkhead as follows:

> The majority of the construction consisted of masonry walls on a variety of foundation systems, with quarry-faced ashlar granite block forming the visible face along nearly 80 percent of the armored frontage. The carefully built granite walls created a consistent monumental surface to waterfront sections seen by many thousands of transatlantic passengers, reinforcing an image of New York's commercial prominence. The bulkhead also incorporates two sections of older timber design. Approximately 18 percent of the bulkhead has concrete facing on a low-water relieving platform, a type which began to be used ca. 1920 and became the standard for new or replacement pile-supported bulkheads (AKRF 1998:7.5).

Proposed Treatment Recommendation and Mitigation

The EIS described the proposed treatment recommendation as follows:

> As presently proposed, repair work in sections of the bulkhead that are faced with granite would be done using either granite that has been salvaged from other sections of the bulkhead to replace its coping (or top layer). The proposed plan, which has been approved by SHPO, would involve rehabilitation of large sections/length of the granite bulkhead in relatively good/intact condition using granite salvaged from areas of the wall where the wall is either in poor conditions or where only a small length of the wall remains. In areas where the granite wall is either in deteriorated condition or of a short length, repairs would be made in concrete…. (AKRF 1998).

East River Waterfront Esplanade and Piers

Character of the Bulkhead

Typically, the visible bulkhead above the water line consisted of rough-cut granite ashlar with a capping course of larger granite blocks, with beveled upper edges surmounted by a simple squared timber

"backing-log." The granite walls were backed by mass concrete and originally included four courses of granite blocks laid as alternating headers and stretchers to an elevation of about 9.4 feet above mean low water.

All sections of the East River bulkhead within the project area have been altered to various degrees since their construction. On sections retaining the highest degree of integrity, such as the area between Broad Street and Coenties Slip, the visible alteration has been the replacement of the "backing-log" with a new piece of timber that, rather than being laid atop the granite cap stone, has been bolted into the face of the cap stone. Furthermore, a substantial metal railing has been added atop the bulkhead for much of its length, the majority of which likely dates to the construction of the FDR Drive along the waterfront (AKRF 2006:6-17).

Proposed Treatment Recommendation and Mitigation

The EIS for the proposed project indicates that the following changes would be made:

> From Broad Street to Old Slip, the esplanade would be developed with a new, approximately 20-foot-wide structure built out over the water, beyond the existing bulkhead. The new archipelago area is expected to be an independent structure on pilings.
>
> The proposed reconstruction of Pier 15 would require new piles, as well as presumably, minor alterations for attachments to the bulkhead.
>
> …the original granite bulkhead remains in good condition from Broad Street to Coenties Slip. The area would be visible from the new independent structure carrying the archipelago. The bulkhead structure itself would not be altered. In addition, the original granite bulkhead would remain visible at other locations within the project area. From Coenties Slip to Old Slip, the bulkhead may be in very poor condition behind the concrete wall which was built in the mid-20th century (AKRF 2006:6-24-25).

New Whatcom Redevelopment Project (Washington State)

Character of the Project and Bulkhead

Among the potentially eligible historic resources include the bulkhead/wharf defining the Whatcom Waterway in Bellingham, which is reflective of historic maritime use.

Proposed Treatment Recommendation and Mitigation

The proposed mitigation of the action would include HABS/HAER documentation for eligible structures that are scheduled for demolition, an interpretation plan for the Whatcom Waterway area and potentially eligible buildings and structures onsite that are scheduled for demolition or major modification, and salvage and reuse developed for potentially eligible for buildings and structures scheduled for demolition (Port of Bellingham 2008:3-11-12).

World Trade Center Transportation Hub, Route 9A Pedestrian Underpass

Character of the Project and Bulkhead

The project involves construction of a pedestrian concourse to provide access between the former World Trade Center site, Battery Park City, and the World Financial Center. The portion of the pedestrian concourse that crosses Route 9A will be constructed as an underpass, and this proposed construction intersects the expected location of a portion of the Hudson River Bulkhead (HRB).

Based on Michael Raber's 2000 study, it was expected that the bulkhead design would employ wide concrete blocks supporting a granite wall with wood log backing, receiving platform, inclined bracing and vertical posts. This design was used between 1899 and 1915 (Louis Berger Group, Inc. 2006:3).

Proposed Treatment and Mitigation

Based upon drawings in the Port Authority of New York and New Jersey (PANYNJP) it is thought that the upper portion of the bulkhead may have already been disturbed by installation of a flume/outfall for the World Trade Center. To confirm the condition of the HRB in the project area, Louis Berger suggested archeological monitoring during the Underpass construction.

Berger indicated a planned strategy if the configuration of the HRB was as expected:

> It is anticipated that the HRB will extend to a depth of 50 feet from the top of the granite wall. At a depth of approximately 15 feet from the top of the granite wall, it is anticipate that the material will change to concrete….The archaeologist will record the exposed granite/stone wall supported by stone and logs as the excavation contractor exposes this wall along the length of the trench…The archeologist will record evidence of the exposed HRB by drawing a plan view of it's [sic] extent across the archaeological trench, photograph the exposed portions, collect any archaeological material in association with the HRB, and draw the nearest soil profile (Louis Berger Group, Inc. 2006:9).

363-365 Bond Street, Brooklyn, New York

Character of the Project and the Bulkhead

The applicant, Toll Brothers, Inc., proposed to redevelop two blocks along the west waterfront of the Gowanus Canal. The proposed development would include a mixture of residential, commercial, community facility, and open space uses.

The portion of the canal bulkhead within the proposed project area is of wood crib construction.

Proposed Treatment and Mitigation

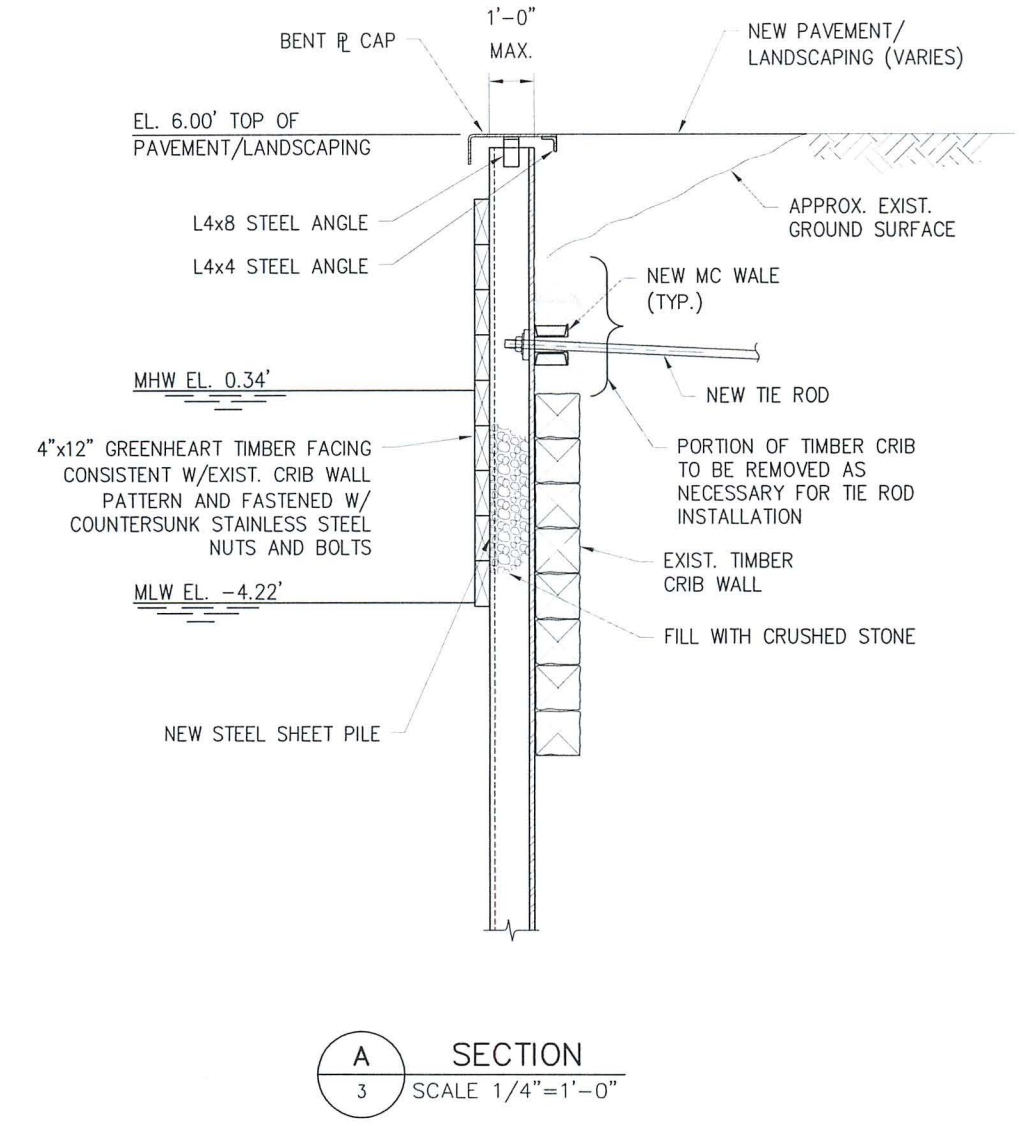
The proposed treatment of the portion of the bulkhead within the project area was the subject of a July 2008 memorandum from Joseph Silva, an engineer with Halcrow HPA. The initial plan called for the installing of a new steel sheet pile wall outboard of the existing timber crib bulkhead as close as constructability would allow. However, this plan was rejected by the New York State Department of Environmental Protection (Halcrow HPA 2009).

The memorandum evaluated four strategies: no action; repair the existing rock filled timber crib bulkhead; install a new steel sheet pile bulkhead behind the existing timber bulkhead; or complete demolition, excavation, removal, and replacement of the existing bulkhead.

The no action alternative would permit the bulkhead to continue to deteriorate and eventually collapse. Repairs to the bulkhead were viewed as providing only a short-term solution to the ongoing deterioration and eventual failure of the bulkhead. Repairs would consist of patching and possibility fortifying it in selected locations. However, since the deterioration was so widespread, these types of repairs would only be partially effective.

The third alternative, installation of a new sheet pile bulkhead behind the existing timber bulkhead was determined impractical because it would disrupt the framework of timbers causing the risk of failure of the bulkhead. The final alternative, demolition and rebuilding, was deemed too extreme, disruptive to the environment, and cost prohibitive.

As a solution, Halcrow HPA suggested the construction of a new steel sheet pile wall placed up against the existing bulkhead. The sheet pile wall would mimic the existing timber crib wall through use of timber facing consistent with the existing crib wall pattern (see Figure 17) (Halcrow HPA 2009).



3.2 TREATMENT RECOMMENDATIONS FOR DEWATERED BULKHEADS

As part of the proposed remedy, dewatering of the canal may be applicable. An initial literature search failed to identify references specifically related to dewatering bulkheads. Sources were identified that discuss the effects of dewatering timber pile building foundations. As Russo, Brainerd, and Vatovec indicate in an article in *Structure*, dewatering poses substantial risk to structural members which remain continually immersed:

> Dewatering has the potential to cause ground settlement, settlement of pile foundations due to drawdown (negative skin friction), or rotting of untreated wood pile foundation systems.
>
> Removing water from weaker, compressible soil strata such as soft clay, peat and silt [as is apparently present in portions of the Gowanus Canal], effectively increases the stress on the soil, which can cause consolidation. Depending on the extent of compressible soils and the profile of the water-elevation drawdown, settlement can either be uniform or differential….Consolidation of soil around piles can create negative friction resulting in a downward force on the piles and subsequent settlement.
>
> When sections of previously immersed, untreated wood piles become exposed to air, conditions such as moisture and abundant oxygen, necessary for fungal growth, are created and initiate an accelerated decay process. The rate of deterioration of piles is highly sensitive to even minor variations in the environment around the piles: wood species, soil chemistry and makeup, etc. Consequently, the duration of exposure necessary to significantly impair the structural integrity of piles is unpredictable, but is usually longer than the length of most construction-related dewatering operations (Russo, Brainerd, and Vatovec 2008).

A similar caution is raised concerning pilings in a National Park Service Preservation Tech Note in which the author cautions that previously submerged timber piles that are exposed to air can quickly undergo dryout. Strategies suggested to mitigate this effect include using watertight excavation support systems such as slurry walls (NPS n.d.:3).

Because of the risk of structural deterioration during dewatering, it would be prudent to have a structural engineer or other professional familiar with timber deterioration on site or on call during the dewatering.

PURPOSE: PROPOSED NEW BULKHEAD PREPARED BY HPA ENGINEERS, P.C.	363–365 BOND STREET SHEETPILE BULKHEAD SECTION A	PROPOSED: STEEL SHEET PILE BULKHEAD CITY: BROOKLYN COUNTY: KINGS APPLICANT: TOLL BROTHERS, INC. SHEET 4 OF 7 DATE: 6/19/2008

Figure 17. Proposed alterations to timber crib bulkheads on portion of Gowanus Canal near 363-365 Bond Street (HPA Engineers, PC 2008).

The appropriate treatment strategy for deteriorated bulkheads will depend, of course, on its materials and method of construction. A discussion of treatment options is included in the Naval Engineering Facilities Command's (NEFC) *Maintenance of Waterfront Facilities* (UFC 4-150-07) available on the Internet (http://www.wbdg.org/ccb/DOD/UFC/ufc_4_150_07.pdf.) Some of the recommendations included in this publication are summarized below.

Repair of Timber Piles

Marine borers are the cause of extensive damage to wood piles, and due to the carcinogenic character of the leading marine wood preserver, creosote, some states have banned its use in marine waters. The United Facilities Criteria handbook for maintenance and operation of waterfront facilities discusses six repair methods for damaged wood piles:

1) Wrapping them with polyvinyl chloride or polyethylene wraps;

2) Partial posting of a damaged wood pile by joining a new pile but with bolted prestressed timber fish plates;

3) Encasement of the pile in concrete;

4) Repair or retrofit of timber piles with an underwater-curing epoxy and fiber-reinforced wraps;

5) Replacement with a new wood pile; and

6) Replacement of the wood pile with a new concrete pile.

Clearly, several of these methods would not adhere to the provisions of the Secretary of Interior's Standard due to either removal or covering of historic fabric. Suggestions 5 and 6 would permit the removal of the historic fabric with no attempt to retain the historic character of the structure. Suggestions 1 and 3 would involve obscuring the historic fabric of the bulkhead. Clearly, the remaining two alternatives: sistering a portion of the old pile to the new pile, and use of epoxy consolidates, represent approaches in keeping with accepted preservation practice with the exception of the application of a fiber-reinforced wrap to the column's exterior (Lopez-Anido et al. 2005:78-79).

Repair of Timber Sheet Piling Walls

The NEFC indicates that three repair strategies may be used on timber sheet piling walls. First, in the case of light to moderate movement of the upper portion of the wall, the existing tie-back system should be reinforced. If a tie-back system is not present, movement may be reduced by installing a tie-back system at the top of the wall. In the case of deterioration of pilings, a repair strategy includes installing a concrete cap or face on the timber sheet piling wall (NEFC 2001:6-4).

Clearly, the first two alternatives would be in keeping with the Secretary of the Interior's Standards for Rehabilitation, while the third would not. It must, however, be recognized, that the third alternative has already been used in sections of the Gowanus Canal.

Repair of Steel Sheet Pile Wall Bulkheads

The NEFC cites six repair techniques for sheet piling walls:

1. Coating and cathodic protection to slow corrosion;
2. Patching of missing portions of the wall;
3. Reinforcing the tie-back systems;
4. Replacement of the existing wall;
5. Installation of a concrete cap or face;
6. Scour protection.

Clearly, the first three repair techniques will not greatly alter the appearance of the existing wall so would be in accordance with the Secretary of the Interior's Standards. Coating and cathodic protection involves the installation of wiring and a power source to insure the cathodic protection and covering of the existing surface with a protective coating, as discussed on pages 3.21 and 3.22 of the UFC manual. Patching of the wall generally consists of either the use of epoxy or steel plate or both. Reinforcement of the tie back system can stabilize a wall that suffers from light to moderate movement. This repair (shown in Figure 17) would include installing a new wale above the existing wales, trenching for tie rods and deadman anchors, and installation of zinc or magnesium anodes to prevent future corrosion of the rods. A final strategy is to change the soil loading acting on the wall. For example, stone riprap dumped against its exterior toe will add resistance to movement (NEFC 2001:8-4-5).

Repair of Earth-Filled Structures

In the case of bulkheads used to retain the surrounding shoreline, the NEFC recommends using riprap to shore up the structure or reduce seepage and loss of backfill rather than performing expensive repairs to the structure. Specific recommendations include:

> Where there is evidence of erosion or loss of soil, protective coverings, such as rock fill or armor units, should be removed and the internal fill inspected. Any necessary repairs in the form of replacement of properly compacted soil should be made…A series of soil layers of varying coarseness may be used to insure that the finer, central materials cannot be washed out through the coarser shell materials (NEFC 2001:10-2).

A potentially useful material for retention of soil is geotextiles, porous, flexible polymeric fabrics used for separating soil types, soil retention, and strength reinforcement. Geotextiles may also be used to seal structures to prevent further loss of material (NEFC 2001:10-1-4).

3.3 MITIGATION OPTIONS FOR ADVERSE EFFECTS ON BULKHEADS

At the time of Brown's 2000 survey, an estimated 41.7 percent of the bulkhead length was in fair condition or worse. Fair condition was noted as characterized by timber deterioration sufficient to let fill escape. Because of lack of preventive maintenance in the intervening years, it is likely that the proportion of timber deterioration may have increased. Clearly, a portion of this length will not be able to be repaired.

For that portion of the bulkhead, several mitigation activities are recommended:

1) thorough archeological investigation of the timber cribs including photography and measured drawings to document the varieties in crib construction;

2) additional historical documentation including an intensive-level context development for both canal bulkheads and bulkheads of the New York area, as well as to obtain as much information as possible concerning the evolution of the Gowanus Canal bulkheads; and

3) a public history component consisting of an illustrated popular history of the Gowanus Canal; a website on the Gowanus Canal's history and cleanup; a video history of the canal and cleanup activities; and/or one or more interpretative panels concerning the canal placed at locations of public gathering near the canal.

4.0 SUGGESTIONS FOR ADDITIONAL AREAS OF RESEARCH AND REPOSITORIES

This preliminary investigation has yielded some information useful to the preparation of environmental compliance documentation for the Gowanus Canal, but it has also pointed to areas where additional information would be very useful. These areas of recommended further research include the following:

- Background information on timber crib construction using sources from the mid-nineteenth century and more recent research.

Such information would provide insight into the varieties of timber crib construction and how the Gowanus Canal cribs are typical or atypical of construction practices. Such sources may include digitized documents available on a variety of on-line public databases (such as Google Books and Internet Archives), and subscription databases (including JSTOR, American History and Life, etc.).

In addition, further information may be available in a variety of research collections, such as the American Philosophical Society, the Library Company of Philadelphia, and the Hagley Library (Wilmington, Delaware).

- Chronological information concerning construction of and alterations to the Gowanus Canal bulkhead.

A potentially critical source may be the archival records of the New York Department of Docks, an agency established in 1870. According to Raber, most surviving plans and drawings related to New York City's municipal waterfront construction are deposited at the Municipal Archives in Lower Manhattan.

Another useful Department of Docks source is likely to be the annual reports of the Department. Scattered earlier years are available on-line through Google Books, and an initial perusal yielded some references to bulkhead construction on the Gowanus Canal. These reports are available in the collection of the Main Research Library, New York Public Library, or at the Municipal Records and Research Center, New York Department of Records and Information Services.

Other sources may include newspaper articles and historic photographs. The *Brooklyn Daily Eagle* newspaper has been digitized from the 1840s into the early 1900s and will be a useful source of information for earlier changes to the canal, while articles on later canal alterations may be available in the Brooklyn Collection vertical files of the Brooklyn Public Library. The Brooklyn Collection also contains many historic photographs of the Gowanus Canal, as does the New York Public Library Research Library, and the Municipal Archives.

One other potential source of information on the construction and the evolution of the canal and its bulkheads is the New York Canal Records available at the New York State Archives in Albany. It is recommended that an initial reference inquiry be made to ascertain whether the collection does indeed contain information on the Gowanus Canal.

- Additional information concerning treatment recommendations for bulkhead components.

Up-to-date information on material conservation for bulkhead components may be available in a variety of sources including Naval and Army Corps of Engineers technical manuals, publications of the American Institute for Conservation and the Association for Preservation Technology, and the Texas A&M University Underwater Archeology program and Institute for Nautical Archeology. In addition, the

Maritime Conservation Program of East Carolina University may be able to provide guidance on materials conservation issues.

One specific study that may contain useful guidance is the 1965 *Bulkhead Stabilization Survey, Study and Report at Various Locations*, prepared by Christopher J. Foster Consulting Engineers. This report incorporates data from field survey of bulkhead failure areas and provides practical methods to stabilize existing steel sheet pile bulkheads and timber bulkheads with tie-rod anchorages. This report is available through the Defense Technical Information Center.

Introduction

As part of the on-going Gowanus Canal Preliminary Bulkhead Study, high-frequency side scan sonar data were collected in Gowanus Canal, Brooklyn, NY. Side scan sonar data were collected along the entire length of the canal, from the mouth to the upstream limits above Douglas Street, including three large boat basins and a small boat basin (Figure 1). The purposes and goals of the investigation were to identify site conditions, anomalies, obstructions, and potential submerged cultural resources in the canal and boat basins and along the various bulkheads that canalized the waterway.

Description of Work Area

Sonar coverage extended from the mouth of the canal marked by a Hess marine terminal, all the way up to the head of the canal, including the four boat basins in the canal system. For the purposes of this side scan sonar survey, the four boat basins are referred to as Cove 1, Cove 2, etc. from north to south. Under our labeling designations, Cove 1 is the 5th St. boat basin, Cove 2 is the 6th St. boat basin, Cove 3 is the 7th St boat basin, and Cove 4 is the 11th St. (Lowes) boat basin.

At the mouth of the canal water depth generally exceeded 30 feet. While the entire canal is tidal water depth averaged 6-10 feet at mean low water (mlw) during our investigations. At the head of the canal and within the boat basins, water depth dropped to less than three feet (mlw). A large diameter aeration pipe extended from below the 3rd St. Bridge to Douglas St., near the head of the canal.

To access the entire range of the canal all work was conducted at or near high tide. Due to DGPS limitations while navigating under several of the five bridges that span the canal, accurate sonar coverage under the bridges was limited.

Summary of Field Survey and Equipment

Project horizontal reference is the New York (East) State Plane Coordinate System, NAD 83, in feet.

Side scan sonar survey operations were conducted from a 23-foot aluminum *SeaArk* survey vessel. A *Marine Sonic* Sea Scan HDS all-digital side scan sonar system with a dual frequency, 600/1200 kHz tow fish, was used to conduct the acoustic survey. *Hypack*, a laptop PC-based software package in conjunction with a Differential Global Positioning System (DGPS) onboard the survey vessel, provided positioning accuracy for the survey area of +/- three (3) feet. The sonar unit was operated at a 100-foot range with in the canal and boat basins to provide comprehensive coverage and sufficient detail of all features. At the mouth of the canal, south of the Hamilton Avenue Bridge, the sonar was set to a range of 150-feet since the water was deeper and the project area was considerably wider at this location.

The side scan sonar derives its information from reflected acoustic energy that is recorded onto a laptop survey computer. Side looking sonar, which transmits and receives swept high frequency bandwidth signals from transducers mounted on a sensor that is towed from a survey vessel. Two sets of transducers mounted in an array along both sides of the towfish generate the short duration acoustic pulses required for high resolution images. The pulses are emitted in a thin, fan-shaped pattern that spreads downward to either side of the towfish in a plane perpendicular to its path. As the fish is towed along the survey trackline this acoustic beam sequentially scans the bottom from a point beneath the fish outward to each side of the trackline.

Sonar data were gathered to document the nature and condition of the submerged portions of the canal floor and the various bulkheads that canalized the canal and the boat basins. Acoustic energy reflected from any discontinuities on the canal floor or along the faces of the bulkheads (exposed portions of cribbing, gaps in the sheet piles or cribbing, or blow-outs where rip-rap or other fill material has failed and spilled out onto the canal floor) is received by the set of transducers, amplified and transmitted to the survey vessel via a tow cable. The digital output from state-of-the-art units is essentially analogous to a high-angle oblique photograph and it provided detailed representations of submerged features and structural characteristics in the canal.

Raw sonar data files were edited using software from *Chesapeake Technology*. Data files were processed by adding the appropriate layback, and removing the water column from the records. A layback program in *Chesapeake Technology* provided sensor positioning. The actual sensor position was calculated by integrating two components; 1) offsets from the GPS antenna to the towing point, and 2) cable out to the sensor. The software then automatically calculated the sensor position for every sonar ping. The layback calculation was checked for each sonar set-up by conducting reciprocal passes on one end of a bulkhead corner.

All processed sonar files were then compiled into a geo-referenced sonar mosaic of the canal. The sonar mosaic was then overlaid onto a geo-referenced aerial photograph of the canal. All sonar records were inspected for potential man-made features and obstructions present on the canal floor. Individual acoustic data files were initially examined using Marine Sonic's *SeaScan* acoustic data review software to identify any unnatural or man-made features in the canal. Individual targets, e.g. localized obstructions, are described and displayed independently in Table 1, below. Acoustic targets are normally defined according to their spatial extent, configuration, location and environmental context.

Data Analysis & Discussion

While detailed and comprehensive sonar data were collected throughout the canal and all four boat basins, a few limiting factors were encountered. Various locations between the 3rd Street Bridge and the head of the canal were being actively aerated. The aeration process generated large volumes of air bubbles into the water column that effectively blanked-out sonar returns in the immediate vicinity of the aeration outfall points. Double-berthed construction and work barges also prevented comprehensive acoustic coverage at two locations at the mouth of the canal.

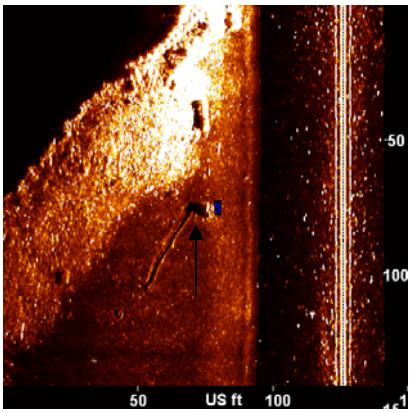
Locations of sonar contacts were typically described relative to the closest side of the canal. Since the path of the canal changes directions, the listed side of the canal (starboard – right, or port – left) was oriented to ascending the canal, or moving upstream.

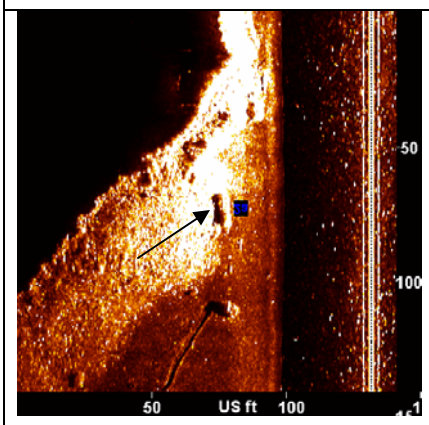
Sonar Findings

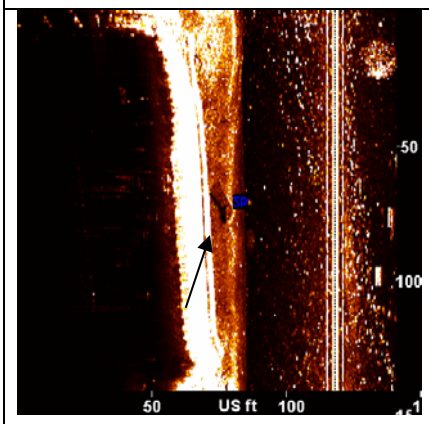
Sonar records confirm the presence of isolated debris and general debris scatters, ship and/or barge wrecks, debris from bulkhead failures, and isolated objects and obstructions at various locations across the canal. A sonar mosaic of the entire canal was produced (Figure 1). Details of the mosaic at five locations within the canal are presented in Figures 2-6. A total of 29 features/obstructions or other noteworthy bottom characteristics were identified in the canal. See Table 1, below, for a complete listing and description of the bottom features identified on the sonar records. Locations of the 29 targets are depicted in Figures 7-9.

The 29 sonar targets and target clusters can be generally characterized into four groups: potential submerged cultural resources (7); isolated debris – potential cars (2); linear and circular debris or

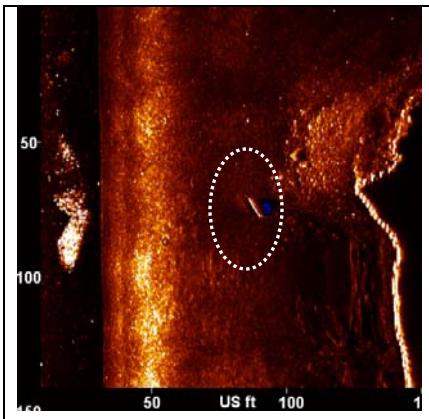
debris fields (13); and rip-rap debris associated with apparent bulkhead failures (7). Typical examples of all the target types are found in Figures 10 – 18.

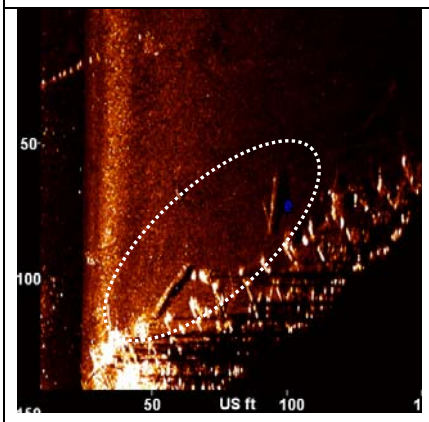


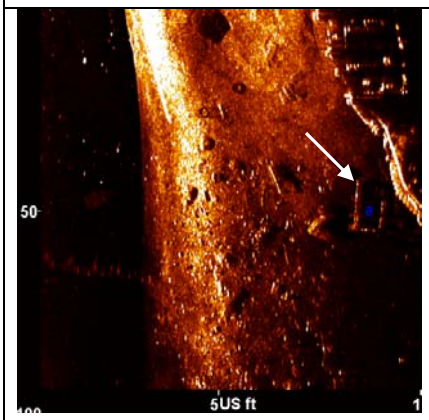


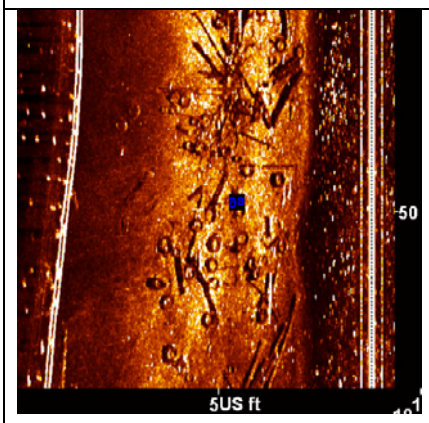


Sonar contacts **31, 31a, 31b, 37a, 37b, 37c,** and **39** are considered to be associated with potential submerged cultural resources. All seven contacts are located in Coves 1 and 2. A 60' long, round-ended shipwreck in Cove 1 was identified as Contact **31a.** Two large square-ended wood barges (contacts 37a & 37b) were identified in Cove 2. The other four potential submerged cultural resources are not intact ship wrecks but may represent material from ships.









Sonar contacts **2a** and **2b**, rectangular features partially buried close to bulkheads, have the potential to be automobiles or large containers discarded from the shoreline. Sonar contacts **2, 3, 5, 9, 9a, 24, 26, 28, 31c, 35, 42a, 48,** and **52** have been classified as linear or circular debris or debris fields. While debris is widespread across much of the canal these locations had prominent clusters or clearly defined individual objects and were designated as contacts. Sonar contacts **11, 11a, 11b, 17, 37, 42,** and **42b** were associated with debris fields that have spilled away from bulkheads – that are assumed to been compromised.

Analytical Soil Results

2010

Gowanus Canal –

Remedial Investigation

Brooklyn, NY

Property Address: 201 Douglass St. - Gowanus Pump Station (Head of Gowanus Canal)
Monitoring Well Soil Borings Installed at Address: GC-MW-01I & GC-MW-2I
Intermediate Monitoring Wells Installed at Address: GC-MW-01I & GC-MW-2I
Shallow Monitoring Wells Installed at Address: GC-MW-01S & GC-MW-2S

GC-MW-01

The soil samples from the soil boring installed for the intermediate well (situated approximately 37 feet from the canal) contained 53 VOCs, 95 SVOCs, 4 pesticides, 1 PCBs, and 119 metals. From these, 7 VOCs, 1 SVOC, 0 pesticides, 0 PCBs, and 3 metals exceeded the screening value. The VOC occurring at the highest concentration above screening value was acetone (90,500 µg/kg). The SVOC occurring at the highest concentration above screening value was phenol (531 µg/kg). The metal occurring at the highest concentration above screening value was mercury (1.5 mg/kg).

Shallow groundwater

The shallow well (depth of approximately17 ft bgs and situated approximately 37 feet from the canal) contained 7 VOCs, 7 SVOCs, 0 pesticides, 0 PCBs, and 10 metals. From these, 1 VOC, 0 SVOCs, 0 pesticides, 0 PCBs, and 4 metals exceeded the screening criteria. The VOC occurring at the highest concentration above screening criteria was benzene (1.1 µg/L). The metal occurring at the highest concentration above screening criteria (excluding sodium) was iron (3,950 µg/L).

Shallow groundwater at this location is expected to discharge to the canal.

Intermediate groundwater

The intermediate well (depth of approximately40 ft bgs and situated approximately 37 feet from the canal) contained 13 VOCs, 9 SVOCs, 0 pesticides, 0 PCBs, and 15 metals. From these, 3 VOCs, 0 SVOCs, 0 pesticides, 0 PCBs, and 5 metals exceeded the screening criteria. The VOC occurring at the highest concentration above screening criteria was vinyl chloride (31.5 µg/L). The metal occurring at the highest concentration above screening criteria (excluding sodium) was iron (19,900 µg/L).

Intermediate groundwater at this location is expected to discharge to the canal.

Contaminated groundwater discharging to the canal would affect the quality of the water in the canal.

GC-MW-02

The soil samples from the soil boring installed for the intermediate well (situated approximately 59 feet from the canal) contained 27 VOCs, 42 SVOCs, 2 pesticides, 0 PCBs, and 115 metals. From these, 6 VOCs, 0 SVOC, 0 pesticides, 0 PCBs, and 0 metals exceeded the screening value. The VOC occurring at the highest concentration above screening value was acetone (48,300 µg/kg).

Shallow groundwater

The shallow well (depth of approximately13 ft bgs and situated approximately 59 feet from the canal) contained 0 VOCs, 0 SVOCs, 0 pesticides, 0 PCBs, and 9 metals. From these, 0 VOCs, 0 SVOCs, 0 pesticides, 0 PCBs, and 3 metals exceeded the screening criteria. The metal occurring at the highest concentration above screening criteria (excluding sodium) was iron (5,480 µg/L).

Shallow groundwater at this location is expected to discharge to the canal.

Intermediate groundwater

The intermediate well (depth of approximately35 ft bgs and situated approximately 59 feet from the canal) contained 2 VOCs, 2 SVOCs, 0 pesticides, 0 PCBs, and 12 metals. From these, 1 VOC, 0 SVOCs, 0 pesticides, 0 PCBs, and 3 metals exceeded the screening criteria. The VOC occurring at the highest concentration above screening criteria was vinyl chloride (2.7 µg/L). The metal occurring at the highest concentration above screening criteria (excluding sodium) was iron (4,540 µg/L).

Intermediate groundwater at this location is expected to discharge to the canal.

Contaminated groundwater discharging to the canal would affect the quality of the water in the canal.

Gowanus Canal Remedial Investigation – Brooklyn, NY

Notes on Soil and Groundwater Analytical Tables:

Analytical laboratory results of soil and groundwater samples collected within this property are presented in the following tables. Samples were collected in the summer of 2010 during the USEPA led remedial investigation of the Gowanus Canal Superfund Site. Analytical results for each sample collected within this property are shown including detected chemical concentrations and non-detected concentrations (designed with a U qualifier). The analytical method detection limit (MDL) is shown for non-detected compounds. The units for analytical results are specified in each table header.

Data Qualifiers:

B – Analyte detected in an associated blank

J – Concentration Estimated

N – Presumptive evidence of a compound based on a mass spectral library search

U – Constituent not detected above the MDL

R-Rejected

Table Acronyms

ft – feet

S-Split Sample

N-Normal sample

Analytical Soil Results

2010

Gowanus Canal –

Remedial Investigation

Brooklyn, NY

Property Address: Former Fulton Manufactured Gas Plant (Located along Degraw St. on the eastern side of the canal)
Monitoring Well Soil Borings Installed at Address: GC-MW-30I, GC-MW-31I, & GC-MW-32I
Intermediate Monitoring Wells Installed at Address: GC-MW-30I, GC-MW-31I, & GC-MW-32I
Shallow Monitoring Wells Previously Installed at Address: GC-MW-30S, GC-MW-31S, & GC-MW-32S

GC-MW-30

The soil samples from the soil boring installed for the intermediate well (situated approximately 37 feet from the canal) contained 49 VOCs, 141 SVOCs, 3 pesticides, 0 PCBs, and 146 metals. From these, 11 VOCs, 4 SVOC, 0 pesticides, 0 PCBs, and 2 metals exceeded the screening value. The VOC occurring at the highest concentration above screening value was trichloroethylene (TCE) (13,000 µg/kg). The SVOC occurring at the highest concentration above screening value was chrysene (3,000 J µg/kg). The metal occurring at the highest concentration above screening value was arsenic (58.4 mg/kg).

Shallow groundwater

The shallow well (depth of approximately19 ft bgs and situated approximately 37 feet from the canal) contained 6 VOCs, 10 SVOCs, 0 pesticides, 0 PCBs, and 14 metals. From these, 4 VOCs, 1 SVOC, 0 pesticides, 0 PCBs, and 3 metals exceeded the screening criteria. The VOC occurring at the highest concentration above screening criteria was benzene (2,100 µg/L). The SVOC occurring at the highest concentration above screening criteria was biphenyl (48 µg/L). The metal occurring at the highest concentration above screening criteria (excluding sodium) was manganese (717 µg/L).

Shallow groundwater at this location is expected to discharge to the canal.

Intermediate groundwater

The intermediate well (depth of approximately37 ft bgs and situated approximately 37 feet from the canal) contained 6 VOCs, 9 SVOCs, 0 pesticides, 0 PCBs, and 8 metals. From these, 4 VOCs, 1 SVOC, 0 pesticides, 0 PCBs, and 3 metals exceeded the screening criteria. The VOC occurring at the highest concentration above screening criteria was benzene (5,200 µg/L). The SVOC occurring at the highest concentration above screening criteria was biphenyl (19 µg/L). The metal occurring at the highest concentration above screening criteria (excluding sodium) was iron (4,000 µg/L).

Intermediate groundwater at this location is expected to discharge to the canal.

Contaminated groundwater discharging to the canal would affect the quality of the water in the canal.

GC-MW-31

The soil samples from the soil boring installed for the intermediate well (situated approximately 31 feet from the canal) contained 27 VOCs, 88 SVOCs, 18 pesticides, 1 PCB, and 122 metals. From these, 8 VOCs, 9 SVOCs, 0 pesticides, 0 PCBs, and 0 metals exceeded the screening value. The VOC occurring at the highest concentration above screening value was ethylbenzene (59,000 µg/kg). The SVOC occurring at the highest concentration above screening value was naphthalene (410,000 µg/kg).

Shallow groundwater

The shallow well (depth of approximately15 ft bgs and situated approximately 31 feet from the canal) contained 4 VOCs, 7 SVOCs, 0 pesticides, 0 PCBs, and 11 metals. From these, 0 VOCs, 0 SVOCs, 0 pesticides, 0 PCBs, and 3 metals exceeded the screening criteria. The metal occurring at the highest concentration above screening criteria (excluding sodium) was manganese (1,200 µg/L).

Shallow groundwater at this location is expected to discharge to the canal.

Intermediate groundwater

The intermediate well (depth of approximately35 ft bgs and situated approximately 31 feet from the canal) contained 7 VOCs, 9 SVOCs, 2 pesticides, 0 PCBs, and 12 metals. From these, 5 VOCs, 1 SVOC, 1 pesticide, 0 PCBs, and 3 metals exceeded the screening criteria. The VOC occurring at the highest concentration above screening criteria was ethylbenzene (1,400 µg/L). The SVOC occurring at the highest concentration above screening criteria was biphenyl (80 µg/L). The pesticide occurring at the highest concentration above screening criteria was beta BHC (0.084 J µg/L). The metal occurring at the highest concentration above screening criteria (excluding sodium) was iron (2,740 µg/L).

Intermediate groundwater at this location is expected to discharge to the canal.

Contaminated groundwater discharging to the canal would affect the quality of the water in the canal.

GC-MW-32

The soil samples from the soil boring installed for the intermediate well (situated approximately 605 feet from the canal) contained 26 VOCs, 164 SVOCs, 15 pesticides, 1 PCB, and 164 metals. From these, 6 VOCs, 18 SVOCs, 0 pesticides, 0 PCBs, and 7 metals exceeded the screening value. The VOC occurring at the highest concentration above screening value was ethylbenzene (790,000 µg/kg). The SVOC occurring at the highest concentration above screening value was naphthalene (670,000 µg/kg). The metal occurring at the highest concentration above screening value was lead (1,190 J mg/kg).

Shallow groundwater

The shallow well (depth of approximately22 ft bgs and situated approximately 605 feet from the canal) contained 0 VOCs, 18 SVOCs, 0 pesticides, 0 PCBs, and 9 metals. From these, 0 VOCs, 0 SVOCs, 0 pesticides, 0 PCBs, and 2 metals exceeded the screening criteria. The metal occurring at the highest concentration above screening criteria (excluding sodium) was iron (9,810 J µg/L).

Shallow groundwater at this location is expected to discharge to the canal.

Intermediate groundwater

The intermediate well (depth of approximately46 ft bgs and situated approximately 605 feet from the canal) contained 6 VOCs, 7 SVOCs, 0 pesticides, 0 PCBs, and 12 metals. From these, 4 VOCs, 1 SVOC, 0 pesticides, 0 PCBs, and 3 metals exceeded the screening criteria. The VOC occurring at the highest concentration above screening criteria was ethylbenzene (6,300 µg/L). The SVOC occurring at the highest concentration above screening criteria was biphenyl (63 µg/L). The metal occurring at the highest concentration above screening criteria (excluding sodium) was iron (4,130 J µg/L).

Intermediate groundwater at this location is expected to discharge to the canal.

Contaminated groundwater discharging to the canal would affect the quality of the water in the canal.

Gowanus Canal Remedial Investigation – Brooklyn, NY

Notes on Soil and Groundwater Analytical Tables:

Analytical laboratory results of soil and groundwater samples collected within this property are presented in the following tables. Samples were collected in the summer of 2010 during the USEPA led remedial investigation of the Gowanus Canal Superfund Site. Analytical results for each sample collected within this property are shown including detected chemical concentrations and non-detected concentrations (designed with a U qualifier). The analytical method detection limit (MDL) is shown for non-detected compounds. The units for analytical results are specified in each table header.

Data Qualifiers:

B – Analyte detected in an associated blank

J – Concentration Estimated

N – Presumptive evidence of a compound based on a mass spectral library search

U – Constituent not detected above the MDL

R-Rejected

Table Acronyms

ft – feet

S-Split Sample

N-Normal sample

National Grid – Fulton (MW30 & MW31 & MW32)

Analytical Soil Results

2010

Gowanus Canal –

Remedial Investigation

Brooklyn, NY

Property Address: 495 & 510 Sackett St.
Monitoring Well Soil Borings Installed at Address: GC-MW-3I & GC-MW-34I
Intermediate Monitoring Wells Installed at Address: GC-MW-3I & GC-MW-34I
Shallow Monitoring Wells Installed at Address: GC-MW-3S & GC-MW-34S

GC-MW-3

The soil samples from the soil boring installed for the intermediate well (situated approximately 14 feet from the canal) contained 39 VOCs, 136 SVOCs, 16 pesticides, 0 PCBs, and 113 metals. From these, 9 VOCs, 18 SVOCs, 0 pesticides, 0 PCBs, and 1 metal exceeded the screening value. The VOC occurring at the highest concentration above screening value was ethylbenzene (160,000 µg/kg). The SVOC occurring at the highest concentration above screening value was naphthalene (1,300,000 µg/kg).

Shallow groundwater

The shallow well (depth of approximately16 ft bgs and situated approximately 14 feet from the canal) contained 5 VOCs, 17 SVOCs, 0 pesticides, 0 PCBs, and 10 metals. From these, 0 VOCs, 1 SVOC, 0 pesticides, 0 PCBs, and 3 metals exceeded the screening criteria. The SVOC occurring at the highest concentration above screening criteria was benzo(a)pyrene (0.42 µg/L). The metal occurring at the highest concentration above screening criteria (excluding sodium) was selenium (51.2 J µg/L).

Shallow groundwater at this location is expected to discharge to the canal.

Intermediate groundwater

The intermediate well (depth of approximately43 ft bgs and situated approximately 14 feet from the canal) contained 7 VOCs, 16 SVOCs, 0 pesticides, 0 PCBs, and 13 metals. From these, 1 VOCs, 0 SVOCs, 0 pesticides, 0 PCBs, and 3 metals exceeded the screening criteria. The VOC occurring at the highest concentration above screening criteria was vinyl chloride (5.9 J µg/L). The metal occurring at the highest concentration above screening criteria (excluding sodium) was manganese (2,070 µg/L).

Intermediate groundwater at this location is expected to discharge to the canal.

Contaminated groundwater discharging to the canal would affect the quality of the water in the canal.

GC-MW-34

The soil samples from the soil boring installed for the intermediate well (situated approximately 27 feet from the canal) contained 21 VOCs, 116 SVOCs, 18 pesticides, 0 PCBs, and 95 metals. From these, 6 VOCs, 20 SVOCs, 0 pesticides, 0 PCBs, and 0 metals exceeded the screening value. The VOC occurring at the highest concentration above screening value was ethylbenzene (26,000 µg/kg). The SVOC occurring at the highest concentration above screening value was acenaphthene (140,000 µg/kg).

Shallow groundwater

The shallow well (depth of approximately14 ft bgs and situated approximately 27 feet from the canal) contained 8 VOCs, 9 SVOCs, 0 pesticides, 0 PCBs, and 15 metals. From these, 0 VOCs, 1 SVOC, 0 pesticides, 0 PCBs, and 3 metals exceeded the screening criteria. The SVOC occurring at the highest concentration above screening criteria was biphenyl (5.7 J µg/L). The metal occurring at the highest concentration above screening criteria (excluding sodium) was iron (2,750 µg/L).

Shallow groundwater at this location is expected to discharge to the canal.

Intermediate groundwater

The intermediate well (depth of approximately34 ft bgs and situated approximately 27 feet from the canal) contained 9 VOCs, 10 SVOCs, 0 pesticides, 0 PCBs, and 12 metals. From these, 1 VOC, 1 SVOC, 0 pesticides, 0 PCBs, and 2 metals exceeded the screening criteria. The VOC occurring at the highest concentration above screening criteria was

vinyl chloride (4.1 J µg/L). The SVOC occurring at the highest concentration above screening criteria was biphenyl (41 J µg/L). The metal occurring at the highest concentration above screening criteria (excluding sodium) was manganese (1,140 J µg/L).

Intermediate groundwater at this location is expected to discharge to the canal.

Contaminated groundwater discharging to the canal would affect the quality of the water in the canal.

Gowanus Canal Remedial Investigation – Brooklyn, NY

Notes on Soil and Groundwater Analytical Tables:

Analytical laboratory results of soil and groundwater samples collected within this property are presented in the following tables. Samples were collected in the summer of 2010 during the USEPA led remedial investigation of the Gowanus Canal Superfund Site. Analytical results for each sample collected within this property are shown including detected chemical concentrations and non-detected concentrations (designed with a U qualifier). The analytical method detection limit (MDL) is shown for non-detected compounds. The units for analytical results are specified in each table header.

Data Qualifiers:

B – Analyte detected in an associated blank

J – Concentration Estimated

N – Presumptive evidence of a compound based on a mass spectral library search

U – Constituent not detected above the MDL

R-Rejected

Table Acronyms

ft – feet

S-Split Sample

N-Normal sample

Analytical Soil Results

2010

Gowanus Canal –

Remedial Investigation

Brooklyn, NY

Property Address: 318 Nevins St.
Monitoring Well Soil Borings Installed at Address: GC-MW-28, GC-MW-29 & GC-MW-35
Intermediate Monitoring Wells Installed at Address: GC-MW-28I, GC-MW-29I & GC-MW-35I
Shallow Monitoring Wells Installed at Address: GC-MW-28S, GC-MW-29S & GC-MW-35S

GC-MW-28

The soil samples from the soil boring installed for the intermediate well (situated approximately 36 feet from the canal) contained 36 VOCs, 109 SVOCs, 1 pesticide, 0 PCBs, and 122 metals. From these, 3 VOCs, 7 SVOCs, 0 pesticides, 0 PCBs, and 1 metal exceeded the screening value. The VOC occurring at the highest concentration above screening value was acetone (1,200 µg/kg). The SVOC occurring at the highest concentration above screening value was benzo(a)anthracene (71,000 µg/kg). The metal occurring at the highest concentration above screening value was mercury (34.1 J mg/kg).

Shallow groundwater

The shallow well (depth of approximately14 ft bgs and situated approximately 36 feet from the canal) contained 0 VOCs, 8 SVOCs, 0 pesticides, 0 PCBs, and 19 metals. From these, 0 VOCs, 0 SVOCs, 0 pesticides, 0 PCBs, and 4 metals exceeded the screening criteria. The metal occurring at the highest concentration above screening criteria (excluding sodium) was iron (23,300 µg/L).

Shallow groundwater at this location is expected to discharge to the canal.

Intermediate groundwater

The intermediate well (depth of approximately37 ft bgs and situated approximately 36 feet from the canal) contained 5 VOCs, 7 SVOCs, 0 pesticides, 0 PCBs, and 13 metals. From these, 3 VOCs, 0 SVOCs, 0 pesticides, 0 PCBs, and 3 metals exceeded the screening criteria. The VOC occurring at the highest concentration above screening criteria was cis-1,2-dichloroehylene (53 J µg/L). The metal occurring at the highest concentration above screening criteria (excluding sodium) was iron (11,800 J µg/L).

Intermediate groundwater at this location is expected to discharge to the canal.

Contaminated groundwater discharging to the canal would affect the quality of the water in the canal.

GC-MW-29

The soil samples from the soil boring installed for the intermediate well (situated approximately 152 feet from the canal) contained 19 VOCs, 23 SVOCs, 1 pesticide, 0 PCBs, and 104 metals. From these, 2 VOCs, 0 SVOCs, 0 pesticides, 0 PCBs, and 0 metals exceeded the screening value. The VOC occurring at the highest concentration above screening value was acetone (71 µg/kg).

Shallow groundwater

The shallow well (depth of approximately14 ft bgs and situated approximately 152 feet from the canal) contained 7 VOCs, 11 SVOCs, 0 pesticides, 0 PCBs, and 19 metals. From these, 0 VOCs, 0 SVOCs, 0 pesticides, 0 PCBs, and 6 metals exceeded the screening criteria. The metal occurring at the highest concentration above screening criteria (excluding sodium) was iron (16,500 µg/L).

Shallow groundwater at this location is expected to discharge to the canal.

Intermediate groundwater

The intermediate well (depth of approximately37 ft bgs and situated approximately 152 feet from the canal) contained 13 VOCs, 10 SVOCs, 0 pesticides, 0 PCBs, and 14 metals. From these, 5 VOCs, 0 SVOCs, 0 pesticides, 0 PCBs, and 3 metals exceeded the screening criteria. The VOC occurring at the highest concentration above screening criteria was benzene (19 J µg/L). The metal occurring at the highest concentration above screening criteria (excluding sodium) was iron (9,530 J µg/L).

Intermediate groundwater at this location is expected to discharge to the canal.

Contaminated groundwater discharging to the canal would affect the quality of the water in the canal.

GC-MW-35

The soil samples from the soil boring installed for the intermediate well (situated approximately 29 feet from the canal) contained 42 VOCs, 108 SVOCs, 9 pesticides, 0 PCBs, and 102 metals. From these, 21 VOCs, 21 SVOCs, 0 pesticides, 0 PCBs, and 0 metals exceeded the screening value. The VOC occurring at the highest concentration above screening value was acetone (420,000 µg/kg). The SVOC occurring at the highest concentration above screening value was naphthalene (1,100,000 µg/kg).

Shallow groundwater

The shallow well (depth of approximately14 ft bgs and situated approximately 29 feet from the canal) contained 8 VOCs, 19 SVOCs, 0 pesticides, 0 PCBs, and 17 metals. From these, 2 VOCs, 1 SVOC, 0 pesticides, 0 PCBs, and 3 metals exceeded the screening criteria. The VOC occurring at the highest concentration above screening criteria was ethylbenzene (18 µg/L). The SVOC occurring at the highest concentration above screening criteria was biphenyl (16 µg/L). The metal occurring at the highest concentration above screening criteria (excluding sodium) was iron (11,100 J µg/L).

Shallow groundwater at this location is expected to discharge to the canal.

Intermediate groundwater

The intermediate well (depth of approximately33 ft bgs and situated approximately 29 feet from the canal) contained 11 VOCs, 18 SVOCs, 0 pesticides, 0 PCBs, and 15 metals. From these, 3 VOCs, 1 SVOC, 0 pesticides, 0 PCBs, and 3 metals exceeded the screening criteria. The VOC occurring at the highest concentration above screening criteria was ethylbenzene (19 µg/L). The SVOC occurring at the highest concentration above screening criteria was biphenyl (15 µg/L). The metal occurring at the highest concentration above screening criteria (excluding sodium) was iron (9,450 J µg/L).

Intermediate groundwater at this location is expected to discharge to the canal.

Contaminated groundwater discharging to the canal would affect the quality of the water in the canal.

Gowanus Canal Remedial Investigation – Brooklyn, NY

Notes on Soil and Groundwater Analytical Tables:

Analytical laboratory results of soil and groundwater samples collected within this property are presented in the following tables. Samples were collected in the summer of 2010 during the USEPA led remedial investigation of the Gowanus Canal Superfund Site. Analytical results for each sample collected within this property are shown including detected chemical concentrations and non-detected concentrations (designed with a U qualifier). The analytical method detection limit (MDL) is shown for non-detected compounds. The units for analytical results are specified in each table header.

Data Qualifiers:

B – Analyte detected in an associated blank

J – Concentration Estimated

N – Presumptive evidence of a compound based on a mass spectral library search

U – Constituent not detected above the MDL

R-Rejected

Table Acronyms

ft – feet

S-Split Sample

N-Normal sample

Analytical Soil Results

2010

Gowanus Canal –

Remedial Investigation

Brooklyn, NY

Property Address: 322 3rd Ave.
Monitoring Well Soil Borings Installed at Address: GC-MW-25 & GC-MW-26
Intermediate Monitoring Wells Installed at Address: GC-MW-25I & GC-MW-26I
Shallow Monitoring Wells Installed at Address: GC-MW-25S & GC-MW-26S

GC-MW-25

The soil samples from the soil boring installed for the intermediate well (situated approximately 60 feet from the canal) contained 11 VOCs, 84 SVOCs, 7 pesticides, 1 PCB, and 130 metals. From these, 2 VOCs, 3 SVOCs, 0 pesticides, 0 PCBs, and 12 metals exceeded the screening value. The VOC occurring at the highest concentration above screening value was acetone (82 µg/kg). The SVOC occurring at the highest concentration above screening value was benzo(b)fluoranthene (3,200 µg/kg). The metal occurring at the highest concentration above screening value was lead (34,700 mg/kg).

Shallow groundwater

The shallow well (depth of approximately24 ft bgs and situated approximately 60 feet from the canal) contained 2 VOCs, 3 SVOCs, 0 pesticides, 0 PCBs, and 11 metals. From these, 0 VOCs, 1 SVOC, 0 pesticides, 0 PCBs, and 3 metals exceeded the screening criteria. The SVOC occurring at the highest concentration above screening criteria was bis(2-ethylhexyl) phthalate (5.1 µg/L). The metal occurring at the highest concentration above screening criteria (excluding sodium) was iron (3,900 J µg/L).

Shallow groundwater at this location is expected to discharge to the canal.

Intermediate groundwater

The intermediate well (depth of approximately43 ft bgs and situated approximately 60 feet from the canal) contained 10 VOCs, 14 SVOCs, 0 pesticides, 0 PCBs, and 14 metals. From these, 2 VOCs, 0 SVOCs, 0 pesticides, 0 PCBs, and 2 metals exceeded the screening criteria. The VOC occurring at the highest concentration above screening criteria was 1,2,4-trichlorobenzene (52 J µg/L). The metal occurring at the highest concentration above screening criteria (excluding sodium) was manganese (388 µg/L).

Intermediate groundwater at this location is expected to discharge to the canal.

Contaminated groundwater discharging to the canal would affect the quality of the water in the canal.

GC-MW-26

The soil samples from the soil boring installed for the intermediate well (situated approximately 210 feet from the canal) contained 13 VOCs, 25 SVOCs, 6 pesticides, 0 PCBs, and 68 metals. From these, 0 VOCs, 0 SVOCs, 0 pesticides, 0 PCBs, and 1 metal exceeded the screening value. The metal occurring at the highest concentration above screening value was mercury (2.8 mg/kg).

Shallow groundwater

The shallow well (depth of approximately24 ft bgs and situated approximately 210 feet from the canal) contained 10 VOCs, 8 SVOCs, 0 pesticides, 0 PCBs, and 15 metals. From these, 5VOCs, 0 SVOCs, 0 pesticides, 0 PCBs, and 4 metals exceeded the screening criteria. The VOC occurring at the highest concentration above screening criteria was 1,3-dichlorobenzene (29 J µg/L). The metal occurring at the highest concentration above screening criteria (excluding sodium) was iron (17,400 J µg/L).

Shallow groundwater at this location is expected to discharge to the canal.

Intermediate groundwater

The intermediate well (depth of approximately39 ft bgs and situated approximately 210 feet from the canal) contained 14 VOCs, 9 SVOCs, 0 pesticides, 0 PCBs, and 14 metals. From these, 1 VOC, 0 SVOCs, 0 pesticides, 0 PCBs, and 3 metals exceeded the screening criteria. The VOC occurring at the highest concentration above screening

criteria was cis-1,2-dichloroethylene (14 µg/L). The metal occurring at the highest concentration above screening criteria (excluding sodium) was iron (5,930 J µg/L).

Intermediate groundwater at this location is expected to discharge to the canal.

Contaminated groundwater discharging to the canal would affect the quality of the water in the canal.

Gowanus Canal Remedial Investigation – Brooklyn, NY

Notes on Soil and Groundwater Analytical Tables:

Analytical laboratory results of soil and groundwater samples collected within this property are presented in the following tables. Samples were collected in the summer of 2010 during the USEPA led remedial investigation of the Gowanus Canal Superfund Site. Analytical results for each sample collected within this property are shown including detected chemical concentrations and non-detected concentrations (designed with a U qualifier). The analytical method detection limit (MDL) is shown for non-detected compounds. The units for analytical results are specified in each table header.

Data Qualifiers:

B – Analyte detected in an associated blank

J – Concentration Estimated

N – Presumptive evidence of a compound based on a mass spectral library search

U – Constituent not detected above the MDL

R-Rejected

Table Acronyms

ft – feet

S-Split Sample

N-Normal sample

Analytical Soil Results

2010

Gowanus Canal –

Remedial Investigation

Brooklyn, NY

Property Address: Carroll St. (West Side of the Canal)
Monitoring Well Soil Borings Installed at Address: GC-MW-36 & GC-MW-43
Intermediate Monitoring Wells Installed at Address: GC-MW-36I & GC-MW-43I
Shallow Monitoring Wells Installed at Address: GC-MW-36S & GC-MW-43S

GC-MW-36

The soil samples from the soil boring installed for the intermediate well (situated approximately 33 feet from the canal) contained 30 VOCs, 87 SVOCs, 8 pesticides, 0 PCBs, and 96 metals. From these, 1 VOC, 4 SVOCs, 0 pesticides, 0 PCBs, and 0 metals exceeded the screening value. The VOC occurring at the highest concentration above screening value was ethylbenzene (3,100 µg/kg). The SVOC occurring at the highest concentration above screening value was benzo(a)anthracene (4,900 µg/kg).

Shallow groundwater

The shallow well (depth of approximately14 ft bgs and situated approximately 33 feet from the canal) contained 9 VOCs, 14 SVOCs, 0 pesticides, 0 PCBs, and 16 metals. From these, 0 VOCs, 1 SVOC, 0 pesticides, 0 PCBs, and 3 metals exceeded the screening criteria. The SVOC occurring at the highest concentration above screening criteria was bis(2-ethylhexyl) phthalate (5.8 µg/L). The metal occurring at the highest concentration above screening criteria (excluding sodium) was iron (13,000 µg/L).

Shallow groundwater at this location is expected to discharge to the canal.

Intermediate groundwater

The intermediate well (depth of approximately38 ft bgs and situated approximately 33 feet from the canal) contained 4 VOCs, 15 SVOCs, 0 pesticides, 0 PCBs, and 15 metals. From these, 0 VOCs, 1 SVOC, 0 pesticides, 0 PCBs, and 3 metals exceeded the screening criteria. The SVOC occurring at the highest concentration above screening criteria was biphenyl (39 µg/L). The metal occurring at the highest concentration above screening criteria (excluding sodium) was iron (2,000 µg/L).

Intermediate groundwater at this location is expected to discharge to the canal.

Contaminated groundwater discharging to the canal would affect the quality of the water in the canal.

GC-MW-43

The soil samples from the soil boring installed for the intermediate well (situated approximately 58 feet from the canal) contained 60 VOCs, 111 SVOCs, 16 pesticides, 0 PCBs, and 157 metals. From these, 5 VOCs, 14 SVOCs, 1 pesticide, 0 PCBs, and 1 metal exceeded the screening value. The VOC occurring at the highest concentration above screening value was ethylbenzene (100,000 µg/kg). The SVOC occurring at the highest concentration above screening value was naphthalene (580,000 µg/kg). The pesticide occurring at the highest concentration above screening value was alpha BHC (72 NJ µg/kg). The metal occurring at the highest concentration above screening value was cadmium (8.5 mg/kg).

Shallow groundwater

The shallow well (depth of approximately14 ft bgs and situated approximately 58 feet from the canal) contained 13 VOCs, 17 SVOCs, 0 pesticides, 0 PCBs, and 18 metals. From these, 3 VOCs, 0 SVOCs, 0 pesticides, 0 PCBs, and 3 metals exceeded the screening criteria. The VOC occurring at the highest concentration above screening criteria was ethylbenzene (9.3 µg/L). The metal occurring at the highest concentration above screening criteria (excluding sodium) was iron (19,600 µg/L).

Shallow groundwater at this location is expected to discharge to the canal.

Intermediate groundwater

The intermediate well (depth of approximately38 ft bgs and situated approximately 58 feet from the canal) contained 9 VOCs, 19 SVOCs, 0 pesticides, 0 PCBs, and 16 metals. From these, 4 VOCs, 1 SVOC, 0 pesticides, 0 PCBs, and 4

metals exceeded the screening criteria. The VOC occurring at the highest concentration above screening criteria was ethylbenzene (23 J µg/L). The SVOC occurring at the highest concentration above screening criteria was biphenyl (8.4 µg/L). The metal occurring at the highest concentration above screening criteria (excluding sodium) was iron (1,390 µg/L).

Intermediate groundwater at this location is expected to discharge to the canal.

Contaminated groundwater discharging to the canal would affect the quality of the water in the canal.

Gowanus Canal Remedial Investigation – Brooklyn, NY

Notes on Soil and Groundwater Analytical Tables:

Analytical laboratory results of soil and groundwater samples collected within this property are presented in the following tables. Samples were collected in the summer of 2010 during the USEPA led remedial investigation of the Gowanus Canal Superfund Site. Analytical results for each sample collected within this property are shown including detected chemical concentrations and non-detected concentrations (designed with a U qualifier). The analytical method detection limit (MDL) is shown for non-detected compounds. The units for analytical results are specified in each table header.

Data Qualifiers:

B – Analyte detected in an associated blank

J – Concentration Estimated

N – Presumptive evidence of a compound based on a mass spectral library search

U – Constituent not detected above the MDL

R-Rejected

Table Acronyms

ft – feet

S-Split Sample

N-Normal sample
