The *Underground Storage Tank Remedial Investigation Report, Former Guyon General Piping Facility,* dated February 3, 1995, describes soil sampling to investigate three USTs at the Guyon property (PAP-00031077). Samples were analyzed for total petroleum hydrocarbons (TPH) and PAHs, and all PAH results were below method detection limits (PAP-00031082-83). Based on a summary table provided in the report, it appears these tanks were 12 to +15 years old at the time of removal and/or in-place abandonment (PAP-00031071 and 74).

The *Phase 2 Site Investigation Report and Remedial Action Work Plan, Harrison Redevelopment Former Crucible Steel Site*, dated February 16, 2005, states that 38 soil borings were advanced during the Phase 2 Site Investigation (SI) (PAP-00031291). This document concluded that in general, soil contamination is associated with the presence of historical fill compounds (PAP-00031292).

Soil-Spiegel Property

According to the *Site Investigation Report/Remedial Action Work Plan*, dated February 1, 2002, soil samples were collected at the Spiegel property, and lead was determined to be associated with fill materials and not site operations (PAP-00030310).

As part of the *Site Investigation Report Addendum*, dated June 24, 2004, 53 soil borings were installed (PAP-00028063; PAP-00028383). The *Site Investigation Report Addendum* concluded that lead and copper exceedances in soil were consistent with the Historic Fill Database and were therefore related to historic fill (PAP-00028064; PAP-00028395).

The *Interim Remedial Investigation Report, September 2006-December 2006, Netti Spiegel Trucking*, dated October 9, 2007, included 44 soils borings to investigate historic fill materials (PAP-00028081). Metallic slag was observed at three borings, and coal fragments/coal debris were observed at two borings (PAP-00028082). Soil samples were also collected from multiple areas of concern (AOCs) within the Spiegel property. Sampling of water and sediment within a basement, as well as sampling of concrete, were also conducted as part of the *Interim Remedial Investigation Report, September 2006-December 2006, Netti Spiegel Trucking*. The *Interim Remedial Investigation Report, September 2006-December 2006, Netti Spiegel Trucking*, dated October 9, 2007, concluded that exceedances of PAHs, lead, and copper in soil were consistent with the Historic Fill Database and were therefore related to historic fill (PAP-00028108-110).

The *Interim Remedial Investigation Report II and Interim Remedial Action Report for January 2007-September 2007, Netti Spiegel Trucking*, dated May 28, 2008, included sampling of soil and concrete as well as interim remedial actions (see Remedial Activities discussion below for more detail regarding these actions). The *Interim Remedial Investigation Report II and Interim Remedial Action Report for January 2007-September 2007, Netti Spiegel Trucking*, dated May 28, 2008, concluded that exceedances of PAHs, and metals were consistent with typical historic fill (PAP-00028527).

According to the *6th Street Remedial Action Report Update, Netti Spiegel Trucking*, dated August 4, 2008, sampling of soil borings and test pits occurred at the Spiegel property. PAH and metals concentrations were consistent with typical historic fill (PAP-00030707-08, 12).

Remedial Activities

Guyon Property

According to a R*emediation/Decommissioning Results, Fabco Piping Inc.*, dated March 25, 1990, contaminated soil at the Guyon property was excavated and disposed from the exterior of a paint shop, stained soils were excavated and disposed from between railroad ties, and stained sediments were removed and disposed from the concrete floor of a lean-to that housed a No. 2 fuel oil aboveground storage tank (AST), located at the north end of the annealing and bending operations (PAS-00083217, 25-26). The excavation occurred on March 2, 1990, and removed soils/sediments were stockpiled on site prior to off-site disposal. No confirmation sampling was conducted following the excavation between railroad ties (PAS-00083225). According to the *Sampling Plan Results and Cleanup Plan Addendum for Fabco Piping Incorporated*, dated December 14, 1990, 70 tons of contaminated soil were excavated, and excavation extended to depths of 16 to 22 inches (PAP-00030271).

According to a R*emediation/Decommissioning Results, Fabco Piping Inc.*, dated March 25, 1990, sandblasting grit was scrapped up on October 31 and November 1, 1989, and stockpiled on site. Off-site disposal occurred on December 11 and 12, 1990 (PAS-00083227). The *Sampling Plan Results and Cleanup Plan Addendum for Fabco Piping Incorporated*, dated December 14, 1990, states that 579.1 tons of sandblasting grit was removed (PAP-00030274).

The *Underground Storage Tank Remedial Investigation Report, Former Guyon General Piping Facility,* dated February 3, 1995, states that four USTs were removed and three USTs were closed in place, but the dates of closure/removal are not specified (PAP-00031074). Based on the information provided regarding the age of the tanks, it appears they were all installed after Crucible Steel sold the Guyon property (1970s and 1980s). On January 3, 1995, 130 tons of contaminated soil was removed from the former location of UST 9, along with its associated piping. Excavation extended to a depth of 7 feet bgs in the area of the former tank and 3.5 to 4.5 feet bgs along the piping trench (PAP00031087).

Spiegel Property

According to the *Interim Remedial Investigation Report II and Interim Remedial Action Report for January 2007-September 2007, Netti Spiegel Trucking*, dated May 28, 2008, soil excavation and removal of concrete, as well as removal of product from shallow groundwater, occurred at the Spiegel property (PAP-00028513). Contaminated soil not characterized as historic fill was excavated and disposed of off-site, and confirmation sampling was conducted, which showed that concentrations were consistent with historic fill (PAP-00028513-20, 26). Removed concrete with exceedances above the NRDCSCC were disposed of off-site, while removed concrete with concentrations below the NRDCSCC was reused on site (PAP-00028519).

The removal of a UST containing 1,500 gallons of oily water occurred on September 6 and 7, 2007, followed by confirmation sampling, which confirmed that the tank held diesel/fuel oil No. 2 (PAP-00028520-21, 52).

According to the *Remedial Action Report Addendum 6th Street Area during April 2009-August 2009, Netti Spiegel Trucking*, dated June 2010, the future construction of a sports complex will serve as part of proposed engineering controls (i.e., cap) in conjunction with institutional controls (PAP-00030115). During 2008 and 2009, 949.6 tons of material was excavated and disposed of offsite to remove soil hot spots and/or non-aqueous phase liquid (NAPL) source areas (PAP-00030118-19).

Approximately 500 feet of 2-inch diameter steel piping positioned approximately two feet bgs was discovered on June 2, 2009, during utility installations. The piping contained residual No. 2 and/or No. 4 fuel oil. On July 8, 2009, two 6-inch diameter steel pipes approximately 100 feet long were discovered near the intersection of 6th Street and Cape May Street, located parallel to Cape May Street and positioned approximately four feet bgs. The piping contained residual No. 2 and/or No. 4 fuel oil (PAP-00030120). The pipes were removed and disposed of offsite, along with 60 gallons of product collected from the pipes (PAP-00030121).

The *Remedial Action Report - Soil, Former Netti Spiegel Trucking*, dated April 11, 2012, states that all structures previously present at the Spiegel property were removed and the Red Bull Area was installed (PAP-00030877). This included installation and placement of certified clean fill; installation of impervious site improvements, including building foundations, playing field, concrete sidewalks/pavement, and asphalt driveways; and, installation of a sub-slab vapor mitigation system (PAP-00030884-85).

8. Summary of Asserted Defenses

EnPro asserts that if and to the extent PAHs were present in fuel oil that may have been released to the environment during Crucible operations, Respondent [EnPro Holdings, Inc.] contends that such releases are excluded from CERCLA [Comprehensive Environmental Response, Compensation, and Liability Act] coverage pursuant to the petroleum exclusion, 42 U.S.C. § 9601(33).

Respondent [EnPro Holdings, Inc.] has, and Crucible Steel Corporation had, no relationship to any parties that released or disposed of COCs at the Facility following Crucible Steel Corporation's sales of the western portion (Guyon Property) in 1947 and 1967 and the eastern portion (Spiegel Property) in 1974.

Diamond Alkali OU2 Allocation
ADR Confidential
Facility Data Report

EPEC POLYMERS, INC.

Facility Name, Address and Size: Tenneco Chemicals, Inc., 290 River Drive, Garfield, New Jersey. The facility was 6.9 acres and had up to 250 employees with 3 shifts operating 7 days per week in 1970 and 1972 (PAP-00039956; PAP-00324651).

1. **Business Type:** Manufacturer of bulk intermediate chemicals such as formaldehyde, benzoic acid, salicylic acid, and fumaric acid for the resin, plastic, food, and pharmaceutical industries (PAP-00039956).

2. **Time Period of Ownership/Operations**

   Operator: ~1900 – December 1, 1982
   Owner: ~1900 – December 1, 1982

   1965: On March 1, 1965, Heyden Newport Chemical Corporation (Heyden Newport) changed its name to Tenneco Chemicals, Inc. (Tenneco) and Tenneco Corporation was identified as the sole stockholder of the company (PAP-00039737-42). A Revised ECRA [*Environmental Cleanup Responsibility Act] Sampling Plan Investigation Report*, dated September 1991, stated that Heyden had owned and operated the facility since the early 1900s as several forms of the Heyden name (PAP-00040999).

   1982: Tenneco Chemicals, Inc. operated at the Garfield facility until December 1, 1982, when the facility and the business that sold products manufactured at the plant were sold to Kalama Chemical Inc. (Kalama) in an Asset Sales Agreement. Assets identified in the sale included the machinery, equipment, furniture, fixtures, raw materials, work in progress, finished goods, operating supplies, etc. (PAP-00039792-95). Kalama Chemical Inc. took over the facility and is the current owner of the site. Kalama is a wholly owned subsidiary of Goodrich Corporation.

   On December 3, 1982, Tenneco Polymers, Inc. was incorporated in the State of Delaware (PAP-00039804-07). On December 15, 1982, Tenneco Polymers, Inc. was granted certain assets from Tenneco Chemicals, Inc. Some notable assets included all of the former Heyden's Newport's issued and outstanding shares, and notes, contracts and agreements relating to Tenneco's PVC, methanol, and former acetylene and ammonia businesses, as well as all owned or claimed real property. Several plant sites were listed, but the Garfield facility was not included because it was previously sold to Kalama (PAP-00039831-36).

   1983: On February 14, 1983, Tenneco Chemicals, Inc. changed its name to Tenneco Resins, Inc. (PAP-00039811). EPEC noted in its Statement of Position, dated May 24, 2012, that Tenneco Resins, Inc. continued to operate as a subsidiary of Tenneco Polymers, Inc. for three more years (PAP-00039758). On August 26, 1985, Tenneco Resins, Inc. filed for Dissolution (PAP-00039827).

1988: Pursuant to a Corporate Substitution Agreement between Tenneco Resins, Inc. and Kalama Chemicals, Inc. effective August 25, 1988, Tenneco Polymers, Inc. was substituted for Tenneco Resins, Inc. and agreed to assume Tenneco Resins ' responsibilities and liabilities for ECRA cleanup of the Garfield Plant if any as well as the obligations and liabilities to Kalama pursuant to Section 8(b) of the Asset Sales Agreement. This section stated that all liabilities arising out of the condition of the plant premises at or prior to the Closing Date and the operation of the plant prior to the closing date during the period of Seller's ownership, i.e., since October 4, 1963, would remain the liability of Tenneco Resins, Inc. and that Tenneco Resins had provided Kalama with evidence of liability insurance in customary form on an "occurrence" basis, which had been in effect during Tenneco's period of ownership (PAP-00039838-40).

1994: A Settlement Agreement between Tenneco Polymers, Inc. and Kalama dated April 28, 1994, describes the previous disputes between the two companies and t responsibilities with respect to remediation activities at the Garfield property. This Agreement also identified Tenneco Polymers, Inc. with the Tenneco, Inc. family of businesses (PAP-00039844-72).

1996: On December 12, 1996, Tenneco Polymers, Inc. changed its name to EPEC Polymers, Inc. (PAP-00039829). Based on several Remedial Investigation Reports and Remedial Action Progress Reports, EPEC participated in the remediation of the facility in the early 2000s (see PAS-00008864, PAS-00008946, PAS-00009143, PAS-00009261, PAS-00009298, PAS-00009411, PAS-00009458, PAS-00009505, PAS-00009545).

On December 11, 1996, El Paso Merger Company merged with Tenneco Inc. of Delaware into El Paso Tennessee Pipeline Co. (PAP-00039744). A Certificate of Conversion of a Delaware Corporation of El Paso Tennessee Pipeline Co. to El Paso Tennessee Pipeline Co., LLC, dated September 29, 2011, identified Tenneco Holdings, Inc. as the original name of the company (PAP-00039750, 52-53).

3. Operational History/COC Use and Presence at the Facility

A *Sampling Plan for Site Evaluation*, (Sampling Plan) dated August 1987, stated that the facility had been used to manufacture salicylic acid, formaldehyde, and methyl salicylate since 1903. As discussed in this Sampling Plan, the buildings used to manufacture benzoic acid and benzaldehyde were constructed in 1967. This operation was shut down in 1984. Manufacturing of formaldehyde ceased in 1982. Additional chemicals manufactured at the facility included methyl, propyl, ethyl, and butyl esters of para-hydroxybenzoic acid, methylene disalicylic acid, and sodium, potassium, and magnesium salicylate salts (PAP-00040251).

According to a Waste Effluent Survey dated May 19, 1972, the facility manufactured bulk intermediate chemicals such as formaldehyde, benzoic acid, salicylic acid, and fumaric acid for the resin, plastic, food, and pharmaceutical industries (PAP-00039956). The survey stated that water from the Passaic River was used for non-contact cooling water

and for barometric condensers. All manufacturing waste was reported to go to sanitary/chemical sewers (PAP-00039957, 59).

A report prepared for the EPA by Acurex Corporation titled *Verification Sampling and Analysis for Priority Pollutants at Tenneco Chemicals (Garfield, New Jersey)*, dated October 1980, described the sampling of waste streams discharged to the wastewater treatment facility from five of the facility's products (PAP-00040067-68). Results for metal chemicals of concern (COCs) are reported in the table below, as well as results for two samples of inlet water from the municipal water system and the Passaic River. The processes used to manufacture these five products and their waste streams were described as follows:

- Benzoic Acid/Benzaldehyde: Benzoic acid was manufactured by liquid phase oxidation of toluene in the presence of a cobalt catalyst. The reactor overhead gas was condensed and sent to a scavenger tank, where water was separated and disposed. Reactor effluent was stripped and washed, then sent to the benzaldehyde still. The still bottoms were discharged as waste (PAP-00040071-74).

- Sodium Benzoate: Benzoic acid was reacted with sodium carbonate, condensate, and carbon. The reactor effluent was filtered and scrubbed. The solids were removed from a liquid product stream and disposed (PAP-00040076).

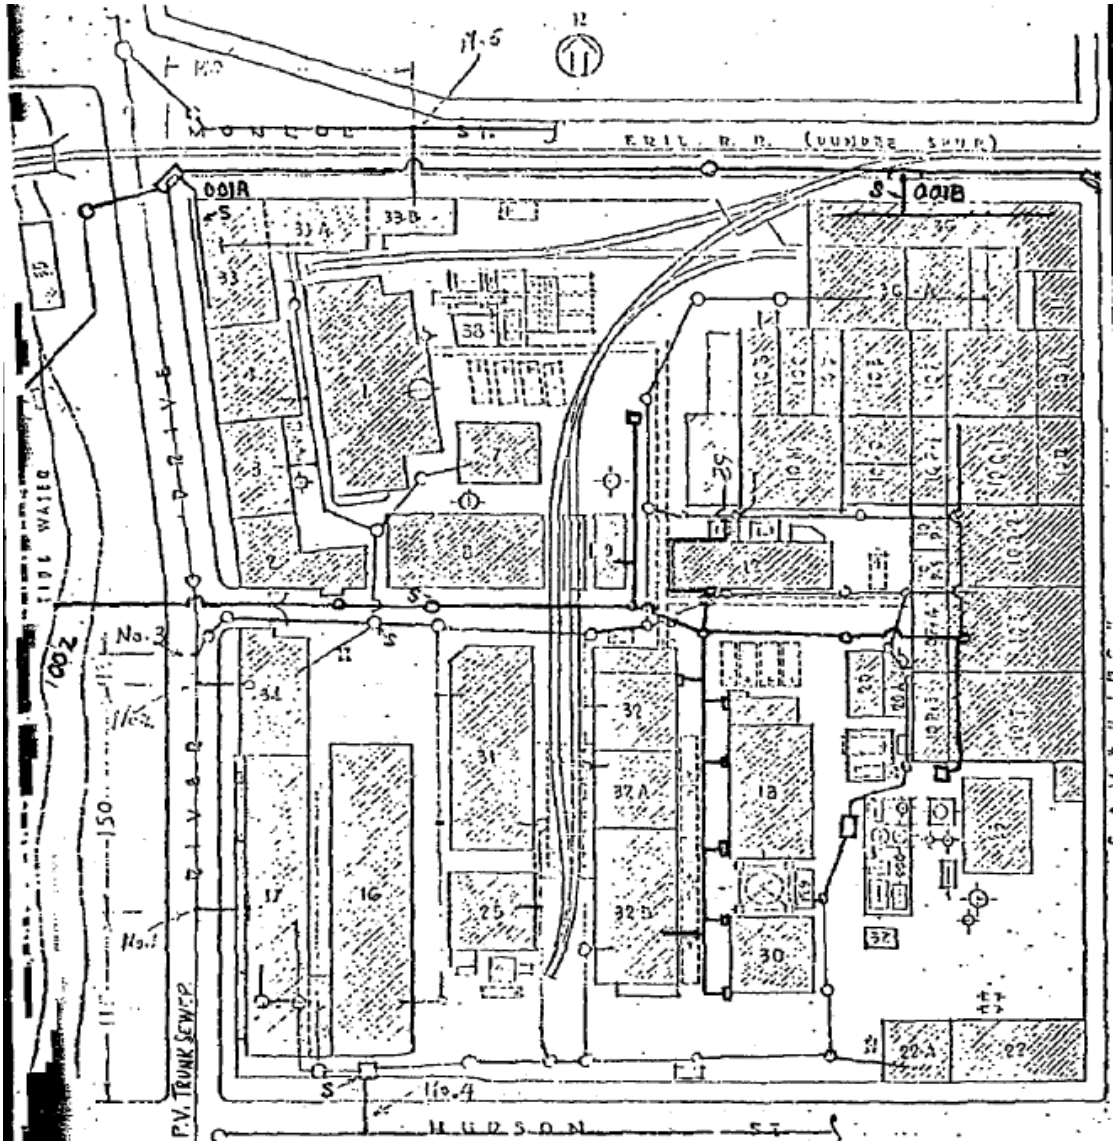
- Salicylic Acid: Phenol and 50 percent sodium hydroxide were mixed and dried in a spray dryer. The dried product was reacted with carbon dioxide in a reactor and then neutralized with sulfuric acid and water. The product was then carbon treated and precipitated by adding more sulfuric acid. The precipitator effluent was cooled using a non-contact flash cooler, and the overhead was condensed and then discharged as waste (PAP-00040078).

- Methyl Salicylate: Salicylic acid, methanol, and sulfuric acid were reacted and then neutralized with soda ash and water. The aqueous phase was recycled, while the non-aqueous organic phase from the neutralizer was washed then sent to a vacuum still to generate the product (PAP-00040081, 84).

- Fumaric Acid: Maleic acid was reacted with a catalyst and steam and then vacuum cooled. The vacuum cooler overhead went to a contact condenser, where fumaric acid was recovered via centrifuge (PAP-00040085).

Maximum Concentrations of Metals in Each Product Effluent					
Product	**Composite Sample Sources (flow in gallons per day [gpd])**	**Sample Location / Site**	**Copper (µg/L)**	**Lead (µg/L)**	**Mercury (µg/L)**
Benzoic Acid/ Benzaldehyde	Scavenger tank effluent, scrubber liquor, wash tank, still bottom residue (2,320 gpd)	OPQRS	18	<10	<1
Sodium Benzoate	Reactor scrubber effluent (72,000 gpd)	L	11	<10	<1
Salicylic Acid	Spray dryer scrubber, vacuum jet for Reactor No.3, flash cooler, "10E-1 sal acid nutsche" (194,720 gpd)	CDEG	450	<25	1.5
Methyl Salicylate	Spent acid tank and wash column overflow (7,140 gpd)	IJ	3,200	450	1
Fumaric Acid	Centrifuge effluent and contact condenser (91,300 gpd)	AB	39	<10	1*
Passaic River	River water	U	104	15	<1
Passaic Valley	Municipal water	T	14	<10	1.3
References	PAP-00040093, 96	PAP-00040093	PAP-00040130	PAP-00040131	PAP-00040132

µg/L: micrograms/liter



*Note: the mercury result was listed as 1 µg/L for Day 3 of sampling in the raw analytical data table, but the adjusted concentration table listed the mercury result for Day 3 as not detected (PAP-0040142). It is not clear how the data were adjusted.

A New Jersey Department of Environmental Protection (NJDEP) Pretreatment/Residual Waste Survey, dated July 27, 1981, stated that copper and mercury were present in the discharge of over 25,000 gallons per day to the publicly owned treatment works (POTW) (PAP-00040183, 188). An application for permit to discharge to a domestic treatment works, dated February 26, 1982, listed the City of Garfield sewer and the Passaic Valley Sewerage Commission (PVSC) treatment plant as the recipients of the effluent, which contained 19.53 milligrams/liter (mg/L) copper and 0.001 mg/L mercury. Polycyclic aromatic hydrocarbons (PAHs), PCBs, lead and pesticides were not detected in the effluent (PAP-00040202, 210-211).

Five outlets to the sanitary sewer (Outlets Nos. 1 through 5) were identified in an undated PVSC application for a sewer connection permit and a letter to the PVSC from Tenneco dated December 16, 1980. Outlet Nos. 3 and 4 were stated to contain industrial waste. Outlet No. 5 was stated to be eliminated as wastewater was diverted to

Outlet No. 3. It was also noted that Outlet No. 4 was in the process of being eliminated with most wastewater already diverted to No. 3 (PAP-00040044; PAP-00040165-66).

The PVSC permit application provided the following site map with Outlets Nos. 1 through 3 along River Drive, Outlet No. 4 to the south at Hudson Street, and Outlet No. 5 to the north at Monroe Street:

(PAP-00040045)

Outfalls to the Passaic River

Three outfalls to the Passaic River were identified in the facility's National Pollutant Discharge Elimination System (NPDES) permit to discharge No. NJ 0000124, effective June 30, 1974 (PAP-00039966). Outfalls with the following discharge serial numbers

were identified: 001A and 001B; 002; 005. Effluent limitations on these outfalls did not identify COCs. Outfall 005 was limited to containing chemicals or other substances less than or equal to what was found in the receiving waters (PAP-00039969).

An application to renew the NPDES permit No. NJ 0000124, dated November 28, 1978, stated discharges through outfall 001 began in 1940 and outfall 002 had been used since 1953 (PAP-00324735, 43).

A NJDEP Application for Approval of Plans, dated April 1, 1975, outlined Tenneco's plans to monitor its cooling water return to the Passaic River and reduce sources of pollution entering the Passaic River (PAP-00039995). The application identified the outfalls as follows (see above figure for locations along Monroe Street and at the middle of the facility):

- 001A: Cooling water effluent from Building 33 was connected to the Monroe Street drainpipe and discharged from the drainpipe into the Passaic River (PAP-00039997).

- 001B: Cooling water effluent from Building 36 was connected to a catch basin in the Monroe Street drainpipe (PAP-00039998).

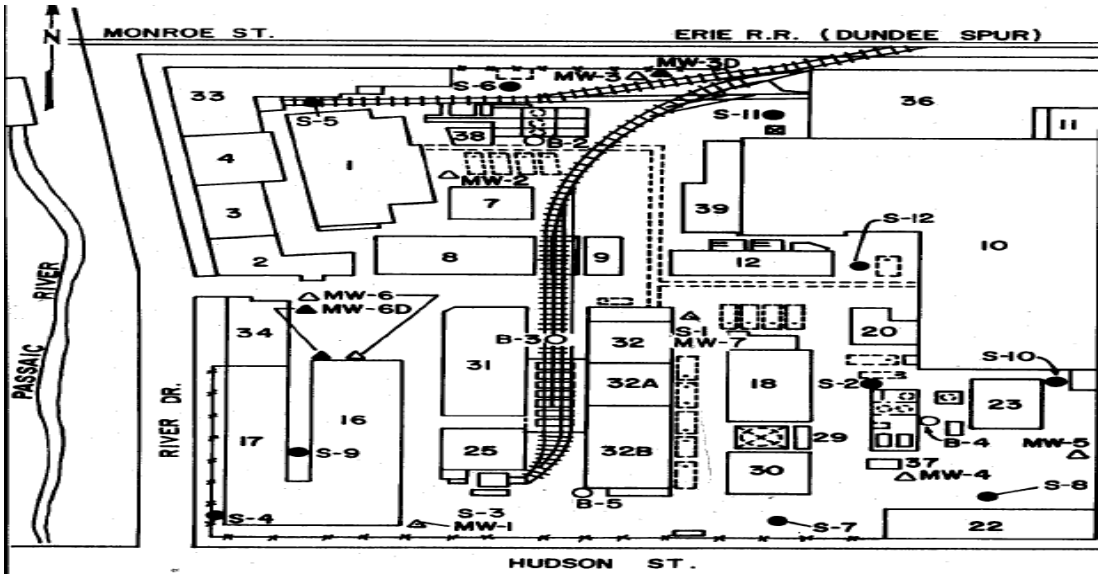
- 002: The major effluent stream containing all of the river water returns from the plant, except Buildings 33 and 36 (PAP-00039998).

The plans stated that droplets of process water were entering the cooling water returned to the Passaic River and proposed a filter to remove the pollutants as well as discharging contaminated cooling water to the sanitary sewer (PAP-00039997-40000). An April 1, 1975 letter to the PVSC submitted with the application stated the contaminated cooling water would increase the volume of water discharged to the PVSC by "75M" gallons per day (PAP-00040008).

A letter to the NJDEP from Tenneco, dated April 18, 1975, identified outfall 005 as river water screens used at the pump house to keep leaves and debris out of the pumps. The screens were kept clean with a continuous backwash to the river (PAP-00040018).

4. Identified COCs

- PCBs (used, detected)
- PAHs (detected)
- Copper (used, detected)
- Lead (detected)
- Mercury (detected)



PCBs

A NJDEP Pretreatment/Residual Waste Survey, dated July 27, 1981, stated equipment such as transformers, high voltage capacitors, or heat transfer systems containing PCB fluids were present at the facility (PAP-00040185). According to a Revised Sampling Plan Addendum, dated March 1990, the transformers at Buildings 1 and 12 were

inspected in 1981 and found not to contain PCBs. Site personnel stated that these transformers had not contained PCBs for at least 10 years and it is possible that they may never have contained PCBs. Soil samples were proposed to verify the absence of contamination in soils in these areas due to leakage from the transformers (PAP-00040585).

Two areas containing transformers were identified as areas of environmental concern (AECs) in the *Revised Remedial Action Work Plan*, dated March 31, 1995 (1995 RAWP) (PAP-00041652). PCBs were not detected in site soil at AEC-23 (Transformers at Building 1), but were detected in soil samples collected from AEC-24 (Transformer at Building 12) at a maximum of 2.2 milligrams/kilogram (mg/kg) for Aroclor-1260 (PAP-00041881-2).

The *Remedial Investigation and Remedial Actions Report, Building 17 Former Sewer Lines*, dated February 26, 2003, (2003 RI/RAR) identified additional AECs associated with the demolition of Building 17, the former laboratory and pilot plant. Fill was discovered within the foundation walls of the building and was analyzed for PCBs as part of the waste disposal characterization. PCBs were detected at 15.8 parts per million (ppm) in one soil sample, but additional delineation samples did not detect PCBs. An area of 19 feet by 27 feet was excavated to a depth of 4 feet around the sample location (PAP-00044391-92). Building 17 was located in the southwestern corner of the site. Note that the fill with PCBs was within the foundation walls of Building 17.

(PAP-00040419)

PAHs

According to a *Preliminary Investigation of Soil Quality Conditions at the Kalama Chemical, Inc. Facility in Garfield, New Jersey*, dated December 1986, PAHs were detected in soil samples collected from the following areas: underground storage tanks (USTs) containing fuel oil, the benzaldehyde production area, and a chemical transfer area (PAP-00040240, 43).

Further investigation noted that PAHs were detected in soil samples collected all over the site. According to the data reported in the 1995 RAWP, PAHs were detected at most AECs when soil samples were analyzed for these parameters (PAP-00041858-86). Concentrations were generally less than or equal to 1 mg/kg, which is less than average concentrations associated with historic fill (see discussion of historic fill below). The highest concentrations were detected at AEC-11 (Former No. 2 Fuel Oil USTs), AEC-15 (Salicylic Acid/Salicylate Production Buildings 10/36/39), and AEC-21 (Drum Storage Area Buildings 16 and 17). The maximum concentrations of PAHs were detected from soil sample AEC-15-1C at AEC-15 (see concentrations in the discussion of Historic Fill and in Section 7, Response Actions) (PAP-00042265).

The *Revised Remedial Action Work Plan Addendum*, dated February 29, 1996 (RAWP Addendum) stated that fill material, including sand, gravel, brick and rock fragments, cinders, and ash, had been noted at the site and extending off site. The RAWP Addendum investigated soil boring B-52-A, detecting concentrations of benzo(a)pyrene up to 42 ppm, and attributed the elevated PAH concentrations to the presence of fill (PAP-00042178-79).

The 2003 RI/RAR found elevated PAHs detected in mud from a concrete basin (AEC-32A) north of Building 17 (i.e., 6.1 ppm of benzo(a)anthracene; 4.45 ppm of benzo(b)fluoranthene; 3.04 ppm of benzo(k)fluoranthene; and 4.42 ppm of benzo(a)pyrene). It was stated that this basin drained sinks in the laboratory, but did not connect to a sewer and instead had vents to allow for evaporation (PAP-00044389, 91).

Copper

Although descriptions of the manufacturing processes did not specifically identify copper as being used at the facility, an application for permit to discharge to a domestic treatment works, dated February 26, 1982, stated copper was a component of a substance used and/or manufactured at the facility over the next five years (PAP-00040212).

A NJDEP Pretreatment/Residual Waste Survey, dated July 27, 1981, stated copper was present in the discharge to the POTW (PAP-00040183, 188). Furthermore, copper was detected in effluent samples collected in 1979, 1980, and 1982 as follows:

- An undated PVSC sewer connection application included results for composite samples collected from industrial waste outlet Nos. 3 and 4 in June 1979. Copper was detected at a maximum of 0.070 mg/L (PAP-00040046-47; PAP-00040048).

- According to a report for the EPA titled *Verification Sampling and Analysis for Priority Pollutants at Tenneco Chemicals (Garfield, New Jersey)*, dated October 1980, copper was detected in all five waste streams from the facility's products (see Section 3, Operational History/COC Use and Presence at the Facility above). However, the report identified copper as detected above trace levels in only three of the product waste streams: salicylic acid (copper at 450 µg/L), methyl salicylate (copper at 3,200 µg/L), and fumaric acid (copper at 39 µg/L)

(PAP-00040067-68, 130). Copper was also detected in the municipal water (14 µg/L; see table in Section 3 above) (PAP-00040130).

- A *Heavy Metals Source Determination Study* by the PVSC, dated April 1980, identified Tenneco as discharging 0.189 mg/L (0.922 pounds per day) of copper (PAP-00322628).

- According to an application for permit to discharge to a domestic treatment works, dated February 26, 1982, copper was detected in the effluent discharged to the PVSC at 19.53 mg/L (PAP-00040210, 12).

Copper was detected in surface soil (Sample B-47-Fill) at AEC-15 (Salicylic Acid/Salicylate Production Buildings 10/36/39) at a maximum concentration of 550 mg/kg (PAP-00041872). Copper was also detected in filter cake material at 223 mg/kg located between crushed white rock found in a 40-foot-long concrete trough at Building 17 (AEC-32C, Concrete Trough). The soil sample collected beneath the trough detected copper at 52.4 ppm. An area of 12.5 feet by 60 feet and 5 feet deep was excavated around the concrete trough in 2002, and included 216 tons of soil (PAP-00044395-97, 455).

Lead

According to a report for the EPA titled *Verification Sampling and Analysis for Priority Pollutants at Tenneco Chemicals (Garfield, New Jersey)*, dated October 1980, lead was detected in the waste stream from the manufacture of methyl salicylate at 450 µg/L (PAP-00040067-68, 131). A *Heavy Metals Source Determination Study* by the PVSC, dated April 1980, identified Tenneco as discharging 0.394 mg/L (1.922 pounds per day) of lead (PAP-00322628).

Lead was detected in surface soil (Sample B-47-Fill) at AEC-15 (Salicylic Acid/Salicylate Production Buildings 10/36/39) at an elevated concentration of 820 mg/kg. The 1996 RAWP Addendum attributed this concentration to fill material present at the site (PAP-00042177, 80).

According to the 2003 RI/RAR, lead was detected in filter cake material at 594 ppm found at AEC-32C (Concrete Trough) in Building 17. Soil beneath the trough contained lead at 43.6 ppm (PAP-00044395-97, 455). After the trough was excavated in 2002, the loading dock between Building 16 and Building 17 was investigated. Fill material consisting of crushed rock, brick, wood chips, and glass was found beneath the loading dock. The fill was 1 foot thick, while the native soil beneath consisted of a fine sandy silt. A sample from the fill material contained 42,000 ppm lead, while the native soil beneath this location detected lead at 35.9 ppm. Approximately 166 tons of soil were excavated from this area in 2002 (PAP-00044397-99, 457).

Mercury

Although mercury was not identified as used in the facility processes, purchase orders from 1973 identified the purchased caustic soda as mercury cell material. Analytical results from the caustic soda manufactured using the mercury cell process were not available to verify that the caustic soda did not contain any trace impurities of mercury (PAP-00324677; PAP-00324679; PAP-00324684).

A NJDEP Pretreatment/Residual Waste Survey, dated July 27, 1981, stated mercury was present in the discharge to the POTW (PAP-00040183, 188). Furthermore, mercury was detected in effluent samples collected in 1979, 1980, and 1982 as follows:

- An undated PVSC sewer connection application included results for composite samples collected from industrial waste outlets No. 3 and 4 in June of 1979. Mercury was detected at a maximum of 0.00123 mg/L (PAP-00040046-47; PAP-00040048).

- According to a report for the EPA titled *Verification Sampling and Analysis for Priority Pollutants at Tenneco Chemicals (Garfield, New Jersey)*, dated October 1980, mercury was detected in the waste stream from the manufacture of salicylic acid (0.0015 mg/L), methyl salicylate (0.001 mg/L), and fumaric acid (0.001 mg/L), as well as the municipal water (PAP-00040067-68, 132).

- A *Heavy Metals Source Determination Study* by the PVSC, dated April 1980, identified Tenneco as discharging 0.001 mg/L (0.0044 pounds per day) of mercury (PAP-00322628).

- An application for permit to discharge to a domestic treatment works, dated February 26, 1982, stated mercury was detected at 0.001 mg/L in the effluent discharged to the PVSC (PAP-00040210).

Mercury was detected in subsurface soil (depth of 4 to 4.5 feet, Sample B-53 Fill) at AEC-15 (Salicylic Acid/Salicylate Production Buildings 10/36/39) at a maximum concentration of 18.6 mg/kg (PAP-00041873). Mercury was also detected in filter cake material at 100 mg/kg located between crushed white rock found in a 40-foot-long concrete trough at Building 17 (AEC-32C, Concrete Trough). The soil sample collected beneath the trough detected mercury at 0.58 ppm. An area of 12.5 feet by 60 feet and 5 feet deep was excavated around the concrete trough in 2002, and included 216 tons of soil (PAP-00044395-97, 455).

According to the 2003 RI/RAR, mercury was detected in soil at a maximum concentration of 15.5 ppm from beneath the sewer line that ran from Building 17 south to the Hudson Street sewer line. The soil along the sewer line consisted of crushed stone/slag fill material underlain by sand, silt, and silty sands. Approximately 110 tons of soil were excavated from this sewer line (AEC-33) (PAP-00044400-1).

Historic Fill

The Allocation Team has determined that the majority of the facility site is not located on regional historic fill as designated by the NJDEP.[1] However, there may be historic fill present at the northwest corner of the site under Monroe Street. In addition, the 1996 RAWP Addendum attributed elevated concentrations of PAHs and lead at the former Salicylic Acid/Salicylate Production Buildings located at the northeast portion of the site to the presence of fill (PAP-00042177-80).

NJDEP has established that historic fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 COCs: PAHs, lead, copper, and mercury.[2] Accordingly, NJDEP technical requirements for property containing historic fill requires sampling for the EPA Target Compound List for PAHs and Target Analyte List for metals, including lead, copper, mercury, and the OU2 PAH COCs.[3] PAHs, lead, copper, and mercury are recognized by NJDEP to be constituents of historic fill at varying levels, not atypically at or exceeding residential soil standards.[4]

The levels of PAHs, copper, lead and mercury detected at the site in soils are presented in the table below (PAP-00041873; PAP-00042265).

COCs Found in Onsite Soils	
COC	**Max Detected Concentration**
Lead	42,000 mg/kg
Copper	550 mg/kg
Mercury	18.6 mg/kg
Benzo(a)anthracene	41.0 mg/kg
Benzo(a)pyrene	42.0 mg/kg
Benzo(b)fluoranthene	38.0 mg/kg
Benzo(k)fluoranthene	13.0 mg/kg
Dibenzo(a,h)anthracene	5.5 mg/kg
Indeno(1,2,3-cd)pyrene	33.0 mg/kg
PCBs	15.8 mg/kg

[1] *Digital Geodata Series, DGS04-7, Historic Fill for New Jersey*, https://www.nj.gov/dep/njgs/geodata/dgs04-7.htm, Quadrangle #42 (NJDEP map identifying locations of recognized historic fill).
[2] *Characterization of Ambient Levels of Selected Metals and cPAHs In New Jersey Soils* (2002) and *Characterization of Ambient Levels of Selected Metals and Other Analytes In New Jersey Soils* (1997), studies prepared for NJDEP, Division of Science and Research, by BEM Systems, Inc.
[3] New Jersey Department of Environmental Protection (NJDEP), *N.J.A.C. 7:26E Technical Requirements for Site Remediation,* Table 4-2, November 2009 [Note that Table 4-2 has been deleted from the current version of N.J.A.C. 7:26E (May 7, 2012) and the updated *Historic Fill Technical Guidance* (April 2013) as NJDEP believed that the tables list of historic fill constituents was too restrictive].
[4] NJDEP Table 4-2 (PAHs and lead) and a summary of NJDEP records regarding investigations of properties in the vicinity of the Passaic River recognized to be located in areas of historic fill indicate that the following average/maximum (mg/kg) contamination levels of OU2 COCs exist in area historic fill: PAHs (1.91/160), lead (574/10,000), copper (11.2/1,200), and mercury (0.21/3.7).

5. COC Pathways

Sanitary and Storm Sewer

A letter from Tenneco to the PVSC, dated January 14, 1970, stated there was an unknown break in the sanitary sewer line near the south outfall from the facility. The facility stated they plugged the outfall and all discharge was diverted to the chemical sewer (PAP-00324649).

A PVSC questionnaire dated February 28, 1970, stated the facility discharged sanitary and industrial waste to the PVSC trunk line at an average rate of 355,000 gallons per day (PAP-00324652).

According to an application submitted to the Department of the Army Corps of Engineers for a permit to discharge or work in navigable waters and their tributaries, dated June 25, 1971, the facility used 0.5 million gallons of process water per day. The facility discharged 0.75 million gallons per day to the municipal waste treatment system (PAP-00039877; PAP-00039897, 901).

Tenneco submitted a Waste Effluent Survey, dated May 19, 1972, to the PVSC. This survey listed 750,000 gallons of water discharged to the sanitary sewer per day. The effluent was stated to contain less than 1 ppm (or 6.2 pounds per day) each of lead, copper, and mercury. The discharges were stated to continue 24 hours per day (PAP-00039957-58).

An undated PVSC sewer connection application stated that 488 million gallons were discharged to the sanitary sewer in 1978. Five outlets to the sewer were identified; three outlets were stated to contain industrial waste. Composite samples collected from industrial waste outlet Nos. 3 and 4 in June of 1979 contained maximums of 0.070 mg/L copper, less than 0.125 mg/L lead, and 0.00123 mg/L mercury (PAP-00040042, 44, 47; PAP-00040048).

Five outlets to the sanitary sewer were identified in an undated PVSC application for sewer connection permit (PAP-00040044) and a letter to the PVSC from Tenneco dated December 16, 1980 (PAP-00040165). The flow in 1980 was identified as:

- Outlet No. 1: 5,000 gallons per day to the sanitary sewer
- Outlet No. 2: 5,000 gallons per day to the sanitary sewer (PAP-00040044)
- Outlet No. 3: 540,000 gallons per day containing industrial waste
- Outlet No. 4: 1,000 gallons per day containing steam condensate
- Outlet No. 5: no flow as this outlet was eliminated (PAP-00040166)

Outlet No. 5 was stated to be eliminated with wastewater diverted to outlet No. 3. It was also stated that most of the wastewater from Outlet No. 4 was diverted to No. 3 (PAP-00040165). The undated PVSC permit application stated the flow through Outlet Nos. 4 and 5 were 150,000 and 4,000 gallons per day, respectively. The flow for Outlet No. 3 was 1,100,000 gallons per day, but was noted to be incorrect (PAP-00040044).

The report titled *Verification Sampling and Analysis for Priority Pollutants at Tenneco Chemicals (Garfield, New Jersey)*, dated October 1980, stated 1.034 million gallons per day were discharged to the municipal sewage treatment plant (PAP-00040089). However, a Heavy Metals Source Determination Study by the PVSC, dated April 1980, identified a flow rate of 0.585 million gallons per day for Tenneco (PAP-00322628).

The individual flow rates for each process discharged through Outlet No. 3 to the City of Garfield sewer and the PVSC treatment plant were identified in an application for permit to discharge to a domestic treatment works, dated February 26, 1982:

- Formaldehyde: 100,800 gallons per day
- Benzoic acid/benzaldehyde: 36,000 gallons per day
- Sodium benzoate: 66,200 gallons per day
- Salicylic acid: 154,100 gallons per day
- Fumaric acid: 46,100 gallons per day
- Methyl Salicylate: 36,000 gallons per day (PAP-00040202).

A letter to the PVSC submitted with the Application for Approval of Plans, dated April 1, 1975, stated that diverting the contaminated cooling water to the sanitary sewer would increase the volume of water discharged to the PVSC by “75M” gallons per day (PAP-00040008).

Direct Release

A *Report on the Quality of the Interstate Waters of the Lower Passaic River and Upper and Lower Bays of New York Harbor*, dated November 1969, identified four outfalls from Tenneco with large flows at Passaic River mile 16.2. The remarks stated that the discharge may contain detergent and dead fish were noted in the outfalls (PAS-00114006).

A letter from Tenneco to the PVSC, dated January 14, 1970, stated Tenneco was investigating possible sources of pollution to the Passaic River from their plant. Tenneco found old drains which may have received overflows from the pilot plant. In addition, Buildings 32 and 36 were connected to conduits that fed to the river. Tenneco stated they would tie the floor drains from the pilot plant and the process area floor drains to the chemical sewer (PAP-00324647-8).

A PVSC questionnaire dated February 28, 1970, stated the facility discharged cooling water waste (thermal pollution only) to the Passaic River at an average rate of 2.8 million gallons per day (PAP-00324652).

According to an application submitted to the Department of the Army Corps of Engineers for a permit to discharge or work in navigable waters and their tributaries, dated June 23, 1971, the facility used 5.8 million gallons per day of cooling water sourced from the river. The river water return outfall was stated to be sampled and analyzed periodically, but the results were not available (PAP-00039877; PAP-00039897, 901).

Tenneco submitted a Waste Effluent Survey, dated May 19, 1972, to the PVSC. This survey listed 5.48 million gallons of water discharged to the Passaic River per day. The effluent was stated to contain less than 0.1 mg/L (or 5 pounds per day) each of lead, copper, and mercury. The river water was stated to be used for non-contact cooling water and barometric condensers (PAP-00039957, 59).

According to the PVSC Annual Report for 1973, Tenneco had a 2-inch boiler blow down line to the Passaic River, and it was confirmed that the discharge was polluting in November 1973 based on a collected sample. Information for this sample was not provided (PAS-00008608). According to the PVSC Annual Report for 1974, the equipment was installed to divert this discharge to the sanitary sewer, and this violation was eliminated on June 6, 1974 (PAS-00008610).

An Engineer's Preliminary Report, dated October 28, 1974, stated Outfalls 001 and 002 contained cooling water return and stormwater runoff from Monroe Street and the facility. It was stated that the discharge through 001 contained contact cooling water from Building 36. This report also identified potential sources of contamination in Outfall 002, including contact cooling water discharged from Building 12, effluent from a scrubber in Building 10-T, and floor drains in Building 32. The report recommended eliminating the contact cooling water from the outfalls and directing the potential sources of pollution to the sanitary sewer (PAP-00324693-95).

According to a Tenneco Status Report dated April 18, 1975, from August 1974 to March 1975, the daily volume of discharge from Outfall 001 ranged from 4.3 million to 15.3 million gallons per day. For the same time period, the daily volume discharged through Outfall 002 was 24 million to 32.5 million gallons per day (PAP-00040019).

A NPDES Plant Inspection performed on September 29, 1977 stated approximately 1.0 million gallons per day were discharged from Outfall 001, 3.2 million gallons per day were discharged through Outfall 002, and approximately 1 million gallons per day were discharged through Outfall 005 (PAP-00040027).

An undated PVSC sewer connection application stated that 1,100 million gallons per year were discharged to a storm sewer, river, or ditch in 1978 (PAP-00040042).

The report titled *Verification Sampling and Analysis for Priority Pollutants at Tenneco Chemicals (Garfield, New Jersey)*, dated October 1980, stated 3.309 million gallons per day of untreated wastewater was discharged through two outfalls to the Passaic River (PAP-00040089).

A NJDEP Application for Approval of Plans, dated April 1, 1975, outlined Tenneco's plans to monitor its cooling water return to the Passaic River and reduce sources of pollution entering the Passaic River (PAP-00039995). The plans stated that process water was entering the cooling water returned to the Passaic River and proposed a filter to remove the pollutants as well as discharging contaminated cooling water to the sanitary sewer (PAP-00039997-40000). An April 1, 1975 letter to the PVSC submitted with the application stated the contaminated cooling water would increase the volume of water discharged to the PVSC by "75M" gallons per day (PAP-00040008).

6. Regulatory History/Enforcement Actions

Inspections

A NPDES Plant Inspection was performed September 29, 1977. The inspection report identified the three outlets and found several exceedances of the temperature limits (PAP-00040026).

Violations

A violation and elimination was identified in the PVSC Annual Report for 1972. According to this report, a leak developed in the sewer line under River Road and was sealed as soon as it was detected. An inspector noted that the by-passed waste was being pumped into a storm sewer that led to the Passaic River on December 28, 1972. The flow was then diverted to the sanitary sewer to halt the pollution. The sewer line was repaired on December 29, 1972 (PAS-00008606).

A violation was identified in the PVSC Annual Report for 1973. The report stated Tenneco had a 2-inch boiler blow down line to the Passaic River, and it was confirmed that the discharge was polluting in November 1973 based on a collected sample. Information for this sample was not provided. According to the Annual Report, Tenneco was purchasing equipment to divert this discharge to the sanitary sewer (PAS-00008608). According to the PVSC Annual Report for 1974, the equipment was installed and this violation was eliminated on June 6, 1974 (PAS-00008610).

The PVSC Annual Report for 1976 identified a violation and elimination due to a complaint of suds entering the Passaic River from Tenneco on September 1, 1971. Tenneco had been cleaning their 2,000-gallon Reactor No. 1 on the fourth floor and the soap drained into the sanitary sewer at too high a flow rate. The soapy water overflowed into the yard, draining into the storm sewer and then the Passaic River. The overflow was stopped and Tenneco stated they would use an alternate hose to drain the soapy water. A sample collected from the storm sewer was stated to be acceptable, but information for this sample was not provided (PAS-00008612-13).

Permits

NPDES permit No. NJ 0000124 to discharge to the Passaic River was effective for the facility on June 30, 1974, and expired June 30, 1979 (PAP-00039966). The following discharge serial numbers were identified: 001A and 001B; 002; 005. Limitations on these outfalls did not contain COCs. Outfall 005 was limited to containing chemicals or other substances less than or equal to what was found in the receiving waters (PAP-00039969).

On September 21, 1978, the NPDES permit was modified effective October 21, 1978, for the limitations of non-COCs (PAP-00324725-29). Tenneco applied to renew their NPDES permit on November 28, 1978 (PAP-00324732).

NJPDES SIU Permit No. NJ0000124 for the discharge of industrial wastewater to the PVSC facility was effective December 1, 1982, and expired November 30, 1987. The permit stated the facility was subject to effluent limits and monitoring requirements, but these criteria were not available (PAP-00040237).

7. Response Actions

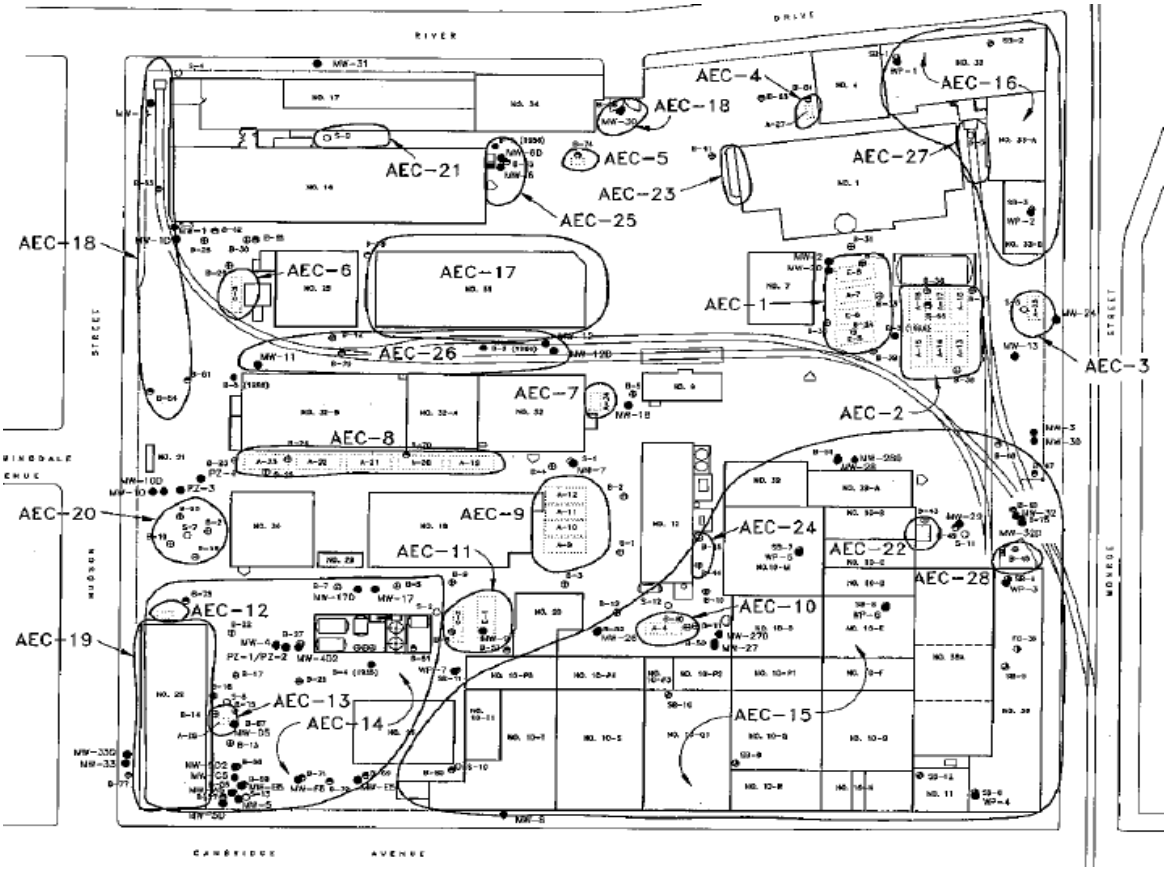
Characterization Activities

The following characterization activities have taken place at the facility:

- *Verification Sampling and Analysis for Priority Pollutants at Tenneco Chemicals (Garfield, New Jersey)*, dated October 1980, by Acurex Corporation (PAP-00040062).
- *Preliminary Investigation of Soil Quality Conditions at the Kalama Chemical, Inc. Facility in Garfield, New Jersey*, dated December 1986, by Geraghty & Miller, Inc. (PAP-00040239).
- *A Sampling Plan for Site Evaluation*, dated August 1987, by Geraghty & Miller, Inc. (PAP-00040248).
- *ECRA Soil and Groundwater Investigation at the Kalama Chemical, Inc. Facility, Garfield, New Jersey*, dated June 1988, by Geraghty & Miller, Inc. (PAP-00040387).
- *Revised Sampling Plan Addendum*, dated March 1990, by Geraghty & Miller, Inc. (PAP-00040575).
- *Revised ECRA Sampling Plan Investigation Report, Kalama Chemical, Inc. Facility*, dated September 1991, by Geraghty & Miller, Inc. (PAP-00040980).

- *Draft ECRA Investigation Report and Proposed Remedial Action Workplan*, dated December 1993, by Geraghty & Miller, Inc. (PAP-00041189).
- *Revised Remedial Action Work Plan*, dated March 31, 1995, by SECOR International Inc. (PAP-00041624).
- *Revised Remedial Action Work Plan Addendum*, dated February 29, 1996, by SECOR International Inc. (PAP-00042155).
- *Remedial Investigation and Remedial Actions Report*, dated September 17, 2001, by Sovereign Consulting Inc. (PAP-00043851).
- *Remedial Investigation and Remedial Actions Report, Building 17 Former Sewer Lines*, dated February 26, 2003, by Sovereign Consulting Inc. (PAP-00044382).
- *Comprehensive Remedial Action Work Plan Addendum*, dated March 14, 2008, by Sovereign Consulting Inc. (PAP-00323651).

Soil



Soil sampling was performed from 1986 through 1993 and summarized in the 1995 RAWP. The 1995 RAWP identified 28 AECs that generally included former locations of USTs (e.g., AECs 1, 3, 6, 10, 11 contained fuel oil USTs), drum and scrap metal storage areas (AECs 19, 20, 21), production areas (AECs 14, 15, 16, 17), transformers (AECs 23, 24), and loading/unloading areas (AECs 24 through 28) (PAP-00041648-52).

EPEC Polymers, Inc.

Diamond Alkali OU2 Allocation

ADR Confidential

Facility Data Report

(PAP-00041795; note north is to the right in this figure)

Metal COCs were detected at AEC-14, AEC-15, and AEC-18 as listed in the table below. Highest levels of metals contamination in soil were noted at AEC-15 (Salicylic Acid/Salicylate Production Buildings 10/36/39). The 1996 RAWP Addendum attributed the lead concentration at AEC-15 to the presence of fill at the site (PAP-00042180).

Metal COCs Detected in Soil				
AEC	**Description**	**Copper**	**Lead**	**Mercury**
AEC-14	Benzoic Acid/ Benzaldehyde Production Area	7.8 mg/kg	(3.4 U)	(0.11 U)
AEC-15	Salicylic Acid/ Salicylate Production Buildings 10/36/39	550 mg/kg	820 mg/kg	18.6 mg/kg
AEC-18	Sewer Lines	190 mg/kg	446 mg/kg	0.68 mg/kg

U: Not detected (PAP-00041871-73, 76)

PCBs were detected in site soil at AEC-24 (Transformer at Building 12) at a maximum of 2.2 mg/kg for Aroclor-1260 (PAP-00041882). In addition, according to the 2003 RI/RAR, PCBs were detected at 15.8 pm in one sample collected from the fill “within the foundation walls” of Building 17, but additional delineation samples did not detect PCBs (PAP-00044391-92).

PAHs were detected at most AECs, but concentrations were generally low (less than average concentrations associated with historic fill as discussed in Section 4, Identified COCs), with the highest concentrations detected at AEC-15 (Salicylic Acid/Salicylate Production Buildings 10/36/39). The 1996 RAWP Addendum attributed these concentrations to the presence of fill at the site (PAP-00042179). The maximum concentrations of PAHs were detected as follows:

Maximum PAHs Detected in Soil Samples			
PAHs (ppm)	**S-2 at AEC-14**	**B-52-A at AEC-15**	**AEC-15-1C**
Anthracene	0.85	1.3	13.0
Benzo(a)anthracene	3.0	12.0	41.0
Benzo(a)pyrene	2.4	10.0	42.0
Benzo(b)fluoranthene	5.69	13.0	38.0
Benzo(ghi)perylene	0.96	3.0	43.0
Benzo(k)fluoranthene	NR	2.5	13.0
Chyrsene	4.0	12.0	45.0
Dibenzo(a,h)anthracene	NR	1.0	5.5
Fluoranthene	4.1	14.0	41.0
Fluorene	0.66 U	NR	1.8
Indeno(1,2,3-cd)pyrene	0.95	2.9	33.0
Naphthalene	2.8	0.12 J	0.27 J
Phenanthrene	3.4	4.6	39.0
Pyrene	6.91	20	260

NR: not reported J: estimated concentration U: not detected
(PAP-00041870, 72; PAP-00042265)

The *Remedial Investigation and Remedial Actions Report*, dated September 17, 2001, identified three additional AECs, where PAHs and metals were detected in site soil at concentrations less than the maximums reported above (PAP-00043883-9). The *Remedial Investigation and Remedial Actions Report, Building 17 Former Sewer Lines*, dated February 26, 2003, identified additional AECs associated with the demolition of Building 17, the former laboratory and pilot plant. Elevated PAHs were detected in a concrete basin (AEC-32A) north of Building 17 (i.e., 6.1 ppm of benzo(a)anthracene; 4.45 ppm of benzo(b)fluoranthene; 3.04 ppm of benzo(k)fluoranthene; and 4.42 ppm of benzo(a)pyrene). It was stated that this basin drained sinks in the laboratory, but did not connect to a sewer and instead had vents to allow for evaporation (PAP-00044389, 91).

Sewer

In the 1995 RAWP, AEC-18 was identified as the western portion of the sewer line that ran along Hudson Street to south, as well as the sewer outfall 002 near the main gate (PAP-00041651). Metals and PAHs were detected in soil samples collected along the sewer lines at maximum concentrations of 190 ppm copper (Sample B-55-Fill), 446 ppm lead (Sample B-54-Fill), and 0.68 ppm mercury (Sample B-54-Fill) (PAP-00041876).

The sewer lines from Building 17 (AEC-33), Building 32 (AEC-34), and Hudson Street (AEC-35) were removed in 2002. Maximum concentrations of metals in soil beneath the Building 17 line were 92.9 ppm copper, 132 ppm lead, and 15.5 ppm mercury. The soil along the Building 17 sewer line consisted of crushed stone/slag fill material underlain by sand, silt, and silty sands. Soil samples collected at the Building 32 and Hudson Street sewer lines were not analyzed for metals. Approximately 110 tons, 756 tons, and 1,312 tons of soil were removed with each sewer line, respectively (PAP-00044401, 03-04, 13, 59).

Remedial Activities

The *ECRA Soil and Groundwater Investigation at the Kalama Chemical, Inc. Facility, Garfield, New Jersey*, dated June 1988, stated 11 of the 27 USTs were removed from the site in 1987. Five of these USTs contained No. 2 Fuel Oil and ranged from 5,000 to 16,500 gallons in volume (PAP-00040392, 406). According to the Revised Sampling Plan Addendum, dated March 1990, the remaining USTs containing methanol, hexane, MIBK (methyl isobutyl ketone), and No. 6 Fuel Oil were removed between 1987 and 1990 (PAP-00040593-94).

An Administrative Consent Order, dated December 8, 1988, was issued by NJDEP to Kalama Chemical, Inc. the owner of the site at the time (PAS-00008625-33). The remediation agreement was modified September 13, 1996, and Tenneco became the lead responsible party (PAS-00008621-24).

The 2003 RI/RAR identified additional AECs associated with the demolition of Building 17, the former laboratory and pilot plant. Fill was discovered “within the foundation walls” of the building and was analyzed for PCBs as part of the waste disposal characterization. PCBs were detected at 15.8 ppm in one soil sample, but additional delineation samples did not detect PCBs. An area of 19 feet by 27 feet was excavated to depth of 4 feet around the sample location (PAP-00044391-92).

This investigation also excavated a concrete trough with elevated metals concentrations located at Building 17, including an area of 12.5 feet by 60 feet and 5 feet deep and consisting of 216 tons of soil (PAP-00044395-97). After the trough was excavated in 2002, the loading dock between Building 16 and Building 17 was investigated. Fill material consisting of crushed rock, brick, wood chips, and glass was found beneath the loading dock. The fill was 1 foot thick, while the native soil beneath consisted of a fine sandy silt. A sample from the fill material contained 42,000 ppm lead, while the native soil beneath this location detected lead at 35.9 ppm. Approximately 166 tons of soil were removed from this area in 2002 (PAP-00044397-99, 457).

The sewer lines from Building 17 (AEC-33), Building 32 (AEC-34) and Hudson Street (AEC-35) were removed in 2002. Maximum concentrations of metals in soil beneath the Building 17 sewer line were 92.9 ppm copper, 132 ppm lead, and 15.5 ppm mercury. Approximately 110 tons, 756 tons, and 1,312 tons of soil were removed with each sewer line, respectively (PAP-00044401, 04, 13).

According to a *Comprehensive Remedial Action Work Plan Addendum*, dated March 14, 2008, no further action (NFA) was approved by NJDEP for the following AECs in a letter dated September 6, 1995: AEC-1 through 8, 10, 16, 22 through 25, 27, and 28. This Work Plan also stated AEC-31 received NFA approval on June 18, 2002, and AEC-32A, 32B, 32C, 32D, 33, 34, and 35 were approved for NFA by NJDEP on October 21, 2003 (PAP-00323694-702, 708, 729, 737-739, 741-742, 749-766).

A letter from NJDEP dated December 30, 2008 approved NFA for the following AECs: 9, 12, 13, 15, 17, 18, 19, 20, 21, 26, and 32A. The letter stated a site-wide cap engineering control was required due to the presence of contaminated historic fill at the site (PAP-00324631).

8. Summary of Asserted Defenses

EPEC asserts that EPEC Polymers, Inc. (“EPI”) and El Paso Tennessee Pipeline Co. (“EPTP”) received GNL letters from EPA; however, EPI and EPTP never owned or operated the Facility, nor were either company ever successors to any party or parties that owned or operated the Facility. Further, neither party assumed any liability for the alleged discharges at the Facility that are at issue in this allocation. EPI and EPTP respond on behalf of Tenneco Chemicals, Inc. (“TCI”), which was a former owner and operator of the Facility during the Relevant Time Period [October 4, 1963 to December 1, 1983].”

The "Heyden Newport" entity that changed its name to Tenneco Chemicals, Inc. in 1965 was not the same entity that owned the Garfield Facility prior to Tenneco's acquisition. The following statement was provided: “In 1919, Heyden Chemical Company of America, Inc., a New York corporation, reportedly acquired the Garfield Site. In 1925, Heyden Chemical Company of America was consolidated with Denhey Corporation to form Heyden Chemical Corporation, a New York corporation. In March 1943, Heyden Chemical Corporation merged into its parent company, Denhey Holding Corporation, a Delaware corporation, and Denhey Holding Corporation was renamed Heyden Chemical Corporation, also incorporated in Delaware. In March 1943, the Garfield Site was transferred by deed from Heyden Chemical Corporation, a New York corporation, to Heyden Chemical Corporation, a Delaware corporation. Heyden Chemical Corporation then changed its name to Heyden Newport Chemical Corporation (“Old Heyden”). In 1963, Tennessee Gas Transmission Company (“TGT”), Old Heyden, and HDN Corporation, a subsidiary of TGT, entered into a transaction whereby Old Heyden sold its assets to HDN in exchange for shares of TGT common stock and the assumption by HDN of certain of Old Heyden’s liabilities. After the transaction, HDN changed its name to “Heyden Newport Chemical Corporation” (“Heyden Newport”) and filed and recorded in Delaware a change of name amendment on October 4, 1963. At the same time, Old Heyden changed its name to “Denport Corporation” and dissolved”” (2019 Letter, p. 2).

On December 15, 1982, Tenneco Chemicals and Tenneco Polymers entered into an agreement whereby Tenneco Chemicals transferred certain assets to Tenneco Polymers. Pursuant to that agreement, Tenneco Chemicals did not transfer any liabilities related to the Garfield Site, and any transfer of liabilities was limited to litigations and claims known or existing at the time of the conveyance—and expressly

referenced in exhibits consisting of litigation dockets generated at the time of the transaction. In 1983, Tenneco Chemicals changed its name to Tenneco Resins, Inc. ("Resins"), and filed for dissolution two years later, in 1985. Tenneco Polymers changed its name to EPEC Polymers, Inc. in 1996, shortly following El Paso Merger Company's acquisition of the energy assets of Tenneco Inc. As the aforementioned facts demonstrate, at no time did Tenneco Polymers merge or consolidate with Resins. In addition, Tenneco Chemicals was a separate corporation from Tenneco Polymers with assets and operations. Although Tenneco Chemicals was a party to various asset transfers over the course of its corporate existence, it retained any and all liabilities associated with the Garfield Site, and those liabilities ceased to exist upon its dissolution in 1985."

Diamond Alkali OU2 Allocation

ADR Confidential

Facility Data Report

ESSEX CHEMICAL CORPORATION

Facility Name, Address and Size: Essex Chemical Corporation (Essex); 330 and 352 Doremus Avenue, Newark, New Jersey; 15 acres (PAP-00116509).

In 1989, the Essex property was bordered to the south by Hoechst-Celanese Corporation, to the north by Quantum Chemical Corporation and the Nimco commercial bus crushing facility, to the northeast and west by steel scrap salvage yards, and to the west by vacant property owned by the Housing Authority of the City of Newark and leased by the Waterside Urban Renewal Development Corporation. Conrail owned and maintained a 35-foot wide strip of land which ran parallel to Doremus Avenue adjacent to the eastern yard of the Essex facility (PAP-00116863).

1. **Business Type:** Manufacturer of sulfuric acid and related inorganic products (PAP-00116859)

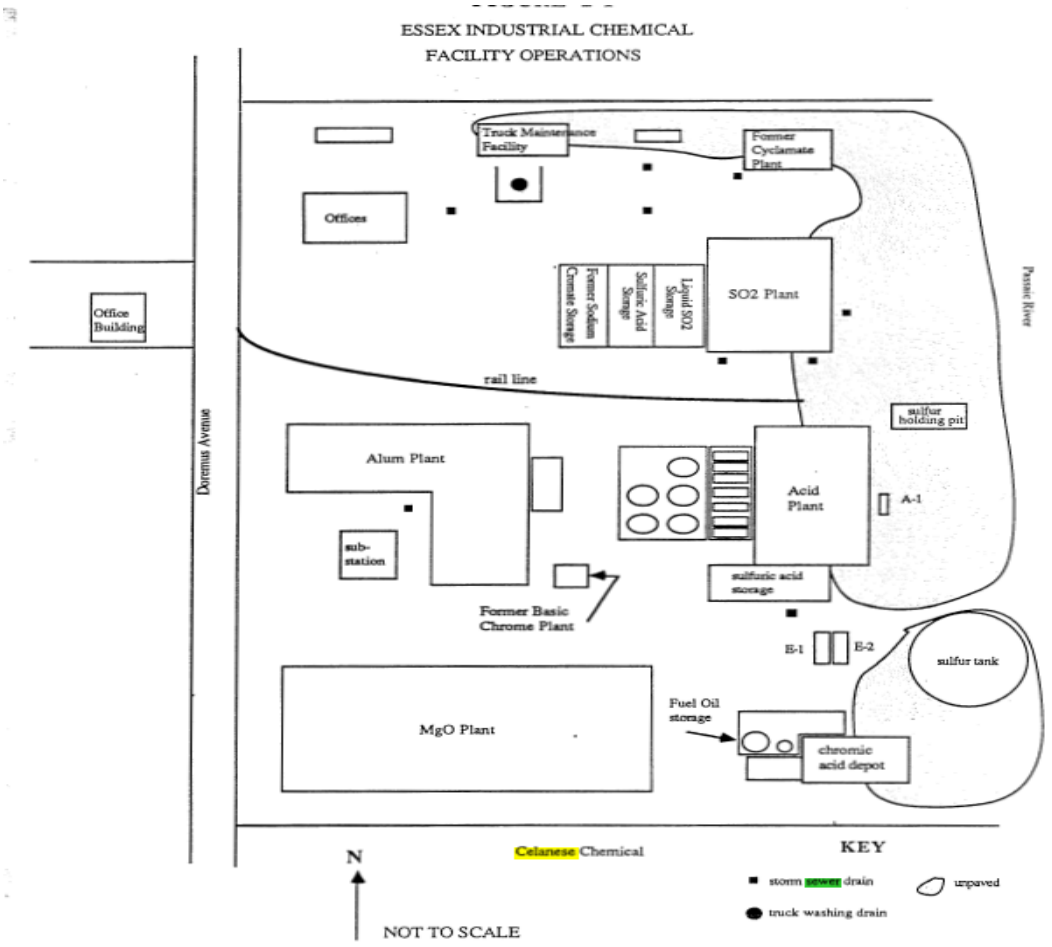
2. **Time Period of Ownership/Operations**

330 Doremus Avenue	352 Doremus Avenue
Operator: 1956 to 1989	**Operator:** 1965 to 1989
Owner: 1955 to 1989	**Owner:** 1965 to 1989

1953: Dixon Chemical and Research, Inc. (DCR), a successor to Dixon Chemical, Inc., was established in 1953 (PAS-00061383).

1955/1956: DCR acquired the 330 Doremus Avenue property from Reilly Industries (at the time, known as Reilly Tar and Chemical Corporation), erected a sulfuric acid plant, and began operating in 1956 (PAP-00115992).

1962: DCR changed its name to Essex on June 20, 1962 (PAS-00061383).



1965: Essex bought the 352 Doremus Avenue property from 352 Doremus Avenue Co., Inc. on June 25, 1965 (PAP-00115993).

~1982: Essex Industrial Chemicals, Inc. (Essex Industrial) was formed, and operated as a wholly-owned subsidiary of Essex (PAS-00061379).

1988: Dow Chemical Company acquired all the issued and outstanding stock of Essex in October 1988 (PAP-00116862).

1989: Essex sold the stock of Essex Industrial to Peridot Chemicals (New Jersey), Inc. (Peridot) on December 22, 1989 (PAP-00116862).

Note: Pan Am Sulfur Company leased one-half acre in the northeast corner of 352 Doremus Avenue from April 6, 1962 to March 31, 1970 on which it operated a large tank for the storage of molten sulfur (PAP-00115993).

(PAP-00115991)

Essex's manufacturing operations were situated on the east side of Doremus Avenue and administrative operations were conducted on the west side of Doremus Avenue (PAP-00115990).

3. Operational History/COC Use and Presence at the Facility

Essex manufactured industrial chemicals, including sulfuric acid, oleum, liquefied sulfur dioxide, and aluminum sulfate; warehoused chromium and phosphate chemicals; and operated a magnesium oxide regeneration plant for the Philadelphia Electric Company (PAP-00115988).

Available documents do not include information that Essex manufacturing processes entailed the use, storage, handling, or generation of Operable Unit 2 (OU2) contaminants of concern (COCs) (PAP-00115988; PAP-00115990; PAS-00061379, 81). According to a 1989 Essex Industrial Chemicals Newark Facility Hazardous Substance/Waste Inventory sheet, 15 pounds of mercury was present in the laboratory in 1989 (PAP-00116301).

4. Identified COCs

- PAHs (detected)
- Copper (detected)
- Lead (detected)
- Mercury (used and detected)

PAHs

According to a Phase I ECRA Sampling Plan Results and Phase II Sampling Proposal, dated February 28, 1990 (1990 Phase I ECRA), total petroleum hydrocarbons and polycyclic aromatic hydrocarbons (PAHs) were the primary organic constituents found at concentrations above the New Jersey Department of Environmental Protection's (NJDEP's) "informal ECRA [Environmental Cleanup Responsibility Act] action levels" in on-site soil. According to the 1990 Phase I ECRA, the extent of these substances appeared to be limited to an acid plant boiler area and a truck maintenance building area (PAP-00116505). The 1990 Phase I ECRA states that a suite of 5-10 PAHs were consistently identified in many of the soil samples analyzed (PAP-00116562).

The 1990 Phase I ECRA states that in some sample locations, PAH concentrations were found to increase with depth, especially in the eastern areas of the plant near the former underground tank locations. However, the 1990 Phase I ECRA also stated that in other areas, PAHs concentrations "appeared randomly with no apparent vertical distribution" (PAP-00116562). The 1990 Phase I ECRA states that, while these compounds may have originated from former Essex operations [e.g., leaks from fuel oil (No. 6) tanks or asphalt], "it is believed that historical operations at the site prior to Essex ownership may have also contributed to the levels found" (PAP-00116505, 562, 606).

According to the Phase II ECRA Sampling Plan Results and ECRA Cleanup Plan Proposal, dated April 1991 (1991 Phase II ECRA), several PAHs were detected in soil (PAP-00116908-10). Detections were identified at maximum concentrations that exceeded the calculated "RCRA [Resource Conservation and Recovery Act] Action Level" identified in the report (PAP-00116998-99). PAHs were reported at the following maximum concentrations (note that parts per million [ppm] is equivalent to mg/kg):

- Benzo(a)anthracene – up to 62 ppm
- Benzo(a)pyrene – up to 37 ppm
- Benzo(b)fluoranthene – up to 110 ppm
- Benzo(k)fluoranthene – up to 98 ppm
- Dibenzo(a,h)anthracene – up to 4 ppm
- Indeno(1,2,3-cd)pyrene – up to 26 ppm (PAP-00116999)

The following represents a complete table of samples with PAH concentrations exceeding calculated soil cleanup levels for the "Direct Contact Pathway":

Chemical	Direct Contact Action Level (mg/kg)	Phase II Soils Soil Sample	Phase II Soils Concentration (mg/kg)	Phase I Soils Soil Sample	Phase I Soils Concentration (mg/kg)
SVOAs

(PAP-00117022)

Copper

According to the 1991 Phase II ECRA, copper was detected in site soil at a maximum concentration of 150 ppm at location TMB-3, at a depth of 4-4.5 feet below ground surface (bgs). This sample was described as “black sandy fill” in its boring log (PAP-00116912; PAP-00117390). Copper was detected in 9/9 samples collected (PAP-00116999).

Lead

According to a Memorandum: Responsible Party Investigation, received on April 3, 1991, the Division of Environmental Quality, Right to Know Survey states that Essex Industrial used several chemicals, including lead (PAP-00031631). Review of the available file material did not identify any other documentation of lead use.

According to the Phase II ECRA Sampling Plan Results and ECRA Cleanup Plan Proposal, prepared for Essex, dated April 1991, lead was detected in site soil at a maximum concentration of 7,000 ppm in sample Q-3 (3.5-4 ft bgs), within the Quantum Chemicals Property Area (PAP-00116922). Lead was also detected in several locations within the Truck Maintenance Building, including TMB-2 (4-4.5 ft bgs) at 100 ppm and TMB-4 (6.5-7 ft bgs) at 2,000 ppm. Additional detections were identified in the Chrome Sulfate and Chemical Unloading Area at location CR-4 (5-5.5 ft bgs) at 3,000 ppm (PAP-00117022). Lead exceeded the NJDEP ECRA "Action Level" identified in the report (PAP-00116922). Lead was detected in 9 out of 9 samples collected (PAP-00116999). Review of soil boring logs for the referenced sample locations shows that fill was identified at these locations (PAP-0017386, PAP-00117430, PAP-00117430).

A Remedial Action Report, dated September 2, 1994 (1994 Remedial Action Report) noted that lead was identified exceeding NJDEP cleanup levels in the Chromium Area. Following excavation, the confirmation samples collected were below cleanup criteria. The maximum concentration reported was 700 ppm at sample location CA-3 (PAP-00117542).

Mercury

According to the 1991 Phase II ECRA, mercury was detected in site soil at a maximum concentration of 7 ppm, at CR-4, at a depth of 5-5.5 feet bgs, beneath "coal fragments". Mercury exceeded the NJDEP ECRA "Action Level" identified in the report and was detected in 9 out of 9 samples collected (PAP-00116999; PAP-00116932; PAP-00117430).

A 1989 Essex Industrial Chemicals Newark Facility Hazardous Substance/Waste Inventory sheet noted that 15 pounds of mercury were stored in a laboratory (PAP-00116301).

Historic Fill

The Allocation Team has determined that the facility site is located on regional Historic Fill as designated by the NJDEP.[1]

[1] *Digital Geodata Series, DGS04-7, Historic Fill for New Jersey*, https://www.nj.gov/dep/njgs/geodata/dgs04-7.htm, Quadrangle No. 52 and No. 53 (NJDEP map identifying locations of recognized historic fill).

NJDEP has established that historic fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 COCs: PAHs, lead, copper, and mercury.[2] Accordingly, NJDEP technical requirements for property containing Historic Fill requires sampling for the EPA Target Compound List for PAHs and Target Analyte List for metals, including lead, copper, mercury, and the OU2 PAH COCs.[3] PAHs, lead, copper, and mercury are recognized by NJDEP to be constituents of Historic Fill at varying levels, not atypically at or exceeding residential soil standards.[4]

According to the 1990 Phase I ECRA, total petroleum hydrocarbons and PAHs were the primary organic constituents found at concentrations above NJDEP's "informal ECRA action levels" in on-site soil. The 1990 Phase I ECRA states that the extent of these substances appeared to be limited to an acid plant boiler area and a truck maintenance building area and that a suite of 5 to10 PAHs were consistently identified in many of the soil samples analyzed (PAP-00116505; PAP-00116562). According to the report, in some sample locations, PAH concentrations were found to increase with depth, especially in the eastern areas of the plant near the former underground tank locations. However, the report also stated that in other areas, PAHs concentrations "appeared randomly with no apparent vertical distribution" (PAP-00116562). The 1990 Phase I ECRA states that, while these compounds may have originated from Essex operations [e.g., leaks from fuel oil (No. 6) tanks or asphalt], "it is believed that historical operations at the site prior to Essex ownership may have also contributed to the levels found" (PAP-00116505, 562, 606).

The 1991 Phase II ECRA, states that "Soil (fill material) quality is impacted primarily by elevated levels of TPHCs [total petroleum hydrocarbons], BNs [Base/Neutral-Extractable organic compounds, which can include PAHs], and chromium. Although Essex has handled compounds containing these constituents, the widespread nature is believed partly attributable to combustion residues (coal, slag, cinders) deposited during the early development of the site and to historical operations by previous site owners" (PAP-00116859).

According to an ECRA Site Evaluation Submission, dated January 31, 1989 (1989 ECRA Site Evaluation), the facility is constructed on approximately 12-15 feet of man-made fill materials overlying former salt marsh deposits (PAP-00115999). The unconsolidated man-made fill at the site reportedly consists of rubble, construction debris, cinders, and varying amounts of silt and gravel (PAP-00116000). According to a

[2] Characterization of Ambient Levels of Selected Metals and cPAHs In New Jersey Soils (2002) and Characterization of Ambient Levels of Selected Metals and Other Analytes In New Jersey Soils (1997), studies prepared for NJDEP, Division of Science and Research, by BEM Systems, Inc.

[3] NJDEP, N.J.A.C. 7:26E Technical Requirements for Site Remediation, Table 4-2, November 2009 [Note that Table 4-2 has been deleted from the current version of N.J.A.C. 7:26E (May 7, 2012) and the updated Historic Fill Technical Guidance (April 2013) as NJDEP believed that the tables list of historic fill constituents was too restrictive].

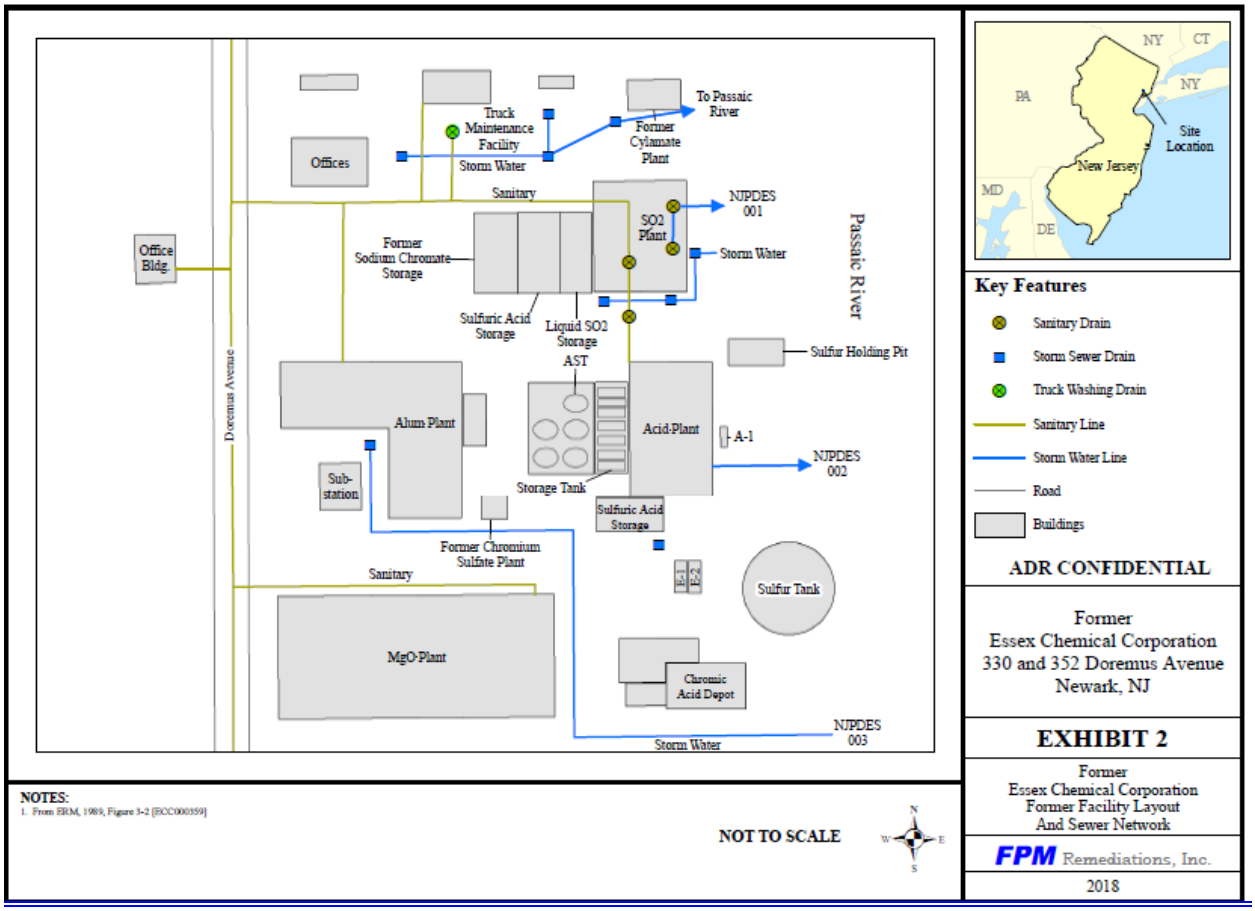
[4] NJDEP Table 4-2 (PAHs and lead) and a summary of NJDEP records regarding investigations of properties in the vicinity of the Passaic River recognized to be located in areas of Historic Fill indicate that the following average/maximum (mg/kg) contamination levels of OU2 COCs exist in area Historic Fill: PAHs (1.91/160), lead (574/10,000), copper (11.2/1,200), and mercury (0.21/3.7).

Declaration of Environmental Restrictions, originally recorded on June 27, 1997, lead and PAHs, among other chemicals, are stated to be present in the Historic Fill (PAP-00116198; PAP-00116206-07). A review of available documents did not provide any evidence of disturbance of Historic Fill at the facility. As discussed in the 1994 Remedial Action Report, soil removed to address onsite contamination "appeared to consist primarily of fill material mixed with some construction debris. The fill was dark brown to black and consisted primarily of cinders and construction debris in a silty clay matrix. In general the debris consisted of brick, concrete, and wood" (PAP-00117522).

The levels of PAHs, copper, lead and mercury detected at the site in soils are presented in the table below (PAP-00116999).

COCs Found in Onsite Soils	
COC	**Max Detected Concentration**
Lead	7,000 mg/kg
Copper	150 mg/kg
Mercury	7 mg/kg
Benzo(a)anthracene	62 mg/kg
Benzo(a)pyrene	37 mg/kg
Benzo(b)fluoranthene	110 mg/kg
Benzo(k)fluoranthene	98 mg/kg
Dibenzo(a,h)anthracene	4 mg/kg
Indeno(1,2,3-cd)pyrene	26 mg/kg

A review of available documents did not provide any evidence of disturbance of Historic Fill.



5. COC Pathways

Sanitary Sewer

Essex discharged all sanitary wastes from the facility and process effluent from the magnesium oxide regeneration operation, and wash water from a truck washing area to the PVSC system, pursuant to Sewer Connection Permit No. 20402313 (PAP-00116000; PAP-00116184). The ECRA Site Evaluation Submission, Request for Hydrogeological Assessment Facility Sampling Plan dated January 1989 (the 1989 Facility Sampling Plan) states that truck wash water was discharged from 1956-1987 (PAP-00115970).

Storm Sewer

Non-contact cooling water and condensate water associated with production of liquefied sulfur dioxide, along with storm water runoff, was discharged to the Passaic River via three outfalls pursuant to the New Jersey Pollutant Discharge Elimination System (NJPDES) Permit No. NJ0002283 (PAP-00115965, 5970, 5988-5989, 5970; PAP-00116075, 6102; PAP-116324; PAP-00117660).

(PAP-00116339)

Direct Release

There is no information regarding direct releases in the available file material.

Spills

There is no information regarding spills in the available file material.

6. Regulatory History/Enforcement Actions

According to a Report on the Quality of the Interstate Waters of the Lower Passaic River and Upper and Lower Bays of New York Harbor, dated November 1969, the New Jersey State Department of Health issued “pollution abatement orders” to Essex (PAP-00140967). The reason for the order, including associated contaminants, is not specified in available file material.

Releases to the Passaic River from Essex were reported in 1972 and 1983; however, none of the releases involved OU2 COCs (PAS-00014546; PAS-00062738, 745).

Criminal charges were filed against Essex in United States District Court, District of New Jersey on July 11, 1974, arising from a 1972 release to the Passaic River from Essex (PAS-00062740). The charges were brought against Essex for "the unlawful discharge into the Passaic River of refuse matter, including acid and acid solutions" (PAS-00062738). As described by a PVSC inspector, a 20,000 gallon tank car with oleum and nitric acid overflowed through a vent pipe due to internal pressure. The ground was covered with soda ash and water to neutralize the overflow, and the fire department then washed the residue into the Passaic River (PAS-00062745).

Inspections

On May 2, 1974, PVSC inspected the facility and collected samples from their outlets for a routine inspection. Analysis revealed that a yard drain outlet "was polluting." The inspector contacted Essex and investigation revealed that some truckers, "despite orders to the contrary," had washed some trucks over a yard catch basin. To prevent this from recurring, it is reported that the yard catch basin in the truck area was plugged and the washing of trucks was moved to an area "whereby the waste enters the sanitary sewer (PAS-00034881)". No citations were noted in the provided sources.

Violations

There is no information regarding violations in the available file material.

Permits

From 1956 to 1989 non-contact cooling water and storm water were discharged without treatment; truck wash water was discharged and treated by PVSC from 1956 to 1987; and magnesium oxide plant effluent was discharged to PVSC from 1982 to 1989 (PAP-00115970).

Essex had three NJPDES permitted discharges to the Passaic River from 1956 to 1989: NJDEPS Permit No. NJ0002283 was issued for discharge into the Passaic River, with an issue date of September 2, 1988 and expiration date of October 31, 1993 (PAP-00115965, 5970) Outfalls No. 001 discharge included noncontact cooling water, boiler blowdown, and storm water runoff; Outfall No. 002 discharge included non-contact cooling water and storm water runoff; and, Outfall No. 003 discharge included non-contact cooling water from the magnesium oxide plant (PAP-00116116, 6118, 6120; PAP-00116283).

The NJPDES Permit No. NJ0002283 Summary Table lists monitoring of copper, among other chemicals (PAP-0016116-6121); however, copper was only required to be monitored if a corrosion inhibitor containing this metal was used for water treatment purposes (PAP-00116118). Review of discharge monitoring reports shows that Essex did not monitor for copper (PAP-00116139-83). Per a Public Notice regarding issuance of Draft NJPDES Permit to Discharge into the Waters of the State of New Jersey, dated 1982, copper effluent was allowed a maximum limit of 1.0 milligrams per liter (mg/L) at a required monthly monitoring frequency for Outfalls No. 001, No. 002, and No. 003 (PAP-00116117, PAP-00116119, PAP-00116120).

PVSC Sewer Connection Permit No. 20402313 was issued and effective September 18, 1985 and expired September 13, 1990 (PAP-00116184). No monitoring related to OU2 COCs was required (PAP-0011686-89).

7. Response Actions

Characterization Activities

The following characterization activities have taken place at the facility:

- ECRA Site Evaluation Submission, Essex Industrial Chemicals, Inc., Volumes 1 and 2 (January 31, 1989) (PAP-00115963-00116495)
- Phase I ECRA Sampling Plan Results and Phase II Sampling Proposal for Essex Chemicals Corporation (February 28, 1990) (PAP-00116496-PAP00116846)
- Phase II ECRA Sampling Plan Results and ECRA Cleanup Plan Proposal, Essex Chemical Corporation, Volumes 1 and 2 (April 1991) (PAP-00116847-7464)
- Remedial Action Report (September 1994) (PAP-00117511-644)

Sewer

There is no information regarding sewer sampling in the available file material.

Soil

As discussed in the 1990 Phase I ECRA and 1991 Phase II ECRA reports, the Essex property underwent two phases of an ECRA Site Investigation. According to a 1994 Remedial Action Report, soils at this facility were found to contain PAHs and lead, among other chemicals. As a result, remedial actions were conducted to achieve the NJDEP “non-residential cleanup levels” for contaminated soils at the site and approximately 2,525 tons of soil and debris were removed from five on-site excavations and one off-site excavation (PAP-00117516). Because of the presence of chromium, zinc, and total petroleum hydrocarbons in soil, along with Historic Fill containing PAHs and lead, among other metal contaminants, a Declaration of Environmental Restrictions, originally recorded on June 27, 1997, was approved by NJDEP as a remedial measure and placed on the site in 1997 to restrict the use of the site to non-residential (PAP-00116197-98).

On June 30, 1997, NJDEP issued a “no further action” approval letter for the site and established a “Classification Exception Area” designation for a portion of the site “because levels of contaminants remain above their Ground Water Quality Criteria pursuant to the Ground Water Quality Standards (N.J.A.C. [New Jersey Administrative Code] 7:9-6.1 et seq.) and/or Primary Drinking Water Standards (N.J.A.C. 7:10), respectively” (PAP-00116195). These contaminants included lead and copper, among others (PAP-00117468).

Remedial Activities

A 1994 Remedial Action Report noted that lead was identified exceeding NJDEP cleanup levels in the Chromium Area. Following excavation, the confirmation samples collected were below cleanup criteria. The maximum concentration reported was 700 ppm at sample location CA-3, which was below the NJDEP non-residential soil cleanup criteria and no action was required (PAP-00117540-42). .

8. Summary of Asserted Defenses

Essex Chemical Corporation asserts that, “Essex is not a person responsible for the release of COC’s pursuant to the decision in CDMG Realty Co., et al. v. the Sharkey Landfill Agreement Group, 96 F. 3d. 706 (3rd Cir. 19946).

COCs detected at the former Essex property, other than minor petroleum spills, were exclusively from Historic Fill which was placed at the property well before Essex’ acquired it by parties unconnected to Essex.

In addition, any PAHs on site which may have resulted from tank or pipe leakage were contained in fuel oil and are subject to the petroleum exclusion under CERCLA. Any contaminants emanating onto the site from off-site sources are subject to the CERCLA contiguous property exception”.

Everett Smith Group Ltd.

Diamond Alkali OU2 Allocation
ADR Confidential
Facility Data Report

EVERETT SMITH GROUP LTD.

Facility Name, Address and Size: Everett Smith Group Ltd. (ESG) as successor to Blanchard Bro & Lane, 20 Bruen Street, Newark, New Jersey; 4.21 acres (PAS-00032776).

1. **Business Type:** Leather tannery (PAP-0044885).

2. **Time Period of Ownership/Operations**

Operator: 1937 to 1939
Owner: 1937 to 1941

Note: A company by the name of Blanchard Bro. appears in City of Newark directories at 20 Bruen street in 1872, 1874, and 1939 (PAS-00032777, -814).

However, it appears that there have been two Blanchard Bro. & Lane companies. One that was incorporated in 1887 ("Blanchard 1887") to operate a leather tannery at 20 Bruen Street and ceased to exist in 1937 pursuant to the terms of its 50-year incorporation certificate (PAP-00000009); and another incorporated in 1937 ("Blanchard 1937") operating a leather tannery at the same location incorporated in 1937 (PAP-00000053). The names of two officers of Blanchard 1887, H. Gay Crawford and Joseph H. Gay, are consistently listed as of two of the officers of Blanchard 1937 (PAS-00032899-900; PAP-00000052; PAP-00000010-14).

The corporate history of the Blanchard Bro. & Lane companies is as follows:

1887: An entity named Blanchard Bro. & Lane was incorporated (PAP-00000052). The New Jersey Secretary of State "List of Certificates" dated December 31, 1911 states that Blanchard 1887 was not given a "perpetual" existence when incorporated, but rather had a legal existence limited to 50 years (PAP-00000005-6).

Blanchard 1887 purchased the 20 Bruen Street property by a deed recorded on January 6, 1888 (PAP-00000039).

1937: The 20 Bruen Street property was sold by Blanchard 1887 to Frank Deckert (PAP-00000047-52). This sale was accompanied by a stamp of the common seal of "Blanchard Bro. & Lane, Incorporated 1887" (PAP-00000052).

Blanchard Bro. & Lane was incorporated (hereinafter "Blanchard 1937") on June 29, 1937 (PAP-00000007).

Frank Deckert sold the 20 Bruen Street property to Blanchard on July 1, 1937 (PAP-00000053) (describing, "Blanchard Bro. & Lane" as "a corporation of the State of New Jersey (organized 1937). Blanchard 1887's corporate existence terminated November 11, 1937, according to the terms of its charter (PAP-00000005-6).

1939: The last year in the available source documents that Blanchard Bro. & Lane was listed in the City of Newark directories for 20 Bruen Street (PAS-00032814).

1941: The 20 Bruen Street property was sold to Ironbound Land Development Company on December 26, 1941 (PAP-00000058).

1961: A 1961 letter from Warner, Norcross, and Judd Attorneys states that Eagle Ottawa Leather owns all of the "issued and outstanding stock of Blanchard 1937 (PAP-00432364-65).

1964: A liquidation plan was adopted to accomplish the dissolution of Blanchard 1937 on August 31, 1964. Eagle Ottawa Leather assumed all of Blanchard's debts, obligations and liabilities on that day (PAP-00432366-67; PAP-00432368). Blanchard 1937 was dissolved on February 24, 1965 (PAS-00032820).

1966: Articles of Merger for Eagle Ottawa Leather Company and Albert Trostel & Sons are dated December 19, 1966 (PAS-00032908-09).

2007: On May 15, 2007, Everett Smith Group Ltd. acquired Albert Trostel & Sons Co (PAS-00032797).

There is no information in the available files of a direct transaction between Blanchard 1887 and Blanchard 1937. Blanchard 1937 purchased the real estate at issue from an individual who had acquired it from Blanchard 1887. No information is available regarding the shareholders of Blanchard 1887 and Blanchard 1937 in 1939. The information available with respect to any overlap of officers of Blanchard 1887 and Blanchard 1937 is summarized below and states that two individuals, H. Gay Crawford and Joseph H. Gay, were associated with Blanchard 1887 and Blanchard 1937.

- The New Jersey Secretary of State "List of Certificates" dated December 31, 1911, lists the Agent of Blanchard Bro and Lane as Matthew T. Gay (PAP-00000006).

- According to *Newark, the City of Industry,* a 1912 publication of the Board of Trade of the City of Newark, Matthew T. Gay, had been with Blanchard Bro & Lane nearly a half century, was president, and his sons Joseph H. and Herbert S. Gay held the positions of secretary and treasurer (PAS-00032773, 899-900).

- The Treasurer listed on the sale of the facility in 1937 to Frank Deckert is listed as Herbert S. Gay and the Secretary is listed as H. Gay Crawford (PAP-00000052).

- A Certificate of Amendment dated December 28, 1939, lists the President of Blanchard Bro & Lane as Joseph H. Gay and the Secretary as H. Gay Crawford (PAP-00000010-14).

- The 1941 deed to Ironbound Land Development Company from Blanchard Bro and Lane was signed by Karl Koeniger, Vice President and H. Gay Crawford as Secretary (PAP-00000058-63).

3. Operational History/COC Use and Presence at the Facility

The operations at this facility involved tanning and finishing of leather (PAS-00032775-816; PAS-00032899-900). There are no facility records available. Information from other sources are provided below regarding the typical operations of leather tanning facilities and information available from Sanborn maps of the area.

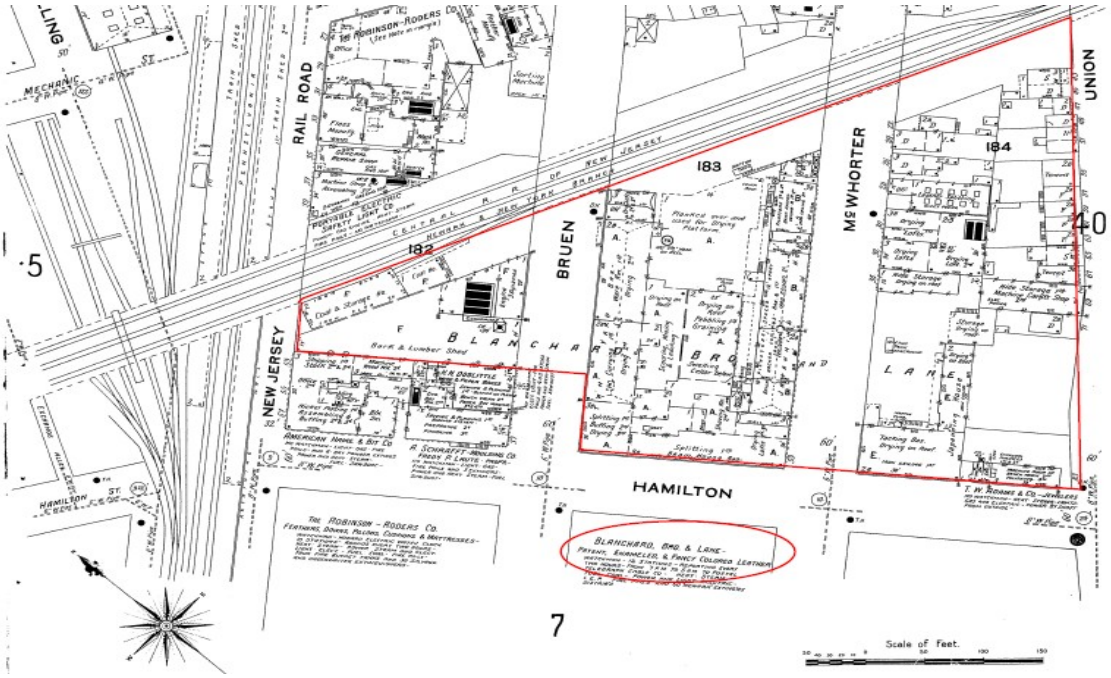
An industrial health hazard survey done in Ohio in 1915 included an assessment of the leather tanning and dyeing industry. At the time, this involved clearing the hides with sulfuric acid and bleaching with lead acetate, as well as tanning with chromium. Hides also contained arsenic from preservatives and from arsenic sulfide added to the lime used in unhairing. This survey also states that in the leather coloring and japanning houses, lead-containing dye and aniline dyes were being used. Additionally, benzene was in use as a solvent and mottling was done with a solution made up of naphtha, amyl acetate and wood alcohol. White lead, lamp black, oil, ferrous sulphate, tannic acid, and logwood were in use at various locations to produce the leather coloring agents (PAS-00032841-45). This survey did not discuss the nature or content of any wastewater effluent generated through leather tanning and dyeing operations.

A 1922 book regarding leather manufacturing discusses wastes from tanneries and states that wash waters in large volumes contained undissolved or suspended solids which, when removed left practically pure water.[1]

A Sanborn map from 1926-1931 shows a section of the facility was used for Japanning and describes Blanchard Bro. as producing “patent enameled & fancy colored leather.” It also shows an underground naphtha tank and two coal storage buildings (PAS-00032816-18).

General references from the 1940s regarding leather tanning show the use of materials including naphtha, chrome, calcium sulfate, and linseed oil to process the hides, and carbon black, Prussian blue (ferric oxide and cyanide), raw umber (iron oxide and manganese oxide) and litharge (lead oxide) to finish it.[2] Copper and zinc may also have been used in the finishing process (PAS-00032852-53).

According to a 1967 Department of Interior report entitled *The Cost of Clean Water-Industrial Waste Profiles No. 7 - Leather Tanning and Finishing*, leather tanning generally involves the steps presented below, although the specifics may have changed over time. There are ten major steps in the tanning and finishing process:



1. Shipping, storing & trimming
2. Soaking & washing (to remove salt, blood and dirt)
3. Green fleshing (to improve chemical penetration for later steps)
4. Unhairing (to improve appearance and remove unwanted protein)
5. Lime splitting (to separate the valuable grain layer from the flesh layer)
6. Bating (the first process in the tanhouse, to improve the feel of the grain)

[1] Rogers, A. (1922). *Practical Tanning*. New York, NY: Henry Carey Baird & Co., Inc. (pp. 665-666).
[2] Wilson, J. A. (1941). *Modern Practice in Leather Manufacture*. New York, NY: Reinhold Publishing Corporation. (pp. 607-613).

7. Pickling (to prevent precipitation of chromium salts during tanning)
8. Degreasing (to remove grease from sheep, pig or goat hides)
9. Tanning (to convert the hides into leather)
10. Retan-color-and-fatliquor processes (to ensure excellent leather and desired appearance) (PAS-00032773, 824-25).

The “significant pollutants” from a tannery identified in the 1967 Department of the Interior report were “1) free lime; 2) high pH; 3) potentially toxic chromium; 4) high BOD: 5) high suspended solids (hair and fleshings; 6) milky color from lime or green-brown color from tanning; 7) hardness; 8) high sulfides” (PAS-00032826). This list does not include any of the Lower Passaic River COCs.

ESG retained Steven Lange, an expert on the leather tanning process, to review the relevant information in the submission of information in a related State litigation, conduct his own research, and apply his own expertise to opine on the likelihood that any of the OU 2 COCs would have been a constituent in the wastewater effluent produced by the Blanchard 1937 manufacturing process. He has concluded that it is highly unlikely, given the period in which the manufacturing occurred and the type of products reported to have been manufactured at the Blanchard 1937 tannery, that any of the OU2 COCs would have been a part of the facility’s effluent (Early Settlement, p. 3). In a supplemental letter report dated September 7, 2018, Mr. Lange stated that the “observations and conclusions made with respect to operation of the tannery and the potential for discharge of Contaminants of Concern to the facility waste water from 1937 to 1939 apply equally to its operation and discharges to waste water prior to 1937” (Steven Lange Letter to Linda Benfield dated September 7, 2018).

(PAS-00032816)

4. Identified COCs

- Lead (possible use)
- Copper (possible use)

No records regarding facility operations during the relevant time-period were identified and provided by ESG. The possible use of these chemicals is taken from the description of leather tanning methods above.

Historic Fill

The Allocation Team has determined that the facility site is not located on regional Historic Fill as designated by the NJDEP.[3]

NJDEP has established that historic fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 COCs: PAHs, lead, copper, and mercury.[4] Accordingly, NJDEP technical requirements for property containing Historic Fill requires sampling for the EPA Target Compound List for PAHs and Target Analyte List for metals, including lead, copper, mercury, and the OU2 PAH COCs.[5] PAHs, lead, copper, and mercury are recognized by NJDEP to be constituents of Historic Fill at varying levels, not atypically at or exceeding residential soil standards.[6]

There is no information regarding analytical data in the available file material.

5. COC Pathways

Sanitary Sewer

After the establishment and operation of the PVSC system in 1924, the facility would have discharged to the City Dock CSO district (PAS-00032870; PAS-00032915). However, no information documenting the volume or content of wastewater discharged from the facility was identified and no such records have been found from public sources as reported by ESG (PAP-00432360).

[4] Characterization of Ambient Levels of Selected Metals and cPAHs In New Jersey Soils (2002) and Characterization of Ambient Levels of Selected Metals and Other Analytes In New Jersey Soils (1997), studies prepared for NJDEP, Division of Science and Research, by BEM Systems, Inc.

[5] NJDEP, N.J.A.C. 7:26E Technical Requirements for Site Remediation, Table 4-2, November 2009 [Note that Table 4-2 has been deleted from the current version of N.J.A.C. 7:26E (May 7, 2012) and the updated Historic Fill Technical Guidance (April 2013) as NJDEP believed that the tables list of historic fill constituents was too restrictive].

[6] NJDEP Table 4-2 (PAHs and lead) and a summary of NJDEP records regarding investigations of properties in the vicinity of the Passaic River recognized to be located in areas of Historic Fill indicate that the following average/maximum (mg/kg) contamination levels of OU2 COCs exist in area Historic Fill: PAHs (1.91/160), lead (574/10,000), copper (11.2/1,200), and mercury (0.21/3.7).

The overflow chamber for the City Dock CSO district is “on the east side of intersection of Raymond Blvd. and Raymond Plaza East.” The district is served by one 108” x 90” rectangular concrete sewer outfall to the Passaic River. A PVSC report states that this outfall served as the wet-weather overflow point for sewers within the district when the volume of combined flow was more than the system could handle. It states that “Under normal dry weather flow conditions, the flow is diverted to the PVSC interceptor via the regulator. During periods of rainfall, a portion of the combined flow enters the interceptor, with the balance overflowing the stop logs and being discharged through the outfall line into the Passaic River” (PAS-00032869-70).

Storm Sewer

There is no information regarding storm sewers in the available file material.

Direct Release

There is no information regarding direct release in the available file material.

Spills

There is no information regarding spills in the available file material.

Remedial Activities

There is no information regarding remedial activities in the available file material.

8. Summary of Asserted Defenses

Everett Smith Group Ltd. asserts that, “ESG has no connection to or responsibility for Blanchard 1887’s ownership and operation of the Facility prior to May 3, 1937”. ESG states that, mere “substantial continuity” of business is no basis for successor liability under CERCLA. Rather a “de facto merger” must be proven which requires, among other things, an assumption of seller’s liability.

Additionally, Blanchard 1937 was dissolved in 1965 by the corporation that owned its stock at that time, Eagle-Ottawa Leather Company (PAS-00032820). In anticipation of such dissolution, Eagle Ottawa Company assumed on August 31, 1964, all existing fixed and contingent debts, obligations and liabilities of Blanchard 1937 (PAP-00432366-67; PAP-00432368). There was no merger of the Blanchard 1937 and Eagle Ottawa Leather Company corporate entities (PAP-00432366-67; PAP-00432368). Since there was no assumption of Blanchard 1937 debts, obligations, or liabilities that did not exist on August 31, 1964, and no merger of Blanchard 1937 and Eagle-Ottawa Leather Company, Everett Smith Group asserts that it could have no liability for any potential CERCLA liabilities associated with the dissolved Blanchard 1937 that may have arisen with the enactment of CERCLA in 1980.

Foundry Street Corp.

Diamond Alkali OU2 Allocation

ADR Confidential

Facility Data Report

FOUNDRY STREET CORPORATION

Facility Name, Address and Size: Foundry Street Corporation (Foundry); 185 Foundry Street, Newark, New Jersey; 9.4 acres (PAS-00044626). Available references did not include information on the number of employees and work shifts at Foundry.

1. **Business Type:** This property has been a multitenant facility.

2. **Time Period of Ownership/Operations**

   Owner: Foundry Street Corporation – 1970-At least 2006 (PAS-00109628-9; PAS-00114494)

   Foundry Street Corporation was started in 1970 and incorporated in the State of New Jersey as of April 14, 1971 (PAS-00114494; PAS-00109628). Various tenants operated at the Foundry Street Complex. Some are shown on the map on the next page.

   A subdivision of Lot 4 Block 5005 was approved by the City of Newark, and consequently, Lot 22, 159-169 Foundry Street was formed from the southern portion of Lot 4. Kem Realty Company conveyed this new parcel containing approximately 1.65 acres to the Foundry Street Corporation on May 3, 1971. The property was leased to Automatic Electroplating Corporation, Sun Chemical Corporation and Fleet Auto Electric (PAS-00044990).

   Foundry Street Corporation was an active corporation in New Jersey in 2006 (PAS-00114782).

   According to a letter July 1990 letter from a law firm to NJDEP, Foundry Street Corporation was planning to sell a portion of 185 Foundry Street to Sun Chemical consisting of a single building at the northwestern corner (PAP-00117800-2).

3. **Operational History/ COC Use and Presence at the Facility**

   The numerous chemical companies and other entities that operated at the Foundry Street Complex after 1960 include the following:

   - ABC Demolition Company (contractor)
   - Ace Chemical Corporation
   - Ashland Chemical Company (bulk chemical repackaging; See Ashland Data Report)
   - Automatic Electro-Plating Corporation (plating; See AEP Data Report)
   - Avon Drum Corporation (drum washing; known Aroclor 1248 soil detections)
   - Berg Chemical Company, Inc. (chemical repackaging)
   - Conus Chemical Company, Inc. (chemical repackaging; known Aroclor 1248 detections in drain sediment)
   - Coronet Chemical (reclaimed naphthalene; developing a sodium dispersion to destroy PCBs; known Aroclor 1248 in drain sediment)
   - County Lift Truck Service, Inc. (forklifts)

Foundry Street Corp.

Diamond Alkali OU2 Allocation

ADR Confidential

Facility Data Report

- CWC Industries, Inc. (solvent coatings)
- Fleet Auto Electric Company, Inc. (repairs)
- Grignard Chemical Company, Inc. (petroleum and chemical products; known Aroclor 1248 in drain sediment)
- Essex Chemical Company (inorganic chemicals; See Essex Chemical Data Report)
- Honig Chemical and Processing Company
- Hummel Chemical (organic and pyrotechnical chemicals)
- Morrel Truck Service (repairs)
- Ohmlac Paint and Refinishing Company (roofing felts and coatings)
- RFE Industries
- Sequa Corporation (organic pigment manufacturing); See Sequa Data Report)
- Sun Chemicals (organic pigment manufacturing); See Sun Chemicals Data Report)
- Tennant Chemical Corporation
- Weston Chemical Corporation (PAS-00044629-630).

(PAS-00044654)

4. Identified COCs

- PCBs (detected)
- PAHs (detected)
- Copper (used, detected)
- Lead (detected)
- Mercury (used, detected)

There is no information pertaining to use of COCs by Foundry Street Corporation; however, there is evidence of use and generation of COCs by tenants of the Foundry Street Complex owned by Foundry Street Corporation. See individual Data Reports for Ashland Chemical, Automatic Electroplating, Sequa Corporation, Sun Chemicals and Essex Chemical as examples.

Historic Fill

The Allocation Team has determined that the facility site is located on regional Historic Fill as designated by the NJDEP[1].

NJDEP has established that Historic Fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 COCs: PAHs, lead, copper, and mercury.[2] Accordingly, NJDEP technical requirements for property containing Historic Fill requires sampling for the EPA Target Compound List for PAHs and Target Analyte List for metals, including lead, copper, mercury, and the OU2 PAH COCs.[3] PAHs, lead, copper, and mercury are recognized by NJDEP to be constituents of Historic Fill at varying levels, not atypically at or exceeding residential soil standards.[4]

5. COC Pathways

During a November 1990 site inspection at the Foundry Street Complex conducted by NJDEP, NJDEP observed a series of strip drains outside on both the northern and southern sides of Buildings 21 and 22. It is reported that the two strip drains appear to connect to another strip drain located along the western side of the facility. This strip drain, in turn, appears to be routed through the Foundry Street Complex and towards

---

[2] *Characterization of Ambient Levels of Selected Metals and cPAHs In New Jersey Soils* (2002) and *Characterization of Ambient Levels of Selected Metals and Other Analytes In New Jersey Soils* (1997), studies prepared for NJDEP, Division of Science and Research, by BEM Systems, Inc.

[3] New Jersey Department of Environmental Protection (NJDEP), *N.J.A.C. 7:26E Technical Requirements for Site Remediation,* Table 4-2, November 2009 [Note that Table 4-2 has been deleted from the current version of N.J.A.C. 7:26E (May 7, 2012) and the updated *Historic Fill Technical Guidance* (April 2013) as NJDEP believed that the tables list of historic fill constituents was too restrictive].

[4] NJDEP Table 4-2 (PAHs and lead) and a summary of NJDEP records regarding investigations of properties in the vicinity of the Passaic River recognized to be located in areas of Historic Fill indicate that the following average/maximum (mg/kg) contamination levels of OU2 COCs exist in area Historic Fill: PAHs (1.91/160), lead (574/10,000), copper (11.2/1,200), and mercury (0.21/3.7).

Roanoke Avenue located to the north of the site (PAS-00105573; PAS-00105583; PAS-00114186).

It is reported that the Roanoke Avenue sewer connects to a sewer on Doremus Avenue, which flows to the Passaic Valley Sewerage Commission (PVSC) treatment works. There is a combined sewer overflow (CSO) outfall to the Passaic River at the foot of Roanoke Avenue (approximately River Mile 1.1). In 1969, the City of Newark constructed a dam near this CSO to increase flow to the Doremus Avenue sewer, and ultimately, the PVSC treatment works (PAS-00044625-PAS-00044626). It is reported that the Roanoke Avenue combined sewer system and outfall to the Passaic River was documented by PVSC to have been inoperative from 1971 through late 1979, and that discharges of hazardous substances into the sewer system of the Foundry Street Complex would have ultimately discharged directly to the Passaic River via the Roanoke Avenue CSO during periods when it was known to be in a chronic malfunctioning condition (PAS-00109572; PAS-00114295; PAS-00114311; PAS-00114320).

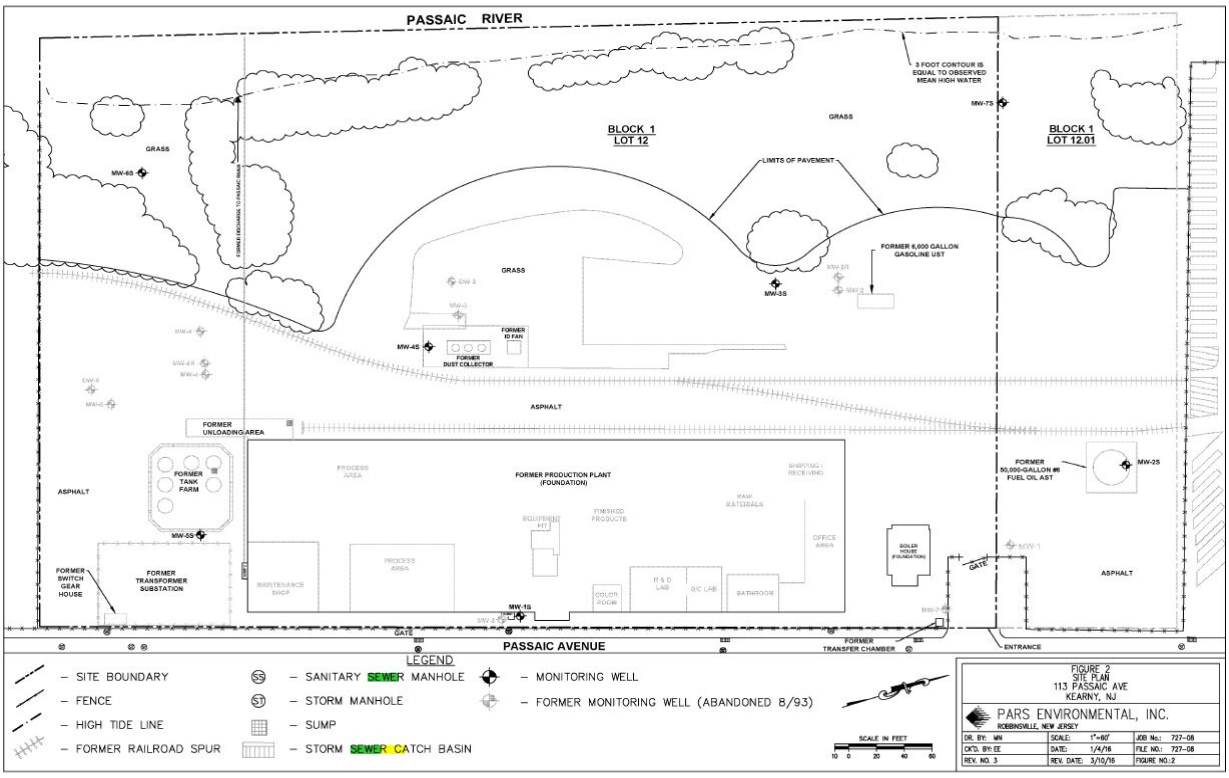
8. Summary of Asserted Defenses

No legal defenses were identified in the available file material.

Franklin-Burlington Plastics, Inc.

Diamond Alkali OU2 Allocation

ADR Confidential



Facility Data Report

FRANKLIN-BURLINGTON PLASTICS, INC.

Facility Name, Address and Size: Franklin-Burlington Plastics, Inc., 113 Passaic Avenue, Kearny, New Jersey, Block 1, Lot 12 (PAP-00056120). Block 1, Lot 12 historically may have been known by other street addresses including 127 Passaic Avenue (PAP-00054083).

According to a New Jersey Department of Environmental Protection Preliminary Assessment Report, in 1976, when Franklin Plastics Corporation, which later became Franklin-Burlington Plastics, Inc., purchased Block 1, Lot 12, the facility occupied approximately 8.44 acres (PAP-00220430; PAP-00054646). In 1977, Franklin Plastics Corporation subdivided the parcel and sold 1.37 acres of the parcel (identified as Block 1, Lot 12.01 or 143 Passaic Avenue) to Kearny Holdings Corporation (PAP-00056121; PAP-00456789, 802-803). As part of the 1977 transaction, Franklin Plastics Corporation retained limited easement rights to access and use a 50,000-gallon No. 6 fuel oil above ground storage tank (AST) and the associated underground piping, railroad lines and a parking lot located under the eastern portion of Lot 12.01 (PAP-00056121; PAP-00456789-91, 800-801). Franklin Plastics Corporation did not own or have any rights to the remaining portion of Lot 12.01 after the 1977 sale (PAP-00456796; PAP-00056120-21). Franklin-Burlington Plastic's operations were conducted on the then 7.07 acre parcel known as 113 Passaic Avenue, Kearny, New Jersey (Block 1, Lot 12)(PAP-00056120).

In 1984, the Franklin-Burlington Plastics Facility employed an average of 70 people operating three shifts a day for five days a week (PAP-00054090). See site plan and property boundaries for Block 1, Lot 12 and Block 1 Lot 12.01 below.

(PAP-00056163)

Franklin-Burlington Plastics, Inc.

Diamond Alkali OU2 Allocation

ADR Confidential

Facility Data Report

1. **Business Type:** Compounder of polyvinyl chloride (PVC) cubes and pellets (PAP-00337323; PAP-00056122); manufacturer and prime supplier of vinyl compounds used for both injection molding and extrusion by its customers to manufacture finished products for automotive, aircraft, wire and cable, and shoe manufacturing industries, as well as extrusion processes (PAP-00057038; PAP-00054645).

2. **Time Period of Ownership/Operations**

   Operator: 1976 - 2010
   Owner: 1976 - 2017

   1946: Congoleum Corporation, Floor Covering Division (also known as Congoleum-Nairn, Inc. and Congoleum Industries, Inc.), an entity unrelated to Franklin-Burlington Plastics, Inc., owned the property between 1946 and 1976 and conducted operations thereon from approximately 1946 to 1974 (PAP-00337307; PAP-00337323; PAP-00056120-21).

   1950s: From the 1950s until approximately 1973 or 1974, Congoleum entities manufactured Asphalt Tile (AT) and (Vinyl Tile) in Building 115 on the property (PAP-00233590; PAP-00724244). Additional information concerning Congoleum entity ownership and operation of the Building 115 property is set forth in the *Congoleum Corporation Facility Data Report*.

   1962: According to a February 1997 Response to an EPA Request for Information completed by Franklin-Burlington Plastics, Inc. (hereinafter the February 1997 Response), Franklin Plastics incorporated in April 1962 in the State of New Jersey (PAS-00063625).

   1968: According to the February 1997 Response, Spartech Corporation (Spartech) incorporated in April 1968 in the State of Delaware (PAS-00063624) and was a plastics manufacturer (PAS-00063625).

   1976: On February 16, 1976, Congoleum Corporation conveyed to Franklin Plastics Corporation a parcel of land (Block 1, Lot 12) that was described through metes and bounds (PAP-00220430). The EDR Chain of Title Report indicates this to be Block 1, Lot 12 (PAP-00456810).

   Franklin Plastics Corporation purchased an 8.44 acre parcel, which at the time was known as Block 1, Lot 12 on the Tax Map of the Township of Kearny, New Jersey (113 Passaic Avenue), from Congoleum Corporation and commenced plastics manufacturing compounding operations.

   1977: According to a *Remedial Investigation Report, Volume 1 of 4*, dated March 2016, prepared by PARS Environmental, Inc., for Franklin-Burlington Plastics, Inc. (the 2016 PARS RIR), a 1.37-acre adjoining parcel classified as Block 1 Lot 12.01, 143 Passaic Avenue was used by Franklin Plastics. After purchasing an 8.44 acre parcel from Congoleum in 1976, the parcel was subdivided and a 1.37 acre parcel (Lot 12.01) was sold in 1977 to Kearny Holding Corporation. As part of the 1977 transaction, Franklin Plastics Corporation retained limited easement

rights to access and use a 50,000 gallon No. 6 fuel oil AST and the associated underground piping, railroad lines and a parking lot located on and under the eastern portion of Lot 12.01 (PAP-00056121; PAP-00456789-91, 800-801). Franklin Plastics Corporation did not own or have any rights to the remaining portion of Lot 12.01 after the 1977 sale (PAP-00456796; PAP-00056120-21). The AST, which supplied fuel oil to the boiler house, was removed in April 2012 by Kleinfelder East, Inc. (PAP-00056121).

See figure below for 50,000-gallon No. 6 fuel oil AST location.

(PAP-00056165)

1986: In February 1986 Franklin-Plastics entered into an Administrative Order of Consent (AOC) with the New Jersey Department of Environmental Protection (NJDEP) Division of Waste Management, which allowed Franklin Plastics Corporation to sell all outstanding shares of capital stock of Franklin Plastics Corporation prior to completing the standard Environment Clean-up Responsibility Act (ECRA) administrative process. (PAP-00337244-50). According to the 1994 *Final Report on Cleanup Plan Implementation and Finalization of ECRA/Industrial Site Recovery Act (ISRA) Responsibilities*, Franklin Plastics Corporation was sold to Spartech and became Spartech-Franklin Plastics (PAS-00063471, 73).

1987: Franklin-Burlington Plastics, Inc. incorporated on November 25, 1987 in the State of Delaware (PAS-00063626-32).

1989: On August 17, 1989, a Registration of a Fictitious/Alternate Name was filed with the New Jersey Secretary of State by Franklin-Burlington Plastics, Inc. The fictitious name was Spartech Polymers (PAP-00338665). Later that year, on November 6, 1989, a Registration of a Fictitious/Alternate Name was filed with the New Jersey Secretary of State by Franklin Plastics Corporation. The fictitious name was Spartech-Franklin Plastics (PAP-00338666).

1990: On April 23, 1990, a Certificate of Merger was filed with the State of Delaware merging Franklin Plastics Corporation into Franklin-Burlington Plastics, Inc., and continued plastics compounding operations (PAP-00338667-69; PAS-00063633-36).

On June 29, 1990, a Registration of a Fictitious/Alternate Name was filed with the New Jersey Secretary of State by Franklin-Burlington Plastics, Inc. The fictitious name was Spartech Franklin Plastics (PAP-00338670). On July 17, 1990, a memo was sent to announce that Spartech-Franklin was now known as Franklin-Burlington Plastics, Inc., doing business as (d/b/a) Spartech-Franklin effective July 1, 1990 (PAP-00338671).

1993: On May 5, 1993, Franklin-Burlington Plastics, Inc. filed a Registration of Alternate Name in New Jersey for a period of five years. The alternate name to be used was Spartech Franklin Plastics (PAP-00338679).

2010: On February 16, 2010, Franklin-Burlington Plastics ceased manufacturing operations at 113 Passaic Ave (PAP-00056563; PAP-00054628).

2014: All buildings were demolished in April 2014. The buildings stood vacant from February 2010 until they were demolished in 2014 (PAP-00056563; PAP-00056121).

2017: On May 22, 2017, 113 Passaic Avenue Urban Renewal, LLC acquired the site from Franklin-Burlington Plastics (PAP-00338807).

3. Operational History/COC Use and Presence at the Facility

According to the 2016 PARS RIR, in 1976, Franklin Plastics Corporation purchased the Property then known as 113 Passaic Avenue and began operations in the Production Plant located on the Property, which was identified by the former owner/operator, Congoleum, as Building 115 (PAP-00056121; PAS-00048607). The site contained the 55,000-square foot Production Plant and an 840-square foot boiler house. The Production Plant included a maintenance shop in the southeastern corner and an office area in the northeastern corner. Two laboratories (research and development and quality control) were located on the eastern side of the Production Plant. Site manufacturing operations ceased in 2010 and all buildings were razed in April 2014 (PAP-00056121).

Plastic Compounding Operations

According to the 2016 PARS RIR, from 1976 to 2010 plastic manufacturing at the site included the addition of various colorants, stabilizers, and plasticizers to vinyl resin to create pellets and cubes. The pellets and cubes were manufactured in a variety of colors and hardness based on recipe variations and client specifications (PAP-00056122; PAS-00048607).

Three production lines were utilized where fully polymerized PVC resin was blended with plasticizers and additives to produce PVC compounds. According to the 2016 PARS RIR, during the manufacturing process solid resin was automatically weighed and fed by augers and then transferred into either one of eight blenders or directly into a mixer (PAP-00056122). The March 1986 *Site Evaluation Submission* prepared by Franklin Plastics Corporation (the 1986 Franklin Plastics SES) noted production began with weigh feeding resin into either of two lorry cars that transferred the resins into one of six or eight blenders or a mixer (PAP-00057020).

According to both the 2016 PARS RIR and the 1986 Franklin Plastics SES, fillers pigments and stabilizers were manually added, and liquid plasticizers and other select oils were pumped into the blenders or directly to the mixer to complete the loading. A Kleisler designed dust collector was continually employed and a combined ventilation exhaust system captured and removed free dust from the surrounding atmosphere to outdoor bins (PAP-00056122; PAP-00057020-21).

According to the PARS 2016 RIR, after cycle completion, the blenders discharged the powdered mix to feeders into continuous mixers or extruders, which fluxed the dry powder to create a plastic material. The plastic material was then cut into pellets or cubes before being packaged and shipped to customers (PAP-00056122).

According to the 1986 Franklin Plastics SES, the blenders discharged the powdered mix via covered containers to Vibra feeders for metered feeding into continuous mixers (similar to Banbury mixers). The hot plastic mass was continuously extruded and conveyed to feed the nip of a 2-roll mill. The rolled ribbon went through a refrigerated water bath to cool until it was semi-rigid. The cooled ribbon continued into a dicer and shaker to produce pellets for storage in hoppers. The hoppers contained the pellets until they were bagged, boxed, and at times, pneumatically loaded onto railroad hopper cars. Other bagged or boxed pellets were transferred to warehousing pending shipping (PAP-00057021). There was no chemical manufacturing or processing conducted at the Facility other than mechanical mixing and blending (PAP-00057021).

Product Unloading Procedure

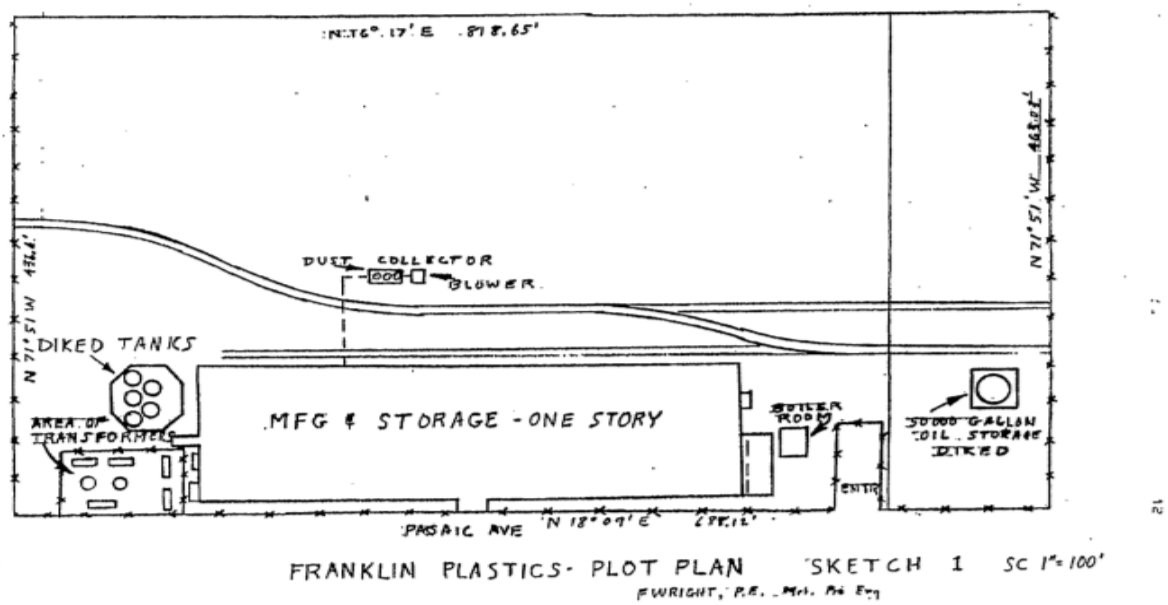
According to a 1986 Franklin Plastics SES, the majority of purchased PVC resin was delivered to the facility via railcar and/or container truck and transported into any of three silos above the roof. The resin came in 50-pound bags (at times), and the plasticizers were delivered and pumped into storage tanks (PAP-00057020).

According to the *Combined Spill Prevention, Control, and Countermeasure Plan and Discharge Prevention, Containment and Countermeasure Plan/Discharge Cleanup and Removal Plan for the Facility*, dated July 23, 2009 (2009 SPCC/DPCC/DCR Plan), a tanker truck unloading station for plasticizers is located in the southwest corner of the Production Plant. The tanker truck unloading area was a concrete spill containment area that extended below grade to provide secondary spill containment for the contents of the tanker truck should a spill occur (PAP-00055759). The plasticizers were transferred from the delivery trucks to individual ASTs located in the tank farm and within the Production Plant. The tank farm located on the southwest portion of the Facility contained six plasticizer storage tanks constructed of steel and coated with a corrosion resistant material. The tanks were located in an epoxy-sealed block wall containment area, which provided secondary spill containment for these tanks (PAP-00055751-52). Pigments and stabilizers were delivered via truck to the Production Plant's exterior, asphalt paved receiving area in boxes, bags, and fiber drums. The receiving area, located on the north side of the Production Plant, was sloped towards the Production Plant, covered with an overhang, and did not contain any storm drains (PAP-00055758).

No. 6 fuel oil, which was stored in a 50,000-gallon AST, was delivered to the Facility via tanker truck. Unloading was performed within a bermed area adjacent to the 50,000-gallon AST (PAP-00055754). The *Spill Prevention, Control and Countermeasure Plan,* dated February 5, 1992 (1992 SPCC Plan) states that the 50,000-gallon No. 6 fuel oil AST was located north of the Production Plant within a containment area comprised of a concrete pad with concrete block walls. After the Facility was converted to natural gas circa 1992, fuel oil was not delivered to this AST on a regular basis (PAP-00338487). The 2009 SPCC/DPCC/DCR Plan specifically notes this AST was taken out of service in accordance with applicable New Jersey regulations (PAP-00055751).

No. 2 fuel oil was occasionally delivered to the two 275-gallon ASTs located on an asphalt-paved surface on the northeastern portion of the Facility. These two ASTs were used as a backup fuel supply for the boiler house, so fuel was not delivered to these ASTs on a regular basis. The 2009 SPCC/DPCC/DCR Plan specifically notes that these ASTs were taken out of service in accordance with applicable New Jersey regulations (PAP-00055751).

Powdered PVC resins are not a regulated substance as defined by the EPA SPCC and NJDEP SPCC regulations, so there is no discussion of their delivery and unloading procedure in the 2009 SPCC/DPCC/DCR Plan (PAP-00055745). According to the PARS 2016 RIR, powdered PVC resins were delivered to the west side of the Production Plant in bulk by rail cars and tank trucks. The resins were pneumatically transferred from the rail cars into one of three silos located on the roof of the Production Plant (PAP-00056122).



Product Waste Stream

According to the 1986 Franklin Plastics SES, there were three waste streams generated by plastic compounding at the facility:

- The mixer jacket and 2-roll mill were cooled by a closed, non-contact water cooling system. Overflows were discharged into the floor trench system to a sump located by the transformer substation at the southeast corner of the Production Plant. The sump flowed directly into the Passaic River through a nine-inch pipe via a permit (PAP-00057021). According to New Jersey Pollution Discharge and Elimination System (NJPDES) direct discharge permit No. NJ0002194, both contact and non-contact cooling water was discharged through an 8-inch outfall pipe from February 1976 through May 2004 (PAP-00057110; PAP-00057276; PAP-00057271; PAP-00056126).

- A Kleisler designed dust collector captured free dust that was “almost entirely” recycled back into the process (PAP-00057021). The dust collector located to the west of the Production Plant was continually employed and a combined ventilation exhaust system captured and removed free dust. The dust was collected in outdoor bins. Periodically the bins were emptied and the collected materials were reclaimed and recycled back into the process (PAP-00056122; PAP-00057021).

- Precipitate derived from electrostatic precipitators located on the roof was piped to a collection drum within the facility. The precipitate was largely recycled back into the process (PAP-00057021). See the following undated Plot Plan for the location of the dust collector and manufacturing building (also known as the Production Plant).

(PAP-00057048)

Raw Material

According to the 2016 PARS RIR, the approximate percentages of raw materials based on an air permit application from 1989 were 50% PVC resin, 30% plasticizers, 19% calcium carbonate filler, and 1% stabilizer and pigments (PAP-00056122). The approximate percentages of raw materials is the same in the air permit application from 1979 (PAP-00338652).

On August 17, 1990, Spartech-Franklin Plastics stated in an Industrial Waste Survey that the raw material used for their operations consisted of PVC Resin, (62% of material used in final product) and Phthalate Oils (30% of material used in final product). The unused material was internally recycled for future use (PAP-00338674). Spartech-Franklin also stated that 25 tons of PVC dry blend pellets and 25 tons of PVC pellets that it generated were classified as reusable material and were re-used in house (PAP-00338675).

According to the September 17, 1990 *Site Inspection Report*, prepared by NUS Corporation for the Environmental Protection Agency (the 1990 EPA SI), Franklin Plastics Corporation used phthalates such as bis(2-ethylhexyl) phthalate, butylbenzyl phthalate, di-n-butyl phthalate, and di-n-octyl phthalates as plasticizers in its manufacturing process (PAP-00337321).

An August 15, 2008 Spartech Polycom, Inc. letter to the EPA stated that the Facility was working to reduce the use of lead compounds. The Facility targeted lead compounds specifically through the reduction of non-product output (NPO) of lead compounds. Lead compounds were used as a PVC stabilizer in electrical insulators. Many of these applications were required in order for that the material to meet Underwriters Laboratory (UL) listing specifications related to electrical fire protection product properties. The Facility implemented efforts to reduce NPO in these applications of lead compounds. It was achieved through handling changes as well as product substitution (using barium and zinc compounds in place of lead compounds - a polybutylene terephthalate [PBT] - whenever the application or specifications did not require the addition of lead compounds to the product) (PAP-00338386-87).

Sumps

According to the 2016 PARS RIR, the plastics pelletizing process used cooling water. Contact cooling water from the dicer and pelletizer operations were released to trenches in the Production Plant floor and directed to the collection sump on the east side of the Production Plant (Sump No. 1) (PAP-00056126).

Non-contact cooling water consisting of water from the air compressor cooling jacket, lab mill and blender cooling water and cooling tower overflow was also directed to Sump 1 (PAP-00057133; PAP-00057203; PAP-00056126). Water in Sump 1 drained via a pipe to Sump 2, located at the south end of the Production Plant. Water was also discharged from the Production Plant's maintenance shop directly to Sump 2 (PAP-00056126).

Sump 2 contained two chambers. The water from Sump 1 and the maintenance shop entered the first, east side, chamber where water flowed across a baffle with a cutout weir that held back floating materials from entering the second, west side, chamber. The outlet from the second chamber was elevated and allowed solids to settle. Water from the second chamber of Sump 2 flowed through the 8-inch diameter outfall pipe into the Passaic River via a NJPDES Permit No. NJ002194 (PAP-00056126). The discharge from Sump 2 continued until prior to June 2004, when the discharge pipe was sealed. All water generated at the Facility at that time was redirected from Sump 1 to the Passaic Valley Sewerage Commission (PVSC) sanitary sewer system (PAP-00057271; PAP-00056126).

Facility Storage Area

A *Combined Spill Prevention, Control, and Countermeasure Plan and Discharge Prevention, Containment, and Countermeasures Plan/Discharge Cleanup and Removal Plan (Three-Year Plan Renewal)* prepared by Levine-Fricke (LFR) dated February 22, 2000 (the 2000 LFR Three-Year Plan Renewal) was submitted on behalf of Franklin-Burlington Plastics, Inc. (d/b/a Spartech Polycom). Additionally, a *Combined Spill Prevention, Control, and Countermeasure Plan and Discharge Prevention, Containment, and Countermeasures Plan/Discharge Cleanup and Removal Plan (Three-Year Plan Renewal)* prepared by LFR Levine-Fricke dated July 1, 2003 (the 2003 LFR Three-Year Plan Renewal) was submitted on behalf of Franklin- Burlington Plastics, Inc. (d/b/a Spartech Polycom). The plans incorporated the Discharge Prevention, Containment and Countermeasure (DPCC) and Discharge Cleanup and Removal (DCR) Plans required by the NJDEP and the Spill Prevention, Control, and Countermeasures (SPCC) Plan which is required by the EPA (PAP-00338541-637; PAP-00055157-294). The following is a brief description of the Facility storage areas as stated in the 2000 LFR Three-Year Plan Renewal and the 2003 LFR Three-Year Plan Renewal. It should be noted that SPCC plans were prepared for the site beginning in 1985 (PAP-00055011-28). The SPCC plan and DPCC/DCR plans were combined beginning in 1997 (PAP-00055072-115).

Outdoor Oil Storage Tanks

- The 2000 LFR Three-Year Plan Renewal states that a 50,000-gallon No. 6 fuel oil storage tank was located in a diked area. The storage tank was no longer in use and had been taken out of service. All associated piping has been disconnected and the contents of this tank were planned to be removed in the near future (PAP-00338551). In the 2003 LFR Three-Year Plan Renewal, the tank was listed as cleaned and its contents removed (PAP-00055167). The AST was removed in April 2012 (PAP-00337663).

- The 2000 LFR Three-Year Plan Renewal states that two 275-gallon No. 2 fuel tanks were located in an un-diked area. These fuel tanks had been disconnected and were located within a shed outside the eastern wall of the boiler room. These tanks were small enough and far enough from the Passaic River that a spill was not likely to pose an environmental threat. The tanks were located

below the Passaic Avenue elevation, so a spill would not pose a threat to the roadway (PAP-00338551).

- The 2000 LFR Three-Year Plan Renewal states that one 500-gallon waste oil storage tank is located outside within a brick wall containment area (5-feet high and 1-foot wide walls). The brick wall containment area has a capacity of approximately 100,000 gallons. The containment walls and floor were covered with concrete to prevent subsurface contamination. A valved drain extending out from the containment wall allowed for removal of any collected water inside the containment wall. Before removal, a sample of accumulated water was visually analyzed for contamination. If contaminated, the oil was removed from the water using absorbent pads, or the water was collected and properly disposed of (PAP-00338551-52).

- The 2003 LFR Three-Year Plan Renewal states that the block wall containment area was sealed with epoxy and repainted in September 2002. There is no mention of the valved drain beginning in the 2003 LFR Three-Year Plan Renewal. The 2003 LFR Three-Year Plan Renewal and subsequent plans state that a trained employee manually pumped accumulated water within the block wall containment area. Before removal, a sample of accumulated water was visually analyzed for contamination. If contaminated, the oil or hazardous material was removed from the water using absorbent pads, or the water was pumped into 55-gallon drums and properly disposed (PAP-00055167).

Outdoor Hazardous Substance Storage Tanks

- The 2000 LFR Three-Year Plan Renewal states that there were five hazardous substance storage tanks located outside the production area on the southwest portion of the Facility within a brick wall containment area (5-feet high and 1-foot wide walls). The floor inside the containment area was covered with concrete to prevent subsurface contamination. The brick wall containment area has the capacity of approximately 100,000 gallons. The combined storage capacity of the five tanks was approximately 72,500 gallons. A valved drain extending outside the containment area allowed for removal of any collected water inside the containment wall. Before removal, a sample of accumulated water was visually analyzed for contamination. If contaminated, the material was removed from the water using absorbent pads, or the water was collected and properly disposed of (PAP-00338552). It should be noted that this is the same brick wall (block wall) containment area as discussed above regarding the 500-gallon waste oil storage tank.

  The number of tanks located within this area changed depending on the time period. The 2003 LFR Three-Year Plan Renewal identified six plasticizer tanks in this area. The 2003 LFR Three-Year Plan Renewal also states that the block wall containment area (which was sealed with epoxy and repainted in September 2002) had a capacity to hold the largest tank volume plus six inches of rainwater. There is no mention of the valved drain beginning in the 2003 LFR Three-Year Plan Renewal. The 2003 LFR Three-Year Plan Renewal and subsequent plans

state that a trained employee manually pumped accumulated water within the block wall containment area. Before removal, a sample of accumulated water was visually analyzed for contamination. If contaminated, the oil or hazardous material was removed from the water using absorbent pads, or the water is pumped into 55-gallon drums and properly disposed (PAP-00055167-68).

Indoor Bulk Storage Tanks

- The 2000 LFR Three-Year Plan Renewal states that there are 13 plasticizer storage tanks located indoors throughout the Production Plant. These tanks were all located far enough away from outside doorways that a spill was unlikely to escape the Production Plant (PAP-00338553).

Raw Material Storage Area

- The 2000 LFR Three-Year Plan Renewal states that totes and drums of raw materials were stored outside and adjacent to the 100,000-gallon containment area. The property is relatively flat and a spill would not likely reach the storm drains, the river, or the street (PAP-00338554).

- The 2000 LFR Three-Year Plan Renewal states that fiber and metal drum storage was located inside the Production Plant. The indoor area is slightly pitched and because of its location a spill would not exit the Production Plant or enter a storm drain (PAP-00338553).

- The 2003 LFR Three-Year Plan Renewal states that the totes and drums of raw materials are stored inside the Production Plant within the shipping and receiving area. The materials are stored far enough away from any door entrances so that any spills would not likely exit the Production Plant (PAP-00055169).

Waste Oil Storage Area

- The 2000 LFR Three-Year Plan Renewal states that waste oil drums were stored outside near the 100,000-gallon containment area on the southwest portion of the Facility. These drums stored rags and speedy dry contaminated with used oils from minor spills and leaks that occur within the Production Plant. All wastes are stored in 55-gallon drums. The drums were stored for 90 days or less and were removed by a licensed waste handler. Since this waste was mostly solid material, spills from this area are not expected to reach the storm drains, the river, or the street (PAP-00338554).

Bulk Unloading Areas - Plasticizer Unloading Area

- The 2000 LFR Three-Year Plan Renewal states that plasticizers, D10P/J25 l and DINP were received in the outdoor tanks located outside of the Production Plant. The plasticizers were transferred from the delivery tank truck to the individual storage tanks at approximately 25 gallons per minute (gpm). Each tank had a level indicator which extended the full height of the tank and gave a clear liquid

level indication during filling of the tank. It was standard procedure for a Plant employee to be present at all times to observe the tank filling (PAP-00338554).

- The 2000 LFR Three-Year Plan Renewal states that the truck unloading station for plasticizers was located in the west corner of the Production Plant, near the Passaic River[1]. The unloading area was a bermed ramp that extended below grade to provide secondary containment for the contents of the truck. Any accumulated rainwater was usually left to evaporate; however, a manually operated 250 gpm pump was available to pump the rainwater into the adjacent diked area for Tanks 12 and 13 (the previously discussed 100,000-gallon brick wall containment area) (PAP-00338555; PAP-00338585).

Bulk Unloading Areas - Oil Unloading Area

- The loading area for the two disconnected 275-gallon No. 2 fuel tanks located outside the eastern wall of the boiler room was located on a gravel parking lot below the Passaic Avenue elevation (PAP-00338555).

Transformer Area

- The 2000 LFR Three-Year Plan Renewal states that there were five transformers and two oil-containing circuit breakers located outside, adjacent to the Production Plant and were completely enclosed by a chain-link fence. The total volume of oil contained within the five transformers and two circuit breakers was approximately 4,400 gallons (PAP-00338556). It should be noted that the Amended Stormwater Pollution Plan updated by Argus Regulatory Management, LLC on November 11, 2005 stated that the transformers were located outside on a concrete pad within a bermed area (PAP-00054786). The transformer substation was located within a wholly contained bermed and fenced area, approximately 375 feet east of the Passaic River (PAP-00056131; PAP-00056579).

- The transformer substation located on the Property was installed and used by the former owner of the Property, Congoleum Corporation (PAP-00725660-61; PAP-00725626; PAP-00725627; PAP-00725628-30). The transformer substation was utilized by Franklin-Burlington Plastics from 1976 until 2010. The substation was located within a wholly contained bermed area and contained by a chain-link fence (PAP-00056131). Polychlorinated biphenyl (PCBs) were a component of the dielectric mineral oil that was sealed within electrical equipment consisting of five pad-mounted transformers, two circuit breakers, and 17 brushings (PAP-00056565; PAP-00056163; PAP-00055954). The five transformers consisted of two Allis Chambers (K-14098 and K-14301), two Westinghouse (K-14463 and K-14306), and one Pittsburgh transformer (PAP-00338663-64; PAP-00056565).

[1] The description of the truck unloading station in the 2000 LFR Three-Year Plan Renewal is misleading. Figure 2 – Site Plan of the 2016 PARS RIR shows the location of the truck unloading area (denoted on the Figure as "FORMER UNLOADING AREA"). The location is approximately 285 feet east of the River (PAP-00056163).

- On October 7, 1987, RECON Systems Inc. (RECON) informed the Kearny Fire Department that the two Westinghouse transformers had levels of PCBs concentrations greater than 50 parts per million (ppm); K-14463 at 115 ppm and K-14306 at 80 ppm. The remaining three were below 50 ppm (PAP-00338663-64). One of the transformers was retrofitted in July 1996 by replacing the dielectric mineral oil to lower the PCB concentration of the transformer from 616 ppm to 18 ppm (PAP-00338683; PAP-00055088).

- The electrical equipment was removed from the Facility in August 2013 (PAP-00056565). Demolition of the concrete pads, supports, and switchgear house of the former substation was conducted in April 2014 (PAP-00056566). Further discussion on the decommissioning of the transformer substation is available in the "Remedial Activities" section below.

Process Areas

- The 2000 LFR Three-Year Plan Renewal states that Spartech Polycom's production processes consisted of three production lines in which polymer resins are blended with plasticizers to alter the physical properties of the polymer. The plasticizer was pumped from the storage tank to a process tank on the production line, from which it is fed to the blender. The process tanks were not contained but were indoors located sufficiently far away from the outside doorways, so that no material would be expected to escape the Production Plant to become a discharge in the event of a leak. Contact and non-contact cooling water were used in the process. Due to the design of the process, hazardous substances would not enter this cooling water even during a process upset (PAP-00338557).

Loading Dock Area

- The 2000 LFR Three-Year Plan Renewal states that the loading dock area was located on the east side of the Production Plant. Drums of raw materials were transferred in this area. The loading dock area did have an overhang to protect the area from rainwater (PAP-00338557).

- The 2003 LFR Three-Year Plan Renewal describes the location of the loading dock area as being on the North side of the Production Plant. The loading dock area was paved with bituminous macadam and sloped slightly back to the Production Plant in order to act as secondary containment. Since minimal amounts of drummed materials were unloaded in this area and no storm drains are present, spills would not likely reach a navigable waterway. This area was not located near the river and is below the elevation of Passaic Avenue (PAP-00055173)

Chemical Storage

The following table shows the types of chemicals, amount of chemicals stored, number of days being stored, and where the chemical was located at the Facility. The source of

January 1 to December 31, 2009 (PAP-00338469)	PVC-Chloroethylene Polymer (Pure Solid in bag)	1,000 – 9,999	365	Warehouse - Northwest area of facility
January 1 to December 31, 2009 (PAP-00338469)	PVC-Chloroethylene Polymer (Pure Solid in Railcar)	25,000 - 99,999	365	Rail tracks at the west side of facility

4. Identified COCs

- PCBs (used, released, detected)
- PAHs (used, released, detected)
- Copper (used, released, detected)
- Lead (used, released, detected)
- Mercury (used, released, detected)

PCBs

On August 21, 1996, EPA was informed that the Westinghouse transformer K14306 (1995 Sample results that showed 616 ppm contamination) retrofill had been completed (PAP-00338683). After the retrofill, the PCB concentration in Westinghouse transformer K-14306 was 18 ppm (PAP-00055088). Upon success of the retrofill for transformer K14306, the spare transformer may be retro filled as well (PAP-00338683).

According to the 2017 *Former Transformer Substation Remedial Action Report, Volume 1 of 2*, prepared by PARS Environmental, Inc., for Franklin-Burlington Plastics (the 2017 PARS RAR) soil samples by PARS were taken between December 2013 and March 2015 within the former transformer substation. PARS installed 29 borings within the former substation and a soil sample was collected from each boring location at the ground surface or at 0.5 foot depth interval immediately below the gravel layer. PCBs were detected in the sample collected from No. TS-24 at a concentration of 2.05 mg/kg. Low concentrations of PCBs were detected in samples TS-8, TS-10, TS-15, and TS-15DUP (PAP-00056565). PCBs were not detected above the laboratory MDLs in the remaining samples.

In 2014, Dallas Industrial Services, Inc. demolished structures at the site that included the concrete pads, supports and the switchgear house for the former transformer substation. Prior to the demolition, PARS collected in-situ concrete samples as per the NJDEP Guidance for Characterization of Concrete and Clean Material Certification for Recycling. One concrete chip sample from the former transformer substation, No. C-3 had a PCB concentration of 0.044 mg/kg. PCBs were not detected above the laboratory MDL in the remaining samples(PAP-00056566).

PAHs

The sampling results from the 1984 Hart PSA identified 6,690 ug/kg pyrene, 5,100 ug/kg phenanthrene, and 5,740 ug/kg fluoranthene in sample No. TankSA (PAP-00057074).[2] All samples were collected from the tank area south of the Production Plant. The depth of the soil samples was not provided in the reviewed material. The location of the soil samples are shown in the 1984 Hart PSA map located in the Copper section. According to the 1987 RECON SAP Results report, the following results were found for PAHs. See the 1987 sample location map provided above in the Copper section.

RECON 1987 PAH Data Summary		
Analyte:	**High Range Result (mg/kg):**	**Sample/Depth:**
Acenaphthene	8.7	B31/3 3.5-4.0"
Acenaphthylene	1.5 J	B31/3 3.5-4.0"
Anthracene	26	B31/3 3.5-4.0"

[2] The referenced sample results were originally taken as part of the 1984 Hart PSA. The 1984 Hart PSA is only available as an appendix to the 1986 Franklin Plastics SES. The 1986 Franklin Plastics SES does not include the lab data from the 1984 samples, so there is no way to verify the reported data is correct and/or to check whether there were any accidental transcription errors.

On June 5, 1990, soil samples collected by NUS Corporation as part of the 1990 EPA SI identified the following PAH concentrations:

- 1,500 ug/kg benzo(a)pyrene in soil sample No. NJEP-S8 (Dilution Factor of 1) collected near the Production Plant gate (PAP-00337330).
- 4,600 ug/kg phenanthrene was identified in soil sample No. NJEP-S8 and 1,300 ug/kg phenanthrene in soil sample No. NJEP-S9 (DUP) (PAP- 00337330). Both samples were collected near the Production Plant gate.
- An estimated concentration of 3,600 ug/kg benzo(b)fluoranthene (Dilution Factor of 1) was found in soil sample No. NJEP-S8 (PAP-00337330). The depth of the soil samples was not provided in the reviewed material.

NJEP SED1 was taken north of the tank farm and NJEP SED2 was collected from the facility's sump pit (PAP-00337317; PAP-00337372). NJEP SED3 and NJEP SED4 were taken from the two storm drains bordering the facility on Passaic Avenue (PAP-00337311). The following table shows the analytic results.

NUS Corporation June 1990 PAH Sediment Data Summary

E = estimated value
N = Presumptive evidence of the presence of the material
(PAP-00337327-28)

According to the 1990 EPA SI, no PAH compounds were identified in the surface water samples (No. NJEP-SW1 collected directly from the Facility's discharge pipe nor in samples No. NJEP-SW2 and No. NJEP-SW3 were collected from the sump pit) (PAP-00337327-28; PAP-00337317).

The 2016 PARS RIR showed the following results for PAHs for the below AOCs which had at least one PAH detection above the NJ RDCSRS:

- AOC 1 (50,000-gallon No. 6 Fuel Oil Aboveground Fuel Tank) had 0.85 mg/kg benzo(a)anthracene and 0.68 mg/kg benzo(b)fluoranthene in soil sample No. PL-1, collected on January 8, 2016 at a depth of 2.3 to 2.8 feet (PAP-00056183).

- AOC 5/7 - Unloading Area Tank Farm Soil ranged from non-detect to 52 mg/kg benzo(a)anthracene, 56 mg/kg benzo(a)pyrene, 69 mg/kg benzo(b)fluoranthene and 31 mg/kg indeno[1,2,3-cd]pyrene were found in soil sample No. TF-17 collected between 0.5 and 1.0 feet bgs from the southwestern outside corner of the Production Plant (PAP-00056192). In addition, 1.4 mg/kg dibenz(a,h)anthracene was noted in Tank Farm soil sample No. TF-12 collected between 0.5 and 1.0 foot bgs between the boundaries of the Production Plant and tank farm (PAP-00056189).

Copper

According to the *Preliminary Site Assessment* prepared by Fred C. Hart, Inc. dated September 1984 (1984 Hart PSA), four surface soil samples were collected for chemical analysis and subsurface soil samples for physical inspection and OVA analysis. One surface sample consisted of a composite of several samples in a spill and vegetative stress area near the air pollution control units, and the other three samples were collected inside the tank containment area (PAP-00057068). See the 1984 sample location map below.

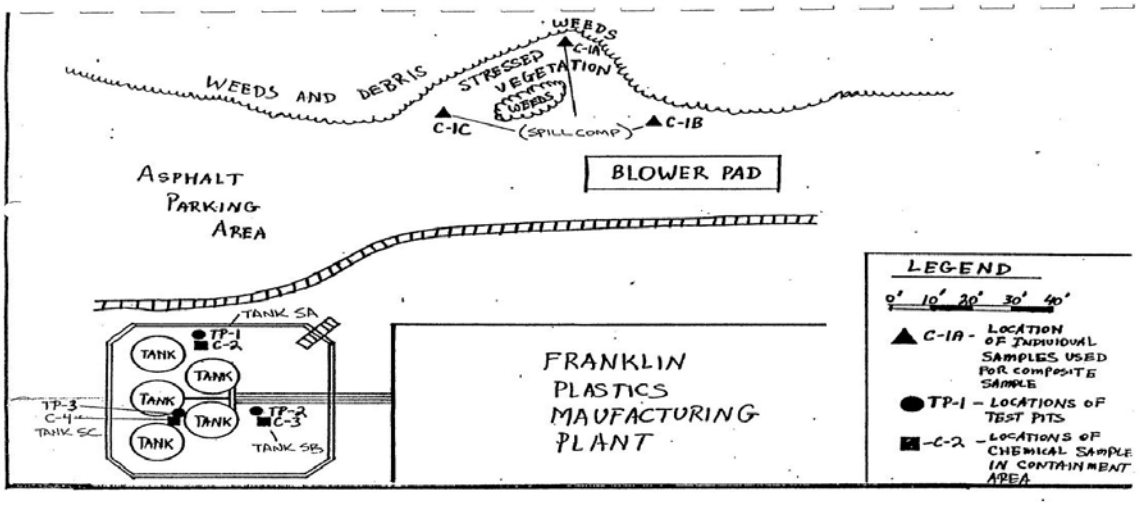

FIGURE 2. LOCATION OF SAMPLING SITES

(PAP-0057071).

The sampling results from the four samples collected on June 27, 1984 identified the following for copper:

- SPILLCOMP - 79,000 micrograms per kilogram (ug/kg)
- Sample Tank SA - 120,000 ug/kg
- Sample Tank SB - 290,000 ug/kg
- Sample Tank SC - 38,000 ug/kg (PAP-00057074)[3].

Note: The exact depth of the surface soil samples was not provided in the available file materials.

According to the *Sampling and Analyses Plan Results for Franklin Plastics Corporation* prepared by Recon Systems, Inc., dated October 1, 1987 (the 1987 RECON SAP) Results, Recon Systems, Inc. collected soil samples from 33 soil borings as part of the ECRA-required sampling. The following table shows location, depth and results for copper. See the following 1987 sample location map for locations.

(PAP-00337310)

[4] Random Sampling is clarified in the 1987 RECON SAP Results as soil samples collected at three borings (B-31, B-32 and B-33) in an area of urban fill between the Production Plant and the Passaic River (PAP-00337263).

On June 5, 1990, as part of the 1990 EPA SI, a total of 16 environmental samples were collected by NUS Corporation that included three surface water, four sediment, and nine surface soil samples. The copper concentrations were detected as follows:

NUS Corporation, June 1990, Copper Data			
Sample ID:	**Matrix:**	**Copper Result:**	**Units:**
NJEP-SW1	Surface Water	28.8	µg/L
NJEP-SW2	Surface Water	38.7	µg/L

(PAP-00337311; PAP-00337332-22)

Lead

According to the 1984 Hart PSA, the sampling results from the four surface soil samples collected on June 27, 1984 identified the following for lead:

- SPILLCOMP - 6,900,000 ug/kg
- Sample Tank SA - 640,000 ug/kg
- Sample Tank SB - 1,100,000 ug/kg
- Sample Tank SC - 64,000 ug/kg (PAP-00057074).[7]

The depth of the soil samples was not provided in the available file materials. See the 1984 sample location map provided above in the Copper section.

In July 1987, Recon Systems, Inc. collected 33 samples from soil borings as part of ECRA-required sampling. See the 1987 sample location map provided above in the Copper section. The following table shows location, depth and results for lead.

[5] NJDEP-SED3 and NJDEP-SED4 were collected from two storm drains bordering the Facility on Passaic Avenue (PAP-00337311)

[6] NJDEP-SED3 and NJDEP-SED4 were collected from two storm drains bordering the Facility on Passaic Avenue (PAP-00337311)

[7] The referenced sample results were originally taken as part of the 1984 Hart PSA. The 1984 Hart PSA is only available as an appendix to the 1986 Franklin Plastics SES. The 1986 Franklin Plastics SES does not include the lab data from the 1984 samples, so there is no way to verify the reported data is correct and/or to check whether there were any accidental transcription errors.

(PAP-00337252-64; PAP-00056285-94; PAP-00056300-21)

On June 5, 1990, samples collected by NUS Corporation identified the following highest lead concentrations:

- 818 mg/kg estimated value in sediment sample NJEP-SED2, collected from the facility's sump pit (PAP-00337311; PAP-00337332-33)[9]
- 2,520 mg/kg estimated value in soil sample NJEP-S6, collected near the sludge pile at a depth of 0 to 6" (PAP-00337311; PAP-00337332-33).[10]

The following table shows the results of the remaining samples collected by NUS in June 1990.

NUS Corporation, June 1990, Lead Data			
Sample ID:	**Matrix:**	**Lead Result:**	**Units:**
NJEP-SW1	Surface Water	3.4	µg/L

NJEP-S8	Soil	304	mg/kg
NJEP-S9	Soil	90.8	mg/kg

E = estimated value
(PAP-00337306; PAP-00337311; PAP-00337332-33)

According to the 2016 PARS RIR, the following soil sampling results exceeded the New Jersey Residential Direct Contact Soil Remediation Standards (RDCSRC) for lead of 400 mg/kg:

- AOC 5 – Plasticizer Tank Farm and AOC 7 – Unloading Area, 1,770 mg/kg lead was noted in Tank Farm soil sample No. TF-16 collected on October 30, 2014 between 2.0 and 2.5 feet below ground surface (bgs), south of the Former Tank

[9] The reported value in the 1990 EPA SI was 818 E. Per the notes from the sampling results chart, the "E" indicates that this was an estimated value.
[10] The reported value in the 1990 EPA SI was 2,520 E. Per the notes from the sampling results chart, the "E" indicates that this was an estimated value.
[11] NJDEP-SED3 and NJDEP-SED4 were collected from two storm drains bordering the Facility on Passaic Avenue (PAP-00337311).
[12] NJDEP-SED3 and NJDEP-SED4 were collected from two storm drains bordering Facility on Passaic Avenue (PAP-00337311).

Farm. 595 mg/kg lead was detected in Tank Farm soil sample No. TF-17, collected at 2.0 – 2.5 feet bgs (PAP-00056192).

- AOC 6 – Floor Drains, Trenches, and Piping, 2,220 mg/kg lead was noted in soil sample No. WL-01 collected on October 30, 2014, between 1.8 and 2.3 feet bgs in from within the trench system located in the foundation of the former Production Plant (PAP-00056212).

- Historical data contained in the 2016 PARS RIR showed that 3,100 mg/kg lead was found in March 2002 in soil sample No. SB2/B collected between 3.3 and 3.9 feet bgs a little north of the central gate (PAP-00056300).

As referenced in the 2016 PARS RIR, remaining structures at the site were demolished in April 2014. Prior to the demolition, PARS collected in-situ concrete and concrete block samples as per the NJDEP Guidance for Characterization of Concrete and Clean Material Certification for Recycling (PAP-00056148). The following concrete chip samples had concentrations of lead above the New Jersey RDCSRS of 400 mg/kg:

- 1,750 mg/kg lead was found in a concrete chip collected near the exit door from the Production Plant walls in sample No. C-21 C collected on March 14, 2014 (PAP-00056258).

- 623 mg/kg of lead was detected in the concrete chip sample collected from the Q/C lab Production Plant wall (PAP-00056256).

- 493 mg/kg of lead was detected in the concrete chip sample collected from the process area Production Plant concrete support (PAP-00056258).

Mercury

According to the 1984 Hart PSA, the sampling results from the four samples collected on June 27, 1984 showed the mercury concentrations for Sample Tank SA at 7,100 ug/kg and Sample Tank SB at 200 ug/kg. The other two results were detected below the method detection limit (MDL) (PAP-00057074, 76)[13]. The depth of the soil samples was not provided in the available file materials. See the 1984 sample location map provided above in the Copper section.

According to the 1987 RECON SAP Results, Recon Systems, Inc. collected soil samples from 33 borings as part of the ECRA-required sampling. The following table shows location, depth and results for mercury. See the 1987 sample location map for locations provided above in the Copper section.

[13] The referenced sample results were originally taken as part of the 1984 Hart PSA. The 1984 Hart PSA is only available as an appendix to the 1986 Franklin Plastics SES. The 1986 Franklin Plastics SES does not include the lab data from the 1984 samples, so there is no way to verify the reported data is correct and/or to check whether there were any accidental transcription errors.

(PAP-00337252-64; PAP-00056285-94; PAP-00056300-21)

On June 5, 1990, samples collected by NUS Corporation identified the following highest mercury concentrations:

- 0.44 mg/kg in sediment sample NJEP-SED3, collected from an off-site storm drain located southeast of the Facility.

- 0.25 mg/kg estimated in soil sample NJEP-S-3, collected in Drum Area No. 3 at a depth of 0 to 6 inches (PAP-00337306, 311, 332-33)

The following table shows the mercury results of the remaining samples collected by NUS in June 1990.

NUS Corporation, June 1990, Mercury Data			
Sample ID:	**Matrix:**	**Mercury Result:**	**Units:**
NJEP-SW1	Surface Water	Not Detected[15]	µg/L
NJEP-SW2	Surface Water	Not Detected	µg/L
NJEP-SW3	Surface Water	Not Detected	µg/L
NJEP-SED1	Sediment	0.31	mg/kg
NJEP-SED2	Sediment	0.25 E	mg/kg
NJEP-SED4[16]	Sediment	0.33	mg/kg
NJEP-S1	Soil	0.17	mg/kg
NJEP-S2	Soil	0.16	mg/kg
NJEP-S4	Soil	0.1	mg/kg
NJEP-S5	Soil	0.2	mg/kg
NJEP-S6	Soil	0.12	mg/kg
NJEP-S7	Soil	Not Detected	mg/kg
NJEP-S8	Soil	0.16	mg/kg
NJEP-S9	Soil	0.11	mg/kg

E = estimated value
(PAP-00337311; PAP-00337332-33)

[15] According to the Notes of Table 4 of the 1990 EPA SI, a blank space indicated that the compound was analyzed for but not detected (PAP-00337332).
[16] NJDEP-SED4 was collected from a storm drain bordering the Facility on Passaic Avenue (PAP-00337311).

Historic Fill

The Allocation Team has determined that the facility site is located on regional Historic Fill as designated by the NJDEP.[17]

NJDEP has established that historic fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 COCs: PAHs, lead, copper, and mercury.[18] Accordingly, NJDEP technical requirements for property containing Historic Fill requires sampling for the EPA Target Compound List for PAHs and Target Analyte List for metals, including lead, copper, mercury, and the OU2 PAH COCs.[19] PAHs, lead, copper, and mercury are recognized by NJDEP to be constituents of Historic Fill at varying levels, not atypically at or exceeding residential soil standards.[20]

The levels of PAHs, copper, lead and mercury detected at the site in soils are presented in the table below (PAP-00056223-24).

COCs Found in Onsite Soils	
COC	**Max Detected Concentration**
Lead	879 mg/kg
Mercury	168 mg/kg
Benzo(a)anthracene	8.8 mg/kg
Benzo(a)pyrene	9.1 mg/kg
Benzo(b)fluoranthene	5.3 mg/kg
Benzo(k)fluoranthene	6.2 mg/kg
Dibenzo(a,h)anthracene	2.8 mg/kg
Indeno(1,2,3-cd)pyrene	1.0 mg/kg

The Sampling and Analysis Plan Results Report - ECRA Case No. 86206 prepared by RECON Systems, Inc. dated October 1, 1987 (1987 RECON SAP Results) reported that the site is on the former flood plain of the Passaic River which forms the western property boundary. Substantial filling with urban refuse (excluding household waste) has taken place over the years. A substantial amount of urban fill has been placed in

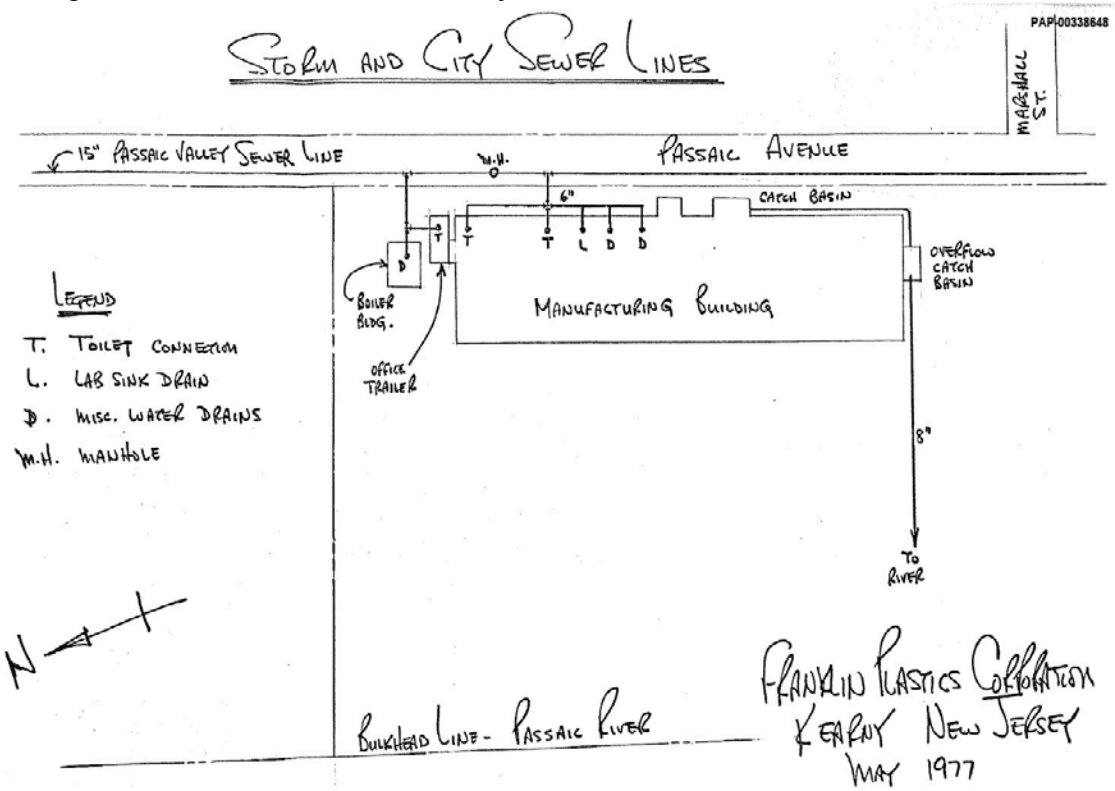
[17] *Digital Geodata Series, DGS04-7, Historic Fill for New Jersey*, https://www.nj.gov/dep/njgs/geodata/dgs04-7.htm, Quadrangle #52 & #53 (NJDEP map identifying locations of recognized historic fill).
[18] *Characterization of Ambient Levels of Selected Metals and cPAHs In New Jersey Soils* (2002) and *Characterization of Ambient Levels of Selected Metals and Other Analytes In New Jersey Soils* (1997), studies prepared for NJDEP, Division of Science and Research, by BEM Systems, Inc.
[19] New Jersey Department of Environmental Protection (NJDEP), *N.J.A.C. 7:26E Technical Requirements for Site Remediation,* Table 4-2, November 2009 [Note that Table 4-2 has been deleted from the current version of N.J.A.C. 7:26E (May 7, 2012) and the updated *Historic Fill Technical Guidance* (April 2013) as NJDEP believed that the tables list of historic fill constituents was too restrictive].
[20] NJDEP Table 4-2 (PAHs and lead) and a summary of NJDEP records regarding investigations of properties in the vicinity of the Passaic River recognized to be located in areas of Historic Fill indicate that the following average/maximum (mg/kg) contamination levels of OU2 COCs exist in area Historic Fill: PAHs (1.91/160), lead (574/10,000), copper (11.2/1,200), and mercury (0.21/3.7).

increasing depths as the Property gradually slopes westward toward the river (PAP-00337408).

According to the 2010 ISRA *Preliminary Assessment Report* (2010 ISRA PAR) prepared by Arcadis, the entire site contained nonindigenous fill material that was used to raise the elevation of the site. The material covered approximately 85% of the site and ranged in depth from between 5 and 7 feet deposited upon tidal marsh sediments. The western portion of the site along the Passaic River contained the most fill. A review of aerial photographs showed that the first stage of fill occurred between 1933 and 1946. The second stage occurred between 1953 and 1966. The fill was comprised of silty sand, course sand, cinders, gravel, brick fragments, rocks, wood pieces, glass, ceramics and scrap metal. Even with the fill events, the site was still subject to periodic flooding from the Passaic River (PAP-00054694).

According to a 1929 map prepared for Congoleum Nairn, Inc. depicting the land owned by Nairn Linoleum Co., bulkheading and fill operations on the Property began prior to 1929, when the Property was owned by "Watts Kearny" (PAP-00724491).

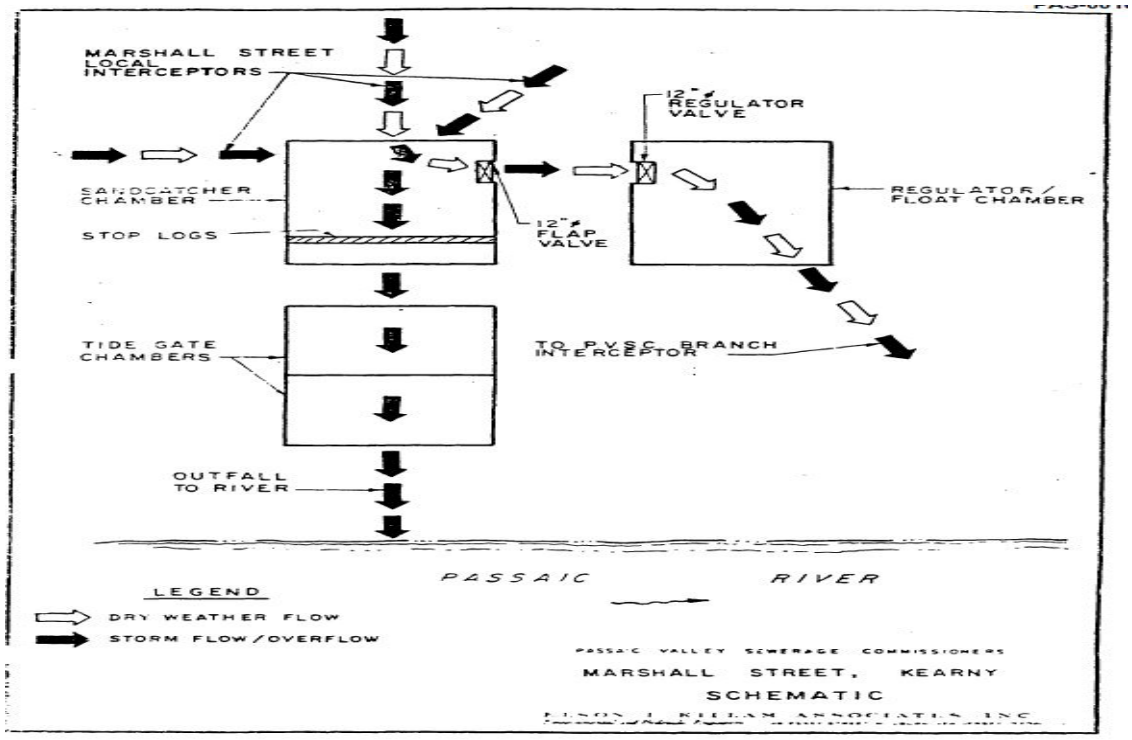
The 2016 PARS RIR confirmed the entire site was underlain by fill material (PAP-00056120). The 2016 PARS RIR subsurface investigation alleged that five to seven feet of fill material appeared to have been placed prior to development in 1946 PARS stated that additional fill material was placed along the riverbank circa 1966 (PAP-00056120). According to the 2016 PARS RIR, contaminants associated with Historic Fill included petroleum hydrocarbons, semi volatile organic compounds and metals that exceeded the RDCSRS. In the 2016 PARS RIR, PARS concluded that all contamination with the exception of extractable petroleum hydrocarbons (EPH) in the tank farm area, PCBs in the former transformer substation area, bis (2-ethylhexyl)phthalate (DEHP) and butyl benzyl phthalate (BBP) were related to Historic Fill (PAP-00056137). PARS Environmental, Inc. documented in the 2016 PARS RIR that remedial action was required to address Historic Fill. They recommended engineering controls for the entire site to cap soil impacts exceeding the RDCSRS and a deed notice (PAP-00056143).



According to the 2017 PARS RAR, Historic Fill covers the majority of 113 Passaic Avenue and extends offsite to the north and south (PAP-00056563).

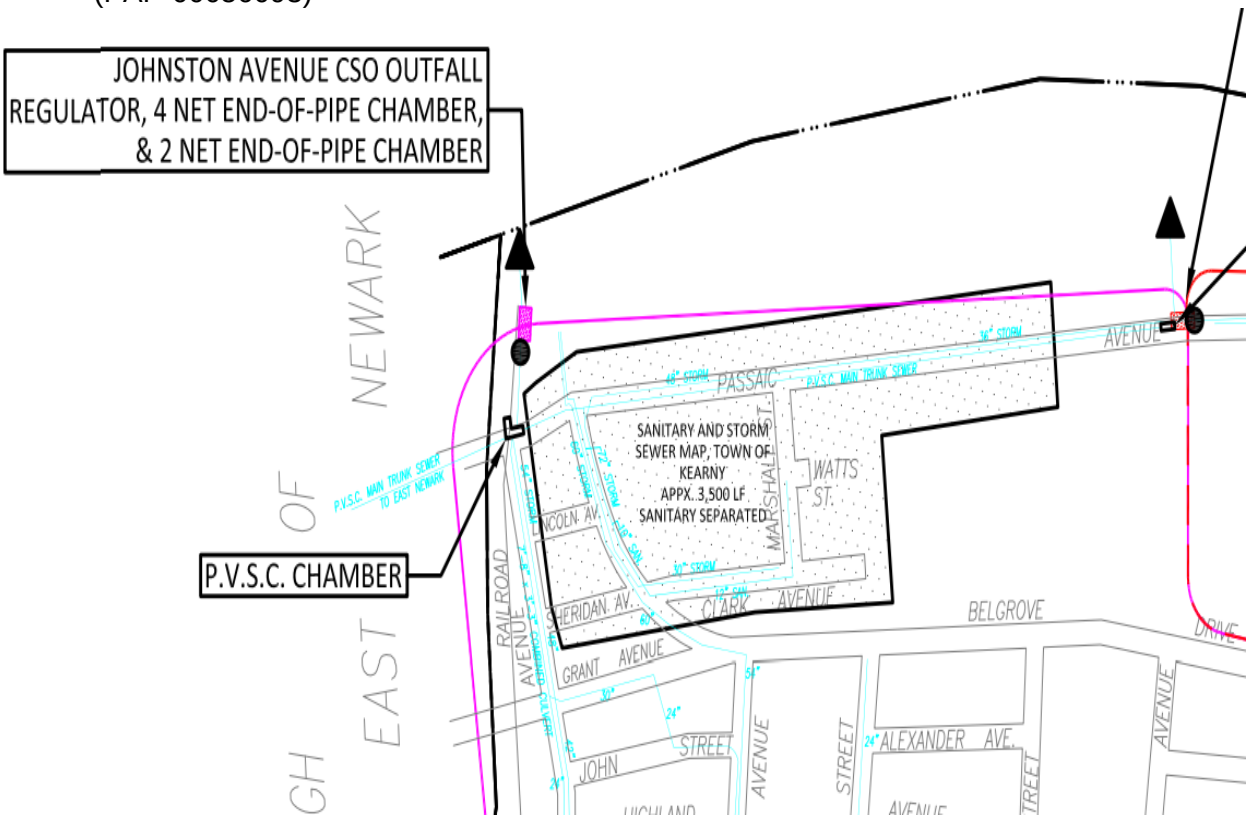
5. COC Pathways

Sanitary and Combined Sewer



According to the 2016 PARS RIR, the Production Plant was connected to the municipal sanitary sewer system since its construction by the prior owner, Congoleum, in 1946 (PAP-00054650). The Facility was connected to the PVSC for the entire period of Franklin-Burlington Plastics' operations from 1976 to 2010. Sanitary waste and water from the laboratory, boiler blowdown, and floor drains in the boiler house and laboratory area were discharged to the sanitary sewer system at all times during Franklin-Burlington's operation of the Facility through two connections to a collection main along Passaic Avenue (PAP-00056128; PAP-00338648). One connection was for the boiler house. This connection carried boiler blowdown and water from a floor drain in the boiler

house. The other connection directed sanitary wastewater, water from the laboratory, and floor drains in the lavatory and laboratory areas to the PVSC (PAP-00338648). Contact and non-contact cooling water from the Facility was discharged to the PVSC from 2004 to 2010 (PAP-00057271). All buildings were razed in April 2014 (PAP-00056121). No discharges to PVSC occurred thereafter. See the 1977 drawing below showing the location of the storm and city sewer lines.



(PAP-00338648)

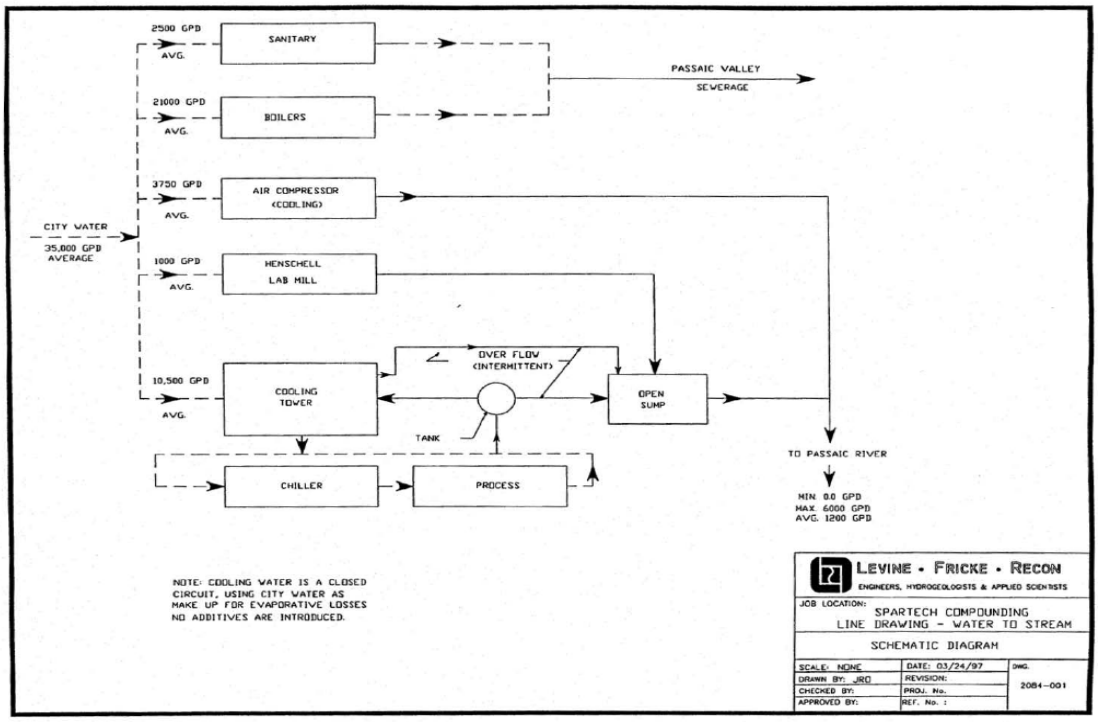
Flows in the Main Interceptor (Main Trunk Sewer) did not enter the Regulator. The Regulator's function was to divert flow into the Branch Interceptor. If the flow to the Regulator exceeded the capacity of the Regulator, the excess flow was diverted to the River as a combined sewer overflow (CSO). See Overflow Analysis Diagram below.

(PAP-00056093)

(PAP-00402441)

According to the 2014 Neglia Engineering CSO Map of Kearny above, the Marshall Street Regulator was located downstream (south) of Franklin's direct connections to the PVSC Main Interceptor. The Local Branch Interceptors connected to the Marshall Street Regulator were all on the east side of Passaic Avenue. The Franklin facility was on the west side and connected directly to the PVSC Main Interceptor (referenced as the PVSC Main Truck Sewer) through two direct connections. The flow from the Franklin facility entered the Main Interceptor pipe before the flow from the Marshall Street Regulator entered the PVSC Main Interceptor pipe (PAP-00402441).

The Marshall Street pump station was "sewer separated" sometime between May 27, 2005, where it was referenced in a Compliance Evaluation Report, and January 2014, where the sewer map prepared by Neglia Engineering Associates shows that wastewater from the Marshall Street collection area combined with and was transported to the Johnston Avenue pump station (PAP-00402441; PAP-00402441). After separation, the Marshall Street outfall is no longer a CSO.



The Johnston Avenue CSO is located approximately 920 feet downstream from the Marshall Street Regulator and similarly collected combined wastewater and stormwater from Branch Interceptors and directed it into the PVSC Main Interceptor. The flow from the FBP Facility was already in the PVSC Main Interceptor at the point at which the flow diverted by the Johnston Avenue Regulator entered the PVSC Main Truck Sewer pipe (PAP-00402441).

Direct Release

Between 1976 and 2004, Franklin discharged water to the Passaic River via a NJPDES permit. The discharge water included both non-contact cooling water and contact cooling water from cooling baths (PAS-00048607). Non-contact cooling water was for a lab mill, air compressor cooling, and cooling tower overflow (PAP-00057133; PAP-00057203). According to the 2016 PARS RIR, the production plant at 113 Passaic contained floor drains and trenches that connected to two sumps (PAP-00056128). As discussed in more detail in the "Sumps" section above, Sump 2 flowed through the 8-inch diameter outfall pipe into the Passaic River via NJPDES Permit No. NJ002194 (PAP-00056126).

The 1990 EPA SI stated that overflow from the cooling tower, cooling water from the mixer jacket and roller mills, and drainage from indoor trenches was collected in the concrete-lined open sump pit along the south wall of the Production Plant (PAP-00337323).

See the following 1997 Schematic showing the flow of the water through the facility and to the Passaic River or Passaic Valley Sewerage.

(PAP-00057219)

According to the 2016 PARS RIR, in 2013 Production Plant trenches were cleaned and inspected by Arcadis. Significant cracks and deterioration were noted in the main trench in the central part of the Production Plant (PAP-00056128). PARS conducted an additional investigation of the drains and trenches in the Production Plant and found no OU2 COCs attributable to the former production activities at the site in the soil beneath the drains and trenches (PAP-00056128, 40).

On February 27, 2004, Spartech Polycom requested authorization for the discharge of non-contact and contact cooling waters to the sewerage collection systems serviced by PVSC. The proposed discharge consisted of an approximate maximum discharge of 11,000 gallons per day of non-contact cooling tower blowdown. The remainder of the Facility's discharge consisted of periodic discharges of approximately 2,000 gallons per week of pellet cooling water (PAP-00338803).

On September 16, 2004, Spartech Polycom sent a letter to NJDEP Division of Water Quality, Bureau of Point Source Management stating the facility had implemented wastewater re-use and conservation measures. The closed loop chiller was installed to replace the existing cooling tower thereby eliminating the facilities non-contact cooling water discharge to the Passaic River. The remaining small quantity of contact cooling water was discharged to the sanitary sewer as approved by PVSC. The discharge pipe utilized for the discharge of wastewaters to the Passaic River (under NJ0002194) was removed prior to June 1, 2004, from the river bank and the remaining underground portion capped securely at both ends (PAP-00338060).

On March 13, 2008, PVSC granted permission to discharge 100 gallons per day of mineralized cooling water blowdown that must be in compliance with all PVSC Rules and Regulations. The letter also notes that the Facility was authorized to discharge 2,000 gallons per week of contact pellet cooling water to the PVSC (PAP-00338804).

Flooding and Surface Water Runoff

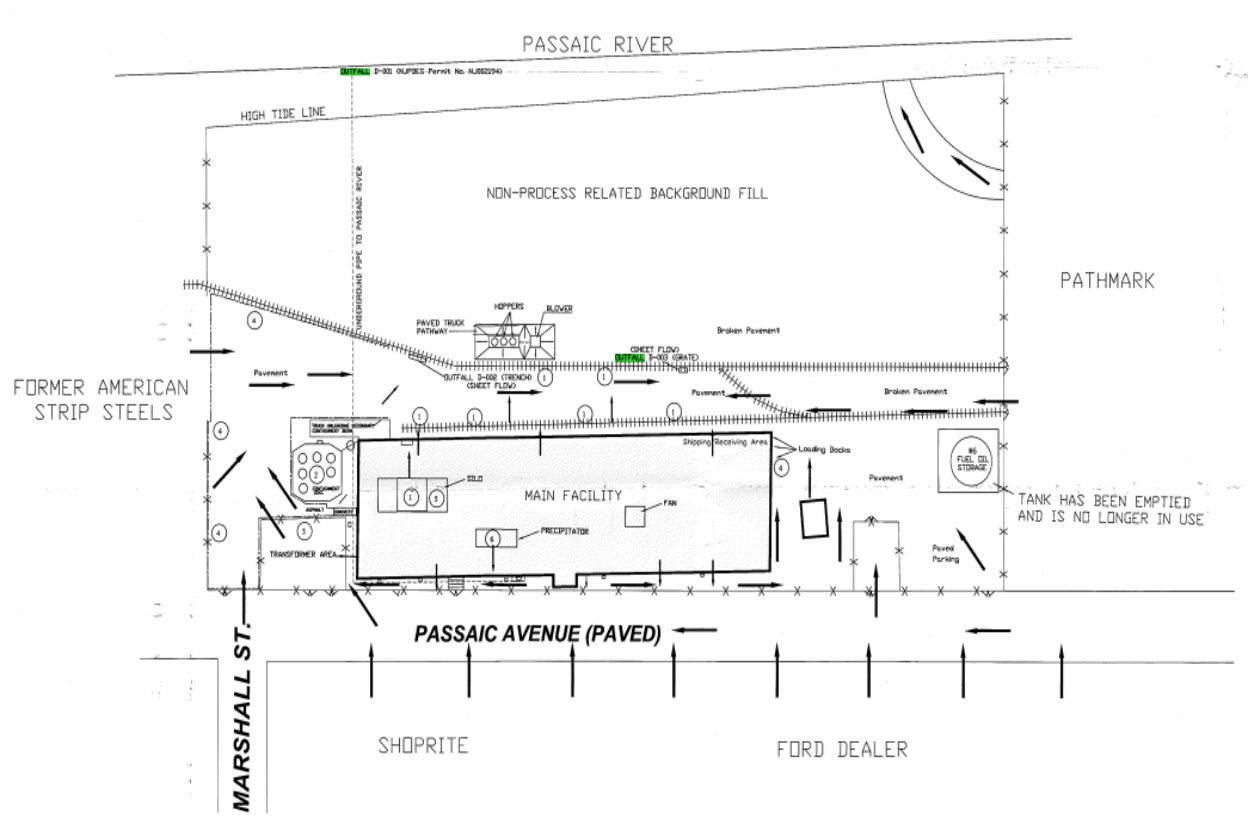
Surface Water Runoff

A 1980 EPA *Potential Hazardous Waste Site Identification and Preliminary Assessment* form identified an open dump, landfill, drums, aboveground tanks, a railroad, and other major site activities. Overturned drums potentially contaminating the soil were noted onsite, as well as "many" 55-gallon drums that were leaking and overflowing.[21] The EPA staff member who prepared the form identified the apparent seriousness of the problems at the site as "low" (PAP-00337386-89).

As reported in the 1990 EPA SI, an onsite reconnaissance performed by NUS Corporation in April 1990 "noted a condenser blowdown drainage pathway between the southwest edge of the manufacturing building and the tank farm (PAP-00337303). The NUS Corporation also observed soil runoff from a stained soil area east of the Production Plant into two storm drains on Passaic Avenue (PAP-00337320-21). However, the Topographic Survey prepared by Dennis W. Sklar, Inc dated October 6, 2014 (the 2014 Topographic Survey) shows that these storm drains are topographically upgradient of the Facility (PAP-00056268).

The 2017 PARS RAR stated that storm water runoff from impermeable surfaces on the eastern portion of the Site flowed west toward the Passaic River. There were a few low lying areas on the central portion of the site where storm water may have accumulated. A drainage feature near the northwest corner of the Site (on Lot 12.01) collected storm water from paved areas at the site and from offsite run-on and drained into the Passaic River (PAP-00056563).

The 2009 SPCC/DPCC/DCR Plan states that stormwater runoff from the relatively flat site collected in a slight but broad general depression or basin on the West side of the property. Any spill would be contained in this basin and would not reach the Passaic River, which is adjacent to the Property. In addition, a vegetative buffer between this basin and the Passaic River served as a spill containment barrier between potential spill areas and the Passaic River (PAP-00055750).



The 2009 SPCC/DPCC/DCR Plan also states that there were no storm sewers located on the Property (PAP-00055750). The Individual NJPDES Stormwater Discharge Permit issued by NJDEP on June 20, 2006 (the 2006 Individual Stormwater Permit) confirms that there were no storm drains, stormwater conveyance systems, or stormwater outfalls at the site. NJDEP further stated in the 2006 Individual Stormwater Permit that most of the Facility's stormwater was discharged to ground water (PAP-00056937). This is

[21] The Potential Hazardous Waste Site Identification and Preliminary Assessment form specifically notes that "The information submitted on this form is based on available records and may be updated on subsequent forms as a result of additional inquiries and on-site inspections" (PAP-00337386).

consistent with the 2014 Topographic Survey which shows there were no major flow channels or ditches to direct stormwater across the 113 Passaic Avenue (PAP-00056268).

According to the *Amended Stormwater Pollution Prevention Plan* prepared by LFR dated October 10, 2002 (2002 Amended SPPP), stormwater flows entered the Franklin Burlington Plastics site from the neighboring properties. The 2002 Amended SPPP found that, based on conservative calculations, greater than three acres of the surrounding properties are located upgradient of the Facility. This drainage area corresponds to hundreds of thousands of gallons of stormwater for each inch of rainfall. A percentage of this drainage does enter the site during large rainfall events. The offsite drainage area that affect the Facility include two supermarket parking lots, an auto dealership, city streets, and abandoned manufacturing sites. Numerous contaminants originating from these offsite sources have the potential to negatively impact the site's stormwater quality (PAP-00056780). The significant water flow from the neighboring areas can be seen in the photos of the site taken during August of 2003 (PAP-00338070-78).

NJDEP stated in the 2006 Individual Stormwater Permit that the site is located on a low point of Passaic Ave., and "a large portion of offsite contaminated stormwater enters the property during periods of heavy rainfall." NJDEP further concluded that the Facility had no control over the event of receiving contaminated stormwater and that there was no reasonably available remedy (PAP-00056937). See the 2003 Surface Water Flow diagram below (PAP-00338638).

Site Flooding

According to the 1990 EPA SI, a portion of the property is occasionally flooded by high tides from the Passaic River. The Passaic River is located approximately 400 feet west of Franklin's Production Plant and forms the western border of the site (PAP-00337317). According to the 2016 PARS RIR, the site is periodically flooded by the Passaic River. Potentially contaminated sediments from the Passaic River are deposited onto the site during these flood events (PAP-00056133).

Spills

An August 1, 1984 Investigative Report for Franklin Plastics Corporation noted an oil-like substance that heavily contaminated the southwestern corner inside of the Production Plant. Two spills being cleaned by the workers were noted on the ground during the inspection in an area where a liquid plasticizer was discharged from tank trailers into pipes for storage (PAP-00338659).

The Sampling Analysis Plan (SAP) submitted as an appendix to the 1986 Initial Notice SES, focused on possible areas of spillage of the following:

- Phenols associated with asphalt storage in the tank farm at the souths side of the Facility during Congoleum Corporation ownership/operation of the Facility,
- Phthalates associated with unloading, storage, and processing of plasticizer compounds at transfer lines, around the dust collector system blower, and around the two storage tanks used for plasticizer storage,
- Heavy metal bearing pigments on and around process equipment within the Production Plant and the dust collector system blower,
- Transformer fluids associated with the transformer substation on the south side of the property,
- Petroleum hydrocarbons associated with oil lubricated compressor discharges throughout the Facility, and
- Gasoline from the underground storage tank or related plumbing system (PAP-00057055).

A NUS Corp. Region 2 FIT on-site reconnaissance of April 30, 1990 observed a stained soil area east of the manufacturing building (PAS-00063677). Surface soil samples were collected by NUS Corp. Region 2 FIT on June 5, 1990 from the stained soil area, from a run-off pathway outside the fence, and from two storm drains on Passaic Ave. The samples results were for constituents not related to this allocation (PAS-00063677).

6. Regulatory History/Enforcement Actions

Inspections

On January 7, 1980 NJDEP conducted a site visit for the Franklin Plastics facility. As a follow-up, EPA performed a Preliminary Assessment of Franklin Plastics on June 16, 1980. (PAP-00338653-56). Some overturned drums were identified as a potential hazard to the soil onsite, and "many" 55-gallon drums, both waiting for removal and stored for use, that were leaking and overflowing were identified as a potential hazard (PAP-00338653). On August 6, 1980, a Tentative Disposition, completed by the same government official who performed the Preliminary Assessment, determined that no further action was needed by EPA and recommended that there was no hazard (PAP-00338657).

According to the *Site Inspection Prioritization Evaluation*, dated September 29, 1995, in June 1984 a Preliminary Site Assessment (the 1984 PSA) was conducted by Hart Associates. As part of the 1984 PSA, Hart associates collected four soil samples. Sampling results showed plasticizers (phthalates), copper, lead, and mercury, along with other priority pollutant metals. The quality assurance/quality control (QA/QC) used for these samples was unknown (PAP-00054202).

On July 23, 1984, according to a memorandum dated August 16, 1984, the Bureau of Industrial Site Evaluation conducted a Preliminary ECRA Inspection and found that a waste paper basket fire in an office that occurred prior to the inspection had left "quite a few hundred gallons of water in the plant area." There were numerous violations that included spillage, discolored soils, oil saturated soils, improperly labeled drums, unmarked drums, disposal of drums, and other storage of material concerns. The inspector found thirty-three (33) 55-gallon drums in the parking lot that the plant manager, Joseph Ronzo stated was "rain water". Upon puncturing one of the drums, brownish, green liquid ran onto the ground and Joseph Ronzo stated "See, its"rainwater. Hundreds of unmarked sample bottles were noted in the Quality Assurance/Control Product Laboratory and were not mentioned in ECRA SES. The company was instructed to include documentation of wastes stored and disposed of from the Laboratory (PAP-00337237).

On August 1, 1984, the Division of Waste Management, Bureau of Field Operations conducted an inspection of the Facility for the purpose of checking on company storage practice of chemicals as stated in incident report No. 84-07-24-0lN. The following observations were made:

- On the area east of a boiler room there were four drums of No. 2 fuel oil and four drums of kerosene palletized and sitting on the ground. The inspector was informed by the Plant Manager that those drums would be transferred into the building (the Production Plant).

- On the yard by the south-western corner of the Production Plant, there was a large area of about 150-200 sq. yards, heavily contaminated with an oil-like substance. The area where the oil-like substance was observed corresponds to

the area where a liquid plasticizer was discharged from the tank trailers into the pipes for storage. The spill occurred when hoses were connected and some oils dripped from the tractors onto the asphalt paved surface.

- On the eastern side of the Production Plant and on the electric transformers area it was observed that the ground was heavily contaminated with and oil-like substance. The Franklin Plastics representative stated that the spots of contaminated ground by the Production Plant wall came from the steam releasing pipes, but there was no explanation regarding the transformer area.

- Some 40-50 steel, 35-gallon empty blue drums were noted to be stored on the southern area of the facility. The drums were palletized, stacked three high. The inspector was informed by the Plant Manager that the empty drums would be removed as soon as a scrap metal dealer willing to take them was located.

It was recommended that Franklin Plastics clean up all contaminated areas and to dispose of the clean out material properly (PAP-00338658-59).

According to the August 16, 1984 Preliminary ECRA Inspection memo, the Spill Prevention, Containment and Control (SPCC) Plan was never implemented and additionally, two gasoline underground storage tanks were not mentioned in the ECRA SES (PAP-00337238). Also reported was a large transformer substation containing PCB dielectric oil located at the Facility. The substation was located on an earthen surface, and no berms were present around the substation (PAP-00337238).

On December 20, 1984, a follow-up inspection of Franklin Plastics facility was conducted. The inspector found the premises clean and in good order except for minor spills of a white powder along the railroad tracks and minor spills of oil in the truck unloading area. The Franklin Plastics representative identified the white powder as resin used in the manufacturing process. The Franklin Plastics representative stated that the types of spills observed occur during working hours and are cleaned up each working day. The transformer area was observed to be free of any leaks or spillages and appeared to have new crushed stone in the area. The empty 35-gallon drums observed during the inspection on August 1, 1984 were gone and records showed that they were disposed properly. The inspector observed some oily spills on the eastern side of the Production Plant caused by the releasing of steam, and recommended cleaning those areas within the completion time. The Plant Manager agreed to start cleaning that spill the same day. There was a field Notice of Violation filed due to oily spills on the eastern side of the Production Plant. The inspector noted that there was a possibility of ground water contamination but since it was not determined, no recommendation were made on this matter (PAP-00338661). The inspector also noted that the operations and housekeeping appeared to be usual for this type of industry (PAP-00338662).

On January 5, 1985, Franklin Plastics informed the NJDEP that they had removed and disposed of the 25-45 pounds of material from the contaminated area on the eastern side of the Production Plant (PAP-00337303).

On July 22, 1986, NJDEP Bureau of Industrial Site Evaluation conducted a Preliminary Inspection under ECRA Case No. 86026. The inspector noted two deficiencies. First, there were two 20,000-gallon fuel oil tanks located outside the production area within a containment wall. The ground inside the wall was visibly contaminated with oil. Second, there was a wash sink south of the Production Plant which discharged to the ground. The inspector recommended that Franklin remove the contaminated soil and take measures to prevent subsurface contamination. The inspector also instructed that Franklin should cease the discharge to the ground from the wash sink (PAP-00057224).

An EPA contractor's on-site reconnaissance in April 1990, as part of the 1990 EPA SI, discovered three areas of abandoned drums along the Passaic River. The drums were in poor condition and some drums were partially buried. The contents of the drums appeared to be crumbled pieces of tile. Solidified sludge from the vinyl tile manufacturing process was also observed on the Property. According to the report, the former operator of the property, Congoleum Corporation/Floor Covering Division, manufactured asphalt and/or vinyl tile on site from approximately 1946 to 1974 (PAP-00337307; PAP-00054201-02). Based on the available file materials, there is no evidence that Franklin Burlington manufactured tile at any point during its operation from 1976 to 2010.

The site was also subject to periodic permit Compliance Evaluation and Assistance Inspections by the NJDEP. The NJDEP inspector noted no major deficiencies and found the Facility to be in compliance with requirements of the Facility's NJPDES permits based on the inspections and analysis of wastewater on multiple occasions, such as the inspections conducted on March 12, 1980 (PAP-00057289-90), March 29, 1982 (PAP-00057293-94), April 16, 1996 (PAP-00057311-12), and March 4, 2009 (PAP-00057405), among others. While some inspections reported that the Facility was not in compliance with one of the terms of its permits, none of the incidents of non-compliance related in any way to the storage, handling, or discharge of an OU2 COC (PAP-00057306; PAP-00057315; PAP-00057342; PAP-00057351-57).

NJDEP also inspected the Facility annually pursuant to the Discharge Prevention, Containment and Countermeasures and Discharge Cleanup and Removal Plans annual audit requirement. The available records for five of the inspections show that there were no violations found, and the Facility was in compliance when inspected on November 27, 2001 (PAP-00055147), November 21, 2002 (PAP-00055148), August 12, 2004 (PAP-00055297) and July 12, 2007 (PAP-00055348), and the Facility was substantively in compliance when inspected on November 30, 2000 (PAP-00055146).

Violations

According to the 1990 EPA SI, at an unknown date Franklin Plastics received a Notice of Violation for oily spills along the eastern wall of the Production Plant (PAP-00337303).

According to a NJDEP letter dated September 27, 1985, the NJDEP Division of Water Resources, inspected the facility in July 1985 and gave it an "unacceptable" rating due to permit limit exceedances of temperature, chromium, and zinc concentrations. The letter mandated that Franklin Plastics Corporation submit a written report detailing remedial

measures and an implementation timetable (PAP-00057085-89;). According to a letter from Franklin Plastics to NJDEP, dated October 22, 1985, after conversations with NJDEP about the exceedances, Franklin Plastics resampled the water and all constituents were below the levels required by the permit (PAP-00057090).

NJDEP sent a letter to Franklin Plastics Corporation in June 1998 notifying them that they had not received a response pertaining to a Declaration of Environmental Restrictions and a proposed Groundwater Classification Exception Area for the site. Franklin Plastics was notified that the company was currently in violation of ISRA and NJDEP, and was therefore permitted to draw upon the posted financial assurance to proceed with the appropriate compliance and enforcement actions, if it so chose. The ISRA Case number was No. E86026 (PAS-00105243-44).

The site was placed on the Known Comprehensive Site List, a listing of all contaminated sites in New Jersey. NJDEP additionally rescinded approval of the Remedial Action Workplan, dated August 22, 1990, because aerial photographs from 1940 to 1991 showed that all potential areas of environmental concern were not identified during the investigation phase. Areas of concern not identified included storage areas (possible drum and other vessels) throughout the site, and spills/discharges or unknown materials. These areas were not investigated during the Site Investigation/Remedial Investigation, nor were they addressed in the Remedial Action Workplan (PAS-00105243-44).

NJDEP also noted that an EPA evaluation report, dated September 20, 1995, and NJDEP files state that Franklin Plastics site operations contributed to the metals in soil at the site. A sediment sample collected from the open sump at the southern side of the manufacturing building exhibited significant concentrations of metals. According to the NJDEP, these metals could only have been generated from within the plant since the sump collects process water generated only from within the plant. The sump reportedly is cleaned out annually by Franklin Plastics. The metals detected in the sump sediment are generally the same metals contained within pigments reportedly used by Franklin Plastics. These metals are also generally the same metals as those found in the fill onsite (PAS-00105244).

In order for Franklin Plastics to be in compliance with ISRA according to NJDEP, they were to: 1) make a distinction between metals in fill due to site operations and metals in contaminated Historic Fill, 2) identify all potential areas of concern based on the aerial photographs and EPA SI and evaluate the remediation conducted at the site, 3) submit a Remedial Action Workplan that:

- identifies all potential and known areas of concern;
- evaluate previous remediation;
- evaluate the source of priority pollutant metals onsite;
- conduct a baseline ecological evaluation; and,
- Conduct a draft Declaration of Environmental Restrictions and Classification Exception Area (PAS-00105244-45).

In response to the June 3, 1998 letter, Franklin Plastics submitted a Remedial Investigation Report dated February 5, 1999 (1999 RIR) (PAP-00054673). In a letter dated February 8, 2000, NJDEP stated that it had rescinded Franklin Plastics Corporation's Remedial Action Workplan, dated August 22, 1990, and referred the case to the Bureau of Federal Case Management for enforcement actions due to Franklin Plastics Corporation's lack of response to outstanding NJDEP administrative requirements. In the same letter, the NJDEP indicated what Franklin Plastics would need to do to come into compliance and provided associated comments on the 1999 RIR (PAP-00054673-85). All of NJDEP's comments were responded to and ultimately resolved by the submission of subsequent ISRA/ECRA filings, culminating in the submission of the 2016 PARS RIR (PAP-00056115-466).

Permits

NJPDES NJ0002194 - Discharge to Surface Water Permit:

Permit Start Date: 04/24/1976 (PAP-00057096)
Expiration Date: 09/30/2004 (PAP-00057276)

Permit No. NJ0002194 did not contain any numerical effluent limitations involving OU2 COCs nor did it require monitoring for any OU2 COCs (PAP-00057123; PAP-00057169; PAP-00057178; PAP-00057234).

Permit No. NJ0002194 was renewed with the effective of August 1, 1979 and an expiration date of July 31, 1984 (PAP-00057122).

According to the Application for Renewal of NJPDES NJ0002194, dated July 31, 1984, the operations that contributed to the discharge were overflow from cooling tower; discharge from cooling system of Henschel Blender in lab; and overflow from central collection tank, which would have an average maximum flow of 250 gallons per minute (PAP-00337952).

In June 1985, Franklin Plastics Corporation received a letter from NJDEP, Division of Water Resources, acknowledging that Franklin Plastics had a Final NJPDES/DSW Permit and Notice of Authorization to discharge pollutants to the Passaic River under NJPDES Permit No. NJ0002194 (PAP-00057149). The permit was issued on June 28, 1985, effective August 1, 1985 and expired on July 31, 1990 (PAP-00057150).

According to the Application for Renewal of NJPDES NJ0002194, dated November 1, 1989, the operations that contributed to the discharge were overflow from cooling tower (normally no flow); discharge from cooling system jacket laboratory Henschel Blender (occasional use, normally inoperative, 1,000 gallons per day average flow); overflow from central collection tank (normally no flow); and air compressor cooling (200 gallon per hour average flow) (PAP-00337981).

A renewal of Permit No. NJ0002194 was issued on March 13, 1992 with an effective date of May 1, 1993 and an expiration date of April 30, 1997 (PAP-00057176). According to the Application for Renewal of NJPDES NJ0002194, dated April 22, 1997,

the operations that contributed to the discharge were overflow from cooling tower (normally no flow); discharge of cooling water jacket from laboratory Henschel Blender (normally inoperative, 1,000 gallons per day average flow); overflow from central collection no-contact cooling (normally no flow); and air compressor cooling jacket (200 gallon per hour, 16 hour operation average flow) (PAP-00057203).

A renewal of Permit No. NJ0002194 was issued on November 26, 1997 with an effective date of January 1, 1998 and an expiration date of December 31, 2002 (PAP-00057225). The permit stated that the Facility discharged an average of 11,124 gallons per day of non-contact cooling water from machinery used in plastics processing and contact cooling water (approximately 450 gallons) on an intermittent basis from tanks where plastic resins have been submerged through Discharge Serial Number (DSN) 001 (PAP-00057233).

According to the Application for Renewal of NJPDES NJ0002194, dated December 30, 2002, the operations that contributed to the discharge were discharge of noncontact cooling water at an average flow rate of 11,124 gallons per day and discharge of contact cooling water at an average flow rate of 0.00015 million gallons per day (PAP-00338016). The average frequency of the flow through outfall number 0001A was reported as 2 days per week, with an average monthly volume of 4,500 gallons (PAP-00338017).

In May 2004, the permitted direct discharge pipe to the Passaic River was capped at both ends, and the cooling water flow was redirected to the PVSC collection main along Passaic Avenue. On October 21, 2004, Spartech Polycom requested that NJDEP terminate the processing of the pending permit re-application and revoke permit No. NJ0002194 (PAP-00338061). By letter dated October 29, 2004, NJDEP administratively revoked Permit No. NJ0002194, effective September 30, 2004 (PAP-00057276).

According to the 1990 EPA SI, NJPDES Permit No. NJ0002194 approved 15,000 gallons of discharge per day into the Passaic River via outfall DSN001 located at the southwest corner of the property (PAP-00337304).

NJPDES NJ0088315 Industrial Storm water General Permit:

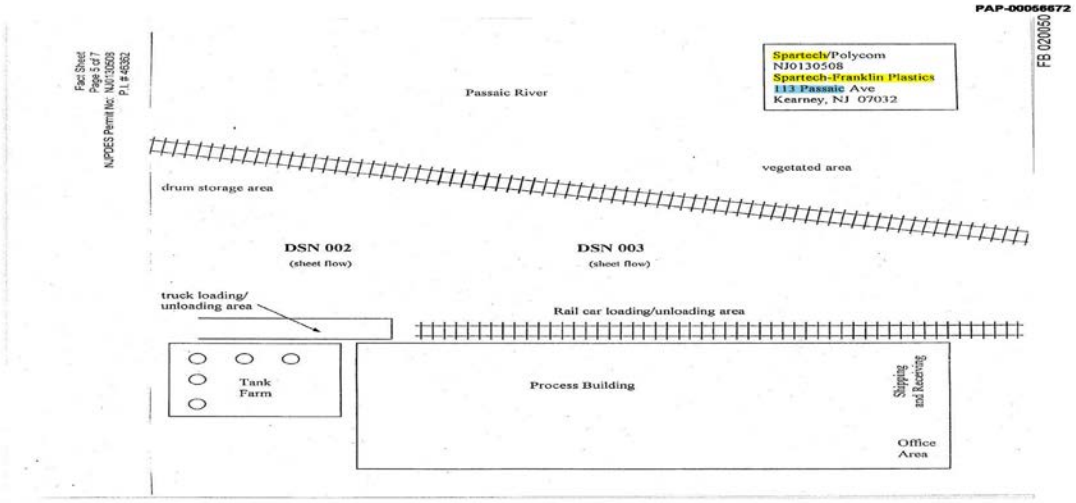
Permit Start Date: 1992 (PAP-00337719)
Expiration Date: 11/01/2002 (PAP-00056668; PAP-00056675)

Permit No. NJ0088315 did not contain numerical effluent limitations or monitoring requirements involving COCs or any other parameters (PAP-00337717-45).

On January 14, 1997, Franklin Burlington Plastics, Inc. submitted a Request for Authorization under NJPDES Industrial General Permit No. NJ0088315 to discharge stormwater from its thermoplastics compounding plant at 113 Passaic Avenue (PAP-00056623-28). On February 6, 1997, Franklin Burlington Plastics Request for Authorization, under NJPDES General Permit No. NJ0088315, was approved by the Bureau of Nonpoint Pollution Control of NJDEP. The Authorization to Discharge Stormwater to Surface Water was effective February 6, 1997 and expired on November

1, 1997 (PAP-00337715). Franklin Burlington Plastics' Authorization to Discharge under NJPDES General Permit No. NJ0088315 was approved again on May 5, 1997 with an expiration date of January 31, 2002 (PAP-00337718). The permit allowed all new and existing storm water discharges associated with industrial activity (PAP-00337724).

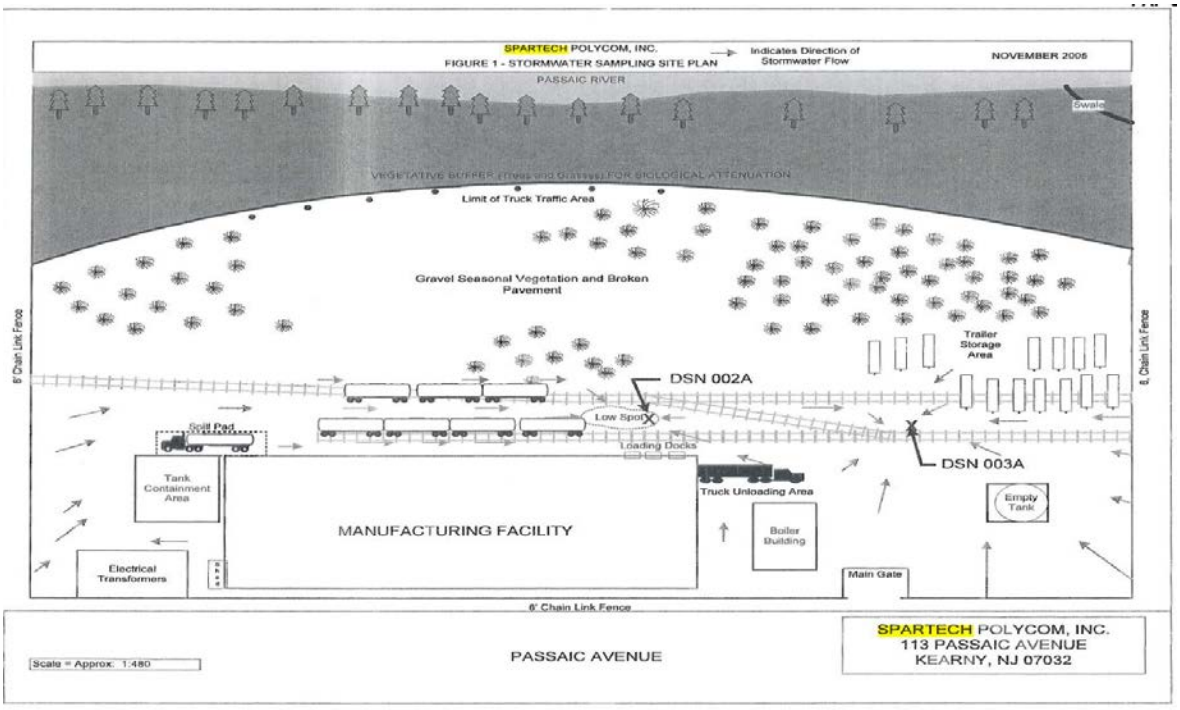
A renewal of Franklin Burlington Plastics Authorization to Discharge under General Permit No. NJ0088315 was issued on September 5, 2002, with an effective date of June 1, 2002 and an expiration date of May 31, 2007 (PAP-00056644). NJDEP revoked Franklin Burlington Plastics Authorization to Discharge under General Permit No. NJ0088315 on the effective date of NJDEP's authorization of the individual stormwater permit for the Facility (PAP-00056668).



NJPDES NJ0130508 Individual Industrial Storm Water Permit:

Permit Start Date: 11/01/2002 (PAP-00056675)
Expiration Date: 03/31/2010 (PAP-00057091)

Individual Industrial Storm Water Permit No. NJ0130508 did not contain any numerical effluent limitations involving OU2 COCs, but did require the reporting of sampling results for O&G, COD, TSS, pH, phosphorus, lead, and zinc (on a quarterly basis) and volatile organic hydrocarbons (biannually) (PAP-00056669; PAP-00056940-42; PAP-00056960; PAP-00056985). The requirement to report a numerical value for O&G was removed from the permit on June 19, 2006 (PAP-00056933). In addition, the permit required a Stormwater Pollution Prevention Plan to be implemented at the Facility (PAP-00056669).



According to the permit issued October 15, 2002, Spartech was required to monitor its storm water discharge from the following DSNs (drainage areas not served by stormwater outfalls): See the following Site Plan from the Fact Sheet of the permit issued October 15, 2002 for the locations of the DSNs.

- DSN002 between the drum storage area and the tank farm
- DSN003 at the rail car loading/unloading area (PAP-00337769)

(PAP-00056672)

At some point prior to the first Discharge Monitoring Report submission required under the permit, the monitoring locations were changed to DSN002A (drum storage area/down-gradient from the tank farm and rail car area) and DSN003A (loading and unloading area/between the loading dock and trailer storage area) (PAP-00056933, PAP-00056939). See the following November 2005 Site Plan for the locations of these DSNs.

(PAP-00337773)

Surface Water Discharge Monitoring Report forms were submitted quarterly to the NJDEP Division of Water Quality, beginning with the fourth quarter of 2002 through the fourth quarter of 2010.

Surface Water Discharge Monitoring Report for monitoring period of April 1, 2008 to June 30, 2008 stated the following:

- Effluent gross value - concentration of lead at 31.2 µg/l. The sampling location was 002A located by the tank farm/rail car (PAP-00338085).
- Effluent gross value - concentration of lead at 90.4 µg/l. The sampling location was 003A located by the loading dock (PAP-00338088)

Surface Water Discharge Monitoring Report for monitoring period of January 1, 2010 to March 31, 2010 stated the following:

- Effluent gross value - concentration of lead at 2.4 µg/l. The sampling location was 002A located by the tank farm/rail car (PAP-00338095).
- Effluent gross value - concentration of lead at 1.1 µg/l. The sampling location was 003A located by the loading dock (PAP-00338098).

Surface Water Discharge Monitoring Report for monitoring period of October 1, 2010 to December 31, 2010 stated the following:

- Effluent gross value - concentration of lead at 2.4 µg/l. The sampling location was 002A located by the tank farm/rail car (PAP-00338115).
- Effluent gross value - concentration of lead at 128.0 µg/l. The sampling location was 003A located by the loading dock (PAP-00338118).

By letter dated August 8, 2011, NJDEP confirmed that Franklin Burlington Plastics was no longer performing any activities requiring a permit under the NJPDES permitting program and administratively revoked NJPDES Permit No. NJ0130508 effective March 31, 2010 (PAP-00057091).

7. Response Actions

Characterization Activities

The following characterization activities have taken place at the facility:

- Preliminary Site Assessment dated September 1984 (PAP-00057067);
- Sampling and Analysis Plan Results Report - ECRA Case No. 86206 dated October 1, 1987 (PAP-00337251; PAP-00337406);
- USEPA Site Inspection Report prepared by NUS Corporation dated September 17, 1990 (PAP-00337300);
- Remedial Investigation Report dated June 28, 2002 (PAP-00402442);
- Remedial Investigation Report dated July 14, 2004 (PAP-00402497);
- NJDEP Site Remediation Program Preliminary Site Assessment dated December 2010 (PAP-00054628);
- Receptor Evaluation Report dated June 29, 2011 (PAP-00337542);
- Remedial Action Report, Kearny Passaic Ave Waterfront BDA, Site Investigation Report, dated August 9, 2013 (PAP-00337659);
- Remedial Investigation Report, dated March 2016 (PAP-00056115);
- Former Transformer Substation Remedial Action Report, dated June 2017 (PAP-00056559); and,
- Interim Remedial Measures (IRM) Report and Remedial Action Workplan (RAW) dated October 2017 (PAP-00055492).

According to the 1984 Hart PSA, four soil samples were collected for chemical analysis and subsurface soil samples were collected for physical inspection and OVA analysis. One surface sample consisted of a composite of several samples in a spill and vegetative stress area near the air pollution control units, and the other three samples were collected inside the tank containment area (PAP-00057068).

Composite Sample: The surface soils of the locations chosen for the composite chemical sample were described as black, compact, and largely composed of fine sandy silt with large amounts of debris such as plastics, broken bottles, metal scraps, bricks, etc. At one of the composite sample locations, C1-A, the soils were covered with a silvery material (PAP-00057070).

Tank Containment Area: This area consisted of a square concrete walled structure within which was five columnar tanks formally used (by the previous owner of the Facility, Congoleum Corporation) for asphalt storage. One or two tanks were used in the plastics manufacturing process. Around the base of the tanks, and formerly covering a majority of the containment area, were solidified asphalt flows. Surface samples and test pit locations were selected to provide as fairly even distribution as well as possible worst case conditions (PAP-00057070).
A January 10, 1986 ECRA Initial Notice General Information Submission (GIS) was submitted to NJDEP for ECRA review due to the pending sale of all issued and outstanding stock of Franklin Plastics Corporation to Spartech-Franklin Plastics (PAP-00337241).

On February 14, 1986, Franklin Plastics entered into an Administrative Consent Order (ACO) with the NJDEP since Franklin Plastics Corporation was not able to comply with all of the requirements of ECRA and the Regulations prior to date of sale. Therefore, Franklin Plastics Corporation requested that NJDEP prepare an ACO which allowed the transaction to be consummated prior to the completion of all administrative requirements. The ACO required that Franklin initiate, complete, and submit to NJDEP the results from any NJDEP-approved Sampling Plan. The ACO also provided that if a Cleanup Plan was required, the Cleanup Plan shall address remediation of any contamination identified on or from Franklin Plastics Facility (PAP-00337244-46).

On March 25, 1987 NJDEP, Bureau of Environmental Cleanup and Responsibility Assessment (BEECRA) approved the SAP and SAP Amendments submitted on March 18, 1986 and February 12, 1987, respectively (PAP-00337272).

The 1987 RECON SAP Results report - ECRA Case No. 86206 identified the following environmental areas of concern:

- Area 1 - 50,000-gallon fuel tank;
- Area 2 - 275-gallon aboveground fuel tanks;
- Area 3 - 6,000-gallon underground gasoline tank;
- Area 4 - Discharge sump covered by NJPDES and Drywell;
- Area 5 - Plasticizer Tank Farm;
- Area 6 - Expansion Chamber and Contaminated Soils;
- Area 7 - Loading/Unloading Area;
- Area 8 - Dust Collector and Former Material Storage Area;
- Area 9 - Boiler Blowdown Discharged to Soils;
- Area 10 - Discharge Sink;
- Area 11 - The transformer substation; and,
- Area 12 - Random Sampling (PAP-00337251-70).

The 1987 RECON SAP Results report - ECRA Case No. 86206 made the following conclusions:

- The data showed that soil contamination is present on site however; it appears that shallow groundwater has not been materially impacted.

- Specific contaminants found were phthalates; polynuclear aromatic hydrocarbons (PAHs); lead; and cadmium.

- PAHs were found at various locations on the Site. Also found throughout the fill were coal cinders and ash. Coal cinders and ash are associated with PAHs which could account for the detection of PAHs.

- Phthalates were most often associated with areas where plasticizer oils were stored or loaded and were also found in areas where fugitive dusts may settle. (PAP-00337297)

The 1990 EPA SI identified the following Waste Management Areas and Areas of Concern:

- Stained Soil Area No. 1 located southwest of Blower Pad;
- Stained Soil Area No. 2 located east of Expansion Chamber;
- Noncontact Cooling Water Discharge under NJPDES Permit No. NJ0002194;
- Tank Farm Area located at the Plasticizer Tank Farm; and,
- Abandoned Drums and Sludge Pile (PAP-00337303).

According to the 1990 EPA SI, previous studies included an ECRA Investigation that involved installing seven onsite monitoring wells; collecting core samples to a depth of 6 to 12 inches below ground surface and at a depth of 6 inches above groundwater; and collecting 33 soil borings from depths ranging between 6 to 74 inches (PAP-00337307-08). In 1990, NUS Corporation Region 2 FIT collected four sediment and nine surface soil samples from the Franklin Plastics Corporation site. Two of the four sediment samples were collected from two storm drains bordering Franklin Plastics Corporation on Passaic Avenue (PAP-00337311). The 1990 EPA SI noted that at the time of the report, Franklin was implementing a second phase of ECRA sampling which involved the installation of three deep production wells and collection of six additional soil borings (PAP-00337324).

According to the letter summarizing the Site Inspection Prioritization Evaluation, dated September 29, 1995, quality assurance/quality controls were unknown for soil samples collected as part of the 1984 for the Preliminary Site Assessment, the 1986 ECRA Investigation (which also lacked adequate background sampling), and the 1990 ECRA Investigation (PAP-00054202).

According to the 2004 LFR Remedial Investigation, activities for the remedial investigation included the delineation of impacted soils identified at the former dust collector/drum storage areas (collectively known as Area 8) and the former boiler condensate transfer chamber; investigation of soil conditions beneath and downgradient of Sump No. 2 (Area 4); and documentation of an adequate physical boundary immediately east of the site within the Passaic Avenue road bed, to prevent lateral migration of impacted soils identified onsite (Areas 5 and 6). In addition, pursuant to the NJDEP letter dated July 17, 2003, a "hot spot" was excavated at the location of former soil sample SB13, near the southwestern corner of the site (PAP-00402506).

From November 2003 through February 2004, LFR excavated soil from the southwestern corner of the site and collected post-excavation soil samples. LFR also collected soil samples at other locations for the purpose of delineation and/or investigation, and consulted with Kearny and Hudson County officials regarding the construction specifications of the roadbed for Passaic Avenue, a manmade barrier to contaminant migration immediately east of the site (PAP-00402501).

Soil sample results for the post-excavation samples collected from the excavation state significant removal of the impacted soils, to which elevated total petroleum hydrocarbon (TPH) concentrations had previously been attributed. Although PAH concentrations were identified in post-excavation samples at concentrations exceeding the NJDEP Restricted Use Soil Cleanup Criteria (RUSCC), there is not a direct correlation between the PAH and TPH concentrations, thus confirming that the PAHs are present as the result of historic fill material (PAP-00402501).

Select compounds specifically analyzed to delineate the former boiler condensate transfer chamber were detected at concentrations below the UUSCC, thus completing delineation of these compounds previously identified in the vicinity of the transfer chamber. Soil samples collected to vertically delineate existing data for Sump #2 and to investigate conditions beneath and downgradient of the sump's base confirmed that the concentrations of detectable compounds are below the UUSCC, thus completing delineation of this area (PAP-00402501-02).

Soil samples collected towards the center of the property for delineation near the center of the site (Area 8) confirmed the presence of PAHs at concentrations in excess of the UUSCC in four of the five samples collected. Concentrations detected historically throughout Area 8 and other areas onsite confirm a randomness to the concentrations in relation to one another, indicative of the historic fill at the site. Select metals analysis for soil samples collected in this location were detected at concentrations below the RUSCC with one exception. Sample location SB32, which was collected to delineate Area 8 to the south, contained a lead concentration of 640 mg/kg, which marginally exceeds the RUSCC of 600 mg/kg. However, based on the absence of a consistent trend with regards to lead concentrations detected laterally and vertically sitewide, there is a randomness to the presence of elevated lead concentrations, as expected, based on the historical filling on-site (PAP-00402502).

It was concluded by LFR based on the findings, the delineation of all remaining AOCs has been completed. The implementation of engineering controls (i.e. asphalt cap or vegetative cover, fencing) and institutional controls (i.e. Deed Notice) are proposed to prevent exposure to the impacted soils and close this ISRA case (PAP-00402502).

According to the Preliminary Assessment Report prepared for the NJDEP Site Remediation Program dated December 20, 2010 (2010 NJDEP PAR), the 1986 acquisition was subject to the NJDEP Industrial Site Recovery Act (ISRA) and Case No. 86026 was assigned. When Franklin-Burlington Plastics ceased operations on February 16, 2010, it triggered the requirement to comply with ISRA. The 2010 NJDEP PAR was prepared to comply only with Franklin-Burlington Plastics, Inc. ISRA obligations in

support of the waiver request and covers the period from March 1986 to February 26, 2010 (PAP-00054628).

According to the Receptor Evaluation Report (RER) prepared by ARCADIS dated June 29, 2011 (2011 ARCADIS RER), from 2002 to 2004, ARCADIS U.S., Inc. (formerly known as LFR, Inc.) implemented a Remedial Investigation Workplan. The remedial investigation included soil sampling to delineate concentrations of BNs and metals in excess of the RUSCC to the property boundaries, inspect/investigate process water sumps and former boiler condensate chamber, and to collect sediment samples from the Passaic River. Analytical results for the sediment samples SB-15, SB-16, SB-17 and SB-18 collected immediately to the west of the site beyond the low tide line in the Passaic River confirmed that any potential contaminant sources previously identified on the Site have minimal, if any, impact upon the Passaic River (PAP-00337566).

According to the 2016 PARS RIR, AOC 1 was the 50,000-gallon No. 6 Fuel Oil Aboveground Storage Tank located on Block 1, Lot 12.01 (143 Passaic Avenue). Kleinfelder removed the tank and associated underground piping on behalf of the owner (not Franklin-Burlington Plastics) in April 2012 along with approximately five cubic yards of impacted soil. Benzo(a)pyrene was detected at a concentration that exceeded RDCSRS, and approximately ten cubic yards of soil were excavated in July 2012. Post-excavation soil samples identified no benzo(a)pyrene concentrations that exceeded RDCSRS (PAP-00056124).

Following soil investigation activities in 2013 and 2016, PARS Environmental determined that no further action or investigation was required for the 50,000 gallon No. 6 Fuel Oil AST (AOC 1); the discharge sump covered by NJPDES and drywell(s) (AOC4); floor drains, trenches and piping (AOC 6), boiler blowdown discharge to soil/transfer chamber (AOC 9), discharge sink (AOC 10), railcars and railroad spur (AOC 14), the spill area (AOC 22), the drum storage area (AOC 23) and the sludge pile (AOC 24). Remedial action in the form of engineering controls and a deed notice were required at the plasticizer tank farm (AOC 5) and unloading area (AOC 7) and remedial action was required at the transformer substation (AOC 11) (PAP-00056137-44). The fill area required remedial action to address Historic Fill contamination. Engineering and institutional controls were required to address the historic fill which is located throughout entire Site (PAP-00056159). All remaining structures at the Site were demolished in April 2014 (PAP-00056148-49).

The 2016 PARS RIR also identified a discharge sink in the Production Plant that discharged to the ground surface outside the Production Plant, adjacent to Sump 2 (AOC 10) (PAP-00056130). The Site Inspection Report prepared by NUS in 1990 referenced three drum storage areas were identified in the 1990 EPA SI in the northwest portion of the site with the drums reportedly in poor condition and partially buried. Contents of the drums appeared to be crumbled pieces of tile associated with the former Congoleum Corporation asphalt and vinyl tile plant. There was also a solidified sludge pile near the drum storage area identified in the 1990 EPA SI that was associated with Congoleum Corporation (PAP-00056135; PAP-00337307).

Remedial Activities

According to the Final Report on Cleanup Plan (CUP) Implementation and Finalization of ECRA/ISRA Responsibilities, Franklin Plastics Corporation submitted a CUP to NJDEP on August 22, 1990. The CUP proposed combining areas of environmental concern (AEC), encapsulating AECs 1 and 2 and encapsulation with pavement and recovering free product from a monitoring well. NJDEP required delineation of non-aqueous phase liquid (NAPL) near monitoring well MW-1 before approval (PAS-00063475). The approved CUP acknowledged NJDEP's approval of partial capping and use restrictions. Areas of Concern 1-12 were either encapsulated, capped, or received no further action, except Area 7 which required secondary containment pursuant to the Facility's Spill Prevention, Control, and Countermeasures Plan (PAS-00063480-82). With submission of the final CUP, final site inspection and institutional control approval, Franklin Plastics would satisfy all ISRA requirements (PAS-00063477).

The 1994 Final Report on Cleanup Plan Implementation and Finalization of ECRA/ISRA Responsibilities stated Areas 1 through 8 and the Tank Farm Area were encapsulated as required per the NJDEP final cleanup plan approval letter dated June 17, 1993. A secondary containment berm (to facilitate transfer of plasticizer oils from trucks) was constructed, as required by the Facility's SPCC Plan (PAS-00063471; PAS-00063488-92).

In August 2013, Kleinfelder submitted an unrestricted use Response Action Outcome for AOC-1 - 50,000-gallon No. 6 Fuel Oil Aboveground Storage Tank located at 143 Passaic Avenue, Block 1, Lot 12.01. It was concluded that remediation had been completed in compliance with the Administrative Requirements for the Remediation of Contaminated Sites N.J.A.C. 726C that is protective of public health, safety, and the environment. (PAP-00337614-16).

According to the *Former Transformer Substation Remedial Action Report (RAR), Volume 1 of 2*, prepared by PARS Environmental and dated June 2017 (the 2017 PARS RAR), the Transformer Substation contained five transformers, 2 circuit breakers and 17 bushings, that was decommissioned in 2013. The transformer oil was transported to Veolia ES Technical Solutions in Fort Arthur, Texas, and solids were transported to Chemical Waste Management located in Emelle, Alabama. Between December 2013 and March 2015 PARS Environmental, Inc. installed 29 borings within the area of the former transformer substation. A soil sample was collected from each location at the ground surface or at the 0.5 foot depth intervals immediately beneath the gravel layer. PCBs were detected in one sample at a concentration of 2.05 mg/kg. Low concentrations of PCBs were detected in three samples. PCBs were not detected in the remaining samples above the laboratory MDLs (PAP-00056565). In 2014, Dallas Industrial Services, Inc. demolished structures at the site that included the concrete pads, supports and the switchgear house for the former transformer substation (PAP-00056566). Remediation activities from three impacted areas within the transformer substation was performed between March 20 and 27, 2017. Post-excavation soil samples were collected from each excavation and analyzed for EPH and PCBs. PCBs were not detected in any of the samples above the laboratory MDLs from the PITTS and K-14306 Transformer Area. At the K-14463 Transformer Area, PCBs were detected at a

concentration of 0.22 mg/kg in sample No. 016, which slightly exceeded the most stringent Soil Remediation Standard of 0.2 mg/kg. PCBs were not detected above the laboratory MDL in the remaining post-excavation soil samples. The excavation was extended, and three additional soil samples were collected. PCBs were not detected in the additional post-excavation soil samples above the laboratory MDLs. At the K-14098 and K-14301 Transformer Area, PCBs were detected on one post-excavation soil sample at a concentration of 0.12 mg/kg, which was well below the most stringent Soil Remediation Standards. PCBs were not detected in the remaining samples from this excavation above the laboratory MDLs. A total of 103.38 tons of soil was excavation as part of the remedial action and transported to Pure Soil Technology in Jackson, New Jersey (PAP-00056568-70; PAP-00056575-76).

On February 12, 2019, a Deed Notice was issued for the property at Block 1, Lot 12, (7.82-acres), by the 113 Passaic Avenue Urban Renewal, LLC, (the current owner of the property) because Franklin Burlington Plastics, Inc. and 113 Passaic Avenue Urban Renewal, LLC have remediated contaminated soil at the site, such that soil contamination remains at certain areas of the property which contains contaminants in concentrations that do not allow for the unrestricted use of the property. Due to the presence and concentration of these contaminants, the current owner has agreed, as part of the remedial action for the site, to restrict the use of certain parts of the property and to the placement of engineering controls on the property. The objective of the institutional control is to provide notification of the impacted soil on the site and notification that the site has been capped with an engineering control to prevent direct contact with the impacted soil, which may contain exceedances of the NJDEP regulatory standards. The objective of the engineering control is to prevent direct contact with the impacted soil, which may contain exceedances of the NJDEP Soil Remediation Standards. The engineering cap, which encompasses the entirety of the residential use portion of the property, consists of the following elements:

- Building Foundation and Concrete: Building Foundation and Concrete elements consist of 4-inch minimum concrete over 4 inches of clean quarry material (or equivalent) with a visible demarcation boundary.

- Asphalt: Asphalt elements consist of 4-inch minimum bituminous surface course over a 4-inch minimum bituminous base course with a visible demarcation boundary.

- Landscape Area: The Landscape elements consist of 24 inches minimum of NJDEP compliant certified clean fill and topsoil material (12-inch barrier and 12-inch buffer layer) underlain by a contaminant boundary marker (geotextile liner).

- Lawn Area and Pavers: The Lawn Areas and Pavers elements consist of 12 inch minimum of NJDEP compliant certified clean fill and topsoil material (6-inch barrier and 6-inch buffer layer) underlain by a contaminant boundary marker (geotextile liner). In the Pavers element areas, approximately 3-inch landscape pavers have been placed over the 12-inch minimum of NJDEP compliant certified clean fill.

- Utility Corridors: The Utility Corridors element consists of 12 inches minimum of NJDEP compliant certified clean fill (6-inch barrier and 6-inch buffer layer) surrounding utilities with a visible demarcation boundary (PAP-00337696-714).

8. Summary of Asserted Defenses

Franklin-Burlington Plastics asserts that FBP cannot be held liable for or be required to pay response costs based on actions or inactions by FBP that arise out of conduct lawfully undertaken in compliance with permits or other approvals issued by relevant government agencies. Any discharges of COCs that may have contributed to the contamination of the Lower Passaic River were authorized under permits issued under federal and state laws – the Federal Water Pollution Control Act, 33 U.S.C. 1251 et seq.; the Clean Air Act, 42 U.S.C. § 7401 et seq.; the National Pollutant Discharge Elimination System, 40 CFR 122.1 et seq.; the New Jersey Water Pollution Control Act, N.J.S.A. 58:10A-1 et seq.; the Air Pollution Control Act, N.J.S.A. 26:2C-1 et seq.; and the New Jersey Pollutant Discharge Elimination System, N.J.A.C. 7:14A-1.1 et seq. In addition, CERCLA's petroleum exclusion is applicable to the FBP Facility.

Facility Data Report

GARFIELD MOLDING COMPANY, INC.

Facility Name, Address and Size: Garfield Molding Company, Inc. (Garfield), 10 Midland Avenue, Wallington Borough, Bergen County, Block 71, Lot 1 and Block 26A, Lot 13 New Jersey 07057, approximately 3.43 acres (PAS-00102867; PAS-00123366). Garfield Molding Company, Inc., employed 28 people (PAS-00123364). Available references did not include the number of work shifts at Garfield.

1. **Business Type:** The Garfield Molding Company was engaged in the molding of plastics, cement, and other materials for use in the electrical industry (PAS-00123366).

2. **Time Period of Ownership/Operations**

   Operator: 1917 to 2014 (PAS-00123364)
   Owner: 1917 to 2014 (PAS-00123364)

3. **Operational History/COC Use and Presence at the Facility**

   Operations at the Garfield Molding Company principally involved the molding of plastics and other materials for use in the electrical industry (PAS-00123366).

   Types of molding operations conducted at the facility are known to have included (PAS-00123366):

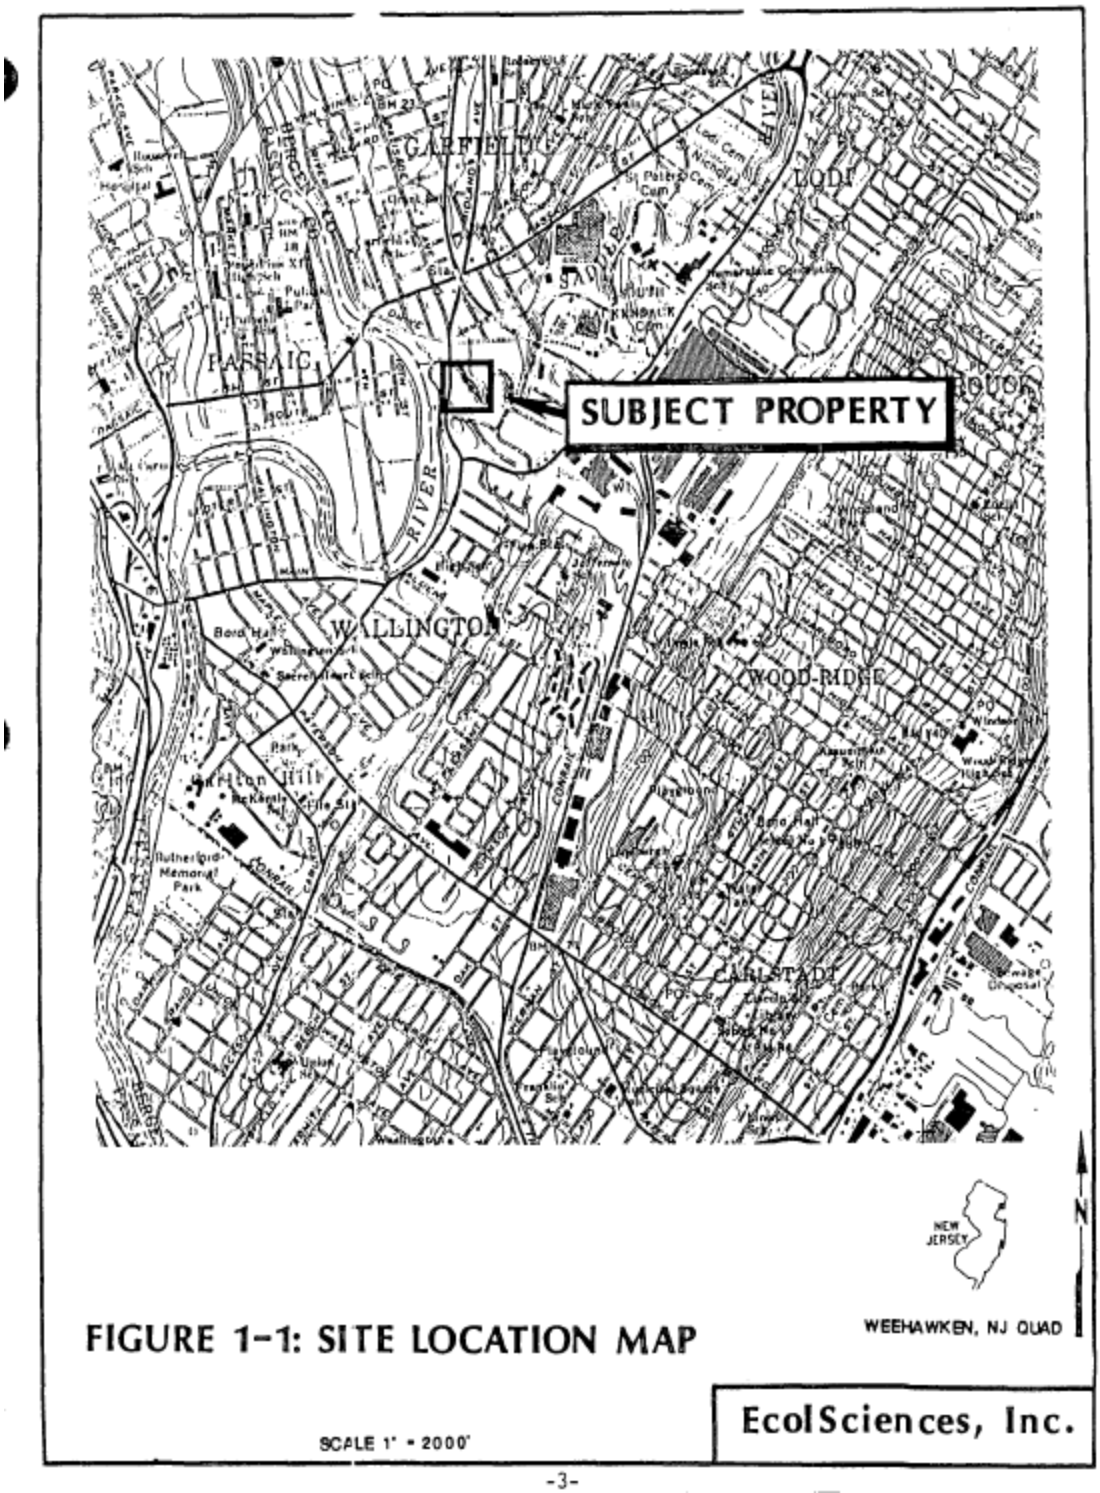
   - Compression molding
   - Custom molding
   - Injection molding
   - Prototype and production runs
   - Thermoset molding
   - Transfer molding

   As reported by the *PRP Data Extraction Form* dated 2005, cold molding, thermal transfer molding, and injection molding are reported as all being “thermoset methods” that involve the heating of thermosetting materials. Cold molded pieces are impregnated with hot paraffin in certain processes at the facility. Operations at the Garfield Molding Site included the following process areas (PAS-00123366-67)

   - Administrative functions
   - Asbestos storage
   - Automotive repair
   - Boiler
   - Box shop
   - Coal storage
   - Drum storage
   - Electrical motor storage
   - Finishing – drill presses and grinders
   - Heat treatment
   - Hemit building
   - Impregnation building
   - Injection molding
   - Laboratory
   - Mixing and blending
   - Mold storage
   - Molding (press)
   - Motor room
   - Oven department – baking and high humidity
   - Pipe shop
   - Pipe storage
   - Power house

- Press department
- Receiving, shipping and inspection
- Sand blasting
- Sewer pump house
- Steel storage
- Storage shed
- Switch room
- Thermoset compounds storage
- Tool and die shop
- Transformers
- Vehicle parking

Manufacturing processes and waste materials used in or generated by site operations include the following (PAS-00123367-68):



- Acetylene
- Aliphatic petroleum distillate
- Alkyd molding compounds
- Ammonia
- Asbestos
- Base resins (homopolymers)
- Bitumen (including uintaute)
- Cement
- Clay
- Cutting oils
- Fiberglass/additives
- Fibrous materials
- Fish oil
- Formaldehyde
- Fuel oil
- Furfural
- Gasoline
- Hydraulic oil
- Hydrocarbon waxes in solvents
- Isopropanol/Isopropyl alcohol
- Lead
- Lubricant/Lubricating Oil
- Melamine – formaldehyde resin
- Melamine-phenol formaldehyde
- Methylene chloride
- Mineral spirits
- Nonhalogenated solvents and still bottoms
- Number 2 fuel oil
- Paraffin
- Phenol formaldehyde polymeric molding compounds
- Polyester molding compounds (styrene based)
- Polyester molding compounds (vinyl toluene based)
- Polyester/alkyd polymeric molding compounds
- Resins/polymeric materials (commercial premixes)
- Tars
- Toluene
- Urea-formaldehyde molding compounds
- Used oil/waste oil
- Vegetable waxes
- Wollastonite

Facility Data Report

-3-

(PAS-00102868)

(PAS-00102959)

According to the *Data Presentation Report for Garfield Molding, ECRA Case 88439*, dated October 19, 1990, Report (1990 Report), a brief description of the manufacturing operations at the Garfield Molding Company with respect to each of the industrial buildings are as follows:

Building 1 – Injection presses used for thermal transfer molding of electrical switchboard components. The administrative offices of the Garfield Molding Company are also housed in Building 1 (PAS-00102869).

Building 1A – Building 1A houses mixing operations where water-based compounds are blended for cold molding processes (PAS-00102869).

Building 2 – Grinding and polishing machinery associated with finishing operations for the electrical switchboard equipment. Dust from these grinding operations is exhausted from the building via a network of ducts connected to the three cyclone dust collectors found immediately to the rear of the building (PAS-00102869).

Building 3 – Storage vault for the molds used in the cold molding of electrical switchboard components (PAS-00102869).

Building 3A – Drying ovens used in conjunction with the cold molding process (PAS-00102869).

Building 3C – Mold storage vault annex (PAS-00102869).

Building 4 – Natural gas fired high pressure steam boiler and hallway space linking cold molding production areas (PAS-00102869).

Building 4A – Impregnating operations associated with the cold molding process and contains two hot wax dip tanks (PAS-00102869).

Building 5 – Second active boiler unit and houses a small pipe fitting shop (PAS-00102869).

Building 5A – Centralized pumping equipment associated with the lubrication system for the thermal transfer molding presses. The injection presses found in Building 1 are interconnected by a common oil lubricating system, with the piping for this system found in a network of concrete troughs beneath the production area floor. Oil lines and oil return sump lines were connected to the pumping equipment in Building 5A via a tunnel connecting Building 1 and 5A (PAS-00102869-70).

Building 5B – Former coal fired boilers which were no longer in service as of 1990 (PAS-00102870).

Building 6A – Additional floor space associated with the preparation of water-based compounds for cold molding processes. Mixing facilities we on the first floor of Building 6A, while raw materials, mainly Type IV Portland cement, were stored on the second floor (PAS-00102870).

Building 7 – Housed the feedstocks used in the thermal transfer molding operations. Used to warehouse finished electrical switchboard components. Chemical feedstocks were stored on the first floor of the building while finished products were stored on the second floor (PAS-00102870).

Building 8A – Vacant storage (PAS-00102870).

Building 9 – Storage of heavy machinery being dismantled as part of the closure activities of the Garfield Molding Company (PAS-00102870).

Building 9A – Miscellaneous storage purposes (PAS-00102870).

Building 10 – Sublet to an automotive repair shop (PAS-00102870).

Building 11 – Open roofed structure that once served as a coal bin for the coal-fired boilers found in Building 5B. Was also used to store automobiles and trucks (PAS-00102870).

Buildings 13 and 13A – Vacant structures (PAS-00102870).

Building 14A – Machine shop facilities for the maintenance of onsite mechanical equipment (PAS-00102870).

Building 16 – Vacant (PAS-00102870).

Building 17 – Sanitary sewer pump station connecting the sewer units from the Garfield Molding Company to the sewer system for Wallington Borough (PAS-00102870).

4. Identified COCs

- PCBs (detected)
- PAHs (detected)
- Copper (use, storage)
- Lead (use, detected)
- Mercury (detected)

PCBs

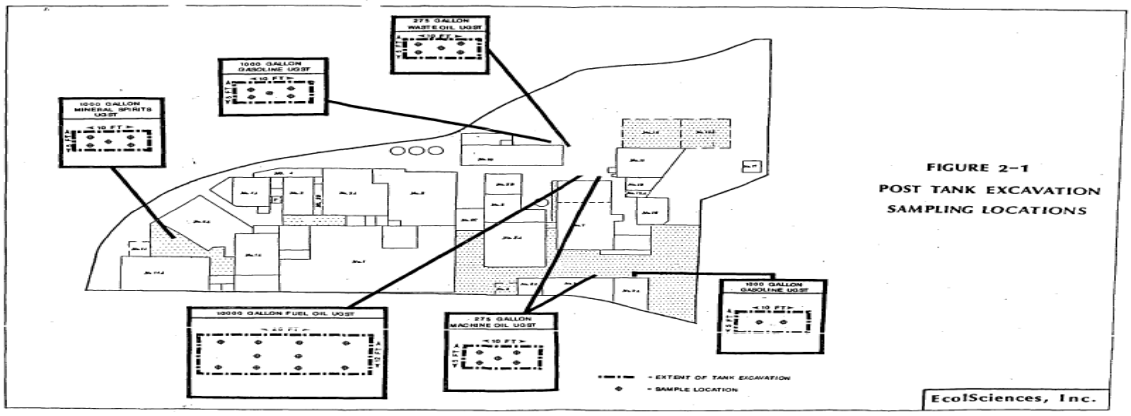
According to the 1990 Report, post tank excavation sampling entailed the collection of soil samples beneath the six underground storage tanks removed from the subject property during June 1990 (PAS-00102880-83).

Post tank excavation soil sampling results revealed an elevated concentration of PCBs (Aroclor-1260) detected in soil beneath the 275-gallon waste oil tank at a concentration of 1,400 µg/kg (Aroclor-1260 in sample T-W-5) (PAS-00102882).

PAHs

According to the 1990 Report, post tank excavation sampling entailed the collection of soil samples beneath the six underground storage tanks (USTs)removed from the subject property during June 1990 (PAS-00102880-83).

Post tank excavation soil sampling results revealed elevated concentrations of PAHs detected in soils beneath the 275-gallon waste oil tank at concentrations ranging from 1,400 to 7,100 micrograms per kilogram (µg/kg) (PAS-00102878-82). The figure below presents the locations of the post tank excavation sampling locations.



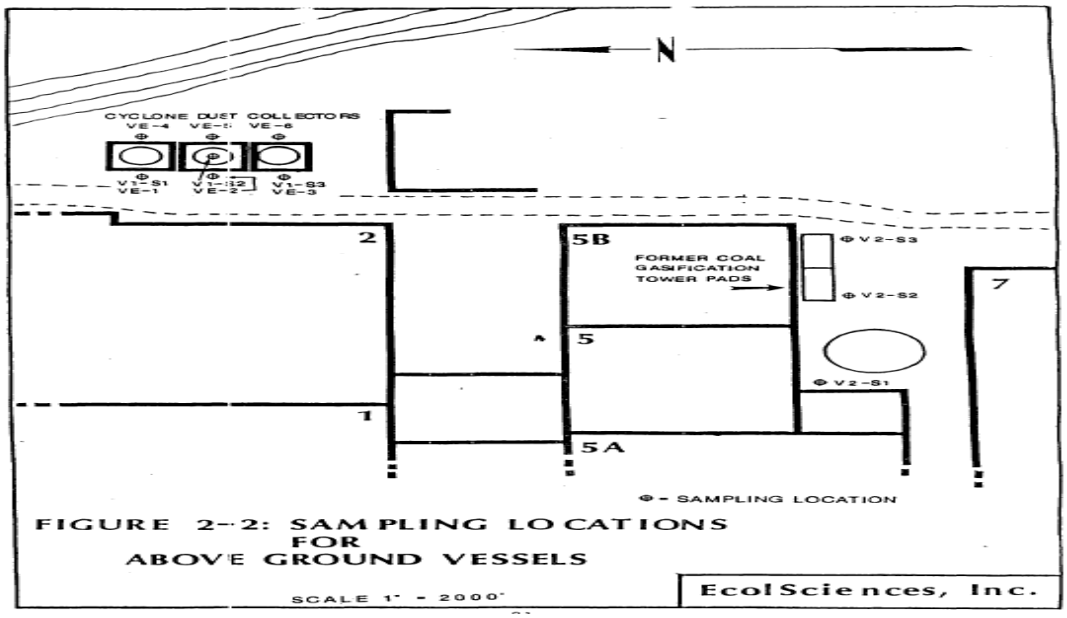


FIGURE 2-1
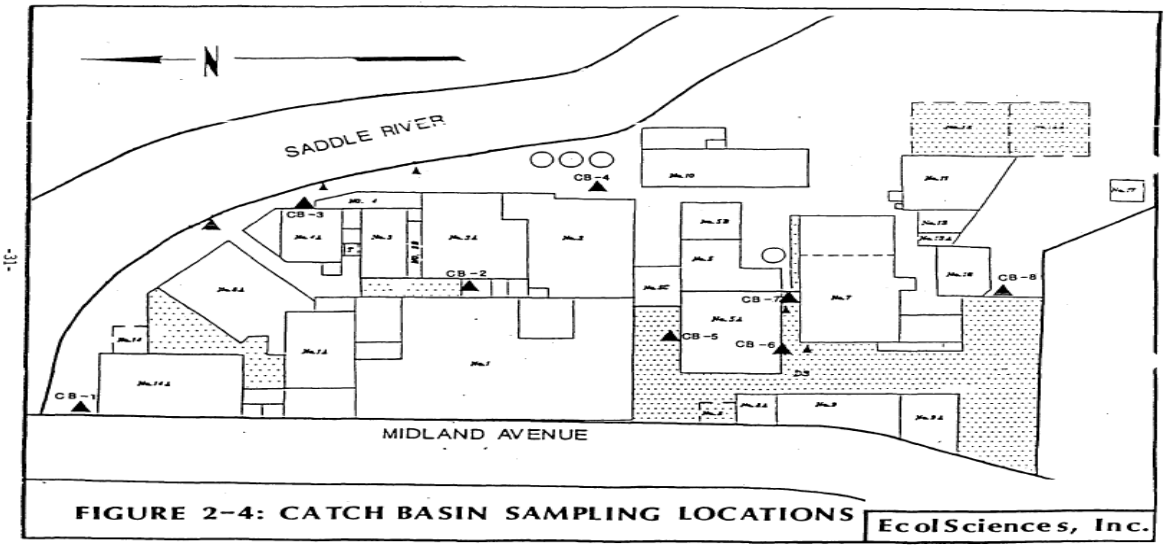
POST TANK EXCAVATION
SAMPLING LOCATIONS

(PAS-00102879)

In addition, soil samples were collected beneath three cyclone dust collectors found east of Building 2. Soil samples were also collected adjacent to the former coal gasification tower pads found along the south side of Building 5 (PAS-00102884). Soil samples surrounding the cyclone dust collectors showed elevated concentrations of phenanthrene from 550 µg/kg in sample V1-S2 at a depth of 0-6 inches to 640 µg/kg in sample V1-S3 at a depth of 0-6 inches) (PAS-00102888). The figure below presents the location of the cyclone dust collectors.



(PAS-00102886)

Soil samples were also collected at the former drum storage area. Sampling at the former drum storage areas entailed the collection of shallow surface soils at three temporary drum storage areas having permeable surfaces to determine if leakage or spillage from drums resulted in residual contamination of the underlying soils (PAS-00102890). Soil samples were taken from the former drum storage areas found in the alleyway separating Buildings 1 and 3A (Area D3), adjacent to the north side of Building 14A (Area D4), and adjacent to the northeast corner of Building 11 (Area D5) (PAS-00102890). Soil samples collected from this area revealed concentrations of PAHs ranging from 820 µg/kg (phenanthrene in sample D4-51) to 14,000 µg/kg (pyrene in sample D4-54) (PAS-00102892).

Twelve surface water inlets are connected to four NJPDES-permitted discharge points on the Garfield Molding Company property. Eight catch basins were sampled at the locations where these surface water inlets function as receiving points for site runoff or potential spills (PAS-00102894). Sediment samples collected from catch basins found to the south and west of Building 5A, to the southeast of Building 3A, and to south of Building 16 were used to assess the environmental impact associated with the past storage of drums at these locations. Further, sediment samples taken from the catch basins found to the north of Building 5A, to the east of Buildings 4A and 2, and to the

north of Building 14A were used to assess the potential Impact of site runoff upon the NJPDES-permitted discharge points (PAS-00102894). Elevated concentrations of PAHs were detected in five of eight catch basin sediment samples at concentrations ranging from 2,900 µg/kg (pyrene in sample CB-5) to 34,000 µg/kg (benzo(b)fluoranthene in sample CB-3) (PAS-00102895, 7). The catch basin sampling locations are presented on the figure below:

PAS-00102896

Copper

Soil samples were collected beneath three cyclone dust collectors found east of Building 2. Soil samples were also collected adjacent to the former coal gasification tower pads found along the south side of Building 5 (PAS-00102884). Soil samples surrounding the cyclone dust collectors showed elevated concentrations of copper from 586 to 1,800 mg/kg (PAS-00102887). Post excavation soil samples collected upon removal of potentially contaminated soils surrounding the dust collectors showed concentrations of copper from 704 mg/kg in sample VE-3 at a depth of 24-30 inches to 2,585 mg/kg in sample VE-1 at a depth of 24-30 inches (PAS-00102889). These concentrations are likely attributed to the presence of coal cinders and coal fragments in the soil base supporting the dust collection towers (PAS-00102887-9).

Lead

Soil samples were collected beneath three cyclone dust collectors found east of Building 2. Soil samples were also collected adjacent to the former coal gasification tower pads found along the south side of Building 5 (PAS-00102884). Post excavation soil samples collected upon removal of potentially contaminated soils surrounding the dust collectors showed concentrations of lead from 558 mg/kg in sample VE-6 at a depth of 24-30 inches to 738 mg/kg in sample VE-3 at a depth of 24-30 inches (PAS-00102889). These concentrations are likely attributed to the presence of coal cinders and coal fragments in the soil base supporting the dust collection towers (PAS-00102887, 9).

Lead was listed as a material used at the site, but no further information on how or where it was used was provided in the available references (PAS-00123367-68).

Mercury

Soil samples were collected beneath three cyclone dust collectors found east of Building 2. Soil samples were also collected adjacent to the former coal gasification tower pads found along the south side of Building 5 (PAS-00102884). Post excavation soil samples collected upon removal of potentially contaminated soils surrounding the dust collectors showed concentrations of mercury from 1.0 mg/kg in sample VE-6 at a depth of 24-30 inches to 2.5 mg/kg in sample VE-3 at a depth of 24-30 inches (PAS-00102889). These concentrations are likely attributed to the presence of coal cinders and coal fragments in the soil base supporting the dust collection towers (PAS-00102887).

Historic Fill

The Allocation Team has determined that the facility site is partially located on regional Historic Fill as designated by the NJDEP.[1] According to the 1990 Report, Historic Fill was identified during prior investigations conducted at the Garfield Molding Company (PAS-00102872, 83; PAS-00102913, PAS-00102922).

The New Jersey Department of Environmental Protection (NJDEP) has established that Historic Fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 COCs: PAHs, lead, copper, and mercury.[2] Accordingly, NJDEP technical requirements for property containing Historic Fill requires sampling for the United States Environmental Protection Agency (EPA) Target Compound List (TCL) for PAHs and Target Analyte List (TAL) for metals, including lead, copper, mercury, and the OU2 PAH COCs.[3] PAHs, lead, copper, and mercury are recognized by NJDEP to be constituents of Historic Fill at varying levels, not atypically at or exceeding residential soil standards.[4]

The levels of PAHs, copper, lead and mercury detected at the site in soils are presented in the table below (PAS-00102889, 92).

---

[1] *Digital Geodata Series, DGS04-7, Historic Fill for New Jersey*, https://www.nj.gov/dep/njgs/geodata/dgs04-7.htm, Quadrangle #52 and #53 (NJDEP map identifying locations of recognized historic fill).

[2] *Characterization of Ambient Levels of Selected Metals and cPAHs In New Jersey Soils* (2002) and *Characterization of Ambient Levels of Selected Metals and Other Analytes In New Jersey Soils* (1997), studies prepared for NJDEP, Division of Science and Research, by BEM Systems, Inc.

[3] New Jersey Department of Environmental Protection (NJDEP), *N.J.A.C. 7:26E Technical Requirements for Site Remediation,* Table 4-2, November 2009 [Note that Table 4-2 has been deleted from the current version of N.J.A.C. 7:26E (May 7, 2012) and the updated *Historic Fill Technical Guidance* (April 2013) as NJDEP believed that the tables list of historic fill constituents was too restrictive].

[4] NJDEP Table 4-2 (PAHS and lead) and a summary of NJDEP records regarding investigations of properties in the vicinity of the Passaic River recognized to be located in areas of Historic Fill indicate that the following average/maximum (mg/kg) contamination levels of OU2 COCs exist in area Historic Fill: PAHs (1.91/160), lead (574/10,000), copper (11.2/1,200), and mercury (0.21/3.7).

COCs Found in Onsite Soils	
COC	**Max Detected Concentration**
Lead	738 mg/kg
Copper	2,585 mg/kg
Mercury	2.5 mg/kg
Benzo(a)anthracene	2.8 mg/kg
Benzo(a)pyrene	3.8 mg/kg
Benzo(b)fluoranthene	5.4 mg/kg
Benzo(k)fluoranthene	2.1 mg/kg
Dibenzo(a,h)anthracene	ND
Indeno(1,2,3-cd)pyrene	ND

5. COC Pathways

Sanitary and Storm Sewer

Sanitary wastewater was discharged directly from Garfield Molding Company to Saddle River from 1908 through 1918 (PAP-00165373; PAS-00102790). In addition, humidity room condensate wastewater was discharged from the Garfield Molding Company to the Saddle River from 1960 through 1988 (PAP-00165373; PAS-00102790). From 1969 through 1974 boiler blowdown wastewater was discharged directly from the Garfield Molding Company to the Saddle River (PAP-00165373; PAS-00102790).

In accordance with NJPDES Permit Number NJ0027146, Garfield Molding Company was permitted to discharge site stormwater runoff through outfalls 001, 002, 003, 004, 005, and 006 (PAS-00102808; PAS-00123371). Available references did not include permit dates, permitted flow rates and effluent monitoring requirements or results.

Available references state that Garfield held Permit NJ0070211. This permit was for discharge of industrial site storm water runoff without toxic and hazardous pollutants to State surface waters, excluding those classified as FW1 or located within the Pinelands Area, from facilities not requiring an individual NJPDES Permit, a DPCC/DCR plan, or treatment other than gravity separation, and in accordance with effluent limitations, monitoring requirements, and other conditions as set forth in Parts I, II, III, and IV of the permit (PAS-00102809). The permit was effective from September 1, 1987 to August 31, 1992. Available references did not include permitted flow rates and effluent monitoring requirements or results.

6. Regulatory History/Enforcement Actions

Violations

According to the 1974 *PVSC Annual Report*, on June 6, 1974, Inspector Cupo inspected Garfield Molding Company. He discovered that one of four active discharge pipes were covered with debris, making it impossible to sample. Two others that were discharging were sampled, and the fourth was a 2-inch boiler blowdown pipe, which discharged at 7:00 A.M. for a short time. In addition, there were three other visible inactive pipes. The

samples of the two cooling water discharges were satisfactory, but the boiler blowdown was polluting, and Inspector Cupo informed Mr. J. Minaberry, Vice President, Mr. Lombardi, Plant Manager, and Mr. LaRose Jr., Safety Manager in addition to uncovering the outlet that was inaccessible to him so that a sample could be taken of the discharge. Mr. Cupo reported that they complied with Passaic Valley Sewerage Commission (PVSC) directions and that intended corrections to the boiler blowdown were planned for about July 15, 1974, when the plant was shut down for vacation (PAS-00102945).

According to the 1974 *PVSC Annual Report*, on July 2, 1974, Mr. Lubetkin wrote to Garfield confirming that their boiler blowdown was polluting, and directing them to make accessible the covered outlet. The available references did not specify the pollutants in the discharge. Mr. Lubetkin also informed them that they must have a NPDES permit from the USEPA in order to discharge into the Passaic River. Although no reply was received by PVSC, Inspector Cupo reported that he had questioned Mr. Bauer, a Vice-President, on July 22, and was told that the equipment delivery was causing the installation delay. He gave Inspector Cupo a copy of the report on a new Fulton Blowdown Separator, dated July 19, 1974, from the Fulton Boiler Works of Pulaski, New York (PAS-00102945)

According to the 1974 *PVSC Annual Report*, on August 24, 1974, Mr. Cupo inspected the work and reported that the boiler blowdown installation was completed and was now being discharged through a separator, into the sanitary sewer, thus eliminating this violation. Inspector Cupo also reported that the No. 3 outlet was now uncovered and it was sampled. Analysis showed that the discharge was satisfactory (PAS-00102945). According to an *Industrial Site Evaluation Element* dated June 1, 1989, in the past, stormwater, humidity room condensate, wastewater from slop sink, non-contact cooling water, boiler blowdown, and sanitary wastewater were all discharged to the Saddle River. Several unpermitted discharges and other violations of the NJPDES-discharge permit were noted to have occurred during the historical operations (PAS-00102947). Several deficiencies were noted at the Garfield Molding Company. These include: (PAS-00102948-9)

- Several unpermitted discharges and other violations of the existing NJPDES-discharge permit had occurred during the historical operations of the facility.
- It had been stated that past industrial practices at the facility included spreading waste oil on the unpaved driveways in an effort to control dust.
- Much of the machinery utilized on site was situated within concrete pits located inside the buildings. These pits were observed to contain lubricating oils. Drainage from these pits entered a concrete trough which ultimately emptied into a common concrete sump.
- Information addressing the plumbing/drainage system within the buildings was not provided.
- A suspected vent pipe was observed outside along Building 5 in the area of the cistern. It is unknown whether an additional UST was present in this area.
- A concrete trench was observed along the side of Building 5A. The trench was observed to be stained with an oily residue. This trench discharged to a catch basin located in the shipping/receiving area.

- Within a courtyard located between Building 14A and Building 1A, there was a pit covered with a steel plate and a discharge of a grayish dust which impacted the soils within the area.
- A catch basin was observed between Building 4A and Building 1A. This area had historically been used for drum storage.
- Overhead pipes were observed between Building 2 and Building 5B and also between Building 5B and Building 7. The insulation covering these pipes was deteriorated.
- Empty drums were stored outside of the former coal storage area (Building 11) and along the southwest corner of Building 16.
- The floor of Building 16 was heavily soiled. A portion of the roof was missing which had allowed rain water to reach the floor.
- A six-inch diameter pipe was observed along the south side of Building 7. This pipe apparently extended down to the water table.
- Two covered pits were observed in the area of the cistern; one located outside of the doors on the south side of the Building 5 and the other located immediately adjacent to the cistern.

Permits

In accordance with NJPDES Permit Number NJ0027146, Garfield Molding Company was permitted to discharge site stormwater runoff through outfalls 001, 002, 003, 004, 005, and 006 (PAS-00102808; PAS-00123371). The permit was effective from July 1, 1991 to August 31, 1992. Available references did not include permitted flow rates and effluent monitoring requirements or results.

Available references state that Garfield held Permit NJ0070211. This permit was for discharge of industrial site storm water runoff without toxic and hazardous pollutants to State surface waters, excluding those classified as FWI or located within the Pinelands Area, from facilities not requiring an individual NJPDES Permit, a DPCC/DCR plan, or treatment other than gravity separation, and in accordance with effluent limitations, monitoring requirements, and other conditions as set forth in Parts I, II, III, and IV of the permit (PAS-00102809). The permit was effective from September 1, 1987 to August 31, 1992. Available references did not include permitted flow rates and effluent monitoring requirements or results.

7. Response Actions

Characterization Activities

The following characterization activities have taken place at the facility:

- *Data Presentation for Garfield Molding ECRA Case 88439*, prepared by EcolSciences, Inc., dated October 1990 (PAS-00102862).
- *Cleanup Plan for the Garfield Molding Company*, prepared by EcolSciences, Inc., dated October 1990 (PAS-00102926).

Sewer

There is no information regarding sewer sampling in the available file material.

Soil

According to the 1990 Report, ten AECs were identified at the Garfield Molding Company. These AECs are (PAS-00102870-72):

- AEC 1 (Underground Storage Tanks (USTs)
- AEC 2 (Cistern)
- AEC 3 (Above Ground Vessels)
- AEC 4 (Former Drum Storage Areas)
- AEC 5 (New Jersey Pollutant Discharge Elimination System Discharge Points)
- AEC 6 (Unpaved Roadway Areas)
- AEC 7 (Groundwater)
- AEC 8 (Asbestos)
- AEC 9 (Former Production Wells)
- AEC 10 (Building Interiors)

Eight separate environmental sampling programs were designed and implemented to address the environmental concerns identified at the subject property. These sampling programs entailed the collection of 110 environmental samples for analyses of a combination of parameters including priority pollutants, petroleum hydrocarbons, and asbestos (PAS-00102873).

Remedial Activities

According to the 1990 Report, ten AECs were identified at the Garfield Molding Company (PAS-00102870). In addition, six USTs containing gasoline, fuel oil, light machine oils, waste oil and mineral spirits were previously found onsite. Following is a brief description of each AEC (PAS-00102871).

AEC 1 (USTs) – Following is an inventory of the USTs removed from the subject property listed by tank size, contents, age, and location relative to the onsite buildings:

USTs			
Tank Size	**Contents**	**Age**	**Location**
10,000 gallons	Fuel Oil	1957	East of Building 7A
275 gallons	Machine Oil	1908	East of Building 7A
275 gallons	Machine Oil	1908	East of Building 9A
275 gallons	Waste Oil	1985	South of Building 10
1,000 gallons	Gasoline	1975	East of Building 10
1,000 gallons	Mineral Spirits	1908	North of Building 6A

The 1,000-gallon mineral spirits tank was found to be leaking upon removal. All other tanks appeared to be intact (PAS-00102871).

AEC 2 (Cistern) – A brick-lined cistern was located onsite between Buildings 5 and 7. This cistern once contained non-contact cooling water for recirculation in thermal transfer molding process. Condensate from air compressors housed in Building 5A was also directed to the cistern (PAS-00102871).

AEC 3 (Above Ground Vessels) – Three cyclone dust collectors associated with product grinding and finishing operations were found to the east of Building 2. Normal operation of this dust collection system impacted the soils adjacent to the concrete pads supporting these towers. In addition to these cyclone dust collectors, two former coal gasification towers were once located adjacent to the south side of Building 5B; however, only remnant concrete pads were onsite. Former operations of a coal gasification plant raised several environmental concerns which were addressed through various onsite sampling programs (PAS-00102871).

AEC 4 (Former Drum Storage Areas) – Former drum storage areas were identified at the subject property. These drum storage areas consisted of drums stored in Building 16 and temporary drum storage areas at the southwest corner of Building 5A, at the northeast corner of Building 14A, and in the alleyway separating Buildings 1 and 3A (PAS-0010872).

AEC 5 (NJPDES Discharge Points) – Four surface water discharge points at the Garfield Molding Company were regulated under NJPDES permits. These discharge points received surface water runoff diverted from the subject property. NJPDES permitted discharge points posed an environmental concern, as this drainage network may have trapped contaminants associated with the surface areas of the subject property (PAS-0010872).

AEC 6 (Unpaved Roadway Areas) – An unpaved roadway traversed the eastern portion of the subject property, extending from the south side of Building 16, encircling Building 11 to the east, passing between Buildings 5B and 10, and finally ending at the east side of Building 6A. This roadway was an environmental concern as past maintenance practices included the spreading of motor oil across the roadway surface to control dust (PAS-00102872).

AEC 7 (Groundwater) – Groundwater contamination beneath the subject property is a potential environmental concern as the 1,000-gallon mineral spirits tank, at the north side of Building 6A was found to be leaking upon removal. Further, coal cinders found as fill material along the eastern-most perimeter of the site may have leached contaminants into the underlying groundwater (PAS-00102872).

AEC 10 (Building Interiors) – Floor space within several buildings showed oil staining attributed to manufacturing operations. The injection presses found in Building 1 were interconnected via a common oil lubrication system. Piping for this system was found in a network of concrete troughs beneath the production area floor. These oil lines and oil return sump lines were connected to a large central pump found in Building 5A, with the piping routed within a small tunnel connecting the two buildings. Portions of the concrete in Building 5 were oil stained as were major portions of the concrete trough network (PAS-00102872).

According to the 1990 Report, eight separate environmental sampling programs were designed and implemented to address the environmental concerns identified at the subject property. These sampling programs entailed the collection of 110 environmental samples for analyses of a combination of parameters including Priority Pollutants, petroleum hydrocarbons, and asbestos. The AEC sampling results are discussed below (PAS-00102873).

Post Tank Excavation Sampling Results – According to the 1990 Report, post tank excavation sampling entailed the collection of soil samples beneath the six USTs removed from the subject property during June 1990. Additional samples were also taken to screen an area suspected of once containing an underground tank, although no evidence of a former tank was found (PAS-00102878).

Overall, five of six USTs removed from the subject property visually appeared to be intact. Post tank excavation soil sampling results revealed elevated concentrations of PAHs and PCBs (one Aroclor-1260 detection) detected in soils beneath the 275-gallon waste oil tank. Potentially contaminated soil beneath the tank was excavated to the point of contact with the underlying water table and temporarily staged onsite prior to disposal (PAS-0010883). Soil samples collected from beneath the 275-gallon tank showed concentrations of the PAHs phenanthrene, fluoranthene, pyrene, benzo(a)anthracene, chrysene, benzo(b)fluoranthene, benzo(k)fluoranthene, ranging from 1400 µg/kg (benzo(k)fluoranthene in sample T-W-5) to 7100 µg/kg (pyrene in sample T-W-5). In addition, the PCB Aroclor-1260 was detected at 1,400 µg/kg (PAS-00102882).

Aboveground Vessel Sampling Results – According to the 1990 Report, the collection of soil samples surrounding the cyclone dust collectors showed that these soils contained elevated concentrations of phenanthrene 550 µg/kg in sample V1-S2 at a depth of 0-6 inches to (640 µg/kg in sample V1-S3 at a depth of 0-6 inches) and copper at a concentration of 586 mg/kg in sample V1-S3 at a depth of 0-6 inches to 1,800 mg/kg in sample V1-S1 at a depth of 0-6 inches. Post excavation samples collected upon the removal of potentially contaminated soils surrounding the dust collectors showed concentrations of copper (704 mg/kg in sample VE-3 at a depth of 24-30 inches to 2,585 mg/kg in sample VE-1 at a concentration of 24-30 inches), lead (558 mg/kg in sample VE-6 at a depth of 24-30 inches to 738 mg/kg in sample VE-3 at a depth of 24-30 inches), and mercury (1.0 mg/kg in sample VE-6 at a depth of 24-30 inches to 2.5 mg/kg in sample VE-3 at a depth of 24-30 inches) were detected in the post excavation soil samples. These elevated metal concentrations were likely attributed to the presence of coal cinders and coal fragments in the soil base supporting the dust collection towers. Upon removal of the upper 2 feet of soils beneath the dust collectors, the underlying material was found to consist primarily of coal cinders (PAS-00102887-89).

Soil samples were collected adjacent to the former coal gasification tower pads. The initial sampling results showed that these soils contained fluoranthene (3,000 µg/kg in sample V2-S3 at a depth of 24-30 inches) and pyrene (2,800 µg/kg in sample V2-S3 at a depth of 24-30 inches). Post excavation samples collected upon the removal of potentially contaminated soils surrounding the concrete pads showed slightly elevated concentrations of mercury (2.5 mg/kg). Again, as in the area surrounding the dust

collectors, soils beneath the former coal gasification tower pads contained varying amounts of coal cinders and coal fragments (PAS-00102887-89).

Approximately 90 tons of potentially contaminated soils were removed beneath the dust collectors and 30 tons of potentially contaminated soils were removed at the location of the former coal gasification tower pads. Soils at both locations were excavated to a depth of 2 feet below grade. Upon excavation, the underlying soil material was determined to consist primarily of coal cinders. Post excavation sampling results reflect the composition of these cinder deposits, with elevated concentrations of metals detected in the samples. Additional remediation was not proposed with respect to the soils beneath either the dust collectors or former coal gasification tower pads. Rather, the coal cinder deposits encountered at these locations were covered with a layer of certified clean fill material to minimize erosion and potential exposure to the underlying cinder-laden soil (PAS-00102919).

Former Drum Storage Area Sampling Results – Sampling at the former drum storage areas entailed the collection of shallow surface soils at three temporary drum storage areas having permeable surfaces to determine if leakage or spillage from drums resulted in residual contamination of the underlying soils (PAS-00102890).

Additional soil remediation was proposed for these areas, with each excavation to encompass a 20 by 20 foot area. Approximately 200 tons of potentially contaminated soils were expected to be staged for disposal (PAS-00102919).

Drum Storage Area D3 (East of Building 1) – Soil samples collected from this former drum storage area contained the PAHs phenanthrene, fluoranthene, pyrene, benzo(a)anthracene, chrysene, benzo(b)fluoranthene, and benzo(a) pyrene at concentrations ranging from 2,100 to 12,000 µg/kg (PAS-00102890; PAS-00102892).

Drum Storage Area D4 (North of Building 14A) – Soil samples collected from this former drum storage area contained the PAHs phenanthrene, fluoranthene, pyrene, benzo(b)fluoranthene and benzo(a) pyrene at concentrations ranging from 820 to 14,000 µg/kg (PAS-00102894; PAS-00102892).

Catch Basin Sampling Results – Twelve surface water inlets are connected to the four NPDES-permitted discharge points on the Garfield Molding Company property. Eight catch basins were sampled at those locations where these surface water Inlets function as receiving points for site runoff or potential spills. Once sampling was completed, all surface water inlets were cleared of sediment deposits and steam cleaned (PAS-00102894).

PAHs were detected in five of eight catch basin sediment samples. Maximum concentrations were as follows:

PAHs in Catch Basins		
Constituent	**Concentration (µg/kg)**	**Location**
Dibenzofuran	7,100	CB-3
Naphthalene	5,600	CB-3
Acenaphthene	7,900	CB-3
Fluorene	9,000	CB-3
Phenanthrene	19,000	CB-3
Anthracene	9,700	CB-3
Fluoranthene	17,000	CB-3
Pyrene	17,000	CB-3
Benzo(a)anthracene	19,000	CB-3
Benzo(b)fluoranthene	34,000	CB-3
Benzo(k)fluoranthene	12,000	CB-3
Benzo(a)pyrene	27,000	CB-3
Chrysene	26,000	CB-3
Indeno(1,2,3-cd)pyrene	17,000	CB-3
Dibenz(a,h)anthracene	4,500	CB-3

(PAS-00120897)

Unpaved Roadway Sampling Results – Unpaved roadway sampling entailed the collection of shallow soil samples from beneath the gravel roadway traversing the eastern portion of the subject property. The gravel roadway extends from the south side of Building 16, encircles Building 11 to the east, passes between Buildings 5B and 10, then follows the eastern boundary of the property to the end of the roadway at the east side of Building 6A. Sampling of this roadway corridor was undertaken to address potential environmental concerns arising from past practices of spreading oil on the roadbed to control dust (PAS-00102895). PAHs were detected at low concentrations. No PCBs were found in the roadway samples (PAS-00102899).

Groundwater Sampling Results – Four overburden monitoring wells were installed at the Garfield Molding Company property on August 9 to 13, 1990, as part of an initial hydrogeological assessment of the subject property (PAS-00102902).

The initial groundwater sampling results showed that leakage from the former 1,000-gallon mineral spirits tank had impacted the adjacent groundwater. PAHs were found at concentrations ranging from 29 to 430 micrograms per liter (µg/L). Only trace concentrations of metals were detected in groundwater (PAS-00102913).

8. Summary of Asserted Defenses

No legal defenses were identified in the available file materials.

Facility Data Report

GENERAL ELECTRIC COMPANY

Facility Name, Address and Size: General Electric Company and RCA; 1000 South 2nd Street, Harrison, New Jersey (known as 2nd Street Facility or Building No. 55); approximately 2.66 acres (PAP-00075203; PAP-00341690); 450 employees, 1 shift per day, 5 days per week (PAP-00075203).

1. **Business Type:** Manufacturing of vacuum tubes (PAP-00342923; PAP-00340701-02)

2. **Time Period of Ownership/Operations**

   Operator: 1950 to 1975
   Owner: 1950 to 1976

   1940s: Otis Elevator Company owned the property prior to World War II, and deeded the property to the Defense Plant Corporation during the early 1940s (PAP-00075178).

   1943: Defense Plant Corporation constructs Building No. 55 on the property (PAP-00341711).

   1945: The 2nd Street Facility sold to Zauzner Cheese Corp. (PAP-00075178).

   1950: RCA purchased the 2nd Street Facility from Zauzner Cheese Corp. (PAP-00075179, PAP-00341711; PAP-00343578).

   1975: RCA ceased operations at the 2nd Street Facility on December 31, 1975 and the property was vacant until it was sold in 1976 (PAP-00341690).

   1976: RCA sold the 2nd Street Facility to International Fastener Research Corporation in June 1976 (PAP-00343486). In November 1976, the David Weist Auctioneer Company held a 12-day public auction to liquidate all of the RCA machinery, equipment, instruments, and supplies at Harrison (PAP-00074229).

   1986: GE acquired RCA (PAS-00122713, 843). GE combined the consumer electronic operations of both RCA and GE into what was known as the GE Consumer Electronics Business (PAS-00122776-77).

   1987: GE sold the GE Consumer Electronics Business to Thomson S.A. on December 31, 1987 (PAS-00122777, 837, 843).

3. **Operational History/COC Use and Presence at the Facility**

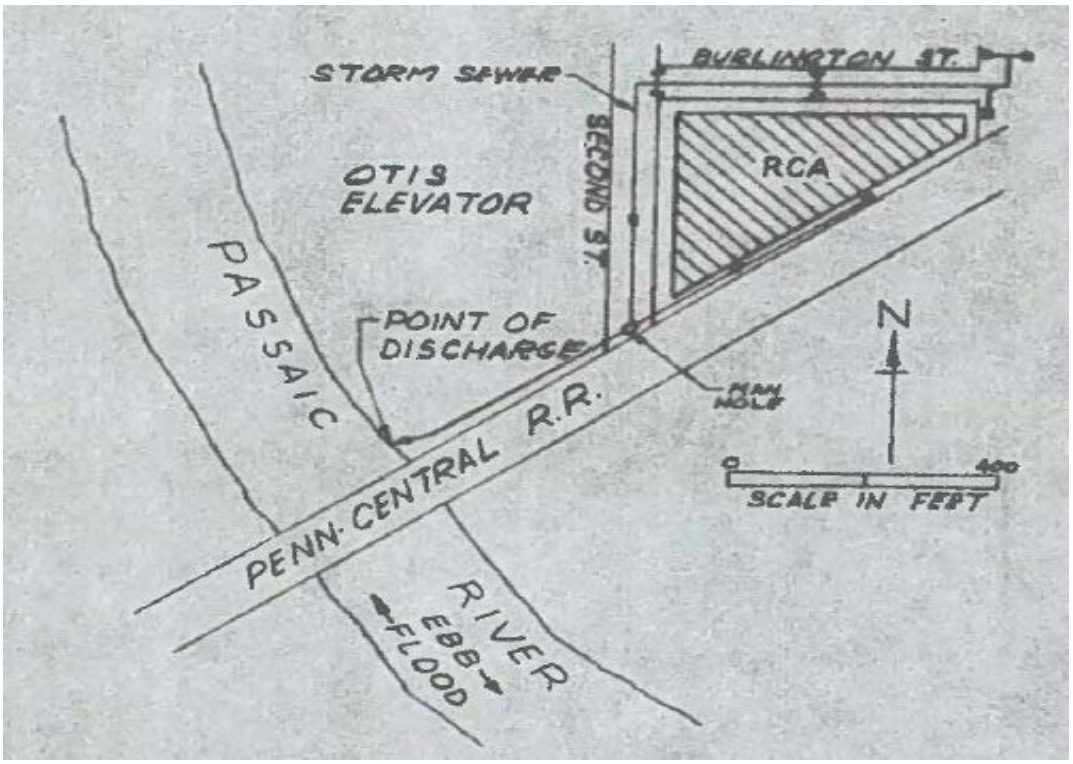
   There is a single 147,000-square-foot building, located adjacent to the Pennsylvania Path Railroad. The building was constructed by Defense Plant Corporation, for manufacturing heavy equipment, such as the Sherman Tank (PAP-00075178; PAP-00343741). The building, Building No. 55, was constructed in 1943 and acquired by

RCA in 1950 (PAP-00341711). Building No. 55 has two floors and is constructed of brick walls, steel frame, and concrete floors (PAP-00341710).

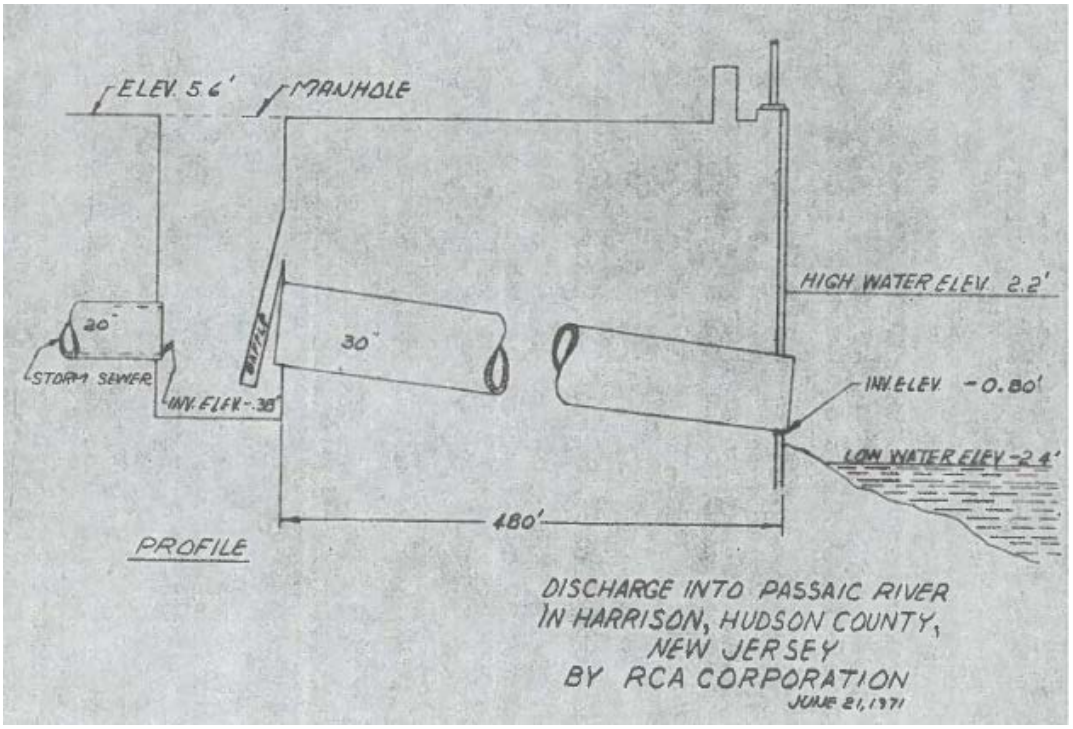
Operations included production of receiving tubes, photo tubes, power tubes, and other products (PAP-00075179). Raw materials used in tube manufacturing included nigrosine, porcelain, petroleum jelly, zinc, calcium aluminum fluoride, resin, ethyl alcohol, lead acetate, malachite green, glycerine, zinc chloride, iron, marble dust, wood fiber, strontium nitrate, lead oxide, zinc oxide, mica, tin, sodium carbonate, sodium nitrate, silver oxide, barium carbonate, isolantite, molybdenum, alumina, borax, barium, copper, carbon, chromium, calcium, cesium, cobalt, iridium, monel, mercury, calcium oxide, barium nitrate, calcium carbonate, ammonium chloride, potassium carbonate, bakelite, phosphorus, silicon, shellac, tungsten, titanium, silica, glass, magnesia, platinum, strontium, magnesium, rosin, nickel, cobalt oxide, and thorium nitrate. (PAP-00074226; PAP-00074217-23). Equipment used included grid winders, cathode sprayers, test consoles, glass sealing machines, spot welders and tube aging racks (PAP-00074229).

Materials containing copper, lead and mercury were used in vacuum tube production (PAP-00074226). Exterior parapet lighting was self-ballasted mercury vapor (PAP-00075183).

Former employees testified in a litigation relating to an insurance coverage dispute that process wastes were not disposed down floor drains, but instead would be poured into a special container and hauled off-site for disposal (PAP-00341794).



The large plating room had a cyanide collection tank. Separate acid drains passed into neutralizing tanks and then passed into the sanitary sewer system which discharged to the Passaic Valley Sewerage Commissioners (PVSC) system. Cooling water entered a drain piping system in the overhead utility distribution rack and joined with roof drains, cooling tower discharge, and various sprinkler and street drains, to the combined storm sewer drain system that passes through the adjacent Otis Elevator property and into the Passaic River (PAP-00075182).



A drawing of the discharge point, as well as a profile drawing of the discharge point, are presented below (PAP-00074199):

Diamond Alkali OU2 Allocation

ADR Confidential

Facility Data Report

4. Identified COCs

- PCBs
- Copper (use)
- Lead (use)
- Mercury (use)

Detections of COCs in environmental samples are not reported in the available references. No sampling data for the 2nd Street Facility was located in the available file materials. The majority of the historic information and investigations in the file materials focused on the main plant, located on South 5th Street, which is addressed in a separate Data Report.

PCBs

According to an *RCA Plant Facilities Survey*, dated December 31, 1975, the main service transformers were owned by RCA (PAP-00341691). A summary table of PCB sales for Harrison New Jersey states that RCA purchased 1,850 pounds of Aroclor 1254 between 1958 and 1963, but the table does not specify which RCA facility made this purchase (PAP-00342156).

Copper

No information regarding the volumes of copper used and/or stored at the 2nd Street Facility was identified in the available file materials.

Lead

No information regarding the volumes of lead used and/or stored at the 2nd Street Facility was identified in the available file materials.

Mercury

No information regarding where mercury was used and/or stored at the 2nd Street Facility was identified in the available file materials.

Historic Fill

The Allocation Team has determined that the 2nd Street Facility is located entirely on regional Historic Fill as designated by the NJDEP.[1]

[1] *Digital Geodata Series, DGS04-7, Historic Fill for New Jersey*, https://www.nj.gov/dep/njgs/geodata/dgs04-7.htm, Quadrangle #52 and #53 (NJDEP map identifying locations of recognized historic fill).

The NJDEP has established that Historic Fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 COCs: PAHs, lead, copper, and mercury.[2] Accordingly, NJDEP technical requirements for property containing Historic Fill requires sampling for the United States Environmental Protection Agency (EPA) Target Compound List (TCL) for PAHs and Target Analyte List (TAL) for metals, including lead, copper, mercury, and the OU2 PAH COCs.[3] PAHs, lead, copper, and mercury are recognized by NJDEP to be constituents of Historic Fill at varying levels, not atypically at or exceeding residential soil standards.[4]

There is no information regarding sampling results in the available file material.

5. COC Pathways

The 2nd Street Facility is located approximately 500 feet from the Passaic River (PAS-00048608). The entire property is covered by the single building present, Building No. 55 (PAP-00341690).

Sanitary and Storm Sewer

Effluent from the 2nd Street Facility passed into neutralizing tanks and then into the sanitary sewer system which discharged into the PVSC system. The 2nd Street Facility is not located within the Bergen Street combined sewer outfall (CSO) district. Effluent from the 2nd Street Facility discharged into a 10-inch sewer line that emptied directly into the PVSC trunk line at the intersection of Middlesex Street and 2nd Street, which then transported the effluent to the PVSC treatment works (PAP-00075182).

Process equipment cooling water, water from roof drains, cooling tower discharge, blowdown, and various sprinkler and street drains discharged to a storm sewer drain system that passed through the adjacent Otis Elevator property and discharged into the Passaic River (PAP-00075182). Application Number 000051 to the Army Corps of Engineers covered this discharge (PAP-00075182).

---

[2] *Characterization of Ambient Levels of Selected Metals and cPAHs In New Jersey Soils* (2002) and *Characterization of Ambient Levels of Selected Metals and Other Analytes In New Jersey Soils* (1997), studies prepared for NJDEP, Division of Science and Research, by BEM Systems, Inc.
[3] New Jersey Department of Environmental Protection (NJDEP), *N.J.A.C. 7:26E Technical Requirements for Site Remediation,* Table 4-2, November 2009 [Note that Table 4-2 has been deleted from the current version of N.J.A.C. 7:26E (May 7, 2012) and the updated *Historic Fill Technical Guidance* (April 2013) as NJDEP believed that the tables list of historic fill constituents was too restrictive].
[4] NJDEP Table 4-2 (PAHs and lead) and a summary of NJDEP records regarding investigations of properties in the vicinity of the Passaic River recognized to be located in areas of Historic Fill indicate that the following average/maximum (mg/kg) contamination levels of OU2 COCs exist in area Historic Fill: PAHs (1.91/160), lead (574/10,000), copper (11.2/1,200), and mercury (0.21/3.7).

Documented wastewater discharge volumes are as follows:

- According to a *PVSC Waste Effluent Survey*, dated May 22, 1972, the 2nd Street Facility, in 1971, discharged 32,250,000 gallons of waste water to the sanitary sewer (PAP-00075204). The waste effluent sampling results for this discharge contained 97 µg/L copper (PAP-00075207; PAS-00124484). Lead was <10 µg/L (PAP-00075207; PAS-00124484).

- According to a *PVSC Waste Effluent Survey*, dated May 22, 1972, the 2nd Street Facility, in 1971, 12,900,000 gallons of water were discharged to the "Storm Sewer, River, or Ditch" (PAP-00075204). This effluent consisted of cooling water with 75 percent of the volume consisting of untreated city water and the remaining 25 percent of the volume being from the air conditioning cooling towers. The cooling water contained no metals (PAS-00048608). The discharge point is located just north of the Penn-Central Railroad Bridge, on the adjacent Otis Elevator property (PAP-00075204).

- According to an *RCA Plant Facilities Survey*, dated December 31, 1975, there was no liquid waste including, sanitary, industrial, cooling water, and other (PAP-00341693).

Direct Release

Process equipment cooling water, water from roof drains, cooling tower discharge, blowdown, and various sprinkler and street drains discharged to a storm sewer drain system that passed through the adjacent Otis Elevator property and discharged into the Passaic River (PAP-00075182). Application Number 000051 to the Army Corps of Engineers covered this discharge (PAP-00075182). No additional information on direct releases to the Passaic River was identified in the available file materials.

Spills

There is no information regarding spills in the available file material.

6. Regulatory History/Enforcement Actions

Inspections

There is no information regarding inspections in the available file material.

Violations

There is no information regarding violations in the available file material.

Permits

Application Number 000051 to the Army Corps of Engineers covered the discharge of process equipment cooling water, water from roof drains, cooling tower discharge, blowdown and various sprinkler and street drains discharged to a storm sewer drain system that passed through the adjacent property and discharged into the Passaic River (PAP-00075182).

According to a letter to EPA dated April 9, 1980, RCA submitted a signed Affidavit of Exemption from NPDES No. NJ0000230 for the Harrison Plant (PAP-00343675). However, no location information was provided in this letter, so it is not clear which property the exemption pertains to. No other permit information specific to the 2nd Street Facility was identified in the available file materials.

7. Response Actions

Characterization Activities

Sewer

There is no information regarding sewer sampling in the available file material.

Soil

There is no information regarding soil sampling in the available file material.

Remedial Activities

There is no information regarding remedial actions in the available file material.

8. Summary of Asserted Defenses

No legal defenses were identified in the available file material.

Facility Data Report

GENERAL ELECTRIC COMPANY

Facility Name, Address and Size: General Electric Company and Radio Corporation of America (RCA); 415 South 5th Street, Harrison, New Jersey (known as the 5th Street Facility or Main Plant); also identified as 400 South 5th Street (PAP-00074230; PAS-00122713); approximately 12.75 acres (PAP-00341685); other addresses used for this facility include 420 South 5th Street for Building C, 530 Bergen Street for Building B, and 400 South 5th Street for Building A (PAS-00049080; PAP-00074238); up to 20,000 workers with round the clock shifts 7 days per week during World War II (PAP-00074228); 2,900 employees, 2 shifts per day, 5 days per week in 1972 (PAS-00122720); reduced to 1,300 employees, 1 shift per day, 5 days per week in 1975 (PAS-00122728).

1. **Business Type:** Manufacturing of incandescent lamps and vacuum tubes (PAP-00075192, PAP-00075193, PAP-00075193)

2. **Time Period of Ownership/Operations**

   Operator: 1882 to 1976
   Owner: 1882 to 1976

The *Remedial Action Work Plan*, dated July 15, 2015 (2015 RAWP), the *Onsite Remedial Investigation Report*, dated January 28, 2015 (2015 RI Report), and an undated *Archive of Industry for Harrison, NJ* provided a corporate history of the site as follows. Any discrepancies in the dates as noted in other sources are identified.

1877: The property was developed by Peters Manufacturing Company (PAP-00074237; PAP-00074666).

1882: The Edison Lamp Company acquired the property to manufacture incandescent lamps (PAP-00074237; PAP-00074666; PAP-00075192). It is noted that a Building Assessment Summary Report, dated January 2019 (2019 Building Assessment), stated that The Edison Lamp Company acquired the property in May 1881 (PAP-00342922).

1889: The Edison Lamp Company was consolidated into the Edison General Electric Company (PAP-00074237; PAP-00074666). The undated Archive of Industry for Harrison, NJ stated that this occurred in 1885 (PAP-00075192).

1892: The Edison General Electric Company and the Thompson-Houston Electric Company were consolidated to create General Electric Company (GE) (PAP-00074237; PAP-00074666). GE owned/operated the 5th Street Facility until 1929 (PAP-00074237).

1919: According to a Media Profile Chronology, RCA was incorporated in 1919 (PAS-00122833).

Diamond Alkali OU2 Allocation

ADR Confidential

Facility Data Report

1930: RCA purchased the 5th Street Facility from GE to manufacture radio vacuum tubes (PAP-00074237; PAP-00075193). According to the 2019 Building Assessment, RCA purchased the 5th Street Facility in 1927 (PAP-00342923).

1932: Based on an online article, RCA was spun off as an independent corporation in 1932 (PAS-00122713, 834).

1943: According to the 2006 Extraction Form, RCA had operated at the 5th Street Facility on or before August 27, 1943 (PAS-00122713).

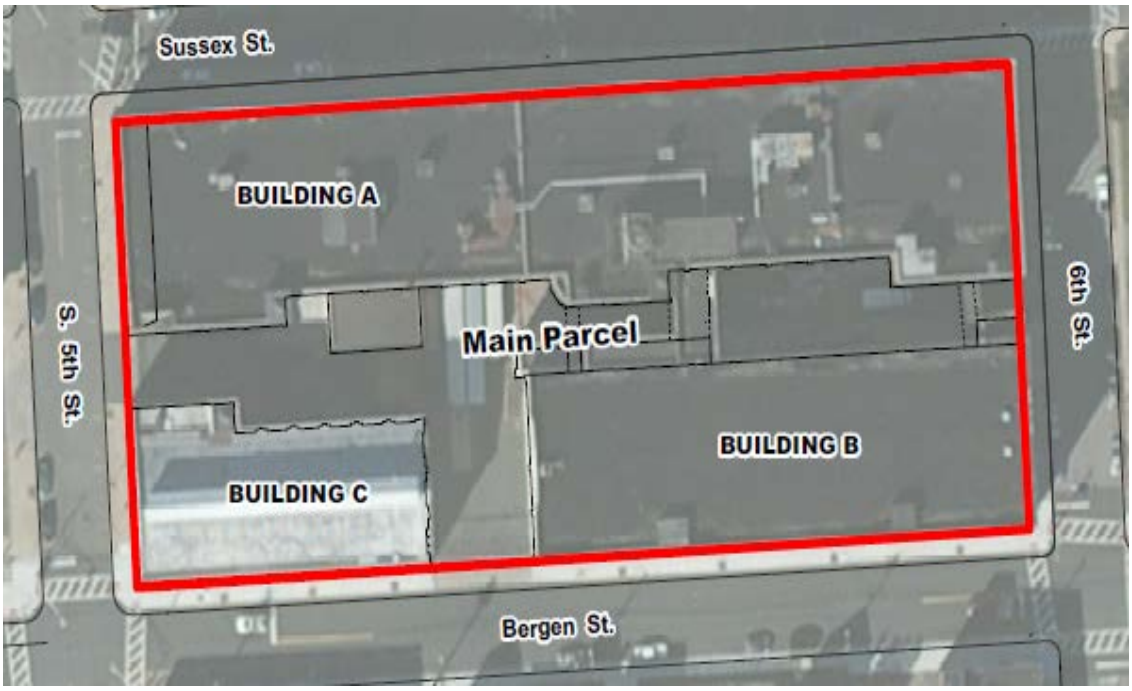
1976: According to a letter from RCA to the Passaic Valley Sewerage Commissioners (PVSC), dated March 9, 1977, RCA phased out operations at the Harrison facility in June 1976 (PAS-00122770). RCA sold the 5th Street Facility to International Fastener Research Corporation on June 17, 1976 (PAP-00074238; PAP-00343542). The article titled "*RCA Tube Production, Harrison, New Jersey, 1930-1976*" in the Vacuum Tube Valley Issue 8 from 1997 stated that the David Weisz Auctioneer Company held a 12-day public auction in November 1976 to liquidate all of the RCA machinery, equipment, instruments, and supplies from the Harrison Plant (PAP-00074229).

1977: International Fastener Research Corporation sold the 5th Street Facility to Vo-Toys, a subsidiary of VIP Realty Associates (PAP-00074238). VIP Realty Associates leased portions of the 5th Street Facility to various tenants over time (PAP-00074237).

1986: The 2006 Extraction Form stated GE acquired RCA in mid-1986 (PAP-00342923; PAS-00122713, 843). A letter from Thomson Consumer Electronics to EPA, dated February 21, 1997, stated that GE combined the consumer electronic operations of both RCA and GE into what was known as the GE Consumer Electronics Business (PAS-00122776-77).

1987: The February 21, 1997 letter from Thomson Consumer Electronics to EPA stated that GE sold the GE Consumer Electronics Business to Thomson S.A. on December 31, 1987 (PAS-00122777).

1990: VIP Realty Associates acquired the 5th Street Facility from Vo-Toys on December 17, 1990 (PAP-00074238; PAP-00074666). Vo-Toys used the 5th Street Facility for warehousing and distribution until May 2015, according to a *Mercury Data Summary Report*, *Vo-Toys Site*, dated October 2016 (2016 Mercury Report) (PAP-00074842).



2015: According to the 2016 Mercury Report, VIP Realty Associates sold the 5th Street Facility to BRG Harrison Lofts Urban Renewal, LLC (BRG) in May 2015 (PAP-00074842). The First Amended Complaint brought by BRG against GE, filed November 17, 2016, stated that BRG acquired the 5th Street Facility on June 9, 2015 (PAS-00049079). BRG is still the current owner of the 5th Street Facility as of January 2019 (PAP-00342919).

3. Operational History/COC Use and Presence at the Facility

As discussed in the 2015 RAWP, the 5th Street Facility was developed in the early 1900s with three multi-story industrial buildings designated as Buildings A, B, and C, which covered a total area of approximately 68,000 square feet. Buildings A and B were connected by two enclosed, elevated walkways. The parking lot is approximately 0.46 acres and paved with asphalt (PAP-00074238).

According to the 2019 Building Assessment, Building A was also known as Building No. 36/37, Building B was also known as Building No. 33, and Building C was also known as Building No. 34 (PAP-00342921). A *RCA Plant Facilities Survey*, dated December 31, 1975, documented the total areas of the buildings as follows: Building A was a three story slab on grade building with an interior area of approximately 109,500 square feet. Building B was a three story slab on grade building with an interior area of approximately 60,700 square feet. Building C had a basement and two floors, with an interior area of approximately 30,700 square feet (PAP-00341704-07). The 2019 Building Assessment and the 1975 Plant Facilities Survey stated Building A was constructed in 1913 and 1914, Building B was constructed in 1907, and Building C was constructed in 1902 (PAP-00341705, 07; PAP-00342921).

A figure of the 5th Street Facility buildings from the 2015 RAWP is presented below (PAP-00074296):

According to the undated Archive of Industry for Harrison, NJ, operations at the Harrison plant consisted of incandescent lamp manufacturing from 1882 until approximately 1929 (PAP-00075192-93). During this time, the raw materials used in incandescent lamp manufacturing included lead glass, wood, plaster, metals, cotton, zinc chloride, alcohol, and filaments made of cellulose, tantalum, and tungsten (PAP-00075192; PAP-00075196-98). Lamp making was largely done by hand until mechanization in 1895 (PAP-00075200).

According to an article titled "*History Corner, A Short History: The Role of Mercury in Vacuum and PVD Technology*," by Donald M. Mattox in a 2016 SVC Bulletin publication, Thomas Edison patented an all-mercury combination vacuum pump in 1881 that used banks of pumps in parallel to evacuate incandescent lamps, and these pumps were used by Edison up to 1896. This pump type required continuous cleaning, maintenance, repair, and replacement (PAP-00341717).

In 1930, RCA purchased the 5th Street facility to make vacuum tubes, according to the 2015 RAWP and 2015 RI Report (PAP-00074237; PAP-00075193). An article titled "*RCA Tube Production, Harrison, New Jersey, 1930-1976*" in the Vacuum Tube Valley Issue 8 from 1997 stated that sixty-five various types of metal, chemical compounds and gases were used to manufacture these tubes, including mercury, copper, lead acetate, and lead oxide . During World War II, RCA developed tubes for communications, radar, sonar and related defense electronics at the 5th Street Facility (PAP-00074226-28). According to a United States Navy Security Report, dated February 26, 1942, the 5th Street Facility was producing glass and metal radio receiving and power tubes, phototubes, gas triodes and tetrodes, cathode-ray and television tubes, voltage regulation tubes, acorn tubes and special amplifier tubes (PAP-00074212). The article titled "*RCA Tube Production, Harrison, New Jersey, 1930-1976*" in the Vacuum Tube Valley Issue 8 from 1997 identified equipment used as including grid winders, cathode sprayers, test consoles, glass sealing machines, spot welders and tube aging racks (PAP-00074229).

Former employees testified in a litigation relating to an insurance coverage dispute that solvent wastes were not disposed down floor drains, but instead were poured into containers and hauled off-site for disposal (PAP-00341796-98).

4. Identified COCs

- PCBs (detected)
- PAHs (detected)
- Copper (used, detected)
- Lead (used, detected)
- Mercury (used, detected)

PCBs

PCBs were not noted to be used in manufacturing either incandescent lamps or vacuum tubes. According to the 2015 RI Report, historical records stated that a transformer substation was located adjacent to the western side of Building No. 33 (also known as Building B) (PAP-00074681), and PCBs appeared to have been used in the transformer substation in 1958, 1959 and 1963 (PAP-00074681). According to the *RCA Plant*

Facilities Survey, dated December 31, 1975, the main service transformers were owned by RCA (PAP-00341686). A Sales Summary Analysis table of PCB sales for Harrison, New Jersey stated that RCA purchased 1,850 pounds of Aroclor 1254 between 1958 and 1963 (PAP-00342156; PAP-00304327-33).

Soil and building material samples were collected in 2014 and reported in the 2015 RAWP and 2015 RI Report. PCBs were detected in shallow soil adjacent to a transformer substation and in concrete and wood floor material in Building B. An area of approximately 750 square feet of PCB-impacted soil was identified between 0.5 feet below ground surface (bgs) to 4.5 feet bgs at the former transformer substation (PAP-00074246; PAP-00074682). Concentrations ranged from non-detect to 2.12 milligrams per kilogram (mg/kg) (PAP-00074308).

Floor scape samples from Building B and samples of wood and concrete debris were analyzed for PCBs and concentrations ranged from 0.8 to 736 mg/kg, but PCBs were not detected in soil samples beneath the building floors (PAP-00074247; PAP-00074684).

PAHs

According to the 2015 RAWP and 2015 RI Report, PAH-impacted soil was encountered to a depth of approximately 3 feet bgs in a small area stained with hydraulic oil at Building B (PAP-00074249). Concentrations were as high as 380 mg/kg for benzo(a)anthracene, 290 mg/kg for benzo(a)pyrene, 360 mg/kg for benzo(b)fluoranthene, 54 mg/kg for dibenzo(a,h)anthracene, and 150 mg/kg for indeno(1,2,3-cd)pyrene (PAP-00074732).

Six of the seven concrete filled pits in the western concrete floor area of Building B were analyzed for PAHs and all six had detections of PAHs (PAP-00074797). Sampling determined that approximately one-third of the slab in Building B was impacted with PAHs. Redevelopment is anticipated to require removal of the first floor of Building B as well as the underlying soils to a depth of 3 feet below the top of the existing floors (PAP-00074688). Concentrations were as high as 11 mg/kg for benzo(a)anthracene, 7.8 mg/kg for benzo(a)pyrene, 15 mg/kg for benzo(b)fluoranthene, 2.0 mg/kg for dibenzo(a,h)anthracene, and 7.7 mg/kg for indeno(1,2,3-cd)pyrene (PAP-00074726, 797).

Copper

It is possible that copper was used as a raw material in the manufacture of incandescent lamps. Early production of lamps involved a copper plated wire connected to the filament (PAP-00342147).

Copper was used in the manufacture of RCA radio tubes, as listed in the article "*RCA Tube Production, Harrison, New Jersey, 1930-1976*" in the Vacuum Tube Valley Issue 8 from 1997 (PAP-00074226). A RCA Standardization Notice 34-36-5A, dated September 9, 1941, reported the use of DuPont's high speed copper solution in copper plating operations (PAP-00075219). Another Standardization Notice 34-36-7D, dated April 14,

1942, was for silver plating of copper radiator fin spacers for power tubes (PAP-00075213). In addition, the United States Navy Security Report, dated February 26, 1942, identified copper sulfate, copper flashed steel wire, and copper wire as used at the facility (PAP-00074217, 20-21). No information regarding the volumes of copper used at the 5th Street Facility was identified in the available file materials.

The 2015 RI Report included metals results for soil and building material samples at AOC-A and AOC-L. Copper was reported at a maximum concentration of 100 mg/kg in soil samples collected at AOC-A. The maximum concentration of copper in wood and concrete pit samples collected from Building B at AOC-L was 3,400 mg/kg, while soil samples contained up to 200 mg/kg copper (PAP-00074775, 97).

Lead

The publication titled "A Century of Light" dated 1979 stated leaded glass was used in incandescent lamp manufacturing until 1914, when lime glass was developed for machine production (PAP-00075192). Raw materials containing lead were used in vacuum tube production, according to the article "*RCA Tube Production, Harrison, New Jersey, 1930-1976*" in the Vacuum Tube Valley Issue 8 from 1997 (PAP-00074226). No information regarding the volumes of lead used at the 5th Street Facility was identified in the available file materials.

According to the 2015 RI Report, lead was detected at AOC-L in soil beneath the eastern wood floor area of Building B, as well as in the soil beneath the seven concrete filled pits in the western concrete floor area of Building B, with a maximum concentration of 130 mg/kg (PAP-00074683, 770). Lead at the seven concrete filled pits was detected as high has 2,500 mg/kg (PAP-00074726, 95).

Lead was also detected in soil at the former UST areas, including AOC-A (Former 550 Gallon Unknown Oil UST), at a maximum concentration of 37 mg/kg, and AOC-E2 (Historical Gasoline ASTs [Aboveground Storage Tanks]) at a maximum concentration of 76 mg/kg (PAP-00074770, 90).

Mercury

Mercury was not noted to be used as a raw material in incandescent lamp manufacturing at the 5th Street Facility, according to the undated Archive of Industry for Harrison, NJ and a publication titled "A Century of Light" dated 1979 (PAP-00075192; PAP-00075196-98), but an article titled "*History Corner, A Short History: The Role of Mercury in Vacuum and PVD Technology*," by Donald M. Mattox in a 2016 SVC Bulletin publication stated that mercury pumps may have been used to create a vacuum in lamp bulbs during incandescent lamp production until 1896 (PAP-00341717).

The manufacturing of vacuum tubes by RCA was reported to include mercury (PAP-00074226). Mercury was identified as a raw material in the manufacturing of radio vacuum tubes at the 5th Street Facility in a United States Navy Security Report, dated February 26, 1942 (PAP-00074211, 20). In addition, RCA Radiotron Company, Inc. issued a Standardization Notice No. 34-8-1, dated June 19, 1942, to standardize the

process of reclaiming mercury that had been used at the laboratories and factories (PAP-00075216-18).

The 2015 RI Report identified two Areas of Concern (AOCs) at which mercury was detected: AOC-A (Former 550 Gallon UST) and AOC-L (Sumps and Pits) (PAP-00074677, 83). At AOC-A, it was determined that an area of soil approximately 200 square feet extending to an approximate depth of 6.0 feet bgs was impacted by mercury in the vicinity of the former 550-gallon unknown petroleum hydrocarbon underground storage tank (UST) (PAP-00074677-78). According to the 2015 RAWP, concentrations in soil ranged from non-detect to 3.4 mg/kg (PAP-00074305-07).

At AOC-L, concrete slab samples were collected from seven concrete filled pits based on field observation, and soil samples were collected directly beneath the wood floor as well as beneath the concrete pits in Building B. Mercury was detected in soil beneath the eastern wood floor area of Building B, as well as in the soil beneath the seven concrete filled pits in the western concrete floor area of Building B up to 26 mg/kg (PAP-00074683, 798). Mercury at the wood area and seven concrete filled pits was as high as 650 mg/kg (PAP-00074726, 95).

According to the 2016 Mercury Report, the maximum mercury concentration in soil at Building A was 7.3 mg/kg within an elevator pit at a depth of 5.5 feet bgs. The maximum mercury concentration in soil at Building B was 75 mg/kg at a depth of 4.2 feet bgs. The maximum mercury concentration in soil at Building C was 56 mg/kg within an elevator pit at a depth of 11.5 feet bgs (PAP-00074857-58).

As discussed in the 2016 Mercury Report, elevated concentrations of mercury vapors were identified during the 2013 Preliminary Assessment in two areas on the third floor of Building C (PAP-00074842). Mercury vapor was detected at a concentration of 0.370 micrograms per cubic meter (ug/m^3) (PAP-00074849). Additional mercury vapor investigations in October 2015 and January 2016 determined that concentrations of mercury vapors were higher than the 2013 concentrations and mercury vapors were detected on all three floors in all three buildings (PAP-00074843). The maximum vapor concentrations were as follows:

- Building A: October 2015 maximum reading of 10.39 ug/m^3 on the second floor, at floor level (six inches above the floor). January 2016 maximum reading of 5.06 ug/m^3 on the first floor at floor level.

- Building B: October 2015 maximum reading of 274 ug/m^3 on the first floor at the breathing zone (5 feet above the floor). January 2016 maximum reading of 25.26 ug/m^3 on the first floor at floor level.

- Building C: October 2015 maximum reading of 34.546 ug/m^3 on the first floor at the breathing zone. January 2016 maximum reading of 34.128 ug/m^3 on the first floor at floor level (PAP-00074850-51).

As noted in the 2016 Mercury Report, elemental mercury beads were found in two locations within the subfloor of the first floor of Building B. One area contained one mercury bead, and the other area contained elemental mercury beads over an area of approximately 40 feet by 10 feet (PAP-00074859).

Historic Fill

The Allocation Team has determined that the 5th Street Facility is not located on regional Historic Fill as designated by the NJDEP.[1]

The NJDEP has established that Historic Fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 COCs: PAHs, lead, copper, and mercury.[2] Accordingly, NJDEP technical requirements for property containing Historic Fill requires sampling for the United States Environmental Protection Agency (EPA) Target Compound List (TCL) for PAHs and Target Analyte List (TAL) for metals, including lead, copper, mercury, and the OU2 PAH COCs.[3] PAHs, lead, copper, and mercury are recognized by NJDEP to be constituents of Historic Fill at varying levels, not atypically at or exceeding residential soil standards.[4]

According to cross-sections included in the 2015 RI Report, fill is present and ranges in thickness from approximately 8 feet to 20 feet (PAP-00074707-11). However, this fill is not identified as Historic Fill.

[1] *Digital Geodata Series, DGS04-7, Historic Fill for New Jersey*, https://www.nj.gov/dep/njgs/geodata/dgs04-7.htm, Quadrangle #52 (NJDEP map identifying locations of recognized historic fill).

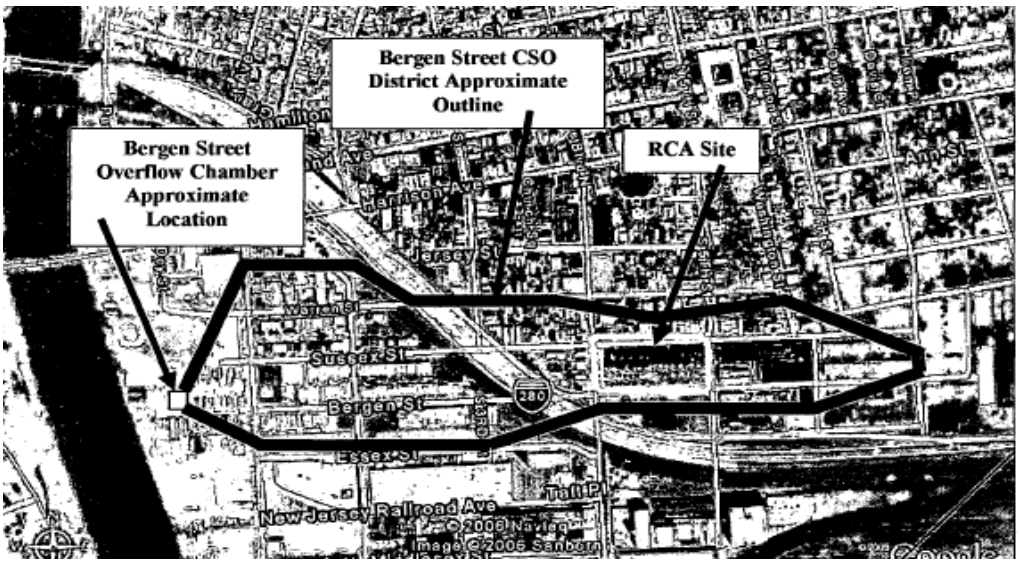
[2] *Characterization of Ambient Levels of Selected Metals and cPAHs In New Jersey Soils* (2002) and *Characterization of Ambient Levels of Selected Metals and Oher Analytes In New Jersey Soils* (1997), studies prepared for NJDEP, Division of Science and Research, by BEM Systems, Inc.

[3] New Jersey Department of Environmental Protection (NJDEP), *N.J.A.C. 7:26E Technical Requirements for Site Remediation,* Table 4-2, November 2009 [Note that Table 4-2 has been deleted from the current version of N.J.A.C. 7:26E (May 7, 2012) and the updated *Historic Fill Technical Guidance* (April 2013) as NJDEP believed that the tables list of historic fill constituents was too restrictive].

[4] NJDEP Table 4-2 (PAHS & lead) and a summary of NJDEP records regarding investigations of properties in the vicinity of the Passaic River recognized to be located in areas of Historic Fill indicate that the following average/maximum (mg/kg) contamination levels of OU2 COCs exist in area Historic Fill - PAHs (1.91/160), lead (574/10,000), copper (11.2/1,200), and mercury (.21/3.7).

The levels of PAHs, copper, lead and mercury detected at the site in soils from the 2015 RI Report are presented in the table below (PAP-00074732, 95).

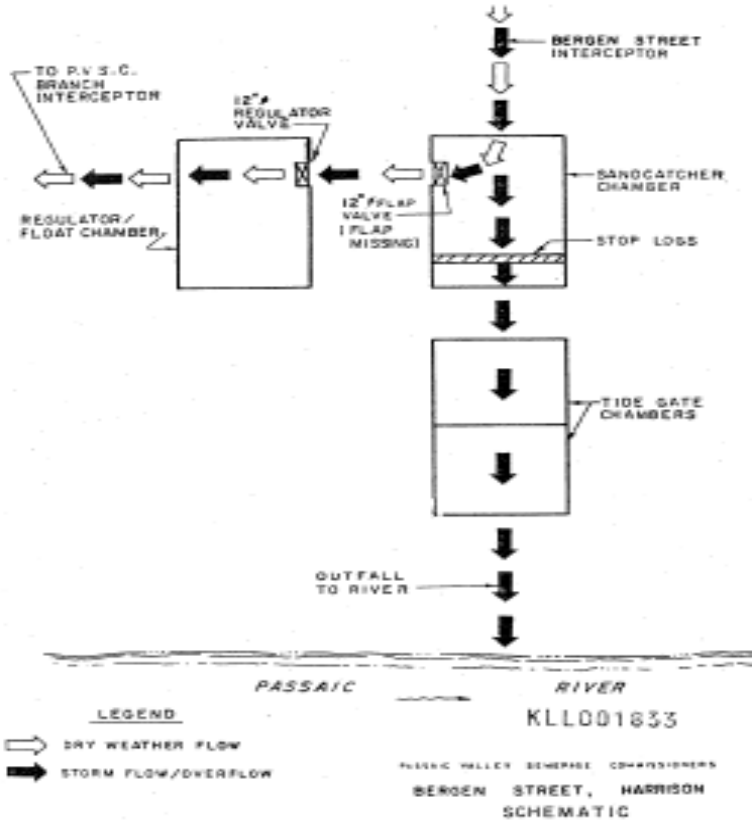
COCs Found in Onsite Soils	
COC	**Max Detected Concentration**
Lead	2,500 mg/kg
Copper	3,400 mg/kg
Mercury	650 mg/kg
Benzo(a)anthracene	380 mg/kg
Benzo(a)pyrene	290 mg/kg
Benzo(b)fluoranthene	360 mg/kg
Benzo(k)fluoranthene	Not Applicable
Dibenzo(a,h)anthracene	54 mg/kg
Indeno(1,2,3-cd)pyrene	150 mg/kg



5. COC Pathways

Approximately 75 percent of the 5th Street Facility is occupied by buildings, and the remaining area is paved. The 5th Street Facility is located approximately a half a mile inland from the Passaic River (PAP-00074239; PAS-00048608).

Sanitary and Storm Sewer



The 5th Street Facility was connected to the PVSC system in 1924 (PAP-00342795). The 2006 Extraction Form stated that the 5th Street Facility was located within the Bergen Street combined sewer outfall (CSO) district (PAS-00122715).

A figure showing the extent of the Bergen Street CSO as provided in the 2006 Extraction Form is presented below (PAS-00122716):

Historical PVSC reports stated that during wet weather events, a portion of the combined sewer and storm water flow from the Bergen Street CSO entered the main interceptor, with the balance overflowing the stop logs and being discharged through the outfall line into the Passaic River (PAS-00122716, 36). The approximate length of the combined sewers in the Bergen Street district was 9,200 linear feet, and the estimated combined flow needed to produce an overflow was 4.4 MGD (million gallons per day), according to the PVSC *Report Upon Overflow Analysis, Bergen Street, Harrison*, dated 1976. The Bergen Street CSO served 72 acres and had an average daily flow of 0.83 MGD during dry weather and 1.13 MGD during wet weather. Of the 9,200 linear feet of combined sewer, 5,800 linear feet are made up of 8 to 12-inch diameter pipes, while 3,400 linear feet are made up of 15 to 24- inch diameter pipes (PAS-00122740, 42).

A schematic of the Bergen Street CSO is presented below (PAS-00043989):

According to the 2015 RI Report, historical foundation plans showed floor drains from Building A that were connected to piping that led to sewers in 5th Street, 6th Street, and Sussex Street in Harrison. Floor drains were also observed in the Vo-Toys rawhide flavoring production area on the second floor of Building A, as well as the wash room, in the northwestern part of the warehouse area in Building B, and in the boiler room. Some floor drains were noted to be clogged; however, an attempt to clean out clogged drains was not successful. No evidence of discharge to the floor drains was observed (PAP-00074685).

In addition, there were seven catch basins located at the 5th Street Facility. The seven catch basins were located within the courtyard area between the buildings; one of these seven catch basins was situated on top of the former methanol and trichloroethene USTs and was removed during removal of these USTs, but the other six catch basins remain in place at the 5th Street Facility (PAP-00074685). No information regarding when the catch basins were installed could be located in the available file materials.

Waste Effluent Surveys from 1972 and 1975 reported effluent sample results for copper and lead; mercury was not reported in either survey. The waste Effluent Survey dated June 16, 1972 reported a result for copper only (<0.05 milligrams per liter [mg/L]). The Waste Effluent Survey dated October 2, 1975 reported copper detected at 0.097 parts per million (ppm) and lead detected at 0.010 ppm (PAS-00122717, 22, 32). Available references did not include specific effluent sampling/monitoring data reports.

Documented wastewater discharge volumes were as follows:

- According to a *PVSC Waste Effluent Survey*, dated June 16, 1972, for the 5th Street Facility in 1971, 184,985,038 gallons of waste water were discharged to the sanitary sewer. No volume was discharged to "Storm Sewer, River, or Ditch." No COCs were detected above detection limits in the effluent (PAS-00122721-22). The principal discharge was from 8 am to 4 pm, Monday through Friday. The average discharge rate was 791.43 gallons per minute over the sampling period (PAS-00122722).

- According to a *PVSC Waste Effluent Survey*, dated October 2, 1975, for the 5th Street Facility in 1974, 145,094,048 gallons of waste water were discharged to the sanitary sewer. No volume was discharged to "Storm Sewer, River, or Ditch" (PAS-00122729, 32).

- According to the *RCA Plant Facilities Survey*, dated December 31, 1975, the 5th Street Facility reported that sanitary wastewater was discharged at a rate of 173 gallons per minute, industrial wastewater at 209 gallons per minute, cooling water at 8 gallons per minute, and other discharges at 15 gallons per minute (PAP-00341688).

Direct Release

There is no information regarding direct release in the available file material.

Spills

As discussed in the 2015 RAWP and 2015 RI Report, during the 2012 UST removals, visual evidence of a release from the 550-gallon UST was observed in soil. NJDEP was notified and case No.12-06-06-0920-51 was assigned to the 550 gallon UST (contents unknown). Case No.12-06-07-1005-05 was assigned to the 3,000 gallon trichloroethene (TCE) UST when holes were noted in the UST (PAP-00074242; PAP-00074662).

6. Regulatory History/Enforcement Actions

Inspections

There is no information regarding inspections in the available file material.

Violations

There is no information regarding violations in the available file material.

Permits

The PVSC discharge permit number for the Bergen Street CSO is 015/H-006 (PAP-00211195).

According to a letter from RCA to EPA dated April 9, 1980, RCA submitted a signed Affidavit of Exemption from NPDES No. NJ0000230 for the Harrison Plant due to its closure in 1976 (PAP-00343675-77). No permits specific to the 5th Street Facility were included in the available file materials.

7. Response Actions

Characterization Activities

The following characterization activities have taken place at the facility:

- *Onsite Remedial Investigation Report, Vo-Toys Site*, dated January 28, 2015 (PAP-00074652);
- *Remedial Action Work Plan, Vo-Toys Site*, dated July 15, 2015 (PAP-00074230);
- *Mercury Data Summary Report, Vo-Toys Site*, dated October 2016 (PAP-00074833); and.
- *Building Assessment Summary Report, Vo-Toys Site*, dated January 2019 (PAP-00342910).

Sewer

According to the 2015 RAWP, sediments were removed from the catch basins and the catch basins were visually inspected. The catch basins were constructed of brick with pipe between them. The sidewalls had a cement coating, with the exception of CB-01, which had no cement on the sidewalls, and CB-04, which was constructed more recently and connected to the sewer system. Samples were collected at the catch basins, but the samples were not analyzed for COCs (analyzed for volatile organic compounds [VOCs] only) (PAP-00074248).

Soil

A remedial investigation was conducted between August 2013 and August 2014 to investigate ten AOCs (PAP-00074242-43). According to the 2015 RI Report, soil sampling included collection from multiple soil borings at multiple depths at each of the ten AOCs (PAP-00074749-56).

An area of approximately 750 square feet of PCB-impacted soil was identified between 0.5 feet bgs to 4.5 feet bgs at the former transformer substation (PAP-00074682). Concentrations ranged from non-detect to 2.12 milligrams per kilogram (mg/kg) (PAP-00074308). Floor scape samples from Building B and samples of wood and concrete debris were analyzed for PCBs and concentrations ranged from 0.8 to 736 mg/kg, but PCBs were not detected in soil samples beneath the building floors (PAP-00074684).

PAH-impacted soil was encountered to a depth of approximately 3 feet bgs in a small area stained with hydraulic oil at Building B (PAP-00074249). Concentrations were as high as 380 mg/kg for benzo(a)anthracene, 290 mg/kg for benzo(a)pyrene, 360 mg/kg for benzo(b)fluoranthene, 54 mg/kg for dibenzo(a,h)anthracene, and 150 mg/kg for indeno(1,2,3-cd)pyrene (PAP-00074732).

According to the 2016 Mercury Report, the maximum mercury concentration in soil at Building A was 7.3 mg/kg within an elevator pit at a depth of 5.5 feet bgs. The maximum mercury concentration in soil at Building B was 75 mg/kg at a depth of 4.2 feet bgs (PAP-00074857). The maximum mercury concentration in soil at Building C was 56 mg/kg within an elevator pit at a depth of 11.5 feet bgs (PAP-00074858).

Remedial Activities

According to 2015 RI Report and 2015 RAWP, one 550 gallon unknown content UST, two 1,500 gallon methanol USTs, and one 3,000 gallon TCE UST were removed between June and August 2012. Previously, in June 1998, a 10,000-gallon No. 2 fuel oil UST was decommissioned and NJDEP issued a “no further action” (NFA) letter for this decommissioning in February 1999 (PAP-00074242; PAP-00074662). Given the presence of fuel oil, water, and sand in the 550 gallon UST, it was determined to be an unknown petroleum hydrocarbon tank (PAP-00074254). Approximately 21 tons of soil excavated during the UST removals was disposed off-site (PAP-00074255).

The 2019 Building Assessment stated that lead paint abatement power washing was conducted at Building B and on the third floor of Building A in October 2015 (PAP-00342926).

The 2015 RAWP proposed removal of approximately 2,900 cubic yards of mercury impacted soil at AOC-A (Former Waste Oil UST) and removal of approximately 2,700 cubic yards of PCB impacted soil at AOC-J1 (Former Transformer Substation) (PAP-00074275). In addition, the removal of the entire floor slab of Building B, as well as three feet of soil below the slab, was proposed (PAP-00074276). According to the 2016 Mercury Report, this work began in December 2015 with saw cutting of the building

slabs, but work was stopped in January 2016 due to the mercury vapor survey results (PAP-00074845). The 2019 Building Assessment stated that a polyethylene sheeting cover was installed over the first-floor slab within Building B in June 2016 as a housekeeping measure until the RAWP implementation could be restarted (PAP-00342925).

Mercury vapor monitoring was conducted between January and July 2016 during site preparation for implementation of the RAWP. The maximum reading was 762 ug/m^3 recorded on June 22, 2016 on the first floor of Building B. The reading was from floor level and a visible bead of elemental mercury was present (PAP-00074851-52).

Several building materials were sampled for mercury in preparation for implementation of the RAWP. Maximum mercury concentrations were as follows:

- Concrete – 650 mg/kg (lab analysis of total mercury);
- Tar paper (part of wood subfloor) – 52 mg/kg (lab analysis of total mercury);
- Wood floor – 29,000 mg/kg (lab analysis of total mercury);
- Concrete columns – 655 mg/kg (x-ray fluorescence [XRF] reading);
- Concrete ceilings/beams – 1,156 mg/kg (XRF reading); and
- Masonry walls/windows – 1,099 mg/kg (XRF reading) (PAP-00074856).

During floor removal, elemental mercury was observed on the first floor of Building B (PAP-00074859).

According to the 2019 Building Assessment, building assessments were conducted at Buildings A, B, and C between June 26, 2018 and October 4, 2018 and included pre-investigation cleaning (bird guano and carcasses), mercury vapor and XRF surveys, building material sampling, and a subsurface structure assessment (PAP-00342928). Visible mercury was not observed at Building A (PAP-00342937). Visible mercury was observed in four locations within Building B: three locations were observed on the first floor and one location was observed on the third floor (PAP-00342945). Visible mercury was observed in six locations on the second and third floors within Building C during the building assessment activities (PAP-00342953).

Photographs of visible mercury observed at Buildings B and C are presented below (PAP-00342946 and 54):

Visible Mercury; Third Floor Building B

Visible Mercury; Second Floor Building C

Note:
Mercury observed on tar paper layer, between two layers of wood flooring.

The 2019 Building Assessment concluded that the presence of elemental mercury (based on the total mercury analytical results) within the various floor layers and walls of Buildings A, B, and C meant there may be multiple potential long-term mercury vapor sources that cannot be readily accessed and remediated. In addition, based on the distribution of mercury vapor readings in the buildings, the extent of building materials generating mercury vapors appears to be throughout the buildings, rather than concentrated within a single area of the buildings (PAP-00342942, 51, 60).

Tables of mercury results for samples of various building materials from Buildings A, B, and C are presented below (PAP-00342939, 49, 57):

Building A Building Material Sample Results Summary

Material	Total Mercury Range (mg/kg)	TCLP Mercury Range (mg/L)
Flooring – Concrete	ND–242	ND–0.0915
Flooring – Wood	0.093–207	ND–0.0755
Flooring – Cinder	8.26–1580	0.0005–0.019
Flooring – Debris	1160	0.0006
Flooring – Tar Paper	16.4–1800*	0.0092–3.355*
Roof – Tar Paper	ND–7.76	ND
Wall – Masonry and Concrete	ND–464	0.0035–0.955
Wall – Brick	0.287–58.4	ND
Wall – Wood	22.1	Not Analyzed
Column – Concrete	0.404–128	Not Analyzed
Window – Concrete	0.768	Not Analyzed

Notes:
*Highest reported concentration
ND not detected above the laboratory detection limit.

Building B Building Material Sample Results Summary

Material	Total Mercury Range (mg/kg)	TCLP Mercury Range (mg/L)
Flooring – Concrete	ND–1900	ND–0.1940
Flooring – Wood	0.274–2560	ND–2.764*
Flooring – Cinder	3.35–1420	0.0570–0.3535
Flooring – Tar Paper	2880*	1.900
Flooring – Expansion Joint	126	0.0112
Roof – Tar Paper	ND–1.94	ND
Wall – Masonry and Concrete	0.464–45.8	ND–0.0115
Wall – Brick	0.836–145	0.0011
Wall – Plaster and Parge	2.09–31.7	ND–0.0017
Wall – Wood	1.97–583	0.0180–0.0530
Column and Window – Concrete	1.00–59.2	Not Analyzed
Window – Wood	1.29–53.3	Not Analyzed

Notes:
*Highest reported concentration
ND not detected above the laboratory detection limit

Building C Building Material Sample Results Summary

Material	Total Mercury Range (mg/kg)	TCLP Mercury Range (mg/L)
Flooring – Concrete	0.032–418	ND–0.0228
Flooring – Wood	3.83–7310	0.0029–2.800
Flooring – Cinder	9.74	0.0011
Flooring – Tar Paper	182–10800*	0.7000–5.200*
Flooring – Linoleum	7.28–101	0.0021–0.0327
Wall – Brick	1.5–139	ND–0.0313
Wall – Parge and Miscellaneous	0.441–106	Not Analyzed
Column, Beam and Ceiling – Wood and Miscellaneous	0.256–929	0.0005–0.0955
Window – Brick	0.992–220	0.0032–0.0158
Window – Wood	0.395–38.5	ND–0.0035
Window – Masonry and Parge	1.57–184	0.0020–0.0408

Notes:
*Highest reported concentration
ND not detected above the laboratory detection limit.

8. Summary of Asserted Defenses

No legal defenses were identified in the available file material.

Diamond Alkali OU2 Allocation

ADR Confidential

Facility Data Report

GIVAUDAN FRAGRANCES CORPORATION

Facility Name, Address and Size: Givaudan Fragrances Corporation (Corp.) former Clifton Facility; Burton T. Bush, Inc.; The Givaudan Corporation; Givaudan-Delawanna; Givaudan Roure; Givaudan; Givaudan Fragrances Corp.; 125 Delawanna Avenue, Clifton, New Jersey; maximum build-out was approximately 31 acres; approximately 750 employees, three shifts per day during peak operations (PAS-00035827).

1. **Business Type:** Fine chemicals and fragrances (PAP-00345884)

2. **Time Period of Ownership/Operations**

Operator: 1924 to 1998
Owner: 1924 to 1998 (with the exception of a two-acre parcel on block 73.03, Lot 2.02 (PAP-00345330)

1924: Burton T. Bush, Inc. acquired the assets of the Antoine Chiris company on March 1, 1924, which occupied approximately 12.9 acres of the site. On August 14, 1924, Burton T. Bush, Inc. purchased an adjoining parcel also owned by Antoine Chiris. Givaudan Fragrances Corporation (Givaudan) purchased the assets of Burton T. Bush, Inc. on February 25, 1924 (PAS-00048099).

Givaudan acquired additional portions of the site through the purchase of adjoining and nearby parcels between 1924 and 1982 (PAS-00122997).

1963: The Roche Group acquired Givaudan in 1963 (PAS-00083378).

1991: The Roche Group spun-off its flavors and fragrances division, known worldwide as the Givaudan Roure companies. The Givaudan Roure companies operating in the United States prior to the spin-off were “Givaudan Roure Corporation,” the fragrance operating company, and “Givaudan Roure Flavors Corporation,” the flavors operating company. As a result of this spin-off, Givaudan Roure Corporation was merged into a new Delaware corporation, Givaudan Fragrances Corporation, in 1991 (PAP-00175934; PAS-00083378).

1998: Givaudan ceased manufacturing operations in June 1998. The cleaning of plant processing equipment continued until September 1998. All raw materials and chemicals were removed from the facility by the end of October 1998 and by December 1999 the plant was demolished (PAP-00178473; PAP-00175640).

1999: On March 8, 1999, Givaudan executed an Agreement of Sale with Reckson Morris Operating Partnership, LLP (Morris) (PAS-00033758; PAP-00168962; PAP-00175933).

2000: Givaudan Roure spun off as Givaudan in 2000 (PAS-00083378). The parent company is identified as Givaudan, SA, a Swiss corporation (PAS-00083377).

2000: Properties on the north side of Delawanna Avenue were sold in 2000. The 125 Delawanna Avenue property was sold in 2001. Givaudan retained ownership of a two-acre parcel located at 275 River Road in Clifton, New Jersey (PAS-00122997).

3. Operational History/COC Use and Presence at the Facility

General Operations

This subsection describes the operations that occurred at the site in general.

According to a *Request for Information Response Document*, dated July 9, 2004, in the 1940s and 1950s, Givaudan manufactured fine chemicals and fragrances referred to generally at that time as aromatic chemicals. From the 1960s through 1998, Givaudan also compounded and stored flavors and essences at Buildings 103 and 105, located on the north side of Delawanna Avenue. As stated in a letter from Givaudan counsel to NJDEP, dated July 26, 1983, there was no chemical synthesis in operations on the north side of Delawanna Avenue, which is where Buildings 103 and 105 were located (PAS-00083416). Feedstock raw materials consisted mostly of spices, essential oils, solvents, and acids. The raw materials were processed onsite using various processing and refining techniques such as compounding, mixing, distilling, purifying, drying, and autoclaving. The majority of finished goods were transferred into steel drums (liquid product) or bags (powdered product). The final products were either stored indoors or outside for collection by truck or railcar for distribution (PAS-00083342; PAS-00083350). According to a 1975 *Waste Effluent Survey*, the average production was listed as 15,000,000 pounds per year (PAS-00035827).

In addition, it is noted that according to a letter prepared by Givaudan, dated May 25, 1983, 2,4,5-trichlorophenol (2,4,5-TCP) was used as a raw material by Givaudan to prepare hexachlorophene (HCP), an antiseptic and germicidal agent employed in surgical soaps and pharmaceutical preparations. The product, also known as G-11®, was manufactured at the site beginning in the early 1940s starting with “relatively small quantities” and reaching an annual volume of a few million pounds (PAP-00174267). The early 1940s represented a time when HCP pilot studies were completed and small-scale production was done before ramping up to full production. As noted in the July 26, 1983 letter to NJDEP, Givaudan started industrial production of HCP in 1947 (PAS-00083414). Givaudan reported that the process to manufacture HCP involved the condensation of 2,4,5-TCP with formaldehyde. The only waste material resulting from the process was reportedly bentonite clay (PAP-00174267). The May 25, 1983, letter states that 331,000 pounds of 2,4,5-TCP were brought onsite and consumed onsite per year on average from 1978 through 1982 (PAP-00174269). According to a *NIOSH Dioxin Registry Site Visit Report of Givaudan Corporation*, prepared by the National Institute for Occupational Safety and Health, dated March 1990 (1990 NIOSH Report), Givaudan produced HCP from 1945 to May 1984 (PAP-00170545). As noted above, actual industrial production did not start until 1947 (PAS-00083414).

Finally, according to the 1990 NIOSH Report, Givaudan also produced 2,4,5-TCP for use in HCP production between 1945 and 1949 (PAP-00170545); however, dates for 2,4,5-TCP production vary in the available file material. According to an *Administrative Consent Order*, dated March 5, 1987, Givaudan manufactured 2,4,5-TCP at the site in 1947 and 1948 (PAS-00001808). Similarly, in a letter from Givaudan to the U.S. Environmental Protection Agency (U.S. EPA), dated October 26, 1983, Givaudan stated that they produced 2,4,5-TCP in 1948 and 1949 (PAS-00048133-34).

According to a letter from Givaudan to EPA, dated October 26, 1983, Givaudan records show the purchase of a “small amount” of “technical grade” 2,4,5-TCP from Dow Chemical for experimental purposes only. In 1948 and 1949, Givaudan developed its own method to manufacture technical grade 2,4,5-TCP, which was distilled into "pre-purified" 2,4,5-TCP and used in HCP manufacture. During this time, Givaudan manufactured approximately 305,000 pounds of pre-purified 2,4,5-TCP for on-site consumption in making HCP (PAS-00048134). Givaudan licensed the pre-purified 2,4,5-TCP method to Hooker in return for Hooker producing pre-purified 2,4,5-TCP (using Givaudan’s method) exclusively for sale to Givaudan. This agreement was in effect from 1949 until 1971 (PAP-00168592; PAS-00084000).

HCP and 2,4,5-TCP production are discussed further in a subsequent subsection below.

OU2 COCs Associated with Operations

This subsection lists the OU2 contaminants of concern (COCs) identified in the available file material as being associated with site operations, organized by date.

In 1980, the facility reported that copper chloride (3,360 pounds), copper chromite (960 pounds), lead acetate (240 pounds), naphthalene (46,080 pounds), “trichlorophenol” (360,000 pounds), diesel fuel (34,560 pounds), No. 2 fuel oil (45,120 pounds), and No. 6 fuel oil (21,646,800 pounds) were “transferred, refined, processed or stored” at the site at that time (PAP-00182118-19, 21).

According to a *Hazardous Waste Investigation,* dated June 5, 1980, it was ascertained that Givaudan was generating and storing polychlorinated biphenyls (PCBs) onsite. The report states that U.S. EPA inspectors had a report concerning Givaudan's PCB practices, but additional details were not available (PAP-00172019). An undated record titled “Exhibit No. 2, Transformers – PCB Oil-Filled Electrical Transformers” states that the facility historically had 30 PCB-containing transformers (PAP-00176671-72). According to a *Plans for Discharge Prevention, Containment, and Countermeasure (DPCC) and Discharge Cleanup and Removal (DCR)*, dated July 1982, Givaudan had 38 transformers in operation containing PCBs (PAP-00182108). According to a *Plans for Discharge Prevention, Containment, and Countermeasure (DPCC) and Discharge Cleanup and Removal (DCR)*, dated April 1985, Givaudan had 32 transformers in operation containing PCBs (PAP-00183371). Between 1975 and 1983, one drum of waste PCBs was shipped offsite for disposal (PAS-00083999).

According to a *Selected Substances Report,* dated August 13, 1980, cuprous chloride and copper chromite were used by the facility. The facility reported that cuprous chloride contained 64% copper, and that copper chromite contained 41% copper. The total amount of copper brought to the site at that time was reported as 1,997 pounds (PAP-00180568-70, 77).

According to a letter from Givaudan to U.S. EPA, dated October 26, 1983, although Givaudan manufactured HCP for many years, all the HCP manufactured and marketed by Givaudan was produced from pre-purified 2,4,5-TCP as opposed to technical grade 2,4,5-TCP. In 1948 and 1949, Givaudan also produced technical grade 2,4,5-TCP, which it purified (i.e. distilled) prior to use for the manufacture of HCP. HCP manufactured using technical grade 2,4,5-TCP may result in 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) contamination, while TCDD contamination "is not expected to occur" in the manufacture of HCP made with pre-purified 2,4,5-TCP, using a reaction which occurs at rather low temperatures and at an acidic pH (PAS-00048133-34; PAS-00033680). This is discussed further in a subsequent subsection below.

A *Community Right to Know Survey for 1995* identified copper chromate, creosote oil, No. 2 fuel oil, No. 6 fuel oil, naphthalene, and "trichlorophenol" as being present at the facility (PAS-00084216, 17, 25, 42, and 59).

Waste disposal records state the following OU2 COCs were disposed by the facility in 1999 during facility demolition:

- mercury (300 pounds)
- waste containing mercury (225 pounds)
- waste containing lead nitrate (200 pounds)
- mercury (600 pounds)
- PCBs (182 kilograms)
- mercury in manufactured articles (5 gallons) (PAS-00084328-34).

General Wastewater Disposal Practices

This subsection presents a description of wastewater disposal practices in general.

According to a *Documentation of Environmental Indicator Determination*, dated September 29, 2008, Givaudan and previous owners of the site used portions of the property for waste disposal including various cesspools, spent acid pits, a chemical landfill, and two chemical effluent pits. The document states a chemical sewer system was installed in the 1960s to collect and discharge process wastewater. However, Givaudan's December 3, 2009 Supplemental Response for Information confirmed that the date of original sewer installation was "prior to March 1946" and the reference to a sewer installation in the 1960s was incorrect (PAS-00033657-8). A sewer map dated March 1946 depicts the historical layout of the chemical sewer system at Givaudan (PAS-00084318). However, revisions were made to this drawing as late as 1969, as stated in the title block of the drawing. An aerial photograph from 1947 does not contain the infrastructure shown on the March 1946 drawing in the southern portion of the site

and an area of undisturbed land is present to the south of two surface impoundments observed in the eastern-central portion of the site (PAS-00048105-108). Based on this, it is unclear if the sewer line extending to the southernmost intersection with River Road where it connects to the City of Clifton sewer system existed in 1946. A 1949 photograph shows that a Spent Acid Pit and Wastewater Detention Pond appear as local depressions with defined embankments/berms as sidewalls. The photograph also states that a handwritten note from June 1949 states that according to a well driller, there are five wells at the facility and that waste is dumped into pits adjacent to the plant (PAS-00048109). In 1951, the Wastewater Detention Pond was no longer present and the area appeared to have been re-graded (PAS-00048474). A 1953 photograph shows the chemical sewer discharged to the City of Clifton sewer (PAS-00048114). In 1954, the Spent Acid Pit was no longer present (PAS-00048115).

According to a letter prepared by Givaudan, dated November 19, 1980, much of the operations included discharge of liquid waste, mostly aqueous, into a site sewer system which underwent pretreatment to adjust the pH before it was discharged to the Passaic Valley Sewage Commissioners (PVSC) system. Combustible waste, both hazardous and nonhazardous, after blending, was used as a noncommercial fuel to produce steam for the site's operation beginning in 1950 (PAP-00182084). The treatment system was in place at least as early as 1978 as it is referenced in regard to the sewer line break that occurred in the City of Clifton sewer line that was suspended along the bridge over the Third River (PAP-00170539).

Portions of the original sewer were abandoned and replaced in the mid-1980s, while other portions were retrofitted with the new chemical sewer that consisted of fiberglass-reinforced plastic pipe with secondary containment (PAP-00168962).

Wastewater disposal practices are discussed further in Section 5 below.

HCP Production

This subsection presents a description of the HCP (also known as G-11®) production process.

According to a letter prepared by legal counsel on behalf of Givaudan, dated July 26, 1983, production of HCP started in 1947 and continued in Buildings 58, 59, and 60. Additionally, in 1970, 1971, and 1972, HCP was produced in Building 9. Grinding and packaging of the final product was performed in Buildings 47, 75, and 75A (PAS-00083414; PAP-00176628; PAP-00170546). According to a letter prepared by Givaudan, dated May 25, 1983, the process to manufacture HCP involved the condensation of 2,4,5-TCP with formaldehyde (PAP-00174267). This is consistent with the 1990 NIOSH Report, which states that Givaudan produced HCP by the condensation of purified 2,4,5-TCP and paraformaldehyde in the presence of a sulfuric acid catalyst. A typical batch used 1,500 pounds of 2,4,5-TCP to produce 1,500 pounds of HCP (PAP-00170546-47). The only waste material resulting from the process was reportedly bentonite clay (PAP-00174267).

A schematic of the HCP production process is presented in **Appendix B-1**.

HCP production volume by year between 1947 and 1984 is presented in **Appendix A-1.**

According to *Givaudan Fragrances Corporation Supplemental Response to 104(e) Request for Information*, dated November 10, 2016, information from "published sources" stated that it was "highly unlikely" that Givaudan's HCP manufacturing process generated TCDD because it used acidic conditions and low temperatures in its process. It states that documents prepared by Dow Chemical (a 2,4,5-TCP supplier) state that TCDD may be produced during use of TCP under alkaline conditions and in temperatures greater than 100 degrees centigrade, which is distinct from the acid process employed at Givaudan (PAS-00048081).

Use of Technical Grade 2,4,5-TCP

This subsection describes documented handling and use of technical grade 2,4,5-TCP by Givaudan. This is relevant as, according to a letter from Givaudan to U.S. EPA, dated October 26, 1983, HCP manufactured using technical grade 2,4,5-TCP may result in TCDD contamination (PAS-00048133-34; PAS-00033680). As stated previously, according to a letter from Givaudan to EPA, dated October 26, 1983, Givaudan records show the purchase of a "small amount" of technical grade 2,4,5-TCP from Dow Chemical for experimental purposes only. From 1948 to 1949, Givaudan developed its own method to manufacture technical grade 2,4,5-TCP, which was distilled into pre-purified 2,4,5-TCP and used in HCP manufacture. During this time, Givaudan manufactured approximately 305,000 pounds of pre-purified 2,4,5-TCP for on-site consumption in making HCP (PAS-00048134).

According to a January 18, 1978, internal report prepared by Givaudan, samples of "Pure-Dow" and "Tech.-Dow" 2,4,5-TCP were analyzed for their suitability in making HCP (PAP-00168661). The report states that regardless of the method of analysis, it was apparent that Dow's "Tech. Grade of TCP" led to a HCP of much lower quality than either Dow's "TCP, Pure" or Celamerck's TCP (another 2,4,5-TCP supplier). It states that work was in progress to identify both the impurities in the "TCP, Tech." and in the HCP produced from it. In addition, it states that an attempt would be made to purify the "TCP, Tech." to the point where it could be used to produce an acceptable grade of HCP (PAP-00168665).

According to an internal document prepared by Givaudan, dated September 13, 1978, an internal report was prepared to put into record a proposed method by which it might be possible to make "acceptably pure" HCP from technical grade 2,4,5-TCP in existing equipment in Buildings 58-61 (PAP-00182221).

According to a December 8, 1978 internal report, three batches of HCP were produced in experimental runs, from 3,600 pounds of technical grade 2,4,5-TCP (94% purity) by a new process in plant equipment (PAP-00168698). The 2,4,5-TCP had a TCDD concentration of 8 parts per billion (ppb) (PAP-00168698-701).

According to a February 11, 1981 internal report, the plant had an inventory of 8,950 pounds of 2,4,5-TCP ("TCP, Tech grade"). Givaudan's production and marketing departments requested an investigation into the possibility of converting this 2,4,5-TCP into HCP (PAP-00168735).

According to a letter prepared by Givaudan, dated October 5, 1983, there are no records describing 2,4,5-TCP equipment decontamination procedures, but that isopropyl alcohol, soap solutions, caustic, and steam were used at the time to clean existing processing equipment. It was unknown if these practices were used in the early 1950s (PAP-00181273; PAS-00048135).

According to a letter from Givaudan to U.S. EPA, dated October 26, 1983, Givaudan stated that the following wastes in the following approximate quantities were generated during the 2,4,5-TCP purification step in 1948 and 1949: (1) 2-3 pound/pound of light fractions; and, (2) 0.2-0.3 pound/pound of still bottoms. It was believed that the light fractions and still bottoms were drummed; however, Givaudan had no records describing the methods of collection, storage, or disposal of such wastes, the names and addresses of haulers who might have hauled such wastes, or disposal site locations (PAS-00048135). Givaudan had no records from which the total amount of such wastes generated during the history of its facility could be determined, and no records from which the total amount of wastes generated in the manufacture of technical grade 2,4,5-TCP could be determined. Finally, Givaudan could not determine the dates of disposal, the amount disposed on each occasion, the waste hauler, or the disposal location (PAS-00048136).

2,4,5-TCP Production

This subsection describes Givaudan's manufacture of 2,4,5-TCP.

According to a letter prepared by legal counsel for Givaudan, dated July 26, 1983, 2,4,5-TCP production occurred in Buildings 54 and 60 in 1947, 1948, and 1949 (PAS-00083414). As discussed previously, the years during which Givaudan produced 2,4,5-TCP vary in the available records. According to the 1990 NIOSH Report, Givaudan produced 2,4,5-TCP for use in HCP production from 1945 to 1949 (PAP-00170545). According to an *Administrative Consent Order*, dated March 5, 1987, Givaudan manufactured 2,4,5-TCP in 1947 and 1948 (PAS-00001808). In a letter from Givaudan to the U.S. EPA, dated October 26, 1983, Givaudan stated that they produced 2,4,5-TCP in 1948 and 1949 (PAS-00048133-34).

A figure depicting the location of the 2,4,5-TCP production is presented in **Appendix B-2**.

According to an internal report on a U.S. EPA visit to the site, dated August 20, 1976, Givaudan stated that processing of 2,4,5-TCP was done in an acidic medium, and assured U.S. EPA that no TCDD was formed (PAS-00048294).

According to a letter from Givaudan to U.S. EPA, dated October 26, 1983, Givaudan manufactured technical grade 2,4,5-TCP, which was distilled into pre-purified 2,4,5-TCP and used in HCP manufacture. It states that 305,000 pounds of pre-purified 2,4,5-TCP was produced from technical grade 2,4,5-TCP. All technical grade 2,4,5-TCP was believed to have been used to produce pre-purified 2,4,5-TCP. The letter also notes that records show the purchase of a small amount of technical grade 2,4,5-TCP from Dow Chemical for experimental purposes only. Givaudan believes that technical grade 2,4,5-TCP was manufactured by the alkaline hydrolysis of 1,2,4,5-tetrachlorobenzene with caustic soda dissolved in ethylene glycol. After reaction, a batch was neutralized with muriatic acid and a sodium chloride precipitate was removed by filtration. The filtrate was diluted with water and the 2,4,5-TCP was extracted with benzene. The benzene extract was washed with water and the benzene was removed by distillation. Ethylene glycol was recovered by fractionation and was reused in the process (PAS-00048134-35, 254, and 256).

It is noted that according to the 1990 NIOSH Report, there are insufficient records to reconstruct the detailed process information for 2,4,5-TCP manufactured by Givaudan (PAP-00170546).

Documentation of TCDD Contamination Associated with HCP and 2,4,5-TCP Production

According to the 1990 NIOSH Report, TCDD is a contaminant found in 2,4,5-TCP and/or its sodium salt, which are raw materials used to produce chemical compounds such as 2,4,5-trichlorophenoxyacetic acid (2,4,5-T) and 2,2'-methylene-bis (3,4,6-trichlorophenol) hexachlorophene (HCP) (PAP-00170544).

The following is a discussion of documentation of TCDD contamination associated with HCP and 2,4,5-TCP production at the site:

- According to an undated file prepared by Givaudan, Givaudan's specification called for less than 10 ppb TCDD in 2,4,5-TCP. The file also reported that wastewater from the manufacture of HCP had been tested and no detectable quantities of TCDD were found (PAS-00033680).

- According to the 1990 NIOSH Report, Givaudan collected six HCP samples, each being a bulk from two to four lots of HCP, manufactured during the second half of 1969 and five samples of HCP from single, random lots produced in 1970. No detectable levels of TCDD were found in the 11 samples; the limit of detection ranged from 0.01 parts per million (ppm) to 0.03 ppm. An additional nine HCP samples were analyzed on October 27, 1970, and one sample on March 12, 1971. All 10 samples were non-detect for TCDD; the lower limit of detection ranged from 0.01 ppm to 0.1 ppm. Givaudan began monthly sampling of random lots of HCP for TCDD in January 1976. A total of 212 samples were analyzed between January 1976 and July 1977. It is reported that 90 percent of the HCP sample results contained less than 1.0 ppb TCDD. Seventeen samples had detectable concentrations of TCDD ranging from 1.5 ppb to 4.0 ppb with an arithmetic mean of 2.4 ppb (PAP-00170552-53).

- A sample data record, dated March 30, 1970 states that TCDD was detected at the following concentrations in various samples from the 2,4,5-TCP process at the Hooker facility:

  - Extractor feed sample: 3.0 ppm;
  - "Crude Charged to Still" sample: 12.0 ppm; and,
  - TCP Still Residue sample: 230 ppm.

  TCDD was not detected in a remaining nine samples, with detection limits ranging from 0.01 ppm to 1.0 ppm (PAS-00048146).

- According to an *Investigations Concerning the Possible Presence of 2,3,7,8-Tetrachlorodibenzo-p-Dioxin in Givaudan's Commercial Hexachlorophene*, dated August 4, 1970, 2,4,5-TCP was purchased by Givaudan exclusively from Hooker Chemical Corporation who manufactured a specially purified grade of 2,4,5-TCP for Givaudan. Hooker Chemical Corporation gave Givaudan "firm assurance" that their TCP did not contain any TCDD down to a level of less than 0.1 ppm (PAS-00048356). According to the report, in the samples of commercial HCP investigated, no TCDD could be detected at a limit of sensitivity of 0.03 ppm (PAS-00048357).

- Analysis of three samples of 2,4,5-TCP from Givaudan's supplier in 1976, ICMESA, by U.S. EPA, identified TCDD at concentrations ranging from <2.0 ppb to 1.9 ppb. According to the memorandum, the TCDD concentrations reported by Givaudan for these same three samples are 2.0 ppb, 2.0 ppb and 14.0 ppb. However, the memorandum further states that "[t]he results are quite consistent with those reported by Givaudan … and indicate a very low level of 2,3,7,8-tetrachlorodibenzo-p-dioxin" (PAS-00048297-98).

- An inter-office memorandum, dated June 29, 1976 stated that a quality control specification should be officially established at the site governing the TCDD content of the 2,4,5-TCP used in the production of G-11®. It states that the TCDD limits should have been set to less than 50 ppb (0.05 ppm) (PAP-00183316).

- A subsequent inter-office memorandum, dated July 1, 1976, stated "most lots" of Icmesa 2,4,5-TCP, for which Givaudan had analyses, had TCDD contents below 50 ppb. However, some had concentrations up to "about 80 ppb." The memorandum states that Dow's specification sheet for TCP stipulated less than 0.1 ppm or 100 ppb TCDD (PAP-00183315).

- According to an inter-office memorandum, dated December 6, 1976, the "official Finished Product Specifications for G-11" was a TCDD concentration of less than 20 ppb (PAP-00168618).

- A letter prepared by Givaudan, dated December 17, 1976 states that the limit for TCDD in their final HCP had "recently been established at a value of 20 ppb maximum. This is a value that could possibly exist if 10 ppb of TCDD were in the T.C.P." (PAP-00168620).

- According to an internal report prepared by Givaudan, dated November 19, 1976, due to quality issues associated with Dow 2,4,5-TCP, Givaudan requested a lot of G-11® be analyzed by Dow. It was found to contain less than 1 ppb TCDD. This same material was analyzed by Givaudan and found to contain 15 ppb to 20 ppb TCDD after repetitive analyses (PAP-00169584).

- According to an inter-office memorandum, dated June 13, 1977, Dow committed to providing Givaudan with TCP with a maximum TCDD concentration of 0.01 ppm (PAP-00168658).

- According to an affidavit of the Givaudan Manager of Quality Assurance, the Quality Control Department began this routine analysis for TCDD content in HCP in May 1977. According to the document, review of the results since this laboratory began performing TCDD analysis stated that, prior to June 1978 the majority of samples analyzed were found to be less than 1.0 ppb with several samples (three to four) being below 4.0 ppb. It states that in many instances, the higher TCDD levels were attributed to interferences in the analysis which probably could be eliminated through reanalysis or additional sample clean-up. However, since the TCDD limit at that time was established at 10 ppb, these samples were not reevaluated. All samples evaluated after June 1978 were found to contain less than 1.0 ppb TCDD (PAS-00084004).

- According to an internal Givaudan letter, dated March 9, 1978, although the TCDD specification for pre-purified Dow TCP was less than 10 ppb, Givaudan believed that it consistently contained less than 1 ppb TCDD. Based on this, Givaudan personnel requested that Celamerck agree to provide TCP with less than 5 ppb TCDD. If this was not possible, Givaudan insisted that Celamerck provide the exact TCDD analysis for each batch or lot with a maximum of 10 ppb, noting that Celamerck proposed a maximum TCDD concentration of 15 ppb (PAS-00048194).

- According to a *NIOSH TCDD Registry Site Visit Report of Givaudan Corporation*, dated December 1990, eight samples of process by-products were collected in May 1983. The samples were analyzed for TCDD. Seven of the samples were non-detect for TCDD, with the lower limit of detection ranging from 0.1 ppb to 1.0 ppb. For the eighth sample, 150 nanograms per bottle was reported; however, no sample volume or concentration was given. In addition, three HCP process samples from Givaudan were analyzed by U.S. EPA as part of an analytical methods development study of process wastes and related materials from plants with potential TCDD contamination. No TCDD in excess of the minimum detectable concentrations, which ranged between 50 parts per trillion (ppt) to 140 ppt, was found in the Givaudan samples (PAS-00033689).

- Drums of HCP sampled in 1983 had concentrations of TCDD ranging from 16.1 ppt to 21.8 ppt, where the compendial limit was 50 ppb (PAS-00048299-302).

- According to a letter prepared by Givaudan, dated May 25, 1983, the only waste material resulting from the HCP production was reportedly bentonite clay. Analysis of the clay showed "some G-11," "about 1.0% Trichlorophenol," and no TCDD at the lowest detectable limit of 1.0 ppb. Process water was also analyzed for TCDD and found to be below detectable limits of 1 ppb (PAP-00174267-68).

- According to an interoffice memorandum, dated June 22, 1983, review of laboratory results stated that, prior to June 1978, the majority of samples of HCP analyzed were found to contain less than 1.0 ppb TCDD with several samples (three to four) having a concentration below 4.0 ppb. In many instances, the higher TCDD levels were attributed to interferences in the analysis "which probably could be eliminated through reanalysis or additional sample clean-up." However, since the TCDD limit at that time was established at 10 ppb, these samples were not reevaluated. All samples evaluated after June 1978 were found to contain less than 1.0 ppb TCDD (PAS-00048373).

- The 1990 NIOSH Report states that there was insufficient process information to comment on the potential degree of TCDD contamination of the 2,4,5-TCP. It states that the process was reported to have a distillation step, which would have removed "some or essentially all" of the TCDD. It goes on to state that the amount of TCDD contamination of the 2,4,5-TCP that would be carried through the subsequent production of HCP would depend on process operating conditions and the degree of purification that took place in the 2,4,5-TCP process, but that it was unlikely that any TCDD was formed during the production of HCP due to the process operating conditions. After 1949, with the closure of the on-site 2,4,5-TCP process, exposure to TCDD would have been limited to the amount of TCDD contamination in 2,4,5-TCP Givaudan purchased from outside suppliers (PAP-00170549).

A table presenting TCDD concentrations detected in 2,4,5-TCP feedstock from 1970 to 1983 is presented in **Appendix A-2**. A table presenting TCDD concentrations detected in HCP from 1970 to 1979 is presented in **Appendix A-3**.

4. Identified COCs

- PCBs (used, detected)
- Dioxins / Furans (generated, detected)
- PAHs (used, detected)
- Copper (used, detected)
- Lead (used, detected)
- Mercury (used, detected)

PCBs

According to a *Hazardous Waste Investigation,* dated June 5, 1980, it was ascertained that Givaudan was generating and storing PCBs onsite. The report states that U.S. EPA inspectors had a report concerning Givaudan's PCB practices, but additional details were not available (PAP-00172019). An undated record titled "Exhibit No. 2, Transformers – PCB Oil-Filled Electrical Transformers" states that the facility historically had 30 PCB-containing transformers (PAP-00176671-72). According to a *Plans for*

Discharge Prevention, Containment, and Countermeasure (DPCC) and Discharge Cleanup and Removal (DCR), dated July 1982, Givaudan had 38 transformers in operation containing PCBs (PAP-00182108). According to a *Plans for Discharge Prevention, Containment, and Countermeasure (DPCC) and Discharge Cleanup and Removal (DCR)*, dated April 1985, Givaudan had 32 transformers in operation containing PCBs (PAP-00183371).

According to a *Remedial Action Work Plan for Soils*, dated April 2000, surface soil samples were collected from eight locations surrounding two transformer pads that did not have secondary containment, which were located in the vicinity of Building 99. In addition, surface soil samples were collected from immediately below the asphalt in front of the doorways to two electrical switching stations. No PCBs were detected (PAP-00175777-78).

Dioxins / Furans

As discussed in Section 3 above, TCDD contamination was identified at the site associated with HCP and 2,4,5-TCP production.

According to Givaudan's November 10, 2016, Supplemental Response to 104(e) Request for Information, documentation states that prior to 1947, waste was discharged onsite into cesspools and pits. Further, a 1951 Givaudan memo discusses the recovery of HCP from the former waste pits, which also supports the facility's practice of discharging and handling its process waste water from HCP on site before the plant connected to the city sewer line on River Road by 1951-52 (PAS-00048078-79). According to an inter-office memorandum prepared by Givaudan, dated September 14, 1982, it was necessary to capture all discharges before they entered the central sewer and to remove any contaminants that were present. In order to do this, the memorandum states that all "dumps" from equipment/leaks and wash waters must be collected. It went on to propose that G-11® (HCP) grinding be moved to Building 58 in order to consolidate operations, and a pipe within a trench on each side of the Buildings 58, 59, and 60 be constructed. The trench was to channel all leaks and floor washes, and the pipe was to conduct all equipment dumps and washes through a closed pipe. Contaminants would be removed and drummed for disposal, materials dissolved in water would be sent to a steam still for separation, and water would be sent to the chemical sewer when tested and accepted (PAP-00181773). Note: No discharge monitoring data from this time period was identified in the available file material.

According to an *Administrative Consent Order*, dated March 5, 1987, pursuant to New Jersey Pollutant Discharge Elimination System (NJPDES) Permit (No. NJ0099414), effective October 1, 1982, Givaudan discharged industrial wastewater into the PVSC system and analyzed that wastewater discharge for TCDD contamination on a monthly basis at a detection level at or below 1 ppb. The document states that no TCDD contamination had been detected in any of the industrial wastewater discharge from the site (PAS-00001812; PAP-00173361). Note: Related discharge monitoring reports were not identified in the available file material.

A *Discharge Surveillance Report,* prepared by the New Jersey Department of Environmental Protection (NJDEP), dated August 25, 1989, states that Outfall 001 effluent was monitored for TCDD. The concentration reported was 1 ppt (PAP-00170514). Note: Additional related discharge monitoring reports were not identified in the available file material.

According to a *NIOSH TCDD Registry Site Visit Report of Givaudan Corporation*, dated December 1990, samples of the sanitary sewer discharge from the facility were collected in October, November, and December of 1982 and analyzed for TCDD. All three samples were below the 10 ppb limit of detection (PAS-00033689).

According to a letter from Tierra Solutions, Inc. to NJDEP, dated October 20, 2008, sediment samples collected from the stormwater pond had a TCDD detection of 214 ppb (PAP-00179607). Note: The source of this data is unclear and additional details regarding this data were not identified in the referenced document. According to a *Status Report, Remedial Investigation, Dioxin Contamination Non-Process Area*, dated November 15, 1984, in July 1984, a composite of the liquid and a bottom sediment sample were obtained from the stormwater pond for analysis as part of the remedial investigation for TCDD contamination at the site. No TCDD “was present” in the pond sediment sample nor in liquid from the pond itself (PAP-00183454-58). Concentration data were not included in the referenced document.

Givaudan entered into an *Administrative Consent Order* with NJDEP on March 5, 1987; an *Amended Administrative Consent Order TCDD* was signed on February 16, 1988. These consent orders required the investigation and remediation of TCDD contamination in soil (PAS-00001767-73). It is noted that NJDEP originally established a 1.0 ppb action level and 7.0 ppb cleanup goal for TCDD; a site-specific cleanup goal of 20.0 ppb was established in the early 1990s (PAP-00179704). Subsequently, a remedial action objective of 2.0 ppb for TCDD-impacted soils from zero to 12 feet below ground surface (bgs) was established in 1999 (PAP-00180350).

The *Draft TCDD Feasibility Study Report*, dated March 16, 1992 summarized all historical data TCDD collected for soil between 1983 and 1990, including: eight soil samples had been collected at the site with concentrations greater than the site-specific cleanup goal of 20.0 ppb TCDD; concentrations of these eight samples ranged from 22 ppb to a maximum of 200 ppb. Sample depths ranged from zero to 12 inches bgs (PAP-00179717-18). Numerous additional samples which were collected had concentrations greater than 1 ppb but less than 20 ppb, as discussed in Section 7 below.

PAHs

In 1980, the facility reported naphthalene (46,080 pounds), diesel fuel (34,560 pounds), No. 2 fuel oil (45,120 pounds), and No. 6 fuel oil (21,646,800 pounds) were “transferred, refined, processed or stored” at the site at that time (PAP-00182118-19, 21).

According to a NJDEP *Discharge Surveillance Report*, dated November 15, 1991, in June, July, and September 1991, the concentration of petroleum hydrocarbons detected at Outfall 001 exceeded the permit limit of 100 milligrams per liter (mg/L). The maximum detected concentration was 837 mg/L (PAP-00170853-55; PAP-00170938).

According to a *Plans for Discharge Prevention, Containment and Countermeasure (DPCC) and Discharge Cleanup and Removal (DCR)*, dated April 1985, surface water run-off from the chemical plant was discharged to an on-site stormwater pond (PAP-00183367). A sample of stormwater pond sludge had a fuel oil concentration of 1,700 milligrams per kilogram (mg/kg) (PAP-00181906-08).

According to a *Remedial Action Report for Sewer Decommissioning*, dated February 2000, over 11,000 lineal feet of chemical sewer and storm sewer line were removed from the site for disposal at off-site disposal facilities. Post-excavation samples were collected from the sewer line excavations at the frequency of one per 30 linear feet from the sidewall of the excavation, and one per 50 linear feet from the base of the excavation (PAS-00033755, 87). High molecular weight polynuclear aromatic hydrocarbons (PAHs) were detected in post-excavation soil samples collected along the sewer lines (PAS-00033862-84).

According to a *Remedial Action Report for Sewer Decommissioning*, dated February 2000, high molecular weight PAHs were detected in a sample collected from the stormwater pond in 1998/1999 (PAS-00033887-88).

Copper

It is noted that the southern part of the Givaudan site previously was occupied by National Anoid, whose operations related to the cleaning and melting of copper wire into copper ingots. The plant burned down in 1926 (PAS-00083993).

According to a PVSC *Heavy Metals Source Determination Study*, dated April 1980, Givaudan contributed 5.661 pounds of copper per day to the PVSC system (PAS-00035841). Copper data reported in wastewater discharge monitoring reports are summarized in **Appendix A-6**. As shown in Appendix A-6, the concentration of copper in wastewater in November 1994 (0.105 mg/L and 0.188 mg/L) exceeded the permit limit of 0.092 mg/L; otherwise, none of the reported detections were above the discharge limit of the permit.

According to a *Plans for Discharge Prevention, Containment and Countermeasure (DPCC) and Discharge Cleanup and Removal (DCR)*, dated April 1985, surface water run-off from the chemical plant was discharged to an on-site stormwater pond (PAP-00183367). A sample collected from the stormwater runoff collection pond collected in 1982 contained copper at a concentration of 0.17 mg/L (PAP-00181896, 98). A sample of pond sludge had a copper concentration of 490 mg/kg (PAP-00181906-08).

According to a *Remedial Action Report for Sewer Decommissioning*, dated February 2000, over 11,000 lineal feet of chemical sewer and storm sewer line were removed from the site for disposal at off-site disposal facilities. Post-excavation samples were

collected from the sewer line excavations at the frequency of one per 30 linear feet from the sidewall of the excavation, and one per 50 linear feet from the base of the excavation (PAS-00033755, 87). Copper concentrations detected in post-excavation soil samples along the sewer lines ranged from 660 mg/kg to 53,000 mg/kg (PAS-00033862-84).

According to a *Remedial Action Report for Sewer Decommissioning*, dated February 2000, copper (1,100 mg/kg) was detected in a sample collected from the stormwater pond in 1998/1999 (PAS-00033887).

Lead

According to a PVSC *Heavy Metals Source Determination Study*, dated April 1980, Givaudan contributed 17.039 pounds of lead per day to the PVSC system (PAS-00035841). Lead data reported in wastewater discharge monitoring reports are summarized in **Appendix A-6**. As shown in Appendix A-6, the concentration of lead in wastewater in November 1994 (0.464 mg/L) exceeded the permit limit of 0.029 mg/L; otherwise, none of the reported detections were above the discharge limit of the permit.

According to a *Plans for Discharge Prevention, Containment and Countermeasure (DPCC) and Discharge Cleanup and Removal (DCR)*, dated April 1985, surface water run-off from the chemical plant was discharged to an on-site stormwater pond (PAP-00183367). A sample collected from the stormwater runoff collection pond collected in 1982 contained lead at a concentration of 2.01 mg/L (PAP-00181896, 98).

According to a *Remedial Action Report for Sewer Decommissioning*, dated February 2000, over 11,000 lineal feet of chemical sewer and storm sewer line were removed from the site for disposal at off-site disposal facilities. Post-excavation samples were collected from the sewer line excavations at the frequency of one per 30 linear feet from the sidewall of the excavation, and one per 50 linear feet from the base of the excavation (PAS-00033755, 87). Lead concentrations detected in post-excavation soil samples along the sewer lines ranged from 440 mg/kg to 92,000 mg/kg (PAS-00033862-84). In addition to sewer lines, excavation was conducted in areas of subsurface features identified during sewer decommissioning activities such as cesspools and tanks (PAS-00033781-82). In the area of the former cesspools, lead was detected at a concentration of 19,000 mg/kg (PAS-00033854, 85).

According to a *Remedial Action Report for Sewer Decommissioning*, dated February 2000, lead (1,500 mg/kg) was detected in a sample collected from the stormwater pond in 1998/1999 (PAS-00033887-88).

Mercury

According to a PVSC *Heavy Metals Source Determination Study*, dated April 1980, Givaudan contributed 0.0947 pounds of mercury per day to the PVSC system (PAS-00035841). Mercury data reported in wastewater discharge monitoring reports are summarized in **Appendix A-6**. As shown in Appendix A-6, none of the reported detections were above the discharge limit of the permit.

According to a *Plans for Discharge Prevention, Containment and Countermeasure (DPCC) and Discharge Cleanup and Removal (DCR)*, dated April 1985, surface water run-off from the chemical plant was discharged to an on-site stormwater pond (PAP-00183367). A sample of stormwater pond sludge had a mercury concentration of 0.24 mg/kg (PAP-00181906-08).

According to a *Remedial Action Report for Sewer Decommissioning*, dated February 2000, over 11,000 lineal feet of chemical sewer and storm sewer line were removed from the site for disposal at off-site disposal facilities. Post-excavation samples were collected from the sewer line excavations at the frequency of one per 30 linear feet from the sidewall of the excavation, and one per 50 linear feet from the base of the excavation (PAS-00033755, 87). Mercury concentrations detected in post-excavation soil samples along the sewer lines ranged from 15 mg/kg to 130 mg/kg (PAS-00033862-84).

According to a *Remedial Action Report for Sewer Decommissioning*, dated February 2000, mercury (23 mg/kg) was detected in a sample collected from the stormwater pond in 1998/1999 (PAS-00033887-88).

Historic Fill

The Allocation Team has determined that the facility site is partially located on regional Historic Fill as designated by the NJDEP.[1]

NJDEP has established that Historic Fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 COCs: PAHs, lead, copper, and mercury.[2] Accordingly, NJDEP technical requirements for property containing Historic Fill requires sampling for the U.S. EPA Target Compound List for PAHs and Target Analyte List for metals, including lead, copper, mercury, and the OU2 PAH COCs.[3] PAHs, lead, copper, and mercury are recognized by NJDEP to be constituents of Historic Fill at varying levels, not atypically at or exceeding residential soil standards.[4]

[2] *Characterization of Ambient Levels of Selected Metals and cPAHs In New Jersey Soils* (2002) and *Characterization of Ambient Levels of Selected Metals and Other Analytes In New Jersey Soils* (1997), studies prepared for NJDEP, Division of Science and Research, by BEM Systems, Inc.

[3] New Jersey Department of Environmental Protection (NJDEP), *N.J.A.C. 7:26E Technical Requirements for Site Remediation,* Table 4-2, November 2009 [Note that Table 4-2 has been deleted from the current version of N.J.A.C. 7:26E (May 7, 2012) and the updated *Historic Fill Technical Guidance* (April 2013) as NJDEP believed that the tables list of historic fill constituents was too restrictive].

[4] NJDEP Table 4-2 (PAHs and lead) and a summary of NJDEP records regarding investigations of properties in the vicinity of the Passaic River recognized to be located in areas of Historic Fill indicate that the following average/maximum (mg/kg) contamination levels of OU2 COCs exist in area Historic Fill: PAHs (1.91/160), lead (574/10,000), copper (11.2/1,200), and mercury (0.21/3.7).

According to a *Geotechnical Investigation*, dated July 2, 1981, a review of a 1955 topographic map of the site showed that a difference in ground surface elevation of approximately 20 feet previously existed across the site. At the time of the report, the difference in elevation at the site was approximately eight feet, which led to the conclusion that portions of the site were filled since 1955. It appeared that the fill may have been placed between about 1955 and 1960, possibly during the construction of nearby Route 3 (PAP-00181329).

The levels of PAHs, copper, lead and mercury detected at the site in soils are presented in the table below (PAS-00033862-84, 86).

COCs Found in Onsite Excavation Soils		
COC	**Max Detected Concentration**	**Location**
Lead	92,000 mg/kg	Post-Excavation taken along stormwater sewers (PAS-00033852)
Copper	53,004 mg/kg	Former cesspools (PAS-00033854)
Mercury	130 mg/kg	Post-Excavation taken along stormwater sewers (PAS-00033852)
Benzo(a)anthracene	49 mg/kg	Excavation FYI samples (PAS-00033858)
Benzo(a)pyrene	79 mg/kg	Excavation FYI samples (PAS-00033858)
Benzo(b)fluoranthene	29 mg/kg	Post-Excavation bottom samples (PAS-0003384)
Benzo(k)fluoranthene	120 mg/kg	Excavation FYI samples (PAS-00033858)
Dibenzo(a,h)anthracene	14 mg/kg	Excavation FYI samples (PAS-00033858)
Indeno(1,2,3-cd)pyrene	25 mg/kg	Excavation FYI samples (PAS-00033858)

5. COC Pathways

According to an *Administrative Consent Order*, dated March 5, 1987, the Passaic River is located approximately one-third of a mile southeast of the site (PAS-00001783). According to a *Givaudan Fragrances Corporation Supplemental Response to 104(e) Request for Information*, dated November 10, 2016, there is no evidence of a defined drainage swale either on or off the property to the Passaic River in any of historical aerial photographs (PAS-00048077).

Sanitary and Storm Sewer

Process Wastewater Discharges

According to a *Givaudan Fragrances Corporation Supplemental Response to 104(e) Request for Information*, dated November 10, 2016, the site was connected to the Clifton City sewer system as early as 1926 and no later than 1951/1952. In the early 1950s, the chemical sewer system was connected to the City of Clifton sewer system on River Road. The earliest engineering drawing referencing a plant sewer system for the site was originally dated 1946 and contains a revision through 1969. Until 1946, the documentation stated some sanitary wastewater and process wastewater generated by

the plant was disposed of in cesspools and pits, with some waste used as supplemental fuel in the plant boiler (PAS-00048079-80, 114). A *Request for Information Response Document*, dated July 9, 2004, also states that up until approximately the 1950s on-site sanitary wastewater from Buildings 2, 3, 4, 5, and 6 was discharged to septic cesspools located onsite (PAS-00083366). The installation of a dedicated plant sewer system in 1946 and the appearance of a spent acid pit in 1947, followed by the development of a third surface water impoundment by 1949, supported the conclusion that plant process wastewater was initially handled onsite. The document goes on to state that an on-site stormwater management system was evident by 1947 and was supported by the appearance of a stormwater pond and a stormwater conveyance system, which remained in use until the plant closed (PAS-00048079).

According to the *Request for Information Response Document*, dated July 9, 2004, during the 1940/1950 timeframe, Givaudan had two sewer systems in place:

(1) Sanitary sewers collected sanitary wastewater via six-inch vitrified clay pipelines connected to an eight-inch vitrified clay main sanitary sewer line located on Delawanna Avenue. The six-inch vitrified clay sanitary sewer line collected sanitary sewage from Buildings 3, 4, 5, 6, 12, 34, 36, and 21 and directed the sanitary sewage to the City of Clifton via Delawanna Avenue.

(2) Industrial wastewater was collected by a chemical sewer and directed south to River Road for treatment by the City of Clifton. The chemical sewer collected wastewater from the manufacturing buildings. Wastewater was collected from floor drains and trenches constructed within concrete or tiled flooring. The drains consisted of vitrified clay pipe of various sizes that led to a main 18-inch vitrified clay chemical sewer that ran directly south and then southwest towards River Road (PAS-00083349).

According to the *Givaudan Fragrances Corporation Supplemental Response to 104(e) Request for Information*, dated November 10, 2016, the connection of the plant process waste stream (subsequently identified as Outfall 001) to the River Road sewer system appeared to have been made no later than 1951/1952, and perhaps several years earlier (PAS-00048080).

A *Remedial Action Report for Sewer Decommissioning*, dated February 2000, states that in the mid-1980s, portions of the original chemical sewer were abandoned and replaced, or retrofitted with the new chemical sewer consisting of secondary contained fiberglass reinforced plastic pipe. In addition, as manufacturing operations at the facility were altered or shut down, portions of the old chemical sewer were abandoned and not replaced (PAS-00033773; PAS-00083367-68).

In addition, Givaudan constructed a primary wastewater pretreatment plant in the mid-1980s to treat industrial wastewater that was being discharged to the PVSC system. Prior to construction of the pretreatment system, Givaudan discharged industrial wastewater directly to PVSC without pretreatment, pursuant to a user's fee arrangement with PVSC (PAS-00083365-66). According to a letter prepared by Givaudan, dated April 6, 1978, several steps were taken to eliminate the reoccurrence of pipe corrosion

including the repair of liming equipment and the purchase of additional equipment to better control the pH of effluent (PAP-00170539).

According to a letter prepared by Givaudan, dated September 26, 1988, the only wastewater pretreatment conducted was pH correction and an oil-water separation to comply with PVSC permit requirements. The wastewater was not physically or chemically treated to reduce suspended solids using a clarifier, settling tank or other means (PAP-00168740).

It appears that prior to the 1980s, contaminated wastewater may have been discharged to the PVSC system directly. According to an inter-office memorandum prepared by Givaudan, dated September 14, 1982, it was necessary to capture all discharges before they entered the central sewer and to remove any contaminants that were present. In order to do this, the memorandum states that all "dumps" from equipment, leaks and wash waters must be collected. It went on to propose that G-11® (HCP) grinding be moved to Building 58 in order to consolidate operation, and a pipe within a trench on each side of the Buildings 58, 59, and 60 be constructed. The trench was to channel all leaks and floor washes, and the pipe was to conduct all equipment dumps and washes through a closed pipe. Contaminants would be removed and drummed for disposal, materials dissolved in water would be sent to a steam still for separation, and water would be sent to the chemical sewer when tested and accepted (PAP-00181773).

The facility first received a NJPDES permit (No. NJ0099414) from NJDEP to discharge industrial wastewater to the PVSC system on October 1, 1982, effective through September 30, 1987 (PAP-00173361). The permit identified three outfalls (001, 002, 003) through which the site was allowed to discharge wastewater. Monitoring requirements included that for TCDD at Outfall 001. The TCDD discharge limit was "below method detection limit" (PAP-00173364).

According to historical aerial photograph notes, Outfall 002 discharged to the City of Clifton sewer line located on Delawanna Avenue which connected directly to the PVSC system. This line is believed to have been used primarily for sanitary waste water discharge (PAS-00048106, 114). Outfall 003 received "non-regulated wastewaters" from the cafeteria, laboratory, Building 105, Building 106 (used for storage of furniture and unused equipment), and Building 102 (used for packaging of printed material) (PAS-00036518).

The first record of a PVSC Sewer Connection Permit identified in the available file material following the NJPDES permit was a PVSC Sewer Connection Permit (No. 03401024) effective beginning March 17, 1991 (PAP-00170725). It is noted that a fourth outfall was identified in this permit (PAP-00170732). Details of this permit and other related records (and subsequent permits) are presented in the table below, which summarizes wastewater sources (or outfall descriptions), monitoring requirements for OU2 COCs, and discharge volumes for each outfall, as available.

It is noted that according to a letter prepared by Givaudan, dated September 12, 1995, Outfalls 003 and 004 were combined into one outfall (003) (PAP-00172207).

Summary of PVSC Outfall Information by Reference				
Reference	**Outfall**	**Wastewater Source/Description**	**Monitoring Requirements**	**Discharge Volume**
NJPDES Permit (No. NJ0099414), effective October 1, 1982, to September 30, 1987	001	Not documented (identified as "River Road outlet")	TCDD = below method detection limit	Not documented
	002	Building 103	None	Not documented
	003	Building 105	None	Not documented
Plans for Discharge Prevention, Containment and Countermeasure (DPCC) and Discharge Cleanup and Removal (DCR), dated July 1982 (PAP-00182102-03)	001	Effluent from chemical plant and sanitary waste	Not documented	30 million gallons/month
	002	Waste from sanitary and cleaning sources	Not documented	20,000 gallons/month
	003	Waste from office and non-chemical laboratory Building 100, also Flavor Manufacturing Center	Not documented	one million gallons/month
PVSC Sewer Connection Permit #03401024, effective March 17, 1991 to March 17, 1996 (PAP-00170725, 29-32)	001	River Road	None	Not documented
	002	Building 103	None	Not documented
	003	Building 105	None	Not documented
	004	Buildings 34, 36, and 72	None	Not documented
Letter prepared by Givaudan, dated June 15, 1993 (PAP-00171801, 06)	001	Aroma chemical manufacturing operation	Lead = 690 microgram per liter (µg/L) (maximum per day)	Not documented
	002	Fragrance compounding	Not documented	Not documented
	003	Sanitary wastewater, previously flavor operations	Not documented	Not documented
	004	Sanitary wastewater	Not documented	Not documented
Application for a Sewer Connection Permit, dated March 1996 (PAP-00172478)	001	River Road	Not documented	302,400 gallons/day
	002	Building 103	Not documented	26,100 gallons/day
	003	Buildings 100 and 102	Not documented	71,600 gallons/day
	004	Sanitary wastewater to Delawanna Ave.	Not documented	21,600 gallons/day
PVSC Sewer Connection Permit #03401023, effective March 17, 1996 to March 17, 2001 (PAP-00172521, 23-28, 30)	001	River Road	Copper = 3.02 mg/L Mercury = 0.08 mg/L (monthly averages) Lead = 690 µg/L (maximum per day)	Not documented
	002	Building 103	Copper = 3.02 mg/L Lead = 0.54 mg/L Mercury = 0.08 mg/L (monthly averages)	Not documented

The PVSC Sewer Connection Permit (No. 03401023) was terminated in February 1999 (PAP-00175005) following facility closure in 1998.

The City of Clifton sewer system connects to the Yantacaw Bypass operated by the PVSC. At the direction of PVSC, this manual bypass discharged to the Third River at the confluence with the Passaic River (PAP-00345562). In 1976, the overflow was classified by PVSC as inactive (PAP-00345562).

The locations of the wastewater outfalls are presented in **Appendix B-3**. Wastewater flow diagrams are presented in **Appendix B-4**.

According to a *Selected Substances Report* dated August 13, 1980, the facility discharged 2,000,000 to 3,000,000 gallons of wastewater per day to the PVSC system (PAP-00180554). According to an *Application for a Sewer Connection Permit*, dated March 1996, between July 1994 and June 1995, the facility discharged 2,000,000 gallons of sanitary wastewater; 102,147,000 gallons of process wastewater; and, 17,312,000 gallons of cooling water to the combined sewer (PAP-00172475).

A summary of wastewater discharge volumes identified in the available file material by year and outfall is presented in **Appendix A-4**.

Figures depicting the layout of the facility sewer system are presented in **Appendix B-5**.

Stormwater Discharges

A stormwater detention pond is visible onsite in aerial photographs as early as 1947 (PAS-00048105).

According to the *Givaudan Fragrances Corporation Supplemental Response to 104(e) Request for Information*, dated November 10, 2016, there was no overland path for runoff to the east from the site to the Passaic River and that any surface runoff would have been collected in the City of Clifton storm sewer system on River Road near the railroad underpass (PAS-00048077-8). It also states that historical aerial photographs stated that there was no visible channelized flow or surface drainage feature visible on or off of the plant property, and that the alleged existence of a possible surface water pathway that could have conveyed storm water flow from the site directly to the Passaic River was not supported by historical aerial photographs (PAS-00048077).

According to a document titled “Plant Storm Water” dated December 30, 1981, runoff from “a large part” of the plant went into the stormwater retention pond (capacity of 250,000 gallons) outside of Building 50. This included water from the surface as well as that which was piped; it then evaporated or seeped into the ground. In addition, water from the land surrounding Building 93 ran over the drum farm area onto River Road, and water from the area along the railroad tracks, Buildings 79, 93, and 95, drained onto the railroad property. Stormwater from remaining areas percolated into the ground (PAS-00048426).

According to a *Plans for Discharge Prevention, Containment and Countermeasure (DPCC) and Discharge Cleanup and Removal (DCR)*, dated April 1985, surface water run-off from the chemical plant was discharged to the on-site stormwater pond, a gully adjacent to the railroad tracks, the gutter of River Road, and the Passaic River via an existing storm sewer (PAP-00183367). There were originally two locations where stormwater exited from the site to the Clifton stormwater system: one at Delawanna Avenue; one at River Road. A third location was added along River Road as part of road work completed to improve Route 3 and Route 21 in 1961-1962. The Delawanna stormwater system discharged into Yantacaw Pond; the River Road storm sewer system at the eastern end of the site discharged into the Passaic River; the storm sewer at the River Road railroad overpass juncture conveyed stormwater to the Third River (PAS-00048128).

Stormwater drainage patterns in 1991 are depicted in **Appendix B-6**.

The facility held a NJPDES permit (No. NJ0088374), effective July 1, 1992 through June 30, 1997, for discharge of stormwater to "infiltration/percolation lagoons." Discharges to the pond were not required to be monitored for OU2 COCs (PAP-00170994-995, 1000).

Stormwater runoff rates in 1993 identified in the available file material are presented in **Appendix A-5**.

A *Lagoon Closure Plan*, dated May 1, 1996, states that stormwater sewer inlets were located throughout the facility. At that time, the stormwater sewers and overland flow discharged to the Clifton stormwater sewer at Delawanna Avenue, a stormwater collection lagoon, the swale beside the railroad, River Road at the railroad crossing, and an inlet at River Road that all discharged through the City of Clifton storm sewer system and, ultimately, into the Passaic River (PAP-00181291).

According to the *Request for Information Response Document*, dated July 9, 2004, the stormwater pond was decommissioned (drained and filled) in 1999 (PAS-00083368-69).

It is noted that according to a *Request for Information Response Document*, dated July 9, 2004, Givaudan maintained a Stormwater Pollution Prevention Plan and stormwater permit (No. NJ0088315), which required monthly monitoring of stormwater effluent (PAS-00083363); however, no permits related to the discharge of stormwater to the Clifton storm sewer were identified in the available file material. Therefore, information related to discharge volumes, receiving water bodies, and monitoring requirements potentially presented in the permits are unavailable. A letter from NJDEP dated May 5, 1999, states the permit was revoked on that date (PAP-00175062).

Spills

According to a 1983 *Summary of Fires/Explosions/Accidents* document, three "TCP accidents" occurred at the site: one on August 13, 1976; one on January 17, 1977; and, one on September 11, 1980. The accidents were described as "TCP drum spilled in hot box." In addition, a "G-11 accident" occurred on April 21, 1981, and was described as "G-11 reactor raw materials flew out of unsecured manhole cover onto building floor"

(PAP-00183358-59). According to an internal memorandum, dated January 18, 1977, the TCP accident on January 17, 1977 involved the spillage of one drum of TCP (PAP-00183530). Note: Additional information related to these spills/incidents was not identified in the available file material, and it is unclear if these incidents resulted in releases of OU2 COCs.

According to a letter prepared by Givaudan, dated April 6, 1978, the sanitary sewer line on River Road failed on March 15 and 21, 1978. The letter stated that the quantity of effluent discharged into the Third River because of these leaks was "extremely difficult to determine." The letter states it could have varied from 10 gallons to 100 gallons per hour depending on the flow from the plant. The nature of the effluent at the time of the breaks was also "difficult to determine" (PAP-00170539; PAP-00181215). According to a memorandum, dated March 21, 1978, on March 20, 1978, PVSC personnel visited Givaudan in order to review their pH control system. This visit was due to the failure of the sanitary sewer line. The memorandum states that Givaudan was the largest contributor to this sewer line, and improper pH control by Givaudan "most likely" was the major cause of the failure. It was noted that Givaudan had replaced this section of sewer line at the end of July 1977 (PAP-00181217). According to a letter prepared by Givaudan, dated May 5, 1978, in August of 1977, Givaudan had replaced a leaking sanitary sewer line owned by the City of Clifton which was suspended from Passaic County Bridge No. 80 crossing the Third River. Although the line was actually owned by the City of Clifton, it carried domestic sewerage as well as industrial waste. The new sewer line was "eaten through" in eight months resulting in a "serious spill" into the river on March 15, 1978, and a less serious spill on March 21, 1978. As of April 10, 1978, the line had again been replaced (PAP-00181224). According to the April 6, 1978 Letter wastewater analysis taken in 1977 contained 0.212 copper, 0.766 lead and 0.0038 mercury the units were not specified (PAP-00181220).

According to an interoffice memorandum, dated August 5, 1981, because the "spent acid tank" was full, spent acid from the G-11® process was to be disposed by "very slowly" discharging to the sewer until the disposal problem could be resolved. The rate of dumping was specified to be approximately 2,750 pounds of acid every other day (PAP-00178319). Note: It is unclear if OU2 COCs were associated with the spent acid based on review of available file material.

According to an undated document titled *Investigation of G-11 Loss*, in August 1982, approximately 1,212 pounds of G-11® was accidentally washed down the sewer (PAP-00177132). Note: Additional details of this incident were not identified in the referenced document.

6. Regulatory History/Enforcement Actions

Inspections

According to correspondence issued by NJDEP, dated December 26, 1990, the facility received an "unacceptable" rating following a compliance evaluation inspection in part due the lack of a "Discharge to Ground Water (DGW) Permit" for the stormwater collection system which carried condensate from various pipes around the facility and

stormwater from the chemical storage areas into the on-site pond. The facility was directed to submit an associated permit application within 45 days (PAP-00170661-62). Givaudan filed the associated discharge permit application on April 12, 1991 (PAP-00170756). On May 29, 1992, the facility received a NJDPES permit (No. NJ0088374) which included amendments for a proposed surface impoundment and closure of the existing pond (PAP-00170991; PAP-00170994).

Violations and Enforcement Actions

On June 17, 1983, the governor of New Jersey issued an Executive Order declaring a state of emergency due to TCDD contamination at the site (PAS-00001801). The order required that all areas where TCDDs were detected at concentrations greater than or equal to 1.0 ppb be restricted from access, and that HCP production be suspended (PAS-00001801-03).

Givaudan entered into an *Administrative Consent Order* with NJDEP on March 5, 1987; an *Amended Administrative Consent Order TCDD* was signed on February 16, 1988. These consent orders required the investigation and remediation of TCDD contamination in soil (PAS-00001767-73).

On March 12, 2002, NJDEP issued a “no further action” letter for soils containing TCDD, which included the site use restrictions (PAS-00106564-66).

Permits

The facility first received a NJPDES permit (No. NJ0099414) from NJDEP to discharge industrial wastewater to the PVSC system on October 1, 1982, effective through September 30, 1987 (PAP-00173361).

The first record of a PVSC Sewer Connection Permit identified in the available file material following the NJPDES permit was a PVSC Sewer Connection Permit (No. 03401024) effective beginning March 17, 1991 (PAP-00170725). The PVSC Sewer Connection Permit was renewed on March 17, 1996, under permit No. 03401023 (PAP-00172521). The PVSC Sewer Connection Permit (No. 03401023) was terminated in February 1999 (PAP-00175006).

The facility also held a NJPDES permit (No. NJ0088374), effective July 1, 1992 through June 30, 1997, for discharge of stormwater to “infiltration/percolation lagoons” (PAP-00170994).

According to a *Request for Information Response Document*, dated July 9, 2004, Givaudan maintained a Stormwater Pollution Prevention Plan and stormwater permit (No. NJ0088315), which required monthly monitoring of stormwater effluent (PAS-00083363); however, no permits related to the discharge of stormwater to the Clifton storm sewer were identified in the available file material. A letter from NJDEP dated May 5, 1999, states the permit was revoked on that date (PAP-00175062). Givaudan ceased manufacturing operations in June 1998 (PAP-00178473).

Additional details regarding these permits are presented in Section 5 above.

7. Response Actions

Characterization Activities

The following characterization activities have taken place at the facility:

- *Chemical Sewer Investigation*, dated September 20, 1983 (PAS-00001730);
- *Status Report, Remedial Investigation, Dioxin Contamination Non-Process Area*, dated November 15, 1984 (PAP-00183454);
- *Draft TCDD Investigation Report*, dated May 18, 1989 (PAP-00170281);
- *TCDD Investigation Report and Limited Investigation Report*, dated January 1991 (PAP-00170664);
- *Draft TCDD Feasibility Study Report*, dated March 16, 1992, (PAP-00179675);
- *Remedial Investigation Report for Soils*, dated October 1997 (PAP-00182246);
- *Remedial Action Report for On-Site Containment of 2,3,7,8-TCDD-Impacted Soils*, dated October 1999 (PAP-00345755);
- *Preliminary Assessment Report*, dated November 1999 (PAP-00175239);
- *Remedial Action Report for Sewer Decommissioning*, dated February 2000 (PAS-00033747);
- *Remedial Action Work Plan for Soils*, dated April 2000 (PAP-00175624); and,
- *Remedial Action Report for 2,3,7,8-TCDD Excavation and Disposal*, dated September 2000, Revised February 2001 (PAP-00180344).

Sewer

Integrity of Chemical Sewer System

This subsection discusses the integrity of the chemical sewer system as documented in the available file material.

According to a *Chemical Sewer Investigation*, dated September 1983, investigation of the chemical sewer stated that many defects were present within the piping system and structures comprising the chemical sewer and its branches. Defects identified included misaligned and open joints in the piping system (indicating a potential for exfiltration), as well as cracked and broken pipe in many locations. Some of the manhole structures were also found to be in poor condition. The results of the exfiltration hydrostatic test suggested a potential for leakage from the system. The report states that although some leakage could be expected from all piping systems constructed of similar materials utilized in the chemical sewer, the leakage from this particular system was felt to be higher than normal. An inspection of the connections to the chemical sewer and its branches found many locations where exfiltration could occur. Significant deterioration of discharge troughs, traps, and connections were evident, providing locations where direct exfiltration could occur (PAS-00001735). The potential daily total of exfiltration for the entire chemical sewer system was estimated to be 80,400 gallons per day (PAS-00001746). The location where the majority of leakage was occurring was along the

main branch of the chemical sewer and the branch starting at manhole No. 11. These two piping systems were estimated to contribute over 75% of the exfiltration in the system while comprising only 65% of the total length of the system (PAS-00001747).

Explosions in the chemical sewer were reported in 1973, 1980, and twice in 1982 (PAP-00181228-29).

Sewer Sampling Data

According to a letter prepared by NJDEP, dated August 27, 1984, Givaudan planned construction of new chemical sewer lines at the site as soon as an assessment stated the presence or absence of TCDD contamination along the proposed sewer line. All samples showed non-detectable levels of TCDD with the exception of four samples with concentrations ranging from 0.095 ppb to 0.398 ppb (PAP-00183328). According to the letter, these values were below the residential action level of 1 ppb so NJDEP authorized Givaudan to proceed with construction of the chemical sewer line (PAP-00183329).

According to a *Remedial Action Report for Sewer Decommissioning*, dated February 2000, over 11,000 lineal feet of chemical sewer and storm sewer line were removed from the site for disposal at off-site disposal facilities. Post-excavation samples were collected from the sewer line excavations at the frequency of one per 30 linear feet from the sidewall of the excavation, and one per 50 linear feet from the base of the excavation (PAS-00033755, 87). 2,4,5-TCP was detected in post-excavation soil samples at concentrations ranging from 62,000 micrograms per kilogram (µg/kg) to 290,000 µg/kg. In addition, high molecular weight PAHs were detected in post-excavation soil samples collected along the sewer lines, along with the following OU2 COCs (PAS-00033862-84):

Range of Concentrations of OU2 COCs Detected in Post-Excavation Soil Samples along the Sewer Lines

COC	Minimum Detected Concentration (mg/kg)	Maximum Detected Concentration (mg/kg)
Copper	660	53,000
Lead	440	92,000
Mercury	15	130

In addition to the sewer lines, excavation was conducted in areas of subsurface features identified during sewer decommissioning activities such as cesspools and tanks (PAS-00033781-82). In the area of the former cesspools, lead was detected at a concentration of 19,000 mg/kg and copper was detected at a concentration of 53,000 mg/kg (the sample depth was not reported) (PAS-00033854, 85).

Spent Acid Pit

According to a Givaudan document titled *Recovery of G-11 from Sediment in Sewer Ditch,* dated August 27, 1951, sediment had collected in “the pond.” Individual samples of sediment from various locations in the pond, as well as representative samples of the

whole pond, were collected and found to consist of principally G-11® (HCP) and inorganic matter (e.g., sand, “filtercel,” grit, and calcium salts). Representative samples of the sediment yielded 60% “G-11 Pure” (based on the dry solid content of the sediment). The G-11® content was not uniform over the whole pond. The solids near the west end of the pond were approximately 70% G-11®, while the G-11® content near the middle and east end of the pond was about 50% G-11® (PAP-00183732). The referenced document does not identify the name of the pond; however, according to Givaudan’s November 10, 2016, Supplemental Response to 104(e) Request for Information, documentation states that prior to 1947, waste was discharged onsite into cesspools and pits. Further, a 1951 Givaudan memo discusses the recovery of HCP from the former waste pits, which also supports the facility's practice of discharging and handling its process waste water from HCP on site before the plant connected to the city sewer line on River Road by 1951-52 (PAS-00048078-79).

Stormwater Pond

As discussed in the previous subsection, surface water run-off from the site was discharged to an on-site stormwater pond (PAP-00183367).

According to a *Status Report, Remedial Investigation, TCDD Contamination Non-Process Area*, dated November 15, 1984, in July 1984, a composite of the liquid and a bottom sediment sample were obtained from the stormwater pond for analysis as part of the remedial investigation for TCDD contamination at the site. No TCDD “was present” in the pond sediment sample nor in liquid from the pond itself (PAP-00183454-58). Concentration data were not included in the referenced document.

According to a *Remedial Action Report for Sewer Decommissioning*, dated February 2000, lead (1,500 mg/kg), copper (1,100 mg/kg), and mercury (23 mg/kg) were detected in a sample collected from the stormwater pond, along with high molecular weight PAHs, in 1998/1999 (PAS-00033887-88).

Building Interior

According to an *Administrative Consent Order*, dated March 5, 1987, on July 9, 1983, Givaudan conducted a TCDD sampling program including sweep and wipe sampling of the interiors of buildings on portions of the site where HCP or 2,4,5-TCP were being or had been manufactured. Of the 31 samples analyzed, TCDD was present in detectable concentrations in 20 samples. Of those 20 samples, nine chip samples had TCDD concentrations of less than 1 ppb, four had TCDD concentrations between 1.0 ppb and 7.0 ppb, one chip sample had TCDD present in excess of 7.0 ppb (in Building 54 where TCP was believed to have been manufactured), and six wipe samples had TCDD concentrations of between 1.0 and 7.0 nanograms per square foot (PAS-00001809).

According to a letter prepared by Givaudan, dated March 29, 1996, five wipe samples also were collected from Building 54 for TCDD analysis in 1996. The maximum concentration detected was 373 nanograms per square meter (PAP-00172551-52).

Soil

This subsection is divided into a discussion of TCDD characterization activities at the site, and site characterization activities for all other OU2 COCs.

TCDD Characterization

Givaudan entered into an *Administrative Consent Order* with NJDEP on March 5, 1987; an *Amended Administrative Consent Order TCDD* was signed on February 16, 1988. These consent orders required the investigation and remediation of TCDD contamination in soil (PAS-00001767-73). It is noted that NJDEP originally established a 1.0 ppb action level and 7.0 ppb cleanup goal for TCDD; a site-specific cleanup goal of 20.0 ppb was established in the early 1990s (PAP-00179704). Therefore, the referenced documents summarized below often refer to TCDD concentrations relative to these concentration targets. It appears that subsequently, a remedial action objective of 2.0 ppb for TCDD-impacted soils from zero to 12 feet bgs was established in 1999 (PAP-00180350).

According to the *Administrative Consent Order*, dated March 5, 1987, on June 3, 1983, Givaudan agreed to conduct a sampling program designed to ascertain the presence or absence of TCDD in or on the soils, waters, equipment and/or structures at the site. Givaudan reported to NJDEP that the analyses of 15 out of 22 samples collected stated the presence of TCDD in detectable concentrations. Of those 15 samples, six had concentrations of less than 1.0 ppb, eight had concentrations between 1.0 ppb and 7.0 ppb, and one had a TCDD concentration in excess of 7.0 ppb. All samples whose analysis stated the presence of TCDD in concentrations over 1.0 ppb were collected in the area of the site where HCP had been manufactured (referred to as the "Contaminated Process Area"). No TCDD was detected in samples collected off site (PAS-00001808-10).

According to the 1990 NIOSH Report, Givaudan collected soil samples in the vicinity of the main HCP production building on approximately June 14, 1983. Results from 12 samples had TCDD concentrations ranging from 0.94 ppb to 11 ppb (PAP-00170554).

According to the *Administrative Consent Order*, dated March 5, 1987, on June 18 and 25, 1983, Givaudan conducted TCDD sampling at the site. Of the 41 samples collected, 25 had TCDD contamination in detectable concentrations. Of those 25 samples, 13 had TCDD concentrations less than 1.0 ppb, 11 had TCDD concentrations between 1.0 ppb and 7.0 ppb, and one sample had TCDD present in excess of 7.0 ppb (PAS-00001809).

According to a *Status Report, Remedial Investigation, TCDD Contamination Non-Process Area*, dated November 15, 1984, in July 1984, soil sampling was conducted around the stormwater pond as part of the remedial investigation for TCDD contamination at the site (PAP-00183454-58). TCDD contamination in soils around the stormwater pond existed at a number of locations and to depths of 12 inches bgs (PAP-00183458). TCDD concentrations in excess of 1.0 ppb were encountered at four borings in the vicinity of the stormwater pond. TCDD was present in the surface sample

in two of these borings and to a depth of 12 inches bgs in the other two borings at concentrations ranging up to 16.89 ppb (PAP-00183457).

According to the *Administrative Consent Order*, dated March 5, 1987, during the course of a TCDD sampling program conducted by Givaudan and U.S. EPA through July 30, 1985, a total of 402 samples were analyzed for TCDD. Findings were as follows:

- All samples analyzed as having TCDD contamination in concentrations of 1.0 ppb or more were located in the "Contaminated Process or Contaminated Non-Process Areas."

- Twenty-six samples were collected and analyzed by U.S. EPA in the area surrounding the site, all of which were analyzed as containing no TCDD contamination at concentrations of 1.0 ppb or more.

- Three hundred twenty-nine samples were collected and analyzed by Givaudan outside the buildings located on the site, 255 of which were analyzed as containing no TCDD contamination in concentrations of 1.0 ppb or more, 51 of which were analyzed as having TCDD contamination in concentrations between 1.0 ppb and 7.0 ppb, and 23 of which were analyzed as having TCDD contamination in excess of 7.0 ppb.

- Forty-seven samples were collected and analyzed at various locations inside the buildings located on the site, six of which were analyzed as having TCDD contamination at concentrations of 1 nanogram per square foot or more (none of which were analyzed as having TCDD contamination in concentrations in excess of 7 nanograms per square foot) and 41 of which were analyzed as having no TCDD contamination in concentrations of 1 nanogram per square foot or less (PAS-00001812).

Between 1988 and 1989, field investigations were conducted at the site to delineate the presence and extent of TCDD contamination to partially fulfill the March 1987 *Administrative Consent Order*. The investigation concluded that soils impacted by TCDD were confined to the upper 24 inches of the soil profile (PAS-00106329-30).

According to a *Draft TCDD Feasibility Study Report*, dated March 16, 1992, based on the results of the comprehensive site investigation, two areas of potential concern were identified: the Contaminated Process Area and the Contaminated Non-Process Area. The area consisting primarily of buildings formerly used for the manufacture of chemicals and some immediately-adjacent soils was designated as the Contaminated Process Area, while the Contaminated Non-Process Area was comprised of three distinct sub-areas which were identified as former drum storage locations. It was believed that the residual TCDD contamination present in the soil profile was a result of inadvertent spills and leaks originating from the drums (PAP-00179682). The locations of the Contaminated Process Area and Contaminated Non-Process Area are depicted in **Appendix B-7**. At the Contaminated Process Areas, with the exception of one sample, the vertical extent of TCDD contamination was limited to the upper 18 inches bgs of the

soil profile within the area (PAP-00179699-700). The deepest TCDD contaminated soils found were at 10 to 12 inches bgs at Contaminated Non-Process Areas A and B. The deepest TCDD contaminated soils found were at 12 to 18 inches bgs at Contaminated Non-Process Area C. Sample data collected in 1988 and 1989 for TCDD and as discussed in the report were as follows:

- On May 21-22, 1988, 46 samples collected in the Contaminated Non-Process Area were analyzed for TCDD. Of these 46 samples, 36 samples demonstrated the presence of TCDD at concentrations less than 1.0 ppb, eight samples demonstrated the presence of TCDD concentrations in the range of 1.0 ppb to 7.0 ppb, and two samples had TCDD concentrations greater than 7.0 ppb (PAP-00179696).

- Of 80 samples collected at the Contaminated Non-Process Area on November 19, 1988, 57 samples (71 percent) had TCDD concentrations below 1.0 ppb, 19 samples (24 percent) had TCDD concentrations ranging from 1.0 ppb to less than 7.0 ppb, and four samples (5 percent) had TCDD concentrations in excess of 7.0 ppb (PAP-00179696, 98).

- Of the 65 samples collected on March 18, 1989 at the Contaminated Non-Process Area, 33 samples (51 percent) had TCDD concentrations below 1.0 ppb, 28 samples (43 percent) had TCDD concentrations ranging from 1.0 to less than 7.0 ppb, and 4 samples (6 percent) had TCDD concentrations in excess of 7.0 ppb (PAP-00179698).

- On 18 March 1989, 18 additional soil samples, and three Building 54 samples (located above the chemical sewer line) were collected from the Contaminated Process Area. Of the 16 soil samples analyzed, six samples had TCDD concentrations below 1.0 ppb, 10 samples had TCDD concentrations ranging from 1.0 to 7.0 ppb, and two samples had TCDD concentrations in excess of 7.0 ppb (PAP-00179698).

To summarize the historical data described above, the *Draft TCDD Feasibility Study Report*, dated March 16, 1992, stated that between 1983 and 1990, eight soil samples had been collected at the site with concentrations greater than the site-specific cleanup goal of 20.0 ppb TCDD; concentrations of these eight samples ranged from 22 ppb to a maximum of 200 ppb. Sample depths ranged from zero to 12 inches bgs. The volume of soil containing greater than 20.0 ppb TCDD was calculated to be approximately 12,400 cubic feet (PAP-00179717-18).

According to a *Remedial Action Report for 2,3,7,8-TCDD Excavation and Disposal*, dated September 2000, a remedial action objective for TCDD-impacted soils at the site was the removal of TCDD-impacted soils having concentrations greater than 2.0 ppb in the 0 to 12-foot bgs soil profile (PAP-00180350). Additional sampling for TCDD was conducted in areas identified as past drum storage areas at the site. In addition, areas of suspected TCDD contamination, which were identified during previous site investigations, but could not be sampled due to production operations in the buildings,

were sampled (PAP-00180351). The maximum detected TCDD concentration was 18.79 ppb at five to six feet bgs. In the surface soil interval (zero to two feet, at original grade), TCDD concentrations ranged from 0.012 ppb to 16.2 E ppb (the "E" states the concentration of TCDD exceeds the upper end of the method's calibration curve (PAP-00180358, 81).

The location of the drum storage area is depicted in **Appendix B-8**.

Other OU2 COCs

According to the *Remedial Investigation Report for Soils*, dated October 1997, the remedial investigation was completed in three phases. The initial phase was conducted during the period from February 26, 1996 to March 8, 1996, and consisted of the installation of 88 soil borings. Based on the findings of the initial phase, 10 additional soil borings were installed in the investigation areas during a supplemental investigation implemented in May 1996 to further delineate the horizontal and vertical extent of impacted soil. On October 28, 1996, two soil borings were installed during a Supplemental Soil Investigation conducted to complete the delineation of the perimeter of the site (PAP-00182317). The following are the maximum detected concentrations of COCs in soil, along with the depths at which the maximum detected concentrations were detected and the locations (PAP-00182344):

Maximum Detected Concentrations of COCs in Soil Reported in *Remedial Investigation Report for Soils*, dated October 1997			
COC	**Concentration (mg/kg)**	**Depth**	**Location of Maximum Detected Concentration**
Copper	1,800	10-12 feet bgs	Chemical Sewer
Lead	4,800	10-12 feet bgs	Former Spent Acid Pit
Mercury	35	10-12 feet bgs	Chemical Sewer

High molecular weight PAHs were also detected with maximum concentrations reported in the 10 to 12-foot bgs depth interval at the drum storage area and warehouse (PAP-00182319, 29, 41-47). 2,4,5-TCP was detected at the 10 to 12-foot bgs depth interval at the drum storage area at a concentration of 170,000 µg/kg (PAP-00182342). Noting that maximum detected concentrations were in deep subsurface soil, the following concentrations of OU2 COCs were also reported for surface soil: lead (1,900 mg/kg) and mercury (17 mg/kg) in a sample collected from zero to two feet bgs in the area of the chemical sewer (PAP-00182344).

Remedial Activities

According to a letter prepared by NJDEP, dated December 17, 1991, NJDEP originally determined that a site-specific TCDD soil cleanup level of 20.0 ppb was acceptable for the site (PAP-00170898). According to a letter prepared by Givaudan, dated April 25, 1991, the volume of soil in the Contaminated Process and Contaminated Non-Process areas with TCDD concentrations in excess of 7.0 ppb was estimated to be 900 cubic

yards. The volume of soil in the Contaminated Process and Contaminated Non-Process areas with TCDD concentrations in excess of 20.0 ppb was estimated to be 510 cubic yards (PAP-00170773). According to the *Draft TCDD Feasibility Study Report*, dated March 16, 1992, the areal extent of soils containing TCDD greater than 1.0 ppb was calculated to be approximately 101,700 square feet. The volume of soil containing greater than 1.0 ppb but less than or equal to 20.0 ppb TCDD was calculated to be approximately 7,100 cubic yards. In addition to this volume of soil,128 55-gallon drums of soil removed from north of Building 68 were classified as greater than 1.0 ppb but less than or equal to 20.0 ppb TCDD (PAP-00179717-19).

According to a letter prepared by Givaudan, dated February 27, 1995, in February 1988, TCDD-contaminated soil was excavated to a concentration of 1 ppb, and placed in 128 drums (PAP-00172020). According to the October 1999 Remedial Action Report for On-Site Containment of 2,3,7,8-TCDD-Impacted Soils, the soil from these drums, in addition to soils above 1 u/g/kg TCDD excavated from Work Areas, was placed in the onsite containment cell (PAP-00345774).

According to a *Remedial Action Report for Sewer Decommissioning*, prepared for Givaudan, dated February 2000, over 11,000 lineal feet of chemical sewer and storm sewer line, five underground storage tanks, four cesspools, miscellaneous features such as manholes, catch basins, and 15,600 tons of impacted soils were removed from the site for disposal at off-site disposal facilities. In addition, the stormwater pond was taken out of service (including removal of 135,000 gallons of water) and underlying soils were removed, and 2,558 tons of asphalt from paved areas in the plant were removed and sent offsite for disposal. Soils not suitable for reuse were sent offsite for recycling. Concrete from the demolished buildings and various storage pads were crushed, sampled, and reused onsite as backfill, and for rough grading of the property (PAS-00033755; PAP-00168968-69). This work was conducted as part of an ISRA remediation after the plant was closed (PAP-00180344).

According to a *Documentation of Environmental Indicator Determination*, prepared on behalf of U.S. EPA, dated September 29, 2008, 610 tons of soil containing TCDD above the subsequent NJDEP-approved cleanup level of 2.0 ppb was excavated and incinerated offsite (PAP-00168968; PAP-00180360). Note: This work was conducted as part of an ISRA remediation after the plant was closed. The document states that the selected remedy for soils incorporated the installation of a low-permeability asphalt cover over the majority of the site, construction of warehouses, installation of a fence around the perimeter of the site, and recording of a deed notice to restrict future uses of the property (PAP-00168962). This remedy was approved by NJDEP in a letter dated June 21, 2000, and was subsequently implemented by Givaudan as part of the site redevelopment process. The deed notice for the northern parcel of the site restricted the entire site to non-residential use and was recorded on June 29, 1999. The document goes on to state that the soil containing TCDD at concentrations less than 2.0 ppb was managed in an engineered containment cell near the southern end of the site. Givaudan retained ownership of this southern parcel and placed a deed restriction on this site in 1999 (PAP-00168972).

A figure depicting TCDD-impacted areas is presented in **Appendix B-9**.

On March 12, 2002, NJDEP issued a “no further action” letter for soils containing TCDD, which included the site use restrictions (PAS-00106564-66).

8. Summary of Asserted Defenses

No legal defenses were identified in the available file material.

Appendix A-5				
Peak Stormwater Runoff Rates in 1993				
Stormwater Discharge Point Number and Name	**Stormwater Source Description**	**Ultimate Stormwater Discharge Point**	**Acres Drained**	**Peak Rate of Runoff - 25-Year Storm (gallons per minute)**
1 - NW Corner	Sheet flow into Delawanna Avenue gutter	Third River	0.062	49
2 - Building 9	Building 9 roof drainage into storm sewer in Delawanna Avenue	Third River	0.577	1,776
3 - Guard House	Sheet flow into Delawanna Avenue gutter	Third River	0.213	655
4 - NJDOT Inlet	Stormwater runoff collected via swales and pipes from southeastern portion of site into stormsewer in River Road	Passaic River	6.249	12,701
5 - SW Curb Cut	Sheet flow and gutter flow from southern portion of site and south of Building 95 into River Road gutter	Third River	3.306	8,356
6 - Railroad Curb Cut	Stormwater runoff collected via swales and pipes from southeastern portion of site into stormsewer in River Road	Third River	2.945	5,292
5 + 6 - Curb Cut	Not available	Not available	3.251	10,686

Source: PAP-00178571, 77-80

Note: Storm water runoff rates were calculated after the site was paved in 1983. Prior to that date, the Clifton Site was not paved and storm water infiltrated into the site soils and / or was directed to the on-site storm water pond (PAS-00048098).

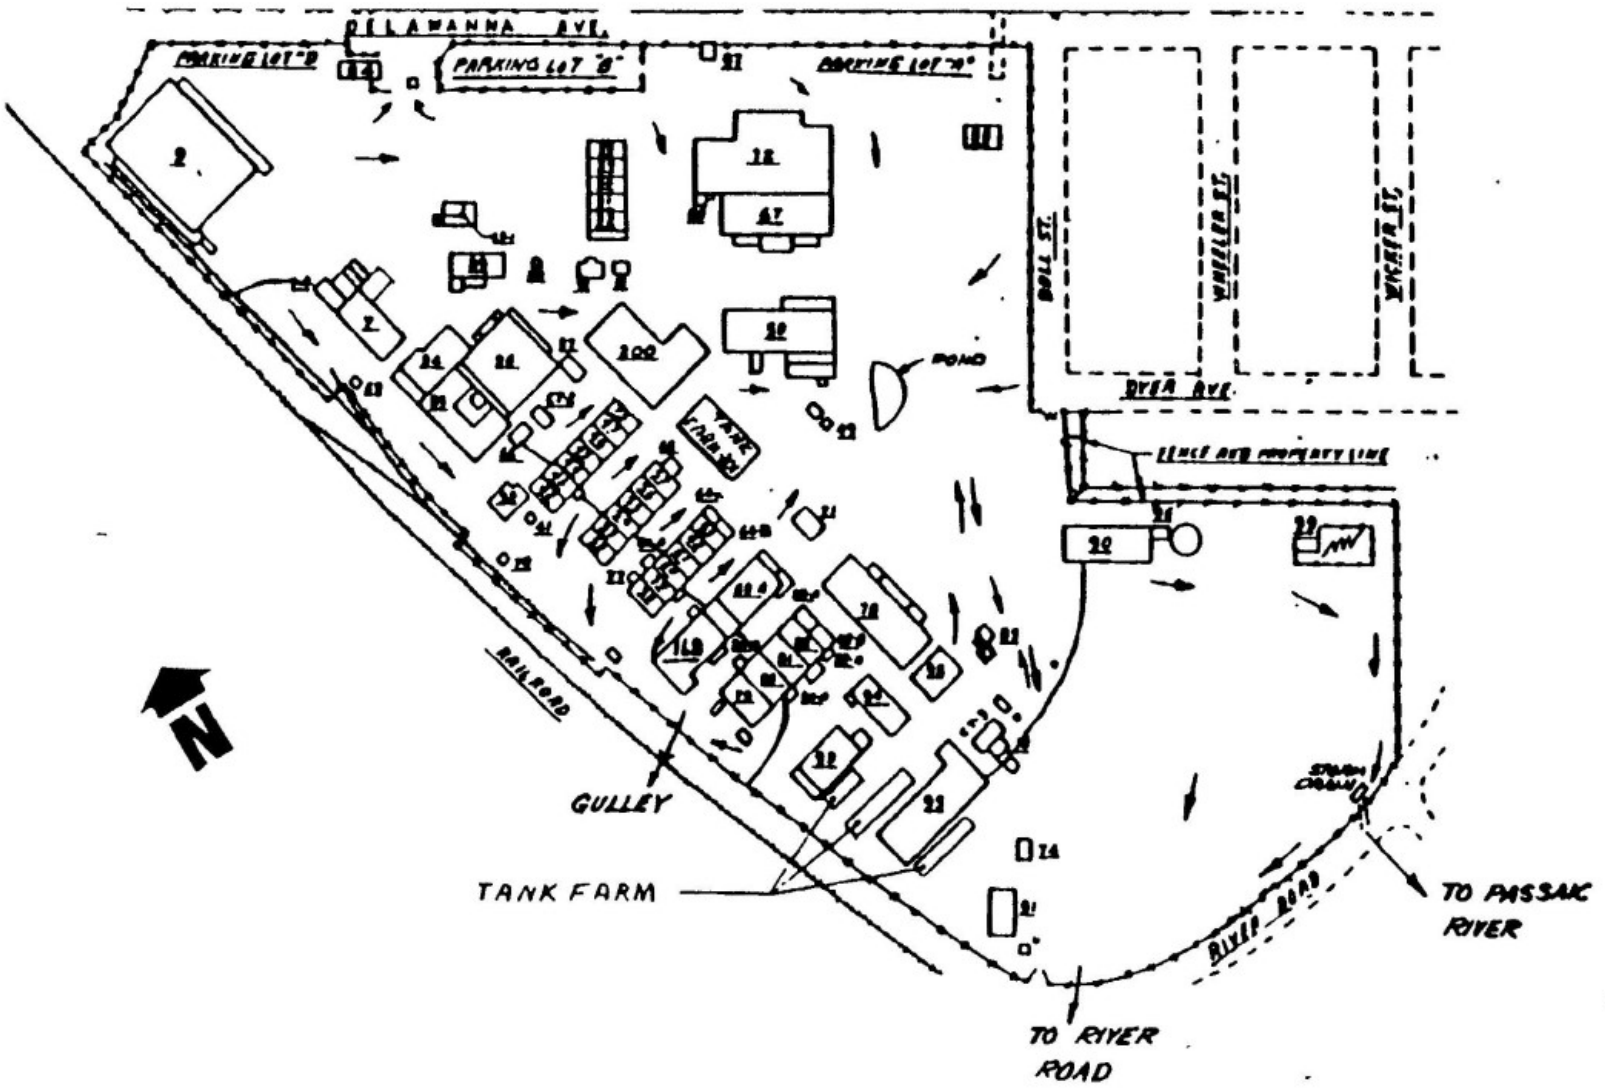
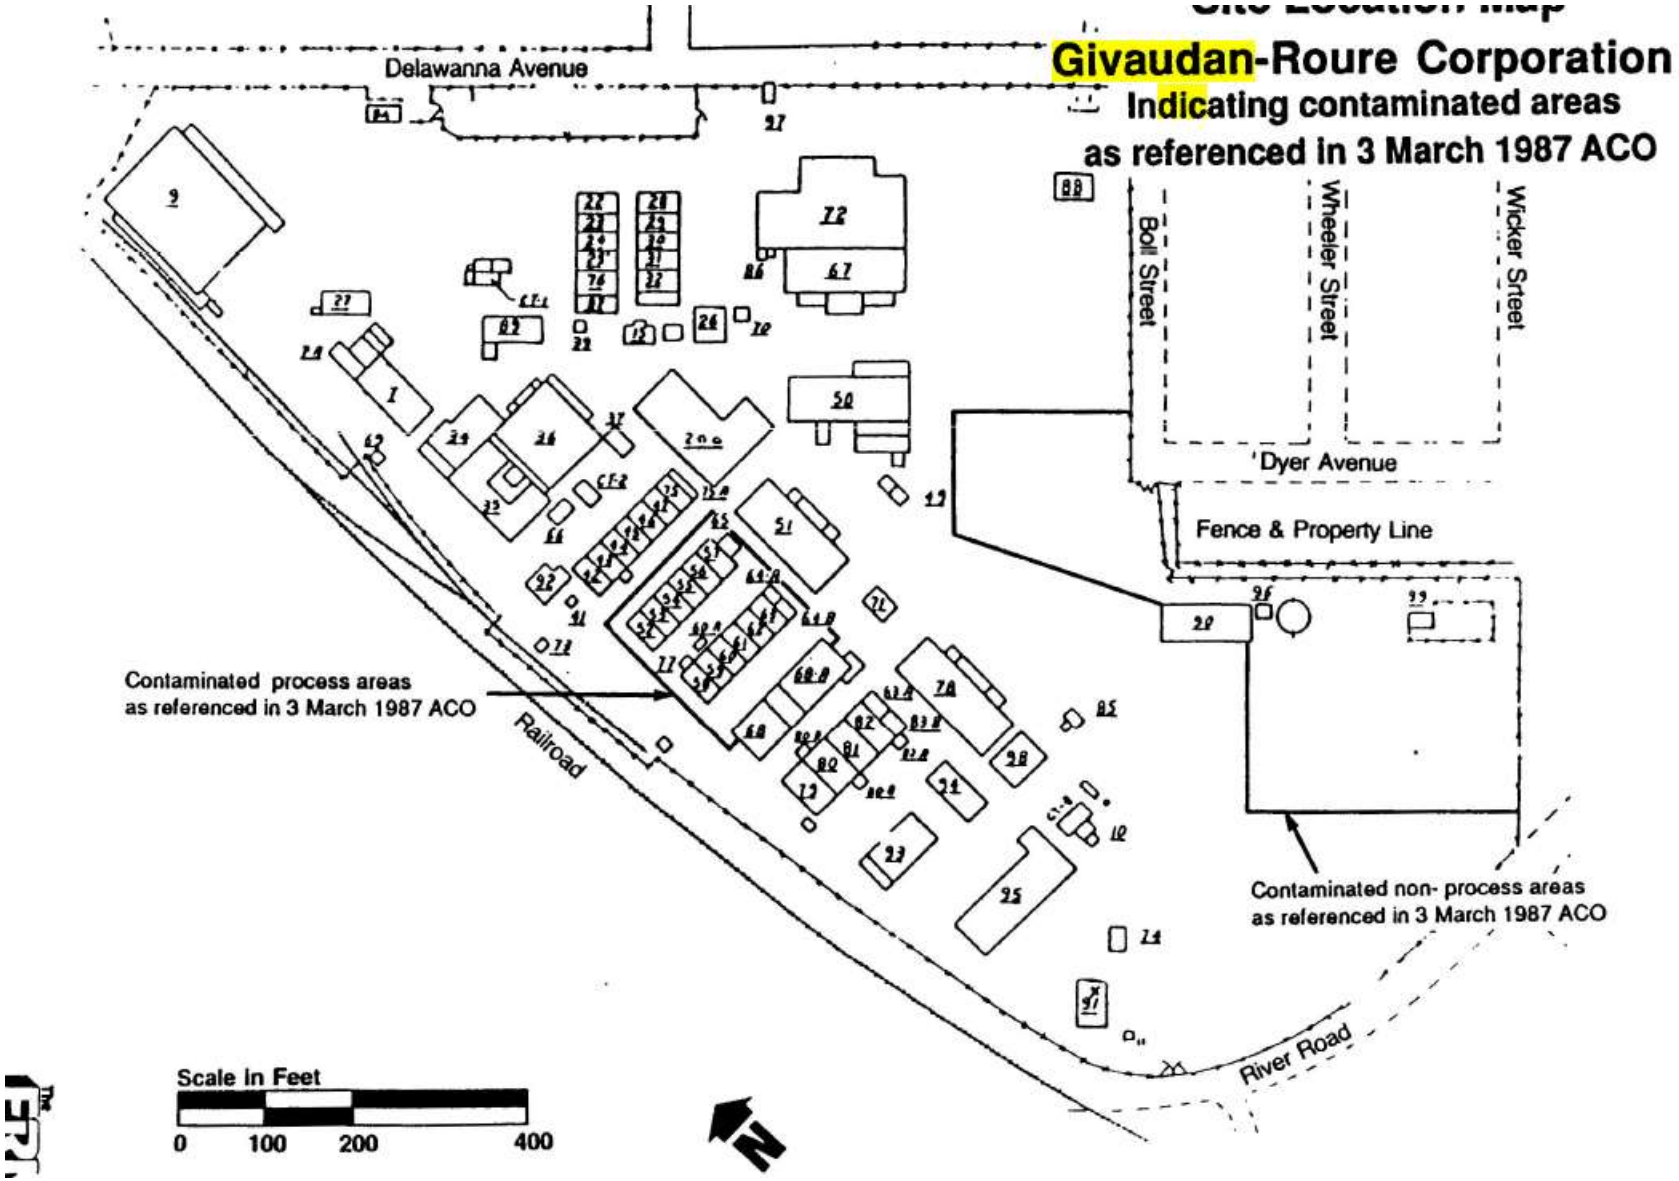
Appendix B-5. Facility sewer system in 1946 and 1979 (PAS-00048106, PAS-00048128).

1946 Sewer System Overlay

- Three primary systems appear active at the site, including:
  - Stormwater (blue) - discharging to the Stormwater Detention Pond
  - Sanitary (gold) – discharging to the City of Clifton Sewer at Outfall 002 on Delawanna Avenue
  - Chemical (purple) – discharging to dry wells throughout the site and to the Spent Acid Pit and the future Wastewater Detention Pond.
- Future aerial photos (see Exhibit 13) indicate the presence of the wastewater treatment building (Building 74). This building provided pre-treatment of process water (chemical system) prior to discharge to the City of Clifton Sewer at Outfall 001 on River Road.
- A series of drawings from 1927, titled "Sanitary Sewer Record Drawing" from the City of Clifton Bureau of Engineering, indicates city sanitary sewer lines were in place near the facility in 1927. As such, it is likely the facility's sanitary sewer system discharged to the City of Clifton system at Outfall 002 prior to 1946.
- A letter dated November 30, 1953 from Givaudan to the County Council, references an August 20, 1946 letter from City of Clifton to Givaudan that indicates the City and Givaudan were in discussions regarding the City's sewer system in 1946; suggesting Givaudan was connected in some capacity to the City sewer at that time.

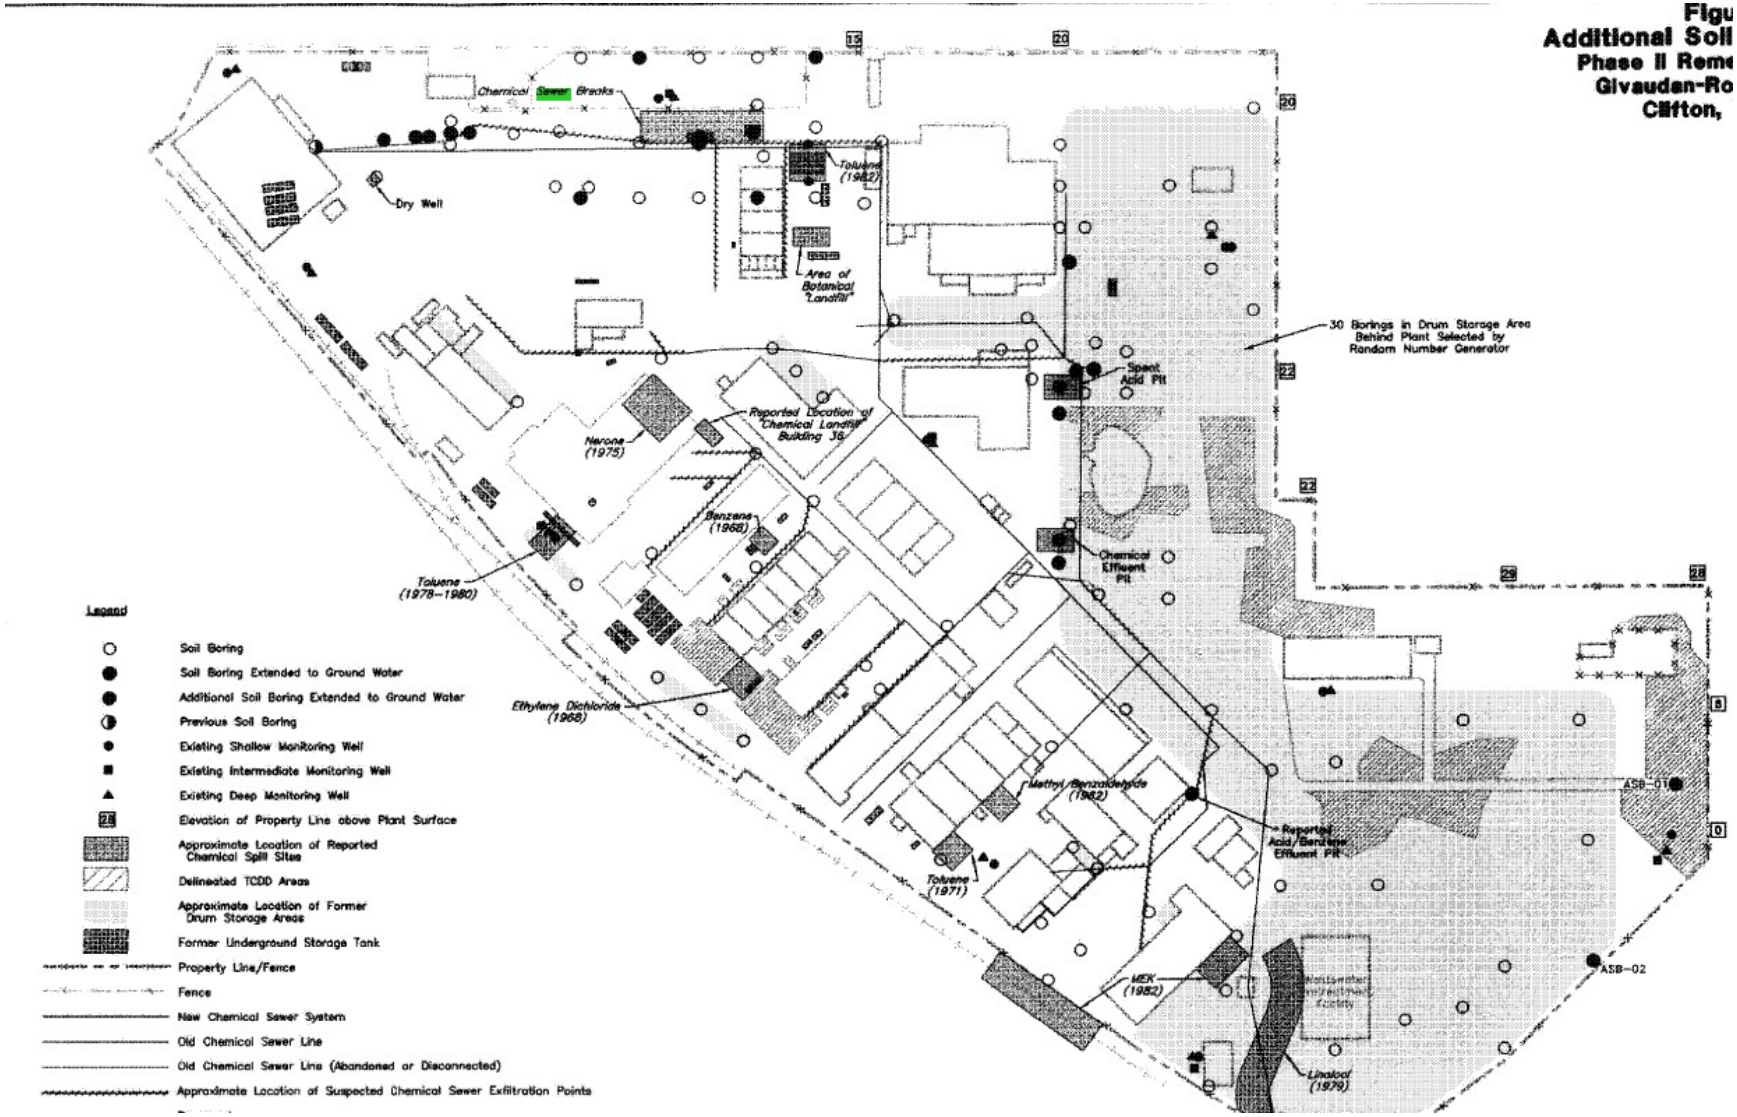


:

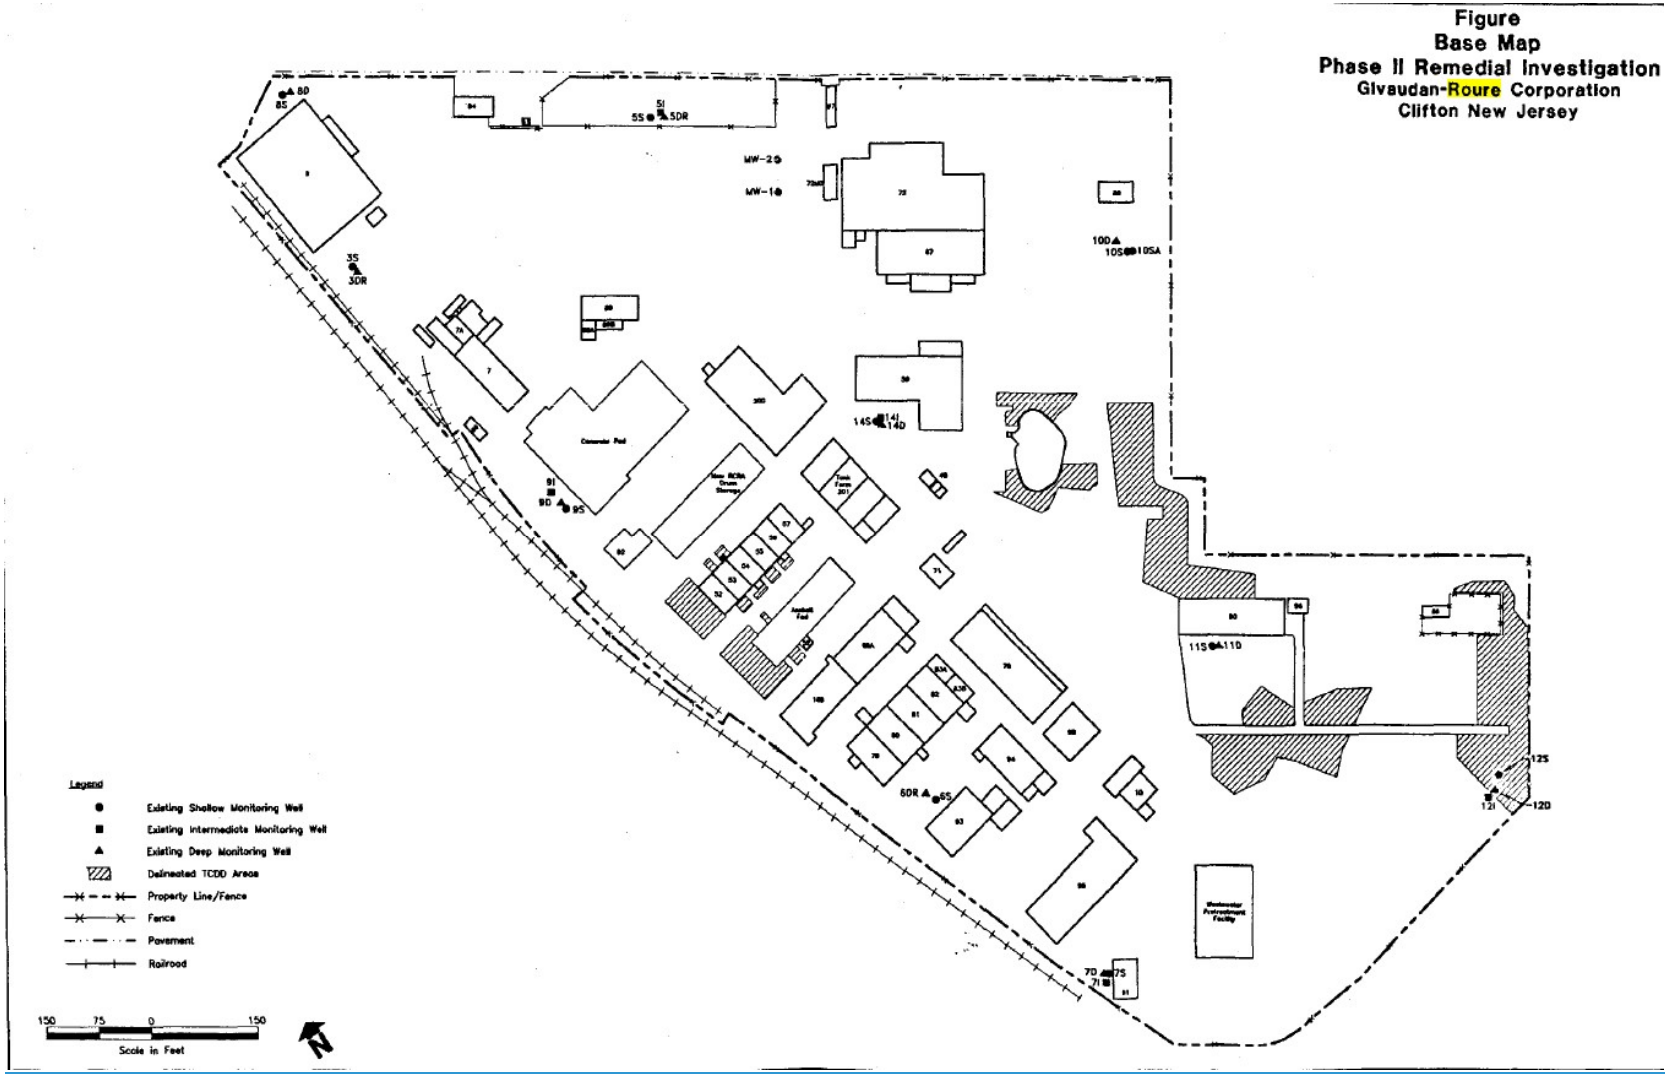


1979 Sewer System Overlay

- Three primary systems appear active at the site, including:
  - Stormwater (blue) - discharging to the Stormwater Detention Pond.
  - Sanitary (gold) – discharging to the City of Clifton Sewer at Outfall 002 on Delawanna Avenue and on-site septic tanks.
  - Chemical (Purple) – discharging to the City of Clifton Sewer at Outfall 001 on River Road.
- Chemical sewer lines with system with yellow highlights represent areas of poor condition lines (e.g., exfiltration areas) identified during a 1980s investigation.
- Brown dashed lines indicate areas of open storm water ditches.
- Chemical sewer system passes through Building 74 prior to leaving the site at River Road. Building 74 was first observed in the 1951 aerial photo.



Appendix B-6. Stormwater Drainage Patterns (PAP-00179824).



Appendix B-7. Locations of Contaminated Process Area and Contaminated Non-Process Area (PAP-00179697).

Appendix B-8. Location of drum storage area (PAP-00182357).

Appendix B-9. TCDD-impacted areas (PAS-00083406).

Facility Data Report

GOODRICH CORPORATION

Facility Name, Address and Size: Goodrich Corp./Kalama Chemical, 290 River Drive, Garfield, New Jersey, 07026 (PAS-00123393); approximately 7 acres (PAS-00123393; PAS-00123398). 85 employees, 365 days per year, and 3 shifts per day in 1990 (PAP-00016715) and 1993 (PAP-00206151).

1. **Business Type:** Manufacturing of chemicals used in pharmaceuticals, cosmetics, food packaging, and preservatives, synthetic flavorings, printing inks, dyestuffs, and other products (PAS-00008962).

2. **Time Period of Ownership/Operations**

   Operator: December 1982 to May 1994
   Owner: December 1982 to Present (PAS-00123395-6, 8)

   1982: The Site was sold by Tenneco to Kalama Chemical, Incorporated (Kalama) in an Asset Sales Agreement. Assets identified in the sale included the machinery, equipment, furniture, fixtures, raw materials, work in progress, finished goods, operating supplies, etc. (PAP-00039792-95).

   1986: Partial ownership of Kalama was acquired by BC Sugar Refining Company, a Canadian sugar refining company (PAS-00008962; PAS-00123395).

   1990: BC Sugar acquired complete ownership of Kalama (PAS-00123396). Kalama filed lawsuit against Tenneco Polymers, Inc. (PAP-00046294).

   1991: During Kalama's tenure, operations were reduced in scale, and by 1991, operations were conducted in only one-third of the plant (PAP-00206156).

   1994: BC Sugar sold Kalama Chemical to Freedom Chemical Company (Freedom Chemical) (PAS-00123396). The lawsuit with Tenneco Polymers, Inc. (TPI) was settled, and TPI assumed primary responsibility for compliance with the New Jersey Department of Environmental Protection (NJDEP) Industrial Site Recovery Act (ISRA) regulations in accordance with the revised Administrative Consent Order (PAP-00046294). Operations at Kalama Chemical ceased in May and the manufacturing equipment and chemicals were removed from the facility by August (PAS-00008963; PAS-00123396).

   1998: Freedom Chemical was acquired by and merged into B.F. Goodrich Company. Media sources also note that Kalama, as a subsidiary of Freedom Chemical, was transferred to B.F. Goodrich (PAS-00123396).

3. **Operational History/COC Use and Presence at the Facility**

   According to the *Remedial Investigation Report and Remedial Action Work Plan for the Northern Phenol Area and Dowtherm DNAPL Areas,* dated February 13, 2004, the site was used for chemical manufacturing since 1891. Kalama took ownership in 1982 and

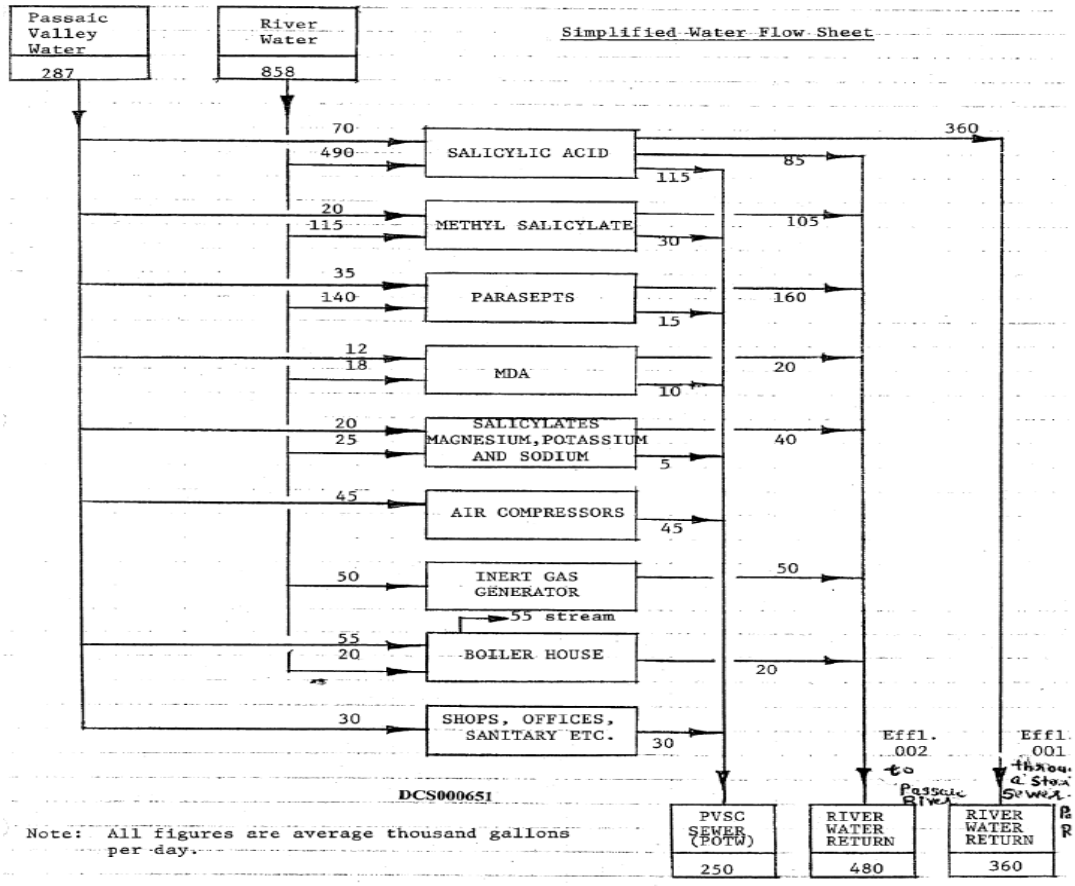
manufactured chemicals used in pharmaceuticals, cosmetics, food packaging and preservatives, synthetic flavorings, printing inks, dyestuffs, and other products (PAS-00008962).

A letter from Kalama to the Passaic Valley Sewerage Commissioners (PVSC), dated June 15, 1988, listed the following chemicals as used or produced at the site:

Salicylic Acid
Methyl Salicylate
Parasepts® (a registered trademark of Kalama for its brand of methyl, ethyl, propyl, and butyl esters of p-hydroxy benzoic acid, also known as Parabens)
Methylene Disalicylic Acid (M.D.A.®)

Raw materials used for production of these products:

Water	Formaldehyde
Phenol	Toluene
Methanol	Sodium hydroxide
Sulfuric acid	Carbon dioxide
Propanol	Ethanol
Butanol	Pottassium Hydroxide



(PAP-00206172-73; PAP-00433761)

According to the *ECRA Investigation Report and Proposed Remedial Action Workplan, Volume I of IV*, dated December 1993 (ECRA Investigation Report), Kalama stopped synthesizing benzoic acid and benzaldehyde in early 1984, a little over a year after it acquired the property (PAP-00041526).

A schematic of the water flow at the facility for each process was provided in a 1989 fact sheet for Draft NJPDES Permit to Discharge into the Waters of the State of New Jersey (Permit No. NJ0000124). Two outfalls to the Passaic River and one outlet to the PVSC sewer were identified (PAP-00206141). A report titled *Environmental Assessments, Draft Report for B.C. Sugar*, dated September 3, 1991 (1991 EA) stated that all process waste was discharged to the PVSC under permit number 09404292 (PAP-00433578).

Facility Data Report

(PAP-00206141)

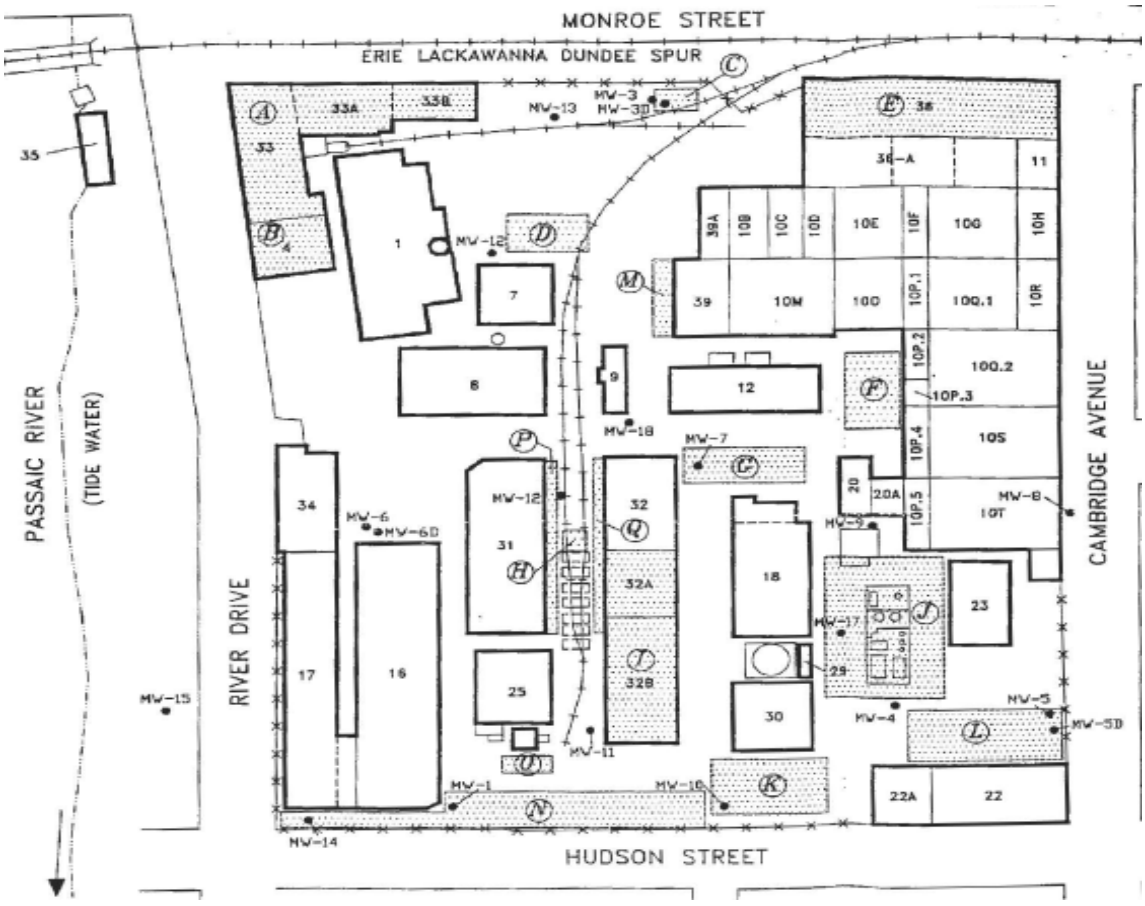
As discussed in the ECRA Investigation Report, the site consists of two properties; the manufacturing facility (6.4 acres) and the former employee parking area (0.5 acres) located across River Drive and along the Passaic River. The site is surrounded by mixed residential, commercial and industrial properties on the north, south and east. The Passaic River borders the site on the west, approximately 100 feet from the former manufacturing operations (PAP-00041522-23).

The 1991 EA identified areas of potential environmental concern resulting from on-site operations and hazardous materials handling practices (PAP-00433546). It also discussed buildings where the following operations were identified:

- Building 1: boiler room, housing oil-fired steam boilers, compressors and other ancillary power-generation equipment, six transformers located between Building 1 and Building 33 were each labeled with a sticker stating that the PCB content of the transformer was <50 parts per million (ppm).

- Building 7: formerly a copper shop where sheet metal was fabricated; used for maintenance and equipment storage at that time.

- Building 11: reportedly used for naphthalene distillation but appeared to be idle at the time. The *Revised Remedial Action Work Plan*, dated March 31, 1995 (1995 RAWP) stated this building was inactive since 1965 (PAP-00041642).



- Building 12: a transformer labelled with a sticker stating that the unit contained <50 ppm PCB was outside Building 12 on a concrete pad.

- Building 16: previously rented by Glare Industries, which was described as having manufactured urinal blocks (Note: As noted below, other documentation establishes that Glare Industries only packaged urinal blocks (PAP-00433528-9)).

- Building 17: leased to Chemo Dynamics Inc. and contained laboratories.

- Building 35: pump house located on the banks of the Passaic River; a transformer was observed and appeared to have a label indicating that the PCB content of the unit was <50 ppm.

- Building 36: three transformers located on the second floor; appeared to be labeled as containing <50 ppm of PCB. (PAP-00433546-57)

(PAP-00433612)

According to the 1993 ECRA Investigation Report, approximately 38 buildings once existed on the site, half of which were used for manufacturing operations by Kalama (PAP-00041525). The 1995 RAWP stated most manufacturing equipment and all production-related chemicals were removed from the site between May and August 1994. Ten buildings (2, 3, 8, 10-A, 10-N, 37, 38, 39, and 39A) had been dismantled over the years (PAP-00041636).

After Kalama took ownership of the site in 1982, portions of the site were operated by other companies.

- A November 25, 1985, registration form for the City of Garfield Bureau of Fire Protection identified "Bldg. 16 (Glair) AMK Manufacturing" as operating an industrial packaging plant for urinal blocks at the Garfield facility owned by Kalama (PAP-00433528), while the 1991 EA stated a "Glare Industries" had previously rented Building 16 for the manufacturing of urinal blocks (PAP-00433552).

- Hart Chemical Co. was identified at the facility site in a December 15, 1988, Garfield Fire Department Application for Certificate of Inspection and an October 4, 1989, New Jersey Bureau of Fire Safety verification/update request. The 1989 document noted Hart Chemical was not open for business (PAP-00433766).

- A February 11, 1991, Addendum to the Lease Agreement dated December 22, 1988, between Landlord Kalama Chemical, Inc. and Tenant, Chemo Dynamics, Inc. stated Chemo Dynamics, Inc. leased the area immediately behind their laboratories in Building 17 (1,600 square feet). Chemo Dynamics performed custom synthesis in small batches (1-25 kilograms) for the pharmaceutical and food industries (PAP-00433552). An additional Addendum dated August 10, 1992, stated Chemo Dynamics, Inc. also leased 729 square feet east of their pilot plant in Building 17 (PAP-00433536, 38).

4. Identified COCs

- PCBs (, used detected)
- PAHs (detected)
- Copper (used, detected)
- Lead (detected)
- Mercury (detected)

PCBs

The 1991 EA identified several transformers at the site and each was noted to be labeled as containing less than 50 ppb PCBs (PAP-00433546-57).

Two areas containing transformers were identified as areas of environmental concern (AECs) in the 1995 RAWP (PAP-00041652). According to the *Comprehensive Remedial Action Work Plan Addendum*, dated March 14, 2008 (Comprehensive RAWP), PCBs were not detected in site soil at AEC-23 (Transformers at Building 1), but were detected in soil samples collected from AEC-24 (Transformer at Building 12) at a maximum of 2.2 milligrams/kilogram (mg/kg) for Aroclor-1260. This sample (B-44-01

DUPE) was collected from a depth of 0.3-0.8 feet, and two of eight delineation samples collected later from a depth of 0.3-0.8 feet and 1.5-2.0 feet to confirm the findings detected PCBs up to 0.22 mg/kg (PAP-00046359-60).

The *Remedial Investigation and Remedial Actions Report, Building 17 & Former Sewer Lines*, dated February 26, 2003, (2003 RI/RAR) identified additional AECs associated with the demolition of Building 17, the former laboratory and pilot plant. Fill was discovered within the foundation walls of the building and was analyzed for PCBs as part of the waste disposal characterization. PCBs were detected at 15.8 mg/kg in one soil sample, but additional delineation samples did not detect PCBs. An area of 19 feet by 27 feet was excavated to a depth of 4 feet around the sample location (PAP-00044391-92). Building 17 was located in the southwestern corner of the site as shown on the figure above.

PAHs

The Comprehensive RAWP identified AECs 1, 3, 6, 10, and 11 as formerly containing fuel oil underground storage tanks (USTs). The USTs were excavated between 1987 and 1990. Only the soil at AEC-11 showed PAH-impacted soil. Sample S-2, collected from a depth of 2 to 4 feet, had a maximum concentration of benzo(b)fluoranthene of 5.69 ppm (see Section 7 for all PAH concentrations at S-2) (PAP-00046310, 16, 18, 20-21, 31-33).

As discussed in the 1993 ECRA Investigation Report, PAHs were detected in 50 of 69 soil samples analyzed for PAHs. The total PAH concentrations ranged from an estimated 0.018 ppm in Sample B-43-A to approximately 101 ppm in Sample B-52-A, collected just south of former fuel oil UST A-4 (PAP-00041235).

According to the data reported in the 1995 RAWP, PAHs were detected at most AECs when soil samples were analyzed for these parameters (PAP-00041858-86). The highest concentrations were detected at AEC-11 (Former No. 2 Fuel Oil USTs), AEC-15 (Salicylic Acid/Salicylate Production Buildings 10/36/39), and AEC-21 (Drum Storage Area Buildings 16 and 17). The maximum concentrations of PAHs were detected from soil sample AEC-15-1C at AEC-15 (see concentrations in the discussion of Historic Fill and in Section 7, Response Actions) (PAP-00042265).

The *Revised Remedial Action Work Plan Addendum*, dated February 29, 1996 (RAWP Addendum) stated that fill material, including sand, gravel, brick and rock fragments, cinders, and ash, had been noted at the site and extending off site. The RAWP Addendum investigated soil boring B-52-A, detecting concentrations of benzo(a)pyrene up to 42 ppm, and attributed the elevated PAH concentrations to the presence of fill (PAP-00042178-79). The Comprehensive RAWP attributed PAHs at several AECs (e.g., AEC-14 and AEC-15) to the fill material at the site since PAHs would not have been used at the facility (PAP-00046341, 44).

The 2003 RI/RAR found elevated PAHs detected in mud from a concrete basin (AEC-32A) north of Building 17 (i.e., 6.1 ppm of benzo(a)anthracene; 4.45 ppm of benzo(b)fluoranthene; 3.04 ppm of benzo(k)fluoranthene; and 4.42 ppm of benzo(a)pyrene). It was stated that this basin drained sinks in the laboratory, but did not connect to a sewer and instead had vents to allow for evaporation (PAP-00044389, 91).

Copper

The 1991 EA identified Building 7 as a former copper shop where sheet metal was fabricated, but it is unclear when this building was used for this purpose (PAP-00433547). A 1989 fact sheet for Draft NJPDES Permit to Discharge into the Waters of the State of New Jersey (Permit No. NJ0000124) noted that the limitation on copper was removed because the facility informed NJDEP that they did not use copper (PAP-00206137, 44).

A NJDEP Hazardous Waste Generator Annual Report lists hazardous wastes shipped offsite in the year 1989, including 18 pounds of Waste Poison B solids identified as P029 (copper cyanide) among others (PAP-00433733).

According to the 1990 PVSC Application for a Sewer Connection Permit, Effluent 003 is the Kalama designation for outlet 09404292-21040-0091, which contained industrial waste discharged to the PVSC. This permit application also noted copper was detected at 9 mg/L in the waste water effluent (PAP-00016718, 21). A previous PVSC Application for a Sewer Connection Permit from 1986 stated copper was detected at 2.3 mg/L (PAP-00206124).

An undated NJDEP application for permit to discharge to a domestic treatment works stated the process waste (effluent 003) had copper at 1.0 mg/L (PAP-00433687). Copper was detected in surface soil (Sample B-47-Fill) at AEC-15 (Salicylic Acid/Salicylate Production Buildings 10/36/39) at a maximum concentration of 550 ppm (PAP-00041872). Copper was also detected in filter cake material at 223 ppm located between crushed white rock found in a 40-foot-long concrete trough at Building 17 (AEC-32C, Concrete Trough). The soil sample collected beneath the trough detected copper at 52.4 ppm. The concrete trough was excavated in 2002, including an area of 12.5 feet by 60 feet and 5 feet deep and consisting of 210 tons of soil (PAP-00044395-97, 455).

Lead

Although lead was not reported to be included in the operations at the site, a sample of Methylsalicylate Still Bottoms collected April 10, 1991, was analyzed by Toxicity Characteristic Leaching Procedure and resulted in lead concentration of 0.132 mg/L (PAP-00433740).

A NJDEP Hazardous Waste Generator Annual Report lists hazardous wastes shipped offsite in the year 1989, including 107 pounds of hazardous waste solids identified as D008 (lead) among others (PAP-00433733).

Pretreatment monitoring reports for discharges to the PVSC included results for lead in composite samples collected during three months in 1991 as reported below. The monitoring reports stated that metals were not used at the facility (PAP-00433622; PAP-00433632; PAP-00433642).

Effluent Monitoring of Lead		
Month in 1991	**Result (µg/L)**	**Average Flow (GPD)**
July	150	251,000
October	140	271,000
November	120	129,000

(PAP-00433625; PAP-00433635; PAP-00433645)

Results for a sample of "PV 003 Effluent – Pretreatment (composite)" collected March 2, 1993, had lead (0.0020 mg/L) (PAP-00433666-67). According to the 1990 PVSC Application for a Sewer Connection Permit, Effluent 003 is the Kalama designation for outlet 09404292-21040-0091, which contained industrial waste. This permit application also noted that lead was not expected to be present in the waste water (PAP-00016718, 21).

An undated NJDEP application for permit to discharge to a domestic treatment works stated the process waste (effluent 003) had lead at 0.09 mg/L (PAP-00433687).

Analytical results for outfalls to the Passaic River were reported in an undated EPA form 3510 2C (Rev. 2-85). Lead (15 µg/L) was detected in Outfall 002 (PAP-00433658). The long-term average value for lead in the intake water was listed as 16 µg/L (PAP-00433658).

According to the 2003 RI/RAR, lead was detected in filter cake material at 594 ppm found at AEC-32C (Concrete Trough) in Building 17. Soil beneath the trough contained lead at 43.6 ppm (PAP-00044395-97, 455). After the trough was excavated in 2002, the loading dock between Building 16 and Building 17 was investigated. Fill material consisting of crushed rock, brick, wood chips, and glass was found beneath the loading dock. The fill was 1 foot thick, while the native soil beneath consisted of a fine sandy silt. A sample from the fill material contained 42,000 ppm lead, while the native soil beneath this location detected lead at 35.9 ppm. Approximately 166 tons of soil were excavated from this area in 2002 (PAP-00044397-99, 457).

The 2008 Comprehensive RAWP stated that lead was detected up to 820 ppm in AEC-15, but the lead was attributed to historic fill because it was never used in any of the manufacturing processes at the site (PAP-00046343-44). Lead was also detected up to 2,830 ppm in crushed concrete in the basement of former Building 33-B. The concrete was generated during demolition activities. The text stated that the lead contamination in the crushed concrete would be addressed by the site wide institutional and engineering controls that will be implemented for the historic fill material (PAP-00046395-96).

Mercury

A NJDEP Hazardous Waste Generator Annual Report lists hazardous wastes shipped offsite in the year 1989, including 107 pounds of hazardous waste solids identified as D009 (mercury) among others (PAP-00433733).

An undated NJDEP application for permit to discharge to a domestic treatment works stated the process waste (effluent 003) had mercury at <0.0005 milligrams/liter (mg/L) (PAP-00433687).

Analytical results for outfalls to the Passaic River were reported in an undated EPA form 3510 2C (Rev. 2-85). Mercury was detected at 0.2 µg/L in Outfall 002 (PAP-00433658).

Mercury was detected in subsurface soil (depth of 4 to 4.5 feet, Sample B-53 Fill) at AEC-15 (Salicylic Acid/Salicylate Production Buildings 10/36/39) at a maximum concentration of 18.6 ppm (PAP-00041873). Mercury was also detected at a concentration of 15.5 ppm from the soil along the sewer line (depth of 2.5 to 3 feet, Sample SL-17-1) at AEC-33 (Building 17 Sewer Line). Approximately 110 tons of soil were excavated from the sewer line and disposed off-site (PAP-00046380-1).

According to the 2003 RI/RAR, mercury was also detected in filter cake material at 100 ppm located between crushed white rock found in a 40-foot-long concrete trough at Building 17 (AEC-32C, Concrete Trough). The soil sample collected beneath the trough detected mercury at 0.58 ppm. An area of 12.5 feet by 60 feet and 5 feet deep was excavated around the concrete trough in 2002, and included 216 tons of soil (PAP-00044395-97, 455).

Historic Fill

The Allocation Team has determined that the majority of the facility site is not located on regional historic fill as designated by the NJDEP.[1]

However, NJDEP-designated regional historic fill is present at the northwest corner of the site under Monroe Street. Site investigations found man-made materials (crushed stone, brick and sandstone fragments, cinders ash,) characteristic of historic fill in the subsurface throughout the facility and offsite at depths up to 10 feet below ground surface (bgs) (PAP-00041645, PAP-00042178). In addition, the 1996 RAWP Addendum attributed elevated concentrations of PAHs and lead at the former Salicylic Acid/Salicylate Production Buildings located at the northeast portion of the site to the presence of fill (PAP-00042177-80). The 2008 Comprehensive RAWP attributed elevated concentrations of PAHs at AECs 14, 15, 21, 26, 30, 31, and 34 to “historic fill” (PAP-00046341, 44, 58, 62, 67-8, 70, 82).

[1] *Digital Geodata Series, DGS04-7, Historic Fill for New Jersey*, https://www.nj.gov/dep/njgs/geodata/dgs04-7.htm, Quadrangle No. 42 (NJDEP map identifying locations of recognized historic fill).

NJDEP has established that historic fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 COCs: PAHs, lead, copper, and mercury.[2] Accordingly, NJDEP technical requirements for property containing historic fill requires sampling for the EPA Target Compound List for PAHs and Target Analyte List for metals, including lead, copper, mercury, and the OU2 PAH COCs.[3] PAHs, lead, copper, and mercury are recognized by NJDEP to be constituents of historic fill at varying levels, not atypically at or exceeding residential soil standards.[4]

The levels of PAHs, copper, lead and mercury detected at the site in soils are presented in the table below (PAP-00041872-3; PAP-00042265).

COCs Found in Onsite Soils	
COC	**Max Detected Concentration**
Lead	42,000 mg/kg
Copper	550 mg/kg
Mercury	18.6 mg/kg
Benzo(a)anthracene	41.0 mg/kg
Benzo(a)pyrene	42.0 mg/kg
Benzo(b)fluoranthene	38.0 mg/kg
Benzo(k)fluoranthene	13.0 mg/kg
Dibenzo(a,h)anthracene	5.5 mg/kg
Indeno(1,2,3-cd)pyrene	33.0 mg/kg

5. COC Pathways

Sanitary/Combined Sewer

A letter from Kalama to the PVSC, dated December 21, 1982, stated that the Garfield, New Jersey, facility had been acquired by Kalama as of December 9, 1982, and waste water was discharged to the PVSC Treatment Works under Sewer Connection Permit No. 0940722, which had been issued to the previous owner Tenneco Chemicals, Inc. on January 23, 1981, and expired January 26, 1986. The letter also stated that the flow rate, analysis, and flow characteristics of wastewater effluent remained the same even though the ownership had changed (PAP-00208804). A list of the waste water flow rates from each department at the facility to the "PV Sewer" was dated May 1981, and identified the total flow to the sewer at that time as 85.48 million gallons per year (PAP-00433614, 20).

---

[2] *Characterization of Ambient Levels of Selected Metals and cPAHs In New Jersey Soils* (2002) and *Characterization of Ambient Levels of Selected Metals and Other Analytes In New Jersey Soils* (1997), studies prepared for NJDEP, Division of Science and Research, by BEM Systems, Inc.

[3] New Jersey Department of Environmental Protection (NJDEP), *N.J.A.C. 7:26E Technical Requirements for Site Remediation,* Table 4-2, November 2009 [Note that Table 4-2 has been deleted from the current version of N.J.A.C. 7:26E (May 7, 2012) and the updated *Historic Fill Technical Guidance* (April 2013) as NJDEP believed that the tables list of historic fill constituents was too restrictive].

[4] NJDEP Table 4-2 (PAHs and lead) and a summary of NJDEP records regarding investigations of properties in the vicinity of the Passaic River recognized to be located in areas of historic fill indicate that the following average/maximum (mg/kg) contamination levels of OU2 COCs exist in area historic fill: PAHs (1.91/160), lead (574/10,000), copper (11.2/1,200), and mercury (0.21/3.7).

The 1991 EA stated that all process waste was discharged to the PVSC under permit number 09404292 (PAP-00433578). This PVSC Sewer Connection Permit was effective May 27, 1986, and expired May 27, 1991. Effluent limitations were defined for two outlets, 09404291-21040-0091 (discharge point No. 3) and 09404292-21040-0091 (discharge points No. 1 and 2), including a daily maximum total for lead of 690 µg/L and a maximum monthly average of 320 µg/L to be reported semiannually (PAP-00016682, 86-89, 90-92).

An undated NJDEP Application for Permit to discharge to a domestic treatment works identified outlets 001 (Sanitary Building No. 17), 002 (Sanitary Building No. 34), and 003 (process wastes, boiler house, air compressors, shops, offices, sanitary, etc.) to the PVSC. Outlet 003 had a pH neutralization listed for its treatment. In addition, this outlet was stated to have copper at 1.0 mg/L, lead at 0.09 mg/L, and mercury at less than 0.0005 mg/L. PAHs were listed as not detected (PAP-00433684, 87-88).

As of March 14, 1986, daily flow at outlet 09404291 was reported as 315,000 gallons (PAP-00206123). The Baseline Monitoring Report submitted under the OCPSF (Organic Chemicals, Plastics and Synthetic Fibers) Category (40 CFR 414 and 416), dated June 15, 1988, listed the total waste water from the facility as an average flow rate of 335,000 GPD (for OCPSF-regulated wastewater, 270,000 GPD) and a maximum flow rate of 380,000 GPD (for OCPSF-regulated wastewater, 310,000 GPD). (PAP-00206174). Information on Compliance with OCPSF Category stated the annual volume of wastewater from the facility was 119,435,000 gallons, while the daily average was 327,000 gallons in 1989 (PAP-00433668, 73). In 1990, pretreatment standards for discharge to the PVSC treatment plant were a daily maximum of 690 ppb and a monthly average of 320 ppb for lead. Kalama's total waste water flow was listed as 275,000 gallons per day (GPD), while flow from Kalama's OCPSF operations was 265,000 GPD (PAP-00016701-2). In 1993, pretreatment standards for lead discharge were the same as in 1990. Kalama's total waste water flow to the PVSC treatment plant was listed as 327,000 GPD, while flow from Kalama's regulated waste water flow was 322,000 GPD (PAP-00433676-77).

According to a PVSC Application for a Sewer Connection Permit, dated May 5, 1986, 113,607,000 gallons of process waste water and approximately 1,440,000 gallons of sanitary service water went to the combined sewer from January 1985 through December 1985 (PAP-00206120-21, 29).

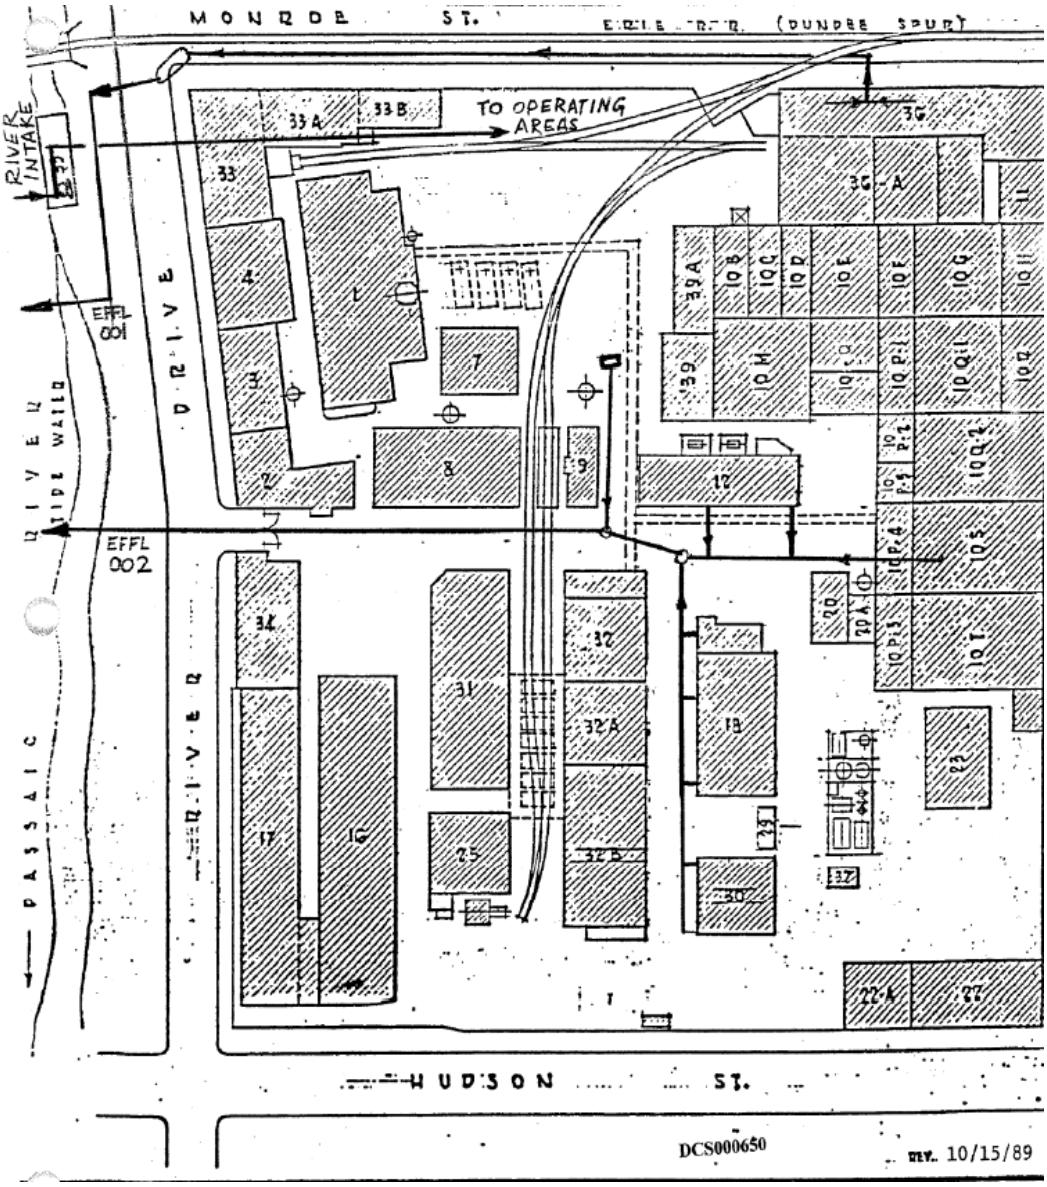
According to a PVSC Application for a Sewer Connection Permit, dated November 27, 1990, 80,699,000 gallons of process waste water and approximately 1,440,000 gallons of sanitary service water went to the combined sewer from October 1989 through September 1990 (PAP-00016715-17).

The flow rates through outlet No. 09404290-21040-0091 during three months in 1991 were reported in Pretreatment Monitoring Reports for the PVSC.

Total Flow		
Month in 1991	**Maximum (GPD)**	**Average Flow (GPD)**
July	318,000	251,000
October	361,000	271,000
November	191,000	129,000

(PAP-00433621; PAP-00433631; PAP-00433641)

Results for a sample of "PV 003 Effluent – Pretreatment (composite)" collected March 2, 1993, had lead (0.0020 mg/L) but PAHs were not detected (PAP-00433666-67). According to the 1990 PVSC Application for a Sewer Connection Permit, Effluent 003 is the Kalama designation for outlet 09404292-21040-0091, which contained industrial waste. This permit application also noted that lead was not expected to be present in the waste water, but copper was detected at 9.0 mg/L (PAP-00016718, 20, 21).



An Industrial User Charge/Pretreatment Inspection Report stated an annual inspection was performed March 25, 1993. Meter readings for average daily water use were reported as 700,000 GPD of river water and 150,000 GPD of waste water. The report also stated contaminated storm water was treated and then discharged to the sewer, while uncontaminated water was discharged to the river (PAP-00206151, 53, 55).

According to the 1993 ECRA Investigation Report, the process waste water lines connected to the PVSC trunk line beneath River Drive (PAP-00041523).

Direct Release

According to the 1991 EA, Kalama had two separate outfalls that discharged to the Passaic River. Outfall 001 was for non-contact cooling water, which was pumped from the river, screened, used once and returned without treatment to the river. Outfall 002 was similar to 001, but included storm water and boiler blowdown (PAP-00433579).

A fact sheet for Draft NJPDES Permit to Discharge into the Waters of the State of New Jersey (Permit No. NJ0000124) listed approximately 360,000 GPD of non-contact cooling water from the Salicylic Acid plant as discharged through a storm sewer to Outfall 001. Approximately 480,000 GPD of storm water and non-contact cooling water from the Salicylic Acid derivatives were discharged through Outfall 002. The following site map showing the outfall locations was dated October 15, 1989 (PAP-00206137, 40).

(PAP-00206140)

According to two PVSC Applications for a Sewer Connection Permit, dated May 5, 1986, and November 27, 1990, 340,078,600 gallons and 404,358,000 gallons, respectively, of cooling water were discharged to the Passaic River from January to December 1985 and October 1989 through September 1990, respectively (PAP-00206119-20; PAP-00016715-16).

An Industrial User Charge/Pretreatment Inspection Report stated an annual inspection was performed March 25, 1993. Meter readings for average daily water use were reported as 700,000 GPD of river water and 150,000 GPD of waste water. The report also stated contaminated storm water was treated and then discharged to the sewer, while uncontaminated water was discharged to the river (PAP-00206151, 53, 55)

Analytical results for each outfall were reported in an undated EPA form 3510 2C (Rev. 2-85). Concentrations of PAHs, PCBs, total lead, total copper, and total mercury were not detected in Outfall 001 (PAP-00433647-55), while total lead (15 µg/L) and total mercury (0.2 µg/L) were detected in Outfall 002 (PAP-00433658). The long-term average value for lead in the intake water was listed as 16 µg/L (PAP-00433649, 58).

6. Regulatory History/Enforcement Actions

Inspections

An Industrial User Charge/Pretreatment Inspection Report stated an annual inspection was performed March 25, 1993. Meter readings for average daily water use were reported as 700,000 GPD of river water and 150,000 GPD of waste water. The report also stated contaminated storm water was treated and then discharged to the sewer, while uncontaminated water was discharged to the river (PAP-00206151, 53, 55).

An Application for Certificate of Inspection by the Garfield Fire Department stated Hart Chemical Co. at the 290 River Drive location was inspected by the New Jersey Bureau of Fire Safety on December 15, 1988 (PAP-00433530-31).

A Right to Know Compliance inspection was conducted by the New Jersey Department of Health on September 14, 1992. The violations noted were all due to failure to label containers (PAP-00433862-65).

Violations

Violations were noted for Hart Chemical Co. at the facility based on a December 15, 1988, inspection by the New Jersey Bureau of Fire Safety. The violations included permits needed for the flammable and corrosive areas, and a diked area for the manufacturing area (PAP-00433532).

The PVSC sent a notice of violation on May 2, 1991, for non-COCs (chloroform and toluene) but these were noted by the facility to be sampling error and subsequent results showed compliance (PAP-00208805). Another PVSC notice of violation for permit 0949429 based on a non-COC (methylene chloride) was dated April 13, 1994 (PAP-00208813).

Permits

A letter from Kalama to the PVSC, dated December 21, 1982, stated that the Garfield, New Jersey, facility had been acquired by Kalama as of December 9, 1982, and discharged water under Sewer Connection Permit No. 0940722, which had been issued to Tenneco Chemicals, Inc. on January 23, 1981, and expired January 26, 1986 (PAP-00208804).

PVSC Sewer Connection Permit No. 09404292 was effective May 27, 1986, and expired May 27, 1991. Effluent limitations were defined for two outlets, 09404291-21040-0091 (discharge point No. 3) and 09404292-21040-0091 (discharge points No. 1 and 2), including a daily maximum for total lead of 690 µg/L and a maximum monthly average of 320 µg/L to be reported semiannually (PAP-00016682, 86-89, 90-92).

A letter to the PVSC from Kalama dated April 6, 1990, documented standard limits for discharge to the PVSC treatment plant. The total wastewater flow was 275,000 gallons per day, while flow from Kalama's OCPSF operations was 265,000 GPD. The limits for total lead were a daily maximum of 690 ppb (combined waste water formula application 665 ppb) and a monthly average of 320 ppb (combined waste water formula application 309 ppb) (PAP-00016700-02).

A letter from the NJDEP to Kalama, dated January 29, 1993, served as a final notice of termination of the New Jersey Pollutant Discharge Elimination System/Significant Indirect User (NJPDES/SIU) Permit (No. NJ0000124) to discharge pollutants into a delegated local agency's wastewater treatment plant, because the criteria for individual NJPDES/SIU permits did not apply to the facility (PAP-00016712).

NJDEP Permit No. NJ0000124 allowed discharge to the Passaic River, and was effective January 1, 1985, and expired December 31, 1989. According to the *Environmental Site Assessment, Phase I Property Transfer Report*, dated May 1994, Kalama submitted a renewal application to NJDEP, but it was still under review by NJDEP (PAP-00433807). Effluent limitations included copper (1.0 mg/L), but monitoring was only stated to be necessary if a corrosion inhibitor containing copper was used (PAP-00206157-58).

A 1989 fact sheet for Draft NJPDES Permit to Discharge into the Waters of the State of New Jersey (Permit No. NJ0000124) identified the two outfalls to the Passaic River. Limitations for non-COCs were specified and it was noted that the limitation on copper was removed because the facility informed NJDEP that they did not use copper (PAP-00206137, 44).

7. Response Actions

Characterization Activities

Numerous site characterization activities have taken place at the facility. The most significant reports include:

- *Environmental Assessments, Draft Report for B.C. Sugar*, dated September 3, 1991, prepared by Dames & Moore (PAP-00433539).
- *ECRA Investigation Report and Proposed Remedial Action Workplan, Volume I of IV*, dated December 1993 (ECRA Investigation Report), prepared by Geraghty & Miller, Inc. (PAP-00041187).
- *Environmental Site Assessment, Phase I Property Transfer Report*, dated May 1994, prepared by IT Corporation (PAP-00433767).
- *Revised Remedial Action Work Plan*, dated March 31, 1995 (PAP-00041624)

- *Revised Remedial Action Work Plan Addendum*, dated February 29, 1996, by SECOR International Inc. (PAP-00042155).
- *Remedial Investigation and Remedial Actions Report, Building 17 Former Sewer Lines*, dated February 26, 2003 (RI/RAR), by Sovereign Consulting Inc. (PAP-00044380).
- *Remedial Investigation Report and Remedial Action Work Plan for the Northern Phenol Area and Dowtherm DNAPL Areas,* dated February 13, 2004 (PAS-00008946).
- *Comprehensive Remedial Action Work Plan Addendum*, dated March 14, 2008, prepared by Sovereign Consulting Inc. (PAP-00046273).

Soil

Soil sampling was performed from 1986 through 1993 and summarized in the 1995 RAWP. The 1995 RAWP identified 28 AECs that generally included former locations of USTs (e.g., AECs 1, 3, 6, 10, and 11 contained fuel oil USTs), drum and scrap metal storage areas (AECs 19, 20, 21), production areas (AECs 14, 15, 16, 17), transformers (AECs 23, 24), and loading/unloading areas (AECs 24 through 28) (PAP-00041648-52).

According to the 1995 RAWP, PCBs were detected in site soil at AEC-24 (Transformer at Building 12) at a maximum of 2.2 mg/kg for Aroclor-1260 (PAP-00041882). In addition, according to the 2003 RI/RAR, PCBs were detected at 15.8 pm in one sample collected from the fill within the foundation walls of Building 17, but additional delineation samples did not detect PCBs (PAP-00044392-93).

The 1995 RAWP stated metal COCs were detected in soil at AEC-14, AEC-15, and AEC-18 as listed in the table below. Highest levels of metals contamination in soil were noted at AEC-15 (Salicylic Acid/Salicylate Production Buildings 10/36/39). The 1996 RAWP Addendum attributed the lead concentration at AEC-15 to the presence of fill at the site (PAP-00042180).

Metal COCs Detected in Soil				
AEC	**Description**	**Copper**	**Lead**	**Mercury**
AEC-14	Benzoic Acid/ Benzaldehyde Production Area	7.8 mg/kg	(3.4 U)	(0.11 U)
AEC-15	Salicylic Acid/ Salicylate Production Buildings 10/36/39	550 mg/kg	820 mg/kg	18.6 mg/kg
AEC-18	Sewer Lines	190 mg/kg	446 mg/kg	0.68 mg/kg

U: Not detected
(PAP-00041871-73, 76)

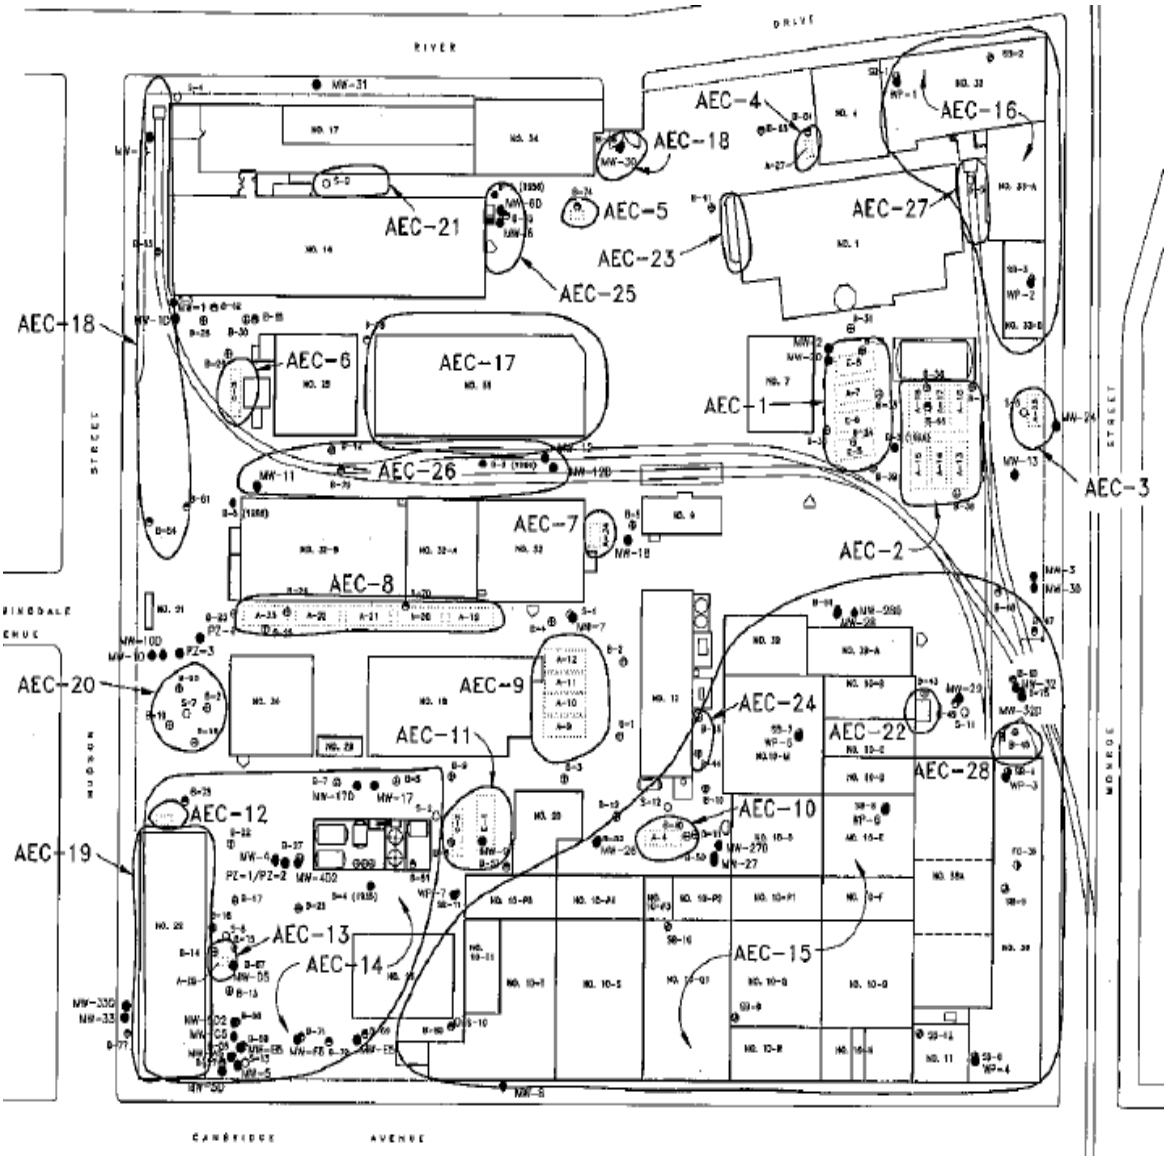
PAHs were detected at most AECs, but concentrations were generally low, with the highest concentrations detected at AEC-15 (Salicylic Acid/Salicylate Production Buildings 10/36/39). The 1996 RAWP Addendum attributed these concentrations to the presence of fill at the site (PAP-00042179). The maximum concentrations of PAHs were detected as follows:

Maximum PAHs Detected in Soil Samples			
PAHs (ppm)	**S-2 at AEC-11**	**B-52-A at AEC-15**	**AEC-15-1C**
Anthracene	0.85	1.3	13.0
Benzo(a)anthracene	3.0	12.0	41.0
Benzo(a)pyrene	2.4	10.0	42.0
Benzo(b)fluoranthene	5.69	13.0	38.0
Benzo(ghi)perylene	0.96	3.0	43.0
Benzo(k)fluoranthene	NR	2.5	13.0
Chyrsene	4.0	12.0	45.0
Dibenzo(a,h)anthracene	NR	1.0	5.5
Fluoranthene	4.1	14.0	41.0
Fluorene	0.66 U	NR	1.8
Indeno(1,2,3-cd)pyrene	0.95	2.9	33.0
Naphthalene	2.8	0.12 J	0.27 J
Phenanthrene	3.4	4.6	39.0
Pyrene	6.91	20	260

NR: not reported J: estimated concentration U: not detected
(PAP-00041870, 72; PAP-00042265)

The 2003 RI/RAR identified additional AECs associated with the demolition of Building 17, the former laboratory and pilot plant. Elevated PAHs were detected in mud from a concrete basin (AEC-32A) north of Building 17 (i.e., 6.1 ppm of benzo(a)anthracene; 4.45 ppm of benzo(b)fluoranthene; 3.04 ppm of benzo(k)fluoranthene; and 4.42 ppm of benzo(a)pyrene). It was stated that this basin drained sinks in the laboratory, but did not connect to a sewer and instead had vents to allow for evaporation (PAP-00044389-91).

Sewer



In the 1995 RAWP, AEC-18 was identified as the western portion of the sewer line that ran along Hudson Street to south, as well as the sewer outfall 002 near the main gate (PAP-00041651). Metals and PAHs were detected in soil samples collected along the sewer lines at maximum concentrations of 190 ppm copper (Sample B-55-Fill), 446 ppm lead (Sample B-54-Fill), and 0.68 ppm mercury (Sample B-54-Fill) (PAP-00041876).

The sewer lines from Building 17 (AEC-33), Building 32 (AEC-34), and Hudson Street (AEC-35) were removed in 2002. Maximum concentrations of metals in soil beneath the Building 17 line were 92.9 ppm copper, 132 ppm lead, and 15.5 ppm mercury. Soil samples collected at the Building 32 and Hudson Street sewer lines were not analyzed for metals, but PAH concentrations detected at Building 32 were attributed to fill material at the site. Approximately 110 tons, 756 tons, and 1,312 tons of soil were removed with each sewer line, respectively (PAP-00016753-56; PAP-00044401, 03-04, 13, 59).

Remedial Activities

The 1993 ECRA Investigation Report discussed five phases of ECRA-related investigations from 1986 to 1993 and the removal of 27 underground storage tanks during September 1987 to February 1990. In addition, an Administrative Consent Order (ACO) was executed between Kalama and NJDEP in December 1988 (PAP-00041518, 28-32).

The 1995 RAWP identified 28 AECs that generally included former locations of USTs (e.g., AECs 1, 3, 6, 10, and 11 contained fuel oil USTs), drum and scrap metal storage areas (AECs 19, 20, 21), production areas (AECs 14, 15, 16, 17), transformers (AECs 23, 24), and loading/unloading areas (AECs 24 through 28) (PAP-00041648-52).

(PAP-00041795; note north is to the right in this figure)

The 2003 RI/RAR identified additional AECs associated with the demolition of Building 17, the former laboratory and pilot plant. Fill was discovered within the foundation walls of the building and was analyzed for PCBs as part of the waste disposal characterization. PCBs were detected at 15.8 ppm in one soil sample, but additional delineation samples did not detect PCBs. An area of 19 feet by 27 feet was excavated to depth of 4 feet around the sample location (PAP-00044391-92).

This investigation also excavated a concrete trough with elevated metals concentrations located at Building 17, including an area of 12.5 feet by 60 feet and 5 feet deep and consisting of 216 tons of soil (PAP-00044395-97). After the trough was excavated in 2002, the loading dock between Building 16 and Building 17 was investigated. Fill material consisting of crushed rock, brick, wood chips, and glass was found beneath the loading dock. The fill was 1 foot thick, while the native soil beneath consisted of a fine sandy silt. A sample from the fill material contained 42,000 ppm lead, while the native soil beneath this location detected lead at 35.9 ppm. Approximately 166 tons of soil were removed from this area in 2002 (PAP-00044397-99, 457).

The sewer lines from Building 17 (AEC-33), Building 32 (AEC-34) and Hudson Street (AEC-35) were removed in 2002. Maximum concentrations of metals in soil beneath the Building 17 sewer line were 92.9 ppm copper, 132 ppm lead, and 15.5 ppm mercury. The soil along the Building 17 sewer line consisted of crushed stone/slag fill material underlain by sand, silt, and silty sands. Approximately 110 tons, 756 tons, and 1,312 tons of soil were removed with each sewer line, respectively (PAP-00044401, 04, 13).

The 2008 Comprehensive RAWP stated no further action (NFA) was approved by NJDEP for the following AECs in a letter dated September 6, 1995: AEC-1 through 8, 10, 16, 22, 23, 25, 27, and 28. It was also stated that AEC-31 received NFA approval on June 18, 2002, and AEC-32A, 32B, 32C, 32D, 33, 34, and 35 were approved for NFA by NJDEP on October 21, 2003 (PAP-00323694-702, 708, 729, 737-739, 741-742, 749-766).

A letter from NJDEP dated December 30, 2008 approved NFA for the following AECs: 9, 12, 13, 15, 17, 18, 19, 20, 21, 26, and 32A. The letter stated a site-wide cap engineering control was required due to the presence of contaminated historic fill at the site (PAP-00324631).

8. Summary of Asserted Defenses

Goodrich asserts that to the extent it is claimed that PAHs from released petroleum products impacted the River, such discharges are excluded from CERCLA by the petroleum exclusion at 42 USC 9601(14). To the extent it is claimed that PAHs impacted the River, Respondent also intends to assert a transport and fate defense.

Newell Brands Inc. (f/k/a Newell Rubbermaid Inc.)

Diamond Alkali OU2 Allocation

ADR Confidential

Facility Data Report

NEWELL BRANDS INC. (f/k/a Newell Rubbermaid Inc.)

Facility Name, Address and Size: Goody Products, Inc. (formerly known as H. Goodman & Sons, Inc.) 969 Newark Turnpike, Kearny, New Jersey 07032.[1] Approximately 10.3 Acres (PAP-00104322). In a Pollutant Discharge form dated December 1975, the plant reported 300 employees. In a July 24, 1991, Sewer Connection Application, the plant reported 300 full-time employees with two shifts per day (PAP-00103450; PAP-00105520). A Community Right To Know Survey for 1991 completed by Goody Products, Inc. reported 320 employees (PAS-00002034).

1. **Business Type:** Manufacturer of nickel-plated hair care accessories (PAP-00104322).

2. **Time Period of Ownership/Operations**

Operator: ~1968 to May 13, 1994 (PAP-00103485; PAP-00104911; PAP-00104832; PAP-00105268; PAS-00001863)
Owner: Jeryl Industries, Inc., from pre-1969 to at least 1996 (PAS-00001835; PAS-00002050)

H. Goodman & Sons, Inc. leased the Site from Jeryl Industries, Inc. on May 26, 1966 (PAP-00350468; PAS-00002050-89). On January 2, 1976, H. Goodman & Sons, Inc. filed a Restated Certificate of Incorporation (PAS-00002091-98). The corporate name was changed to Goody Products, Inc. on May 22, 1980, according to a Certificate of Amendment of Certificate of Incorporation of H. Goodman & Sons, Inc. (PAS-00002099-104). Note: A 1996 Assignment and Assumption of Lease stated the name was changed to Goody Products, Inc. on June 2, 1982 (PAP-00350469). Goody Products became a wholly owned subsidiary of Newell Company by a stock purchase of August 2, 1993 (PAP-00350690; PAS-00001867). According to the 1997 Response to Request for Information completed by Newell Company, Goody Products operated at the facility for approximately 25 years from approximately 1968 to 1994. Operations at the site ceased in May 1994 (PAP-00104911; PAP-00104832; PAP-00105268; PAS-00001863).

On June 15, 2018, the stock of Goody Products, Inc. was transferred from Newell Brands Inc. (f/k/a Newell Rubbermaid Inc., f/k/a Newell Co.), through a series of internal contributions, ultimately to its wholly owned indirect subsidiary Sunbeam Diversified Holdings LLC, a Florida limited liability company. On August 31, 2018, Newell Brands Inc. assumed the liability of Goody Products, Inc., if any, in connection with the Diamond Alkali Superfund Site arising from alleged discharges from the past operation of the Facility by Goody Products, Inc. (PAP-00718033; PAP-00718036). On that same day, Newell Brands Inc. then caused the sale of the stock of Goody Products, Inc. from Sunbeam Diversified Holdings LLC to GP Midco, L.L.C., a Delaware limited liability company that is unrelated to Newell Brands Inc. (PAP-00717943, 54-57). Newell

[1] The property where the Goody Products, Inc. facility was located was commonly known as 969 Newark Turnpike. Google Maps currently lists the property's address as 969 Newark-Jersey City Turnpike.

Brands Inc. further agreed to indemnify Goody Products, Inc. for that assumed liability (PAP-00717954-57, PAP-00718033-4, PAP-00718036).[2]

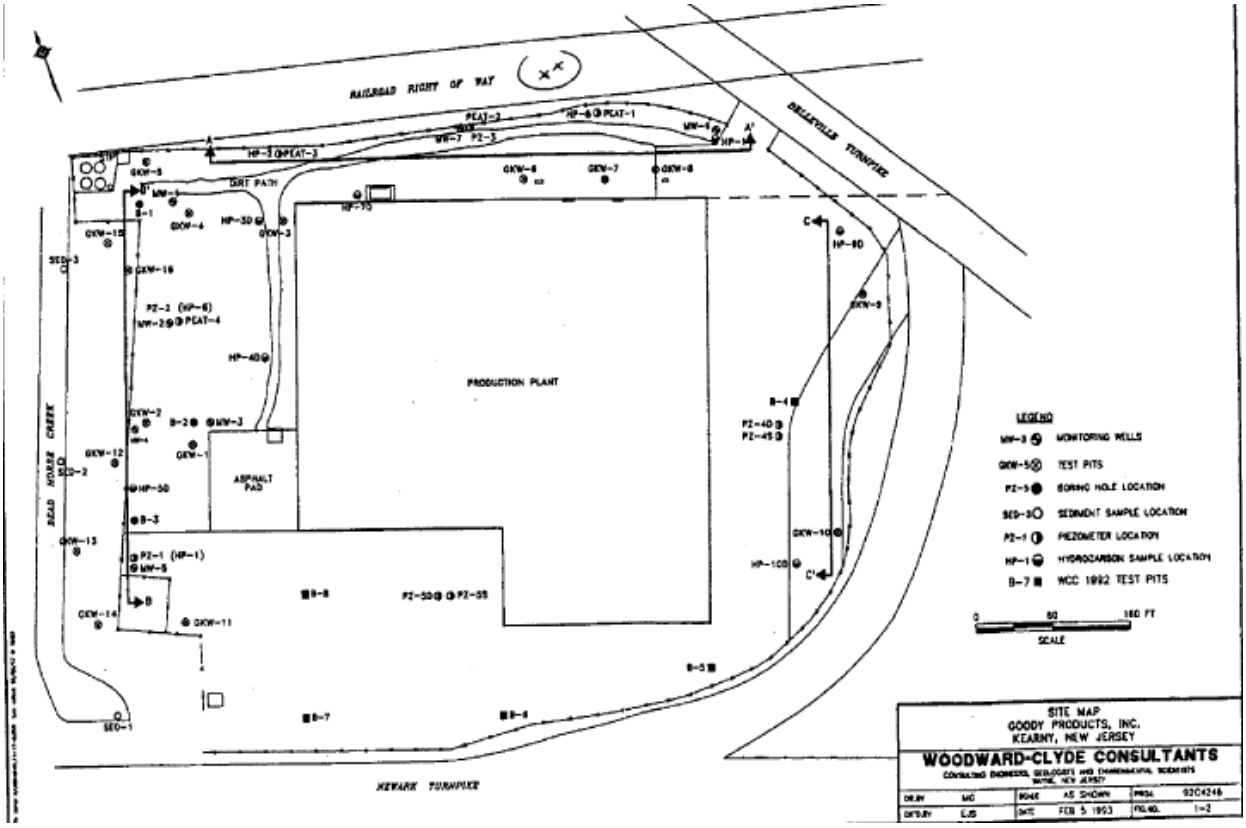
3. Operational History/COC Use and Presence at the Facility

According to the 1997 Response to Request for Information completed by Newell Company, the products manufactured at the facility were hair barrettes, and other metal hair accessories such as pins. Base metals such as steel, stainless steel, and aluminum were purchased and processed to make the final products. These base metals contained variable amounts of aluminum, iron, and chromium. The manufacturing processes to make the final products included stamping and forming to obtain semi-finished metal parts which were heat-treated and annealed. This process utilized oils. Metal parts were also subjected to burnishing or polishing. Scale removal involved acid and caustic water mixtures. Certain products underwent dry process metallizing with aluminum. Electroplating of nickel onto steel from an acid solution of nickel ions was also conducted. Some zinc plating from cyanide solutions may also have taken place. Lacquer coating of metal parts that utilized thinners containing ethylbenzene, toluene, and xylene also occurred. Hazardous wastes were generated as a result of the manufacturing processes (PAP-00103473; PAS-00001864).

Goody Products operated under NJPDES discharge permit No. NJ0029505, which granted the company permission to discharge to Dead Horse Creek. The permit was issued June 2, 1984, and effective August 1, 1984, and had an expiration date of July 31, 1989 (PAP-00350677; PAS-00001878). Contaminants to be monitored under this permit included lead and copper, with daily discharges of each not to exceed 0.1 mg/L; and oil and grease, with daily discharge not to exceed 20 mg/L (PAS-00001891). Note: PAHs may be present in oils.

According to the 1983 Public Notice for the issuance of draft NJPDES permit No. NJ0029505, there were two existing surface water discharge outfalls at the Goody Products facility. Discharge 001 was industrial process wastewater generated from various metal finishing operations that would receive treatment consisting of equalization, neutralization, flocculation, clarification, and filtration. Discharge 002 was sanitary wastewater which received treatment consisting of primary settling, aeration, secondary settling, and chlorination (PAP-00105420; PAP-00105440-41).

A Discharge Monitoring Report from July 1989 stated that a new Industrial Process Waste Water Treatment Plant was installed in July (PAP-00446234-37). In August 1989, it was reported that Goody Products was adjusting and debugging the new treatment system. The old treatment system, which was being used for neutralization of alkaline cleaners, appears to be the source of unexpected nickel, cadmium and lead residues, thereby contributing to exceedances (PAP-00446296).



[2] This Report was revised to include documents received on June 15, 2020. The additional documents did not change Newell Brands Inc.'s previous certification

A Community Right-to-Know Survey for 1991 completed by Goody Products states that Goody Products' nature of business included manufacturing, assembly, and warehousing of hair care accessories (PAS-00002034).

The 1991 Survey shows areas where chemicals were stored. This included: The tool room; boiler room; plating room; maintenance department; warehouse; metalizing-stripping room; waste treatment area; waste storage area; and, outside sanitary sewer treatment plant. Chemicals listed included among others, waste oils, acetone, acetylene, naphtha solvent, kerosene, hydrogen peroxide, hydrochloric acid, ferrous sulfate, sodium hydroxide, sulfuric acid, sodium bisulfite, sodium hypochlorite, nickel plugs and nickel compounds, 2-butoxyethanol, and ammonia (PAS-00002035-43).

A map included with the June 1993 report *Results of Field Investigation and Review of Remedial Options* (included below) prepared by Woodward-Clyde Consultants for Goody Products shows the location of the production plant in relation to Dead Horse Creek to the west. According to the map at the end of this section the sanitary wastewater treatment plant was located in the northwestern corner of the facility (PAS-00001945; PAS-00001959).

Newell Company stated in the 1997 *Response to Request for Information* that there was no further discharge by Goody Products personnel from the treated sanitary wastewater outfall (002A) after the property was vacated in October 1994. No flow reports were filed with the New Jersey Department of Environmental Protection (NJDEP) until August 1996 (PAS-00001863; PAS-00001876-77). In 1994 and 1995, all hazardous waste generated at Goody Products was disposed of at off-site facilities (PAS-00001911-26; PAS-00001930-43). Hazardous wastes disposed of in 1994 included filter cake from metals treatment of wastewater, and rinse and wash water from electroplating (PAS-00001911-26). Note: It was stated in the *Response to Request for Information* that the site was vacated in October 1994 and confirmed in a waste report that manufacturing operations ceased May 13, 1994 (PAS-00001929). The last shipments of hazardous waste from the facility were on August 14, 1995 (PAS-00001930-43).

4. Identified COCs

- PAHs (potentially used and detected
- Copper (used)
- Lead (used)
- Mercury (released)

PAHs

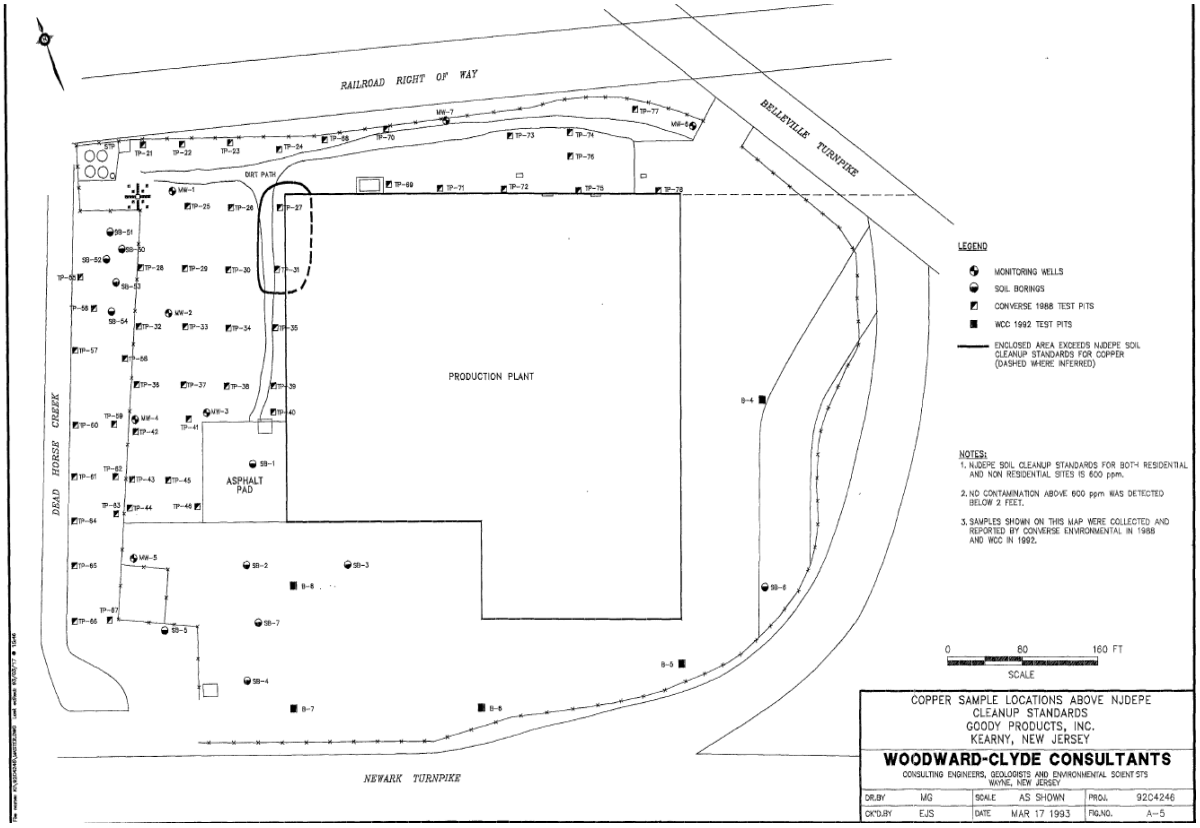
Newell stated in the 1997 Response to EPA Request for Information that PAHs may be present in heating fuel oil, lubricating oils, and heat quench oil (PAS-00001864). Fuel Oil No. 4 was stored in a 10,000-gallon underground storage tank (UST) located in the northern portion of the Goody site. The tank was removed in February 1990 (PAP-00105060; PAP-00350612).

Following the excavation, confirmation samples were collected from the sidewalls. Five base-neutral compounds (benzo(a)anthracene, benzo(b)fluoranthene, benzo(a)pyrene, benzo(k)fluoranthene and indeno(1,2,3-cd)pyrene) were detected in the deeper sample obtained from the southern sidewall (PAP-00105061). The total concentration of the PAHs was 7.34 mg/kg, which is below the cleanup guideline of 10 mg/kg (PAP-00350625). A 1990 Report on UST Removal found that soil remediation was not necessary following UST removal because elevated petroleum hydrocarbon concentrations were attributable to historic fill (PAP-00350612-13). A October 1994

Preliminary Remedial Investigation Workplan concluded the presence of PAHs was attributable to historical urban fill materials placed at the site in conjunction with site development, and no further action was proposed with regard to the 10,000 gal. UST (PAP-00105061). Soil, surface water, and groundwater sampling on the site and within Dead Horse Creek has detected several PAHs (PAS-00002018-19; PAS-00002021-22; PAS-00002024-25; PAP-00104829-97; PAP-00104783-801).

Copper

According to the May 1972 Waste Effluent Survey conducted for Passaic Valley Sewerage Commissioners, some materials used at the facility contained metals and metal alloys (brass and white metal) (PAP-00350464). Brass contains copper (PAP-00350483). The white metal may have contained copper (PAP-00350467; PAP-00103466; PAP-00350478-508; PAP-00350509-10). The type of white metal used by the facility and its chemical composition is not known. The 1972 Waste Effluent Survey reported a concentration of copper of 1,675 micrograms per liter (µg/L) in the facility's industrial wastewater (PAP-00350467).



According to a NJDEP memorandum dated February 11, 1976, field samples collected on three different occasions in June 1975 and in September 1975 from two-inch discharge hoses emanating from the rear of H. Goodman & Sons, Inc., premises and discharging to the ground revealed excessive heavy metals parameters (PAP-00105499). The concentration of copper in these samples ranged from 105 µg/L to 430 µg/L (PAP-00105511-13). In addition, the samples collected on June 5 and 12, 1975 had low pH readings of 2.7 and 2.3, respectively (PAP-00105511-12). It appears that as of 1983, the Facility was no longer using brass or white metal (PAP-00105322).
In the 1997 Response to EPA's Request for Information, Newell stated that it received, utilized, manufactured, discharged, released, stored or disposed of materials containing copper at the Goody Products facility included (PAS-00001863-64).

According to a December 17, 1976 Regarding Aeration Studies, the Facility's industrial wastewater discharges contained copper (PAP-00104750; PAP-00104753).

A 1979 treatability study of facility wastewater noted pretreatment levels of copper of 0.19 mg/l; and post treatment levels of copper of 0.03 mg/l (PAP-00105365 According to the NJPDES permit application materials from 1991, copper was known to be present in the facility's discharge (PAP-00103466).

Soil, surface water, and groundwater sampling on the site and within Dead Horse Creek has detected copper (PAS-00001965-69; PAS-00001973-76 PAS-00001994-96; PAP-00104185-88;; PAP-00104829-97; PAP-00104783-801;).

The June 1993 Results of Field Investigation and Review of Remedial Options prepared by Woodward-Clyde Consultants for Goody Products included maps delineating the locations of the contaminants which exceeded New Jersey Department of Environmental Protection and Energy (NJDEPE) residential and non-residential soil cleanup standards. The following map shows the area where copper exceeded cleanup standards:

(PAP-00103569)

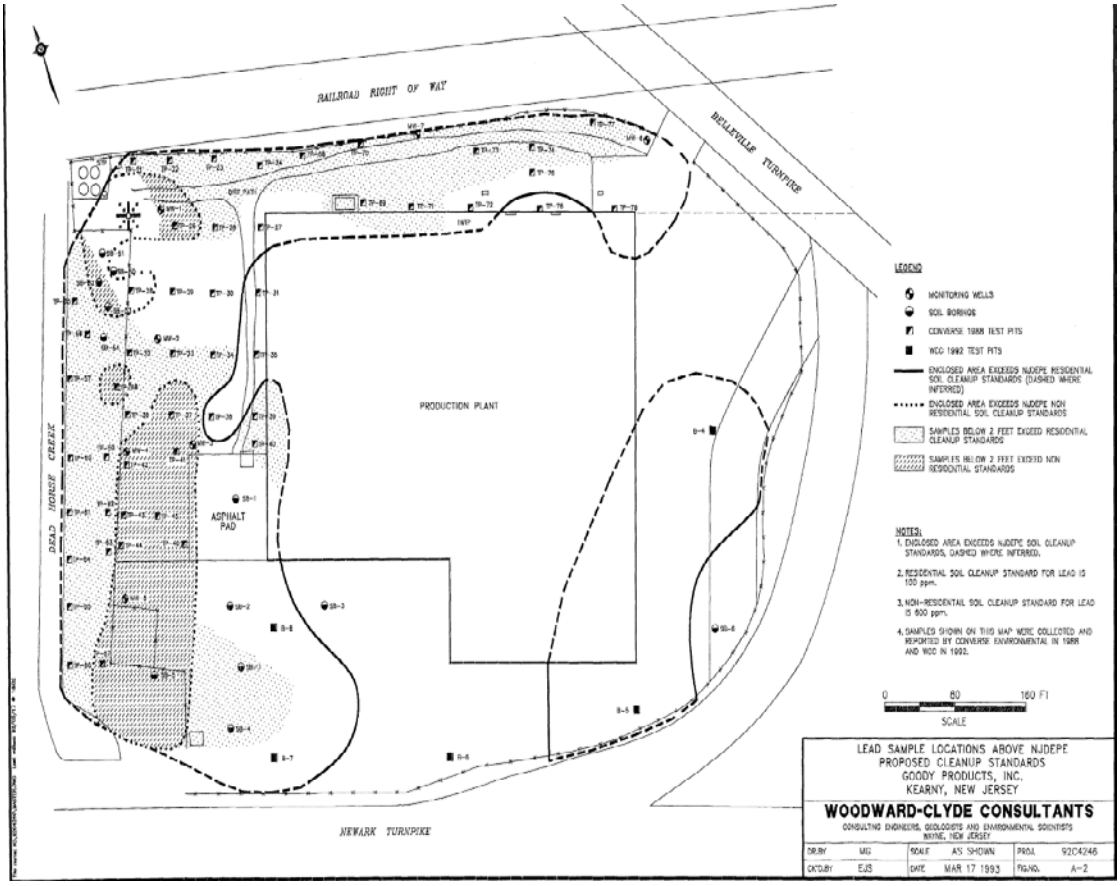
Discharge Monitoring Reports for Industrial Process Wastewater discharges (Discharge 001) from 1984 through 1994 reported numerous detections for copper (PAP-00446408-735).

Lead

According to the May 1972 Waste Effluent Survey, white metal was used at the facility (PAP-00350464). The white metal may have contained lead (PAP-00350478-508). The type of white metal used by the facility and its chemical composition is not known. It appears that as of 1983, the facility was no longer using brass or white metal (PAP-00105322). Lead was not reported in the chemical testing results recorded in the 1975 New Jersey Department of Health Stream or Wastewater Analysis (PAP-00105511-13).

A 1979 treatability study of facility waste water noted pretreatment levels of lead of 6.40 mg/l; and post treatment levels of lead of 0.40 mg/l (PAP-00105365). In other instances, such as in 1983 and 1991, lead was not detected in facility wastewater discharges (PAP-00105310). According to the NJPDES permit application materials from 1991, lead was suspected to be absent from the facility's discharges (PAP-00103466).

In the 1997 Response to EPA's Request for Information, Newell stated that it received, utilized, manufactured, discharged, released, stored or disposed of materials containing lead at the Goody Products facility (PAS-00001863-64).



Newell Brands Inc. (f/k/a Newell Rubbermaid Inc.)
Diamond Alkali OU2 Allocation
ADR Confidential
Facility Data Report

Discharge Monitoring Reports for Industrial Process Wastewater discharges (Discharge 001) from 1984 through 1994 reported numerous detections for lead (PAP-00446408-735).

Soil, surface water, and groundwater sampling on the site and within Dead Horse Creek has detected lead, (PAS-00001965-79; PAS-00001994-96; PAS-00002009; PAS-00002016-17; PAS-00002023; PAP-00104156; PAP-00104185-98; PAP-00104829-97; PAP-00104783-801).

In 2002, NJDEP accepted information provided by Killam that lead in groundwater is associated with historic fill. Based on the presence of lead in groundwater in both process and non-process areas of the property, and on the fact that lead is a common constituent of fill materials, NJDEP accepted that the lead in groundwater is associated with the historic fill on the property and required no further delineation for lead in groundwater (PAP-00105242).

The following map from the June 1993 Results of Field Investigation and Review of Remedial Options shows areas where lead exceeded cleanup standards:

(PAP-00103563)

Mercury

Mercury was not reported in the chemical testing results recorded in the 1975 New Jersey Department of Health Stream or Wastewater Analysis (PAP-00105511-13) or in a 1979 wastewater treatability analysis (PAP-00105365). A 1979 NPDES Permit Application Form states that mercury was not present in wastewater (PAP-00105310). According to the NJPDES permit application materials from 1991, mercury was suspected to be absent (PAP-00103466).

Soil, surface water, and groundwater sampling on the site and within Dead Horse Creek detected mercury, (PAS-00001994-96; PAP-00104166; PAP-00104173; PAP-00104175; PAP-00104829-97; PAP-00104783-801).

In 2002, NJDEP Bureau of Groundwater Pollution Assessment (BGWPA) accepted Newell's conclusions that the mercury in the surface water did not originate from the facility (PAP-00105250). According to a 2003 memo from the BGWPA, mercury was not identified above the standard in the shallow wells proximate to Dead Horse Creek or in any other shallow wells at the site. Therefore, the BGWPA concluded that mercury in Dead Horse Creek probably originated from an off-site source (PAP-00105243).

Historic Fill

The Allocation Team has determined that the facility site is located on regional Historic Fill as designated by the NJDEP.[3]

NJDEP has established that historic fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 COCs: PAHs, lead, copper, and mercury.[4] Accordingly, NJDEP technical requirements for property containing Historic Fill requires sampling for the EPA Target Compound List for PAHs and Target Analyte List for metals, including lead, copper, mercury, and the OU2 PAH COCs.[5] PAHs, lead, copper, and mercury are recognized by NJDEP to be constituents of Historic Fill at varying levels, not atypically at or exceeding residential soil standards.[6]

---

[3] *Digital Geodata Series, DGS04-7, Historic Fill for New Jersey*, https://www.nj.gov/dep/njgs/geodata/dgs04-7.htm, Quadrangle No. 52 and No. 53 (NJDEP map identifying locations of recognized historic fill).

[4] *Characterization of Ambient Levels of Selected Metals and cPAHs In New Jersey Soils* (2002) and *Characterization of Ambient Levels of Selected Metals and Other Analytes In New Jersey Soils* (1997), studies prepared for NJDEP, Division of Science and Research, by BEM Systems, Inc.

[5] New Jersey Department of Environmental Protection (NJDEP), *N.J.A.C. 7:26E Technical Requirements for Site Remediation,* Table 4-2, November 2009 [Note that Table 4-2 has been deleted from the current version of N.J.A.C. 7:26E (May 7, 2012) and the updated *Historic Fill Technical Guidance* (April 2013) as NJDEP believed that the tables list of historic fill constituents was too restrictive].

[6] NJDEP Table 4-2 (PAHs and lead) and a summary of NJDEP records regarding investigations of properties in the vicinity of the Passaic River recognized to be located in areas of Historic Fill indicate that the following average/maximum (mg/kg) contamination levels of OU2 COCs exist in area Historic Fill: PAHs (1.91/160), lead (574/10,000), copper (11.2/1,200), and mercury (0.21/3.7).

The levels of PAHs, copper, lead and mercury detected at the site in soils are presented in the table below.

COCs Found in Onsite Soils	
COC	**Max Detected Concentration**
Lead	13,572 mg/kg
Copper	2,550 mg/kg
Mercury	11.2 mg/kg
Benzo(a)anthracene	49 mg/kg
Benzo(a)pyrene	48 mg/kg
Benzo(b)fluoranthene	63 mg/kg
Benzo(k)fluoranthene	24 mg/kg
Dibenzo(a,h)anthracene	8.6 mg/kg
Indeno(1,2,3-cd)pyrene	31 mg/kg

Available documentation and information suggests the soil samples were taken from areas containing historic fill materials. According to the Report of Environmental Record Check and Review prepared by S&S Environmental Sciences, Inc. for Jeryl Industries, Inc., dated May 24, 1994, the site was previously undeveloped marshland, which was reclaimed for construction before 1968 with fill material (PAP-00103480). The entirety of the site is located on historic fill material starting from the surface and going to a depth of 9.5 feet below grade (PAP-00105254-255). Investigation by Killam in connection with the Industrial Site Recovery Act (ISRA) process confirmed the presence of fill material throughout the property (PAP-00104915). During sampling at the facility, the presence of fill material was noted at all interior and exterior sample locations (PAP-00104918, 41).

Documentation and information also suggests sediment samples included historic fill material. According to Hatch Mott MacDonald, Jeryl Industries created the current surface water feature (i.e., Dead Horse Creek) as part of the property's development in the late 1960s. The linear, channelized water body currently present at the property was believed to have been created both through the removal of indigenous soil material and emplacing fill materials from an off-site source to form the bedding of the channel (PAP-00104787).

There is no indication from a review of provided documents that facility operations disturbed contamination located in historic fill.

Further, according to S&S Environmental Sciences, Inc.. report, \ the background sampling and testing conducted at the site since 1988 stated that the fill materials used at the site also contain some of the pollutants (metals and organics) also used and/or discharged by Goody Products. However, due to S&S Environmental Science's conclusion that long-term use of hazardous substances and generation of hazardous wastes by Goody Products during its operation, combined with periodic on-site disposal and/or spills of hazardous substances/wastes, it was their opinion that the operations of Goody Products have had significant adverse environmental impact on the property soils and groundwater (PAP-00103476; PAP-00103485). Notably, the S&S report was

prepared while a suit was pending between Jeryl Industries, Inc. and Goody Products, and the report's author was later designated in the suit as an expert for Jeryl Industries, Inc. (PAP-00402669; PAP-00402673).

5. COC Pathways

Sanitary Sewage

Goody Products operated a sanitary sewage treatment plant at the northwestern corner of the facility. The plant included four below-grade cylindrical tanks and a control building. Effluent discharge was to Dead Horse Creek, located immediately adjacent, and to the west, of the plant (PAP-00103326; PAP-00104611).

Available references include information on the sanitary sewage treatment plant at the site, but do not include specific information regarding COCs that may have entered the system or been discharged through it. Correspondence from May 4, 1970, provided a response to a March 31, 1970, surveillance report concerning an incident where the chlorine contact tank was overflowing due to the receiving stream (Dead Horse Creek) being blocked, raising the level of the creek and backing up onto Plant property (PAP-00351060-61). NJDEP Discharge Surveillance Reports dated October 18, 1979 similarly described the chlorine contact tank as being flooded by receiving stream backup (PAP-00351068).

A Plant Diagram and Flow Sequence included with a NJDEP Plant Inspection and Status Report Form dated August 23, 1983 shows the sanitary wastewater to flow to the treatment plant and then to Dead Horse Creek (PAP-00105320-22).

An application for EPA permit to discharge wastewater, dated January 26, 1989, listed the average flow through outfall 002 as 9,000 gallons per day (PAP-00717921, 24).[7]

Correspondence dated November 13, 1989, described the sewage treatment plant as a compact, activated sludge return, package unit. It was designed to handle 100,000 gallons per day. The normal processing is 15,000 gallons per day. Sludge generated at the contact aerator is return-pumped back to a primary settling tank for recycling. Sludge is not routinely removed from the system and it had been several years since anything had been removed from any tank (PAP-00446792; PAP-00446953). It was stated that Goody Products does not produce sludge on a daily basis and they pump out the system only when maintenance dictates so. In September 1989, the entire system was completely pumped out to perform maintenance work (PAP-00446793; PAP-00446954). In April 1989, a sample of the slurry was taken from the bottom of the primary settling tank for analysis (PAP-00446792). The reported results included copper at 2.45 mg/L, lead at 0.6 mg/L, and oil and grease at 528 mg/L (PAP-00446797-98).

[7] This Report was revised to include documents received on June 15, 2020. The additional documents did not change Newell Brands Inc.'s previous certification.

Correspondence dated May 29, 1990, reported that Goody Products had no sludge wasting capabilities built into their treatment systems. They did not have thickening tanks, dewatering equipment, incinerator, or removal pumps. If they desired to waste or remove sludge, they would call a commercial vacuum to suction directly from their digester (PAP-00447846-47).

Numerous Domestic Wastewater Sludge Reports reported copper and lead and in some cases mercury. The domestic sludge waste was disposed of by off-site incineration (PAP-00446844; PAP-00448131; PAP-00447543-45, 641, 841).

Industrial Wastewater

The volume of industrial wastewater discharged through outfall 001 to Dead Horse Creek was an average of 25,000 gallons per day with a maximum of 40,000 gallons per day, according to an application for EPA permit to discharge wastewater, dated January 26, 1989. The wastewater was discharged five days per week and twelve months per year (PAP-00717922, 24). This application also reported concentrations for the industrial effluent of 0.1 mg/L copper and 0.1 mg/L lead. PAHs were not detected in the one industrial effluent sample collected (PAP-00717925-33).[8]

In addition to other non-COC pollutants, the industrial wastewater from discharge Outfall 001 has been reported to contain copper and lead (PAP-00350678; PAP-00446368-76).

A memo from the NJDEP dated February 9, 1988, reported that before the installation of the computerized industrial treatment system about four years prior, untreated industrial waste water was discharged to the ground. The computerized treatment system reportedly had never worked as planned and excessive nickel above Permit limits was being discharged at that time. NJDEP noted that the treatment system may need in house design changes (PAP-00105285). NJDEP also noted that Goody Products would need a Discharge to Groundwater Permit for past and present use. A minimum of four monitoring wells would be required, one upgradiant and three downgradiant. If the groundwater monitoring results were acceptable, Goody Products may not have been required to renew the Groundwater Permit after five years (PAP-00105285-86).

The following results for Industrial Process Wastewater discharges (Discharge 001) at Goody Products, Inc. were reported on monthly Discharge Monitoring Reports and/or in the May 1990 New Jersey Pollution Discharge Elimination System Discharge to Groundwater Permit Application:

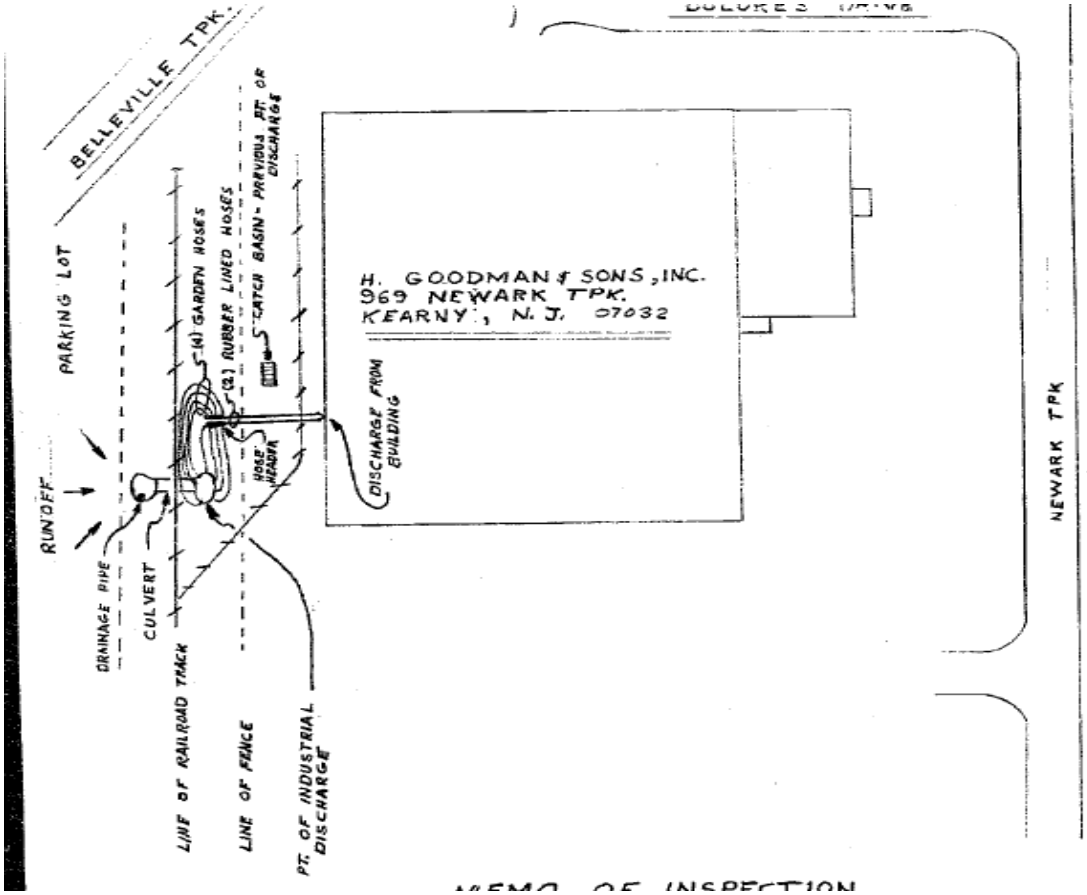
Note: Reported results which appear to exceed the permit limitations are highlighted grey.

A NJDEP letter to Goody Products dated September 27, 1989, discussing the results of an August 9, 1988, Compliance Evaluation Inspection stated that the Goody Products facility received an "Unacceptable" rating due to several deficiencies which included Discharge Monitoring Report violations for August 1988 through June 1989, the final effluent pipe at discharge 002 (sanitary wastewater) being inaccessible due to high weeds, and that a portion of the wastewater from the effluent pit for discharge 001 (industrial wastewater) discharges to ground and surface waters of the State. This deficiency had been cited in previous directive letters and it was stated again that Goody Products must apply for a Discharge to Groundwater Permit (PAP-00105282-84).

Numerous Industrial Process Wastewater Sludge Reports reported detections of copper, lead, and mercury (PAP-00446809; PAP-00447493-95; PAP-00447587, 762, 772, 786, 799, 960; PAP-00448032; PAP-00448065; PAP-00448076; PAP-00448115). Numerous other Industrial Process Wastewater Sludge Reports reported detections of just copper and lead (PAP-00446832; PAP-00446831; PAP-00446845; PAP-00447677, 678, 730, 744, 806, 814, 822; PAP-00448018; PAP-00448037; PAP-00448045; PAP-00448053; PAP-00448090, 97; PAP-00448105; PAP-00448139). These sludge wastes were disposed of as hazardous waste off-site (PAP-00447447-58).

A January 1993 NJDEP monitoring report stated that on December 11, 1992, both the sanitary and industrial wastewater treatment systems were out of service due to flooding in the area. Both systems were restored by December 21, 1992 (PAP-00105280-81).

Release



According to a NJDEP memorandum dated October 21, 1975, after a September 18 1975 inspection by the NJDEP it was noted that there were no provisions in place for containment or treatment of the industrial wastewaters at the point of discharge. Two discharge hoses were used for the conveyance of collected plating room floor drain wastewaters out of the plant. The untreated industrial wastewaters were being allowed to discharge onto plant grounds. According to a representative of H. Goodman & Sons, Inc., this had been the procedure followed by the facility for a number of years. It was noted that the hoses were evident in a 1974 inspection, but it was suggested at that time that the hoses were not in use (PAP-00105514).

An October 18, 1979, NJDEP Discharge Surveillance Report included a Plant Diagram and Flow Sequence for the Plating and Etching operation showing the batch tanks rinse waste would flow to floor drains, then to sump pit, then pumped to ground surface behind plant property (PAP-00351067).

A Plant Diagram and Flow Sequence included with a NJDEP Plant Inspection and Status Report Form dated August 23, 1983, shows the acid rinse sump, burnishing sump, and caustic rack strip sump all draining directly into Dead Horse Creek (PAP-00105320-22). The NJDEP Plant Inspection and Status Report Form dated August 23, 1983 states that the Goody facility was waiting for the industrial wastewater treatment system to be installed (PAP-00105320-21).

Starting in September 1984, the industrial waste effluent from the electroplating and burnishing operations were treated at the facility's industrial wastewater treatment plant and discharged to Dead Horse Creek at Outfall 001, located near the northwest corner of the Facility building. A concrete block tank (discharge pit) was constructed in the facility's west yard to act as a collection point so that the IWTP effluent could be pumped to Dead Horse Creek (PAP-00104321-22; PAP-00105318; PAP-00105373).

According to a NJDEP memorandum dated November 3, 1978, an investigation was conducted on October 6, 1978, by the NJDEP to verify the direction of the treated sewage treatment plant discharge from the H. Goodman & Sons, Inc. facility. According to the November 1978 memorandum (PAP-00105486) and a separate memo dated October 6, 1978 (PAP-00105489), NJDEP found that the discharge flowed through a 12" reinforced concrete pipe under the Newark Turnpike, through a wetland area, entering a 60" culvert which then emptied into a drainage ditch between the railroad line and the U.S. Post Office, through another 60" culvert flowing under the Post Office property, through a second wetland area, then flowing through an underground drainage canal along an abandoned transformer building, out of the drainage canal, flowing under the Erie Lackawanna Railroad track, then finally entering the tide pump well and being discharged to the waters of the Passaic River (PAP-00105486; PAP-00105489).

(PAP-00105491)

The NJDEP inspected the Facility in May 1971 and observed that the "ditch" (i.e. Dead Horse Creek) was blocked and the blockage caused the wastewater to back up and flood the Facility (PAP-00103321). Goody believed that the construction of the U.S. Post Office had blocked the flow of Dead Horse Creek causing wastewater to back up on the Facility property (PAP-00104747).Observations of dye testing at the Facility have shown that industrial wastewater discharges prior to 184 on the norther side of the building did not flow to Dead Horse Creek (PAP-00105515).

NJDEP Discharge Surveillance Reports dated August 27, 1987, and March 10, 1988, gave unsatisfactory ratings to several categories due to flooding and the lack of drainage and flow under Newark Turnpike (PAP-00105293-95).

NJDEP performed a dye study to verify the drainage of Dead Horse Creek in 1980. According to NJDEP, a dye tablet dropped at the mouth of the sewage treatment plant effluent discharge pipe remained in Dead Horse Creek on the facility side of Newark Turnpike and was not transported through the 12-inch RCP culvert under the Newark Turnpike (PAP-00105480). It was stated that there is only a flow when there is severe flooding on the Goody side of the road (PAP-00105480).

A March 24, 1988, evaluation of the system by Converse Environmental East for Goody Products found surface water drainage problems that may be caused by one or more of the following: an earth berm across the creek, a fully or partially blocked culvert under the Newark Turnpike adjacent to and south of the site, and a non-operating pump station at Dead Horse Creek's discharge into the Passaic River. The evaluation noted that the earthen berm across the creek "has been breached, to some degree." It was also noted the existing 12 to 15-inch culvert under the Newark Turnpike was scheduled to be replaced by a larger 24-inch culvert within the next two weeks from the report date. The pump was noted as being inoperable for about two months (PAP-00104611-12). There is no record of the culvert ever being replaced.

Converse Environmental East surveyed surface water elevations in Dead Horse Creek on March 23, 1989. Surface water elevation at the time of the survey was above normal stage due to precipitation that had occurred several days before the survey. The survey points were located near the culvert at the Newark Turnpike and near the Sanitary Treatment Plant in the northwest portion of the site. The surface water elevation at both locations was 2.49 feet. It was observed that the creek was ponding due to damming effects at the culvert orifice (PAP-00104344-45).

Culverts located under Newark Turnpike and the Passaic were frequently clogged resulting in elevated water levels in Cedar Marsh and flooding on surrounding properties (PAP-00104728-29).

The Pumping Station (also referred to as the Cedar Creek Pumping Station, the Hudson County Pumping Station or the HCMC Pumping Station, Tide Well) was funded and built by the NJ State Mosquito Control Commission between 1953 and before 1962 to provide drainage for the Cedar Creek Marsh. A major storm in 1962 caused severe damage of the mosquito control installations. The Pumping Station was having chronic problems since the 1960's and HCMC eventually stopped fixing it. As of at least 1991, the

Pumping Station was inoperable (PAP-00104661). A 1991 report also noted that water flowed from Cedar Marsh through a culvert (when it was not clogged) and then out to the Passaic River during low water levels in the Passaic River through a gravity outlet (Id.). No mention of the gravity outlet has been seen in other documents.

According to the May 1996 Remedial Investigation Report / Remedial Action Workplan for Goody Products, Inc., Dead Horse Creek analytical results from samples collected on March 22, 1996 from 0.0 – 0.5 feet from the base of the stream contained max concentrations of PAHs in sample 03226-78 including benzo(a)anthracene (4,800 mg/kg), Benzo(b)fluoranthene (6,200 mg/kg), Benzo(k)fluoranthene (2,400 mg/kg), Benzo(a)pyrene (4,600 mg/kg), indeno(1,2,3 cd)pyrene (3,000 mg/kg), copper (382 mg/kg), lead (780 mg/kg) and mercury (2.10 mg/kg) (PAP-00104964; 5040).

6. Regulatory History/Enforcement Actions

Violations and Enforcement Actions

In November 1975, the NJDEP issued an order to H. Goodman & Sons, Inc. to cease the discharge of all polluting materials (PAP-00105499; PAP-00105516-17).

In a letter received on December 1, 1975, the NJDEP issued a Notice of Violation and Offer of Settlement to H. Goodman & Sons, Inc. for the discharges of industrial waste allowing the flow of polluting materials into the waters of Dead Horse Creek, a tributary to the Passaic River. The discharges were noted in inspections conducted on June 5, 1975, June 12, 1975, and September 18, 1975 by NJDEP and included excessive heavy metal parameters (PAP-00105499; PAP-00105518-19). Note: The specific metals which exceeded permit levels were not specified.

On July 17, 1978, the U.S. EPA issued a Findings of Violation and Order to Show Cause to H. Goodman & Sons, Inc., for violating the Clean Water Act by discharging pollutants without a National Pollutant Discharge Elimination System (NPDES) permit (PAP-00103534-43). Note: The specific pollutants which exceeded permit levels were not specified.

A NJDEP Discharge Surveillance Report for an inspection conducted on June 5, 1979 noted a major deficiency as 6,000 gallons per day of an unspecified liquid were discharging into Dead Horse Creek. The majority of the evaluation parameters were noted to be “flooded.” This included the grounds and buildings, the settling units, aeration (contact), effluent (residual), contact tank, and final effluent appearance (PAP-00105481-83). Note: The Surveillance Report did not specify which outfall discharged the 6,000 gallons.

According to a NJDEP letter to Goody Products dated September 26, 1983, the Goody Products facility earned an “acceptable” rating after a Compliance Monitoring Inspection conducted on September 15, 1983 (PAP-00105425).

According to a December 13, 1985, NJDEP Discharge Surveillance Report, two discharges observed exceeded permit limitations for pH, cyanide, nickel and total suspended solids (PAP-00105297).

According to November 24, 1987, correspondence, a Compliance Evaluation Inspection was conducted by NJDEP on August 27, 1987, and September 8, 1987. The Goody Products facility received a rating of “Unacceptable” due to several deficiencies. These deficiencies included that the bypass of the effluent filter and filter press at Industrial Treatment, discharge 001, due to pump failure had not been reported as required by NJPDES Permit No. NJ0029505, and the final effluent contained visible solids (PAP-00447020-21). Deficiencies at the Sewage Treatment, discharge 002, included the fact that the sanitary wastewater treatment plant was flooded, so that representative effluent samples could not be obtained; and the primary settling units, contact aeration tanks, secondary settling units, sludge holding, and chlorine contact tanks were flooded in violation of N.J.A.C. 7:9-1.39(a) (PAP-00447021). Soil samples taken from the surface of the ground surrounding the industrial waste discharge pit were taken on September 8, 1987. Exceedances included lead at 210 ppm (PAP-00447021-22, 27). Copper was detected at 82 ppm (PAP-00447027). Goody Products responded to the NJDEP on January 18, 1988 (PAP-00447047-51).

A NJDEP letter to Goody Products dated September 27, 1989, discussing the results of an August 9, 1988, Compliance Evaluation Inspection stated that a Notice of Violation was issued for Discharge Monitoring Report violations for August 1988 through June 1989. These violations included copper on three occasions. Another deficiency listed was that a portion of the wastewater from the effluent pit for DSN 001 discharges to ground and surface waters of the State. It was stated that Goody Products must apply for a Discharge to Groundwater Permit. Goody Products was required to submit a written report concerning specific details of remedial measures to be instituted, as well as an implementation timetable within 30 days (PAP-00105282-84; PAP-00447388-91). According to the November 22, 1989, Administrative Order and a Notice of Civil Administrative Penalty Assessment issued by NJDEP to Goody Products, in September 1988 and June 1989 copper was detected at Outfall 001 at 0.30 mg/L and 0.24 mg/L, respectively (PAP-00350677-88).

A Compliance Evaluation Inspection was conducted on September 19, 1991, by NJDEP. The Goody Products facility received a rating of “Unacceptable” because a review of the Discharge Monitoring Reports revealed that permit effluent limitations were exceeded at discharges 001 and 002. These violations included a February 1991 discharge of copper 0.15 mg/L (PAP-00447037-38).

A September 29, 1993, Administrative Consent Order Affidavit included a Summary of Enforcement Actions for Violation of Environmental Laws or Regulations which discussed 11 violations which occurred from December 1975 through August 1993. Violations included effluent limitation exceedances, alleged discharges to ground surface, and unpermitted discharges (PAP-00350695-98). Note: The pollutants which exceeded effluent limitations were not specified in the source document.

According to the May 1994 *Report of Environmental Record Check and Review*, on November 22, 1989, the NJDEPE issued an Administrative Order and a Notice of Civil Administrative Penalty Assessment to Goody Products. The penalty was for violations which occurred in 1988, 1989, and 1990. The parameters for which the permit limits were violated included copper amongst others. In September 1988 and June 1989 copper was detected at Outfall 001 at 0.30 mg/L and 0.24 mg/L, respectively. NJDEP determined that a penalty of $859,500 should be assessed (PAP-00350677-88). The penalty was settled on May 28, 1991 for $1.1 million (PAP-00402685-88). In addition, S&S Environmental Sciences, Inc. noted that based on information supplied by Goody Products on its ISRA Site Evaluation Submission, other NJPDES effluent violations occurred after 1990 and as late as August 25, 1993 (PAP-00103482-83).

In 1996, a Remedial Action Work Plan dated May 1996 was submitted to NJDEP for approval as part of the November 1993 Remediation Agreement. NJDEP stated in a letter to Newell that further delineation of the groundwater was needed, but the soil remediation plan could be conditionally approved as a Partial Remedial Action Work Plan. The approved cleanup plan was to remove the soil hot spots, collect post-excavation samples and place capping on the property (PAS-00002044). The four areas of concern (AOC) were the wastewater discharge pit and the area south of the wastewater discharge pit (AOC 1) which contained lead above 600 ppm; the west yard which includes the hazardous waste storage area, central west yard, and former waste

discharge pipe (AOC 2) which included copper and lead as contaminants of concern; the north yard which includes the heating system condensate slowdown pipe discharge area, the burnishing room pipes/hoses discharge area, and compressor blowdown pipe discharge area (AOC 3); and Dead Horse Creek (AOC 4). It was noted that the vertical delineation of the metal contamination in several areas had to be completed (PAS-00002044-46). The PAH levels in soil samples associated with the former UST location were above the impact to groundwater criteria; however, it was noted that there were no monitoring wells installed in this area. Therefore, it was requested that Goody Products submit a proposal to investigate the impact of the PAH contamination on the groundwater (PAS-00002048).

Permits

Goody Products operated under NJPDES discharge permit No. NJ0029505, which granted the company permission to discharge to Dead Horse Creek. The permit was issued June 2, 1984 and effective August 1, 1984 and had an expiration date of July 31, 1989 (PAP-00350677; PAP-00447426; PAS-00001878). Contaminants to be monitored under this permit included lead and copper which daily discharges were not to exceed 0.1 mg/L and oil and grease which daily discharge was not to exceed 20 mg/L (PAP-00446410; PAP-00447439; PAS-00001891). Note: PAHs may be present in oils.

According to the 1983 Public Notice for the issuance of draft NJPDES permit No. NJ0029505, there were two existing surface water discharge outfalls at the Goody Products facility. Discharge 001 was industrial process wastewater generated from various metal finishing operations that would receive treatment consisting of equalization, neutralization, flocculation, clarification, and filtration. Discharge 002 was sanitary wastewater which received treatment consisting of primary settling, aeration, secondary settling, and chlorination (PAP-00105420; PAP-0010540-41).

7. Response Actions

The following characterization activities have taken place at the facility:

- October 1994 Preliminary Remedial Investigation Workplan (PAP-00105052)
- August 1995 Industrial Site Recovery Act Site Investigation Report/Revised Remedial Investigation Workplan Addendum (PAP-00446881)
- May 1996 *Remedial Investigation Report/Remedial Action Workplan and Groundwater Evaluation Report* (PAP-00104898)
- October 1997 Industrial Site Recovery Act Remedial Action Report (PAP-00425794)

According to the June 1993 *Results of Field Investigation and Review of Remedial Options*, an environmental site investigation was conducted at the Goody Products facility by Converse Environmental East in May, June, and September, 1988 in response to a letter from the NJDEPE dated November 24, 1987. Phase I included soil sampling conducted by Converse Environmental East from 54 test pits excavated mainly in the western portion of the site to characterize the extent of contamination. Phase II, which was conducted in September 1988, included additional soil sampling to further delineate

the horizontal and vertical extent of contamination identified in Phase I as well as the installation and sampling of seven overburden monitoring wells, finished below the peat layer (PAP-00104155; PAS-00001964).

The Phase I soil sample results which exceeded the NJDEPE Proposed Cleanup Standards Residential Surface Soil for copper (600 milligram/kilogram [mg/kg]) and lead (100 mg/kg) ranged as follows:

- Copper: 757.1 mg/kg in sample TP-27, collected at a depth of 0 to 0.5 feet on June 3, 1988 to 1,121 mg/kg in sample TP-31, collected at a depth of 0 to 0.5 feet on June 3, 1988 (PAP-00104185-88; PAS-00001966-69)

- Lead: 101.3 mg/kg in sample TP-44 collected at a depth of 0 to 0.5 feet on June 6, 1988 to 13,572 mg/kg in sample TP-48, collected at a depth of 0 to 0.5 feet on June 8, 1988 (PAP-00104185-88; PAS-00001966-69)

The Phase II soil sample results which exceeded the NJDEPE Proposed Cleanup Standards Residential Surface Soil for lead (100 mg/kg) ranged as follows:

- Lead: 100.8 mg/kg in sample TP-71D collected at a depth of 4 to 4.5 feet on September 30, 1988 to 3,459 mg/kg in sample SB-5D collected at a depth of 3 to 3.5 feet on September 22, 1988 (PAP-00104189-91; PAS-00001970-72)

The specific locations of the samples discussed above could not be determined from the available references as the sample location map was not legible.

According to the June 1993 *Results of Field Investigation and Review of Remedial Options*, the highest levels of metals occurred in samples collected near the waste water treatment plant (WWTP) Discharge Pit, the yard area northwest of the hazardous waste storage area, and adjacent to the north side of the building (PAS-00001965). The concentrations of lead and copper exceeded both residential and non-residential cleanup standards. See Phase I and Phase II results above for the specific concentrations. No contaminants of concern were detected in any of the groundwater samples collected in 1988 (PAS-00001981-82).

According to the June 1993 *Results of Field Investigation and Review of Remedial Options*, a preliminary round of groundwater sampling in the seven existing wells was started on October 26 and October 27, 1992, to confirm the previous groundwater sampling results (PAS-00001984). In general, the total metals concentrations were above the previous results (PAS-00001992). One groundwater monitoring well (MW-7) contained lead (145 µg/L) above the proposed standard of 10 µg/L (PAS-00001994).

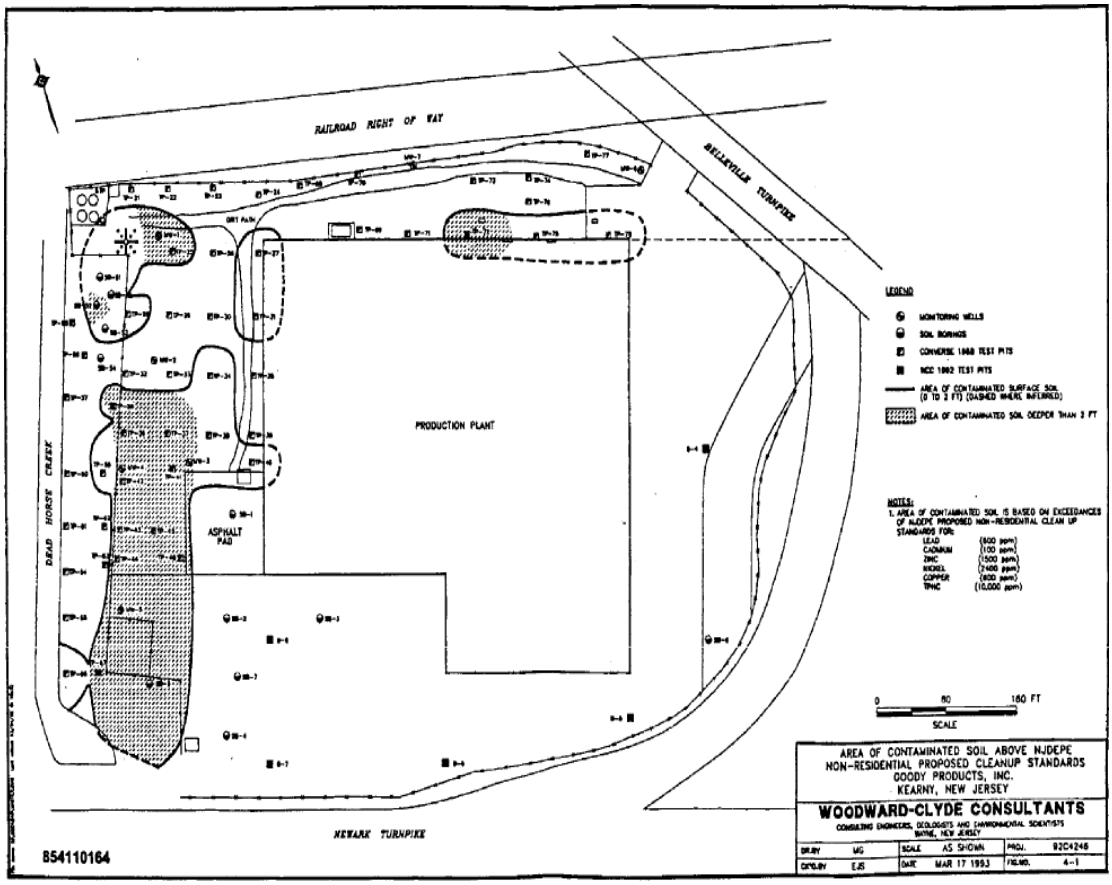
Five shallow piezometers were also sampled for metals to evaluate the effects of the metal contamination in the fill on the shallow groundwater (PAS-00001984-86). Lead was above the NJDEPE proposed cleanup standard (10 µg/L) in the five samples with concentrations ranging from 49 µg/L in PZ-3 to 2,030 µg/L in PZ-5S. Mercury was detected above the 2 µg/L standard in four samples with concentrations of 116 µg/L in PZ-1, 7.9 µg/L in PZ-2, 66.4 µg/L in PZ-4S, and 3.2 µg/L in PZ-5S (PAS-00001995-96).

It was noted by Woodward-Clyde Consultants in the June 1993 *Results of Field Investigation and Review of Remedial Options* that the metal contamination detected in the piezometer samples may be the result of the high turbidity of the samples. Woodward-Clyde Consultants recommended that monitoring wells be installed and both filtered and unfiltered groundwater samples should be sampled after the wells have been properly developed (PAS-00001997). Note that the available references did not provide conclusive information regarding groundwater flow patterns at the site or specific information regarding the potential connection of groundwater to the Dead Horse Creek or to other potential pathways connected to the Passaic River.

On November 9 and 10, 1992, 16 test pits were excavated and sampled. Each test pit was excavated to the groundwater table, or refusal, with the depths ranging from 1.67 to 4.5 feet. Soil samples were collected from the six-inch interval which appeared to be most contaminated (PAS-00001989). The specific locations of the samples discussed above are shown on a Site Map included with the report (PAS-00001959). Six PAHs exceeded the proposed cleanup standards in multiple samples. These PAHs were also detected in several other samples at levels below the cleanup standards.

The PAHs detected included benzo(a)anthracene (concentrations ranging from 201 J µg/kg to 7,206 µg/kg in 14 samples), chrysene (concentrations ranging from 256 J µg/kg to 5,421 µg/kg in 14 samples), benzo(k)fluoranthene (concentrations ranging from 51 J µg/kg to 4,655 µg/kg in 15 samples), benzo(a)pyrene (concentrations ranging from 82 J µg/kg to 6,861 µg/kg in 14 samples), indeno(1,2,3-cd)pyrene (concentrations ranging from 111 J µg/kg to 2,350 µg/kg in six samples), and benzo(g,h,i)perylene (concentrations ranging from 222 J µg/kg to 2,098 µg/kg in nine samples). In addition, dibenzo(a,h)anthracene was detected below cleanup standards in three samples at concentrations ranging from 308 J µg/kg to 610 µg/kg. The sample locations with the highest concentrations were located in the western portion of the site. As for metals, two samples (GKW-4 and GKW-5 located in the northwest corner of the site) had lead concentrations at 6.98 parts per million (ppm) and 7.25 ppm which exceeded the toxicity characteristic leaching procedure (TCLP) regulatory limit of 5 ppm (PAS-00001959, 2009, 2012, 2016).

Creek bed sediment samples were collected on November 16, 1992, at three locations in Dead Horse Creek to evaluate potential contamination to the creek. The sample locations were at the south end of Dead Horse Creek (SED1), the middle (SED2, and the north end (SED3) near the Goody Sewer Treatment Plant (PAS-00001959). The samples were collected at depths ranging from 0.5 feet to 3 feet (PAS-00001959, 1991, 2025). Woodward-Clyde Consultants reported that no PAHs exceeded the proposed NJDEPE subsurface soil cleanup standards (PAS-00002024). However, according to the sampling results, chrysene in one sediment sample (SED2) had an estimated concentration of 675 J µg/kg, exceeding the proposed cleanup standard of 660 µg/kg (PAS-00002025). Additional PAHs detected in the SED2 sediment sample included acenaphthene (338 J µg/kg), phenanthrene (981 J µg/kg), fluoranthene (552 J µg/kg), pyrene (1,342 µg/kg), benzo(a)anthracene (634 J µg/kg), benzo(b)fluoranthene (585 J µg/kg), benzo(k)fluoranthene (579 J µg/kg), and benzo(a)pyrene (487 J µg/kg). The sediment sample SED1 also had the following PAHs detected below cleanup standards: acenaphthene (52 J µg/kg), phenanthrene (102 J µg/kg), fluoranthene (166 J µg/kg),



pyrene (286 J µg/kg). Likewise, the SED3 sediment sample had the following PAHs detected below cleanup standards: naphthalene (547 J µg/kg), anthracene (540 J µg/kg) and pyrene (496 J µg/kg) (PAS-00002025).

Subsurface soil samples were also collected from eight borings in the peat layer located throughout the site to determine whether the peat had absorbed contamination from the overlying soil and/or groundwater (PAS-00001990). These samples were analyzed for volatile organics and base neutral compounds. The results of the peat samples were consistent with the overlying fill according to Woodward-Clyde Consultants. Contaminants of concern were below NJDEPE proposed subsurface soil cleanup standards with the exception of naphthalene. The concentration of naphthalene (198 ppm) in one sample PEAT-3 collected from boring MP-2 at a depth of 12 to 14 feet below ground surface near the northwest corner of the plant building exceeded the NJDEPE 100 ppm standard. The PAHs detected include chrysene (PEAT-2, PEAT-3, and PEAT-4) in concentrations up to 1,176 parts per billion (ppb), benzo(a)pyrene (PEAT-2, PEAT-3, and PEAT-4) up to 1,170 ppb, and benzo(k)fluoroanthene (PEAT-3 AND PEAT-4) up to 22,229 ppb (PAS-00002018, 21). Note: Many of the reported results were flagged “J” indicating the result was detected below the method detection limit and is considered an estimated value.

Background samples were also collected in 1992 at locations along the eastern and southern portions of the site. These samples also had detections of PAHs (four of five samples) and metals (five of five samples) both above and below cleanup standards. The concentrations ranged as follows: 2-methylnaphthalene (40 J µg/kg), acenaphthylene (71 J µg/kg to 118 J µg/kg), acenaphthene (43 J µg/kg to 390 J µg/kg), fluorene (41 J µg/kg to 405 µg/kg), phenanthrene (443 µg/kg to 3,574 µg/kg), anthracene (121 J µg/kg to 1,065 µg/kg), fluoranthene (734 µg/kg to 5,285 µg/kg), pyrene (573 µg/kg to 4,630 µg/kg), benzo(a)anthracene (293 J µg/kg to 2,782 µg/kg), chrysene (319 J µg/kg to 2,596 µg/kg), benzo(b)fluoranthene (480 µg/kg to 2,948 µg/kg), benzo(k)fluoranthene (660 µg/kg to 2,060 µg/kg), benzo(a)pyrene (329 J µg/kg to 2,672 µg/kg), indeno(1,2,3-cd)pyrene (198 J µg/kg to 211 J µg/kg), dibenzo(a,h)anthracene (93 J µg/kg to 467 µg/kg), benzo(g,h,i)perylene (110 J µg/kg to 788 µg/kg), copper (39.6 mg/kg to 101mg/kg), lead (48.3 mg/kg to 377 mg/kg), and mercury (0.28 mg/kg to 3.7 mg/kg) (PAS-00001959, 2022-23).

Regarding the 1992 field investigation, Woodward-Clyde Consultants concluded in the June 1993 *Results of Field Investigation and Review of Remedial Options* that there did not appear to be any migration of contamination from soil to groundwater at the site. According to Woodward-Clyde Consultants, the shallow groundwater quality seemed consistent with soil contaminants found in the man-placed fill (PAS-00002028).

The following map from the *Results of Field Investigation and Review of Remedial Options* delineates the areas of contaminated soil above the NJDEPE non-residential proposed cleanup standards:

(PAS-00002026)

According to a May 1996 *Remedial Investigation Report/Remedial Action Workplan and Groundwater Evaluation Report* prepared by Killam Associates for Newell Company remedial investigation activities were implemented at the facility in November 1995 through March 1996 inside the manufacturing building and in exterior areas to delineate the vertical and horizontal extent of PAHs and certain priority pollutant metals (PAP-00104917).

According to the August 1995 Industrial Site Recovery Act Site Investigation Report/Revised Remedial Investigation Workplan Addendum for the Goody Products, Inc. Site, Goody initiated compliance with the ISRA due to its acquisition by Newell Company by providing the NJDEP with a Remediation Agreement in November of 1993. A Proposed Cleanup Plan was submitted along with the Remediation Agreement. The Cleanup Plan included an overview of previous environmental investigations and costs associated with potential site capping activities. Goody submitted a General Information Submission in December of 1993 and a Site Evaluation Submission (SES) in January of 1994. A report entitled Results of Field Investigation dated October 1993 was provided under separate cover along with the SES. Representatives of the NJDEP conducted a site inspection on March 30, 1994 and issued a Report of Inspection on April 20, 1994. The Report of Inspection noted a number of deficiencies and identified actions required on the part of the responsible party (PAP-00446887).

The purpose of the Site Investigation Report/Revised Remedial Investigation Workplan was to summarize the site investigation activities performed in June-August of 1995 and to set forth remedial investigation activities for those areas of concern identified through implementation of the site investigation activities (PAP-00446890). One area of concern was an underground storage tank (UST) that was formerly located at the northern portion of the Goody site, adjacent to the north wall of the building. The tank had a capacity of 10,000 gallons and was reported to have contained No. 4 fuel oil. Following the removal of the UST, confirmation samples were collected and five PAHs (benzo(a)anthracene, benzo(b)fluoranthene, benzo(a)pyrene, benzo(k)fluoranthene and indeno(1,2,3-cd)pyrene) were detected above corresponding NJDEP Cleanup Criteria in the deeper sample obtained from the southern sidewall. These results were initially attributable to historical urban fill materials placed at the site in conjunction with site development. As such, no further action was proposed with regard to the former UST. The NJDEP reviewed the May 1990 UST report included in the July 1994 Preliminary RIW and issued comments regarding same. The NJDEP required that Goody collect additional soil samples to identify the presence/absence of contaminants at the north side of the former excavation area and at the former fill pipe area as well as to delineate the presence of base-neutral compounds detected in the confirmation sample collected from the south side of the former excavation (PAP-00446891-92).

Analytical results from this additional sampling revealed the presence of seven PAH compounds above respective NJDEP Cleanup Criteria in sample UST-W1. Benzo(a)anthracene was detected at 19 ppm, chrysene at 19 ppm, benzo(b)fluoranthene at 20 ppm, benzo(k)fluoranthene at 8.4 ppm, benzo(a)pyrene at 16 ppm, indeno(1,2,3-cd)pyrene at 12 ppm and dibenz(a,h)anthracene at 2.7 ppm. In addition, samples were collected from two test pits installed west and east of a previous sample which had PAH detections in excess of NJDEP Cleanup Criteria. Benzo(a)pyrene was detected at 0.73 ppm and indeno(1,2,3-cd)pyrene at 1.4 ppm. The report concluded that based on analytical results from the April 1995 sampling round, additional sampling was warranted to delineate the presence of PAH compounds detected in these samples (PAP-00446895).

According to the August 1995 Industrial Site Recovery Act Site Investigation Report/Revised Remedial Investigation Workplan Addendum the March 1995 SI/RIW Addendum identified four areas of potential environmental concern at the site. The four areas of potential environmental concern identified were as follows: interior process areas, pipe discharge areas, the sanitary treatment plant, and two stained areas adjacent to air conditioner units. The identification of these areas necessitated the performance of site investigation activities and a sampling program to identify the presence/ absence of contaminants. In addition, review of previous environmental investigations stated that two previously identified areas of environmental concern (i.e., sediment at Dead Horse Creek and sample locations for which the minimum detection limit was noted to exceed the current NJDEP Cleanup Criteria) required acquisition of samples to identify current conditions (PAP-00446898).

Sample results at areas of environmental concern which included COCs of the OU2 Project site included the portion of the North Yard located between the two former openings in the northern exterior wall of the Burnishing Room and the northern fence line. In general, analytical results at this location revealed varying concentrations of PAH compounds and priority pollutant metals in all samples. Copper was detected at 962 ppm and 2,550 ppm; lead at 861 ppm and 2,320 ppm; benzo(a)anthracene at 1.7 ppm, 1.8 ppm, and 1.9 ppm; benzo(b)fluoranthene at 1.4 ppm, 2.7 ppm, 3.1 ppm, and 3.4 ppm; benzo(k)fluoranthene at 1.0 ppm, 1.1 ppm, and 1.2 ppm; and benzo(a)pyrene at 0.95, 1.5 ppm, 1.9 ppm and 1.9 ppm (PAP-00446905-06). Another area of environmental concern which included COCs of the OU2 Project site were the Heating System - Blowdown/Condensate pipes. Samples collected in this area had detections which included benzo(b)fluoranthene at 0.93 ppm and 1.1 ppm, benzo(a)pyrene at 0.76 ppm, and copper at 1,290 ppm (PAP-00446909-10).

Three sediment samples were collected June 30, 1995, from the eastern bank of Dead Horse Creek. One sample was obtained upstream of industrial and sanitary system discharge points (STR-15), one sample was obtained near the southern limit of the stream (STR-17) and the remaining sample was obtained at a representative mid-point area (STR-16). The sample locations were biased toward natural accumulation points along Dead Horse Creek. The former industrial wastewater discharge pipe was not located; therefore, no sample was obtained from the discharge point (PAP-00446914).

PAH compounds and lead were detected in the three sediment samples. Sample STR-15 had detections of benzo(a)anthracene at 2.8 ppm, benzo(b)fluoranthene at 3.8 ppm, benzo(k)fluoranthene at 1.4 ppm, benzo(a)pyrene at 2.7 ppm, indeno(1,2,3-cd)pyrene at 0.97 ppm, and lead at 228 ppm. Sample STR-16 had detections of benzo(a)anthracene at 1.4 ppm, benzo(b)fluoranthene at 2.3 ppm, benzo(a)pyrene at 1.6 ppm, and lead at 169 ppm. Sample STR-17 had detections of benzo(a)anthracene at 1.2 ppm, benzo(b)fluoranthene at 2.7 ppm, benzo(k)fluoranthene at 0.94 ppm, benzo(a)pyrene at 1.3 ppm, and lead at 547 ppm (PAP-00446915-16).

Since historical information states that fill material was placed at the site in conjunction with site development activities, it was proposed to evaluate conditions at non-process areas of the site to determine the presence/ absence of fill at these areas and to ascertain the environmental quality of same. Based on historical information and observations rendered during site reconnaissance, no process operations and/or storage has been conducted at the eastern portion of the site, east of the loading dock area. As such, it was proposed to install nine soil borings and collect one sample from the fill layer and one sample from the peat layer at this area to establish background conditions. The NJDEP approved the proposed actions in its June 1995 response letter (PAP-00446918).

A variety of fill materials including brick fragments, metal pieces, asphalt pieces, wood pieces was noted with regard to the fill layer during soil boring installation activities. Six of the nine samples collected from the fill material exhibited concentrations of PAHs in excess of NJDEP Cleanup Criteria (BG-2, BG-4A, BG-5, BG-7A, BG-8A and BG-9). Sample BG-2 contained benzo(b)fluoranthene at 1.1 ppm and benzo(a)pyrene at 0.84 ppm. Five PAHs were detected in each of samples BG-4A, BG-5, and BG-7A:

benzo(a)anthracene at 3 ppm, 4.3 ppm and 2.8 ppm respectively; benzo(b)fluoranthene at 3.4 ppm, 4.5 ppm, 3.4 ppm respectively; benzo(k)fluoranthene at 1.2 ppm, 1.8 ppm, and 1.4 ppm respectively; benzo(a)pyrene at 2. 7 ppm, 3.4 ppm, and 2.6 ppm respectively; and indeno(1,2,3-cd)pyrene at 1.3 ppm, 1.7 ppm and 1.3 ppm respectively. Samples BG-SA and BG-9 each contained three PAHs: benzo(a)anthracene at 1.2 ppm and 1.3 ppm respectively; benzo(b)fluoranthene at 1.5 ppm in both samples; and benzo(a)pyrene at 1.2 ppm and 1.1 ppm respectively. In addition, one of the three samples collected from the peat layer also exhibited PAHs in excess of NJDEP Cleanup Criteria. Sample BG-8B contained benzo(a)anthracene at 4.6 ppm, benzo(b)fluoranthene at 4.8 ppm, benzo(k)fluoranthene at 1.9 ppm, benzo(a)pyrene at 4 ppm and indeno(1,2,3-cd)pyrene at 2.3 ppm (PAP-00446919-20).

None of the samples from the fill layer exhibited concentrations of metals in excess of NJDEP Cleanup Criteria. However, numerous metals were detected, in varying concentrations, in these samples. [Note: The source document does not provide these concentrations.] Mercury was detected in one of the samples collected from the peat layer in excess of NJDEP Cleanup Criteria. Sample BG-8B contained mercury at 23.8 ppm (PAP-00446920).

The report determined that based on analytical results, one or more PAHs exist at concentrations in excess of corresponding NJDEP Cleanup Criteria in the samples collected from the fill layer at the non-process area of the site. Furthermore, it appears that PAHs and certain priority pollutant metals are also present in a sample from the peat layer at the non-process area of the site. As the contaminants detected in these samples were not the result of process operations, no remedial investigation activities were proposed at this time for these locations (PAP-00446920).

Based on the results of the site investigation activities, additional actions were determined to be warranted to delineate the presence of contaminants detected at elevated concentrations in samples collected during site investigation activities. Remedial investigation activities for the site were proposed (PAP-00446922-38).

Analytical results from samples collected in March 1996 reveal the presence of one or more PAH compounds above corresponding NJDEP Cleanup Criteria in eight of the 10 Dead Horse Creek sediment samples. Specifically, benzo(a)anthracene, benzo(b)fluoranthene, benzo(k)fluoranthene, benzo(a)pyrene, and indeno(1,2,3-cd)pyrene were detected in excess of NJDEP Cleanup Criteria in two or more samples. Lead was detected in all samples but was in excess of its NJDEP Cleanup Criteria of 600 ppm in three samples with a maximum concentration of 996 ppm. Copper was detected in all samples with a maximum concentration of 510 ppm and mercury was detected in all samples with a maximum concentration of 2.10 ppm. The remaining priority pollutant metals were either not detected or were detected in concentrations below corresponding NJDEP Cleanup Criteria The maximum concentrations detected for the PAHs were as follows: acenaphthene (3.5 ppm), acenaphthylene (0.95 ppm), anthracene (1.6 ppm), naphthalene (1.2 ppm), phenanthrene (6.9 ppm), benzo(a)anthracene (4.1 ppm), benzo(a)pyrene (4.6 ppm), benzo(b)fluoranthene (6.2 ppm), benzo(g,h,i)perylene (3.1 ppm), benzo(k)fluoranthene (2.4 ppm), chrysene (4.7 ppm), dibenzo(a,h)anthracene (0.55 ppm), fluoranthene (12 ppm), indeno(1,2,3-

cd)pyrene (3.0 ppm), and pyrene (9.1 ppm) (PAP-00104964-65, 5040). Note: The locations of these samples within the Dead Horse Creek streambed were not provided in the source document.

A remedial strategy for soil and sediment was approved by NJDEP in a letter dated September 4, 1996, which included “hot spot” excavation, sediment removal, placement of an environmental cap, and imposition of a site-wide Declaration of Environmental Restriction. The “hot spot” excavation for soil was performed from September 1996 through September 1997 (PAP-00104770).

According to the October 1997 Industrial Site Recovery Act Remedial Action Report, Soil, investigative efforts performed in conjunction with, and prior to, this ISRA compliance effort revealed the presence of historic fill throughout the subject site including areas beneath the site building. The primary contaminants which have been identified in the historic fill material at this site include heavy metals and PAHs. The investigative efforts also identified areas of environmental concern (AECs) at the site unrelated to the historic fill material. Analytical results from samples collected at some of these identified the presence of contaminants in soil unlikely to be related to historic fill. Therefore, further evaluation of these areas was performed to delineate contaminants unrelated to historic fill. Analytical results from samples collected at the remaining AECs revealed the presence of contaminants which could be attributed to either the historic fill material or process operations. In addition, analytical results from a few areas revealed contaminants related to fill material and did not reveal the presence of contaminants related to process operations. The report states that therefore, investigative efforts confirmed that contaminants at concentrations in excess of NJDEP Cleanup Criteria were related to historic fill material (PAP-00425805).

Investigative efforts also identified the presence of a limited number of contaminants (i.e., certain priority pollutant metals and PAH compounds) in samples from the stream sediments. Based on information gained through soil sampling efforts, the presence of contaminants in stream sediments is attributable to fill material and overland storm water flow and, to some degree, contaminants may be attributable to process operations (PAP-00425805). However, a site survey determined that the western portion of Dead Horse Creek is situated beyond the property limits of the Goody site. Therefore, the remedial activities for sediments in Dead Horse Creek would commence upon execution of an access agreement with the adjacent property owner (PAP-00425807).

To verify the success of the remedial efforts (i.e. “hot spot” excavation), confirmation samples were collected from the majority of the site AECs. However, confirmation samples were not collected in those instances where excavations were advanced to “clean” samples (PAP-00425845).

A summary of analytical results for the Burnishing Room Pipes/Hoses Discharge Area listed the following concentrations:

Remedial Action Report Samples		
COC	**Concentration Ranges**	**Depth of Max**
Benzo(a)anthracene	0.350 mg/kg – 6.000 mg/kg	3.0-3.5 ft.
Benzo(a)pyrene	0.340 mg/kg – 4.800 mg/kg	3.0-3.5 ft.
Benzo(b)fluoranthene	0.470 mg/kg – 6.700 mg/kg	3.0-3.5 ft.
Benzo(g,h,i)perylene	0.270 mg/kg – 1.800 mg/kg	3.0-3.5 ft.
Benzo(k)fluoranthene	0.200 mg/kg – 2.600 mg/kg	3.0-3.5 ft.
Dibenzo(a,h)anthracene	0.068 mg/kg – 0.630 mg/kg	3.0-3.5 ft.
lndeno(1,2,3-cd)pyrene	0.240 mg/kg – 2.200 mg/kg	3.0-3.5 ft.
Copper	27.6 mg/kg – 213 mg/kg	3.0-3.5 ft.
Lead	37 mg/kg – 352 mg/kg	3.0-3.5 ft.
Mercury	0.08 mg/kg – 6.3 mg/kg	0.0-0.5 ft.

(PAP-00425856-57)

A summary of analytical results for the KTP-1/TP-27 Area listed concentrations of copper ranging from 32.6 mg/kg to 331 mg/kg (PAP-00425863). The KTP-1 area was located approximately 15 feet southwest of the northwest corner of the Goody building (PAP-00425821).

A summary of analytical results for the TP-31 Area listed concentrations of copper ranging from 56.3 mg/kg to 498 mg/kg (PAP-00425864). The TP-31 area was located in the west yard (PAP-00425797).

A summary of analytical results for the SB-5 Area listed concentrations of lead ranging from 200 mg/kg to 353 mg/kg (PAP-00425868). The SB-5 area was located in the west yard (PAP-00425798).

A summary of analytical results for the TP-67 Area listed concentrations of lead ranging from 208 mg/kg to 323 mg/kg (PAP-00425869). The TP-67 area was located in the west yard (PAP-00425798).

A summary of analytical results for the Central West Yard - PHC Impacted Area and Former Hazardous Waste Storage Area listed the following concentrations:

Remedial Action Report Samples		
COC	**Concentration Ranges**	**Depth of Max**
Benzo(a)anthracene	0.920 mg/kg – 5.600 mg/kg	2.5-3.0 ft.
Benzo(a)pyrene	1.000 mg/kg – 6.200 mg/kg	2.5-3.0 ft.
Benzo(b)fluoranthene	1.400 mg/kg – 7.700 mg/kg	2.5-3.0 ft.
Benzo(g,h,i)perylene	0.340 mg/kg – 2.900 mg/kg	2.5-3.0 ft.
Benzo(k)fluoranthene	0.480 mg/kg – 2.800 mg/kg	2.5-3.0 ft.
Dibenzo(a,h)anthracene	0.110 mg/kg – 0.780 mg/kg	2.5-3.0 ft.
lndeno(1,2,3-cd)pyrene	0.370 mg/kg – 3.000 mg/kg	2.5-3.0 ft.

(PAP-00425867)

Sediment removal activities in Dead Horse Creek were conducted in 1999. Visual observations during the sediment removal effort noted the presence-of fill material during the sediment removal activities. Hatch Mott MacDonald collected post-remedial sediment samples from the base of the Dead Horse Creek and analytical results from the sampling revealed the presence of metals in excess of nonresidential soil remediation standards in place at that time. However, a comparison of the March 1996 and February 1999 sampling events revealed a dramatic decrease in the concentrations of contaminants detected in samples from stream sediment. Killam Associates concluded that the sediment removal undertaken at Dead Horse Creek substantially reduced the overall contaminants present in the stream corridor (PAP-00104787).

According to a May 2001 *Surface Water and Groundwater Evaluation Summary Report* prepared by Killam Associates for Newell Company, an investigation was conducted by Killam Associates in 2000-2001 to evaluate the Site surface water and groundwater (PAP-00104829-35). Five surface water samples were collected from Dead Horse Creek on September 20, 2000, to assess the potential for impacts from the presence of the Historic Fill and/or contaminants in soil. The samples were collected from representative locations upstream, midstream and downstream and were located approximately 100 feet apart. Lead and mercury were detected in surface water samples at concentrations in excess of the corresponding NJDEP Surface Water Quality Criteria of 5 µg/L and 0.144 µg/L, respectively. Lead was detected at the following concentrations: 13.6 µg/L in sample DownStream-1, 10.4 µg/L in sample DownStream-2, 16.3 µg/L in MidStream-3, 15.7 µg/L in sample Upstream-4, and 15.4 in UpStream-5. Mercury was detected at 0.25 µg/L in sample DownStream-1, 0.16 µg/L in DownStream-2, and 0.15 µg/L in MidStream-3. In addition, eighteen groundwater wells were sampled. Lead was detected in excess of the NJDEP Groundwater Quality Standard (GWQS) (10 µg/L) in groundwater samples from three shallow wells and one deeper well (PAP-00104829-97).

During 2007 and 2009, a follow-on Remedial Investigation was conducted in order to further delineate remaining areas of concern at the Site in preparation for the assignment of a Classification Exception Area for groundwater and site-wide Deed Notice to address Historic Fill. According to a Remedial Investigation Report dated July 2009 prepared by Hatch Mott MacDonald for Goody Products, the investigation included additional soil delineation and sampling in the area of the WWTP Discharge Pit (AOC 1), additional soil investigation in the area of the Compressor Blowdown Pipe/Test Pit TP-75 Area (AOC 3E) and the installation of six monitoring wells and performance of groundwater sampling to investigate groundwater conditions at the Site (PAP-00104765-73). The majority of the investigation involved hexavalent chromium, arsenic, ethylbenzene, total xylenes, and nickel. However, elevated concentrations of metals above the NJDEP GWQS which included lead were also detected at the western portion of the Site. Lead was detected at concentrations of 170 µg/L (MW-10S), 55 µg/L (MW-13), and 10 µg/L (MW-15); exceeding the GWQS of 5 µg/L (PAP-00104783-801 Note that the available references did not provide conclusive information regarding groundwater flow patterns at the site or specific information regarding the potential connection of groundwater to the Dead Horse Creek or to other potential pathways connected to the Passaic River.

On February 28, 2012, a Deed Notice was issued for the property at 969 Newark Turnpike (this site) because soil contamination remained in certain areas of the property which contains contaminants in concentrations that do not allow for the unrestricted use of the property. Due to the presence and concentration of these contaminants resulting from Historic Fill, restrictions regarding the use of the property, and the placement of capping over the ground as an engineering control were instituted. The restriction against subsurface intrusion included the entire 9.55-acres of the property (PAP-00104217-56). According to an April 2012 NJDEP Remedial Action Permit Application – Soil, the contaminants and the concentrations which required the Deed Notice included the metals copper (1,320 mg/kg, depth of 0 to 0.5 feet) and lead (1,780 mg/kg, depth of 2.0 to 2.5 feet); and PAHs benzo(a)anthracene (19 mg/kg, depth of 4.5 to 5.0 feet), chrysene, (19 mg/kg, depth of 4.5 to 5.0 feet), benzo(b)fluoranthene (20 mg/kg, depth of 4.5 to 5.0 feet), benzo(k)fluoranthene (8.4 mg/kg, depth of 4.5 to 5.0 feet), benzo(a)pyrene (16 mg/kg, depth of 4.5 to 5.0 feet), indeno(1,2,3-cd)pyrene (12 mg/kg, depth of 4.5 to 5.0 feet), and dibenzo(a,h)anthracene (2.7 mg/kg, depth of 4.5 to 5.0 feet) (PAP-00104212-4).

On April 25, 2012, NJDEP issued Remedial Action Soil Permit No. RAP120002 requiring Goody Products to conduct monitoring, maintenance and evaluation for compliance and effectiveness of the remedial action, and the associated institutional and engineering controls (PAP-00104269-76). In addition, on April 26, 2012, NJDEP issued a Conditional No Further Action Letter stating that as long as each subsequent owner, lessee, and operator of the Site complied with the conditions of the Remedial Action Soil Permit then no further remedial action would be required (PAP-00104419-21). The remediation that was covered by this Conditional No Further Action Letter did not address the remediation of hazardous substances that may exist in building interiors or equipment; including, but not limited to, lead. As a result, any risks to human health presented by any building interior or equipment remained (PAP-00104421).

In a letter dated April 25, 2015, NJDEP established a Classification Exception Area/Well Restriction Area for lead and other metals contamination in the groundwater above the NJDEP GWQS at the Goody Products Site, which may limit the groundwater use at the Site. The maximum concentration of lead detected at the site was 2,070 µg/L (PAP-00104257-62; PAP-00104483-500).

On March 13, 2018, a Soil Remedial Action Permit Modification (RAP170001) was issued by NJDEP. RAP170001 superseded RAP130001, which presumably superseded RAP120002. The permit modification requires the permittee to conduct monitoring, maintenance and evaluation for compliance and effectiveness of the remedial action and its associated institutional control. The permit modification established requirements necessary for demonstrating that the remedial action and control continue to be protective of public health, safety and the environment (PAP-00104518-19).

8. Summary of Asserted Defenses

Neither Newell nor Goody Products, Inc. ("Goody") is a "covered person" (i.e., a responsible party) under CERCLA Section 107(a), 42 U.S.C. § 9607(a), with respect to the Diamond Alkali Superfund Site, including because Newell and Goody (a) do not, and never did, own or operate any portion of the Site; (b) did not arrange for the disposal of any hazardous substances at the Site (including because neither discharged any hazardous substances from the Facility to the Lower Passaic River); and (c) did not transport any hazardous substances to the Site.

Some or all of Goody's releases of hazardous substances to the Lower Passaic River, if any, were "federally permitted releases" within CERCLA Section 107(j), 42 U.S.C. § 9607(j), and resulting response costs or damages, if any, may not be recovered under CERCLA.

Pursuant to CERCLA Section 107(b), 42 U.S.C. § 9607(b), Newell and Goody are not liable for the releases or threatened releases of hazardous substances from the Facility, if any, because such releases or threatened releases were caused solely by: an act of God; an act of war; or the acts or omissions of persons or entities other than Newell or Goody, for whom Newell and Goody are not responsible.

Each release or threat of release of hazardous substances, if any, and any costs or damages resulting there from was caused solely by the negligence, acts or omissions of third-parties over whom Newell and Goody had no control and no duty to control, including without limitation: (a) the State of New Jersey and its agencies, instrumentalities and officials, including, without limitation, Trustees for tidelands; and (b) the United States and its agencies, instrumentalities and officials.

Neither Newell nor Goody is a successor to any person or entity that owned or operated any portion of the Facility property.

L3 Harris Technologies, Inc.

Diamond Alkali OU2 Allocation

Facility Data Report

L3 HARRIS TECHNOLOGIES, INC. F/K/A HARRIS CORPORATION

Facility Name, Address and Size: The facility has historically comprised three contiguous areas owned and operated during different periods. The buildings comprising the facility carried the following street addresses: 100 Kingsland Road (now 77 River Road), Clifton, New Jersey; 500 Washington, 390 Washington, 417 River Road, 483 River Road, and 491/493 River Road, Nutley, New Jersey; 492 River Road, Nutley, New Jersey. At its largest, the area of the facility was approximately 149 acres; currently it consists of 26 acres. The facility was owned and operated under different names over time, including, International Telephone & Telegraph Corporation; ITT Avionics; ITT Defense Communications; ITT Industries, Inc.; ITT Corporation; ITT Avionics Div.; ITT Defense; ITT Aerospace Communications Division; Federal Telephone & Radio Corp.; Exelis, Inc. Information on the number of employees and shifts per day was not identified in the available file material.

1. **Business Type:** Defense communications, research and development, defense contractor, telephone/telegraph equipment (PAP-00204915; PAP-00199552)

2. **Time Period of Ownership/Operations**

   The facility has historically comprised three contiguous areas:

   - Kingsland Road Area [100 Kingsland Road (now 77 River Road), Clifton, New Jersey];
   - Washington Avenue Area (500 Washington, 390 Washington, 417 River Road, 483 River Road, and 491/493 River Road, Nutley, New Jersey); and,
   - River Road Area (492 River Road, Nutley, New Jersey).

   Each area has been owned and operated during different, but overlapping periods.

   Operator: 1946 to present (the operations and size of the facility have varied over time, as further described below).

   Owner: 1941 to present (the size of the facility has varied over time, as further described below).

   1941: ITT purchased the Washington Avenue Area in 1941 (PAP-00205092).

   1946: ITT purchased the Kingsland Road Area in 1946 (PAP-00199552).

   1952: ITT purchased the River Road Area in 1952 (PAP-00202991).

   1993: Operations at the Washington Avenue Area and River Road Area ceased in 1993 (PAP-00203242-43).

1996: ITT Industries, Inc. sold the Kingsland Road Area in 1996 to Related Retail Corporation and then leased-back the area. After transfer of the title and execution of the lease, ITT Avionics Division continued to operate on-site (PAP-00199552; PAP-00204976).

1998: ITT Industries purchased the Kingsland Road Area back from Related Retail Corporation, excluding 10 acres (i.e., the western portion of the property), in 1998 (PAP-00199552).

2001: The Kingsland Road Area was subdivided into Block 83.01, Lot 1.01 and Block 83.01, Lot 1.02 in 2001. Lot 1.02 was sold for redevelopment. The address of the remaining 26 acres was changed from 100 Kingsland Road to 77 River Road (PAP-00204976; PAP-00199552).

The facility layout circa 1990 is depicted below (PAP-00202318):

3. Operational History/COC Use and Presence at the Facility

Kingsland Road Area

According to a *Preliminary Assessment and Site Investigation Report*, dated July 26, 2012, historical operations at the Kingsland Road Area included the manufacture of television and radio tubes, telephones, radios, and printed circuit boards (PAP-00199552).

Facility operations included metal finishing and electroplating which were historically performed in an area of the facility directly east of the chemical storage room. These operations included solvent degreasing, acid etching, pickling, aqueous alkaline cleaning, plating, and electroplating (i.e., via plating baths consisting of cadmium, chromium, copper, lead, molybdenum, nickel, silver, tin, and zinc). Process baths were reportedly located throughout the area on elevated gratings. Process rinse water was discharged to concrete troughs, which drained to an industrial wastewater pretreatment system (PAP-00199563). The pretreatment system was located in the subbasement of the main building. Pretreatment consisted of chrome reduction (i.e., hexavalent to trivalent), metal hydroxide precipitation, and neutralization (PAP-00199806).

Pretreated process wastewater was discharged to the municipal sanitary sewer operated by the Passaic Valley Sewerage Commission (PVSC) pursuant to a permit between 1982 and 1990 (PAP-00199536; PAS-00111061-62). Sewer discharge monitoring was automatically performed at this location (PAP-00199559). During the period that the pre-treatment process was in operation, pretreated discharges were monitored for metals (including copper and lead), among other parameters (PAP-00203244). The pretreatment system began operation in 1982 and was discontinued in 1990 because of the termination of process operations generating industrial wastewater (PAP-00199559). The *Preliminary Assessment and Site Investigation Report*, dated July 26, 2012, states that sanitary waste was discharged to the PVSC system beginning in 1946 (PAP-00199536). On July 6, 1990, the facility certified to PVSC that all uses of cadmium, nickel, silver, zinc, copper and lead had been discontinued for manufacturing purposes (PAP-00203260). Review of a *Community Right to Know Survey for 1995* states no OU2 contaminants of concern (COCs) were present as part of the facility's chemical inventory in 1995 (PAP-00199675-722). A *Community Right to Know Survey for 2000* also identified no OU2 COCs in the facility's chemical inventory (PAS-00110830-57).

As reported in the *Preliminary Assessment and Site Investigation Report*, dated July 26, 2012, in 2012 the property was being utilized for assembly, laboratory, testing, and office activities. Assembly operations included ancillary drilling, soldering, and wiring of units, some painting, printing, degreasing, machining, and grinding. The facility also performed some associated laboratory and product testing (PAP-00199554).

Washington Avenue Area

According to a *Site Evaluation Submission and Cleanup Plan Report*, dated July 1993, ITT operations at the Washington Avenue Area consisted primarily of research and development activities in support of manufacturing and assembly of electronic components and equipment for defense and intelligence applications. This included prototype designs and model construction in an electronic laboratory setting. Model construction involved soldering, printing, degreasing, drilling, machining, grinding, and testing of the products. Degreasing operations involved small spot degreasers in laboratory areas (PAP-00205011).

According to a *Community Right to Know Survey for 1992*, lead was present at the facility. According to a *1992 Hazardous Waste Report*, "tin/lead solder dross bars for recycling" were generated by the facility and properly drummed and sent of off-site to an EPA-licensed disposal facility, Halpern and Company, Inc. (PAP-00205075; PAP-00205039).

It is noted that a former dry well near the 500 Washington Avenue area may have received plating or acid wastes (PAP-00205108).

As reported in the *Site Evaluation Submission and Cleanup Plan Report*, dated July 1993, in 1993, the facility was inactive. Buildings remaining at the facility were 500 Washington Avenue, 390 Washington Avenue, the cafeteria/clubhouse at 417 River Road, the carpenter shop at 483 River Road, and the Admiral's house at 493 River Road. Only the building at 390 Washington Avenue was being used, serving as a temporary outplacement services office. All other buildings were closed (PAP-00205011).

River Road Area

According to a *Site Evaluation Submission and Remedial Action Plan*, dated October 1993, ITT operations at the River Road Area consisted of testing and assembling communications equipment used for satellite defense applications. Most of the facility housed small offices and electronics laboratories, with some rooms devoted to assembly of equipment. Manufacturing consisted mainly of assembly operations which included drilling, soldering and wiring of the units. Assembly involved manual, table-top operations, including soldering, printing, small scale plating, degreasing, acid/alkali cleaning, drilling, machining, grinding, assembling and testing of products. It is reported that "on occasion," ITT conducted small-scale plating operations at the facility in one small laboratory at the east end of the building (PAP-00199237).

According to a *Community Right to Know Survey for 1992,* no OU2 COCs were specifically listed as being present as part of the facility's chemical inventory in 1992 (PAP-00199251-268).

According to the *Site Evaluation Submission and Remedial Action Plan*, dated October 1993, process rinse waters from the plating laboratory were disposed off-site as hazardous waste (PAP-00199237); however, a former plating rinse water dry well was also identified on the east side of the building. In addition, a former non-contact cooling water dry well was located on the east side of the building, and a former machine shop sink discharge point to a dry well was identified on the north side of the building (PAP-00199279, 287).

It is noted that according to the *Site Evaluation Submission and Remedial Action Plan*, dated October 1993, prior to the purchase of the River Road Area, the eastern portion of that property was reportedly landfilled with municipal refuse immediately prior to construction of the facility. There were no records regarding the period of landfill activity, the types of waste disposed, or the manner of landfill closure; however, drilling revealed fill material to include coal, ash, glass, china, leather, rubber, cast iron and steel (PAP-

00199213). NJDEP concurred that Historic Fill occupied a "much larger" area of the site than previously thought in a letter dated August 31, 1994 (PAP-00202981-83).

4. Identified COCs

- PCBs (detected)
- PAHs (detected)
- Copper (used, detected)
- Lead (used, detected)
- Mercury (detected)

PCBs

Kingsland Road Area

According to a *Preliminary Assessment and Site Investigation Report*, dated June 26, 2012, during visual inspection of transformers and switchgear conducted at the Kingsland Road Area in May 1996, three transformers were identified as having stains on concrete pads adjacent to the transformers as follows: 1) staining was observed on a transformer pad located on the south side of the boiler house (100 Kingsland Road (now 77 River Road) ; 2) staining was observed on an interior concrete floor in a subbasement adjacent to electrical systems; and, 3) staining was observed on the concrete transformer pad located on the north side of the main building. Concrete chip samples were collected at the stained areas and analyzed for polychlorinated biphenyls (PCBs) (PAP-00199564; PAS-00111066). The maximum detected concentration of total PCBs in concrete chips was 6.24 milligrams per kilogram (mg/kg) in 1997 (PAP-00200025). PCBs were detected in two soil samples collected below the concrete. The maximum detected concentration of total PCBs detected in soil below the concrete was 0.054 mg/kg in 1997 (PAP-00200026).

PAHs

Kingsland Road Area

Six underground storage tanks (USTs), identified as UST systems El through E6, were closed and removed from the northern side of the Kingsland Road Area, north of the former boiler house between July 12, 1990, and October 25, 1990. UST systems El through E4 were 22,000 gallons in capacity and were used for the storage of No. 6 fuel oil. UST systems E5 and E6 were 2,000 and 6,000 gallons in capacity, respectively, and were used for the storage of No. 4 fuel oil. Four post-excavation subsurface soil samples were analyzed for PAHs. Detected concentrations of PAHs (in mg/kg) were as follows (PAP-00199883):

Semi-Volatile Organic Compounds:												
Fluoranthene	<0.71	NA	NA	0.29	NA	<0.78	0.35	NA	NA	NA	NA	0.11
Pyrene	<0.71	NA	NA	0.76	NA	<0.78	0.72	NA	NA	NA	NA	0.24
Bis (2-Ethylhexyl) phthalate	<0.71	NA	NA	0.39	NA	<0.78	5.60	NA	NA	NA	NA	1.40
Chrysene	<0.71	NA	NA	3.90	NA	<0.78	0.40	NA	NA	NA	NA	0.12
Benzo (A) anthracene	<0.71	NA	NA	0.37	NA	<0.78	0.38	NA	NA	NA	NA	0.11
Benzo (B) fluoranthene	<0.71	NA	NA	0.31	NA	<0.78	0.36	NA	NA	NA	NA	<0.72
Benzo (K) fluoranthene	<0.71	NA	NA	0.11	NA	<0.78	0.087	NA	NA	NA	NA	<0.72
Benzo (A) pyrene	<0.71	NA	NA	0.20	NA	<0.78	0.25	NA	NA	NA	NA	0.13
Indeno (1,2,3-C,D) pyrene	<0.71	NA	NA	0.14	NA	<0.78	0.15	NA	NA	NA	NA	<0.72
Benzo (G,H,I) perylene	<0.71	NA	NA	0.11	NA	<0.78	0.18	NA	NA	NA	NA	0.20
Phenanthrene	<0.71	NA	NA	<0.74	NA	<0.78	0.25	NA	NA	NA	NA	1.50
Acenaphthene	<0.71	NA	NA	<0.74	NA	<0.78	<0.74	NA	NA	NA	NA	0.37
Fluorene	<0.71	NA	NA	<0.74	NA	<0.78	<0.74	NA	NA	NA	NA	0.66

According to the June 2012 Preliminary Assessment and Site Investigation Report, no further action was required for the soils in this area, since all parameters were below NJDEP's Impact to Groundwater Soil Cleanup Criteria and NJDEP's Residential Direct Contact Soil Cleanup Criteria (PAP-00199805).

Washington Avenue Area

According to a *Site Evaluation Submission and Cleanup Plan Report*, dated July 1993, a former dry well near the 500 Washington Avenue area was considered a potential concern because it may have received plating or acid wastes (PAP-00205108). High and low molecular weight PAHs were detected in subsurface soil associated with the dry well at a depth of three to four feet (PAP-00205108, 136). Detected concentrations of PAHs (in µg/kg) were as follows (PAP-00205136):

fluorene	390 J
phenanthrene	2,200
anthracene	560
fluouranthene	2,400
pyrene	1,900
benzo(a)anthracene	1,200
chrysene	1,200
benzo(b,k)fluouranthene	1800 L
benzo(a)pyrene	1,100
indeno(1,2,3-cd)pyrene	710
dibenz(a,h)anthracene	390 J
benzo(g,h,i)perylene	610

River Road Area

According to a *Site Evaluation Submission and Remedial Action Plan*, dated October 1993, between October 31, 1990 and November 2, 1990, a 20,000-gallon UST system used to store No. 2 fuel oil was evacuated of its contents, excavated and removed in accordance with a New Jersey Department of Environmental Protection (NJDEP)-approved UST closure plan. Post-excavation samples were collected and high and low molecular weight PAHs were detected (PAP-00199288, 315). Detected concentrations of PAHs (in mg/kg) were as follows (PAP- 00199315):

phenathrene	.32	.077
anthracene	.08	ND
fluouranthene	.37	.11
pyrene	.29	.08
bis(2 ethylhexyl)phthalate	.12	.18
chrysene	.16	.044
benzo(a)anthracene	.16	.049
benzo(b)fluouranthene	.19	.054
benzo(k)fluouranthene	.089	ND
benzo(a)pyrene	.15	.042
indeno(1,2,3-cd)pyrene	.08	ND
benzo(g,h,i)perylene	.073	ND

The NJDEP certified by letter dated July 13, 1992, that ITT Corporation had properly complied with the requirements regarding the 20,000 gallon UST and no additional corrective actions were necessary (PAP-00199231, 288).

Copper

Kingsland Road Area

According to Pretreatment Monitoring Reports, copper was detected in wastewater discharges as follows. The pre-treatment standard under the PVSC permit for copper was 3.36 mg/L (PAP-00203271). :

- Between January and June 1987, copper was detected in facility wastewater at concentrations ranging between 0.34 milligrams per liter (mg/L) and 2.44 mg/L (PAP-00203228-39).

- Between July and December 1987, copper was detected in facility wastewater at concentrations ranging between 0.34 mg/L and 5.0 mg/L (PAP-00203271-86). According to the associated monitoring report, “A single analysis exceeded the permit requirement [for copper] due to solids in the sample. Upon preservation of the sample, copper was released. Additional analyses were performed and are attached to show compliance with pre-treatment standards” (PAP-00203272).

- In January through June 1988, copper was detected in facility wastewater at a maximum concentration of 1.28 mg/L. In July through December 1988, copper was detected in facility wastewater at a maximum concentration of 1.03 mg/L (PAP-00426083).

- In January through June 1989, copper was detected in facility wastewater at a maximum concentration of 4.07 mg/L (PAP-00426124). The three-day average was 1.81 mg/L (PAP-00426145). In July through December 1989, copper was detected in facility wastewater at a maximum concentration of 1.20 mg/L (PAP-00426152).

- Copper was detected in facility wastewater at a maximum concentration of 0.765 mg/L between January and June 1990 (PAP-00203246).

- In November 1994, copper was detected at outfalls 003 and 005 at maximum concentrations of 1 mg/L and 0.15 mg/L, respectively (PAP-00426311).

- In December 1996, copper was detected at outfall 003 at a concentration of 70 µg/L (PAP-00426318).

- In October 1997, copper was detected at outfall 003 at a maximum concentration of 80 µg/L (PAP-00426522).

- Copper was detected in facility wastewater in January 1998 at a concentration of 0.4 mg/L (PAP-00203321). In February 1998, copper was detected at outfall 003 at a concentration of 0.1 mg/L (PAP-00427182). In April 1998 it was detected at a concentration of 0.6 mg/L (PAP-00427339). In May 1998, it was listed at a concentration of 0.07 mg/L (PAP-00427432). In June 1998, it was listed at a concentration of 0.05 mg/L (PAP-00427528). In July 1998, it was listed at a concentration of 0.09 mg/L (PAP-00427598). In August 1998, it was listed at a concentration of 0.06 mg/L (PAP-00427667).

- The maximum detection of copper reported in the monitoring reports from January to May 1999 was 0.13 mg/L for both outfalls 003 and 005 (PAP-00722746-64). This was noted to exceed the threshold value for copper of 0.092 mg/L, but not the monthly average limit of 3.02 mg/L (PAP-00722287-9, 386-7, 768, 772).[1]

Washington Avenue Area

According to a *Site Evaluation Submission and Cleanup Plan Report*, dated July 1993, a former dry well near the 500 Washington Avenue facility was considered a potential concern because it may have received plating or acid wastes (PAP-00205108). Copper was detected in subsurface soil at concentrations of 52.1 mg/kg at a depth of three to four feet (PAP-00205137).

River Road Area

According to a *Site Evaluation Submission and Remedial Action Plan*, dated October 1993, a discharge from a machine shop sink in the building was released via a pipe directly to a subsurface dry well in the ground on the north side of the building (PAP-00199292, 89). In addition, a former dry well for plating rinse water was located at the northeast corner of the building (PAP-00199293). Finally, a former dry well for non-contact cooling water was located at the northeast corner of the building (PAP-00199289). It is noted that according to a *Remedial Action Report*, dated February

[1] This Report was revised to include documents received on July 13, 2020. The additional documents did not change L3 Harris Technologies' previous certification.

1997, facility personnel stated that the non-contact cooling water dry well did not receive industrial waste, but rather was a discharge point for storm water (roof drains) (PAP-00203004). All of these dry wells, except the machine shop sink discharge point, were located in historic fill, as confirmed by NJDEP (PAP-00202983).

It is noted that initially, the eastern portion of the River Road Area was reportedly landfilled with municipal refuse immediately prior to construction of the facility, prior to ITT's ownership of the property. It is reported that there are no records regarding the period of landfill activity, the types of waste disposed, or the manner of landfill closure, but that on-site drilling has revealed fill material to include coal, ash, glass, china, leather, rubber, cast iron, and steel (PAP-00199213). Later, additional evidence provided to NJDEP showed that the fill that predated ITT's ownership extended to almost the entire River Road Area. NJDEP itself concurred with the conclusion that fill "extends throughout the site…" in a letter dated August 31, 1994 (PAP-00202983). Metals detected in this area were attributed to former landfill activities (PAP-00199291). The NJDEP concurred that this area was historic fill (PAP-00202983).

Maximum concentrations of copper detected in 1991 and 1993 at the above-listed areas were as follows (PAP-00199290-293, 312, 316):

Maximum Copper Concentrations by Area of Concern (mg/kg)				
	Machine Shop Sink Discharge	**Dry Well for Non-Contact Cooling Water**	**Dry Well for Plating Rinse Water**	**Municipal Landfill**
Copper	2,380 (at 0.5 to one foot)	360 (at one to three feet)	360 (at one to three feet)	865 (at zero to two feet)

Lead

Kingsland Road Area

According to Pretreatment Monitoring Reports, lead was reported in conformance with the PVSC lead permit limit of 0.69 mg/L in wastewater discharges as follows:

- Between January and June 1987, lead was reported in facility wastewater at concentrations ranging between 0.04 mg/L and 0.16 mg/L (PAP-00203228-39).
- Between July and December 1987, lead was reported in facility wastewater at concentrations ranging between 0.03 mg/L and 0.14 mg/L (PAP-00203271-86).
- In January through June 1988, lead was detected in facility wastewater at a maximum concentration of 0.13 mg/L. In July through December 1988, lead was detected in facility wastewater at a maximum concentration of 0.03 mg/L (PAP-00426083).

- In January through June 1989, lead was detected in facility wastewater at a maximum concentration of 0.237 mg/L (PAP-00426124). In July through December 1989, lead was detected in facility wastewater at a maximum concentration of 0.139 mg/L (PAP-00426152).

- Lead was reported in facility wastewater at a maximum concentration of 0.0283 mg/L between January and June 1990 (PAP-00203246).

- In 1991, the cooling water was listed as having a lead concentration of 0.0216 (PAP-00426050).

- In November 1994, lead was detected at outfalls 003 and 005 at maximum concentrations of 0.087 mg/L and 0.015 mg/L, respectively (PAP-00426311).

- In December 1996, lead was detected at outfalls 003 and 005 at concentrations of 18.1 µg/L and 20.5 µg/L (PAP-00426318, 19).

- In October 1997, lead was detected at outfall 005 at a maximum concentration of 163 µg/L (PAP-00426579). It was detected at outfall 003 at a maximum concentration of 8.4 µg/L (PAP-00426669).

Washington Avenue Area

According to a *Site Evaluation Submission and Cleanup Plan Report*, dated July 1993, a former dry well near the 500 Washington Avenue area was considered a potential concern because it may have received plating or acid wastes (PAP-00205108). Lead was detected in subsurface soil at concentrations of 57.6 mg/kg at a depth of three to four feet (PAP-00205137).

River Road Area

According to a *Site Evaluation Submission and Remedial Action Plan*, dated October 1993, a discharge from a machine shop sink in the building was released via a pipe directly to a subsurface dry well in the ground on the north side of the building (PAP-00199292). In addition, a former subsurface dry well for plating rinse water was located at the northeast corner of the building (PAP-00199293). Finally, a former subsurface dry well for non-contact cooling water was located at the northeast corner of the building (PAP-00199289). It is noted that according to a *Remedial Action Report*, dated February 1997, facility personnel stated that the non-contact cooling water dry well did not receive industrial waste, but rather was a discharge point for storm water (roof drains) (PAP-00203004). All of these areas, except the machine shop sink discharge, were located within the historic fill placed on the property prior to ITT's ownership, as confirmed by letter from NJDEP (PAP-00202983).

It is noted that initially, the eastern portion of the River Road Area was reportedly landfilled with municipal refuse immediately prior to construction of the facility, prior to ITT's ownership of the property. It is reported that there are no records regarding the

period of landfill activity, the types of waste disposed, or the manner of landfill closure, but that on-site drilling has revealed fill material to include coal, ash, glass, china, leather, rubber, cast iron, and steel (PAP-00199213). Later, additional evidence provided to NJDEP showed that the fill that predated ITT's ownership extended to almost the entire River Road Area. NJDEP itself concurred with the conclusion that fill "extends throughout the site…" in a letter dated August 31, 1994 (PAP-00202983). Metals detected in this area were attributed to former landfill activities (PAP-00199291). The NJDEP concurred that this area was historic fill (PAP-00202983).

Maximum subsurface detected concentrations of lead detected in 1991 and 1993 at the above-listed areas were as follows (PAP-00199290-293, 312, 316-317):

Maximum Lead Concentrations by Area of Concern (mg/kg)				
	Machine Shop Sink Discharge	**Dry Well for Non-Contact Cooling Water**	**Dry Well for Plating Rinse Water**	**Municipal Landfill**
Lead	1,400 (at two to four feet)	2,470 (at one to three feet)	2,470 (at one to three feet)	1,710 (at zero to two feet)

Mercury

Washington Avenue Area

According to a *Site Evaluation Submission and Cleanup Plan Report*, dated July 1993, a former dry well near the 500 Washington Avenue facility was considered a potential concern because it may have received plating or acid wastes (PAP-00205108). Mercury was detected in a subsurface soil sample at a concentration of 0.83 mg/kg at a depth of three to four feet (PAP-00205137).

River Road Area

According to a *Site Evaluation Submission and Remedial Action Plan*, dated October 1993, a discharge from a machine shop sink in the building (492 River Road) was released via a pipe directly to a subsurface dry well on the north side of the building (PAP-00199292). In addition, a former dry well for plating rinse water was located at the northeast corner of the building (PAP-00199293, 89). Finally, a former dry well for non-contact cooling water was located at the northeast corner of the building (PAP-00199289). It is noted that according to a *Remedial Action Report*, dated February 1997, facility personnel stated that the non-contact cooling water dry well did not receive industrial waste, but rather was a discharge point for storm water (roof drains) (PAP-00203004).

It is noted that initially, the eastern portion of the River Road Area was reportedly landfilled with municipal refuse immediately prior to construction of the facility, prior to ITT's ownership of the property. It is reported that there are no records regarding the period of landfill activity, the types of waste disposed, or the manner of landfill closure, but that on-site drilling has revealed fill material to include coal, ash, glass, china,

leather, rubber, cast iron, and steel (PAP-00199213). Later, additional evidence provided to NJDEP showed that the fill that predated ITT's ownership extended to almost the entire River Road Area. NJDEP itself concurred with the conclusion that fill "extends throughout the site…" in a letter dated August 31, 1994 (PAP-00202983). Metals detected in this area were attributed to former landfill activities (PAP-00199291). The NJDEP concurred that this area was historic fill (PAP-00202983).

Maximum concentrations of mercury detected in 1991 and 1993 (with the concentration at the machine shop sink discharge location being detected at 0.5 to one feet) at the above-listed areas were as follows (PAP-00199290-293, 312, 316-317):

Maximum Mercury Concentrations by Area of Concern (mg/kg)				
	Machine Shop Sink Discharge	Dry Well for Non-Contact Cooling Water	Dry Well for Plating Rinse Water	Municipal Landfill
Mercury	2.1	Not Detected	Not Detected	Not Detected

Historic Fill

The Allocation Team has determined that the facility site is not located on regional Historic Fill as designated by the NJDEP.[2]

NJDEP has established that Historic Fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 COCs: PAHs, lead, copper, and mercury.[3] Accordingly, NJDEP technical requirements for property containing Historic Fill requires sampling for the United States Environmental Protection Agency (EPA) Target Compound List for PAHs and Target Analyte List for metals, including lead, copper, mercury, and the OU2 PAH COCs.[4] PAHs, lead, copper, and mercury are recognized by NJDEP to be constituents of Historic Fill at varying levels, not atypically at or exceeding residential soil standards.[5]

[2] *Digital Geodata Series, DGS04-7, Historic Fill for New Jersey*, https://www.nj.gov/dep/njgs/geodata/dgs04-7.htm, Quadrangle #52 and #53 (NJDEP map identifying locations of recognized historic fill).
[3] *Characterization of Ambient Levels of Selected Metals and cPAHs In New Jersey Soils* (2002) and *Characterization of Ambient Levels of Selected Metals and Other Analytes In New Jersey Soils* (1997), studies prepared for NJDEP, Division of Science and Research, by BEM Systems, Inc.
[4] New Jersey Department of Environmental Protection (NJDEP), *N.J.A.C. 7:26E Technical Requirements for Site Remediation,* Table 4-2, November 2009 [Note that Table 4-2 has been deleted from the current version of N.J.A.C. 7:26E (May 7, 2012) and the updated *Historic Fill Technical Guidance* (April 2013) as NJDEP believed that the tables list of historic fill constituents was too restrictive].
[5] NJDEP Table 4-2 (PAHs and lead) and a summary of NJDEP records regarding investigations of properties in the vicinity of the Passaic River recognized to be located in areas of Historic Fill indicate that the following average/maximum (mg/kg) contamination levels of OU2 COCs exist in area Historic Fill: PAHs (1.91/160), lead (574/10,000), copper (11.2/1,200), and mercury (0.21/3.7).

According to a *Site Evaluation Submission and Remedial Action Plan*, dated October 1993, fill was encountered at the River Road Area. Boring log descriptions of the fill included ash, glass, china, leather, rubber, cast iron, steel and coal. The thickness of the fill ranged from approximately three feet to approximately 12 feet (PAP-00199283). The report goes on to state that the eastern portion of the River Road Area was reportedly landfilled with municipal refuse immediately prior to construction of the facility and predated ITT's ownership. It is reported that there are no records regarding the period of landfill activity, the types of waste disposed, or the manner of landfill closure (PAP-00199213), but metals detected in soil in this area were attributed to former landfill activities (PAP-00199291). In 1994, based on additional evidence provided by NJDEP, NJDEP concurred that historic fill "extends throughout the site [River Road Area]" (PAP-00202983).

The levels of copper, lead and mercury detected at the site in soils are presented in the table below (PAP-00199312, 316-317).

COCs Found in Onsite Soils	
COC	**Max Detected Concentration**
Lead	2,470 mg/kg
Copper	865 mg/kg
Mercury	2.1 mg/kg

5. COC Pathways

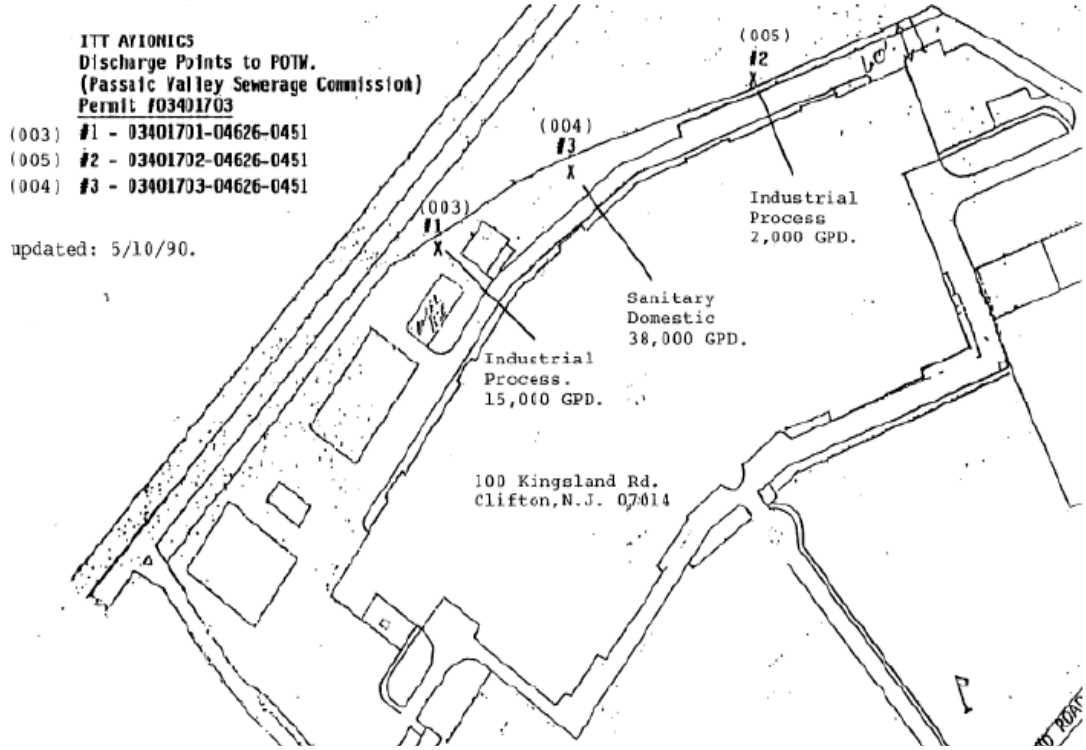
Prior to 1998, the Third River, a tributary of the Passaic River, bordered part of the Kingsland Road Area to the west, and flowed around to the facility to the west, north and east. To the north, the facility was bordered by State Highway Route 3. This tributary discharges to the Passaic River approximately one-quarter mile east of the facility (PAP-00199799).

Sanitary Sewer

Each area of the facility had its own PVSC sanitary sewer permit:

- The Kingsland Road Area held PVSC Sewer Connection Permit (03401703) (PAP-00203263). A copy of the permit was not identified in the available file material.
- The Washington Avenue Area held PVSC Sewer Connection Permit (24401713) (PAP-00205012, 32).
- The River Road area held PSVC Sewer Connection Permit (24403740) (PAP-00199240).

Additional details are discussed below by facility area.



Kingsland Road Area

Sanitary wastewater, along with industrial process wastewater that was pretreated in an on-site wastewater treatment system, was discharged to the PVSC system between 1982 and 1990 pursuant to the PVSC permit. Discharge was monitored for copper and lead, among other parameters (PAP-00203244). The *Preliminary Assessment and Site Investigation Report*, dated July 26, 2012, states that sanitary waste was discharged to the PVSC system beginning in 1946 (PAP-00199536). As documented in 1990, discharges from the Kingsland Road Area to the PVSC system were via three outfalls. Industrial process wastewater was discharged to outfall 003 and outfall 005. Sanitary waste was discharged to outfall 004 (PAP-00203263). Discharge through outlets 003 and 005 appears to have been permitted through 2001 (PAP-00722300, 85-87).[6]

For the period of January through June 1988, a maximum flow volume of 140,950 gallons per day was reported for outfall 005 (PAP-00426063). For the period of July through December 1988, a maximum flow volume of 160,729 gallons per day was reported for outfall 005 (PAP-00426083). For the period of January through June 1989, a maximum flow volume of 163,658 gallons per day was reported for outfall 005 (PAP-00426124). For the period of July through December 1989, a maximum flow volume of 111,000 gallons per day was reported for outfall 005 (PAP-00426152). In 1990, process wastewater was discharged at a rate of 15,000 gallons per day out of outfall 003 and 2,000 gallons per day out of outfall 005. Sanitary waste was discharged out of outfall 004 at a discharge rate of 38,000 gallons per day (PAP-00203263).

A figure depicting the locations of the outfalls is below (PAP-00203263):

[6] This Report was revised to include documents received on July 13, 2020. The additional documents did not change L3 Harris Technologies' previous certification.

According to a *Preliminary Assessment and Site Investigation Report*, dated July 26, 2012, facility operations historically included metal finishing and electroplating (i.e., via plating baths consisting of cadmium, chromium, copper, lead, molybdenum, nickel, silver, tin, and zinc). Between 1982 and 1990, process baths were reportedly located throughout the area on elevated gratings. Process rinse water was discharged to concrete troughs which drained to an industrial wastewater pretreatment system (PAP-00199563). The pretreatment system was located in the subbasement of the main building. Pretreatment consisted of chrome reduction (i.e., hexavalent to trivalent), and metal hydroxide precipitation and neutralization (PAP-00199806). Process operations generating industrial wastewater ceased in 1990 (PAP-00199806).

From April 1 through June 30, 1991, the flow volume at outfall 003 was listed as 902,080 gallons and the flow volume at outfall 005 was listed as 265,450 gallons (PAP-00426044, 46). For June 1992, the flow volume at outfall 003 was listed as 14,734 gallons and the flow volume at outfall 005 was listed as 4,385 gallons (PAP-00426194). In October 1997, the flow volume at outfall 003 was listed as 23,698 gallons per day (PAP-00426674). In February 1998, the flow volume at outfall 003 was listed as 26,626.52 gallons per day and at outfall 005 was listed as 2,753.8 gallons per day (PAP-00427182, 84). In March 1998, the flow volume at outfall 003 was listed as 589,305 gallons and at outfall 005 was listed as 113,882 gallons (PAP-00427258, 60). In April 1998, the flow volume at outfall 003 was listed as 371,143 gallons and at outfall 005 was listed as 143,181 gallons (PAP-00427327, 29). In May 1998, the flow volume at outfall 003 was listed as 200,978 gallons and at outfall 005 was listed as 168,095 gallons (PAP-00427419, 21). In June 1998, the flow volume at outfall 003 was listed as 526,948 gallons and at outfall 005 was listed as 395,707 gallons (PAP-00427521, 23). In July

1998, the flow volume at outfall 003 was listed as 270,906 gallons and at outfall 005 was listed as 932,774 gallons (PAP-00427593, 95). In August 1998, the flow volume at outfall 003 was listed as 17,658 gallons per day and at outfall 005 was listed as 16,092 gallons per day (PAP-00427667, 68). In December 1998, the flow volume at outfall 003 was listed as 32,845 gallons per day and at outfall 005 was listed as 4,434 gallons per day (PAP-00428078, 80).

Additional monitoring reports from January to May 1999 provided data for discharges through outfalls 003 and 005. The maximum flow through outlet 003 during this time period was reported as 29,052.1 gallons per day, and the maximum flow through outfall 005 was reported as 4,500.1 gallons per day (PAP-00722758, 60).[7]

According to the *Remedial Action Report*, dated September 1997, the pretreatment system continued to operate as a neutralization system in the event the pH of other industrial wastewater generated throughout the facility was outside of discharge limits (PAP-00199975).

The *Preliminary Assessment and Site Investigation Report*, dated July 26, 2012, states that at that time of the report, all industrial process wastes were containerized and staged on-site prior to off-site disposal (PAP-00199536).

Washington Avenue Area

According to the *Site Evaluation Submission and Cleanup Plan Report*, dated July 1993, sanitary wastewater was discharged to the PVSC system beginning as early as 1981 via a PVSC Sewer Connection Permit (24401713) (PAP-00204993, 5032). No discharge monitoring was required under this permit, which included discharge of sanitary waste only via three outfalls (PAP-00205015-18). ITT informed PVSC that operations and discharges had ceased on November 3, 1993 (PAP-00203242).

River Road Area

According to the *Site Evaluation Submission and Remedial Action Plan*, dated October 1993, sanitary wastewater was discharged to the PVSC system beginning as early as 1991 to at least 1996 via one outfall (PAP-00199207, 240, 242). ITT was not required to monitor this discharge for OU2 COCs (PAP-00199242). On July 13, 1992, ITT certified that they did not have any discharges from the River Road Area (PAP-00426189).

Non-Contact Cooling Water and Stormwater Discharges

Kingsland Road Area and Washington Avenue Area

The Kingsland Road Area had a New Jersey Pollutant Discharge Elimination System (NJPDES) permit (NJ0020214) for discharge to the Third River and Passaic River at least as early as 1983 (PAP-00026354; PAP-00203103). According to a *Site Evaluation*

[7] This Report was revised to include documents received on July 13, 2020. The additional documents did not change L3 Harris Technologies' previous certification.

Submission and Cleanup Plan Report, dated July 1993, the Washington Avenue Area was also covered under this NJDPES permit (PAP-00204991). It is noted that ITT was not required to monitor discharges for OU2 COCs under this permit (PAP-00203109-11).

Discharges included stormwater and non-contact cooling water (PAP-00026354; PAP-00203103). Discharges were via outfall 001 (which discharged to the Third River) and outfalls 002 and 003 (which discharged to the Passaic River) (PAP-00204991, 5007).

According to a modification to the NJPDES permit, approved by NJDEP on October 31, 2001, ITT requested to eliminate discharge 001 and to monitor the discharge of non-contact cooling water out of outfalls 002 and 003 (PAP-00203113). The outfalls 002 and 003 referenced in the modification request discharged to the Third River, not the Passaic River (PAP-203119-121). On January 14, 2003, ITT requested that their NJPDES permit be revoked, as it had ceased non-contact cooling water discharges, and installed a closed loop recirculation system (PAP-00203162).

The *Preliminary Assessment and Site Investigation Report*, dated July 26, 2012, states that stormwater catch basins were observed throughout the exterior of the site during an October 2011 site reconnaissance. The report states that stormwater followed sheet flow across paved areas of the site and was collected in stormwater catch basins that ultimately discharge to the Third River located north and east of the site. ITT filed a "No Exposure Certification" and did not require permit authorization for its stormwater due to the existence of a condition of no exposure. No exterior hazardous material storage areas were observed during the October 2011 site reconnaissance. As stated above, the report states that historically the facility held a NJPDES Permit for the discharge of stormwater and non-contact cooling water to the Third River (PAP-00199568; PAP-00203173).

River Road Area

The River Road Area also had a NJPDES permit (NJ0020435) for stormwater discharges to the Third River and Passaic River (PAP-00199205, 216; PAP-00203149). The permit was issued on August 22, 1985, and discharges were described as "thermal surface water" discharges (PAP-00203157, 59). Information on volume of discharges was not identified. The permit was terminated on June 21, 1996 (PAP-00203157). A copy of the permit was not identified in the available file material. According to a July 7, 1980 NJDEP letter, the permittee shall discharge so as not to violate Water Quality Standards for tributaries to the Third River Classified as TW-2 waters pursuant to N.J.A.C.7:9-4.6(e) including: floating, suspended, colloidal, and settleable solids, color; Petroleum Hydrocarbons and other oils and grease, pH (between 6.5 and 8.5), and temperature (PAP-00203151-52).

Spills

There is no information regarding spills in the available file material.

6. Regulatory History/Enforcement Actions

Inspections

NJDEP inspected the Kingsland Road Area on February 17, 1988, and gave the facility a rating of 'acceptable' for their NJPDES compliance (PAP-00203144).

Violations/Enforcement Actions

No violations or enforcement actions associated with OU2 COCs were identified in the available file material.

Settlements

It is noted that ITT entered into a Natural Resources Damages settlement with NJDEP in 2007 that provided ITT with a release and covenant not to sue for natural resource damages under the state Spill Act and federal CERCLA in return for conducting a storm water and park restoration project (PAP-000204429-49). NJDEP in responding to comments to the proposed settlement stated that the settlement was intended to apply to all areas both on-site and off-site, as based on their review of the environmental documentation, there had been no releases from the Facility off-site, and the only impact to natural resources from Facility operations was to on-site groundwater (PAP-00204430; PAP-00204909).

Permits

Each area of the site had its own PVSC permit:

- The Kingsland Road Area held PVSC Sewer Connection Permit (03401703) (PAP-00203263).
- The Washington Avenue Area held PVSC Sewer Connection Permit (24401713) (PAP-00205032).
- The River Road area held PSVC Sewer Connection Permit (24403740) (PAP-00199240).

The terms of each permit are described in the "Sanitary/Storm Sewer" subsection above. The Kingsland Road Area and Washington Avenue Area had a NJPDES permit (NJ0020214) for discharge to the Third River and Passaic River at least as early as 1983. Discharges included stormwater and non-contact cooling water (PAP-00026354; PAP-00203103; PAP-00204991). Discharges were via outfall 001 (which discharged to the Third River) and outfalls 002 and 003 (which discharged to the Passaic River) (PAP-00204991, 5007). On January 14, 2003, ITT requested that their NJPDES permit be revoked, as it had ceased non-contact cooling water discharges, and installed a closed loop recirculation system (PAP-00203162).

The River Road Area also had a NJPDES permit (NJ0020435) for stormwater discharges to the Third River and Passaic River at least as early as 1985 (PAP-00199205, 216; PAP-00203149). The permit was terminated on June 21, 1996 (PAP-00203157).

7. Response Actions

Characterization Activities

The following characterization activities have taken place at the facility:

- *Site Evaluation Submission and Cleanup Plan Report*, dated July 1993 (PAP-00204989) (Washington Avenue Area);
- *Site Evaluation Submission and Remedial Action Plan*, dated October 1993 (PAP-00199203) (River Road Area);
- *Remedial Action Report*, dated February 27, 1995 (PAP-00200046, 48) (River Road Area);
- *Remedial Investigation Report and Remedial Action Work Plan*, dated August 8, 1996 (PAP-00199792) (Kingsland Road Area);
- *Remedial Action Report*, dated February 1997 (PAP-00202986) (River Road Area);
- *Remedial Action Report*, dated September 1997 (PAP-00199971) (Kingsland Road Area);
- *Preliminary Assessment and Site Investigation Report*, dated June 26, 2012 (PAP-00199530) (Kingsland Road Area);
- *Site Investigation Report*, dated October 29, 2012 (PAP-00203487) (Kingsland Road Area);
- *Baseline Ecological Evaluation, ITT Avionics Division*, dated July 1, 2004 (PAP-00204912) (Facility-wide).

Soil

Kingsland Road Area

According to a *Preliminary Assessment and Site Investigation Report*, dated June 26, 2012, during visual inspection of transformers and switchgear conducted at the Kingsland Road Area in May 1996, three transformers were identified as having stains on concrete pads adjacent to the transformers. Concrete chip samples were collected at the stained areas and analyzed for PCBs (PAP-00199564). The maximum detected concentration of total PCBs in concrete chips was 6.24 mg/kg in 1997 (PAP-00200025). The maximum detected concentration of total PCBs in soil below the concrete was 0.054 mg/kg in 1997 (PAP-00200026).

In addition, in 2005, concrete chip samples and wipe samples were collected from the surface of the concrete upon which interior building transformers were historically staged (PAP-00199564). Total PCBs were detected at a maximum concentration of 1,890 µg/kg in concrete chip samples from an interior floor (PAP-00199591). It is reported that

all concrete core bottom sample and soil sample data were reported as non-detected for PCBs (PAP-00199585; PAP-00203490). According to a *Site Investigation Report*, dated October 29, 2012, based on these results, no further investigation was recommended for soil in proximity to the building transformer areas (PAP-00203490).

Washington Avenue Area

According to a *Site Evaluation Submission and Cleanup Plan Report*, dated July 1993, a former dry well near the 500 Washington Avenue facility was considered a potential concern because it may have received plating or acid wastes (PAP-00205108). High and low molecular weight PAHs were identified in soil associated with the dry well (PAP-00205108, 136). Mercury, copper, and lead were detected at concentrations of 0.83 mg/kg, 52.1 mg/kg, and 57.6 mg/kg, respectively, at a depth of three to four feet (PAP-00205137).

River Road Area

According to a *Site Evaluation Submission and Remedial Action Plan*, dated October 1993, a discharge from a machine shop sink in the building was released via a pipe directly to a subsurface dry well on the north side of the building (PAP-00199292, 89). In addition, a former dry well for plating rinse water was located at the northeast corner of the building (PAP-00199293). Finally, a former dry well for non-contact cooling water was located at the northeast corner of the building (PAP-00199289). It is noted that according to a *Remedial Action Report*, dated February 1997, facility personnel stated that the non-contact cooling water dry well did not receive industrial waste, but rather was a discharge point for storm water (roof drains), further corroboration that the metals detections in the dry well were related to the recognized historic fill. (PAP-00203004).

It is noted that initially, the eastern portion of the River Road Area was reportedly landfilled with municipal refuse immediately prior to construction of the facility, prior to ITT's ownership of the property. It is reported that there are no records regarding the period of landfill activity, the types of waste disposed, or the manner of landfill closure, but that on-site drilling has revealed fill material to include coal, ash, glass, china, leather, rubber, cast iron, and steel (PAP-00199213). Later, additional evidence provided to NJDEP showed that the fill that predated ITT's ownership extended to almost the entire River Road Area. NJDEP itself concurred with the conclusion that fill "extends throughout the site…" in a letter dated August 31, 1994 (PAP-00202983). Metals detected in this area were attributed to former landfill activities (PAP-00199291). The NJDEP concurred that this area was historic fill (PAP-00202983).

Maximum detected concentrations of mercury, copper, and lead detected in 1991 and 1993 at of the above-listed areas were as follows (PAP-00199290-293, 312, 316-317):

Maximum Metals Concentrations by Area of Concern (mg/kg)				
COC	**Machine Shop Sink Discharge**	**Dry Well for Non-Contact Cooling Water**	**Dry Well for Plating Rinse Water**	**Municipal Landfill**
Mercury	2.1 (at 0.5 to one foot)	Not Detected	Not Detected	Not Detected
Copper	2,380 (at 0.5 to one foot)	360 (at one to three feet)	360 (at one to three feet)	865 (at zero to two feet)
Lead	1,400 (at two to four feet)	2,470 (at one to three feet)	2,470 (at one to three feet)	1,710 (at zero to two feet)

Remedial Activities

In 1989, ITT initiated an investigation of environmental conditions at the site as part of a corporate-wide environmental assessment of all ITT properties (PAP-00203472; 77). ITT participated in New Jersey's Voluntary Cleanup Program and entered into three Memoranda of Agreement with NJDEP for the investigation and remediation of the three separate areas of the site in 1993 (PAP-00203454-69).

Kingsland Road Area

According to a *Preliminary Assessment and Site Investigation Report*, dated June 26, 2012, six USTs, identified as UST systems El through E6, were closed and removed from the northern side of the Kingsland Road Area site, north of the former boiler house between July 12, 1990, and October 25, 1990. UST systems El through E4 were 22,000 gallons in capacity and were used for the storage of No. 6 fuel oil. UST systems E5 and E6 were 2,000 and 6,000 gallons in capacity, respectively, and were used for the storage of No. 4 fuel oil. Four post-excavation soil samples were analyzed for PAHs, and according to the report, no further action was required (PAP-00199804-05, PAP-00199883).
Beginning in 1985, PCB-containing transformers were retro-filled and retested until concentrations were below 50 parts per million (ppm) and PCB-impacted concrete was removed from the facility in 2005 (PAP-00199564; PAP-00203490).

The Kingsland Road Area received an "Unrestricted Use (Soils Only) No Further Action Letter and Covenant Not to Sue" for soil from NJDEP on June 2, 1998. This designation did not include PCB contamination at the building transformer pads because the investigation was ongoing (PAP-00199578-79; PAP-00026342-43). The *Preliminary Assessment and Site Investigation Report*, dated June 26, 2012, states that this "no further action" designation applied to the above-referenced USTs as well (PAP-00199558). It is reported that a "no further action" letter was not issued for the transformer pads because the investigation was ongoing (PAP-00199572).

Additional sampling work was performed in 2005 (PAP-00203490). A New Jersey Licensed Site Remediation Professional determined that no further remedial action was required for the transformer pads on November 19, 2012 and issued a Response Action Outcome (PAP-00026345-53).

Washington Avenue Area

According to a *Site Evaluation Submission and Cleanup Plan Report*, dated July 1993, a former dry well near the 500 Washington Avenue facility was considered a potential concern because it may have received plating or acid wastes (PAP-00205108). Affected subsurface soils were removed in 1993 and confirmation samples were collected (PAP-00200077-80; PAP-00199293).

According to a *Site Evaluation Submission and Cleanup Plan Report*, dated July 1993, a 20,000-gallon heating oil UST and a 3,000-gallon heating oil UST located at the 500 Washington Avenue facility were identified by ITT's environmental consultant as an area of potential concern because of the age of the tanks. The USTs were removed under NJDEP oversight in 1990. Post-excavation soil samples were collected (PAP-00205103). According to the report, although there was one sample that exceeded the NJDEP action limit for total base neutral compounds. "the sample depths and the sound condition of the tank system suggest that the elevated contaminant levels may be attributed to historical conditions (i.e. construction fill material) unrelated to the UST system operation." (PAP-00202323).

In addition, an *Underground Storage Tank Closure Plan Implementation Summary Report* was prepared for ITT in March 1993. This closure plan addressed the decommissioning of two USTs at 390 Washington Avenue and one UST at 417 River Road. The USTs at 390 Washington Avenue were a 10,000-gallon No. 4 fuel oil tank and a 10,000-gallon No. 2 fuel oil tank. The UST at 417 River Road was a 3,000-gallon No. 2 fuel oil tank. The USTs were removed under NJDEP oversight and post-excavation samples were collected (PAP-00205094-95). The two tanks at 390 Washington Avenue were intact with no signs of leaking (PAP-00205106-08). Similarly, the UST at 417 River Road did not show signs of leaking (PAP-00205105). NJDEP issued a "no further action" designation for the Washington Avenue Area on July 31, 1995 (PAP-00204398; PAP-00204388).

River Road Area

According to a *Site Evaluation Submission and Remedial Action Plan*, dated October 1993, between October 31, 1990 and November 2, 1990, a 20,000-gallon UST system used to store No. 2 fuel oil was evacuated of its contents, excavated and removed in accordance with an NJDEP-approved UST closure plan. Post-excavation samples were collected. High and low molecular weight PAHs were detected. The report states that based on the analytical results and a no further action letter received from NJDEP, no further action was proposed (PAP-00199288, 315). On July 13, 1992, NJDEP issued a letter stating that no additional corrective action related to the USTs at the River Road Area was needed (PAP-00199231).

According to a *Site Evaluation Submission and Remedial Action Plan*, dated October 1993, a discharge from a machine shop sink in the building was released via a pipe directly to a subsurface dry well in the ground on the north side of the building (PAP-00199292). Subsurface soil sampling in the area of the machine shop sink surface discharge identified copper and lead (PAP-00199279, 292). The machine shop sink dry

well and associated subsurface soils were excavated and disposed of off-site (PAP-00199293). NJDEP stated that this area should be restricted to non-residential use based on a single sampling result that exceeded the residential direct contact soil cleanup criteria for lead (PAP-00203066, PAP-00202984).

According to a *Remedial Action Report*, dated February 1997, in 1995, ITT excavated soil containing lead from the area of the municipal landfill, which included the former plating, rinse water dry well and the non-contact cooling dry well. Approximately 5.4 (3.6 + 0.6 + 1.2) cubic yards of soil was removed (PAP-00203019, 22-23). Lead remained in subsurface soil following the excavations at a concentration as high as 598 ppm (PAP-00203029). According to the report, this area also included the former dry well for plating rinse water, and the non-contact cooling water dry well and lead detected in these areas was attributed to historic fill (PAP-00203036).

NJDEP issued a "no further action" designation for all areas of the River Road Area on November 18, 1997. A "Declaration of Environmental Restriction" was required for the municipal landfill area because of exceedances of zinc, which is not a COC (PAP-00204414, PAP-00203100). The deed notice was terminated on July 15, 2015 (PAP-00382267).

8. Summary of Asserted Defenses

ITT believes that its operations at the Facility did not result in a discharge or release of COCs to the Third River or the Passaic River, or to OU 2. However, to the extent an allocation to ITT is based on discharges to the PVSC or stormwater discharges, these discharges of copper and lead to the PVSC were permitted discharges conducted in compliance with federal and state permit conditions, and thus are exempt under CERCLA. In addition, PAHs contained in petroleum products that came from tanks or associated piping in subsurface soils are subject to the petroleum exclusion under CERCLA…. [A]lthough ITT asserts that it is not liable for the conditions in the LPR [Lower Passaic River], if it is determined to have any liability, ITT has already contributed more than its fair share to response costs…. ITT cannot be liable for or be required to pay for a release that arises out of conduct lawfully undertaken in compliance with permits or other approvals issued by relevant government agencies, including the States and/or the United States and/or in compliance with applicable laws, regulations, rules, orders, ordinances, directives and common law ('applicable Environmental Laws'). It is constitutionally impermissible to impose retroactive liability for acts that were previously authorized or condoned by law including applicable Environmental Laws. At all relevant times, ITT complied with all applicable Environmental Laws, regulations, industry standards and ordinances, and otherwise conducted itself reasonably, prudently, in good faith and with due care. ITT exercised due care with respect to hazardous substances, if any, that may have been handled at the Facility, took precautions against foreseeable acts or omissions of others and the consequences that could reasonably result from such acts or omissions, and because any release or threat of release of any hazardous substances, if any, and costs arising therefrom were caused solely by the negligence, acts or omissions of third parties over whom ITT had no control.

Hartz Consumer Group, Inc.

Diamond Alkali OU2 Allocation

ADR Confidential

Facility Data Report

Hartz Consumer Group, Inc.

Facility Name, Address and Size: The Hartz Mountain Corporation Site, owned by the Hartz Consumer Group Inc./Hartz Mountain Corporation (Hartz); 600/700 Frank E. Rodgers Boulevard (formerly South 4th Street), Harrison, New Jersey; 10.3 acres (PAP-00216527); 550 employees, 1 shift per day, 5 days per week (PAS-00002440). Another source says 770 employees, up to 3 shifts per day in some areas, 251 days per year (PAS-00002444).

1. **Business Type:** Pet products and supplies (PAS-00002440)

2. **Time Period of Ownership/Operations**

Operator: Hartz Mountain Corporation 1971 to 1996
Owner: Sternco-Dominion Real Estate Corporation December 11, 1970 to September 15, 1999

1895: Hyatt Roller Bearing Facility operated independently at the property before being acquired by General Motors (GM) (PAS-00124165; PAS-00125353). Hyatt Roller Bearing Company operating on-site from 1897 and was acquired by GM in 1918 (PAP-00005292), but other sources identify Reuther Bros Foundry and other industrial uses prior to 1918 (PAS-00002123).

1918: General Motors-Hyatt Roller Bearing Facility was the previous site owner and operator (PAS-00002123). GM began operations providing roller bearings, and the manufacturing process included machining, heat treating, bearing assembly and fabrication, and recovery of machining fluid and scrap. Waste materials generated included hydraulic, lubricating, and soluble oils, scrap metal shavings/chips, off-specification products, and sludge from grinding solutions (PAP-00005292). Operations at this property were phased out between 1966 and 1968 (PAP-00005292).

1970: Hartz operated the site from 1971 until 1993, when operations ceased. Other sources state that Sternco Dominion Real Estate Corp. purchased the property on December 11, 1970 and leased it to Sternco Industries, Inc. on August 19, 1971. The lease expired in 1991 and the tenancy continued month to month until the property was vacated in 1995 (PAP-00211208; PAP-00005292-93). However, correspondence regarding the property purchase were addressed from Hartz Mountain Products Corp. (PAP-00211220-21).

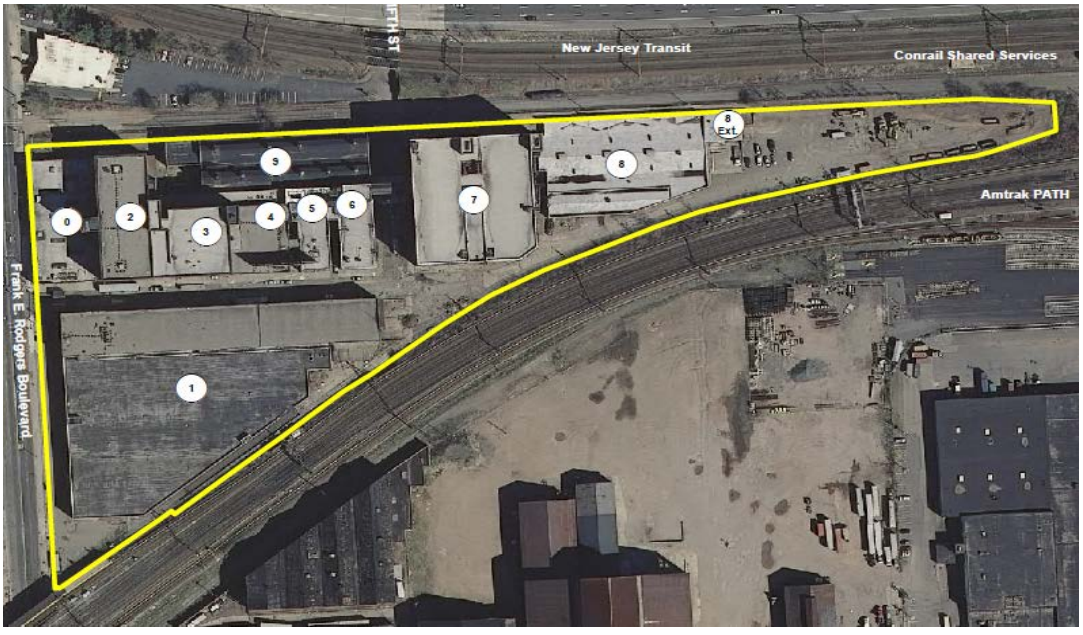
1973: Sternco Industries, Inc. merged with Hartz Mountain Pet Foods, Inc. on May 31, 1973, and the name was changed to Hartz Mountain Corporation (PAP-00165391; PAP-00211207-8).

1995: Property vacant after transfer of warehouse operations (PAP-00216533).

1999: The site was sold to FER Boulevard Realty Corp. in 1999 (PAP-00005354; PAP-00216533; PAS-00002123).

2000: Hartz was jointly purchased by the company's management and an investment group named J.W. Childs (PAP-00165391).

2004: Hartz was acquired by Sumitomo Corporation of America in September 2004 (PAP-00165391; PAS-00125317).



2011: Property taken by Harrison Redevelopment Agency (HRA) via eminent domain in June 2011 (PAP-00006537; PAP-00216533).

2012: All buildings demolished under ownership of HRA (PAP-00216533).

2015: Title transferred from HRA to Heller Urban Renewal, LLC (Heller) (PAP-00216533).

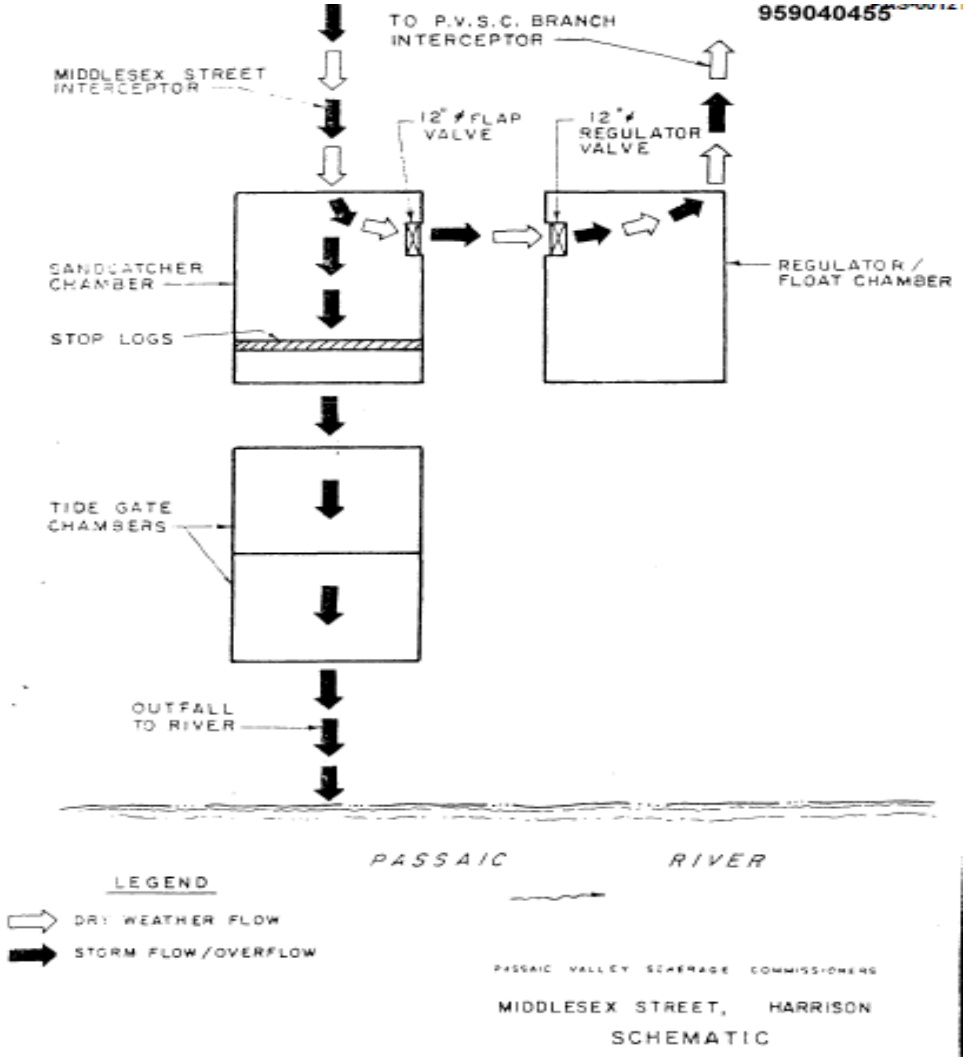
3. Operational History/COC Use and Presence at the Facility

Buildings 0 through 9 were present at the site during operations by Hartz. Buildings 0 through 9 were constructed between 1910 and 1954, during ownership/operations by GM (PAP-00210588). The property is bound to the north, south, and east by active railroad easements (Conrail and Amtrak), and bound to the west by the former South 4th Street (now Frank E. Rodgers Boulevard). Approximately 90 percent of the property was impervious surfaces. Two large building complexes were separated by a central roadway (Middlesex Street). Building 1 was located south of Middlesex Street, was approximately 80,000 square feet, and contained offices, warehouses, plant utilities (heating plant, fire cistern, pumping station), and a rooftop parking deck. Buildings 0 and 2 through 9 were located north of Middlesex Street, and contained assembly, lab, and office areas. The buildings to the north totaled approximately 190,000 square feet (PAS-00121274; PAS-00123454). A map of the building locations is presented below (PAP-00216586):

When the property was purchased by Hartz, the buildings were in a state of disrepair as the facility had not been used for years (PAP-00211059, 65-67). The pit furnaces left by GM in Building 9 were removed by Hartz in 1971 (PAP-00211061-62, 209). Two 30,000 gallon fuel oil aboveground storage tanks (ASTs) located east of Building 8 were moved to the east end of Building 1 (PAP-00211208-09).

Hartz Consumer Group operations consisted of the following:

- Packaging of fish food, charcoal, and aquarium gravel on the third floor of Building 7, from 1971 to 1982 (PAP-00210605);
- Blister packaging on the third floor of Building 7 from the early 1970s to 1982 (PAP-00210605);
- Aquarium operations (steel/glass) at Buildings 3 and 4 at grade level from the early to late 1970s (PAP-00210605);
- Aquarium operations (all-glass) at Buildings 3 and 4 at grade level from the late 1970s to early 1990s (PAP-00210605);
- Display rack assembly, including powder painting and vapor degreasing in the basement of Building 0, from 1972 to the early 1990s (PAP-00210605);
- Shipping at Buildings 1 and 8, from the early 1970s to 1995 (PAP-00210605)
- "Carpet Magic" machine maintenance and repair on the first floor of Buildings 3 and 4 from the late 1970s to early 1990s (PAP-00210605);
- Research and Development (R&D) Laboratories at Buildings 4, 5, and 6 from 1975 to 1995 (PAP-00210605); and
- Warehousing throughout the facility from the early 1970s to 1995 or 1996 (PAP-00210605).



During production of stainless steel aquariums in Buildings 3 and 4, tar was heated in a tank and wax was added until the mixture was in a flowing state. This occurred on the first floor of the buildings (PAP-00211114). A tank on the second floor of the building was used to store tar and gravity fed the tar to the first floor (PAP-00211114-15). Residual tar from the day was left in the tank and re-heated the next day for use (PAP-00211115). Tar was purchased in corrugated-wrapped 50 pounds logs, stored on pallets (PAP-00211118). The tar AST on the second floor was a 3,000 gallon AST, but was removed in 1989 (PAP-00211210).

Small quantities of COC-containing compounds (copper, mercury, and lead) were used and stored in small bottles at the R&D laboratories in Buildings 4, 5 and 6 (PAP-00210638). The R&D laboratory only used and/or stored very small quantities of chemicals and used only gram amounts or less for any experiments. Materials were poured down the laboratory sink, which was connected to the sewer system. The daily flow of water discharged by the Hartz facility was 13,000 gallons per day (PAS-00048703). Other sources state that waste materials from the laboratory were not poured down the sink drains, but were instead collected and placed in lab packs for off-site disposal (PAP-00210638).

Equipment used to manufacture pet food was washed down at the end of the work day using hot water and the rinse water was discharged to the sewer (PAP-00211108). Dry waste was placed in compactors in Building 7 (PAP-00211112). Stainless steel scrap was collected in drums and taken by scavengers (sometimes Hartz was paid, other times they had to pay, depending on the scrap metal market) (PAP-00211124).

Hartz did not use several areas of the site where COCs were found, including the subsurface tunnels and the chip pit (PAP-00210606). Equipment left by GM but not used by Hartz included a kerosene tank at Building 8, three rectangular steel tanks in a subsurface processing room, and two hot water tanks in the Building 5 pump room (PAP-00211209).

A schematic of the Middlesex Street combined sewer system is presented below (PAS-00121700):

4. Identified COCs

- PCBs (detected)
- PAHs (used, detected)
- Copper (used, detected)
- Lead (used, detected)
- Mercury (used. detected)

PCBs

Except for transformers owned by others, there were no operations or processes used by Hartz that used or contained PCBs. GM used PCBs in their manufacturing process as high temperature hydraulic fluid (PAP-00210552).

GM purchased approximately 250,000 lbs of Pydraul F-9 (48 to 53% PCBs) from Monsanto (PAP-00210580, 89). GM also purchased approximately 25,000 lbs of Pydraul A-200 (99% PCBs) hydraulic fluids from Monsanto (PAP-00210589). Other sources specify 249,250 lbs of Pydraul F-9 and 26,610 lbs of Pydraul A-200 from Monsanto between 1958 and 1963, with the Pydraul F09 consisting of 48% Aroclor 1248 and the Pydraul A-200 consisting of 66% Aroclor 1248 and 33% Aroclor 1242 (PAP-00005297-98).
Transformers located at the property and owned by Public Service Electric and Gas (PSE&G) did not contain PCBs (PAS-00048701).

PCBs contained in transformers and capacitors owned by Hartz were properly disposed of in 1990 and 1995 (PAP-00210649).

See Section 7, Characterization Activities, for environmental media sampling and detection information for PCBs.

PAHs

Tar used in aquarium assembly operations during the early to late 1970s likely contained PAHs. Tar was originally formulated on-site, but later arrived on-site as asphalt (PAP-00211114-16).

The list of chemicals used by the R&D laboratory contained a substance called coal tar solution topical, which contains PAHs, but the release of these solutions to the laboratory sink, if it occurred, would not be an amount that would be measurable once diluted in the sewer (PAP-00210551-52).

Copper

Copper-containing chemicals used in the R&D laboratory included hampene 14.5% copper, hampene 7.5% copper, and cupric sulfate, which are all water soluble substances (PAP-00210552-53).

See Section 7, Characterization Activities, for environmental media sampling and detection information for copper.

Lead

Lead-containing compounds would have been received in small bottles or jars. Residual laboratory chemicals were placed in lab packs and sent off-site for disposal in accordance with applicable waste management (PAP-00210638).

Lead IV oxide was listed as a R&D laboratory chemical; because this compound is insoluble it would not be poured down the laboratory sink if appropriate laboratory practices were followed (PAP-00210553).

See Section 7, Characterization Activities, for environmental media sampling and detection information for lead.

Mercury

Colloidal mercury was listed as a chemical used in the R&D laboratory (PAP-00210552).

See Section 7, Characterization Activities, for environmental media sampling and detection information for mercury.

Historic Fill

The Allocation Team has determined that the property is not located on regional Historic Fill as designated by the NJDEP.[1]

However, historic fill, including brick, cinders, weathered concrete, discarded metal pieces, and other indications of historic fill were identified in soil borings advanced across the property (PAP-00216377).

The NJDEP has established that Historic Fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 COCs: PAHs, lead, copper, and mercury.[2] Accordingly, NJDEP technical requirements for property containing Historic Fill requires sampling for the United States Environmental Protection Agency (EPA) Target Compound List (TCL) for PAHs and Target Analyte List (TAL) for metals, including lead, copper, mercury, and the OU2 PAH COCs.[3] PAHs, lead, copper, and mercury are recognized by NJDEP to be constituents of Historic Fill at varying levels, not atypically at or exceeding residential soil standards.[4]

[4] NJDEP Table 4-2 (PAHs and lead) and a summary of NJDEP records regarding investigations of properties in the vicinity of the Passaic River recognized to be located in areas of Historic Fill state that

COCs Found in Onsite Soils	
COC	**Max Detected Concentration**
Lead	6,400 mg/kg
Copper	4,100 mg/kg
Mercury	3.2 mg/kg
Benzo(a)anthracene	0.57 mg/kg
Benzo(a)pyrene	0.82 mg/kg
Benzo(b)fluoranthene	1.2 mg/kg
Benzo(k)fluoranthene	0.33 mg/kg
Dibenzo(a,h)anthracene	0.14 mg/kg
Indeno(1,2,3-cd)pyrene	0.57 mg/kg

The *Remedial Action Workplan for Heller Redevelopment Parcel/Hub at Harrison Station, Former Hartz Mountain Corporation Site*, dated June 2018, includes several cross-section figures that depict the presence of fill, ranging in thickness from 2 to 10 feet (PAP-00216606-13).

5. COC Pathways

Sanitary and Storm Sewer

During 1974, the facility received 3,285,515.2 gallons of water; no well water or river water was used by the facility (PAS-00002441). Water was purchased from the Harrison Water Department (PAS-00002445). All the water used was discharged to the sanitary sewer and a sample of the discharge water was collected over a 10-hour period on February 4, 1976 (PAS-00002441-42). No specifics regarding COCs were provided in available references and it is unknown if the sample was analyzed for COCs.

Cooling water was discharged directly to the sewer system as of May 24, 1988, and a closed, non-contact cooling water system was installed in January 1989 (PAP-00165392; PAP-00210498). The non-contact cooling water system was in operation as of April 1989 (PAP-00210499).

Documented wastewater discharge volumes are as follows:

- According to a *Waste Effluent Survey* dated June 27, 1972, 11,290,000 gallons of wastewater were discharged to the sanitary sewer in 1971 (PAP-00210437-38; PAS-00125321).

- According to a *Waste Effluent Survey* dated November 24, 1975, 328,551.52 gallons of wastewater were discharged to the sanitary sewer in 1974 (PAP-00210445-46).

---

the following average/maximum (mg/kg) contamination levels of OU2 COCs exist in area Historic Fill - PAHs (1.91/160), lead (574/10,000), copper (11.2/1,200), and mercury (0.21/3.7).

- According to a *Waste Effluent Survey* dated March 30, 1976, 3,285,515.2 gallons of wastewater were discharged to the sanitary sewer in 1974 (PAP-00210447-48; PAS-00002441-42).

- According to an Application for a Sewer Connection Permit to the Passaic Valley, 9,664,160 gallons of wastewater were discharged to the sanitary sewer in 1985, of which 3,865,400 gallons were from sanitary service only and 5,798,760 gallons were cooling water (PAS-00002445). Sample results of the waste water taken at three outlets on June 18, 1986 include lead from <0.1 to 0.3 ppb, mercury at <0.002 ppb, and pesticides at <1 ppb (PAS-00002450-53).

- According to a letter dated June 2, 1995 and a follow-up letter dated June 27 1995, a request was made to PVSC for approval to discharge 34,000 gallons of pre-treated water to the combined sewer system. The water was generated during sediment removal from the on-site sewers (approximately 25,000 gallons) and dewatering of an on-site tunnel (approximately 15,000 gallons). Sample results state that post-treatment concentrations were as follows: copper <25 micrograms per liter (µg/L), lead <3.0 µg/L, mercury <0.20 µg/L, total PCBs 0.55 µg/L (PAP-00008294; PAP-00008323-25). According to a letter dated July 18, 1995, 20,000 gallons were approved by PVSC and was discharged to the combined sewer system on July 3, 1995. The July letter also requested approval to discharge 10,000 gallons of water to the combined sewer system from an on-site tunnel (PAP-00008334).

- According to a letter dated November 9, 1995, a request was made to PVSC to discharge 7,000 to 10,000 gallons of pre-treated monitoring well development water to the combined sewer system (PAP-00008358).

Direct Release

According to the *Lower Passaic River Study Area PRP Data Extraction Form - Hartz Mountain Corp./Sternco Industries, Inc. and the Maxus Energy Corporations and Tierra Solutions, Inc.'s Third-Party Complaint "B",* PVSC reports state that during rainfall or wet weather, a portion of the combined flow in the Middlesex Street combined sewer outfall (CSO) entered the interceptor, with the balance of the combined flow being discharged via the outfall pipe to the Passaic River (PAP-00165392; PAS-00125327).

Spills

A PVSC *Stream Contamination Report Violation Elimination* report, dated October 5, 1981, states on September 29, 1981, a leak was discovered in the No. 2 oil storage tank during a boiler start up. Approximately 500 gallons of No. 2 oil was released before the valve was shut off. Hartz contacted the Coast Guard and NJDEP immediately and retained Moran-Crowley Service to clean up the spill. Water from the storm outlet was collected and pumped into a tank truck to prevent discharge to the river and booms were placed around the outlet and downstream. The Coast Guard and NJDEP were checking daily on the cleanup and the river inspector stated that PVSC involvement would not be needed (PAS-00002462-63). It should be noted that the address on the PVSC *Stream*

Contamination Report Violation Elimination report, dated October 5, 1981 is 1000 First Street, which is not the location of the Hartz facility. Hartz states they never owned nor operated at the 1000 First Street property, and therefore is not responsible for this spill (PAP-00210639-40; PAS-00048701). Hartz Harrison Limited Partnership was the owner of the 1000 First Street property, after purchasing this property from Otis Elevator Company in December 1980. Hartz Harrison Limited Partnership was an affiliate of Hartz Mountain Industries, Inc. (HMI), a real estate development and management company (PAP-00210640). It should be noted that Hartz and HMI were sister companies (privately owned but separately managed) for a period of time until 2000, when Hartz was sold to a third party (PAP-00210640).

6. Regulatory History/Enforcement Actions

Inspections

NJDEP conducted a preliminary ISRA inspection on June 30, 1993. Staining of the concrete around the transformers was observed (PAP-00007551).

Violations

There is no information regarding violations in the available file material.

Permits

According to the *Lower Passaic River Study Area PRP Data Extraction Form - Hartz Mountain Corp./Sternco Industries, Inc.,* Hartz did not have a PVSC-issued wastewater discharge permit prior to or as of 1985 (PAS-00125322). There are no citations or available underlying documents to support these statements. A letter from Hartz to PVSC dated March 12, 1986, states that an application for a sewer connection permit was submitted (PAP-00210461). However, the permit was not located in the available file materials.

According to the *NJDEP ECRA Initial Notice Site Evaluation Submission (SES)*, dated March 29, 1993, Hartz did not have a NJPDES permit. Hartz did have permits from the New Jersey Bureau of Air Pollution Control for stack discharge from the Hudson Regional Health Commission for air and hazardous waste generation (PAP-00007282).

NJDEP issued a soil remedial action permit to Hartz Mountain Corp. effective March 11, 2020, requiring the permittee to conduct monitoring, maintenance and evaluation for compliance and effectiveness of the remedial action and its associated institutional control, as specified in a deed notice dated February 21, 2019 (PAP-00466312-67). The deed notice restricts land use and specifies the placement of engineering controls on an 1,800 square-foot area on Block 133 Lot 1.03 and a 2,950 square-foot area on Block 133 Lot 1.02 to protect the public from contact with PCB-contaminated soils. The area is developed with commercial and residential buildings, road, sidewalks, parking, and landscaping (PAP-00466358).[5]

[5] This Report was revised to include documents received on May 15, 2020. The additional documents did not change Hartz's previous certification.

Another deed notice, dated April 20, 2020, requires the owner to obtain another solid remediation permit, and restricts the land use of a 4,500 square-foot area within Block 133 Lot 1.02, near the Port Authority Trans-Hudson Northeast Station House (formerly AOC-10) due to the presence of PCBs (PAP-00466273-304, 6).[5]

7. Response Actions

Characterization Activities

The following characterization activities have taken place at the facility:

- *Phase I Site Assessment Letter Report*, dated August 30, 1990 (PAP-00007110);
- *Report on UST Closure Plan Implementation for Hartz Mountain Corporation, Vol 1*, dated July 24, 1991 (PAP-00007133);
- *Discharge Investigation and Corrective Action Report for Hartz Mountain Corporation*, dated November 5, 1991 (PAP-00007188);
- *ECRA Sampling Plan, Hartz Mountain Corporation*, dated May 1993 (PAS-00123448);
- *Remedial Investigation Report and Remedial Investigation Workplan*, dated June 1994 (PAS-00123582);
- *Phase II Remedial Investigation Report, Hartz Mountain Corporation*, dated April 1995 (PAP-00008035);
- *Phase III Remedial Investigation Report, Hartz Mountain Corporation, Vol I and II*, dated June 1996 (PAS-00104756; PAP-00008784);
- *Phase IV Remedial Investigation Report, Hartz Mountain Corporation, Vol I and II*, dated December 1997 (PAP-00005048; PAP-00005248);
- *Phase IV Remedial Investigation Report, Hartz Mountain Corporation*, dated December 1997 (PAS-00121518);
- *Remedial Action Workplan for Heller Redevelopment Parcel/Hub at Harrison Station, Former Hartz Mountain Corporation Site*, dated June 2018 (PAP-00216518);
- *Phase V Remedial Investigation Report, Vol I of I*, dated March 2000 (PAP-00005373);
- *Self-Implementing Cleanup & Disposal Plan, Former Hartz Mountain Facility*, dated May 2011 (PAP-00006176);
- *LNAPL Interim Remedial Measures Report, Former Hartz Mountain Corp.*, dated December 2012 (PAP-00006301)
- *Remedial Investigation Report/Remedial Action Report, PCB Soil Remediation (AOC-21), Former Hartz Mountain Facility*, dated January 2016 (PAP-00006417);
- *Supplemental Remedial Action Workplan, Chip Pit (AOC-8), Former Hartz Mountain Facility*, dated May 2016 (PAP-00006533)
- *Memorandum, AOC-8 Former Chip Pit Investigation/Remediation Summary*, dated June 26, 2015 (PAP-00006666);
- *Supplemental Remedial Action Report, Chip Pit Soil Remediation (AOC-8), Former Hartz Mountain Corporation Facility*, dated December 2016 (PAP-00006751); and,

- *AOC-18 Remedial Investigation Report, Former Hartz Mountain Corporation Site*, dated April 2017 (PAP-00006866).

Sewer

Six stormwater catch basins were assessed, sampled, and cleaned during the Phase I RI and two more stormwater catch basins were assessed, sampled, and cleaned during the Phase III RI (PAS-00104758). The maximum PCB result was from CB-7, at 110 ppm. Other catch basin sample results ranged from 27.4 ppm to 98 ppm. Only CB-4 was sampled for SVOCs, but no SVOCs were detected above regulatory values (PAS-00104759). [Note: concentrations of SVOCs were not identified in the cited document]. Copper results ranged from 6.1 ppm to 1,200 ppm; lead ranged from <11 ppm to 2,400 ppm; and mercury ranged from <0.10 ppm to 2.9 ppm (PAS-00104761). Another source states that sediment samples collected from the combined sewer system had PCB concentrations as high as 78 parts per million (ppm) (PAP-00006623).

Soil

Several investigations were conducted at the property, including five phases of remedial investigation. Both concrete and soil sampling was conducted. Based on data collected during several remedial investigations, concrete samples contained total PCB concentrations as high as 6,800 ppm (PAP-00006195; PAP-00006609). PCB concentrations in soil were as high as 816 ppm (PAP-00006618). Sediment from within the subsurface tunnels had PCB concentrations as high as 1,900 ppm (PAP-00006624).

According to the *Remedial Investigation Report/Remedial Action Report, PCB Soil Remediation (AOC-21), Former Hartz Mountain Facility*, dated January 2016, 47 soil borings were installed within the footprint of Building 3 following demolition, and PCBs exceed 10 ppm at eight locations, with a maximum concentration of 120 ppm. 37 soil borings were installed within the footprint of Building 4 following demolition, and PCBs exceed 10 ppm at three locations, with a maximum concentration of 53 ppm. 121 soil borings were installed within the footprint of Building 9 following demolition, and PCBs exceed 10 ppm at 45 locations, with a maximum concentration of 280 ppm (PAP-00006427-28).

According to the *Memorandum, AOC-8 Former Chip Pit Investigation/Remediation Summary*, dated June 26, 2015, soil sampling occurred at test pits and at soil borings for AOC-8 (Former Chip Pit), and six of the 11 samples had PCB concentrations above 10 milligrams per kilogram (mg/kg), with a maximum concentration of 42.79 mg/kg (PAP-00006671, 87).

Remedial Activities

Three steel gasoline underground storage tanks (USTs) of unknown age were removed in April 1991 and granted closure approval by the NJDEP (C-91-0517). The tanks had capacities of 550 gallons, 1,000 gallons, and 5,000 gallons, and all contained water with sludge. Approximately 200 cubic yards of soil were removed during the UST removals (PAP-00007128-29; PAP-00007136-37, 39-40).

Two USTs south of Building 8 were removed prior to the ISRA investigation under Case Number 91-04-09-1745 (approval of UST closure granted by NJDEP in letter dated April 30, 1992) (PAP-00216533). A 550-gallon UST for a steam boiler behind Building 7 was removed in 1991 (PAP-00211209-10).

Three 6,200-gallon quench oil ASTs, three 6,200-gallon machine oil ASTs, two 30,000-gallon fuel oil ASTs, and one 6,200-gallon machine oil AST, previously located to the east of Building 8, were removed by 1993. NJDEP issued a No Further Action Determination on November 11, 1996 (PAP-00216374).

During the initial site inspection in 1993, NJDEP identified staining on an active transformer pad that was located in a courtyard north of Building 3. The transformers were determined to be owned by PSE&G, and the pad, transformer, and surrounding building walls were stained, though PSE&G had no records of a spill. A chip sample of concrete collected from a stained area on the transformer pad, along the flow path to an adjacent storm water drain, detected PCBs. The stormwater drain was dye tested, and the results showed the storm water drain was connected to the storm sewer system located within Fourth Street. Steam cleaning the transformer pad to remove mobile residue and chip sampling from the cleaned transformer pad were conducted in 1994. The transformers were removed by PSE&G in 2001 (PAP-00216375).

During the initial site inspection in 1993, NJDEP identified subsurface tunnels beneath Buildings 4 and 9. Sediment in the tunnels was sampled in 1994 and contained PCBs. In 1996, materials from Tunnels A through F were removed and the tunnels were visually inspected; all were in good condition, with the exception of Tunnel D, which had a crack in the floor. The tunnels were removed during building demolition in 2012 (PAP-00216375).

A 1,000 gallon kerosene UST was located beneath the foundation of the eastern portion of Building 8 and this UST was abandoned in place per the January 2, 1995 UST Closure Report, using low-density concrete. NJDEP issued a No Further Action Determination on November 11, 1996. This UST was later removed following demolition of the buildings (PAP-00216374).

A 2,000 gallon diesel UST located beneath the basement floor of Building 2, used as a fuel source for a backup generator, was proposed for closure in place during 1996, after the backup generator was taken out of service. A UST Closure Application was submitted on May 2, 1996 and approved by NJDEP on May 31, 1996. This UST was later removed following demolition of the buildings (PAP-00008505-16; PAP-00216374).

In 1997 a riveted steel 8,000 to 9,000 gallon UST was identified beneath Building 9. The UST contained approximately 40 tons of sand and 3,000 gallons of residual oily liquid. Based on the piping configuration, the UST appeared to be a process flow-through tank. The UST was emptied and cleaned. Three soil samples were collected beneath the UST's centerline and TPHs and PCBs were detected. The UST was filled with cement to grade, and abandoned in place. In 2012, the process UST was excavated and removed as part of the demolition activities. A sample of the concrete from within the UST had PCB concentrations below applicable standards, so the concrete was crushed and reused on site. The UST shell was disposed offsite as PCB-containing material

(>50 ppm). Following removal of the building foundations and process UST, PCB-and petroleum-contaminated soils were excavated to a depth of 30 feet bgs (PAP-00216376).

Six stormwater catch basins were assessed, sampled, and cleaned during the Phase I RI and two more stormwater catch basins were assessed, sampled, and cleaned during the Phase III RI. Integrity testing was conducted at all catch basins, with the exceptions of CB-1, CB-3, and CB-4. Most of sediments removed were from CB-2 (PAS-00104758). Catch basin CSS-2 was excavated and backfilled and was then no longer functional (PAS-00104760). Approximately 80 tons of PCB contaminated sediment and other debris were removed from the stormwater catch basins/combined sewer (PAS-00121267).

According to the *Self-Implementing Cleanup & Disposal Plan, Former Hartz Mountain Facility*, dated May 2011, concrete impacted by PCBs was washed with PCB cleaning solution until wipe results showed PCB concentrations below 10 µg/cm^2 (PAP-00006181). This document also states that soil investigations determined that PCB concentrations in soils beneath Buildings 3, 4, and 9 exceeded 10 ppm, to a depth of 12 feet below grade beneath Buildings 3 and 4, and between 28 and 30 feet below grade beneath Building 9 (PAP-00006185). Following PCB cleaning, all buildings were demolished in 2012 for future site redevelopment (PAP-00216533).

According to the *Memorandum, AOC-8 Former Chip Pit Investigation/Remediation Summary*, dated June 26, 2015, excavation with offsite disposal was conducted at AOC-8 (Former Chip Pit) to remediate soil with PCB concentrations above 50 ppm. At the catch basin CB-CSS2 area, excavation with offsite disposal was conducted to remove the catch basin feature and PCB impacts above 10 ppm (PAP-00006672). According to the *Supplemental Remedial Action Workplan, Chip Pit (AOC-8), Former Hartz Mountain Facility*, dated May 2016, 2,000 tons of PCB-contaminated soil were removed from the Chip Pit area (AOC-8) in 2015, but PCB concentrations above 10 mg/kg remained in some areas (PAP-00006539).

According to the *Remedial Investigation Report/Remedial Action Report, PCB Soil Remediation (AOC-21), Former Hartz Mountain Facility*, dated January 2016, all soil and concrete with PCB concentrations greater than 10 ppm was removed and disposed offsite during building demolition, while soils and concrete with PCB concentrations less than 10 ppm were used for re-grading and placed under an on-site cap with a deed notice filed in perpetuity (PAP-00006422). Approximately 19,000 tons of material with PCB concentrations between 10 and 50 ppm and approximately 29,000 tons of material with PCB concentrations greater than 50 ppm were removed and disposed of offsite (PAP-00006435). During soil excavation activities, dewatering occurred, which include the removal of 10,559,339 gallons of water, which was treated for total suspended solids, PCBs, and volatiles, prior to discharge to the sewer, under a PVSC permit (the permit was referenced to be in Appendix E of the cited document, but this appendix was not included in the file materials) (PAP-00006432).

According to the *Supplemental Remedial Action Report, Chip Pit Soil Remediation (AOC-8), Former Hartz Mountain Corporation Facility*, dated December 2016, "hot spot" excavation occurred on July 5, 2016 to remove PCB concentrations greater than 50 ppm to a depth of 10 feet below ground surface (bgs) at AOC-8. July 6-13, 2016, "warm spot" excavation occurred to remove PCB concentrations greater than 10 ppm, but less than 50 ppm at AOC-8. Approximately 245 tons of "hot spot" soil and approximately 2,100 tons of "warm spot" soil were removed. Approximately 30 tons of concrete removed from the subsurface adjacent to AOC-8 was analyzed and disposed of offsite (PAP-00006760-62).

According to a NJDEP Confirmed Discharge Notification Form submitted on October 4, 2017, a 3,000-gallon UST was uncovered during site redevelopment, near the southwest corner of former Building 7. The UST was registered and removed on August 17, 2017. Soil samples were collected and PCBs exceed 10 mg/kg. Delineation occurred between October 2017 and February 2018 and PCBs greater than 10 mg/kg were excavated (PAP-00006990-92; PAP-00216377).

According to a PCB Impacted Soil and Liquids Disposal Summary, dated May 7, 2020, a total of 36,095 tons of soil with >50 ppm PCBs and 27,707 tons of soil with <50ppm PCBs were disposed of from the site between 1995 and 2018 (PAP-00466272).[6]

8. Summary of Asserted Defenses

Hartz and its consultants and remediation contractors are "response action contractors" protected under §119(a) of CERCLA. They are thus protected from liability in connection with any incidental discharges or releases during its remediation of (GM-Hyatt's) contamination in cleaning up the Harrison Site. This is consistent with the law of the Third Circuit (See U.S. v. CMDG Realty Co., 96 F.3d 706 (3d Cir. 1996) (requiring a showing that contractor negligence exacerbated contamination before a remediation contractor would be subject to "operator" liability). Hartz also claims "innocent landowner" status, having done the appropriate level of due diligence when it acquired the site in 1970. See 42 U.S.C. §9601(35). Remediation of petroleum hydrocarbons may also be covered by the CERCLA "petroleum exclusion" See 42 U.S.C. §9601(14).

[6] This Report was revised to include documents received on May 15, 2020. The additional documents did not change The Hartz Mountain Corporation's previous certification.

Diamond Alkali OU2 Allocation

ADR Confidential

Facility Data Report

HEXCEL CORPORATION

Facility Name, Address and Size: Hexcel Corporation (Hexcel), 205 Main Street, Lodi, New Jersey. The site is an approximately two-acre parcel (PAS-00002498). According to an *Application for a Sewer Connection Permit*, dated July 9, 1985, Hexcel had 39 full-time employees that worked one shift per day, 260 days per year (PAP-00326658, 68).

1. **Business Type:** Manufacturer of specialty chemicals and industrial cleaning compounds (PAS-00091294; PAS-00091237).

2. **Time Period of Ownership/Operations**

Operator:	Hexcel Corporation (1973-1986)
	Fine Organics, Inc. (1944-1973)
Owner:	Hexcel Corporation (1973-1986) and (1998-2017)

According to an Environmental Cleanup Responsibility Act (ECRA) General Information Submission from January 7, 1986, Hexcel Industrial Chemicals Group, a subdivision of Hexcel Corporation, had been operating at the site, but the property was in the process of being sold to FOA Corporation of Wyckoff, New Jersey. Hexcel Corporation of San Francisco, California, was identified as the owner of the property prior to the sale, which was anticipated to be finalized on January 29, 1986. The form states that Hexcel operated at the site starting in 1973 when it merged with Fine Organics, Inc. Fine Organics, Inc. manufactured specialty chemicals and had owned and operated the site since 1944. United Piece Dye Works operated at the site manufacturing dyestuffs for the textile industry from the early 1900s to 1944 (PAS-00091293-95).

A letter dated April 5, 1991, from Fine Organics Corporation states they purchased the facility from Hexcel Corporation on April 1, 1986, suggesting that FOA Corporation had changed their name to Fine Organics Corporation (PAS-00089207).

A Remedial Action Work Plan (RAWP) Addendum, dated November 1999 states the facility had been sold to Fine Organics Corporation in 1985, who operated at the facility until September 1998. Once Fine Organics Corporation was removed from the site, Hexcel demolished the buildings to improve accessibility for remediation of the site. The RAWP Addendum identified Hexcel Corporation as the owner of the site at that time (PAS-00002491, 96).

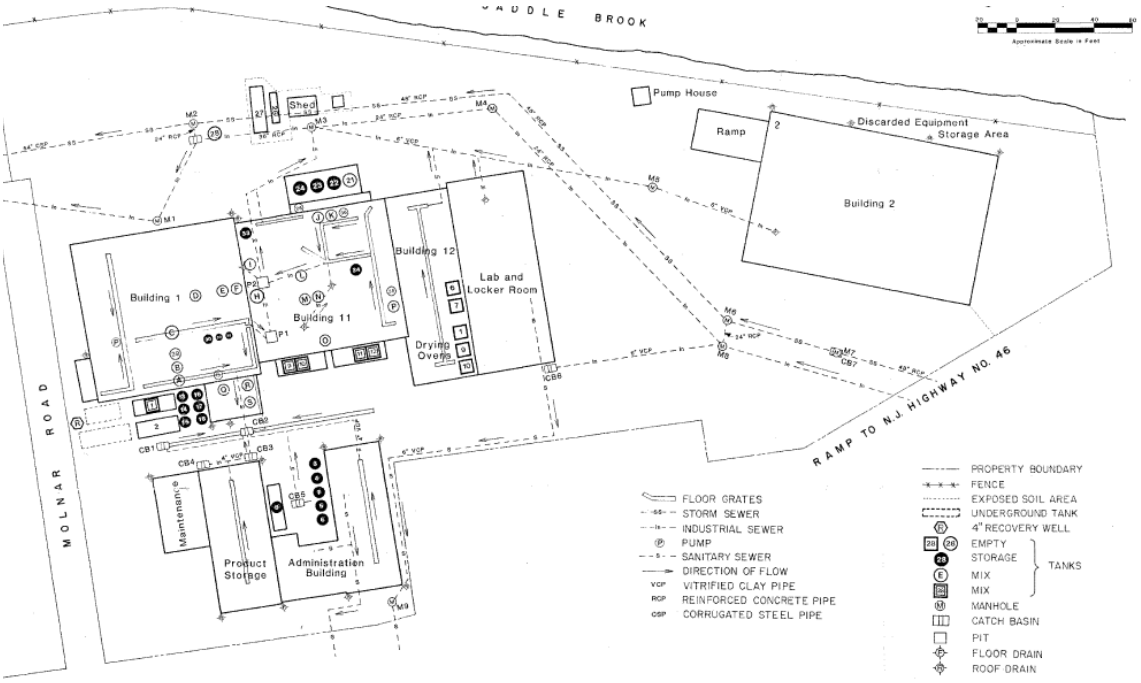
According to a Remediation Agreement between Hexcel and the New Jersey Department of Environmental Protection (NJDEP), signed in April 1997, Hexcel would purchase the property from Fine Organics Corporation. Hexcel agreed to remediate the site under the NJDEP Industrial Site Recovery Act (ISRA) (PAP-00047398-405).

3. **Operational History/COC Use and Presence at the Facility**

According to a 1986 Inspection Report by NJDEP, Hexcel manufactured, blended, and packaged industrial cleaning compounds. They also produced certain resins, but the report stated this was expected to be phased out by January 30, 1986. The Inspection

Report also stated that different chemical manufacturing operations have occupied the site for more than 80 years (PAS-00091237).

The *Application for ECRA Review, Initial Notice, Site Evaluation Submission*, dated January 14, 1986 (the 1986 SES), stated manufacturing of industrial cleaning compounds occurred in Buildings Nos. 1, 11, and 12 and under the canopy east of Building No. 1. Raw materials were blended in 17 mixing tanks that ranged in size from 50 to 7,500 gallons. The blending process did not produce hazardous wastes as by-products. However, any off-spec product or finished product not marketed was disposed as hazardous waste if appropriate. Wastewater (from wash-outs and cooling water) was discharged to the Passaic Valley Sewerage Commission (PVSC) system under permit and monitored by a 24-hour sampling device. The yard adjacent to the Saddle River was paved in 1963 and used as an outside drum storage area for raw, work-in-process, and waste materials, according to the 1986 SES. Spill containment curbs were installed in the drum storage area along Saddle Brook in 1980 and 1981. The portion east of Building No. 2 has been used for outside storage of finished industrial maintenance chemicals (PAP-00326360, 63, 65-67, 70).



As reported in the Investigation of Fuel Oil Leak for Hexcel, Lodi, New Jersey, dated June 1984, investigation at the site began in 1984 in response to leaking fuel oil underground storage tanks (USTs). Fuel oil was found to be in the soil and gravel surrounding the USTs from depths of 0.5 to 8 feet below ground surface (ft bgs) and at least 10 feet away from the USTs (PAS-00091704, 16). It was suspected that two USTs had been leaking fuel oil for years. During the subsequent investigation, analysis of an oil sample collected from a nearby existing recovery well detected polychlorinated biphenyls (PCBs) at 43 parts per million (ppm) (PAS-00091430, 39). Lead was also detected at low levels (96 and 130 ppm) in soil samples from the site, but according to the report on the Investigation of Fuel Oil Leak for Hexcel, lead had never been used or stored onsite (PAS-00091426, 36-37).

It was stated in the *Summary Report of Preliminary Environmental Sampling*, dated October 14, 1987, that PCBs were not used as part of the ongoing operations of the facility (PAS-00091023, 52). However, according to the *Presentation of the ECRA Sampling Results for Hexcel Corporation*, dated December 1988, PCBs had been used in the heat exchange system of Building No. 1, which was not in operation at that time (PAS-00090284). Investigation of the decommissioned heating oil system, overhead wooden flooring in the boiler room, and subsurface concrete pits beneath the boilers detected PCBs up to 5,500 milligrams per kilogram (mg/kg). PCBs were also found in oil in the industrial sewer system, specifically catch basin CB8 and manhole M1 (PAS-00091037-38).

A list of Manufacturing Equipment from 1969 includes a reactor with a hot Therminol® heating system (PAP-00326349). Therminol® would have contained PCBs.

In 1987, Environ Corporation inspected the storm drain and industrial sewer systems at the Hexcel facility and traced their outfall points. As documented in the letter report from Environ Corporation to NJDEP, dated March 25, 1987, two major drain systems crossed the facility property, shown on the drainage system figure below. The storm drain ran

parallel and directly west of the industrial sewer line, which was part of the PVSC system. The storm drain entered the property near manhole M7, then flowed south to manholes M6 and M2. After exiting the property, the storm drain pipe was traced to an outfall into Saddle Brook approximately 900 feet south of the facility and immediately south of the Hendrix wastewater pumping station. A second drain pipe entered the property near manhole M8, but then joined with the storm drain at this manhole because the path to the southwest (likely to manhole M4) was almost completely clogged with sediment. The industrial sewer line behind the property ran from manhole M4 to manhole M3, a catch basin, and then manhole M1. Several smaller sewer drains from the facility were observed at manhole M3. The industrial sewer discharged to the south across Molnar Road and to the Hendrix pump station, where water was discharged into a wet well and then combined with other sanitary sewer lines before it was pumped into the PVSC system. It was also noted that the connection between M2 of the storm sewer and the catch basin of the industrial sewer was blocked, so the systems were not interconnected at this point (PAP-00326356-58).

(PAS-00326352)

Additional investigation of the industrial sewer system on April 14, 1987, found that process wastewater was flowing upstream from manhole M4 to M8, possibly due to high inflow to the sewer system or blockage downstream. A dye test conducted on that day confirmed that water in the industrial sewer was flowing from manhole M4 to manhole M8 at which point it entered the storm drainage system. This reversal of flow had been observed on only one occasion throughout the period of sewer inspection and testing during 1987, and was stated to be a short-term condition that occurred during periods of high inflow into the sewer system (PAS-00091047).

As discussed in the *Preliminary Feasibility Study Report for Alternate Discharge to the PVSC*, dated March 16, 1992, pretreatment of seepage water from the basement was initiated when PCBs were discovered at the site in 1985. The report presumed that prior to 1985, the water had been discharged directly to the PVSC industrial sewer without treatment. Pretreatment consisted of diatomaceous earth and granular activated carbon filtration with batch testing for PCBs. Water was discharged to the PVSC after sample results did not detect PCBs. In 1989, complete removal of PCBs became more difficult, so seepage water was sent off-site to the Chambers Works DuPont facility in Deepwater, New Jersey. However, DuPont discontinued acceptance of the seepage water in August 1989 due to the presence of PCBs at unacceptable levels. Treatment of the seepage water was added to the site remediation activities in September 1990. A batch chemical treatment with carbon filtration was used, and the water was discharged in accordance with the terms of the PVSC discharge permit. An average total of 200 gallons of basement seepage water were discharged per day in 1991 (PAS-00088621).

4. Identified COCs

- PCBs (released/used)
- PAHs (detected)
- Copper (detected)
- Lead (detected)
- Mercury (detected)

PCBs

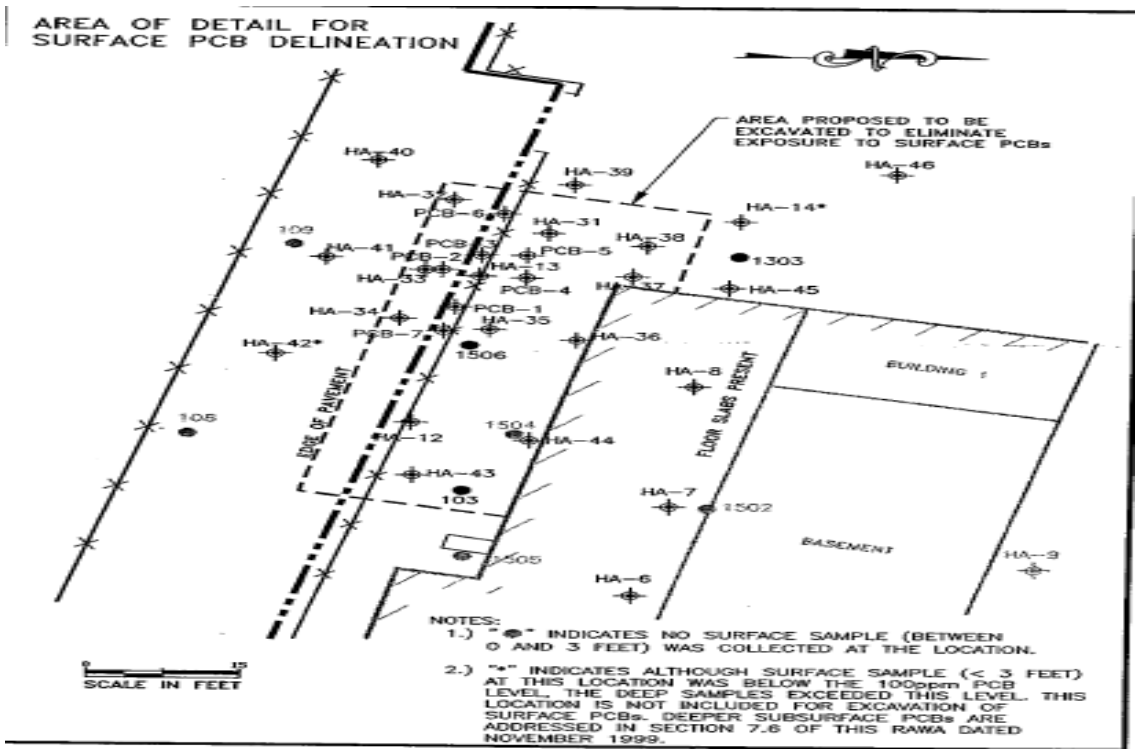
Site investigations have been performed since 1984, when leaking fuel oil USTs were noted at the site (PAS-00091706). The reports summarized below state PCB contamination was found in soil surrounding the former boiler room and along the industrial sewer line. The PCBs appear to be related to the oil used in the boiler room (PAS-00091037-40).

The following table summarizes the maximum PCB concentrations detected in site media and river sediment from the adjacent Saddle River:

Maximum PCB Concentrations in Site Media (mg/kg)				
PCBs	**Aroclor-1242**	**Reference**	**Aroclor-1248**	**Reference**
Soil	4,500	PAP-00325568	26,000	PAS-00002559
Oil	9,970	PAS-00091032	10,940	PAS-00091041
Sewer Sediment			240	PAS-00091037
Saddle River Sediment	Not detected	PAS-00086066	0.42	PAS-00086066

A *Review of Prior Sampling Programs at HEXCEL'S Lodi Facility*, dated January 10, 1986, identified ten Areas of Concern (AOCs), two of which were contaminated with PCBs (i.e., AOCs A and B) (PAS-00091335-36). According to the *Summary Report of Preliminary Environmental Sampling at the Fine Organics Corporation Facility, Lodi, NJ*, dated October 14, 1987, the level of PCB contamination ranged from 4 to 11.6 ppm in soil samples collected from the vicinity of the USTs (AOC A), while the pit in Building No.

1 (AOC B) had PCB concentrations up to 9,970 mg/kg (Aroclor-1242) in the oil floating on water. PCB analyses of the water inside the pit were non-detect (<10 ug/L) and 0.8 mg/kg, while the PCB concentration for the "wall scraping" from the pit was 62 mg/kg (PAS-00091030).



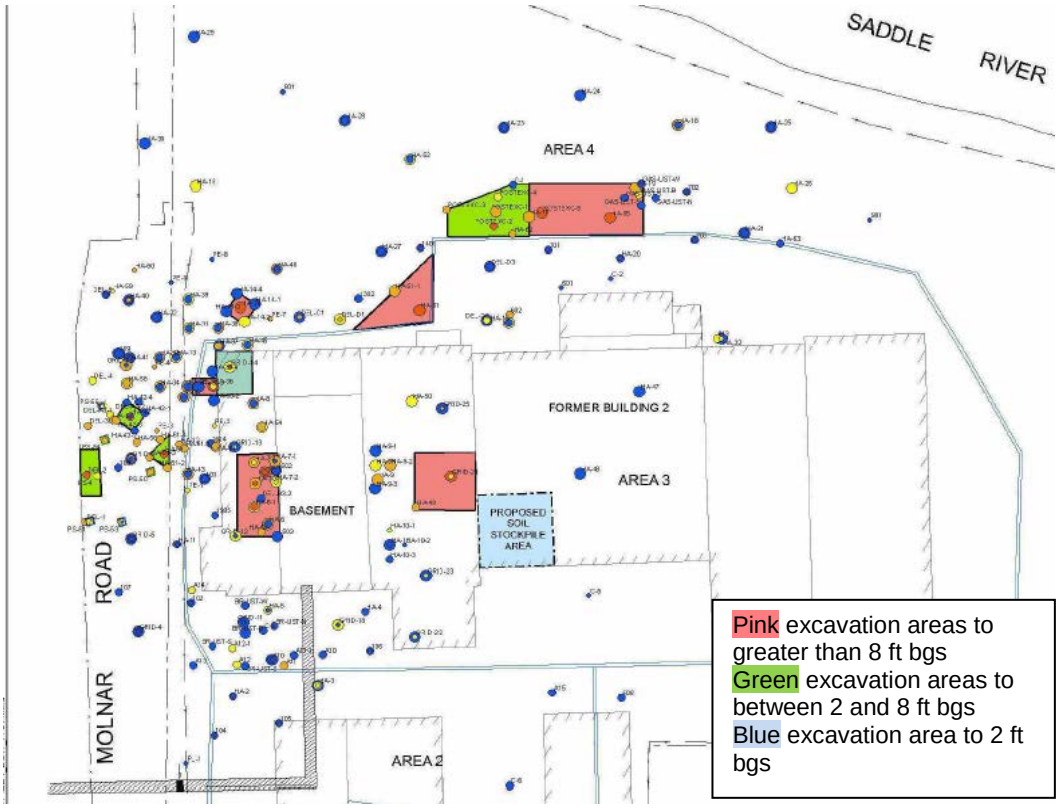
Further investigation of the facility in 1987 determined that oil was in sandy soil (with soil PCB concentrations up to 150 ppm) beneath the boiler room in Building 1. PCB concentrations in soil generally decreased with depth to the clay layer below. A sample of the oil floating on groundwater in a boring installed in the boiler room detected PCBs at 10,940 mg/kg (PAS-00091039-40). Oil was also found to be accumulating in Manhole M1 and stormwater catch basin CB8 of the industrial sewer at the rear of the property. PCBs were detected in sediment samples along the main line of the industrial sewer system on the facility property, ranging from 10 mg/kg to 240 mg/kg, with generally increasing concentrations toward the Hendrix pump station sewer system (PAS-00091036-38).

According to a report titled *Characterization of Oil Samples – Hexcel Project 536A*, dated February 12, 1987, three oil samples were collected from the site and analyzed for PCBs, metals, volatile organic compounds (VOCs), and infrared spectra to determine if they were derived from the same source. The analyte list was determined based on preliminary information that suggested the oil could be Mobiltherm oil, which was produced for heat transfer operations and could also include reclaimed mixtures of oil products from various manufacturers. Mobiltherm oil is reported to handle high temperatures (550°F) where normal, petroleum oils decompose (PAS-00091111). The oil sample collected from the floor drain in the concrete pit from Building No. 1 had the highest PCB content (maximum of 1,350 ppm), and the sample from the manhole M1, which is part of the PVSC industrial sewer located outside Building No. 1, had slightly lower PCB content (900 ppm). The sample collected from the recovery well had the lowest PCB content (60 ppm) (PAS-00091116). The letter from Environ Corporation to NJDEP documenting these analyses stated that the oil in manhole M1 appears to be chemically different than the oil from the other two locations. Oil in the manhole was being removed weekly by bailing and was estimated to accumulate 10 to 15 gallons per month (PAS-00091104).

According to the *Summary Report of Preliminary Environmental Sampling at the Fine Organics Corporation,* dated October 14, 1987, characterization of sediment in the industrial sewer line closer to and including the Hendrix pump station detected PCBs, but a potential additional offsite source was also identified. The PCB detected in the sediment sample from the manhole on the Napp Chemical Co. property was Aroclor-1260, while Aroclors-1242 and -1248 were detected in the samples at the Hexcel facility. Sediment sampling at the Hendrix Pump Station outfalls reported 7,660 mg/kg PCBs (Aroclor-1242) from the industrial sewer system and 1420 mg/kg PCBs (Aroclor-1242) from the sanitary sewer. The sediment samples collected from Saddle Brook at the outfall from the storm drain system detected PCBs at 0.3 and 2.4 mg/kg (Aroclor-1242) (PAS-00091041-42).

Three abandoned USTs were removed on June 19 and 20, 1991, according to the *Underground Storage Tank Closure Assessment Report*, dated August 27, 1991 (PAS-00089015). A 500-gallon gasoline tank was located north of Building 6 and two fuel oil tanks (4,000-gallon and 2,000-gallon) were located east of Building 1 and adjacent to the boiler room (PAS-00089015). Upon removal, the tanks were noted to be corroded with holes. Soil samples collected from the walls of both excavations detected PCBs (Aroclor-1242 at 0.024, 0.048, and 0.187 mg/kg). The soil sample collected from the bottom of the gasoline UST excavation detected Aroclor-1242 at 2.357 mg/kg. In addition, a water sample collected from the pit of the fuel oil UST excavation detected Aroclor-1242 at 48 micrograms/liter (µg/L) (PAS-00089019-23).

The 1999 RAWP Addendum categorized the PCB contamination in site soil into two areas: the elevated levels of PCBs on the ground surface in the vicinity of the former boiler room and PCBs primarily associated with dense non-aqueous phase liquid (DNAPL) at depth and detected in the upper overburden soil samples. The 1999 RAWP Addendum proposed to excavate the surface soil to a depth of 2 ft bgs and from Molnar Road to the edge of the former boiler room, as shown in the figure below. A 2-Phase Extraction remediation process was proposed for the DNAPL, so the 1999 RAWP Addendum stated the PCBs detections at depth would be reassessed after this process was implemented (PAS-00002506-07).



(PAS-00002606)

The 1999 RAWP Addendum also stated that the industrial sewer line was reported to be filled with sediments with elevated levels of PCBs. The sewer line was a 24-inch reinforced concrete pipe that ran from the vicinity of the existing warehouse to the

Hendrix pump station (PAS-00002508). According to a *Status Report*, dated May 10, 2005, the entire length of the industrial sewer on the Hexcel property from manhole M-8 to manhole M-1 was removed in 2003. At the same time, a hot-spot excavation at HA-17 was performed to remove the 1,800 ppm detection of PCBs. Approximately 400 tons of contaminated soil were removed during these excavations; however, soil with concentrations up to 300 mg/kg Aroclor-1242 were left in place near HA-17 (PAP-00325152, 61).

The *Self-Implementing PCB Cleanup and Disposal Plan*, dated June 20, 2008 (the Cleanup Plan), discussed the two areas of suspected PCB impacts, including the area associated with the former boiler room and the area associated with the former industrial sewer. The Cleanup Plan proposed to excavate several additional areas due to PCB contamination. These excavations would address detections of PCBs over 100 ppm. The deeper excavations were stated to extend only to the top of the confining clay layer because it would protect the lower formation from residual contamination in the confining layer. According to Table 1 of the Cleanup Plan, the maximum detection of PCBs was 13,000 ppm (Aroclor-1248) at HA-7, located under the former boiler room (see area adjacent to the basement in the figure below) (PAP-00325538, 40, 72, 86).

(PAP-00325586)

According to the *Remedial Investigation Report and RAWP Addendum*, dated January 28, 2011 (the 2011 RIR), excavation of soil approximately 10 feet by 5 feet by 1-foot deep around sample Surf-7 was performed to remove surficial PCB contamination in order to facilitate the installation of a utility pole (PAP-00324823). Investigation of the storm sewer detected only Aroclor-1260 in one sample of eight samples collected at a concentration of 0.77 mg/kg (PAP-00324827, 977).

The *Soil Remedial Investigation Report/Remedial Action Report*, dated August 25, 2015 (the 2015 RIR/RAR) documented the excavations performed at the site. The following soils were removed from 2010 to 2015:

Excavations Performed in 2010-2011			
Excavation	**Area (square feet)**	**Depth (ft bgs)**	**Volume (cubic yards)**
L2	225	2	17
L3	140	17	40
L4	320	16	200
L5	420	13.5	160
L6	800	14-15	487
L7	400	11	163
L8	480	8.5-10	250
SURF-7	40	1	
SURF-13	25	1	
SURF-20	100	1	
REM-1	150	4	
REM-5	730	13	

(PAP-00047433-37)

PAHs

A report of soil data for the site was undated and did not include the title of the report but provided soil sampling results from the 1980s through 1992. This report stated PAHs were detected at low levels in several soil samples (see discussion for Historic Fill below) (PAS-00088282, 319).

The *Summary of Historical Soil Data*, dated July 1997, concluded that base neutral organics are not of concern for the site. The *Summary of Historical Soil Data*, dated July 1997 did not provide all of the data, but specified the concentrations that exceeded the soil cleanup criteria in the 46 soil samples collected at the site. Benzo(a)anthracene was the only PAH that exceeded the criteria and was detected at 1.4 mg/kg (PAS-00087498, 516).

The 2015 RIR/RAR stated that naphthalene was detected in two post-excavation samples for the industrial sewer at 13 mg/kg and 37 mg/kg. These sample locations were excavated in 2011 (PAP-00047449-50).

Metals - Copper, Lead and Mercury

As documented in the *Summary of Historical Soil Data*, dated July 1997, mercury was detected at 236 mg/kg in site soil (PAS-00087516).

According to the *Presentation of the ECRA Sampling Results for Hexcel Corporation*, dated December 1988, copper was detected in three soil samples at concentrations of 8 to 96 mg/kg (PAS-00090408-411).

A Narrative Report of Interpretation on Results for Hexcel Facility, dated July 18, 1985, identified lead detected at the site. Lead was detected in sample C-1 (96 ppm) at a depth of 24 to 30 inches and at C-5 (130 ppm) at 18 to 24 inches. This report states that lead was never used or stored onsite (PAS-00091426, 36-37).

According to the *Presentation of the ECRA Sampling Results for Hexcel Corporation*, dated December 1988, lead was detected in soil samples from across the site at concentrations of 3 to 72 mg/kg (PAS-00090393-411).

Historic Fill

The Allocation Team has determined that the facility site is not located on regional Historic Fill as designated by the NJDEP.[1] However, the 2011 RIR states that the metals contamination in site groundwater may be due to the presence of Historic Fill (PAP-00324817).

NJDEP has established that historic fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 COCs: PAHs, lead, copper, and mercury.[2] Accordingly, NJDEP technical requirements for property containing Historic Fill requires sampling for the EPA Target Compound List for PAHs and Target Analyte List for metals, including lead, copper, mercury, and the OU2 PAH COCs.[3] PAHs, lead, copper, and mercury are recognized by NJDEP to be constituents of Historic Fill at varying levels, not atypically at or exceeding residential soil standards.[4]

[1] *Digital Geodata Series, DGS04-7, Historic Fill for New Jersey*, https://www.nj.gov/dep/njgs/geodata/dgs04-7.htm, Quadrangle #31 (NJDEP map identifying locations of recognized historic fill).

[2] *Characterization of Ambient Levels of Selected Metals and cPAHs In New Jersey Soils* (2002) and *Characterization of Ambient Levels of Selected Metals and Other Analytes in New Jersey Soils* (1997), studies prepared for NJDEP, Division of Science and Research, by BEM Systems, Inc.

[3] New Jersey Department of Environmental Protection (NJDEP), *N.J.A.C. 7:26E Technical Requirements for Site Remediation,* Table 4-2, November 2009 [Note that Table 4-2 has been deleted from the current version of N.J.A.C. 7:26E (May 7, 2012) and the updated *Historic Fill Technical Guidance* (April 2013) as NJDEP believed that the tables list of historic fill constituents was too restrictive].

[4] NJDEP Table 4-2 (PAHS and lead) and a summary of NJDEP records regarding investigations of properties in the vicinity of the Passaic River recognized to be located in areas of Historic Fill indicate that the following average/maximum (mg/kg) contamination levels of OU2 COCs exist in area Historic Fill: PAHs (1.91/160), lead (574/10,000), copper (11.2/1,200), and mercury (0.21/3.7).

The levels of PAHs, copper, lead and mercury detected at the site in soils are presented in the table below (PAS-00087498, 516; PAS-00088282, 319-20; PAS-00090408-411; PAS-00091426).

COCs Found in Onsite Soils	
COC	**Max Detected Concentration**
Lead	290 mg/kg
Copper	123 mg/kg
Mercury	236 mg/kg
Benzo(a)anthracene	1.4 mg/kg
Benzo(a)pyrene	0.25930 J mg/kg
Benzo(b)fluoranthene	0.13949 J mg/kg
Benzo(k)fluoranthene	0.25307 J mg/kg
Dibenzo(a,h)anthracene	0.13161 mg/kg
Indeno(1,2,3-cd)pyrene	0.08747 mg/kg

The PAHs and metals results were provided in a document without a title page prepared by Killam. The document summarized the data collected at the site in the 1980s and early 1990s (PAS-00088172).

5. COC Pathways

Sanitary Sewer

According to the 1986 SES, cooling water and wastewater from washing out the blending tanks were discharged to the PVSC under permit and monitored by a 24-hour sampling device (PAP-00326370). The amount of wastewater discharged to the PVSC in 1978 was an estimated 135,600 gallons per day for continuous operations six days a week, according to an Industrial Sewer Connection Application, dated May 30, 1978 (PAP-00326713-14). An application for a Sewer Connection Permit, dated July 9, 1985, stated that Hexcel discharged 130,000 gallons of process water and 4,552,982 gallons of cooling water to the sanitary/combined sewer system from third quarter 1984 to second quarter 1985. The daily flow through outlet 17402370 was an estimated 19,550 gallons (PAP-00326659, 62, 68).

As discussed in the *Preliminary Feasibility Study Report for Alternate Discharge to the PVSC*, dated March 16, 1992, pretreatment (diatomaceous earth and granular activated carbon filtration) of seepage water from the basement was initiated when PCBs were discovered at the site in 1985. The report presumed that prior to 1985, the water had been discharged directly to the PVSC industrial sewer without treatment (PAS-00088621).

A letter report from Environ Corporation to the PVSC, dated March 14, 1988 describes the remedial actions taken at the site to address the PCBs and oil in the industrial sewer. Oil was observed floating on the water in the last manhole on the property, and oil absorbent pillows were installed in the manhole and a catch basin on the industrial sewer system to remove any floating oil. The letter stated the manhole and catch basin were acting as an oil trap to prevent the release of oil downstream through the sewer

system to the pump station. Monthly monitoring of the sewer system began in October 1987, and samples from the farthest downstream manhole detected PCBs one time at 0.072 ppm in the first six months of monitoring. PCBs were also detected at the Hendrix pump station at 0.006 ppm during the same month that PCBs were detected in the sewer (PAS-00090938-39).

Additional monthly monitoring detected PCBs at concentrations up to 1.2 milligrams/liter (mg/L) in the manhole; PCBs were only detected one time (650 µg/L) at the Hendrix pump station from June to October, 1988 and August to October, 1990 (PAS-00090901; PAS-00089431). The sample from the manhole with the highest PCB concentration was collected in October 1990 and was stated to be slightly higher than levels detected in previous samples due to active construction activities that were part of the overall site remediation. The samples collected at the wet well of the Hendricks pump station stated no detectable levels of PCBs in the industrial sewer inlet pipe to the pump station during this time (PAS-00089431). Monthly monitoring continued through 1991 (PAS-00088902).

The letter from Environ Corporation to NJDEP regarding the Characterization of Oil Samples – Hexcel Project 536A, dated February 12, 1987 stated that the oil in manhole M1 was being removed weekly by bailing and was estimated to accumulate 10 to 15 gallons per month (PAS-00091104).

The letter from Environ Corporation to the PVSC, dated March 14, 1988 also stated a small amount of oil was accumulating with water in a below-ground pit in Building No. 1. These accumulating liquids were previously pumped into a dual-stage diatomaceous earth/granulated activated carbon treatment system for removal of oils and any aqueous phase PCBs, with the effluent discharged through the PVSC permitted sewer outfall into the industrial sewer system (PAS-00090938-39). As discussed in the *Preliminary Feasibility Study Report for Alternate Discharge to the PVSC*, dated March 16, 1992, the basement seepage water was treated this way until 1989, when complete removal of PCBs became more difficult. It was shipped offsite briefly before being treated onsite again using batch chemical treatment with carbon filtration in 1990 and discharged at an average rate of 200 gallons per day in 1991 (PAS-00088621).

According to the letter from Hexcel to the PVSC, dated May 20, 1994, all discharges to the PVSC ceased as of November 30, 1992. The basement seepage water was then treated and shipped offsite for disposal. Due to Hexcel's filing for bankruptcy, the basement seepage water was not treated (PAS-00087885-86).

A letter report to the NJDEP regarding the Hexcel site, dated July 17, 1995, stated that a new sewer line for a groundwater treatment system was installed in 1995 (PAS-00087777). According to a *Status Report*, dated May 10, 2005, the entire length of the industrial sewer on the Hexcel property from manhole M-8 to manhole M-1 was removed in 2003 (PAP-00325152).

Storm Sewer

As discussed in the March 25, 1987, letter report by Environ Corporation to the NJDEP, the storm drain entered the property at the northeast corner of the property near manhole M7, then flowed south to manholes M6 and M2. After exiting the property, the storm drain pipe was traced to an outfall into Saddle Brook approximately 900 feet south of the facility and immediately south of the Hendrix wastewater pumping station (PAP-00326356-57).

The 2003 Report on Sediment and Surface Water Sampling Program stated that samples from the storm sewer outfall area delineated previous PCB contamination characterized in October 1997 (PAS-00086066). The maximum detected PCB concentration was 1.3 mg/kg (Aroclor-1242) collected from sediment location directly downstream from the outfall (PAS-00086092). Historical sediment sample results from 1997 are provided in Table D-4 (Historical Sediment Quality Data) of the report and state PCBs were detected in Saddle River sediment up to 300 mg/kg; note the range of the other sediment samples was non-detect to 2.7 mg/L (PAS-00086124).

The Status Report, dated May 10, 2005, stated that surface water and sediments in the Saddle River adjacent to the site were minimally impacted by the potential migration of compounds of concern from the site (PAP-00325153). According to the 2011 RIR, NJDEP approved that no further investigation was required for the storm sewer outfall in a letter from July 2010 (PAP-00324827). Soil samples collected along the storm sewer on the property detected only Aroclor-1260 in one sample of eight samples collected at a concentration of 0.77 mg/kg (PAP-00324827, 977).

Direct Release

The Review of June and August 1985 Sampling Programs discusses the surface water flow across the site to the Saddle River. At the north of the site, stormwater from the parking lot flows into storm sewers and not the Saddle River. Stormwater can discharge to the river behind Building No. 2 (PAS-00091276).

The 2003 Report on Sediment and Surface Water Sampling Program concluded that surface water quality in the Saddle River adjacent to the site has not been adversely impacted by the potential migration of compounds of concern from the site. PCBs were not detected in any of the surface water samples collected. In addition, the report concluded that there was no significant migration of PCBs offsite based on the non-detection of Aroclor-1242, the primary PCB Aroclor of concern, and the one detection of Aroclor-1248 at a relatively low concentration (0.42 mg/kg) in the 14 sediment samples collected (PAS-00086066, 69, 91).

Spills

As discussed above in Section 3, investigation at the site began in 1984 in response to leaking fuel oil USTs. Fuel oil was found to be in the soil and gravel surrounding the USTs (PAS-00091716). It was suspected that two USTs had been leaking fuel oil for years (PAS-00091430).

6. Regulatory History/Enforcement Actions

When Hexcel sold its Lodi business and property to FOA Corporation in 1986, the facility was assigned ECRA case No. 86009. Due to this transaction, an Administrative Consent Order was signed in March 26, 1986 to move the facility through the NJDEP ECRA process (PAS-00091243). According to the *Remedial Investigation Report*, dated May 2016, investigation and remediation activities were conducted under NJDEP Site Remediation Program case manager oversight until the spring of 2010, when the case oversight was transferred to the Office of Brownfields. In February 2012, Hexcel opted into the Licensed Site Remediation Professional (LSRP) program to oversee and review documents related to remediation at the site. Christopher Schmitt (LSRP IDNo. 586933) is the LSRP for the site (PAP-00047694).

Inspections

Inspections performed by NJDEP on August 15 and September 2, 1986 as part of the ECRA process identified deficiencies, including an uncertain drainage network (interior floor drains, roof drains, storm, domestic and industrial sewer) and unknown composition of the lubricating oil and the age of the transformer (PAS-00091237-38).

Violations

Two violations were noted in the ECRA application. One is stated to be related to failure to submit information to local agencies, while the other is a notice that spills and leaking drums were observed close to the east bank of the Saddle River during a state inspection in the September of 1984. Both violations were stated to be resolved (PAS-00091296-97). The document does not state these violations involved OU2 COCs.

Permits

PVSC permit No. 17402370 was effective January 26, 1981 and expired January 26, 1986. The permit allowed discharge to the PVSC through outfall 17402370-37430-01l71 (PAP-00326695, 99; PAS-00091296).

PVSC permit No. 17402372 was effective January 21, 1986 and expired January 21, 1991. The permit allowed discharge to the PVSC through outfall 17402371-37430-0171 (industrial waste outlets 1 through 4) and 17402372-37430-0171 (sanitary waste outlets 5 and 6) (PAP-00326679, 83-84).

Fine Organics Corporation Sewer Connection Permit No. 17405042 was effective on May 27, 1991. It included discharge and monitoring requirements for pretreated groundwater and basement seepage resulting from Hexcel Corporation's operation of a groundwater pretreatment system. The Hexcel portion of the sewer connection permit expired on November 30, 1991 (PAS-00088620).

New Jersey Pollutant Discharge Elimination System (NJPDES) Permit No. NJ0081507 was effective November 11, 1992 and expired August 31, 1997. The permit was for discharges to the PVSC and to surface water (PAP-00047893).

PVSC permit No. 17407540 was effective May 16, 1996 and expired May 16, 2001. The permit allowed discharge from outlet number 17407540-37430-0171 with monthly monitoring for PCBs and metals, including lead, copper, and mercury (PAP-00047871-77).

The NJPDES Permit No. NJ0145378 from was effective January 1, 2004 and expired December 31, 2008 (PAP-00047855, 58).

7. Response Actions

Characterization Activities

The following characterization activities have taken place at the facility:

- Investigation of Fuel Oil Leak for Hexcel (June 27, 1984) (PAS-00091704)
- Narrative Report of Interpretation on Results for Hexcel Facility (July 18, 1985) (PAS-00091417)
- Review of Prior Sampling Programs at Hexcel's Lodi Facility (January 10, 1986) (PAS-00091332)
- June and August 1985 Sampling Programs (January 13, 1986) (PAS-00091270)
- Administrative Consent Order (March 26, 1986) (PAS-00091241-48)
- Characterization of Oil Samples (February 12, 1987) (PAS-00091110)
- Summary Report of Preliminary Environmental Sampling at the Fine Organics Corporation (October 14, 1987) (PAS-00091023)
- Presentation of the ECRA Sampling Results for Hexcel Corporation (December 1988) (PAS-00090232; PAS-00090378)
- Underground Storage Tank Closure Assessment Report (August 27, 1991) (PAS-00089012)
- Summary of Historical Soil Data (July 1997) (PAS-00087494)
- Summary of Historical Groundwater Data (July 1997) (PAS-00087475)
- Remedial Action Work Plan Addendum (November 1999) (PAS-00002490)
- Report on Sediment and Surface Water Sampling Program (October 8, 2003) (PAS-00086055)
- Self-Implementing PCB Cleanup and Disposal Plan (June 20, 2008) (PAP-00325528)
- Remedial Investigation Report and Remedial Action Work Plan Addendum (January 28, 2011) (PAP-00324786)
- Soil Remedial Investigation Report and Remedial Action Report (August 25, 2015) (PAP-00047406-407)

Soil

As discussed in the 2008 Cleanup Plan, the two areas of suspected PCB impacts are the area associated with the former boiler room and the area associated with the former industrial sewer. The 2008 Cleanup Plan proposed to excavate several areas due to PCB contamination in soil over 100 ppm. According to Table 1 (Soil PCB Data) of the

2008 Cleanup Plan, the maximum detection of PCBs was 13,000 ppm (Aroclor-1248) at HA-7, located under the former boiler room (PAP-00325538, 72, 86).

Sewer

During an investigation of the facility's industrial sewer system in December 1986, oil was observed to be floating on the water surface in manhole M1, which is located to the rear of Building No. 1. Oil was not observed in the other manholes and structures on the industrial sewer. Manual bailing removed approximately 75 gallons of oil during the investigation and 30 gallons several weeks after (PAS-00091033-34). The concentration of PCBs (Aroclor-1248) in sediments from the industrial sewer ranged from 10 mg/kg to 240 mg/kg, with generally increasing concentrations toward the Hendrix pump station sewer system (PAS-00091037-38).

According to a *Status Report*, dated May 10, 2005, the entire length of the industrial sewer on the Hexcel property from manhole M-8 to manhole M-1 was removed in 2003. At the same time, a hot-spot excavation at HA-17 was performed to remove the 1,800 ppm detection of PCBs. Approximately 400 tons of contaminated soil were removed during these excavations; however, soil with concentrations up to 300 mg/kg Aroclor-1242 were left in place near HA-17 (PAP-00325152, 61).

Sediment

Surface water and sediment of the Saddle River were characterized in the *Report on Sediment and Surface Water Sampling Program*, dated October 8, 2003. This report documented surface water and soil samples collected from the Saddle River adjacent to the site, as well as samples from a storm sewer outfall located approximately 750 feet south and downstream of the site (PAS-00086056). According to this report, PCBs were not detected in any of the surface water samples collected adjacent to the site. Aroclor-1242, the primary PCB Aroclor of concern, was not detected in any of the 14 sediment samples collected along the site. However, Aroclor-1248 was detected in one sediment sample at 0.42 mg/kg. Aroclor-1254 was detected at 0.49 mg/kg adjacent to the facility (PAS-00086063, 65, 91). Samples from the storm sewer outfall area delineated previous PCB contamination characterized in October 1997 (PAS-00086066). The maximum detected PCB concentration was 1.3 mg/kg (Aroclor-1242) collected from sediment located directly downstream from the outfall (PAS-00086092). Historical sediment sample results from 1997 are provided in Table D-4 (Historical Sediment Quality Data) and report PCB concentrations detected in Saddle River sediment ranged from non-detect to 2.7 mg/kg with the exception of a maximum detection of 300 mg/kg (PAS-00086124).

According to the 2011 RIR, NJDEP approved that no further investigation for the Saddle River and stormwater outfall was required at that time in a letter from July 2010. Although the NJDEP did not require any further investigation of the Saddle River, the July 2010 letter required that Hexcel propose a remediation for contaminated groundwater to ensure that no groundwater discharges enter the Saddle River at concentrations that exceed the Surface Water Quality Standards (SWQS) (PAP-00324826).

Remedial Actions

The *Investigation of Fuel Oil Leak for Hexcel, Lodi, New Jersey*, dated June 27, 1984, describes soil sampling for an oil leak from a UST. The investigation found visible oil in nine of 12 soil borings (PAS-00091712). Saddle Brook River is located 150 to 200 feet to the west of the UST (PAS-00091715). The report concluded that the oil is present in sand and gravel layers from 0.5 to 8 ft bgs, and that vertical movement of the oil is limited by a sandy silt layer, which has not been contaminated by the fuel oil (PAS-00091716).

According to a *Narrative Report of Interpretation on Results for Hexcel Facility*, dated July 18, 1985, lead and PCBs were detected at the site. Lead was detected in sample C-1 (96 ppm) at a depth of 24 to 30 inches and at C-5 (130 ppm) at 18 to 24 inches. This report states that lead was never used or stored onsite (PAS-00091423, 26, 36-37).

The *Review of June and August 1985 Sampling Programs*, dated January 13, 1986, discussed differences between the summer sampling results and reported additional sampling performed in December 1985. Discussion of the PCBs detected in the recovery well stated heat transfer oils that may have contained PCBs were used prior to 1981 in the boiler room adjacent to the oil recovery well (PAS-00091273). Additional sampling of a concrete-lined pit located within Building No. 1 was performed to confirm that the contamination was present. This area was actively used at that time for organic chemical formulation. Previous sampling had detected PCBs in wall wipe samples (62 ppm) and in the water at the base (173 ppm). A sample was collected from the oil floating on water in the drain, and PCBs were detected at 8,070 to 9,970 ppm. A sample of the water did not detect PCBs (PAS-00091282-83). It was noted that the pit was periodically pumped to the industrial sewer to remove accumulated seepage or spillage within the building (PAS-00091286).

Hexcel and NJDEP signed an Administrative Consent Order on March 26, 1986 for the cleanup of the site (PAS-00091241-8).

A letter report from Environ Corporation to the PVSC, dated March 14, 1988, describes the remedial actions taken at the site for remediation of the PCBs and oil in the industrial sewer. Beginning in early 1987, the sewer system was regularly monitored for any accumulation of oil and to remove any floating product. Oil absorbent pillows were installed in a manhole and catch basin on the industrial sewer system to remove any floating oil. These pillows were inspected weekly and changed as frequently as necessary. The removed oil was retained onsite in sealed drums until it was shipped offsite for final destruction and disposal in accordance with State and Federal regulations (PAP-00325294).

The *Presentation of the ECRA Sampling Results for Hexcel Corporation*, dated December 1988, defined 15 areas of environmental concern (AECs) at the facility (PAS-00090240). PCBs were detected at three AECs, including a soil sample collected from AEC 15, the boiler room, at a depth of 8 to 8.5 ft bgs with PCBs at 31 mg/kg (PAS-00090266-67). PCBs were also detected near USTs and aboveground storage tanks

(ASTs) at AEC 1 (0.26 mg/kg) (PAS-00090390) and AEC 7 (0.68 mg/kg) (PAS-00090407).

Three abandoned USTs were removed on June 19 and 20, 1991. The 500-gallon gasoline tank was located north of Building 6, and the two fuel oil tanks (4,000-gallon and 2,000-gallon) were located east of Building 1 and adjacent to the Boiler room (PAS-00089015). Upon removal, holes in the tanks were noted due to corrosion. Soil samples collected from the walls of both excavations detected PCBs (Aroclor-1242 at 24, 32, and 187 µg/kg). Aroclor-1242 was detected in the soil sample collected from the bottom of the gasoline UST excavation at 2,357 µg/kg. In addition, Aroclor-1242 was detected in a water sample collected from the pit of the fuel oil UST excavation at 48 µg/L (PAS-00089019-23).

A 1997 Summary of Historical Soil Data provides an overview of the soil samples collected from 1984 to 1992. As stated in this report, PCBs were detected in soil samples from borings around the boiler room and from borings around the ASTs located west of Building 2. The detection of metals was sporadic, and it was concluded that metals were not of significant concern for this site (PAS-00087498-99).

The November 1999 RAWP Addendum identified several areas of environmental concern, including Base/Neutral and Acid Extractable Organics (BNAs) and Priority Pollutant Metals (PPMs) (AOC 3), PCB contamination at the site (AOC 6), the Saddle River (AOC 8), the storm sewer outfall (AOC 9), and the industrial sewer line (AOC 10) (PAS-00002503).

Surface water and sediment of the Saddle River were characterized in the *Report on Sediment and Surface Water Sampling Program*, dated October 8, 2003. This report documented surface water and soil samples collected from the Saddle River adjacent to the site, as well as samples from a storm sewer outfall located approximately 750 feet south and downstream of the site (PAS-00086056).

The 2011 RIR stated excavation of PCB contaminated soil was expected to be completed in spring of 2011. Additionally, excavation of soil approximately 10 feet by 5 feet by 1-foot deep around sample Surf-7 was performed to remove surficial PCB contamination in order to facilitate the installation of a utility pole (PAP-00324823).

8. Summary of Asserted Defenses

Hexcel asserts, Permitted releases are exempt from the definition of “release” under CERCLA [Comprehensive Environmental Response, Compensation, and Liability Act]. 42 U.S.C. § 9601(10)(H). Applicable permits are described in response to Question 4.3. With respect to PAHs, Hexcel asserts the petroleum exclusion. 42 U.S.C. § 9601(14). Some or all of Hexcel’s liability for the Diamond Alkali Superfund Site was discharged in a Chapter 11 bankruptcy reorganization plan that was approved January 12, 1995.

Diamond Alkali OU2 Allocation

ADR Confidential

Facility Data Report

HOFFMANN-LA ROCHE, INC.

Facility Name, Address and Size: Hoffmann-La Roche (Roche), 340 Kingsland Road, Nutley, NJ 07710 (PAS-00123422). As of 1960-61, the site on Kingsland Road consisted of approximately 100 acres in size. Reports dated 1998 and 2004 stated the site as 123 and 125 acres, respectively (PAS-00123422). The Roche site employed 3,000 employees in 2005 (PAS-00123423). Available references did not include the number of work shifts at the site.

1. **Business Type:** From 1940 to 1946, Roche manufactured "ethical prescription medicines." In 1960-61, Roche manufactured bulk "ethical pharmaceuticals" and vitamins and aromatic chemicals. As of 1998, the operations at the site were described as "manufacturing of pharmaceutical preparations." The facilities on the site consist of administration, research and development, and pharmaceutical/medicinal chemical production (PAS-00123424).

2. **Time Period of Ownership/Operations**

   Operator: 1930 to 2015
   Owner: 1928 to 2016

3. **Operational History/COC Use and Presence at the Facility**

   Historical operations on the site in the 1930s included Roche's Strychnine Building (former Building 6), Carpenter/Maintenance Shop (former Building 12), Laradon Building (former Building 10), Sodium Building (former Building 5), Barbituric Building (former Building 4), Raw Product Storage (former Building 9), Boiler Building (former Building 3), garages, storage buildings, and sheds (former Building 2) (PAS-00123423).

   By the 1940s, Roche occupied 90 acres of the site with approximately 28 buildings and a 640,000-gallon aboveground No. 6 fuel oil tank. From 1940 to 1946, Roche manufactured "ethical prescription medicines" (PAS-00123424). As of 1951, Roche still did not own the western portion of the site (west of the rail line); however, Haberland Manufacturing (converted to a chemical company) owned and operated a portion, including a 250,000-gallon reservoir. By the 1960s, many adjoining industrial parcels were acquired by Roche which formed the main complex (PAS-00123423).

   In 1960-61, Roche manufactured bulk "ethical pharmaceuticals" and vitamins and aromatic chemicals. As of 1998, there were fourteen main products manufactured at the site and were described as "manufacturing of pharmaceutical preparations" (PAS-00123424).

Facility Data Report

The facilities on the site consisted of administration, research and development, and pharmaceutical/medicinal chemical production. Drum storage of virgin materials and hazardous waste occurred in Building 106. Warehousing of virgin materials, products, intermediates, and equipment occurred in Buildings 103 and 104. Offices and parking were located in Building 112. Vehicle maintenance and storage occurred in Building 70. Trash compaction and vehicle storage occurred in Building 111. Numerous additional buildings (mostly production), storage tanks, and parking lots existed on the side of the site east of the Conrail line (PAS-00123424).

Raw materials were often conveyed to production buildings via underground pipes. In 1993, Roche initiated a program to replace pipes remaining directly in the ground with piping set into concrete trenches (PAS-00123245). Historical storage in tanks on site included the following materials (PAS-00123424-25):

Materials Stored in Tanks			
Hexane	Toluene	1-pentol	3-pentol
Fuel Oil No. 2	Fuel Oil No.6	Kerosene	Gasoline
Diesel Fuel	Solvents	Alcohols	Acids; bases
Product intermediates	Methanol	Dehydrolinalool	Wet Skelly
Dry Skelly	Ethyl Heptanone	Methylene Chloride	Ether
Formamide	Butendiol	Isobutylaldehyde	Waste Oil
Methyl Ethyl Ketone	Methyl Carbitol	Acetone	Methyl Formate
Isophytol	Ethyl Butynol	Beta Ionone	Chloroform
Pseudo Ionone	Propylene Glycol	Sulfuric Acid	Tetrahydrofuran (THF)
Trimethylphenol	Sodium Hydroxide	Acetic Anhydride	Ammonia
Toluene	Dowtherm	Pyridine	

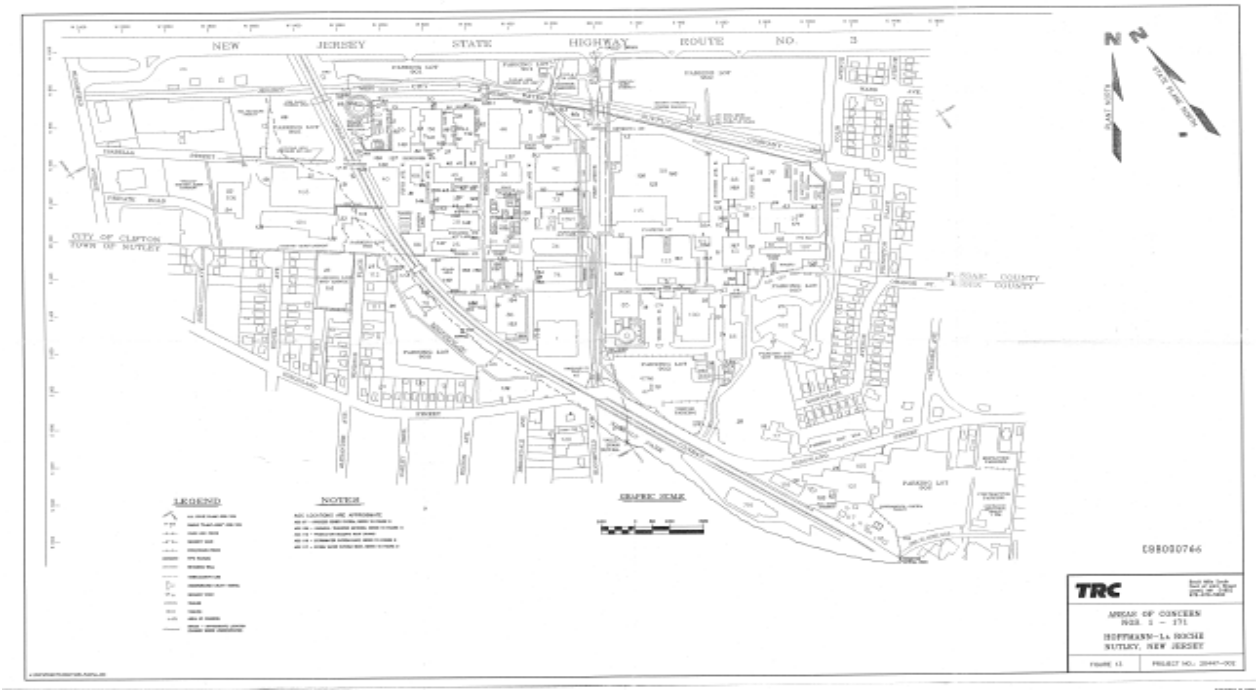
A total of 171 Areas of Concern (AOCs) was identified at Roche, of which 109 AOCs were identified as warranting additional investigation (PAS-00002999-3014). Of these areas, AOC 67 was identified as the process sewer system. This AOC consists of Roche's process sewer system and all service connections to production buildings. The process sewer system was a subgrade piping system used to transport process waste water from manufacturing, laboratory, and support buildings, and also carried sanitary wastes from the facility to Roche's Environmental Control Facility. Many of the service connections were formerly constructed of glass piping. Formerly, many process sewer lines were in direct communication with subgrade soils. In the 1980s and 1990s, cracks in pipes may have released an undetermined volume of process water to the subsurface. Several releases involved oil that contains the COC PAHs (PAS-00003114-7).

Several AOCs (Nos. 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, and 78) were related to the presence of transformers located at the facility. These transformers were managed in accordance with Roche's Discharge Prevention Containment and Countermeasure (DPCC). The transformers were surrounded by an oil containment soil media which permits permeation of rainwater but disallows permeation of oils. This area was slightly bermed and covered with a layer of pea gravel. No releases were documented at these AOCs and therefore no further investigation was warranted (PAS-00003118-28).

Hoffmann-La Roche, Inc.

Diamond Alkali OU2 Allocation

ADR Confidential



Facility Data Report

AOC 116 was identified as the Storm Sewer System – East Side of Conrail Rail Easement. This storm sewer system was used to drain rainwater from the facility and to convey non-contact cooling water. Historically, the stormwater system may have been connected to the Valley Drain. A former stormwater outfall located across Kingsland Avenue in Nicholas Park was at one time used by Roche as the outlet for stormwater, in addition to the Valley Drain. Several releases were noted from 1988-1994, including 50 gallons of kerosene and 1,000 gallons of No. 6 fuel oil in 1989, but both were diverted to Roche's pretreatment facility (PAS-00003186-87).

AOC 117 was identified as the Storm Sewer System – West Side of Conrail Rail Easement. This storm sewer system was used to convey rainwater from the Roche property west of the Conrail Rail Easement. Stormwater from this area of the facility is discharged to St. Paul's Brook, south east of Building 70. There were no reported releases related to the OU2 COCs (PAS-00003188).

AOC 118 was identified as the Storm Water Outfall – St. Paul's Brook. This outfall received stormwater runoff from the Roche property west of the railroad easement. Storm sewer plans from the 1970s stated that drainage from Building 70 may have connected to the stormwater system in the vicinity of the stormwater outfall. However, during an environmental audit in 1995, a dye test was conducted. The results stated that the drains connected to the Clifton sewer system. Several releases to the storm sewer from chemical storage areas have been documented on the western side of the facility. Due to the documented releases to the storm sewer system from the chemical storage areas, investigation was planned for at this AOC (PAS-00003189).

The figure below identifies the 171 AOCs: (PAS-00003027)

According to the *PRP Data Extraction Form*, dated August 22, 2005, "'[s]urface water from the drainage basin in which (the site) resides are routed ultimately to the Passaic River, located slightly greater than one mile east' of the site. St. Paul's Brook, on the southwest side of the site is enclosed within a subgrade conduit on site except for a 100-foot stretch southeast of Building 70. St. Paul's Brook discharges to the Passaic River (via the Third River). The Valley Drain, which discharges to St. Paul's Brook, is also enclosed within a subgrade conduit. The Valley Drain runs north to south across the site. Both the Valley Drain and St. Paul's Brook are 'natural features that existed prior to the development of the region and contain flows on a year-round basis'" (PAS-00123430).

4. Identified COCs

- PCBs (released)
- PAHs (used, released)
- Dieldrin (detected)
- Copper (used)
- Lead (used, detected)
- Mercury (used, detected)

PCBs

Roche purchased the northwest corner of the site (referred to as northern IA-10) in 1967 (PAP-00215458). This parcel included a former industrial fill area; the filling preceded Roche's purchase. The former industrial fill area contained a variety of waste materials, and PCBs were detected at a range of concentrations, some in excess of 100 milligrams per kilogram (mg/kg) (PAP-00214426).

PCBs were detected at concentrations below 1 mg/kg throughout the site in surface and subsurface soils. Detections greater than 1 mg/kg were primarily located in the northwest corner of the site (PAP-00717667-8).[1]

AOC 107 was identified as the Spill Location on Street North of Building 100. On March 2, 1991, a 10-15 gallon, 100-foot trail of PCB-contaminated transformer oil was released to the roadway due to a broken valve during a transformer relocation by an outside contractor. Federal and state authorities were notified and the area was cleaned by Roche's personnel (PAS-00003177).

Upon the demolition of Building 86 in 2005, Roche sampled demolition debris being used as fill and found that concrete, caulking, paint, and other materials contained PCBs. Two hotspot locations (>50 mg/kg) were identified and excavated and were disposed offsite at appropriate licensed disposal facilities. Engineering controls in the form of layers of sand and geotextile, aggregate, and asphalt, and a deed notice were implemented (PAP-00189813-4).

[1] This Report was revised to include information contained in documents received on May 19, 2020. The additional documents did not change Hoffmann-LaRoche's previous certification.

PAHs

PAHs were detected throughout the site in subsurface soils (PAP-00717657-62).[2]

AOC 105 was identified as the Building 61 Pump House and Appurtenant Piping (Memorandum of Agreement (MOA) IA-4). This area was located in the northern portion of the facility. The building pumped No. 6 fuel oil from the 640,000-gallon aboveground storage tank (AST) located in the northern corner of the facility to the Building 39 boiler house. Historically, the oil transfer pipe was buried directly in the ground. In 1989, the underground line was removed from service and replaced with an aboveground line. This aboveground line was inspected regularly by Roche's personnel. On December 18, 1989, Roche's personnel discovered No. 6 fuel oil in a storm water catch basin on the south side of the facility. The underground line which carried fuel oil from the 640,000-gallon AST to Building 39 had developed a leak in the vicinity of the pump house (Building 61) and oil had flowed into the storm sewer system. At that time this storm sewer was being routed through Roche's pretreatment facility and no oil was discharged to surface water (PAS-00003171).

There were several releases of fuel oils to shallow soils in the immediate vicinity of fuel storage facilities. The following PAHs were detected at the Roche facility at AOC 155 at depths of 4.5-4 feet below ground surface (bgs) collected on February 20, 2002 (PAS-00101494, PAS-00123427):

- Benzo(a)anthracene – 11 mg/kg
- Benzo(a)pyrene – 8.5 mg/kg
- Benzo(b)fluoranthene – 11 mg/kg
- Benzo(k)fluoranthene – 4.6 mg/kg
- Dibenz(a,h)anthracene – 1.1 mg/kg
- Indeno(1,2,3-cd)pyrene – 4.7 mg/kg

Dieldrin

Dieldrin was detected at a maximum concentration of 0.0626 mg/kg in the concrete demolition materials at the former Building 86 (PAP-00189916). Engineering controls in the form of layers of sand and geotextile, aggregate, and asphalt, and a deed notice were implemented (PAP-00189813-4).

Lead

Lead was detected throughout the site in surface and subsurface soils at concentrations less than 10,700 mg/kg. Detections with concentrations above 10,700 mg/kg were almost exclusively located in the northwest corner of the site (PAP-00717663-4).[2]

[2] This Report was revised to include information contained in documents received on May 19, 2020. The additional documents did not change Hoffmann-LaRoche's previous certification.

Hoffmann-La Roche used a lead catalyst that was coated with palladium in the manufacture of Vitamin A in Building 68 (in IA-3, in the northeastern part of the Site). All From 1960 through 1984, an average of 1,760 kilograms (kg) per year of lead acetate was used (PAS-00002944). Lead was detected in soil samples collected at location TP-01-03 from the Proposed Daycare Center Area 2 at a concentration of 3,080 mg/kg (PAS-00101356).

Roche purchased the northwest corner of the site (referred to as northern IA-10) in 1967 (PAP-00215458). This parcel included a former industrial fill area; the filling preceded Roche's purchase. The former industrial fill area contained a variety of waste materials, and lead was detected as high as 153,000 mg/kg (PAP-00214421).

Copper

Small amounts of copper sulfate (average of 616 pounds per year) were purchased for use in production (PAS-00002942).

Mercury

Mercury was detected throughout the site in surface and subsurface soils at concentrations less than 65 mg/kg. The few detections with concentrations above 65 mg/kg were not located together (PAP-00717665-6).

AOC 109 was identified as the Mercury Release Underground Tunnel Building 56 (identified in MOA as IA-5). Mercury (1-2 ounces) was identified by a contractor during tunnel upgrade activities under Building 56. The material was recovered by Roche's personnel (PAS-00003179).

Soil samples were collected in AOC 174 (which was the proposed daycare center Area 2) to assess environmental conditions during a project to site a potential Roche-operated daycare center. This area was located on Roche-owned parcels west of the Conrail easement within Parking Lot 900 Annex and east and south of the former Roche Buildings 111 and 112. Roche had never utilized the subject parcels for pharmaceutical/chemical manufacturing, although, former property owners may have conducted manufacturing operations. Mercury was found at location EB-111-16-2 in Area A at a concentration of 18.5 mg/kg, which exceeded the highest background value reported for inorganic datasets from urban background and New Jersey state-wide background concentrations (PAP-00213097, PAS-00101356).

Historic Fill

The Allocation Team has determined that the facility site is not located on regional Historic Fill as designated by the NJDEP.[3]

[3] *Digital Geodata Series, DGS04-7, Historic Fill for New Jersey*, https://www.nj.gov/dep/njgs/geodata/dgs04-7.htm, Quadrangle #52 and #53 (NJDEP map identifying locations of recognized historic fill).

The New Jersey Department of Environmental Protection (NJDEP) has established that Historic Fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 COCs: PAHs, lead, copper, and mercury.[4] Accordingly, NJDEP technical requirements for property containing Historic Fill requires sampling for the United States Environmental Protection Agency (EPA) Target Compound List (TCL) for PAHs and Target Analyte List (TAL) for metals, including lead, copper, mercury, and the OU2 PAH COCs.[5] PAHs, lead, copper, and mercury are recognized by NJDEP to be constituents of Historic Fill at varying levels, not atypically at or exceeding residential soil standards.[6]

According to a Preliminary Assessment/ RCRA Facility Assessment Report dated May 1998, an assessment of non-indegneous fill "failed to reveal any evidence that non-indigenous fill material was brought to the Roche site to raise topographic elevations or to replace indigenous soils" (PAP-00067784).

Based on a Remedial Investigation (RI) report for Investigative Area No.15 (IA-15), located in the southeast corner of the site, an evaluation of soil boring logs for IA-15 in conjunction with prior investigations performed at adjacent IA-14 determined that historic fill material is present throughout this entire area and appears to extend beyond the IA-15 boundary. IA-15 comprises Tax Block 2101, Lot 1. Kingsland Street borders IA-15 to the north/northwest, IA-14 to the east/northeast, St. Paul's Brook and commercial establishments to the south, and a Conrail railroad line to the west/southwest. Fill material, including bricks, concrete, asphalt, coal/ash, wood and black granular debris are present and widespread over much of the area and ranged in thickness from four feet to 12 feet, with the thickness increasing as the bedrock surface slopes downward towards the south. Fill material across the IA has been reworked during construction of the former buildings and installation of the numerous process, storm sewer and sanitary sewer lines and subsurface vaults associated with the Environmental Control Facility (ECF) (PAP-00068195-96).

According to the Remedial Investigation Report, Investigative Area 11, A total of 13 AOCs 10a, 10b, 28, 58, 59, 67, 116, 164, 165, 173, 181, 188 and the stockpiled Soil Area (no AOC designation) were identified in IA-11 (PAP-00068768). Historic Fill was identified over an extensive portion of IA-11 (PAP-00068770).

---

[4] *Characterization of Ambient Levels of Selected Metals and cPAHs In New Jersey Soils* (2002) and *Characterization of Ambient Levels of Selected Metals and Other Analytes In New Jersey Soils* (1997), studies prepared for NJDEP, Division of Science and Research, by BEM Systems, Inc.

[5] New Jersey Department of Environmental Protection (NJDEP), *N.J.A.C. 7:26E Technical Requirements for Site Remediation,* Table 4-2, November 2009 [Note that Table 4-2 has been deleted from the current version of N.J.A.C. 7:26E (May 7, 2012) and the updated *Historic Fill Technical Guidance* (April 2013) as NJDEP believed that the tables list of historic fill constituents was too restrictive].

[6] NJDEP Table 4-2 (PAHs and lead) and a summary of NJDEP records regarding investigations of properties in the vicinity of the Passaic River recognized to be located in areas of Historic Fill indicate that the following average/maximum (mg/kg) contamination levels of OU2 COCs exist in area Historic Fill: PAHs (1.91/160), lead (574/10,000), copper (11.2/1,200), and mercury (0.21/3.7).

In addition, Roche purchased the northwest corner of the site (referred to as northern IA-10) in 1967 (PAP-00215458). The IA-10 site geology was described as historic fill material in the Remedial Investigation Report Investigative Area 10, dated December 19, 2013 (PAP-00214329). This parcel included a former industrial fill area; the filling preceded Roche's purchase. The former industrial fill area contained a variety of waste materials, and PCBs were detected at a range of concentrations, some in excess of 100 mg/kg (PAP-00214426). Lead was detected as high as 153,000 mg/kg (PAP-00214421). This former industrial fill area is one of six areas at the site where soils were not remediated and are subject to the Deed Notice (PAP-00215456; 465)

The levels of PAHs, copper, lead and mercury detected at the site in soils are presented in the table below (PAP-00214421, PAS-00123427-8, PAP-00717657-62).[7]

COCs Found in Onsite Soils	
COC	**Max Detected Concentration**
Lead	153,000 mg/kg
Copper	6,740 mg/kg
Mercury	18.5 mg/kg
Benzo(a)anthracene	>160 mg/kg
Benzo(a)pyrene	>120 mg/kg
Benzo(b)fluoranthene	>110 mg/kg
Benzo(k)fluoranthene	>93 mg/kg
Dibenzo(a,h)anthracene	>25 mg/kg
Indeno(1,2,3-cd)pyrene	>67 mg/kg

5. COC Pathways

Sanitary Sewer

Since 1987, the Passaic Valley Water Supply Company and the Jersey City Water Company exclusively supplied water for all aspects of Roche's Nutley, NJ operations. These operations included: non-contact cooling water, production, sanitary and general uses. The amount of water used by the facility was generally equal to the amount of wastewater discharged to the local POTW. The Roche facility discharged approximately 1.8 million gallons of wastewater per day to the Passaic Valley Sewerage Commission (PVSC) under a local permit (PAS-00002877).

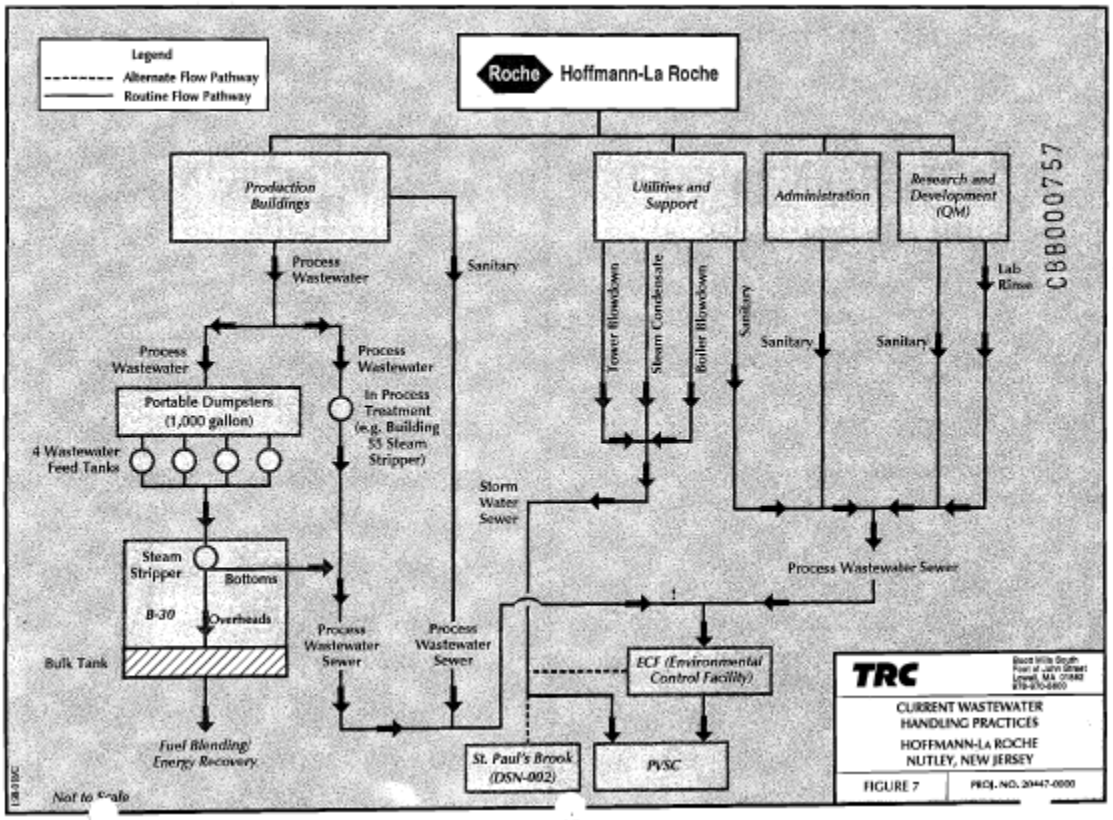
The Roche Nutley facility produced several different wastewater streams from site operations including sanitary wastewater, laboratory rinse water, non-contact cooling water, cooling tower blowdown, steam condensate, boiler blowdown and process wastewater. These wastewater streams, in addition to stormwater were managed by Roche to prevent unpermitted discharges to the waters of the State of New Jersey (PAS-0002877).

[7] This Report was revised to include information contained in documents received on May 19, 2020. The additional documents did not change Hoffmann-LaRoche's previous certification.

The Roche site is equipped with two types of sewer systems, process sewer system (commingled with the sanitary sewer) and the storm sewer system which is a completely separate sewer system from the process/sanitary sewer. Effluent discharges from these systems are permitted by the state of New Jersey under the following Roche permits:

- NJPDES/DSW Permit No. NJ0034185 for stormwater runoff commingled with noncontact cooling water (thermal water) discharge to St. Paul's Brook (DSN 002A) for the Roche property east of the Conrail railroad tracks and north of Kingsland Street.

- PVSC Sewer Connection Permit, Permit No. 24402882.



- NJPDES Industrial General Permit No. NJ0088315 for stormwater runoff from the area of the property west of the Conrail railroad easement (PAS-00101296-9). Stormwater from this area discharges directly to St. Paul's Brook upstream of DSN-002A (PAS-00002879, PAS-00101310).

The effluent from Roche to PVSC in August 1978, contained the following contaminants, with a flow rate of 6.304 million gallons per day (gpd): copper at 0.156 ppm, lead at 0.243 ppm, and mercury at 0.002 ppm (PAS-00123426).

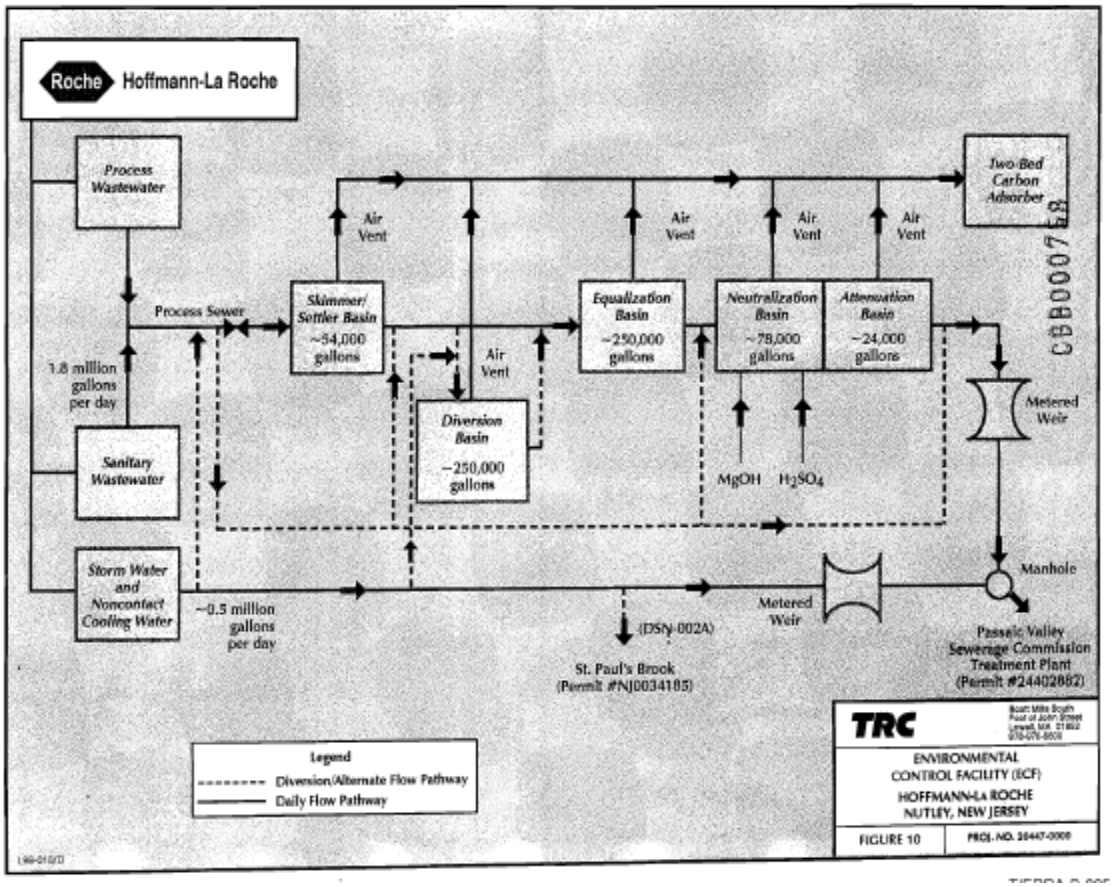
It is known that stormwater from the main part of the facility east of the railroad easement was discharged to the City's stormwater system until 1982 when stormwater runoff was rerouted to St. Paul's Brook. In addition, facility drawings from the mid-1960s show that stormwater catch basins east of the railroad easement may have been connected to the Valley Drain, which is a sub-grade water body that flows from north to south through the approximate center of the facility. Having been developed separately from Roche's main facility, stormwater from areas west of the railroad easement (i.e., Building 103/104 area and Building 70 area) flowed into St. Paul's Brook. Process wastewater was channeled through subsurface pipes constructed of materials such as glass, vitrified clay or asbestos concrete which converged at the southern portion of the site. Following the construction of the lime house (Building 47) in the late 1940s, process wastewater was neutralized before it was discharged to the municipal/sanitary wastewater system (PAS-0002878).

Prior to the construction of Roche's ECF in 1982, all of Roche's wastewater was discharged through piping to the city sewer system south of Roche's Kingsland Street entrance. However, this pipe is currently plugged. Roche maintains several regulatory required environmental management plans, including an Industrial Stormwater Pollution Prevention Plan, and a combined Discharge Prevention, Containment and Countermeasure (DPCC), Spill Prevention Control and Countermeasure (SPCC), and Discharge Cleanup and Removal (DCR) Plan. Roche has also developed comprehensive Environmental Health and Safety Standard Operating Procedures (SOPs) and Preventative Maintenance Programs to maintain compliance with a wide-array of environmental regulations. The Environmental Health and Safety SOPs include detailed management practices for solid and hazardous waste management throughout the facility (PAS-0002878-9).

The majority of the process sewer lines lie west of the Valley Drain, where historically the majority of production occurred at the facility. Process sewer lines from the western and eastern halves of the facility converge immediately north of Building 47. From there, the process sewer follows Kingsland Street to the ECF. Process wastewater passed through steam stripping units to reduce/eliminate the solvent loads before the wastewater was discharged to the process sewer. The primary stripping unit was located within Building 30. Wastewater from various production buildings was collected in portable 1,000-gallon tanks (dumpsters) that were located directly outside each production building. On a regular basis (typically within 72 hours of filling), Roche personnel transported the dumpsters to Building 30 where the water was transferred to several wastewater feed tanks. The feed tanks fed into the steam stripping unit. The solvent overheads were directed to a bulking tank and sent offsite for fuel blending in cement kiln operations. The steam stripper bottoms were discharged to the process sewer. Other process wastewater (e.g., from Building 55) was treated in steam stripping units located within the process building itself. Solvents recovered during this operation were recycled for reuse in the process. Wastewater was then discharged to the process sewer. The process sewer system drained wastewater generated from all facility buildings through service connections from all areas of the plant. Process wastewater was gravity fed through the subgrade piping network to Building 47. From there, the sewer pipes left the property and ran along Kingsland Street to Roche's ECF (PAS-00002880-81).

(PAS-00003018)

Storm Sewer and Catch Basins



Stormwater from the main part of the Roche facility east of the railroad easement was commingled with non-contact cooling water, steam condensate, and cooling tower blowdowns. During periods of light precipitation or during low flow conditions, the commingled flow was combined with the process sewer wastewater and discharged to the PVSC. During large rain events, Roche was permitted to discharge non-contact cooling water and runoff to St. Paul's Brook at Outfall 002A under NJPDES-DSW Permit No. NJ0034185. Roche's discharge records stated that the last time stormwater was discharged to St. Paul's Brook through Outfall 002A was June 1992.

An Application for Permit to Discharge Wastewater dated January 31, 1990, for Outfall 001, reports that approximately 3.59 million gpd were discharged to the PVSC sewage treatment plant, including 1,142,500 gpd from chemical production, 141,000 gpd from pharmaceutical production, 1,220,000 gpd from utilities and maintenance and 443,850 gpd from stormwater and cooling water (PAP-00717651).[8]

Roche also utilized the Insituform process to reline portions of the storm sewer system that lies beneath production areas both west and east of the Valley Drain. Roche maintained a separate storm sewer system for areas west of the railroad easement (Building 104/103 and Building 70 area). Areas west of the easement were used for administration support and to house general equipment and raw materials warehousing. Roche maintained a General Permit, NJPDES Permit No. 0088315 for discharge of storm water runoff directly into St. Paul's Brook for this area (PAS-00002882). Roche's ECF is located south of Kingsland Street and was identified as Building 116. Roche's ECF was brought online in the summer of 1982. Prior to that time, all process water was channeled through Building 47 where lime and sulfuric acid were used to adjust pH prior to discharge into the municipal sanitary sewer. The ECF was a pretreatment facility that was designed to provide flow equalization, pH neutralization and spill control for treatment of wastewater prior to its discharge to the PVSC Treatment Works. Although Roche maintained both a Sewer Connect Permit (Permit No. 24402882) for discharge of wastewater to the PVSC, and a New Jersey Pollutant Discharge Elimination System (NJPDES) permit (permit No. NJ0034185) for discharge to St. Paul's Brook, all process water, and storm water from the main part of the facility, located east of the Conrail tracks was discharged to PVSC since 1992. Roche carefully monitored the storm water and process sewer systems for releases of volatile organic compound materials using on-line lower explosive limit (LEL) meters which were located within process sewer and storm water manholes. The process sewer system is equipped with 17 LEL meters located at various positions within the system. Six LEL meters were also positioned within the storm sewer system: 3 meters within the plant proper and 3 meters at the ECF. During normal operations, process wastewater entered the ECF through manhole PR-4. The wastewater was pumped through a skimmer/settler basin, through a flow equalization basin, and into a neutralization and attenuation basin, where it was neutralized with either magnesium hydroxide or sulfuric

[8] This Report was revised to include information contained in documents received on May 19, 2020. The additional documents did not change Hoffmann-LaRoche's previous certification.

acid. From the neutralization basin, the water exited the facility and discharged through subgrade piping to PVSC's public treatment works.

(PAS-00003019)

Direct Release

During large rain events, Roche was permitted to send non-contact cooling water and runoff to St. Paul's Brook at Outfall 002A under the NJPDES-DSW Permit No. NJ0034185 (PAS-00002882).

6. Regulatory History/Enforcement Actions

Permits

The facility had a NJPDES/DSW Permit No. NJ0034185 for stormwater runoff commingled with noncontact cooling water (thermal water) discharge to St. Paul's Brook (DSN 002A) for the Roche property east of the Conrail railroad tracks and north of Kingsland Street (PAS-00101310-322; PAS-00002879).

During the period beginning “Modified EDP” and lasting through July 31, 1990, the permittee was authorized to discharge from discharge points designated as Outfalls DSN-001, DSN-003, DSN-004, and DSN-005. The discharge limitation for mercury (total) was 181 grams/day (PAS-00101514). In addition, the final permit was modified to delete the previous conditional limits and monitoring requirements for copper since the permittee did not use any corrosion inhibitors, biocides, or other cooling water additives containing this metal in its non-contact cooling water or cooling water blowdown (PAS-00101321-22).

The facility also held PVSC Sewer Connection Permit, Permit No. 24402882 (PAS-00002879).

Finally, the facility held NJPDES Industrial General Permit No. NJ0088315 for stormwater runoff from the area of the property west of the Conrail railroad easement (PAS-00101299, 305). Stormwater from this area discharges directly to St. Paul’s Brook upstream of DSN-002A (PAS-00002879).

Violations

On April 10, 1947, an inspector discovered oil on Nichol’s Pond, a tributary to Third River. The source was traced to Roche’s power plant upstream on Nichol’s Brook. It was found that a tank truck delivering fuel oil had a spill and lost approximately 100 gallon of fuel oil which escaped through a yard drain into the ditch along the railroad and into Nichol’s Brook. The inspector had the remaining oil cleaned from the yard, and most of the oil having collected in the railroad ditch, this accumulation was skimmed off and carted away (PAS-00101231; PAS-00123430).

On May 19, 2004, a leak was found in the excavation going to the storm drain. The substance released was “oil fue.l” The document states that cleanup was underway (PAS-00101278).

Spills

The following table summarizes known discharges and releases at the Hoffmann-La Roche Facility (note that not all of these releases may be related to releases of OU2 COCs):

Hoffmann- La Roche Discharges				
Date	**Location**	**Media**	**Material Released**	**Estimated Amount**

11/97	Building 118	Soil	Diesel Fuel	~ 1 gallon

(PAS-00002988-89)

AOC 105 was identified as the Building 61 Pump House and Appurtenant Piping (Memorandum of Agreement (MOA) IA-4). This area was located in the northern portion of the facility. The building pumped No. 6 fuel oil from the 640,000-gallon AST located in the northern corner of the facility to the Building 39 boiler house. Historically, the oil transfer pipe was buried directly in the ground. In 1989, the underground line was removed from service and replaced with an aboveground line. This aboveground line was inspected regularly by Roche's personnel. On December 18, 1989, Roche's personnel discovered No. 6 fuel oil in a storm water catch basin on the south side of the facility. The underground line which carried fuel oil from the 640,000-gallon AST to Building 39 had developed a leak in the vicinity of the pump house (Building 61) and oil had flowed into the storm sewer system. At that time this storm sewer was being routed through Roche's pretreatment facility and no oil was discharged to surface water (PAS-00003171).

AOC 107 was identified as the Spill Location on Street North of Building 100. On March 2, 1991, a 10-15 gallon, 100-foot trail of PCB-contaminated transformer oil was released to the roadway due to a broken valve during a transformer relocation by an outside contractor. Federal and state authorities were notified and the area was cleaned by Roche's personnel (PAS-00003177).

AOC 109 was identified as the Mercury Release Underground Tunnel Building 56 (identified in MOA as IA-5). Mercury (1-2 ounces) was identified by a contractor during tunnel upgrade activities under Building 56. The material was recovered by Roche's personnel (PAS-00003179).

7. Response Actions

Characterization Activities

The following characterization activities have taken place at the facility:

- *Heavy Metals Source Determination Study*, Appendix A, Industrial Waste Surveys, Part A – Industrial Site Interviews, Volume 3, dated August 15, 1978
- *Direct Discharge PRP Cases for the Lower Passaic River Study Area, Hoffmann-La Roche*, dated August 22, 2005 (PAS-00101228)
- *Remedial Action Report, Concrete Demolition Materials Contamination MOA Investigative Area 6, Hoffmann-La Roche, Nutley/Clifton, Essex/Passaic County, PI No. 009949*, dated September 2012 (PAP-00189811)
- *Remedial Investigation Report for Investigative Area 10 (IA-10)*, dated December 19, 2013 (PAP-00214315)
- *Ecological Evaluation and Surface Water Remedial Investigation Report*, Hoffmann-La Roche Inc., dated April 2014 (PAP-00214766)
- *Soil Remedial Action Permit Modification*, dated March 2018 (PAP-00215482)
- *PRP Data Extraction Form, Lower Passaic River Study Area* (PAS-00123422)

Sewer

There is no information regarding sewer sampling in the available file material.

Soil

Roche purchased the northwest corner of the site (referred to as northern IA-10) in 1967 (PAP-00215458). This parcel included a former industrial fill area; the filling preceded Roche's purchase. This former industrial fill area contained a variety of waste materials, and PCBs were detected at a range of concentrations, some in excess of 100 mg/kg (PAP-00214426). Lead was detected as high as 153,000 mg/kg (PAP-00214421).

Sediment

According to the surface water and sediment data collected, Roche's operations did not have an impact on St. Paul's Brook, and that contaminants detected in the Brook are the result of runoff from roads and urbanized surrounding areas. Concentrations of COCs adjacent to and downstream of the site were comparable to background concentrations. St. Paul's Brook did not transport COCs from the Roche Site to the Third River (PAP-00214764-831).

8. Summary of Asserted Defenses

No legal defenses were identified in the available file material.

Honeywell International Inc.

Diamond Alkali OU2 Allocation
ADR Confidential
Facility Data Report

HONEYWELL INTERNATIONAL INC.

Facility Name, Address and Size: Allied-Signal, Inc., Dundee Warehouse, 65 Lodi Street at Eighth St., Passaic, New Jersey; Block 1029, Lot 25 (PAP-00101453; PAS-00047956); approximately 2 acres (PAP-00198137, PAP-00198138; PAP-00456821). No information for the number of workers and shifts was available in the file material.

1. **Business Type:** Nitrating plant until 1960, and bulk acid distribution facility until 1974 to 1976. After 1976, the facility was used by Allied-Signal, Inc. (Allied-Signal) as a storage facility for engineered plastics and pellets (finished products only) (PAS-00047823).

2. **Time Period of Ownership/Operations**

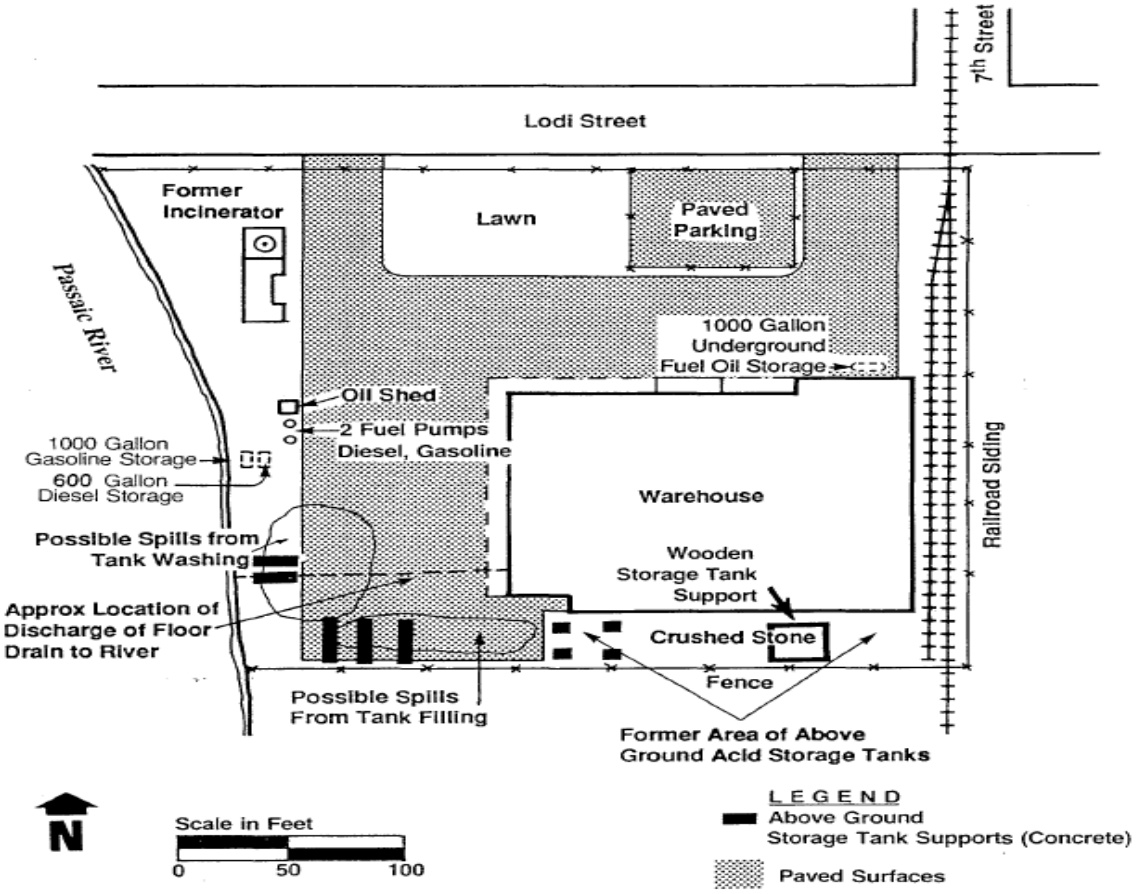
Operator: 1899 - 1987 (General Chemical/Allied Chemical & Dye Corporation/Allied-Signal, Inc./Honeywell)
Owner: 1899 - 1987 (General Chemical/Allied Chemical & Dye Corporation/Allied-Signal, Inc./Honeywell)

1899: General Chemical Company purchased the site from Dundee Chemical Works on February 25, 1899 (PAP-00198129).

1915: General Chemical Company granted a portion of the site on Eighth Street and south of the General Chemical Company to Paterson Parchment Paper Company on May 14, 1915 (PAP-00198135).

1954: Allied Chemical & Dye Corporation granted a portion of the site on Eighth Street to Donori Corporation on August 30, 1954. General Chemical Company is noted to be the predecessor to Allied Chemical & Dye Corporation (PAP-00198148). A site map showed Donori Corporation was located east of the Dundee Warehouse (PAS-00048059).

1987: Allied Corporation sold facility site to Anthony R. and Elaine Triolo on May 18, 1987 (PAP-00198137-38), who subsequently sold the site to Charles Cangialosi (PAP-00198139-40).



1988: According to an Environmental Cleanup and Responsibility Act (ECRA) Inspection performed on December 8, 1988, Tri-State Building Products was the new owner operating at the facility (PAS-00047956).

3. **Operational History/COC Use and Presence at the Facility**

According to the *ECRA Sampling Plan*, dated January 1987 (ECRA Sampling Plan), Allied-Signal had owned and operated the Dundee Warehouse facility since approximately 1899. The facility operated as a bulk acid distribution facility and a nitrating plant through 1960, when the nitrating operations were discontinued. The acid distribution operations were discontinued in 1974 through 1976. From 1976 through 1986, the facility was used for storage of finished plastic products (i.e., engineered plastics and pellets, such as AC Polyethylene®, Capron [Nylon]® and high density

polyethylene). At the time of the 1987 ECRA Sampling Plan, all on-site activities had been discontinued and the warehouse was vacant (PAP-00197580, 83).

A facility site map from the 1987 ECRA Sampling Plan is included below:

(PAP-00197582)

Note the potential presence of the discharge of the floor drain to the Passaic River as depicted on this figure is discussed in Section 5, Potential COC Pathways.

Hazardous substances reportedly present at the facility and listed in the ECRA Sampling Plan included fuel oil (1,000-gallon subsurface storage tank) and diesel fuel (600-gallon subsurface storage tank) (PAP-00197581). Although the specific processes used at the facility were not identified in the available in the file material, a general description of nitric acid production in the early 1900s was provided. The book *Manufactures 1905, Part IV Special Reports on Selected Industries*, from the Department of Commerce and Labor Bureau of the Census, stated that nitric acid was made commercially by distilling sodium nitrate with sulfuric acid. Sulfuric acid from the “lead pan evaporation” was reported to be used to obtain weaker grades of nitric acid (PAP-00432529-30). According to this reference, the byproduct of this process was a nitre cake, composed of sodium hydrogen sulfate or sodium bisulfate (PAP-00432532).

According to the Compilation of Air Pollutant Emission Factors, Volume I: Stationary Point and Area Sources, dated January 1995, nitric acid production also utilized high temperature catalytic oxidation of ammonia over a platinum catalyst. The Sanborn map from 1899 identified "platinum concentrators" adjacent to the "lead acid pans" in the "Sulphuric Acid Chambers" (the same building as the Warehouse in the figure above) (PAP-00445860). This type of process starts with the oxidation of ammonia to create nitric oxide, followed by subsequent further oxidation to nitrogen dioxide, then separation and purification steps. Potential byproducts of this process are water, nitrogen tetroxide, and gaseous nitrogen oxides (PAP-00432459-61, PAP-00432464-67).
While lead was not identified as used in the nitric acid production process, historical Sanborn facility maps from 1899, 1903, and 1910 (show the presence of lead-lined acid storage tanks and lead-lined acid pans known to be used in acid production (PAP-00445860-2).

The *Soil Investigation, Report of Findings,* dated December 5, 1989 (1989 Soil Report), and the *Determination of Ambient Site Conditions and Phase II Supplemental Sampling Report of Findings,* dated April 29, 1991 (1991 Phase II Report) summarized the results of sampling of 10 areas at the site. The areas as well as the chemicals of concern (COCs) that were detected include the following (note: concentrations are provided in the COC-specific portions of Section 4, Identified COCs):

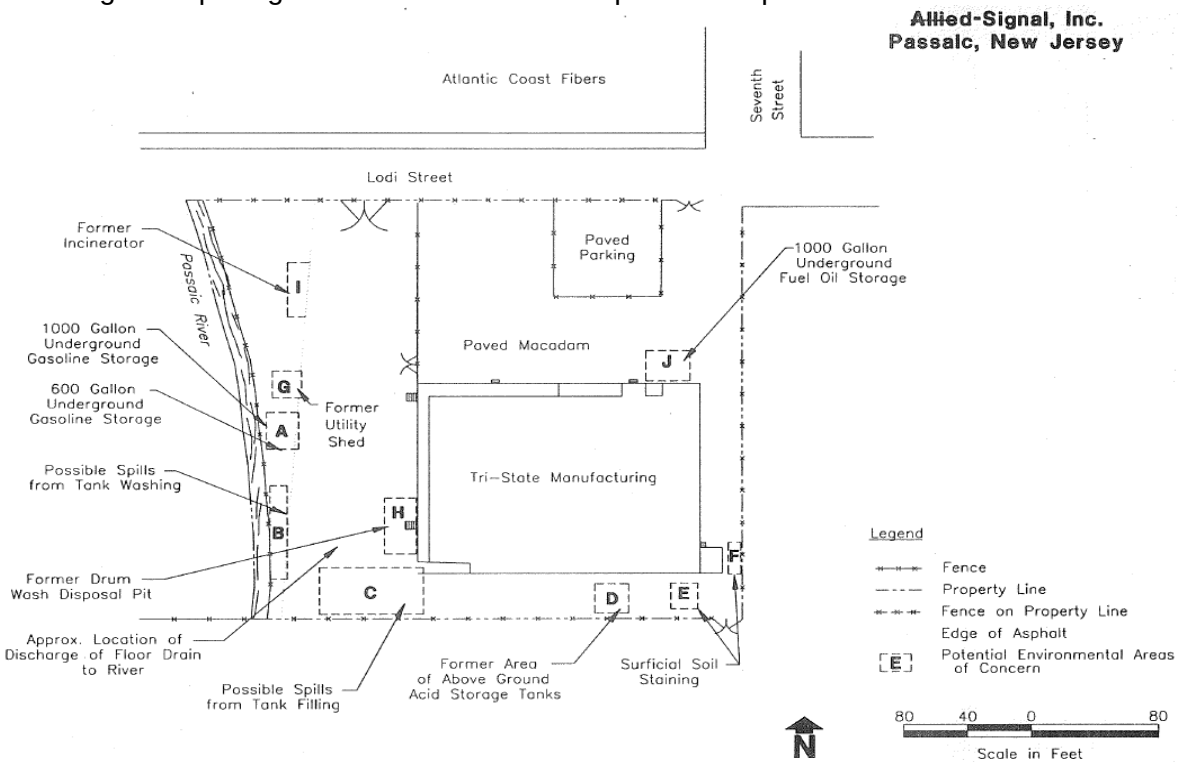
- Sample Area A was characterized by the former presence of subsurface gasoline and diesel storage tanks. Soil sampling results detected maximum concentrations of PAHs at sampling location 1 Mid (depth of 18 to 24 inches) (PAP-00101532).

- Sample Area B was utilized for both tank washing and above ground acid storage (PAP-00101534-35). Lead and polycyclic aromatic hydrocarbons (PAHs) were detected in soils in this area with the highest concentrations in soil sample B-2 (I) and B-3 (I) respectively collected at 3 ft bgs (PAS-00047242).

- Sample Area C was a tank truck delivery area. Raw materials handled in this area included hydrochloric acid, sulfuric acid, ammonia, and liquid silicates (PAP-00101536).

- Sample Area D was the former location of aboveground acid storage tanks (PAP-00101536).

- Sample Areas E and F were characterized by the presence of surficial soil staining (PAP-00101539). The maximum lead concentration in these areas was detected in subsurface soil (PAS-00047239-41).



- Sample Area G was the former location of a small utility shed used for the storage of small quantities of gasoline and motor oil (PAP-00101539). Lead was detected at a maximum concentration in subsurface soil in this area (PAS-00047240).

- Sample Area H contained a former drum wash disposal pit that had been filled with cement, preventing access to the pit. The maximum mercury concentration in this area was detected at a depth of 7 to 8 feet below ground surface (ft bgs). PAHs were stated to have been detected at "low concentrations" (PAP-00101543-44). Samples were also collected upstream and downstream of a suspected pipe discharge. The referenced report stated that mercury and lead were detected in the upstream sample (identified as H4) and should, therefore, be considered as occurring as background contamination (PAP-00101546). Note that the subsequent *Report of Findings, Determination of Ambient Site Conditions and Phase II Supplemental Sampling*, dated April 29, 1991 (1991 Phase II Report) identified H5 as the upstream sample (PAS-00109682).Based upon the location of the samples in the figure on PAP-00101545 and the site layout figure above, the site is located at a jog in the Passaic River and H5 was located upstream of H4.

- Sample Area I was the former incinerator. Soil sampling identified maximum concentrations of copper and mercury in surface sample I4 (0 to 6 inches) (PAP-00101546-48). Lead was detected at maximum concentration in surface soil and PAHs were detected at maximum concentrations in subsurface soil in this area (PAS-00047227, 242).

- Sample Area J was characterized by the presence of an abandoned 1,000-gallon underground storage tank (UST) used for storage of fuel oil (PAP-00101548-50).

A figure depicting the location of each Sample Area is presented below:

(PAP-00101352)

The loading docks were located approximately 100-125 feet east of the Passaic River (PAP-00197571). The gasoline and diesel underground storage tanks (USTs) were located along the river (PAP-00101478).

4. Identified COCs

- PAHs (used, detected)
- Copper (detected)
- Lead (used, detected)
- Mercury (detected)

PAHs

USTs containing diesel fuel (600-gallon UST) and fuel oil (1,000-gallon UST) were identified in the ECRA Sampling Plan. Precision testing performed in 1986 found that the diesel and fuel oil tanks were tight. An oil shed and fuel pumps for the diesel and gasoline were also identified on site. In addition, oil staining was noted on the floor of the utility shed (PAP-00197582-83). On June 2, 1987, the diesel UST was excavated and removed (PAP-00101478). PAHs were detected in the samples collected from 18 to 24 inches beneath the base of the excavation, with the highest concentrations from beneath the diesel tank (PAP-00101479, 82).

Based on the ECRA investigations performed in the late 1980s and early 1990s, PAHs were detected at several investigative areas. Maximum detected concentrations in surface soil (0-0.5 ft bgs) at each area are provided in the following table:

Maximum PAH Concentrations in Surface Soil (0-0.5 ft bgs)			
Area	**B**	**H**	**I**
Sample	**B1**	**H5***	**I4**
benzo(a)anthracene	6.0	2.9	7.91
benzo(a)pyrene	5.0	2.1	9.23
benzo(b)fluoranthene	3.8	1.8	9.82
benzo(g,h,i)perylene	2.8	1.1	6.90
benzo(k)fluoranthene	4.2	1.5	6.84
chrysene	5.6	2.8	8.90
dibenzo(a,h)anthracene	1.2	ND	2.33
fluoranthene	10	5.5	11.4
indeno(1,2,3-cd)pyrene	ND	1.2	5.97
pyrene	17	4.5	11.2
Source	(PAP-00101556)	(PAP-00101554)	(PAP-00101560)

All results in mg/kg
ND: Not Detected

*This is a sediment sample collected from 0.5-1 ft bgs upstream from a suspected discharge pipe (PAP-00101543, 46; PAS-00109682).

The *Supplemental Project Tasks, Former Allied-Signal, Dundee Warehouse, Passaic, New Jersey, ECRA Case Number 87133*, dated January 8, 1992 (Supplemental Project Tasks Letter) estimated that the volume of soil in Area B that contained residual carcinogenic PAH compounds above the New Jersey Department of Environmental Protection (NJDEP) soil cleanup guideline of 2.5 mg/kg was approximately 22 cubic yards (PAS-00048047). In addition, the *Focused Feasibility Study and Cleanup Plan*, dated September 15, 1992 (1992 Cleanup Plan), calculated the volume of soil impacted by carcinogenic PAHs to be 47.4 cubic yards (PAP-00101433).

The *Remedial Action Report,* dated June 1994 (1994 RAR), stated that elevated concentrations of base neutral compounds in Area B may be a result of the historical operation of the site (PAS-00047832). In addition, an NJDEP approval letter, dated May 4, 1993, for the 1992 Cleanup Plan noted that the base neutral contamination detected during the August 1989 sampling event at sample locations B-1 (Area B) and I-1, I-3, and I-4 (Area I) appeared to be related to previous site operations (PAP-00101455-56).

PAHs were also detected in subsurface soil at Area A (former USTs) and Area I (former incinerator):

Maximum PAH Concentrations in Subsurface Soil			
Area	**A**	**A**	**I**
Sample (depth)	**1M (18")**	**SB6 (12-14")**	**I2 (3')**
benzo(a)anthracene	139	88	8.1
benzo(a)pyrene	21.1	70	9.7
benzo(b)fluoranthene	109*	68	10.2
benzo(g,h,i)perylene	28.7	37	6.8
benzo(k)fluoranthene	*	50	5.8
chrysene	136	93	8.0
dibenzo(a,h)anthracene	ND	21	2.8
fluoranthene	293	371	9.5
indeno(1,2,3-cd)pyrene	20.2	32	4.9
pyrene	346	156	11.9

All results in mg/kg
ND: Not detected
*The isomers benzo(b)fluoranthene and benzo(k)fluoranthene could not be chromatographically separated under the analyte conditions for these samples. Therefore, the reported concentrations represent the total of these two isomers (PAP-00101552).

Copper

Sample Area I soil results identified copper at a maximum concentration of 257 mg/kg in surface sample I4 (PAP-00101548, 60).

Lead

Lead acid pans were located at the northwest corner of the warehouse building in the 1899 and 1903 Sanborn maps, but were “sulphur furnaces” in the 1910 map. The lead acid tank was located between the lead acid pans and the Passaic River in the 1899, 1903, and 1910 maps. A structure at the same location was present in the 1935 Sanborn map, but was not labeled (PAP-00445860-63).

Lead was detected in site soil at several areas investigated under ECRA in the late 1980s and early 1990s. The highest concentrations of lead in surface soil (0 to 6 inches) detected at each area were as follows: Area B [163 parts per million (ppm)], Area F (1,260 ppm), Area G (845 ppm), and Area I (1,610 ppm) (PAP-00101534, 39, 43, 48; PAS-00047149-50). In subsurface soil, maximum lead concentrations detected at each area were as follows: Area B (816 ppm), Area E (8,030 ppm), Area F (2,250 ppm), Area G (3,560 ppm), Area I (5,350 ppm) (PAP-00102025-28; PAS-00047150).

A 1992 Supplemental Project Tasks Letter estimated the volume of soil in Area E that contained residual lead above the NJDEP soil cleanup guideline of 1,000 mg/kg as being approximately 42 cubic yards. The volume of soil in Area I with residual lead above 1,000 mg/kg was estimated to be approximately 40 cubic yards. Soil in Area F was identified for excavation due to sample results for lead above 1,000 mg/kg, but the volume of contaminated soil was not specified (PAS-00048047-48, 50).

Areas E, F, and I also were stated to be impacted by lead in the 1992 Cleanup Plan. The volumes at each Area to be addressed in the 1992 Cleanup Plan were estimated as follows: Area E (21.3 cubic yards), Area F (13 cubic yards), and Area I (336 cubic yards) (PAP-00101367-69). The 1992 Cleanup Plan noted that these volumes were the amount of soil assumed to contain lead above the proposed Non-residential Surface Soil Cleanup Standard (PAP-00101434-36).

The 1994 RAR stated that the distribution of lead in the soil profile was sporadic and random. However, it also stated that the presence of elevated concentrations of lead, primarily in Area I, may be a result of the use of an incinerator formerly located on the site (PAS-00047832).

Mercury

Mercury was detected at two areas sampled during the ECRA investigation. At Area H, the former drum wash disposal pit, mercury was detected at 0.2, 1.1, and 1.5 mg/kg at depths of 5 to 6, and 7 to 8 feet below ground surface (bgs), respectively (PAP-00101543-44, 56). Samples were also collected from sediment located upstream and downstream of a suspected pipe discharge at Area H (1.3 and 0.3 mg/kg, respectively). The report stated that mercury was detected in the upstream sample and should, therefore, be considered to be occurring as background contamination (PAP-00101546, 54). The subsequent 1991 Phase II Report discussed the upstream and downstream sample locations as opposite to the upstream/downstream locations originally reported in the 1989 Soil Report (PAS-00109682).

At Area I, the former incinerator, soil results identified mercury at concentrations up to a maximum of 8.2 mg/kg in surface sample I4 (PAP-00101548, 60).

Historic Fill

The Allocation Team has determined that the facility site is located on regional Historic Fill as designated by the NJDEP. [1]

NJDEP has established that historic fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 COCs: PAHs, lead, copper, and mercury.[2] Accordingly, NJDEP technical requirements for property containing Historic Fill requires sampling for the EPA Target Compound List for PAHs and Target Analyte List for metals, including lead, copper, mercury, and the OU2 PAH COCs.[3] PAHs, lead, copper, and mercury are recognized by NJDEP to be constituents of Historic Fill at varying levels, not atypically at or exceeding residential soil standards.[4]

The levels of PAHs, copper, lead and mercury detected at the site in soils are presented in the table below (PAP-00101552; PAP-00101548; PAP-00102025, 29).

COCs Found in Onsite Soils	
COC	**Max Detected Concentration**
Lead	8,030 mg/kg
Copper	257 mg/kg
Mercury	8.2 mg/kg
Benzo(a)anthracene	139 mg/kg
Benzo(a)pyrene	70 mg/kg
Benzo(b)fluoranthene	109 mg/kg
Benzo(k)fluoranthene	50 mg/kg
Dibenzo(a,h)anthracene	21 mg/kg
Indeno(1,2,3-cd)pyrene	32 mg/kg

According to the 1991 Phase II Report, ambient soil was sampled to determine whether the observed constituents on site were the result of past site activities or a result of ambient conditions in the native soil/fill profile. The report states that the fill material was

[1] *Digital Geodata Series, DGS04-7, Historic Fill for New Jersey*, https://www.nj.gov/dep/njgs/geodata/dgs04-7.htm, Quadrangle #42 (NJDEP map identifying locations of recognized historic fill).
[2] *Characterization of Ambient Levels of Selected Metals and cPAHs In New Jersey Soils* (2002) and *Characterization of Ambient Levels of Selected Metals and Other Analytes In New Jersey Soils* (1997), studies prepared for NJDEP, Division of Science and Research, by BEM Systems, Inc.
[3] New Jersey Department of Environmental Protection (NJDEP), *N.J.A.C. 7:26E Technical Requirements for Site Remediation,* Table 4-2, November 2009 [Note that Table 4-2 has been deleted from the current version of N.J.A.C. 7:26E (May 7, 2012) and the updated *Historic Fill Technical Guidance* (April 2013) as NJDEP believed that the tables list of historic fill constituents was too restrictive].
[4] NJDEP Table 4-2 (PAHs and lead) and a summary of NJDEP records regarding investigations of properties in the vicinity of the Passaic River recognized to be located in areas of Historic Fill indicate that the following average/maximum (mg/kg) contamination levels of OU2 COCs exist in area Historic Fill: PAHs (1.91/160), lead (574/10,000), copper (11.2/1,200), and mercury (0.21/3.7).

imported and used to modify the site's topography dating back to the inception of site activities in the late 1800s (PAS-00047213). It goes on to state that the occurrence of the analytes in Areas B, E, F, and G, although at concentrations above ECRA guidelines, was considered to be within the range of expected variability based upon the range of analyte concentrations detected at background locations (PAS-00047211-12).

The 1992 Supplemental Project Tasks Letter stated that fill material had been observed at depths that vary from a minimum of approximately 3 feet in the central portion of the site to a maximum of approximately 16 feet in the vicinity of Area A. The fill was characterized by the presence of loose, poorly sorted sand, silt and clay which contained cobbles, brick, ceramics, glass, wood, and ash waste. The fill material was non-homogeneous and discontinuous across the site. In the areas adjacent to the Passaic River (Areas A and I), significant void spaces were encountered during the drilling activities (PAS-00048039).

5. COC Pathways

Sanitary Sewer

A Trip Report Memorandum, dated February 6, 1978, stated municipal water and sanitary wastes were discharged to the municipal water system (PAP-00197571).

A subsequent Trip Report Memorandum, dated April 5, 1978, documented dye tests performed to determine the discharge point from the sewers in the building floor. No dye was observed in the Passaic River, and the report concluded that both the floor drains and sanitary effluents from the warehouse discharged into the municipal sewer system (PAS-00048054).

A municipal trunk sewer line was installed beneath Lodi Street, approximately 150 feet north of the warehouse (PAS-00048054).

Storm Sewer

A storm sewer line was noted to be on site in a Trip Report Memorandum, dated April 5, 1978. The memorandum stated that a pipe entering the river was visible during periods of low river flow; however, according to the Trip Report Memorandum, it appeared that the 16-inch diameter storm sewer drain line had been tied into the municipal system (PAS-00048054).

A Plan & Profile Showing Sewer Conduits & Pipe Lines along Lodi St., dated 1938, identified a 24-inch storm sewer that ran along Lodi Street and discharged to the Passaic River (PAP-00198147).

Direct Release

A Trip Report Memorandum, dated February 6, 1978, identified “three floor drains that discharge directly into the nearby Passaic River,” but the document stated it was unknown if the drains discharged into a storm sewer or directly into the Passaic River. A

storm drain from the parking lot was also stated to discharge to the river (PAP-00197571).

A Trip Report Memorandum, dated April 5, 1978, stated that a pipe entering the river was visible during periods of low river flow; however, it appeared that the 16-inch diameter storm sewer drain line had been tied into the municipal system. Dye testing performed during the site visit determined that the floor drains and sanitary effluents from the warehouse discharged into the municipal sewer system, as no dye was noted in the Passaic River at the proximate location of the sewer (PAS-00048054).

Facility maps from 1965 and 1969 show a 16-inch concrete sewer running across the northern end of the warehouse building and to the Passaic River (PAS-00048059-60), but this feature is not shown on other maps from 1918, 1954, 1974 and 1980. In addition, none of the maps show floor drains in the building connected to the concrete sewer or to the Passaic River as shown in the figure in Section 3 of this report (PAS-00048056-62).

According to the ECRA Sampling Plan, the interior of the warehouse had several floor drains that were believed to be connected to one conduit that ultimately discharged to the Passaic River (PAP-00197583). However, the *ECRA Sampling Plan Addendum*, dated February 1989, stated that the floor drains had been filled with cement, so access to these structures was no longer possible. In addition, the “drainage location, if any,” of the conduit that may have drained to the Passaic River was unknown (PAP-00101494, 98).

According to a letter report regarding the Supplemental Project Tasks, Former Allied-Signal, Dundee Warehouse, Passaic, New Jersey, ECRA Case Number 87133, dated January 8, 1992 (Supplemental Project Tasks Letter), it was proposed to use ground penetrating radar (GPR) or other appropriate geophysical surveying techniques to locate the suspected outfall pipe to the Passaic River. A sample would be collected if the pipe was located (PAS-00048049). No records of these samples and no further information for the geophysical survey results were provided in the available file material.

Spills

There is no information regarding spills in the available file material.

6. Regulatory History/Enforcement Actions

Inspections

The facility was inspected by the NJDEP as part of the ECRA review process on December 8, 1988. The inspection identified several deficiencies in the proposed characterization activities that would be addressed in the Sampling Plan (PAS-00047955-58).

Violations

There is no information regarding violations in the available file material.

Permits

A Trip Report Memorandum, dated February 6, 1978, stated the facility did not have any NJDEP or National Pollutant Discharge Elimination System (NPDES) permits (PAP-00197570). At this time, no manufacturing activities were taking place at the facility as it was being used for finished plastic storage (PAP-00197580).

7. Response Actions

Characterization Activities

The following characterization reports have been published for the facility:

- 1989 Soil Report prepared by Environmental Resources Management, Inc. (PAP-00101521)
- *Report of Findings, Supplemental Sampling*, dated August 3, 1990 (Supplemental Sampling Report), prepared by Environmental Resources Management, Inc. (PAP-00101995).
- *Report of Findings, Determination of Ambient Site Conditions and Phase II Supplemental Sampling*, dated April 29, 1991, prepared by Environmental Resources Management, Inc. (PAS-00047158).
- 1994 RAR, submitted by AlliedSignal Engineered Materials (PAS-00109740).

Soil

In general, soil sampling in the late 1980s and early 1990s under ECRA found concentrations of lead and PAHs above the ECRA guidelines. PAHs were detected in samples collected at Area A from the base of the 1987 UST excavation, with the highest concentrations from beneath the diesel tank (PAP-00101479, 82). The 1994 RAR stated that elevated concentrations of base neutral compounds in Area B may be a result of the historical operation of the site (PAS-00047832). The highest concentrations of lead were detected in subsurface soil at Area E (8,030 ppm) (PAP-00102025-28). The 1994 RAR stated that the distribution of lead in the soil profile was sporadic and random. However, it also stated that the presence of elevated concentrations of lead, primarily in Area I, may be a result of the use of an incinerator formerly located on the site (PAS-00047832).

Copper and mercury were also detected in site soil. At Area H, the former drum wash disposal pit, mercury was detected at 1.1 and 1.5 mg/kg at depths of 5 to 6 and 7 to 8 ft bgs, respectively (PAP-00101543-44), while Area I soil results detected copper with a maximum of 257 mg/kg in surface sample I4 (PAP-00101548, 60).

The 1989 Soil Report and 1991 Phase II Report summarized the results for sampling of 10 areas at the site. Areas where COCs were detected include the following:

- Sample Area A was characterized by the former presence of subsurface gasoline and diesel storage tanks. Soil sampling results detected maximum concentrations of PAHs at sampling location 1 Mid (depth of 18 to 24 inches) (PAP-00101532).

- Sample Area B was utilized for both tank washing and above-ground acid storage. Lead was detected at 163 mg/kg in a surface sample (0 to 6 inches depth), and PAHs were detected at maximum concentrations in soil sample B-3 (I) at 3 ft bgs (PAP-00101534-35; PAS-00047242).

- Sample Areas E and F were characterized by the presence of surficial soil staining (PAP-00101539). Concentrations of lead ranged from a minimum of 32 mg/kg in E-1 (I) (0.5 to 1 ft bgs) to a maximum of 8,030 mg/kg in E-4 (I) (0.5 to 1 ft bgs) (PAS-00047239).

- Sample Area G was the former location of a small utility shed used for the storage of small quantities of gasoline and motor oil (PAP-00101539, 42-43). Lead was detected up to a maximum concentration of 3,560 mg/kg in soil sample G-1 (I) from 3 ft bgs (PAS-00047240).

- Sample Area H contained a former drum wash disposal pit area that has been filled with cement preventing access to the pit. Mercury was detected at 1.5 mg/kg at a depth of 7 to 8 ft bgs (PAP-00101543-44). PAHs were detected at low concentrations (PAP-00101543-44). Samples were also collected upstream and downstream of a suspected pipe discharge. The report stated that mercury and lead were detected in the upstream sample and should therefore be considered as occurring as background contamination (PAP-00101546). The subsequent 1991 Phase II Report discussed the upstream and downstream sample locations as opposite to the upstream/downstream locations originally reported in the 1989 Soil Report (PAS-00109682).

- Sample Area I was the former incinerator. Soil results detected copper (maximum of 257 mg/kg; sample I4), mercury (8.2 mg/kg; sample I4), (PAP-00101548), and lead (maximum of 5,350 mg/kg; sample I-3 (I)) (PAS-00047242). PAHs were also detected at maximum concentrations in samples SB-6 (PAS-00047238).

- Sample Area J was characterized by the presence of an abandoned 1,000 gallon UST used for storage of fuel oil. PAHs were detected below the quantitation limit of the analytical procedure at 7 to 8 ft bgs (PAP-00101548-50).

Additional sampling to delineate the vertical extent of contamination was reported in the 1990 Supplemental Sampling Report. The report stated that base neutral compounds and lead exhibited a relatively ubiquitous distribution across the site. With the exception of areas A, G and I, no definable centroids of contamination were isolated. The report

stated that nonindigenous fill material may be acting as a residual contaminant source beneath the site (PAP-00102041).

Sampling of four background soil borings from the perimeter of the site was performed in 1991 to determine the ambient soil conditions, according to the *Report of Findings Determination of Ambient Site Conditions and Phase II Supplemental Sampling*, dated April 29, 1991. Lead was detected at concentrations ranging up to a maximum of 1,120 mg/Kg in the 0 to 2 foot sample interval of BG-4 (PAS-00047195-96). Total base neutral organic compounds were detected at a maximum of 158,400 µg/kg from within the fill material. The report concluded that lead and base neutral organic compounds were detected at elevated levels in the background locations, and fill material has impacted the native soil. The report also stated, "the occurrence of the analytes in Areas B, E, F, and G, although at concentrations above ECRA guidelines, is considered to be within the range of expected variability based upon the range of analyte concentrations detected at background locations" (PAS-00047211-12).

Sediment

Samples at Area H were collected from Passaic River sediment upstream of and downstream from a suspected drain pipe. The 1989 Soil Report stated that mercury, lead, and semivolatile organic compounds were detected in the upstream sample and should therefore be considered to be as occurring as background contamination (PAP-00101546). However, it is noted that the subsequent 1991 Phase II Report discussed the upstream and downstream samples as located in opposite directions compared to the upstream/downstream locations originally reported in the 1989 Soil Report (PAS-00109682). Concentrations were as follows:

Sediment Sample Concentrations		
COC (mg/kg)	**H4 (downstream)**	**H5 (upstream)**
Lead	369	101
Mercury	1.3	0.3
Copper	101 J	32 J
Benzo(a)anthracene	1.6	2.9
Benzo(a)pyrene	1.6	2.1
Benzo(b)fluoranthene	1.5	1.8
Benzo(k)fluoranthene	1.3	1.5
Dibenzo(a,h)anthracene	0.6	1.2
Indeno(1,2,3-cd)pyrene	ND	ND

ND: Not Detected
J: estimated concentration (PAP-00101554)

Remedial Activities

NJDEP approved the 1992 Cleanup Plan in a letter dated May 4, 1993 with the following conditions. The letter stated that active remediation of lead was not required by NJDEP due to the apparent sporadic distribution of the lead across the facility. However, the asphalt pavement to be placed over the impacted areas should cover all areas of the site

that were unpaved at that time unless soil sampling was performed to confirm the absence of contamination in exposed areas. In addition, the letter stated that the base neutral contamination detected during the August 1989 sampling event at sample locations B-1 (Area B) and I-1, I-3, and I-4 (Area I) appeared to be related to previous site operations. However, it stated that institutional controls proposed to address site-wide arsenic and lead contamination would also be adequate to address the base neutral contamination. In addition, a Declaration of Environmental Restrictions was required to ensure that the site remained industrial and that the asphalt cap was not disturbed without prior NJDEP notification and proper health and safety precautions (PAP-00101455-56).

The 1994 RAR documented how each area of concern was addressed. Areas A, B, G, and I were capped with a 3-inch stabilized base and 2-inches of asphalt. Areas E and F were capped with a permeable geomembrane and 5-inches of stone (PAS-00109757).

A Remedial Action Protectiveness/Biennial Certification Form - Soil was submitted to NJDEP on June 24, 2013, for the existing deed notice at the Dundee Warehouse property (PAP-00432471). The form included the Declaration of Environmental Conditions, dated March 1, 1994, which limited all alterations, improvements, and disturbances of the affected areas to require previous written consent from NJDEP (PAP-00432479-80). The Remedial Action Permit Application – Soil noted that the Deed Notice was for historic fill at the site (PAP-00432474).

A Soil Remediation Permit was granted to Charles Cangialosi, President of Cangialosi Family Realty LLC by NJDEP on August 28, 2013, to conduct monitoring, maintenance, and evaluation to maintain compliance and effectiveness of the remedial action and its associated institutional and engineering controls (PAP-00432521).

8. Summary of Asserted Defenses

Honeywell asserts that any releases of PAHs at the site were the result of releases of petroleum or fuel oil, which are excluded from CERCLA liability under the petroleum exclusion. See 42 U.S.C. §9601(14); see also Scope of CERCLA Petroleum Exclusion Under Sections 101(14) and 104(a)(2), Memorandum from Francis S. Blake, General Counsel to J. Winston Porter, Assistant Administrator for Solid Waste and Emergency Response, OSWER 9838.1, U.S. EPA, July 31, 1987, at 5.

Facility Data Report

ISP CHEMICALS LLC

Facility Name, Address and Size: ISP Van Dyk, Inc. (ISP), 11 William Street, Belleville, New Jersey (PAS-00010070); 2 parcels, 0.79 acres (chemical plant south of William Street) and 1.49 acres (2 warehouses north of William Street) (PAS-00110586); operated 24 hours/day, 7 days/week; 30 employees (20 operators, 4 shift supervisors, and 6 maintenance mechanics staffed the plant) (PAP-00094606).

1. **Business Type:** Manufacture of specialty chemicals for the personal care industry, such as sunscreens and cosmetic chemicals for both skin care and hair care (PAP-00094606).

2. **Time Period of Ownership/Operations**

   Operator: 1992 to 2001
   Owner: 1992 to present

   1992: International Specialty Products acquired Van Dyk in 1992. ISP Van Dyk, Inc. was a wholly owned subsidiary of International Specialty Products (PAP-00094606). On March 31, 1992, ISP Van Dyk, Inc. purchased the property from Mallinckrodt, Inc. (PAP-00092134; PAS-00010177, 90). Mallinckrodt, Inc. sold the fixed and operating assets of Van Dyke & Company, including the real property at the Belleville facility, to ISP (PAS-00110293).

   2001: ISP Van Dyk, Inc. ceased operations at the facility on or about March 31, 2001 (PAS-00110294). On June 27, 2001, the site was granted from ISP Van Dyk, Inc. to ISP Chemicals LLC (PAS-00010180), and on June 29, 2001, ISP Van Dyk, Inc. merged into ISP Chemicals Inc. (PAS-00010189). ISP Chemicals, Inc. is the corporate successor to ISP Van Dyk, Inc. (PAS-00110294).

   2010: The buildings on the parcel south of William Street were demolished from June 2010 to March 2011. The parcel to the north of William Street was predominantly utilized for warehouse space and employee parking, and continues to be used for document storage by ISP (PAP-00093884).

3. **Operational History/COC Use and Presence at the Facility**

   According to the *Preliminary Assessment for the ISP Chemicals Inc. Facility*, dated April 12, 2002 (2002 Preliminary Assessment), ISP produced and manufactured personal care and cosmetic ingredients (PAP-00092159). A letter from ISP to EPA, dated June 17, 2005, stated that the cosmetic products included a main component in sunscreens (ultraviolet absorbers), emulsifiers, and emollients (PAS-00110586).

   A *Description of Process and Manufacturing Activities Since Acquisition in 1992* (Description of Activities) was prepared by the production supervisor for ISP Van Dyk and dated December 3, 2001. The 2001 Description of Activities stated that the facility separated its product lines by building. Buildings 3, 4, and 4A were primarily dedicated to the manufacture of sunscreen products, which involved creating the ester or "crude" in glass-lined carbon steel reactors. The sunscreens then would undergo a purifying step

by distillation in stainless steel batch distillation units. In addition, cosmetic products requiring solvents, strong acid catalyst, or activated carbon treatment and filtration were produced in Building 4. All other cosmetic products were manufactured in Building 7. The cosmetic product line primarily manufactured in stainless steel reactors were fatty acid-based esters that were either packaged as a liquid or flaked prior to packaging. The plant had two "hot rooms" for re-mobilizing solidified material charged as a liquid (PAP-00094609).

The 2001 Description of Activities also provided a list of each of ISP's products and associated raw materials and manufacturing processes. No chemicals of concern (COCs) were identified on this list (PAP-00094616-75). In addition, a list of chemicals handled at the facility was compiled by ISP in 1995, but did not include any COCs (PAP-00094082).

A list of chemicals that have been used at the property was compiled in the 2002 Preliminary Assessment using Material Safety Data Sheets available from historical operations at the facility. The table included copper chloride 99.995%, copper iodide 99.999%, copper cyanide 99%, mercury, and polychlorinated biphenyls (PCBs) (PAP-00092198, 201-202). However, the document does not specify to what timeframe this list of chemicals used at the facility corresponds. It is noted that the 2002 Preliminary Assessment also stated that ISP never used any substances containing PCBs or mercury (PAP-00092160).

4. Identified COCs

- PCBs (detected)
- PAHs (used, detected)
- Copper (used)
- Lead (detected)
- Mercury (detected)

PCBs

The 2002 Preliminary Assessment stated that ISP never used any substances or chemicals containing PCBs (PAP-00092160). In addition, according to an undated list titled Soil Delineation Status and provided as part of the "Changes Made by ISP (1992 to 2001)" document, ISP did not use nor manufacture PCBs (PAS-00110305). The 2002 Preliminary Assessment stated that PCB contamination of various areas within the facility occurred as a result of the PCB-containing heating oil leaking from valves or other fixtures in the oil lines of the hot oil heating system operated by Van Dyk, Inc. prior to 1979 (PAP-00092136). According to a letter from ISP to EPA, dated June 17, 2005, process oil containing PCBs was utilized from 1965 to 1979 as part of the manufacturing process to heat reaction vessels in Building 7 and distillation columns in Building 4. On July 16, 1979, the entire oil system was drained and cleaned to remove PCB contaminated oil in accordance with requirements set forth by the Toxic Substances Control Act (TSCA) (PAS-00110586).

A list of chemicals that have been used at the property was compiled in the 2002 Preliminary Assessment using Material Safety Data Sheets available from historical operations at the facility. The table included PCBs (PAP-00092202). However, the document does not specify to what timeframe this list of chemicals used at the facility corresponds.

ISP Chemicals LLC

Diamond Alkali OU2 Allocation
ADR Confidential
Facility Data Report

As discussed in the 2002 Preliminary Assessment, PCBs were detected on site soil and remedial excavations were performed by the previous owner, Avon Products, Inc. (Avon). The document stated that Avon was the responsible party (PAP-00092138-40, 61, 80). According to a letter from ISP to EPA, dated June 17, 2005, Avon hired IT Corp. to delineate PCB contamination at the site, which was completed in 1995 (PAS-00110585-86). Maximum concentrations of PCBs in soil samples at identified areas of concern (AOCs) as presented in the *Remedial Investigation Report*, dated August 15, 2006 (2006 RI Report) and the *Remedial Investigation/Remedial Action Progress Report*, dated October 27, 2011 (RI/RA Progress Report) are as follows (see Section 7 for a description of each AOC):

Maximum PCB Concentrations in Soil at Each AOC			
AOC	**PCBs (mg/kg)**	**Sample ID**	**Depth (ft bgs)***
AOC 1 [Fuel Oil Underground Storage Tanks (USTs]	4.63	A1-SS-7A	4.5-5
AOC 4 (Alleyway)	15,800	A27-13A**	1-1.5
AOC 5 (Drum Storage Areas)	0.972	A5B-1B	4.5-5
AOC 7 (Beneath Boiler Room)	10,000	B-15	7-9
AOC 11 (Building No.4 Vent Staining)	4.88	A11-SS-1A	0-0.5
AOC 13 (Building No.7 Hot Room)	0.3254	A27-51C	1.5-2.0
AOC 14 (Historic Filling Station)	0.764	A14-SS-1	4.5-5
AOC 16A (Building No.1 Subsurface Conditions)	2.3	A16A-4A	0-0.5
AOCs 6, 21, 22, 23, 24, 25, and 26 (Floor Staining, Cracks and Deterioration)	336	SB-4B	1-1.5
AOC 27 (Manufacturing Facility Drainage)	15,800	A27-13A**	1-1.5

(PAP-00092622, 24, 26, 28, 32, 34, 65, 71, 72, 74; PAP-00093930)
ft bgs: feet below ground surface
mg/kg: milligrams/kilogram
* The soil boring logs in Appendix F of the 2006 RI Report show that most of the referenced sample locations in this table were covered with 5 to 8 inches of concrete. Only the boring A11-SS-1 at AOC 11 was not installed through concrete (PAP-00092377, 399, 430, 434, 441, 447, 470, 510). The sample at AOC 7 was collected from beneath Building 2 (PAP-00093930).
** Note this appears to be the same sample reported in the 2006 RI Report for both AOCs.

PAHs

Fuel oil underground storage tanks (USTs) were used at the facility as identified in the 2002 Preliminary Assessment:

- Two 25,000-gallon fuel oil USTs were located in the alleyway between Buildings No. 1 and No. 4. The southern tank was reported to have leaked and been abandoned in place by previous site owner Avon in 1993. The northern tank was abandoned in place by ISP on January 16, 1999. The tank was reportedly in good condition with no visibly-observable holes or cracks (PAP-00092137).

- A former 1,000-gallon No. 2 fuel oil UST was located adjacent to the southwestern corner of the facility warehouse building adjacent to William Street. This UST was abandoned in place by ISP on February 23, 1999. The tank was reportedly in good condition with no visibly observable rust holes (PAP-00092141).

- A former 550-gallon No. 2 fuel oil UST was located adjacent to the west side of the warehouse. On September 30, 1998 this 550-gallon UST was excavated and removed (PAP-00092142).

Based on a review of the 2006 RI Report data tables, PAHs were detected at several AOCs. A map depicting the AOC locations is provided in Section 7. Maximum concentrations were detected at the following AOCs:

Maximum PAH Concentrations (in mg/kg) in Soil			
AOC	**4**	**6**	**27**
Sample	**B-30A (1-1.5 ft bgs)**	**SB-11A (0.5-1 ft bgs)**	**A27-9A (2-2.5 ft bgs)**
benzo(a)anthracene	0.944	2.05	8.05
benzo(a)pyrene	1.98	1.51	7.64
benzo(b)fluoranthene	2.14	1.32	5.80
benzo(g,h,i)perylene	1.41	0.880	4.62
benzo(k)fluoranthene	1.55	1.06	5.56
chrysene	6.01	2.85	8.58
dibenzo(a,h)anthracene	0.248 J	0.307	1.58
fluoranthene	0.595	5.71	16.9
indeno(1,2,3-cd)pyrene	0.943	0.914	4.39
pyrene	2.50	5.74	17.7
Source	(PAP-00092651-52)	(PAP-00092681-82)	(PAP-00092687-88)

J: estimated concentration

The *Soils Remedial Action Workplan*, dated October 2008 (Soils RAWP) attributed the detections of PAHs in site soil to the presence of fill material used during construction and grading of the facility (PAP-00099895, 912).

Copper

The 2002 Preliminary Assessment identified copper chloride 99.995%, copper iodide 99.999%, copper cyanide 99% as being used at the site based on Material Safety Data Sheets available from historical operations at the facility (PAP-00092198). The 2002 Preliminary Assessment did not specify the timeframe that copper was used at the facility, and available records did not provide information regarding the use of copper at the facility. No sampling data for copper were identified in the available file material.

Lead

According to the 2006 RI Report, lead was detected at one AOC (AOC 14, Historic Filling Station), at a maximum concentration of 299 mg/kg and a depth of 5.5-6.0 feet below ground surface (ft bgs). Only subsurface soil was sampled in this area. However, the RI Report stated that this AOC was identified based on 1951 and 1961 Sanborn maps, which depicted a filling station with two USTs. A chain of title search stated that Tulsa Oil Company owned a portion of the property north of William Street from 1947 to 1976 (PAP-00092601, 30, 72).

Mercury

The 2002 Preliminary Assessment stated that ISP never used any substances or chemicals containing mercury (PAP-00092160). In addition, according to an undated list titled Soil Delineation Status, ISP did not use nor manufacture mercury (PAS-00110305). According to the 2011 RI/RA Progress Report, the Napier Hat Company historically may have used site buildings or portions of the site for their operations in the early 1900s. Since the hat manufacturing process involved the use of mercury salts, the document stated that those operations are believed to be the source for low levels of mercury found in some soil samples on the site (PAP-00093883).

A list of chemicals that have been used at the property was compiled in the 2002 Preliminary Assessment using Material Safety Data Sheets available from historical operations at the facility. The table included mercury (PAP-00092201). However, the document does not specify to what timeframe this list of chemicals used at the facility corresponds. Mercury was detected at several AOCs as identified in the 2006 RI Report:

Maximum Mercury Concentrations in Soil at Each AOC			
AOC	**Mercury (mg/kg)**	**Sample**	**Depth (ft bgs)***
AOC 1 (Fuel Oil USTs)	3.2	A1-SS-8B	10-10.5
AOC 4 (Alleyway)	11.7	A27-13A	1-1.5
AOC 5 (Drum Storage Areas)	14.8	A5B-4A	0-0.5
AOC 7 (Beneath Boiler Room)	1.9	B-3B	9.5-10.0
AOC 11 (Building No.4 Vent Staining)	4.6	A11-SS-1A	0-0.5

Maximum Mercury Concentrations in Soil at Each AOC			
AOC	**Mercury (mg/kg)**	**Sample**	**Depth (ft bgs)***
AOC 12 (Building No.3 Storage Room Floor/Wall Gap)	1.5	A12-SS-1A	0-0.5
AOC 13 (Building No.7 Hot Room)	0.19	A27-51A	0-0.5
AOC 16A (Building No.1 Subsurface Conditions)	16.4	A16A-2A	0-0.5
AOCs 6, 21, 22, 23, 24, 25, and 26 (Floor Staining, Cracks and Deterioration)	180	SB-4A	0-0.5
AOC 27 (Manufacturing Facility Drainage)	84	A27-23A	0.5-1

(PAP-00092626, 30-32, 35, 50, 58, 64-65, 67, 69, 71)
* The soil boring logs in Appendix F of the 2006 RI Report show that most of the referenced sample locations in this table were covered with 4 to 21 inches of concrete. Only the boring A11-SS-1 at AOC 11 and A27-51 at AOC 13 were installed at the surface without first drilling through concrete (PAP-00092378, 402, 404, 430, 432, 439, 447, 470, 509).

According to an undated list titled Soil Delineation Status and provided as part of the "Changes Made by ISP (1992 to 2001)" document, mercury was present in samples of floor sweepings up to a maximum concentration of 19 parts per million (ppm), and mercury was present in concrete flooring to a maximum level of 4.5 ppm (PAS-00110304).

Historic Fill

The Allocation Team has determined that the facility site is not located on regional Historic Fill as designated by the NJDEP.[1]

NJDEP has established that historic fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 COCs: PAHs, lead, copper, and mercury.[2] Accordingly, NJDEP technical requirements for property containing Historic Fill requires sampling for the EPA Target Compound List for PAHs and Target Analyte List for metals, including lead, copper, mercury, and the OU2 PAH COCs.[3] PAHs, lead,

[1] *Digital Geodata Series, DGS04-7, Historic Fill for New Jersey*, https://www.nj.gov/dep/njgs/geodata/dgs04-7.htm, Quadrangle #41 (NJDEP map identifying locations of recognized historic fill).
[2] *Characterization of Ambient Levels of Selected Metals and cPAHs In New Jersey Soils* (2002) and *Characterization of Ambient Levels of Selected Metals and Other Analytes In New Jersey Soils* (1997), studies prepared for NJDEP, Division of Science and Research, by BEM Systems, Inc.
[3] New Jersey Department of Environmental Protection (NJDEP), *N.J.A.C. 7:26E Technical Requirements for Site Remediation,* Table 4-2, November 2009 [Note that Table 4-2 has been deleted from the current

copper, and mercury are recognized by NJDEP to be constituents of Historic Fill at varying levels, not atypically at or exceeding residential soil standards.[4]

The levels of PAHs, lead and mercury detected at the site in soils are presented in the table below (PAP-00092632, 72, 87-88).

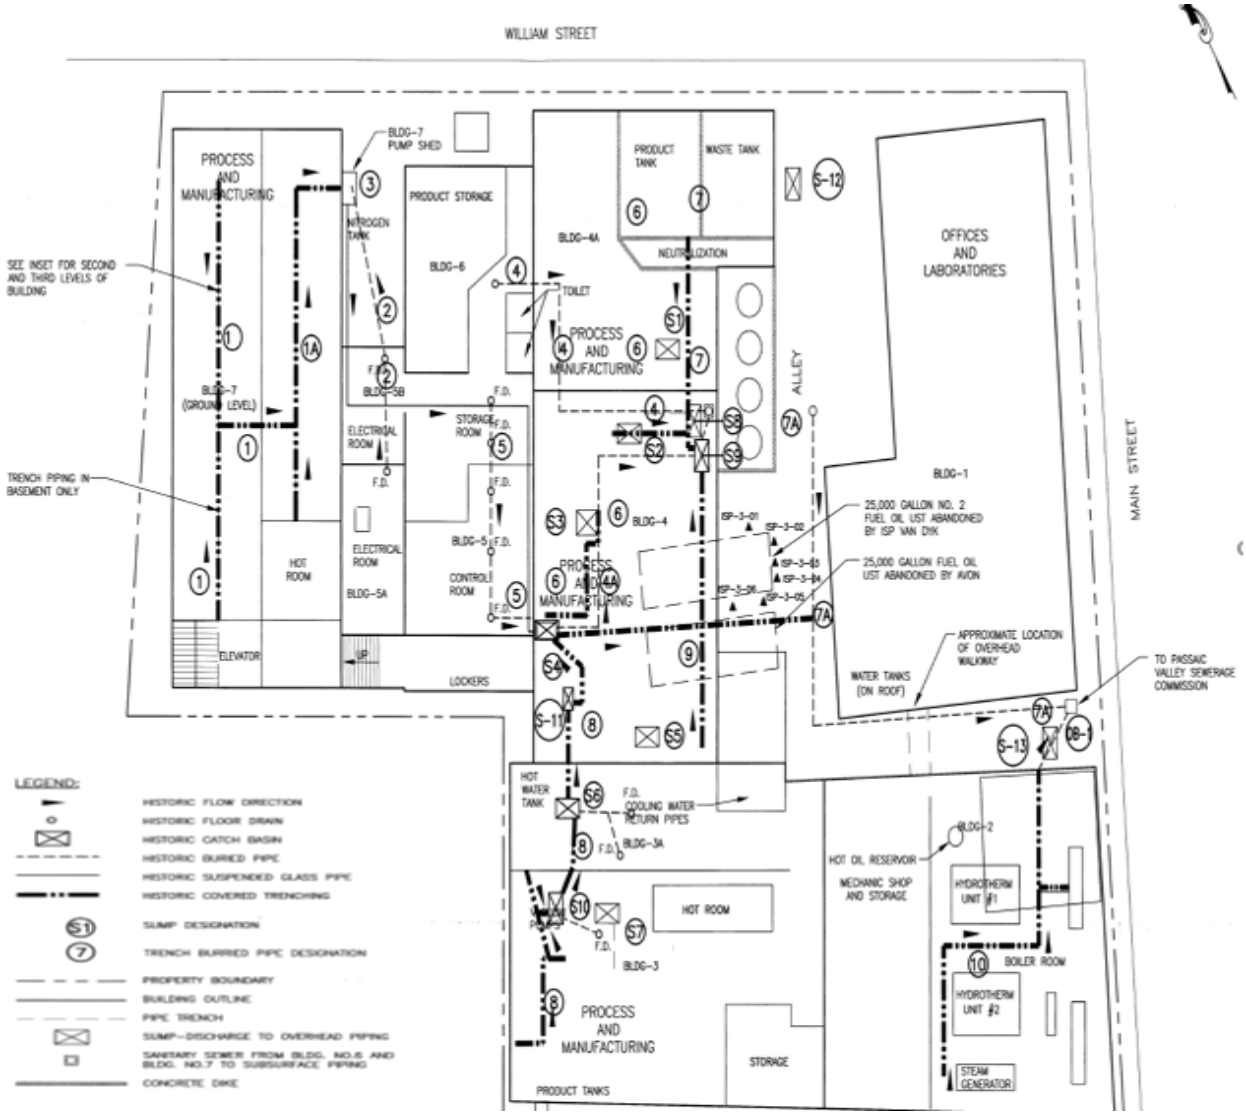
COCs Found in Onsite Soils	
COC	**Max Detected Concentration**
Lead	299 mg/kg
Mercury	180 mg/kg
Benzo(a)anthracene	8.05 mg/kg
Benzo(a)pyrene	7.64 mg/kg
Benzo(b)fluoranthene	5.80 mg/kg
Benzo(k)fluoranthene	5.56 mg/kg
Dibenzo(a,h)anthracene	1.58 mg/kg
Indeno(1,2,3-cd)pyrene	4.39 mg/kg

The 2008 Soils RAWP attributed the detections of PAHs in site soil to the presence of fill material used during construction and grading of the facility (PAP-00099895, 912).

5. COC Pathways

Sanitary Sewer

The 2001 Description of Activities stated that contact process wastewater was treated separately for both manufacturing buildings. Contact process wastewater generated in Building 7 was treated for pH if necessary in an available reactor prior to discharge. Wastewater generated in Buildings 3, 4, and 4A was treated by a neutralization system for pH prior to discharge into the sewer. The neutralization system in Building 4A was installed in 1995. In October 1997, an open trench drainage system in Buildings 4 and 4A was removed and collection sumps were installed throughout the buildings. The floors were pitched toward the sumps for proper drainage. Level switches triggered pumps which transferred the collected water to the overhead piping to the wastewater connection to the Passaic Valley Sewerage Commission (PVSC) (PAP-00094608-10).



In October 1999, the wastewater outfall system was modified to include additional monitoring equipment, interlocks, piping changes and a tank installation. All water leaving the plants and labs was monitored continuously for lower explosive limit (LEL) and pH (PAP-00094608-10). According to the 2002 Preliminary Assessment, process water from Buildings 3, 4, and 7 was pumped into a wastewater tank prior to discharging to the PVSC (PAP-00092166).

---

version of N.J.A.C. 7:26E (May 7, 2012) and the updated *Historic Fill Technical Guidance* (April 2013) as NJDEP believed that the tables list of historic fill constituents was too restrictive].

[4] NJDEP Table 4-2 (PAHs and lead) and a summary of NJDEP records regarding investigations of properties in the vicinity of the Passaic River recognized to be located in areas of Historic Fill indicate that the following average/maximum (mg/kg) contamination levels of OU2 COCs exist in area Historic Fill: PAHs (1.91/160), lead (574/10,000), copper (11.2/1,200), and mercury (0.21/3.7).

A map of the historical floor drains, catch basins, and trenches was provided in a letter to NJDEP dated February 25, 2005 (see below). This figure also shows that the site connects to the PVSC sewer under Main Street (PAP-00098699). ISP has submitted specific documentation that the company asserts confirms that there is no combined sewer overflow (CSO) in the vicinity of the Belleville Site. The Allocation Team will take this information into account in its review of relevant sewer systems (PAP-00095359)"

Direct Release

There is no information regarding direct releases in the available file material.

Spills

There is no information regarding COC spills in the available file material.

6. Regulatory History/Enforcement Actions

Inspections

According to the 2002 Preliminary Assessment, the property was inspected by a representative of the NJDEP on June 14, 2001. The NJDEP inspector noted several areas of stained floors, paving, and walls during the site inspection. The NJDEP inspector required that ISP identify each area, provide its location, identify the substances that were discharged to these areas, and determine whether the discharge had impacted the soil and/or groundwater beneath the subject property (PAP-00092135-36). It is unclear if COCs were associated with these areas.

Violations

As discussed in the 2002 Preliminary Assessment, the PVSC did not note any violations associated with COCs as of January 2, 2002 (PAP-00092176).

Permits

According to a 1999 Superior Court case between the PVSC and ISP (Docket No. C-210-99), the PVSC issued Sewer Connection Permit No. 01407090, with an effective date of July 14, 1997 and an expiration date of July 13, 2002 (PAP-00095324). The permit was not identified in the available records.

7. Response Actions

Characterization Activities

The following characterization activities have taken place at the facility:

- 2002 Preliminary Assessment, prepared by URS Corporation (PAP-00092119). *Baseline Ecological Evaluation for the ISP Chemicals Inc. Facility*, dated August 15, 2006, prepared by URS Corporation (PAP-00092964).
- 2006 RI Report prepared by URS Corporation (PAP-00092577).
- 2008 Soils RAWP, prepared by Geosyntec Consultants (PAP-00099868).
- 2011 RI/RA Progress Report, prepared by Geosyntec Consultants (PAP-00093871).

Soil

The 2002 Preliminary Assessment identified 14 AOCs at the site (PAP-00092136-37). Note that several of the AOCs were not attributed to ISP, and previous owner Avon Products, Inc. was identified as the responsible party. The 14 AOCs were as follows:

- AOC 1: Two 25,000-gallon Fuel Oil USTs Located in the Alleyway Between Buildings No. 1 and No. 4. The southern tank was stated to have leaked and been abandoned in place by previous site owner, Avon Products, Inc., in 1993. The northern tank was abandoned in place by ISP on January 16, 1999. The

tank was reportedly in good condition with no visibly-observable holes or cracks (PAP-00092137).

- AOC 2: Suspected 1,000-Gallon No. 2 Fuel Oil. This UST was determined not to exist (PAP-00092138).

- AOC 3: Exterior Stained Soil Areas Located at the Rear Portions of the Main Manufacturing Building. PCBs were detected at 1.9 ppm in soil, but Avon Products, Inc. was identified as the responsible party and excavated the soil (PAP-00092138-39).

- AOC 4: Main Manufacturing Building Alleyway Soil Contamination. Soil was collected from beneath the main manufacturing building alleyway in 1986. The PCB concentration at 0 to 2.0 ft bgs was 1,300 ppm and the PCB concentration at 6.0 to 8.0 ft bgs was 3.0 ppm (PAP-00092139).

- AOC 5: Drum Storage Areas. Raw and finished materials were stored in the covered outdoor storage area and hazardous waste for disposal was stored in the open outdoor storage area. The 2002 Preliminary Assessment stated there have been no reported spills in the area, the area is paved with asphalt, and no staining or other evidence of a release was observed during a site inspection (PAP-00092139-40).

- AOC 6: PCB Contaminated Building Interior Surfaces. PCBs were detected in chip samples collected from the ceilings, walls, and floors of the buildings in 1986 (PAP-00092140).

- AOC 7: PCB Soil Contamination Located Beneath the Boiler Room Floor. Soil sampling conducted beneath the floor of the boiler room revealed that PCB soil contamination was present at concentrations up to 10,000 ppm. Avon Products, Inc. was identified as the responsible party (PAP-00092140). As stated in the 1994 RI Report prepared by IT Corporation: "There were eight soil borings of the 20 which were advanced along the boiler room/property line perimeter, four each on the eastern and southern property lines… Analytical results of the PCB analysis of these soil samples state there is no surficial or deep PCB soil contamination extending beyond the facility boiler room/property." Total PCB concentrations collected at either one to three feet (four samples along eastern property line; paved surface) or zero to two feet (four samples along southern property line; unpaved surface) below grade, ranged from 0.018 mg/kg to 0.49 mg/kg. Total PCB concentrations in deeper soil samples ranged from not detected to 16 mg/kg (PAP-00101162).

- AOC 8: Former 1,000-Gallon No. 2 Fuel Oil UST. The former 1,000-gallon No. 2 fuel oil UST was located adjacent to the southwestern corner of the facility warehouse building adjacent to William Street. This UST was abandoned in place by ISP on February 23, 1999. The tank was reportedly in good condition with no visibly observable rust holes (PAP-00092141).

- AOC 9: Former 550-Gallon No. 2 Fuel Oil UST. This UST was located adjacent to the west side of the warehouse north of AOC 8. On September 30, 1998, this 550-gallon UST was excavated and removed (PAP-00092142).

- AOC 10: Groundwater Monitoring Well No. 2 (MW-2). A Classification Exception Area (CEA) was established for groundwater based on the presence of PCBs in samples collected from monitoring well MW-2. The NJDEP approved the CEA in a letter dated December 18, 1996 (PAP-00092142).

- AOC 11: Building No. 4 Vent Staining. Black staining from a vent pipe on the roof of Building No. 4 was observed on the roof, the side of the building, and on the landscape stone area below during an initial site inspection (PAP-00092185).

- AOC 12: Building No. 3 Storage Room Floor/wall Gap. An open trench between the wall and floor approximately four inches wide was observed at the eastern side of the room near Tank No. 455, and a one-inch gap between the wall and floor was observed at the southern side of the room. The trench was concrete-lined, but a small crack (approximately 0.1 inch in width) was observed between the wall and the bottom of the south trench. An oily absorbent boom was observed in the trench and the floor and walls appeared to be oil stained PAP-00092186).

- AOC 13: Building No. 7 Hot Room. A small area of deteriorated concrete with exposed soil below was noted in the hot room floor (PAP-00092186).

- AOC 14: Historic Filling Station. The portion of the property located to the north of William Street and at the northwest comer of the intersection of William and Main Streets was noted to be a filling station with two underground storage tanks in 1951 and 1961 Sanborn maps (PAP-00092186-87).

The AOCs relevant to ISP operations included the fuel oil USTs (AOC 1, 8, and 9), drum storage areas (AOC 5), staining on the facility buildings (AOCs 11 and 12), and deteriorated concrete (AOC 13) (PAP-00092137, 39-40, 42, 85-86).

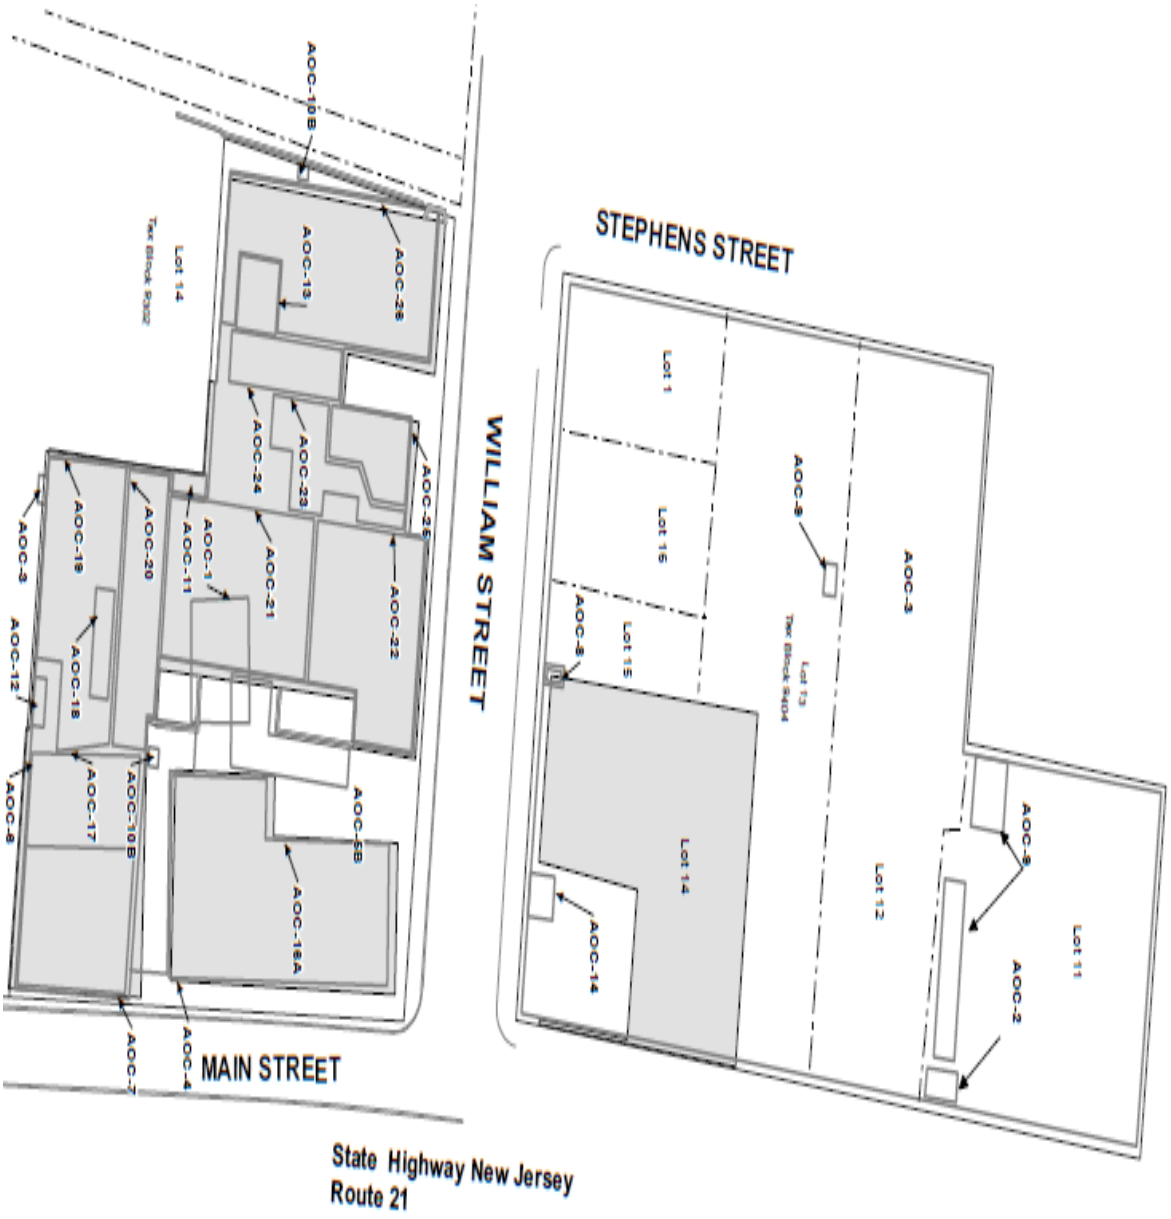
Additional AOCs were identified in the 2006 RI Report:

- AOC 15: 1993 Toluene Spill

- AOC 16/16A: Building No. 1 Elevator Hydraulic Fluid and Subsurface Conditions. A sample of oil from the elevator drip pan in Building No. 1 was reported in 1987 to have had a PCB concentration of 56 ppm, possibly from the elevator hydraulic oil itself.

- AOC 17: Staining Present on Floors and Walls in Building No. 2.

- AOC 18: Building No. 3 Hot Room. Heavy staining was noted to be present in four troughs.



- AOC 19: Open AST Area in Building No. 3. Thick oily sludge was noted to be present on the floor.
- AOC 20: Building No. 3A. Heavy staining was noted to be present on all surfaces. In addition, a floor drain exists near the hot water tank.
- AOC 21: Building No. 4. Heavy staining was noted to be present on the floor.
- AOC 22: Building 4A. Heavy staining was noted to be present on the floor.
- AOC 23: Staining Observed in The Hallway Between Building No.4 and Building No.7
- AOC 24: Building No. 5A and Building No. 5b: Heavy staining was noted to be present on the floor.
- AOC 25: Building No.6 AST Area. Heavy staining was noted to be present on the floor.
- AOC 26: Stained Surfaces in Building No. 7
- AOC 27: Manufacturing Facility Drainage (PAP-00092602-06)

Finally, AOCs 31, 32, and 33 were identified in the 2011 RI/RA Progress Report as follows (AOCs Nos. 29 and 30 were not used in the numbering scheme):

- AOC 31: Subject Property Located North of William Street
- AOC 32: Vapor Intrusion
- AOC 33: Baseline Ecological Evaluation (PAP-00093914)

The AOCs are identified on the following figure from the 2011 RI/RA Progress Report (PAP-00093923):

Diamond Alkali OU2 Allocation
ADR Confidential
Facility Data Report

The following figure shows the AOCs in more detail, including the locations of the former USTs, trenches, drains, and the building numbers (PAP-00098696):

PCBs, mercury, and PAHs were detected in soil at several AOCs. The 2008 Soils RAWP identified soils with PCB concentrations up to 15,800 mg/kg as being present at the site. The Soils RAWP stated that leaks and spills associated with a "Therminol" hot oil heating system used from 1965-1976 and a "significant release" from the north Hydrotherm boiler in the early 1970s were believed to be the source of the PCB-impacted soils below certain sections of the site. Mercury was detected at concentrations up to 180 mg/kg, and the mercury-impacted soils were attributed to a previous owner's hat manufacturing process that used mercury salts. In addition, this document attributed the concentrations of PAHs in site soil to the presence of fill material used during construction and grading of the facility (PAP-00099875, 881-2, 895, 912).

Remedial Activities

According to a letter from ISP to EPA, dated June 17, 2005, the NJDEP Environmental Cleanup Responsibility Act (ECRA) was initially triggered when Mallinckrodt Inc. obtained the property from Avon Capitol Corporation on May 3, 1986. Avon Capitol Corporation hired IT Corp. to delineate PCB contamination at the site, which was completed in 1995. On April 7, 1992, the NJDEP Industrial Site Recovery Act (ISRA) was triggered when ISP purchased the site from Mallinckrodt Inc. When ISP operations ceased in April 2001, ISRA was triggered for a third time. ISP entered into a remediation agreement with the NJDEP to combine the three ECRA/ISRA cases, to allow ISP to complete all of the Responsible Party ISRA obligations, and to comply with the TSCA PCB rules (PAS-00110585-86). The Remediation Agreement was signed by ISP on January 8, 2002 (PAS-00110301).

As documented in the 2008 Soils RAWP and 2011 RI/RA Progress Report, six AOCs have received no further action (NFA) approval from NJDEP (i.e., AOCs 2, 3, 5A, 8, 9, 15, and 31), eight were approved for no further investigation (i.e., AOCs 5A, 12, 18, 20, 23, 24, 25, 26) and five AOCs were not related to soil contamination or were due to an error in numbering (i.e., AOCs 10A, 10B, 28, 29, 30, 32) (PAP-00093886-90; PAP-00099889-90).

The 2008 Soils RAWP proposed to excavate all contaminated soils with PCB concentrations in excess of 100 mg/kg and implement engineering (i.e., a cap of at least 6 inches thick extending over the entire) and institutional controls (i.e., deed notice) to limit access and exposure to the contaminants remaining at the site (PAP-00099876-77).

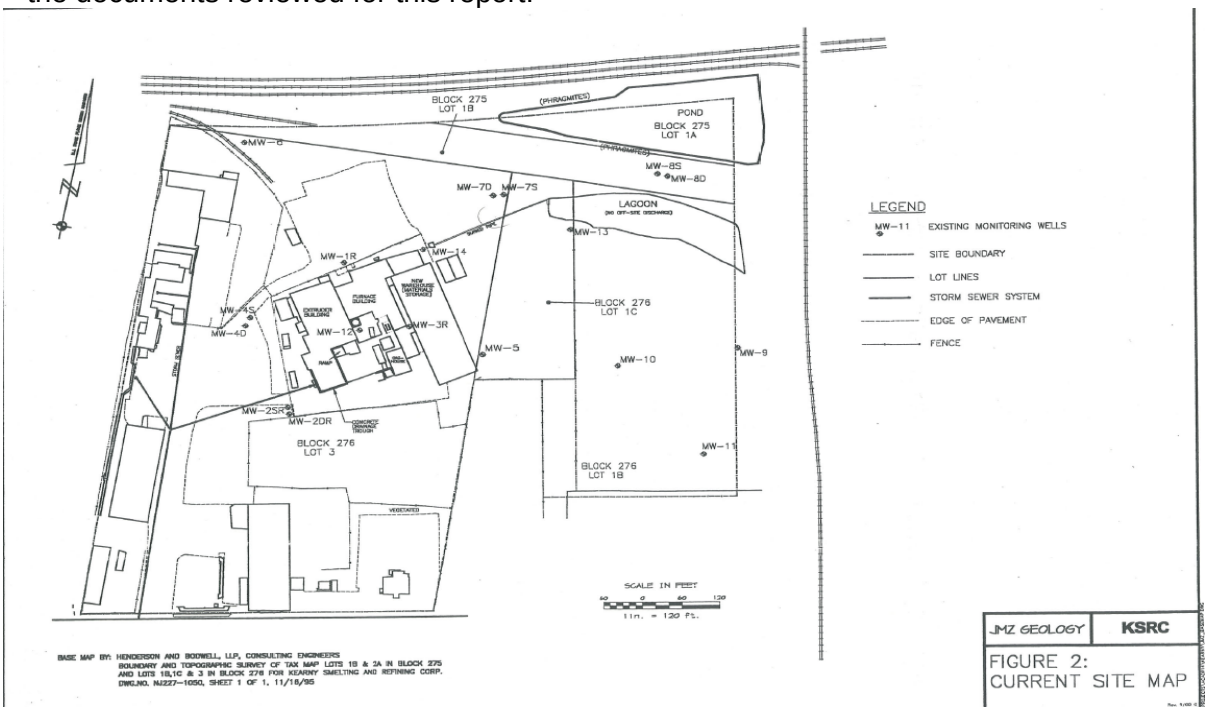
8. Summary of Asserted Defenses

No legal defenses were identified in the available file material.

Diamond Alkali OU2 Allocation
ADR Confidential
Facility Data Report

KEARNY SMELTING AND REFINING CORP

Facility Name, Address and Size: Kearny Smelting and Refining Corp. (KSRC), 936 Harrison Ave., Kearny, NJ,11.8 acres (PAP-00190121). The site is bounded to the north by the Erie-Lackawanna Railroad (originally the Newark and Hudson Railroad), to the east by the Delaware - Lackawanna and Western Railroad, to the south by Harrison Avenue and two industrial properties, and to the west by residential and industrial properties (PAP-00217329). According to the "Current Site Map" created by JMZ Geology, the site includes Block 275 Lots 1B and 2A and Block 276 Lots 1B, 1C, and 3 (PAP-00004657). See Site Map below.



The *Revised Phase II Remedial Investigation Workplan*, dated August 1996 (1996 Rev. Phase II RIWP) provided the following owners of the site:

Property	Acreage	Owner
Block 276 Lot 3	9.61	KRSC
Block 276 Lot 1C	0.594	Michel G Rothschild
Block 275 Lot 1B	0.893	M. Rothschild
Block 275 Lot 2A	0.675	M. Rothschild
Total acreage	11.772	

(PAS-00032551)

Note: Property conveyances were not available in the documents reviewed for this report to verify the ownership and acreage provided in the above table.

Information regarding the number of employees and hours worked was not available in the documents reviewed for this report.

Facility Data Report

1. **Business Type:** Casting and extrusion of brass and bronze

2. **Time Period of Ownership/Operations**

Operator: 1944 to Present
Owner: 1944 to Present
(PAP-00190066)

The 1996 Rev. Phase II RIWP listed the following businesses operating on the site:

Business	Nature of Operations
Kearny Smelting	casting and extrusion of brass and bronze
D R Tweed	repair and service of lift trucks
Mac Metals Inc	sales/showroom for architectural metals
West Hudson Auto Body	auto body repair
Athens Diner	restaurant
Delbros Inc	sanitation truck storage
M&G Tool and Die Co	machine shop

(PAS-00032551)

Note: The location of the businesses operating on the site was not provided in the 1996 Rev. Phase II RIWP and no other documents were available to review for verification.

3. **Operational History/COC Use and Presence at the Facility**

KSRC operated a non-ferrous metals manufacturing facility from approximately 1945 until 1975. During the smelting process, KSRC melted approximately 50,000 to 60,000 pounds of scrap metal per day containing copper, tin and/or zinc alloys in a rotary smelting furnace. This process resulted in discharges to a lagoon at the facility (PAS-00003777-78).

A 1986 US EPA Potential Hazardous Waste Site Preliminary Assessment states that substances present at the Kearny Smelting facility included zinc oxide, copper, tin, lead, iron, nickel, and zinc, and that NJDEP alleged that wastewater originating onsite has been discharged to the ground and surface waters (PAP-00004622-24).
According to the 2018 Phase I Environmental Site Assessment, dated April 13, 2018 (2018 Phase I ESA), the site consists “of a 16 acre parcel of land improved with three buildings that are occupied by Kearny Smelting & Refining, two buildings occupied by Mac Metals and three vacant buildings being prepared for demolition. The majority of the existing structures on the site were constructed in the 1940's with the addition of the KSR inventory storage warehouse which was constructed in 2006. KSR's operations include manufacturing custom bronze, brass and nickel silver profiles, sections and extrusions. Mac Metals operations include sales/showroom of architectural metals for KSR. The three vacant buildings are unrelated to KSR's operations” (PAP-00431830).

According to the 2018 Phase I ESA, the following hazardous substances and petroleum products were observed during the site inspection:

Summary

Material	Quantity	Use	Comments
Various Cleaners and Lubricants	Small quantities in plastic bottles and metal spray cans	General Maintenance of industrial operations equipment	Various cleaners and lubricants were observed throughout the Site. All of the materials observed appeared to be properly labeled and stored with no significant evidence of leaks or spills apparent. These materials do not comprise a REC to the Site.
Used Hydraulic Oil	55-gallon drums	Maintenance of industrial operations equipment	The material was observed to be stored inside drums (see subsequent section) and properly labeled.
Hydraulic Oil	55-gallon drums	Maintenance of industrial operations equipment	The material was observed to be stored inside drums (see subsequent section) and properly labeled.
Waste Oil	55-gallon drums	General Maintenance of warehouse equipment	Waste oil is temporarily collected in a series of portable waste oil cans. Waste oil is then transferred to waste oil 55-gallon drums present on the Site (see subsequent sections). Waste oil is reportedly periodically collected by a licensed waste hauler.
Motor Oil	Small quantities in plastic bottles	General Maintenance of warehouse equipment	Various motor oil was observed throughout the Site. All of the materials observed appeared to be properly labeled and stored with no significant evidence of leaks or spills apparent. These materials do not comprise a REC to the Site.
Diesel Fuel	55-gallon drums	Warehouse equipment	The material was observed to be stored inside a drum (see subsequent section) and properly labeled.

(PAP-00431881)

4. Identified COCs

- PCBs (detected)
- PAHs (used, detected)
- Copper (used, detected)
- Lead (used, detected)
- Mercury (detected)

PCBs

The *Phase II Remedial Investigation Workplan,* dated October 1995 (1995 RIWP) states that based on previous investigations, onsite soils have been determined to be adversely impacted by PCBs through both current and historical facility processes and the historical filling of the site (PAP-00190077).

According to the 1996 Rev. Phase II RIWP, the following results for PCBs were reported above the NJDEP Non-residential Direct Contact Soil Cleanup Criteria from the March 1993 soil sampling event:

March 1993 PCB Soil Sampling			
COC	**Sample No.**	**Depth [below ground surface (bgs)]**	**Result (parts per million (ppm)]**
Aroclor 1254	MW1S	8.5 to 9 feet	14.0
Aroclor 1254	SB 1B	0 to 0.5 feet	11.0
Aroclor 1248	SB 12	0 to 0.5 feet	7.2

(PAS-00032615, 17)

PAHs

The 1995 RIWP states that based on previous investigations, onsite soils have been determined to be adversely impacted by metals and PAHs through both current and historical facility processes and the historical filling of the site (PAP-00190077).

According to the 1996 Rev. Phase II RIWP, the following results for PAHs were reported above the NJDEP Non-residential Direct Contact Soil Cleanup Criteria from the March 1993 soil sampling event:

Benzo(a)anthracene NJDEP Non-residential Direct Contact Soil Cleanup Criteria = 4.0 ppm		
Sample No.	**Depth (bgs)**	**Results (ppm)**
SB 10	0 to 0.5 feet	8.6
MW4S	10 to 10.5 feet	4.6
MW7SA	0 to 0.5 feet	3.9

(PAS-00032616, 18, 19)

Benzo(a)pyrene NJDEP Non-residential Direct Contact Soil Cleanup Criteria = 0.66 ppm		
Sample No.	**Depth (bgs)**	**Results (ppm)**
SB 1A	0 to 0.5 feet	2.4
SB 1B	0 to 0.5 feet	3.4
SB 3	0 to 0.5 feet	1.0
SB 5A	0 to 0.5 feet	0.750
SB 7A	0 to 0.5 feet	0.820
SB 8	0 to 0.5 feet	1.2
SB 10	0 to 0.5 feet	7.2
SB 12	0 to 0.5 feet	1.5
SB 13	0 to 0.5 feet	1.8
SB 16	10.5 to 11 feet	0.670
MW2S	8 to 8.5 feet	2.0
MW3S	0 to 0.5 feet	0.860
MW4S	10 to 10.5 feet	3.3
Sample No.	**Depth (bgs)**	**Results (ppm)**
MW5S	10 to 10.5 feet	1.3
MW7SA	0 to 0.5 feet	3.9
MW7SB	0 to 0.5 feet	1.1
MW7D	0 to 0.5 feet	2.7

(PAS-00032615-19)

Benzo(b)fluoranthene NJDEP Non-residential Direct Contact Soil Cleanup Criteria = Not Established (NE)		
Sample No.	**Depth (bgs)**	**Results (ppm)**
SB 10	0 to 5feet	6.2
MW7SA	0 to 5 feet	5.5

(PAS-00032616, 19)

Benzo(k)fluoranthene NJDEP Non-residential Direct Contact Soil Cleanup Criteria = NE		
Sample No.	**Depth (bgs)**	**Results (ppm)**
SB 10	0 to 5 feet	6.6

(PAS-00032616)

A March 4, 2011, Deed Notice states that engineering controls have been implemented to prevent direct contact to underlying PAHs and metals in soils attributed to the underlying slag and historic fill materials across the site (PAP-00190095; PAP-00190123).

Mercury

According to the 1991 Administrative Consent Order (ACO), on September 24, 1986, NJDEP conducted sampling of the facility site. On October 30, 1986, soil sample results revealed that the onsite soils were contaminated with 10 ppm of mercury (PAS-00003779). Note: The 1991 ACO did not provide further details regarding depth and location of the samples. The 1986 NJDEP sampling report was not available for review for this report. Note: The copy of the 1991 ACO provided for this report was an incomplete copy.

According to the 1996 Rev. Phase II RIWP, mercury was not detected above the NJDEP Non-residential Direct Contact Soil Cleanup Criteria (i.e., 270 ppm) during the March 1993 soil sampling event (PAS-00032615-19).

Copper

The October 30, 1986, soil sample results revealed that the onsite soils were contaminated with 17,200 ppm of copper (PAS-00003779). Note: The 1991 ACO did not provide further details regarding depth and location of the samples. The 1986 NJDEP sampling report was not available for review for this report. Note: The copy of the 1991 ACO provided for this report was an incomplete copy.

According to the 1996 Rev. Phase II RIWP, the following results for copper were reported above the NJDEP Non-residential Direct Contact Soil Cleanup Criteria (i.e., 600 ppm) from the March 1993 soil sampling event:

Copper NJDEP Non-residential Direct Contact Soil Cleanup Criteria = 600 ppm		
Sample No.	**Depth (bgs)**	**Results (ppm)**
SB 1A	0 to 0.5 feet	809
SB 3	0 to 0.5 feet	5,120
SB 4	0 to 0.5 feet	7,160
SB 5A	0 to 0.5 feet	926
SB 5B	0 to 0.5 feet	2,170
SB 6	0 to 0.5 feet	13,200
SB 7A	0 to 0.5 feet	1,560
SB 8	0 to 0.5 feet	26,600
SB 9	0 to 0.5 feet	4,420
SB 10	0 to 0.5 feet	10,800
SB 11	0 to 0.5 feet	9,780
SB 12	0 to 0.5 feet	5,640
SB 14	10 to 10.5 feet	1,210
SB 15	11.5 to 12 feet	739
MW3S	0 to 0.5 feet	4,660
MW4S	0 to 0.5 feet	4,070
MW4D	0 to 0.5 feet	4,220
MW5S	0 to 0.5 feet	19,300
MW5S	10 to 10.5 feet	3,180
MW6S	0 to 0.5 feet	24,100
MW7SA	0 to 0.5 feet	1,930
MW7SB	0 to 0.5 feet	1,130
MW7S	8.5 to 9 feet	2,130
MW7D	0 to 0.5 feet	8,710
MW7D	6 to 6.5 feet	2,490

(PAS-00032615-19)

Lead

The October 30, 1986, soil sample results revealed that the onsite soils were contaminated with 15,300 ppm of lead and other metals (PAS-00003779). Note: The 1991 ACO did not provide further details regarding depth and location of the samples. The 1986 NJDEP sampling report was not available for review for this report. Note: The copy of the 1991 ACO provided for this report was an incomplete copy.

According to the 1996 Rev. Phase II RIWP, the following results for lead were reported above the NJDEP Non-residential Direct Contact Soil Cleanup Criteria (i.e., 600 ppm) from the March 1993 soil sampling event:

Lead NJDEP Non-residential Direct Contact Soil Cleanup Criteria = 600 ppm		
Sample No.	**Depth (bgs)**	**Results (ppm)**
SB 3	0 to 0.5 feet	1,820
SB 4	0 to 0.5 feet	1,070
SB 5B	0 to 0.5 feet	3,280
SB 6	0 to 0.5 feet	3,420
SB 9	0 to 0.5 feet	942
SB 10	0 to 0.5 feet	2,140
SB 11	0 to 0.5 feet	2,000
SB 12	0 to 0.5 feet	2,620
MW2S	0 to 0.5 feet	787
MW2S	8 to 8.5 feet	2,610
MW3S	0 to 0.5 feet	2,750
MW4S	0 to 0.5 feet	1,180
MW4D	0 to 0.5 feet	1,240
MW5S	0 to 0.5 feet	3,570
MW5S	10 to 10.5 feet	1,560
MW6S	0 to 0.5 feet	2,520
MW7SA	0 to 0.5 feet	671
MW7SB	0 to 0.5 feet	1,170
MW7D	0 to 0.5 feet	2,500
MW7D	6 to 6.5 feet	896

(PAS-00032615-19)

Historic Fill

The Allocation Team has determined that the facility site is located on regional Historic Fill as designated by the NJDEP.[1]

NJDEP has established that historic fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 COCs: PAHs, lead, copper, and mercury.[2] Accordingly, NJDEP technical requirements for property containing Historic Fill requires sampling for the EPA Target Compound List for PAHs and Target Analyte List for metals, including lead, copper, mercury, and the OU2 PAH COCs.[3] PAHs,

[1] *Digital Geodata Series, DGS04-7, Historic Fill for New Jersey*, https://www.nj.gov/dep/njgs/geodata/dgs04-7.htm, Quadrangle #52 & #53 (NJDEP map identifying locations of recognized historic fill).
[2] *Characterization of Ambient Levels of Selected Metals and cPAHs In New Jersey Soils* (2002) and *Characterization of Ambient Levels of Selected Metals and Other Analytes In New Jersey Soils* (1997), studies prepared for NJDEP, Division of Science and Research, by BEM Systems, Inc.
[3] New Jersey Department of Environmental Protection (NJDEP), *N.J.A.C. 7:26E Technical Requirements for Site Remediation,* Table 4-2, November 2009 [Note that Table 4-2 has been deleted from the current version of N.J.A.C. 7:26E (May 7, 2012) and the updated *Historic Fill Technical Guidance* (April 2013) as NJDEP believed that the tables list of historic fill constituents was too restrictive].

lead, copper, and mercury are recognized by NJDEP to be constituents of Historic Fill at varying levels, not atypically at or exceeding residential soil standards.[4]

The levels of PAHs, copper, lead and mercury detected at the site in soils are presented in the table below.

The following table shows the 1993 results from soil sampling (PAS-00032615-19):

COCs Found in Onsite Soils	
COC	**Max Detected Concentration**
Lead	3,570 mg/kg
Copper	26,660mg/kg
Mercury	5.02 mg/kg
Benzo(a)anthracene	8.6 mg/kg
Benzo(a)pyrene	7.2 mg/kg
Benzo(b)fluoranthene	6.2 mg/kg
Benzo(k)fluoranthene	6.6 mg/kg
Dibenzo(a,h)anthracene	0.47 mg/kg
Indeno(1,2,3-cd)pyrene	2.7 mg/kg

According to the 1996 Rev. Phase II RIWP, the area in which the site lies was originally marsh land that was reclaimed by filling for the express purpose of industrial development (PAS-00032552). Based on the "historical maps and aerial photos reviewed the majority of the site was filled between 1908 and 1938. Portions of the site along Harrison Ave were filled as early as the 1890s. By 1938 the site filling was completed, and the surface of the site was similar to its present condition….he southern end of the lagoon has been filled over the years reducing the lagoon to its current extent" (PAS-00032553-54).

5. COC Pathways

Sanitary Sewer

According to the *Analysis and Evaluation of Potential Discharges to the Passaic River* report, dated August 2010 (2010 Report), with the exception of the furnace building, all of the buildings on-site were connected to the municipal sanitary sewer system from the time of their construction. All of these buildings discharged sanitary waste only; none had process or industrial discharges. In 1996, the furnace building sanitary discharges were connected to the municipal sanitary sewer system. Verbal approval to connect the plant washrooms with the municipal sewer was given to KSRC by Mr. Mike Petriello, the plumbing inspector with the Town of Kearny construction code office (PAP-00004545).

[4] NJDEP Table 4-2 (PAHs and lead) and a summary of NJDEP records regarding investigations of properties in the vicinity of the Passaic River recognized to be located in areas of Historic Fill indicate that the following average/maximum (mg/kg) contamination levels of OU2 COCs exist in area Historic Fill: PAHs (1.91/160), lead (574/10,000), copper (11.2/1,200), and mercury (0.21/3.7).

Storm Sewer

A September 22, 1989, letter from NJDEP states that the stormwater runoff from the facility was discharging to the surface waters of the state via a newly installed storm drain and sewer (PAP-00004631).

According to the 2010 Report, KSRC was issued a Stormwater Discharge Permit (No. NJ0120073) on May 28, 2001 (effective date: August 1, 2001) (PAP-00004546). There are two stormwater discharge points on the site: DSN-001A is an on-site discharge of stormwater runoff to the lagoon; DSN-002A is a discharge to the municipal storm sewer on Harrison Ave. The Harrison Avenue storm sewer discharges to the Passaic River. DSN-002A is part of an on-site storm sewer which drains the western portion of the site. As such, it receives runoff from building roofs and paved surfaces only. In all of the stormwater discharge monitoring samples collected from DSN-002A since the Permit was issued, the concentrations of all the metals were below the NJ surface water quality standards. Based on the discharge monitoring analytical data, there has been no discharge of contaminants at concentrations exceeding the surface water quality standards to the municipal storm sewer system (PAP-00004546).

According to the 2010 Report, historically, the KSRC lagoon was used as a settling pond for acetylene manufacturing waste water from the S.O.S. Gases facility located adjacent to KSRC on Harrison Avenue. In addition, the lagoon supplied both contact and non-contact cooling water to the KSRC plant. The lagoon also received discharges from the KSRC quality control laboratory. All of these discharges were ceased in 1995; there were no process-related discharges to the lagoon at the time of the report. Although historic process-related discharges to the lagoon did result in contamination of the lagoon water and sediment, no off-site migration or discharge of water from the lagoon occurred because there is no surface water pathway to the surrounding environment (PAP-00004536).

The 2010 Report states that since 2001, on-site groundwater concentrations of cadmium, lead, and zinc continued to decrease; contaminants from off-site upgradient sources continued to migrate onto the site, but due to attenuation are reduced to concentrations below the GWQS on-site; and there has been no migration of contaminants from KSRC to the surrounding area (PAP-00004544).

The 2010 Report concludes that KSRC's process-generated contaminants remain on-site, and do not migrate off-site via groundwater, surface water, movement of soil, or discharges to the municipal sewer systems (PAP-00004533).

Direct Release

According to the 1995 RIWP, there has been filling at the facility related to the construction of railroads located near the northern border of the facility consisting of earth materials mixed with coal combustion ash and cinders. The report also states that an 1871 railroad map shows a number of man-made drainage ditches in the area then occupied by the smelter building and the lagoon. The ditches are noted not to have crossed Harrison Ave, but appear to have drained to Frank Creek approximately 1,000 feet to the east of the site. By 1896, these ditches are no longer present and the marsh

line had moved eastward from its 1839 location. In addition, the construction of the DL&W embankment created two ponded areas—one of which was the KSRC lagoon. A 1938 Map showed that the entire area had been filled by that time with the exception of the lagoon and that the lagoon was landlocked (PAP-00190059-60). Logs from soil borings and monitoring wells stated that the fill material was heterogeneous and that the most common materials found in the fill were brick, concrete, asphalt, wood and glass (PAP-00190060).

The 1995 RIWP states that the KSRC lagoon was used historically to supply both contact and non-contact cooling water to the plant. Cooling water was circulated through the systems requiring cooling and discharged to the lagoon. In addition, the lagoon received discharges from a small quality control laboratory located in the northeast corner of the plant, and from the billet casting pit (PAP-00190078).

A March 10, 1998, letter from JMZ Geology to NJDEP states that the discharge of contact cooling water from the ingot conveyor pit to the lagoon located to the northeast of the plant was ceased in 1995. It also notes that non-contact cooling water from the extrusion line heat exchanger, formerly discharged to the lagoon, was currently being supplied by a closed loop system with water from the contact cooling water holding tank and there were no longer any discharges to either surface or groundwater (PAP-00004665).

A July 10, 1991, letter to NJDEP from KSRC counsel states that he had personally inspected the facility and it was not draining into Frank's Creek and ultimately the Passaic River, as the facility does not border Frank's Creek. It notes that the lagoon on site is completely landlocked (PAP-00004634).

Spills

On October 23, 1987, the Hudson Regional Health Commission sent KRSC a Notice of Violation for a discharge of a hazardous substance (No. 4 Fuel Oil). The oil leak was from the pipes in the pump house which caused approximately 100 to 150 gallons of No. 4 Fuel Oil to spill to the ground (PAS-00032753-55). See further discussion in Section 6 - Regulatory History/ Enforcement Actions and Section 7 - Remedial Activities.

Groundwater

According to the 2010 Report the following five potential discharges to groundwater were formerly present at the KSRC:

<u>Septic Systems</u>

The two septic systems were hooked up to the furnace building and discharged directly to groundwater. One of the septic systems was located to the north of the building and served the office lavatory; the second was located near the southeast corner of the building and served the employee shower room.

Laboratory Sink Discharge

The sink in the facility QA laboratory originally discharged small amounts of spent acids and wash water to the lagoon. In 1995, the lab sink was reconfigured to receive only wash water and condensate from lab equipment and was connected to the office septic system.

Non-Contact Cooling Water

Non-contact cooling water from the extrusion line heat exchanger was also formerly discharged to the lagoon. This practice was also ceased in 1995. The non-contact cooling water is now supplied by a closed loop system with water from the cooling water holding tank. Make-up water is obtained from municipal supply.

Contact Cooling Water

Contact cooling water from the ingot conveyor pit was also formerly discharged to the lagoon. This discharge was ceased in 1995 when new cooling water systems were put into operation. At that time, contact cooling water was pumped to a cooling tower and holding tank located outside of the south wall of the furnace building. Make-up water was obtained from municipal supply. Therefore, there have been no discharges of contact cooling water from that date. In March 2000, ingot manufacturing was ceased and the rotary furnace was taken out of service. The use of contact cooling water ceased at that time.

Exposure of Process Raw Materials and Wastes at the Site Surface

Process raw materials were formerly stored uncovered on gravel paved areas to the south and east of the furnace building. Zinc oxide, a by-product of the ingot manufacturing process, was collected in a baghouse and stored in a shed, both of which were also located to the south of the furnace building. Slag, the waste material of the ingot manufacturing process, was cooled and subsequently crushed in a gravel-paved area to the southeast of the furnace building. In all of these areas, the potential existed for process contaminants to migrate to groundwater through surface water infiltration (PAP-00004536-39).

6. Regulatory History/Enforcement Actions

Permits

KSRC was issued a Stormwater Discharge Permit (No. NJ0120073) on May 28, 2001 (effective date: August 1, 2001). One of the two stormwater discharge points was to the Passaic River (PAP-00004546).

A Soil Remediation Action Permit (RPC 000001) was issued to KSRC on May 16, 2011. The permit required monitoring and maintenance pursuant to Exhibit C of the attached Deed Notice. In addition, it required periodic inspections of any excavations or disturbances that resulted in unacceptable exposure of the soil contamination (PAP-00190090-91).

Inspections/Violations

An inspection conducted at KSRC in January 1984 observed that there were numerous empty and damaged drums stored in the rear of the property. In addition, wastewater was being discharged into the surface or groundwater of the state including overflow from the cooling tower and settling tanks and a surface impoundment used to collect wastewater discharged from the facility. The facility did not have an NJPDES permit at the time (PAS-00003772-73).

On April 14, 1986, NJDEP conducted an inspection of the facility which revealed the mismanagement of hazardous waste and/or solid waste including mounds of incinerator ash, hundreds of metal drums, and transformers on the eastern side of the building, as well as poor housekeeping throughout the site (PAS-00003779).

On October 23, 1987, the facility was issued a Notice of Violation from the Hudson Regional Health Commission for discharge of a hazardous substance (No. 4 oil) and discharge of hazardous substances lead and zinc into surface water (lagoon) (PAP-00004626). A December 16, 1987 letter to the facility from NJDEP states that the facility had been inspected on October 27 and November 5 and that wastewater originating from contact and non-contact cooling water, contaminated storm water runoff, laboratory waste, and a venture air pollution scrubber device was being discharged to an on-site drainage ditch and surface impoundment. The wastewater was noted to ultimately discharge to the groundwater of the State (PAP-00004628).

On December 3, 1990, an investigation at the facility was conducted by NJDEP and the New Jersey State Police. Sampling conducted at this time revealed the presence of zinc, lead and cyanide in the lagoon. The Department maintained that the zinc and lead were the result of a leaking scrubbing device (PAS-00003781).

On October 11, 1991 KSRC entered into an ACO to address the violations that had occurred throughout the years of operation. KSRC was ordered to conduct a Remedial Investigation and Feasibility Study to determine the nature and extent of the problem presented by the discharging of pollutants and hazardous substances at and around the site and the mismanagement of wastes (PAS-00003777-81). Note: The copy of the 1991 ACO provided for this report was an incomplete copy.

An Investigation Report dated December 27, 1994, states that the facility had not implemented best management practices (BMPs) for its General Stormwater Permit. Raw material, scrap, product, slag, and waste was still exposed to stormwater. A bypass line from the contact cooling pit was eventually discharging to the storm sewer. The findings note that the facility was no longer using its lagoon for water for contact cooling water for the ingot furnaces and molds (PAS-00003766).

A July 7, 2010, NJDEP Notice of Deficiency states that concentrations of lead, cadmium and zinc were consistently well above the GWQS in eight sampling episodes. It notes that the Department recognized that groundwater contamination at MW-9 was representative of background contamination levels, but since contaminant levels for cadmium and lead at MW-13 were greater than the levels measured at MW-9, they

considered that an onsite source (lagoon) had been contributing to a portion of the groundwater contamination detected beneath the KSRC facility (PAP-00004672-73).

According to the 2018 Phase I ESA, on October 12, 2012, a site-wide, restricted use Response Action Outcome (RAO) letter was issued for the KSR site. The RAO includes Block 275, Lots 1B and 2A and Block 276, Lots 1B, 1C and 3 (PAP-00431839). Note: The 2012 RAO was not provided for this review.

As part of the 2018 Phase I ESA, site observations were conducted in order to obtain information indicating the likelihood of Recognized Environmental Conditions (RECs) to be present at the site. RECs are defined in the ASTM Standard Practice E 1527-13 as the presence or likely presence of any hazardous substances or petroleum products in, on, or at a property: (1) due to release to the environment; (2) under conditions indicative of a release to the environment; or (3) under conditions that pose a material threat of a future release to the environment. The following were determined as RECs:

- Two Abandoned in Place Underground Storage Tanks (USTs)
- Former Rail Line Spur
- Former Solvent Aboveground Storage Tanks (ASTs)
- Former Auto Junk Yard
- Vinnie's Sunoco, including the following:
    - Soil and groundwater contamination associated with previously removed gasoline USTs
    - Groundwater contamination associated with previously removed 5,000-gallon No. 2 fuel oil or diesel fuel UST
    - Suspected offsite groundwater plume migration onto subject site

(PAP-00431830)

The following table summarizes the recommendations reached during the 2018 Phase I ESA:

REC/BER	Recommended Action
Filled in Place USTs	Peak recommends site investigation surrounding abandoned in place USTs
Kearny Smelting & Refining Corp (KSR)	Peak recommends the continued monitoring, maintenance, and evaluation for compliance and effectiveness of the CEA institutional control and the filing of Remedial Action Protectiveness/ Biennial Certification Form (Groundwater) in accordance with NJDEP regulations
Vinnie's Sunoco	Peak recommends additional soil and groundwater investigations for impacts associated with Site operations, as well as, potential migration of contaminated groundwater from an offsite source
Two Abandoned in Place USTs	Peak recommends a Phase II site investigation to evaluate potential impacts associated with this REC.

REC/BER	Recommended Action
Former Rail Line Spur	Peak recommends a Phase II site investigation to evaluate potential impacts associated with this REC.
Former Solvent ASTs	Peak recommends a Phase II site investigation to evaluate potential impacts associated with this REC.
Former Auto Junk Yard	Peak recommends a Phase II site investigation to evaluate potential impacts associated with this REC.
Potential Heating Oil USTs Associated with Former Structures	Peak recommends a geophysical survey in the areas of the former buildings to investigate for obvious evidence of USTs or excavation areas from former USTs

(PAP-00431840-41)

7. Response Actions

Characterization Activities

The following characterization activities have taken place at the facility:

- *Draft Remedial Investigation Report* dated November 1993 (PAS-00003790)
- *Phase II RI Workplan* dated October 1995 (PAP-00190051)
- *Revised Phase II RI Workplan* dated August 1996 (PAS-00032543)
- *Phase I Environmental Site Assessment* dated April 13, 2018 (PAP-00431824)

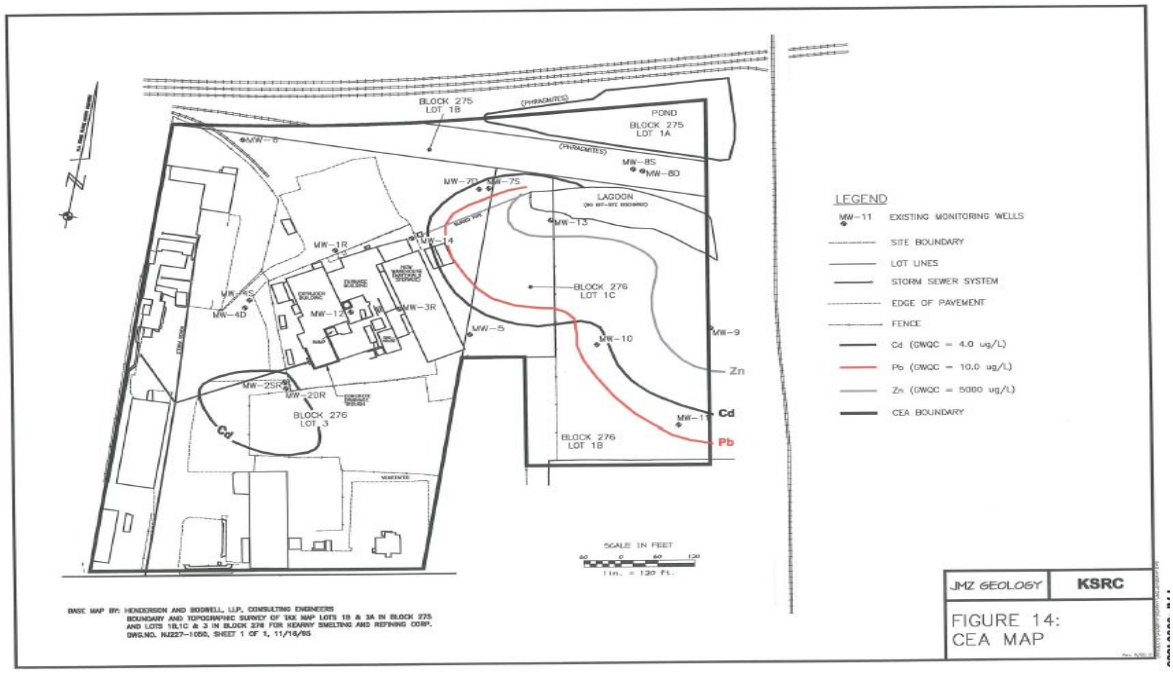
The 1993 *Draft Remedial Investigation Report* (RIR) (1993 Draft RIR) states that soil analytical data demonstrated that copper and other metals were not in compliance with current soil cleanup criteria and lead was detected in one well. However, it notes that after 50 years of operation, the impact of the on-site metal contamination in the soils is insignificant in relation to the groundwater and surface water qualities (PAS-00003796). It also states that the water in the lagoon was likely adversely impacting the groundwater quality in the shallow perched zone surrounding the lagoon (PAS-00003799). Note: The pdf of the 1993 Draft RIR was an incomplete version of the report. Neither a complete copy of the Draft nor the Final RIR was available for review for this report.

The 1995 RIWP, states that based on previous investigations the following conclusions can be drawn:

- Site soils have been adversely impacted by metals, PAHs and PCBs through both current and historical on-site processes and the historical filling of the site.

- In general, historical fill and process related soil contamination are indistinguishable due to the presence of similar constituents.
- Lagoon sediments contain contaminants that are derived from run-off, KSRC's processes, and sources unrelated to KSRC.

- The shallow and deep groundwater zones are in communication and both have been contaminated with lead and other metals.



- Discharges to the septic tanks and the lagoon have contributed to shallow groundwater contamination.

- Shallow groundwater flow is currently dominated by a recharge area located beneath the smelter building. (PAP-00190077)

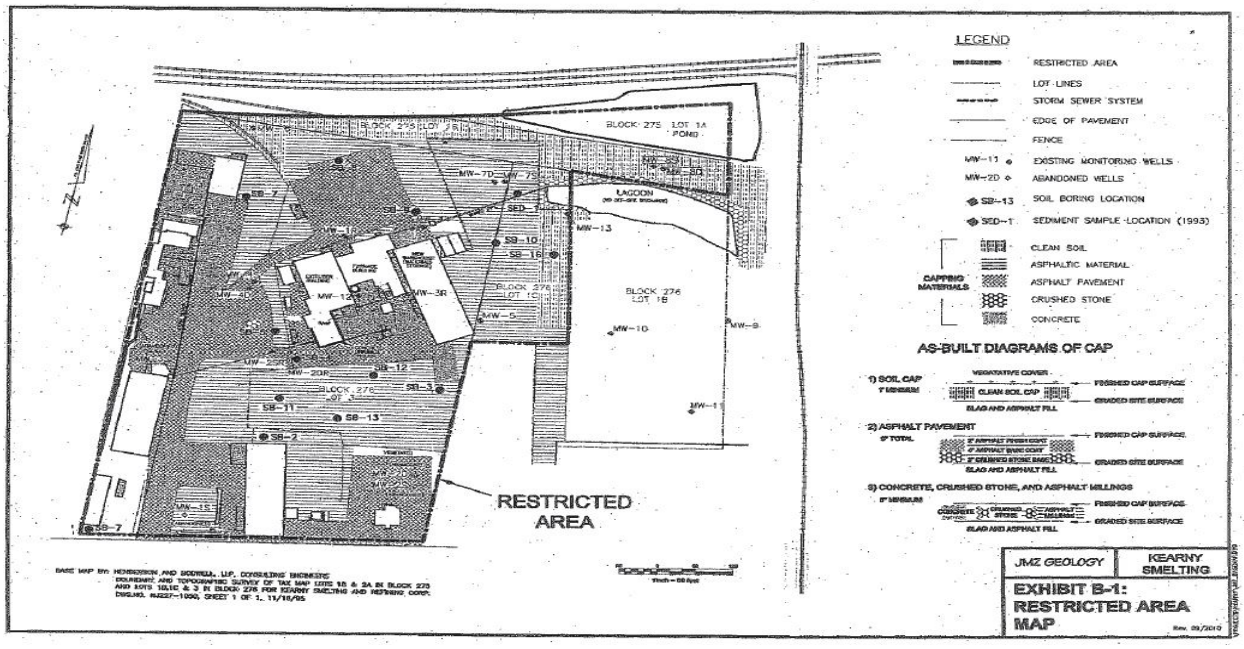
KSRC submitted the 1996 Rev. Phase II RIWP, to address comments received from NJDEP regarding the 1995 RIWP. The purpose of this 1996 Rev. Phase II RIWP was to obtain additional environmental quality information and to complete the characterization of the site (PAS-00032549).

In the Justification for Recommendation of No Further Action letter dated August 3, 2009 (2009 Letter), it is stated that a RAW/CEA, was submitted to NJDEP on September 29, 2000. The RAW/CEA was focused on the use of monitored natural attenuation for those groundwater contaminants "which result from KSRC activities" − cadmium, lead and zinc. The 2009 Letter states that on-site groundwater monitoring demonstrated that all contaminant concentrations, both those originating on-site as well as those from off-site sources were reduced to levels below the GWQS before reaching the downgradient site boundary. It also notes that there was no off-site migration of contaminants at that time (PAP-00004550-52).

The 2009 letter included the following figure from the 2000 RAW/CEA workplan shows the CEA site boundary, monitoring well locations, and the locations of the lead, cadmium, and zinc plumes.

(PAP-00004558)

According to the 2010 Report, the only water that could have migrated from the property to the River was stormwater collected on Harrison Avenue. Stormwater sampling pursuant to KSRC's permit reflect that the samples were always below permit limits and surface water quality standards (PAP-00004546).



On February 16, 2011, NJDEP approved the Revised RAW stating the workplan was in compliance with the Technical Requirements for Site Remediation, N.J.A.C.7:26E and other applicable requirements. NJDEP concluded that there was insufficient evidence in the groundwater data to conclude that arsenic and nickel are derived exclusively due to migration from offsite sources. The CEA was to include arsenic and nickel as COCs in addition to cadmium, lead and zinc in accordance with TRSR N.J.A.C. 7:26E-8.3(a) (PAP-00217360).

Remedial Activities

In a letter report dated December 4, 1987, KSRC informed NJDEP that upon receipt of the Notice of Violation for No. 4 Oil Fuel spill, the clean-up procedure started with the removal of the pump and pump house. Once removed, an area of approximately 17 feet by 30 feet with a depth of 2 feet was excavated. When the odor of fuel could no longer be detected, digging stopped and five samples were taken; one from each corner and one from the center of the excavation area. Further excavation was required and a total of 16,200 pounds of soil was removed from the excavation area. The samples were analyzed for Total Petroleum Hydrocarbons but not for PAHS (PAS-00032755-56).

The 2009 Letter states that a conceptual Remedial Action Work Plan (RAW) was submitted to NJDEP in May 1997 and was implemented in 1997/1998. Post-remedial groundwater monitoring was also conducted in 1997/1998. Additional groundwater monitoring was conducted during 1999 and 2000. Groundwater monitoring results demonstrated that the capping of the site combined with many other site improvements and process modifications had significantly reduced the concentrations of metals in groundwater across the property (PAP-00004534; PAP-00004549-50).

A March 4, 2011, Deed Notice states that engineering controls have been implemented to prevent direct contact to underlying PAHs and metals in soils attributed to the underlying slag and historic fill materials across the site. The primary control is a cap composed of clean soil, asphalt pavement, concrete, and crushed stone or asphaltic millings (PAP-00190095, 123). See the following site map that shows the restricted area of the site and composition of the cap.

(PAP-00190112)

According to the 2018 Phase I ESA, "*On December 20, 2016, a deed notice termination was submitted to the NJDEP for the redevelopment of a portion of the property for new commercial uses. The existing structures will be razed and new structures will be constructed. On January 26, 2017, the NJDEP approved the deed notice termination. Once the construction is complete and the new caps are in place, the Deed Notice Termination will be filed with the county along with a new deed notice to describe and incorporate the new caps. A modified SRAP [Soil Remedial Action Permit] application will be required after the new deed notice is filed with the county. During redevelopment, construction activities will need to be monitored to ensure that contaminated soil is property handled and disposed, if required. The new engineering controls/caps will need to be approved by the Licensed Site Remediation Professional (LSRP)"* (PAP-00431839). Note: The 2016 Deed Notice Termination and the NJDEP approval was not available in the documents reviewed for this report.

8. Summary of Asserted Defenses

No legal defenses were identified in the available file materials.

Facility Data Report

Leemilt's Petroleum Inc.

Facility Name, Address and Size: Leemilt's Petroleum Inc. (successor by merger to Power Test of New Jersey, Inc.); 86 Doremus Avenue, Newark, New Jersey 07114 (the Newark Terminal); 15.3 acres (PAP-00084077; PAP-00086173); another source states the property is 14.5 acres (PAP-00066677); no information was available in the file material regarding the number of employees that worked at the Newark Terminal. The property is referred to as both the Getty Terminal and the Newark Terminal in the file materials, but is referred to as the Newark Terminal in this Data Report.

1. **Business Type:** Former bulk petroleum storage and distribution terminal (PAP-00066676; PAP-00066932).

2. **Time Period of Ownership/Operations**

Operator: Operators vary by source, but include the following:

- Clay Terminals (an affiliate of Leemilt's Petroleum Inc.) 1985-1997
- Getty Petroleum Marketing, Inc. (GPMI, an unrelated entity) 1997-2012
- Getty Terminals 1985-2011 (PAP-00066678).

Owner: Power Test Realty Company Limited Partnership (PTRC, an affiliate of Leemilt's Petroleum Inc.) 1985-September 18, 2013 (PAP-00084077).

The tables below present a list of owners and operators identified in the *Preliminary Assessment/Site Investigation Report, Former Getty Terminal 56230,* dated March 2014 (PA/SIR) (PAP-00084082):

Name of Operator / Use	From	To
Vacant	2012	Present
Getty Petroleum Marketing Inc.	1984	2012
Texaco Refining and Marketing, Inc.	1960	1984
Tide Water Associated Oil Co	~1952	1960
The Atlantic Refining Company	Before 1950	~1952
Loujac Co.	Before 1931	~1950

Name of Property Owner	From	To
125 Doremus Avenue, LLC	9/18/2013	Present
Power Test Realty Co. Ltd. Partnership	2/1/1984	9/18/2013
Texaco Refining and Marketing, Inc.	1960	1984
Tide Water Associated Oil Co. (1952)	~1952	1960
The Atlantic Refining Co. (1950)	Before 1950	~1952
Loujac Co. (1931)	Before 1931	~1950

Pre-1931: A 1931 Sanborn Map shows that the property located at 86 Doremus Avenue was owned by Loujac Co. and the buildings in the West Yard were vacant

(PAP-00084169). According to the 1931 Sanborn Map, one building in the East Yard is labeled MFG Lacquers and one building is labeled MFG soap (PAP-00084169). There is no additional information regarding any prior use and/or ownership of the property by Loujac Co in the available file materials.

1930: Newark Terminal was constructed for use as a petroleum storage and distribution facility by the Atlantic Refining Company, which operated the facility until approximately 1950 (PAP-00432453, PAP-00066677).

1931: The Newark Terminal was owned by Loujac Co. and all buildings in the West Yard were vacant. The buildings in the East Yard were used for manufacturing of soap and lacquers (PAP-00084077).

1950: Newark Terminal was acquired by The Tidewater Associated Company and was operated by Getty Refining and Marketing Company (GRMC) (PAP-00066677).

1960s: The Tidewater Associated Company merged with the Getty Oil Company (PAP-00066677).

1984: Texaco Inc. acquired the Getty Oil Company in January 1984, and GRMC was re-named Texaco Refining and Marketing Inc. (TRMI) (PAP-00066677).

1984: On December 21, 1984, Texaco Inc., and its affiliated entity TRMI, sold the Newark Terminal to PTRC (an affiliate of Power Test Corp.) (PAP-00084080). The *Remedial Investigation Report, Former Getty Newark Terminal – Area A, 86 Doremus Avenue*, dated July 2014 (the Area A RIR) shows that PTRC was affiliated with Getty Properties Corporation and Getty Realty Corporation (PAP-00066677).

1985: Power Test of New Jersey, Inc. purchased the Newark Terminal from Texaco, Inc. in January 1985 and began its operation of the property (PAP-00020763). The Area A RIR states that Getty Terminals was responsible for operations from 1985 to 2011 (PAP-00066678).

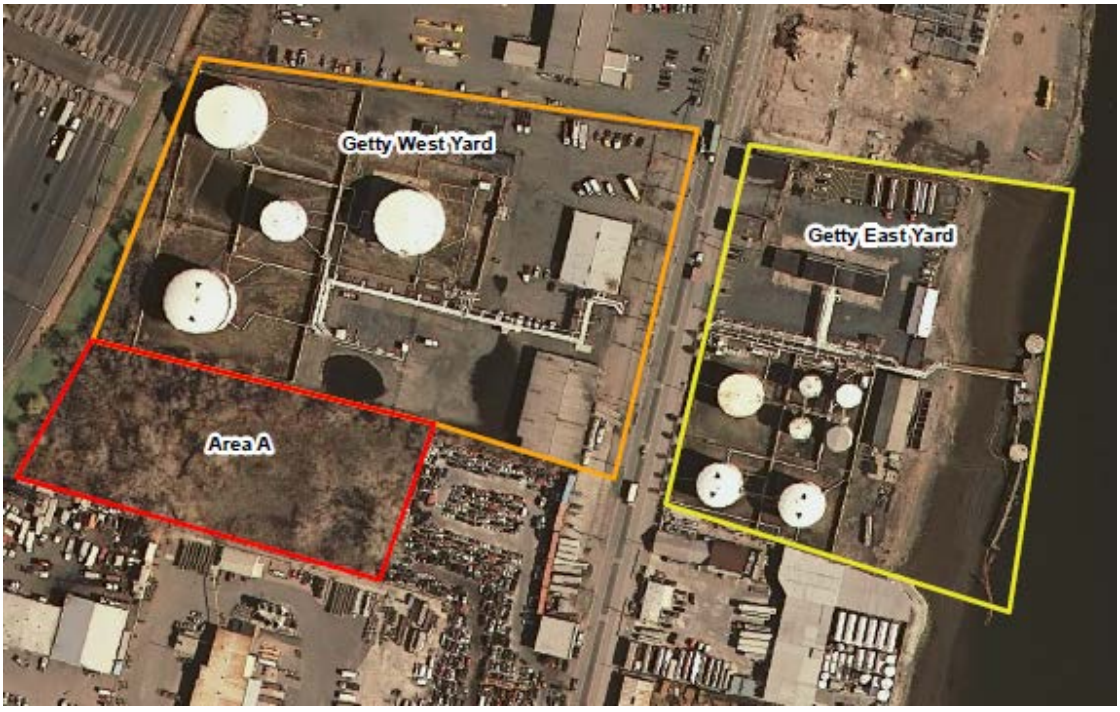
1985: In January 1985, TRMI entered into an administrative consent order (ACO) with NJDEP requiring TRMI to investigate and remediate existing contamination at the Newark Terminal under the Environmental Clean-up and Responsibility Act (ECRA) (PAP-00020764; PAP-00066677).

1995: Power Test of New Jersey, Inc. merged into Leemilt's Petroleum Inc. on January 10, 1995 (PAP-00020762).

1997: GPMI was spun off from Getty Petroleum Corporation as a separate, publicly listed company (PAP-00432452). Getty Petroleum Corporation changed its name to Getty Realty Group on March 21, 1997 (PAP-00020762).

2001: On October 9, 2001, Chevron Corporation (Chevron) and Texaco Inc. merged to form the Chevron Texaco Corporation (PAP-00020762).

2011: GPMI filed for bankruptcy in December 2011 (PAP-00432452). Getty Terminals entered bankruptcy proceedings in 2011 (PAP-00066678). Another source states that GPMI filed for bankruptcy in December 2012 (PAP-00084077).



2011/2012: Getty Realty/PTRC took over the Newark Terminal (PAP-00066678).

2012: Site operations ceased in 2012 following the bankruptcy of GPMI (PAP-00083961; PAP-00084077).

2013: On September 18, 2013, PTRC sold the Newark Terminal to 125 Doremus Avenue, LLC (PAP-00066678; PAP-00084080-81).

3. Operational History/COC Use and Presence at the Facility

The Newark Terminal is bounded on the east by the Passaic River, on the west by Interstate 95, and on the north and south by industrial properties (PAP-00083963). Doremus Avenue bisects the property. The Newark Terminal consisted of an area known as the "East Yard" (bounded by the Passaic River and Doremus Avenue) and an area known as the "West Yard" and Area A (bounded by the New Jersey Turnpike/Interstate 95 and Doremus Avenue) (PAP-001661116). The East Yard is identified as Block 5011, Lots 8, 8.01, 8.02 and 8.03, and the West Yard and Area A are identified as Block 5010, Lot 7 (PAP-00066676), although another source identified the property as Block 5010, Lot 21 (PAP-00020762). Area A was formerly Lot 18 in Block 5010 but was later incorporated into Lot 7 (PAP-00066677). A figure presenting the site layout is provided below (PAP-00066705):

According to the *Underground Storage Tank Remedial Investigation Report, Getty No. 56230 – Newark Terminal,* dated April 7, 2006 (UST RIR), the East Yard included two, two-story masonry office buildings, a one-story masonry building that housed the dispatch office and locker room facilities, a fuel loading rack, a foam building, a barge dock, several large capacity above ground storage tanks (ASTs), and multiple containment dikes (PAP-00083018).

The West Yard included an area known as Area A, which was a vacant parcel not used for facility operations (PAP-00066677). According to the *Underground Storage Tank Site Investigation Report, Getty Terminal (West Yard),* dated February 28, 2003 (West Yard UST RIR), the West Yard included a one-story masonry automotive repair building and a one-story masonry warehouse (PAP-00082725).

The PA/SIR states that a review of historic maps and aerial photographs did not show any onsite wastewater treatment, septic systems, or discharge sources (PAP-00084090).

According to the West Yard UST SIR, a 1,000-gallon unleaded gasoline UST, three 54,000-gallon unleaded gasoline ASTs, and one 21,000-gallon No. 2 fuel AST were located at the West Yard (PAP-00082725). The table below presents a list of USTs at the Newark Terminal from the PA/SIR, reflecting the status as of 2014 (PAP-00084135):

Facility Data Report

The table below presents a list of hazardous materials stored or used at the Newark Terminal from the PA/SIR. The list of materials is based on NJDEP Community Right to Know (CRTK) Surveys for CRTK Facility ID Number 94156800000 (GPMI, 2010-2012) and CRTK Facility ID Number 61763700000 (Getty Petroleum Corporation, 1992-1997). No CRTK records were available for the period of 1998-2009 (PAP-00084086-90):

Material Name	CAS #	Max Inventory Range	Storage method	Location
(Ambitrol) Diethylene Glycol		10,001 to 50,000 lbs	Steel Drums	East Yard Garage
(Ambitrol) Dipotassium Phosphate		10,001 to 50,000 lbs	Steel Drums	East Yard Garage
(Ambitrol) Ethylene Glycol		10,001 to 50,000 lbs	Steel Drums	East Yard Garage
(Lubrizol 8166) Alkylamine		10,001 to 50,000 lbs	AST	East Yard
(Lubrizol 8166) Ethylbenzene	100-41-4	10,001 to 50,000 lbs	AST	East Yard
(Lubrizol 8166) Isopropyl Alcohol	67-63-0	10,001 to 50,000 lbs	AST	East Yard
(Lubrizol 8166) Xylene	1330-20-7	10,001 to 50,000 lbs	AST	East Yard
(Lubrizol 8192) Ethylbenzene	100-41-4	10,001 to 50,000 lbs	AST	East Yard
(Lubrizol 8192) Xylene	1330-20-7	10,001 to 50,000 lbs	AST	East Yard
(Lubrizol 8195) Ethylbenzene	100-41-4	50,001 to 100,000 lbs	AST	East Yard
(Lubrizol 8195) Ethylhexanone		50,001 to 100,000 lbs	AST	East Yard
(Lubrizol 8195) Xylene	1330-20-7	50,001 to 100,000 lbs	AST	East Yard
(Lubrizol 8247) Xylene	1330-20-7	10,001 to 50,000 lbs	AST	East Yard
(Nalco 5302) Heavy Aromatic		1,001 to 10,000 lbs	Steel Drums	East Yard Garage
(Nalco 5302) Xylene	1330-20-7	1,001 to 10,000 lbs	Steel Drums	East Yard Garage
(Nalco 5312) Amine Fatty Acid		10,001 to 50,000 lbs	Portable Metal Container	East Yard Garage
(Nalco 5312) Amine Substituted R		10,001 to 50,000 lbs	Portable Metal Container	East Yard Garage
(Nalco 5312) Heavy Aromatic NA		10,001 to 50,000 lbs	Portable Metal Container	East Yard Garage
(Nalco 5312) Octyl Nitrate		10,001 to 50,000 lbs	Portable Metal Container	East Yard Garage
(Nalco 5312) Oxtylnitrate		10,001 to 50,000 lbs	Portable Metal Container	East Yard Garage
(Nalco 5313) Heavy Aromatic NA		10,001 to 50,000 lbs	Portable Metal Container	East Yard Garage
(Nalco 5330) Ethylbenzene	100-41-1	10,001 to 50,000 lbs	AST	East Yard
(Nalco 5330) Heavy Aromatic NA		10,001 to 50,000 lbs	AST	East Yard
(Nalco 5330) Naphthalene	91-20-3	10,001 to 50,000 lbs	AST	East Yard
(Nalco 5330) Xylene		10,001 to 50,000 lbs	AST	East Yard
(Valvtect Diesel Guard) Xylenes	1330-20-7	10,001 to 50,000 lbs	Steel Drums	East Yard Garage
(Valvtect) Diethylene Glycol		101 to 1,000 lbs	Steel Drums	East Yard
(Valvtect) Isooctyl Alcohol	26952-21-6	101 to 1,000 lbs	Steel Drums	East Yard
(Valvtect) Kerosene		1,001 to 10,000 lbs	Steel Drums	East Yard
(Valvtect) Propylene Glycol Methyl Ether A		1,001 to 10,000 lbs	Steel Drums	East Yard
(Valvtect) Trimethylbenzene	95-63-6	101 to 1,000 lbs	Steel Drums	East Yard
(Valvtect Diesel G 7RD) Cumene	98-82-8	10,001 to 50,000 lbs	Steel Drums	East Yard Garage
1,1,1-Trichloroethane	71-55-6	11-100 lbs	Can	West Yard Auto Repair Shop
1,2,4-Trimethylbenzene	95-63-6	2,500 to 4,999 lbs	AST	East Yard
Additive Puradd AP6000		2,500 to 4,999 lbs	AST	East Yard
Adhesives		1-10 lbs	Can	West Yard Auto Repair Shop
Calcium Arsenate	7778-44-1	100,000 to 499,999 lbs	Bag	East Yard Garage
Calcium Chloride		101 to 1,000 lbs	Bag	West Yard Warehouse

Lacquer			Unknown	East Yard
Methanol	67-56-1	10,001 to 50,000 lbs	Steel Drums	East and West Yards, East Yard Loading Rack
Methyl Ether	115-10-6	1,000 to 2,499 lbs	Steel Drums	East Yard
Mineral Spirits		1,001 to 10,000 lbs	Steel Drums	East Yard Garage and West Yard Warehouse
Multi-Purpose Gear Lubricant			Steel Drums	
Nalco 5403 Corrosion Inhibitor		Unknown	Steel Drums	West Yard Warehouse
Naphthalene	91-20-3	500 to 999 lbs	Steel Drums	East Yard
No. 2 Fuel Oil		Greater than 10 million lbs	AST and UST	East and West Yards
Paints, Enamel		10,001 to 50,000 lbs	Can	East Yard Garage and West Yard Warehouse
Petroleum Oils		50,001 to 100,000 lbs	Steel Drums	Warehouse West Yard
Petroleum Oils		250,001 to 500,000 lbs	Can	Warehouse West Yard
Polyurethane			Metal Cans	East Yard
Premium Gasoline			Tanks	East and West Yard
Propane	74-98-6	500 to 999 lbs	Cylinder	Auto Repair Shop
Propylene Glycol Monomethyl Ether	107-98-2	1,001 to 10,000 lbs	Steel Drums	East Yard Garage and West Yard Warehouse
Puradd AP-6000 Additive		3,000 gallons	AST	East Yard

Sodium Arsenate	7631-89-2	1,000 to 2,499 lbs	Bag	East Yard Garage
Sodium Chlorate	7775-09-9	10,001 to 50,000 lbs	Bag	West Yard Warehouse
Sodium Chloride		101 to 1,000 lbs	Bag	East Yard Garage
Spirax 75W-90 Synthetic Axle Oil			Steel Drums	
Sulfuric Acid	7664-93-9	11 to 100 lbs	Plastic bottles or jugs	West Yard Warehouse
Tetrahydrofuran	109-99-9		Steel Drums	East Yard
Thinners		11 to 100 lbs	Can	Auto Repair Shop
Tolad 3880R Additive		Unknown	Tote Bin	West Yard Warehouse
Tolad 3881 Additive		5,000 to 9,999 lbs	Tote Bin	East Yard, West Yard Warehouse
Tolad 9110 Additive		Unknown	Unknown	East Yard
Trimethyl Benzene	15551-13-7	10,001 to 50,000 lbs	Steel Drums	East Yard Garage
Vinyl Acetate	108-05-4	2,500 to 4,999 lbs	Steel Drums	East Yard
Waste Oil			AST and UST	East and West Yards
Wax Liquid		11 to 100 lbs	Can	East Yard Broom Closet (Building Unknown)
Xylene	1330-20-7	1,001 to 10,000 lbs	Steel Drums, AST	East Yard Garage and West Yard Warehouse

4. Identified COCs

- PCBs (detected)
- PAHs (stored, detected)
- Copper (detected)
- Mercury (detected)
- Lead (stored, detected)

PCBs

Concentrations of total PCBs ranged from non-detect to 67 milligrams per kilogram (mg/kg) (PAP-00066714-15, 66).

The PA/SIR states that transformers were located in six locations at the Newark Terminal: three locations in the East Yard and three locations in the West Yard. Three wall-mounted transformers were located on the northern office building in the East Yard and appeared to be in good condition with no signs of staining or leaking. Three large pad-mounted transformers were located on a concrete pad, east of the northern office building. The transformers and pad had rust stains and the center transformer had black staining near the base and on the pad directly surrounding the transformer. One pad-mounted transformer was located on a concrete pad in the East Yard, adjacent to Doremus Avenue, which appeared to be in good condition with no significant stains on the transformer or the pad. There were two poles holding pole-mounted transformers in the West Yard, located adjacent to Doremus Avenue. One pole had three transformers and the second pole had one transformer. The pole-mounted transformers appeared to be in good condition with no signs of staining or leaking. A pad-mounted transformer was located on a concrete pad between the automotive repair show and Doremus Avenue, and appeared to be in good condition with no signs of staining or leaking. None of the transformers were labeled as PCB-containing (PAP-00084117-118).

PAHs

According to the *Remedial Investigation Report, Former Getty Newark Terminal – Area A, 86 Doremus Avenue* (Area A RIR), PAH detections in soil are attributed to Historic Fill (PAP-00066685). Concentrations of PAHs in soil included benzo(a)anthracene, ranging from non-detect to 12 mg/kg; benzo(a)pyrene ranging from non-detect to 19 mg/kg; benzo(b)fluoranthene, ranging from non-detect to 23 mg/kg; benzo(k)fluoranthene, ranging from non-detect to 26 mg/kg; indeno(1,2,3-cd)pyrene, ranging from non-detect to 10 mg/kg; and dibenzo(a,h)anthracene, ranging from non-detect to 2.8 mg/kg (PAP-00066716-18).

Copper

Concentrations of copper in soil were as high as 2,030 mg/kg (PAP-00086279-296). No additional information regarding the presence or use of copper at the Newark Terminal could be located in the available file materials.

Lead

Paint was stored in one-gallon and five-gallon cans and stacked in plastic wrapped cardboard boxes on pallets located in a garage area at the East Yard of the Newark Terminal (PAP-00432453).

In addition, several racks of clear-cased batteries were stored at the Newark Terminal in connection with a telephone system and fire alarm system (PAP-00432453-54). The batteries were the approximate size of a motorcycle or tractor battery (PAP-00432454). Concentrations of lead in soil were as high as 2,160 mg/kg (PAP-00086279-296).

Leaded gasoline was stored at the Newark Terminal, based on the table of hazardous materials provided in the PA/SIR (PAP-00084086-90).

No additional information regarding the presence or use of lead at the Newark Terminal could be located in the available file materials.

Mercury

Concentrations of mercury in soil were as high as 2.3 mg/kg (PAP-00086279-296). No additional information regarding the presence or use of mercury at the Newark Terminal could be located in the available file materials.

Historic Fill

The Allocation Team has determined that the property is located on regional Historic Fill as designated by the NJDEP.[1]

[1] *Digital Geodata Series, DGS04-7, Historic Fill for New Jersey*, https://www.nj.gov/dep/njgs/geodata/dgs04-7.htm, Quadrangle No. 52 and No. 53 (NJDEP map identifying locations of recognized historic fill).

The NJDEP has established that Historic Fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 COCs: PAHs, lead, copper, and mercury.[2] Accordingly, NJDEP technical requirements for property containing Historic Fill requires sampling for the United States Environmental Protection Agency (EPA) Target Compound List (TCL) for PAHs and Target Analyte List (TAL) for metals, including lead, copper, mercury, and the OU2 PAH COCs.[3] PAHs, lead, copper, and mercury are recognized by NJDEP to be constituents of Historic Fill at varying levels, not atypically at or exceeding residential soil standards.[4]

The levels of PCBs, PAHs, copper, lead and mercury detected at the site in soils are presented in the table below (PAP-00066714-15, 66; PAP-00086279-296; PAP-00086279-296).

COCs Found in Onsite Soils	
COC	**Max Detected Concentration**
Lead	2,160 mg/kg
Copper	2,030 mg/kg
Mercury	2.3 mg/kg
Benzo(a)anthracene	12 mg/kg
Benzo(a)pyrene	19 mg/kg
Benzo(b)fluoranthene	23 mg/kg
Benzo(k)fluoranthene	26 mg/kg
Dibenzo(a,h)anthracene	10 mg/kg
Indeno(1,2,3-cd)pyrene	2.8 mg/kg
Total PCBs	67 mg/kg

* Metals data taken from the data tables in the *Remedial Investigation Report, Former Getty Terminal 56230, 86 Doremus Avenue*, dated April 2016 (PAP-00086279-96); PAHs data taken from Table 3 in the Remedial Investigation Report, Former Getty Newark Terminal – Area A, 86 Doremus Avenue, dated July 2014 (the Area A RIR) (PAP-00066716-18); PCBs data taken from Table 2 of the Area A RIR (PAP-00066714-15).

[2] *Characterization of Ambient Levels of Selected Metals and cPAHs In New Jersey Soils* (2002) and *Characterization of Ambient Levels of Selected Metals and Other Analytes In New Jersey Soils* (1997), studies prepared for NJDEP, Division of Science and Research, by BEM Systems, Inc.
[3] New Jersey Department of Environmental Protection (NJDEP), *N.J.A.C. 7:26E Technical Requirements for Site Remediation,* Table 4-2, November 2009 [Note that Table 4-2 has been deleted from the current version of N.J.A.C. 7:26E (May 7, 2012) and the updated *Historic Fill Technical Guidance* (April 2013) as NJDEP believed that the tables list of historic fill constituents was too restrictive].
[4] NJDEP Table 4-2 (PAHs and lead) and a summary of NJDEP records regarding investigations of properties in the vicinity of the Passaic River recognized to be located in areas of Historic Fill indicate that the following average/maximum (mg/kg) contamination levels of OU2 COCs exist in area Historic Fill - PAHs (1.91/160), lead (574/10,000), copper (11.2/1,200), and mercury (0.21/3.7).

According to the affidavit of Dale Holden, a former employee of Getty Petroleum Corporation, Historic Fill at the Newark Terminal was not disturbed, with the exception of the removal of USTs. Any Historic Fill excavated as part of the UST removals was properly handled and disposed of off-site, and was replaced with clean fill (PAP-00432454).

According to the Area A RIR, the presence of Historic Fill in Area A has been confirmed based on multiple lines of evidence including characterization of soil borings completed at the property, aerial photograph review, NJDEP Historic Fill maps, and the results of soil sampling that has confirmed the presence of PAHs and metals often associated with Historic Fill (PAP-00066685). Historic Fill is approximately two to ten feet deep in Area A. The Historic Fill was placed periodically between the early 1900s to the early 1970s (PAP-00066678).

According to the *LNAPL Interim Remedial Measures Report, Former Getty Terminal 56230,* dated December 2013, the entire Newark Terminal is within an area of Historic Fill, as mapped by NJDEP. Fill material was typically observed from the surface to approximately five to eight feet below ground surface (bgs) (PAP-00083961). The PA/SIR states that an evaluation of Historic Fill was conducted in the East and West Yard in November 2006 by Conestoga-Rovers & Associates (CRA) on behalf of Chevron. CRA concluded, based on soil analytical data, boring logs, historic fill maps, and correspondence with NJDEP, that Historic Fill was present throughout the full extent of the East and West Yards. CRA also concluded that PAHs and lead in soil were indicative of Historic Fill (PAP-00084092).

The *Remedial Investigation Report, Former Getty Terminal 56230, 86 Doremus Avenue*, dated April 2016, identified four metals and eight PAHs that were determined to be related to Historic Fill based on statistical analysis, including: arsenic, beryllium, lead, vanadium, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthese, bis(2-ethylhexyl)phthalate, chrysene, dibenz(a,h)anthracene, and ideno(1,2,3-cd)pyrene (PAP-00086186).

5. COC Pathways

The Newark Terminal is located on the west bank of the Passaic River. The East Yard is bounded to the east by the Passaic River (PAP-00083019; PAP-00083962). The Passaic River is located approximately 580 feet east of the West Yard (PAP-00082725; PAP-00083310). Area A is covered with vegetation, which according to the Area A RIR, mitigates the risk of potential erosion of PCB, PAH, and lead-impacted surface soil (i.e., Historic Fill) and transport via surface water runoff. No permanent surface water bodies exist on the property. The Passaic River is located approximately 1,000 feet east of Area A (PAP-00066697).

According to the PA/SIR, the entire Newark Terminal, as well as other properties along Doremus Avenue, are subject to flooding during significant storm events. The entire Newark Terminal and surrounding areas were flooded during an October 2012 storm (PAP-00084094). During flooding events, regional contamination from the Passaic

River, other industrial sites in the area, and regional Historic Fill are comingled with potential site-related impacts from the Newark Terminal AOCs (PAP-00084099).

Sanitary and Storm Sewer

Stormwater in the East Yard was collected in storm drains that led to an oil/water separator that discharged to the Passaic River, and was regulated pursuant to New Jersey Pollutant Discharge Elimination System Permit No. NJ0026034. Monitoring requirements pursuant to the NJPDES Permit included quarterly stormwater sampling, analysis, and reporting on Discharge Monitoring Reports (DMRs) (PAP-00432454).

The PA/SIR states that no storm sewer drains were observed in the West Yard (PAP-00084115).

Sanitary waste at the Newark Terminal was discharged to the PVSC system (PAP-00432454). Both the city water lines and the sanitary sewer lines are located on Doremus Avenue (PAP-00083311).

According to the PA/SIR, multiple storm drains and trench drains were identified within the loading rack area in the East Yard. These drains eventually connect to the oil/water separator that discharged to the Passaic River. The loading rack area is paved with concrete (PAP-00084096). The oil/water separator flooded in October 2012 and the area around the separator is frequently flooded by the Passaic River (PAP-00084105).

The PA/SIR also stated that the automotive repair shop in the West Yard includes eight floor drains, but the integrity of the drain piping and the final drainage point of these floor drains have not been determined. Some of the floor drains were filled with debris and the floor of the shop was heavily stained and greasy (PAP-00084115).

According to the PA/SIR, there were two slop sinks located in the automotive repair shop of the West Yard. There was also a slop sink in a closet in the locker room/dispatch office building. All three slop sinks had slight staining and are believed to be connected to the municipal sewer system (PAP-00084120).

Although plans of the drainage systems in the West Yard (PAP-00717684; dated 1983) and East Yard (PAP-00717679; dated 1984) show a connection between the yards under Doremus Avenue, an affidavit from former employee Mr. Dale Holden states that the connection was never installed (PAP-00717677). In addition, in 1994, a tracer dye test was performed by Tyree Organization, Ltd. The tracer study concluded that the final discharge point for the West Yard trench drain system and the Vehicle Repair Garage floor drain system was the City of Newark sanitary sewer system and not the East Yard oil/water separator (PAP-00717681).[5]

Direct Release

[5] This Report was revised to include documents received on June 5, 2020. The additional documents did not change Leemilt's Petroleum Inc.'s previous certification.

According to the PA/SIR, stormwater at the Newark Terminal was regulated pursuant to New Jersey Pollutant Discharge Elimination System (NJPDES) Permit No. NJ0026034, which applies specifically to an oil/water separator located in the East Yard adjacent to the Passaic River. This oil/water separator discharges directly to the river (PAP-00084091). No additional information regarding direct releases to the Passaic River at the Newark Terminal could be located in the available file materials.

Spills

The PA/SIR identified several NJDEP case numbers including:

- case No. 97-2-21-1337-13 (associated with AOC 10);
- case No. 97-2-21-1736-56 (associated with AOC 17);
- case No. 03-05-16-1549-38 (associated with AOC 1);
- case No. 04-02-13-0606-39 (associated with AOC 13);
- case No. 04-02-13-0619-23 (associated with AOC 13);
- case No. 05-02-23-1219-45 (associated with AOC 2 and AOC 20);
- case No. 06-02-10-1135-08 (associated with AOC 25);
- case No. 06-03-06-1407-55 (associated with AOC 1); and
- case No. 10-01-22-0348-17 (associated with AOC 14) (PAP-00084077, 91).

Case E20120316 is also identified in the RA/SIR (PAP-00084077). Case No. 03-05-16-1549-38 was determined to be an air release in the PA/SIR (PAP-00084095). The PA/SIR states that the incident associated with case No. 06-03-06-1407-55 appeared to be a simulated spill associated with a containment drill based on the description, but also states that it cannot be determined if an actual discharge occurred based on the available documentation (PAP-00084094). Similarly, the PA/SIR states that the incident associated with case No. 05-02-23-1219-45 appeared to be a simulated spill associated with a containment drill based on the description, but also states that it cannot be determined if an actual discharge occurred based on the available documentation (PAP-00084095). The case numbers associated with AOCs 13 and 14 appear to be related to unleaded gasoline releases and are unlikely to have contained OU2 COCs (PAP-00084101-102). The case number associated with AOC 25 appears to be related to a leaded gasoline release (PAP-00084106). It is unclear if the remaining case numbers are associated with OU2 COCs based on the available file materials.

A list of the 70 AOCs (not all of which are spills) identified at the Newark Terminal, including those associated with the case numbers listed above, is provided in Section 7 below.

6. Regulatory History/Enforcement Actions

Inspections and Violations

According to the PA/SIR, approximately 1,500 cubic yards of soil and debris were illegally placed in two piles at Area A in 1996. In addition to soil, the identified piles included tires, wood, concrete, metal, and other debris. The material was removed for

off-site disposal (PAP-00084093). It is unclear if the piles of soil and debris contained OU2 COCs based on the available file materials.

Permits

Stormwater at the Newark Terminal was regulated pursuant to NJPDES Permit No. NJ0026034 (PAP-00066869).

According to the PA/SIR, the permits noted above apply specifically to an oil/water separator located in the East Yard adjacent to the Passaic River, which discharges directly to the river (PAP-00084091).

7. Response Actions

Characterization Activities

The following is a list of major response action documents identified in the available file material:

- *LNAPL Interim Remedial Measures Report, Former Getty Terminal 56230,* dated September 2017 (PAP-00086766);
- *Remedial Investigation Report, Former Getty Terminal 56230, 86 Doremus Avenue*, dated April 2016 (PAP-00086165);
- *Remedial Investigation Report, Former Getty Newark Terminal – Area A, 86 Doremus Avenue*, dated July 2014 (Area A RIR) (PAP-00066671);
- *Preliminary Assessment/Site Investigation Report, Former Getty Terminal 56230,* dated March 2014 (PA/SIR) (PAP-00084072);
- *LNAPL Interim Remedial Measures Report, Former Getty Terminal 56230,* dated December 2013 (PAP-00083957);
- *LNAPL Free Product Interim Remedial Measures Report, Getty Terminal No. 56230 (West Yard),* dated May 27, 2011 (PAP-00083305);
- *Remedial Action Work Plan*, dated January 23, 2008 (PAP-00066671);
- *Underground Storage Tank Remedial Investigation Report, Getty No. 56230 – Newark Terminal,* dated April 7, 2006 (UST RIR) (PAP-00083013);
- *Baseline Ecological Evaluation Report,* dated February 23, 2006 (PAP-00066799);
- *Remedial Investigation Sampling Results for Area A*, dated March 31, 2005 (PAP-00066676);
- *Remedial Investigation Report, Getty Terminal No. 56230 (West Yard),* dated June 16, 2004 (PAP-00082888);
- *Underground Storage Tank Site Investigation Report, Getty Terminal No. 56230 (West Yard),* dated February 28, 2003 (West Yard UST SIR) (PAP-00082720);
- *Remedial Action Report for PCB Soils in Area A, Volume I Report, Getty Newark Terminal*, dated July 25, 1997 (PAP-00066760, PAS-00005678); and
- *Area A Closure Report, Newark Terminal, Newark New Jersey, ECRA Case No. 84455,* dated November 1991 (PAP-00066737).

Sewer

According to the PA/SIR, the loading rack drains and associated manholes were inspected in 1997. Soil and debris underneath the steel grating were manual removed and a high pressure water jet was used to flush the remaining sediment from the pipes into the collection system, which discharges to the oil/water separator. Following the cleaning activities, the drains were visually inspected and found to be constructed of concrete and lined with steel sheeting. The integrity of the collected drains was intact (PAP-00084096). The site visits conducted during the preliminary assessment/site investigation found that several of the loading rack drains were blocked with debris and were not functioning (PAP-00084097, 116).

The PA/SIR states that four sumps are located in the East Yard: one associated with the vapor recovery unit for Tank No. 5 and three associated with the fire protection or sewer systems, including a sump on the west side of the locker room/dispatch office building, a sump on the west side of the foam building, and a sump inside the northern office building. Black stains were visible near the bottom of the sump adjacent to the locker room/dispatch office building. There is one sump located in the West Yard, northeast of the foam building. Water in this sump had a sheen which may have been due to surface runoff from the adjacent loading area and heavy rain during the inspection (PAP-00084116).

Soil

Soil sampling was conducted at the East Yard and West Yard on behalf of Getty Petroleum Corporation between April 2013 and April 2014, specifically focusing on 12 of the 70 AOCs identified at the Newark Terminal (PAP-00086183).

Remedial Activities

According to the PA/SIR, there were two Industrial Site Recovery Act (ISRA) cases: E84455 related to the sale of the Newark Terminal to PTRC by Texaco Inc. in 1984 and E20120316 related to the cessation of operations by the bankruptcy of the operator, GPMI, in 2012 (PAP-00084077). Various remedial activities related to these two cases are presented below.

Implemented by Texaco/Chevron

According to the PA/SIR, two 2,000-gallon diesel USTs identified as Tanks G-1 and G-2 were removed from the East Yard of the Newark Terminal on January 29, 1986. The USTs were located to the north of the locker room/dispatch office building. Tank G-1 had previously been abandoned and filled with sand. During excavation of Tank G-1, a second sand-filled tank (Tank G-2) was found beneath the HVAC system pad. Piping was found on three sides of the excavation, but all piping appeared to be abandoned. Both USTs, associated piping, and stained soil were removed to a depth of 8-10 feet. The USTs were both observed to be corroded around the seams. Correspondence from NJDEP stated that they had no registration or records of the installation or removal of these USTs (PAP-00084108).

The PA/SIR states that a 2,000-gallon UST and a 1,500-gallon UST identified as Tanks H-1 and H-2 were removed from the East Yard of the Newark Terminal on January 29, 1986. The USTs were located to the west of the locker room/dispatch office building. The former contents of these USTs were not identified. Tank H-1 had previously been abandoned and filled with sand. During excavation of Tank H-1, a second sand-filled tank (Tank H-2) was found. Tank H-2 was strapped into an open-bottomed concrete-walled vault. The USTs were both observed to be corroded around the seams. Both the USTs and stained soil were removed to a depth of 6-8 feet. A vacuum truck was used to remove oily water from the excavation. Correspondence from NJDEP stated that they had no registration or records of the installation or removal of these USTs (PAP-00084108-109).

The PA/SIR states that a 2,000-gallon No. 2 fuel oil UST identified as Tank E, located south of the southern office building, was removed from the East Yard on January 30, 1986. Prior to removal, the tank was reported as a 1,000-gallon UST, but during removal it was discovered to be a 2,000-gallon UST. The tank appeared to be previously abandoned and had been filled with sand. Stained soil was removed to 8 feet bgs and the excavation was backfilled with sand. Correspondence from NJDEP stated that they had no registration or records of the installation or removal of this UST (PAP-00084107).

According to the PA/SIR, contractors attempted to remove a 4,000-gallon fuel oil UST identified as Tank N from the West Yard between January 31 and February 3, 1986. Prior to removal, the tank was reported as a 2,000-gallon UST, but during removal it was discovered to be a 4,000-gallon UST. Tank N had previously been abandoned and filled with sand. Tank N was located near footings that support overhead piping and could not be removed. Correspondence from NJDEP stated that they had no registration or records of the installation or removal of this UST (PAP-00084111);

The PA/SIR states that a 1,000-gallon waste oil UST identified as Tank I, located west of the automotive repair shop, was removed from the Newark Terminal on February 3-4, 1986. Prior to removal, the tank was reported as a 100-gallon waste oil UST, but during removal it was discovered to be a 1,000-gallon UST located inside an open bottomed concrete-walled vault. Water with an oil layer was present inside the UST prior to removal. Following tank removal, soil within the vault was removed to a depth of 6-8 feet and a new 550-gallon fiberglass tank was installed within the vault. The replacement 550-gallon waste oil UST was removed on February 21, 1997 under closure number No. C96-1146. The UST contained no holes, but stained soils and a sheen were noted during tank removal. NJDEP assigned case number No. 97-2-21-1337-13. Post-excavation samples were analyzed for total petroleum hydrocarbons (TPHC) (PAP-00084099).

According to the Area A RIR, remedial investigation and reporting activities in Area A of the Newark Terminal occurred between May 1988 and March 2005 (PAP-00066676). In 1988, eleven soil borings (SB-1 through SB-11) were advanced to groundwater within Area A to investigate and characterize the soil and a total of 35 soil samples were submitted for analysis of TPHC and lead (PAP-00066679). Total lead concentrations ranged from 1.3 mg/kg to 8,200 mg/kg (PAP-00066680).

The Area A RIR, states that in May 1990 soil containing TPHC and lead was delineated and excavated to the approved cleanup levels (500 ppm for TPHC; 1,000 ppm for lead; 1 ppm for volatile organic compounds (VOCs); and 10 ppm for Base Neutrals). PCBs were found during waste classification sampling, requiring another phase of investigation. Area A Phase II Investigation activities were performed in November 1990 to further delineate and investigate PCBs, TPHC, lead, BNs, and VOCs. Soil with levels of TPHC, PCBs, and BNs exceeding cleanup levels was excavated. The ECRA cleanup guideline of 5 ppm was used for PCBs. Post-excavation samples were collected in January 1991 and some sample results for PCBs and TPHC exceeded the cleanup levels (PAP-0006680).

The Area A RIR also summarizes the Phase III investigation activities that were performed from May 1991 through September 1991, as well as a final soil excavation. Approximately 4,000 tons of soil were excavated from Area A during Phases II and III (PAP-00066681). In a letter dated June 12, 1992, the NJDEP declined the request for a No Further Action (NFA) determination because post-excavation sampling was not deemed sufficient (PAP-00066681, 754-758).

According to the Area A RIR, Phase IV investigation activities were performed at Area A in March 1993, which found that PCBs were detected at various locations within Area A at concentrations exceeding the Non-Residential Direct Contact Soil Cleanup Criteria (DCSCC) (PAP-00066681).

According to the Area A RIR, further investigation of soil was conducted between December 1994 and January 1995. A total of 36 samples were collected to delineate PCBs and 25 samples were collected to delineate PAHs. Six samples were also collected off-site, to the southwest of Area A. Results showed that the most elevated PCB concentrations (10 to 67 ppm) existed in soil along the southwestern property boundary and in off-site sampling locations (PAP-00066681-82).

Results also showed that PAHs were detected throughout Area A soils. Investigative activities for Area A also included review of aerial photographs from the 1947, 1959, 1963, 1969, 1973, and 1982, which provided evidence of historic fill placement. Areas observed to undergo the most disturbances in Area A correspond to areas of highest PCB concentrations. In a letter dated December 6, 1996, the NJDEP accepted the evidence of historic fill (PAP-00066681-82).

In 1996, Area A was divided into Areas 1 through 4 to facilitate addition delineation of soil contamination. Following delineation efforts, 229 tons of soil were excavated from Area A to remove PCBs above 20 mg/kg (PAP-00066682).

In February 2004, additional sampling efforts were conducted which included the installation and sampling of eleven soil borings along the perimeter of Area A and four borings within Area A. Surface soil samples were also collected at six locations (PAP-00066686-87).

According to the PA/SIR, Chevron proposed a deed notice and cap for Area A in August 2013 (PAP-00084100).

Implemented by GPMI

According to the PA/SIR, a steel 1,000-gallon No. 2 fuel oil UST identified as Tank 7 was removed from the East Yard on February 21, 1997. The tank closure was associated with approval No. C96-1146. During tank removal, groundwater with a sheen was encountered at 2-3 feet bgs and NJDEP assigned case number No. 97-2-21-1736-56. Post-excavation samples showed that soil was impacted with TPHC at concentrations ranging from 26,500 to 39,000 mg/kg (PAP-00084104).

According to the West Yard UST SIR, a 1,000-gallon unleaded gasoline UST (Registration No. 004475) identified as Tank 6 was closed at the West Yard. Closure activities were completed on January 13, 2003, under closure number No. N02-1799 (PAP-00082725-26; PAP-00084103). Prior to excavation work, approximately 1,688 gallons of water and unleaded gasoline were removed from the UST and transported off-site for disposal via vacuum truck (PAP-00082726). The removal of 1,688 gallons of water and gasoline implied that the UST may have leaked (PAP-00084103). The UST was removed and transported for scrap recycling. No associated piping was uncovered during tank removal. No holes or corrosion were observed upon inspection of the tank. There were no visual observations of impacted soils within the excavation. Six post-excavation samples were collected from the sidewalls and analyzed for total VOCs. No exceedances of NJDEP soil criteria were detected. The excavation was then backfilled with pea gravel (PAP-00082727-28).

According to the UST RIR, a 2,000-gallon fiberglass gasoline UST (Registration No. 004475) was closed at the East Yard and closure activities were completed on February 2, 2006 (PAP-00083018, 20). Approximately 625 gallons of liquid were removed from the UST via vacuum truck. Due to the presence of product lines and utility lines, the UST was removed from the excavation in pieces. Subsurface soils were impacted, as demonstrated by petroleum odors, stained soils, and elevation PID readings ranging from 80 to 2,400 ppm. No associated piping was uncovered during tank removal. Fifty tons of soil were removed and disposed offsite during UST removal activities (PAP-00083020-21). Four post-excavation samples were collected from the sidewalls and analyzed for total VOCs, and benzene was detected above the NJDEP soil criteria of 1 mg/kg in three of the four samples. The excavation was backfilled with clean fill (PAP-00083022-23). Table 2 shows that samples were also analyzed for lead and concentrations ranged from 18.2 to 50.4 mg/kg (PAP-00083030).

Implemented by Getty Properties Corp

According to the PA/SIR, there was an initial list of 70 AOCs identified at the Newark Terminal, 53 of which require additional investigation or remediation. A list of AOCs is presented below (PAP-00084078-80):

- AOC 1: Vapor Recovery Unit in Tank #5 Basin
- AOC 2: 8,000-Gallon Fuel Additive AST and Tank Pump (Tank #1/#3 Basin)
- AOC 3: Pump and Bleeder Valves Staining (North of Tanks #1-#4)
- AOC 4: Loading Rack Drainage System
- AOC 5: West Yard Valve Units by Southeast Wall of Tank #11 Basin
- AOC 6: 10,000-Gallon Diesel AST in Tank #11 Basin
- AOC 7: Sandblasting Grit (Tank #8 and #9)
- AOC 8: Closure of Well MW-10
- AOC 9: River Mass Loading Assessment
- AOC 10: Auto Repair Shop Former 1,000-Gallon Waste Oil UST (UST I) and 550-Gallon Waste Oil UST (Tank E2)
- AOC 11: Area A (Chevron)
- AOC 12: West Yard Free Product in MW-18 Area
- AOC 13: 2004 Gasoline Spill
- AOC 14: Tank #11 Gasoline Spill
- AOC 15: East Yard Free Product in MW-12 Area
- AOC 16: West Yard Former 1,000-Gallon Unleaded Gasoline UST (Tank 6)

- AOC 17: Northern Office Former 1,000-Gallon No. 2 Fuel Oil UST (Tank 7)
- AOC 18: Regional Site-Wide Ground Water
- AOC 19: Oil/Water Separator
- AOC 20: 3,000-Gallon Fuel Additive AST (Tank #2/#4 Basin)
- AOC 21: East Yard Garage 275-Gallon Fuel Oil AST
- AOC 22: East Yard Northern Office 600-Gallon Fuel Oil AST
- AOC 23: East and West Yard 1,000-Gallon and 1,500-Gallon Foam ASTs
- AOC 24: East Yard Garage Tank A (Potential UST)
- AOC 25: Former 2,000-Gallon Leaded Gasoline UST (Tank E1)
- AOC 26: 2,000-Gallon Unleaded Gasoline Sump (Tank E5)
- AOC 27: East Yard Southern Office Former 2,000-Gallon No. 2 Fuel Oil UST (UST E)
- AOC 28: UST F
- AOC 29: Dispatch Office/Locker Room Former Two 2,000-Gallon Diesel USTs (UST G-1 & G-2)
- AOC 30: East Yard Former 1,500-Gallon UST and 2,000-Gallon UST (UST H-1 & H-2)
- AOC 31: Auto Repair Shop 4,000-Gallon No. 2 Fuel Oil UST (UST J)
- AOC 32: West Yard Warehouse 4,000-Gallon No. 2 Fuel Oil UST (UST K)
- AOC 33: East Yard 2,000-Gallon Dropout UST (UST L)
- AOC 34: West Yard 2,000-Gallon Dropout UST (UST M)
- AOC 35: Auto Repair Shop Abandoned 4,000-Gallon No. 1 Fuel Oil UST (UST N)
- AOC 36: West Yard Fuel Loading Area
- AOC 37: Warehouse Loading Docks
- AOC 38: Garage Loading Dock
- AOC 39: Dumpsters and Shipping Container
- AOC 40: Chemical Storage Cabinets
- AOC 41: Garage Material Storage
- AOC 42: Locker Room/Dispatch Office Electrical Room Material Storage
- AOC 43: Auto Repair Shop Material Storage

- AOC 44: Warehouse Material Storage
- AOC 45: West Yard Former Drum Storage Area
- AOC 46: Auto Repair Shop Floor Drains
- AOC 47: Locker Room Floor Drain
- AOC 48: Storm Sewer Collection System and Drains
- AOC 49: Fire and/or Sewer Sumps
- AOC 50: Roof Leaders
- AOC 51: Historic Fill
- AOC 52: Electrical Transformers
- AOC 53: Terminal Piping
- AOC 54: Open Pipes
- AOC 55: Compressor Vent Discharge
- AOC 56: East Yard Northern Office Fire Pump/Boiler Room
- AOC 57: Auto Repair Shop Boiler Room
- AOC 58: Slop Sinks
- AOC 59: Air Vents and Ducts
- AOC 60: West Yard – Northeast Side Adjacent to Doremus Avenue
- AOC 61: Potential Former Septic System
- AOC 62: Site Flooding
- AOC 63: Former Railroad Siding and Rail Cars
- AOC 64: Former West Yard Boiler House (1931)
- AOC 65: Former West Yard Chemical Storage (1931)
- AOC 66: Former Elevators (1931)
- AOC 67: Former Soap Manufacturing (1931) / East Yard Barrel Storage (1950)
- AOC 68: Former Lacquer Manufacturing (1931) / Motor Oil Warehouse (1950)
- AOC 69: Former Gasoline Pump Equipment Storage (~1950 – 1952)
- AOC 70: Former Oil Filling Area (1950 – 2003)

The locations of the AOCs are depicted on the two figures included above in Section 2, which show the features of the East Yard and West Yard, as well as the AOC numbers (numbers within the green circles) (PAP-00084131-132).

8. Summary of Asserted Defenses

Leemilt's asserts that while there are reports of petroleum releases and/or discharges at the Facility, these releases fall within CERCLA's petroleum exclusion, including any constituent PAH COCs. See Section 101(14) of the Comprehensive Environmental Response, Compensation, and Liability Act, 42 U.S.C. § 9601(14).

Legacy Vulcan, LLC

Diamond Alkali OU2 Allocation

ADR Confidential

Facility Data Report

LEGACY VULCAN, LLC

Facility Name, Address and Size: Balbach Smelting and Refining Corporation Site/Vulcan Site/Kolker Site/Inland Chemical Corporation Site/McKesson Envirosystems Site/Safety-Kleen Envirosystems Site; 600 Doremus Avenue (also 504-508 Doremus Avenue), Newark, New Jersey 07105; 29 acres; 150 employees working seven days per week, three shifts per day (PAS-00010501).

1. **Business Type:** Production, distribution and sale of construction materials and industrial chemicals (PAS-00010515). Primary chemical manufacturing products included chlorine, caustic soda, chloromethane, methylene chloride, hydrochloric acid, bleach, chloroform, and plasticizers (PAP-00188319; PAP-00366038-39; PAP-00366830; PAS-00010506)

2. **Time Period of Ownership/Operations**

Operator: 1952-1975
Owner: 1952-1974

1952: According to a *Remedial Investigation Report*, prepared for Safety-Kleen Envirosystems Company, dated August 1994, Vulcan's predecessor, Kolker Chemical Company (Kolker) (and/or Leon A. Kolker), owned the facility from approximately May 5, 1952, to approximately July 19, 1963, when Vulcan acquired Kolker (PAP-00188319-20). [It is noted that according to a November 4, 1991, Directive and Notice to Insurers Letter, prior to Vulcan's ownership, Kolker produced nonferrous inorganic salts from the 1920s until 1962. The document also states that in 1961, Vulcan purchased Kolker and dissolved Kolker in 1964 (PAS-00010336).

1962: Vulcan operated the site as a chemical production facility from 1962 until May 1975 (PAP-00188320).

1974: According to a January 14, 1976, letter from Vulcan Materials Company, Inland purchased certain assets of Vulcan, including a chlor-alkali plant and real property on May 1, 1974. This included agreements that Vulcan would continue operation of their chlor-alkali facilities and chloromethanes plants at the site in part using chlorine and other raw materials supplied by Inland (PAP-00186853; PAP-00186886-93; PAP-00188783-89; PAP-00187163-75).

1975: On or about May 1, 1975, Inland shut down operations of the chlor-alkali plant, and Vulcan terminated operation of the chloromethanes plant on or about May 15, 1975 (PAP-00186853).

1981: According to a September, 2001, *Documentation of Environmental Indicator Determination*, Inland and McKesson Envirosystems Company (MEC) merged in 1981 (PAS-00091937).

1982: On October 10, 1982, an explosion and fire destroyed much of the facility. The New Jersey Department of Environmental Protection (NJDEP) closed the site two days later (PAS-00091937).

1987: According to the *Certification of Virgil W. Duffie, III, Esq.*, in March 1987, the issued and outstanding shares of common stock of MEC were sold to Nucer, a former wholly owned subsidiary of Safety-Kleen Systems, Inc. Subsequent to March 31, 1987, Nucer and MEC merged into a new corporation named Safety-Kleen Envirosystems Company (PAS-00187236).

1998: In 1998, Safety-Kleen Systems, Inc. was acquired by, and became a wholly owned subsidiary of Laidlaw Environmental Services, Inc. At or about the same time, Laidlaw Environmental Services, Inc. changed its name to Safety-Kleen Corp. and renamed its newly acquired subsidiary Safety-Kleen Systems, Inc. (PAP-00187236).

3. Operational History/COC Use and Presence at the Facility

Kolker manufactured a number of organic and inorganic chemicals, including non-ferrous inorganic salts, chlorine, chloroform, methyl chloride, methylene chloride, and plasticizers (PAP-00188319; PAP-00366038-39; PAP-00366830). In addition, Kolker's use of PCBs at the facility is documented by sales records from Monsanto indicating they purchased at least 183,000 pounds of PCBs (including Aroclors 1242, 1248, 1254, and 1260) between 1958 and 1962 (PAP-00366041-53; PAP-00366040). It is noted that documentation of the use of PCBs at the facility was not identified in the available file material.

Vulcan acquired Kolker in 1963 and produced a variety of chemicals during its 13 years in operation at the site, including, but not limited to, chlorine, caustic soda, chloroform, methyl chloride, hydrochloric acid and methylene chloride, as noted in a November 4, 1991, Directive and Notice to Insurers Letter (PAS-00010337). As reported by a June 20, 1972, Waste Effluent Survey, chlorine and caustic soda were produced by the electrolysis of sodium chloride brine solution, in the chlor-alkali facility. In the chloromethanes facility methylene chloride was produced by the thermal chlorination of methyl chloride. Byproduct hydrogen chloride was reacted with methanol to produce methyl chloride (PAS-00010501).

According to a January 14, 1976, letter from Vulcan Materials Company, Inland purchased certain assets of Vulcan on May 1, 1974. This included agreements that Vulcan would continue operation of their chlor-alkali and chloromethanes plant at the site, in part using chlorine and other raw materials supplied by Inland until May 1975 (PAP-0186853; PAP-00186886; PAP-00188783; PAP-00187163).

According to a letter prepared by Inland, dated June 27, 1975, lead was generated as a result of the chlor-alkali process (PAP-00188223). An Inland memorandum, dated December 7, 1973, explains how lead was generated in this process. According to the memorandum, the tops of the anodes in which the chlorine was manufactured were cast from concrete. When a cell top was rebuilt, graphite anodes were bolted to a bus bar

assembly in the cell top. The junction between the graphite and the bus bar assembly was fixed by pouring molten lead into the cell top. The lead was painted with asphalt to protect the lead from exposure to chlorine (PAP-00362239). This operation was shut down in May 1975 (PAP-00188218).

4. Identified COCs

- PCBs (used by Kolker)
- Copper (released by Balbach)
- Lead (released by Balbach, released by Vulcan, detected)
- Mercury (released by Balbach)

It is noted that, according to an Administrative Consent Order, dated June 23, 1993, the site constitutes a portion of a larger tract of land on which Balbach Smelting and Refining, Inc. (Balbach) conducted smelting and refining of lead, copper, and precious metal-based ores from at least the 1890s until 1938 (PAP-00186325-6). Balbach was reportedly one of the largest metals refiners in the world at the time (PAP-00186326), and according to a *Phase II Remedial Investigation Work Plan*, prepared by Blasland, Bouck, & Lee, Inc., dated March 1995, Balbach processed "substantial quantities" of ores and generated a variety of "toxic" heavy metals, resulting in lead, copper, and mercury contamination attributable to Balbach's operations (PAS-00011253-4; PAP-00362426, 35-38). In addition, according to a *Phase II Remedial Investigation Report*, prepared by BBL, dated December 1995 (1995 Phase II RI), Balbach filled the site with smelter slag (PAP-00364135; PAP-00188312, 52-53; PAP-00186325-6; PAP-00362426, 36). In 1993, an Administrative Consent Order was issued by NJDEP which exempted Safety-Kleen Environsystems Company from responsibility for remedying conditions resulting from the former metal refining practices at the site, or from any other activities which pre-dated 1952 (PAS-00011257).

Further, according to the 1995 Phase II RI, metallic constituents detected in soil during Safety-Kleen Envirosystems Company's Phase I and Phase II remedial investigations were related to historical smelting operations conducted by Balbach, and were not related to post-1952 operations. This was confirmed by the results of statistical analyses performed on the Phase I RI soils data. The report states that the results of this statistical analysis were accepted by NJDEP in a May 3, 1995, Phase II RI Work Plan conditional approval letter (PAP-00364123; PAS-00010852-3).

PCBs

Kolker's use of PCBs at the facility is documented by sales records from Monsanto indicating they purchased at least 183,000 pounds of PCBs (including Aroclors 1242, 1248, 1254, and 1260) between 1958 and 1962 (PAP-00366041-53; PAP-00366040). It is noted that documentation of the use of PCBs at the facility was not identified in the available file material.

No sampling data were available from the time period during which Vulcan operated at the site.

Lead

According to a letter prepared by Inland, dated June 27, 1975, lead was generated as a result of the chlor-alkali process (PAP-00188223). Vulcan issued a report on November 29, 1972, titled *Vulcan Materials Company Newark, New Jersey Plant* that detailed a number of environmental concerns at the site, including the presence of "high levels" of contaminants in the plant effluent which discharged to the Newark Bay. Samples collected from the effluent from July 11, 1972, to July 22, 1972, show the water to be contaminated with lead (10 pounds per day), among other contaminants (PAS-00010465). The report also discussed the installation of a "spillage collection system" to reduce caustic losses from equipment malfunctions, operator errors and weekly equipment washouts (PAS-00010337).

According to the *Vulcan Materials Company Newark, New Jersey Plant* dated November 29, 1972, the calculated quantity of lead added to the plant effluent as a result of process operations was 10 pounds per day (PAS-00010465). Vulcan reported that they did not know of any feasible method for a significant reduction in lead, and that the lead concentration in the total plant effluent and in the chlorine-caustic unit effluent was 0.1 to 0.3 parts per million (ppm). The methylene chloride unit effluent contained about 1 ppm lead, while the cathode wash water contained lead at 0.1 to 14 ppm. Vulcan stated that part of the lead could be removed from the latter two streams, but that they contained only 10 to 15 percent of the average of 10 pounds per day discharged in the effluent. They went on to state that only a 10 percent reduction of lead was practical, and that this would be achieved by the fourth quarter of 1973 (PAS-00010469).

The following lead data were available from 1973 and 1974:

- In April 1973, the concentrations of lead in plant effluent ranged from 0.015 ppm to 0.076 ppm (PAP-00217718).
- In October 1973, the concentrations of lead in plant effluent ranged from 0.003 ppm to 0.090 ppm (PAP-00219175).
- In November 1973, the concentrations of lead in plant effluent ranged from 0.001 ppm to 0.009 ppm (PAP-00219176).
- In March 1974, after Vulcan's outside lab began using a new sample preparation methodology, the concentrations of lead in plant effluent ranged from 0.16 ppm to 0.45 ppm; net pounds per day ranged from 4 to 28 net pounds per day (PAP-00219181).
- In April 1974, the concentrations of lead in plant effluent ranged from 0.14 ppm to 0.65 ppm; net pounds per day ranged from 4 to 48 net pounds per day (PAP-00188992).
- In June 1974, the concentrations of lead in plant effluent ranged from 0.004 ppm to 0.3 ppm and 0.06 to 20 net pounds per day (PAP-00219184).

It is noted that Vulcan's monthly discharge monitoring results from January 1974 through April 1974 describe that the independent laboratory used by Vulcan to analyze its wastewater samples changed its method of sample preparation resulting in increases in reported lead discharges (PAP-00188996; PAP-0185401; PAP-00185411; PAP-00188992).

According to the *Expert Report of Michael Werth*, prepared for McKesson Corporation, dated April 2019, the mass of lead discharged to Newark Bay from the site via Outfall 001 during Vulcan's operations was approximately 6,600 pounds. An estimated 820 pounds of lead were discharged by Inland in excess of permit limits (PAP-00402571-573, 583, 595-602).

Historic Fill

The Allocation Team has determined that the facility site is located on regional Historic Fill as designated by the NJDEP.[1]

NJDEP has established that Historic Fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 COCs: PAHs, lead, copper, and mercury.[2] Accordingly, NJDEP technical requirements for property containing Historic Fill requires sampling for the EPA Target Compound List for PAHs and Target Analyte List for metals, including lead, copper, mercury, and the OU2 PAH COCs.[3] PAHs, lead, copper, and mercury are recognized by NJDEP to be constituents of Historic Fill at varying levels, not atypically at or exceeding residential soil standards.[4]

It is noted that according to a memo prepared by NJDEP, dated December 14, 1979, three soil borings show compacted fill and cinder from 0 to 10 feet (PAP-00187208). According to a *Remedial Investigation Report*, prepared for Safety-Kleen Envirosystems Company, dated August 1994, the entire site is covered with fill which dates back to before 1911 (PAP-00188312). In addition, according to a *Phase II Remedial Investigation Work Plan*, dated March 1995, surface soil extending to 7 to 10 feet is composed of fill material of variable composition (PAP-00362435). Finally, according to the 1995 Phase II RI, metallic constituents detected in soil during Safety-Kleen Envirosystems Company's Phase I and Phase II remedial investigations were related to

[1] *Digital Geodata Series, DGS04-7, Historic Fill for New Jersey*, https://www.nj.gov/dep/njgs/geodata/dgs04-7.htm, Quadrangle #52 and #53 (NJDEP map identifying locations of recognized historic fill).
[2] *Characterization of Ambient Levels of Selected Metals and cPAHs In New Jersey Soils* (2002) and *Characterization of Ambient Levels of Selected Metals and Other Analytes In New Jersey Soils* (1997), studies prepared for NJDEP, Division of Science and Research, by BEM Systems, Inc.
[3] New Jersey Department of Environmental Protection (NJDEP), *N.J.A.C. 7:26E Technical Requirements for Site Remediation,* Table 4-2, November 2009 [Note that Table 4-2 has been deleted from the current version of N.J.A.C. 7:26E (May 7, 2012) and the updated *Historic Fill Technical Guidance* (April 2013) as NJDEP believed that the tables list of historic fill constituents was too restrictive].
[4] NJDEP Table 4-2 (PAHs and lead) and a summary of NJDEP records regarding investigations of properties in the vicinity of the Passaic River recognized to be located in areas of Historic Fill indicate that the following average/maximum (mg/kg) contamination levels of OU2 COCs exist in area Historic Fill: PAHs (1.91/160), lead (574/10,000), copper (11.2/1,200), and mercury (0.21/3.7).

historical smelting operations conducted by Balbach, and were not related to post-1952 operations. This was confirmed by the results of statistical analyses performed on the Phase I RI soils data. The report states that the results of this statistical analysis were accepted by NJDEP in a May 3, 1995, Phase II RI Work Plan conditional approval letter (PAP-00364123; PAS-00010852-53).

No sampling data were available from the time period during which Vulcan operated at the site.

5. COC Pathways

The facility is located at the mouth of the Passaic River where it enters Newark Bay (just north of River Mile 0.0) (PAP-00402573, 76).

Sanitary and Storm Sewer

As reported by a June 20, 1972, Waste Effluent Survey, Vulcan was not connected to the Passaic Valley Sewerage Commission (PVSC) system; sanitary wastes were disposed in septic tanks (PAS-00010503).

Direct Release

According to a *Vulcan Materials Company Chemicals Division* report, dated March 4, 1969, water drawn from Newark Bay was used by the facility for cooling, barometric condensers, and "other" condensers and then returned to Newark Bay (PAS-00058035). The report goes on to state that pollutants could enter effluent at the barometric condensers or through accidental spills or leaks in the system (PAS-00058037). This would have included the lead contaminated effluent discussed in Sections 4 and 5 above.

As reported by a June 20, 1972, Waste Effluent Survey, Vulcan discharged 5,387,000,000 gallons of wastewater to Newark Bay (PAS-00010502). The facility also reported in the 1972 Waste Effluent Survey that they were not connected to the PVSC system; sanitary wastes were disposed in septic tanks (PAS-00010503).

According to a letter prepared by Vulcan, dated April 26, 1972, the only facility discharge point was a main plant drain discharging into Newark Bay (PAS-00010499).

According to a National Pollutant Discharge Elimination System (NPDES) Application dated September 27, 1976, the facility held a NPDES permit (#NJ0001279) at least as early as December 30, 1972. The application states the facility had one discharge point to a surface water body via outfall 001; the receiving water body was listed as "Tidal Waters #3; Newark." The discharge volume was listed as 10,000 gallons per day (PAP-00185803-07).

According to a memo prepared by Inland, dated June 3, 1974, a flooding condition due to heavy rains was documented by Vulcan, and consisted of a drainage ditch overflowing across plant property, picking up contaminants from the soil. A pump was

installed to transfer surplus water in the ditch back into the plant water disposal system (PAP-00188969).

Spills

There is no information regarding spills in the available file material.

6. Regulatory History/Enforcement Actions

Inspections

According to a *Vulcan Materials Company Chemicals Division* report, dated March 4, 1969, “some discoloration” at the point of wastewater discharge to Newark Bay was observed during an inspection on March 4, 1969 (PAS-00058036).

Enforcement Actions

According to a *Report on the Quality of the Interstate Waters of the Lower Passaic River and Upper and Lower Bays of New York Harbor*, dated November 1969, the New Jersey State Department of Health had issued “pollution abatement orders” to Vulcan (PAS-00058707). Details of the reason for the order are not provided in the report. According to a letter prepared by legal counsel for Vulcan, dated November 5, 1969, Vulcan was given notice to install and provide wastewater treatment and disposal facilities, and to cease discharging “industrial waste or polluting matter” into the Passaic River (PAP-00217398). There is no indication that COCs were associated with the referenced discharge. According to the letter, Vulcan was in the process of addressing the order. It also states that water was taken into the plant from Newark Bay at a point north of the “main sewer," which was used for cooling purposes, and “it picks up a minimal amount of waste which will be the subject of intensive treatment and control” (PAP-00217398-404).

NJDEPE issued a Directive and Notice to Insurer, dated October 31, 1991, to Vulcan directing Vulcan to pay NJDEPE for the completion of a remedial investigation and feasibility study of the site (PAS-00010336-38).

Permits

As reported by a September 27, 1976, NPDES Application, the facility held a NPDES permit (#NJ0001279) as early as December 30, 1972 (PAP-00185805).

7. Response Actions

There is no information regarding sampling data during which Vulcan operated in the available file material.

8. Summary of Asserted Defenses

No legal defenses were identified in the available file material.

Diamond Alkali OU2 Allocation
ADR Confidential
Facility Data Report

NATIONAL-STANDARD COMPANY

Facility Name, Address and Size: National-Standard Company – Athenia Steel Site; 714-716 Clifton Avenue, Clifton, New Jersey; 35 acres (PAP-00382569); Information on number of employees and shifts per day was not identified in available file material.

1. **Business Type:** Rolling and heat-treating of flat spring steel (PAP-00382575)

2. **Time Period of Ownership/Operations**

   Operator: 1938 to 1988
   Owner: 1938 to 1999

   1907: National-Standard Company (National Standard) was founded in Chicago, Illinois, in 1907. At the same time, Athenia Steel Company began its operations at 714-716 Clifton Avenue, Clifton, New Jersey (PAS-00012920).

   1938: National Standard acquired the site from Athenia Steel Company in 1938 (PAP-00090916).

   1988: Operations at the Clifton Avenue site were terminated in 1988 (PAP-00090916; PAP-00091040).

   1999: National Standard sold the property to the City of Clifton in September 1999 (PAP-00197478).

3. **Operational History/COC Use and Presence at the Facility**

   According to a *Decommissioning and Demolition Report*, dated September 25, 1989 (1989 D&D Report), operations at the site included the production of various flat wire and strip steel products, including high carbon steel wire and strips from hot rolled steel bands and strips (PAP-00090960, 62). Acid baths were utilized to clean steel stock and the finished product was coated with petroleum oil to retard oxidation (PAP-00090990). Molten lead was historically used to heat and soften steel stock (PAP-00090925). Site studies commissioned by National Standard reported that drawing, cutting, heat treating, cleaning, and other site operations required the use of, or resulted in the generation of, the following materials of note:

   - Gasoline (leaded and unleaded);
   - Lead (elemental lead);
   - Lubricating oils;
   - Mineral spirits;
   - No. 2 fuel oil;
   - No. 4 fuel oil;
   - Preservative oils;
   - Waste oil and water; and,
   - Water soluble oil (PAP-00090962, 66, 70, 72).

According to the 1989 D&D Report, on-site heat and hot water were historically produced via the burning of coal. By the mid- to-late 1960s, No. 2 fuel oil, natural gas, and propane were substituted for coal as a source for heat and hot water production (PAP-00090962, 85). According to an *ECRA Cleanup Plan Report*, dated August 21, 1989 (1989 ECRA), a former coal gasification plant was also located on the site. The coal gasification plant was used to convert coal into "usable gas product" and to supplement energy needs for daily manufacturing operations. The specific time-period that the coal gasification plant operated is not reported (PAP-00197095; PAP-00090985).

The 1989 ECRA states that there were two landfill areas present on the site that received site generated production waste materials, and off-site soils, asphalt, and concrete debris, until this practice was discontinued in the mid-1970s. Ash and cinders from the operation of the on-site power house and coal gasification plant were present within the landfill areas and beneath portions of the main plant buildings (PAP-00197095). According to a *Disruption and Closure Permit Application*, dated June 1, 1989, lead dross (scum from the surface of the molten lead) and soils with elemental lead associated with operations at the site also were placed in the landfill; however, investigations, including borings and test pits, did not reveal lead dross in the landfill (PAP-00197231). It was estimated that a total of 170,000 cubic yards of miscellaneous debris was present within the landfilled areas (PAP-00197232).

According to a *Report of Findings, Phase I Sampling and Analysis for National Standard*, dated March 29, 1988 (1988 Phase I Report), site rinse water from the manufacturing lines was originally discharged to at least three, and possibly five, cesspools or dry wells until the 1970s when the discharges were connected (after pre-treatment) to the Passaic Valley Sewerage Commission (PVSC) system (PAP-00196946; PAP-00090922; PAS-00101870).

Based on review of available file material, it is unclear what OU2 COCs may have been in the rinse water, if any; however, copper, lead, and mercury were identified in soil when the bottoms of the cesspools/dry wells were sampled. This is discussed further in Section 4 below. According to the 1989 *ECRA*, there were three on-site cesspools, which reportedly received rinse waters from the manufacturing lines from the early 1900s to approximately 1973. The cesspools were approximately 18 feet deep. They were believed to be constructed of fitted rock walls without caulking, and to have soil bottoms, which facilitated the dissipation of the rinse waters into the subsurface. The 1989 ECRA states that it should be noted that the term “cesspool” was used, but in actuality they were dry wells, since they did not receive sanitary waste or wastewater discharges. In addition, a drywell was located north of the site which reportedly received surface runoff from the roof drains and the surrounding site areas (PAP-00197122).

4. Identified COCs

- PCBs (detected)
- PAHs (generated, detected)
- DDx (detected)
- Copper (detected)
- Lead (used, detected)
- Mercury (detected)

PCBs

A landfill area was located in the central portion of the site and was reportedly used for disposal of construction debris (PAS-00101893). According to a *Report of Findings, Hydrogeologic Investigation, Phase II*, dated February 10, 1989 (1989 Phase II Report), PCBs were detected in soil in the vicinity of the landfill in one soil sample at a concentration of 4.68 parts per million (ppm) at a depth of 10 to 12 feet in 1987 (PAP-00091630).

An oil separator pond was located adjacent to the area of a process wastewater treatment building into which wastewater and oil were pumped. Solids were settled and oil was skimmed from the pond prior to the discharge of the wastewater to Weasel Brook (PAP-00090963). It is reported that use of the oil separator pond was discontinued as of 1976 (PAP-00091003). According to the 1988 Phase I Report, PCBs were detected in one soil sample in this area at a concentration of 0.17 ppm at a depth of 4.5 to five feet in 1987; no surface soil samples were collected. All other samples were reported as non-detect for PCBs (PAP-00196960).

PCBs were identified in soil near the railroad right-of-way (PAP-00091024). According to the 1988 Phase I Report, PCBs were detected in one soil sample in this area at a concentration of 16 ppm at a depth of zero to 0.5 feet in 1987. All other samples were reported as non-detect for PCBs (PAP-00196988).

PCBs were identified in soil in the vicinity of three transformers owned by the electrical utility (PAP-00090965, 1012, 1015-17). According to the 1988 Phase I Report, PCBs were detected in surface soil (zero to 0.5 feet) in this area at concentrations ranging from 0.465 ppm to 8.4 ppm in 1987 (PAP-00196973, 77).

PAHs

According to the 1989 D&D Report, on-site heat and hot water were historically produced via the burning of coal. By the mid- to-late 1960s, No. 2 fuel oil, natural gas, and propane were substituted for coal as a source for heat and hot water production (PAP-00090962, 85).

According to an *ECRA Cleanup Plan Report*, dated August 21, 1989 (1989 ECRA), a former coal gasification plant was also located on the site. The coal gasification plant was used to convert coal into "usable gas product" and to supplement energy needs for daily manufacturing operations. The specific time-period that the coal gasification plant operated is not reported (PAP-00197095; PAP-00090985).

According to the 1989 Phase II Report, high molecular weight PAHs were detected in soil associated with the landfill used for disposal of construction debris (PAS-00101893; PAP-00091634). In addition, the 1989 D&D Report indicates that PAHs were identified in soil beneath several of the site's underground storage tanks (PAP-00090976-81).

DDx

According to a *Northern Area Soil Remedial Investigation Report and Remedial Investigation Work Plan*, dated December 21, 2005, dichlorodiphenyldichloroethylene (4,4-DDE) and dichlorodiphenyltrichloroethane (4,4-DDT) were detected in soil samples at "trace concentrations" (PAP-00197495, 541-44). 4,4-DDE was detected at a maximum concentration of 0.0028 ppm, and 4,4-DDT was detected at a maximum concentration of 0.0043 ppm in 2005 (PAP-00197495).

Copper

Copper was identified in soil in the vicinity of the landfill used for construction debris (PAS-00101909, 913). According to the 1988 Phase I Report, copper was detected at concentrations of 3 ppm to 610 ppm at a depth of 13 to 15 feet in 1987 (PAP-00196953).

Copper was identified in soil in the vicinity of the oil separator pond (PAP-00091001, 1003, 1007). According to the 1988 Phase I Report, copper was detected at concentrations of 3.3 ppm to 198 ppm at a depth of four to five feet in 1987 (PAP-00196962).

The site used three on-site cesspools/drywells from the early 1900s to approximately 1973. The three cesspools were noted to have received rinse waters from manufacturing lines. In addition, the site had a dry well located to the north which received surface runoff from the site's roof drains and surrounding site area (PAP-00090965). Copper was identified in soil near the cesspools (PAP-00090998). According to the 1988 Phase I Report, copper was detected at a maximum concentration of 175 ppm in samples collected from the bottom of the cesspools at a depth of 20 feet in 1987 (PAP-00196945).

A drum storage area was located along the western section of the main site area and was used for waste oil storage. It is reported that stained soils were observed in this area (PAP-00091013-14; PAP-00090965). According to the 1988 Phase I Report, copper was detected in one sample at a concentration of 38 ppm at a depth of 22 to 28 inches in 1987 (PAP-00196981).

Copper was identified in soil near the railroad right-of-way. According to the 1988 Phase I Report, copper was detected at concentrations of 19.6 ppm to 99 ppm at a depth of zero to six inches (PAP-00196988).

Lead

Molten lead was historically used to heat and soften steel stock (PAP-00090925). According to a *Disruption and Closure Permit Application*, dated June 1, 1989, lead dross (scum from the surface of the molten lead) and soils with elemental lead associated with operations at the site also were placed in the landfill; however, investigations, including borings and test pits, did not reveal lead dross in the landfill (PAP-00197231).

Lead was identified in soil in the vicinity of the landfill used for construction debris (PAS-00101872, 885-88, 909, 913-14). According to the 1989 Phase II Report, lead was detected in this area at concentrations at high as 240,000 ppm at a depth of five to seven feet. A sample collected from zero to two feet had a lead concentration of 8,200 ppm; a sample collected from one to three feet had a lead concentration of 160,000 ppm (PAP-0091628).

Lead was identified in soil in the vicinity of the oil separator pond (PAP-00091000-01, 1003, 1007). According to the 1988 Phase I Report, lead was detected at concentrations of 10.5 ppm to 17,650 ppm at a depth of four to five feet (PAP-00196962).

A drum storage area was located along the western section of the main site area and was used for waste oil storage. It is reported that stained soils were observed in this area (PAP-00091013-14; PAP-00090965). According to the 1988 Phase I Report, lead was detected in one sample at a concentration of 13 ppm at a depth of 22 to 28 inches in 1987 (PAP-00196981).

Lead was identified in soil near the railroad right-of-way (PAP-00091023-24). According to the 1988 Phase I Report, lead was detected at concentrations of 190 ppm to 705 ppm at a depth of zero to 0.5 feet (PAP-00196988).

According to the 1988 Phase I Report, lead concentrations detected in soil samples in the area of the three on-site cesspools/drywells were as high as 1,470 ppm in samples collected from the bottom of the cesspools at a depth of 18 to 20 feet (PAP-00196947). According to a *Pilot Response on Soil Delineation*, dated February 24, 1997, National Standard collected a soil sample from beneath a former underground process sewer line in approximately 1988 or 1989. Lead was detected at a concentration of 590 ppm. This area of contamination was subsequently excavated in 1990. Post-excavation sample data identified lead at a maximum concentration of 217 ppm, below the New Jersey Department of Environmental Protection's (NJDEP) "residential direct contact soil cleanup criterion" of 400 ppm (PAS-00101976-78). National Standard also collected a soil sample beneath a second underground process sewer line at the same time. Excavation of this area also was conducted. Post-excavation confirmation samples had lead concentrations of 2,350 ppm (at 13-13.5 feet) and 3,770 ppm (at 16 feet). A second round of excavation occurred, and another post-excavation confirmation sample had a lead concentration of 3,840 ppm (at 23-23.5 feet). Therefore, a third round of excavation was conducted. Post-excavation sample data identified lead at a maximum concentration of 205 ppm, below the NJDEP "residential direct contact soil cleanup criterion" of 400 ppm (PAS-00101979-83). Based on review of available file material, it is unclear how these process sewer lines were connected to the site's sewer system.

Lead was identified in soil in the vicinity of three transformer pads (PAP-00090769). According to an *Expedited Remediation Investigation Report for Northern and Southern Areas*, dated February 2000, lead was detected at concentrations of 120 mg/kg to 3,500 mg/kg at a depth of zero to 0.5 feet (PAP-00090789).

Mercury

Mercury was identified in soil in the vicinity of the landfill used for construction debris. According to the 1988 Phase I Report, mercury was detected at a maximum concentration of 0.41 ppm at a depth of 13 to 15 feet in 1987 (PAP-00196953).

Mercury was identified in soil in the vicinity of the oil separator pond. According to the 1988 Phase I Report, mercury was detected at concentrations of 0.3 ppm to 0.54 ppm at a depth of three to five feet in 1987 (PAP-00196962).

The site used three on-site cesspools/drywells from the early 1900s to approximately 1973. The three cesspools were noted to have received rinse waters from manufacturing lines. In addition, the site had a dry well located to the north which received surface runoff from the site's roof drains and surrounding site area (PAP-00090965). According to the 1988 Phase I Report, mercury was detected at a maximum concentration of 0.4 ppm in samples collected from the bottom of the cesspools at a depth of 15 to 17 feet in 1987 (PAP-00196945).

A drum storage area was located along the western section of the main site area and was used for waste oil storage. It is reported that stained soils were observed in this area (PAP-00091013-14; PAP-00090965). According to the 1988 Phase I Report, mercury was detected in one sample at a concentration of 0.16 ppm at a depth of 22 to 28 inches in 1987 (PAP-00196981).

Mercury was identified in soil near the railroad right-of-way. According to the 1988 Phase I Report, mercury was detected at concentrations of 0.28 ppm to 0.31 ppm at a depth of zero to six inches (PAP-00196988).

Historic Fill

The Allocation Team has determined that the facility site is partially located on regional Historic Fill as designated by the NJDEP.[1]

NJDEP has established that Historic Fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 contaminants of concern (COCs): PAHs, lead, copper, and mercury.[2] Accordingly, NJDEP technical requirements for property containing Historic Fill requires sampling for the United States Environmental Protection Agency (EPA) Target Compound List for PAHs and Target Analyte List for metals, including lead, copper, mercury, and the OU2 PAH COCs.[3] PAHs, lead, copper,

[1] *Digital Geodata Series, DGS04-7, Historic Fill for New Jersey*, https://www.nj.gov/dep/njgs/geodata/dgs04-7.htm, Quadrangle #41, #52 & #53 (NJDEP map identifying locations of recognized historic fill).
[2] *Characterization of Ambient Levels of Selected Metals and cPAHs In New Jersey Soils* (2002) and *Characterization of Ambient Levels of Selected Metals and Other Analytes In New Jersey Soils* (1997), studies prepared for NJDEP, Division of Science and Research, by BEM Systems, Inc.
[3] New Jersey Department of Environmental Protection (NJDEP), *N.J.A.C. 7:26E Technical Requirements for Site Remediation,* Table 4-2, November 2009 [Note that Table 4-2 has been deleted from the current

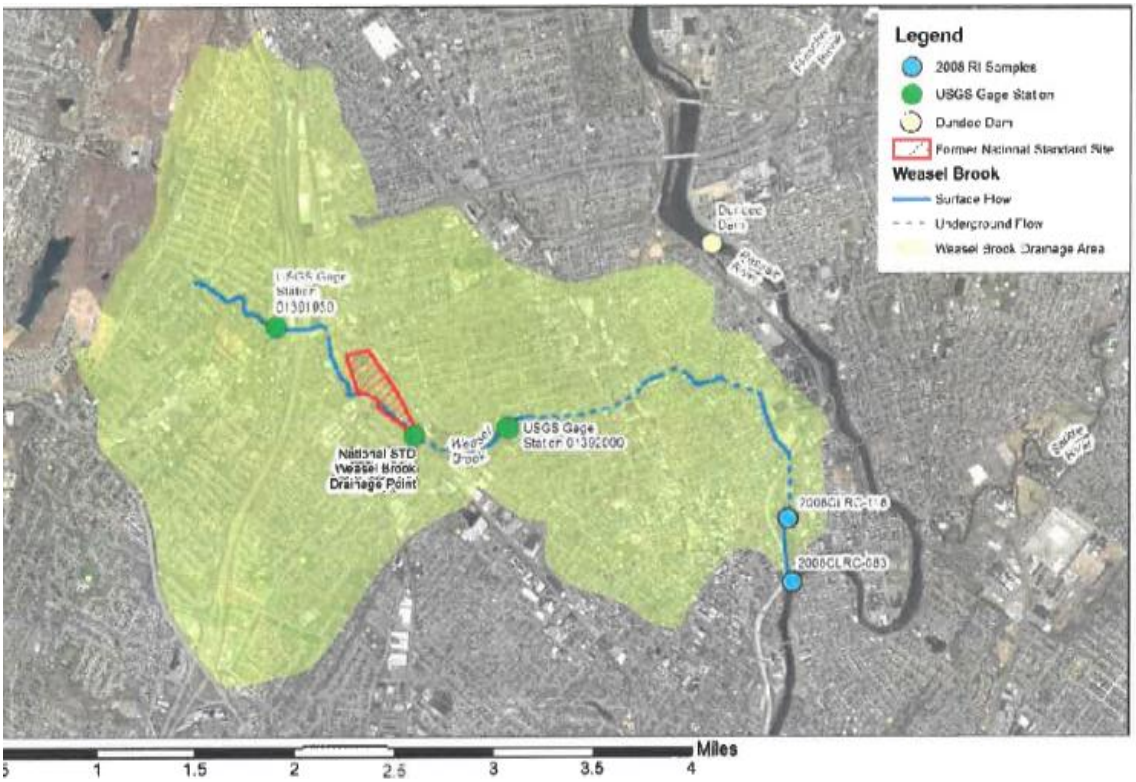
and mercury are recognized by NJDEP to be constituents of Historic Fill at varying levels, not atypically at or exceeding residential soil standards.[4]

While the Allocation Team has determined that the facility is not located in an area designated by NJDEP as containing Historic Fill, it is noted that according to a *Delineation Soil Sampling in AOCs as Referenced in NJDEP Letter of May 18, 1994*, dated November 4, 1994, the upper five to ten feet of the oldest portions of site was underlain by fill material. The fill material consisted of brick fragments, reworked sand and gravel, and coal ash that was distributed over the site during former site operations as structural fill. The area where these materials were found all lie within the presently defined landfill (PAP-00091421).

Finally, it is noted that Weasel Brook was culverted in 1987 along the entire length of the site, and runs in a concrete channel in the northern portion of the site and in an enclosed culvert adjacent to the central portion of the site (i.e., Active Area) (PAP-00090921).

The maximum levels of PCBs, PAHs, copper, lead and mercury detected at the site in soils are presented in the table below (PAP-00197401-19; PAP-00196962; PAP-00196953; PAP-0091628).

COCs Found in Onsite Soils	
COC	**Max Detected Concentration**
Lead	240,000 mg/kg
Copper	610 mg/kg
Mercury	0.54 mg/kg
Benzo(a)anthracene	12.2 mg/kg
Benzo(a)pyrene	8.963 mg/kg
Benzo(b)fluoranthene	15.359 mg/kg
Benzo(k)fluoranthene	18.105 mg/kg
Dibenzo(a,h)anthracene	0.304 mg/kg
Indeno(1,2,3-cd)pyrene	5.57 mg/kg



5. COC Pathways

Weasel Brook, a tributary to the Passaic River, runs along the western border of the site; the site is two miles inland and three miles upstream of the Passaic River (PAP-00090916).

version of N.J.A.C. 7:26E (May 7, 2012) and the updated *Historic Fill Technical Guidance* (April 2013) as NJDEP believed that the tables list of historic fill constituents was too restrictive].

[4] NJDEP Table 4-2 (PAHS and lead) and a summary of NJDEP records regarding investigations of properties in the vicinity of the Passaic River recognized to be located in areas of Historic Fill indicate that the following average/maximum (mg/kg) contamination levels of OU2 COCs exist in area Historic Fill: PAHs (1.91/160), lead (574/10,000), copper (11.2/1,200), and mercury (0.21/3.7).

The location of the site relative to the Passaic River is depicted below (PAP-00090916):

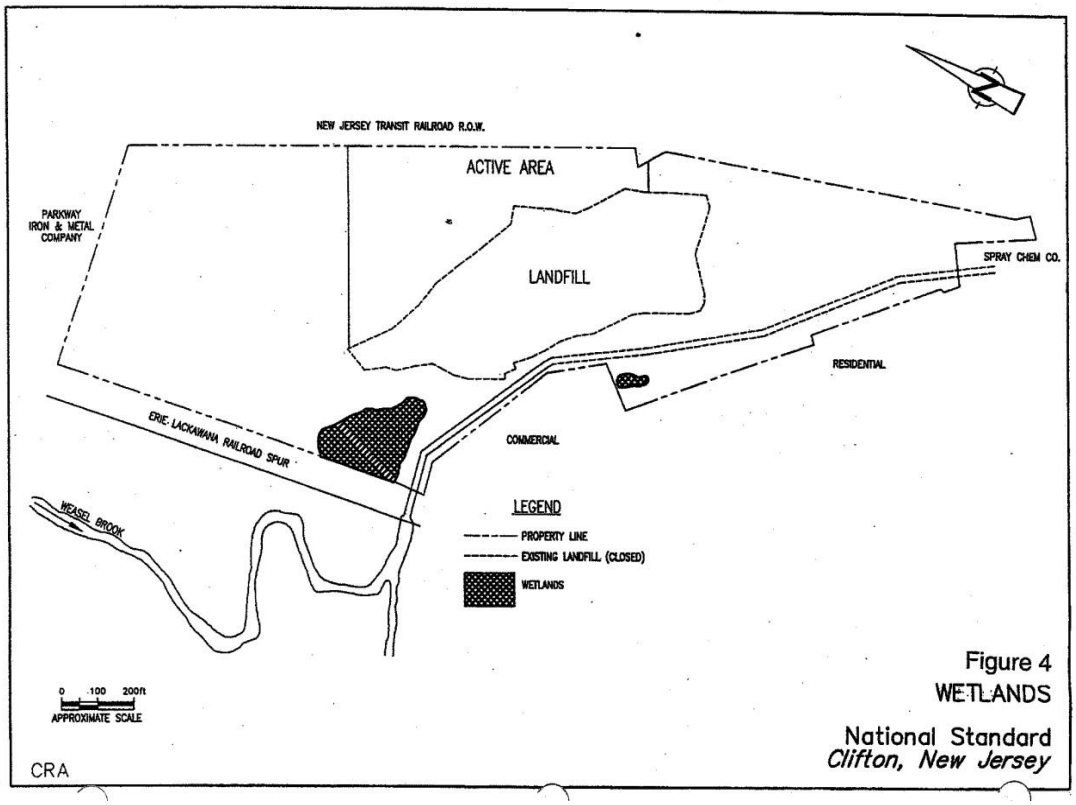
* USGS Gauging Station 01392000 also represents the location of Weasel Brook Pond.

Sanitary and Storm Sewer

Historically, rinse waters from manufacturing lines were discharged directly into cesspools from the early 1900s until approximately 1973, as discussed in a *Preliminary Assessment Report*, dated November 17, 2016 (PAP-00382596). The 1988 Phase I Report states that site pickling rinse water lines discharged to at least three, and possibly five, cesspools or dry wells until the 1970s when the discharges were connected (after pre-treatment) to the PVSC system (PAP-00196946; PAP-00090922; PAS-00101870).

As noted previously, the cesspools were approximately 18 feet deep. They were believed to be constructed of fitted rock walls without caulking, and to have soil bottoms, which facilitated the dissipation of the rinse waters into the subsurface. The 1988 Phase I Report states that it should be noted that the term “cesspool” was used, but in actuality they were dry wells, since they did not receive sanitary waste or wastewater discharges. In addition, a drywell was located north of the site which reportedly received surface runoff from the roof drains and the surrounding site areas (PAP-00197122).

According to a letter prepared by National Standard, dated June 27, 2017, various site wastewaters were discharged to the PVSC system from the mid-1970s to 1988 under a PSVC permit (PAP-00090922). A process wastewater treatment facility was built in the mid-1970s, which was used to adjust the pH of industrial wastewater prior to discharge to the PVSC system (PAS-00101870).



National Standard received Industrial Waste Permit (3402932) for discharge into the PVSC system in 1981. The permit was effective June 1, 1981 to June 1, 1986. The permit covered sanitary waste to Outlet 1 and a second outlet that was to be metered. By August 1981, the site was to re-route non-contact cooling water away from Outlet 1 and were required to comply with monitoring requirements contained in “Interim Mercury Pretreatment Regulations” (PAP-00196916-23). The permit indicates that National Standard was not required to monitor their discharges for OU 2 COCs (PAP-00196921-22).

It is noted that according to an undated memorandum prepared by NJDEP, process wastewater discharges received no treatment, with the exception of pH adjustment, before discharge to the PVSC system, but that completion of a treatment plant was scheduled for 1983. The process wastewater volume was approximately 10,000 gallons per day and the sanitary water volume was approximately 3,000 gallons per day (PAP-00196914).

Direct Release

As stated previously, Weasel Brook, a tributary to the Passaic River, runs along the western border of the site (PAP-00090916).

The location of the site relative to Weasel Brook is depicted below (PAP-00090788):

According to an undated memorandum prepared by NJDEP, the site had two discharges to Weasel Brook which consisted of non-contact cooling water from metal rolling operations (discharge 001) and from air compressors (discharge 002) (PAP-00196914). The site had a New Jersey Pollutant Discharge Elimination System (NJPDES) permit NJ0000035 for discharge of site stormwater to surface water. It is reported that non-contact cooling water from rolling operations and air compressors, as well stormwater were discharged via Outfalls 001 and 002 to Weasel Brook (PAP-00090932). A copy of the permit was not identified in the available file material. It is noted that PVSC reported that, as of July 1972, "polluting discharges" were occurring from three of four outlets to Weasel Brook (as opposed to two outfalls) (PAS-00101850, 52-54).

Based on review of the PVSC violation documentation for August 14 to December 31, 1972, following the PVSC inspection in July 1972 which reported "polluting discharges" to Weasel Brook, the site agreed at the end of 1972 to connect the boiler house drain to the city sewer, seal the site cesspools, and pump their waste into holding tanks for scavenger disposal. PVSC reported that the required steps to end the discharges were made by July 1973 (PAS-00101850, 52-54).

According to the 1989 D&D Report, an oil separator pond was located adjacent to the area of the process wastewater treatment facility into which wastewater and oil were pumped. Solids were settled and oil was skimmed from the pond prior to the discharge of the wastewater to Weasel Brook (PAS-00101870). Use of the oil separator pond was discontinued as of 1976 (PAS-00101910).

It is noted that Weasel Brook was culverted in 1987 along the entire length of the site, and runs in a concrete channel in the northern portion of the site and in an enclosed culvert adjacent to the central portion of the site (i.e., Active Area) (PAP-00090921).

According to a *Disruption and Closure Permit Application*, dated June 1, 1989, site drainage occurred through sheet flow to Weasel Brook or conveyance through existing concrete pipe storm sewer lines. One pipeline conveyed water from the northern most buildings and discharged along the slope, north of landfill. The other pipeline drained the southern half of the buildings and conveyed water through a 15-inch pipe at a manhole, near the wastewater treatment plant. Additional drainage from the building roofs discharged to the surface along a railroad spur. Drainage of the southern portion of the site occurred through drop inlets in the piped section of Weasel Brook (PAP-00197245).

An *Expedited Remedial Investigation Report for Northern and Southern Areas*, dated February 2000, states that Weasel Brook drained the site and the surrounding area. Rain ran off to the low area to the southwest of the former Main Building area, and to the low area to the southeast of the former Main Building area. This runoff and all other local surface runoff was received by Weasel Brook, which flowed through the site, and discharged into the Passaic River to the east of the site (PAP-00090753; PAP-00090767). Further, groundwater was reported to discharge into Weasel Brook during the seasonal low water table that occurs in October (PAS-00101871). However, NJDEP concluded that there is no hydraulic connection between the site and Weasel Brook since culverting was completed (PAP-00090921).

Spills

With respect to the observed releases to Weasel Brook, it is noted that in 1947, patches of oil film observed in Weasel Brook were traced by PVSC to the site. A waste lubricating oil separator pit was found to be flooded and overflowing into the "clear water discharge line" to Weasel Brook. National Standard reportedly cleaned the pit out “at once” (PAS-00101848).

6. Regulatory History/Enforcement Actions

Inspections

According to an undated memorandum prepared by NJDEP, the site was inspected on June 17, 1981, to determine whether the permittee was in compliance with the requirements of their NPDES Permit (No. NJ0000035) issued on September 30, 1980 (PAP-00196914). No deficiencies with respect to COCs were noted based on review of the document.

Violations/Enforcement Actions

According to a PVSC *Annual Report*, dated 1973, on August 14, 1972 PVSC inspectors collected samples of discharges from site outfalls, and analysis showed the samples “were polluting.” On August 16, 1972, PVSC wrote to National Standard, informing them

of the pollution and directing that they cease polluting at once. On August 21, 1972, National Standard replied that they had temporarily diverted the flow from entering Weasel Brook. On December 14, 1972, National Standard agreed to connect the boiler house drains to the city sewer and to seal the cesspools and handle the waste by pumping it to holding tanks for scavenger disposal. They estimated they could complete the work by the end of March 1973. On July 9, 1973, PVSC received a call and inspection revealed that the cesspool had been sealed, a 6,000-gallon fiberglass storage tank and piping installed, and the system ready for operation (PAS-00034750-52). No information on whether COCs were detected in the discharge was available.

NJDEP issued an Administrative Order and Notice of Civil Administrative Penalty Assessment to National Standard in August 1987 due to improper hazardous waste storage and management (PAS-00004222-28).

Permits

According to a letter prepared by National Standard, dated June 27, 2017, various site wastewaters were discharged to the PVSC system from the mid-1970s to 1988 under a PSVC permit (PAP-00090922). A process wastewater treatment facility was built in the mid-1970s, which was used to adjust the pH of industrial wastewater prior to discharge to the PVSC system (PAS-00101870).

The site had a NJPDES permit (NJ0000035) for discharge of site stormwater to surface water. It is reported that non-contact cooling water from rolling operations and air compressors, as well stormwater were discharged via Outfalls 001 and 002 to Weasel Brook (PAP-00090932). A copy of the permit was not identified in the available file material.

National Standard received Industrial Waste Permit (3402932) for discharge into the PVSC system in 1981. The permit was effective June 1, 1981 to June 1, 1986. The permit covered sanitary waste to Outlet 1 and a second outlet that was to be metered. By August 1981, the site was to re-route non-contact cooling water away from Outlet 1 and were required to comply with monitoring requirements contained in Interim Mercury Pretreatment Regulations (PAP-00196916-23). The permit indicates that National Standard was not required to monitor their discharges for OU 2 COCs (PAP-00196921-22).

7. Response Actions

Characterization Activities

The following is a list of major response action documents identified in the available file material:

- *Report of Findings, Phase I Sampling and Analysis for National Standard*, dated March 29, 1988 (PAP-00196932);
- *Report of Findings, Hydrogeologic Investigation, Phase II*, dated February 10, 1989 (PAP-00091594);

- *ECRA Cleanup Plan Report***,** dated December 1989 (PAP-00091429);
- *Delineation Soil Sampling in AOCs as Referenced in NJDEP Letter of May 18, 1994*, dated November 4, 1994 (PAP-00091412);
- *Expedited Remediation Investigation Report for Northern and Southern Areas*, prepared for National-Standard, dated February 2000 (PAP-00090753);
- *Site Investigation Report*, dated October 2001 (PAP-00090726); and,
- *Northern Area Soil Remedial Investigation Report and Remedial Investigation Work Plan*, dated December 21, 2005 (PAP-00197474).

Sewer

National Standard collected a soil sample from beneath a former underground process sewer line in approximately 1988 or 1989, as discussed in a *Pilot Response on Soil Delineation*, dated February 24, 1997. Lead was detected at a concentration of 590 ppm. This area of contamination was subsequently excavated in 1990. National Standard also collected a soil sample beneath a second underground process sewer line at the same time. Excavation of this area also was conducted. Post-excavation confirmation samples had lead concentrations of 2,350 ppm and 3,770 ppm. A second round of excavation occurred, and another post-excavation confirmation sample had a lead concentration of 3,840 ppm. Therefore, a third round of excavation was conducted and confirmation sample concentrations were below the NJDEP's "residential direct contact soil cleanup criterion" (PAS-00101976-80). Based on review of available file material, it is unclear how these process sewer lines were connected to the site's sewer system.

Weasel Brook

According to a letter report prepared by National Standard's environmental consultant, dated October 13, 2006, surface water and sediment samples were collected from three locations in Weasel Brook after National Standard's receipt of EPA's General Notice Letter in November 2005. The purpose of collecting the data was twofold: (1) determine whether there are contaminants of concern in Weasel Brook at levels that could potentially impact the Passaic River and (2) determine whether the site could potentially be a source of any impact (PAS-00107896). One surface water/sediment sample was collected upstream of the site and two surface water/sediment samples were collected downstream of the site (approximately 2,400 feet and 2,800 feet downstream, respectively). Samples were analyzed for PCBs, PAHs, and metals. Results were as follows:

- Benzo(b)fluoranthene and pyrene were detected in the surface water sample collected from Weasel Brook Park Lake inlet (i.e., the first downstream sample) at concentrations below their respective "NJDEP surface-water standards" (PAS-00107899). Neither constituent was detected in the sample collected from the Weasel Brook Park Lake discharge location (i.e., the furthest downstream sample location) (PAS-00107902).

- The concentration of mercury [(0.157 micrograms per Liter (µg/L)] slightly exceeded its "standard" (0.144 µg/L) in the Weasel Brook Park Lake inlet sample (PAS-00107899, 912). According to the letter report prepared by National Standard's consultant, dated October 13, 2006, the "isolated, low-level" observance of mercury is not indicative of any identifiable potential source (PAS-00107900).

- The sediment sampling results showed the presence of "several PAHs and metals at concentrations exceeding applicable sediment screening criteria." These exceedances were identified in the sample collected from the Weasel Brook Park Lake discharge (i.e., the furthest downstream sample) and in the upriver sample. The intermediate sample location (i.e., the first downstream sample location) exhibited "no PAH detections above applicable guidance values." The same observation was reported for metals.

- Overall, the letter report prepared by National Standard's consultant, dated October 13, 2006, concluded that while select PAHs and metals, "marginally exceed their surface water or sediment quality criteria," the data show that the National Standard site "is not the source for these observed constituents in water and sediment." The letter report also concluded that "the distribution of these constituents points to potential upriver as well as potential alternate downriver sources (including natural background) for the constituents and concentrations observed in Weasel Brook" (PAS-00107901).

- No PCBs were detected in either sediment or water samples along the study reach of Weasel Brook (PAP-00090920; PAS-0010789-900).

Based on the results of the evaluation, the consultant concluded "there is no data to support U.S. EPA's assertion that the former National-Standard facility in Clifton, New Jersey is connected to the contamination in the Study Area" (PAS-00107896).

Soil

Between 1984 and 1994, COCs were identified in soil associated with the following operations (petroleum hydrocarbons detections are noted as they may be indicative of COC releases):

- A landfill area was located in the central portion of the site and was reportedly used for disposal of construction debris (PAS-00101893). Petroleum hydrocarbons, lead, copper, and PCBs were identified in soil in the vicinity of the landfill (PAS-00101872, 909, 911-13). According to the 1988 Phase I Report, lead was detected at a concentration of 41,200 ppm at a depth of 13 to 15 feet. Copper was detected at concentrations of 3 ppm to 610 ppm at a depth of 13 to 15 feet. Mercury was detected at a maximum concentration of 0.41 ppm at a depth of 13 to 15 feet (PAP-00196953). In addition, according to the 1989 Phase II Report, lead was detected in this area at concentrations at high as 240,000 ppm at a depth of five to seven feet. A sample collected from zero to two feet

had a lead concentration of 8,200 ppm; a sample collected from one to three feet had a lead concentration of 160,000 ppm (PAP-0091628). PCBs were detected at a maximum concentration of 4.68 ppm (PAP-00091630). High molecular weight PAHs were detected in soil associated with the landfill area (PAP-00091634).

- A spray pond was located adjacent to the power house and former coal gasification and steam power plants and used as a cooling pond (PAP-00090963; PAP-00091008). Petroleum hydrocarbons were identified in soil in the vicinity of the spray pond (PAP-00091008, 1011; PAP-00196964).

- An oil separator pond was located adjacent to the area of a process wastewater treatment facility into which wastewater and oil were pumped. Solids were settled and oil was skimmed from the pond prior to the discharge of the wastewater to Weasel Brook (PAP-00090963). It is reported that use of the oil separator pond was discontinued as of 1976 (PAP-00091003). Petroleum hydrocarbons, lead, copper, and PCBs were identified in soil in the vicinity of the oil separator pond (PAP-00091000-01, 1003, 1007). According to the 1988 Phase I Report, lead was detected at concentrations of 10.5 ppm to 17,650 ppm at a depth of four to five feet. Copper was detected at concentrations of 3.3 ppm to 198 ppm at a depth of four to five feet. Mercury was detected at concentrations of 0.3 ppm to 0.54 ppm at a depth of three to five feet (PAP-00196962). PCBs were detected in soil in this area at a maximum concentration of 0.17 ppm (PAP-00196960).

- Petroleum hydrocarbons, PCBs, pesticides, metals, and lead were identified in soil near the railroad right-of-way (PAP-00091023-24). According to the 1988 Phase I Report, lead was detected at concentrations of 190 ppm to 705 ppm at a depth of zero to 0.5 feet. Copper was detected at concentrations of 19.6 ppm to 99 ppm at a depth of zero to six inches. Mercury was detected at concentrations of 0.28 ppm to 0.31 ppm at a depth of zero to six inches (PAP-00196988). PCBs were detected in soil in this area at a maximum concentration of 16 ppm in 1987 (PAP-00196988).

- The site used three on-site cesspools/drywells from the early 1900s to approximately 1973. The three cesspools were noted to have received rinse waters from manufacturing lines. In addition, the site had a dry well located to the north of which received surface runoff from the site roof drains and surrounding site area (PAP-00090965). Petroleum hydrocarbons, lead, and copper were identified in soil near the cesspools (PAP-00090996-98). According to the 1988 Phase I Report, lead concentrations detected in soil samples were as high as 1,470 ppm in samples collected from the bottom of the cesspools at a depth of 18 to 20 feet (PAP-00196947). Copper was detected at a maximum concentration of 175 ppm in samples collected from the bottom of the cesspools at a depth of 20 feet. Mercury was detected at a maximum concentration of 0.4 ppm in samples collected from the bottom of the cesspools at a depth of 15 to 17 feet (PAP-00196945).

- A drum storage area was located along the western section of the main site area and was used for waste oil storage. It is reported that stained soils were observed in this area (PAP-00090965, 1013-14). Petroleum hydrocarbons and metals were identified in soil near the drum storage area (PAP-00091013, 1018-19). According to the 1988 Phase I Report, copper was detected in one sample at a concentration of 38 ppm at a depth of 22 to 28 inches. Lead was detected in one sample at a concentration of 13 ppm at a depth of 22 to 28 inches. Mercury was detected in one sample at a concentration of 0.16 ppm at a depth of 22 to 28 inches (PAP-00196981).

- Petroleum hydrocarbons, PCBs, and lead were identified in soil in the vicinity of three transformer (PAP-00090965, 1012, 1015-17; PAP-00090769). According to the Phase I Report, PCBs were detected in soil in this area at a maximum concentration of 8.4 ppm in 1987 (PAP-00196973, 77). According to an *Expedited Remediation Investigation Report for Northern and Southern Areas*, prepared for National-Standard, dated February 2000, lead was detected at concentrations of 120 mg/kg to 3,500 mg/kg at a depth of zero to 0.5 feet (PAP-00090789).

- Petroleum hydrocarbons, PAHs, and lead were identified in soil beneath "several" of the site's underground storage tanks (PAP-00090966, 976-81, 1028-29). According to a 1989 D&D Report, PAHs were identified in soil beneath several of the site's underground storage tanks (PAP-00090976-81). Lead concentration data were not identified in the 1989 D&D Report.

According to a *Revised Soil and Groundwater Remedial Investigation Work Plan*, dated February 25, 2005, a total of 44 areas of concern (AOCs) have been identified at the site (PAP-00197351). Lead was detected in soil at each AOC based on sampling conducted in 1990 and 1991 (PAP-00197400-49). The maximum reported concentration of lead was 87,000 ppm. This data is listed as being associated with both AOC 8 (the area between the former Main Building and the railroad track areas) and AOC 37 (the area of the former transformer located within former Building No. 5) (PAP-00197360, 363, 418, 44). In addition, PCBs were associated with AOC 6 (former locations of Buildings 2, 3, 4, 6, and 14), AOC 8 (the area between the former Main Building and the railroad track areas), AOC 9 (Transformer Substation No. 1), AOC 36 (stained soil along railroad tracks), AOC 37 (former transformer in Building 5), and the landfill area. The maximum detected concentration of PCBs was 16 mg/kg (PAP-00197408-10, 17-18, 20, 43-44). The northern section of the site was acquired separately in the mid-to-late 1950s. According to a *Northern Area Soil Remedial Investigation Report and Remedial Investigation Work Plan*, dated December 21, 2005, DDx compounds were detected in soil samples at "trace concentrations" (PAP-00197495, 541-44). 4,4-DDE was detected at a maximum concentration of 0.0028 ppm, and 4,4-DDT was detected at a maximum concentration of 0.0043 ppm in 2005 (PAP-00197495).

Remedial Activities

The site was closed and demolished in 1988/1989. Numerous site investigations and remedial activities were conducted at the site following its closure in 1988 under the oversight of the NJDEP (PAP-00090917-18; PAP-00195394). National Standard entered into a Remediation Agreement with NJDEP in 1999 (PAP-00382460-67).

Responses to NJDEPE Letter of May 18, 1994, with Regard to the 0-2 Foot Activities Conducted at the National Standard Company, dated August 15, 1994, states that the soil interval from zero to two feet below ground surface (bgs) was excavated at 22 AOCs, primarily to address lead contamination (PAP-00091124-47).

According to a *Delineation Soil Sampling in AOCs as Referenced in NJDEP Letter of May 18, 1994*, dated November 4, 1994, as a result of all the field investigative sampling activities at the site, remedial action was proposed to address 12 "cleanup areas." The remedial activities involved the excavation of soils in the 12 identified areas. These 12 cleanup areas included the cesspools and drywells, landfill, oil separating pond, spray pond and fuel house, transformer west of Building 28-A, former PSE&G (Public Service Electric and Gas Company) substations, drum storage area, compressor blowdown area, stained soils along railroad tracks, inactive septic tanks, underground storage tanks, aboveground storage tanks, and building demolition areas. In July 1990, an *Addendum to the ECRA Cleanup Plan Report***,** dated July 27, 1990, was submitted to the NJDEP. This addendum report focused on additional excavation of the cleanup areas to depths greater than originally proposed to achieve a former site cleanup standard of 250 ppm for lead. As a result, 29 cleanup areas were then identified as requiring further action. Eight of these cleanup areas were new areas located outside the boundaries established for the original 12 cleanup areas. The other 21 proposed cleanup areas were deeper excavations within the original 12 proposed cleanup areas. This totaled 41 proposed cleanup areas at the site (PAP-00091427-28). From August through November 1990, field work was conducted, and 870 post-excavation samples were collected (PAP-00091428).

As discussed in a *Pilot Response on Soil Delineation*, dated February 24, 1997, National Standard collected a soil sample from beneath a former underground process sewer line in approximately 1988 or 1989. Lead was detected at a concentration of 590 ppm. This area of contamination was subsequently excavated in 1990. National Standard also collected a soil sample beneath a second underground process sewer line at the same time. Excavation of this area also was conducted. Post-excavation confirmation samples had lead concentrations of 2,350 ppm and 3,770 ppm. A second round of excavation occurred, and another post-excavation confirmation sample had a lead concentration of 3,840 ppm. Therefore, a third round of excavation was conducted and confirmation sample concentrations were below the NJDEP's "residential direct contact soil cleanup criterion" (PAS-00101976-80). Based on review of available file material, it is unclear how these process sewer lines were connected to the site's sewer system.

Petroleum hydrocarbons, PCBs, and lead were identified in soil in the vicinity of three transformer owned by the electrical utility (PAP-00090965, 1012, 1015-17). According to an *Expedited Remediation Investigation Report for Northern and Southern Areas*, dated

February 2000, this area was excavated to a depth of 2.5 feet bgs, and seven confirmation sample results were below the NJDEP "Residential Direct Contact Soil Cleanup Criteria" (PAP-00195403). According to a *Site Investigation Report*, dated October 2001, approximately 146 cubic yards of PCB and petroleum-impacted soil was excavated from this area and disposed off-site (PAP-00090728).

Petroleum hydrocarbons, lead, and copper were identified in soil near the cesspools (PAP-00090996-98). According to an *Expedited Remediation Investigation Report for Northern and Southern Areas*, dated February 2000, National Standard excavated 260 cubic yards of soil from this area to a depth of 27 feet bgs to remove lead above concentrations of 250 mg/kg (PAP-00090771).

According to a *Revised Soil and Groundwater Remedial Investigation Work Plan*, dated February 25, 2005, for the purpose of redeveloping the property, the former National Standard site was divided into four large areas including: , (1) the Southern Area; (2) the Northern Area; (3) the Active Area of the former steel plant; and (4) the Landfill Area. Previous soil sampling conducted by National Standard has established "clean" boundary lines separating the "relatively uncontaminated" Northern and Southern Areas from the contaminated Active Area and the Landfill. A total of 44 areas of concern AOCs were identified at the site (PAP-00197351). The following is a list of excavations that were conducted at the AOCs:

- AOC 9 consists of the former transformer pads in the Southern Area. AOC 9 was excavated to a depth of 2.5 feet bgs.
- AOC 10 consists of a former dry well and underground stoup sewer lines located in the Northern Area. The area was excavated to a depth of 15.5 feet bgs.
- AOC 14 consists of the former cesspool D area located in the Northern Area. AOC 14 was excavated to a depth of 27 feet bgs and 260 cubic yards of soil were removed.
- AOC 15 is the location of former Building No. 39. This area was excavated to depths ranging from 4.75 to 7.5 feet bgs.
- AOC 18 is located within the area of former Building No. 39 and within AOC 5. This area was excavated to a depth of 8 feet bgs.
- AOC 24 is the area of former Building No. 39 and is located within AOC 5. The area was excavated to 11.5 feet bgs.
- AOC 26 is in the area of former Building No. 9 and is located within AOC 5. AOC 5 was excavated to an average depth of 6 feet bgs. AOC 26 was excavated to a depth of 14 feet bgs.
- AOC 27 is in the area of former Building No. 8 and is located within AOC 5. This area was excavated to a depth of 9.5 feet bgs.
- AOC 30 is located in the area of former Building No. 7 and was excavated to a depth of 5 feet bgs.
- AOC 4 is the location of former Building No. 7. AOC 4 was excavated to a depth of 5 feet bgs.
- AOCs 6E and 6F are located within AOC 6, which was excavated to 5 feet bgs. AOCs 6E and 6F were excavated to depths of 10 feet and 8 feet bgs.

- AOCs 11 and 17 are located in the area of the former underground process sewer. The resulting excavation was 14.5 feet bgs.
- AOC 12 is the former underground storm sewer line. The area was excavated to a depth of 11.5 to 16 feet bgs.
- AOC 16 is an area of the former underground process sewer lines. AOC 16 was excavated to a depth of 8.5 feet bgs.
- AOC 19 is the area of former Building No. 30 and is located west and outside of AOC 5. The area was excavated to a depth of 3.5 to 4.0 feet bgs.
- AOC 20 is the location of the former underground process sewer line located within AOC 2. AOC 2 was excavated to a depth of 5 feet bgs. The excavation in AOC 20 was extended to 9 feet bgs.
- AOC 21 is the location of the former underground process sewer line. The area was excavated to depths ranging from 13 to 18 feet bgs.
- AOC 22 is located between AOC 21 and the on-site landfill. This area was excavated to 22 feet bgs.
- Area 25 is the former concrete pipe trench located west of Building Nos. 28 and 28A and adjacent to AOC 2. The area was excavated to 10 feet bgs.
- AOC 28 is the area of former Building No. 7A and is located within AOC 4, which was excavated to a depth of 5 feet bgs. Several phases of excavation were conducted in AOC 28 with the resulting excavation extended to 9 feet bgs.
- AOC 29 is located in the area of former Building No. 8. The area was excavated to a depth of 4.0 to 4.5 feet bgs.
- AOC 31 is the area of former Building No. 28 and is located within AOC 5. AOC 5 was initially excavated to 5 feet bgs and the excavation in AOC 31 was extended to 8 feet bgs.
- AOC 32 is the area of former Building No. 28 and is located within AOC 5. The area was excavated to 9.5 feet bgs.
- AOC 34 is the area of former Building No. 10 and is located within AOC 5. This area was excavated to 13 feet bgs, but the excavation was extended to 19 feet bgs.
- AOC 35 is the area of former Building No. 8 and is located within AOC 5. The area was excavated to a depth of 9.5 feet bgs. Two additional excavations were conducted in this area: one was extended to 12 feet bgs and the other was extended to 15 feet bgs.
- AOC 36 is located in the former railroad area along the northern property boundary. The area was excavated to a depth of 8.5 feet bgs.
- AOC 37 is the area of the former transformer located within former Building No. 5. The area was excavated to 20 feet bgs.
- AOC 38 is the area of the former Building No. 6 and is located within AOC 6. The area was excavated to 9.5 feet bgs.
- AOC 40 is the area of the former Building No. 4 and is located within AOC 6. The area was excavated to 10 feet below.
- AOC 42 is the location of removed subsurface piping. The subsurface pipe and surrounding soils were excavated and post-excavation samples were collected from the 6.5 to 7.0-foot depth interval.

- AOC 1 consists of a former oil/water separator located on the western side of the on-site landfill and includes AOC 41 (Area Adjacent to the Former Oil/Water Separator). AOC 1, including AOC 41, was excavated to a depth of 4.5 feet bgs.
- AOC 2 is the location of former Building No. 28 and includes portions of AOC 20 (Former Location of Process Sewer Line) and AOC 25 (Area of Former Concrete Pipe Trench Located West of Building Nos. 28 and 28A). Remediation of this AOC was conducted via many small excavations over many phases.
- AOC 3 is the location of former Building Nos. 7 and 4. AOC 3 was excavated to a depth of 8.5 feet bgs.
- AOC 5 is a large area that incorporates many smaller AOCs. AOC 5 was excavated to an average depth of 5 feet bgs. Areas 33A and 35A were excavated to depths of 18 and 15 feet bgs, respectively.
- AOC 6 consists of the area of former Building Nos. 2, 3, 4, 6 and 14 (includes a portion of AOC 8) and is located to the northeast of the on-site landfill. The area was excavated to a depth of 5 feet bgs.
- AOC 6C is located immediately north of the on-site landfill in the southern portion of AOC 6. The area was excavated to a depth of 5 feet bgs.
- AOC 7 is in the area between former Building Nos. 6A and 8. The area was excavated to a depth of 6 feet bgs.
- AOC 8 is the area between the former Main Building and the railroad track areas. The area was excavated to a depth of 3 feet bgs.
- AOC 13 is the former Cesspool B area and is located within the western corner of AOC 5. AOC 5 was excavated to a depth of 6 feet bgs. AOC 13 was excavated further to a depth of 20.5 feet bgs.
- AOC 23 is the former concrete pipe trench located west of the plant building. The concrete pipe trench and adjacent soils were excavated to a depth of 3 feet bgs initially. The excavation was extended to 7 feet bgs.
- AOC 33 is the area of former Building Nos. 10 and 11 and underground process sewer lines (located within AOC 5). The area was excavated to 12 feet bgs initially. The excavation was extended to 18 feet bgs.
- AOC 39 is the area of the former Building No. 4 and is located within AOC 6. The area was excavated to a depth of 10 feet bgs initially. The excavation was extended to 15 feet bgs (PAP-00197355-64).

Each of the excavations were conducted primarily to address lead contamination. PCBs detected at AOCs 36, 37, and 8 were also addressed via these excavations. Post-excavation confirmation samples were collected at each excavation (PAP-00197355-64).

NJDEP issued a “no further action” determination for the Southern Area in a letter dated May 10, 2002. This portion of the site was subsequently redeveloped as senior housing by the City of Clifton (PAP-00197351). The Northern Area also received a “no further action” determination for soil from NJDEP on November 17, 2006 (PAP-00384059). The central and eastern portions of the site were capped and “closed.” Buildings in the area formerly used for manufacturing operations in the northeastern portion of the site were demolished and soil remediation was conducted (PAP-00090917-18; PAP-00195394). Further information on the remedial efforts in the northeastern portion of the site was not identified in the referenced document. Review of a *Remedial Investigation Report*

Addendum, dated February 28, 2017, indicates that remediation of the Active Area of the former steel plant and Landfill Area is ongoing (PAP-00384059-60).

8. Summary of Asserted Defenses

National Standard asserts the following:

- That any release of petroleum, including crude oil of any fraction thereof, is not a CERLCA hazardous substance under 42 U.S.C. §9601(14).

- The federally permitted exclusion applies to National Standard's discharge under 42 U.S.C. §9607(J).

Facility Data Report

NEU HOLDINGS U.S. CORPORATION

Note: EPA originally identified Eden Wood Corporation, a Delaware Corporation, ("Eden Wood") as the PRP and successor entity to the Whippany Paper Board Co., Inc. ("WPBC") facility at 1 Ackerman Avenue in Clifton, NJ ("Clifton Mill") that is the subject of this data report. Additional corporate research completed in responding to a 104(e) request received from EPA confirmed that Neu Holdings U.S. Corporation ("Neu Holdings")—and not Eden Wood—is the successor to WPBC. Neu Holdings will henceforth be identified as the PAP associated with the WPBC facility.

Facility Address and Size: 1 Ackerman Avenue, Clifton, New Jersey. According to a 1987 boundary survey of the site, the site consisted of a "Clifton Tract" (5.497 acres) and "Passaic Tract" (1.488 acres) totaling 6.985 acres (PAP-00198414-415). According to the New Jersey Department of Environmental Protection (NJDEP) Environmental Cleanup Responsibility Act (ECRA) General Information Submission (GIS) in 1987, the legal description was City of Clifton Block 4-15, Lot 1 and 2 and City of Passaic Block 51 Lot 1. The document did not state the acreage (PAS-00113546). The site is to the east by the Passaic River, to the west by the former Dundee Canal, and to the north by Ackerman Avenue. The Passaic River bank is shored up by sheet pilings (PAS-00113605). Note: The Dundee Canal no longer exists. It was filled to accommodate Route 21 Freeway between 1997 and 2005 (PAP-00198505). According to Neu Holdings U.S. Corporation's Response to the EPA's Request for Information pursuant to CERCLA 104(e), this facility is located at RM 17.2, 8.9 miles from the northern terminus of OU2. According to the Industrial Directory of New Jersey the number of employees for 1940-1941 was 189 (PAS-00113455-56). According to the Industrial Directory of New Jersey the number of employees for 1946 was 275 (PAS-00113458-59). A Herald-News article from June 11, 1982, stated that the facility once employed 150 employees (PAS-00113961). Note: No other information regarding the number of employees was found in the documents provided for this report. A Securities and Exchange Annual Report dated 1971 stated that the business worked a 24-hour day, five to six days a week (PAP-00102308).

See the following 2017 EDR Aerial Photo for site location. The site is outlined in red.

(PAP-00374493)

Facility Data Report

1. **Business Type:** Manufactured paperboard products using recycled waste paper as raw material. The plant produced unbleached container board, unbleached box board, and other unbleached paper boards. The plant also produced roofing felt for a time in the 1970s (PAP-00102359-62).

2. **Time Period of Ownership/Operations**

Owner: 1933-1987
Operator: 1933-1980

1933: On January 5, 1933, Frank Desiderio Sons, Inc. transferred title to the Clifton Plant to Clifton Paper Board Co., Inc. (PAP-00374468), which was incorporated in New Jersey in October 1932 (PAP-00198402). .
WPBC was incorporated in November 1933 (PAP-00198401).

1946: Botany Worsted Mills transferred title to Block 1051 Lot 1 to Clifton Paper Board Company, Inc. on February 1, 1946 (PAP-00374471).

1955: Clifton Paper Board Company, Inc. and WPBC were merged in 1955 and the surviving entity of the merger was WPBC (PAP-00198403, 7).

1980: WPBC filed for Chapter 11 Bankruptcy proceedings in February 1980 and planned to reorganize and partially liquidate assets, including the Clifton Mill (PAP-00102373-417).

According to the 2006 PRP DEF, WPBC filed for Chapter 11 bankruptcy in February 1980 but continued to operate the company until June 1980, when funds ran short (PAS-00113427); however, an article in The Herald News, dated June 1982, noted that the Clifton Mill had been partially gutted by fire in April 1980 and had never reopened (PAS-00113961).

On November 10, 1980, WPBC submitted a proposed Plan of Reorganization under Chapter 11 of the Bankruptcy Code. The plan of reorganization is by means of partial liquidation of assets (PAP-00102373).

1981: In March 1981, the Bankruptcy Court issued a Confirmation Order for WPBC's Chapter 11 Plan, which discharged WPBC from any and all debts arising prior to entry of the Confirmation Order (PAP-00102386-87). WPBC did not operate the Clifton Mill after issuance of the Confirmation Order (PAS-00113953).

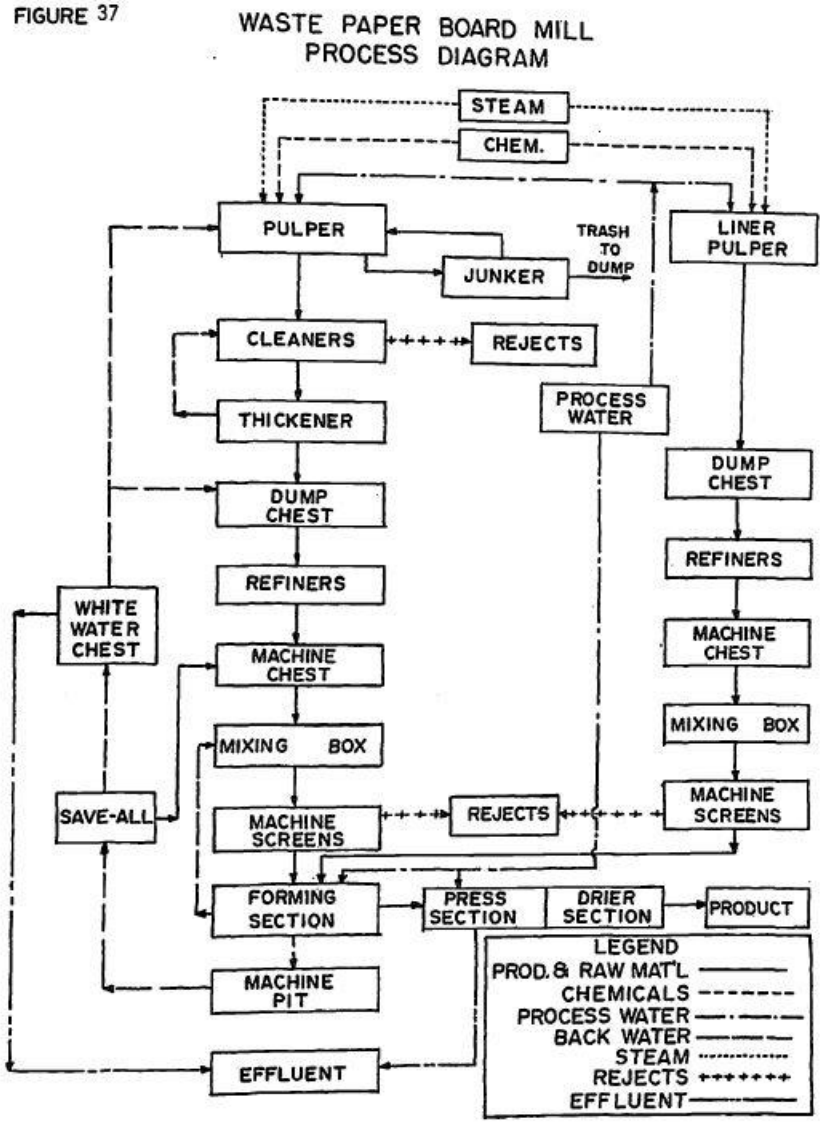
1986: NPN, Inc., a Delaware corporation, acquired approximately 76% of the outstanding shares of WPBC and subsequently merged into WPBC (PAS-00113547-48). A December 1986 Administrative Consent Order ("1986 ACO") in connection with an NJDEP ECRA-triggered transaction states that NPN, Inc. had made a tender offer for all of WPBC's stock (PAS-00113661).

1987: On October 1, 1987, WPBC sold the facility site (City of Clifton Block 4-15, Lot 1 and 2 and City of Passaic Block 1051, Lot No. 1) to an unrelated third party, V. Ponte & Sons, Inc., a New York Corporation (PAP-00102234-42). On October 8,

1987, Ponte's counsel informed NJDEP that pursuant to the contract of sale with WPBC, Ponte agreed to assume the responsibility of achieving ECRA compliance for the facility site under the 1986 ACO (PAS-00113513).

In December 1988, Ponte sold Clifton Block 4-15, Lot 1 and 2 and Passaic Block 1051, Lot No. 1 to Recycled Paper Board, Inc. of Clifton, New Jersey (PAP-00102243).

2005: Recycled Paper Board, Inc. ceased operations at the facility (PAP-00198428).



3. Operational History/COC Use and Presence at the Facility

Based on title research and Sanborn maps, the property was developed and owned/operated by others for paper board product manufacturing dating back to at least 1903, when it was owned by Carlton Paper Co (PAP-00374489). In 1971 the facility had an estimated annual capacity of approximately 82,500 tons and operated at 75% capacity (PAP-00102308). In 1978, WPBC had an estimated annual capacity of approximately 82,500 tons of product and was operating at 58% of capacity. At that time, WPBC occupied 169,600 square feet of floor space, truck-docking facilities were located onsite, and rail transportation was nearby (PAP-00102357; PAS-00113427).

According to a 1971 Securities and Exchange Annual Report, the facility engaged in the business of manufacturing and selling containerboard, boxboard and other grades of paperboard. The products were processed from substantially all recycled material. During 1970, the facility also commenced production and sale of roofing felt used in the building industry (PAP-00102302, 308).

According to the publication, *State-of-the-Art Review of Pulp and Paper Waste Treatment*, prepared by Dr. Harry Gehm for EPA and dated April 1973, the Clifton Mill was categorized as a Waste Paper Board Mill by EPA (PAP-00102579). The following diagram shows the process of a typical Waste Paper Board Mill.

FIGURE 37

(PAP-00102568)

The initial breakdown of the waste paper involved mixing the waste paper with hot water in hydrapulpers. The hot water softened the paper which made separation easier. After the hydrapulpers, the materials were transferred to heavy-duty “beaters” that mechanically separated the paper fibers. After mechanical separation, the pulp was ready to be made into paper. This process involved the use of various paper making machines—e.g., foundriniers and cylinders. This process orients the fibers to make paper more or less stiff and involves drying, forming, and rolling the pulp into finished paper board. The wastewater from this process was sent to the Passaic Valley Sewerage Commission (PVSC) (PAP-00198586-87).

An Inventory and Appraisal dated August 1980 (1980 Inventory and Appraisal) in connection with WPBC’s bankruptcy proceeding listed the following chemicals were listed as being at the Clifton Mill:

WPBC Chemical List	
Quantity	**Chemical**
900 Pounds	Acc-Cyfor Drylite
1200 Pounds	Aluminum Paste
2000 Pounds	Aluminum Sulphate
400 Pounds	Alamask 308 DX
500 Pounds	Basic Brown TB
150 Pounds	Calco Nigro 02P
1000 Pounds	Calcocid Orange RR
1000 Pounds	Chrysodine Y
1700 Pounds	Lycoid 250
1760 Pounds	Paracol 802D
400 Pounds	Starch
1400 Pounds	Alum Sulph STD GRD Dry
500 Pounds	BA-11
1600 Pounds	Burolock
110 Gallons	Burn Rite
440 Pounds	Calgon NFL 25
120 Pounds	Flake Caustic Soda
9 Drums	Resin-HCR-5
200 Pounds	Sal Soda
450 Pounds	Santosite Sodium
800 Pounds	Felt Wash Dricid
500 Gallons	Mineral Spirits

(PAP-00102400)

According to the 1980 Inventory and Appraisal, the Clifton Mill site contained 52,000 gallons of No. 6 fuel oil, 500 gallons of No. 2 fuel oil, as well as five cartons of mercury and incandescent lamps (PAP-00198594, 97). The Inventory and Appraisal did not include any entries for bleaching equipment or bleaching chemicals (PAP-00102414-15; PAP-00102391-400; PAP-00198589-97).

According to a *Section 4M/6J Remedial Investigation Report Route 21 Freeway Extension*, dated 1995 (1995 Route 21 Report), a portion of the subject property had the Dundee Canal running adjacent to it. According to the report: A 1935 Sanborn Map of the canal shows the Clifton Paper Board Company had two “Acid Tanks” and a “Coal Pile” bordering the eastern shore of the canal. The coal pile is not visible in the 1940 aerial photograph (PAS-00114024). A 1961 aerial photograph showed that drums were stored adjacent to the Clifton Paper Board facility on the eastern shore of the Dundee Canal, and a 1974 aerial photograph showed that the drums present on the eastern shore of the canal in the 1961 aerial photograph had been removed and replaced by tractor trailers (PAS-00114025). Note: The sampling investigation for the 1995 Remedial Investigation occurred in the canal and not on the former Clifton Mill property or the Passaic River. In addition, the aerial photos and Sanborn maps referenced in the 1995 Route 21 Report were not attached to the report and have not been reviewed. The interpretation of the aerials and Sanborn Maps was included in this report to describe facility operations.

4. Identified COCs

- PCBs (detected)
- PAHs (detected)
- Copper (detected)
- Lead (detected)
- Mercury (detected)

Note: Detections of the COCs discussed below were obtained in connection with investigations and remedial actions under ECRA and ISRA by owners of the site after WPBC sold it in 1987. These subsequent owners (V. Ponte & Sons, Inc. and Recycled Paper Board, Inc.) are not related to WPBC and are not PAPs in this allocation process.

PCBs

According to undated results of EPA Priority Pollutant Volatile Compounds included in the 2006 PRP DEF, 2,100 µg/kg (2.1 mg/kg) of PCB-1254 was detected in soil sample No. VP/DS1 (PAS-00113687). Location of the sample was not identified in this report; however, sample VP/DS1 was cited in the HWEC Phase I soil cleanup report as being a post excavation sample that was located at the drum storage area on the west side of the building (PAS-00113518-19).

A February 1986 memorandum from NJDEP regarding its review of the July 25, 1985 Sampling Plan and February 4, 1986, Addendum stated that an inspector identified two transformers on the site and that documentation must be provided stating that they did not contain PCBs (PAS-00113605-7). A May 1988 report by HWEC in connection with ECRA-related sampling said that 3 soil samples were collected on May 18, 1988 at an interval of zero to six inches from the transformer area and tested for PCBs (PAS-00113523-4). The report summarized the PCB results as follows: “The total PCBs detected in the soil samples collected in the transformer area ranged from 0.05 mg/kg to 1.3 mg/kg. Since the NJDEP threshold level for total PCB’s in soil is between 1 mg/kg to 5 mg/kg, excavation of these materials is not proposed.” (PAS-00113525). An undated ECRA *Environmental Concern Tracking Sheet* identified the transformer area as a location of concern for potential PCB contamination, noted a PCB concentration of “1.3” and an action level of “5.0”, and stated that the “outcome” was no further action required (PAS-00113602-3).

According to the *Remedial Investigation Report and Remedial Action Workplan (RIR/RAW) for the Property Known As Former Recycled Paperboard* and prepared by Environmental Waste Management Associates (EWMA) dated October 2007 (2007 EWMA RIR/RAW), during a January 27, 2006 site inspection by EWMA, three transformers were identified on the Property. It was determined that all three transformers did not contain PCBs. In addition, no staining or other evidence of discharges was noted in the vicinity of any of the transformers (PAP-00198528).

PAHs

On March 22, 1989, Hazardous Waste Engineering Consultants (HWEC) on behalf of Recycled Paper Board of Clifton, Inc., ECRA Case No. 85193 submitted analysis results to NJDEP (PAS-00113531-541). The analytical results were from the soil testing around the abandoned drum storage area (PAS-00113531). Three grab samples were collected on November 29, 1988 on the west side of the structure. The results follow:

WP GS-1 (Depth 6-12 inches)	
Compound detected	**Results micrograms/kilogram (µg/kg)**
phenanthrene	130 J
anthracene	34 J
pyrene	220 J

J indicates that the compound was present in the soil sample, but the concentration is estimated as it is below the specified minimum detection limit.

(PAS-00113692; PAS-00113535, 541)

WP GS-2 (Depth 13-19 inches)	
Compound detected	**Results µg/kg**
naphthalene	590
phenanthrene	36 J
pyrene	26 J

J indicates that the compound was present in the soil sample, but the concentration is estimated as it is below the specified minimum detection limit.
(PAS-00113692; PAS-00113535, 541)

WP GS-3 (Depth 20-26 inches)	
Compound detected	**Results µg/kg**
naphthalene	34 J
phenanthrene	96 J
pyrene	120 J
benzo(b)fluoranthene	110 J
benzo(a)pyrene	6 J

J indicates that the compound was present in the soil sample, but the concentration is estimated as it is below the specified minimum detection limit.
(PAS-00113692-93; PAS-00113535, 541)

Undated results of EPA Priority Pollutant Volatile Compounds state that 150 (J) micrograms/kilogram (µg/kg) of benzo(a)anthracene and 450 µg/kg of pyrene were found in soil sample VP/DS1 (PAS-00113683-84). Location of the sample was not identified in this report; however, sample VP/DS1 was cited in the HWEC Phase I soil cleanup report as being a post-excavation sample that was located at the drum storage area on the west side of the building (PAS-00113518-19).

Dioxins/Furans

Sampling of soil and groundwater carried out in 2005 did not detect dioxins/furans in facility site soils (PAP-00198542-55).

Copper

On March 22, 1989, HWEC on behalf of Recycled Paper Board of Clifton, Inc., ECRA Case No. 85193 submitted analysis results to NJDEP (PAS-00113531-541). The analytical results were from the soil testing on the soil around the abandoned drum storage area (PAS-00113531). Three grab samples were collected on November 29, 1988 on the west side of the structure and all samples were analyzed for Priority Pollutant Metals which included copper.

Copper		
Sample Number	**Depth**	**Results mg/kg**
WP GS-1	6-12 inches	27
WP GS-2	13-19 inches	705
WP GS-3	20-26 inches	147

(PAS-00113535, 541; PAS-00113699)

Undated results of EPA Priority Pollutant Volatile Compounds included in the 2006 PRP DEF stated that 2,440 mg/kg of copper was found in soil sample VP/DS1 (PAS-00113688). Location of the sample was not identified in this report; however, sample VP/DS1 was cited in the HWEC Phase I soil cleanup report as being a post excavation sample that was located at the drum storage area on the west side of the building (PAS-00113518-19).

Lead

On March 22, 1989, HWEC on behalf of Recycled Paper Board of Clifton, Inc., ECRA Case No. 85193 submitted analysis results to NJDEP (PAS-00113531-541). The analytical results were from the soil testing on the soil around the abandoned drum storage area (PAS-00113531). Three grab samples were collected on November 29, 1988 on the west side of the structure and all samples were analyzed for Priority Pollutant Metals which included lead.

Lead		
Sample Number	**Depth**	**Results mg/kg**
WP GS-1	6-12 inches	173
WP GS-2	13-19 inches	2,420
WP GS-3	20-26 inches	277

(PAS-00113535, 541; PAS-00113699)

Undated results of EPA Priority Pollutant Volatile Compounds included in the 2006 PRP DEF stated that 457 mg/kg of lead was found in soil sample VP/DS1 (PAS-00113688). Location of the sample was not identified in this report; however, sample VP/DS1 was cited in the HWEC Phase I soil cleanup report as being a post-excavation sample that was located at the drum storage area on the west side of the building (PAS-00113518-19). .

A *Remedial Action Report* (RAR) prepared by EWMA dated November 2016 (2016 EWMA RAR) stated that sixteen soil borings were installed at the Former Recycled Paperboard property on August 9, 2005, to investigate the gross leaching potential in areas where elevated lead concentrations had been previously detected in connection with investigation of historic fill on the property (PAP-00198429). Soil samples were collected for analysis from the layer of fill material in all sixteen of the borings installed on August 9, 2005. A review of analytical results from the August 9, 2005 of soil sampling event showed that total lead was detected at concentrations ranging from 467 ppm to 29,400 ppm (PAP-00198525). The analytical results stated that total lead concentrations ranged from 467 parts per million (ppm) to 29,400 ppm. The TCLP analysis method stated that concentrations of lead were detected at approximately 3 orders of magnitude less than the total lead analysis method (PAP-00198525). The leachability testing showed that the lead was very non-leachable, even under extreme acidic conditions of the test (PAP-00198524). The report concluded that although lead was detected at elevated concentrations at the property, the horizontal and vertical sampling showed that lead is contained in the layer of fill material at the property and not a result of previous on-site operations (PAP-00198429-30).

Groundwater samples collected in December 2005 exhibited lead concentrations above the GWQS in only one monitoring well, 11.2 µg/L in MW-3. Samples from the other 2 wells did not identify lead above the method detection limit (PAP-00198430). A confirmatory groundwater sampling round was conducted in December 2006. All samples exhibited lead concentrations that were non-detectable above the method detection level in all monitoring wells. Based on the two groundwater sampling rounds, EWMA concluded that lead contamination associated with the historic fill does not impact the groundwater conditions at the property (PAP-00198431).

Mercury

On March 22, 1989, HWEC on behalf of Recycled Paper Board of Clifton, Inc., ECRA Case No. 85193 submitted analysis results to NJDEP (PAS-00113531-541). The analytical results were from the soil testing on the soil around the abandoned drum storage area (PAS-00113531). Three grab samples were collected on November 29, 1988 on the west side of the structure and all samples were analyzed for Priority Pollutant Metals which included mercury.

Mercury		
Sample Number	**Depth**	**Results mg/kg**
WP GS-1	6-12 inches	Undetected
WP GS-2	13-19 inches	2.4
WP GS-3	20-26 inches	1.8

(PAS-00113535, 541; PAS-00113699)

Undated results of EPA Priority Pollutant Volatile Compounds included in the 2006 PRP DEF identified 2.9 milligrams/kilogram (mg/kg) of mercury in soil sample VP/DS1 (PAS-00113688). Location of the sample was not identified in this report; however, sample VP/DS1 was cited in the HWEC Phase I soil cleanup report as being a post-excavation sample that was located at the drum storage area on the west side of the building (PAS-00113518-19).

Historic Fill

The Allocation Team has determined that the facility site is located on regional historic fill as designated by the NJDEP.

NJDEP has established that historic fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 COCs: PAHs, lead, copper, and mercury.[1] Accordingly, NJDEP technical requirements for property containing Historic Fill requires sampling for the EPA Target Compound List for PAHs and Target Analyte List for metals, including lead, copper, mercury, and the OU2 PAH COCs.[2] PAHs, lead, copper, and mercury are recognized by NJDEP to be constituents of historic fill at varying levels, not atypically at or exceeding residential soil standards.[3]

Two excavations on the east side of the site building during an ECRA investigation in 1988 encountered significant historic fill material consisting of "bricks, concrete, cinders and metal intermixed with sand and gravel" at a depth of 10.5 feet (PAS-00113518). EWMA conducted subsurface investigation during July and August of 2005 under ISRA for the express purpose of determining the extent and makeup of fill material, which had been identified as an Area of Concern for the site (PAP-00198503. 521-528). A total of 33 soil borings were installed to investigate the presence of historic fill (PAP-00198521). Fill material consisting of ash, cinders, concrete and wood pieces was observed in each of 17 borings ranging from one foot to 12.5 feet thick (PAP-00198425, 429; PAP-00198521). The 2007 EWMA RIR/RAW, concluded as follows: "Based on the fact that only PAH compounds and metals were detected in soil at concentrations greater than their respective NJDEP MSSCC and since the contamination is concentrated within the fill layer, EWMA considers the elevated PAH and metals in soil to be a result of the fill material on the subject site and not a result of former operations conducted at the site." (PAP-00198523).

The 2016 EWMA RAR noted that historic fill was discovered on the property during the removal of four underground storage tanks in 1988 (PAP-00198429). Later investigations performed in 2005 determined that the fill material ranged from "one foot thick to 12.5 feet thick in certain areas." (PAP-00198429).

The levels of PAHs, copper, lead and mercury detected at the site in soils are presented in the table below (PAP-00198481).

---

[1] *Characterization of Ambient Levels of Selected Metals and cPAHs In New Jersey Soils* (2002) and *Characterization of Ambient Levels of Selected Metals and Other Analytes In New Jersey Soils* (1997), studies prepared for NJDEP, Division of Science and Research, by BEM Systems, Inc.

[2] New Jersey Department of Environmental Protection (NJDEP), *N.J.A.C. 7:26E Technical Requirements for Site Remediation,* Table 4-2, November 2009 [Note that Table 4-2 has been deleted from the current version of N.J.A.C. 7:26E (May 7, 2012) and the updated *Historic Fill Technical Guidance* (April 2013) as NJDEP believed that the tables list of historic fill constituents was too restrictive].

[3] NJDEP Table 4-2 (PAHs and lead) and a summary of NJDEP records regarding investigations of properties in the vicinity of the Passaic River recognized to be located in areas of Historic Fill indicate that the following average/maximum (mg/kg) contamination levels of OU2 COCs exist in area Historic Fill: PAHs (1.91/160), lead (574/10,000), copper (11.2/1,200), and mercury (0.21/3.7).

COCs Found in Onsite Soils	
COC	**Max Detected Concentration**
Lead	94,800 mg/kg
Copper	7,880 mg/kg
Mercury	52.7 mg/kg
Benzo(a)anthracene	5.04 mg/kg
Benzo(a)pyrene	4.7 mg/kg
Benzo(b)fluoranthene	3.8 mg/kg
Benzo(k)fluoranthene	3.56 mg/kg
Dibenzo(a,h)anthracene	1.34 mg/kg
Indeno(1,2,3-cd)pyrene	2.67 mg/kg

The maximum detected concentrations of all COCs listed above were found to be associated with historic fill at the site as determined by a Licensed Site Remediation Professional (LSRP) pursuant to ISRA after extensive investigation of fill material at the site in 2005 (PAP-00198550; PAP-00198553; PAP-00198554; PAP-00198549).

Due to the presence of lead, mercury, and copper, related to historic fill above their respective NJDEP soil standards, restricted land use and engineering controls were implemented in a Deed Notice (PAP-00198447). NJDEP approved the Deed Notice to address the contamination in the historic fill. The Deed Notice was recorded on April 4, 2016 (PAP-00198488-97).

A 1931 aerial photograph shows that there are structures in existence at the Clifton Mill site 1931, two years before WPBC's predecessor acquired it in 1933 (PAP-00374506).

There is no indication from a review of provided documents that WPBC facility operations disturbed contamination located in historic fill.

5. COC Pathways

Direct Release

According to the 2006 PRP DEF, the following releases occurred at the Clifton Paper Mill, during the time periods of Clifton Paper Board Company and WPBC.

- In February, May, July and September, 1947, PVSC stream contamination reports documented Clifton Paper Board Company, at 1 Ackerman Ave., Clifton, New Jersey, was discharging industrial waste consisting of paper pulp, oily industrial waste liquid, and paper waste board into the Passaic (PAS-00113923, 925, 927, 929). These events are discussed in more detail in the Violations section of Section 6, below.

- According to a New Jersey Department of Health Field Information Report from 1971, a 12-inch pipe of unknown origin was discharging from WPBC into the Passaic River. The report states that the pipe was located near an unspecified bridge.

- According to a New Jersey Department of Health Field Information Report from 1972, a 10-inch pipe of unknown origin was discharging from WPBC via the bulkhead into the Passaic River. The report notes that the "entire area was steaming from hot water." (PAS-00113429).

- The facility discharged to the Passaic River pursuant to five National Pollution Discharge Elimination System (NPDES) permitted outfalls for some period during facility operations and ceasing in 1977. Outlet 002 was used for filter backwash and Outlet 004 for boiler blowdown. The use of the other outlets was not identified in the report (PAS-00113566-67). See also the Violations section of Section 6, below.

Sanitary and Storm Sewer

WPBC stated in their March 1985 *NJDEP ECRA General Information Submission* that the industrial facility discharged to the Passaic Valley Sewage Authority (PVSA) [sic] system (PAS-00113609).

According to the 2006 PRP DEF, the City of Clifton sanitary sewer line runs south on Ackerman Avenue, then east on Randolph Avenue. The line then runs south on Highland Avenue before it empties into the PVSC Trunk Line (PAS-00113432).

Spills

In January 1948, PVSC documented Clifton Paper Board Company had an incident with a discharge consisting of pulp waste and sewage into the Passaic River. The discharge was due to a slightly open by-pass valve (PAS-00113931) and was eliminated immediately by the facility by closing the valve tightly.

On October 3, 1949, PVSC reported that a flood in the heater room at Clifton Paper Board caused wastes to be discharged to the river. It was reported that ‘‘the waste was diverted to their by-pass and into Passaic River due to an electrical failure and the issue was repaired and eliminated." (PAS-00113933).

On March 2, 1956, a mixture of oil and water flowing out of a 16-inch pipe was observed on Clifton Paper Board Company property. The flow was coming out of a flap valve and discharging into the Passaic River from the Clifton Paper Board Company property. It was discovered that the pipe was clogged which prevented the flow from going into the sanitary sewer. The clog was removed which remedied the situation that same day (PAS-00113935).

On December 18, 1956, there was a small oil slick flowing from a 14-inch pipe into the Passaic from the Clifton Paper Board Company property. The pipe had a flap valve attached to it with a wooden wedge keeping the valve open. The superintendent was notified, and he stated that the pipe was used to drain rainwater from the loading area and that the oil was from trucks parked there. He was unable to provide an explanation for the wedge, and it was removed and the issue was corrected (PAS-00113937).

On August 8, 1969, WPBC was informed that they had a leak in the 20-inch steel pipeline carrying waste to the trunk sewer causing a small amount of pollution to reach the Passaic River. PVSC wrote a letter to WPBC asking the company to fix the line and received a response from WPBC that it would replace the entire line while company employees were on strike. . During the strike, no material would be in this line and therefore there would be no pollution. The repair was made by August 21, 1969 and all sources of potential pollution had been eliminated (PAS-00113559-60).

On December 29, 1969, a sanitary sewer line underneath a sidewalk broke, allowing industrial waste to enter into a catch basin that flowed into the Passaic River. The plant was shut down with the discovery of this break and repairs were made before the plant reopened on January 5, 1970 (PAS-00113560).

On June 1, 1977, WPBC called to advised the PVSC that a ¾-inch cleanout cap had blown off the 20-inch company force main and discharged sewage to the Passaic River. All operations in the plant were stopped. A new cap was installed, and the plant was back in operation the same day (PAS-00113563).

A review of available documents did not provide information regarding the volume or constituents of any discharges or spills to the Passaic River, with the exception of the 1976 outlet discharge exceedances described in the Violations section of Section 6, below. However, the PVSC reports for the incidents described above state that releases to the Passaic were of short duration.

6. Regulatory History/Enforcement Actions

Inspections

During a January 27, 2006, site inspection when the facility was owned by an unrelated third party, EWMA identified three transformers on the property. One transformer was located on the eastern side of the building on the property and the remaining two were located on the western side of the building. EWMA stated that the transformer on the eastern side of the building was installed in the last three years and did not contain PCB fluids. The remaining two transformers on the western side of the building had been refurbished within the last three years and had never contained PCB fluids. All three of the transformers were located over competent concrete within fenced-in enclosures. No staining or other evidence of discharges was noted in the vicinity of any of the transformers (PAP-00198528).

Violations

In 1947, PVSC stream contamination reports documented four incidents of discharge from Clifton Paper Board Company, at 1 Ackerman Ave., Clifton, New Jersey, into the Passaic. The February incident involved paper pulp being discharged. This was caused by the failure of the main pump occurring over the weekend and the smaller reserve pump not being able to handle the total load. The issue was fixed within a day of the inspection (PAS-00113923). The May report involved industrial paper pulp due to a valve not being closed fully; the report states the valve was closed thus resolving the violation (PAS-00113925). The July report involved an oily discharge

from a partly open valve, which was corrected after notification by the inspector (PAS-00113927). The September report involved paperboard discharge intended for the sanitary sewer due to an electrical breakdown in the main sewer pump which was corrected "within the hour" (PAS-00113923, 925, 927, 929).

In March and December 1956, Clifton Paper Board received violations for oil and water discharges from a pipe, described in the Spills section of Section 5, above (PAS-00113935; PAS-00113937). The violations were eliminated on the next day in March and on the same day in December.

On June 1, 1977, WPBC called to advise the PVSC that a ¾-inch cleanout cap had blown off the 20-inch company force main and discharged sewage to the Passaic River. All operations in the plant were stopped. A new cap was installed and the plant was back in operation the same day. This eliminated the violation (PAS-00113563).

In September 1976, PVSC notified WPBC that they had two of five outlets (002 and 004) were above values that PVSC did not consider acceptable for discharge limits into the Passaic River for suspended solids, turbidity, and pH, none of which are COCs. WPBC was advised to connect the outlet to the sanitary sewer for permit compliance or treat the effluent before discharge. WPBC determined they would pipe the discharge into the sanitary sewer temporarily, but recycle the water in the future (PAS-00113566). Lines for boiler blowdown (discharge outlet 004) were installed on March 12, 1977, and the discharge to the Dundee Canal was eliminated. After taking five months to receive the pump from the vendor, discharge outlet 002 (filter backwash) was fixed by October 1977 (PAS-00113567). It is noted that flow from the filter backwash was polluting suspended solids and turbidity for approximately 10 minutes at 9:00 a.m. and 1:00 a.m. each day, and the flow was estimated at 300 gallons per minute. Outside of those times, the discharge was non-polluting (PAS-00113566-67).

Permits

The Facility discharged to the Passaic River pursuant to five National Pollution Discharge Elimination System (NPDES) permitted outfalls for some period during facility operations and ceasing in 1977. Outlet 002 was used for filter backwash and Outlet 004 for boiler blowdown. The use of the other outlets was not identified in the report (PAS-00113566-67).

On November 7, 1980, EPA sent a letter to WPBC regarding NPDES Application Permit No. NJ0001457. Upon review of application documents, EPA determined that a NPDES permit may not be necessary since the company was bankrupt and the plant was shut down (PAP-00374507).

An NJDEP ECRA General Information Submission was issued in March 1985 that was triggered by the agreement of sale between WPBC and Ponte. It stated that WPBC did not have a New Jersey Pollutant Discharge Elimination System permit at the time (PAS-00113609, 612). Note: The Clifton Mill had been shut down since April of 1980 (PAS-00113953, 961).

Copies of the above-described permits were not available for review for this report.

7. Response Actions

Characterization Activities

The following characterization activities have taken place at the facility. These documents were prepared in connection with investigations of the subject facility under ECRA and ISRA conducted by subsequent owners of the Clifton Mill facility – V. Ponte & Sons and Recycled Paper Board – that are not related to WPBC. However, these documents are relevant because they evidence site conditions, including the absence of COCs in site soils from WPBC operations at the facility and the existence of COCs in historic fill on the site. These reports provide evidence that there were no potential or known off-site migration of contaminants during WPBC's period of ownership from 1933 to 1987.

- *Final Report of Site Remedial Activities* of WPBC NJDEP- ECRA Case No. 85193 for Recycled Paper Board of Clifton, NJ dated January 11, 1991 (PAS-00113481).
- *Preliminary Assessment/Site Investigation Report* completed in May 2006 (PAP-00198427). This document was not available for review but was referenced in the November 2016 *Remedial Action Report*, listed below.
- *Remedial Investigation Report/Remedial Action Workplan* for Property known as Former Recycled Paperboard, 1 Ackerman Ave., Clifton, NJ dated October 2007 (PAP-00198498).
- *Remedial Action Report* Former Recycled Paperboard, dated November 2016 (PAP-00198421).

Soil

A February 24, 1986, ~~a~~ NJDEP internal memorandum (1986 NJDEP Memorandum) cited six areas of concern after the review of the July 25, 1985, Sampling Plan and its February 4, 1986, Addendum plus a NJDEP site inspection report of October 2, 1986:

- Tank 1, a 1,000-gallon underground tank containing mineral spirits
- Tank 2, a 3,000-gallon underground tank containing mineral spirits
- Tank 3, a 4,000-gallon underground tank containing hydraulic oil
- Tank 4, a 1,000-gallon underground tank containing No. 2 fuel oil
- Stained soils at the fill line for an aboveground 160,000-gallon No. 6 fuel oil tank
- Stained soils in the drum storage area (PAS-00113605)

According to the 1986 NJDEP Memorandum, petroleum hydrocarbon contamination of soils in excess of 100 ppm had been identified at all of the underground tank storage areas and the stained soil at the aboveground storage tank and drum storage area had not been sampled and analyzed. The memorandum recommended that NJDEP require these areas to be addressed further in the Sampling Plan (PAS-00113605-07).

In December 1986, NJDEP issued an Administrative Consent Order (1986 ACO) for NPN, Inc. and WPBC, ECRA Case 85193. This ACO was entered in connection with NPN, Inc.'s acquisition of WPBC stock, which triggered ECRA obligations. The ACO required NPN, Inc. to submit a complete delineation of environmental contamination onsite and any off-site environmental contamination resulting from discharges of hazardous wastes or substances on or from the property (PAS-00113660-68). WPBC subsequently sold the Clifton Mill to an unrelated third party, V. Ponte & Sons on October 1, 1987 (PAP-00102234 –0102242).

By letter October 8, 1987, attorneys for Ponte notified NJDEP that Ponte assumed responsibility for achieving ECRA compliance at the Clifton Mill facility at 1 Ackerman Ave in accordance with the 1986 ACO (PAS-00113513-14). Ponte assured NJDEP they would assemble the technical information and prepare an implementation schedule in a timely fashion (PAS-00113513-14). Ponte thereafter completed the ECRA process which consisted of the investigation and remediation, where necessary, of the 6 areas of concern noted in the 1986 NJDEP Memorandum. NJDEP issued a No Further Action determination letter on February 27, 1991, stating that cleanup of ECRA Case 85193 was completed and that the site was considered to be in full compliance with ECRA (PAP-00198509; PAP-00102547)

According to the 2007 EWMA RIR/RAW, characterization activities conducted in connection with ECRA Case 85193 included four underground storage tanks (containing mineral spirits, hydraulic oil and No. 2 fuel oil), stained soil beneath a fill pipe of a 160,000-gallon aboveground No. 6 fuel oil storage tank and stained soil in a drum storage area (PAP-00198508-19). The 2007 EWMA RIR/RAW noted that the consultant conducting the work under ECRA Case 85193 (HWEC) concluded that elevated concentrations of total petroleum hydrocarbons (TPHC) were due to the presence of fill material and not the result of a discharge from the former USTs~~.~~ (PAP-00198511-12).

According to the 2007 EWMA RIR/RAW, EWMA completed the PA/SIR in May 2006. The 2006 PA/SIR was submitted to NJDEP in conjunction with the Former Recycled Paperboard facility, ISRA Case E20050496, which had ceased operations at the facility in 2005~~.~~ (PAP-00198424).
The 2006 EWMA PA/SIR investigated nine AOCs of which the following six were recommended for No Further Action:

- AOC 1: Above Ground Storage Tanks
- AOC 3: Silo
- AOC 4: Above Ground Piping
- AOC 5: Former Drum Storage Area/Hazardous Material Storage
- AOC 8: Transformers
- AOC 9: Loading/Unloading Area/Railroad Spur (PAS-00198502)

The 2006 EWMA PA/SIR identified three AOCs that required further investigation. They were AOC 2: Underground Storage Tanks; AOC 6: Piping Trenches; and AOC 7: Historic Fill (PAP-00198502-503). The 2006 EWMA RIR/RAW documented the investigation into these three AOCs and provided recommendations if further action was

necessary under the New Jersey Technical Requirements for Remediation (PAP-00198502). With respect to the underground storage tanks (AOC 2) EWMA requested that a no further action determination be issued based on the facts that impacted soils had been removed from the vicinity of the former underground tanks, that TPHC concentrations were determined to be the result of fill material (not releases from the tanks) and that NJDEP had issued a NFA determination for the tanks in February 1991 (PAP-00198512, 14, 16, 17). EWMA also requested a no further action determination for the piping trenches based on the results of an inspection of the trenches that showed they were intact with no holes, cracks or breaches (PAP-00198520).

EWMA conducted soil and groundwater of the property to investigate AOC 7 (Historic Fill) (PAP-00198521-28). The investigation consisted of 33 soil borings - 17 throughout the site in July 2005 and 16 more in August 2005 in areas where the results from the July borings were elevated for lead. The investigation also included groundwater testing of five monitoring wells and an additional 2 rounds of groundwater testing from 3 wells to further evaluate the impact of lead in the fill material. Analytical results of soil and groundwater testing stated that several contaminants typically associated with historic fill were present in soil and groundwater at the facility. EWMA summarized the investigation results as follows: "The results of the Preliminary Assessment and Site Investigation sampling conducted to date have not revealed any on-site sources of contamination other than historic fill that has been identified at the site. Sampling of the fill material has revealed concentrations of PAHs and metals that exceed the NJDEP MSSCC. Fill material is generally present throughout the site at depths ranging from site grade to approximately 12.5 feet…Based on the two groundwater sampling rounds, EWMA has concluded that lead contamination is associated with the historic fill and does not impact groundwater conditions at the Property." (PAP-00198528).
The 2016 EWMA RAR stated: "Based on the fact that only PAH compounds and metals were detected in soil at concentrations greater than their respective NJDEP RDCSCC and since the contamination is concentrated in the fill material, EWMA considers the elevated PAH and metals in soil to be the result of the fill material on the Property and not a result of former operations conducted at the Property. (PAP-00198429). Note: The PA/SIR discussed above was not included in the documents provided for review of this Data Facility Report. Instead, the above information was obtained from the November 2016 RAR.

Groundwater

By letter of March 22, 1989, regarding Recycled Paper Board ECRA Case No. 85193 to NJDEP, HWEC reported the results of groundwater samples collected in November 1988 from five groundwater monitoring wells that were installed at the former Recycled Paper Board facility in 1986. In addition to the sampling of these wells, HWEC conducted a "half-mile radius well search." The study of the half-mile well search revealed 46 groundwater supply and groundwater monitoring wells installed in the vicinity of the facility that had Petroleum Hydrocarbon odors in their water. Of the 46 wells listed in the search, at least ten have recorded in their installation logs the detection of a gas, oil or petroleum hydrocarbon odor. One such well installation record from a gas station, located up-gradient to the Recycled Paper Board facility, stated there were very strong petroleum hydrocarbon vapors at 15 to 22 feet below grade. Another

site upriver from Recycled Paper Board recorded in the monitoring well installation log that there was a strong solvent odor during installation of the wells (PAS-00113533).

HWEC stated that based on the groundwater contours developed for this report there was a southeastern flow of groundwater and that according to the groundwater elevations, MW-1 served as the background well (PAS-00113533). The monitoring well MW-1 is located along the western property boundary which is up-gradient with respect to the site's easterly groundwater flow direction (PAP-00198426).

HWEC concluded that all relevant information showed the groundwater contamination detected in the monitoring wells is similar to that detected in the background well, MW-1. HWEC concluded that the detected groundwater contamination at the Recycled Paperboard facility "is from an off-site location and not from soil contamination on the property", so further remediation should not be required (PAS-00113533).

The 2007 EWMA RIR/RAW report ~~by EWMA~~ stated that soil boring activities in July, August and December of 2005 encountered groundwater at depths ranging from 7 to 14 feet below ground surface (bgs). Based upon the groundwater elevation, data recorded from the monitoring wells, which were installed during the historic fill investigation, groundwater was noted to flow in the easterly direction across the site, which corresponds to the topography and flow of the Passaic River (PAP-00198504). As noted above, the 2005 investigation by EWMA determined that groundwater exceedances of PAHs and metals were attributed to historic fill (PAP-00198425). In addition, lead contamination associated with the historic fill did not impact groundwater conditions at the property (PAP-00198531).

Remedial Activities

By a letter dated May 24, 1988, Ponte's consultant, HWEC, notified NJDEP they had completed the Phase I soil cleanup program initiated for WPBC under ECRA Case Number 85193 (PAS-00113516). Areas of environmental concern included in the soil cleanup program were a 1,000 and a 3,000-gallon mineral spirits tanks; a 4,000-gallon hydraulic oil tank; a 1,000-gallon fuel oil tank; a 160,000-gallon aboveground fuel oil storage tank; and the former drums storage area (PAP-00113516-17). These were the 6 Areas of Concern identified in the 1986 NJDEP Memorandum (PAS-0113605). Approximately 1,180 cubic yards of Petroleum Hydrocarbons-contaminated (PHC) - soil was excavated and removed from these areas in May 1988 (PAS-00113516-17).

Underground Storage Tanks

Excavation No. 1 was associated with the former 1,000-gallon mineral spirits tank on the northeast side of the site building (PAS-00113516, 26). The final depth of the excavation was measured at about 14.5 feet bgs (PAS-00113517; PAP-00198512). Post-excavation soil samples were collected from 3 locations within the excavation and the analytical results for TPHCs ranged from 5 mg/kg to 18 mg/kg (PAS-00113519-20; PAP-00198512).

Excavation No. 2 was associated with the former 3,000-gallon mineral spirits tank on the east-central side of the building. (PAS-00113516, 27; PAP-00198573; PAP-00198514) The depth of the excavation was 10.5 feet and fill material was noted to 10.5 feet (PAP-00198514). Eight post-excavation soil samples were collected from within the excavation and samples submitted for TPHC analysis. Detected TPHCs ranged from 45 mg/kg to 674 mg/kg (PAP-00198514). HWEC conducted a sieve analysis on a representative sample of fill material and concluded that the elevated concentrations of TPHC were due to the presence of fill material in the excavation and not the result of a discharge from the former UST (PAS-00113518; PAP-00198515, 17).

Excavation No. 3 was associated with the former 4,000-gallon hydraulic oil UST on the southeast side of the site building (PAS-00113528; PAP-00198516; PAP-00198573). The depth of the excavation was 10.5 feet bgs (PAS-00113518, 28). Materials encountered during the excavation were considered fill and consisted of bricks, concrete, cinders and metal intermixed with sand and gravel (PAS-00113518). Post-excavation soil samples were collected from 8 locations within the excavation and analyzed for TPHC. Detected TPHC ranged from 48.7 mg/kg to 411 mg/kg (PAS-00113520-21; PAP-00198516). HWEC conducted a sieve analysis on a representative sample of fill material and concluded that the elevated concentrations of TPHC were due to the presence of fill material in the excavation and not the result of a discharge from the former UST (PAP-00198517).

Excavation No. 4 was associated with the former 1,000-gallon No. 2 fuel oil tank on the northwest side of the building (PAS-00113517, 29; PAP-00198511; PAP-00198573). The depth of the excavation was 8 feet bgs (PAS- 00113518; PAP-00198511). Fill material was noted to 8 feet bgs (PAP-00198511). Four post-excavation soil samples were collected within the excavation and analyzed for TPHC. Analytical results for TPHC ranged from 55.3 to 2,990 mg/kg. Vapor analyzer screening of the same sample that had the concentration of 2,990 mg/kg showed a concentration of less than 100 mg/kg. Examination of the non-odorous material revealed blackish pieces of unburned coal like material mixed in the sandy soil (PAS-00113522). HWEC conducted a sieve analysis on a sample of fill material within the excavation and concluded that the elevated concentrations of TPHC were due to the presence of fill material (including coal/unburned cinders) in the excavation and not the result of a discharge from the former UST (PAS-00113522-23; PAP-00198511-12).

Drum Storage Area

Excavation of impacted soil at the drum storage area on the west side of the building could not be completed during the May 1988 excavation activities because a concrete pad was encountered along the building wall at a depth of 12 inches (PAS-00113518). A sample (Sample No. VP-DS1) was collected at a depth of 12 inches below the surface along the edge of the concrete and analyzed for PP+40 and PHC (PAS-00113519). The PHC result was 1,340 mg/kg and HWEC determined that additional excavation in this area would be necessary. Soil was removed from the drum storage area to a depth of 4 feet bgs on October 31, 1989 PAS-00113485; PAP-00198518). Four post-excavation samples were collected at depths ranging from 13 inches to 19 inches below grade. The post excavation samples were analyzed for total PAHs, PCB's, BN+15, antimony, cadmium, copper, mercury, and zinc. The analytical results from these analyses stated

that the level of compounds detected in the post-excavation samples were below the respective NJDEP soil action levels (PAS-00113485; PAP-00198519). PCBs were non-detect (PAP-00198519).

160,000-gallon Aboveground No. 6 Fuel Oil Storage Tank

The excavation of impacted soil beneath the fill pipe of the 160,000-gallon aboveground No. 6 fuel oil storage tank (AST) could not be completed during the May 1988 excavation activities because groundwater was encountered at seven inches bgs (PAS-00113518). HWEC determined that further excavation and testing was needed for the area of the AST (PAS-0011351818). The AST was located on the southwest side of the site building (PAP-00198573). Between October 31, 1989 and August 1990, the stained soil was excavated from around the fill pipe of the AST (PAS-00113485-86). Post excavation samples were collected and analyzed for PHCs content after each excavation. The report did not state the depth of the samples taken only that each time more soil was excavated. By July 13, 1990, 26 cubic yards of soil had been excavated. The following is a breakdown of the series of sampling events results.

- October 31, 1989 PHCs ranged from 572 mg/kg to 1,380 mg/kg
- December 22, 1989 PHCs ranged from 271 mg/kg to 1,150 mg/kg
- January 30, 1990 PHCs ranged from 270 mg/kg to 2.920 mg/kg
- June 29, 1990 PHCs ranged from 16 mg/kg to 301 mg/kg
- July 13, 1990 three post-excavation samples were taken for the final post excavation sample analysis. Surficial water was encountered at 5 feet bgs therefore a base sample could not be collected. Three sidewall samples were taken 0” to 6” intervals above water level. One sample detected PHCs at 182 mg/kg.
- On August 17, 1990, three additional excavation samples were taken at the same location as the July 13, 1990 sampling.
- August 22, 1990 half a cubic yard of soil was excavated due to the July 13, 1990 sample result of 182 mg/kg (PAS-00113485-87).

The level of lead detected in the site soils that were excavated from the drum storage area and from beneath the fill pipe to the AST was slightly above the RCRA threshold level and classified the soil as a RCRA hazardous waste. The lead was detected at 5.02 ppm and 5.08 ppm (PAS-00113491).

The results from the post-excavation sample analysis stated that the highest detected level of lead was 14 µg/kg (ppb). Almost equal levels of lead were detected in each area during the waste classification analysis, thus indicating that the level of lead is characteristic of the site soils. Similarly, the detected level of lead in the post-excavation samples collected from the drum storage area can be assumed to be characteristic of the site soils (PAS-00113491).

On February 27, 1991, NJDEP issued a Full Compliance Letter for the WPBC facility stating that the Clean-up Plan dated October 21, 1989 had been implemented and completed for ECRA Case Number 85193 (PAP-00102547).

According to the 2016 EWMA RIR/RAR, on April 13, 2015, four soil borings (SB-I to SB-4) were installed on the southern portion of the property to evaluate the subsurface conditions in the area under the former 160,000-gallon No. 6 Fuel Oil AST within AOC-1 (PAP-00198437-38). The boring depths were 20 feet bgs. Historic fill material was encountered in all borings on the Property ranging in depth from site grade to as deep as 12.5 feet below surface grade. This fill material consisted of ash, cinders, crushed brick, concrete and wood pieces followed by sandy silt and clay (PAP-00198438).

The soil samples taken from the soil borings were visually inspected and screened using a Mini-RAE 2000 PID for the presence of total volatile organic compounds (VOCs). Soils were also examined for evidence of free product contamination, discoloration or odors. There was no indication of organic vapors or contamination or discharge. Therefore, samples were not submitted for analysis (PAP-00198437-38). EWMA concluded that soils beneath the former AST were not impacted by any discharge or spill from the AST (PAP-00198447).

According to the 2016 EWMA RAR, based on the presence of contaminants related to historic fill (AOC 7) above their respective NJDEP soil standards, a Deed Notice and engineering controls (i.e., surface cap) was filed with the Passaic County Clerk on April 4, 2016. The surface cap over the entire Property is to prevent exposure to the contaminants of concern (PAP-00198444).

8. Summary of Asserted Defenses

Neu Holdings asserts the “Respondent denies that WPBC released COCs from its operation of the Clifton Plant to the Passaic River and OU 2. Even if it did, WPBC’s liability for any such releases was discharged as a matter of law in bankruptcy on March 31, 1981. On February 8, 1980, WPBC commenced a voluntary proceeding under Chapter 11 of the United States Bankruptcy Code, 11 U.S.C. §§101 et seq. (the “Bankruptcy Code”) in the United States Bankruptcy Court for the District of New Jersey (the “Bankruptcy Court”), said proceedings having been designated In re Whippany Paper Board Co. Inc., Case No. 80-00426”. USEPA was aware at the time of WPBC’s bankruptcy proceedings and had an opportunity to participate in the same.

On March 31, 1981, the Bankruptcy Court entered an Order confirming WPBC’s reorganization plan. Per the plan of reorganization and the bankruptcy code, the confirmation of the reorganization plan discharged WPBC from any and all “debts that arose before the date of such confirmation.” (PAP-00102386)

“USEPA has suggested that the bankruptcy discharge does not pose a barrier to USEPA’s claim because the bankruptcy discharge occurred long before EPA initiated a response action at the Diamond Alkali Site. However, the Bankruptcy Code Section 101(5) defines a “claim” to include a right to payment that at the time of a debtor’s bankruptcy remains “unmatured” and/or “contingent,” and it is well-established that a potential liability may qualify as a “claim” for bankruptcy discharge purposes even if it has not yet fully accrued into a cognizable cause of action under applicable non-bankruptcy law. 1 Collier on Bankruptcy, 101.05 at 101-39 (16th Ed. 2017) (As defined in the Bankruptcy Code, the term “‘[c]laim’ . . . include[s] a cause or action or right to payment that has not yet accrued or become cognizable.”). In the environmental

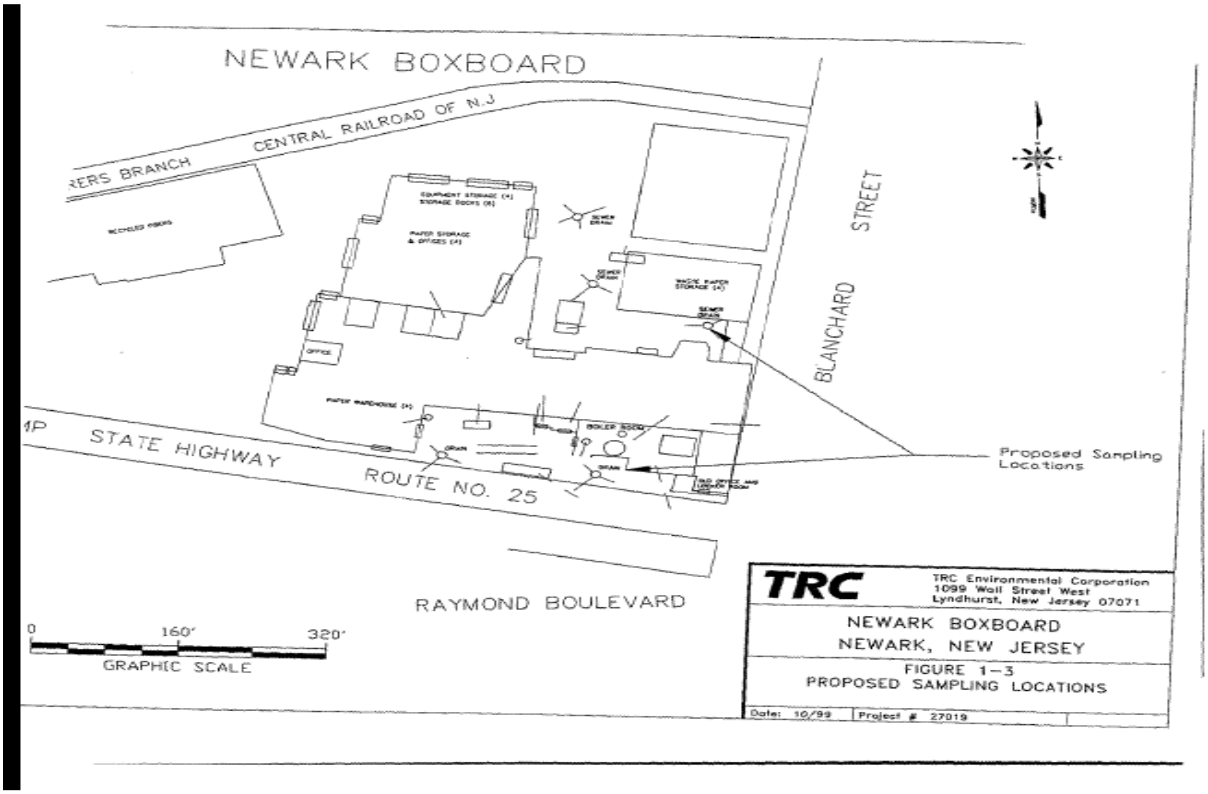
context, a Chapter 11 bankruptcy debtor may be discharged from any and all potential liabilities related to a pre-confirmation release or threatened release of hazardous substances even if such release does not become the subject of any investigation and/or resulting response costs until several years (or even decades) after the debtor's Chapter 11 plan has been confirmed.

"In this case, WPBC ceased operating the Clifton Plant in April of 1980, before the March 31, 1981 confirmation of its Chapter 11 Plan and never resumed operation of the Clifton Plant before selling it to V. Ponte & Sons on October 1, 1987 (PAS-00113953). Accordingly, even if WPBC's operation of the Clifton Plant resulted in the release of COCs into the Passaic River (of which there is no evidence), the liability of WPBC for any such release was discharged upon the court's confirmation of its Chapter 11 Plan".

Evidence shows that the Clifton Plant operations during the period of WPBC's ownership and operation did not include COCs and that the Clifton Plant property was not a conduit for discharging COCs into the River. As such, the former Clifton Plant, which is located nearly nine miles from OU2, did not discharge COCs that could have had any material impact to the Passaic River or OU2. Especially considering that Neu Holdings' wholly-owned subsidiary contributed approximately $1.8 million toward lower Passaic River investigation and a removal action for which it had no responsibility at all, Neu Holdings should bear no further liability for the Diamond Alkali Site or OU2.

Neu Holdings also asserts the following defenses to liability that will be set forth in more detail in its position papers: (i) the petroleum exclusion, (ii) the permitted discharge defense, (iii) that any releases of COCs from the site occurred when the facility was owned/operated by others before or after WPBC (i.e. Ponte and/or Recycled Paper Board), and/or (iv) liability for the Lower Passaic River Site is the responsibility of Ponte, who expressly assumed and notified NJDEP of its environmental responsibility for the former Clifton Mill. (PAS- 00113513-14) Neu Holdings reserves the right to assert other defenses to liability and raise other accompanying litigation risks.

The Newark Group, Inc.



Diamond Alkali OU2 Allocation

ADR Confidential

Facility Data Report

NEWARK GROUP, INC.

Facility Name, Address and Size: Newark Boxboard/Newark Boxboard Company, Inc./Newark Boxboard Company; 17 Blanchard Street, Newark, New Jersey. (PAP-00114815; PAS-00000432)." 150 employees reported in 1978, manufacturing 24 hours per day, 6-7 days per week (PAS-00000432). In 2003, it was reported that the facility employed 45 hourly employees and approximately 12 other employees (PAS-00004277). The acreage of the facility is approximately 7 acres (PAP-00352934; PAP-00114812). See the following figure for location of facility.

(PAP-00352940)

1. **Business Type:** Paperboard manufacturer through the recycling of wastepaper (PAS-00000432; PAS-00103684).

2. **Time Period of Ownership/Operations**

   Operator: 1912/1913 to 2003 (PAP-00114815-16; PAS-00123408)

   Owner: 1912 or 1968 to March 28, 2013 (PAS-00004272; PAP-00352946-49)

   According to a Site History section of the *Remedial Investigation Report with LNAPL Interim Remedial Measures Report*, dated November 2016, the site was operated by Newark Board Paper Mills from approximately 1892 to approximately 1908, then by George W. Downs Company Paper Mill from approximately 1908 to 1912 with Newark

Boxboard beginning operations in 1912 (PAP-00114815-16; PAP-00352928-29). Note: The *Response of The Newark Group, Inc. to the USEPA Request for Information*, dated April 2003 (Response to Request for Information) described The Newark Group's ownership as "1968 to 'present" (PAS-00004272). There is no documentation available to state that the operations of Newark Board Paper Mills or George W. Downs Company Paper Mill are affiliated with Newark Boxboard.

Newark Boxboard was incorporated as a New Jersey corporation on April 10, 1912 (PAP-00428161).

According to the Response to Request for Information, The Newark Group purchased the Newark Boxboard facility from R.W. "Dick" Lewis on September 13, 1968 (PAS-00004277; PAS-00076564). From 1940 to 1968, the facility was owned and operated by Margaret Lewis and R.W. "Dick" Lewis; neither being related to The Newark Group (PAS-00004277).

The Newark Group, Inc. is the successor to Newark Group Industries, Inc., which is the successor to the Newark Boxboard Company (PAS-00004278).

On March 28, 2013, The Newark Group, Inc. conveyed the property to 60 Lockwood Associates, LLC (PAP-00352946-49).

3. Operational History/COC Use and Presence at the Facility

The Newark Boxboard facility produced recycled paperboard in various caliper ranges. The facility recycled approximately 42,000 tons per year of old newspapers, old corrugated containers and municipal curbside collection papers. Grades produced were plain chip, laminating chip, partition chip, and lined chip (PAS-00004269).

Reports to the PVSC during the years 1925, 1926, and 1927 identified Newark Boxboard as discharging self-identified wash water via the storm sewer to the Passaic River. The "polluting" discharge was characterized as having high suspended solids and odors. The wash-water discharge reportedly frequently blocked a nearby creek (PAS-00103660, 682, 689, 695, 945, 950). The 1926 and 1927 reports note that Newark Boxboard was connected to the PVSC (PAS-00103694-95; PAS-00103945).

A February 6, 1926, Letter to Passaic Valley Sewerage Commissioners identified Newark Boxboard as a polluter with the listed pollutant being "foul paper wastes" (PAS-00103660). In March 1926, Newark Boxboard stated in a letter to the Passaic Valley Sewerage Commission (PVSC) that they had stopped all pollution (PAS-00103682). However, according to the *Report on the Status of Pollutions from Industrial Establishments* prepared in November 1926, Newark Boxboard was still considered a polluter discharging old paper sludge at times to the Passaic River (PAS-00103695). The Report also notes that Newark Boxboard was connected to the PVSC (PAS-00103694).

According to the Response to Request for Information, Book Covers, Inc., a New Jersey corporation incorporated on October 19, 1960, was merged into Newark Group

Industries, Inc. on May 2, 1988 to form BCI Newark. BCI Newark formerly operated at the site and was a separate division of The Newark Group. During the time it operated at the site, it was reported that no hazardous substances, other than those contained in "over-the-counter" cleaners and similar products generally available to the consuming public and in their original packaging, were used, generated, stored, disposed or otherwise handled in its manufacturing process (PAS-00004278).

According to a *Notice of Administrative Revocation from NJDEP*, dated October 2005, the New Jersey Department of Environmental Protection (NJDEP) confirmed that Newark Boxboard had ceased all activities requiring a NJPDES permit. Therefore, NJPDES permit No. NJG0107000 was revoked effective August 31, 2005 (PAP-00114672).

In a "1978/1979 City of Newark, New Jersey Feasibility Study, Pollution Abatement Program," industrial discharge was noted on the easterly line of the Morris Canal storm sewer with Newark Boxboard identified as the sole industrial contributor to the discharge in that segment of the line. An estimated discharge of 0.16 million gal per day (MGD) was identified from Newark Boxboard (PAS-00103883). The Feasibility Study characterized that discharge as "polluted" (PAS-00103891), but none of the "pollutants" analyzed in the stormwater samples taken along the Morris Canal storm sewer east of Lockwood Street (MC-100 and MC-104) were COCs (PAS-00103903-PAS-00103905; PAS-00103873)."

Newark Boxboard's 1980 PVSC Sewer Connection Application noted concentrations in wastewater discharged to the sanitary sewer of the parameters lead, mercury, and copper (PAP-00115480). Samples collected as part of Newark Boxboard's PVSC Sewer Connection Application in January 1980 reported copper at 0.316 milligrams per liter (mg/L), lead at 0.942 mg/L, and mercury at 0.0016 mg/L (PAP-00115480). It also was reported in the Application that a total of 365,000 gallons was discharging annually to the storm sewer (PAP-00115476)."

In 1986, a *Worker and Community Right to Know Survey* reported that polychlorinated biphenyls (PCBs) were on site in a transformer casing (PAP-00113837). According to a Response to Request for Information, dated April 2003, PCB-bearing transformers were removed from the facility in 1988. No information regarding releases associated with transformers at the facility was identified based on a review of available documents.

Polycyclic aromatic hydrocarbons (PAHs) were detected in the surrounding soil in sampling conducted in 2012 at the former 30,000-Gal No. 6 Fuel Oil Underground Storage Tank (UST) (PAP-00114705-06).

A Community Right to Know Survey from 1992 reported that Newark Boxboard's chemical inventory included copper as a component (60-69%) of a product (Certanium 70F) which was stored in the Store Room (PAP-00114452). In 1993, the Community Right to Know Survey reported that Newark Boxboard's chemical inventory included lead as a component (25-49%) of dry film and copper as a component (60-69%) of a product which were still stored in the Store Room (PAP-00114465-66)."

Test results for boxboard stock, plain chip paperboard, old newspaper, and old corrugated cuts from 1993 and 1994, included with the Response to Request for Information, were all reported as "Pass" for lead, mercury, PCBs, dichlorodiphenyltrichloroethane (DDD), dichlorodiphenyldichloroethane (DDE), and dioxin indicating the results were less than their respective limits (PAS-00075522-46).

Community Right to Know Surveys from 1994 through 1998, and 2000 through 2002 reported that Newark Boxboard's chemical inventory included pure, solid copper (PAP-00114472; PAP-00114488; PAP-00114519; PAP-00114521; PAP-00114524; PAP-00114538; PAP-00114570; PAP-00114644).

According to a Response to Request for Information, the Site has operated under the Resource Conservation and Recovery Act (RCRA) Hazardous Waste Generator ID Number EPA ID NJD000556837 (PAS-00004267). The Response additionally reported that hazardous substances being utilized, manufactured, discharged, released, stored or disposed of by Newark Boxboard included PCBs, copper, lead, and mercury (PAS-00004267-68).

4. Identified COCs

- PCBs (present in transformers)
- PAHs (used and released)
- Copper (used and released)
- Lead (used and released)
- Mercury (generation and release)

PCBs

A December 10, 1985 letter from Newark Boxboard to the Newark Fire Department reported the discovery of PCBs in one of the transformers at the site (PAP-00352912). The transformers were properly disposed of in 1988 (PAP-00112964-65).

PAHs

During the removal of the 2,500 gallon No. 6 fuel UST in 1991, an inspection of the tank and excavation revealed signs of corrosion on the fuel oil tank and visual evidence of contamination in the excavation. During excavation the piping and the tank were observed to be leaking. 13 discrete soil samples were collected from the underground tank excavation and submitted to a laboratory for analysis to assess the condition of the soil surrounding the tank. All soil samples collected from the excavation were analyzed for Petroleum Hydrocarbons utilizing EPA Method 418.1. Because some samples contained greater than 100 ppm of petroleum hydrocarbons, five samples were analyzed for base neutrals utilizing EPA Method 8250+15. Pyrene was detected at 12,000 µg/kg in one sample (PAP-00114157-58, 61, 64).

As noted in the *Remedial Investigation Report with LNAPL Interim Remedial Measures Report*, dated November 2016, samples were collected in 2012 as part of the remediation of the soils at the location of the former 30,000-Gallon No. 6 Fuel Oil UST. One sample location southeast of the former UST location contained benzo(a)anthracene at 5 ppm; benzo(a)pyrene at 3.6 ppm; benzo(b)fluoranthene at 2.0

ppm and, dibenzo(a,h)anthracene at 0.91 ppm. In addition, the Low Molecule Weight (LMW) PAH, naphthalene was detected at 36 ppm (PAP-00114705-06).

Metals – Copper, Lead and Mercury

An April 1980 PVSC Heavy Metals Source Determination Study, Phase II reported that Newark Boxboard had an average daily flow to the PVSC determined during two consecutive days of sampling of 0.3560 MGD and flow-proportioned results of composite samples on two consecutive days expressed on a mass basis were 0.938 pounds (lbs.) per day of copper, 0.891 lbs. per day of lead, and 0.0048 lbs. per day of mercury (PAS-00103655; PAP-00206256; PAP-00206296).

A March 1975 Waste Effluent Survey for PVSC reported that a semi-quantitative scan of metal ions found copper to be less than 0.20 parts per million (ppm) and lead between 0.20 to 1.0 ppm (PAP-00114473). A five-day average found that the waste effluent was being discharged at 317,000 gal per day in 1975 (PAP-00114474).

A 1978 Industrial Waste Questionnaire stated that facility wastewater was not treated prior to discharge to the sewer (PAS-00000441), but the facility's 1980 PVSC Sewer Connection Application described the following pretreatment process: "A Sinclair floatwash unit is used to remove fibers from the white water so that it can be reused on showers, sealing water, hoses, etc. The excess of this clarified water is discharged to city sewer. Screens have 60 [micron] openings" (PAP-00115477). The 1978 Questionnaire reported that previous measurements showed a daily flow of 563,000 gal per day with sample results for lead and copper at 1.0 mg/L and 0.2 mg/L, respectively (PAS-00000441).

Wastewater analysis results from 1974 to 2002 included with the Response to Request for Information reported results for copper ranging from 0.042 to 0.64 ppm; lead ranging from 0.004 to 0.942 ppm; and, mercury ranging from 0.0002 to 0.001 ppm (PAS-00075548). Pounds generated per year in wastewater from 1975 to 2002 were reported ranging from 6.5 to 352.21 lbs. for copper; 0.97 to 283.3 lbs. for lead; and 0 to 0.55 lbs. for mercury (PAS-00075550).

Samples collected in December 1994 from the PVSC discharge show that in regards to copper, two of the three samples were above the Threshold Value, but all three were below the Local Limit. The average results were above the Threshold Value and below the Local Limit. For lead and mercury, all three samples were below the Threshold Value and Local Limits with the average results also below both limits. The results for copper ranged from 0.06 mg/L to 1.7 mg/L; lead ranged from 0.005 mg/L to 0.016 mg/L; and mercury was not detected (less than 0.001 mg/L) (PAP-00114480, 83-85).

According to the Response to Request for Information, Newark Boxboard began reporting the concentrations of metals in its effluent in approximately 1997. From 1997 to 2002, the annual paperboard production at the site ranged from 73,426,000 lbs. to 79,788,000 lbs. and the average total daily wastewater flows ranged from 47,419 gal to 91,332 gal. For 1997 to 2002, the annual range of metals discharged to the PVSC (expressed as pounds of metal per pound of product) by the facility was as follows:

- Copper (9 x 10^{-8} to 6 x 10^{-7})
- Lead (1 x 10^{-8} to 4 x 10^{-8})
- Mercury (0 to 3 x 10^{-9}) (PAS-00004270)

Pretreatment Monitoring Reports from July 1997 through December 2002 reported copper, mercury, and lead concentrations all within the Permit requirements. Copper, mercury, and lead were detected at low levels in various samples over the five year period (PAP-00112755-818).

Pretreatment Monitoring Reports Concentration Range			
Year	**Copper**	**Lead**	**Mercury**
1997	<.01	<0.001 – 0.047	<0.001
1998	0.01 - 1.4	<0.001 - 0.087	<0.001
1999	<0.001 – 2.0	<0.001 – 0.033	<0.001
2000	0.01 – 0.71	<0.001 –0.018	<0.001 – 0.004
2001	<0.01 – 1.94	<0.001 – 0.023	<0.001 – 0.003
2002	<0.01 – 0.19	<0.001 – 0.046	<0.0005 – 0.001

The following table presents the results of PVSC discharge analysis for samples collected from January to June 2003:

PVSC Discharge Monitoring Data					
Month	**Copper**	**Lead**	**Mercury**	**Total Volume Discharged**	**Citation**
January 2003	0.16 mg/L	0.047 mg/L	Not detected	2,688,600 gal	PAP-00114572, 77
February 2003	0.41 mg/L	0.029 mg/L	Not detected	2,042,450 gal	PAP-00114586-87
March 2003	0.07 mg/L	0.029 mg/L	Not detected	1,655,300 gal	PAP-00114600, 08
April 2003	0.03 mg/L	0.018 mg/L	Not detected	1,788,900 gal	PAP-00114611, 19
May 2003	0.04 mg/L	0.021 mg/L	Not detected	2,678,700 gal	PAP-00114623, 30
June 2003	0.02 mg/L	Not detected	0.0004 mg/L	4,422,300 gal	PAP-00114633, 40

Historic Fill

The Allocation Team has determined that the property boundary for 17 Blanchard does partially overlap the regional Historic Fill as designated by the NJDEP.[1]

NJDEP has established that historic fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 COCs: PAHs, lead, copper, and

[1]*Digital Geodata Series, DGS04-7, Historic Fill for New Jersey*, https://www.nj.gov/dep/njgs/geodata/dgs04-7.htm, Quadrangle #52 and #53 (NJDEP map identifying locations of recognized historic fill).

mercury.[2] Accordingly, NJDEP technical requirements for property containing Historic Fill requires sampling for the EPA Target Compound List for PAHs and Target Analyte List for metals, including lead, copper, mercury, and the OU2 PAH COCs.[3] PAHs, lead, copper, and mercury are recognized by NJDEP to be constituents of Historic Fill at varying levels, not atypically at or exceeding residential soil standards.[4]

The levels of PAHs, copper, lead and mercury detected at the site in soils are presented in the table below.

COCs Found in Onsite Soils	
COC	**Max Detected Concentration**
Lead	68.1 mg/kg
Copper	60.1 mg/kg
Mercury	0.13 mg/kg
Benzo(a)anthracene	5 mg/kg
Benzo(a)pyrene	3.6 mg/kg
Benzo(b)fluoranthene	2 mg/kg
Dibenzo(a,h)anthracene	0.91 mg/kg

Note: The sample results for metals listed in this table are from the soil sampling done in the area assumed to be where the historic creeks had existed. It was concluded that historic fill was present on 17 Blanchard based on visual inspection of soil borings along the property boundary of 17 Blanchard and 60 Lockwood Street, therefore no analysis was available.

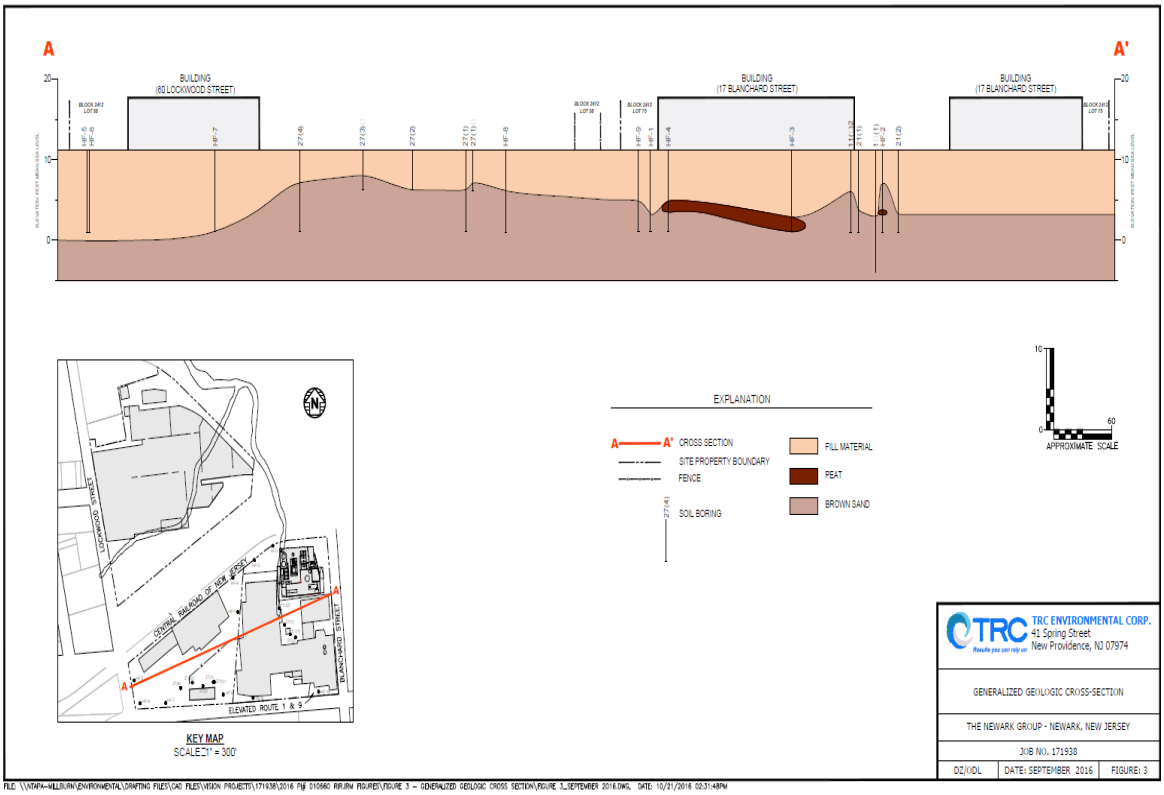
The *Remedial Investigation Report with LNAPL Interim Remedial Measures Report*, The Newark Group, Inc. Facility, 60 Lockwood Street (Block 2412; Lot 58), 84 Lockwood Street (Block 2412; Lot 17), 17-61 Blanchard Street (Block 2412; Lot 75) dated November 2016 (2016 RIR), stated that according to the NJDEP's GIS database and New Jersey Geological Survey's 2009 Historic Fill of the Elizabeth Quadrangle map, the site is located within mapped Historic Fill boundaries. This was corroborated by observations made during the site soil investigation, which identified fill material consisting primarily of sand and gravel, with varying amounts of ash, glass, wood, and brick in the upper five to eight feet of soil (PAP-00114681-82). Note this report includes sites that are not part of this allocation and the historic fill discussed above is for all Newark Group properties.

---

[2] *Characterization of Ambient Levels of Selected Metals and cPAHs In New Jersey Soils* (2002) and *Characterization of Ambient Levels of Selected Metals and Other Analytes In New Jersey Soils* (1997), studies prepared for NJDEP, Division of Science and Research, by BEM Systems, Inc.

[3] New Jersey Department of Environmental Protection (NJDEP), *N.J.A.C. 7:26E Technical Requirements for Site Remediation,* Table 4-2, November 2009 [Note that Table 4-2 has been deleted from the current version of N.J.A.C. 7:26E (May 7, 2012) and the updated *Historic Fill Technical Guidance* (April 2013) as NJDEP believed that the tables list of historic fill constituents was too restrictive].

[4] NJDEP Table 4-2 (PAHs and lead) and a summary of NJDEP records regarding investigations of properties in the vicinity of the Passaic River recognized to be located in areas of Historic Fill indicate that the following average/maximum (mg/kg) contamination levels of OU2 COCs exist in area Historic Fill: PAHs (1.91/160), lead (574/10,000), copper (11.2/1,200), and mercury (0.21/3.7).



The 2016 RIR stated that according to a 1908 historical Sanborn map, two creeks historically crossed the 17 Blanchard Street property. The creeks were reportedly filled sometime between 1892 and 1908; however, no detailed information or sampling data are available for this fill material. Therefore, in September 2012, soil sampling was conducted to evaluate potential impacts associated with the fill material. Two soil borings were advanced in the area of the two former creeks to approximately 5 feet bgs. No discoloration or elevated PID readings were observed during field screening; therefore, one soil sample was collected from each boring from approximately 0 to 0.5 feet bgs. Copper, lead and mercury were detected; however, it was concluded that the SPLP analytical results demonstrated that the low levels of lead and mercury in the soil would not have the potential to impact groundwater; therefore, further investigation of these metals was not warranted. This area was to be included in the site-wide historic fill investigation (PAP-00114710-11).

The 2016 RIR reported the following investigation into the site-wide historic fill. “In the February 2012 SIR, 16 soil borings were advanced to investigate nine specific areas of concern. Based on the characterization of the recovered soils, materials consistent with the presence of historic fill materials (i.e., cinders, ash, wood, glass, and concrete fragments) were identified in the shallow subsurface throughout the site.

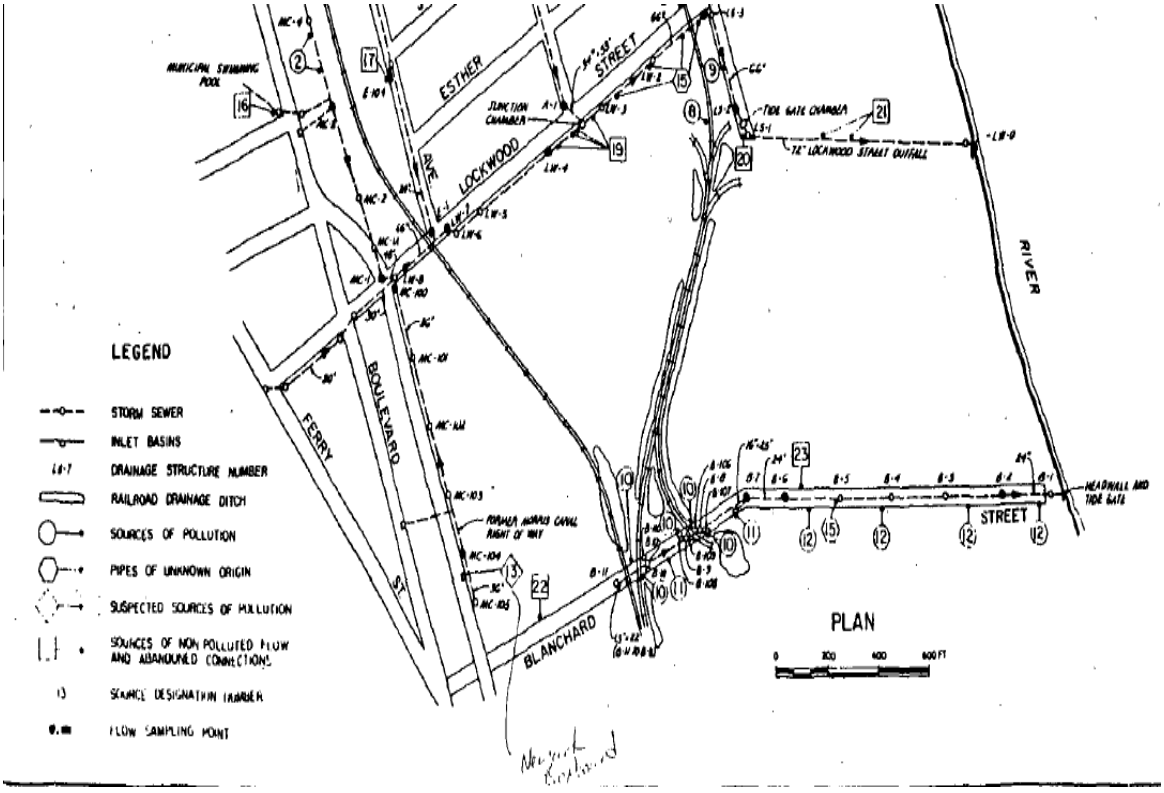
In addition, four of the five soil samples collected from fill material within AOC 27: Railroad Tracks (60 Lockwood Street) contained elevated concentrations of arsenic and PAHs above the Residential Direct Contact Soil Remediation Standard (RDCSRS), Non-Residential Direct Contact Soil Remediation Standards (NRDCSRS), or Default Impact to Ground Water Soil Screening Levels (DIGWSSL). These constituents and the concentrations detected are consistent with those typically observed in historic fill material. Therefore, in accordance with the Technical Requirements for Site Remediation (TRSR), additional soil characterization was conducted to determine if historic fill material is present throughout the site (PAP-00114711-12).

Further investigation for the historic fill at 17 Blanchard and 60 Lockwood Street was conducted in 2014. Soil borings were advanced along the property boundary of 17 Blanchard Street and 60 Lockwood Street parcels. The borings were advanced to the top of native material (approximately 10 feet bgs) to visually evaluate the extent and thickness of the fill material. Fill material consisting of cinders, brick fragments and crushed concrete was identified in all borings. The fill material extended to between approximately 8.5 and 10 feet bgs, but did not intersect the shallow ground water table, which was encountered between approximately 8 and 13 feet bgs (PAP-00114712). Note: Only visual inspection was conducted on these samples; no soil sampling was analyzed.

See the following figure obtained from the 2016 RIR for a geological cross-section to demonstrate fill material that exists beneath 17 Blanchard.

(PAP-00114722)

A *Response Action Outcome*, dated December 23, 2016 was issued by TRC Environmental Corp. for the remediation of several Areas of Concern at the Newark Group properties. The Response Action Outcome stated that it did not include contamination resulting from the presence of historic fill (PAP-00115447-51).



5. COC Pathways

Storm Sewer

A 1977 data verification sheet identified the following sources of intermittent wastewater discharges from Newark Boxboard to the Passaic River via a storm sewer: (1) Rewinder Brake Cooling Water; (2) Floor Drains; (3) Sump Pump Discharge; and, (4) Vent Line from Condensate Tank (PAS-00103684-85).

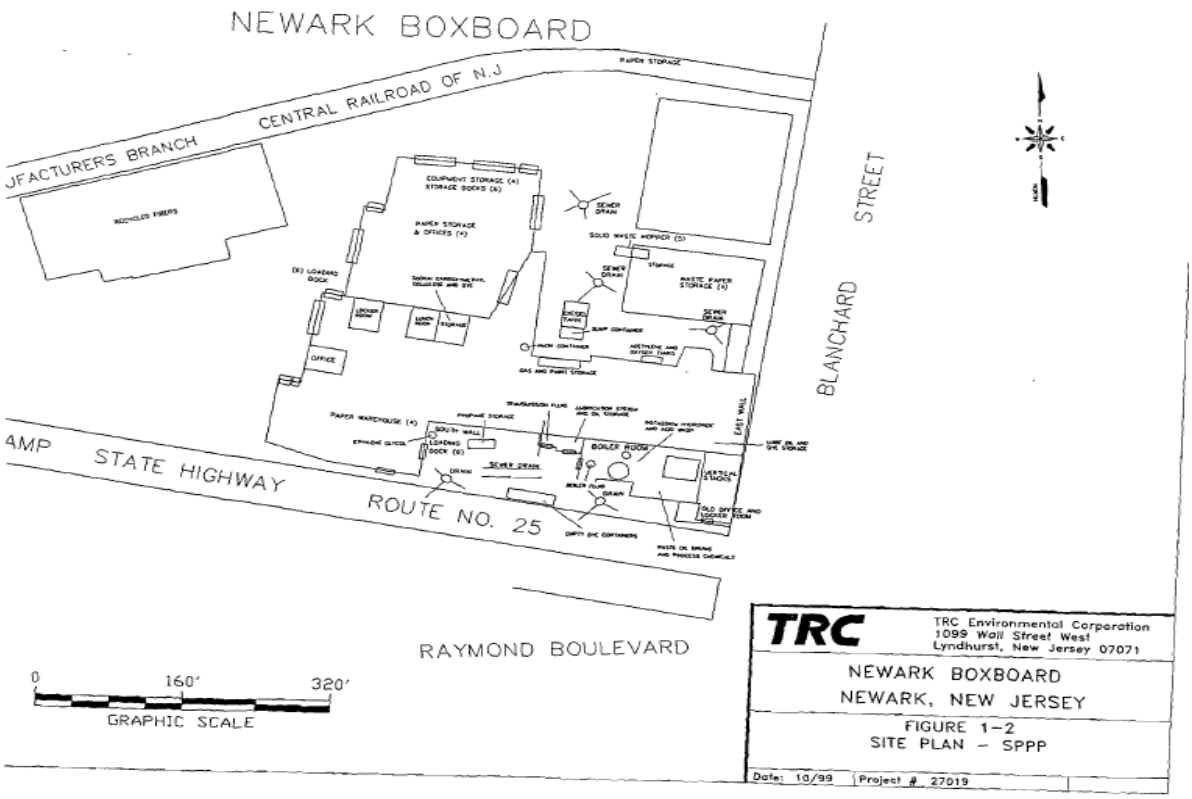
An August 30, 1977 letter from the PVSC to Newark Boxboard Company noted that during an inspection, several of Newark Boxboard discharges to the Morris Canal storm sewer appeared to contain objectionable materials such as boiler blowdown, process wash down, and minor amounts of spilled petroleum products. The discharge was noted to reach the Passaic River through the Lockwood Street outfall (PAS-00103713-14).

The following map shows the location of Newark Boxboard relative to the storm sewer and the Passaic River. Number 22 shows the location of the continuous low volume discharge of cooling water entering the gutter from Newark Boxboard.

(PAS-00004238)

According to the Response to Request for Information, in approximately 1980, Newark Boxboard rerouted the non-contact cooling water, process wash down water, and boiler blow down wastewater to discontinue its discharge to the Morris Canal storm sewer. These waters were discharged to the PVSC. Currently the connection to the storm sewer is sealed. Floor drains in collection areas and process areas return excess water to a central collection tank where it is re-used in the papermaking process. Excess water that is not reused is discharged to the PVSC (PAS-00004273).

According to a March 30, 2000, letter report to NJDEP, Water Discharge Permit No. NJ0107000, there were five sewer drains around the facility, three located around the waste paper storage building and the other located at the loading dock. All five drains empty into surface water (PAP-00352933).



All stormwater in open paved areas was directed to a series of storm sewers, stormwater generated on unpaved areas abutting the northern portion of the facility building was piped to a stormwater intake trench. Stormwater from the storm drains flows directly to a storm main which ultimately joined a main for disposal via the municipal sewerage system. The facility diverted several of the roof drains to the

storage sump for use in the recycling process or discharge to the local publicly owned treatment works (POTW) through PVSC Non-Domestic Wastewater Permit No. 2040 1402, expiration date of July 4, 2001 (PAP-00352934).

The 2000 letter report also stated that the main area of potential pollutant sources which may affect the quality of stormwater discharges were the three sewer drains around the waste paper storage facility. As part of the Stormwater Pollution Prevention Plan (SPPP), Newark Boxboard proposed to divert three of the storm drains in the Waste Paper Storage Area to the building sump. It was reported that the only other potential areas where stormwater discharge exposed to source materials which could not practicably be prevented or eliminated are storm drains located in parking areas (PAP-00352934).

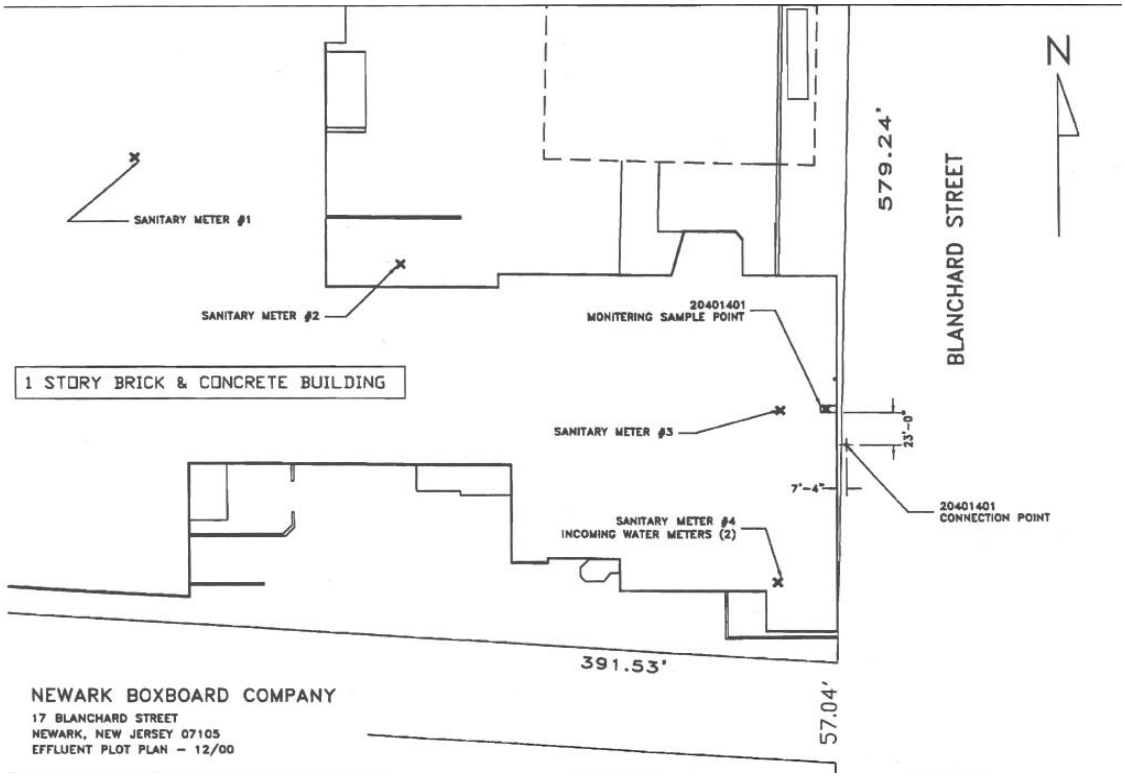
On October 3, 2000 NJDEP confirmed that the diverting of the three sewer drains around the waste paper storage facility to the basement sump was a sound Best Management Practice to eliminate the exposure of stormwater to these source materials. Once the project was complete an inspection was needed to evaluate eligibility for coverage under the General Industrial Stormwater Permit (NJ0088315) (PAP-00352942).

See the following Site Plan from the above discussed SPCC.

(PAP-00352941)

Sanitary Sewer

According to a 1979 Sewer Connection Application, 127,527,500 gallons of water was used for sanitary sewer (PAS-00103669).



According to a June 25, 1979 letter to EPA, Newark Boxboard stated that "all process and sanitary waste were discharged to the Newark City Sewer. At that time the following processes were discharged:

- Point A: 1-inch pipe from Rewinder Brake Cooling Water and two 4-inch floor drains
- Point B: Two 1 ¼-inch Sump Pump discharge and a 2-inch vent line from condensate tank

(PAP-00115469)

Newark Boxboard had Sewer Connection Permit Number 20402400, for the discharge of wastewater to the PVSC effective July 27, 1981 with an expiration date of July 27, 1986 (PAP-00352943). According to the Response to Request for Information, the connection to PVSC was the only point of discharge from the site. Newark Boxboard reported that it had always been in compliance with its PVSC permit (PAS-00004267).

The following map included in the site's 2001 sewer use permit application shows the location of the effluent connection point and the monitoring sample collection point:

(PAP-00114536)

6. Regulatory History/Enforcement Actions

Inspections

On July 30 and 31, 2002, a Compliance Evaluation and Assistance Inspection (CEAI) was conducted by NJDEP. No potential violations were noted. It was noted that a revised SPPP was submitted December 22, 2000. The inspection also noted that contaminated stormwater goes to PVSC via floor drains. The stormwater from roof-drains and areas with no source materials was discharged through three outfalls where sampling and monitoring were required (PAP-00352930-32).

Violations

A 1970 Stream Contamination Report reported that on April 6, 1970, as a result of negligence, a violation occurred at Newark Boxboard when approximately 500 gal of paper pulp overflowed into a driveway and then into the Blanchard Street storm sewer (PAS-00035386).

Permits

Newark Boxboard Permit Summary				
Permit No.	**Issued by:**	**Use**	**Dates**	**Discharge Limits**
20401400	PVSC	Sewer Connection	July 27, 1981 - March 1992	Copper, Lead, Mercury
20402402	PVSC	Sewer Connection	March 1992 - July 14, 2001	Copper, Lead, Mercury
20200033	PVSC	Sewer Connection	July 15, 2001 - June 30, 2006,	Copper, Lead, Mercury
NJ0107000	NJDEP	Stormwater	1997 - May 31, 2002	Not known

A Public Notice of Newark Boxboard's application for a NPDES permit was issued on August 1, 1980 (PAP-00113923-25). The final permit, NJ0031682, did not become effective, however, because USEPA ultimately determined that a permit was not required because the subject discharge had been rerouted to the PVSC (PAP-00114014-16).

The site operated with a PVSC Sewer Connection Permit No. 20401400, issued on July 27, 1981 (PAP-00352943). The permit expired July 27, 1986 (PAP-00352943). The permit was renewed and was effective from July 14, 1986 through July 14, 1991 and July 14, 1991 through July 14, 1996 (PAP-00113822; PAP-00113854-67).

In March 1992, Permit No. 20401400 was revised and the site operated a PVSC Sewer Connection Permit No. 20402402 through July 14, 1996 (PAP-00113854; PAP-00114405). The permit was renewed and was effective from July 14, 1996 through July 14, 2001 (PAP-00114495).

From July 15, 2001, through June 30, 2006, the site operated with a PVSC Sewer Connection Permit No. 20200033 (PAP-00114546).

A March 30, 2000, letter from Newark Boxboard to the NJDEP stated that Newark Boxboard at the time operated under stormwater discharge permit Number NJ0107000 and was requesting the NJDEP to re-issue the facility a general permit upon implementation of the SPPP since contact between the stormwater and source materials would be eliminated upon the implementation of the plan (PAP-00352933).

An April 2003 letter from Newark Boxboard to the NJDEP transmitted an application for permit renewal as the stormwater discharge permit Number NJ0107000 expired May 31, 2002. The permit renewal application removed one of the outfalls and stated the flow from that outfall was redirected for internal use (PAP-00114646-71).

7. Response Actions

Characterization Activities

The following characterization activities have taken place at the facility:

- Closure Report at Newark Boxboard 17 Blanchard St, UST No. 106607 dated November 1991 (PAP-00114144)
- Remedial Investigation Report with LNAPL Interim Remedial Measures Report, The Newark Group, Inc. Facility, 60 Lockwood Street (Block 2412; Lot 58), 84 Lockwood Street (Block 2412; Lot 17), 17-61 Blanchard Street (Block 2412; Lot 75) dated 2016 (PAP-00114673)

According to the 2016 RIR, additional remediation was conducted in 2012 at the location of the former UST. In September 2012, five soil borings were installed and five soil samples were collected to further delineate light nonaqueous phase liquid (LNAPL) and evaluate potential petroleum-related PAH impacts to soil. At one sample location southeast of the former UST location benzo(a)anthracene was detected at 5 ppm; benzo(a)pyrene was detected at 3.6 ppm; and, dibenzo(a,h)anthracene was detected at 0.91 ppm. In addition, the PAH, naphthalene was detected at 36 ppm (PAP-00114705-06).

According to the 2016 RIR, soil sampling was conducted in September 2012 to evaluate potential impacts associated with fill material suspected at the location of two former creeks. Two soil samples were collected. PAHs were not detected above the most stringent remediation standards or screening levels in either sample. Mercury was detected at 0.13 mg/kg in one sample (PAP-00114710-11, 5135). Lead and copper were also detected, but not above the most stringent remediation standards or screening levels (PAP-00114711, 5159, 5161). The concentrations detected were as follows:

Analyte	Sample 1 Result	Sample 2 Result
Copper	60.1 mg/kg	37.7 mg/kg
Lead	10.3 mg/kg	68.1 mg/kg
Mercury	Not detected	0.13 mg/kg

Analyte	Sample 1 Result	Sample 2 Result
Benzo(a)anthracene	Not detected	0.0480 mg/kg
Benzo(a)pyrene	Not detected	0.0441 mg/kg
Benzo(b)fluoranthene	Not detected	0.0417 mg/kg
Benzo(k)fluoranthene	Not detected	0.0322 mg/kg
Benzo(g,h,i)perylene	Not detected	0.0493 mg/kg
Chrysene	Not detected	0.0476 mg/kg
Dibenzo(a,h)anthracene	Not detected	0.0134 mg/kg
Fluoranthene	Not detected	0.0927 mg/kg
Indeno(1,2,3-cd)pyrene	Not detected	0.0325 mg/kg
Phenanthrene	Not detected	0.0483 mg/kg
Pyrene	Not detected	0.0797 mg/kg

(PAP-00115134-35, 58-61)

Remedial Activities

As reported in the 1991 Closure Report for Newark Boxboard Company, on June 18, 1991, 2,500 gallons of No. 6 heating oil were transported from the NBB facility for offsite disposal (PAP-00114156, PAP-00114175). On September 24-27, 1991, approximately 1,050 tons of soil were excavated at the NBB facility and transported for offsite recycling (PAP-00207817). According to the Official Certificate of Recycling by TPS Technologies Inc., 1,036.14 tons of petroleum-contaminated soil were received for recycling from Newark Boxboard (PAP-00208199).

On March 12, 1992, NJDEP notified Newark Boxboard Co. that they had complied with the Departments existing requirements regarding corrective action for the investigated UST system. Therefore, no further corrective action was required (PAP-00112753).

According to a Discharge Investigation and a Corrective Action Report, dated April 22, 1992, prepared by Vectre Corporation, analysis of post-excavation soil samples following the removal of the 30,000-gallon No. 6 heating oil UST on June 19-21, 1991 stated that soils in the vicinity of the UST had been impacted by heating oil. In September and October 1991, soil borings and additional monitoring wells were drilled to delineate the extent of free product and soil contamination (PAP-00207811). PAHs were found in several soil samples. Naphthalene concentrations ranged from 83,000 to 120,000 mg/kg; fluorene ranged from 12,000 to 18,000 mg/kg; phenanthrene ranged from 42,000 to 57,000 mg/kg; and, pyrene was found in one soil sample at 12,000 mg/kg (PAP-00114164-65). Laboratory comments accompanying the results for fluorene and pyrene note that the compounds were detected below the method detection limit (PAP-00114164-65).

8. Summary of Asserted Defenses

A 2016 Request for *De Minimis* Settlement on behalf of The Newark Group stated that they were not associated with any release or discharge of dioxins, furans, or PCBs into the Lower Passaic River (PAP-00115458). Because Newark Boxboard used recycled feedstock, and not virgin pulp, it did not perform chlorine or any other pulp-bleaching

processes that may result in the formation of dioxin (PAP-00115459). It was also stated that the only association between Newark Boxboard and any of the three primary COCs is Newark Boxboard's off-site disposal of PCB-containing transformers in 1988 (PAP-00115460).

The Newark Group asserts the following:

- PAHs in Newark Boxboard facility soil and groundwater associated with the release from a UST of No. 6 fuel oil cannot give rise to CERCLA liability under the Act's petroleum exclusion, CERCLA § 101(14) [42 U.S.C. § 9601(14)]; and,

- To the extent a nexus is alleged between the Newark Boxboard's discharges to the PVSC and COCs in the Passaic River, some or all of such discharges are subject to CERCLA's federally permitted release exemption, CERCLA §§ 101(10) & 107(j) [42 U.S.C. §§ 9601(10), 9607(j)]

Newark Morning Ledger Co.

Diamond Alkali OU2 Allocation

ADR Confidential

Facility Data Report

NEWARK MORNING LEDGER COMPANY

Facility Name, Address and Size: Newark Morning Ledger Co. (NML); 1 One Star Ledger Plaza Newark, NJ 07101 [Block 104, Lot 21 (Building) and Block 105, Lot 6 (Parking Lot)]; approximately two acres (PAP-00000636). In 1978, NML had 793 full time and 458 part time employees working three shifts per day, seven days per week (PAS-00077359). By 1990 NML employed 950 full time and 100 part time employees working three shifts per day, 365 days per year (PAS-00077384). In August 1992, printing operations ceased and former production areas were repurposed (PAP-00000636).

1. **Business Type:** NML is a newspaper publishing company that published The Star-Ledger and The Sunday Star-Ledger newspaper (PAP-00000492; PAS-00077054). The principal raw materials include newsprint, ink, and photo substances (PAP-00000439).

(PAP-00000677)

2. Time Period of Ownership/Operations

Operator: 1966 to December 2014 (PAP-00000636)
Owner: 1964 to 2015 (PAP-00000946)

According to the Case Inventory Document (CID) for Newark Star Ledger, Sanborn Maps identified historical operations at the site from 1892 to 1966 consisted of a former tannery, various manufacturing tenants, a leather finishing business, and a printing press/printing machine rebuilding operation. A deed notice, with an engineering control, for contaminants of concern (COCs), which include polynuclear aromatic hydrocarbons (PAHs), and mercury, was filed for the site on December 19, 2014. The CID reported the exceedances of multiple SVOCs and metals are attributable to historic fill. In addition, groundwater was presumed to be impacted by Historic Fill COCs found in site soils (PAP-00000515, PAP-00212775).

NML began operations at its Star-Ledger Plaza, Newark, New Jersey site in 1966. In or about August 1992, NML ceased production operations at the site. From that time to the present, operations at the Newark site have consisted of advertising, editorial, circulation, administration, composition, and office support (PAS-00077005).

3. Operational History/COC Use and Presence at the Facility

As reported in the *Preliminary Assessment (PA)/Site Investigation (SI)/Remedial Investigation (RI)/Remedial Action Report (RAR)*, dated February 2015 (2015 Report), historical NML operations at the site included:

1966 - 1972 Printing Operations

Printing operations from 1966 to 1972 consisted of two processes: typesetting and photoengraving (PAP-00000639).

Typesetting consisted of the setting of words for each story and advertisement into metal type on a linotype machine. The metal was an alloy of lead, tin, and antimony. The lines of type were melted down onsite and the alloy was reused. Typesetting produced no waste. NML maintained smelters in which they would melt down the alloy plates and reuse the materials. The smelters were reportedly removed in the 1970s after the alloy platemaking operations ceased (PAP-00000639). Based on the available file material, it is unclear if the reference to smelters is to a traditional definition of a smelter or rather a melting pot.

Photoengraving operations involved the etching of photographs onto zinc plates. Waste from these operations included film scraps, which were discarded for off-site disposal, and the zinc plates, which were melted down and reused. Spent nitric acid from etching operations was diluted with water and discharged to the sanitary sewer pursuant to a permit issued by Passaic Valley Sewerage Commission (PVSC). Available references did not include a copy of this permit. Photodeveloping solutions were diluted and discharged in the same manner (PAP-00000639).

Platemaking involved an assembly process of the typesetting operations discussed above. Once the page of type was assembled, it was pressed by a device called a "mat roller" onto a sheet of damp, soft cardboard. The cardboard, once pressed with the words and pictures for a particular page, were dried in a special dryer. Dried mats were sent to the stereotyping department where they were set in a casting machine. Molten lead alloy flowed against the mat creating a metal copy of it; plates were then cooled with water. After the newspaper was printed, the lead plates were melted down and reused. Small quantities of impurities generated during the melting process were sent offsite for disposal. Cardboard mats were discarded off-site and wastewater from the cooling process was discharged to the sanitary sewer via a permit with PVSC. Available references did not include sampling data for this wastewater discharge (PAP-00000639-40).

Waste ink and waste solvent used to clean the presses were combined and collected in drums. Minute amounts of lubricating oils were also drummed. All drums were stored in a designated room awaiting proper disposal. Waste inks and solvents were picked up by the suppliers and transported to facilities chosen by the supplier. Used lubricating oils were sent to a recycling facility (PAP-00000640; PAS-00077009).

1972 - 1992 Printing Operations

Printing operations during this time were done by keyboarding the letters onto photon tape, the tape was then fed into a reader that printed in a form suitable for transfer to a dummy page. Photographs were taken with special cameras and converted to dots; this was called "velox". The velox was pasted onto the dummy page with the type and the entire page was then photographed (PAP-00000641).

Beginning in 1979 all liquid photographic wastes were run through a silver recovery unit. All silver recovered from the unit was sold to a private vendor. The remaining waste was diluted with water and discharged to the sanitary sewer via a permit with PVSC. The negative of the dummy page was applied to a plate made of photopolymer plastic; the plate was then subjected to ultraviolet light and rinsed with water. The wastewater was discharged to the PVSC via NML's permit. Waste negatives were sold for scrap (PAP-00000640).

According to a letter dated February 23, 1990, NML generated two types of "waste process materials" including: 1) waste ink (non-hazardous) and 2) waste petroleum naptha (waste solvents). Approximately 60-70 55-gallon drums of waste ink (non-hazardous were produced per month. NML purchased approximately 508 55-gallon drums of ink per month. The ink was used to print the newspaper. The drums of waste ink were stored in a separate designated and contained area in the building basement. The empty ink drums were sent back to the manufacturer, not manifested. Waste petroleum naptha (waste solvents) was sent out to a sales/service company. All solvents were stored in a solvent safety room in the building (PAS-00077448).

The majority of chemicals/hazardous materials were stored/used in the basement area Mezzanine, and second floor of the site. Those areas included the Reel Room/Press Room, Maintenance Shop/Department, Lift Area, Machine Shop, Forklift Area, and Press Deck (PAP-00000644). Black ink containing PAHs was stored in aboveground storage tanks (ASTs) in the Tank Room of the basement area.

1992 - October 2014

Platemaking, printing, and mailroom processes at the site ceased in August 1992. Versions of typesetting and photoengraving were now paginated on computers. Occasionally hand-pasted dummy pages were produced (PAP-00000640).

In 1996, NML installed a unit that recycled the small quantity of photochemicals, which were used until operations ceased at the site. The photochemicals were recycled through the unit multiple times before they were diluted, filtered and slowly discharged to the sanitary sewer (PAP-00000640). Available references did not report the composition of the photochemicals and whether they contained any of the COCs. NML's PVSC permit was terminated in November 1993 since the newspaper was not being printed at the site. Domestic waste was still discharged to the sanitary sewer (PAP-00000640).

4. Identified COCs

- PAHs (use, detected)
- Copper (detected)
- Lead (use, storage)
- Mercury (detected)

PAHs

According to Community Right-to-Know surveys ranging from 1988 through 1992, hazardous materials included small amounts of napthalene (PAP-00000645).

A Statement Regarding the Presence of PAHs in Carbon Black by the International Carbon Black Association reported trace levels of PAHs are associated with carbon black in ink (PAP-000264260). Carbon black is a component of the black newsprint ink used by NML (PAP-00000642).

According to the CID for Newark Star Ledger, the two 5,000-gallon aboveground ink tanks formerly located in the Ink Tank Room located in the basement of the site were removed during cessation of operations in 1992. Two soil borings were advanced through the concrete in the former Ink Tank Room. No exceedances of the most stringent SRS were detected in either sample. Specific contaminant concentration data results for this area were not included in the available references. No further investigation was warranted for this AOC (PAP-00000513).

There were two minor fires in the Newark site's pressroom. During both occasions, the automatic sprinkler system was activated. The water discharged by the sprinkler system was released to the floor drains, which discharge to the sanitary sewer (PAS-00077014, PAS-00077545).

Metals – Copper, Lead and Mercury

Based on a document entitled "*Executive Summary"*, prepared by Occidental or its consultants, dated July 13, 1995, hazardous substances stored, used or produced at the site included copper, lead and mercury of which documented discharges via CSO to the river included copper 0.133 milligrams per liter (mg/L), lead 0.061 mg/L and mercury 0.003 mg/L (PAP-00212775). According to the *PVSC - Heavy Metal Source Determination Phase II Industrial Contribution after Pretreatment Sub Area 0*, drafted in 1978, the concentrations and sampling results were sometime between 1976-1978.

According to a Response to *Request for Information Letter*, dated March 6, 1997, from 1966 to 1972 NML used a lead, tin, and antimony alloy for typesetting; however, it produced no waste. The lines of type were melted down on site and the alloy was reused (PAS-00077008). Note samples of effluent discharged to PVSC and collected in 1972 contained less than 0.030 milligrams per kilogram (mg/kg) of lead and in 1975 lead concentrations were not detected (PAP-00212784, 89). Note the available documents do not specify where the samples were collected or the discharge flow rate.

Historic Fill

The Allocation Team has determined that the facility site is located on regional Historic Fill as designated by the NJDEP.[1]

NJDEP has established that Historic Fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 COCs: PAHs, lead, copper, and mercury.[2] Accordingly, NJDEP technical requirements for property containing Historic Fill requires sampling for the EPA Target Compound List for PAHs and Target Analyte List for metals, including lead, copper, mercury, and the OU2 PAH COCs.[3] PAHs, lead, copper, and mercury are recognized by NJDEP to be constituents of Historic Fill at varying levels, not atypically at or exceeding residential soil standards.[4]

The levels of PAHs, copper, lead and mercury detected at the site in soils are presented in the table below (PAP-00000558; PAP-00212775).

---

[1] *Digital Geodata Series, DGS04-7, Historic Fill for New Jersey*, https://www.nj.gov/dep/njgs/geodata/dgs04-7.htm, Quadrangle #52 & #53 (NJDEP map identifying locations of recognized historic fill).

[2] *Characterization of Ambient Levels of Selected Metals and cPAHs In New Jersey Soils* (2002) and *Characterization of Ambient Levels of Selected Metals and Other Analytes In New Jersey Soils* (1997), studies prepared for NJDEP, Division of Science and Research, by BEM Systems, Inc.

[3] New Jersey Department of Environmental Protection (NJDEP), *N.J.A.C. 7:26E Technical Requirements for Site Remediation,* Table 4-2, November 2009 [Note that Table 4-2 has been deleted from the current version of N.J.A.C. 7:26E (May 7, 2012) and the updated *Historic Fill Technical Guidance* (April 2013) as NJDEP believed that the tables list of historic fill constituents was too restrictive].

[4] NJDEP Table 4-2 (PAHS and lead) and a summary of NJDEP records regarding investigations of properties in the vicinity of the Passaic River recognized to be located in areas of Historic Fill indicate that the following average/maximum (mg/kg) contamination levels of OU2 COCs exist in area Historic Fill: PAHs (1.91/160), lead (574/10,000), copper (11.2/1,200), and mercury (0.21/3.7).

COCs Found in Onsite Soils	
COC	**Max Detected Concentration**
Lead	240 mg/kg
Mercury	0.99 mg/kg
Benzo(a)anthracene	49 mg/kg
Benzo(a)pyrene	39 mg/kg
Benzo(b)fluoranthene	44 mg/kg
Benzo(k)fluoranthene	24 mg/kg
Dibenzo(a,h)anthracene	5.8 mg/kg
Indeno(1,2,3-cd)pyrene	24 mg/kg

Based on the undated *Initial Receptor Evaluation Narrative*, soil results obtained from site investigation activities, the following compounds were in exceedance of the most stringent Soil Remediation Standards (SRS) benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, chrysene, dibenzo(a,h)anthracene, indeno(1,2,3-cd)pyrene, napthalene, lead, and mercury. Since the compounds were found across the site, they were attributable to Historic Fill (PAP-00000549). The chart below details the concentrations.

Contaminant	Concentration (mg/kg)	Depth (feet)
Naphthalene	14	5-5.5
Chrysene	64	4.5-5
Benzo(a)anthracene	49	4.5-5
Benzo(b)fluoranthene	44	4.5-5
Benzo(k)fluoranthene	24	4.5-5
Dibenzo(a,h)anthracene	5.8	4.5-5
Indeno(1,2,3-cd)pyrene	24	4.5-5
Beryllium	0.8	4.5-5
Lead	240	4.5-5
Mercury	0.99	4.5-5

(PAP-00000558)

According to a *Response Action Outcome Form*, dated June 23, 2015, groundwater sampling has not been conducted at this site, but based on the observed presence of Historic Fill, it was concluded that contamination related to regional Historic Fill may be present in the groundwater underlying the site (PAP-00004510). NML was issued a soil remedial action permit No. RAP150001, effective on June 1, 2015 for the entire site and a Classification Exception Area (CEA) VIC15001 was established as of May 28, 2015 (PAP-00004512).

According to the Deed Notice, dated December 10, 2014 (Deed Notice), Historic Fill materials were present at the site on Block 104, Lot 21 and Block 105, Lot 6. At Block 104, Lot 21, Historic Fill materials were observed to extend to a maximum depth of approximately 12.5 feet below ground surface (bgs). Historic Fill materials on Block 105,

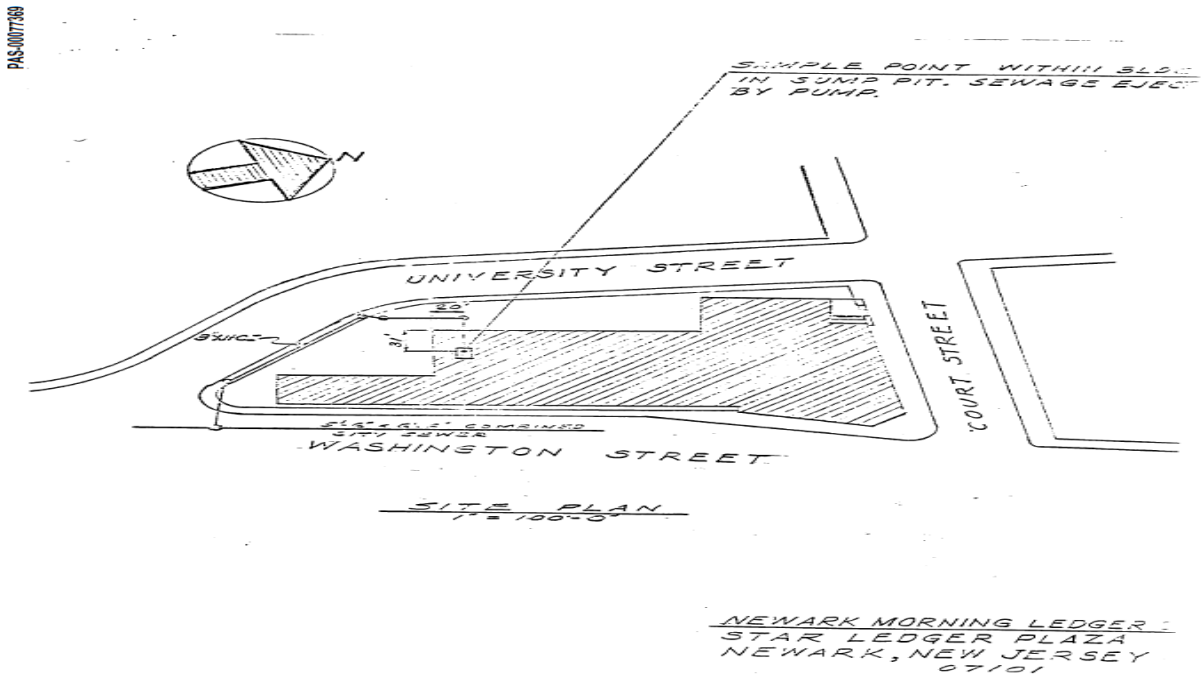
Lot 6 were found to terminate at a depth of approximately 5 feet bgs. Fill materials were comprised predominantly of cinders, ash, concrete, and "cave-in" asphalt. COCs comprised metals, PAHs, and naphthalene. Fill material were identified in each of the seven advanced soil borings taken on Block 105, Lot 6 (PAP-00004500; PAP-00000565-72).

5. COC Pathways

Direct Release

According to a 1976 *Overflow Analysis of Passaic River Overflows,* the overflow chamber for the City Dock CSO district is "on the east side of intersection of Raymond Blvd. and Raymond Plaza East." The district is served by one 108" x 90" rectangular concrete sewer outfall to the Passaic River. Under normal dry weather flow conditions, the flow is diverted to the PVSC interceptor via the regulator. During periods of rainfall, a portion of the combined flow enters the interceptor, with the balance overflowing the stop logs and being discharged through the outfall line into the Passaic River (PAS-00032870).

Storm Sewer



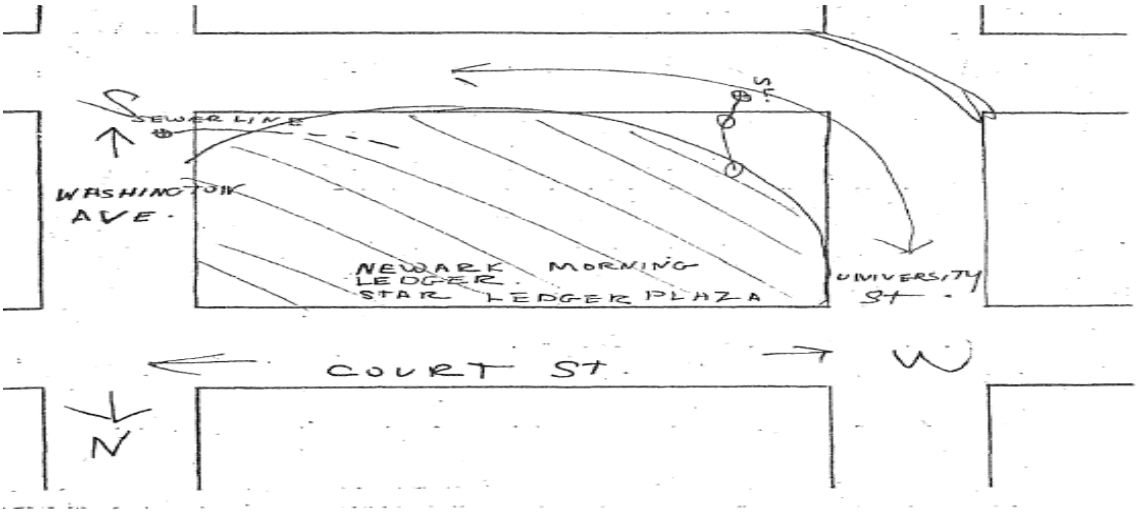
According to a Response to *Request for Information Letter*, dated March 6, 1997, there are storm sewers on site, which receive storm runoff from external areas of the site, such as parking lots. It is believed the storm sewers were first installed between 1965 and 1966 when the building was constructed at the site. Some storm sewers may have been installed after that date (PAS-00077013). Discharges to the storm sewer were directed to the PVSC sewers in University Avenue. The 2015 Report reported that inks were delivered to the site via tanker truck and were unloaded at the Ink Fill Port located adjacent to the southwestern corner of the site. In addition, a storm sewer grate was observed at the end of the Loading & Unloading/Ink Fill Port area (PAP-00000644).

According to 2015 Report interviews, pits existed beneath the Reel/Press Room, which was located in the basement area of the site and operated until 1992. The pits contained drains, which were connected to the sanitary sewer and were blocked in the early 1980s. The Reel/Press Room pits were blocked and cemented over in the early 1990's. During the 2015 Report site inspections, multiple floor drains were observed within the former Paper storage area, Mechanical Room, in the basement, and throughout the upper floors of the site (PAP-00000646).

In addition, newspaper printing operations from 1966 through 1972 included hot type setting which involved the use of lead smelters to melt down used lead plates and create new lead plates for printing (PAP-00000646). According to the Case Inventory Document (CID) for Newark Star Ledger, lead dust from the smelters would have vented to the roof and been discharged by the roof leaders to the storm water drains surrounding the subject property (PAP-00000515). Based on the 2015 Report, storm water during the time of hot type setting printing operations (1966-1972) was connected and managed by the PVSC (PAP-00000646). Based on the available file material, it is

unclear if the reference to smelters is to a traditional definition of a smelter or rather a melting pot.

A storm water grate was observed at the southern end of the Loading/Unloading Area. Approximately five single storm water sewers were observed adjacent to the sidewalks within the roadway of Washington Street, University Avenue, and Court Street. No staining and/or evidence of a release were observed during the 2015 Report site inspection (PAP-00000647).



(PAS-00077369)

Sanitary Sewer

There had been two minor fires in the Newark site's pressroom and during both occasions; the automatic sprinkler system was activated. The water discharged by the sprinkler system was released to the floor drains, which discharge to the sanitary sewer (PAS-00077014, PAS-00077545).

According to the *PVSC - Heavy Metal Source Determination Phase II Industrial Contribution after Pretreatment Sub Area 0*, drafted in 1978 with sampling results from sometime between 1976-1978, NML contributed 0.133 mg/L of copper, 0.061 mg/L of lead, and 0.003 mg/L of mercury to the Passaic River through the combined sewer outfalls (PAP-00212776-77).

(PAP-00212790)

According to a *Waste Effluent Survey*, dated July 18, 1972, NML used 26,506,876 gallons of water from the City of Newark, New Jersey in 1971 (PAP-00212780). According to a *Report of Water and Wastewater Analysis*, dated April 16, 1975, copper sampled in a 24 hour composite sample equaled 0.20 mg/l (PAP-00212789). NML's applications for sewer connection permits documented the following water usage:

Reporting Year	Sanitary Water (gallons)	Process Water (gallons)	Cooling Make-up Water (gallons)	Total Water Use (gallons)
1972	13,253,438	11,928,094	1,325,344	26,506,876
1978	9,195,912	8,276,321	919,591	18,391,824
1986	17,222,814	12,500,000	4,128,300	33,851,114
1990	16,858,690	15,172,821	1,685,869	33,717,380
1991	10,273870	9,246,483	1,027,387	20,547,740

(PAS-00077049-109; PAS-00077311-475)

6. Regulatory History/Enforcement Actions

A NJDEP Site Remediation Program Remedial Action Protectiveness/Biennial Certification Form - Soil states a Deed Notice was filed on December 22, 2014 (PAP-00004521).

According to a Soil Remedial Action Permit for Historic Fill letter from NJDEP, dated May 28, 2015, NML received a Soil Remedial Action Permit No. RAP15001 (Deed Notice with engineering control for Historic Fill) which became effective on June 1, 2015 for Block 104, Lot 21 and Block 105, Lot 6 and required monitoring, maintenance, and evaluation for compliance and effectiveness of the remedial action and its associated institutional and engineering controls (PAP-00004474-77, 83)

Inspections

There is no information regarding inspections in the available file material.

Violations

There is no information regarding violations in the available file material.

Permits

According to the PVSC Application for a Sewer Connection Permit, NML held NJPDES Industrial Waste Permit No. 991304296. Sewer water was received by an unknown body of water (PAS-00077365) and was intermittently occurring between the hours of 6pm and 6am averaging 90,000 gallons daily (PAS-00077367, 403). Pretreatments included silver filtration systems and a wet scrubber for dust on press (PAS-00077368). Note flow rates, discharge monitoring and concentrations were not provided in the application.

NML held wastewater discharge permit number 20402590 between September 22, 1981 and September 15, 1996 (PAS-00077328, 340-41; PAP-00000406, 421) and discharged from outlet(s) number(ed) 20402590-42500-0201 located in the basement on the University Street side) (PAP-00000480). Storm sewer grates were observed in this area and discharges of storm sewer water were directed to the Passaic Valley sewers (PAP-00000644). Note flow rates, discharge monitoring and concentrations were not provided in the permit.

On November 8, 1993, permit 20402590 was terminated and NML was no longer required to submit monitoring data to PVSC since only domestic waste would be discharged from this site (PAS-0077407).

NML was issued identification number NJD991304296 in connection with its manifesting small quantities of Resource Conservation and Recovery Act (RCRA) waste (PAS-00077005). According to a 1988 Annual Generators Report this site generated greater than 10 tons of hazardous waste, but less than 100 tons during the calendar year (PAS-00077072).

7. Response Actions

Characterization Activities

The following characterization activities have taken place at the facility:

- A Preliminary Assessment (PA) / Site Investigation (SI) / Remedial Investigation (RI) / Remedial Action Report “2015 Report” was completed on February 9, 2015 (PAP-00000628-660 (written report) to 4473 with attachments).

Soil

As reported to the NJDEP *Site Remediation Program Preliminary Assessment/Site Investigation*, soil analytical results were greater than the most stringent Direct Contact Soil Remediation Standards as well as the Ground Water Soil Screening Levels (IGWSSL) for PAHs, metals, and mercury in AOC 1 (Underground Storage Tank), AOC 3 (Loading and Unloading Areas/Ink Fill Port), and AOC 12 (Historic Operations) (PAP-00000520, 649-50, 651-652).

AOC 1 - Underground Storage Tank (Abandoned)

According to the 2015 Report, samples were collected from the tank invert, which was extrapolated to be from 12-12.5 feet bgs. Samples were analyzed for Extractable Petroleum Hydrocarbons (EPH) Category II (CATII) with contingent PAH analysis on 25% of the results where EPH was detected a concentrations greater than 100 mg/kg (PAP-00000648).

Soil samples SB-3, SB-4, and SB-5 exhibited EPH concentrations above 100 mg/kg (172, 266, and 401 mg/kg, respectively). Therefore, soil borings SB-4 and SB-5 were analyzed for PAHs. Both samples exhibited concentrations exceeding the NJDEP Direct Contact SRS and default IGWSSLs for multiple PAHs including benzo(a)anthracene (5.9 mg/kg). benzo(a)pyrene (5.7 mg/kg), benzo(b)fluoranthene (7.5 mg/kg), dibenzo(a,h)anthracene (0.99mg/kg) and indeno(1,2,3-cd)pyrene (3.0 mg/kg) (PAP-00000648; PAP-00000663).

Based on the constituents identified, the concentrations of PAHs were assumed to be associated with Historic Fill at the site and not a release from the UST. PAHs detected in samples associated with AOC 1 were therefore addressed through a deed notice and engineering controls (PAP-00000648).

AOC 3 - Loading and Unloading Areas/Ink Fill Port

According to the 2015 Report, soil samples collected at AOC 3 (Loading and Unloading Areas/Ink Fill Port) exceeded the default IGWSSL for mercury at 0.24mg/kg, 0.84 mg/kg, and 0.16 mg/kg, respectively in soil samples SB-9, SB-10(4.0-4.5 ft. bgs) and SB-10 (9.5-10 ft. bgs) (PAP-00000649).

PAHs were detected in SB-9 in excess of the NJDEP Direct Contact SRS and default IGWSSLs. The PAHs detected were indicative of Historic Fill and not a release from the loading and unloading areas. Therefore, the PAHs were addressed through a deed notice and engineering controls (PAP-00000649).

AOC 12 - Historic Operations

Building Parcel

According to the 2015 Report, two soil borings SB-6 and SB-7 were advanced to investigate historical operations conducted at the site prior to the construction of the NML building (PAP-00000651).

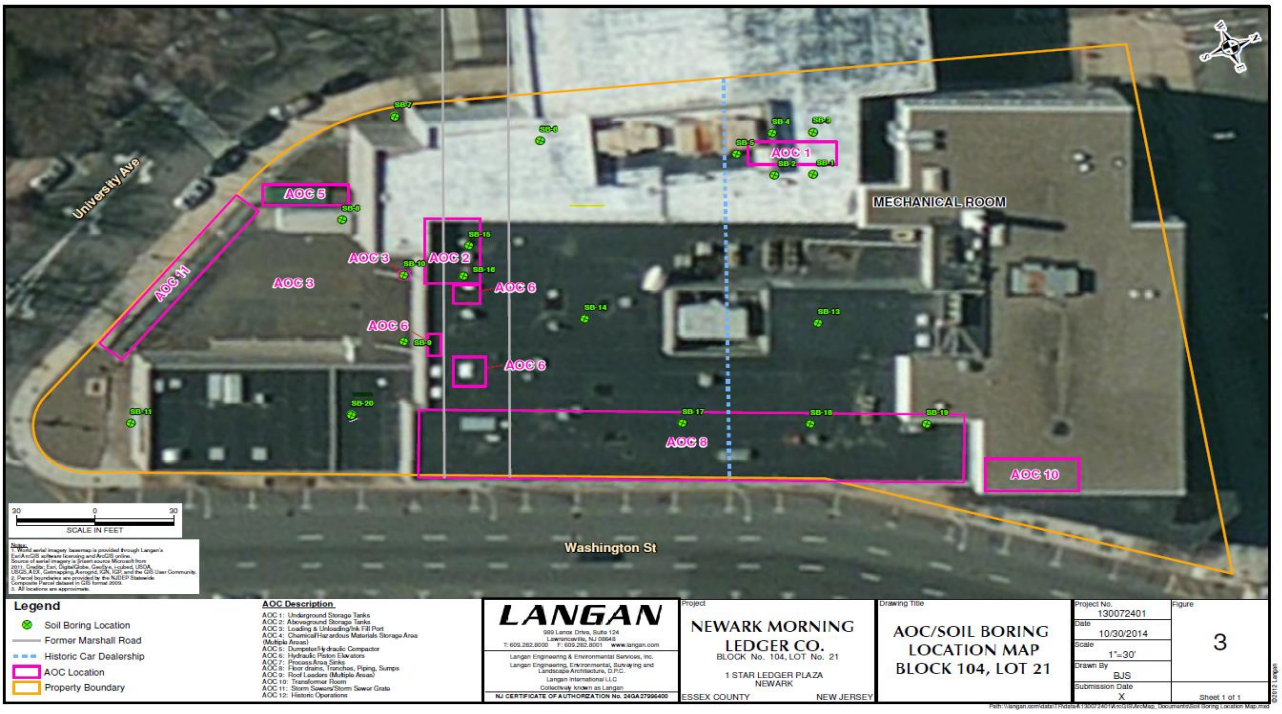
Analytical results exhibited exceedances of multiple SVOCs and metals, including: napthalene (14 mg/kg) and chrysene (64 mg/kg) exceeded Residential Direct Contact SRS (RDCSRS) and IGWSSL and benzo(a)anthracene (49 mg/kg), benzo(a)pyrene (39 mg/kg), benzo(b)fluoranthene (44 mg/kg), benzo(k)fluoranthene (24 mg/kg), dibenzo(a,h)anthracene (5.8 mg/kg), and indeno(1,2.3-cd)pyrene (24 mg/kg) exceeded NRDCSRS, RDCSRS, and IGWSSL. Several metals including lead (240 mg/kg) and mercury (0.99 mg/kg) were detected in exceedance of their respective default IGWSSLs (PAP-00000651, 664-66).

- Mercury was detected at a concentration of 0.99 mg/kg in SB-6. The NJDEP's default IGWSSLs for mercury is 0.1 mg/kg. The concentration of mercury detected was consistent with NJDEP background studies for urban areas within the state. Therefore, the concentration of mercury detected in SB-6 was attributable to natural background concentrations (PAP-00000651).

- Lead was detected at concentrations in exceedance of its respective IGWSSL of 90 mg/kg in soil sample SB-6. However, analytical data collected from a deeper soil sample collected from soil boring SB-6 demonstrated that the concentration of lead extinguishes to levels below the default IGWSSL at depths greater than two feet above the groundwater table (PAP-00000651).

- SB-7 exhibited exceedances of multiple PAHs including: naphthalene (exceeded RDCSRS), benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, dibenzo(a,h)anthracene [exceeded Non-Residential Direct Contact Soil Remediation Standards (NRDCSRS), RDCSRS, and IGWSSL] and indeno(1.2,3-cd)pyrene (exceeded RDCSRS) (PAP-00000651).

Parking Lot Parcel



According to the 2015 Report, seven soil borings were advanced on August 4, 2014 to investigate surficial anomalies identified during the geophysical survey (PAP-00000652).

- A soil sample (1.5-2.0 feet bgs) analyzed for metals and exceedances included lead and mercury above their respective IGWSSLs (PAP-00000652).

- A soil sample (3.5-4.0 feet bgs) exhibited exceedances of multiple PAHs and metals. PAH exceedances included: benzo(a)anthracene (exceeded RDCSRS

and IGWSSL), benzo(a)pyrene (exceeded RDCSRS, NRDCSRS, and IGWSSL), and indeno(1,2,3 cd)pyrene (exceeded IGWSSL). Several metals including lead and mercury were also detected in exceedance of their respective IGWSSLs (PAP-00000652).

SVOCs and metal exceedances were assumed to be associated with Historic Fill at the site and were addressed through a Deed Notice and engineering controls (PAP-00000652).

(PAP-00000678)

Remedial Activities

As reported by the 2015 Report, the following remedial activities were implemented:

- A Deed Notice was filed restricting the use of the site to nonresidential uses. The Deed Notice boundary included the entirety of the property boundary (Building Parcel and the Parking Lot Parcel) as identified by the metes and bounds for the site

- The existing NML building footprint, the asphalt paving, the building, and the existing parking lot serve as the contaminant cap (engineering control) restricting direct contact with the subsurface soils and have to remain in place.

- A Remedial Action Permit for Soils was submitted for NJDEP approval. The permit requires maintenance of the cap and biennial inspection and certification of the cap

to demonstrate that the cap is competent and protective of public health, safety, and the environment.

- A groundwater CEA/WRA associated with Historic Fill was established. The CEA/WRA included the entirety of the property boundary (including the Building Parcel and the Parking Lot Parcel) (PAP-00000634).

8. Summary of Asserted Defenses

No legal defenses were identified in the available file materials.

Diamond Alkali OU2 Allocation

ADR Confidential

Facility Data Report

NOKIA-LUCENT TECHNOLOGIES INC.

Facility Name, Address and Size: Lucent Technologies Inc., 100 Central Avenue, Kearny, New Jersey. The property is 147 acres on the South Kearny peninsula. The facility is located on the Town of Kearny Block 288, Lots 7, 9, 10.01 and 10.02 (PAP-00367653, 663). In 1978, the facility had 6,350 employees (PAS-00080317), while in 1984, the facility had 4,000 employees (PAS-00080504). Available references did not state the number of shifts at the facility.

1. **Business Type:** Manufacturing and assembly of electro-mechanical devices required to interconnect the national telephone network (PAS-00080505).

2. **Time Period of Ownership/Operations**

   Operator: Western Electric Company Kearny Works (1925 to 1984)
   Owner: Western Electric Company Kearny Works (1925 to 1984)

   Nokia-Lucent Technologies Inc. (Lucent) operated and owned the facility as Western Electric Company Kearny Works (Kearny Works) from 1925 to 1984, according to the February 28, 1997 response to an EPA Request for Information (PAS-00080504). The Western Electric Company, Inc. had purchased the property in 1925 and sold it to the Union Minerals and Alloys Corporation in May 1984 (PAS-00080509). In addition, on January 27, 1983, the Western Electric Company announced plans to close the Kearny Works manufacturing facility in stages over several years (PAS-00080463). Western Electric Company, Inc. changed their name to AT&T Technologies, Inc. on January 3, 1984 (PAS-00080509). On December 29, 1989, the company merged into American Telephone and Telegraph Company, which changed its name to AT&T Corp. on April 20, 1994 (PAS-00080510).

   According to Lucent's February 28, 1997, response to an EPA information request, Lucent Technologies Services Company was a subsidiary of AT&T Corp. that was transferred to Lucent Technologies Inc. on February 1, 1996 (PAS-00080510). According to the *Supplemental Preliminary Assessment/Site Investigation/Remedial Investigation Report* (PA/SI/RI Report), dated May 2016, Lucent merged with Alcatel SA of France in 2006, forming Alcatel-Lucent (PAP-00367663). In January 2016, Alcatel-Lucent USA Inc. (ALU) became an indirect subsidiary of Nokia Corporation. The PA/SI/RI Report stated that the transaction through which Nokia Corporation would obtain ownership interest in ALU's ultimate parent corporation, Alcatel-Lucent SA, was expected to be finalized sometime in 2016 (PAP-00367653).

   The current owner of the site is RTC Properties. As stated above, Union Minerals and Alloys Corporation purchased the property in 1984. This company is a subsidiary of Neu, Hugo Corp., which changed its name to River Terminal Development Company ("RTC") in 1988 (PAS-00073217).

3. Operational History/COC Use and Presence at the Facility

Operations

Lucent's 1997 response to an EPA information request stated that the facility manufactured parts (e.g., switchboards and consoles, cables and wire, key equipment, connectors and molding, precious metal plating, sheet metal piece parts, etc.) for electromechanical assembly operations. Operations included plating, cleaning or degreasing, organic coating, and lubrication. The operations generated wastes and used small quantities of containerized chemicals, solvents, coating materials and oils that were stored primarily in workshops and occasionally outdoor storage yards. Auxiliary functions necessary for plant operation, such as a Powerhouse, a Garage, and electrical distribution required fuel tanks and oil containing transformers (PAS-00080505).

According to an Affidavit signed in May 1996 by former employee Mr. Daniel Bartel, the facility manufactured transformers for 25 years. The plant also manufactured copper wire and cables lined with lead and polyethylene (PAS-00080249).

An undated list of the chemicals used in the metal finishing processes at Kearny Works included copper cyanide and lead fluoborate (PAS-00080261).

A 1977 *Spill Control and Countermeasure Plan* for the facility documented the procedures for a welded steel oil storage tank located about 480 feet from the river bulkhead, two feet above grade on a piled concrete foundation, and surrounded by a steel dike. The oil was used to generate steam in the adjacent powerhouse facility. The tank was 60-feet in diameter and 40-feet high and oil was delivered by barge. The plan stated that the tank had been in operation since 1962 and no spills had occurred (PAS-00080375).

Waste Water

Lucent stated in their 1997 response to an EPA information request that waste water was discharged to the municipal sewer from 1925 to 1984 (PAS-00080507). A letter documenting a telephone discussion between Western Electric and the Passaic Valley Sewerage Commissioners (PVSC) on March 8, 1972, stated that all industrial waste water was disposed into the sanitary sewer for treatment at the municipal sewerage treatment plant located in South Kearny on the Hackensack River (PAP-00126611-12).

A 1969 *Report on the Quality of the Interstate Waters of the Lower Passaic River and Upper and Lower Bays of New York Harbor* listed five pipes from Western Electric as discharging directly to the Passaic River in a table titled "Direct Waste Discharges, Passaic River" (PAS-00114005). A 1972 letter documenting a telephone discussion between Western Electric and the PVSC stated the effluent discharged to the Passaic River was from storm drains and the power house cooling water (PAP-00126611-12). According to an *Environmental Information Survey of 1972*, dated June 1, 1973, there were five discharges from the facility containing untreated industrial and sanitary waste to the sanitary sewer, and the additional (sixth) discharge was stated to be to the

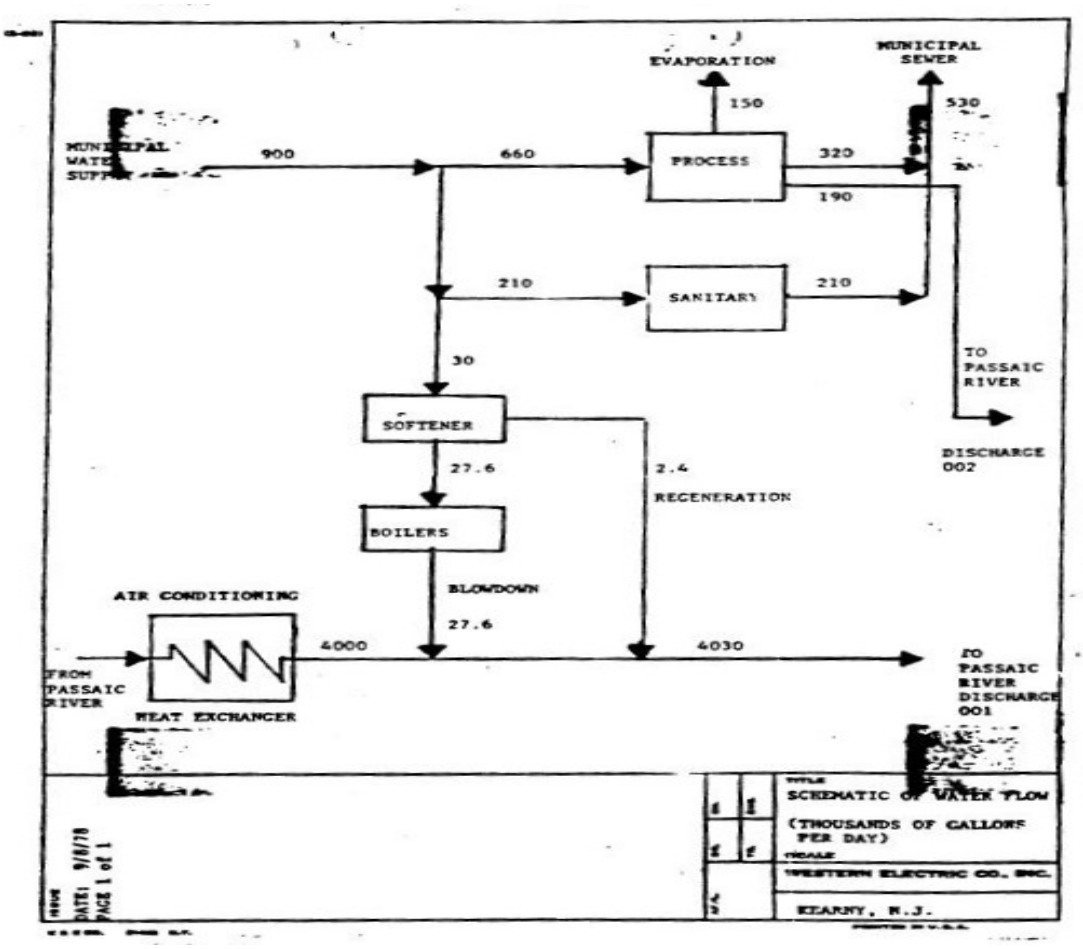
"stream." This discharge consisted of the untreated "once-through" cooling water used for the power house air conditioning. The survey noted that a waste treatment plant was under construction (PAS-00080294).

Once the on-site water treatment plant was built in 1974, the facility submitted an application for a National Pollutant Discharge Elimination System (NPDES) permit to discharge to the Passaic River. The confirmation of this application stated the wastewater was previously discharged to the municipal sewerage system (PAP-00126621). The NPDES permit NJ 002 0443 was issued with an effective date of April 30, 1974 and expired April 30, 1979 (PAP-00127219). The permit set maximum limits for discharge 002 for total and soluble lead (1.05 and 0.05 milligrams/liter [mg/L], respectively), total and soluble copper (1.2 and 0.2 mg/L, respectively), and volume (1.1 "MGD") (PAP-00127223).

Six discharges to the Passaic River were identified in the 1974 NPDES permit: A, B, C, D, 001, and 002 (PAP-00127222-23). A letter from Kearny Works to the EPA, dated January 15, 1976, stated Outfall 002 was from the treatment plant, Outfall 001 was from the plant air-conditioning, and Outfalls A, B, C, and D were storm water lines that went through or under the buildings. The four storm water outfalls carried street and parking lot runoff, as well as roof drainage, building sumps, and emergency city water drains. Tide water was stated to run up the full length of these drains (PAP-00126620).

A NPDES permit renewal application for Western Electric Company, dated September 15, 1978, details four of the outfalls from the facility. The outfalls appear to be the same as the outfalls identified above, but the lettered outfalls were numbered instead (PAS-00073224-28).

- Outfall 001 was from the power house and has been used since September 1966. Water was taken from the lower Passaic River and used during the summer months (when the outside temperature is greater than 60 degrees F) to cool the heat exchanges of the air conditioning system prior to discharge back to the river through this outfall (approximately 4,000,000 gallons/day for three months of the year). Municipal water was used for the continuous boiler blowdown (30,000 gallons/day), yearly chemical free cleaning and blowdown of four boilers (100,000 gallons/boiler), and regeneration of water softeners, and then discharged through this outfall (PAS-00073229-31).

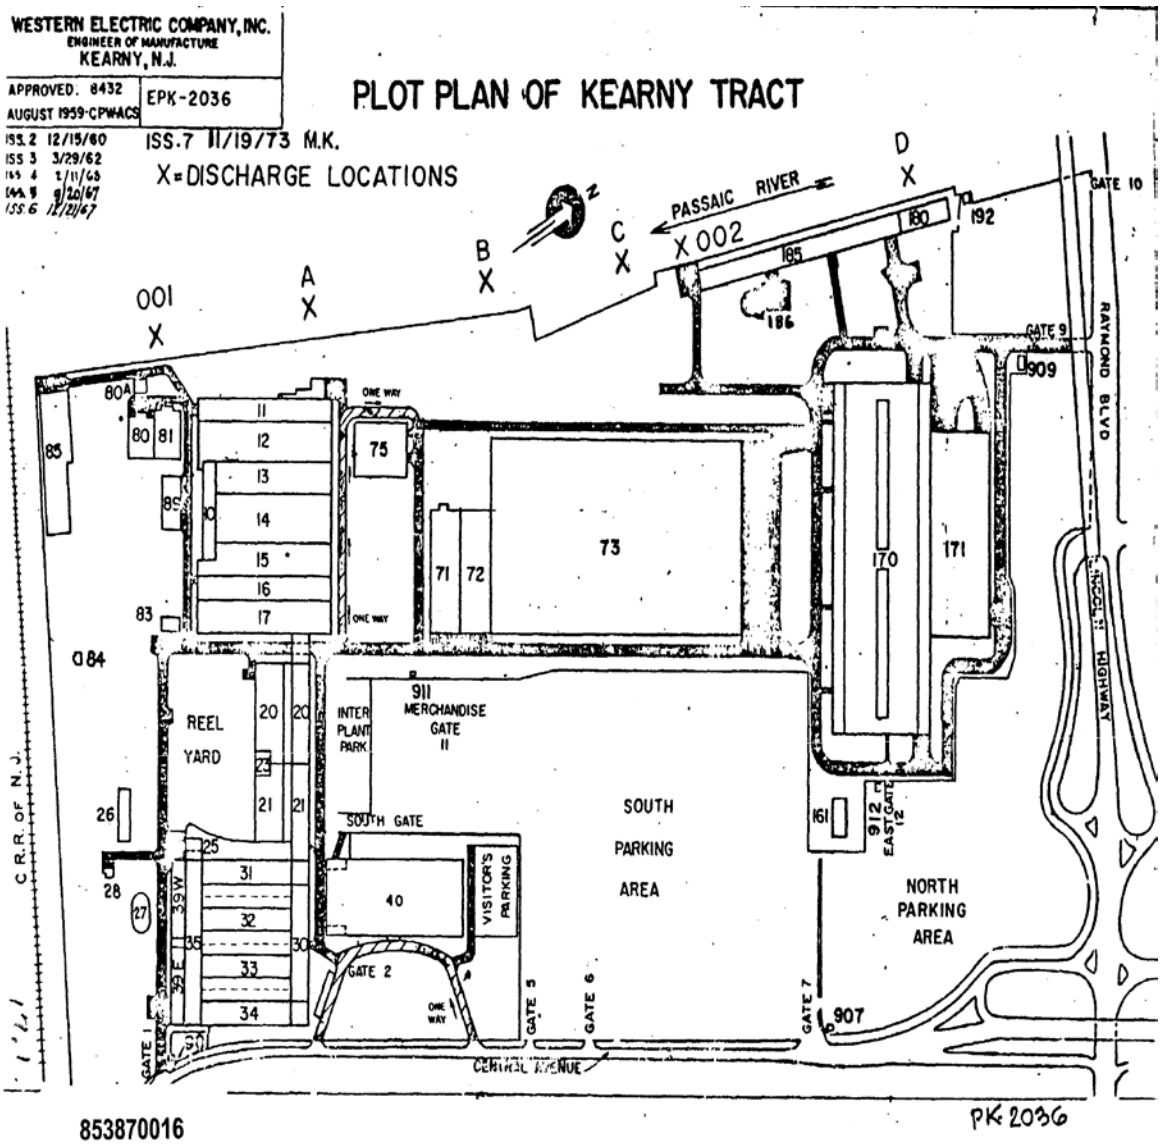


- Outfall 004 was continuous surface water from streets, parking lot, and roof drains. It was identified as the "Mdse. Bldg. South Outfall" and noted to have begun in 1925 (PAS-00073239-41).

- Outfall 005 was continuous surface water from streets, parking lot, and roof drains. It was identified as the "Mdse. Bldg. North Outfall" and noted to have begun in 1925 (PAS-00073248-50).

- Outfall 006 was continuous surface water from streets, parking lot, and roof drains. In addition, some cooling water, drinking fountain water, steam condensate, fire mains, and miscellaneous sources of small volumes of clean

water were discharged through this outfall. It was identified as the “170-171 Bldgs. Outfall” and noted to have begun in 1925. The previous serial number was 000D (PAS-00073257-59).



The following diagram of the water flow at the facility in 1978 was included in the NPDES application. It showed 190,000 gallons per day were discharged to the Passaic River through Outfall 002, and 4,030,000 gallons per day were discharged to the Passaic River through Outfall 001:

(PAS-00073226)

An Affidavit from former employee Mr. Bartel discusses the six outfalls; four from storm sewers, one from the waste water treatment plant, and one from the power plant condenser. The storm sewers were stated to be connected to two drains located within the drum storage area at the southern end of the facility. The Affidavit stated that the waste water treatment plant discharged treated water to the Passaic River, and prior to the construction of the waste water treatment plant in 1973, treated process water was discharged to the Passaic River through storm sewers. The treatment procedures for this waste water were unknown to the employee (PAS-00080249-50).

Diagram PK-2036 was provided with the 1997 response to an EPA information request and shows the approximate locations of the six outfalls to the Passaic River, which are the "x" locations on the figure below:

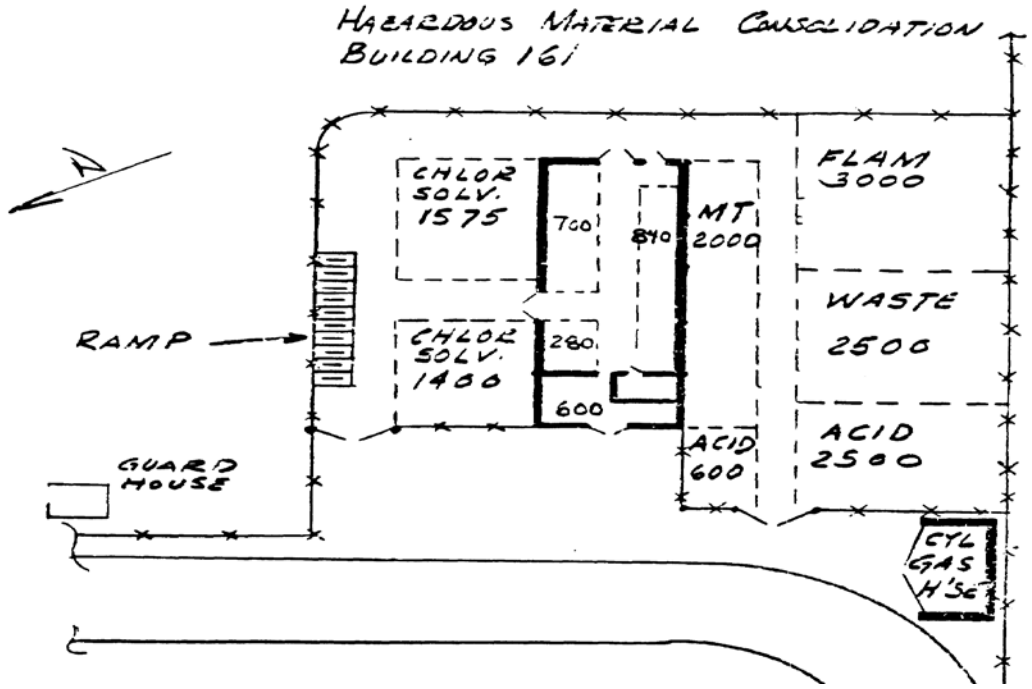
853870016
(PAS-00080516)

An undated list of chemicals regularly drained to the city sewers included paint spray booth flocculent, dyes, soap, emulphor (emulsifying agent), wire drawing compound, copper sludge, oil, phosphates, acids, and photographic chemical developers. The list stated it was exclusive of those chemicals intended for the waste treatment plant (PAP-00126613). An undated diagram of the copper plating process showed that rinse water was discharged to a waste treatment pit (PAP-00126618), but it is not clear where the pit was located at the facility and if it was part of the waste water treatment plant.

According to a memorandum dated April 25, 1977, circuit board cleaner CU-3 and Oakite 90 solution could be disposed into the sanitary sewer sump without treatment (PAP-00126619). In addition, two memoranda dated January 29, and February 2, 1979, state that spent diluted silk screen chemicals were disposed to the sanitary sewer at a rate of ten gallons per week in 1979 (PAP-00126615-16). The documents do not include information for if these discharges contained OU2 COCs.

Hazardous Waste

According to the 1997 response to an EPA information request, the facility was an authorized hazardous waste generator and storage facility under EPA ID No. N.J.D. 002139053 (PAS-00080504). In addition, waste materials were accumulated in an authorized waste yard prior to disposal in accordance with the Resource Conservation and Recovery Act (RCRA). Prior to the issue of RCRA regulations, the facility followed the various company instructions for storage, transfer, use, and disposal of hazardous substances (PAS-00080505-6). A 1961 Hazards-Toxic, Corrosive, and Flammable Materials instruction defined the hazardous materials and handling requirements used to minimize hazards at the plant (PAS-00080278). However, only the first two pages of this plan were available in the file material.

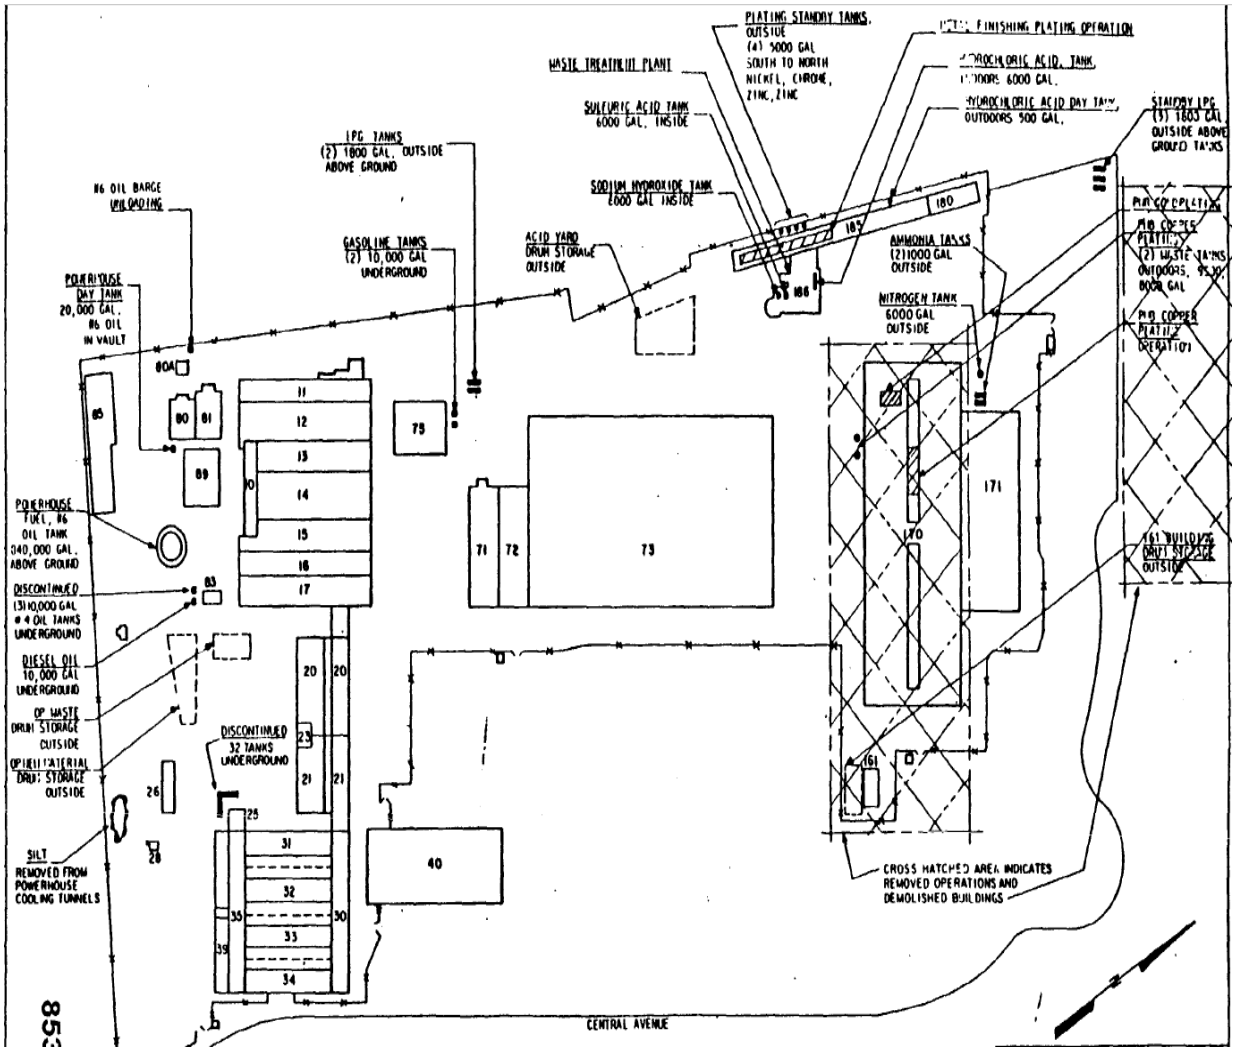


Correspondences from September 1976 discussed the disposal of copper protecting wastes. A Copper Cleaner solution was stated to be a hazardous waste disposed in drums to be shipped off-site. Another flammable chemical solution Redox was stated to contain mostly Stoddard solvent to be disposed as a hazardous waste (PAS-00080295-96).

A letter to a Mr. J.R. Mandel, dated December 7, 1979, described the hazardous material storage areas located outside in the Acid Yard south of 185 Building and the “O.P. yard” south of Building 20. Subdivisions in the Acid Yard included the metal finishing area to the north, an empty drum area, and a “PWB” (acronym was not defined) area to the south. The O.P. Yard included a waste area to the north and a new material area to the south (PAS-00080313).

A memorandum dated November 12, 1979, stated that partially filled drums of hazardous waste had been consolidated at the O.P. yard, but the practice of tipping the drums to pour out the waste was hazardous and would be discontinued in accordance with New Jersey’s new spill law (PAS-00080312).

According to hazardous waste survey forms from 1980, in addition to the solvent wastes, the facility produced 3,850 gallons of caustic waste, 2,350 gallons of acid wastes, and 3,700 gallons of solid waste per year (PAS-00080339-44).



Building 161 appears to have been a consolidation point for hazardous material:

(PAS-00080315)

Miscellaneous

An inventory of the facility's storage locations was provided on a grid-based facility map. The list included various oil and gasoline underground and above ground storage tanks, but no spills or leaking tanks were noted. The list also stated that silt pumped from Powerhouse cooling water tunnels was examined for contaminants, found to be "environmentally innocuous" and deposited at Grid Index J-2. Buildings 170 and 161, shown as the cross hatched rectangles at Grid Index 1-15, were environmentally cleaned and demolished in 1981. Building 170 was the former location of copper plating operations. In addition, dried copper-bearing sludge was present on the basement floor of Building 85, which is located near the Passaic River at the southwestern corner of the site. Finally, it was noted that prior to 1963, a large coal pile was maintained in the area defined by Grid Indices F-H-2-3. The weight of the coal probably produced soil settlement, and there may be a thin layer of coal fines under the current gravel surface (PAS-00080497-99).

(PAS-00080500)

4. Identified COCs

- PCBs (used, released)
- PAHs (detected)
- Dieldrin (detected)
- DDx (detected)
- Mercury (used)
- Copper (used, released)
- Lead (used, released)

Lucent stated in their 1997 response to an EPA information request that PCBs, copper, and lead were used at the facility (PAS-00080504).

PCBs

According to an Affidavit from former employee Mr. Bartel, the facility manufactured transformers for 25 years. Although the exact time period for this manufacturing is not specified, Mr. Bartel worked at the Kearny Works from 1952 to 1985 (PAS-00080249).

No further information for the manufacturing of transformers at the facility was found in the available references.

A Selected Substance Report, dated July 1, 1980, stated PCBs were in fixed transformers and a small stock, but were not used in the production operations (PAS-00080319).

During a 1981 inspection, PCBs were stated to be in the 13 transformers located at the site. The transformers used "pyranol" and "abestol" as the dielectric fluid. Seven transformers were located inside installations and the remaining six were outside. Two of the outdoor transformers were not functional and considered storage tanks. A drum storage area was located inside the basement of Building 32 with a total of 12, 30-gallon drums containing virgin PCB liquid used for transformer make-up (PAS-00080395-96). The transformers used as storage tanks were disposed in 1982, and the drum storage area was moved to the fifth floor of Building 25 to be above the 100-year flood level (PAS-00080456).

A memorandum dated January 8, 1982, stated that all transformers had less than 50 parts per million (ppm) PCBs except four transformers that had 56 to 120 ppm PCBs. Three were located at the wire mill, while the fourth was located at the west end of the row outside “170-S.” The four transformers would be disposed as PCB contaminated (PAS-00080419-20).

As presented in the Amended Environmental Cleanup Plan, dated July 1985, soil samples were collected May 2-10, 1985, and the reported maximum detection of total PCBs (89,000 µg/g – or ppm) was at two to three feet at the Kearny Works site. A maximum total PCBs concentration of 33,000 µg/g was reported for surface soil (PAS-00129816-17).

PAHs

The 2016 PA/SI/RI Report attributed most of the concentrations of PAHs in soil to Historic Fill, but noted that PAHs concentrations in soil near Building 170 were likely due to the demolition of Building 170 (PAP-00367770). Building 170 was identified as the former “assembly” building inherited from Ford Motor Company and demolished in 1981 (PAP-00367664).

Dieldrin and DDx

Pesticides were analyzed in soil samples collected and reported in the 2016 PA/SI/RI Report. Dichlorodiphenyltrichloroethane (DDT), Dichlorodiphenyldichloroethane (DDD), and Dichlorodiphenyldichloroethylene (DDE) were detected in site soil at various locations. Maximum concentrations of each were 1,600 micrograms per kilogram (µg/kg) (DDT), 400 µg/kg (DDD), and, 720 µg/kg (DDE). Dieldrin was detected at one background location at a depth of 2.5 to three feet a concentration of 0.0075 milligrams per kilogram (mg/kg) (PAP-00367769, 887-893).

Metals – Copper, Lead and Mercury

A letter dated October 18, 1977, regarding the transportation of hazardous materials stated that mercury was used in various Kearny products (mercury switches, relays, etc.) (PAS-00080307). In addition, a "residue from printed wiring board land area copper plating" is identified as a hazardous waste generated by the facility in a *Generator Annual Hazardous Waste Report* for 1981 (PAS-00080436).

Characterization of the wastewater treatment plant effluent was documented in a 1981 Wastewater Treatment Plant survey. The average concentrations over the first nine months of 1981 reported total and soluble lead (0.05 mg/L for both) and copper (0.21 and 0.16 mg/L, respectively). The survey noted that there were two instances in 1981 when the NPDES permit levels were not met, but the exceeding parameters and concentrations are not specified. The 9-month averages proceeding the inspection for lead and copper were at or below Permit levels (PAS-00080368-69).

Metals were noted to be present in the waste water generated by the facility, as monitoring of the treatment plant sludge in 1980 through 1982 detected copper and lead at concentrations ranging from 940 to 4,300 mg/kg for copper and 270 to 80,000 mg/kg for lead (PAP-00126742-84). A sample of the sludge filter cake analyzed in 1982 was determined to contain 1.1% copper and 0.44% lead (PAS-00080423). A seven-day composite sample of the sludge filter cake from 1982 detected copper and lead at 2,300 and 2,400 mg/kg, respectively, but the concentrations were based on the wet weight of the sample with 79% moisture (PAS-00080422). According to the Industrial Process Wastewater Sludge Reports from the early 1980s, the sludge was transported to and disposed at the Hackensack Meadowlands Landfill in Kearny, New Jersey (PAP-00126741).

An undated letter stated the waste water treatment sludge produced at the facility from electroplating operations did not have concentrations of contaminants above the RCRA Part 261, Subpart D, "Hazardous Waste from Nonspecific Sources" levels (PAS-00080316). The Selected Substance Report attached to the letter was dated July 1, 1980, and identified contaminants present at the site, including copper and lead, but concentrations were not provided (PAS-00080316-9).

A laboratory report on a sample of "tunnel sludge" collected in 1981 did not have detections of mercury or lead (PAS-00080356).

Historic Fill

The Allocation Team has determined that the facility site is located on regional Historic Fill as designated by the NJDEP[1].

[1] *Digital Geodata Series, DGS04-7, Historic Fill for New Jersey*, https://www.nj.gov/dep/njgs/geodata/dgs04-7.htm, Quadrangle No. 53 (NJDEP map identifying locations of recognized historic fill).

NJDEP has established that historic fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 COCs: PAHs, lead, copper, and mercury[2]. Accordingly, NJDEP technical requirements for property containing Historic Fill requires sampling for the EPA Target Compound List for PAHs and Target Analyte List for metals, including lead, copper, mercury, and the OU2 PAH COCs.[3] PAHs, lead, copper, and mercury are recognized by NJDEP to be constituents of Historic Fill at varying levels, not atypically at or exceeding residential soil standards[4].

The levels of PAHs, copper, lead and mercury detected at the site in soils are presented in the table below (PAP-00367853, 57, 66; PAP-00371976).

COCs Found in Onsite Soils	
COC	**Max Detected Concentration**
Lead	7,650 mg/kg
Copper	12,000 mg/kg
Mercury	20.5 mg/kg
Benzo(a)anthracene	120 mg/kg
Benzo(a)pyrene	120 mg/kg
Benzo(b)fluoranthene	170 mg/kg
Benzo(k)fluoranthene	62 mg/kg
Dibenzo(a,h)anthracene	22 mg/kg
Indeno(1,2,3-cd)pyrene	81 mg/kg

The 2016 PA/SI/RI Report attributed the widespread PAHs and metals contamination detected across the site to Historic Fill. To support this conclusion, the PA/SI/RI Report established a historic fill profile that would be used to evaluate results in operating areas of the site where AOCs are located. In addition, fill material was observed to be present in 210 of 220 soil borings installed (PAP-00367723-24, 31-34). The PA/SI/RI Report also stated: "The average lead concentration is substantially higher in topsoil than in either fill material and likewise provides a strong indicator for DAP [diffuse anthropogenic pollution], as the most likely source for lead in surface soils is historic emissions associated with leaded gasoline, particularly given the vicinity of the Site to Route 1 and 9 bypass (Lincoln Highway), Pulaski Skyway, New Jersey Turnpike and other high-volume, long standing roadways" (PAP-00367737); indicating that elevated lead concentrations are possibly not site-related, but anthropogenic.

[2] *Characterization of Ambient Levels of Selected Metals and cPAHs In New Jersey Soils* (2002) and *Characterization of Ambient Levels of Selected Metals and Other Analytes in New Jersey Soils* (1997), studies prepared for NJDEP, Division of Science and Research, by BEM Systems, Inc.

[3] New Jersey Department of Environmental Protection (NJDEP), *N.J.A.C. 7:26E Technical Requirements for Site Remediation,* Table 4-2, November 2009 [Note that Table 4-2 has been deleted from the current version of N.J.A.C. 7:26E (May 7, 2012) and the updated *Historic Fill Technical Guidance* (April 2013) as NJDEP believed that the tables list of historic fill constituents was too restrictive].

[4] NJDEP Table 4-2 (PAHS and lead) and a summary of NJDEP records regarding investigations of properties in the vicinity of the Passaic River recognized to be located in areas of Historic Fill indicate that the following average/maximum (mg/kg) contamination levels of OU2 COCs exist in area Historic Fill: - PAHs (1.91/160), lead (574/10,000), copper (11.2/1,200), and mercury (0.21/3.7).

Historic Fill at the site was likely disturbed during construction and demolishing of the plant's buildings. In addition, the excavations performed in 1985 likely disturbed the Historic Fill. A Classification Exception Area / Well Restriction Area (CEA/WRA) associated with Historic Fill was established December 18, 2018 (PAP-00373377). The CEA/WRA was identified for PAHs and metals, including lead and mercury (PAP-00373323, 26).

5. COC Pathways

Sanitary Sewer

Lucent stated in their 1997 response to an EPA information request that waste water was discharged to the municipal sewer from 1925 to 1984 (PAS-00080507). A letter documenting a telephone discussion between Western Electric and the Passaic Valley Sewerage Commissioners (PVSC) on March 8, 1972 stated that all industrial waste water was disposed into the sanitary sewer for treatment at the municipal sewerage treatment plant located in South Kearny on the Hackensack River (PAP-00126611).

An *Environmental Information Survey of 1972*, dated June 1, 1973, discussed the water flow at the facility in 1972. The Survey stated that 1,710,000 gallons of city water and 8,000,000 gallons of water from the Passaic River were used at the facility each day. The river water was stated to be used as air-conditioning cooling water. The once-though, untreated cooling water for the power house air conditioning plant was then discharged to the river, while the rest of the plant's wastewater was discharged to the sanitary sewer. The levels of oil and grease in this discharge exceeded the acceptable levels in the Kearny sewer code for 3 of 5 days. In addition, copper was detected at a "significantly high" concentration (not specified), but the Kearny sewer code did not have a standard for this metal. It was noted that copper was from various plating operations that were planned to be transferred to a new centralized plating facility with a water treatment plant (PAS-00080294).

A NPDES permit application for Western Electric Company, dated September 15, 1978, stated 320,000 gallons per day of process water and 210,000 gallons per day of sanitary water were discharged to the municipal sewer (see the diagram associated with this permit application in Section 3 [Operational History/COC Use and Presence at the Facility]) (PAS-00073226).

A Selected Substance Report dated July 1, 1980, documented the water flow at the facility in 1980. The estimated average daily volume of wastewater discharged to the sanitary sewer was 500,000 gallons. The discharge included process water, non-contact cooling water, and domestic sewage (PAS-00080319).

An undated list of chemicals regularly drained to the city sewers included paint spray booth flocculent, dyes, soap, emulphor (emulsifying agent), wire drawing compound, copper sludge, oil, phosphates, acids, and photographic chemical developers. The list stated it is exclusive of those chemicals intended for the waste treatment plant (PAP-00126613).

Storm Sewer

According to a 1996 Affidavit from former employee Mr. Bartel, who worked at the facility as a plumber, waste lines from two buildings were connected to the facility's storm sewer. Mr. Bartel stated that prior to the construction of the waste water treatment plant, treated process water was discharged to the Passaic River through storm sewers. The treatment procedures for this waste water were unknown to Mr. Bartel. In addition, Mr. Bartel noted that there were two drains to the storm sewer from the hazardous waste storage areas at the southern end of the facility (PAS-00080249-50).

Lucent's 1997 response to an EPA information request stated that air conditioning drains, water sumps and water fountain effluent were drained to storm sewer outfalls to the Passaic River. Storm sewers contained runoff oil and grease (PAS-00080507).

Direct Release

According to a 1969 *Report on the Quality of the Interstate Waters of the Lower Passaic River and Upper and Lower Bays of New York Harbor*, Western Electric was listed as having five pipes that discharged directly to the Passaic River (PAS-00114005). A 1972 letter documenting a telephone discussion between Western Electric and the PVSC stated the effluent discharged to the Passaic River was from storm drains and the power house. The effluent was specified to contain the power house cooling water (8 million gallons per day), boiler blowdown (25,000 gallons per day), as well as periodic regenerated water from the water softeners (4,000 gallons) (PAP-00126611-12). This was also stated by an *Environmental Information Survey of 1972,* dated June 1, 1973, which identified 8 million gallons of water from the Passaic River used at the facility each day as air-conditioning cooling water, and that the once-though, untreated cooling water for the power house air conditioning plant was discharged to the river (PAS-00080294).

In 1974, approximately one-third of the waste water flow was diverted to the new on-site industrial waste treatment plant, which discharged treated effluent to the Passaic River under a NPDES permit, according to the 1997 response to an EPA information request. The treatment plant had acid/alkali neutralization, chrome reduction, and cyanide destruction followed by solids removal. The sludge from the solids removal was stored on-site and later sent to landfills. Lucent's response states that waste was not treated on-site prior to 1974; however, some waste was sent to disposal or recycling firms (PAS-00080507).

A 1996 Affidavit from a former employee stated that the waste water treatment plant discharged treated water to the Passaic River, and prior to the construction of the waste water treatment plant, treated process water was discharged to the Passaic River through storm sewers. The treatment procedures for this waste water were unknown to the employee (PAS-00080249-50).

As discussed in Section 3 (Operational History/COC Use and Presence at the Facility) above, the facility had six permitted outfalls to the Passaic River, including the power house cooling water, industrial waste treatment plant discharge, and four "run-off, oil and grease" outfalls (PAS-00080508), shown above on diagram PK-2036 (PAS-00080516).

The four runoff discharge outfalls were primarily storm water drainage and were monitored with samples collected from manholes, except for one that was located in the 12 building basement below the old Cable Shop (PAS-00080421). The storm water drains were stated to be connected to street and parking lot runoff, roof drainage, building sumps, and emergency city water drains, according to a letter from Western Electric to EPA, dated January 15, 1976. Tide water was stated to run up the full length of these drains (PAP-00126620).

A NPDES permit renewal application dated September 15, 1978 stated three surface water outfalls began in 1925 (PAS-00073239, 48, 57), which is when operations at the plant began. Outfall 001 from the power house was noted to have been used since September 1966 (PAS-00073229). The 1978 NPDES application stated that 190,000 gallons per day were discharged to the Passaic River through Outfall 002 (PAS-00073226).

A Selected Substance Report dated July 1, 1980, documented the water flow at the facility in 1980. The estimated average daily volume of treated wastewater discharged to the Passaic River was 250,000 gallons and included process water, contact cooling water, and scrubber water. The form stated the water was treated by destroying cyanide, reducing chrome, neutralizing acid-alkalis, and precipitating metals (PAS-00080319).

According to a 1981 Wastewater Treatment Plant survey, the average flow through the plant was approximately 56,000 gallons per day during the period of October 1 through 28, 1981 (PAS-00080368).

During remediation of the site, eleven drains from the former concrete drum storage pad were found (PAS-00129850). Remediation of the concrete pad stated catch basins associated with the pad were cleaned (PAS-00129860).

6. Regulatory History/Enforcement Actions

Permits

The NPDES permit NJ 002 0443 had an effective date April 30, 1974 and expired April 30, 1979. Discharge limits for temperature and pH were specified for the five outfalls to the Passaic River, and it was stated that the poundage of metals in the effluent should equal the poundage in the intake water. Daily and maximum limits for outfall 002 from the treatment plant were specified for metals (see table below), and a maximum volume of 1.1 MGD was identified.

Contaminant	Daily Maximum per 0.1 MGD (pounds/day)	Maximum (mg/L)
Total Copper	1.00	1.2
Soluble Copper	0.167	0.2
Total Lead	0.876	1.05
Soluble Lead	0.042	0.05

(PAP-00126620; PAP-00127219, 22-23)

A NPDES permit renewal application for Western Electric Company was dated September 15, 1978 (PAS-00073224).

NPDES permit number 0020443 for the facility was effective August 1, 1979 through June 30, 1981. In addition to a maximum flow limit of 1.1 MGD, the following limits were specified for outfall 002:

Contaminant	Daily Maximum Load Limit per 0.1 MGD (pounds/day)	Daily Maximum Concentration (mg/L)
Total Copper	0.834	1.0
Soluble Copper	0.167	0.2
Total Lead	0.834	1.0
Soluble Lead	0.042	0.05

(PAP-00127237-39)

According to an Affidavit of Exemption from the New Jersey Pollutant Discharge Elimination System, dated June 28, 1985, Permit NJPDES 0020443 was administratively extended past June 30, 1981 and allowed the discharge of industrial surface water to the waters of the State of New Jersey through December 31, 1985 (PAS-00080494-95).

In March 1981, a permit from the NJDEP authorized discharge from the Western Electric Co to the Passaic River in accordance with the New Jersey Discharge Elimination System Regulations (PAP-000127252). It is not clear what discharge was authorized by this permit.

According to the 1997 response to an EPA information request, the facility was an authorized hazardous waste generator and storage facility under EPA ID No. N.J.D. 002139053 (PAS-00080504). In addition, waste materials were accumulated in an authorized waste yard prior to disposal in accordance with the Resource Conservation and Recovery Act (RCRA). Prior to the issue of RCRA regulations, the facility followed the various company instructions for storage, transfer, use, and disposal of hazardous substances (PAS-00080505). A 1961 Hazards-Toxic, Corrosive, and Flammable Materials instruction defined the hazardous materials and handling requirements used to minimize hazards at the plant (PAS-00080278). However, only the first two pages of this plan were available in the file material.

Inspections

An inspection of the waste water treatment plant was performed in October 1981. The average water flow through the plant was approximately 56,000 gallons per day. The inspection report stated that the printed wiring board operations in the 170 building had been discontinued, so the majority of the treated water was from the 185 building. The waste water treatment plant contained acid-alkali neutralization, chrome reduction, cyanide destruction, solids removal, and sludge dewatering systems. One sludge pump had leaked and was being replaced (PAS-00080368-70).

A RCRA and PCB Inspection was performed October 27, 1981. The RCRA inspection concluded that Kearny Works satisfactorily met the RCRA requirements for a hazardous waste generator and storage location. However, weaknesses were identified in the hazardous waste storage area. The area had a large drain at the center that could be opened with a valve to drain rainwater to the river within four hours after a heavy rain. The inspection noted that the collection system for spills could allow hazardous waste into the storm drain. Roofing was recommended to keep rainwater off the drums. In addition, the drain system valve could be a problem in freezing weather, and the asphalt pad was cracked but should be impervious (PAS-00080394-95). The PCB inspection found several areas of non-compliance, including unlabeled transformers and drums, inadequate roofing over two transformers, a storage area below the 100-year flood level, and transformers and storage areas without dikes (PAS-00080396). A December 8, 1981, memorandum stated these issues were resolved with a new storage area located on the fifth floor of Building 25 (PAS-00080397).

NJDEP inspected the Kearny Works facility on November 19, 1981. A *Memorandum for Record* stated that the inspection concluded that the facility was in compliance with the existing water pollution laws and the facility spill plans were satisfactory. One request was made to address the potential for spills from acid carboys stored on pavement south of Building 185 to reach groundwater (PAS-00080373).

A *Compliance Monitoring Repor*t dated October 1, 1982 documented a Preliminary Inspection performed February 3, 1982 and an Effluent Survey performed April 28-29, 1982. The inspection reviewed the facility's self-monitoring results and found outfall 002 out of compliance for soluble copper one time in the previous year (PAP-00127263). The report concluded that the facility was in compliance with the terms and conditions of the NPDES permit (PAP-00127254-63).

A RCRA and PCB Survey was performed June 20 and 23, 1983. The RCRA survey identified minor issues with the storage facility (valves in the curbing around the storage pad were left open), but concluded the RCRA program was satisfactory. The PCB survey noted 11 transformers in use. The two transformers in outside storage at the south side of Building 170 were removed and disposed in Emelle, Alabama, on September 29, 1982. The storage area on the fifth floor of Building 25 had ten 30-gallon drums and two partial drums of virgin PCB liquid. The PCB program was concluded to be in compliance with applicable TSCA regulations (PAS-00080455-6).
A waste treatment plant survey was conducted June 21 and 23, 1983. The plant treated 120,000 gallons of water each day. The clarifier effluent was noted to be very clear, and no violations of the NPDES permit levels had occurred since the previous inspection in 1981 (PAS-00080457-9).

Violations

An *Environmental Information Survey of 1972*, dated June 1, 1973, stated the levels of oil and grease in the discharge to the sanitary sewer exceeded the acceptable levels in the Kearny sewer code for 3 of 5 days. In addition, copper was detected at a "significantly high" concentration (not specified) in 1972, but the Kearny sewer code did not have a standard for this metal (PAS-00080294).

A letter dated September 12, 1977, to Western Electric Company from EPA stated the results presented in the previous Discharge Monitoring Report exceeded the NPDES effluent limitations (PAS-00073276). A response letter from Western Electric Company addressed the exceedances, indicating the oil and grease and cyanide concentrations were reported as not detected (less than the reporting limits), and stated that the dissolved lead concentration was reported as 0.02 minimum to 0.03 maximum (no unit specified), which did not exceed the permit limit of 0.05 (PAP-00127236).

An inspection report noted that there were two instances in 1981 when the NPDES permit levels were not met, but the exceeding parameters and concentrations were not specified. The average concentrations over the first nine months of 1981 for lead and copper were at or below the permit levels. The maximum permit limits for total and soluble lead were identified as 1.0 and 0.05 mg/L, respectively, and total and soluble copper were 1.0 and 0.2 mg/L, respectively (PAS-00080369).

A *Compliance Monitoring Report* dated October 1, 1982 stated outfall 002 was out of compliance for soluble copper one time in the previous year. The concentration of soluble copper that exceeded the criterion in the previous year was not specified. A sample collected at this outfall point detected soluble copper at 0.08 mg/L, which was less than the permit daily maximum limit of 0.2 mg/L. Total copper was 0.09 mg/L in the sample from this outfall, which was less than the permit daily maximum of 1.0 mg/L, and lead was not detected (PAP-00127263, 65).

7. Response Actions

Characterization Activities

The following is a list of major response action documents identified in the available file material:

- Environmental Evaluation Measurement Plan, dated May 1984 (PAP-00371663)
- Environmental Cleanup Plan, dated October 1984 (PAP-00371683)
- Environmental Cleanup Plan, dated November 1984 (PAP-00371772)
- Amended Environmental Cleanup Plan, dated July 1985 (PAS-00129806)
- Addendum to Amended Environmental Cleanup Plan, dated June 21, 1985 (PAS-00129820)
- Certification of ECRA Soil Cleanup, dated January 1986 (PAP-00372057)
- Certification of ECRA Soil Cleanup, dated February 1986 (PAP-00372075)
- Supplemental Preliminary Assessment/Site Investigation/Remedial Investigation Report (PA/SI/RI Report), dated May 2016 (PAP-00367644)

Soil

Remediation under NJDEP began in 1985 (PAS-00080506), when the site was owned by RTC. Cleanup was part of the New Jersey's Environmental Cleanup Responsibility Act (ECRA) Program due to the cessation of operations and sale of the property (PAS-00129775).

Diamond Alkali OU2 Allocation

ADR Confidential

Facility Data Report

According to the 2016 PA/SI/RI Report, excavations were performed in 1985 and included the removal of 31,915 cubic yards of soil from a total area of 477,775 square feet, as well as cleaning out 18 catch basins (PAP-00367667). Completion of these excavations was reported in the *Certification of ECRA Soil Cleanup*, dated January 1986 (PAP-00372057). The planned excavation areas were determined in the *Amended Environmental Cleanup Plan*, dated July 1985 using action criteria for several parameters, including copper (170 mg/kg), lead (400 mg/kg), and PCBs (5 mg/kg) (PAP-00371881-2). This Plan attributed PCB contamination in soil at Areas 11, 12, 21, and 22 to the transformers at Buildings 21 and 170, and the surface soil PCB contamination at Areas 4, 5, and 6 to a concrete pad that was formerly used for storage of chemicals and petroleum products (PAP-00371886-89).

The following table shows the maximum concentrations of each COC, if analyzed, for each area identified for excavation, as well as the volumes of soil planned for excavation based on the action criteria. The table is adapted from Tables 2-2, A-1, A-6, A-7, and A-12 from the Amended Environmental Cleanup Plan, dated July 1985 (clean-up locations and volumes and results for contaminants sampled in each area; PAP-00371884, 931-47, 963-65, 976).

Excavations Planned in 1985				
AOC	**Volume removed (cubic yards)**	**Maximum Lead (ppm)**	**Maximum Copper (ppm)**	**Maximum PCBs (ppm)**
1	1,667	790	620	
2	463	760	600	
3	630	610	270	
4,5,6	7,424 (7,320 +104)	1,200	1,110	3,800
7	167	710	210	
8A,8B	974 (830+144)	360	450	
9	93	290	250	
11A,11B	1,068 (370+698)			89,000

44-2	36	520	130	
45-1,45-5*	904 (830+74)			
47	889	460	68	

Excavations Planned in 1985				
AOC	**Volume removed (cubic yards)**	**Maximum Lead (ppm)**	**Maximum Copper (ppm)**	**Maximum PCBs (ppm)**
Historic Fill Averages		*574*	*11.2*	
Historic Fill Maximums		*10,700*	*92.9*	

Blank cells indicate no analyses were performed for the contaminant.
*These AOCs did not have samples analyzed for COCs (PAP-00371931-47, 63-65, 76).
Note: the 2016 PA/SI/RI Report attributed metals contamination in site soil to historic fill (PAP-00367723). The maximum concentrations of lead in soil are all less than the maximum concentrations in historic fill. With the exception of AOC 47, copper concentrations at each area exceed the historic fill maximum concentration.

As documented in the 2016 PA/SI/RI Report, the site received No Further Action (NFA) status from NJDEP for all of the ECRA Areas of Concern (AOCs) identified in 1985 (AOCs 1 through 47), with the exception of the Former Drum Storage Area (AOC 4, 5, 6). The 2016 PA/SI/RI Report provided four closure letters from NJDEP in Appendix G, including the following:

- June 26, 1987; NJDEP states that Section 2 (Soil Cleanup) of the approved Cleanup Plan is complete (PAP-00372094).

- June 23, 1994; NJDEP states that NFA is acceptable for all soil areas of concern except Area 4-6 and ATT11 (PAP-00372095).

- July 8, 1997; NJDEP states that NFA is approved for the 20,000-gallon No. 6 fuel oil UST at Building 80 (PAP-00372098). The PA/SI/RI Report identifies this as AOC 8A (PAP-00367773).

- March 26, 1999; NJDEP states that NFA is approved for one 4,000-gallon gasoline UST and one 4,000 gallon diesel fuel UST (PAP-00372099). The PA/SI/RI Report identifies this as AOC 15 (PAP-00367774).

The 2016 PA/SI/RI Report identified additional AOCs at the site, and conducted investigations at several ECRA AOCs to confirm that remediation was performed to current standards (PAP-00367654, 70-73). It was concluded that the PAHs and metals detected in soils across the site could be attributed to Historic Fill (see discussion above), and most sites did not require further action. The following table defines the AOCs investigated in the PA/SI/RI, as well as the COCs for which further action was proposed.

*No contaminants are identified if additional investigation is proposed for non-COCs. (PAP-00367772-791, 800-801)

At AOC 4/5/6, Former Drum Storage Area, ongoing investigations have been performed since it was initially excavated in 1985, including additional source area excavation and soil vapor extraction through 1993. The PA/SI/RI Report collected additional soil samples and concluded that the metals and PAHs detections were related to Historic Fill. Total PCBs detected at Area B9-6-1 are proposed to be addressed as part of AOC 75 (PAP-00367739-42).

AOC 7 included three 10,000-gallon No. 4 oil and diesel fuel USTs located south of Building 17 and below a paved parking area and roadway adjacent to recently constructed Building 19. Tanks 0001 and 0002 were abandoned in place around 1970, while Tank 0003 was abandoned in place on August 22, 2000. Results reported in the PA/SI/RI Report show naphthalene was detected in soil at a maximum concentration of 40 mg/kg (PAP-00367743-744, 837).

AOC 11 A/B was the location of an historical release of PCB-containing transformer fluids. Excavation was performed in 1985 to a depth exceeding 10 feet below ground surface (ft bgs) immediately adjacent to the Building 21 loading dock and along a former railroad line. The PA/SI/RI Report collected additional soil samples and PCBs were detected up to a concentration of 0.42 mg/kg (PAP-00367747-48, 990).

AOC 31 was an area of demolition rubble or other materials near former Building 170 and was previously excavated to 0.5 ft bgs under ECRA. The PA/SI/RI Report collected additional soil samples and concluded that the metals and PAHs detections were related to Historic Fill. Total PCBs were detected up to a concentration of 3.6 mg/kg (PAP-00367757-758, 998).

AOC 58 is the former Building 161 Drum Storage Area located south of Building 161 and an Oil Heater formerly located inside of Building 161. The function of the oil heater and contents of the drums were not known, but assumed to be related. The PA/SI/RI Report collected soil samples and concluded that the metals and PAHs detections were related to Historic Fill. PCBs detected AOC 58 were proposed to be addressed as part of AOC 31 (PAP-00367759-60, 64).

AOC 75 is comprised of several separate areas where PCBs were detected in areas located away from any likely historical operation and at concentrations that are not consistent with Historic Fill. At Area A5-2-1, total PCBs were detected up to 8.18 mg/kg; at Area B9-6-1, PCBs were detected up to 0.71 mg/kg; at Area C10-4-1, total PCBs were detected up to 3.9 mg/kg; at Area D7-5-1, total PCBs were detected up to 41.4 mg/kg; and at Area 17-2-1, PCBs were detected up to 0.671 mg/kg (PAP-00367764-69, 8003-8005).

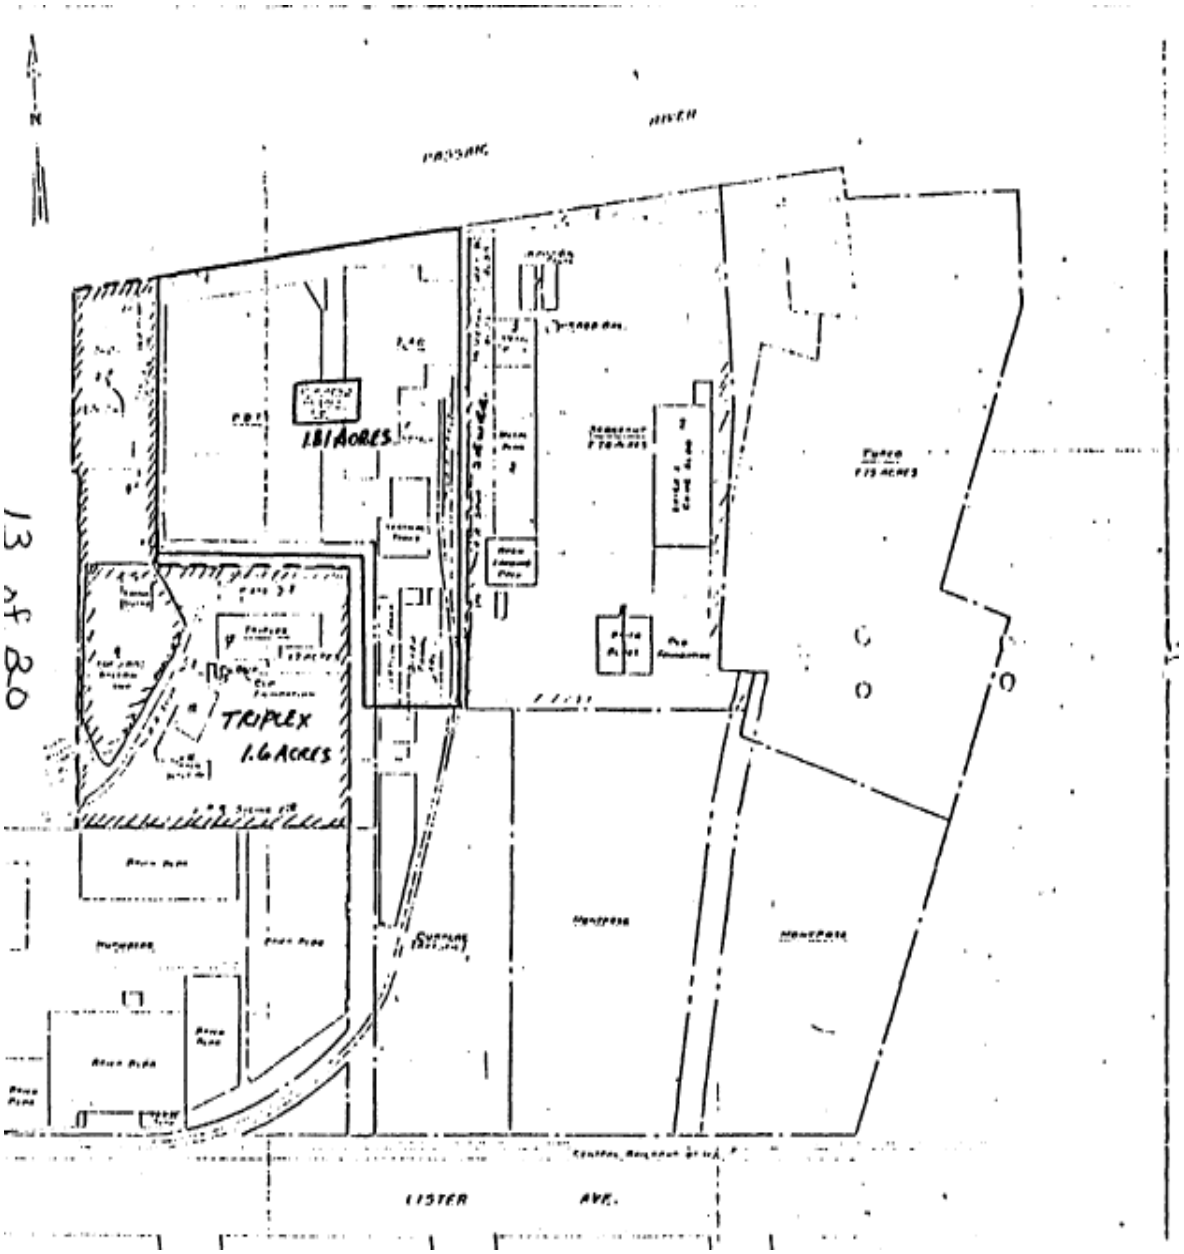
AOC 76 refers to the past use of pesticides at the site. The following maximum concentrations were detected in site soil: DDT at 1.6 mg/kg, DDE at 0.72 mg/kg, and DDD at 0.4 mg/kg. Dieldrin was detected in one sample at a concentration of 0.0075 mg/kg (PAP-00367769, 887-889).

AOC Ford-7 is the location of the former Ford Assembly Building and Western Electric Building 170. It was the site of numerous historical manufacturing and assembly operations prior to its demolition in 1981. The PA/SI/RI Report attributed the detections of PAH, metals, and PCBs in soil to demolition materials related to Building 170. Maximum detections of COCs included PCBs at 1.39 mg/kg, copper at 201 mg/kg, lead at 1,000 mg/kg, mercury at 2.6 mg/kg, and PAHs up to 20 mg/kg (benzo(a)anthracene). (PAP-00367769-7771, 7850, 7869-70, 8006).

8. Summary of Asserted Defenses

No legal defenses were identified in the available file material.

Occidental Chemical Corporation



Diamond Alkali OU2 Allocation

ADR Confidential

Facility Data Report

OCCIDENTAL CHEMICAL CORPORATION

Facility Name, Address and Size: Occidental Chemical Corporation (OCC), 80 and 120 Lister Avenue, Newark, NJ. The 80 Lister Avenue property is comprised of approximately 3.4 acres on the north side of Lister Avenue consisting of an approximately 1.81-acre parcel and an approximately 1.6-acre parcel (PAS-00126895, PAS-00126915). See the map below. The 120 Lister Avenue portion consists of an additional 2.2 acres (PAS-00091776) (80 and 120 Lister Avenue are collectively referred to herein as the Lister facility).

(PAS-00128481)

Occidental Chemical Corporation

Diamond Alkali OU2 Allocation

ADR Confidential

Facility Data Report

1. **Business Type:** Chemical Manufacturing

2. **Time Period of Ownership/Operations**

Operator:	February 1946–August 1969
Owner 80 Lister 1.81-acre parcel:	February 1946–March 1971; January 27, 1986–August 1986
Lessor 80 Lister 1.6-acre parcel:	August 1957–March 1971
Owner 80 Lister 1.6-acre parcel:	January 27, 1986–August 1986
Owner 120 Lister 2.2-acre parcel:	April 19, 1984–August 1986

In 1946, American Agricultural Chemical Company subdivided the 80 and 120 Lister Avenue properties along the present property boundaries and sold the parcels. The 1.8-acre parcel (the northeast portion of the present site) was acquired by the Kolker Chemical Works, Inc. (Kolker), which operated it as an agricultural chemicals plant (PAS-00126895-96: PAP-00026393). Kolker operated the facility at 80 Lister Ave. from February 1946 until March 1951 (PAP-00159316; PAS-00126897). Diamond Alkali Company (later Diamond Shamrock Chemicals Company) operated the facility from March 1951 to March 1971 (PAP-00143159; PAS-00126897).

According to a Memorandum of Lease, starting July 29, 1957, Diamond Alkali Company leased the 80 Lister 1.6-acre parcel from Triplex Oil Refining Company, Inc. (PAP-00403492-94). Manufacturing ceased August 1969 (PAP-00143159). In March 1971, the 1.8-acre parcel was purchased by Chemicaland Corporation (PAS-00126899). Also in March 1971, the 1.6-acre parcel was sold to Walter Ray Holding Company and the lease for the parcel was assigned to Chemicaland Corporation (PAS-00128470; PAS-00126899).

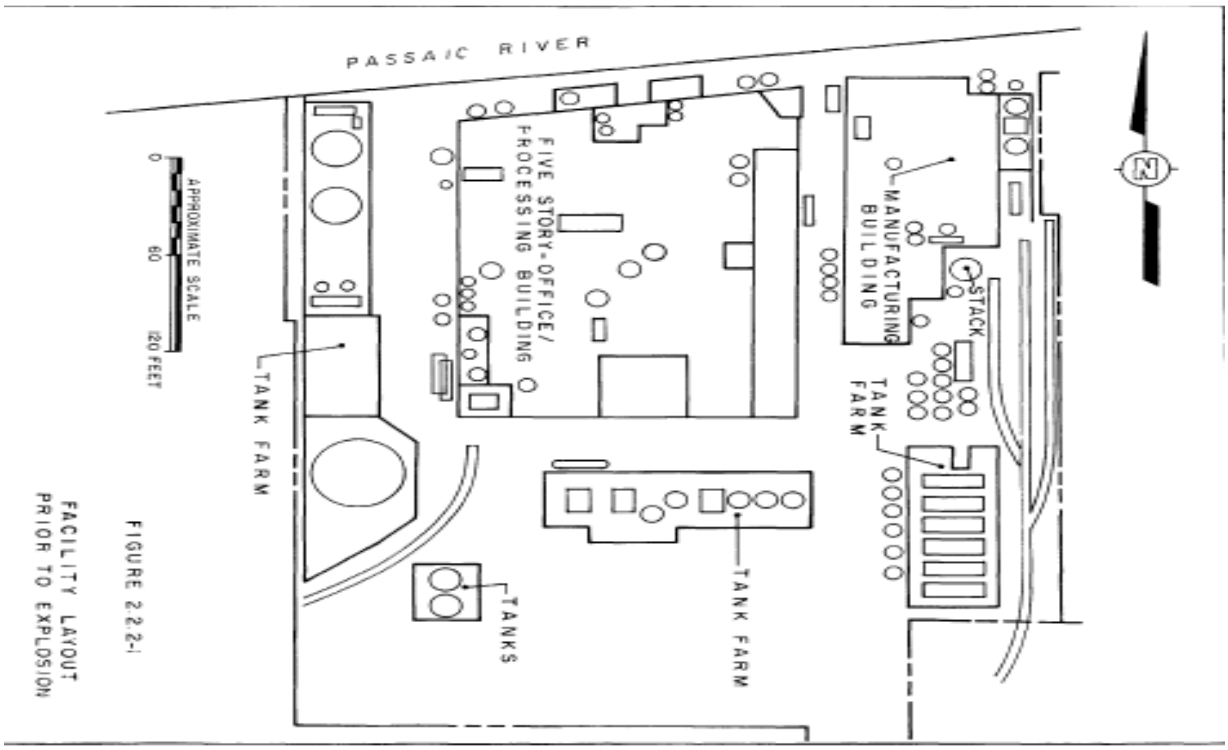
A *1983 Overview of the History and Operations of the Site* prepared by Diamond and provided to the New Jersey Department of Environmental Protection (*1983 History and Operations Overview of Lister Avenue Facility*), states that after the plant and property were sold to Chemicaland "[i]t appears the plant was involved in the production of benzoic acid, with a small amount of 2,4,-D being manufactured for Diamond Shamrock for a limited time." (PAS-00128470; PAS-00126899–900).

According to the *February 1985 Site Evaluation for 80 Lister Avenue* prepared by Diamond Shamrock Chemicals Company for the New Jersey Department of Environmental Protection (*1985 80 Lister Avenue Site Evaluation*), "[i]n November 1976, while [Occidental Chemical Company was] considering acquisition of Chemicaland, [it] assumed control of the management of the plant and continued to manage the plant until February 24, 1977, when [it] returned control of the plant to Chemicaland. Because Chemicaland did not have the resources to continue operating without the support of Occidental, they laid off all plant personnel and shut down the plant as it was on the morning of February 24, 1977." (PAS-00126900).

William Leckie (the successor to Walter Ray Holding Company) purchased the plant and 1.8-acre property at a tax sale in 1980 and held the premises until 1981. Walter Ray Holding Company sold the property in early 1981 to Marisol, Inc. (PAS-00128470; PAS-00126900). According to the 1985 80 Lister Avenue Site Evaluation "[l]ittle is known of the use of the property by Marisol, but eventually this company started cleaning and clearing the site." (PAS-00126901). Regarding the cleanup, the 1985 80 Lister Avenue Site Evaluation states: "[t]he product left in the equipment when the plant was shut down on February 24, 1977, was removed and placed in drums, of which 570 remain on site today"; [s]ome equipment known to be on site following the site was removed"; "[w]arehouse space and tankage was leased to SCA Corporation which used it in conjunction with waste disposal operations at their neighboring plant." (PAS-00126901).

As documented by a deed dated April 19, 1984, Diamond Shamrock Chemicals Company acquired the property located at 120 Lister Avenue from E. M. Sergeant Pulp and Chemical Co., Inc. to assist with the cleanup of the Site (PAP-00403442; PAS-00091776**)**. Similarly, according to a deed, Diamond Shamrock Chemicals Company acquired the plant and property at 80 Lister Avenue from Marisol, Inc. on January 27, 1986 (PAP-00403433).

According to the Administrative Settlement Agreement and Order on Consent for Removal Action between EPA and Occidental Chemical Corporation and Tierra Solutions, Inc., the entity which operated the Diamond Alkali Facility from 1951 to 1969 was Diamond Alkali Company. It changed its name in 1967 to Diamond Shamrock Corporation, and again in 1983, to Diamond Shamrock Chemicals Company. Also in 1983 a corporation named Maxus Energy Corporation ("Maxus") became the owner of Diamond Shamrock Chemicals Company's stock (PAS-00033288; 296).



A 1989 signed Consent Decree between the United States, the State of New Jersey, Occidental Chemical Corporation, and Chemical Land Holdings, Inc. (1989 Consent Decree) states that on "September 4, 1986, Diamond Shamrock Corporation sold all the outstanding stock in Diamond Shamrock Chemicals Company to Oxy-Diamond Alkali Corporation, a wholly-owned indirect subsidiary of Occidental Petroleum Corporation. Diamond Shamrock Chemicals Company was then renamed Occidental Electrochemicals Corporation. Title to the Site had previously been transferred by way of an intra-holding company transaction to Diamond Shamrock Chemical Land Holdings, Inc., a wholly-owned indirect subsidiary of Diamond Shamrock Corporation. Effective November 30, 1987, Occidental Electrochemicals Corporation was merged into Occidental Chemical Corporation, a wholly-owned indirect subsidiary of Occidental Petroleum Corporation. On December 4, 1987, the name of Diamond Shamrock Chemical Land Holdings, Inc. was changed to Chemical Land Holdings, Inc." The 1989 Consent Decree also notes that Chemical Land Holdings, Inc., was a subsidiary of Maxus Energy Corporation (PAS-00091776-77).

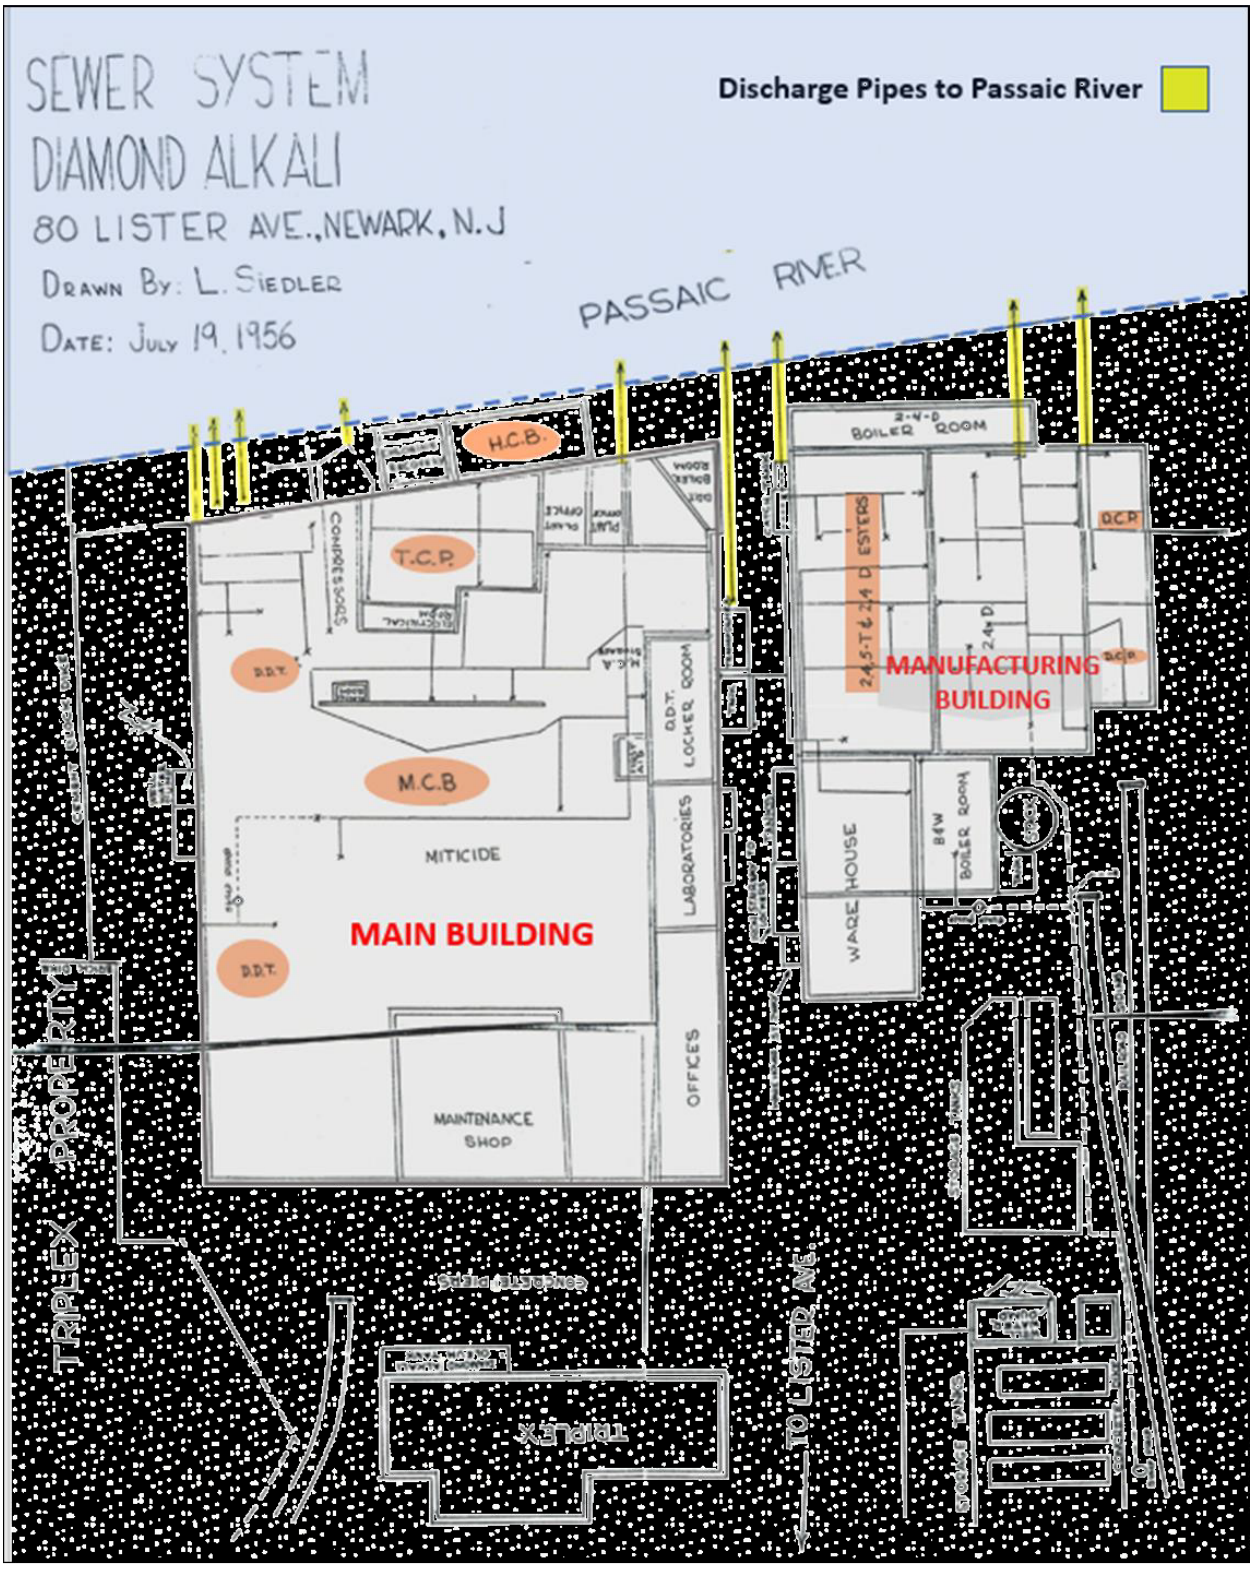
3. Operational History/COC Use and Presence at the Facility

According to the *1985 80 Lister Avenue Site Evaluation*, industrial development on the site is reported to date from the 1870s. Drawings from 1914, revised in 1922, show the site to be part of the former Lister Agricultural Chemical Company (Lister) property that

extended for some distance along the Passaic River. The report states that "During the period of ownership by Lister, the site reached its present dimensions following filling along the south shore of the Passaic River to form the northernmost 30 percent of the property. Much of the remainder of the site is also filled with the granular material reportedly used to fill the marshland that existed in the natural state. Several buildings were on the site, including the Lister power plant, which was later the chemical manufacturing building. The report also notes that when Lister ceased operations, the property was subdivided along the present property boundaries and sold. The 1.81-acre parcel was acquired by Kolker, which, by the mid-1940's, was operating an agricultural chemicals plant on the site (PAS-00126895-96).

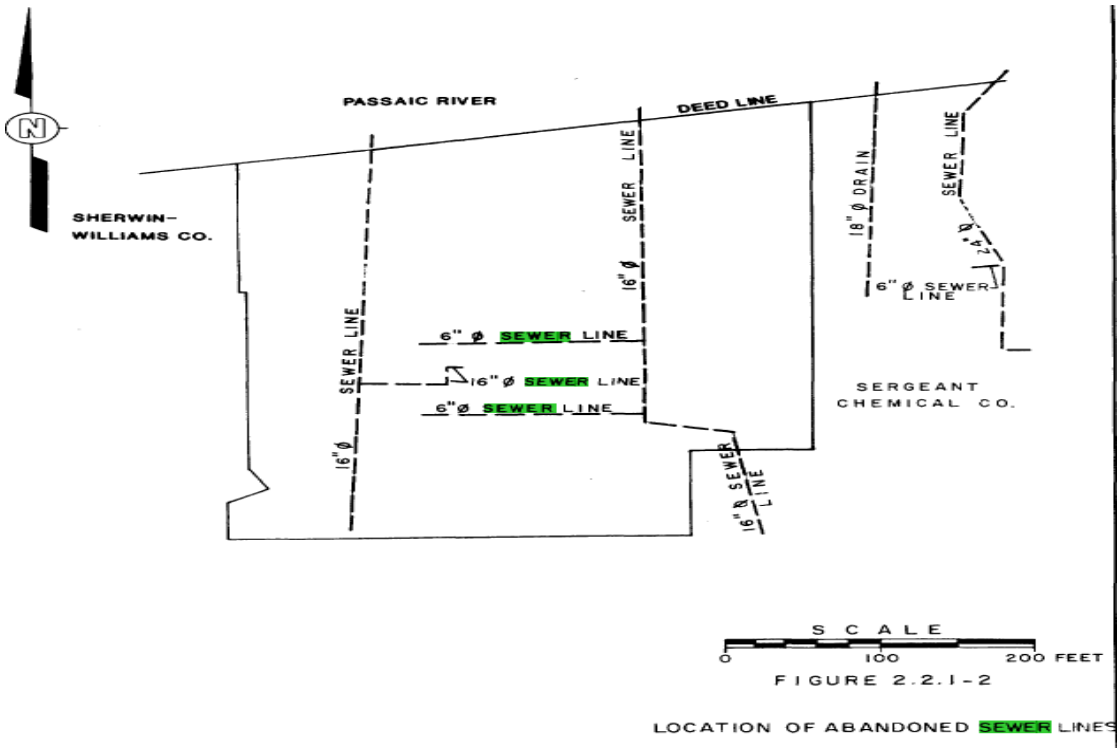
According to the deposition of James Burke, an electrician that worked at the 80 Lister facility starting in January 1946, there were two buildings on-site during Kolker's operations--a 3-story brick building used to manufacture DDT (referred to in other documents as a 5-story building) and a 1-story brick building used to produce 2,4-dichlorophenoxy acetic acid (2,4-D) and 2,4,5-trichlorophenoxy acetic acid (2,4,5-T). He stated that these buildings had a common wall but maps from pre-1960 show two separate buildings as shown in the map below (PAP-00168275; PAP-00168285-88; PAS-00128471-72).

Pre-1960 Site Layout
(PAS-00126918).



A 1956 map of the "Diamond Alkali 80 Lister Ave Sewer System," shows 9 sewer lines to the Passaic River. A copy of the map from the Parette expert report is presented below with the sewer line highlighted in yellow.

Occidental Chemical Corporation



Diamond Alkali OU2 Allocation

ADR Confidential

Facility Data Report

For at least a portion of time, the site and adjacent property were traversed by a system of 16- to 24-inch sewers and drains leading to the Passaic River (PAS-00126895-96). See the map below showing abandoned sewer lines in 1984.

Abandoned Sewer Lines in 1984
(PAS-00126917)

According to an October 23, 2015, *Expert Report by Cynthia Moomaw*, PE, of Geomega, Inc., prepared for Archer and Greiner, PC (legal counsel for OCC) (the Moomaw Report), Diamond occupied the facility from March 1951 to March 1971. Manufacturing ceased August 1969. Chemicaland operated at the site from March 1971 to February 1977, pursuant to toll manufacturing agreements[1] with Diamond from September 1973 to September 1974, and Occidental Chemical Corporation (OCC) from September 1975 to February 1977 (PAP-00143159-60).

Kolker and Diamond Production History

According to a 1983 *Report Prepared by Review of Documents Received from Diamond Shamrock Company* by Marilyn Fingerhut and David Marlow at the National Institute for Occupational Safety and Health (Fingerhut and Marlow Report), Kolker operated the 80 Lister facility from “February 1946 until Diamond Shamrock acquired it by an exchange

[1] In a toll manufacturing arrangement, a company provides its raw materials or semi-finished goods to a third-party service provider. The service provider, who often has specialized equipment or infrastructure, provides a subset of manufacturing processes on behalf of the company using those materials or goods for a fee (Practical Law Company, Toll Manufacturing Transactions: Trade Secret and IP Protection, Bruce Goldner and Jonathan Hillel, Skadden, Arps, Slate, Meagher & Flom LLP, with Intellectual Property & Technology, 2013).

of stock in August 1951" (PAP-00159313; PAP-00159316). The *1985 80 Lister Avenue Site Evaluation* states that ownership by Kolker ceased in March 1951 when Kolker was acquired by Diamond Alkali Company (later Diamond Shamrock Chemicals Company) (PAS-00126867; PAS-00126897). As stated above, the Kolker and Diamond Escrow Agreement states that Diamond acquired all of the issued and outstanding shares of the capital stock of Kolker in August 1951 (PAP-00402324).

Kolker produced both dichlorodiphenyltrichloroethane (DDT) and phenoxy herbicides. Manufacture started with readily available raw materials and the principal intermediates were made on the site (PAS-00126896). The raw materials and finished products reported to have been handled during the time that Kolker and Diamond operated the plant are as follows (PAS-00126908):

Raw Material and Finished Products During Kolker and Diamond Ownership	
Raw Materials	**Finished Products**
Acetic acid	2,4,5-trichlorophenoxy acetic acid (2,4,5-T)
Acetic anhydride	2,4,5-trichlorophenol
Acetaldehyde*	2,4,6-trichlorophenol
Benzene*	2,4-dichlorophenol
Monochlorobenzene*	Monochloroacetic acid (MCA)
Tetrachlorobenzene	Hexachlorobenzene (HCB)*
Chlorosulfonic acid*	Dichlorodiphenyltrichloroethane (DDT)*
Methanol	p-chlorophenyl-p-chlorobenzene sulfonate (ovex)*
Oleum (20%)*	1,1,1-trichloroacetaldehyde*
Phenol	Benzensulfonyl chloride*
Sulfuric acid	p-chlorobenzenesulfonyl chloride*
Dimethylamine (DMA) (40%)	p-chlorobenzenesulfonamide*
Triethylamine	4,4' -dichlorodiphenylsulfone*
Chlorine	p-acetylaminobenzene sulfonyl chloride*
2-Ethylhexanol	p-methoxybenzene sulfonyl chloride*
Butyl alcohol	1,2,4,5-tetrachlorobenzene*
Isopropyl alcohol	Amine salts of 2,4-D (dimethyl and triethyl amines)
Butoxyethoxypropanol	Amine salts of 2,4,5-T (dimethyl and triethyl amines)
Nicotine*	Esters of 2,4-D (butyl, 2-ethylhexyl, isopropyl, butoxyethoxypropyl)
Sodium Hydroxide	Esters of 2,4,5-T (butyl, 2-ethylhexyl, isopropyl, butoxyethoxypropyl)
	Amine salts of Noleyl-1,3-propylenediamine
	Nicotine sulfates*
	Muriatic Acid
	2,5-dichlorophenyl-p-chlorobenzene sulfonate*

* = raw materials and products not used or made after an explosion in February 1960

Other chemicals produced and/or utilized at the site include pentachlorophenol, Velsicol AR-50G, kerosene, and heavy aromatic naphtha (PAP-00399355; PAP-00142894; PAP-00402810).

Diamond's 1983 History and Operations Overview of Lister Avenue Facility states that all of the manufacturing took place on the 1.8-acre parcel. Additionally, in April 1960, 1.6 acres of property were leased from Triplex Oil and Refining Company (subsequently Walter Kay Holding Company and eventually William Leckie) and this property accommodated storage facilities and warehouses. Other property associated with the plant was a parking lot leased in 1963 from Sergeant Chemical Company (PAS-00128468; PAS-00128470).

In March 1971, the 1.6-acre site was sold and the associated lease was assigned to Chemicaland Corporation. Principals of Chemicaland were George W. Mitchell and Raymond A. Guidi, a former plant manager of the facility. The plant was involved in the production of benzoic acid, with 2,4-D being manufactured for Diamond Shamrock for a limited time. In 1980, the 1.8 acre site was purchased in a tax sale by Mr. William Leckie (Ray Holding Company) and was subsequently sold to Marisol Company in early 1981 (PAS-00128470).

According to the *1985 80 Lister Avenue Site* Evaluation, "The production units were cleaned out as they were shut down, and between September and December 1969 the remaining raw materials and products were sold and shipped" (PAS-00126899). However, as described in Section 7, equipment left on site was found to be contaminated with dioxins (PAP-00164662).

Volume

According to the *1985 80 Lister Avenue Site Evalu*ation "[t]he principal products made on site by Kolker were DDT and the phenoxy herbicides with estimated total output of 100 and 110 million pounds, respectively. Production of other products is not believed to have significantly exceeded 10 million pounds." (PAS-00126896). A 1985 internal Diamond memo regarding production volume from the Lister Plant states that "DDT was the most important product of the plant prior to the transfer of its manufacture to Texas in 1958–59. Annual production reached 8–10 MM lbs. at one time and total output was near 100 MM lbs." (PAP-00402822-23). As noted above, Diamond began operating the plant in 1951 (PAP-00143159; PAS-00126897).

Estimated output of the major products reportedly produced by Kolker and Diamond is presented in the following table from the 1985 80 Lister Avenue Site Evaluation (PAS-00126909). While the 1985 80 Lister Avenue Site Evaluation states that these production numbers are for Kolker, it is believed these amounts include Kolker and Diamond operations combined, as indicated in the following tables.

Chemical Produced By Kolker and Diamond	
Product	**Estimated Total Production**
2,4-D	85 million pounds
2,4,5-T	25 million pounds
DDT	100 million pounds
HCB	10 million pounds
Ovex	10 million pounds
Lindane	Unknown
Low y-BHC	<10 million pounds

Note that, while Lindane and BHC are listed in the *1985 80 Lister Avenue Site Evaluation*, the deposition testimony from Stanley B. Honour, a Kolker/Diamond employee from December 1951 to February 1979, states that the Lindane process "was not used at Newark," but rather "was used at the plant at Greens Bayou" (PAP-00403321; PAP-00403316-17; PAP-00403400).

When operated by Kolker and Diamond, the production capacity of TCP and 2,4,5-T acid was as follows (PAS-00128479):

Date	TCP (MM lb/yr-approximate)	2,4,5-T Acid (MM lb/yr-approximate)
January 1951	0.5	0.65
February-March 1953	1.5	2.0
February 1961	1.9	2.5
November 1967	2.3	3.0

Lister site production data for the major phenoxy herbicides is as follows:

YEAR	2,4,5-T (lb/yr)	2,4-D (lb/yr)
1951	NA	NA
1952	342,132	NA
1953	305,868	NA
1954	244,704	NA
1955	526,488	NA
1956	508,032	NA
1957	747,612	NA
1958	762,492	NA
1959	912,840	NA
1960	564,972	5,200,000
1961	1,206,222	4,400,000
1962	1,301,754	5,400,000
1963	1,472,813	5,000,000
1964	1,343,877	6,200,000
1965	685,427	6,300,000
1966	678,674	7,900,000
1967	1,456,692	6,300,000
1968	2,864,487	10,000,000
1969	84,207*	571,126*
1970	0	--
1971	0	0
1972	0	0
1973	0	NA
1974	0	Limited quantities
1975	0	4,077,500 toll period (year) 300,000 (April-June total) 409,500 (October 1-December 5 total)

NA=data not available; Lb/yr = pounds per year unless otherwise noted; * = Average monthly value (pounds per month from 11/68 to 1/69) (PAP-00143186; PAP-00394457; PAP-00400518; PAP-00142922).

According to Maxus Energy Corporation's original complaint against the United States in *Maxus Energy Corporation v. United Sates*, Case Number 3:92CV1655-X (Maxus Complaint), commencing in 1961 and continuing through 1968, Diamond produced and delivered to the United States over 820,000 gallons of Agent Orange pursuant to contracts with the Defense General Supply Center, the Defense Fuel Supply Center, the U.S. Army, or the U.S. Air Force (PAS-00058776).

According to correspondence from an attorney representing the United States Army in the litigation brought against it by Maxus, the United States entered into contracts with Diamond for the production of Agent Pink, Purple and Orange as follows:[2]

DATE	CONTRACT NO.	PRODUCT
11/21/1961	DA30-070-CML-1635 (also identified as NY-2-612)	Agent Pink
02/12/1963	NY-3-1237	Agent Purple
05/22/1963	NY-3-1695	Agent Purple and Pink
03/1964	08-635-64-194	Agent Orange
06/22/1964	DSA-6-6790	Agent Purple
08/18/1966	DSA-400-67-C-1297	Agent Orange
10/18/1966	DSA-400-67-C-2893	Agent Orange
05/08/1967	DSA-400-67-C-8642	Agent Orange
02/29/1968	DSA-400-68-C-4708	Agent Orange
05/09/1968	DSA-400-68-C-5898	Agent Orange

(PAS-00075269-71).

The correspondence also noted that between November and December 1966, the Department of Commerce advised Diamond that the United States would require all T-acid to be produced at Newark. In connection with the United States' consideration of whether to build its own facility for the production of Agent Orange, representatives of Edgewood Arsenal visited Newark in December 1966. The United States, simultaneous with its directive requiring Diamond to accelerate delivery of Agent Orange, acted to increase Diamond's Agent Orange production capacity. In February 1967, the Department of Commerce authorized Diamond to apply a DO-D4 priority rating to obtain equipment and material needed for the Newark Plant expansion. On September 8, 1968, the Department of Commerce's Business and Defense Services Administration (BDSA) notified Diamond that it was no longer required to deliver Agent Orange at a monthly rate of 55,000 gallons as previously required (PAS-00075269, 71).

[2] According to a *Plaintiff's [Maxus Energy Corporation] Proposed Findings of Fact and Conclusions of Law (Annotated)* Civil Action No. 3:92CV1655-X, the term "Agent Orange" means the phenoxy herbicide formulations "Agent Orange" (approximately 50% the n-butyl ester of 2,4-D and 50% the n-butyl ester of 2,4,5-T), "Agent Pink" (approximately 60% the n-butyl ester of 2,4,5-T and 40% the iso-butyl ester of 2,4,5-T), and "Agent Purple" (approximately 50% the n-butyl ester of 2,4-D, 30% the nbutyl ester of 2,4,5-T, and 20% the iso-octyl ester of 2,4,5-T) (PAP-00182624).

A 1983 letter from Diamond to EPA, states that 702,185 gallons of Agent Orange were manufactured from October 1966 to October 1968; and 9,775 gallons of Agent Orange were manufactured in April 1964. It presents the following data regarding sales of product in pounds from 1960 to 1967:

Sales of Product in Pounds (Technical Equivalent)							
	July-June 1960-1961	July-June 1961-1962	July-June 1962-1963	July-June 1963-1964	July-June 1964-1965	July-June 1965-1966	July-June 1966-1967
T-Acid	156,908	250,342	430,355	484,705	145,854	302,569	---
Isopropyl T	22,049	45,253	38,529	84,769	141,803	8,708	31,856
Butyl-T	34,447	403,947	484,640	258,712	241,171	71,923	1,139,271
EH-T	580,343	885,688	996,687	738,791	510,523	459,344	431,788

(PAS-00075501).

An April 1960 Diamond memorandum states that the Lister facility was producing approximately 2,000 tons of 2,4-D per year with a yield slightly less than 60%. According to the memorandum, they were discarding approximately 400 tons of 2,4-D per year with at least three quarters in the form of 2,6-dichlorophenol, 2,4-dichlorophenol, and 2,4,6-trichlorophenol, consisting of about 110 tons of chlorophenols. The memorandum also estimated that they lost 50 tons of 2,4-D acid, 2,4-D sodium salt and 2,4-D esters. The 2,4,5-T effluent was noted to be generally similar to 2,4-D, but only approximately one quarter the amount. The effluent consisted mostly of trichlorophenols with some 2,4,5-T acid and 2,4,5-T esters (PAP-00155169-70). At the *Aetna* trial (PAP-00145100), John Burton testified to corrected discharge calculations of 852 tons of 2,4-D acid equivalent, 471 tons of chlorophenols, and 213 tons of 2,4-D acid, 2,4-D sodium salt and 2,4-D esters (PAP-00145135-38).

DDT Production (1946-1958)

Kolker and Diamond produced DDT in the five-story, approximately 50 year-old main building located adjacent to the Passaic River[3] (PAP-00167643-4; PAS-00128471). DDT was produced from February 1946 until August 1958. A table in the 1983 Fingerhut and Marlow report states Kolker had yearly production capacity of 100 MM pounds (PAP-00142913). This is contradicted by a 1985 Diamond memo that states "annual production reached 8-10 MM lbs. at one time and total output was near 100 MM lbs." (PAP-00402823). The 1985 80 Lister Avenue Site Evaluation also reports a total output of 100 MM lbs. (as opposed to an annual output of 100 MM lbs.) (PAS-00126896), and that DDT production was then subsequently moved from Newark to Texas in late 1958 or early 1959 (PAS-00126897).

[3] According to Diamond's 1983 History and Operations Overview of Lister Avenue Facility, during the 1951-1960 period "[m]anufacture of starting and intermediate chemicals was" also conducted in the main building (PAS-00128471-72).

As described in Section 5 below, DDT was directly discharged to the Passaic River in multiple ways including:

- As a result of the discharges of spent oleum (used in the manufacture of DDT) to the LPR. (1) Some amount of the liquid DDT/chlorobenzene mixture in the reactor was directly discharged to the Lower Passaic River with the spent oleum as operators relied upon a color change in a sight glass (red oleum to hazy to white) to determine when to close the valve. (2) Some amount of DDx would also be dissolved in the spent oleum which was directly discharged to the Lower Passaic River (PAP-00399543-57; PAP-00399561-2; PAP-00143633-9; PAP-00158345).

- Direct release through sewers (i.e., floor trenches in manufacturing buildings) from floor washing and DDT material spills (PAP-00167786-88; PAP-00155385-86; PAP-00155405; PAP-00155436; PAP-00160985; PAP-00394773-74).

- Dumping of good and bad batches of DDT in the river (PAP-00160328-29; PAP-00145264-65). Nicholas Centanni, who worked for Kolker and Diamond at the Lister Plant from 1948 to 1969, testified that "[s]ometimes . . .an operator . . . instead of letting just the acid go to the river, something would distract them or he'd put the valve in the wrong position and he would send DDT, acid and everything to the river." (PAP-00145264).

These DDT discharges from the site resulted in the formation of a large pile of DDT wastes in the LPR (PAP-00145264-65; PAP-00155439). Employees were sent into the river in boats and with rope harnesses to chop the DDT pile down below the water line (PAP-00143643-47; PAP- 00159660; PAP-00160322–23).

2, 4-D and 2,4,5-T Production (1949-1969)

Kolker and Diamond produced 2,4-D and its derivatives in a second building. Production of 2,4-D was carried out in batches by the alkaline condensation of the 2,4-DCP and monochloroacetic acid (MCA) in the presence of caustic soda. The resulting sodium 2,4-D slurry was filtered and washed to remove unwanted sodium 2,6-D which was discarded. The sodium 2,4-D was then continuously acidified with sulfuric acid, washed to remove sodium sulfate, and dried in an evaporator. The resulting anhydrous, molten 2,4-D was stored for later flaking or for use in the preparation of the various 2,4-D esters or Dacamines (a proprietary line of oil-soluble amines) (PAS-00126903).

A November 22, 1949 Kolker memo with the subject "Preparation of 2,4,5-Trichlorophenol" describes "work done to date on the preparation of 2,4,5-Trichlorophenol as a basis for plant production." The temperatures used in the laboratory ranged from 160 to 180 °C (PAP-00167168-72).

A 1951 Diamond document indicated that Kolker had sales of 2,4,5-T esters amounting to $278,997 for the fiscal year which ended January 31, 1950. A May 1950 article states that Kolker was producing 2,4,5-T at the site (PAP-00400305). One of the raw materials, tetrachlorobenzene (TCB or T4CB) was also produced on site because it could not be purchased at that time (PAP-00167644-47; PAP-00167658).

After acquiring Kolker in 1951 until July 1969, Diamond manufactured the phenoxy herbicides 2,4-D and 2,4,5-T, at the 80 Lister facility (PAS-00058771). Production of 2,4,5-T was carried out by an analogous process to that used for the manufacture of the 2,4-D. All components of the process for manufacture of 2,4,5-T were operated in the same manner as those for 2,4-T, although at slightly different temperatures and pressures (PAS-00126903).

In a 1987 deposition, John Burton, a plant manager at the Lister facility for both Kolker and Diamond, stated that, from approximately 1951 to 1953, Diamond used the same equipment to produce both 2,4-D and 2,4,5-T (PAP-00167686-87). The Moomaw Report states that "Diamond's use of the same process equipment to manufacture 2,4,5-T and 2,4-D would have likely introduced dioxin into this 2,4-D equipment and any 2,4-D equipment used in the process downstream of this equipment." In addition, Diamond produced 2,4-D and 2,4,5-T esters and amines in the same reactor. The Dacamine reactor, which was used to produce both 2,4-D and 2,4,5-T Dacamines by Diamond was later used by Chemicaland in their 2,4-D production (PAP-00143149; PAP-00143160).

TCP

TCP production was started in 1950 in the main building. A 500-gallon autoclave was purchased for the production of TCP. One of the raw materials, tetrachlorobenzene (TCB) was also produced on site, as it could not be purchased at that time (PAP-00167643-47; PAP-00167658; PAP-00167666). Laboratory work pertaining to the production process of TCP was also conducted on the first floor of the main building beginning in 1949 (PAP-00167645).

According to the Maxus Complaint, Diamond prepared the TCP, the intermediate used to produce 2,4,5-T, in a heated autoclave using the starting ingredient TCB. During that step, 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD)[4] was formed in trace amounts as a result of side reactions that occurred in the autoclave (PAS-00058771). A second autoclave with a volume of 1,000 gallons was added in 1953 (PAP-00167666).

TCP was produced at the site from 1,2,4,5-tetrachlorobenzene (T4CB), sodium hydroxide (NaOH), and methanol in the autoclave. NaOH and methanol would combine to form sodium methoxide, which reacted with T4CB to form the intermediate product 2,4,5-trichloroanisole (TCA). TCA would then react with another molecule of sodium methoxide to form TCP. In the autoclave and TCP storage tanks, the TCP would

[4] Note that "**dioxins**" are referred to in this report using the various terms consistent with that presented in the document cited. These terms include dioxin; tetrachlorodibenzo-p-dioxin (TCDD); 2,3,7,8-TCDD; polychlorinated dibenzo-p-dioxins (PCDD); and polychlorinated dibenzofurans (PCDF). Also note that 2,4-D (2,4-dichlorophenoxy acetic acid), 2,4,5-T (2,4,5-trichlorophenoxy acetic acid), and 2,4,6-TCP (2,4,6-trichlorophenol) are products that can result in the generation of dioxins as discussed in this report.

actually be present as its sodium salt (Na-TCP) which was soluble in water. TCP produced at the site was combined with NaOH and monochloroacetic acid to produce the herbicide 2,4,5-T. 2,3,7,8-TCDD contained in the TCP was carried through to the 2,4,5-T process (PAS-00126901–02; PAP-00210489-90). Esters and amine salts of 2,4,5-T were also made (PAS-00126903).

As reported by Diamond in its 1985 80 Lister Avenue Site Evaluation, NaTCP was made in a batch reaction by the alkaline hydrolysis with caustic soda of T4CB in the presence of methanol at temperatures and pressures near 165 °C and 350 psig, respectively. Methanol was distilled from the reaction mass and recycled (PAS-00126901-2). However, plant operating instructions called for use from 180 °C to 186 °C, and this temperature range was maintained from June 1954 to September 1954 (PAP-00159096). Temperatures in Diamond's autoclave ranged from 164 °C to 180 °C in 1966 to 1969 (PAP-00143163). John Burton states that the autoclave was run at temperatures from 160 °C to 172 °C (PAP-00167737).

According to *Parette, et al. (2018)*, from 1949 until 1954, a "dilution-filtration" process was employed at the site to purify TCP for approximately five years until September 1954 (PAP-00210172). In this process, "2,4,5-TCP (coming from the autoclave following methanol removal) was diluted with water to a concentration of 5-10%. As 2,4,5-TCP was present as its sodium salt (Na-TCP), it was soluble in this added water. However, the unreacted organics, the raw material 1,2,4,5-tetrachlorobenzene (TCB) and the intermediate product 2,4,5-trichloroanisole (2,4,5-TCA), were dense and relatively insoluble. In the dilution-filtration process, the unreacted organics were allowed to settle out for a period of one hour, forming a sludge in the bottom of the dilution tank. . . . 2,3,7,8-TCDD is also a dense, relatively insoluble organic with a high octanol/water partition coefficient . . . , suggesting that it would have preferentially partitioned to, or concentrated in this organic sludge phase. The operating instructions for the dilution-filtration process indicated that the settled waste organic sludge was discharged to the LPR . . . .(PAP-00210172; PAP-00168381-5; PAP- 00149641-51; PAP-00159145-49; PAP-00155450-52.)

According to Diamond's *1983 History and Operations Overview of Lister Avenue Facility*, "all processing equipment for the manufacture of sodium NaTCP and other primary chemicals were located within the main building. Little information is available as to the exact location of the NaTCP equipment within the building . . ." Wastes produced in this process included a filter cake which contained water insoluble materials, such as T4CB, 2,4,5-trichloroanisole (TCA), and would likely trap any dioxin present in the reaction product. This process was replaced in 1954 with a steam distillation to remove TCB and TCA. Any dioxin present, because of its volatility, would also be removed either partially or totally. The distillate (organics) from this process step were stored for recycling in the future, subject to development of a process for their use. The first recycle of recovered organics from the steam distillation was made in December 1956 and was then made a routine operation (PAS-00128471-72).

Diamond's *1983 History and Operations Overview of Lister Avenue Facility* also states that liquid wastes from the process consisted of aqueous solutions of sodium chloride and sodium sulfate. Prior to October 1954, the aqueous solutions of sodium chloride

and sodium sulfate were separate. After this date, the process was modified such that the sodium chloride and sodium sulfate were discharged as a single solution from the 2,4,5-T acid process. Condensate (aqueous layer) from the steam distillation was the other liquid waste from the process. Muriatic acid was also produced as a by-product in the main process building from the hydrogen chloride produced in the chlorination of acetic acid/anhydride to monochloroacetic acid (MCA) and the chlorination of phenol to 2,4-dichlorophenol. This acid was produced in processes not related to the production of TCP and was generally sold to re-claimers (PAS-00128472).

An April 4, 1960 memo from John Burton, states that "[a]ll of our unsold muriatic acid is dumped in the Passaic. . . . In 1958 we dumped 2000 tons; in 1959 we dumped 4400 tons." (PAP-00155170.)

Beginning in October 1954 (one month after the switch from dilution-filtration to steam stripping to purify the Na-TCP), the plant discontinued the practice of acidifying the Na-TCP to remove the NaCl, and the NaCl was carried through to the Na-TCP storage tank and ultimately to the 2,4,5-T process (PAP-00159095-6).

During the late 1950's several process changes were instituted to improve the operating efficiency of the plant. Among these was a change instituted around 1956 to the TCP process to recycle TCA. A change in the handling of process effluent also occurred in 1956 with the installation of an industrial sewer connecting to the PVSC Lister Avenue line (PAS-00126897). See below for additional disposal information.

In 1967, "the basic process for preparation of NaTCP was not changed but provision was made for the removal of sodium chloride by filtration from the stream-stripped solution of NaTCP and the removal of dioxin 2,3,7,8-TCDD by adsorption on activated carbon . . . . The sodium chloride recovered in the filter was dissolved in water for disposal by the industrial sewer. The activated carbon in the adsorption column was treated with muriatic acid and hot water washes to remove iron hydroxide. These treatment solutions were then disposed of in the industrial sewer. Spent carbon was removed from the unit and handled by a disposal firm. The basic processes for manufacturing the 2,4,5-T acid, esters or amine salts were not changed." (PAS-00128473.)

The resulting NaTCP solution was then steam distilled to remove by-product TCA that also was recycled to the reactor. Following steam distillation, the NaTCP solution was diluted with water, and then passed through a carbon bed to remove dioxin. The purified but dilute NaTCP solution was then reconcentrated for use in the 2,4,5-T process by acidifying two-thirds of the stream, then separating the TCP from the water to raise the TCP content to 93 percent. This concentrated TCP was neutralized with caustic soda to reform the NaTCP and then mixed with the remaining third of the diluted NaTCP, yielding NaTCP of the correct concentration for use in the manufacture of 2,4,5-T (PAS-00126901-902).

Phenoxy Acids, Esters, Amine Salts and Formulations

The phenoxy acids, esters, amine salts and formulations were prepared in the separate smaller building located to the east of the main manufacturing building (PAS-00128471-72).

Esters of 2,4-D and 2,4,5-T

The production of 2,4,5-T esters involved the following steps:

- production of sodium trichlorophenol (NaTCP)
- reaction with sodium monochloroacetate to yield a sodium salt of trichlorophenocxyacetic acid
- trichlorophenocxyacetic acid was reacted with sulfuric acid to yield the 2,4,5-T with a suitable alcohol at the proper reaction conditions to give the corresponding ester or with a suitable amine to give the corresponding amine salt (PAS-00128470).

According to the *1985 80 Lister Avenue Site Evaluation*, the esters of both 2,4-D and 2,4,5-T were formed by batch reaction with the appropriate alcohol in the presence of sulfuric acid which acted as a catalyst. The alcohol and by-product water were distilled throughout the reaction and the alcohol was held for later reuse in the process. On completion of the reaction, the last traces of water were removed under vacuum, and the ester was then transferred to storage to await sale (PAS-00126903).

Amines of 2,4-D and 2,4,5-T

The *1985 80 Lister Avenue Site Evaluat*ion states that the water-soluble dimethylamine (DMA) salts of 2,4-D or 2,4,5-T were formed by the reaction of a water solution of DMA with either wet or dry 2,4-D or 2,4,5-T. The resulting amine salt solutions were adjusted for concentration and then stored for later sale. A proprietary line of oil-soluble amines (the Dacamines) was prepared by the reaction of N-oleyl-1,3 propylenediamine with either dry, molten D or T acids or the flaked acids (PAS-00126903).

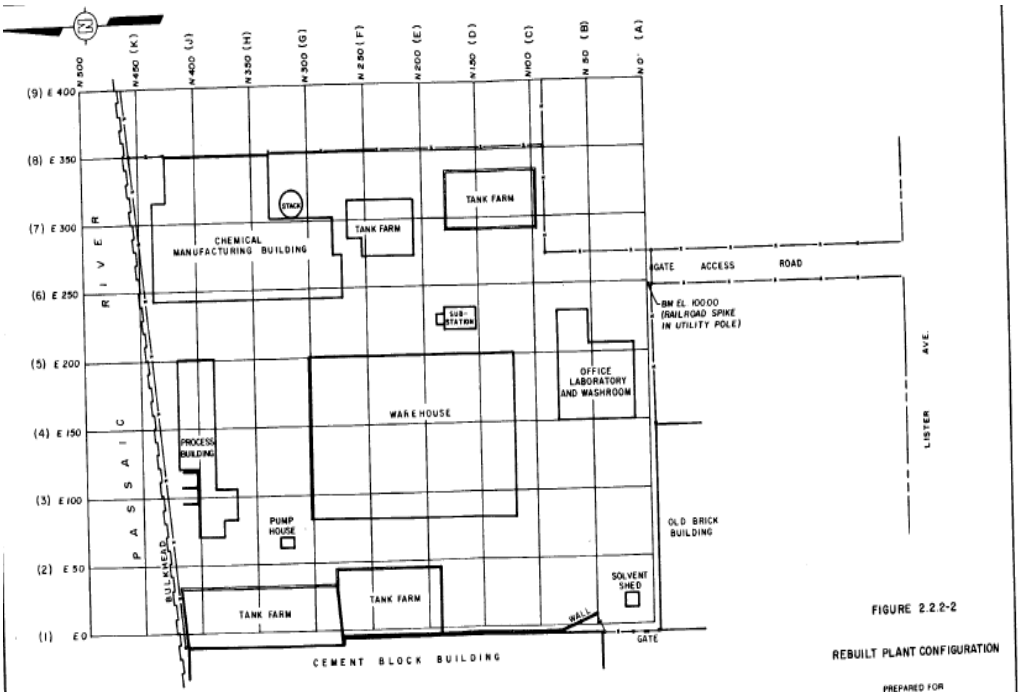
2,4-DCP

According to the *1985 80 Lister Avenue Site Evaluation*, the direct chlorination of phenol in the presence of a ferric chloride catalyst was used to make 2,4-DCP. The reaction was carried out in batches at atmospheric pressure. Detailed chromatographic studies of the process to optimize the 2,4 content were correlated with the freezing point of the reaction mass, and the results were used as the routine means of process control. The 2,4-DCP was stored and handled as produced in the molten state (PAS-00126902).

MCA

The *1985 80 Lister Avenue Site Evaluation* states that MCA was made by the chlorination of a mixture of acetic acid and acetic anhydride in batches. Routine process control was again effected by measuring the freezing point of the product. MCA, similar to the 2,4-DCP, was stored and used in the molten state without dilution or purification (PAS-00126902).

MCB/T3CB/T4CB/DCB



Monochlorobenzene (MCB) was used as a solvent and as an intermediate in the manufacture of DDT and other organic products (PAP-00398133). MCB was also produced at the site. In the production of MCB, dichlorobenzene (DCB) was produced, corresponding to ~10% of MCB. The DCB byproduct was utilized as a raw material in the manufacture of T4CB during the Kolker period of plant ownership. 1,2,4-trichlorobenzene (T3CB) was utilized as a raw material in the manufacture of 2,5-dichlorophenol, and 1,2,4-T3CB was also an impurity in the 1,2,4,5-T4CB that was utilized as the raw material in the production of TCP. A mixture of 1,2,4-T3CB and 1,2,3-T3CB was used at the site as a raw material in the production of HCB (PAP-00403438; PAP-00403533; PAP-00403534; PAP-00400425).

HCl

According to the *1985 80 Lister Avenue Site Evaluation*, HCl, produced as a by-product of the 2,4-DCP and MCA processes, was absorbed in water to form 32-percent muriatic acid, which was sold in the local area (PAS-00126901-903). This conflicts with the 1960 memo from Diamond plant manager Burton, which said “All of our unsold muriatic acid is dumped in the Passaic. . . .In 1958 we dumped 2000 tons; in 1959 we dumped 4400 tons.” (PAP-00155170).

1960 Explosion

The *1985 80 Lister Avenue Site Evaluation* states that during the period of operation of Diamond the manufacture of several products was either transferred to other locations or discontinued, leaving the phenoxy herbicides as the only products of the plant. A major impetus for this change was an explosion in February 1960 which destroyed several plant processes. When rebuilt the plant only included processes for the manufacture of the phenoxy herbicides and their intermediates. The layout of the plant site after it was rebuilt is shown below. Modernization and expansions continued during the 1960’s, which saw total phenoxy capacity more than double to 15 million pounds per year (PAS-00126897).

(PAS-00126919).

The February 1960 explosion occurred in the TCP unit and destroyed the large five-story building in which it and several other plant processes had been located. Following the explosion, a decision was made to limit future production of phenoxy herbicides, ending output of HCB, ovex and the benzene sulfonyl chloride derivatives (PAS-00126897-98).

According the *1985 80 Lister Avenue Site Evaluation*, since a larger site was required for rebuilding the plant, the adjacent 1.6-acre parcel was leased. This property, which had been used for reclaiming oil, contained several buildings and large tanks which were razed to permit installation of a new laboratory and office building, a maintenance shop/warehouse building, and a tank farm for flammable raw materials along the west side of the property (PAS-00126898).

Following demolition of the remains of the damaged building, a new process building devoted to the manufacture of sodium trichlorophenol (NaTCP), 2,4-dichlorophenol (2,4-DCP), MCA, and by-product hydrochloric acid (HC1) was erected along the river near what had been the north end of the old building. Following this construction, the manufacture of the intermediates was carried out in the new buildings, leaving the old undamaged chemical manufacturing building for the production of 2,4-D; 2,4,5-T and their esters and amines (PAS-00126898).

Diamond's *1983 History and Operations Overview of Lister Avenue Facility states*: "Two additional buildings separate from the process building were also provided. The largest of these housed the maintenance shop, production and shipping offices, and an area for materials storage. The smaller building housed the general plant offices, the quality control laboratory, and the dressing room. . . . Other improvements related to bulk

materials storage were also made at this time. The new process building was designed to have all drainage trenches discharge through a sump into the industrial sewer. The plant was expanded in 1967 by the addition of a new 2,4-D acid unit and conversion of the old 2,4-D acid unit to 2,4,5-T acid manufacture. The warehouse was expanded and an extension added to the Process Building to house the NaTCP purification process" (PAS-00128472).

The *1985 80 Lister Avenue Site Evaluation* described changes in the process and manufacturing buildings from 1963-1967 as follows:

> The process building remained largely unchanged—the only addition was equipment installed in 1967 to purify the NaTCP by removing dioxin. The period 1963 to 1967 saw several major projects in the 2,4-D and 2,4,5-T manufacturing areas including:
>
> 1963: The 2,4-D acid process was rehabilitated. The roof was raised permitting installation of new ventilating ducts to carry process fumes to a new and larger caustic scrubber.
>
> 1965: The melt, washing, and drying process for the production of dry, flaked 2,4-D was installed, with a 40 percent increase in capacity. These changes also reduced personnel contact with the 2,4-D.
>
> 1967: The final plant expansion saw the construction of a new and larger 2,4-D unit and the conversion of the former 2,4-D unit to the manufacture of 2,4,5-T. The TCP purification process for dioxin removal via carbon filtration was added as part of this same expansion. Capacity increased by 54 percent for 2,4-D and 67 percent for 2,4,5-T (PAS-00126898-99; PAS-00126910-11).

In August 1969, Diamond discontinued operation at the plant. The plant was listed for sale and remained idle throughout 1970 until it was purchased by Chemicaland Corporation in March 1971. Chemicaland purchased the 1.8 acres and improvements owned by Diamond, which then assigned rights to the 1.6 acres it had leased from Walter Ray Holding Company to Chemicaland (PAS-00126899).

According to the *Moomaw Report*, after unsuccessfully operating on their own, Chemicaland entered into a tolling agreement with Diamond from September 1973 to September 1974 to produce 2,4-D. The plant required repairs to bring it online, including replacement of missing equipment (e.g., flaker), repairs to piping in the dichlorophenol (DCP) and MCA areas, and replacement of tankage that was in poor condition (e.g., TCP storage tank may have been used to replace the sulfuric acid storage tank). Several pieces of equipment previously used to manufacture 2,4,5-T were repurposed by Chemicaland and used in the 2,4-D process. This repurposing of equipment and the potential cross-contamination of dioxin from the 2,4,5-T to the 2,4-D process was recognized by Diamond personnel who commented that "*We should be sure to assay the 2,4-D that is produced for any levels of Dioxin that might show up from use of the 'T' equipment . . . ."* (PAP-00143161- italics in original).

The *Moomaw Report* states that Chemicaland entered into a second tolling agreement with OCC to produce 2,4-D from September 1975 to February 1977, when manufacturing at the Lister Site ceased. The property remained idle through 1980 and eventually was sold to Marisol Inc. in March 1981. Marisol filled 570 drums with solid and liquid waste left in equipment when the plant was shut down in February 1977 (PAP-00143161).

Dioxin Producing Processes

The following table shows the chemicals for which the manufacturing process resulted in the production of dioxin (PAP-00208962):

Dioxin in Chemicals Manufactured at the 80 Lister Avenue Site	
Chemicals	**Component/Byproducts**
Agent Orange	2,4,5-T
2,4,5-T	NaTCP
NaTCP	TCA and TCB

According to *Parette, et. al. (2018)*, the 2,4,5-T "dilution-filtration" purification process used for approximately five years until September 1954 was a significant source of 2,3,7,8-TCDD to the Passaic River. This purification process generated a dioxin-rich sludge that was discharged to the river (PAP-00210169). Operating instructions for the 2,4,5-TCP process at the site for 1951 through 1954 indicated that 2,4,5-TCP (coming from the autoclave reactor following methanol removal) was diluted with water to a concentration of 5-10%. As 2,4,5-TCP was present as its sodium salt (Na-TCP), it was soluble in this added water. According to the article, the raw material 1,2,4,5-tetrachlorobenzene (TCB) and the intermediate product 2,4,5-trichloroanisole (2,4,5-TCA), are dense and relatively insoluble. In the dilution-filtration process, the unreacted organics were allowed to settle out for a period of one hour, forming a sludge in the bottom of the dilution tank. 2,3,7,8-TCDD is also a dense, relatively insoluble organic, suggesting that it would have preferentially partitioned to, or concentrated in this organic sludge phase. The operating instructions for the dilution-filtration process indicated that the settled waste organic sludge was discharged to the river. In the process, settled unreacted organics sludge was left in the dilution tanks. When sufficient sludge had accumulated to overflow, any remaining 2,4,5-TCP was extracted from this organic sludge by adding water and raising the pH. Following extraction of the 2,4,5-TCP, the unreacted organic sludge was discarded to the "sewer". In this context, "sewer" referred to a series of drain pipes leading from the buildings at the site to the river. In September of 1954, the dilution-filtration process was replaced by a steam stripping purification process to remove 2,4,5-TCA from the crude 2,4,5-TCP (PAP-00210172; PAP-00168381-5; PAP-00149641-51; PAP-00159145-49; PAP-00155445-52).

A report by Neil M. Ram, an expert retained by Repsol, S.A. in 2015 (Ram Report), states that 2,3,7,8-TCDD was present in both the NaTCP and 2,4,5-T that Diamond produced. In 1965, analysis of an unspecified number of samples of dilute TCP solution and 2,4,5-T (acid) yielded 2,3,7,8-TCDD concentrations up to 40 ppm. Samples of TCA (a recovered byproduct of NaTCP manufacturing) also exhibited measureable levels of

2,3,7,8-TCDD. Tests on an unspecified number of samples of undiluted (100%) TCP assayed later in 1965 yielded 2,3,7,8-TCDD concentrations ranging from 80 ppm to 140 ppm, while 2,4,5-T samples assayed later in 1965 yielded 2,3,7,8-TCDD concentrations ranging from 7 ppm to 26 ppm (PAP-00208934; PAP-00208962-63).

The *Ram Report* further states that in September 1967, Diamond Shamrock began treating all NaTCP produced, using an activated carbon adsorption column to remove 2,3,7,8-TCDD. As a result, 2,3,7,8-TCDD concentrations in the NaTCP and 2,4,5-T that Diamond produced from September 1967 to August 1969 (when plant operations were suspended) were reduced from those experienced prior to treatment. Six samples of NaTCP assayed in 1968 and 1969 (one per quarter) exhibited 2,3,7,8-TCDD concentrations ranging from 0.2 ppm to 9.0 ppm (PAP-00208962-63).

According to the *Ram Report*, although literature indicates that dioxin is not present in T4CB, dioxin was detected in samples collected from the former T4CB storage tank and from the T4CB rail car unloading line (PAP-00208962). The Ram Report states that documents indicate the presence of 2,3,7,8-TCDD in the TCB that Diamond used to manufacture NaTCP. Hooker Chemical Company (Hooker) supplied the T4CB and shipped it to the 80 Lister Avenue site via railcars, where it was subsequently unloaded into a T4CB storage tank at the facility via a dedicated unloading line. In or around 1991, 2,3,7,8-TCDD was detected at a concentration of 4,200 ppb, in a sample of residue collected from the T4CB storage tank (PAP-00208961-63; PAP-00208935).

The *Ram Report* also states that a second sample of the T4CB tank residue, collected in 1992, contained 13,000 ppb of 2,3,7,8-TCDD; another sample collected in 1992 from the T4CB unloading line contained 6.7 ppb of 2,3,7,8-TCDD. The lower 2,3,7,8-TCDD concentration in the unloading line (6.7 ppb) compared to that those in the storage tank (4,200 ppb and 13,000 ppb) was attributed to the absence of visible residue in the line (the sample “consisted primarily of pipe rust”) (PAP-00208961-63; PAP-00208935).

Dioxin in TCP and 2,4,5-T

A July 25, 1988 *Statement of Factual Premises* submitted on behalf of Diamond Shamrock Chemicals Company in *Diamond Shamrock Chemicals Company v. Aetna Casualty & Surety Co.*, Docket No. C-3939-84 (“DSCC’s *Statement of Factual Premises*”),states that all of the 2,4,5-T manufactured at the 80 Lister Avenue plant from approximately January 1951, when production began, through mid-1969, when production ended, contained dioxin (PAP-00149735-36).

Dioxin formation has been identified to occur in the production of TCP by the caustic hydrolysis of TCB. At the Diamond plant, this reaction was carried out in the autoclave reactor, a closed high-pressure vessel operated at a high temperature. The autoclave was located inside the process building before the 1960 explosion in the TCP unit, and outside of the new building after the explosion on the north side in concrete bunkers along the river (PAP-00143163).

According to a Diamond Interoffice memorandum, a survey of 31 autoclave batches from 12/28/53 to 6/7/54 indicated a plant practice of operating about 170°c with some batches as low as 160 c. Operating instructions called for 180-186 c. so this temperature range was maintained from 6/54 to 9/54 (PAP-00159096). Temperatures in Diamond's autoclave ranged from 164 to 180°C in 1966 to 1969 (PAP-00143163). John Burton states that the autoclave was run at temperatures from 160 to 172 degrees (PAP-00167737).

According to an internal Diamond memorandum dated September 18, 1957, a representative from C.H. Boehringer Sohn visited the Lister Plant in September 1957 and identified 2,3,7,8-TCDD as the likely chloracnegen and higher autoclave temperatures as the cause of dioxin generation in TCP production (PAP-00155172).

According to the *Moomaw Report*, Diamond started to look for ways to reduce dioxin in TCP and 2,4,5-T starting in approximately1965. Dilution and filtration of the TCP solution was tested from 1965 to 1967 with some success, but better results were obtained using activated carbon, which was pilot tested starting in September 1967. A permanent carbon column was installed in July of 1968. Testing that took place during the dilution and filtration period showed dioxin concentrations in TCP ranging from 6,500 to 140,000 ppb in the unfiltered samples, and from <1,000 to 90,000 ppb in the filtered samples. The majority of the data during this period ranged from ~5,000 to 60,000 ppb. During testing with the pilot and permanent carbon column, dioxin concentrations in unfiltered samples ranged from <1,000 to 19,000 ppb, and dioxin concentrations in the carbon filtered samples ranged from 200 to 9,600 ppb. Less data were collected for the final product 2,4,5-T, but the dioxin concentrations were generally within the same range for the filtered and unknown filtration categories. Dioxin concentrations in Diamond's Agent Orange, a ~50/50 mixture of 2,4,5-T and 2,4-D ranged from 50 to 17,000 ppb (PAP-00142931; PAP-00143163-64).

According to the *Moomaw Report*, dioxin was detected in samples taken in the process downstream of the autoclave, with 73,000 ppb detected in recovered TCA in 1965 and 75,000 ppb detected in waste from a sump north of the process building where TCP was produced in 1968 (PAP-00143164).

Agent Orange

According to the DSCC's *Statement of Factual Premises*, Agents Orange, Purple and Pink each contained the ester 2,4,5-T, which in turn contained the contaminant, dioxin (PAP-00149723). The statement notes that during manufacturing operations at the 80 Lister Avenue plant small quantities of dioxin were created as an unintended impurity in the manufacture of TCP, an intermediate chemical used to manufacture 2,4,5-T acid and other products (esters and amines) derived from 2,4,5-T acid. This resulted in dioxin being present as an impurity in all the 2,4,5-T acid and its derivatives which Diamond manufactured and sold and at the plant site and its immediate environment. Agent Orange and other Agents consisted of either mixtures of 2,4,5-T esters or mixtures of 2,4,5-T esters and an ester of another product, 2,4-D (PAP-00149735).

Dioxin and 2,4-D

According to the *Moomaw Report*, the EPA has identified the manufacture of 2,4-DCP and 2,4-D as having a possibility of being associated with halogenated dibenzo-p-dioxins (PCDD) because of the reaction of an orthohalogenated phenol at high temperature (≥145°C) and alkaline conditions. However, the direct chlorination process used by Diamond and Chemicaland to produce DCP was carried out at a low temperature and low pressure. Temperatures in Diamond's DCP reactor and 2,4-D reactor ranged from 73 to 110°C and 99 to 109°C, respectively, from 1966 to 1969. These temperatures were lower than the temperature postulated by the EPA and, therefore, not conducive to dioxin formation. Dioxin was not expected to be associated with and was not tested for in DCP or 2,4-D during Diamond's "p-dioxin" testing in 1960 (PAP-00143165).

The *Moomaw Report* states that in a review of literature, dioxin was not found in samples of 2,4-D, 2,4-DCP, or 2,6-DCP from the 1960s or 1970s with detection limits ranging from 10 to 1,000 ppb. By the 1990s, with improved method detection limits, dioxin was detected in a subset of 2,4-D samples of unknown origin at a maximum of 0.13 ppb, and was not detected in 2,4-DCP at a detection limit of 0.1 ppb (PAP-00143165). As noted above, however, the use of the same equipment for 2,4,5-T and 2,4-D resulted in dioxin in the 2,4-D.

Other COCs

An August 2004 *Pre-assessment Screen and Determination for the Diamond Alkali Superfund Site* issued by the NJDEP and the Natural Resource Trustees, concludes that PAHs, PCBs and metals present on the Diamond Alkali property are also a legacy of manufacturing operations. The report notes that the total PCB maximum concentration was 47.7 ppm in a Passaic River core slightly downstream of the Lister facility. It did not discuss PCB contamination at the Lister facility (PAP-00210437; PAP-00210452).

An analysis of a soil sample from the site, appearing in a 1987 paper published in the scientific literature, found pentachlorophenol (PCP) in a site soil sample at a concentration five to six times greater than measured for either TCP or 2,4-dichlorophenol (DCP) (PAP-00399864-9). OCDF and OCDD were measured in this same site soil sample at concentrations greater than that measured for 2,3,7,8-TCDD (PAP-00399864-9).

Dieldrin

It is possible that dieldrin was present at the facility as a plant drawing dated February 14, 1959, shows four vessels labeled "Black Leaf 40" (a nicotine-based insecticide) (PAP-00402810). In March 1955, Diamond formed Diamond Black Leaf Corp. with Virginia-Carolina Chemical Corp. (PAP-00397571)**.** The Diamond Black Leaf formulating plants were located in Richmond, Va., Louisville, KY, Montgomery, AL, and Waco, TX. (PAP-00397571). Black Leaf advertisement shows a pesticide with 5% dieldrin; however, there is also a Black Leaf 40 product next to this product that does not state that it includes dieldrin (PAP-00400429).

PCBs

According to a ChemRisk 1990 Progress Report, MCB, DCB, T3CB, T4CB, HCB, and chlorinated pesticides are "rated as having high or very high potential for PCB contamination" (PAP-00184827). MCB, DCB, T4CB, and HCB were manufactured at the site via the chlorination of benzene (or lesser chlorinated benzenes), and MCB, DCB, 1,2,4-T3CB, 1,2,3-T3CB, and T4CB were utilized at the site as raw materials in various chemical processes (PAP-00399570-72; PAP-00399606-07; PAP-00402886; PAP-00403437-39). A Diamond Process Memorandum shows that Diamond knew that PCBs were a "possible byproduct" in the manufacture of HCB (PAP-00403454). PCBs were detected in soils, sumps and tanks on site. In 2015, contaminated soil samples from the site were collected and analyzed for contaminants including PCB congeners. In two of the five soil samples from this study (designated as DWC-3-0608 and DWC-3-0406), PCB-209 was the dominant PCB congener, with its concentration estimated at 58 percent and 49 percent of the total PCBs respectively in these samples. In these same two samples, PCB-12/13 was the PCB congener with the second greatest concentration (PAP-00398173-88.)

Therefore, PCBs were generated at the site as byproducts during chemical production. As discussed below, the autoclave sump overflowed to the Passaic River and the main building where HCB was manufactured and sumps were never connected to the industrial sewer.

In addition, Monsanto sales records show the purchase of 5,000 pounds of 16 1050 200 transformer inerteen PPO by Diamond Alkali in 1967 (PAP-00207137). Inerteen coolant contained PCBs.

PAHs

Kolker is listed as a producer of naphthaleneacetic acid in a 1948 article in *Chemical Industries (*PAP-00401714; PAP-00401717)**.** According to a 1950 article in the Journal of the American Chemical Society, the direct condensation of naphthalene with MCA was a synthesis pathway that was used to produce α-naphthaleneacetic acid (PAP-00400430**).** As described above, MCA was produced at the Diamond facility as it was a raw material in the manufacture of 2,4-D and 2,4,5-T. The production of α-naphthaleneacetic acid occurred during the pre-1956 time period when the site was not connected to the industrial sewer and all effluents were discharged to the Passaic River.

A Diamond Chlorinated Products Division – Newark January 1, 1962 Standard Cost document, lists Velsicol AR-50G as a raw material for a brush killer formulation (PAP-00399447). According to a 1947 advertisement, Velsicol AR-50G, contained methylnaphthalenes and provided co-toxicant properties for DDT and other insecticide solutions (PAP-00401702). A 1959 plant drawing of the facility showed a tank designated "Solvent AR50G" next to a "DDT solution" tank (PAP-00402810).

According to a 1968 Diamond Interoffice Memorandum regarding Dacamine History, with new laboratory facilities in 1961, a Dacamine formula was developed containing 880 Solvent. This solvent was blended at the Newark facility and was a blend of kerosene

and heavy aromatic naphtha (HAN). In 1965, the 880 solvent was replaced by an all-aromatic HAN (PAP-00396638-39). The use of kerosene and 880 solvent is documented earlier also as a kerosene storage tank and an 880 solvent storage tank appeared in the 1959 plant drawing (PAP-00402810). Kerosene contains a number of PAHs.

120 Lister

According to a May 1985 *Site Evaluation, 120 Lister Avenue,* the 2.2-acre property located at 120 Lister Avenue is a former chemical storage and shipping facility. An investigation by the NJDEP and EPA in the spring of 1983 established that portions of the property were contaminated with 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD), as was the adjoining property at 80 Lister Avenue (PAS-00125770; PAS-00125781).

During the period of ownership by Diamond of the adjoining 80 Lister Avenue property, Sergeant Chemical Company owned the 120 Lister Avenue property. The site was comprised of several major structures, including a brick building, a block building, and a tile building. The site was used by Sergeant to store, repackage, and distribute a variety of small-lot-quantity organic and inorganic chemicals (PAS-00125787-88). In November 1963, Diamond leased the parking lot from Sergeant. The lease was terminated when Diamond ceased production operations on the 80 Lister Avenue site in 1969 (PAS-00125787-88).

Recalcitrant Activities

In 1984, Diamond sued a number of its insurers in New Jersey Superior Court seeking coverage for environmental costs and property damage and personal injury claims (hereinafter referred to as the "*Aetna* litigation" or "*Aetna* trial") (PAS-00128423-24). Judge Stanton found that Diamond, as a matter of corporate policy, intentionally and continuously discharged dioxin, DDT, and other hazardous substances from the Lister Plant into the Passaic River during the entire period of its plant operations (PAS-00128449). Specifically, the trial court found that:

- "From 1951 to 1956, Diamond intentionally discharged all of its waste chemical effluent into the Passaic River." (PAS-00128425).

- In 1956, the Passaic Valley Sewerage District insisted that DSCC discontinue their discharges into the Passaic River and, in response, DSCC "purportedly tied its entire complex at the (Lister Plant) into an industrial sewer constructed by the Passaic Valley Sewerage Commission." (PAS-00128426).

- However, "(a)lthough Diamond purported to tie the whole (Lister Plant) into the sewer in 1956, it actually tied only the 2,4-D building into the sewer. The chemical effluent from the main building continued to be discharged directly into the Passaic River." (PAS-00128426).

- Those discharges "were intentional, planned discharges from processing equipment through pipes or ditches." (PAS-00128426).

- "In addition, from 1951 through 1969, spills onto floors and ground surfaces drained mostly into the Passaic River. These spills were constant, and, collectively, they were substantial in volume." (PAS- 00128426).

- "Diamond was conscious that its discharges into the (Passaic) (R)iver were illegal. It deliberately concealed them, and over a period of many years employed an alarm system to warn employees to stop the discharges when Passaic Valley inspectors were on the premises." (PAS- 00128426).

- "Over the years, discharges from the (Lister Plant) into the Passaic River included 2,4,5-T acid (and dioxin), caustic soda, DDT, sulfuric acid, TCP (and dioxin), muriatic acid and monochlorobenzene." (PAS- 00128426).

- "Housekeeping at the (Lister Plant) ranged from inadequate to poor throughout the entire period of its operation by (DSCC). . . . Spills of liquid and solid chemical products and wastes were literally continuous during every day of the plant's operations. Some pipes were always leaking." (PAS-00128427).

Walter Klosowski, who worked as a chemical operator at the Lister facility from July 1947 until 1953, stated in a deposition that "they would only clean up when they had an inspection" and that Mr. Kolker would notify the employees when there was going to be an inspection. According to Mr. Klosowski, "you faked everything" for an inspection and basically stopped working while the inspector was there so they did not see any materials get on the floor (PAP-00143640-42).

Mr. Burton noted in his 1987 deposition that "we didn't want to be caught violating the regulations" (PAP-00393948). In his 1988 deposition he explained that when an inspector checked in the receptionist would sound "I think it *was* three buzzes" on the inter-plant communication system which would alert the foreman and the operators that an inspector was at the plant. They would then take steps to see that anything going into the river at that moment was stopped (PAP-00159724-25). Mr. Burton also stated at the *Aetna* trial that he thought the alarm system was "a clever strategy" that he was "proud of" and it was a "joke within one echelon of the division" (PAP-00145115).

A deposition of Aldo Andreini who worked at the 80 Lister Avenue facility from 1955 to 1969 states that they were told not to "drop anything out to the river" when an inspector was there on a boat (PAP-00149596-98, 604, 607).

Arthur Scureman, a Lister Plant employee from 1951 until 1969, noted the following activities:

- He conducted early morning overtime work, which meant "put(ting) some stuff away in the river." He testified, "(a)nd I used to come in early, work overtime to drop it in the river because they didn't want the barges and everything going up and down see us dropping anything in the river."

- He further testified about the dumping of contents of barrels of waste material from the 2,4-D or 2,4,5-T Building into the Passaic River early in the morning while it was dark. Dumping occurred at night because Diamond management didn't want anybody along the river to see them dumping it. Employees were instructed to dump the unwanted product and waste slowly so that it would not later be visible in the water. He said that if a batch fouled up they would move it from the kettles that were maybe 500-1,000 gallons into drums and then get rid of it.

- Mr. Scureman also described his orders upon seeing the company's guard come in with inspectors, which was to "try and stop them so they don't go to the river front; and run in the building and the ester room and 2,4-D building and tell them to stop dropping all their stuff to the sewer, close off the valves." (PAP-00159632, 657-660, 670, 672).

In a July 10, 1956 memorandum regarding the "Newark Effluent Problem," Plant Manager Mr. Burton explained to B.D. Gleissner, an officer in Diamond's corporate office, prior to 1956 the Lister Plant had "rerouted our lines containing HCl to underneath the surface of the water so that they were never detected as a source of acid effluent." The memorandum continues:

> (PVSC) particularly specified that the 2,4-D alkaline filtrate would be satisfactory to go into the sanitary sewer, although at the time at least, they did not know about its high phenolic content. In general, I feel that if we clean up some of the materials which have some noticeable content of solids that we are not appreciably contaminating the river which has a tremendous flow at this point. The proof of this is our own planned river pump installation. The high phenolic content of our effluent however might some day be a serious problem if they try to make this an area where fish would live, but on the other hand they would first have to clean up the oil scum from the river which to date they have not been able to do. Nevertheless, in view of their strict rules which these various agencies have, we will have to continue to out-wit them as we have in the past or spend a substantial amount of money for neutralizing our effluent and for construction of a larger sanitary sewer out to Lister Avenue. Every year that we can stall this off we are saving ourselves a substantial amount of money and increasing the likelihood that we may have more land at that time to give us room to install some type of neutralization system. . . . Therefore, I think our fundamental position is safe at this location, although we may have to spend some capital and operating money to keep out of trouble if we are not able to continue to outwit the various agencies concerned with the Passaic River. In view of the recent activity of the (PVSC), we are going to study our effluent problem as much as time permits . . . and determine what we might do in the event that we are subject to really strict inspection and control (PAP-00143565-67).

A July 31, 1956 memorandum regarding the Newark Effluent Problem from Diamond's Central Engineering Department in Cleveland to John Burton states that "[e]vasive tactics are fine as long as they work, but discovery of such action by the Commission can lead to a change of attitude which could be serious" (PAP-00143600).

In addition, instead of tying the whole Lister Plant to the sanitary sewer as he told the PVSC, Plant Manager Burton informed his superiors of his plan to tie the 2,4-D process building to the sanitary sewer, but not the main building: "I think our best hope at this time is that we can keep out of serious trouble until we get our 2,4-D filtrate diverted to the local sewer and to hope that we will be able to get by with our various acidic effluents from the DDT, HCB and Miticide operations in our main building." (PAP-00396608).

In an October 16, 1957, Interoffice Correspondence from W. R. Taylor of Diamond's corporate office in Cleveland, OH to J. Burton, Mr. Taylor offered to talk to Mr. Burton prior to a meeting of the Water Pollution Committee of the Manufacturing Chemists Association about any problems or questions he wanted to bring up at the meeting. He offered to do this to reduce the possibility of "information leaking out that you and the company would rather not have outside our organization" (PAP-00143599).

A deposition of Chester Mysko, an employee at Diamond Shamrock, noted that he saw bad and good batches of product dumped into the Passaic River from the Lister plant and that this happened better than once a month. He also stated, "Anything could have been going on at night. That's when it usually went down in there anyway. They saved it until nighttime" (PAP-00161237). When asked if he noticed any difference between how much DDT was dumped into the river on different shifts he stated in trial testimony that it was done mostly at night. "If they had a bad batch it was at night. That's when there -- they clean their -- what do you call it on the boiler, the stack. They used to blow that. Everything was done at night." (PAP-00160328).

Health-Related Issues

Mr. Burton recalled that as early as 1950, Diamond's employees contracted a skin condition known as chloracne (PAP-00393911-12, PAP-00209828-29). According to the *Parette et. al. (2018)* article, not long after the dilution-filtration process was replaced by a steam stripping purification process in September of 1954, to remove 2,4,5-TCA from the crude 2,4,5-TCP, a chloracne outbreak occurred among the operators of the 2,4,5-TCP process at the facility (PAP-00210172).

At least by 1954, Diamond was aware that the chloracne was associated with the operation of the TCP production unit, specifically the autoclave (PAP-00144048). In his March 18, 1987 deposition, John Burton stated that they realized that the chloracne trouble was centered in the TCP unit. The individuals that operated the TCP unit were the first to get chloracne. He also noted that they had chloracne trouble in the 1950 to 1951 time period, which they blamed on making their own tetrachlorobenzene because of impure materials. However, the workers involved with the tetrachlorobenzene manufacturing would have also worked in the TCP unit (PAP-00167625; PAP-00167669).

According to *Supplemental Answers from Interrogatories*, from October 3, 1952 through October 24, 1968, 60 Diamond employees filed New Jersey Department of Labor (NJDOL) incident reports with respect to various dermatological conditions including chloracne experienced while employed at 80 Lister Avenue (PAP-00144040; PAP-00144046-47).

Nicholas Centanni, who worked for Kolker and Diamond at the Lister plant from 1948 to 1969, testified that he developed chloracne "around" 1955 (PAP-00149589); according to interrogatory responses, he was one of the individuals that filed a New Jersey Dept. of Labor incident report on April 29, 1953 for "various dermatological conditions, including chloracne" (PAP-00144046). Mr. Klosowski estimated that, 90 percent of the employees at the plant were experienced these conditions (PAP-00143679-80).

The *Supplemental Answers from Interrogatories* also states that after the 1955 chloracne outbreak, Diamond "installed improved ventilation in the production facilities and renovated the floors to facilitate cleaning and to improve housekeeping. Employees were informed of the necessity to be scrupulously careful to avoid contact with material within the process stream. TCP workers were issued fresh uniforms daily and were afforded an opportunity for a daily shower at 80 Lister Avenue on company time" (PAP-00144049).

Maintaining temperatures below 155°C to minimize the formation of dioxin was recommended by a German company producing TCP (PAP-00155172). A September 18, 1957 Diamond memorandum, regarding pentachlorophenol and chloracne, states that an individual from the company Boehringer visited the plant and stated that the production of TCP produced a very toxic chemical, 2,3,7,8-TCDD, linked to chloracne if the autoclave temperatures were above 155°C (PAP-00155172). The same memo states that "[i]t is quite likely that by dropping our reaction temperature 15° or more from . . . our current level of operation of 170° C, we may suffer a significant decrease in reaction rate and prolongation of our reaction cycle time. (PAP-00155172).

A Diamond employee in 1957 also diagrammed 2,3,7,8-TCDD and identified it as the cause of chloracne (PAP-00155172). A 1959 Diamond memo recognized that Diamond understood temperature to be the primary factor in the incidence of chloracne, but the memo did not indicate any plan to lower autoclave temperatures (PAP-00159618). Diamond found that higher autoclave temperatures created faster chemical reactions in the autoclave, which in turn lowered costs. However, the higher temperature also generated more 2,3,7,8-TCDD. In former Diamond plant manager Gordon Steward's testimony as a witness for Diamond in the *Aetna* litigation by Diamond against its insurers, he acknowledged that if Diamond had reduced the temperature in the autoclave, it would have reduced the production of dioxin, but also reduced the amount of product that was made (PAP-00144510, 523-526). Dr. T. W. Fraser Russell, Diamond's expert in the personal injury litigation by former Diamond employees and neighbors, opined that adopting Boehringer Sohn's suggestions "would have resulted in a far less productive and significantly less economic operation of the plant." (PAP-00455678-80).

A 1963 Diamond memo states that "[a]s long as [the Lister P]lant has been in operation, there has been a chronic problem in the employees hired of an acne condition which is referred to as chloracne. At one time, some 40 of these 72 workers in the plant were so affected with the chloracne." (PAP-00143596). In March 1963, a doctor from the United States Department of Health, Education, and Welfare investigated the plant and found "breaks in the process, evidenced by contamination of equipment, ceilings, floors, stairs, and hand railings, particularly in the old building." (PAP-00154191). The doctor recommended that every man in the plant be subject to testing due to chloracne (PAP-00210167). Harry Weiner of Diamond's corporate office rejected this recommendation due to his concern that a "disorganized group from a government agency entering the plant . . . might well result in very wide and unfair newspaper publicity as is usually done to sensationalize." (PAP-00143541).

According to DSCC's *Statement of Factual Premises*, Dow identified dioxin as the chloracnegen in 1965 and provided Diamond and others in the industry with a method to measure the very small quantities of dioxin present in the "T" process stream (PAP-00149741). According to DSCC's *Statement of Factual Premises*, thereafter Diamond attempted to devise a method to reduce or eliminate the dioxin present in its process stream. After other unsuccessful efforts, Diamond installed a carbon adsorption tower in 1967. Thereafter, the amount of dioxin present in the 2,4,5-T process stream at the 80 Lister Avenue plant was substantially reduced, although the amount that did remain was above the "action level" for dioxin that regulatory authorities eventually adopted in the 1980's (PAP-00149741).

4. Identified COCs

- PCBs (used, released, detected)
- Dioxins and furans (used, released, detected)
- PAHs (used, detected)
- DDT (used, released, detected)
- Dieldrin (detected)
- Mercury (detected)
- Copper (detected)
- Lead (detected)

5. COC Pathways

Effluents to Passaic River

On June 28, 1949, an inspector with the PVSC found Kolker was discharging "rusty scale and soda wash water" into the Passaic through floor drains. This was noted to be due to cleaning out of condenser tubes which was done once every 6 months. The report of this inspection notes that the owner "promised that he would divert the discharge into the sanitary sewer" going forward (PAP-00394464-65). A deposition of John Burton stated that the USACE also informed Kolker that its discharges were illegal (PAP-00167643; PAP-00167779).

An April 1960 Diamond memorandum from John Burton states that until approximately 1956 Diamond disposed of all of its plant effluents in the Passaic River. According to the memorandum, in approximately 1956, the PVSC officially objected to Diamond's pollution of the river and the company spent about $15,000 for a sewer connection to the Newark city sewer. The memorandum further states that "[s]ince that time, we run some of our effluents to each of these outlets." (PAP-00155169).

According to Mr. Burton in his October 17, 1988 deposition, there were several pipes projecting out from the river bulkhead and he believed that most of the individual sources of effluent each had its individual pipe that was connected to it that led to the river (PAP-00159710). Walter Blair, who worked as a pipefitter and mechanic at the Lister Plant from 1953 to 1969, stated that there were a "half dozen or so" pipes leading to the river (PAP-00160987).

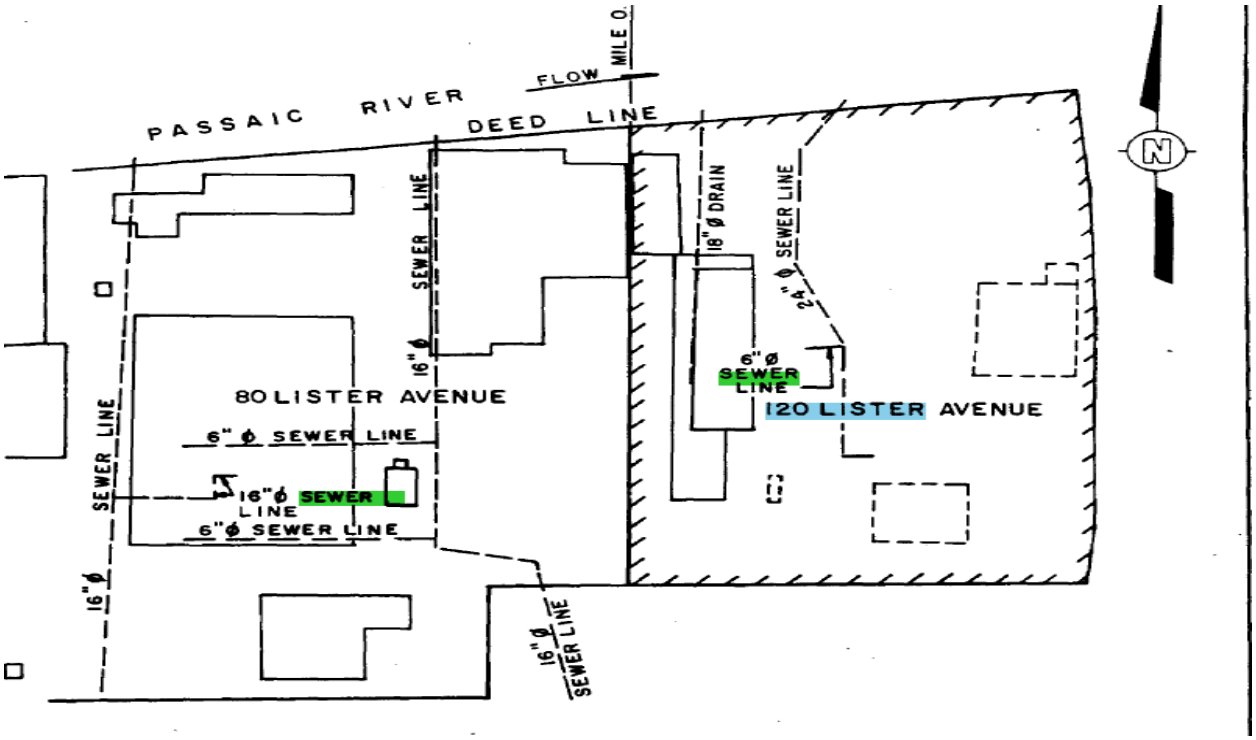
According to the *1985 80 Lister Avenue Site Evaluation*, an easement was obtained to construct a 10-inch sewer under the Central Railroad of New Jersey tracks in January 1956. A sewer connecting the plant to the PVSC sewer was subsequently installed. The report notes that following construction, most process wastes were diverted from the river to the PVSC treatment plant (PAS-00126867**;** PAS-00126910). However, as stated in the 1960 memorandum referenced above only some of the effluent was sent to the PVSC (PAP-00155169).

Mr. Burton stated in his March 18, 1987, deposition that in 1956, the sewer line was connected only to the 2,4-D building. He noted that it would have been possible for us to have pumped some waste material from the main building to the sewer connection in the 2,4-D building, but he did not recollect doing that and said it was very probably they did not do it. In other words, the effluents from the trichlorophenol, DDT and monochloroacetic areas continued to go directly to the river after 1956 (PAP-00167625; PAP-00167786-88). The Lister plants post-1956 discharges were from its ongoing production of DDT and dioxin-generating chemicals in the Main Building as follows:

Chemical	Building	Years
DDT	Main Building	1956-1957
TCP TCP	Main Building Reconstructed Main Building	1956-1960 1960-1969
2,4,5-T	2,4-D Building (partially connected to PVSC)	1956-1969
2,4-D	2,4-D Building (partially connected to PVSC)	1956-1969

(PAP-00167625; PAP-00167786-88).

Diamond discharged TCP and 2,4,5-T contaminated wastewaters directly into the Passaic River until its operations ceased in 1969. Based on the record presented at trial, the Appellate Division concluded: "A number of former plant employees testified concerning Diamond's waste disposal policy which essentially amounted to 'dumping everything' into the Passaic River." Former plant manager John Burton reported that as of 1959, Diamond discharged about 100 tons of 2,4,5-T effluents to the river. According to Mr. Burton, the effluent "would consist of mostly trichlorophenols…" (PAP-00155170).



At the *Aetna* trial, Burton revised his earlier estimates and stated that 471 tons of chlorophenols would have been discharged in waste each year (PAP-00145137). An engineering firm retained by the insurance companies in the *Aetna* litigation estimated that 100 tons of 2,4,5-T containing a 1 ppm dioxin concentration would have resulted in a single-year discharge to the river of four pounds of dioxin. Diamond's 2,4,5-T streams contained 2,3,7,8-TCDD as high as 140 ppm (PAP-00143526).

The discharges included wastewater from the operation of the anisole still from September of 1954 through February 1960. The Na-TCP solution (coming from the autoclave following distillation of methanol) was steam stripped to remove the unreacted TCA. The water (condensed from steam) and TCA were condensed and separated in the anisole still. The water from the anisole still, approximately 4 pounds for every pound of TCP produced, was discarded to the Lower Passaic River (PAP-00399786; PAP-00144997; PAP-00145089–90). In 1965, recovered trichloroanisole was measured to contain 73 ppm of 2,3,7,8-TCDD (PAP-00167096).

A reconstruction by *Parette et al. (2018)* of the chemical processes at the site "identified dilution-filtration, a 2,4,5-TCP purification process [that was utilized prior to September 1954], as the major pathway by which 2,3,7,8-TCDD was discharged to the [Passaic River] from the Lister Avenue site." (PAP-00210175).

In 1960, Diamond stated that it was discharging 30,000 gallons of process wastewaters per day, one-third of which "could have contained some dioxins." (PAS-00128474). Diamond also estimated that in 1960 the plant was generating up to 15,000 gallons per day of waste water from the 2,4-D and 2,4,5-T esters alone (PAP-00162277). Later in a confidential report on water pollution control to the Manufacturing Chemists Association in 1967, Diamond reported that it had three water-borne waste discharges to surface waters, and a fourth that discharged both to the sewer and to the river. In the report, Diamond acknowledged that it discharged to the river 8,700 pounds of dissolved inorganics and 1,780 pounds of dissolved organics each day (PAP-00154809). In 1969, Diamond completed another confidential MCA survey concerning its waste practices. In it, Diamond disclosed it was discharging 8,540 gallons per day of untreated effluent to the River (PAP-00399044).

According to the March 1986 *Passaic River Sediment Study* prepared by International Technology Corporation, in 1960, during work required to stabilize the river bank at 80 Lister Avenue, several sewer pipe discharge lines to the river were discovered. All of the uncovered conduits were plugged with concrete when the new bulkheads were constructed. Information available at the time of the report indicated that there were no conduits open to the river remaining at this installation. The figure below shows the locations of several lines at the 80 and 120 Lister Avenue sites (PAP-00151172; PAP-00151185).

(PAP-00151199)

Mr. Centanni testified that sulfuric acid from the plant was “riverized” (sent to the river through aboveground lines). These lines could be seen at the river, particularly at low tide (PAP-00149554, 559-564). He said that all of the buildings had trenches going to the river (PAP-00149574; PAP-00145255). Mr. Burton also described trenches in the TCP and 2,4-D/2,4,5-T buildings that released to the river (PAP-00167674-77).

Arthur Scureman also testified about Diamond’s discharges to the Passaic River. He described dumping the contents of drums into the River following the 1960 explosion (PAP-00145048). He described the trench system outside the building in which 2,4-T and 2,4,5-T was made, which led to the Passaic River and that before Diamond installed a catch basin, “everything used to go . . . to the river.” (PAP-00159632, 657-659, 670, 721). Mr. Centanni stated that liquids in the sump were pumped out into catch basins that went to the river or they would send it out through the city line (PAP-00144132-33).

Mr. Blair testified that in the mid-1950’s a pit was constructed to hold the wash waters from the D and T acid building and any overflows were rerouted so they no longer flowed into the river. When they first put the pit in they did clean it and put the wastes into drums and then they stopped doing that and started pumping to the river; when the pit filled, Diamond heated the pit contents and sent those to the Passaic River (PAP-00155385-86; PAP-00155426-28; PAP-00155411-12). Diamond was cited by the USACE on two occasions in 1965 for spillage of overflow to the Passaic River from the TCP acidification unit in mother liquor recovery (PAP-00403309; PAP-00144701-02). In 1966 the overflow from the T sodium sulfate tank was diverted from the river to the sewer (PAP-00403431).

Former employee, Mr. Papciak, stated that there were two 10,000-gallon TCP storage tanks alongside the process building. Sometime after 1960 he cleaned the tanks when necessary. He emptied the product and filled it up about two-thirds with water, draining to the river (PAP-00394595-96).

A Diamond internal March 26, 1960, memorandum, states that the "waste disposal problem" pertained to muriatic acid, the 2,4,5-T acid process, the 2,4-D acid process, the caustic scrubber (2,000 gallons to the river daily), wash waters from 2,4-D and 2,4,5-T esters, and sulfuric acid from the scrubbing towers. The plant was noted to have a 10" clay pipe sewer line which connected to the "City Industrial sewer." This line was principally used for dumping wastes from the D and T acid units (PAP-00394422-24).

Sludge and Residue to Passaic River

February 5, 1954, Operating Instructions for 2,4,5-Trichlorophenol, state that sludge and acid waters were discarded (PAP-00155445; PAP-00155450). Following extraction of the 2,4,5-TCP, the unreacted organic sludge was discarded to the "sewer." In this context, "sewer" referred to a series of drain pipes leading from the buildings at the site to the Passaic River as, all plant effluents, including sludges, were discharged into the river prior to connecting to the PVSC in 1956 (PAP-00210172).

Mr. Centanni testified that sometimes, an "operator would follow up and instead of letting just the acid go to the river, something would distract them or he'd put the valve in the wrong position and he would send DDT, acid and everything to the river and there was a time they had a mountain of DDT and I mean a mountain of it because [it] solidifies when it hits [the] water (PAP-00145264). He also testified that [w]hen it got real cold, the Passaic River would stay at low tide and then you would see it" (PAP-00145265). Mr. Blair also testified that there was a pile of DDT in the river (PAP-00155439). Mr. Mysko testified that he "was sent in the river at low tide to chop what we used to refer to as the mountain of DDT" and his supervisor told him "[t]o get this DDT out of the river because it was too obvious for boats going by." (PAP-09160322–23).

According to Arthur Scureman, when the tide would go down, there was like an island of DDT in the river. He said they would put a rope around him and he would go down in there and watch the tide and chop the DDT with an ice chopper and put it in drums (PAP-00159626; PAP-00159660661).

In his deposition, Mr. Klosowski also described being hired by Mr. Kolker in around 1951 to go out into the river on his day off on a boat with his father to hoe down a big mound of residues in the Passaic that had come from the 2,4-D plant because the mound was sticking out of the water. They would chop it down and spread it out in the river so it was not visible. He said the same thing happened in 1954 but he was not the one who went out as the first time the paint on his boat was damaged (PAP-00143643-46).

2,3,7,8-TCDD was discharged to the Lower Passaic River with the disposal of waste salt (NaCl) from the cleaning of the Na-TCP storage tanks. The reactions to manufacture TCP resulted in the formation of approximately 800 pounds of NaCl in each batch of TCP (large autoclave), of which approximately half would precipitate (PAP-00159095-6;

PAP-00399789-92). A 1960 Diamond memo stated that the NaCl precipitated in the Na-TCP storage tank, requiring cleaning approximately every 6 months (PAP-00399789-92). The Na-TCP solution retained in the precipitated NaCl was discharged to the River in this cleaning process (PAP-00167697-700). Plant manager Burton testified that the Na-TCP storage tank was cleaned by pumping it as empty as possible, washing the tank with water, physically shoveling the contents (primarily NaCl), and disposing the shoveled-out contents and the wash water into the river (PAP-00144997; PAP-00145091–92). The residue from the cleaning of the Na-TCP storage tank was recognized in a 1987 site report prepared for Defense Steering Committee in the *Aetna* litigation as a source of "dioxin-containing materials." (PAP-00160071; PAP-00160077).

After the 1960 explosion which destroyed the Main Building, but prior to the 1961 start-up in the new Process Building, the two 15,000 gallon "[Na-]TCP storage tanks were washed out, repaired, and relocated." (PAP-00399797). In 1965 Diamond estimated that the TCP in the Na-TCP storage tanks contained approximately 12 pounds of 2,3,7,8-TCDD (PAP-00399568-69).

According to Diamond's *1983 History and Operations Overview of Lister Avenue Facility*, process wastes included filter cake from product filtration, spent carbon from the carbon column and sludge removed from the process area waste sump. In 1967, these wastes totaled eight tons per year. In 1969, the wastes totaled three and a half tons per year. A carbon column was installed to remove dioxin from the TCP production in September 1967. The first column was a "pilot" unit and was 12" in diameter. This unit was used from September 8, 1967, until the installation of a full-scale column in July 1968 during the plant's annual shutdown. In January 1969, the carbon in the "new" column was replaced. This carbon was in use when production of 2,4,5-T was discontinued in July 1969. The carbon bed was washed with acid when the dioxin level of the TCP could not be maintained at an acceptable level, or the column plugged. The dioxin was bonded to the carbon. The spent carbon was drummed and disposed of off-site by a waste disposal contractor. This appeared to be done in January 1969. After the process was shut down, the column was reportedly included in the sale to Chemicaland Corporation (PAS-00128475).

Spills and Leaks

DSCC's *Statement of Factual Premises* notes that contamination of the Lister facility from Diamond's 2,4,5-T production process resulted from numerous small, largely unidentifiable, leaks and spills (PAP-00149742).

However, the trial Court's Opinion in the *Aetna* litigation, decided April 12, 1989, stated that there were constant spills and leaks onto the factory floors and the outdoor ground surfaces of the "Newark plant." According to the Opinion, considered one at a time and in isolation from each other, many of those spills and leaks might qualify as accidental. However, considered in their totality, as they must be in order to do justice to the realities of this situation, the spills and leaks establish a definite pattern of operation. Toleration of substantial and continuous spilling and leaking was the way of life at the "Newark plant." The Opinion also states that factory floors at the "Newark plant" were so badly corroded by acid spills that they had to be replaced nearly every summer. Trenches and

sumps frequently backed up and overflowed onto ground surfaces. Chemical stains and deposits on ground surfaces throughout the site were clearly visible to the naked eye. Visitors to the plant had to wear overshoes and slickers to protect their clothing. Floors were replaced so that people could walk without falling and hand trucks could be wheeled where needed, but nothing was done to mitigate the polluting effect the spills and leaks had upon the physical environment (PAS-00128449-50).

According to the documents and deposition testimony, the Aetna defendants' engineering consultants estimated that the process spills and leaks resulted in 96 pounds of 2,3,7,8-TCDD in the soil at 80 Lister Avenue. The consultants did not estimate how much 2,3,7,8-TCDD the Lister facility discharged to the Passaic River (PAP-00160078).

According to the *Moomaw Report*, after the explosion in 1960, the new process building was equipped with a concrete-lined trench that ran its full length and serviced the tank farm on the east end of the building and collected floor spills and leaks from the MCA and DCP chlorinator and TCP methanol areas and process discharges (e.g., spent acid from the carbon column). The trench led to a sump that overflowed to the industrial sewer and then to PVSC. Two additional concrete-lined sumps were located outside of the process building on the north side by the autoclaves and the hydrochloric acid process. Overflows from these sumps were connected to the river and received dioxin wastes from autoclave upsets, TCP vents routed through the air scrubber, and the anisole still (PAP-00143166). As stated above, in 1968, dioxin was found at 75,000 ppb in the sump receiving anisole waste.

Information from depositions regarding spills and leaks include the following:

- **Scureman**: In the 2,4,5-T and 2,4-D Building, material was all over the floor and the pumps and centrifuges leaked (PAP-00159649-51). Every summer they would shut everything down and fix the floor and sewers. After a year the sewers used to fall apart and the acid running on the floor ate up the concrete (PAP-00145044).

  Mysko: In later years when I was a mechanic, I used to drain pumps and drain piping right on the ground. I was told to do it. Drain it, fix it, hose everything down into the river (PAP-00160310). Mr. Mysko also stated that if you walked in the 2,4,5-T area you went sliding. You had to be very careful because it was all over the place, it was like an oily substance, and the water did not even wash it down. Therefore, what they used to do was wash it down with sulfuric acid. They used to soak the whole floor with sulfuric acid, let it sit for an hour or two and hose it down and everything went into the river, sulfuric acid and 2,4,5-T and everything that was on that floor (PAP-00161238). When employee Mr. Mysko was asked if his supervisor knew spills were being washed into the River, he responded, "[i]t was company procedure." (PAP-00161212-13).

- **Centanni**: Sump pits would overflow and go all over the land (PAP-00144130).

- **Blair**: When the floors at the Lister Plant were washed down, the wash water went directly into the Passaic River. He also stated that there were open trenches in the

floor of the DDT Building and the 2,4-D Building that released to the Passaic River (PAP-00155385-86; PAP-00155436; PAP-00155405; PAP-00160985).

- **Centanni**: Sulfuric acid was used to clean the concrete floors of the 2,4-D and 2,4,5-T plants and warehouse, “cause we’d get all that gum, you know, from a spill, from a spill of chemicals.” He noted the floors where the DDT was made were dirt (PAP-00149565-66; PAP-00145246). When cleaning the concrete floors they scraped the material from the floors and put the “hard stuff” in drums for disposal at the dump and whatever else was left would go into an open sewer that released to the river. When asked what chemicals were spilled he said 2,4-D and 2,4,5-T (PAP-00149568-70; PAP-00145249).

- **Andreini:** Worked in the formulations area from 1955 to 1969, which had trenches so that if there was a spill, which occurred if a drum had a leak, the discharge would go on the floor and it would be washed down into the trench and go out into the river. He noted that this occurred through 1969 when the operations ceased. He also stated that he had seen wastewater being discharged to the river from the ester unit and possibly from the 2,4-D unit and the warehouse. He did not know what was being discharged specifically. In addition, drums leaked when being filled and this material would go into the trenches to the river (PAP-00149596-98, 604, 607).

- **Papciak**: The old building was a dump (PAP-00394782). The railings had about half an inch of DDT all over. There was DDT hanging all over the place, up on the ceilings. Like somebody blew a batch and wasn't finished. In the dryer they would shoot up the vent and DDT would come up the vent, hit the ceiling and it would just stick up there. . . . All the dust would be all over the place. The walls, everything, got DDT on it. The floor was always white with DDT (PAP-00394773-74).

Autoclave Blowdown Sump Discharges

After the reconstruction of the Lister facility in 1960, the two (2) new 1,000-gallon autoclaves for TCP manufacturing were located outside the Process Building between the building and the LPR (PAP-00403468-69). A sump, referred to as the autoclave blowdown sump, was located between these autoclaves and the river (PAP-00403441). Pressure relief valves from the autoclaves (where 2,3,7,8-TCDD was formed) were directed to pipes which were submerged in this sump so that methanol released from the autoclaves could be adsorbed by the water for additional safety (PAP-00403469). The sump was maintained full of water by passing process cooling water through the sump before the water overflowed to the river (PAP-00403469; PAP-00144430). Sediments in this sump were analyzed in 1968 and showed 2,3,7,8-TCDD levels of 75 ppm (PAP-00167212).

Air Dispersion

According to DSCC’s *Statement of Factual Premises*, the contamination of "offsite" locations by dioxin that migrated from the 80 Lister Avenue plant site appears to have been the result of windblown and personal and vehicular tracking. The major concern of

the USEPA and the NJDEP in 1983 was "wind blown spread of dust" and tracking by persons or vehicles. In addition, during the time the plant was operating small amounts of dioxin may have escaped into the environment through vents or even through the scrubber system. Vents and scrubbers operated continuously while TCP and 2,4,5-T was being manufactured. On occasion safety discs on the TCP autoclave ruptured, releasing some of the autoclave's contents to the atmosphere in whatever stage the TCP reaction was in at the time of rupture (PAP-00149743). Numerous rupture disc releases occurred at the site (PAP-00403308; PAP-00143619-20; PAP-00159095-6; PAP-00399842-4; PAP-00159874-80).

Prior to the 1960 explosion in the main building, rupture disc releases were directed towards the river (PAP-00167812–13). Releases from the rupture disc also went onto the cement adjacent to the river and the residue was washed with hot water to the river (PAP-00143667–68). Following the plant rebuild, rupture disc releases were directed to atmosphere above the roof (PAP-00154262-63).

A former employee, Mr. Blair, recalled one incident when a disc in the autoclave ruptured and material was found on the cars in the parking lot. He testified that the plant manager at the time “told us to get them cleaned up” (PAP-00155397-98). Mr. Blair did not recall the date this happened (PAP-00155397). Mr. Homer Smith also recalled gasses being released to the atmosphere when a disc ruptured in the TCP autoclave (PAP-00159874-75). Mr. Centanni stated that material from the scrubber would settle on the cars in the parking lot and “pit the paint jobs” (PAP-00144140-41).

In his deposition, Mr. Michael Catania, former Deputy Commissioner of NJDEP, stated that dioxin had been found in an eight to ten square block area around the 80 Lister plant. He noted the source of the dioxin to be dioxin particles on soil that was blown around by the wind, mud in vehicle tires and on shoes, as well as rain washing sediments around (PAP-00394121-22).

1960 Explosion

On February 20, 1960, an explosion and fire occurred in the NaTCP autoclave reactor in the Main Building. The pressure and temperature rose rapidly in the reactor first causing a rupture disc on the reactor to blow and venting the reactor material to the Passaic River (PAP-00142884). The explosion knocked the northwest corner of the building into the river (PAP-00159643). The Aetna court concluded that “The explosion must have spread dioxin contamination throughout the plant site and onto nearby properties.” (PAS-00128438). Diamond stated that there “may have been some residual materials that entered the River system during the cleanup.” (PAP-00151185).

Flooding and Rain Runoff

DSCC’s *Statement of Factual Premises* states that other mechanisms for migration that have been identified are tidal flooding and the movement of dioxin-bearing earth particles in rain runoff (PAP-00149743). Stormwater from the site entered the LPR via storm sewers and surface runoff (PAP-00209638; PAP-00209650).

Some amount of 2,3,7,8-TCDD was discharged to the river through the Process Building roof drain as a result of precipitation. Following the construction of the new Process Building, the roof drain from this building discharged directly to the river. Discharges from the TCP process, specifically the vent from the anisole drop tank and the release point for rupture discs were directed to the roof (PAP-00154266). Wipe samples taken from the roof of the Process Building detected 2,3,7,8-TCDD (PAS-00127131). Partial inundation of the Lister facility from the Passaic River was reported in 1983. (PAS-00126928).

6. Regulatory History/Enforcement Actions

Violations

1949: On June 28, 1949, an inspector with the PVSC found Kolker was discharging "rusty scale and soda wash water" into the Passaic through floor drains. As stated above, John Burton, plant manager, testified that the USACE also informed Kolker that its discharges were illegal (PAP-00167643; PAP-00167779).

1956: On Monday July 2, 1956, Inspector Frank Capone and Mr. Burton, the Diamond Alkali Chemical Co. plant manager, inspected various pipes that were discharging cooling water. During the inspection, Inspector Capone noticed a colored discharge coming from a 6" broken cast iron pipe. A sample was taken of the pink colored fluid coming out of this pipe and was sent for analysis. On July 5, 1956, Inspector Capone, Mr. Andoline, and Mr. Goldberg made another inspection of the plant and told Mr. Burton about the violation after taking another sample. Mr. Burton promised to cooperate and make a change within one week (PAP-00147843; PAP-00168549).

A letter dated July 7, 1956 was received by the PVSC from the Diamond Alkali Chemical Co. signed by Mr. Burton stating that the 6-inch broken clay pipe that was discharging into the river was diverted into the Newark city sewer. On July 20, Inspector Frank Capone made an inspection at Diamond and found the 6-inch pipe again discharging into the river. A sample was taken from the 6-inch pipe and also from the pump with a one and half inch pipe connected to an open tee discharging on the concrete flooring and flowing into the river. Two other samples were taken, one from a wooden flume and the other from the rear of the south end building flowing over planking on the dock. Analysis of these samples indicated that all of the samples had a bad odor, oily content, pH 9 or more and were polluting the river (PAP-00147848).

On July 31, 1956, men were digging, laying pipes, and breaking concrete when PVSC Inspector Frank Capone visited the premises. Mr. Burton explained that he was rearranging the pipelines to clear up the situation (PAP-00147856).

On August 3, 1956 the Diamond Alkali Co. received a notice of violation (NOV). The provisions of a law of the State of New Jersey known as Title 58, Chapter 14, Sections 7 and 8 of the Revised Statutes of New Jersey (PAP-00143727). Section 7 of Title 58, Chapter 14 indicate that discharge of sewage or other

polluting matter into certain waters was prohibited. Section 8 of Title 58, Chapter 14 indicates that discharge of sewage or certain other matter, particles, or substances into enumerated waters was prohibited (PAP-00143728).

During the daily inspection of District No. 8 from August 13 to August 17 and from August 27 to August 31, 1956 it was found that the Diamond Alkali Co., plant was discharging to the Passaic River (PAP-00147865).

As indicated in a letter dated September 4, 1956, PVSC indicated that the Diamond Alkali Co. has been cooperating in every way. They completed a piping program, which emptied their industrial waste into the sanitary sewer. Their deck area had been thoroughly cleaned and nothing but cooling and condenser water was noted as going to the river. Additional repeated inspections showed no violations (PAP-00147936). However, as noted above, Diamond only connected one of its buildings to the PVSC system.

1964: In a letter dated October 13, 1964, during a routine inspection of the waterfront facilities along the south shore of the Passaic River, the Assistant Supervisor of the New York Harbor observed a concentration of foreign matter, which contained an acid content. The letter stated that further investigation of this matter revealed that this pollution was caused by an acid discharge from inside the Diamond Alkali plant into discharge pipes located in the east and west end of the bulkhead and emptied into the Passaic River at the foot of Lister Avenue. This violation was brought to the attention of Messrs. Homer Smith, Plant Manager, and W.C. Hill, Engineer Production Supervisor at Diamond Alkali. The Diamond Alkali plant was given 30 days to investigate this discharge, after which a reinspection of the area was to be conducted to ensure compliance with Federal regulations (PAP-00143387).

1968: On August 23, 1968, the U.S. Coast Guard reported that while on a routine antipollution inspection of the facilities along the Passaic River in the vicinity of Newark, New Jersey, it tested the liquid effluent from the Diamond plant at Lister Avenue and found it to be acidic in nature. Mr. E. Bak, Production Superintendent was contacted and made cognizant of this violation (PAP-00143378).

Diamond employee A.L. Gregoric wrote an internal memo on October 18, 1968 to W.R. Taylor of the corporate office informing him of the violation. The memo stated that Diamond typically discharged about 1,000 gallons of used sulfuric acid containing organic materials twice per week (PAP-00143604-06). Shortly after, Taylor wrote an internal memo noting that Lister has “a history of repeated violations. It seems that on every Coast Guard spot check of this plant we have a bad violation . . . .” (PAP-00143601).

As found by the New Jersey trial court in the *Aetna* litigation, Diamond “intentionally and continuously discharged highly toxic chemical effluent into the Passaic River from 1951 to 1969.” (PAS-00128449). According to the court, Diamond’s discharges were “intentional, planned discharges from processing

equipment through pipes or ditches." (PAS-00128426). On appeal, the New Jersey Appellate Division agreed with the trial court's conclusions: "We are convinced from our examination of the record that Diamond intentionally and knowingly discharged hazardous pollutants with full awareness of their inevitable migration to and devastating impact upon the environment." (PAP-00158858).

Regulatory Actions / Administrative Consent Orders

1983: On June 2, 1983 Administrative Order No. E0-40-1 was adopted, which issued a presumptive fishing advisory in certain waters pending the analysis of fish and shellfish samples. The results of the testing indicated that fish and shellfish from the Passaic River were contaminated with dioxin in excess of the safe level thereof established by the Food and Drug Administration (PAP-00142877).

On October 10, 1983 New Jersey Governor Thomas H. Kean issued Executive Order No. 40 declaring that a state of emergency exists arising from the dioxin contamination of the premises at 80 Lister Avenue, in the City of Newark, New Jersey, and authorized New Jersey Commissioner Robert E. Hughey to make any necessary emergency measures deemed necessary to protect the health, safety and welfare of the citizens of New Jersey (PAP-00142877).

Commissioner Hughey issued Administrative Order E0-40-17, prohibiting the sale or consumption of fish and shellfish taken from the Dundee Dam in Garfield/Clifton to the mouth of that River at Newark Bay (PAP-00142877).

Diamond Shamrock Chemicals Co. v. Aetna Cas. & Sur. Co., Civ. Action No. C-3939-84 (Sup. Ct. N.J, April 12, 1989) ("Aetna"); *Diamond Shamrock Chemicals Co. v. Aetna Cas. & Sur. Co., 609 A. 2d 440 (N.J. Super. A.D. 1992)*; *cert. denied*, 634 A. 2d 528 (N.J. 1993). – The Aetna court denied Diamond's claim for environmental cleanup costs. The Aetna court found that Diamond's waste disposal practices for the entire time it operated the facility were intentionally violative of both good practices and the law. The court found that despite specific statutory prohibition, Diamond intentionally discharged all of its waste chemical effluent into the Passaic River, and that the "[t]he discharges were . . . intentional, planned discharges from processing equipment through pipes or ditches." (PAP-00159460).

1984: On March 13, 1984, Diamond Shamrock entered into an administrative consent order with the NJDEP. The order required that Diamond Shamrock undertake certain actions to secure the site, prevent exposure to contaminants, and determine the vertical and horizontal extent of chemical contamination. The initial phase of the order required the preparation of a work plan, the completion of a site evaluation, and a feasibility study of remedial alternatives (PAP-00149705).

Diamond Shamrock submitted a Work Plan for the initial phase to the NJDEP on April 18, 1984. As a result of NJDEP review comments, the Work Plan was revised and an addendum was submitted on June 20, 1984. Subsequently,

NJDEP approved the amended Work Plan and it was implemented. Mobilization of equipment and personnel to the site along with initial remedial activities commenced August 20, 1984. The actual investigation/sampling effort was conducted from September 5, 1984 through October 26, 1984 (PAP-00149705-706).

1994: OCC signed an Administrative Order on Consent (AOC) with the EPA to investigate a 6-mile stretch of the Passaic River centered on the Diamond Alkali plant. The primary objectives of the investigation were to determine: (1) the spatial distribution and concentration of hazardous substances, both horizontally and vertically in the sediments; (2) the primary human and ecological receptors of contaminated sediments; and (3) the transport of contaminated sediment (PAS-00033297).

Sampling results from this study, as well as other earlier sampling events taken across from and immediately downstream of the Diamond Alkali Facility portion of the Site show concentrations of 2,3,7,8-TCDD that significantly exceed the levels that can produce toxic effects to biota. Recent studies have shown that 2,3,7,8-TCDD bioaccumulates in fish, to levels rendering the fish unfit for human consumption, from sediment with a much lower level of 2,3,7,8-TCDD than found in these sediments (PAS-00033335).

These sampling results demonstrated that evaluation of a larger area was necessary because sediments contaminated with hazardous substances and other potential sources of hazardous substances are present along at least the entire 17-mile stretch of the Lower Passaic River and were further dispersed by the tidal nature of the river. As a result, in January 2001, EPA directed OCC to suspend certain work under the 1994 AOC (PAS-00033297).

2004:

EPA and a partnership of federal and State of New Jersey agencies have undertaken a joint CERCLA-Water Resources Development Act (WRDA) study of the 17-mile tidal stretch of the Passaic River. During the course of the 17-mile study, the sediments of the lower 8 miles of the Passaic River were found to be a major source of on-going contamination to the tidal river and Newark Bay (PAS-00033334).

While the distribution of dioxin is being studied in these investigations, based on data gathered by EPA and by other entities, including OCC, the most concentrated inventory of 2,3,7,8-TCDD, appears to be in the sediments immediately adjacent to the Diamond Alkali Facility portion of the Site (PAS-00033298).

2008: In 2008, OCC and EPA signed an Administrative Order on Consent (AOC) to remove approximately 200,000 cubic yards of contaminated sediment in two phases from the Passaic River in the vicinity of the Lister Avenue facility (PAP-00143281, 327)). Phase I removed 40,000 cubic yards of sediment and was

completed in 2012. Phase II removal and disposal of 160,000 cubic yards of sediment has not yet been completed (PAP-00360737, 77).

2012: In June 2012, the Cooperating Parties Group (CPG) entered an AOC to remove contaminated sediment and install a cap at River Mile 10.9 (PAP-00204764, 869-870).

2016: EPA and OCC entered into an Administrative Settlement Agreement and Order on Consent for Remedial Design on September 30, 2016. Under this agreement, OCC has agreed to conduct the engineering and design work needed to implement EPA's 2016 ROD for the lower 8.3 miles of the LPR (PAP-00456012).

7. Response Actions

Site characterization data and information is organized below by building/process equipment data, soil data, and groundwater data.

Buildings/Process Equipment Data

As discussed in the *1985 80 Lister Avenue Site Evaluation* and a September 1987 *Record of Decision* (1987 ROD) prepared by EPA, the following data were obtained as a result of an investigation that took place in 1984:

- Wipe samples were collected from coated floors, walls, fixtures, and air ducts in on-site buildings. All wipe samples were analyzed for dioxin only. Dioxin concentrations in wipe samples were as high as 41,600 nanograms per square meter (ng/m^2); the highest concentration was detected in the process building. In addition, chip samples were collected from exposed concrete floors and building exterior or brick surfaces. All chip samples were analyzed for dioxin only. Dioxin concentrations in chip samples were as high as 1,280 ppb (PAP-00150852-53).

- According to the *1985 80 Lister Avenue Site Evaluation*, dioxin contamination appeared to be greatest in the process building, where all 29 samples collected yielded positive dioxin levels. The chemical manufacturing building (with 26 out of 28 samples producing positive results) also had "significant levels" of contamination. The report goes on to state that contamination in the warehouse was significantly less than that determined in the process and chemical manufacturing buildings with some "high levels" detected in the concrete slab floor and in the dust collected from flat elevated surfaces inside the building (PAS-00127250-51). Samples collected from the outside (exterior) walls and roofs of buildings contained lower 2,3,7,8-TCDD concentrations. Chip samples of the outside wall of the warehouse had 2,3,7,8-TCDD concentrations up to 16.5 ppb. A wipe sample from the roof had a 2,3,7,8-TCDD concentration of 13 ng/m^2 (PAP-0015641).

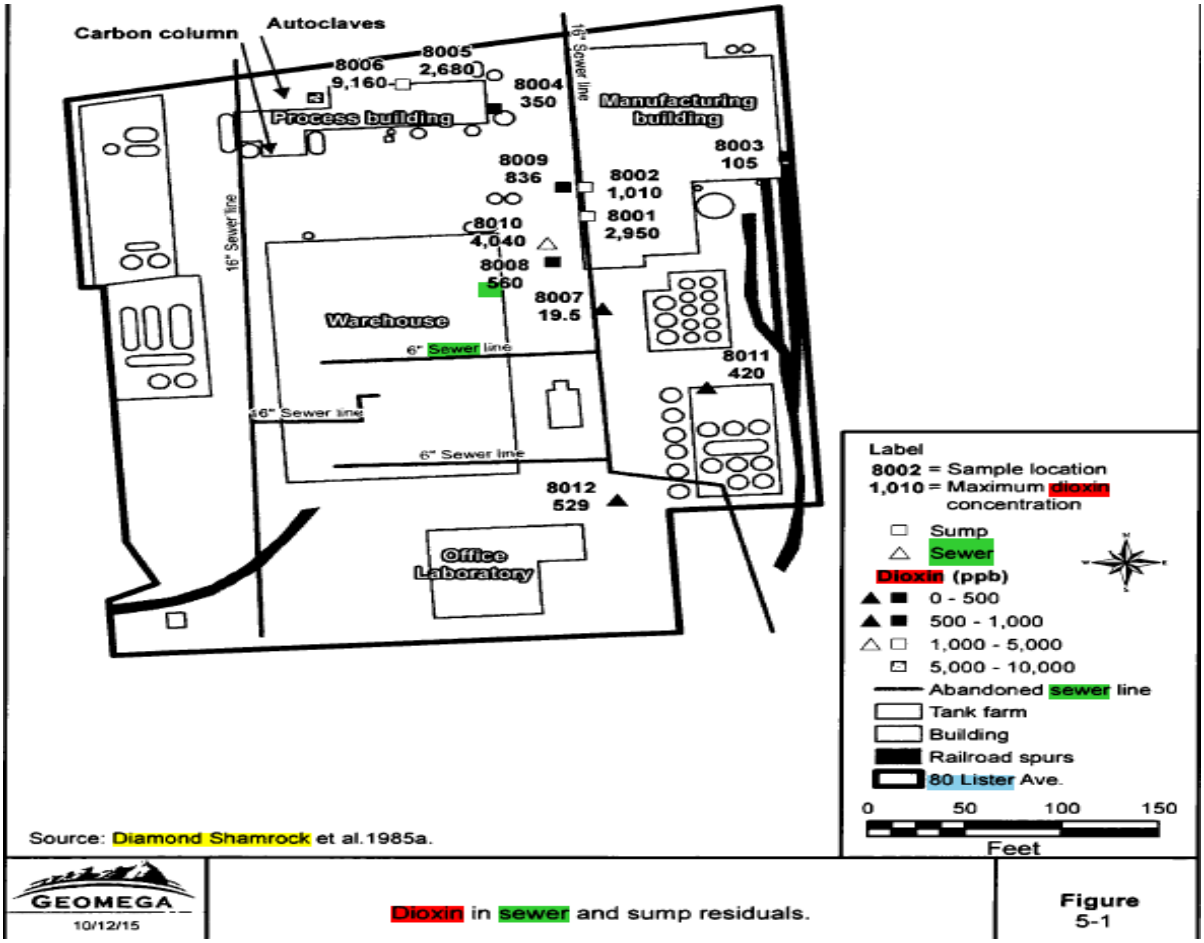
- According to the *Moomaw Report*, the highest concentrations were generally found near process vessels, trenches, drains, vents, and on floors near entrances leading outdoors. Concentrations of dioxin were found in all samples from the interior of the manufacturing, laboratory/office, and warehouse buildings. Contamination detected

in wipe and chip samples "was consistent with, and was caused by, releases from Diamond's TCP and 2,4,5-T manufacturing operations" (PAP-00164659). The highest concentration detected in a sample collected from a chemical process vessel was 60,800 ppb (PAS-00127123, 134-135).

- According to the *Moomaw Report*, solid and liquid waste that remained in process vessels after operations ceased were removed sometime during or after 1981 and placed in 570 drums that were stored on-site in the manufacturing and process buildings (PAP-00164662).

- The *Moomaw Report* states that "[d]ioxin analysis was performed on 22 selected drum samples. Drums to be tested were selected using one of two criteria – either the drum was representative of a major group of drums or it had some particular association with the manufacturing process. Of the 22 drums analyzed, 15 indicated positive results, ranging from 1.5 ppb to 12,200 ppb" (PAP-00150858; PAS-00127185).

- According to the *Moomaw Report*, the "testing confirms that Diamond left dioxin on-site in 1969 because process waste containing dioxin was found in drums that originated from equipment used to produce Diamond's TCP (anisole receiver) and 2,4,5-T (2,4,5-T press filter). The highest concentration was found in the TCP equipment (12,220 ppb) and an 'intermediate level' was found in 2,4,5-T equipment (476 ppb)". The report also notes the dioxin concentration found in drummed waste from the TCP unit was within the range found in the Diamond TCP unit in the 1960s (PAP-00164662).



In addition, four sewer and eight manufacturing and process building sump bulk samples were collected for dioxin analysis as part of the 1984 investigation. Of the 12 samples collected, all indicated positive dioxin results, with concentrations ranging from 105 ppb to 9,160 ppb (PAP-00150853; PAS-00127137). The highest concentration was detected in a process building sump sample (PAP-00151034; PAS-00127137).

It is reported that the sumps generally had higher levels of dioxin contamination than sewers, especially those near the process building, and that contamination levels decreased with increasing distance from the process area (PAS-00127251-52, 73). Solids collected from a "Pit 3" had the second highest dioxin concentration (8,750 ppb). It is reported that these solids were likely collected from one of the sumps in the process building that received waste from the TCP process (PAP-00164663). Coplanar PCBs were also detected in three sump samples collected adjacent to the Process Building, with concentrations as high as 180 ppb (maximum concentration measured for PCB-118). Coplanar PCBs were measured in a sump residue sample collected adjacent to the Manufacturing Building in 1992, with concentrations as high as 27 ppb (maximum concentration measured for PCB-77) (PAP-00210621-41).

According to the *Moomaw Report*, the highest dioxin concentration measured in 1984 (9,160 ppb) was found in the sump by the autoclaves in a cement bunker along the river where TCP was produced. The report notes that this concentration was lower than that measured in 1968 from the same area, but still within the range of concentrations found

in tests of Diamond's TCP in the late 1960s. The report goes on to note that "high" concentrations (> 1,000 ppb) were also found in the other sump along the process building and in two sumps located along the formulations area in the manufacturing building, and that all three of these sumps were in locations where materials and wastes containing dioxin from TCP, 2,4,5-T, or, their derivatives were handled or discharged during Diamond's operations (PAP-00164659). The report concludes that the dioxin contamination detected in sumps and sewers "is consistent with, and was caused by releases from Diamond's TCP and 2,4,5-T manufacturing operations" (PAP-00164659).

A figure depicting the sewer and sump data is presented below (PAP-00164687):

The *1985 80 Lister Avenue Site Evaluation* concludes that due to the biased sample location strategy used to sample the buildings and process equipment, extrapolation of the results to quantify a total amount of dioxin in the 80 Lister Avenue structures was not feasible. However, an estimate of the volume of various types of materials in each of the major buildings that was potentially contaminated with dioxin was made. The total volume of material from all four major site buildings was estimated to be 3,180 cubic yards (PAS-00127251).

As discussed in the *1985 120 Lister Avenue Site Evaluation*, prepared by Diamond Shamrock for NJDEP, and the 1987 ROD, chip and wipe samples also were collected from the 120 Lister Avenue buildings and structures to evaluate potential contamination as part of the 1984 investigation. Chip samples were collected from the interior walls, exterior walls, floor, and roof of each of the three buildings. Wipe samples were collected from the tanks, trailers, equipment, and assorted hardware and supplies. Of the 18 chip samples collected from the three buildings on the 120 Lister Avenue site, positive dioxin results were obtained for nine of these samples; however, none of the results exceeded the NJDEP "action level" of 7.0 ppb. Dioxin concentration in the nine chip samples ranged from 0.13 ppb to 6.3 ppm. Sixteen wipe samples were collected from the tanks, trailers, and equipment located at the 120 Lister Avenue site. Two of the 16 samples were positive for dioxin with concentrations of 7.9 ng/m^2 and 11.0 ng/m^2 (PAP-00150859; PAS-00125849-50).

Soil Data

According to *Priority Pollutant Analytical Results from 80 Lister Avenue Study Area, Newark, New Jersey*, prepared for EPA, dated March 30, 1984, in April 1983, NJDEP collected two soil samples from the 80 Lister Avenue property. One sample had a 2,3,7,8-TCDD concentration of 1,220 ppb. Data were not reported for the other sample. In addition, on May 27, 1983, EPA sampled soil at nine on-site locations and verified 2,3,7,8-TCDD contamination. Concentrations ranged from 60 ppb to greater than 50,000 ppb. On June 2, 1983, the NJDEP collected nine off-site soil samples. The results indicated that contamination existed off-site. Concentrations ranged from non-detected to 15 ppb (PAS-00125540).

According to *A Proposal for Integrated Engineering Investigation/Remedial Action Program for Diamond Alkali*, prepared for Diamond Shamrock Corp., dated July 20, 1983, as a result of the sampling discussed above, EPA and NJDEP requested that a stabilization fabric be placed over the site and security fencing be placed along the northern property limits adjacent to the Passaic River to control potential fugitive dust transport and erosion of TCDD soil-bound particles (PAP-00152285; PAP-00150817).

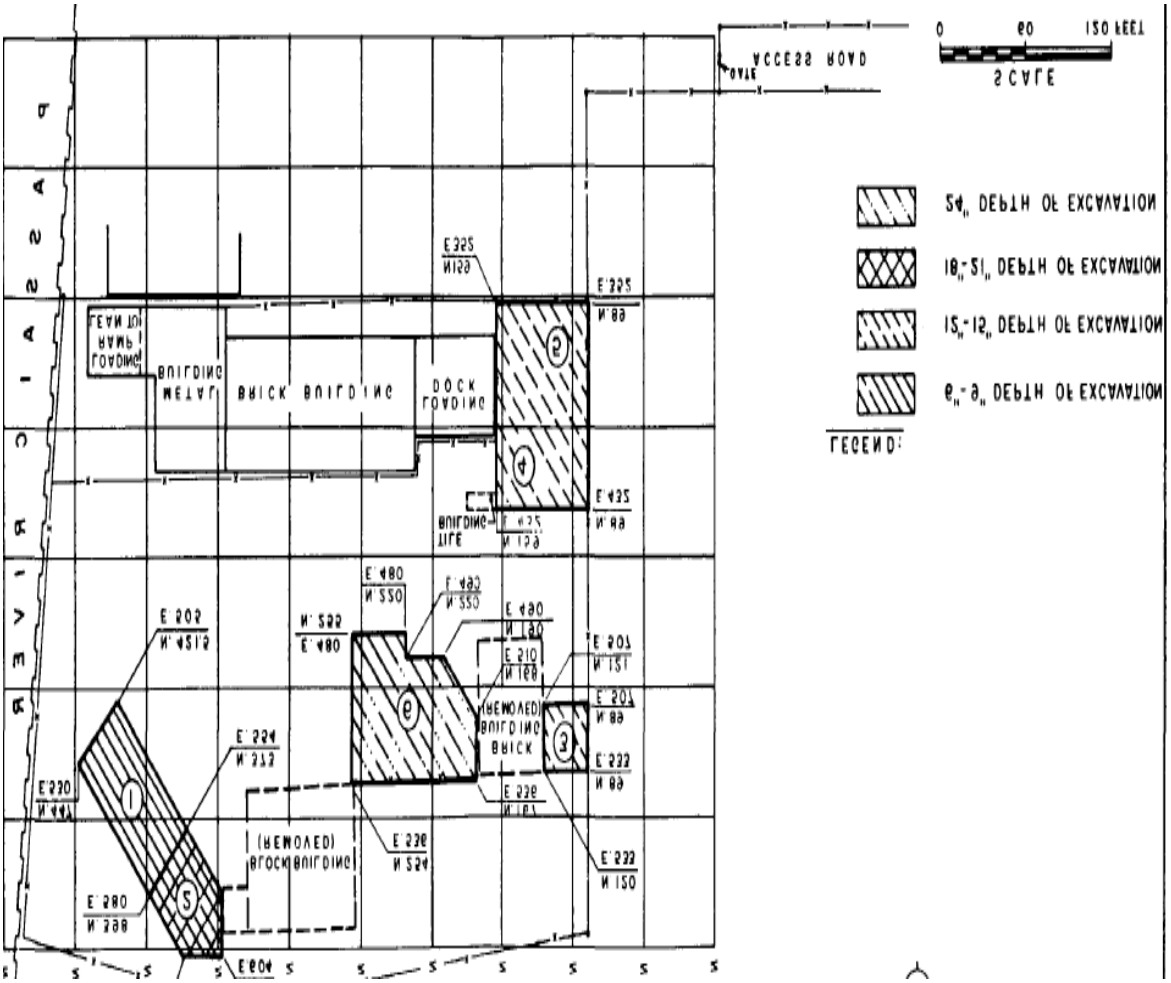
To further define the extent of contamination, Diamond Shamrock's consultant REACT collected four surface soil samples from the adjacent Sergeant's property under the supervision of the NJDEP and an additional 30 samples from the Diamond Shamrock property, including samples in the office building, warehouse, process buildings, sumps, and core borings along the northern property limits. According to the report, detected concentrations of TCDD reduced with depth; however, near the former location of the activated carbon column, concentrations remained as high as 531 ppb five feet below the surface. Preliminary estimates of contaminated materials were reported to be 14,000 cubic yards or 19,000 tons of subsurface materials contaminated with TCDD (PAP-00152285).

According to *Priority Pollutant Analytical Results from 80 Lister Avenue Study Area, Newark, New Jersey*, prepared for EPA, dated March 30, 1984, in December 1983, 35 soil samples were collected from the neighborhood surrounding 80 Lister Avenue. Significant results are summarized below:

- 2,3,7,8-TCDD was detected at all 35 samples. Concentrations ranged from 0.07 ppb to 4.1 ppb (PAS-00125547).
- PAHs were detected in all 35 samples. Concentrations ranged from non-detect to 87 milligrams per kilogram (mg/kg) (PAS-0125548).
- Dieldrin was detected in 5 samples. Concentrations ranged from 0.02 mg/kg to 0.09 mg/kg (PAS-00125549).
- 4,4-DDT, 4,4-DDE and 4,4-DDD were detected in 23 samples. Concentrations ranged from 0.01 mg/kg to 7.7 mg/kg. (PAS-00125549).
- Copper was detected in all 35 samples. Concentrations ranged from 12 mg/kg to 1,200 mg/kg (PAS-00125550).
- Lead was detected in all 35 samples. Concentrations ranged from 71 mg/kg to 1,600 mg/kg (PAS-00125550).
- Mercury was detected in 32 samples. Concentrations ranged from 0.054 mg/kg to 1.7 mg/kg (PAS-00125551).

According to the 1985 80 Lister Avenue Site Evaluation and the 1987 ROD, as part of the investigation that took place in 1984, near-surface soil samples were collected to a depth of 60 inches (PAP-00150854; PAS-00127074). In addition, 39 samples from soil borings were collected from the silt layer (PAS-00126998; PAS-00127074). The following is summary of the maximum detected concentrations of COCs (PAS-00127141-58):

Maximum Detected Concentrations of COCs in Soil		
80 Lister Avenue Site Evaluation - February 1985		
COC	**Maximum Detected Concentration (ppb)**	**Depth (in inches below ground surface)**
Concentrations in ppb		
2,3,7,8,-TCDD	19,500	12-24
2,4,6-Trichlorophenol	1,700,000	12-24
2,4-D	85,000	12-24
2,4,5-T	86,000	12-24
Benzo (a) pyrene	44,000	12-24
Benzo (b) fluoranthene	71,000	12-24
Chrysene	120,000	12-24
Acenaphthylene	860	12-24
Benzo (g,h,i) perylene	32,000	12-24
Fluorene	320	0-6
Phenanthrene	61,000	12-24
Indeno (1,2,3,CD) pyrene	21,000	12-24
Pyrene	78,000	12-24
2- Methylnaphthalene	21,000	12-24
4,4-DDT	5,090,000	12-24
4,4-DDE	297,000	12-24
4,4-DDD	182,000	12-24
Concentrations in ppm		
Copper	6,600	“Above Silt”
Lead	11,000	“Above Silt”
Mercury	95	“Above Silt”



The *1985 80 Lister Avenue Site Evaluation* concludes that the soil data indicated that the surficial fill layer was contaminated, and the contamination extended to the greatest depths on the northern boundary of the site adjacent to the Passaic River where the fill is thickest (PAS-00127273).

According to the *1985 120 Lister Avenue Evaluation* and the 1987 ROD, of 72 soil samples collected to a depth of 60 inches and analyzed for TCDD, 54 had identifiable concentrations ranging from 0.19 to 490 ppb. Of 15 samples analyzed for TCDD from 60 to 132 inches, 10 had identifiable concentrations of TCDD ranging from 0.23 to 93.7 ppb (PAP-00150859). The following is summary of the maximum detected concentrations of COCs (PAS-00125867-72):

Maximum Detected Concentrations of COCs in Soil		
120 Lister Avenue Site Evaluation - May 1985		
COC	**Maximum Detected Concentration (ppb)**	**Depth (in inches below ground surface)**
Concentrations in ppb		
2,3,7,8,-TCDD	>490	6-12
2,4-D	280	6-12
2,4,5-T	400	6-12
Acenaphthene	2,400	6-12
Fluoranthene	15,000	12-24
Napthalene	1,800	12-24
Benzo(a) anthracene	16,000	12-24
Benzo(a)pyrene	16,000	12-24
Benzo (b) fluoranthene	4,100	6-12
Benzo (k) fluoranthene	5,400	0-6
Chrysene	12,000	12-24
Acenaphthylene	2,000	6-12
Anthracene	3,900	6-12
Benzo (g,h,i) perylene	3,800	6-12
Fluorene	2,500	6-12
Phenanthrene	15,000	12-24
Indeno (1,2,3,CD) pyrene	4,000	12-24
Pyrene	39,000	12-24
2- Methylnaphthalene	15,000	12-24
4,4-DDT	480,000	0-6
4,4-DDE	7,500	6-12
4,4-DDD	17,100	0-6
Concentrations in ppm		
Copper	350	0-6
Lead	880	12-24
Mercury	10.3	0-6

The *1985 120 Lister Avenue Evaluation* also notes that six soil samples were collected for dioxin analysis after excavation of five "hot spots" that were identified. Samples from excavation Nos. 1 and 3 were below the “acceptable level” of 7.0 ppb after the removal of 6 and 12 inches of soil, respectively. Excavation No. 2 required removal of 18 inches of soil before the dioxin level dropped to less than 7.0 ppb. Both excavations Nos. 4 and 5 showed “high levels” of dioxin (19.1 and 31.0 ppb, respectively) after 12 inches of soil was removed; no further testing was performed on samples from these locations (PAS-00125853).

A figure depicting the locations of the “hot spots” is presented below (PAS-00125843):

According to a *Review of Certain Information Related to the 80 Lister Avenue Site, Newark, New Jersey*, prepared by Woodward-Clyde Consultants, dated May 1987 (the document does not state for whom the report was prepared), “concentrations of dioxin on and in the vicinity of the 80 Lister Avenue property correspond generally with the locations of the manufacturing and handling of compounds found to contain dioxin; are consistent with accidental releases, spillages, and leakage over time; and appear to be inconsistent with deposits of such compounds as the result of dumping or other incidents . . .” (PAP-00154203).

According to the 1987 ROD, the 1984 investigation indicated that hazardous substances were being released from the site to the Passaic River through the routes of groundwater migration and surface runoff of stormwater. The 1987 ROD also notes that the investigation identified TCDD and other hazardous substance in Passaic River sediments, that a separate study of the contamination of Passaic River sediments was being conducted by Diamond at the time, and that results of that study showed that the more recent sediments contained relatively little TCDD compared to older sediments.

The 1987 ROD concludes that the data suggested that releases of TCDD to the Passaic River were much greater in the past during the period of pesticide production at the site than at the present (PAP-00150861).

An *Assessment of Potential Sources of Release of Dioxin to the Environment from Reported Manufacturing Operations and Activities at the Diamond Shamrock Facility, 80 Lister Avenue, Newark, New Jersey* (related to Diamond Shamrock v. Aetna, et al, prepared for the Defense Steering Committee) dated May 29, 1987, states that according to the 1985 80 Lister Avenue Site Evaluation, an estimated 96.2 pounds of dioxin were present in soil at the 80 Lister Avenue site (PAP-00160133). The report also notes that a dioxin concentration of 75 ppm "reported in the pit near the river was likely the result of autoclave discharges, scrubber effluent discharge, or anisole still releases." (PAP-00160135). The report also notes that "estimated quantities of dioxin released, based on particular discharges that have been documented, fall short of the 96.2 pounds reported by I.T." (Diamond's consultant) (PAP-00160135). The report describes the following sources of dioxin from the Lister facility:

- "Airborne emissions (particulates, fumes) were likely a source of dioxin migration. . . . [d]uring the 1950's, emissions from the TCP building were discharged to the atmosphere by exhaust fans. . . . [f]ume exposure was present in TCP production . . . . According to John Burton, the plant manager in the 1950's, the pressure from the autoclave was relieved by venting to the atmosphere after each autoclave batch reaction, indicating gaseous and likely vapor releases to the atmosphere. Based on Diamond Shamrock operating reports from the period November 1966 to July 1969, about 58 autoclave batch reactions occurred per month . . . . The venting system reportedly posed 'problems of contamination' as noted in a November 1968 operating report." (PAP-00160076).

- "Reportedly, organic particulates were controlled to 10 pounds per day by a scrubber by the late 1960's, with sodium trichlorophenate (NaTCP) "mist" emissions controlled to 0.06 pounds per hour from the 1.2 pounds per hour that would have been emitted on an uncontrolled system. Scrubber effluents in which dioxin was likely present would have been discharged to the sewer, to a pit near the river, or to the river. Sources to the scrubber included losses from the T reactor, vapor losses from acidification and dust formed in the flaking process." (PAP-00160076).

- "The 1960 explosion in the autoclave where NaTCP was being manufactured could have released as much as one-third of a pound of dioxin. The explosion may also have indirectly caused dioxin discharge by disturbing "concrete slabs" and "drums" in the area." (PAP-00160076).

- "Other incidental discharges may have resulted from at least five rupture disc releases, . . . causing releases of material to the atmosphere, to the river, and possibly to a pit." (PAP-00160076).

- "Discharges also occurred from reported leaks in the autoclave, from the TCP recovery tank that "burped over" on at least one occasion, from reported leakage in the acidification tank, and possibly from the TCP intermediate storage tank which reportedly presented a 'pollution and safety hazard'. According to a 1968 operating report, TCP was also lost due to its limited solubility in acid-water and, when wastewaters were discharged, the solubilized TCP possibly carried some dioxin with it. In addition, NaTCP storage tank residue flushing would have likely caused the release of dioxin-containing materials into the environment." (PAP-00160077).

- "Also suspected for their potential to release dioxin are the stripping unit, which separated anisole from NaTCP, and filter units, which separated product streams from impurities. According to former Diamond Shamrock employees, the stripper residues were flushed into the river or to a sewer sump, while a small amount of spillage occurred at the unit's sample tap. The condenser tubes in the unit also had leakage problems, while process wastewaters from the stripper were routed to the river. With respect to filters, dioxin would likely have accumulated in filter cakes. Dioxin also was likely carried over into product or with filter washwaters, which, in turn, were sometimes discarded. In addition, the sewering of acid used to regenerate the carbon purification column was another means for the release of dioxin into the environment." (PAP-00160077).

- "The T area was also a likely source of release of dioxin containing materials. The T centrifuge and a manhole on the T reactor were reportedly sources of fume exposure, while odor problems and evidence of material discharge reportedly existed during the process of flaking T acid. Particulate releases from this flaking operation were a likely source of release of dioxin-containing materials." (PAP-00160077).

- "Plugging problems in lines and pumps were reported in depositions and operating reports. Disassembling and flushing of pipes, as well as reported leakage in transfer and product lines, would have contributed to further releases of dioxin." (PAP-00160077).

- "Process wastewaters were discharged in large volumes to the Passaic River before 1956. These discharges continued after 1956 with some of the wastewaters going to the sewer. Reportedly, 100 tons of unrecycled 2,4,5-T effluents per year were discharged into the Passaic River in 1959. Sources of these wastes include filter and ester wash water. Sewer and sump samples reported in a 1985 report prepared for Diamond Shamrock by I.T. Corp., et al, titled 'Site Evaluation, 80 Lister Avenue' noted eight sumps that were sampled. All samples contained dioxin ranging from 19.5 to 9,160 parts per billion (ppb) (PAP-00160077-78).

- "Materials that were discharged to the sumps reportedly included discharges from the TCP area, sulfuric acid from the scrubbers, process streams related to the anisole stripper, and chlorophenolic wastes. Process wastewaters were routed to a sump in the area of the manufacturing building (2,4-dichlorophenoxyacetic acid (D) and T), with the overflow discharging to a sewer. Cleaning of accumulated residues from the sumps was reportedly a 'dirty, messy operation' which might have resulted in the discharge of dioxin-containing materials." (PAP-00160078).

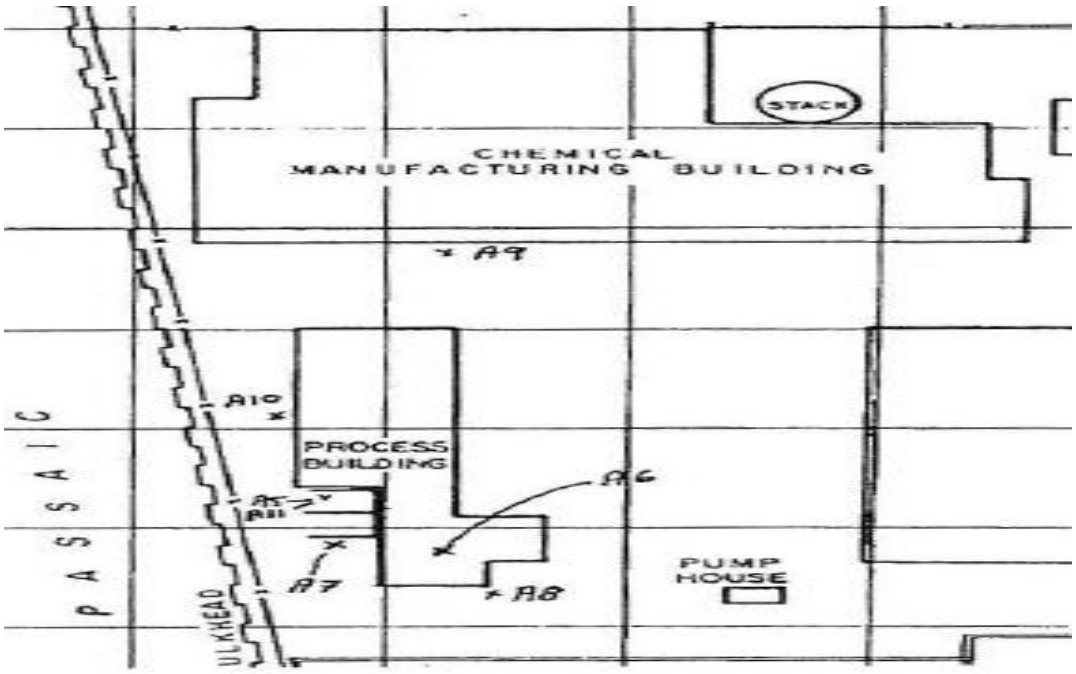
- "According to depositions, there are indications that general maintenance and housekeeping practices also contributed to dioxin releases. Maintenance would have included flushing of residue from process vessels and discarding of old pipes and debris. "Gunk from tanks' was reportedly discarded during plant shutdown. Some evidence of 'poor housekeeping' was also noted at the riverfront, where drums and equipment were reportedly stored on a concrete pad. In addition, spillage in quality control sampling procedures and disposal of unused or wasted samples would have resulted in further discharge of dioxin into the environment." (PAP-00160078).

- "Packaging and transport would likely have contributed to some release of dioxin-containing materials. The 'bagging' area reportedly had a certain amount of dust, and any spillage in loading and transport for shipping may have gone into the ground since depositions did not indicate any special practices of isolating or cleaning up spills. Furthermore, truck traffic likely provided an additional means for dioxin-contaminated dust migration in the vicinity of the site." (PAP-00160078).

- "The aforementioned 1985 report projected that 96.2 pounds of dioxin are contained in the soil at the 80 Lister Avenue site. Based on an assessment of potential dioxin (2,3,7,8-TCDD) content in documented releases, the total projected amount of dioxin would appear to be far less than the 96.2 pounds reported. This assessment suggests that the bulk of the dioxin on site arose from routine process emissions through leaks and operations that allowed for material to be lost. Based on available discovery documents, such as depositions and operating reports from the late 1960's, it appears that these discharges were likely persistent throughout the period of operation of the Diamond Shamrock plant." (PAP-00160078).

According to an undated *Remedial Design Investigation Report*, which states it was prepared pursuant to the Consent Decree entered into by the State of New Jersey and OCC, soil sampling occurred at the site in June 1994 "to confirm and delineate the dioxin concentrations in some areas of the Site and to measure the concentration of dioxin in areas of the Site where there are no data." (PAP-00160409).

TCDD was detected at concentrations as high as 50,000 ppb in a sample collected from zero to six inches below ground surface (PAP-00160413). The location of this sample is not described in the text of the report, but appears to be located northwest of the warehouse and west of a debris pile (PAP-00160400).



According to the *Moomaw Report*, soil samples were collected in 1984, 1994, and 1997. The 1984 and 1994 data also are discussed in previous paragraphs above. According to the report, for all three datasets, dioxin was detected at all locations in at least one depth interval sampled. "The highest concentration, at 50,000 ppb, was found in 1994 on the west side of the process building near the autoclave and carbon column . . . . For the other years sampled, the highest concentrations were 19,500 ppb in 1984 and 4,790 ppb in 1997 in the area between the process, manufacturing, and warehouse buildings." (PAP-00164660).

The report states that many of the areas sampled around the process and manufacturing buildings had concentrations comparable to that found in Diamond's TCP in the 1960s. The report goes on to state that "'[m]uch lower' concentrations (50 ppb) were found in areas away from the process and manufacturing buildings, likely originating from occasional spills, process emissions, the 1960 explosion, or subsequent construction." The report concludes that the "dioxin contamination detected in these soil samples is consistent with, and was caused by, releases from Diamond's TCP and 2,4,5-T manufacturing operations." (PAP-00164660).

Sampling at the 80 Lister facility in 1992 showed PCBs in sumps and tanks as follows (see map below for location of samples):

80 Lister Sampling					
Sample	**PCB-77 (ng/g)**	**PCB-105 (ng/g)**	**PCB-118 (ng/g)**	**PCB-126 (ng/g)**	**PCB-169 (ng/g)**
A5-Sump Residue-Mixed Soil/Liquid Matrix	4.3	4.0	6.5	--	0.77
A6-T4CB Tank Residue	1.4	0.36	0.5	--	0.12
A7-T4CB Unloading Line	0.38	0.81	5.0	--	0.24
A8-Anisole Still Soil	4.1	7.7	19.0	1.4	0.43
A9-Sump Residue	27	11	18	1.0	--
A10- Sump Residue--Mixed Soil/Liquid Matrix	2.5	23	33	0.23	0.084
A11-Adjacent to Sump	2.2	53	180	0.37	0.038

(PAP-00210639)

(PAP-00210629)

As reported by a *Draft Focused Feasibility Study for Comparison of the Consent Decree Remedy and Hypothetical Excavation and Incineration Alternatives, Diamond Alkali Superfund Site, Newark, New Jersey*, prepared for Chemical Land Holdings, Inc., dated August 11, 1997 (1997 FFS), soil sampling data were collected for dioxin during the Site Evaluation and the Remedial Design Investigation, both discussed in previous above. The following is a summary of the data as presented in the 1997 FFS:

- At 80 Lister Avenue, the data in the upper two feet of soil indicated "widespread" dioxin concentrations above preliminary remediation goals (PRGs).[5] "The dioxin concentration exceeds 7 ppb in 101 of 117 samples (86 percent) collected within the upper two feet of soils and exceeds 1 ppb in 114 of 117 samples (97 percent)." (PAP-00160672) The maximum concentration detected was 50,000 ppb (PAP-00160682).

- At 80 Lister Avenue, "[t]he next data set available was at the interface between the Fill and the underlying Silt layer, which was encountered at approximately 8 feet below grade across most of the Site and as deep as 16 feet below grade near the existing bulkhead along the Passaic River. Samples collected directly above the Silt layer also indicate the presence of dioxin above PRGs. The dioxin concentration exceeds 7 ppb in three of eight samples (38 percent) collected directly above the Silt layer, and exceeds 1 ppb in five of eight samples (62 percent)" (PAP-00160673). The maximum concentration detected was 71.8 ppb (PAP-00160684).

- The majority of the samples collected from the 120 Lister Avenue property during the Site Evaluation were within the upper two feet of soil. Dioxin concentrations exceeded 7 ppb in 18 of 81 samples (22 percent) collected within the upper two feet of soil, and exceeded 1 ppb in 45 of 81 samples (56 percent) (PAP-00160673). The maximum concentration detected was 520 ppb (PAP-00160686).

- At 120 Lister Avenue, at depths greater than two feet, samples were collected in 1.5-foot increments. The number of samples for each depth interval within the fill varied from one to seven. The dioxin concentrations exceeded 7 ppb in five of 26 samples (19 percent), and exceeded 1 ppb in eight of 26 samples (30 percent) (PAP-00160673). The maximum concentration detected was 155 ppb (PAP-00160687).

The 1997 FFS notes that for dioxin, two PRGs were considered: 1) a soil cleanup standard of 1 ppb listed in Appendix II of the Judicial Consent Decree, and 2) a PRG of 7 ppb that was considered in a 1985 Feasibility Study. As noted in the 1987 ROD and the Judicial Consent Decree, the 1 ppb PRG for dioxin is a soil concentration that was developed by the Center for Disease Control and had been applied at cleanups throughout New Jersey. The 7 ppb PRG was used for interim remedial activities on the 120 Lister Avenue property, which were performed during 1984-85 (PAP-00160698):

[5] The PRGs were taken from the 1985 FS (a dioxin PRG of 7 ppb), from the Judicial Consent Decree, and from soil cleanup criteria published by NJDEP (1996) if no soil cleanup standard is listed in the Judicial Consent Decree for a hazardous substance (PAP-00160672).

The following is a summary of maximum detected concentrations of COCs detected above the PRGs as listed in the 1997 FFS (PAP-00160682-88):

Exceedances of Preliminary Remediation Goals at 80 Lister Ave			
Contaminant of Concern	**Preliminary Remediation Goal**	**Maximum concentration 0-2 feet**	**Maximum Concentration >2 feet**
Concentrations in ppb			
2,4,6-Trichlorophenol	10,000	1,700,000	360,000
2,4,5-Trichlorophenol	50,000	7,500,000	270,000

Lead	400	880	530
Mercury	1	1.9	None reported

According to a the 1997 FFS, an estimated 38,122 cubic yards of soil were present at 80 Lister Avenue with dioxin concentrations greater than 7 ppb, and 50,246 cubic yards of soil were present at 80 Lister Avenue with dioxin concentrations greater than 1 ppb (PAP-00160689-90).

Groundwater Data

According to the 1985 80 Lister Avenue Site Evaluation and the 1987 ROD, as part of the investigation that took place in 1984, 17 groundwater samples were collected. The following table identifies the maximum detected concentrations of COCs in groundwater (PAP-00150855; PAS-00127164-68):

Maximum Detected Concentrations of COCs in Groundwater 80 Lister Avenue Site Evaluation - February 1985	
COC	**Maximum Detected Concentration (ppb)**
Concentrations in ppb	
2,3,7,8,-TCDD	10.4
2,4,6-Trichlorophenol	11,000
Acenaphthene	30
Fluoranthene	120
Napthalene	480
Benzo (a) anthracene	8
Anthracene	4
Fluorene	32
Phenanthrene	110
Pyrene	46
2- Methylnaphthalene	900
2,4-D	27,000
2,4,5-T	5,600
4,4-DDT	22,000
4,4-DDE	54

Maximum Detected Concentrations of COCs in Groundwater	
80 Lister Avenue Site Evaluation - February 1985	
COC	**Maximum Detected Concentration (ppb)**
Concentrations in ppb	
4,4-DDD	13,000
Copper	2.9
Lead	47
Mercury	0.16

The *1985 80 Lister Avenue Site Evaluation* concludes that analysis of samples collected from eight on-site wells confirmed the presence of dioxin in groundwater, and that contamination was present in 15 of 17 water samples collected, ranging from 0.0059 ppb to 10.4 ppb. The report also concludes that the results indicated that "contamination is greatest at the north end of the site along the river, near the process and chemical manufacturing buildings" (PAS-00127261).

According to the May 1985 *Site Evaluation for 120 Lister Avenue* and the 1987 ROD, dioxin was not detected in any of the five ground water samples collected from the 120 Lister Avenue site (PAP-00150860; PAS-00125854). 4,4-DDT, 4,4-DDE, and 4,4-DDD were detected at maximum concentrations of 2.5 ppb, 3.2 ppb, and 1.8 ppb, respectively (PAS-00125875). Copper, lead, and mercury were detected at maximum concentrations of 1.46 ppb, 6.6 ppb, and 0.062 ppb, respectively (PAS-00125876).

According to an undated *Remedial Design Investigation Report*, which states it was prepared pursuant to the Consent Decree entered into by the State of New Jersey and OCC, groundwater was sampled in 1994. The following table identifies the maximum detected concentrations of COCs in groundwater (PAP-00160507-08).

Maximum Detected Concentrations of COCs in Groundwater	
Remedial Design Investigation - 1994	
COC	**Maximum Detected Concentration**
Concentrations in ppb	
2,3,7,8,-TCDD	28,000

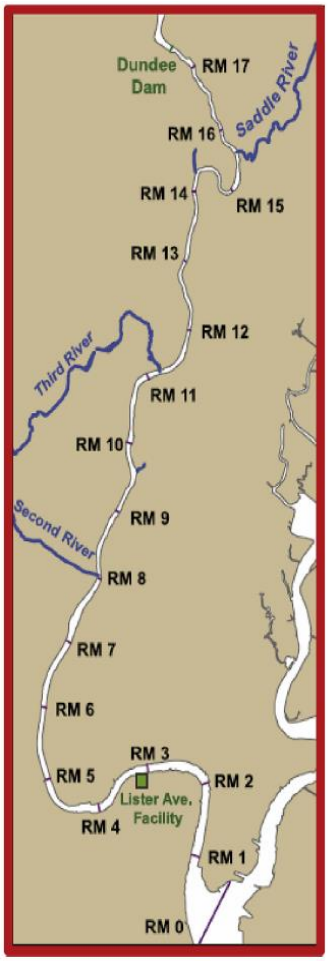
Mercury	12.7

According to an August 29, 2019 *Site Evaluation Work Plan Addendum* for the Diamond Alkali Superfund Site, findings presented in a March 29, 2019 Site Evaluation Report confirmed the presence of dense non-aqueous phase liquid (DNAPL) on the Site. EPA has directed OCC to conduct "additional investigation activities . . . to delineate the vertical extent of [DNAPL] that was previously identified below the organic silt layer underlying the Site." (PAP-00422963).

Fate and Transport

A 2014 paper *Fate and Transport of Hydrophobic Organic Chemicals in the Lower Passaic River: Insights from 2,3,7,8-Tetrachlorodibenzo-p-Dioxin* by Israelsson, et. al. concludes the following:

- "H[ydrophobic] O[rganic] C[hemicals (HOCs)}] trapping processes within the LPR have been highly effective in the past; approximately ¾ of the LPR/Newark Bay 2,3,7,8-TCDD inventory was estimated to reside in the lower six miles and more than half within approximately 1 mile of the dominant 2,3,7,8-TCDD source location (not accounting for recent removal actions).



- Upstream transport processes (tidal pumping and gravitational circulation) have distributed HOCs as far upstream as approximately RM 14.

- Trapping of 2,3,7,8-TCDD downstream of RM 2 has likely been more effective than trapping upstream of RM 4, consistent with expectations based on system geomorphology, the strong influence of freshwater discharge on net sediment transport, and HOC-specific transport processes.

- Although the LPR 2,3,7,8-TCDD signal declines moving away from the LPR mouth (based on concentrations and the ratio of 2,3,7,8-TCDD to total TCDD), the signal remains visible in lower Newark Bay" (PAP-00149637).

A 2015 paper regarding fingerprinting by Quadrini, et. al., states that peak 2,3,7,8-TCDD concentrations in the lower Passaic River cores 'date to the 1950s, as evidenced by the horizontal shaded bands established through radioisotope age dating . . . . This peak date is consistent with the known 2,3,7,8-TCDD discharge history from the site [Diamond facility]. Also evident in the cores are secondary 2,3,7,8-TCDD peaks, roughly at 80 inches . . . and 55 inches . . . below the sediment surface. The timing of these secondary peaks generally coincides with the February 1960 trichlorophenol autoclave explosion at the site that released 2,3,7,8-TCDD and other compounds to the surrounding area . . . . The decline in 2,3,7,8-TCDD concentrations after this explosion presumably reflects smaller mass discharge from the site after the replacement of the main processing facility in 1961 and the end of 2,4,5-trichlorophenoxyacetic acid production in 1969 . . . , as well as a natural recovery of surface sediments. Surface 2,3,7,8-TCDD concentrations in the 3 cores range from 418 ng/kg to 776 ng/kg, roughly 3.0 to 4.5 orders of magnitude lower than the peak 2,3,7,8-TCDD concentrations." (PAP-00162747).

In conclusion, "[t]he sediments of the lower 14 miles of the lower Passaic River contain a relatively uniform PCDD/F composition that resembles the composition of sediments adjacent to the Lister Avenue site, which in turn matches the composition of samples taken on the upland site. The match has been demonstrated using several fingerprints: 15-congener PCDD/F composition, PCDD/F homolog composition, 1,3,7,8-TCDD to 2,3,7,8-TCDD ratios, and 2,3,7,8-TCDD to total TCDD ratios. The match strongly indicates that the Lister Avenue site is the dominant source of the examined PCDD/Fs over this region. The upstream influence of the site, which extends to approximately RM 14 (congener ratios indicate a gradually declining influence over the RM 13–15 interval in particular), is consistent with upstream contaminant transport and salinity intrusion considerations, particularly during the peak site discharge period" (PAP-00162754).

According to *Parette, et. al. (2018)*, the 80 Lister facility is the major source of TCDD in the sediments of the Passaic River. A reconstruction of the chemical processes at the site identified dilutionfiltration, a TCP purification process that was utilized prior to September 1954, as the major pathway by which TCDD was discharged to the Passaic River from the Lister Avenue site. This process concentrated TCDD in a waste organic sludge that was subsequently discharged to the river. Annual TCP production, coupled with modeling to predict concentrations of TCDD, indicate that TCDD discharges to the LPR from this one process (20-80 kg) are consistent with mass estimates of TCDD in the river (30-50 kg). TCDD and cesium-137 data from nearby sediment cores support this purification process as a major pathway by which TCDD entered the river (PAP-00210169-176). The paper also states that the highest concentrations of TCDD in the LPR were found in sediments directly adjacent to the Lister Avenue site, and approximately 70% of the estimated TCDD in the LPR is contained within one RM of this site. The bulk of the TCDD is concentrated between RM 2 and RM 4, with only 10% above RM 6 (PAP-00210170).

Facility Data Report

OKONITE COMPANY

Facility Name, Address and Size: Okonite Company, Inc., (Okonite) Canal and Jefferson Streets, Passaic, NJ, 07055 (PAS-00108491). The current site address is 220 Passaic Street, Passaic, NJ 07055 (PAS-00123415). However, Okonite sold this property in February 1993 and has not operated this site since July 5, 1989 (PAP-00240078). The current acreage of the site is 13 acres (PAP-00256257). The available references did not include information on the number of site employees and typical work shifts.

1. **Business Type:** The Okonite Company was founded in 1878 making it one of the original insulators of electrical wire and cable in the United States. Okonite is the premier manufacturer of high quality insulated electric wire and cable, specializing in high voltage cable (up to 345kV), medium voltage cables (from 5 to 35kV) and low voltage power, control and instrumentation cables. The cables are manufactured with a variety of materials including laminated polypropylene paper, thermosetting and thermoplastic insulation and jacketing compounds. Many products feature Okonite's Okoguard all EPR insulation system. These constructions are further complemented by a wide selection of metallic and nonmetallic coverings to provide added mechanical protection to the wire and cable for various environments (PAS-00102060).

   The basic raw materials were copper, aluminum, rubber, and plastic. Okonite also manufactured the rubber compounds used to insulate the electrical conductors. This process involved the mixing and extruding of solid and liquid raw materials. Raw materials included clay, paraffin, carbon black, lead, and zinc oxide (PAP-00256284, PAP-00242981-82, 90).

2. **Time Period of Ownership/Operations**

   Operator: 1885 to 1989 (PAP-00240078)
   Owner: 1885 to 1993 (PAP-00240078)

3. **Operational History/COC Use and Presence at the Facility**

   As mentioned in Section 1 above, the Okonite facility manufactured electrical power cables at its Passaic Plant. Processes included wire drawing, stranding, taping shielding, insulating, jacketing, and testing. Basic raw materials used were copper, aluminum, rubber, and plastic. Okonite also manufactured the rubber compounds used to insulate the electrical conductors. Raw materials used in these processes included clay, paraffin, carbon black, lead and zinc oxide (PAP-00256284, PAP-00242981-82, 90).

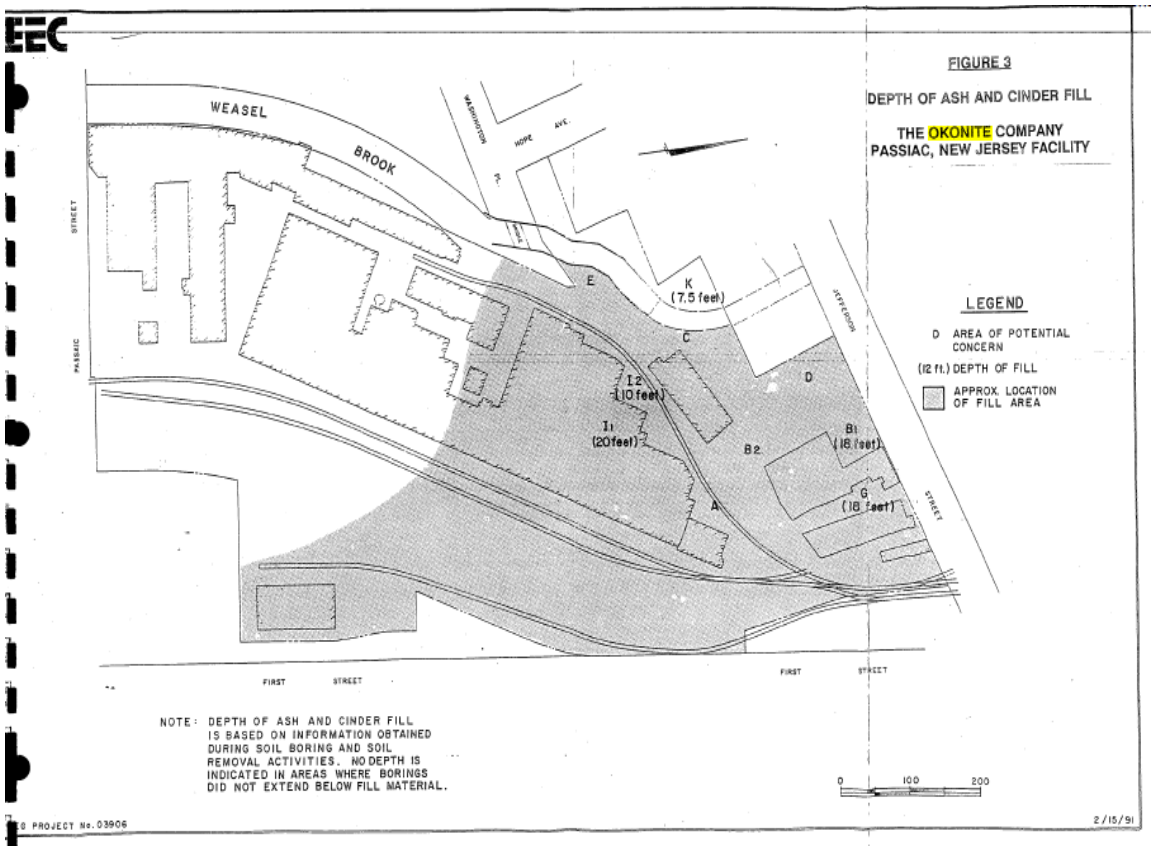
Facility Data Report

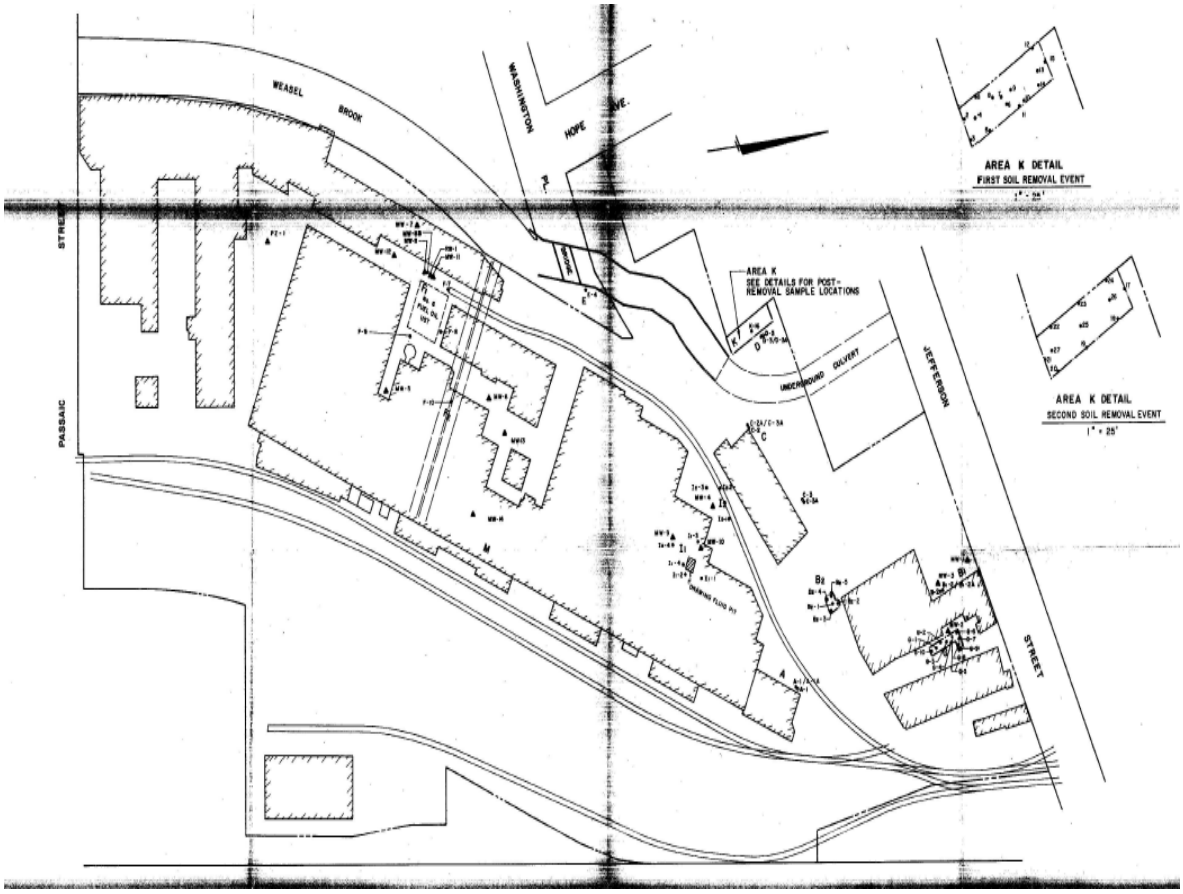
(PAS-00102115)

Based on review of available documents, the following Areas of Concern (AOCs) were identified in a February 1991 *Result of Sampling Plan Implementation and Supplemental At-Peril Activities* report prepared by Environmental and Energy Consultants, Inc. (ECC) on behalf of Okonite:



Okonite AOCs	
Area A – Facility drummed hazardous waste storage area	Area F2 – Piping trench in Engine Room and nearby area
Area B1 – Drummed raw material storage area	Area G – 8000-gallon steel gasoline Underground Storage Tank (UST) and abandoned 1,000-gallon UST of uncertain usage
Area B2 – Unpaved empty drum storage area	Area I1 – 9,000-gallon concrete drawing fluid pit
Area C – Paved empty drum storage area	Area I2 – Exterior area west of drawing fluid pit, location of historic boring I-2

Okonite AOCs	
Area D – Historic drummed raw material storage area	Area K – Unpaved area of oil-stained soils with water softener resin beads and tar-like material
Area E – 300-gallon, concrete encased, steel underground storage tank (UST) historically used to store waste kerosene, oil, and solvents	Area M – Banbury mixer area
Area F1 – 76,000-gallon concrete No. 6 fuel oil UST	Various drainage structures – Catch basins, drains, troughs and machinery pits, most with permitted outfalls to Weasel Brook



(PAP-00244643-84, 725)

Of the AOCs identified at the Site, Historic Fill was identified at Area 16 (PAP-00260097). Several other AOCs were determined to be located within areas of historic fill material, as discussed further in the following sections. The AOCs discussed in the above table are generally co-located with historic fill material (including ash and cinder), as determined by extensive subsurface investigations at the Site.

The AOCs identified in the 1991 report are depicted on the figures below:

(PAP-00244638)

(PAP-00244631)

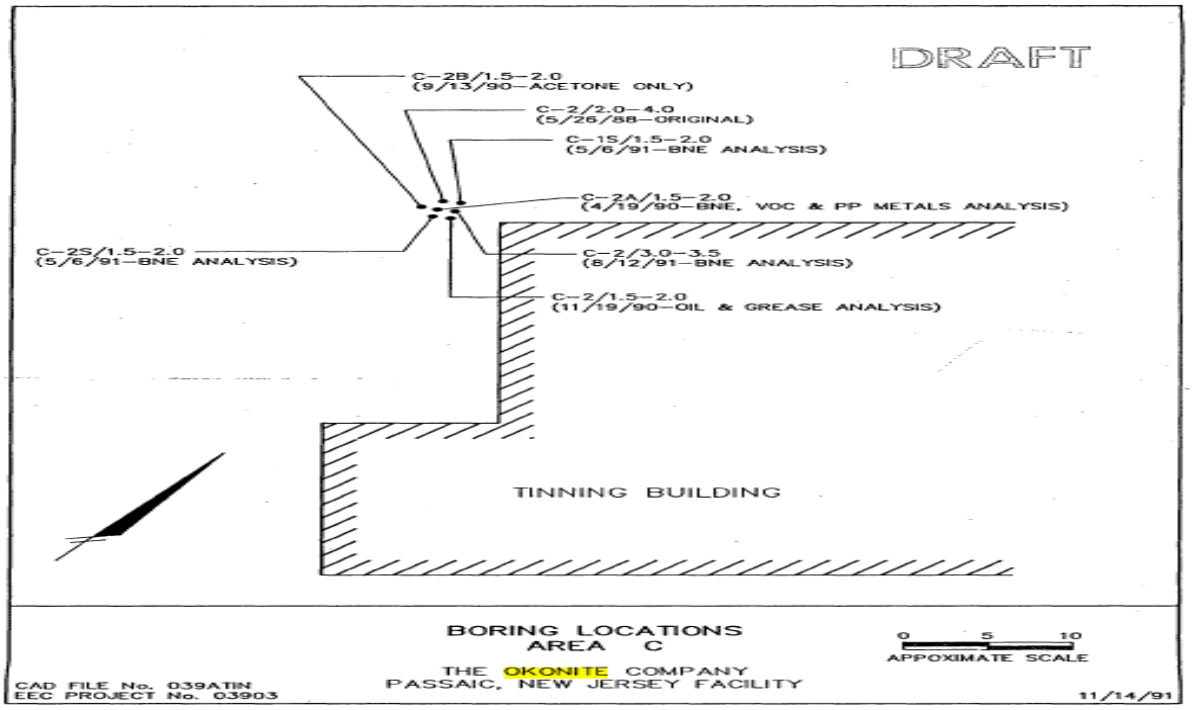
Presented below is a summary of findings at the different AOCs as reported by the *Results of Sampling Plan Implementation and Supplemental At-Peril Activities* dated February 1991.

Areas A, B1, and D

Area A is the facility hazardous waste drum storage area. The area is controlled by a concrete spill control system. Waste chlorinated and non-chlorinated solvents and oils were stored in this area.

Areas B1 and D are recent and historic drummed material storage areas, respectively. Materials stored in these areas include all liquid materials used in facility processes. All three areas are asphalt paved. No evidence of contamination (i.e., oil staining, odor and/or elevated monitoring instrument response) was observed in any of these areas during the historic sampling events (PAP-00244643).

The New Jersey Department of Environmental Protection (NJDEP) approved No Further Action (NFA) for these AOCs A, B1 and D in their letter dated April 11, 1994 (PAP-00240168-70).



Area B2

This area is a small unpaved area that was used for storage of empty drums that were previously used for liquid raw materials used in the facility processes.

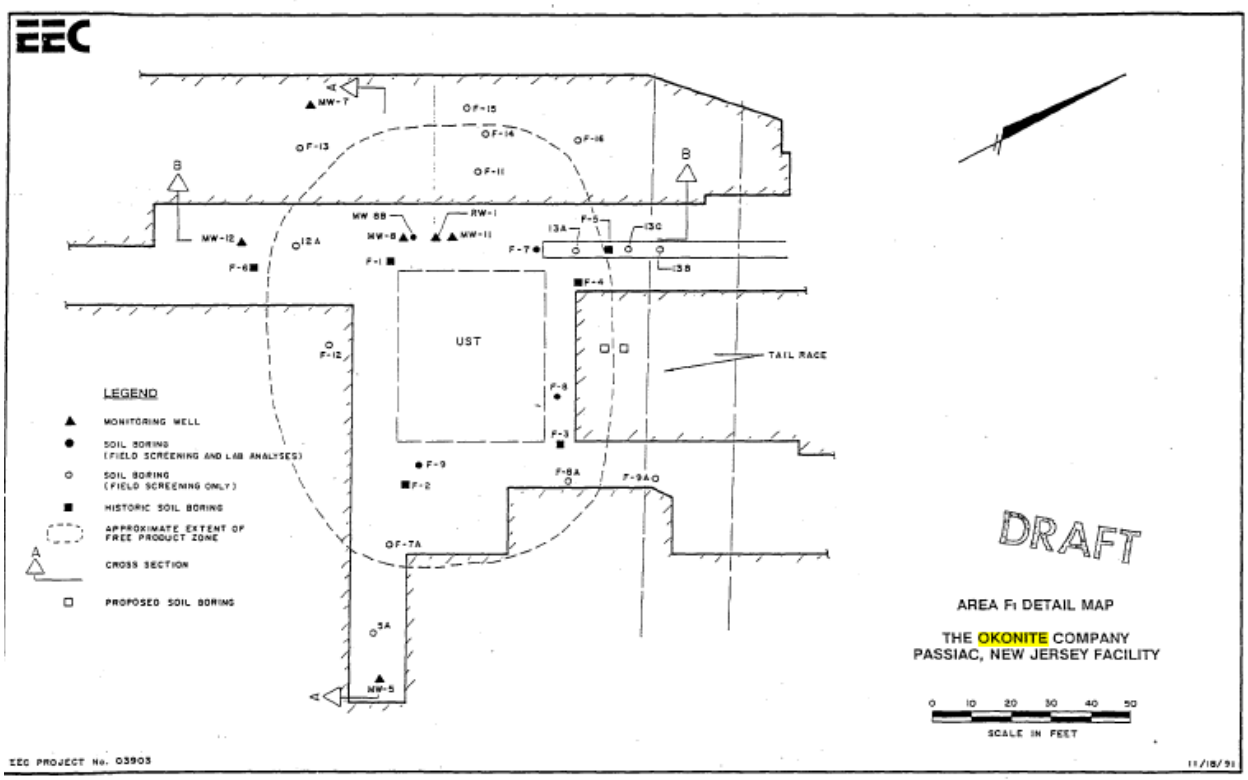
The NJDEP approved NFA for AOC B2 in their letter dated April 11, 1994 (PAP-00240168-70).

Area C

Area C is a paved area and was used to store empty drums of facility process-related materials.

(PAP-00244335)

Area E



This area was the location of an abandoned approximately 300-gallon steel UST encased in concrete that was historically used to store waste kerosene and other compounds that may have been used as degreasers at the facility. The UST was properly decommissioned through removal in accordance with facility Decontamination/ Decommissioning Plan. The UST was disposed as scrap metal along with the USTs from Area G. No evidence of a release was found in the removal of the USTs (PAP-00244653). The NJDEP approved NFA for Area E in their letter dated April 11, 1994 (PAP-00240168-70).

Area F1

This area is the location of a 76,000-gallon concrete UST that was used to store No. 6 fuel oil. The UST was installed in approximately 1922. The UST was emptied and cleaned in 1991 (PAP-00244655).

Area F2

This area consists of a piping trench located beneath a metal plate in the floor of the facility engine room, which houses the facility air compressors. This area was identified as an area of potential concern subsequent to conditional sampling plan approval during implementation of decontamination/decommissioning activities for machinery pits and other subgrade structures at the facility. Condensate from the air compressors was determined to have been historically discharged to the trench, which was earthen-bottomed (PAP-00244657).

(PAP-00244342)

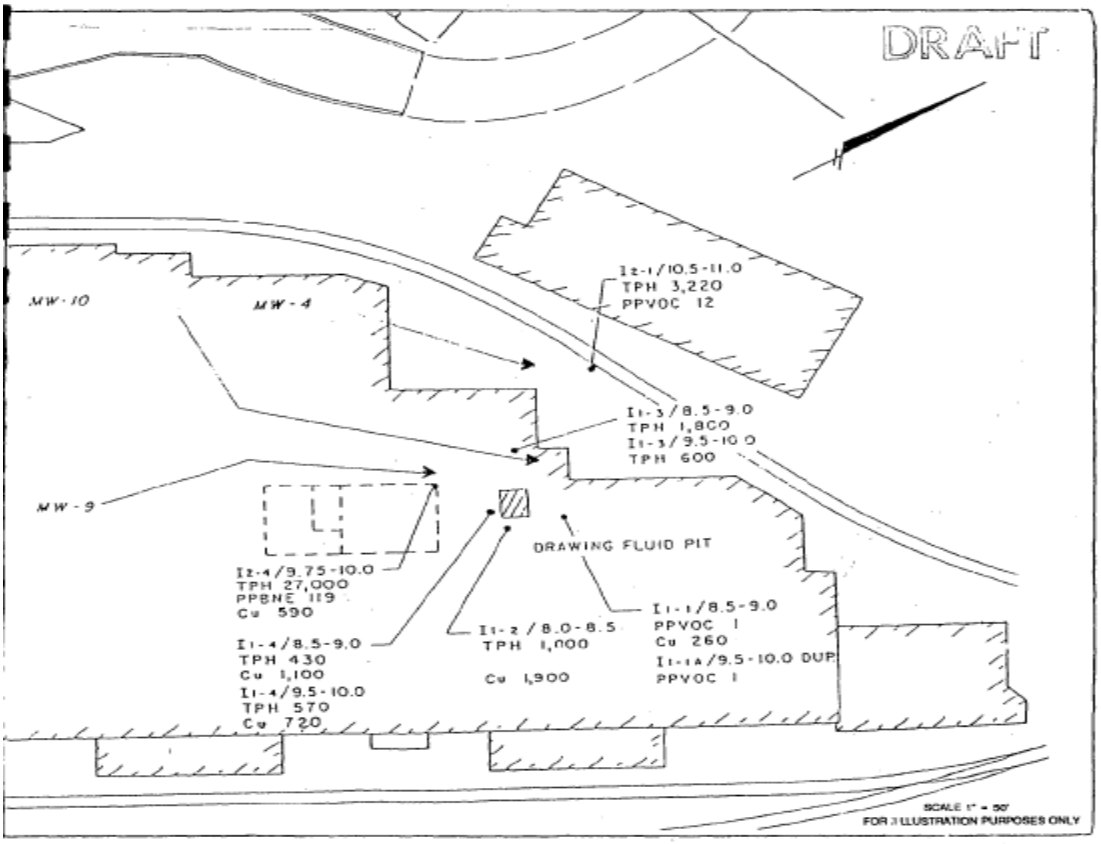
Area G

Area G is the location of an 8,000-gallon gasoline UST. In addition, a small, approximately 1,000-gallon, abandoned UST that contained sand and a small amount of water, was discovered immediately adjacent to the gasoline UST during removal of the gasoline UST. Both USTs were properly closed (PAP-00244657-8). The NJDEP approved NFA for Area G in their letter dated April 11, 1994 (PAP-00240168).

Okonite Company

Diamond Alkali OU2 Allocation

ADR Confidential



Facility Data Report

Area I1

This area is the location of a 9,000-gallon concrete pit that was used to store drawing fluid for copper wire. The pit was installed in approximately 1976. No evidence of contamination was encountered above the water table (PAP-00244661). NJDEP approved NFA for Area I1 in 1994 (PAP-00240168-70).

Area I2

This area is an exterior area to the west of the drawing fluid pit and the basement area of Building 25 in which above ground drawing fluid tanks were located (PAP-00244664).

LOCATIONS OF SOIL BORINGS AND MONITORING WELLS IN AREA I AND BUILDING 25 BASEMENT

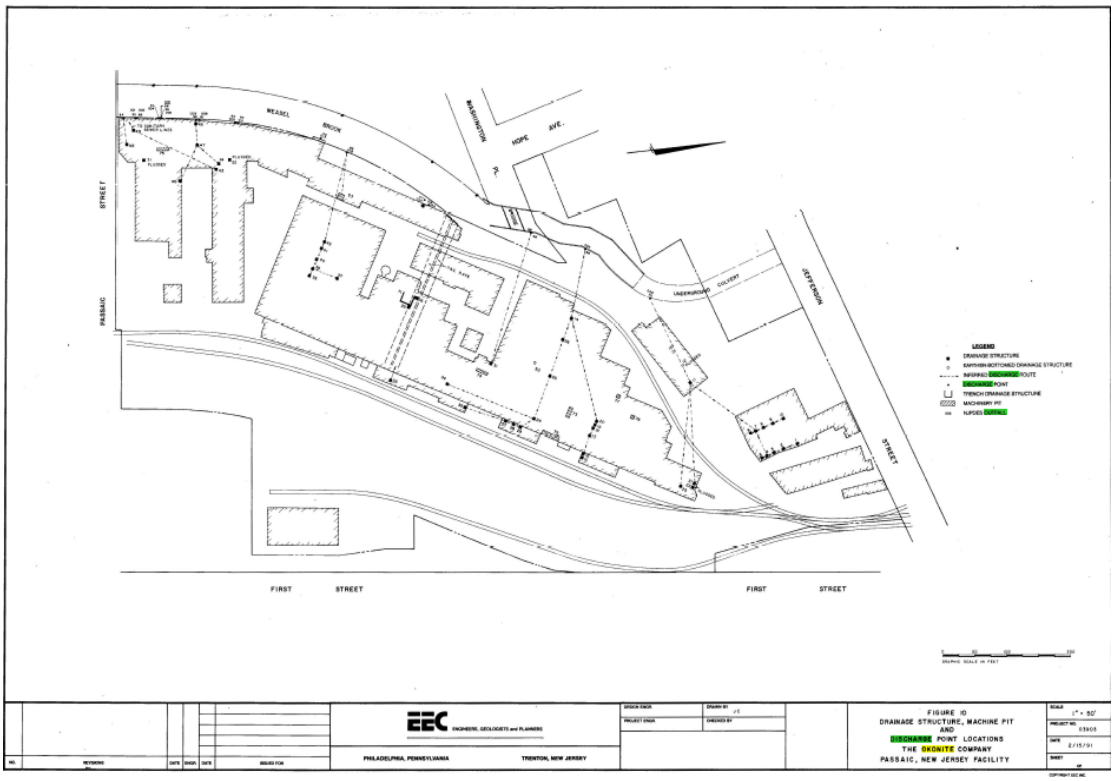
(PAP-00244344)

Area K

Area K is an unpaved area that was partially covered with a tar-like substance and resin beads from the facility water softeners. Plant personnel reported that empty drums were also historically stored in this area (PAP-00244665).

Area M

This area was identified as an area of potential environmental concern during facility decontamination/decommissioning activities when the Banbury mixer (rubber compounding machine) was removed. The area is approximately 20 by 10 feet in size and, the bottom of the pit is approximately 3 feet below grade, and consisted of several concrete sub-chambers (PAP-00244684). The sub-chambers were mostly filled with soil and sediment but also contained minor amounts of rubber compounding waste. Removal of the fill material revealed that the floors and walls of the sub-chambers are not continuous throughout the structure (i.e., gaps are present) (PAP-00244684).



This Area was subsequently divided into Areas M1 and M2. Area M1 was described as the pit beneath the former Banbury mixer inside the main building and Area M2 was the groundwater in the vicinity of the former Banbury mixer. Area M2 contained different COCs than those found in Area M1. Based on the distribution of impacted soils and field observations, the impacts at Area M1 were attributed to not only the Banbury pit but also fill material in the area or historical operations through the former wooden floor in the area of that building (PAP-00245788-93).

Drainage Structures and Machinery Pits

Several drainage structure, machinery pits, and discharge points to Weasel Brook were identified at Okonite (PAP-00244725). Detailed information on the discharge points to Weasel Brook is summarized in Sections 4 and 5 below.

Most of the interior drainage structures in the facility were identified as access-ways to storm drain lines. These structures were covered with metal plates and were not located near machinery except for one structure 15 (which fed into 16-20). In addition, most of the facility contact and non-contact cooling water was discharged directly to Weasel Brook, via underground piping under the New Jersey Pollution Discharge Elimination System (NJPDES) permit (PAP-00244720).

In addition to drains 13, 18-20, 30, 53, and 54, and the Weasel Brook discharge points, three areas of potential environmental concern were identified in the course of decontamination and decommissioning activities. These were the stream bank adjacent to Building 37, where lead strips were found; the baghouse area, an unpaved area beneath the Banbury mixer where oil-stained soils were observed; and the hydraulic lift pit, the location of lift equipment for the loading dock, where oil-stained soils were also found (PAP-00245798-802).

(PAP-00244375)

According to the December 17, 2003 *Remedial Action Report (RAR)*, no sediments are present at the site; however, Weasel Brook forms the western boundary of the site. Okonite discharged wastewater to Weasel Brook via several outfall pipes, as permitted by NJPDES Permit No. NJ0002615 (PAP-00259165).

4. Identified COCs

- PCBs (used)
- PAHs (used, detected)
- Copper (used, detected)
- Lead (used, detected)
- Mercury (detected)

PCBs

According to a December 14, 1992 Administrative Consent Order Affidavit, PCBs were present in exterior transformers (PAP-00240541)..

PAHs

The International Carbon Black Association states that PAHs can only be extracted from the surface of industrially manufactured Carbon Black under vigorous laboratory conditions, and that the risks to human health associated with presence of PAHs originating from carbon black in its final product form is extremely low (PAP-00264260). Based on review of the *Result of Sampling Plan Implementation and Supplemental At-*

Peril Activities dated February 1991 and *Results of Supplemental Sampling Plan Implementation and Additional At-Peril Activities*, dated October 1992, PAHs were detected in soil samples collected from the various AOCs. Presented below are the PAH concentrations detected at the various AOCs:

Max PAH Concentrations detected at AOCs (mg/kg)						
PAH	**Area A**	**Area B1**	**Area B2**	**Area C**	**Area D**	**Area E**
Acenaphthylene			0.029 J	0.23 J		0.031 J
Acenapthene				5.8		0.026 J
Anthracene				9.4		0.065
Benzo(a)anthracene		0.45	1	23	0.019	0.36
Benzo(a)pyrene		0.23 J		16	0.012	0.3 J
Benzo(b)fluoranthene			0.25 J	1.5	0.014	1.1
Benzo(g,h,i)perylene				17		0.36 J
Benzo(k)fluoranthene			0.2 J	15	0.012	
Chrysene		0.47	3.7	22	0.024	0.45
Fluoranthene	0.061 J	0.66	1.7 J	42	0.037	0.74
Fluorene				0.23 J		0.034 J
Indeno(1,2,3-cd)pyrene			0.73	17	0.003	0.44
Naphthalene				1.8		
Phenanthrene	0.027 J	0.54	0.84	43	0.014	0.57
Pyrene	0.095 J	1.1	1.9	46	0.024	0.73

J: Estimated
(PAP-00244645-56, PAP-0245810-1)

Areas A, B1 and D

Soil sampling conducted at Areas A and B1 in 1990 showed carcinogenic polycyclic aromatic hydrocarbons (cPAHs) were below 10 milligrams per kilogram (mg/kg) (PAP-00244643-44).

The following PAHs: phenanthrene, fluoranthene, and pyrene were detected at estimated concentrations of 0.027 mg/kg, 0.061 mg/kg, and 0.095 mg/kg collected from sample A-1 at a depth of 2.5-3.0 feet below ground surface (ft bgs) (PAP-00244645).

The following PAHs: phenanthrene, fluoranthene, pyrene, benzo(a)anthracene, and benzo(a)pyrene were detected at concentrations of 0.54 mg/kg, 0.66 mg/kg, 1.1 mg/kg, 0.45 mg/kg, and 0.23 mg/kg from sample B-2B at a depth of 1-1.5 ft bgs (PAP-00244646).

The following PAHs: benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, chrysene, fluoranthene, indeno(1,2,3-cd)pyrene, phenanthrene, and pyrene were detected at concentrations of 0.019 J mg/kg, 0.012 J mg/kg, 0.014 J mg/kg, 0.012 J mg/kg, 0.024 J mg/kg, 0.037 mg/kg, 0.003 J mg/kg, 0.014 J mg/kg, and 0.024 J mg/kg collected from sample D-3A at a depth of 1.5-2.0 ft bgs (PAP-00245811).

Historical soil sampling data from Areas A, B1, and D complied with applicable RDCSCC and were subsequently granted NFA by the NJDEP on April 11, 1994 (PAP-00240168-70).

Area B2

Soil sampling conducted in 1990 at Area B2 showedconcentrations of PAHs to be below 10 mg/kg. The following PAHs; acenaphthylene, phenanthrene, anthracene, fluoranthene, pyrene, and benzo(a)anthracene were detected at maximum concentrations of 0.0029 J mg/kg, 0.84 mg/kg, 0.17 J mg/kg, 1.7 mg/kg, 1.9 mg/kg, 1 mg/kg (from sample B2-4 at a depth of 4.5-5 ft bgs); chrysene was detected at 3.7 mg/kg in sample B2-3 at a depth of 4.5-5 ft bgs; and, benzo(b)fluoranthene and benzo(k)fluoranthene were detected at estimated concentrations of 0.25 J mg/kg and 0.2 J mg/kg (from sample B2-2 at a depth of 4.5-5 ft bgs) (PAP-00244648-49). The soil was disposed at the American Landfill in Youngstown, Ohio and the excavation was backfilled with offsite fill after laboratory results revealed that contamination had been removed (PAP-00244650). The NJDEP approved NFA for AOC B2 in their letter dated April 11, 1994 (PAP-00240168-70).

Area C

Area C is a paved area and was used to store empty drums of facility process-related materials. Two soil borings were completed within one foot of previous borings C-2 and C3 to a depth of three feet. No evidence of contamination (i.e., staining or odor) was observed in either boring. Samples were collected from 1.5 to 2 ft bgs and analyzed for volatile organic compounds (VOCs), base neutral compounds (BNs), and priority pollutant metals. Subsequent sampling of Area C on August 12, 1991, was conducted to determine whether the previous concentrations were representative of conditions in the area or were related to the presence of coal, ash or cinder fill material. Three additional soil samples were collected and analyzed for BNs. Results of this additional sampling revealed that the previous PAH concentrations in sample C-2A/1.5-2 were not representative of conditions in Area C and other samples were compliant with applicable standards (PAP-00245760, 778-79, 804).

The maximum concentrations of PAHs detected during the two soil sampling events were as follows (PAP-00244650-52, PAP-00245810):

Okonite Area C PAH Detections	
Contaminant	**Concentration/Sample ID/Depth**
Acenaphthylene	0.23 J mg/kg / C-15 at a depth of 1.5-2 ft bgs
Acenapthene	5.8 mg/kg / C-2A at a depth of 1.5-2 ft bgs
Anthracene	9.4 mg/kg / C-2A at a depth of 1.5-2 ft bgs
Benzo(a)anthracene	23 mg/kg / C-2A at a depth of 1.5-2 ft bgs
Benzo(a)pyrene	16 mg/kg / C-2A at a depth of 1.5-2 ft bgs
Benzo(b)fluoranthene	1.5 mg/kg / C-2A at a depth of 1.5-2 ft bgs
Benzo(g,h,i)perylene	17 mg/kg / C-2A at a depth of 1.5-2 ft bgs
Benzo(k)fluoranthene	15 mg/kg / C-2A at a depth of 1.5-2 ft bgs
Chrysene	22 mg/kg / C-2A at a depth of 1.5-2 ft bgs
Fluoranthene	42 mg/kg / C-2A at a depth of 1.5-2 ft bgs
Fluorene	0.23 J mg/kg / C-2A at a depth of 1.5-2 ft bgs
Indeno(1,2,3-cd)pyrene	17 mg/kg / C-2A at a depth of 1.5-2 ft bgs
Naphthalene	1.8 mg/kg / C-2A at a depth of 1.5-2 ft bgs
Phenanthrene	43 mg/kg / C-2A at a depth of 1.5-2 ft bgs
Pyrene	46 mg/kg / C-2A at a depth of 1.5-2 ft bgs

J: estimated

Following an evaluation of the data, the NJDEP approved conditional NFA for Area C in their April 11, 1994 letter “if Okonite applies appropriate institutional and/or engineering controls” (PAP-00240168-70).

Area E

This area was the location of an abandoned approximately 300-gallon steel UST encased in concrete that was historically used to store waste kerosene and other compounds that may have been used as degreasers at the facility. The UST was properly decommissioned through removal in accordance with facility Decontamination/Decommissioning Plan. The UST was disposed as scrap metal along with the USTs from Area G. No evidence of a release was found in the removal of the USTs. Soil sampling results upon UST removal showed concentrations of phenanthrene, anthrancene, fluoranthene, pyrene, benzo(a)anthracene, and benzo(a)pyrene to be 0.57 mg/kg, 0.065 mg/kg, 0.74 mg/kg, 0.73 mg/kg, 0.36 mg/kg, and 0.3 mg/kg (from sample E-4 collected at a depth of 5.5 ft bgs) (PAP-00244654). Based on the post-removal analytical results, NJDEP approved NFA for Area E in their letter dated April 11, 1994 (PAP-00240168-70).

Area F1

This area is the location of a 76,000-gallon concrete UST that was used to store No. 6 fuel oil. The UST was installed in approximately 1922. The UST was emptied and cleaned in 1991. Soil borings F-7 through F-9 were completed to the northwest, north, east, and west (immediately downgradient) of the UST respectively. These borings were

completed within ten feet of the UST and to depths of 11 ft. Oil staining and odor were observed in all four borings from depths starting from 7 to 10 ft bgs. Samples for laboratory analyses were collected from 10 to 10.5 ft bgs. Presented below in a tabular format are the concentrations of PAHs detected at Area F1 collected during a 1990 soil sampling event (PAP-00244656):

Okonite Area F1 PAH Detections	
Contaminant	**Concentration/Sample ID/Depth**
Anthracene	2.4 mg/kg / F-8 / 10-10.5 ft bgs
Benzo(a)anthracene	5.6 mg/kg / F-8 / 10-10.5 ft bgs
Benzo(a)pyrene	5.9 mg/kg / F-8 / 10-10.5 ft bgs
Chyrsene	8.8 mg/kg / F-8 / 10-10.5 ft bgs
Fluorene	5 mg/kg / F-8 / 10-10.5 ft bgs
Napthalene	16 mg/kg / F-8 / 10-10.5 ft bgs
Phenanthrene	19 mg/kg / F-8 / 10-10.5 ft bgs

Subsequent to the original sampling, a duplicate sample was collected to evaluate the previous PAH detections at Area F1, identified as sample F-10A/10.5-11. No PAHs were detected in this sample (PAP-00245760, 84).

Multiple soil excavations were conducted at Area F1 in 2002, as well as in 2007 following the demolition of former Building 37 (PAP-00259691; PAP-00264067). Post-excavation soil samples complied with applicable soil standards to the west (toward Weasel Brook) following the 2007 excavation activities (PAP-00264067).

Max PAH Concentrations detected at AOCs (mg/kg)

J: estimated

(PAP-00244662-79, PAP-00245836-49, PAP-00259185-7)

Area I1

This area is the location of a 9,000-gallon concrete pit that was used to store drawing fluid for copper wire. The pit was installed in approximately 1976. No evidence of contamination was encountered above the water table. Two samples for laboratory analyses were collected from each boring from the six-inch interval above that apparently affected by normal fluctuations of the water table (8 to 8.5 or 8.5 to 9 ft) and from the six-inch interval at the bottom of the pit (9.5 to 10 ft). Soil samples collected during a 1990 soil sampling event showed maximum detections of the following PAHs: phenanthrene (0.048 J mg/kg), fluoranthene (0.037 J mg/kg), and chrysene (0.04 J mg/kg), collected from sample I1-3 at a depth of 8.5-9 ft bgs and pyrene (0.052 J mg/kg), from sample I1-4 at a depth of 8.5-9 ft bgs (PAP-00244661-79). NJDEP approved NFA for Area I1 in 1994 (PAP-00240168-70).

Area I2

This area is an exterior area to the west of the drawing fluid pit and the basement area of Building 25 in which above ground drawing fluid tanks were located. Soil borings I2-1 through I2-3 were completed outside the building to the water table at distances of approximately 20 ft to the north, west, and south of I-2 in an effort to determine the source of conditions encountered in the previous boring. A fourth boring, I2-4 was completed to the east of I-2 inside the building in the hole in the basement floor. No evidence of contamination was observed in any of the exterior borings until the water table, which was encountered at a depth of approximately 10 ft bgs. Soil at the water table was oil stained and had an odor of weathered oil. Evidence of contamination in the form of oil staining and odor was observed throughout I2-4. A sample for laboratory analysis was collected within six inches of the water table and analyzed for VOCs, copper, mercury, and lead, with the exception of I2-4, which was not analyzed for mercury and lead (PAP-00244664).

The following PAHs were detected: phenanthrene (0.025 J mg/kg), pyrene (0.031 J mg/kg), and naphthalene (1.8 mg/kg) from sample I2-4 at a depth of 9.75-10 ft bgs; and chrysene (0.025 J mg/kg) and benzo(a)anthracene (0.026 J mg/kg) from sample I2-1B at a depth of 9.5-10 ft bgs (PAP-00244666-67).

Further soil delineation investigations at Area I2 in 1992 were not evaluated for COCs associated with OU2 and included only petroleum hydrocarbons. Based on additional delineation conducted, and the very limited access to this Area due to its location in a building basement, Okonite proposed institutional controls for Area I2 (PAP-00260513, 524, 551). NJDEP conditionally approved institutional controls for Area I2 in 1994 (PAP-00240168, 72).

Area K

Area K is an unpaved area that was partially covered with a tar-like substance and resin beads from the facility water softeners. Plant personnel reported that empty drums were also historically stored in this area (PAP-00244665). Approximately 200 cubic yards of soil was removed. A total of 15 post-removal soil samples were collected following the

first excavation on January 23, 1993. Samples were analyzed for TPH, VOCs, BNs, lead, and zinc. Several PAHs were detected in this area following round 1 excavation. The soils removed during the first soil event consisted entirely of ash and cinder fill. The fill is this area contained parts of plumbing fixtures, glass vials, metals lids, etc. (PAP-00244668). Okonite concluded that, due to the analytical results of the first round of post-removal samples, a second soil removal event was required. Subsequently, an additional 100 cubic yards were removed and post-removal sampling was conducted on December 7, 1990. Following the second excavation, 11 post-removal soil samples were collected from the excavation base and the base of the sidewalls and analyzed for TPH, BNs, lead, zinc, mercury, copper, and PCBs. The maximum concentrations of PAHs and metals detected in this area are presented below in a tabular format (PAP-00244669-77).

Okonite Area K PAH Max Detections	
Contaminant	**Concentration/Sample ID/Depth**
Acenapthene	0.36 J / K-5 / 5.5-6 ft bgs
Acenaphthylene	0.3 J mg/kg / K-4 / 5.5-6 ft bgs
Anthracene	1.5 mg/kg / K-5 / 5.5-6 ft bgs
Benzo(a)anthracene	5.1 mg/kg / K-9 / 1.5-2 ft bgs
Benzo(a)pyrene	3.1 mg/kg / K-17 / 7-7.5 ft bgs
Benzo(b)fluoranthene	5.5 mg/kg / K-17 / 7-7.5 ft bgs
Benzo(g,h,i)perylene	3.2 J mg/kg / K-5 / 5.5-6 ft bgs
Benzo(k)fluoranthene	4 mg/kg / K-17 / 7-7.5 ft bgs
Chrysene	6.7 mg/kg / K-9 / 1.5-2 ft bgs
Fluoranthene	12 mg/kg / K-5 / 5.5-6 ft bgs
Fluorene	0.39 J mg/kg / K-5 / 5.5-6 ft bgs
Ideno(1,2,3-cd)pyrene	3.2 J mg/kg / K-5 / 5.5-6 ft bgs
Naphthalene	0.33 J mg/kg / K-5 / 5.5-6 ft bgs
Phenanthrene	8.9 mg/kg / K-5 /5.5-6 ft bgs
Pyrene	11 mg/kg / K-5 / 5.5-6 ft bgs

J: estimated

In the October 1992 *Results of Supplemental Sampling Plan Implementation*, NFA was recommended (PAP-00245760, 806). The NJDEP conditionally approved NFA with the requirement that the previous data be reevaluated to the then-applicable RDCSCC (PAP-00240172-73). The data for sample K-16/9.5-10.0 met then-applicable RDCSCC for BN compounds (PAP-00260518). The NJDEP approved NFA for Area K in their comment letter dated January 20, 1995 (PAP-00240079, 81).

Area M

This area was identified as an area of potential environmental concern during on-going facility decontamination/decommissioning activities when the Banbury mixer (rubber compounding machine) was removed. The area is approximately 20 by 10 feet in size and, the bottom of the pit is approximately 3 feet below grade, and consisted of several concrete sub-chambers. The sub-chambers were mostly filled with soil and sediment but also contained minor amounts of rubber compounding waste. Removal of the fill

material revealed that the floors and walls of the sub-chambers are not continuous throughout the structure (i.e., gaps are present). The fill material that was removed prior to the submittal of the February 1992 *Results of Sampling Plan Implementation and Supplemental At-Peril Activities* report (approximately 15 cubic yards) was staged beside the pit. A waste classification sample was collected from this material. No PAHs were detected (PAP-00244684).

Drainage Structures

Soil samples were collected, and in some cases soils were removed from drainage structure areas. Samples were analyzed for TPH, VOCs, BNs and metals (PAP-00245793-99). Maximum PAH detections from the drainage structures and pits are presented below:

Max PAH Concentrations detected at Drainage Structures (mg/kg)						
PAH	**#13**	**#18**	**#19**	**#20**	**#30**	**#54**
Acenaphthene			1.4	1.4		0.14 J

(PAP-00245836-49)

No sediments are present at the site; however, Weasel Brook forms the western boundary of the site. Okonite collected 13 sediment samples from Weasel Brook in July 1992. The samples were analyzed for metals, VOCs, base neutrals, and total organic carbon. Sample locations were biased towards the areas where outfall pipes discharged to Weasel Brook. Samples of stream bank and/or bottom sediments were collected where available, beneath three of the facility outfall pipes to Weasel Brook and at a location downstream of the facility outfall pipes. Bank and bottom sediment samples were also collected at the furthest upstream end of the brook on the site (PAP-00243477), and at a location downstream of the facility outfall pipes. A sample was not collected at the upstream end of the brook at the property because the brook enters the property boundary in a covered culvert. The bottom of the brook was concrete and stone where it exited the culvert and no sediment was present for sampling. A number of PAHs were detected in two bank sediment samples and three bottom sediment

samples, including SS-3 at a depth of 0-6 inches. According to the Remedial Action Report (RAR), dated December 17, 2003, the source of these PAHs was unknown. However, a possible source was the historic fill in the area, which also contained PAHs (PAP-00259165). A significant amount of time had passed since Okonite's industrial discharges to the brook ceased. Normal processes of erosion and deposition have likely made sediment conditions at that time non-representative of any impacts Okonite's operations may have had (PAP-00243478).

Presented below are the maximum detected concentrations of PAHs in sediment samples collected from Weasel Brook (PAP-00259185-91):

Okonite Weasel Brook PAH Detections (mg/kg)	
Contaminant	**Concentration/Sample ID/Depth**
Acenaphthene	0.58 J / SS-4 / 0-6"
Acenaphthylene	0.95 J / SS-7 / 0-6"
Anthracene	2.5 J / SS-7 / 0-6"
Benzo(a)anthracene	14 / SS-4 / 0-6"
Benzo(a)pyrene	24 / SS-4 / 0-6"
Benzo(b)fluoranthene	17 / SS-4 / 0-6"
Benzo(g,h,i)perylene	7.1 / SS-4 / 0-6"
Benzo(k)fluoranthene	27 / SS-4 / 0-6"
Chrysene	18 / SS-4 / 0-6"
Dibenzo(a,h)anthracene	1.8 J / SS-4 / 0-6"
Fluoranthene	13 / SS-2 / 0-6"
Fluorene	1.5 J / SS-7 / 0-6"
Ideno(1,2,3-cd)pyrene	5.6 / SS-4 / 0-6"
Naphthalene	0.014 J / SS-3 / 0-6"
Phenanthrene	11 / SS-2 / 0-6"
Pyrene	21 / SS-4 / 0-6"

J: estimated

On May 5, 2004, additional sediment samples were collected from Weasel Brook at a previous location of SS-3/0-6" collected in 1992 for total organic carbon, TPH, and BNs. During the 2004 sampling event, waste automotive parts were observed in Weasel Brook and had been dumped from the bank opposite of Okonite . (PAP-00258638).

Copper

Based on review of the *Result of Sampling Plan Implementation and Supplemental At-Peril Activities* dated February 1991; copper was only detected in soil samples collected from the following AOCs. Presented below are the copper concentrations at the various AOCs:

Max Copper Concentrations detected at AOCs (mg/kg)						
Metal	**Area C 1.5-2 ft bgs**	**Area I1 8-8.5 ft bgs**	**Area I2 9.75-10 ft bgs**	**Area K 7.5-8 ft bgs**	**Drain 20**	**Weasel Brook 0-6" bgs**
Copper	95	1,900	590	260	12,000	430

(PAP-00244652, 662, 667, 679; PAP-00245845, PAP-00259186)

Area C

Area C is a paved area and was used to store empty drums of facility process-related materials. Two soil borings were completed within one foot of previous borings C-2 and C3 to a depth of three feet. No evidence of contamination (i.e., staining or odor) was observed in either boring. Samples were collected from 1.5 to 2 ft bgs and analyzed for volatile organic compounds (VOCs) and priority pollutant metals. Copper was detected at a maximum concentration of 95 mg/kg in sample C-3A at a depth of 1.5-2 ft bgs (PAP-00244652).

Area I1

This area is the location of a 9000-gallon concrete pit that was used to store drawing fluid for copper wire. The pit was installed in approximately 1976 and was approximately 9.5 ft bgs. Soil borings were completed on all four sides of the pit. Soil borings could not be completed adjacent to the pit on the north and west sides due to numerous subsurface obstructions such as metal plates, subsurface concrete slabs, etc., that were historically located in this area. A total of nine borings were installed. No evidence of contamination was encountered above the water table in any of the soil borings. Two samples for laboratory analyses were collected from each boring from the six-inch interval above the water table (8 to 8.5-9 ft bgs) and from a six-inch interval at the bottom of the pit (9.5-10 ft. bgs). All samples were analyzed for VOC and copper. Copper was detected at a maximum concentration of 1,900 mg/kg from sample I1-2B at a depth of 8-8.5 ft bgs (PAP-00244662). NJDEP approved NFA for Area I1 in 1994 (PAP-00240168-70).

In their comment letter dated April 11, 1994, NJDEP noted that the concentration of 1,900 mg/kg copper did not meet the then-applicable Residential Direct Contact Soil Cleanup Criteria (RDCSCC) (PAP-00240168, 70). Although elevated metal concentrations were detected in downgradient wells in one round of samples, the concentrations were attributed to incomplete field filtering and not to dissolved metals. As the soil sample was collected at 8 feet below grade and beneath the building, this did not require remediation. NJDEP approved NFA for Area I1 in 1994 (PAP-00240168-70).

Area I2

This area is an exterior area to the west of the drawing fluid pit and the basement area of Building 25 in which above ground drawing fluid tanks were located. Soil borings I2-1 through I2-3 were completed outside the building to the water table at distances of approximately 20 ft to the north, west, and south of I-2 in an effort to determine the source of conditions encountered in the previous boring. A fourth boring, I2-4 was

completed to the east of I-2 inside the building in the hole in the basement floor. No evidence of contamination was observed in any of the exterior borings until the water table, which was encountered at a depth of approximately 10 ft bgs. Soil at the water table was oil stained and had an odor of weathered oil. Evidence of contamination in the form of oil staining and odor was observed throughout I2-4. A sample for laboratory analysis was collected within six inches of the water table and analyzed for VOCs, copper, mercury, and lead, with the exception of I2-4, which was not analyzed for mercury and lead (PAP-00244664). Copper was detected at a concentration of 590 mg/kg in sample I2-4 at a depth of 9.75-10 ft bgs (PAP-00244667).

Area K

Area K is an unpaved area that was partially covered with a tar-like substance and resin beads from the facility water softeners. Plant personnel reported that empty drums were also historically stored in this area. Approximately 200 cubic yards of soil was removed during the first soil removal event. A total of 15 post-removal soil samples were collected following the first excavation on January 23, 1993. Samples were analyzed for TPH, VOCs, BNs, lead, and zinc. The soils removed during the first soil event consisted entirely of ash and cinder fill. The fill is this area contained parts of plumbing fixtures, glass vials, metals lids, etc. Okonite concluded that, due to the analytical results of the first round of post-removal samples, a second soil removal event was required. Subsequently, an additional 100 cubic yards were removed and post-removal sampling was conducted on December 7, 1990. Following the second excavation, 11 post-removal soil samples were collected from the excavation base and the base of the sidewalls and analyzed for TPH, BNs, lead, zinc, mercury, copper, and PCBs (PAP-00244676). The maximum detected concentration of copper in this area during the second soil sampling event was 260 mg/kg collected from sample K-25 at a depth of 7.5-8 ft bgs (PAP-00244679). The NJDEP approved NFA for Area K in their comment letter dated January 20, 1995 (PAP-00240081).

Drainage Structures

Soil borings were advanced and samples were collected from the drainage structures. Maximum detected copper concentrations are presented in the following table:

Max Copper Concentrations detected at Drainage Structures (mg/kg)			
Drain #	**Sample**	**Depth**	**Concentration**
13	DR-3	0-6”	4,300
18	DR-2	0-6”	870
19	19	4.5-5 ft	300
20	DR-1	0-6"	12,000
30	30	2-2.5 ft	260
53	DR53	0.5 ft	100
54	DR54	2.5-3 ft	860

(PAP-00245837, 41, 43, 45, 47, 49)

The highest copper concentration was located at Drain 20. Soil was removed in the vicinity of Drains 18-20 to a depth of 5 ft bgs. Copper was not detected in the Drain 20 post-removal sample. The removed soil was sample and classified as non-hazardous but was disposed in bulk with other waste as hazardous waste D008 (PAP-00245795).

No sediments are present at the site; however, Weasel Brook forms the western boundary of the site. Okonite discharged wastewater to Weasel Brook via several outfall pipes, as permitted by NJPDES Permit No. NJ0002615 (PAP-00259165). As documented in a Priority Pollutants Monitoring Report, dated December 6, 1977, copper was found at a concentration of 27 J micrograms per liter (µg/L) in the raw influent water. Effluent samples from water discharged from Site operations during that same sampling event exhibited lower concentrations of copper, at 12 J and 15 J µg/L, indicating that the manufacturing process did not introduce a measurable quantity of copper to the waste stream (PAP-00264228, 55). As required by NJEDP, Okonite collected 13 sediment samples from Weasel Brook in July 1992. The samples were analyzed for metals, VOCs, base neutrals, and total organic carbon. Sample locations were biased towards the areas where outfall pipes discharged to Weasel Brook. Samples of stream bank and/or bottom sediments were collected where available, beneath three of the facility outfall pipes, at the furthest upstream end of the brook on the site (PAP-00243477), and at a location downstream of the facility outfall pipes. A sample was not collected at the upstream end of the brook at the property boundary because the brook enters the property in a covered culvert. The bottom of the brook was concrete and stone where it exited the culvert and no sediment was present for sampling (PAP-00243477). The most downstream sample location (SS-8, located adjacent to the former facilities southwest corner) had a copper concentration of 48 mg/kg (PAP-00243537). However, the most upstream sample (SS-3) had a copper concentration of 57 mg/kg (PAP-00243535). However, sample SS-4 at a depth of 0-6 inches had a concentration of 430 mg/kg (PAP-00243535).

Lead

Based on review of the RAR, dated December 17, 2003, lead was detected only at the following AOCs:

Max Lead Concentrations detected at AOCs (mg/kg)							
Metal	**Area C 1.5-2 ft bgs**	**Area G 6.5-7 ft bgs**	**Area I2 9-9.5 ft bgs**	**Area K 1.5-2 ft bgs**	**Area M 3.5-4 ft bgs**	**Drain 13**	**Weasel Brook 0-6" bgs**
Lead	270	370	106	87,500	6,700	110,000	8,200

(PAP-00244652, 659, 667, 672; PAP-00245837; PAP-00259186)

Area C

Area C is a paved area and was used to store empty drums of facility process-related materials. Two soil borings were completed within one foot of previous borings C-2 and C3 to a depth of three feet. No evidence of contamination (i.e., staining or odor) was observed in either boring. Samples were collected from 1.5 to 2 ft bgs and analyzed for

volatile organic compounds (VOCs) and priority pollutant metals. Lead was detected at a maximum concentration of 270 mg/kg in sample C-3A at a depth of 1.5-2 ft bgs (PAP-00244652).

Area G

Area G is the location of a former gasoline 8,000-gallon UST. In addition, a small, approximately 1,000-gallon, abandoned UST that contained sand and a small amount of water, was discovered immediately adjacent to the gasoline UST during removal of the gasoline UST. Both USTs were properly closed (PAP-00244657-58). Following removal of the two USTs, field observations and monitoring instrument responses showed that a small amount of contaminated soil remained in place at the west end of the excavation. Analytical results showed that lead was detected at a concentration of 370 mg/kg from sample G-3 at a depth of 6.5-7 ft bgs (PAP-00244659). The NJDEP approved NFA for Area G in their letter dated April 11, 1994 (PAP-00240168-9).

Area I2

This area is an exterior area to the west of the drawing fluid pit and the basement area of Building 25 in which aboveground drawing fluid tanks were located. Soil borings I2-1 through I2-3 were completed outside the building to the water table at distances of approximately 20 feet to the north, west, and south of I-2 in an effort to determine the source of conditions encountered in the previous boring. A fourth boring, I2-4 was completed to the east of I-2 inside the building in the hole in the basement floor. No evidence of contamination was observed in any of the exterior borings until the water table, which was encountered at a depth of approximately 10 feet bgs. Soil at the water table was oil stained and had an odor of weathered oil. Evidence of contamination in the form of oil staining and odor was observed throughout I2-4. A sample for laboratory analysis was collected within six inches of the water table and analyzed for VOCs, copper, mercury, and lead, with the exception of I2-4, which was not analyzed for mercury and lead (PAP-00244664). Lead was detected at a concentration of 106 mg/kg in sample I2-1B at a depth of 9-9.5 ft bgs (PAP-00244667).

Area K

Area K is an unpaved area that was partially covered with a tar-like substance and resin beads from the facility water softeners. Plant personnel reported that empty drums were also historically stored in this area. Approximately 200 cubic yards of soil was removed. A total of 15 post-removal soil samples were collected following the first excavation on January 23, 1993. Samples were analyzed for TPH, VOCs, BNs, lead, and zinc.. The soils removed during the first soil event consisted entirely of ash and cinder fill. The fill is this area contained parts of plumbing fixtures, glass vials, metals lids, etc. Okonite concluded that, due to the analytical results of the first round of post-removal samples, a second soil removal event was required. Subsequently, an additional 100 cubic yards were removed and post-removal sampling was conducted on December 7, 1990. Following the second excavation, 11 post-removal soil samples were collected from the excavation base and the base of the sidewalls and analyzed for TPH, BNs, lead, zinc, mercury, copper, and PCBs (PAP-00244676). The maximum detected concentration of

lead in this area during the second soil sampling event was 87,500 mg/kg collected from sample K-9 at a depth of 1.5-2 ft bgs (PAP-00244672).

In the October 1992 Results of Supplemental Sampling Plan Implementation, NFA was recommended (PAP-00245806). The NJDEP conditionally approved NFA with the requirement that the previous data be reevaluated to the then-applicable RDCSCC (PAP-00240168, 72-3). The NJDEP approved NFA for Area K in their comment letter dated January 20, 1995 (PAP-00240081).

Area M

This area was subsequently divided into Areas M1 and M2. Area M1 was described as the pit beneath the former Banbury mixer inside the main building and Area M2 was the groundwater in the vicinity of the former Banbury mixer. Area M2 contained different COCs than those found in Area M1. Soil sampling conducted in late 1991-early 1992 consisted of the installation of 36 soil borings and collection of 22 soil samples for TPH, BN, VOC, lead and zinc analysis. Lead concentrations ranged from not detected to 6,700 mg/kg; the concentration was below 400 mg/kg in all but one sample, M-16-3.5-4. The average lead concentration in Area M1 was approximately 400 ppm. Based on the distribution of impacted soils and field observations, the impacts at Area M1 were attributed to not only the Banbury pit but also fill material in the area or historical operations through the former wooden floor in the area of that building (PAP-002457 88-91).

Drainage Structures and Machinery Pits

Soil borings were advanced and samples were collected from the drainage structures. Maximum detected lead concentrations are presented in the following table:

Max Lead Concentrations detected at Drainage Structures and Pits (mg/kg)			
Drain # / Location	**Sample**	**Depth**	**Concentration**
13	DR-3	0-6”	110,000
18	DR-2	0-6”	17,000
19	DRX-2	6-6.5 ft	2,700
20	DR-1	0-6"	9,800
30	30	2-2.5 ft	990
53	DR53	0.5 ft	1,100
54	DR54	2.5-3 ft	490
Stream Bank	SB-1	1-1.5 ft	1,800
Baghouse	BH-3N	0-0.5 ft	2,200

(PAP-00245837, 41, 43, 45, 47, 49, 60, 62)

The highest lead concentration was located at Drain 13. Soil was removed in the vicinity of the drain to a depth of 4.5 ft bgs. Lead was detected in a post-removal sample at a concentration of 37 mg/kg, which was below the action level at the time. The excavation was backfilled with stone and capped with concrete (PAP-00245794).

No sediments are present at the site; however, Weasel Brook forms the western boundary of the site. Okonite discharged wastewater to Weasel Brook via several outfall pipes, as permitted by NJPDES Permit No. NJ0002615. As documented in a Priority Pollutants Monitoring Report, dated December 6, 1977, lead was found at a concentration of 2,200 J micrograms per liter (µg/L) in the raw influent water originating from the PVWC. Effluent samples from water discharged from Site operations during that same sampling event exhibited lower concentrations of lead, at 49 J and 700 J µg/L, indicating that the manufacturing process did not introduce a measurable quantity of lead to the waste stream (PAP-00264228, 55). As required by NJDEP, Okonite collected 13 sediment samples from Weasel Brook in July 1992. The samples were analyzed for metals, VOCs, base neutrals, and total organic carbon. Sample locations were biased towards the areas where outfall pipes discharged to Weasel Brook. Samples of stream bank and/or bottom sediments were collected where available, beneath three of the facility outfall pipes, at the furthest upstream of the brook on the site (PAP-00243477), and at a location downstream of the facility outfall pipes. A sample was not collected at the upstream end of the brook at the property boundary because the brook enters the property in a covered culvert. The bottom of the brook was concrete and stone where it exited the culvert and no sediment was present for sampling. Lead was detected in two bank samples. According to the RAR, dated December 17, 2003, lead was detected at a maximum concentration of 8,200 mg/kg from sample SS-2 at a depth of 0-6 inches (PAP-00259186). A significant amount of time had passed since Okonite's industrial discharges to the brook ceased. Normal processes of erosion and deposition have likely made sediment conditions at that time non-representative of any impacts Okonite's operations may have had (PAP-00243478). In addition, there was evidence of others dumping into this section of the river as evidenced by observations of industrial discharges from a number of outfall pipes directly across the brook from Okonite (PAP-00243478), and waste automotive parts that had been dumped from the bank of Weasel Brook opposite of Okonite(PAP-00258638).

Mercury

Based on review of the *Result of Sampling Plan Implementation and Supplemental At-Peril Activities* dated February 1991; mercury was only detected in soil samples collected from the following AOCs. Presented below are the mercury concentrations at the various AOCs:

Max Mercury Concentrations detected at AOCs (mg/kg)					
Metal	**Area C 1.5-2 ft bgs**	**Area I2 9.0-9.5 ft bgs**	**Area K 7-7.5 ft bgs**	**Drain 19 6-6.5 ft bgs**	**Weasel Brook 0-6" bgs**
Mercury	0.56	0.8	430	40	18

(PAP-00244652, 662, 667, 679; PAP-00245843, PAP-00259186)

Area C

Area C is a paved area and was used to store empty drums of facility process-related materials. Two soil borings were completed within one foot of previous borings C-2 and

C3 to a depth of three feet. No evidence of contamination (i.e., staining or odor) was observed in either boring. Samples were collected from 1.5 to 2 ft bgs and analyzed for volatile organic compounds (VOCs) and priority pollutant metals. Mercury was detected at a maximum concentration of 0.56 mg/kg in sample C-3A at a depth of 1.5-2 ft bgs (PAP-00244652).

Area I2

This area is an exterior area to the west of the drawing fluid pit and the basement area of Building 25 in which above ground drawing fluid tanks were located. Soil borings I2-1 through I2-3 were completed outside the building to the water table at distances of approximately 20 ft to the north, west, and south of I-2 in an effort to determine the source of conditions encountered in the previous boring. A fourth boring, I2-4 was completed to the east of I-2 inside the building in the hole in the basement floor. No evidence of contamination was observed in any of the exterior borings until the water table, which was encountered at a depth of approximately 10 ft bgs. Soil at the water table was oil stained and had an odor of weathered oil. Evidence of contamination in the form of oil staining and odor was observed throughout I2-4. A sample for laboratory analysis was collected within six inches of the water table and analyzed for VOCs, copper, mercury, and lead, with the exception of I2-4, which was not analyzed for mercury and lead (PAP-00244664). Mercury was detected at a maximum concentration of 0.8 mg/kg from sample I2-1B at a depth of 9.09.5 ft bgs (PAP-00244667).

Area K

Area K is an unpaved area that was partially covered with a tar-like substance and resin beads from the facility water softeners. Plant personnel reported that empty drums were also historically stored in this area. Approximately 200 cubic yards of soil was removed. A total of 15 post-removal soil samples were collected following the first excavation on January 23, 1993. The soils removed during the first soil event consisted entirely of ash and cinder fill. The fill is this area contained parts of plumbing fixtures, glass vials, metals lids, etc. Okonite concluded that, due to the analytical results of the first round of post-removal samples, a second soil removal event was required. Subsequently, an additional 100 cubic yards were removed and post-removal sampling was conducted on December 7, 1990. Following the second excavation, 11 post-removal soil samples were collected from the excavation base and the base of the sidewalls. These samples were analyzed for TPH, BNs, lead, zinc, mercury, copper, and PCBs (PAP-00244676). The maximum detected concentration of mercury in this area during the second soil sampling event was 430 mg/kg collected from sample K-24 at a depth of 7-7.5 ft bgs (PAP-00244679). Mercury was remediated at Area K to the satisfaction of the NJDEP (PAP-00240079, 81).

Area M

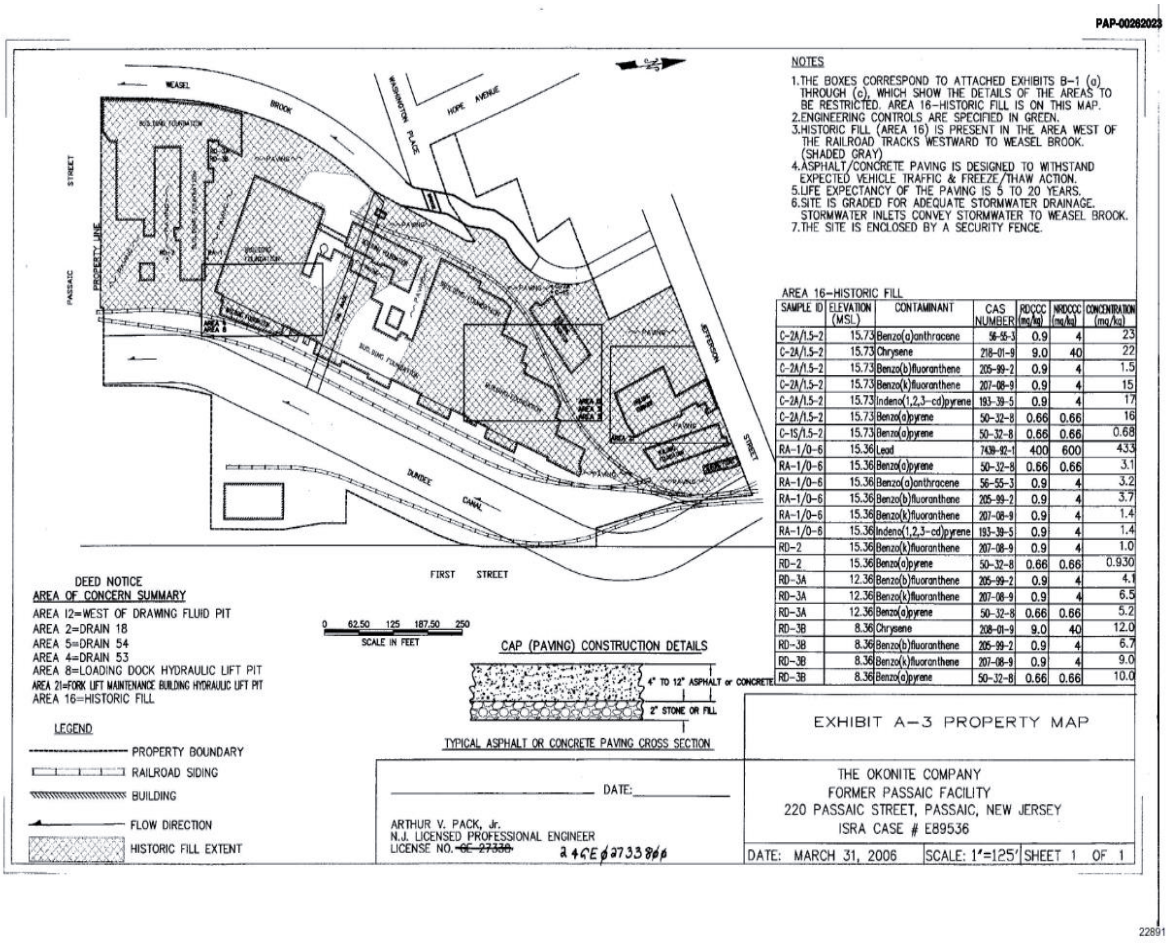
Mercury was not detected in the soil samples collected from Area M (PAP-00244684).

Drainage Structures

Soil borings were advanced and samples were collected from the drainage structures. Maximum detected mercury concentrations are presented in the following table:

Max Mercury Concentrations detected at Drainage Structures (mg/kg)			
Drain #	**Sample**	**Depth**	**Concentration**
13	DR-3	0-6”	1.4
18	DRX-1	6-6.5 ft	11
19	DRX-2	6-6.5 ft	40
20	DR-1	30-36"	24
30	30	2-2.5 ft	0.9
53	DR53	0.5 ft	0.06 J
54	DR54	2.5-3 ft	12

(PAP-00245837, 41, 43, 45, 47, 49)



The highest mercury concentration was located in a post-removal sample at Drain 19. Soil had been removed in the vicinity of the Drains 18-20 to a depth of 5 ft bgs. The removed soil was sample and classified as non-hazardous but was disposed in bulk with other waste as hazardous waste D008 (PAP-00245795-6).

No sediments are present at the site; however, Weasel Brook forms the western boundary of the site. Okonite collected 13 sediment samples from Weasel Brook in July 1992. The samples were analyzed for metals, VOCs, base neutrals, and total organic carbon. Sample locations were biased towards the areas where outfall pipes discharged to Weasel Brook. Samples of stream bank and/or bottom sediments were collected where available, beneath three of the facility outfall pipes , at the furthest upstream end of the brook on the site (PAP-00243477), and at a location downstream of the facility outfall pipes. A sample was not collected at the upstream end of the brook at the property because the brook enters the property boundary in a covered culvert. The bottom of the brook was concrete and stone where it exited the culvert and no sediment was present for sampling. According to the RAR, dated December 17, 2003, mercury was detected at a maximum concentration of 18 mg/kg from sample SS-4 at a depth of 0-6 inches (PAP-00259186). A significant amount of time had passed since Okonite’s industrial discharges to the brook ceased. Normal processes of erosion and deposition have likely made sediment conditions at that time non-representative of any impacts Okonite’s operations may have had (PAP-0024378). In addition, during the May 2004 sampling event, waste automotive parts were observed in Weasel Brook, and had been dumped from the bank opposite of Okonite (PAP-00258638).

Historic Fill

The Allocation Team has not determined whether the site is located on regional Historic Fill as designated by the NJDEP.[1]

However, historical documents including a historical site plan establishes historic fill on two thirds of the property based on soil investigations conducted at the Site (PAP-00264490). Of the AOCs identified at the Site, Historic Fill was identified as Area 16 (PAP-00260097). The AOCs discussed above are generally collocated with historic fill material (including ash and cinder), as determined by extensive subsurface investigations at the Site. The following figure depicts the extent of historic fill material encountered at the Site:

(PAP-00262023)

[1] *Digital Geodata Series, DGS04-7, Historic Fill for New Jersey*, https://www.nj.gov/dep/njgs/geodata/dgs04-7.htm, Quadrangle #52 & #53 (NJDEP map identifying locations of recognized historic fill).

The New Jersey Department of Environmental Protection (NJDEP) has established that Historic Fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 COCs: PAHs, lead, copper, and mercury.[2] Accordingly, NJDEP technical requirements for property containing Historic Fill requires sampling for the United States Environmental Protection Agency (EPA) Target Compound List (TCL) for PAHs and Target Analyte List (TAL) for metals, including lead, copper, mercury, and the OU2 PAH COCs.[3] PAHs, lead, copper, and mercury are recognized by NJDEP to be constituents of Historic Fill at varying levels, not atypically at or exceeding residential soil standards.[4]

The levels of PAHs, copper, lead and mercury detected at the site in soils are presented in the table below (PAP-00244645-67).

COCs Found in Onsite Soils	
COC	**Max Detected Concentration**
Lead	110,000 mg/kg
Copper	12,000 mg/kg
Mercury	430 mg/kg
Benzo(a)anthracene	23 mg/kg
Benzo(a)pyrene	24 mg/kg
Benzo(b)fluoranthene	17 mg/kg
Benzo(k)fluoranthene	27 mg/kg
Dibenzo(a,h)anthracene	0.14J mg/kg
Indeno(1,2,3-cd)pyrene	17 mg/kg

J: estimated

5. COC Pathways

Storm Sewer

There were 22 discharge outfalls from the facility to Weasel Brook. The discharge consisted of contact cooling water, non-contact cooling water, and storm water run-off (PAP-00242102, 48-49).

[2] *Characterization of Ambient Levels of Selected Metals and cPAHs In New Jersey Soils* (2002) and *Characterization of Ambient Levels of Selected Metals and Other Analytes In New Jersey Soils* (1998), studies prepared for NJDEP, Division of Science and Research, by BEM Systems, Inc.
[3] New Jersey Department of Environmental Protection (NJDEP), *N.J.A.C. 7:26E Technical Requirements for Site Remediation,* Table 4-2, November 2009 [Note that Table 4-2 has been deleted from the current version of N.J.A.C. 7:26E (May 7, 2012) and the updated *Historic Fill Technical Guidance* (April 2013) as NJDEP believed that the tables list of historic fill constituents was too restrictive].
[4] NJDEP Table 4-2 (PAHs and lead) and a summary of NJDEP records regarding investigations of properties in the vicinity of the Passaic River recognized to be located in areas of Historic Fill indicate that the following average/maximum (mg/kg) contamination levels of OU2 COCs exist in area Historic Fill: PAHs (1.91/160), lead (574/10,000), copper (11.2/1,200), and mercury (0.21/3.7).

Facility Data Report

According to an Application for Permit to Discharge Wastewaters dated March 28, 1988 Outfalls 006, 008, 011, 016, 019, 020, and 022 had an average flow of 50,000 GPD of stormwater discharge into Weasel Brook (PAP-00263525-28).

The same application reported Outfalls 001, 002 004, 005, 006, 008, 011, 015, and 021 were outfalls for contact cooling water, non-contact seal water, and steam condensate. The average flow of contact cooling water at the facility ranged from 6200 GPD to 12500 GPD (PAP-00263525-28).

(PAP-00263524)

(PAP-00263523)

Direct Discharge

According to a 2005 PRP Data Extraction Form for the Lower Passaic River Study Area, PVSC reported on the discharge of “polluting” boiler blowdown from the Okonite facility in 1973. PVSC did not indicate if the facility boiler blowdown outlet was discharged to the river or sewer. The company was directed to halt the pollution and discharge the boiler blowdown to the sanitary sewer. The 1973 PVSC Annual report noted that Mr. Strandberg, Plant Manager, replied that they had studied the situation and that it was feasible to install a boiler blowdown tank, with a discharge into the sanitary sewer. He further stated that this could only be done when the boilers were shut down, and they intended to do this during their summer shutdown in 1974. Since the pollution was not

great, the PVSC believed this to be reasonable. (PAS-00034781; PAS-00102011). PVSC documentation stated the polluting discharge continued from November 1973 through August 1974 (PAS-00123419). Note: The 1973 PVSC Annual Report did not specify COCs analyzed and there is no indication that any of the eight specific COCs at issue herein formed a part of the boiler blowdown discussed.

Okonite discharged wastewater to Weasel Brook via several outfall pipes, as permitted by NJPDES Permit No. NJ0002615. As documented in a Priority Pollutants Monitoring Report, dated December 6, 1977, copper was found at a concentration of 27 J µg/L in the raw influent water. Effluent samples from water discharged from Site operations during that same sampling event exhibited lower concentrations of copper, at 12 J and 15 J µg/L. Similarly, lead was found at a concentration of 2,200 J micrograms per liter (µg/L) in the raw influent water originating from the PVWC. Effluent samples from water discharged from Site operations during that same sampling event exhibited lower concentrations of lead, at 49 J and 700 J µg/L, indicating that the manufacturing process did not introduce a measurable quantity of copper or lead to the waste stream. (PAP-00264228, 55).

According to a 2005 PRP Data Extraction Form for the Lower Passaic River Study Area, sediment samples collected from Weasel Brook in July 1992 identified copper, lead, and mercury contamination. The samples were collected in the area of facility outfall pipes to Weasel Brook (Passaic River tributary), in the area of the stream bank, in sediments beneath three of the outfall pipes, at the furthest upstream end of the brook on the site (PAP-00243477), and at a location downstream of the outfall pipes (PAS-00123419). The most downstream sample location (SS-8, located adjacent to the former facilities southwest corner) had a copper concentration of 48 mg/kg. However, the most upstream sample (SS-3) had a copper concentration of 57 mg/kg.

Copper was detected at a maximum concentration of 430 mg/kg at sample location SS-4 (adjacent to the bank of the river in an area of historic fill) (PAP-00243535). Lead was detected in two bank samples (PAP-00243478). Lead was detected at a maximum concentration of 8,200 mg/kg at sample location SS-2 (on the bank of the river in an area of historic fill) (PAP-00259186). Industrial discharges from a number of outfall pipes directly across the brook from the Okonite facility were noted (PAP-00243478). Mercury was detected at a maximum concentration of 18 mg/kg at sample location SS-4 (adjacent to the bank of the river in an area of historic fill). All the maximum detected concentrations of copper, lead, and mercury were collected at a depth of 0-6 inches bgs (PAP-00259185-91). A figure showing the sediment sampling locations is available in Figure 6 of the October 1992 *Results of Supplemental Sampling Plan Implementation* (PAP-00243554). A significant amount of time had passed since Okonite's industrial discharges to the brook ceased. Normal processes of erosion and deposition have likely made sediment conditions at that time non-representative of any impacts Okonite's operations may have had (PAP-00243478). In addition, during a May 2004 sampling event, waste automotive parts were observed in Weasel Brook, and had been dumped from the bank opposite of Okonite (PAP-00258638).

Spills

There is no information regarding spills in the available file material.

6. Regulatory History/Enforcement Actions

Permits

According to 2005 *PRP Data Extraction Form for the Lower Passaic River Study Area*, Okonite discharged facility wastewater to Weasel Brook via several outfall pipes and held NPDES Permit NJ0002615 (PAS-00123418).

Okonite discharged stormwater, contact, and non-contact cooling waters to Weasel Brook. Prior to issuance, a draft permit application to discharge was released for public comment; no objections to Okonite's proposed discharges to Weasel Brook were raised, and the original NJPDES permit #NJ0002615 was issued. Permit #NJ0002615 was approved to discharge to Weasel Brook from a total of 22 discharges (PAP-00244709-719):

The NJPDES permits from 1974 to 1983 required Okonite to monitor the discharges and submit Discharge Monitoring Reports quarterly. Specific analytical parameters were required by the facility, including: flow, pH, and temperature. From 1983 to 1993, the permits added monitoring of petroleum hydrocarbons, chemical oxygen demand, total suspended solids, and total copper (PAP-00242145-56).

The monitoring results from March 21, 1989 NJPDES permit application contained copper ranging from less than 0.03 milligrams per liter (mg/L) to 0.64 mg/L, which was below the permitted limit of 1 mg/L (PAP-00242145-56).

Violation

As reported by the 1973 *Passaic Valley Sewerage Commissioners Annual Report*, while reviewing the Okonite outlet permit application, Mr. Lubetkin noted that outlet #018 was a boiler blowdown outlet. Since, generally speaking, boiler blowdown is polluting, and since it was easy to correct where a sanitary sewer was available (install a blowdown tank and discharge it to the sewer), Mr. Lubetkin requested that the Inspection Department check this and get a sample. A sample was obtained, found polluting, and the company was directed by the Inspector to halt this pollution. This order was confirmed in a letter to the Okonite Company by Mr. Lubetkin dated December 13, 1973 (PAS-00034781; PAS-00102011). Note: The 1973 PVSC Annual Report did not specify COCs analyzed and there is no indication that any of the eight specific COCs at issue herein formed a part of the boiler blowdown discussed.

In addition, the 1973 *PVSC Annual Report* noted that Mr. Strandberg, Plant Manager, replied that they had studied the situation and that it was feasible to install a boiler blowdown tank, with a discharge into the sanitary sewer. He further stated that this could only be done when the boilers were shut down, and they intended to do this during

their summer shutdown in 1974. Since the pollution was not great, the PVSC believed this to be reasonable (PAS-00034781; PAS-00102011).

On August 27, 1985 NJDEP issued Okonite an Administrative Order concerning a violation of the Solid Waste Management Act, N.J.S.A. 13:1E-1 et seq and regulations promulgated thereunder, specifically N.J.A.C 7:26-7.6(f) 2 for failure to file an annual report (PAS-00102064-5). This violation was not related to any discharges from the site (PAS-00102066-8).

7. Response Actions

Characterization Activities

The following characterization activities have taken place at the facility:

- *Results of Sampling Plan Implementation and Supplemental At-Peril Activities*, the Okonite Company, Canal and Jefferson Streets Facility, Passaic, New Jersey Facility, ECRA Case Number 89536, dated February 1991 (PAP-00244621).

- *Results of Supplemental Sampling Plan Implementation and Additional At-Peril Activities*, The Okonite Company, ECRA Case #89536, dated October 1992 (PAP-00245760).

- *Remedial Action Report*, The Okonite Company, Former Passaic Plant, ISRA Case # 89536, dated December 17, 2003 (PAP-00259153).

Sewer

There is no information regarding sewer sampling in the available file material.

Mercury

Of the Site AOCs, mercury has only been identified in soil samples at the following AOCs (Area C, Area I2, and Area K).

Area C

Area C is a paved area and was used to store empty drums of facility process-related materials. Two soil borings were completed within one foot of previous borings C-2 and C3 to a depth of three feet. No evidence of contamination (i.e., staining or odor) was observed in either boring. Samples were collected from 1.5 to 2 ft bgs and analyzed for volatile organic compounds (VOCs), base neutral compounds (BNs), and priority pollutant metals. Mercury was detected at a maximum concentration of 0.56 mg/kg in sample C-3A at a depth of 1.5-2 ft bgs (PAP-00244652).

Area I2

This area is an exterior area to the west of the drawing fluid pit and the basement area of Building 25 in which above ground drawing fluid tanks were located. Soil borings I2-1 through I2-3 were completed outside the building to the water table at distances of approximately 20 ft to the north, west, and south of I-2 in an effort to determine the source of conditions encountered in the previous boring. A fourth boring, I2-4 was completed to the east of I-2 inside the building in the hole in the basement floor. No evidence of contamination was observed in any of the exterior borings until the water table, which was encountered at a depth of approximately 10 ft bgs. Soil at the water table was oil stained and had an odor of weathered oil. Evidence of contamination in the form of oil staining and odor was observed throughout I2-4. A sample for laboratory analysis was collected within six inches of the water table and analyzed for VOCs, copper, mercury, and lead, with the exception of I2-4, which was not analyzed for mercury and lead (PAP-00244664). Mercury was detected at a maximum concentration of 0.8 mg/kg from sample I2-B at a depth of 9.0-9.5 ft bgs (PAP-00244667).

Area K

Area K is an unpaved area that was partially covered with a tar-like substance and resin beads from the facility water softeners. Plant personnel reported that empty drums were also historically stored in this area. Approximately 200 cubic yards of soil was removed. A total of 15 post-removal soil samples were collected following the first excavation on January 23, 1993... The soils removed during the first soil event consisted entirely of ash and cinder fill. The fill in this area contained parts of plumbing fixtures, glass vials, metals lids, and other similar materials. Okonite concluded that, due to the analytical results of the first round of post-removal samples, a second soil removal event was required. Subsequently, additional 100 cubic yards were removed and post-removal sampling was conducted on December 7, 1990. Following the second excavation, 11 post-removal soil samples were collected from the excavation base and the base of the sidewalls. These samples were analyzed for TPH, BNs, lead, zinc, mercury, copper, and PCBs (PAP-0024462176). The maximum detected concentration of mercury in this area during the second soil sampling event was 430 mg/kg collected from sample K-24 at a depth of 7-7.5 ft bgs (PAP-00244679).

Drainage Structures

In addition to drains 13, 18-20, 30, 53, and 54, and the Weasel Brook discharge points, three areas of potential environmental concern were identified in the course of decontamination and decommissioning activities. These were the stream bank adjacent to Building 37, where lead strips were found; the baghouse area, an unpaved area beneath the Banbury mixer where oil-stained soils were observed; and the hydraulic lift pit, the location of lift equipment for the loading dock, where oil-stained soils were also found (PAP-00245798-802).

No sediments are present at the site; however, Weasel Brook forms the western boundary of the site. Okonite collected 13 sediment samples from Weasel Brook in July 1992. The samples were analyzed for metals, VOCs, base neutrals, and total organic

carbon. Sample locations were biased towards the areas where outfall pipes discharged to Weasel Brook. Samples of stream bank and/or bottom sediments were collected where available, beneath three of the facility outfall pipes, at the furthest upstream end of the brook on the site (PAP-00243477), and at a location downstream of the facility outfall pipes. A sample was not collected at the upstream end of the brook at the property boundary because the brook enters the property in a covered culvert. The bottom of the brook was concrete and stone where it exited the culvert and no sediment was present for sampling. According to the RAR, dated December 17, 2003, mercury was detected at a maximum concentration of 18 mg/kg from sample SS-4 at a depth of 0-6 inches (PAP-00259186). A significant amount of time had passed since Okonite's industrial discharges to the brook ceased. Normal processes of erosion and deposition have likely made sediment conditions at that time non-representative of any impacts Okonite's operations may have had (PAP-00243478). In addition, during the May 2004 sampling event, waste automotive parts were observed in Weasel Brook, and had been dumped from the bank opposite of Okonite (PAP-00258638).

Copper

Based on review of the RAR, dated December 17, 2003, copper was detected only at the following AOCs:

Area C

Area C is a paved area and was used to store empty drums of facility process-related materials. Two soil borings were completed within one foot of previous borings C-2 and C3 to a depth of three feet. No evidence of contamination (i.e., staining or odor) was observed in either boring. Samples were collected from 1.5 to 2 ft bgs and analyzed for volatile organic compounds (VOCs) and priority pollutant metals. Copper was detected at a maximum concentration of 95 mg/kg in sample C-3A at a depth of 1.5-2 ft bgs (PAP-00244652).

Area I1

This area is the location of a 9000-gallon concrete pit that was used to store drawing fluid for copper wire. The pit was installed in approximately 1976 and was approximately 9.5 ft bgs. Soil borings were completed on all four sides of the pit. Soil borings could not be completed adjacent to the pit on the north and west sides due to numerous subsurface obstructions such as metal plates, subsurface concrete slabs, etc., that were historically located in this area. A total of nine borings were installed. No evidence of contamination was encountered above the water table in any of the soil borings. Two samples for laboratory analyses were collected from each boring from the six-inch interval above the water table (8 to 8.5-9 ft bgs) and from a six-inch interval at the bottom of the pit (9.5-10 ft. bgs). All samples were analyzed for VOC and copper. Copper was detected at a maximum concentration of 1900 mg/kg from sample I1-2B at a depth of 8-8.5 ft bgs (PAP-00244662). NJDEP approved NFA for Area I1 in 1994 (PAP-00240168-70).

In their comment letter dated April 11, 1994, NJDEP noted that the concentration of 1,900 mg/kg copper did not meet the then-applicable RDCSCC. Although elevated metal concentrations were detected in downgradient wells in one round of samples, the concentrations were attributed to incomplete field filtering and not to dissolved metals. As the soil sample was collected at 8 feet below grade and beneath the building, it did not require remediation. NJDEP approved NFA for Area I1 in 1994 (PAP-00240168-70).

Area I2

This area is an exterior area to the west of the drawing fluid pit and the basement area of Building 25 in which above ground drawing fluid tanks were located. Soil borings I2-1 through I2-3 were completed outside the building to the water table at distances of approximately 20 ft to the north, west, and south of I-2 in an effort to determine the source of conditions encountered in the previous boring. A fourth boring, I2-4 was completed to the east of I-2 inside the building in the hole in the basement floor. No evidence of contamination was observed in any of the exterior borings until the water table, which was encountered at a depth of approximately 10 ft bgs. Soil at the water table was oil stained and had an odor of weathered oil. Evidence of contamination in the form of oil staining and odor was observed throughout I2-4. A sample for laboratory analysis was collected within six inches of the water table and analyzed for VOCs, copper, mercury, and lead, with the exception of I2-4, which was not analyzed for mercury and lead (PAP-00244664). Copper was not in soil samples collected from this area (PAP-00244664).

Area K

Area K is an unpaved area that was partially covered with a tar-like substance and resin beads from the facility water softeners. Plant personnel reported that empty drums were also historically stored in this area. Approximately 200 cubic yards of soil was removed. A total of 15 post-removal soil samples were collected following the first excavation on January 23, 1993. Samples were analyzed for TPH, VOCs, BNs, lead, and zinc. The soils removed during the first soil event consisted entirely of ash and cinder fill. The fill is this area contained parts of plumbing fixtures, glass vials, metals lids, etc. Okonite concluded that, due to the analytical results of the first round of post-removal samples, a second soil removal event was required. Subsequently, an additional 100 cubic yards were removed and post-removal sampling was conducted on December 7, 1990. Following the second excavation, 11 post-removal soil samples were collected from the excavation base and the base of the sidewalls and analyzed for TPH, BNs, lead, zinc, mercury, copper, and PCBs (PAP-00244676). The maximum detected concentration of copper in this area during the second soil sampling event was 260 mg/kg collected from sample K-25 at a depth of 7.5-8 ft bgs (PAP-00244679). The NJDEP approved NFA for Area K in their comment letter dated January 20, 1995 (PAP-00240081).

Area M

This area was identified as an area of potential environmental concern during on-going facility decontamination/decommissioning activities when the banbury mixer (rubber compounding machine) was removed. The area is approximately 20 by 10 feet in size

and, the bottom of the pit is approximately 3 feet below grade, and consisted of several concrete sub-chambers. The sub-chambers were mostly filled with soil and sediment but also contained minor amounts of rubber compounding waste. Removal of the fill material revealed that the floors and walls of the sub-chambers are not continuous throughout the structure (i.e., gaps are present). The fill material that was removed prior to the submittal of the February 1992 *Results of Sampling Plan Implementation and Supplemental At-Peril Activities* report (approximately 15 cubic yards) was staged beside the pit. A waste classification sample was collected from this material. Copper was not detected in the soil samples collected from Area M (PAP-00244684).

Drainage Structures

No sediments are present at the site; however, Weasel Brook forms the western boundary of the site. As mentioned above, Okonite discharged wastewater to Weasel Brook via several outfall pipes, as permitted by NJPDES Permit No. NJ0002615. As documented in a Priority Pollutants Monitoring Report, dated December 6, 1977, copper was found at a concentration of 27 J micrograms per liter (µg/L) in the raw influent water. Effluent samples from water discharged from Site operations during that same sampling event exhibited lower concentrations of copper, at 12 and 15 µg/L, indicating that the manufacturing process did not introduce a measurable quantity of copper to the waste stream (PAP-00264228, 55). Okonite collected 13 sediment samples from Weasel Brook in July 1992. The samples were analyzed for metals, VOCs, base neutrals, and total organic carbon. Sample locations were biased towards the areas where outfall pipes discharged to Weasel Brook. Samples of stream bank and/or bottom sediments were collected where available, beneath three of the facility outfall pipes, at the furthest upstream end of the brook on the site (PAP-00243477), and at a location downstream of the facility outfall pipes. A sample was not collected at the upstream end of the brook at the property because the brook enters the property boundary in a covered culvert. The bottom of the brook was concrete and stone where it exited the culvert and no sediment was present for sampling. The most downstream sample location (SS-8, located adjacent to the former facilities southwest corner) had a copper concentration of 48 mg/kg. However, the most upstream sample (SS-3) had a copper concentration of 57 mg/kg. According to the RAR, dated December 17, 2003, copper was detected at a maximum concentration of 430 mg/kg from sample SS-4 at a depth of 0-6 inches (PAP-00259186). A significant amount of time had passed since Okonite's industrial discharges to the brook ceased. Normal processes of erosion and deposition have likely made sediment conditions at that time non-representative of any impacts Okonite's operations may have had (PAP-00243478).

In addition, during a May 2004 sampling event, waste automotive parts were observed in Weasel Brook, and had been dumped from the bank opposite of Okonite (PAP-00258638).

Lead

Based on review of the RAR, dated December 17, 2003, lead was detected only at the following AOCs:

Area C

Area C is a paved area and was used to store empty drums of facility process-related materials. Two soil borings were completed within one foot of previous borings C-2 and C3 to a depth of three feet. No evidence of contamination (i.e., staining or odor) was observed in either boring. Samples were collected from 1.5 to 2 ft bgs and analyzed for volatile organic compounds (VOCs) and priority pollutant metals. Lead was detected at a maximum concentration of 270 mg/kg in sample C-3A at a depth of 1.5-2 ft bgs (PAP-00244652).

Area G

Area G is the location of a former gasoline 8,000-gallon UST. In addition, a small, approximately 1,000-gallon, abandoned UST that contained sand and a small amount of water, was discovered immediately adjacent to the gasoline UST during removal of the gasoline UST. Both USTs were properly closed (PAP-00244657-58). Following removal of the two USTs, field observations and monitoring instrument responses showed that a small amount of contaminated soil remained in place at the west end of the excavation. Analytical results showed that lead was detected at a concentration of 370 mg/kg from sample G-3 at a depth of 6.5-7 ft bgs (PAP-00244659). The NJDEP approved NFA for Area G in their letter dated April 11, 1994 (PAP-00240168-70).

Area K

Area K is an unpaved area that was partially covered with a tar-like substance and resin beads from the facility water softeners. Plant personnel reported that empty drums were also historically stored in this area. Approximately 200 cubic yards of soil was removed. A total of 15 post-removal soil samples were collected following the first excavation on January 23, 1993. Samples were analyzed for TPH, VOCs, BNs, lead, and zinc. The soils removed during the first soil event consisted entirely of ash and cinder fill. The fill is this area contained parts of plumbing fixtures, glass vials, metals lids, etc. Okonite concluded that, due to the analytical results of the first round of post-removal samples, a second soil removal event was required. Subsequently, an additional 100 cubic yards were removed and post-removal sampling was conducted on December 7, 1990. Following the second excavation, 11 post-removal soil samples were collected from the excavation base and the base of the sidewalls and analyzed for TPH, BNs, lead, zinc, mercury, copper, and PCBs (PAP-00244676). The maximum detected concentration of lead in this area during the second soil sampling event was 2700 mg/kg collected from sample K-23 at a depth of 7-7.5 ft bgs (PAP-00244679). The remediation was completed to the satisfaction of the NJDEP and a No Further Action Letter was issued on January 20, 1995 (PAP-00240081).

Area M

This area was identified as an area of potential environmental concern during on-going facility decontamination/decommissioning activities when the Banbury mixer (rubber compounding machine) was removed. The area is approximately 20 by 10 feet in size and, the bottom of the pit is approximately 3 feet below grade, and consisted of several

concrete sub-chambers. The sub-chambers were mostly filled with soil and sediment but also contained minor amounts of rubber compounding waste. Removal of the fill material revealed that the floors and walls of the sub-chambers are not continuous throughout the structure (i.e., gaps are present). The fill material that was removed prior to the submittal of the February 1992 *Results of Sampling Plan Implementation and Supplemental At-Peril Activities* report (approximately 15 cubic yards) was staged beside the pit. A waste classification sample was collected from this material. Copper was not detected in the soil samples collected from Area M (PAP-00244679).

Drainage Structures and Machinery Pits

No sediments are present at the site; however, Weasel Brook forms the western boundary of the site. As mentioned above, Okonite discharged wastewater to Weasel Brook via several outfall pipes, as permitted by NJPDES Permit No. NJ0002615. As documented in a Priority Pollutants Monitoring Report, dated December 6, 1977, lead was found at a concentration of 2,200 J µg/L in the raw influent water originating from the PVWC. Effluent samples from water discharged from Site operations during that same sampling event exhibited lower concentrations of lead, at 49 J and 700 J µg/L, indicating that the manufacturing process did not introduce a measurable quantity of copper or lead to the waste stream (PAP-00264228, 55). Okonite collected 13 sediment samples from Weasel Brook in July 1992. The samples were analyzed for metals, VOCs, base neutrals, and total organic carbon. Sample locations were biased towards the areas where outfall pipes discharged to Weasel Brook. Samples of stream bank and/or bottom sediments were collected where available, beneath three of the facility outfall pipes, at the furthest upstream end of the brook on the site (PAP-00243477), and at a location downstream of the facility outfall pipes. A sample was not collected at the upstream end of the brook at the property because the brook enters the property in a covered culvert. The bottom of the brook was concrete and stone where it exited the culvert and no sediment was present for sampling. Lead was detected in two bank samples. According to the RAR, dated December 17, 2003, lead was detected at a maximum concentration of 8200 mg/kg from sample SS-2 at a depth of 0-6 inches (PAP-00259186). A significant amount of time had passed since Okonite's industrial discharges to the brook ceased. Normal processes of erosion and deposition have likely made sediment conditions at that time non-representative of any impacts Okonite's operations may have had (PAP-00243478) In addition, there was evidence of others dumping into this section of the river as evidenced by observations of industrial discharges from a number of outfall pipes directly across the brook from Okonite (PAP-00243478), and waste automotive parts that had been dumped from the bank of Weasel Brook opposite of Okonite (PAP-00258638).

PAHs

The International Carbon Black Association states that PAHs can only be extracted from the surface of industrially-manufactured Carbon Black under vigorous laboratory conditions, and that the risks to human health associated with presence of PAHs originating from carbon black in its final product form is extremely low (PAP-00264260-1). Based on review of the RAR, dated December 2003; PAHs were detected in soil

samples collected from the various AOCs. Presented below are the PAH concentrations at the various AOCs:

Area A, B1, and D

Soil sampling conducted at Areas A and B1 in 1990 showed carcinogenic polycyclic aromatic hydrocarbons (cPAHs) were below 10 milligrams per kilogram (mg/kg) (PAP-00244643-44).

The following PAHs; phenanthrene, fluoranthene, and pyrene were detected at concentrations of 0.027 mg/kg, 0.061 mg/kg, and 0.095 mg/kg collected from sample A-1 at a depth of 2.5-3.0 feet below ground surface (ft bgs) (PAP- 00244645).

The following PAHs; phenanthrene, fluoranthene, pyrene, benzo(a)anthracene, and benzo(a)pyrene were detected at concentrations of 0.54 mg/kg, 0.66 mg/kg, 1.1 mg/kg, 0.45 mg/kg, and 0.23 mg/kg from sample B-2B at a depth of 1-1.5 ft bgs (PAP-00244646).

No PAHs were detected in soil samples collected from Area D (PAP-00244647).

Historical soil sampling data for these Areas A, B1 and D complied with applicable RDCSCC. The NJDEP approved NFA in their letter dated April 11, 1994 (PAP-00240168-70).

Area B2

Soil sampling conducted in 1990 at Area B2 indicated concentrations of PAHs to be below 10 mg/kg. The following PAHs; phenanthrene, fluoranthene, pyrene, benzo(a)anthracene were detected at maximum concentrations of 0.84 mg/kg, 1.7 mg/kg, 1.9 mg/kg, 1 mg/kg (from sample B2-4 at a depth of 4.5-5 ft bgs) and benzo(b)fluoranthene and benzo(k)fluoranthene were detected at estimated concentrations of 0.25 mg/kg and 0.2 mgkg (from sample B2-2 at a depth of 4.5-5 ft bgs) (PAP-00244648-49). The soil was disposed at the American Landfill in Youngstown, Ohio and the excavation was backfilled with offsite fill after laboratory results revealed that contamination had been removed (PAP-00244650). The NJDEP approved NFA for Area B2 in their letter dated April 11, 1994 (PAP-0024016870).

Area C

Area C is a paved area and was used to store empty drums of facility process-related materials. Two soil borings were completed within one foot of previous borings C-2 and C3 to a depth of three feet. No evidence of contamination (i.e., staining or odor) was observed in either boring. Samples were collected from 1.5 to 2 ft bgs and analyzed for volatile organic compounds (VOCs) and priority pollutant metals.

Sample C-2A/1.5-2 was later determined to be non-representative, based on the presence of ash and cinder fill material in the sample (PAP-00245778). The NJDEP approved conditional NFA for Area C "if Okonite applies appropriate institutional and/or engineering controls" (PAP-00240168, 70).

Area E

This area was the location of an abandoned approximately 300-gallon steel UST encased in concrete that was historically used to store waste kerosene and other compounds that may have been used as degreasers at the facility. The UST was properly decommissioned through removal in accordance with facility Decontamination/Decommissioning Plan. The UST was disposed as scrap metal along with the USTs from Area G. No evidence of a release was found in the removal of the USTs. Soil sampling results upon UST removal indicated concentrations of phenanthrene, anthrancene, fluoranthene, pyrene, benzo(a)anthracene, and benzo(a)pyrene to be 0.57 mg/kg, 0.065 mg/kg, 0.74 mg/kg, 0.73 mg/kg, 0.36 mg/kg, and 0.3 mg/kg (from sample E-4 collected at a depth of 5.5 ft bgs) (PAP-00244654). Based on the post-removal analytical results, the NJDEP approved NFA for Area E in their letter dated April 11, 1994 (PAP-00240168-70).

Area F1

This area is the location of a 76,000-gallon concrete UST that was used to store No. 6 fuel oil. The UST was installed in approximately 1922. The UST has been emptied and cleaned. Soil borings F-7 through F-9 were completed to the northwest, north, east, and west (immediately downgradient) of the UST respectively. These borings were completed within ten feet of the UST and to depths of 11 ft. Oil staining and odor were observed in all four borings from depths starting from 7 to 10 ft bgs. Samples for laboratory analyses were collected from 10 to 10.5 ft bgs.

Subsequent to the original sampling, a duplicate sample was collected to evaluate the previous PAH detections at Area F1, identified as sample F-10A/10.5-11. No PAHs were detected in this sample (PAP-00245794).

Multiple soil excavations were conducted at Area F1 in 2002, as well as in 2007 following the demolition of former Building 37 (PAP-00259691-750; PAP-00264067-227).

Area F2

This area consists of a piping trench located beneath a metal plate in the floor of the facility engine room, which houses the facility air compressors. This area was identified as an area of potential concern subsequent to conditional sampling plan approval during implementation of decontamination/decommissioning activities for machinery pits and other subgrade structures at the facility. Condensate from the air compressors was determined to have been historically discharged to the trench, which was earthen-bottomed. One soil boring was completed within the trench to the depth of the water table. Two samples were collected from this boring from the first six-inch interval of soil

within the trench and from the six-inch interval above that apparently affected by normal fluctuations of the water table. PAHs were not detected at Area F2 (PAP-00244657).

The NJDEP conditionally approved NFA for Area F2 (also identified as AOC 10), provided an institutional control be established (PAP-00240084). The institutional control was required for previous detections of Total Petroleum Hydrocarbons, and not specific to PAHs in this AOC.

Area G

Area G is the location of a former gasoline 8,000-gallon UST. In addition, a small, approximately 1,000-gallon, abandoned UST that contained sand and a small amount of water, was discovered immediately adjacent to the gasoline UST during removal of the gasoline UST. Both USTs were properly closed. No PAHs were detected at Area G (PAP-00244659-70). The NJDEP approved NFA for Area G in their letter dated April 11, 1994 (PAP-00240168-70).

Area I1

This area is the location of a 9,000-gallon concrete pit that was used to store drawing fluid for copper wire. The pit was installed in approximately 1976 years ago. No evidence of contamination was encountered above the water table. Two samples for laboratory analyses were collected from each boring from the six-inch interval above that apparently affected by normal fluctuations of the water table (8 to 8.5 or 8.5 to 9 ft) and from the six-inch interval at the bottom of the pit (9.5 to 10 ft). Soil samples collected during a 1990 soil sampling event indicated maximum detections of the following PAHs: phenanthrene (0.048 mg/kg), fluoranthene (0.037 mg/kg), and pyrene (0.042 mg/kg) collected from sample I1-3 at a depth of 8.5-9 ft bgs (PAP-00244661-62). NJDEP approved NFA for Area I1 in 1994 (PAP-00240168-70).

Area I2

This area is an exterior area to the west of the drawing fluid pit and the basement area of Building 25 in which above ground drawing fluid tanks were located. Soil borings I2-1 through I2-3 were completed outside the building to the water table at distances of approximately 20 ft to the north, west, and south of I-2 in an effort to determine the source of conditions encountered in the previous boring. A fourth boring, I2-4 was completed to the east of I-2 inside the building in the hole in the basement floor. No evidence of contamination was observed in any of the exterior borings until the water table, which was encountered at a depth of approximately 10 ft bgs. Soil at the water table was oil stained and had an odor of weathered oil. Evidence of contamination in the form of oil staining and odor was observed throughout I2-4. A sample for laboratory analysis was collected within six inches of the water table and analyzed for VOCs, copper, mercury, and lead, with the exception of I2-4, which was not analyzed for mercury and lead (PAP-00244664). Only the following PAHs were detected; phenanthrene (0.025 mg/kg), pyrene (0.031 mg/kg), chrysene (0.025 mg/kg), and benzo(a)anthracene (0.026 mg/kg) from sample I2-1B at a depth of 9.5-10 ft bgs.

Further soil delineation investigations at Area I2 in 1992 were not evaluated for COCs associated with OU2 and included only petroleum hydrocarbons and bis(2-ethylhexyl)phthalate. Based on additional delineation conducted, and the very limited access to this Area due to its location in a building basement, Okonite proposed institutional controls for Area I2 (PAP-00260513). NJDEP conditionally approved institutional controls for Area I2 in 1994 (PAP-00240168, 72).

Area K

Area K is an unpaved area that was partially covered with a tar-like substance and resin beads from the facility water softeners. Plant personnel reported that empty drums were also historically stored in this area. Approximately 200 cubic yards of soil was removed. A total of 15 post-removal soil samples were collected following the first excavation on January 23, 1993. Samples were analyzed for TPH, VOCs, BNs, lead, and zinc. Several PAHs were detected in this area following round 1 excavation. The soils removed during the first soil event consisted entirely of ash and cinder fill. The fill is this area contained parts of plumbing fixtures, glass vials, metals lids, etc. Okonite concluded that, due to the analytical results of the first round of post-removal samples, a second soil removal event was required. Subsequently, an additional 100 cubic yards were removed and post-removal sampling was conducted on December 7, 1990. Following the second excavation, 11~~12~~ post-removal soil samples were collected from the excavation base and the base of the sidewalls. These samples were analyzed for TPH, BNs, lead, zinc, mercury, copper, and PCBs.

In the October 1992 Results of Supplemental Sampling Plan Implementation, NFA was recommended (PAP-00245806). The NJDEP conditionally approved NFA with the requirement that the previous data be reevaluated to the then-applicable RDCSCC (PAP-00240168, 72-3). The data for sample K-16/9.5-10.0 met then-applicable RDCSCC for BN compounds (PAP-00260518). The NJDEP approved NFA for Area K in their comment letter dated January 20, 1995 (PAP-00240081).

Area M

This area was identified as an area of potential environmental concern during on-going facility decontamination/decommissioning activities when the Banbury mixer (rubber compounding machine) was removed. The area is approximately 20 by 10 feet in size and, the bottom of the pit is approximately 3 feet below grade, and consisted of several concrete sub-chambers. The sub-chambers were mostly filled with soil and sediment but also contained minor amounts of rubber compounding waste. Removal of the fill material revealed that the floors and walls of the sub-chambers are not continuous throughout the structure (i.e., gaps are present). The fill material that was removed prior to the submittal of the February 1992 Results of Sampling Plan Implementation and Supplemental At-Peril Activities report (approximately 15 cubic yards) was staged beside the pit. A waste classification sample was collected from this material. No PAHs were detected (PAP-00244684).

Drainage Structures

No sediments are present at the site; however, Weasel Brook forms the western boundary of the site. Okonite collected 13 sediment samples from Weasel Brook in July 1992. The samples were analyzed for metals, VOCs, base neutrals, and total organic carbon. Sample locations were biased towards the areas where outfall pipes, at the furthest upstream end of the brook on the site (PAP-00243477), discharged to Weasel Brook. Samples of stream bank and/or bottom sediments were collected where available, beneath three of the facility outfall pipes and at a location downstream of the facility outfall pipes. A sample was not collected at the upstream end of the brook at the property because the brook enters the property boundary in a covered culvert. The bottom of the brook was concrete and stone where it exited the culvert and no sediment was present for sampling. A number of PAHs were detected in two bank sediment samples and three bottom sediment samples, including SS-3 at a depth of 0-6 inches. According to the Remedial Action Report (RAR), dated December 17, 2003, the source of these PAHs was unknown (PAP-00259165). However, a possible source was the historic fill in the area, which also contained PAHs (PAP-00259165). A significant amount of time had passed since Okonite's industrial discharges to the brook ceased. Normal processes of erosion and deposition have likely made sediment conditions at that time non-representative of any impacts Okonite's operations may have had (PAP-00243478).

On May 5, 2004, additional sediment samples were collected from Weasel Brook at a previous location of SS-3/0-6" collected in 1992 for total organic carbon, TPH, and BNs. During that sampling event, waste automotive parts were observed in Weasel Brook, and had been dumped from the bank opposite of Okonite (PAP-00258638).

8. Summary of Asserted Defenses

No legal defenses were identified in the available file material.

Diamond Alkali OU2 Allocation

ADR Confidential

Facility Data Report

OTIS ELEVATOR COMPANY

Facility Name, Address and Size: Otis Elevator Company (Otis), 1000 First Street and 1001 South Second Street, Harrison, New Jersey, 07029. According to a February 25, 1980 Passaic Valley Sewerage Commissioners (PVSC) Sewer Connection Application the site consisted of: Block 73, Lots 1-19, Lot 20A, Lots 22-26, Blocks 74-77, Block 80, Lot 1, Lot 2, Lot 13, Block 101, Block 102, Lots 1-11, Lot 33B, and Lots 34-45) (PAS-00076743). At its peak size (during World War II), the site consisted of approximately 40 acres (PAS-00076875). Post-war, the site consisted of approximately 33 acres (PAP-00233774; PAS-00076657), and then decreased as various and ultimately all parcels were sold off (see below).

The original site was about six acres. The first payroll in 1910 covered about 90 employees. There were approximately 850 employees in 1929, (PAS-00076851), followed by significant decreases during the Great Depression. Employment rebounded to 500 by 1941, shortly before the United States' entry into World War II, and peaked during World War II at 1,500 employees (PAP-00233755), also reported as "close to 2,000 employees" (PAP-00233755; PAS-00076871). Following a significant decrease at the end of World War II in 1945, total employment fluctuated (1,000 in 1972 (PAS-00076657), 260 in 1977 (PAS-00076856); 487 in 1979 (PAP-00233785), 430 and then 200 in early 1980 (PAS-00076743; PAS-00076856) until the facility closed in 1980 (PAS-00076854; PAS-00076856).

1. **Business Type:** The purpose of the Otis plant was to form and assemble elevator cabs, doors and platforms. The manufacturing process involved receiving sheet metal and steel beams from other sources and then bending, cutting, and stamping metal into the shapes required to form and assemble the products. Metal scrap was collected and sold to a metal scrap dealer off-site. In addition, for approximately four years, Otis manufactured airplane engine crankcases and other military equipment under direction of the U.S. government (PAS-00076817).

2. **Time Period of Ownership/Operations**

Operator: February 1, 1910 – August 31, 1980
Owner: 1910 - -– December 16, 1980
(PAS-00076732; PAS-00076854; PAS-00076828; PAS-00076834)

According to a Response from Otis Elevator Company dated August 1996, the plant began with a limited number of buildings and space, originally purchased from the Marine Engine and Machinery Company, and both increased and decreased in capacity and size during its years of operation. During those years, there were a large number of purchases and sales to and from individuals and corporations. In addition, as noted below, in the years immediately following World War II, there were various limited lease relationships for certain buildings.

1910: On January 1, 1910, Otis leased all the lands and premises bound by Railroad Avenue, Second Street, Somerset Street, and the Passaic River with all their appurtenances, including all riparian rights, machinery, tools, fixtures, materials, and generally all its property and entire manufacturing plant from Marine Realty and Improvement Company (PAP-00233843).

On February 1, 1910, an agreement was made whereby Otis took possession of a machine shop (February 1, 1910), foundry and pattern shop (April 1, 1910), and blacksmith shop and small frame building on the corner of First and Middlesex Streets, in which the plant, machinery, pattern storage building, and offices were located (September 1, 1910) (PAP-00233851).

According to an August 26, 1996 response to an Environmental Protection Agency (EPA) Request for Information, Otis began operations at 1000 First Street (the "Harrison Plant" or the "Plant") in 1910. At that time, the Plant consisted of a gray iron foundry, machine shop, a powerhouse and office, the total floor area was approximately 95,000 square feet. As the need for additional manufacturing facilities occurred, several buildings were erected between 1910 and 1929 reaching 334,750 square feet (PAP-00233776; PAS-00076817; PAS-00076850).

1928: As part of this construction, an 115,000 square feet heavy capacity general manufacturing building was constructed, and Otis opened the Central Heating Plant, which was designed for heating and to provide facilities for cold storage handling of highly explosive powdered fuel (PAS-00076733).

1941- 1942: The U.S. government acquired from Otis the large undeveloped parcels at the southern and southeastern ends of the Facility site. Under U.S. government oversight, Otis constructed and operated two new manufacturing buildings (Aeronautical Division Buildings One and Two) on these parcels to produce military parts and equipment for the government (PAP-00404016; PAS-00404038; PAS-00048611, PAS-00076724, PAS-00076870).

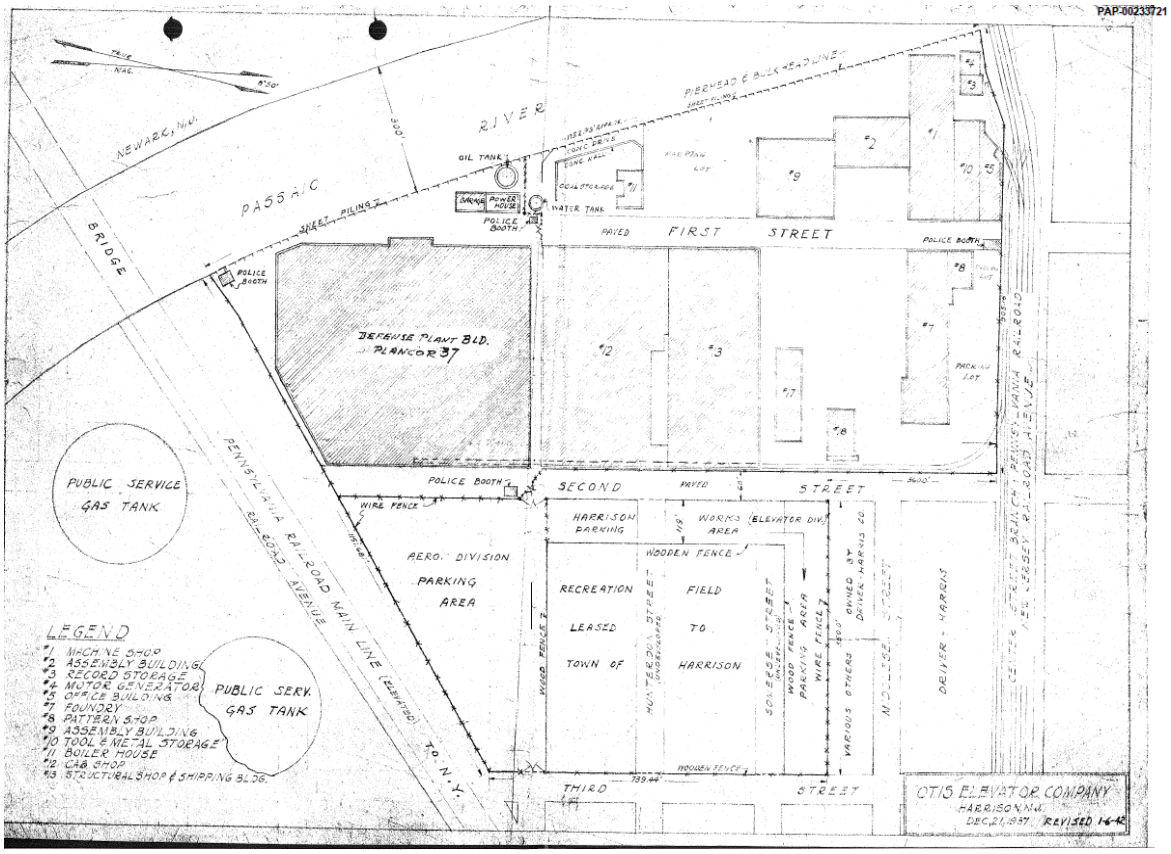
1946: Otis acquired the southern parcel and Aero Building One from the U.S. government (PAS-00048611).

1947: Otis leased four aisles, Nos. 1-4, in Aero Building Two at 1001 South Second Street, Harrison, New Jersey (PAP-00233766).

1957: Radio Corporation of America deeded property to Otis Elevator on November 4, 1957 and recorded on November 12, 1957 in Book 2733 at page 490 (PAP-00233793).

1958: Buildings at the facility used for manufacturing operations totaled approximately 556,000 square feet of manufacturing space, and 138,000 square feet for storage, power production, offices, and other nonmanufacturing uses (PAP-00233774).

1974: United Technologies purchased Otis making Otis a wholly owned subsidiary of United Technologies (PAS-00076819).



1978: Otis deeded lots 23 to 32 and part of lot 33 in Block 100, lots 13 to 32 and parts of lots 12 and 33 in Block 101, lots 13-32 and part of lots 12 and 33 in Block 102 to Pathparc Associates, a partnership (PAS-00076832).

1979: Plant area for manufacturing was 27,585.35 square meters (approximately 293,000 square feet) and for office was 3,993.20 square meters (approximately 43,000 square feet), with 241 employees for production, 146 technical and clerical, and 100 management employees for a total of 487 (PAP-000233789, PAP-00233785).

1979: Otis deeded parts of lots 1 through 11, part of lot 12A, and all of lot 46C in Block 101 to Newark Public Radio, Inc. on October 3, 1979 (PAP-00233793).

1980: The plant limited its operations to clearing out unfinished orders and reduced its total employee count from 200 to 85-90 on May 19, 1980 (PAS-00076856). The plant ended all operations on August 31, 1980 (PAS-00076854). Block 101, Lot 1-A (was sold on December 16, 1980 to Hartz Harrison Limited Partnership (PAS-00076828) and Harrison Riverside Limited Partnership (PAS-00076834).

1991: As reported in a letter from Otis to the U.S. Environmental Protection Agency (EPA) regarding EPA's Notice of Potential Liability dated January 1998, Harrison Riverside Limited Partnership leased a portion of the facility to its tenant, Intrex Corporation (PAS-00076579; PAS-00076603).

(PAP-00233721)

3. Operational History/COC Use and Presence at the Facility

According to *Otis Harrison Plant Parallels Growth of Hudson County*, dated March 8, 1971, the original Otis plant in Harrison opened for business on February 1, 1910. At that time, the plant comprised eight buildings occupied by the Marine Engine and Machinery Company, located on the east bank of the Passaic River. The original layout had a machine shop, an iron foundry, a structural steel shop (to assemble elevator car frames and safety devices), a forge shop, powerhouse, and general office building. Improvements through the years added 10 new buildings, modernized all the original structures, and spread the plant over an area of about forty acres at its peak during World War II. In 1928, a building of 115,000 square feet of heavy capacity floor space for general manufacturing was added. The same year also witnessed the opening of the Central Heating Plant, designed not only for heating, but also to provide facilities for cold storage handing of highly explosive powdered fuel (PAS-00076732-33). A May 29, 1939, booklet also reported another building entirely devoted to the company's elevator lubricants. This included oils and greases for all of the various requirements for elevator, escalator, and hoisting apparatus (PAP-00404032).

According to an August 26, 1996 response to an EPA Request for Information from Otis, the purpose of the Harrison Plant was to form elevator cabs, doors and platforms. The manufacturing process involved receiving sheet metal and steel beams from other sources and then bending, cutting and stamping metal into the shapes required to form the products. Metal scrap was collected and sold to a metal scrap dealer in Harrison (PAS-00076817). In addition, the plant manufactured airplane engine crankcases under direction of the U.S. government from August 1941 until August 14, 1945. An early production target for the first type of crankcase produced was for 2,500 units per month (PAP-00233746-48). There is no information in the documentation provided regarding actual production levels.

According to Harrison Works of Otis Elevator Company, in 1941, Otis also started war production of elevator platforms and ammunition hoists for the U.S. Navy Cruisers, and within a relatively short time it was producing machine tools, gun turrets, aircraft landing gear, steam pumps, cowl rings, parts for 27,000 welding generators, cradles for nearly 4,000 recoil mechanisms, assemblies for torpedo hoisting equipment, portions of mine handling elevators for mine layers, and more than 1,300 aluminum-alloy crankcases for airplane auxiliary power units (PAP-00233754; PAP-00233764-65).

Otis's response to the *Request for Information*, dated August 1996, reported there was a small section of the Harrison Plant that performed spray painting in enclosed booths. The excess paint was collected into 55-gallon drums, which were then sealed and stored in the parking lot until collected and taken off-site by a waste hauler (PAS-00076817; PAS-00076716).

A small incinerator was located at the site on or after 1941, within a 160-square-foot enclosure (Building 23), as depicted below (PAP-00233774).

Diamond Alkali OU2 Allocation

ADR Confidential

Facility Data Report

According to an inter-office correspondence letter dated Aug 14, 1929, at the time of purchase in 1910, a gray iron foundry was reported to be a part of the plant as depicted as Building 7 in the facility layout (PAS-00076850; PAP-00233721).

4. Identified COCs

- PCBs (potentially used)
- PAHs (used)
- Coper (released, detected)
- Lead (reported used, released, detected)
- Mercury (released, detected)

According to a November 21, 1996 Memorandum, processes utilized at the facility generated wastes, including metals, solvents and paint sludge. The facility also stored highly explosive powdered fuel for some period of time (PAS-00076710). According to a January 17, 1977 Industrial Waste Survey estimated quantities of paint sludge was 100 cubic yards per year (PAP-00456839).

PCBs

According to an *Environmental Due Diligence Assessment of Habitat International, Ltd.,* as of 1988, three transformers were located in the building leased by Intrex on the opposite side of First Street. Intrex leased these transformers as part of the building. The transformers were tested by the site owner at that time with the results reported as "less than 50 parts per million (ppm)" PCBs (PAS-00076788). No staining was noted in the investigation of the area (PAS-00076738).

PAHs

According to an *Environmental Due Diligence Assessment of Habitat International, Ltd.,* there was one aboveground fuel oil tank on a diked pad with a capacity of 120,000 gallons. This tank was located on the opposite side of First Street, and it reportedly contained No. 2 fuel oil used to fire the boiler (PAS-00076790). The fill location for the tank was observed and noted to be diked and clean (PAS-00076796). Available references did not include soil characterization data for PAHs.

Metals - Mercury, Copper, Lead

As reported by the *PVSC Industrial Waste Survey Results*, dated June 26-28, 1978, Otis's wastewater metal measurements contained 0.199 milligrams per liter (mg/L) copper contributing 0.159 lbs/day to PVSC; 0.141 mg/L lead contributing 0.113 lbs/day; and, 0.0057 mg/L mercury contributing 0.0046 lbs/day to PVSC (PAS-00125049, PAS-00076719).

According to the July 25, 1972 *Waste Effluent Survey Chart* of plant waste attributable to Otis, lead concentrations were 0.07 mg/L with a daily discharge of 0.11 lbs per day; copper concentrations were 0.03 mg/L with a daily discharge of 0.05 lbs per day (PAS-00076661).

According to an *Environmental Concerns Tracking Sheet for ECRA Case 91646* by Intrex Corporation, an underground storage stank (UST) was reportedly used by Otis to fuel vehicles. The tank and pump were removed in November 1986. Soil samples were

collected and contained a maximum lead concentration of 1,624 milligrams per kilogram (mg/kg) (PAS-00076739).

Historic Fill

The Allocation Team has determined that the facility site is located on regional Historic Fill as designated by the New Jersey Department of Environmental Protection (NJDEP).[1]

NJDEP has established that historic fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 COCs: PAHs, lead, copper, and mercury.[2] Accordingly, NJDEP technical requirements for property containing Historic Fill requires sampling for the EPA Target Compound List for PAHs and Target Analyte List for metals, including lead, copper, mercury, and the OU2 PAH contaminants of concern COCs).[3] PAHs, lead, copper, and mercury are recognized by NJDEP to be constituents of Historic Fill at varying levels, not atypically at or exceeding residential soil standards.[4]

The levels of lead detected at the site in soils are presented in the table below (PAS-00076739).

COCs Found in Onsite Soils	
COC	**Max Detected Concentration**
Lead	1,624 mg/kg

A Specification for Cab Manufacturing Building (Building 12) reports the previous building operation noted that the upper 6-8 feet of soil is fill (PAP-00233804). Historic mapping shows that the southern portion of the site was filled and subdivided at some point between 1905 and 1907, prior to Otis' ownership and operations beginning in 1910. Subsequent historic aerial photos and mapping also show that at least some of the shoreline of the filled area was stabilized or reinforced. Additional bulkhead was later added along the entire shoreline of the Facility (PAP-00233720; PAP-00233775; PAP-00233864; PAP-00233721). There is no indication from a review of provided documents that facility operations disturbed contamination located in historic fill; however, a Specification for Cab Manufacturing Building (Building 12) reports excavation was required for the piers and wall beams (PAP-00233806).

---

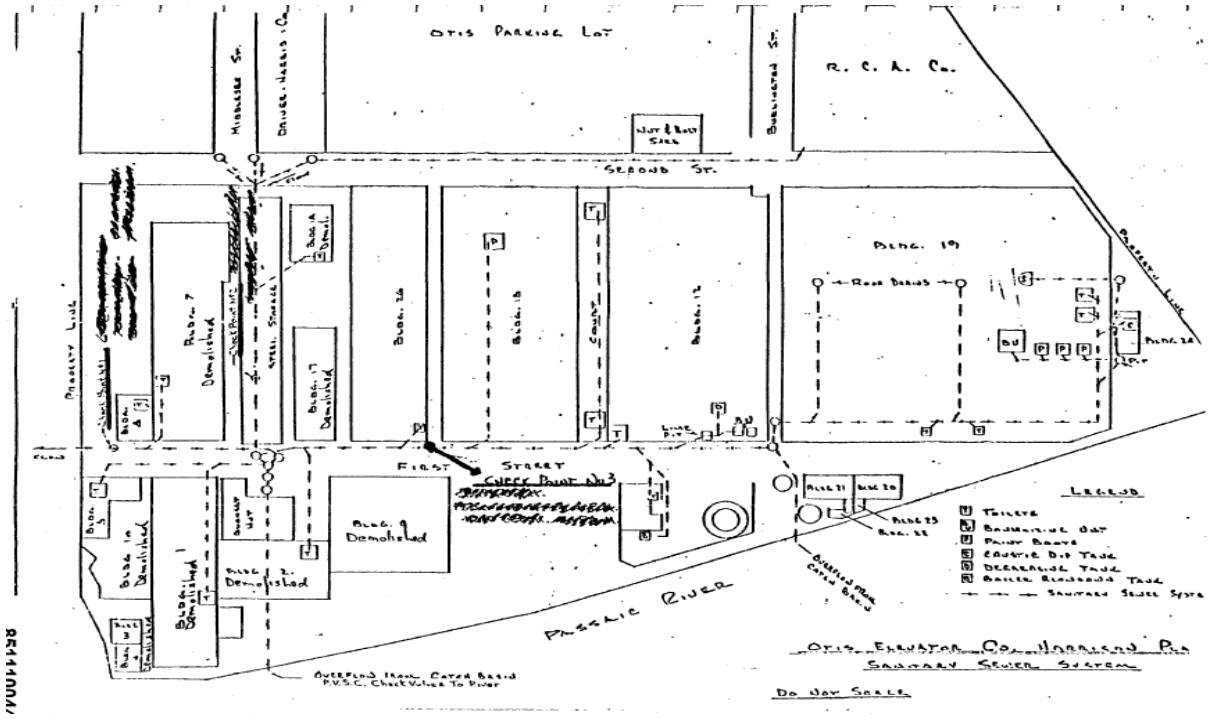
[1] *Digital Geodata Series, DGS04-7, Historic Fill for New Jersey*, https://www.nj.gov/dep/njgs/geodata/dgs04-7.htm, Quadrangle #52 and #53 (NJDEP map identifying locations of recognized historic fill).
[2] *Characterization of Ambient Levels of Selected Metals and cPAHs In New Jersey Soils* (2002) and *Characterization of Ambient Levels of Selected Metals and Other Analytes In New Jersey Soils* (1997), studies prepared for NJDEP, Division of Science and Research, by BEM Systems, Inc.
[3] New Jersey Department of Environmental Protection (NJDEP), *N.J.A.C. 7:26E Technical Requirements for Site Remediation,* Table 4-2, November 2009 [Note that Table 4-2 has been deleted from the current version of N.J.A.C. 7:26E (May 7, 2012) and the updated *Historic Fill Technical Guidance* (April 2013) as NJDEP believed that the tables list of historic fill constituents was too restrictive].
[4] NJDEP Table 4-2 (PAHs and lead) and a summary of NJDEP records regarding investigations of properties in the vicinity of the Passaic River recognized to be located in areas of Historic Fill indicate that the following average/maximum (mg/kg) contamination levels of OU2 COCs exist in area Historic Fill: PAHs (1.91/160), lead (574/10,000), copper (11.2/1,200), and mercury (0.21/3.7).

According to a May 18, 1942 Resolution by the Town of Harrison Otis was granted permission to grade, pave, curb, and install catch basins on Third Street and Burlington Street in accordance with specifications approved by the Town Engineer's Department (PAP-00456842).

5. COC Pathways

Storm Sewers

An *Environmental Due Diligence Assessment of Habitat International, Ltd.* prepared for CIT Group/Business Credit, Inc., dated May 1988, states that "[s]tormwater drains directly to the Passaic River" (PAS-00076789). The NJDEP EPCRA Environmental Concerns Tracking Sheet for Intrex states, "all storm drains to the Passaic River" (PAS-00124586). However, a site plan from the period of Otis' ownership and operation shows certain roof drains as draining to the PVSC and catch basin draining to the PVSC subject to an overflow to the river (PAS-00076750). The same undated document also stated that the northeast loading dock had a drain to the river, which was sealed in 1985 (PAS-00076736).



Sanitary Sewer

According to a letter to Otis from the Town of Harrison's Chief Engineer, Joseph A. Cundari, dated December 9, 1997, the Town of Harrison connected to the PVSC's sanitary sewer interceptor system in 1924. Otis connected to the Town of Harrison's combined sanitary and stormwater sewerage system prior to 1924, noting that the exact date was not available. The only discharges allowed to the River were those which were considered as non-polluting, such as non-contact cooling water or treated effluent (PAS-00076655; PAS-00076592).

According to a May 18, 1942 Resolution by the Town of Harrison Otis was granted permission to provide connection for sanitary sewage to the PVSC that was already in existence for the erection of a building to be used in the manufacture of war time equipment and to install suitable storm and surface sewers to connect to with the Passaic River (PAP-00456842-43).

According to the Affidavit of Seymour A. Lubetkin dated January 8, 1998, toward the end of the 1970s, the PVSC required each of its industrial users to obtain sewer connection permits. PVSC required this even though the users may have been previous long time dischargers to the PVSC system (PAS-00076595).

According to the February 1980 PVSC Sewer Connection Application, Otis discharged 11,784,920 gallons of sanitary sewer water and 19,100,000 gallons of water ascribed to the application form category of "separate storm sewer, river, or ditch" in 1978 (PAS-00076744). Otis stated it discharged 48,000 gallons of water containing industrial waste to the PVSC daily. The discharge of industrial waste was continuous and occurred between 7:45 A.M. to 6:15 P.M. (PAS-00076745-46).

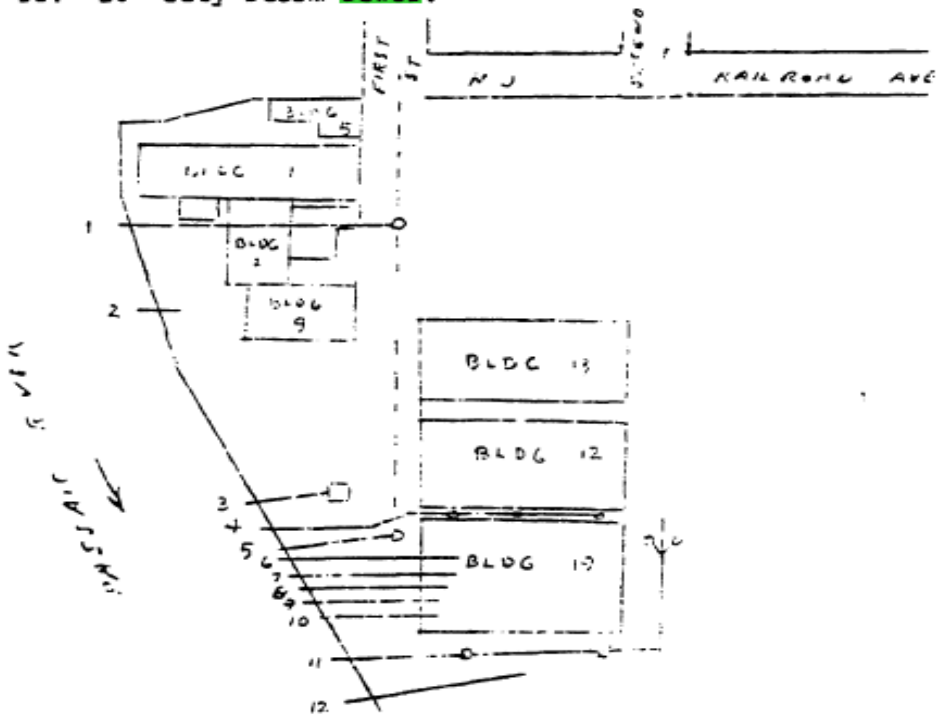
(PAS-00076750)

According to a notebook kept by Seymour A. Lubetkin of the PVSC and prepared in approximately 1971, Otis had four storm sewer lines discharging and twelve outlets in total from its property to the Passaic River (PAS-00076711; PAS-00076741), as depicted below:

Otis Water Usage in gallons			
Reporting Year	***Discharged to Sewer***	***Discharged to River***	***Total Water Use***
1971	46,440,000	17,610,730	64,050,730
1974	27,412,720	26,174,000	53,586,720
1976	26,294,900	10,805,900	37,100,800
1978	11,784,920	19,100,000	30,884,920

(PAS-00076744; PAS-00076665; PAS-00076667; PAS-00076658)

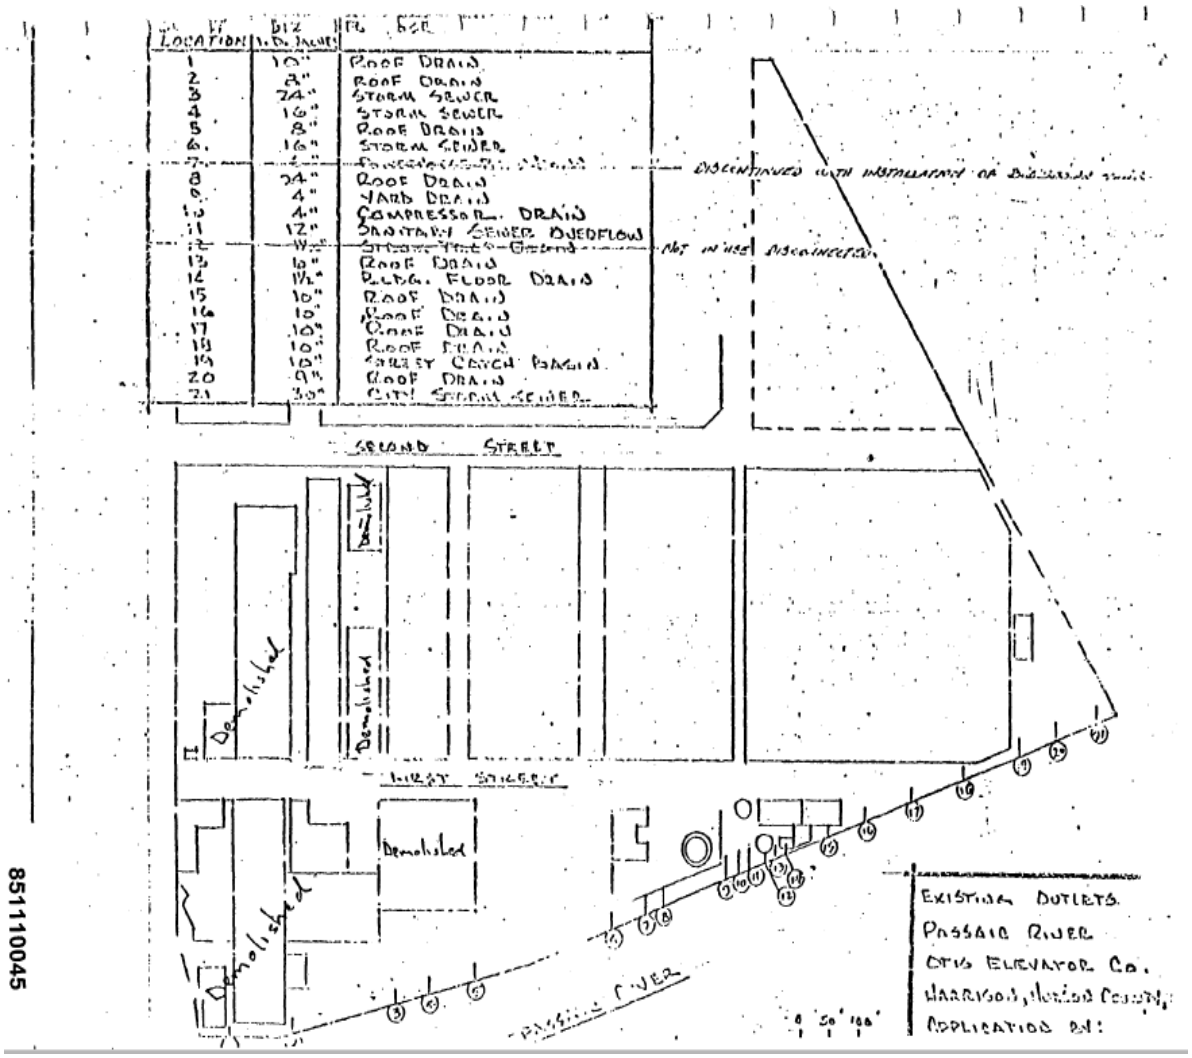
According to a PVSC Sewer Connection Application dated February 25, 1980, Otis had one 12-inch sewer connection to the PSVC discharging 48,000 gallons of water containing industrial waste daily (PAS-00076746).



According to a June 1, 1977 Industrial Sewer Connection Application, Otis continuously discharged 101,000 gallons per day to the PVSC system (PAP-00233778).

Water bills from January 3 to February 1, 1910 show a total of 59,000 cubic feet of water being consumed (PAP-00233854; PAP-00233855).

Otis Elevator Company



This company has twelve outlets from its property to the Passaic River, as follows:

1. 24" storm and overflow sewer;
2. 12" storm sewer;
3. 6" line from drain area;
4. 6" catch basin drain line;
5. 10" sanitary sewer overflow;
6. 12" cooling water and roof drain line;
7. 10" cooling water and roof drain line;
8.
9. 10" roof drain lines;
10.
11. 10" street catch basin line;
12. 16" city storm sewer.

(PAS-00076741)

According to a PVSC Sewer Connection Application dated February 1980, the facility reported 19 existing outfalls and 2 discontinued/disconnected outfalls to the Passaic River, as shown below (PAS-00076743-51).

(PAS-00076751)

According to a 1976 Overflow Analysis, the Middlesex Street overflow chamber was located 150 feet south of Otis's main gate and during periods of rainfall would discharge to the Passaic River instead of the PVSC (PAS-00115713).

Direct Discharge

According to a site *Description and Environmental Characterization Report,* stormwater drained directly to the Passaic River (PAS-00076789).

According to an a January 8, 1998 affidavit of Seymour A. Lubetkin, Chief Engineer of the PVSC from 1954 to 1978, prior to the completion of the PVSC treatment plant and trunk sewer in 1924, when the PVSC accepted the wastes from the municipalities (including Harrison), the municipalities discharged their wastewater into the Passaic River (PAS-00076577; PAS-00076592; PAS-00076596).

According to the *Report on the Quality of the Interstate Waters of the Lower Passaic River and Upper and Lower Bays of New York Harbor*, dated November 1969 and prepared by the U.S. Department of the Interior, the Federal Water Pollution Control Administration and the New Jersey State Department of Health (NJDOH) conducted an outfall study from June to November 1969 to locate wastewater discharges to the Passaic River. The report noted PVSC conducted its own survey, which was not available for inclusion. The report stated that Otis had various pipes (18-inch, 8-inch, 6-inch, and "small pipes") discharging to the river. No samples were taken (PAS-00115428; PAS-00115445; PAS-00115448).

As reported by a Memorandum to EPA from Chemical Land Holdings, Inc. on behalf of Occidental Chemical Corporation, dated November 1996, NJDOH issued a Cease and Desist Order to Otis. According to the Cease and Desist Order, dated October 3, 1969, NJDOH found after conducting an investigation that Otis was "discharging harmful, deleterious and polluting matter from a sewer or drain into the Passaic River," including, but not limited to, "industrial waste". NJDOH ordered Otis to "install and provide wastewater treatment and / or disposal facilities" and cease the discharge (PAS-00076756). According to a NJDOH memo dated January 9, 1970, on December 9, 1969, a representative of NJDOH visited the facility to determine compliance with the administrative order. The memo states company officials believed they found the source of pollutants; an overflow from the sanitary sewer. The pipe ran past a collection basin into which a generator blow down was discharged. The joints on the overflow pipe were broken, and a crack existed in the bottom of the collection basin. The company repaired the joints in the pipe, poured new concrete in the floor in the collection basin, and ceased the discharge" (PAS-00076758). According to a January 7, 1970 NJDOH letter to Otis, the December 9, 1969 inspection confirmed that the company's work was sufficient to correct the suspected source of pollution material and upon which the October 3, 1969 Order was issued (PAS-00233777).

According to the *Annual Report to the PVSC Commissioners for the Year 1972*, prepared by PVSC Chief Engineer S. A. Lubetkin, on December 20, 1971, S. A. Lubetkin directed Otis to halt pollution caused by the discharge of boiler blowdown water into the Passaic River. Work on a pipeline to re-route this discharge to the sanitary sewer was completed as of February 3, 1972 (PAS-00076762-63).

According to attorney notes associated with 1996-97 and 2006 interviews of former Otis employees, a few former employees spoke of personnel occasionally throwing poorly machined metal parts into the river, but it is not clear whether any employees actually observed any such incidents. Another former employee stated that a fellow employee had occasionally disposed of water-based coolant collected from metal cutting operations into an exterior drain or other such structure, believed to drain to the primary wastewater discharge line that ran from the facility to the PVSC sewer system. It is unclear whether any of these materials referenced by former employees contained COCs.

According to a 1976 *Report on Overflow Analysis* submitted to the Passaic Valley Sewerage Commissioners, prepared by Elson T. Killam Associates, Inc., the Middlesex Street Overflow Chamber was located 150 feet south of Otis's main gate. Under dry

flow normal conditions, the flow was diverted to the PVSC interceptor via the regulator. During periods of rainfall, a portion of the combined flow entered the PVSC interceptor, with the balance overflowing the stop logs and discharging through the outfall line into the Passaic River during periods of rainfall (PAS-00115713).

In early 1980, the facility reported 19 existing outfalls and 2 discontinued / disconnected outfalls to the Passaic River in a PVSC Sewer Connection Application (PAS-00076751).

The 1972 Annual Report by PVSC Chief Engineer Seymour Lubetkin stated that per PVSC direction, Otis re-routed its boiler blowdown to the sanitary sewer effective March 3, 1972 (PAS-00006172). However, according to the November 24, 1997, Affidavit of Alan Mercer, the Environmental and Safety Supervisor for Intrex from 1986 to 1991, the Site Evaluation Summary (SES) prepared by Interx in 1991 states that boiler blowdown was discharged to the Passaic River from 1940 until 1983. Mr. Mercer further states that Intrex took possession of the property in 1981 as leasee to the Harrison Riverside Limited Partnership. Mr. Mercer states that when Intrex took possession of the property in 1981, it renovated Building 21 and installed oil-gas boilers for heating the facility. For a time, boiler blowdown was discharged through a floor drain in this building to the Passaic River until approximately 1987. In 1987, NJDEP ordered Intrex to cease its discharge of boiler blowdown to the River. Intrex dug up the floor and rerouted the discharge to the PVSC. Mr. Mercer states that in completing the SES, he had assumed Otis had been operating the same way as Intrex, but did not know whether Otis had discharged any blowdown to the River (PAS-00076603-06).

According to an undated NJDEP *Environmental Concerns Tracking Sheet* for Intrex, several inactive paint drains from the paint spray room went to the Passaic River which were sealed prior to Intrex's occupancy in 1981 (PAS-00076737). Note the date of sealing was not provided in the available documents.

According to the Affidavit of Seymour A. Lubetkin dated January 8 1998, Otis's paint booths were connected to the sanitary sewer system and did not discharge to the Passaic River (PAS-00076582). However, the sewer connection map below shows the sanitary sewer connecting to a catch basin that sent overflow to the Passaic River.

According to the Affidavit of Robert J. Bodnar dated November 29, 1997, while Mr. Bodnar was employed at Otis, Building 21 housed water-cooled air compressors. The cooling water never came in contact with any of the industrial processes at the facility. The compressors' cooling water was discharged from this building to the Passaic River. In addition, Building 21 was never used for the generation of steam to heat the facility. Otis held a permit for the discharge of its compressor cooling water to the Passaic River; all samples tested were satisfactory, and Otis never had a violation because of its cooling water discharge. In the early 1970s, a governmental agency had notified Otis that a discharge of blowdown from the Otis facility to the Passaic River had occurred, and upon receiving the notice, Otis ceased the discharge (PAS-00076599-600).

Spills

A May 1998 *Environmental Due Diligence Site Assessment* by the subsequent operator Intrex, did not identify any indications of spills or releases associated with Otis and noted no major stains (PAS-00076736-38, 772).

6. Regulatory History/Enforcement Actions

Inspections and Violations

According to the January 8, 1998 Affidavit of Seymour A. Lubetkin, the PVSC had set up a river monitoring system to determine if any parties were discharging polluting material to the Passaic River. A review of the annual reports from 1969 through 1976 and the 1977 Draft Report only mention Otis in 1969, 1971, and 1972 for two minor violations (PAS-00076592-93).

According to a Cease and Desist Order from NJDOH to Otis dated October 3, 1969, Otis had been found to be in violation of RS 58:12-2. NJDOH found that Otis had been discharging harmful, deleterious and polluting matter (discussed below) from a sewer or drain into the Passaic River (PAS-00076756-58).

According to the January 8, 1998, Affidavit of Seymour A. Lubetkin, in 1969, a four-inch underground oil pipe had cracked, and oil seeped underground to an adjacent storm overflow pipe that had also cracked. The pipes were excavated and repaired by Otis as soon as Otis was notified. The pollution was discovered on November 14, 1969 and eliminated three days later on November 17, 1969 (PAS-00076593).

According to the Annual Report to the Passaic Valley Sewerage Commissioners for the Year 1972, prepared by Chief Engineer S. A. Lubetkin, Otis received a violation for samples taken on December 14, 1971 from the five outlets that were flowing (7, 8, 10, 15, and 16). The discharge from Outlet 7 had been polluting. On January 6, 1972, Otis notified the Commissioners that steps had been taken to reroute the boiler blowdown discharge to the sanitary sewer. On March 6, 1972, PVSC staff checked the work and confirmed that all work was completed and that the 6-inch pipe to the river had been sealed off, thus eliminating the pollution (PAP-00319432-33; PAS-00006171-72; PAS-00076763-64).

Permits

According to Otis's January 30, 1998 response to EPA's Notice of Liability dated July 1, 1997, Otis had not been able to obtain a copy of its NPDES permit, draft permit, or permit application (PAS-00076582-83). However, according to a Right-to-Know Network's printout obtained by Otis, NPDES permit NJ0002941 for Otis was issued on May 31, 1974 for five outfalls. The printout also states that the permit authorized discharge of "SANI COOLING" effluent, indicating sanitary wastewater and non-contact cooling water. The permit parameters included: chemical oxygen demand (COD) (daily maximum 50 mg/L), oil and grease Freon extra-grav meth (daily maximum 10 mg/L), pH (minimum pH 6, maximum pH 9, daily maximum 10 mg/L), chromium (daily maximum

500 micrograms per liter (µg/L)), zinc (daily maximum 1000 µg/L), and flow (PAS-00076669-81). According to the Affidavit of Seymor A. Lubetkin Assistant Chief Engineer of the PVSC the printout notation for "SANI" is likely an error, since (among other things) it is not consistent with the permit having no monitoring or limits for suspended solids, fecal coliform or biochemical oxygen demand (BOD) (PAS-00076595).

A June 1, 1977 Industrial Sewer Connection Application to the PVSC is signed by Otis, approved and signed by the Town of Harrison, but the PVSC approval and signature fields are blank (PAP-00233778). According to a response to EPA's Notice of Potential Liability dated 1998, Otis submitted an application to the PVSC in February of 1980 for its existing sewer connection. Otis did not receive Permit 98151-13280 because it closed its facility sometime later in 1980 (PAS-00076584; PAS-00076753).

7. Response Actions

Characterization Activities

- May 1998 Environmental Due Diligence Assessment of Habitat International, Ltd. (PAS-00076782).

The February 26, 1998 Application for ECRA Review Initial Notification filed with NJDEP stated that Otis Elevator operations did not involve spills or discharges of hazardous substances or wastes into the soil, groundwater or air (PAP-00456848). The due diligence inspection of April 20, 1988 noted the potential for impacts from fill material at the site, but did not find any indication of spills of discharges (PAS-00076784, 795, 800). An October 6, 1988 Report of Inspection for Intrex noted a stain inside alley- looks like side door was opened and unknown material dumped down storm drain (PAP-00456858). According to an October 31, 1988 Habitat Letter to NJDEP Intrex acknowledged responsibility (PAP-00456860).

A May 1998 *Environmental Due Diligence Site Assessment* by the subsequent operator Intrex of the largest manufacturing building at the sire and adjacent support buildings (leased by Intrex in 1981), did not identify any indications of spills or releases and noted no major stains caused by Intrex with lead impacts in at-depth soils at a former UST location reportedly used by Otis Elevator to fuel vehicles (PAS-00076736-39, 772, 811). The *Environmental Concerns Tracking Sheet* specifies "no staining" in various Potential Areas of Concern (PAS-0076736, PAS-0076738). For one AEC (former location of a UST), NJDEPE required two rounds of subsurface sampling. First-round sampling results for lead at 4.5 bgs were 324 ppm, 228 ppm, 181 ppm, and 887 ppm, with an average of 405 ppm. Second-round sampling results for lead, also at 4.5 bgs, were 303 ppm, 1624 ppm, 396 ppm and 218 ppm, with an average of 520 ppm (PAS-0076739).

Remedial Activities

NJDEP ECRA documents reported that Intrex cleaned the minor staining area identified in the NJDEP inspection (PAP-00456862). NJDEP then approved a Negative Declaration on January 12, 1989 (PAP-00456863).

According to the *Environmental Concerns Tracking Sheet* for Intrex, who leased a portion of the facility starting in 1981, No Further Actions (NFAs) were issued by NJDEPE in 1993 for the following areas of concern (AOCs): dust collectors and spray booths, sump in boiler house, sump in northwest corner of production building, storm drains, exterior temporary drum storage, interior of storage building, waste storage interior, oil water separator in southwest corner, floor drains from paint spray room, paint storage room, loading docks, 120,000-gallon aboveground storage tank (AST), three transformers, battery house, boiler room, dumpster area, hazardous waste from paint spray booths, discharges to Passaic River, and 1,000-gallon gasoline underground storage tank (UST) (PAS-00076735-39). Note that NFA letters were not available in the available material.

On December 7, 1993, the former Otis building located on 1000 First Street, Harrison Town, Hudson County Block 86, Lot 1 (now Intrex Corporation) was issued a No Further Action Letter (i.e., approval of Negative Declaration Affidavit). According to the letter, appropriate institutional controls are in place including, but not limited to, DER, which has been recorded with the County Clerk's Office (PAP-00233795).

8. Summary of Asserted Defenses

To the extent it is determined that a gasoline or oil release occurred at the Facility during the Relevant Time Period and impacted the Passaic River with COC(s), Otis will assert the CERCLA petroleum exclusion (42 U.S.C. §9601(14)).

To the extent it is determined that any discharge associated with another party crossed on, through or under the Facility during the Relevant Time Period and impacted the Passaic River with COC(s), Otis will assert that any liability for such a discharge falls outside the scope of Otis' potential liability under CERCLA.

Diamond Alkali OU2 Allocation

ADR Confidential

Facility Data Report

PABST BREWING COMPANY, LLC

Facility Name, Address and Size: Pabst Brewing Company/Pabst Brewing Co./E. Hoffman & Son Soda and Mineral Water Works; 400 Grove Street, Newark, New Jersey; Historically approximately 11 to 14 acres; 900 employees, 3 shifts per day, 6-7 days per week (PAS-00031808).

1. **Business Type:** Malt beverage production and distribution

2. **Time Period of Ownership/Operations**

   Operator: 1945 or 1946 to 1985
   Owner: 1945 or 1946 to 2003

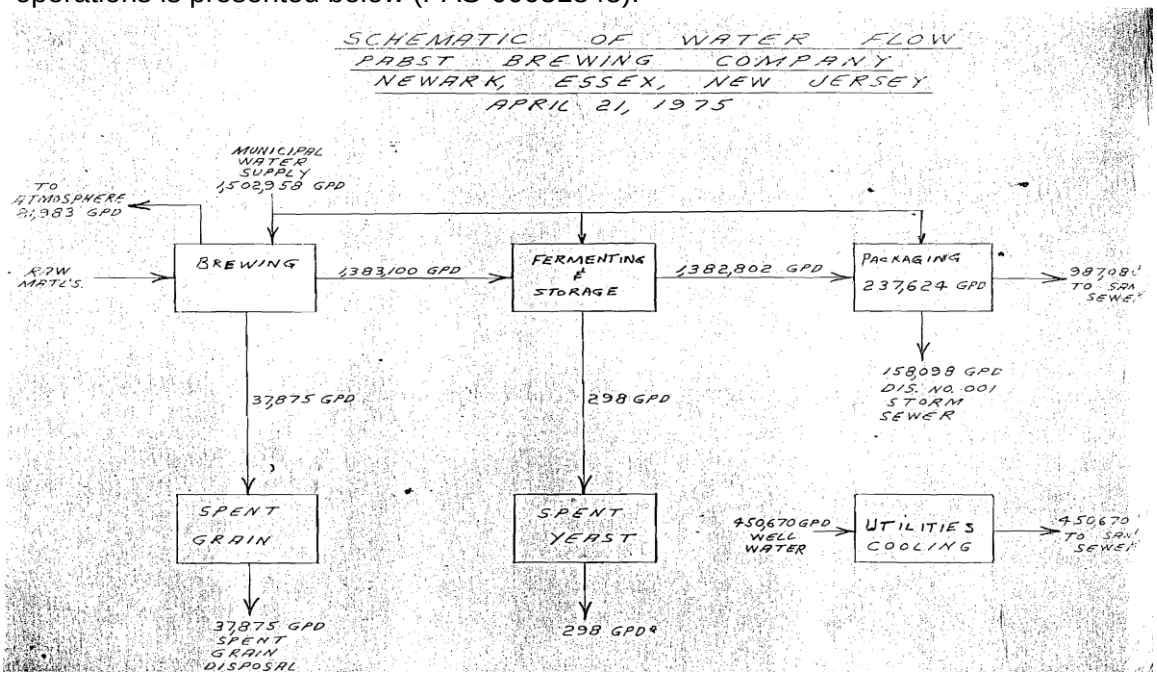
   1945: A March 26, 1992 Discharge Investigation and Corrective Action Report prepared by H&GCL states that Pabst Brewing Company (Pabst) purchased the site from E. Hoffman & Son Soda and Mineral Water Works (Hoffman) on November 15, 1946, and Hoffman and Pabst shared joint tenancy and production facilities for an unreported amount of time (PAS-00031669).

   1961: In 1961, Pabst sold 100% of the stock of Hoffman to investors headed by Robert Sealfon (PAP-00286546).

   1985: According to a July 21, 2004 data monitor company profile, prepared by Factiva, Inc., Pabst Brewing Company was acquired by S&P Company in 1985, whose ownership was given over to the Kalmanovitz Charitable Trust in July 2000 (PAS-00031659). In addition, according to a *Discharge Investigation and Corrective Action Report*, prepared by H*GCL, dated March 26, 1992, the facility ceased operation in July 1985 (PAS-00031669).

   2003: Pabst sold the facility to New West Developers, LLC pursuant to a deed made on March 26, 2003, and recorded with the Essex County Register on April 3, 2003 (PAP-00293838).

   2010: Pabst is currently a wholly-owned subsidiary of Pabst Holding, Inc., which acquired Pabst from S&P Company in 2010 (PAP-00293835).



3. **Operational History/COC Use and Presence at the Facility**

   Pabst Brewing Company operations consisted of malt beverage production (PAS-00031711). Raw materials used in production did not include OU2 COCs, nor did operations include use of COCs (PAS-00031803). However, nine USTs were present at the facility that contained No.6 heating oil, No.2 diesel fuel and unleaded gasoline (PAS-00031922-23, 29).

The locations of the USTs are depicted below (PAP-00287097):

A schematic of how water was used and discharged by the facility as part of its operations is presented below (PAS-00031848):

4. Identified COCs

- PCBs (detected)
- PAHs (detected)
- Copper (detected)
- Lead (detected)
- Mercury (detected)

PCBs

Nine USTs were present at the facility, containing No.6 heating oil, No.2 diesel fuel, and unleaded gasoline (PAS-00031922-23, 29). According to an *Underground Storage Tank Closure Summary Report*, dated March 1992, sand fill material exhibiting high petroleum odors was found inside Tanks E5, E7, and E8. Excavated soil from around those tanks also exhibited high petroleum odors. The excavated soil and sand fill material was stockpiled (Lot "D"). PCB Aroclor-1254 was detected at a maximum concentration of 2,560 parts per billion (ppb) in combined samples taken from the soil stockpile. (PAS-00031936, 56).

PAHs

Nine USTs were present at the facility, containing No.6 heating oil, No.2 diesel fuel, and unleaded gasoline (PAS-00031922-23, 29). According to an *Underground Storage Tank Closure Summary Report*, dated March 1992, and a *Remedial Investigation, LNAPL IRM, and Groundwater Classification Exception Area Report for Regulated Underground Storage Tanks*, prepared by EcolSciences, Inc., dated May 6, 2016, low and high molecular weight PAHs were detected in soil in the area of the USTs at the facility (PAP-00287067, 145-48; PAS-00031946). The *Remedial Investigation, LNAPL IRM, and Groundwater Classification Exception Area Report for Regulated Underground Storage Tanks*, dated May 6, 2016, states that the detections of PAHs were consistent with concentrations of PAHs identified in Historic Fill (PAP-00287067, 76).

Copper

According to a *Heavy Metals Source Determination Study*, prepared by PVSC, dated August 15, 1978, copper was detected in facility wastewater in 1978 at a concentration of 0.179 mg/L, or 2.344 pounds per day (PAS-00031647; PAS-00031832).

According to a 1984 Discharge Surveillance Report, Discharge 001 was required to be monitored for copper, with a discharge limit of 1.0 (no units were listed). The sample result was listed as 0.005 (no units were listed) (PAP-00406396).

Lead

According to a *Heavy Metals Source Determination Study*, prepared by PVSC, dated August 15, 1978, lead was detected in facility wastewater in 1978 at a concentration of 0.117 mg/L, or 1.532 pounds per day (PAS-00031647; PAS-00031832).

Nine USTs were present at the facility, containing No.6 heating oil, No.2 diesel fuel, and unleaded gasoline (PAS-00031922-23, 29). According to an *Underground Storage Tank Closure Summary Report*, dated March 1992, lead was detected in soil associated with the USTs at the facility. Lead was detected at a maximum concentration of 12,000 ppb (PAS-00031918).

Mercury

Mercury was detected in facility wastewater effluent at concentrations up to 0.0063 [units were not available in the file, but it is assumed the concentrations are in milligrams per liter (mg/L)] (PAS-00031816-18).

According to a *Heavy Metals Source Determination Study*, prepared by PVSC, dated August 15, 1978, mercury was detected in facility wastewater in 1978 at a concentration of 0.0012 mg/L, or 0.0157 pounds per day (PAS-00031647; PAS-00031832).

Historic Fill

The Allocation Team has determined that the facility site is not located on regional Historic Fill as designated by the NJDEP.[1]

The NJDEP has established that Historic Fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 COCs: PAHs, lead, copper, and mercury.[2] Accordingly, NJDEP technical requirements for property containing Historic Fill requires sampling for the United States Environmental Protection Agency (EPA) Target Compound List (TCL) for PAHs and Target Analyte List (TAL) for metals, including lead, copper, mercury, and the OU2 PAH COCs.[3] PAHs, lead, copper, and mercury are recognized by NJDEP to be constituents of Historic Fill at varying levels, not atypically at or exceeding residential soil standards.[4]

The levels of PAHs, copper, lead and mercury detected at the site in soils are presented in the table below (PAP-00292425).

---

[1] *Historic Fill for New Jersey*, https://www.nj.gov/dep/njgs/geodata/dgs04-7.htm, Quadrangle No.52 & No.53 (NJDEP map identifying locations of recognized historic fill).
[2] *Characterization of Ambient Levels of Selected Metals and cPAHs In New Jersey Soils* (2002) and *Characterization of Ambient Levels of Selected Metals and Other Analytes In New Jersey Soils* (1997), studies prepared for NJDEP, Division of Science and Research, by BEM Systems, Inc.
[3] New Jersey Department of Environmental Protection (NJDEP), *N.J.A.C. 7:26E Technical Requirements for Site Remediation,* Table 4-2, November 2009 [Note that Table 4-2 has been deleted from the current version of N.J.A.C. 7:26E (May 7, 2012) and the updated *Historic Fill Technical Guidance* (April 2013) as NJDEP believed that the tables list of historic fill constituents was too restrictive].
[4] NJDEP Table 4-2 (PAHs and lead) and a summary of NJDEP records regarding investigations of properties in the vicinity of the Passaic River recognized to be located in areas of Historic Fill indicate that the following average/maximum (mg/kg) contamination levels of OU2 COCs exist in area Historic Fill: PAHs (1.91/160), lead (574/10,000), copper (11.2/1,200), and mercury (0.21/3.7).

COCs Found in Onsite Soils	
COC	**Max Detected Concentration**
Lead	610 mg/kg
Benzo(a)anthracene	7.633 mg/kg
Benzo(a)pyrene	5.94 mg/kg
Benzo(b)fluoranthene	9.733 mg/kg
Benzo(k)fluoranthene	3.82 mg/kg
Dibenzo(a,h)anthracene	0.546 mg/kg
Indeno(1,2,3-cd)pyrene	1.76 mg/kg

It is noted that according to a *Remedial Investigation, LNAPL IRM, and Groundwater Classification Exception Area Report for Regulated Underground Storage Tanks*, prepared by EcolSciences, Inc., dated May 6, 2016, the facility is underlain by "Urban Land" (i.e., Urban Fill). The original characteristics of the native soils at the site have been extensively reworked due to the long history of development in this area. Approximately five to ten feet of additional soil and construction type debris (up to twenty feet in certain areas) have also been placed on the site (PAP-00287062).

5. COC Pathways

Sanitary Sewer

The facility received a New Jersey Pollutant Discharge Elimination System (NJDPES) permit (No.NJ0028088) to discharge wastewater to the PVSC system on November 30, 1982 (PAS-00031712). This was designated as Discharge 002 (PAS-00031755). According to a *NJDEP Discharge Surveillance Report* dated April 3, 1985, wastewater discharged to Discharge 002 included water from wash down of vessels, piping, equipment, and sinks; and, non-contact cooling water for production equipment, air compressors, and air conditioning (PAS-00031757-58). The Clay Street CSO, which discharged to the Passaic River, was located approximately three miles from the facility, between the point at which the facility connected to the PVSC system and the PVSC treatment plant (PAS-00032016).

Documented wastewater discharge volumes are as follows:

- According to a *Waste Effluent Survey* dated June 6, 1972, 594,568,000 gallons of wastewater were discharged to the sanitary sewer, and 96,790,000 gallons of wastewater were discharged to the storm sewer in 1971 (PAS-00031804).

- According to a *Waste Effluent Survey* dated April 14, 1975, 440,507,570 gallons of wastewater were discharged to the sanitary sewer, and 49,484,560 gallons of wastewater were discharged to the storm sewer in 1974 (PAS-00031809).

- According to a *Heavy Metals Source Determination Study*, prepared by PVSC in 1978, wastewater discharge from the facility was 1.57 million gallons per day (MGD). The 1978 study also showed detection of mercury, copper and lead in facility wastewater (PAS-00031647).

- In 1978, the facility reported that 401,467,017 gallons of wastewater were discharged to the sanitary sewer, and 106,215,100 gallons of wastewater were discharged to the storm sewer (PAS-00031828).

- According to an *NJDEP Public Notice* dated September 15, 1982, the facility discharged 1.44 MGD, and no pretreatment occurred (PAS-00031714).

- According to a 1983 Facility Wastewater Report, the facility discharged a maximum of 1.3422 MGD at Discharge 002 between February 1983 and April 1983 (PAP-00406403).

- In 1984, PVSC listed the average daily wastewater flow from the facility as 1.426 MGD (PAP-00016793).

- According to a 1985 Facility Wastewater Report, the facility discharged a maximum of 1.4594 MGD at Discharge 002 between February 1985 and April 1985 (PAP-00406602).

Storm Sewer

According to an undated EPA Fact Sheet for Draft NPDES Permit to Discharge into the Waters of the United States, non-contact cooling water was discharged through Discharge 001. The receiving water body was listed as Maybaum Creek (PAS-00031709-11). It appears Maybaum Creek may be connected to the Rahway River (PAS-00031749). Maybaum Creek is a tributary of the Rahway River, which discharges to the Atlantic Ocean (PAS-00031750). Average non-contact cooling water discharges were 0.158 MGD to Discharge 001 (PAS-00031709, 11; PAP-00406427).

According to a letter prepared by Pabst Brewing Company, dated May 22, 1981, the facility had been discharging cooling water into the South Orange Avenue storm sewer since 1964 at the suggestion of the City of Newark to avoid hydraulically overloading the sanitary sewer system. According to the letter, the storm sewer discharged to the Rahway River and the Atlantic Ocean (PAS-00031750).

Direct Release

There is no information regarding direct release in the available file material.

Spills

There is no information regarding spills in the available file material.

6. Regulatory History/Enforcement Actions

Inspections

There is no information regarding inspections in the available file material.

Violations

Pabst and New West Developers, Inc. received Notices of Violation (NOV) on May 5, 2005 and April 28, 2011, for failure to conduct a remedial investigation and conduct remediation (PAP-00286348-49; PAP-00286135).

To address the May 5, 2005 NOV, New West Developers, Inc.'s consultant submitted a letter for NJDEP stating that remedial investigation activities would commence in August 2005 (PAP-00286599).

According to a *Remedial Investigation, LNAPL IRM, and Groundwater Classification Exception Area Report for Regulated Underground Storage Tanks*, prepared by EcolSciences, Inc., dated May 6, 2016, Pabst received two NOVs from the NJDEP dated April 28, 2011 and July 19, 2011 in a February 9, 2012 letter. The February 9, 2012 letter states that as a result of management reorganization at Pabst in 2010 and a change of address, the new management of Pabst did not immediately receive the 2011 NOVs. Therefore, Pabst's response to the NOVs was delayed. Upon receipt and review of the NOV's and discussions with the NJDEP, Pabst complied with the NOV and retained EcolSciences's Licensed Site Remediation Professional (LSRP) to oversee the investigation and remediation of the regulated USTs (PAP-00287061).

Permits

The facility first received a NPDES permit (No.NJ0028088) on May 1, 1976 (PAS-00031750).

The facility received a NPDES permit (No.NJ0028088) to discharge to Maybaum Creek on October 30, 1981 (PAS-00031722). Discharge 001 was required to be monitored quarterly for copper, with a discharge limit of 1.0 mg/L; however, the permit noted that monitoring for this parameter was not required unless a corrosion inhibitor containing this metal was used for water treatment purposes (PAP-00406523).

The facility received a NJDPES permit (No.NJ0028088) to discharge wastewater to the PVSC system on November 30, 1982 (PAS-00031712).

According to a 1984 Discharge Surveillance Report, Discharge 001 was required to be monitored for copper, with a discharge limit of 1.0 (no units were listed) (PAP-00406396).

A NJDEP memorandum, dated November 5, 1986, states it verified an Affidavit of Exemption from Pabst related to their NJPDES permit (No. NJ0028088), confirming that discharges has ceased (PAP-00406740). The NJPDES permit was cancelled in June 1986 (PAP-00406744).

7. Response Actions

Characterization Activities

The following characterization activities have taken place at the facility:

- *Underground Storage Tank Closure Summary Report*, dated March 1992 (PAP-00293902);
- *Remedial Investigation Report Addendum*, dated August 1995 (PAP-00293902);
- *Remedial Investigation Report/Remedial Investigation Workplan Addendum*, dated January 2000 (PAP-00293902);
- *Remedial Investigation Report/Remedial Action Workplan*, dated November 2002 (PAP-00293902);
- *Supplemental Remedial Investigation Report for Soils*, dated March 5, 2010 (PAP-00286143); and,
- A *Remedial Investigation, LNAPL IRM, and Groundwater Classification Exception Area Report for Regulated Underground Storage Tanks*, prepared by EcolSciences, Inc., dated May 6, 2016 (PAP-00287058).

Sewer

There is no information regarding sewer sampling data in the available file material.

Soil

Nine USTs were present at the facility, containing No.6 heating oil, No.2 diesel fuel, and unleaded gasoline (PAS-00031922-23, -29). According to an *Underground Storage Tank Closure Summary Report*, dated March 1992, lead and PAHs were detected in soil at the facility (PAS-00031918, 46). Lead was detected at a maximum concentration of 12,000 ppb (PAS-00031918). In addition, PCB Aroclor-1254 was detected at a maximum concentration of 2,560 ppb in combined samples taken from a soil stockpile associated with Tanks E5, E7, and E8 at the facility (PAS-00031956). The *Remedial Investigation, LNAPL IRM, and Groundwater Classification Exception Area Report for Regulated Underground Storage Tanks*, prepared by EcolSciences, Inc., dated May 6, 2016, also states that lead and PAHs were detected in soil at the facility. As discussed further below, according to the report, the detections of PAHs were consistent with concentrations of PAHs identified in Historic Fill (PAP-00287067, 76).

According to a letter to NJDEP prepared on behalf of New West Developers, Inc., dated July 17, 2008, requesting a determination of No Further Action for Soil, from 1994 to 2004 Pabst conducted a multi-phase Remedial Investigation of the various former tank areas. Based on the results of the investigation there were five tank areas where regulated compounds subject to remediation provisions remained in soil at that time (PAP-00286131).

According to a *Remedial Investigation, LNAPL IRM, and Groundwater Classification Exception Area Report for Regulated Underground Storage Tanks*, prepared by EcolSciences, Inc., dated May 6, 2016, supplemental soil investigation in the Tank E1 through E4 area was needed to confirm that the PAH exceedances historically identified were associated with Historic Fill rather than former USTs. In every test pit conducted onsite by EcolSciences, fill material consisting of soil mixed with concrete, asphalt, demolition debris, and other household type material throughout the test pit depth (generally extending to at least ten to fifteen feet below grade). In many locations, test pits could not be completed to the native soils given the thickness of the Historic Fill and the overlying fill/construction debris. Based on these observations, EcolSciences concluded that the PAH concentrations identified in this area are the result of Historic Fill contamination and the remedial investigations for Tanks E1 through E4, as well as the remedial investigations for soil relative to all tank areas, were complete (PAP-00287076).

Groundwater

Based on the *Remedial Investigation, LNAPL IRM, and Groundwater Classification Exception Area Report for Regulated Underground Storage Tanks*, prepared by EcolSciences, Inc., dated May 6, 2016, groundwater data are not indicative of a plume containing OU2 COCs (PAP-00287098).

Remedial Activities

According to a *Remedial Investigation Status Report* (November 2002 – January 2003), prepared by ENSR Corporation, dated February 2003, nine USTs were removed or abandoned at the site in 1991/1992 (PAP-00293902). The *Underground Storage Tank Closure Summary Report*, dated March 1992, states that the USTs were closed under the oversight of NJDEP (PAP-00293457). According to the *Remedial Investigation, LNAPL IRM, and Groundwater Classification Exception Area Report for Regulated Underground Storage Tanks*, prepared by EcolSciences, Inc., dated May 6, 2016, one of the USTs received a “no further action” designation from NJDEP on January 3, 2001 (PAP-00287066); it is unclear if the remaining USTs have yet to receive “no further action” designations (PAP-00287053-55).

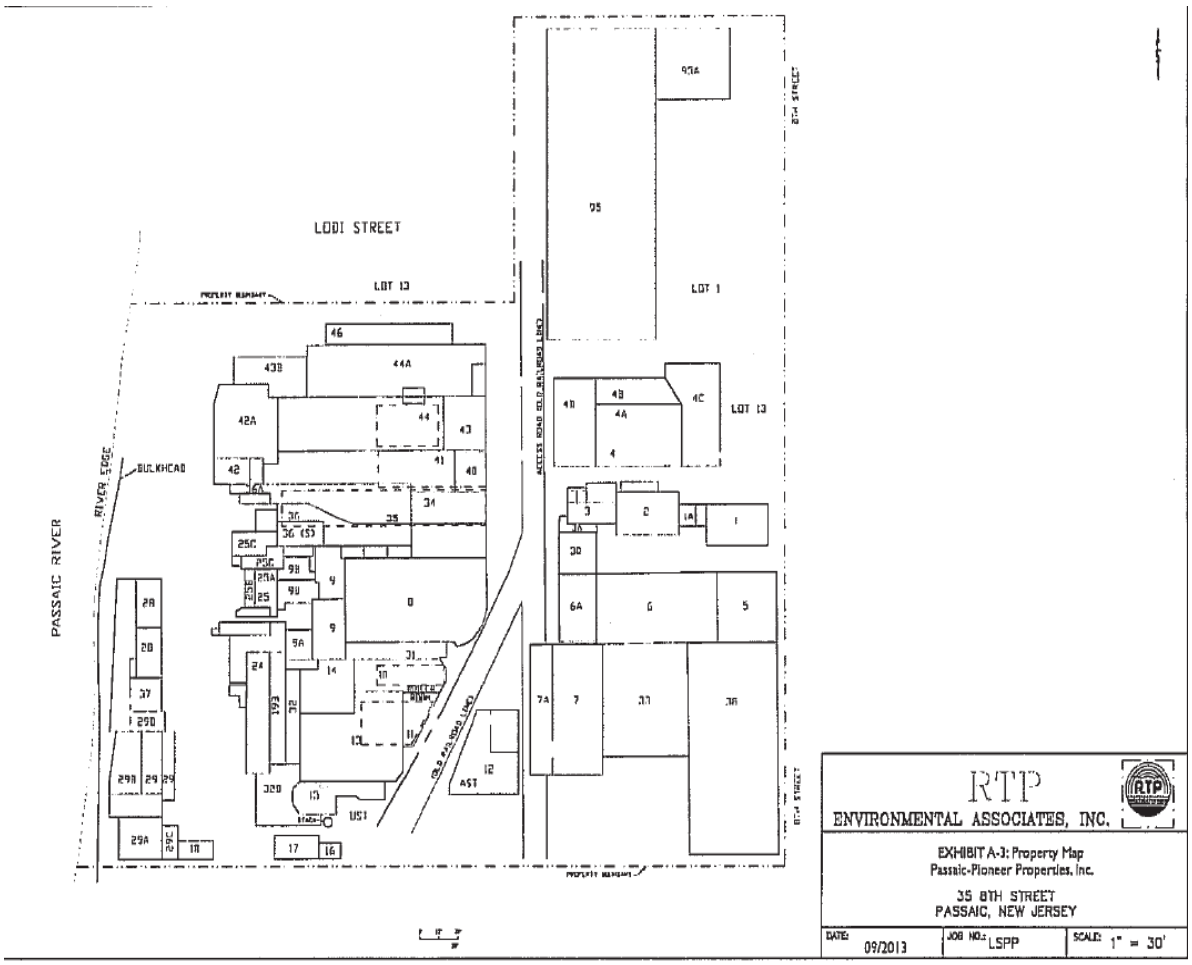
8. Summary of Asserted Defenses

Pabst asserts that Pabst is not liable under the CERCLA Third Party defense for heavy metals in its wastewater because the City of Newark provided all of Respondent’s water for use at the Facility. The Facility’s discharges to the PVSC system were federally permitted discharges with very limited deviations. COC releases related to underground storage tanks at the Facility are subject to the CERCLA petroleum exclusion.

There have never been any direct discharges of COCs from the Pabst Facility to the Passaic River. While the COCs lead, copper, and mercury have been identified on intermittent occasions in wastewater discharged from the Pabst Facility to the PVSC system, Pabst’s use of water from the City of Newark’s water system historically known

to contain copper and lead, along with Pabst's location almost 3 miles from the Clay Street CSO, makes it questionable that what is an extremely de minimis volume of COCs discharged from the Facility to the PVSC system would have made it 3 miles to the Clay Street CSO, into the Passaic River and settled into the sediment or is remain there today.

Records containing specific information regarding brewery operations are no longer available. The current owners of Pabst acquired the company in 2014 approximately 35 years after brewery operations ceased in 1985. In a 1997 response to a CERCLA Section 104(e) request concerning the Diamond Alkali Superfund Site, counsel for Pabst explained that "Pabst has no information or documentation at this time which is responsive in any fashion" to the Request. During a search for historic insurance information in 2013, it was disclosed that many of the records may have been destroyed by water damage.



Passaic Pioneer Properties Company

Diamond Alkali OU2 Allocation
ADR Confidential
Facility Data Report

PASSAIC PIONEER PROPERTIES COMPANY

Facility Name, Address and Size: Passaic Pioneer Properties Company (PPP), 35 Eighth Street, Passaic, NJ. 9.34 acres (PAS-00115127; PAP-00047948; PAP-00194128). The property consists of two lots on Block 1029, lots 1 and 13 (facility) (PAP-00194161). This was a multi-tenant industrial/manufacturing facility. Information regarding the number of employees and hours worked was not available in the documents reviewed for this report.

1. **Business Type:** PPP was the property owner of a multi-tenant industrial building complex. There are five separate buildings at the subject property. The buildings are grouped as follows: Buildings 18, 28, 29 and 37 make up one building (contiguous and separated by walls only); Buildings 4, 4A, 4B, 4C, 4D are grouped to make up a building; Buildings 1, 2, 3, 5, 6, 7, 12, 30, 33, and 38 are grouped together; Building 95 is a standalone structure; and the remaining Building numbers make up the fifth building. Although there are separate building numbers, the majority of the buildings are contiguous and are separated by walls only (PAP-00193872) See the following schematic of property layout below.

(PAP-00047950)

Diamond Alkali OU2 Allocation

Facility Data Report

2. Time Period of Ownership/Operations

Operator: N/A
Owner: 1936/1966 to 2006

PPP owned the facility property from 1936 until February 2006 (PAP-00193845; PAP-00193848; PAS-00115312). More than fifty (50) tenants have leased buildings and other areas of the facility property from PPP for industrial, manufacturing, and storage operations during that period (PAP-00194148-50).

- The facility began operations in the late 1800s as an area of industrial and manufacturing operations.
- PPP purchased a large portion of the facility from Patterson Parchment Paper Company in 1936 and the remainder of the property in 1966 (PAP-00193868).
- PPP sold the property in February 2006 to Passaic Commercial Properties, LLC (the current owner).

3. Operational History/COC Use and Presence at the Facility

PPP leased buildings and land surface to tenants for the operation of industrial, manufacturing, and storage operations space from 1936 to 2006 (PAP-00193865-66).

The primary business type occupying the subject property since 1936 consisted of fabric dyeing, finishing, and knitting operations. This included the following companies:

- Inter-State Dyeing and Finishing (1936 to 2000)
- American Brand Textile Company (1954 to the late 1980s)
- Marijon Dyeing & Finishing Company (1954 to 1968)
- Regent Manufacturing (1959 to 1983)
- EI & EF Meyer, Inc. (1958 to 1990)
- Sunbrite Dye Company (1965 to present)
- Baltic Dyeing & Finishing (1968 to 2001)

A variety of other business types leased the property as well, including:

- Applikay Textile Processing Corp., (1958 to 1985) which consisted of printing and finishing of textile materials
- Bal-Ray (1954 to 1958), which was also a printing company with operations similar to Applikay (PAP-00193868).
- Other types of businesses included woodworking, construction, and storage (PAP-00193873-74).

Sunbrite Dye Company, Inc. (Sunbrite) is the largest tenant at the subject property. Sunbrite is the parent company to Ralon Textile Processing and East Coast Embossing, both operating on site in conjunction with Sunbrite. Sunbrite occupies Buildings 8, 9 (9, 9A, 9B), 14, 17, 18, 19B, 24, 24A, 25 (25, 25A, 25B, 25C), 28B, 28C, 29 (29, 29A, 29B, 29C, 29D), 31, 32, 32B, 34, 35, 36 (first and second floors), 36A, 37, 40, 41, 42, 42A, 43, and 44. Sunbrite also occupies Buildings 10 and 11, which are the boiler operations. Operations at Sunbrite primarily consist of dyeing, finishing, and drying of fabric material. Raw undyed material is placed in mesh bags which are closed and placed into dyeing machines. The bags containing the material are submerged in a dye bath consisting of water, steam, and aqueous-based dyes. Upon completion of dyeing the material, the mesh bags are removed from the dye bath and the dye bath was discharged into floor drains and troughs. Finishing of the dyed materials would include adding a starch-based material to the fabric prior to being dried through the frame (large capacity gas or steam dryers) (PAP-00193872).

Appendix 4 of a Hazardous Substances/Waste Inventory of a NJDEP *Site Remediation Program Preliminary Assessment Report*, dated April 14, 2006 (2006 NJDEP PAR) identifies hydraulic oil, paints, sealants, adhesives, and cutting oils as materials used by multiple PPP tenants (PAP-00193875-81). These substances can contain PCBs and lead. In addition, copper compounds were noted to be used by one tenant − Superior Dyeing Corporation (PAP-00193879). It also notes that none of the facilities on the property was identified as RCRA hazardous waste generators (PAP-00193881).

The 2006 NJDEP PAR also notes that Sanborn Fire Insurance Maps show that there was a 550-gallon naphthalene storage tank located at the western side of Building 28 (PAP- 00193885). In December 2000 and April 2008, ground-penetrating radar efforts were conducted to locate this underground storage tank (UST), neither of which showed the presence of an underground anomaly. Further, soil sampling confirmed that no COCs were detected in this location (PAP-00194174; PAP-00194211-12).

4. Identified COCs

- PCBs (possibly used and detected)
- PAHs (possibly used and detected)
- Copper (used and detected)
- Lead (detected)
- Mercury (detected)

PCBs

The *2014 RIR/RAP* report notes that there were soil samples that identified “hot spots” of PCBs. The extent of contamination was delineated for the PCBs which showed very small areas, specifically along the rail line for the PCBs (PAP-00048067-74). PCB sampling, which was conducted in March 2011, was evaluated in accordance with the Soil Remediation Standard – Impact to Groundwater Guidance, SPLP for PCBs and the results were noted as non-detect (PAP-00048074). A second round of sampling was conducted in August 2011 specific to the PCB SPLP sample locations, and these results were also noted as non-detect (PAP-00048074). PCBs identified at the facility were

attributed to non-indigenous historic fill, and therefore the proposed remedial action was an engineering control in the form of a cap for the facility in conjunction with a Deed Notice (PAP-00048082-83; PAP-00048087).

PAHs

According to the 2002 SI/RI Report, sampling conducted in November 2000 and May 2002 of the crawl space from four access points (A, B, C, and D) below Buildings 44 and 41, detected the following concentrations of PAHs.

November 2000 sampling event

- Benzo(a)anthracene 75,000 µg/kg and 35,000 µg/kg
- Benzo(a)pyrene 62,000 µg/kg and 38,000 µg/kg
- Benzo(b)fluoranthene 76,000 µg/kg and 43,000 µg/kg
- Benzo(k)fluoranthene 45,000 µg/kg and 41,000 µg/kg
- Chrysene 78,000 µg/kg and 40,000 µg/kgDibenzo(a,h)anthracene 20,000 µg/kg
- Indeno(1,2,3-cd)pyrene 39,000 µg/kg and 23,000 µg/kg (PAP-00193926-27; PAS-00115279-81).

The following PAHs were detected during the May 2002 sampling event

- Benzo(a)anthracene 46,000 µg/kg; 39,000 µg/kg; and 33,000 µg/kg
- Benzo(a)pyrene 47,000 µg/kg; 55,000 µg/kg; 20,000 µg/kg; and 1,200 µg/kg
- Benzo(b)fluoranthene 6,700 µg/kg; 97,000 µg/kg; 32,000 µg/kg; and 2,200 µg/kg
- Benzo(k)fluoranthene 12,000 µg/kg; 82,000 µg/kg; 32,000 µg/kg and 2,400 µg/kg
- Chrysene 60,000 µg/kg and 28,000 µg/kg
- Dibenzo(a,h)anthracene 6,600 µg/kg and 2,500 µg/kg
- Indeno(1,2,3-cd)pyrene 1,100 µg/kg; 1,100 µg/kg; and 4,500 mg/kg (PAP-00193927; PAS-00115281).

These compounds were noted to be identical to those identified in the “Target Contaminant Concentrations of Typical Historical Fill Material” table in the Technical Requirements for Site Remediation (PAP-00193928). A third and fourth round of sampling in April and May 2003 only identified the following PAHs above the RDCSCC in one sample location:

- Benzo(a)pyrene 1,100 µg/kg;
- Benzo(b)fluoranthene 1,000 µg/kg.

(PAP-00194094-). As previously noted, this AOC was re-designated as AOC-5B (Building 44), AOC-5C (Building 35) and AOC-5D (Building 41) during a subsequent investigation (PAP-00194218-21).

One soil sample was collected in the crawl space under Building 44 (AOC-5B) in April 2008 and the results of this sample did not detect any contaminants above the most stringent remediation standards (PAP-00194189; PAP-00194435). Sampling below the concrete layer exhibited contaminants typical of historical fill only and a no further action determination was recommended for AOC-5B (PAP-00194457).

A soil sample collected in 2008 beneath Building 41 (AOC-5D) detected benzo(a)anthracene (3.55 mg/kg), benzo(b)fluoranthene (3.21 mg/kg), benzo(a)pyrene (4.03 mg/kg), indeno(1,2,3-cd)pyrene (3.34 mg/kg), and dibenzo(a,h)anthracene (1.2 mg/kg). However, since the contaminants are consistent with those found in historical fill material, a no further action determination along with the institution of a deed notice was recommended, since the soils beneath the crawl space were already capped (PAP-00194459-60; 65-66).

Remedial investigation activities conducted in 2009 in the crawl space beneath Building 35 (AOC-5C) also detected PAHs and required further investigation. The crawl space was cleaned and in 2011 eight additional samples were taken. Analysis of the sampling concluded that the contaminants identified were not related to on-site operations and were instead consistent with those observed in historic fill material (PAP-00048081).

Copper

According to the 2002 SI/RI Report discussed above, copper was detected in two samples during the November 2000 sampling; 784 mg/kg and 647 mg/kg. Copper was detected in three of the four samples taken during the May 2002 sampling; 1,720 mg/kg, 1,730 mg/kg, and 628 mg/kg (PAP-00193926-28; PAS-00115279-82). These samples were part of the investigation of the crawl space below Buildings 44, 41 and 35, designated as AOC-1. The contaminants identified during these investigatory activities were determined to be identical to those identified in the "Target Contaminant Concentrations of Typical Historical Fill Material" table in the Technical Requirements for Site Remediation (PAS-00115279-82). A No Further Action Letter was recommended by RTP (PAS-00115261; PAP-00193909). The NJDEP required additional sampling beneath and/or outside of the area of the crawl space to verify the integrity of the sampling, which was documented in the 2003 Addendum to the SI/RIR (PAP-00194076-78; 93-95). Copper was identified under Building 44 during the 2003 sampling (2.08 mg/kg at 5.25-5.75 feet and 8.07 mg/kg at 6-6.5 feet bgs) (PAP-00194189); and was detected in sampling related to Building 41 (261 mg/kg at 5.25-5.75 feet and 351 mg/kg at 6-6.5 feet bgs) (PAP-00194191).

The following table shows the highest concentration of copper for Building 35 (AOC-1) for the subsequent sampling events in 2006, 2008, 2009 and 2011 as reported in the 2014 RIR/RAP.

Copper Concentrations		
Sample Year	**Depth (bgs)**	**Results**
2006	0.5-1 feet	999 mg/kg
2008	1-1.5 feet	279 mg/kg
2009	1.5-2 feet	173 mg/kg
2011	0.0-0.5 feet	98.5 mg/kg

(PAP-00048092)

Lead

A November 2002 Site Investigation/Remedial Investigation Report (SI/RIR) for Inter-State Dyeing and Finishing Company detected lead in three of the four samples taken during November 2000 sampling; 608 mg/kg, 1,470 mg/kg, and 692 mg/kg. Lead was detected in four samples taken during May 2002 sampling; 1.260 mg/kg, 1,690 mg/kg, 4,430 mg/kg, and 425 mg/kg (PAP-00193926-28; PAS-00115279-82). These samples were part of the investigation of the crawl space below Buildings 44, 41 and 35, designated as AOC-1. The contaminants identified during these investigatory activities were determined to be identical to those identified in the "Target Contaminant Concentrations of Typical Historical Fill Material" table in the Technical Requirements for Site Remediation (PAS-00115279-82). A No Further Action Letter was recommended (PAP-00193909; PAS-00115261). The NJDEP required additional sampling beneath and/or outside of the area of the crawl space to verify the integrity of the sampling, which was documented in an Addendum to the SI/RIR (PAP-00194076-78; PAP-00194093-95). A third and fourth round of sampling in April and May 2003 showed that there was no direct contamination from the crawl space and good crawl space integrity, therefore, No Further Action was requested (PAP-00194095). This AOC remained active and was subject to further investigation as part of the Memorandum of Agreement between PPP and the NJDEP (PAP-00193826). Ultimately, the crawl spaces under these buildings were re-designated as AOC-5B (Building 44), AOC-5C (Building 35) and AOC-5D (Building 41) (PAP-00194218-21). AOC-5B and AOC-5D warranted No Further Action as of June 2009 (PAP-00048005-07). During the 2003 sampling, lead was not detected above the Residential Direct Contact Soil Cleanup Criteria ("RDCSCC") under Building 44 (PAP-00194189) and determined by RTP to be consistent with levels found in historic fill under Building 41 (PAP-00194190-92). The contaminants identified in AOC-5C were determined by RTP to be consistent with those observed in historic fill as of the RIR/RAR completed in May 2014 (PAP-00048081).

Additional sampling for the 2014 RIR/RAP revealed the presence of lead (along the railroad line ranging from 0.202 mg/kg to 2.8 mg/kg) greater than the NJSRS and IGWSSL. It was concluded these constituents were the result of historic fill and it was proposed to cap the entire facility with registering of a deed notice regarding site conditions (PAP-00048082).

Mercury

The *2014 RIR/RAP* report notes that soil sampling was conducted and analyzed within the crawl space (sediment sample) and the crawl space exterior of Building 35, as requested by NJDEP. The contaminants detected were those noted as typical Historic Fill (PAP-00048079-83; 104). The report includes sampling information showing that the maximum concentration of mercury noted above (642 mg/kg) a crawl space soil sample (CS-5) during 2006 (PAP-00048098). During the same sampling event, 35.1 mg/kg of mercury were detected in another crawl space sample (CS-4). Both of these samples were in Building 11 Boiler Room, and designates as AOC-5A (PAP-00048066, 104).

These soil samples were further evaluated in accordance with the Soil Remediation Standard – Impact to Groundwater Guidance as using the Synthetic Precipitation Leaching Procedure ("SPLP") sampling method, and all results were noted as non-detect (PAP-00048073-74). The remedial outcome for this AOC was recommendation of no further action with engineering controls (PAP-001994431-33, 454-456).

Historic Fill

The Allocation Team has determined that the facility site is located on regional Historic Fill as designated by the NJDEP.[1]

NJDEP has established that historic fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 COCs: PAHs, lead, copper, and mercury.[2] Accordingly, NJDEP technical requirements for property containing Historic Fill requires sampling for the EPA Target Compound List for PAHs and Target Analyte List for metals, including lead, copper, mercury, and the OU2 PAH COCs.[3] PAHs, lead, copper, and mercury are recognized by NJDEP to be constituents of Historic Fill at varying levels, not atypically at or exceeding residential soil standards.[4]

The levels of lead, PCBs, and PAHs detected on the facility site do not exceed the maximum concentrations levels of contamination considered by NJDEP to be typical of that found in Historic Fill. Mercury and copper levels significantly exceed Historic Fill maximum concentrations.

The levels of PAHs, copper, lead and mercury detected at the site in soils are presented in the table below (PAP-00047953-55).

[1] *Digital Geodata Series, DGS04-7, Historic Fill for New Jersey*, https://www.nj.gov/dep/njgs/geodata/dgs04-7.htm, Quadrangle No. 52 and No. 42 (NJDEP map identifying locations of recognized historic fill).
[2] *Characterization of Ambient Levels of Selected Metals and cPAHs In New Jersey Soils* (2002) and *Characterization of Ambient Levels of Selected Metals and Other Analytes In New Jersey Soils* (1997), studies prepared for NJDEP, Division of Science and Research, by BEM Systems, Inc.
[3] New Jersey Department of Environmental Protection (NJDEP), *N.J.A.C. 7:26E Technical Requirements for Site Remediation,* Table 4-2, November 2009 [Note that Table 4-2 has been deleted from the current version of N.J.A.C. 7:26E (May 7, 2012) and the updated *Historic Fill Technical Guidance* (April 2013) as NJDEP believed that the tables list of historic fill constituents was too restrictive].
[4] NJDEP Table 4-2 (PAHs and lead) and a summary of NJDEP records regarding investigations of properties in the vicinity of the Passaic River recognized to be located in areas of Historic Fill indicate that the following average/maximum (mg/kg) contamination levels of OU2 COCs exist in area Historic Fill: PAHs (1.91/160), lead (574/10,000), copper (11.2/1,200), and mercury (0.21/3.7).

Diamond Alkali OU2 Allocation
ADR Confidential
Facility Data Report

COCs Found in Onsite Soils	
COC	**Max Detected Concentration**
Lead	8,830 mg/kg
Copper	1,730 mg/kg
Mercury	642 mg/kg
Benzo(a)anthracene	20 mg/kg
Benzo(a)pyrene	13.1 mg/kg
Benzo(b)fluoranthene	11.3 mg/kg
Benzo(k)fluoranthene	9.56 mg/kg
Dibenzo(a,h)anthracene	2.61 mg/kg
Indeno(1,2,3-cd)pyrene	7.99 mg/kg

(PAP-00047954, PAP-00115281)

A Deed Notice with Engineering Controls was issued October 18, 2013, subject to benzo(a)anthracene, benzo(b)fluoranthene, benzo(k)fluoranthene, benzo(a)pyrene, indeno(1,2,3-cd)pyrene, dibenzo(a,h)anthracene, arsenic, lead, mercury, and PCBs. An attachment to the 2013 Deed Notice states that the only contaminants identified at the subject property are those contained in Historic Fill. Nonindigenous fill material consisting of grey to black soil (coal dust), coal fragments with some crushed brick, gravel, wood, and glass was identified in some areas of the property from zero to approximately nine feet below grade (PAP-00047937). The remedial action for the facility is an engineering control in the form of a cap for the site in conjunction with the deed notice (PAP-00048087).

5. COC Pathways

Sanitary and Storm Sewer

According to the 2006 Preliminary Report (PAR), all sanitary and industrial waste generated at the PPP property is discharged to the public sanitary sewer system and treated at the PVSC treatment plant located in Newark, New Jersey. According to the Passaic City Engineering Department, the subject property has been hooked up to the public sanitary sewer system since prior to 1900 (PAP-00193883). Per the 2006 PAR, tenant, Sunbrite Dye Company was issued a Sewer Use Permit by the PVSC for process wastes. Channels and floor drains were observed in the Sunbrite tenant area, predominately in the dyeing locations. The dye bath discharged to the channels and floor drains, which then discharged to reclamation tanks located in Building 14. The reclamation tanks temporarily stored process waste for the dyeing operations. Monitoring of the pH was conducted and adjusted to permitted levels before discharge to the sanitary sewer. Three former tenants, Superior Dyeing Corporation, Baltic Dyeing & Finishing Company, and Inter-State Dyeing & Finishing had similar Sewer Use Permits from PVSC. Their operations also utilized channels and floor drains that discharged to reclamation tanks for pH adjustment prior to discharging the process waste to the sanitary sewer system (PAP-00193883).

The Direct Discharge PRP Cases for the Lower Passaic River Study Area pertaining to PPP notes historical violations from PVSC. The discharges were noted generally as "dye waste". Dye waste has not been documented to contain any of the COCs (PAS-00115134-39).

The 2002 SI/RI stated that water in the crawl space beneath Buildings 35, 41, and 44 had been present on numerous occasions over the years and on a regular basis, predominately after periods of rainfall, the water was pumped out and discharged to the sanitary sewer. During a second round of SI activities conducted in May 2002, it was noted that roof leaders discharged to the crawl space. Based on the three observations made of the crawl space, it was determined that the likely source of the water found in the crawl space was from storm water, surface water runoff, and on occasion floodwater from the adjacent Passaic River (PAP-00193926-28).

The 2006 NJDEP PAR for the PPP Property notes that there have been above-ground storage tanks, underground storage tanks, piping, aboveground and belowground pumping stations, sumps, pits and storage pads including drum and/or waste storage at the facility. It notes the existence of floor drains, trenches and piping, and sumps at the facility. The local surface water body is identified as the Passaic River. Other areas of concern are noted to be transformers, hazardous material storage and handling areas, discolored or spill areas, non-contact cooling water discharges from a boiler room, and areas which receive flood or storm water from potentially contaminated areas (PAP-00193852-53).

According to the 2006 NJDEP PAR, the Passaic River is located directly adjacent to the west of the subject property. Based on mapping of flood zones and wetlands, the subject property and direct vicinity are applicable to flood zoning (100-year flood zone). According to the PAR, it was reported that the Property had been subject to flooding in the past, most recently September 1999. Reportedly, no process waste was ever discharged to the Passaic River, nor was the river used as a source of process water. Sampling of the Passaic River was not proposed relative to the facility (PAP-00193888).

According to a 2008 Baseline Ecological Evaluation for PPP, a metal bulkhead exists between the Passaic River and the facility property on the western boundary of the facility (PAP-00194174,210-11, 308). The date this bulkhead was installed was not specified.

6. Regulatory History/Enforcement Actions

Permits

Sunbrite Dye Company

NJPDES Permit No. 157157 belonged to the tenant Sunbrite Dye Company. The NJPDES permit is a General Permit for storm water discharge. The facility did not receive any violations from the NJDEP regarding this stormwater discharge permit (PAP-00194147).

Sunbrite Dye Company was also issued a Sewer Use Permit by PVSC for process wastes, which predominantly included spent dye materials from the dyeing operations. Channels and floor drains were apparent in the Sunbrite tenant area, predominantly in the dyeing locations. The dye bath discharged to the channels and floor drains, which then discharged to reclamation tanks located in Building 14. The reclamation tanks are temporary storage of process waste for the dyeing operations. Monitoring of pH was conducted, and adjusted to permitted levels before discharge to the sanitary sewer system (PAP-00193883).

Superior Dyeing Corporation

NJPDES Permit No. 157274 belonged to a former tenant Superior Dyeing Corporation. Superior Dyeing Corporation filed for bankruptcy and is no longer in existence. Specific information regarding this permit is not available. Superior Dyeing Corporation was subject to ISRA and received a No Further Action letter from the NJDEP on February 22, 2005. This permit was identified as part of that ISRA Case No. 20030290 (PAP-00194147).

Superior Dyeing Corporation also had a PVSC Sewer Use Permit and its operations also utilized channels and floor drains in the dyeing locations in which the dye bath was discharged to reclamation tanks for pH adjustment prior to discharging the process waste to the sanitary sewer system (PAP-00193883).

Inter-State Dyeing and Finishing Company

Inter-State Dyeing and Finishing Company was issued a Sewer Use Permit by the PVSC. Permit number No. 26400150 was issued June 16, 1996 with an expiration date of June 2000 (PAS-00115131; PAS-00115134). Inter-State Dyeing and Finishing Company operations also utilized channels and floor drains in the dyeing locations in which the dye bath was discharged to reclamation tanks for pH adjustment prior to discharging the process waste to the sanitary sewer system (PAP-00193883).

Baltic Dyeing and Finishing

Baltic Dyeing and Finishing Company also had a PVSC Sewer Use Permit and its operations also utilized channels and floor drains in the dyeing locations in which the dye bath was discharged to reclamation tanks for pH adjustment prior to discharging the process waste to the sanitary sewer system (PAP-00193883).

Violations

Some tenants had PVSC permits as well as NJDEP permits for storm water discharge to the Passaic River. Although there were documented instances of dye wastes being released to the Passaic River, there is no information in available documents that stated these wastes contained COCs (PAS-00115415-426).

A *PVSC Stream Contamination Report*, dated August 25, 1947 (PAS-00115125) states that on July 14, 1947, dye waste was observed discharging into the Passaic River through the storm sewer at Eclipse Piece Dye Works, a tenant at PPP. The inspector had found that the sewer system in this group of properties was in need of repairs. The tenant was noted to have made some emergency repairs, which eliminated the violation temporarily (PAS-00115396). A *PVSC Stream Contamination Report*, dated November 17, 1947, states that on October 22, 1947 (PAS-00115125), dye wastes were observed discharging into the Passaic River from PPP. A small leak in the sanitary sewer was identified under the mill buildings (PAS-00115398).

A *PVSC Stream Contamination Report*, dated January 13, 1948 (PAS-00115125), states that on November 15, 1947, dye waste was observed discharging into the Passaic River from PPP by way of a storm drain. Investigations revealed a broken pipeline form the plant of a tenant, Millbank, Inc., Textile Printers. The break was repaired and the violation eliminated (PAS-00115400).

An October 1951 letter states that there were intermittent discharges of industrial waste to the Passaic River from the PPP property. The letter notes that recollection of the original dual drainage system as put in by the previous owners (Paterson Parchment Paper Company), a single process concern, leaves the present explanation of heavy trucks frequently breaking the plant sewers underground insufficient to account for the intermittent pollution. The old dual drainage system from a single process appears to have been utilized to take care of a number of industrial wastes from various processes in a multiple tenant mill, and the careful separation of clean and dirty wastes seems to have become lost (PAS-00035373).

A PVSC Weekly Summary of Inspections by Inspectors from January 1952 states that daily inspections have not revealed any discharges of dye waste since some of the outlets to the Passaic River were blocked up the previous month. The weekly summary stated that the cessation of discharge could also be contributed to the shutting down of one of the tenant dyeing concerns. Work on the plumbing underneath the buildings was delayed due to weather but efforts were being continued (PAS-00035374).

A PVSC Weekly Summary of Inspections by Inspectors from January 1956 states that red-colored fluid was observed discharging from a 6-inch pipe into the river on the Inter-State Dyeing and Finishing Company property (PAS-00115406).

A PVSC Memorandum, dated March 31, 1970, states that PPP was an industrial terminal of approximately 46 buildings. A discharge of supposed cooling water into the Passaic River was observed between December 3, 1969 and December 17, 1969, which was sampled and found to be polluting. The constituents of the pollution were not noted, but it did state that one of the firms had boiler blow-down water connected, together with cooling water into a line and it was the boiler blow-down water that contained the compounds that were polluting the river. Upon being informed of the situation, the company had the boiler blow-down line disconnected from the river discharge and reconnected to a pipe leading to the sanitary sewer (PAS-00006216-17).

A 1971 *Violations and Eliminations Report*, states that in December 1971, Parra Print at the PPP complex had one of its outlets sampled. The results showed pollution from this company. The constituents of the pollution were not specified. An inspector found that polluting material was discharging from a 1-inch pipe to the Passaic River. The plant manager was informed and he immediately arranged to plug the line with concrete and discharge the material to the sanitary sewer. This was completed by December 10, 1971 (PAS-00115411).

A PVSC *Stream Contamination Report,* dated December 7, 1978, states that a multi colored dye was observed discharging to the Passaic River from Inter-State Dyeing and Finishing. It should be noted that analysis of samples did not include specific chemicals (PAS-00115416-21).

7. Response Actions

Characterization Activities

The following characterization activities have taken place at the facility:

- Site Investigation/Remedial Investigation Report for Inter-State Dyeing and Finishing Company, dated November 2002 (PAP-00193904)
- Addendum to the Site Investigation / Remedial Investigation Report for Inter-State Dyeing and Finishing Company, dated July 2003 (PAP-00194073)
- NJDEP Site Remediation Program, Preliminary Assessment Report for Passaic Pioneer Properties Company, dated April 4, 2006 (PAP-00193844)
- Addendum to the Preliminary Assessment Report for Passaic Pioneer Properties Company, dated January 10, 2007 (PAP-00194120)
- Revised Addendum to the Preliminary Assessment Report for Passaic Pioneer Properties Company, dated May 3, 2007 (PAP-00194124)
- Remedial Investigation Report, Remedial Action Workplan for Passaic Pioneer Properties Company, dated August 2008 (PAP-00194155)
- Addendum to the Remedial Investigation Report, Remedial Action Workplan for Passaic Pioneer Properties Company, dated January 2009 (PAP-00194325)
- Remedial Investigation Workplan for Passaic Pioneer Properties Company, dated May 8, 2009 (approved June 22, 2009) (PAP-00048000)
- Remedial Investigation Report, Remedial Action Workplan for Passaic Pioneer Properties Company, dated October 23, 2009 (PAP-00194412)
- Remedial Investigation Report/Remedial Action Report, dated May 2014 (PAP-00048061)

The 2002 *SI/RI Report,* dated November 2002, for the Inter-State Dyeing and Finishing Company prepared for PPP states that Inter-State was a tenant from 1936 until May 2000 when the company filed for bankruptcy and ceased operations. Two potential AOCs were investigated—crawl space/areas and historical fill. Sediment sampling in the crawl space showed that PAHs, copper and lead were detected above the Residential Direct Contact Soil Cleanup Criteria. Based on the results of the SI/RI activities

conducted at the subject facility, No Further Action was requested. The report noted that although soil sampling from within the crawl space showed base neutral and metal contamination, it is unlikely that any water or soil/sediment materials would egress to the environment below the crawl space flooring. Any water pumped out from the crawl space is discharged to the sanitary sewer. Any soil will remain in the crawl space due to the concrete flooring and wall with the impermeable layer (PAP-00193908-19).

According to the 2006 *NJDEP PAR*, various areas of the property reportedly utilized fill material, specifically in areas adjacent to the Passaic River bank. Exact locations could not be determined, and it was assumed, based on conversations with the property owner, that there is the potential for the fill to be coal ash (PAP-00193889).

In addition, the report notes that an extensive file review of surrounding properties was conducted at the NJDEP in March 2002 and that many of the facilities reviewed have encountered historical fill. The properties with noted historical fill as well as base neutral and metal contamination include 100 Eighth Street, Lodi & Eighth Street, and 27 Eighth Street, all properties directly adjacent to the facility and subject property, indicating a regional problem. It was anticipated that additional investigations would be conducted regarding the fill material (PAP-00193889).

The 2006 NJDEP PAR for the entire property identified 52 AOCs (four of which were administrative and not contaminant based). Of these, AOCs 23 were No Further Actions and 29 were investigated further between 2003 and 2008. PAHs, PCBs and metals (including copper, mercury and lead) were detected, but all of these AOCs, with the exception of two, were also deemed to require No Further Action. These two areas were the crawl spaces under the buildings at Inter-State Dyeing and Finishing and the potential Historic Fill on the property (PAP-00193845; PAP-00048065-68; PAP-00194167). The report notes that information in the report was from inspections at the property in 2000, 2001, 2002, 2003 and 2006 (PAP-00193861). The crawl space was noted to be an area that received storm water and surface runoff. Soil sampling results of this crawl space showed base neutral and priority pollutant metal contaminants, identical to those identified in the “Target Contaminant Concentrations of Typical Historical Fill Material" table in the Technical Requirements for Site Remediation. Although the soil samples were not obtained from points with direct access to the environment, it was concluded that the soil (sediment) found in the crawl space is the result of years of storm water, as well as surface runoff from the facility and floodwaters from the adjacent Passaic River (PAP-00193886-87).

Appendix 7 − Aerial Photograph Review of the 2006 NJDEP PAR Report, states that in April 1973 aerial photography, Building 95 is apparent at the northeastern portion of the parking area. An additional building group (Buildings 28, 29 and 37) was constructed along the river’s edge of the property. It appears that this area had been filled to accommodate the new buildings (PAP-00193891, 93). Only this area is not reported to have an impact of COC contamination, as only low levels of PAHs were detected in sampling in this area (between 0.274 and 0.667 mg/kg benzo(a)pyrene and 0.621 benzo(a)anthracene) (PAP-00048704; PAP-00048104). It also notes that there was no evidence of above ground storage tanks, waste dumping or burial pits, ponds, lagoons, or landfills in aerial photographs of the facility (PAP-00193893).

A 2008 *Remedial Investigation Report, Remedial Action Workplan* states that additional sampling conducted at the request of the NJDEP adjacent to the crawl spaces confirmed the presence of contaminants below the New Jersey Soil Remediation Standards ("NJSRS") and at levels much lower than those found in the crawl spaces, indicating no direct contamination from the crawl spaces and good crawl space integrity (PAP-00194217-18; PAP-00194433-39).

A May 2014, *RIR/RAP* states that PPP initially started site investigations and remediation as part of its ISRA compliance and obligation. The initial ISRA Case was for tenant, Inter-State Dyeing & Finishing Company, due to its cessation of operations, and it was given the ISRA Case No. E20000341. As stated above, site investigations were conducted at the Inter-State Dyeing & Finishing Company portion of the subject property in November 2002 and July 2003. Soil sampling was conducted and analyzed within the crawl space (sediment sample) and the crawl space exterior, as requested by NJDEP. The contaminants detected were those noted as typical Historic Fill. The Inter-State Dyeing & Finishing Company case was currently active at that time. In addition, two former tenant spaces received No Further Action determinations from the NJDEP; they are Superior Dyeing Corporation (ISRA Case No. E20030290) and Baltic Dyeing and Finishing Company (ISRA Case No. E20010450). Both of these tenants were fabric dyeing and finishing companies, similar to one of the current tenants on-site, Sunbrite Dye Company. The report includes sampling information showing that the maximum concentration of mercury noted above (642 mg/kg) was detected in crawl space soil sample (CS-5) during 2006. During the same sampling event, 35.1 mg/kg of mercury were detected in another crawl space sample (CS-4). Both of these samples were in Building 11 (PAP-00048061, 64-74, 79-83, 98, 104).

In addition, multiple General Information Notifications (GINs) were submitted to the NJDEP for the various current and past ISRA applicable tenants. Ultimately, PPP entered into a Memorandum of Agreement and Remediation Agreement with NJDEP, which combined all of the tenant areas into a single ISRA case, effective March 20, 2006 (PAP-00048065; PAP-00193827-43). PPP sold the property in February 2006 to Passaic Commercial Properties, LLC (the current owner), and ceased doing business. Starting with the ISRA Case for the Inter-State Dyeing & Finishing Company and continuing through the Memorandum of Agreement and Remediation Agreement, the ISRA Case Number for the subject property is E20000341. A Response Action Outcome was issued for the entire facility on January 5, 2015, with a Remedial Action Permit for Soils issued on October 6, 2014 (PAP-00047930-63; PAP-00047969-71).

The *2014 RIR/RAP* report also notes that soil sampling to identify the presence of Historic Fill was conducted throughout the property in 2009. Soil logs identified soils throughout the facility consisting of grey to black non-indigenous soils starting from directly below the asphalt cover and ranging from a depth of two feet to nine feet. The area with the low range of depth was located directly adjacent to the Passaic River at the southwestern boundary of the facility. The area with the higher range of depth was also located adjacent to the Passaic River at the northwestern boundary of the facility. Soil sample results identified contaminants as target contaminants of typical Historic Fill. In addition, there were soil samples that identified "hot spots" of PCBs and mercury. The extent of contamination was delineated for the PCBs and mercury, which showed very

small areas, specifically along the rail line for the PCBs and within the boiler room crawl space for the mercury (PAP-00048067-74).

Based on the remedial investigation activities conducted in 2009, further investigations were warranted for AOC 5C – Crawl Space – Building 35. It was initially proposed to remove the accumulated sediment within this crawl space area and then to institute a deed notice for the Historic Fill compounds detected below the crawl space (PAP-00048069).

In addition, only one AOC warranted a Remedial Action Workplan; Historic Fill (AOC 11). While certain AOCs exhibited contaminant concentrations greater than the current New Jersey Site Remediation Standards (NJSRS), the contaminants identified were not specific to the AOC, but specific to target compounds identified in Historic Fill (PAP-00048069).

Additional sampling revealed the presence of lead, mercury and PCBs greater than the NJSRS and IGWSSL. It was concluded these constituents were the result of historic fill and it was proposed to cap the entire facility with registering of a deed notice regarding site conditions (PAP-00048079-83).

According to the 2014 RIR/RAP report, soil Sampling and Synthetic Precipitation Leaching Procedure (SPLP) sampling showed that there was no impact to groundwater concerning any of the COCs identified in Historic Fill at the facility. Furthermore, taking guidance from the NJDEP's *Guidance from the Evaluation of Immobile Chemicals for the Impact to Ground Water Pathway (June 2008)*, those samples that were greater than the Impact to Ground Water Screening Levels and greater than two feet from ground water, were considered not likely to have impact to ground water (PAP-00048070-74; PAP-00048079-83; PAP-00048094; PAP-00048554-57; PAP-00048652-79).

Remedial Activities

The following engineering and institutional controls were completed on the facility site in three phases: July 2012, April 2013, and July 2013:

- Asphalt Cap: Building exterior − 6 inches (four inches of asphalt underlain by two inches of compacted gravel subgrade) ;
- Concrete Cap: Building interior − 8 inches (four inches of concrete underlain by four inches of dense grade aggregate); and
- Crawl Space: Locked and Signage.

(PAP-00048087-88; PAP-00048105 (Figure 4 − Capping Plan); PAP-00048680-85 (Attachment H − Photographs − Remedial Action); PAP-00048686-713 (Attachment I − Deed Notice)).

8. Summary of Asserted Defenses

No legal defenses were identified in the available file materials.

Pharmacia LLC

Diamond Alkali OU2 Allocation

Facility Data Report

PHARMACIA LLC

Facility Name, Address and Size: The Monsanto Company Site/The Monsanto Site/Kearny, New Jersey Plant/26-Acre Former Monsanto Property; Foot of Pennsylvania Avenue/1 Pennsylvania Avenue/8 Pennsylvania Avenue, Kearny, New Jersey; 26 acres; 100 employees, 7 days per week, three shifts per day (PAS-00003876).

1. **Business Type:** Manufacturing of detergent additives and phosphorus-based products (PAS-00073343).

2. **Time Period of Ownership/Operations**

Operator: 1955 to 1991
Owner: 1954 to 1994

1954: Monsanto Company (Monsanto) constructed its Kearny, New Jersey plant in 1954. The site served as a railyard prior to Monsanto's purchase in 1954 (PAS-00073343).

1955: Process operations began in 1955 (PAS-00073344).

1988: According to a *Site Evaluation Submission*, dated October 25, 1991, approximately 8 acres of the eastern portion of the property were leased to American Presidential Intermodal Company (PAS-00073453, 84, 89).

1991: Process operations were terminated in 1991 (PAS-00073344).

1992: The process areas were demolished in 1992 (PAS-00073344).

1994: Monsanto sold the property to the Motor Carriers Service Corp. in December 1994 (PAS-00073437).

1997: According to a letter prepared by legal counsel for Pharmacia Corporation (Pharmacia), dated March 26, 2004, in 1997, pursuant to a Distribution Agreement, Monsanto (known at the time of the letter as Pharmacia, as discussed below) spun off its chemical business into a separate company, Solutia Inc. (Solutia). As part of this transaction, assets and liabilities associated with the historical chemical business were transferred to Solutia. The letter states that, “generally speaking,” responsibilities associated with the former manufacturing facility in Kearny, New Jersey, were among the liabilities transferred to and directly assumed by Solutia (PAS-00121816, 19). Solutia is a publicly held corporation with no corporate parent (PAS-00081751).

2000: According to a November 26, 2003 letter, the corporate entity that was known as Monsanto prior to March 31, 2000, is now called Pharmacia as a result of a name change filed on that date. In 2000, Pharmacia offered a portion of its ownership interest in Monsanto to the public (PAS-00081751).

2002: According to a November 26, 2003 letter, in 2002, Pharmacia distributed the rest of its ownership interest in Monsanto to its shareholders. Consequently, Monsanto is now a publicly-held corporation with no corporate parent and has no direct connection to the site (PAS-00081751).

2003: The March 26, 2004 letter, on December 17, 2003, Solutia and 14 of its United States subsidiaries filed for bankruptcy protection and reorganization under Chapter 11 of the United States Code, in the United States Bankruptcy Court for the Southern District of New York. Solutia has taken the position that the bankruptcy filing relieves Solutia of its obligations under the 1997 Distribution Agreement, which include all obligations associated with the Kearny site (PAS-00121816-17).

3. Operational History/COC Use and Presence at the Facility

A letter prepared by Roux Associates, Inc. (Roux) on behalf of Monsanto, dated March 1, 1996 (March 1, 1996 letter), states that during Monsanto's ownership, the plant primarily manufactured detergent additives used in home laundry and phosphorus-based products used in a variety of consumer applications (PAS-00073343). The site manufactured phosphoric acid and sodium tripolyphosphate from 1955 until 1985. The manufacturing of Sterox® (ethoxylated alkylphenol) began in 1956 and ended in 1990. Alkylphenol (AP) was manufactured on site from 1960 to 1991 (PAS-00073344).

According to a *Remedial Investigation Work Plan*, dated December 18, 1989, phosphoric acid, sodium tripolyphosphate, “Sterox®,” and AP were manufactured as follows:

- To manufacture phosphoric acid, phosphorous was received by railroad tank cars and unloaded into storage tanks using water displacement. From the storage tanks, phosphorous was pumped to the top of a burning tower and oxidized with air to form phosphorous pentoxide gas. The hot phosphorous pentoxide gas would pass through the bottom of the tower into a hydrator and absorber. Weak phosphoric acid was sprayed into the hydrator to cool the hot gases which then continued toward the absorber. In cooling the gases, the dilute acid was concentrated by evaporation (PAP-00035278).

- The sodium tripolyphosphate process consisted of continuously mixing soda ash and phosphoric acid in varying proportions, drying and calcining the mixture, and grinding the dried solids to produce sodium tripolyphosphate (PAP-00035278).

- Various Sterox formulations were manufactured by reacting an AP with ethylene oxide in the presence of potassium hydroxide as a catalyst. The three basic process steps were reaction, neutralization, and filtration (PAP-00035283).

- APs were manufactured by reacting an olefin with phenol in the presence of a catalyst. The three basic process steps were catalyst activation, alkylation, followed by distillation (PAP-00035280).

Facility Data Report

A diagram depicting the process inputs and wastes for each production unit is presented below (PAP-00036352):

In addition to home laundry and phosphorus-based products, according to the March 1, 1996 letter, vinyl siding was produced between 1967 and 1970. Monsanto imported polyvinyl chloride (PVC) pellets which were then shredded and used in the production of the vinyl siding during controlled extrusion processes (PAS-00073346).

The majority of files reviewed state that, with the exception of PCBs used for non-contact heat-transfer fluid in production equipment (as discussed below) and use of fuel oil (No. 4 and No. 6), COCs were not used or handled in production processes (PAS-00073430, 84-93, 98-99). However, the following potential exceptions were identified in the file material:

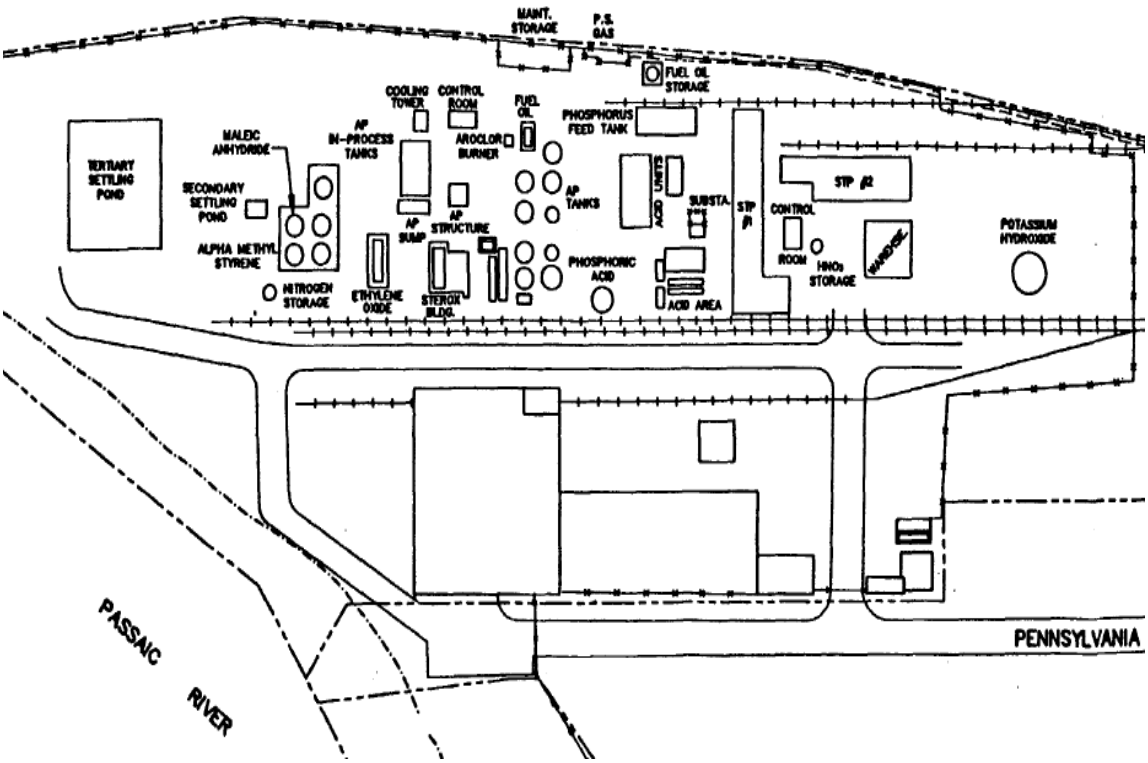
- According to an *Environmental Assessment*, dated December 1, 1982, “major” raw materials used at the site included copper sulfate (PAP-00035075). The report provides no details on how it was used or handled, and it is noted that reference to use of copper sulfate is not identified in other files reviewed.

- In addition, according to a civil complaint filed by the New Jersey Department of Environmental Protection (NJDEP) against Monsanto on November 1, 1988, Monsanto used naphthalene in its operations (PAP-00212793-94). The document provides no details on how it was used or handled, and it is noted that reference to use of naphthalene is not identified in other files reviewed.

- Finally, according to a *Site Evaluation Submission*, dated October 25, 1991, one to ten pounds of mercury in a glass bottle was present in the maintenance shop (PAS-00073501).

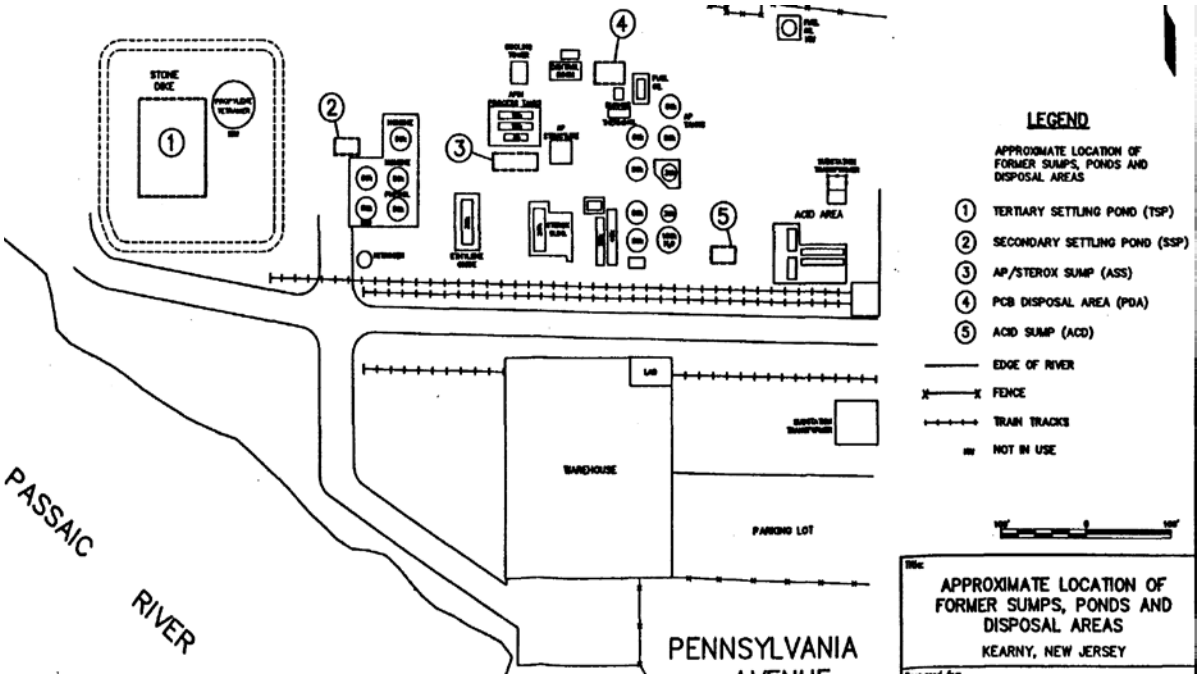
It is also noted that according to the March 1, 1996 letter, the Kearny plant only served as a distribution point for maleic anhydride, and that this material was not used as a raw material or produced at the plant. It states that an assertion by Maxus Energy Corporation that maleic anhydride is a "dioxin precursor" is incorrect, and that maleic anhydride converts to maleic acid upon contact with water (PAS-00073346).

According to the March 1, 1996 letter, PCBs were used at the site from 1960 to 1972 as a non-contact heat-transfer fluid in production equipment (PAS-00073344). The PCB-containing heat-transfer fluid consisted of Aroclor 1248 and was used in the thermal system for the AP process. During a process upset in 1967 to 1968, the reactants accidentally mixed into the thermal circulating system. Upon recirculating back into the storage tank, the mixture became gel-like and unusable. A disposal pit was excavated next to the control room, and approximately 2,000 gallons of PCB thermal fluid were drained from the storage tank and heater via an earthen trench to the excavated containment pit which is currently referred to as the PCB Disposal Area. The PCB Disposal Area was then covered with clean fill and trap rock. The thermal system was recharged with PCB heat transfer fluid consisting of Aroclor 1248 at that time. When the system was converted in 1972 to a non-PCB containing fluid, the tank containing 2,000 gallons of PCB thermal fluid was again drained to the PCB Disposal Area and re-covered with clean fill and trap rock (PAS-00073345). The trench and PCB Disposal Area were unlined (PAS-00073363) and was underlain by a peat layer (PAS-00074781). According to March 1, 1996 letter, the PCB Disposal Area was located approximately 560 feet from the Passaic River (PAS-00073344).



PCB-containing products were warehoused at the site pending final shipment to local customers between 1975 and 1977. The PCB-containing products were “Inerteen 70-30” and “Pyranol A13B3B-3” which both contained Aroclor 1254 (PAP-00207162). A site map is presented below (PAS-00073481):

Pharmacia LLC



Diamond Alkali OU2 Allocation

ADR Confidential

Facility Data Report

The location of the PCB disposal area relative to the Passaic River is depicted below (PAS-00073509):

In addition to Monsanto's operations at the site, a *Site Evaluation Submission*, dated October 25, 1991, states that approximately eight acres of the site were leased for use by American Presidential Intermodal Company as a trucking terminal (PAS-00073453, 84, 89).

4. Identified COCs

- PCBs (used and detected)
- PAHs (used and detected)
- Copper (detected)
- Lead (detected)
- Mercury (used and detected)

PCBs

According to a March 1, 1996 letter, PCBs were used at the site from 1960 to 1972 as a non-contact heat-transfer fluid in production equipment. The heat-transfer fluid consisted of Aroclor 1248. On two occasions (1968 and 1972), 2,000 gallons of PCB-containing heat transfer fluids were drained into an excavated containment pit via an earthen trench next to a plant control room, located approximately 560 feet from the Passaic River (PAS-00073344). The trench and disposal area were unlined (PAS-00073363) but were covered with soil and trap rock (PAS-00073345; PAP-00035295-96) and underlain by a peat layer (PAS-00074781).

In 1983, Aroclor 1248 was detected in soil at a maximum concentration of 507,000 mg/kg (PAS-00073515). Aroclor 1260 was detected at a maximum concentration of 200 mg/kg in 1991 (PAP-00036359). According to a Memorandum re: Comments on Monsanto 104(e) Response, dated June 29, 1995 (1995 Memorandum), maximum soil concentrations measured in 1983 and 1984 in the PCB Disposal Area were 436,000 parts per million (ppm), 507,000 ppm, 195,000 ppm, and 186,000 ppm. The 1995 Memorandum also states that PCBs were detected at elevated concentrations in the Secondary Settling Ponds west of the PCB Disposal Area at concentrations as high as 280 ppm (PAS-00013251).

According to a *Remedial Investigation Work Plan*, dated December 18, 1989, the PCB disposal area was initially excavated in 1979 and 85 cubic yards of PCBs and PCB saturated soils were removed from the containment pit and transported off-site by SCA Chemical Services for disposal at Chemical Waste Management's Model City, New York facility (PAP-00035290-91, 473-475; PAP-00212803). A December 1, 1982, *Environmental Assessment Report*, prepared by Monsanto, also notes "The buried PCB material has been dug up and drummed. The material has been sent to an approved Class I chemical landfill site" (PAP-00035150). In addition to the foregoing, according to a Remedial Action Report, dated November 11, 1994, in 1994, 5,521.65 tons of PCB-contaminated soil and 308.18 tons of PCB-contaminated concrete demolition debris were removed from the site and disposed off site (PAS-00074804).

PCB-containing products were warehoused at the site pending final shipment to local customers between 1975 and 1977. The PCB-containing products were “Inerteen 70-30” and “Pyranol A13B3B-3” which both contained Aroclor 1254 (PAP-00207162).

PAHs

According to a civil complaint filed by the NJDEP against Monsanto on November 1, 1988, Monsanto used naphthalene in its operations (PAP-00212793-94). The document provides no details on how it was used or handled, and it is noted that reference to use of naphthalene is not identified in other files reviewed. According to an *Environmental Assessment*, dated December 1, 1982, naphthalene was detected in sanitary waste at a concentration of 5.4 microgram per liter (µg/L) (PAP-00035161) but not in the process wastewater (PAP-00035157, 161). High molecular weight polynuclear aromatic hydrocarbons (PAHs) were detected in site soil (PAS-00073823).

Copper

According to an *Environmental Assessment*, dated December 1, 1982, “major” raw materials used at the site included copper sulfate (PAP-00035075). The report provides no details on how it was used or handled, and it is noted that reference to use of copper sulfate is not identified in other files reviewed.

In 1976, copper was detected in site wastewater at a concentration of 0.2 milligrams per liter (mg/L) (PAP-00034841). In May 1978, copper was detected in site wastewater at a concentration of 0.3 mg/L (PAP-00034943). According to the *Environmental Assessment*, dated December 1, 1982, site wastewater was sampled in December 1978, and copper was identified in process wastewater at a concentration of 38 µg/L. In addition, copper was identified in sanitary waste at a concentrations of 240 µg/L (PAP-00035149-50, 57). It is noted that copper also was detected in the city water at the facility at a concentration of 72 µg/L (PAP-00035164).

In 1990, copper was detected in soil at a maximum concentration of 645 mg/kg (PAS-00073580).

Lead

In 1976, lead was detected in site wastewater at a concentration of 0.8 mg/L (PAP-00034841). In May 1978, lead was detected in site wastewater at a concentration of 0.28 mg/L (PAP-00034943). According to an *Environmental Assessment*, dated December 1, 1982, lead was identified in sanitary waste at a concentration of 400 µg/L in December 1978 (PAP-00035149-50, 57). It is noted that lead also was detected in the city water at the facility at a concentration of 44 µg/L (PAP-00035164).

In 1990, lead was detected in soil at a maximum concentration of 676 mg/kg (PAS-00073580).

Mercury

According to a *Site Evaluation Submission*, dated October 25, 1991, one to ten pounds of mercury in a glass bottle was present in the maintenance shop (PAS-00073501).

In 1976, mercury was detected in site wastewater at a concentration of 10 µg/L (PAP-00034841). In May 1978, mercury was detected in site wastewater at a concentration of 2.2 µg/L (PAP-00034943). According to an *Environmental Assessment*, dated December 1, 1982, mercury was identified in sanitary waste at a concentration of 43 µg/L in December 1978 (PAP-00035149-50, 57).

In 1990, mercury was detected in soil at a maximum concentration of 74 mg/kg (PAS-00073580).

Historic Fill

The Allocation Team has determined that the facility site is located on regional Historic Fill as designated by the NJDEP.[1]

NJDEP has established that Historic Fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 COCs: PAHs, lead, copper, and mercury.[2] Accordingly, NJDEP technical requirements for property containing Historic Fill requires sampling for the EPA Target Compound List for PAHs and Target Analyte List for metals, including lead, copper, mercury, and the OU2 PAH COCs.[3] PAHs, lead, copper, and mercury are recognized by NJDEP to be constituents of Historic Fill at varying levels, not atypically at or exceeding residential soil standards.[4]

According to a *Draft Interim Report*, dated April 1993, solid fill material has been periodically distributed over the area of the site to sufficiently build a permanent land base above the water table, and that successive surface grading and accumulation of solid fill material provided the subbase for the current site. The report states that the origin and composition of the solid fill material is unknown, and that filling occurred prior to 1940 (PAS-00013367).

---

[1] *Digital Geodata Series, DGS04-7, Historic Fill for New Jersey*, https://www.nj.gov/dep/njgs/geodata/dgs04-7.htm, Quadrangle No. 52 & No. 53 (NJDEP map identifying locations of recognized historic fill).

[2] *Characterization of Ambient Levels of Selected Metals and cPAHs In New Jersey Soils* (2002) and *Characterization of Ambient Levels of Selected Metals and Other Analytes In New Jersey Soils* (1997), studies prepared for NJDEP, Division of Science and Research, by BEM Systems, Inc.

[3] New Jersey Department of Environmental Protection (NJDEP), *N.J.A.C. 7:26E Technical Requirements for Site Remediation,* Table 4-2, November 2009 [Note that Table 4-2 has been deleted from the current version of N.J.A.C. 7:26E (May 7, 2012) and the updated *Historic Fill Technical Guidance* (April 2013) as NJDEP believed that the tables list of historic fill constituents was too restrictive].

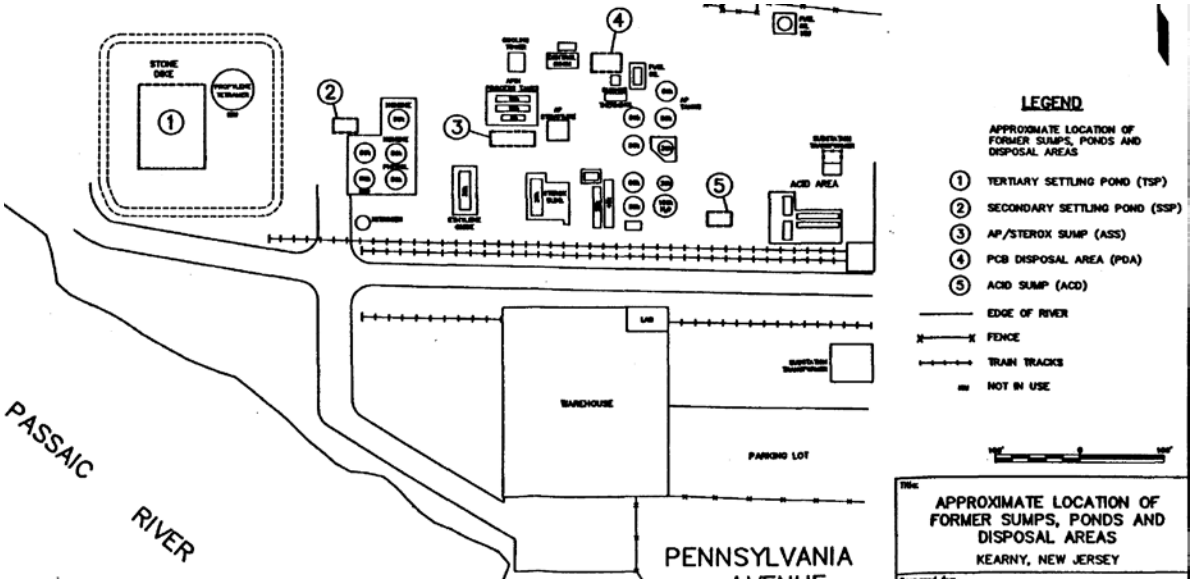
[4] NJDEP Table 4-2 (PAHS and lead) and a summary of NJDEP records regarding investigations of properties in the vicinity of the Passaic River recognized to be located in areas of Historic Fill indicate that the following average/maximum (mg/kg) contamination levels of OU2 COCs exist in area Historic Fill: PAHs (1.91/160), lead (574/10,000), copper (11.2/1,200), and mercury (0.21/3.7).

Fill has been reported in the *Preliminary Remedial Investigation Report,* dated August 30, 1991, between approximately 0 to 6 feet below ground surface (bgs) (PAS-00073616).

The levels of PAHs, copper, lead and mercury detected at the site in soils are presented in the table below (PAS-00073580; PAS-00073823).

COCs Found in Onsite Soils	
COC	**Max Detected Concentration**
Lead	645 mg/kg
Copper	676 mg/kg
Mercury	74 mg/kg
Benzo(a)anthracene	16 mg/kg
Benzo(a)pyrene	14 mg/kg
Benzo(b)fluoranthene	30 mg/kg
Dibenzo(a,h)anthracene	2.7 mg/kg
Indeno(1,2,3-cd)pyrene	9 mg/kg

5. COC Pathways



Settling Ponds

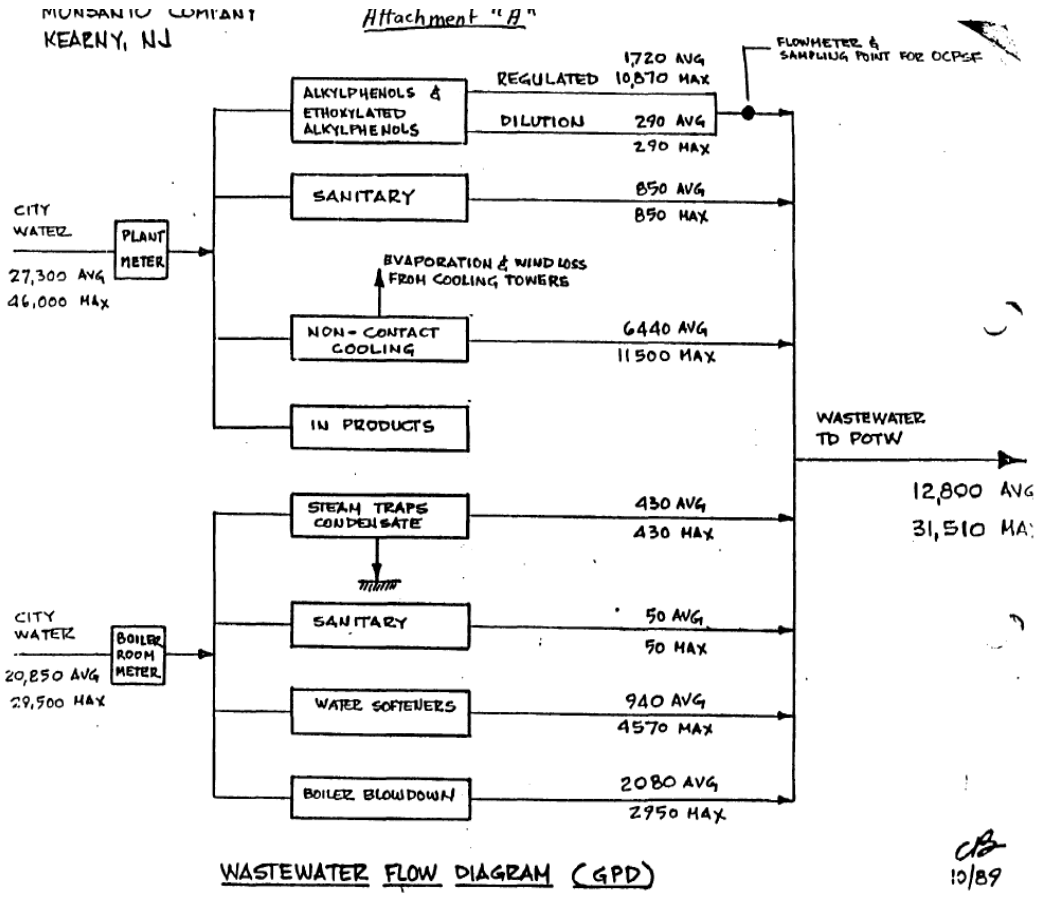
Settling ponds were used between approximately 1960 and 1977. According to a *Preliminary Remedial Investigation Report*, dated August 30, 1991, past disposal practices for the AP/Sterox production included the use of a former AP/Sterox Sump and settling ponds. The AP/Sterox Sump received Sterox filter cake and floor wash water from the AP/Sterox production area during maintenance operations. The waste wash water entered the sump through concrete troughs under the process pumps servicing the AP/Sterox structures. According to interviews with Monsanto employees, the area flooded under heavy precipitation due to shallow water table conditions and relatively low permeable soils. The AP/Sterox Sump was connected by an underground clay-tile pipe to a Secondary Settling Pond and a larger Tertiary Setting Pond to catch overflow from the sump. The AP/Sterox Sump was manually cleaned of settled solid wastes with the solids transported off site to a landfill. The AP/Sterox Sump and Secondary Settling Pond were operated from about 1960 to 1977. The larger Tertiary Setting Pond was operated from about 1966 to 1970 (PAS-00073612-13).

According to a March 1, 1996 letter, during high precipitation events, flooding in the area of the PCB Disposal Area was controlled via a system of earthen trenches, subsurface overflow piping, and ponds that linked the PCB Disposal Area, the AP/Sterox Sump, and the Secondary Settling Pond. According to the March 1, 1996 letter, in previous interviews with site personnel, the only known flood event in which substantial flooding had occurred over the last thirty years (from process area to the north of the warehouse) occurred in 1992. It goes on to state that although minor flooding occurred on occasion within small localized areas around the plant, no evidence of flood events carrying contaminated soils to the storm sewer or Passaic River have ever been documented. The approximate distance from the edge of the river to these features reportedly ranged

from 350 feet to the beginning of the process area to 560 feet to the PCB Disposal Area (PAS-00073349).

The locations of the settling ponds relative to the Passaic River are depicted below (PAS-00073509):

Sanitary Sewer



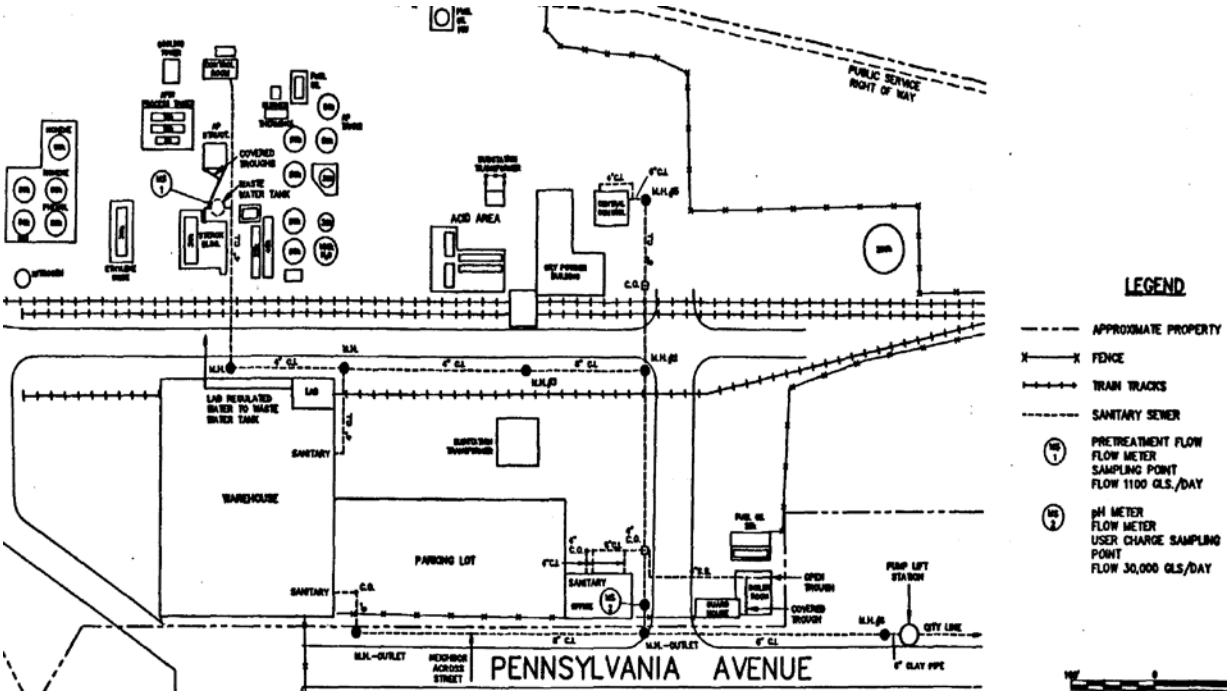
According to *Monsanto's Response to Request for Information Concerning the Diamond Alkali Superfund Site Passaic River Study Area,* dated February 3, 1995, the site was "not a direct discharger and all such sewer discharges since 1955 went to POTW [publicly owned treatment works]" (PAS-00073429).

According to a *Waste Effluent Survey,* dated April 12, 1972, Monsanto discharged 19,345,000 gallons of wastewater to the sanitary sewer and 20,805,000 gallons of wastewater to the "storm sewer, river, or ditch" in 1971. No OU2 COCs were reported in the discharge according to the form (PAS-00003878). Wastewater was not pretreated prior to discharge (PAS-00003879).

According to a July 25, 1975 letter, all wastewater discharge went to the "South Kearny treatment plant" which emptied to the "Hackensack system." The letter stated that at one time, the site had a storm drain from the property which emptied into the Passaic River, but that this drain no longer exists (PAS-00003881).

According to a December 30, 1976 Monsanto file titled *Water Quality Control,* "the only direct discharge" to the Town of Kearny sanitary sewer system is pumped from a collection sump at the east end of the site to the Kearny sewer system. It states that the flow rate averaged 35 gallons per minute, and the effluent consisted primarily of sanitary wastes plus process wastes from the Sterox/AP area. No OU2 COCs were identified as being present in the discharge (PAP-00034838).

A wastewater flow diagram dated October 1989 is presented below (PAS-00013319):



According to an *Industrial Pretreatment Inspection Report*, dated September 13, 1990, the site was connected to the Kearny POTW under a New Jersey Pollutant Discharge Elimination System (NJPDES) permit (No. 0022161). The report also states that wastewater was discharged to the public sewer only, and that the discharge volume was approximately 1,200 gallons per day. It is reported that no pretreatment of the wastewater occurred (PAS-00013312-14).

According to a *Site Evaluation Submission*, dated October 25, 1991, beginning in November 1990, wastewater was pretreated through an oil/water separator before being discharged to the PVSC system (PAS-00073446). Prior to the 1990 connection to the PVSC, the sewage system was connected to the Kearny Waste Water Treatment Plant (PAS-00073495).

This report goes on to state that industrial and sanitary wastewater was discharged to an on-site sanitary sewer, which was permitted for connection to a POTW operated by the PVSC. Two permitted sewerage connections occurred on the site. Within the process area, industrial waste streams included the laboratory, Sterox process, and the AP process. Floating organic product possibly present was skimmed and separated to a

tank for non-hazardous waste disposal. The combined water stream was sampled monthly for 32 priority pollutants. After treatment, the wastewater was piped to the on-site sanitary sewer system where it was combined with sanitary waste water from the other on-site buildings (PAS-00073495). The report also states that PVSC permitted this sewage connection under permit number 15406751-00000-0151; a second permitted sewage connection from permit number 15406752-00000-0151 was monitored by a separate meter. This discharge included only the sanitary waste from the warehouse (PAS-00073495).

A figure depicting the sanitary sewer lines at the site is presented below (PAS-00073496):

Storm Water Discharges

According to a March 1, 1996 letter, to Monsanto's knowledge, the only historical direct discharge pipe from the site to the Passaic River was a 27-inch diameter storm sewer pipe which was abandoned in October 1973. Prior to this date, the storm sewer line did not enter nor receive surface water discharge from the process area (PAS-00073348). *PVSC Annual Reports for 1972 through 1976* state that Monsanto also had an indirect discharge of storm water to the Passaic River via a 24-inch city storm sewer used by others besides Monsanto (PAS-00003885, PAP-00329967; PAS-00035315). According to the March 1, 1996 letter, the 24-inch diameter pipe was owned by the Town of Kearny, and the site discharged storm water from "an isolated portion of its plant (upgradient of the PCB Disposal Area)" through a 10-inch diameter line which tied into the 24-inch diameter Kearny storm sewer line; however, this line was also disconnected in 1973 (PAS-00073348).

In addition, according to the *PVSC Annual Report*, dated 1973, Monsanto planned to abandon the plant sewer system and plug it so that no flow would come from the site to the Passaic River; they also stated they would disconnect their connections to the 10-inch sewer line running along Pennsylvania Avenue (PAS-00034749). On October 17, 1973, Monsanto informed the United States Environmental Protection Agency (EPA) that it would abandon and seal its No. 001 outlet to the Passaic River before December 31, 1973, and it would withdraw its application for a discharge permit as of January 1, 1974. On October 25, 1973, Monsanto sealed its outlet to the Passaic River (PAS-00034750).

Groundwater Discharge

A *PVSC Annual Report,* dated 1974, states that groundwater entered the storm sewer and discharged to the Passaic River. The report states that phosphate in groundwater was entering the storm sewer, which is not an OU2 COC (PAS-00034924).

According to a March 1, 1996 letter, a downgradient recovery/interceptor trench and product recovery systems were installed in the mid-1980s as a safeguard to intercept and contain any potential discharges to the Passaic River (PAS-00073346).

Spills

According to an *Environmental Assessment*, dated December 1, 1982, a study was underway in 1982 “to evaluate and correct” wastewater discharge to the ground (PAP-00035068). It is unclear if OU2 COCs were associated with wastewater discharges to the ground.

6. Regulatory History/Enforcement Actions

Inspections

According to a *PVSC Annual Report,* dated 1972, samples collected from 24-inch municipal storm sewer and 27-inch Monsanto storm sewer discharging to the Passaic River were found to be “polluting;” however, there is no indication that COCs were the source of contamination. Rather, the document stated that ortho phosphate was the contaminant (PAS-00003885). This issue remained in 1973 but was addressed that year (PAS-00034748-50). Because no OU2 COCs were reported to be associated with the discharge, this is not discussed further herein.

Violations/Enforcement Actions

According to an Administrative Consent Order between NJDEP and Monsanto, dated July 24, 1989 (1989 ACO), on November 14, 1986, Monsanto submitted to NJDEP a report which stated that in the mid-1960s approximately 2,000 gallons of heat transfer liquid containing PCBs were landfilled on site. NJDEP filed a civil complaint against Monsanto on November 1, 1988 for failure to immediately notify NJDEP of the full nature and extent of discharges of hazardous substances which it caused to occur at the site, including the release of PCBs and petroleum hydrocarbons (PAP-00212791-801).

Monsanto entered into the 1989 ACO with the NJDEP, requiring completion of a remedial investigation and feasibility study (PAS-00075167; PAP-00212802-17). The 1989 ACO resolved the civil complaint (PAP-00212863).

Permits

According to an *Industrial Pretreatment Inspection Report*, dated September 13, 1990, the site was connected to the Kearny POTW under a NJPDES permit (No. 0022161). Prior to a 1990 connection to the PVSC, the sewage system was connected to the Kearny Waste Water Treatment Plant (PAS-00073495). According to a *Site Evaluation Submission*, dated October 25, 1991, industrial and sanitary wastewater was discharged to an on-site sanitary sewer, which was permitted for connection to a POTW operated by PVSC. Two permitted sewerage connections occurred on the site. PVSC permitted the sewage connections under permit numbers 15406751-00000-0151 and 15406752-00000-0151 (PAS-00073495).

According to an *Environmental Assessment*, dated December 1, 1982, in 1982 the site did not have a National Pollutant Discharge Elimination System (NPDES) permit, but would be required to obtain one in 1983-1984 due to “new state regulations” (PAP-00035068).

7. Response Actions

Characterization Activities

The following characterization activities have taken place at the facility:

- *Site Evaluation Submission*, dated October 25, 1991 (PAS-00073442).
- *Preliminary Remedial Investigation Report*, dated August 30, 1991 (PAS-00073591)
- *Focused Feasibility Study and Identification of Site Specific Cleanup Standards*, dated June 18, 1993 (PAS-00104087);
- *Remedial Action Report,* dated November 11, 1994 (PAS-00074723).

Sewer

According to an *Environmental Assessment*, dated December 1, 1982, naphthalene was detected in sanitary waste at a concentration of 5.4 µg/L (PAP-00035157, 161) but not in the process wastewater (PAP-00035157, 161).

In 1976, mercury was detected in site wastewater at a concentration of 10 µg/L (PAP-00034841). In May 1978, mercury was detected in site wastewater at a concentration of 2.2 µg/L (PAP-00034943). According to an *Environmental Assessment*, dated December 1, 1982, mercury was identified in sanitary waste at a concentration of 43 µg/L in December 1978 (PAP-00035149-50, 57).

In 1976, copper was detected in site wastewater at a concentration of 0.2 milligrams per liter (mg/L) (PAP-00034841). In May 1978, copper was detected in site wastewater at a concentration of 0.3 mg/L (PAP-00034943). According to the *Environmental Assessment*, dated December 1, 1982, site wastewater was sampled in December 1978, and copper was identified in process wastewater at a concentration of 38 µg/L. In addition, copper was identified in sanitary waste at a concentrations of 240 µg/L (PAP-00035149-50, 57). It is noted that copper also was detected in the city water at the facility at a concentration of 72 µg/L (PAP-00035164).

In 1976, lead was detected in site wastewater at a concentration of 0.8 mg/L (PAP-00034841). In May 1978, lead was detected in site wastewater at a concentration of 0.28 mg/L (PAP-00034943). According to an *Environmental Assessment*, dated December 1, 1982, lead was identified in sanitary waste at a concentration of 400 µg/L in December 1978 (PAP-00035149-50, 57). It is noted that lead also was detected in the city water at the facility at a concentration of 44 µg/L (PAP-00035164).

Soil

According to a March 1, 1996 letter, PCBs were used at the site from 1960 to 1972 as a non-contact heat-transfer fluid in production equipment. On two occasions (1968 and 1972), 2,000 gallons of PCB-containing heat transfer fluids consisting of Aroclor 1248 were drained into an excavated containment pit via an earthen trench next to a plant control room, located approximately 560 feet from the Passaic River (PAS-00073344).

According to a Memorandum re: Comments on Monsanto 104(e) Response, dated June 29, 1995, maximum Aroclor 1248 soil concentrations measured in 1983 and 1984 in the PCB Disposal Area were 436,000 ppm, 507,000 ppm, 195,000 ppm, and 186,000 ppm at sample locations B-2A, B-5, B-24, and B-26, respectively. The Memorandum also states that PCBs had been detected at elevated concentrations in the Secondary Settling Ponds, west of the PCB Disposal Area. Aroclor 1248 was detected at a maximum concentration of 1,100 mg/kg at the Secondary Settling Ponds. Sample location SSP-1, located approximately 340 feet from the Passaic River, contained Aroclor 1248 at 280 ppm and Aroclor 1260 at 43 ppm. In contrast, sample location SSP-5, also just over 300 feet from the Passaic River, contained Aroclor 1260 at a maximum concentration of 200 ppm, but no Aroclor 1248 (PAP-00036357, 59; PAS-00013251; PAS-00073515).

According to the March 1, 1996 letter, the four sample locations cited above (B-2A, B-5, B-24, B-26) were the four locations with the highest PCB concentrations. The letter states that ChemRisk correctly noted that these samples were collected at a depth of 4 to 6 feet bgs; however, ChemRisk does not mention that continuous split-spoon sampling was performed in the PCB Disposal Area to a depth of 28 feet bgs and that PCB concentrations decreased from the four to six feet interval to the six to eight feet interval by one to three orders of magnitude. The March 1, 1996 letter states that this decrease illustrates the limited mobility and vertical migration of PCBs at the site (PAS-00073351). According to data presented in a *Site Evaluation Submission*, dated October 25, 1991, PCB were detected at depths at least as deep as 16 feet bgs, with a maximum Aroclor 1248 concentration of 16,500 mg/kg. The highest concentrations

were in samples collected from four to six feet bgs. Concentrations of Aroclor 1248 in surface soil were as high as 36,000 mg/kg (PAS-00073515).

In addition to the PCB Disposal Area, according to the *Focused Feasibility Study and Identification of Site Specific Cleanup Standards*, dated June 18, 1993, the AP/Sterox Sump was targeted for investigation based on its historical use as a waste wash water sump. According to plant personnel, the AP/Sterox Sump served as a collection point for wash water which collected in concrete troughs beneath the process area. The AP/Sterox Sump was manually cleaned of settled solid wastes which were disposed off-site. This unit was sampled at the four to six-foot and nine to 11-foot intervals. The concentrations of PCBs were several orders of magnitude less than the PCB Disposal Area. The higher concentrations were detected at four to six feet bgs which corresponded to the nominal depth of this unit (PAS-00104096). The Secondary Settling Pond was operated from about 1960 to 1977. As described above, waste wash water was directed to the AP/Sterox Sump; however, during heavy rainfall the AP/Sterox Sump unit could not handle the influent water and overflow was directed to the Secondary Settling Pond by an underground terra-cotta pipe. Residual materials were carried to the Secondary Settling Pond by this mechanism. The PCB concentrations in the Secondary Settling Pond were in the range, but lower than the AP/Sterox Sump, and many orders of magnitude less than the PCB Disposal Area. The highest concentration was observed at the four to six-foot interval bgs (PAS-00104096).

With respect to metals, the following maximum concentrations were detected in surface soil at the AP/Sterox Sump, Secondary Settling Pond, and Tertiary Settling Pond in 1990 (PAS-00073580-81):

Maximum Metals Concentrations in Surface Soil at the AP/Sterox Sump, Secondary Settling Pond, and Tertiary Settling Pond in 1990			
Metal	**AP/Sterox Sump**	**Secondary Settling Pond**	**Tertiary Settling Pond**
Mercury	1.2 mg/kg	0.4 mg/kg	0.6 mg/kg
Copper	645 mg/kg	95 mg/kg	76.4 mg/kg
Lead	676 mg/kg	217 mg/kg	160 mg/kg

In addition, the following maximum concentrations were detected in subsurface soil (4 to 6 feet below ground surface) at the AP/Sterox Sump, Secondary Settling Pond, and Tertiary Settling Pond in 1990 (PAS-00073561, 65, 69):

Maximum Metals Concentrations in Subsurface Soil at the AP/Sterox Sump, Secondary Settling Pond, and Tertiary Settling Pond in 1990			
Metal	**AP/Sterox Sump**	**Secondary Settling Pond**	**Tertiary Settling Pond**
Mercury	1.8 mg/kg	0.4 mg/kg	0.9 mg/kg
Copper	316 mg/kg	91.4 mg/kg	140 mg/kg
Lead	380 mg/kg	149 mg/kg	137 mg/kg

Remedial Activities

Soil

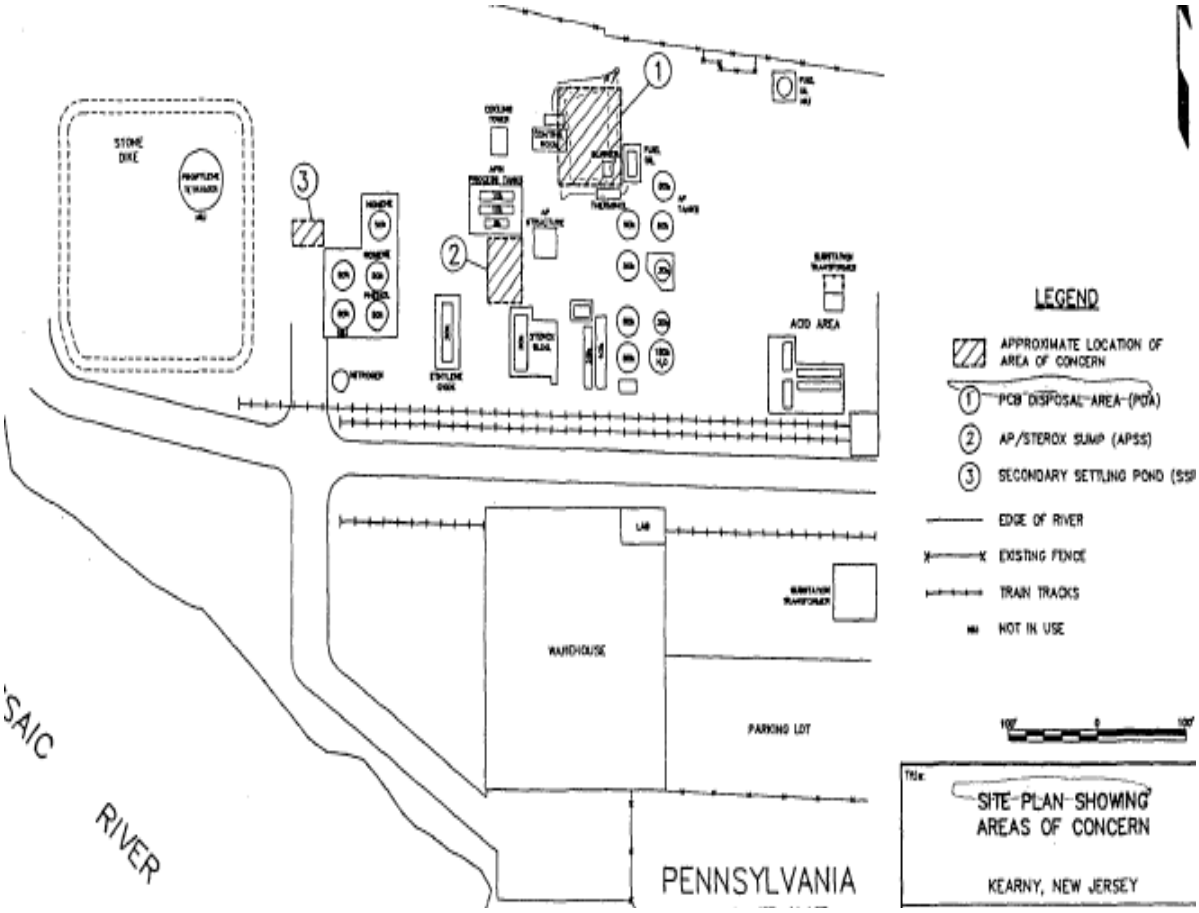
According to the 1989 ACO, on November 14, 1986, Monsanto submitted to NJDEP a report which stated that in the mid-1960s approximately 2,000 gallons of heat transfer liquid containing PCBs were landfilled on site. According to a civil complaint filed by NJDEP against Monsanto on November 1, 1988, in 1979, Monsanto attempted to resolve the discharge of the heat transfer liquid through performance of self-determined cleanup activities. It states that Monsanto "apparently removed" approximately 85 cubic yards of PCB contaminated soil which was subsequently disposed of at an undesignated, off-site hazardous waste landfill (PAP-00212791-96). According to a *Remedial Investigation Work Plan*, dated December 18, 1989, the PCB disposal area was initially excavated in 1979 and 85 cubic yards of PCBs and PCB saturated soils were removed from the containment pit and transported off-site by SCA Chemical Services for disposal at Chemical Waste Management's Model City, New York facility (PAP-00035290-91, 473-475; PAP-00212803). According to the 1989 ACO, NJDEP was supplied with copies of the associated waste manifests (PAP-00212803). The civil complaint goes on to state that Monsanto was unsuccessful in removing the entire quantity of contaminated soil as evidenced by a subsequent finding. It goes on to state that in 1984**,** without coordinating and obtaining approval from NJDEP, Monsanto installed a series of shallow and deep monitoring wells on the site to monitor the presence of hazardous substances and pollutants in groundwater. Thereafter, in October 1984, without coordinating and obtaining approval from NJDEP regarding remedial action to be taken at the property, Monsanto began sampling the wells. This sampling activity resulted in the discovery of Aroclor 1248 as well as petroleum hydrocarbons. In October 1984, without coordinating and obtaining approval from NJDEP regarding remedial action to be taken at the property, Monsanto collected soil borings which revealed quantities of Aroclor 1248 in soil surrounding the AP/Sterox Sump at concentrations up to 123,000 ppm (PAP-00212791-96).

Additionally, Monsanto discovered the presence of petroleum hydrocarbons in the site's soil and dug four "test pits" in the area of the AP/Sterox Sump. Subsequent to this, excavation revealed the presence of a floating organic layer of petroleum hydrocarbons. In September 1986, during the installation of a dike around an above-ground fuel oil tank at the property, Monsanto discovered a viscous floating substance containing No. 4 and No. 6 fuel oils (PAP-00212791-96).

According to a *Focused Feasibility Study and Identification of Site Specific Cleanup Standards*, dated June 18, 1993, in correspondence dated September 16, 1992, NJDEP identified that the areas of concern (AOCs) at the site have been fully characterized, are media- specific, and "are of limited extent." It also states that NJDEP and Monsanto agreed that the three site AOCs include the PCB Disposal Area, the AP/Sterox Sump, and the Secondary Settling Pond impacted by PCBs, and that any low-level, residuals outside of these AOCs would be managed by engineering and institutional controls (PAS-00104095).

According to a March 1, 1996 letter, PCB-impacted soils were delineated, and subsequently remediated, during two separate remedial events (1979 and 1994). These activities were documented in reports submitted to NJDEP including Roux 's *Preliminary Remedial Investigation Report,* dated August 30, 1991 and *Remedial Action Report,* dated November 11, 1994. According to the March 1, 1996 letter, “no PCBs were ever found to be discharged to the Passaic River, either directly or indirectly, by overland flow, ground-water flow, or through underground sewer pipe, conduits, or any other manner” (PAS-00073344).

According to a *Remedial Action Report*, dated November 11, 1994, the following remedial activities took place in 1994:



- Approximately 305 cubic yards of PCB-contaminated soil were excavated from the Secondary Settling Pond. Post-excavation soil samples in the Secondary Settling Pond showed that total PCB concentrations were less than 33 mg/kg at a depth of nine to 10.5 feet bgs following excavation activities.

- Approximately 806 cubic yards of contaminated soil were excavated from the AP/Sterox Sump. Post-excavation soil samples in AP/Sterox Sump showed that total PCB concentrations were less than 14 mg/kg at a depth of nine feet bgs following excavation activities.

- Approximately 1,718 cubic yards of contaminated soil were excavated from the inner PCB Disposal Area. Post-excavation soil samples in the inner PCB Disposal Area showed that total PCB concentrations were non-detect at 24 feet bgs following excavation activities.

- Approximately 1,157 cubic yards of contaminated soil were excavated from the outer PCB Disposal Area. Post-excavation soil samples in the outer PCB Disposal Area showed that total PCB concentrations were less than 51 mg/kg at a depth of nine feet bgs following excavation activities (PAS-00074803-04).

In addition to the 85 cubic yards of PCB-contaminated soil excavated in 1979, in 1994 5521.65 tons of PCB-contaminated soil and 308.18 tons of PCB-contaminated concrete demolition debris were removed from the site and disposed off-site (PAS-00074804). Presented below is a figuring depicting the extent of AOCs (PAS-00104121):

Monsanto received a “no further action” designation for soil from NJDEP on December 13, 1995 (PAS-00073348; PAS-00073369). Areas of the site remained which contained contaminant concentrations above NJDEP residential direct contact soil cleanup criteria, so institutional controls to restrict use of the site were implemented (PAS-00073369).

According to a *Description of the Affected Area* document, NJDEP had provided approval to obtain a Declaration of Environmental Restrictions (DER) for the "Affected Area”. The size of the "Affected Area" was estimated to be approximately 135,811 square feet. Surface and subsurface soil analytical results showed that some exceedances of the NJDEP’s residential direct contact soil cleanup criteria remained on the site following the completion of remedial activities. According to the document, the OU2 COCs that were detected at levels exceeding NJDEP guidance criteria included the following:

- Mercury
- Lead
- PCBs
- Benzo(a)pyrene
- Benzo(a)anthracene
- Indeno(l,2,3-cd)pyrene
- Benzo(k)fluoranthene
- Chrysene (PAS-00124920).

Monsanto received a Conditional No Further Action Letter from NJDEP on November 5, 2010, which states that a No Further Action Letter for soils only was issued on July 12, 1996. The Conditional No Further Action Letter required "monitoring for compliance with engineering and institutional controls" and to submit biennial certifications that the institutional and engineering control(s) are being properly maintained and continue to be protective of public health and safety and the environment (PAP-00036343-46).

Groundwater

According to the March 1, 1996 letter, the presence of clean boundary wells at the site, as demonstrated by numerous sampling events, refuted arguments by Maxus Energy Corporation regarding the discharge of PCB–contaminated groundwater from the site into the Passaic River. Both deep and shallow wells adjacent to the river were sampled by Roux between 1990 to present (1996). According to the March 1, 1996 letter, over 50 groundwater samples were collected from these wells, starting in 1985, and since the land disposal of PCBs occurred; and, to-date, PCBs have never been detected above practical quantitation limits in these downgradient monitoring wells (PAS-00073349-50). According to a *Remedial Action Work Plan*, dated December 18, 1989, PCBs were detected consistently only in a shallow and deep well cluster located in the approximate location of the former PCB Disposal Area. The maximum concentration was reported to be 131 parts per billion (ppb) (PAP-00035331).

A NJDEP Ground Water Remedial Action Permit issued on May 24, 2013, does not identify any OU2 COCs in groundwater (PAP-00212877).

8. Summary of Asserted Defenses

Pharmacia asserts that, Occidental Chemical Company (OCC) is currently the sole party implementing the Remedial Design for OU2 which is projected by EPA to cost approximately $165 million. OCC released 41 parties, including Pharmacia, from Occidental's claim for these Remedial Design Costs related to OU2. Accordingly, any allocation of OU2 costs that includes OCC and Pharmacia must reflect this release of liability by OCC for the OU2 RD [remedial design] which OCC is performing. The release was entered into in the context of the Maxus bankruptcy proceeding and is explained at paragraph 44 of Occidental's June 30, 2018 Complaint. This information was also provided to EPA on June 23, 2017. It's also noteworthy that the pleadings in the bankruptcy proceeding explained the rationale for settling these claims as against some parties, and not others. Specifically, 'The Debtors sought to eliminate those parties that (a) appeared to either be de minimis contributors or (b) had previously contributed to the investigation and remediation costs in amounts roughly proportionate to their share of liability.' Maxus Bankruptcy Docket No. 1232 at 24, filed April 19, 2017.

Diamond Alkali OU2 Allocation

ADR Confidential

Facility Data Report

PITT-CONSOL CHEMICAL COMPANY

Facility Name, Address and Size: Pitt-Consol Chemical Company (Pitt-Consol), 191 Doremus Ave, Newark, New Jersey. Approximately 37 acres (PAS-00051381). A 1972 Waste Effluent Survey states there were 80 employees, three shifts per day, seven days per week (PAS-00014143).

1. **Business Type:** Manufacturer of cresylic acids (PAS-00014143).

2. **Time Period of Ownership/Operations**

   Operator: Pitt-Consol - 1955 to May 1983
   Owner: Pitt-Consol - 1955 to present

   According to the February 27, 1995 joint response by E. I. du Pont de Nemours and Company (DuPont), Conoco, Inc., and Consol, Inc. to an EPA information request, Pitt-Consol purchased the site in 1955 from Reilly Tar & Chemical, Inc. Pitt-Consol operated at the site until 1983 when all manufacturing was discontinued. The site was then dismantled and decontaminated from 1984 to 1986 (PAS-00051359; PAS-00014550).

   A Summary of Existing Environmental Data, dated July 24, 1989, stated that chemical manufacturing had been performed at the site dating back to the late 1800s (PAP-00016417), before Pitt-Consol began operating in 1955. In a February 3, 1995 response to an EPA information request, Reilly Industries, Inc., acknowledged that they operated a coal tar refinery, a tar acid plant, and a phenolic resin plant at the site from 1932 to 1955. Pitt-Consol was not affiliated with Reilly Tar (PAS-00051618, 19-20).

   The 1995 joint response to an EPA information request also provided a summary of the corporate history of the company and facility as follows:

   1955: Pitt-Consol was a wholly-owned subsidiary of Consolidation Coal Company (Consolidation Coal).

   1966: Conoco Inc. purchased Consolidation Coal; however, Consolidation Coal continued to own all of the Pitt-Consol stock.

   1969: Pitt-Consol operations became a division of Conoco Chemicals, but Consolidation Coal continued to own the corporate stock.

   1981: DuPont purchased Conoco, Inc. Consolidation Coal continued to own all of the Pitt-Consol stock, and the profits and losses were recorded on Conoco Chemical's books as a division operation. Conoco Chemicals was de facto administratively under DuPont's Petrochemical Department.

   1983: Manufacturing at the Pitt-Consol site was discontinued. In late 1983/early 1984, the Petrochemical Department was given the responsibility for the Pitt-Consol site.

1984: Conoco Chemicals was sold to Vista Chemical Company. Pitt-Consol remained a separate corporation; however, the Board of Directors was changed to DuPont personnel. Dismantlement of the facilities at the site began in late third quarter/early fourth quarter.

1985: The Resource Conservation and Recovery Act (RCRA) facilities were closed and acknowledged as satisfactory by the New Jersey Department of Environmental Protection (NJDEP).

1986: Dismantling of all production facilities was completed.

1988: All Pitt-Consol stock owned by Consolidation Coal was transferred to DuPont (PAS-00051364-5, PAS-00051580, PAP-00016314).

It should also be noted that a letter from Pitt-Consol to the Passaic Valley Sewerage Commissioners (PSVC) dated July 22, 1977, stated that the company was a wholly owned affiliate of Continental Oil Company (PAS-00014577).

The Remedial Investigation Report, dated May 4, 2016 (2016 RIR), stated that DuPont was the current owner of the site (PAP-00009969).

3. Operational History/COC Use and Presence at the Facility

Operations

As documented in an undated description of manufacturing and synthetic processes provided with the 1995 joint response to an EPA information request, Pitt-Consol had several processing units for generating cresylics, including a synthetic unit, alkylation unit, natural extraction unit, isomerization unit, and thiophenol unit. The following describes each unit:

- The synthetic unit began operating in 1967 with an initial capacity of 10 million pounds per year, and over time was expanded to generate up to 50 million pounds per year. During manufacturing, methanol and phenol were reacted, dehydrated, and then distilled to separate the different cresols.

- The alkylation plant was a stainless steel 3,000-gallon kettle reactor and two fractionators used to upgrade phenol or cresols by alkylating them with an alcohol or olefin. It could also be used for esterification. The alkylation plant went into production in 1961 and was used until 1970 at the site (PAP-00016314).
- The natural process consisted of contacting crude cresylic acids contaminated with neutral hydrocarbons and aromatic mercaptans with aqueous methanol and hexane in a Scheibel tower. This plant was brought up to a capacity of over 33 million pounds per year, but was phased out and shut down in 1971 (PAP-00016314). A rubber reclaiming plant was also identified for the facility as a way to use one of the products (disulfide

oil) from the natural cresylic acid operation. This operation was retained using purchased disulfide after the natural plant was phased out. As the natural plant was phased out, a unit consisting of a furnace and large catalytic converter was constructed to isomerize orthocresol to meta/para cresol, but because of increased availability of imported sources and reduced demand for meta/para cresol, the plant was not operated.

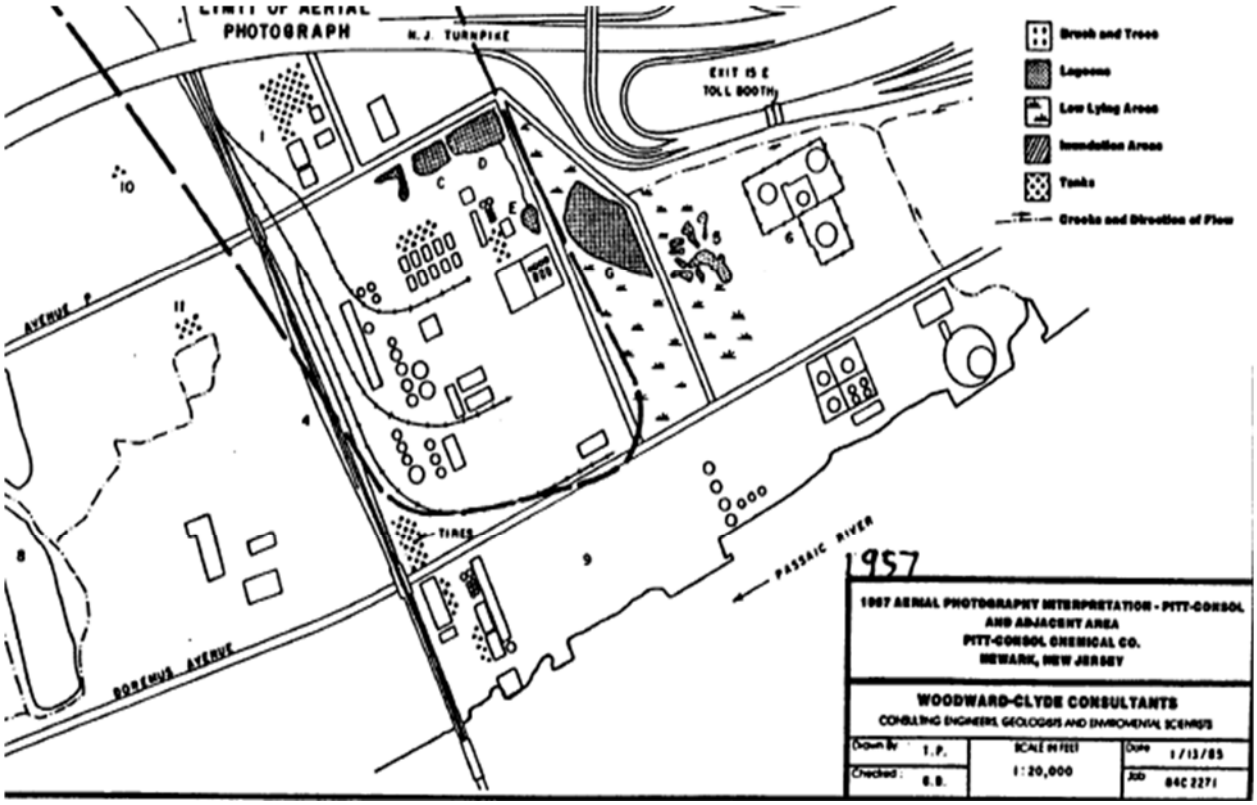
- The thiophenol plant was designed to react cyclohexane with sulfur to produce thiophenol. This plant was not used to produce commercial quantities due to an odor problem at startup and the ability to obtain thiophenol elsewhere (PAS-00051391-93).

At the time of the sale of the facility to Pitt-Consol in 1955, materials used at the facility included cresols, cresylic acid, phenols, resins, and pigments/dyes (PAS-00051640-53).

The main business conducted at the facility beginning in at least 1972 was the synthetic manufacturing of cresylic acids. A Waste Effluent Survey, dated August 30, 1972 specified the plant operations as manufacturing cresylic acids in a continuous reactor with phenol and methanol, using distillation to separate the products (PAS-00014143). According to a RCRA Section 3007 Questionnaire, dated March 31, 1983, only cresol/cresylic acid by methylation of phenol was manufactured at the facility (PAS-00051396).

Storage Facilities

The 1995 response to an EPA information request stated that raw materials were stored in tank farms, while by-products, storm water, and possibly products were stored in the lagoons (PAS-00051360).



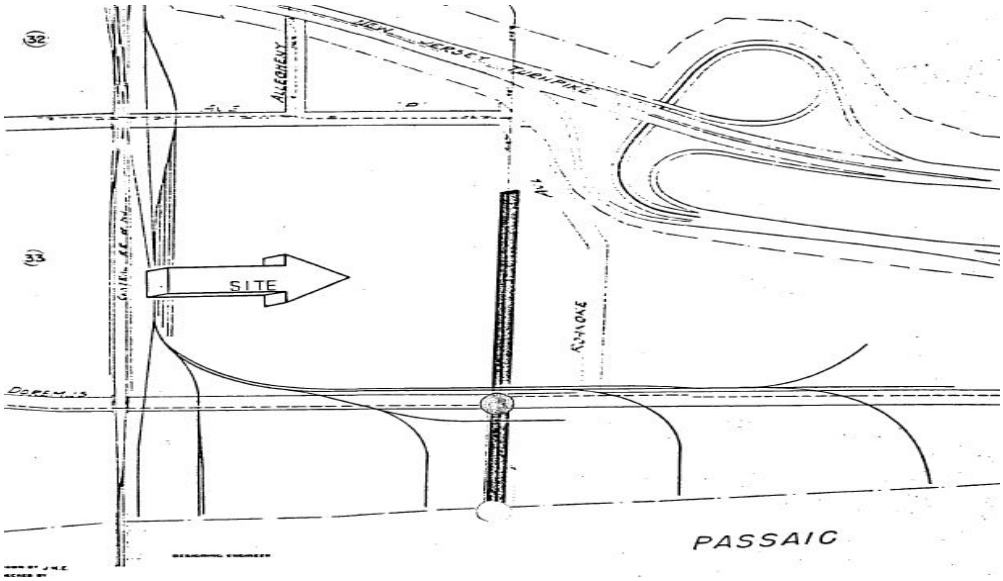
A Hazardous Waste Permit Application prepared in 1980 stated the facility was capable of storing 50,000 gallons in containers on-site, as well as a 130 cubic yard waste pile. A treatment tank was listed as having a process design capacity of 720,000 gallons per day. It was specified that a drum cleaning area included a "hot box" that could melt 50 drums at one time to allow recovery of off-spec or solidified spilled materials. The facility also had two racks capable of steaming out 12 drums each, and a 3,000 gallon agitated reactor for neutralizing spent and/or scrap acid and/or caustic (PAS-00051374-75). Waste codes for materials in these storage areas included 100,000 pounds per year combined of F004 (cresols, cresylic acid, and nitrobenzene), U052 (cresol and methylphenol), U101 (2,4-dimethylphenol), and U188 (phenol), and 100 pounds per year of D008 (lead) (PAS-00051376).

A Draft Phase I Report, Preliminary Assessment of Environmental Impacts, dated January 17, 1985 (Draft Phase I Report) prepared by Woodward Clyde Consultants, identified several lagoons and tank farms at the facility. The lagoons were reported to be approximately three feet deep. Manufacturing by-products, including tars and possibly a variety of phenolic compounds, were held in the lagoons (PAS-00051420). The seven lagoons were present in 1954, before Pitt-Consol acquired the site. Two

lagoons (Lagoons A and F) were closed and covered with fill between 1954 and 1957, four lagoons (Lagoons B, C, D, and G) were closed between 1957 and 1966, and one lagoon (Lagoon E) was closed and filled between 1966 and 1970 (PAS-00051422-23, PAP-00016314-16). A Site Inspection Report documenting an inspection performed by an EPA contractor on September 12, 1984, stated that these lagoons were unlined (PAP-00352899).

The Draft Phase I Report interpreted historical aerial photographs of the site. Based on a 1954 aerial photograph, it was stated that liquids in Lagoon G appeared to be overflowing the north bank and draining into a shallow ditch that emptied into the Passaic River. According to the document, the last lagoon to remain open was Lagoon E and was closed between 1966 and 1970 (PAS-00051422-4).

A diagram based on the 1954 aerial photo showed the locations of Lagoons A through G (see figure below). The Passaic River runs along the bottom of this figure, from north to south. The creek is represented by a dashed line running north from Lagoon G (center of the figure) to join with another creek, and then east to discharge into the Passaic River. The figure also shows the railroad tracks at the south, the locations of tank farms (circles), barrel storage, and tire storage at the site. The addition of Roanoke Avenue north of Lagoon G and along the northern and western property line occurred between 1954 and 1957 (PAS-00051422, 37-38).



(PAS-00051437)

Disposal Practices - Liquid Waste

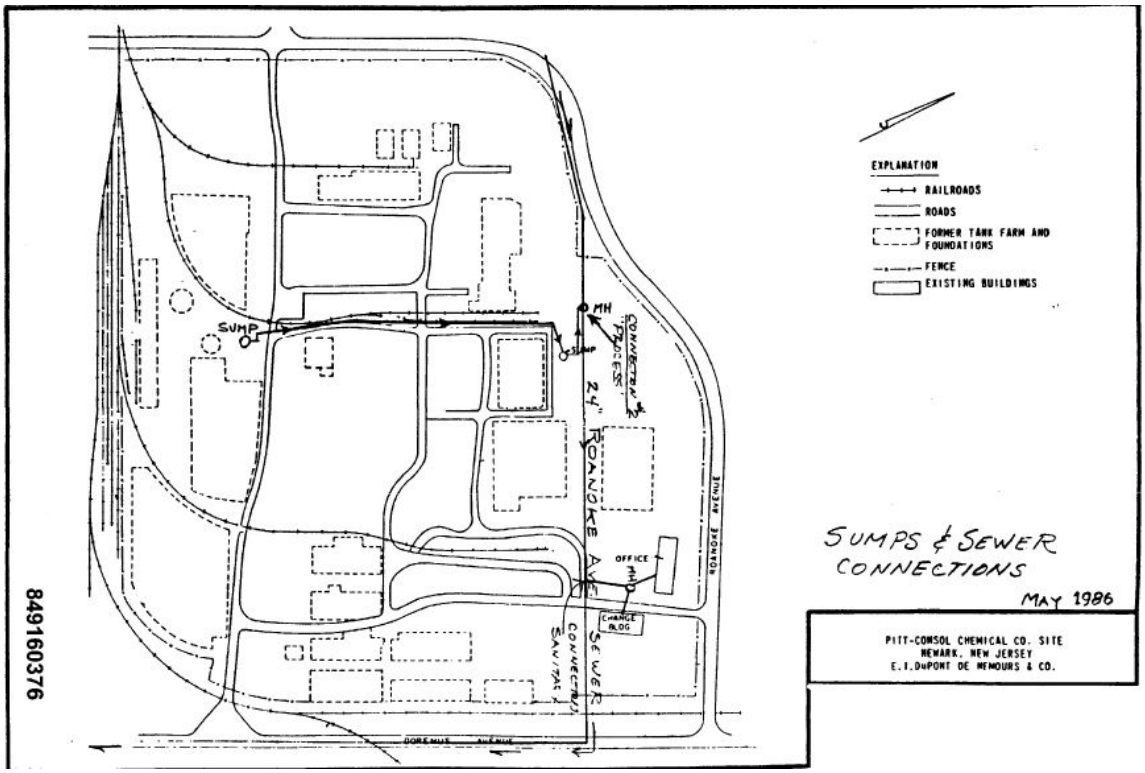
An internal PVSC letter dated April 1, 1958, documented the discovery of a substantial discharge of gray industrial waste from a sump on the Pitt-Consol property to the Roanoke Avenue storm sewer. An on-site interview with a Pitt-Consol chemical engineer stated that 200-300 gallons per minute were being discharged to the storm sewer and that the discharge was approved by the City of Newark. The engineer also stated that the facility's waste was usually pumped to an elevated settling pond on the north side of Roanoke Avenue, where it was then discharged into the storm sewer after a reasonable detention period. The letter stated that intermittent pollution to the Passaic River from this storm sewer had been occurring over the past few years (PAS-00044123).

A May 28, 1958, internal PVSC letter documented another investigation of the Roanoke Avenue storm sewer with another interview of the Pitt-Consol engineer that suggested the sanitary sewer would not be able to handle the flow from this discharge, which was identified as 500 gallons per minute. The letter concluded that Pitt-Consol was likely the sole polluter of the storm sewer (PAS-00044125).

A letter from PVSC to the Director of the Newark Department of Public Works dated June 3, 1958 documented that Pitt-Consol was discharging their waste directly to the Roanoke Ave storm sewer instead of the sanitary sewer (PAS-00006271). A letter from PVSC to the City of Newark, dated July 21, 1958, stated that Pitt-Consol "still discharges its industrial wastes to the Roanoke Avenue Storm Sewer, which goes into the Passaic River." A subsequent letter from PVSC to the City of Newark dated December 7, 1960 stated the Roanoke Avenue sewer was overflowing polluting matter into the Passaic River and had been for "quite a period of time" (PAS-00044129, 33). The following undated diagram shows the location of the site and the Roanoke Avenue storm sewer outfall to the Passaic River:

(PAS-00035582)

A PVSC letter dated March 31, 1970, described a court action started against the City of Newark to stop the polluted discharges from storm sewers to the Passaic River. In December 1969, the City built a dam to divert the dry weather flow into the sanitary and industrial sewers. The only discharge through the Roanoke Avenue storm sewer would be during storm events when the dam overflowed (PAS-00044141-2).



The PVSC Annual Report for 1972 stated that industrial waste was discharging to the Passaic River from the Roanoke Ave storm sewer, even though a concrete dam had been built to prevent overflow from the sanitary sewer into the storm sewer. In order to locate the source of the pollution, the Roanoke Avenue storm sewer was cleaned in late 1971. While preparing a visual inspection of the storm sewer, a manhole on the Pitt-Consol property exploded, injuring three men. Inspection of the sewer with a camera in January 1972 found a 10 inch connection discharging polluted water from the Pitt-Consol facility (PAS-00006274-5).

A 1977 letter from Pitt-Consol to the PVSC stated that the plant wished to continue to discharge industrial waste water to the City of Newark sanitary sewer and therefore the PVSC treatment plant (PAS-00014577).

A Feasibility Study for the City of Newark Pollution Abatement Program, revised January 1979, reported results from a physical inspection of the Roanoke Avenue sanitary sewer. The report stated that the sanitary sewer received flow from the Pitt-Consol facility downstream of the Avenue P Regulator, and about 0.5 feet of a black, tar-like sediment was found in the sewer downstream of the Pitt-Consol connections. The same black material was observed on the ground surface at the Pitt-Consol plant, but was not found upstream or at the Roanoke outfall. Although no connections between Pitt-Consol and the Roanoke outfall to the Passaic River were found, chemicals used at the facility were detected in outfall samples. The report attributed this contamination to groundwater contamination at the Pitt-Consol site (PAS-00006261).

The 1995 joint response to an EPA information request stated that waste water was discharged to the PVSC sewer system and that oils were decanted and neutralized prior to discharge to sewer (PAS-00051361). An Application for Permit to Construct, Install or Alter Control Apparatus or Equipment from NJDEP Bureau of Air Pollution Control stated that an oil/water phase separator for their effluent was put in use September 1, 1981 (PAS-00014138).

A fact sheet for a NJPDES permit from 1986 noted that there were two in-ground concrete sumps at the site that discharged storm water to the PVSC (PAS-00051526). The diagram below shows the sumps and sewer connections used during dismantling of the site in 1986:

(PAS-00014563)

Disposal Practices - Solid Waste

A 1981 Notification of Hazardous Waste Site from the plant to EPA stated, “Based on employee interviews, it appears that industrial wastes may have been deposited at several locations throughout the Plant. Some of this material most likely meets the definition of hazardous waste” (PAS-00051381).

According to the 1995 joint response to an EPA information request, waste materials were sent to Chem Waste Management in Newark, New Jersey in 1987. Wastes representative of the accumulation of spill cleanup materials (contaminated soil/gravel/absorbents) were collected and stored in DOT-approved drums and sent to SCA Chemical Services Company for disposal in their Pinewood, South Carolina landfill (PAS-00051360-1).

A hazardous waste manifest provided for disposal in 1992 included an entry for 1,500 pounds of lead contaminated soil (PAS-00051484).

4. Identified COCs

- PCBs (used, detected)
- PAHs (used, released)
- Copper (detected)
- Lead (used, released)
- Mercury (released)

PCBs

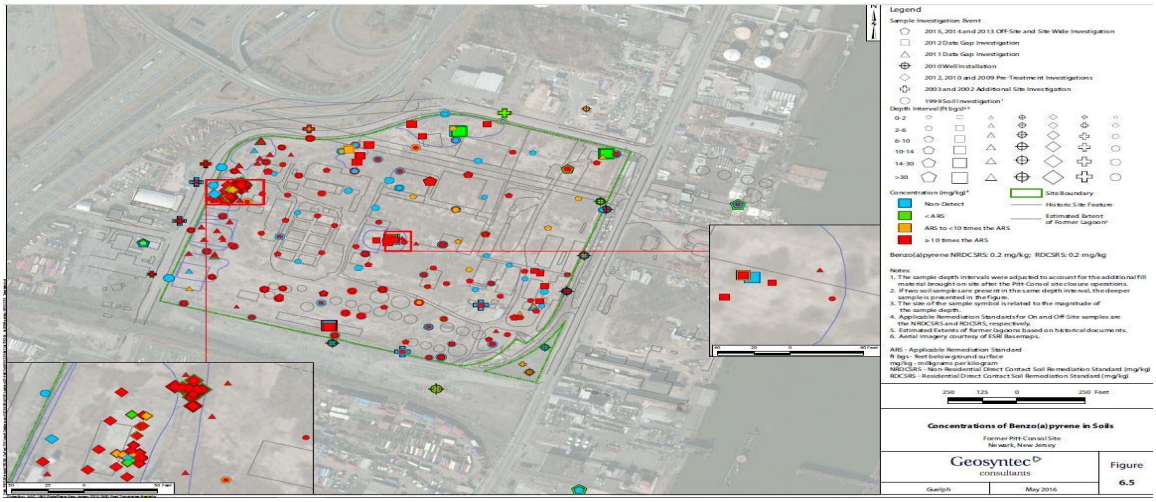
A letter to EPA from Pitt-Consol, dated August 25, 1983, documented PCBs at the site, including three hot oil heat transfer systems and the unexpected discovery of PCBs in a feedstock storage tank. The heaters used PCB-containing oils (Therminol FR-2) until 1968 (one heater) and 1972 (two heaters), when they were replaced with non-PCB oils and/or taken out of service. In 1978, oils from two of the heaters were analyzed, and PCBs were not detected with a reporting limit of 100 parts per million (ppm). Subsequent analyses of the drained oil from these heaters detected at most 60 ppm PCBs in oil for one heater. After all three heaters were taken out of service, residual oils in the piping from two of the drained heaters contained less than 10 ppm PCBs, while the third heater that had not been previously sampled had results as high as 148 ppm. This heater was decontaminated in 1983 (PAS-00014148-49).

According to sales records, Pitt-Consol purchased Therminol FR-1 and Therminol FR-2 in the late 1960s to early 1970s. Pitt-Consol purchased 13,800 pounds of Therminol FR-2 in 1968; 1,200 pounds of Therminol FR-1 and 7,200 pounds of Therminol FR-2 in 1970; 13,200 pounds of Therminol FR-1 and 1,800 pounds of Therminol FR-2 in 1971 (PAP-00304330-33).

In addition, as discussed in the August 25, 1983 letter from Pitt-Consol to EPA, during dismantling of the site, PCBs were detected at 1,150 ppm in liquids from one of the feedstock storage tanks. Other tanks were sampled, but did not contain more than 50 ppm PCBs. The source of the PCBs was not known (PAS-00014148-50). Soil sampling in 1991 in the vicinity of the tank did not detect PCBs as reported in the Site Investigation Summary and Report of Findings, dated April 1992 (PAP-00016403-05).

PCBs were detected in site soil during a 2015 PCB soils investigation performed at the site and reported in a Memorandum dated April 29, 2016 and included as Appendix D in the 2016 RIR. Detected PCB concentrations were stated to be distributed across the site at low levels and typically decreased with depth. Concentrations of total PCBs were above 10 milligrams/kilogram (mg/kg) at three boring locations (SW15-SC-3, SW15-SC-5, and SW15-SC-11) with concentrations ranging from 29 to 37 mg/kg and non-detect values of 46U mg/kg. PCBs had also been found in concrete that was removed in 2014. The 2016 RIR stated that a site-related source for PCBs in soil was unknown (PAP-00009988, 14723, 14727).

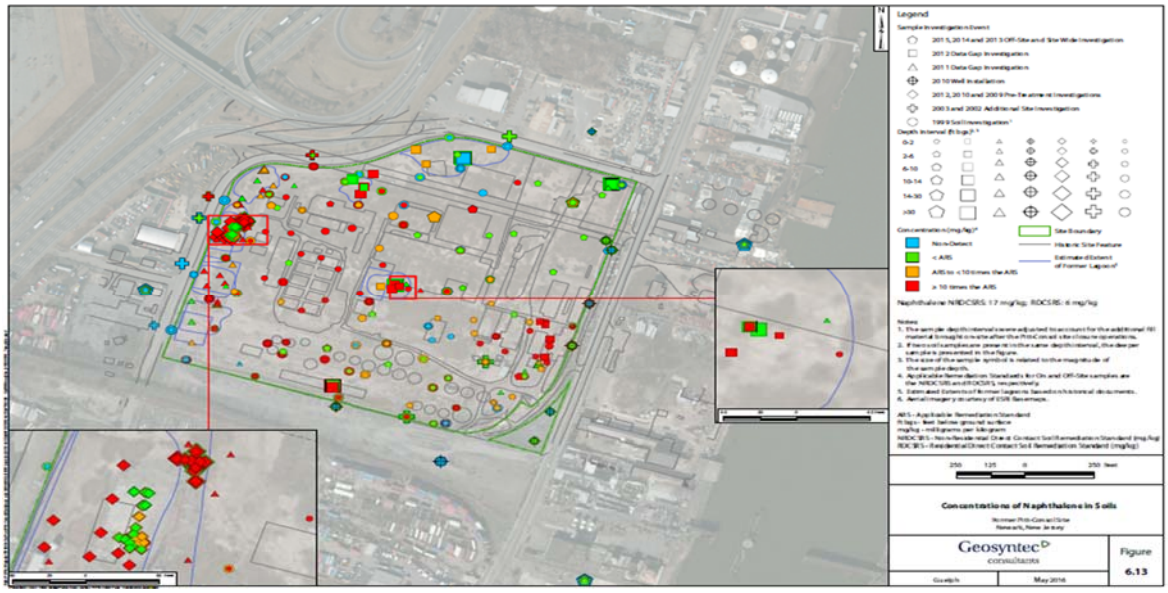
A Memorandum prepared by Geosyntec Consultants, Inc. dated October 23, 2017, documented the removal of 1,160 square feet of PCB-impacted soil surrounding boring SW15-SC-3. The contaminated soil had PCB concentrations above Toxic Substance Control Act (TSCA) requirements for high-occupancy site use (10 mg/kg). The highest concentration detected in soil and excavated was 418 mg/kg. Additional PCB-impacted soil with concentrations below TSCA requirements for high-occupancy site use are planned to be capped (PAP-00009382-83, 418-419, data table on p. 46 of pdf).



PAHs

A Waste Effluent Survey, dated August 30, 1972, stated phenol, cresols, and xylenols were identified in the effluent from the site. Although concentrations of the above-listed chemicals were documented, the units were not listed and the concentrations are unclear (PAS-00014145).

A sump sample was collected in 1984 during decontamination of the equipment at the site. The sample was analyzed for PAHs, dioxin, pesticides, PCBs, and metals. Naphthalene was detected at 390 ppb, but the other PAHs were not detected with a method detection limit of 10 ppb (PAS-00014550, 57-59).



The 1995 joint response to an EPA information request provided a list of chemicals detected in a subsurface composite sample of the coal tar and sludge analyzed in 1987 when tanks were removed from the site. Results for the composite sample analysis detected PAH concentrations as follows: 2,200 mg/kg anthracene, 2,700 mg/kg benzo(a)anthracene, 3,100 mg/kg benzo(b)fluoranthene, 1,600 mg/kg benzo(a)pyrene, 2,900 mg/kg chrysene, 7,300 mg/kg fluoranthene, 130 mg/kg indene, 1,200 mg/kg 1-methylnaphthalene, 2,800 mg/kg naphthalene, 9,200 mg/kg phenanthrene, and 7,700 mg/kg pyrene (PAS-00051359-60, PAS-00051383, PAP-00016469). The sample also was leached using a TCLP procedure and the leachate analyzed for organics. The results showed that many PAHs were below detection limits in the leachate sample (PAP-00016465, 69).

The 2016 RIR reported concentrations of certain PAHs in soil that exceeded the direct contact soil remediation standards and impact to groundwater soil remediation standards. PAHs were linked to the former lagoons, tank farm, and naphthalene area, but were also noted to be ubiquitous across the site (PAP-00009986). The figure below shows the distribution of benzo(a)pyrene in site soil. Sample locations in orange exceeded 0.20 mg/kg and locations in red exceeded 2.0 mg/kg for benzo(a)pyrene.

(PAP-00010380)

According to the 2016 RIR, the former naphthalene area was dismantled in 1953 (PAP-00009972), which is before Pitt-Consol took ownership of the site. The following figure shows the distribution of naphthalene at the site. Sample locations in orange exceeded 17 mg/kg and locations in red exceeded 170 mg/kg for naphthalene.

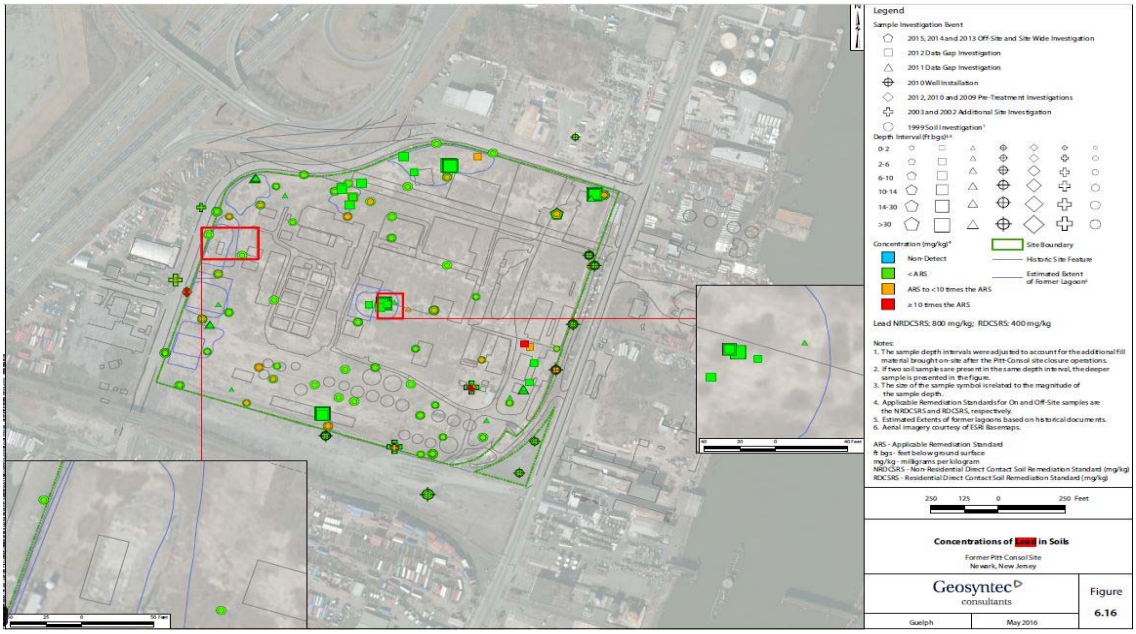
(PAP-00010388)

The following table identifies the maximum concentration of PAHs found in soil samples collected at the site as reported in Tables 2, 3, and 4 of the 2016 RIR:

Maximum Detected PAHs in Site Soil			
PAHs (mg/kg)	**AOC 4**	**AOC 5**	**AOC 6**
acenaphthene	500	2,400	6,400
anthracene	1,700	4,100	29,000
benzo(a)anthracene	3,300	8,600	3,900
benzo(a)pyrene	3,000	7,400	3,600
benzo(b)fluoranthene	3,500	8,700	3,400
benzo(ghi)perylene	1,700	2,900	1,200
benzo(k)fluoranthene	1,500	4,100	1,400
chrysene	3,400	8,900	3,800
dibenz(a,h)anthracene	490	980	430
fluoranthene	6,100	17,000	6,000
fluorene	900	2,700	8,600
indeno(1,2,3-c,d) pyrene	2,000	3,500	1,500
naphthalene	57,000	21,000	49,000
phenanthrene	5,900	18,000	18,000
pyrene	5,200	12,000	7,800
References (pdf page)	80-81	119, 129, 143, 161-2	203-4, 206-7, 212, 218-9

Metals - Copper, Lead and Mercury

A Waste Effluent Survey dated August 30, 1972, stated copper was detected in the effluent at a concentration from 1 to 10 ppm (PAS-00014145). Other metals COCs were not reported. According to an Industrial Wastewater Questionnaire, dated August 29, 1978, wastewater from Pitt-Consol was listed as containing 0.05 milligrams per liter (mg/L) copper and less than 0.2 mg/L lead (PAS-00000577).



A Heavy Metal Determination completed by Elson T. Killam Associates, contractors for PVSC, determined the heavy metal concentrations in effluent from several companies in 1978. Results for the Pitt-Consol facility were 0.017 pounds per day (lbs/day) (0.048 milligrams/liter [mg/L]) copper, 0.007 lbs/day (0.021 mg/L) lead, and 0.0001 lbs/day (0.000 mg/L) mercury (PAS-00052111). A sump sample was collected in 1984 during decontamination of the equipment at the site. Only copper (63 micrograms/liter [µg/L]) and lead (103 µg/L) were detected (PAS-00014550, 57-62).

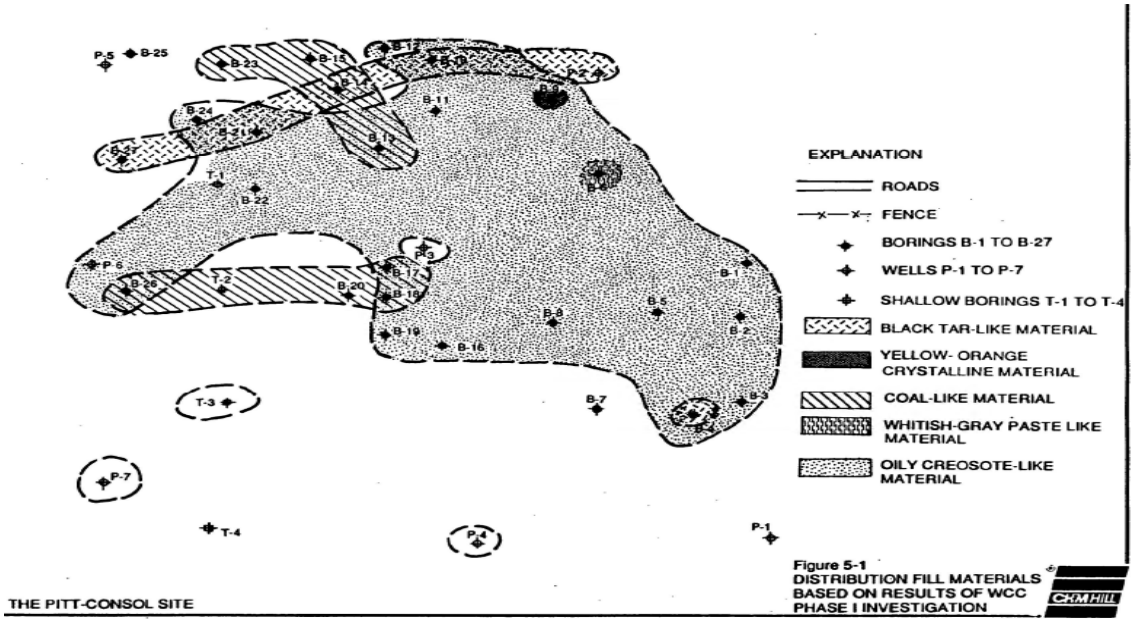
The 1995 joint response to an EPA information request provided a list of chemicals detected in a subsurface composite sample of the coal tar and sludge analyzed in 1987 when tanks were removed from the site. Results for the tar material subsurface composite sample analysis detected mercury (0.16 mg/kg) and lead (580 mg/kg) (PAP-00016465, 69-71, PAS-00051359-60, 83).

The 2016 RIR defined four Areas of Concern (AOCs) at the site, consisting of AOC 4 (Historic Fill), AOC 5 (Historic Fill with solid crystalline tar pieces and soil lightly impacted with staining), AOC 6 (soil impacted to heavily impacted with free product [liquid tar/non-aqueous phase liquid (NAPL)]), and AOC 7 (Groundwater impacted by AOCs 4, 5, and 6) (PAP-00009961). Lead detected in soil was shown to be distributed across the site, while mercury was only detected above criteria in a limited number of soil samples. The distribution of metals was shown to be random and related to the historic fill at the site (PAP-00009988). Maximum concentrations of metals detected in soil at each AOC are as follows (note that the data tables do not have Bates reference numbers, so the number listed is the pdf page in the 2016 RIR document):

Metals in Site Soil		
Metal (mg/kg)	**Max Detected**	**Reference**
AOC 4 (Table 2 of 2016 RIR)*		
Lead	18,900	76
Copper	2,770	91
Mercury	11.1	79
AOC 5 (Table 3 of 2016 RIR)		
Lead	21,100	163
Copper	1,010	109
Mercury	111	133
AOC 6 (Table 4 of 2016 RIR)		
Lead	2,560	226
Copper	280	184
Mercury	270	181

The figure below from the 2016 RIR shows the distribution of lead concentrations at the site. Locations in orange exceeded the remediation standard of 800 mg/kg, and sample locations in red exceeded 10 times the standard (8,000 mg/kg).

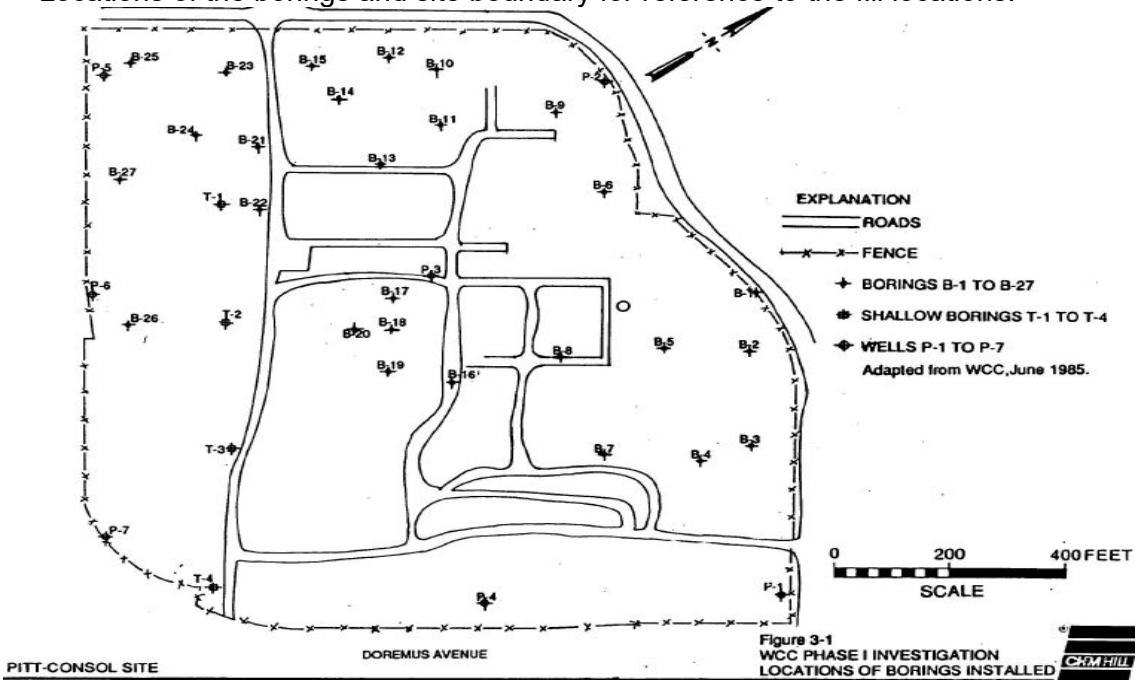
(PAP-00010391)



Historic Fill

The Allocation Team has determined that the facility site is located on regional Historic Fill as designated by the NJDEP[1].

An IntraSearch Aerial Photographic Analysis report on a 1944 photograph stated that fill material was likely placed prior to 1940 at the site to build a permanent land base above the water table, as the site was initially low-lying marshland (PAS-00014091). According to the Summary of Existing Environmental Data, Pitt-Consol Site, dated July 24, 1989, a layer of fill exists over the entire site; the fill material is less than two feet thick at the southwestern corner and approximately 10 feet thick in the center and northeast portions of the site. Much of the fill consists of rubble, including bricks, concrete, and wood debris in a sandy matrix. Coal-like and tar-like materials have been observed, primarily in the western half of the facility. An oily, creosote-like staining was observed throughout much of the northern half of the site (see figure below for locations of the different types of fill). The fill unit is an unconfined water-bearing zone that is saturated to grade in some portions of this site (PAP-00016509-10).



[1]*Digital Geodata Series, DGS04-7, Historic Fill for New Jersey*, https://www.nj.gov/dep/njgs/geodata/dgs04-7.htm, Quadrangle #52 & #53 (NJDEP map identifying locations of recognized historic fill).

A general distribution map of coal-derived materials in fill at the Pitt-Consol site is presented in the figure below from the Summary of Existing Environmental Data, Pitt-Consol Site, dated July 24, 1989. Since the orientation of the site is not presented in this figure, another figure showing the soil borings relative to the site boundaries is provided below this figure..

(PAP-00016466)

Locations of the borings and site boundary for reference to the fill locations.

(PAP-00016429)

NJDEP has established that historic fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 COCs: PAHs, lead, copper, and mercury[2]. Accordingly, NJDEP technical requirements for property containing Historic Fill requires sampling for the EPA Target Compound List for PAHs and Target Analyte List for metals, including lead, copper, mercury, and the OU2 PAH COCs.[3] PAHs, lead, copper, and mercury are recognized by NJDEP to be constituents of Historic Fill at varying levels, not atypically at or exceeding residential soil standards[4].

The levels of PAHs, copper, lead and mercury detected at the site in soils are presented in the table below.

COCs Found in Onsite Soils	
COC	**Max Detected Concentration**
Lead	21,100 mg/kg
Copper	2,770 mg/kg
Mercury	270 mg/kg
Benzo(a)anthracene	8,600 mg/kg
Benzo(a)pyrene	7,400 mg/kg
Benzo(b)fluoranthene	8,700 mg/kg
Benzo(k)fluoranthene	4,100 mg/kg
Dibenzo(a,h)anthracene	980 mg/kg
Indeno(1,2,3-cd)pyrene	3,500 mg/kg

(See Tables 2, 3, and 4 in the 2016 RIR [Specific pages listed in the table above] for soil concentrations)

5. COC Pathways

An EPA letter dated December 13, 1995 documented potential connections between the facility and the Passaic River based on the joint response to the EPA information request. The pathways identified included waste water discharges to the storm and sanitary sewers, as well as the possible drainage from Lagoon G to the Passaic River based on the conclusions from 1954 aerial photographs in the Woodward Clyde report. In addition, this letter noted that the high water table at the site is likely in contact with the material in the former lagoons (PAS-00051345-7).

---

[2] *Characterization of Ambient Levels of Selected Metals and cPAHs In New Jersey Soils* (2002) and *Characterization of Ambient Levels of Selected Metals and Oher Analytes In New Jersey Soils* (1997), studies prepared for NJDEP, Division of Science and Research, by BEM Systems, Inc.

[3] New Jersey Department of Environmental Protection (NJDEP), *N.J.A.C. 7:26E Technical Requirements for Site Remediation,* Table 4-2, November 2009 [Note that Table 4-2 has been deleted from the current version of N.J.A.C. 7:26E (May 7, 2012) and the updated *Historic Fill Technical Guidance* (April 2013) as NJDEP believed that the tables list of historic fill constituents was too restrictive].

[4] NJDEP Table 4-2 (PAHS and lead) and a summary of NJDEP records regarding investigations of properties in the vicinity of the Passaic River recognized to be located in areas of Historic Fill indicate that the following average/maximum (mg/kg) contamination levels of OU2 COCs exist in area Historic Fill: - PAHs (1.91/160), lead (574/10,000), copper (11.2/1,200), and mercury (0.21/3.7).

Sanitary Sewer

Based on the PVSC letters from 1958, 1960, 1970, and 1977, as well as the PVSC Annual Report for 1972 and a 1979 *Feasibility Study for the City of Newark Pollution Abatement Program* (see discussion in Section 3 [Operational History/COC Use and Presence at the Facility]), Pitt-Consol discharged their waste water to the Roanoke Avenue storm sewer from at least 1958 to December 1969, when the City of Newark built a dam to divert the dry weather flow into the sanitary and industrial sewers. The Roanoke Avenue storm sewer discharged directly to the Passaic River (PAS-00006271; PAS-00006274-5; PAS-00044119, 23, 25, 33, 41-42).

The waste effluent from the site was shown to contain copper, phenols, and cresols, according to a 1972 Waste Effluent Survey (PAS-00014145). A 1977 letter from Pitt-Consol to the PVSC states that the plant wished to continue to discharge industrial waste water to the City of Newark sanitary sewer and therefore the PVSC treatment plant (PAS-00014577).

The rate of discharge was identified in several documents as outlined below.

- According to a PVSC letter dated April 1, 1958, 200-300 gallons per minute of wastewater were being discharged to the storm sewer (PAS-00044123). A PVSC letter dated May 28, 1958, stated wastewater was being discharged into the Roanoke Avenue storm sewer from a sump on the Pitt-Consol property at a rate of 500 gallons per minute. The letter concluded that Pitt-Consol was likely the sole polluter of the storm sewer (PAS-00044125).

- A Waste Effluent Survey, dated August 30, 1972, listed 67,447,908 gallons as discharged to the sanitary sewer in 1974 (PAS-00014145-46).

- A Waste Effluent Survey dated March 10, 1975, stated 72,000 gallons per day were discharged to the municipal system (PAS-00014573-74).
- An undated Waste Effluent Survey stated 141,000 gallons per day were discharged to the “municipal system” (PAS-00014566).

- According to an Industrial Wastewater Questionnaire, dated August 29, 1978, Pitt-Consol did not pretreat its wastewater, which was discharged from one line at 185,000 gallons per day. The wastewater was listed as containing 0.05 mg/L copper and less than 0.2 mg/L lead (PAS-00000577).

- The Preliminary Assessment identified an annual volume of 309 million pounds per year for wastewater discharged to the PVSC (PAP-00016318).

A permit application to the NJDEP Bureau of Air Pollution Control states Pitt-Consol used an oil/water phase separator for the effluent as of September 1, 1981 (PAS-00014138). By 1986, the site was not discharging any water to the sanitary sewer, storm sewer, or the Passaic River (PAS-00014564).

Direct Release

The 1985 Draft Phase I Report stated that liquids in Lagoon G appeared to be overflowing the north bank and draining into a shallow ditch that emptied into the Passaic River, based on 1954 aerial photographs. Lagoon G and the shallow ditch were present in a 1957 aerial photograph, but Lagoon G was closed and the ditch adjacent to Lagoon G was not present in the interpretation of a 1966 aerial photograph. According to the 1985 Phase I Report, the lagoons contained manufacturing by-products, including tars and possibly a variety of phenolic compounds (PAS-00051420, 22, 24, 37-39).

Based on the *Summary of Existing Environmental Data, Pitt-Consol Site*, dated July 24, 1989, an oily, creosote-like staining was observed in fill on the northern portion of the site and coal-like and tar-like material have been observed in areas of the site, primarily on the western half of the facility in fill material (PAP-00016509-10). This material could be tar-like or hard like coal and had elevated concentrations of PAHs (total PAHs at 40,000 mg/kg) and lead (580 mg/kg). Mercury was detected at 0.16 mg/kg in the subsurface composite coal-tar sample analyzed (PAP-00016471-73).

The RIR identified the Passaic River as located approximately 600 feet from the site boundary (PAP-00009967).

6. Regulatory History/Enforcement Actions

Inspections

A site inspection by EPA in March 1983 noted that the impoundments and buildings at the site were leveled and empty rusty drums were at the site, but no spilled waste, runoff, standing liquids, or leaking drums were visible. Discolored water was occasionally noted when the groundwater level rose above ground during rain events. An incidence report to the Coast Guard, dated May 12, 1981, is listed on the inspection report and states that an "unknown" red liquid was released into the Passaic River by dumping or illegal discharge from Pitt-Consol on May 11, 1981. (PAS-00051363, PAS-00051497, PAS-00051507).

Violations

On February 29, 1984, an Administrative Complaint was filed by EPA alleging violations of Sections 6(e) and 15 of the Toxic Substances Control Act and EPA's regulations promulgated thereunder at 40 CFR 761. The complaint was due to the alleged failure to test the heat transfer system that had once contained PCBs and alleged disposal of liquid PCBs with a concentration greater than 500 ppm in a landfill in Model City, New York. Both parties agreed to settle the matter for $21,000 (PAP-00352865-66; PAS-00051520).

Permits

According to the Summary of Existing Environmental Data, Pitt-Consol Site, dated July 24, 1989, the facility was issued an Industrial Waste Permit by the PVSC in 1981 (PAP-00016423). PVSC permit number 20401072 allowed discharge from industrial outlet 20401071-44100-0201 with effective dates May 13, 1981 to May 13, 1986. Monitoring was required for non-COCs only, and no volume requirement was specified (PAP-00352848, 52).

In October 1986, a NJPDES permit was issued for the facility to discharge to ground waters of the State (PAS-00051526; PAP-00016417, 76). According to the public notice of NJDEP's draft permit, the NJPDES permit required the installation and sampling of groundwater monitoring wells to determine the facility's impact on the quality of groundwater (PAS-00051524).

7. Response Actions

Characterization Activities

The following characterization activities have taken place at the facility:

- Woodward Clyde Consultants (WCC) submitted the Draft Phase I Report, Preliminary Assessment of Environmental Impacts, Pitt-Consol Chemical Co. to DuPont on January 17, 1985 (PAS-00051414).
- CH2M Hill prepared a Summary of Existing Environmental Data, Pitt-Consol Site, dated July 24, 1989, which discussed a Phase I (Preliminary Environmental Assessment) performed by WCC in February and March 1985; a Phase II (Hydrogeologic Investigation) performed in August 1985; a hydrogeologic investigation performed by Roy F. Weston, Inc. in July 1986; and a November 1986 investigation of the characteristics of the buried tar materials by Mittelhauser Corporation (PAP-00016410).
- CH2M Hill prepared a Site Investigation Summary and Report of Findings, dated April 1992, that included groundwater, test pit, and soil sample results (PAP-00016343).
- Preliminary Assessment prepared by Corporate Remediation Group, April 15, 1998 (PAP-00016298)
- A Remedial Investigation Report (RIR) prepared by Geosyntec Consultants, dated May 4, 2016 (PAP-00009951)
- A Memorandum from Geosyntec Consultants dated October 23, 2017 (PAP-00009381)

Soil

Based on the Summary of Existing Environmental Data, Pitt-Consol Site, dated July 24, 1989, an oily, creosote-like like staining was observed in fill on the northern portion of the site and coal-like and tar-like material have been observed in areas of the site, primarily on the western half of the facility in fill material (PAP-00016509-10). The 2016 RIR presented the results for 780 on-site soil samples (PAP-00009962). Soil

investigations detected certain PAHs, PCBs, and certain metals at the site, but only the PAHs concentrations were attributed to site activities (PAP-00009985-88). Concentrations of PAHs were up to 49,000 mg/kg (naphthalene; p. 204 of 2016 RIR pdf). The sources of the site-related contamination, including free product, were identified as the former lagoons, former tank farm area, and former naphthalene area (PAP-00009965-67).

The results for PCBs were shown by the 2016 RIR to be distributed across the site with an unknown source and were not attributed to historical operations. PCBs were detected at concentrations up to 418 mg/kg and elevated concentrations were excavated in 2017 (PAP-00009382-83, 418-419, data table on p. 46 of pdf). Concentrations of metals were up to 21,100 mg/kg lead, 2,770 mg/kg copper, and 270 mg/kg mercury (See Tables 2, 3, and 4 in the 2016 RIR [p. 163, 91, 181 of pdf]), and were attributed to Historic Fill (PAP-00009988).

Sewer

A 1972 Waste Effluent Survey stated effluent from the site contained copper, phenols, and cresols. Copper was stated to be 1-10 ppm (lead and mercury were not analyzed), and while concentrations were listed next to the phenols and cresols, the units were not listed (PAS-00014145).

According to an Industrial Wastewater Questionnaire, dated August 29, 1978, Pitt-Consol did not pretreat its wastewater, which was discharged from one line at 185,000 gallons per day. The wastewater was listed as containing 0.05 mg/L copper and less than 0.2 mg/L lead (PAS-00000577). No other data for the sewer or effluent were in the available references.

According to the Feasibility Study for the City of Newark Pollution Abatement Program, revised January 1979, the Roanoke Avenue sanitary sewer received flow from the Pitt-Consol facility, and about 0.5 feet of a black, tar-like sediment was found in the sewer downstream of the Pitt-Consol connections. The same black material was observed on the ground surface at the Pitt-Consol plant, but was not found upstream or at the Roanoke outfall (PAS-00006261).

Remedial Activities

Woodward Clyde Consultants (WCC) prepared a Draft Phase I Report, Preliminary Assessment of Environmental Impacts, Pitt-Consol Chemical Co. on January 17, 1985. This report presented background information on the hydrogeology and groundwater quality, as well as interpretation of historical aerial photography (PAS-00051414).

CH2M Hill presented a Summary of Existing Environmental Data, Pitt-Consol Site, dated July 24, 1989, which summarized the previous investigations performed at the site. The following reports were discussed:

- A Phase I (Preliminary Environmental Assessment) was performed by WCC in February and March 1985 and provided a preliminary assessment of subsurface conditions at the site. During this investigation, 27 borings were installed to an average depth of 11 feet below grade to determine the nature and thickness of the fill materials above the peaty clay layer at the site. Bricks, concrete, and wood debris in a sandy matrix were observed, and an oily creosote-like material was found throughout the site. Additional materials noted were a black tar-like material, a dry crumbly, powdery coal-like material; a whitish-gray, paste-like sludge; and a yellowish orange crystalline material. Four additional borings were installed, and samples from 1 to 3 feet below ground surface (a total of 12 samples) were collected and analyzed for total phenolics and total organic carbon (TOC) (PAP-00016427-28, PAP-00016464).

- In November 1986, Mittelhauser Corporation investigated the characteristics of the buried tar materials to evaluate possible beneficial use of these materials. Eighteen test pits were excavated in and around Lagoons A, B, and F. A composite coal tar sample was analyzed for physical characteristics, metal contents, and organics. The sample was also subjected to the Toxicity Characteristic Leaching Procedure (TCLP) to measure the constituents potentially present in leachate from this material. Several PAHs, lead, and mercury were detected in the tar sample, while only naphthalene and phenanthrene were detected in the TCLP extract. Results for TCLP metals were not included (PAP-00016437, PAP-00016469-71).

The Site Investigation Summary and Report of Findings, dated April 1992, presented test pit results. Test pits determined the boundaries of the lagoons were generally consistent with the boundaries visible in historical aerial photographs. PCBs were not detected in soil samples from the former locations of tanks, so it was concluded that tank sludges did not contaminate the soil (PAP-00016353). The report concluded that the lagoon contents were materials that would be expected at a coal tar manufacturing facility (PAP-00016353).

The Preliminary Assessment, April 15, 1998, summarized the previous investigations at the site and defined three Areas of Concern: the former manufacturing/storage area, the former pitch storage/tar tank farm, and the former lagoons. Relevant COCs were identified as PAHs, naphthalene, and lead (PAP-00016333).

The RIR, dated May 4, 2016, identified four AOCs that redefined the original three AOCs based on common impacts: AOC-4 (historic fill and native geologic material), AOC-5 (historic fill/native geologic material, with solid crystalline tar pieces and soil lightly impacted with staining), AOC-6 (historic fill/native geologic material soil impacted to heavily impacted with free product (liquid tar/NAPL), and AOC-7 (groundwater impacted by AOCs-4, -5, and -6) (PAP-00009961, PAP-00009976, PAP-00010009-10).

The 2016 RIR stated the four AOCs were designated so remedial actions could be applied based on the nature of impacts to soil. The approximate areas and volumes of the soil AOC are as follows:

AOC Dimensions			
AOC	**Description**	**Area**	**Volume**
4	Historic Fill/ native geologic material (HF/NGM)	11.6 acres	414,000 cubic yards (CY)
5	HF/NGM with solid tar and light staining	18.9 acres	221,000 CY
6	HF/NGM and soil impacted with liquid tar	7.3 acres	36,000 CY**

**Could be up to 56,200 CY if the entire Lagoon F area requires remediation (PAP-00010009).

The RIR soil results had exceedances of the direct contact soil remediation standards and impact to groundwater soil remediation standards for certain PAHs, lead, and mercury, and PCBs exceeded the TSCA high occupancy screening criteria in at least one sample. The Historic Fill was stated to contain metals and PAHs in a random distribution. In addition, PCBs in soil were detected in localized areas distributed around the site with no correlation to historical operational practice. The RIR concluded that sources of the PAHs above soil remediation standards and free product, appeared to be linked to the former lagoons, former tank farm area, and former naphthalene area (PAP-00009961-67).

A Memorandum from Geosyntec Consultants dated October 23, 2017 documented the investigation and removal of PCB contaminated soil from the site. The contaminated soil had PCB concentrations above TSCA requirements for high-occupancy site use in one localized area. The soil removed was 1,160 square feet in surface and located near the center of the site (PAP-00009382).

8. Summary of Asserted Defenses

No legal defenses were identified in the available file material.

Diamond Alkali OU2 Allocation

Facility Data Report

PMC, INC.

Facility Name, Address and Size: PMC Inc./Kleer Kast, Inc.; 450 Schuyler Avenue, Kearny, New Jersey; Block 226, Lots 3, 4, and 11; approximately 19 acres (PAS-00015074; PAS-00015106). The facility operated continuously on a 24-hour per day basis, 7-days per week, all year with overtime, and had a workforce of between 30 and 60 employees (PAS-00014848; PAS-00014918).

1. **Business Type:** Production of plastic products.

2. **Time Period of Ownership/Operations**

   Operator: 1971 to at least 2007
   Owner: 1971 to at least 2007

   Kleer Kast, Inc. (Kleer Kast) was incorporated in New Jersey on September 10, 1971. Kleer Kast utilized other company names including: (1) American Polymers, Inc., and (2) Ampol Division (PAS-00015610). Kleer Kast had estimated sales ranging from $1 million to $4.9 million in 1999, while operating as King Finishing, Inc. a division of PMC, Inc. (PAS-00015649-650). PMC Inc. (PMC) of Sun Valley, California, is the owner of the Kleer Kast site in Kearny, NJ, and operates Kleer Kast as a division. PMC was founded in 1971 and incorporated in the State of Delaware on August 11, 1993. PMC's ultimate domestic parent is PMC Global, Inc., which operates PMC as a subsidiary (PAS-00015595-PAS-599; PAS-00015634).

3. **Operational History/COC Use and Presence at the Facility**

   Site operations commenced in 1971 and continued until at least 2007 (PAS-00014918; PAS-00015613). From the late 1970s through at least 1999, operations at the facility involved several processes for the production of plastic products. These involved clear and black plastic sheeting for the graphic arts, stationery and packaging industries; cellulose acetate sheeting; acetate pellets; compounded and extruded cellulose; butyrate; propionate; acetate tool handles; and plasticized compounds (PAS-00014919; PAS-00014976; PAS-00014988; PAS-00015022; PAS-00015038; PAS-00015063; PAS-00015270; PAS-00015342).

   The facility operated continuously on a 24-hour per day basis, 7-days per week, all year with overtime, and had a workforce of between 30 and 60 employees (PAS-00014848; PAS-00014918). In 1994, casting was occurring 24 hours per day, 7 days per week; blending was occurring 24 hours per day, 5 days per week. The average daily wastewater flow was 160,000 gallons per day 4 days per week (PAS-00014914).

(PAS-00014834)

4. Identified COCs

- PAHs (release)
- Copper (use, release)
- Lead (use, release)
- Mercury (use, release)

PAHs

In 1994 and 1995, petroleum hydrocarbons were known or suspected to be present in the wastewater discharged to PVSC (PAS-00014838).

Metals – Copper, Lead and Mercury

Sampling from 1988 to 1995 of wastewater discharged to the Passaic Valley Sewer Commission (PVSC) from Kleer Kast contained copper, lead, mercury and oil (PAS-00014844).

In 1991, Kleer Kast advised PVSC that lead and mercury may have been present that year in the wastewater discharged to the PVSC system in excess of 15 kilograms per calendar month (PAS-00014838).

In 1994, the company stored pigments (containing chromium, cadmium and mercury) in drums located in the facility's pigment room which did not have any floor drains (PAS-00014915).

In 1994 and 1995, copper, lead, and mercury were known or suspected to be present in the wastewater discharged to PVSC (PAS-00014838). A 1994 Local Limits Baseline Monitoring Report shows copper (0.258 mg/l), lead (0.0302 mg/l) and mercury (<0.001 mg/l). The average daily flow in 1994 was 135,425 gallons (PAS-00014967).

In 1995 and 1996, raw, process and hazardous materials found onsite included copper, mercury and oil (PAS-00014976; PAS-00015214; PAS-00015226-235).

Historic Fill

The Allocation Team has determined that the facility site is not located on regional Historic Fill as designated by the NJDEP.[1]

NJDEP has established that historic fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 COCs: PAHs, lead, copper, and mercury.[2] Accordingly, NJDEP technical requirements for property containing Historic Fill requires sampling for the EPA Target Compound List for PAHs and Target Analyte List for metals, including lead, copper, mercury, and the OU2 PAH COCs.[3] PAHs, lead, copper, and mercury are recognized by NJDEP to be constituents of Historic Fill at varying levels, not atypically at or exceeding residential soil standards.[4]

[2] *Characterization of Ambient Levels of Selected Metals and cPAHs In New Jersey Soils* (2002) and *Characterization of Ambient Levels of Selected Metals and Other Analytes In New Jersey Soils* (1997), studies prepared for NJDEP, Division of Science and Research, by BEM Systems, Inc.
[3] New Jersey Department of Environmental Protection (NJDEP), *N.J.A.C. 7:26E Technical Requirements for Site Remediation,* Table 4-2, November 2009 [Note that Table 4-2 has been deleted from the current version of N.J.A.C. 7:26E (May 7, 2012) and the updated *Historic Fill Technical Guidance* (April 2013) as NJDEP believed that the tables list of historic fill constituents was too restrictive].
[4] NJDEP Table 4-2 (PAHs and lead) and a summary of NJDEP records regarding investigations of properties in the vicinity of the Passaic River recognized to be located in areas of Historic Fill indicate that

There is no information regarding sampling data in the available file material.

5. COC Pathways

Direct Discharge

The facility utilized water from wells and municipal sources for both cooling and process purposes. In the late 1970s and early 1980s, Kleer Kast discharged approximately 280,800 gallons per day of wastewater, including 10,000 gallons per day of contact water from the distillation column used for solvent recovery (PAS-00015015; PAS-00015023; PAS-00015039; PAS-00015041; PAS-00015045).

According to a 1977 NPDES Application and follow-up letter, 280,800 gallons of cooling water and 7,000 gallons of process water were discharged to Frank's Creek to the Hackensack River (PAS-00015012-14). A 1978 Process Flow sheet shows discharge to Frank's Creek with the receiving waters being listed as Passaic (PAS-00015023).

In February 1985, sampling of wastewater showed 0.1 mg/l lead, 0.019 mg/l of copper and 16 mg/l oil and grease (PAS-00015274).

Prior to July 1986, the facility discharged all wastewater to Frank's Creek, a tributary of the Passaic River, via a single outfall, designated as DSN001. This wastewater discharge was routed to a ditch that flowed to Frank's Creek. The facility's discharge to Frank's Creek was comprised of stormwater (roof and roadway runoff) as well as contact and non-contact cooling water (PAS-00015023; PAS-00015039; PAS-00015045).

In November 1990, the facility reported discharge of 44,497,504 gallons of process water and cooling water to the sanitary combined sewer and 84,486,143 gallons to the storm sewer/river/ditch (Franks Creek/Hackensack River) from October 1989 to September 1990 (PAS-00014848-49; PAS-00014856).

Testing of the industrial waste water showed 0.3 mg/l copper and 57 mg/l of petroleum hydrocarbons at outlet 15405031, which was receiving 121,911 gallons of daily flow at that time (PAS-00014852-3). Copper, lead and mercury were expected to be present in the wastewater (PAS-00014858).

The facility was discharging 7,000,000 gallons of process water and 13,300,000 gallons of cooling water to the sanitary combined sewer and 45,000,000 gallons to the storm sewer/river/ditch from October 1994 to September 1995 (PAS-00014975). Samples of effluent in 1995 showed copper at 39.8 µg/l (PAS-00015000).

---

the following average/maximum (mg/kg) contamination levels of OU2 COCs exist in area Historic Fill: PAHs (1.91/160), lead (574/10,000), copper (11.2/1,200), and mercury (0.21/3.7).

Sanitary Sewers

The facility is located in the PVSC's Ivy Street CSO district. The 1976 PVSC Overflow Analysis report states that overflows from the Ivy Street CSO District and outfall occur during periods of rainfall (PAS-00014842-3).

Kleer Kast advised PVSC in April 1985 that it was planning to rebuild its wastewater discharge system to conform to NJDEP's requirements and that the company would be applying for a sewer connection permit. The permit request was filed in September 1985 in response to a civil action by the United States Environmental Protection Agency against Kleer Kast for violation of the federal Clean Water Act for discharging contact cooling water to Frank's Creek. At that time, the facility had two sanitary sewer lines tied into the PVSC system and was requesting the tie-in of additional industrial lines into the PVSC system to eliminate the surface water discharge of contact cooling water. On July 1, 1986, the company began discharging contact cooling water to the PVSC system rather than to surface water (PAS-00015237; PAS-00015262; PAS-00015264; PAS-00015296-298; PAS-00015302-303).

By 1987, all process wastewater, contact cooling water and sanitary wastewater was directed to the PVSC treatment plant (PAS-00015063). Sampling of the facility's wastewater discharge to the sewer system in 1988 and 1990, following the rebuild of Kleer Kast's wastewater discharge system, identified copper (PAS-00015093; PAS-00015095; PAS-00015143). In November 1990, results for a PVSC Composite/Grab sample included 0.03 mg/l copper (PAS-00015143).

6. Regulatory History/Enforcement Actions

Inspections

During a June 9, 1994 facility inspection, NJDEP documented that an oil-like substance was leaking from the foundation of the loading dock area of Alexandria Plastics, a tenant at the Kleer Kast Site. The oil-like substance was observed discharging to the waters of the State. Kleer Kast was directed by NJDEP to determine the source of the oil-like substance, to immediately and permanently cease the unpermitted discharge and to submit a written report detailing the corrective actions taken by Kleer Kast. No further information has been obtained concerning the investigation and disposition, if any, of this unpermitted discharge (PAS-00014840; PAS-00015208).

On March 21, 1985, dye testing conducted at the Kleer Kast/ Ampol facility documented that process overflows discharged to facility drains ultimately flowed to Frank's Creek. The dye test was performed on a drain that received the water from the quench baths; these baths were sampled in December 1984 and copper and lead were detected (PAS-00014840).

Violations

On March 6, 1990, Kleer Kast reported to PVSC that approximately 50 gallons of Number 6 fuel oil were discharged to the sewer during a 1-hour period. The discharge resulted from a leak in a fuel oil recirculating line. PVSC issued a Notice of Violation (NOV) to Kleer Kast on March 7, 1990 for the discharge (PAS-00015134-136; PAS-00015134-6).

Permits

The facility had NJPDES Permit No. NJ0031313 for facility wastewater discharge to Frank's Creek, a tributary of the Passaic River from October 1, 1984 through February 28, 1992 (PAS-00014839; PAS-00015056; PAS-00015239). Petroleum hydrocarbons had a maximum limit of 15 mg/l (PAS-00015066). This permit did not require monitoring of any specific COCs.

PVSC Sewer Connection Permit No. 15405032 for facility wastewater discharge to the PVSC system was effective May 27, 1991 through May 24, 2001 (PAS-00014864; PAS-00014883). The facility had limits on discharge of lead, copper and mercury (PAS-00014907). However, available references did not include effluent monitoring data.

7. Response Actions

In April 1993, four underground fuel oil storage tanks (USTs) were excavated and removed from the facility. Sampling of the soils surrounding the USTs identified the following hazardous substances in soils:

- Fluoranthene
- Indeno(1,2,3-cd)pyrene
- Pyrene
- Benzo(g,h,i)perylene
- Total petroleum hydrocarbons (PAS-00014839).

8. Summary of Asserted Defenses

No legal defenses were identified in the available file material.

PPG Industries Inc.

Diamond Alkali OU2 Allocation
ADR Confidential
Facility Data Report

PITTSBURGH PLATE GLASS (PPG) INDUSTRIES INC.

Facility Name, Address and Size: Pittsburgh Plate Glass (PPG) Industries, Inc. formerly known as Pittsburgh Plate Glass Company was located at 29 Riverside Avenue, Newark, New Jersey (PAS-00006296). The Site has been subdivided into 15 parcels/lots in Block 614. The lots in the northern portion of the Se southern portion of the site have McCarter Highway addresses (Lots 61, 62, 63, 64, 65, 66, 67, and 68) (PAP-00037403). PPG is approximately seven acres and is located on the west bank of the Passaic River (PAP-00037403). The available references did not include information on the number of site employees and typical work shifts.

1. **Business Type:** PPG manufactured paints, lacquer, enamels, varnishes, linseed oil, and resins (PAP-00037400; PAS-00044277).

2. **Time Period of Ownership/Operations**

   Operator: 1902 to 1971
   Owner: 1902 to 1971 (PAP-00037404)

3. **Operational History/COC Use and Presence at the Facility**

   As reported by Woodard and Curran in the *Report on PPG Industries,* dated September 9, 2016 (Woodard Report), PPG manufactured paint, lacquer, enamels, varnishes, linseed oil, and resins. Flax seed oil and coal (for power) were brought into the property by barge until 1946. The majority of liquid raw materials were stored in aboveground storage tanks (ASTs) with ASTs in two buildings (Buildings 4 and 15). Large exterior ASTs were located south of Building 12, on the north side of Building 7, and adjacent to the Riverside Avenue vehicle entrance. Flax seed silos/grain elevators were located along the river next to the flax seed oil mill. Ten 10,000-gallon underground storage tanks (USTs) adjacent to Building 12 also stored non-chlorinated solvents (PAS-00044244).

   The primary coating manufacturing operations took place in the following buildings:
   - Buildings 2 and 3 – paint (early 1900s)
   - Building 12 – paint
   - Buildings 7 and 9 – varnish
   - Building 10 – flax seed oil mill
   - Building 14 – lacquer
   - Building 17 – resin (PAS-00044244)

   The report also notes that PPGs operations were gravity-based systems. Raw materials were stored on upper floors and piped to lower floors via gravity for mixing, thinning, and blending. Paint and resins vessels and vats were rinsed with caustics or non-chlorinated solvents to clean them. The resulting rinseate was reused typically in lesser quality coatings, recycled, or sent off-site for disposal/treatment. For a period of time, non-chlorinated solvents were recovered in a small building between Buildings 12 and 17. This building is no longer present (PAS-00044244).

As described in the Woodard Report, the manufacturing operations included the following:

Paint Manufacturing

PPG manufactured oil-based paints and enamels in Buildings 2, 3, 4, 5, and 12 (PAP-00037404; PAS-00044285). The primary products produced at PPG were oil-based paints and enamels. Paints were primarily composed of binders (e.g., polymers, resins), solvents or diluents, primary pigments (e.g., fine organic or inorganic particles), extenders (e.g., clays, chalk, gypsum, anhydrite), and additives (e.g., catalysts, driers). A simplified version of the paint making process included resin preparation and filtering, grinding pigments and mixing with the resins, adding additional resins if needed, adding and/or adjusting solvents and driers, and including any other additives, quality control checks, and product packaging (PAP-00037405; PAS-00044244).

The report also stated that according to company history, dry pigments and mixing varnishes or oils were brought to the top floor and mixed to form a paste. The paste mixture was fed through chutes to grinding mills on the next floor. Batches would then be sent again via chutes to a lower floor where thinning oils and solvents were added in large processing tanks. Tinting was also typically done on this floor. The product was then fed via pipes to the filling department. The filled one- and five-gallon cans were transferred by conveyer for packing for shipment or storage. Some paint was placed into 55-gallon drums. The filling equipment along with other equipment were air pressure operated machines (PAS-00044245).

The raw materials known to have been used by PPG during the paint manufacturing process included: natural gums, natural resins, flax seeds, non-chlorinated solvents, pigments, caustic soda, dyes, alkyd resins, chromium, lead, titanium, zinc, lead carbonate, mercury, copper oxide, and cadmium. Solvents included water, toluene, xylene, ethylbenzene, linseed oil, methyl ethyl ketone (MEK), naphtha, turpentine, and mineral spirits. Some of these solvents were also used in making resin, varnish, and lacquer (PAS-00044245). The primary metal pigments used at PPG contained lead or titanium oxides. Cadmium (yellow color) and chromium (durability) were used in some paints. Mercury was probably used in certain paints as a preservative (PAS-00044245).

Resin Manufacturing

Alkyd resin production occurred at PPG in Building 17 from approximately 1930 until 1969. The alkyd resins at PPG were produced from polyunsaturated fatty acids (i.e., vegetable oil, linseed oil) and polyols (i.e., glycerin). With heat, the process creates glyceride oil to which anhydride is added to increase the molecular weight. Synthetic phenolic resins were added as a secondary component for some coatings. Resins manufactured at PPG were then diluted with a non-chlorinated solvent and used in paint and varnish manufacturing. Phenolic resins were not made at the PPG, but rather purchased in solid flake form from a supplier (PAS-00044245).

Varnish Manufacturing

PPG began varnish manufacturing in 1910, which is when the original varnish building was constructed. In 1936, a new varnish building was constructed at the current Building 7 location. The new building was identified as Building 7 while the original Building 7 was subsequently identified as Building 7A. Building 7A was subsequently torn down (PAS-00044245).

Similar to the paint operation that occurred in other buildings at PPG, upper levels of the varnish building were used for mixing and preparing the varnish for heat treatment in the first floor pots. Varnish was made from drying oils/polymers (i.e., linseed oil) and non-chlorinated solvents. The primary non-chlorinated solvents were white spirits, mineral turpentine and kerosene with minor amounts occasionally of toluene, xylene, and naphtha (PAS-00044245).

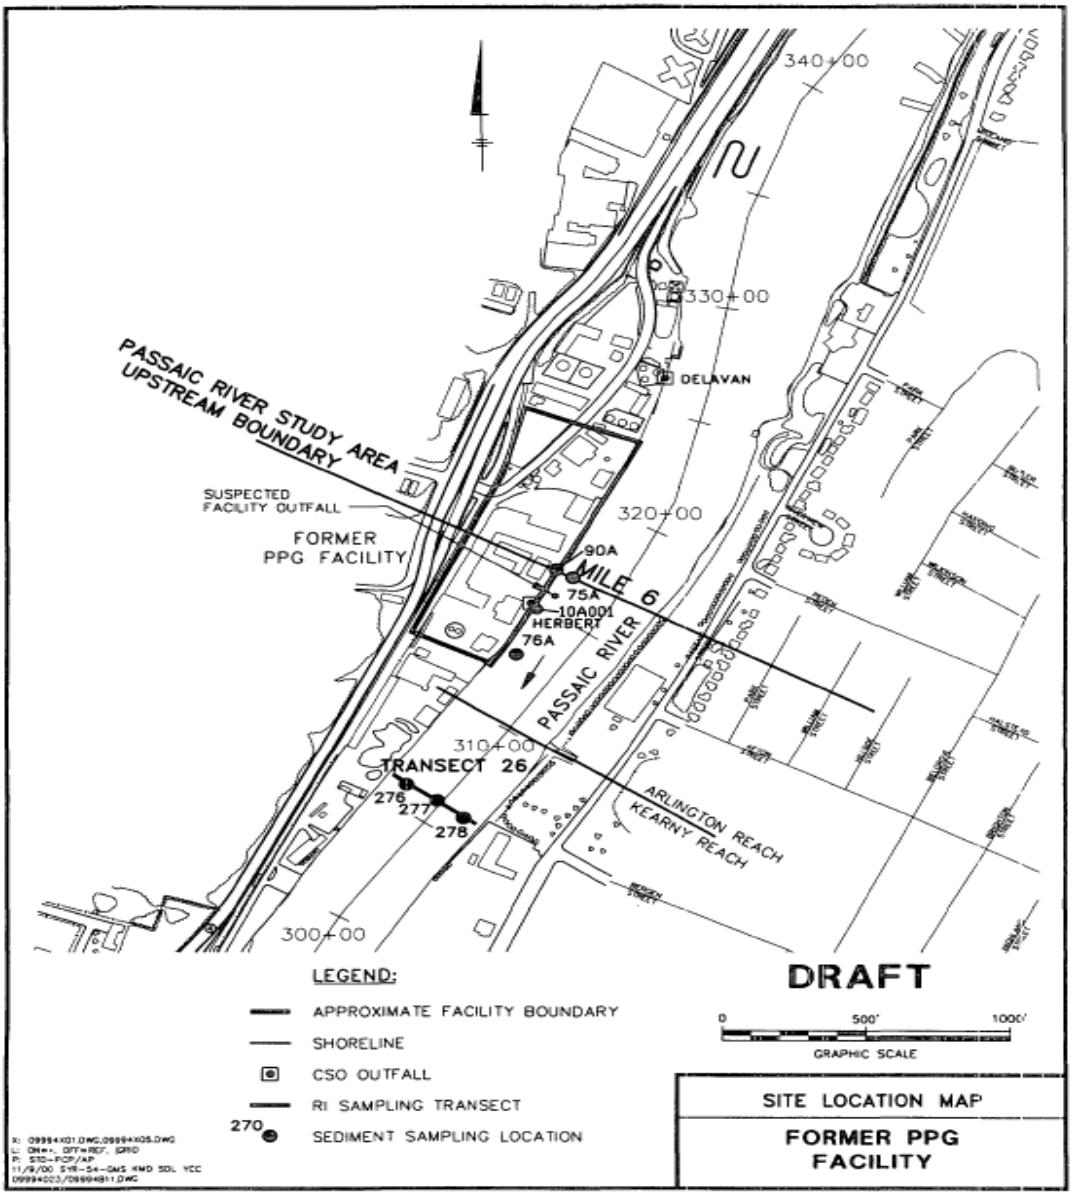
Linseed Oil Manufacturing

Linseed oil was manufactured from flax seed at PPG from 1923 to 1947. The typical primary steps were pressing the seed to release the oil, then refinement of the oil with caustic soda (PAS-00044245). According to a September 18, 1996, Letter from PPG regarding the Passaic River Study Area, basic raw materials included natural gums and resins, flax seed, non-chlorinated solvents and pigments, though the chemical constituents of some of these materials changed over time (PAS-00006297).

Lacquer Manufacturing

As described in the Woodard Report, lacquers are a subset of paints with a high solvent content. At PPG, lacquer was primarily a combination of nitrocellulose (a resin) and solvents (such as butyl acetate). Nitrocellulose-based lacquers were developed in the early 1920s, and extensively used in the automobile industry for 30 years (PAS-00044287). Small amounts of flake naphthalene was reportedly used in lacquer production and small amounts of copper oxide was reportedly used in paint production (PAS-00006297).

Materials Use



Materials used in manufacturing are provided below:

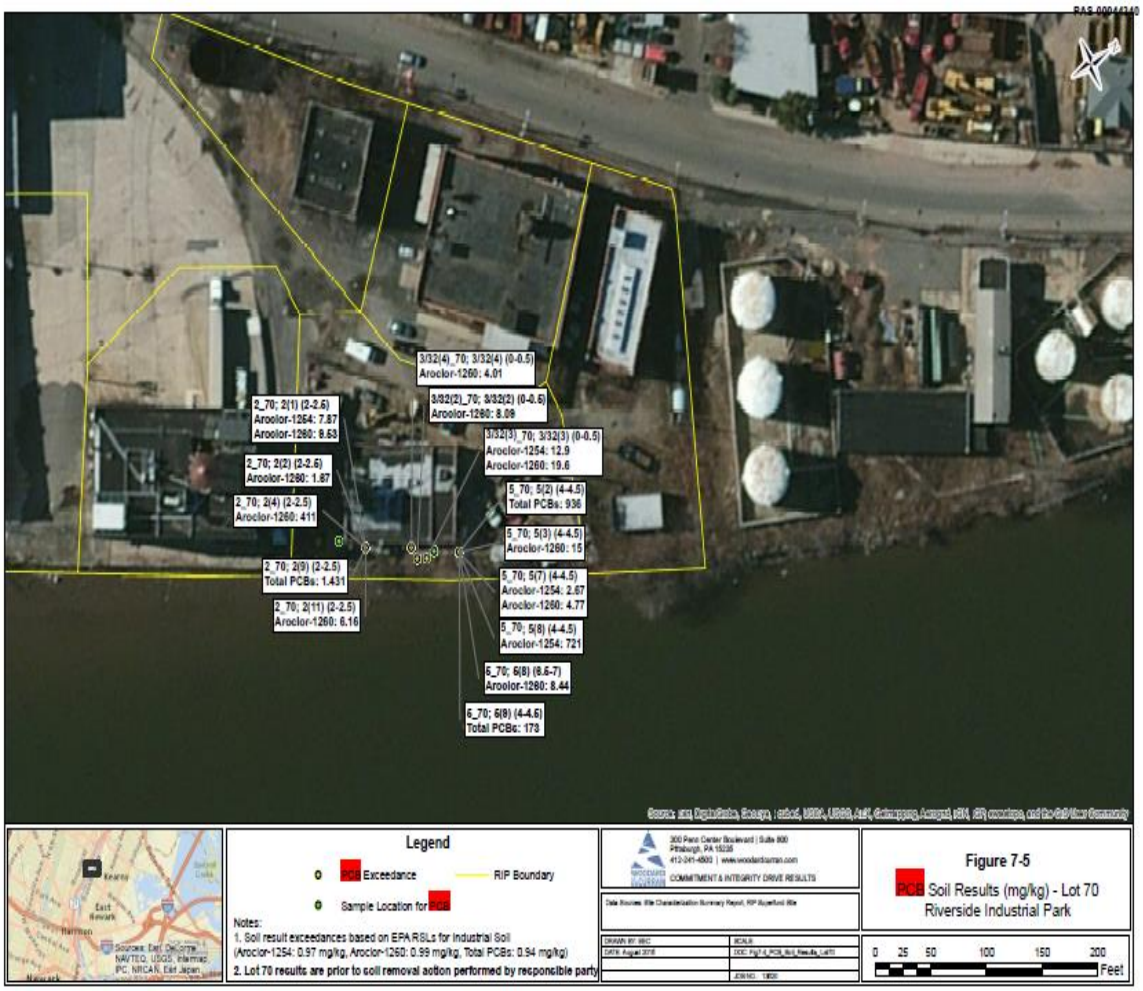
- Alkyd resins were manufactured at the site. These products were used by PPG as raw materials in paint and varnish manufacture. Phenolic resins were not manufactured, but would have been received at the site and used as raw materials in the manufacture of paints and varnishes (PAS-00006297).

- Toluene, xylene, ethylbenzene, and MEK were received at the site and used as raw materials in the manufacture of paints and varnishes (PAS-00006297).

- Pigments were brought to the site and used in the manufacture of paints. These were often metallic chemicals and included compounds of cadmium, chromium, lead, titanium, and zinc. Basic lead carbonate (white lead) was one of the pigments used as a raw material. Mercury was used as a preservative in certain paints (PAS-00006297).

- Polychlorinated biphenyls (PCBs), dioxins, 2,4-dichlorophenoxyacetic acid, and 2,4,5-trichlorophenoxyacetic acid were not received, utilized, manufactured, discharged, released, or disposed of the Newark site (PAS-00006297).

(PAS-00124660)



(PAP-00037403)

4. Identified COCs

- PCBs (detected)
- PAHs (used, detected)
- Dioxins (detected)
- Copper (used, detected)
- Lead (used, detected)
- Mercury (used, detected)

PCBs

PPG did not use PCBs in its coating operations at the facility. There is no information in the available references evidencing that PCBs were or would have been generated by PPG's operations, or released from or disposed at the facility during PPG's time of operations. PCBs have been detected in soil sampling at the facility, but those detected PCBs are reportedly not attributable to PPG. Rather, Federal Refining Company (a scrap metal recycler), and other parties are reportedly responsible for PCBs at the Facility. In addition, PCBs likely were deposited onto Facility soils due to flooding from the Passaic River (PAS-00044273-304). PCBs may have also been present in historic fill (PAS-00044273-304). The highest concentrations of PCBs at the facility were 721 mg/kg for Aroclor 1254 (Sample 5_70; collected at a depth of 4-4.5 feet bgs) and 411 mg/kg for Aroclor 1260 (Sample 2_70; collected at a depth of 2-2.5 feet bgs), both located on Lot 70 where Federal Refining Company conducted a metals reclamation operation (PAS-00044302, PAS-00044340).

(PAS-00044340)

Nearly all of the PCB exceedances (14 of 16 exceedances) are associated with Building 16 on Lot 70 and NJDEP Case E2000550 (Federal Refining Company) (PAS-00044302, PAS-00044339). PPG used Building 16 as a maintenance shop, which did not involve the use of PCBs (PAS-0044302). Beginning in 1985, Federal Refining Company operated a scrap metal recycling process that used an incinerator with various acidic and caustic liquids in Building 16 on Lot 70. Prior to initiating its operations and after the previous company (railroad ties and rails storage) vacated the property, Federal Refining undertook an environmental assessment of Lot 70 which included soil sampling (PAS-00044302). Federal Refining did not detect PCBs in soils on Lot 70 prior to its operations (PAS-00044302). In the early 2000s, Federal Refining undertook another environmental assessment as the responsible party for Case Number E2000550. That investigation and subsequent reports identified PCBs in soils on Lot 70, indicating that Federal Refining was the source of PCBs on Lot 70 (PAS-00044303). As further evidence of its responsibility for the PCBs on Lot 70, in March 2012, Federal Refining undertook a soil removal action to address the PCB-impacted soil and implemented engineering and institutional controls to address the remaining contamination. Federal Refining excavated soil containing PCBs greater than 50 mg/kg (PAS-00044303).

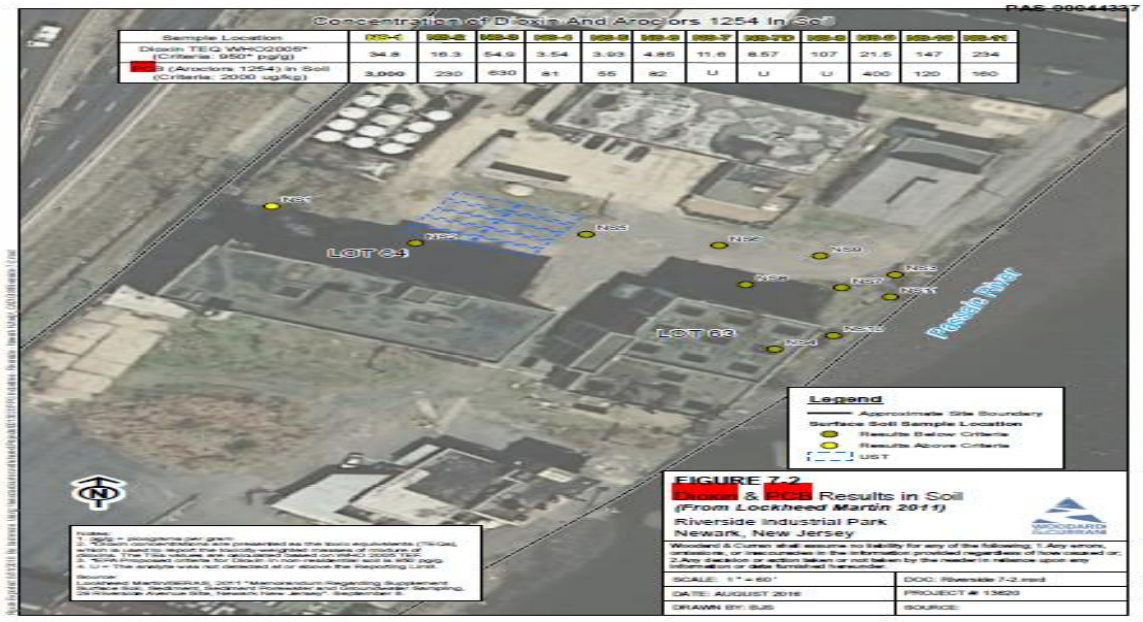
(PAP-00305940)

Other than Lot 70, there were limited PCB soil detections at the facility. All of the non-Lot 70 PCB detections were consistent with or less than the PCB sediment concentrations in the river (PAS-00044303). The low PCB soil concentrations (other than on Lot 70) likely reflect residual contaminated sediment from past flooding events. (PAS-00044303).

PCB detections have also been attributed to historic fill (PAS-00044301). Finally, of 134 recent soil samples taken at the property, the maximum detection of Aroclor 1254 was 3.1 mg/kg from sample B-40 collected on September 2017 at a depth of 0-1 feet bgs and the maximum detection of Aroclor 1260 was 10 mg/kg from sample B-67 collected on October 2017 at a depth of 2.5-3.8 feet bgs (PAP-00305856-69).

Dioxins

PPG has no information indicating that dioxins and furans were or would have been generated by its operations, or released from or disposed of at the facility during its period of operation. Dioxins were detected in soil sampling at the facility in 2017 and 2011 (PAP-00478818-19; PAS-00044273-306). The highest 2,3,7,8-TCDD concentration detected in samples collected in 2017 was at location DF-4 at 20.8 nanograms per kilogram (ng/kg). The soil samples were collected from zero to six inches on the eastern edge of the site adjacent to the Passaic River (PAP-00478818-19; PAP-00479072).[1]



[1] This Report was revised to include documents received on May 22, 2020. The additional documents did not change PPG Industries Inc.'s previous certification.

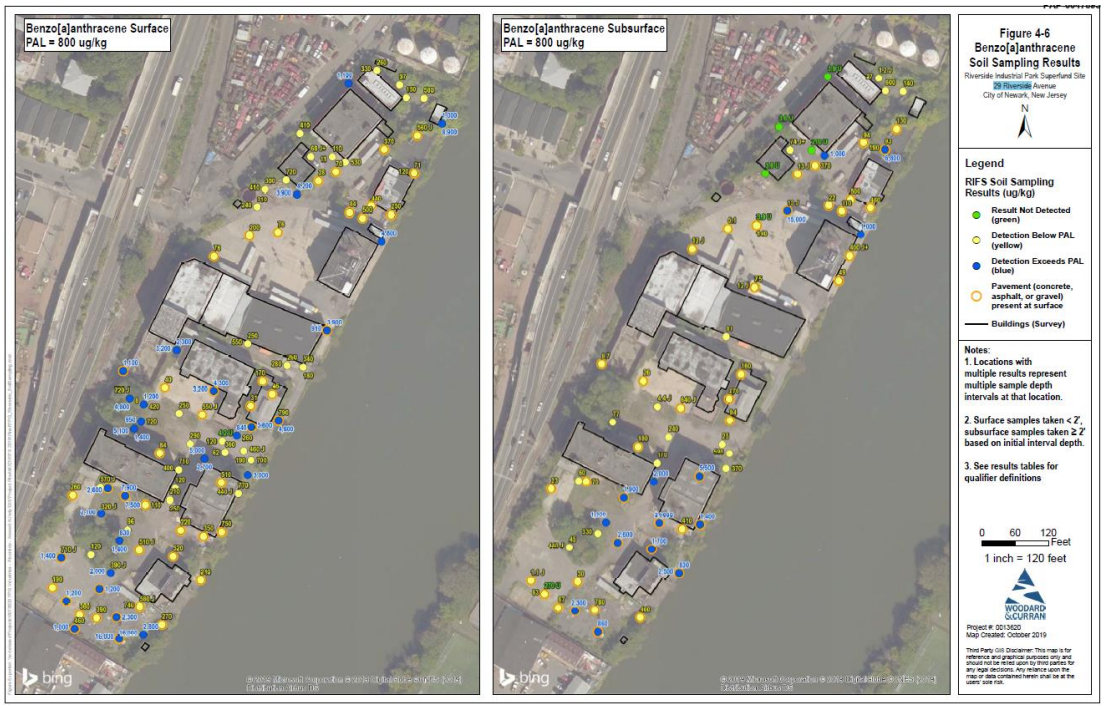
For samples collected in 2011 from a depth of zero to six inches, the highest soil concentration of the dioxin toxicity equivalency quotient (TEQ) was 234 picograms per gram (pg/g) in a sample (NS-11) along the river wall. The 2,3,7,8-Tetrachlorodibenzo-p-dioxin (2,3,7,8-TCDD) concentration was 216 pg/g. The ratio of 2,3,7,8-TCDD to total TCDD was 0.7. The soil dioxin concentration is less than the average sediment 2,3,7,8-TCDD concentration adjacent to the Riverside Industrial Property indicating this area is not a source of dioxin, but its proximity to the river probably reflects residual sediment from past flooding events. The 2,3,7,8-TCDD/total TCDD ratio indicated that the source of the soil dioxin is herbicide manufacturing and is consistent with the 2,3,7,8-TCDD/total TCDD identified by others for a former manufacturing facility located at 80 and 120 Lister Avenue in Newark, New Jersey (near River Mile 3), which began producing pesticides and other products in the 1940s (PAS-00044302).

Presented below is a figure depicting the soil sampling locations at the Riverside Industrial Park (PAS-00044336):

Presented below is a figure depicting the dioxin detections in soil (From Lockheed Martin 2011) (PAS-00044337):

PAHs

Small amounts of flake naphthalene were used in lacquer (PAS-00044273-87; PAP-00039511). From December 1933 to May 1934, approximately 82 pounds of flake naphthalene was used in lacquer manufacturing (PAP-00039511).



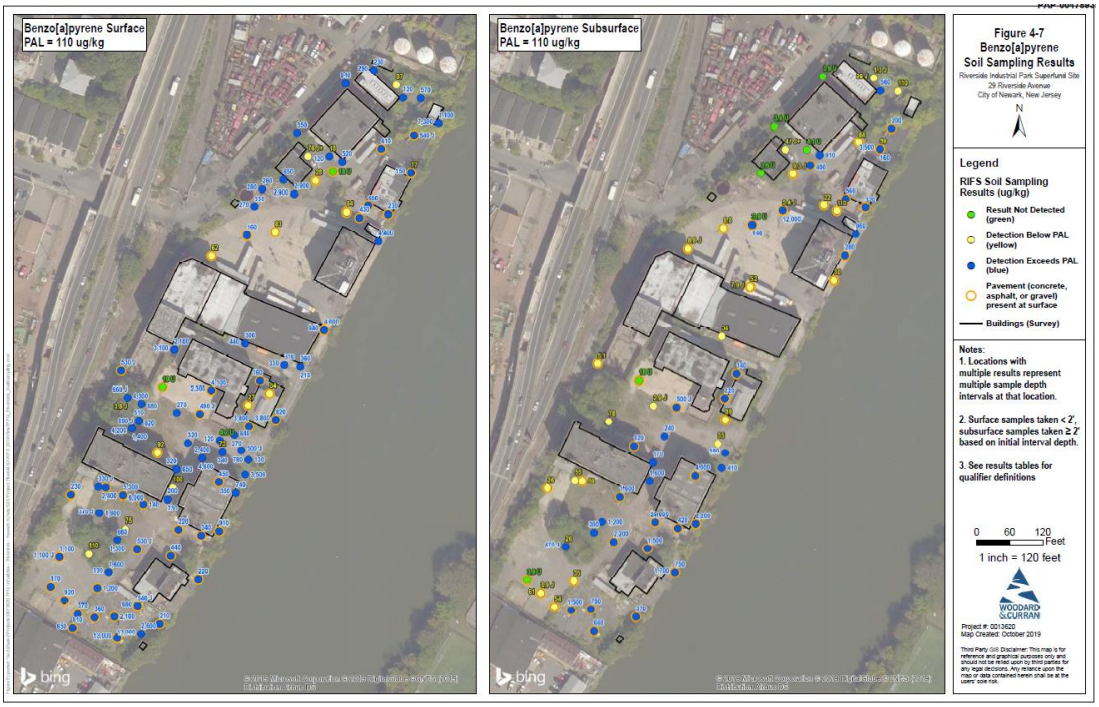
Raw materials were brought to the property by rail, tanker truck, or trailer truck (PAS-00044273-85). Until 1946, flax seed and coal were brought to the property by barges that tied up along the length of the Facility shoreline (PAP-00037406; PAS-00044273-85, 86).

PAHs are present in historic fill in New Jersey and have been detected in soils at the facility (PAS-00044273-96). As stated in the Final Remedial Investigation Report, dated April 20, 2020, the detection of PAHs above project action limits is primarily in the Lots 63/64 area with relatively higher concentrations in surface than subsurface soil. An onsite source for isolated detections has been identified as historic fill in NJDEP led remediation. The PAHs to the north of Buildings #7 and #12 are likely related to the UST or surface activities, including surface waste piles, vehicle dismantling, and 2012 UST removal activities which broke a water line causing overland flow of petroleum contaminated water. Presented below in a tabular format are the maximum concentrations of PAHs detected at the facility (PAP-00478816; PAP-00479027):[2]

[2] This Report was revised to include documents received on May 22, 2020. The additional documents did not change PPG Industries Inc.'s previous certification.

PPG's Max PAH concentrations		
Constituent	**Concentration**	**Sample ID/Depth**
Benzo(a)anthracene	34 mg/kg	B-85/2.5-3.5 ft bgs
Benzo(a)pyrene	28 mg/kg	B-85/2.5-3.5 ft bgs
Benzo(b)fluoranthene	29 mg/kg	B-85/2.5-3.5 ft bgs
Benzo(k)fluoranthene	27 mg/kg	B-85/2.5-3.5 ft bgs
Dibenz(a,h)anthracene	5 mg/kg	B-85/2.5-3.5 ft bgs
Ideno(1,2,3-cd)pyrene	16 mg/kg	B-85/2.5-3.5 ft bgs

Presented below are figures depicting the various PAH concentrations:[3]



(PAP-00478934)

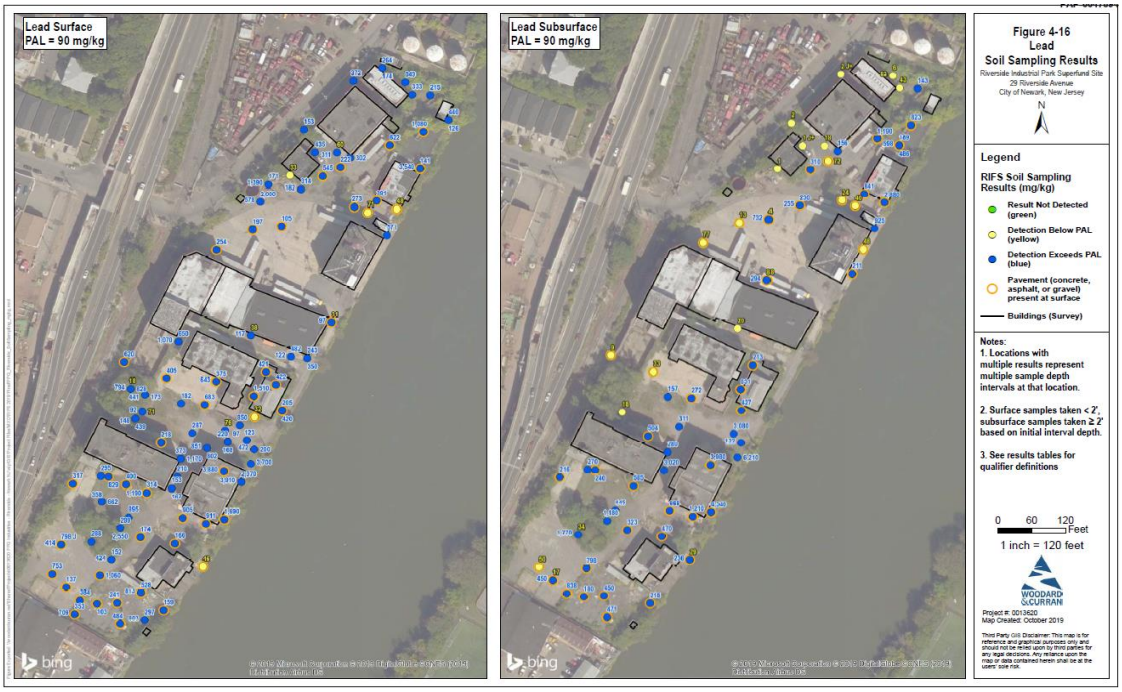
(PAP-00478937)

Copper



PPG used materials containing copper in paint manufacturing (PAS-00044273-286; PAP-00039510). Raw materials were brought to the property by rail, tanker truck, or trailer truck (PAS-00044285). Copper is present in historic fill in New Jersey and has been detected in soils at the facility (PAS-00044273-296; PAP-00305842-55). Copper was detected at a maximum concentration of 1,040 mg/kg from sample B-33 collected in October 2017 from a depth of 0.5-1 feet bgs (PAP-00305847). In addition, copper was also detected at a concentration of 145 mg/kg (PAP-00305852) in sample B-60 (FILL) collected in October 2017 at a depth of 4 feet bgs (PAP-00305842-55). These concentrations exceed concentrations NJDEP has identified as typical of historic fill. No figures showing the copper detections were available in the reference documents.

Lead

Certain pigments used in PPG's paint and lacquer manufacturing contained lead (PAS-00044286; PAP-00039505-508). Draft paint chip sampling results from Block 614, Lots 63 and 64 at the Riverside Industrial Park collected by a contractor for the City of Newark in August 2009 showed that the paint chips contained lead (PAP-00304521). The levels of lead detected in paint chip samples are presented below:

- Sample JA26014-1 – 8,620 mg/kg
- Sample JA26014-2 – 10,800 mg/kg
- Sample JA26014-3 – 5,620 mg/kg (PAP-00304521)

Small amounts of hot lead were used in refining linseed oil (PAP-00039505-508; PAP-00039459). As of November 1934, materials containing lead were used in the manufacture of paint, lacquer, and linseed oil (PAP-00039459; PAP-00039505-508). Paint manufacturing occurred in Buildings 2 and 3 in the early 1900s, in Buildings 4 and 5 as of 1934, and in Building 12 after 1925 (PAS-00044273-285). Raw materials were brought to the property by rail, tanker truck, or trailer truck (PAS-00044285). In an October 2017 soil sampling event (i.e., after the Relevant Time Period), lead was detected at a maximum concentration of 8,690 mg/kg collected from sample B-75 at a depth of 1 to 3 feet bgs (PAP-00305854). Lead was detected at a concentration of 2,550 mg/kg in sample B-60 (FILL) at a depth of 4 feet bgs (PAP-00305852).

(PAP-00478944)[4]

Mercury

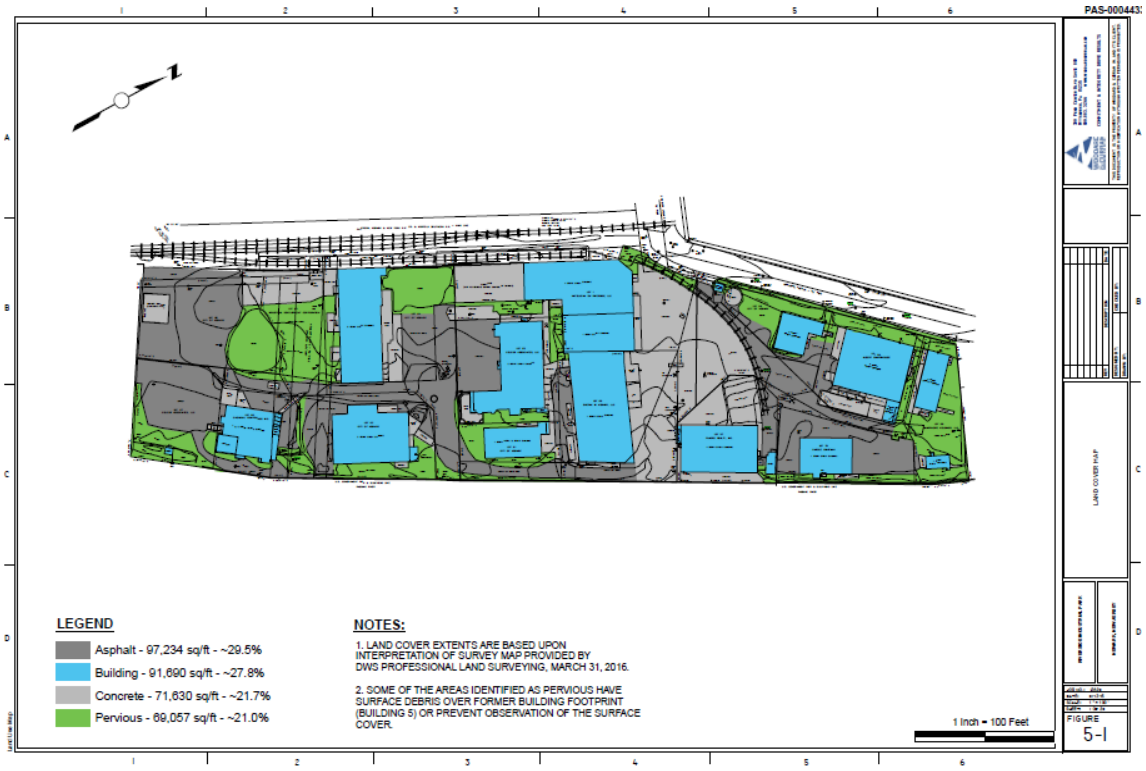
Extremely low quantities of mercuric oxide and phenylmercuric acetate, which partially consists of mercury-containing material, were used in certain paints as preservatives (PAS-00044273-286; PAP-00039510). Draft paint chip sampling results from Block 614, Lots 63 and 64 at the Riverside Industrial Park collected by a contractor for the City of Newark in August 2009 showed that the paint chips contained low levels of mercury at the following concentrations:

- Sample JA26014-1 – 45.8 mg/kg
- Sample JA26014-2 – 17.2 mg/kg
- Sample JA26014-3 – 37.8 mg/kg (PAP-00304521)

[4] This Report was revised to include documents received on May 22, 2020. The additional documents did not change PPG Industries Inc.'s previous certification.

Soil sampling data collected at the Riverside Industrial Park showed a maximum detection of 31.4 mg/kg collected from sample B-80 in December 2018 at a depth of 0.3-1.3 feet below ground surface (bgs) (PAP-00479054).[5] Mercury is present in historic fill in New Jersey and has been detected in soils at the facility at a concentration of 8.3 mg/kg from sample B-60 (FILL) in September 2017 at a depth of 4 feet bgs (PAP-00305842-55). The concentration of mercury in soils at the facility exceeds concentrations NJDEP has identified as typical of historic fill.

Presented below are the mercury soil sampling results in surface and subsurface soil as presented in the Final Remedial Investigation Report, dated April 20, 2020 (PAP-00478946):[5]



Historic Fill

According to the Woodard Report, a 1892 Certified Sanborn Map showed that the majority of the Site was part of the Passaic River (PAS-00044282). Specifically, the majority of Lots 57, 61, 62, 63, 64, 66, 67, 68, and 70 were originally within the footprint of the Passaic River (PAS-00044282). The origin of the fill material the site is built on is unknown, but soil boring data from several New Jersey Department of Environmental Protection (NJDEP) related investigations (NJDEP Case Numbers E88434; E20110199; E88483; E20080157; E98132; E89257; and E2000550) describe the presence of ash, cinders, and brick in the fill (PAS-00044282). River dredge spoils also could have been

[5] This Report was revised to include documents received on May 22, 2020. The additional documents did not change PPG Industries Inc.'s previous certification.

used for fill. The Riverside property is identified on NJDEP's historical fill map as having fill material (http://www.nj.gov/dep/njgs/geodata/dgs04-7.htm) (PAS-00044282).

Approximately 80 percent of the property at the facility is paved (PAS-00044290, PAS-00044334). An asphalt cap has been installed on Lots 68 and 70 and portions of Lots 61, 63, 66, and 67 as an NJDEP-approved engineering control (PAS-00044273-304).

(PAS-00044334)

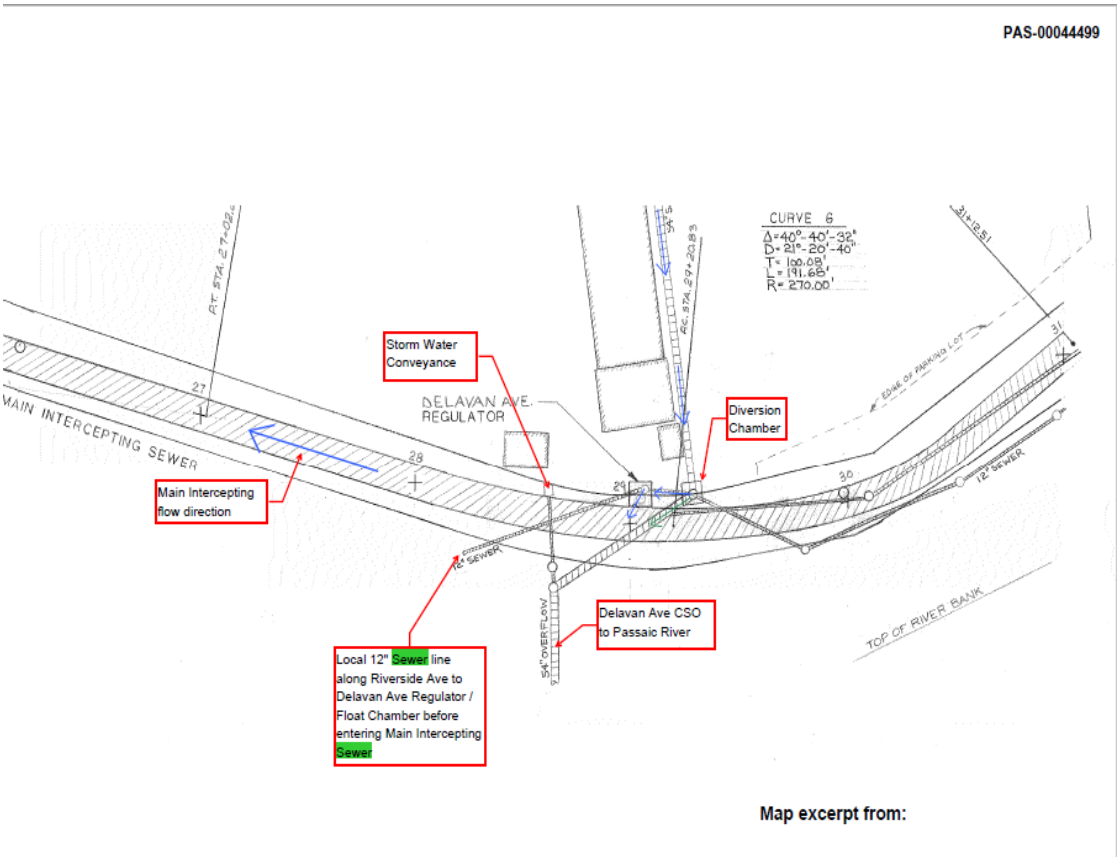
The Allocation Team has determined that the facility site is partially located on regional Historic Fill as designated by the NJDEP.[6]

The New Jersey Department of Environmental Protection (NJDEP) has established that Historic Fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 COCs: PAHs, lead, copper, and mercury.[7] Accordingly, NJDEP technical requirements for property containing Historic Fill requires sampling for the United States Environmental Protection Agency (EPA) Target Compound List (TCL) for PAHs and Target Analyte List (TAL) for metals, including lead, copper, mercury, and the

[6] *Digital Geodata Series, DGS04-7, Historic Fill for New Jersey*, https://www.nj.gov/dep/njgs/geodata/dgs04-7.htm, Quadrangle #52 and #53 (NJDEP map identifying locations of recognized historic fill).
[7] *Characterization of Ambient Levels of Selected Metals and cPAHs In New Jersey Soils* (2002) and *Characterization of Ambient Levels of Selected Metals and Other Analytes In New Jersey Soils* (1997), studies prepared for NJDEP, Division of Science and Research, by BEM Systems, Inc.

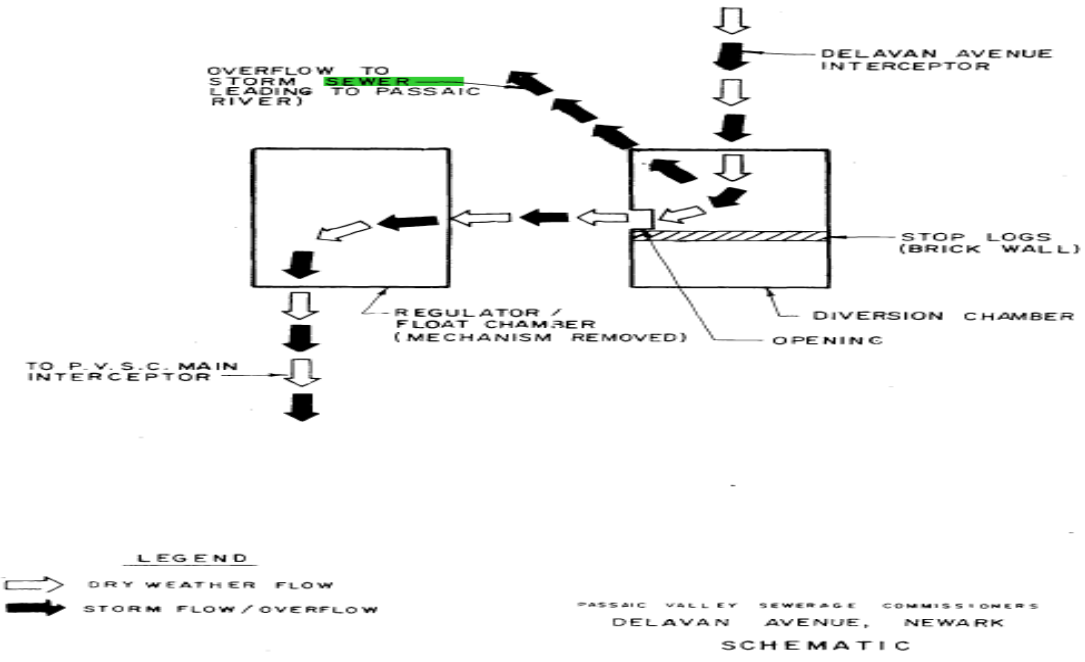
OU2 PAH COCs.[8] PAHs, lead, copper, and mercury are recognized by NJDEP to be constituents of Historic Fill at varying levels, not atypically at or exceeding residential soil standards.[9]

The levels of PAHs, copper, lead and mercury detected at the site in soils are presented in the table below (PAP-00305837, 47, 54).



COCs Found in Onsite Soils	
COC	**Max Detected Concentration**
Lead	8,690 mg/kg
Copper	1,040 mg/kg
Mercury	13.9 mg/kg
Benzo(a)anthracene	16 mg/kg
Benzo(a)pyrene	13 mg/kg
Benzo(b)fluoranthene	17 mg/kg
Benzo(k)fluoranthene	5.4 mg/kg
Dibenzo(a,h)anthracene	2.3 mg/kg
Indeno(1,2,3-cd)pyrene	7.3 mg/kg

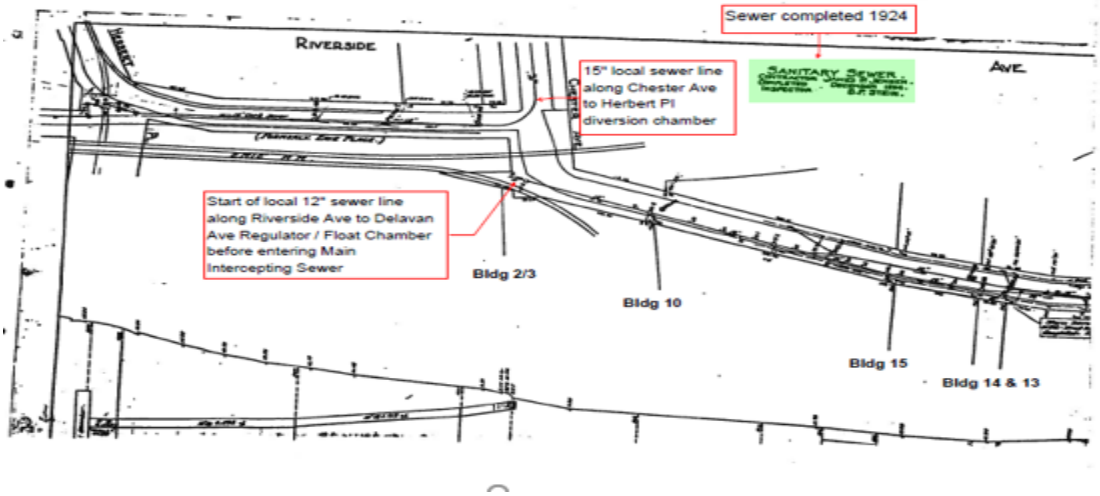
5. COC Pathways



Storm Sewer

When the facility began operations in the early 1900s, it was connected to the Passaic Valley Sewerage Commissioners (PVSC) Delavan Avenue connector (PAS-00044291). Based upon PVSC Drawings, the 12-inch sewer line pipe from the facility is connected to the Delavan Avenue regulator chamber/float chamber before entering the Main Intercepting sewer (PAS-00044499). The connection of the facility sewer pipe to this chamber prevented facility discharges to the river during high flow or bypass events at the Delavan Avenue Combined Sewer Outlet (CSO) connection (PAS-00044293). Instead, facility sanitary wastewater entered the regulator chamber and flowed into the main PVSC intercepting sewer and to the PVSC treatment plant (PAS-00044293). Therefore, during high-flow conditions, such wastewater should not have reached the diversion chamber where bypass flow to the river occurs (PAS-00044293). Further, PVSC's reports state that the Delavan Avenue connector was not subject to high-flow conditions or overflow events. Based on investigation made of the upstream collection system, it was found that an overflow facility located within the City of Newark upstream of this regulator chamber was activated during period of rainfall (PAP-00305639).

[8] New Jersey Department of Environmental Protection (NJDEP), *N.J.A.C. 7:26E Technical Requirements for Site Remediation,* Table 4-2, November 2009 [Note that Table 4-2 has been deleted from the current version of N.J.A.C. 7:26E (May 7, 2012) and the updated *Historic Fill Technical Guidance* (April 2013) as NJDEP believed that the tables list of historic fill constituents was too restrictive].
[9] NJDEP Table 4-2 (PAHs and lead) and a summary of NJDEP records regarding investigations of properties in the vicinity of the Passaic River recognized to be located in areas of Historic Fill indicate that the following average/maximum (mg/kg) contamination levels of OU2 COCs exist in area Historic Fill: PAHs (1.91/160), lead (574/10,000), copper (11.2/1,200), and mercury (0.21/3.7).



(PAS-00044499)

(PAS-00044500)

The only building at PPG that did not discharge to the Delavan connector was Building 17. Based on a 1959 revision of a 1942 drawing, a sewer from Building 17 existed going to the southwest, presumably connecting to the PVSC main sewer line.

(PAS-00044501)

PPG lacks information regarding the discharge rates, discharge volumes, and water quality data for discharge to the PVSC system. However, PPG would not have discharged any COC-containing effluent through facility pipes or the PVSC system because (1) it manufactured oil-based coatings that did not generate much liquid process waste, (2) any liquid process waste either was reused in other coatings or disposed off-site, and (3) it would have been impractical to discharge any liquid process waste through pipes because coating residue would clog those conveyances (PAS-00044273-85; PAP-00037406).

Direct Discharge

According to the November 1994 *Passaic River Study Area PRP Investigation, Summary of Evidence Pertaining to: Pittsburgh Plate Glass Company*, prepared by Kroll Associates (Kroll Summary), the former PPG facility potentially discharged hazardous substances to the Passaic River through the following mechanisms (PAS-00080135):

- Direct process discharge to the river via the combined sewer system – A combined sewer outfall (CSO) exists on facility property immediately downstream of PPG's connection to the local combined sewer line on Riverside Avenue. This outfall is known as the Herbert Place combined sewer outfall. Process-related discharges to the combined sewer were likely discharged from this outfall during periods of wet weather or CSO regulator malfunction (PAS-00080135; PAS-00080232). However, according to the Woodard Report, there is no evidence that wastewater discharged to the Herbert Place sewer at any time and wastewater could not be diverted to the Passaic River given the connection of piping to the Delavan regulator chamber (where no bypass option is available) (PAS-00044294).

- Direct dumping of containers to river, as reported in an affidavit of a former employee, though he stated that he had no knowledge of the contents of the containers (PAS-00080135; PAS-00080161-62).

- Interior spills, etc., disposed of via floor drains – Each building had 4-inch to 6-inch sewer pipes, which led to Passaic River. Numerous outfalls exist today along the former PPG facility bulkhead which are consistent with floor drain elevation (PAS-00080135). The affidavit of Willie Moore, a former PPG employee, dated September 1994, states that "[e]very building at the PPG facility had a 4-inch to 6-inch sewer pipe running directly to the river." He further had "witnessed PPG employees sweeping residue, including spills of products and raw materials, down these floor drains" (PAS-00080161). In contrast, according to the *Remedial Investigation and Feasibility Study Work Plan* dated July 28, 2017 (July 2017 RI/FS Work Plan), pipes in the river bulkhead wall are consistent with PVSC notes that state that the pipes are related to a water tank drain or compressor cooling water (PAP-00037438), and the only building documented to have floor drains was the Ardmore Chemical building (Building No. 14) (PAP-00037436, PAS-00044508). Affidavits from other former employees further refute the presence of floor drains in every building (PAP-00402709-10, PAP-00402712).

The *Final Remedial Investigation Report, dated April 20, 2020*, described a river wall pipe investigation. Figure 2-14 shows the locations of bulkhead wall pipes and associated pipes that were traced from the survey. Several pipes were traced to within Building #6, including a pipe connected to a roof drain. Pipes were not traceable inside other buildings. No residue or material which would be suggestive of manufacturing wastewater was observed in the pipes (PAP-00478776).[10]

Of the 21 pipes observed, seven have been identified as those described in the 1971 PVSC field notes. PVSC identified only seven river wall pipes and determined that these pipes were not associated with process wastewater discharges, and instead were either plugged/inoperable or associated with water tanks or non-contact cooling water. Of the 14 additional pipes identified during the RI, four pipes were associated with a roof drain, a fire suppression water tank drain, a storm water drain, and a hot water boiler drain. The use of the remaining 10 pipes identified during the RI could not be determined; these pipes may potentially have episodic discharge flow; however, these flows were not observed during the RI (PAP-00478777).[10]

During the river wall investigation, flow was observed coming from a pipe located in the wall bulkhead behind Building #10. Aroclor-1260 (0.13 J ug/L) and copper (51.1 ug/L), lead (41.4 ug/L), and mercury (1.8 ug/L) were detected in a water sample collected from this pipe (PAP-00478777; PAP-00479136).[10]

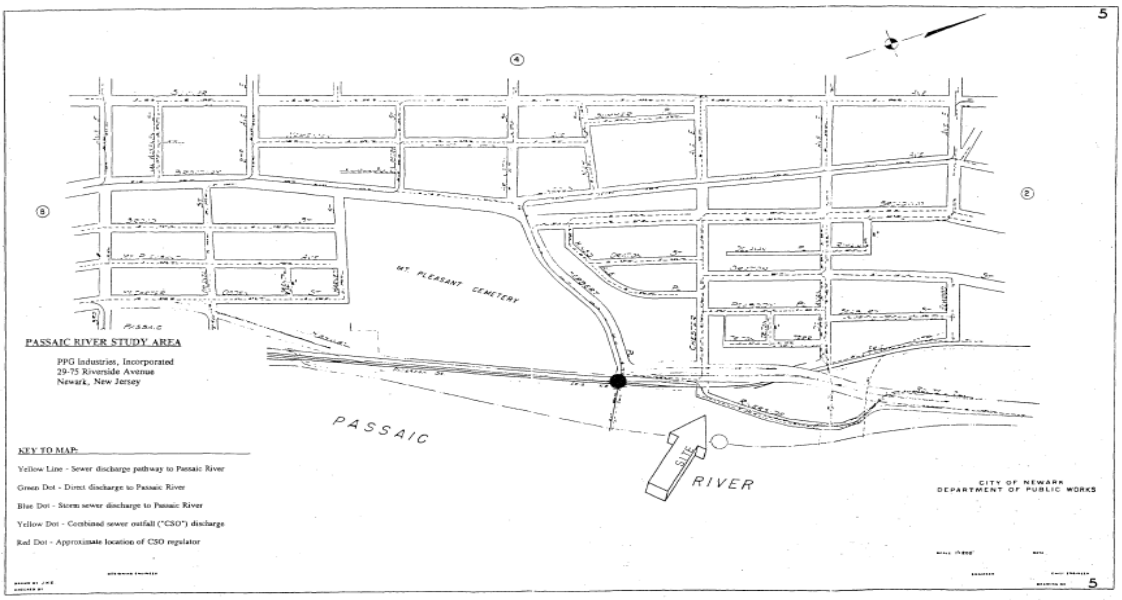


Figure 2-14 shows the location of the river wall pipe sample collected (in purple; PAP-00478906):[10]

[10] This Report was revised to include documents received on May 22, 2020. The additional documents did not change PPG Industries Inc.'s previous certification.

Floor Drains

According to the July 2017 RI/FS Work Plan, the only building documented to have floor drains was the Ardmore Chemical building (Building No. 14) (PAP-00037436, PAS-00044508). The Woodard Report and the July 2017 RI/FS Work Plan assert that the facility had no lagoons, ponds, landfills, disposal pits, dry wells, settling basins, disposal units, or surface water control measures (PAS-00044277; PAP-00037406).

(PAS-00129573)

Spills

There were no reported major spills or releases in the available references. Employees recalled that the company was concerned about safety and that minor spills were cleaned up promptly and placed in 55-gallon drums for disposal off property (PAS-00044290).

The only significant incident mentioned by former employees was a resin building fire in 1969. According to former employees, the 1969 resin building did not result in resin material reaching the river. The resin material was confined to the building (PAS-00044290). According to a PPG employee, a vapor cloud was released from one of the resin reactors in Building 17. Newark City firefighters pumped water from the river into the building and nearby storage tanks to attempt to contain the fire. The building was damaged beyond repair during the fire and was later demolished (PAS-00006303).

6. Regulatory History/Enforcement Actions

Inspections

There is no information regarding inspections in the available file material.

Violations

There is no information regarding violations in the available file material.

Permits

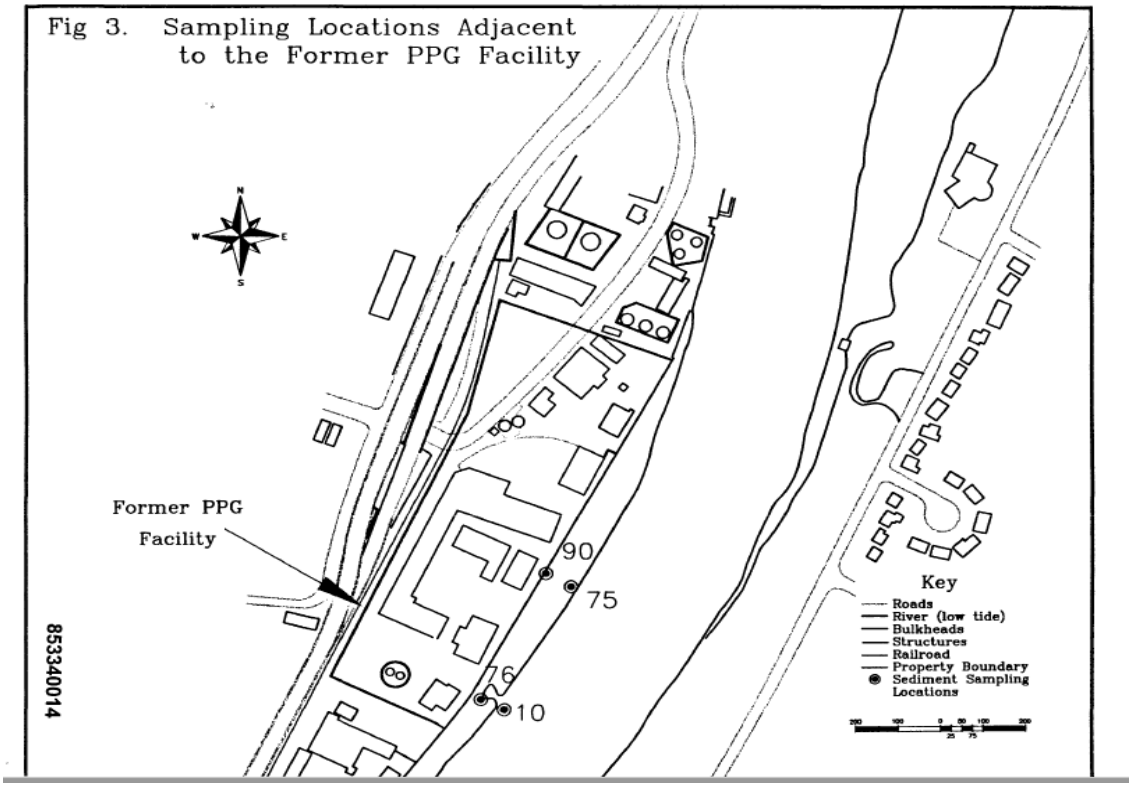
There is no information regarding permits in the available file material.

7. Response Actions

Characterization Activities

The following characterization activities have taken place at the facility:

- *Passaic River Study Area, Potentially Responsible Party Investigation, Summary of Evidence Pertaining to: Pittsburgh Plate Glass Company*, prepared by Kroll Associates (Kroll Report), dated November 1994 (PAS-00080125).
- *Report on PPG Industries, Nexus to Lower Passaic River Study Area*, prepared by Woodard & Curran (Woodard Report), dated September 2016 (PAS-00044232).
- *Remedial Investigation and Feasibility Study Work Plan*, prepared by Woodard & Curran (2017 RI/FS Work Plan), dated July 18, 2017 (PAP-00037395).
- *Site Characterization Summary Report Addendum, Riverside Industrial Park Superfund Site, PPG, Inc.*, dated October 2018 (PAP-00305739).



According to the Kroll Report, sediment sampling was conducted at locations in the Passaic River adjacent to the former PPG facility. These sediment samples were analyzed for the presence of organic and inorganic constituents and are detailed below (PAS-00080136).

PAHs/Semi-Volatiles

Elevated background concentrations of semi-volatile compounds were generally found in all sediments collected from this reach of the river. Compounds such as phenanthrene, pyrene, and chrysene were detected at significant concentrations in sediments and are likely resultant from handling, producing, or filling with coal tar and/or petroleum-related materials in the local vicinity. Neighboring facilities of the PPG site have included a bulk oil storage facility and an asphalt plant, which, in addition to PPG's expected use of oil for heating purposes, were likely sources of these materials. Additionally, some of the pigments that may have been used on-site by PPG were produced from coal tars, which may have contributed to the detected concentrations of certain compounds Naphthalene was reportedly used as a raw material for production at the facility (PAS-00080138). Detection limits for this compound in the sample collected immediately adjacent to the site were as high as 19,000 µg/kg. Naphthalene may have been present in this sample at concentrations as high as this, however, according to the Kroll Summary, naphthalene was reported as not detectable (PAS-00080139).

Dioxins

Elevated concentrations of the dioxin 2,3,7,8-TCDD were detected in sediments collected from this reach of the river. Sample 75, collected in March, 1993, adjacent to the facility bulkhead contained concentrations ranging up to 4,400 nanograms (ng)/kg of 2,3,7,8-TCDD. Sample 10, collected in November or December, 1991, in the vicinity of the Herbert Place CSO, and directly offshore of the former resin manufacturing building, contained concentrations ranging up to 32,000 ng/kg of 2,3,7,8-TCDD. The former resin manufacturing building is the anticipated location of phthalic anhydride use by PPG at the facility (PAS-00080139-40). However, the soil dioxin concentration is less than the average concentration in sediment, adjacent to the facility, indicating that this area is not a source of dioxin (PAS-00044302). Additionally, sediment from locations adjacent to and slightly downriver from the facility were selected for congener and homolog fingerprinting to identify a source site. The results of this analysis stated that the source of the soil is herbicide manufacturing and consistent with the 2,3,7,8-TCDD identified for 80 and 120 Lister Avenue (PAS-00044302, 8-9).

(PAS-00080137)

Metals

Based on the Kroll Report, metals utilized by PPG in the production of paint at the facility were also detected in sediments adjacent to the site. Copper, lead, and mercury are all known to have been used at the site (PAS-00080139). The Kroll Report also states that copper was detected at a maximum concentration of 794 mg/kg from sample location 90 at a depth of 22 inches; lead was detected at a maximum concentration of 1050 mg/kg from sample location 90 at a depth of 46 inches; and, mercury was detected at a maximum concentration of 16.3 mg/kg from sample location 90 at a depth of 22 inches (PAS-00080140).

8. Summary of Asserted Defenses

No legal defenses were identified in the available file materials.

Facility Data Report

PUBLIC SERVICE ENTERPRISE GROUP (PSEG) SERVICES CORP
PUBLIC SERVICE ELECTRIC AND GAS
ESSEX GENERATING STATION

Facility Name, Address and Size: Essex Generating Station; 155 Raymond Blvd, Newark, New Jersey 07102. The PSE&G Essex Generating Station ranged in size over the years and currently occupies approximately 43 acres.

According to the *Discharge Prevention Containment and Countermeasure Plan and Discharge Cleanup and Removal Plan and Spill Prevention Control and Countermeasure Plan*, dated April 1999 and *PSEG Fossil LLC Essex Generating Station Discharge Prevention, Containment, and Countermeasure (DPCC) Plan and Discharge Cleanup and Removal (DCR) Plan and Spill Prevention, Control, and Countermeasure (SPCC) Plan* (SPCC Plan), amended January 2011, the Essex Generating Station occupied approximately 46 acres of land (PAP-00131917).

According to a March 12, 1975 Waste Effluent Survey, the Essex Generating Station had 200 employees working three shifts a day, seven days a week. [Note: This survey listed the acreage as 61 acres.] (PAP-00130792).

According to an August 9, 1988 *Questionnaire for Potential Large Commercial Users*, there were zero full time employees at the Essex Generating Station and that employees "remote report" from the Kearny Generating Station (PAP-00130886).

According to a June 30, 1989 Passaic Valley Sewerage Commission (PVSC) sewer connection application there were 10 full time employees working three shifts a day 365 days a year (PAP-00130915).

According to an August 6, 1990, letter transmitting an application to renew Permit No. NJ0000639, the Essex Generating Station was essentially an unmanned facility; the Manager of the Kearny Generating Station and his staff had overall responsibility for the operations at Essex (PAP-00132110).

1. **Business Type:** Electric generating plant (PAP-00130792).

2. **Time Period of Ownership/Operations:**

   Operator: 1915 to Present (PAP-00131333)
   Owner: 1915 to Present (PAP-00354146)

   The following figure from the *Response to USEPA April 30, 1996 Request for Information Essex Generating Station*, dated August 13, 1996 summarizes the various transactions pertaining to the ownership of the site:

(PAP-00354363)

According to the *Response to USEPA April 30, 1996 Request for Information Essex Generating Station*, dated August 13, 1996, in 1973, an Amerada Hess Corporation underground fuel oil pipeline, originating at Hess' Bayonne terminal was installed under the site and placed into service. The Hess Oil Company owned and operated the pipe and held two easements related to the site, dated 1973 and 1977 (PAP-00354207).

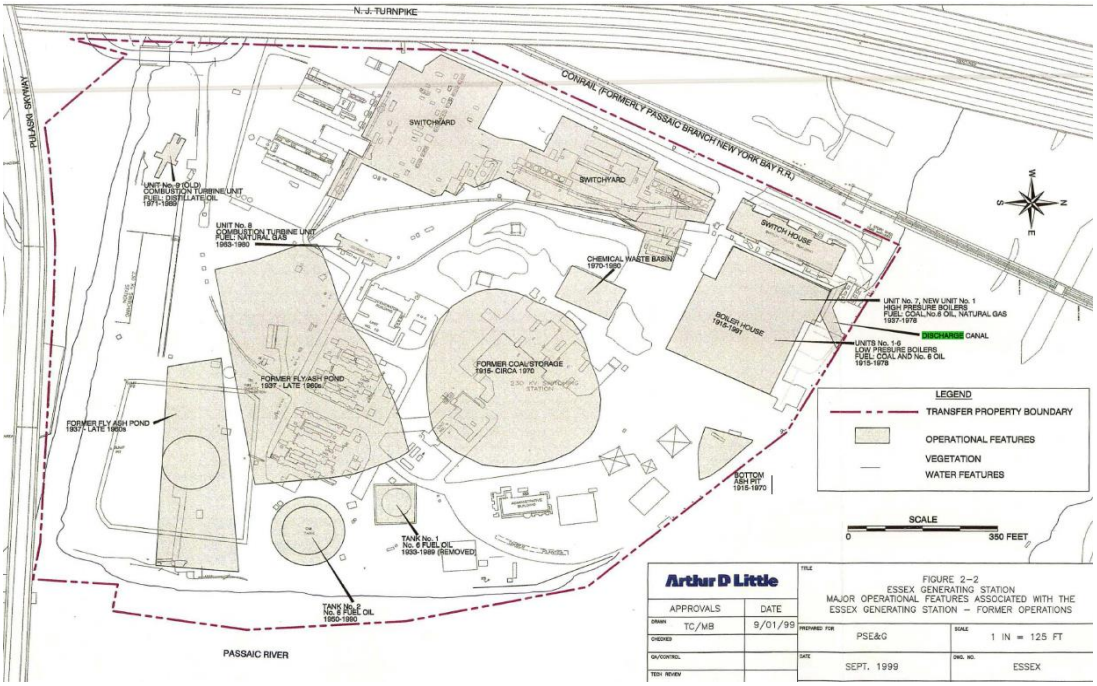
3. Operational History/COC Use and Presence at the Facility

According to a *Public Service Electric and Gas Company Essex Generating Station Remedial Action Report*, dated July 1995, PSE&G has been generating electricity at the Essex Generating Station since 1915. In 1995, electricity was produced by four combustion turbine generators that were fueled by either kerosene or natural gas. Natural gas was the primary fuel; kerosene was used as a secondary fuel. Kerosene used for the operation of the combustion turbine generators was stored in an aboveground storage tank located on-site (PAP-00131333).

According to the *Essex Generating Station Assessment*, prepared in September 1999 by Arthur D. Little, the Station began commercial operation in 1915 using two low-pressure turbine generators powered by four low-pressure coal-burning boilers. By 1924, the Station added 20 low-pressure coal-burning boilers and four low-pressure turbine generators. The coal for the boilers was stored in a coal pile located in the approximate center of the property. The low-pressure coal-burning boilers produced bottom ash as a byproduct. This ash was quenched, crushed, and transferred via small rail cars to a wood lined concrete ash pit at the north end of the Station, referred to as the bottom ash pit. The ash was allowed to settle. Decant water was routed to the Passaic River. Settled bottom ash was transported off-site for beneficial commercial use, transported to the Kearny Generating Station and used as fill, or used on the Essex Station property as fill. Twelve low-pressure boilers and one low-pressure turbine generator were removed from service and removed from the property between 1937 and 1946. The remaining low pressure units ceased burning coal in 1966, but continued in service using No. 6 fuel oil (PAP-00132578-79).

In 1937, the electric generating capacity of the station was increased with the addition of one high-pressure turbine generator powered by two high-pressure boilers that were designed to burn either coal or No. 6 fuel oil. Another high-pressure turbine generator and a high-pressure boiler were installed in 1947. This unit was designed to burn coal, No. 6 fuel oil, or natural gas. The high-pressure coal-burning boilers also produced bottom ash and fly ash. Production of ash ended in approximately 1966 when the Station stopped using coal and began burning No. 6 fuel oil on a full-time basis. In the early 1970s, the Station began a phase-out of its steam-powered electric generation. The low-pressure and high-pressure units were completely removed from service in 1978 and were demolished in 1991 (PAP-00132579).

In 1970, a 5.4 million-gallon above ground storage tank was installed in the location of the former fly ash ponds to store distillate oil for use in the combustion turbine units. Oil-burning combustion turbine units have automatic purge oil collection systems to collect unburned fuel that remains in the engine each time a unit is shut down. The system typically collects less than five gallons of fuel each time a unit shuts down. The original collection system consisted of 275-gallon underground tanks and associated valves and piping. In the early 1990s, these purge oil tanks were replaced with new tanks that are contained in underground concrete vaults (PAP-00132579-80).



The following figure from the *Essex Generating Station Assessment*, prepared in September 1999 by Arthur D. Little shows the major operational features associated with the Essex Generating Station former operations (PAP-00132596):

Facility Data Report

The following figure from the *Essex Generating Station Assessment*, prepared in September 1999 by Arthur D. Little shows the major operational features associated with the Essex Generating Station operations as of 1999 (PAP-00132598):

The following figure from the SPCC Plan, amended January 2011, shows the site layout as of August 2010. Note that the cross-hatched areas are under the jurisdiction of PSE&G.

(PAP-00354933)

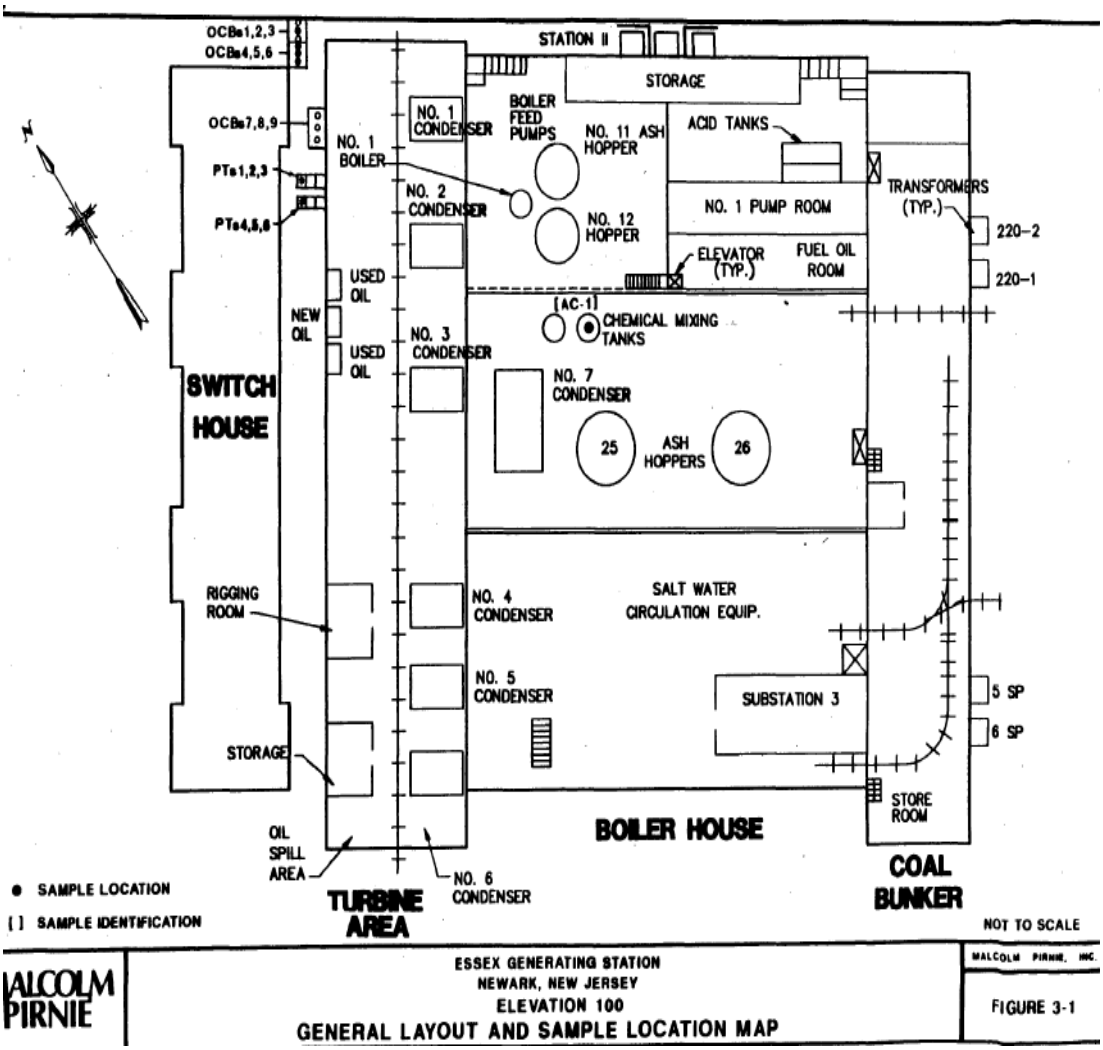
4. Identified COCs

- PCBs (used, generated, released)
- Dioxins (detected)
- PAHs (used, generated, released)
- Copper (detected)
- Lead (used, detected)
- Mercury (used, released)

PCBs

According to the *Environmental Documentation of Demolition Phase 3 Report, Essex Generating Station*, dated June 1993, during the structural demolition of the decommissioned Essex Generating Station a battery of six oil circuit breakers was observed located bordering the eastern wall of the switch house at the north end of the unpaved area, located between the switch house and turbine area. Three additional oil circuit breakers were also located in this alleyway adjacent to the turbine building (PAP-PAP-00726575). PCBs were detected in many of the drums of oil that were drained from pieces of electrical equipment (i.e., oil circuit breakers) (PAP-00726563).

Sampling of the oil removed from the oil circuit breakers revealed PCB concentrations from 6 ppm to 33,000 ppm. Seven soil samples were also collected below six of the Oil Circuit Breakers. Four of the samples contained PCBs ranging from 170 to 730 µg/kg. The remaining three oil circuit breakers were determined to contain less than 2 ppm PCBs; accordingly no additional soil samples were collected. The interim soil action level for PCBs used by NJDEPE at the time was 1,000 to 5,000 µg/kg. As none of the samples contained PCBs at these concentrations, no further sampling was recommended for this area (PAP-00726575-76).



Diamond Alkali OU2 Allocation

ADR Confidential

Facility Data Report

According to the *Environmental Documentation of Demolition Phase 3 Report, Essex Generating Station,* during the structural demolition of the decommissioned Essex Generating Station concrete surfaces located within two areas of the Essex Generating Station were observed to be oil stained. These areas were the concrete floor in the turbine building; and the two underlying concrete slabs where the oil pots containing percent levels of PCBs were removed from the potential transformer cabinets. No PCBs were detected in the samples collected within the building. The sample collected below potential transformer 1 contained 13,000 ppm of PCBs, and the sample collected below potential transformer 4 contained 60 ppm. In August 1992, a temporary enclosure was erected around the concrete slabs and the top three inches of the slabs were scarified and drummed (PAP-00726577).

The following figure from the *Environmental Documentation of Demolition Phase 3 Report, Essex Generating Station* shows the locations of the oil circuit breakers (labeled "OCB" on figure) and potential transformers (labeled "PT" on figure):

(PAP-00726585)

According to the SPCC Plan, dated April 1999, the regulated substances and wastes used, stored, handled, and transferred at Essex Generating Station included dielectric fluid (PAP-00131919). [Note: PCBs may be present in dielectric fluid.]

A mineral oil leak from a transformer, located hundreds of feet from the Passaic River or Lawyer's Ditch, occurred on September 16-17, 1993. No discharge to the Passaic River occurred. The mineral oil from the transformer and from the spill area was analyzed and shown to contain 10-11 ppm PCBs. It was estimated that 900 gallons of mineral oil were discharged to the gravel/soil beneath the transformer. Public Service implemented a remedial program, including removal and off-site disposal of all impacted soils (213 tons; soil PCB levels unknown), under NJDEP oversight. Post-excavation soil samples for total petroleum hydrocarbons and polynuclear aromatic hydrocarbons (PAHs) showed the contaminated soil had been removed to Residential Direct Contact Soil Cleanup Criteria (RDCSCC). However, the post-excavation samples were not analyzed for PCBs (PAP-00354243; PAP-00354017, 20-24, 45, 47). PSE&G received a No Further Action in June 1996 (PAP-00354243).

According to correspondence and *Discharge Confirmation Report*, dated September 16, 2005, on August 18, 2005, a discharge was reported in the PSE&G switchyard located on the Essex Generating Station with the probable sources of the discharge being three recently removed 26-KVA oil-filled reactors (Circuit D368). The release involved di-electric mineral oil. It was noted that it was unclear how much dielectric fluid was discharged. PSE&G believed the release was historic, and that the fluid may have been released from a leak in the reactors over a period of time. No sampling was conducted. All impacted bluestone and soil were removed to a depth beyond the level of visual impact. Further, all impacted bluestone was replaced to reestablish the secondary containment area (PAP-00133603-605). [Note: PCBs may be present in dielectric fluid.]

Dioxins

According to the Environmental Screening Study for the New Jersey Turnpike, Eastern Spur, Milepost 107.2 to 108.5, from Louis Berger & Associates, Inc. to the New Jersey Turnpike Authority dated January 1991, the Passaic River bed was dredged in the early 1960s, and the dredged materials were deposited on the river bank, as well as on New Jersey Turnpike Authority property, north of the Passaic River, between the river and Harrison Avenue. Dioxin concentrations from samples taken in 1991 beneath the New Jersey Turnpike bridge ranged from non-detect to 3.2 ppb. In the early to mid-1960s, the river bed was dredged and the dredged materials were deposited on the river bank. In 1960, the New Jersey Turnpike Authority granted approval to Gahagan and Bryan Associates to deposit dredged material on Turnpike property, north of the Passaic River, between River and Harrison Avenue. It is uncertain whether any dredged material was deposited on Turnpike property between the transcontinental pipeline located west of the Turnpike's western spur and the New Jersey Turnpike. Additionally, in 1965, the Authority granted permission to the Public Service Electric and Gas Company for the installation of a temporary dredge pipeline on Turnpike Property in order to pump mud to a disposal area located on Newark Paraffin Company property, on the west side of the Turnpike. The material was presumed to be from a submarine trench that may have contained dioxin (PAS-00013528-39, 47).

According to the *Potential PCB Sources to PRSA*, prepared for Chemical Land Holdings, the area where the dioxin was detected was reported to be part of the PSE&G Essex Generating Station property until at least 1965 (PAS-00124558). There are no citations or available underlying documents to support these statements in the available file material.

PAHs

According to an *Essex Generating Station Assessment*, prepared in September 1999 by Arthur D. Little, the low-pressure coal-burning boilers produced bottom ash as a byproduct. Settled bottom ash was sometimes used on the Essex Station property as fill. Production of ash ended in approximately 1966 when the Essex Generating Station stopped using coal (PAP-00132578-79). [Note: Coal ash could be a source for PAHs.]

Also according to the *Response to USEPA April 30, 1996 Request for Information Essex Generating Station,* dated August 13, 1996, PAHs were potentially present in trace amounts in feedstock coal (PAP-00354270).

Soil sampling on the site has detected PAHs (PAP-00139798, 800, 802-803; PAP-00139963-74, 77-78; PAP-00131454-59, 61; PAP-00131719-24; PAP-00131794-801, 816-819; PAP-00132435-47, 52-61; PAP-00354578-82; PAP-00354627-28; PAP-00138506-30). See Section 7, Response Actions, for further information on PAH releases and detection.

Metals – Copper, Lead and Mercury

According to the *Environmental Documentation of Demolition Phase 3 Report, Essex Generating Station*, dated June 1993, during the structural demolition of the decommissioned Essex Generating Station, several Bailey steam gauges were located on the low pressure boilers which contained elemental mercury. During asbestos removal activities, the steam gauges were disturbed, and a small amount of the mercury was accidentally spilled on the floor inside the building. No notification was made since it was determined that the spill was less than the reportable mercury quantity, which is one pound. PSE&G immediately cleaned up the spilled mercury using a mercury spill cleanup kit. Gauge carcasses, mercury contaminated debris, and contaminated personal protective equipment (i.e., gloves, Tyveks) was drummed for disposal. Liquid mercury was drained into appropriate storage containers so that it could be recycled (PAP-00726576-77).

According to the *Response to USEPA April 30, 1996 Request for Information Essex Generating Station,* dated August 13, 1996, copper, lead, and mercury were potentially present in trace amounts in feedstock coal. Typical maximum concentrations of copper, lead, and mercury were reported as 160, 590, and 1.25 parts per million by weight, respectively (PAP-00354268-70).

A 2008 Community Right to Know Survey completed on February 25, 2009, listed solid lead as being located at the Essex Generating Station. The location was listed as “facility wide” (PAP-00135721).

Soil sampling on the site has detected copper, lead, and mercury (PAP-00139963-74, 77-78).

Historic Fill

The Allocation Team has determined that the facility site is located on regional Historic Fill as designated by the New Jersey Department of Environmental Protection (NJDEP).[1]

NJDEP has established that historic fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 contaminants of concern (COCs): PAHs, lead, copper, and mercury.[2] Accordingly, NJDEP technical requirements for property containing Historic Fill requires sampling for the EPA Target Compound List for PAHs and Target Analyte List for metals, including lead, copper, mercury, and the OU2 PAH COCs.[3] PAHs, lead, copper, and mercury are recognized by NJDEP to be constituents of Historic Fill at varying levels, not atypically at or exceeding residential soil standards.[4]

The levels of PAHs, copper, lead and mercury detected at the site in soils are presented in the table below (PAP-00139963-74; PAP-00132410; PAP-00131794-801).

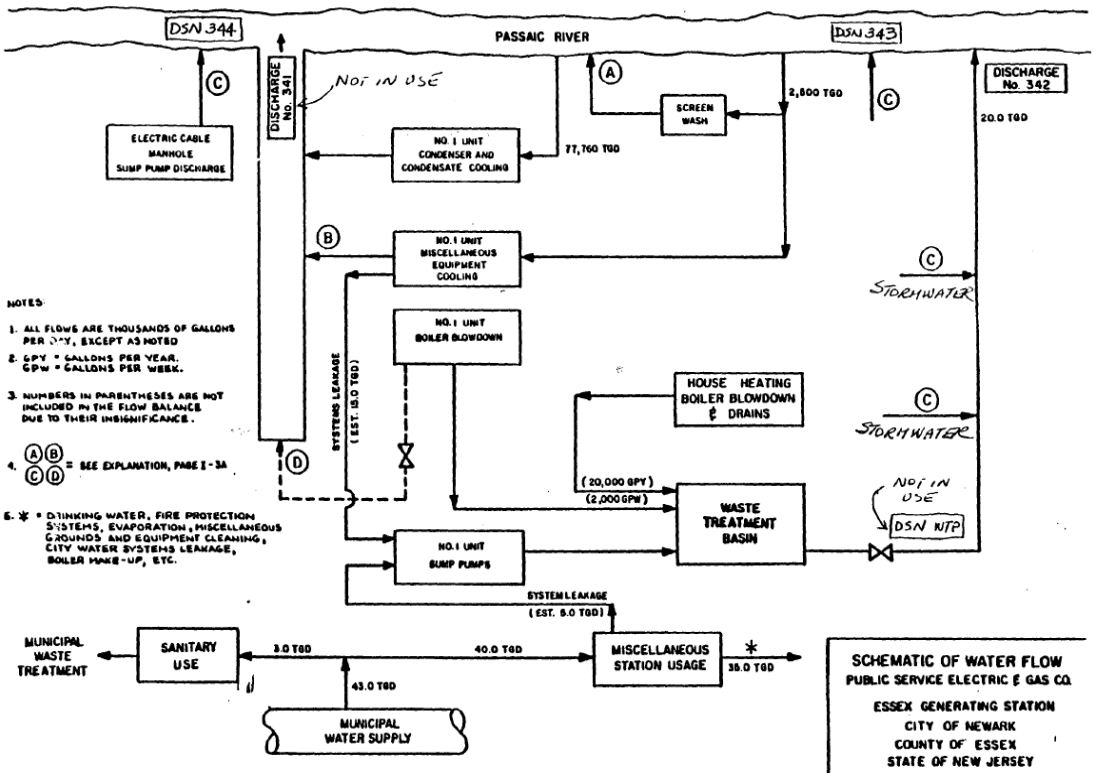
COCs Found in Onsite Soils	
COC	**Max Detected Concentration**
Lead	1,080 mg/kg
Copper	1,850 mg/kg
Mercury	3.5 mg/kg
Benzo(a)anthracene	12.0 mg/kg
Benzo(a)pyrene	8.4 mg/kg
Benzo(b)fluoranthene	7.8 mg/kg
Benzo(k)fluoranthene	3.7 mg/kg
Dibenzo(a,h)anthracene	0.81 mg/kg
Indeno(1,2,3-cd)pyrene	2.4 J mg/kg

[1] *Digital Geodata Series, DGS04-7, Historic Fill for New Jersey*, https://www.nj.gov/dep/njgs/geodata/dgs04-7.htm, Quadrangle #52 & #53 (NJDEP map identifying locations of recognized historic fill).

[2] *Characterization of Ambient Levels of Selected Metals and cPAHs In New Jersey Soils* (2002) and *Characterization of Ambient Levels of Selected Metals and Other Analytes In New Jersey Soils* (1997), studies prepared for NJDEP, Division of Science and Research, by BEM Systems, Inc.

[3] NJDEP, *N.J.A.C. 7:26E Technical Requirements for Site Remediation,* Table 4-2, November 2009 [Note that Table 4-2 has been deleted from the current version of N.J.A.C. 7:26E (May 7, 2012) and the updated *Historic Fill Technical Guidance* (April 2013) as NJDEP believed that the tables list of historic fill constituents was too restrictive].

[4] NJDEP Table 4-2 (PAHs and lead) and a summary of NJDEP records regarding investigations of properties in the vicinity of the Passaic River recognized to be located in areas of Historic Fill indicate that the following average/maximum (mg/kg) contamination levels of OU2 COCs exist in area Historic Fill: PAHs (1.91/160), lead (574/10,000), copper (11.2/1,200), and mercury (0.21/3.7).



According to a *Public Service Electric and Gas Company Essex Generating Station Remedial Action Report*, dated July 1995, the Essex Generating Station property was filled for industrial development circa 1915 (PAP-00131333).

According to the *Essex Generating Station Assessment,* prepared in September 1999 by Arthur D. Little, the soils at the station property are generally comprised of 10 to 12 feet of fill materials consisting of sand, gravel, silt, and clay with fragments of brick, glass, and metal debris. Below the fill materials are tidal marsh sediments composed of gray to black highly organic silts, meadow mat, and peat ranging in thickness from 7 to 20 feet (PAP-00132583).

According to the *Site Investigation Report for Area of Concern A,* dated December 2015, soils observed during the Site Investigation (SI) performed between June and September 2015 are generally consistent with the soils previously described. Fill material having a thickness of 4 to 10 feet consists of sand, gravel, silt, and clay with fragments of miscellaneous debris such as anthracite coal, glass slag, brick, wood, and crushed cinder slag (PAP-00139929).

5. COC Pathways

The September 10, 1985, Fact Sheet for a draft New Jersey Pollutant Discharge Elimination System (NJPDES) Permit No. NJ0000639 provided the following diagram showing the discharge points at the Essex Generating Station:

(PAP-00130856; PAP-00132175)

Sanitary Sewer

According to the *Response to USEPA April 30, 1996 Request for Information Essex Generating Station*, dated August 13, 1996, from 1917 through 1927 sanitary sewage consisting of wastes from cafeteria, bathrooms and showers was collected and transported via pipeline to a cistern. No information is available with respect to the specific character of the wastes and whether, and, if so, what treatment of the wastes was performed there. Available information states that the cistern discharged to the Passaic River. The cistern was abandoned in 1927. Sewage ejectors, receiving pits, sewage pumps and piping were installed and the station's sanitary sewer piping system was connected to the PVSC system. Thereafter, all sanitary sewage from the station was routed to the PVSC. Circa 1970, wastewater from the station's laundry was also routed to the PVSC (PAP-00354211-12, 28).

According to a March 12, 1975, Waste Effluent Survey, the Essex Generating Station discharged 0.015 x 10^9 gallons of water to the sanitary sewer system in 1974 (PAP-00130793). [Note: The constituent characteristics of the effluent were not provided in the source document.]

A March 13, 1975, letter concerning discharges to the Passaic River stated that the Essex Generating Station only discharged normal sanitation wastes into the municipal sewage system; no other wastes including industrial wastes were included (PAP-00130794).

According to a June 30, 1989, letter transmitting a PVSC sewer connection application, the production of electricity using a water cycle at the Essex Generating Station ceased on February 17, 1978, with the retirement of Essex No. 1 Unit. The current (as of 1989) combustion turbine process did not use water in the production of electricity and produced no discharge to the sewerage system (PAP-00130913).

Storm Sewer

According to a March 12, 1975 Waste Effluent Survey, the Essex Generating Station discharged 27.395 x 10^9 gallons of water to the “Storm sewer, River, or Ditch” in 1974 (PAP-00130793). [Note: The constituent characteristics of the effluent were not provided in the source document.]

According to the SPCC Plan, dated April 1999, Essex was issued a revised NJPDES Discharge to Surface Water (DSW) permit on July 1, 1995. The permit authorized the station to discharge treated stormwater, from various secondary containments, to the Passaic River. The primary components of treatment works for this NJPDES facility were a holding tank and an oil/water separator. The oil/water separator was needed to remove any residual oils that may be carried off the surface of the equipment during a storm event. The station was only required to use the oil/water separator when the concentration of petroleum hydrocarbons within the holding tank was in excess of 15 milligrams per liter (mg/L). Otherwise, the stormwater could be discharged directly to the Passaic River. As an alternative to processing contaminated stormwater on the

premises, the Plan stated that Essex may also send this stormwater off-site for treatment (PAP-00131922).

Direct Release

According to the *Response to USEPA April 30, 1996 Request for Information Essex Generating Station*, dated August 13, 1996, circa 1948, after New Unit No. 1 commenced commercial operations, non-contact cooling and wastewater effluents were managed for discharge by outfall to the Passaic River via the Discharge Canal Outfall as follows:

Turbine Room Discharges to Discharge Canal Outfall
Saltwater • Discharge and drains from # 1-6 Condensers. • Discharge and drains from # 11-12 Condensate Coolers. • Discharge and drains from #3-6 Generator Air Coolers. • Discharge and drains from #2-6 Turbo Air Pumps. • Discharge and drains from #6A Steam Jet Air Pump. • Discharge and drains from #2-6 Turbine Oil Cooler. • Discharge and drains from #7 Turbine H2 & Oil Coolers. • Cooling water and gland leak-off #2-6A Circulators. • Cooling water and gland leak-off #4-5-6 Saltwater Pumps. • Cooling water and gland leak-off #l-4-5 Air Compressors. • Sump pump and steam syphon discharges. [Note: The sump pump and steam syphon discharges were re-routed in 1959 directly to the Passaic River.] Condensate - City or Service Water • Seal catch-all drains # 11 & 12 Circulators. • Seal catch-all drains # 11 & 12 Condensate Pumps. • Seal catch-all drains #3 & 7 Saltwater Pumps. • Seal catch-all drains #2-6A Condensate Pumps. • Drain from # 1 Condenser Hotwell. • Overboard from #2-6A Condensate Pumps.
No. 2 Pump Room Discharges to Discharge Canal Outfall Indirectly via Station Sewer System
Saltwater • Cooling water #1-3 Primary Feedwater Pumps. • Cooling water #1-3 Secondary Feedwater Pumps. • Turbine seal evactor #1-3 Secondary Feedwater Pumps. • No. 16 Sump Pump and syphon. Condensate - City or Service Water • Gland leak-off catch-alls #1-3 Primary Feedwater Pumps. • Gland leak-off catch-alls #1-3 Secondary Feedwater Pumps: • Freeblows on steam headers. • Overboard and drain from #7 Open Drip Tank. • Overflow from #7 Turbine seals. • Steam Trap discharge from chemical mix tanks. • Overflow from #3 Station Hotwell. Boiler Water

Turbine Room Discharges to Discharge Canal Outfall
• Drains from #25 & 26 Boilers. Feedwater Treatment • Drains from #11-12 & Triplex Chemical Mix Tanks drain to sewer.
No. 3 Pump Room Discharges to Discharge Canal Outfall Indirectly via Station Sewer System
Saltwater • Cooling water #6-8 Boiler Feedwater Pumps. • Steam syphon from trench. • Discharge from steam header manifolds. Condensate • Gland leak-off catch-alls #6-9 Boiler Feedwater Pumps. • Drains from #6-9 Boiler Feedwater Pumps. • Overflow and drains #5-6-7 Open Heaters. • Overflow #3 Surge Tank. • Freeblows and traps from steam headers.
Fuel Oil Room Discharge To Discharge Canal Outfall Indirectly Via Station Sewer System
Saltwater • Cooling water #1-3 Fuel Oil Pump Reduction Gears. Condensate • L.P. Steam Traps on #1-3 Fuel Oil Pump Turbines.
Switch House Discharge To Discharge Canal Outfall Indirectly Via Station Sewer System
• Sump pump discharges condensate from steam traps and seepage. [Note: This line was rerouted directly to the Passaic River in 1959.]
Chlorine and Screen House Discharges to Discharge Canal Outfall
Saltwater • Wash water for Canal Screens. Condensate • Heating system traps.
No. 1 Unit - Elev. 100 Feet
Saltwater • Cooling water # 11-12-13 Mills. • Drain and overflow #11-12 Acid Cleaning Tanks. • Overflow from seal #11-12 Ash Tanks. Condensate • Catch-all drains #11-12-13 Boiler Feedwater Pumps. • Drain from #11 Drain Tank. • Drain from Condensate System. Boiler Water • Drains from #1 Boiler

(PAP-00354219-23)

[Note: The constituent characteristics of the effluents were not provided in the source document.]

According to the *Response to USEPA April 30, 1996 Request for Information Essex Generating Station*, dated August 13, 1996, circa 1948, the ash sluice trench was modified and the ash pit was removed from service. The modified ash sluice trench was tied directly to the ash pit overflow outfall. Wastewater effluents routed to this modified outfall included the following:

- Surface runoff
- Laundry effluent
- Boiler Nos. 25 and 26 sluiceway effluents included boiler seal water overflow and miscellaneous leakage from piping and valves
- Surface water runoff and spillage from the chemical unloading area
- Miscellaneous roof and floor drains (PAP-00354223-24)

According to the *Response to USEPA April 30, 1996 Request for Information Essex Generating Station*, dated August 13, 1996, the remaining outfalls included the Cable Vault Sump Pump Outfall which drained groundwater and surface water runoff in an electrical cable vault located in the northwest section of property; and the Ash Lake Overflow Outfall which drained overflow in the ash lake from ash sluice from No. 1, No. 25 and No. 26 boilers; and overflow in the ash lake from Air Heater Wash Water from No. 1, No. 25 and No. 26 boilers (PAP-00354224).

According to the *Response to USEPA April 30, 1996 Request for Information Essex Generating Station*, dated August 13, 1996, certain wastewater effluents were routed to a naturally occurring on-site drainage ditch which flowed to the Passaic River. Wastewater effluents routed to the drainage ditch included groundwater and surface water collections in the station's other electrical cable vault. Circa 1963, the following effluents were routed to the drainage ditch: boiler blowdown pit overflow, No. 8 combustion gas turbine building and equipment drain and non-contact cooling water, and surface water runoff (PAP-00354224-25).

According to the *Response to USEPA April 30, 1996 Request for Information Essex Generating Station*, dated August 13, 1996, circa 1970, the Essex Generating Station, modified certain processes associated with the management of cooling and wastewater effluents. The principal modification involved the installation of a 288,000-gallon chemical waste basin. The 288,000-gallon chemical waste basin was an above ground structure with a liner and a dike. The installation of the chemical waste basin coincided with the termination of use of coal as a fuel, and the removal of the ash lakes and ash lake overflow outfall from service at the Essex Generating Station. The basin discharge was routed to the former ash pit overflow outfall, Discharge Serial Number (DSN) 342. Certain wastewater effluents were re-routed to the basin for primary treatment prior to discharge to the Passaic River via DSN 342. These wastewater effluents included wastewaters from low pressure boiler blowdown, high pressure boiler air heater washes and high pressure boiler washes. In addition, spent cleaning solutions generated by the chemical cleaning of major equipment were no longer discharged to the Passaic River, but disposed off-site (PAP-00354225).

According to the *Essex Generating Station Assessment,* prepared in September 1999 by Arthur D. Little, the primary wastewater effluent generated at the station was non-contact cooling water, which was discharged to the discharge canal. The volume of this discharge varied over the life of the Station, but normal operation required a flow of greater than 500 million gallons per day. Since 1975, this discharge was authorized by the station's NPDES/NJPDES permit. Secondary wastewater effluents included ash sluice water and wastewaters from building sumps, floor drains, boiler blowdown, and boiler equipment cleanings. These effluents were of low volume, particularly as compared to the non-contact cooling water flow. In some cases, they were intermittent. Prior to circa 1970, with the exception of ash sluice water, these low-volume process wastewaters were routed to the discharge canal where they were commingled with non-contact cooling water prior to discharge to the river. From circa 1970 to 1978, the low-volume process wastewaters were routed to a chemical waste basin for neutralization prior to discharge to the discharge canal. After 1975, all wastewaters were discharged in accordance with the station's NPDES/NJPDES permit (PAP-00132582). By 1999, the only wastewater was stormwater collected from process areas. This stormwater was collected in a 20,000-gallon frac tank and disposed of off-site at an approved facility (PAP-00132582-83).

The *Passaic Valley Sewerage Commissioners Monthly Report* for January and February 1976 reported an incident in January 1976 in which Inspector McLaughlin, accompanied by Supervisor F. D'Ascensio, observed a maintenance crew from Public Service pumping a black oily liquid from a manhole near their Essex Generating Station to the ground where it flowed to Lawyer's Ditch, a tributary of the Passaic River (PAP-00130801-02; PAP-00130804; PAS-00006732-33; PAS-00007007; PAS-00035291-92). The report noted that the manhole from which liquid was pumped was 75 feet from Lawyer’s Ditch. On January 19, 1976, Mr. Rutledge of PSEG called Mr. D’Ascensio of the PVSC to explain that the normal PSE&G procedure for removing liquids from manholes was to pump the materials into a tank truck and subsequently treat it at an oil skimming facility. Additionally, Mr. Rutledge noted that Essex Generating Station employees were aware of this procedure and that the January 14th occurrence was caused by personnel from a different PSE&G facility, and that subsequent to the incident, all PSE&G personnel, had been notified of this procedure in writing (PAS-00006732).

According to the SPCC Plan, dated April 1999, a revised New Jersey Pollutant Discharge Elimination System (NJPDES) Discharge to Surface Water (DSW) permit issued on July 1, 1995 for Essex authorized discharge of treated stormwater, from various secondary containments, to the Passaic River. As an alternative to processing contaminated stormwater on the premises, Essex could send this stormwater off-site for treatment. In addition to the treatment pursuant to the NJPDES permit, stormwater in parts of Essex Station either sheet-flows to the Passaic River, or flows into a drainage ditch southwest of the Essex Station which ultimately discharges to the river (PAP-00131922).

Spills

In addition, according to the report *Potential PCB Sources to PRSA*, prepared for Chemical Land Holdings, dated December 2001, the analysis of a 1940 aerial photograph reportedly identified two discharges (locations not specified) from the site to the Passaic River (PAS-00124557). This was also reported in the undated *Sources of Hazardous Substances in the Passaic River Study* (PAS-00013509, 12). The source of this statement for both of these reports was the report *Historical Aerial Photography Analysis, PSE&G Essex Generating Station, Essex County, New Jersey*, dated February 24, 1995, which also concluded that "no other discharges of liquid into the Passaic River are recognized on any aerial photography studied for this report" (PAS-00013512). According to the *Annual Report by Chief Engineer S. A. Lubetkin to the Passaic Valley Sewerage Commissioners for the Year 1973,* on June 15, 1973, traces of fuel oil were noticed by PSE&G in the circulating water discharge canal. Investigation revealed that the oil came from the pipe trench in the fuel oil room, specifically from a leak in the oil reclaim tank, and it was estimated that approximately 20 gallons of No. 6 oil leaked to the river. The leaking oil for the most part was contained by a fuel oil barge that was moored at the station dock. The spill was reported at 11:15 a.m. to the U.S. Coast Guard, PVSC, U.S. Army Corps of Engineers, NJDEP and EPA were notified. Workmen from Coastal Services Inc. arrived at 11:40 a.m. and vacuumed the oil into a tank truck and removed oil stained rocks from the Passaic River bank approximately fifty yards downstream. The clean-up was completed by 1:45 P.M. the same day (PAS-00034760; PAS-00124558).

According to the *Annual Report by Chief Engineer S. A. Lubetkin to the Passaic Valley Sewerage Commissioners for Operations during the Year 1974,* on November 26, 1974 the PVSC received a call from the Chief Engineer of Public Service Essex Generating Station that the watchman had observed some oil going into the Passaic River at 12:30 P.M. on November 26, 1974. This was traced to a leak from a relief valve which allowed oil to enter the trench leading to their cooling water which discharged to the Passaic River. A boat with a float and absorbent pillows was launched to contain the oil while it was removed from the river. ·Both PVSC and U.S. Coast Guard were notified. PVSC inspected the premise on November 27, 1974, and the inspector reported the clean up as satisfactory (PAS-00034902). [Note: No estimate of the quantity spilled was given.]

According to the *Annual Report by Chief Engineer S. A. Lubetkin to the Passaic Valley Sewerage Commissioners for Operations during the Year 1975,* on June 11, 1975, PVSC received a call from Public Service about an oil spill in a ditch on their property leading to the Passaic River. The EPA and U.S. Coast Guard were also informed. Inspector McLaughlin investigated and saw a boom across the ditch with absorbent pads holding back and absorbing an oily film in a small ditch located approximately 300 feet west of the N.J. Turnpike. In the vicinity were four 5-gallon cans with remains of a petroleum type liquid which had apparently been dumped into the ditch. In addition, about 50 feet away was another area where oil had been dumped and flowed into the ditch. Investigation revealed that the latter dump could be attributed to a PSE&G tank truck working with Electric Transmission Distribution Division, which had pumped water from a Public Service manhole at 400 Market Street, Newark. When the dump was made they realized the liquid also contained oil and gasoline. They were investigating a

possible underground leak from a nearby gasoline station. Clean-up was completed June 13, 1975. As per the PVSC request, residue from the manhole cleaning truck was discharged into existing skimming facilities located at Irvington and Roseland. This was confirmed in a letter from Public Service dated June 19, 1975 (PAS-00035072). [Note: No estimate of the total quantity spilled was given.]

The *Passaic Valley Sewerage Commissioners Monthly Report for January and February 1976* reported an incident in January 1976 in which Inspector McLaughlin, accompanied by Supervisor F. D'Ascensio, observed a maintenance crew from Public Service pumping a black oily liquid from a manhole near their Essex Generating Station to the ground where it flowed to Lawyer's Ditch, a tributary of the Passaic River (PAP-00130801-02, PAP-00130804; PAS-00007007; PAS-00035291-92). The report noted that the manhole from which liquid was pumped was 75 feet from Lawyer's Ditch (PAS-00006732). On January 19, 1976, Mr. Rutledge of PSE&G called Mr. D'Ascensio of the PVSC to explain that the normal PSE&G procedure for removing liquids from manholes was to pump the materials into a tank truck and subsequently treat it at an oil skimming facility. Additionally, Mr. Rutledge noted that Essex Generating Station employees were aware of this procedure and that the January 14th occurrence was caused by personnel from a different PSE&G facility, and that subsequent to the incident, all PSEG personnel, had been notified of this procedure in writing (PAS-00006732).

On November 2, 1989, NJDEP issued a Duty Officer Notification Report documenting a spill of 800 gallons of mineral oil at the Essex Generating Station (PAP-00130937). Note: The report stated contamination of land and not water. Similarly, a Duty Officer Notification Report from June 4, 1990 stated that a leak of 200 gallons of No. 2 fuel oil was contained within the containment dike area (PAP-00130938). Further, the November 2, 1989 report states that the spill was terminated and spilled substance was contained (PAP-00130937).

According to a September 25, 1992, amendment to the application to renew NJPDES-DSW Permit No. NJ0000639, the amendment addressed a pump and treat surface water discharge to the Passaic River which resulted from a groundwater remediation project at Essex. On January 28, 1991, an underground fuel transfer line at Essex developed a leak, resulting in the discharge of kerosene to the local ground and surface waters. On May 5, 1992, PSE&G and the DHWM concurred that the operation of the pump and treat system should be discontinued pending a review of the most recent well sample data. This concurrence was followed on May 12, 1992 by a request by PSE&G to permanently terminate the pump and treat operation at Essex due to a significant reduction in the levels of pollutants in the groundwater over time. A response from the DHWM was pending the review of well sample data for the month of August 1992 (PAP-00131058; PAP-00132118).

Correspondence dated December 8, 1992, and an undated *Discharge Confirmation Report* reported that on November 24, 1992, PSE&G Essex Generating Station reported a discharge of approximately 3,000 gallons of kerosene to the ground. The soils which came in contact with the product were removed and disposed of in accordance with applicable regulations (PAP-00131140-45). The documents do not state that the spill reached the Passaic River. The discharge confirmation report provided to the NJDEP

states that the cleanup began within hours of the reported spill and was completed the following day. The report states that "[a]reas where product made contact with the soil were removed and placed into an onsite oily waste dumpster for future disposal. Liquid waste was placed in storage on the hazardous waste pad for future disposal at an approved TSDF" (PAP-00131142).

In November 1992, sixteen purge oil USTs were removed (each designated as an AOC #1-16), and a discharge was discovered (PAP-00132404). An *Underground Storage Tank Site Assessment Summary*, dated April 1, 1993, documented a diesel fuel discharge which resulted in contamination of the ground. Sampling was conducted and 292,700 ppb of base-neutral compounds were still in the ground (PAP-00131209-11). [Note: The specific base-neutral compounds detected were not provided.]

A mineral oil leak from a transformer, located hundreds of feet from the Passaic River or Lawyer's Ditch, occurred on September 16-17, 1993. The cited document states no discharge to the Passaic River occurred. The mineral oil from the transformer and from the spill area was analyzed and shown to contain 10-11 ppm PCBs. It was estimated that 900 gallons of mineral oil were discharged to the gravel/soil beneath the transformer. Public Service implemented a remedial program, including removal and off-site disposal of all impacted soils (213 tons; soil PCB levels unknown), under NJDEP oversight (PAP-00354243; PAP-00354017, 20-24, 45, 47). No Further Action was approved in June 1996 for this spill (PAP-00354243).

Correspondence dated May 26, 1995, submitted a Confirmation Report for Case No. 95-5-3-1312-02 documenting a historical spill at the Essex Generating Station. The spill involved turbine lubricating oil and was reported on May 3, 1995. The area of concern was located near the center of the site, distant from the Passaic River (PAP-00131412). The Unit No. 9 Gas Turbine Generator had been decommissioned after a fire in 1988 (it had operated from 1971 until 1988); while the turbine section was decommissioned, the generating section remained, but was inactive. The generator section was left intact on top of a concrete foundation. On April 26, 1995, PSE&G personnel discovered oil in a vault located in the northeastern comer of the unit's concrete foundation. On April 27, 1995 and May 2, 1995, PSEG personnel and its consultants discovered that the soil beneath the foundation had settled, creating a void where the oil collected. The cited document states "PSE&G experts have posited that the oil was discharged from the unit's lubricating oil storage tank, which had previously been dismantled and removed" (PAP-00131411-12). Reportedly 2,845 gallons of product had been removed with about ¼-inch remaining (PAP-00139670-71). PSE&G had a sample of the discharged oil analyzed. COCs which were detected in the oil included acenaphthene at 80,000 μg/kg, fluorene at 18,000 μg/kg, fluoranthene at 26,000 μg/kg, and pyrene at 70,000 μg/kg (PAP-00139692-93). The soil remediation of both the lubricating oil and kerosene oil areas was deemed complete as of November 1995 when TPH concentrations were below 10,000 ppm and all VOCs and PAHs met the NJDEP RSCC (PAP-00131413-14). An NFA was issued for this remediation in March 2012 (PAP-00139729).

According to correspondence and attached *Discharge Confirmation Report*, dated September 16, 2005, on August 18, 2005, a discharge was reported in the PSE&G switchyard located on the Essex Generating Station with the probable sources of the discharge being three-recently removed 26-KVA oil-filled reactors (Circuit D368). The release involved di-electric mineral oil. It was noted that it was unclear how much dielectric fluid was discharged. PSE&G believed the release was historic, and that the fluid may have been released from a leak in the reactors over a period of time. Underlying gravel and soil was removed to a depth where visually it was not impacted. The total volume of material removed was approximately 30 cubic yards, or 19,000 kilograms. No sampling was conducted because, according to PSE&G, all impacted bluestone and soil were removed to a depth beyond the level of visual impact (PAP-00133603-605). [Note: PCBs may be present in dielectric fluid.]

On March 5, 2009, PSE&G submitted a *Historical Fuel Oil Discharge Notification* to NJDEP for oily soil discovered on February 25, 2009, during excavation activities on the Essex site. Immediate containment measures were implemented followed by cleanup and removal activities. It was reported that oil was immobilized within the soil, never entering the waters of the state or migrating off-site. PSE&G attributed the source to underground kerosene lines which had been removed prior to 1978 and this discharge could only have occurred prior to January 23, 1980 (PAP-00135754).

According to the *Preliminary Assessment Report for Historical Kerosene Discharge*, dated September 2010, oily soil was discovered on February 25, 2009, during excavation activities on the Essex site. The discharge occurred at the southeast corner of Generator Unit No. 11. Generator Unit No. 11 is located in the central portion of the property. The area where visually impacted soil was observed was approximately 30 feet long by 10 feet wide to a depth of 4 feet. An inquiry was conducted to identify the source of the oil. It was found that underground kerosene piping was situated in the vicinity of the excavation area. This piping was removed prior to 1978 and replaced with above ground piping. The above ground kerosene piping was in excellent condition, with no sign of leakage and inspected regularly by operators during their environmental rounds. As there was no other known potential source of the discharge, Essex asserted that the underground kerosene lines were the source of the discharge discovered during excavation on February 25, 2009 and this discharge could only have occurred prior to January 23, 1980. Following the discovery, work in the vicinity of the discharge was stopped and immediate containment measures were implemented, followed by cleanup and removal activities. A Case number for this spill was not assigned; the site was referred to as AOC-1 (PAP-00136876, 86, 96, 98). [Note: This appears to be the same spill described in the March 2009 *Historical Fuel Oil Discharge Notification*.]

According to the SPCC Plan, dated April 1999, potential off-site discharge points from Essex which could be impacted from potential spill events included Lawyers Ditch and the Passaic River. The Plan described the potential spill events as pipeline failure, Tank No. 3 failure, truck unloading area spill, or a transformer leak (PAP-00131981).

The SPCC Plan, amended January 2011, reported the following spills which may have involved COCs (PAP-00355050-51):

Diamond Alkali OU2 Allocation

ADR Confidential

Facility Data Report

Spills				
Substance	**Date**	**Quantity**	**Location**	**Corrective Actions Taken**
Oily water	1/31/2009	~150 gallons	Construction Excavation-site	Vacuum trucks used, oily gravel removed and taken off-site for disposal.
Oily soaked soil	2/25/2009	Unknown (Historic spill)	Former underground kerosene piping	Contaminated soil was excavated and disposed. Cleanup and removal activities were implemented. Upon sampling soil and groundwater in 2012, no contaminants associated with the historical kerosene discharge were identified. An unrestricted response action outcome was recommended (PAP-00139753).
Oil Water	2/26/2009	<1 gallon	Unit No. 9 Fuel Oil Filter secondary containment area	Oily water was pumped out of the containment and the surround gravel was excavated and removed
Oil	1/3/2010	40 gallons	Unit No. 10 sensing line	Oil was vacuumed out of the engine compartment and oil the contaminated gravel was excavated, placed inside drums and removed.
Oil	5/4/2010	1 quart	PSE&G Transmission & Distribution Oil Circuit Breakers (OCBs) located on-site	Contaminated gravel was excavated and removed. A secondary containment was installed around the OCB.
Dielectric Fluid for Transformer	10/5/2010	½ gallon	Spill on asphalt surface	Speedy dry placed on area. Area swept and speedy dry was placed in a drum and taken off-site.
Dielectric Fluid from a Pole Top Transformer	10/26/2010	40 gallons	Parking lot	Drains were blocked to prevent the escape of fluid. Speedy dry and absorbent pads were used to soak up oil. Waste material was taken off-site for disposal.
Oil	3/12/2011	10 gallons	Inside new product storage area	This leak was inside a secondary containment. The leaked product was cleanup up and disposed of.
Lube Oil	4/14/2011	10 gallons	Unit No. 9 Lube Cooler Head	Vacuum truck used to remove freestanding product. Absorbent pads and speedy dry was used to soak up the liquid.

6. Regulatory History/Enforcement Actions

Inspections

The *Passaic Valley Sewerage Commissioners Monthly Report for January and February 1976* reported an incident in January 1976 in which Inspector McLaughlin, accompanied by Supervisor F. D'Ascensio, observed a maintenance crew from Public Service pumping a black oily liquid from a manhole near their Essex Generating Station to the ground where it flowed to Lawyer's Ditch, a tributary of the Passaic River (PAP-00130801-02, PAP-00130804; PAS-00006732-33; PAS-00007007; PAS-00035291-92). The report noted that the manhole from which liquid was pumped was 75 feet from Lawyer's Ditch (PAS-00006732).

On January 19, 1976, Mr. Rutledge of PSE&G called Mr. D'Ascensio of the PVSC to explain that the normal PSE&G procedure for removing liquids from manholes was to pump the materials into a tank truck and subsequently treat it at an oil skimming facility. Additionally, Mr. Rutledge noted that Essex Generating Station employees were aware of this procedure and that the January 14th occurrence was caused by personnel from a different PSE&G facility, and that subsequent to the incident, all PSE&G personnel, had been notified of this procedure in writing (PAS-00006732).

On February 23, 1991, NJDEP investigated the Essex Generating Station as follow-up to the January 28, 1991 discharge of kerosene from a leaking underground fill line. It was noted that 125 gallons of product had been recovered February 22, 1991. It was also noted that there was an area approximately 10-12 feet wide where some light discharge was still occurring. This was being addressed through the use of absorbent sweep pads. An inspection of the ends of the boom showed no accumulation of escaping product and only an occasional sheen was observed outside the boom (PAP-00131046-47). The February 23, 1991 NJDEP Investigation report stated that "Any product that continued to discharge into the river through the shoreline was captured by absorbent booms placed in the water. A hard boom was placed beyond that to trap anything that escaped the absorbent boom." (PAP-00131046-47). NJDEP issued an NOV requiring PSE&G to implement a remedial action program for the incident. This NOV was resolved by entering into a Memorandum of Agreement (MOA), pursuant to which a site remediation program was implemented. This program included media characterization, excavation and off-site disposal of contaminated soils and a groundwater recovery and monitoring program. PSE&G completed the site remedial program and the NJDEP issued PSE&G a No Further Action Letter in June 1994 (PAP-00354241).

Violations

According to the *Annual Report by Chief Engineer S. A. Lubetkin to the Passaic Valley Sewerage Commissioners for the Year 1973,* on June 15, 1973 traces of fuel oil were noticed by PSE&G in the circulating water discharge canal. Investigation revealed that the oil came from a leak in the oil reclaim tank, and it was estimated that approximately 20 gallons of No. 6 oil leaked to the river. The leaking oil for the most part was contained by a fuel oil barge that was moored at the station dock. The U.S. Coast Guard, PVSC, U.S. Army Corps of Engineers, NJDEP and EPA were notified. Workmen

vacuumed the oil into a tank truck and removed oil stained rocks from the Passaic River bank approximately fifty yards downstream. The clean-up was completed 1:45 P.M. the same day (PAS-00034760).

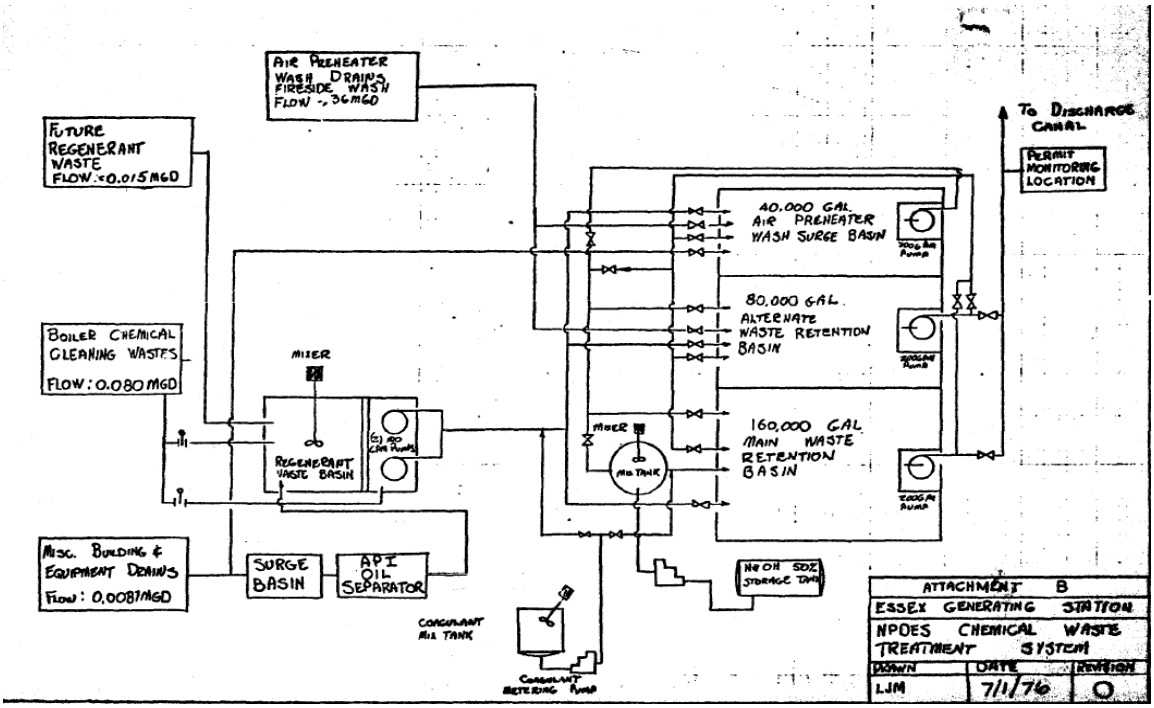
According to the *Annual Report by Chief Engineer S. A. Lubetkin to the Passaic Valley Sewerage Commissioners for Operations during the Year 1974,* on November 26, 1974 the PVSC received a call from the Chief Engineer of Public Service Essex Generating Station that the watchman had observed some oil going into the Passaic River at 12:30 PM on November 26, 1974. This was traced to a leak from a relief valve which allowed oil to enter the trench leading to their cooling water which discharged to the Passaic River. A boat with a float and absorbent pillows was launched to contain the oil while it was removed from the river. ·Both PVSC and U.S. Coast Guard were notified. PVSC inspected the premise on November 27, 1974 and the inspector reported the clean up as satisfactory (PAS-00034902). [Note: No estimate of the quantity spilled was given.]

According to the *Annual Report by Chief Engineer S. A. Lubetkin to the Passaic Valley Sewerage Commissioners for Operations during the Year 1975,* on June 11, 1975 PVSC received a call from Public Service about an oil spill in a ditch on their property leading to the Passaic River. The EPA and U.S. Coast Guard were also informed. Inspector McLaughlin investigated and saw a boom across the ditch with absorbent pads holding back and absorbing an oily film in a small ditch located approximately 300 feet west of the N.J. Turnpike. In the vicinity were four 5-gallon cans with remains of a petroleum type liquid which had apparently been dumped into the ditch. Note: The Report does not in any way attribute this spill to PSE&G or its operations. In addition, about 50 feet away was another area where oil had been dumped and flowed into the ditch. Investigation revealed that the latter dump could be attributed to a PSE&G tank truck working with Electric Transmission Distribution Division, which had pumped water from a Public Service manhole at 400 Market Street, Newark. When the dump was made they realized the liquid also contained oil and gasoline. They were investigating a possible underground leak from a nearby gasoline station. Clean-up was completed June 13, 1975. As per the PVSC request, residue from the manhole cleaning truck was discharged into existing skimming facilities located at Irvington and Roseland. This was confirmed in a letter from Public Service dated June 19, 1975 (PAS-00035072). Note: No estimate of the total quantity spilled was given.

In January 1991, PSEG was issued a *Notice of Violation* by the NJDEP for the January 28, 1991 discharge of kerosene from a leaking underground fill line at its Essex Generating Station at 155 Raymond Blvd. (PAP-00131028-29; PAP-00131033; PAP-00131037). A citizen report to the NJDEP the same day and NJ State Police report on February 2, 1991, reported oil sheen on the Passaic River (PAP-00131038-39). On February 4, 1991, NJ State Police issued Summons No. 55756 to PSE&G, Essex Generating Station for the kerosene pollution (PAP-00131040; PAP-00131041). A February 14, 1991, letter from PSE&G to NJDEP discussing the initial and follow on response to the spill stated that 10,700 gallons of the calculated maximum of 13,000 gallons had been recovered (PAP-00131043). A second phase of the remediation was being commenced to address remaining free product. NJDEP issued an NOV requiring PSE&G to implement a remedial action program for the incident. This NOV was resolved by entering into an MOA, pursuant to which a site remediation program was

implemented. This program included media characterization, excavation and off-site disposal of contaminated soils and a groundwater recovery and monitoring program. PSE&G completed the site remedial program and the NJDEP issued PSE&G a No Further Action Letter in June 1994 (PAP-00354241).

Permits



PSE&G Essex Generating Station Permit Summary				
Permit No.	**Issued**	**Use**	**Dates**	**Discharge Limits**
NJ0000639	EPA	All discharges	January 31, 1975 to January 3, 1980	Beginning July 1, 1977: Daily maximum of 1.0 mg/L for total copper and 20 mg/L for oil & grease. The daily average limitation for oil & grease was 15 mg/L.
On July 31, 1979 (revised February 4, 1980) PSE&G submitted an Application to renew Permit NJ0000639. Note: The actual permit was not provided.				
NJ0000639	EPA	All discharges	March 1, 1986 to February 28, 1991	Aldrin/dieldrin [0.0019 micrograms per liter (μg/L)], PCBs (0.03 μg/L), Dichlorodiphenyl-trichloroethane (DDT) and metabolites (0.001 μg/L), petroleum hydrocarbons (15 mg/L)
79-8-76 NJ0000639	NJDEP	Discharge Prevention, Containment	September 1, 1986 with no expiration date.	Not listed
91-01-28-1450	DHWM	Emergency discharge to surface water from treatment system	February 25, 1991, 90 day reauthorizations, last issued March 24, 1992.	Same as NJPDES-DSW NJ0000639
On August 6, 1990, Essex Generating Station filed an application to renew Permit No. NJ0000639. [Note: The actual permit was not provided.]				
NJ0000639	EPA	All discharges	July 1, 1995 to June 30, 2000	Petroleum hydrocarbons (15 mg/L)
On December 22, 1999, PSE&G submitted their application to renew NJPDES-DSW Permit No. NJ0000639. [Note: The actual permit was not provided.]				
NJ0000639	EPA	All discharges	June 1, 2004 to May 31, 2009	Petroleum hydrocarbons (15 mg/L)
Draft NJ0000639	EPA	All discharges	February 17, 2009 to Unknown	Petroleum hydrocarbons (15 mg/L)
NJ0000639	NJDEP	Stormwater discharges	July 1, 2009 to June 30, 2014	Petroleum hydrocarbons (15 mg/L)
Not applicable	NJDEP	Discharge of dewatering groundwater	180 calendar beginning on occurrence of discharge	Not listed

On December 30, 1974, the EPA issued NJPDES-DSW Permit No. NJ0000639 to Essex Generating Station. The permit authorized the Station to discharge to the Passaic River. The permit was effective from January 31, 1975 to January 3, 1980 (PAP-00130732). Discharge limitations for DSNs 341, 342A and 342B did not include that for any COCs (PAP-00130735-76). Discharge limitations for the waste treatment plant effluent beginning July 1, 1977, and lasting until the date of expiration included a daily maximum of 1.0 mg/L for total copper and 20 mg/L for oil & grease. The daily average limitation for oil & grease was 15 mg/L. The waste treatment plant effluent was noted to include low volume wastes, boiler blowdown and metal cleaning wastes (PAP-00130737).

According to the Engineering Report for Essex Generating Station Environmental Protection Agency National Pollutant Discharge Elimination System Permit No.: NJ 0000639 during the period beginning July 1, 1977, and lasting until the date of expiration for the permit the discharge limits for copper were as follows:

- DSN 342A (Air Heater Wash): 1.6 kg/wash or 3.6 lb/wash
- DSN 342B (Fireside Wash Water: 0.57 kg/wash or 1.25 lb/wash (PAP-00353613)

The discharge limitations for copper were previously 0.8 kg/wash or 1.8 lb/wash (PAP-00353612). An included diagram of the NPDES Chemical Waste Treatment System dated July 1, 1976 included the following flow rates: Air Preheater Wash Drains/Fireside Wash (0.36 MGD); Future Regenerant Waste (0.015 MGD); Boiler Chemical Cleaning Wastes (0.080 MGD); and Misc. Building and Equipment Drains (0.0081 MGD) (PAP-00353624).

(PAP-00353624)

On July 31, 1979 (revised February 4, 1980) PSE&G submitted an Application to renew Permit NJ0000639. The application was for two discharge points: DSN 341, main circulating water, and DSN 342, waste treatment basin discharge (PAP-00130818-43).

The water discharge rates were given as follows:

- Two Discharge Points to Surface Water: 80,265,000 gallons/day
- One Discharge Point to Sanitary Sewer: 3,000 gallons/day (PAP-00130820; PAP-00353627).

The July 31, 1979 (revised February 4, 1980) Application also stated that boiler drains periodically go to the discharge canal. This may occur once or twice during the proposed operational period. The volume of approximately 20,000 gallons was expected to contain less than 1.0 mg/L of copper (PAP-00130821). [Note: The actual permit was not provided.]

According to a March 31, 1985 *Fact Sheet* for Permit No. NJ0000639, the facility at the time had a permit to discharge stormwater through three outfalls, DSNs 342, 343, and 344; and treated groundwater through one outfall DSN 345T. However, the permittee no longer discharges stormwater through DSN 342,343, or 344. Instead, the permittee proposed to discharge stormwater that accumulated within secondary spill containment areas through a new outfall designated as outfall DSN 346. This permit action would simultaneously terminate outfalls DSN 342, 343, 344, and 345T and permit outfall DSN 346 in this permit renewal. DSN 346 would intermittently discharge an average of approximately 0.006 MGD of stormwater, once per week, to the Passaic River. When necessary, the stormwater was treated through an oil/water separator prior to discharge (PAP-00131288-89). The discharge limitation for petroleum hydrocarbons was 15 mg/L (PAP-00131291). [Note: No other discharge limitations were listed.]

On January 6, 1986, Essex Generating Station was issued NJPDES Final Permit No. NJ0000639. The permit took effect on March 1, 1986, and expired February 28, 1991 (PAP-00130859; PAP-00132139). The discharge limitation for petroleum hydrocarbons was 15 mg/L (PAP-00130877). Additional effluent discharge limitations included aldrin/dieldrin (0.0019 μg/L), PCBs (0.03 μg/L), DDT and metabolites (0.001 μg/L) (PAP-00130879; PAP-00132159).

On August 27, 1986, NJDEP issued to Essex Generating Station a Discharge Prevention, Containment and Countermeasure (DPCC) and Discharge Cleanup and Removal (DCR) Permit No 79-8-76 NJ0000639. The permit was effective beginning September 1, 1986, with no expiration date. It was noted that the permit did not relieve PSE&G from obligations to meet effluent limitations (PAP-00130881). [Note: No effluent limitations were listed.]

On August 3, 1990, Essex Generating Station filed an Application for Exemption for NJPDES Permit No. NJ0000639 retaining discharge No. 343 and terminating discharge Nos. 341, 342 and 344 which were no longer discharging as sections of the facility were no longer in service (PAP-00130986; PAP-00131000-02). Discharge No.343 was

described as untreated sump pump discharge from the basement of Essex's service building; this was untreated stormwater and river water that collected inside of the building. This discharge was only used in case of water ingress from heavy rains, high tide seepage through the walls, etc. Since this discharge was located in a remote section of an inactive building, it was rarely used. The last reported flow was 75 gallons on March 1988 (PAP-00131018).

On August 6, 1990, Essex Generating Station filed an application to renew Permit No. NJ0000639 which allowed the discharge of sump pump discharge from the basement of Essex's service building of untreated stormwater and river water that collected inside the building into the Passaic River (PAP-00130989; PAP-00132110). On September 24, 1992, Essex Generating Station requested an endorsement from PVSC for an amendment adding two additional sources; a proposed surface water discharge of stormwater collected from existing on-site secondary containments and an existing discharge to surface waters resulting from an on-site groundwater remediation program (PAP-00132112). [Note: The actual permit was not provided.]

On February 25, 1991, an Emergency Discharge Permit (Division of Hazardous Waste Management [DHWM] Permit No. 91-01-28-1450) was issued by the DHWM, which authorized an emergency discharge to surface water from the groundwater treatment system installed at Essex. The Emergency Discharge Permit required PSE&G to sample weekly for contaminants which included base neutral compounds. The Emergency Permit was subsequently reauthorized by the DHWM via 90-day Emergency Discharge Authorizations, the last of these authorizations being issued on March 24, 1992 and therefore approved through June 22, 1992. It was stated that by way of this submittal, PSE&G was seeking authorization to discharge treated groundwater from the pump and treat system at Essex to the Passaic River under the authority of NJPDES-DSW Permit No. NJ0000639 (PAP-00131063-64; PAP-00131123; PAP-00132118-19).

On September 25, 1992, PSE&G amended its application for renewal of NJPDES-DSW Permit No. NJ0000639 to discharge stormwater which accumulates in various secondary spill containments located on the site to the Passaic River. This stormwater had the potential to be contaminated with petroleum hydrocarbons. It was estimated that approximately 2,210,500 gallons per year of stormwater would be discharged from the site. The amendment also addressed a pump and treat surface water discharge to the Passaic River which resulted from a groundwater remediation project at Essex (PAP-001310561-62).

Essex Generating Station was issued NJPDES-DSW Permit No. NJ0000639 on May 25, 1995. The permit authorized the Station to discharge stormwater to the Passaic River. The permit was effective from July 1, 1995 to June 30, 2000 (PAP-00132098-100). The discharge limitation for petroleum hydrocarbons was 15 mg/L. There were no limitations for the daily flow (PAP-00132105).

On December 22, 1999, PSE&G submitted their application to renew NJPDES-DSW Permit No. NJ0000639. Only one discharge (DSN 346) was permitted to discharge stormwater that collected in secondary spill containments to the Passaic River (PAP-00132491-92, 506). The included Pollution Analysis Summary noted that "no sampling was performed due to no discharge" (PAP-00132523). [Note: The actual permit was not provided.]

On April 30, 2004, Essex Generating Station was issued a final NJPDES-DSW Permit No. NJ0000639 (PAP-00133386, 93). The permit was valid from June 1, 2004 to May 31, 2009 (PAP-00133393). The discharge limitation for discharge 346A for petroleum hydrocarbons was 15 mg/L (PAP-00133394). [Note: No other discharge limitations were listed.]

On December 1, 2008, PSEG Fossil LLC Essex Generating Station applied to renew NJPDES-DSW Permit No. NJ0000639 (PAP-00135572). The current permit was to expire on May 31, 2009 (PAP-00135585). The application was for DSN 346A to discharge containment water through oil/water separator to the Passaic River (PAP-00135594-95). It was noted that no storm water had been discharged at the facility, as the containment water was removed by an outside contractor, and there had been no spills or leaks at the facility since the previous Permit Renewal Application (PAP-00135596).

On February 17, 2009, NJDEP issued draft NJPDES-DSW Permit No. NJ0000639 to PSEG Fossil Essex Generating Station (PAP-00135673). The included Fact Sheet notes that this site was unique in the fact that there had been no stormwater discharges in over 17 years. Stormwater from secondary containment areas was collected via vacuum truck after each rainfall and transferred to a storage tank. This storage tank, when full, was removed by an outside contractor for off-site treatment and disposal. Though there were no stormwater discharges to surface water, PSEG Fossil Essex Generating Station had elected to continue with the renewal of their individual permit for stormwater discharges to surface water (PAP-00135677-78). The discharge limitation for petroleum hydrocarbons remained at 15 mg/L (PAP-00135680).

On May 29, 2009, NJDEP issued NJPDES-DSW Permit No. NJ0000639 to PSEG Fossil Essex Generating Station. The permit was effective July 1, 2009 through June 30, 2014 (PAP-00428178). The discharge limitation for petroleum hydrocarbons remained at 15 mg/L (PAP-00428176).

On August 17, 2017, the NJDEP issued a NJPDES-Discharge to Groundwater (DGW) permit to PSEG Fossil LLC to allow the discharge of groundwater associated with construction dewatering activities. The construction activities included trenching and excavation for the installation of a water line. The discharge approved through this authorization would be to the ground surface for percolation back to the water table at the site. The approved discharge to ground was not to exceed 180 calendar days beginning on the day the discharge first occurs (PAP-00140059-61).

7. Response Actions

Characterization Activities

The majority of sampling and site characterization activities took place in conjunction with the remedial actions. Therefore, other than the two areas discussed below, these activities are discussed in the next section.

Area of Concern 1

As noted above, according to the *Preliminary Assessment Report for Historical Kerosene Discharge*, dated September 2010, oily soil was discovered on February 25, 2009 at the southeast corner of Generator Unit No. 11. Essex asserted that the underground kerosene lines, which were removed prior to 1978, were the source of the discharge discovered during excavation on February 25, 2009 and this discharge could only have occurred prior to January 23, 1980. Following the discovery, work in the vicinity of the discharge was stopped and immediate containment measures were implemented, followed by cleanup and removal activities. A Case number for this spill was not assigned; the site was referred to as AOC-1 (PAP-00136876, 86, 96, 98). According to the *Case Inventory Document - PSEG Fossil LLC Essex Generating Station Historical Discharge*, dated November 4, 2009, a preliminary assessment was conducted in 2010 which identified this discharge as an area of concern (AOC) and recommended a SI (PAP-00139753).

According to the *Site Investigation Report for The Historical Kerosene Discharge*, dated January 2013, a SI was conducted at the historical kerosene discharge AOC in June and August 2012. The purpose was to determine if any contaminants associated with the discharge were present in soil and groundwater at concentrations above the applicable NJDEP standards and to evaluate the presence or absence of product in the subsurface (PAP-00139774). The SI included the collection of eight soil samples from six new borings. The soils samples were analyzed for naphthalene and 2-methylnapthalene. Naphthalene and 2-methylnaphthalene were not detected above the NJDEP Direct Contact Soil Remediation standards in any sample. Naphthalene was not detected in any sample above the NJDEP default Impact to Groundwater Screening Level (IGWSL). 2-Methylnaphthalene was detected above the NJDEP default IGWSL in three samples at concentrations of 7, 9.6, and 18 mg/kg. However, the SI noted that the impact to groundwater pathway did not apply because these samples were collected from the saturated zone (PAP-00139786-87).

The concentration ranges for detected COCs in the SI samples were as follows:

AOC-1 Site Investigation Samples		
COC	**Concentration Ranges**	**Depth of Max Concentration**
Naphthalene	Non-detected to 0.17 J mg/kg – 0.88 mg/kg	4-4.5 ft
2-Methylnaphthalene	Non-detected to 0.19 mg/kg – 18 mg/kg	4-4.5 ft

(PAP-00139798, 800)

The SI concluded that no soil contaminants associated with the historical kerosene discharge were identified during the SI. Several PAHs were identified above regulatory standards, but were associated with fill at the site and would be addressed separately. Based on this, the SI recommended an unrestricted use response action outcome (PAP-00139794).

Area of Concern A

The *Site Investigation Report for Area of Concern A*, dated December 2015, documented the results of a soil and groundwater investigation that was conducted at AOC-A between June and September 2015. This AOC was identified by PSE&G on 23 April 2015 when sheen was observed on groundwater in test pits being excavated within the former 26 kilovolt (kV) Essex Switchyard on the site. The test pits were excavated to characterize soil for waste disposal in support of PSE&G's construction of a new 238 kV switchyard (PAP-00139925). As part of the construction of a switching station in the area of the former switchyard, nine test pits were excavated to characterize soil intended for future disposal. AOC-A was assigned when sheen was observed on groundwater at six test pit sampling locations. Waste classification samples were collected from the nine test pits. Benzo(a)pyrene (three test pits) and benzo(b)fluoranthene (one test pit) were detected at concentrations exceeding the NJDEP Residential Direct Contact (RDC) and Non-Residential Direct Contact (NRDC) Soil Remediation Standard (SRS) (PAP-00139930).

The objective of the SI was to characterize soil and groundwater quality at AOC-A. The SI involved the following: advancement of 14 soil borings (one soil boring was advanced per quarter acre); collection of soil samples; installation of four monitoring wells; and collection of groundwater samples. Soil borings at AOC-A were advanced to varying depths down to approximately 15 feet bgs. A total of 43 soil samples, including three duplicates, were collected (PAP-00139925, 32).

The majority of the samples were analyzed for extractable petroleum hydrocarbons (EPH). Twenty-five percent of the samples with EPH detections were analyzed for contingent analyses including SVOCs, PCBs, and metals. Contingent analyses were biased towards those samples with the highest EPH concentrations (PAP-00139934-35).

PAHs, including benzo(a)anthracene, benzo(a)pyrene, and benzo(b)fluoranthene were detected in six of the ten soil samples analyzed for SVOCs, at concentration exceeding the NJDEP Direct Contact SRS and/or default IGWSL. The PAHs dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene were also detected in three of ten soil samples. Concentrations of PAH exceedances identified in soil were reported to be consistent with those in historic fill, which was known to be present at the site based on NJDEP historic fill maps and a review of boring logs (PAP-00139941).

Four metals were present above the NJDEP Direct Contact SRS in the soil samples. Lead was detected above the NJDEP RDC SRS of 400 mg/kg in three soil samples and also above the NRDC SRS of 800 mg/kg in two of those samples, at concentrations ranging from 734 to 1,080 mg/kg (PAP-00139941). Several metals were also present

above the NJDEP default IGWSL in the soil samples. These metals included lead in six of ten samples, and mercury in eight of ten samples (PAP-00139941-42).

PCBs were not detected in any soil sample. No further investigation of PCBs was recommended at AOC-A (PAP-00139941, 65, 69, 73).

The concentration ranges for detected COCs in the AOC-A SI samples were as follows:

AOC-A Site Investigation Samples		
COC	**Concentration Ranges**	**Depth of Max Concentration**
Benzo(a)anthracene	0.060 mg/kg – 1.9 mg/kg	0.5-1 ft
Benzo(a)pyrene	0.040 mg/kg – 2.4 mg/kg	5-5.5 ft
Benzo(b)fluoranthene	0.17 mg/kg – 4.3 mg/kg	0.5-1 ft
Benzo(g,h,i)perylene	0.073 J mg/kg – 1.0 mg/kg	0.5-1 ft
Benzo(k)fluoranthene	0.046 mg/kg – 1.5 mg/kg	0.5-1 ft
Dibenzo(a,h)anthracene	Non-detected to 0.066 mg/kg – 0.36 mg/kg	5-5.5 ft
Indeno(1,2,3-cd)pyrene	Non-detected to 0.081 mg/kg – 1.2 mg/kg	0.5-1 ft 5-5.5 ft
Copper	7.0 mg/kg – 1,850 mg/kg	0.5-1 ft
Lead	4.8 mg/kg – 1,080 mg/kg	0.5-1 ft
Mercury	0.033 mg/kg – 3.5 mg/kg	10.5-11 ft

(PAP-00139963-74)

Remedial Activities

The following reports on remedial investigations at the Essex Generating Station are summarized in this Section:

- Public Service Electric and Gas Company Essex Generating Station Remedial Action Report NJDEP Case No. 91-01-28-1450-16, dated July 1995, described the remediation which occurred as a result of the January 28, 1991 kerosene spill.

- Public Service Electric and Gas Company Essex Generating Station Remedial Action Report NJDEP Case Nos. 93-9-17-1855-42 and 93-9-28-1503-15, dated June 1996, documented the remediation of a mineral oil discharge that occurred at the Essex Generating Station on September 16, 1993.

- Essex Generating Station Retired Gas Turbine Unit No. 9, NJDEP Case 95-5-3-1312-02, Remedial Action Report, dated June 1996 documented the remediation of lubricating oil and kerosene discharges (NJDEP Case No. 95-5-3-1312-02) that occurred at the Essex Generating Station former Unit No. 9 Gas Turbine Generator.

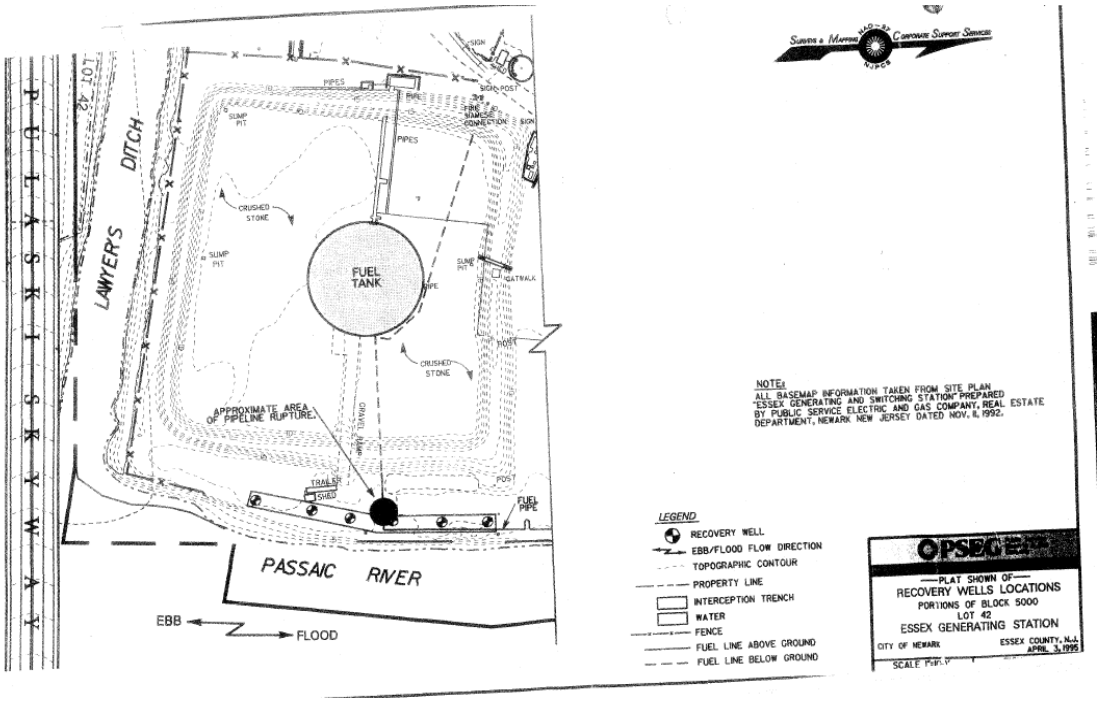
- Essex Generating Station Supplemental Remedial Action Report, NJDEP Case No. 95-5-3-1312-02, dated November 1997, documented the replacement of well MW-6 during June 1997 with a new well identified as MW-6A and resampling.

- Initial Receptor Evaluation Report for Historical Oil and Kerosene Discharge, completed February 2012 for Case No. 95-5-3-1312-02, the former Unit No. 9 generators determined that there no sensitive land use receptors within 200 feet of the Essex Station-site.

- Remedial Investigation Report and Remedial Action Work Plan for the Underground Storage Tanks at Generator Units #11 and #12, dated December 1997 documented the remediation of 16 kerosene underground storage tanks (USTs) which were removed from the Essex Generating Station during November 1992 and the results of the soil and groundwater investigation that was conducted

- Supplemental Remedial Investigation Report and Revised Remedial Action Work Plan for the Underground Storage Tanks at Generator Units #11 and #12, dated November 1999 documented the results of a soil and groundwater investigation that was conducted during 1998 and 1999 in the area of the former USTs at the direction of NJDEP.

- August 2004 Groundwater Monitoring Report for the Underground Storage Tanks at Generator Units #11 and #12, dated November 2004, documented the groundwater monitoring event conducted in August 2004 at the site.



- Remedial Action Progress Report for the Underground Storage Tanks at Generator Units #11 and #12, dated April 2008 discussed groundwater quality for natural attenuation during the period of October 1, 2007 to March 31, 2008.

- Initial Receptor Evaluation Report Underground Storage Tanks at Generators Units #11 and #12, dated October 2011.

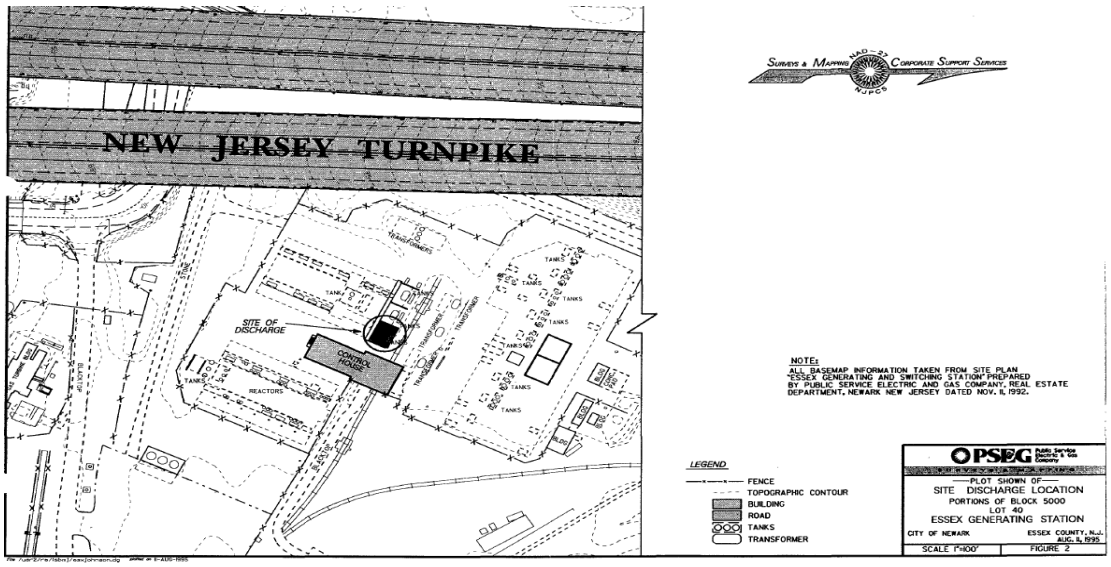
NJDEP Case No. 91-01-28-1450-16

The *Public Service Electric and Gas Company Essex Generating Station Remedial Action Report NJDEP Case No. 91-01-28-1450-16,* dated July 1995, described the remediation which occurred as a result of the January 28, 1991 kerosene spill. These remedial actions took place from January 28, 1991 to May 1993 and included the application of sorbent booms and mechanical oil skimmers, excavation of an interceptor trench, and groundwater pump and treat operations. Treated groundwater was discharged into the Passaic River. NJDEP required PSE&G to sample and analyze the treated groundwater prior to being discharged to the Passaic River. Groundwater samples were taken on August 6, 1992 and again for a final time on May 17, 1993 and submitted to the NJDEP. The report concluded that no further action was necessary (PAP-00131331-38). Note: The results of the sampling discussed were not included in the source document.

The following figure from the *Remedial Action Report* shows the location of the spill relative to the Passaic River:

(PAP-00131341)

On October 24, 1995, the NJDEP approved the proposal for No Further Action for the January 28, 1991 kerosene spill (PAP-00131342-43).



NJDEP Case Nos. 93-9-17-1855-42 and 93-9-28-1503-15

The *Public Service Electric and Gas Company Essex Generating Station Remedial Action Report NJDEP Case Nos. 93-9-17-1855-42 and 93-9-28-1503-15*, dated June 1996, documented the remediation of a mineral oil discharge that occurred at the Essex Generating Station on September 16, 1993. Specifically, the discharge was from a mineral oil transformer1 identified by the Station as Transformer No. 132-1, Phase 3 Unit. The discharge was immediately reported to the NJDEP and assigned Case No. 93-9-17-1855-42. On September 28, 1993, the NJDEP was again notified of the same discharge and a second case number was assigned (i.e., Case No. 93-9- 28-1503-15). A Discharge Confirmation Report was submitted to the NJDEP by letter dated October 18, 1993 (PAP-00354017).

The *Remedial Action Report* provided a summary of the mineral oil discharge events and relevant documentation. The activities occurred in two phases. The mineral oil discharge was discovered on September 17, 1993 at 6:40 p.m., reported to the NJDEP at 6:55 p.m., and stopped by 7:00 p.m. Immediately following this discovery, the leaking radiator was cut off from the main mineral oil reservoir within the transformer by closing the connecting valves. This action helped to reduce the leak. A drum was placed under

the leaking radiator to prevent further discharge of mineral oil to the gravel. The NJDEP assigned this discharge Case No. 93-9-17-1855-42. It was believed that the discharge began sometime on September 16, 1993 and it was estimated that approximately 900 gallons of mineral oil were discharged from the transformer. On September 18, 1993 cleanup of the area surrounding the transformer was begun using a vacuum truck to remove the visibly stained gravel and accumulated mineral oil. A visual inspection of the soil beneath the gravel did not show the presence of mineral oil. A total of fifteen cubic yards of gravel was excavated. By September 21, 1993 an additional fifteen cubic yards of stained gravel were removed and temporarily staged on a plastic liner until it could be classified for waste disposal. The purpose of this additional excavation was to determine the lateral extent of the discharge. Total Petroleum Hydrocarbons (TPH) field testing to determine if TPHs were present in the soil directly below the gravel showed negative results and no further excavations were made. On September 21, 1993 the transformer was detached from its support rails and removed for repair (PAP-00354020).

The following figure from the *Remedial Action Report* shows the site of the discharge:

(PAP-00354030)

NJDEP Case No. 95-5-3-1312-02

The *Essex Generating Station Retired Gas Turbine Unit No. 9, NJDEP Case 95-5-3-1312-02, Remedial Action Report*, dated June 1996 documented the remediation of lubricating oil and kerosene discharges (NJDEP Case No. 95-5-3-1312-02) that occurred at the Essex Generating Station former Unit No. 9 Gas Turbine Generator. The Unit No. 9 Gas Turbine Generator was put in-service on June 25, 1971, and was used for the production of electricity during periods of peak demand. The generator was fueled by kerosene via underground pipelines from an on-site aboveground storage tank. Lubricating oil was used to cool the bearings of the turbine engine (PAP-00131409-16). In 1988, the generator was destroyed by a fire and the turbine section was dismantled and removed. On April 26, 1995, PSE&G personnel discovered oil in a vault located in

the northeastern corner of the generator's concrete foundation. Upon further investigation it was found that the soil beneath the foundation had settled, creating a void where the oil collected. During the remediation of the lubricating oil spill, residual kerosene was discovered. The remediation of contaminated soils took place during November and December 1995. About 1,540 cubic yards of lubricating oil contaminated soil and 1,327 cubic yards of kerosene contaminated soil were excavated (PAP-00131409-16).

Post-excavation samples were collected from the area formerly contaminated with lubricating oil and analyzed for petroleum hydrocarbons and contingent PAHs. Post excavation samples from the kerosene spill area were analyzed for naphthalene. Soil samples were not collected from the bottom of the kerosene excavation due to the presence of groundwater. In January 1996, groundwater samples were collected from five of six wells and analyzed for base neutral compounds. The report concluded that post remediation soil and groundwater samples confirmed that all of the contaminated soil was removed and that groundwater was unaffected. PSE&G believed that no further remediation was warranted (PAP-00131409-16).

The concentration ranges for all detected COCs in the post-excavation samples were as follows:

NJDEP Case 95-5-3-1312-02 Post-Excavation		
COC	**Concentration Ranges**	**Depth of Max Concentration**
Benzo(a)anthracene	0.11 J ppm (only one detection)	41-47 inches
Benzo(a)pyrene	0.084 J ppm (only one detection)	41-47 inches
Benzo(b)fluoranthene	0.11 J ppm (only one detection)	41-47 inches
Benzo(g,h,i)perylene	0.062 J ppm (only one detection)	41-47 inches
Benzo(k)fluoranthene	0.064 J ppm (only one detection)	41-47 inches
Indeno(1,2,3-cd)pyrene	0.05 J ppm (only one detection)	41-47 inches
Phenanthrene	0.06 J ppm – 0.46 J ppm	42-48 inches
Pyrene	0.33 ppm – 2.5 ppm	42-48 inches

(PAP-00131454-59)

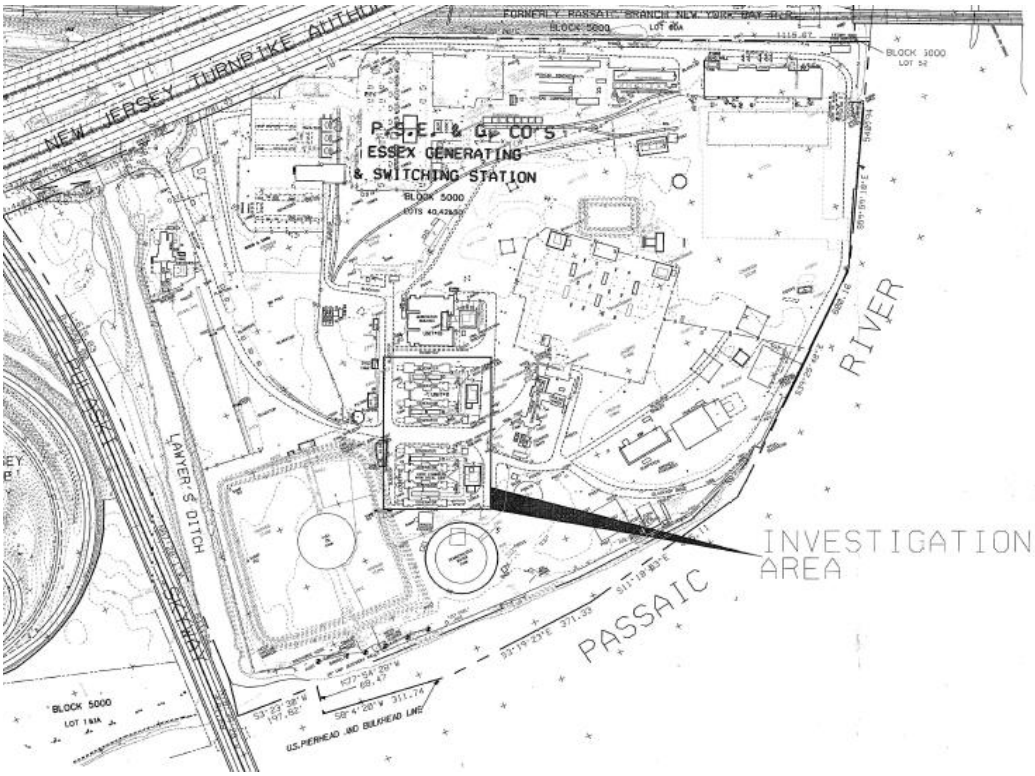
On March 9, 2012, NJDEP issued a No Further Action Letter for Case No. 95-5-3-1312-02 acknowledging the completion of the Remedial Investigation and/or Remedial Action discussed above and allowing unrestricted use for the Former Unit No. 9 AOC (PAP-00139729-31).

NJDEP Case No. 92-12-04-1433

On October 1, 1992, PSE&G Essex Generating Station applied for a Memorandum of Agreement with NJDEPE concerning the closeout of the remedial action which resulted from contamination which was the result of a discharge from an underground kerosene pipeline resulting in the discharge of approximately 13,000 gallons into the ground (PAP-00131119-22). On April 7, 1993, the Memorandum of Agreement went into effect (PAP-00131214-18).

Correspondence from NJDEP to PSE&G dated July 17, 1995, discussed existing underground storage tanks (UST) cases requiring additional remedial action. The letter referenced an April 7, 1993 letter report containing soil and groundwater analytical data and documenting the removal of sixteen 275-gallon kerosene tanks. It was noted that a formal remedial investigation report had not been received. The letter also noted that five of the tank excavation had analytical results with base neutral compounds exceeding the Departments most restrictive Soil Cleanup Criteria. The letter stated that additional remedial actions were required (PAP-00353920-26).

The *Remedial Investigation Report and Remedial Action Work Plan for the Underground Storage Tanks at Generator Units #11 and #12,* dated December 1997 documented the remediation of 16 kerosene USTs which were removed from the Essex Generating Station during November 1992 and the results of the soil and groundwater investigation that was conducted in the area of the 16 former USTs. Each UST location was identified as a separate AOC (AOCs 1-16). The soil investigation conducted when the USTs were removed detected several base neutral SVOCs above their respective NJDEP proposed RDCSCC. Based on these results the NJDEP required a formal remedial investigation of these contaminants. This was conducted during 1997. The remedial investigation for soil included initial confirmation sampling at the five areas where contaminants were detected above their respective RDCSCC and horizontal delineation of soil contaminants detected by the initial confirmation sampling (PAP-00131769-75).



The concentration ranges for all detected COCs in the post-excavation samples were as follows:

Generator Units 11 and 12 Post Excavation Samples		
COC	**Concentration Ranges**	**Depth of Max Concentration**
Benzo(a)anthracene	0.26 J mg/kg – 12.0 mg/kg	7.5-8.0 ft
Benzo(a)pyrene	0.23 J mg/kg – 5.0 mg/kg	7.5-8.0 ft
Benzo(b)fluoranthene	0.20 J mg/kg – 5.8 mg/kg	7.5-8.0 ft
Benzo(g,h,i)perylene	0.16 J mg/kg – 2.6 J mg/kg	7.5-8.0 ft
Benzo(k)fluoranthene	0.22 J mg/kg – 3.7 mg/kg	7.5-8.0 ft
Dibenzo(a,h)anthracene	0.47 mg/kg (only one detection)	10.0-10.5 ft
Indeno(1,2,3-cd)pyrene	0.18 J mg/kg – 2.4 J mg/kg	7.5-8.0 ft

(PAP-00131794-801)

The *Remedial Investigation Report* concluded that the 16 AOCs associated with the soil had been fully delineated. PSE&G submitted that no further action should be required for AOCs 1, 3 through 5, and 7 through 16. Soil sample results of AOCs 2 and 6 detected base-neutral compounds above NJDEP's RDCSCC; however, due to their location excavation was not possible. Institutional control through a Declaration of Environmental Restriction (DER) was recommended for these two AOCs (PAP-00131783-84).

The following figure from the *Remedial Investigation Report* shows the location of the UST remedial investigation relative to the Passaic River:

(PAP-00131825)

The *Supplemental Remedial Investigation Report and Revised Remedial Action Work Plan for the Underground Storage Tanks at Generator Units #11 and #12,* dated November 1999 (Supplemental Remedial Investigation) documented the results of a soil and groundwater investigation that was conducted during 1998 and 1999 in the area of the former USTs at the direction of NJDEP. The Supplemental Remedial Investigation addressed data gaps that remained following the completion of the 1997 Remedial Investigation which included the delineation of soil and groundwater contamination (PAP-00132402).

The Supplemental Remedial Investigation for soil included the collection of soil samples to complete horizontal and vertical delineation at AOCs 1 through 10, and 13 through 16. Horizontal delineation of soil contaminants was conducted in the 7.5 to 8.0 feet bgs soil horizon. Vertical delineation of soil contaminants was conducted in the soil horizon below the respective former UST, which was at 10 to12 feet bgs. A total of 60 soil borings were completed. Each soil sample was collected at a depth of 7.5 to 8.0 feet bgs. Soil samples were also collected from below the base of the former UST (10 to12 feet bgs) and/or from the peat layer below the former UST (12 to 16 feet bgs) and held for analysis to complete vertical delineation. These samples were analyzed only if contaminants were detected at concentrations above their respective NJDEP RDCSCC in the shallower sample (PAP-00132407-08).

The soil results show that several base neutral compounds exceeded their respective NJDEP RDCSCC in six of the 38 samples collected to complete horizontal delineation at the 7.5 to 8.0 foot depth interval bgs. These six samples were collected from AOCs 1, 3, 6, 9, 10, and 15. The compounds , and their corresponding maximum concentration, that exceeded their respective NJDEP RDCSCC are benzo(a)anthracene (6.3 mg/kg in boring 3-S), benzo(b)fluoranthene (4.9 mg/kg in boring 1-N), benzo(k)fluoranthene (2.3 mg/kg in boring 1-N), benzo(a)pyrene (3.8 mg/kg in boring 1-N), and indeno(1,2,3-cd)pyrene (1.4 mg/kg in boring 1-N) (PAP-00132407-08).

In the soil horizon below the former USTs, several base neutral compounds exceeded their respective NJDEP RDCSCC in four of the five samples collected. These four samples were collected from borings 1-S, 9-W, 10-W, and 15-E. The compounds , and their corresponding maximum concentration, that exceeded their respective NJDEP RDCSCC are benzo(a)anthracene (9.1 mg/kg in boring 1-S), chrysene (9.6 mg/kg in boring 1-S), benzo(b)fluoranthene (7.8 mg/kg in boring 1-S), benzo(k)fluoranthene (3.0 mg/kg in boring 1-S), benzo(a)pyrene (8.4 mg/kg in boring 1-S), indeno(1,2,3-cd)pyrene (2.4 mg/kg in boring 15-E), and dibenzo(a,h)anthracene (0.81 mg/kg in boring 15-E) (PAP-00132410).

In the peat layer, several base neutral compounds exceeded their respective NJDEP RDCSCC in four of the seven samples collected. These four samples were collected from 1-S, 2-W, 3-S, and 6-E. The compounds, and their corresponding maximum concentration, that exceeded their respective NJDEP RDCSCC are benzo(a)anthracene (9.6 mg/kg in boring 1-S), chrysene (9.5 mg/kg in boring 1-S), benzo(b)fluoranthene (6.0 mg/kg in boring 1-S), benzo(k)fluoranthene (2.0 mg/kg in boring 1-S), benzo(a)pyrene (6.0 mg/kg in boring 1-S), and indeno(1,2,3-cd)pyrene (1.7 mg/kg in boring 2-W) (PAP-00132410-11).

The concentration ranges for all detected COCs in the supplemental remedial investigation samples were as follows:

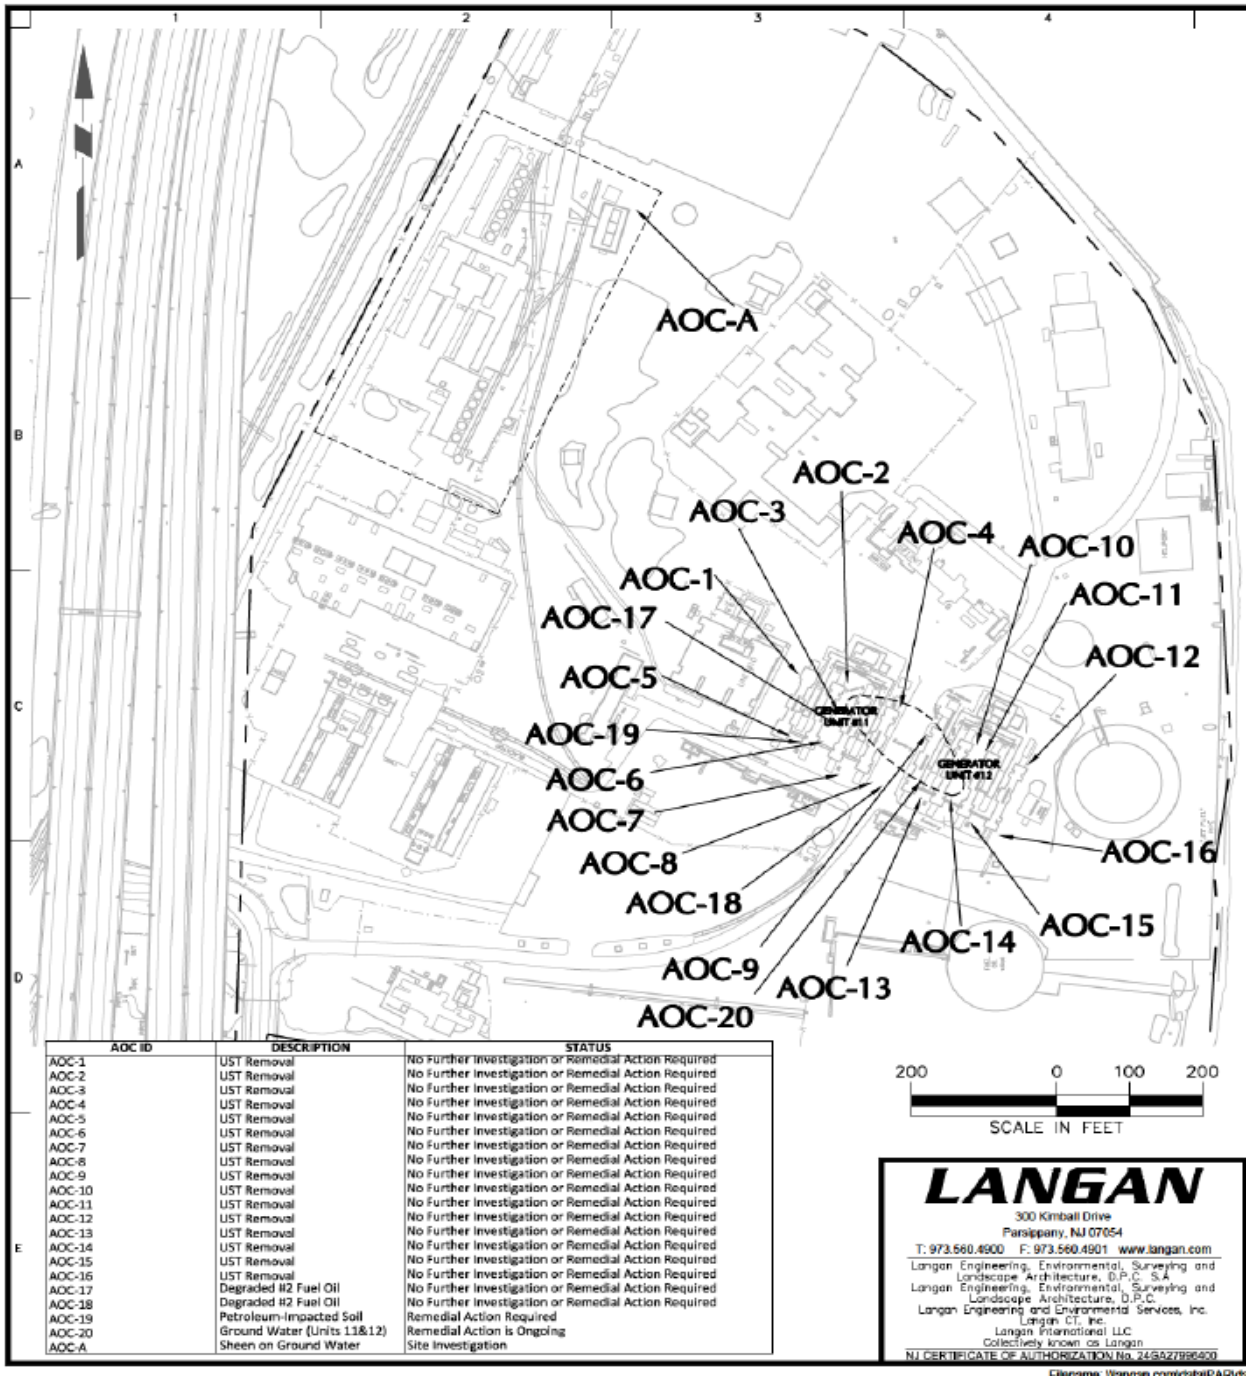
Supplemental Remedial Investigation Samples		
COC	**Concentration Ranges**	**Depth of Max Concentration**
Benzo(a)anthracene	0.019 J mg/kg – 9.6 mg/kg	13.0-13.5 ft
Benzo(a)pyrene	0.0099 J mg/kg – 8.4 mg/kg	10.5-11.0 ft
Benzo(b)fluoranthene	0.015 J mg/kg – 7.8 mg/kg	10.5-11.0 ft
Benzo(g,h,i)perylene	0.011 J mg/kg – 2.4 mg/kg	11.5-12.0 ft
Benzo(k)fluoranthene	0.010 J mg/kg – 3.0 mg/kg	10.5-11.0 ft
Dibenzo(a,h)anthracene	0.020 J mg/kg – 0.81 mg/kg	11.5-12.0 ft
Indeno(1,2,3-cd)pyrene	0.0098 J mg/kg – 2.4 mg/kg	11.5-12.0 ft

(PAP-00132435-47)

The Supplemental Remedial Investigation concluded that random distribution of base neutral compounds generally shows their likely association with the fill placed around the former USTs and at the site in general and not any particular discharge of unused fuel oil. There did not appear to be any correlation between the contamination detected in

the horizontal delineation samples from the 7.5 to 8.0 foot bgs and the vertical delineation samples collected from the 10 - 12 feet soil horizon and the peat layer. PSE&G stated that they were not contemplating any remedial activities for the soil at this time. The analytical results show that contamination present within soil was most likely randomly distributed both horizontally and vertically in the area of the former USTs. Furthermore, contamination present with the peat layer also appeared to be randomly distributed and possibly naturally occurring (PAP-00132419-21).

The NJDEP also required that soil sampling be conducted in the area of MW-5 to document that no residual free product soil contamination was present. MW-5 was sampled on January 17, 2003. Sheen was visible on the water surface, but no measurable product was detected in the well. Base-neutral compounds were not detected above the GWQS. PSEG responded in a letter dated January 31, 2003 that the elevated base-neutral concentrations detected in April 2002 were related to the free product that was encountered in MW-5 at that time but had since been removed. PSEG collected soil samples for AOC-17, AOC-18, and AOC-19 (free product areas) in December 2003. No free product, odors, sheen or staining were observed in soil borings. Soil samples collected from AOC-17 showed the presences of PAHs greater than the NJDEP Soil Cleanup Criteria. Contaminants were attributed to fill and not with any particular discharge or free product. Soil samples collected from AOC-18 revealed no impacts. Soil samples collected for AOC-19 showed elevated levels of petroleum hydrocarbons, but PAHs were below the NJDEP Soil Cleanup Criteria (PAP-00138495-96).



The Receptor Evaluation Report listed the following concentration ranges for all detected COCs in two soil samples collected December 4, 2003 at a depth of 3.0-3.5 ft:

Benzo(a)anthracene:	0.431 mg/kg – 0.931 mg/kg
Benzo(b)fluoranthene	0.766 mg/kg – 0.91 mg/kg
Benzo(k)fluoranthene:	0.699 mg/kg (only one detection)
Benzo(a)pyrene:	0.405 mg/kg – 0.928 mg/kg
Dibenzo(a,h)anthracene:	0.0729 J mg/kg (only one detection)
Benzo(g,h,i)perylene:	0.219 mg/kg – 0.437 mg/kg (PAP-00138506)

According to the *Remedial Action Work Plan for AOC-19 at Generator Units #11 and #12*, dated July 2016, 21 AOCs were associated with the site. Sixteen of these (AOCs 1 through 16) relate to former USTs. Three (AOC-17, AOC-18, and AOC-19) relate to monitoring wells MW-3, MW-8, and MW-5, respectively, where free product was historically detected. One (AOC-20) was related to groundwater contamination. The final AOC (AOC-A), was discovered in April 2015 and was identified as a sheen observed on groundwater in test pits excavated for a construction project. AOCs 1 through 20 were being addressed under the NJDEP *Case No. 92-12-04-1433.* AOC-A was being addressed under a separate NJDEP activity number under the Licensed Site Remediation Professional program. No further investigation or remedial action was required for AOCs 1 through 18. For AOC-20, groundwater contamination had been fully investigated and was being remediated via monitored natural attenuation remedial action with a groundwater remedial action permit and CEA. AOC-A was currently being investigated and the remedial action at AOC-19 was planned for 2017 (PAP-00140017-

19, 32). [Note: No further discussion of the remedial action for AOC-19 is included here as the COC for that AOC was EPH.]

The following figure from the *Remedial Action Work Plan for AOC-19 at Generator Units #11 and #12*, shows the locations of the 21 AOCs at the site:

AOC ID	DESCRIPTION	STATUS
AOC-1	UST Removal	No Further Investigation or Remedial Action Required
AOC-2	UST Removal	No Further Investigation or Remedial Action Required
AOC-3	UST Removal	No Further Investigation or Remedial Action Required
AOC-4	UST Removal	No Further Investigation or Remedial Action Required
AOC-5	UST Removal	No Further Investigation or Remedial Action Required
AOC-6	UST Removal	No Further Investigation or Remedial Action Required
AOC-7	UST Removal	No Further Investigation or Remedial Action Required
AOC-8	UST Removal	No Further Investigation or Remedial Action Required
AOC-9	UST Removal	No Further Investigation or Remedial Action Required
AOC-10	UST Removal	No Further Investigation or Remedial Action Required
AOC-11	UST Removal	No Further Investigation or Remedial Action Required
AOC-12	UST Removal	No Further Investigation or Remedial Action Required
AOC-13	UST Removal	No Further Investigation or Remedial Action Required
AOC-14	UST Removal	No Further Investigation or Remedial Action Required
AOC-15	UST Removal	No Further Investigation or Remedial Action Required
AOC-16	UST Removal	No Further Investigation or Remedial Action Required
AOC-17	Degraded #2 Fuel Oil	No Further Investigation or Remedial Action Required
AOC-18	Degraded #2 Fuel Oil	No Further Investigation or Remedial Action Required
AOC-19	Petroleum-Impacted Soil	Remedial Action Required
AOC-20	Ground Water (Units 11&12)	Remedial Action is Ongoing
AOC-A	Sheen on Ground Water	Site Investigation

(PAP-00140056)

8. Summary of Asserted Defenses

Public Service asserts a number of defenses, including but not limited to the following:

- Discharges from the site were permitted discharges exempt from Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) and Emergency Planning and Community Right-to-Know Act (EPCRA) release reporting requirements pursuant to CERCLA section 101(10).

- Discharges of “petroleum, including crude oil or any fraction thereof” are excluded from CERCLA’s definition of “pollutant or contaminant.”

Facility Data Report

PUBLIC SERVICE ENTERPRISE GROUP (PSEG) SERVICES CORP
PUBLIC SERVICE ELECTRIC AND GAS
HARRISON GAS PLANT

Facility Name, Address and Size: Public Service Enterprise Group Services Corp., 2000 Frank E. Rodgers Boulevard, Harrison, New Jersey, 07029. The facility ranged in size over the years; it is currently 32 acres in size (PAP-00130581). According to the *Remedial Alternatives Evaluation, Former Harrison Gas Plant*, prepared April 1999, the facility covered approximately 32 acres and was designated as Lot 1 of Block 78 (PAP-00128412). According to a *Fact Sheet for Draft NJPDES Permit to Discharge into the Waters of the State of New Jersey,* dated October 1, 1985, the site occupied an area of approximately 37.5 acres in Lots 3, 7A, and 1; Blocks 128, 143, and 78 (PAP-00140281, 84).

According to a March 28, 1979, *Waste Effluent Survey*, the Public Service Electric and Gas (PSE&G) Harrison Gas Plant employed 158 full time employees working three shifts a day, seven days a week (PAP-00134897). This survey reported the area of the property as 68.9 acres, which included liquefied petroleum gas storage facilities, not associated with the manufactured gas plant (PAP-00134897).

According to a *PVSC Application for Sewer Connection Permit,* as of January 1986, the PSE&G Harrison Gas Plant employed 124 full-time employees working three shifts a day, 365 days a year (PAP-00140314).

According to a Passaic Valley Sewerage Commission (PVSC) Application for Sewer Connection Permit, as of January 1991, the PSE&G Harrison Gas Plant employed 62 full-time employees and 15 part-time employees working three shifts a day, 365 days a year (PAP-00140810).

1. **Business Type:** Retired oil-gas production plant, natural gas storage, metering and regulating operations, liquid propane air production plant, and retired pilot synthetic-natural gas production plant (PAP-00140468; PAP-00140812).

2. **Time Period of Ownership/Operations**

   Operator: 1902 or 1909 to present (PAP-00140468; PAS-00007043-44)
   Owner: 1884 to present (PAS-00007043-44)

   According to the *Spill Prevention, Control and Countermeasure; Discharge Prevention, Containment and Countermeasure; Discharge Cleanup and Removal; and, Hazardous Waste Contingency Plans Prepared for Public Service Electric and Gas Company's Gas Business Unit, Harrison Gas Plant, Linden Synthetic Natural Gas Plant* (SPCC Plan) prepared March 1989, the Harrison Gas Plant began operation as an oil and gas storage area in 1909 (PAP-00140468). However, according to the May 1985 *Harrison Gas Plant, Preliminary Site Assessment and Proposed Monitoring Plan*, and the *Public Service Electric and Gas ("PSE&G") Company's Initial Response to USEPA Request For Information* (Response to Request for Information), site operations began in 1902, but from 1902 to 1926 included only storage of oil and gas manufactured from the former Market Street Manufactured Gas Plant (PAP-00140229; PAS-00007043-44).

According to the *Response to Request for Information*, the Harrison Gas Plant site was generally acquired in separate transactions over a period from 1884 through 1924 by the Newark Consolidated Gas Company. Newark Consolidated Gas Company leased its plant properties and franchises to the United Gas Improvement Company in 1898 which assigned the lease that same year to the Essex and Hudson Gas Company. In 1903, Public Service Corporation of New Jersey acquired the plant, property and franchises of the Essex and Hudson Gas Company, which included the site. The Essex and Hudson Gas Company and Newark Gas Company merged with, and into PSE&G in 1939 (PAS-00007043-44).

According to the *Conceptual Site Model and Non-Aqueous Phase Liquid Migration Barrier Wall Remedial Action Approach Report*, dated August 2016, a small part of the Site in the northeast corner was recently sold by PSE&G to the Port Authority Trans-Hudson Corp (PATH) and a minor subdivision of the site has occurred. The site is now designated as Lots 1.01 (PATH) and Lot 1.02 (PSE&G) within Block 78 (PAP-00361735).

3. Operational History/COC Use and Presence at the Facility

According to an April 1999 *Remedial Alternative Evaluation* prepared by Langan Engineering and Environmental Services, Inc. (Langan), PSE&G first utilized the site commencing in 1902 as a large oil and manufactured gas storage facility for the Company's former Market Street Gas Works, located on the west side of the Passaic River in Newark (PAP-00128412). According to the *Response to Request for Information*, circa 1915, a tunnel was constructed under the river connecting the Harrison Gas Plant site with the Market Street Gas Works in Newark, New Jersey. The tunnel contained four six-inch steel lines at the bottom encased in concrete which were used for tar and oil transfer between the Harrison Gas Plant site and the Market Street Gas Works in Newark (PAS-00007045).

According to the May 1985 *Harrison Gas Plant, Preliminary Site Assessment and Proposed Monitoring Plan*, and April 1999 *Remedial Alternative Evaluation*, the former Harrison gas plant was constructed at the site from 1924 to 1926 and commenced commercial operations in 1926. The primary gas manufacturing process utilized at the Site was the carbureted water gas process. The primary liquid and solid raw materials utilized in this process included coal for steam generation, and coke and carburetion oil for gas generation. The peak annual quantities of raw materials utilized in this manufacturing process included in excess each of 100,000 tons of coal and coke, respectively, and in excess of 1.5 million barrels of oil. Various chemicals were also utilized in this process in connection with liquid and dry gas purification processes. The primary product and by-products generated were manufactured gas and tars/light oils, respectively. Peak annual production of manufactured gas was approximately 30,000 MCF (thousand cubic feet). Peak annual production of tars and light oils was approximately 18,000,000 gallons and approximately 600,000 gallons, respectively. Residual from the manufacturing processes generated in bulk included clinker ash and purification wastes (PAP-00128412-13; PAP-00140229).

According to a 1995 *Application for Standard Memorandum of Agreement* between New Jersey Department of Environmental Protection and Energy (NJDEPE) and PSE&G, because of the nature of the by-products and wastes generated, stored, handled and/or disposed of at the site relating to the manufactured gas plant operation, the NJDEPE had determined that a potential existed that constituents of the above by-products and wastes which were classified as hazardous substances may be present in the subsurface at the site (PAP-00128154-55).

According to the *Remedial Alternatives Evaluation* and *Harrison Gas Plant Preliminary Site Assessment and Proposed Monitoring Plan*, during the period 1926-1954, the only change in facility operation was the addition of liquefied petroleum gas-air production equipment in the late forties and the use of natural gas instead of reformed bunker oil for Btu enrichment in 1950. From 1954 to 1963 additional gas manufacturing capability utilizing the cyclic catalytic reforming process, with natural gas or kerosene as the feedstock, was installed. The plant operated as a baseload plant until approximately 1963 when it was converted to peak shaving status. Between 1963 and 1965 six of the carbureted water gas sets were converted to a high Btu oil gas process with kerosene as the feedstock for peak shaving purposes (PAP-00128412-13; PAP-00140229).

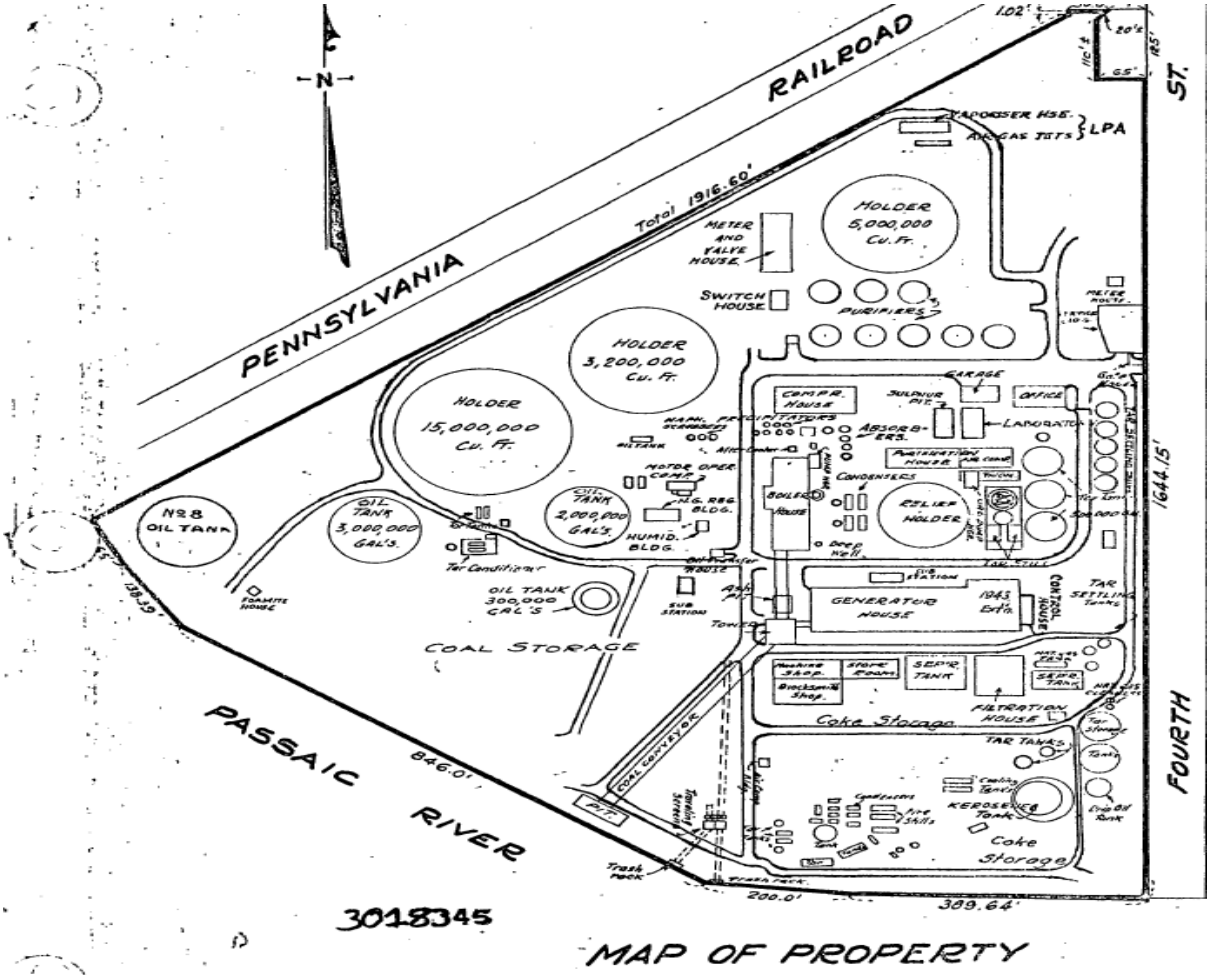
According to *Harrison Gas Plant Preliminary Site Assessment and Proposed Monitoring Plan* dated May 17, 1985, since 1965 the Harrison Plant was primarily a metering and distribution point for pipeline natural gas, with only the high Btu oil gas sets and liquefied petroleum gas-air (LPG-A) on peak loading service. During the spring of 1973, a small 20-million cubic feet per day substitute natural gas facility, utilizing naphtha as a feedstock, was put into operation to supplement the supplies of gas for distribution. Use of this facility was discontinued in 1980. From 1975-1985, the plant operated, on average, only 25 days/year. In 1985, the Harrison Gas Plant was producing high Btu oil gas and liquefied petroleum gas-air mixtures to supplement the amounts of pipeline natural gas distributed through the plant to meet peak demand (PAP-00140229-30).

According to the *Remedial Alternatives Evaluation* prepared April 1999, the plant was retired from service after the 1986/87 winter period. As of the 1999 Evaluation, the site was used as a sub headquarters for a PSE&G gas distribution and customer service operations, and as a headquarters facility for PSE&G's Gas Construction Division. The site also contained a major natural gas metering and regulating station (PAP-00128412-13).

According to a March 28, 1979 *Waste Effluent Survey*, natural gas was received and distributed by the plant without processing throughout the year. During winter months, when this supply was insufficient, gas was produced from kerosene. The gas made from kerosene produced a tar which was separated from a tar water emulsion. The separated dry tar was sold and the water was treated. All of the Passaic River Water taken in was used for non-contact cooling in gas condensers and in barometric condensers and was returned to the river. The above mentioned treated water constituted never more than 1 percent of the total plant effluent during production periods (PAP-00134897).

PSEG Services Corp - Harrison

Diamond Alkali OU2 Allocation



ADR Confidential

Facility Data Report

According to the March 28, 1979 *Waste Effluent Survey*, the Harrison Gas Plant used 3,580,815,260 gallons of water in 1978. Of this, 800,000 gallons were discharged to the sanitary sewer and 3,579,225,260 gallons were discharged to a "Storm sewer, River, or Ditch" (PAP-00134898). The reported waste effluent characteristics did not specifically identify any COCs; however, it was reported that the effluent to the sanitary sewer contained 2.7 mg/L of emulsified oils and the effluent to a "Storm sewer, River, or Ditch" contained 2.0 mg/L of emulsified oils (PAP-00134899-900).

Also according to the April 28, 1987 *RCRA Compliance Evaluation Inspection Report*, *PSE&G Harrison Gas Plant*, in 1987 the Plant was phasing down operations. The Synthetic Natural Gas Plant operation was abandoned in approximately 1981, and the oil/gas plant operation which involved the thermal cracking of kerosene was closed March 1987 (PAP-00140393).

The following site layout plan for the Harrison Gas Plant facility was provided with a June 1971 Initial Application to the U. S. Army Corps of Engineers for permit to discharge or work in navigable waters and their tributaries:

(PAP-00140736)

Diamond Alkali OU2 Allocation

ADR Confidential

Facility Data Report

According to the *SPCC Plan* prepared March 1989 the following aboveground storage tanks were located at the Harrison Gas Plant facility:

- Six (6) tanks for kerosene and diesel fuel
  7.6 million gal capacity. Estimated volume in 1989 - 1.9 million gallons

- Three (3) # 6 fuel oil tanks
  Total storage capacity - 2,028,400 gallons. Total stored at any one time - approx. 900,000 gallons

- Twenty seven (27) tar tanks
  Only eight (8) in use in 1989. Total combined storage capacity for these eight tanks is 2,040,000 gallons; however, in 1989, approximately 450,000 gallons of tar were stored at the plant.

- One (1) spent oil tank
  Primarily kerosene used to scrub the oil-gas of its naphthalene. No longer used in 1989. Contains residuals (PAP-00140475-76)

The March 1989 *SPCC Plan* also noted that Drip Oil pumped from the drip collection system on the natural gas mains was stored in fifty-five gallon drums in the drum storage area (PAP-00140476).

The March 1989 *SPCC Plan* also stated that there was an underground tank removal program underway at the Harrison Gas Plant. Many of the underground tanks had been taken out of service. In 1989, there was one (1) 2,000-gallon gasoline tank in use (PAP-00140477). The remainder of the underground tanks still in service in 1989 would fall under the category of oil-water separators (PAP-00140478). The March 1989 *SPCC Plan* described the following process areas within the Harrison Gas Plant facility where hazardous materials were handled:

- <u>Four tank truck unloading/receiving stations</u>.
  # 6 Fuel Oil – located at the Transfer House, west of the Boiler Room
  Tar – located at the #25 Tar Tank, southeast corner of the main office building. The 1989 Plan states that this tar station would no longer be needed and would be taken out of service.
  Kerosene – located at the Transfer House, west of the Boiler Room. The 1989 Plan states that the kerosene station was rarely used at this time and would be taken out of service.
  Gasoline – located behind the garage

- <u>Barge and Dock Facilities</u>
  Barge transfer station for both Kerosene and # 6·Fuel Oil is located at the southern portion of the plant at the Passaic River. The piping manifold is situated on a fender barge. A spill pan with a capacity of approximately one hundred and forty (140) gallons is located on the fender barge. Spill and containment equipment are located adjacent to the barge/dock area on shore.

Deployment of the spill and containment equipment could be accomplished within minutes of a discharge should one occur.

- Drum Storage/Handling Areas
  Polychlorinated biphenyl (PCB) contaminated liquids stored in drums in the Generator House basement
  Lubricating oils, boiler fuel treatment chemicals, and boiler feed water chemicals stored west end of the Generator House basement and outside the Generator House basement. Non-PCB waste oils are stored inside the TK-8 tank dike area (PAP-00140482-83).

4. Identified COCs

- PCBs (used, detected)
- Dioxins (detected)
- PAHs (used, generated, released, detected)
- Mercury (used, detected)
- Copper (used, detected)
- Lead (used, detected)

According to *Excerpts from Final Pretrial Order, PSE&G v. Certain Underwriters at Lloyd's of London, CA No. 88-4811*, dated October 1994, included in the Tierra/Maxus summary report *Sources of Hazardous Substances in the Passaic River Study Area: Potentially Responsible Party Public Service Electric & Gas Company,* former employees who worked at the Harrison Gas Plant prior to 1944 allegedly stated that on-site disposal of tar wastes on the ground occurred at the site. Reportedly, heat in the summers would cause the tar in the tar/soil mixture to rise to the surface (PAS-00013565-66). During testimony, a PSE&G chemist testified in deposition that he observed an area in the north corner of the Harrison Plant where solidified tar, clinkers, and debris had been buried and covered with gravel. As early as the 1940s, he noticed that the solidified tar associated with the buried waste would re-liquefy during the summer months and rise to the surface (PAS-00013567). It was also testified in deposition that some gas plant materials, such as coke, were stored on the ground and that other gas plant materials, such as tar, tarry and oily wastes, condensates, light oils, and spent oxide wastes were present in or on the ground due to leaks, spills, and occasional on-site disposal (PAS-00013571).

PCBs

According to the August 13, 1996 *Public Service Electric and Gas Company's ("PSE&G") Initial Response to USEPA Request for Information* (Response to Request for Information), circa 1981, PSE&G received notice that the gas condensate collected at PSE&G gas system interconnections with certain of its natural gas suppliers was contaminated with PCBs (PAP-00356878).

According to the April 28, 1987 *RCRA Compliance Evaluation Inspection Report a* Natural Gas Metering - Regulation Station (Gate Station) was at the Harrison Gas Plant location. The function of the Gate Station was to reduce pressure from the high pressure distribution main to the lower pressure required for public distribution. At this

point of pressure reduction, the plant had four scrubber systems (125-150 gal apiece) which led to a 600-gallon underground condensate collection tank. The condensate material was periodically tested for PCB contamination, and if the concentration was greater than 50 ppm, the material was considered hazardous waste (PAP-00140393-94).

Also according to the April 28, 1987 *RCRA Compliance Evaluation Inspection Report*, the PSE&G Harrison Gas Plant acted as the receiving facility for PCB contaminated wastes greater than 50 ppm from different PSE&G plants and Regulating Stations throughout the state. The facilities transported their waste material in 55-gallon drums to PSE&G Harrison using facility vehicles (PAP-00140394).

PCB waste manifested and transported from the Harrison Gas Plant was as follows:

- March 31, 1987 – 1,450 gal
- March 30, 1987 – 1,100 lbs
- June 12, 1986 – 15,150 lbs
- November 21, 1985 – 3,250 gal
- April 28, 1983 – 3,500 gal (PAP-00140387; PAP-00140395)

Correspondence from PSE&G to NJDEP in December 1987 stated that soil contaminated with tar was one of two major concerns of former gas plant operations. PSE&G was participating in a program to ship tar contaminated soils to Canada to be burned for fuels. As part of this, a sample of soil contaminated with tar was analyzed. The sample was found to contain PCBs at 4 ppm and lead at 0.194 ppm (PAP-00140408-14). Note: The location where the soil sample was taken was not provided in the source document.

In September 1988, a *Consent Agreement and Consent Order* were executed for PCB violations at the Harrison Gas Plant discovered during the April 8, 1987 inspection of the Harrison Gas Plant facility by representatives of the Environmental Protection Agency (EPA). The inspection found several violations concerning annual documentation, container labeling, and storage of PCB waste for more than one year (PAP-00140436-37).

According to the March 1989 *SPCC Plan*, PCB-contaminated liquids were stored in drums in the Generator House basement, located south of the Boiler House. The area was isolated from other areas of the basement and was clearly marked with PCB posters. The drums were stored in catch pans, eight drums to a pan, stacked as a single layer. This waste was disposed of in accordance with 40 CFR 761 (PAP-00140483).

On March 16, 1990, the PSE&G Harrison Gas Plant filed an EPA Notification of PCB activity. The notification included a map; however, it is not clear what is being identified on the map (PAP-00140700-01).

October 1990 correspondence from the manager of the PSE&G Harrison Gas Plant to NJDEP provided notification of PCB hazardous waste storage at the site. Storage for potential PCB-containing material began August 11, 1982. The storage area for PCB and any other hazardous waste from plant operations was inside the concrete first floor of what was known as the generator house. The PCB storage area was posted and marked; area drains were sealed to provide secondary containment. PCB drums were further protected by placing into metal troughs containing a maximum of 7-55 gallon drums each. There were 10 trays available with a maximum capacity of 70 drums. Daily inspections were made of the areas for leakage, container closure, and label application. The PCBs were in light hydrocarbon distillates from natural gas pipelines. There could also be a small amount of PCBs in some water condensate and also from gas pipelines. Other hazardous wastes stored included materials used in operations such as used engine lubricants and cleanup materials (PAP-00140781-85). In November 1990, the NJDEP responded that based on the review of the information, the Bureau of Hazardous Waste Engineering had determined that the submitted information was acceptable and PSE&G met the requirements of N.J.A.C. 7:26-9.l(c)(l7)iii and v. It was noted that PSE&G was required to dispose of the PCB hazardous waste within one year of placing it into storage (PAP-00140790).

A NJDEP Division of Hazardous Waste Management printout of hazardous waste manifests from January 1991 to April 1994 for the PSE&G Harrison Gas Plant on Fourth Street (Generator NJD000768028) included quantities of PCB-contaminated liquids and solids as well as lead being transferred to various treatment, storage, and disposal facilities (PAP-00128124-30).

A June 1996 letter from PSE&G to the NJDEP reported that the PCB storage at the Harrison Gas Plant had been moved to another building. PSE&G managed its PCB waste by shipping the waste off-site to an authorized facility within one year of the time the PCB waste was placed into the storage area (PAP-00128244).

A list of wastes generated by the PSE&G Harrison Gas Plant facility for the year 1997 included 6.78 tons of lead waste and 8 tons of lead and PCB waste. These waste streams were both transported off-site and landfilled (PAS-00104679-80).

A Classification Exception Area (CEA)/Well Restriction Area (WRA) for the PSE&G Harrison Gas Plant was established in August 2001 as a result of two aquifers being impacted. COCs which have impacted the aquifers include PCBs (Aroclor-1242, Aroclor-1248) (PAP-00128856-58; PAP-00357330-32).

According to the EPA *PCB National Report* dated February 25 2010, PSE&G Harrison Gas Plant is a classified as a generator of PCBs (PAP-00129920-21).

Soil sampling on the site has detected PCBs. Aroclor 1248 was detected in site soil at concentrations ranging from non-detected to 8.88 mg/kg; Aroclor 1254 was detected in site soil at concentrations ranging from non-detected to 2.1 mg/kg; Aroclor 1260 was detected in site soil at concentrations ranging from non-detected to 0.65 mg/kg (PAP-00128416-17; PAP-00128592; PAP-00128608; PAP-00128653-94; PAP-00128749-65; PAP-00129038-55).

Dioxins and Furans

A January 2007 *Notice of Deficiency* from the NJDEP to PSEG Services Corporation discussed a November 2006 Progress Report which identified a dioxin waste stream for which the Remedial Action Work Plan did not identify as an area of concern or provide specific details, delineation and data. Required corrective actions included revising the progress report within 45 days to include all data that was used for delineation and characterization of the dioxin waste stream area (PAP-00128884-85). A meeting was held on February 6, 2007, at the NJDEP to discuss the Notice of Deficiency. The meeting was attended by PSEG Services Corporation, MACTEC Engineering and Consulting, Inc. and the NJDEP. Tables summarizing the dioxin results and a map showing the locations where the samples were collected were presented at the meeting. NJDEP stated that submission of these documents would address the deficiency (PAP-00128889-93). 2,3,7,8-TCDD was detected at concentrations up to 14,600 pg/g (parts-per-trillion per gram) (PAP-00128893). According to the Remedial Action Report – Phase I River Front Stage, prepared for PSE&G, dated March 2009, the analytical results of this sample were consistent with results from shallow samples collected in sediments from the "Harrison Reach" of the Passaic River by EPA. These results showed that the dioxins detected can be attributed to migration from the Passaic River and are not associated with the former Harrison Gas Plant operations (PAP-00128997-98). This position was accepted by the NJDEP in correspondence dated May 30, 2007 (see Harrison Attachment 1.pdf). [Note: A map showing the location of the samples was not included in the source document.]

PAHs

An August 4, 1969 Surveillance Report described locating a settling lagoon with oil floating on the surface (PAS-00013591). Note: PAHs may be present in oils and kerosene.

According to a January 1991 *PVSC Application for Sewer Connection Permit*, principal raw materials used at the Harrison Gas Plant included #6 Fuel Oil and kerosene (PAP-00140812).

According to the August 13, 1996 Response to Request for Information, PAHs have generally been detected in No. 6 Fuel Oil, gas oils, coke oven coal tars, and carbureted water gas tars (PAP-00356897-98, 901). Note: This data is from literature and does not necessarily reflect the materials actually used at the Harrison Gas Plant.

A CEA/WRA for the PSE&G Harrison Gas Plant was established in August 2001 as a result of two aquifers being impacted. COCs which have impacted the aquifers include PAHs (naphthalene, 2-methylnaphthalene, acenaphthylene, acenaphthene, fluorene, phenanthrene, fluoranthene, pyrene, benzo(a)anthracene, chrysene, benzo(b)fluoranthene, benzo(k)fluoranthene, benzo(a)pyrene, indeno(1,2,3-cd)pyrene, dibenzo(a,h)anthracene, and benzo(g,h,i)perylene) (PAP-00128856-58; PAP-00357330-32). Soil on the site has detected PAHs (PAP-00128330-34; PAP-00128644-51, 53-93; PAP-00128722-44, 49-65; PAP-00129020-55; PAP-00129399-417; PAP-00129669-70,

683-707; PAP-00360110-18; PAP-00358052-62, 66-73; PAP-00359382-84; PAP-00360509-11; PAP-00360596-97; PAP-00360622-25).

Metals - Copper, Lead and Mercury

According to *Harrison Gas Plant Preliminary Site Assessment and Proposed Monitoring Plan* sampling was conducted in 1983 as part of the assessment on water samples taken upstream of the plant and at the plant discharge from the Passaic River and from the well located on the site. The Plan concluded that these analyses showed that any contamination which may exist on-site has not migrated from the site (PAP-00140252). Copper was detected in the well water sample (28 ppb), in the upstream sample (45 ppb), and in the discharge effluent sample (76 ppb). Mercury was detected in the well (0.7 ppb) and upstream samples (0.7 ppb) but was not detected in the discharge effluent sample. Lead was not detected in any of these samples (PAP-00140261).

According to a *Community Right to Know Survey* for 1989 for the PSE&G Harrison Gas Plant, chemicals stored on-site included copper stored in the R&D Lab; fuel oil stored in the auto garage, generator house, and yard; lead and lead nitrate stored in the R&D Lab; mercury stored in the R&D Lab; mercuric sulfate stored in the TAR-Lab; and petroleum oil in several locations (PAP-00140702-20). Note: R&D and TAR-Lab are not defined in the source document.

According to the August 13, 1996 Response to Request for Information, metals including lead and copper have generally been detected in No. 6 Fuel Oil and would have similar concentrations in heavy gas oils. In addition, lead has generally been detected in tars found at three unrelated non-PSE&G gas plant sites (not including the Harrison Gas Plant) where the carbureted water gas and oil gas processes were used (PAP-00356899, 903). Note: This data is from literature and does not necessarily reflect the materials actually used at the Harrison Gas Plant.

A list of wastes generated by the PSE&G Harrison Gas Plant facility for the year 1997 included 6.78 tons of lead waste and 8 tons of lead and PCB waste. These waste streams were both transported off-site and landfilled (PAS-00104679-80).

A CEA/WRA for the PSE&G Harrison Gas Plant was established in August 2001 as a result of two aquifers being impacted. COCs which have impacted the aquifers include lead and mercury (PAP-00128856-58; PAP-00357330-32).

According to a Standard Compliance Inspection of the Harrison Gas Plant conducted by the NJDEP on September 11, 2007, the site used fluorescent lamps, batteries and mercury regulators. The mercury regulators were found to be stored in compliance with no signs of breakage. Neither lamps nor batteries were found being stored on-site during the inspection (PAP-00128907-22). Soil a sampling on the site has detected metals including lead, mercury, and copper (PAP-00128336-39, 54-56; PAP-00128655-93; PAP-00128722-44, 49-65; PAP-00129020-56; PAP-00129399-417; PAP-00129670, 681-705; PAP-00358052-62, 66-73; PAP-00359382-84; PAP-00360110-18; PAP-00360509-11; PAP-00360596-97; PAP-00360627-30).

Historic Fill

The Allocation Team has determined that the facility site is located on regional Historic Fill as designated by the NJDEP.[1]

NJDEP has established that historic fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 COCs: PAHs, lead, copper, and mercury.[2] Accordingly, NJDEP technical requirements for property containing Historic Fill requires sampling for the EPA Target Compound List for PAHs and Target Analyte List for metals, including lead, copper, mercury, and the OU2 PAH COCs.[3] PAHs, lead, copper, and mercury are recognized by NJDEP to be constituents of Historic Fill at varying levels, not atypically at or exceeding residential soil standards.[4]

The levels of PAHs, copper, lead and mercury detected at the site in soils are presented in the table below (PAP-00129034, 38, 43; PAP-00129400).

COCs Found in Onsite Soils	
COC	**Max Detected Concentration**
Lead	4,890 mg/kg
Copper	3,330 mg/kg
Mercury	65.8 mg/kg
Benzo(a)anthracene	2,050 mg/kg
Benzo(a)pyrene	1,990 mg/kg
Benzo(b)fluoranthene	1,630 mg/kg
Benzo(k)fluoranthene	1,100 mg/kg
Dibenzo(a,h)anthracene	427 mg/kg
Indeno(1,2,3-cd)pyrene	1,200 mg/kg
PCBs	8.88 mg/kg

No information is available regarding when fill materials were placed on the facility site.

[1] *Digital Geodata Series, DGS04-7, Historic Fill for New Jersey*, https://www.nj.gov/dep/njgs/geodata/dgs04-7.htm, Quadrangle #52 and #53 (NJDEP map identifying locations of recognized historic fill).
[2] *Characterization of Ambient Levels of Selected Metals and cPAHs In New Jersey Soils* (2002) and *Characterization of Ambient Levels of Selected Metals and Other Analytes In New Jersey Soils* (1997), studies prepared for NJDEP, Division of Science and Research, by BEM Systems, Inc.
[3] New Jersey Department of Environmental Protection (NJDEP), *N.J.A.C. 7:26E Technical Requirements for Site Remediation,* Table 4-2, November 2009 [Note that Table 4-2 has been deleted from the current version of N.J.A.C. 7:26E (May 7, 2012) and the updated *Historic Fill Technical Guidance* (April 2013) as NJDEP believed that the tables list of historic fill constituents was too restrictive].
[4] NJDEP Table 4-2 (PAHs and lead) and a summary of NJDEP records regarding investigations of properties in the vicinity of the Passaic River recognized to be located in areas of Historic Fill indicate that the following average/maximum (mg/kg) contamination levels of OU2 COCs exist in area Historic Fill: PAHs (1.91/160), lead (574/10,000), copper (11.2/1,200), and mercury (0.21/3.7).

5. COC Pathways

Available references include information on the sanitary and storm sewers at the site, but do not include specific information regarding COCs that may have entered the system or been discharged through it.

Sanitary Sewer

A 1926 *Report on the Status of Pollutions from Industrial Establishments* reported that the Public Service Gas Company facilities in Harrison and Newark were classified as plants where treated sewage goes to the sewer and then is discharged to the river. Separating tanks, chemical coagulation, and filters were the treatment methods used at both plants and both plants were rated satisfactory (PAP-00129826-27).

According to a March 28, 1979 *Waste Effluent Survey*, the PSE&G Harrison Gas Plant discharged approximately 800,000 gal of water to the sanitary sewer in 1978 (PAP-00134898). The reported waste effluent characteristics did not include any COCs (PAP-00134899-900).

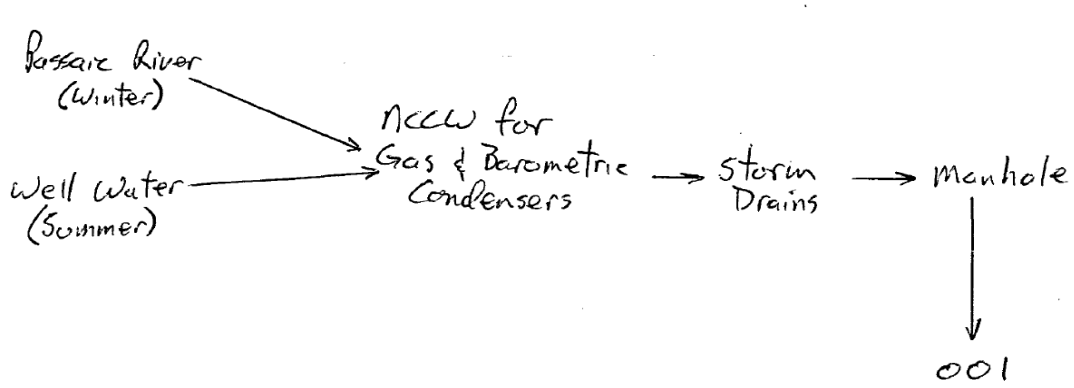
According to the March 1989 *SPCC Plan*, boiler condensate and oily waste water from various building floor drains, fire walls, and dikes discharged to the plant's oil-water separation system. This system consisted of a Pielkenroad Corrugated Plate Interceptor (CPI) separator, sedimentation and sand filtration. The pH of the outflow was adjusted with soda ash as needed to meet specifications prior to discharge to the Passaic Valley Sewerage System. Waste oil from the CPI was transferred to waste storage for disposal (PAP-00140487).

According to a *PVSC Application for Sewer Connection Permit # 13403712* dated January 13, 1986, the Harrison Gas Plant discharged the 10,221,200 gallons of process waste water to the sanitary/combined sewer and 11,126,792,000 gallons of cooling water to the river the previous year (PAP-00140315). The daily flow for outlet 13403711 was reported as 21,589 to 35,902 gallons (PAP-00140318). Results for a sample collected December 24, 1985 reported “0.000” for mercury. No other COCs were reported (PAP-00140319-20).

According to a January 1991 PVSC Application for Sewer Connection Permit, process waste water and effluent go through oil separators and sand filters before discharging at outlet # 13403712. An estimated daily flow rate of 24,000 gal was reported. Samples were collected December 13, 1990 from this outlet. Lead was reported at 0.007 mg/L, copper and mercury were not detected (reported as 0.00 mg/L and 0.000 mg/L, respectively) (PAP-00140813-14; PAP-00428220-22).

Storm Sewer

According to a March 28, 1979 *Waste Effluent Survey*, the PSE&G Harrison Gas Plant discharged approximately 3,579,225,260 gal~~lons~~ of water to a "Storm Sewer, River or Ditch" in 1978 (PAP-00134898). The reported waste effluent characteristics did not include any COCs (PAP-00134899-900).



According to the March 1989 *SPCC Plan*, non-contact cooling water from various equipment which was uncontaminated, was discharged to the Passaic River at outfall DSN002. Stormwater which was uncontaminated was allowed to run to a storm sewer system which ran parallel to Frank E. Rogers Boulevard and also discharged to the Passaic River at outfall #DSN002 as authorized by NJPDES-DSW Permit # NJ0000560. A permanent containment boom was installed at this outfall as a precaution (PAP-00140487).

According to an August 1990 *Application for Renewal NJPDES Permit # NJ0000566,* both the stormwater from the Harrison Gas Plant and the non-contact cooling water system discharge to the municipal storm sewer system which then discharges to the Passaic River. Samples for monitoring purposes are collected prior to the blending of the municipal and site discharges (PAP-00140791-92).

According to a *Fact Sheet for Draft NJPDES Permit to Discharge into the Waters of the State of New Jersey*, dated October 1, 1985 for Permit # NJ0000566, there were two permitted discharges, Discharge 001 and Discharge 002. Discharge 001 was a discharge of non-contact cooling water for compressors and barometric and gas condensers. The flow rate was 14.4 MGD during gas production and 2.9 MGD in non-operating periods. The Passaic River was the source of the water. Discharge 002 consisted of stormwater runoff from the site and from bordering Fourth Street (PAP-00140281, 84).

The following flow diagrams for Discharge 001 and Discharge 002 were presented in an October 15, 1985 *Discharge Surveillance Report:*

PLANT DIAGRAM AND FLOW SEQUENCE:

Note: The sample collected here did not report any COCs (PAP-00140291).

PLANT DIAGRAM AND FLOW SEQUENCE:

Note: No sample was collected here as there was no discharge (PAP-00140292).

The December 10, 1979 *Water Pollution Violation Report* stated that approximately 75 gal of kerosene had leaked from an underground 6-inch pipe (PAP-00137126). The kerosene was observed to flow out of the pipe into a storm sewer which allowed it to reach the Passaic River. Coast Guard investigators observed that approximately 75 gal of kerosene was contained by the boom. The Coast Guard noted that some of the product was entraining under the boom due to current action. The sheen that was surfacing was dissipating rapidly (PAP-00137128).

Direct Release

PVSC Correspondence from 1927 through 1931 states that on several occasions, tar and oily matter from the Harrison Gas Plant were bypassed and/or leaked directly into the Passaic River as a result of malfunctions with PSE&G's filtering system (PAS-00013696-98).

Correspondence from December 8, 1927, discussed gas plants operated by Public Service along the Passaic River which included one at Newark and one at Harrison. At each of these places the author of the letter reported that he had received frequent reports of tar and oily matter being allowed to escape. It was stated that the indications were that this was being purposely by-passed to the river instead of going to the treatment plant. The author stated that it was a matter of faulty operations of the purification plant that they were complaining about, and that they had not charged that PSE&G had made no efforts to avoid pollution of the river (PAP-00139719; PAS-00013696).

Correspondence from August 31, 1928, discussed possible sources for tar oil on the Passaic River, a bilge tank of a boat was mentioned as a possible source, but the PSE&G Harrison Gas Plant was thought to be the source of tar oil seen on the river on August 15, 1928 (PAP-00134894; PAP-00140154; PAS-00013697).

Correspondence from August 6, 1931, regarding the Public Service Gas Plant, Harrison, New Jersey reported that an investigation took place after considerable quantities of tarry oils were observed to be discharging from the plant. It was reported that the tar line in the plant had started leaking and that the tar reached the waste treatment plant,

smearing up the sand in the filter and rendering the treatment plant inoperative. It was stated that when the leak had been traced and repaired, it would be necessary to replace the filter sand with new material. This would cause pollution tor several days, depending on how long it took to locate and repair the tar line leak (PAP-00355295; PAS-00013698).

A PVSC report titled *Stream Contamination during May 1947* described an incident where a very oily slick was observed next to the PSE&G Harrison Gas Plant dock. No leaks in the pipeline were observed. It was noted that sludge on the river bed was gassing and bringing up large blotches of oil film (PAP-00355300).

An August 4, 1969 Surveillance Report described locating a settling lagoon with oil floating on the surface (PAS-00013591). Note: PAHs may be present in oils and kerosene. A December 15, 1969 letter from PSE&G to the NJ Department of Health confirmed the presence of oil in the plants outfall and the past operation of two temporary ponds used for the separation of oil-water mixture resulting from a surface drainage condition. These ponds were completely removed by the time of the 1969 letter (PAS-00013592-93).

A June 1971, *Initial Application* to the U.S. Army Corps of Engineers for permit to discharge or work in navigable waters and their tributaries for the Harrison Gas Plant identified three water inlets and two outfalls from the facility. The two outfalls identified were: # 004, the Plant Flume Outlet and # 005, the outlet for Tar Conditioner Steam condensate to the Passaic River. Both outlets had estimated flows of 50,050 MGD (PAP-00140730-73). No COCs were stated as being present.

According to the August 13, 1996, *Response to Request for Information*, an SPCC Study Plan dated 1974 referenced the occurrence of six floods at the site on the following dates: November 25, 1950; November 7, 1953; September 12, 1960; April 3, 1961; March 6, 1962; and January 23, 1966. The referenced SPCC Study did not contain any information regarding any leaks, spills, discharges or disposal activities associated with these six floods (PAP-00356867).

According to the report *Potential PCB Sources to PRSA*, prepared by Tierra / Maxus dated December 2001, process waste water from the plant was discharged directly to the Passaic River until January 1979, at which time effluent was diverted to the PVSC sewer system. These direct discharges historically included tarry water effluent from the filter house; effluent from the purification sedimentation basin; boiler water blowdown; overflow water from the ash settling pit; steam condensate from various processes; non-contact cooling water from various processes; and site stormwater (PAS-00124584). [Note: There are no citations or available underlying documents to support these statements.]

Spills

According to the March 1989 *SPCC Plan*, there were several different types of secondary containment and diversion structures used to keep spilled hazardous substances from reaching State waters. These structures included: dikes, curbs, liquid waste treatment systems, segregated waste streams, drip pans, and catch basins which direct flow to oil water separators (PAP-00140486).

The March 1989 *SPCC Plan*, stated that on October 18, 1983, five gallons of tar leaked from a discharge line to the separators at a point where the line crosses a vault directly on top of the storm sewer that runs parallel to the separators. The vault had a hole allowing tar to get into the storm sewer which was connected to the plant outfall. The spill was contained by the permanent boom at the outfall. Tar was removed from water with skimmer pump and absorbent pads (PAP-00140504). Note: PAHs may be present in tar.

According to the August 13, 1996, *Response to Request for Information* and other source documents, the following spills to the Passaic River were reported at the Harrison Gas Plant:

Spills				
Date	**Reporting Entity**	**Substance Spilled**	**Volume**	**Citation**
January 25, 1977	U.S. Coast Guard	Discolored, oily water	Approx. 2-3 gal	PAP-00129995-96; PAP-00130026; PAP-00356862
December 10, 1979	U.S. Coast Guard	Kerosene	50-75 gal	PAP-00137126; PAP-00137729; PAP-00356862-63
July 11, 1981	U.S. Coast Guard	Tar	Approx. 10 gal	PAP-00140116; PAP-00140138; PAP-00356863
October 18, 1983	U.S. Coast Guard	Tar Oil	Approx. 5 gal	PAP-00140219-23; PAP-00140157-59; PAP-00356863-64
May 23, 1994	U.S. Coast Guard	Oily substance	Unknown	PAP-00128131; PAP-00128132; PAP-00128135; PAP-00128136; PAP-00130590

6. Regulatory History/Enforcement Actions

Inspections

According to the September 1988 *Consent Agreement and Consent Order*, on April 8, 1987, representatives of the EPA conducted an inspection of the Harrison Gas Plant facility for the purpose of enforcing the federal PCB regulations. The inspection found

several violations concerning documentation, and storing PCB waste more than one year after being placed into storage for disposal (PAP-00140392-95; PAP-00140436-37). As a result of these violations, PSE&G was assessed a penalty of $8,500 (PAP-00140440).

A Standard Compliance Inspection of the Harrison Gas Plant was conducted by the NJDEP on September 11, 2007. The hazardous waste generated by PSEG was gas condensate and silica gel. The gas condensate was generated infrequently in drip pots from gas lines. The drip pots collected impurities and condensation from natural gas, which was then pumped to a 55-gallon drum once the drip pot was full. One 55-gallon drum of waste gas condensate filters was the only waste found. This drum was being stored in the hazardous waste storage building. The weight of this drum was 101 lbs. It was also noted that the site generates fluorescent lamps, batteries and mercury regulator solid wastes. No lamps or batteries were found being stored on-site at the time of the inspection. The mercury regulators were found to be stored in compliance with no signs of breakage (PAP-00128907-22). It was noted that the site was last inspected on April 27, 2000, and no violations were found regarding Large Quantity Generators requirements (PAP-00128910).

Violations

Correspondence from PSE&G to the NJ Department of Health on December 15, 1969 discussed an October 3, 1969, letter notifying PSE&G of violations concerning pollutants from the Harrison Gas Plant entering the Passaic River. A sample of the plant's outfall collected by the Department of Health on August 21, 1969, contained 363 parts per million (ppm) of ether soluble matter (usually inferred as oil). A duplicate sample was not available for PSE&G analysis. A sample taken by PSE&G at the same location during the forenoon of the same date found a chloroform soluble matter content of 18 ppm (PAP-00140328-29; PAP-00140419-20).

Additionally, the correspondence noted that the plant was potentially in violation of statutes by virtue of the operation of two temporary ponds used for the separation of an oil-water mixture resulting from a surface drainage condition. This latter condition had been corrected with the result that the two ponds, being no longer necessary, having been completely removed (PAP-00140419-20).

On January 25, 1977, a discharge of discolored oily water from the PSE&G Harrison Gas Plant reached the Passaic River. PSE&G paid a $50 fine to the U.S. Coast Guard for this violation (PAP-00129995-96; PAP-00130026). It was noted that approximately 2-3 gal reached the Passaic River (PAP-00129995).

February 29, 1980 correspondence from the U.S. Coast Guard to PSE&G concerned a violation for the discharge of 50 gal of oil from the PSE&G Harrison Gas Plant to the Passaic River which occurred on December 10, 1979. A preliminary penalty of $600 was assessed (PAP-00137729). The December 10, 1979, *Water Pollution Violation Report* stated that approximately 75 gal of kerosene had leaked from an underground 6-inch pipe (PAP-00137126). The kerosene was observed to flow out of the pipe into a storm sewer which allowed it to reach the Passaic River (PAP-00137128). It was

reported that Coast Guard investigators observed approximately 75 gal of kerosene contained by boom and kerosene still exiting the outfall; however, the PSE&G Harrison Gas Plant Manager estimated that approximately 30 gallons of oil had entered the water. Clean-up operations consisted of sorbents, a vacuum truck and a steam operated diaphragm pump to remove the kerosene from the water (PAP-00137128-29).

November 19, 1980 correspondence from the U.S. Coast Guard to PSE&G concerned a violation for improper containment which occurred on May 30, 1980 (PAP-00139880). The violation pertained to an oil drain catchment at the dock front that was portable rather than fixed. The inspector who rejected it on May 30, 1980, approved the revised arrangement on November 10, 1980 (PAP-00139885).

On October 5, 1981, the U.S. Coast Guard sent notice to PSE&G concerning a possible violation resulting from a discharge of approximately 10 gallons of tar to the Passaic River on July 11, 1981 (PAP-00140138-39). According to an August 14, 1981, Water Pollution Violation Report, the discharge involved approximately10 gal of tar from Tank #21 which leaked from the discharge line. Approximately 5-10 gallons of tar entered and were then removed from the River using a skimmer to remove tar contained by the facility boom. No samples were taken (PAP-00140116, 18).

On January 29, 1985, the U.S. Coast Guard assessed a $100 penalty to PSE&G for a October 18, 1983, violation at the Harrison Gas Plant. During an October 30, 1984, hearing, PSE&G disputed the findings that the release was to a navigable waterway as the release, caused by a leak in pipe, occurred into the flume and the oil was contained by a boom (PAP-00140219-23). According to an October 18, 1983 Water Pollution Violation Report, the discharge involved approximately 5 gal of tar as a result of the sump pump discharge line developing a leak (PAP-00140157). The report also stated that the U.S. Coast Guard observed sheen emitting from the flume discharge point into the Passaic River (PAP-00140159).

On September 25, 1987, the EPA found PSE&G Harrison in violation of general facility requirements pertaining to PCBs. A penalty of $8,500 was assessed (PAS-00104676-77). Note: The nature of the violation was not described in further detail.

In May 1994, an oily discharge to the Passaic River occurred at the PSE&G Harrison Gas Plant. Black oil was evident seeping from the river bank into the river (PAP-00128131; PAP-00128132; PAP-00128135; PAP-00128136; PAP-00356865). As a result of this spill, PSE&G was issued Notices of Violation by the U.S. Coast Guard and the Hudson County Regional Health Commission and required to develop and implement a long-term site remediation plan (PAP-00128137-38; PAP-00128156-59; PAP-00356865). In July 1994, PSE&G entered into a Memorandum of Agreement with the New Jersey Department of Environmental Protection and Energy to conduct Remedial Investigation and Remedial Actions as needed (PAP-00128139-61; PAS-00013585-89; PAP-00356865).

According to a July 1994 *Memorandum of Agreement* and September 1988 *Consent Agreement and Consent Order*, the PSE&G was found to be in violation of regulations relating to the labeling, duration of storage, or compilation and maintenance of annual documents for the storage and disposal of PCB contaminated soils by the U.S. EPA in 1988 and was fined $8,500.[5] (PAP-00128156; PAP-00140401-07; PAP-00140440).

On August 8, 1994, there was another discharge from the former Harrison Gas Plant in an area of the Passaic River not addressed by containment devices installed after the May event. The discharge was reported to the NJDEP and assigned Case # 94-8-8-1608-37 (PAP-00128212; PAP-00128214). [Note: Other source documents list the case number as 94-8-8-1607-37 (PAP-00128214-19).] As the source for both discharges was determined to be the same it was requested that the cases be consolidated (PAP-00128214-19).

In November 2004, PSE&G voluntarily reported an un-manifested PCB shipment from the Harrison Gas Plant facility. It was believed that the PCB contamination in the waste shipped on October 11, 2004, may have come from sludge material removed from a manhole. The shipped waste included material removed from a particular manhole which was later determined to contain a non-leaking transformer with a PCB concentration of 208 mg/kg. Other possible sources of the PCBs could be from a previously removed transformer or other cross-contamination (PAP-00128850-52). As a result of this violation, the U.S. EPA stated that it anticipated issuing an administrative complaint in this matter, seeking a civil penalty in the amount of $19,500 but offered to settle the matter for $11,375 (PAP-00128853-54; PAP-00128855; PAP-00128859-66).

In April 2010, PSE&G voluntarily reported an un-manifested PCB shipment from the Harrison Gas Plant facility which occurred on March 29, 2010. One drum of waste oil which was not expected to contain PCBs was shipped for disposal and was tested and found to contain regulated levels of PCBs (PAP-00129922-23; PAP-00129928). The drum contained 223 ppm PCBs (PAP-00129928).

In April 2011, PSE&G and U.S. EPA entered into a Consent Agreement and Final Order in which PSE&G agreed to pay a civil penalty of $13,670 for violating TSCA on three occasions by storing PCB waste and/or shipping PCB waste for disposal without identifying it as PCB on EPA Manifest Form 8700-22 (PAP-00130040-47; PAP-00130049-55).

[5] The Harrison Gas Plant site was used as a storage facility before ultimate proper disposal of various materials. The PCB materials in question, which appear to have been received at the Harrison site from off-site, were securely stored in containers and drums on-site. These violations concerned the improper labeling of these containers/drums, failure to dispose of these materials within one year of storage, or failure to maintain annual records of these materials (PAP-00140401-07).

Permits

PSE&G Harrison Gas Plant Permit Summary				
Permit #	**Issued**	**Use**	**Dates**	**Discharge Limits**
NJ0000566	EPA	All discharges	Sept. 30, 1974 - Sept. 30, 1979	Oil & Grease
98042-13280-052-292	PVSC	Sewer Connection	Oct. 24, 1978	< 100 mg/L of mineral oil or grease. No discharge containing floatable oil or grease.
NJ0000566	EPA	All discharges	Oct. 31, 1980 - Oct. 31, 1985	Discharge 001: petroleum hydrocarbons (5 mg/L), and copper (1 mg/L) Discharge 002 petroleum hydrocarbons (15 mg/L)
13403712	PVSC	Sewer Connection	July 31, 1981 - July 31, 1986,	< 100 mg/L of mineral oil or grease. No discharge containing floatable oil or grease.
NJ0000566	EPA	All discharges	Feb. 1, 1986 – Jan. 31, 1991	aldrin/dieldrin (0.0019 μg/L), PCBs (0.03 μg/L), DDT and metabolites (0.001 μg/L), petroleum hydrocarbons (5 mg/L)
NJG0088323	NJDEP	Stormwater	June 4, 2008	Not known

An October 18, 1972 Memo concerning the PSE&G Harrison Gas works stated that at that time the plants wastewater treatment facilities had not been approved by the NJDEP nor had permits been issued (PAS-00013596).

In March 1974, Public Service Electric and Gas Company submitted revised National Pollutant Discharge Elimination System (NPDES) applications to the U.S. EPA for Outfall #'s 004 and 005, "Plant Outlet Flume" and "Tar Conditioner Cooling and Steam Condensate Drain to River" for the Harrison Gas Plant (PAP-00128123).

On August 30, 1974, a final determination was made by the EPA to issue PSE&G NPDES Permit # NJ0000566. Discharge limitations included oil and grease (which may have contained PAHs). The discharge limit for oil and grease applying from September 30, 1974 to September 30, 1979 was 5.0 lb/day during non-production periods. The discharge limits for oil and grease applying from September 30, 1976 to September 30, 1979 were: 1 mg/L (anytime), 5.0 lb/day average and 10.0 lb/day maximum (non-production) and 20.8 lb/day average and 40.0 lb/day maximum (PAP-00128187-203). The permit was effective September 30, 1974 and expired September 30, 1979 (PAP-00128247-63).

On October 24, 1978, PVSC issued Permit # 98042-13280-052-292 to allow PSE&G Harrison Gas Plant to discharge 187,000 gallons per day to the industrial sewer (PAP-00132788). Discharge limitations included any discharge containing more than 100 mg/L of mineral oil or grease and any discharge containing floatable oil or grease (PAP-00132789).

On September 3, 1980, PSE&G Harrison Gas Plant renewed NPDES Permit # NJ0000566. The permit was effective October 31, 1980, and expired October 31, 1985 (PAP-00140073; PAP-00355998). The maximum daily discharge limitations for Discharge 001 included petroleum hydrocarbons (5 mg/L) and copper (1 mg/L). The discharge limitations for Discharge 002 included petroleum hydrocarbons (15 mg/L) but no COCs (PAP-00140074-75; PAP-00355999-6000).

From July 31, 1981 to July 31, 1986, the PSE&G Harrison Gas Plant operated under PVSC Sewer Permit # 13403712 (PAP-00140101; PAP-00140330). Discharge limitations included any discharge containing more than 100 mg/L of mineral oil or grease and any discharge containing floatable oil or grease. No discharge limitations were given for the effluent characteristics, biological oxygen demand (BOD), total suspended solids (TSS), and volume from either Outlet #1 Industrial Flow, or Outlet #2 Sanitary Waste (PAP-00140101-02, 05-06; PAP-00140330-31, 34-35).

The *Fact Sheet for Draft NJPDES Permit to Discharge into the Waters of the State of New Jersey,* dated October 1, 1985 for Permit # NJ0000566 reported the discharge limitations for Discharges 001 and 002. The discharge limitations for Discharge 001 included petroleum hydrocarbons (5 mg/L) and copper (no limit given). Because the cooling water was both pumped from and discharged to the Passaic River, net effluent limitations are applicable. The discharge limitations for Discharge 002 included petroleum hydrocarbons (15 mg/L) but no specific COCs (PAP-00140281, 84-86).

The Harrison Gas Plant was issued NJPDES Permit # NJ0000566 on December 30, 1985. The permit was effective February 1, 1986, through January 31, 1991, and granted permission to discharge stormwater runoff and non-contact cooling water to the Passaic River (PAP-00140293). The surface water quality maximum concentrations included aldrin/dieldrin (0.0019 μg/L), PCBs (0.03 μg/L), DDT and metabolites (0.001 μg/L), petroleum hydrocarbons (5 mg/L) (PAP-00140311, 13).

In August 1990, PSE&G Harrison Gas Plant filed an *Application for Renewal NJPDES Permit # NJ0000566* to discharge to the municipal storm sewer system (PAP-00140791-92).

According to the August 1990 *Application for Renewal NJPDES Permit # NJ0000566,* the PSE&G Harrison Gas Plant held Air Permits for thirteen storage tanks which included a gasoline storage tank, tar process & storage tanks, spent oil tank, and a naphtha storage tank (PAP-00140800).

In January 1991, PSE&G Harrison Gas Plant filed an Application for Sewer Connection Permit # 13403712 (PAP-00140810).

In a letter dated September 22, 1994, PSE&G reported to the Bureau of Standard Permits Division of Water Resources, that by September 13, 1994 the Harrison Gas Plant facility had ceased discharging any non-contact cooling water. Because there was no longer a non-contact cooling water discharge, PSE&G requested an Application for Exemption to terminate that portion of NPDES Permit # NJ0000566 (PAP-00128204-05; PAP-00128226-29).

In July 1996, PSE&G Harrison Gas Plant requested a modification of Sewer Connection Permit # 13403712 because operational changes had reduced their process waste water discharge, and resulted in a sole constant industrial discharge of an average 500 gallons per day from an analytical laboratory (PAP-00128245-46). On August 2, 1996, the PVSC stated that they would not renew the permit because the facility no longer met the criteria to be classified as an industrial user (PAP-00128264-65). Any wastewater generated from site demolition or remediation projects would need to be approved by PVSC before it could be discharged to the sanitary sewer (PAP-00128264-65).

On March 21, 2012, NJDEP issued Remedial Action Soil Permit No.: RAP120002 to PSE&G to conduct remedial activities at the PSE&G Future Substation Area A/K/A: Red Bull Substation/ Former Harrison Gas Plant. The permit became effective March 26, 2012 (PAP-00130508).

7. Response Actions

Characterization Activities

April 21, 1980, correspondence from PSE&G to Hackensack Meadowlands Development Commission concerned the chemical analysis of five samples of dredged material taken from the Passaic River in the dock area of the Harrison Gas Plant. Thirteen thousand cubic yards of this material had been dredged from the river and PSE&G was asking about the suitability of this material in a landfill or as a cover for a landfill (PAP-00139407). PCBs, copper, lead and mercury were detected in all five samples at the following concentration ranges: Aroclor-1242 (1.9-4.6 ppm), Aroclor-1254 (not detected-2.9 ppm), copper (3.45-6.35 ppm), lead (8.35-11.32 ppm), mercury (0.003-0.007 ppm) (PAP-00139408, 10-11). As of May 1979, maintenance dredging had last been performed at the Harrison Gas Plant facility in 1975 (PAP-00135615).

In 1985, a Preliminary Site Assessment was conducted at the PSE&G Harrison Gas Plant. According to *Harrison Gas Plant Preliminary Site Assessment and Proposed Monitoring Plan* dated May 17, 1985, waste deposits were described as sludge from oil tanks, tar tanks, and the tar separator as well as spent oxide, clinker, gas set brick, and ash which were apparently deposited at two locations along the north property line, prior to 1930. One deposit was removed and trucked off the property in 1953. The second deposit was partly removed during construction of a Vaporizer Building in 1954. Noticeable tar accumulations were noted to be visible at several locations on the ground east of the vaporizer building. It was also noted that priority pollutant analyses for phenols, base neutrals, and metals were performed on water samples taken upstream of the plant and at the plant discharge from the Passaic River and from the well located on the site showed that any contamination which may exist on-site had not migrated from

the site (PAP-00140252). The results for the samples collected September 20, 1983 were non detected for PAHs, and 2,4,6-trichlorophenol (PAP-00140256-59). Copper was detected in the well water sample at 28 μg/L, 45 μg/L in the upstream sample, and 76 μg/L in the discharge effluent sample. Lead was not detected in any sample, and mercury was detected at 0.70 μg/L in the well and upstream samples but was not detected in the discharge effluent sample (PAP-00140261).

Remedial Activities

According to the *Focused Remedial Investigation Report* dated February 1997, a focused remedial investigation was conducted in 1996 by Golder Associates, Inc. for PSE&G at the PSE&G Harrison Gas Plant. This investigation was in response to the Memorandum of Agreement with the NJDEP which was the result of the May 1994 spill. The investigation was not designed to fully investigate and delineate environmental conditions at the site but was intended to identify potential interim remedial actions at the site which would minimize hydraulic communication between the site and the adjacent Passaic River. Groundwater and soils samples were collected as part of this investigation. Samples were collected from four test pits, four soil borings, and seven groundwater monitoring well locations. Analytical results for soil samples from the layer of soil identified as fill had exceedances of NJDEP Soil Cleanup Criteria for PAHs in two samples and exceedances of NJDEP Soil Cleanup Criteria for metals (primarily arsenic, cadmium, and / or lead) in eight samples. The concentration ranges of the COCs detected in the soils samples were as follows:

Soil Concentrations	
COC	**Concentration**
Benzo(a)anthracene	Not detected to 160 μg/kg – 2,400 μg/kg
Benzo(a)pyrene	Not detected to 160 μg/kg – 3,500 μg/kg
Benzo(b)fluoranthene	Not detected to 150 μg/kg – 1,800 μg/kg
Benzo(k)fluoranthene	Not detected to 130 μg/kg – 1,500 μg/kg
Indeno(1,2,3-cd)pyrene	Not detected to 140 μg/kg – 1,400 μg/kg
Benzo(g,h,i)perylene	Not detected to 170 μg/kg – 2,200 μg/kg
Copper	5.68 mg/kg – 75.93 mg/kg
Lead	4.39 mg/kg – 455.97 mg/kg
Mercury	Not detected to 0.28 mg/kg – 2.62 mg/kg

(PAP-00128330-39)

An April 1999 *Remedial Alternative Evaluation* prepared by Langan for PSE&G included a summary of the affected media at the PSE&G Harrison Gas Plant. The fill layer of the soil had significant contamination by semi-volatile organic compounds (SVOCs), primarily PAHs and various metals at levels exceeding the Residential Direct Contact Soil Cleanup Criteria (RDCSCC) as well as VOCs (PAP-00128416-17).

An RI was conducted by Langan for PSE&G between November 1997 and July 1999. The results of the RI were reported in the *Remedial Investigation Report (Including Remedial Action Selection Report) Former Harrison Gas Plant,* prepared September 1999. As part of the RI, a total of 126 test pits were excavated to determine subsurface

conditions within the fill at suspected areas of contamination *(e.g.,* gas main, manufactured gas plant gas production and product storage areas). Soil samples were collected from selected test pits for PAH screening and subsequent laboratory analyses. One soil sample was collected from the zero to two foot depth interval from each of 60 test pits to represent surface (zero to two feet) soil conditions. The samples were biased towards fill material that appeared to be most contaminated based on visual observations or photoionization detector readings. The soil samples were field screened in a mobile laboratory for PAHs. Thirteen of the PAH screening samples with the highest analytical results were analyzed at the laboratory for SVOCs, PCBs, and Target Analyte List Inorganics in addition to other analyses. In addition to the 13 samples that were laboratory analyzed based on PAH screening results, 10 samples were collected from pre-determined locations. Additionally, one sample of tar was collected from each of two test pits excavated from the buried tar area near the former vaporizer house at the north end of the Site (PAP-00128557-59).

The results of the field screening showed that samples collected in manufactured gas plant production and tar storage areas typically possessed higher concentrations of PAHs than samples collected in non-production or tar storage areas. The most common PAHs detected were benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, chrysene, dibenz(a,h)anthracene and indeno(1,2,3-cd)pyrene. These were detected at low concentrations in most samples. The highest benzo(a)pyrene concentrations were detected in the tar storage area south of the office building, in the area of the purifier boxes, and in the tar storage area south of the machine shop. PAHs were not detected in seven test pit samples (PAP-00128589-90).

A total of 143 soil borings were drilled between November 1997 and October 1998 to gather stratigraphic information at various locations and to determine contaminant distribution (PAP-00128560-61). No exceedances of NJDEP RDCSCC were detected in the three soil samples collected off-site in the fill. Exceedances were detected in 22 of 27 on-site samples. Organic and inorganic contaminant concentrations decrease by at least a factor of five between on-site and off-site samples along Frank E. Rodgers Boulevard (PAP-00128591).

PAH exceedances were detected in 22 of 22 surface samples. The most common PAH exceedances were benzo(a)pyrene, benzo(a)anthracene, and benzo(b)fluoranthene. These and other SVOCs were typically present in the gas production and storage areas on-site (PAP-00128591). Inorganic exceedances which include lead were detected in 14 of 20 surface samples. PCB exceedances were detected in four of 24 surface samples. However, none were detected at the former transformer pads (PAP-00128592).

PAH exceedances of RDCSCC were detected in eight of 12 subsurface fill samples. All exceedances were from on-site samples. PAHs were widely distributed over the site. No off-site exceedances were detected. Inorganic exceedances of RDCSCC were detected in 7 of 11 subsurface fill samples. The most common inorganic exceedances detected included lead. Less common were copper and other metals. The analysis of the tar samples detected high levels of several SVOCs. The analysis of the sample from TP-39 detected high levels of several SVOCs, copper, lead, and other metals. One off-site exceedance of RDCSCC was detected for lead (PAP-00128593).

The concentration ranges for detected COCs from the on-site soil samples were as follows:

Soil Concentrations (mg/kg)	
COC	**Concentration**
Benzo(a)anthracene	Not detected to 0.01 mg/kg – 780 mg/kg
Benzo(a)pyrene	Not detected to 0.0091 mg/kg – 660 mg/kg
Benzo(b)fluoranthene	Not detected to 0.017 mg/kg – 600 mg/kg
Benzo(k)fluoranthene	Not detected to 0.033 mg/kg – 230 mg/kg
Dibenzo(a,h)anthracene	Not detected to 0.017 mg/kg – 60 mg/kg
Indeno(1,2,3-cd)pyrene	Not detected to 0.008 mg/kg – 280 mg/kg
Benzo(g,h,i)perylene	Not detected to 0.01 mg/kg – 270 mg/kg
Copper	5.8 mg/kg – 2,490 mg/kg
Lead	3.0 mg/kg – 4,890 mg/kg
Mercury	Not detected to 0.05 mg/kg – 1.9 mg/kg
Aroclor-1260	Not detected to 0.11 mg/kg – 0.65 mg/kg
Aroclor-1254	Not detected to 0.11 mg/kg – 2.1 mg/kg
Aroclor-1248	Not detected to 0.17 mg/kg – 3 mg/kg

(PAP-00128653-79)

Several SVOC (mostly PAHs) exceedances were detected in 14 of 31 on-site shallow aquifer piezometers distributed over the entire site. The SVOCs included naphthalene, 2-methylnaphthalene, acenaphthylene, acenaphthene, fluorene, phenanthrene, fluoranthene, pyrene, benzo(a)anthracene, chrysene, benzo(b)fluoranthene, benzo(k)fluoranthene, benzo(a)pyrene, indeno(1,2,3-cd)pyrene, dibenz(a,h)anthracene, and benzo(g,h,i)perylene. No SVOCs were detected in exceedance of the Class IIA GWQS in any of the off-site piezometers (PAP-00128601-02). A minimum of one inorganic exceedance was detected in each of the 31 on-site shallow aquifer piezometers distributed over the entire site. These inorganics included copper, lead, and mercury in addition to other metals (PAP-00128602).

The concentration ranges for detected COCs from the on-site shallow aquifer piezometer samples were as follows:

Shallow Aquifer Concentrations (µg/L)	
COC	**Concentration**
Benzo(a)anthracene	0.9 µg/L – 210 µg/L
Benzo(a)pyrene	0.8 µg/L – 160 µg/L
Benzo(b)fluoranthene	0.9 µg/L – 130 µg/L
Benzo(k)fluoranthene	1.0 µg/L – 59 µg/L
Dibenzo(a,h)anthracene	1.3 µg/L – 26 µg/L
Indeno(1,2,3-cd)pyrene	1.2 µg/L – 83 µg/L
Benzo(g,h,i)perylene	1.6 µg/L – 110 µg/L
Copper	4.1 µg/L – 4,520 µg/L
Lead	5.2 µg/L – 4,730 µg/L
Mercury	0.13 µg/L – 81.5 µg/L

(PAP-00128722-44)

Additional post-excavation soil samples were collected during the RI following the removal of six underground storage tanks (USTs). A total of 30 post-excavation soil samples were collected from the six UST excavations (PAP-00128572-73)

The concentration ranges for detected COCs from the post-excavation soil samples were as follows:

Post-Excavation Soil Concentrations (mg/kg)	
COC	**Concentration**
Benzo(a)anthracene	2.4 mg/kg - 7.2 mg/kg
Benzo(a)pyrene	2.3 mg/kg - 5.8 mg/kg
Benzo(b)fluoranthene	2.6 mg/kg - 5.6 mg/kg
Benzo(k)fluoranthene	0.86 mg/kg - 1.9 mg/kg
Dibenzo(a,h)anthracene	Not detected to 0.36 mg/kg - 0.81 mg/kg
Indeno(1,2,3-cd)pyrene	0.94 mg/kg - 2.9 mg/kg
Benzo(g,h,i)perylene	1.3 mg/kg - 4 mg/kg
Copper	5.2 mg/kg - 261 mg/kg
Lead	22.4 mg/kg - 210 mg/kg
Mercury	0.04 mg/kg - 3.3 mg/kg
Aroclor-1260	0.097 mg/kg (only one detection)

(PAP-00128680-93)

The *Remedial Investigation Report (Including Remedial Action Selection Report) Former Harrison Gas Plant* concluded that onsite soils within the fill had been impacted by Harrison Gas Plant operations. Contamination was widely distributed over the site with regions of greater contamination in former gas plant production and storage areas. Tar and/or oil staining was identified at most subsurface exploration locations across the site extending down to the Organic Clay (PAP-00128618). It was also concluded that Harrison Gas Plant operations had impacted off-site soils within the fill to the west of the

site along the Railroad right-of-way (ROW). Tar and/or staining was identified at many subsurface exploration locations extending to the Organic Clay, especially west of the former No. 3 gas storage holder (PAP-00128618).

The *Remedial Investigation Report* also noted that three hardened tar masses had been identified: one by the former vaporizer house at the north end of the site, one west of the former No. 3 gas storage holder along the western property boundary and extending onto the Railroad ROW, and the last on the Railroad ROW northwest of the No. 1 gas storage holder. The tar mass at the north end of the Site was approximately 2,000 cubic yards (cy) in size, the second tar mass was approximately 1,300 cy in size and the last tar mass was approximately 13 cy in size. Tar, present as free product, was observed at four locations: south of the tar separators, south of the former No. 3 gas storage holder, west of the former tar storage tank Nos. 28 and 29, and within the Railroad ROW west of the former No. 3 gas storage holder (PAP-00128618).

The *Remedial Investigation Report* estimated that 3,000 gallons of recoverable tar were present south of the former tar separators, that 150 gallons of recoverable tar were present south of the No. 3 gas storage holder, that 1,200 gallons of recoverable tar were present west of the tar storage tanks, and that 250 gallons of recoverable tar were present west of the former No. 3 gas storage holder (PAP-00128618-19).

Light non-aqueous liquids (LNAPLs) such as oil were observed at five locations: two were south of the current office building in the vicinity of the relief holder, one was west of the former gas purifiers, one was along the gas main in the center of the Site, and one was along the gas main trench near the bulkhead. It was estimated that 3,338 gallons of recoverable LNAPL was present along the gas main trench near the bulkhead (PAP-00128619).

According to the *Remedial Action Report - Phase I Riverfront Stage, Former PSE&G Harrison Gas Plant Site,* excavation activities were completed in July 2005 to expose underground utilities for the purpose of upgrading the natural gas supply service main. Although this excavation was not part of a remedial action, soil was removed which was comprised of historic fill. A total of 85 tons of soil (historic fill material) were excavated from the northeastern section of the site along the fence line near Frank E. Rodgers Boulevard, and 6,284 gallons of groundwater were pumped for off-site disposal to a licensed facility. There were no observations of oil material and/or tar material, related to the historic operations of the former Harrison Gas Plant during excavation activities. Post excavation side wall samples were not collected. The area was backfilled with 91 tons of certified clean sand (PAP-00128948).

During the Phase 1 Riverfront Stage remedial action which took place between July 1, 2006 and January 11, 2008, a total of 53,690 cubic yards of contaminated soils were excavated from the Harrison Gas Plant site. With the exception of two specific areas containing COCs in soil identified during previous Phase II RI/waste classification sampling events (Former Area D Benzene and Former Area E Dioxin) the objective of the remedial action was the removal of source material (oil material and tar material) (PAP-00128952-53, 97). Each excavation was extended to the depths sufficient for removal of oil material and tar material, removal of historic plant structures and/or to the

maximum extent practicable. Post-excavation samples were collected at the 10 remediation excavation areas (PAP-00128966).

According to the *Remedial Action Report - Phase I Riverfront Stage, Former PSE&G Harrison Gas Plant Site*, Remediation Area 3 contained elevated levels of chlorinated dibenzo-p-dioxins in soils from 5.5 to 11.0 feet bgs. Soils in this area were removed to approximately 22 feet bgs with the exception of the northeast comer which was removed to a depth of approximately 14 feet bgs. Therefore according to the *Remedial Action Report*, the soils that contained elevated levels of dioxin were effectively removed. Four post excavation samples were collected and analyzed for dioxins in addition to the other post excavation parameters. Dioxins were detected in each of the samples. The results state that the dioxin concentrations are highest at sample PEB-AE-5B located closest to the waterfront. This sample was collected from material that was located below the former relieving platform and presumed to be sediment based on its physical characteristics. The analytical results of sample PEB-AE-5B was consistent with results from shallow samples collected in sediments from the “Harrison Reach” of the Passaic River by EPA. These results state that the dioxins detected in the post excavation samples can be attributed to migration from the Passaic River and are not associated with the former Harrison Gas Plant operations. The area was capped. Residual dioxin concentrations would be documented in the deed notice to be filed upon completion of the subsequent phases of remedial actions at the site (PAP-00128997-98).

The following table compares the analytical data EPA sediment RI data from the Passaic River for selected dioxin compounds: (PAP-00128998).

Harrison Post-Excavation Data with Comparison to Sediment EPA RI Data[a]

Congener	PEB-A3-5A	PEB-A3-5B	PES-A3-5A	PES-A3-5B	12A001[a]	13A020[b]

April-95: "Analytical Data Summary Tables - Passaic River Study Area Remedial Investigation"

According to the *Remedial Action Report - Phase I Riverfront Stage, Former PSE&G Harrison Gas Plant Site*, the remedial action was effective in removing source material (oil material and tar material) and several former structures possibly related to these sources from the areas excavated. However, based on field observations, oil material and tar material remained at the site beyond the limits of the excavation at several locations. These locations included the following: 1) in the shallow fill material above the silty clay confining layer at numerous locations north of the landside sheeting, and north, east and west of Area 7-8-9; 2) in native soils below the silty clay/peat confining layer at depths that exceeded the maximum practicable depth permitted by the sheeting design at

the southeastern corner of Area 1-4; 3) in sediments located beneath the former relieving platform in Area 3 (in cells A3-2, A3-3, A3-4, and A3-5); 4) in native soils below the silty clay/peat confining layer north of the landside sheeting at Area 3, 4b, 5, 6 and 10; and 5) in a small pocket of sand/gravel north-northwest of Area 10 at approximately -27 to -32 msl (PAP-00128998-99). The report recommended conducting additional remedial investigations to determine the horizontal and vertical extent of the remaining oil material and tar material (PAP-00129000).

According to the *Interim Remedial Action Report, Former Harrison Gas Plant, Future Substation Area (Interim Remedial Action Report)*, dated March 2009, an Interim Remedial Action was conducted on a portion of the former Harrison Gas Plant known as the Future Substation Area in 2008. This area was remediated to allow for construction of a new electrical substation. The purpose of the Interim Remedial Action was to remove tar material from the area of the proposed substation construction, and prevent recontamination of the area. The Interim Remedial Action included the excavation and removal of soils containing tar material within the Future Substation Area; placement and compaction of clean backfill; installation of a low-permeability seal between the clean fill and excavation side walls where tar material was present at the boundary of the planned excavation, and; establishment of an institutional control in the form of a deed notice (PAP-00129342). The Future Substation Area was located in the north-eastern most corner of the former Harrison Gas Plant site (PAP-00129392).

The figure on the next page shows the extent of the tar identified during the Interim Remedial Action for the future substation at the Harrison Gas Plant site:

(PAP-00129394)

From August 2008 to September 2008, excavation was conducted to remove the tar material. Not all of the tar material could be removed due to groundwater entering the excavation from the deeper aquifer. Tar material was observed seeping from the southern end of the western wall and the southern side wall. These areas were covered with a bentonite geotextile (Bentomat™) to prevent tar material from reentering the excavation. Soils containing tar material were excavated into the top of the organic clay layer, approximately 10 feet below grade (PAP-00129372-73). A total of 16,895.87 tons of soil excavated from the site were transported for off-site thermal treatment and reuse as daily landfill cover (PAP-00129378).

The *Interim Remedial Action Report* concluded that the remedial activities at the Future Substation Area successfully removed tar material to the extent practicable as necessary to allow construction of the electrical substation. This included removal of tar material within and near the footprint of the substation to the top of the underlying Organic Clay Layer. The environmental conditions that could not be addressed by this Remedial Action would be addressed by the future sitewide Remedial Action for the former Harrison Gas Plant (PAP-00129387). A deed notice was to be established for the substation area to serve as an institutional control to prevent potential exposure to affected soils. The deed notice extends to the limits of the excavation and includes soil contamination that remains in place on the substation area following completion of the excavation activities (PAP-00129357, 80).

The concentration ranges for detected COCs from the samples collected for the deed notice are as follow:

Deed Notice Future Substation Area		
COC	**Concentration Ranges**	**Depth of Max Concentration**
Benzo(a)anthracene	0.029 J mg/kg – 6.5 mg/kg	-9.5 to -10.0
Benzo(a)pyrene	0.02 J mg/kg – 4.9 mg/kg	-9.5 to -10.0
Benzo(b)fluoranthene	0.016 J mg/kg – 3.1 mg/kg	-9.5 to -10.0
Benzo(g,h,i)perylene	0.011 J mg/kg – 0.74 J mg/kg	-9.5 to -10.0
Benzo(k)fluoranthene	0.018 J mg/kg – 4.8 mg/kg	-9.5 to -10.0
Dibenzo(a,h)anthracene	Not detected to 0.036 J mg/kg – 0.52 mg/kg	-9.5 to -10.0
Indeno(1,2,3-cd)pyrene	0.0089 J mg/kg – 0.97 mg/kg	-9.5 to -10.0
Copper	26.3 mg/kg – 3,330 mg/kg	-6.0 to -6.5
Lead	82.8 mg/kg – 4,890 mg/kg	-6.0 to -6.5
Mercury	0.19 mg/kg – 2.1 mg/kg	-4.5 to -5.0

(PAP-00129399-400)

As reported in the *Supplemental Remedial Investigation Report, Future PATH Substation Investigation*, dated August 2009, additional investigations were conducted in June 2009 at the location of the PATH substation to delineate the horizontal and vertical extent of areas of tar material and oil material in the footprint of the Future PATH Substation Area. This investigation included obtaining soil samples within the footprint of the Future PATH Substation Area to provide data necessary for conducting a remedial action (soil removal) and implementing institutional controls (deed notice), as well as

obtaining additional groundwater samples in the shallow and intermediate aquifers to identify groundwater COCs (PAP-00129653, 64-65).

SVOCs above the Soil Remediation Standards or Impact to Groundwater Soil Screening Levels were primarily 2-methylnaphthalene, fluorene, fluoranthene, pyrene, naphthalene and suspected carcinogenic PAHs (benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, chrysene, dibenzo(a,h)anthracene and indeno(1,2,3-cd)pyrene were detected in approximately half of the samples collected from borings installed in fill material. Samples obtained from glaciofluvial soils below the meadow mat stratum did not contain SVOCs above the Remediation Standards or Soil Screening Levels. Observations of oil material/sheens generally coincided with sampling locations where elevated levels of SVOCs were identified (PAP-00129669).

The highest levels detected above the Remediation Standards were found in one boring at a depth of 9.0-9.5 bgs. The concentrations were as follows: (PAP-00129669-70)

Soil Boring Concentrations (mg/kg)	
COC	**Concentration**
Benzo(a)anthracene	139 mg/kg
Benzo(a)pyrene	129 mg/kg
Benzo(b)fluoranthene	53.9 mg/kg
Benzo(k)fluoranthene	54.8 mg/kg
Dibenzo(a,h)anthracene	15.8 mg/kg
Indeno(1,2,3-cd)pyrene	41.7 mg/kg

Approximately 25 percent of samples obtained from the fill material contained metals above the NJDEP Soil Remediation Standards or Impact to Groundwater Soil Screening Levels which included lead and mercury (PAP-00129670). The highest levels of lead and mercury detected were as follows:

June 2009 Supplemental Remedial Investigation		
COC	**Concentration**	**Depth**
Lead	1,240 mg/kg	1.5 to 2.0
Mercury	6.4 mg/kg	8.0 to 8.5

(PAP-00129670)

The concentration ranges for detected COCs from the June 2009 Supplemental Remedial Investigation soil sampling were as follows:

June 2009 Supplemental Remedial Investigation	
COC	**Concentration**
Benzo(a)anthracene	Not detected to 0.0354 J mg/kg – 139 mg/kg
Benzo(a)pyrene	Not detected to 0.0376 J mg/kg – 129 mg/kg
Benzo(b)fluoranthene	Not detected to 0.0308 J mg/kg – 53.9 mg/kg
Benzo(k)fluoranthene	Not detected to 0.0295 J mg/kg – 54.8 mg/kg
Dibenzo(a,h)anthracene	Not detected to 0.0198 J mg/kg –15.8 mg/kg

Indeno(1,2,3-cd)pyrene	Not detected to 0.0216 J mg/kg – 41.7 mg/kg
Benzo(g,h,i)perylene	Not detected to 0.0347 J mg/kg – 55 mg/kg
Copper	9.6 mg/kg – 373 mg/kg
Lead	3.3 mg/kg – 1,240 mg/kg
Mercury	Not detected to 0.12 mg/kg – 6.4 mg/kg

J= Estimated (PAP-00129681-707).

A total of 33,459.26 tons of excavated soil, debris and fragmented piping as well as 5,355.74 tons of soil containing hazardous lead were removed for disposal (PAP-00360064).

The report concluded that the Interim Remedial Action was successful in that the following specific remedial action objectives were completed:

- Removal of soils above and below the shallow groundwater table that were considered to be a source of groundwater contamination;
- Removal of subsurface former gas plant structures considered to be a source of site soil and groundwater contamination;
- Inhibit re-contamination of imported certified clean backfill with the installation of a Vertical Hydraulic Barrier and Geosynthetic Clay Liner bottom panels; and,
- Allow for long-term use of the future PATH Substation #9 construction area with the implementation of a Deed Notice and continued operation and maintenance of the site engineering controls and institutional controls (e.g., groundwater classification exception area) (PAP-00360074).

On March 2, 2011, the Deed Notice for the former PSE&G Harrison Gas Plant facility designated as Block 78, Lot 1 was finalized (PAP-00359951). The remaining contamination which prevents unrestricted use was reported using the concentrations noted above in the table titled “Deed Notice Future Substation Area”.

On July 11, 2012, a Deed Notice for the former PSE&G Harrison Gas Plant facility designated as Block 78, Lot 1 was issued (PAP-00360452). This deed notice was terminated on August 10, 2016 (PAP-00361883). On January 5, 2017 and December 22, 2017, deed notices were issued for Lots 1.02 and 1.01, respectively (PAP-00361786; PAP-00361844).

According to the *Remedial Investigation Report Former Harrison Gas Plant*, in 2014, Paulus, Sokolowski & Sartor, LLC implemented and managed a Pre-Design Investigation on behalf of PSE&G. The Pre-Design Investigation was conducted from April through June of 2014 for Parcels A and B (western half of the Site) and September through December of 2014 for Parcels C and D (upper half of Site). The focus of the Pre-Design Investigation was to characterize soils underlying the property and to identify the presence of contamination as related to the former on-site manufactured gas plant operations (PAP-00130613). A total of 389 soil borings were installed via direct push drilling techniques. The sample locations were chosen using an approximate sampling

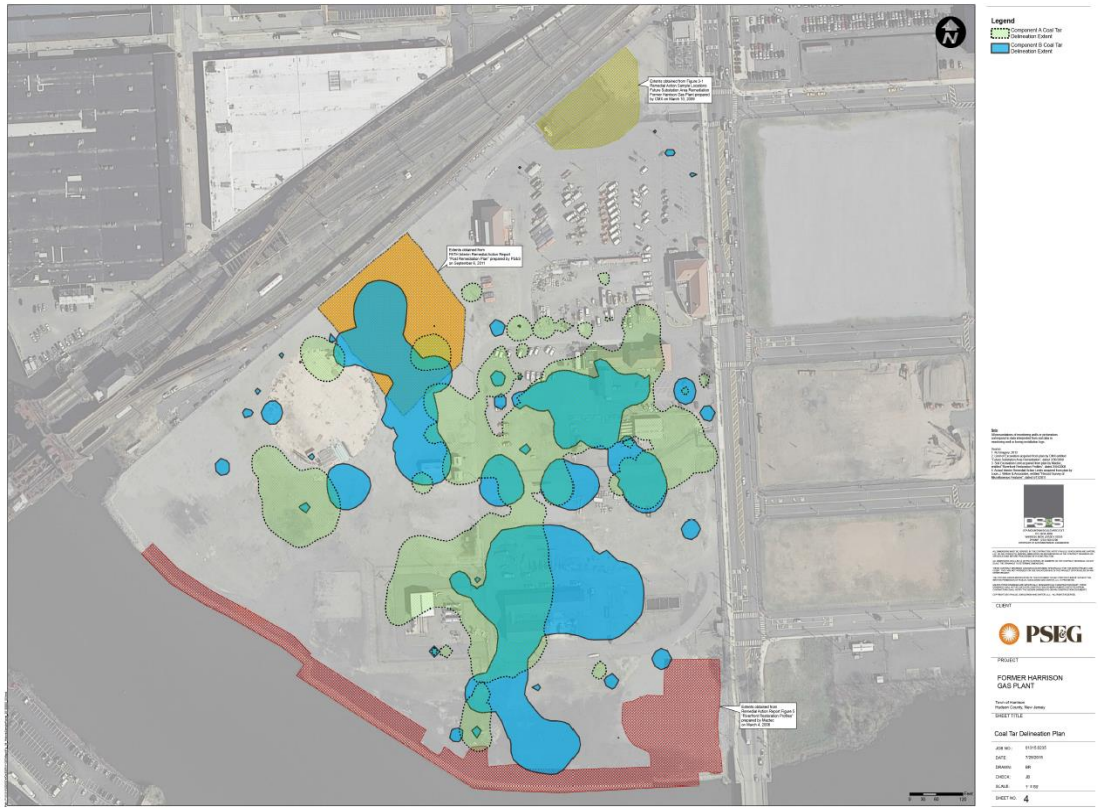
grid of 50 foot center to center, and were advanced to a maximum depth of 49 feet bgs. 156 soil borings were field screened and 188 soil samples were collected for laboratory analysis (PAP-00130613).

The *Remedial Investigation Report Former Harrison Gas Plant* reported the following findings of the Pre-Design Investigation:

- Previous explorations and investigations had stated the presence of coal tar or NAPL in a layer of coarse sand located between 15-35 feet bgs northeast of Former Gas Holder No. 3 through the southern half of Former Gas Holder No. 1. This coarse sand layer was observed during sampling activities performed during this investigation in April 2014. The coarse sand tested positive for oil hydrocarbons and typically had PID readings greater than 9,999 ppm.

- Locations near the historical naphthalene drip tanks had a separate fluorescent tar signature in observed logs. This could potentially be the result of the historical naphthalene storage. A sample taken from 39.5 to 40 feet bgs in Boring B-2-16 had an observed naphthalene concentration of 960 mg/kg.

- Using the 3-D model developed from the investigative data, a significant mass of 130,000 cubic yards of manufactured gas plant waste was found in the subsurface across Parcels A through D. Thickness of the soil impact within the model ranges between 6 and 49 feet bsg. The model also shows the likely presence of additional manufactured gas plant waste in other portions of the site.



- Vadose zone impact as related to NJDEP's Default IGWSSL's are minimal due to the majority of coal tar identified being below the shallow water table.
- The thickest accumulations of manufactured gas plant waste are located adjacent and below the former gas holders.

- The 3-D model identifies that coal tar in the man-emplaced fill material totals 6,000 cubic yards of the coal tar mass, where the average depth of the fill is approximately 9 feet bgs. The model shows that 45,000 cubic yards of coal tar mass are identified within the clay/peat (meadow mat), ranging from approximately 9 to 15 feet bgs. The model shows the remaining 79,000 cubic yards of coal tar mass within the sand below the meadow mat, ranging from approximately 15 feet to 49 feet (maximum depth of borings during the investigation) (PAP-00130615-16).

The Pre-Design Investigation concluded that that much of the un-remediated portions of the Site are impacted with coal tar or manufactured gas plant waste. It was also noted that there was a high degree of variability in coal tar PAH concentrations and PAH distributions. An output of the Pre-Design Investigation was the development of the 3-D Model to be used as a management strategy for expediting characterization of the site. The Model was constructed by using historical soil and groundwater data from all prior Remedial and Field Investigations of the site, site lithology and historical buildings and

features along with aerial photography and the data developed during the 2015 Pre-Design Investigation (PAP-00130616-19).

The following figure presents the Component A (green) and Component B (blue) Coal Tar delineation extents:

(PAP-00130658)

Note: The different components were based upon the PAH molecular structure (PAP-00130614). The report did not state which PAHs were found in each component.

8. Summary of Asserted Defenses

Public Service asserts a number of defenses, including but not limited to the following:

- Discharges from the site were permitted discharges exempt from Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) and Emergency Planning and Community Right-to-Know Act (EPCRA) release reporting requirements pursuant to CERCLA section 101(10).

- Discharges of “petroleum, including crude oil or any fraction thereof” are excluded from CERCLA’s definition of “pollutant or contaminant.”

Diamond Alkali OU2 Allocation

ADR Confidential

Facility Data Report

PURDUE PHARMA TECHNOLOGIES

Facility Name, Address and Size: Lemke Chemicals, Inc./Napp Chemicals, Inc./Napp Technologies, Inc.; 199-201 Main Street, Lodi, New Jersey; 1.728 acres; 108 employees; the number of shifts was unavailable (PAP-00127288)

1. **Business Type:** Bulk pharmaceutical manufacturing and processing (PAP-00127288)

2. **Time Period of Ownership/Operations**

Operator: 1971 to 1995
Owner: Not Applicable

1946: B.L. Lemke & Co. Inc. owned and operated the site from 1946 to 1970 (PAS-00085127).

1970: According to a *Remedial Investigation Report/Remedial Action Work Plan*, dated June 17, 2004, Nappwood Land Corporation took ownership of the site beginning in 1970 (PAP-00127496; PAS-00085127). Purdue Pharma Technologies, Inc. (PPTI) was incorporated in the State of Delaware under the name “195-203 Fine Products Corporation” on December 17, 1970 (PAS-00081948).

1971: B.L. Lemke & Co. Inc. was merged into PPTI on March 13, 1971, with PPTI as the surviving corporation and doing business under the new name of "Lemke Chemicals, Inc." (PAS-00081948). PPTI (known as Lemke Chemicals, Inc.) began operating the site on or about March 13, 1971 (PAS-00081939).

1973: A Certificate of Amendment was filed on January 30, 1973, changing the name from "Lemke Chemicals, Inc." to "Napp-Lodi, Inc." On March 30, 1973, Napp-Lodi, Inc. was merged with Napp-Clifton, Inc. and Napp Chemicals, Inc., with Napp-Lodi, Inc. surviving under the name "Napp Chemicals, Inc." (PAS-00081948).

1981: In 1981, to accommodate a need for additional warehouse space, Napp Chemicals, Inc. leased 18,000 square feet of an adjacent “Sawwood Warehouse.” The Sawwood Warehouse, located at 175 Main Street, was used solely by Napp Chemicals, Inc. for the warehousing of non-flammable raw materials and finished products (PAS-00084885). This property was leased from Robert Fortunato (doing business as R&R Realty) (PAS-00084885; PAP-00127468).

1993: A Certificate of Amendment was filed on April 17, 1993, changing the name from Napp Chemicals, Inc. to Napp Technologies, Inc. (PAS-00081948).

1995: On April 21, 1995, an industrial accident at the site destroyed a portion of the site and caused plant operations to cease (PAP-00127495).

2002: A Certificate of Amendment was filed on March 26, 2002, changing the name from Napp Technologies, Inc. to Purdue Services, Inc.; and, a Certificate of Amendment was filed on October 7, 2002, changing the name from Purdue Services Inc. to the current name of PPTI (PAS-00081948).

2018: According to a Soil Remedial Action Permit, Deed Notice with Engineering Control, dated July 2, 2018, Douglas Kanter/KLS LODI LLC is the property owner (PAP-00374435). It is unclear when ownership of the property was transferred from Nappwood Land Corporation to Douglas Kanter/KLS LODI LLC, and if there were any intermediate property owners.

It is noted that the site was comprised of three distinct areas:

- PPTI site: the property leased by PPTI from Nappwood Land Corporation;
- Sawwood Warehouse: located at 175 Main Street, leased from Robert Fortunato (doing business as R&R Realty), and used solely for the warehousing of non-flammable raw materials and finished products; and,
- Common Area: the parking area behind the Sawwood Warehouse leased by PPTI from Robert Fortunato (PAS-00084885; PAP-00127468).

According to a *Soil Remedial Action Report*, dated April 22, 2016, prior to 2003, the remedial investigation for the PPTI site included the Sawwood Warehouse and the Common Area (hereinafter, the Fortunato property). According to the report, the remedial investigation documented delineation of contamination to NJDEP “Residential Direct Contact Soil Cleanup Criteria” based on data collected on the Fortunato property. Thereafter, counsel for the Fortunato property owner notified PPTI's counsel that the property owner would be remediating the contamination at the Fortunato property, and terminated PPTI's right to access the Fortunato area. In a May 20, 2004 letter to NJDEP from its counsel, the Fortunato property owner committed to undertake appropriate actions to achieve NJDEP Industrial Site Recovery Act compliance for the Fortunato area. In an e-mail letter to Mr. John Graham, NJDEP supervisor, dated June 8, 2004, the Fortunato property owner's counsel confirmed that the property owner's environmental consultant would undertake all future field and other remedial activities necessary to remediate the Fortunato property and other property owned by the property owner. Mr. Graham, in a telephone conversation with PPTI's legal counsel on June 8, 2004, advised PPTI's legal counsel that NJDEP had no objection to this division of activity as long as NJDEP received all of the data collected. From 2004 to 2008 several remedial actions were completed on the Fortunato property to remediate the soil and the property was redeveloped (PAP-00127855). Note: Details of these remedial actions on the Fortunato property were not available in the file material.

The location of the Fortunato property is depicted in Section 7 below (PAP-00127644).

3. Operational History/COC Use and Presence at the Facility

According to a *Preliminary Assessment Report*, dated February 1996, PPTI manufactured bulk generic drugs and performance chemicals for the cosmetic and pharmaceutical industries. Processes included the synthesis and drying of compounds mixed with water and/or solvent, the blending and grinding of mixtures of dry powder, sometimes mixed with water to produce other products, and micronizing and other particle size reduction operations. Specific processes included, but were not limited to, para-hydroxybenzoic acid production, methylparaben production, and trimethoprim production. Operations were conducted on a contract basis. Raw materials used and finished products varied with each contract (PAS-00085143).

According to a *Draft Environmental Priorities Initiative, Visual Site Inspection Report for Napp Chemicals Inc.*, dated December 1992, chief products were methylparaben (methyl para-hydroxybenzoate) and propylparaben (propyl para-hydroxybenzoate), which are used as preservatives in the food, beverage, pharmaceutical, and cosmetics industries. The parabens were produced via an esterification reaction involving 4-hydroxybenzoic acid and methanol or propanol. The site also finished (e.g., pulverized, ground) the parabens to meet customer specification. According to the document, the principle hazardous materials were sodium hydroxide, hydrochloric acid, methanol, n-propanol, isopropanol, and acetone (PAP-00128041).

According to a *Community Right to Know Survey for 1991*, the following materials containing OU2 COCs were present at the site: copper, copper chloride, cupric nitrate, cupric sulfate, lead acetate, lead nitrate, lead perchlorate, mercuric acetate, mercuric chloride, mercuric iodide, mercuric oxide, mercuric sulfate, mercury, naphthalene, copper gluconate. These chemicals were also reported in 1992 and 1993 (PAS-00081981-2168). With the exception of copper gluconate, these materials were listed as being present in the site laboratory (PAS-00082050-168). According to a *Community Right to Know Survey for 1994*, only copper gluconate was handled at the site (PAP-00127291). Copper gluconate was listed as being present at the pulverizing and blending area and finished goods warehouse (PAS-00081957). Finally, according to a *Preliminary Assessment Report*, dated February 1996, copper acetate monohydrate, lead, and various petroleum products were handled at the site (PAS-00085146-51).

It is noted that according to a *Preliminary Assessment Report*, dated February 1996, United Pierce and Dye Works (UPDW) operated at the site between 1903 and 1939. The report states that it appeared that the site was used for office space and shipping activities (PAS-00085127-28); however, a *Remedial Investigation Report/Remedial Action Workplan*, dated June 17, 2004, states that the site began manufacturing dyestuffs during World War I. The document states that prior to 1939, when UPDW closed, dyestuffs were almost exclusively manufactured from coal tar products. Coal tar is comprised primarily of polynuclear aromatic hydrocarbons (PAHs). In addition, it states that metals, including copper, were historically used as mordants or laking compounds, and that these COCs were found at the site, “supporting a conclusion that UPDW operations resulted in several of the constituents found beneath the former plant areas,” including PAHs and metals (PAP-00127496-97).

4. Identified COCs

- PCBs (detected)
- Dioxins/Furans (detected)
- PAHs (detected)
- Copper (used, detected)
- Lead (used, detected)
- Mercury (used, detected)

A figure depicting the locations of contaminant source areas referenced in this section is included in Section 7 below (PAP-00127644).

PCBs

According to the *Remedial Investigation Report/Remedial Investigation Workplan Addendum*, prepared for Napp Technologies, Inc., dated June 1999 (1999 RIR/RIWP Addendum), PPTI never used polychlorinated biphenyls (PCBs), nor operated any heat exchange equipment that would potentially contain PCBs (PAS-00084970); however, PCBs were detected at the site as discussed below.

An industrial sewer line historically ran north to south across the site, beginning at the adjacent Hexcel property and continuing to the Hendricks pump station located adjacent to the Fortunato property (PAP-00127468, 559). It appears that the Hendricks pump station discharged to the Passaic Valley Sewerage Commission (PVSC) treatment plant (PAS-00087289). The following PCB concentrations by media were detected at sample locations along the trace of the industrial sewer line on PPTI property, as discussed in the 1999 RIR/RIWP Addendum, and the *Remedial Investigation Report/Remedial Action Work Plan*, dated June 17, 2004:

- Soil: Ranging from 0.6 milligrams per kilogram (mg/kg) at a depth of four feet below ground surface (bgs) to 8,500 mg/kg collected from seven to 7.5 feet bgs at sample location TP-7, and 1,700 mg/kg collected from nine to 9.5 feet bgs at sample location TP-7B (PAS-00084957; PAP-00127670).

- Sewer residue: Aroclor 1242 was detected at 26,000 mg/kg at sample location TP-7-Pipe at the northern property boundary with Hexcel, 6,300 mg/kg at sample location MH-1(PAS-00084957). It should be noted that the *Remedial Investigation Report/Remedial Action Work Plan*, dated June 17, 2004, identified the concentration of PCBs in sample TP-7-Pipe as 26 mg/kg, rather than 26,000 mg/kg reported in the 1999 RIR/RIWP Addendum (PAP-00127670; PAS-00084957). In addition, the *Remedial Investigation Report/Remedial Action Work Plan*, dated June 17, 2004, states that Aroclor 1242 was detected at a maximum concentration of 820 mg/kg in the industrial sewer line manhole/sumps (PAP-00127748).

- PCB-laden (Aroclor 1242) light non-aqueous phase liquid (LNAPL): 3,400 mg/kg at well MW-E14 installed just south of Molnar Avenue adjacent to Hexcel (PAS-00084957).

PCBs also were present in soil along approximately 200 feet of the Saddle River riverbank at concentrations as high as 94 mg/kg, as discussed in the *Remedial Investigation Report/Remedial Action Work Plan*, dated June 17, 2004. The PCBs extended south from the Hexcel property line, where the primary Aroclor detected was 1242, to the Fortunato property line, where the primary Aroclors detected were 1254 and 1260. Horizontal delineation was achieved to the west at the majority of locations immediately adjacent to the Saddle River, with the exception of three sample locations where PCBs were present immediately adjacent to the river at concentrations "just slightly greater" than the NJDEP "Residential Direct Contact Soil Cleanup Criteria" (0.49 mg/kg) at a maximum concentration of 3.18 mg/kg. However, no PCBs were present in sediment. Vertical delineation was achieved at depths ranging from approximately one to 1.5 feet at the Saddle River to approximately five feet at the PPTI fence line. Based on the 200 feet of riverbank, an average width of 15 feet and an average depth of four feet, it was approximated that 670 cubic yards of soil contained PCBs at a concentration greater than the "Residential Direct Contact Soil Cleanup Criteria" (0.49 mg/kg) (PAP-00127627, 56).

With respect to the origin of PCB contamination, the following is noted:

- According to the 1999 RIR/RIWP Addendum, the presence of PCB Aroclors 1242 in site soils was a result of an upgradient off-site source. Aroclor 1242 was never used by PPTI, nor was it detected in any of the soil samples from PPTI's process areas. PPTI contends in the document that these PCB Aroclors were from the adjacent property, Hexcel's "signature compounds," and were associated with LNAPL that migrated onto the PPTI property via the industrial sewer line and other utility pipelines and trenches which traverse the PPTI property. Aroclor 1242 was detected only along the northern property boundary with Hexcel and in the western portion of the PPTI property along underground utilities that originated on Hexcel property. Reworking of soils as a result of earthmoving activities conducted in the western portion of the site (associated with periodic utility line maintenance) was believed to be responsible for the detection of Aroclor 1242 in the near-surface soils (PAS-00084899-900).

- The 1999 RIR/RIWP Addendum, states further that "early in the investigation of the Hexcel property, Hexcel acknowledged that off-site migration of PCB oils via its sewer system was of concern due to the sewer's questionable integrity." No supporting original documentation related to this acknowledgement was identified in the available file material. The highest concentration of PCBs on the PPTI site existed along the trace of the industrial sewer line at the northern property boundary between PPTI and Hexcel. The report states that "it is clear" from visual observations, comparison of LNAPL constituents, and the proximity the sample locations, that the LNAPL is migrating onto the PPTI site from the Hexcel property (PAS-00084957).

- Finally, according to the 1999 RIR/RIWP Addendum, in the late 1980s, PVSC required Hexcel to eliminate the introduction of PCB-contamination into their sewer system. Hexcel, in correspondence to PVSC dated October 14, 1987, reported that the industrial sewer onsite and downstream from the property was "substantially clogged" with sediments and sludge containing PCBs (Aroclor 1242) ranging in concentration from 10 mg/kg to 7,660 mg/kg. The concentrations of PCBs (Aroclor 1242) were reported to increase downstream in the sewer system, with the highest concentration reported in the wet well at the Hendrix pump station. The only PCB Aroclor detected in the PVSC sewer system was Aroclor 1242 (PAS-00084958; PAS-00091036-38, 46-48). It is also noted that according to a *Summary Report of Preliminary Environmental Sampling at the Fine Organics Corporation Facility, Lodi, NJ*, prepared for Hexcel, dated October 14, 1987, sludge and sediment samples collected from the industrial sewer system in 1987 by Hexcel included a sample from a manhole on the PPTI site. Aroclor 1260 was detected at a concentration of 490 mg/kg (PAS-00091040-41).

According to the *Remedial Investigation Report/Remedial Action Work Plan*, dated June 17, 2004, although NJDEP agreed that constituents found adjacent to portions of the industrial sewer line running north to south through the PPTI site were caused by upstream source(s), it maintained that PPTI should remediate constituents found downstream of its tie-in to the sewer line. PPTI was required to further characterize the industrial sewer line and document the extent of the suspected disposal area that had previously been found adjacent to the sewer line (PAP-00127501).

With respect to the Fortunato property, the following is also noted: Brick-lined trenches were used to collect and transfer process wastewater historically at the PPTI site, based on review of the *Preliminary Assessment Report*, dated February 1996. Use of these trenches dated back to UPDW's ownership of the site (PAP-00373427, PAS-00085049). According to the 1999 RIR/RIWP Addendum, four catch basins were identified in the concrete slab floor of the Sawwood warehouse of the Fortunato property. The catch basins were connected to trenches, similar to those observed on the PPTI site. It was concluded that both trench systems were part of one large gravity-drainage central trench systems (PAS-00084863-64). Sediment samples were collected from four catch basins in 1996. Total PCBs were detected in all sediment samples at concentrations ranging from 0.97 mg/kg to 3,100 mg/kg (PAS-00084970).

Dioxins and Furans

2,4,6-Trichlorophenol was detected in soil at the Hexamethylene Diamine Loading Area at an estimated concentration of 0.025 J mg/kg (PAP-00127741). According to the *Remedial Investigation Report/Remedial Investigation Workplan Addendum*, dated June 1997, hexamethylene diamine was periodically loaded from tank trucks to holding vessels located in Building 5 (PAS-00085072). Note: No information as to the source of the 2,4,6-trichlorophenol was identified in the available file material. In addition, the size of the holding vessel and if any spills occurred is not addressed in available references.

PAHs

PAHs were detected in soil sampled in 1998 and 2002, as discussed in the *Remedial Investigation Report/Remedial Action Work Plan*, dated June 17, 2004, primarily at sample location PIT A/B/C (a former wastewater collection sump located in the westerly section of the pulverizing and blending area), along the historical wastewater collection trench system, at the Hexamethylene Diamine Loading Area, and along the industrial sewer line in subsurface soil. The highest concentrations were detected along the industrial sewer line at depths of four to 10 feet (PAP-00127697, 718, 729, 741, 744 and 747). A figure depicting the PAH exceedances in these areas was not identified in the referenced document.

According to the *Remedial Investigation Report/Remedial Investigation Workplan Addendum*, dated June 1997, PPTI did not use or store PAH compounds at the site (PAS-00085034). The *Preliminary Assessment Report*, dated February 1996, also states that PAH compounds were not identified as a potential COC based on a review of the inventory of material used in PPTI's operations (PAS-00085178). However, operations at the PPTI site between 1903 and 1939 by UPDW reportedly involved the use of coal tar products that would include PAH compounds (PAP-00127496-497).

Copper

According to the *Remedial Investigation Report/Remedial Action Workplan*, dated June 17, 2004, copper was detected in soil sampled in 1998 and 2002, with maximum concentrations being detected along the industrial sewer line. The concentrations detected along the sewer line ranged from 12.8 mg/kg at a depth of 6.5 to seven feet to 1,740 mg/kg at a depth of 8.0-8.5 feet (PAP-00127745).

Lead

Review of the Sewer Connection Permit (No. 17401142), effective from 1991 to 1996, statess that monitoring for lead was required. Effluent limitations for lead were listed as a maximum for one day of 690 micrograms per liter (µg/L) and maximum monthly average of 320 µg/L (PAP-00128029, 38). According to a letter prepared by an analytical laboratory, dated November 20, 1990, lead was detected in a wastewater effluent sample collected on October 30, 1990 at a concentration of 85 parts per billion (ppb) (PAP-00128098). No other monitoring data were identified in the available file material.

In addition, according to the *Remedial Investigation Report/Remedial Action Workplan*, dated June 17, 2004, lead was detected in soil sampled in 1998 and 2002, with maximum concentrations being detected along the industrial sewer line. The concentrations detected along the sewer line ranged from 6.6 mg/kg at a depth of 6.5-7 feet to 2,800 mg/kg at a depth of 9 feet (PAP-00127745).

Mercury

According to the *Remedial Investigation Report/Remedial Action Workplan*, dated June 17, 2004, mercury was detected in soil sampled in 1998 and 2002, with maximum concentrations being detected along the industrial sewer line. The concentrations detected along the sewer line ranged from 0.05 mg/kg at a depth of 6.5-7 feet to 11.7 mg/kg at a depth of 9.5 feet (PAP-00127745).

Historic Fill

The Allocation Team has determined that the facility site is not located on regional Historic Fill as designated by the NJDEP.[1]

The NJDEP has established that Historic Fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 COCs: PAHs, lead, copper, and mercury.[2] Accordingly, NJDEP technical requirements for property containing Historic Fill requires sampling for the United States Environmental Protection Agency (EPA) Target Compound List (TCL) for PAHs and Target Analyte List (TAL) for metals, including lead, copper, mercury, and the OU2 PAH COCs.[3] PAHs, lead, copper, and mercury are recognized by NJDEP to be constituents of Historic Fill at varying levels, not atypically at or exceeding residential soil standards.[4]

The levels of PAHs, copper, lead and mercury detected at the site in soils are presented in the table below (PAS-00084903).

---

[1] *Digital Geodata Series, DGS04-7, Historic Fill for New Jersey*, https://www.nj.gov/dep/njgs/geodata/dgs04-7.htm, Quadrangle #52 & #53 (NJDEP map identifying locations of recognized historic fill).

[2] *Characterization of Ambient Levels of Selected Metals and cPAHs In New Jersey Soils* (2002) and *Characterization of Ambient Levels of Selected Metals and Other Analytes In New Jersey Soils* (1997), studies prepared for NJDEP, Division of Science and Research, by BEM Systems, Inc.

[3] New Jersey Department of Environmental Protection (NJDEP), *N.J.A.C. 7:26E Technical Requirements for Site Remediation,* Table 4-2, November 2009 [Note that Table 4-2 has been deleted from the current version of N.J.A.C. 7:26E (May 7, 2012) and the updated *Historic Fill Technical Guidance* (April 2013) as NJDEP believed that the tables list of historic fill constituents was too restrictive].

[4] NJDEP Table 4-2 (PAHs and lead) and a summary of NJDEP records regarding investigations of properties in the vicinity of the Passaic River recognized to be located in areas of Historic Fill indicate that the following average/maximum (mg/kg) contamination levels of OU2 COCs exist in area Historic Fill: PAHs (1.91/160), lead (574/10,000), copper (11.2/1,200), and mercury (0.21/3.7).

COCs Found in Onsite Soils	
COC	**Max Detected Concentration**
Copper	1,280 mg/kg
Benzo(a)anthracene	17 mg/kg
Benzo(a)pyrene	18 mg/kg
Benzo(b)fluoranthene	22 mg/kg
Benzo(k)fluoranthene	8.7 mg/kg
Dibenzo(a,h)anthracene	2.5 mg/kg
Indeno(1,2,3-cd)pyrene	7.4 mg/kg
PCBs	36 mg/kg

According to the *Remedial Investigation Report/Remedial Action Workplan*, dated June 17, 2004, the site is underlain by fill material. The fill material ranges in thickness from several inches to more than 10 feet at the western edge of the site. Several fill events have occurred on the site since the mid-1930s, the most significant of which involved the filling and redirection of flow of the adjacent Saddle River (PAP-00127468; 504). The fill material varied in its composition, and consists of a mix of clays, silts, sand and gravels, with fragments of brick, glass, wood and other materials interspersed throughout it. The fill material on the eastern side of the site is more typical of industrial fill, and consists of stone, brick, concrete and other fill material (PAP-00127504).

With respect to PCBs, according to a 1999 RIR/RIWP Addendum, “background levels” of PCBs were detected in the fill material located within the western portion of the site. It states that PCBs were detected throughout the fill materials at heterogeneous concentrations ranging from “levels below the NJDEP unrestricted use criteria to levels indicative of an historic discharge.” PCBs were observed at all depths at varying concentrations and a variety of Aroclors (1242, 1248, 1254 and 1260) were detected. It also states that PCBs were not used in commerce until approximately 1930; and, therefore, it is unlikely that PCB-contaminated fill material was placed beneath the buildings on the eastern portion of the site prior to 1917. It goes on to state that it is possible that the fill material used beneath the most recent building on the northern boundary of the site could have contained PCBs. It was concluded that the Historic Fill placed in the Saddle River between 1939 and 1951 contained PCBs when it was deposited on the site. Finally, the report states that the highest concentration of PCBs observed in the fill material was 36 mg/kg at a depth of 1.5-2 feet. It states that the data supported a conclusion that background levels of PCBs in the fill material are 36 mg/kg or greater (PAS-00084900-01).

With respect to PAHs, the 1999 RIR/RIWP Addendum, also states that PAHs are randomly distributed on the western portion of the site which is consistent with the heterogeneous nature of fill material. It states that the concentrations of contaminants are consistent with the historical fill values reported by NJDEP (PAS-00084902). The *Preliminary Assessment Report*, dated February 1996, states that PAH compounds were not identified as a potential COC based on a review of the inventory of material used in PPTI’s operations, suggesting that the PAHs detected in upgradient and downgradient soil samples may be the result of regionally affected river sediments that had been

deposited along the shoreline or were historically present in fill materials used in previous site development along the river. The document goes on to state that this was supported by a review of aerial photographs from 1940,1951, and 1961 which showed inundated, low lying areas along the Saddle River shoreline immediately west and southwest of the PPTI buildings (PAS-00085178).

Finally, according to the 1999 RIR/RIWP Addendum, copper was detected in the fill material at concentrations exceeding the "NJDEP unrestricted soil cleanup criteria." It states that the random distribution pattern is consistent with a Historic Fill origin and that the analytical data is similar to Historic Fill concentrations reported by NJDEP. Trends with depth or distance from any specific location were not apparent, and there were some locations where concentrations increased with depth (PAS-00084902).

It is noted that according to the *Remedial Investigation Report/Remedial Action Workplan*, dated June 17, 2004, NJDEP disagreed with the conclusion that all PCBs, PAHs, and metals present in the filled portion of the site were associated with the fill (PAP-00127499).

According to the 1999 RIR/RIWP Addendum, Historic Fill was sampled for PAHs, copper, and PCBs. The report states that the presence of Historic Fill was demonstrated by the heterogeneous and random distribution of the contaminants detected (PAS-00084900-02).

5. COC Pathways

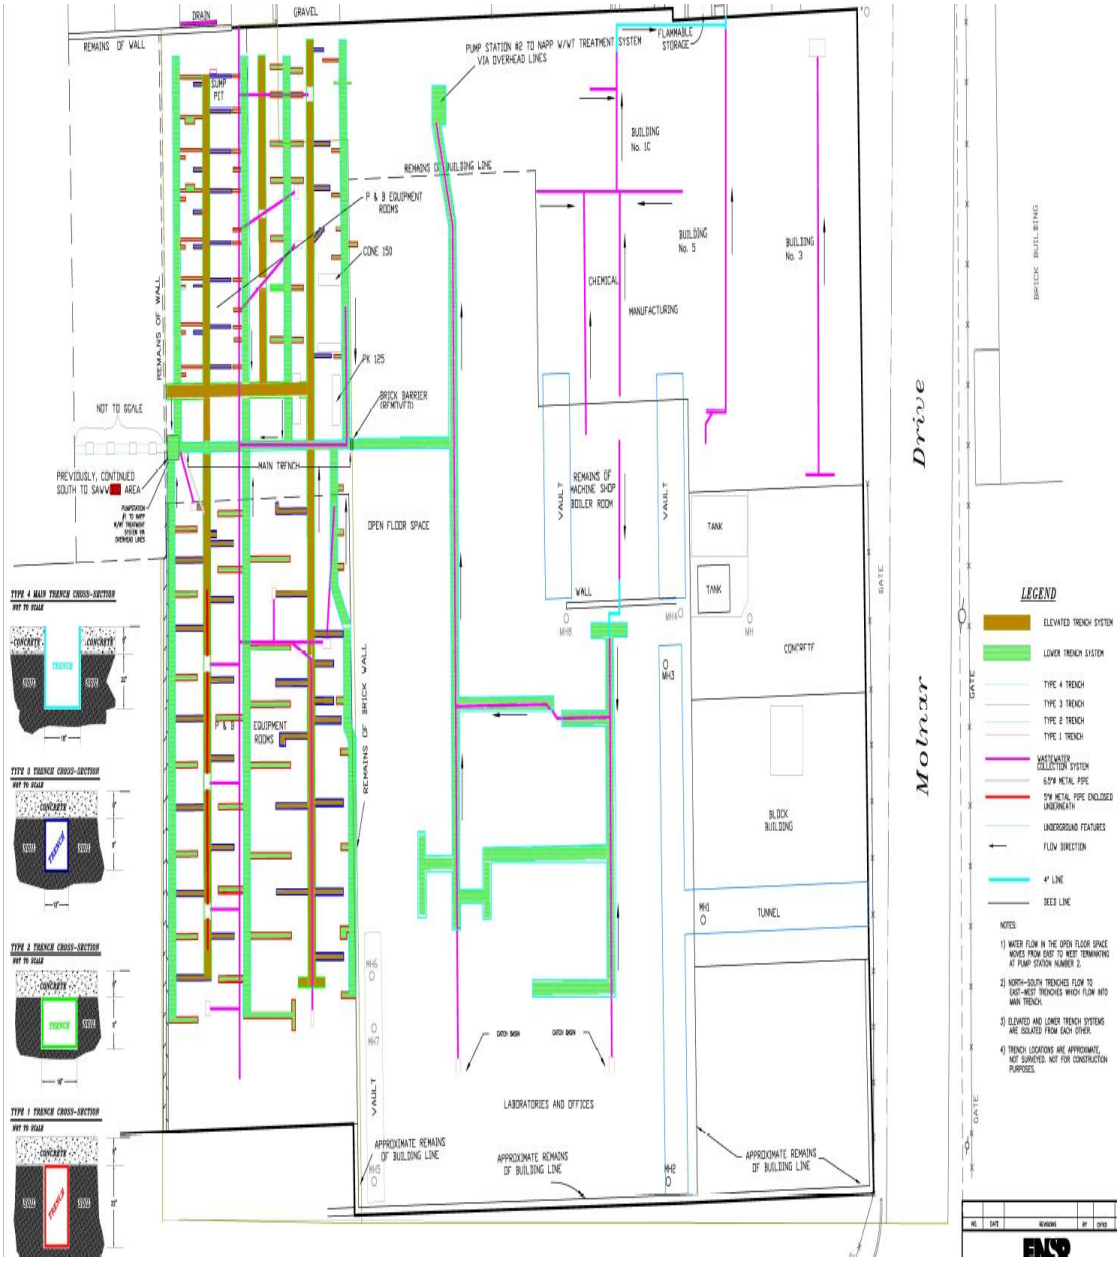
The approximately two-acre site is adjacent to the Saddle River (PAS-00084796), a tributary to the Passaic River. The site is two miles upstream of the confluence of the Saddle River with the Passaic River (PAS-00007951).

Sanitary and Storm Sewer

According to the *Preliminary Assessment Report*, dated February 1996, the site sewer system was installed in 1916, and was expanded in 1930, specifically to handle the volume of water discharged by UPDW (the occupant of the site at the time). Therefore, the report states that it can be inferred that the site was hooked into the municipal sewer system as early as 1930 and probably as early as 1916. The site system pumped from Lodi to Wallington, New Jersey, then directly to the PVSC system (PAS-00085154).

Historically, brick-lined trenches were used to collect and transfer process wastewater, based on review of the *Preliminary Assessment Report*, dated February 1996. Use of these trenches dated back to UPDW's ownership of the site. The system was upgraded between 1981 and 1990 (PAP-00373427, PAS-00085049). The piping systems constructed and installed between 1981 and 1990 were constructed of a variety of materials compatible with the type of process wastewater collected and discharged from manufacturing and processing areas.

Wastewaters discharged to this system included the following:



- boiler blowdown;
- compressor condensate;
- stormwater runoff from the drum storage pad and hazardous waste storage area;
- floor wash water from manufacturing and processing areas;
- wash water from equipment change-outs discharged to trench drains in manufacturing and processing areas;
- condensate from site non-contact recirculation system; and,
- spills and leaks from manufacturing and processing areas of the site (PAP-00373423).

Based on review of available file material, it is unclear if OU2 COCs were associated with these discharges.

Concrete pits were associated with final collection and treatment of process wastewater within the site effluent treatment system. A 500-gallon pit received all process wastewater from the manufacturing site via gravity flow from an adjacent concrete basin and weir structure. Process wastewater then flowed by gravity to a 1,000-gallon effluent treatment pit where it was monitored and treated for discharge to PVSC (PAP-00373423, 25). The document does not state for what parameters the wastewater was monitored. The 500-gallon and 1,000-gallon pit were constructed after 1981 when the site began pretreatment of its process wastewater. Effluent treatment operations consisted solely of pH adjustment of process wastewaters. According to the *Preliminary Assessment Report*, dated February 1996, this system was operated in compliance with a Sewer Connection Permit (No. 17401142) from the PVSC (PAP-00373423).

Review of the Sewer Connection Permit (No. 17401142), effective from 1991 to 1996, statess that monitoring for lead was required. Effluent limitations for lead were listed as a maximum one-day concentration of 690 µg/L and maximum monthly average of 320 µg/L (PAP-00128029, 38). Discharges were permitted through two outfalls (PAP-00128024-26); however, information on the sources of discharge and volumes discharged were not identified.

A 1997 figure depicting the layout of the process wastewater system at the site is presented on the next page (PAP-00127454):

It is noted that according to the *Remedial Investigation Report/Remedial Action Workplan*, dated June 17, 2004, an industrial sewer line ran north to south across the property, beginning at the adjacent Hexcel property and continuing to the Hendricks pump station located adjacent to the Fortunato property (PAP-00127559). The industrial sewer line was a cast iron pipe that was encountered at 8 to 10 feet bgs (PAP-00127899).

Direct Release

According to a *Purdue Pharma Technologies, Inc. Response to USEPA Request for Information, Lower Passaic River Study Area*, dated April 7, 2004, stormwater discharge was governed by a "Storm Water Discharge Permit" (NJ0088315) (PAS-00081945). A copy of the permit was not identified in the available file material. According to the *Remedial Investigation Report/Remedial Investigation Workplan Addendum*, dated June 1997, stormwater from the site was directed to a storm sewer emanating from the northeast portion of the manufacturing building (PAS-00085105).

According to the *Preliminary Assessment Report*, dated February 1996, stormwater from raw material and waste storage areas located outside the manufacturing building did not enter this collection system; these areas were contained via berms, curbs or grading of the area to direct discharge to the site effluent treatment system (PAP-00373429). The *Remedial Investigation Report/Remedial Investigation Workplan Addendum*, dated June 1997, states that during site operations, only stormwater expected to be non-contaminated was discharged through this system. The system was kept closed during non-operating hours at the site. There was no history of hazardous material or waste releases from the site. However, due to the emergency response activities associated with the explosion/fire in 1995, it is possible that contaminated material may have entered the storm sewer system. The sewer ultimately discharged to the Saddle River through a single outfall. The total length of the storm sewer piping was approximately 230 feet, and included four known manholes/inlets (PAS-00085105).

According to a *Purdue Pharma Technologies, Inc. Response to USEPA Request for Information, Lower Passaic River Study Area*, dated April 7, 2004, there were no direct discharges of wastewater to the Saddle River from the site. Since PPTI began operating at the site in 1970, and for decades before under prior operations, all process wastewater discharges were sent to the PVSC sewer system (PAS-00081939, 45).

Spills

According to a U.S. EPA *Pollution Report*, dated April 25, 1995, following an explosion and fire at the site on April 21, 1995, firefighting runoff was "very evident" in the Saddle River as the river exhibited a bright green coloration, caused by fluorescein, a non-hazardous dye used for eye treatment, for its entire two-mile length to its confluence with the Passaic River (PAS-00007951).

The reports states that no PCBs were detected in a downstream Saddle River sample collected following the fire (PAS-00085178). Data were not identified in the referenced report, and no discussion of other OU2 COCs was included in the report.

6. Regulatory History/Enforcement Actions

Inspections

There is no information regarding inspections concerning COCs in the available file material.

Violations

There is no information regarding violations concerning COCs in the available file material.

Permits

The site obtained a PVSC Sewer Connection Permit (17401142) on February 24, 1991, effective through February 24, 1996 (PAP-00128020; PAS-00085632). It appears that the site had a PVSC permit prior to this date (at least as early as 1990, and possibly as early as 1982, based on a letter dated September 25, 1990); however, the dates are not specified in the available references (PAS-00085255).

According to a *Purdue Pharma Technologies, Inc. Response to USEPA Request for Information, Lower Passaic River Study Area*, dated April 7, 2004, stormwater was discharged to the Saddle River via a "Storm Water Discharge Permit" (NJ0088315) (PAS-00081945). According to the *Preliminary Assessment Report*, dated February 1996, the permit was issued in 1993 for the discharge of stormwater runoff (PAP-00373403); additional information was not included in the referenced document. A copy of the permit was not identified in the available file material.

7. Response Actions

Characterization Activities

The following characterization activities have taken place at the facility:

- *Preliminary Assessment Report*, dated February 1996 (PAS-00085125);
- *Remedial Investigation Report/Remedial Investigation Workplan Addendum*, dated June 1997 (PAS-00084984);
- *Remedial Investigation Report/Remedial Investigation Workplan Addendum*, dated June 30, 1999 (PAS-00084846);
- *Remedial Investigation Report/Remedial Action Work Plan*, dated June 17, 2004 (PAP-00127464);
- *Remedial Action Work Plan Addendum*, dated April 7, 2008 (PAP-00127768); and,
- *Soil Remedial Action Report*, dated April 22, 2016 (PAP-00127852).

The site became subject to the NJDEP Industrial Site Recovery Action in 1995 when operations at the site ceased because of an industrial accident. Remedial investigations of the site were completed from 1995 to 2012 under the oversight of the NJDEP Site Remediation Program. In April 2012, the site entered into the Licensed Site Remediation Profession program. Remedial investigation reports were submitted to the NJDEP in 1997, 1999, and 2004 (PAP-00127853).

According to a *Soil Remedial Action Report*, dated April 22, 2016, three source areas and two areas of concern (AOCs) were identified on the PPTI site (after combining numerous smaller AOCs into larger AOCs):

- Source Area 1 (SA1): Hazardous Waste Storage Area, Drum Storage Area, Dry Well, Pavement Cracks, and Soil Boring SB-09;
- Source Area 2 (SA2): Pit A/B/C (a former wastewater collection sump located in the westerly section of the pulverizing and blending area) and Pump Station F-2;
- Source Area 3 (SA3): Historic Trench System;
- Courtyard Dry Well; and,
- Sample Locations E-1, E-2A and E-1E and Hexamethylene Diamine Loading Area (PAP-00127874).

Source areas are depicted on the figure below (PAP-00127644):

Sewers

According to *Remedial Investigation Report/Remedial Investigation Workplan Addendum*, dated June 1997, the storm sewer was cleaned out and inspected to the extent possible, and on April 24 and May 14, 1996, samples of material removed from the storm sewer were collected. Note that this was conducted following the explosion and fire in 1995. Data showed the presence of PCBs at concentrations above NJDEP "soil cleanup criteria" (PAS-00085105). The PCB concentrations were not available in the file material; it is unclear what concentration is equivalent to the "soil cleanup criteria."

An industrial sewer line historically ran north to south across the site, beginning at the adjacent Hexcel property and continuing to the Hendricks pump station located adjacent to the Fortunato property (PAP-00127468, 559). It appears that the Hendricks pump station discharged to the PVSC treatment plant (PAS-00087288-89). The following PCB concentrations by media were detected at sample locations along the trace of the industrial sewer line on PPTI property, as discussed in the 1999 RIR/RIWP Addendum, and the *Remedial Investigation Report/Remedial Action Work Plan*, dated June 17, 2004:

- Soil: Ranging from 0.6 mg/kg at a depth of four feet bgs to 8,500 mg/kg collected from seven to 7.5 feet bgs at sample location TP-7, and 1,700 mg/kg collected from nine to 9.5 feet bgs at sample location TP-7B (PAS-00084957; PAP-00127670).

- Sewer residue: Aroclor 1242 was detected at 26,000 mg/kg at sample location TP-7-Pipe, at the northern property boundary with Hexcel, 6,300 mg/kg at sample location MH-1(PAS-00084957). It should be noted that the *Remedial Investigation Report/Remedial Action Work Plan*, dated June 17, 2004, identified the concentration of PCBs in sample TP-7-Pipe as 26 mg/kg, rather than 26,000 mg/kg reported in the 1999 RIR/RIWP Addendum (PAP-00127670; PAS-00084957). In addition, the *Remedial Investigation Report/Remedial Action Work Plan*, dated June 17, 2004, states that Aroclor 1242 was detected at a maximum concentration of 820 mg/kg in the industrial sewer line manhole/sumps (PAP-00127748).

- PCB-laden (Aroclor 1242) LNAPL: 3,400 mg/kg at well MW-E14 installed just south of Molnar Avenue adjacent to Hexcel (PAS-00084957).

It is reported that horizontal delineation of PCBs found along the industrial sewer line was achieved to the east within the SA1 and SA2/3 areas. In these areas, vertical delineation was achieved at a consistent depth of 13.5 to 14.0 feet (PAP-00127565).

The *Remedial Investigation Report/Remedial Action Work Plan*, prepared for PPTI, dated June 17, 2004, states that results of the investigation demonstrated that the industrial sewer line potentially represented an ongoing primary source of discharges to soil and groundwater (PAP-00127560). The report states that the PCBs found along the

northern portion of the sewer line and throughout SA1 (and into the northern portion of SA2) were exclusively the Hexcel "signature" Aroclor 1242. The PCBs in the free product found in MW-E14 and adjacent to the sewer line also were exclusively Aroclor 1242. The report states that the data support a conclusion that discharges of PCBs on the Hexcel property were the source of Aroclor 1242 found along the northern portion of the sewer line and in SA1 and SA2 (PAP-00127561). The report states that the highest concentrations of PCBs found in any sediment sample were found in sample Hexcel TP-11, located at the northern end of the sewer line, at a concentration of 820 mg/kg (PAP-00127563, 670).

South of SA1 (at approximately the Fortunato property line), the Aroclor signature changed to 1254 and 1260 (PAP-00127561). In addition, PCBs obtained from the pit and manhole on the PPTI site contained primarily Aroclors 1254 and 1260, and were found at much lower concentrations than those found in the main sewer line samples. The report states that the difference in Aroclors found in different locations along the industrial sewer line was very pronounced (PAP-00127563). The source of Aroclors 1254 and 1260 is not discussed in the *Remedial Investigation Report/Remedial Action Work Plan*, dated June 17, 2004. The 1999 RIR/RIWP Addendum, states that PPTI never used PCBs, nor operated any heat exchange equipment that would potentially contain PCBs (PAS-00084970). It is also noted that according to a *Summary Report of Preliminary Environmental Sampling at the Fine Organics Corporation Facility, Lodi, NJ*, prepared for Hexcel, dated October 14, 1987, sludge and sediment samples collected from the industrial sewer system in 1987 by Hexcel included a sample from a manhole on the PPTI site. Aroclor 1260 was detected at a concentration of 490 mg/kg (PAS-00091040-42).

With respect to the Fortunato property, the following is also noted: Brick-lined trenches were used to collect and transfer process wastewater historically, based on review of the *Preliminary Assessment Report*, dated February 1996. Use of these trenches dated back to UPDW's ownership of the site (PAP-00373427, PAS-00085049). According to the 1999 RIR/RIWP Addendum, four catch basins were identified in the concrete slab floor of the Sawwood warehouse of the Fortunato property. The catch basins were connected to trenches, similar to those observed on the PPTI site. It was concluded that both trench systems were part of one large gravity-drainage central trench systems (PAS-00084863-64). Sediment samples were collected from four catch basins in 1996. Total PCBs were detected in all sediment samples at concentrations ranging from 0.97 mg/kg to 3,100 mg/kg (PAS-00084970).

Soil

According to a letter sent to NJDEP, dated October 5, 1987, PPTI employees collected soil samples from under an existing floor slab during pipeline modifications at the pulverizing and blending area of the PPTI site. Two composite soil samples were sent to Malcolm Pirnie, Inc. for evaluation. PCBs were detected at a concentration of 62.5 parts per million (ppm) in the first composite sample and 7.5 ppm in the second composite sample (PAP-00128061).

According to the *Preliminary Assessment Report*, dated February 1996, PPTI took responsibility for the remediation of the soil, and the remediation was completed "to EPA's satisfaction" (PAS-00085254).

The *Remedial Investigation Report/Remedial Action Work Plan*, dated June 17, 2004, states that PCBs were found at four locations on the PPTI site including: along the industrial sewer line, at sample locations PIT-A/B/C (a former wastewater collection sump located in the westerly section of the pulverizing and blending area, part of SA2) and TREN-12 (collected beneath the trench system), and along the Saddle River riverbank (PAP-00127599). Detected concentrations reported in the document were as follows:

- Aroclor 1242 was detected adjacent to the sewer line at concentrations ranging from 0.42 mg/kg (10-10.5 feet) to 8,500 mg/kg (7-7.5 feet) (PAP-00127645, 70).

- Total PCBs were detected at concentrations ranging from 280 mg/kg (3.5 feet) to 8,000 mg/kg (2.5 feet) at PIT-A/B/C, and from 0.1 mg/kg (2.5-3 feet) to 230 mg/kg at TREN-12 (PAP-00127553, 660-61).

- Total PCBs were detected in soil along approximately 200 feet of the Saddle River riverbank at concentrations ranging from 0.2 mg/kg (zero to 0.5 feet) to 94 mg/kg (3-3.5 feet). The PCBs extended south from the Hexcel property line, where the primary Aroclor was 1242, to the Fortunato property line, where the primary Aroclors were 1254 and 1260. Horizontal delineation was achieved to the west at the majority of locations immediately adjacent to the Saddle River, with the exception of three sample locations where PCBs were present immediately adjacent to the river at concentrations just slightly greater than the NJDEP "Residential Direct Contact Soil Cleanup Criteria" (0.49 mg/kg). However, no PCBs were present in sediment. Vertical delineation was achieved at depths ranging from approximately one to 1.5 feet at the Saddle River to approximately five feet at the PPTI fence line. Based on the 200 feet of riverbank, an average width of 15 feet and an average depth of four feet, it was approximated that 670 cubic yards of soil contained PCBs at a concentration greater than the "Residential Direct Contact Soil Cleanup Criteria" (0.49 mg/kg) (PAP-00127627, 56).

In addition to the above-listed areas, it is noted that PCBs were also identified at the following locations:

- Aroclor 1242 was detected in soil sampled in 2002 at SA1 (Hazardous Waste Storage Area, Drum Storage Area, Dry Well, Pavement Cracks, and Soil Boring SB-09) at concentrations ranging from 1 mg/kg (6-6.5 feet) to 690 mg/kg (20-20.5 feet bgs) (PAP-00127707).

- A total PCB concentration of 1,500 mg/kg was found at sample location V-11 (located south of the PPTI property boundary in the leased parking area of the Fortunate property) at a depth of 0.58 to 1.08 feet (PAS-00084907).

In addition to PCBs, copper, lead, and mercury were detected in soil sampled in 1998 and 2002, as shown in the *Remedial Investigation Report/Remedial Action Work Plan*, dated June 17, 2004. The following concentrations of these metals were detected along the industrial sewer line:

- Copper detections ranged from 12.8 mg/kg at a depth of 6.5-7 feet to 1,740 mg/kg at a depth of 8.0-8.5 feet

- Lead detections ranged from 6.6 mg/kg at a depth of 6.5-7 feet to 2,800 mg/kg at a depth of 9 feet; and,

- Mercury detections ranged from 0.05 mg/kg at a depth of 6.5-7 feet to 11.7 mg/kg at a depth of 9.5 feet (PAP-00127745).

PAHs also were detected in soil sampled in 1998 and 2002, as shown in the *Remedial Investigation Report/Remedial Action Work Plan*, dated June 17, 2004, primarily at sample location PIT A/B/C, at SA3 (the historic trench system), at the Hexamethylene Diamine Loading Area, and along the industrial sewer line in subsurface soil. The highest concentrations were detected along the industrial sewer line at depths of four to 10 feet (PAP-00127697, 718, 729, 741, 744 and 747). A figure depicting the PAH exceedances in these areas was not identified in the referenced document.

Finally, 2,4,6-trichlorophenol was detected in soil at the Hexamethylene Diamine Loading Area at an estimated concentration of 0.025 J mg/kg at a depth of 3.5-4.0 feet (PAP-00127741).

Saddle River

According to the *Preliminary Assessment Report*, dated February 1996, in order to determine the potential impact of potentially contaminated firewater and/or other materials potentially discharged into the stream through the outfall, stream and sediment sampling was conducted. Samples of river water were collected at the outfall as well as upstream and downstream of the outfall. Samples were analyzed for base neutral/acid extractable organics, metals, pesticides, and PCBs, among others. The report states that in general, concentrations detected in upstream samples were higher than or approximately the same as concentrations detected in downstream samples or at the outfall. Additional testing was conducted to determine the potential effect on the river sediments and aquatic life in the river. Sediment samples were collected upstream and downstream of the site. PCBs were detected upstream of PPTI, but not in the downstream sample. The report concludes that the sample data showed that river conditions were “essentially the same” upgradient and downgradient of the PPTI site, which demonstrated that there had been no “significant” discharges from the site, either historically or as a result of the fire/explosion, which had adversely affected the environment (PAP-00373430). The referenced data were included and discussed in the 1999 RIR/RIWP Addendum. Aroclor 1242 and Aroclor 1254 were detected in the sediment samples. Both PCB Aroclors were detected at their highest concentration at

sample location SED-5a (a total PCB concentration of 1,210 µg/kg), which was obtained upstream of the Napp property line. A total PCB concentration of 360 µg/kg was also detected at sample location SED-2; however, the document does not discuss whether this sample location was up- or downgradient of the PPTI site (PAS-00084944-49).

According to the *Remedial Investigation Report/Remedial Action Work Plan*, dated June 17, 2004, 14 sediment samples were collected during the 2002 and 2003 investigations of the Saddle River. No PCBs were detected in any sediment samples collected from eight locations in the Saddle River, two of which were located upstream of the site, four of which were located adjacent to the site, and two of which were located downstream of the site (PAP-00127594-95). The results of the 2002 sediment investigation were used in conjunction with sediment data from previous investigations completed in 1995, 1996, and 1998. Only one compound, benzo(a)pyrene, was detected at a concentration of 0.55 mg/kg. Benzo(a)pyrene was also detected in the upstream sediment sample at a concentration of 0.22 mg/kg. However, the report states that other PAHs were detected at comparable concentrations in both the upstream and downstream samples. The report states that detection of numerous PAHs in sediment of an urban river was expected because PAHs are common constituents in urban runoff. It goes on to state that the Saddle River received surface water runoff from numerous sources, including roads and parking areas, in which PAHs and other constituents are present (PAP-00127596). Other than the benzo(a)pyrene concentration, PAH data were not identified in the referenced document.

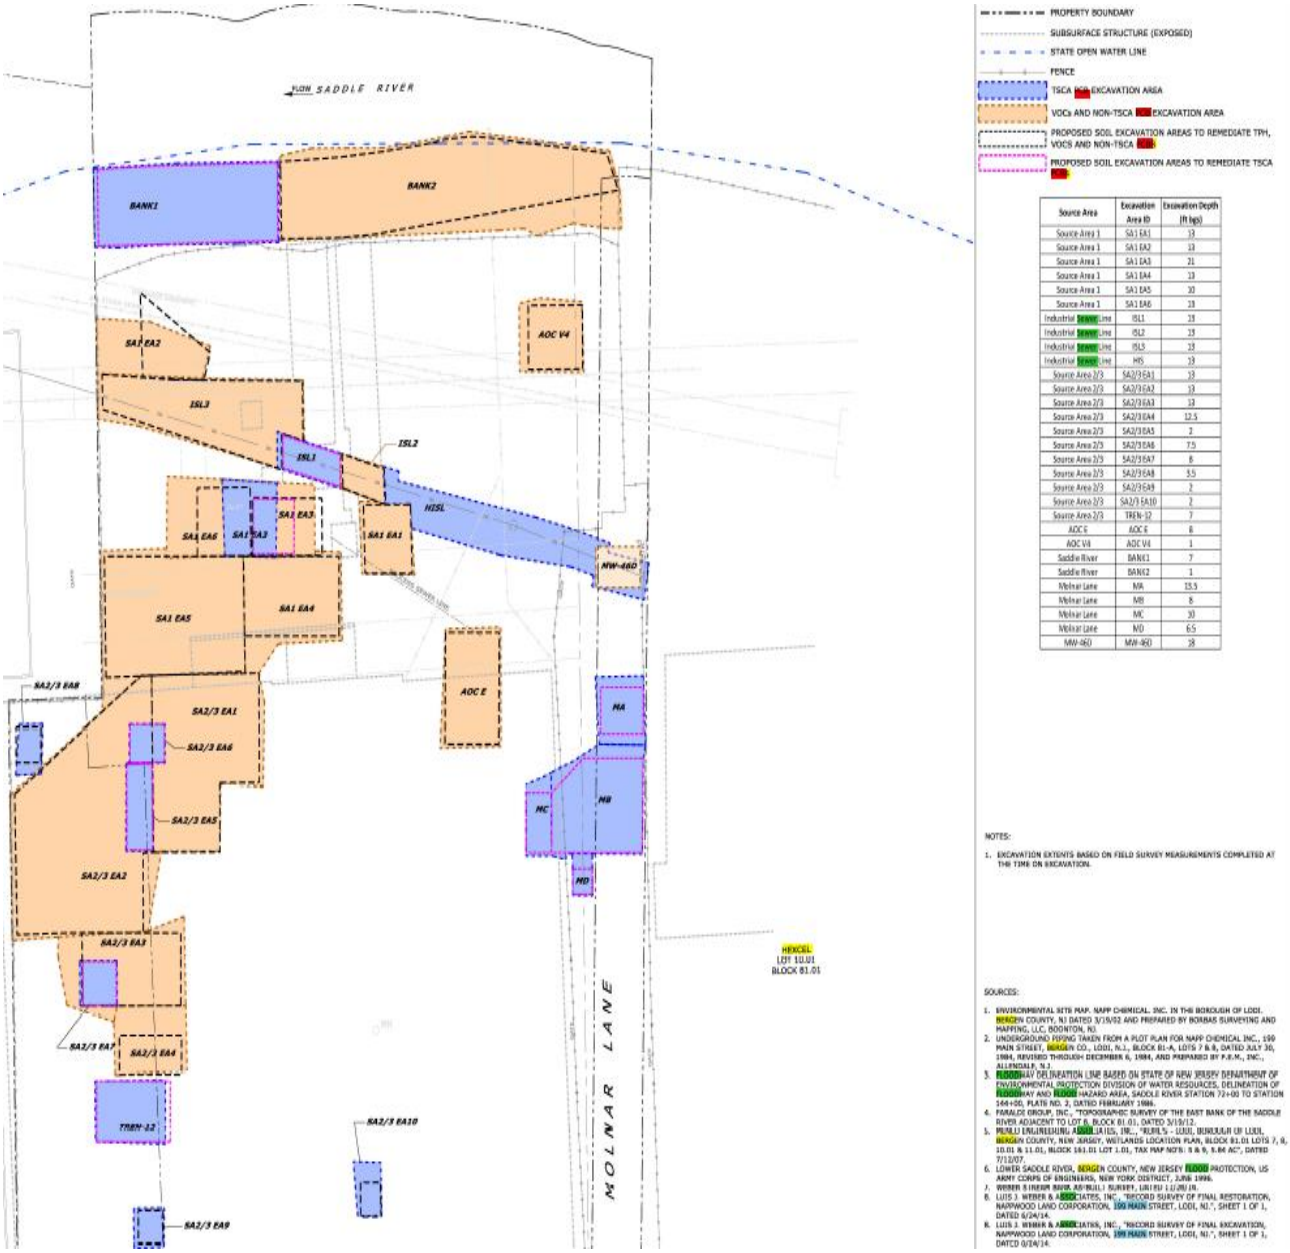
Remedial Activities

According to a letter sent to NJDEP dated October 5, 1987, PPTI employees collected soil samples from under an existing floor slab during pipeline modifications at the site. Two composite soil samples were sent to Malcolm Pirnie, Inc. for evaluation. PCBs were detected at a concentration of 62.5 ppm in the first composite sample and 7.5 ppm in the second composite sample (PAP-00128061). According to the *Preliminary Assessment Report*, dated February 1996, PPTI took responsibility for the remediation of the soil, and the remediation was completed “to EPA's satisfaction” (PAS-00085254).

According to a *Draft Environmental Priorities Initiative Visual Site Inspection Report for Napp Chemicals, Inc*., dated December 1992, PCB-contaminated soil was identified during an excavation beneath an existing floor slab in the center of the site. PPTI was unable to determine the source of the PCB contamination (PAP-00128044).

According to the document, never having used PCB equipment in its operations, PPTI speculated that the contamination must have come from transformers owned by the electrical utility or from previous industrial activity in the vicinity. PPTI excavated soils and disposed them offsite in 1988 and 1990. According to site representatives, no additional samples were taken after the removal of the contaminated soil (PAP-00128044).

On April 21, 1995, an industrial accident at the PPTI destroyed a portion of the site and caused the plant operations to cease. Following the industrial accident, the buildings on the site were demolished (PAP-00127779).



The industrial sewer line remedial action included the removal of a former 24-inch industrial sewer line that traversed the western portion of the PPTI site, as discussed in the *Soil Remedial Action Report*, dated April 22, 2016. According to the report, the sewer line and its contents (sludge/liquids) were remnants of the former UPDW site that operated on all three properties. The industrial sewer line was a cast iron pipe that was encountered at 8 to 10 feet bgs. The section of the industrial sewer line to the north on the Hexcel site was removed in May/June 2003 and April 2010 as a part of the remedial actions for the Hexcel site. The industrial sewer line was not removed on the Fortunato property site because the industrial sewer line was located beneath an active force sewer main and the industrial sewer line could not be removed without compromising the force sewer main. Four separate excavations were completed to remove the industrial sewer line and adjacent soil that contained PCBs at concentrations above remedial action objectives (PAP-00127898-99).

According to a *Soil Remedial Action Report*, dated April 22, 2016, soil remedial action objectives included the following, among others: (1) removal of PCBs in soil as set forth in an "October 2011 Self-Implementing PCB Cleanup and Disposal Plan" based on identified "high and low occupancy use" areas with a cap; (2) removal of soil containing PCBs, metals, and PAHs from the Saddle River bank to meet the NJDEP "Residential Direct Contact Soil Cleanup Criteria;" and, (3) capping the site to prevent direct contact to residual concentrations of PAHs, PCBs and metals, among other contaminants, that remained in soil (not on the river bank) at concentrations greater than the NJDEP "Residential Direct Contact Soil Cleanup Criteria" (PAP-00127854). The report states that site contamination was horizontally delineated except for "a few" areas at the property boundary with the adjacent properties (PAP-00127854-55). The report states that an internal NJDEP memorandum dated October 5, 2004, documented that site related discharges were not migrating off-site and no additional perimeter sampling was warranted (PAP-00127876).

According to the *Soil Remedial Action Report*, dated April 22, 2016, PCB concentrations for the site were horizontally delineated to the NJDEP "Residential Direct Contact Soil Cleanup Criteria" of 0.49 mg/kg (PAP-00127896).

Soil remedial actions for the site were completed from February through June 2014, February/March 2015 and October 2015. The remedial actions included excavation of 29 areas (PAP-00127856). The PCB excavation areas for SA1 and SA2/3 were remediated to the EPA "high or low occupancy use cleanup criteria" of 10 mg/kg and 100 mg/kg, respectively, depending on the use of the excavation area. Post excavation sample results that achieved the EPA cleanup criteria but exceeded the NJDEP criteria were included in the PPTI site deed notice and capped (PAP-00127896). Approximately 12,628 tons of contaminated soil was removed from the site and disposed of off-site (PAP-00127856). In addition, the Saddle River bank was remediated to meet the NJDEP "Residential Direct Contact Soil Cleanup Criteria" for PCBs, metals, and PAHs; therefore, no engineering controls or institutional controls were required (PAP-00127856). The NJDEP remediation goal for PCBs was listed as 0.49 mg/kg (PAP-00127895). The NJDEP "Residential Direct Contact Soil Cleanup Criteria" for the remaining COCs was not identified in the referenced document.

Areas requiring excavation are depicted below (PAP-00127941):

A Deed Notice was filed for the site on April 15, 2016. The “Restricted Area” encompassed 84% of the horizontal extent of the property, totaling 1.7 acres and extending to a depth of 21.5 feet below ground surface. The Deed Notice states that the Restricted Area is associated with former operations and consists of soil with concentrations of PCBs, PAHs, metals, and VOCs above the 1999 NJDEP “Residential Direct Contact Soil Cleanup Criteria.” An engineering control for the Restricted Area consists of a cap consisting of a combination of impervious (asphalt or concrete) and impervious (gravel) surface cover (PAP-00374297, 322-25).

According to the *Soil Remedial Action Report*, dated April 22, 2016, the remedial investigation of groundwater for the site is in progress (PAP-00127868). Based on a Groundwater Remedial Action Permit, dated April 4, 2018, it appears that remediation is ongoing (PAP-00374444-45).

With respect the Fortunato property, the 1999 RIR/RIWP Addendum, states that PPTI conducted voluntary removal and disposal of "significant volumes" of accumulated sediment found within the historical trench system discovered under the concrete slab flooring which was attributable to prior owners/operators of the properties unrelated to PPTI. Because a number of incoming trenches were identified within the Sawwood Warehouse of the Fortunato property, and there was evidence of contaminants being introduced into the trench system from off-site, PPTI proposed no further action with regard to any trenches lying below areas outside of the Sawwood Warehouse (PAS-00084973).

8. Summary of Asserted Defenses

No legal defenses were identified in the available file material.

Diamond Alkali OU2 Allocation

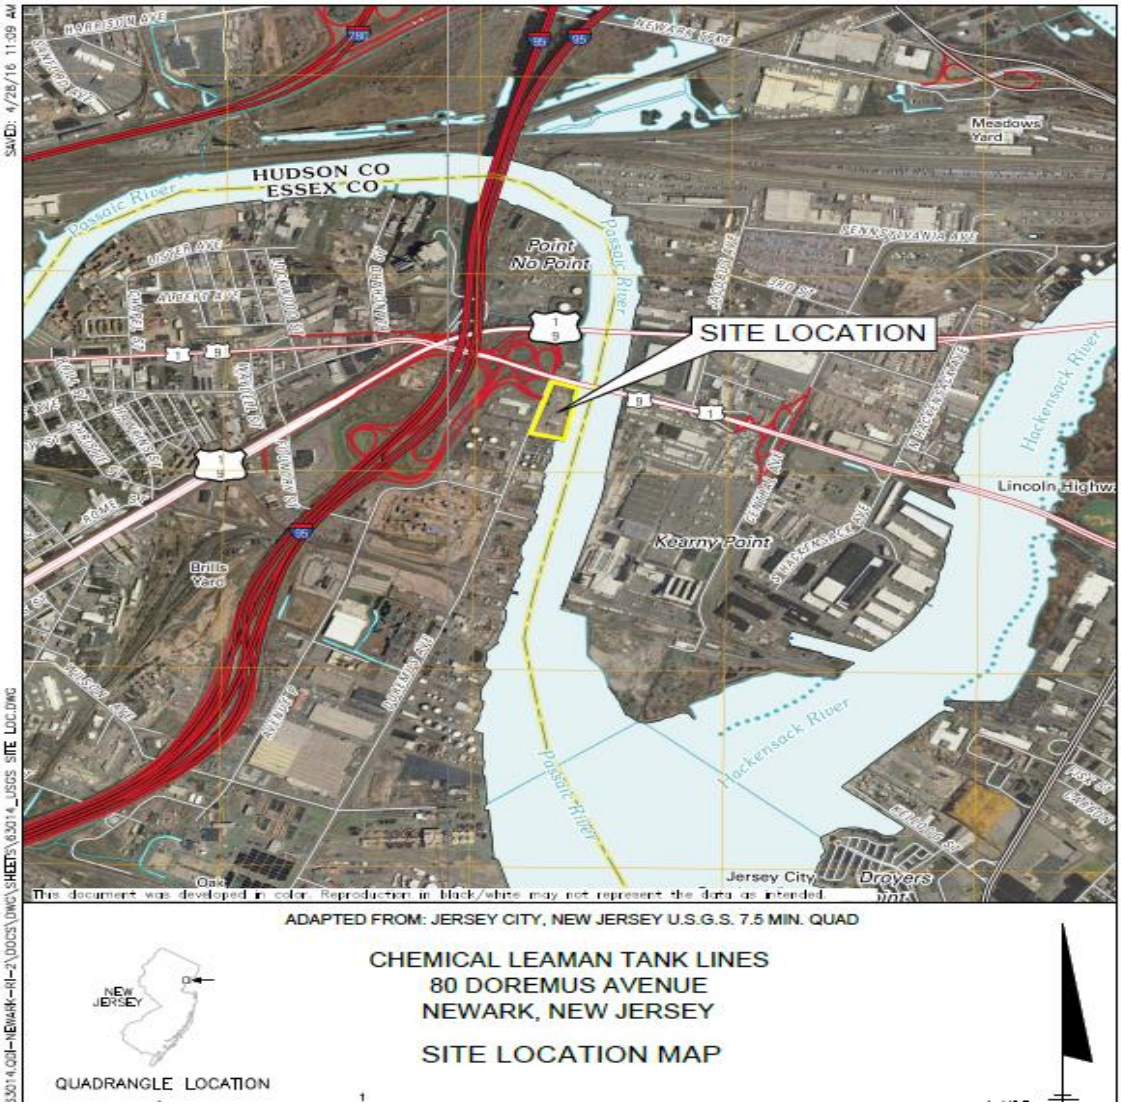
ADR Confidential

Facility Data Report

QUALITY CARRIERS INC.

Facility Name, Address and Size: 80 Doremus Avenue, Newark, New Jersey Block 5011, Lot 1; 7 acres (PAP-00145607). According to the Chemical Leaman Tank Lines, Inc. (CLTL) Permit No. 20404242 Renewal Application, in 1992 there were 20 employees, 260 work days per year with one shift per day for the office workers; two shifts per day for the tank cleaning operations and 3 shifts per day for the Maintenance – Operations (PAP-00328856). According to the July 3, 1997, Permit No. 20404242 Renewal Application, at the time of the application, there were 11 full time employees, 312 work days per year with three shifts per day (PAP-00328880). According to the March 8, 2002, Permit No. 20404242 Renewal Application, at the time of the application, there were 8 full time employees, 312 work days per year with three shifts per day (PAP-00328968). The site abuts the west bank of the Passaic River (PAP-0145642).

1. **Business Type:** Trucking terminal, including repair shop and tanker truck cleaning (PAP-00145606).



2. **Time Period of Ownership/Operations**

   Operator: 1970 to 2007 (PAP-00145606)
   Note: QCI operated the transportation terminal from 1970 to 2007 and a tank wash from 1970 until 1992; Quala Systems, Inc. (QSI) operated the tank wash from 1993 to 2007 (PAP-00145606)
   Owner: 1970 to present (PAP-00145606)

   According to the May 2016 *Final Remedial Investigation Report* (RIR) by OBG, (2016 OBG Final RIR) the site was originally developed in the early 1900s and has been used for various industrial purposes throughout its history. Historical activities at the Facility included trolley car maintenance by a predecessor of PSE&G and oil storage and distribution by a predecessor of Chevron. CLTL acquired the property in 1970. In January 1993, operations began on site by a corporate affiliate, Quala Systems, Inc. In 1998, CLTL merged with Montgomery Tank Lines to become Quality Carriers, Inc. Quality Carriers' corporate parent is Quality Distribution, Inc. (QDI). In 2007-2008, the site was redeveloped by QDI in order to accommodate storage and cleaning facilities for intermodal bulk storage containers. As part of redevelopment, all buildings and above-grade structures were demolished to allow for new construction (PAP-00145606).

   On May 8, 2008, an Agreement of Sale between Quality Carriers, Inc., and Metro Port LLC was reached. According to the agreement, the Property was offered for sale in its "as-is" and "where-is" condition. Quality Carriers, Inc. was to complete remediation of the Property pursuant to the Amended Remediation Agreement, until Seller receives a "no further action" letter, case closure, or approval of a Negative Declaration or other written communication from NJDEP confirming that no further investigation, remediation or operation and maintenance is required on the Property and shall contain the NJDEP's covenant not to sue (PAP-00331099, 103)

   The new facility is presently operated by Boasso America Corporation, a QDI-affiliated company (PAP-00145606). A site location map is provided below.

(PAP-00145642)

3. Operational History/COC Use and Presence at the Facility

According to a *Site Investigation Report*, prepared by BCM Engineers Inc., dated January 1999, (1999 BCM SI Report) the Sanborn Maps collected for the SI Report showed that the site was the location of a portion of the operations of the Public Service Corporation of New Jersey from prior to 1908 until sometime between 1950 and 1973. Trolley car maintenance was performed on site during that time period. Sanborn Maps also identify Paragon Oil Co. at the site in 1973. The exact years that Paragon operated onsite are unknown. However, according to the available information from the 1999 BCM SI Report, Paragon received bulk fuel oil shipments by barge and pumped the oil into a 3 million-gallon aboveground on-site storage tank. The oil was then transferred to tank trucks for local delivery to residential and industrial users (PAS-00084612-13).

The 1999 BCM SI Report stated that the CLTL the predecessor of QCI, had operated a trucking company and tank truck washing facility onsite since 1970 (PAS-00084613). The sewer connection was established in 1970 by a preceding unrelated operator of the Facility, Charter Bulk (PAP-00147738; PAP-00328827).

In January 1993, the tank trailer cleaning operations were conducted by QSI. Following the merger between CLTL and Montgomery Tank Lines, Quality Carriers Inc., resumed the trucking terminal operations. The terminal was used for parked storage of empty tank trucks utilized for transporting bulk liquids including chemicals, food products, and other materials. A daily average of 80 tank trucks were parked in the terminal. A majority of these tank trucks were not owned by QCI. (PAS-00084613).

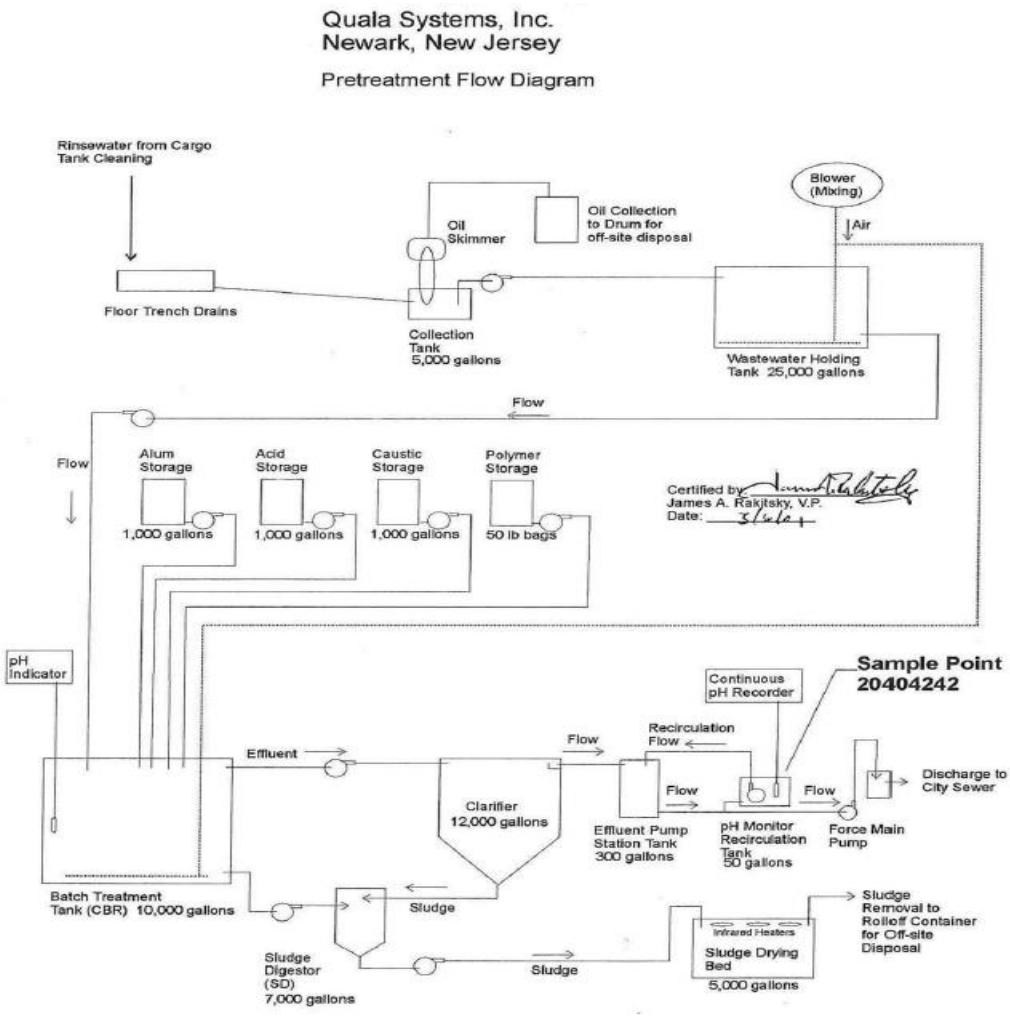
According to a September 23, 1998 New Jersey Department of Environmental Protection (NJDEP) Inspection Report, QSI maintained an on-site, enclosed, three-bay truck-washing structure. The tank trucks were washed in Bay No. 1, No. 2, or No. 3, depending upon the previous contents of the tank truck. Bay Nos. 1 and 2 were "full-services" bays that were used for washing tank trucks that contained non-food product liquids. Bay No. 3 was solely used for washing tank trucks that contained liquid food products (PAS-00084712-13; PAS-00084668).

The 1999 BCM SI Report stated that the wash process generally consisted of using diesel fuel or caustic solution and steam to clean individual tankers, followed by a cold or hot water rinse. Other documents reported that cleaning involved: 1) hot water wash or rinse, 2) cold water wash or rinse, 3) caustic cleaning solution, 4) detergent cleaning solution, or 5) high temperature steam (PAP-00328544; PAS-00084713). All rinseate was collected and diverted to the onsite wastewater treatment plant (WWTP) through concrete trenches on the bay floors The onsite WWTP consisted of a liquid collection basin and a modular unit comprised of a holding tank, batch treatment tank, clarifier, sludge tank, and sludge drying bed. Each of these units is described below.

- Liquid Collection/Settlement Tank − The washwater collection/settlement tank was a sub-grade, steel-lined, concrete basin. Liquids from the wash bays drain to this tank. During the preliminary assessment, liquid in this tank appeared dark-brown and oily. Oil was skimmed from this tank and placed into drums. The drums are stored in the drum storage area. Sediment/sludge from the bottom of the tank was collected and was placed in the sludge drying bed.

- Holding Tank − Liquid in the collection/settlement tank was pumped into the holding tank for blending and equalization. From the holding tank, the wastewater was pumped to the batch treatment tank.

- Batch Treatment Tank − The batch treatment tank was charged with a polymer and aluminum hydroxide for flocculating suspended solids. Caustic or sulfuric acid was added for pH level control.



- Clarifier − The treated wastewater flows to a clarifier. Following clarification, the treated wastewater was discharged into the Passaic Valley Sewage Authority sewage collection system.

- Sludge Tank − Sludge formed in the clarifier was pumped to a sludge tank. Residual liquid which separates from the sludge in the sludge tank was pumped back to the collection/settlement tank.

- Drying Bed − Sludge from the sludge tank was pumped to a drying bed. Once dried, the sludge was placed into a roll-off container and shipped off-site for disposal by Philip Services Corporation.

(PAS-00084613-14).

The following Pre-Treatment Flow Diagram demonstrates in further detail the process described above (PAP-00328562).

In addition, spent caustic solution was generated from cleaning of flexible hoses used by the tank trucks. Hoses were soaked in two horizontal hose troughs containing caustic solution. The hose troughs were drained every 1.5 months to the floor drain in Bay No. 1 (PAS-00084614).

According to the 1992 renewal application for Sewer Connection Permit No. 20404240, the following principal raw materials were used at the Facility:

- Naphtha used for maintenance
- Sodium Hydroxide; Potassium Hydroxide; Trichloroethane used for tank cleaning
- Sulfuric Acid; Sodium Hydroxide; Aluminum Sulfate used for wastewater treatment (PAP-00328857).

The 1999 BCM SI Report stated that QSI maintains two contiguous drum storage areas used for storing 55-gallon drums containing liquid waste or semi-liquid residues drained from tank trucks being washed at the wash building. All drums are properly sealed, labeled, and stored for less than 90 days. The storage areas are constructed with impermeable concrete floors and concrete dikes. Records for the drummed wastes generated onsite are maintained at the facility. All drummed waste is subsequently sent offsite for disposal at a permitted facility (PAS-00084658).

A facility layout is presented below (PAS-00084658).

Facility Data Report

A Partial Plot Plan showing the piping connections for tank washing and wastewater treatment areas at the time of the 1999 BCM Report is presented below:

(PAS-00084623)

According to the *Preliminary Assessment Report*, prepared by BCM Engineers Inc., under NJDEP Industrial Site Recovery Act (ISRA) dated April 1998, (1998 BCM ISRA PSA), the following hazardous substances were kept on site:

- Between 1991 and 1996, between 50,000 and 250,000 pounds of Diesel Fuel were stored in an aboveground storage tank. Location of storage tank listed as on the east end of yard, inside containment area.

- In 1991, 1993, and 1996, 101 to 1,000 gallons of Corrosive Liquids NOS were stored in plastic drums on the east end of the yard on the Drum Storage Pad.

- In 1994, 1 gallon of High Range Cod Reagent was stored in a glass container in the Waste Room. Location of the Waste Room was not listed.

- In 1996, 1,001 to 12,810 pounds of Sulfuric Acid was being stored in a tank in the WW Pre-treatment building. In 1994, 500 gallons of Sulfuric Acid was being stored in a plastic container in the Waste Room. The location of the Waste Room was not listed.

- In 1997, 5,000 to 8,000-gallons of Fuel No. 2 were stored in an aboveground storage tank. Location of storage tank not listed (PAP-00147673-87).

On August 5, 2003, QSI requested that Section 2 - "Monitoring Requirements and Discharge Limitations" of Permit Number 20200022 be changed to allow QSI to submit a Pollutant Management Plan (PMP) as a means for compliance for non-polar material, copper and mercury. According to the attached PMP, approximately 5,750 trucks were cleaned yearly at the Newark Facility. The products commonly cleaned at the facility included latex, oils, adhesives, resins, and organic chemicals. QSI removed any drainable residual before performing interior cleaning. These residuals comprised the typical types of wastes generated at the facility. Commercial cleaners and diesel fuel are used in the tank cleaning process (PAP-00329018).

A Product Inventory in compliance with Sewer Use Permit No.: 20200022 was submitted to PVSC. The inventory included the following potential products to be cleaned;

- aromatic solvents,
- copper compounds,
- diesel fuels,
- diesel fuel type compounds,
- ethylbenzene,
- fuel oil additives,
- gasoline,
- gasoline additives,
- heavy aromatic petroleum distillates,
- herbicides,
- insecticides,
- jet fuel compounds,
- kerosene,
- lube oil additives,
- lube oil,
- motor oil,
- naphtha type compounds,
- pesticides,
- petroleum oils,
- transmission fluid (ATF; hydrotreated paraffinic oil)

(PAP-00329286-91).

As noted above, in 2007-2008 the site was re-developed by an Affiliate of QCI, Boasso America, to accommodate the storage and cleaning of intermodal bulk storage containers (ISO Containers). Tank truck transportation and cleaning related activity at the site ended prior to this redevelopment. All buildings and above-grade structures were demolished to allow for the construction of a new ISO tank cleaning building and associated treatment structures.

4. Identified COCs

- PCBs (detected)
- PAHs (used, detected)
- Copper (detected)
- Lead (detected)
- Mercury (detected)

PCBs

According to the 2000 ENVIRON Supplemental SI Report further soil sampling was conducted as requested by NJDEP based on the 1999 BCM SI Report (PAS-00084493, 97). The following table is a Summary of Soil Samples (highest concentration) taken for PCBs:

Max PCB Soil Samples				
COC	**ASTs 4-4.5 feet bgs**	**Drum Storage Pad 1-1.5 feet bgs**	**Wastewater Handling System .5-1 feet bgs**	**Historic Fill 7-8 feet bgs**
Aroclor 1248	N/A	N/A	N/A	0.892 ppm
Aroclor1260	0.0337 mg/kg	0.0567 mg/kg	0.0937 mg/kg	3.55 ppm

(PAS-00084545-61)

According to a 1994 CLTL Environmental Compliance Program Manual, QCI and its predecessors did not transport or handle PCBs or clean tanks that had previously contained PCBs pursuant to its tank cleaning policy (PAP-00328833).

PAHs

Polynuclear aromatic hydrocarbon (PAH) containing materials such as No. 2 fuel oil, No. 4 fuel oil, and gasoline were handled at the site as a part of plant operations. The Analysis Results Sampling Map from the 1999 BCM SI Report shows that the fuel tanks were surrounded by a concrete wall located in the southern part of the Facility (PAS-00084655). See the map below for locations of the fuel tanks. A 10,000-gallon aboveground storage tank containing fuel oil was located at the Facility and was part of the Spill Prevention Control and Countermeasures Plan (PAP-00329152).

A report from International Testing Laboratories Inc., dated December 1, 1988, stated that petroleum hydrocarbons were detected on site at a maximum concentration of 77.5 ppm (PAS-00084757).

The 1999 BCM SI Report stated that a total of four surface soil samples were collected from the 3 million-gallon aboveground storage tank (AST) area. The results from these soil samples showed the presence of total petroleum hydrocarbons (TPH) and PAHs in shallow soils. Concentrations of TPH ranged from 101 mg/kg to 2,640 mg/kg. In sample GP-1 (0 to 2 feet bgs), a total Priority Pollutant PAH concentration of 34.1 mg/kg was detected (PAS-00084634). The following is a breakdown of the PAH COCs:

- Benzo[a)anthracene − 3.2 mg/kg
- Benzo[b)fluoranthene − 3.0 mg/kg
- Benzo[k]fluoranthene − 3.7 mg/kg
- Benzo[a)pyrene − 3.7 mg/kg
- lndeno[1,2,3-cd]pyrene − 1.4 mg/kg (PAS-00084646)

In two soil samples that were collected from the south side of the facility near the area of three gasoline underground storage tanks (UST), TPH was detected in the shallower interval at a concentration of 1,510 mg/kg and in the deeper interval at a concentration of 1,150 mg/kg (PAS-00084634-35).

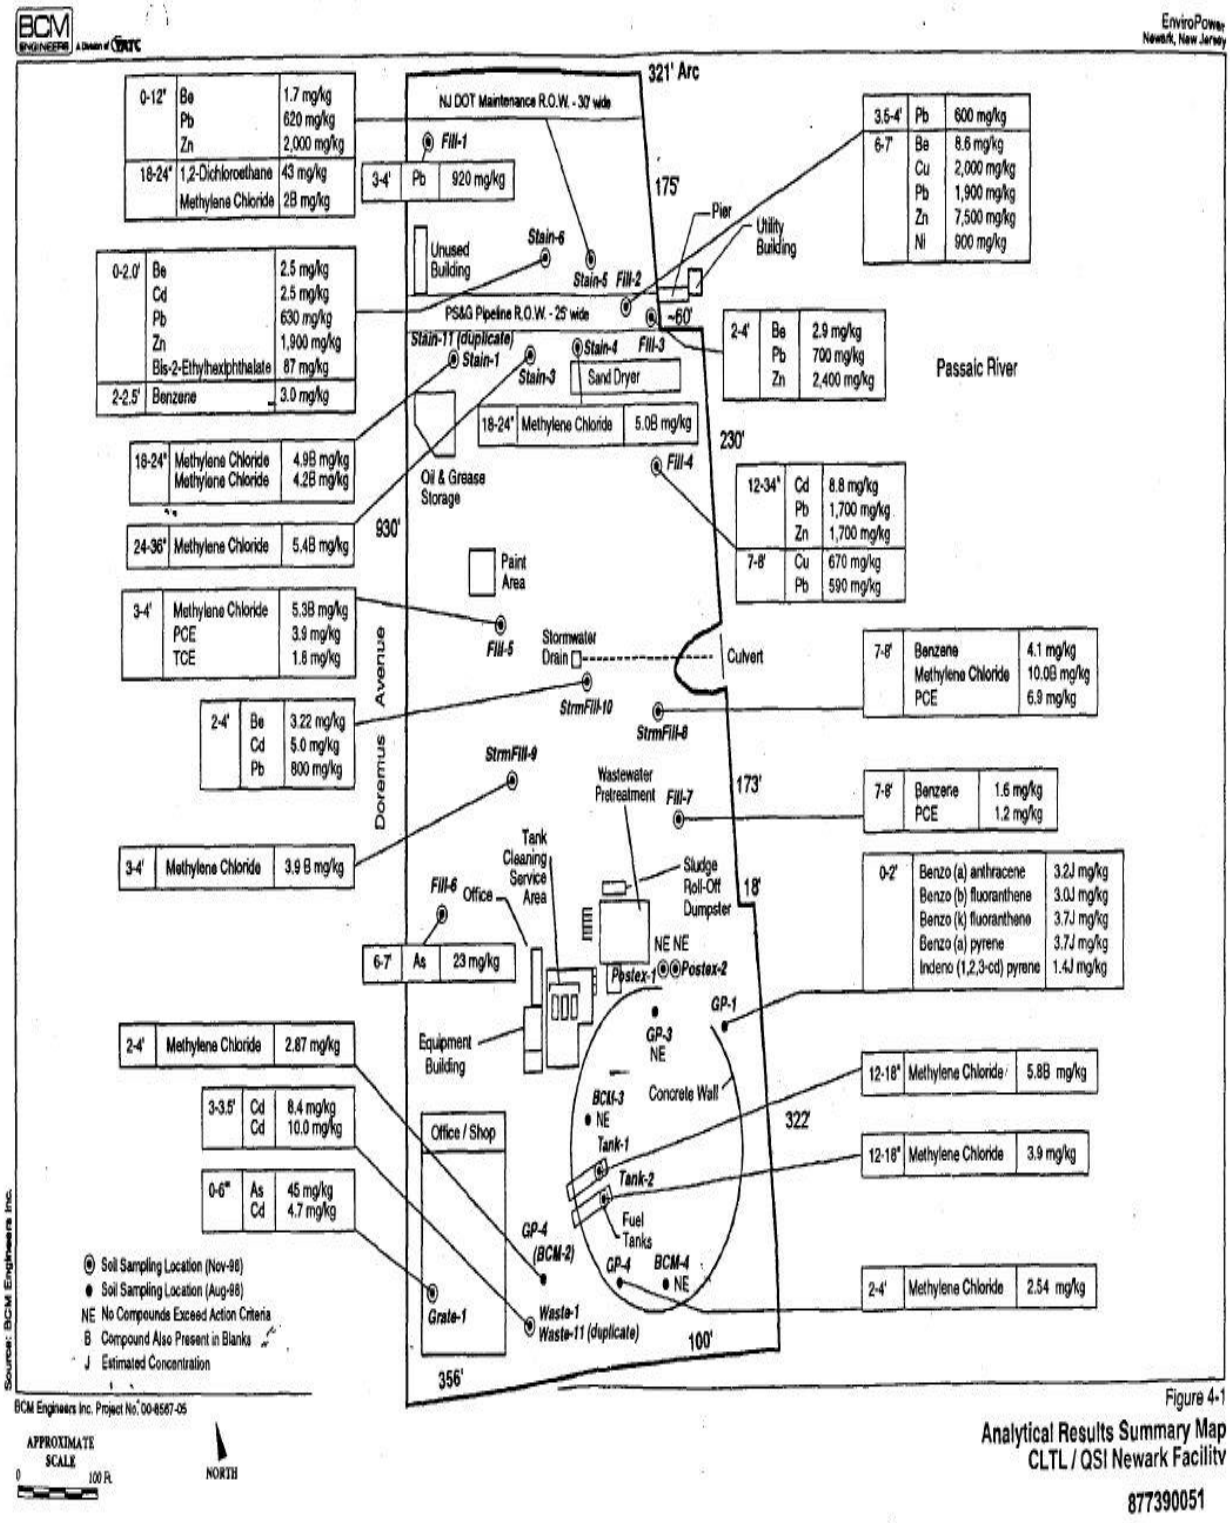
According to the 1999 BCM SI Report, TPH concentrations in soil samples taken at the north end of the site near the trailer staging area ranged from a low of 170 mg/kg in sample Stain-1 at a depth of 0-18" to a high of 5,200 mg/kg in sample Stain-5 at a depth of 0-12 inches (PAS-00084637).

One sample of soil/sediment was collected from below the metal grate on the left rear side of the maintenance building and TPH was detected at 1,500 mg/kg (PAS-00084635).

TPH was detected at a concentration of 188 mg/kg at the Pre-Solv filling area (PAS-00084635).

Low levels of TPH (310 mg/kg and 230 mg/kg) were detected in two surface soil samples collected from beneath each of the two 20,000-gallon diesel fuel ASTs which provide product to the Pre-Solv area (PAS-00084636).

TPH concentrations reported from the 1999 BCM SI Report ranged from non-detectable to a high of 13,700 mg/kg for the Historic Fill. TPH concentrations seemed to be highest in the central area of the site with TPH being present throughout the fill profile and with some of the highest concentrations present at 7 to 8 feet below grade (bgs) (PAS-00084638).



See the following Analysis Results Sampling Map from the 1999 BCM SI Report for the locations of the PAH samples discussed above.

Facility Data Report

In the *Supplemental Site Investigation Results Report* for Chemical Leaman Tank Lines, prepared by ENVIRON International Corporation, dated December 2000 (2000 ENVIRON Supplemental SI Report), further sampling was conducted as requested by NJDEP based on the 1999 BCM SI Report (PAS-00084493, 97).
The following table is a Summary of Soil Samples (highest concentration) taken for PAHs:

COC	Above Ground Storage Tanks mg/kg	Drum Storage Pad mg/kg	Staining near Trailer Staging Area mg/kg	Incident Spill Report mg/kg	Wastewater Handling System mg/kg	Historic Fill mg/kg
Depth	**4-4.5 feet bgs**	**1-1.5 feet bgs**	**0.-0.5 inches bgs**	**1.5-2 feet bgs**	**2-2.5 feet bgs**	**7-8 feet bgs**
Benzo(a)anthracene	2.87	4.44	29.7 g	1.52	0.141 (estimated)	7.17
Benzo(a)pyrene	2.54	5.11	25.4	1.44	0.255	5.23
Benzo(b)fluoranthene	2.57	4.31	27.6	2.11	0.218 g	4.48
Benzo(k)fluoranthene	1.7	3.93	11.1	1.45	0.132	5.96
Dibenzo(a,h)anthracene	0.641	1.16	8.72	0.639	NA	N/A
Chrysene	1.52	4.62	30.5	2.32	.177	6.81
Indeno(1,2,3-cd)pyrene	1.33	3.12	17.6	1.24	.014	2.01
Pyrene	2.3	7.9	57.4	2.18	1.61	

(PAS-00084545-61)

It was reported in the 2004 RIR that concentrations for Aroclor-1254 was at 1. 71 mg/kg (4 feet bgs) and Aroclor-1260 was 1.31 mg/kg (4 feet bgs) and 3.74 mg/kg (3 feet bgs). These results were from the eastern portion of the site (D11) as determined during the Doremus Avenue Roadway reconstruction and widening project (PAP-00328668-70). See Section 7 for further information on the sampling done for the Doremus Avenue Roadway project.

According to the 2009 RIR, redevelopment occurred on site with the demolition of site buildings and the removal of several concrete pads. Two areas that were affected were the Wash Bay Drainage System (AOC 9) and the Wastewater System Settlement Tank (AOC 10). Once the foundation was removed, soil was excavated to a depth of approximately 3 feet bgs and was designated at Pit No. 2 (PAP-00330037-38). The soil was analyzed for PAHs and the results can be found in the following table.

Sample Location	Sample Depth (fbgs)	Compound	Concentration In mg/kg	Non-Residential NJDEP Criteria Exceeded
Pit #2 W-NW	1.0-1.5	Benzo(a)anthracene	6.88	NRDCSCC
Pit#2 N-NW	1.0-1.5		5.43	NRDCSCC
Pit#2 N-NE	1.0-1.5		4.61	NRDCSCC
Pit #2 W-NW	1.0-1.5	Benzo(a)pyrene	5.10	NRDCSCC
Pit#2 N-NW	1.0-1.5		3.82	NRDCSCC
Pit#2 N-NE	1.0-1.5		3.84	NRDCSCC
Pit#2 W-SW	1.0-1.5		0.295	NRDCSCC
Pit #2 W-NW	1.0-1.5	Benzo(b)fluoranthene	5.01	NRDCSCC
Pit#2 N-NW	1.0-1.5		5.07	NRDCSCC
Pit#2 N-NE	1.0-1.5		3.37	NRDCSCC
Pit #2 W-NW	1.0-1.5	Dibenzo(a,h)anthracene	1.28	NRDCSCC
Pit#2 N-NW	1.0-1.5		1.07	NRDCSCC
Pit#2 N-NE	1.0-1.5		0.738	NRDCSCC
Pit #2 W-NW	1.0-1.5	Indeno(1,2,3-cd)pyrene	3.05	NRDCSCC
Pit#2 N-NW	1.0-1.5		2.42	NRDCSCC
Pit#2 N-NE	1.0-1.5		2.21	NRDCSCC
Pit#2 S-SE	1.0-1.5	Ethylbenzene	148	IGWSCC
Pit#2 S-SE	1.0-1.5	PCE	1.61	IGWSCC
Pit#2 S-SW	1.0-1.5		1.52	IGWSCC
Pit#2 W-SW	1.0-1.5		2.48	IGWSCC
Pit#2 S-SE	1.0-1.5	Xylenes	190	IGWSCC

(PAP-00330039)

Wastewater System Settlement tank was removed along with the soils surrounding the tank and designated as Pit No. 1 (PAP-00330041). The results for SVOCs were reported as no exceedances and no further delineation of the constituents was provided.

Additional soils were removed east-southeast of the tank as part of the construction of a building foundation and designated as Pit No. 3 (PAP-00330042). The following results for PAHs were taken at a depth of 1-1.5 feet bgs:

- benzo(a)anthracene (1.08 mg/kg),
- benzo(a)pyrene (1.22 mg/kg),
- benzo(b)fluoranthene (1.33), and
- indeno(1,2,3-cd)pyrene (0.959) (PAP-00330092)

According to the 2016 OBG Final RIR, further sampling was conducted in 2014. The PAH results are shown in the following table. RI-08 is located on the eastern edge of the site bordering the river; RI-17 is located on the northeast corner of the site; RI-18 is located north of the truck cleaning site; RI-19 is west of RI-18; RI-20 is near the Paint Center; and RI-21 near the PS&G Right of Way in the northern part of the site.

PAH Concentrations (mg/kg)					
COC	**RI-08 1-1.5 feet bgs**	**RI-17 1.5-2 feet bgs**	**RI-19 1-1.5 feet bgs**	**RI-20 2.5-3 feet bgs**	**RI-21 1.5-2 feet bgs**
Benzo(a)anthracene	2.39	0.769	3.0	3.06	0.249
Benzo(a)pyrene	2.66	0.649	2.3	3.25	0.293
Benzo(b)fluoranthene	2.54	1.32	3.5	5.99	0.31
Benzo(k)fluoranthene	1.11	0.461	1.13	1.07	0.101
Indeno(1,2,3-cd)pyrene	1.55	0.581	1.38	2.03	.154

(PAP-00145636-37)

DDx

According to the 2000 ENVIRON Supplemental SI Report further soil sampling was conducted as requested by NJDEP based on the 1999 BCM SI Report (PAS-00084493, 97). The following table is a Summary of Soil Samples (highest concentration) taken for Pesticides.

DDx Concentrations (mg/kg)		
COC	**Drum Storage Pad 1-1.5 feet bgs**	**Wastewater Handling System .5-1 feet bgs**
4,4'-DDD	0.0016	0.0046
4,4'-DDE	Not available	0.0016
4,4'-DDT	0.0011	0.0226

(PAS-00084552-54)

Copper

The 1999 BCM SI Report stated the following results (0-4 feet bgs) for the soil sampling done in 1998. See the Analysis Results Sampling Map from the 1999 BCM SI Report located in the previous PAHs section.

Location	Depth	Results
Fill 1 - northwest corner of property	2-3 feet bgs	30 mg/kg
Fill 1 - northwest corner of property	3-4 feet bgs	300 mg/kg
Fill 2 - northeast corner in the PS&G pipeline	3.5-4 feet bgs	110 mg/kg
Fill 3 - south of Fill 2	2-4 feet bgs	520mg/kg
Fill 4 - southeast of sand dryer	12-34 inches bgs	440 mg/kg
Fill 5 - south of the Paint Center	3-4 feet bgs	140 mg/kg
Fill 6 - southwest part of property	2-3 feet bgs	120 mg/kg
Fill 7 - southeast of culvert	2-4- feet bgs	70 mg/kg
Strmfill 8 - south of culvert	2-4 feet bgs	160 mg/kg
Strmfill 9 - southeast of storm drain	3-4 feet bgs	9.1 mg/kg
Strmfll 10 - south of storm drain	2-4 feet bgs	360 mg/kg

Location	Depth	Results
Stain 5 - north of the PS&G pipeline near eastern border of property	0-12 inches bgs	340 mg/kg
Stain 6 - center of property and north of the PS&G pipeline	0-2 feet bgs	500 mg/kg
Grate 1 - in the Office Building located in the southwest corner of property	0-6 inches bgs	42 mg/kg
Post Ex-1 - north of the tank farm	0-6 inches bgs	130 mg/kg
Post Ex-2 - north of the tank farm	0-6 inches bgs	50 mg/kg
Waste 1 - southwest of tank farm	3-3.5 feet bgs	21 mg/kg
Waste11 - southwest of tank farm (Duplicate)	3-3.5 feet bgs	25 mg/kg

(PAS-00084647-51)

According to the 2000 ENVIRON Supplemental SI Report further soil sampling was conducted as requested by NJDEP based on the 1999 BCM SI Report (PAS-00084493, 97). The following table is a Summary of Soil Samples (highest concentration) taken for copper:

ASTs depth 4-4.5 feet bgs	Former 250-Gallon Waste Oil UST) depth 3-3.5 feet bgs	Drum Storage Pad depth 1-1.5 feet bgs	Wastewater Handling System 0.5-1 feet bgs
43.5 mg/kg	8.3 mg/kg	93.5 mg/kg	142 mg/kg

(PAS-00084545-61)

Lead

The 1999 BCM SI Report stated the following results (0-4 feet bgs) for the soil sampling done in 1998. See the Analysis Results Sampling Map from the 1999 BCM SI Report located in the previous PAHs section.

Location	Depth	Results
Fill 1 - northwest corner of property	2-3 feet bgs	90 mg/kg
Fill 1 - northwest corner of property	3-4 feet bgs	920 mg/kg
Fill 2 - northeast corner in the PS&G pipeline	3.5-4 feet bgs	600 mg/kg
Fill 3 - south of Fill 2	2-4 feet bgs	700 mg/kg
Fill 4 - southeast of sand dryer	12-34 inches bgs	1,700 mg/kg
Fill 5 - south of the Paint Center	3-4 feet bgs	180 mg/kg
Fill 6 - southwest part of property	2-3 feet bgs	180 mg/kg
Fill 7 - southeast of culvert	2-4 feet bgs	90 mg/kg
Strmfill 8 - south of culvert	2-4 feet bgs	310 mg/kg
Strmfill 9 - southeast of storm drain	3-4 feet bgs	Non-detect (ND)
Strmfll 10 - south of storm drain	2-4 feet bgs	800 mg/kg
Stain 5 - north of the PS&G pipeline near eastern border of property	0-12 inches bgs	620 mg/kg

Location	Depth	Results
Stain 6 - center of property and north of the PS&G pipeline	0-2 feet bgs	630 mg/kg
Grate 1 - in the Office Building located in the southwest corner of property	0-6 inches bgs	99 mg/kg
Post Ex-1 - north of the tank farm	0-6 inches bgs	300 mg/kg
Post Ex-2 - north of the tank farm	0-6 inches bgs	140 mg/kg
Waste 1 - southwest of tank farm	3-3.5 feet bgs	ND
Waste11 - southwest of tank farm (Duplicate)	3-3.5 feet bgs	ND

(PAS-00084647-51)

According to the 2000 ENVIRON Supplemental SI Report further sampling was conducted as requested by NJDEP based on the 1999 BCM SI Report (PAS-00084493, 97). The following table is a Summary of Soil Samples (highest concentration) taken for lead:

Above Ground Storage Tanks	Underground Storage Tank - South End of Site	Drum Storage Pad	Wastewater Handling System	Historic Fill
34.8 mg/kg depth 4-4.5 feet bgs	128 mg/kg depth 0.5-1.0 feet bgs	101 mg/kg depth 1-1.5 inches bgs	282 mg/kg depth .05-1 inches bgs	727 mg/kg

(PAS-00084545-61)

The 2000 ENVIRON Supplemental SI Report stated that additional soil sampling for lead at the Stained Soil near Red Storage Area post excavation was conducted. The sampling results for lead were POSTEX1 (727 mg/kg) and POSTEX2 (2,060 mg/kg) at a depth of 0.5 - 1 inch (PAS-00084518; PAS-00084555).

Mercury

The 1999 BCM SI Report stated the following results (0-4 feet bgs) for the soil sampling done in 1998. See the Analysis Results Sampling Map from the 1999 BCM SI Report located in the previous PAHs section.

Location	Depth	Results
Fill 4 - southeast of sand dryer	12-34 inches bgs	1.5 mg/kg
Fill 5 - south of the Paint Center	3-4 feet bgs	2.1 mg/kg
Stormfill 10 - south of the stormwater drain	2-4 feet bgs	3.6 mg/kg
Grate 1 - in the Office Building located in the southwest corner of property	0-6 inches bgs	1.0 mg/kg

(PAS-00084647-51)

According to the 2000 ENVIRON Supplemental SI Report further soil sampling was conducted as requested by NJDEP based on the 1999 BCM SI Report (PAS-00084493, 97). The following table is a Summary of Soil Samples (highest concentration) taken for mercury:

ASTs 4-4.5 feet bgs	Drum Storage Pad 1-1.5 feet bgs	Wastewater Handling System 2-2.5 feet bgs
0.07 mg/kg	0.23 mg/kg	0.17 mg/kg

(PAS-00084545-61)

Historic Fill

The Allocation Team has determined that the facility site is located on regional historic fill as designated by the NJDEP.[1]

NJDEP has established that historic fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 COCs: PAHs, lead, copper, and mercury.[2] Accordingly, NJDEP technical requirements for property containing Historic Fill requires sampling for the EPA Target Compound List for PAHs and Target Analyte List for metals, including lead, copper, mercury, and the OU2 PAH COCs.[3] PAHs, lead, copper, and mercury are recognized by NJDEP to be constituents of Historic Fill at varying levels, not atypically at or exceeding residential soil standards.[4]

[1] *Digital Geodata Series, DGS04-7, Historic Fill for New Jersey*, https://www.nj.gov/dep/njgs/geodata/dgs04-7.htm, Quadrangle #52 and #53 (NJDEP map identifying locations of recognized historic fill).
[2] *Characterization of Ambient Levels of Selected Metals and PAHs In New Jersey Soils* (2002) and *Characterization of Ambient Levels of Selected Metals and Other Analytes In New Jersey Soils* (1997), studies prepared for NJDEP, Division of Science and Research, by BEM Systems, Inc.
[3] New Jersey Department of Environmental Protection (NJDEP), *N.J.A.C. 7:26E Technical Requirements for Site Remediation,* Table 4-2, November 2009 [Note that Table 4-2 has been deleted from the current version of N.J.A.C. 7:26E (May 7, 2012) and the updated *Historic Fill Technical Guidance* (April 2013) as NJDEP believed that the tables list of historic fill constituents was too restrictive].
[4] NJDEP Table 4-2 (PAHs and lead) and a summary of NJDEP records regarding investigations of properties in the vicinity of the Passaic River recognized to be located in areas of Historic Fill indicate that

The levels of PAHs, copper, lead and mercury detected at the site in soils are presented in the table below.

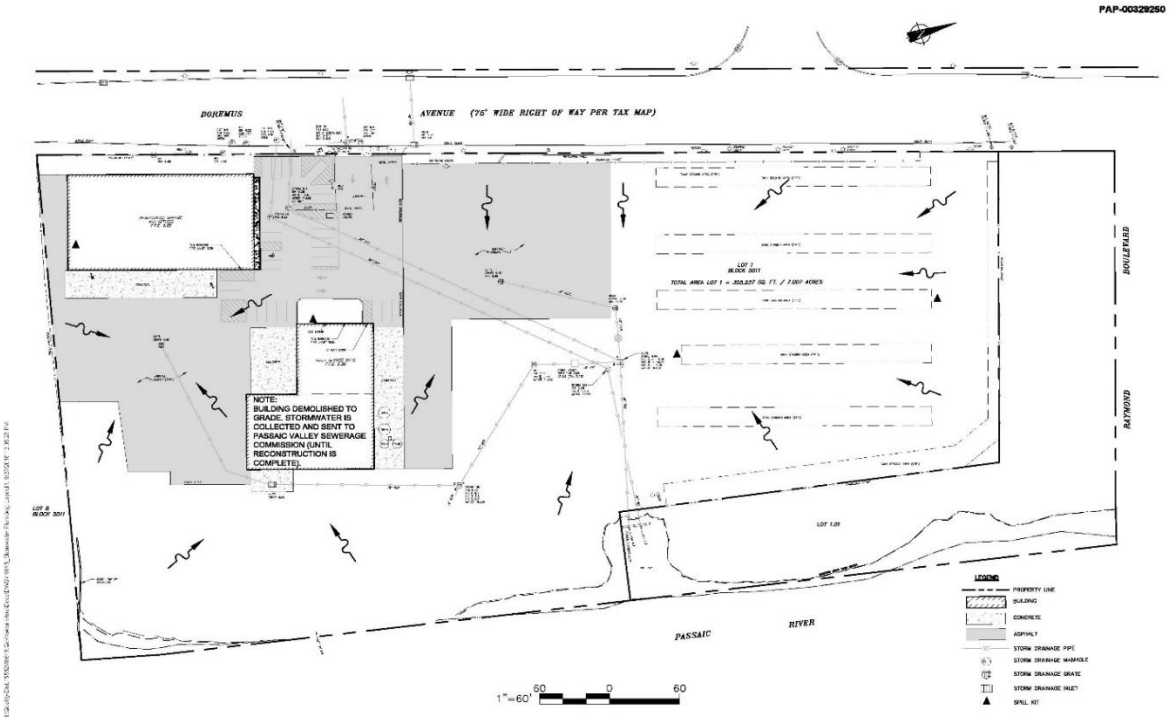
COCs Found in Onsite Soils	
COC	**Max Detected Concentration**
Lead	1,900 mg/kg
Copper	2,000 mg/kg
Mercury	2.1 mg/kg
Benzo(a)anthracene	7.17 mg/kg
Benzo(a)pyrene	5.23 mg/kg
Benzo(b)fluoranthene	4.48 mg/kg
Benzo(k)fluoranthene	5.96 mg/kg
Dibenzo(a,h)anthracene	2.01 mg/kg

As reported by the 1999 BCM SI Report, the site consists largely of fill material brought in to create land at a location formerly occupied by the Passaic River regime. Results of the fill material investigation also show that materials were likely obtained from more than one source. Evidence of this is provided by observations of fill characteristics made during the soil sampling program and in the results of chemical analyses. Because of the varying characteristics of the fill material, it is also probable that filling of the majority of the site was not performed at one time (PAS-00084639).

Also the 1999 BCM SI stated that the majority of the site was constructed via historic filling activity prior to 1908. Subsequently, filling of the northeast corner of the site occurred between 1908 and 1931 and a former stream channel was primarily filled between 1951 and 1961, and completely filled between 1969 and 1974. Observations made during the BCM fill material investigation performed in November 1998, reported that the site is largely composed of a thick layer (up to 14.5 feet thick) of fill material (PAS-00084612).

5. COC Pathways

Storm Sewer



According to the 1998 BCM ISRA PA Report, stormwater was discharged to the Passaic River via an open-end pipe discharge. The facility has provided measures to contain stormwater as much as possible by conducting truck wash operations in an enclosed building, providing concrete dikes for the drum storage pads and observing good management practices (PAS-00084733).

Two storm water drains are located at the Site. One is present in the center of the truck parking area and drains stormwater from the parking area and the areas north of the building. The second stormwater drain is located near the former tank cleaning building.

---

the following average/maximum (mg/kg) contamination levels of OU2 COCs exist in area Historic Fill: PAHs (1.91/160), lead (574/10,000), copper (11.2/1,200), and mercury (0.21/3.7).

Only the stormwater drain in the center of the site drained to the outfall in the Passaic River. While tank washing activities at the Site were ongoing, stormwater from a small portion of the Site east of the maintenance building was also processed through the on-site wastewater pretreatment facility (PAP-00329227). Since 2015, all stormwater on Site has drained to storm drains or been collected and discharged directly to the sewer system (PAP-00329250). See drawing below.

Sanitary Sewer

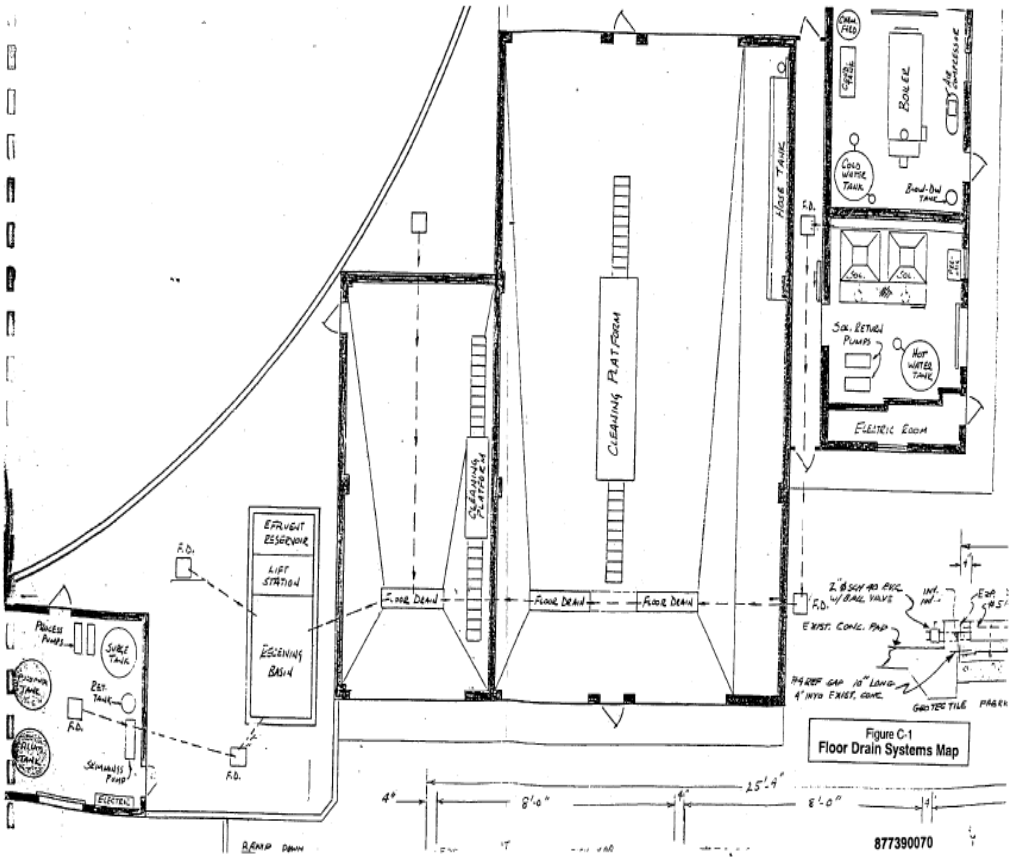
The Facility is located at 80 Doremus Avenue in Newark. The City of Newark sewers are part of the PVSC system, but only serve the City of Newark. The sewer line serving Doremus Avenue is reported as a “Separate Sewer” and is differentiated from the Combined Sewer along Roanoke Avenue (PAP-00329827) The Facility permit documents show a wastewater connection to the Sanitary Sewer running along Doremus Avenue (PAP-00328859; PAP-00328892). The Doremus Avenue sewer has been a sanitary sewer at least as far back as 1973. (PAP-00329977)

Wastewater System

It is believed that prior to 1951 wastewaters from the northern Doremus Avenue area were directed to the Roanoke Avenue regulator system during surcharging of the sewer system. Any process wastewaters flowing to the Roanoke Avenue regulator were discharged to the Passaic River at the Roanoke Avenue outfall. The facility operations in place at the site prior to/as of 1951 were the operations of Public Service Coordinated Transport (PAS-00124548). Note that Quality Carriers operations at the site began in 1970 (PAP-00145606).

Quality Carriers Inc.

Diamond Alkali OU2 Allocation



ADR Confidential

Facility Data Report

The following description of the Wastewater System was taken from the QSI Accident Spill Prevention Plan dated 1994:

> "The cargo tank cleaning facility consists of a metal building enclosing three concrete wash bays. Each cleaning bay is sloped to an individual sump where wastewater first collects and then gravity flows through a pipe to a 2,000-gallon steel collection tank. After an oil separation procedure, the wastewater is pumped to a 20,000-gallon steel equalization and blending tank. After equalization and blending, the wastewater is pumped to a 10,000-gallon steel chemical batch reactor. At this stage of the process, chemicals are added to separate out emulsions, precipitate solids, adjust pH, and if necessary, oxidize organics. The chemically-conditioned wastewater is then transferred to a primary clarifier where floating and settleable solids are removed. Air lift pumps are utilized to transfer sludge to the aerobic sludge digester. Oil and grease skimmed from the water surface is also transferred to the aerobic sludge digester. The clarifier effluent overflows the double-edged effluent weir and into an effluent pump tank. The effluent is then pumped through overhead piping to the city sewer system" (PAP-00328873-74).

A diagram of the floor drain system which shows historic discharges to a settlement basin and on-site WWTP is presented below (PAS-00084674).

On November 17, 1994, QSI notified PVSC of the proposed increased average daily flow from the current rate of 15,000 to 25,000 gallons to the proposed rate of 25,000 to 35,000 gallons. It stated that additional equipment which served as slug prevention were the 20,000-gallon holding tank and the 10,000-gallon chemical batch reactor. All process drains in the tank cleaning and wastewater treatment areas were connected directly or indirectly to the 20,000-gallon holding tank. Any slug entering the system would then be isolated in the 10,000-gallon chemical batch reactor. It was proposed that to detect a slug occurrence would be the daily process testing in the chemical batch reactor (PAP-00328866-67).

6. Regulatory History/Enforcement Actions

Inspections

An inspection of the facility was performed by NJDEP on September 28, 1998. According to the report of inspection the following deficiencies were noted:

- Heavy staining and evidence of oil around the 250-gallon aboveground waste oil tank located in the maintenance/office building inside and outside of the containment area (PAS-00084668).

- Inside the maintenance building, on the left rear side closest to Doremus Avenue, is a metal grate in the floor. It appeared to be a sewer cleanout, however, there was exposed soil below the grate which appeared to be heavily stained (PAS-00084668-69).

- The areas on both sides of the diesel fuel oil pumping station were heavily stained. One area is where the pumping occurs, the other area is the fill intake pipe which transports the fuel to the tank via gravity (PAS-00084669).

- There was a spill of diesel fuel when a tank line was ruptured in January 1996. There is no mention of any sampling occurring as a result of this spill. In addition, since the tanks have been in service since the 1930s and do not have secondary containment, the area of the two 20,000-gallon diesel fuel tanks including the piping to the boiler room was to be investigated (PAS-00084669).

- The floor drains associated with the tank wash operations were filled with liquid and could not be checked (PAS-00084669).

- The concrete settlement tank associated with the rinsate collection and wastewater treatment system was filled with liquid and therefore the construction and integrity could not be checked. In addition, the preliminary assessment report (PAR) states that the settlement tank was installed in 1993, a year after QSI started operations at the site. It is not clear where the rinsate discharged prior to the installation of the settlement tank (PAS-00084669).

- The drum storage pad located next to the oil skimmer was filled with approximately three inches of oily liquid waste. The integrity of the pad could not be determined (PAS-00084669).

- There was a stained soil area between the red storage shed and the waste water pretreatment area (PAS-00084669).

- The former 1000-gallon underground waste oil tank was not sampled in accordance with N.J.A.C. 7:26E. In addition, it is not clear if this tank was replaced by the 250-gallon aboveground waste oil tank present in the maintenance room (PAS-00084669).

A summary of the investigations performed for the above listed areas is found in the Characterization Activities located in Section 7 Response Actions.

Violations

According to the 1998 BCM ISRA PSA, the following summary of PVSC rule violations occurred:

- Between April 26, 1989 and August 6, 1997 - Multiple violations of discharging corrosive waste

- July 31, 1990 - pH monitoring equipment was not operating in conformance with its intended use.

- Between January 30, 1991 and May 8, 1995 - Multiple violations of Petroleum Hydrocarbons results exceeding limits.

Permits

According to a letter prepared by CLTL addressed to US EPA, dated January 29, 1982, CLTL submitted an application for a hazardous waste permit in November 1980. The application was approved and given the following EPA generator number: NJD 040743072 (PAS-00084676).

On September 6, 1987, PVSC issued a Sewer Connection Permit (No. 20404240) authorizing CLTL to discharge into the PVSC system. The effective date was September 6, 1987 until September 6, 1992. A 24-hour composite sampler on Outlet No. 1 was to be installed by CLTL with acceptance by PVSC. In addition, CLTL was to install a water consumption meter on Outlet No. 2 (PAP-00328836-38, 41, 46).

The renewal application for Sewer Connection Permit No. 20404240 was submitted by CLTL on March 6, 1992 for continuation to discharge to the PVSC sewerage. Process wastewater was to be discharged to a Combined Sewer on an intermittent basis (PAP-00328855-57).

According to the 1998 BCM ISRA PA Report, CLTL held a sewer connection permit with the PVSC since at least September 6, 1987 through at least September 6, 2002~~2007~~. They also held a hazardous materials facility permit with the Newark Fire Department from January 29, 1997 through January 29, 2002 (PAS-00084779).

A Sewer Use Permit Number 20200022 was granted to Quala Systems, Inc. effective September 6, 2002 with the expiration date of August 31, 2007 (PAP-00329025). According to a September 6, 2007 QSI letter to PVSC, all discharges from outlet 20200022-1 had ceased and the process to dismantle the existing wastewater pretreatment plant had begun. It was requested that Permit Number 20200022 be retained with modifications (PAP-00329195).

7. Response Actions

Characterization Activities

The following characterization activities have taken place at the facility:

- NJDEP and Energy Division of Responsible Party Site Remediation, ISRA Preliminary Site Assessment, Quala Systems Inc./Chemical Leaman Tank Lines dated April 1998 (PAP-00147645)
- Site Investigation Results Report, Quala Systems Inc./Chemical Leaman Tank Lines dated January 1999 (PAS-00084605)
- Supplemental Site Investigation Results Report, Quala Systems Inc./Chemical Leaman Tank Lines dated December 2000 (PAS-00084493)
- ISRA Revised Remedial Investigation Work Plan, dated February 2002 (PAP-00328578).
- Remedial Investigation Results Report, Chemical Leaman Tank Lines, Inc. dated July 2004 (PAP-00328639).
- Remedial Action Report, Doremus Avenue Improvements, May 2007, The Louis Berger Group, Inc. (PAP-00328606).
- Addendum to the Supplemental RI Work Plan, June 2007, (PAP-00445912).
- Remedial Investigation Report, Chemical Leaman Tank Lines, Inc. dated July 2009, ISRA Case Number E98308, Volume 1 of 2 (PAP-00329995).
- Remedial Investigation Report, Chemical Leaman Tank·Lines, Inc. dated July 2009, ISRA Case Number E98308, Volume 2 of 2 (PAP-00330307)
- Final Remedial Investigation Report, Quality Carriers Incorporated, dated May 2016 (PAP-00145600)

The 1998 BCM ISRA PSA provided a narrative for several areas of concern which were subsequently investigated during an 18-year ISRA investigation process, culminating in the 2016 OBG Final RIR. A brief summary of the areas of concern follows:

Bulk Storage Tanks

Aboveground tanks and piping

- Two elevated 20,000-gallon tanks used for storing diesel fuel; one used by CTLT and one used by QSI Environmental Services. The tanks are approximately 10 feet bgs off the ground, within the perimeter of a 226-foot diameter circular containment wall. At the time of the site assessment the tanks were in good shape.

- A three million-gallon steel storage tank used for storing No. 4 Fuel Oil was stored at one time in the 226-foot containment wall. It was reported that the tank was removed in the 1980s. No physical evidence of its existence was visible, and no information of removal or spills was obtained so further investigation was recommended.

- Five tanks for storing reagents for the on-site WWTS. Four were stored in the Reagent Building on concrete pads with a concrete dike perimeter: 1,000-gallon tank for storing sulfuric acid; 500-gallon tank intended for storing polymer reagent (not currently use); 1,000-gallon tank for storing aluminum sulfate; 1,000-gallon tanks for storing sodium hydroxide solution. The fifth tank containing sodium hydroxide was located outside of the Reagent Building on a concrete pad. At the time of the site assessment the tanks were in good shape.

- A horizontal 250-gallon aboveground storage tank used for storing waste oil was located at the southwest corner of the maintenance building. At the time of the site assessment the tank appeared to be in good condition.

Underground Tanks and Associated Piping

- In October 1987, CTLT removed a 1,000-gallon steel underground storage tank. Excavation samples were taken and analyzed for TPH. Based on the test results the levels of PAHs were acceptable. No further action was recommended.

- Sanborn maps dated 1931, 1950, and 1973 show that three underground gasoline storage tanks existed at the site at these times and were located along the southwest side of the concrete wall of the three million-gallon storage tank area. During the site visit no visible signs of vent pipes were found to document the tanks existence. No further information was found on these tanks, therefore; further investigation on the status of the tanks was recommended.

Pits

- In 1993 one concrete settlement tank associated with the rinsate collection and WWTS was installed. It was located adjacent and to the east of the truck washing facility. The tank did not appear to have any deficiencies therefore no further action was recommended.

Storage Pads and Drum/Waste Storage Area

- CLTL stored used empty 55-gallon drums and 55-gallon drums containing motor, transmission, and hydraulic oil lubricants and antifreeze coolant on a concrete floor along the north side of the maintenance building. During the site assessment about 20 drums were being stored (11 empty). Evidence of oil staining was seen in this area as well as along the nearby floor seam. Since no significant level of contamination was observed, no further investigation was recommended.

- QSI maintained three contiguous storage areas for 55-gallon drums containing liquid waste or semi-liquid residues that are drained from tank trucks brought in for washing at the wash building. The storage areas were constructed with impermeable concrete pads and dikes and visual observation determined to be adequate. No further investigation was recommended.

Dumpster

- A10 cubic-yard steel dumpster was located beside the modular WWTS. It was used for the collection of the dewater sludge from the WWTS. The practice of using the dumpster had been in effect for five years. No odor from the dumpster was observed so no further investigation was recommended.

Drainage Systems and Areas

Floor Drains

- Three floor drains were observed in the truck washing building and one in the reagent room. No cracking and clogging were observed so no further investigation was recommended.

Discharge and Disposal Areas

Open Pipe Discharge

- Stormwater is discharged to the Passaic River via an open-end discharge. Visual inspection did not show oil sheen or signs of discolored areas. Corporate management stated that EPA had issued a company-wide general storm discharge permit but at the time an NJDEP stormwater permit was not in effect.

Other Areas of Concern

Discolored Areas of Spill Areas

- The facility used diesel fuel as a “Pre-solv” material for truck washing. The diesel fuel was taken by gravity via a discharge pipe from a 20,000-gallon tank that belongs to QSI to five-gallon pails. The filling area appeared to have been

heavily stained suggesting that spills could have occurred. The extent of possible contamination is not known, therefore further investigation is required.

- During the site assessment the ground within the circular wall containment for the former three million-gallon storage tank was observed to be grayish in color. The area had been in existence since 1931 and since no evidence of what caused the discoloration was found, further investigation was required. (PAS-00084730-34).

According to 2000 ENVIRON Supplemental SI Report, 15 potential areas of environmental concern (AOCs) were characterized (PAS-00084541) based on the 1998 ISRA PSA discussed above. These areas were subsequently investigated further, as reported in the subsequent reports prepared in 2002, 2007, 2009, 2011, and 2016. The long term remedy proposed for the site includes an engineering control (cap) with respect to the continued presence of historic fill, an institutional control (deed notice), and establishing two groundwater classification exception areas (CEAs). The following is a summary of the investigations and conclusions for each AOC.

Areas of Concern

Former No. 4 Fuel Oil AST (AOC 1)

During August 1998, BCM Engineers Inc. (BCM) collected four surface soil samples to characterize soil quality in the area surrounding the former No. 4 fuel oil AST location. In their November 23, 1999 correspondence, NJDEP requested that additional soil sampling be completed to delineate the vertical and horizontal extent of the impacted soils at soil boring GP-1, located northeast of the concrete retaining wall associated with the former AST. NJDEP also requested that additional soil borings be completed within the former secondary containment area at locations around the perimeter of the former AST. In July 2000, ENVIRON completed soil borings and soil sampling in the vicinity of prior sample location GP-1 and around the perimeter of the former No. 4 fuel oil AST. Based on the results of the supplemental site investigation, ENVIRON proposed that further soil borings and sampling was required (PAS-00084501-03).

On October 4, 2002, ENVIRON completed seven soil borings (GP1I through GP1O) to delineate the horizontal and vertical extent of TPHC-impacted soils and further evaluate free-phase hydrocarbons identified at soil boring SB-5. Each soil boring was completed to 12 feet bgs, with the exception of vertical delineation soil boring GP1I which was completed to 16 feet bgs (PAP-00328647). The sample results for the horizontal and vertical delineation were reported for TPHC concentrations only (PAP-00328648, 84).

Further soil investigations was performed and the results were reported in the 2009 RIR by Science Applications International Corporation (SAIC). According to the 2009 RIR, the investigation was to confirm the 123 mg/kg TPH concentration in sample SB-5 (4.5 to 5 feet bgs) and provide TPH concentration data below formerly identified free product (PAP-00330016).

The AOC 1 soil borings had been delineated to the extent of TPH impact exceeding 10,000 mg/kg to an area of approximately 4,000 cubic feet located northeast of the former AST. In addition, there appeared to be an area with a smear zone of petroleum hydrocarbon northeast of the former AST and delineated by the installed soil borings to an area approximately 800 square feet in size (PAP-00330017).

Note: PAHs were not delineated in the sample results for AOC 1.

Two 20,000-Gallon Diesel Fuel ASTs (AOC 1A)

During November 1998, BCM collected one surface soil sample and one shallow subsurface soil sample from beneath each of the two 20,000-gallon diesel fuel ASTs which provided product to the Pre-Solv Area (PAS-00084504).

It was concluded that soil sampling activities completed at the two 20,000-gallon diesel fuel ASTs during the supplemental site investigation in 2000 and remedial investigation in 2004 did not identify VOC concentrations at levels above the analytical laboratory detection limit; therefore no further action was recommended (PAP-00328651; PAS-00084504)

Waste Oil AST (AOC 2)

During an NJDEP site inspection on September 23, 1998, staining was noted on concrete surfaces in the vicinity of the 250-gallon waste oil AST located inside the Maintenance Building. Following NJDEP's inspection, CLTL cleaned all concrete surfaces in the vicinity of the AST and BCM visually inspected the integrity of the concrete during the site investigation. BCM's inspection of the concrete floor did not identify cracks or pitting that would compromise the integrity of the floor. In their June 15, 2000 correspondence, NJDEP requested additional sampling be completed in the area outside of the Maintenance Building (PAS-00084505).

On November 7, 2000, ENVIRON completed one soil boring (SB30) outside of the Maintenance Building, in the vicinity of the waste oil AST. The reported TPHC concentration of 14,300 mg/kg exceeded NJDEP's 10,000 mg/kg health-based criterion for total organic contaminants. Reported VOC, BN, and PCB concentrations did not exceed the most stringent NJDEP soil cleanup criteria. It was recommended that three soil borings be completed in the vicinity of soil boring SB30 to delineate elevated TPHC (PAS-00084505).

According to the RIR report, Chemical Leaman Tank Lines, Inc. dated July 2004 (2004 RIR), soil sampling activities were completed outside the Maintenance Building that delineated the horizontal and vertical extent of TPHC-impacted soils in the vicinity of the waste oil AST. A remedial action plan was to be prepared (PAP-00328652).

SAIC reported in the July 2009 RIR that NJDEP agreed that no further soil characterization was required based on the results of the previous sampling events. Remedial actions to address the soils with TPH concentrations above 10,000 mg/kg (immediately around SB-30 between 3 and 5 feet) were required (PAP-00330022).

Note: PAHs were not delineated in the sample results for AOC 2.

Former Gasoline USTs - South End of Site (AOC 3)

During August 1998, BCM completed a geophysical survey to determine whether USTs were present at the southwestern portion of the site. In addition, two soil samples were collected from one soil boring (GP-4[BCM-2]) and analyzed for TPHCs and VOC+10. The geophysical survey did not identify reflective signatures characteristic of a UST. In the November 23, 1999, letter, NJDEP requested that two additional soil samples be collected in the area and analyzed for VOC+10 and lead. Following review of the *Supplemental Site Investigation Work Plan*, NJDEP requested (in a letter dated June 15, 2000) that sampling in the area be completed in accordance with the Technical Requirements for Site Remediation. The revised scope of work was provided to NJDEP as an attachment to a letter from QDI dated July 26, 2000 (PAS-00084506).

On August 3 and September 11, 2000, ENVIRON completed a total of eight soil borings (SB-6, SB-7, and SB-24 through SB29) in the vicinity of the former USTs. Each soil boring was completed to 12 feet bgs, with the exception of soil borings SB-6 and SB-7, which were completed to 4 feet bgs. One soil sample was collected from each soil boring and analyzed for VOC+10 and lead (PAS-00084506). ENVIRON reported constituent concentrations in the soil samples collected during the supplemental site investigation were all below the most stringent NJDEP soil cleanup criteria. Lead was detected in four of the samples (11.6 mg/kg, 16.6 mg/kg, 29.9 mg/kg and 128 mg/kg (PAS-00084547-48).

According to the 2004 RIR, on March 1 and 2, 2004, ENVIRON completed a total of five soil borings to characterize soils below the former gasoline USTs (SB31 and SB32). Lead concentrations were reported for samples collected from soil borings SB31 at 12.9 mg/kg and SB32 at 12.8 mg/kg (PAP-00328653-54).

It was reported in the 2009 RIR that it was anticipated that the dissolved detections of benzene, PAHs, and metals would be addressed by establishing a CEA and deed notice prohibiting the use of groundwater for the site (PAP-00330025, 27).

Former 250-Gallon Waste Oil UST (AOC 4)

Site investigation activities performed by BCM during November 1998 included the completion of one soil boring near the former 250-gallon waste oil UST. One soil sample (Waste-1) was collected from the boring and was analyzed for VOC+10, BN+15, PCBs, Priority Pollutant metals, and TPHCs. NJDEP rejected the VOC, BN, PCB, and metals data based on QA/QC issues and required that additional sampling be completed (PAS-00084508).

On August 3, 2000, ENVIRON completed one soil boring at BCM's prior sampling location. The soil boring (WASTE-1) was completed to depth of 4 feet bgs. Analytical results reported that VOCs and PCBs were not detected in the soil sample and the reported bis(2-ethylhexyl)phthalate and di-n-ocryl phthalate concentrations were below the most stringent NJDEP soil cleanup criteria. Based on the results, ENVIRON recommended no further action for AOC 4 (PAS-00084509).

According to the 2004 RIR and the 2009 RIR, AOC 4 was approved by NJDEP for no further action for soil. This was based on the results of the site investigation and supplemental site investigation activities (PAP-00328646; PAP-00330028).

Former Gasoline USTs - North End of Site (AOC 5)

Historical Sanborn maps depict gasoline USTs in the vicinity of the northern site boundary. Activities completed during BCM's site investigation included the completion of a geophysical survey to identify the location of the gasoline USTs. Geophysical survey results were inconclusive due to surface and shallow subsurface interferences. In the November 23, 1999 correspondence, NJDEP requested that trench pits be excavated, and soil samples be collected to characterize soil quality in the vicinity of the former USTs (PAS-00084509).

In the 2000 ENVIRON Supplemental SI Report, it was determined that the former USTs are positioned beyond the northern Site boundary and are not part of the CLTL facility. No further action was recommended (PAS-00084509).

According to the 2004 RIR, AOC 5 was approved by NJDEP for no further action for soil. This was based on the results of the site investigation and supplemental site investigation activities (PAP-00328646).

The 2009 RIR reported that trench pits were excavated and soil samples collected. No impacted soils or USTs were discovered during the investigation. It was concluded that additional characterization or remediation was not necessary for this AOC.

Pre-Solv Filling Area (AOC 6)

During August 1998, BCM collected one surface soil sample and one shallow subsurface soil sample from one soil boring (GP-4) at the Pre-Solv Filling Area. Because this area was concrete-covered, additional samples could not be collected. However, the November 23, 1999, correspondence from NJDEP requested that one additional soil boring be completed at the Pre-Solv Filling Area due to the long operational period (PAS-00084509-10).

On August 3, 2000, ENVIRON completed one soil boring (SB08) to a depth of 4 feet bgs at the Pre-Solv Filling Area. Based on the results of the supplemental site investigation, it was proposed to complete 3 additional soil borings in the vicinity of soil boring SB08 to delineate the elevated TPHC and benzene concentrations (PAS-00084511).

According to the 2004 RIR, on March 1 and 2, 2004, ENVIRON completed three soil borings (SB08A, SB08B and SB08C) to delineate the horizontal and vertical extent of TPHC and VOC-impacted soils in the vicinity of the Pre-Solv Filling Area. Soil sampling activities completed in the vicinity of the Pre-Solv Filling Area during the remedial investigation delineated the extent of VOC. Further evaluation of the soil and ground water quality in the vicinity of the Pre-Solv Filling Area was needed (PAP-00328656). Note: The VOCs analyzed were for PAHs not relevant to the current allocation.

It was reported in the 2009 RIR, that the horizontal and vertical delineation for benzene was completed since benzene was detected at a concentration below the NJDEP criteria. Horizontal delineation for TPH results reported one sample at 18,800 mg/kg. Further sampling was necessary to delineate the extent of TPH in soils (PAP-00330031-32).

Drum Storage Pad (AOC 7)

The current drum storage pad was cleaned and inspected by BCM during the site investigation. The drum storage area was found to be intact and no visible cracks or pitting was observed in the concrete. The November 23, 1999 correspondence from NJDEP requested that additional sampling be completed to characterize soil quality in the vicinity of the former drum storage pad at the site. The former drum storage pad was located immediately east of the current pad at the location of the wastewater pre-treatment plant (PAS-00084511).

On August 10, 2000, ENVIRON completed two soil borings (SB15 and SB16) adjacent to the former drum storage pad to evaluate potential releases associated with the former drum storage pad (PAS-00084511). Reported PAHs in soils at AOC 7 included Benzo(a)anthracene, Benzo(a)pyrene, Benzo(b)fluoranthene, Benzo(k)fluoranthene, Dibenzo(a,h)anthracene, chrysene, and Indeno(1,2,3-cd)pyrene (PAS-00084552). It was recommended that a deed notice be established to address the PAH concentrations in the historic fill material at the Site. Based on the results, it was also recommended that no further action was warranted with respect to the drum storage pad (PAS-00084512).

According to the 2004 RIR, AOC 7 was approved by NJDEP for no further action for soil. This was based on the results of the site investigation and supplemental site investigation activities (PAP-00328646).

Maintenance Shop Drum Storage (AOC 8)

In the November 23, 1999, correspondence, NJDEP requested that a sample be collected from the floor seam in the vicinity of the Maintenance Shop drum storage area. As the elevated TPHC concentration warranted removal of sediment from within the floor seam, additional characterization (i.e. VOC analysis) was not performed (PAS-00084513).

On August 1, 2000, one sample (SB17-SS01) was collected from the sediments present within the floor seam near the northern garage bay of the Maintenance Shop in the vicinity of the drum storage area. The reported TPHC concentration (23,200 mg/kg) exceeded the NJDEP health-based criterion of 10,000 mg/kg for total organic contaminants. As the elevated TPHC concentration warranted removal of sediment from within the floor seam, additional characterization (i.e. VOC analysis) was not performed. It was recommended that accumulated sediment be removed from the floor seam and transported for appropriate off-site disposal. Upon removal of the sediments, the floor seam was to have been visually inspected to characterize the integrity of the seam (PAS-00084513).

In the 2004 RIR, it was reported that the sediment was removed and disposed off-site. The visual inspection of the floor seam determined it to be in good condition with no significant cracks or pitting. No further action was recommended (PAP-00328657). According to the 2009 RIR, NJDEP agreed that no further action was required for the soils at this AOC (PAP-00330035).

Wash Bay Drainage System (AOC 9)

During NJDEP's September 1998 site inspection, the floor drains associated with the wash bays were filled with liquid and the integrity of the drains could not be assessed. Results of a subsequent visual integrity inspection completed by BCM described the floor drains as intact. In the November 23, 1999 correspondence, NJDEP requested that an additional investigation be completed to characterize the floor drains in accordance with the Technical Requirements for Site Remediation (PAS-00084513-14).

On August 4, 2000, ENVIRON completed three soil borings (SB09, SB10, and SB11) along the northern edge of the Tank Cleaning Building to characterize soil quality and identify potential releases associated with the floor drains. Reported PAHs in soils at AOC 9 included Benzo(a)anthracene, Benzo(a)pyrene, Benzo(b)fluoranthene, Benzo(k)fluoranthene, Dibenzo(a,h)anthracene, chrysene, and Indeno(1,2,3-cd)pyrene and pyrene. The following pesticide concentrations (maximum detected) were reported for; 4,4'-DDD at .0046 mg/kg, 4,4'-DDE at .0016 mg/kg, and 4,4'-DDT at .0226 mg/kg. The highest concentration for Aroclor 126 was 0.0937 mg/kg. The reported highest concentrations of metals were; copper at 142 mg/kg, lead at 282 mg/kg, and mercury at .17 mg/kg (PAS-00084554). No further sampling was needed for the above discussed constituents since the concentrations results were below the NJDEP soil cleanup criteria. Based on the results of the supplemental site investigation, ENVIRON proposed to complete one boring in the area north of sample location SB10 to delineate the horizontal extent of the elevated phthalate concentration (PAS-00084515).

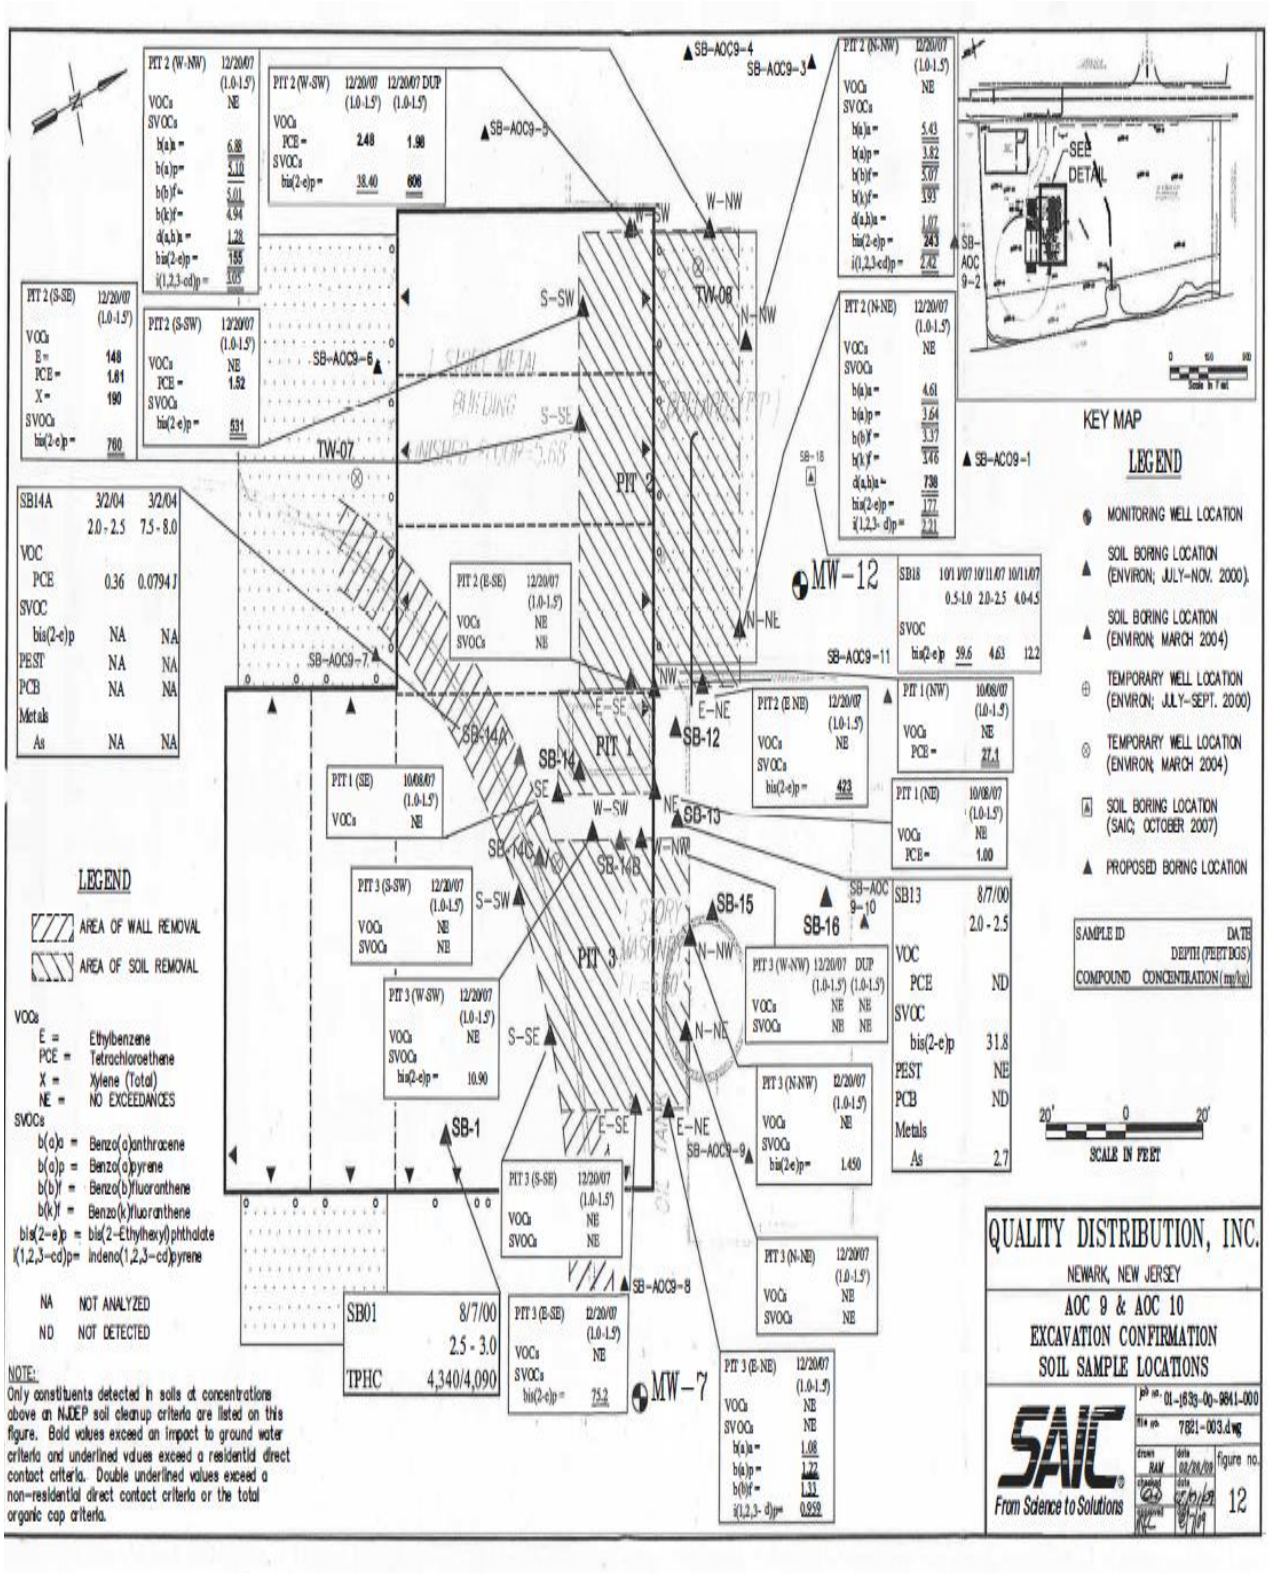
Vertical and horizontal delineation of bis(2-ethylhexyl)phthalate at AOC 9 was conducted in 2004 and 2007 (PAP-00328657-58; PAP-00330036).

It was reported in the 2009 RIR, that during the sampling event in 2007, the redevelopment of the site occurred. The demolition of the site buildings and the removal of several concrete pads in AOC 9 and the adjacent AOC (AOC 10 wastewater system settlement tank) took place. Additionally, soils were removed to allow for the

construction of a new building. Three different excavations were completed as part of the historic foundation excavation activities resulting in the generation of approximately 3,458 tons of soils/backfill material in total. The "Pit No. 2" excavation focused around AOC 9 and effectively remediated a portion of the previously characterized near-surface soils which were impacted by bis(2-ethylhexyl)phthalate. Upon the completion of the foundation removal, soil was excavated to a depth of approximately 3 feet bgs. Soil samples were collected from the sidewalls because groundwater flooded the excavation and eliminated access for bottom sample collection (PAP-00330038).

Sampling results reported the highest concentration at a depth of 1-1.5 feet for the following:

- Benzo(a)anthracene 6.88 mg/kg
- Benzo(a)pyrene 5.1 mg/kg
- Benzo(b)fluoranthene 5.07 mg/kg
- Dibenzo(a,h)anthracene 1.28 mg/kg
- lndeno(1 ,2,3-cd)pyrene 3.05 mg/kg (PAP-00330039)



The location and sample results can be seen in the following figure.

Facility Data Report

(PAP-00330092)

Wastewater System Settlement Tank (AOC 10)

The wastewater settlement tank was visually inspected and photo-documented by BCM during the site investigation. The tank was noted to be lined with steel plating and no evidence of leakage from the steel lining was observed. The settlement tank was constructed in conjunction with the initial tank truck washing activities at the site and the steel lining was installed in the settlement tank during 1993. In the November 23, 1999 correspondence, NJDEP requested that sampling be completed to evaluate potential historic releases from the settlement tank (PAS-00084516).

To further assess potential releases associated with the wastewater system settlement tank, ENVIRON completed three soil borings (SB12, SB13, and SB14) around the perimeter of the settlement tank. Soil borings SB12 and SB13 were completed to approximately 8 feet bgs. Due to access restrictions, soil boring SB14 was completed to 5 feet bgs. Reported PAHs in soils at AOC 10 included Benzo(a)anthracene, Benzo(a)pyrene, Benzo(b)fluoranthene, Benzo(k)fluoranthene, Dibenzo(a,h)anthracene, chrysene, Indeno(1,2,3-cd)pyrene and pyrene. ENVIRON concluded that with the exception of tetrachloroethane (PCE) concentration at soil boring SB14, all other PAHs were below the NJDEP soil cleanup criteria (PAS-00084516-17).

Additional soils were removed east-southeast of the tank as part of the construction of a building foundation and was designated as Pit No. 3. After completing the excavation to construct the building foundation, eight soil samples were collected from the perimeter based on visual staining and PID readings (PAP-00330042). One sample taken at the east-northeast corner, reported the following concentrations for PAHs; benzo(a)anthracene (1.08 mg/kg), benzo(a)pyrene (1.22 mg/kg), benzo(b)fluoranthene (1.33), and indeno(1,2,3-cd)pyrene (0.959). All other samples results for SVOC were reported as no exceedances (PAP-00330092). See figure above for location and analytical results.

Stained Soil Near Red Storage Area (AOC 11)

A small area of stained soil, measuring approximately 8 feet bgs by 15 feet bgs by 4 inches bgs deep, was excavated during November 1998, in conjunction with BCM's site investigation. Two post-excavation soil samples were collected, and each sample was analyzed for TPHCs and Priority Pollutant metals. NJDEP's November 23, 1999, and June 15, 2000, letters requested that additional samples be collected and analyzed for VOC+10 and Priority Pollutant metals as the reported TPHC concentrations exceeded 1,000 mg/kg in the post-excavation samples (PAS-00084517-18).

On August 1, 2000, ENVIRON completed two soil borings (POSTEX1 and POSTEX2) within the prior excavation area to further evaluate soil quality in the area. Each soil boring was completed to a depth of approximately 1 foot bgs. Reported lead concentrations for the soil samples collected at POSTEX1 (727 mg/kg) and POSTEX2 (2,060 mg/kg) exceed NJDEP's Residential Direct Contact and Non-Residential Direct Contact Soil Cleanup Criteria of 400 mg/kg and 600 mg/kg, respectively. Additionally, reported copper (772 mg/kg) concentrations in soil sample POSTEX2-SS01 exceed
