NJDEP's Residential and Non-Residential Soil Cleanup Criteria. It was reported that the metals concentrations are within the range of concentrations typically detected in historic fill. Recommendation for a deed notice be established to address the metals concentrations in the historic fill material at the Site (PAS-00084518-19)

Per NJDEP request, additional soil sampling was completed during the remedial investigation to support a future establishment of appropriate institutional and engineering controls. On March 2, 2004, ENVIRON completed three soil borings (P0STEX2A, P0STEX2B, and P0STEX2C) within the vicinity of P0STEX2 to delineate the horizontal extent of copper-impacted soils. In addition, prior sample location P0STEX2 was re-sampled from a slightly deeper interval to delineate the vertical extent of copper-impacted soils. Horizontal delineation soil boring P0STEX2B was completed to 4 feet bgs, while vertical delineation soil boring POSTEX2 was completed to 8 feet bgs. Reported copper concentrations associated with the horizontal and vertical delineation soil samples collected in the vicinity of prior sample location POSTEX2 ranged up to 117 mg/kg. A remedial action plan was recommended to address the metals concentrations at levels above NJDEP soil cleanup criteria (PAP-0032861-62)

The 2009 RIR reported that NJDEP agreed that no further characterization was required at this AOC. An area of soils impacted by the metals antimony, copper, lead, and zinc had been delineated and were to be addressed in the remedial action work plan (PAP-00330045).

Staining Near Trailer Staging Area (AOC 12)

Five borings were completed at the north end of the site during BCM's site investigation to evaluate an area of potentially discolored soils that had been identified on a 1974 aerial photograph. Soil samples collected from each soil boring were analyzed for VOC+10 and TPHCs. Because TPHCs were detected, 25% of the soil samples were also analyzed for BN+15, PCBs, and metals. Based on the sampling results, , the site Investigation Report proposed to remediate soils in the vicinity of one stained area (Stain-5). NJDEP's November 23, 1999, correspondence requested that additional sampling be completed to delineate VOC and BN compounds detected in soil samples Stain-5 and Stain-6, and to characterize groundwater quality (PAS-00084519).

On July 19, 2000, ENVIRON completed three soil borings (Stain-5A, Stain-5B, and Stain-5C) in the vicinity of sample location Stain-5 and three borings (Stain-6A, Stain-6B, and Stain-6C) in the vicinity of sample location Stain-6 to delineate VOC and BN compounds detected in soil samples collected during BCM's site investigation. Each soil boring was completed to 8 feet bgs, with the exception of soil borings Stain-5 A, Stain-5B, and Stain-6C where Geoprobe refusal was encountered at depths ranging from 4.4 to 5.5 feet bgs. Analytical results associated with soil sampling conducted in the vicinity of Stain-5 and Stain-6 reported that benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(g,h,i)perylene, benzo(k)fluoranthene, chrysene, dibenzo(a,h)anthracene, fluoranthene, indeno(1,2,3-cd)pyrene and pyrene and VOCs were detected in soil samples at concentrations exceeding the NJDEP residential and non-residential soil cleanup criteria; however, the PAHs were within the range of

concentrations typically detected in historic fill material, and were not believed to be associated with historical releases or Site operations (PAS-00084520-21).

Additional soil borings were completed on August 8, 2000 to further delineate the impacted soils in the vicinity of Stain-5 (soil borings Stain-5D through Stain-5G) and Stain-6 (soil borings Stain-6D through Stain-6G). Soil sampling in the vicinity of soil boring Stain-6, did not detected benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(g,h,i)perylene, benzo(k)fluoranthene, chrysene, dibenzo(a,h)anthracene, fluoranthene, indeno(1,2,3-cd)pyrene and pyrene; however, the results identified VOCs at concentrations above NJDEP's corresponding Residential Direct Contact and Impact to Ground Water Soil Cleanup Criteria. It was recommended that a deed notice be established to address the VOC, SVOC, and metals concentrations above NJDEP's Residential Direct Contact Criteria in soils near soil boring Stain-6 (PAS-00084523-24, 558).

According to the 2004 RIR, a RAWP was recommended to address VOC and SVOC constituents in soil at levels above the most stringent NJDEP soil cleanup criteria (PAP-00328663).

According to the 2009 RIR, NJDEP agreed that no further characterization was required at AOC 12. A RAWP addressing the presence of VOCs and PAHs above the NJDEP's applicable soil cleanup criteria was required (PAP-00330047).

Incident Spill Report (AOC 13)

In June 1999, approximately 30 gallons of an oil-like substance were released in the parking area at the site. In a letter dated June 15, 1999, QSI included a confirmation report indicating that the impacted soils were excavated. According to QSI personnel, the excavation was completed to a depth of approximately 1.5 feet bgs. However, as there is no indication of post-excavation sampling activities, NJDEP requested in the November 23, 1999, correspondence that post-excavation sample be collected from the discharge area (PAS-00084524).

On July 19, 2000, ENVIRON completed three soil borings (SB18, SB19, and SB20) to characterize the remaining soil quality at the reported spill location. VOC's benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(g,h,i)perylene, benzo(k)fluoranthene, chrysene, dibenzo(a,h)anthracene, fluoranthene, indeno(1,2,3-cd)pyrene and pyrene were detected in the soil sample collected from soil boring SB18 at concentrations exceeding NJDEP's Residential and Non-Residential Direct Contact Soil Cleanup Criteria. However, ENVIRON concluded that the reported PAH concentrations were within the range of concentrations typically detected in historic fill material, and were not believed to be associated with historical releases or Site operations (PAS-00084525, 560).

On August 10, 2000, ENVIRON completed three additional borings (SB21, SB22, and SB23) in the vicinity of the former excavation to delineate the elevated VOC concentrations detected in soil sample SB18-SS01. It was reported that VOC concentrations in the soil samples collected at soil borings SB21 and SB22 were below the most stringent NJDEP soil cleanup criteria. VOCs were not detected in the soil sample collected at soil boring SB23. ENVIRON recommended that a deed notice be established to address the PAH concentrations in the historic fill material at the site (PAS-00084526, 560).

On March 1, 2004, ENVIRON completed two soil borings (SB18 and SB19) to delineate the horizontal and vertical extent of VOC-impacted soils at AOC 13. Analytical results associated with the soil sampling activities at AOC 13 reported that VOCs were not detected in the vertical delineation soil sample collected at SB18, with the exception of benzene. The reported benzene concentration of 0.0114 mg/kg is well below the most stringent NJDEP soil cleanup criteria. In addition, reported VOC concentrations for the soil sample collected at SB19 were below the most stringent NJDEP soil cleanup criteria. ENVIRON concluded that soil sampling activities completed at AOC 13 during the supplemental site investigation and remedial investigation delineated the horizontal and vertical extent of VOC concentrations at levels above the most stringent NJDEP soil cleanup criteria. A remedial workplan was to be prepared to address VOCs in soil at levels above the most stringent NJDEP soil cleanup criteria (PAP-00328664-65). According to the 2009 RIR, NJDEP agreed that no further characterization was required at AOC 13. A RAWP addressing the presence of TCE and cis-1 ,2-DCE above the NJDEP's applicable soil cleanup criteria was required (PAP-00330049).

Maintenance Building Concrete Vault (AOC 14)

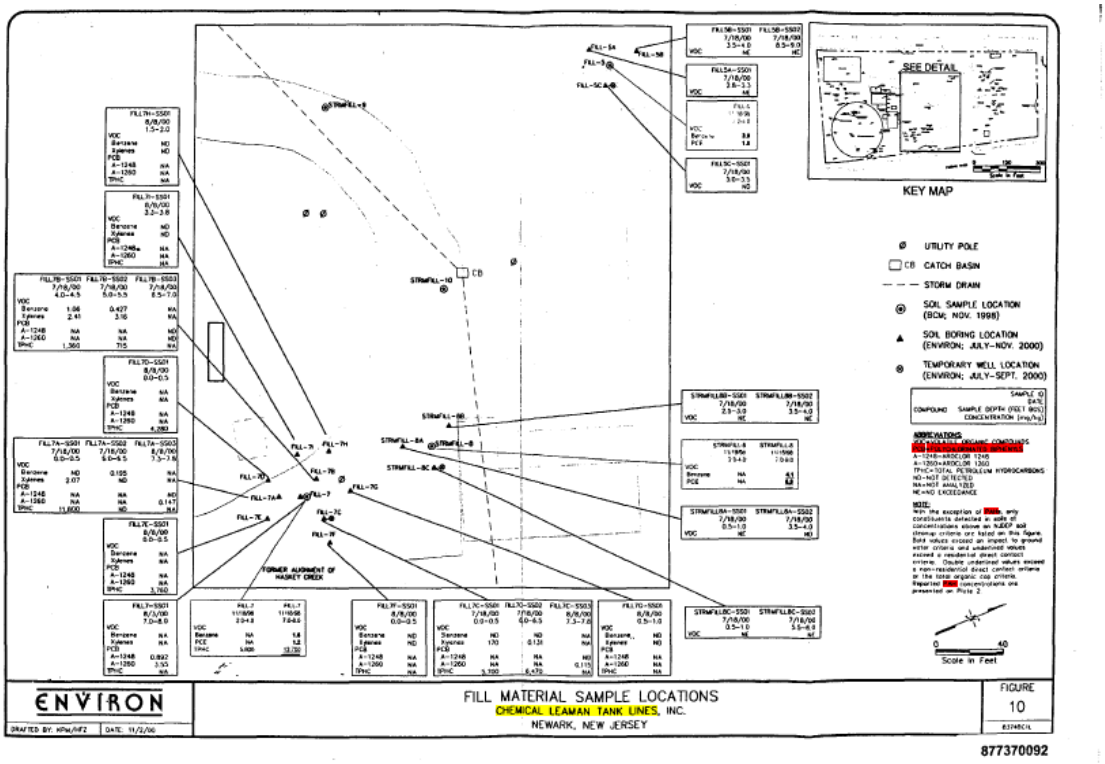
During November 1998, BCM collected one soil sample (Grate-1) from below a metal grate in the Maintenance Building. The metal grate covers a concrete vault where the municipal water main enters the site. BCM's site Investigation Results Report proposed to remove all accumulated sediments from the concrete vault. In addition to the cleaning activities, NJDEP's November 23, 1999 correspondence requested that soil samples be collected from the base of the vault (PAS-00084526).

Investigations at this AOC did not detect any of the allocation COCs.

Unused Building (AOC 15)

Based on a review of Sanborn fire insurance maps for the site, an unused building at the northern end of the site was formerly used as an office in the 1950s and was vacant by 1973. No indication was given on the Sanborn maps as to a source of heat for the building. NJDEP requested that an investigation be completed to identify the former heat source for the building and identify any potential areas of environmental concern (PAS-00084528).

Investigations at this AOC did not detect any of the allocation COCs.



Historic Fill (AOC 16)

According to the 2000 ENVRON Supplemental SI Report, a total of 10 soil borings were completed during BCM's site investigation to characterize the quality of the historic fill material at the Site. Samples collected from each soil boring were analyzed for TPHCs and Priority Pollutant metals. Samples from two soil borings (Fill-6 and Fill-7) were also analyzed for PAHs and PCBs. Samples displaying elevated PID readings were analyzed for VOC+10. NJDEP rejected the BN and PCB data based on QA/QC issues. NJDEP's November 23, 1999 correspondence requested that additional soil sampling be completed to delineate the elevated VOC and TPHC concentrations and to provide valid PAH and PCB sampling data (PAS-00084529).

Soil sampling activities completed during the 2000 supplemental site investigation identified lead and zinc concentrations at levels above corresponding NRDCSCC and/or RDCSCC for soil samples collected in the vicinity of the red storage area; however, according to the report the reported concentrations were within the range of concentrations typically detected in historic fill (as defined in the Historic Fill Database presented in the Technical Requirements for Site Remediation). In addition, the reported copper concentrations for a soil sample collected at POSTEX2 during the supplemental site investigation exceeded the 600 mg/kg RDCSCC and NRDCSCC. NJDEP requested additional soil sampling completed during the remedial investigation to support a future establishment of appropriate institutional and engineering controls.

The additional sampling locations follow and are shown in the Fill Material Sample Locations map below:

- Sample Location Fill-5
- Sample Location Fill-6
- Sample Location Fill-7
- Sample Location Strmfill-8 (PAS-00084529)

(PAS-00084584)

In the 2004 RIR, the following conclusions were made for Historic Fill (AOC 16) sample locations:

Sample Location Fill-5

- Soil sampling activities completed during the remedial investigation delineated the extent of free-phase hydrocarbons previously observed at sample location Fill-5B and delineated the vertical extent of VOC concentrations at levels above the most stringent NJDEP soil cleanup criteria (PAP-00328667).

Sample Location Fill-7

- Soil sampling activities completed during the supplemental site investigation and subsequent remedial investigation have delineated the horizontal and vertical extent of VOC, TPHC and PCB concentrations at levels above the most stringent NJDEP soil cleanup criteria were detected (PAP-00328668).

Sample Location Strmfill-8

- Vertical delineation soil sampling activities completed at Strmfill-8 during the remedial investigation identified elevated VOCs concentrations for a soil sample collected from within the meadow mat immediately below the historic fill material (i.e., 11.5 to 12.0 feet bgs) (PAP-00328669).

Sample Location D11 and E8

In December 2001, the Louis Berger Group, Inc. completed a Property Acquisition Environmental Cost Estimate (PAECE) for the site, on behalf of New Jersey Department of Transportation (NJDOT), as part of the Doremus Avenue Roadway reconstruction and widening project. Analytical results associated with the PAECE were consistent with the prior site investigation and supplemental site investigation soil sampling results, as soil samples collected within historic fill material during the PAECE evaluation identified several PAHs and metals at concentrations exceeding NJDEP soil cleanup criteria.

It was reported in the 2004 RIR that based on the results of the PAECE evaluation, ENVIRON proposed to complete soil borings in the vicinity of sample location D11 to delineate the horizontal extent of PCB-impacted soil and E8 to delineate the horizontal and vertical extent of VOC, BN, PCB and selenium-impacted soils (PAP-00328669).

The results of the 2004 sampling showed exceedances of Aroclor-1254 and Aroclor-1260 for D11 and E8 (PAP-00328669-70).

The following conclusions and recommendations by SAIC for the sample locations discussed above, were reported in the 2009 RIR:

Sample Location Fill-5

- The sample analysis demonstrated that none of the samples collected exceeded any NJDEP action level. Therefore, the impacts around Fill-5 have been delineated with no additional characterization necessary. SAIC concluded that remediation to delineate the impact to soils which exceed the applicable NJDEP criteria for TCE, PCB, and benzene was not needed, since the property will be limited in industrial use as a result of deed restrictions to be imposed (PAP-00330054-55).

Sample Location Fill-6

- The previously conducted soil sampling events demonstrated that the detected PAH concentrations were within the range of concentrations typically detected in historic fill material and were not believed to be associated with historical releases or site operations. It was recommended that the PAH impacts to soils be addressed in a site-wide deed restriction with no additional characterization or remediation required for either soils or groundwater (PAP-00330056)

Sample Location Fill-7

- The NJDEP has agreed that no additional soil characterization was required for this location as all soil impacts have been delineated. An RA WP for addressing remediation of soils with TPH, benzene, xylenes, and PCBs with concentrations above the NJDEP criteria is not proposed due to the fact that the property will be deed restricted to prevent residential use (PAP-00330057-58).

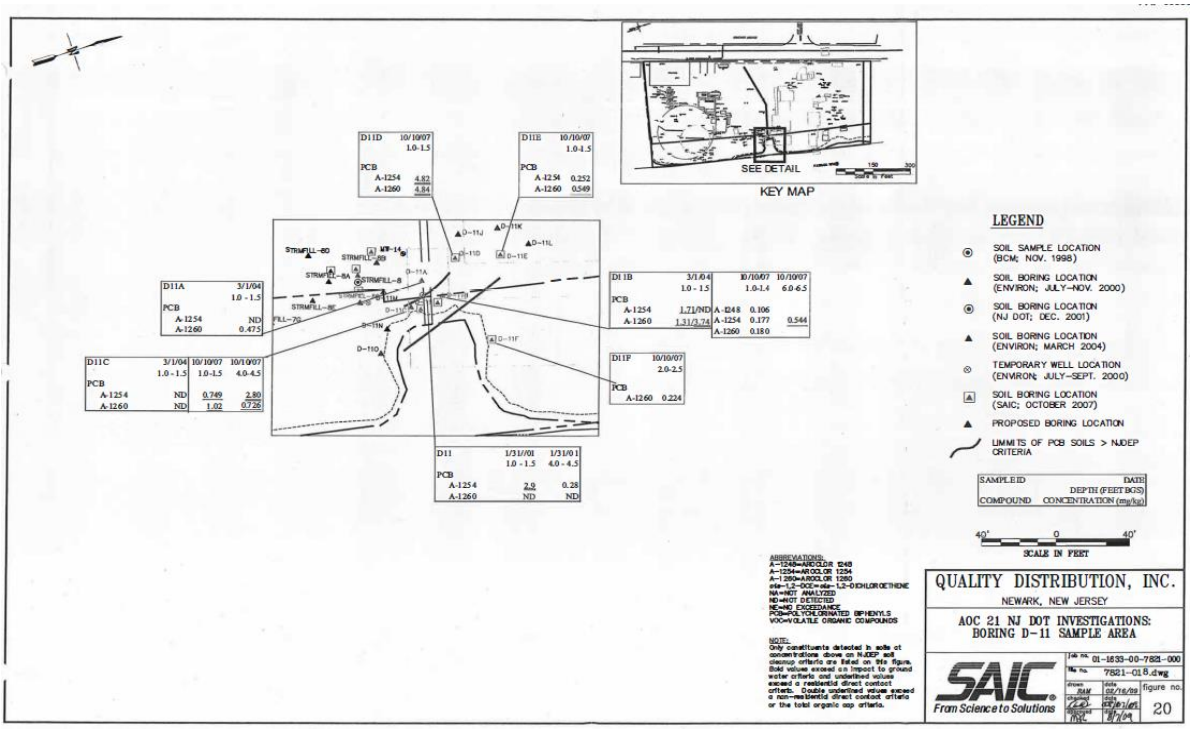
Quality Carriers Inc.

Diamond Alkali OU2 Allocation

ADR Confidential

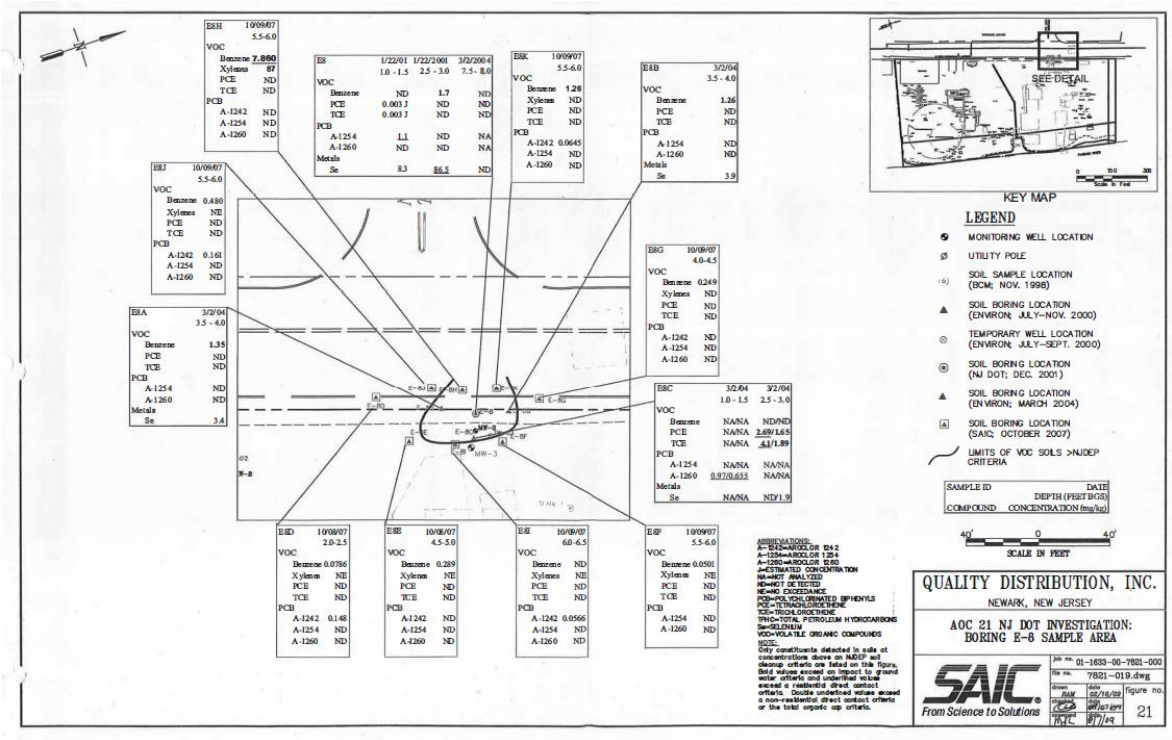
Facility Data Report

Sample Location Strmfill-8



- Three additional borings were completed at formerly installed boring locations for horizontal delineation and were advanced to 16 feet bgs. . It was recommended that a remediation plan not be developed to address the delineated impact to soils which exceed NJDEP criteria for benzene and PCE due to the proposed deed restriction. The dissolved detections of VOCs will be addressed by establishing a CEA and deed notice prohibiting the use of groundwater for the site (PAP-00330061).

Sample Location D11 and E8



- At former boring location D-11B, two samples were collected at depth of 1.0-1.5 feet and 6-6.5 feet. The horizontal delineation borings were sampled at an interval of elevated PID measurements or from the 1-1.5 feet bgs interval to target the depth of the impacted zones in borings D-11 and D-11B (PAP-00330067).

- At former boring location E8, seven soil borings were completed to an approximate depth of 8 feet bgs to vertically and horizontally delineate VOC and PCB impacts (PAP-00330069). SAIC recommended a remediation plan to address the exceedances in the PCB impacted soils (PAP-00330070).

See the following figures for locations and results from the 2004 and 2009 sampling events for D11 and E8.

(PAP-00330100)

(PAP-00330101)

According to the 2009 RIR, a buried concrete structure measuring approximately 27 feet by 27 feet square was discovered while fencing was installed along the eastern side of the site during construction activities in the fall of 2008. This area was designated as AOC 22. The structure was in place prior to QDI's ownership and operation of the property and was identified in the early Sanborn® Maps. Upon removing the soils which covered the structure, it was observed to be filled with water. Excavation revealed a square concrete box, resembling a building footer, with a concrete top. The top was removed to expose the interior containing water, sediment, and discarded hoses. Results from the soil sampling showed that all four borings had detections for Benzo(a)anthracene; Benzo(a)pyrene, benzo(b)fluoranthene, dibenzo(a,h)anthracene, lndeno(1,2,3-cd)pyrene, and lead (PAP-00330073). SAIC recommended that further soil delineation was needed (PAP-00330075).

The 2016 OBG Final RIR concluded that PCBs, PAHs, EPH, and metals were found in soil above the RDCSRS. The PAHs and metals are being attributed to Historic Fill and are not Site related and the PCBs and EPH above the RDCSRS are not attributed to previous owner/operators at the site (PAP-00145617).

Remedial Activities

According to the 2002 Remedial Investigation Work Plan, in 2001 the CLTL property was part of the Doremus Avenue Roadway Improvement project conducted by the NJDOT. The reconstruction involved Wilson Avenue through Raymond Boulevard in the City of Newark, Essex County, to include one 12-foot lane and a 13-foot shoulder in each

direction. Based on concerns that past and current land use practices may have impacted the soil and ground water quality in the vicinity of Doremus Avenue, NJDOT conducted a Contamination Site Investigation (CSI). The conclusion of the CSI follows:

- Soil exceedances were likely associated with non-indigenous historic fill
- Approximately 1,080 cubic feet of contaminated soil will be excavated and if not able to reuse, appropriate off-site disposal will be required
- Since soil contamination above the NJDEP NRDCSCC exists on the subject property parcel, NJDEP will likely require engineering controls (i.e., impermeable asphalt concrete, concrete, or topsoil surface) and institutional controls (PAP-00328607). Note: The remediation results were not available for review for this allocation.

8. Summary of Asserted Defenses

No legal defenses were identified in the available file materials.

Diamond Alkali OU2 Allocation

Facility Data Report

REVERE SMELTING AND REFINING

Facility Name, Address and Size: Revere Smelting and Refining Corporation (Revere), 387 Avenue P, Newark, New Jersey (PAS-00051953). The site is four acres (PAP-00728419). Fourteen employees have been identified by Revere (PAP-00728524; PAS-00051953). The Declaration made by Mr. John A. De Paul stated the facility operated seven days per week (PAP-00728417).

1. **Business Type:** Secondary lead smelter and refinery (PAS-00051943).

2. **Time Period of Ownership/Operations**

   Operator: ~1964-December 1972 (PAS-00008100; PAS-00013085; PAS-0051943)
   Owner: ~1957- 1970 (PAS-00013085; PAS-00051950; PAP-00125848)

   Based on available references, site operations were conducted by two separate entities using variations of the name Revere Smelting and Refining between 1964 and 1972. The initial Revere Smelting & Refining Corp. was a New Jersey incorporated business that operated at the site from at least 1964, but potentially as early as 1953. Available references (e.g., the purchase agreement) state that Revere Holding Corp. owned the site and potentially some of the assets of the initial Revere Smelting & Refining Corp. until 1970, and the Housing Authority of the City of Newark owned the site from 1970 through 1972 when Revere-DE ceased operations. In 1970, a different Revere Smelting & Refining Corp. incorporated in Delaware acquired certain assets in Newark from two New Jersey Corporations, Revere Smelting & Refining Corp. and Revere Holding Corp., as well as four individual shareholders. (For simplicity, the original company will be referred to as Revere-NJ and the allocation party as Revere-DE, although Revere-DE has undergone subsequent corporate changes). Revere-DE's response to an EPA information request, dated April 3, 2003, and underlying asset purchase agreement stated that the corporations operated sequentially at the same Avenue P address, but Revere-DE was not the same company as the previous owners or parent companies of the New Jersey incorporated Revere Smelting & Refining Corp (PAP-00728413, PAS-00008100, PAS-00013085, PAS-00051957-61, PAS-00051953, PAP-00126184, 94-95, PAP-00126209-11). A Federal Trade Commission Opinion in 1976 supports this corporate history (PAP-00728423).

   As documented in the purchase agreement dated April 14, 1970, the Delaware incorporated Revere Smelting & Refining Corp. purchased fixed assets, including but not limited to all of the machinery and equipment, office furniture, fences, smoke stack, raw materials and finished goods, customer contracts, governmental licenses and permits, all trademarks, trade names, patents, applications for patents, and the use of the name "Revere Smelting & Refining Corp." at the 387 Avenue P address (PAP-00126184, 94-95).

The Delaware incorporated Revere Smelting & Refining Corp. changed its name to Revere Smelting and Refining Corporation of New Jersey in December 1971 (PAS-00051965-68). It then changed its name to Revere Smelting and Refining Corporation in November 1992 (PAS-00051975-76).

According to the response to an EPA Request for Information, dated April 3, 2003, Revere Smelting and Refining Corporation is a wholly owned subsidiary of RSR Corporation (RSR). For the purposes of this report, the term Revere-DE will be used to denote the site operator from April 1970 to December 31, 1972. Revere-DE ceased operations at the site in December 1972 (PAS-00051942-43), when operations were relocated to New York State (PAS-00051946; PAP-00728414).

The 2003 response to an EPA information request stated that The Housing Authority of the City of Newark owned the property in the early 1970s (PAS-00051950), and this statement is supported by the April 17, 1972 letter between Revere and the Housing Authority of the City of Newark identifying Revere-DE as a tenant on one of their parcels (Block 5020, Parcel 21) (PAP-00727633; PAP-00125807). Based on the Preliminary Assessment for the Avenue P site, the Newark Redevelopment and Housing Authority (NRHA) owned the property (Block 5020, Parcel 21) in 1988 (PAP-00727867). The *Remedial Investigation Report, Avenue P Landfill Site, 357-405 Avenue P*, dated January 2008, by GeoTrans, Inc., a Tetra Tech Company, (RIR) states that Mr. Anthony Cerone obtained title to the property in 2005 (PAP-00125848).

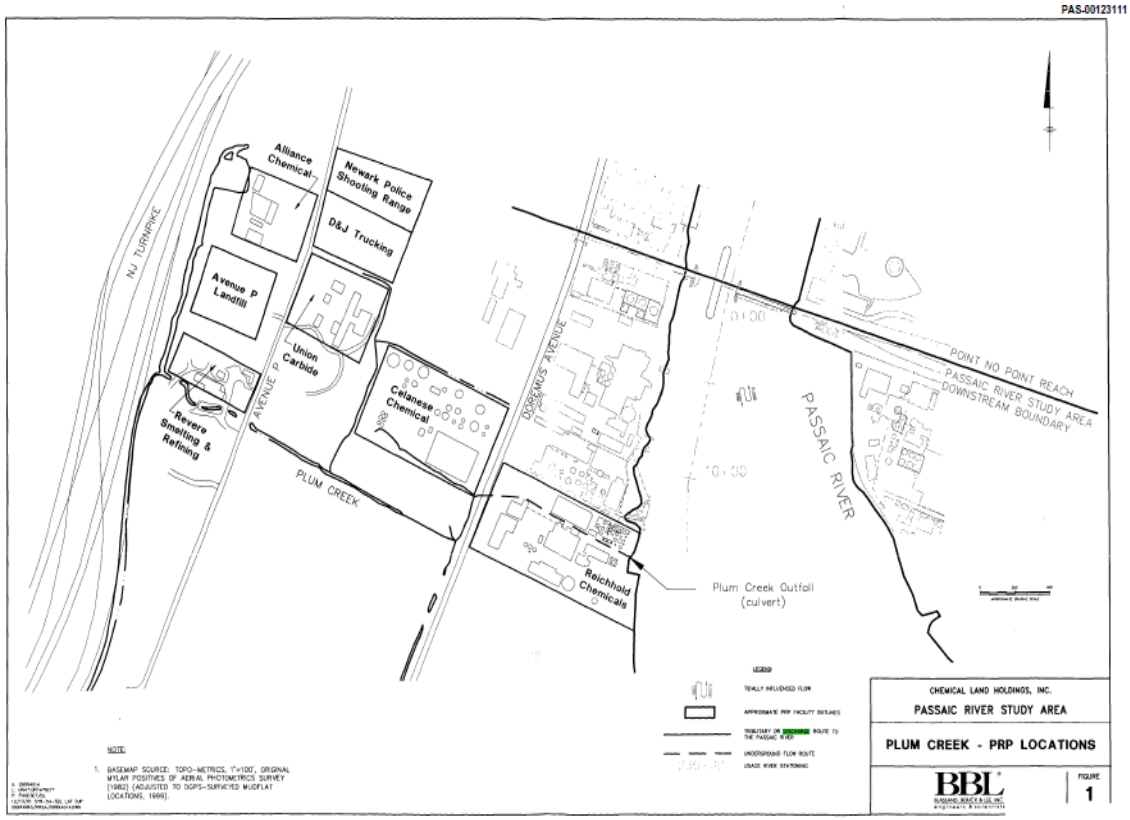
3. Operational History/COC Use and Presence at the Facility

As detailed in their April 3, 2003, response to an EPA information request, Revere-DE reclaimed scrapped lead-acid automobile batteries and recycled them into lead and lead alloys. Battery manufacturers shipped their waste/used automobile batteries, industrial batteries, battery plates, and scrap lead to Revere, and Revere reclaimed the metal for return to the battery manufacturers (PAS-00051944).

Revere processed and refined metal values from the batteries using one battery wrecker to separate metal values from the battery cases and the battery acid; a blast furnace which smelted metal values into bullion and slag; and a refinery which produced specification lead alloys. Lead dust, lead oxide, and other lead compounds were sold to companies in Japan. Battery acid was neutralized and discharged to a small storm sewer during at least 1970-1972. Revere-DE also stated that rainwater, surface waters, and treated sulfuric acid were discharged into the creek adjacent to the facility (PAS-00051944-47).

The April 3, 2003 response to an EPA information request also stated that battery acid was stored onsite in tanks and drums and an unlined surface impoundment. Drums were stored on a paved area (PAS-00051944-46). Lead dust was stored onsite in tanks and drums and then in a surface impoundment (PAS-00051945). It was noted in the 2018 Declaration made by Mr. John A. De Paul, the co-plant manager at the Avenue P location from 1970 to 1972, that lead dust was not stored in a surface impoundment, but was stored in drums until it was recycled. Lead dross (skimming from refining kettles)

was also stored in drums onsite and recycled (PAP-00728416). The location of the drum storage area was not available in the file material.



According to an Inspection Report from December 2, 1971, lead was reclaimed from batteries in a furnace where the lead scraps were melted down and purified. Residual solids from the acid waste and scrubber overflow were also introduced into the furnace. When the material in the furnace was primarily battery plates, iron borings were added to remove residual sulfuric acid and prevent sulfur dioxide emissions through the conversion of sulfuric acid to FeS, which was disposed in the slag from the furnace (PAP-00125798).

In their 2003 response to an EPA information request, Revere-DE stated that it manufactured an estimated 24 thousand tons of finished lead annually, 18 thousand tons of which came from scrap metallic lead, 3 thousand tons from whole batteries, and 3 thousand tons from battery plates (PAS-00051948).

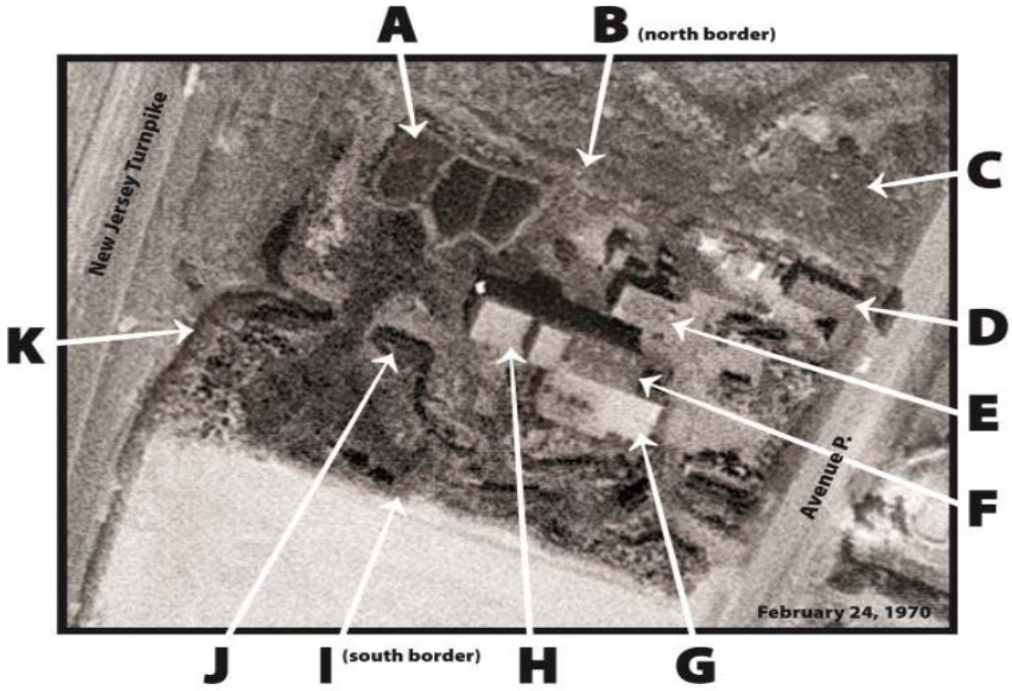
As described in the 2018 Declaration made by former Revere plant manager Mr. De Paul, the smelting and refining processes were stated to be different than what was previously utilized by the prior operator at the facility and other smelting and refining operations during this time period (PAP-00728415). In addition, Mr. De Paul stated that lead smelting and refining operations were performed by other companies at the site as far back as 1941 (PAP-00728414).

A Pollution Report by the Passaic Valley Sewerage Commissioners (PVSC) stated Revere-NJ (the NJ incorporated entity) was polluting Plum Creek, a tributary of the Passaic River, with acid from its battery reclamation processes in 1969. The report stated that the batteries were broken up at an outdoor disassembly platform, where acid flowed across the ground into yard drains that reach Plum Creek. Lime pebbles were used on the ground to neutralize the acid, but the report states that this was completely inadequate (PAP-00126183). The RIR from 2008 noted that the current configuration of Plum Creek was a “man made drainage ditch that was designed to control and drain the surface runoff from the adjacent New Jersey Turnpike” (PAP-00125899).

As shown in the figure below from a Plum Creek PRP Investigation report, dated December 18, 2001, a drainage ditch/creek runs along the western and southern edges of the location at which Revere-DE operated from April 1970 to December 31, 1972. This water feature is identified in the report as Plum Creek, which discharged to the Passaic River (PAS-00123102).

(PAS-00123111)

NJDEP officials observed in an Elimination Report that Revere-NJ had ceased discharging to Plum Creek by March 1970, which is just prior to acquisition of the assets by Revere-DE (PAP-00126138-39). A 1971 Inspection Report by the New Jersey Department of Environmental Protection (NJDEP), noted that Revere-DE had updated the pollution control equipment by installing a new air pollution control apparatus and a neutralization tank immediately after purchasing the plant in April 1970 (PAP-00125798). A February 14, 1972 letter from NJDEP to Revere-DE formally concluded that the operation was in compliance. (PAP-00125802).



As discussed in the 1990 Avenue P Landfill Investigative Summary, aerial photographs taken on March 31, 1971 depict three lagoons at the rear of the facility. The Declaration of Mr. De Paul stated that the three impoundment lagoons were present on the property when Revere-DE's operations began in 1970 (PAP-00728419 and see 1970 aerial photograph used to document the site layout below). Subsequent photographs taken in 1974 (two years after Revere-DE operated at the location) showed a road leading onto the Avenue P landfill from the Revere Plant (PAS-00013085).

The following site layout was provided in the Declaration by Mr. De Paul and the Preliminary Expert Report titled *Potential Contribution of Selected Chemicals from the Revere Smelting & Refining Operation to the Lower Passaic River,* dated April 16, 2019, by Dr. Katherine von Stackelberg of NEK Associates LTD:

Diamond Alkali OU2 Allocation

ADR Confidential

Facility Data Report

A: Three aboveground storage lagoons (not subject to flooding and never overflowed)
B: Northern border of the land leased by Revere
C: Land not owned or used in the Revere operation. Area where open dumping was observed during the Revere operations
D: Office building
E: Maintenance building and limited battery crushing
F: Open-sided building with two kettles and limestone used for neutralizing battery acid outside
G: Smaller blast furnace and two kettles
H: Larger blast furnace and two kettles. Small white speck is the stack just adjacent to the impoundments or lagoons. The scrubber was later installed nearby.
I: Southern border of the leased property
J: Drainage ditch
K: Same drainage ditch after it flows under short bridge and flows south
(PAP-00728424; PAP-00728477)

According to the Declaration of Mr. DePaul, the report by Dr. Katherine von Stackelberg, and the 2008 RIR, there were illegal hazardous waste disposal operations in the vicinity of the Revere-DE operations, particularly to the north of the Revere-DE operations (PAP-00728421; PAP-00125846-53). Hazardous waste disposal in this vicinity occurred perhaps as early as 1926 in the Avenue P Landfill areas and evidence of landfilling activities is documented in aerial photographs from the 1940s (PAP-00125850-52, 97-98). The Avenue P Site History Analysis, dated March 17, 1986, reviewed the available records including aerial photographs and documented the illegal paint disposal activities. The Analysis stated a dump or landfill appeared to be operating at the Avenue P site in 1970 and 1972 aerial photographs (PAP-00008600-15).

4. Identified COCs

- PCBs (detected)
- PAHs (detected)
- DDx (detected)
- Mercury (detected)
- Copper (stored, detected)
- Lead (used, stored, detected)

PCBs

PCBs were detected in site media during the 2008 RIR. Soil sampling results stated PCBs were associated with the landfill material at the site (PAP-00125886; see discussion for Historic Fill below).

PAHs

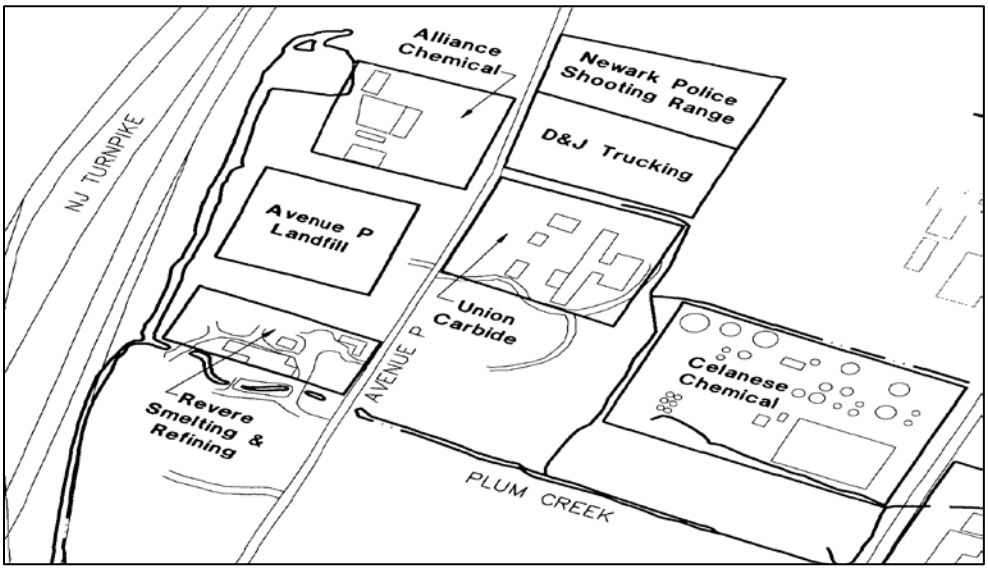
PAHs were detected in site media during the 2008 RIR. Soil sampling results stated PAHs were associated with the landfill material at the site (PAP-00125885-86; see discussion for Historic Fill below).

DDx

According to the New Jersey Turnpike Widening Project: Interchange 11 to Route 14: Phase I Remedial Investigations Milepost [illegible] to Passaic River, by the New Jersey Turnpike Authority, dated May 1989 (Turnpike Phase I RI), DDE was detected in three of16 samples taken in September, 1988, from borings in sites 78/79. Sample depths and locations were not included in the sample results, and report text was not provided. Concentrations ranged from 160 J (estimated) to 620 µg/kg. DDD was detected in three of 16 samples with concentrations ranging from 61 J to 1200 µg/kg, and DDT was detected in two of 16 samples with concentrations ranging from 1500 to 6800 µg/kg (PAP-00728573-76).[1]

Metals – Mercury, Copper and Lead

In the April 3, 2003 response to an EPA information request, Revere stated that acids, arsenic, cadmium, copper, and lead were present at the site (PAS-00051943-4). The Declaration made by the Revere-DE former plant manager Mr. De Paul states that the smelted product was lead bullion, which was transported off site by truck, and then occasionally by train, to various locations as specified in the contractual arrangements. According to Mr. De Paul, copper was an impurity in the lead values that were smelted and refined, and would have been present at trace levels from copper battery wiring that stayed with batteries sent for recycling. The amount of copper was not commercially viable to recycle for sale. Any copper in the sludge, lead dust, or other solids was treated the same way as lead and recycled in the smelter furnace or sent offsite.



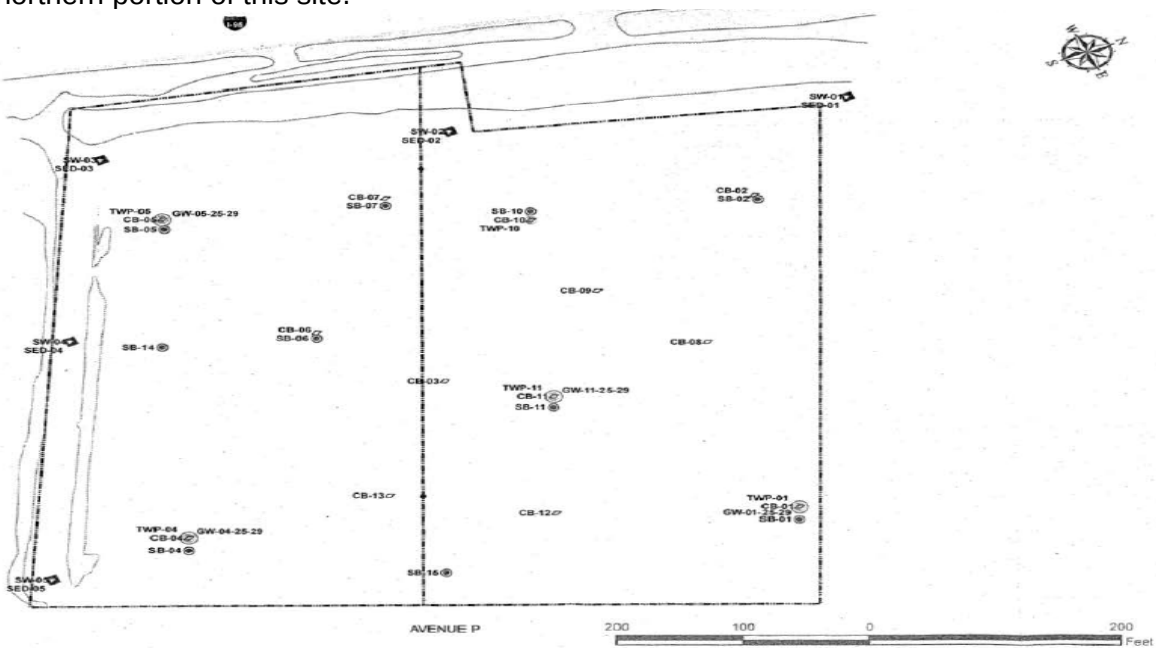
[1] A table of sample results from the *New Jersey Turnpike Widening Project: Interchange 11 to Route 14: Phase I Remedial Investigations Milepost [illegible] to Passaic River*, by the New Jersey Turnpike Authority, dated May 1989, was received as part of a submission of documents on May 14, 2020. This Report was revised to include detections of DDx and metals. The additional documents did not change Revere's previous certification.

Mercury was not part of the lead-acid battery or lead scrap feedstock or recycling process (PAP-00728416).

Based on the available file material, no soil sampling was performed during the period of the Revere-NJ or Revere-DE's operations. According to the Turnpike Phase I RI, mercury, copper, and lead were detected in each of 16 samples taken in September, 1988, from borings in sites 78/79. Sample depths and locations were not included in the sample results, and report text was not provided. Mercury concentrations ranged from 0.2 to 3.4 mg/kg, copper concentrations ranged from 444 to 3940 mg/kg, and lead concentrations ranged from 911 to 182,000 mg/kg (PAP-00728573-76).

The 1990 Avenue P Landfill Investigative Summary discussed exploratory excavations made on the southern portion of the site that noted coke waste extending from the surface to a depth of 13 feet. In addition, the summary states that concentrations of lead and antimony have been detected in soil samples obtained from the Avenue P site. The term "Avenue P site" refers to the eight acre Avenue P Landfill and adjacent properties that were used as an illegal dump. The Investigative Summary noted that lead and antimony contamination was found at the site, and both of these materials were reclaimed by the facility (PAS-00013063, 85-86).

The Plum Creek PRP Investigation, dated December 18, 2001, discussed the Revere location as south of the Avenue P landfill and abutting Plum Creek. The relative locations of Revere and nearby Avenue P companies are shown in the figure below from this report. The report states that Revere's historical operations used lead, copper, and zinc, which were also found at elevated concentrations in the Plum Creek and Passaic River sediments (concentrations in Plum Creek sediment of 1,550 ppm for lead and 6.6 ppm for copper) (PAS-00123109, 24). It is not clear when the sediment samples were collected relative to the operations of Revere-DE.



Locations of companies (PAS-00123111)

A NJDEP Inspection Report from 1971 included results from a water sample collected from coolant for the jacket of the furnace. This overflow from furnace cooling was intermittently discharged to the creek. The results stated lead was detected at 0.59 milligrams/liter (mg/L) (PAP-00125798-800).

Metals at Avenue P Landfill

A 1986 Avenue P Work Plan provides data for soil samples collected at the Avenue P Landfill site; however, the locations and depths of the samples were not provided. The maximum detections of lead and mercury in the Avenue P site soil were 63,007 milligrams/kilogram (mg/kg) and 137.5 mg/kg, respectively. A sample of "creek muck" was also collected and detected lead at 0.24 ppm and mercury at 3.8 ppm (PAP-00727906, 914).

The 2008 RIR states the Revere facility was located at the Avenue P landfill site, which consists of addresses 347-405 Avenue P (PAP-00125850). Based on the figure from this report below, the southern part of the site investigated by this report was the Revere location along the surface water features. It is assumed that the landfill occupied the northern portion of this site.

(PAP-00125928)

Several test pits were excavated on November 13, 2007, and the RIR states that the former building foundation found at TP-2 (located in the central portion of the southern rectangle above) could "possibly" be the Atlantic Metal and Refining Inc./Revere building (PAP-00125880). The RIR states that the landfill was used from the 1920s until the 1970s, and it was believed that the surrounding industrial companies and manufacturing plants used the landfill and adjacent areas beyond the property border of the site as an illegal dump to dispose of hazardous materials, manufacturing by-products, solid waste/junk and process wastes (PAP-00125850).

Soil samples were collected from one soil boring installed in the southern portion of the site (SB-05). A soil sample was collected from the landfill material (12.5-13 feet below ground surface [ft bgs]) and from just below the confining layer (24.5-25 ft bgs). The concentration of lead detected in the landfill sample was 6,470 mg/kg, while the deeper sample was 8.1 mg/kg. The concentration of copper was 2,220 mg/kg in the landfill sample and 54.5 mg/kg in the deeper sample. The concentration of mercury was 4.5 mg/kg and not detected in the deeper sample (PAP-00125884, 908).

Historic Fill

The Allocation Team has determined that the facility site is located on regional Historic Fill as designated by the NJDEP.[2]

NJDEP has established that historic fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 COCs: PAHs, lead, copper, and mercury.[3] Accordingly, NJDEP technical requirements for property containing Historic Fill requires sampling for the EPA Target Compound List for PAHs and Target Analyte List for metals, including lead, copper, mercury, and the OU2 PAH COCs.[4] PAHs, lead, copper, and mercury are recognized by NJDEP to be constituents of Historic Fill at varying levels, not atypically at or exceeding residential soil standards.[5]

The levels of PAHs, copper, lead and mercury detected at the site in soils are presented in the table below (PAP-00125905, 07-08, PAP-00728573-76).

COCs Found in Onsite Soils	
COC	**Max Detected Concentration**
Lead	182,000 mg/kg
Copper	3,940 mg/kg
Mercury	4.5 mg/kg
Benzo(a)anthracene	0.750 mg/kg
Benzo(a)pyrene	0.660 mg/kg
Benzo(b)fluoranthene	0.544 mg/kg
Benzo(k)fluoranthene	0.738 mg/kg

[2] *Digital Geodata Series, DGS04-7, Historic Fill for New Jersey*, https://www.nj.gov/dep/njgs/geodata/dgs04-7.htm, Quadrangle #52 (NJDEP map identifying locations of recognized historic fill).

[3] *Characterization of Ambient Levels of Selected Metals and cPAHs In New Jersey Soils* (2002) and *Characterization of Ambient Levels of Selected Metals and Other Analytes In New Jersey Soils* (1997), studies prepared for NJDEP, Division of Science and Research, by BEM Systems, Inc.

[4] New Jersey Department of Environmental Protection (NJDEP), *N.J.A.C. 7:26E Technical Requirements for Site Remediation,* Table 4-2, November 2009 [Note that Table 4-2 has been deleted from the current version of N.J.A.C. 7:26E (May 7, 2012) and the updated *Historic Fill Technical Guidance* (April 2013) as NJDEP believed that the tables list of historic fill constituents was too restrictive].

[5] NJDEP Table 4-2 (PAHs and lead) and a summary of NJDEP records regarding investigations of properties in the vicinity of the Passaic River recognized to be located in areas of Historic Fill indicate that the following average/maximum (mg/kg) contamination levels of OU2 COCs exist in area Historic Fill: PAHs (1.91/160), lead (574/10,000), copper (11.2/1,200), and mercury (0.21/3.7).

COCs Found in Onsite Soils	
COC	**Max Detected Concentration**
Dibenzo(a,h)anthracene	0.320 mg/kg
Indeno(1,2,3-cd)pyrene	0.152 mg/kg

The 2008 RIR stated the Avenue P Landfill Site included land upon which the Revere-DE operated from April 1970 to December 31, 1972 as well as additional adjacent properties for a total of eight acres. The Avenue P site was created by filling in salt marshes in the early 1900s (PAP-00125850). The RIR reported soil samples collected from the fill material and from soil just beneath the landfill confining layer. It was concluded that the marsh sequence present below the landfill material acts as a natural lithologic barrier to prevent migration of the heavily impacted landfill material (PAP-00125884). Concentrations of the fill material greatly exceeded the concentrations from the soil below as shown in the following table for the two samples collected at SB-05, located at the former Revere facility.

In addition, the RIR noted that the highest concentrations of metals were detected in samples collected at the base of the landfill, indicating that the ash and glass layer present at the landfill/marsh interface is a likely source. This debris was likely deposited on site at a time when the area was predominantly marshland (PAP-00125886). The RIR states that "[a]t the bottom of the landfill layer, at a depth ranging from 12.5' to 19.0' b.g. [below ground], is a layer of ash and glass assumed to be deposited at the site in the early to mid 1900s" (PAP-00125856).

Contamination was also found in a perched groundwater table at the site. The perched groundwater was in direct contact with the fill material and in communication with the surface water in a drainage ditch at the site (PAP-00125890, 99).

Maximum Detection in Perched Groundwater		
COC	**µg/L**	**NJDEP GWQS**
Lead	449,000	5
Copper	31,500	1,300
Mercury	7.1	2
Benzo(a)anthracene	0.55 J	0.1
Benzo(b)fluoranthene	3.5	0.2
Naphthalene	546	300
Aroclor-1254	5.9	0.5
Aroclor-1260	2.4	0.5

J- Data indicates the presence of a compound that meets the identification criteria. The result is less than the quantitation limit, but greater than zero. The concentration given is an approximate value (PAP-00125911-3)

The RIR noted that rainwater and leachate from the landfill collected in the drainage ditch that ran along the edges of the property. As shown in the figure in Section 3 (Operational History/COC Use and Presence at the Facility), this drainage ditch is part of Plum Creek, which discharges to the Passaic River. According to the 2008 RIR, the connection of the drainage ditch to adjacent surface water bodies and the Passaic

River/Newark Bay is assumed, but has not been confirmed because the drain pipe traveling beneath Avenue P appeared to have been entirely clogged and/or broken over time (PAP-00125860-61). No information for when it became clogged was provided. The Report on the Quality of the Interstate Waters of the Lower Passaic River and Upper and Lower Bays of New York Harbor, dated November 1969, identified an open ditch from Revere-NJ as discharging to the Passaic River in 1969 (PAS-00058698). Surface water and sediment samples were collected from four locations to the south and west of the Revere site (see figure above; PAP-00125928) and also had elevated concentrations of COCs (PAP-00125890-91).

Surface Water and Sediment Concentrations		
COC	**Maximum detection in surface water (µg/L)**	**Maximum detection in sediment (mg/kg)**
Lead	383	12400
Copper	93.6	1580
Mercury	0.27	6.6
Benzo(a)anthracene	1.3 J	1.92
Benzo(a)pyrene	1.5 J	2.04
Benzo(b)fluoranthene	2.0 J	2.28
Benzo(k)fluoranthene	1.2 J	2.49
Dibenz(a,h)anthracene	ND	0.315 J
Indeno(1,2,3-cd)pyrene	1.4 J	1.10
Aroclor-1248	ND	1.44
Aroclor-1254	ND	6.61
Aroclor-1260	ND	9.36

ND- Compound was not detected in the surface water samples.
J- Data indicates the presence of a compound that meets the identification criteria. The result is less than the quantitation limit, but greater than zero. The concentration given is an approximate value (PAP-00125915-21).

5. COC Pathways

Sanitary and Storm Sewer

According to the April 3, 2003 response to an EPA information request, there were storm sewers present at the site that received discharges (PAS-00051946, 47). However, the Declaration by Mr. De Paul stated the storm sewer was likely the drainage ditch known as Plum Creek (PAP-00728418).

A PVSC Pollution report for 1969, dated March 30, 1970, stated the site had not connected to the Newark sewer system as it was not yet available in the area (PAP-00126183).

Lagoons

According to a 1971 NJDEP Inspection Report, Revere obtained a stainless steel tank in 1970. The tank was used to collect and neutralize the acid with sodium hydroxide prior

to discharging it into a lagoon. The treated waste was allowed to dry in the lagoon. Overflow from the air pollution scrubbers was also discharged to the lagoon, and any solids remaining were returned to the plant for reprocessing (PAP-00125798). The April 2003 response to an EPA information request stated that the lagoon was unlined (PAS-00051947).

However, Mr. De Paul stated that although the 1971 Inspection Report by NJDEP states the neutralized acid was discharged to the lagoons, he remembers this material as being discharged to the drainage ditch instead (PAP-00728417).

As discussed in the 1990 *Avenue P Landfill Investigative Summary*, aerial photographs taken on March 31, 1971, depict three lagoons at the rear of the facility (PAS-00013085). In addition, the 2018 Declaration by Mr. De Paul stated that the three surface impoundments were approximately 13% of the area leased (PAP-00728419). The Declaration describes the lagoons as unlined and aboveground, with berms approximately six feet above the surrounding land surface to confine and store the contents for recycling. The lagoons were cleaned out all the way down to the soil level at least once in the April 1970 to the December 1972 time period. The material pumped to the lagoons was from the Venturi high energy air pollution controls ("scrubbers"), which collected lead dust, lead oxide, metallic lead, sulfides, sulfates, and hydrocarbons. The solids from the surface impoundments were later recovered and recycled or sold (PAP-00728415-16).

Regarding the material left in the lagoons, the 2018 Declaration by Mr. De Paul stated, “Since lead and other metals had economic value, I directed that the material be recycled or removed from the impoundments prior to the end of use of the site. To the best of my knowledge, Revere recycled or sold all remaining material in the three impoundments before ending operations” (PAP-00728419).

Direct Release

Battery Acid Process

A 1969 PVSC Pollution Report stated that Revere-NJ (the previous NJ incorporated entity), was polluting Plum Creek, a tributary of the Passaic River, with acid from battery reclamation processes. The report stated that the batteries were broken up at an outdoor disassembly platform, where acid flowed across the ground into yard drains that reached Plum Creek. Lime pebbles were used on the ground to neutralize the acid, but the report states that this approach was completely inadequate (PAP-00126183).

As stated by a 1971 NJDEP Inspection Report, Revere-DE updated the battery acid treatment processes when it purchased the plant in 1970 (PAP-00125798). According to the 2018 Declaration by Mr. De Paul, the sulfuric acid from those batteries was neutralized with caustic soda in the tanks and then allowed to discharge from the tanks to flow over a bed of lime which provided further treatment. The neutralized battery acid was passed through settling tanks that served to remove the solids through gravity (PAP-00728416-17; PAP-00728478-82).

Revere stated in its 2003 response to an EPA information request that rainwater, surface waters, and treated sulfuric acid were discharged into the creek adjacent to the facility (PAS-00051947-48). However, the 2018 Declaration by Mr. De Paul stated that the liquid output from the neutralization process (typically called "neutralent") was discharged to the drainage ditch that flowed past the property (now known as Plum Creek). The pipe that discharged the neutralent was approximately 18-24 inches in diameter. Mr. De Paul stated that he believed little to no lead migrated with the neutralent, since the treatment process was designed to recapture all lead in the settling tanks prior to discharging the liquid neutralent. The solids from the settling tanks were fed directly into the furnace (PAP-00728417).

Releases from Furnace Coolant Overflow

The NJDEP Inspection Report from 1971 stated that overflow from furnace cooling was also intermittently discharged to the creek. The 1971 Report included results from a water sample collected from coolant for the jacket of the furnace. The results stated lead was detected at 0.59 mg/L (PAP-00125798-800).

According to the 2018 Declaration by Mr. De Paul, the cooling water did not contact the lead or furnace and was recycled (PAP-00728416-18). Occasional overflow of cooling water was discharged to the drainage ditch (PAP-00728418). Each of these potential sources should contain little or no lead, copper, or PAHs (PAP-00728415-16).

Flooding

Revere also stated in its 2003 response to an EPA information request that spills and leaks occurred, such as a burning of a stack, which caused process waters to be discharged on the ground (PAS-00051948). The response also stated that there were many incidents of flooding in the 1970-1972 time period (PAS-00051949). The Revere operation was located in an area where flooding was not likely except once every 500 years, according to government estimates (PAP-00728471). Mr. De Paul stated in his Declaration that he never observed the Passaic River overflowing its banks directly onto Revere's property during the period from April 14, 1970 to December 31, 1972 (PAP-00728420). During flooding, water flowed from the Passaic River up the drainage ditch, but this water never entered the three impoundments (PAP-00728420). Water in the drainage ditch occasionally flowed onto the site, but he never observed this water overflow the berms surrounding the three impoundment lagoons (PAP-00728420).

Spills

There is no information regarding spills in the available file material.

6. Regulatory History/Enforcement Actions

Inspections

Inspections of discharge to Plum Creek were performed and the continued pollution was documented in Stream Pollution Reports from January and February 1970 (prior to Revere-DE's operations) (PAP-00125840, PAP-00126085, PAP-00126178, and PAP-00126136). The final report, dated March 6, 1970, noted that the company had installed a dilution tank to collect and neutralize the acid prior to discharging it onto the ground, where it did not flow into Plum Creek (PAP-00126138).

An inspection for compliance with an Administrative Order was performed December 2, 1971. The inspection report stated that an Administrative Order was issued to Revere-NJ on August 15, 1969, to cease discharging by November 10, 1969. The inspection found that the sulfuric acid was no longer being discharged to Plum Creek, and instead a stainless steel tank was used to collect the acid. The acid was then neutralized with sodium hydroxide flakes and discharged to a lagoon where it was allowed to dry. Overflow from the air pollution scrubbers was also discharged to the lagoon, and any solids remaining were returned to the plant for reprocessing (PAP-00125798).

A letter dated February 14, 1972, regarding the Administrative Order to Abate Water Pollution from August 15, 1969, documented that the company (Revere-DE by February 1972) had corrected all of the deficiencies associated with the Administrative Order (PAS-00008123).

Violations

A 1990 Avenue P Landfill Investigative Summary states the site was found in violation of the Newark Air Pollution Control Ordinance on five occasions from 1965 through 1968 (PAP-00013085).

According to a PVSC Stream Contamination Report dated March 22, 1960, a violation and elimination was noted in 1966 for the location. The violation stated that acid waste was discharging into Plum Creek, but was eliminated November 4, 1966, when it was noted that steel drums were being used to collect the waste. The acid waste was then neutralized with limestone. Any spills were neutralized by lime spread on the ground (PAS-00026651).

A March 31, 1970, Pollution Report by the PVSC stated the site was polluting Plum Creek, a tributary of the Passaic River, with acid from their battery reclamation processes in 1969. The report stated that the batteries were broken-up at an outdoor disassembly platform, where acid flowed across the ground into yard drains that reach Plum Creek. Lime pebbles were used on the ground to neutralize the acid, but the report states that this was completely inadequate (PAP-00126183). No violations were noted in the file material after March 1970.

Permits

There is no information regarding permits in the available file material.

7. Response Actions

Characterization Activities

The following characterization activities have taken place at the facility:

- The NJDEP issued an Administrative Consent Order, dated April 17, 1985, to the NRHA for remedial and investigatory measures to be taken at the Avenue P site, described as Block 5024, Lots 21, 22, and 23 in the City of Newark (PAP-00727863-67).
- A letter to NRHA dated October 24, 1985, from their contractor Cavanaugh Group regarding their removal of drums with PCB-contaminated product from the creek (PAP-00728629)
- A letter to NJDEP dated May 21, 1986 from the NRHA described the remedial activities taken at the Avenue P site (PAP-00728631-34).
- Avenue P Work Plan, dated October 1986, by the Cavanaugh Group (PAP-00727898)
- Preliminary Assessment for the Avenue P Site, 309-465 Avenue P, dated January 11, 1988 (PAP-00727867).
- New Jersey Turnpike Widening Project: Interchange 11 to Route 14: Phase I Remedial Investigations Milepost [illegible] to Passaic River, by the New Jersey Turnpike Authority, dated May 1989 (PAP-00728568)
- The 1990 Avenue P Landfill Investigative Summary discusses exploratory excavations made on the southern portion of the site, but it is unclear where these excavations were performed (PAS-00013085).
- A Passaic River Study Area Potentially Responsible Parties summary for the Newark Housing and Redevelopment Authority, dated September 1993 (PAS-00076956).
- A Remedial Investigation of the Avenue P Landfill Site is documented in the RIR, dated January 2008 (PAP-00125842).

Sediment

A 1986 Avenue P Work Plan provides data for a sample of “creek muck,” although it is unclear from where in Plum Creek this sample was collected. The results detected lead at 0.24 ppm and mercury at 3.8 ppm (PAP-00727906, 14).

The 2008 RIR collected four sediment samples from the drainage ditch located along the southern and western border of the Revere site; one additional sediment sample was collected from the ditch north of the Revere site. Concentrations of the four sediment samples ranged from 234 to 1,580 mg/kg for copper, 681 to 12,400 mg/kg for lead, and 1.2 to 6.6 mg/kg for mercury. PAH concentrations ranged up to 3.96 mg/kg (pyrene) and

total PCBs were detected from 1.27 to 15.97 mg/kg in sediment samples (PAP-00125874, 915-17, 925).

Soil

According to the Turnpike Phase I RI sample results Table 78/79, 16 samples were collected in September, 1988, from borings in sites 78/79. Sample depths and locations were not included in the sample results, and report text was not provided. DDE concentrations ranged from 160 J (estimated) to 620 µg/kg. DDD was detected in three of 16 samples with concentrations ranging from 61 J to 1200 µg/kg, and DDT was detected in two of 16 samples with concentrations ranging from 1500 to 6800 µg/kg. Mercury concentrations ranged from 0.2 to 3.4 mg/kg, copper concentrations ranged from 444 to 3940 mg/kg, and lead concentrations ranged from 911 to 182,000 mg/kg (PAP-00728573-76).

According to the 1990 Avenue P Landfill Investigative Summary, exploratory excavations noted coke waste extending from the surface to a depth of 13 feet. Coke was noted to be a byproduct of metal refining, such as lead. Concentrations of lead were detected in soil samples obtained from the Avenue P site (PAS-00013085).

As part of the 2008 RIR, 14 test pits and ten soil borings were installed. It was determined that landfill material was between 15 and 20 feet thick, with native marsh surface underlying the fill comprised of metal objects, concrete blocks, building debris, municipal waste, and ash and glass. Four soil samples were collected from the fill material and four samples were collected from the same borings just below the native material interface. Based on the elevated concentration of contaminants in the landfill material and lower concentrations in the native material, the RIR concluded that the boundary between the landfill and the native material has low permeability and minimizes the vertical migration of landfill constituents. The soil samples collected from the one soil boring installed in the southern portion of the site (SB-05) were collected at 12.5-13 ft bgs and from just below the confining layer at 24.5-25 ft bgs. The concentration of lead detected in the landfill sample was 6,470 mg/kg, while the deeper sample was 8.1 mg/kg. The concentration of copper was 2,220 mg/kg in the landfill sample and 54.5 mg/kg in the deeper sample. The concentration of mercury was 4.5 mg/kg and not detected in the deeper sample (PAP-00125872-873, 884, 898, 908).

Surface Water

The 2008 RIR collected four surface water samples from the drainage ditch located along the southern and western border of the Revere site; one additional surface water sample was collected from the ditch north of the Revere site. Concentrations ranged from not detected to 93.6 µg/L for copper, not detected to 383 µg/L for lead, and not detected to 0.27 µg/L for mercury. PAHs were detected up to 2.7 µg/L (pyrene) and PCBs were not detected in surface water samples (PAP-00125874, 919-21).

Remedial Activities

None of the remedial activities were demanded of or performed by Revere-DE. An Administrative Consent Order, dated April 17, 1985, between NJDEP and the NRHA initiated remediation at the Avenue P site, which included the former location of the Revere-DE plant (PAP-00727863-67). Remedial activities were performed, including dredging of the stream at the rear of the Revere-DE location of operations (Plum Creek) and removal of 3,000 gallons of waste water from the 1,800 drums found in the Creek, some of which contained PCB-contaminated product (PAP-00728629; PAP-00728631). According to the 1986 Avenue P Work Plan, soil was excavated and stockpiled in berms for removal (PAP-00727901). However, a letter from NRHA dated May 21, 1986, stated the funds for remediation had been depleted due to large amount of drums and other debris found at the site (PAP-00728632).

The 1988 Preliminary Assessment for the Avenue P site stated there were large quantities of hazardous wastes found at the site, but no subsurface explorations had been conducted to determine the nature or extent of subsurface contamination (PAP-00727868).

The 2008 RIR discussed the prior remediation performed at the site. Drums, cans, and other containers were found to be buried as discussed above, and when remedial activities were suspended in 1987, steel plate(s) were installed to contain leachate and prevent it from entering the adjacent surface water drainage ditch (PAP-00125851-52). The RIR stated a geophysical investigation was performed in 1999 and identified anomalies that could be buried metal or other large objects for investigation during the RI (PAP-00125851-52).

8. Summary of Asserted Defenses

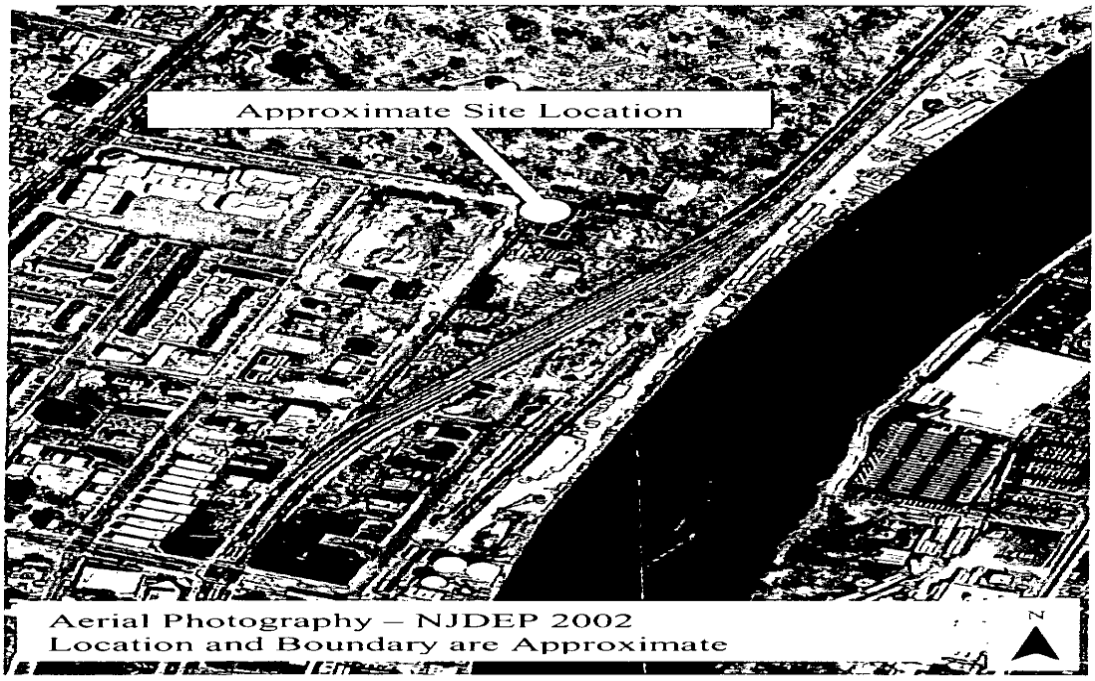
No legal defenses were identified in the available file material.

Diamond Alkali OU2 Allocation
ADR Confidential
Facility Data Report

ROMAN ASPHALT CORPORATION

Facility Name, Address and Size: Roman Asphalt Corporation (Roman Asphalt); 14 Ogden Street, Newark, New Jersey (PAS-00111327); approximately 1 acre (PAS-00111362); Roman Asphalt operated with between 20 and 65 employees, depending on the season, (PAS-00111350; PAS-00111362)

1. **Business Type:** Heavy highway and street construction contractor (PAS-00111327).



2. **Time Period of Ownership/Operations**

   Operator: 1964-At least 2006 (PAS-00111350; PAS-00111326)
   Owner: Leased from Michael Lamorgese (PAS-00111362)

   Roman Asphalt began operations in 1964; additional informational regarding ownership history was not available.

3. **Operational History/ COC Use and Presence at the Facility**

   Roman Asphalt began operations in 1964 (PAS-00111350). Operations include asphalt processing for highway and street construction (PAS-00052085). According to a Dun and Bradstreet report, the facility leased a 3,000 sq. ft. two-story brick building, yard space, which includes 1 acre of yard space with a 4,000 square-foot garage from its officer, Michael Lamorgese (PAS-00111362). Additional information on material handling was not available. A figure depicting the location of the facility is presented below (PAS-00111328).

4. Identified COCs

- PAHs (used)
- Metals (used)

PAHs and Metals

There is no information regarding sampling and raw material use in the available file material. However, releases of crankcase oil and waste oils have been reported as described below in Section 6 (PAS-00111340-41). PAHs and metals contamination may be associated with these materials.

Historic Fill

The Allocation Team has determined that the facility site is not located on regional Historic Fill as designated by the NJDEP[1].

NJDEP has established that Historic Fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 COCs: PAHs, lead, copper, and mercury.[2] Accordingly, NJDEP technical requirements for property containing Historic Fill requires sampling for the EPA Target Compound List for PAHs and Target Analyte List for metals, including lead, copper, mercury, and the OU2 PAH COCs.[3] PAHs, lead, copper, and mercury are recognized by NJDEP to be constituents of Historic Fill at varying levels, not atypically at or exceeding residential soil standards.[4]

5. COC Pathways

Limited information on pathways through which contaminants could be discharged to the Passaic River was available. As discussed in Section 6 below, Roman Asphalt reportedly discharged waste oil to the storm sewer in 1986. According to the 2006 *PRP Data Extraction Forms and Evidence for Roman Asphalt*, an engineer with the City of Newark Sewers and Water Supply Division confirmed this storm sewer was connected to the Passaic River (PAS-00111330).

---

[1] *Digital Geodata Series, DGS04-7, Historic Fill for New Jersey*, https://www.nj.gov/dep/njgs/geodata/dgs04-7.htm, Quadrangle #52 & #53 (NJDEP map identifying locations of recognized historic fill).

[2] *Characterization of Ambient Levels of Selected Metals and cPAHs In New Jersey Soils* (2002) and *Characterization of Ambient Levels of Selected Metals and Other Analytes In New Jersey Soils* (1997), studies prepared for NJDEP, Division of Science and Research, by BEM Systems, Inc.

[3] New Jersey Department of Environmental Protection (NJDEP), *N.J.A.C. 7:26E Technical Requirements for Site Remediation,* Table 4-2, November 2009 [Note that Table 4-2 has been deleted from the current version of N.J.A.C. 7:26E (May 7, 2012) and the updated *Historic Fill Technical Guidance* (April 2013) as NJDEP believed that the tables list of historic fill constituents was too restrictive].

[4] NJDEP Table 4-2 (PAHs and lead) and a summary of NJDEP records regarding investigations of properties in the vicinity of the Passaic River recognized to be located in areas of Historic Fill indicate that the following average/maximum (mg/kg) contamination levels of OU2 COCs exist in area Historic Fill: PAHs (1.91/160), lead (574/10,000), copper (11.2/1,200), and mercury (0.21/3.7).

6. Regulatory History/ Enforcement Action

Inspections and Violations

On July 25, 1983, the dumping of crankcase oils onto a slope at the facility by mechanics was reported in a Division of Waste Management *Investigation Report*. The area on which the dumping took place was 20 feet by 40 feet in size (PAS-00111334). According to a memo prepared by the New Jersey Department of Environmental Protection (NJDEP), the facility reported that the contaminated soil was removed on July 30, 1983 (PAS-00111335).

A Notice of Violation (NOV) was issued to Roman Asphalt on September 18, 1986, due to "hazardous substance discharge" which included reported "pooling oil in facility yard and running off to Rt. 21 drainage system and bank" (PAS-00111340). According to a memo filed by NJDEP on September 19, 1986, oil had been found pooling in a storm drain in the vicinity of State Highway 21. NJDEP representatives observed the following at the facility: "We found the southernmost end of the lot to be saturated with numerous oil pools. We found two points where the oil was running off Roman's lot, down the bank to the roadside and into the storm drain. The lot was full of heavy paving machinery. A few drums were also noted in and amongst the machinery. The source of the oil may have been leaking drums (damaged by heavy machinery)" (PAS-00111341). Another NOV was issued to Roman Asphalt on October 6, 1986, due to "discharge of hazardous substance." The NOV reported that "oil has run off property onto embankment of State Hwy 21 South" (PAS-00111343). On October 8, 1986, Roman Asphalt reported that they had excavated the contaminated soil and replaced it with "clean fill" (PAS-00111345). On December 17, 1986, NJDEP reported that oil stains were observed on the embankment, but no active runoff was observed and recommended that a NOV be issued to Roman Asphalt (PAS-00111346). No further information was available.

Permits

There is no information regarding permits in the available file material.

7. Response Actions

There is no information regarding response actions except for the two above in the available file material.

8. Summary of Asserted Defenses

No legal defenses were identified in the available file material.

Diamond Alkali OU2 Allocation
ADR Confidential
Facility Data Report

ROYCE ASSOCIATES

Note: This Data Report has been written for Royce Chemical Company that operated on the site from 1929 to 1982. There is no documentation linking Royce Associates to Royce Chemical Company in the available file material.

Facility Name, Address and Size: Royce Chemical Company (Royce Chemical); 17 Carl Avenue, East Rutherford, New Jersey (PAS-00034489); site acreage not available; Available references did not provide information regarding the number of employees and work shifts at Royce Chemicals.

1. **Business Type:** Manufacturer of ingredients for the textile and rubber manufacturing industries (PAS-00008156).

2. **Time Period of Ownership/Operations**

   Operator: 1929-1982
   Owner: 1955-1964 (PAS-00008156; PAS-00008137)

   According to a March 26, 1982, *Hazardous Waste Inspection Report*, Virginia Chemical of Portsmouth, VA, bought all of Royce Chemical's major assets on October 1, 1981 and decided to close the manufacturing operations on February 12, 1982. Royce Chemical was noted to have changed its name to Royce Industries, Inc. and to have been operating another plant in Newark, NJ (PAS-00008156). A 1987 letter from the former Secretary of Royce Chemical states that the company discontinued business during October 1981, liquidated and was dissolved (PAS-00102199).

   According to a letter prepared by legal counsel for Royce Associates, LP, dated December 8, 2005, Royce Chemical Company was liquidated after its assets were purchased by Virginia Chemical. Royce Associates, LP was a newly formed entity in 1982. According to the letter, Royce Associates, LP, is an entirely different and distinct entity from Royce Chemical Company and there is no surviving or continuing corporation related to Royce Chemical Company (PAS-00034489).

3. **Operational History/ COC Use and Presence at the Facility**

   Royce Chemical manufactured sodium hydrosulfite, zinc oxide, sodium sulfoxalate formaldehyde, and zinc sulfoxalate formaldehyde as ingredients for the textile and rubber manufacturing industries. All of these materials were made through mixing, filtering and drying processes. The raw materials used did not include any COCs (PAS-00008156). A large portion of the raw materials and products left on site were shipped to Royce Industries in Newark after the plant shut down (PAS-00008157).

   According to a *Preliminary Assessment Report*, a review of industrial directories dating back to 1931 indicates that Royce Chemical was also involved with the production of other products including: water softeners, textile gums, finishes, sulphonated oils, royox, desizing agents, water repellents and concentrated cleaners. It is unknown what other raw materials may have been used for these processes (PAS-00008137-38).

According to the 1982 *Inspection Report*, when Royce Chemical was operating, they recycled all of their waste by reusing it in their products (PAS-00008157). The *Inspection Report* notes that the operator at the time was Royce Chemical Company and the owner of the property was listed as Carlton Hill Construction Co. (PAS-00008156).

The site was completely razed by the end of 1983 (PAS-00008141).

4. Identified COCs

- PCBs (used, detected)
- PAHs (used, detected)

PCBs

The 1982 Inspection notes that the only chemical waste sent off site were eight 55-qallon drums of PCB waste. This material was contaminated soil generated by a leaking transformer in an approximate 3-inch cement diked area with three transformers and a drain that led to the Passaic Valley Sewer Commission (PVSC) treatment plant. Analysis of the contaminated soil indicated greater than 50 ppm PCBs (PAS-00008157; PAS-00008159).

PCBs were detected at two sampling locations at <0.016 and <0.018 ppm (PAS-00008149-50; PAS-00102253-4).

PAHs

During the 1982 inspection by NJDEP, four 55-gallon drums of compressor oil remained onsite in the bottom floor of Building No. 2 (PAS-00008158). Also noted during the inspection was a black oily sludge next to unused subsurface fuel oil tanks (approximately 20 feet by 10 feet) in the rear lot of the facility and an oil spill of approximately 20 feet by 15 feet under old horizontal railroad car tanks in the rear lot of the facility (PAS-00008159).

An inspection of the facility was conducted on April 23, 1982 by NJDEP personnel to determine the progress and status of the cleanup operation noted that all tanks had been emptied, including 12 underground gasoline tanks. Approximately 20 drums of waste oil were being shipped off site (PAS-00008140).

Spills of No. 6 heating oil reportedly caused soil contamination at the site. Waste disposal manifests indicate that soils and oily waste were removed from the Royce Chemical facility in May and August 1983 (PAS-00008141).

Oil was visibly present in the on-site pond during February 1984 sampling (PAS-00102226-8).

Historic Fill

The Allocation Team has determined that the facility site is not located on regional Historic Fill as designated by the NJDEP[1].

NJDEP has established that Historic Fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 COCs: PAHs, lead, copper, and mercury.[2] Accordingly, NJDEP technical requirements for property containing Historic Fill requires sampling for the EPA Target Compound List for PAHs and Target Analyte List for metals, including lead, copper, mercury, and the OU2 PAH COCs.[3] PAHs, lead, copper, and mercury are recognized by NJDEP to be constituents of Historic Fill at varying levels, not atypically at or exceeding residential soil standards.[4]

However, prior to construction of residential units, at the site location, soil borings were conducted at the site for engineering purposes. Materials recovered from the borings indicate that the site is underlain with mixed fill of thickness ranging from 5 to 10 feet. The fill is a fine to medium grained reddish-brown soil which may contain pebbles, gravels, pieces of brick, metallic debris or wood splinters (PAS-00008149).

5. COC Pathways

The *Preliminary Site Assessment* states that aerial photographs from 1941 to 1961 showed a large pond at the rear of the property. This pond received non-contact cooling water, the overflow of which was received by a drainage ditch (also referred to in NJDEP reports as an "unnamed tributary") along the southern border of the property and "ultimately discharging to the Passaic River." (PAS-00008138-9).

A 1971 PVSC Annual Report notes that Royce Chemical was pumping industrial waste into a storm drain on Carlton Avenue. The material was reportedly diverted to a sanitary line when the Inspector informed them of the violation (PAS-00034516; PAS-00034633). According to a 1973 PVSC Annual Report, in January and February 1973 materials from Royce Chemical were discharged to the Carlton Hill storm drain, and ultimately to the Passaic River. The material was referred to as a polluting material and white substance,

---

[1] *Digital Geodata Series, DGS04-7, Historic Fill for New Jersey*, https://www.nj.gov/dep/njgs/geodata/dgs04-7.htm, Quadrangle #52 & #53 (NJDEP map identifying locations of recognized historic fill).

[2] *Characterization of Ambient Levels of Selected Metals and cPAHs In New Jersey Soils* (2002) and *Characterization of Ambient Levels of Selected Metals and Other Analytes In New Jersey Soils* (1997), studies prepared for NJDEP, Division of Science and Research, by BEM Systems, Inc.

[3] New Jersey Department of Environmental Protection (NJDEP), *N.J.A.C. 7:26E Technical Requirements for Site Remediation,* Table 4-2, November 2009 [Note that Table 4-2 has been deleted from the current version of N.J.A.C. 7:26E (May 7, 2012) and the updated *Historic Fill Technical Guidance* (April 2013) as NJDEP believed that the tables list of historic fill constituents was too restrictive].

[4] NJDEP Table 4-2 (PAHs and lead) and a summary of NJDEP records regarding investigations of properties in the vicinity of the Passaic River recognized to be located in areas of Historic Fill indicate that the following average/maximum (mg/kg) contamination levels of OU2 COCs exist in area Historic Fill: PAHs (1.91/160), lead (574/10,000), copper (11.2/1,200), and mercury (0.21/3.7).

but no further information regarding its contents was provided (PAS-00034660; PAS-00034762-3). Twice in 1974 wastes were again noted to be flowing to the storm drain from a ditch and pond at Royce Chemical. The first was referred to as a foam and samples were taken; however, no specific substances were tested for. The second was noted to be a brownish material. The company noted that they planned to block off the storm sewer to prevent future releases to the Passaic River (PAS-00034785; PAS-00034904-5).

However, an August 1979 *Stream Pollution Report* states that Royce Chemical was using the Carlton Hill storm ditch leading to the Passaic River for disposal of caustic material (PAS-00008134).

An October 1981 NPDES Permit Application Certification states that there was one discharge point consisting of overflow from a non-contact cooling water pond with an average daily flow of 100,000 gallons. The receiving stream was noted to be an unnamed tributary of the Passaic River (PAS-00102190).

During the 1982 inspection a series of troughs were noted throughout the process building that Mr. Royce stated emptied into the PVSC. In addition, some flow was noted going to the sewer (PAS-00008158).

Spills

Spills of No. 6 heating oil reportedly caused soil contamination at the site. Waste disposal manifests indicate that soils and oily waste were removed from the Royce Chemical facility in May and August 1983 (PAS-00008141).

6. Regulatory History/ Enforcement Actions

Inspections

There is no information regarding inspections in the available file material.

Violations

There is no information regarding violations in the available file material.

Permits

Under NJPDES Permit No. 0002682, issued July 31, 1976, Royce Chemical discharged non-contact cooling water via a drainage ditch along the southern border of the property from its onsite pond/lake and ultimately into the Passaic River. Zinc was the only metal being monitored (PAS-00102191-5).

The company also had PVSC (pretreatment) Permit No. 06401173. Industrial process wastes were discharged from Royce Chemical to the PVSC system. The effective dates of the permit were November 2, 1981 through November 2, 1986, although as stated above the facility ceased operations in 1982 (PAS-00102216). No monitoring for specific chemicals was required.

7. Response Actions

On February 29, 1984 a series of soil samples were collected by Dan Raviv Associates of West Orange, New Jersey and analyzed for volatile organic compounds, metals, pH and PCBs to determine if contamination was present in preparation for sale of the site. Results included lead and mercury as follows:

1984 Sampling Concentrations (mg/kg)						
Metal	**RC-1S**	**RC-1SA**	**RC-2S**	**RC-3S**	**RC-4S**	**RC-7S**
Lead	82.2	37.1	9.83	197.0	273.0	6.49
Mercury	0.17	0.12	<0.055	2.52	7.08	<0.056

PCBs were detected at two sampling locations at <0.016 and <0.018 ppm (PAS-00008149-50; PAS-00102253-4).

During demolition activities at the site, a spill of 350 gallons of diesel fuel flowing to a southeast pond on the site was observed. Remedial activity relating to this spill reportedly occurred during the three days following the spill, as well as in September 1984, during the construction of townhouses at the site (PAS-00008140). A vac truck was mobilized to the site which removed in excess of 1,000 gallons of oil and water from the lagoon. Sampling of the pond in March and August 1984 revealed elevated levels of benzene, toluene, ethylbenzene and zinc in pond sediments. As a result, decontamination of the pond area was conducted on August 16, 1984 (PAS-00008153).

No information regarding sampling in the onsite unnamed tributary or "drainage ditch" to the Passaic River was located in the available documents.

8. Summary of Asserted Defenses

No legal defenses were identified in the available file material.

Safety-Kleen Envirosystems Company
Diamond Alkali OU2 Allocation
ADR Confidential
Facility Data Report

SAFETY-KLEEN ENVIROSYSTEMS COMPANY/MCKESSON CORP.

Facility Name, Address and Size: Vulcan Facility/Inland Facility/Newark Facility/McKesson Facility; 600 Doremus Avenue, Newark, New Jersey (also associated with 500, 504, 504-508, and 604 Doremus Avenue); Currently 8.5 acres; 40 employees in 1982 (PAP-00189214). The facility ran 24 hours per day, 7 days per week, three shifts per day, at least up until and through April 16, 1979 (PAP-00187327). At some point in time between that date and March 22, 1982, the facility operated 24 hours per day, but only 5 days per week (PAP-00189214).

1. **Business Type:** Solvent recovery (PAP-00186363-65).

2. **Time Period of Ownership/Operations**

   Operator: 1975-1982 [Safety-Kleen Envirosystems, as successor to McKesson Envirosystems Company (MEC), successor by merger to Inland Chemical Company, after Nucer (Safety-Kleen Systems, Inc.) purchased MEC from its parent company, McKesson Corporation, in 1987]
   Owner: 1974-1987 (Safety-Kleen Envirosystems, as successor to MEC)
   1987-present (McKesson Corporation, after title transfer from Inland/MEC)

   1974: Inland purchased certain assets of Vulcan, including a chlor-alkali plant and real property on May 1, 1974. *See the Legacy Vulcan Facility Data Report for additional information on Vulcan.* This included agreements that Vulcan would continue operation of their former chlor-alkali facilities, as well as their chloromethanes plant at the site, in part using chlorine and other raw materials supplied by Inland (PAP-00186853; PAP-00186886-93; PAP-00188783-89; PAP-00187163-75).

   1975: On or about May 1, 1975, Inland shut down operations of the chlor-alkali plant, and Vulcan terminated operation of the chloromethanes plant on or about May 15, 1975 (PAP-00186853). After these chemical manufacturing operations were terminated, Inland solely conducted solvent recovery operations (PAP-00188225; PAP-00188236-37; PAS-00011254).

   1981: Inland and MEC merged in 1981 (PAS-00091937) when McKesson Corporation acquired the facility through a stock purchase of Inland (PAP-00365505).

   1982: On October 10, 1982, an explosion and fire destroyed much of the facility. The New Jersey Department of Environmental Protection (NJDEP) closed the site two days later (PAS-00091937).

   1987: In March 1987, McKesson Corporation sold all of the issued and outstanding shares of common stock of MEC to Nucer, a former wholly owned subsidiary of Safety-Kleen Systems, Inc. Subsequent to March 31, 1987, Nucer and MEC merged into a new corporation named Safety-Kleen Envirosystems Company. Upon such merger, Safety-Kleen Envirosystems Company succeeded to the rights and obligations of Nucer and MEC under the sale agreement (PAP-00187236).

According to certified statements by the Vice President and Assistant General Counsel of Safety-Kleen Systems, Inc., neither Safety-Kleen Systems, Inc., nor Safety-Kleen Envirosystems Company ever owned or operated the Doremus Avenue site. He states that title to the property was transferred to McKesson Corporation at the same time as MEC became Safety-Kleen Envirosystems Company. In addition, he states that McKesson Corporation agreed to indemnify Safety-Kleen Envirosystems Company for any claims related to the Doremus Avenue site (PAP-00187236; PAS-00129878). A letter prepared by McKesson Corporation, dated March 20, 1987, also states that McKesson Corporation sold its wholly owned subsidiary, MEC, but retained the Doremus Avenue site (PAS-00010384).

References state that Safety-Kleen Systems Inc. never operated the facility and the site has been inactive and vacant (PAS-00091937; PAS-00011077; PAP-00187236).

1998: In 1998, Safety-Kleen Systems, Inc. was acquired by, and became a wholly owned subsidiary of Laidlaw Environmental Services, Inc. At or about the same time, Laidlaw Environmental Services, Inc. changed its name to Safety-Kleen Corp. and renamed its newly acquired subsidiary Safety-Kleen Systems, Inc. (PAP-00187236).

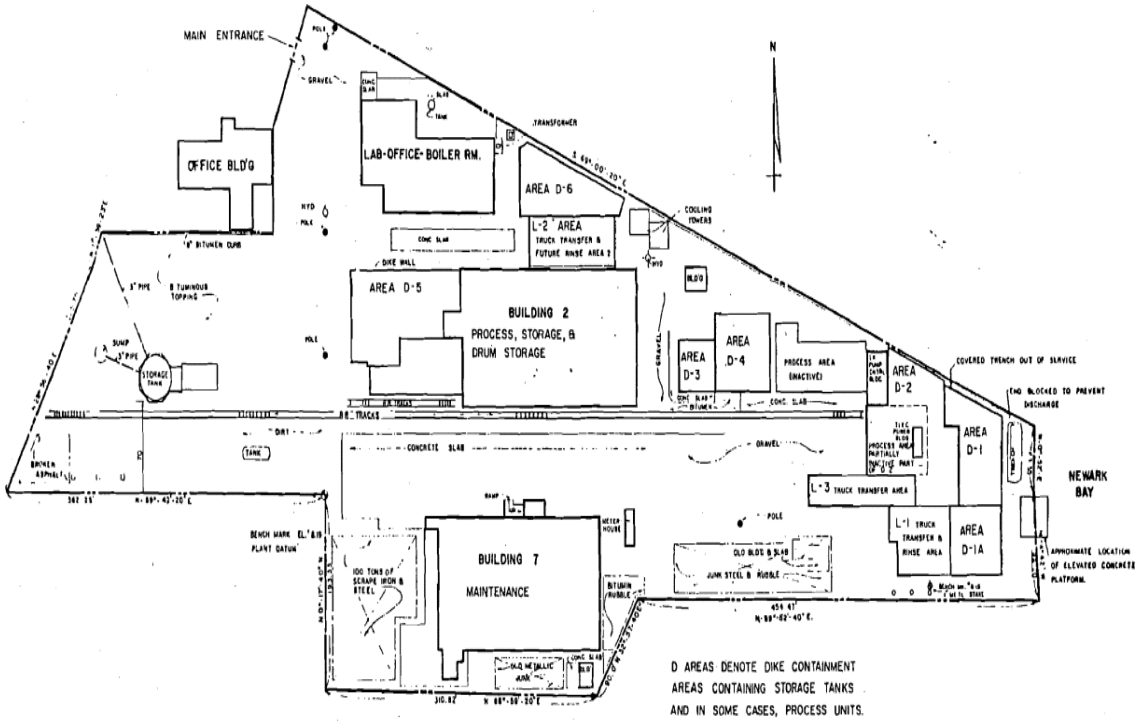
3. Operational History/COC Use and Presence at the Facility

According to an undated NJDEP report prepared for EPA, a summary of general operations is as follows: Inland operated at the site from May 1974 to October 1981 (PAP-00187256). Under contracts with Inland, Vulcan operated the chlor-alkali facilities and chloromethane facility from May 1974 to May 1975 (PAP-00186886-93; PAP-00188783-89; PAP-00187163-75). The first year of operation included chemical manufacturing (chloromethane and chlor-alkali) operations; these operations were terminated in May 1975 (PAP-00186853) and replaced by solvent recovery operations. McKesson acquired the site in 1981 and continued solvent recovery operations until an explosion occurred on October 10, 1982 and the facility was ordered closed by NJDEP on October 12, 1982 (PAP-00187256; PAS-00091937).

According to a letter prepared by EPA, dated November 24, 1976, as of the January 31, 1975 effective date of the NPDES permit, Inland produced chlorine, caustic soda, methylene dichloride, chloroform, and bleaching agents, as well as associated by-products (PAP-00186109; PAP-00362242). According to a letter prepared by Inland, dated June 27, 1975, lead was generated as a result of the chlor-alkali process (PAP-00188223). An Inland memorandum, dated December 7, 1973, explains how lead was generated in this process. According to the memorandum, the tops of the anodes in which the chlorine was manufactured were cast from concrete. When a cell top was rebuilt, graphite anodes were bolted to a bus bar assembly in the cell top. The junction between the graphite and the bus bar assembly was fixed by pouring molten lead into the cell top. The lead was painted with asphalt to protect the lead from exposure to chlorine (PAP-00362239).

Solvent recovery operations commenced by Inland included the recovery of dimethylaniline and phenoxyacetic acid from penicillin manufacturing waste, as noted in a memo prepared by EPA dated October 6, 1975, and an *Engineering Plan for Inland Chemical Corporations' Existing Chemical Resource Recovery Plants in Newark, New Jersey*, dated April 16, 1979 (1979 Engineering Plan). The associated file materials do not state that COCs were used, handled, or generated as part of these processes (PAP-00187067; PAP-00186359; PAP-00188276; PAP-00188297-99; PAP-00365752; PAP-00366823-29). According to a memo prepared by McKesson, dated June 20, 1985, the dimethylaniline and phenoxyacetic acid were vacuum distilled out leaving behind in the still residue only inorganic sulfates, chlorides and phosphates (sodium sulfate, chloride and phosphates). This mixture, along with a small amount of fresh water for ease of transfer and wash out, constituted the bulk of the water generated at the facility. The balance of generated water was derived from the crystallization step of phenoxyacetic acid, where, after being converted to free acid, the product was crystallized, centrifuged, and washed with sufficient clean fresh water to remove residual color and dissolved salts. That centrifuged wash water, combined with the vacuum distillation residue "salts" solution, constituted the water shipped from the facility offsite. The memo goes on to state that wastewater would have contained salts, trace levels of phenoxyacetic acid, and dimethylaniline methanol (PAP-00188213).

Facility operations included other types of solvent recovery and processing (PAP-00186363-65). According to a memo prepared by NJDEP, dated December 14, 1979, Inland recovered and purified the following liquid chemicals and returned them to industrial use: trichloroethane, methylene chloride, dimethylaniline, isopropanol, methyl phenoxyacetate, methanol, toluene, aliphatic naphtha, acetone, butanol, heptane, perchlorethylene, trichloroethylene, siloxane, methyl ethyl ketone, xylene (PAP-00187208).



According to letters prepared by the facility dated July 9 and December 17, 1980, at that time, facility wastewater was being moved by tank truck to Modern Transportation Company's wastewater plant in Kearny, New Jersey, and had been since 1976. It was used as makeup water for making lime slurry which was used to neutralize mineral acids, which was then discharged to the Kearney sewer system. During this time, the Inland facility was attempting to obtain approval from Passaic Valley Sewerage Commission (PVSC) to discharge wastewater to the PVSC system via the Newark sewer system (PAP-00185373-74; PAP-00185455). A memo prepared by McKesson, dated June 20, 1985, also states that beginning in 1976, Inland shipped for disposal to Kin-Buc Landfill wastewater generated from the recovery and washing of pharmaceutical grade phenoxyacetic acid and dimethylaniline, which continued until 1977, when Kin-Buc Landfill closed. (PAP-00188213-4). Finally, the 1979 Engineering Plan states that when the chemical recovery process produced a residual liquid chemical waste, it was temporarily stored at the plant until it could be transported to the Modern Transportation Company of Kearny or to Inland's Kentucky plant for treatment and disposal.

The April 1979 Engineering Plan states that there were approximately 94 storage tanks within the plant ranging in capacity from 800 gallons to 230,000 gallons. Several pumps and pipe networks were used to transfer incoming wastes through the processing plants, and to transfer finished products and residual wastes into their respective storage tanks. Secondary piping was used to circulate filtered stormwater through a cooling system, and to provide fuel (PAP-00186370).

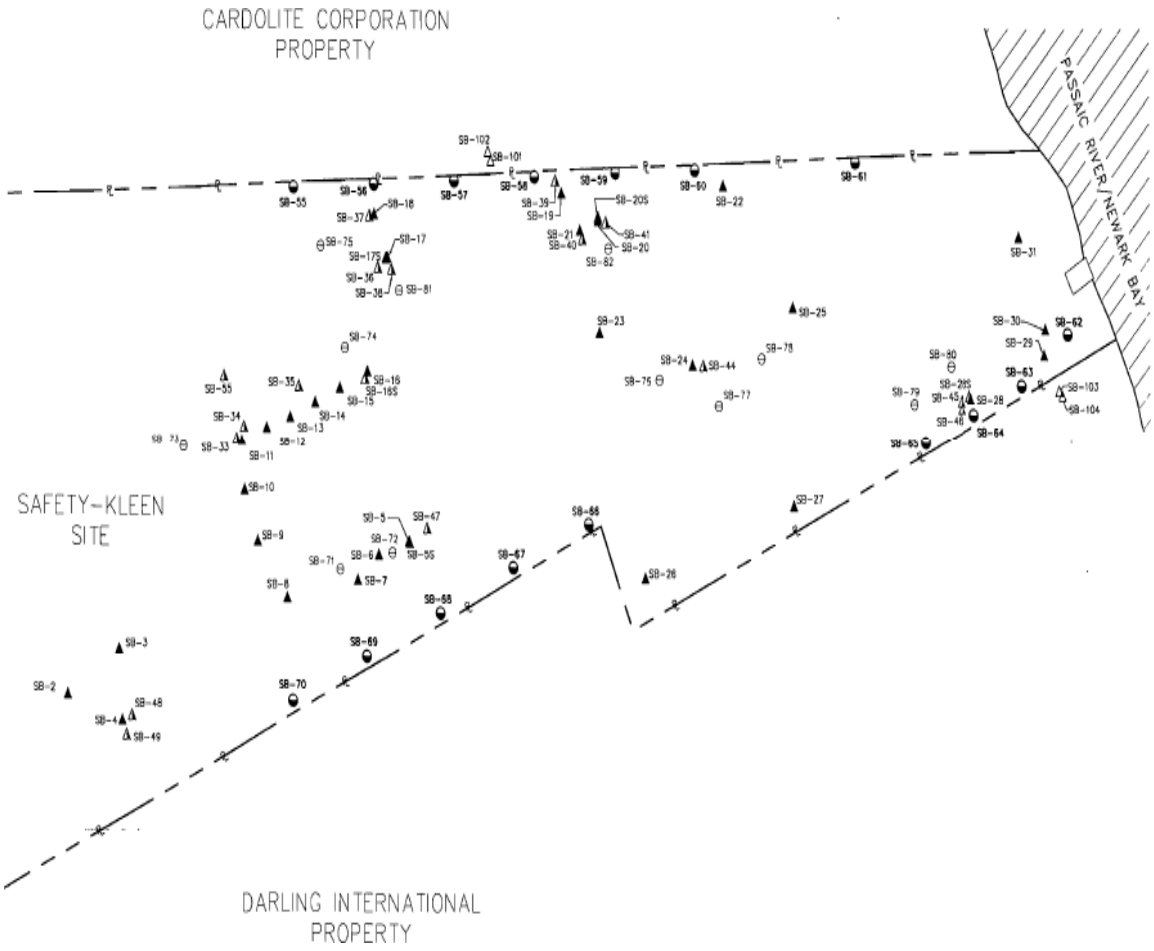
According to a memo prepared by NJDEP, dated December 14, 1979, all tank areas containing liquids were diked or curbed. At the time, all diked containments were to be provided with common sumps for the purpose of collecting and discharging spills, rain and wash waters (PAP-00187208).

According to the April 1979 Engineering Plan, the only waste produced at the site other than wastewater from the cooling system was a “considerable volume” of residual liquid chemical wastes approximating 384,000 gallons per month (PAP-00186371). According to a letter from the facility to PVSC, dated June 15, 1979, there were five sources of wastewater at the facility: “L/L Bottoms,” “Crystallizer,” “DMA Washer,” “Reactor,” and “Still boilout” (PAP-00185880). The 1979 Engineering Plan states that when the chemical recovery process produced a residual liquid chemical waste, it was temporarily stored at the plant until it could be transported to the Modern Transportation Company of Kearny or to Inland’s Kentucky plant for treatment and disposal. The document states that “at no time is waste or wastewater discharged into existing storm or sanitary sewers.” The document goes on to state that the plant's sanitary facilities consisted of septic tanks within the site, rather than service connections to the city sanitary sewer system (PAP-00186371).

A facility layout is presented below (PAP-00187144):

On October 10, 1982, an explosion and fire destroyed much of the facility. The NJDEP closed the site two days later (PAS-00091937).

According to a *RCRA Facility Assessment Narrative*, dated May 1987, a walk-through survey of the facility conducted on May 12, 1986, revealed that the site was being used by nearby industries as a parking lot and storage area for wastes and equipment. It is reported that there were fourteen trailers on the site, two of which contained drums, and that a black chemical resin was leaking out of the back of nine trailers. One of these trailers was labeled with a poison placard. One of five trucks parked on the northwestern side of the site contained drums. Twelve drums of oil were reportedly stored outside a maintenance building, and a pile of soil reported to be contaminated with a metallic residue and blue crystals was dumped next to these containers. Bottled chemicals were observed to be stored in a small building located in front of the storage tanks by Newark Bay. Soil on the eastern side of the plant near the former truck transfer area was observed to be discolored (PAP-00185895).



4. Identified COCs

- PCBs (detected)
- PAHs (used, detected)
- Copper (detected)
- Lead (generated
- Mercury (detected)

It is noted that, according to an Administrative Consent Order, dated June 23, 1993, the site constitutes a portion of a larger tract of land on which Balbach conducted smelting and refining of lead, copper, and precious metal-based ores from at least the 1890s until 1938 (PAP-00186325-6). Balbach was reportedly one of the largest metals refiners in the world at the time (PAP-00186326), and according to a *Phase II Remedial Investigation Work Plan*, prepared by Blasland, Bouck, & Lee, Inc. (BBL), dated March 1995, Balbach processed “substantial quantities” of ores and generated a variety of “toxic” heavy metals, resulting in lead, copper, and mercury contamination attributable to Balbach’s operations (PAS-00011253-54; PAS-00091937; PAP-00362426, 35-38). In addition, according to a *Phase II Remedial Investigation Report*, prepared by BBL, dated December 1995 (1995 Phase II RI), Balbach filled the site with smelter slag (PAP-00364135; PAP-00188312, 52-3; PAP-00186325-6; PAP-00362426, 36). In 1993, an Administrative Consent Order was issued by NJDEP which exempted Safety-Kleen Envirosystems Company from responsibility for remedying conditions resulting from the former metal refining practices at the site, or from any other activities which pre-dated 1952 (PAS-00011257). Further, according to the 1995 Phase II RI, metallic constituents detected in soil during Safety-Kleen Envirosystems Company’s Phase I and Phase II remedial investigations were related to historical smelting operations conducted by Balbach, and were not related to post-1952 operations. This was confirmed by the results of statistical analyses performed on the Phase I RI soils data. The report states that the results of this statistical analysis were accepted by NJDEP in a May 3, 1995, Phase II RI Work Plan conditional approval letter (PAP-00364123; PAS-00010852-53). Data for lead and copper are discussed further in Section 8 below.

PCBs

According to a *Remedial Action Report*, prepared for Safety-Kleen Envirosystems Company, dated August 2001, concentrations of polychlorinated biphenyls (PCBs) in soils that exceeded 50 parts per million (ppm) were detected in the vicinity of one soil boring (SB-24). The extent of soils containing PCBs greater than 50 ppm was defined to be within a 50-foot by 20-foot rectangular area surrounding the soil boring (PAS-00010854). The highest concentration of PCBs (161 ppm) was detected in a soil sample collected from soil boring SB-24 at a depth of 0 to 0.5 feet below ground surface (PAS-00010899). The location of SB-24 (located in the east-central portion of the site) is depicted below (PAS-00010895):

With respect to stormwater runoff in the area of SB-24, it is noted that according to the 1979 Engineering Plan and a memo prepared by NJDEP, dated December 14, 1979, all precipitation and stormwater runoff was collected from “potentially contaminated areas” and contained within the site for storage and filtration via a system of drainage swales and pumps, and later use in the plant's cooling system. “Wasted" cooling water was pumped into storage tanks and transported to treatment and disposal facilities at the Modern Transportation Company. The cooling system wastewater was retained and stored for subsequent offsite treatment and disposal (PAP-00186369; PAP-00187208).

Soil that contained 50 ppm or more PCBs was excavated and disposed off-site (PAS-00010849). PCBs also were detected at several Areas of Environmental Concern (AECs). This is discussed further in Section 8 below.

It is noted that Kolker Chemical Company owned the site in 1952, and between approximately 1953 and 1962, it manufactured a number of organic and inorganic chemicals, including non-ferrous inorganic salts, chlorine, chloroform, methyl chloride, methylene chloride, and plasticizers (PAP-00188319; PAP-00366038-39; PAP-00366830). Kolker Chemical Company's use of PCBs at the facility is documented by sales records from Monsanto indicating they purchased at least 183,000 pounds of PCBs (including Aroclors 1242, 1248, 1254, and 1260) between 1958 and 1962 (PAP-00366041-53; PAP-00366040). Moreover, Inland's Temporary Operating Authority permits issued by NJDEP on May 9, 1978, and April 30, 1979, prohibited Inland from accepting any solvent effluent streams containing PCBs (PAP-00188259; PAP-00188271).

PAHs

According to a *Remedial Investigation Report* (1994 Phase I RI) dated August 1994, several polynuclear aromatic hydrocarbons (PAHs) were detected in soil at concentrations that exceeded the NJDEP "soil cleanup criteria" (PAP-00188353). These included high and low molecular weight PAHs (PAP-00188361-87). According to the 1994 Phase I RI, the pattern of organics, especially volatile organic compounds, in soil samples is consistent with organics being discharged from recent (post-1952) operations on the plant (PAP-00188353).

Based on a January 14, 1975, table of tank capacity and contents at the site, five fuel oil (No. 4 and No. 6) tanks were present at the boiler room ranging in capacity from 15,000 to 20,000 gallons (PAP-00185445).

Copper

The copper concentration in a wastewater sample collected on January 6, 1982, was 0.824 mg/L. According to a letter prepared by MEC, dated April 30, 1982, samples were collected in order to establish a set of baseline data for discharge into the PVSC system. The wastewater sample came out of tank "C-19," which is a 230,000-gallon tank on the property (PAP-00185787-88).

In addition, the copper concentration in a wastewater sample collected on February 25, 1982, was 0.445 mg/L. Based on the available references, it is unclear from where the sample was collected or with what discharge location/receiving body it was associated (PAP-00187534).

Copper was also detected in soil at concentrations at high as 8,400 milligrams per kilogram (mg/kg). This is discussed further in Section 8 below.

Lead

According to a letter prepared by Inland, dated June 27, 1975, lead was generated as a result of the chlor-alkali process (PAP-00188223). This operation was shut down in May 1975 (PAP-00188218). With the exception of lead generation prior to 1975, lists of hazardous substances at the facility state that operations did not involve lead after that date (PAP-00187242; PAP-00187498; PAP-00187507).

The following is a discussion of relevant available wastewater discharge data:

- Inland reported that on April 10, 1975, their wastewater discharge met all requirements of their National Pollutant Discharge Elimination System (NPDES) permit with the exception of lead (PAP-00188222). As mentioned above, the operation that generated the lead was shut down in May 1975 (PAP-00188218).

- Between February and May 1975, the facility reported a maximum of 71.5 pounds per day of lead in their effluent (for the month of May), with an intake level of 19.0 pounds per day, for a net discharge amount of 52.5 pounds per day. In February and April 1975, Inland reported net discharges of -2 lbs. and -21.5 lbs. per day of lead (i.e. water discharged contained less lead than intake water) (PAP-00188240).

- According to a NPDES discharge monitoring report, the maximum detected concentrations of lead in 1976 were as follows:

    - 0.49 mg/L for the first seven months of 1976 (PAP- 00185800; PAP-00185815);
    - 0.52 mg/L in September 1976 (PAP-00188983);
    - 0.19 mg/L in October 1976 (PAP-00186123);

    The original NPDES permit for the facility (No. NJ0001279) became effective on January 31, 1975, and allowed for a daily discharge of 38 pounds of lead per day (PAP-00362242; PAP-00189115). However, on October 22, 1976, EPA stated its intention to issue a modified permit, given that the effluent discharge flow was greatly reduced following the cessation of chemical manufacturing in May 1975, and Public Notice of the permit modification was published on December 3, 1976 (PAP-00189054; PAP-00186107-9). According to this public notice prepared by EPA, a maximum concentration limitation of 1.0 mg/L was imposed for total lead, and the effluent limitation for lead was reduced from 38 pounds/day to 1.20 pounds/day (PAP-00189198).

- According to a memo prepared by EPA, dated October 22, 1976, the facility was no longer discharging wastewater that contained lead in “excessive” amounts (PAP- 00186102). Ultimately, all discharges through Outfall 001 ceased on or before July 1, 1977 (PAP-00186120). Thereafter, surface water runoff was captured and used for cooling water, and was periodically disposed of off-site by truck (PAP-00187346, 48).

- A sample of facility wastewater collected on February 29, 1980, showed that lead was present at a concentration of 1.9 mg/L. Based on available references, it is unclear from where the sample was collected or with what discharge location/receiving body it was associated (PAP-00185448).

- A sample dated March 3, 1980, had a lead concentration of 2.4 mg/L. Based on available references, it is unclear from where the sample was collected or with what discharge location/receiving body it was associated (PAP-00185463).

- Lead was detected in a wastewater sample collected on January 6, 1982, at a concentration of 0.114 mg/L. According to a letter prepared by MEC, dated April 30, 1982, samples were collected in order to establish a set of baseline data for discharge into the PVSC system. The wastewater sample came out of tank "C-19," which is a 230,000-gallon tank on the property (PAP-00185787-88).

- Lead was detected in a wastewater sample collected on February 25, 1982, at a concentration of 0.872 mg/L. Based on available references, it is unclear from where the sample was collected or with what discharge location/receiving body it was associated (PAP-00187534).

Lead was also detected in soil at concentrations as high as 30,000 mg/kg. This is discussed further in Section 8 below.

Mercury

A sample of facility wastewater collected on February 29, 1980, showed that mercury was present at a concentration of 0.0025 milligrams per liter (mg/L). Based on the available references, it is unclear from where the sample was collected or with what discharge location/receiving body it was associated (PAP-00185448).

The mercury concentration in a wastewater sample collected on January 6, 1982, was 0.001 mg/L. According to a letter prepared by MEC, dated April 30, 1982, samples were collected in order to establish a set of baseline data for discharge into the PVSC system. The wastewater sample came out of tank "C-19," which is a 230,000-gallon tank on the property (PAP-00185787-88). The mercury concentration in a wastewater sample collected on February 25, 1982, was 0.0009 mg/L. Based on the available references, it is unclear from where the sample was collected or with what discharge location/receiving body it was associated (PAP-00187534).

Historic Fill

The Allocation Team has determined that the facility site is located on regional Historic Fill as designated by the NJDEP.[1]

[1] *Digital Geodata Series, DGS04-7, Historic Fill for New Jersey*, https://www.nj.gov/dep/njgs/geodata/dgs04-7.htm, Quadrangle No. 52 and No. 53 (NJDEP map identifying locations of recognized historic fill).

NJDEP has established that Historic Fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 COCs: PAHs, lead, copper, and mercury.[2] Accordingly, NJDEP technical requirements for property containing Historic Fill requires sampling for the EPA Target Compound List for PAHs and Target Analyte List for metals, including lead, copper, mercury, and the OU2 PAH COCs.[3] PAHs, lead, copper, and mercury are recognized by NJDEP to be constituents of Historic Fill at varying levels, not atypically at or exceeding residential soil standards.[4]

The levels of PAHs, copper, lead and mercury detected at the site in soils are presented in the table below.

COCs Found in Onsite Soils	
COC	**Max Detected Concentration**
Lead	30,000 mg/kg
Copper	8,400 mg/kg
Mercury	23 mg/kg
Benzo(a)anthracene	17 mg/kg
Benzo(a)pyrene	27 mg/kg
Benzo(b)fluoranthene	26 mg/kg
Benzo(k)fluoranthene	12 mg/kg
Dibenzo(a,h)anthracene	6.1 mg/kg
Indeno(1,2,3-cd)pyrene	12 mg/kg
PCBs	161 mg/kg

It is noted that according to a memo prepared by NJDEP, dated December 14, 1979, three soil borings show compacted fill and cinder from 0 to 10 feet (PAP-00187208). According to the August 1994 Phase I RI, the entire site is covered with fill which dates back to before 1911 (PAP-00188312). In addition, according to a *Phase II Remedial Investigation Work Plan*, dated March 1995, surface soil extending to 7 to 10 feet is composed of fill material of variable composition (PAP-00362435). Finally, according to the 1995 Phase II RI, metallic constituents (including lead, copper, and mercury) detected in soil during Safety-Kleen Envirosystems Company's Phase I and Phase II remedial investigations were related to historical smelting operations conducted by Balbach, and were not related to post-1952 operations. This was confirmed by the results of statistical analyses performed on the Phase I RI soils data. The report states that the results of this statistical analysis were accepted by NJDEP in a May 3, 1995, Phase II RI Work Plan conditional approval letter (PAP-00364123; PAS-00010852-53;

[2] *Characterization of Ambient Levels of Selected Metals and cPAHs In New Jersey Soils* (2002) and *Characterization of Ambient Levels of Selected Metals and Other Analytes In New Jersey Soils* (1997), studies prepared for NJDEP, Division of Science and Research, by BEM Systems, Inc.
[3] New Jersey Department of Environmental Protection (NJDEP), *N.J.A.C. 7:26E Technical Requirements for Site Remediation,* Table 4-2, November 2009 [Note that Table 4-2 has been deleted from the current version of N.J.A.C. 7:26E (May 7, 2012) and the updated *Historic Fill Technical Guidance* (April 2013) as NJDEP believed that the tables list of historic fill constituents was too restrictive].
[4] NJDEP Table 4-2 (PAHs and lead) and a summary of NJDEP records regarding investigations of properties in the vicinity of the Passaic River recognized to be located in areas of Historic Fill indicate that the following average/maximum (mg/kg) contamination levels of OU2 COCs exist in area Historic Fill: PAHs (1.91/160), lead (574/10,000), copper (11.2/1,200), and mercury (0.21/3.7).

PAP-00362437-38). In 1993, an Administrative Consent Order was issued by NJDEP which exempted Safety-Kleen Envirosystems Company from responsibility for remedying conditions resulting from the former metal refining practices at the site, or from any other activities which pre-dated 1952, and acknowledged that "most if not all" of the metals contamination at the site was attributable to fill (PAS-00011257; PAP-00188476).

5. COC Pathways

The facility is located at the mouth of the Passaic River where it enters Newark Bay (just north of River Mile 0.0) (PAP-00402573, 76).

Sanitary and Storm Sewer

The 1979 Engineering Plan document states that "at no time is waste or wastewater discharged into existing storm or sanitary sewers." The document goes on to state that the plant's sanitary facilities consisted of septic tanks within the site, rather than service connections to the city sanitary sewer system (PAP-00186371).

The facility filed a sewer connection application with PVSC on February 15, 1980, for intermittent discharge of 14,000 gallons of wastewater per day (PAP-00185459). According to a letter prepared by PVSC, dated August 18, 1982, the facility intended to install a sanitary sewer line to connect to the City of Newark sewer to handle approximately 1,200 gallons per day of domestic waste. This was in response to an Administrative Consent Order requiring resolution of septic tank overflows at the facility (PAP-00185368).

The facility also filed a sewer connection application with PVSC on February 4, 1983, for intermittent discharge of industrial waste to the sanitary sewer, after the October 1982 explosion and fire, and facility closure, but in anticipation of the facility being rebuilt and reopened. This application states that pumped groundwater would be mixed with industrial wastes from the reopened facility and the resulting mixture would be monitored to establish that the waste would be acceptable for to discharge to the PVSC. Documentation appears to show that discharges would occur temporarily through a neighboring property outfall, and then subsequently through facility tie-in to the PVSC system. A NJDEP construction and discharge permits form dated May 24, 1983, states that tie-in to the PVSC system would allow for discharge of stormwater, treated groundwater, and septic wastes into the PVSC system (PAP-00185469-72; PAP-00185776; PAP-00185877). The facility obtained a sewer connection permit from PVSC on May 13, 1983 (PAP-00186214).

The following information was available regarding the volumes of wastewater proposed to be discharged from the facility:

- According to a June 15, 1979, letter prepared by Inland, as part of their intent to obtain approval to discharge wastewater to the PVSC system, they estimated that they would discharge 400,000 gallons per month (PAP-00185880).

- The facility filed a sewer connection application with PVSC on February 15, 1980, for intermittent discharge of 14,000 gallons of wastewater per day (PAP-00185459).

- On February 10, 1982, the facility projected that they would generate 23,580 gallons of wastewater per day (PAP-00185856).

Direct Release

According to a September 27, 1976 National Pollutant Discharge Elimination System Application, the facility held a NPDES permit (No. NJ0001279) at least as early as December 30, 1972 (PAP-00185805).

According to a public notice NPDES fact sheet prepared by EPA, dated July 19, 1974, the facility had one discharge point to Newark Bay (Discharge 001) (PAP-00189108). Discharges were reported to consist of cooling water and process water. The point of discharge was approximately 50-100 feet north of Wilson Avenue (PAP-00189197).

According to a letter prepared by the facility dated August 2, 1977, the facility stopped discharging from Discharge 001 pursuant to their NPDES permit as of July 1, 1977 (PAP-00186120-1).

According to a letter prepared by the facility dated July 18, 1977, underground drains leading from the property to Newark Bay had been sealed off (PAP-00186857).

According to the 1979 Engineering Plan and a memo prepared by NJDEP, dated December 14, 1979, the site drainage system is completely overland. It is reported that underground pipelines and drainage structures were not used within the plant, nor did the plant discharge stormwater into a storm or sanitary sewer system. It was further reported that all precipitation and stormwater runoff was collected from “potentially contaminated areas” and contained within the site for storage, filtration, and later use in the plant's cooling system. A system of drainage swales and pumps collected and discharged the stormwater directly into a filtering system, and then into temporary storage. As the cooling facilities required additional water, the filtered stormwater was fed from storage into the cooling system. The entire cooling system water supply was replaced at “regular intervals” with the "wasted" cooling water being pumped into storage tanks and later transported to treatment and disposal facilities at the Modern Transportation Company. The cooling system wastewater was retained and stored for subsequent offsite treatment and disposal (PAP-00186369; PAP-00187208).

The following information was available regarding the volume of wastewater discharged from the facility:

- According to a memo prepared by EPA dated October 6, 1975, the facility was no longer performing the types of manufacturing activities they were when their permit was issued, and the effluent flow had been reduced from 14.4 million gallons per day (MGD) to 0.016 MGD (PAP-00187067).

- According to a memo prepared by EPA, dated October 22, 1976, average discharge flow was 0.092 MGD; however, the NPDES permit was based on an average flow of 10.5 MGD (PAP-00189054).

- According to a letter prepared by EPA, dated November 24, 1976, at the time the facility was issued a NPDES permit effective January 31, 1975, on average the facility discharged 10.5 MGD to Newark Bay (PAP-00186109; PAP-00362242).

- According to a public notice prepared by EPA, dated December 3, 1976, the plant had one discharge point to Newark Bay (Discharge 001), consisting of cooling water and process water, with average and maximum flows of 92,000 and 144,000 gallons per day, respectively (PAP-00189197).

Spills

There is no information regarding spills in the available file material.

6. Regulatory History/Enforcement Actions

Inspections and Violations

According to a letter prepared by the facility dated July 3, 1975, the U.S. Coast Guard observed an “oil-like material” in Newark Bay, and it was determined to be coming from the facility sewer system (PAP-00187098). Investigation revealed material originated from the DMA-Phenoxy unit. The facility also reported that they discovered several leaks in the waste water system and, therefore, “the oils etc. from the phenoxy crystallization” were dripping on the concrete floor and migrating to the sewer. In addition, the facility reported that they washed down the entire area causing the material collected on the floor previously to flow to the main sewer (PAP-00187106).

At least 11 inspections conducted by NJDEP between January 18, 1980, and May 19, 1982, identified what was described as “leachate of an oil substance is presently entering Newark Bay” and/or “leachate into bay” and/or an “oil like material,” among other similar descriptions. The source of the discharge was documented as being unknown (PAP-00186512-21, 6530-1, 6881, 6908, 6913, 7305, 7310; PAP-00365518-9). In addition, on January 18, 1980, a “leak in wastewater holding tank” was observed (PAP-00186512-3). On January 28, 1980, a leak or spill associated with a wastewater holding tank was noted, as was “Waste water holding tank equalization not functioning resulting in spill” (PAP-00186514-5). On March 5, 1980, “several spills located around facility” was noted (PAP-00186884-5).

According to a NJDEP memo, dated March 10, 1981, at the time of a September 10, 1980 inspection at the facility, NJDEP personnel observed a purple discharge at the facility’s bulkhead along the Newark Bay (PAP-00185827). This was also noted during a September 2, 1980, inspection and one in September 1979 (PAP-00365518-19). Information as to whether COCs were present in the discharge was not provided in the cited document. The document also notes that dating back to 1979, NJDEP personnel had noted the following deficiencies at the facility: (1) poor, careless housekeeping

resulting in extensive spillage; (2) a contaminated stormwater discharge into Newark Bay; (3) open drums in deteriorated condition stored in improper storage areas; (4) an oily material surfacing in the Newark Bay near the facility's shoreline; and (5) a purple-colored groundwater discharge into Newark Bay (PAP-00185827).

According to an undated Inland Temporary Operating Authority Compliance Status document, the following had been noted at the facility:

- Inspectors have stated that Inland has not been responding as quickly as possible to excavate, remove, and properly dispose of soils contaminated by spills or leaks of waste materials or sludges (PAP-00185870).

- Inspectors have stated that there have been "a number" of unauthorized discharges of pollutants into the soils, surface water and ambient air at the facility, and that the facility failed to submit formal reports regarding these incidents. The document goes on to state that major discharges that should have been addressed in this fashion included the "long present" purple discharge into Newark Bay; the overflow and spillage of "DMA" out of the C-19 waste water tank on September 19, 1980; septic tank overflow out of the pipe at the rear of the facility; and, the chronic overflowing and spillage of water out of the cooling towers (PAP-00185870).

An inspection on October 10, 1982, following the facility explosion that day, identified contaminated runoff from the fire discharging at a rate of 500 to 1,000 gallons per minute to a storm drain on an adjacent property which drained to Newark Bay. The inspection report does not document if OU2 COCs were present in the runoff (PAP-00365540).

In November 1985, a RCRA Facility Assessment was performed by NJDEP, which identified "a number" of environmental concerns at the site. In addition, a site inspection conducted by NJDEP in 1987 stated that "a number" of surface units and structures (remaining after the explosion) were deteriorating and/or leaking (PAS-00091937).

According to a June 23, 1993, Administrative Consent Order, on October 30, 1979, the facility was issued an Administrative Order by the New Jersey Department of Environmental Protection and Energy (NJDEPE). The order stated that routine inspections conducted by NJDEPE on September 19, October 9, October 16 and October 24 revealed that the facility grounds were contaminated with various chemicals; therefore, the facility was to cease accepting waste and clean up all spills and contaminated soil (PAS-00011254).

According to a Civil Action brought by the State of New Jersey against Inland, dated March 19, 1980, Inland failed to comply with and implement all of NJDEP's requirements of Inland's Temporary Operating Authority; Inland since or from about October 30, 1979, had failed and continued to fail to comply with the October 30, 1979, Administrative Order; and, Inland's acts since or from about October 30, 1979, had constituted and continued to constitute pollution of the environment or a potential threat of pollution of the environment (PAP-00365511).

In August 1982, NJDEP issued an Administrative Consent Order due to the facility's failure to obtain authorization to conduct hazardous waste treatment and storage operations. The Administrative Consent Order also states that the facility was in need of maintenance and operational design changes, and materials accumulated from chronic spills and leaks needed to be removed from the site and properly disposed (PAS-00010424-25; PAS-00011254).

On October 10, 1982, a major explosion occurred on the company's premises destroying the hazardous waste processing area. Therefore, NJDEP ordered that the facility cease operations (PAP-00185865-66).

NJDEP issued an Administrative Consent Order to MEC in 1990 requiring them to conduct a remedial investigation and feasibility study of remedial action alternatives (PAP-00362286-87).

NJDEP issued an Administrative Consent Order to Safety-Kleen Envirosystems Company on June 23, 1993, requiring them to conduct a remedial investigation and feasibility study of remedial action alternatives (PAS-00011255).

Permits

It appears the facility held a NPDES permit (No. NJ0001279) as early as December 30, 1972; however, a copy of the permit was not available in the file material (PAP-00185805; PAP-00185375). This is the discharge point that received cooling and process wastewater containing the COC lead (PAP-00189106; PAP-000189197).

The original NPDES permit for the facility (No. NJ0001279) issued by EPA became effective on January 31, 1975 (PAP-00362242). The facility was required to sample for lead twice monthly (PAP-00362249).

On October 22, 1976, EPA stated its intention to issue a modified permit, given that the effluent discharge flow was greatly reduced following the cessation of chemical manufacturing in May 1975, and Public Notice of the permit modification was published on December 3, 1976 (PAP-00189054; PAP-00186107-9). According to a letter prepared by the facility dated August 2, 1977, the facility stopped discharging pursuant to their NPDES permit as of July 1, 1977 (PAP-00186120-21).

The facility filed a sewer connection application with PVSC on February 15, 1980, for intermittent discharge of 14,000 gallons of wastewater per day (PAP-00185459). This permit was not granted due to PVSC's contention that some of the wastewater originated from outside the PVSC service area (PAP-00185373).

The facility also filed a sewer connection application with PVSC on February 4, 1983, for intermittent discharge of industrial waste to the sanitary sewer, after the October 1982 explosion and fire, and facility closure, but in anticipation of the facility being rebuilt and reopened. This application states that pumped groundwater would be mixed with industrial wastes from the reopened facility and the resulting mixture would be monitored to establish that the waste would be acceptable for discharge to the PVSC.

Documentation appears to show that discharges would occur temporarily through a neighboring property outfall, and then subsequently through facility tie-in to the PVSC system. A NJDEP construction and discharge permits form dated May 24, 1983, states that tie-in to the PVSC system would allow for discharge of stormwater, treated groundwater, and septic wastes into the PVSC system (PAP-00185469-72; PAP-00185776; PAP-00185877). The facility obtained a sewer connection permit from PVSC on May 13, 1983 (PAP-00186214).

7. Response Actions

Characterization Activities

The following characterization activities have taken place at the facility:

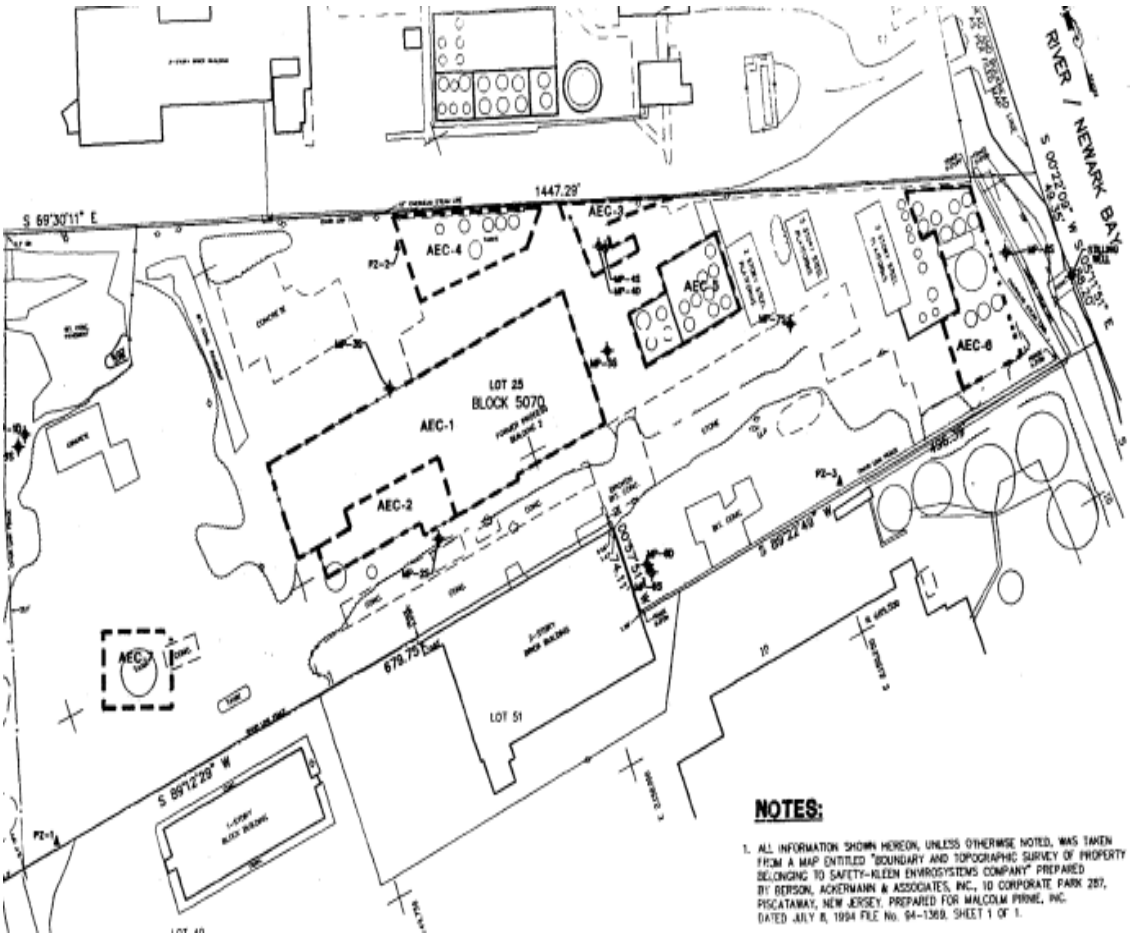
- Preliminary Assessment conducted by EPA in 1983 (PAP-00365520).
- RCRA Facility Assessment conducted by NJDEP in 1985 (PAS-00091937).
- Several Remedial Investigation reports between 1994 and 1999 (PAP-00363061).
- *Remedial Action Selection Report*, dated January 1996 (PAP-00362984).
- *Remedial Action Report*, prepared for Safety-Kleen Envirosystems Company, dated August 2001 (PAS-00010843).
- *Supplemental Groundwater Remedial Action Selection Report,* dated November 2002 (PAP-00363273).
- *Supplemental Groundwater Remedial Action Work Plan*, dated October 2003 (PAP-00363048).
- *Addendum to the Supplemental Groundwater Remedial Action Work Plan*, dated October 2003 (PAP-00363048).
- *Remedial Action Report, prepared for Safety-Kleen Envirosystems Company*, dated September 2004 (PAP-00364590; PAP-00364973).

Sewer

There is no information regarding sewer sampling data in the available file material.

Soil

It is noted that in 1993, an Administrative Consent Order was issued by NJDEP which exempted Safety-Kleen Envirosystems Company from responsibility for remedying conditions resulting from the former Balbach metal refining practices at the site, or from any other activities which pre-dated 1952 (PAS-00011257). Further, according to the 1995 Phase II RI Work Plan, metallic constituents (including COCs lead, copper and mercury) detected in soil during Safety-Kleen Envirosystems Company's Phase I and Phase II remedial investigations were related to historical smelting operations conducted by Balbach, and were not related to post-1952 operations (PAP-00362426, 35–38). This was confirmed by the results of statistical analyses performed on the Phase I RI soils data (PAP-00362437-38). The report states that the results of this statistical analysis were accepted by NJDEP in a May 3, 1995, Phase II RI Work Plan conditional approval letter (PAP-00364123; PAS-00010852-53).



According to an NJDEP memorandum, dated March 10, 1981, between September 2, 1980, and January 8, 1981 NJDEP inspectors collected at least 33 samples at the facility. A sample from a spill on the ground near "tank farm 5" contained the COCs PCBs (670 ppm) and lead (10 ppm). It is noted that the memorandum states that "Unfortunately, our sample chain of custody, record keeping and storage procedures were probably not rigorous enough to meet court standards." (PAP-00185829).

In 1988, the COCs lead and copper were detected in soil at concentrations as high as 6,250 mg/kg and 13,600 mg/kg, respectively (PAP-00188322). According to the 1994 Phase I RI, the concentrations of metals were consistent with the use of the site for lead smelting and metal refining by Balbach (PAP-00188322).

According to a Documentation of Environmental Indicator Determination, prepared by EPA, dated September 27, 2001, seven Areas of Environmental Concern (AECs) were identified at the site (PAS-00091938-39). The following is a description of each AEC at which COCs were detected:

- AEC 1 contained several aboveground storage tanks (ASTs) which supported operations in the process building. From 1962 to 1974, the former process building housed operations to process benzoic acid and produce plasticizers.
- AEC 2 was used as a truck transfer area associated with transport of the materials in the ASTs at AEC 1 (PAS-00091945).
- AEC 3 contained two cooling towers that circulated 2,400 gallons per minute of water (PAS-00091938).
- AEC 4 was used as a loading dock and tank storage area for empty ASTs (PAS-00091946).
- AEC 5 contained approximately 12 ASTs situated within two adjacent berms. From 1962 to 1974, methylene chloride manufactured at the site was stored in this area (PAS-00091939).
- AEC 6 consisted of several tanks which were associated with chemical processing (PAS-00091946).
- AEC 7 contained a 225,000-gallon AST which contained mixed organics (PAS-00091946).

The location of each AEC is depicted below (PAP-00364294):

Maximum detected concentrations of metals and PCBs detected at each AEC, as reported in the 1994 Phase I RI and 1995 Phase II RI, are summarized below. In addition to metals and PCBs, low and high molecular weight PAHs were detected in soil samples collected at each AEC (PAP-00188348-52, 60-87; PAP-00364270, 4).

1994 Phase I RI and 1995 Phase II RI Maximum COC Concentrations in Soil							
COC	**AEC 1 mg/kg)**	**AEC 2 (mg/kg)**	**AEC 3 (mg/kg)**	**AEC 4 (mg/kg)**	**AEC 5 (mg/kg)**	**AEC 6 (mg/kg)**	**AEC 7 (mg/kg)**
Copper	4,700	4,700	8,400	8,400	2,800	1,000	4,900
Lead	14,000	8,700	30,000	5,700	4,600	4,500	6,800
Mercury	5.6	4.6	8.7	6.2	19	23	4.4
PCBs	5.7	34	1.2	0.93	161	14	3.2

According to the 1994 Phase I RI, the highest metals concentrations were detected at AEC-1 and AEC-2, adjacent to a former Balbach production building. In addition, the report states that the high concentrations of copper, lead, and other metals throughout the site are indicative of the filling of the site and adjoining areas by Balbach with materials from metal refining operations (PAP-00188352-53).

Remedial Activities

According to the *Remedial Action Report*, prepared for Safety-Kleen Envirosystems Company, dated August 2001, concentrations of PCBs in soils that exceeded 50 ppm were detected in the vicinity of one Phase I RI soil boring (SB-24). PCB concentrations in soils were subsequently delineated for concentrations of both 2 ppm and 50 ppm. The extent of soils containing PCBs greater than 50 ppm was defined to be within a 50-foot by 20- foot rectangular area surrounding soil boring SB-24 located in the east-central portion of the site (PAS-00010854, 95). Based on June 1999 PCB soil sampling results, the horizontal limits of the excavation were defined to be a 50-foot by 20-foot rectangular area surrounding SB-24. PCBs were not detected at concentrations greater than 50 ppm within this area at depths greater than one foot below ground surface (PAS-00010859). Soil that contained 50 ppm or more PCBs was excavated and disposed off-site (PAS-00010849). According to a *Supplemental Groundwater Remedial Action Work Plan*, prepared by BBL, dated May 2003, the volume of soil with concentrations of PCBs greater than 50 ppm was 137 tons (PAP-00363064).

According to the Documentation of Environmental Indicator Determination, prepared by EPA, dated September 27, 2001, each of the AECs discussed above were covered with an asphalt cap in 2000/2001 as part of a site-wide capping program implemented to prevent exposure to contaminated soil and prevent further infiltration of contaminants to groundwater (PAS-00091938-39; PAP-00363064). As part of installation of the cap, a stormwater runoff control system was installed with two outfalls to Newark Bay (PAP-00363064).

NJDEP issued a Conditional No Further Action Letter for site soil to McKesson Corporation on May 6, 2011, subject to continued implementation of institutional and engineering controls (PAP-00365990-1).

8. Summary of Asserted Defenses

McKesson intends to assert, if necessary, that its and Safety-Kleen Envirosystems Company's allocation, if any, should be reduced or eliminated based on a number of defenses:

- Because Inland acquired the facility after a valid NPDES permit application had been filed with the Army Corps of Engineers (ACOE) and accepted by the ACOE and EPA, any discharges from the facility in compliance with the limitations set forth in NPDES permit No. NJ0001279 covering Outfall 001 are subject to the federally permitted release exemption under CERCLA. 42 U.S.C. §9607(j) prohibits recovery for CERCLA response costs or damages resulting from federally permitted releases.

- Any non-background PAH contamination at the facility that could be associated with spills or leaks of fuel oil or diesel oil by Inland or MEC would not result in any CERCLA liability pursuant to the petroleum exclusion, 42 U.S.C. §9601(14).

- To its knowledge, McKesson did not employ, produce or discharge PCBs at the facility. Rather, the on-site PCB contamination was likely caused by prior facility owner and operator Kolker Chemical Company/Vulcan. McKesson further notes that the PAH contamination at the facility is most likely from background sources, as is the heavy metal contamination, given the Historic Fill onsite and the historic Balbach operations on and discharges to the facility. McKesson therefore intends to assert a third-party defense as to each of these COCs, 42 U.S.C. §9607(b)(3).

- Based on pertinent CERCLA case law, despite Inland's ownership of the chlor-alkali plant during 1974-75, the allocation should assign McKesson little to no responsibility for lead discharges exceeding NPDES permit limits during that period because it played no role in those discharges. McKesson should be allocated minimal or no responsibility for the 1974-75 lead discharges because, pursuant to the parties' Operating Agreement, Vulcan, rather than Inland, was entirely responsible for the plant's operation. Further, Vulcan had represented to Inland that the continued operation of the plant would not violate any pending or existing environmental law. Vulcan was responsible for all of the lead discharges from the plant, as Inland had no experience operating the chlor-alkali facility and relied on Vulcan to operate the plant in accordance with the law based on Vulcan's contractual representations. An operator whose actions are the sole cause of environmental damage must be allocated the majority of the responsibility. McKesson deserves a lesser allocation than Inland because it had limited knowledge about the chlor-alkali process, did not believe it to be an environmentally hazardous operation and did not accept lead discharge limit exceedances under the Purchase Agreement.

Facility Data Report

SCHIFFENHAUS PACKAGING CORPORATION

Facility Name, Address and Size: Schiffenhaus Packaging Corporation (Schiffenhaus); 1909 to 1924: 49 Fourth Street, Newark, NJ (acreage unavailable)

1. **Business Type:** Manufacturer of pre-printed linerboard and corrugated and solid fiber boxes; specializes in corrugated boxes and corrugated display items, coated or laminated packaging paper or plastic film; manufactures non-wooden partitions, shelving or lockers. The facility manufactures corrugated sheets that are, in turn converted into corrugated cartons, displays and other corrugated products (PAS-00017806-07).

2. **Time Period of Ownership/Operations**

   Operator: 1909 - 1924
   Owner: 1909 - 1924

   Schiffenhaus was started by William and Max Schiffenhaus under the name "Schiffenhaus Bros" in 1895; it was incorporated in the state of New Jersey on February 4, 1926, as "Schiffenhaus Packaging Corporation" (PAS-00017804; PAS-00018007). On July 28, 1981, Schiffenhaus Industries, Inc. was incorporated in the state of New Jersey. Schiffenhaus Industries, Inc. purchased the outstanding capital stock of privately held Schiffenhaus Packaging Corp. on November 24, 1981 and continued the business as a subsidiary (PAS-00017804; PAS-00018005).

   In March 2006, Southern Container Corporation announced the acquisition of Schiffenhaus Industries, Inc. (PAS-00017804; PAS-00018063). Southern Container Corporation is also listed as having ownership of Schiffenhaus in a 2006 permit application (PAS-00017855). On January 1, 2009 Schiffenhaus Packaging Corporation was merged into Southern Container Corp. (PAS-00033644). According to a letter prepared by legal counsel for Schiffenhaus, dated May 11, 2010, Southern Container Corporation is a wholly-owned subsidiary of Rock-Tenn Company (PAS-00033644).

3. **Operational History/COC Use and Presence at the Facility**

   The facility manufactures corrugated sheets that are converted into corrugated cartons, displays, and other corrugated products (PAS-00017806). According to the "PRP Extraction Form and Evidence Concerning: Schiffenhaus Packaging Corporation," site operations have been consistent since they began in 1895 (PAS-00017809). However, it is noted that according to a letter prepared by Toner and DiBenedetto on behalf of Schiffenhaus, dated March 11, 2010, operations did vary over time as follows:

   1909: Schiffenhaus moved its operations to a facility located at 49 Fourth St.

   1909-1915: Schiffenhaus reported that they continued to use the same raw materials and manufacture the same products as was done at the Academy Street facility (PAS-00033645)

4. Identified COCs

There is no information regarding COCs in the available file material.

Historic Fill

The Allocation Team has determined that the facility site is not located on regional Historic Fill as designated by the NJDEP[1].

NJDEP has established that Historic Fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 COCs: PAHs, lead, copper, and mercury.[2] Accordingly, NJDEP technical requirements for property containing Historic Fill requires sampling for the EPA Target Compound List for PAHs and Target Analyte List for metals, including lead, copper, mercury, and the OU2 PAH COCs.[3] PAHs, lead, copper, and mercury are recognized by NJDEP to be constituents of Historic Fill at varying levels, not atypically at or exceeding residential soil standards.[4]

5. COC Pathways

Sanitary and Storm Sewer

There is no information regarding sewers in the available file material.

Direct Discharge

According to the "PRP Extraction Form and Evidence Concerning: Schiffenhaus Packaging Corporation," between 1895 and 1924 wastewaters discharged from the facility were likely discharged directly to the Passaic River via the Delavan Avenue CSO until the municipal sewers were tied into the PVSC system in 1924 (PAS-00017809; PAS-00031298).

Facility Data Report

SCHIFFENHAUS PACKAGING CORPORATION

Facility Name, Address and Size: Schiffenhaus Packaging Corporation (Schiffenhaus); 1895 to 1908: 204 Academy Street, Newark, NJ (acreage unavailable)

1. **Business Type:** Manufacturer of pre-printed linerboard and corrugated and solid fiber boxes; specializes in corrugated boxes and corrugated display items, coated or laminated packaging paper or plastic film; manufactures non-wooden partitions, shelving or lockers. The facility manufactures corrugated sheets that are, in turn converted into corrugated cartons, displays and other corrugated products (PAS-00017806-07).

2. **Time Period of Ownership/Operations**

   Operator: 1895 - 1908
   Owner: 1895 - 1908

   Schiffenhaus was started by William and Max Schiffenhaus under the name "Schiffenhaus Bros" in 1895; it was incorporated in the state of New Jersey on February 4, 1926, as "Schiffenhaus Packaging Corporation" (PAS-00017804; PAS-00018007). On July 28, 1981, Schiffenhaus Industries, Inc. was incorporated in the state of New Jersey. Schiffenhaus Industries, Inc. purchased the outstanding capital stock of privately held Schiffenhaus Packaging Corp. on November 24, 1981 and continued the business as a subsidiary (PAS-00017804; PAS-00018005).

   In March 2006, Southern Container Corporation announced the acquisition of Schiffenhaus Industries, Inc. (PAS-00017804; PAS-00018063). Southern Container Corporation is also listed as having ownership of Schiffenhaus in a 2006 permit application (PAS-00017855). On January 1, 2009 Schiffenhaus Packaging Corporation was merged into Southern Container Corp. (PAS-00033644). According to a letter prepared by legal counsel for Schiffenhaus, dated May 11, 2010, Southern Container Corporation is a wholly-owned subsidiary of Rock-Tenn Company (PAS-00033644).

3. **Operational History/COC Use and Presence at the Facility**

   The facility manufactures corrugated sheets that are converted into corrugated cartons, displays, and other corrugated products (PAS-00017806). According to the "PRP Extraction Form and Evidence Concerning: Schiffenhaus Packaging Corporation," site operations have been consistent since they began in 1895 (PAS-00017809). However, it is noted that according to a letter prepared by Toner and DiBenedetto on behalf of Schiffenhaus, dated March 11, 2010, operations did vary over time as follows:

   1895-1908: Schiffenhaus manufactured paper hat boxes and wood boxes/cases for the shipment of the paper hat boxes. Paper and wooden boxes were cut and glued by hand using purchased sheets of paper, wood and small pots of glue. Manufacturing took place at 204 Academy Street. Reportedly, no printing was conducted at this facility (PAS-00033645).

   1909: Schiffenhaus moved its operations to a facility located at 49 Fourth St.

The company reported in December 1994 that its production of corrugated products averaged 42 million square feet per month (PAS-00017806-07). It is noted that according to a letter prepared by Toner and DiBenedetto on behalf of Schiffenhaus dated March 11, 2010, this description is only accurate for the time period 1980 to the present (PAS-00033647).

4. Identified COCs

There is no information regarding COCs in the available file material.

Historic Fill

The Allocation Team has determined that the facility site is not located on regional Historic Fill as designated by the NJDEP[1].

NJDEP has established that Historic Fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 COCs: PAHs, lead, copper, and mercury.[2] Accordingly, NJDEP technical requirements for property containing Historic Fill requires sampling for the EPA Target Compound List for PAHs and Target Analyte List for metals, including lead, copper, mercury, and the OU2 PAH COCs.[3] PAHs, lead, copper, and mercury are recognized by NJDEP to be constituents of Historic Fill at varying levels, not atypically at or exceeding residential soil standards.[4]

Facility Data Report

SCHIFFENHAUS PACKAGING CORPORATION

Facility Name, Address and Size: Schiffenhaus Packaging Corporation (Schiffenhaus); 1925 to 2007: 2013 McCarter Highway, Newark, NJ; Approximately 4 acres (PAS-00031298; PAS-00017835; PAS-00018010). In 2006, there were 150 employees working 250 days a year, 2 shifts a day (PAS-00017835).

1. **Business Type:** Manufacturer of pre-printed linerboard and corrugated and solid fiber boxes; specializes in corrugated boxes and corrugated display items, coated or laminated packaging paper or plastic film; manufactures non-wooden partitions, shelving or lockers. The facility manufactures corrugated sheets that are, in turn converted into corrugated cartons, displays and other corrugated products (PAS-00017806-07).

2. **Time Period of Ownership/Operations**

   Operator: 1925 - 2007
   Owner: 1925 - 2007

   Schiffenhaus was started by William and Max Schiffenhaus under the name "Schiffenhaus Bros" in 1895; it was incorporated in the state of New Jersey on February 4, 1926, as "Schiffenhaus Packaging Corporation" (PAS-00017804; PAS-00018007). On July 28, 1981, Schiffenhaus Industries, Inc. was incorporated in the state of New Jersey. Schiffenhaus Industries, Inc. purchased the outstanding capital stock of privately held Schiffenhaus Packaging Corp. on November 24, 1981 and continued the business as a subsidiary (PAS-00017804; PAS-00018005).

   In March 2006, Southern Container Corporation announced the acquisition of Schiffenhaus Industries, Inc. (PAS-00017804; PAS-00018063). Southern Container Corporation is also listed as having ownership of Schiffenhaus in a 2006 permit application (PAS-00017855). On January 1, 2009 Schiffenhaus Packaging Corporation was merged into Southern Container Corp. (PAS-00033644). According to a letter prepared by legal counsel for Schiffenhaus, dated May 11, 2010, Southern Container Corporation is a wholly-owned subsidiary of Rock-Tenn Company (PAS-00033644).

3. **Operational History/COC Use and Presence at the Facility**

   The facility manufactures corrugated sheets that are converted into corrugated cartons, displays, and other corrugated products (PAS-00017806). According to the "PRP Extraction Form and Evidence Concerning: Schiffenhaus Packaging Corporation," site operations have been consistent since they began in 1895 (PAS-00017809). However, it is noted that according to a letter prepared by Toner and DiBenedetto on behalf of Schiffenhaus, dated March 11, 2010, operations did vary over time as follows:

   1925: Schiffenhaus moved to its current location on McCarter Highway, and phased out the production of paper and wooden boxes. Similar to historical operations, the original corrugating machine employed at this facility used silicate of soda as an adhesive (PAS-00033646).

1930s: Schiffenhaus began performing a “very limited amount” of printing directly on corrugated boxes. The machines utilized for printing were "printer slotters" that creased, slotted and printed sheets to be made into boxes. Reportedly, all printing involved oil-based inks, which could not be removed with wash water. The printer slotters were cleaned by hand with rags. Schiffenhaus employed a service which laundered the rags on a regular basis. Reportedly, there was “very little waste (and no process wastewater)” associated with the early printing process (1930s-1965) (PAS-00033647).

1948: Schiffenhaus purchased a new corrugator machine which used a corn starch-based adhesive (PAS-00033647).

1965: Schffenhaus purchased its first flexographic printing machine. Printing was limited to only 10% coverage of a regular slotted carton box and was performed at slow speeds. At this point in time, Schffenhaus began purchasing water-based flexographic inks (PAS-00033647).

1965-1975: Schffenhaus used primarily red and black water-based inks. A greater variety of inks were introduced once Schffenhaus began manufacturing display boxes. A new “Langston” corrugator was purchased in 1972, which continued to use the same type of cornstarch-based adhesive (PAS-00033647).

1975: Schffenhaus purchased a new flexographic printing machine with increased printing capability. At this time, Schffenhaus also began producing display boxes for the display industry. Schffenhaus noted that any discharge of wastewater associated with the increased printing operations occurred at the same time a federal NPDES permit was issued to PVSC (It is reported that PVSC obtained a NPDES permit on February 28, 1975 (PAS-00018073).

1979/1980: Schffenhaus purchased its first preprint machinery in late 1979 and begin pre-print operations in 1980. According to Schiffenhaus, any wastewater associated with the preprint operations was discharged during the time period that PVSC was covered under the NPDES permit (PAS-00033648).

The company reported in December 1994 that its production of corrugated products averaged 42 million square feet per month (PAS-00017806-07). It is noted that according to a letter prepared by Toner and DiBenedetto on behalf of Schiffenhaus dated March 11, 2010, this description is only accurate for the time period 1980 to the present (PAS-00033647). With respect to wastewater treatment, since at least 1998, Schiffenhaus has employed a batch wastewater pretreatment process using filter presses. Wastewater is collected in a 5,000-gallon holding tank, which then undergoes alum flocculation to remove copper and zinc so that these contaminants can be filtered out of the wastewater. All wastewater, including condensate from the facility boilers, is routed to the pretreatment system prior to its discharge to the municipal combined sewers. Wastewater pretreatment processes employed prior to 1998 are unknown (PAS-00017808). This wastewater treatment process to remove metals was also reported by the facility in 2006 (PAS-00017840).

4. Identified COCs

- Copper (use and generated)
- Lead (generated)
- Mercury (generated)

Metals – Copper, Lead, Mercury

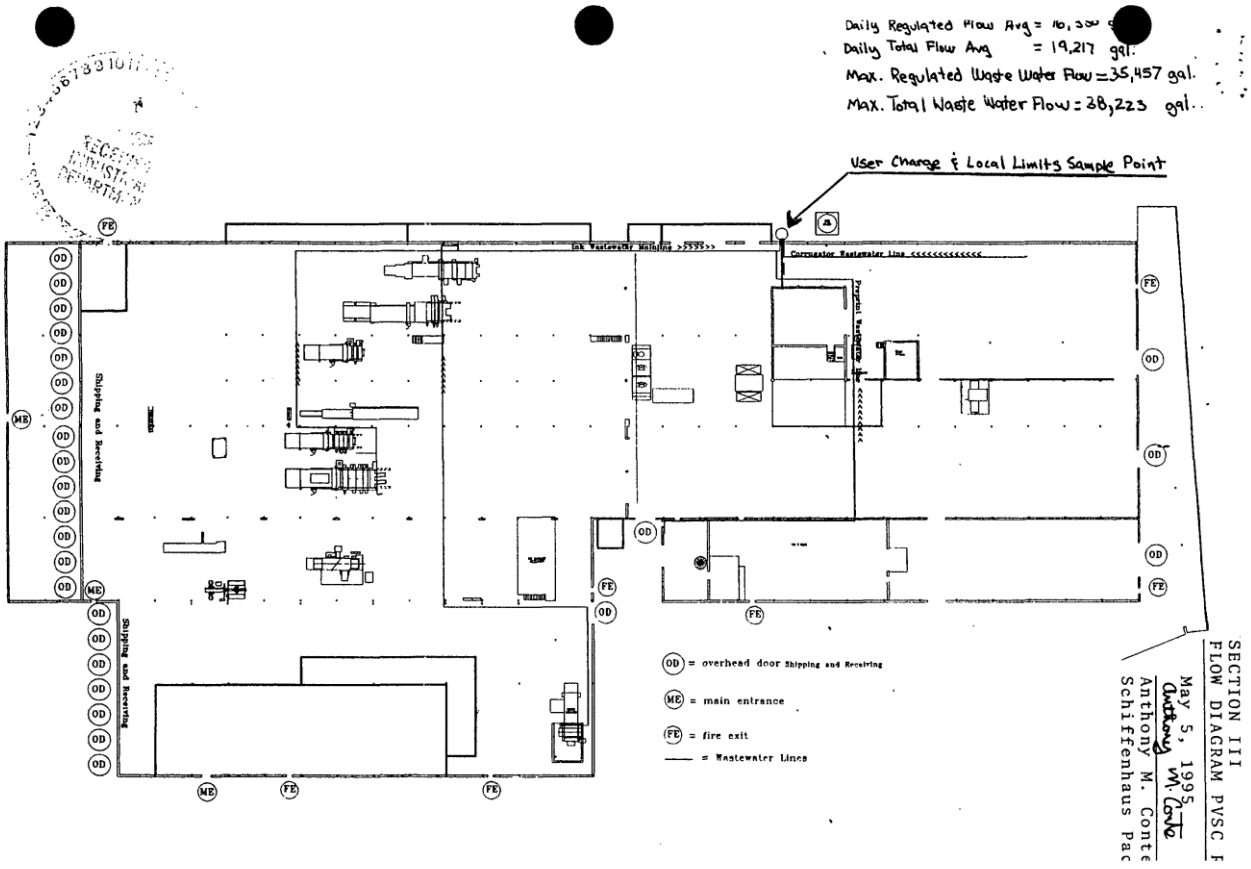
In 1995, Schiffenhaus determined that a source of copper in facility wastewater was printing inks utilized at the facility (PAS-00017999). Hazardous material use reported by the facility in 1996-1997 included "copper in pigments" (PAS-00017807).

Notices of violation and/or reports of non-compliance detailed in Section 7 below indicate that copper, lead, and mercury have been identified in facility wastewater at concentrations that exceed established compliance limits.

Historic Fill

The Allocation Team has determined that the 2013 McCarter Highway facility site is located on regional Historic Fill as designated by the NJDEP[1].

NJDEP has established that Historic Fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 COCs: PAHs, lead, copper, and mercury.[2] Accordingly, NJDEP technical requirements for property containing Historic Fill requires sampling for the EPA Target Compound List for PAHs and Target Analyte List for metals, including lead, copper, mercury, and the OU2 PAH COCs.[3] PAHs, lead, copper, and mercury are recognized by NJDEP to be constituents of Historic Fill at varying levels, not atypically at or exceeding residential soil standards.[4]



[1] *Digital Geodata Series, DGS04-7, Historic Fill for New Jersey*, https://www.nj.gov/dep/njgs/geodata/dgs04-7.htm, Quadrangle #52 & #53 (NJDEP map identifying locations of recognized historic fill).
[2] *Characterization of Ambient Levels of Selected Metals and cPAHs In New Jersey Soils* (2002) and *Characterization of Ambient Levels of Selected Metals and Other Analytes In New Jersey Soils* (1997), studies prepared for NJDEP, Division of Science and Research, by BEM Systems, Inc.
[3] New Jersey Department of Environmental Protection (NJDEP), *N.J.A.C. 7:26E Technical Requirements for Site Remediation,* Table 4-2, November 2009 [Note that Table 4-2 has been deleted from the current version of N.J.A.C. 7:26E (May 7, 2012) and the updated *Historic Fill Technical Guidance* (April 2013) as NJDEP believed that the tables list of historic fill constituents was too restrictive].
[4] NJDEP Table 4-2 (PAHs and lead) and a summary of NJDEP records regarding investigations of properties in the vicinity of the Passaic River recognized to be located in areas of Historic Fill indicate that the following average/maximum (mg/kg) contamination levels of OU2 COCs exist in area Historic Fill: PAHs (1.91/160), lead (574/10,000), copper (11.2/1,200), and mercury (0.21/3.7).

5. COC Pathways

Sanitary Sewer

In 1996 and 2006, all sanitary and process wastewater was reported by the facility to be discharged to the sanitary/combined sewer. No stormwater discharges were reported (PAS-00017909**;** PAS-00017838). In 1998, the facility reported that stormwater was discharged to the sanitary sewer (PAS-00017961).

A facility layout is presented below (PAS-00017984).

Direct Discharge

PVSC documentation indicates that wastewater generated at the 2013 McCarter Highway facility, including its industrial wastewater, are routed into a combined sewer located on McCarter Highway along the eastern border of the site. The sewer tie-in is situated approximately 350 feet south of the intersection of McCarter Highway and Verona Avenue in Newark (PAS-00017809).

It is noted, however, that PVSC did not obtain a NPDES permit until February 28, 1975 (PAS-00018073). Therefore, it is reported in the "PRP Extraction Form and Evidence Concerning: Schiffenhaus Packaging Corporation" that between 1924 and 1975, the wastewater discharge from Schiffenhaus to the PVSC system and its Delavan Avenue CSO location was likely bypassed to the Passaic River from the municipal tie-in. Based on this, it is reported in the "PRP Extraction Form and Evidence Concerning: Schiffenhaus Packaging Corporation" that discharge from Schiffenhaus was released to the Passaic River over an approximately 51-year period without a NPDES permit (PAS-00017811); however, COC uses and releases from the facility were not documented in the available file material until the mid-1990s (PAS-00017807; PAS-00017812; PAS-00017999).

6. Regulatory History/Enforcement Actions

Inspections and Violations

The following Notices of Violation (NOVs) and/or reports of non-compliance with wastewater discharge permits are associated with Schiffenhaus:

According to a letter prepared by PVSC, dated January 10, 1997, a December 1994 Baseline Monitoring Report indicated Schiffenhaus was "out of compliance" for copper. A NOV was issued by PVSC to Schiffenhaus for this exceedance in October 1996. Schiffenhaus subsequently advised in a July 1996 letter that the copper source may be copper phthalocyanine pigments (PAS-00017812; PAS-00017942; PAS-00017954). Note that available references do not include copies of the Baseline Monitoring Report and sewer connection permits.

In May 1995, Schiffenhaus was "out of compliance" with "Local Pretreatment Limitations" for copper (PAS-00017986-87). Reportedly, the facility was over the "threshold limit" for cadmium, chromium, copper, mercury and lead (PAS-00017991).

Sampling conducted by PVSC in September 1996 indicated that Schiffenhaus was "out of compliance" for both copper and zinc. A NOV was issued by PVSC to Schiffenhaus for this exceedance in October 1996 (PAS-00017812; PAS-00017951; PAS-00017986-88).

In January 1997, a NOV was issued by PVSC to Schiffenhaus due to the facility's failure to meet compliance milestones established in its Sewer Connection Permit for "local limits" on metals. According to the NOV, Schiffenhaus had advised a PSVC inspector that it was considering the installation of either chemical filtration or membrane filtration systems, but had yet to do so by the stipulated compliance schedule. PVSC advised that "several other milestones" stipulated in the Sewer Connection Permit had not been met at the time of the January 1997 inspection. PVSC advised that Schiffenhaus was determined to be in "significant non-compliance" with PVSC rules and regulations (PAS-00017812; PAS-00017941-42).

On October 17, 1997, PVSC filed a complaint in the Superior Court of the State of New Jersey against Schiffenhaus. The complaint alleged that Schiffenhaus violated its PVSC discharge permit by not being in compliance with “local pretreatment limits” established by the permit. Schiffenhaus agreed to pay a fine of $1,000 to settle the PVSC legal action (PAS-00017813; PAS-00017933).

Permits

Available file material indicates Schiffenhaus held PVSC Sewer Connection Permit No. 20403642 from July 14, 1996, through July 14, 2001 (PAS-00017935). In approximately 2006, Schiffenhaus applied for a PVSC Sewer Use Permit for the McCarter Highway location (PAS-00017835); the permit (20220038) was effective April 1, 2006, through March 31, 2011 (PAS-00017886). The application states that there were 150 employees working 250 days a year, 2 shifts a day (PAS-00017835). There was an estimated 3,349,403 gallons of process wastewater released to the sanitary combined sewer in 2005 (PAS-00017838). Outlet 20210037 received 13,398 gallons per day of process wastewater (PAS-00017841). An analysis of the industrial wastewater showed 0.102 mg/l copper and <0.0005 mg/l mercury (PAS-00017842). In the application, copper is noted as known to be present in the wastewater (PAS-00017847).

7. Response Actions

There is no information regarding response actions in the available file material.

8. Summary of Asserted Defenses

No legal defenses were identified in the available file material.

Diamond Alkali OU2 Allocation
ADR Confidential
Facility Data Report

SEQUA CORPORATION

Facility Name, Address and Size: Sequa Corporation, 185 Foundry Street, Newark, New Jersey; Approximately 0.8 acres (PAS-00044626); Sun Chemical Company occupied Building Nos. 23, 31, 32, 33, 34 and 34A on Lot 22.01 from 1967 to 1991 (PAS-00000242).

9 employees as of 1975; Operated 2 shifts per day, 5 days a week (PAS-00111828)
11 employees as of 1976 (PAP-00049166)
16 employees as of 1978; Operated 24 hours, 5 days a week (PAS-00000672)
15 employees as of 1980 (PAP-00374549; PAS-00014623)
10 employees as of 1985; Operated 3 shifts per day, 209 days per year (PAS-00044688)

1. **Business Type:** Organic pigment manufacturer (PAS-00000672). The pigments are used in the automobile industry, printing inks, and plastics (PAS-00000190; PAS-00105580; PAS-00128904).

2. **Time Period of Ownership/Operations**

   Operator: 1967 to December 31, 1986
   Owner: KEM Realty (1962-1971)/Foundry Street Corp. (1971-1990)

   The site at 185 Foundry Street was owned by KEM Realty Company from May 17, 1964 to May 3, 1971; then by Foundry Street Corporation from May 3, 1971 to November 20, 1990 (PAS-00008259; PAS-00008343-48; PAS-00008356-57; PAS-00111410). However, according to a *Request for Information*, dated August 23, 1996, the site at 185 Foundry Street was owned by KEM Realty Company from May 17, 1962 to May 3, 1971 (PAS-00008307).

   The lessee and operator of the site was Sun Chemical Corporation from 1967 to December 31, 1986 (PAS-00008259-60; PAS-00008307; PAS-00044098; PAS-00044630; PAS-00045525; PAS-00047105; PAS-00111390; PAS-00111410).

   According to *the Sequa Corporation Nexus and Request for De Minimis Settlement*, dated September 9, 2016, in December 1986, Sun/DIC Acquisition Corporation (the entity that changed its name to Sun Chemical Corporation) acquired certain pigment operations, including those at the Foundry Street site, from Sun Chemical Corporation (the entity that changed its name to Sequa Corporation) in an asset transaction (PAS-00047084). Sequa Corporation's 1987 Annual Report lists the date of sale as December 30, 1986 (PAS-00053981). Sun Chemical Corporation changed its name to Sequa Corporation on May 8, 1987 (PAS-00053973; PAS-00053978).

3. **Operational History/COC Use and Presence at the Facility**

   According to the *Evaluation of Alleged Nexus of Sequa Corporation to Lower Passaic River Study Area Superfund Site*, prepared for Sequa Corporation, dated September 9, 2016, manufacturing operations did not include the use of OU2 contaminants of concern (COCs) (PAS-00044631-33). In addition, according to a *Sun/DIC Acquisition Corporation Site Evaluation Submission*, dated February 22, 1987, a 1987 chemical

inventory did not include any of OU2 COCs for the Passaic River site (PAS-00044731-32).

According to a *Responsible Party Investigation Memorandum*, dated April 3, 1991, the production of red pigment utilized glacial acetic acid. Spent acid generated from the process was pumped to a tank where it was neutralized with caustic soda and discharged to the Passaic Valley Sewerage Commission (PVSC) (PAS-00000190; PAS-00044721; PAS-00047107; PAS-00111740; PAS-00128852).

According to the *Responsible Party Investigation Memorandum*, dated April 3, 1991, effluent generated from the production of violet pigment consisted of alcohol and phosphoric acid and was pumped to a neutralization tank for treatment with caustic soda. After the pH was adjusted the effluent was discharged into the PVSC (PAS-00000191; PAS-00047107; PAS-00128852). Caustic soda was used to neutralize process effluent in two interconnected 1,500-gallon aboveground storage tanks situated between Building Nos. 23 and 31. The treated effluent was discharged into a sump connected to an industrial sewer located on the adjacent property (Lot 4) owned by Norpak Corporation. Sun Chemical Corporation discharged its effluent into the strip drainage system located on the west side of the site before the installation of the wastewater treatment unit (PAS-00000191; PAS-00044721; PAS-00047107).

4. Identified COCs

- PCBs (detected)
- PAHs (used, detected)
- Copper (detected)
- Lead (detected)
- Mercury (detected)

PCBs

According to the *Responsible Party Investigation Memorandum*, dated April 3, 1991, polychlorinated biphenyls (PCBs) were detected as part of the October 1986 Environmental Cleanup Responsibility Act (ECRA) sampling conducted at the site (PAS-00000191). The soil sample contained PCBs at 13 ppm and the swipe sample contained PCBs as PCB-1242 with a total concentration of 14 milligram per square foot (mg/ft^2) (PAS-00104286, 294; PAS-00111611). According to a letter prepared by NJDEP, dated October 11, 1995, NJDEP agreed with Sun Chemical Corporation's assessment that PCB contamination in soil was attributable to fill (PAS-00045465).

PAHs

According to the *Evaluation of Alleged Nexus of Sequa Corporation to Lower Passaic River Study Area Superfund Site*, prepared for Sequa Corporation, dated September 9, 2016, No. 2 fuel oil was used in the facility boiler (PAS-00044631).

According to the *Responsible Party Investigation Memorandum*, dated April 3, 1991, polynuclear aromatic hydrocarbons (PAHs) were detected as part of the October 1986 ECRA sampling conducted at the site (PAS-00000191, 203). Note: The results table for the October 1986 sampling only reported a total base neutral compound concentration of 1,700 ppm in the sediment rather than the individual PAH concentrations (PAS-00104294).

Metals – Cooper, Lead and Mercury

COCs found in discharges to the sewer include copper, lead, and mercury (PAP-00049170-75; PAP-00374554; PAS-00000682; PAS-00014611; PAS-00014626-28; PAS-00044679-81; PAS-00128871-73).

A December 3, 1976 Sun Chemical letter to PVSC stated that the sampling results of the effluent showed that minute quantities of mercury, copper, and lead could be residual contaminants in the sewer lines from previous chemical manufacturing at the site. It was stated that these chemicals were not used in any processes at the site and were not believed to be present as impurities in the chemicals Sun Chemical Corporation used (PAP-00049201). Note: The date of the sampling was not provided.

An August 1978 PVSC Industrial Wastewater Questionnaire reported previous sampling results for copper (0.16 milligrams per liter [mg/l]), lead (0.1 mg/l), and mercury (0.06 mg/l), with a daily flow of 46,100 gallons per day (PAS-00000682). It appears these data were collected over 16 hours on December 30, 1975 (PAS-00014611).

Results reported with a 1980 PVSC sewer connection application for samples collected on December 17, 1979 listed copper (0.16 mg/l), lead (0.90 mg/l), and mercury (<0.002 mg/l), with a daily flow of 55,000 gallons per day (PAP-00049170-75; PAP-00374554; PAS-00014626-28; PAS-00044679-81; PAS-00128871-73).

According to a *Responsible Party Investigation Memorandum*, dated April 3, 1991, in October 1986, sampling was conducted at the site as part of a preliminary investigation. One soil sample from adjacent to the solid waste dumpster, and one sediment sample from the catch basin were collected as well as one swipe sample taken of an oily stain on the boiler room floor. The sediment and soil samples contained priority pollutant metals (including copper, lead, and mercury) (PAS-00000191, 203). According to the *Results of Sampling and Analysis Plan and Clean Up Plan*, dated November 30, 1988, copper was detected at 3.0 parts per million (ppm) (sediment) and 5.4 ppm (soil); lead was detected at 150 ppm (sediment) and 380 ppm (soil); and, mercury was detected at 0.45 ppm (sediment) and 0.82 ppm (soil) (PAS-00104294). According to the *Responsible Party Investigation Memorandum*, dated April 3, 1991, contamination could have migrated onto the facility through the drainage system and leaks in the sewer system, and that recurring flooding of the drainage system may have distributed past sources of contamination throughout the facility (PAS-00000192).

Historic Fill

The Allocation Team has determined that the facility site is not located on regional Historic Fill as designated by the New Jersey Department of Environmental Protection (NJDEP).[1]

NJDEP has established that historic fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 COCs: PAHs, lead, copper, and mercury.[2] Accordingly, NJDEP technical requirements for property containing Historic Fill requires sampling for the EPA Target Compound List for PAHs and Target Analyte List for metals, including lead, copper, mercury, and the OU2 PAH COCs.[3] PAHs, lead, copper, and mercury are recognized by NJDEP to be constituents of Historic Fill at varying levels, not atypically at or exceeding residential soil standards.[4]

However, according to a letter prepared by NJDEP, dated October 11, 1995, NJDEP agreed with Sun Chemical Corporation's assessment that PCB contamination in soil was attributable to fill at the site (PAS-00045465).

The levels of copper, lead and mercury detected at the site in soils are presented in the table below.

COCs Found in Onsite Soils	
COC	**Max Detected Concentration**
Lead	380 mg/kg
Copper	5.4 mg/kg
Mercury	0.82 mg/kg

5. COC Pathways

Sanitary and Storm Sewer

According to a memorandum prepared by NJDEP dated April 3, 1991, the site is part of the Foundry Street Complex. Approximately 30 buildings were situated throughout the complex, separated by narrow driveways which had strip-like drains in the middle of the

[1] *Digital Geodata Series, DGS04-7, Historic Fill for New Jersey*, https://www.nj.gov/dep/njgs/geodata/dgs04-7.htm, Quadrangle #52 & #53 (NJDEP map identifying locations of recognized historic fill).
[2] *Characterization of Ambient Levels of Selected Metals and cPAHs In New Jersey Soils* (2002) and *Characterization of Ambient Levels of Selected Metals and Other Analytes In New Jersey Soils* (1997), studies prepared for NJDEP, Division of Science and Research, by BEM Systems, Inc.
[3] New Jersey Department of Environmental Protection (NJDEP), *N.J.A.C. 7:26E Technical Requirements for Site Remediation,* Table 4-2, November 2009 [Note that Table 4-2 has been deleted from the current version of N.J.A.C. 7:26E (May 7, 2012) and the updated *Historic Fill Technical Guidance* (April 2013) as NJDEP believed that the tables list of historic fill constituents was too restrictive].
[4] NJDEP Table 4-2 (PAHs and lead) and a summary of NJDEP records regarding investigations of properties in the vicinity of the Passaic River recognized to be located in areas of Historic Fill indicate that the following average/maximum (mg/kg) contamination levels of OU2 COCs exist in area Historic Fill: PAHs (1.91/160), lead (574/10,000), copper (11.2/1,200), and mercury (0.21/3.7).

lane. The drains were connected to an industrial sewer line on Roanoke Avenue and received surface water run-off and industrial discharge from companies in the complex (PAS-00000186).

A December 1975 Waste Effluent Survey for Sun Chemical Corporation reported that 4,196,337 gallons of water were discharged to the sanitary sewer system in 1974. No water was reported as being discharged to a storm sewer or ditch (PAS-00111828-29; PAS-00128843-44).

A November 1976 Waste Effluent Survey for Sun Chemical Corporation reported that 8,454,000 gallons of water were discharged to the sanitary sewer system in 1976. No water was reported as being discharged to a storm sewer or ditch. The survey included results for copper (0.16 mg/l), lead (0.1 mg/l), and mercury (0.06 mg/l) from a 16 hour timeframe sample collected on December 30, 1975 (PAP-00049166-68). According to a letter from Sequa Corporation to PVSC, dated December 3, 1976, copper, lead, and mercury were not used in any form in Sequa Corporation's processes and to their knowledge were not present as impurities in any chemicals used. The letter stated the COCs were possibly attributable to residual trace metals in the sewer lines from previous manufacturers (PAP-00049201).

As a result of an October 1978 discharge of red dye to the Passaic River (which was not documented to contain OU2 COCs), Sun Chemical Corporation's discharge was inspected (PAS-00044634; PAP-00374544). It was stated that a concrete channel covered with metal plates diverts the wastes to a catch basin on Foundry Street from whence it flows to a combined sewer (PAP-00374544). This combined sewer consists, in part, of outdoor surface trench drains at portions of adjacent operators Arkansas Chemical and Automatic Electro Plating and subsurface piping to Roanoke Avenue. The Roanoke Avenue sewer then connects to a sewer on Doremus Avenue, which flows to the PVSC treatment works. There is a combined sewer overflow outfall to the Passaic River at the foot of Roanoke Avenue (PAS-00044625-26). According to a October 23, 1978 letter prepared by PVSC, since the city sanitary line on Doremus Avenue does not have the capacity to accept all of the flow from Roanoke Avenue, it overflows into the storm sewer and enters the Passaic River (PAP-00374544). It was also stated that Arkansas Co. Inc. was a chemical company next door which also used the same concrete channel (PAP-00374545).

A June 1979 Effluent Neutralization and pH Control Report documents that all of Sun Chemical Corporation's production effluent was discharged to the PVSC system (PAP-00374547; PAS-00105476-77; PAS-00128867).

An Industrial Pretreatment Program Annual Report, dated September 27, 1984, covering the period August 1, 1983 to July 31, 1984, reported that Sun Chemical had an average daily flow of 0.080 million gallons per day (mgd) into the PVSC sewer (PAP-00120043).

An *Industrial Pretreatment Program Annual Report*, dated July 1987, covering the period August 1, 1986 to July 31, 1987, reported that Sun Chemical Corporation had an average daily flow of 0.043 mgd into the PVSC sewer (PAP-00123478).

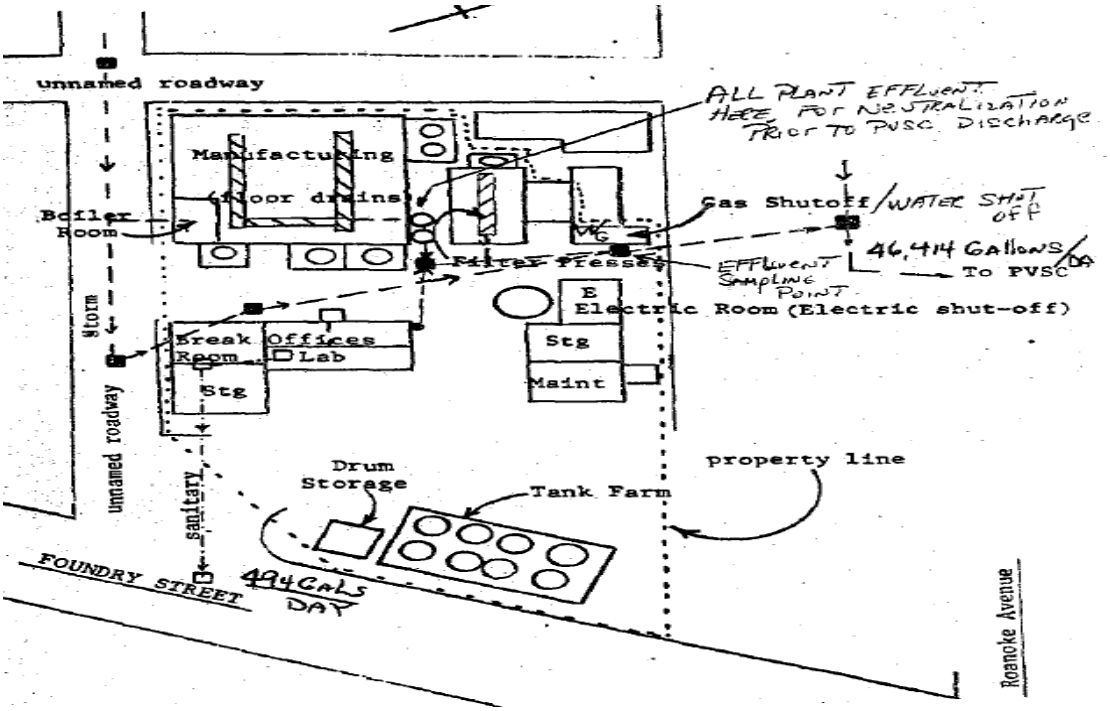
Facility Data Report



The following diagram illustrates the drainage system at Sun Chemical Corporation's site in 1986 (PAS-00044655):

A sewer layout from the 1970s is presented below (PAS-00044682):

A drainage plan in 1988 is presented below (PAP-00049180):

It is reported that the Roanoke Avenue combined sewer system and outfall to the Passaic River was documented by PVSC to have been inoperative in the late 1970s, allowing “polluting discharges” to enter the sewer system and discharge to the Passaic River. No discharges were specifically attributed to Sequa Corporation (PAS-00114295, 311, 320).

6. Regulatory History/Enforcement Actions

Inspections

There is no information regarding inspections in the available file material.

Violations

There is no information regarding violations with respects to COCs in the available file material.

Permits

A June 1977 Industrial Sewer Connection Application for Sun Chemical reported a discharge rate of 37,000 to 45,000 gallons per day (PAP-00374662).

Residuals from the manufacturing process are processed through on-site wastewater treatment works for pH adjustment and discharged to the PVSC sewer system under permit No. 204-010-42 (PAS-00111371, 388, 395).

7. Response Actions

Characterization Activities

According to a *Responsible Party Investigation Memorandum*, dated April 3, 1991, in October 1986, sampling was conducted at the site as part of a preliminary ECRA investigation. One soil sample from adjacent to the solid waste dumpster, and one sediment sample from the catch basin were collected as well as one swipe sample taken of an oily stain on the boiler room floor. The sediment and soil samples contained PCBs and priority pollutant metals (including copper, lead, and mercury) in addition to VOCs and petroleum hydrocarbons. The soil sample contained PCB at 13 ppm. Copper was detected at 3.0 ppm (sediment) and 5.4 ppm (soil); lead was detected at 150 ppm (sediment) and 380 ppm (soil); and, mercury was detected at 0.45 ppm (sediment) and 0.82 ppm (soil) (PAS-00104294). PCBs were also detected in the swipe sample as PCB-1242 with a total concentration of 14 mg/ft^2 (PAS-00000191, 203; PAS-00104286; PAS-00111611). This initial investigation identified three areas of environmental concern: the catch basin and drain system; the soil adjacent to solid waste dumpster; and, the boiler room (PAS-00044892; PAS-00104286; PAS-00111691; PAS-00128962).

Remedial Activities

All remedial activities took place following the December 31, 1986 asset transfer from Sun Chemical to Sun/DIC Acquisition Corporation.

Soil sampling and remediation took place to remove PCB contaminated soils and groundwater from the site. A total of 1,400 cubic yards of PCB-impacted soils were removed from accessible exterior areas, which were generally excavated to a depth of two feet. A total of 165 cubic yards of PCB-impacted soils were removed from the former Boiler Room floor, which was excavated to a maximum depth of 5.5 feet (PAP-00124050). To accommodate excavation in the former Boiler Room, approximately 2,300 gallons of impacted groundwater was also removed (PAP-00124085).

On July 25, 1997, the NJDEP issued No Further Action letters for the soil and groundwater investigation and remediation activities conducted at the site under Industrial Site Recovery Act Case Numbers 86960 and 90690 (PAP-00382238-41).

8. Summary of Asserted Defenses

Sequa asserts that at most, Sequa is a de minimis party and should receive an allocation share that comports with its de minimis status. Specifically, under CERCLA [Comprehensive Environmental Response, Compensation, and Liability Act], a party is de minimis when both of the following are minimal in comparison to other hazardous substances at the site: (i) the amount of the hazardous substances contributed by that party to the site, and (ii) the toxic or other hazardous effects of the substances contributed by that party to the site. 42 U.S.C. § 9622(g)(1)(A). Sequa satisfies both criteria.

Diamond Alkali OU2 Allocation

Facility Data Report

SETON COMPANY, INC. /SETON LEATHER COMPANY

Facility Name, Address and Size: Seton Leather Company (Seton); 10 acres (PAS-00124506)

- 62 Verona Avenue, Newark, New Jersey
- 349 Oraton Street, Newark, New Jersey
- 849 Broadway, Newark, New Jersey (PAS-00000628; PAS-00102324);

In 1980, a Sewer Connection Application with the Passaic Valley Sewerage Commission (PVSC) states that there were 450 employees, 5 days per week with 3 shifts per day (PAS-00102304-305).

1. **Business Type:** Leather tanning and finishing (PAS-00000628). The facility was primarily engaged in tanning and distribution of leather goods to the automobile and furniture upholstery industries (PAS-00008182).

2. **Time Period of Ownership/Operations**

   Operator: 1906-2006
   Owner: 1906-2006 (PAS-00124506)

   Seton was founded by Joseph Kaltenbacher, Joseph V. Clark, and Philip Murray in 1906. It was originally located at 62 Verona Avenue. It is reported the company expanded twelve hundred feet down Oraton Street to Broadway. It appears that the Verona Avenue, Oroton Street and Broadway addresses are all contiguous to each other. Seton became a public company in 1927. Seton moved to 849 Broadway in the late 1950s (PAS-00102324). In 1990, Philip Kaltenbacher was identified as the chief executive officer of Seton (PAS-00008182).

3. **Operational History/ COC Use and Presence at the Facility**

   Seton began operations in 1906; this included patent leather manufacturing. In the 1940s, the facility produced leather for the shoe and handbag industries. In 1956, patent leather was reported to be 40 percent of annual output (PAS-00102324). In 1972, it was reported that salt-cured cowhides were dehaired, tanned and dyed and the resultant leather was dried and finished for offsite shipment (PAS-00102287). Cowhide byproduct processing was also reported in 1980 (PAS-00102304). The general location of the facilities is shown on the map below.

   A June 6, 1975 Waste Effluent Survey states that the 849 Broadway location had 350 employees working 5 days per week with 3 shifts per day (PAS-00102299). In 1974, 93,100,000 gallons of wastewater was released to the sanitary sewer (PAS-00102300).

   In 1980, a Sewer Connection Application with the Passaic Valley Sewerage Commission (PVSC) states that there were 450 employees, 5 days per week with 3 shifts per day (PAS-00102304-305).

(PAS-00102389)

4. Identified COCs

- PCBs (use and detected)
- Copper (detected)
- Lead (detected)
- Mercury (detected)

PCBs

According to a letter prepared by Metcalf & Eddy (Seton's environmental consultant), dated April 24, 1990, in September 1989, Metcalf & Eddy collected two soil samples from stained soil located adjacent to several transformers at the facility. The staining was reported to be the result of dripping valves. PCBs were detected at concentrations of 5.4 ppm and 39 ppm. The contaminated soil was excavated and disposed offsite (PAS-00008173).

Metals – Copper, Lead and Mercury

In 1972, raw materials used by the facility were reported to be cured cowhides, salt, sulfuric acid, calcium hydroxide, basic chromium sulfate, and various leather finishes (PAS-00102287). Trivalent chromium was the only contaminant listed as a component of wastewater (PAS-00102289). In 1975, a sample of waste effluent contained copper at a concentration of "less than 0.946" parts per million (ppm) (likely indicating that the result was "non-detect" for copper) and lead at 0.95-4.75 ppm; these results were

described as "semiquantitative" (PAS-00102293-PAS-00102294). A 24-hour flow-proportioned composite sample was collected in 1979, and lead was reported at a concentration of 4.08 mg/l and mercury was reported at a concentration of 0.135 mg/l (PAS-00102307).

Historic Fill

The Allocation Team has determined that the facility site is not located on regional Historic Fill as designated by the NJDEP[1].

NJDEP has established that Historic Fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 COCs: PAHs, lead, copper, and mercury.[2] Accordingly, NJDEP technical requirements for property containing Historic Fill requires sampling for the EPA Target Compound List for PAHs and Target Analyte List for metals, including lead, copper, mercury, and the OU2 PAH COCs.[3] PAHs, lead, copper, and mercury are recognized by NJDEP to be constituents of Historic Fill at varying levels, not atypically at or exceeding residential soil standards.[4]

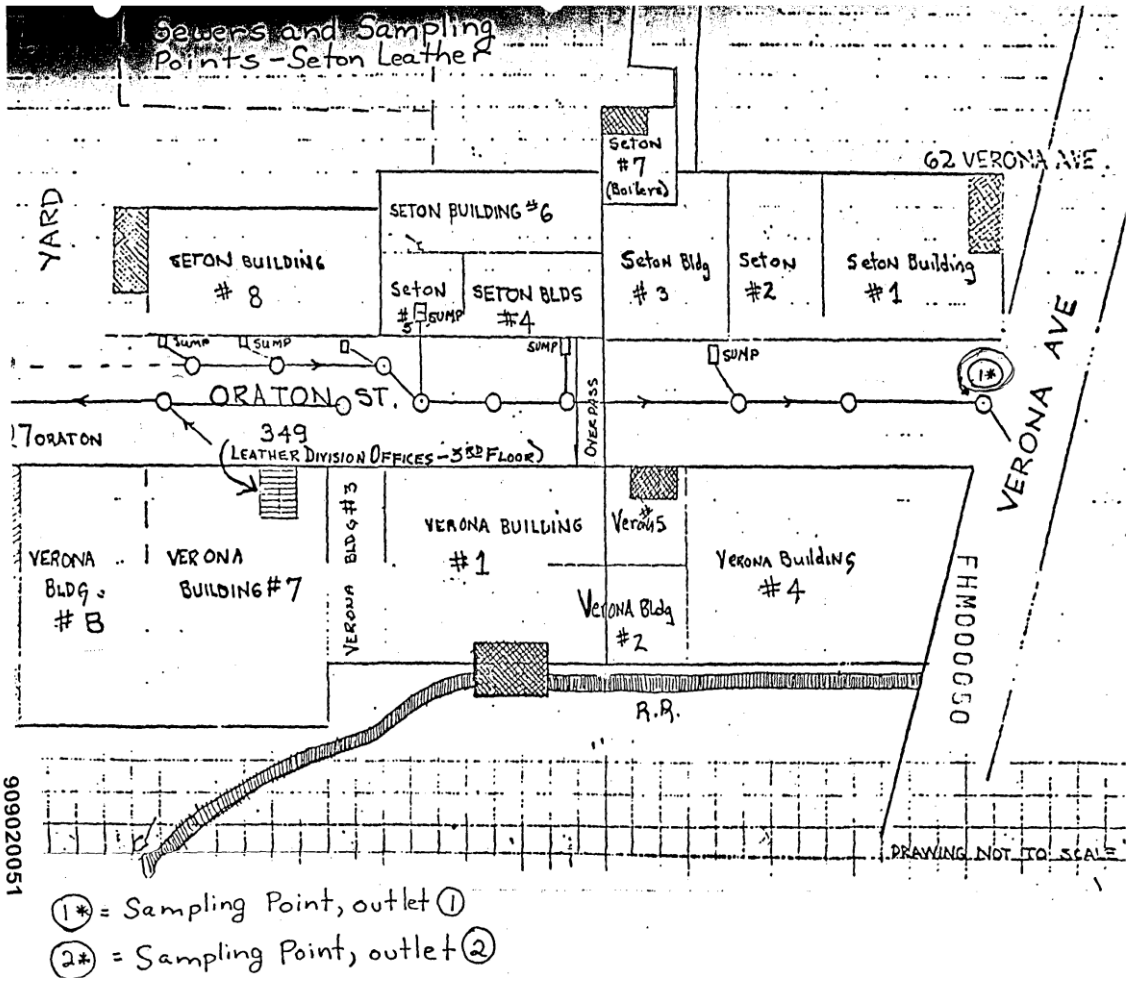
There is no information regarding sampling in the available file material.

5. COC Pathways

Combined Sewer Outlet

According to a letter prepared by Seton, dated February 12, 2007, Seton is located approximately 1,000 feet inland from the Passaic River. Seton stated that "the only alleged connection between Seton's former operations and the Passaic River are possibly some inadvertent discharges by the combined sewer outlet ("CSO") due to sewer overflows or otherwise heavy rain conditions" (PAS-00124505 - PAS-00124509).

No additional information on pathways through which contaminants could be discharged to the Passaic River were available. A facility layout is presented below (PAS-00102309).



---

[1] *Digital Geodata Series, DGS04-7, Historic Fill for New Jersey*, https://www.nj.gov/dep/njgs/geodata/dgs04-7.htm, Quadrangle #52 & #53 (NJDEP map identifying locations of recognized historic fill).

[2] *Characterization of Ambient Levels of Selected Metals and cPAHs In New Jersey Soils* (2002) and *Characterization of Ambient Levels of Selected Metals and Other Analytes In New Jersey Soils* (1997), studies prepared for NJDEP, Division of Science and Research, by BEM Systems, Inc.

[3] New Jersey Department of Environmental Protection (NJDEP), *N.J.A.C. 7:26E Technical Requirements for Site Remediation,* Table 4-2, November 2009 [Note that Table 4-2 has been deleted from the current version of N.J.A.C. 7:26E (May 7, 2012) and the updated *Historic Fill Technical Guidance* (April 2013) as NJDEP believed that the tables list of historic fill constituents was too restrictive].

[4] NJDEP Table 4-2 (PAHs and lead) and a summary of NJDEP records regarding investigations of properties in the vicinity of the Passaic River recognized to be located in areas of Historic Fill indicate that the following average/maximum (mg/kg) contamination levels of OU2 COCs exist in area Historic Fill: PAHs (1.91/160), lead (574/10,000), copper (11.2/1,200), and mercury (0.21/3.7).

Sanitary Sewer

In 1971, 1974, and 1979, the facility reported that all wastewater was discharged to the sanitary sewer, and no water was discharged to the “storm sewer, river, or ditch.” Discharge was reported to be continuous over a 24-hour period (PAS-00102288-89; PAS-00102300-PAS-00102301; PAS-00102306).

6. Regulatory History/ Enforcement Actions

Inspections and Violations

There is no information regarding discharges of COCs or associated violations in the available file material; however, the following is noted:

- A letter prepared by PVSC, dated April 13, 1956, stated that on that same date PSVC had visited Seton to discuss “the problem of dumping solid industrial waste into the sanitary sewer.” According to the letter, Mr. Weldon, the plant

superintendent, “readily admitted dumping various solids into their sanitary sewer in the process of cleaning. He also stated that frequently his men have to clean out the Newark sewer outside their building because of clogging with their waste” (PAS-00102266).

- According to a memo prepared by PVSC, dated July 10, 1978, PSVC documented poor housekeeping and illegal industrial discharges to the combined sanitary and storm sewer system on Verona Avenue. Reportedly, the discharged material contained “high pH liquids as well as animal fats, greases and oils.” Seton representatives indicated that they could not afford the pre-treatment that was required (PAS-00008172).

- It was reported in 1990 that PVSC and Seton were engaged in litigation in Superior Court in Newark over the company's alleged violation of its sewer connection permit and its alleged violation of PVSC rules concerning the pre-treatment of discharge into the sewer system (PAS-00008182). According to the Civil Action Consent Order filed on May 2, 1991, Seton’s wastewater discharge continued to exceed “pretreatment effluent limitations” for chromium, sulfur, and pH (PAS-00102337-338).

- On December 11, 1990, the New Jersey Department of Environmental Protection (NJDEP) filed a “Duty Office Notification Report” stating that a blue liquid was observed discharging into the Passaic River; Seton was listed as the responsible party (PAS-00102267). According to a letter prepared by Seton, dated February 12, 2007, “the New Jersey Department of Environmental Protection's claims of direct discharge by Seton to the Passaic River on December 11, 1990 are incorrect. Specifically, an investigation on December 11, 1990 by the New Jersey State Police, the U.S. Coast Guard and the PVSC exonerated Seton as the discharger and identified a neighboring company as the true and actual source of direct discharge to the Passaic River” (PAS-00124506).

Permits

On February 12, 1980, Seton filed a Sewer Connection Application with the Passaic Valley Sewerage Commission (PVSC) (PAS-00102304-305). Analytical results of effluent showed lead at 4.08 mg/l and mercury at 0.0135 mg/l (PAS-00102307). There were two sewer outlets noted. One on Verona Street that had a daily flow of 810,660 gallons and one on Grafton Avenue that had a daily flow of 19,392 gallons. Both were noted to contain industrial wastes. The Verona outlet showed 0.025 mg/l mercury and 0.04 mg/l lead; and the Grafton outlet showed 0.0135 mg/l mercury and 4.08 mg/l lead (PAS-00102309- PAS-00102314).

According to an undated *Pretreatment Compliance Report*, Seton holds a New Jersey Pollutant Discharge Elimination System (NJPDES) permit (No. NJ0098582) and a PVSC Sewer Connection permit (No. 20401363) (PAS-00102335). Available references did not include the permits or information for permitted flow rates and effluent monitoring requirements

For Public Disclosure by Consent of the Participating Allocation Parties and EPA (Fall 2022)

7. Response Actions

According to a letter prepared by Metcalf & Eddy, dated April 24, 1990, in September 1989, Metcalf & Eddy collected two soil samples from stained soil located adjacent to several transformers at the facility. The staining was reported to be the result of dripping valves. PCBs were detected at concentrations of 5.4 ppm and 39 ppm. The contaminated soil was excavated and disposed offsite (PAS-00008173).

8. Summary of Asserted Defenses

No legal defenses were identified in the available file material.

Diamond Alkali OU2 Allocation

ADR Confidential

Facility Data Report

SHERWIN WILLIAMS COMPANY

Facility Name, Address and Size: Sherwin Williams Company (Sherwin Williams), 60 Lister Avenue, Newark, New Jersey 11.04 acres (PAP-00126535) to approximately 13 acres (PAP-00126441); 69 employees (August 17, 1990) to 230 employees (December 31, 1983) (PAP-00126265)

1. **Business Type:** Sherwin Williams has operated a paint manufacturing facility producing both interior and exterior paints (oil-based, solvent-based, latex and alkyd), lacquers, thinners, oils, solvents, and alkyl resins. Since 1984, Sherwin Williams has only produced water-based latex paint (PAS-00124574; PAP-00126442).

2. **Time Period of Ownership/Operations**

   Operator: 1901 to 1999 (PAP-00126589-90)
   Owner: 1900 to 2011 (PAP-00126589; PAP-00126557)

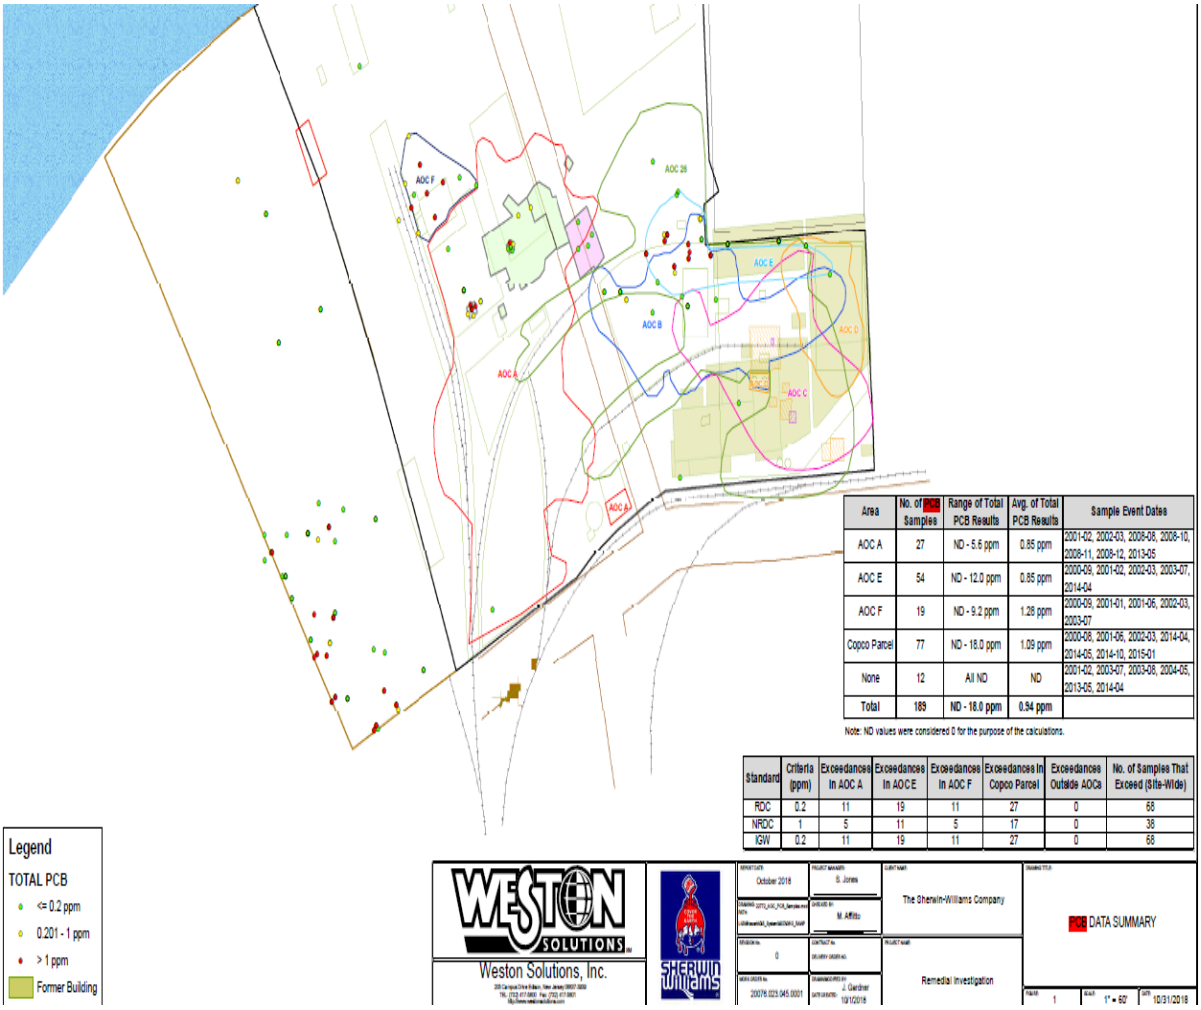
   Sherwin Williams operated at 60 Lister Avenue, Newark, New Jersey from 1901 to 1999. Sherwin Williams purchased the property west of Brown Street (Portion of Block 2437, Lot 62) in 1900. Production of paints and varnish began in 1901 (PAP-00126589-90). In September 1999, Sherwin Williams ceased operations (PAP-00126504; PAP-00126590). On January 14, 2011, the site was transferred from Sherwin Williams to Morris Lister Avenue Associates Urban Renewal, LLC (PAP-00126557).

3. **Operational History/COC Use and Presence at the Facility**

   According to a Waste Effluent Survey, dated May 16, 1972, the facility produced paints and varnishes using pigments, oils, and synthetic resins (PAS-00013182).

   According to a Hazardous Waste Investigation, dated February 4, 1982, the facility manufactured latex and alkyd resin (oil) based paints for consumer use only. Approximately 90% of production was latex material. Raw materials were received in dry or liquid forms. All materials were put into liquid forms on the third floor where pigments were dispersed into paint and blended. The paint then flowed to the second floor for cleaning. The first floor was used for filling. A facility representative stated at the time of inspection that no heavy metals were used in the paints. The main solvents used in the alkyd paints were mineral spirits and xylene. Small amounts of methyl ethyl ketone and toluene were also used (PAS-00123266).

   According to the Hazardous Waste Investigation, dated February 4, 1982, wastes produced from the latex manufacturing process included latex tank washes with water that was pumped into a settling tank where liquid was disposed into the sewer, and solids were removed for off-site disposal. Wastes produced from the alkyd manufacturing process included solvents used for tank wash, spent dirty solvent, and still bottoms from solvent distillation. Tank wash and spent solvents were reclaimed in a distillation process and still bottoms from distillation were disposed off site. Quality control lab wastes were put into 55 gallon drums and removed for off-site disposal or distilled on site (PAS-00123266).



According to the Hazardous Waste Investigation, dated February 4, 1982, discharges to the Passaic Valley Sewerage Commission (PVSC) consisted of domestic sewage and wash water from latex manufacturing (PAS-00123266-67).

4. Identified COCs

- PCBs (detected)
- Dioxins (detected)
- PAHs (detected)
- DDx (possible use, detected)
- Copper (detected)
- Lead (possible use, detected)
- Mercury (detected)

PCBs

The following *PCB Data Summary for Project: Remedial Investigation* map, dated October 2018 (October 2018 Map) provides a graphical summary of PCB data on the Sherwin Williams site and the adjacent Copco parcel (PAP-00367461). Note: The complete remedial investigation report was not provided.

The October 2018 Map shows three areas of concern (AOC) within the Sherwin Williams site with detected concentrations of PCBs. AOC A encompasses a large area in the south central portion of the site and had an average concentration of 0.85 parts per million (ppm) from 27 samples collected during seven sampling events from 2001 to 2013. The highest concentration of PCBs in this area was 5.6 ppm. AOC E encompasses an area on the north side of the southeastern portion of the site and also had an average concentration of 0.85 ppm from 54 samples collected during five sampling events from 2000 to 2014. The highest concentration of PCBs in this area was 12.0 ppm. AOC F is a small area just north and adjacent to AOC A. AOC F had an average concentration of 1.28 ppm from 19 samples collected during five sampling events from 2000 to 2003. The highest concentration of PCBs in this area was 9.2 ppm (PAP-00367461).

According to a *Final Soil Remedial Investigation Report*, prepared for Sherwin Williams, dated February 2017, sampling was conducted to delineate PCB contamination at the site in 2014. According to the report, PCBs detected above NJDEP standards in the southwest portion of the site ranged from "non-detect" in the downgradient portion of the Copco Parcel to 18.0 mg/kg in the southwestern (upgradient) corner of the former Copco Parcel. The PCB contamination begins and is most elevated at the property boundaries along the southwestern margin of the parcel and decreases in a northeasterly direction across the Copco Parcel. According to the report, the contaminant gradient, along with site-specific data (topography, surface water and groundwater flow direction) and the lack of historic use of PCBs on the Copco Parcel, show that the PCB contamination is due to an off-site source. The report states that based on the available historic data, Acme, a former oil refinery, historically located along the southwestern boundary of the Copco Parcel, is the probable source (PAP-00126581-82).

Dioxins

The *Assessment of Potential Sources of Release of Dioxin to the Environment from Reported Manufacturing Operations and Activities at the Diamond Shamrock Facility*, dated May 1, 1987, prepared by Paulus, Sokolowski and Sparton for the “Defense Steering Committee” (May 1987 Report) included depositions which discussed reports of several rupture disc releases. These releases were safety features resulting from an excess in pressure in the autoclave. The Homer Smith deposition reported that after the 1960 explosion and reconstruction, one release occurred while the ground was covered with snow. As a result of the snow, Homer Smith was able to trace the trail of discharged materials into and beyond the Sherwin Williams parking lot which was adjacent to the 80 Lister Avenue site. (PAP-00148674).

PAHs

According to the *ISRA Investigation Report Addendum*, dated August 2002 (August 2002 ISRA), as part of the investigative activities at the site, a Historic Fill investigation was performed. A total of 619 borings were installed (PAS-00126541). The report states that semi-volatile organic compounds (SVOC) and metal analytes (excluding lead in the area of a former foundry) detected in the soils were related to the extensive

historic filling operations conducted and not site operations (PAS-00126542). Note: SVOCs can include PAHs.

In addition, the August 2002 ISRA reported the analytical results of the samples collected during the Historical Fill investigation show that “low levels” of base neutral contamination exist on the site. Benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, indeno(1,2,3-cd)pyrene, had occasional detections.The August 2002 ISRA concluded that PAH contaminants were not considered to be COCs at this facility as they were related to Historic Fill and not historic site operations (PAP-00126545).

DDx

According to an affidavit of a former employee (employed from 1945 to 1984) Sherwin Williams made and packaged DDT prior to his employment with Sherwin Williams and until the 1950s. The packaging of the DDT reportedly was performed in building No. 7 at the facility. Building No. 7 was removed after production of DDT ceased (PAS-00013180). A survey drawing of the facility in 1934 depicts a building that was used for storage of “thinner, reducer, roof paint, and insecticides,” but no building No. 7 was identified (PAP-00126219).

A Transcript of Proceedings concerning Diamond Shamrock Chemicals, dated October 1988 described an instance where DDT solution overflowed from a tanker at the adjacent, former Diamond Shamrock site and ran down the tracks onto the Sherwin Williams site (PAP-00145018-19).

No other documentation regarding the potential for DDT manufacture or use at the facility was identified. However, insecticides may have been stored at the facility in the 1940s through 1960s (PAP-00126219). According to an *ISRA Investigation Report*, dated October 2001 (October 2001 ISRA), an insecticide storage area was identified as an area of concern at the site; however, only a portion of the cited documented was available for review, and a description of the area of concern was not identified (PAP-00126497).

Metals – Copper, Lead and Mercury

According to a letter prepared by Sherwin Williams, dated August 31, 1972, facility waste effluent contained copper at 0.1 ppm, lead at 0.3 ppm, and no mercury (PAS-00013186).

An undated *Heavy Metals Source Determination Study,* conducted between 1976 and 1978, prepared by Killam Associates for PVSC, to study the sources of heavy metals in the influent to the PVSC's treatment plant reported a flow of 0.3250 million gallons per day (mgd) for Sherwin Williams with concentrations reported in pounds per day (lb/day) and milligram per liter (mg/L) for copper (1.480 lb/day or 0.546 mg/L), lead (0.347 lb/day or 0.128 mg/L), and mercury (0.0027 lb/day or 0.001 mg/L) (PAS-00052110-11).

An undated form titled *Industrial Waste Contribution to Municipal System* (possibly from May 1981) listing the characteristics of the wastewater discharged by Sherwin Williams reported copper (0.132), lead (1.16), and mercury (0.001) (PAS-00014648). Note: The units of the measurement were not provided.

A letter from Sherwin Williams to PVSC, dated April 28, 1995 regarding a Baseline Monitoring Report requested non-discharger status for five metals including copper and mercury (PAP-00126240-41).

Historic Fill

The Allocation Team has determined that the facility site is located on regional Historic Fill as designated by the NJDEP.[1]

NJDEP has established that historic fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 COCs: PAHs, lead, copper, and mercury.[2] Accordingly, NJDEP technical requirements for property containing Historic Fill requires sampling for the EPA Target Compound List for PAHs and Target Analyte List for metals, including lead, copper, mercury, and the OU2 PAH COCs.[3] PAHs, lead, copper, and mercury are recognized by NJDEP to be constituents of Historic Fill at varying levels, not atypically at or exceeding residential soil standards.[4]

According to a *Final Soil Remedial Investigation Report*, prepared for Sherwin Williams, dated February 2017, the entire site has been reclaimed with historic fill which is heterogeneous in composition and texture and is approximately 10 feet thick (PAP-00126564). The report states that filling of the site began prior to 1892 to raise the grade prior to construction of the former paint manufacturing plant (PAP-00126562-63). In addition, the document notes that during Sherwin Williams's ownership, approximately 90% of the site was covered by pavement or building foundations, with the exception of two rail spurs and the former AST Farm No. 1 located in the southwest portion of the property (PAP-00126563).

---

[1] *Digital Geodata Series, DGS04-7, Historic Fill for New Jersey*, https://www.nj.gov/dep/njgs/geodata/dgs04-7.htm, Quadrangle #52 & #53 (NJDEP map identifying locations of recognized historic fill).

[2] *Characterization of Ambient Levels of Selected Metals and cPAHs In New Jersey Soils* (2002) and *Characterization of Ambient Levels of Selected Metals and Other Analytes In New Jersey Soils* (1997), studies prepared for NJDEP, Division of Science and Research, by BEM Systems, Inc.

[3] New Jersey Department of Environmental Protection (NJDEP), *N.J.A.C. 7:26E Technical Requirements for Site Remediation,* Table 4-2, November 2009 [Note that Table 4-2 has been deleted from the current version of N.J.A.C. 7:26E (May 7, 2012) and the updated *Historic Fill Technical Guidance* (April 2013) as NJDEP believed that the tables list of historic fill constituents was too restrictive].

[4] NJDEP Table 4-2 (PAHs and lead) and a summary of NJDEP records regarding investigations of properties in the vicinity of the Passaic River recognized to be located in areas of Historic Fill indicate that the following average/maximum (mg/kg) contamination levels of OU2 COCs exist in area Historic Fill: PAHs (1.91/160), lead (574/10,000), copper (11.2/1,200), and mercury (0.21/3.7).

The levels of PAHs, copper, lead and mercury detected at the site in soils are presented in the table below PAP-00367331-57).

COCs Found in Onsite Soils	
COC	**Max Detected Concentration**
Lead	111,000 mg/kg
Copper	7,010 mg/kg
Mercury	6,030 mg/kg
Benzo(a)anthracene	200 mg/kg
Benzo(a)pyrene	210 mg/kg
Benzo(b)fluoranthene	250 mg/kg
Benzo(k)fluoranthene	89 mg/kg
Dibenzo(a,h)anthracene	24 mg/kg
Indeno(1,2,3-cd)pyrene	94 mg/kg

According to the August 2002 ISRA, as part of the investigative activities at the site, a Historic Fill investigation was performed. A total of 619 borings were installed (PAS-00126541). The report states that SVOC and metal analytes (excluding lead in the area of a former foundry) detected in the soils were related to the extensive historic filling operations conducted and not site operations (PAS-00126542). Note: SVOCs can include PAHs.

In addition, the August 2002 ISRA reported the analytical results of the samples collected during the Historical Fill investigation show that low levels of base neutral contamination exist on the site. Benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, indeno(1,2,3-cd)pyrene, and lead had occasional detections. In addition, the report stated that other contaminants that had been detected during the course of the site investigation that were not associated with the Sherwin Williams operations were likely associated with the Historic Fill including copper (PAP-00126543).

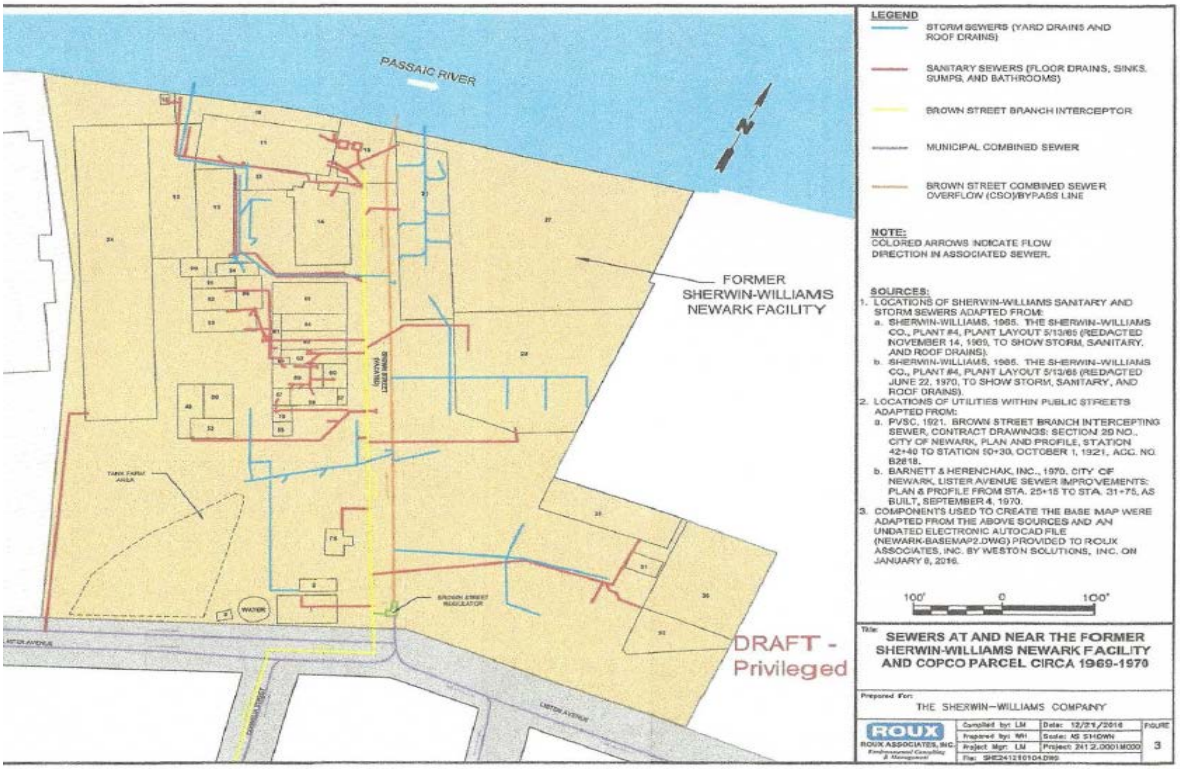
Finally, the August 2002 ISRA concluded that PAH and metal contaminants, with the exception of lead, were not considered to be COCs at the Sherwin Williams facility as they were related to Historic Fill and not historic site operations (PAP-00126545).

5. COC Pathways

Sanitary Sewer

According to the Hazardous Waste Investigation, dated February 4, 1982, discharges to the PVSC consisted of domestic sewage and wash water from latex manufacturing (PAS-00123266-67).

In addition, a *PVSC Brown Street Branch Interceptor Evaluation*, dated July 1981, also states that the Brown Street Branch Interceptor was placed in service in the 1920s to intercept dry weather flows in the Polk Street, Freeman Street, and Brown Street combined sewers. Prior to construction of the interceptor these combined sewers discharged directly into the Passaic River. The interceptor enabled dry weather sewage



flows to be to the PVSC's Newark Bay WWTP (PAP-00056471). It also states there were no provisions for bypassing the interceptor during wet weather and that interceptor was a safeguard to water quality in the Passaic River (PAP-00056471-72).

Finally, Sherwin Williams provided diagrams PVSC prepared in 1921 and 1922 of the interceptor connection which show that the connection box was constructed by PVSC to explicitly prevent any process wastewater generated at the Sherwin Williams site from entering the PVSC CSO system. Therefore, Sherwin Williams's process wastewater reportedly did not discharge into the Passaic River during wet weather flows; all of Sherwin Williams' site process wastewater after 1924 entered the PVSC municipal sewer system (PAP-00367228-36).

According to a Waste Effluent Survey, dated May 16, 1972, in 1971, 64,429,000 gallons of water were discharged to the sanitary sewer; no water was discharged to the "storm sewer, river or ditch (PAS-00013183).

According to a Hazardous Waste Investigation, dated February 4, 1982, a facility representative estimated the average flow into PVSC at 150,000 gallons/day. Review of measurements kept by Sherwin Williams for the last six months stated a flow range of 60,000 to 250,000 gallons/day (PAS-00123267).

The following diagram shows the locations and pathways of the various sewer lines on the Sherwin Williams site:

(PAP-00367458)

Storm Sewer

According to an affidavit of a former employee (employed from 1967 to 1988), mixing tanks were used to make oil base paints and water based paints. Depending on the paint being made in the mixing tank, either a thinner or water solution was used to clean the mixing tanks. The cleaning solution was funneled into the sewer system that discharged directly to Passaic River. The discharging of the thinner solution to the Passaic River occurred primarily at night (PAS-00123255). Note: Details regarding the cleaner, the contents of the paint-contaminated solutions, and the quantities discharges are not provided. It is not documented that the discharges contained OU2 COCs.
As stated in the Affidavit of Raymond A. Cebulski, a former Sherwin Williams employee, the City of Newark installed a lateral connection between the Brown Street storm and sanitary sewer lines sometime between 1971 and 1981. He reported that wastewater could flow between the storm and sanitary sewers by way of this lateral connection (PAS-00123253). No documentation to support this affidavit was identified in the file material.

As reported in the *1971 Annual Report to the Passaic Valley Sewerage Commissioners*, the end of Brown Street Sewer at Lister Street was sealed during April 1971. The sewer now only drained stormwater from the Sherwin Williams site. Observations from April 19 to 26, 1971 by Inspector J. McLaughlin stated no discharge from the pipe (PAS-00034624).

Direct Release

There is no information regarding direct release in the available file material.

Spills

According to a *Newark Site Investigation Plant History and Example Areas of Concern*, dated May 21, 1999, a leak in an aboveground storage tank (AST) containing slurry and cracks in the AST pad resulted in a release to the Passaic River in March 1998. No known samples were collected from this area following the cleanup (PAP-00126438). The document does not state if OU2 COCs were associated with the slurry.

According to an affidavit of Raymond A. Cebulski, a former Sherwin Williams employee (from 1942 to 1981) emulsion paint spills occurred in building # 11 and some of the paint would wash down the storm sewer and over the bulkhead and into the Passaic River (PAS-00123253). The document does not state if OU2 COCs were associated with the spills.

6. Regulatory History/Enforcement Actions

Inspections and Violations

Correspondence from January and February 1986 discusses violations of PVSC regulations caused by the cleaning of Sherwin Williams's effluent discharge sewer on Brown Street. The cleaning was necessary as a result of an accidental in-plant chemical

spill, which caused blockages within their waste piping disposal system. The cleaning of this line caused an accumulation of gray viscous material in the PVSC sand catcher located at the entrance of the Sherwin Williams site (PAS-00014642-47). No specifics regarding the constituents of the material was provided. Therefore, it us unknown if it contained OU2 COCs.

NJDEP filed an Incident Notification Report on June 9, 1986 for a discharge of white paint pigment from a 12-inch storm drain into the Passaic River caused by cleaning a storm drain. An investigation was conducted by NJDEP on June 16, 1986, and noted that there were not any discharges evident at that time (PAS-00123288, 90). No specifics regarding the constituents of the material was provided. Therefore, it us unknown if it contained OU2 COCs.

On September 10, 1986, NJDEP issued a Notice of Violation of Title 23:5-28, NJ Revised Statutes for the reported discharge of paint pigments into the Passaic River. It had been determined during an investigation on June 9, 1986 and subsequent dates that the pigments had been released from the Sherwin Williams site during a cleaning operation. A fine of $300.00 was assessed (PAP-00367264-65; PAS-00008237; PAS-00008238-39; PAS-00123292-4). The notice did not state if any COCs were present or expected in the waste.

Correspondence from May and June 1987 discusses the continued problem of paint materials discharging from Sherwin Williams and clogging up the PVSC sand catcher located at the entrance of the Sherwin Williams site (PAS-00014638-41). No specifics regarding the constituents of the material was provided. Therefore, it us unknown if it contained OU2 COCs.

Permits

According to a Hazardous Waste Investigation, dated February 4, 1982, Sherwin Williams received Permit No. 20401500 to discharge to PVSC on May 29, 1981. This permit expired on May 29, 1986 (PAS-00123267).

There is no additional information regarding permits in the available documents.

7. Response Actions

Characterization Activities

The following characterization activities have taken place at the facility:

- ISRA Investigation Report (October 2001)
- Site Evaluation of 80 Lister Avenue (February 1985)
- ISRA Investigation Report Addendum (August 2002)
- Remedial Action Report (December 2006)

Evaluation of Dioxin Contamination Attributed to Adjacent Diamond Shamrock

According to an *ISRA Investigation Report*, dated October 2001 (October 2001 ISRA), the first investigation conducted at the site in the mid-1980s was related to a reported chemical spill from a rail car tanker on a rail spur located on Sherwin Williams's site. The chemical spill was associated with production operations at the adjacent CLH Superfund site. An investigation of railroad tracks located on the Sherwin Williams site was performed by IT Corporation (PAP-00126513-14). The October 2001 ISRA reported that during June and July of 1983, 41 soil samples were collected from two railroad spurs adjacent to and in the vicinity of the Sherwin Williams site. The results of the sampling showed that elevated levels of dioxin above the NJDEP action level of 1.0 parts per billion (ppb) were present on the Sherwin Williams site. This contamination was limited to the railroad spur south of the Sherwin Williams site along Lister Avenue, the railroad spur located on the Sherwin Williams site, and a small paved area used for truck storage, loading and unloading of product and materials, respectively. Remediation activities, consisting of excavation and post-excavation sampling, were conducted in 1985 (PAP-00126514; PAP-00149957-58).

The April 10, 1984 *Evaluation of the 80 Lister Avenue 2,3,7,8-Tetrachlorodibenzo-P-Dioxin (TCDD) Data in Conjunction with Available CDC Guidance Documents* reported the results of sampling conducted in 1983. Three of four composite soil samples collected from the Sherwin Williams site reported concentrations of 2,3,7,8-TCDD ranging from 0.88 ppb to 1.6 ppb. 2,3,7,8-TCDD was not detected in the fourth composite sample (PAS-00125463). Three of four "sweep" samples reported concentrations of 2,3,7,8-TCDD ranging from 0.11 ppb to 1.6 ppb. 2,3,7,8-TCDD was not detected in the fourth "sweep" sample. A soil sample also collected reported a concentration of 2,3,7,8-TCDD of 0.35 ppb (PAS-00125465).

According to the *Site Evaluation of 80 Lister Avenue*, dated February 1985, as part of the 1984-1985 remedial investigation of the adjoining Diamond Shamrock property, five samples at multiple depths were taken from the Sherwin Williams site and analyzed for dioxin and priority pollutants (PAS-00128232; PAS-00127089-90). 2,3,7,8-TCDD was detected in three samples at concentrations ranging from 1.2 (0-6 inches) to 5.1 ppb (6-12 inches), 2,3,7,8-tetrachloro-dibenzofuran was detected in one sample at 19.9 ppb (12-24 inches), and octachlorodibenzo-p-dioxin was detected in one sample at 15.7 ppb (12-24 inches) (PAS-00127967). Base neutral compounds detected included acenaphthene (1,600 μg/kg, 12-24 inches), fluoranthene (3,000-26,000 μg/kg, 0-24 inches), naphthalene (1,100 μg/kg, 12-24 inches), chrysene (3,700-27,000 μg/kg, 0-24 inches), acenaphthylene (290 μg/kg, 12-24 inches), anthracene, (330-4,300 μg/kg, 0-24 inches), benzo(a)anthracene (1,800-15,000 μg/kg, 0-24 inches), benzo(a)pyrene (18,000 μg/kg, 12-24 inches), benzo(b)fluoranthene (29,000 μg/kg, 12-24 inches), benzo(g,h,i)perylene (9,300 μg/kg, 12-24 inches), fluorene (2,200 μg/kg, 12-24 inches), phenanthrene (2,200-21,000 μg/kg, 0-24 inches), indeno(1,2,3-cd)pyrene (6,300 μg/kg, 12-24 inches), and pyrene (5,300-28,000 μg/kg, 0-24 inches) (PAS-00127970-72). The chlorinated herbicide 2,4-D was detected at 220-250 μg/kg (0-24 inches). Metals detected included lead (3.1-44 ppm, 0-12.5 feet), copper (71-180 ppm, 0-12.5 feet), and mercury (0.5-11 ppm, 0-12.5 feet) (PAS-00127974).

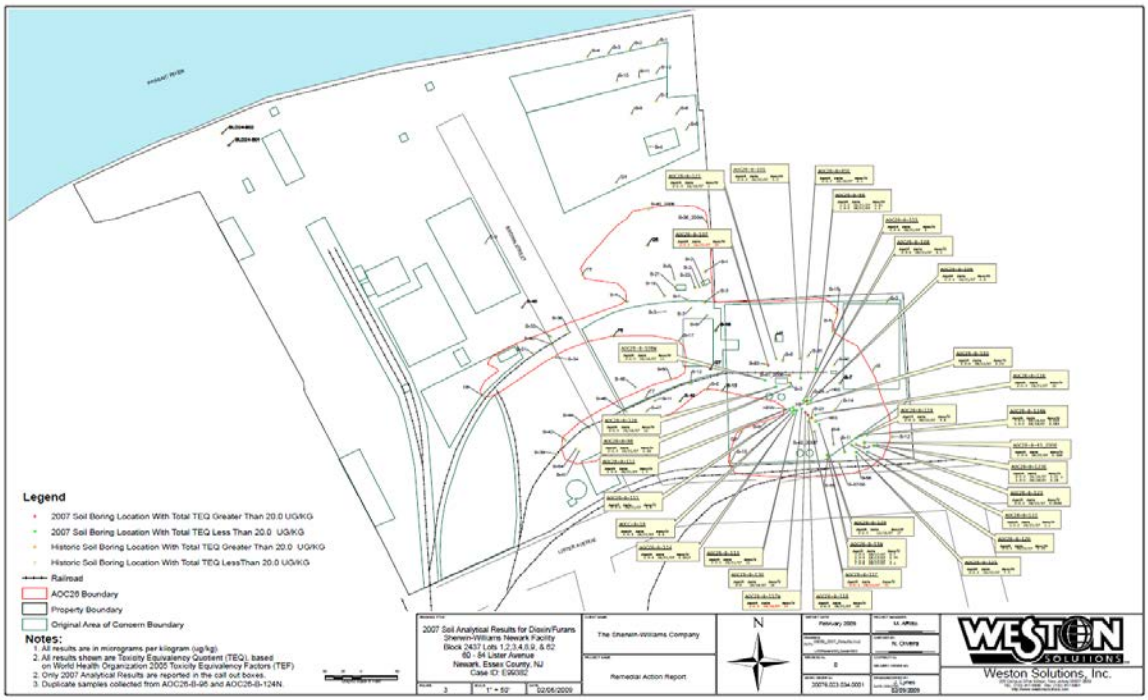
Diamond Alkali OU2 Allocation



ADR Confidential

Facility Data Report

The *Site Evaluation Addendum for 80 & 120 Lister Ave*, dated February 1986 reported that following the original remedial investigation of the adjoining Diamond Shamrock property, additional sampling was conducted. Soil samples were obtained from an additional seven borings located drilled in the spring and early summer of 1985 on the Sherwin Williams site (PAS-00126244).

The August 2002 ISRA concluded that all dioxin contamination is related to historic operations by CLH and that it was likely that a significant portion of the pesticide contamination identified at the Sherwin Williams site is related to CLH. PAH and metal contaminants, with the exception of lead, were not considered to be COCs as they were related to Historic Fill and not historic site operations (PAP-00126545).

According to the *Remedial Action Report to Address Soils Contamination in AOC 26, Former Sherwin-Williams Newark Facility*, dated February 2009, a comprehensive soil boring program was conducted in December 2006 to collect soil samples in an effort to determine both vertical and horizontal extent of any previously confirmed dioxin/furan-impacted soils at the site. In June, August, and October 2007, additional soil sampling activities were conducted to determine the vertical and horizontal extent of previously identified soil-boring locations where dioxin levels exceeded 20 μg/kg Toxicity Equivalency Quotient (TEQ). The soil sampling was done to prepare for the remedial action activities in AOC 26. The total TEQ concentration was above 20 μg/kg in three soil samples collected from the surface interval (PAP-00367375-77). All three of these sample locations were near the center of the southeastern portion of the facility (PAP-00367389). See figure on the next page:

(PAP-00367389)

Evaluation of Other COCs at Sherwin Williams Site

In September 1999, Sherwin Williams ceased operations. This cessation of operations triggered the requirements of the NJDEP ISRA under which the owner or operator must conduct remedial activities (PAP-00126504). Accordingly, a Preliminary Assessment (PA) was conducted in accordance with the NJDEP Technical Requirements for Site Remediation. The PA identified 26 areas of potential AOCs at the site. Several of the AOCs involved COCs including lead, dioxins, and PCBs. In addition, the AOCs which involved mostly VOCs also included the COC, naphthalene. Site Inspection (SI) activities were conducted at each individual potential AOC. The purpose of the SI was to determine the presence of contaminants at the AOC and characterize the contaminants, if necessary (PAP-00126497).

According to the October 2001 ISRA, lead contamination was a concern at a former lead foundry location and a portion of the former acid underground storage tank (UST) and AST location. The concentrations of lead exceed the Residential Direct Contact Soil Cleanup Criteria (RDCSCC), Non-Residential Direct Contact Soil Cleanup Criteria (NRDCSCC), and the maximum Historic Fill concentrations as listed in the NJDEP Historic Fill Database. Lead concentrations exceeded the maximum Historic Fill values in four locations (PAP-00126500). Note: The concentrations of lead were not provided in the source document. The October 2001 ISRA states that there are two likely sources of lead contamination: historic filling activities that were performed to bring the site up to the current grade and/or a former lead foundry identified on historical figures. It was also noted that additional delineation would not be performed since the documented historic fill prevented delineation to RDCSCC (PAP-00126500).

According to the October 2001 ISRA, PCB contamination was a concern at the former transformer pad No. 1, former UST No. 1, and a portion of former drum storage area No. 4. The potential source of the PCB contamination identified at the former transformer pad No. 1 was the pad-mounted transformers formerly located south of Building 28. The PCB concentrations exceeded the RDCSCC in six samples. The NRDCSCC was exceeded in four samples. Additional PCB delineation was required at this area (PAP-00126501). Note: The concentrations of the PCBs were not provided in the source document.

According to the October 2001 ISRA, PCB contamination was also a concern at the former transformer pad No. 2, former varnish storage area, and the northern portion of the former railroad tracks. The potential source of the PCB contamination identified in this location was the pad-mounted transformers formerly located west of Buildings 92 and 93. The PCB concentrations at this location exceeded the RDCSCC in seven samples. The NRDCSCC was exceeded in three samples. Additional PCB delineation was also required at this area (PAP-00126501). Note: The concentrations of the PCBs were not provided in the source document. The October 2018 Map indicates this area had an average concentration of 1.28 ppm from 19 samples collected during five sampling events from 2000 to 2003. The highest concentration of PCBs in this area was 9.2 ppm (PAP-00367461).

The October 2001 ISRA concluded that PCB soil contamination was identified at the site but below EPA action levels. SVOC and metals contamination was also identified during the remedial investigation (RI), but this was attributed to historic fill underlying the site. Based on the results of the site investigation (SI)/RI activities, no further investigative action was required for several AOCs including the former insecticide storage area (PAP-00126498). Note: Concentrations were not provided in the source document.

According to the August 2002 ISRA, as part of the investigative activities at the site, a Historic Fill investigation was performed. A total of 619 borings were installed (PAS-00126541). SVOCS, PCBs, pesticides, and metals were detected above their respective NJDEP Soil Cleanup Criteria (SCC). The PCB, pesticide, and lead detections in the area of the historic lead foundry would be addressed as part of the soil remedial action. The SVOC and metal analytes (excluding lead in the area of a former foundry) detected in the soils were related to the extensive historic filling operations conducted and not site operations (PAS-00126542). Note: SVOCs can include PAHs.

Additionally, the August 2002 ISRA reported the analytical results of the samples collected during the Historical Fill investigation show that low levels of base neutral contamination exist on the site. Benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, indeno(1,2,3-cd)pyrene, and lead had occasional detections.In addition, other contaminants that had been detected during the course of the site investigation that were not associated with the Sherwin Williams operations were likely associated with the Historic Fill including copper (PAP-00126543).

The August 2002 ISRA concluded that all dioxin contamination is related to historic operations by CLH and that it was likely that a significant portion of the pesticide contamination identified at the Sherwin Williams site is related to CLH. PAH and metal contaminants, with the exception of lead, were not considered to be COCs as they were related to Historic Fill and not historic site operations (PAP-00126545).

Remedial Activities

The *Remedial Action Report to Address Soils Contamination in AOC 26 Former Sherwin-Williams Newark Facility*, dated February 2009 described the remediation completed to treat dioxin/furan soil contamination present in AOC 26. AOC 26 is composed of several areas with known dioxin/furan contamination, including a former railroad track area and employee parking area in the southeastern portion of the property. The remediation was conducted from February 25, 2008 through March 3, 2008 and consisted of excavation and off-site disposal of approximately 406 cubic yards of contaminated soil with dioxin/furan concentrations above 20 μg/kg TEQ. Soil samples collected in 2007 and previous years served as in-situ remedial confirmation soil samples. The excavated areas were backfilled with certified clean fill. It was noted that soil sample locations with concentrations greater than 1 μg/kg TEQ would be addressed separately under the site-wide Remedial Action Work Plan which would include engineering and institutional controls for the re-development of the site as well as a draft deed notice (PAP-00367356-83).

Facility Data Report

A May 4, 2018 Deed Notice for the former Sherwin Williams facility at 60 Lister Avenue described the remaining contamination which prevents unrestricted use. The Deed Notice includes the entire Sherwin Williams site as well as the adjacent Copco parcel. Maps were included showing the sample locations and sample results. The deed notice separated the sample results into four divisions based on the sample locations within the facility (PAP-00367278-355).

For the purpose of this report, these divisions are called North-half Main portion, South-half Main portion, Southeast Corner and Southern boundary.

The sample IDs were searched by the Allocation Team and located on the maps to determine the division to be assigned. Several sample IDs could not be located on the maps and are summarized separately. The ranges of reported concentrations for the COCs in each division were as follows:

North-half Main Portion

- Lead ranged from 18.6 mg/kg to 75,800 mg/kg (PAP-00367333, 337)
- Copper ranged from 21.4 mg/kg to 7,010 mg/kg (PAP-00367334, 337)
- Mercury ranged from not detected to 6,030 mg/kg (PAP-00367332)
- Benzo(a)anthracene ranged from 0.15 mg/kg to 160 mg/kg (PAP-00367330)
- Benzo(a)pyrene ranged from 0.14 mg/kg to 210 mg/kg (PAP-00367330)
- Benzo(b)fluoranthene ranged from not detected to 250 mg/kg (PAP-00367330)
- Benzo(k)fluoranthene ranged from not detected to 89 mg/kg (PAP-00367330)
- Dibenzo(a,h)anthracene ranged from not detected to 24 mg/kg (PAP-00367330)
- Indeno(1,2,3-cd)pyrene ranged from not detected to 94 mg/kg (PAP-00367330)
- Naphthalene ranged from 0.041 mg/kg to 26 mg/kg (PAP-00367326, 328)
- Dieldrin ranged from not detected to 0.093 mg/kg (PAP-00367341)
- 4,4'-DDE ranged from not detected to 0.23 mg/kg (PAP-00367342)
- 4,4'-DDD ranged from not detected to 0.15 mg/kg (PAP-00367342)
- Total PCBs ranged from not detected to 9.2 mg/kg (PAP-00367341)
- Dioxins/Furans (reported as Total TEQ) ranged from 0.120 μg/kg to 4.393 μg/kg (PAP-00367345, 46)

South-half Main Portion

- Lead ranged from 47.4 mg/kg to 9,540 mg/kg (PAP-00367335, 36)
- Copper ranged from 29 mg/kg to 6,020 mg/kg (PAP-00367334, 35)
- Mercury ranged from 0.08 mg/kg to 54 mg/kg (PAP-00367332, 34)
- Benzo(a)anthracene ranged from not detected to 160 mg/kg (PAP-00367328)
- Benzo(a)pyrene ranged from not detected to 150 mg/kg (PAP-00367328)
- Benzo(b)fluoranthene ranged from not detected to 160 mg/kg (PAP-00367328)
- Benzo(k)fluoranthene ranged from not detected to 66 mg/kg (PAP-00367328)
- Dibenzo(a,h)anthracene ranged from not detected to 16 mg/kg (PAP-00367328)
- Indeno(1,2,3-cd)pyrene ranged from not detected to 54 mg/kg (PAP-00367328)
- Naphthalene ranged from not detected to 96 mg/kg (PAP-00367325, 28)

- Naphthalene as VOC ranged from 9 mg/kg to 320 mg/kg (PAP-00367320)
  Note: Sample AOC3-04-5.5-6.0 could not be located on the maps. It is assumed to be located in the same general area as the other three AOC3 samples.
- 4,4'-DDE ranged from 0.087 mg/kg to 0.2 mg/kg (PAP-00367342)
- 4,4'-DDD ranged from 0.13 mg/kg to 0.15 J mg/kg (PAP-00367342)
- Total PCBs ranged from 0.37 mg/kg to 3.3 mg/kg (PAP-00367342)
- Dioxins/Furans (reported as Total TEQ) ranged from 1.964 μg/kg to 1.992 μg/kg (PAP-00367346)

Southeast Corner

- Lead ranged from 35 mg/kg to 111,000 mg/kg (PAP-00367331, 37)
- Copper ranged from 15.4 mg/kg to 564 mg/kg (PAP-00367331, 35)
- Mercury ranged from 0.15 mg/kg to 7 mg/kg (PAP-00367331, 35)
- Benzo(a)anthracene ranged from 0.18 J mg/kg to 200 mg/kg (PAP-00367324, 27)
- Benzo(a)pyrene ranged from 0.13 J mg/kg to 140 mg/kg (PAP-00367324, 27)
- Benzo(b)fluoranthene ranged from 0.25 J mg/kg to 160 mg/kg (PAP-00367324, 27)
- Benzo(k)fluoranthene ranged from not detected to 63 mg/kg (PAP-00367324)
- Dibenzo(a,h)anthracene ranged from not detected to 16 mg/kg (PAP-00367324)
- Indeno(1,2,3-cd)pyrene ranged from not detected to 60 mg/kg (PAP-00367324)
- Naphthalene ranged from not detected to 5.4 mg/kg (PAP-00367324, 27)
- Total PCBs ranged from 0.254 mg/kg to 12 mg/kg (PAP-00367341)
- Dioxins/Furans (reported as Total TEQ) ranged from 1.008 μg/kg to 15.378 μg/kg (PAP-00367346)

Southern boundary

- Lead ranged from 6.3 mg/kg to 5,060 mg/kg (PAP-00367332, 36)
- Copper ranged from 8.7 mg/kg to 1,530 mg/kg (PAP-00367332, 37)
- Mercury ranged from not detected to 36 mg/kg (PAP-00367335)
- Benzo(a)anthracene ranged from not detected to 29 mg/kg (PAP-00367323, 27)
- Benzo(a)pyrene ranged from not detected to 24 mg/kg (PAP-00367323, 27)
- Benzo(b)fluoranthene ranged from not detected to 28 mg/kg (PAP-00367323, 27)
- Benzo(k)fluoranthene ranged from not detected to 12 mg/kg (PAP-00367323, 27)
- Dibenzo(a,h)anthracene ranged from not detected to 3.9 mg/kg (PAP-00367323, 27)
- Indeno(1,2,3-cd)pyrene ranged from not detected to 13 mg/kg (PAP-00367323, 27)
- Naphthalene ranged from 0.043 mg/kg to 66 mg/kg (PAP-00367323, 29)
- 4,4'-DDE ranged from 0.017 mg/kg to 0.094 J mg/kg (PAP-00367342)
- 4,4'-DDD ranged from not detected to 0.018 mg/kg (PAP-00367342)
- Total PCBs ranged from not detected to 11 mg/kg (PAP-00367342)
- Dioxins/Furans (reported as Total TEQ) ranged from 1.057 μg/kg to 17 μg/kg (PAP-00367345)

The following results were reported on the Deed Notice but could not be matched up to corresponding locations on the maps:

- Lead ranged from 54.1 mg/kg to 35,000 mg/kg (PAP-00367336, 38)
- Copper ranged from 45.4 mg/kg to 633 mg/kg (PAP-00367336, 38)
- Mercury ranged from 0.1 mg/kg to 54.2 mg/kg (PAP-00367336, 38)
- Benzo(a)anthracene ranged from not detected to 1.5 mg/kg (PAP-00367330)
- Benzo(a)pyrene ranged from not detected to 0.76 mg/kg (PAP-00367330)
- Benzo(b)fluoranthene ranged from not detected to 0.54 mg/kg (PAP-00367330)
- Benzo(k)fluoranthene ranged from not detected to 0.19 mg/kg (PAP-00367325)
- Dibenzo(a,h)anthracene ranged from not detected to 0.2 mg/kg (PAP-00367330)
- Indeno(1,2,3-cd)pyrene ranged from not detected to 0.38 mg/kg (PAP-00367330)
- Naphthalene ranged from not detected to 7 mg/kg (PAP-00367325, 30)
- Total PCBs ranged from 0.23 mg/kg to 18 mg/kg (PAP-00367342)
- Dioxins/Furans (reported as Total TEQ) ranged from 0.450 μg/kg to 23.5 μg/kg (PAP-00367345)

8. Summary of Asserted Defenses

No legal defenses were identified in the available file material.

Spectraserv, Inc.

Diamond Alkali OU2 Allocation

Facility Data Report

SPECTRASERV, INC.

Facility Name, Address and Size: Spectraserv site; 75 Jacobus Avenue, Kearny, New Jersey; 6.5 acres (PAP-00457350) ; Information on number of employees and shifts per day not identified in available file material. The west side of the facility is adjacent to the Passaic River (PAS-00054936-37).

1. **Business Type:** Sludge treatment and dewatering (PAP-00206802)

2. **Time Period of Ownership/Operations**

   Operator: 1962 to present
   Owner: 1969 to present

   1962: Spectraserv, Inc. (Spectraserv) began operating the facility in 1962 (PAS-00009567; PAS-00124553)

   1969: Spectraserv became owner of the facility in 1969 (PAP-00457414). Note: Spectraserv was previously known as Modern Transportation (PAP-00457348).

3. **Operational History/COC Use and Presence at the Facility**

   Three types of operations historically took place at the facility based on review of the available file material: (1) sewage sludge processing; (2) acid/caustic neutralization; and (3) waste oil reprocessing. Each operation is described further below.

   Sewage Sludge Processing

   According to a New Jersey Pollutant Discharge Elimination System (NJPDES) permit, issued October 27, 2017, Spectraserv operates a residual storage, processing, and transfer facility under NJPDES Permit No. NJ0079570. Septage, liquid food processing residual, and liquid residual generated in the treatment of potable water and domestic wastewater are currently stored, consolidated, and dewatered at the facility prior to being managed off-site at approved sludge management sites. Dewatered sewage sludge and grit and screenings are also accepted and transferred in an enclosed transfer building before being managed off-site at approved sludge management sites (PAP-00206855). Prior to March 17, 1991, the sludge generated was disposed at sea (PAS-00124553).

   The residual process generates a wastewater that is pretreated at the facility and discharged to the Kearny sewer system under a Passaic Valley Sewerage Commission (PVSC) Sewer Use Permit (No. 15200004); ultimate treatment and disposal then occurs at the PVSC treatment facility (PAP-00206855-56; PAP-00192809-12; PAP-00193160). The pretreatment process consists of the filtrate (water removed from the residual via a belt filter press) flowing through a bioscrubber and two settling tanks/clarifiers prior to discharge (PAP-00206856).

A flow diagram for process residuals and filtrate disposal is presented below (PAP-00192741):

Acid/Caustic Neutralization

According to an *Administrative Consent Order* signed in 1993 and a *Remedial Investigation Report* prepared for Spectraserv, dated May 2014, between 1976 or 1978 and 1988, facility processes also included an acid/caustic neutralization operation, which involved the mixing of inorganic acid waste with inorganic caustic waste and lime slurry to achieve a neutral pH. After settling, the sludge was removed, dewatered, and disposed off-site, and the neutralized liquid was discharged to the Kearny sewer system under the facility's NJPDES permit (PAP-00216881; PAS-00009568). The Kearny Municipal Utilities Authority operated a combined sewer system (PAP-00193156). The related NJPDES permit was not identified in the available file material. No documentation of OU2 contaminants of concern (COCs) being potentially present in this waste stream was identified in the available file material.

According to a *Revised Report, Remedial Investigation, ACO Compliance*, prepared for Spectraserv, dated February 23, 1995, the acid/caustic neutralization operation was closed as certified by the New Jersey Department of Environmental Protection (NJDEP) on August 25, 1992 (PAS-00054897, 907).

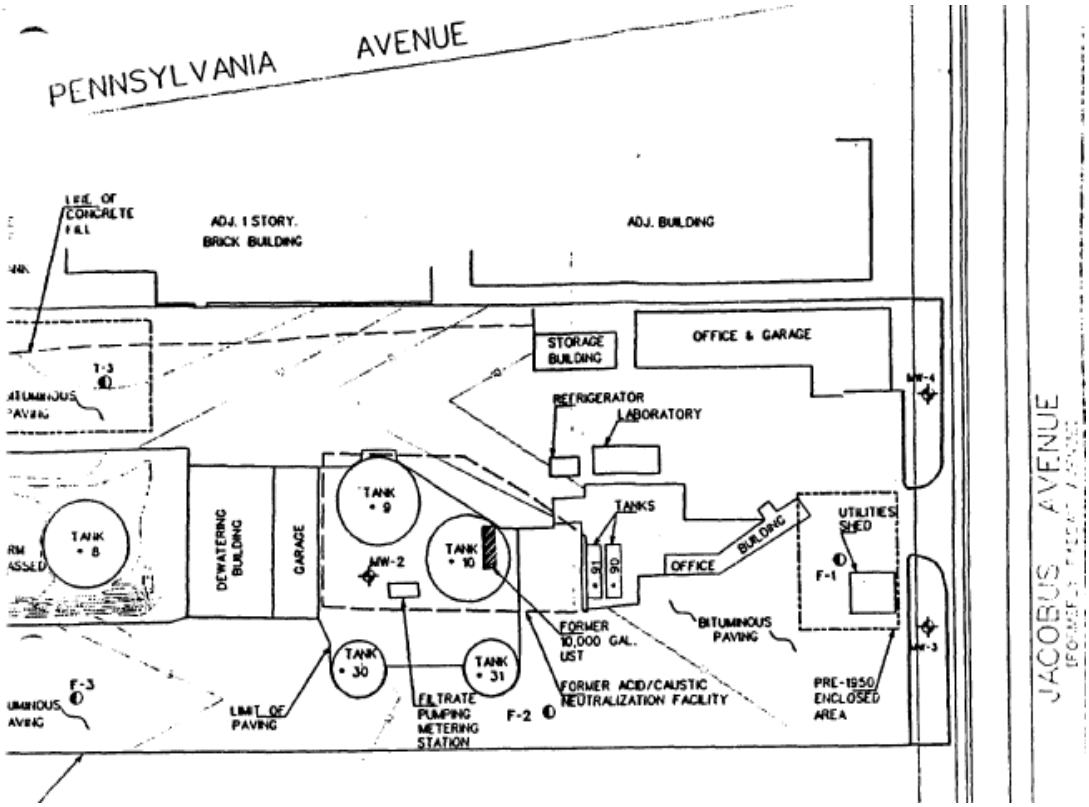
Facility Data Report



Waste Oil Reprocessing

According to the *Administrative Consent Order* signed in 1993, from 1978 to 1981, Spectraserv operated a waste oil reprocessing facility, whereby waste oil was treated through filtration, decanting, heating, and sedimentation via 16 aboveground storage and processing tanks. In addition, the facility reprocessed organic solvents, which were subsequently mixed with the reprocessed waste oil. The reprocessed waste oil was sold for use as fuel oil, motor oil stock, and forming oils, among others (PAS-00009568).

According to a *Revised Report, Remedial Investigation, ACO Compliance*, prepared for Spectraserv, dated February 23, 1995, the waste oil reprocessing facility was closed as certified by the NJDEP on August 25, 1992 (PAS-00054897, 907).

A site layout is presented below in two sections (west side, followed by east side) (PAS-00054936-37):

4. Identified COCs

- PCBs (detected)
- PAHs (detected)
- Copper (detected)
- Lead (detected)
- Mercury (detected)

PCBs

According to a *Waste Oil Facility Soil Sampling Results* report, prepared for Spectraserv, dated October 10, 1990, soil sampling was conducted at the site in September 1990 following the withdrawal of the facility's application to operate the waste oil reprocessing facility (PAS-00054840). Samples were collected from an exterior receiving and treatment area and an interior storage area (PAS-00054841). All soil samples were collected from the surface depth present when the waste oil facility was in operation (zero to one foot) (PAS-00054842, 53). Polychlorinated biphenyls (PCBs) were detected in 6 of 21 samples collected at an interior storage area. Concentrations detected ranged from 1.4 parts per million (ppm) to 52 ppm (PAS-00054847). The report states that PCBs were found to have the highest concentrations in the area around storage tank T-18 on the northern side of the waste oil area near an adjacent SYNCON site. The report states that the concentrations suggest a gradient across the waste oil facility, with the gradient flowing from north to south from SYNCON toward Spectraserv, and the possibility that the PCBs migrated from an adjacent SYNCON facility is "high" (PAS-00054850-51).

PAHs

According to a *Waste Oil Facility Soil Sampling Results* report, prepared for Spectraserv, dated October 10, 1990, soil sampling was conducted at the site in September 1990 following the withdrawal of the facility's application to operate the waste oil reprocessing facility (PAS-00054840). Samples were collected from an exterior receiving and treatment area and an interior storage area (PAS-00054841). All soil samples were collected from the surface depth present when the waste oil facility was in operation (zero to one foot) (PAS-00054842, 53). High and low molecular weight polynuclear aromatic hydrocarbons (PAHs) were detected in all soil samples associated with the interior storage area (PAS-00054846-47).

According to a *Revised Report, Remedial Investigation, ACO Compliance*, prepared for Spectraserv, dated February 23, 1995, soil sampling was conducted at the facility in 1994 consistent with an *Administrative Consent Order* issued by NJDEP in March 1993 (PAS-00054902). High and low molecular weight PAHs were detected in one soil sample (TP-4) collected from a depth of 3.5 to 4 feet from the "Area of Passaic River Filling" (PAS-00054914, 19, 26). The report noted that the contaminants represented organic chemicals contamination (PAS-00054926-27) consistent with that found in historic fill (PAP-00216883-34). According to *Report Remedial Investigation ACO Compliance Spectraserv, Inc.*, by BEM Systems and dated November 21, 1994, four test pits were sampled, and sample TP-4 contained the highest concentrations of all constituents. They are as follows, in mg/kg: anthracene (16.67), fluorene (7.011), fluoranthene (103.2), phenanthrene (57.26), pyrene (96.95), benzo(a)anthracene (56.82), chrysene (50.69), benzo(b)fluoranthene (70.91), benzo(k)fluoranthene (14.19 J), benzo(a)pyrene (45.16), indeno(1,2,3-cd)pyrene (14.31), dibenz(a,h)anthracene (8.484) and benzo(g,h,i)perylene (13) (PAP-00457329).[1]

Copper

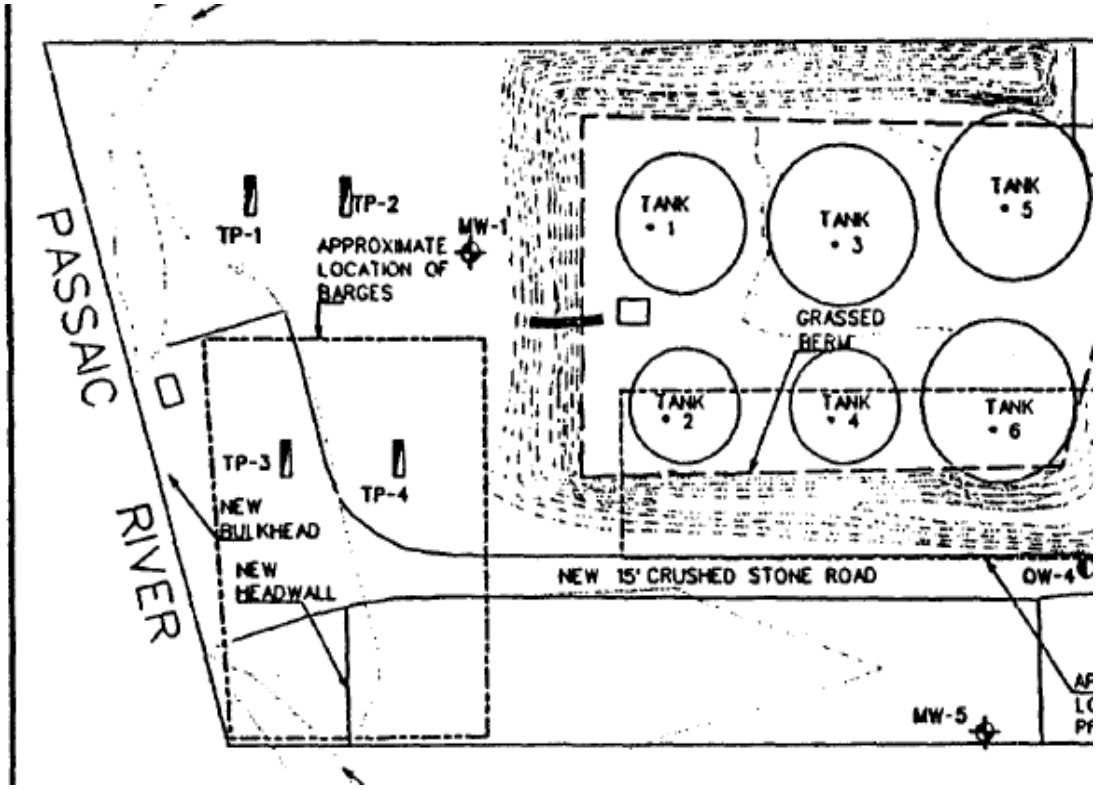
According to a *Waste Oil Facility Soil Sampling Results* report, prepared for Spectraserv, dated October 10, 1990, soil sampling was conducted at the site in September 1990 following the withdrawal of the facility's application to operate the waste oil reprocessing facility (PAS-00054840). Samples were collected from an exterior receiving and treatment area and an interior storage area (PAS-00054841). All soil samples were collected from the surface depth present when the waste oil facility was in operation (zero to one foot) (PAS-00054842, 53). The maximum copper concentration detected was 2,530 ppm. This concentration was reported in a sample collected from the interior storage area (PAS-00054863). The report noted that concentrations of metals were "consistent with the historically industrialized area and the ambient coal sources historically found in this area" (PAS-00054851-52).

[1] This Report was revised to include documents received on May 8, 2020. The additional documents did not change Spectraserv 's previous certification.

According to *Report Remedial Investigation ACO Compliance Spectraserv, Inc.*, by BEM Systems and dated November 21, 1994, copper was detected in each of 17 subsurface samples collected in June 1994, at concentrations ranging from 9.53 to 354 ppm (in sample TP-4) (PAP-00457332-3).[2]

A Chemical Land Holdings *Executive Summary* dated October 31, 1996, compiled data indicating that the Passaic River sediment contamination in the vicinity of Spectraserv includes copper, (PAS-00054947-49). According to this summary report, copper was reported to have been discharged to soil at a concentration of 5,030 ppm (PAS-00054947); however, the summary report does not provide the source of the detection nor does it state if it was the result of a release related to Spectraserv operations. Additional details regarding this detection, including sample location and depth, were not identified in the available file material.

The facility holds a NJPDES permit (No. NJ0104167), renewed in 2015 and renewed again in draft form in 2017 for the discharge of stormwater to the Passaic River (PAP-00206941). According to a Fact Sheet prepared by NJDEP included in a draft Stormwater Discharge Renewal Permit Action dated July 20, 2017, NJDEP's review of all Discharge Monitoring Reports submitted by Spectraserv showed “significant excursions” from the existing individual permit design criteria, including copper on 17 occasions between 2008 and 2016 (PAP-00206942-43). Reported copper concentrations ranged from a minimum of 0.011 mg/L in 2009 to a maximum of 79.90 mg/L in 2015 (PAP-00206942). These findings served as a basis to move the facility from numerical stormwater standards, which NJDEP deemed to be “not feasible,” to a new, best management practice standard whereby stormwater discharges would be controlled by the implementation of a stormwater pollution prevention plan (PAP-00206944-45). It is unclear if the facility had discharge limits for copper between 2008 and 2016; however, in 2017, the draft permit limitation for copper was listed as ≤ 0.0048 mg/L (PAP-00206946). Discharge volumes were not included in the permit.



Lead

According to a *Waste Oil Facility Soil Sampling Results* report, prepared for Spectraserv, dated October 10, 1990, soil sampling was conducted at the site in September 1990 following the withdrawal of the facility’s application to operate the waste oil reprocessing facility (PAS-00054840). Samples were collected from an exterior receiving and treatment area and an interior storage area (PAS-00054841). All soil samples were collected from the surface depth present when the waste oil facility was in operation (zero to one foot) (PAS-00054842, 53). The maximum lead concentration detected was 3,770 ppm. This concentration was reported in a sample collected from the interior storage area (PAS-00054859). The report noted that concentrations of metals were “consistent with the historically industrialized area and the ambient coal sources historically found in this area” (PAS-00054851-52).

[2] This Report was revised to include documents received on May 8, 2020. The additional documents did not change Spectraserv ’s previous certification.

According to *Report Remedial Investigation ACO Compliance Spectraserv, Inc.*, by BEM Systems and dated November 21, 1994, lead was detected in each of 17 subsurface samples collected in June 1994, at concentrations ranging from 23.6 to 1485 ppm (in sample TP-4) (PAP-00457332-3).[3]

According to a *Revised Report, Remedial Investigation, ACO Compliance*, prepared for Spectraserv, dated February 23, 1995, soil sampling was conducted at the facility in 1994 consistent with an *Administrative Consent Order* issued by NJDEP in March 1993 (PAS-00054902). Lead was detected in one soil sample (TP-4) at a concentration of 1,485 mg/kg at a depth of 3.5 to 4 feet in the "Area of Passaic River Filling" (PAS-00054914, 20, 26). The report noted that the contaminants represented metals contamination (PAS-00054926-27) consistent with that found in historic fill (PAP-00216883-34). A figure showing the location of sample TP-4 is presented below (PAS-00054937):

The facility holds a NJPDES permit (No. NJ0104167), renewed in 2015 and renewed again in draft form in 2017 for the discharge of stormwater to the Passaic River (PAP-00206941). According to a Fact Sheet prepared by NJDEP included in a draft Stormwater Discharge Renewal Permit Action dated July 20, 2017, NJDEP's review of all Discharge Monitoring Reports submitted by Spectraserv "significant excursions" from

[3] This Report was revised to include documents received on May 8, 2020. The additional documents did not change Spectraserv 's previous certification.

the existing individual permit design criteria, including lead on seven occasions occurred between 2012 and 2016 (PAP-00206942-43). Reported lead concentrations ranged from a minimum of 5.1 mg/L in 2016 to a maximum of 60.46 mg/L in 2014 (PAP-00206942-3). These findings served as a basis to move the facility from numerical stormwater standards, which NJDEP deemed to be "not feasible," to a new, best management practice standard whereby stormwater discharges would be controlled by the implementation of a stormwater pollution prevention plan (PAP-00206944-45). It is unclear if the facility had discharge limits for lead between 2008 and 2016; however, in 2017, the draft permit limitation for lead was listed as ≤ 0.21 mg/L (PAP-00206946). Discharge volumes were not included in the permit.

Mercury

According to a *Waste Oil Facility Soil Sampling Results* report, prepared for Spectraserv, dated October 10, 1990, soil sampling was conducted at the site in September 1990 following the withdrawal of the facility's application to operate the waste oil reprocessing facility (PAS-00054840). Samples were collected from an exterior receiving and treatment area and an interior storage area (PAS-00054841). All soil samples were collected from the surface depth present when the waste oil facility was in operation (zero to one foot) (PAS-00054842, 53). Mercury was detected at the interior storage area and exterior receiving/treatment area (PAS-00054847; PAS-00104043). The maximum mercury concentration detected was 5.6 ppm. This concentration was reported in a sample collected from the interior storage area (PAS-00054863). The report noted that concentrations of metals were "consistent with the historically industrialized area and the ambient coal sources historically found in this area" (PAS-00054851-52).

According to *Report Remedial Investigation ACO Compliance Spectraserv, Inc.*, by BEM Systems and dated November 21, 1994, mercury was detected in each of 17 subsurface samples collected in June 1994, at concentrations ranging from 0.12 to 1.68 ppm (in sample TP-4) (PAP-00457332-3).[4]

Historic Fill

The Allocation Team has determined that the facility site is located on regional Historic Fill as designated by the NJDEP.[5]

The NJDEP has established that Historic Fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 COCs: PAHs, lead,

[4] This Report was revised to include documents received on May 8, 2020. The additional documents did not change Spectraserv 's previous certification.

[5] *Digital Geodata Series, DGS04-7, Historic Fill for New Jersey*, https://www.nj.gov/dep/njgs/geodata/dgs04-7.htm, Quadrangle #52 and #53 (NJDEP map identifying locations of recognized historic fill).

copper, and mercury.[6] Accordingly, NJDEP technical requirements for property containing Historic Fill requires sampling for the United States Environmental Protection Agency (EPA) Target Compound List (TCL) for PAHs and Target Analyte List (TAL) for metals, including lead, copper, mercury, and the OU2 PAH COCs.[7] PAHs, lead, copper, and mercury are recognized by NJDEP to be constituents of Historic Fill at varying levels, not atypically at or exceeding residential soil standards.[8]

According to *Report Remedial Investigation ACO Compliance Spectraserv, Inc.*, by BEM Systems and dated November 21, 1994, surface and near surface soils on the Spectraserv property can be classified as fill material (PAP-00457263).[9]

A *Remedial Investigation Report*, prepared for Spectraserv, dated May 2014 states that Historic Fill is present at the facility, and contains lead and PAH contamination. It notes that findings suggested that specific soil contamination at the "Area Along Jacobus Avenue" (PAHs), "Southern Site Boundary Area" (PAHs), and "Passaic River Filling Area" (PAHs, lead) are attributable to regional Historic Fill contamination (PAP-00216883-4, 19-20).

The levels of PAHs, copper, lead and mercury detected at the site in soils are presented in the table below (PAS-00054863; PAS-00054947-48, PAP-00457184, PAP-00457281).

COCs Found in Onsite Soils	
COC	**Max Detected Concentration**
Lead	3,770 mg/kg
Copper	5,030 mg/kg
Mercury	5.6 mg/kg
Benzo(a)anthracene	56.82 mg/kg [9]
Benzo(a)pyrene	58.11 mg/kg
Benzo(b)fluoranthene	70.91 mg/kg
Benzo(k)fluoranthene	35.3 mg/kg
Dibenzo(a,h)anthracene	8.484 mg/kg [9]
Indeno(1,2,3-cd)pyrene	38.65 mg/kg

5. COC Pathways

[6] *Characterization of Ambient Levels of Selected Metals and cPAHs In New Jersey Soils* (2002) and *Characterization of Ambient Levels of Selected Metals and Other Analytes In New Jersey Soils* (1997), studies prepared for NJDEP, Division of Science and Research, by BEM Systems, Inc.
[7] New Jersey Department of Environmental Protection (NJDEP), *N.J.A.C. 7:26E Technical Requirements for Site Remediation,* Table 4-2, November 2009 [Note that Table 4-2 has been deleted from the current version of N.J.A.C. 7:26E (May 7, 2012) and the updated *Historic Fill Technical Guidance* (April 2013) as NJDEP believed that the tables list of historic fill constituents was too restrictive].
[8] NJDEP Table 4-2 (PAHs and lead) and a summary of NJDEP records regarding investigations of properties in the vicinity of the Passaic River recognized to be located in areas of Historic Fill indicate that the following average/maximum (mg/kg) contamination levels of OU2 COCs exist in area Historic Fill: PAHs (1.91/160), lead (574/10,000), copper (11.2/1,200), and mercury (0.21/3.7).
[9] This Report was revised to include documents received on May 8, 2020. The additional documents did not change Spectraserv 's previous certification.

The facility is located adjacent to the Passaic River at River Mile 1 (PAP-00206802; PAP-00193151; PAP-00124669).

Sanitary Sewer

According to the *Killam Annual Inspection and Assessment Report for the Town of Kearny*, dated July 1998, a separate sewer and transport system service the area of the City known as South Kearny. This area is a tributary to the Kearny Municipal Utilities Authority Pumping Station which pumps flow directly to the PVSC WPCF in Newark through a joint force main owned and operated by Jersey City, Bayonne, and the Kearny MUA. The Kearny system under the control of the Utilities Authority does not have any CSO discharge points (PAP-00455848-49).

According to an Administrative Consent Order Letter from NJDEP, dated May 1, 1989, On November 17, 1986, the Town of Kearny entered into an Administrative Consent Order (ACO) with the NJDEP regarding the conversion of the Kearny Sewage Treatment Plant to a pumping station. Upon completion of this conversion, all sewage flows in the Kearny service area would be pumped to the PVSC treatment plant in Newark. On December 13, 1987, Neglia Engineering obtained the ACOE permit and completed the design of the pump station and force main (PAP-00455911-12).

Spectraserv held PVSC Sewer Connection Permit # 15406882 and was authorized to discharge to the PVSC Treatment Works in accordance with the following discharge limitations and monitoring requirements from September 16, 1991 to September 16, 1996 (PAP-00455914):

Outlet 1 (15406881-00000-0151)

EFFLUENT CHARACTERISTIC	DISCHARGE LIMITATIONS		MONITORING REQUIREMENTS		
		DAILY MAX	MEASUREMENT FREQUENCY	SAMPLE TYPE	REPORTING PERIOD
BOD (0310)	XXXXX	XXXX	Daily	24 hr. comp.	Monthly
TSS (0530)	XXXXX	XXXX	Daily	24 hr. comp.	Monthly
COD (0340)	XXXXX	XXXX	Daily	24 hr. comp.	Monthly

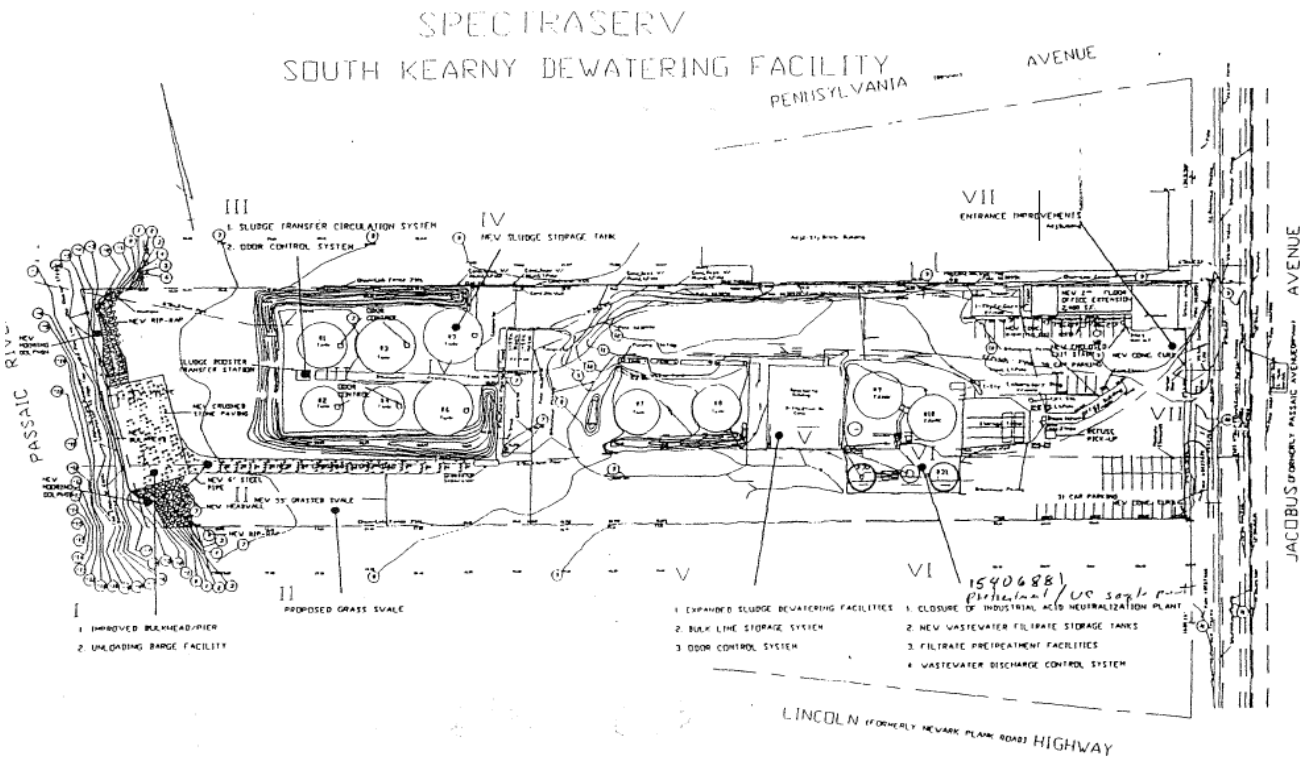
(PAP-00455919)

According to PVSC Sewer Connection Permit # 15406882, Spectraserv was allowed to discharge lead at a monthly average of 0.43 mg/l with a max of 0.69 mg/l (PAP-00455921). The permit was issued for the annual discharge of 164,250,000 gallons (PAP-00455923).



According to PVSC Sewer Permit # 15200004 effective September 01, 2015 – August 31, 2020, Spectraserv permit has the following parameters for outlet 15200004-1 (PAP-00192810).

PVSC LOCAL LIMITS	DISCHARGE LIMITATIONS		MONITORING REQUIREMENTS		
PARAMETER	(a) mg/l DAILY MAXIMUM	mg/l THRESHOLD VALUE	MEASUREMENT FREQUENCY	SAMPLE TYPE	REPORTING PERIOD
Cu	3.98	XXXXX	Twice/Month	Composite	Monthly
Pb	1.3	XXXXX	Twice/Month	Composite	Monthly

* Permittee must meet 40 CFR 437 Categorical limit on Page 7of 15 for this parameter.

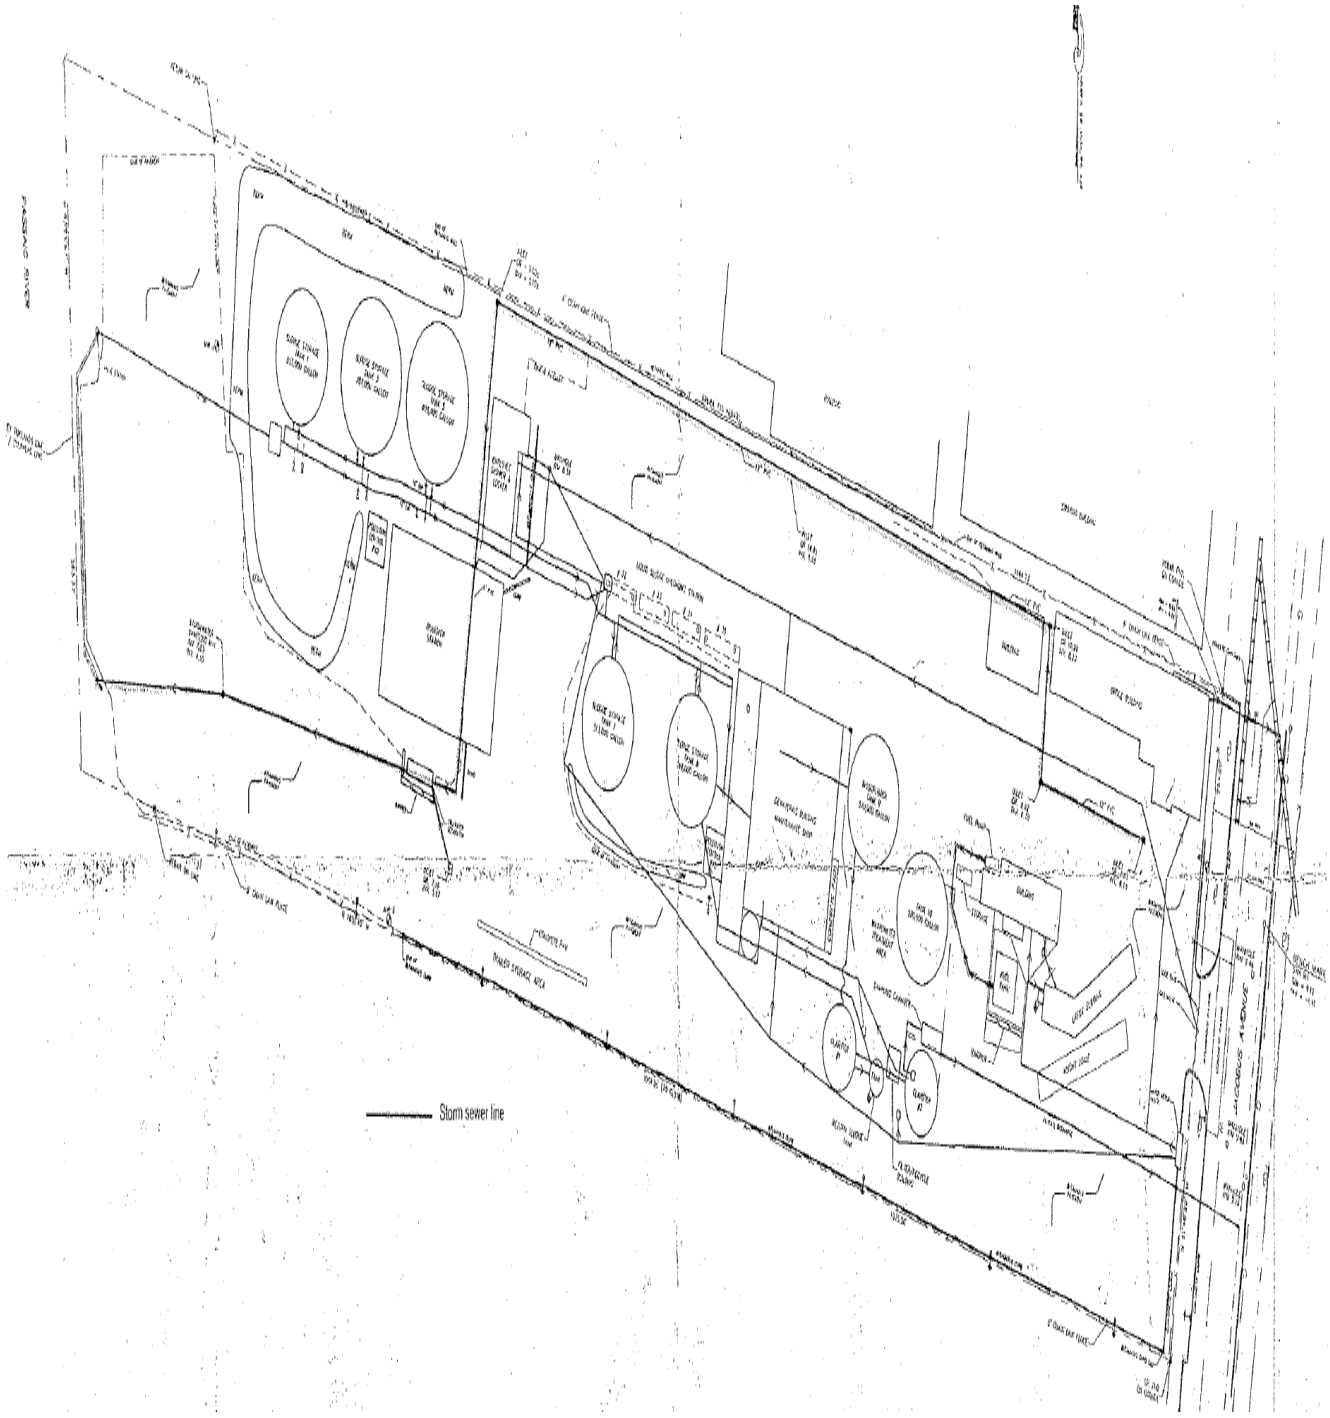
(PAP-0012818)

The residual process generates a wastewater that is pretreated at the facility and discharged to the Kearny sewer system under a PVSC Sewer Use Permit (No. 15200004); ultimate treatment and disposal then occurs at the PVSC treatment facility (PAP-00206855-56; PAP-00192809-12; PAP-00193160). The pretreatment process consists of the filtrate (water removed from the residual via a belt filter press) flowing through a bioscrubber and two settling tanks/clarifiers prior to discharge (PAP-00206856).

(PAP-00455930)

Stormwater

According to an October 24, 1990 NJDEP letter regarding Waterfront Development and Stream Encroachment Permits 0907-90-0006.1WD and 0907-90-0006.2SE, Spectraserv was authorized to construct a single stormwater outfall structure within Lots 10, 10R, 11 and 11R of Block 289 in the Town of South Kearny and required all fill and other earth work shall be stabilized to prevent eroded soil from entering the waterway at any time during and after construction (PAP-00455962, 64).



The 2007 Spectraserv Facility Improvements map below shows stormwater from the site does not discharge to the KMUA or PVSC sewer systems but a separate stormwater collection and conveyance system at the Facility with an outfall to the Passaic River. The image shows several inlets in the northeast part of the site (near the Office Building) which would capture stormwater from the northeast portion of the site, and a storm line heading west. After the Employee Shower and Locker Building, the line turns south, and then west again after the Transfer Station Building, goes through the oil / water separator and jogs a bit to the south at the sampling manhole and ends at the outfall on the river. There is another inlet just to the southeast of the oil / water separator that captures runoff from the southeast portion of the site. Stormwater from the westernmost portion of the site flows overland to the river (PAP-00455969).

Spectraserv, Inc.

Diamond Alkali OU2 Allocation

ADR Confidential

Facility Data Report

According to a July 20, 2017 NJDEP Discharge to Stormwater Discharge Renewal Permit Action Letter, Spectraserv holds permit NJ0104167 for outfall 001A (PAP-00206940-43).

According to a *Stormwater Pollution Prevention Plan* prepared for Spectraserv, dated February 2017 (2017 SWPPP), stormwater generated onsite is discharged either to the Passaic River via the onsite stormwater collection system, or to the combined sewer system operated by Kearny Municipal Utilities Authority; ultimate disposal is at the PVSC treatment facility (PAP-00193156-58). The 2017 SWPPP states that stormwater from the southeast parking area of the facility runs off to Jacobus Avenue and a Conrail railroad right-of-way and is discharged to the combined sewer system (PAP-00193159).

Direct Release

According to National Pollutant Discharge Elimination System Permit # NJ0022161 effective December 31, 1978 until December 31, 1983, the Town of Kearny Wastewater Treatment Plant which Spectraserv was connected to was authorized to discharge to the Hackensack River (PAP-00455933, 43).

The facility holds a NJPDES permit (No. NJ0104167) for the discharge of stormwater. It was renewed in 2015, and was renewed in draft form in 2017 (PAP-00206937, 40, 42). The receiving water body is listed as the Passaic River (PAP-00206941). According to the 2017 SWPPP, stormwater from the northern half of the facility, including administrative building roof drains, is collected in a series of interconnected inlets and pipes, and is sent to an in-line oil/water separator on the southern half of the property. The oil/water separator provides pretreatment and removal of potential pollutants prior to discharge to the Passaic River (PAP-00193159).

Spills

There is no information regarding spills in the available file material.

6. Regulatory History/Enforcement Actions

Inspections

There is no information regarding inspections in the available file material.

Violations

NJDEP issued an *Administrative Consent Order* to Spectraserv in March 1993 requiring Spectraserv to prepare a remedial investigation and feasibility study (PAS-00009572).

The facility has received numerous notices of violation (NOV) from PVSC since 1999. However, the NOVs, which focus on biochemical oxygen demand and suspended solids, were resolved without admission of liability and without any adjudication of the facility's culpability for the allegations contained in the NOVs. The NOVs are as follows:

- On January 28, 1999, for petroleum hydrocarbon detections exceeding the PVSC "daily maximum limit" (PAS-00009592).

- On April 12, 2000, and August 13, 2002, for failing to provide a PVSC inspector proper access to the facility (PAS-00009615; PAS-00009624).

- On April 24, April 28, May 15, and May 25, 2000, for discharge of sludge to the sanitary sewer (PAS-00009610; PAS-00009609; PAS-00009606; PAS-00009599).

- On May 25, 2000, and on June 1, 2000, for use of water to dilute a discharge (PAS-00009604; PAS-00009598).

- On July 18, 2000, for discharge of floatable greases to the sanitary sewer. Two samples collected associated with this release had total petroleum hydrocarbon and oil and grease concentrations that exceeded the "daily maximum limit" (PAS-00009595).
- On October 19, 2000; June 6 and August 14, 2001; January 11, June 25, August 13, and October 3, 2002; and, January 17, 2003, for discharge of solids to the sanitary sewer (PAS-00009594; PAS-00009620; PAS-00009621; PAS-00009622; PAS-00009623; PAS-00009625; PAS-00009626).

- On April 30, 2003, for failing to maintain equipment to prevent solids from being discharged without being sampled (PAS-00009617).

- On June 10, 2003, for improper discharge monitoring (PAS-00009618).

- On March 31, 2005, for exceedance of the "daily maximum limit" for TPH (PAS-00009619).

No documentation of OU2 COCs being present in any of the above-listed discharges was identified in the available file material.

Permits

Spectraserv held PVSC Sewer Connection Permit # 15406882 and was authorized to discharge to the PVSC Treatment Works in accordance with the following discharge limitations and monitoring requirements from September 16, 1991 to September 16, 1996 (PAP-00455914)

The facility holds two permits with respect to the sewage sludge processing operation: a NJPDES Residual Transfer Facilities permit (No. NJ0079570) for process residuals and PSVC Sewer Use Permit (No. 15200004) for filtrate discharge (PAP-00206852, 56):

- The NJPDES Residual Transfer Facilities permit (No. NJ0079570) was issued to the facility (renewed) on October 27, 2017, effective December 1, 2017 (PAP-00206871). A permit modification was issued on December 15, 2017 to reduce the frequency of sampling in the transfer station as a response to the final permit. The effective date of the major modification is January 1, 2018 (PAP-00192743). It is noted that it appears the facility held the permit prior to this date, as the

December 1, 2017 permit was a renewal (PAP-00206871); however, the prior dates held are unclear based on review of available file material.

- The PVSC Sewer Use Permit (No. 1520004) is currently effective through August 31, 2020 (PAP-00192810).

The facility also holds a NJPDES permit (No. NJ0104167) for the discharge of stormwater. It was renewed in 2015, and it was renewed in draft form in 2017 (PAP-00206937, 40, 42). The receiving water body is listed as the Passaic River (PAP-00206941).

Additional details regarding these permits is presented below:

NJPDES Residual Transfer Facilities permit (No. NJ0079570)

Authorizations covered under the NJPDES Residual Transfer Facilities permit (No. NJ0079570) are listed as "Z – Residual Transfer Facilities." (PAP-00206871). The permit states that it contains the conditions necessary to regulate the operation of a residuals transfer station with a maximum capacity of 95 dry metric tons per day (PAP-00206852).

According to the permit, residual is off-loaded from barges and trucks via two sludge pump stations and held in six storage tanks. Dewatered residual produced via filter presses then falls onto a conveyor located inside the dewatering building that moves the material to a pug mill. There the residual can be mixed with lime of varying quantities as required by the ultimate management site. Dewatered residuals travel via belt conveyor from the dewatering building and are loaded into trucks in an enclosed loading area prior to transport to off-site management facilities. In addition, an enclosed cake transfer building receives dewatered sewage sludge and grit and screenings via trucks and containers. The dewatered sewage sludge is reloaded into empty dump trailers or rail containers stationed inside the cake transfer building (PAP-00206855-56).

The following "discharges" are monitored according to the NJPDES Residual Transfer Facilities permit (No. NJ0079570):

- Z001 Pug Mill Stabilized Cake: Lime-stabilized dewatered residual discharged from the pug mill. This discharge was required to be monitored for copper, lead, and mercury. Discharge limits were not listed, nor were discharge volumes (PAP-00206876, 78).

- Z002 Pug Mill Cake: Dewatered residual discharged from the pug mill in the dewatering building. This discharge was required to be monitored for copper, lead, mercury, PAHs, PCBs, dichlorodiphenyltrichloroethane, dichlorodiphenyldichloroethane, dichlorodiphenyldichloroethylene, and 2,4,6-trichlorophenol. Discharge limits were not listed, nor were discharge volumes (PAP-00206881, 83, 85-92).

- Z003 Cake Transfer Building: Dewatered residuals and grit and screenings being transferred in the cake transfer building. This discharge was required to be monitored for copper, lead, and mercury. Discharge limits were not listed, nor were discharge volumes (PAP-00206894-95).

- Z004 Sludge Storage Tanks: The liquid sludge received for processing at the facility. This discharge was not required to be monitored for OU2 COCs (PAP-00206898).

- Z005 Total – Production: All residuals being transferred at the facility. This discharge was not required to be monitored for OU2 COCs (PAP-00206900).

Liquid discharges related to the above-referenced processes are discharged to the PVSC sewer pursuant to the PVSC Sewer Use Permit. Solids generated are removed from the facility by truck (PAP-00206855-56; PAP-00192812). Data related to monitoring of these discharges were not identified in the available file material.

PVSC Sewer Use Permit (No. 1520004)

According to the PVSC Sewer Use Permit (No. 15200004) renewed on September 1, 2015, the facility was permitted to discharge 0.082 million gallons of wastewater per day through one outfall (PAP-00192812). It is noted that at the time of a *Preliminary Assessment Report* prepared by EPA, dated June 15, 1986, Spectraserv discharged 50,000 to 100,000 gallons of dewatered supernatant per day (PAS-00054825).

The permit states that average monthly discharge limitations included that for copper (1.06 mg/L), lead (0.283 mg/L), and mercury (0.000739 mg/L) (PAP-00192816).

NJPDES permit (No. NJ0104167)

Spectraserv is required to monitor stormwater discharges for copper and lead (PAP-00206942). The draft permit limitations for copper and lead were listed as ≤ 0.0048 mg/L and ≤ 0.21 mg/L, respectively, in 2017 (PAP-00206946).

Discharge volumes were not included in the permit.

7. Response Actions

Characterization Activities

The following characterization activities have taken place at the facility:

- *Waste Oil Facility Soil Sampling Results* report, prepared for Spectraserv, dated October 10, 1990 (PAS-00054837);
- *Report Remedial Investigation ACO Compliance Spectraserv, Inc.*, by BEM Systems, dated November 21, 1994 (PAP-00457243);

- *Revised Report, Remedial Investigation, ACO Compliance*, prepared for Spectraserv, dated February 23, 1995 (PAS-00054897);
- *Remedial Investigation Report*, prepared for Spectraserv, dated May 2014 (PAP-00216874);
- *Remedial Action Report*, dated September 2003 (PAP-00192841).

Sewer

There is no information regarding sewer sampling in the available file material.

Soil

According to a *Waste Oil Facility Soil Sampling Results* report, prepared for Spectraserv, dated October 10, 1990, soil sampling was conducted at the site in September 1990 following the withdrawal of the facility's application to operate a waste oil reprocessing facility (PAS-00054840). Samples were collected from an exterior receiving and treatment area and an interior storage area (PAS-00054841). All soil samples were collected from the surface depth present when the waste oil facility was in operation (zero to one foot) (PAS-00054842, 53). PCBs were detected in 6 of 21 samples collected at an interior storage area. Concentrations detected ranged from 1.4 ppm to 52 ppm (PAS-00054847). The report states that PCBs were found to have the highest concentrations in the area around storage tank T-18 on the northern side of the waste oil area near an adjacent SYNCON site. The report states the concentrations suggest a gradient across the waste oil facility, with the gradient flowing from north to south from SYNCON toward Spectraserv, and the possibility that the PCBs migrated from an adjacent SYNCON facility is "high" (PAS-00054850-51).

In addition, according to the *Waste Oil Facility Soil Sampling Results* report, prepared for Spectraserv, dated October 10, 1990, lead, copper, and mercury were detected at both the interior storage area and exterior receiving/treatment area (PAS-00054847; PAS-00104043). The maximum lead concentration detected was 3,770 ppm; the maximum copper concentration detected was 2,530 ppm; the maximum mercury concentration detected was 5.6 ppm (PAS-00054859, 63). These concentrations were reported in samples collected from the interior storage area (PAS-00054863). The report noted that concentrations of metals were "consistent with the historically industrialized area and the ambient coal sources historically found in this area" (PAS-00054851-52). High and low molecular weight PAHs were detected in all soil samples associated with the interior storage area (PAS-00054846-47).

According to *Report Remedial Investigation ACO Compliance Spectraserv, Inc.*, by BEM Systems, dated November 21, 1994, work was conducted to fulfill the terms of the administrative consent order effective on March 28, 1993, and specifically to determine whether groundwater was impacted by contaminants originating from the former acid/caustic neutralization facility and waste oil treatment facility (RCRA closure areas) and to determine whether other areas of environmental concern exist (PAP-00457249).

Metals and PAHs were detected in subsurface soils, discussed in relevant paragraphs in Section 4, Identified COCs. PCBs were not detected in soils (PAP-00457330-1).[10]

According to a *Revised Report, Remedial Investigation, ACO Compliance*, prepared for Spectraserv, dated February 23, 1995, soil sampling was conducted at the facility in 1994 (PAS-00054896). The report states that previous soil sampling stated that site soils were primarily contaminated with metals (the metals were not specified), localized in the acid/caustic neutralization facility, and base/neutral organic compounds and PCBs, localized in the waste oil treatment area (PAS-00054908). PCB concentrations were not included in the report (PAS-00054920). In addition, the report states that high and low molecular weight PAHs and lead (at a concentration of 1,485 mg/kg) were detected in one soil sample (TP-4) collected from at a depth of 3.5 to 4 feet from the "Area of Passaic River Filling" (PAS-00054914, 19-20, 26). The report noted that the contaminants represented organic chemicals and metals contamination (PAS-00054926-27) consistent with that found in historic fill (PAP-00216883-34).

According to a *Remedial Investigation Report*, prepared for Spectraserv, dated May 2014, in 1995, two sediment samples were collected in the Passaic River to evaluate if historical activities at the site had impacted the river. One sample was collected at the approximate midpoint of the western boundary of the site adjacent to the river bulkhead, and another was collected from near the site's drainage effluent pipe. The two samples were analyzed for metals and base/neutral acids. The results were compared to a sample collected upstream of the site. With the exception of arsenic, it was reported that "all impacts were determined at or below average concentrations for the Passaic River." It is further reported that the NJDEP stated in a subsequent comment memorandum that the arsenic concentration "may be an indication that...the oil/water separator...impacting the surface water" (PAP-00216884). However, because Spectraserv agreed to remove the primary source of arsenic contamination around the oil/water separator, NJDEP did not require supplemental ecological studies of the Passaic River and the potential impact of the arsenic-impacted sediments (PAP-00216884).

Remedial Activities

According to a *Revised Report, Remedial Investigation, ACO Compliance*, dated February 23, 1995, as part of previous closure activities, an extensive soil sampling program was undertaken and the results of the soil sampling program stated that site soils were primarily contaminated with metals (the metals were not specified), localized in the acid/caustic neutralization facility, and base/neutral organic compounds and PCBs, localized in the waste oil treatment area. Based on the results of the soil-sampling program, approximately 800 cubic yards of soil were excavated from the former acid/caustic neutralization area and the former waste oil treatment area (PAS-00054908, 20).

[10] This Report was revised to include documents received on May 8, 2020. The additional documents did not change Spectraserv 's previous certification.

Remedial activities to address impacts to site soils were undertaken in 2002 and 2003 in accordance with a February 1999 *Remedial Action Work Plan* (1999 RAWP), approved by NJDEP on April 15, 2002. These activities were summarized in a *Remedial Action Report*, dated September 2003, approved by NJDEP on September 2, 2010. A Deed Notice was recorded on November 5, 2010. Spectraserv was issued a remedial action permit on July 7, 2011, with a conditional "no further action" letter on August 24, 2011. It is reported that all soil remedial investigations were completed and approved by NJDEP in the 1999 RAWP. These actions included soil removal in the "Oil/Water Separator Area" and "Former Waste Oil Facility Area," and capping at the "Passaic River Filling Area" and "Former Waste Oil Facility Area". It is reported that a February 5, 2010 "Response to Comments" letter stated that residual soil contamination would be addressed by a Deed Notice (PAP-00216884-85).

According to *Remedial Action Report AOCs 8 and 10, Spectraserv Site*, dated April 15, 2020, NJDEP issued a site-wide soils NFA letter on August 24, 2011 (PAP-00460270). Remedial investigation and activity related to groundwater continued on the site, and it was concluded in *Preliminary Assessment Report, Spectraserv Site*, dated April 15, 2020, that the source of benzene and chlorobenzene was the neighboring Syncon Resins property (PAP-00457349).[11]

8. Summary of Asserted Defenses

No legal defenses were identified in the available file material.

[11] This Report was revised to include documents received on May 8, 2020. The additional documents did not change Spectraserv 's previous certification.

Stanley Black & Decker Inc.

Diamond Alkali OU2 Allocation

ADR Confidential

Facility Data Report

STANLEY BLACK & DECKER INC.

Facility Name, Address and Size: Stanley Black and Decker; formerly known as The Stanley Works (Stanley), 139 and 140 Chapel Street, Newark, New Jersey. The site is comprised of two parcels of land separated by Chapel Street. The Western Parcel is approximately 1.8 acres; the Eastern Parcel approximately 4.4 acres (PAS-00085749). In 1975, the site had 282 employees working 3 shift per day, 6 days per week (PAP-00019267).

1. **Business Type:** According to the *Site Evaluation Submission*, dated May 24, 1985, Stanley Tools, a division of The Stanley Works, operated a site in Newark that manufactured hand tools. Products at this site included hammers, sledges, mauls, bars, and wedges (PAS-00085686; PAS-00085762). Products were forged, machined, ground, heat-treated, painted, polished, assembled, and shipped (PAS-00124577; PAP-00018774).

2. **Time Period of Ownership/Operations**

   Operator: 1875 – 1985
   Owner: 1875 – December 1997

   According to a *Response to EPA's Request for Information*, dated March 30, 2004, Stanley Tools (or its predecessors) manufactured hand tools at 140 Chapel Street, Newark, NJ from 1875 to 1985, when the site was closed (PAS-00085663).

   According to the May 2016 Remedial Investigation Report, the site was originally operated by the Atha Tool Company from 1875 to 1917 for the manufacture of hammers and sledges. Stanley Rule and Lever (SR&L) acquired the site in 1917 and merged with The Stanley Works in 1920 (PAP-00018960).

   According to the meeting minutes from an Atha Tool Board of Directors meeting, dated April 1, 1913, the stocks of Atha Tool were sold to SR&L pursuant to an agreement that excluded from the sale all accounts and bills receivable, moneys, bank deposits, and all choses of action generally of Atha Tool and such assets were to be held in trust to pay debts and liabilities of Atha Tool arising prior to April 1, 1913 (PAP-00728647).

   According to the *Baseline Ecological Evaluation of the former Stanley Tools Facility*, dated August 1999, the site was purchased by Ramida Rest Brown, Inc. in December 1997 (PAS-00086029).

3. **Operational History/COC Use and Presence at the Facility**

   According to a *Site Evaluation Submission (SES),* dated May 24, 1985, operational history included the following:

   Steel bars were received in fifteen-foot lengths and were stored outside in the paved courtyard east of Building 20. From there, the steel bars were brought inside and cut to length depending on the product to be manufactured. This was a dry operation which did not utilize any chemicals. After the shearing process, work in progress was sent to a

shot cleaning process to remove surface oxidation. The shot cleaning process involved tumbling part on part in an atmosphere of high velocity steel shot. This operation was performed in Buildings 21 and 51. Baghouse filters were located in the alleyway between Buildings 21 and 51, as well as along the east wall of Building 20 in order to collect any of the abrasive dust or particulate matter that resulted from the process. The collected material was handled as non-hazardous solid waste and was disposed of in an ID 26 sanitary landfill (PAS-00085686).

Lead pots were used in the manufacturing process until 1977. The pots were located in Building 21 (PAS-00085695). Stanley states that the pots were discontinued due to improvements in the methods used to manufacture products (PAS-00085665).

After the shot cleaning process, forging was performed in one of three separate buildings on site depending on the product involved. In Building 1, drop forging was performed utilizing oil-fired slot furnaces. In Building 51, parts were press forged utilizing either the oil-fired slot furnace or electric induction heaters. In Building 20A, impact forging was performed utilizing electrical resistance heaters. After the forging operations, all parts were mechanically trimmed regardless of the type of forging performed. Scrap was collected and placed in one of three 40 cubic yard containers stored on site. Material was sold to Schiavone and hauled offsite when the containers were full (PAS-00085687).

The trimmed parts were returned to the shot cleaning operations prior to being ground on a stone wheel or automatic belt grinders. All grinding operations were performed dry and took place in Buildings 21A and 51. Some grinding machines had small dust collectors attached to the machine. These materials were handled as non-hazardous solid waste and were disposed of in an ID 26 sanitary landfill (PAS-00085687).

At this point, parts that were to be drilled or milled were annealed in gas-fired furnaces located in Building 22. After annealing, the parts were machined using Castrol, a water-soluble coolant. Spent coolant was placed in 55-gallon drums. When feasible, spent coolant was filtered and reused. If this procedure was not possible, the drums were ticketed with internal hazardous waste tracking labels and moved to the basement of Building 24-A for storage. Coolants handled as waste may have been combined with waste oil generated from other manufacturing operations. Waste oil/coolant was hauled from the site in bulk by Hitchcock Oil Pollution Systems of Connecticut. The shipments were manifested and listed as New Jersey waste number X726 (PAS-00085687-88).

The next step in the manufacturing process was heat-treating. Heat treating involved heating a part to a desired temperature after which the part was quenched for proper hardness, and tempered for toughness. This operation was conducted in Building 21. Three of the heat-treat furnaces were gas-fired and operated under a nitrogen atmosphere utilizing an internal oil quench. Once per year, the quench oil was pumped from the tank into 55-gallon drums to allow for cleaning of the tank. If the oil was deemed acceptable, it was returned to the quench tank when the cleaning process was completed. Should the oil become contaminated with water and thereby unsuitable for reuse, the oil was ticketed with internal hazardous waste labels and moved to Building 24 for storage (PAS-00085688).

Parts were returned to Buildings 21 or 51 for shot cleaning after tempering. The shot cleaning process was required at this point to clean the surface prior to subsequent painting operations. Painting of the products was performed in both Buildings 20A and 51. This operation utilized a conveyorized dip line capable of coating the product with either black or red water reducible paint. Since this was a dip operation, paint loss was reported to be minimal. Whatever paint that might have dripped off the parts was collected on drip trays and directed back into the dip tank. The painted parts then entered a gas-fired baking oven. Semi-annually, paint was pumped from the dip tank and placed in 55-gallon drums to allow for cleaning of the tank. Should a color be discontinued from use, or should the paint become contaminated, the waste paint drums were labeled with an internal hazardous waste label and placed in Building 24 for storage (PAS-00085688-89).

Parts requiring assembly were transferred to the assembly area in Building 52. Wooden handles were attached to parts utilizing a hydraulic press and metal or wooden wedges. Fiberglass handles were brush coated and then pressed into the hammer head. The lower handle body was dipped into a general purpose nitrile rubber adhesive. The adhesive was then allowed to air dry. The adhesive was then activated by a solution containing 60% methyl ethyl ketone and 40% naphtha. The activation solution was introduced into a rubber handgrip to lightly coat the inside surface. Residual activation solution was removed from the grip and returned to a holding container for reuse. No waste was generated during this operation (PAS-00085690).

The polished surface areas of parts which did not require assembly were coated with a water reducible clear lacquer. This operation was performed in Building 24. The majority of the parts were coated in a dip application, with a minor amount of hand brushing. A small amount of thinner was generated during clean up procedures. This material was drummed and labeled with internal hazardous waste tickets prior to storage in Building 24. The final step for these products was packaging which was performed in Building 24 (PAS-00085690-91).

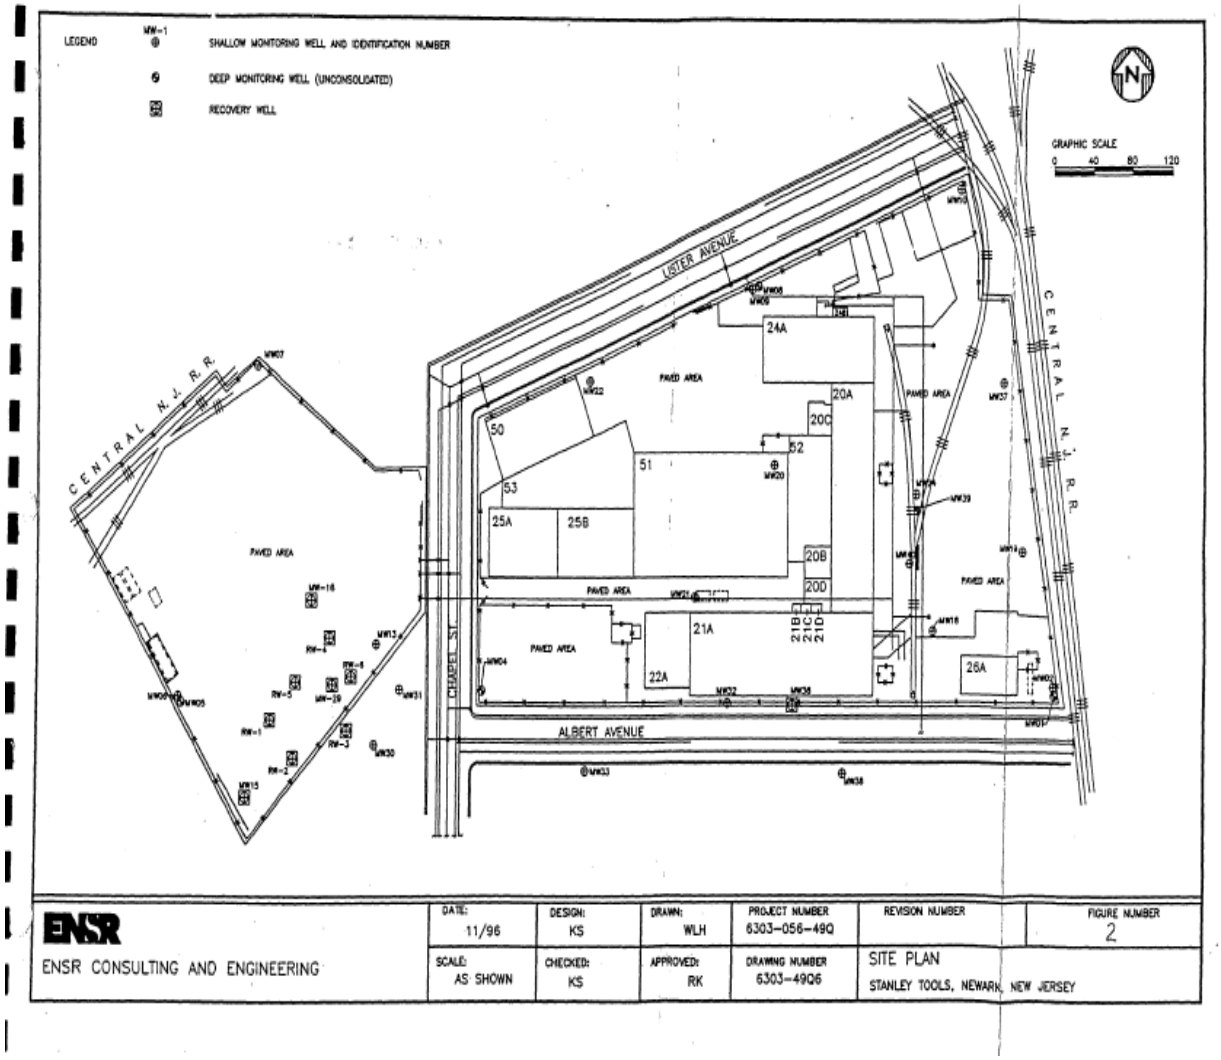
Assembled products were reground to remove run-off (i.e., drip marks, burrs, etc.). This operation was conducted in Building 52. Waste generated at this point was collected in the baghouse filter located along the east wall of Building 20. At this point, the parts were racked in a vertical position where the heads would then go through a finishing operation where they were dipped in a series of 20-gallon tanks.

The finishing operation was comprised of the following steps:

1. Mineral spirits - to remove oil or grease. Once per month the tank was drained into a 55-gallon drum and ticketed with an internal hazardous waste label and stored in the basement of Building 24.

2. Cold water rinse - to remove mineral spirits.

3. Ultrasonic cleaning - once per month this tank was drained to sewer. Note: The sewer utilized is not specified.



4. Cold water rinse - to remove traces of alkaline cleaner.

5. Isopropyl Alcohol dip - to remove residual water. Once per month this tank was drained to a 55-gallon drum ticketed with an internal hazardous waste label then stored in the basement of Building 24.

6. Solvent lacquer dip - Once per month this tank was drained to a 55-gallon drum ticketed with an internal hazardous waste label then stored in the basement of Building 24.

7. Air dry - cured the lacquer coating.

After the assembled parts are finished, they were transferred to Building 24 where labels were applied as required. Parts were then packaged and readied for shipment (PAS-00085691-92).

(PAP-00018740)

For Public Disclosure by Consent of the Participating Allocation Parties and EPA (Fall 2022)

4. Identified COCs

- PCBs (use, detected)
- Dioxins (detected)
- PAHs (used, detected)
- DDx (detected)
- Copper (used, detected)
- Lead (used, detected)
- Mercury (detected)

PCBs

According to a *Summary of Analytical Results for Soil, Sediment, Surface Water, and Wood Block Samples,* dated October 1986, polychlorinated biphenyls (PCBs) (Aroclor 1254) were detected in two samples. Sample 2701 contained 1.3 mg/kg and sample 2801 contained 1.8 mg/kg (PAS-00104507).

According to the 1987 ECRA, concentration of PCBs were detected in matrix soil samples ranging from 0.9 mg/kg to 10 mg/kg (PAP-00017115-55).

As reported by a *Site Evaluation Submission,* dated May 24, 1985*,* a PCB transformer caught fire in 1975. Cleanup did not take place since the release was limited to the area of enclosure. The transformer was repaired and placed back in service with non-PCB oil (PAS-00085703). According to the *Summary Tables of Analytical Results for Soil, Sediment, Surface Water and Wood Block Samples by Sampling Location*, PCBs were found in soil samples taken in this location (AEC 3) contained 2.90 mg/kg (in soil sample taken from 6.5-7.5 ft. bgs) and 1.3 mg/kg (in soil sample taken from 9.5-10 ft. bgs) (PAP-00017501).

The *Site Evaluation Submission,* dated May 24, 1985 also reported that in April 1985, an oil collection device caught fire and resulted in an oil spill outside Building 51 (PAS-00085705).

PCBs were used in a transformer (and possibly other electrical equipment) at the site (PAP-00018252, 257, 328, 332).

According to a *1993 Stanley Tools Report*, Stanley generated and shipped 9.86 tons of undrained electrical transformers containing PCBs in 1993 (PAP-00018238).

According to a *Remedial Action Report for the Stanley Tools Facility*, dated July 1995, PCBs were detected in samples DB0102, DBP315, and DBP316 with concentrations ranging from 52.7 to 110 mg/kg (PAS-00085984; PAS-00085977).

Dioxin

According to the 1987 ECRA, in AEC 3 (area of discolored soil located north of Building 51), dioxins were found only in the surface and 4.0-4.5 foot below ground surface (bgs) samples at concentrations below 0.003 mg/kg (PAS-00104514). According to the 1987 ECRA, 2,4,6-trichlorophenol was not detected in matrix soil samples (PAP-00017182-249).

PAHs

According to the *Phase II Sampling Results*, dated June 1990, analytical results showed that Base Neutrals (BNs) were detected in the upgradient site well MW9 (total BNs: 0.064 mg/kg) and three wells downgradient of the former underground storage tank (UST) locations at AEC22: MW21 (total BNs: 0.073 mg/kg), MW17 (total BNs 0.2

mg/kg), and MW12 (total BNs: 0.072 mg/kg). The BN compounds consisted of PAHs naphthalene, acenaphthalene, anthracene, phenanthrene, and pyrene (PAP-00017603).

According to a *Remedial Action Report for the Stanley Tools Facility*, dated July 1995, Phase III investigations determined that site surface soils at various Areas of Environmental Concern (AECs) were contaminated with PAH compounds. The contaminated soils were addressed by partial excavation, formulation of a cold catch asphalt mix using contaminated soils, and placement of an impervious cap (PAS-00085778). Samples collected in August 1993 contained the following concentrations:

(PAS-00085973-74; PAS-00085976-77; PAS-00085980-8, PAS-00085983-84)

According to a *Classification Exception Area/Well Restriction Area Fact Sheet Form*, dated July 2015, PAHs were above New Jersey Groundwater Standards for benzo(a)anthracene (0.155 mg/l), benzo(b)fluoranthene (0.53 mg/l), benzo(a)pyrene 0.251 mg/l) and indeno(1,2,3-cd)pyrene (0.407) (PAP-00019248, 51).

DDx

According to the *ECRA Sampling Plan Results,* dated April 1987 (1987 ECRA), concentrations of dichlorodiphenyldichloroethane (DDD), dichlorodiphenyldichloroethylene (DDE), and dichlorodiphenyltrichloroethane (DDT) were detected in matrix soil samples ranging from 0.032 J milligram per kilogram (mg/kg) to 0.085 mg/kg. Chlordane was not detected (PAP-00017115-55).

Metals - Copper, Lead and Mercury

According to the *Phase II Sampling Results*, dated June 1990, Phase I and Phase II sampling results showed that lead was the most significant metal of concern at the site, occurring at significantly high levels throughout most of the eastern portion of the site. The detection of lead in soil samples was consistent with the manufacturing processes and materials used historically by Stanley. The general distribution of metals over the eastern part of the site and their concentrations in near surface soils probably resulted from a gradual accumulation of fugitive particles from vents, exhausts, and scrubbers located along the outside walls of nearby buildings (PAP-00017611-12).

According to the 1987 ECRA, concentrations of metals detected in matrix soil samples included: lead ranging from non-detect to 32,740 mg/kg; copper ranging from non-detect to 2,260 mg/kg; and, mercury ranging from non-detect to 1.72 mg/kg (PAP-00017081-110).

The *Phase II Sampling Results*, dated June 1990, also reported lead having been found in unfiltered water samples in monitoring wells (MW) 7, 18, and 21 at concentrations ranging from 82 ppb to 660 ppb. However, lead was not detected in any of the filtered groundwater samples (PAP-00017604).

According to a *Remedial Action Report*, dated July 1995, copper, lead, and mercury were detected at the site at maximum concentrations of copper (121), lead (369), and mercury (0.30) (PAS-00008246). Note: Units were not provided but it is assumed concentrations are in mg/kg.

The *Remedial Action Report,* dated July 1995 also noted widespread soil contamination throughout the site above the Residential and Non-Residential Direct Contract Soil Cleanup Criteria. The principal contaminants are metals (primarily lead) with selected areas of petroleum hydrocarbons (PAS-00085750).

As reported in an April 29, 1996 letter regarding Industrial Site Recovery Act (ISRA) Remediation, lead was detected on one or more occasion at concentrations above the New Jersey Department of Environmental Protection (NJDEP) Groundwater Quality Standards for Class II-A Groundwater between November 1986 and May 1995 (PAS-00008249).

Areas of Environmental Concern

According to a *Sampling Plan*, dated May 1985, revised in May and September 1986, Stanley AECs were as follows (PAS-00104508):

AEC 1 – A small area of slightly discolored soil near the discharge of a roof drain on the west side of Buildings 25A and 53 contained PAHs benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, chrysene, and indeno(1,2,3-cd)pyrene above the NJDEP Direct Contact Soil Cleanup Criteria. The discoloration appeared to be associated with a roof drain that had discharged onto the area (PAS-00104509; PAP-00017866).

PAHs and BNs, detected in the *Remedial Action Report*, dated July 1995, were as high as 55.42 mg/kg and 145.30 mg/kg, respectively (PAP-00018356-7).

AEC 2 – An area of discolored soil between Building 50, the parking lot, and the fence line along Lister Avenue. Lead was detected above NJDEP Direct Contact Soil Cleanup Criteria in this area (PAS-00104509).

According to the *Phase II Sampling Results*, dated June 1990, lead concentrations in soil samples ranged from 988 parts per million (ppm) 0-12 inches bgs to 38 mg/kg 0-12 inches above the water table (PAP-00017636; PAP-00018358).

AEC 3 – An area of discolored soil located north of Building 51 in the vicinity of a transformer whose hatch failed during a fire (PAS-00104509; PAS-00104513). Lead was detected above NJDEP Cleanup Criteria in this area at 1,700 mg/kg. Mercury (0.57 mg/kg) and copper (65.0 mg/kg) were also detected at this AEC (PAS-00104532).

According to the 1987 ECRA, perched groundwater was identified at one foot bgs. Fill was also identified at the AEC and consisted of predominantly orange-brown to red-brown silt and sand with gravel. A hydrocarbon odor was noted below six feet bgs. PCBs were detected in the 6.5 to 7.5 and 9.5 to 10 foot samples, but in concentrations below cleanup guidelines. Dioxins were found only in surface and 4.0-4.5 foot samples at concentrations below 0.003 mg/kg (PAS-00104513-14).

According to the *Phase II Sampling Results*, dated June 1990, lead concentrations in excess of 27,000 mg/kg were reported from this area during Phase I sampling. Excavation exposed stained soils as far as the water table, where an odor of petroleum could be discerned. BNs occurred at concentrations less than 5 mg/kg, and lead was found at concentrations less than 100 mg/kg in samples collected from immediately above the water table. Soil samples for this AEC included copper, lead, and mercury, ranging from 9.60 to 140 mg/kg for copper, 2 to 10,000 mg/kg for lead, and 0.03 to 0.57 mg/kg for mercury. Total BNs concentrations at this AEC were 3.6 mg/kg (PAP-00017579, 81; PAP-00017684-5).

Levels detected in the *Remedial Action Report*, dated July 1995, included copper ranging from 10 to 140 mg/kg, lead ranging from 2 to 27,740 mg/kg, mercury ranging from 0.05 to 1.72 mg/kg, and Total BNs ranging from 0.14 to 3.59 mg/kg. Slight concentrations of PCBs were also found at this location up to 2.90 mg/kg (PAP-00018362-69).

AEC 4 – An area of discolored soil in a drainage way for a former waste storage area. According to the *Phase II Sampling Results*, dated June 1990, lead concentrations in soil samples ranged from 481 mg/kg 0-12 inches bgs to 149 mg/kg 4-5 feet below ground surface (PAP-00017638).

Levels detected in the *Remedial Action Report*, dated July 1995, included total PAHs ranging from 3.07 to 22.48 mg/kg (PAP-00018370-71).

AEC 5 – An area of discolored soil along the north fence line, north of Building 24B. According to the *Phase II Sampling Results*, dated June 1990, lead concentrations in soil samples ranged from 109 mg/kg 6-18 inches bgs to 11 mg/kg 0-12 inches above the water table (PAP-00017638-39; PAP-00018373).

AEC 6 – An area of discolored soil along the north fence line, northeast of Building 24. According to the *Phase II Sampling Results*, dated June 1990, lead concentrations in soil samples ranged from 251 mg/kg 0-12 inches bgs to 8 mg/kg 0-12 inches above the water table (PAP-00017639; PAP-00018374).

AEC 7 – An area of discolored soil located at the former waste storage area. Lead was detected above New Jersey Department of Environmental Protection (NJDEP) Direct Contact Soil Cleanup Criteria in this area (PAP-00018294).

According to the *Phase II Sampling Results*, dated June 1990, lead occurred at concentrations ranging from 720 mg/kg at the surface to ~~7~~ mg/kg above the water table. Soil samples taken at this AEC included copper ranging from 8.3 to 94 mg/kg and mercury ranging from 0.06 to 0.46 mg/kg. Total BNs at this AEC occurred at concentrations as high as 7.0 mg/kg (PAP-00017582; PAP-00017686).

AEC 8, 9, 10, 11, and 43 – A strip of land east of Building 20A (PAP-00018294). PAH concentrations ranged from 0.020 mg/kg for anthracene to 4.0 J mg/kg for pyrene having a total identified compound concentration of 3,191 mg/kg. Metals were detected above NJDEP Cleanup Criteria in this area, copper concentrations ranged from 413 to 447 mg/kg, lead ranged from non-detect to 8,350 mg/kg, and mercury ranged from 0.39 to 3.6 mg/kg (PAS-00085999-86004; PAS-00086008-10).

According to the *Phase II Sampling Results*, dated June 1990, AEC 8 had additional soil samples screened for lead, six samples contained less than 10 mg/kg and the seventh sample contained lead at a concentration of 390 mg/kg (PAP-00017584).

According to the *Remedial Action Report*, dated July 1995, PAHs were detected above NJDEP Direct Contact Soil Cleanup Criteria at AECs 8, 9, 10, and 11 (PAP-00018294-95).

Levels detected in the *Remedial Action Report,* dated July 1995 included copper (320 mg/kg), lead (32,740 mg/kg), mercury (0.76 mg/kg), and Total BNs (207.93 mg/kg) (PAP-00018381-426).

According to a *Summary of Sump Structure and Clay Pipe Soil Sampling Summer/Fall 1994*, AEC 8 surface soil sample SP-1 contained copper at 413 mg/kg, lead at 8,350 mg/kg, and mercury at 3.6 mg/kg (PAP-00210985).

AEC 10 – According to the *Phase II Sampling Results*, dated June 1990, lead concentrations in soil samples ranged from 18,053 mg/kg 0-12 inches bgs to 6,536 mg/kg 0-12 inches above the water table and were above the NJDEP Direct Contact Soil Cleanup Criteria (PAP-00017642; PAP-00018295).

AEC 12 – A narrow strip of land (approximately 1,077 square feet) located south of Building 21A. Lead was detected above NJDEPE Cleanup Criteria in this area (PAP-00018295).

According to the *Phase II Sampling Results*, dated June 1990, lead concentrations in soil samples ranged from 4,870 mg/kg 0-12 inches bgs to 2 mg/kg 0-12 inches above the water table (PAP-00017643). It should be noted that Table 15 (Summary of Soil Results for AEC 12) shows AEC 12 contained lead ranging from 4870 mg/kg 0.5-1 feet bgs to 2.38 mg/kg 8.5-9.0 feet bgs (PAP-00018427).

AEC 14 – Small area of discolored soil located near the northwestern corner of Building 1. PCB Aroclor 1254 (39.4 mg/kg), benzene(a)pyrene (0.85 mg/kg), and lead (1,101 mg/kg) were detected above NJDEP Cleanup Criteria in this area (PAS-00104525). Total PAH concentrations sampled at this AEC were 6.13 mg/kg (PAS-00104533).

According to the *Phase II Sampling Results,* dated June 1990, lead concentrations in soil samples ranged from 1,101 mg/kg 0-12 inches bgs to 8 mg/kg 0-12 inches above the water table. Total BNs were 17.76 mg/kg (PAP-00017644). It should be noted that Table 17 (Summary of Soil Results for AEC 14) shows AEC 14 contained lead ranging from 8.36 mg/kg 10-11 feet bgs to 1101 mg/kg 0-1 foot bgs (PAP-00018429).

AEC 15 – An area of discolored soil near the northeast corner of Building 1. According to the *Phase II Sampling Results*, dated June 1990, lead concentrations in soil samples ranged from 573 mg/kg 0-12 inches bgs to non-detect 0-12 inches above the water table (PAP-00017645; PAP-00018432).

AEC 16 – An area of discolored soil northeast of Building 2A in the vicinity of a transformer. Soil samples analyzed contained PCBs at an estimated level of 42 mg/kg (PAS-00104529).

AEC 17 – An area of discolored soil on the southeastern side of Building 2C and adjacent to the former location of a 10,000-gallon fuel oil storage tank. Lead was detected above NJDEP Direct Contact Soil Cleanup Criteria (PAP-00018296).

According to the *Phase II Sampling Results,* dated June 1990, lead concentrations in soil samples ranged from 627 mg/kg 0-12 inches bgs to 671 mg/kg 12-15 inches bgs (PAP-00017647; PAP-00018438).

AEC 19 – Small area of discolored soil behind the pump house in the western portion of the site. Lead was detected above NJDEP Direct Contact Soil Cleanup Criteria (PAP-00018297).

According to the *Phase II Sampling Results*, dated June 1990, lead concentrations in soil samples ranged from 5,906 mg/kg 0-12 inches bgs to 545 mg/kg 18-24 inches bgs (PAP-00017648).

AEC 20 – Located in the western side of the site. Metals and PAHs were detected above NJDEP Direct Contact Soil Cleanup Criteria in this area (PAP-00018297).

Levels detected in the *Remedial Action Report,* dated July 1995 included copper ranging from 93 to 9,490 mg/kg; lead ranging from 140 to 3,300 mg/kg, mercury ranging from 0.21 from 2.15 mg/kg, and PAHs ranging from 0.37 to 20.45 mg/kg (PAP-00018444-48).

AEC 22 – Located in a driveway between Buildings 51 and 21A/22A. Lead was detected above NJDEP Direct Contact Soil Cleanup Criteria in this area (PAP-00018298).

According to the *Phase II Sampling Results*, dated June 1990, soil samples collected at this AEC contained copper (121 mg/kg), lead (2,610 mg/kg), mercury (0.45 mg/kg) and Total BNs in concentrations ranging from 31 mg/kg to 165.1 mg/kg (PAP-00017691-92).

Levels detected in the *Remedial Action Report*, dated July 1995 included lead (3,982 mg/kg) and Total BNs (123.99 mg/kg) (PAP-00018455-56).

AEC 24 – According to the *Phase II Sampling Results*, dated June 1990, AEC 24 contained two buried fuel oil storage tanks that were excavated, cleaned, and disposed of in October 1989. PAHs were detected above the NJDEP Direct Contact Soil Cleanup Criteria in this area. Contaminant of concern (COC) samples collected in this area were Total BNs (82.6 mg/kg), copper (9,490 mg/kg), lead (3,300 mg/kg), and mercury (2.15 mg/kg) (PAP-00017593; PAP-00017695-98).

Levels detected in the Remedial Action Report, dated July 1995 included copper (556 mg/kg), lead (976 mg/kg), mercury (0.62 mg/kg), and PAHs (230 mg/kg) (PAP-00018471-80).

AEC 26 – Area where two USTs were removed in December 1988.

According to the *Phase II Sampling Results,* dated June 1990, no evidence of free petroleum products in soil was observed during the removal (PAP-00017596). Total BNs sampled at AEC 26 ranged from 79.5 mg/kg to 241.7 mg/kg (PAP-00017701-02).

AEC 27 – An area of oil-stained wood block flooring in the western end of Building 21A. Three chip samples were obtained from the surface of the floor and were analyzed for PCBs. PCB (Aroclor 1254) was detected in one of the three samples at a concentration (1.30 mg/kg) below the Environmental Cleanup Responsibility ACT (ECRA) cleanup guidelines for PCBs in soils (PAS-00104515; PAS-00104534).

AEC 28 – A section of oil-stained wood block floor in the eastern end of Building 2A. One chip sample was obtained from the surface of this area and was analyzed for PCBs. PCB (Aroclor 1254) was detected at a concentration (1.30 mg/kg) below the ECRA cleanup guidelines for PCBs in soils (PAS-00104515; PAS-00104535).

AEC 32 – An unlined trench with discolored soil within Building 20A adjacent to the east wall. Metals were detected above NJDEP Direct Contact Soil Cleanup Criteria (PAP-00018301).

According to the *Phase II Sampling Results*, dated June 1990, lead concentrations in soil samples ranged from 2,030 mg/kg 0-6 inches bgs to 1,241 mg/kg 18-22 inches above the water table (PAP-00017621). Clayey sand fill was encountered in all five borings and at times, metal debris and a hydrocarbon odor were noted (PAS-00104515).

AEC 33 – A dry well into which non-contact cooling water from Building 25 was discharged. According to the *Remedial Action Report,* dated July 1995, BNs were detected above the NJDEP Direct Soil Cleanup Criteria in this area and ranged from non-detect to 52.56 mg/kg (PAP-00018301; PAP-00018496-99).

AEC 34 – A concrete reservoir next to Building 21A which was used for the storage of cooling water at the site. According to the *Phase II Sampling Results,* dated June 1990, samples taken at this location contained elevated levels of lead (1,084 mg/kg). Stanley proposed removal and proper disposal of the remaining water and sediment contained at this AEC (PAP-00017634).

AEC 35 – A former drum storage area north of Building 22A. Lead concentrations in soil samples ranged from 1,365 mg/kg 6-18 inches bgs to 11 mg/kg 0-12 inches above the water table. Copper was detected at 121 mg/kg and mercury was detected at 0.45 mg/kg (PAP- 00017622; PAP-00018503).

AEC 36 – A former drum storage area northwest of Building 2A. Lead concentrations in soil samples ranged from 578 mg/kg 0-12 inches bgs to 10 mg/kg 0-12 inches above the water table. PAHs concentrations levels were 102.7 mg/kg (PAP-00017623; PAP-00018507).

According to the *Remedial Action Report,* dated July 1995, elevated concentrations of PAH compounds were present in this area (PAP-00018302).

AEC 37 – An area located north of Building 2~~C~~6 in the location of a former drum storage area. Lead was detected above NJDEP Cleanup Criteria in this area. This area was paved (PAP-00018302).

According to the *Phase II Sampling Results*, dated June 1990, samples taken at this AEC contained lead ranging from 666 mg/kg 0-12 inches bgs to 128 mg/kg 0-12 inches above the water table (PAP-00017624). It should be noted that Table 37 (Summary of Soil Results for AEC 37) shows AEC 37 contained lead ranging from 666 mg/kg 0.5-1 foot bgs to 128 mg/kg 4.0-4.5 feet bgs (PAP-00018511).

AEC 38 – An area located in a former drum storage area north of Building 2C. According to the *Phase II Sampling Results*, dated June 1990, samples taken at this AEC contained lead ranging from 47 mg/kg 0-12 ~~9-15~~ inches bgs to 42 mg/kg 0-12 inches above the water table (PAP-00017624). It should be noted that Table 38

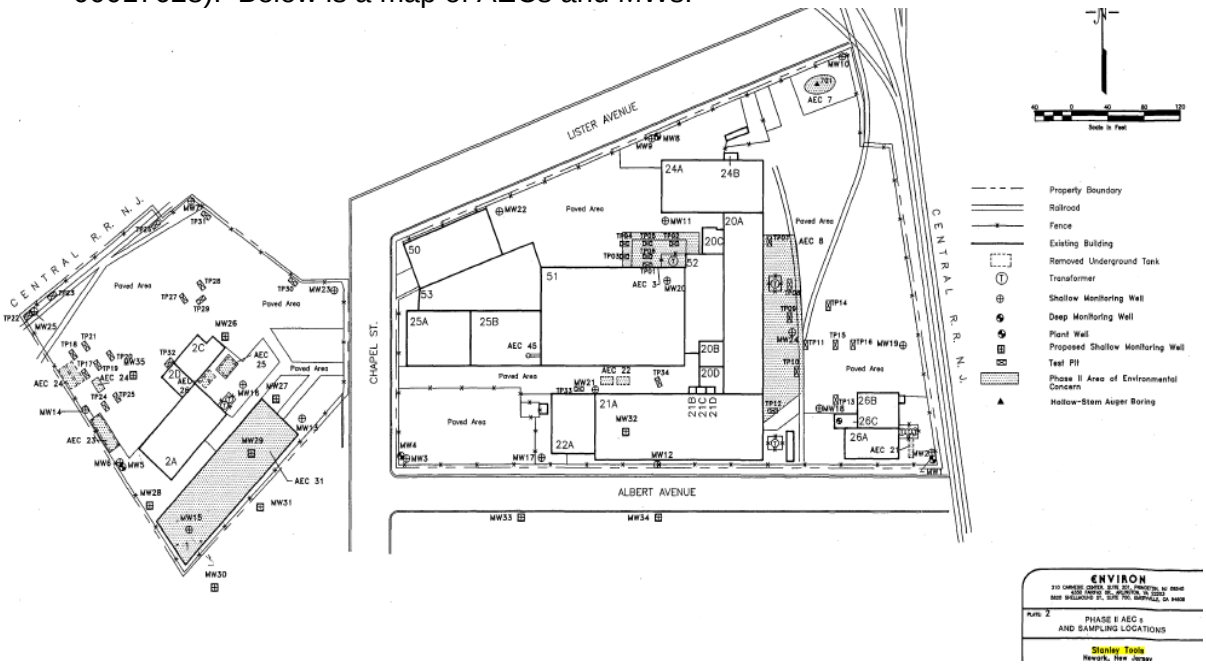
(Summary of Soil Results for AEC 38) shows AEC 38 contained lead ranging from 41.8 mg/kg 5.0-5.5 foot bgs to 47.4 mg/kg 3.5-4.0 feet bgs (PAP-00018516).

AEC 39 – An area located in a former drum storage area east of Building 2C. According to the *Phase II Sampling Results*, dated June 1990, samples taken at this AEC contained lead ranging from 853 mg/kg 9-15 inches bgs to 23 mg/kg 0-12 inches above the water table (PAP-00017625). It should be noted that Table 39 (Summary of Soil Results for AEC 39) shows AEC 39 contained lead ranging from 22.8 mg/kg 5.5-6.0 feet bgs to 853 mg/kg 0.75-1.25 feet bgs (PAP-00018517).

AEC 40 – An area located east of Building 24A and in the location of a former drum storage area. According to the *Phase II Sampling Results,* dated June 1990, additional samples taken at this location contained lead ranging from 493 mg/kg 0-12 inches bgs to 12 mg/kg 0-12 inches above the water table (PAP-00017626). It should be noted that Table 40 (Summary of Soil Results for AEC 40) shows AEC 40 contained lead ranging from 11.9 mg/kg 11.0-11.5 feet bgs to 1,411 mg/kg 4.0-6.048~~-72~~ feet bgs (PAP-00018520).

According to the *Remedial Action Report,* dated July 1995, soil samples collected reported decreasing concentrations of lead to levels below the NJDEP Non-Residential Direct Contact Soil Cleanup Criteria (PAP-00018303).

AEC 41 – An area located in a former drum storage area northeast of Building 24B. According to the *Phase II Sampling Results,* dated June 1990, samples taken at this AEC contained lead ranging from 15 mg/kg 0-12 inches bgs to 213 mg/kg 0-12 inches above the water table (PAP-00017626). It should be noted that Table 41 (Summary of Soil Results for AEC 41) shows AEC 41 contained lead ranging from 14.6 mg/kg 0.0-0.5 foot bgs to 213 mg/kg 10.5-11.0 feet bgs (PAP-00018524).



AEC 42 – An area located in a former drum storage area at the northeast corner of the site. According to the *Phase II Sampling Results*, dated June 1990, samples taken at this AEC contained lead ranging from 705 mg/kg 0-12 inches bgs to 22 mg/kg 0-12 inches above the water table (PAP-00017627). It should be noted that Table 42 (Summary of Soil Results for AEC 42) shows AEC 42 contained lead ranging from 13.03 mg/kg 6.0-6.5 foot bgs to 705 mg/kg 0.0-0.5 feet bgs (PAP-00018527).

According to the *Remedial Action Report*, dated July 1995, lead levels in this AEC were slightly elevated above the NJDEP Non-Residential Direct Contact Soil Cleanup Criteria (PAP-00018303).

AEC 43 – An area located in a former drum storage area northwest of Building 26B. According to the *Phase II Sampling Results*, dated June 1990, additional samples taken at this AEC contained lead ranging from 19,620 mg/kg 0-12 inches bgs to 3 mg/kg 0-12 inches above the water table (PAP-00017627).

AEC 44 – An area reportedly contaminated with lead, north of the entrance to the western part of the site. According to the *Phase II Sampling Results,* dated June 1990,

samples taken at this AEC contained lead at 316 mg/kg 0-6 inches bgs (PAP-00017628). Below is a map of AECs and MWs:

(PAP-00017673)

Max Concentrations of COC in Monitoring Wells (mg/kg)							
	MW01	**MW03**	**MW05**	**MW07**	**MW08**	**MW10**	**MW11**
Cooper	121	17.30	2,260	659	61.50	67.90	119

(PAP-00018530-57)

Historic Fill

The Allocation Team has determined that the facility site is located on regional Historic Fill as designated by the NJDEP.[1]

NJDEP has established that historic fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 COCs: PAHs, lead, copper, and mercury.[2]

[1] *Digital Geodata Series, DGS04-7, Historic Fill for New Jersey*, https://www.nj.gov/dep/njgs/geodata/dgs04-7.htm, Quadrangle No. 52 & No. 53 (NJDEP map identifying locations of recognized historic fill).
[2] *Characterization of Ambient Levels of Selected Metals and cPAHs In New Jersey Soils* (2002) and *Characterization of Ambient Levels of Selected Metals and Other Analytes In New Jersey Soils* (1997), studies prepared for NJDEP, Division of Science and Research, by BEM Systems, Inc.

Accordingly, NJDEP technical requirements for property containing Historic Fill requires sampling for the EPA Target Compound List for PAHs and Target Analyte List for metals, including lead, copper, mercury, and the OU2 PAH COCs.[3] PAHs, lead, copper, and mercury are recognized by NJDEP to be constituents of Historic Fill at varying levels, not atypically at or exceeding residential soil standards.[4]

The levels of PAHs, copper, lead and mercury detected at the site in soils are presented in the table below.

COCs Found in Onsite Soils	
COC	**Max Detected Concentration**
Lead	32,740 mg/kg
Copper	9,490 mg/kg
Mercury	2.5 mg/kg
Benzo(a)anthracene	32.7 mg/kg
Benzo(a)pyrene	27.4 mg/kg
Benzo(b)fluoranthene	30.9 mg/kg
Benzo(k)fluoranthene	0.2 mg/kg
Dibenzo(a,h)anthracene	5.67 mg/kg
Indeno(1,2,3-cd)pyrene	25 mg/kg

According to the 1987 ECRA, the uppermost layer across the site is composed of fill containing a variety of materials, including coal slag, cinders, green glass slag, crushed bricks, assorted gravel, and brown-black sand and silt (PAP-00016872-75).

The *Remedial Action Report for the Stanley Tools Facility*, dated July 1995, reported that Historic Fill material had been documented at the site as well as the surrounding area, including two ISRA sites within one mile of the site. Fill material covers nearly the entire site, varying in depth from about two to 10 feet bgs. The Historic Fill material was believed to contain contaminants including, metals, PAHs, and PCBs. The nature of fill material was such that sporadic areas of contamination and hot spots make delineation of areas specifically impacted by site operations difficult, if not impossible. The entire site was remediated by capping (PAS-00085778). According to a September 10, 2019 Report of Compliance, the former Stanley facility established permanent stabilization of all disturbed areas in accordance with the certified soil erosion and sediment control plan (PAP-00456878).

[3] New Jersey Department of Environmental Protection (NJDEP), *N.J.A.C. 7:26E Technical Requirements for Site Remediation,* Table 4-2, November 2009 [Note that Table 4-2 has been deleted from the current version of N.J.A.C. 7:26E (May 7, 2012) and the updated *Historic Fill Technical Guidance* (April 2013) as NJDEP believed that the tables list of historic fill constituents was too restrictive].

[4] NJDEP Table 4-2 (PAHs and lead) and a summary of NJDEP records regarding investigations of properties in the vicinity of the Passaic River recognized to be located in areas of Historic Fill indicate that the following average/maximum (mg/kg) contamination levels of OU2 COCs exist in area Historic Fill: - PAHs (1.91/160), lead (574/10,000), copper (11.2/1,200), and mercury (0.21/3.7).

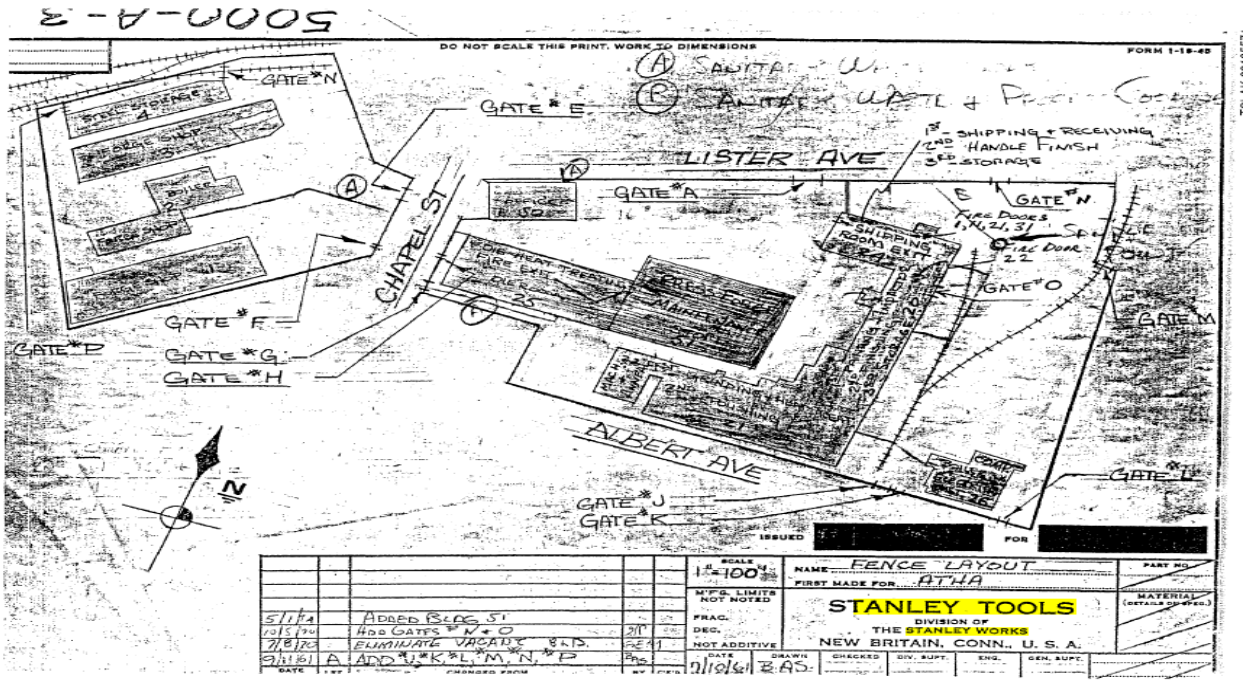
5. COC Pathways

According to a April 3, 2000 NJDEP Letter regarding the 1999 Baseline Ecological Evaluation, the Passaic River is located at its closest point to the former Stanley Tools Newark Facility approximately 400 feet (western parcel). However, because the site is located on the inside of a large meander bend along the Passaic River, the river is located approximately 1,200 feet from the downgradient boundary of the site (PAP-00700827).



Sanitary Sewer

Stanley's Waste Effluent Survey's and PVSC applications document the following water usage (PAP-00019268; PAP-00019293; PAP-00019288; PAP-00019301; PAP-00713751).

Stanley Water Usage in gallons			
Reporting Year	***Sanitary Water***	***Storm Sewer***	***Total Water Use***
1971	8,500,000	0	10,000,000
1974	43,400,000	0	43,800,000
1979	39,186,656	6,000,000	46,566,656
1980	23,103,888	6,480,000	34,075,888
1981	3,963,388	7,826,400	17,455,588

According to a *PVSC Application*, dated April 8, 1980, COC concentration values reported were copper less than 0.009 milligram per liter (mg/l), lead less than 0.033 mg/l, mercury less than 0.0007 mg/l (PAP-00019285).

According to a PVSC Monitoring report for the period of April 1, 1984 thru July 31, 1984, Stanley Tools had an average sample concentration of 0.250 mg/L copper and 0.200 mg/L lead (PAP-00714352).

(PAP-00019290)

According to a *1980 PVSC Sewer Connection Application*, Stanley had eight outlets from the site, four sanitary outlets, two storm sewers, and two undefined outlets (PAP-00019295-96).

Stanley Black & Decker Inc.

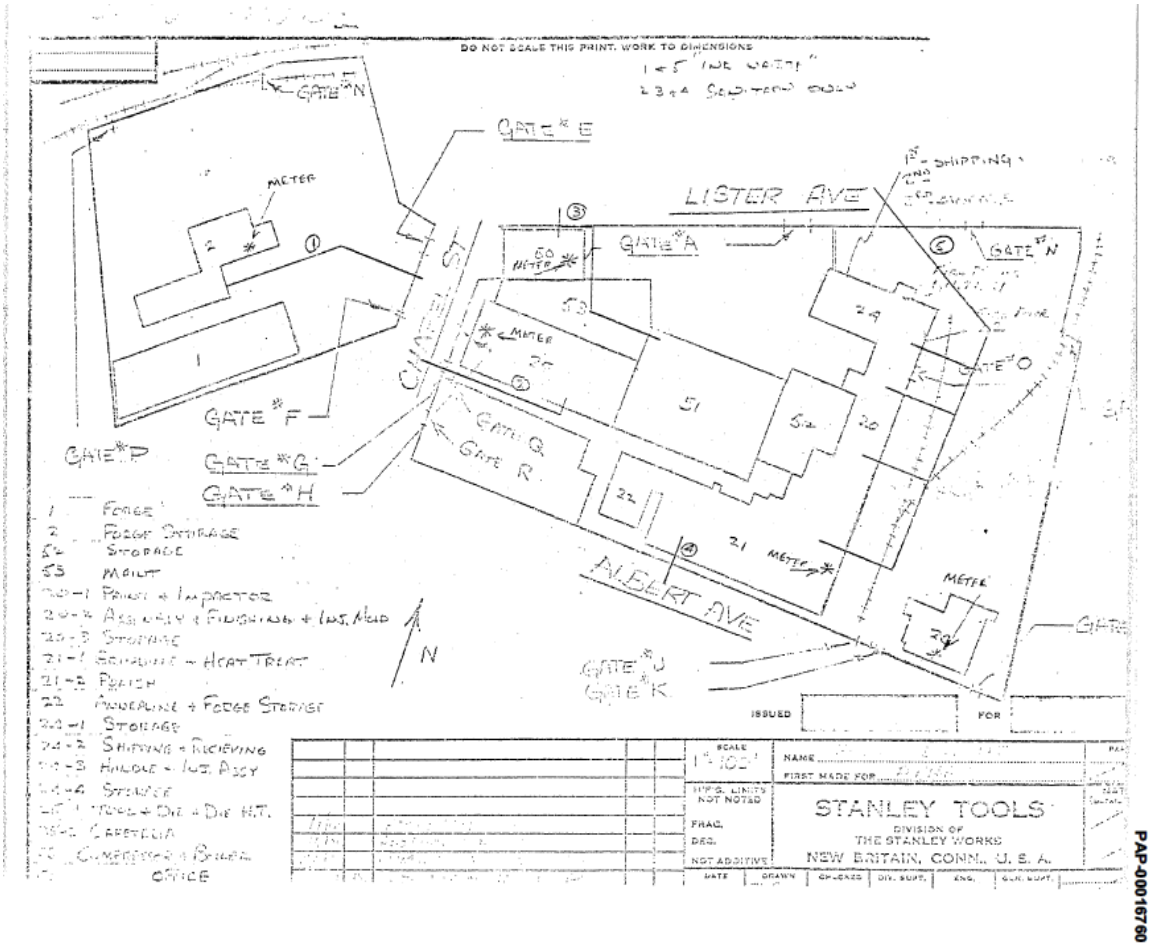
Facility Data Report

OUTLET * NUMBER	SEWER SIZE (INCHES)	DAILY FLOW (GALLONS)	CONTAINS INDUSTRIAL WASTE (YES OR NO)
1	6	19230	No
2	4	1032	Sanitary Only No
3	6	NA Storm	No
4	4	355	No Sanitary only

OUTLET * NUMBER	SEWER SIZE (INCHES)	DAILY FLOW (GALLONS)	CONTAINS INDUSTRIAL WASTE (YES OR NO)
5	4	1412	Sanitary only No
6	6	NA Storm	No
7	4	550	Sanitary only No
8	8	125180	Yes



(PAP-00019295-96)

(PAP-00019299)

However, a January 27, 1982 letter to PVSC reports Stanley had five outlets from the site as detailed and depicted below (PAP-00016759).

Outlet #	Discharge Gal/day	Line size (in)	Discharge type
1	10970	4	Industrial
2	2553	4	Sanitary
3	120	4	Sanitary
4	120	3	Sanitary
5	33763	6	Industrial

(PAP-00016760)

According to a PVSC POTW Industrial Inventory for the period from August 1, 1983 through July 31, 1984 Stanley Tools had and average daily flow of 0.117 millions of gallons per day (mgd) (PAP-00714355, 92).

According to a June 29, 1995 response letter from PVSC, PVSC approved Stanley's one time discharge of approximately 7,500 gallons of well water (PAP-00210699-700).

Storm Sewer

According to a letter from NJDEP regarding ISRA Case No. E85178, dated April 8, 2000, Stanley stated that surface runoff either discharges to the site storm sewer located in the northeast corner of the site or to drains located in the bordering streets (PAS-00085744, 86020). According to the letter from NJDEP regarding ISRA Case No. E85178, dated April 8, 2000, surface run-off drains into the storm sewer systems in the center of the parking lot in the western lot while on the eastern lot run-off drains to the site's perimeter in each of the three large open areas i.e., west of Building 22A, north of Building 51, and east of Building 20A (PAP-00016872).

According to a July 30, 1999 letter regarding Effluent Sampling Results, Stanley had a groundwater treatment system (December 15, 1998 – October 1999) extracting and treating petroleum-impacted groundwater at two to three gallons per minute (gpm) from the aquifer beneath the site. Continuous treatment consisted of oil/water separation, filtration, and carbon/ anthracite clay absorption. Final discharge of two to three gpm was to the Passaic River via a storm sewer outfall No. 001A, in accordance with NJPDES permit No. NJ0132390 (PAP-00018703; PAP-00018769).

A January 9, 2001 letter reported that the primary effluent samples in December 2000 showed that Total Organic Carbon (TOC) (28 mg/l) and Total Suspended Solids (TSS) (43 mg/l) were above the permitted discharge limit. To demonstrate that a discharge violation had not taken place an effluent groundwater sample was collected on January 4, 2001. The concentration for TSS was 15 mg/l and below the permitted allowance of 20 mg/l (PAP-00018780, 82, 97).

As reported by a March 15, 2001 letter regarding an unanticipated bypass, discharge from a small leak on an equalizer tank between the oil/water separator and the liquid phase granular discharged for approximately two to three days (March 10-12 2001). The volume discharged was approximately 55 gallons. Based on analytical results collected on February 12, 2001, pollutants were reported as total petroleum hydrocarbon (TPH) (1,100 mg/l), volatile organic carbons (VOCs) (0.142 mg/l), and pH of 6.5. The receiving water would have been the permitted storm sewer system along Chapel Street (PAP-00018801).

Another July 30, 2001 letter, reported that samples required for Discharge Monitoring Repot of the Mobile Remediation System (MRS) were over the permit limit for TSS (49 mg/l). The permit limit was 40 mg/l and the water was discharged to the permitted storm sewer (PAP-00018831). It was estimated that the discharge occurred for approximately 1-2 weeks. The maximum volume discharged was approximately 42,000 gallons to the Passaic River via the storm sewer (PAP-00018833).

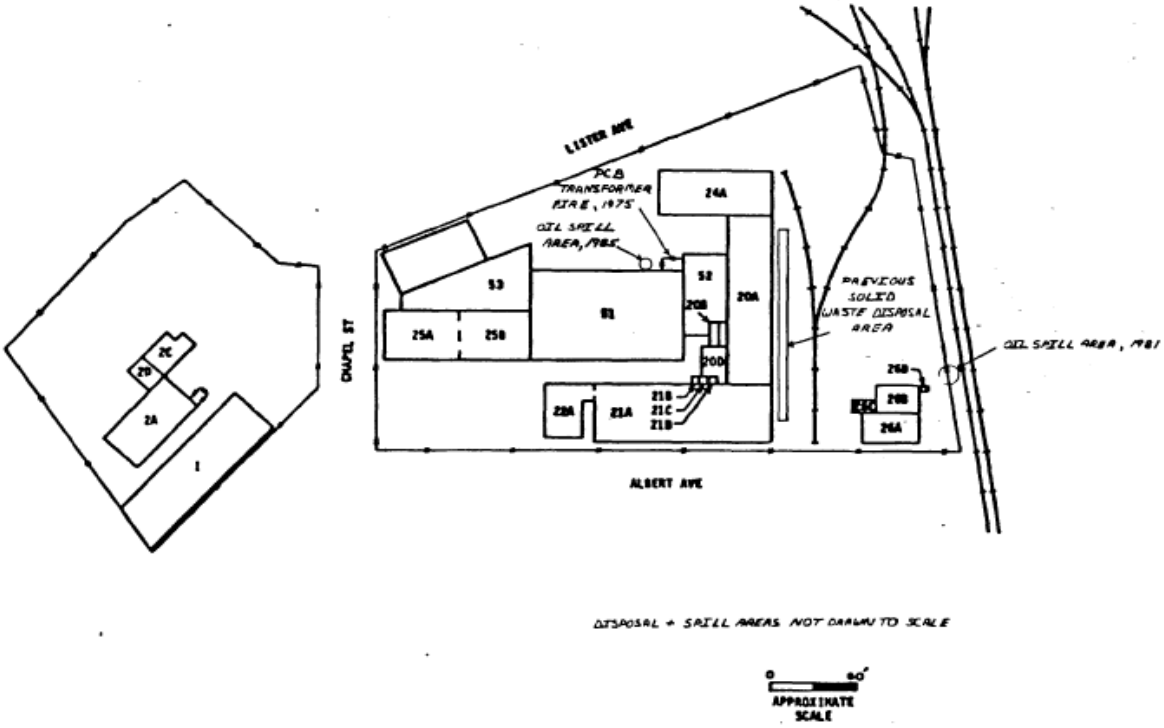
A September 4, 2002 letter reported that the MRS operated at the site at one gallon per minute. The recovered product was transported off site and recycled and the treated groundwater was discharged to the PVSC under Permit No. 20220084. On August 22,

2002, upon inspection of the malfunctioning MRS, it was determined that 3,000 gallons of groundwater had discharged to a nearby storm sewer as evidenced by the rust colored asphalt and unaccounted for 5,900 gallons. Constituents of interest in the groundwater were VOCs, TSS, and metals (PAP-00018842-45).

Direct Releases

There is no information regarding direct releases in the available file material.

Spills



According to a *Site Evaluation Submission*, dated May 24, 1985, during the operations on the site, the following spills occurred:

- In 1975, a PCB transformer caught fire which resulted in the failure of the top hatch of the unit, clean up was not conducted since the release was limited to the area of the enclosure (PAS-00085703).

- In 1981, an operator error resulted in a spill of approximately 100 gallons of oil on the East side of the site while pumping waste oil from 55-gallon drums through a filter into new drums. All oil and soil was scraped up and placed in 20 partially full 55-gallon drums and transported for solidification and subsequent disposal. The spill was reported to the Office of Hazardous Management and assigned case No. 81-9-3-6 (PAS-00085703).

- In April 1985, an oil collection device caught fire and resulted in an oil spill outside Building 51. Since this area is in the direct vicinity of the PCB transformer incident, contaminated soils were not removed. Surficial oil was absorbed utilizing speedi-dri (PAS-00085704).

- The East side of Building 20A was used at one time for disposal of industrial solid waste, some areas of iron oxide scale and grinding swarf deposits were visible (PAS-00085704).

(PAS-00085705)

6. Regulatory History/Enforcement Actions

Inspections and Violations

According to a *Request for Information*, dated March 30, 2004, Stanley received wastewater treatment system violations associated with its remediation system initiated on December 15, 1998 (PAS-00085670).

As reported by a July 30, 1999 letter regarding effluent sampling, the results for the sample collected on July 3, 1999 from the groundwater treatment system effluent showed that TSS were present at 63.0 mg/l. The concentrations were above the daily permit limitation for TSS of 40.0 mg/l (PAP-00018703).

According to a September 16, 1999 letter regarding effluent sampling, groundwater samples taken on August 11 and 27, 1999 showed that TOC was present at 36.6 mg/l and 45.2 mg/l. The TOC concentrations for both samples were above the daily permit limitation for TOC (20.0 mg/l) (PAP-00018761).

According to a January 9, 2001 letter, effluent samples were above the permitted discharge limit of 20 mg/l for TOC and 40 mg/l for TSS. Concentration levels contained 28 mg/l TOC and 43 mg/l TSS (PAP-00018779-80, 82).

According to a May 30, 2001 letter, effluent samples collected on May 8, 2001 showed TPH at 140 mg/L (above the permitted discharge limit of 15 mg/l) and TSS at 46 mg/L (above the permit limit of 40 mg/kg). Stanley's consultant concluded that the elevated results were attributable to laboratory error at the time (PAP-00018807-09, 12).

According to a July 30, 2001 letter, TSS (49 mg/l) results were above the NJPDES NJ 0132390 permit limits of 40 mg/l. It was estimated that the discharge could have occurred for approximately one to two weeks and the maximum volume discharged was approximately 42,000 gallons (PAP-00018831, 33).

Permits

According to *Request for Information*, date March 30, 2004, the site discharged its wastewater to the PVSC under permit No. 20402922, issued February 4, 1983 – February 4, 1987 (PAS-00085668; PAP-00714400). Note: Copies of the permit from PVSC were unavailable.

An October 29, 2002 letter, reported that a PVSC permit No. 20220084 was issued for the mobile remediation system (MRS) that had been discharging to PVSC since January 3, 2002 (PAP-00018853).

Stanley held PVSC permit No. 20630009 from January 1, 2014 to December 31, 2018. (PAP-00361929).

As reported by a NJDEP letter, dated May 01, 1998, Stanley received NJDES permit No. NJ0132390. This individual General Permit Authorization allowed for the discharge of treated groundwater to the Passaic River via storm sewer from Discharge Serial Number (DSN) 001A which expired on November 30, 1998 (PAP-00018673-76). Stanley also held NJPDES permit No. NJ0102709 from October 29, 1993 to November 30, 1998 (PAP-00018680).

According to multiple NJDEP Monitoring Well Records filed in the 1980s and 1990s, Stanley held well permits 26-34386, 26-34387, 26-35021, 26-19005, 26-19799, 26-19800, 26-34990, 26-34991, 26-34388, 26-34391, 26-36586, 26-36587, 26-34989, 26-27419, 26-10407, 26-09705, 26-09674-9, 260965-7, 2609676-5, 2609677-3, 2609678-1, 2609679-0, 2609680-3, 2609681-1, 2609703, 2609705, 2609674-9, and 2610407 (PAS-00021467-93; PAS-00021695; PAS-00074406; PAS-00074412-21; PAS-00074568-69; PAS-00074406).

According to the *Request for Information*, date March 30 2004, the site did not have any permits issued from the Federal Water Pollution Control Act (PAS-00085663).

According to the May 2016 Remedial Investigation Report, Stanley's East site-wide CEA was approved on February 5, 1998 for a duration of 1,000 years, but was considered indeterminate. Stanley's West site-wide CEA was approved for a duration of 60 years (PAP-00018988; PAP-00019168).

According to the May 2016 Remedial Investigation Report, Stanley's consultant proposed an updated CEA for the Eastern Parcel for a duration of 30 years and Western Parcel for 9.27 years (PAP-00018989; PAP-00019169).

7. Response Actions

Characterization Activities

The following characterization activities have taken place at the facility:

- Remedial Action Workplan for Soils for the Former Stanley Tools Facility (October 1993) (PAS-00085927)
- Remedial Action Report for Stanley Tools (July 1995) (PAS-00085748)
- Remedial Action Workplan (1997) (PAP-00019003)
- Baseline Ecological Evaluation for the Former Stanley Tools Facility (August 1999) (PAS-00085809)
- Preliminary Report / Workplan, ISRA Case No. 85178 (February 2006 (PAP-00701670).
- Remedial Action Workplan Addendum – Western Parcel (October 200) (PAP-00702933)
- Remedial Investigation Report for the Former Stanley Tool Facility, Volume 1 (May 2016) (PAP-00018949)
- Remedial Investigation Report for the Former Stanley Tool Facility, Volume 2 (May 2016) (PAP-00019141)

According to the *Baseline Ecological Evaluation of the former Stanley Tools Facility*, dated August 1999, Stanley has been conducting investigations at the site pursuant to the ECRA and the ISRA since the site closed in 1985. The site has undergone extensive remedial activities including groundwater monitoring and remediation, soil sampling and excavation, soil treatment, installation of an asphalt cap and decommissioning of PCB equipment (PAS-00086029).

According to the *Remedial Investigation Report*, dated May 2016, remedial investigation and remedial action were conducted by various consulting firms on behalf of Stanley at the Eastern and Western Parcels. Remedial investigation activities were conducted by ENVIRON from approximately 1986 to approximately 1993; ENSR from 1993 to 2000; Arcadis from 2000 to 2003; and CB&I from 2003 to 2016. Below is a summary of remedial investigation and remedial activities (PAP-00018970; PAP-00019157).

Remedial Activities

Soil

ENSR Remedial Action Report (July 28, 1995): The remedial action at the Eastern Parcel (AEC 3-24, 26, 32-33) primarily involved the excavation and recycling of soils onsite using a cold batch processing technique. The soils were recycled into cold batch material and placed and compacted back into the excavations as a sub-base, utilizing

the cold batch material as a cap. A 2-inch thick asphalt topcoat was placed and compacted over the site to serve as the finish to the cap. The remedial phase also included: 1) removal and off-site disposal of selected soil "hot spots;" 2) removal and off-site disposal of VOC contaminated soil; and, 3) preparation and submittal of an Alternate Cleanup Level (ACL) proposal for VOC contaminated groundwater (PAP-00018970; PAS-00085776, PAP-00018293-301).

As noted by the *Remedial Action Report for the Stanley Tools Facility*, dated July 1995, remediation of soils containing metals and organic chemical constituents was conducted at the site. The remediation consisted of excavation and off-site disposal of 18 cubic yards of soils containing TPHC; excavation and off-site disposal of approximately 230 cubic yards of lead and VOC-contaminated soils; recycling of over 2,500 cubic yards of soils contaminated with metals, PAHs, and TPHC using cold batch asphalt processing; and, placement of a 2-inch asphalt final top course over the entire site (PAS-00085776).

Soil remedial investigations continued to delineate the extents of contamination in preparation for remedial action. Remedial investigations for soil were conducted in May 2010 and April 2012 (PAP-00018975).

According to a May 7, 2018 NJDEP letter, Stanley received No Further Action (NFA) for 55 of the 65 AOCs, six of which no sampling was triggered (PAS-00361922-26).

8. Summary of Asserted Defenses

Stanley asserts that it is not liable for discharges by Atha Tool. Atha Tool owned and operated the site starting in approximately 1875. SR&L purchased the capital stock of Atha Tool pursuant to an agreement that excluded from the sale all accounts and bills receivable, moneys, bank deposits, and all choses of action generally of Atha Tool and such assets would be held in trust to pay debts and liabilities of Atha Tool arising prior to April 1, 1913. Atha Tool continued to operate as a separate corporate entity until approximately July 16, 1917. On or about this date, SR&L acquired the assets of Atha Tool (including the Newark manufacturing facility). Atha Tool was reportedly dissolved on July 31, 1917. SR&L operated the facility from July 16, 1917 until SR&L merged with Stanley in 1920.

Stanley never assumed the liabilities of Atha Tool arising from the operation of the Facility. Stanley does not recognize itself as the successor to any potential Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) liabilities associated with Atha Tool's operations and Atha Tool, as a dissolved corporation, is not subject to being sued. Therefore, Stanley is not responsible for the wastewater discharges to the Lower Passaic River during Atha Tool's ownership and operation of the site.

Lastly, PAHs discharged in wastewater by Stanley contained lubricating oils, grease and other petroleum products used in the manufacturing process. Based on the CERCLA petroleum exclusion, such PAHs should not be considered.

Diamond Alkali OU2 Allocation
ADR Confidential
Facility Data Report

STWB Inc. – Bloomfield

Facility Name, Address and Size: STWB Inc. (STWB) is the corporate successor to Lehn & Fink Products Co., the former property owner/operator (PAS-00032941); 192-194 Bloomfield Avenue, Bloomfield, New Jersey (the Lehn & Fink [L&F] Facility); approximately 10 acres (PAP-00431956); seven buildings were part of the L&F Facility (PAS-00028400, 419); Lehn & Fink Products Co. employed 625 people by December 1925, but no information was provided regarding the number of employees specifically working at the L&F Facility (PAS-00028419).

1. **Business Type:** Formulation, mixing, and packaging of cleaning products, disinfectants, and personal toiletry items (PAS-00028399).

2. **Time Period of Ownership/Operations**

Operator: Lehn & Fink Products Co. 1925 – 1965
Owner: Lehn & Fink Products Co. 1920 – 1965

1874: Lehn & Fink, Inc. was founded in New York City (PAS-00028400, 419).

1890: Lehn & Fink, Inc. introduced Lysol, the first universally branded disinfectant, to the United States by importing it from Schulke & Mayr of Hamburg, Germany (PAS-00028419).

1907: Lehn & Fink, Inc. acquired A.S. Hinds Company (PAS-00028400). A.S. Hinds Company manufactured Hinds' Honey and Almond Cream, a nationally known product. A.S. Hinds, which was founded in 1875, continued to operate independently (PAS-00028419).

1912: Lehn & Fink, Inc. began manufacturing Lysol under a licensing agreement in 1912, and in 1922 Lysol was purchased by the company (PAS-00028419, 423)

1925: In July, a new holdings company, Lehn & Fink Products Co., was created for the purpose of acquiring Lehn & Fink, Inc. and A.S. Hinds Company (PAS-00028400, 419).

1925-1965: Lehn & Fink Products Co. operated the L&F Facility located in Bloomfield, New Jersey from approximately 1925 through 1965 (PAS-00028399).

1926: Lehn & Fink Products Co. acquired the business of Dorothy Gray, consisting of the manufacture of toilet articles and cosmetics (PAS-00028400).

1929: Lehn & Fink Products Co. acquired control of Lesquendieu, Inc. through stock purchase, which was a manufacturer of perfume, cosmetics, and toilet articles (PAS-00028400).

1966: Lehn & Fink Products Co. merged into Sterling Drug Inc. (Sterling) and ceased to exist (PAS-00032941). Sterling later changed its name to Sterling Winthrop Inc. (PAS-00032943). Sterling did continue to use the name as a "doing business as" name and for an operating unit, the "Lehn & Fink Products Division" (PAS-00032941).

1994: On September 26, 1994 Sterling conveyed the assets of its Lehn & Fink Products Division to Kodak and Lehn & Fink Products, Inc., a subsidiary of Kodak, and those two entities conveyed the former Lehn & Fink Products Division assets and specified liabilities to Reckitt Colman plc (PAS-00032941; PAS-00033010). The environmental liabilities of Lehn & Fink were not transferred to Reckitt Colman plc (PAS-00032941). The facility at 192-194 Bloomfield Avenue was not among the properties or leasehold interests acquired by Reckitt Colman (PAS-00032944).

1994: Kodak sold the stock of Sterling Winthrop Inc. to SmithKline Beecham plc, which then sold the stock to Bayer AG. Sterling later changed its name to STWB Inc. STWB Inc., the corporate successor by merger to Lehn & Fink Products Co., continues to exist as a corporate entity, as a subsidiary of Bayer Corporation (PAS-00032941).

1997: Deed Notice filed for 192 Bloomfield Avenue, which appears to be owned and operated by The Hartz Mountain Corporation (PAP-00431976, 95-97). No information could be located in the available file materials regarding when the property was purchased by Hartz Mountain Corporation or how long Hartz Mountain Corporation has operated at this property.

1999: Reckitt Colman merged with Benckiser N.V. to form Reckitt Benckiser plc (PAS-00028400).

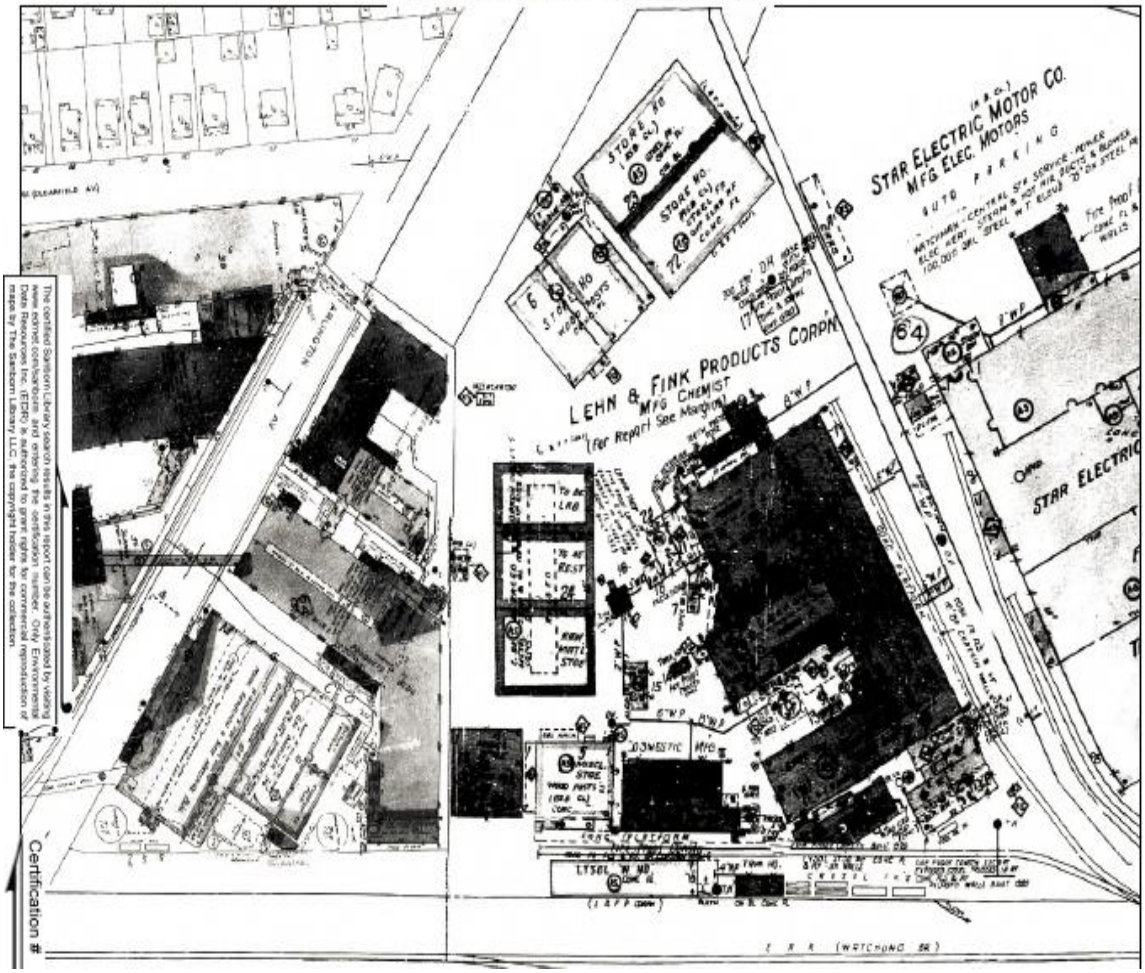
2010: EPA sent a General Notice Letter dated April 20, 2010 to STWB regarding the L&F Facility (PAP-00194929-32).

3. Operational History/COC Use and Presence at the Facility

The L&F Facility consisted of seven buildings that housed the product formulation and packaging areas, research laboratories, corporate administrative offices, and a machine shop. Lehn & Fink, Inc. formulated and packaged cosmetics and consumer products, specifically franchised or name brand cosmetics, acne remedies, and household cleaners, e.g., Dorothy Gray, Tussy, and Ogilvie; Stri-dex and Medi-quick; and, Lysol liquid and aerosol disinfectant, respectively.

The L&F Facility's product line in 1926 included toothpaste, disinfectant, drugs, and chemicals. Trade names included Pebeco Tooth Paste, Lysol Disinfectant and other Lysol products, and Hinds products. The L&F Facility's product line in 1936 included Pebeco tooth paste and powder, Lysol disinfectant, hygienic soap and shaving cream, Hinds cold cream and liquids, Dorothy Gray cold creams and skin lotions, Tussy cosmetics, Amphyl, Lygel, and Henna San (PAS-00028400). In the 1920s, the

formulation of Lysol contained cresols. Amphyl was also a phenol-based disinfectant (PAS-00028401). Another of Lehn & Fink's products starting in the 1950s, O-Syl disinfectant, contained isopropyl alcohol, ortho-benzyl para chlorophenol, and 2-phenylphenol (PAS-00028401-02; PAS-00028642-43).



Initially the active ingredients for Lysol were cresol and soap (PAP-00194787). The current active ingredients in Lysol include: Ethanol/SD Alcohol 40, 1-3%; Isopropyl alcohol, 1-2%; p-Chloro-o-benzylphenol, 5-6%; potassium hydroxide, 3-4%; alkyl (C12-C18) dimethyl benzyl ammonium chloride, 0.08%; alkyl (C12-16) dimethyl benzyl ammonium chloride, 0.02%; Ethanol/SD Alcohol; and, Isopropyl alcohol (PAS-0028633). The file material does not include information regarding when use of the current formulation began.

The L&F Facility was served by two railroad sidings. One wing of the facility was used to manufacture and package Pebeco Toothpaste, while another wing was used to manufacture and package Lysol. A central wing was used for general pharmaceutical manufacturing, such as preparation of fluid extractions and ointments. A machine shop was housed in a separate building to make machinery for the facility. The L&F Facility manufactured and decorated its own collapsible tubes, made its own packing boxes, and printed its own labels and circulars (PAP-00194800).

The L&F Facility also included a laboratory department that tested all raw materials that went into Lehn & Fink products. A biological and chemical research laboratory was also located at the facility. Power was provided to the L&F Facility by an on-site power house served by oil-burning boilers (PAP-00194801).

The 1950 Sanborn Map depicting the L&F Facility layout is presented below (PAP-00431958):

1950 Certified Sanborn Map

No other information regarding Operable Unit 2 (OU2) contaminants of concern (COCs), including whether they were used or stored at the L&F Facility, could be located in the available file materials.

4. Identified COCs

- PCBs (detected)
- PAHs (detected)

PCBs

Data tables included in the Deed Notice filed by The Hartz Mountain Corporation on January 15, 2013 identify the presence of several isolated and sporadic low level detections of polychlorinated biphenyls (PCBs) (PAP-00431961, 91). PCBs were detected in on-site soils at concentrations above their NJDEP Residential and/or Non-Residential Direct Contact Soil Remediation Standards (DCSRS). PCBs were detected at concentrations ranging from 0.083 milligrams per kilogram (mg/kg) in sample L3-1 collected on 11/24/2008 from 10-10.5 ft. bgs to 1.4 mg/kg in sample L4-1 collected on 11/20/2008 from 8-8.5 ft. bgs (PAP-00431991).

According to the Second Supplemental Remedial Investigation Report and Remedial Action Workplan, dated February 24, 2009, the PCB results discussed above were detected in soil at AOC-19, Car Lifts, Lee Myles Building 7. The remains of the former hydraulic lift features were noted to be present in the floor of the northern half of Building 7. The soil samples were collected beneath six hydraulic lift systems after removal of the lifts, pistons, and piping in 2008 (PAP-00485437-9).[1]

No other information regarding PCBs, including whether they were used or stored at the L&F Facility, could be located in the available file materials.

PAHs

The Remedial Investigation/Remedial Action Report, dated January 2014, listed PAHs as COCs for three Areas of Concern (AOCs), including AOC-19 (Lee Myles Car Lifts), AOC-1 (Rail Cars), and AOC B1-1 (Above Ground Storage Tanks). It also stated that PAHs were detected in sediment samples collected in a trench containing utility lines at AOC B7-2 (Floor Drains, Trenches and Piping and Sumps). Concentrations were not included in the available summary table of AOCs from this report (PAP-00485418-23).[1]

PAHs were detected in on-site soils at concentrations above their respective NJDEP Residential and/or Non-Residential DCSRS. The levels of COCs detected included benzo(a)anthracene ranging from 0.61 mg/kg in sample AOC-1I1 collected on 7/24/2006 from 11-11.5 ft. bgs to 52 mg/kg in sample AOC-1I1 collected on 7/24/2006 from 9-9.5 ft. bgs, benzo(a)pyrene ranging from 0.23 mg/kg in sample AOC-1H1 collected on 7/24/2006 from 5-5.5 ft. bgs to 49 mg/kg in sample AOC-1I1 collected on 7/24/2006 from 9-9.5 ft. bgs, benzo(b)fluoranthene ranging from 0.61 mg/kg in sample AOCB1-1B3 collected on 7/24/2006 from 3-3.5 ft. bgs to 60 mg/kg in sample AOC-1I1 collected on 7/24/2006 from 9-9.5 ft. bgs, benzo(k)fluoranthene ranging from 6.5 mg/kg in sample AOC-1H collected on 4/11/2003 from 2.5-3 ft. bgs to 19 mg/kg in sample AOC-1I1 collected on 7/24/2006 from 9-9.5 ft. bgs, dibenzo(a,h)anthracene ranging from 0.21 mg/kg in sample AOCB1-1B collected on 11/17/2000 from 0-0.5 ft. bgs to 11 mg/kg in sample AOC-1I1 collected on 7/24/2006 from 9-9.5 ft. bgs, and indeno(1,2,3-cd)pyrene ranging from 0.62 mg/kg in sample AOCB1-1F4 collected on 7/24/2006 from 1-1.5 ft. bgs to 32 mg/kg in sample AOC-1I1 collected on 7/24/2006 from 9-9.5 ft. bgs (PAP-00431982-87). No other information regarding PAHs, including whether they were used or stored at the L&F Facility, could be located in the available file materials.

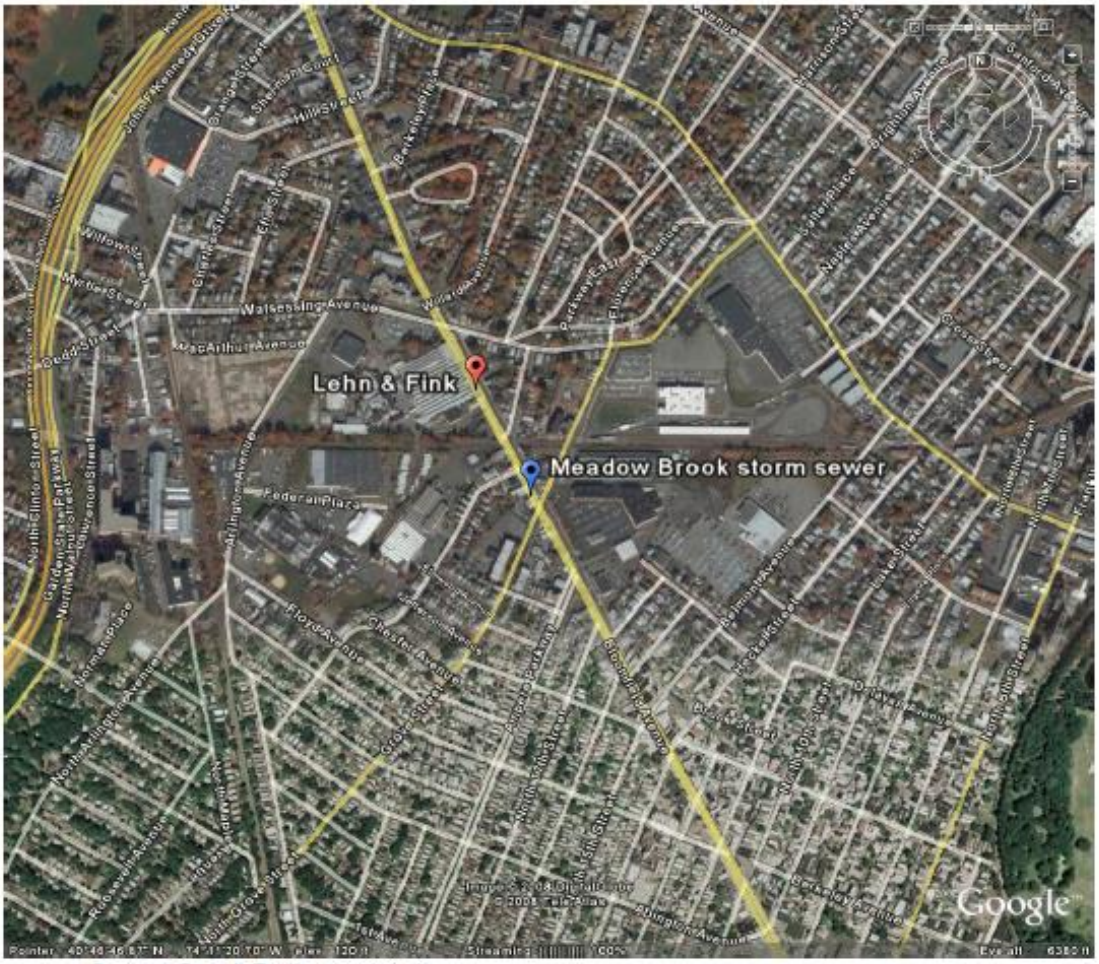
Historic Fill

The Allocation Team has determined that the property is located on regional Historic Fill as designated by the NJDEP.[2]

[1] This Report was revised to include documents received on May 31, 2020. The additional documents did not change STWB Inc.'s previous certification.
[2] *Digital Geodata Series, DGS04-7, Historic Fill for New Jersey*, https://www.nj.gov/dep/njgs/geodata/dgs04-7.htm, Quadrangle #52 & #53 (NJDEP map identifying locations of recognized historic fill).

The NJDEP has established that Historic Fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 COCs: PAHs, lead, copper, and mercury.[3] Accordingly, NJDEP technical requirements for property containing Historic Fill requires sampling for the United States Environmental Protection Agency (EPA) Target Compound List (TCL) for PAHs and Target Analyte List (TAL) for metals, including lead, copper, mercury, and the OU2 PAH COCs.[4] PAHs, lead, copper, and mercury are recognized by NJDEP to be constituents of Historic Fill at varying levels, not atypically at or exceeding residential soil standards.[5]

The levels of PCBS and PAHs detected at the site in soils are presented in the table below (PAP-00431986; PAP-00431991).

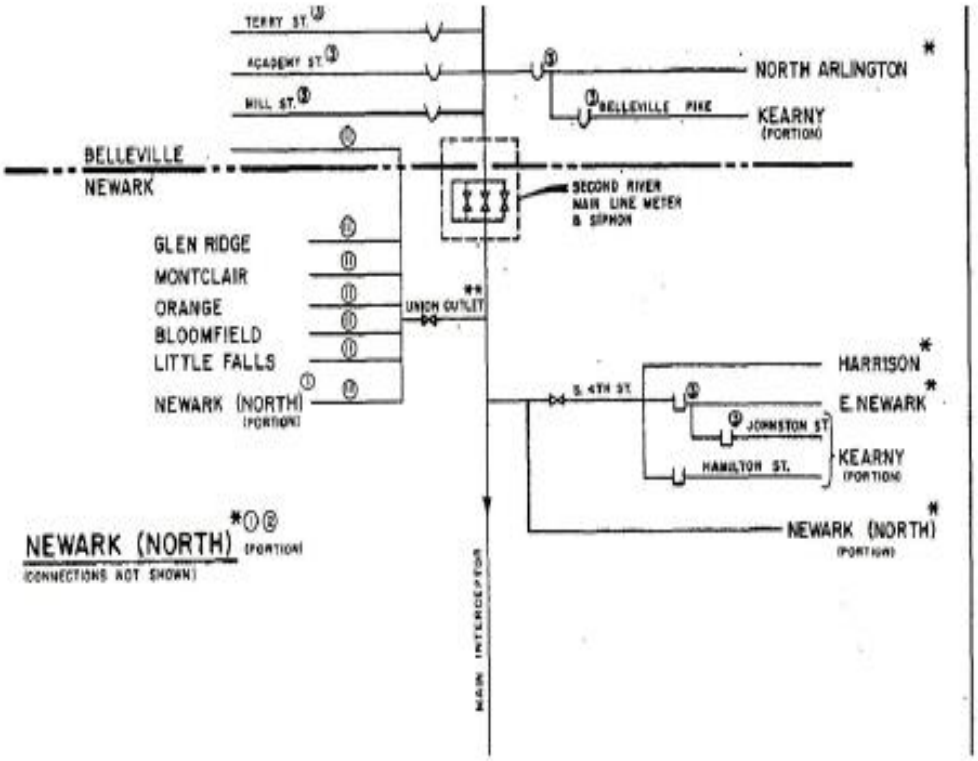


COCs Found in Onsite Soils	
COC	**Max Detected Concentration**
Benzo(a)anthracene	52 mg/kg
Benzo(a)pyrene	49 mg/kg
Benzo(b)fluoranthene	60 mg/kg
Benzo(k)fluoranthene	19 mg/kg
Dibenzo(a,h)anthracene	11 J mg/kg
Indeno(1,2,3-cd)pyrene	32 mg/kg
PCBs	1.4 mg/kg

5. COC Pathways

Sanitary and Storm Sewer

The L&F Facility discharged industrial wastewater through the Meadow Brook sewer, which discharged directly into the Second River (a tributary of the Passaic River) until 1931. After 1931, wastewater from the L&F Facility would have been discharged through the Union Outlet Sewer into the Passaic Valley Sewerage Commission (PVSC) system. The PVSC system is subject to bypassing into the Passaic River during overflow events, or to the Meadow Brook Storm Sewer (which continued to discharge into Second River) (PAS-00028399). The Google Earth image below depicts the location of the L&F Facility relative to the Meadow Brook storm sewer (PAS-00028401).



[3] *Characterization of Ambient Levels of Selected Metals and cPAHs In New Jersey Soils* (2002) and *Characterization of Ambient Levels of Selected Metals and Oher Analytes In New Jersey Soils* (1997), studies prepared for NJDEP, Division of Science and Research, by BEM Systems, Inc.
[4] New Jersey Department of Environmental Protection (NJDEP), *N.J.A.C. 7:26E Technical Requirements for Site Remediation,* Table 4-2, November 2009 [Note that Table 4-2 has been deleted from the current version of N.J.A.C. 7:26E (May 7, 2012) and the updated *Historic Fill Technical Guidance* (April 2013) as NJDEP believed that the tables list of historic fill constituents was too restrictive].
[5] NJDEP Table 4-2 (PAHS & lead) and a summary of NJDEP records regarding investigations of properties in the vicinity of the Passaic River recognized to be located in areas of Historic Fill indicate that the following average/maximum (mg/kg) contamination levels of OU2 COCs exist in area Historic Fill: PAHs (1.91/160), lead (574/10,000), copper (11.2/1,200), and mercury (0.21/3.7).

Source: GoogleEarth, annotated

The Meadow Brook sewer was in use by parts of Bloomfield, including the L&F Facility, in 1927 (PAS-00028402).

In 1930, the municipalities of Newark, Bloomfield, Belleville and East Orange entered into a contract to build a sanitary sewer and a storm sewer, designated as the Meadow Brook Sewers. The sanitary sewer was connected to the Union Outlet Sewer at the Morris Canal, and the storm sewer was connected to the Second River in Belleville (PAS-00028402-3). The Union Outlet Sewer ultimately connects to the PVSC trunk sewer and was used by the PVSC as an overflow point to relieve excessive flow volumes farther down the system (PAS-00028404). On January 6, 1930, meeting minutes state that the connection between the Meadow Brook Sewer and the "new line" had been made. Both of these sewers still received industrial waste from various manufacturing plants as of 1947 (PAS-00028403). A schematic diagram of the PVSC sewer is presented below (PAS-00028404):

The L&F Facility was reported by the PVSC in 1927 for polluting Meadow Brook (a tributary of the Passaic River) with industrial waste containing hazardous substances (PAS-00028399). Industrial wastewater discharge from the L&F Facility was identified in a 1927 memo regarding pollution from municipal sewers as "large in volume." However, a memo dated April 4, 1927 states that the discharge from the L&F Facility contained "cresols and phenol in solution in small amount" (PAS-00028609). The industrial waste from the L&F Facility was discharged into a storm sewer which became an open brook known as Meadow Brook, which constituted a tributary of Second River. The culvert received the L&F Facility's industrial wastewater in the vicinity of where it crossed Bloomfield Avenue. The distance from the L&F Facility to the discharge point at Bloomfield Avenue is just over one-tenth of a mile (PAS-00028405). In May 1928, the L&F Facility was named as a contributor of chemical waste to the Meadow Brook culvert (PAS-00028406, 417). In June 1928, a letter on the same topic states that an investigation was done establishing that pollution entering the Meadow Brook storm culvert did not originate from any location above the L&F Facility (PAS-00028406).

There is no information regarding discharges of OU2 COCs in the available file material.

Direct Release

There is no information regarding direct release in the available file material.

Spills

There is no information regarding spills in the available file material.

6. Regulatory History/Enforcement Actions

Inspections

There is no information regarding inspections in the available file material.

Violations

There is no information regarding violations in the available file material.

Permits

The entire time period of Lehn & Fink's discharges from the L&F Facility occurred prior to the February 1975 effective date of PVSC's NPDES permit and, therefore, were not covered by a federal permit (PAS-00028405). A table of permit information for 192 Bloomfield Avenue for the period after Lehn & Fink Products Co. operations had ceased was located in the file materials (PAP-00194858):

Site Information

Discharge Period		Discharge Type	Discharge Location
From	To		
1965	Present	Sanitary/Industrial – Permit #02200003	Passaic Valley Sewerage Commissioners
1965	Present	Stormwater- NJPDES Gen. Permit #NJ0088315	Raritan River, via municipal storm sewer system

There is no additional information regarding permits in the available file materials.

7. Response Actions

Characterization Activities

The following is a list of major response action documents identified in the available file material:

- *Third Supplemental Remedial Investigation Report and Remedial Investigation Workplan, The Hartz Mountain Facility, 192 Bloomfield Avenue*, Bloomfield, New Jersey, dated April 1, 2011 (PAP-00194815); and,
- *Preliminary Assessment Report, The Hartz Mountain Facility, Bloomfield, New Jersey*, dated June 2001 (PAP-00194857).

Sewer

There is no information regarding sewer sampling in the available file material.

Soil

Soil sampling was conducted at 192 Bloomfield Avenue by Hartz Mountain Corporation in relation to their site use and operations (PAP-00194815); however, based on review of available file material, there was no soil sampling conducted to target site use and operations by Lehn & Fink Products Co.

Remedial Activities

A Deed Notice has been implemented as an institutional control for four areas of concern (AOCs) located at the Hartz Mountain Corporation facility located at 192 Bloomfield Avenue. The four AOCs are as follows:

- AOCB1-1, Former Cresol Aboveground Storage Tanks (ASTs) and AOC-1 Rail Spur – The deed notice addresses PAH concentrations in soil above NJDEP Residential DCSRS (PAP-00431996);

- AOCB2-1, PVC/DCA ASTs – The deed notice addresses bis-2(ethylhexyl) phthalate concentrations in soil adjacent to the ASTs. Excavation of soils was not deemed safe or feasible due to the presence of utility poles/guy wires, steep slopes, and the ASTs (PAP-00431996).

- AOC-19, Lee Myles Building (Building 7) – The deed notice addresses total petroleum hydrocarbons (TPH) concentrations in soil above 10,000 mg/kg in samples collected in November 2008. The area also contains five detections of PCBs, only one of which exceeds the NJDEP Non-Residential DCSRS (PAP-00431996).

- 1997 Declaration of Environmental Restrictions (DER) Area, Former Underground Storage Tank (UST) Case No. 91-11-13-1044 – The deed notice addresses PAH concentrations above the NJDEP Residential DCSRS (PAP-00431996-97).

The NJDEP issued a No Further Action Letter dated May 24, 1999 to Hartz Mountain Corporation for UST No. 0118857, Closure No. N98-2706, located at 192 Bloomfield Avenue, Bloomfield, Essex County (PAP-00194861).

8. Summary of Asserted Defenses

No legal defenses were identified in the available file material.

Diamond Alkali OU2 Allocation

ADR Confidential

Facility Data Report

STWB Inc.

Facility Name, Address and Size: Sterling Winthrop Inc., aka STWB Inc./Thomasset Colors Inc., 120 Lister Avenue, Newark, New Jersey (Block 2438, Lot 56); aka 104-112 Lister Avenue, Newark, New Jersey; 2.6 acres (PAP-00194934; PAP-00057548). In approximately 1980, there were 55 full-time employees working two shifts per day, five days a week (PAP-00431723). The site abuts the south side of the Passaic River.

1. **Business Type:** Manufacturing of organic and inorganic pigments for the automobile, textile, drug, and cosmetic industries (PAP-00057488).

2. **Time Period of Ownership/Operations**

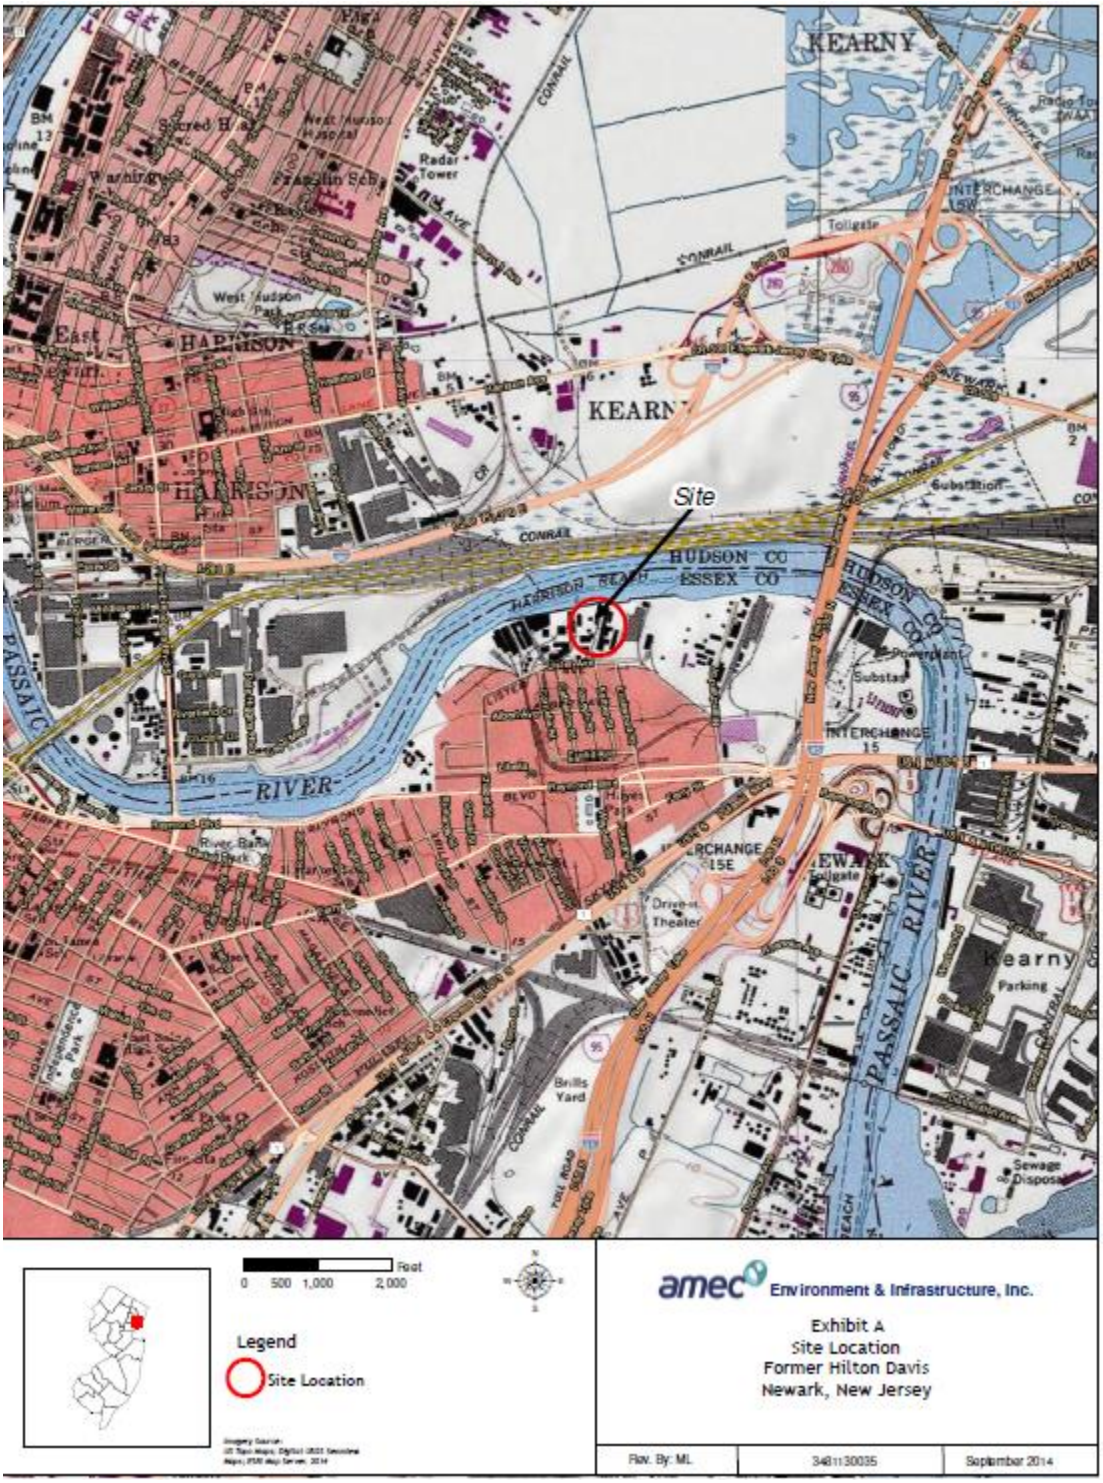
   Operator: March 1957 to October 1986
   Owner: March 1957 to October 1986

   1957: On March 11, 1957, STWB Inc. acquired Thomasset Colors Inc. (TCI) (PAS-00002720).

   1983: On December 28, 1983, STWB Inc. transferred the assets of TCI to its subsidiary, The Hilton-Davis Chemical Company (Hilton-Davis) (PAS-00002720).

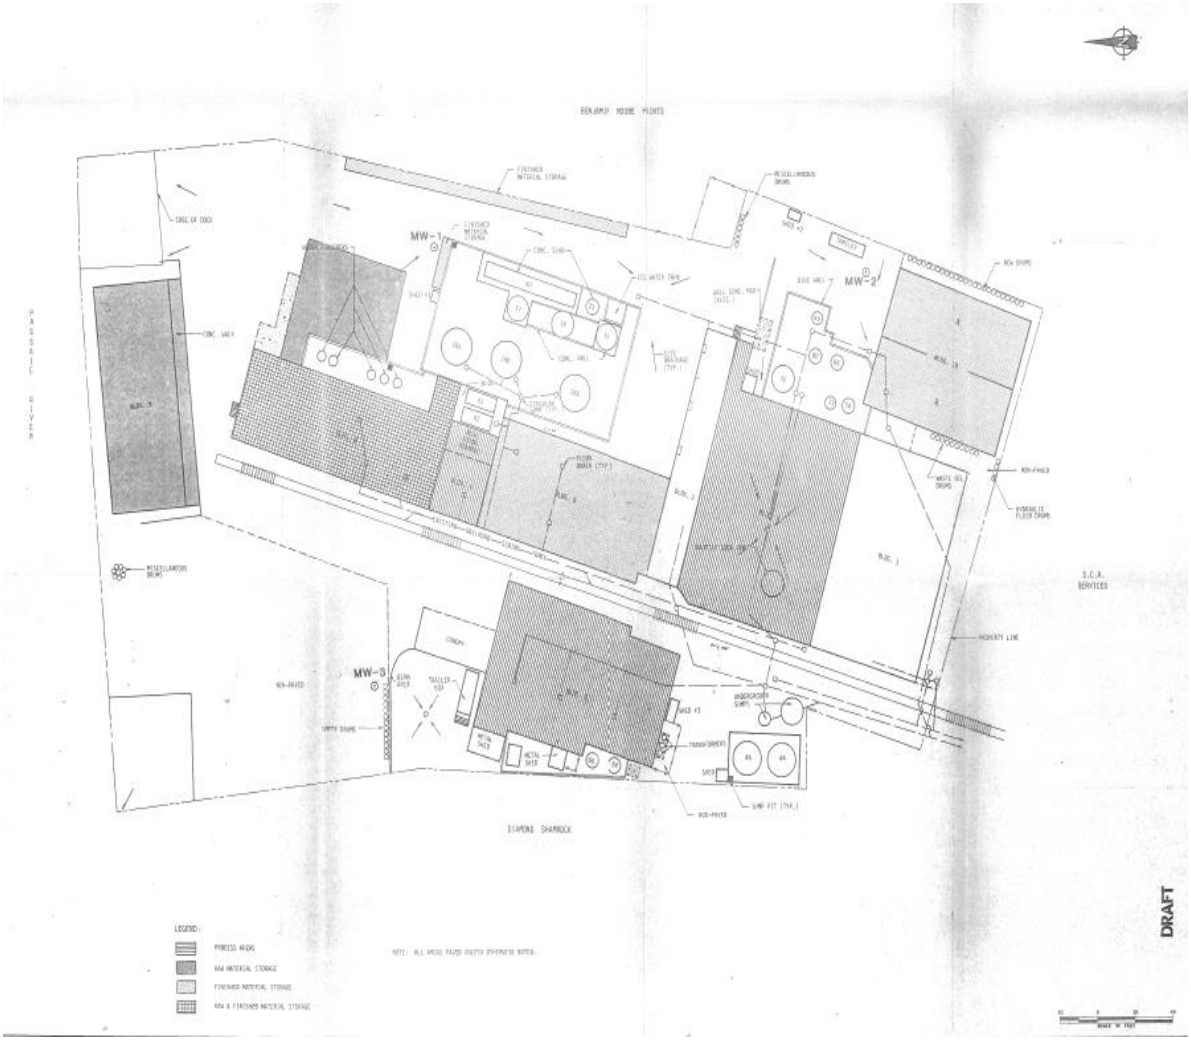
   1986: On October 23, 1986, the assets of Hilton-Davis were sold to H.D. Acquisition Corporation, which later changed its name to Hilton Davis Co., a division of Plastics Manufacturing Corp (PMC) (PAS-00002720).

   1986: TCI ceased operating at the site on October 23, 1986 with the sale of Hilton-Davis to PMC (PAS-00002720).



3. **Operational History/COC Use and Presence at the Facility**

   During the relevant time period, STWB Inc. conducted pigment manufacturing operations at the site that produced three types of pigments: (a) phthalocyanine ("phthalo") pigments for the automobile industry; (b) transoxide-based textile pigments for the textile industry; and, (c) pigments for the drug and cosmetics industries, referred to as D&C Colors (PAP-00057488). A review of available documents showed that the materials used in the production of these three pigments did not contain any of the Operable Unit (OU) 2 COCs, with the exception of a water-soluble form of copper sulfate, which was limited to manufacturing of the phthalo pigments (PAS-00002721-724; PAP-00057496-499). The production of phthalo pigments based on peer-reviewed literature could not generate polychlorinated biphenyls (PCBs), polychlorinated dibenzo-p-dioxins (PCDDs), and/or polychlorinated dibenzofurans (PCDFs), as was possibly the case for other manufacturing methods (PAP-00208780-9). This is borne out by on-site groundwater samples that show that 2,3,7,8-tetrachlorodibenzodioxin (TCDD) and PCB congeners in groundwater samples are either below detection limits or non-detect (PAP-00057501-502; PAP-00057596).



Diamond Alkali OU2 Allocation

ADR Confidential

Facility Data Report

(PAP-00195021)

(PAP-00057500)

Production processes at the site included the following materials and methods:

Building 5 at the site was the production area where the raw materials for phthalo blue pigment were mixed in tanks and baked in ovens. Resultant solid product was ground and dissolved in 98 percent sulfuric acid and pumped into tanks where it was diluted with water to achieve a 10 percent sulfuric acid concentration slurry. The 10 percent slurry was neutralized with ammonia and pumped to filter presses located in Building 2. Filter press wastewater was discharged via floor sump to neutralizing tanks, which subsequently dischargedto the sewer. Finished filter cakes were milled, blended and stored in drums in Building 8 or 10 as the final product prior to off-site shipment (PAP-00057514-515, PAS-00002723).

Transoxide (metal oxide) pigments were also manufactured at the site. Raw material for transoxide included soda ash, ferrous sulfate, and water (PAP-00057515). The raw materials were mixed with air in tanks (Tanks 60, 66 and 69) located in Building 2 at the site. Two slurry batches were produced, transferred to tanks and boiled, and the resulting slurry was pumped to a filter press in Building 4. Wastewater generated from filter pressing was sent to the on-site neutralization tank system which subsequently discharged to the sewer. Filter cakes were extruded to a drying belt and heated and/or steamed to various temperatures depending upon the pigment desired (yellow or red). Final product was milled, blended, and drummed for storage in Building 8 or 10 prior to shipment (PAP-00057515, PAS-00002723).

Lastly, D&C Colors were produced at the site. Raw materials were para-toluidine-meta-sulfonic acid, beta-oxynaphthotic acid, aluminum chloride, sodium bicarbonate, sodium carbonate, and dyes (PAP-00057515). These materials were mixed in tanks in Building 2. Slurries were filter pressed in Building 2 and wastewater generated from filter pressing was sent to the on-site neutralization tank system, which subsequently discharged to the sewer. Filter cakes were dried in tray dryers, then milled in Building 4, blended, drummed, and stored as final product in Building 8 or 10 (PAS-00002722-3; PAP-00057489).

Wastewater containing trace amounts of unreacted water-soluble copper sulfate generated from filter pressing in Building 2 were pumped to the neutralization system which subsequently discharged the neutralized wastewater to the sewer (PAP-00057515, PAS-00002723). Note: Details regarding the offsite discharging location of the filter press wastewater were not provided in available references.

A raw material inventory conducted at the site included copper sulfate monohydrate (PAP-00057496-499).[1]

4. Identified COCs

- PAHs (detected)
- Copper (used, stored, released, detected)
- Lead (detected)
- Mercury (detected)

PAHs

According to the June 28, 1996, Declaration of Environmental Restrictions, PAHs have been detected at various locations in soils throughout the facility property. The Deed Notice for the facility includes PAH detections in areas believed to be located on Historic Fill. The table and map below provide maximum concentrations of PAHs and sampling locations (PAP-00194966-72).

[1] According to an American Elements website, copper sulfate monohydrate and copper chloride are water soluble. https://www.americanelements.com/copper-sulfate-monohydrate-10257-54-2, https://www.americanelements.com/copper-ii-chloride-7447-39-4

(PAP-00194967)

Metals – Copper, Lead and Mercury

Small amounts of copper have been detected in on-site soils. All detections were below NJDEP Direct Contact Soil Remediation Standards and Default Impact to Groundwater Soil Screening Levels, and NJDEP issued a No further Action (NFA) letter in 1995 (PAP-00194944).

Metals (lead and mercury) have been detected at various locations in soils throughout the facility property. The Deed Notice for the facility includes lead detections in areas believed to be located on Historic Fill (PAP-00194956-972). Mercury and copper were not required to be included in the Deed Notice, as they were not detected at the facility above NJDEP Residential Direction Contact Soil Remediation Standards. The table and map at the end of this section provide maximum concentrations of metals and sampling locations (PAP-00194966-972).

Maximum Metal Concentrations (mg/kg)		
Metal	**Concentration**	**Sample Location**
Copper	1,950	Bldg. 5-A
Lead	1,360	Drum Stor. A
Mercury	5.9	Bldg. 5-B

(PAP-00194968-71)

Historic Fill

The Allocation Team has determined that the facility site is located on regional Historic Fill as designated by the NJDEP.[2]

NJDEP has established that historic fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 COCs: PAHs, lead, copper, and mercury.[3] Accordingly, NJDEP technical requirements for property containing Historic Fill requires sampling for the EPA Target Compound List for PAHs and Target Analyte List for metals, including lead, copper, mercury, and the OU2 PAH COCs.[4] PAHs, lead, copper, and mercury are recognized by NJDEP to be constituents of Historic Fill at varying levels, not atypically at or exceeding residential soil standards.[5]

[4] New Jersey Department of Environmental Protection (NJDEP), *N.J.A.C. 7:26E Technical Requirements for Site Remediation,* Table 4-2, November 2009 [Note that Table 4-2 has been deleted from the current version of N.J.A.C. 7:26E (May 7, 2012) and the updated *Historic Fill Technical Guidance* (April 2013) as NJDEP believed that the tables list of historic fill constituents was too restrictive].

[5] NJDEP Table 4-2 (PAHs and lead) and a summary of NJDEP records regarding investigations of properties in the vicinity of the Passaic River recognized to be located in areas of Historic Fill indicate that

The levels of PAHs, copper, lead and mercury detected at the site in soils are presented in the table below.

COCs Found in Onsite Soils	
COC	**Max Detected Concentration**
Lead	1,360 mg/kg
Copper	1,950 mg/kg
Mercury	5.9 mg/kg
Benzo(a)anthracene	408.81 mg/kg
Benzo(a)pyrene	344.03 mg/kg
Benzo(b)fluoranthene	317.09 mg/kg
Benzo(k)fluoranthene	118.832 mg/kg
Dibenzo(a,h)anthracene	92.95 mg/kg
Indeno(1,2,3-cd)pyrene	237.386 mg/kg

5. COC Pathways

Process and Sanitary Water

Discharges from the system to the sewer were monitored for pH, total suspended solids, and biochemical oxygen demand (PAP-00057488).

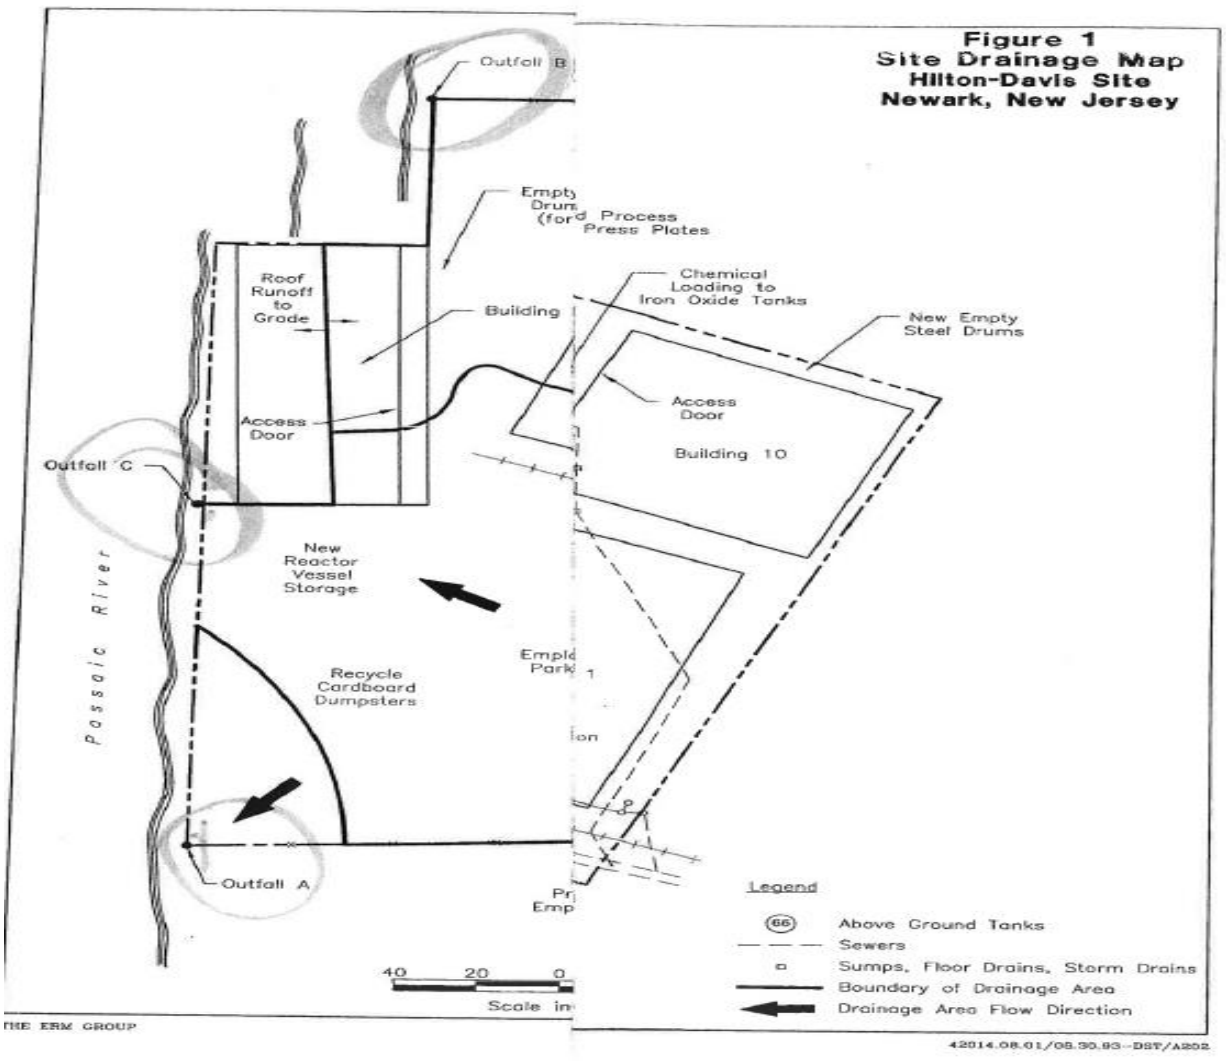
Waste streams from floor drains generated at the site during TCI's period of operation were discharged to a sanitary sewer. A wastewater neutralization system was constructed in June 1971 to neutralize process wastewater prior to discharge to the sanitary sewer (PAS-00002725). Stormwater catch basins and process wastewater were discharged to the City of Newark sanitary sewer in Lister Avenue through a combined 12-inch sewer line. In June 1971, a new 16-inch sewer was constructed to discharge treated process wastewater to the municipal sanitary sewer. At the same time, the existing 12-inch sewer line was converted for stormwater use only and was connected to a municipal storm sewer in Lister Avenue. In March 1972, the 12-inch sewer line was sealed off from the municipal storm sewer (PAS-00002725).

The Montrose Chemical Co. Wastewater and Stormwater Discharges Expert Report dated August 2017 reported the sanitary sewer line under Lister Avenue flowed westward and connected directly to the PVSC Newark Bay Waste Water Treatment Plant (NVWWTP) via the Brown Street Branch Interceptor (BSBI). The BSBI was constructed in 1921 and conveyed all its flow to the NBWWTP. Sewage in the BSBI did not discharge to the Passaic River, even during storm events. There was no hydraulic connection that would allow flow to the BSBI to discharge to the Brown Street Combined Sewer Overflow (CSO) or any other CSO (PAP-00027671).

---

the following average/maximum (mg/kg) contamination levels of OU2 COCs exist in area Historic Fill: PAHs (1.91/160), lead (574/10,000), copper (11.2/1,200), and mercury (0.21/3.7).

Diamond Alkali OU2 Allocation



ADR Confidential

Facility Data Report

Direct Release

A portion of wastewater generated during the production of phthalo blue pigment may have been reportedly discharged to the Passaic River from approximately 1956 to 1958 and then again from 1963 until July 1971 (PAS-00002723-24, 26). This waste stream contained inter alia, sulfuric acid, and trace amounts of unreacted water-soluble copper salts; however, insufficient information was available to accurately estimate the amount of decant water discharged to the Passaic River (PAS-00002726).

STWB Inc. reports that a topographic drainage divide segregated stormwater runoff on the north and south sides of the site. The northern portion of the site drained to the Passaic River through three drainage swales (A, B, and C) (PAP-00194989-991).

(PAP-00194991)

Spills

The table of contents of the *Supplemental Remedial Investigation Report,* Former Hilton-Davis Site, 112 Lister Avenue, Newark, Essex County, New Jersey, NJDEP Case No. E86941, Program Interest No. 192995, dated March 2016, identifies AOC 3 as "Phthalo Blue Discharge Spill Area", but only a few selected pages of response action documents were provided, and no more information about this spill was available (PAP-00057510, 12).

6. Regulatory History/Enforcement Actions

Violations

In a letter dated August 27, 1971, PVSC pointed out that during their inspection on August 19, 1971, a green material was noted in the Passaic River coming from the Lockwood Street storm sewer. Further inspection showed that an accident occurred at the site where a container of green fluorescein dye was discharged into a catch basin within the site area, which reached the Lockwood Street storm sewer and the Passaic River. In addition, PVSC pointed out during their inspection that due to poor housekeeping, pollution could occur not only from spills, but during any rainfall event, as the material lying on the ground could discharge to the storm sewer (PAS-00002739). The poor housekeeping was addressed by September 9, 1971 (PAS-00002740). In March 1972, the 12-inch sewer line was sealed off from the municipal storm sewer (PAS-00002725).

In February 1972, PVSC issued a notice of violation indicating that the sewer department took out a sample from the sewer line and found "chemical in the line." It was recommended that this condition be checked for a defective sewer line (PAS-00002741). Note: The specific "chemical in the line" was not identified.

On April 27, 1976, a $750 fine was imposed on TCI for violations of the Spill Prevention, Control, and Countermeasure (SPCC) regulations under Section 311 of the Federal Water Pollution Control Act (PAS-00002727). Note: No additional information was provided.

Permits

The Passaic Valley Sewerage Commission (PVSC) issued a sewer connection permit (No. 20402690) to the site for the period from May 15, 1981, through May 15, 1986, for discharge of effluent to PVSC. The permit was renewed by PVSC effective May 27, 1986, for a period of five years (PAS-00002721). Available references did not include the permit and a description of effluent flow rate and monitoring requirements.

7. Response Actions

Characterization Activities

The following characterization activities have taken place at the facility:

- *Supplemental Remedial Investigation Report,* Former Hilton-Davis Site, 112 Lister Avenue, Newark, Essex County, New Jersey, NJDEP Case No. E86941, Program Interest No. 192995, dated March 2016 (PAP-00057510).
- *ECRA Cleanup Plan Implementation Report, Hilton Davis Site, Newark, New Jersey, ERA Case No. 86941,* dated December 1994 (PAP-00194984-8).
- *ECRA Cleanup Plan, Hilton Davis Site, Newark, New Jersey, ECRA Case No. 86941,* dated April 16, 1992 (PAP-00057585).
- *Environmental Cleanup Responsibility Act ECRA Initial Notice - Site Evaluation Submission (SES),* Hilton Davis Chemical Company-Thomasset Div., Enviro-Sciences, Inc., dated February 23, 1987 (PAP-00057486).

Sewer

There is no information regarding sewer sampling in the available file material.

Soil

There is no information regarding soil sampling in the available file material.

8. Summary of Asserted Defenses

No legal defenses were identified in the available file material.

Sun Chemical Corp.

Facility Data Report

SUN CHEMICAL CORPORATION

Facility Name, Address and Size: Sun Chemical Corporation, 185 Foundry Street, Newark, New Jersey and approximately 17,000 square feet (0.4 acres) (PAS-00008258). Sun Chemical Corporation occupied Building Nos. 23, 31, 32, 33, 34 and 34A on Lot 22.01 (PAS-00000242). In 1990, Sun Chemical Corporation had 30 employees working three shifts per day 238 days per year (PAP-00049181). One employee and several subcontractors remained at the site as of April 2, 2004 (PAP-00377198).

1. **Business Type:** Organic pigment manufacturer (PAS-00000672). The pigments were used in the automobile industry, printing inks, and plastics (PAS-00000190; PAS-00105580; PAS-00128904).

2. **Time Period of Ownership/Operations**

   Operator: December 31, 1986 to December 31, 2003 (PAS-00008260)
   Owner: November 20, 1990–November 5, 2004 (PAS-00008259)

   The site at 185 Foundry Street was owned by Foundry Street Corporation from May 3, 1971 to November 20, 1990. Sun Chemical Corporation owned the site from November 20, 1990 to November 5, 2004 (PAS-00008259).

NAME OF OWNER (185 Foundry Street)	DATES OF OWNERSHIP
Roanoke, Inc.	<1911 (estimated)–1939
Chemical Industries, Inc.	1939–1964
KEM Realty Company	1964–May 3, 1971
Foundry Street Corporation	May 3, 1971–November 20, 1990
Sun Chemical Corporation	November 20, 1990–November 5, 2004
Fleshment, LLC	November 5, 2004–Unknown

(PAS-00008259)

NAME OF OPERATOR (185 Foundry Street)	DATES OF OPERATION
H.A. Metz Laboratories	<1931–1950
Diamond Alkali	1950–1967
Sequa Corporation (formerly known as Sun Chemical Corporation)	1967–December 31, 1986
Sun/DIC Acquisition Corp. (changed its name to Sun Chemical Corporation in June 1987)	December 31, 1986–December 31, 2003

(PAS-00008260)

According to a *Response to Request for Information*, dated August 23, 1996, prior to purchasing the site, Sun Chemical Corporation leased the site from Foundry Street Corporation (PAS-00008307; PAS-00008350; PAS-00111410). The lease commenced on December 1, 1989 (PAS-00008350).

According to a *Response of Sun Chemical Corporation to "Report on Industrial Waste Streams Bypassed to the Passaic River,"* dated December 1, 1997 (1997 Response), on December 31, 1986, Sun/Dainippon Ink and Chemicals (DIC) Acquisition Corporation acquired certain pigment operations, including those at the Foundry Street site, from Sun Chemical Corporation in an asset transaction (PAS-00053968). Sun/DIC changed its name to Sun Chemical Corporation in June 1987. Sun/DIC Acquisition Corporation operated the site as Sun Chemical Corporation from December 31, 1986 to December 31, 2003 (PAS-00008260).

The 1997 Response states that the former Sun Chemical Company (the entity that changed its name to Sequa Corporation), as seller in the above-referenced asset transaction, agreed that it would remain responsible for off-site disposal, if any, that occurred prior to closing and Sun/DIC Acquisition Corp. (the entity that changed its name to Sun Chemical Corporation), as buyer in the above-referenced asset transaction, did not assume liability arising from such pre-closing disposal. There is no corporate relationship between Sequa Corporation (the former Sun Chemical Company) and the current Sun Chemical Corporation. The current Sun Chemical Corporation is not responsible for discharges, if any, that occurred before the December 31, 1986 acquisition (PAS-00053968).

3. Operational History/COC Use and Presence at the Facility

According to the *Evaluation of Alleged Nexus of Sequa Corporation,* dated September 9, 2016, the production of red pigment utilizes glacial acetic acid. Spent acid generated from the process was pumped to a neutralization tank, where it was neutralized with caustic soda, and discharged to the Passaic Valley Sewerage Commission (PVSC) system pursuant to a permit (PAS-00047107).

The *Evaluation of Alleged Nexus of Sequa Corporation,* dated September 9, 2016 also stated that the effluent generated from the production of violet pigment consisting of alcohol and phosphoric acid was pumped to a neutralization tank for treatment with caustic soda. After the pH was adjusted, the effluent was discharged into the PVSC system pursuant to a permit (PAS-00047107).

According to a *Responsible Party Investigation Summary*, dated April 1991 (1991 Investigation Summary), caustic soda was used to neutralize process effluent in two interconnected 1,500 gallon above ground storage tanks situated between Building Nos. 23 and 31. The treated effluent was discharged into a sump connected to an industrial sewer located on the adjacent property (Lot 4) owned by Norpak Corporation. Sun Chemical Corporation (the entity that changed its name to Sequa Corporation) discharged its effluent into the strip drainage system located on the west side of the plant before the installation of the wastewater treatment unit (PAS-00000191; PAS-00105581).

According to a February 22, 1987 *Site Evaluation Submission*, Sun/DIC Acquisition Corporation's (the entity that changed its name to Sun Chemical Corporation after acquiring assets from Sequa Corporation) chemical inventory did not include any of the contaminants of concern (COCs) for the Passaic River Site (PAS-00044732; PAS-00111848).

According to the *Response to Request for Information,* dated August 23, 1996, trace amounts of lead were present as stormwater contamination from runoff of adjacent upgradient property. It was believed to originate from Arkansas Chemical. Lead was also present in trace amounts in laboratory test paint solvent blend which was manifested offsite to a Resource Conservation and Recovery Act (RCRA) Treatment, Storage and Disposal Facility (PAS-00008294; PAS-00111397).

In a December 22, 2003 letter to PVSC, LFR Levine Fricke Inc. stated that Sun Chemical Corporation had ceased production at the site and planned to remove all raw materials, finished products, and wastes from the site prior to December 31, 2003 (PAP-00374789).

4. Identified COCs

- PCBs (detected)
- PAHs (used, detected)
- Copper (detected)
- Lead (detected)
- Mercury (detected)

According to a February 22, 1987 Site Evaluation Submission, Sun/DIC Acquisition Corporation's chemical inventory did not include any of the COCs for the Passaic River Site (PAS-00044732; PAS-00111848).

PCBs

According to the *Evaluation of Alleged Nexus of Sequa Corporation,* dated September 9, 2016, Arkansas Chemical is the likely source of the PCB (Aroclor 1248) contamination detected at the site. This conclusion was based on the following:

- Arkansas Chemical manufactured textile chemicals including retardants and repellants that were early uses of PCBs, including Aroclor 1248;
- Arkansas Chemical had a historical footprint of operations at the Foundry Street Complex that extended beyond its subsequent property boundary;
- Arkansas Chemical was observed by NJDEP to have poor materials management practices that would release hazardous substances to the sewer and drainage system; and,
- The drainage system and frequent flooding at the Foundry Street Complex would have distributed any Arkansas Chemical PCB releases and likely accounts for the observed Aroclor 1248 contamination at and beyond the Foundry Street site (PAS-00047112-13).

According to a *Report on Industrial Waste Streams Bypassed to the Passaic River*, dated August 1994, contaminants detected onsite in sediment and soils between 1988 and 1993 included PCBs (PAS-00051217-18).

PAHs

An undated *Emergency Response Reference Guide for Sun Chemical Corporation* for the period January 1 to December 31, 1988 reported chemicals stored onsite which included No. 2 fuel oil stored in Tank No. 15 and petroleum oil (lube oil) stored in the maintenance shop (PAP-00381230). Note: PAHs may be present in oils.

According to a *Report on Industrial Waste Streams Bypassed to the Passaic River*, dated August 1994, contaminants detected onsite in sediment and soils between 1986 and 1993 included naphthalene, 2-methylnapthalene, benzo(a)anthracene, chrysene, benzo(b)fluoranthene, benzo(k)fluoranthene, benzo(a)pyrene, indeno(1,2,3-cd)pyrene, benzo(g,h,i)perylene, and dibenzo(a,h)anthracene as well as other contaminants (PAS-00051217-18).

According to a *Preliminary Assessment Report for Sun Chemical Corporation*, dated April 2004, the hazardous substance/waste inventory for Sun Chemical Corporation included gear oil, hydraulic oil, mineral seal oil, waste oil, and No. 2 fuel oil (formerly used) (PAP-00377217; PAP-00377741). Note: PAHs may be present in oils.

Metals – Copper, Lead and Mercury

According to an April 28, 1988 letter from General Testing Corporation, effluent sampling in March 1988 detected the presence of lead at concentrations ranging from 0.084 to 0.219 milligrams per liter (mg/L) which were below the Organic Chemicals, Plastics, and Synthetic Fibers (OCPSF) daily limit of 0.690 mg/L (PAP-00374563-68; PAS-00111619-24; PAS-00128876). The caustic soda used to pretreat the facility effluent, as required by a permit with PVSC, contained trace quantities of mercury, copper and lead (0.0000001%, 0.0001%, and 0.00005%, respectively, by weight) (PAP-00122260). The effluent samples were all non-detected for polynuclear aromatic hydrocarbons (PAHs) (PAS-00111625-46).

A 1990 PVSC Application for a Sewer Connection Permit for Permit No. 20401042 included results from effluent sampling conducted on September 17, 1990. Reported results included copper at 2.74 mg/L and mercury at 0.00109 mg/L (PAP-00049181, 97). The caustic soda used to pretreat the facility effluent, as required by a permit with PVSC, contained trace quantities of mercury, copper and lead (PAP-00122260).

According to a *Report on Industrial Waste Streams Bypassed to the Passaic River*, dated August 1994, contaminants detected in the effluent included mercury in 1976, and lead in 1988 and 1992. In 1990, it was noted that the sewer system onsite was contaminated with metals, polychlorinated biphenyls (PCBs), and base neutral compounds as well as other contaminants (PAS-00051217-18). Note: Concentrations of detected contaminants were not provided. According to the same report,

contaminants detected onsite in sediment and soils between 1986 and 1993 included copper, lead, and mercury (PAS-00051217-18).

Waste manifests from January 1, 1995 to July 6, 2000 from the New Jersey Department of Environmental Protection (NJDEP), Division of Hazardous Waste Management state listed hazardous wastes shipped from Sun Chemical Corporation included mercury on February 25, 1997 and lead on June 21, 1995. Quantities were listed as "5 P" for mercury and "55 G" for lead (PAP-00382258-59). Note: It is assumed "P" means pounds, and "G" means gallons.

Areas of Environmental Concern

A *Review of Past and Present Areas of Concern for Sun Chemical Corporation,* dated January 1993 divided the site into multiple sub-areas and discussed the sample results at each. It was noted that although some non-PCB contamination remained onsite subsequent to the cleanup of the 1/3-acre site, such contamination was generally from offsite sources. The areas of concern as related to the COCs were as follows:

Northeast Corner - Cleanup standards from two soil samples were exceeded for individual PAHs, concentrations are provided below (PAP-00381854; PAS-00045263). The *Review of Past and Present Areas of Concern for Sun Chemical Corporation,* dated January 1993, attributes the PAH detections in this area to offsite sources (Arkansas Chemical) (PAS-00045269). PCB concentrations were less than the site-specific soil cleanup standard of 5 parts per million (ppm) (PAP-00381854; PAS-00045263).

Northeast Corner Concentrations	
PAH	**Concentration Max (ppb)*** (sample collected at 18-24 inches bgs)
benzo(a)anthracene	19,000 J
chrysene	15,000 J
benzo(b)fluoranthene	26,000 (co-eluted)
benzo(k)fluoranthene	
benzo(a)pyrene	14,000 J
indeno(1,2,3-cd)pyrene	5,900 J
benzo(g,h,i)perylene	5,700 J

(PAP-00381874-75; PAS-00045281-83; PAP-00118573)

*Note that the cited reference (PAS-00045281) does not clearly identify the concentration units (ppm is in type, but "billion" is hand written at the top of the table); however, the units appear to be in parts per billion (ppb) based on the NJDEP cleanup standards listed in the table. In addition, the *Results of Phase II Sampling and Cleanup Plan*, dated May 23, 1991, states that the concentration of benzo(a)pyrene detected at this location is 14 ppm (equivalent to 14,000 ppb listed at PAS-00045283) (PAP-00118573).
bgs = below ground surface

Southeast Corner – PCB results from four soil samples were all less than the site-specific soil cleanup standard of 5 ppm. Cleanup standards were exceeded for individual PAH, concentrations are provided below (PAP-00381854-55; PAS-00045263-64). The *Review of Past and Present Areas of Concern for Sun Chemical Corporation,* dated January 1993, attributes the PAH detections in this area to offsite sources (Arkansas Chemical) (PAS-00045269-70).

Southeast Corner Concentrations	
PAH	**Concentration Max (ppb)*** (sample collected at 18-24 inches bgs)
benzo(a)anthracene	9,400
chrysene	8,700
benzo(b)fluoranthene	10,000 (co-eluted)
benzo(k)fluoranthene	
benzo(a)pyrene	8,300
indeno(1,2,3-cd)pyrene	4,300
dibenzo(a,h)anthracene	670 J

(PAP-00381881; PAS-00045289; PAP-00118572)

*Note that the cited reference (PAS-00045289) identifies the concentration units as ppm; however, the units appear to be in ppb based on the NJDEP cleanup standards listed in the table. In addition, the *Results of Phase II Sampling and Cleanup Plan*, dated May 23, 1991, states that the concentration of benzo(a)pyrene detected at this location is 8.3 ppm (equivalent to 8,300 ppb listed at PAS-00045289) (PAP-00118572).

Plant Area – PCB results from six soil samples were all less than the site specific soil cleanup standard of 5 ppm (PAP-00381855; PAS-00045264).

Boiler Room – One PCB sample result at 52 ppm exceeded the site specific soil cleanup standard (PAP-00381855; PAS-00045264).

Automatic Electroplating Alleyway – Of the two soil samples collected, only one PCB sample result at 10 ppm exceeded the site specific soil cleanup standard (PAP-00381856; PAS-00045265).

Walkway Behind Press Room – Of the two soil samples collected, only one PCB sample result at 5.8 ppm slightly exceeded the site specific soil cleanup standard. One sample exceeded cleanup standards for PAHs, concentrations are provided below (PAP-00381856; PAS-00045265). The *Review of Past and Present Areas of Concern for Sun Chemical Corporation,* dated January 1993, attributes the PAH detections in this area to offsite sources (Arkansas Chemical) (PAS-00045269, 72).

Walkway Behind Press Room Concentrations	
PAH	**Concentration Max (ppb)** (sample collected at 0-6 inches bgs)
benzo(a)anthracene	6,600 J
chrysene	8,100 J
benzo(b)fluoranthene	8,700 (co-eluted)
benzo(k)fluoranthene	
benzo(a)pyrene	5,700 J
indeno(1,2,3-cd)pyrene	3,400 J
dibenzo(a,h)anthracene	1,100 J

(PAP-00381906-07; PAS-00045312-15)

Norpak Alleyway – One PCB sample result at 35 ppm exceeded the site specific soil cleanup standard. PAH concentrations at this area of concern are provided below (PAP-00381857; PAS-00045266). Note: The PAH concentrations did not exceed cleanup levels.

Norpak Alleyway Concentrations	
PAH	**Concentration Max (ppb)*** (sample collected at 4-4.5 feet bgs)
benzo(a)anthracene	1,400
chrysene	1,300
benzo(b)fluoranthene	2,300 (co-eluted)
benzo(k)fluoranthene	
benzo(a)pyrene	1,300**
indeno(1,2,3-cd)pyrene	520
dibenzo(a,h)anthracene	210 J
benzo(g,h,i)perylene	470

(PAP-00381918; PAS-00045326; PAP-00118571)

*Note that the cited reference (PAS-00045326) identifies the concentration units as ppm; however, the units appear to be in ppb based on the NJDEP cleanup standards listed in the table and the data at PAP-00118571.
**Based on PAP-00118571, the concentration of benzo(a)pyrene is 520 ppb at this location.

New Tank Area in Front of Press Room – Of the two soil samples collected, two PCB sample results at 12 ppm and 74 ppm exceeded the site specific soil cleanup standard. One sample exceeded cleanup standards for PAHs, concentrations are provided below (PAP-00381856; PAS-00045265)

New Tank Area in Front of Press Room Concentrations	
PAH	**Concentration Max (ppb)** (sample collected at 0-6 inches bgs)
benzo(a)anthracene	110,000
chrysene	120,000
benzo(b)fluoranthene	240,000 (co-eluted)
benzo(k)fluoranthene	
benzo(a)pyrene	74,000
indeno(1,2,3-cd)pyrene	56,000
dibenzo(a,h)anthracene	17,000 J
benzo(g,h,i)perylene	35,000 J

(PAP-00381912-13; PAS-00045320-21)

Still Area – Two PCB sample results at 6.1 ppm and 50 ppm exceeded the site specific soil cleanup standard. One sample exceeded cleanup standards for copper at 762 ppm, and lead at 633 ppm. Cleanup standards were also exceeded for PAHs, concentrations are provided below (PAP-00381857, 926; PAS-00045266, 334).

Still Area Concentrations	
PAH	**Concentration Max (ppb)** (samples collected at 0-6 and 18-24 inches bgs)
benzo(a)anthracene	26,000 J
chrysene	28,000 J
benzo(b)fluoranthene	37,000
benzo(k)fluoranthene	9,600
benzo(a)pyrene	23,000 J
indeno(1,2,3-cd)pyrene	15,000 J
dibenzo(a,h)anthracene	1,200 J
benzo(g,h,i)perylene	14,000 J

(PAP-00381925; PAS-00045333)

Historic Fill

The Allocation Team has determined that the facility site is not located on regional Historic Fill as designated by the NJDEP.[1]

NJDEP has established that historic fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 COCs: PAHs, lead, copper, and mercury.[2] Accordingly, NJDEP technical requirements for property containing Historic Fill requires sampling for the EPA Target Compound List for PAHs and Target Analyte List for metals,

[1] *Digital Geodata Series, DGS04-7, Historic Fill for New Jersey*, https://www.nj.gov/dep/njgs/geodata/dgs04-7.htm, Quadrangle #52 & #53 (NJDEP map identifying locations of recognized historic fill).
[2] *Characterization of Ambient Levels of Selected Metals and cPAHs In New Jersey Soils* (2002) and *Characterization of Ambient Levels of Selected Metals and Other Analytes In New Jersey Soils* (1997), studies prepared for NJDEP, Division of Science and Research, by BEM Systems, Inc.

including lead, copper, mercury, and the OU2 PAH COCs.[3] PAHs, lead, copper, and mercury are recognized by NJDEP to be constituents of Historic Fill at varying levels, not atypically at or exceeding residential soil standards.[4]

The levels of PAHs, copper, lead and mercury detected at the site in soils are presented in the table below.

COCs Found in Onsite Soils	
COC	**Max Detected Concentration**
Lead	690 mg/kg
Copper	762 mg/kg
Mercury	28 mg/kg
Benzo(a)anthracene	110 mg/kg
Benzo(a)pyrene	74 mg/kg
Benzo(b)fluoranthene	240 mg/kg
Benzo(k)fluoranthene	17 J mg/kg
Dibenzo(a,h)anthracene	56 mg/kg
Indeno(1,2,3-cd)pyrene	690 mg/kg

No information is available regarding when fill materials were placed on the site.

A *Response to Request for Information,* dated August 23, 1996 stated that PCBs were found in contaminated soils from historic fill. NJDEP confirmed that PCBs present in soil at Sun Chemical Corporation's site were due to the historic fill (PAS-00008293). The top two feet of soil from approximately half of the site was removed in 1992-1993 and transported offsite for disposal (PAS-00008298). According to a Memorandum, dated November 9, 1992, post-excavation sidewall samples collected in September 1992 contained PCBs above New Jersey Department of Environment Protection and Energy (NJDEPE) approved cleanup level of 5 ppm in 3 of 9 samples with results of 8.7 (PX-5), 19 (PX-6), and 250 ppm (PX-3) (PAS-00008287; PAP-00120254-60). Sample results exceeding 5 ppm were detected in the alleyway adjacent (PX-3) to the Norkpak property or along Foundry Street (PX-5, PX-6) (PAP-00120257, 60). Additional soil excavation was conducted to address the PCB concentrations at PX-3 (PAP-00120257). Supplemental soil excavation in January 1993 extended off the Sun Chemical Corporation property and onto the adjacent Norpak property. Post-excavation soil samples collected from the Norpak property (i.e., PX-34 through PX-39) reported PCB concentrations greater than 5 ppm (8.5 to 250 ppm). The cited report concluded that the PCB contaminant distribution was indicative of historic fill (PAP-00121513-16).

[3] New Jersey Department of Environmental Protection (NJDEP), *N.J.A.C. 7:26E Technical Requirements for Site Remediation,* Table 4-2, November 2009 [Note that Table 4-2 has been deleted from the current version of N.J.A.C. 7:26E (May 7, 2012) and the updated *Historic Fill Technical Guidance* (April 2013) as NJDEP believed that the tables list of historic fill constituents was too restrictive].

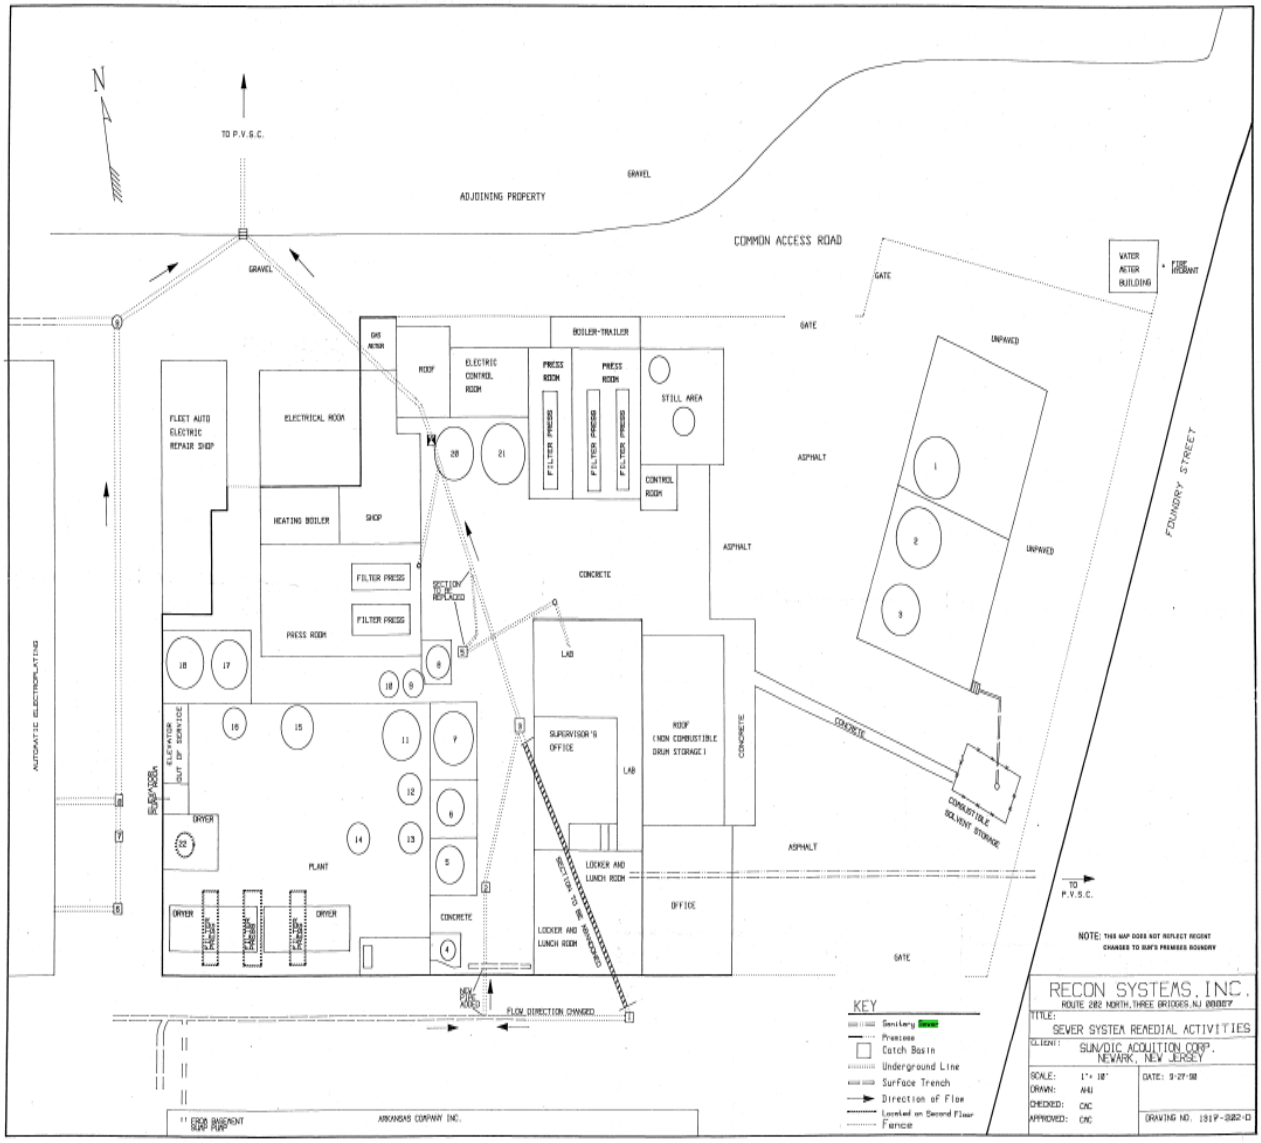
[4] NJDEP Table 4-2 (PAHs and lead) and a summary of NJDEP records regarding investigations of properties in the vicinity of the Passaic River recognized to be located in areas of Historic Fill indicate that the following average/maximum (mg/kg) contamination levels of OU2 COCs exist in area Historic Fill: PAHs (1.91/160), lead (574/10,000), copper (11.2/1,200), and mercury (0.21/3.7).

According to a *Preliminary Assessment Report for Sun Chemical Corporation*, dated April 2004, soil sampling and impacted soil excavation performed during site-wide soil remediation activities confirmed the presence of historic fill material across the entire site. However, no specific information exists to document the period during which the fill was placed on the site (PAP-00377207; PAP-00377731).

5. COC Pathways

Combined Sewer

According to the *Results of Video Inspection at Sun Chemical Corporation*, dated June 1990, the 1991 Investigation Summary, and a *Report on Investigative Activities for Sun Chemical Corporation*, dated October 1990, the drainage system (strip drains) and sewer system were inspected in 1990 to determine its integrity. Video inspection of the sewer system revealed that the sewer lines contained numerous cracks and separations between the pipes. The inspection also noted that the strip drains were connected to the sewer system on the Sun Chemical Corporation site. The video inspection concluded that contamination could have migrated onto the site through the drainage system and leaks in the sewer system. It was also stated that recurring flooding of the drainage system may have distributed past sources of contamination throughout the site (PAP-00374539-41; PAS-00000192; PAS-00044943-45).



According to an August 1996 Request for Information response Letter, soil excavation was conducted at 185 Foundry Street to address the presence of PCBs in the soil. The soil removal was performed at the direction of NJDEP prior to the determination that PCBs were present in Historic Fill (PAS-00008293). According to the March 1992 Soil Erosion and Sediment Control Plan, during the sewer system repair, the sewer line will be plugged at the monitoring catch basin to prevent any sediments from clogging the sewer pipelines or entering the PVSC treatment plant. This line would remain plugged during all excavation, backfilling and sewer repair activates in this area (PAP-00374670). Sewer replacement and repair work is shown below (PAP-00374676).

Sun Chemical Corp.

Diamond Alkali OU2 Allocation

ADR Confidential

Facility Data Report

According to a memorandum prepared by NJDEP dated April 3, 1991, the site is part of the Foundry Street Complex. Approximately 30 buildings were situated throughout the complex, separated by narrow driveways which had strip-like drains in the middle of the lane. The drains were connected to an industrial sewer line on Roanoke Avenue and received surface water run-off and industrial discharge from companies in the complex. According to PVSC Annual Reports the Roanoke Avenue sewer connects to a sewer on Doremus Avenue, which flows to the PVSC treatment works. There is a combined sewer overflow (CSO) outfall to the Passaic River at the foot of Roanoke Avenue (approximately River Mile 1.1). In 1969, the City of Newark constructed a dam near this CSO to increase flow to the Doremus Avenue sewer, and ultimately, the PVSC treatment works (PAS-00044625-626).

A *Preliminary Assessment Report for Sun Chemical Corporation*, dated April 2004 states, “Although all manufacturing operations had ceased and all raw materials and manufactured products had been removed from the site, the discharge permit remained active. Equipment cleaning and dismantling activities were still being conducted as part of the cessation of operations; therefore, some limited discharges would continue until the site was sold. In addition, stormwater discharges would continue during precipitation events. The PVSC permit would be terminated when the sale or the site facility was finalized or when the industrial discharges ceased and the facility site was no longer considered an industrial user, whichever came first” (PAP-00377198; PAP-00377723).

An undated *Industrial Pretreatment Program Annual Report* covering the period from August 1, 1986 to July 31, 1987, reported that Sun Chemical Corporation had an average daily flow of 0.043 million gallons per day (MGD) into the PVSC system (PAP-00123478).

A summary of wastewater sampling data is provided below :

Sample Date	Reported Average Flow Rate (GPD)	Wastewater Sample Concentrations				
		Copper (mg/L or ppm)	Mercury (mg/L or ppm)	Lead (mg/L or ppm)	PCBs (µg/L or ppb)	PAHs (µg/L or ppb)
12/17/1979	55,000*	0.16	0.002	0.9	-

6. Regulatory History/Enforcement Actions

Inspections

As reported by a *NJDEP Report of Inspection*, dated December 10, 1987, proper New Jersey Pollution Discharge Elimination System (NJPDES) permits had not been obtained for the various discharge points found at Sun Chemical Corporation. These discharge points included the boiler blowdown, boiler condensate, the pipe located at ground level east of the operating building, the fire sprinkler system discharge, and the rubber hose emanating from the water booster room. NJDEP suggested that Sun Chemical Corporation either obtain the required permits, or discharge directly to the sanitary sewer with approval from the publicly owned treatment works (POTW) and remove and seal the discharge points (PAS-00111765-67).

According to a *Memo from NJDEP*, dated June 4, 1987, on April 29, 1987, a windshield survey of the Foundry Street site conducted by the Bureau of Planning and Assessment personnel noted that the ground, building surfaces and drums stored near the plant were stained purple. It was stated that it was believed these stains were from pigments manufactured by Sun Chemical Company. The contents of the drums stored near Sun Chemical Company were not known. It was also observed that although most of the ground surface at the site was covered by asphalt or concrete, much of the cover material was cracked or broken which would permit spill materials to enter the soil. Materials could then leach through the soil and contaminate groundwater in the area. Storm drains were also observed which would allow spill materials to migrate off site (PAP-00031574).

According to a *Foundry Street Complex Site Inspection Memorandum*, dated November 15, 1990, on November 7, 1990, the NJDEP Bureau of Compliance and Technical Services, Special Investigations Section conducted a site inspection of the Foundry Street site. It was reported that the driveway located between Arkansas Chemical and Sun Chemical Corporation was stained with a magenta colored substance, which also existed on Sun Chemical Corporation's site. A strip like drain running down the center of the driveway contained standing water with a noticeable sheen on it. Portions of the drain were exposed, because steel plates covering the drain had been removed or fallen into the drain (PAP-00031576-77).

According to a February 13, 1991 Memorandum, on November 26, 1990, a RCRA investigation was conducted at Sun Chemical Corporation to investigate “alleged dumping and sloppy housekeeping practices” at the site. The site tour confirmed the discoloration of the surrounding areas as reported in incident No. 90-10-24-1208. ·The Site Technical Manager stated that the site is subject to heavy flooding due to poor drainage over the entire area and that the extensive discoloration of the pavement was due to this (PAS-00044985; PAS-00111388).

Available information from the process and the material safety data sheets stated that the final product was not hazardous. Since discharges are handled through permit with PVSC, it was recommended that no further action be taken (PAS-00044985; PAS-00111388).

Violations

A May 11, 1992 Memorandum documented a lead violation for Sun Chemical Corporation for a sample collected on April 21, 1992. The result of 1.246 exceeded the daily limit of 0.690 (PAP-00374626; PAS-00111661; PAS-00128931). Note: The units were not included. It is assumed to be mg/L.

Permits

According to a *Preliminary Assessment Report for Sun Chemical Corporation*, dated April 2004, Sun Chemical Corporation discharged process wastewater, stormwater, and sanitary waste to the sanitary sewers under PVSC Permit No. 20200038 (PAP-00377198; PAP-00377723). The permit was approved May 28, 2001 and expired April

30, 2006 (PAP-00124255; PAP-00377206; PAP-00377730). According to *PVSC Permit No. 20200038*, revised August 2003, the monthly average local discharge limits were 3.02 mg/L for copper (threshold 0.092 mg/L), 0.54 mg/L for lead (threshold 0.029 mg/L), and 0.080 mg/L for mercury (threshold 0.001 mg/L) (PAP-00124254-60). Daily regulation limits, which were based on an average flow of 81,100 gallons per day, included total lead (88.23 grams per day), acenaphthene (6.83 grams per day), anthracene (6.83 grams per day), fluorene (6.83 grams per day), naphthalene (6.83 grams per day), phenanthrene (6.83 grams per day), fluoranthene (6.75 grams per day), and pyrene (6.14 grams per day) (PAP-00124262). Although lead was included on the list, Section A-3G (Schedule of Compliance) of the PVSC permit stated the site was exempt from monitoring for lead, based on the Categorical Standard for Organic Chemical Manufacturing 40 CFR 414 (PAP-00124263).

According to a *PRP Data Extraction Form*, dated March 3, 2006, residuals from the manufacturing process are processed through on-site wastewater treatment works for pH adjustment and discharged to the PVSC sewer system under permit No. 204-010-42 (PAS-00111371, 388). Note: A copy of Permit No. 204-010-42 was not provided.

7. Response Actions

Characterization Activities

The following characterization activities have taken place at the facility:

- Site Wide Soil Remediation Report for Sun Chemical Corporation, dated February 16, 1993 (PAS-00045399)
- Final Groundwater Activities Report for Sun Chemical Corporation, dated January 12, 1993 (PAS-00045242)
- Review of Past and Present Areas of Concern for Sun Chemical Corporation, dated January 14, 1993 (PAP-00381846; PAS-00045256)
- Preliminary Assessment Report for Sun Chemical Corporation, dated April 30, 2004 (PAP-00377193)

Soil sampling and remediation took place to remove PCB contaminated soils and groundwater from the site. A total of 1,400 cubic yards of PCB-impacted soils were removed from accessible exterior areas, which were generally excavated to a depth of two feet. A total of 165 cubic yards of PCB-impacted soils were removed from the former Boiler Room floor, which was excavated to a maximum depth of 5.5 feet. To accommodate excavation in the former Boiler Room, approximately 2,300 gallons of impacted groundwater was also removed (PAP-00124085).

According to the 1991 Investigation Summary, in October 1986, sampling was conducted at the site as part of a preliminary Environmental Cleanup Responsibility Act (ECRA) investigation. One soil sample from adjacent to the solid waste dumpster, and one sediment sample from the catch basin were collected as well as one swipe sample taken of an oily stain on the boiler room floor. The sediment and soil samples contained PCBs and priority pollutant metals (including copper, lead, and mercury). The soil sample contained PCBs at 13 ppm. Copper was detected at 3.0 ppm (sediment) and

5.4 ppm (soil); lead was detected at 150 ppm (sediment) and 380 ppm (soil); and, mercury was detected at 0.45 ppm (sediment) and 0.82 ppm (soil) (PAS-00104294). PCBs were also detected in the swipe sample (PAS-00000191, 203).

According to the *Results of Sampling and Analysis Plan,* dated November 30, 1988, the initial investigation identified three areas of environmental concern: the catch basin and drain system; the soil adjacent to solid waste dumpster; and, the boiler room (PAS-00044892). Additional sampling was conducted in 1988 to further delineate the PCB levels in and around the boiler room and underneath and around the manufacturing building (PAS-00044892-93). Laboratory results show that there are elevated levels of PCBs, petroleum hydrocarbons, base neutrals and priority pollutant metals (including copper, lead and mercury) scattered throughout the site. Copper concentrations ranged from 120 mg/kg to 762 mg/kg; lead concentrations ranged from 8.4 mg/kg to 633 mg/kg; and, mercury concentrations ranged from 0.2 mg/kg to 28 mg/kg. PCB concentrations ranged from 0.51 ppm to 390 ppm (PAS-00044905, 906). There did not appear to be a plume or any type of trend as to how the contamination migrated. The aboveground open drain system may have caused the distribution of past sources of contamination throughout the central part of the plant (PAS-00044896). Note: The base neutral compounds were reported as total concentrations; therefore, specific PAH concentrations are not known.

According to the *Review of Past and Present Areas of Concern for Sun Chemical Corporation,* dated January 14, 1993, sampling conducted in 1988 also found several base neutral compounds which exceeded NJDEP cleanup standards. These included the PAHs benzo(a)anthracene, chrysene, benzo(b)fluoranthene, benzo(k)fluoranthene benzo(a)pyrene, indeno(1,2,3-cd)pyrene, dibenzo(a,h)anthracene, and benzo(g,h,i)perylene (PAP-00381854-57; PAS-00045263-66). Sun Chemical Corporation believed that the contamination was from the adjacent Arkansas Chemical site which was known to have base neutral liquids and solids present at the site. Due to flooding problems on the site, Sun Chemical Corporation stated that the base neutral contamination had migrated onto their site (PAP-00381860-65; PAS-00045269-74). See Section 5 above for maximum concentrations detected.

The 1991 Investigation Summary additionally reported that on July 17, 1990, four sediment samples and one water sample were collected from catch basins and the sewer system on the site. The samples contained elevated levels of priority pollutant metals (including copper, lead, and mercury) and base/neutral compounds. PCBs were detected in one sediment sample at a concentration of 100 ppm (PAS-00000192, 203-04). The results were reported in the *Report on Investigative Activities,* dated October 5, 1990. Copper ranged from 56 ppm to 600 ppm, lead ranged from 28.9 ppm to 690 ppm, and mercury ranged from 0.28 ppm to 2.54 ppm in the four sediment samples (PAS-00044953). The base neutral and pesticide compounds were reported as total concentrations; therefore, specific PAH and pesticide concentrations are not known.

According to a *Report on Remedial Activities* dated October 5, 1990 by Recon Systems, in July 1990, remediation of the boiler room was conducted to remove PCB contaminated concrete and soils. Excavation of the soils below 5.5 feet was not conducted to prevent affecting the structural integrity of the building (PAS-00044968).

Post excavation sampling showed that some PCB and base neutral compound contamination were present in the soil under and around the boiler room (PAS-00044975). The concentrations of PCBs (Aroclor-1248) ranged from non-detect to 59.0 ppm (3-3.5 feet bgs) (PAS-00044977-78). The base neutral compounds were reported as total concentrations; therefore, specific PAH concentrations are not known.

According to *Results of Phase II Sampling and Cleanup Plan,* dated May 23, 1991, in April 1991, Phase II soil sampling was conducted to further delineate the extent of PCB contamination at the site. Additional sampling was conducted in May 1991 at the location of one sample due to results inconsistent with the previous sampling (PAS-00045047-48). Concentrations of PCBs ranged from non-detect to 8,100 ppm (in a waste classification samples composited from three borings) (PAS-00045068-69). In addition to PCBs, the base neutral compounds benzo(a)pyrene, dibenzo(a,h)anthracene, benzo(g,h,i)perylene, and 2-methylnaphthalene were also detected (PAS-00045070-79). Excavation of one hot spot to groundwater and capping the remainder of the contaminated site wide soils was proposed (PAS-00045053). It was also proposed that the cracked sewer system would be repaired (PAS-00045056).

According to correspondence concerning the waste profile for the estimated 1,500 tons of soil planned to be excavated, additional delineation sampling was conducted near the sample location which recorded the detection of 8,100 ppm. Analysis of these delineation samples showed levels of PCBs ranging from 2.3 to 910 ppm in the area of the original sample (PAP-00381762-63). These sample locations were in the northeast corner of the site (PAP-00381774).

Remedial Activities

As reported in the *Final Groundwater Activities Report,* dated January 12,1992, site wide soil excavation activities were performed between September 4 and 14, 1992 (PAS-00045245). As reported in the *Site Wide Soil Remediation Report* from 1993, soil was excavated to a depth of at least two feet in all areas of the site where buildings and other permanent structures made excavation possible (PAS-00045407).

As reported in the *Site Wide Soil Remediation Report* from 1993, during the remediation activities, approximately 1,400 cubic yards of soil was excavated and disposed of. During the excavation, almost all onsite sewer piping was removed and replaced throughout the site. The site was backfilled with clean fill and covered with six inches of reinforced concrete. Sun Chemical Corporation also excavated contaminated soils to the fence line in the common alleyway between Sun Chemical Corporation and the Norpak property. Following the excavation, six samples collected from the perimeter of the excavation (on the adjacent Norpak property) still had PCBs exceeding the cleanup criteria of 5 ppm with concentrations up to 250 ppm. These six samples were all collected from the north alleyway between Sun Chemical Corporation and the NorPack property (PAP-00123031-32; PAS-00045418-19).

According to an *Environmental Concerns Tracking Sheet,* dated April 20, 1993, during January 1993, the area with PAH contamination was excavated down to two feet to the perimeter of the site and covered with clean fill. A NJDEP letter dated October 24, 1994 stated no further action was required for this area (PAS-00104305).

A *Response to Request for Information*, dated August 23, 1996 stated that PCBs were found in contaminated soils from Historical Fill. The top two feet of soil from approximately half of the site was removed in 1992-93 and transported offsite for disposal (PAS-00008293, 98). NJDEP confirmed that PCBs present in soil at the site were due to the Historic Fill. The soil removal was performed prior to NJDEP confirming under ISRA that the PCBs were present due to historic fill (PAS-00008293).
In a letter dated October 11, 1995, NJDEP states that since it had been demonstrated that the contamination of the site appears to be due to contaminated historic fill, the zone of the fill contamination on the Sun Chemical Corporation site should be included in a Declaration of Environmental Restrictions. Since contamination also exists in the top two feet of the Sun Chemical Corporation site in various areas throughout the site, engineering controls were required in these areas (PAS-00045465).

The Declaration of Environmental Restrictions was filed with the township on March 21, 1997 and documentation received on May 22, 1997 (PAP-00382242-46; PAS-00045504-08).

According to a *Preliminary Assessment Report for Sun Chemical Corporation* prepared in April 2004, the NJDEP issued No Further Action (NFA) letters on July 25, 1997. The remediation activities performed at the site involved the excavation and offsite disposal of approximately 1,400 cubic yards of PCB-impacted soils from exterior areas and 165 cubic yards of PCB-impacted soil below the former Boiler Room floor (PAP-00377230; PAP-00377743; PAP-00382238-41).

8. Summary of Asserted Defenses

No legal defenses were identified in the available file material.

Facility Data Report

TATE & LYLE INGREDIENTS AMERICAS LLC

Facility Name, Address and Size: A.E. Staley Manufacturing Company and its former division Staley Chemical Company, 100 Third Avenue, Kearny, NJ (PAS-00108740); 5.5 acres (PAS-00108864). As of March 1975, there were 77 employees, working 5-7 days/week, 1, 2, and 3 shifts/day (differs with department) (PAS-00108801).

1. **Business Type:** Organic polymers, rubber-based adhesives, and leather finishes manufacturing (PAS-00108743).

2. **Time Period of Ownership/Operations**

   Operator: November 1968 to October 1978
   Owner: November 1968 to October 1978 (PAP-00208793)

   A.E. Staley Manufacturing Company is a part of Tate & Lyle North America (PAS-00108741).

   1968: A.E. Staley Manufacturing Company purchased the site on November 12, 1968 (PAP-00208793-801).

   1978: 100 Third Avenue was sold to Union Chemicals Division in October 1978 (PAS-00108862).

   1987: A.E. Staley Manufacturing Company merged into Staley Continental Inc. in December 1987 (PAS-00108848).

   1988: Tate & Lyle North America acquired Staley Continental, Inc. (PAS-00108848).

A.E. Staley Manufacturing Company
100 Third Avenue
Kearny, NJ

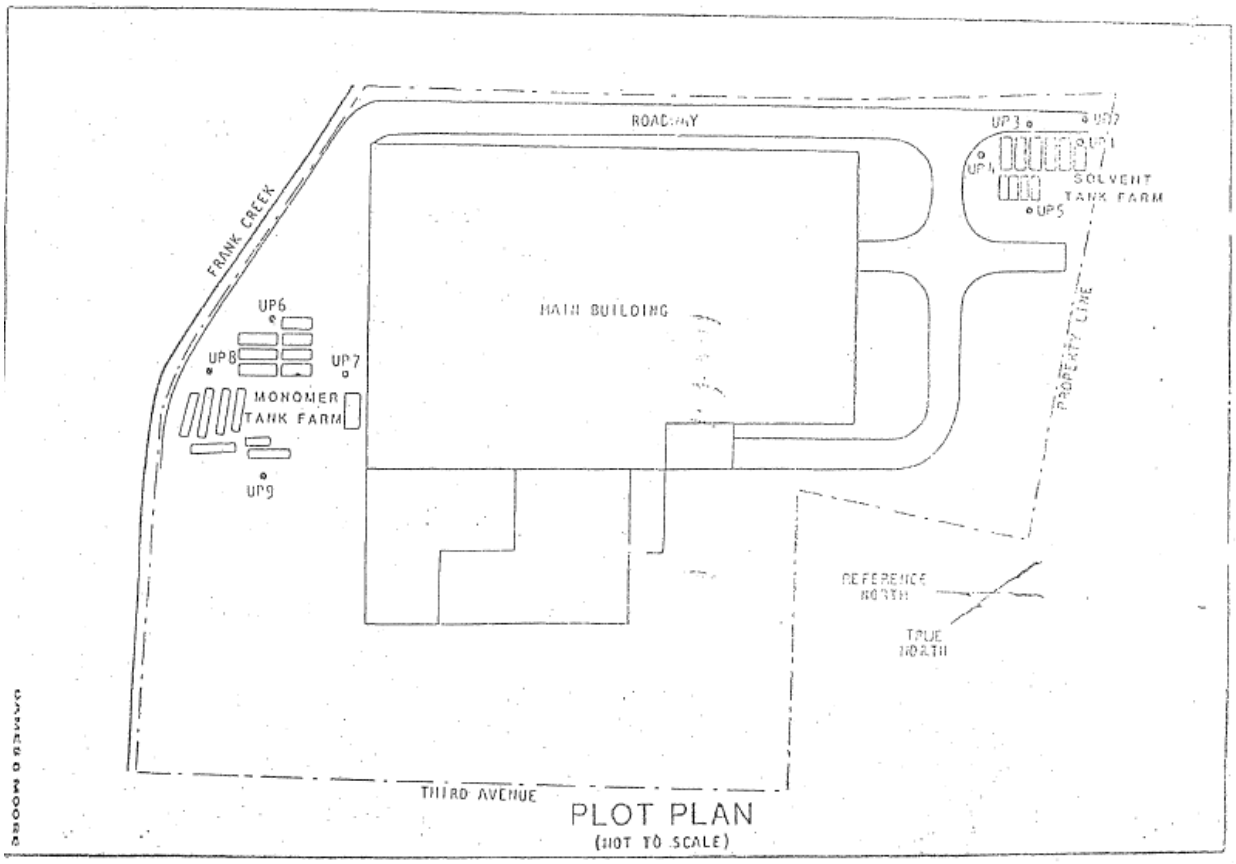
(PAS-00108743)

3. Operational History/COC Use and Presence at the Facility

The 100 Third Avenue site was used for the manufacture of organic polymers, rubber-based adhesives, and leather finishes. Monomers were polymerized into polymers whose emulsions were used by a wide range of other manufacturers as ingredients of other products such as waxes, polishes, paints, and coatings. Rubber was compounded, milled and dissolved in solvents to form adhesives. Pigments were dispersed in lattices to form products used in finishing leather (PAS-00108743-44).

An April 14, 1972, Waste Effluent Survey for the 100 Third Avenue site states that average production at the site was 350,000 gallons per month. The raw materials used included rubber, solvents (methyl ethyl ketone (MEK), acetone, toluene, etc.), monomers (styrene, various acrylates), butadiene latex, and pigments (PAS-00108864). The survey also notes that in 1971, 500,000 gallons of water were released to the sanitary sewer and 11,075,000 gallons of water were released to the storm sewer on Third Avenue and into Frank Creek (PAS-00108865).

A March 13, 1975, Waste Effluent Survey for the 100 Third Avenue site lists the same information with the exception that 44,800,000 gallons of wastewater were released to the storm sewer on Third Avenue and into Frank Creek (PAS-00108801-02).



The Declaration of Lynn Elder, a former employee that served as the project manager for the relocation of Staley Chemical operations to New Jersey, notes that the manufacturing part of the Staley Chemical operation was conducted solely at the Third Avenue buildings in Kearny. Those buildings contained the process equipment, consisting of glass-lined reactor vessels, large holding tanks, and a boiler or boilers for generating process steam. Raw materials were delivered there and finished product was drummed off from the tanks into drums suitable for delivery to customers (PAP-00208510-11).

An October 4, 1978, Agreement of Sale of the Staley Chemical business by A.E. Staley Manufacturing Company confirms that manufacturing and selling of synthetic polymers of the emulsion variety which contained polymerized vinyl monomers, either alone or in combinations, including vinylidene chloride, acrylic and methacrylic acids and their esters, styrene, acrylonitrile and vinyl acetate, and the manufacturing and selling of synthetic polymers supplied in organic solvents was conducted at 100 Third Avenue (PAP-00208440).

According to a June 3, 1980 Selected Substance Report, K.J Quinn & Co., Inc. leased the warehouse at 100 Third Avenue in Kearny, NJ from November 1975 through August 1979 and manufactured coatings & polymers that used lead pigments as an ingredient in coatings stored in the warehouse. According to the report K.J Quinn brought 15,679 pounds of liquid lead onto the site and shipped 15,679 pounds per year off site as (or in) product (PAP-00722959-64). Note: It is unknown if K.J Quinn & Co. leased from Tate & Lyle.[1]

According to an August 30, 2007 Findings Letter and Request to Close Case No. NJDEP Case # 07-05-31-1440-01, two underground tank farms consisting of 33 USTs were present at the property. A solvent tank farm located on the southeast corner of the property had tanks ranging from 3,000 to 8,000 gallons capacity which held solvents, including ethyl acetate, toluene, ethyl alcohol, cyclohexane, methyl ethyl ketone (MEK) and acetone. All of these tanks were reportedly exposed, emptied, cleaned, sand filled and backfilled in 1981 by Dames & Moore. The second tank farm was reportedly located on the northern portion of the property and had tanks ranging from 8,000- to 15,000-gallon capacities. These tanks held monomers including methyl methacrylate, acronitrile, ethyl acrylate, styrene, 2-ethyl hexyl acrylate, lauryl methacrylate and vinyl acetate. All of these tanks were reportedly exposed emptied, cleaned, sand filled and backfilled in 1981 by Dames & Moore. All the tanks have been listed as closed with the NJDEP and no further action was required with regard to the former USTs at the property (PAP-00723055).[1]

[1] This Report was revised to include documents received on May 22, 2020. The additional documents did not change Tate & Lyle's previous certification.

(PAP-00723071)

4. Identified COCs

- Copper (released)
- Lead (possibly used /released)
- Mercury (released)

Metals- Copper, Lead and Mercury

An April 14, 1972, Waste Effluent Survey for the 100 Third Avenue site states that wastewater was released to the sanitary sewer four times a day for 5 minutes at a rate of 4 gallons per minute between 7:00 a.m. and 3:30 p.m. A 24-hour sample collected on March 16, 1972 is stated in a typewritten list to contain these constituents: 32 parts per million (ppm) lead (0.0044 pounds per day) and 0.047-0.47 ppm (0.0000065-0.000065 pounds) of phosphorus, copper, tin, and calcium (PAS-00108864-68). The characteristics of the wastewater released to the storm sewer in a 24-hour sample collected on June 28, 1971, were stated in a separate typewritten list as containing these constituents: 10 ppm lead (0.002 pounds per day), 100 ppm (0.021 pounds per day) of copper, and 0.8 ppm (0.0002 pounds per day) of mercury (PAS-00108867-69). The same discharge information in the same typewritten lists was also attached to a March 13, 1975 Waste Effluent Survey. This survey included an additional page that reported 2,000 gallons a day of waste water continuously discharged six days a week into the municipal system (PAS-00108801-7).

April 17, 1972 and March 13, 1975 cover letters with a response to a "questionnaire" to Staley Chemical state that for discharge to the sanitary sewer "a fully quantitative analysis [was done] for lead and chromium since those are the ions that could possible [sic] be added to the water as a result of any washing of equipment." The letters also state that in answering the section on discharge to the storm sewer, Staley Chemical used the analysis done by its parent company, A.E. Staley Manufacturing Company, on water samples at the time that it made application to the Department of Army Engineers for a permit to discharge into Navigable Waters and their Tributaries (PAS-00108860; PAP-00208348). These are the only data identified in reviewed documents that reference the use and/or discharge of Operable Unit 2 (OU2) contaminants of concern (COCs) from the 100 Third Avenue facility. [2]

---

[2] The Report and Certification of Richard L. Dickinson, Director of Environmental Sciences, Tate & Lyle Ingredients Americas LLC asserts that:

- Almost all the concentration data points about discharges to the storm sewer are in parts per million ("PPM") but should have been stated as parts per billion ("PPB"). This is based on several lines of evidence from analysis of the surveys, and a reasonable understanding of the Kearny municipal water supply, of Staley Chemical's operation, and of prevailing regulatory standards during Staley Chemical's operation from 1968 to 1978. If the constituents were in PPM, the water would have been highly toxic and lethal in short exposures and Staley Chemical would not have received the discharge permit it did. Concentration and mass data for discharge to the sanitary sewer are also mathematically inconsistent and unreliable (PAP-00208428);

- The lead concentration in 1972 and 1975 data was erroneously reported in ppm and that when it is corrected to 10 ppb, or 0.01 ppm, it was below the drinking water standards for lead in 1962 (PAP-00208435; PAP-00208367);

- The corrected concentrations of mercury of 0.0008 ppm and of copper of 0.01 ppm detected in site wastewater to the storm sewer were consistent with typical drinking water supplied by the City of Kearny, which was used as non-contact cooling water for site operations (PAP-00208435; PAP-00208433). The recommended drinking water limit for copper in 1962 was 1 mg/l (or 1 ppm) (PAP-00208366);

- The 1972 cover letters says lead "are the ions which could possibly be added to the water as a result of any washing of equipment" (PAP-00208430);

- There is no indication that mercury or copper were added to the discharge wastewater by Staley Chemical operations (PAP-00208430).

- "It is physically impossible for flows of cooling water through jackets around tanks to leach significant concentrations of ions as reflected in ppm in List "B," particularly given a pH of 7.65 that retards leaching of lead" (PAP-00208434);and,

- All the data about discharges to the storm sewer or the sanitary sewer is on a typewritten page without the original analytical report from which the data were taken (PAP-00208428).

Historic Fill

The Allocation Team has determined that the facility site is located on regional Historic Fill as designated by the NJDEP.[3]

NJDEP has established that historic fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 COCs: PAHs, lead, lead, and mercury.[4] Accordingly, NJDEP technical requirements for property containing Historic Fill requires sampling for the EPA Target Compound List for PAHs and Target Analyte List for metals, including lead, copper, mercury, and the OU2 PAH COCs.[5] PAHs, lead, copper, and mercury are recognized by NJDEP to be constituents of Historic Fill at varying levels, not atypically at or exceeding residential soil standards.[6]

There is no information regarding soil sampling in the available file material.

In 1968 and 1969, a construction project to expand a building included the installation of foundation pilings (PAP-00432014-95). There is no information in the available files regarding migration via groundwater or rainwater.

According to a 1991 Site Evaluation Submission (SES) for Warner Universal Corporation, prior to Staley Chemical Companies ownership and operations in 1950 the site was undeveloped (PAP-00723151).[7]

According to an April 1991 Warner Universal Corporation Sampling Plan, the site is underlain with 2 to 9 feet of red to black miscellaneous fill material composed of medium, fine sands, silts, and clays (PAP-00723184-85). The lands to the south reportedly have been previously filled by Kearny with municipal waste such as leaves, household appliances, solid wastes, etc. (PAP-00723183).[7]

[4] *Characterization of Ambient Levels of Selected Metals and cPAHs In New Jersey Soils* (2002) and *Characterization of Ambient Levels of Selected Metals and Other Analytes In New Jersey Soils* (1997), studies prepared for NJDEP, Division of Science and Research, by BEM Systems, Inc.

[5] New Jersey Department of Environmental Protection (NJDEP), *N.J.A.C. 7:26E Technical Requirements for Site Remediation,* Table 4-2, November 2009 [Note that Table 4-2 has been deleted from the current version of N.J.A.C. 7:26E (May 7, 2012) and the updated *Historic Fill Technical Guidance* (April 2013) as NJDEP believed that the tables list of historic fill constituents was too restrictive].

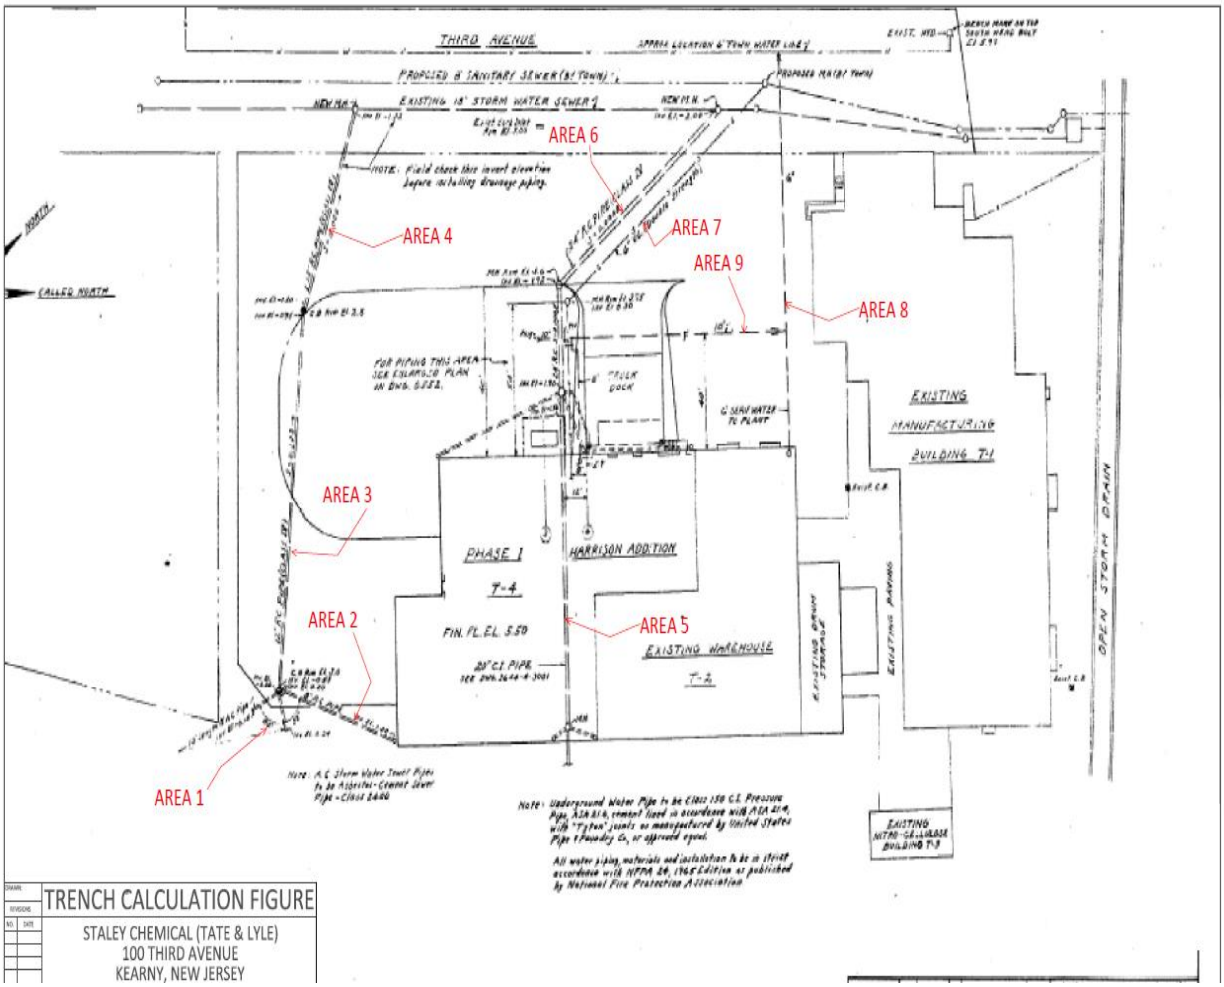
[6] NJDEP Table 4-2 (PAHs and lead) and a summary of NJDEP records regarding investigations of properties in the vicinity of the Passaic River recognized to be located in areas of Historic Fill indicate that the following average/maximum (mg/kg) contamination levels of OU2 COCs exist in area Historic Fill: PAHs (1.91/160), lead (574/10,000), copper (11.2/1,200), and mercury (0.21/3.7).

[7] This Report was revised to include documents received on May 22, 2020. The additional documents did not change Tate & Lyle's previous certification.

5. COC Pathways

Sanitary Sewer

According to a September 26, 1977 Industrial Sewer Connection Application A.E Staley discharged 2.5 thousand gallons per day of waste to the PVSC system intermittently. (PAP-00724090). The following is a description of the waste discharged to the Sanitary Sewer.[8]



Wastes Discharged to Municipal Sanitary Sewer

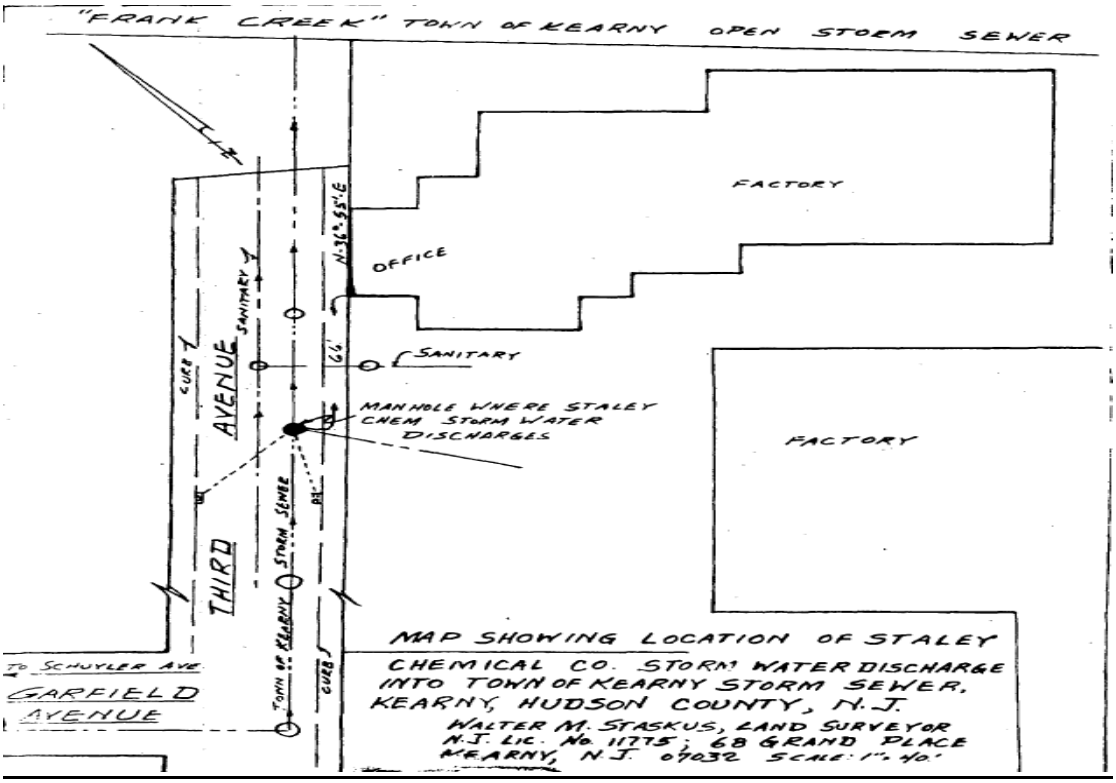
	Waste Type	Daily Volume Est. Gal/Day	Max. Rate, Duration Est. Gal/Min.& Min.
1)	Sanitary Wastes	120	10 GPM - 2 min.
2)	Boiler Blowdown	200	10 GPM - 10 min.
3)	Reactor, Hold Tank, and Storage Tank Rinses	2,000	40 GPM - 10 min.
4)	Water Demineralization Waste	150	15 GPM - 10 min.

(PAP-00724093)

According to an April 18, 1978 PVSC Industrial Wastewater Questionnaire, in that calendar quarter Staley consumed 501,600 gallons of water of which 98% was used in the actual process, <1% of water discharged from process and 1.5% of water discharged from sanitary conveniences (PAP-00724136-37).[8]

[8] This Report was revised to include documents received on May 22, 2020. The additional documents did not change Tate & Lyle's previous certification.

(PAP-00723693)



Storm Sewer

The 100 Third Avenue site had an NPDES Permit to discharge wastewaters to a municipal storm sewer on Third Avenue. The Third Avenue municipal storm sewer discharged into Frank Creek. The figure below shows the location of storm water discharges from the site. The site discharged 11,075,000 gallons of water in 1971 and 44,800,000 gallons of water in 1974 to the Third Avenue storm sewer (PAS-00108802, PAS-00108865).

LIST OF INDUSTRIES WITH NPDES PERMITS

(1) No.	ID#	NPDES PERMIT #	Company Name	Industry	Ave. Water Use (MGD)	Wastewater Discharge (4) Sanitary Ave.Max.	Process Ave. Max.	Cooling Ave. Max.	Total Ave. Max.	Receiving Waters	Remarks
264	M3	NJ0003026	A.E. Staley Co. Chemical Division	Chemicals	M-0.035	M-0.005	PS-0.001	R-0.024	0.003	Storm Sewer Frank Creek	

(PAP-00724141)

(PAS-00108808)

According to a January 28, 1974 Letter to the PVSC Chief Engineer Mr. Lubetkin, samples taken during the week of January 21-25, 1974 characterized A.E Staley's boiler blowdown to storm sewer as polluting samples while they cooling water was characterized as non-polluting (PAP-00724135).[9]

Direct Release

According to the April 1991 Warner Universal Corporation Sampling Plan, the site is located in an industrial section of Kearny. The eastern portions of the site is bordered by railroads siding and marshlands. Frank's Creek border the northern portion of the property and the western and southern sides of the facility are bordered by Third Avenue and other industrial establishments (PAP-00723181-83).[9]

The wetlands are eventually tributary to the Hackensack River which is located approximately 2.5 miles to the east (PAP-00723185).[9]

Spills

There is no information regarding spills in the available file material.

[9] This Report was revised to include documents received on May 22, 2020. The additional documents did not change Tate & Lyle's previous certification.

6. Regulatory History/Enforcement Actions

Inspections

There is no information regarding inspections in the available file material.

Violations

There is no information regarding violations in the available file material.

Permits

A.E Staley held PVSC Industrial Sewer Connection Permit No. 14015-15 (PAP-00724094).[10]

The site discharged wastewaters to a municipal storm sewer on Third Avenue, for ultimate discharge to Frank Creek, pursuant to a NJDES Permit No. 0003026 that expired on April 26, 1979 (PAP-00208504).

7. Response Actions

Characterization Activities

Two prior environmental investigations (in 1986 and 1990) were triggered, due to property transactions, and were evaluated under the then current NJDEP ECRA (Environmental Cleanup Responsibility Act) compliance program. The two ECRA investigations (ECRA# 86-939 and ECRA case number 90-A74) identified several areas of environmental concern at the property. [10]

Extensive soil and ground water investigations were conducted at the property until 1993 under NJDEP oversight. The identified areas of concern were remediated and resolved to the satisfaction of the NJDEP, and the UST areas / property were issued a Negative Declaration No Further Action (NFA) Letter (PAP-00723055-56). [10]

8. Summary of Asserted Defenses

No legal defenses were identified in the available file materials.

[10] This Report was revised to include documents received on May 22, 2020. The additional documents did not change Tate & Lyle's previous certification.

Facility Data Report

TATE & LYLE INGREDIENTS AMERICAS LLC

Facility Name, Address and Size: A.E. Staley Manufacturing Company and its former division Staley Chemical Company. 320 Schuyler Avenue, Kearny, NJ (PAS-00108740). Employee and shift information was not available in the available file material.

1. **Business Type:** Administrative and sales office building (PAP-00208510).

2. **Time Period of Ownership/Operations**

   Operator: November 1968 to August 2, 1976
   Owner: November 1968 to August 2, 1976 (PAP-00193214)

   A.E. Staley Manufacturing Company is a part of Tate & Lyle North America (PAS-00108741).

   1968: A.E. Staley Manufacturing Company purchased the site on November 1968 (PAP-00193214).

   1976: 320 Schuyler Avenue was sold to V.E. Ralph & Son, Inc. on August 2, 1976 (PAP-00193214).

(PAS-00108742)

3. Operational History/COC Use and Presence at the Facility

The Declaration of Lynn Elder states that: The building on Schuyler Avenue in Kearny housed the administrative and sales offices; the manager of the entire operation, including the manager of manufacturing, the general manager, sales people, the accounting office, human resources employees and clerical staff worked in that building; it contained office furniture, files, shelving and general office equipment; and, no manufacturing was conducted in that building (PAP-00208510).

4. Identified COCs

There is no information regarding COCs in the available file material.

Historic Fill

The Allocation Team has determined that the facility is not located on regional Historic Fill as designated by the NJDEP.[1]

NJDEP has established that historic fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 COCs: PAHs, lead, copper, and mercury.[2] Accordingly, NJDEP technical requirements for property containing Historic Fill requires sampling for the EPA Target Compound List for PAHs and Target Analyte List for metals, including lead, copper, mercury, and the OU2 PAH COCs.[3] PAHs, lead, copper, and mercury are recognized by NJDEP to be constituents of Historic Fill at varying levels, not atypically at or exceeding residential soil standards.[4]

There is no information regarding soil sampling in the available file material.

No information is available regarding when fill materials were placed on the facility site.

[4] NJDEP Table 4-2 (PAHs and lead) and a summary of NJDEP records regarding investigations of properties in the vicinity of the Passaic River recognized to be located in areas of Historic Fill indicate that the following average/maximum (mg/kg) contamination levels of OU2 COCs exist in area Historic Fill: PAHs (1.91/160), lead (574/10,000), copper (11.2/1,200), and mercury (0.21/3.7).

5. COC Pathways

Sewer Systems

An undated Standard Form A – Municipal, Section IV-Industrial Waste Contribution to Municipal System, states that Staley Chemical was discharging 2,000 gallons of water per day 6 days per week to the municipal system (PAS-00108807). The address on the form was 320 Schuyler Ave., but there is a handwritten note on the form including the words “now 100 Third St. Kearny” (PAS-00108807). There is no suggestion in the available documents that the Schuyler Avenue property was discharging industrial waste and it is assumed that this address was used as the mailing address for the business.

TEVAL CORPORATION f/k/a CHARLES F. GUYON GENERAL PIPING COMPANY

Facility Name, Address and Size: Teval / Charles F. Guyon General Piping Company; 900-100 Frank E. Rodgers Boulevard South; Block 138, Lot 22A (0.56 acres); Block 138, Lot 1 (28 acres); and, Block 150, Lot 16A (7.091 acres) (PAP-00190146). Employee and shift information was not available in the available file material.

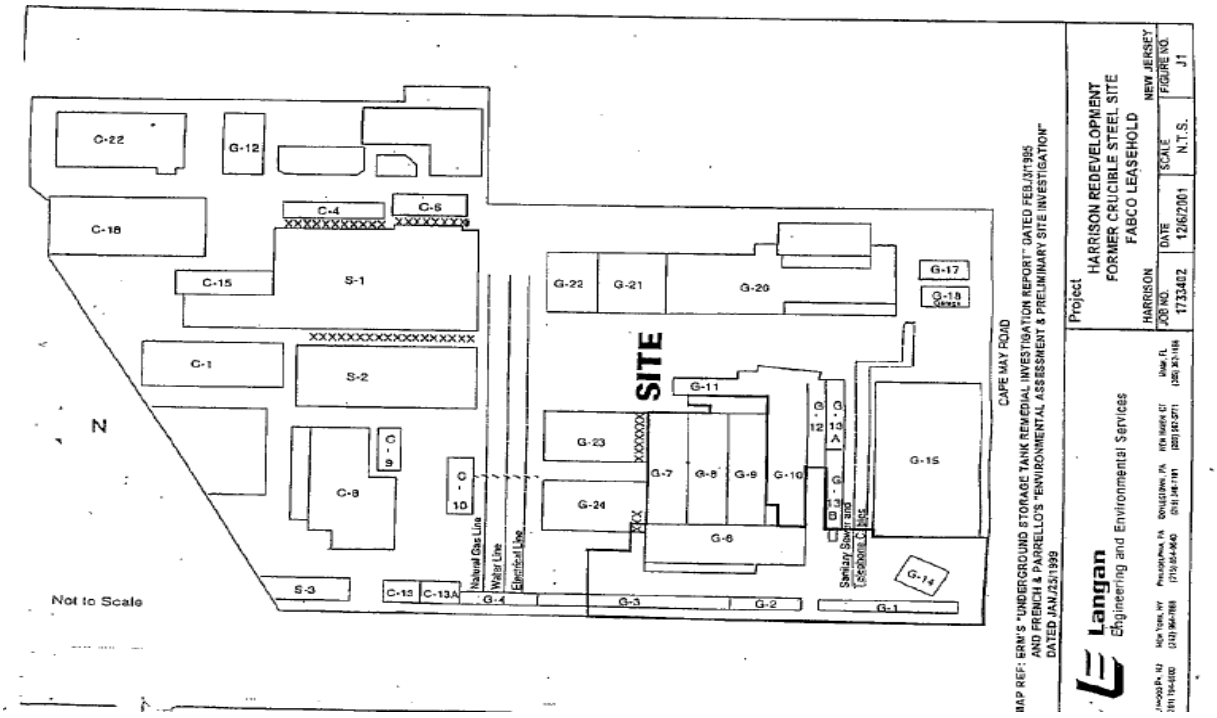
1. **Business Type:** Purchasing, warehousing, light machining activities, and selling pipes (PAP-00190187).

2. **Time Period of Ownership/Operations**

Operator: 1947 to 1992
Owner: 1947 to 2006

1900's: According to an April 1, 2015 letter from Husch Blackwell (on behalf of Coltec Industries, Inc. [Coltec]) to United States Environmental Protection Agency's (USEPA), Crucible Steel Corporation of America (Crucible) operated steel manufacturing facilities in Harrison, New Jersey, adjacent to River Mile 4.0 on the Passaic River. This included the 48-acre "Atha Works" facility, which it operated from 1900 to 1947, and then sold to Charles F. Guyon, Inc., while continuing to operate an adjacent 14-acre "Spaulding Works" facility from 1949 to 1974 (PAS-00048071).

1947-1992: Charles F. Guyon owned the facility from 1947 to 1988 with Charles F. Guyon General Piping, Inc. operating the site from December 27, 1947 to 1992. In 1984, Charles F. Guyon General Piping Company changed its name to Guyon General Piping, Inc. (PAP-00190151; PAP- 00190186).



1980-1988: Fabco Piping, Inc. (Fabco) leased the southwest portion of the Guyon property for pipe fabricating operations from approximately July 1, 1980 until approximately June 30, 1988 (PAP- 00190151; PAP-00190185; PAS-00083189). Fabco's operations were contained to buildings G-1, G-2, a portion of G-3, G-6, G-7, G-8, and G-9, a portion of G-10 and G-14, and a portion of G-15 (PAP-00190160). Locations of buildings are provided on the map at the end of this section. Fabco terminated its lease in 1988 (PAP-00190196).

1991: According to a September 15, 2004 letter from Smith International, Inc., Van Leeuwen purchased certain assets of the distribution business from Chase. F. Guyon, Inc. in 1991. Between 1991 and 1994, Van Leeuwen leased one building on the site for use in its distribution business (PAS-00122929).

1992: Guyon changed its name to Teval Corporation (Teval) on July 7, 1992. From that time on the only business carried out by Teval was the ownership, leasing, and maintenance of the buildings on the property (PAP-00190186).

In the 1990's a number of buildings in the southern portion of the property were demolished (PAP-00190186) while the remaining buildings remained vacant, except for Building 12 which was rented out to Miele-Bros from 1992-2005 (PAP-00190196).

2006: The Guyon property was acquired by the Town of Harrison by eminent domain to build a mixed-use community which included the Red Bull Stadium (PAP-00190196; Factual Statement, p.1).

(PAP-00190165)

3. Operational History/COC Use and Presence at the Facility

Guyon General Piping, Inc. (Guyon)

According to the November 5, 2007 Declaration of Theodore Pichalski, a Facility Engineer at Teval (Pichalski Declaration), Guyon was in the business of selling pipes and valves, including some pipe fabrication. The pipe fabrication operations involved cutting, welding, and shaping of the pipe, including cutting of threads and in some cases, attaching valves (with coating, wrapping and lining furnished to all specifications [PAP-00190203]). The pipe products were sold to industrial customers, particularly those in the oil refining business (PAP-00190183). A facility layout drawing depicting the site which was previously owned by Guyon and subsequently Teval following a name change in 1992 is provided on Page 6 (PAP-00190184).

The Pichalski Declaration reported Guyon's operations were organized into four divisions: The Guyon Piping Division (also known as the Guyon Pipe, Valves and Fitting Division), the Fabrication Division, the Alloy Division, and Elizabeth Industries. The

Piping Division did all the warehousing of pipes prior to their sale and also did some working on the pipes, including the cutting of grooves to facilitate attaching pipes or valves, occasional bending of pipes and some cutting of threads. It did not do any welding (PAP-00190184). The Piping Division sold pipes and valves, plus some related fittings, often in large quantities. The material from which the pipes were made included steel, aluminum, brass, copper and several alloys. The Piping Division operated primarily in Buildings C-1, C-18, C-22, G-15, G-17, G-20, G-21 and G22. G-15 was a large building and was a warehouse in which pipes were stored prior to sale. In addition, pipes and valves were stored in Buildings G-10 and G-11 and in the garages G-1, G-2, G-3, and G-4 (PAP-00190184-85).

The Alloy Division provided products which were specifically designated for certain nuclear industry customers. It did not engage in any fabrication, but simply stored the pipes and sold them (PAP-00190185). Guyon's inventory consisted of over 60,000 tons of prime pipe (PAP-00190203). The Alloy Division operations were conducted in Buildings G-7, G-12, G-13A, G-13B, G23 and G-24 and they had their office in building C-10S. At some point Building G-7 was transferred to the Fabrication Division (PAP-00190185).

Elizabeth Industries bought and sold equipment for customers in bulk-such as a large number of shovels, chain saws, or similar equipment (PAP-00190185). They had their own building, Building C-4, and operated fairly independently of the other divisions. Their operations generated no process wastes, and no process wastewater (PAP-00190186).

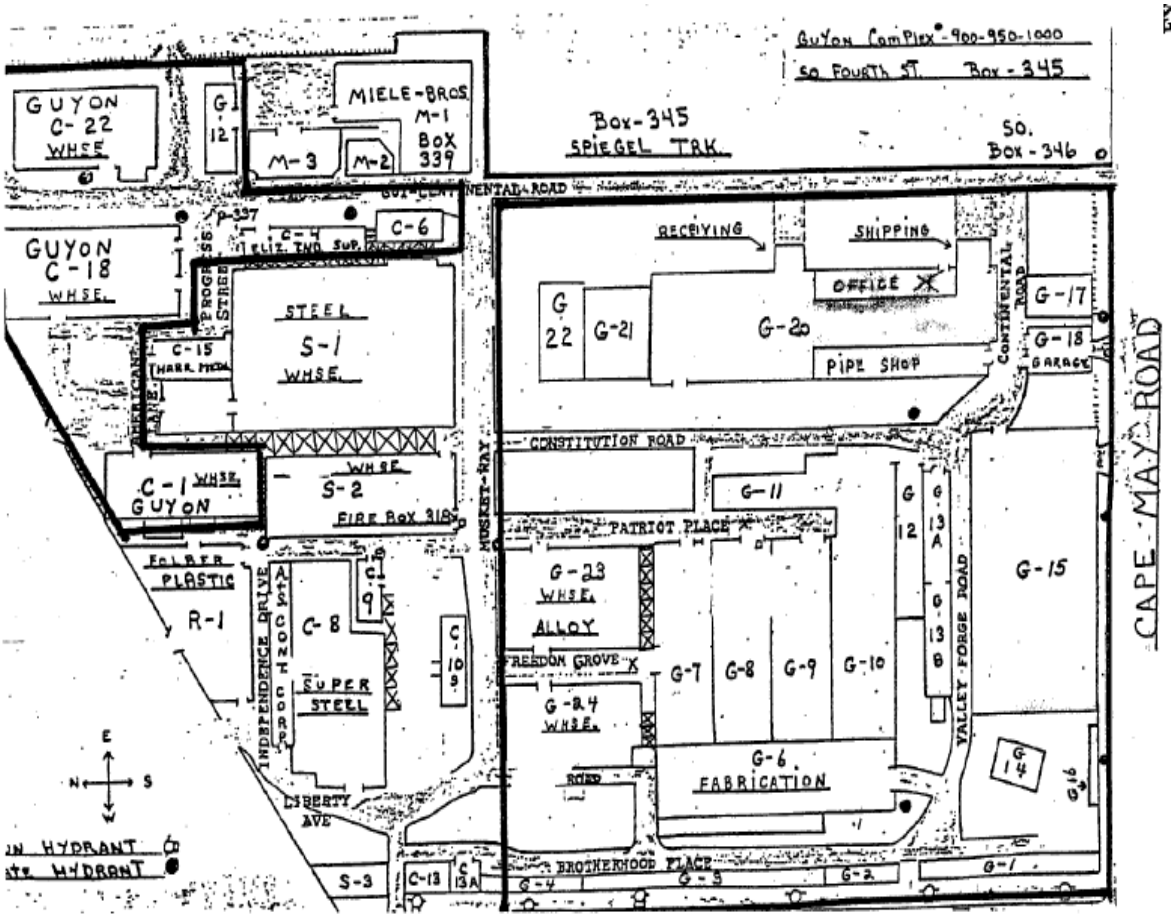
Pipe fabrication operations were conducted by the Fabrication Division in Buildings G-6, G-7, G-8, G-9, G-14 and G-16 as shown in the figure below. The fabrication operations included the cutting, bending, and threading of pipes, as well as some welding (this was done only in Building G-6) (PAP-00190185). When pipes were being cut or threaded, cutting oil was used to keep the pipes and tools from overheating. Cutting oils were purchased and kept in 55-gallon drums that were stored indoors (PAP-00190187).

According to the Pichalski Declaration, there was no waste cutting oil because the heat generated by the cutting tools working on the pipes caused the cutting oil to vaporize (PAP-00190187). The only wastes generated by these processes were metal shavings and particles. These wastes were swept up, placed in drums, and sold to a recycler (PAP-00190187). According to Mr. Pichalski, there were no wastewater discharges from any of these operations to the Passaic River. All sanitary waste was discharged to a piping system which went to the publically owned treatment works operated by the Passaic Valley Sewerage Commission (PVSC) (PAP-00190187).

Guyon operated a fleet of trucks to deliver pipe to its customers. The trucks were housed in a garage building, Building G-18, where they were periodically serviced. Guyon installed a 250-gallon aboveground steel tank (AST) where used motor oil was kept. A company called Northeast Oil periodically came and pumped used oil out and hauled it away for recycling. Extra batteries were stored in Building G-18, and Guyon had several suppliers who periodically provided new batteries and removed old ones (PAP-00190195).

These operations were conducted by Guyon from the time Mr. Theodore Pichalski began work there in 1976 until Guyon leased the fabrication operations to Fabco in 1980. The portion of the property on which fabrication activates took place, and which was leased in 1980 to Fabco is specified in the figure on Page 8 below with diagonal lines and the legend “Former Fabco Piping leasehold” (PAP-00190185).

Guyon changed its name to Teval on July 7, 1992. From that time on the only business carried on by Teval was the ownership, leasing, and maintenance of the buildings on the property (PAP-00190186). Its inventory of pipes and valves and their related business equipment were transferred to Von Leeuwen Pipe and Tool Corporation, who removed them from the facilities. This took place over nearly three years. Thereafter, a number of buildings in the southern portion of the property were demolished in 1990s (PAP-00190186). From 1992 through 2005, the buildings which had not been demolished remained vacant, except Building 12 (near Building C-22) which was rented out to Miele-Bros., also known as North Jersey Appliance (PAP-00190196).



In 2006, the Town of Harrison took title to the Teval property by eminent domain. The site is now part of a 48-acre site, which was restored and developed by Advance Realty Group to include the Harrison Metro Center, housing, offices, real estate, and a soccer stadium for the New York Red Bulls soccer team (PAP-00190196).

According to the Preliminary Assessment Report, Harrison Redevelopment, Former Crucible Steel Site, 900-1000 Frank E. Rodgers Boulevard, Harrison, New jersey 07029, dated January 30, 2002 (2002 PA Report), the following Underground Storage Tanks (USTs) were at the facility (PAP-00190140).

B. Underground Storage Tank Registration Number Facility ID# 0048053, 0262604, 0226244

Size of Tank (Gallons)	Tank Contents
4,000	#0048053 - Leaded Gasoline
5,000	#0262604 - Heating Oil
8,000	#0226244 – Unleaded Gasoline (Tank 0001)
8,000	#0226244 - Medium Diesel Fuel (Tank 0002)
3,000	#0226244 - #2 Fuel Oil (Tank 0003)
1,000	#0226244 - Hydraulic Oil (Tank 6)
1,000	#0226244 - Hydraulic Oil (Tank 7)
3,000	#0226244 - Hydraulic Oil (Tank 9)
3,000	#0226244 - Hydraulic Oil (Tank 10)

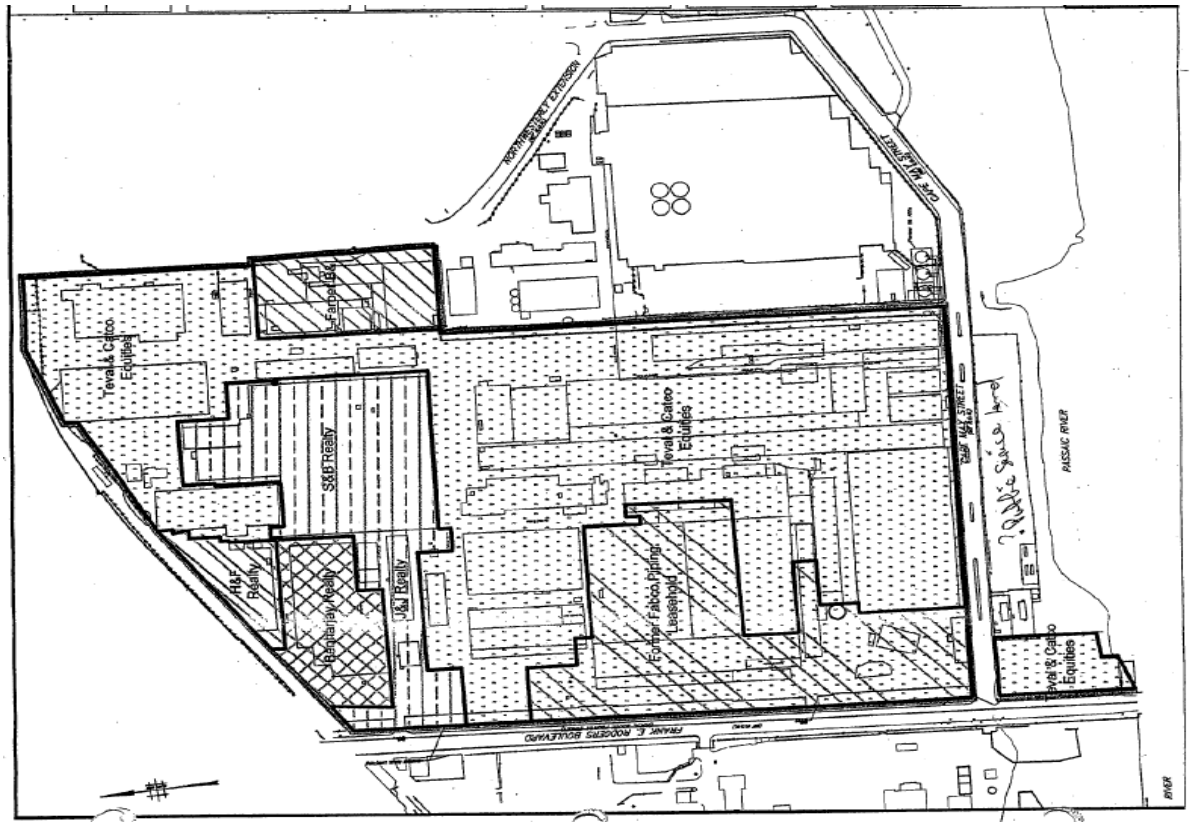
(PAP-00190140)

(PAP-00190199)

Fabco Piping, Inc. Operations

According to the 2002 PA Report, Fabco was involved in the fabrication of pipe until April 1987 when it ceased production activities. The operations included pipe welding, cutting, bending, sandblasting, hardening, and painting. A small staff remained onsite until 1988 (PAP-00190160).

According to the Pichalski Declaration, Fabco conducted pipe fabrication operations from 1980 until 1988 when the company became insolvent, ceased its operations and terminated its lease with Guyon two years prior to its anticipated completion date. Fabco conducted sandblasting operations in Building G-16 and spray painting in Building G-14. According to Mr. Pichalski, there was no discharge to the Passaic River of any waste material generated by Fabco. Mr. Pichalski also stated that there were no discharge pipelines or other conduits from any of these buildings to the Passaic River and he does not recall any floor drains in any of the fabrication buildings (PAP-00190195). According to the Pichalski Declaration, metal threads and particles from pipe threading or cutting operations were collected, drummed, and sent offsite for recycling. Sandblasting waste was stored on the ground just north of Building G-16. Periodically, it would be scooped up and put in a dumpster and then trucked offsite to a disposal facility in Pennsylvania (PAP-00190195).



According to a February 20, 1990 letter to New Jersey Department of Environmental Protection (NJDEP) from Guyon, a darkroom was located adjacent to the cutting and sawing areas on the south side of the large building complex in the leasehold area. The sink in the darkroom was connected to the sanitary sewer system along with the adjoining restroom. According to the letter, all hazardous substances or wastes abandoned by Fabco in the area were disposed by Guyon (PAS-00083193).

A Paint Storage Area was located on the third floor of a large building complex of the leasehold area above the darkroom. Materials abandoned by Fabco and subsequently disposed by Guyon included lead paint, lead primer, and lead primer paint (PAS-00083193, 3200).

Sandblasting operations were located in the southwest corner of the leasehold area. Metal products were apparently sandblasted to clean them after the fabrication process was completed and prior to painting. Excess sandblast grit, approximately 475 tons, abandoned by Fabco was removed and disposed offsite by Guyon. (PAS-00083195).

The Paint Shop was located in the southwest corner of the leasehold property. The building was used for painting operations by Fabco. Materials abandoned by Fabco and subsequently disposed by Guyon included (8) 5-gallon coal tar epoxy, (2) 5-gallon of red lead primer, (3) 55-gallon hydraulic oil, and (3) 1-gallon red lead primer paint (PAS-00083195, 3206).

After Fabco terminated its lease in 1988, the property was inspected by the NJDEP under the Environmental Cleanup Responsibility Act (ECRA) and determined that there was some residual contamination resulting from their activities, notably in the area where sandblast residue had formerly been stored outside Building G-16. NJDEP insisted that Guyon, as the property owner, perform appropriate remedial action. This was done during 1990-1994, at the conclusion of which NJDEP advised Teval (the successor by name change to Guyon) that the remedial action had been satisfactorily completed and NJDEP issued a “No Further Action Letter” dated September 2, 1994 stating the property was “in full compliance with the Industrial Sites Recovery Act (ISRA) (PAP-00190196).

(PAP-00190198)

According to the 2002 PA Report, based on interviews with current property owners and operators, process waste streams were generated within the Benharjay Realty property (Super Steel's operations) and the Teval and Catco Equities property (North Jersey Appliance Warehouse – truck maintenance). Waste oils generated by North Jersey Appliance Warehouse's truck maintenance operations were disposed by Waste Management (PAP-00190154).

North Jersey Appliance Warehouse (North Jersey Appliance)

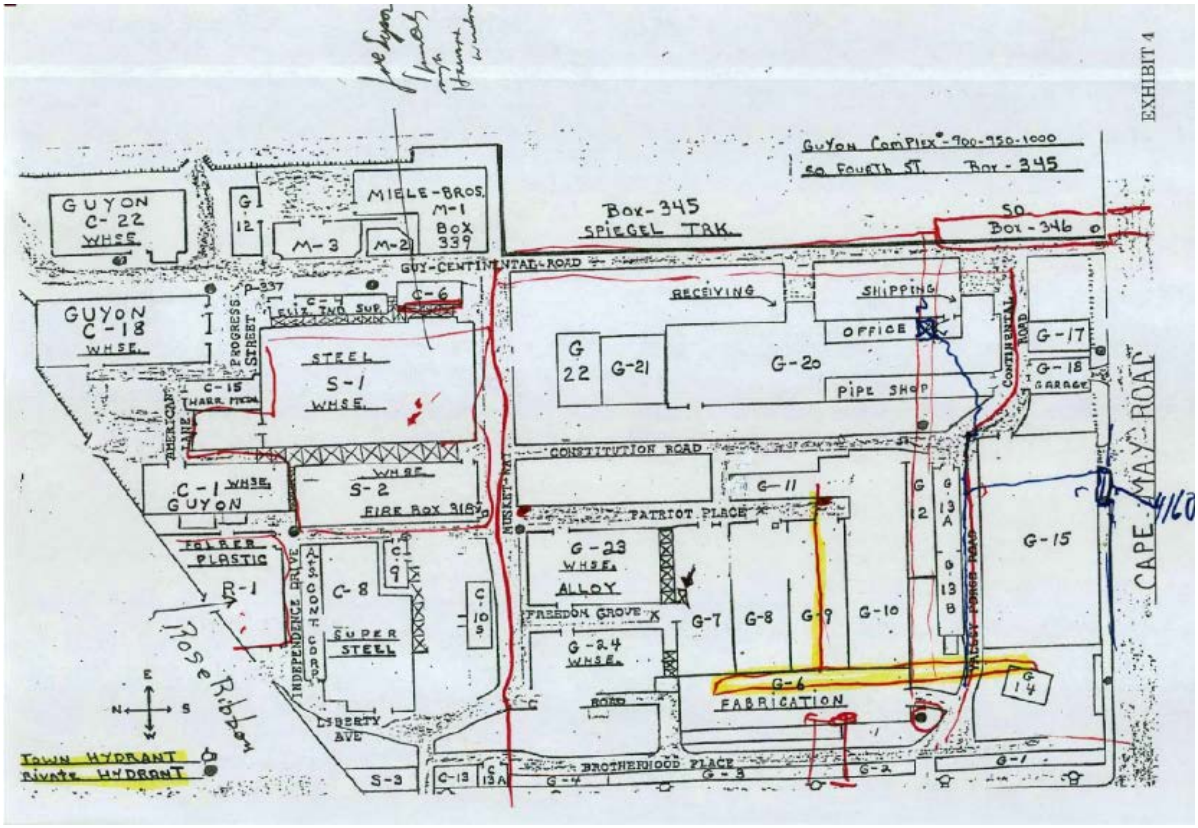
According to a Response to EPA Request for Information by North Jersey Appliance Warehouse, Inc., dated October 17, 1996, North Jersey Appliance operated at 1000 Frank E. Rodgers Boulevard South in Harrison, New Jersey since May-June 1981 (PAS-00076883).

North Jersey Appliance operated an appliance warehouse and distribution center at the facility on behalf of manufacturers, distributors and retail chains, for appliances such as refrigerators, air conditioners, stoves, television sets, and similar 'white goods" and "brown goods" in their original, factory-sealed cartons. North Jersey Appliance trucked these goods in and out of the facility and delivered them to customer locations and other sites. North Jersey Appliance's operations involved solely the storage and distribution of boxed appliances including, on occasion, returns. North Jersey Appliance engaged in no appliance manufacturing, repair, reconditioning, painting or similar operations at the Facility (PAP-00076884-85).

North Jersey Appliance maintained a fleet of about seven trucks to move merchandise and rented garage space for the fleet in a building immediately adjoining the facility from Teval. The maintenance garage performed routine periodic maintenance on vehicles, including oil changes and antifreeze changes. Waste oil and used antifreeze were stored indoors in 55-gallon drums on concrete floors until full, when they were periodically picked up for recycling by Bill's Waste Oil Service. The garage equipment included a self-contained, recirculating parts cleaner which utilized a naphtha solvent degreaser. The parts cleaner was serviced by Safety-Kleen, which at each service visit containerized and removed spent solvent from the unit for recycling, and recharged the unit with fresh solvent (PAS-00076886).

The facility also contained a 4,000 underground gasoline storage tank ("UGST"), which was used for gasoline for trucks. The UST was registered with the NJDEP, Reg. No. 0048053. Gasoline was dispensed from the UST via a standard pump dispenser. The facility also had a separate underground heating oil tank, believed to be 2,000 gallons or less in capacity, which holds heating oil for the furnace that heats the small office section of the primary warehouse building (PAS-00076886). North Jersey did not store drums, either full or empty, outdoors (PAS-00076887).

Van Leeuwen



According to a September 15, 2004 letter from Smith International, Inc., Van Leeuwen purchased certain assets of the distribution business from Guyon in 1991. Between 1991 and 1994, Van Leeuwen leased one building on the site for use in its distribution business (PAS-00122929).

4. Identified COCs

- PCBs (release, detected)
- PAHs (detected)
- Copper (use, release, detected)
- Lead (release, detected)
- Mercury (release, detected)

PCBs

According to the Pichalski Declaration, there were seven electrical transformers at the site located in areas specified in blue on the drawing below (PAP-00190193).

(PAP-00190210)

The main transformer vault was located outside and on the south side of Building G-15, which faced south onto Cape May Road. The transformers themselves were inside the vault, so if there had been any leaking, it would have been contained within the vault (PAP-00190193). Two transformers were located at the north end of Building G-7 and were of comparable size to the four indoor transformers in the office Building G-20 (PAP-00190194). Mr. Pichalski reported he had never observed any leaking from any of the transformers on site at any time (PAP-00190194). All of these transformers were sampled in 1976 for polychlorinated biphenyl (PCB) content. No PCB-containing material as found. Nevertheless, the fluids were drained and replaced at the time with non-PCB oil (PAP-00190194).

According the Remediation/Decommissioning Results, Fabco Piping, Inc., 1000 South Fourth Street, Harrison, New Jersey 07029, dated May 1990 (May 1990 R/D Results), transformers located along the east side of the paint shop in the southwest portion of the site, contained less than 50 milligram per kilogram (mg/kg) of PCBs (PAS-00000961).

According the May 1990 R/D Results, a sample of sand blast grit associated with the steel pipe sand blasting operation of Fabco was collected on February 13, 1989 and analyzed for contaminants (PAS-00083226-27; PAS-00000962). PCB Aroclor-1254 was detected at 1.0 parts per million (ppm). Six other PCB Aroclors were non-detect (PAS-00083258). Aroclor 1254 was also detected at the railroad tracks at a concentration of 3.8 mg/kg (PAS-00000986).

According to the Soil Reuse Plan, Harrison Redevelopment, Former Crucible Steel Site, Harrison, New Jersey, dated August 2006 and Revised January 2007, (August 2006 Soil Reuse Plan), French & Parello (F&P) performed environmental sampling in 1998 and detected PCBs in SP-8 at 5.3 mg/kg, exceeding the non-residential direct contact cleanup criteria of 2 mg/kg. The remaining samples did not contain chemical constituents at concentrations exceeding the applicable cleanup standards (PAP-00190219).

According to the Remedial Investigation/Remedial Action Report, Miles A Galin Property, 1000 4th Street South, Harrison, NJ, dated November 2008 (November 2008 RI/RA Report), PCBs in fill at AOC-1A south of Cape May Street were more extensive than previously characterized. Several samples contained PCBs at concentrations exceeding the USEPA's 50 mg/kg Toxic Substance Control Act (TSCA) threshold and the extent of impacts spanned the entire parcel (PAP-00190180).

According to the November 2008 RI/RA Report, 28 samples were analyzed for PCBs. The samples were derived from the first available soil layer, with deeper samples collected from two borings. PCB concentrations in all but two samples were less than the cleanup criteria. PCBs were detected at 1.3 mg/kg and 0.66 mg/kg in the remaining two samples (PAP-00190177). Approximately 1,400 tons of PCB-impacted soil was removed from the site under the oversight of EPA and NJDEP (PAP-00190182).

According to a Review of Evidence Compiled on Potentially Responsible Parties of the Passaic River Study Area: Crucible Steel Corporation, Guyon Pipe Company, Inc., 1000 South Fourth Street, Harrison, NJ 07029, dated February 12, 2002 (February 2002 Report), concentrations detected during the timeframe of Teval's operation and ownership of the Guyon facility are presented in the table below with locations provided on the maps at the end of this section (PAS-00083179, PAS-00109612)

PAHs

According to the August 2006 Soil Reuse Plan, polycyclic aromatic hydrocarbons (PAHs) were detected in the soil at AOC 8 in 2004 at concentrations exceeding the NJDEP soil cleanup criteria (PAP-00190219). Note: Concentrations were not in the report.

Diamond Alkali OU2 Allocation
ADR Confidential
Facility Data Report

According to the August 2006 Soil Reuse Plan, PAHs [e.g., benzo(a)anthracene, benzo(b)fluoranthene, benzo(k)fluoranthene, and benzo(a)pyrene] were detected in nearly all samples collected at AOC 8 in April 2006 at concentrations exceeding the soil cleanup criteria,(PAP-00190220).

According to the February 2002 Report, concentrations detected during the timeframe of Teval's operation and ownership of the Guyon facility are presented in the table below with locations provided on the map at the end of this section.

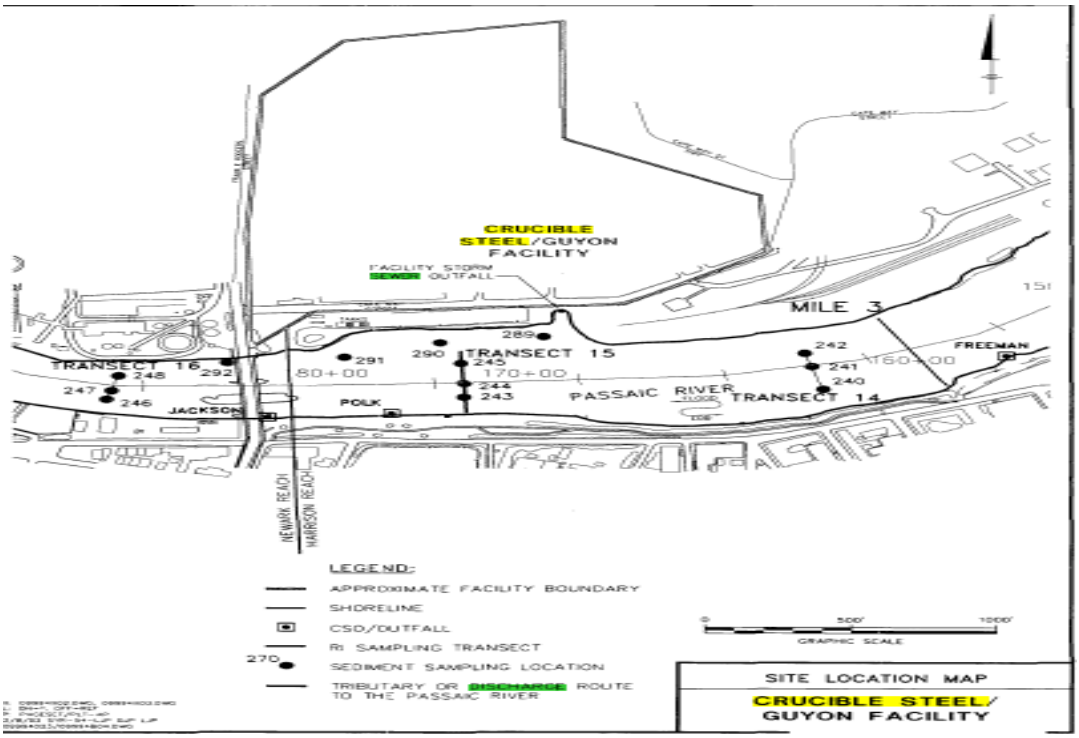
Metals - Copper, Lead and Mercury

According the May 1990 R/D Results, the exterior portion of the paint shop, where empty containers and wood pallets were observed, was investigated on February 13, 1989. Soil samples contained copper and mercury at one or more sample locations at concentrations above the ECRA guidelines at the time (PAS-00000954-55). Copper was detected at S-1 (392 mg/kg), S-2 (239 mg/kg), and S-3 (324 mg/kg). Mercury was detected above ECRA guidelines only at S-3 at a concentration of 2.05 mg/kg. Lead was also detected at S-1 (808 mg/kg), S-2 (525 mg/kg), and S-3 (901 mg/kg) (PAS-00000955-56). Post-excavation samples collected on March 2, 1990 contained copper concentrations at 432 mg/kg and 401 mg/kg at S-202 and S-203, respectively. Similarly two of the analyses for lead were above ECRA guidelines at 3,710 mg/kg and 3,330 mg/kg, respectively. The levels of mercury were 0.595 mg/kg at S-201, 9.13 mg/kg at S-202, 10.2 mg/kg at S-203 and 7.7 mg/kg in the duplicate of S-201 (PAS-00000957, PAS-00083245).

According the May 1990 R/D Results, 12.8 mg/kg of EP Tox lead was detected in the stained soil and asphalt pavement near the railroad tracks running through the Fabco leasehold potion of the site. Post-excavation samples were not collected (PAS-00000960). The results also noted a No. 2 fuel oil aboveground storage tank (AST) was located on a concrete pad in a lean-to structure at the north end of the annealing and bending operations. Stained sediments were removed from the concrete pad on March 2, 1990 and disposed as hazardous waste due to the presence of 12.8 mg/kg of EP Toxicity (EP Tox) lead (PAS-00000961).



According to the February 2002 Report metals, concentrations detected during the timeframe of Teval's operation and ownership of the Guyon facility are presented in the table below with locations provided on the following map. (PAP-00027920; PAS-00083183; PAS-00109604).

Areas of Environmental Concern

According to the 2002 PA Report, 23 Areas of Concern (AOC) were identified in 2001 (PAP-00190217). A map and table with the locations of AOC's, identified in 2001, is provided below (PAP-00210642).

AREAS OF CONCERN		
AOC #1: Aboveground Storage Tanks and Associated Piping	AOC #5: Floor Drains, Trenches, Piping and Sumps	17a) Former Machine Shop (Building #2)
1a) 12 Former Oils ASTs	AOC #6: Roof Leaders	17b) Machine Shop (Building #3 & #11)
1b) Four Former Oil Coolers and Oil Pump House	AOC #7: Stormwater Detention Pond and Fire Ponds	17c) Former Machine Shop (Building #24)
1c) Former Acid Tanks	AOC #8: Waste Piles	17D) Machine Shop (Building #58)
1d) Six Former Fuel Oil Tanks Under Building #8	AOC #9: Former Incinerator	AOC #18: Former Chem Lab
1e) Three Former ASTs	AOC #10: Historic Fill Materials	AOC #19: Former Hydraulic Plant
1f) One 275-Gallon Heating Oil AST	AOC #11: Electrical Transformers and Capacitors	19a) Former Hydraulic Plant (Building #24)
1g) Four Automotive Fluid ASTs	11a) Former Indoor Electrical Sub-Station (Building #26)	19b) Former Hydraulic Pump House (Building #191)
1h) One Empty 275-Gallon AST (Building #65)	11b) Former Outdoor Sub-Station (Building #100)	AOC #20: Former Scrap Yards
1i) Stain AST(s) (Building #52)	11c) Existing Outdoor Transformers (Building #121)	20a) Former Scrap Yard #30
1j) One 1,000-Gallon Heating oil AST (Building #52)	11d) Existing Outdoor Transformers (Building #58)	20b) Former Scrap Yard #106
AOC #2: Underground Storage Tanks and Associated Piping	11e) Existing Outdoor Transformers (Building #52)	20c) Former Scrap Yard #70
2a) Former 4,000-Gallon Leaded Gasoline UST	11f) Existing Indoor Transformer (Building #7)	AOC #21: Former Ash Tunnel
2b) 2,000-Gallon #2 Heating Oil UST	11g) Existing Indoor Transformer (Building #105)	AOC #22: Former Motor Generators
2c) 5,000-Gallon #2 Heating Oil Tank	11h) Existing Capacitors (Building #105)	AOC 23: Painting and Drying Room
2d) One UST (Building #52)	AOC #12: Former Non-Contact Cooling Water Discharges	
2e) Former UST (NJ Transit)	AOC #13: Two Inactive Production Wells	
2f) Former 8,000-Gallon Unleaded Gasoline UST	AOC #14: Boiler Rooms	
2g) Former 8,000-Gallon Medium Diesel Fuel UST	14a) Boiler House (Buildings #7, #20, & #40)	
2h) Former 6,000-Gallon #2 Fuel Oil UST	14b) Former Boiler House (Building #25)	
2i) Former 2,000-Gallon Hydraulic Oil UST	14c) Former Boiler House (Building #19)	
2j) Former 2,000-Gallon Hydraulic Oil UST	14d) Boiler Room (Building #99)	
2k) Former 500-Gallon Hydraulic Oil UST	14e) Boiler Room (Building #52)	
2l) Former 2,000-Gallon Gasoline UST	AOC #15: Settling Pits	
AOC #3: Underground Petroleum Piping	AOC #16: Reclaiming Pits	
AOC #4: Dumpsters	AOC #17: Machine Shops	

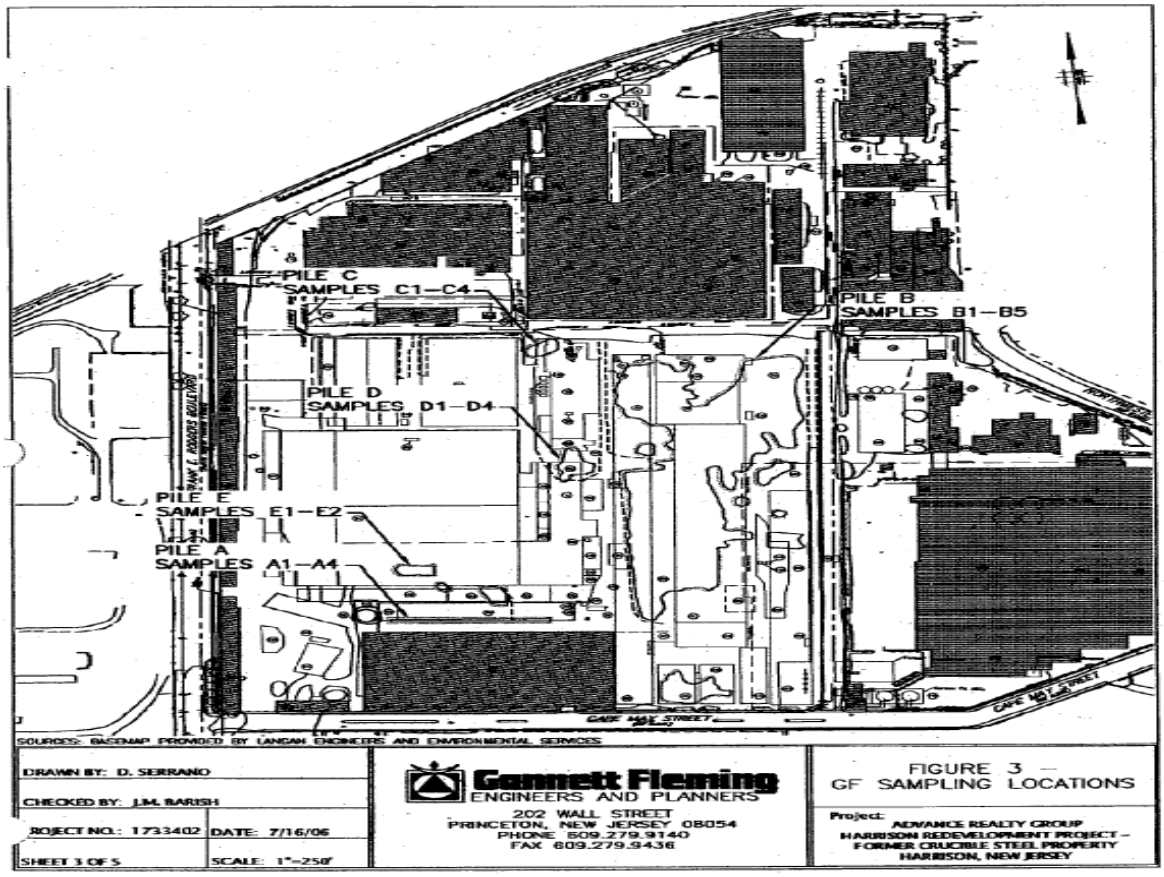
(PAP-00210642)

Historic Fill

The Allocation Team has determined that the facility site is located on regional Historic Fill as designated by the NJDEP.[1]

NJDEP has established that historic fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 COCs: PAHs, lead, copper, and mercury.[2] Accordingly, NJDEP technical requirements for property containing Historic Fill requires sampling for the EPA Target Compound List for PAHs and Target Analyte List for metals, including lead, copper, mercury, and the OU2 PAH COCs.[3] PAHs, lead, copper, and mercury are recognized by NJDEP to be constituents of Historic Fill at varying levels, not atypically at or exceeding residential soil standards.[4]

The levels of PAHs, copper, lead and mercury detected at the site in soils are presented in the table below (PAS-00000957), (PAS-00083180-81, PAS-00109609-10).



COCs Found in Onsite Soils	
COC	**Max Detected Concentration**
Lead	3,710 mg/kg
Copper	432 mg/kg
Mercury	10.2 mg/kg
Benzo(a)anthracene	150 mg/kg
Benzo(a)pyrene	130 mg/kg
Benzo(b)fluoranthene	100 mg/kg
Benzo(k)fluoranthene	630 mg/kg
Dibenzo(a,h)anthracene	250 mg/kg
Indeno(1,2,3-cd)pyrene	570 mg/kg

[1] *Digital Geodata Series, DGS04-7, Historic Fill for New Jersey*, https://www.nj.gov/dep/njgs/geodata/dgs04-7.htm, Quadrangle #52 & #53 (NJDEP map identifying locations of recognized historic fill).
[2] *Characterization of Ambient Levels of Selected Metals and cPAHs In New Jersey Soils* (2002) and *Characterization of Ambient Levels of Selected Metals and Other Analytes In New Jersey Soils* (1997), studies prepared for NJDEP, Division of Science and Research, by BEM Systems, Inc.
[3] NJDEP, *N.J.A.C. 7:26E Technical Requirements for Site Remediation,* Table 4-2, November 2009 [Note that Table 4-2 has been deleted from the current version of N.J.A.C. 7:26E (May 7, 2012) and the updated *Historic Fill Technical Guidance* (April 2013) as NJDEP believed that the tables list of historic fill constituents was too restrictive].
[4] NJDEP Table 4-2 (PAHs and lead) and a summary of NJDEP records regarding investigations of properties in the vicinity of the Passaic River recognized to be located in areas of Historic Fill indicate that the following average/maximum (mg/kg) contamination levels of OU2 COCs exist in area Historic Fill: PAHs (1.91/160), lead (574/10,700), copper (11.2/92.9), and mercury (0.21/3.7).

According to the November 2008 RI/RA Report, unconsolidated subsurface materials consist of historic fill as defined by NJDEP, ranging between two and 20 feet thick across the property. The fill is a mixture of sand, gavel, coal, ash, cinders and other debris (i.e., concrete, brick) derived from various sources, including the Passaic River, to raise the property grade during the initial development in the 1800's to support the development of the property before construction of the Crucible Steel facility (PAP-00190176-77).

According to the November 2008 RI/RA Report, the fill was characterized by analyzing 63 samples for metals and 91 samples for Base Neutral (BN)/PAHs, respectively. PAHs and metals (copper, lead and mercury) were detected at concentrations exceeding the soil cleanup criteria in effect at the time the work was done. The November 2008 RI/RA Report concluded that these constituents were inherent to fill and that no further actions other than installing the engineering and institutional controls described in the RAWP were warranted (PAP-00190177).

According to the August 2006 Soil Reuse Plan, the fill was sampled at 14 locations in April 2006. Each sample was collected from approximately two feet below the fill surface. Sampling locations are shown on the figure below (PAP-00190220). Note: Appendix C, containing laboratory data, was missing from the August 2006 Soil Reuse Plan.

(PAP-00190226)

According to the August 2006 Soil Reuse Plan, the material from AOC 8 (containing PCBs and PAHs below the Residential Direct Contact Soil Remediation Standards [DCSRS]) was to be used as fill for excavations dug during the soil remediation program. Remaining material was to be used as fill during redevelopment activities (PAP-00190222).

5. COC Pathways

According to the November 2008 RI/RA Report, the Passaic River is immediately south of the property and flows west to east along the reach adjacent to the site. No other surface water bodies are present on or immediately adjacent to the property (PAP-00190176).

Sanitary Sewer

According to the 2002 PA Report, since the original construction to present (2002), sanitary and storm discharge went to the PVSC and non-contact cooling water discharge went to a cistern which discharges to the Passaic River (PAP-00190130).

According to a February 20, 1990 letter to NJDEP from Guyon, all sanitary wastes from the leasehold portion of the facility were discharged into common collectors from locations throughout both the leasehold and non-leasehold portion of the industrial complex. Thus, the sanitary waste collection system is considered “common property” of the entire industrial complex. The PVSC verified that sanitary wastes from the entire industrial complex entered the PVSC collection system and treatment plant in Newark, New Jersey (PAS-00083195).

According to the Pichalski Declaration, there were no wastewater discharges from any operations to the Passaic River. All sanitary waste was discharged to a piping system, which went to the publically owned treatment works operated by the PVSC (PAP-00190187).

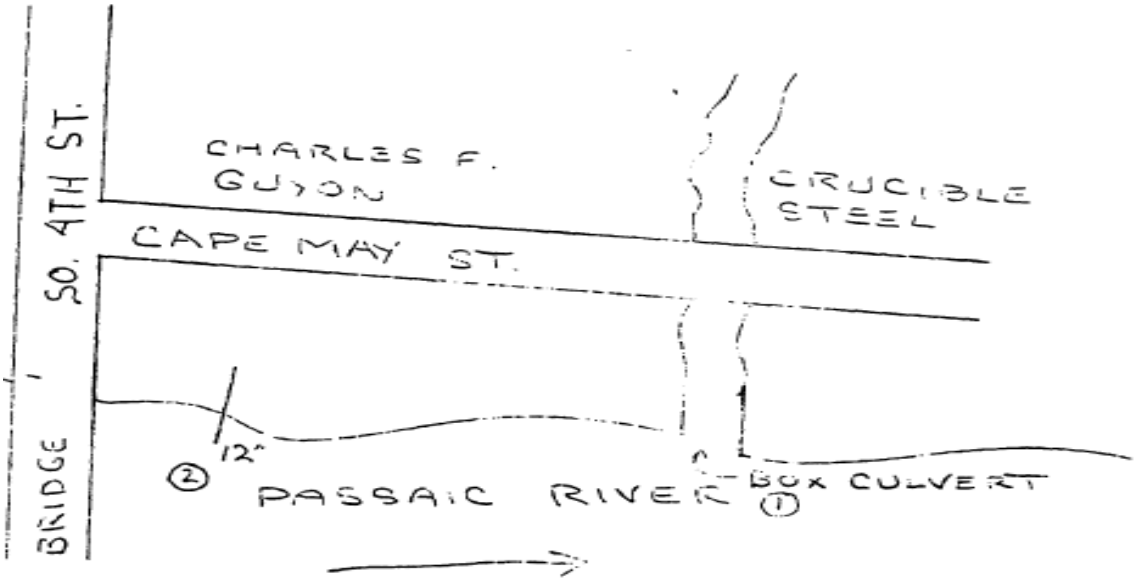
Storm Sewer

According to a February 20, 1990 letter to NJDEP from Guyon, the stormwater from roof drains and surface water runoff from paved areas within the leasehold area collect in a cistern which discharges into the Passaic River (PAS-00083195).

According to a Response to EPA Request for Information by North Jersey Appliance Warehouse, Inc., dated October 17, 1996, the storm sewer system collected and discharged rainwater runoff from roofs and paved surfaces. The storm sewer system was believed to discharge ultimately into the Passaic River (PAS-00076887). However, no diagrams of the storm sewer lines were in the possession of North Jersey Appliance (PAS-00076888).

North Jersey Appliance additionally reported that the facility was prone to storm sewer back up during periods of heavy, persistent rainfall. At such times, it was stated that storm water tended to overload the flow capacity of the storm sewers and pond up at low points on the property, but did not enter the buildings. It was also stated that one of the

storm sewer lines (all of which were believed to date back many decades) running from the loading dock area apparently experienced an internal collapse at one or more locations along the run and had been clogged for several years. North Jersey Appliance stated that they utilized a sump pump at the loading dock area to redirect storm water that collected at the low point of the ramp and that the storm water was pumped through a hose to an outlying collection grate (PAS-00076890).



According to the Pichalski Declaration, in 1976, there were some historic storm water drains at several locations on the site. However, they were all plugged up with dirt and were unusable. Thus, there were at the time no functioning storm drains or conduits. However, Mr. Pichalski stated that he noticed that storm water tended to gather along the onsite roadway known as Valley Forge Road between buildings G-13A and G-13B on the north site and G-15 on the south side (PAP-00190188).

Direct Release

According to the 2002 PA Report, the river water cistern handled surface water runoff as well as non-contact cooling water for former site operations. The river water cistern was located adjacent to the northwest corner of Building 55 and is approximately 35 feet in diameter. *Note Figure G1 in Appendix G with location was missing from the report.* The feature was constructed of brick and contained several large diameter river water intake pipes, as well as, smaller diameter pipes from the site. Mr. Ted Pichalshi stated that process wastes were disposed offsite, however no documentation currently exists. Furthermore, he had no knowledge of disposal onsite (PAP-00190154).

According to a 2015 Husch Blackwell letter, PVSC filed suit against Crucible Steel in 1970 for discharging oil through a box culvert installed by Crucible into the Passaic River from 1969 through 1971 from the adjacent Spaulding Works site (PAS-00076889; PAS-00000875). Crucible took several steps to prevent oil discharges from its plant, but investigations revealed that the oil observed at the outfall was originating from an unknown offsite source discharging to part of the drainage system known as Guyon Lateral No. 1. This is also documented in a 1971 PVSC Annual Report. The oil discharge ceased when the lateral was plugged (PAS-00048071-72; PAS-00070955-56; PAS-00000874-81). It is noted that the documents state that Crucible suspected that Teval could have been a potential source of the oily discharge, but Teval was determined not to be a source of the oily discharge. According to the Pichalski Declaration, Mr. Pichalski did not observe any connections from the Teval property to the outfall associated with the aforementioned discharge (PAS-00070955-56; PAP-00190190).

According to the Pichalski Declaration, during his time at the facility, he only observed two outfalls from the Teval property that discharged to the Passaic River. These included (1) a pipe from a cistern and (2) a plugged eight-foot diameter pipe on the southeast side of the property along the boundary with Spiegel Trucking Company (PAP-00190193). He reported that Teval routed stormwater runoff to the cistern, which previously had been installed at the site by Crucible. The cistern was 40 feet deep and connected to the Passaic River by a large concrete pipe, approximately 48 inches in diameter (PAP-00190188). A site map shows the location of one storm sewer outfall (see below).

(PAS-00083136)

Spills

According to the Pichalski Declaration, spills or dumping of waste material outdoors from any of the Guyon buildings was not observed (PAP-00190187). There were no floor drains in any of the buildings and indoor spills were quickly cleaned up (PAP-00190188). The Pichalski Declaration also reported any spills in the battery storage building G-18 were promptly cleaned up with rags, and the rags were drummed and disposed offsite (PAP-00190195).

The Pichalski Declaration reported that Mr. Pichalski was shown two affidavits which were filed in a case in the Superior Court of New Jersey entitled Passaic Valley Sewerage Commissioners v. Crucible Steel Corporation of America including one dated June 5, 1970 and the other dated January 25, 1971. The subject of that litigation and affidavits was an alleged release of oil to the Passaic River in 1970 from the outfall of a large underground drainage system from the property which at that time, according to the affidavits, extended under the adjacent Crucible Steel property and also under property which was then owned by Guyon and a number of others. The description of the oil found leaking in 1970 from the large pipe was described as having the appearance of a fine number 2 type fuel oil, or mineral oil, which had suspended in it a fine powdery or pulverized substance. Although Mr. Pichalski was not on site in 1970, he was not aware of any oily material that was used or generated by Guyon at any time that would have matched this description of what was apparently released from the large pipe in 1970. He stated that Guyon did not use No. 2 fuel oil and that their fuel was diesel and gasoline, which was stored in USTs in front of Building G-18 (PAP-00190190, PAS-00000862). It should be noted that a No. 2 oil AST was reportedly located on a concrete pad at the north end of the annealing and bending operations area. However, the period of operation for this AST was not noted in the reference material (PAS-00000961).

6. Regulatory History/Enforcement Actions

Inspections and Violation

According to a Report of Inspection, dated March 22, 1990 of Fabco Piping, Inc. involving Guyon Piping, the inspector noted several transformers inside a fenced area beside the garage. There was no staining of the soil beneath the transformers. The owners and PCB content were unknown on the day of inspection. The inspection also notes small quantities of hazardous materials in the form of cleaning substances (mostly phenols) being temporarily stored near the entrance to the main building (PAS-00083208).

According to the 2002 PA Report, no enforcement actions (Notice of Violations, Court Orders, official notices or directives) for violations of environmental laws or regulations were involved at the site (PAP-00190141).

Permits

There is no information regarding permits in the available file material.

7. Response Actions

Characterization Activities

The following characterization activities have taken place at the site:

- Remediation/Decommissioning Results, Fabco Piping, Inc., 1000 South Fourth Street, Harrison, New Jersey 07029 (May 1990) (PAS-00000945-1001)
- Sampling Plan Results and Cleanup Plan Addendum, Fabco Piping, Inc. (Dec 1990) (PAP-00190162)
- Final Remedial Action Report (DRAFT), Fabco Piping, Inc. (1993) (PAP-00190163)
- Underground Storage Tank Remedial Investigation Report (Feb 1995) (PAP-00190164)
- Preliminary Assessment Report, Harrison Redevelopment, Former Crucible Steel Site (January 2002) (PAP-00190126-168)
- Remedial Investigation/Remedial Action Report, Miles A Galin Property, 1000 4th Street South, Harrison, NJ (November 2008) (PAP-00190169-182)

Soil

According to the November 2008 RI/RA Report, an RAWP included with the SI report described the scope of activities to be performed during site redevelopment to address environmental conditions identified by the SI and prior studies. The proposed work included limited “hot spot” soil removal with post excavation sampling; removing USTs; recovering free phase product; reusing stockpiled historic fill as backfill; abandoning the groundwater monitoring well network and the reinstallation of wells (PAP-00190179).

Remedial Activities

According to the 2002 PA Report, two remediation events occurred at the site. The first was completed as part of the closure of the Fabco Piping, Inc. leasehold under the oversight of ECRA/ISRA (No. 88800). The second was UST closure activities (UST Facility No. 0226244, NJ Spill No. 93-05-04-1437) conducted by Guyon (PAP-00190160). These two activities are summaries below.

Fabco Piping, Inc. (ISRA No. 88800)

In 1980, Fabco leased the southwest portion of the Guyon property for pipe fabricating operations. Fabco's operations were contained to buildings G-1, G-2, a portion of G-3, G-6, G-7, G-8, and G-9, a portion of G-10 and G-14 and a portion of G-15 (PAP-00190160). The following descriptions relate to investigations and remediation activities completed in the Fabco leasehold portion of the Guyon property (PAP-00190160):

On May 25, 1990, First Environment reported excavation and disposal of contaminated soils (approximately 69.8 8 tons) from the Exterior of the Paint shop. Collection and analysis of post excavation samples from 16-22 inches below ground surface (bgs) was conducted. Based on the analytical results, soils were excavated and stockpiled for proper offsite disposal in March 1990. The material was disposed in May 1990 as a non-hazardous waste (PAP-00190161, 63; PAS-00000955). Additional soils were removed on September 20, 1993 to the underling clay layer (4.0 to 5.5 feet bgs). Post-excavation samples revealed lead concentrations below the property cleanup level. On September 2, 1994, NJDEP issued a letter stating that the Fabco portion of the site complied with ISRA and that No Further Action was warranted (PAP-00190163).

Railroad tracks were excavated and stained soils were disposed (approximately 2 cubic yards) on March 2, 1990. Excavated soils were disposed of offsite as hazardous waste due to the presence of 12.8 ppm of EP Tox lead. Post-excavation samples were not collected (PAS-00000960; PAP-00190161).

Stained sediments from the floor of a Concrete Floor Lean-To in the annealing and bending area were removed (approximately 0.25 cubic yards). This area contained a No. 2 fuel oil AST according to the May 1990 R/D Results. Excavated soils were disposed of offsite as hazardous waste due to the presence of 12.8 ppm EP Tox lead (PAS-00000961; PAP-00190161).

Sandblasting operations were located in the southwest corner of the leasehold area. Metal products were apparently sandblasted to clean them after the fabrication process was completed and prior to painting. Excess sandblast grit, approximately 475 tons, abandoned by Fabco was removed and disposed offsite by Guyon. (PAS-00083195).

Former Guyon General Piping, Inc. UST Closures (UST Facility No. 0226244; NJ Spill No. 93-05-04-1437)

In 1994, Guyon completed the closure of seven regulated USTs. The following description relates to remediation activities completed by Guyon (PAP-00190164):

A February 3, 1995, Underground Storage Tank Remedial Investigation Report detailed that seven regulated USTs were closed in 1994. The report states that soil contamination did not impact groundwater and that the horizontal and vertical extent of soil contamination was delineated, and over 200 tons of contaminated soil was remediated. On December 22, 1995, NJDEP approved No Further Action for the UST area (PAP- 00190164).

According to the Pichalski Declaration, after Fabco terminated its lease in 1988, the property was inspected by the NJDEP under ECRA, and determined that there was residual contamination resulting from site activities, notably in the areas where sandblast residue had formerly been stored in the area outside Building G-16 and where paint waste had been stored near Building G-14. Mr. Pichalski also stated that Teval remediated the property between 1990 and 1994 (PAP-00190196). NJDEP issued a No Further Action letter dated September 2, 1994 based on the implementation and completion of the Remedial Action Workplan, Final Report, and NJDEP investigation of the site (PAP-00190156; PAP-00190213).

According to a December 22, 1995 letter from NJDEP, Teval complied with the requirements regarding the remedial investigation and remedial action related to one 2,000 gallon leaded gasoline UST, one 8,000 gallon diesel UST, one 8,000 gallon leaded gasoline UST, one 500 gallon hydraulic oil UST, two 2,000 gallon hydraulic oil USTs, and one 6,000 gallon No. 2 Fuel Oil UST. The December 22, 1995 letter from NJDEP, NJDEP issued a No Further Action letter associated with the USTs (PAP-00190157).

According to the November 2008 RI/RA Report, NJDEP recommended that the RA and site closure be coordinated with USEPA due to the presence of TSCA level of PCBs. On April 16, 2007, NJDEP and USEPA agreed that the Self Implementing Cleanup rules under 40 CFR 761 would be an appropriate remedial strategy. The plan was approved by USEPA on November 9, 2007 and by NJDEP on April 1, 2008 (PAP-00190182).

According to the November 2008 RI/RA Report, the RA consisted of excavating fill with PCBs exceeding 10 mg/kg and disposing of the material offsite as TSCA or non-TSCA regulated waste. Analytical results of in-place samples were used to define and segregate the fill for disposal as required by USEPA. The RA was performed in June and July 2008, which resulted in the removal of approximately 1,400 tons of PCB-impacted fill. Imported clean fill was used to backfill the excavations at the request of NJDEP (PAP-00190182).

According to the November 2008 RI/RA Report, after the receipt of NJDEP's "Comfort Letter," the property was to be transferred to the Town of Harrison under an existing agreement. The November 2008 RI/RA Report states that the Town of Harrison was to be responsible for installing and maintaining the final engineering control (PAP-00190182).

8. Summary of Asserted Defenses

No legal defenses were identified in the available file materials.

Diamond Alkali OU2 Allocation
ADR Confidential
Facility Data Report

TEXTRON, INC.

Facility Name, Address and Size: Textron, Inc., 681 Main Street, Belleville, New Jersey; Block 56, Lots 5, 6, 7, 9, and 31; Buildings 4A, 6B, 9-12, 12A, 14, 17, 18, 22, and 23 (PAS-00102978); 15 acres in what is currently the Belleville Industrial Center (PAS-00103078). Note: Conveyance documents were not available for review to verify the site description. Employee and shift information was not available in the available file material.

1. **Business Type:** Production of artificial leather and vinyl plastics (PAP-00145594; PAS-00103079).

2. **Time Period of Ownership/Operations**

Operator: August 13, 1956 to April 1962
Owner: August 1956 to April 1962

1956: On August 13, 1956, Textron, Inc. (Textron) purchased the assets of Federal Leather Company excluding any obligations or liabilities (PAP-00145546; PAP-00208634).

1958: Textron Inc. transferred the business and assets of its Federal Industries Division to Federal Industries, Inc., a subsidiary of Textron, Inc. (PAP-00208626).

1962: On April 25, 1962, Textron Industries, Inc. sold the assets of the Federal Industries Division to Air Reduction Company (also known as Airco) (PAP-00145518).

1962-1966: Cumberland Chemical Company owned the Facility from April 30, 1962 until December 30, 1966 (PAS-00103078).

1970: Belleville Industrial Center owned and operated the site starting in 1968 and from 1975 to 2001 Helion Industries was a tenant of Belleville Industrial Center (PAS-00102979).

3. **Operational History/COC Use and Presence at the Facility**

Note that available references contain minimal information regarding operations, chemicals used and releases for Textron during its period of operation and ownership at this site location.

According to a Preliminary Assessment Report, Ideal Plating and Polishing Company, Inc., Belleville, Essex County, dated July 28, 1993 (1993 PAR), a 1938 Sanborn Company Insurance Map of Belleville shows that Federal Leather covered all of Block 56, Lots 5, 6, 7, 9 and 31. The Sanborn Map shows that Federal Leather contained a foundry, a wire rope factory, numerous solvent/fuel/naphtha tanks, a dye grinding shop, a lacquer storage facility, a varnishing and drying shop, a dope mixing shop, a chemical storage area, a dye house, and a solvent recovery shop (PAS-00103079). It is not known if these features were present during Textron's ownership or operation of the Facility from 1956-1962 or any subsequent operations. Textron operations at the

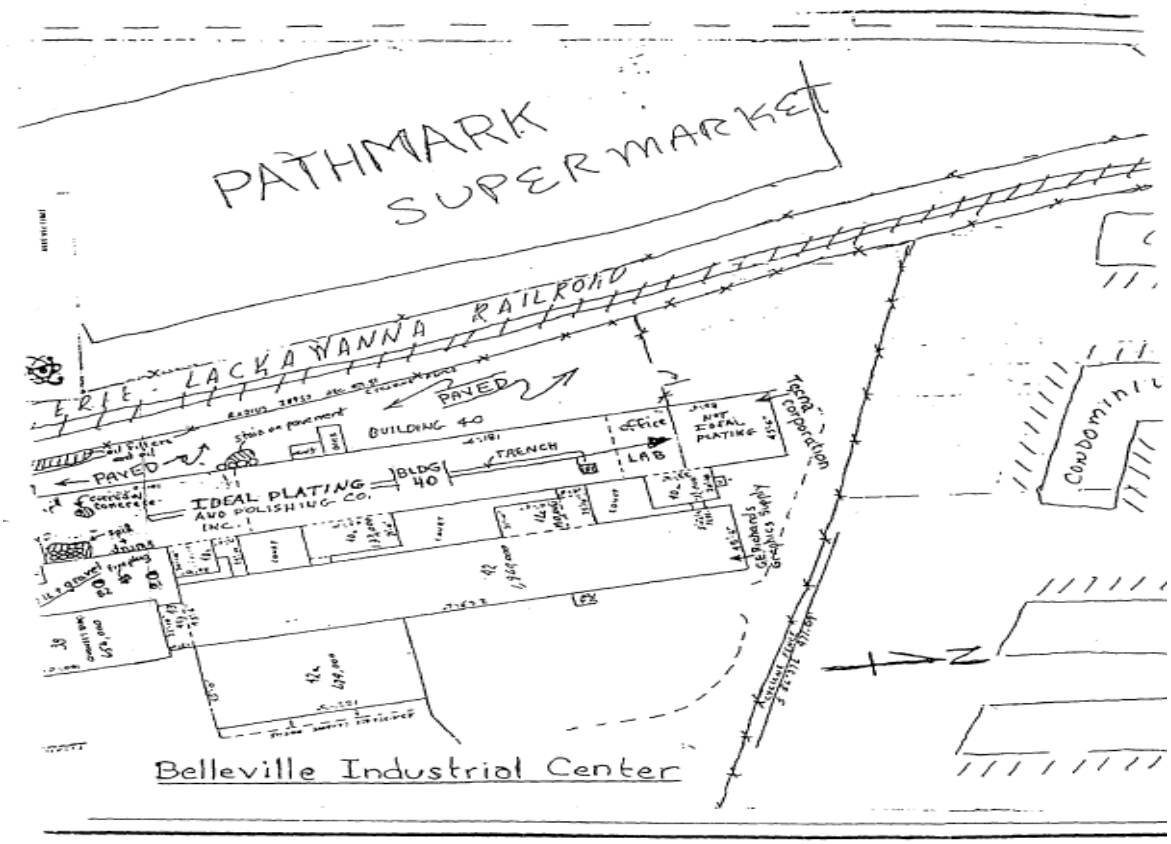
property included producing vinyl coated fabrics, dyeing finishing textiles, and producing automobile seat covers and injection molded vinyl parts (PAP-00145594; PAS-00103079).

In order to impart the properties of flame-retardancy and mildew resistance into textile materials, Textron's subsidiaries impregnated such materials with an antimony triflouride solution. In addition, the company had a method for making a highly stretchable laminated knitted fabric. That process involved applying plasticized vinyl resin to materials using coating machines. The machines applying the plasticized vinyl resin used methyl ethyl ketone as a solvent (PAP-00145594-95).

According to a Preliminary Assessment Report, dated February 10, 2003 (2003 PAR), trenches and sumps were used by Helion to direct process wastewaters to the property's sewer system and ultimately to the Passaic Valley Sewerage Commission (PVSC) (PAS-00103072). A narrative of the Belleville Industrial tenant Helion's disposal processes for all historic and current process waste streams and disposal points describes wastewater management for Buildings 11C and 9C at the site during Helion's occupancy "The wastewaters were pumped through trenches in the floors of the buildings to the production/mixing outlet No. 1 located along the northern end of building 11C. From there, the wastewaters were discharged to a trench that transected building 11B and ultimately discharged through the northwestern end of building 14A to the sewer system" (PAS-00103069).

According to the April 25, 1962 Purchase Agreement between Textron and Air Reduction Company, the following purchase agreements were in effect.

19. Various purchase contracts:



Date	Seller	Item
11/22/61	Amoco Chemical Corporation	Chemicals
9/8/61	Barker Industrial Trucks	Maintenance service for material handling equipment
12/11/61	Celanese Chemical Company	Chemicals
1/1/62-12/31/62	E. I. duPont de Nemours & Co., Inc.	Chemicals
12/13/61	Enjay Chemical Company	Chemicals
1/9/62	Monsanto Chemical Company	Chemicals
1/9/62	Monsanto Chemical Company	Chemicals
1/9/62	Monsanto Chemical Company	Chemicals
1/12/62	Monsanto Chemical Company	Chemicals
1/12/62	Monsanto Chemical Company	Chemicals
1/12/62	Monsanto Chemical Company	Chemicals
6/1/61	Northern New Jersey Oil Co.	Bunker fuel oil
11/22/61	Shell Chemical Co.	Chemicals

(PAP-00145540-41; PAP-00208772-73)

The type and quantity of chemicals was not available in the Purchase Agreement (PAP-00145540).

A review of available documents did not provide any additional information regarding processes or chemicals used in manufacturing processes conducted by Textron or its subsidiaries at the facility site.

PAS-00103096

(PAS-00103096)

4. Identified COCs

- PAHs (detected)
- Copper (detected)
- Lead (detected)
- Mercury (detected)

PAHs

The Site Investigation Report, Former Helion Industries, Inc., Buildings 4A, 6B, 9-12, 12A, 14, 17, 18, 22, and 23, Belleville Industrial Center, 681 Main Street, Belleville, New Jersey 07019, dated December 18, 2003 (2003 SI Report) states the following regarding polycyclic aromatic hydrocarbons (PAHs) “The source of the constituents likely stems from the nearby sump and the former effluent that was received by the sump, and is not believed to be fill related. The exceedances in [Building] 18 were noted directly below a compromised floor drain. As noted in the February 2003 Preliminary Assessment Report, Helion utilized a variety of hazardous materials, including solvents in their operations” (PAS-00102989).

As noted in the 2003 SI Report, sampling concentrations of PAHs including benzo[a]anthracene, benzo[a]pyrene, benzo[b]fluoranthene, and bis(2-ethylhexyl) phthalate were detected in soils adjacent to sumps and floor drains in Buildings 11C and 18 (PAS-00102982; PAS-00102988). Below is a table summarizing the exceedances.

Summary of Parameters that Exceed Unrestricted Use NJDEP Soil Cleanup Criteria

VOCs	NJDEP Soil Cleanup Criteria (mg/kg)			11C-a (mg/kg)	11C-b (mg/kg)	18 (mg/kg)
Benzene	3	13	1	Non Detect	***6.6***	Non Detect
Cis-1,2-Dichloroethene	79	1000	1	***1.8***	0.94	0.13
Tetrachloroethene	4	6	1	***6.3***	***9***	***6.7***
Trichloroethene	23	54	1	***5.8***	***18***	***5.9***
SVOC						
Benzo[a]anthracene	0.9	4	500	***1.1***	0.37	Non Detect
Benzo[a]pyrene	0.66	0.66	100	***0.91***	0.41	Non Detect
Benzo[b]fluoranthene	0.9	4	50	**1.2**	0.48	Non Detect
Bis(2-Ethylhexyl)phthalate	49	210	100	0.079	0.14	***59***
METALS						
Antimony	14	340	NS	Non Detect	Non Detect	***54***
Copper	600	600	NS	17	98	***990***

Bold and italicized font indicates an exceedance of unrestricted use criteria.
NS: Not Specified

(PAS-00102988)

Metals - Copper, Lead and Mercury

In the 2003 SI Report, sampling results showed that copper was identified in soils adjacent to sumps and floor drains in Building 18. The sample was taken at 0.5 foot to 1 foot below ground surfaces (bgs) and contained 990 mg/kg of copper (PAS-00102988).

Further testing from the 2005 RI Report explained that analytical results for soil samples surrounding and adjacent to the 2003 site investigation sampling did not exceed the unrestricted use NJDEP Soil Cleanup Criteria for copper in sample 11C (PAS-00103179).

According to the 2003 SI Report, the following metal concentrations were detected in soil samples taken from Buildings 14B, 17, and 18 from 0.5-1 ft bgs on October 9, 2003 (PAS-00103002):

Metal Concentrations (mg/kg)							
Metal	**14B-a**	**14B-b**	**14B-c**	**14B-d**	**17-A**	**17-B**	**18**
Copper	14	20	21	25	17	13	990
Lead	19	13	17	15	30	15	280
Mercury	0.1	ND	ND	ND	0.12	ND	0.46

According to the 2005 RI Report, Helion operated in Buildings 9C, 11C, 14B and 18 (PAS-00103181; PAP-00445807). The Hazardous Substance/Waste Inventory for Helion reported 1 gallons/lbs. of waste mercury stored in a fiberglass drum (PAS-00103067).

Historic Fill

The Allocation Team has determined that the facility site is located on regional Historic Fill as designated by the NJDEP.[1]

NJDEP has established that historic fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the Operable Unit 2 (OU2) contaminants of concern (COCs): PAHs, lead, copper, and mercury.[2] Accordingly, NJDEP technical requirements for property containing Historic Fill requires sampling for the EPA Target Compound List for PAHs and Target Analyte List for metals, including lead, copper, mercury, and the OU2 PAH COCs.[3] PAHs, lead, copper, and mercury are recognized by NJDEP to be constituents of Historic Fill at varying levels, not atypically at or exceeding residential soil standards.[4]

The levels of PAHs, copper, lead and mercury detected at the site in soils are presented in the table below (PAS-00103002), (PAS-00102988), (PAS-00102988).

COCs Found in Onsite Soils	
COC	**Max Detected Concentration**
Lead	280 mg/kg
Copper	990 mg/kg
Mercury	0.46 mg/kg
Benzo(a)anthracene	1.1 mg/kg
Benzo(a)pyrene	0.91 mg/kg

According to an undated PRP Data Extraction Form for Textron, Inc. (Data Extraction Form), the former Federal Leather Company developed the site in 1916 (PAP-00145593).

There is insufficient information to determine whether referenced soil samples were taken in an area of the site that contained Historic Fill.

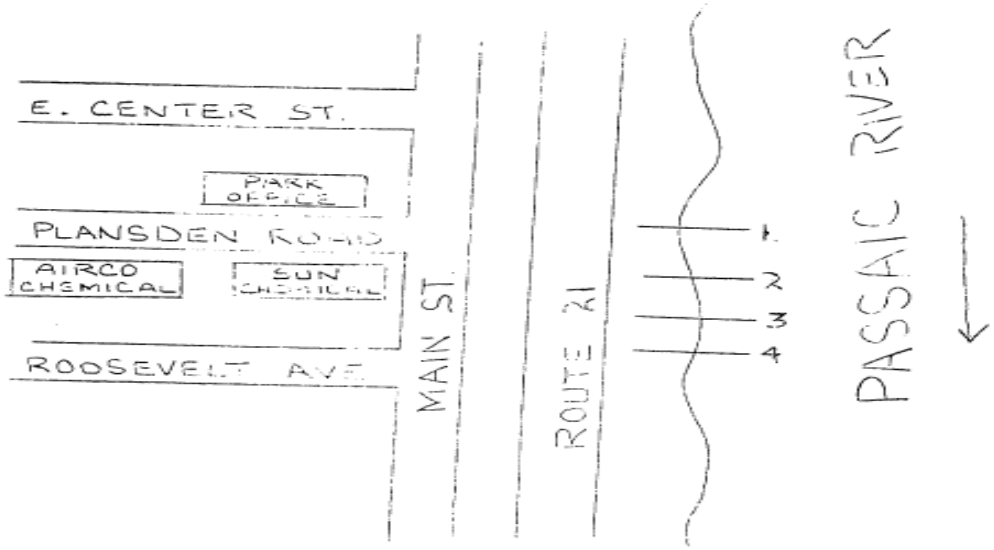
---

[1] *Digital Geodata Series, DGS04-7, Historic Fill for New Jersey*, https://www.nj.gov/dep/njgs/geodata/dgs04-7.htm, Quadrangle #52 & #53 (NJDEP map identifying locations of recognized historic fill).
[2] *Characterization of Ambient Levels of Selected Metals and cPAHs In New Jersey Soils* (2002) and *Characterization of Ambient Levels of Selected Metals and Other Analytes In New Jersey Soils* (1997), studies prepared for NJDEP, Division of Science and Research, by BEM Systems, Inc.
[3] NJDEP, *N.J.A.C. 7:26E Technical Requirements for Site Remediation,* Table 4-2, November 2009 [Note that Table 4-2 has been deleted from the current version of N.J.A.C. 7:26E (May 7, 2012) and the updated *Historic Fill Technical Guidance* (April 2013) as NJDEP believed that the tables list of historic fill constituents was too restrictive].
[4] NJDEP Table 4-2 (PAHs and lead) and a summary of NJDEP records regarding investigations of properties in the vicinity of the Passaic River recognized to be located in areas of Historic Fill indicate that the following average/maximum (mg/kg) contamination levels of OU2 COCs exist in area Historic Fill: PAHs (1.91/160), lead (574/10,000), copper (11.2/1,200), and mercury (0.21/3.7).

5. COC Pathways

Sanitary Sewer

A review of available documents did not provide information on processes used at the facility for the discharge of wastewater or stormwater during the period of Textron operations nor regarding PVSC discharge permits issued to the facility.



According to the Data Extraction Form, "Prior to at least 1926, sewage and wastes were directly discharging to the Passaic River from the Federal Leather facility. … Sometime after 1926, sanitary sewers were installed to route discharge to the PVSC, with the exception of historic Buildings 9-11 and related process areas drainage until at least June 10, 1977" (PAP-00145598).

No information on discharges to the sewer or PVSC during Textron's ownership period was documented in the available file material.

Storm Sewer

At an unknown date, the Federal Industrial park area contained Sun Chemical Corp and Airco Chemical Plastic Company with four sewer outlets as follows and shown in the map below:

1. 24" storm sewer outlet.
2. 24" storm sewer outlet.
3. 24" storm sewer outlet.
4. 30" pipe used for cooling water only.

(PAS-00103192)

The Data Extraction Form notes that in 1969, the United States Federal Water Pollution Control Administration reported the existence of a storm sewer "from Belleville Industrial Center," which was flowing at the time of observation. The Data Extraction Form also states that:

> "It is believed that this storm sewer is part of the same historic infrastructure identified above" (PAP-00145597).
>
> "In April 1977, PVSC reported the discovery of an illegal cross connection between the floor drains in BIC's [Belleville Industrial Center's] Building 11 with the storm sewer line leading to the Passaic River. … The floor drains in Building 11 are shown on Figure 2 of the BIC's 2003 Site Investigation Report to be part of the floor drain, trench, and sump system that was characterized in this report, and shown to discharge to a "sewer in road for industrial complex" (PAP-00145597).
>
> "The 1977 discovery by PVSC and subsequent correspondence indicates that the wastewater sewer in these buildings was part of the historic facility infrastructure operated previously by Federal Leather. As indicated above, discharges made via this storm sewer line would have likely gone undetected by PVSC, as they did with later tenants of the Site" (PAP-00145597).

The additional areas were connected to the sanitary sewers after at least June 10, 1977 (over 15 years after Textron's subsidiaries' ownership) (PAP-00145598).

Direct Release

According to the 1993 PAR, the site is adjacent to the Passaic River. The 1993 PAR also reported a migration pathway of run-off from the facility to the Passaic River via storm drains (PAS-00103088). The 1993 PAR also states that surface water contamination may occur during fires due to runoff, or due to spills to the storm drain system (PAS-00103090).

According to the 1993 PAR, during a July 19, 1993 site investigation by BFO-SA, Captain Vicari of the Belleville Fire Department stated that he was aware of a number of fires at the facility during the 1960s. He recalled one relatively serious fire, which occurred in a drying room and was accelerated by volatile compounds used in the process. Captain Vicari also stated that methyl ethyl ketone was dumped by employees who used the substance to wash parts (PAS-00103080). Note: Documentation supporting the information provided by Captain Vicari was not identified in the available file materials.

Spills

There is no information regarding spills in the available file material.

6. Regulatory History/Enforcement Actions

Inspections

There is no information regarding inspections in the available file material.

Violations

There is no information regarding violations in the available file material.

Permits

There is no information regarding permits in the available file material.

7. Response Actions

Characterization Activities

The following characterization activities have taken place at the site:

- Site Investigation Report, Former Helion Industries, Inc., Buildings 4A, 6B, 9-12, 12A, 14, 17, 18, 22, and 23, Belleville Industrial Center, 681 Main Street, Belleville, New Jersey 07019 (December 2003) (PAS-00102974-3005)
- Remedial Investigation, Former Helion Industries, Inc., - Buildings 11 and 18, Bellville Industrial Center, 681 Main Street, Bellville, New Jersey 07109 (January 2005) (PAS-00103165-190)

Sampling

As noted above, the facility site was the subject of a 2003 site investigation and December 2005 remedial investigation; however, a review of available documents did not provide additional information on response actions undertaken at the site.

8. Summary of Asserted Defenses

No legal defenses were identified in the available file materials.

Diamond Alkali OU2 Allocation
ADR Confidential
Facility Data Report

TIFFANY AND COMPANY

Facility Name, Address and Size: The Tiffany Plant; 820 Highland Avenue, Newark, New Jersey. According to a Contract Agreement between Tiffany and Company and Campy Construction, dated November 26, 1985, 820 Highland Ave consisted of two tracts; Tract 1 – Block 848B, Lots 1 to 22, and Tract 2 – 3 Parcels A-C and Block 852, Lots 9 and 11. No Lot number was provided for Parcel A-C, just metes and bounds. Parcel A contained 0.077 acres, Parcel B contained 2.09 acres and Parcel C contained 3.07 acres (PAP-00435299, 332-333). No acreage was provided for Tract 1 and Block 852. In a 1972 Passaic Valley Sewerage Commissioners (PVSC) Waste Effluent Survey, Tiffany reported that 157 employees were working five days a week on one shift (PAS-00109140).

1. **Business Type:** Manufacture of sterling silver products and the printing of high quality personal paper products (PAP-00206463).

2. **Time Period of Ownership/Operations**

Operator: 1897 to 1986 (PAS-00109172; PAS-00048871)

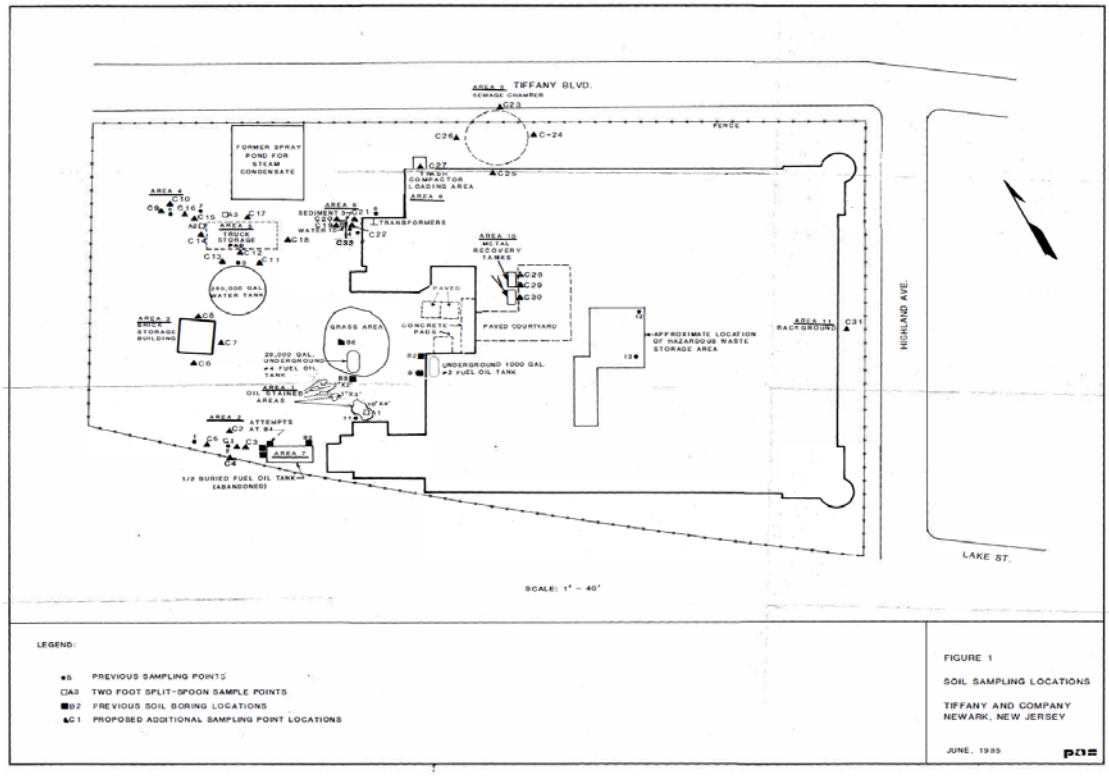
Owner: 1890s to 1991 (PAP-00435339; PAP-00435378; PAS-00048870)

1890s: In the 1890s, Louis Tiffany built a facility on the border of Newark and Belleville, New Jersey, located next to Branch Brook Park. The facility was used as a silver plate jewelry factory and warehouse and was located at 820 Highland Avenue in Newark, New Jersey (PAS-00048870).

1970s: In the late 1970s, Tiffany was acquired by Avon Products Inc. (PAS-00048871).

1984: Tiffany employees purchased the company through an employee buy-out (PAS-00048871). The present owner was listed as Avon Products with the sale involving Blocks 848-B and 852, Lots 1, 7, 9, 15, and 19 (PAP-00019996). In addition, Tiffco, Inc., (Tiffco), a Delaware Corporation, entered into an agreement to purchase the stock of Tiffany, which was owned by Avon Products, Inc. on September 12, 1984 (PAS-00048940).

Tiffany entered into an Administrative Consent Order (ACO) with New Jersey Department of Environmental Protection (NJDEP) effective October 12, 1984, to allow the purchase of Tiffany stock by Tiffco, Inc. effective on or about October 15, 1984. Tiffany also notified NJDEP that Tiffany was going to cease operations at the Newark facility on or about June 28, 1985. NJDEP and Tiffany expressly agreed that the stock transfer and cessation were subject to the NJDEP Environmental Cleanup Responsibility Act (ECRA) (PAP-00435037).



1985: Tiffany informed NJDEP that Tiffany had entered into an Agreement of Sale with Campy Construction on November 25, 1985 (PAP-00435037).

1986: After the Tiffany employee buy-out, the new owners decided to shut the facility down in 1985. The facility was formally closed in 1986 (PAS-00048871). In addition, on September 16, 1986, Tiffany filed an application for a NJDEP ACO for the contract purchase of Block 848B, Lots 1-22 and Block 852, Lots 9 and 11 by Campy Construction (PAP-00442780-86).

1991: Tiffany and Company conveyed to Tiffany Manor Associates, Limited Partnership, (Tiffany Manor), Block 852, Lot 11 in November 1991 (PAP-00435378-79). According to the Title Closing Statement, the Tiffany Factory Building at 820 Highland Avenue was sold to Tiffany Manor Associates, on November 18, 1991 (PAP-00435339). It was agreed that upon closing of the sale, Tiffany Manor would begin the conversion of the building and grounds into 129 residential dwelling units and related parking areas (PAP-00435340).

3. Operational History/COC Use and Presence at the Facility

Operations included the manufacture of sterling silver products and the printing of personal paper products (PAP-00206463; PAS-00048935). In two Tiffany Inter-Departmental Memorandums dated June 7, 1984 and June 18, 1984, the materials used at the facility were stated to include various acids, sodium cyanide, hydrogen peroxide, carbon tetrachloride and potassium cyanide. No OU2 COCs were identified as being used at the facility (PAP-00020031-34). A facility map is included below. The facility map shows that there were transformers on-site; however, there is no documentation that these transformers contained PCBs or that PCBs were detected on site (PAP-00019573).

In the *Environmental Cleanup Responsibility Act (ECRA) Site Evaluation Submission (SES)* dated September 24, 1984 (1984 SES), Tiffany reported that the silver manufacturing process started with silver plates rolled to various thicknesses. These rolled plates were then processed into flatware and hollow ware items. In the process, annealing was required using molten cyanide salts. The parts were then dipped into a 4% solution of sulfuric acid. The residues from these salts and acid were flushed into a below ground concrete holding, diluting, and settling tank. In addition, it was sometimes necessary to clean the parts in a solution of nitric acid and wash them in a solution of ammonia. The residues of the acid and ammonia were also funneled to the settling tank. The effluent, which was reported to be approximately 10,000 gallons per day, was discharged to the PVSC system. Tiffany reported that the effluent was analyzed on a monthly basis. The settling tank was then pumped out approximately once a year and the sludge was refined to reclaim any sterling silver (PAS-00048935).

The stationery manufacturing process included engraving that was completed using copper and steel dies. After pantographing, the dies or plates were placed in an etching tank that contained iron perchloride. This tank was emptied about every four to six weeks. The remains of this tank were then flushed into a below ground concrete holding tank and was discharged to the Passaic Valley Sewerage Commission (PVSC) system under Permit No. 20400950 (PAS-00048935).

4. Identified COCs

- PAHS (used, detected)
- Copper (used, detected)
- Lead (detected)
- Mercury (detected)

PAHs

Polycyclic aromatic hydrocarbon (PAH) containing materials such as No. 2 fuel oil and No. 6 fuel oil, were handled at the site as a part of plant operations as shown in the above facility map. The following fuel tanks were located on site:

- 28,000-gallon underground No. 4 fuel oil
- a half-buried abandoned fuel oil
- 1,000-gallon underground No. 2 fuel oil

According to a 1988 Soil Boring Results and Proposed Cleanup report, base neutral extractable organic contamination was noted in two samples collected from the former location of a partially buried fuel oil tank (PAP-00019943). No PAH data were identified in the referenced report.

Copper

The stationery manufacturing process included engraving that was completed using copper and steel dies. After pantographing, the dies or plates were placed in an etching tank that contained iron perchloride. This tank was emptied about every four to six weeks. The remains of this were flushed into a below ground concrete holding tank and discharged to the PVSC system under Permit No. 20400950 (PAS-00048935). The

copper dies used for engraving were purchased from an off-site manufacturer and were stored inside the facility.

In March 1986, copper was detected in surface soil at a maximum concentration of 2,600 parts per million (PAS-00109231-36).

In April 1988, copper was detected in surface soil at a maximum concentration of 320 parts per million (PAP-00019994-95).

Lead

In August 1984, lead was detected in surface soil at a maximum concentration of 1,300 parts per million at 0-6 inches below ground surface (bgs) (PAP-00434712-13). In March 1986, lead was detected in surface soil at maximum concentration of 2,500 ppm at 0-12 inches bgs (PAS-00109231-36).

In April 1988, lead was detected in surface soil at a maximum concentration of 2,100 parts per million at 0- 2 feet bgs (PAP-00019994-95).

There was no indication of lead being used in the available file material reviewed for this report.

Mercury

In April 1988, mercury was detected in surface soil at a maximum concentration of 2.4 parts per million (PAP-00019994-95).

There was no indication of mercury being used in the available file material reviewed for this report.

Historic Fill

The Allocation Team has determined that the facility site is not located on regional Historic Fill as designated by the NJDEP.[1]

NJDEP has established that historic fill deposited in the Coastal Plain and Piedmont regions of New Jersey is known to contain the OU2 COCs: PAHs, lead, copper, and mercury.[2] Accordingly, NJDEP technical requirements for property containing Historic Fill requires sampling for the EPA Target Compound List for PAHs and Target Analyte List for metals, including lead, copper, mercury, and the OU2 PAH COCs.[3] PAHs, lead,

[1] *Digital Geodata Series, DGS04-7, Historic Fill for New Jersey*, https://www.nj.gov/dep/njgs/geodata/dgs04-7.htm, Quadrangle No. 52 and No. 53 (NJDEP map identifying locations of recognized historic fill).
[2] *Characterization of Ambient Levels of Selected Metals and cPAHs In New Jersey Soils* (2002) and *Characterization of Ambient Levels of Selected Metals and Other Analytes In New Jersey Soils* (1997), studies prepared for NJDEP, Division of Science and Research, by BEM Systems, Inc.
[3] New Jersey Department of Environmental Protection (NJDEP), *N.J.A.C. 7:26E Technical Requirements for Site Remediation,* Table 4-2, November 2009 [Note that Table 4-2 has been deleted from the current

copper, and mercury are recognized by NJDEP to be constituents of Historic Fill at varying levels, not atypically at or exceeding residential soil standards.[4]

The levels of copper, lead and mercury detected at the site in soils are presented in the table below (PAP-00019994-95; PAS-00109231-36).

COCs Found in Onsite Soils	
COC	**Max Detected Concentration**
Lead	2,500 mg/kg
Copper	2,600 mg/kg
Mercury	2.4 mg/kg

It is noted that in 1988 a total of 34 borings were drilled throughout the open area of the site per the conditionally approved 1988 Sampling Plan. Using the data from the 34 borings, five subsurface cross-sections were developed to define a contamination pattern on site. According to the 1988 Soil Boring Results and Proposed Cleanup report, base neutral extractable organic contamination was noted in two samples collected from the former location of a partially buried fuel oil tank. Elevated levels of lead and copper were also detected in certain samples throughout the boring grid. Mercury, and other metals were detected in a few isolated samples with no consistent contamination pattern evident (PAP-00019943). The description of the materials encountered in the boring samples included fill; however, the composition of the fill was not presented (PAP-00019959-92).

5. COC Pathways

The Tiffany facility is situated approximately 250 feet from the Second River. Surface drainage is generally east-northeast from the site (PAP-00019416). It is approximately 1.5 miles from the Passaic River (PAS-00048870). No documentation of possible historical direct discharges of wastewater to the river was identified in the available file material.

Sanitary Sewer

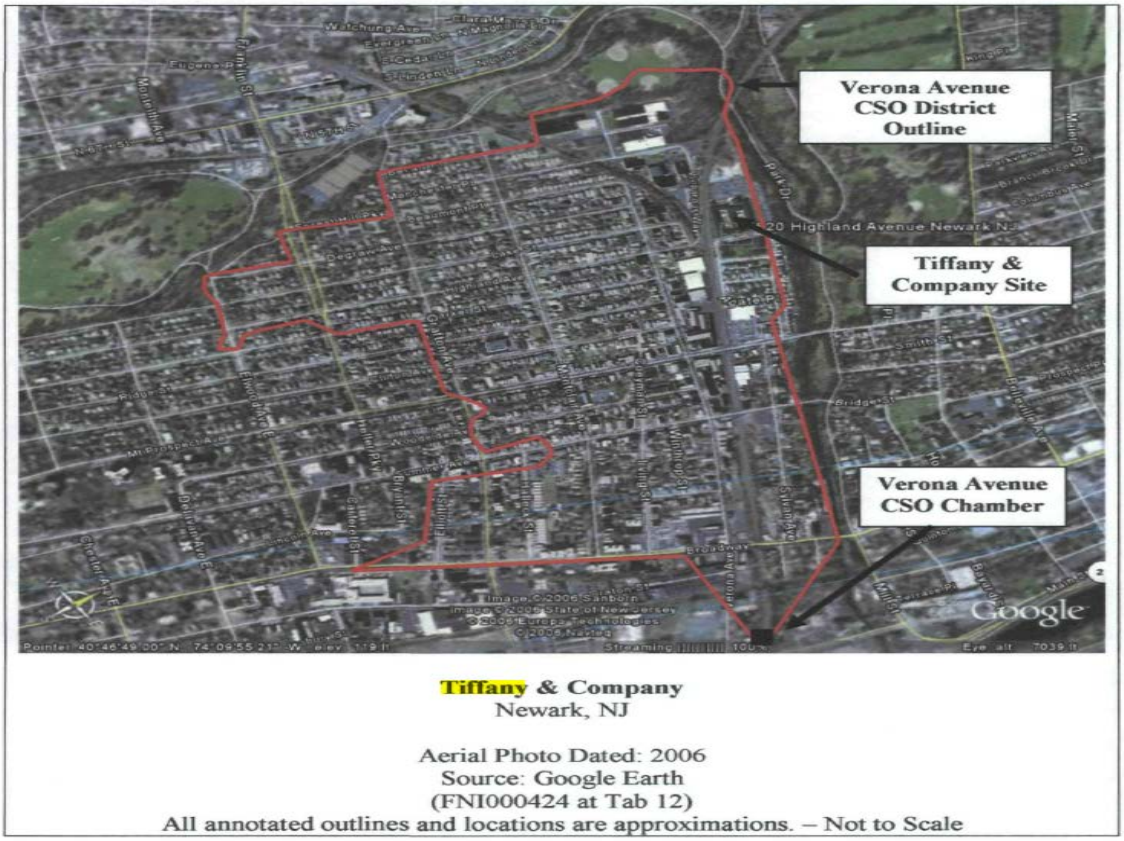
An April 1972 Waste Effluent Survey states that, in 1971, Tiffany discharged 8,042,496 gallons of process wastewater to the sanitary sewer. Zero gallons of process wastewater were released to the “storm sewer, river or ditch” (PAS-00009982-83).

According to Individual Monitoring Discharge reports, the following wastewater volumes were discharged from Outlet 200400950-41100-0201.

---

version of N.J.A.C. 7:26E (May 7, 2012) and the updated *Historic Fill Technical Guidance* (April 2013) as NJDEP believed that the tables list of historic fill constituents was too restrictive].

[4] NJDEP Table 4-2 (PAHs and lead) and a summary of NJDEP records regarding investigations of properties in the vicinity of the Passaic River recognized to be located in areas of Historic Fill indicate that the following average/maximum (mg/kg) contamination levels of OU2 COCs exist in area Historic Fill: PAHs (1.91/160), lead (574/10,000), copper (11.2/1,200), and mercury (0.21/3.7).



Wastewater Discharge Volume	
Monitoring Period	**Volume Discharged (gallons)**
4-1-1983 to 6-31-1983	2,566,203
7-1-1983 to 9-30-1983	1,255,895

(PAS-00048901-04)

According to an October 25, 1984 letter prepared by Tiffany, all floor drains at the facility lead through a single pipe to a settling tank. The settling tank had an overflow pipe, which allowed all solids to settle to the bottom and permitted only liquids to enter into the monitored discharge of the PVSC system (PAP-00206465-68).

According to the 1984 SES, operational wash water from facility operations was discharged to the sanitary sewer pursuant to a PVSC permit at approximately 10,000 gallons per day (PAS-00048935-36).

Based on a PVSC Plan of Collection System, the following annotated aerial photograph was created for the Lower Passaic River Study Area. It identified Tiffany as being in the Verona Avenue CSO District (PAS-00109014, 281). It was reported that during wet weather events, a portion of the sewer flow in the Verona Avenue CSO District was discharged directly to the Passaic River via the Verona Avenue overflow chamber (PAS-00109276).

(PAS-00109014)

Stormwater

In an October 25, 1984 letter, Tiffany stated that two outside stormwater drains were present and were reported to empty into the Newark City storm sewer system which ultimately emptied into the PVSC system (PAP-00206465). According to a February 10, 1993 letter to NJDEP, Tiffany had a cistern to store stormwater which was released during low flow periods to the PVSC (PAP-00019759). No further information was identified from the review of the available documents.

Spills

There is no information regarding spills in the available file material.

6. Regulatory History/Enforcement Actions

In an April 21, 2016, response to EPA request for information, Tiffany's attorney stated that the 1984 buy-out by Tiffany employees triggered the NJDEP ECRA. Tiffany completed the NJDEP Site Evaluation Submission and the cleanup plan as required which was approved by NJDEP in 1984. The cleanup plan stipulated that Tiffany would be responsible for any contamination found in the investigated areas (PAS-00048871).

Inspections

There is no information regarding inspections in the available file material.

Violations

According to an April 21, 2016, response to EPA request for information, Tiffany did not receive any permit violations from PVSC in the 90 years that if operated (PAS-00048870). No information to confirm or refute the claim was identified in available documents.

Permits

According to the 1984 SES, operational wash water was discharged to the sanitary sewer under PVSC Permit No. 20400950 (PAS-00048935). A PVSC permit was identified in the file material for the effective dates 1981 through 1986; no monitoring for COCs was required by the permit (PAS-00048880-84).

7. Response Actions

Characterization Activities

The following is a list of major response action documents identified in the available file material:

- Letter summary report for the sampling and analysis dated August 30, 1984 (PAP-00434711)

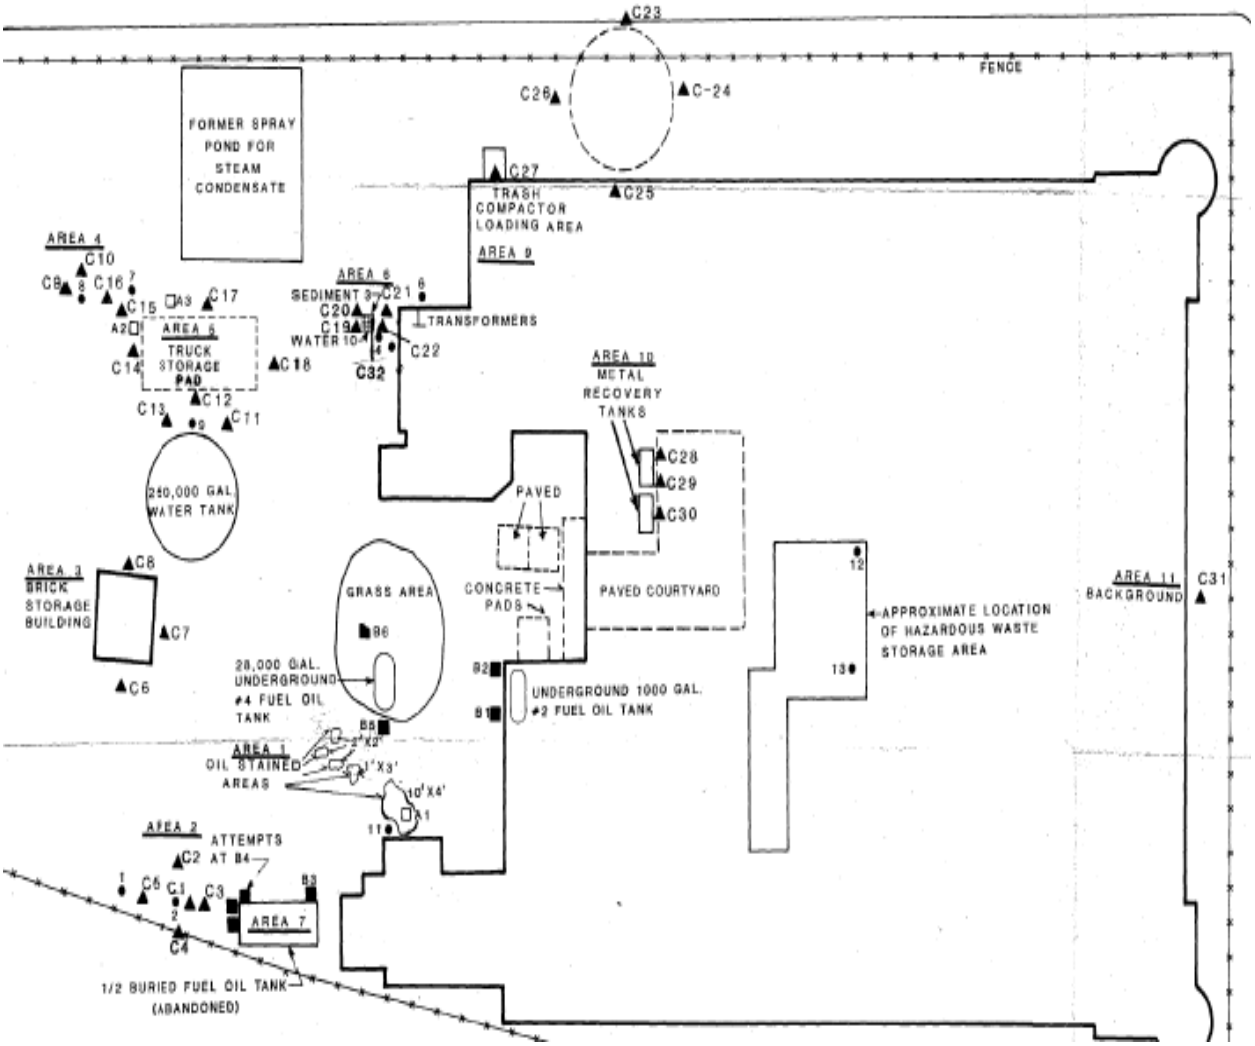
- Sampling and Analysis Plan for Environmental Cleanup Responsibility Act (ECRA) dated September 1984 (PAS-00109155)
- Phase II Sampling and Analysis Plan for Environmental Cleanup Responsibility Act (ECRA) dated August 1985 (PAP-00019736)
- Revised Sampling and Analysis Plan for Environmental Cleanup Responsibility Act (ECRA) dated December 1985 (PAP-00019552)
- Report on Revised Sampling and Analysis Program and Proposed Site Cleanup Plan for Tiffany and Company dated June 1986 (PAS-00109228)
- Report of Sampling and Analysis Program performed at Tiffany and Company Facilities dated February 1987 (PAS-00109240)
- Soil Boring Results and Proposed Cleanup dated 1988 (PAP-00019937)
- Presentation of Findings for Tiffany and Company, ECRA Case No. 84257 dated April 1991 (PAS-00048959)
- Proposed Soil Boring Plan for Tiffany and Company, ECRA Case No. 84257 no date provided (PAP-00434173)

Remedial Activities

In August 1984, 13 areas within the facility were identified as areas of potential environmental concern. Of those, the areas of environmental concern potentially related to releases of COCs, along with location description, and sampling depths are listed below.

Areas of Concern Potentially Related to Releases of COCs			
Site No.	**Description**	**Potential COCs**	**Sampling Depth**
2	Area behind building by Site No. 1 which was the former coal pile area.	Lead	0-6 inches
3	Catch basin with 18 inches of sediment located outside of the boiler room. The catch basin may have received boiler cleaning water.	Lead	6 inches of sediment
4	Soils immediately adjacent to the catch basin (Site No. 3). This sample was obtained to evaluate if stormwater runoff from the catch basin was influencing this area	Lead	0-11 inches
10	Discharge water from catch basin outside of the boiler room. This sample was obtained to identify potential contamination from stormwater runoff and boiler blowdown	Lead	grab water sample

(PAP-00434711-16; PAS-00109181-83)



According to an August 30, 1984, letter report, analytical results showed that there were elevated lead concentrations at Area Nos. 2, 3, 4, and 10 (discharge water). Lead was detected at the following concentrations:

- Site No. 2 – 1,300 parts per million (ppm) at 0-6 inches bgs;
- Site No. 3 – 200 ppm at 6 inches of sediment;
- Site No. 4 – 210 ppm at 0-6 inches bgs; and
- Site No. 10 – 1.4 ppm discharge water sample (PAP-00434712-13)

According to the Sampling and Analysis Plan for ECRA prepared by PAS dated September 1984; the Phase II Sampling and Analysis Plan for Environmental Cleanup Responsibility Act (ECRA) dated August 1985; and, the Revised Sampling and Analysis Plan for ECRA dated December 1985, based on the preliminary investigation of August 3, 1984, described above, 11 Areas were identified for further sampling (only those proposed for COC sampling are described below):

- Area 1: Adjacent to the fill neck for a 28,000-gallon underground No. 4 fuel oil tank. At this location there was a stained area of macadam, believed to be overflow from the hose during tank filling of the underground tank. Samples C1-2 were to be analyzed for petroleum hydrocarbons and lead.
- Area 2: Located in the area surrounding former sampling location No. 2 (coal pile). Samples C3-8 were to be analyzed for lead.
- Area 5: Located at the truck storage pad and the surrounding soil. Samples C11-18 were proposed to be analyzed for petroleum hydrocarbons and lead.
- Area 6: Located from around the catch basin (located across from the truck storage pad). Samples C212-23 were proposed to be analyzed for cyanide and lead.
- Area 7 addressed a half-buried abandoned fuel oil tank located where Tiffany proposed to remove the brick structure that encapsulated the tank.
- Area 10 was located at the metal recovery tanks. To demonstrate the integrity of the tanks, three soil borings were proposed. Samples C28-30 were to be analyzed for metals, among other constituents (PAS-00109159; PAP-00019741-44, PAP-00019561-63).

The following figure provides the locations of the sampling that occurred (PAP-00019573):

The *Report on Revised Sampling and Analysis Program and Proposed Site Cleanup Plan for Tiffany and Company* prepared by International Technology Corporation dated June 1986 reported the results from the sampling that occurred on March 11-14, 1986 and proposed a Cleanup Plan for the areas designated in the SAP (PAS-00109230). The following tables summarize the levels of copper and lead concentrations found:

Lead Concentrations Detected		
Sample No.	**Depth**	**Results (ppm)**
C1	0-6 inches	530
C3	0-6 inches	650
C4	0-6 inches	510
C19	0-12 inches	2,500
C20	0-12 inches	150
C21	0-12 inches	210
C22	0-12 inches	1,500
C32	0-12 inches	580

(PAS-00109231-36).

Copper Concentrations Detected		
Sample No.	**Depth**	**Results (ppm)**
C3	0-6 inches	300
C4	0-6 inches	470
C19	0-12 inches	2,600
C20	0-12 inches	230
C21	0-12 inches	260
C22	0-12 inches	1,500
C29	0-10 feet	920
C32	0-12 inches	650

(PAS-00109231-36).

According to the 1988 Soil Boring Results and Proposed Cleanup report, on February 9-10 and April 8, 1988, sampling was conducted with a total of 34 borings drilled and 43 samples retrieved for analysis (PAP-00019940). According to the report, the following results were obtained:

- Base neutral extractable organic contamination was noted in two samples collected from the former location of a partially buried fuel oil tank. No data for these samples was included in the available references.
- Elevated levels of lead and copper were also detected in certain samples throughout the boring grid.
- Mercury, and other metals were detected in a few isolated samples with no consistent contamination pattern evident (PAP-00442222).

The following data tables present the sampling data identified in the 1988 Soil Boring Results and Proposed Cleanup report ((PAP-00019994-95):

Lead		
Sample No.	**Depth**	**Results (ppm)**
B-03A	2-4 feet	240
B-05A	1-2 feet	280
B-07A	1-2 feet	250
B-09A	1-2 feet	710
B-11A	1-2 feet	130
B-12A	1-2 feet	330
B-14A	0-2 feet	2,100
B-15A	0-2 feet	120
B-16A	0-2 feet	250
B-17A	0-2 feet	130
B-19A	0-2 feet	120
B-20A	0-1.6 feet	720
B-21A	0-1.6 feet	100
B-23A	0-8 inches	330
B-25A	0-6 inches	210
B-26A	0-1.6 feet	270

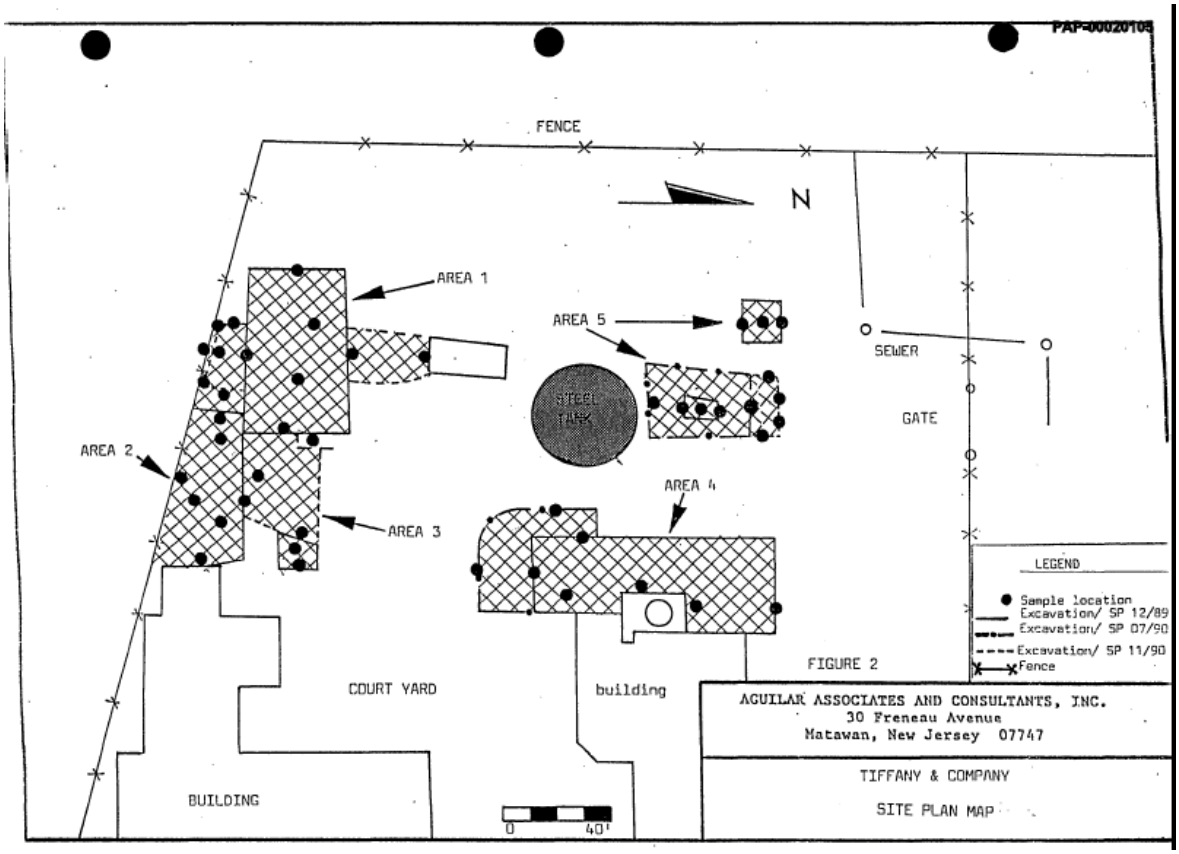
B-09A	1-2 feet	1.2
B-12A	0-2 feet	2.4
B-13C	4-6 feet	1.0

The following site map identifies the locations of the above-referenced soil boring locations (PAP-00019948).



Remedial Activities

According to the *Presentation of Findings for Tiffany and Company*, *ECRA Case No. 84257* prepared by Aguilar Associates & Consultants, Inc. dated April 1991, soil excavation and confirmation sampling activities at the Tiffany facility commenced on December 4, 1989 and were completed on November 29, 1990 for five areas. Of those, COCs were identified at four areas. All excavations were advanced to competent bedrock. Following soil excavation, post-excavation sampling was performed. Soil samples were taken from the sidewalls and from the base of each excavation (PAP-00020104).

Post Excavation Sampling			
Location	**~Total volume of soil excavated**	**~ Depth to competent bedrock**	**COCs**
Area 2	250 – 340 cy	10.5 to 2.0 feet	Base neutral semi-volatile organics, lead, and copper (PAP-00020107)
Area 3	15 cy	2.5 feet	Base neutral semi-volatile organics, copper, lead (PAP-00020111)
Area 4	37 cy	2.5 feet	Base neutrals. Copper, lead (PAP-00020112, 14)
Area 5A	15 cy	2.0 feet	Lead (PAP-00020115)
Area 5B	15 cy; additional 20 feet of soil removed during further excavation on May 8, 1990 and July 17, 1990	Not provided	Lead (PAP-00020117)

The following figure shows the locations of the Areas discussed in the table above (PAP-00020105):

According to the *Presentation of Findings for Tiffany and Company*, *ECRA Case No. 84257* prepared by Aguilar Associates & Consultants, Inc. dated April 1991, Area 10 was identified as an area of concern during an ECRA inspections conducted on August 15, 1990. A drum in the interior courtyard was observed to be leaking an oily substance to the ground. The drum was repacked, and the stained soils were excavated and sampled for base neutral semivolatile organics and total petroleum hydrocarbons. The analytical results showed no base neutral or total petroleum hydrocarbons exceeded ECRA soil action levels (PAP-00020118). No PAH data related to this area was identified in the file material.

According to a letter prepared by legal counsel for Tiffany, data showed that metals contamination identified in soil, including lead and copper, were removed to concentrations below NJDEP "Soil Cleanup Criteria" except for Area 5B where lead marginally exceeded the proposed standard. The letter stated that the areas had been covered with soil and will be covered by a parking lot (PAP-00019733-35). On July 30, 1993, NJDEP deemed the work complete and stated that Tiffany was in "full compliance with ISRA" (PAP-00019721; PAS-00048957)

8. Summary of Asserted Defenses

No legal defenses were identified in the available file materials.

Discharge Calcs	Direct Discharge Information	ASSUMPTIONS, REFERENCES	COMMENTS/NOTES
4.08	FEET/YEAR AVERAGE PRECIPITATION	Long term average annual precipitation includes floods and hurricane events occurring over time.	Data from Rutgers University.
2.8	ACRES - TOTAL SITE AREA (acres)	FDR page 1	
1.0	ACRES - AFFECTED AREA	Rough estimate of site area with exposed fill based on aerial photographs and Google Earth.	
4,046.86	METERS^2/ACRE		
4,047	METERS^2 (AFFECTED AREA)		
0.0001	METERS/YEAR (ERODED SOIL THICKNESS)	For this estimate, used a surface soil erosion rate of 0.1 mm/year, or 0.004 inches/year.	
0	METERS^3/YEAR (ERODED SOIL VOLUME)	VOLUME/YEAR DISCHARGED	
1939	Year site operations began	FDR page 1	
1974	Year site processing and storage operations ceased	FDR page 1	
35	NUMBER YEARS DISCHARGE		
14	METERS^3 (TOTAL SOIL VOLUME DISCHARGED OVER TIME)		
1,963	KG/M^3 SOIL DENSITY	Silt/Sand/Gravel, Dark Brown Blend. Bulk density range 1442 KG/M^3 to 2483 KG/M^3, so use average. (http://structx.com/Soil_Properties_002.html)	
27,797	KILOGRAMS (TOTAL SOIL DISCHARGED OVER TIME)		
		The site is located on regional Historic Fill (FDR page 17)	
Copper (Cu)			
35	YEARS DISCHARGED		
0	MG/KG (MAX CONCENTRATION)	Maximum detected concentration of copper in soils 281 ppm (FDR; PAP-00026600, PAS-00107134, PAP-00026528, PAS-00106903). Set to 0 since less than HF.	
0.000001	kg per mg (Merck Index)		
0	KILOGRAMS DISCHARGED		
Lead (Pb)			
35	YEARS DISCHARGED		
0	MG/KG (AVERAGE CONCENTRATION)	Maximum detected concentration of lead in soils 671 ppm (FDR; PAS-00107134, PAP-00026528, PAS-00106903). Set to 0 since less than HF.	
0.000001	kg per mg (Merck Index)		
0	KILOGRAMS DISCHARGED		

Mercury (Hg)		
35	YEARS DISCHARGED	
0.0	MG/KG (MAX CONCENTRATION)	Maximum detected concentration of mercury in soils 3.6 ppm (PAS-00107134). Set to 0 since less than HF.
0.000001	kg per mg (Merck Index)	
0	KILOGRAMS DISCHARGED	
PAHs (listed in Benzo(a)pyrene Equivalent conversion table)		Total concentration of PAH compounds for Benzo(a)pyrene Equivalent https://floridadep.gov/waste/petroleum-restoration/documents/benzo-pyrene-equivalents-conversion-table-one-sample.
35	YEARS DISCHARGED	
27.6	MG/KG (TOTAL PAH MAX CONCENTRATION)	
0.000001	kg per mg (Merck Index)	
1	KILOGRAMS DISCHARGED	
PAHs (others detected)		Data below the Benzo(a)pyrene Equivalent Table. LMW PAH concentrations reflect a single sample and HMW PAHs are remvoed from the summation of LMW PAHs. Historic fill was not a consideration for PAH concentrations for the purpose of this calculation.
35	YEARS DISCHARGED	
89	MG/KG (TOTAL PAH MAX CONCENTRATION)	Sum of Other PAH compound maximum concentrations listed in documents.
0.000001	kg per mg (Merck Index)	
2	KILOGRAMS DISCHARGED	
PCBs		NJDEP concluded that PCBs are not a site COC in 2016 (PAP-00026459).
35	YEARS DISCHARGED	FDR does not indicated PCBs in site soils.
0	MG/KG (MAX OF REPORTED CONCENTRATIONS)	
0.000001	kg per mg (Merck Index)	
0	KILOGRAMS DISCHARGED	
DDx		
35	YEARS DISCHARGED within DDx Timeline	DDx timeframe 1940-1974 (35 years).
17510	MG/KG (MAX CONCENTRATION)	DDx concentrations reflect a single sample, ABUST-S1-0.5-2.5 (PAP-00026610). Sum of 510 mg/kg 4,4-DDE, and 17000 mg/kg 4,4-DDT.
3.785	L per gallon (Merck Index)	
0.000001	kg per mg (Merck Index)	
487	KILOGRAMS DISCHARGED	
Dieldrin		
24	YEARS DISCHARGED within Dieldrin Timeline	Dieldrin timeframe 1950-1974 (24 years). The end date for years discharge reflects the year the site was sold.
40	MG/KG (MAX CONCENTRATION)	Sample ABUST S1 (PAP-00026610,6495)
3.785	L per gallon (Merck Index)	
0.000001	kg per mg (Merck Index)	
1	KILOGRAMS DISCHARGED	
Dioxins/Furans		2,4-D produced onsite
35	YEARS DISCHARGED	
0.0042	MG/KG (MAX CONCENTRATION)	Detected in range of 0.36-4.2 ug/kg in soils (FDR, PAS-00107212)
0.000001	kg per mg (Merck Index)	
0.00012	calc kg COC discharged	

Sample LA-4-4 (2.5-3.0 ft bgs) (PAP-00026526) Carcinogenic PAH concentrations have been updated to reflect a single sample. Historic fill was not a consideration for PAH concentrations for the purpose of this calculation.

Contaminant	Concentration (mg/kg)	Toxic Equivalency Factor	Benzo(a)pyrene Equivalents
Benzo(a)pyrene	21.000	1.0	21.0000
Benzo(a)anthracene	25.000	0.1	2.5000
Benzo(b)fluoranthene	24.000	0.1	2.4000
Benzo(k)fluoranthene	12.000	0.01	0.1200
Chrysene	22.000	0.001	0.0220
Dibenz(a,h)anthracene	0.840	1.0	0.8400
Indeno(1,2,3-cd)pyrene	7.300	0.1	0.7300

DE Residential = 0.1 mg/kg; DE Industrial = 0.7 mg/kg

Total Benzo(a)pyrene Equivalents = 27.6

Sample LA-4-4 (2.5-3.0 ft bgs) (PAP-00026526)

486.72	kg DDx
1.11	kg Dieldrin
0.0001	kg Dioxins/Furans

491.08	MASS (KG) DISCHARGED FROM SURFACE SOIL

Discharge Calcs	Direct Discharge Information	NOTES, COMMENTS, REFERENCES	
1939	Year site operations began	FDR page 1	Randell Inteview dated 1/25/1994 stated he and other works routinely dumped five gallon pails of waste cresol into the Passaic River (PAS-00003917)
1974	Year site processing and storage operations ceased	FDR page 1	Rothberg's Affidavit dated 2/21/06 states "…..it made no sense for employees to hand carry buckets of process waste to the river. He never observed nor had any other knowledge of any employess carrying buckets of waste from the facility across neighboring properties to the river. "I cannot conceive of any reason that anyone would have done such a thing, when the troughs and other disposal areas at the facility provided a ready means for waste disposal and were within approximately fifteen feet of any location within the facility. Nor was waste cresol, which Mr. Randell said was in the buckets, generated at the Newark Plant." (PAP-00027867-68, PAP-00027868)
			According to Google Maps there is a road that goes to the river just west of the property.
35	NUMBER YEARS DISCHARGE		Assume buckets of waste cresol dumped 1 time per year for years of operation

Cresol could be made from coal tar, which contains a number of PAHs.

PAHs

Assume 5 gallons buckets of Cresol Dumped. 8 buckets per year = 40 gallons per year

Assume Cresol contains 10% PAHs

35 YEARS DISCHARGED

Cresol: 8.89#/gallon

MG/KG (TOTAL PAH MAX CONCENTRATION)

40 gallons x 8.89#/gallon x .453592 kg/# = 161.30 kg/yr x 10% = 16.13 kg/yr

0.000001 kg per mg (Merck Index)

16.13 kg/yr x 35 years = 564.55 kg

564.55 KILOGRAMS DISCHARGED

Chrysene		0.001	0.0000
Dibenz(a,h)anthracene		1.0	0.0000
Indeno(1,2,3-cd)pyrene		0.1	0.0000

DE Residential = 0.1 mg/kg; DE Industrial = 0.7 mg/kg

Total Benzo(a)pyrene Equivalents = **0.0**

SUMMARY CMASS ESTIMATES:

564.55 kg PAHs MAX

564.55 MASS (KG) DISCHARGED BY OVERLAND FLOW

7.304E-5	10.0%	Periodic Noncompliacne	NOVs issued for hazardous discharges (e.g., acid, corrosive waste, greasy material, pH) from 1973 to 1992 (PAS-00049898, PAP-00065863, PAP-0006643, etc.), including exceedances of lead in samples collected in November 1990 (PAP-00066412). PVSC filed a Complaint dated December 17, 1993, due to continued violation of Permit No.20401080 (for zinc and cyanide). Since it was likely to continue to exceed its discharge limitations and adversely affect public health or safety or the operations of the PVSC system, PVSC demanded revoking the sewerage connection permit (PAP-00216733-36). ...some... fill came from the building, which was destroyed in a January 1980 explosion and fire (PAS-00049994). Unable to quantify releases from explosion and firefighting. Alliance also used the Avenue P landfill site to the south to store their drums; FDR says, "The 1990 Avenue P Landfill Investigative Summary noted that a 1974 aerial photograph identified a road entering the northwestern portion of the Avenue P Landfill from Alliance, and the number of drums on the Alliance premises was significantly reduced. Most of the drums were discovered in the northwest portion of the landfill (PAS-00129646-47)."	0.0%	0% Cooperation with conduct of allocation and requests for related information	8.034E-5

3.481E-6	10.0%	Periodic Noncompliacne	NOVs issued in 1988 for copper and lead in wastewater discharge samples (PAP-00351641; PAP-00351653). The December 1989 Report of Inspection noted outdoor soil staining due to oil from leaking indoor machinery. There was a heavily stained drum storage area in the North Yard. Exhaust ventilators for the plating room for Building 3 had condensate drains that were discharging to the stained soil below (PAS-00102607). There was a former spill in the location of the warehouse loading bay, one sample collected - had high PAHs. A compressor on the inside of the building discharged blowdown to the outside. When the boiler for this building was in operation, it also appeared to have discharged blowdown to the exterior (PAS-00102606-07). According to the ECRA Sampling Report and Phase II Sampling Plan, the associated stained soil was later removed (PAS-00102639-40). A compressor on the inside of the building discharged blowdown to the outside. When the boiler for this building was in operation, it also appeared to have discharged blowdown to the exterior (PAS-00102606-07). According to the ECRA Sampling Report and Phase II Sampling Plan, the associated stained soil was later removed (PAS-00102639-40).	-20.0%	-20% CPG/SPG member - Continuous provision of funding and participation in PRP Group(s) actions to cooperate with governmental/regulatory entities to address environmental or public harm created by own activities	3.133E-6

Facility Base Scores, Culpability Factor, Cooperation Factor and Adjusted Base Scores - Protocol Calculation

Ashland Inc.

221 Foundry Street	**Newark**	**NJ**	**07105**

Facility BS	CUF	CUF_Category	CUF_NOTES	COF	COF_NOTES	Facillty Adjusted BS
4.939E-7	10.0%	Periodic Noncompliacne	The facility received a notice of violation from PVSC on August 10, 1990, for failure to maintain continuous monitoring of facility outfalls (PAS-00050635). Ashland was notified on May 26, 1971, to cease pollution at once, and warned against discharge to the sanitary sewer without proper pretreatment, after a sample of washings entering into the Roanoke Avenue Storm Sewer at Avenue P. was “not only highly polluting,” but contained flammable and explosive materials (PAP-00089153). Inspections conducted by NJDEP personnel on March 13 and 28, 1979, noted spillage and/or leakage throughout Ashland’s facility. Areas noted included the following: all tank farms, loading/unloading manifolds, pipe connections, sumps, and the storm sewer system. According to NJDEP, corrective measures were discussed with Ashland’s officials who stated that it would not be economically feasible for the company to implement all of the remedies required by NJDEP.	-20.0%	-20% CPG/SPG member - Continuous provision of funding and participation in PRP Group(s) actions to cooperate with governmental/regulatory entities to address environmental or public harm created by own activities	4.445E-7

Discharge Calcs	Direct Discharge Information	ASSUMPTIONS, REFERENCES	COMMENTS/NOTES		
4.083333333	FEET/YEAR AVERAGE PRECIPITATION	Long term average annual precipitation includes floods and hurricane events occurring over time.			
14	ACRES - TOTAL SITE AREA (acres)				
4.5	ACRES - AFFECTED AREA	FDR page 2: Area A consists of 2.5 undeveloped acres located south of the West Yard. Additionally, based on google earth imagery, and creating polygons using measuring tool, an additional 2 acres of bare soil surrounding the tanks in the West and East Yard combined (grassy areas, see 06/2010 image) were estimated. Total of 4.5 acres of exposed soil. (Google Earth pro image)	Facility is adjacent to Passaic River (East Yard of property boundary abuts river). Chevron FDR page 1.		
4,046.86	METERS^2/ACRE				
18,211	METERS^2 (AFFECTED AREA)				
0.0001	METERS/YEAR (ERODED SOIL THICKNESS)	For this estimate, used a surface soil erosion rate of 0.1 mm/year, or 0.004 inches/year.			
2	METERS^3/YEAR (ERODED SOIL VOLUME)	VOLUME/YEAR DISCHARGED TO PASSAIC RIVER			
1930	Year site operations began	FDR Page 1: ARCO owned and operated the facility sometime in the 1930s. This calculation assumes 1930.	The Newark Terminal was operated as a petroleum storage and distribution facility (Chevron FDR Page 1)		
1951	Year site processing and storage operations ceased	FDR Page 1: ARCO conveyed the site to Tide Water Associated Oil Company on July 23, 1951	FDR Page 2: Facility operations were limited to bulk storage	The terminal was used to store and distribute refined petroleum products. It is believed that products were received via a pipeline system and by barge, and that products were distributed via tanker trucks. (Chevron FDR page 1)	Aerial photographs identified 11 tanks at the site and 2 docks that appeared to be leading to the Passaic River in 1943. The West Yard included three additional large storage tanks surrounded by concrete walls, a gasoline pump storage building, and an unlabeled building (Chevron FDR page 2)
21	NUMBER YEARS DISCHARGE	ARCO liability 21 years, 1930 to 1951 (FDR, page 1-2)			
38.242827	METERS3 (TOTAL SOIL VOLUME DISCHARGED OVER TIME)				
1962.5	KG/M3 SOIL DENSITY	Shallow borings from Area A were composed of a mixture of sand, silt, and gravel with varying amounts of brick fragments, rocks, wood and other debris (PAP-00066671, PDF page 8). Used "silty sand and gravel" soil type from http://structx.com/Soil_Properties_002.html. Bulk density range 1442 KG/M3 to 2483 KG/M3, so use average.			
75,052	KILOGRAMS (TOTAL SOIL DISCHARGED OVER TIME)				
Copper (Cu)					
21	YEARS DISCHARGED	Copper in included in this calculation even though it is not identified as a COC in the FDR (page 4) because it has been detected on site.			
0	MG/KG (MAX CONCENTRATION)	NOTE: No onsite sampling data were available for the time period during which ARCO owned/operated the Terminal; therefore, the data from the Chevron F&T calculation (same location) has been used for these calculations. Set to 0 since less than HF.			
0.000001	kg per mg (Merck Index)				
0	KILOGRAMS DISCHARGED				

Lead (Pb)

21 YEARS DISCHARGED

Maximum concentration in onsite soils (Chevron FDR Page 10, Table)
Concentration changed to 0 mg/kg because the Chevron FDR incorrectly has a concentration of 84,200 mg/kg. The referenced source shows a maximum lead concentration of 8,200 mg/kg (PAP-00339532). This is set to 0 because it is less than HF.

0 MG/KG (MAX CONCENTRATION)
0.000001 kg per mg (Merck Index)
0 KILOGRAMS DISCHARGED

PAHs (listed in Benzo(a)pyrene Equivalent conversion table)

Total concentration of PAH compounds for Benzo(a)pyrene Equivalent https://floridadep.gov/waste/petroleum-restoration/documents/benzo-pyrene-equivalents-conversion-table-one-sample.

21 YEARS DISCHARGED
26.586 MG/KG (TOTAL PAH MAX CONCENTRATION)

Sum of Benzo(a)pyrene Equivalent conversion concentrations. Historic fill was not a consideration for PAH concentrations for the purpose of this calculation.

Maximum concentrations found in surface sample A-2A (0.0-0.5 ft) (PAP-00066671, PDF pg 38).

Contaminant	Concentration (mg/kg)	Toxic Equivalency Factor	Benzo(a)pyrene Equivalents
Benzo(a)pyrene	19.000	1.0	19.0000
Benzo(a)anthracene	12.000	0.1	1.2000
Benzo(b)fluoranthene	23.000	0.1	2.3000
Benzo(k)fluoranthene	26.000	0.01	0.2600
Chrysene	26.000	0.001	0.0260
Dibenz(a,h)anthracene	2.800	1.0	2.8000
Indeno(1,2,3-cd)pyrene	10.000	0.1	1.0000

DE Residential = 0.1 mg/kg; DE Industrial = 0.7 mg/kg

Total Benzo(a)pyrene Equivalents = **26.6**

0.000001 kg per mg (Merck Index)
2 KILOGRAMS DISCHARGED

PAHs (others detected)

Other PAHs detected = Benzo(g,h,i)perylene, Fluoranthene, Phenanthrene, Pyrene (Figure PAP-00066671, pdf pg 38)

21 YEARS DISCHARGED
MG/KG (TOTAL PAH MAX CONCENTRATION)

Sum of other detected PAHs from Figure PAP-00066671, pdf pg 38 from Sample ID A-2A (0.0-0.5 ft). Historic fill was not a consideration for PAH concentrations for the purpose of this calculation.

122
0.000001 kg per mg (Merck Index)
9 KILOGRAMS DISCHARGED

PCBs

21 YEARS DISCHARGED

Historic aerial photographs revealed that Area A has undergone filling activities, which are the likely source of PCBs (PAP-00066682).

67 MG/KG (MAX OF REPORTED CONCENTRATIONS)

PCB (Aroclor 1254) highest concentrations ranging from 10mg/kg to 67 mg/kg (Area 2; SW-75C at 0-0.5 ft) detected along the southern perimeter. (Chevron FDR page 4)
Historic fill was not a consideration for PCBs concentrations for the purpose of this calculation.

0.000001 kg per mg (Merck Index)
5 KILOGRAMS DISCHARGED

SUMMARY CMASS ESTIMATES:
0.00 kg Copper
0.00 kg Lead
2.00 kg PAHs (Benzo(a)pyrene Equivalent)
9.16 kg PAHs (Other)
5.03 kg PCBs

16.18 MASS (KG) DISCHARGED FROM SURFACE SOIL

Discharge Calcs	Direct Discharge Information	ASSUMPTIONS, REFERENCES	COMMENTS/NOTES
4.08	FEET/YEAR AVERAGE PRECIPITATION	Long term average annual precipitation includes floods and hurricane events occurring over time.	Data from Rutgers University.
2.0356	ACRES - TOTAL SITE AREA (acres)		
0.50	ACRES - AFFECTED AREA	Rough estimate of site area with exposed fill determined from review of historical aerial photographs 1995-2020 and Figure (FDR, Page 7). Assume no asphalt until 1960 (50 percent coverage) and 100 percent after for an estimated 0.5 acres.	
4,046.86	$METERS^2$/ACRE		
2,023	$METERS^2$ (AFFECTED AREA)		
0.0001	METERS/YEAR (ERODED SOIL THICKNESS)	For this estimate, used a surface soil erosion rate of 0.1 mm/year, or 0.004 inches/year.	
0	$METERS^3$/YEAR (ERODED SOIL VOLUME)	VOLUME/YEAR DISCHARGED TO PASSAIC RIVER	
1897	Year site operations began	FDR, Page 1	
2020	Year site processing and storage operations ceased	Present (FDR, Page 1)	
123	NUMBER YEARS DISCHARGE	Atlas Refinery liability 123 years, 1897 to present (FDR, page 1)	
25	$METERS^3$ (TOTAL SOIL VOLUME DISCHARGED OVER TIME)		
1,963	KG/M^3 SOIL DENSITY	Silty sand and gravel (PAS-00052052). Bulk density range for silty sand and gravel 1442 KG/M3 to 2483 KG/M3, so use average. (http://structx.com/Soil_Properties_002.html)	
48,856	KILOGRAMS (TOTAL SOIL DISCHARGED OVER TIME)		
		Partially located on historic fill. Metals concentrations on FDR Page 6 are below Historic Fill (FDR page 5-6)	No soil results found for PCBs, PAHs, and pesticides.

142 Lockwood Street	**Newark**	**NJ**	**07105**

Facility BS	CUF	CUF_Category	CUF_NOTES	COF	COF_NOTES	Facillty Adjusted BS
1.361E-5	10.0%	Periodic Noncompliacne	Violations noted in 1972 (PAS-00051992-93; PAS-00052130-31) and 1981 (PAS-00072987) that were related to spills and poor housekeeping practices at the facility. In a March 8, 1989 Civil Action Complaint filed in the Superior Court of New Jersey, PVSC requested the permit be revoked stating that the petroleum hydrocarbon content control system and other pretreatment systems were functioning improperly. The complaint noted that violations were issued to Atlas from 1986 to 1989 (PAS-00052011-12). Atlas installed a Pretreatment System in 1986 (PAS-00052028). In addition, in at least the early 1970s, oil was released as a result of Atlas activities in the railyard near the Central Railroad tracks, and during periods of rainfall this material drained towards Blanchard Street and entered the catch basin and thus the Passaic River.	0.0%	0% Cooperation with conduct of allocation and requests for related information	1.497E-5

Facility BS	CUF	CUF_Category	CUF_NOTES	COF	COF_NOTES	Facillty Adjusted BS
1.430E-3	10.0%	Periodic Noncompliacne	Multiple Administrative Consent Orders from NJDEP related to the air permits, incinerator air emissions, and waste handling and/or documentations in the 1980s and 1990. BASF received an "unacceptable" rating from NJDEP following a Compliance Evaluation Inspection conducted on February 9, 1988 for NJPDES Permit No. NJ0001112. In 1987, all permitted parameters (total organic carbon, petroleum hydrocarbons, temperature, and pH) exceeded established limitations in NPDES permit (PAP-00057827-28). In August 1988, BASF was given a Notification of Reportable Events #22-27 for violating PCB regulations. The July 1987 Annual Report noted PCB contaminated transformer YAR 49871 had been stored for disposal on site for more than one year and the area the unit was stored in did not comply with regulations (PAP-00061053-58). According to the PVSC Annual Report for 1971, dated January 18, 1972, on July 13, 1971 PVSC received a call ...about BASF discharging into the Passaic River. Upon inspection by PVSC, industrial waste was seen coming out of the ground and flowing into the Passaic River. BASF immediately ordered excavation of the area and found a break in a 3-inch pipe which was a temporary sanitary line for a construction trailer. The sewage from the main line was backing up and flowing out through the break. The break was repaired the same day and the line was later removed (PAS-00034592). The PVSC Annual Report for 1973... stated BASF ordered five truckloads of 2-ethyl-hexanol from Eldorado Terminal Corp. for delivery on Saturday, February 10, 1973. During delivery, a welded seam ruptured on the storage tank and 2,500 barrels of alcohol drained into the Passaic River. The loss was not detected by BASF until Sunday, February 11, 1973...(PAS-00034721). Barriers for drainage or flood control, and runoff control systems did not exist at the site (PAP-00062140).	-20.0%	-20% CPG/SPG member - Continuous provision of funding and participation in PRP Group(s) actions to cooperate with governmental/regulatory entities to address environmental or public harm created by own activities	1.287E-3

6.467E-5	10.0%	Periodic Noncompliacne	On August 15, 1969, the WPCP of the NJDOH issued an Administrative Order to Benjamin Moore pursuant to the provisions of R.S. 58:12-2. In response to a Benjamin Moore inquiry for the specific details on which the order was based, in a September 4, 1969 letter the State stated that the alleged violation was based on “pollution of the Passaic River in terms of odor, turbidity, color, biochemical oxygen demand, chemical oxygen demand, other soluble matter and suspended solids.” Benjamin Moore followed up and discovered 3 drains in the vehicle plant that discharged to the storm sewer. These were connected to the sanitary sewer (PAS-00055008-9, 21-22, 26). On March 23, 1978, the Coast Guard notified Benjamin Moore that a Coast Guard helicopter had noticed a spill from the plant in the River. Investigation with the Coast Guard found a 55-gal drum had been punctured approximately amid ships" and part of its contents had migrated to the Passaic River. At 12:50 PM, July 8, 1980, a valve malfunction spilled about 3,000 gallons of wash solvent. Although this was contained by the retaining dike around the tanks, about 25-50 gallons allegedly leaked from the dike into the Passaic River...According to the Site Assessment, “Given the date of the release, the only COC that could have been contained in the wash solvent was naphthalene...” (PAP-CONF-00010225).	-20.0%	-20% CPG/SPG member - Continuous provision of funding and participation in PRP Group(s) actions to cooperate with governmental/regulatory entities to address environmental or public harm created by own activities	5.820E-5

Allocator's Determinations Regarding
Legal Defenses Raised by Allocation Parties

BEROL

Berol argues that OxyChem released Berol and certain other parties (including Berol's parent company, Newell Brands Inc.) from OxyChem's claim for Remedial Design Costs related to OU2. Accordingly, any allocation of OU2 costs that includes OxyChem and Berol (and the other released parties) must reflect this release of liability.

ALLOCATOR'S DETERMINATION – Though I have not had the opportunity to review the underlying settlement document and other potentially relevant facts associated with the release provided by OCC, assuming its validity, it is apparent that there is a high likelihood of success in any action against OCC to enforce the release. Given OCC's lack of participation in the allocation process, however, the Allocator does not believe that it is appropriate to account for the amount of any such release in the assignment of allocated shares. Rather, the Allocator notes the existence of the release and recommends that it be taken into account in determining the appropriate amount of any future settlement with EPA.

Facility BS	CUF	CUF_Category	CUF_NOTES	COF	COF_NOTES	Facillty Adjusted BS
9.516E-5	0.0%	Historically Compliant or No Evidence	During a 1996 inspection of the facility (CBS owned/operated the site 1889-1984), inspection of the Transformer Areas showed oil staining and an actual puddle of oil was apparent on the concrete floor next to Transformer A2. Oil staining was also evident on the floor near the rear of the transformer room. Floor drains were observed (PAP-00347568). A 55-gallon drum of boiler treatment chemical was stored on top of, and leaking into a trench in the engine room. Miscellaneous oils in 55-gallon drums were also stored above the trenches. A leaking oil pump was observed on top of a trench in front of the active boiler in the engine room. Oil staining was also observed on the concrete floor in front of one of the inactive boilers (PAP-00347568). Given date of insepection, difficult to assertain whether actions resulting in contaminantion were during CBS operations on site.	-20.0%	-20% CPG/SPG member - Continuous provision of funding and participation in PRP Group(s) actions to cooperate with governmental/regulatory entities to address environmental or public harm created by own activities	7.613E-5

Discharge Calcs	Direct Discharge Information	ASSUMPTIONS, REFERENCES	COMMENTS/NOTES
4.083333333	FEET/YEAR AVERAGE PRECIPITATION	Long term average annual precipitation includes floods and hurricane events occurring over time.	Data from Rutgers University.
27	ACRES - TOTAL SITE AREA (acres)	Two areas: the East Farm, a 7.5 acre lot situated east of Doremus Avenue and abutting Newark Bay; and, the West Farm, a 19.3 acre lot located west of Doremus Avenue (FDR page 1-2).	
11	ACRES - AFFECTED AREA	According to the facility layout map on page 4 of the FDR, the site appears to be about 40% unpaved. Therefore, the estimated affected area for this calcualtion is about 10.8 or 11 acres	
4,046.86	METERS^2/ACRE		
44,515	METERS^2 (AFFECTED AREA)		
0.0001	METERS/YEAR (ERODED SOIL THICKNESS)	For this estimate, used a surface soil erosion rate of 0.1 mm/year, or 0.004 inches/year.	
4	METERS^3/YEAR (ERODED SOIL VOLUME)	VOLUME/YEAR DISCHARGED TO DITCHES AND PLUM CREEK	
1954	Year site operations began	Celanese purchased the eastern portion of the site in 1954 and the purchased the West Farm in 1957 (FDR page 1)	
1996	Year site operations ceased	FDR page 1	
42	NUMBER YEARS DISCHARGE		
187	METERS^3 (TOTAL SOIL VOLUME DISCHARGED OVER TIME)		
1,963	KG/M^3 SOIL DENSITY	Fill reported as brown to black fine-to coarse-grained sand with some silt or clayey silt. Gravel-sized particles are frequently present in the form of glass, ceramic, brick, plastic, metal or wood fragments (PAP-00020891). Bulk density range for silty sand and gravel is 1442 KG/M3 to 2483 KG/M3, so use average. (http://structx.com/Soil_Properties_002.html)	
366,919	KILOGRAMS (TOTAL SOIL DISCHARGED OVER TIME)		
Copper (Cu)			
42	YEARS DISCHARGED		
0	MG/KG (MAX CONCENTRATION)	Copper was found in surface soil at AEC 36 at a max concentration of 447 mg/kg in soil boring 700A-3603-SB03 (depth of 0.0 to 0.5 ft bgs) (PAP-00020849 PDF page 108). Set to 0 since less than HF.	
0.000001	kg per mg (Merck Index)		
0	KILOGRAMS DISCHARGED		
Lead (Pb)			
42	YEARS DISCHARGED		
0	MG/KG (AVERAGE CONCENTRATION)	Lead was found in surface soil at sample ID 700A-3604-SB01 at a max concentration of 3670 mg/kg (depth 0.0-0.5 ft bgs) PAP-00020849 pdf page 108. Set to 0 since less than HF.	
0.000001	kg per mg (Merck Index)		
0	KILOGRAMS DISCHARGED		
Mercury (Hg)			
42	YEARS DISCHARGED		
12.0	MG/KG (MAX CONCENTRATION)	Mercury was found in surface soil at sample 700A-3603-SB02 at a max concentraiton of 2.8 mg/kg (depth 2.5-3.0 ft bgs) PAP-00020849, pdf page 108. Due to the density of mercury, a deeper sample may be more representative because sampling was not conducted immediately after the release occured.	
0.000001	kg per mg (Merck Index)		
4	KILOGRAMS DISCHARGED		

PAHs (listed in Benzo(a)pyrene Equivalent conversion table)		Total concentration of PAH compounds for Benzo(a)pyrene Equivalent https://floridadep.gov/waste/petroleum-restoration/documents/benzo-pyrene-equivalents-conversion-table-one-sample.
42	YEARS DISCHARGED	
99.4	MG/KG (TOTAL PAH AVERAGE CONCENTRATION)	Sum of Benzo(a)pyrene Equivalent conversion concentrations using maximum concentrations listed in FDR TABLE, PAGE 18
0.000001	kg per mg (Merck Index)	
36	KILOGRAMS DISCHARGED	
PAHs (others detected)		
42	YEARS DISCHARGED	
400	MG/KG (TOTAL PAH MAX CONCENTRATION)	Sum of Other LMW PAHs = Acenaphthene, Acenaphthylene, Anthracene, Fluorene, Napthalene, and Phenanthrene. Concentrations from AEC 59 in surface soil (FDR page 18)
0.000001	kg per mg (Merck Index)	
199	KILOGRAMS DISCHARGED	
PCBs		
42	YEARS DISCHARGED	The highest concentration of PCBs was collected from test pit TP-1, which was located in a non-operational area in the south-central portion of the southern portion of the West Farm
54	MG/KG (MAX OF REPORTED CONCENTRATIONS)	PCBs were detected at a concentration of 54 ppm in a sample collected at a depth of three feet bgs (FDR page 16)
0.000001	kg per mg (Merck Index)	
20	KILOGRAMS DISCHARGED	
DDx		In the shallowest soil sample collected from Retention Pond "D" area located in the northwest corner of the site (1.0 feet bgs), 4,4-DDE (0.058 mg/kg) and 4,4-DDD (0.018 mg/kg) were detected. (FDR page 7) The sum of both 4,4-DDE and 4,4-DDD = 0.076 mg/kg
42	YEARS DISCHARGED within DDx Timeline	
0.076	MG/KG (MAX CONCENTRATION)	
3.785	L per gallon (Merck Index)	
0.000001	kg per mg (Merck Index)	
1	KILOGRAMS DISCHARGED	

NOTE: FDR page 18 lists maximum concentrations of PAHs in surface soil (0.5 to 1 foot bgs) detected at AEC 59 (in ppb). This table has adjusted the concentrations to mg/kg.

Contaminant	Concentration (mg/kg)	Toxic Equivalency Factor	Benzo(a)pyrene Equivalents
Benzo(a)pyrene	62.000	1.0	62.0000
Benzo(a)anthracene	82.000	0.1	8.2000
Benzo(b)fluoranthene	68.000	0.1	6.8000
Benzo(k)fluoranthene	29.000	0.01	0.2900
Chrysene	77.000	0.001	0.0770
Dibenz(a,h)anthracene	18.000	1.0	18.0000
Indeno(1,2,3-cd)pyrene	40.000	0.1	4.0000

DE Residential = 0.1 mg/kg; DE Industrial = 0.7 mg/kg

Total Benzo(a)pyrene Equivalents = **99.4**

SUMMARY CMASS ESTIMATES:	
0.00	kg Copper
0.00	kg Lead
4.40	kg Mercury
36.46	kg PAHs (Benzo(a)pyrene Equivalent)

1.064E-4	5.0%	Occasional Noncompliance	A 1969 Administrative Order issued for discharging industrial waste and “other polluting matter” into the Passaic River (PAS-00071180-81). On May 17, 1991, the facility received a NOV for failure to monitor their effluent for lead to comply with General Pretreatment Regulations (PAS-00071202). Older Celanese employees noted that in the mid-1970s, persons were sometimes seen dumping materials into Plum Creek north of the northwest corner of the Celanese property at night. Employees stated that a certain material deposited was a thick white liquid (PAP-00021048). No evidence of Involvement of Celenese staff.	-15.0%	-20% CPG/SPG member - Continuous provision of funding and participation in PRP Group(s) actions to cooperate with governmental/regulatory entities to address environmental or public harm created by own activities 5% Failure to fully cooperate with conduct of the allocation or requests for related information (Ceased particiation in allcoation in December 2019)	9.577E-5

Discharge Calcs	Direct Discharge Information	ASSUMPTIONS, REFERENCES	COMMENTS/NOTES
4.083333333	FEET/YEAR AVERAGE PRECIPITATION	Long term average annual precipitation includes floods and hurricane events occurring over time.	Data from Rutgers University
14.5	ACRES - TOTAL SITE AREA (acres)		
4.5	ACRES - AFFECTED AREA	Area A consists of 2.5 undeveloped acres located south of the West Yard (FDR p 2). Additional 2 acres of bare soil surrounding the tanks in the West and East Yard combined were estimated (Google Earth).	Facility is adjacent to Passaic River (East Yard of property boundary abuts river). FDR page 1.
4,046.86	$METERS^2$/ACRE		
18,211	$METERS^2$ (AFFECTED AREA)		
0.0001	METERS/YEAR (ERODED SOIL THICKNESS)	For this estimate, used a surface soil erosion rate of 0.1 mm/year, or 0.004 inches/year.	
2	$METERS^3$/YEAR (ERODED SOIL VOLUME)	VOLUME/YEAR DISCHARGED TO PASSAIC RIVER	
1951	Year site operations began	Operated and owned by Chevron from July 1951 to December 1984 (FDR p 1)	
1984	Year ownership ceased	Texaco aquired Getty Oil Company in 1984, property was transferred to Power Test Realty Company Limited Partnership (FDR p 1)	
33.5	NUMBER YEARS DISCHARGE		
61.0064145	METERS3 (TOTAL SOIL VOLUME DISCHARGED OVER TIME)		
1962.5	KG/M3 SOIL DENSITY	Shallow borings were composed of a mixture of sand, silt, and gravel with varying amounts of brick fragments, rocks, wood and other debris (PAP-00066671, PDF page 8). Used "silty sand and gravel" soil type from http://structx.com/Soil_Properties_002.html. Bulk density range 1442 KG/M3 to 2483 KG/M3, so use average. Average is 1962.5 kg/m3	
119,725	KILOGRAMS (TOTAL SOIL DISCHARGED OVER TIME)		
Copper (Cu)			
33.5	YEARS DISCHARGED		
0	MG/KG (MAX CONCENTRATION)	Maximum concentration from table on PAP-00066720 (Sample A-2A, 0-0.5 ft bgs). Set to 0 since less than HF.	
0.000001	kg per mg (Merck Index)		
0	KILOGRAMS DISCHARGED		
Lead (Pb)			
33.5	YEARS DISCHARGED	Concentration set at 0 mg/kg because the FDR incorrectly has a concentration of 84,200 mg/kg. The referenced source shows a maximum lead concentration of 8,200 mg/kg (PAP-00339532). This is set to 0 because it is less than HF.	
0	MG/KG (MAX CONCENTRATION)		
0.000001	kg per mg (Merck Index)		
0	KILOGRAMS DISCHARGED		
PAHs (listed in Benzo(a)pyrene Equivalent conversion table)		Total concentration of PAH compounds for Benzo(a)pyrene Equivalent https://floridadep.gov/waste/petroleum-restoration/documents/benzo-pyrene-equivalents-conversion-table-one-sample.	
33.5	YEARS DISCHARGED

Discharge Calcs	Direct Discharge Information	ASSUMPTIONS, REFERENCES	COMMENTS/NOTES
4.08	FEET/YEAR AVERAGE PRECIPITATION	Long term average annual precipitation includes floods and hurricane events occurring over time.	Data from Rutgers University.
40	ACRES - TOTAL SITE AREA	FDR p 1	
30	ACRES - AFFECTED AREA	Rough estimate of site area with exposed fill determined from review of 1938 map (PAP-00075242). Estimating that 25% of the site had buildings	The Third River is a tributary to the Passaic and formed the southern and eastern boundaries of the site (FDR p 8)
4,046.86	METERS^2/ACRE		
121,406	METERS^2 (AFFECTED AREA)		
0.0001	METERS/YEAR (ERODED SOIL THICKNESS)	For this estimate, used a surface soil erosion rate of 0.1 mm/year, or 0.004 inches/year.	
12	METERS^3/YEAR (ERODED SOIL VOLUME)	VOLUME/YEAR DISCHARGED	
1921	Year site operations began	Coats and Clark (as Clark Thread Company) bought the land 8/10/1921 (FDR p 1)	
1947	Year site processing and storage operations ceased	Coats and Clark (as Clark Thread Company) sold the land on 9/17/1947 to Scientific Glass Apparatus Company Inc (FDR p 1)	
26	NUMBER YEARS DISCHARGE		
316	METERS^3 (TOTAL SOIL VOLUME DISCHARGED OVER TIME)		
1,875	KG/M^3 SOIL DENSITY	Surface soil is 1-5' of sand atop 2-3' silty sand (PAP-00077857). Density of silty sand and gravel ranges from 1378 to 2371 kg/m^3, so the average is used. (http://structx.com/Soil_Properties_002.html)	
591,695	KILOGRAMS (TOTAL SOIL DISCHARGED OVER TIME)		
		Site is partially located on regional Historic Fill (FDR p 7)	AOCs were COCs have been detected in soil but are not specifcally related to Scientific Glass Apparatus Co operations (later owner/operator at this site) were evaluated (FDR p 10)
Copper (Cu)			
26	YEARS DISCHARGED	Copper sulfate was used as part of the dyeing processes (FDR p 1-2)	
238	MG/KG (MAX CONCENTRATION)	Max concentration at AOC 14 Sample TP-12S (1-2 ft bgs) (PAP-00075799, PAP-00076155)	
0.000001	kg per mg (Merck Index)

0.00	kg Dieldrin
0.00	kg Dioxins/Furans

495.61	MASS (KG) DISCHARGED FROM SURFACE SOIL

Total concentration of PAH compounds for Benzo(a)pyrene Equivalent https://floridadep.gov/waste/petroleum-restoration/documents/benzo-pyrene-equivalents-conversion-table-one-sample.

Data below the Benzo(a)pyrene Equivalent table

No info regarding storage or use of PCBs on site (FDR p 4)

PCBs concentration set at 0 mg/kg because the PCB detections in soil were were not associated with site operations, but were likely the result of PCBs in historical building material formulations that were filled on site (such as caulk). PCB-containing caulks were used in buildings between 1950 and 1978, after Coats and Clark owned and operated at the site (FDR pages 1 and 4).

PAH contamination is not attributable to site-specific operations (FDR p 5)

AOC 16 Sample TP-21S (0-1 ft bgs). (PAP-00075806-7, PAP-0007582)

Contaminant	Concentration (mg/kg)	Toxic Equivalency Factor	Benzo(a)pyrene Equivalents
Benzo(a)pyrene	55.000	1.0	55.0000
Benzo(a)anthracene	68.000	0.1	6.8000
Benzo(b)fluoranthene	44.000	0.1	4.4000
Benzo(k)fluoranthene	43.000	0.01	0.4300
Chrysene	79.000	0.001	0.0790
Dibenz(a,h)anthracene	0.000	1.0	0.0000
Indeno(1,2,3-cd)pyrene	29.000	0.1	2.9000

DE Residential = 0.1 mg/kg; DE Industrial = 0.7 mg/kg

Total Benzo(a)pyrene Equivalents = **69.6**

Discharge Calcs	Direct Discharge Information	ASSUMPTIONS, REFERENCES	COMMENTS/NOTES
4.08	FEET/YEAR AVERAGE PRECIPITATION	Long term average annual precipitation includes floods and hurricane events occurring over time.	Data from Rutgers University.
17.1	ACRES - TOTAL SITE AREA (acres)	Acreage in 1920, both Newark mill and East Newark mill (FDR p 1)	
4.28	ACRES - AFFECTED AREA	Looks to be around 75% buildings in 1930-current aerial photos here https://njdep.maps.arcgis.com/apps/webappviewer/index.html and Google Earth Pro	
4,046.86	METERS^2/ACRE		
17,300	METERS^2 (AFFECTED AREA)		
0.0001	METERS/YEAR (ERODED SOIL THICKNESS)	For this estimate, used a surface soil erosion rate of 0.1 mm/year, or 0.004 inches/year.	
2	METERS^3/YEAR (ERODED SOIL VOLUME)	VOLUME/YEAR DISCHARGED TO DITCHES	
1865	Year Coats and Clark operations began	FDR p 1	
1989	Year Coats and Clark sold the Newark mill site (FDR p 1)	Coats & Clark Newark mill operations ceased in 1947, alothough a reseach and development operation remained until 1963. (FDR p 1)	East Newark mill operations ened in 1931 and the site was sold in 1935 (FDR p 2-3)
124	NUMBER YEARS DISCHARGE		
215	METERS^3 (TOTAL SOIL VOLUME DISCHARGED OVER TIME)		
1,931	KG/M^3 SOIL DENSITY	Below foundation slab - silty sand or sell-graded sand with varying amounts of gravel (PAP-00080266). Density ranges from 1378 to 2483 kg/m3, average is used (http://structx.com/Soil_Properties_002.html)	
414,139	KILOGRAMS (TOTAL SOIL DISCHARGED OVER TIME)		
		This site is partially located on regional historic fill (FDR p 9)	
Copper (Cu)		Copper sulfate used on site (FDR p 4)	
124	YEARS DISCHARGED		
588	MG/KG (MAX CONCENTRATION)	Data from sample B-124-2 (1.5-2 ft bgs) collected in 2013 (PAP-00080359)	
0.000001	kg per mg (Merck Index)		
244	KILOGRAMS DISCHARGED		
Lead (Pb)		No info on use of lead on site (FDR p 8)	
124	YEARS DISCHARGED		
1400	MG/KG (MAX CONCENTRATION)	Data from sample B-30-4.5(3.5-4 ft bgs) collected in 2012 (PAP-00080346)	
0.000001	kg per mg (Merck Index)		
580	KILOGRAMS DISCHARGED		
Mercury (Hg)		No info on use of mercury on site (FDR p 8)	
124	YEARS DISCHARGED		
0	MG/KG (MAX CONCENTRATION)	Mercury concentration set at 0 mg/kg because the mercury detections in soil were not associated with the pre-1935 mill complex operations (FDR pages 8-9) and the portion of the site that has mercury data (East Newark Mill) was sold in 1935 (FDR page 1).	
0.000001	kg per mg (Merck Index)		
0	KILOGRAMS DISCHARGED		
PAHs (listed in Benzo(a)pyrene Equivalent conversion table)		Total concentration of PAH compounds for Benzo(a)pyrene Equivalent https://floridadep.gov/waste/petroleum-restoration/documents/benzo-pyrene-equivalents-conversion-table-one-sample.	No specific info on use of SVOCs on site but thread making operations often used coal-tar based aniline dyes (FDR p 7)
124	YEARS DISCHARGED		
4.3	MG/KG (TOTAL PAH AVERAGE CONCENTRATION)		
0.000001	kg per mg (Merck Index)		
2	KILOGRAMS DISCHARGED		
PAHs (others detected)		Data below the Benzo(a)pyrene Equivalent Table	
124	YEARS DISCHARGED		
11.84	MG/KG (TOTAL PAH MAX CONCENTRATION)		
0.000001	kg per mg (Merck Index)		
5	KILOGRAMS DISCHARGED		

Sample B-131-1.5 (1-1.5 ft bgs) collected in 2013 (PAP-00080363)

Contaminant	Concentration (mg/kg)	Toxic Equivalency Factor	Benzo(a)pyrene Equivalents
Benzo(a)pyrene	2.960	1.0	2.9600
Benzo(a)anthracene	3.760	0.1	0.3760
Benzo(b)fluoranthene	4.350	0.1	0.4350
Benzo(k)fluoranthene	1.560	0.01	0.0156
Chrysene	4.120	0.001	0.0041
Dibenz(a,h)anthracene	0.404	1.0	0.4040
Indeno(1,2,3-cd)pyrene	1.100	0.1	0.1100
DE Residential = 0.1 mg/kg; DE Industrial = 0.7 mg/kg			
Total Benzo(a)pyrene Equivalents =			4.3

DISCHARGE CALCULATIONS	DIRECT DISCHARGE INFORMATION	ASSUMPTIONS, REFERENCES	COMMENTS/NOTES
4.08	FEET/YEAR AVERAGE PRECIPITATION	Long term average annual precipitation includes floods and hurricane events occurring over time. Even with the fill events, the site is still subject to periodic flooding from the Passaic River (PAP-00054694).	Data from Rutgers University.
66	ACRES - TOTAL SITE AREA (acres)	FDR, page 1; confirmed on Google Earth	The Kearny Manufacturing Facilities were approximately 58.5 acres and the Kearny Administrative Facilities were approximately 7.5 acres (PAP-00724224).
19	ACRES - AFFECTED AREA	Exclude 46.5 acres of buildings and pavement from total 66 acre area for erosion potential (1995-2020 Google Earth aerial photos)	
4,046.86	METERS^2/ACRE	CONVERSION TO METERS	
76,890	METERS^2 (AFFECTED AREA)		
0.0001	METERS/YEAR (ERODED SOIL THICKNESS)	For this estimate, used a surface soil erosion rate of 0.1 mm/year, or 0.004 inches/year.	
8	METERS^3/YEAR (ERODED SOIL VOLUME)	VOLUME/YEAR DISCHARGED TO PASSAIC	
1886	Year site operations began	Congoleum entities: approximately 1886 – to 1979 (PAP-00220483; PAP-00402989- 90).	
1976	Year site was sold to Franklin Burlington Plastics	FDR page 5.	
90	NUMBER YEARS DISCHARGE		
692	METERS^3 (TOTAL SOIL VOLUME DISCHARGED OVER TIME)		
2,251	KG/M^3 SOIL DENSITY	Fill material consisting of silt and clay with miscellaneous debris (PAP-00056120). Bulk density range 2002 KG/M^3 to 2499 KG/M^3, so use average. (http://structx.com/Soil_Properties_002.html)

Allocator's Determinations Regarding
Legal Defenses Raised by Allocation Parties

CONGOLEUM

Congoleum argues that the current Congoleum never owned and/or operated the Kearny Manufacturing Facilities property that is the subject of this OU2 Allocation proceeding and Current Congoleum is not the successor to any entity or business which did own and/or operate the Kearny Manufacturing Facilities. Accordingly, pursuant to Step 2(d)(9) of the Allocation Protocol, Current Congoleum submits that these facts establish a complete defense to liability for alleged discharges from the Kearny Facility.

ALLLOCATOR'S DETERMINATION – Congoleum states a credible argument regarding the timing of its purchase of assets from its predecessor and the sale of the Kearny Manufacturing facility. However, uncertainties regarding the evolution of the corporation and its predecessor and its use of Kearny facility property raise doubts about its ability to prevail in an action to overturn EPA's determination of Congoleum as a PRP based on the supplied information. Though the Allocator presumes a substantial chance of success should this matter go to litigation, we leave this matter as a topic for settlement discussions between Congoleum and EPA.

Discharge Calcs	Direct Discharge Information	ASSUMPTIONS, REFERENCES	COMMENTS/NOTES
4.08	FEET/YEAR AVERAGE PRECIPITATION	Long term average annual precipitation includes floods and hurricane events occurring over time.	Data from Rutgers University.
17	ACRES - TOTAL SITE AREA (acres)		
6	ACRES - AFFECTED AREA	90 percent of site was covered with impervious material and 40 percent was buildings (FDR Page 24, PAS-00113240). Estimate 20 years (1941-1961) 40 percent buildings without asphalt, 25 years 90 percent impervious with buildings = 5.6 acres	
4,046.86	$METERS^2$/ACRE		
22,662	$METERS^2$ (AFFECTED AREA)		
0.0001	METERS/YEAR (ERODED SOIL THICKNESS)	For this estimate, used a surface soil erosion rate of 0.1 mm/year, or 0.004 inches/year.	
2	$METERS^3$/YEAR (ERODED SOIL VOLUME)	VOLUME/YEAR DISCHARGED TO PASSAIC RIVER	
1941	Year site operations began	FDR page 2 PAS-00113112, 2741, 3149; PAP-00048761	
1986	Year site processing and storage operations ceased	FDR page 2 PAS-00113112, 2741, 3149; PAP-00048761	
45	NUMBER YEARS DISCHARGE	Conopco liability 45 years, 1941 to 1986 (FDR, page 2)	
102	$METERS^3$ (TOTAL SOIL VOLUME DISCHARGED OVER TIME)		
1,963	KG/M^3 SOIL DENSITY	Fill reported as fine to medium sand with trace gravel (PAS-00113242). Bulk density range for silty sand and gravel 1442 KG/M^3 to 2483 KG/M^3, so use average. (http://structx.com/Soil_Properties_002.html)	
200,188	KILOGRAMS (TOTAL SOIL DISCHARGED OVER TIME)		
		Facility is partially located on historic fill (FDR, page 15)	
Copper (Cu)

Facility BS	CUF	CUF_Category	CUF_NOTES	COF	COF_NOTES	Facillty Adjusted BS
5.764E-5	10.0%	Periodic Noncompliacne	The PVSC documented discharges of unknown off-color materials in the storm sewer that were traced to be coming from the facility in 1947, 1948, 1956, 1970-1971, 1974, 1976, 1977, and 1978. Several of these were noted as violations (see Section 6 of Data Report). An October 23, 1990, Progress Report on Cleanup of South Drainage Trench referred to notices of violations Penco of Lyndhurst received concerning unpermitted discharges to the storm sewer and from the drainage ditch (PAS-00113370, 372-73). According to the PVSC Weekly Summary of Inspections by Inspector, on May 3, 1956, inspection of the Lyndhurst storm sewer showed a jet black discharge into the Passaic River that had killed a number of small fish. In May [1977], suppression of a fire on para-nitrophenol (PNP) pallets washed PNP into the storm sewer (PAS-00112802). Many of the chemicals were stored in above- and below-ground tanks and in 55-gallon drums in various locations. Prior to construction Buildings 38 and 39, the area occupied by Building 39 was used for storage of solvents in drums. Infrequently, materials were spilled or drums ruptured. (see FDR p. 6)	-20.0%	-20% CPG/SPG member - Continuous provision of funding and participation in PRP Group(s) actions to cooperate with governmental/regulatory entities to address environmental or public harm created by own activities	5.188E-5

Discharge Calcs	Direct Discharge Information	ASSUMPTIONS, REFERENCES	COMMENTS/NOTES	
4.08	FEET/YEAR AVERAGE PRECIPITATION	Long term average annual precipitation includes floods and hurricane events occurring over time.	Data from Rutgers University.	
15	ACRES - TOTAL SITE AREA (acres) FDR pg 1	Approx 7 acres within property line when surface soil sampled 1986 ECRA SES, (PAP-00049203 pg. 114)		
8	ACRES - AFFECTED AREA	1925 drawing of Silver Lake Plant (PAP-00332567) with 'coke' and 'cake' piles adjacent to 50,000 ga. fuel oil AST, north of Red Iron Oxide Bldg. Preliminary Assessment Report, (Stantec May 24, 2012) Fig 2 has overlay of former buildings prior to parking lot (PAP-00334892). F and T Figures is 9 acres. With parking lot (Google Earth figure), 15 acres includes former sludge pond location.	Due to confirmed airborne surface soil deposition of Hg (FDR pg. 10), 100% of the property is deemed impacted for Hg. Other COCs will be 50% of 1986 acreage or calculations due to presence of buildings.	Per FDR (pp 1 & 2) combined site covers 15 acres.
4,046.86	$METERS^2$/ACRE			
30,351	$METERS^2$ (AFFECTED AREA)			
0.0001	METERS/YEAR (ERODED SOIL THICKNESS)	For this estimate, used a surface soil erosion rate of 0.1 mm/year, or 0.004 inches/year.		
3	$METERS^3$/YEAR (ERODED SOIL VOLUME)	VOLUME/YEAR DISCHARGED		
1900	Year site operations began	Originally operated as Edison Manufacturing Company, a battery manufacturer in the early 1900s. Year operation began is 1900, as supported with FDR Section 3 dating the construction of buildings.		
1987	Year site processing and storage operations ceased	The Final Preliminary Assessment Final Remedial Investigation Report, dated May 6, 2017 (Final RI Report), stated that the buildings associated with the Thomas A. Edison, Inc. Chemical Plant were demolished in the early 1970's, and the property remained vacant until it was redeveloped as a retail grocery store and laundromat with associated parking lots in 1980 (PAP-00334737, 840).		
87	NUMBER YEARS DISCHARGE			
264	$METERS^3$ (TOTAL SOIL VOLUME DISCHARGED OVER TIME)			
1,979	KG/M^3 SOIL DENSITY	layers of unconsolidated sand, silt, and clay. (PAP-00049305). Bulk density range 1602 kg/m^3 to 2355 kg/m^3, so use average of 1978.5 kg/m^3. Sandy or silty clay	The Allocation Team has concluded that the Site is not on regional Historic Fill as designated by the NJDEP.

45121.38	MASS (KG) DISCHARGED FROM SURFACE SOIL

Discharge Calcs	Direct Discharge Information	NOTES, COMMENTS, REFERENCES	
0.46	FEET for 6 flooding events	AVERAGE SHOULD INCLUDE FLOODS AND HURRICANE EVENTS OVER TIME	6 qty, 11,532 gallon release events (6 foot deep 1,992 sf basin), equals 0.46 feet in a 1,992 basin.
15	ACRES - TOTAL SITE AREA (acres)	FDR pg 1	
0.04	ACRES - AFFECTED AREA	ESTIMATED LAGOON AND NEUTRALIZATION AREA (PAS-00109548)	
4,046.86	METERS^2/ACRE	Preliminary Assessment Report, Fig 2 (PAP-00334892) has overlay of former buildings prior to parking lot with former sludge pond in upper left corner. Approximately 1,922 sqft.	Unknown, but given 100,000-gal water released in 1948 flood event and 1,922 sq ft area of lagoon, assume greater than 1,000 gal released. On **May 30, 1984, the sedimentation impoundment overflowed**. The accidental discharge was due to a blockage of the discharge line and extremely heavy rains. The overflow went to a neighboring homeowner's property and accumulated in an area being prepared for an in-ground swimming pool. (PAP-00049278)
162	METERS^2 (AFFECTED AREA)		
0.0170	METERS/YEAR (ERODED SOIL THICKNESS)	With 3.7% solids in sludge (PAP-00332945) and a one time event, 0.037*0.46 feet of flood water in 1,992 basin, eroded soil thickness is 0.01702	12755.10204
2.76	METERS^3/YEAR (ERODED SOIL VOLUME)	ASSUME VOLUME/YEAR DISCHARGED TO DITCHES AND FIRST CREEK	
	YEAR STARTED DISCHARGING TO LAGOON SITE REMEDIATION, GEOTEXTILE, ASPHALT COVER		
1	NUMBER YEARS DISCHARGE	Years of discharge (6 flooding events) converted to one time depth in 1,992 sf pond.	
2.76	METERS^3 (TOTAL SOIL VOLUME DISCHARGED OVER TIME)		
1,024	KG/M^3 SOIL DENSITY	sludge density is 1.024 kg/L at 1000L/m3 = 1024 kg/m3	McGraw-Edison Company to Caldwell Trucking Company, Inc. may 9, 1973 re: sludge contents (PAP-00332945). Total solids of 33,500 mg/L or 3.7% by weight equals a density of 1.024 kg/L for converting the estimated concentration of sludge to solid released during flooding events.
2,821	KILOGRAMS (TOTAL WT OF SOIL AFFECTED OVER TIME)		
Copper (Cu)			
1	YEARS DISCHARGED		
31.25	MG/KG (MAX CONCENTRATION)	Copper from sludge,(32 mg/L * 1000 L/m3)/1024 kg/m3 density of sludge. (FDR, PAGE 6, 2nd paragraph and PAP-00332945).

0.21	kg Mercury

0.33	MASS (KG) DISCHARGED BY OVERLAND FLOW

Discharge Calcs	Direct Discharge Information	NOTES, COMMENTS, REFERENCES
0.46	FEET for 6 flooding events	AVERAGE SHOULD INCLUDE FLOODS AND HURRICANE EVENTS OVER TIME
	ACRES - TOTAL SITE AREA (acres)	
	ACRES - AFFECTED AREA	ESTIMATED 30-ft DIA Scoured hole from 10" pipe break on May 12, 1948 (PAS-00050268) Fire sprinkler line would be below the frost line (6' bgs) so with scour of a 30-ft diameter hole with an average depth of 8-feet would release asproximately 5,652 cubic feet or 160 m^3 of soil. Using the same density as for surface erosion, 1978.5 mg/m^3 equals 163,840 kg
4,046.86	$METERS^2$/ACRE	
0	$METERS^2$ (AFFECTED AREA)	
		PVSC inspection records 1938-1948 noted events such as heavy rains caused flooding at facility site. **5/12/1948 wastes flowed** into Second River from Meadow Brook storm sewer; Second River looked like "river of blood all the way down to its confluence with the Passaic River." Discharge from facility site, caused by waterline break, releasing 100,000 gals water, flooded all north side bldgs, undermined bldgs, produced 30-ft hole in yard resulting in collapse of all 3 industrial sewers. (PAP-00050259)

8.366E-4	10.0%	Periodic Noncompliacne	PVSC issued a notice to desist pollution to Edison Chemical Company at Belleville on May 1, 1939 (PAS-00028126). A record of ten years of inspections performed by the PVSC on the Edison Company, Storage Battery Division, in Silver Lake, Belleville, dated June 15, 1948, documented the investigation of contamination entering the Second River. NJDEP issued a Directive Letter to McGraw Edison on June 6, 1984, to cease operation of the unlined pretreatment lagoons (PAP-00049811). An August 4, 1987, NJDEP Inspection Report stated that the facility did not have a hazardous waste management program consistent with hazardous waste regulations. A NOV would have been issued, but the operations had ceased (PAP-00050211-13). On May 12, 1948, "exceptionally strong iron wastes were found flowing into the Second River from the Meadow Brook storm sewer of such intensity that Second River looked like a river of blood all the way down to its confluence with the Passaic River." The discharge emanated from Edison Storage Battery Division, Belmont Avenue, Belleville facility. The cause was a waterline break that resulted in releasing 100,000 gallons of water that flooded all north side buildings, undermined the buildings and producing a 30-foot hole in the yard and resulting in subsequent collapse of all three industrial sewers. Chemicals, sand, and finished chemical materials were washed into the sewer and caused a blockage. The broken water line was repaired with a sleeve and the pipes broke again. The large hole filled with an acid and iron solution. A pump line from the hole drained the mixture into the clear water line directly to the storm sewer and into Second River. The waste could not be put into the sanitary sewer until new sewer pipes had been installed. The acid corroded the pumps and caused them to fail...(PAP-00050268-69).	-20.0%	-20% CPG/SPG member - Continuous provision of funding and participation in PRP Group(s) actions to cooperate with governmental/regulatory entities to address environmental or public harm created by own activities	7.530E-4

Allocator's Determinations Regarding
Legal Defenses Raised by Allocation Parties

COOPER INDUSTRIES – Bank Street

Cooper argues that it has no connection to or CERCLA liability for the Wiss Family Operations at these locations. The FDR acknowledges that Cooper never owned any of these locations or was connected to the operations at them. When Cooper acquired the assets of a New Jersey corporation, J. Wiss & Sons Co., in 1976, it acquired assets related to J. Wiss & Sons Co.'s then-operations at several locations, including at the Littleton Avenue location in Newark. Cooper assumed only specific and narrowly defined liabilities of J. Wiss & Sons Co. It did not assume any CERCLA liabilities of that corporation, much less those associated with these operations involving individual Wiss family members that ended more than a decade before J. Wiss & Sons Co. was incorporated. *United States v. Gen. Battery Corp.*, 423 F.3d 294, 305 (3d Cir. 2005) (appropriate indirect liability standard for CERCLA actions is the general rule of corporate-successor non-liability, *i.e.*, an acquiring company is generally not liable for the debts and liabilities of a selling company except in certain instances).

Cooper never owned or conducted any operations at any of the Bank Street locations. J. Wiss & Sons, Co. never operated at the Bank Street locations and was not formed until over ten years after the Bank Street real property was sold to Prudential Insurance Company (PAP-00332550; PAP-00331502).

In the 1976 transaction wherein Cooper acquired certain assets of J. Wiss & Sons Co., Cooper did not assume any CERCLA liabilities of J. Wiss & Sons Co. or of any alleged predecessors to J. Wiss & Sons Co., including any such liabilities with respect to the Bank Street locations.

Cooper disputes that it has any liability associated with the Primary Battery Facility operations prior to that period, when those operations were owned and operated by Thomas A. Edison, Inc. ('TAE') or after McGraw-Edison's ownership/operations of the Primary Battery Facility ended in 1985 (i.e., Battery Products, Inc. operations).

In addition, the following statement was provided regarding the Storage Battery Business (Chemical Works plant): Cooper's liability, if any, for purposes of the Allocation does not extend to operations associated with the Storage Battery Business. When Cooper merged with McGraw-Edison in 1985, any liabilities that McGraw-Edison may have had with respect to the Storage Battery Business had already been transferred to and assumed by Electric Storage Battery Company (later referred to as Exide Technologies). Any operations in and after 1960 would be the responsibility of Exide, and Cooper has no connection to or liabilities for any such operations.

In addition, regarding the liabilities transferred to Exide, Cooper contends that those liabilities would not include any liabilities related to the operations prior to the 1957 TAE transaction.

ALLOCATOR'S DETERMINATION – Though Cooper Industries may have a sustainable argument regarding its allegation that it did not accept the CERCLA liability of J. Wiss & Sons, there is an

insufficient demonstration of applicable case law and facts to support this claim based on available data. Though the Allocator presumes a substantial chance of success should this matter go to litigation with sufficient evidence, we leave this matter as a topic for settlement discussions between Cooper Industries and EPA.

Allocator's Determinations Regarding
Legal Defenses Raised by Allocation Parties

COVANTA

Covanta argues that it is not and has never been the current owner or operator or former owner or operator of the LPRSA [Lower Passaic River Study Area]. Nor is there any evidence or suggestion that Covanta was a transporter of hazardous substances to the LPRSA. Accordingly, it appears that USEPA [United States Environmental Protection Agency] is contending that Covanta may be liable under CERCLA [Comprehensive Environmental Response, Compensation and Liability Act] as an arranger. Arranger liability requires that Covanta took intentional steps to dispose of a hazardous substance.…As the United States Supreme Court has explained, intentional steps means that it must be proven that Covanta actually intended to dispose of hazardous substances in the LPRSA.…Covanta operates, and since 1997 has operated, the ECRRF as a zero discharge facility, except during unusual storm events.…The only evidence allegedly connecting Covanta to the LPRSA is the stormwater exceedances in ditches at the Property. These exceedances, however, are not attributable to the ECRRF or Covanta. Instead, these exceedances all stem from pre-existing contamination on the Property – property subjected to illegal dumping, previously owned by the NRHA [Newark Redevelopment and Housing Authority], and currently owned by the Port Authority – as well as offsite, upgradient sources and surface water backflow from the Passaic River. Simply put, there is no evidence that Covanta disposed of anything in the LPRSA (i.e., engaged in some active conduct that caused the discharge, deposit, injection, dumping, spilling, leaking, or placing of any hazardous substances in the LPRSA)….Even if evidence of the disposal of hazardous substances by Covanta did exist (and it does not), there is no evidence that Covanta intended to dispose of any hazardous substances in the LPRSA. Without intent, Covanta cannot be an arranger under CERCLA – even if Covanta knew or should have known that stormwater runoff carrying pre-existing contamination at the Property or contamination from other parties could discharge to the LPRSA.

In addition, Covanta asserts that, even putting aside the lack of evidence that Covanta is an arranger, there is another problem with seeking to hold Covanta liable under CERCLA for LPRSA impacts: Covanta's hazardous substances, if any, have not caused and will not cause the incurrence of response costs. In order to be liable under CERCLA, Covanta's releases of hazardous substances must cause the incurrence of response costs…. although lead is a COC for the LPRSA, USEPA has determined…that lead is not driving any response actions. In addition, none of the other substances detected in stormwater at the Property are COCs for the LPRSA. As hazardous substances in the Property's stormwater discharges will not cause the incurrence of LPRSA response costs, Covanta cannot be liable under CERCLA. Covanta reserves the right to assert additional defenses in the future.

ALLOCATOR'S DETERMINATION – As noted in the information regarding the site submitted by Covanta, it is clear the Covanta had stormwater discharges from their property that have contributed lead, one of the COCs identified by EPA, to the Lower Passaic. While they may be correct that the lead was deposited on their property by a former owner, that they have not intended to have stormwater discharges, and that lead is not the primary driver for the remediation, none of those arguments avoid liability under CERCLA. The Allocator does not

believe that Covanta will prevail in an action to overturn EPA's determination of Covanta as a PRP based on the available information. The possibility that a COC was transported to the facility site from an offsite location was taken into account in determining Covanta's allocated share.

Discharge Calcs	Direct Discharge Information	ASSUMPTIONS, REFERENCES	COMMENTS/NOTES
4.08	FEET/YEAR AVERAGE PRECIPITATION	Long term average annual precipitation includes floods and hurricane events occurring over time.	Data from Rutgers University.
160	ACRES - TOTAL SITE AREA (acres)	FDR page 1	
115.0	ACRES - AFFECTED AREA	In 1951, the main, shared occupancy building is 38 acres, 6 NE-SW orientated buildings cover approximately 7 acres (PAP-00190307). Removing the building coverage from the 160 acres total leaves 115 acres subject to erosion.	
4,046.86	METERS^2/ACRE		
465,389	METERS^2 (AFFECTED AREA)		
0.0001	METERS/YEAR (ERODED SOIL THICKNESS)	For this estimate, used a surface soil erosion rate of 0.1 mm/year, or 0.004 inches/year.	
47	METERS^3/YEAR (ERODED SOIL VOLUME)	VOLUME/YEAR DISCHARGED	
1943	Year site operations began	Curtiss-Wright Corp operated an aircraft engine manufacturing palnt at the site from March 1943 until November 1983. (PAP-00190346).	
2001	Year site processing and storage operations ceased	Curtiss-Wright Corp owned site through 2001 (FDR page 1)	
58	NUMBER YEARS DISCHARGE		
2,699	METERS^3 (TOTAL SOIL VOLUME DISCHARGED OVER TIME)		
1,979	KG/M^3 SOIL DENSITY	Unconsolidated surface deposits generally consist of sand, silt, clay, and fine sand (PAP-00393240). Bulk density range 1,602 KG/M^3 to 2,355 KG/M^3, so use average 1978.5 kg/m3 for Sandy or Silty Clay on (http://structx.com/Soil_Properties_002.html)	
5,340,477	KILOGRAMS (TOTAL SOIL DISCHARGED OVER TIME)	Facility is not located on historic fill (FDR page 4)	
Copper (Cu)			
58	YEARS DISCHARGED		
330	MG/KG (MAX CONCENTRATION)	Soil boring sample (PAP-00393057)	
0.000001	kg per mg (Merck Index)		
1,762	KILOGRAMS DISCHARGED

Discharge Calcs	Direct Discharge Information	ASSUMPTIONS, REFERENCES	COMMENTS/NOTES
4.083	FEET/YEAR AVERAGE PRECIPITATION	Long term average annual precipitation includes floods and hurricane events occurring over time.	Data from Rutgers University.
23	ACRES - TOTAL SITE AREA (acres)	FDR p 1	
5.2	ACRES - AFFECTED AREA	Soil piles and unpaved areas (PAS-00022928 and PAS-0002293)	5.2 acres is based on the estimated pervious area in the figure on PAS-00022928.
4,046.86	METERS^2/ACRE		
21,044	METERS^2 (AFFECTED AREA)		
0.0001	METERS/YEAR (ERODED SOIL THICKNESS)	For this estimate, used a surface soil erosion rate of 0.1 mm/year, or 0.004 inches/year.	
2	METERS^3/YEAR (ERODED SOIL VOLUME)	VOLUME/YEAR DISCHARGED TO PASSAIC RIVER	
1985	Year site operations began	Operated and owned by DII/Dresser from January 1985 to February 1997. (FDR page 1)	
1997	Year site processing and storage operations ceased	Dresser/DII ceased commercial or manufacturing operations at the plant in October 1993 (FDR page 1; PAS-0063866, PAS-00122467).	Dresser/DII sold site in 1997 (FDR page 1; PAS-0063866, PAS-00122467)
12	NUMBER YEARS DISCHARGE		
25.2524064	METERS3 (TOTAL SOIL VOLUME DISCHARGED OVER TIME)		
1962.5	KG/M3 SOIL DENSITY	Fill is red-brown line sands and silts with lesser quantities of medium to coarse-grained sands, gravels, and clays. (PAS-00023130, PDF page 212). Used "silty sand and gravel" soil type from http://structx.com/Soil_Properties_002.html. Bulk density range 1442 KG/M3 to 2483 KG/M3, so use average. Average is 1962.5 kg/m3	
49,558	KILOGRAMS (TOTAL SOIL DISCHARGED OVER TIME)		
		The Allocation Team has determined that the facility site is not located on regional Historic Fill as designated by the NJDEP (FDR page 8)	
Copper (Cu)

PAHs (listed in Benzo(a)pyrene Equivalent conversion table)

Total concentration of PAH compounds for Benzo(a)pyrene Equivalent https://floridadep.gov/waste/petroleum-restoration/documents/benzo-pyrene-equivalents-conversion-table-one-sample.

12 YEARS DISCHARGED

The levels of PAHs, copper, lead and mercury detected at the site in soils are presented in the table below (PAS-00023024; PAS-00023178; PAS-00023171). (FDR page 8).

185.231262 MG/KG (TOTAL PAH AVERAGE CONCENTRATION)

Sum of Benzo(a)pyrene Equivalent conversion concentrations

0.000001 kg per mg (Merck Index)

9 KILOGRAMS DISCHARGED

PAHs (others detected)

Phenanthrene - 14.958 ppm
Acenaphthylene - 0.597 ppm
2-methylnaphthalene - 0.353J ppm
Naphthalene - 0.732 ppm
Fluorene - 0.812 ppm
Acenaphthene - 1.21 ppm
Anthracene - 2.653 ppm

12 YEARS DISCHARGED

21.315 MG/KG (TOTAL PAH MAX CONCENTRATION)

Sample EPL-R8-5A(PAS-0023171, Table 26)

0.000001 kg per mg (Merck Index)

1 KILOGRAMS DISCHARGED

Maximum concentrations from surface sample (EPL-RB-5A (0.5-1.0 ft)) (PAS-00023171).

Contaminant	Concentration (mg/kg)	Toxic Equivalency Factor	Benzo(a)pyrene Equivalents
Benzo(a)pyrene	148.489	1.0	148.4890
Benzo(a)anthracene	104.440	0.1	10.4440
Benzo(b)fluoranthene	122.640	0.1	12.2640
Benzo(k)fluoranthene	54.352	0.01	0.5435
Chrysene	103.142	0.001	0.1031
Dibenz(a,h)anthracene	11.240	1.0	11.2400
Indeno(1,2,3-cd)pyrene	21.476	0.1	2.1476

DE Residential = 0.1 mg/kg; DE Industrial = 0.7 mg/kg

Total Benzo(a)pyrene Equivalents = **185.2**

PCBs

12 YEARS DISCHARGED

31 MG/KG (MAX OF REPORTED CONCENTRATIONS)

The maximum detected PCB concentration was Aroclor-1254 in soil sample 4c-4 at a depth of 0-6 inches (PAS-00023060)

0.000001 kg per mg (Merck Index)

1.5 KILOGRAMS DISCHARGED

SUMMARY CMASS ESTIMATES:

3023.03	kg Copper
391.51	kg Lead
1.75	Mercury
9.18	kg PAHs (Benzo(a)pyrene Equivalent)
1.06	kg PAHs (Other)
1.54	kg PCBs
0.00	kg Dieldrin
0.00	kg Dioxins/Furans
3428.06	MASS (KG) DISCHARGED FROM SURFACE SOIL

Allocator's Determinations Regarding
Legal Defenses Raised by Allocation Parties

ENPRO HOLDINGS

Enpro Holdings asserts that Respondent [EnPro Holdings, Inc.] and Crucible Steel Corporation had, no relationship to any parties that released or disposed of COCs at the Facility following Crucible Steel Corporation's sales of the western portion (Guyon Property) in 1947 and 1967 and the eastern portion (Spiegel Property) in 1974.

ALLOCATOR'S DETERMINATION - While EnPro alleges that it was not an owner or operator under CERCLA, it fails to provide a substantial factual or legal basis to support that claim. The Allocator does not believe that EnPro will prevail in an action to overturn EPA's determination of EnPro as a PRP based on the supplied information.

Discharge Calcs	Direct Discharge Information	ASSUMPTIONS, REFERENCES	COMMENTS/NOTES
4.08	FEET/YEAR AVERAGE PRECIPITATION	Long term average annual precipitation includes floods and hurricane events occurring over time.	Data from Rutgers University.
6.9	ACRES - TOTAL SITE AREA (acres)	PAP-00039956	
2.87	ACRES - AFFECTED AREA	Buildings occupy approximately 50 percent of the facility; paved areas (primarily asphalt) cover an estimated 25 percent of the facility (After 1960). The remaining 25 percent of the surface is unpaved (1991)(PAP-00040989)	
4,046.86	METERS^2/ACRE		
11,614	METERS^2 (AFFECTED AREA)		
0.0001	METERS/YEAR (ERODED SOIL THICKNESS)	For this estimate, used a surface soil erosion rate of 0.1 mm/year, or 0.004 inches/year.	
1	METERS^3/YEAR (ERODED SOIL VOLUME)	VOLUME/YEAR DISCHARGED TO PASSAIC RIVER	
1919	Year site operations began - 1919.	The first buildings at the Garfield Plant were constructed in 1891 by Fritzche Brothers to facilitate chemical manufacturing. Heyden had owned and operated the facility since the early 1900s as several forms of the Heyden name (PAP-00040999)	In 1919, the site was purchased by a newly formed New York corporation called Heyden Chemical Company of America Inc. The company was consolidated into the Heyden Chemical Corporation in 1925, and in 1956 changed its name to the Heyden Newport Chemical Corporation. Heyden Newport Chemical Corporation was purchased in 1963 by Tenneco. Kalama Chemical Inc. purchased the site from Tenneco in December 1982 (PAP-00032378).
1982	Year site processing and storage operations ceased	In an agreement dated December 1, 1982 between Tenneco and Kalama Chemical, all liabilities arising out of the condition of the plant, shall remain the respnsibilities of Tenneco (PAP-00039799)	
63	NUMBER YEARS DISCHARGE	Tenneson liability 91 years, 1891 to 1982 (PAP-00040999)	
738	METERS^3 (TOTAL SOIL VOLUME DISCHARGED OVER TIME)		
1,843	KG/M^3 SOIL DENSITY	The facility was built over a sequence of unconsolidated deposits consisiting of fine to coarse sand, silt and clay (PAP-00040396). Cross referencing as Silty Sand at http://structx.com/Soil_Properties_002.html) has a bulk density range 1410 KG/M3 to 2275 KG/M3, so use average of 1842.5 kg/m3.	
1,359,765	KILOGRAMS (TOTAL SOIL DISCHARGED OVER TIME)	The average bulk density reflects cross reference result.	
		The majority of the facility site is not located on regional historic fill (FDR pg 11)	
Copper (Cu)

Lead (Pb)			
63	YEARS DISCHARGED		
820	MG/KG (AVERAGE CONCENTRATION)		
0.000001	kg per mg (Merck Index)	Lead was detected in surface soil (Sample B-47-Fill) at AEC-15 (Salicylic Acid/Salicylate Production Buildings 10/36/39) at an elevated concentration (PAP-00042177, 80).	
1,115	KILOGRAMS DISCHARGED		
Mercury (Hg)		Although mercury was not identified as used in the facility processes, purchase orders from 1973 identified the purchased caustic soda as mercury cell material. Analytical results from the caustic soda manufactured using the mercury cell process were not available to verify that the caustic soda did not contain any trace impurities of mercury (PAP-00324677; PAP-00324679; PAP-00324684).	It is assumed that a spill was the source of the soil contamination and that the contamination would have migrated from the surface to the depth confirmed by soil sample analysis in 1991. Given the initial erosion would transport Hg impacted soil of greater concentrations than compared to the soil at depth in 1991, the use of the concentration at depth for the OFT estimate is conservative, with decreased soil concentration/mass than experienced at the time of the spill.
63	YEARS DISCHARGED	A NJDEP Pretreatment/Residual Waste Survey, dated July 27, 1981, stated mercury was present in the discharge to the POTW (PAP-00040183, 188).	
18.6	MG/KG (MAX CONCENTRATION)	Max concentration of mercury was detected in subsurface soil (depth of 4 to 4.5 feet, Sample B-53 Fill) at AEC-15 (Salicylic Acid/Salicylate Production Buildings 10/36/39) (PAP-00041873).

Allocator's Determinations Regarding
Legal Defenses Raised by Allocation Parties

EPEC Polymers

EPEC and El Paso argue that they should receive a zero share of responsibility in the Allocation because neither party owned or operated the Garfield Facility, were successors to owners or operators of the Garfield Facility, and never assumed any liability for the alleged discharges at the site that are at issue in this Allocation. EPEC and El Paso have provided the relevant corporate history and supporting documents in prior allocation submissions and have attached the relevant information as Exhibits A and B to this Position Paper. There is no basis to attribute any liabilities associated with TCI's ownership and operation of the Garfield Facility to EPEC and El Paso because TCI retained any and all liabilities associated with the Garfield Facility, and those liabilities ceased to exist upon its dissolution in 1985. See PAP00039823.

EPEC asserts that EPEC Polymers, Inc. ("EPI") and El Paso Tennessee Pipeline Co. ("EPTP") received GNL letters from EPA *(it is assumed that GNL stands for General Notice Letter)*; however, EPI and EPTP never owned or operated the Facility, nor were either company ever successors to any party or parties that owned or operated the Facility. Further, neither party assumed any liability for the alleged discharges at the Facility that are at issue in this allocation. EPI and EPTP respond on behalf of Tenneco Chemicals, Inc. ("TCI"), which was a former owner and operator of the Facility during the Relevant Time Period [October 4, 1963 to December 1, 1983].

The letter from Saul Ewing, Arnstein, & Lehr LLP, dated September 9, 2019, to Mr. David Batson stated that the "Heyden Newport" entity that changed its name to Tenneco Chemicals, Inc. in 1965 was not the same entity that owned the Garfield Facility prior to Tenneco's acquisition. The following statement was provided: "In 1919, Heyden Chemical Company of America, Inc., a New York corporation, reportedly acquired the Garfield Site. In 1925, Heyden Chemical Company of America was consolidated with Denhey Corporation to form Heyden Chemical Corporation, a New York corporation. In March 1943, Heyden Chemical Corporation merged into its parent company, Denhey Holding Corporation, a Delaware corporation, and Denhey Holding Corporation was renamed Heyden Chemical Corporation, also incorporated in Delaware. In March 1943, the Garfield Site was transferred by deed from Heyden Chemical Corporation, a New York corporation, to Heyden Chemical Corporation, a Delaware corporation. Heyden Chemical Corporation then changed its name to Heyden Newport Chemical Corporation ("Old Heyden"). In 1963, Tennessee Gas Transmission Company ("TGT"), Old Heyden, and HDN Corporation, a subsidiary of TGT, entered into a transaction whereby Old Heyden sold its assets to HDN in exchange for shares of TGT common stock and the assumption by HDN of certain of Old Heyden's liabilities. After the transaction, HDN changed its name to "Heyden Newport Chemical Corporation" ("Heyden Newport") and filed and recorded in Delaware a change of name amendment on October 4, 1963. At the same time, Old Heyden changed its name to "Denport Corporation" and dissolved (2019 Letter, p. 2).

EPEC asserts that on December 15, 1982, Tenneco Chemicals and Tenneco Polymers entered into an agreement whereby Tenneco Chemicals transferred certain assets to Tenneco Polymers. Pursuant to that agreement, Tenneco Chemicals did not transfer any liabilities related to the Garfield Site, and any transfer of liabilities was limited to litigations and claims known or existing at the time of the conveyance—and expressly referenced in exhibits consisting of litigation dockets generated at the time of the transaction. In 1983, Tenneco Chemicals changed its name to Tenneco Resins, Inc. ("Resins"), and filed for dissolution two years later, in 1985. Tenneco Polymers changed its name to EPEC Polymers, Inc. in 1996,

shortly following El Paso Merger Company's acquisition of the energy assets of Tenneco Inc. As the aforementioned facts demonstrate, at no time did Tenneco Polymers merge or consolidate with Resins. In addition, Tenneco Chemicals was a separate corporation from Tenneco Polymers with assets and operations. Although Tenneco Chemicals was a party to various asset transfers over the course of its corporate existence, it retained any and all liabilities associated with the Garfield Site, and those liabilities ceased to exist upon its dissolution in 1985.

ALLOCATOR'S DETERMINATION – EPEC Polymers provides a persuasive argument that has the potential for litigation success, but which cannot be definitively determined based on the available data. Though the Allocator presumes a substantial chance of success should this matter go to litigation, we leave this matter as a topic for settlement discussions between EPEC Polymers and EPA.

4.08	FEET/YEAR AVERAGE PRECIPITATION	Long term average annual precipitation includes floods and hurricane events occurring over time.	Data from Rutgers University.
15	ACRES - TOTAL SITE AREA (acres)		
2.4	ACRES - AFFECTED AREA	Based on the figure in the FDR (Page 2), it appears that the paved, manufacturing operations used 80% of the site, so affected area is estimated as 20% of the site	
4,046.86	METERS^2/ACRE		
9,712	METERS^2 (AFFECTED AREA)		
0.0010	METERS/YEAR (ERODED SOIL THICKNESS)	For this estimate, used a surface soil erosion rate of 0.1 mm/year, or 0.004 inches/year.	
5	METERS^3/YEAR (ERODED SOIL VOLUME)	VOLUME/YEAR DISCHARGED	
1974	Year of spill	330 Doremus was operating from 1956-1989 and 352 Doremus was operating from 1965 to 1989 (FDR Page 1). For this pathway, a release occurred in 1972, where nitric acid overflowed from a 20,000 gallon tank car. The ground was covered with soda ash and water and the fire department washed the residue into the Passaic (FDR Page 9).	
1975	Year of spill	Will conservatively assume 1 year. The 20,000 gallon release likely carved a channel to the Passaic.	
1	NUMBER YEARS DISCHARGE		
5	METERS^3 (TOTAL SOIL VOLUME DISCHARGED OVER TIME)		
2,003	KG/M^3 SOIL DENSITY	Most soils at the Newark site consisted of fine grained, clayey silt with organic matter (PAP-00116565). Used structx.com/Soil_Properties_002.html for density. Used the average of silt and clay min (1506 kg/m3) and max (2499 kg/m3).	
10,013	KILOGRAMS (TOTAL SOIL DISCHARGED OVER TIME)		
Copper (Cu)		Site is located on regional historic fill (FDR page 5)	
1	YEARS DISCHARGED	Detected at soil sample location Q-3 (3.5-4 ft bgs) at 110,000 ug/kg (110 ppm); collected 11/21/1990 at the Truck Maintenance Building and Quantum Chemical Areas (PAP-00116914). Selected maximum from shallowest depth.	
110	MG/KG (MAX CONCENTRATION)	Max concentration 110 mg/kg. HF washed into River by 20,000 gallon acid release and by firehose, which washed all impacted/stained soil into the River	
0.000001	kg per mg (Merck Index)		
1	KILOGRAMS DISCHARGED		
Lead (Pb)			
1	YEARS DISCHARGED	Detected at soil sample location Q-3 (3.5-4 ft bgs) at 7,000 mg/kg; collected 11/21/1990 at the Quantum Chemical Area (PAP-00116914; PAP-00117022). 7,000 mg/kg max concentration.HF washed into River by 20,000 gallon acid release and by firehose, which washed all impacted/stained soil into the River.

Allocator's Determinations Regarding
Legal Defenses Raised by Allocation Parties

ESSEX CHEMICAL

Essex argues that it received a partial release of liability from Occidental Chemical (see attached), in the Maxus bankruptcy, along with 41 other parties. The releasing parties explained the rationale for providing this release in that proceeding as follows: "The debtors sought to eliminate those parties that (a) appeared to either be de minimis contributors or (b) had previously contributed to the investigation and the remediation costs in amounts roughly proportionate to their share of liability." Maxus bankruptcy docket no. 1232 at 24, filed April 19, 2017.

ALLOCATOR'S DETERMINATION – Though I have not had the opportunity to review the underlying settlement document and other potentially relevant facts associated with the release provided by OCC, assuming its validity, it is apparent that there is a high likelihood of success in any action against OCC to enforce the release. Given OCC's lack of participation in the allocations process, however, the Allocator does not believe that it is appropriate to account for the amount of any such release in the assignment of allocated shares. Rather, the Allocator notes the existence of the release and recommends that it be taken into account in determining the appropriate amount of any future settlement with EPA.

Allocator's Determinations Regarding
Legal Defenses Raised by Allocation Parties

EVERETT SMITH GROUP

Everett Smith Group states that Blanchard Bro. & Lane, Inc. was incorporated on June 29, 1937 and operated at 20 Bruen Street until sometime in 1939. (PAP-00000007; PAS-00032775). The property was sold in December 1941. (PAP-00000058). Eighteen years later, in 1959, 100% of Blanchard's stock was purchased by Eagle Ottawa Leather Company ("Eagle Ottawa"). (PAP-00432364 thru PAP-00432365). Eagle Ottawa maintained Blanchard as a wholly owned subsidiary until February 24, 1965 when it caused Blanchard to be dissolved. (PAP-00432366 thru PAP-00432367; PAP-00432369). In anticipation of such dissolution, Eagle Ottawa assumed on August 31, 1964 all "fixed or contingent" debts, obligations and liabilities of Blanchard existing as of that date. (PAP-00432368). There was no merger of the Blanchard and Eagle Ottawa Leather Company corporate entities. (PAP-00432364 thru PAP-00432369). There was no assumption of Blanchard's debts, obligations, or liabilities that did not exist on August 31, 1964. Eagle Ottawa Leather Company later merged with Albert Trostel & Sons Company. (PAS-0003297 thru PAS-0003298). ESG purchased the stock of Albert Trostel & Sons Company.

Eagle Ottawa's assumption of Blanchard's "contingent" debts, obligations, and liabilities in 1964 did not include CERCLA liabilities that might otherwise have been created in 1981 by CERCLA, a full 17 years later. The Court of Appeals for the Third Circuit interpreted the meaning of "contingent" liabilities in an analogous case addressing whether CERCLA liability had been discharged in a bankruptcy proceeding. Matter of Reading Co., 115 F.3d 1111, 1122 (3d Cir. 1997) (abrogated on other grounds by E.I. DuPont De Nemours & Co. v. United States, 460 F.3d 515, 518 (3d Cir.2006)). In that case, Reading Co. emerged from a bankruptcy proceeding in 1981 with a "consummation order" granting it protection from all pre-consummation debts and liabilities. Matter of Reading Co., 115 F.3d at 1114. Sixteen years later, Consolidated Rail Corporation ("Conrail") commenced a contribution action seeking recovery of cleanup costs from Reading Co. for pre-consummation releases of hazardous substances. Id. Reading Co. argued that the potential CERCLA liability was a pre-consummation claim for which Reading Co. was protected by the bankruptcy court's consummation order. Id. at 1121. Under the bankruptcy law, claims included "contingent" debts, liabilities and obligations. Id. at 1121-1123. The Third Circuit held that the potential for CERCLA liability had not matured to the level of a claim, or even a contingent claim, before CERCLA was enacted in 1980. Id. In an earlier case, the Third Circuit had succinctly noted:

[I]t was not until the passage of CERCLA that a legal relationship was created between the petitioners and PCC relevant to the petitioners' potential causes of action such that an interest could flow. Because this legal relationship did not evolve until after the Consummation Date, the petitioners did not have contingent claims against PCTC. In re Penn Central Trans. Co., 944 F.2d 164, 167-168 (3d Cir. 1991). Thus, there was no actual or contingent CERCLA debt, obligation, or liability to be assumed by Eagle Ottawa in 1964 when the company was dissolved.

ALLOCATOR'S DETERMINATION – Though the Everett Smith Group makes an argument regarding its lack of successor liability, the Allocator does not believe that Everett has a substantial likelihood of success at litigation based on the abrogated bankruptcy case cited as the

DISCHARGE CALCULATIONS	DIRECT DISCHARGE INFORMATION	ASSUMPTIONS, REFERENCES	COMMENTS/NOTES
4.08	FEET/YEAR AVERAGE PRECIPITATION	Long term average annual precipitation includes floods and hurricane events occurring over time.	Data from Rutgers University.
8.44	ACRES - TOTAL SITE AREA (acres)	FDR, page 1; confirmed with Google Earth	
6	ACRES - AFFECTED AREA	A 55,000-square foot production plant and 840-square foot boiler house were located at the Site. (PAP-00056121) Covering approximatley 1.2 acres of the 8.44 acre site.	
4,046.86	METERS^2/ACRE	CONVERSION TO METERS	
24,281	METERS^2 (AFFECTED AREA)		
0.0001	METERS/YEAR (ERODED SOIL THICKNESS)	For this estimate, used a surface soil erosion rate of 0.1 mm/year, or 0.004 inches/year.	
2	METERS^3/YEAR (ERODED SOIL VOLUME)	VOLUME/YEAR DISCHARGED to Passaic.	
1976	Year site operations began	Franklin Burlington Plastics or its predecessor manufactured plastics at the Site from approximately 1976 to 2010 (PAP-00056120).	
2017	Year site ownership ceased	On May 22, 2017, Urban Renewal, LLC acquired the site from Franklin-Burlington Plastics (FDR page 4; PAP-00338807).	Site manufacturing operations ceased in 2010 and all buildings were razed in April 2014 (PAP-00056121).
41	NUMBER YEARS DISCHARGE		
100	METERS^3 (TOTAL SOIL VOLUME DISCHARGED OVER TIME)		
2,251	KG/M^3 SOIL DENSITY	The fill was comprised of silty sand, course sand, cinders, gravel, brick fragments, rod, wood pieces, glass, ceramics and scrap metal. (PAP-00056120). Bulk density range 2002 KG/M^3 to 2499 KG/M^3, so use average. (http://structx.com/Soil_Properties_002.html)

Facility BS	CUF	CUF_Category	CUF_NOTES	COF	COF_NOTES	Facillty Adjusted BS
4.302E-6	10.0%	Periodic Noncompliacne	According to the 1990 EPA SI, at an unknown date Franklin Plastics received a Notice of Violation for oily spills along the eastern wall of the Production Plant (PAP-00337303). In 1984, there were numerous violations that included spillage, discolored soils, oil saturated soils, improperly labeled drums, unmarked drums, disposal of drums, and other storage of material concerns (PAP-00337237). NJDEP Division of Water Resources, inspected the facility in July 1985 and gave it an “unacceptable” rating due to permit limit exceedances of temperature, chromium, and zinc concentrations (PAP-00057085-89;). A 1980 EPA Potential Hazardous Waste Site Identification and Preliminary Assessment form identified an open dump, landfill, drums, aboveground tanks, a railroad, and other hazardous major site activities. Overturned drums potentially contaminating the soil were noted onsite, as well as “many” 55-gallon drums that were leaking and overflowing. An August 1, 1984 Investigative Report for Franklin Plastics Corporation noted an oil-like substance that heavily contaminated the southwestern corner inside of the Production Plant. Two spills being cleaned by the workers were noted on the ground during the inspection in an area where a liquid plasticizer was discharged from tank trailers into pipes for storage (PAP-00338659). During sampling "spill and vegetative stress area near the air pollution control units" as noted and another sample was collected where "the soils were covered with a silvery material"	-20.0%	-20% CPG/SPG member - Continuous provision of funding and participation in PRP Group(s) actions to cooperate with governmental/regulatory entities to address environmental or public harm created by own activities	3.872E-6

DISCHARGE CALCULATIONS	DIRECT DISCHARGE INFORMATION	ASSUMPTIONS, REFERENCES	COMMENTS/NOTES
4.08	FEET/YEAR AVERAGE PRECIPITATION	Long term average annual precipitation includes floods and hurricane events occurring over time.	Data from Rutgers University.
31	ACRES - TOTAL SITE AREA (acres)	FDR, page 1; confirmed on Google Earth	
12	ACRES - AFFECTED AREA	Exclude 19 acres of buildings and pavement (1995-2020 Google Earth aerial photos)	
4,046.86	METERS^2/ACRE	CONVERSION TO METERS	
48,562	METERS^2 (AFFECTED AREA)		
0.0001	METERS/YEAR (ERODED SOIL THICKNESS)	For this estimate, used a surface soil erosion rate of 0.1 mm/year, or 0.004 inches/year.	
5	METERS^3/YEAR (ERODED SOIL VOLUME)	VOLUME/YEAR DISCHARGED to Yantacaw Pond and Third River discharging to Passaic.	
1924	Year site operations began	Givaudan Fragrances Corporation (Givaudan) purchased the assets of Burton T. Bush, Inc. in 1924 (PAS-00048099).	
1998	Year site operations ceased	Givaudan ceased manufacturing operations in June 1998. The cleaning of plant processing equipment continued until September 1998. All raw materials and chemicals were removed from the facility by the end of October 1998 (FDR page 1; PAP-00178473).	
74	NUMBER YEARS DISCHARGE		
359	METERS^3 (TOTAL SOIL VOLUME DISCHARGED OVER TIME)		
1,963	KG/M^3 SOIL DENSITY	The unconsolidated overburden at the site consists of stratified sand, gravel, silt, and some clay (PAP-00182257). Bulk density range 1442 KG/M^3 to 2483 KG/M^3, so use average. (http://structx.com/Soil_Properties_002.html)	
705,426	KILOGRAMS (TOTAL SOIL DISCHARGED OVER TIME)		
		Some of the site perimeter is located on historic fill material (FDR page 16)

DE Residential = 0.1 mg/kg; DE Industrial = 0.7 mg/kg			
		Total Benzo(a)pyrene Equivalents =	**101.6**

PCBs			
68	YEARS DISCHARGED		
4.4	MG/KG (MAX OF REPORTED CONCENTRATIONS)	Sample SBRR-07 (5-6) had the max concentration of Aroclor-1260 (PAP-00175755); Years of discharge - 68.	According to a Hazardous Waste Investigation, dated June 5, 1980, it was ascertained that Givaudan was generating and storing polychlorinated biphenyls (PCBs) onsite. The report states that U.S. EPA inspectors had a report concerning Givaudan's PCB practices, but additional details were not available (PAP-00172019). An undated record titled "Exhibit No. 2, Transformers - PCB Oil-Filled Electrical Transformers" states that the facility historically had 30 PCB-containing transformers (PAP-00176671-72). According to a Plans for Discharge Prevention, Containment, and Countermeasure (DPCC) and Discharge Cleanup and Removal (DCR), dated July 1982, Givaudan had 38 transformers in operation containing PCBs (PAP-00182108).

Discharge Calcs	Direct Discharge Information	ASSUMPTIONS, REFERENCES	COMMENTS/NOTES
4.08	FEET/YEAR AVERAGE PRECIPITATION	Long term average annual precipitation includes floods and hurricane events occurring over time.	Data from Rutgers University.
7	ACRES - TOTAL SITE AREA (acres)	FDR p 1	
1.8	ACRES - AFFECTED AREA	Rough estimate of site area with exposed fill determined from review of historical aerial photograph from 1995 (Google Earth Pro). Estimating 50% of the site was occupied by buildings and approximately 25% of the site is paved.	
4,046.86	METERS^2/ACRE		
7,082	METERS^2 (AFFECTED AREA)		
0.0001	METERS/YEAR (ERODED SOIL THICKNESS)	For this estimate, used a surface soil erosion rate of 0.1 mm/year, or 0.004 inches/year.	
1	METERS^3/YEAR (ERODED SOIL VOLUME)	VOLUME/YEAR DISCHARGED	
1982	Year site operations began (FDR p 1)	Goodrich (as Kalama Chemical Inc) bought site in 1982 (FDR p 1)	
2020	Goodrich is current owner (FDR p 1)	Goodrich operations ceased in 1994. Manufacturing equipment and chemicals removed that year (FDR p 1)	
38	NUMBER YEARS DISCHARGE		
27	METERS^3 (TOTAL SOIL VOLUME DISCHARGED OVER TIME)		
1,963	KG/M^3 SOIL DENSITY	Fill is described as poorly sorted sand and gravel, brick fragments, and cinders (PAP-00044391). Bulk density range is 1442 KG/M^3 to 2483 KG/M^3, so use average. (http://structx.com/Soil_Properties_002.html)	
52,814	KILOGRAMS (TOTAL SOIL DISCHARGED OVER TIME)		
		The majority of the site is not located on regional historic fill (FDR p 9)	
Copper (Cu)		Building 7 was a copper shop where sheet metal was fabricated (FDR p 7)	
38	YEARS DISCHARGED		
550	MG/KG (MAX CONCENTRATION)	Sample B-47-FILL (0-0.5 ft bgs) (PAP-00041872)	
0.000001	kg per mg (Merck Index)		
29	KILOGRAMS DISCHARGED		
Lead (Pb)		Lead-containing hazardous solid waste was shipped offsite (FDR p 7)

2.837E-6	5.0%	Occasional Noncompliance	The PVSC sent a notice of violation on May 2, 1991, for non-COCs (chloroform and toluene) but these were noted by the facility to be sampling error and subsequent results showed compliance (PAP-00208805). Another PVSC notice of violation for permit 0949429 based on a non-COC (methylene chloride) was dated April 13, 1994 (PAP-00208813). Violations were noted for Hart Chemical Co. (tenant) at the facility based on a December 15, 1988, inspection by the New Jersey Bureau of Fire Safety. The violations included permits needed for the flammable and corrosive areas, and a diked area for the manufacturing area (PAP-00433532). New Jersey Department of Health inspected on September 14, 1992 and noted violations for failure to label containers (PAP-00433862-65).	-20.0%	-20% CPG/SPG member - Continuous provision of funding and participation in PRP Group(s) actions to cooperate with governmental/regulatory entities to address environmental or public harm created by own activities	2.411E-6

DISCHARGE CALCULATIONS	DIRECT DISCHARGE INFORMATION	ASSUMPTIONS, REFERENCES	COMMENTS/NOTES
4.08	FEET/YEAR AVERAGE PRECIPITATION	Long term average annual precipitation includes floods and hurricane events occurring over time.	Data from Rutgers University
10.3	ACRES - TOTAL SITE AREA (acres)	FDR, PDF PAGE 1	
2.6	ACRES - AFFECTED AREA	Affected area = 3 acres. A 1990 report states approximately 7.7 acres of the site are under roof or asphalt (PAP-00104322). Given the period of operation (1968-1996), it can be assumed that much of that was paved during operation.	
4,046.86	METERS^2/ACRE		
10,522	METERS^2 (AFFECTED AREA)		
0.0001	METERS/YEAR (ERODED SOIL THICKNESS)	For this estimate, used a surface soil erosion rate of 0.1 mm/year, or 0.004 inches/year.	
1	METERS^3/YEAR (ERODED SOIL VOLUME)	VOLUME/YEAR DISCHARGED TO DITCHES AND DEAD HORSE CREEK	
1968	Year site operations began	Site developed in 1968 (FDR page 9; PAP-00103480)	
1994	Year site operations ceased	Operations at the site ceased in May 1994 (PAP-00104911; PAP-00104832; PAP-00105268; PAS-00001863). Ending year reflectx the year Goody Products (as H Goodman & Sons, Inc.) stopped operations on the site, which they leased instead of owned (FDR p 1).	Owner: Jeryl Industries, Inc., from pre-1969 to at least 1996 (PAS-00001835; PAS-00002050)
26	NUMBER YEARS DISCHARGE		
27	METERS^3 (TOTAL SOIL VOLUME DISCHARGED OVER TIME)		
1,963	KG/M^3 SOIL DENSITY	Fill reported as silty sand and gravel (FDR). Bulk density range 1442 KG/M^3 to 2483 KG/M^3, so use average. (http://structx.com/Soil_Properties_002.html)	
53,701	KILOGRAMS (TOTAL SOIL DISCHARGED OVER TIME)

Allocator's Determinations Regarding
Legal Defenses Raised by Allocation Parties

HARTZ CONSUMER GROUP

Hartz argues that it is neither responsible nor liable for General Motors; PCB and Metals Contamination United States District Court Judge Walls was similarly convinced. In granting summary judgment to Hartz in the Hartz v. General Motors case, holding GM liable for contribution under CERCLA §113(f) and the New Jersey Spill Compensation and Control Act, N.J.S.A. 58:10-23.11.f.a, the Court found as follows:

Plaintiffs have produced unrefuted expert testimony that the hazardous substances identified at the Site, including the PCBs and chlorinated volatile organic compounds, are expected byproducts from Hyatt's previous operations in Harrison. The facts overwhelmingly demonstrate that Hyatt used PCB laden Pydraul fluid in conjunction with its heat intensive processes, that these fluids regularly spilled and leaked, and that they contaminated the property, seeping into the soil and the sewer system. The Court notes that the locations of the more concentrated levels of hazardous chemicals correspond to areas used exclusively by Hyatt such as the former chip pit (AOC-8) the subsurface tunnels (AOC-11), and the subsurface process room. The highest quantities of PCBs were located in the interior of former Hyatt Building 12, where Hyatt conducted much of its heat treating operations. **PAP-00005302-03 (Citations to the court record omitted).**

General Motors has Settled its Liability for the Passaic River. Following its bankruptcy in the 2008 financial crisis, by Order entered January 30, 2012, General Motors settled its liability for the Diamond Alkalai Superfund Site, pursuant to which the United States received an Allowed General Unsecured Claim in the amount of $19,500,000, classified in Class 3 under the Plan of Liquidation. See PAP-00006549-50 (§V.4 of the Settlement Agreement). In exchange, the liquidating trust (known as the GUC Trust) obtained a Covenant-Not-To-Sue (§¶VII, ¶19), and contribution protection (§VIII, ¶25).

In so doing, General Motors resolved its liability for the Passaic River, as a settling party. Its contribution to the river, if any, must be deemed resolved, and such contribution cannot be treated as an orphan share. See 42 U.S.C. § 9613(f)(2), providing that "A person who has resolved its liability to the United States or a State in an administrative or judicially approved settlement shall not be liable for claims for contribution regarding matters addressed in the settlement. Such settlement does not discharge any of the other potentially liable persons unless its terms so provide, *but it reduces the potential liability of the others by the amount of the settlement."* See In re: Eagle-Picher Industries, 1997 US Dist. Lexis 15436 (S.D. OH) (approving settlement, and off-setting remaining liability by amount of settlement).

Hartz and its consultants and remediation contractors are "response action contractors" protected under §119(a) of CERCLA. They are thus protected from liability in connection with any incidental discharges or releases during its remediation of (GM- Hyatt's) contamination in cleaning up the Harrison Site. This is consistent with the law of the Third Circuit (See U.S. v. CMDG Realty Co., 96 F.3d 706 (3d Cir. 1996) (requiring a showing that contractor negligence exacerbated contamination before a remediation contractor would be

subject to "operator" liability). Hartz also claims "innocent landowner" status, having done the appropriate level of due diligence when it acquired the site in 1970. See 42 U.S.C. §9601(35). Remediation of petroleum hydrocarbons may also be covered by the CERCLA "petroleum exclusion" See 42 U.S.C. §9601(14).

ALLOCATOR'S DETERMINATION – Hartz Consumer Group appears to make two distinct legal arguments, that (1) any liability of Hartz for discharges of COCs during the ownership or operation of the facility by GM-Hyatt or for the subsequent discharge of COCs placed on the facility site by GM-Hyatt was resolved in the settlement between GM and the U.S. and (2) the protections for "response action contractors" afforded by §119(a) of CERCLA should apply to its ownership of the facility site and protect it from liability for any discharges of COCs that occurred after its purchase of the site from GM. Though a full evaluation of Hartz's possible liability for actions outside of those of their remediation contractor is not available from the available information, the Allocator presumes a substantial chance of success should this matter go to litigation. However, we leave this matter as a topic for settlement discussions between Hartz Consumer Group and EPA.

DISCHARGE CALCULATIONS	DIRECT DISCHARGE INFORMATION	ASSUMPTIONS, REFERENCES	COMMENTS/NOTES
4.08	FEET/YEAR AVERAGE PRECIPITATION	Soil and groundwater at Purdue Pharma were contaminated with PCBs from Hexcel.	Data from Rutgers University.
1.73	ACRES - TOTAL SITE AREA (acres)		
0.73	ACRES - AFFECTED AREA	Purdue Pharma was operated by Napp from 1970 until 1995. On April 21, 1995 an industrial accident at the facility resulted in a fire and explosion, destroying a portion of the facility and causing the plant operations to be terminated. (PAS-00084999) The 1966 aerial photograph shows an unpaved area adjacent to the south side of the current facility parking lot, which was later paved and fenced-in for materials storage use. (PAS-00085007)	
4,046.86	METERS^2/ACRE		
2,954	METERS^2 (AFFECTED AREA)		
0.0001	METERS/YEAR (ERODED SOIL THICKNESS)	For this estimate, used a surface soil erosion rate of 0.1 mm/year, or 0.004 inches/year.	
0	METERS^3/YEAR (ERODED SOIL VOLUME)	VOLUME/YEAR DISCHARGED	
1971	Year site operations began	FDR, PDF PAGE 1, Operator: 1971 to 1995; Owner: Not Applicable	
1995	Year site operations ceased		
24	NUMBER YEARS DISCHARGE		
7	METERS^3 (TOTAL SOIL VOLUME DISCHARGED OVER TIME)		
2,250	KG/M^3 SOIL DENSITY	SOIL reported as mix of clays, silts, sand and gravels. Bulk density range 2002 KG/M^3 to 2499 KG/M^3, so use average. (http://structx.com/Soil_Properties_002.html)	The fill material varied in its composition, and consists of a mix of clays, silts, sand and gravels, with fragments of brick, glass, wood and other materials interspersed throughout it. The fill material on the eastern side of the site is more typical of industrial fill, and consists of stone, brick, concrete and other fill material (PAP-00127504).

Total Benzo(a)pyrene Equivalents = **0.0**

PCBs also were present in soil along approximately 200 feet of the Saddle River riverbank at concentrations as high as 94 mg/kg, as discussed in the Remedial Investigation Report/Remedial Action Work Plan, dated June 17, 2004. (PAP-00127627, 56). According to the 1999 RIR/RIWP Addendum, the presence of PCB Aroclors 1242 in site soils was a result of an upgradient off-site source. Aroclor 1242 was never used by PPTI, nor was it detected in any of the soil samples from PPTI's process areas. PPTI contends in the document that these PCB Aroclors were from the adjacent property, Hexcel's "signature compounds," and were associated with LNAPL that migrated onto the PPTI property via the industrial sewer line and other utility pipelines and trenches which traverse the PPTI property. Aroclor 1242 was detected only along the northern property boundary with Hexcel and in the western portion of the PPTI property along underground utilities that originated on Hexcel property. Reworking of soils as a result of earthmoving activities conducted in the western portion of the site (associated with periodic utility line maintenance) was believed to be responsible for the detection of Aroclor 1242 in the near-surface soils (PAS-

4.522E-3	10.0%	Periodic Noncompliacne	Two violations were noted in the ECRA application. One is stated to be related to failure to submit information to local agencies, while the other is a notice that spills and leaking drums were observed close to the east bank of the Saddle River during a state inspection in the September of 1984. Both violations were stated to be resolved (PAS-00091296-97). The document does not state these violations involved OU2 COCs. The Purdue Pharma facility property was impacted by PCBs from Hexcel. An industrial sewer line historically ran north to south across the site, beginning at the adjacent Hexcel property and continuing to the Hendricks pump station located adjacent to the Fortunato property (PAP-00127468, 559). Aroclor 1242, used by Hexcel, was detected in Purdue Pharma soil along the route of the industrial sewer line. Soil: Ranging from 0.6 milligrams per kilogram (mg/kg) at a depth of four feet below ground surface (bgs) to 8,500 mg/kg collected from seven to 7.5 feet bgs at sample location TP-7, and 1,700 mg/kg collected from nine to 9.5 feet bgs at sample location TP-7B (PAS-00084957; PAP-00127670). PCB-laden (Aroclor 1242) light non-aqueous phase liquid (LNAPL): 3,400 mg/kg at [Purdue Pharma] well MW-E14 installed just south of Molnar Avenue adjacent to Hexcel (PAS-00084957). PCBs also were present in [Purdue Pharma] soil along approximately 200 feet of the Saddle River riverbank at concentrations as high as 94 mg/kg, as discussed in the Remedial Investigation Report/Remedial Action Work Plan, dated June 17, 2004. The PCBs extended south from the Hexcel property line, where the primary Aroclor detected was 1242, to the Fortunato property line, where the primary Aroclors detected were 1254 and 1260. Facility Base Scores, Culpability Factor, Cooperation Factor and Adjusted Base Scores - Protocol Calculation

Hoffman-La Roche Inc.

340 Kingsland Road	**Nutley**	**NJ**	**07110**

Facility BS	CUF	CUF_Category	CUF_NOTES	COF	COF_NOTES	Facillty Adjusted BS
3.248E-4	5.0%	Occasional Noncompliance	Spills identified in the data report as occurring in the 1980s and 1990s (mostly fuel oil, one mercury). One large release of No. 6 fuel oil to the process waste lines migrated through the PVSC sewer system to the treatment plant in Newark in the late 1970s or early 1980s, which was a violation of Roche's connection permit (Nachman Synthesis, p. 8). On March 2, 1991, a 10-15 gallon, 100-foot trail of PCB-contaminated transformer oil was released to the roadway due to a broken valve during a transformer relocation by an outside contractor. On April 10, 1947, an inspector discovered oil on Nichol's Pond, a tributary to Third River. The source was traced to Roche's power plant upstream on Nichol's Brook. It was found that a tank truck delivering fuel oil had a spill and lost approximately 100 gallon of fuel oil which escaped through a yard drain into the ditch along the railroad and into Nichol's Brook. Also see spill/release table on pp 15-16 of the FDR.	-20.0%	-20% CPG/SPG member - Continuous provision of funding and participation in PRP Group(s) actions to cooperate with governmental/regulatory entities to address environmental or public harm created by own activities	2.761E-4

Discharge Calcs	Direct Discharge Information	ASSUMPTIONS, REFERENCES	COMMENTS/NOTES
		Long term average annual precipitation includes floods and hurricane events occurring over time.	
4.083333333	FEET/YEAR AVERAGE PRECIPITATION		
			Another source states that the property is 14.5 acres (FDR page 1; PAP-00066677)
15.3	ACRES - TOTAL SITE AREA (acres)	PAP-00086173	
4.5	ACRES - AFFECTED AREA	FDR page 4: Area A consists of 2.5 undeveloped acres located south of the West Yard. Additionally, based on google earth imagery, and creating polygons using measuring tool, an additional 2 acres of bare soil surrounding the tanks in the West and East Yard combined (grassy areas, see image on FDR page 4) were estimated. Total of 4.5 acres of exposed soil.	
4,046.86	$METERS^2$/ACRE		
18,211	$METERS^2$ (AFFECTED AREA)		
0.0001	METERS/YEAR (ERODED SOIL THICKNESS)	For this estimate, used a surface soil erosion rate of 0.1 mm/year, or 0.004 inches/year.	
2	$METERS^3$/YEAR (ERODED SOIL VOLUME)	VOLUME/YEAR DISCHARGED TO PASSAIC RIVER	
1985	Year site operations began	Operated and owned by Power Test Realty Company Limited Partnership (PTRC, an affiliate of Leemilt's Petroleum Inc.) (FDR page 1)	
2013	Year site ownership ceased	Year PTRC sold the Newark Terminal (FDR page 3)	
28	NUMBER YEARS DISCHARGE		
50.990436	METERS3 (TOTAL SOIL VOLUME DISCHARGED OVER TIME)		
1962.5	KG/M3 SOIL DENSITY	Fill is composed of a mixture of sand, silt, and gravel with varying amounts of brick fragments, rocks, wood and other debris (PAP-00066671, PDF page 8). Used "silty sand and gravel" soil type from http://structx.com/Soil_Properties_002.html. Bulk density range 1442 KG/M3 to 2483 KG/M3, so use average.	
100,069	KILOGRAMS (TOTAL SOIL DISCHARGED OVER TIME)		
Copper (Cu)			
28	YEARS DISCHARGED		
0	MG/KG (MAX CONCENTRATION)	The table on FDR page 13 lists the maximum concentration found in onsite soils at AOC4-18GW collected from a depth of 2.5 - 3.0 ft bgs (PAP-00086279, pdf page 123). Set to 0 since less than HF.	
0.000001	kg per mg (Merck Index)		
0	KILOGRAMS DISCHARGED		
Lead (Pb)			
28	YEARS DISCHARGED		
		Maximum concentration in onsite soils (From Chevron FDR Page 10, Table) Concentration set to 0 mg/kg because the FDR incorrectly has a concentration of 84,200 mg/kg. The referenced source shows a maximum lead concentration of 8,200 mg/kg (PAP-00339532). This is set to 0 mg/kg because it is less than HF.	
0	MG/KG (MAX CONCENTRATION)

Discharge Calcs	Direct Discharge Information	ASSUMPTIONS, REFERENCES	COMMENTS/NOTES
4.08	FEET/YEAR AVERAGE PRECIPITATION	Long term average annual precipitation includes floods and hurricane events occurring over time.	Data from Rutgers University.
29	ACRES - TOTAL SITE AREA (acres)	29 acres (FDR p 1, PAS-00010493 p 9)	Other docs say 9.5 acres (PAP-00188306, PAP-00362420, PAP-00364113)
19	ACRES - AFFECTED AREA	Rough estimate of site area with exposed fill determined from review of Figure 1-2 (PAP-00364294) of the 1995 RI (PAP-00364113 p 182). Estimating that 33% of the site had buildings	
4,046.86	METERS^2/ACRE		
77,457	METERS^2 (AFFECTED AREA)		
0.0001	METERS/YEAR (ERODED SOIL THICKNESS)	For this estimate, used a surface soil erosion rate of 0.1 mm/year, or 0.004 inches/year.	
8	METERS^3/YEAR (ERODED SOIL VOLUME)	VOLUME/YEAR DISCHARGED TO DITCHES AND PLUM CREEK	
1952	Year site operations began	Kolker Chemical Co [later Vulcan] acquired facility (FDR p 1, PAP-00188319)	
1975	Year site processing and storage operations ceased	Vulcan sold to Inland in 1974 (FDR p 1, PAP-00186853)	Vulcan/Inland terminated operations of chlor-alkali and chloromethanes plants in May 1975 and dismantled plants in 1975-76 (FDR p 1, PAP-00186853). In 1975 operations were transferred from chemical manufacturing to solvent recovery (PAS-00091936 p 3)
23	NUMBER YEARS DISCHARGE		
178	METERS^3 (TOTAL SOIL VOLUME DISCHARGED OVER TIME)		
1,963	KG/M^3 SOIL DENSITY	Surface soil is fill material with variable composition, including ash, wood, cinders, coal, smelter slag, brick, concrete rubble, cobble, sand, and gravel chips (PAP-00362420 p 16). Density of silty sand and gravel ranges from 1442 to 2483 kg/m^3, so the average is used. (http://structx.com/Soil_Properties_002.html)	
349,621	KILOGRAMS (TOTAL SOIL DISCHARGED OVER TIME)		
		Site is located on regional Historic Fill (FDR p 5)	Same concentrations used for Safety Kleen calculations are used here
Copper (Cu)			
23	YEARS DISCHARGED		
0	MG/KG (MAX CONCENTRATION)	Copper concentration set to 0 mg/kg based on the conclusion accepted by NJDEP that metallic constituents detected in soil are related to operations conducted by Balbach (pre-1952) (FDR page 5)	
0.000001	kg per mg (Merck Index)		
0	KILOGRAMS DISCHARGED		
Lead (Pb)			
23	YEARS DISCHARGED		
0	MG/KG (AVERAGE CONCENTRATION)	Lead concentration set to 0 mg/kg based on the conclusion accepted by NJDEP that metallic constituents detected in soil are related to operations conducted by Balbach (pre-1952) (FDR p 5)	
0.000001	kg per mg (Merck Index)		
0	KILOGRAMS DISCHARGED		
Mercury (Hg)		AEC 6 consisted of several tanks which were associated with chemical processing (FDR page 19)	
23	YEARS DISCHARGED		
0.0	MG/KG (MAX CONCENTRATION)	Mercury concentration set to 0 mg/kg based on the conclusion accepted by NJDEP that metallic constituents detected in soil are related to operations conducted by Balbach (pre-1952) (FDR page 5)	
0.000001	kg per mg (Merck Index)		
0	KILOGRAMS DISCHARGED		

PAHs (listed in Benzo(a)pyrene Equivalent conversion table)		Total concentration of PAH compounds for Benzo(a)pyrene Equivalent https://floridadep.gov/waste/petroleum-restoration/documents/benzo-pyrene-equivalents-conversion-table-one-sample.

Facility BS	CUF	CUF_Category	CUF_NOTES	COF	COF_NOTES	Facillty Adjusted BS
7.538E-10	5.0%	Occasional Noncompliance	On August 14, 1972 PVSC inspectors collected samples of discharges from site outfalls, and analysis showed the samples “were polluting.” On August 16, 1972, PVSC directed that they cease polluting at once. National Standard addressed the issue right away (PAS-00034750-52). NJDEP issued an Administrative Order and Notice of Civil Administrative Penalty Assessment to National Standard in August 1987 due to improper hazardous waste storage and management (PAS-00004222-28). According to a Disruption and Closure Permit Application, dated June 1, 1989, lead dross (scum from the surface of the molten lead) and soils with elemental lead associated with operations at the site also were placed in onsite landfill; however, investigations, including borings and test pits, did not reveal lead dross in the landfill (PAP-00197231). It was estimated that a total of 170,000 cubic yards of miscellaneous debris was present within the landfilled areas (PAP-00197232).	-20.0%	-20% CPG/SPG member - Continuous provision of funding and participation in PRP Group(s) actions to cooperate with governmental/regulatory entities to address environmental or public harm created by own activities	6.408E-10

Allocator's Determinations Regarding Legal Defenses Raised by Allocation Parties

NEU HOLDINGS

Neu Holdings argues that it has no responsibility for cleanup of the Passaic River or OU2 because all liabilities associated with the operations of the Clifton Mill were discharged as a result of WPBC's bankruptcy. WPBC filed for protection under Chapter 11 of the U.S. Bankruptcy Code, 11 U.S.C.§§101 et seq. (the "Bankruptcy Code"), in the United States Bankruptcy Court for the District of New Jersey (the "Bankruptcy Court") on February 8, 1980. The proceedings were designated *In re Whippany Paper Board Co. Inc.*, Case No. 80-00426 (the "Chapter 11 Proceedings"). FDR at 2. The Clifton Mill ceased operations in April of 1980. *Id*.

The Bankruptcy Court established March 11, 1981 as the last day by which parties holding claims against WPBC could file a proof of claim in order to participate in any distribution from WPBC's bankruptcy estate. EPA had actual knowledge of WPBC's Chapter 11 Proceedings well before that date but elected not to file a proof of claim. On March 31, 1981 (the "Confirmation Date"), the Bankruptcy Court entered an order pursuant to 11 U.S.C. §1129 confirming the Chapter 11 Plan for WPBC. FDR 2. Pursuant to Section 9.1 of the Chapter 11 Plan and Bankruptcy Code Section 1141(d), the confirmation of the Chapter 11 Plan discharged WPBC from any and all "debts" that "arose before the date of such confirmation." PAP-00102386; 11 U.S.C. §1141(d)(1)(A).

EPA has suggested that the bankruptcy discharge does not affect its CERCLA claim because the bankruptcy discharge occurred before EPA initiated a response action for the Passaic River. Section 101 of the Bankruptcy Code defines the terms "debt" and "claim" to have "the broadest possible definition[s] . . . [so] that all legal obligations of [a bankruptcy] debtor, *no matter how remote or contingent*, will be able to be dealt with in [a] bankruptcy case" (emphasis added). As a result of these broad definitions, Courts have recognized that a Chapter 11 debtor's discharge extends to any actual or alleged CERCLA liabilities arising from or relating to the debtor's "pre-confirmation" release of hazardous substances. This is true even if such releases do not become the subject of any investigation or response costs until years (or even decades) after the debtor's Chapter 11 plan has been confirmed. For instance, the Second Circuit held that pre- bankruptcy hazardous substance releases are subject to discharge even if such costs relate to CERCLA sites of which EPA is unaware at the time of the bankruptcy proceeding.

The relationship between environmental regulating agencies and those subject to regulation provides sufficient "contemplation" of contingencies to bring most ultimately maturing payment obligations based on [pre-bankruptcy] conduct within the definition of "claims." True, EPA does not yet know the full extent of the …costs that it may one day incur and seek to impose upon [the debtor], and it does not yet even know the location of all the sites at which such wastes may yet be found. But the location of these sites, the determination of their coverage by CERCLA, and the incurring of response costs by EPA are all steps that may fairly be viewed, in the regulatory context, as rendering EPA's claim "contingent," rather than as placing it outside the [Bankruptcy] Code's definition of "claim."

U.S. v. The LTV Corporation (In re Chateaugay Corporation), 944 F. 2d 997, 1005 (2nd Cir. 1991); *see also State of New Jersey Department of Environmental Protection v. The IT Litigation Trust (In re IT Group, Inc., Co.)*, 339 B.R. 338, 343-4 (D. Del. 2006) (post-confirmation environmental remediation order issued by the New Jersey Department of Environmental Protection against successor to Chapter 11 debtor was held to have been discharged as a result of the confirmation of the debtor's Chapter 11 plan).

WPBC ceased all operation of the Clifton Mill in April of 1980, when a fire partially gutted the facility. WPBC never resumed operation of the Clifton Mill prior to selling the Mill to Ponte, an unrelated third-party, on October 1, 1987. FDR 3. Thus, even if WPBC's Clifton Mill operations resulted in the release of COCs into the Passaic River (which, as discussed herein, it did not), any such release would have occurred prior to the March 31, 1981 Confirmation Date. Neu Holdings posits that as a result, any CERCLA liability for any COC released prior to the March 31, 1981 Confirmation Date from the WPBC Clifton Mill was discharged in bankruptcy. Having forgone its right to file a proof of claim and participate in the distributions from WPBC's Chapter 11 bankruptcy estate, EPA is now precluded as a matter of federal bankruptcy law from seeking to recover under CERCLA against Neu Holdings, the successor to NPN/WPBC. *See* 11 U.S.C. §524(a)(2) (providing that a bankruptcy discharge operates as a statutory injunction against any act to collect or recover a discharged debt as a personal liability of the debtor). The bankruptcy discharge is a complete defense to liability and presents a significant litigation risk to EPA should the Agency proceed with a civil case. *See United States v. Davis*, 261 F.3d 1, 26 (1st Cir. 2001) ("party specific discounts may reflect the chances of the United States success in litigation against a given PRP" and it "is appropriate to factor into the equation any reasonable discounts for litigation risks, time savings, and the like that may be justified"); *see also United States v. Fort James Operating Co*., 313 F. Supp. 2d 902, 909 (E.D. Wis. 2004) ("plaintiffs present a number of good reasons for not attempting to obtain top dollar through litigation, including the risks of litigation").

According to Neu Holdings, "Respondent denies that WPBC released COCs from its operation of the Clifton Plant to the Passaic River and OU 2. Even if it did, WPBC's liability for any such releases was discharged as a matter of law in bankruptcy on March 31, 1981. On February 8, 1980, WPBC commenced a voluntary proceeding under Chapter 11 of the United States Bankruptcy Code, 11 U.S.C. §§101 et seq. (the "Bankruptcy Code") in the United States Bankruptcy Court for the District of New Jersey (the "Bankruptcy Court"), said proceedings having been designated In re Whippany Paper Board Co. Inc., Case No. 80-00426". Neu Holdings state that USEPA was aware at the time of WPBC's bankruptcy proceedings and had an opportunity to participate in the same (PAP-00374507).

On March 31, 1981, the Bankruptcy Court entered an Order confirming WPBC's reorganization plan. Per the plan of reorganization and the bankruptcy code, the confirmation of the reorganization plan discharged WPBC from any and all "debts that arose before the date of such confirmation." (PAP-00102386)

"USEPA has suggested that the bankruptcy discharge does not pose a barrier to USEPA's claim because the bankruptcy discharge occurred long before EPA initiated a response action at the Diamond Alkali Site. However, the Bankruptcy Code Section 101(5) defines a "claim" as

including a right to payment that at the time of a debtor's bankruptcy remains "unmatured" and/or "contingent," and it is well-established that a potential liability may qualify as a "claim" for bankruptcy discharge purposes even if it has not yet fully accrued into a cognizable cause of action under applicable non-bankruptcy law. Collier on Bankruptcy, 101.05 at 101-39 (16th Ed. 2017) (As defined in the Bankruptcy Code, the term "'[c]laim' . . . include[s] a cause or action or right to payment that has not yet accrued or become cognizable."). In the environmental context, a Chapter 11 bankruptcy debtor may be discharged from any and all potential liabilities related to a pre-confirmation release or threatened release of hazardous substances even if such release does not become the subject of any investigation and/or resulting response costs until several years (or even decades) after the debtor's Chapter 11 plan has been confirmed.

In this case, WPBC ceased operating the Clifton Plant in April of 1980, before the March 31, 1981 confirmation of its Chapter 11 Plan and never resumed operation of the Clifton Plant before selling it to V. Ponte & Sons on October 1, 1987 (PAS-00113953).

Accordingly, even if WPBC's operation of the Clifton Plant resulted in the release of COCs into the Passaic River (of which there is no evidence), the liability of WPBC for any such release was discharged upon the court's confirmation of its Chapter 11 Plan.

According to the Neu Holdings evidence shows that the Clifton Plant operations during the period of WPBC's ownership and operation did not include COCs and that the Clifton Plant property was not a conduit for discharging COCs into the River. As such, the former Clifton Plant, which is located nearly nine miles from OU2, did not discharge COCs that could have had any material impact to the Passaic River or OU2. Especially considering that Neu Holdings' wholly owned subsidiary contributed approximately $1.8 million toward lower Passaic River investigation and a removal action for which it had no responsibility at all, Neu Holdings should bear no further liability for the Diamond Alkali Site or OU2.

ALLOCATOR'S DETERMINATION – Neu Holdings has noted several arguments why it should not be held responsible for contamination of OU2 caused by the actions of its predecessor. Neu Holdings has posited a legal argument based on the fact that it acquired the entity at issue after it was discharged in bankruptcy, which it argues provides a complete defense to CERCLA liability. The Allocator leaves legal defenses for consideration during future settlement discussions with EPA, at which time Neu Holdings and EPA can discuss the efficacy of its bankruptcy defense and the litigation risk posed thereby. In addition, Neu Holdings has posited several additional equitable arguments. However, there is insufficient available information to determine whether the situation raised overrides the CERCLA doctrine that a legal corporate successor by merger cannot avoid liability for its predecessors acts or omissions on equitable grounds. Therefore, the Allocator likewise leaves this matter for consideration during future settlement discussions with EPA.

11055.156230	MASS (KG) DISCHARGED FROM SURFACE SOIL

360 gallons of PCB oils on 1981 inventory. Assumed PCB transformers made from 1956-1981 (i.e., PCBs were used up in 1981), based on employee affidavit that PCB transformers were manufactured for 25 years (FDR, Page 8; PAS-00129817). Site operations ended and the property was sold in 1984; therefore, reduced PCB discharge period from 54 to 28 years (1956-1984). Also, the investigation for cleanup occurred in 1985, see below, documenting that that PCB-contaminated soil was still in place
Maximum surface soil concentration (FDR, Page 9). Surface sample data on PAS-00129817.

PCB mass calculation adjusted to account for area of erosion shown by PAP-00367959, PAP-00367998, PAP-00368003-6
DDT use began in 1940s - assume present between 1940 and 1984. Period of discharge changed.

DDT concentration in on-site surface soil sample F6-8-1 (1-1.5 ft bgs) (PAP-00367888).

Found in one sample 2.5-3 ft bgs at a low concentration (PAP-00367769)

Sample M6-3-1 (PAP-00367848)	
Anthracene	3.7
Acenaphthene	0.98
Acenapthylene	0.11
Fluorene	0.69
Naphthalene	0.072
Phenanthrene	13
1-methylnaphthalene	0
2-methylnaphthalene	0
SUM	18.552

3.095E-2	5.0%	Occasional Noncompliance	According to an Administrative Consent Order between NJDEP and Monsanto, dated July 24, 1989 (1989 ACO), on November 14, 1986, Monsanto submitted to NJDEP a report which stated that in the mid-1960s approximately 2,000 gallons of heat transfer liquid containing PCBs were landfilled on site. NJDEP filed a civil complaint against Monsanto on November 1, 1988 for failure to immediately notify NJDEP of the full nature and extent of discharges of hazardous substances which it caused to occur at the site, including the release of PCBs and petroleum hydrocarbons. PCBs used as non-contact cooling fluid starting in 1960. 2,000 gallons of PCB oil released during a 1967-1968 production upset were disposed on-site in the PCB disposal area/pit. In 1972, during conversion to non-PCB containing fluid, a tank containing 2,000 gallons of PCB oil was also discarded in the PCB disposal area/pit (PAS-00073345). Placement of PCB containing material intended to contain appropriately contaminants onsite & disposal areas voluntarily remediated in coordination with NJDEP by facility in late 1980s (PAP-00717529-30).	-20.0%	-20% CPG/SPG member - Continuous provision of funding and participation in PRP Group(s) actions to cooperate with governmental/regulatory entities to address environmental or public harm created by own activities	2.630E-2

Discharge Calcs	Direct Discharge Information	ASSUMPTIONS, REFERENCES	COMMENTS/NOTES
4.083333333	FEET/YEAR AVERAGE PRECIPITATION	Long term average annual precipitation includes floods and hurricane events occurring over time.	Data from Rutgers University.
37	ACRES - TOTAL SITE AREA (acres)	FDR page 1; confirmed with Google Earth	
25	ACRES - AFFECTED AREA	Based on PAP-00009386, it is estimated that approximately 1/3 of the site was occupied by buildings. Therefore, 2/3 of the site was assumed to be exposed soil prior to 1986 (approximately 25 acres).	Since the site closed in 1983, and all production facilities were dismantled in 1986, a two-part estimate - pre-1986 and post-1986 have been calculated. According to PAP-00009411 the site cap was still in the planning phase after 2017. It is assumed that the site wide cap has yet to be implemented. This is the first part of the calculation assuming that 2/3 of the site is exposed soil from 1955 to 1986.
4,046.86	METERS^2/ACRE		
101,172	METERS^2 (AFFECTED AREA)		
0.0001	METERS/YEAR (ERODED SOIL THICKNESS)	For this estimate, used a surface soil erosion rate of 0.1 mm/year, or 0.004 inches/year.	
10	METERS^3/YEAR (ERODED SOIL VOLUME)	VOLUME/YEAR DISCHARGED TO PASSAIC RIVER	
1955	Year site operations began	Pitt-Consol purchased the site in 1955 from Reilly Tar & Chemical, Inc. (FDR page 1)	
1986	Year site was dismantled and decontaminated	Pitt-Consol operated at the site until May 1983 when all manufacturing was discontinued. The site was then dismantled and decontaminated from 1984 to 1986 (FDR page 1)	
31	NUMBER YEARS DISCHARGE		
313.63165	METERS3 (TOTAL SOIL VOLUME DISCHARGED OVER TIME)		
1962.5	KG/M3 SOIL DENSITY	Fill includes sand, gravel, rock, cinders, ash, brick, concrete, wood, slag, metal, glass and trash (PAP-00009973). Used "silty sand and gravel" soil type from http://structx.com/Soil_Properties_002.html. Bulk density range 1442 KG/M3 to 2483 KG/M3, so use average. Average is 1962.5 kg/m3

1,704.94	kg Copper
12,925.54	kg Lead
166.19	kg Mercury
6,271.90	kg PAHs (Benzo(a)pyrene Equivalent)
15,929.19	kg PAHs (Other)
257.28	kg PCBs

37255.05 MASS (KG) DISCHARGED FROM SURFACE SOIL

Total concentration of PAH compounds for Benzo(a)pyrene Equivalent https://floridadep.gov/waste/petroleum-restoration/documents/benzo-pyrene-equivalents-conversion-table-one-sample.

Data below the Benzo(a)pyrene Equivalent Table

Used maximum surface sample PTC-S-E03-01 (0-2 ft bgs) (PAP-00009951 pdf p 119-120).

The site contained three hot oil heat transfer systems which used PCB-containing oils until 1968 (one heater) and 1972 (two heaters) (FDR page 8).

Total PCB concentration in sample SW16-SC-3C23-S2-6-8-050417, depth 6-8 ft bgs (PAP-00009381, table on pdf page 46, and FDR page 18)

Max concentrations found in PTC-S-E03-01 (0-2 ft bgs). (FDR page 10; Table 3 of PAP-00009951, pdf page 119)

Contaminant	Concentration (mg/kg)	Toxic Equivalency Factor	Benzo(a)pyrene Equivalents
Benzo(a)pyrene	7400.000	1.0	7400.0000
Benzo(a)anthracene	8600.000	0.1	860.0000
Benzo(b)fluoranthene	8700.000	0.1	870.0000
Benzo(k)fluoranthene	4100.000	0.01	41.0000
Chrysene	8900.000	0.001	8.9000
Dibenz(a,h)anthracene	660.000	1.0	660.0000
Indeno(1,2,3-cd)pyrene	3500.000	0.1	350.0000

DE Residential = 0.1 mg/kg; DE Industrial = 0.7 mg/kg

Total Benzo(a)pyrene Equivalents = **10189.9**

Discharge Calcs	Direct Discharge Information	ASSUMPTIONS, REFERENCES	COMMENTS/NOTES
4.083333333	FEET/YEAR AVERAGE PRECIPITATION	Long term average annual precipitation includes floods and hurricane events occurring over time.	Data from Rutgers University.
37	ACRES - TOTAL SITE AREA (acres)	FDR page 1; confirmed with Google Earth	
37	ACRES - AFFECTED AREA	Since the site closed in 1983, and all production facilities were dismantled in 1986, a two-part estimate - pre-1986 and post-1986 have been calculated. According to PAP-00009411 the site cap was still in the planning phase after 2017. It is assumed that the site wide cap has yet to be implemented. This is the second part of the calculation assuming that all buildings have been demolished and the site is bare soil from 1986 to present day.	
4,046.86	$METERS^2$/ACRE		
149,734	$METERS^2$ (AFFECTED AREA)		
0.0001	METERS/YEAR (ERODED SOIL THICKNESS)	For this estimate, used a surface soil erosion rate of 0.1 mm/year, or 0.004 inches/year.	
15	$METERS^3$/YEAR (ERODED SOIL VOLUME)	VOLUME/YEAR DISCHARGED TO PASSAIC RIVER	
1986	Year site was dismantled and decontaminated	Pitt-Consol purchased the site in 1955 from Reilly Tar & Chemical, Inc. (FDR page 1)	
2002	Pitt-Consol is the current owner of the site (FDR page 1)	Pitt-Consol operated at the site until May 1983 when all manufacturing was discontinued. The site was then dismantled and decontaminated from 1984 to 1986 (FDR page 1) End year of discharge period through 2002. A cover consisting of permeable fabric geomembrane and fill consisting of a layer of crushed stone and gravel, nominally between 2 and 5 ft thick, was placed in 2002 (PAP-00009973).	
16	NUMBER YEARS DISCHARGE		
239.574112	METERS3 (TOTAL SOIL VOLUME DISCHARGED OVER TIME)		
1962.5	KG/M3 SOIL DENSITY	Fill includes sand, gravel, rock, cinders, ash, brick, concrete, wood, slag, metal, glass and trash (PAP-00009973). Used "silty sand and gravel" soil type from http://structx.com/Soil_Properties_002.html. Bulk density range 1442 KG/M3 to 2483 KG/M3, so use average. Average is 1962.5 kg/m3	
470,164	KILOGRAMS (TOTAL SOIL DISCHARGED OVER TIME)		
Copper (Cu)

2.375E-3	10.0%	Periodic Noncompliacne	An incidence report to the Coast Guard, dated May 12, 1981, is listed on the inspection report and states that an "unknown" red liquid was released into the Passaic River by dumping or illegal discharge from Pitt-Consol on May 11, 1981. (PAS-00051363, PAS-00051497, PAS-00051507). Based on the Summary of Existing Environmental Data, Pitt-Consol Site, dated July 24, 1989, an oily, creosote-like staining was observed in fill on the northern portion of the site and coal-like and tar-like material have been observed in areas of the site, primarily on the western half of the facility in fill material (PAP-00016509-10). The PVSC Annual Report for 1972 stated that industrial waste was discharging to the Passaic River from the Roanoke Ave storm sewer, even though a concrete dam had been built to prevent overflow from the sanitary sewer into the storm sewer. In order to locate the source of the pollution, the Roanoke Avenue storm sewer was cleaned in late 1971. While preparing a visual inspection of the storm sewer, a manhole on the Pitt-Consol property exploded, injuring three men. Inspection of the sewer with a camera in January 1972 found a 10 inch connection discharging polluted water from the Pitt-Consol facility (PAS-00006274-5).	-20.0%	-20% CPG/SPG member - Continuous provision of funding and participation in PRP Group(s) actions to cooperate with governmental/regulatory entities to address environmental or public harm created by own activities	2.137E-3

4.923E-3	10.0%	Periodic Noncompliacne	The PVSC permit request filed in September 1985 was in response to a civil action by the EPA against Kleer Kast for violation of the federal Clean Water Act for discharging contact cooling water to Frank's Creek. On July 1, 1986, the company began discharging contact cooling water to the PVSC system rather than to surface water (PAS-00015237; PAS-00015262; PAS-00015264; PAS-00015296-298; PAS-00015302-303). On March 6, 1990, Kleer Kast reported to PVSC that approximately 50 gallons of Number 6 fuel oil were discharged to the sewer during a 1-hour period. The discharge resulted from a leak in a fuel oil recirculating line. PVSC issued a NOV to Kleer Kast on March 7, 1990 for the discharge (PAS-00015134-136; PAS-00015134-6). During a June 9, 1994 facility inspection, NJDEP documented that an oil-like substance was leaking from the foundation of the loading dock area of Alexandria Plastics, a tenant at the Kleer Kast Site (PAS-00014840; PAS-00015208).	20.0%	20% Failed to participate in conduct of allocation as offered by EPA	6.400E-3

PAHs (others detected)

69 YEARS DISCHARGED

68 MG/KG (TOTAL PAH MAX CONCENTRATION)

Other PAHs = Acenaphthene (7.6), Acenaphthylene (0.59 J), Anthracene (10), Fluorene (6.4), Naphthalene (3.9), Phenanthrene (40). Maximum PAH concentrations found in surface soil sample B-53(1-3) - PAP-00305837.

Historic fill was not a consideration for PAH concentrations for the purpose of this calculation.

0.000001 kg per mg (Merck Index)

5.26 KILOGRAMS DISCHARGED

PCBs

Documentation says no PCBs used or generated at the site during PPG owner/operator timeframe, and point to Lot 70 post-PPG owner/operator. However, highest PCB concentration found at other end of site (FDR page 4-7)

41 YEARS DISCHARGED

5 MG/KG (MAX CONCENTRATION)

Number of years reflect a 1930 start date for PCBs.
Total PCBs concentration in on-site surface soil sample B-52 (0-1) (PAP-00305864).
Transformers were likely present at the site because most manufacturing operations had transformers containing PCBs during PPG's period of operation. These could have led to releases from leaks, poor storage or disposal with replacement, or spills of PCB oils during refill.
No change to the PCBs concentration because maximum values are used for the purpose of this calculation. A sample id with an alternative maximum value was not suggested.

64,750	METERS^2 (AFFECTED AREA)		
0.0001	METERS/YEAR (ERODED SOIL THICKNESS)	For this estimate, used a surface soil erosion rate of 0.1 mm/year, or 0.004 inches/year.	
6	METERS^3/YEAR (ERODED SOIL VOLUME)	VOLUME/YEAR DISCHARGED to Passaic.	
1902	Year site operations began	Commencing in 1902 through September 1926, when the Plant commenced commercial operations, the Site was a satellite facility utilized solely for the storage of oil and manufactured gas. (PAP-00356759)	Newark Gas leased its Plant properties and franchises to the United Gas Improvement Company in 1898 which assigned the lease that same year to the Essex and Hudson Gas Company. Public Service Corporation of New Jersey acquired in 1903 the plant, property " and franchises of the Essex and Hudson Gas Company, which included the Site. The Essex and Hudson Gas Company and Newark Gas Company merged with and into PSE&G in 1939. (PAP-
2020	Year site operations ceased	FDR PDF PAGE 1, Operator: 1902 or 1909 to present (PAP-00140468; PAS-00007043-44). Owner: 1884 to present (PAS-00007043-44). On March 4, 2014, PSE&G submitted a Remedial Investigation Timeframe Extension which was approved by NJDEP on March 4, 2014. Therefore, the current applicable timeframe for the completion of a remedial investigation and submission of an RIR for the Site is May 7, 2016. (PAP-00130579)	
118	NUMBER YEARS DISCHARGE		
764	METERS^3 (TOTAL SOIL VOLUME DISCHARGED OVER TIME)		
1,963	KG/M^3 SOIL DENSITY	Fill reported as silt, clay sand and gravel. Bulk density range 1442 KG/M^3 to 2483 KG/M^3, so use average. (http://structx.com/Soil_Properties_002.html)	The historic fill contains heterogeneous mixtures of predominantly sand and gravel that can occur with cinders and other anthropogenic debris such as brick, wood, concrete, coal fragments. Portions of the historic fill material may also contain tar material and oil material (TM and OM) in areas . The Fill Unit is a continuous water-bearing unit that comprises the shallow aquifer beneath the Site, where the depth to groundwater typically ranges from 1 to 8 feet bsg. PCBs		FDR PDF PAGE 6 - PCBs were detected in many of the drums of oil that were drained from pieces of electrical equipment (i.e., oil circuit breakers) (PAP-00726563). Sampling of the oil removed from the oil circuit breakers revealed PCB concentrations from 6 ppm to 33,000 ppm. Seven soil samples were also collected below six of the Oil Circuit Breakers. Four of the samples contained PCBs ranging from 170 to 730 µg/kg. The remaining three oil circuit breakers were determined to contain less than 2 ppm PCBs; accordingly no additional soil samples were collected. The interim soil action level for PCBs used by NJDEPE at the time was 1,000 to 5,000 µg/kg. As none of the samples contained PCBs at these concentrations, no further sampling was recommended for this area (PAP-00726575-76).

3.018E-5	5.0%	Occasional Noncompliance	PVSC Annual Reports noted discharges of oil from the facility to the Passaic River in 1973 and 1974. In January 1991, PSEG was issued a Notice of Violation by the NJDEP for the January 28, 1991 discharge of kerosene from a leaking underground fill line at its Essex Generating Station at 155 Raymond Blvd. (PAP-00131028-29; PAP-00131033; PAP-00131037). According to the Environmental Documentation of Demolition Phase 3 Report, Essex Generating Station, during the structural demolition of the decommissioned Essex Generating Station concrete surfaces located within two areas of the Essex Generating Station were observed to be oil stained. These areas were the concrete floor in the turbine building; and the two underlying concrete slabs where the oil pots containing percent levels of PCBs were removed from the potential transformer cabinets. The sample collected below potential transformer 1 contained 13,000 ppm of PCBs, and the sample collected below potential transformer 4 contained 60 ppm. A mineral oil leak from a transformer, located hundreds of feet from the Passaic River or Lawyer's Ditch, occurred on September 16-17, 1993. No discharge to the Passaic River occurred. The mineral oil from the transformer and from the spill area was analyzed and shown to contain 10-11 ppm PCBs. It was estimated that 900 gallons of mineral oil were discharged to the gravel/soil beneath the transformer.	-20.0%	-20% CPG/SPG member - Continuous provision of funding and participation in PRP Group(s) actions to cooperate with governmental/regulatory entities to address environmental or public harm created by own activities	2.565E-5

7.811E-4	10.0%	Periodic Noncompliacne	Numerous violations: in 1969, violations concerning pollutants from the Harrison Gas Plant entering the Passaic River. A sample of the plant's outfall collected by the Department of Health on August 21, 1969, contained 363 ppm of ether soluble matter (usually inferred as oil) (PAP-00140328-29; PAP-00140419-20). PSE&G Harrison Gas Plant paid fines to the Coast Guard regarding oil/kerosene/tar spills to the Passaic River in the 1970s and 1980s and 1994 (see data report). On September 25, 1987, the EPA found PSE&G Harrison in violation of general facility requirements pertaining to PCBs. A penalty of $8,500 was assessed (PAS-00104676-77). Note: The nature of the violation was not described in further detail. A 1988 inspection found several violations concerning documentation and storing PCB waste more than one year after being placed into storage for disposal (PAP-00140392-95; PAP-00140436-37). In November 2004 and April 2010, PSE&G voluntarily reported un-manifested PCB shipment from the Harrison Gas Plant facility. In April 2011, PSE&G and U.S. EPA entered into a Consent Agreement and Final Order due to violating TSCA on three occasions by storing PCB waste and/or shipping PCB waste for disposal without identifying it as PCB on EPA Manifest Form 8700-22 (PAP-00130040-47; PAP-00130049-55). Facility manufactured gas from oil during early days, which generates wastes high in PAHs; manufactured gas plant (MGP) historical practices disposed of wastes on the facility or adjacent property. Former employees who worked at the Harrison Gas Plant prior to 1944 allegedly stated that on-site disposal of tar wastes on the ground occurred at the site (PAS-00013565-66). During testimony, a PSE&G chemist testified in deposition that he observed an area in the north corner of the Harrison Plant where solidified tar, clinkers, and debris had been buried and covered with gravel. As early as the 1940s, he noticed that the solidified tar associated with the buried waste would re-liquefy during the summer months and rise to the surface (PAS-00013567). It was also testified in deposition that some gas plant materials, such as coke, were stored on the ground and that other gas plant materials, such as tar, tarry and oily wastes, condensates, light oils, and spent oxide wastes were present in or on the ground due to leaks, spills, and occasional on-site disposal (PAS-00013571). Floating free product layers were observed in 7 piezometers along the river at thicknesses up to 1.79 feet (PAP-00128600) - this indicates that free phase product could have been discharged directly to the river with groundwater. Lead was also a site waste. A list of wastes generated by the PSE&G Harrison Gas Plant facility for the year 1997 included 6.78 tons of lead waste and 8 tons of lead and PCB waste. These waste streams were both transported off-site and landfilled (PAS-00104679-80).	-20.0%	-20% CPG/SPG member - Continuous provision of funding and participation in PRP Group(s) actions to cooperate with governmental/regulatory entities to address environmental or public harm created by own activities	7.030E-4

Allocator's Determinations Regarding
Legal Defenses Raised by Allocation Parties

QUALITY CARRIERS

QCI and QSI state that they received a release from Occidental in the Tierra/Maxus bankruptcy and Occidental is not entitled to recover at least $165 million dollars in response costs from QCI or QSI. Any responsibility for such responses costs must be deducted from any share of the OU-2 response costs attributable to QCI or QSI.

ALLOCATOR'S DETERMINATION – Though I have not had the opportunity to review the underlying settlement document and other potentially relevant facts associated with the release provided by OCC, assuming its validity, it is apparent that there is a high likelihood of success in any action against OCC to enforce the release. Given OCC's lack of participation in the allocations process, however, the Allocator does not believe that it is appropriate to account for the amount of any such release in the assignment of allocated shares. Rather, the Allocator notes the existence of the release and recommends that it be taken into account in determining the appropriate amount of any future settlement with EPA.

Revere Smelting & Refining Corp.

387 Avenue P	**Newark**	**NJ**	**07105**

Facility BS	CUF	CUF_Category	CUF_NOTES	COF	COF_NOTES	Facillty Adjusted BS
2.148E-6	0.0%	Historically Compliant or No Evidence	The RIR states that the Avenue P landfill, located just north of Revere Smelting, was used from the 1920s until the 1970s, and it was believed that the surrounding industrial companies and manufacturing plants used the landfill and adjacent areas beyond the property border of the landfill site as an illegal dump to dispose of hazardous materials, manufacturing by-products, solid waste/junk and process wastes (PAP-00125850). A 2008 RIR stated the Avenue P Landfill Site included land upon which the Revere-DE operated from April 1970 to December 31, 1972 as well as additional adjacent properties for a total of eight acres. The Avenue P site was created by filling in salt marshes in the early 1900s (PAP-00125850). In addition, the RIR noted that the highest concentrations of metals were detected in samples collected at the base of the landfill, indicating that the ash and glass layer present at the landfill/marsh interface is a likely source. This debris was likely deposited on site at a time when the area was predominantly marshland (PAP-00125886). Low probability that Revere is source of such contamination.	-20.0%	-20% CPG/SPG member - Continuous provision of funding and participation in PRP Group(s) actions to cooperate with governmental/regulatory entities to address environmental or public harm created by own activities	1.718E-6

Allocator's Determinations Regarding
Legal Defenses Raised by Allocation Parties

REVERE SMELTING

Revere argues that Revere-DE is liable only for the period of its actual ownership/operation of its OU2 related facility. Revere-DE did not indemnify the prior owner and operator of the facility and the seller warranted to Revere-DE that there were "no suits, actions, claims, investigations or inquiries by any governmental body … affecting any of the Corporations or … assets … or the ability to conduct business in the future." Rather the Seller "indemnifies and holds harmless the Buyer." As noted above, Revere-DE cannot be liable for the disposal of chemicals as part of the Avenue P Landfill after Revere-DE ceased operating because Revere-DE: (a) did not own the Avenue P landfill property; (b) Revere-DE did not operate the landfill; (c) did not arrange for the disposal; and (d) did not transport or arrange for transport of chemicals to the Avenue P Landfill. Therefore, Revere-DE is not liable for the COCs in the historic fill and the landfill contaminated soil.

ALLOCATOR'S DETERMINATION - Though Revere Smelting may have a sustainable argument regarding its allegation that it did not accept the CERCLA liability upon purchase of the facility site, there is an insufficient demonstration of applicable case law and facts to support this claim based on available data. Therefore, the Allocator leaves this matter as a topic for settlement discussions between Revere Smelting and EPA.

Secondly, though I have not had the opportunity to review the underlying settlement document and other potentially relevant facts associated with the release provided by OCC to Revere Smelting, assuming its validity, it is apparent that there is a high likelihood of success in any action against OCC to enforce the release. Given OCC's lack of participation in the allocations process, however, the Allocator does not believe that it is appropriate to account for the amount of any such release in the assignment of allocated shares. Rather, the Allocator notes the existence of the release and recommends that it be taken into account in determining the appropriate amount of any future settlement with EPA.

Discharge Calcs	Direct Discharge Information	ASSUMPTIONS, REFERENCES	COMMENTS/NOTES
4.08	FEET/YEAR AVERAGE PRECIPITATION	Long term average annual precipitation includes floods and hurricane events occurring over time.	Data from Rutgers University
5	ACRES - TOTAL SITE AREA (acres)	Acreage noted in the PA Report (PAS-00008137).	
2	ACRES - AFFECTED AREA	Rough estimate of the affected area based on a drawn image of the site on the Royce Global website (https://royceglobal.com/about/). The factory is shown, with the pond and the railroad to the left.	
4,046.86	METERS^2/ACRE		
8,094	METERS^2 (AFFECTED AREA)		
0.0001	METERS/YEAR (ERODED SOIL THICKNESS)	For this estimate, used a surface soil erosion rate of 0.1 mm/year, or 0.004 inches/year.	
1	METERS^3/YEAR (ERODED SOIL VOLUME)	VOLUME/YEAR DISCHARGED TO POND THAT LED TO PASSAIC	
1929	Year site operations began	FDR Page 1.	
1981	Year site processing and storage operations ceased	A 1987 letter noted that the copany discontinued business during Oct 1981, liquidated, and was dissolved (FDR Page 2).	
52	NUMBER YEARS DISCHARGE		
42	METERS^3 (TOTAL SOIL VOLUME DISCHARGED OVER TIME)		
1,979	KG/M^3 SOIL DENSITY	Soil type not specified in documents provided. Used https://websoilsurvey.sc.egov.usda.gov/App/WebSoilSurvey.aspx to get an idea of the soil type out there. Most is "Urban Land" but nearby soil types are loam/silt loam from 0-30 inches. Used structx.com/Soil_Properties_002.html to identify the density, selected silty clay and the average of the min (1602 kg/m3) and max (2355 kg/mg3).	Silt loam has an approximate bulk density of 1.33 g/cm3 (https://cropwatch.unl.edu/documents/USDA_NRCS_bulk_density_guide.pdf)
83,270	KILOGRAMS (TOTAL SOIL DISCHARGED OVER TIME)		
PCBs		PCBs were excavated from the transformer area in 1982 (PAS-0008153).	
51	YEARS DISCHARGED	Number of years reflect a 1930 start date for PCBs.	
50	MG/KG (MAX CONCENTRATION)	Eight 55 gallon drums of waste collected from a transformer leaking onto soil. Analysis indicated greater than 50 ppm PCBs (PAS-00102210; FDR Page 2).	
0.000001	kg per mg (Merck Index)		
4	KILOGRAMS DISCHARGED		
Diesel fuel		Spill in 1983 and was still being remediated in 1984 (PAS-00102173).	
1	YEARS DISCHARGED	Sampling of the pond in March/August of 1984 revealed high levels of benzene, toluene, ethylbenzene and zinc in pond sediments (PAS-00102187).	
	MG/KG (AVERAGE CONCENTRATION)	No data provided.	
0.000001	kg per mg (Merck Index)		
0	KILOGRAMS DISCHARGED		
Lead		Detected in soil samples in 1984 (PAS-00102183).	
52	YEARS DISCHARGED		
273.0	MG/KG (AVERAGE CONCENTRATION)	Highest concentration from RC-3S collected in 1984 (PAS-00102183). Depth and location details were not provided.	
0.000001	kg per mg (Merck Index)		
23	KILOGRAMS DISCHARGED		

PAHs (oils)		
52	YEARS DISCHARGED	Four 55-gallon drums of compressor oil, oily sludge, soil spill identified in 1982 (FDR Page 2). Also, spills of No. 6 heating oil cause soil contamination (FDR Page 2). Oil was still present in February 1984 sampling (PAS-00102226-8).
	MG/KG (TOTAL PAH MAX CONCENTRATION)	No data provided.
0.000001	kg per mg (Merck Index)	
0	KILOGRAMS DISCHARGED	
PAHs (others detected)		Other PAHs = Benzo(g,h,i)perylene, Fluorene, Fluoranthene, Indeno(1,2,3-cd)pyrene, Naphthalene, 2-Methylnaphthalene.
	YEARS DISCHARGED	No data provided.
	MG/KG (TOTAL PAH MAX CONCENTRATION)	
0.000001	kg per mg (Merck Index)	
0	KILOGRAMS DISCHARGED	
DDx		NOT DETECTED (FDR)
0	YEARS DISCHARGED within DDx Timeline	
	MG/KG (MAX CONCENTRATION)	
3.785	L per gallon (Merck Index)	
0.000001	kg per mg (Merck Index)	
0	KILOGRAMS DISCHARGED	
Dieldrin		NOT DETECTED (FDR)
0	YEARS DISCHARGED within Dieldrin Timeline	
	MG/KG (MAX CONCENTRATION)	
3.785	L per gallon (Merck Index)	
0.000001	kg per mg (Merck Index)

3.637E-5	10.0%	Periodic Noncompliacne	A 1971 PVSC Annual Report notes that Royce Chemical was pumping industrial waste into a storm drain on Carlton Avenue. The material was reportedly diverted to a sanitary line when the Inspector informed them of the violation (PAS-00034516; PAS-00034633). Polluting materials from Royce Chemical were again discharged to the Carlton Hill storm drain and ultimately to the Passaic River in January and February 1973, twice in 1974, and in 1979 (PAS-00034660; PAS-00034762-3; PAS-00034785; PAS-00034904-5; PAS-00008134). Spills of No. 6 heating oil reportedly caused soil contamination at the site. Waste disposal manifests indicate that soils and oily waste were removed from the Royce Chemical facility in May and August 1983 (PAS-00008141).	20.0%	20% Failed to participate in conduct of allocation as offered by EPA	4.728E-5

DE Residential = 0.1 mg/kg; DE Industrial = 0.7 mg/kg

Total Benzo(a)pyrene Equivalents = **38.7**

PCBs

13 YEARS DISCHARGED
161 MG/KG (MAX OF REPORTED CONCENTRATIONS)

The highest concentration of PCBs was detected in a surface soil sample collected from soil boring SB-24 at a depth of 0 to 0.5 feet bgs at AEC 5 (FDR page 6; PAP-00364274)

According to a Remedial Action Report, dated August 2001, concentrations of PCBs in soils that exceeded 50 ppm were detected in the vicinity of one soil boring (SB-24). The extent of soils containing PCBs greater than 50 ppm was defined to be within a 50-foot by 20-foot rectangular area surrounding the soil boring. Soil that contained 50 ppm or more PCBs was excavated and disposed off-site (FDR Page 6-7)

0.000001 kg per mg (Merck Index)
7 KILOGRAMS DISCHARGED

SUMMARY CMASS ESTIMATES:

368.59	kg Copper
1,316.38	kg Lead
1.01	kg Mercury
1.70	kg PAHs (Benzo(a)pyrene Equivalent)
193.75	kg PAHs (Other)
7.06	kg PCBs

1,888.49 MASS (KG) DISCHARGED FROM SURFACE SOIL

3.734E-5	10.0%	Periodic Noncompliacne	At least 11 inspections conducted by NJDEP between January 18, 1980, and May 19, 1982, identified what was described as “leachate of an oil substance is presently entering Newark Bay” and/or “leachate into bay” and/or an “oil like material,” among other similar descriptions. The source of the discharge was documented as being unknown (PAP-00186512-21, 6530-1, 6881, 6908, 6913, 7305, 7310; PAP-00365518-9). dating back to 1979, NJDEP personnel had noted the following deficiencies at the facility: (1) poor, careless housekeeping resulting in extensive spillage; (2) a contaminated stormwater discharge into Newark Bay; (3) open drums in deteriorated condition stored in improper storage areas; (4) an oily material surfacing in the Newark Bay near the facility’s shoreline; and (5) a purple- colored groundwater discharge into Newark Bay (PAP-00185827). According to a Civil Action brought by the State of New Jersey against Inland, dated March 19, 1980, Inland failed to comply with and implement all of NJDEP's requirements of Inland’s Temporary Operating Authority; Inland since or from about October 30, 1979, had failed and continued to fail to comply with the October 30, 1979, Administrative Order; and, Inland's acts since or from about October 30, 1979, had constituted and continued to constitute pollution of the environment or a potential threat of pollution of the environment (PAP-00365511). According to a June 23, 1993, Administrative Consent Order, on October 30, 1979, the facility was issued an Administrative Order by the New Jersey Department of Environmental Protection and Energy (NJDEPE). The order stated that routine inspections conducted by NJDEPE on September 19, October 9, October 16 and October 24 revealed that the facility grounds were contaminated with various chemicals; therefore, the facility was to cease accepting waste and clean up all spills and contaminated soil (PAS-00011254). On October 10, 1982, an explosion and fire destroyed much of the facility. The New Jersey Department of Environmental Protection (NJDEP) closed the site two days later (PAS-00091937).	-20.0%	-20% CPG/SPG member - Continuous provision of funding and participation in PRP Group(s) actions to cooperate with governmental/regulatory entities to address environmental or public harm created by own activities	3.360E-5

Facility BS	CUF	CUF_Category	CUF_NOTES	COF	COF_NOTES	Facillty Adjusted BS
1.418E-5	10.0%	Periodic Noncompliacne	A NOV was issued by PVSC to Schiffenhaus for a copper exceedance in October 1996. Schiffenhaus subsequently advised in a July 1996 letter that the copper source may be copper phthalocyanine pigments (PAS-00017812; PAS-00017942; PAS-00017954). In May 1995, Schiffenhaus was “out of compliance” with “Local Pretreatment Limitations” for copper (PAS-00017986-87). Reportedly, the facility was over the “threshold limit” for cadmium, chromium, copper, mercury and lead (PAS-00017991). In January 1997, a NOV was issued by PVSC to Schiffenhaus due to the facility's failure to meet compliance milestones established in its Sewer Connection Permit for “local limits” on metals. PVSC advised that Schiffenhaus was determined to be in "significant non-compliance" with PVSC rules and regulations (PAS-00017812; PAS-00017941-42). On October 17, 1997, PVSC filed a complaint in the Superior Court of the State of New Jersey against Schiffenhaus. The complaint alleged that Schiffenhaus violated its PVSC discharge permit by not being in compliance with “local pretreatment limits” established by the permit. Schiffenhaus agreed to pay a fine of $1,000 to settle the PVSC legal action (PAS-00017813; PAS-00017933).	20.0%	20% Failed to participate in conduct of allocation as offered by EPA	1.844E-5

3.551E-4	10.0%	Periodic Noncompliacne	In 1956, it was noted that Seton dumped solid industrial waste into the sanitary sewer. In 1978, PVSC documented poor housekeeping and illegal industrial discharges to the combined sanitary and storm sewer system on Verona Avenue. Reportedly, the discharged material contained “high pH liquids as well as animal fats, greases and oils.” Seton representatives indicated that they could not afford the pre-treatment that was required (PAS-00008172). According to the Civil Action Consent Order filed on May 2, 1991, Seton’s wastewater discharge continued to exceed “pretreatment effluent limitations” for chromium, sulfur, and pH (PAS-00102337-338)	20.0%	20% Failed to participate in conduct of allocation as offered by EPA	4.616E-4

Discharge Calcs	Direct Discharge Information	ASSUMPTIONS, REFERENCES	COMMENTS/NOTES
4.08	FEET/YEAR AVERAGE PRECIPITATION	Long term average annual precipitation includes floods and hurricane events occurring over time.	Data from Rutgers University
13	ACRES - TOTAL SITE AREA (acres)	FDR Page 1. 11.04 acres (PAP-00126535) to 13 acres (PAP-00126441). Max value used.	
0.65	ACRES - AFFECTED AREA	Lot appears mostly paved based on Google Earth aerial photos from 1995 and Feb 2017 Final Soil RI (PAP-00126443), which states that 95% of the site is paved. The 2017 Soil RI also states that in the past, the site was entirely covered with impervious surfaces (PAP-00126564). Since operations began in 1901, will assume that some of the lot was not paved, ~5%.	
4,046.86	$METERS^2$/ACRE		
2,630	$METERS^2$ (AFFECTED AREA)		
0.0001	METERS/YEAR (ERODED SOIL THICKNESS)	For this estimate, used a surface soil erosion rate of 0.1 mm/year, or 0.004 inches/year.	
0	$METERS^3$/YEAR (ERODED SOIL VOLUME)		
1901	Year site operations began	FDR Page 1. Production of paints and varnish.	
1999	Year site processing and storage operations ceased	FDR Page 1. Ceased operations.	
98	NUMBER YEARS DISCHARGE	FDR Page 1	
26	$METERS^3$ (TOTAL SOIL VOLUME DISCHARGED OVER TIME)		
1,963	KG/M^3 SOIL DENSITY	0-4 ft of fill beneath concerete is reddish brown silt with some fine to medium sand and gravel (PAP-00126564). Bulk density range for silty sand and gravel is 1442 KG/M^3 to 2483 KG/M^3, so use average. (http://structx.com/Soil_Properties_002.html)

4,229.77	MASS (KG) DISCHARGED FROM SURFACE SOIL

Discharge Calcs	Direct Discharge Information	ASSUMPTIONS, REFERENCES	COMMENTS/NOTES
4.08	FEET/YEAR AVERAGE PRECIPITATION	Long term average annual precipitation includes floods and hurricane events occurring over time.	Data from Rutgers University
13	ACRES - TOTAL SITE AREA (acres)	FDR Page 1. 11.04 acres (PAP-00126535) to 13 acres (PAP-00126441). Max value used.	
0.65	ACRES - AFFECTED AREA	Lot appears mostly paved based on Google Earth aerial photos from 1995 and Feb 2017 Final Soil RI (PAP-00126443), which states that 95% of the site is paved. The 2017 Soil RI also states that in the past, the site was entirely covered with impervious surfaces (PAP-00126564). Since operations began in 1901, will assume that some of the lot was not paved, ~5%.	
4,046.86	$METERS^2$/ACRE		
2,630	$METERS^2$ (AFFECTED AREA)		
0.0001	METERS/YEAR (ERODED SOIL THICKNESS)	For this estimate, used a surface soil erosion rate of 0.1 mm/year, or 0.004 inches/year.	
0	$METERS^3$/YEAR (ERODED SOIL VOLUME)		
1998	Year site operations began	Release to the Passaic documented March 1998 (FDR Page 10)	
1999	Year site processing and storage operations ceased	Conservatively assume a one year spill period (FDR Page 10)	
1	NUMBER YEARS DISCHARGE		
0	$METERS^3$ (TOTAL SOIL VOLUME DISCHARGED OVER TIME)		
1,963	KG/M^3 SOIL DENSITY	0-4 ft of fill beneath concrete is reddish brown silt with some fine to medium sand and gravel (PAP-00126564). Bulk density range for silty sand and gravel is 1442 KG/M^3 to 2483 KG/M^3, so use average. (http://structx.com/Soil_Properties_002.html)	
516	KILOGRAMS (TOTAL SOIL DISCHARGED OVER TIME)		
		Specific to the March 1998 release. A leak in an AST with slurry and cracks in the AST pad resulted in a release to the Passaic. No known samples were collected (FDR Page 10, PAP-00126438). Will assume contamination levels from main spreadsheet.	
Copper (Cu)			
1	YEARS DISCHARGED		
1,530	MG/KG (MAX CONCENTRATION)	B8-0.0-0.5 from 0-0.5 ft bgs (PAP-00367337). Used max result from shallowest depth.

DE Residential = 0.1 mg/kg; DE Industrial = 0.7 mg/kg

Total Benzo(a)pyrene Equivalents = **3.3**

PCBs		PCBs were used in a transformer (and possibly other electrical equipment) at the site (PAP-00018252, 257, 328, 332). Transformers were likely present at the site because most manufacturing operations had transformers containing PCBs during the period of operation. These could have led to releases from leaks, poor storage or disposal with replacement, or spills of PCB oils during refill.	Stanley generated and shipped 9.86 tons of undrained electrical transformers containing PCBs in 1993 (PAP-00018238).

Allocator's Determinations Regarding
Legal Defenses Raised by Allocation Parties

STANLEY BLACK & DECKER

Stanley Black & Decker note that OCC is currently implementing the Remedial Design for OU2 ("RD"), which is projected by EPA to cost approximately $165 million. OCC released 41 parties, including Stanley, from OCC's claim for these RD costs. Accordingly, any allocation of OU2 costs that includes OCC and Stanley (and the other parties to the release) must reflect OCC's release of this liability.

ALLOCATOR'S DETERMINATION – Though I have not had the opportunity to review the underlying settlement document and other potentially relevant facts associated with the release provided by OCC, assuming its validity, it is apparent that there is a high likelihood of success in any action against OCC to enforce the release. Given OCC's lack of participation in the allocations process, however, the Allocator does not believe that it is appropriate to account for the amount of any such release in the assignment of allocated shares. Rather, the Allocator notes the existence of the release and recommends that it be taken into account in determining the appropriate amount of any future settlement with EPA.

Discharge Calcs	Direct Discharge Information	ASSUMPTIONS, REFERENCES	COMMENTS/NOTES
4.083333333	FEET/YEAR AVERAGE PRECIPITATION	Long term average annual precipitation includes floods and hurricane events occurring over time.	Data from Rutgers University
0.4	ACRES - TOTAL SITE AREA (acres)	FDR page 1	
0.08	ACRES - AFFECTED AREA	From the facility map on PAS-00044655, it appears there were buildings and other sturctures. Only part of the site was shown as unpaved. For this calculation a conservative estimate of 20% of the total site area was assumed to be unpaved.	
4,046.86	$METERS^2$/ACRE		
324	$METERS^2$ (AFFECTED AREA)		
0.0001	METERS/YEAR (ERODED SOIL THICKNESS)	For this estimate, used a surface soil erosion rate of 0.1 mm/year, or 0.004 inches/year.	
0.03	$METERS^3$/YEAR (ERODED SOIL VOLUME)	VOLUME/YEAR DISCHARGED TO PASSAIC RIVER	
1986	Year site operations began	Sequa Corporation changed its name to Sun Chemical Corporation, December 31, 1986 (FDR Page 1)	
1993	Year of site-wide soil remeditation (PAP-00120463)	Operations ended on December 31, 2003 but equipment cleaning and dismantling activities were still being conducted as part of the cessation of operations. The 1992-1993 site-wide remediation included removal of the top two feet of soil from accessible areas of the site and placement of a concrete/asphalt cap over the entire site (PAP-00120487)	
7	NUMBER YEARS DISCHARGE		
0	$METERS^3$ (TOTAL SOIL VOLUME DISCHARGED OVER TIME)		
1962.5	KG/M3 SOIL DENSITY	Fill reported as 0.504.5 feet of glass, bricks, cement, with brown-black silty/sandy clay and some gravel (PAS-00044960 through PAS-00044964) soil boring logs. Bulk density range 1442 KG/M3 to 2483 KG/M3, so use average. (http://structx.com/Soil_Properties_002.html)	
445	KILOGRAMS (TOTAL SOIL DISCHARGED OVER TIME)		
		The facility site is not located on regional Historic Fill (FDR page 8)

0.000001 kg per mg (Merck Index)
0 KILOGRAMS DISCHARGED

Total concentration of PAH compounds for Benzo(a)pyrene Equivalent https://floridadep.gov/waste/petroleum-restoration/documents/benzo-pyrene-equivalents-conversion-table-one-sample.

Historic fill was not a consideration for PAH concentrations for the purpose of this calculation.

Data below the Benzo(a)pyrene Equivalent Table

Sample B-12/1 depth 0-6 inches. (PAP-00381910-12)
Historic fill was not a consideration for PAH concentrations for the purpose of this calculation.

The highest concentration of PCBs was found in sample 3-107 (depth 0-6 inches) (PAS-00045069)
Historic fill was not a consideration for PCB concentrations for the purpose of this calculation.

During January 1993, the area with PAH contamination was excavated down to two feet to the perimeter of the site and covered with clean fill (FDR page 16)

Maximum concentrations listed in review of past and present areas of concern (table from PAP-00381912; table on FDR page 8 and PAS-00045320). Sample collected from New Tank Area in front of Press Room. Sample B-12/1 depth of 0-6 inches

Table (PAP-00381912) indicates that Benzo(b)fluoranthene and Benzo(k)fluoranthene were coeluted

Contaminant	Concentration (mg/kg)	Toxic Equivalency Factor	Benzo(a)pyrene Equivalents
Benzo(a)pyrene	74.000	1.0	74.0000
Benzo(a)anthracene	110.000	0.1	11.0000
Benzo(b)fluoranthene	240.000	0.1	24.0000
Benzo(k)fluoranthene	240.000	0.01	2.4000
Chrysene	120.000	0.001	0.1200
Dibenz(a,h)anthracene	17.000	1.0	17.0000
Indeno(1,2,3-cd)pyrene	56.000	0.1	5.6000

DE Residential = 0.1 mg/kg; DE Industrial = 0.7 mg/kg

Total Benzo(a)pyrene Equivalents = **134.1**

B-12/1 depth 0-6 inches. (PAP-00381910-12)	
Anthracene	12
Acenaphthene	0
Acenaphthylene	20
Fluorene	0
Naphthalene	47
Phenanthrene	37
2-Methylnaphthalene	0
SUM	116

SUMMARY CMASS ESTIMATES:

0.34 kg Copper
0.28 kg Lead
0.01 kg Mercury
0.06 kg PAHs (Benzo(a)pyrene Equivalent)
0.05 kg PAHs (Other)
0.40 kg PCBs

1.516E-6	5.0%	Occasional Noncompliance	A May 11, 1992 Memorandum documented a lead violation for Sun Chemical Corporation for a sample collected on April 21, 1992 (PAP-00374626; PAS-00111661; PAS-00128931). A 1987 survey found the ground, building surfaces and drums stored near the plant were stained purple, and it was stated that it was believed these stains were from pigments manufactured by Sun Chemical Company (PAP-00031574). In 1990, it was reported that the driveway located between Arkansas Chemical and Sun Chemical Corporation was stained with a magenta colored substance, which also existed on Sun Chemical Corporation's site. A strip like drain running down the center of the driveway contained standing water with a noticeable sheen on it (PAP-00031576-77). According to a February 13, 1991 Memorandum, on November 26, 1990, a RCRA investigation was conducted at Sun Chemical Corporation to investigate “alleged dumping and sloppy housekeeping practices” at the site. The site tour confirmed the discoloration of the surrounding areas as reported in incident No. 90-10-24-1208 (PAS-00044985; PAS-00111388).	-20.0%	-20% CPG/SPG member - Continuous provision of funding and participation in PRP Group(s) actions to cooperate with governmental/regulatory entities to address environmental or public harm created by own activities	1.288E-6

Allocator's Determinations Regarding
Legal Defenses Raised by Allocation Parties

TEXTRON

Textron states that it received a release from Occidental Chemical Corporation ("Occidental") in the Tierra/Maxus bankruptcy and Occidental is not entitled to recover at least $165 million dollars in response costs from Textron. Any responsibility for such responses costs must be deducted from any share of the OU-2 response costs attributable to Textron.

ALLOCATOR'S DETERMINATION – Though I have not had the opportunity to review the underlying settlement document and other potentially relevant facts associated with the release provided by OCC, assuming its validity, it is apparent that there is a high likelihood of success in any action against OCC to enforce the release. Given OCC's lack of participation in the allocations process, however, the Allocator does not believe that it is appropriate to account for the amount of any such release in the assignment of allocated shares. Rather, the Allocator notes the existence of the release and recommends that it be taken into account in determining the appropriate amount of any future settlement with EPA.

HISTORY OF SEWER COLLECTION AND TREATMENT IN THE PASSAIC VALLEY

HISTORY OF SEWER COLLECTION AND TREATMENT IN THE PASSAIC VALLEY

One of the primary pathways for the release of COCs to the Passaic River and OU2 was via connection with the local sewer systems that collected wastes from residential and industrial properties in the Passaic River Valley – the Passaic Valley Sewer Commission (PVSC) and its predecessor sewer collection systems. The great majority of Allocation Parties discharged COCs to the Passaic River via sanitary or stormwater sewer connections.

Encompassing approximately 155 square miles, including 48 municipalities in parts of Bergen, Essex, Hudson, Passaic and Union Counties, the PVSC services approximately 1.4 million residents, more than 5,000 commercial entities and 200 significant users (FEMA - *Environmental Assessment Passaic Valley Sewerage Authority Floodwall and On-Site Power System Construction Newark, Essex County, New Jersey, 4086-DR-NJ PW4701, June 2015*). The PVSC owns, operates and maintains a 22-mile long Main Intercepting Sewer that traverses Paterson, Clifton, Passaic, Nutley, Belleville, and Newark along its route to the Wastewater Treatment Plant, or Publicly Owned Treatment Works (POTW) in Newark, which is located along Wilson and Doremus Avenues adjacent to Newark Bay. Along this Main Intercepting Sewer, or "Trunk Line", there are 11 Branch Interceptor Sewers (18 total miles), as well as several Lateral and Local Sewer Connections (approximately 2,000 total miles) that receive flow from local municipalities' collection systems. In serving the wastewater needs of its residents, businesses, and industries, the PVSC sewer system processes approximately 330 million gallons per day, about a quarter of all the waste generated in all of New Jersey.

The PVSC is one of the oldest and largest regional sewerage commissions in the country, established in 1902, but sewer construction and operation in this part of the country goes back even further. As early as 1854, Newark's first sewer was completed, carrying waste under Broad Street running east under Park Place and Rector Street before emptying into the Passaic River (PAP-00701819). Even though hundreds of miles of sewer and interceptor lines were in place by the turn of the century, accommodating almost all of Newark's homes and business, all waste still flowed into the Passaic River, untreated (PAP-00701823).

Diverting waste away from the immediate vicinity of a residence or business to the river on the other side of town solved one problem, but it created another—a polluted Passaic River. In 1895, the boards of health of the lower Passaic River Valley described the condition of the river as causing "nauseating odors, increased sickness, and economic losses" (PAP-00701823). In the late 1890s, a state investigatory commission, organized to study different sewage disposal options, recommended that a trunk sewer be built along the Passaic River to intercept and carry sewage into Newark Bay. To oversee the ambitious engineering endeavor, the PVSC was established in 1902 and construction of the new Trunk Line began in 1912. By 1924, the Trunk Line was finally complete, linking 22 municipalities along the Passaic River draining 80 square miles from Patterson to Newark Bay, where raw sewage was treated at a pumping station before plunging into the Newark shaft to an outfall in Newark Bay and eventual diffusion into New York Bay. The 280-foot concrete-lined shaft was the nation's first deep shaft outfall pressure tunnel (PAP-00701823).

Given the sheer size, scope, complexity, and engineering challenges of the PVSC Sewer System, its infrastructure and operation has undergone many changes and modifications over the past century, as one would expect. Lines have been added and replaced, treatment systems have been upgraded and expanded, and much more all in the effort to accommodate the volume of wastewater and stormwater while minimizing pollution, within the limitations of physics and engineering. One such addition came in the form of Combined Sewer Overflows, or CSOs. To accommodate larger waste volumes during wet weather overflow events, CSOs were constructed at various locations along the Interceptor Sewer lines, mostly the Trunk Line, but along the Branch Interceptors as well. During dry weather events, the sewer lines (Sanitary, Stormwater, and Combined) eventually all lead to their respective Interceptor sewers, which then carries contained sewerage to the POTW to be treated.

However, in wet weather events, water volume in the PVSC collection system can exceed the POTW's capacity to effectively process and treat it. In such events, the excess wastewater and stormwater is diverted via regulator chambers and then released via bypass valve directly to the Passaic River, via CSOs. The regulator chambers are usually located where sewage districts, or Collection Areas, join the trunk sewer line (PAP-00342195). Collection Areas are sections of the municipalities that are defined by their shared flow to one particular CSO. For example, the Verona Avenue Collection Area on the west side of the Passaic River (river mile 8) covers an area of over 387 acres in northwest Newark. In dry weather events, all discharge from this area makes its way to the Trunk Line (at river mile 8), with eventual flow to the POTW at Newark Bay. But in wet weather events, when the water volumes exceed the capacity of the POTW, the Verona Avenue Bypass may be employed to divert excess wastewater and stormwater into the Passaic River, untreated.

This same operation applies to all of the Collection Areas and CSOs in the PVSC sewer system. In addition to the official CSO Collection areas, there is also the Yantacaw Bypass and the Union River Outlet collection systems. In wet weather events, if the POTW at Newark Bay has exceeded its capacity to handle the water volume, any wastewater and stormwater contents of the Trunk Line north of Yantacaw Bypass (River Mile 11) in Clifton gets released into the Passaic River at the Yantacaw Bypass. Similarly in wet weather events, if the POTW at Newark Bay has exceeded its capacity to handle the water volume, the municipalities of Montclair, Bloomfield, Orange, Belleville, Glen Ridge, East Orange, Newark, West Orange and Little Falls that have sewer discharge below Yantacaw Bypass and above Union Outlet (river mile 8) have their combined wastewater and stormwater released into the Passaic River via bypass at the Union River Outlet.

The PVSC system is large and complex and can look very different at any given time and place. In general, the PVSC Sewer System operates with the Interceptor Sewers (Main and Branch) carrying discharge to the POTW for treatment, except in wet weather events when the POTW is beyond its capacity to process the water volume received. In those cases, the CSOs and Bypasses are employed to divert the untreated discharge from their respective Collection Areas into the Passaic River. Attachment M provides maps indicating the general layout of the PVSC collection system, the location of Allocation Party facilities, and the location of primary CSOs and Bypasses.

6/1/75	6/1/75	1.75	LPRSA0195992	15.9	1.2	1.16	0.01	1.57
Total		3.85				1.46	0.02	2.36
Average dry weather flow (MGD):			LPRSA0195989	**0.14**				
Combined flow to produce an overflow (MGD):			LPRSA0195989	**5.60**				
Total Observation Period:								
4/24/1975	6/6/1975	**1032.00**	LPRSA0195992	LPRSA0195992				

Overflow percentage of total time= **0.37%**
Percentage CSO Overflow/Total Flow = **61.94%**

Note: At times, tidal levels caused tide gates to remain closed during part of rainfall, resulting in reduced overflow to river.

1. PURPOSE

At the request of counsel for the Lower Passaic River Study Area ("LPRSA") Small Parties Group ("SPG"), I was asked to evaluate, based upon available resources, the relative contributions of the main sources of Contaminants of Concern ("COCs") to the LPRSA (the "Site"). In particular, this report evaluates the collective contributions of parties not participating in an allocation proceeding relative to the collective contributions of the Participating Allocation Parties ("PAPs"). This report does not attempt to identify or otherwise assess the existence of orphan shares relating to contamination in the LPRSA, as a solvency review has not been conducted.

2. QUALIFICATIONS

As a Principal and Co-Founder of Axlor Consulting LLC, I work on solutions to economic, environmental, insurance, and product liability issues that arise in litigation, negotiation, business, and regulatory matters. I have been an environmental and business consultant for over 35 years, during which time I have worked on many projects involving contaminated sediment sites and conceptual site models. My experience includes modeling historic industrial processes and the development of mass balances on behalf of private parties and government agencies for litigation and management purposes. I have been retained numerous times regarding complex allocation issues involving evaluation of historic contamination sources to rivers, harbors, groundwater, and land. I have co-authored articles on allocation and have lectured on allocation issues in the context of environmental litigation risk analysis and as a component of the ASTM International best practice standard that addresses environmental allocation issues,[1] for which I have served as technical contact since the standard was first approved in 2001.

[1] ASTM Standard E2137-17, "Standard Guide for Estimating Monetary Costs and Liabilities for Environmental Matters."

I hold a B.S. degree in chemical engineering; a B.S. degree in humanities and engineering (in the Science, Technology & Society Program with a focus on environmental studies); and an M.S. degree in management science (with concentrations in applied economics, corporate strategy, and management of technological innovation) from the Massachusetts Institute of Technology. As part of this education and related research, I studied industrial processes and mass balances; modeled flows of contaminants in air and water; studied environmental science, law and regulations; and developed complex quantitative analyses for decision-making.

Additional information regarding my experience, including examples of mass balance and allocation projects, is contained in my resume, attached in Exhibit 1.

3. METHODOLOGY AND DOCUMENTS CONSIDERED

To develop this report, I reviewed the large collection of Site-related documents listed in Appendix A. I have conducted extensive research to identify the historical sources of COCs to the LPRSA, including review of:

- Numerous historical documents related to industrial development in the Passaic River ("River") area;
- LPRSA investigations conducted for the EPA and other parties;
- Numerous documents related to operations and discharges of the Passaic Valley Sewerage Commission ("PVSC") and local municipalities; and
- Scientific studies related to sources of specific COCs to the Passaic River watershed, including studies of sources of heavy metals (copper, lead and mercury) to the PVSC;

studies conducted by the New York Academy of Sciences related to PCBs, dioxins,[2] mercury, and PAHs; dioxin fingerprinting studies; and studies of copper and lead mass flows.

With the available documents, I estimated the number of parties that likely contributed COCs to the LPRSA and, to the extent feasible, quantified the order of magnitude of these COC contributions. I also researched the contributions of the PAPs relative to the main sources of COCs to the LPRSA. The documents I relied upon for this report, which are typical of those normally relied upon by allocation experts examining the history of pollutant discharges at a site, are cited in the footnotes.

This report is based on the documentation reviewed to date. I will continue to review information as it is made available to me, and may update my opinions accordingly. The opinions offered herein are offered to a reasonable degree of professional certainty.

4. EXECUTIVE SUMMARY

4.1 Background

The current allocation proceeding is being conducted to evaluate the relative contributions by the PAPs of COCs in Operable Unit 2 ("OU-2"), defined as the lower 8.3-mile portion of the 17-

[2] The NYAS study used the term "dioxins" as shorthand for the suite of 210 polychlorinated dibenzo-p-dioxin and polychlorinated dibenzofuran compounds (PCDDs/PCDFs), including 2,3,7,8-TCDD and "dioxin-like compounds" such as coplanar PCBs, polychlorinated naphthalenes, and brominated and chlorinated/brominated dioxins. Of these, the compound 2,3,7,8-TCDD is the most toxic. The report also used "dioxins" to refer to data sets where fewer than the 210 compounds were measured. This report follows the NYAS convention and uses "dioxins" to mean 2,3,7,8-TCDD, TCDD toxic equivalents ("TEQ"), or PCDDs/PCDFs, unless otherwise noted. Source: G.R. Munoz and M.A. Panero, New York Academy of Sciences, Pollution Prevention and Management Strategies for Dioxins in the New York/New Jersey Harbor, August 2006, pp.33-34.

mile LPRSA.[3] Due to the nature of historical contaminant transport into and within the entire LPRSA, discharges of COCs into any portion of the LPRSA are all potential contributors of COCs in in the LPRSA, including OU-2. Therefore, when conducting an equitable allocation for the OU-2 COCs, it is important to consider all historical discharge sources to the LPRSA. As my evaluation shows, many of the sources of such discharges are not included in this allocation.

The COCs identified in EPA's 2016 Record of Decision ("ROD") for OU-2 of the LPRSA are:[4]

- Dioxins and furans
- Polychlorinated biphenyls ("PCBs")
- Mercury
- Dichlorodiphenyltrichloroethane ("DDT")
- Copper
- Dieldrin
- Polycyclic aromatic hydrocarbons ("PAHs")
- Lead

EPA has recognized that there are numerous sources of these COCs, including industrial point sources as well as regional sources such as the Upper Passaic River, Newark Bay, tributaries, and municipal and PVSC and other municipal sewer overflows.[5] As discussed in Section 5 below, EPA's Remedial Investigation indicates that the largest ongoing source of contamination in OU-2 sediments is, by far, the resuspension of legacy (*i.e.*, historical) contamination in sediments. Thus, in performing an allocation for OU-2, it is critical to have as complete a picture as possible of all of the historical sources of contamination to OU-2. This report shows that COCs in OU-2

came from sources far outnumbering the allocation participants and from well beyond the areas considered for the allocation.

As illustrated in Figure 1, historically, COCs from industrial, commercial, and residential sources to the LPRSA were:

- Discharged directly to the Passaic River and its tributaries;
- Transported to the Passaic River via individual municipal and Passaic Valley Sewerage Commission ("PVSC") direct discharges, bypasses and combined sewer overflows ("CSOs");
- Transported over Dundee Dam from the Upper Passaic River and its tributaries;
- Transported from Newark Bay via twice-daily tidal flows; and
- Discharged through aerial deposition, groundwater/leachate flow, and stormwater runoff.

ADR CONFIDENTIAL
NOT BINDING OR TO BE DEEMED AN ADMISSION FOR ANY OTHER PURPOSE OR PROCEEDING

Figure 1. Sources of COCs to the LPRSA

Municipal sewerage systems, and particularly the PVSC, were also significant historical contributors of COCs from both above and below Dundee Dam. While the PVSC interceptor system conveyed much of the wastewater from its collection area to the PVSC treatment plant at Newark Bay and discharged most of the treated effluent in New York Harbor,[6] discharges of untreated sewage into the Passaic River via the PVSC and municipal bypasses and combined sewer overflows alone could account for a material portion of the mass of certain COCs currently found in the OU-2 sediments. The PVSC and municipalities are not participating parties in the

[6] Affidavit of Seymour A. Lubetkin, January 6, 1994 [846680004-846680005]; Memo from R. C Smith to PVSC, February 17, 1947, p. 2 [LPRSA0198629].

allocation, despite the fact that they were, at a minimum, arrangers and transporters of COCs to the LPRSA.

4.2 Conclusions

My investigation of industrial sources as well as residential and commercial sources of COCs to the LPRSA concludes that the PAPs account for only a small percentage of the historical industrial dischargers into the PVSC, municipal, and river systems that were sources of COCs in the LPRSA. Specifically:

1. Of the approximately 11,800 historical industrial dischargers to the Passaic River that were identified through industrial directories both above and below Dundee Dam, ***98.6 percent*** **are not participating in this allocation effort.**

2. While the predominant discharger of dioxin and DDT, the Diamond Alkali facility, is included in the allocation, **the majority of sources of other COCs are not included in the allocation.**

3. Based on historical PVSC research regarding heavy metals, **parties not participating in this allocation comprise *81.5 percent* of the dischargers of heavy metals** to the PVSC sewage system in the late 1970s.

4. Given research showing that **over *450* likely PCB users in the PVSC service area are not included in this allocation**, PCB-related parties are significantly underrepresented in the allocation.

5. Other historical sources also contributed to COCs in the LPRSA. In addition to industrial discharges, residential and commercial discharges contributed COCs. COCs

from numerous tributaries discharged to the Passaic River, both above and below Dundee Dam. Tidal flow also brought contaminants upstream into the LPRSA from Newark Bay. Atmospheric deposition and groundwater/leachate flow also contributed COCs to the LPRSA.

Ultimately, based on my investigation, it is clear that the vast majority of the sources of COCs to OU-2 of the LPRSA (other than dioxins and DDT, for which the Diamond Alkali facility is the predominant source) are not included in the current allocation.

5. BACKGROUND: COCS IN THE LPRSA

According to the 2016 ROD issued by EPA for the lower 8.3 miles of the Lower Passaic River, the eight COCs that currently pose the highest potential risk to human health and/or the environment are:[7]

- Dioxins and furans
- Polychlorinated biphenyls ("PCBs")
- Mercury
- Dichlorodiphenyltrichloroethane ("DDT")
- Copper
- Dieldrin (HEOD or 1,2,3,4,10,10-hexachloro-6,7-epoxy-1,4,4α,5,6,7,8,8α -octahydro-1,4-endo,exo-5,8-dimethanonaphthalene)
- Polycyclic aromatic hydrocarbons ("PAHs")
- Lead

[7] U.S. Environmental Protection Agency, Region II, Record of Decision: Lower 8.3 Miles of the Lower Passaic River, Part of the Diamond Alkali Superfund Site, March 3, 2016, pp. 14-16.

EPA has estimated the mass of several COCs in OU-2 sediments, as shown in Table 1 below (prior to Tierra Phase 2 Removal).[8]

Table 1. Estimated Mass of COCs in Lower 8.3 Miles of LPRSA*

COC	Estimated Total Mass in OU-2 (kg)	Estimated Total Mass in OU-2 (lb)
2,3,7,8-TCDD	38	84
Total 4,4'-DDx	27,000	59,525
Total PCBs	26,000	57,320
Mercury	42,000	92,594
Copper	2,100,000	4,629,708
Lead	3,200,000	7,054,792
Dieldrin	390	860
Total PAHs	410,000	903,895

* This table does not reflect the relative risk of each COC, which is not addressed in this report.

EPA's 2014 Remedial Investigation for OU-2 concludes that resuspension of sediments in the LPRSA through scouring and tidal activity is the primary current (*i.e.,* ongoing) source of COCs to the water and surface sediments, as shown in Table 2.[9] For example, Table 2 shows that the resuspension of legacy contamination accounts for 97 percent of the 2,3,7,8-TCDD and 81 percent of the PCBs in OU-2 sediments.

[8] While interim activities removed some masses of COCs, for allocation purposes it is important to look at the total mass in the LPRSA driving the cleanup. Source: EPA, Additional Contaminant Inventory Analysis for Lower Eight Miles of the Lower Passaic River, April 2019, Table 1.

[9] The Louis Berger Group, Battelle, and HDR/HydroQual, *Lower Eight Miles of the Lower Passaic River: Remedial Investigation Report for the Focused Feasibility Study*, prepared for EPA, 2014, pp. ES-8 to ES 10 and pp. 6-1 to 6-7.

Table 2. Remedial Investigation Estimates of Current COC Sources to LPRSA (%)

Contaminant of Concern (COC)	Upper Passaic River (above Dundee Dam)	Newark Bay	Tributaries	CSOs and SWOs	LPRSA Resuspension of Historical/Legacy Contamination
Solids	32%	14%	6%	1%	48%
2,3,7,8-TCDD	0%	3%	0%	0%	97%
Total TCDD	3%	5%	0%	0%	92%
DDE	10%	8%	3%	1%	78%
Total PCBs	11%	6%	1%	0%	81%
Mercury	11%	14%	0%	0%	75%
Copper	14%	12%	1%	1%	72%
Lead	19%	7%	2%	2%	71%
Chlordane*	32%	3%	11%	3%	52%
PAHs:					
Benzo(a)pyrene	53%	7%	5%	1%	33%
Fluoranthene	47%	5%	6%	2%	40%

*May have similar sourcing to dieldrin.

In addition, while the Remedial Investigation identifies additional sources of COCs in its Conceptual Site Model ("CSM"), the investigation concluded that the following additional sources are not current significant contributors of most COCs to the LPRSA: [10]

- Upper Passaic River (above Dundee Dam)
- Newark Bay (tidal flow)
- Tributaries (e.g., Saddle River, Third River, Second River)
- CSOs and stormwater outfalls ("SWOs") from municipalities and the PVSC
- Industrial sources to the main stem of the Passaic River

[10] The Louis Berger Group, Battelle, and HDR/HydroQual, *Lower Eight Miles of the Lower Passaic River: Remedial Investigation Report for the Focused Feasibility Study*, prepared for EPA, 2014, pp. 6-1 to 6-7.

- Atmospheric deposition
- Groundwater and leachate flow[11]

However, according to the Remedial Investigation's CSM, the Upper Passaic River and Newark Bay combined currently contribute between 15-26 percent of each of Total PCBs, DDE (as an analog for DDx), copper, lead, and mercury; 53 percent of benzo(a) pyrene and 47 percent of fluorathene (PAHs); and insignificant dioxins.[12] In addition, as shown in Table 2, the Upper Passaic River currently accounts for 32 percent, and Newark Bay accounts for 14 percent of the solids flow into the LPRSA. Since each of the COCs tends to bind to fine solids, it is important to note the contribution of solids flowing into the LPRSA from these areas. Limiting the model to only current sources of COCs to the sediments allowed for significant simplification of the CSM to one current source: resuspension of the existing sediments. However, historically, the contributions of COCs from above Dundee Dam and from Newark Bay, as well as from indirect sources, were likely contributing a greater mass of COCs to the LPRSA than currently, given higher historical discharges of industrial effluent and emissions from sources that would not have incorporated or been limited by current environmental regulatory controls (such as required industrial wastewater pre-treatment, or the DDT and PCB bans in the 1970s).

Further, the cessation of historical dredging in the LPRSA increased the accumulation of contamination in LPRSA sediments. As noted in the 2016 ROD for OU-2, after the cessation of broad navigational dredging in 1950, "[t]he coincidence of chemical disposal in the river and the filling-in of the navigation channel created ideal conditions for the accumulation of contaminated

[11] This report does not evaluate the contributions of groundwater and leachate flow from individual facilities, some of which may have significant flows.

[12] The Louis Berger Group, Battelle, and HDR/HydroQual, *Lower Eight Miles of the Lower Passaic River: Remedial Investigation Report for the Focused Feasibility Study*, prepared for EPA, 2014, p. 6-5.

sediments in the Lower Passaic River."[13] This effect, combined with a salt wedge driven by tidal action moving upstream into the LPRSA from Newark Bay, inhibited the movement of suspended solids out of the River and trapped them behind the salt wedge.[14] Since the COCs were hydrophobic, they tended to bind to organic material in the fine silt particles, and were then deposited as sediments.[15]

Consideration of the historical sources of the legacy contamination identified in the surface and deeper sediments is necessary to accurately characterize the relative responsibility of the PAPs for their contributions of COCs to the LPRSA. Research and evaluation beyond the limited information provided in the Remedial Investigation and its Conceptual Site Model shows that the PAPs (other than the Diamond Alkali facility) represent only a very small fraction of the overall profile of contributors to COCs in LPRSA sediments. For DDT and dioxin, the Diamond Alkali facility was the predominant contributor to the LPRSA sediments, as discussed in Appendix B.

6. HISTORICAL SOURCES OF COCS TO THE LPRSA

Because the LPRSA acted as a sink for contaminants from a multitude of sources, including those from above Dundee Dam and from Newark Bay,[16] it is important to evaluate all such sources of COCs over a broad timespan. For example, looking at dated sediment cores to examine historical

[16] See, for example, U.S. Environmental Protection Agency, Region II, Record of Decision: Lower 8.3 Miles of the Lower Passaic River, Part of the Diamond Alkali Superfund Site, March 3, 2016, Decision Summary, pp. 16-19; R.J. Chant, D. Fugate, and E. Garvey, "The Shaping of An Estuarin Superfund Site: Roles of Evolving Dynamics and Geomorphology," *Estuaries and Coasts*, September 10, 2010.

contributions from above Dundee Dam to the LPRSA, one contractor working for EPA determined:

> Dated cores collected above head-of-tide on the Upper Passaic do not provide as extensive a historical record. Nonetheless, the core data are sufficient to suggest that the majority of historical loads of cadmium, lead, mercury, and Total PCB to the Lower Passaic originated in the Upper Passaic River above the Dundee [D]am. Historical loads of copper were more evenly split between Upper Passaic and Lower Passaic sources. Dated sediment cores from the Upper and Lower Passaic River further indicate that relatively little of the Total DDT and much less than 1 percent of the 2,3,7,8-TCDD contamination in the Lower Passaic River originated above the Dundee Dam historically.[17]

This finding supports the conclusion that while a majority of the mass of several COCs (including PCBs) in the LPRSA sediments originated from sources above Dundee Dam, the contaminant mass of TCDD and DDT, which is largely related to the Diamond Alkali facility as discussed in Appendix B, had relatively little input from above the Dundee Dam. For copper, on the other hand, the reported historical loads were more evenly split between Upper Passaic and Lower Passaic sources.

The sections below evaluate all of the historical sources of COCs in the LPRSA more broadly by examining municipal and industrial development around the Passaic River above and below Dundee Dam, the tributaries to the Passaic River, the discharges through municipal and PVSC bypasses and CSOs, atmospheric deposition, and tidal flow into the LPRSA from Newark Bay.[18]

Zamek, Malcolm Pirnie, Inc.,"The Interplay of Dredging and Discharges: A Conceptual Model of Contamination in the Lower Passaic River," presented at the 18th World Dredging Congress 2007, Lake Buena Vista, Florida, May 30, 2007, p. 850.

[18] Since there is limited information available providing measurements of historical sources of COCs, information is also presented on current measurements for the various sources of COCs. While current measurements may be indicative of likely historical sources, the reader is advised to keep the distinction of current versus historical measurements in mind, as this distinction is relevant to allocation considerations.

6.1 Municipal and Industrial Development

The first European colony on the Passaic River was established in 1666 in Newark, with settlements soon expanding throughout the area. By 1671, Newark had a mill in operation to grind corn, powered by the First River. In 1719, copper was found on a tract in Arlington/North Arlington, and a mine was established which operated until the mid-1800s. Iron was also discovered, leading to the establishment of at least five forges on the Whippany River and its tributaries during the late 1600s to early 1700s. The first sawmill was built on the Passaic River in approximately 1727. Various types of mills, such as sawmills, gristmills, paper mills, and flour mills, were erected to use the water power of the Passaic River and its tributaries, with some operating until the early 1900s.[19]

Industrial development in Paterson was fueled by targeted investments in the area. In 1791, Treasury Secretary Alexander Hamilton joined with others to form the Society for Establishing Useful Manufactures ("S.U.M.") to promote industrial development through tax advantages, navigation construction projects, power development, and financing in the State of New Jersey. Paterson was selected as the site for this project, with Great Falls to provide power. Operations were established to produce cotton yarn; spun flax, hemp and wool; woven stockings; and cotton fabrics, cotton wick, and ginned cotton. After financial problems shuttered these operations in 1797, a paper mill was built in 1804, with some of the other mill sites leased to other manufacturers. With the advent of the War of 1812, manufacturing in Paterson increased, with eleven cotton mills and other mills such as a rolling mill, nail factory and wire factory in operation by 1814. Following the enaction of tariffs on foreign goods in 1816, Paterson saw strong

[19] N.F. Brydon, *The Passaic River: Past, Present, Future,* New Brunswick, NJ: Rutgers University Press, 1974, pp. 48-53, 66-69, 127-132, and 152 [MAXUS1394116-1394118, 1394124-1394125, 1394154-1394157, and 1394167].

industrial growth in a variety of industries such as the cotton, locomotive engine, iron products, silk, flax spinning, woolens, dyeing, printing, paper, and chemical industries.[20]

In Passaic, construction of Dundee Dam by Dundee Manufacturing Company in 1845 led to the erection of woolen mills, paper mills, print works, cotton bleaching/printing works, and steam engine casting works along the canal next to the dam by the 1870s. By the end of the 1800s, ten thousand workers were employed in the area around Passaic in the production of cotton prints, woolen goods, rubber-insulated wire, artificial leather, chemicals, stove polish, boxes, and other materials. Further down the Passaic River, mills were also located along the Third River (woolen mills, board milling, paper mills) and Second River (copper factory, print mill, brass rolling mills, chemical factory). By 1894, the Geological Survey identified the following mills along the Passaic River and its major tributaries: 12 grist/flour mills, 15 sawmills, 27 fabric/fiber mills, 3 paper mills, 11 rolling mills/forges/iron works, and 11 miscellaneous mills.[21]

Industrial development in the Passaic River watershed was extensive and occurred over a long period of time. In the Natural Resource Damage Assessment Plan for the Diamond Alkali Superfund Site, the U.S. Department of Interior and National Oceanic and Atmospheric Administration state, "By [1922], nearly 1,000 industrial firms are located in Newark; primary industries include clothing and jewelry manufacturers, printing and publishing, foundry products, and leather goods."[22] New Jersey industrial directories from the early 1920s, 1950s, and 1970s catalogue the extensive industrial development of thousands of facilities in Newark, Paterson,

6.2 Tributaries

As described in the Remedial Investigation, the Passaic River is 80 miles long, fed by a 935-square mile watershed that includes numerous tributaries to the River, and emptying into Newark Bay.[24] The River begins north of Millington in Wendham, New Jersey, flowing northeast to Great Piece meadows north of Caldwell, turning east to Great Falls just above Paterson, then turning south to flow over Dundee Dam and on to Newark Bay. The Passaic River watershed drains land from the eight New Jersey counties of Bergen, Essex, Hudson, Morris, Passaic, Somerset, Sussex and Union, as well as the two New York counties of Rockland and Orange.[25] The PVSC identified 60 tributaries to the Passaic River between Great Falls in Paterson and the mouth of Newark Bay.[26] A map of the Passaic River basin and major tributaries is shown in Figure 3 below.[27]

In the Remedial Investigation, EPA notes that tributaries are currently small sources for COCs in recently-deposited sediments of the LPRSA (see Table 2).[28] However, according to EPA's findings, tributaries still contribute 6 percent of the solids flow into the LPRSA. While historical measurements for these inputs are not available, historically, it is likely that the tributaries carried greater quantities of COC mass to the LPRSA along with the solids flow than they did after imposition of pretreatment and discharge regulations.

6.3 PVSC Discharges of COCs to the Passaic River

The PVSC was created by the New Jersey Legislature in 1902 with the purpose of relieving and preventing pollution in the Passaic River and its tributaries from Great Falls in Paterson to Newark Bay.[29] In August 1924, the PVSC initiated operations, collecting untreated sewage with a trunk line constructed along the Passaic River. This trunk line and its branch lines intercepted municipal sewer systems that previously discharged directly to the River. The interceptor system carried wastewater to the PVSC treatment plant at Newark Bay for treatment and discharge of treated effluent to New York Harbor.[30] Municipalities joined the PVSC over time (see Figure 4 for map),[31] and as the municipalities grew, the flow through the PVSC system increased from 86.2 million gallons per day ("MGD") in 1924, to 201 MGD in 1950, and to approximately 250 MGD by 1976.[32]

Figure 4. Municipalities in the PVSC System

Some municipalities had combined sewer systems, in which stormwater runoff was collected in the same sewers as sanitary waste. As of 1973, a PVSC consultant reported that the municipalities of Paterson, Newark, East Newark, Harrison, Kearny, and Orange used mainly combined sewer systems.[33] The PVSC owned and operated many CSOs in these systems, which automatically discharged untreated waste to the Passaic River during periods of rain and occasionally during dry weather periods. For certain CSOs, the PVSC manually controlled overflow chamber valves. The PVSC also manually controlled additional separate sanitary/industrial sewer outlets. For decades, PVSC staff manually opened and closed these bypasses through chains linked to regulator valves or flaps, or through gates operated by hoists to control flow entering the interceptor and treatment plant during both wet and dry weather. This allowed the PVSC to "bypass" the treatment system and discharge untreated waste directly to the River.[34] In the mid-1980s, the PVSC installed remote controls to allow control of the bypass gates from a central control facility.[35]

As described in detail in Exhibit 2, there is extensive documentation regarding the PVSC's discharges of untreated waste to the Passaic River. The PVSC kept "throw-out" logs to track manual bypasses to the River during rainfall and repair/maintenance events. Bypass times have also been reported more recently in NPDES reports to the NJDEP.[36] A 1976 report by Killam Associates for the PVSC, *Report Upon Overflow Analysis to Passaic Valley Sewerage Commissioners: Passaic River Overflows* ("1976 Killam report"), measured flows to the Passaic River from bypasses and 73 CSOs owned and operated by the PVSC.[37] This information, combined

with total suspended solids ("TSS") data, provides a basis to estimate the PVSC's sewage and solids discharges[38] to the Passaic River for 1924-2016, as summarized in Table 3. (See Exhibit 2 for detailed discussion of estimation methodology.)

Table 3. Summary of Estimated PVSC Flows to the Passaic River (1924-2016)*

	Untreated Sewage Volume	Solids Mass
PVSC Bypasses	617.1 billion gallons	1.155 billion lb (577,636 tons)
PVSC CSOs	569.9 billion gallons	0.587 billion lb (293,499 tons)
Total	1.187 trillion gallons	1.742 billion lb (871,135 tons)

* For Bypasses: Start date is August 2, 1924 and end date is September 30, 2016; For CSOs, start date is October 1, 1924 and end date is September 30, 2016.

Historical information measuring COCs in the PVSC sewage during the early decades of the PVSC operation is sparse. However, studies of influent concentrations for the PVSC and similar systems in the 1970s and 1980s make it possible to estimate PVSC COC contributions to the LPRSA as shown in Table 4 (see Exhibit 2 for detailed calculations and data sources).

[38] Solids flow into the river is important because, as discussed earlier, the COCs tend to bind tightly to the solids.

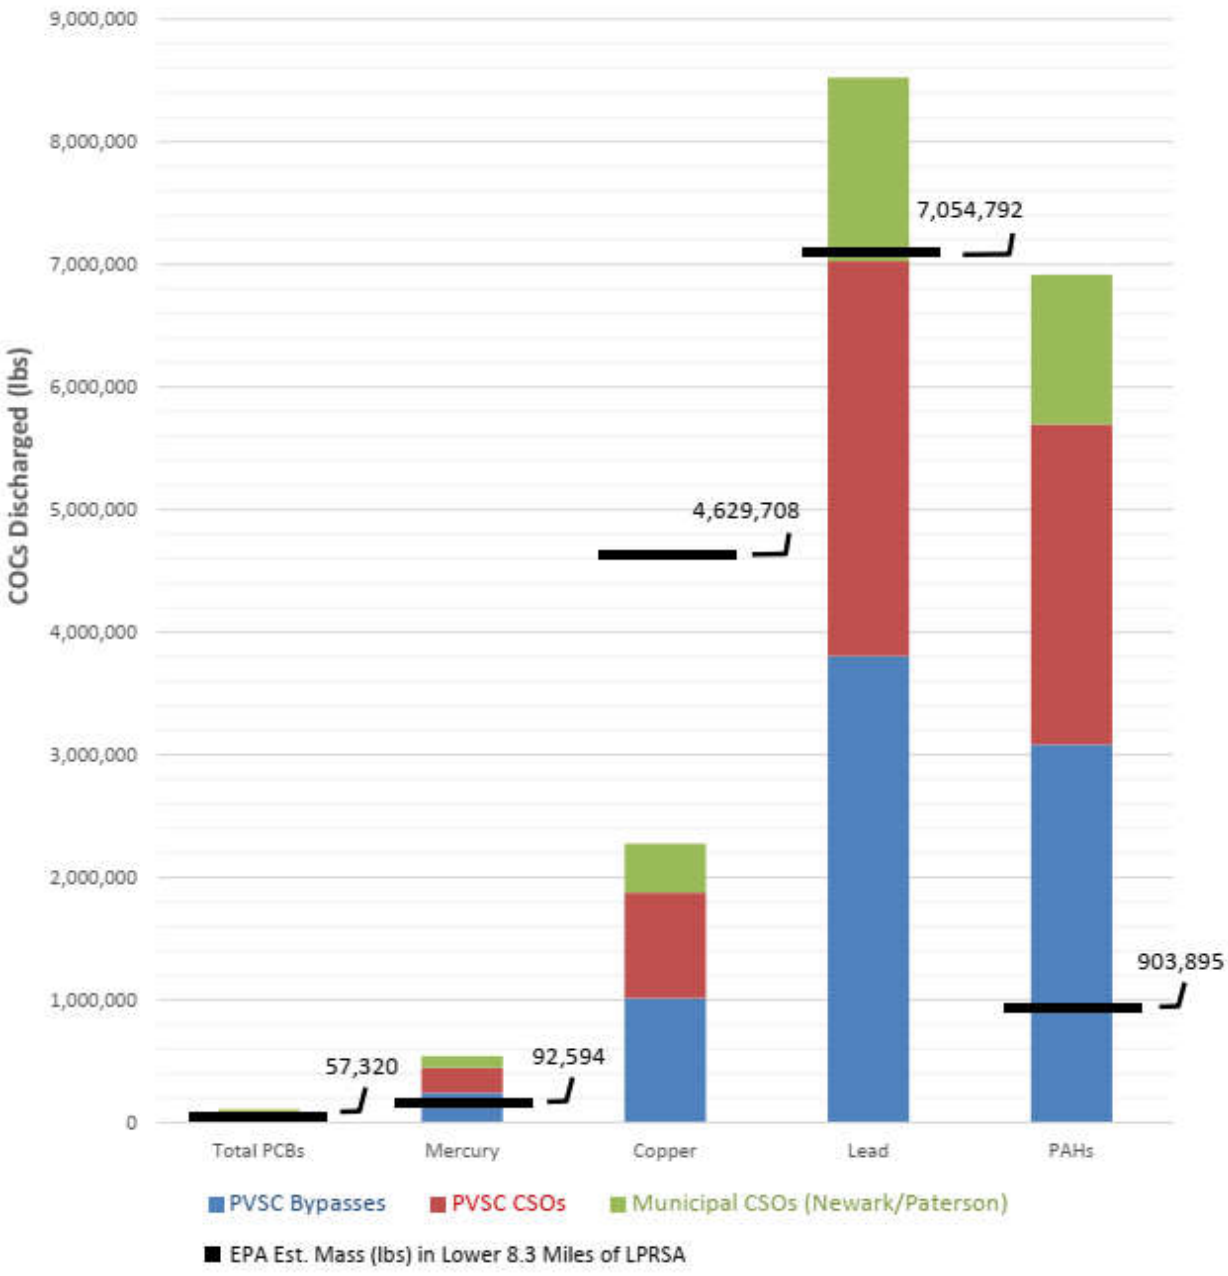
ADR CONFIDENTIAL
NOT BINDING OR TO BE DEEMED AN ADMISSION FOR ANY OTHER PURPOSE OR PROCEEDING

Table 4. PVSC Bypasses and CSO Contaminants of Concern (lb)

COC	Estimated Bypass Mass (1924-2016)**	Estimated CSO Overflow Mass (1924-2016)**	Total Estimated PVSC Mass (1924-2016)**	EPA Estimated Mass in OU-2 Sediments
PCBs*	57,032	34,781	91,813	57,320
Mercury	242,254	205,152	447,406	92,594
Copper	1,015,838	860,258	1,876,096	4,629,708
Lead	3,804,812	3,222,088	7,026,900	7,054,792
Select PAHs (see Exhibit 2-6)	3,083,750	2,611,460	5,695,210	903,895
Total	**8,203,685**	**6,933,739**	**15,137,424**	

* The period for PCB mass estimation is 1930 (start of commercial use) to 1976 (ban).

** Start date is August 2, 1924; end date is September 30, 2016 (with the exception of Yantacaw and Union Outlet, where the end dates are 1975 due to lack of available detailed documentation after this date).



Note: Numbers may not add to totals due to rounding.

As shown in Table 4, the PVSC is estimated to have discharged over 15 million pounds of COCs to the Passaic River during the 1924-2016 time-frame. When comparing these estimates of PVSC-discharged COCs to those estimated by EPA as present in the sediments of the lower eight miles of the River, it is evident that the PVSC discharges alone could account for much of the mass of certain COCs in OU-2 (see Figure 5).

The COC mass values presented in Table 4 are likely conservatively low, as they are based on more recent concentrations that are likely low relative to earlier historical concentrations due to the imposition of industrial waste pretreatment and monitoring requirements in the 1970s. In addition, the available PCB measurements do not cover the period when PCBs were in common use, prior to being phased out by the mid-1970s.

Figure 5. Estimated PVSC and Municipality (Newark/Paterson) Discharges of COCs (lb) Through Bypasses and CSOs (1924-2016) Relative to EPA Estimates of OU-2 Mass

The PVSC may be the only solvent PRP left for some LPRSA COC discharge streams. For PRPs that initiated operations after 1924 (or after the sewers in their area were joined to the PVSC), discharged waste, but did not discharge directly to the River, either the PVSC or in some cases a municipal-owned system likely served as the sole conduit for their waste to the River. Therefore, for those PRPs that had operations after August 1924 but are now insolvent, the PVSC may be the last remaining viable PRP linked to the discharge of their waste into the Passaic River.

6.4 Non-PVSC Municipal Discharges of COCs to the Passaic River

This section describes the history of municipal discharges of COCs from systems that are not collected by the PVSC. This section further provides estimated COC mass contributions for Paterson (above Dundee Dam) and Newark (below Dundee Dam) to the Passaic River using the same methodology employed above for the PVSC CSOs. COCs contributed by other municipalities, as well as COCs discharged before construction of the PVSC interceptor system in 1924, have not been estimated.

The municipalities in the Passaic River basin designed, constructed, and operated their sewer systems before the PVSC initiated operation of a trunk sewer collection/treatment system in late 1924. After the PVSC started operations, some municipalities continued to operate their own sewer/treatment systems, while others operated their sewer lines until they connected to the PVSC-operated interceptor trunk line and system of bypasses and CSOs. Some municipalities, such as Paterson and Newark, also operated their own CSOs outside of the PVSC system.

Direct discharges continued from multiple municipalities for many decades after completion of the PVSC system. In a 1972 report reviewing Passaic River pollution, The Center for Analysis of Public Issues (“CAPI”) noted that polluted municipal sewer discharges into the Passaic River were identified in West Paterson, Paterson, Prospect Park, Fair Lawn, Garfield, Passaic, Clifton, Nutley,

Belleville, Harrison, and Newark.[39] Citing a 1969 federal survey by the Federal Water Pollution Control Administration and N.J. Department of Health, the CAPI report identified:

- 120 municipal sewage treatment plants discharging treated and untreated waste to the Upper Passaic River above Paterson;
- Significant discharge of treated and untreated waste by Paterson above Dundee Dam; and
- 435 pipes discharging waste into the Lower Passaic River, comprised of 210 municipal outlets and 225 industrial outlets.[40]

While a complete description of all municipal discharges to the Passaic River is beyond the scope of this report, details for select municipal discharges are provided below.

6.4.1 Discharges from Upper Passaic Area Municipalities (above Paterson)

CAPI found that in 1972 there were 120 sewage treatment plants discharging a total of 100 MGD of effluent, plus untreated bypassed sewage during heavy rains, to the Upper Passaic area above Paterson, concluding "State, regional and academic experts all agree that the most important sources of pollution above Little Falls are the municipal treatment plants." [41] This effluent accounted for a significant portion of the Upper Passaic River flow. For example, on October 13, 1970, the sewage effluent accounted for 40 million gallons of the total River flow of 102 million gallons at Little Falls, New Jersey. Also on that day, the PVSC tapped 65 million gallons of the Passaic River flow at Little Falls to use for potable water in Paterson, Passaic, and Clifton, further

[39] The Center for Analysis of Public Issues, Pollution Control on the Passaic River, 1972, pp. 27-28 [MAXUS006635-006636].

[40] The Center for Analysis of Public Issues, Pollution Control on the Passaic River, 1972, pp. 11-27 [MAXUS006617-006635].

[41] The Center for Analysis of Public Issues, Pollution Control on the Passaic River, 1972, pp. 11-12 [MAXUS006617-006618].

complicating the flow of pollution.[42] CAPI also noted significant pollution in the Upper Passaic River area by fertilizer and automobile hydrocarbon runoff as well as oil spills, with some routed to municipal treatment plants (occasionally shutting down the treatment plant for cleanup), and some discharged directly to the River. As an example, 16 oil spills greater than 1,000 gallons were reported in the Upper Passaic area in one year; one spill of 3,000 gallons of oil in Wayne Township entered the municipal sewers, leading to pollution discharge to the Pompton River and eventually shutdown of the Wayne plant for a few days for cleanout.[43] Some Upper Passaic municipalities, such as Livingston Township, were noted as operating their treatment plants inefficiently, allowing "highly polluting effluent" to discharge to the River. In addition, about one-fourth of the Upper Passaic area municipal treatment plants operated in excess of design capacity, leading some to discharge untreated sewage directly to the River.[44]

While CAPI identified inefficient and overloaded municipal treatment plants as contributing to pollution of the Passaic River, it also concluded that pollution prevention was not a high priority for the municipalities:

> Far more serious than the problem of direct factory discharges is the relationship between industrial waste and municipal sewer operations. Most municipalities in the Upper Basin are so anxious to attract new property tax ratables that they readily offer the courted industry cheap access to the local sewer system. They repeatedly overlook the fact that their treatment plants are already overloaded or that industrial wastes might contain traces of phenol or heavy metals that the plants are not designed to handle. They are motivated entirely by what one expert calls "the municipal philosophy that residential and industrial ratables must be obtained and let the devil take the waterways" with the result being "an

> intolerable concentration of industrial waste discharge and severe pollution from obsolete and overloaded municipal waste treatment plants."[45]

6.4.2 Discharges from the City of Paterson CSOs

At the time of an 1897 PVSC investigation of sewage disposal to the Passaic River, Paterson had a combined sewage/stormwater system with 22 CSOs discharging to the Passaic River at an estimated total rate of 17 MGD, with an additional 9 MGD estimated as being directly discharged by Paterson manufacturers and facilities.[46] CAPI concluded in 1972 that "[t]he most notorious perpetrator of municipal bypassing today is the City of Paterson."[47] As reported by CAPI, Paterson officials confirmed that most of its 27 miles of sewer lines were combined sanitary-storm sewers, leading to discharge of untreated waste to the Passaic River during storms. However, in addition to discharge during storms, CAPI found that discharge of untreated sewage to the River also occurred during the PVSC's daily peak discharge hours of 10:30 a.m. to 3:30 p.m., when the main interceptor was overloaded. [48]

The 1976 Killam report identified 23 CSOs owned by Paterson (in addition to the 28 active CSOs owned by the PVSC located in Paterson) that emptied into the Passaic River.[49] The Killam report points out that the Paterson combined sewer system was designed at a size below conventional design standards, accommodating only 0.5 cubic feet per second ("cfs") per acre of drainage, versus normal sizes 2- to 3-times larger (1.0-1.5 cfs per acre of drainage). In addition, while the overall capacity of the Paterson combined sewers is 2,520 MGD, the interceptor sewer in Paterson has a capacity ranging from only 21 MGD at the upper terminus to 82 MGD at the lower

terminus, leading to an inability to accommodate the extra flow from rainfall. As a result, rainfall in Paterson surcharges the available piping and then causes flooding and CSO discharges.[50] Killam noted that the largest Paterson-owned overflow was at 19th Avenue and Vreeland Avenue, with a capability of carrying 120-150 MGD to the Passaic River. This CSO was observed to flow during rainfalls as low as 0.04 inches/hour. Nine other Paterson overflows located in the center of the city also overflowed with low-intensity rainfalls, with an estimated overflow pipeline capacity of 150-200 MGD. Field interviews conducted during the 1976 Killam study indicated that many of the Paterson CSOs frequently discharged to the Passaic River during storms. Overall, the study estimated that the 28 Paterson-owned CSOs resulted in a discharge to the Passaic River equivalent to that discharged by the PVSC CSOs in this area, or 54 MG during the year (1974-1975) measured by Killam.[51] Using the same flow/rainfall relationship and COC concentration data described above for the PVSC CSOs (and described in Exhibit 2) yields the following estimate for COCs discharged by the Paterson-owned CSOs (see Table 5).

Table 5. Summary of Estimated Paterson-Owned CSO Discharges to the Passaic River[52]

	Paterson-Owned CSO Discharges (1924-2016)*
Sewage volume	4.1 billion gallons
PCBs[53]	247 lb
Mercury[54]	1,476 lb
Copper	6,189 lb
Lead	23,180 lb
Select PAHs[55]	26,008 lb

* Start date is October 1, 1924; end date is September 30, 2016.

6.4.3 Discharges from Cities of Newark and East Orange through Newark CSOs

The sewers in Newark were largely constructed as combined sanitary-storm sewers during the 1830 to 1930 time-frame.[56] At the time of the PVSC's 1897 investigation, the City of Newark had a combined sewage/stormwater system with outlets at Gully Road, Fourth Avenue, Mill Brook (carrying the sewage from the municipality of East Orange), Rector Street/Ballantine's Dock, City Dock, Jackson Street, and Freeman Street, plus five additional "minor" sewers that discharged to the River. Additional sewers were under consideration at the time. In addition, Newark had constructed a South Street intercepting sewer to collect sewage at this location for discharge to Newark Bay. Sewage flow from Newark and East Orange, including the South Street interceptor sewer, was estimated at 34 MGD.[57]

[57] Report of the Passaic Valley Sewerage Commission, February 26, 1897, pp. 37-38 [MAXUS006879-006880].

In 1965/1966, Newark built the South Side Interceptor to collect sanitary waste from the Peddie, Queen, and Waverly districts and convey it to the PVSC treatment plant. Before this time, the untreated waste from these districts was discharged directly to Petty Ditch in the area of Newark Airport. However, after construction of the interceptor, untreated waste could still flow into Newark Bay. For example, when the collected waste exceeded the capacity of the South Side Interceptor, excess flow is diverted to Newark Bay via the Peripheral Ditch, which also conveys flows from Wheeler Ditch, Adams Ditch, the Newark Airport, and the City of Elizabeth. Waste could also be diverted during maintenance and repair activities, such as the repair of a faulty valve at a pumping station during April to October 1969, which led to the discharge of 30 MGD of untreated waste.[58] This flow was later measured by Killam, as discussed below.

In 1972, CAPI found that approximately half of Newark's 500 miles of sewer lines were combined sanitary-storm sewers. With more than 75 percent of the sewer system almost 100 years old and inadequately maintained, breakdowns and blockages were common, leading to discharges of untreated waste to the Passaic River. The study concluded, "When the Newark collection system is overloaded – and it is an antiquated system subject to frequent breakdowns and unable to accommodate even the slightest storm runoff – the excess finds its way into one of the 49 outfall pipes from Newark into the Passaic."[59]

A 1975 study conducted for Newark notes that most of Newark's sewers were built prior to construction of the PVSC system. Once the PVSC system was built, the existing sewer lines near the PVSC trunk line were connected to it. The report states, "Little maintenance is provided for

[58] Purcell Associates, Pollution Abatement Plan: Newark, New Jersey, prepared for City of Newark, Department of Public Works, 1975, p. II-4 [MAXUS0800504]; U.S. Department of the Interior, Federal Water Pollution Control Administration, Report on the Quality of the Interstate Waters of the Lower Passaic River and Upper and Lower Bays of New York Harbor, November 1969, p. 14.

[59] The Center for Analysis of Public Issues, Pollution Control on the Passaic River, 1972, pp. 25-26 [MAXUS006633-006634].

these facilities and at times they have been known to malfunction and discharge sanitary waste directly into the river even at low flow periods."[60] The report notes numerous Newark outfalls to the Passaic River and Newark Bay were designed to automatically discharge untreated sewage during periods of rainfall and high flow events.[61]

The 1976 Killam report identified at least 14 CSOs owned by Newark (beyond the 15 owned by the PVSC) that emptied into the Passaic River or Newark Bay.[62] The Killam report measured the South Side Interceptor CSO flows (Peddie, Queen, and Waverly districts) at approximately 2,300 MG/yr. Assuming the remaining 11 Newark-owned CSOs had average flow rates similar to PVSC-owned CSO flows, then the average annual flow per CSO is estimated at 103 MG (7,540 MG total measured annual overflow divided by 73 PVSC CSOs).[63] Using this average flow and the same COC concentrations described above for the PVSC CSOs yields an estimated COC discharge estimate for the 14 Newark-owned CSOs, shown in Table 6 below.

6.5 Atmospheric Deposition and Groundwater/Leachate Flow

The Remedial Investigation notes that atmospheric deposition and groundwater/leachate are not significant current contributors to COCs in the LPRSA.[67] However, historically, before implementation of emissions controls and phase-out of lead additives in gasoline, and before implementation of groundwater monitoring and discharge permits, such contributions were likely higher.[68] (Appendix B provides additional discussion of available resources on this topic for each COC.)

[67] The Louis Berger Group, Battelle, and HDR/HydroQual, *Lower Eight Miles of the Lower Passaic River: Remedial Investigation Report for the Focused Feasibility Study*, prepared for EPA, 2014, p. 6-4.

[68] This report does not review these contributions for individual sites, some of which may have more significant flows.

6.6 Tidal Flow from Newark Bay

In the Remedial Investigation, EPA notes that tidal flow from Newark Bay currently accounts for 14 percent of recently-deposited sediments (see Table 2).[69] The investigation estimates that tidal flow from Newark Bay accounts for 6 percent of PCBs, 8 percent of DDE (as an analog for DDx), 23 percent of copper, 14 percent of mercury, and 7 percent of lead in recently-deposited surface sediments in the LPRSA. While data are not available to document historical contributions, the data on current contributions indicate that Newark Bay also historically contributed COCs to the LPRSA.

7. COC CONTRIBUTIONS OF NON-PAPS

Understanding the extensive and lengthy industrial development along the Passaic River is critical when examining allocation issues. Although not included in the current allocation effort, the area serviced by the PVSC above Dundee Dam included numerous industrial facilities that would have contributed COCs to the Passaic River. A review of New Jersey industrial directories dating from the late-1800s to 1970s indicates the number of industrial facilities located in the PVSC service area as shown in Section 6.1, Figure 2. In total, Paterson was found to have over 5,000 industrial facilities listed over the 1874 to 2006 time-frame, with the highest number of facilities peaking at just over 1,000 in 1949. Examples of the industrial activities represented by these facilities include textile production, dyeing, metalworking, casting, printing, and the manufacture of equipment, plastics, chemicals, transformers and electrical equipment, locomotives, paints, and adhesives. As noted in Appendix B, these industries are typically associated with releases of contaminants including those identified as COCs for OU-2. **None of these facilities are included in the current allocation effort.**

[69] The Louis Berger Group, Battelle, and HDR/HydroQual, *Lower Eight Miles of the Lower Passaic River: Remedial Investigation Report for the Focused Feasibility Study*, prepared for EPA, 2014, pp. ES-9 to ES-10.

Similarly, industrial directories for Newark identified over 4,000 industrial facilities listed over the 1920 to 1974 time-frame, with the highest number of facilities found in the 1950s at over 2,700 facilities.[70] As seen in Figure 2, other municipalities connected to the PVSC below Dundee Dam showed similar development patterns, peaking at an additional 1,700 facilities in the mid-1950s, and accounting for approximately 1,300 facilities in the mid-1970s. Types of industries again range broadly, including metals smelting and refining, castings, dental laboratories, copper paints and soaps, equipment manufacture, textiles, tanners, dyeing, metalworking, tanning, printing, plastics, electrical and electronic equipment, lacquers and paints, hatters, and adhesives. Overall, approximately 6,800 industrial facilities were identified during this time frame in the area below Dundee Dam. **Of these 6,800 industrial facilities, approximately 97.6 percent are not participating parties in the allocation. Of the approximate 11,800 industrial facilities identified through industrial directories both above and below Dundee Dam, 98.6 percent are not participating in the allocation.**

In the sections below, more detailed information is provided regarding industrial sources of specific COCs, namely heavy metals (copper, mercury, and lead) and PCBs.

7.1 Sources of Metal COCs (Copper, Lead, Mercury)

The 1980 *Heavy Metals Source Determination Study* (Phase II) conducted by Killam Associates for the PVSC (the "Heavy Metals Study") identified 260 heavy metal-contributing facilities to the PVSC system.[71] The study focused on facilities that had been previously identified in the PVSC files as heavy-metal contributors, and excluded some major heavy-metals dischargers such as

[70] See industrial directories cited for Figure 2. Note that the data for the 1920s is partial information, so the figures for this time-frame are low.

[71] Elson T. Killam Associates, Inc., Heavy Metals Source Determination Study, Phase II, prepared for PVSC, April 1980 [LPRSA0009906-0010069].

hospitals.[72] For these facilities, the study measured flows and metal discharges during operating hours in order to identify the sources of heavy metals observed in PVSC treatment plant influent (measured in Phase I of the study).

In the study, the PVSC system was divided into ten sub-areas (numbered 0-9 based on accessible man-holes for measuring sewage concentrations). The number of facilities identified in each sub-area is shown in Table 7 below.[73] Of the 260 industrial facilities in the study, 89 were located in Sub-Area 0 (Newark), followed by 71 facilities located in Sub-Area 8 (Paterson). The specific industries contributing the most metals included metal finishing and electroplating, textile manufacturers, and organic chemical manufacturers.[74]

[72] Elson T. Killam Associates, Inc., Heavy Metals Source Determination Study, Phase II, prepared for PVSC, April 1980, p. 14 [LPRSA0009931].

[73] Elson T. Killam Associates, Inc., Heavy Metals Source Determination Study, Phase II, prepared for PVSC, April 1980, Phase I Summary Table 1: Mass Balance Analysis, Industrial Metals, Entire Service Area, p. 21 [LPRSA0009938].

[74] Elson T. Killam Associates, Inc., Heavy Metals Source Determination Study, Phase II, prepared for PVSC, April 1980, Phase I Summary Table 1: Mass Balance Analysis, Industrial Metals, Entire Service Area, p. 14 [LPRSA0009931].

Table 7. COC Metals Discharges of 260 Facilities by PVSC Sub-Area as Shown in 1980 Phase II Heavy Metals Study

Sub-Area	Number of Facilities (%)
0: Newark (northern portion)	89 (34%)
1: Newark (southern portion)	13 (5%)
2: East Newark, Harrison, Kearny	8 (3%)
3: Belleville, Bloomfield, Orange	9 (3%)
4: Belleville, Clifton, Lyndhurst, Nutley	14 (5%)
5: Nutley	2 (1%)
6: Clifton, Lodi, Passaic, Saddle Brook	29 (11%)
7: East Rutherford, Garfield, Passaic, Wallington	15 (6%)
8: Elmwood Park, Fairlawn, Glen Rock, Haledon, Paterson	71 (27%)
9: Hawthorne	10 (4%)
Total	**260 (100%)**

As shown in Table 7, a substantial portion of the metals-discharging facilities are attributable to industrial facilities located above Dundee Dam in sub-areas 8-9 (e.g., Paterson). In addition, the results of the study show that significant industrial sources of metals were not included in the 260 studied facilities. For example, in sub-area 8 (Paterson), only 30.6% of industrial copper and 13.5% of industrial lead were accounted for by the study.[75]

In addition to the industrial sources, the Heavy Metals Study estimated contributions for domestic and infiltration/inflow sources to the PVSC system as shown in Table 8.

[75] Elson T. Killam Associates, Inc., Heavy Metals Source Determination Study, Phase II, prepared for PVSC, April 1980, Phase I Summary Table 1: Mass Balance Analysis, Industrial Metals, Entire Service Area, p. 83 [LPRSA001000].

Table 8. Estimated Domestic and Infiltration/Inflow Contributions of Metals to the PVSC as Shown in 1978 Phase I Heavy Metals Study[76]

	Domestic Discharge (lb/day)	Infiltration/Inflow (lb/day)	Total Domestic & Infiltration/Inflow (lb/day)
Copper	120.2	30.6	150.8
Lead	69.9	63.5	133.4
Mercury	1.1	0.5	1.6

Of the total flow into the PVSC system, the study estimated domestic and infiltration/inflow contributions to be 15.1 percent for copper, 7.1 percent for lead, and 1.3 percent for mercury.[77]

Of the 260 facilities accounted for in the Heavy Metals Study, 212 facilities (81.5 percent of the total) are not a part of the current allocation effort. One example of a company not participating in the allocation is Troy Chemical in Newark, even though it was found to be responsible for 327.86 lb/day mercury, or 98.25 percent of the total industrial mercury discharge into the PVSC system measured by the study.[78]

In addition to the facilities identified in the Heavy Metals Study, there were numerous facilities involved in metals processing throughout the industrial history of the Passaic River area. An example of a facility that likely contributed contamination to the Passaic River is Schuyler's Copper Mines, which operated in North Arlington, New Jersey from around 1712 to 1865 and

[76] Elson T. Killam Associates, Inc., Heavy Metals Source Determination Study, Phase I, prepared for PVSC, August 15, 1978, Table 55, p. 6 [MAXUS5490327].

[77] Elson T. Killam Associates, Inc., Heavy Metals Source Determination Study, Phase I, prepared for PVSC, August 15, 1978, Table 55, p. 6 [MAXUS5490327].

[78] Elson T. Killam Associates, Inc., Heavy Metals Source Determination, Phase II, prepared for PVSC, April 1980, Phase I Summary Table 1: Mass Balance Analysis, Industrial Metals, Entire Service Area, pp. 59 and 83 [LPRSA0009976 and 001000].

included ore crushing, separation, and washing operations. Copper milling and reduction was attempted at the site in 1900-1901, but was not successful. It is estimated that 42 shafts were installed, accompanied by drain tunnels.[79] To produce steam engines to drain the mines, a foundry and machine shop were established in Belleville on the Second River (tributary to the Passaic). This shop was turned into the Hendricks Copper Rolling Mill to process copper ore from the Schuyler's mines to produce copper bolts and wire. The copper mill operated until 1928.[80] Copper mines also operated in East Orange, Orange, and Glen Ridge. One was located on the Second River (tributary to the Passaic River), one on Wigwam Brook (tributary to Second River), and another on Toney's Brook (a tributary to the Passaic River).

7.2 Sources of PCBs

There are numerous companies that likely contributed PCBs to the LPRSA that are not PAPs. To identify potential contributors of this COC, facility lists were collected from the following information sources:

- PVSC Significant Industrial User list[81]
- PCB sales data[82]
- EDR data identifying PCB contamination/inspections/violations in the Passaic River area[83]

[79] G.F. Black, Newark Mineralogical Society, "The Belleville Copper-Mine," 1922.

[80] H.P. Woodward, New Jersey Department of Conservation and Development, Copper Mines and Mining in New Jersey, 1944.

[81] Letter from W. Hengemihle, FTI, to S. Flanagan, EPA, regarding PVSC Industrial Users List, Lower Passaic River Study Area, February 10, 2017.

[82] Monsanto PCB Sales Summaries.

[83] EDR DataMap Environmental Atlas, Environmental Data Resources Inc., June 18, 2015.

For the facilities listed in these sources, I evaluated information regarding the types of products manufactured to determine which facilities were likely users of PCBs. The results are provided in Exhibit 3, **showing over 450 non-PAP parties that are likely to have used PCBs in the Passaic River area.** Due to the locations of these facilities, they could have discharged waste streams either through the PVSC sewer system (with its bypasses and CSO discharges to the River), to their municipal sewers (with their own CSO discharges to the River), and/or directly to the River or its tributaries. Appendix C provides more detailed examples of potential PCB-discharging facilities that are not a part of this allocation effort.

8. CONCLUSIONS

Based on my review of the extensive information that is available about sources of contamination to the LPRSA, it is clear that the historical sources of COCs to the LPRSA are very broad. These historical sources include thousands of residential, commercial, and industrial sources from both above and below Dundee Dam that:

- Discharged directly to the Passaic River
- Discharged to the extensive network of tributaries to the Passaic River
- Discharged to the Passaic River by PVSC bypasses and CSOs
- Discharged to the Passaic River through municipality direct discharges
- Flowed back up the River via twice daily tidal flows from Newark Bay
- Discharged indirectly through aerial deposition, groundwater/leachate discharge, and stormwater runoff.

Considering only industrial sources, data show that there were thousands of industrial facilities located on the Passaic River. Of these, over 98 percent are not participating in the current allocation effort. When examining historical PVSC research on heavy metals, non-PAPs comprise

81.5 percent of the parties identified as dischargers of heavy metals to the PVSC sewage in the late 1970s. Finally, when examining several sources of likely PCB users in the PVSC service area, over 450 facilities were identified that are non-PAPs.

EXHIBIT 1
RESUME OF GAYLE SCHLEA KOCH

ADR CONFIDENTIAL
NOT BINDING OR TO BE DEEMED AN ADMISSION FOR ANY OTHER PURPOSE OR PROCEEDING

GAYLE SCHLEA KOCH — Principal

Ms. Gayle Schlea Koch has over 35 years of consulting experience focused largely on environmental, product liability, technology, and insurance related issues. She has worked broadly in the environmental/mass tort area applying her engineering and business background to address the complex technical and economic issues that arise. She has substantial experience in the estimation of environmental and product liabilities in connection with settlements, insurance claims, penalties, acquisitions and divestitures, bankruptcies, real estate transfers, litigation, and strategic planning.

Ms. Koch has worked extensively in the evaluation of environmental damages, estimation of asbestos and other mass tort liabilities, allocation and recovery of cleanup costs, evaluation of potential insurance recovery, and assessment of the impact of environmental regulations. She has served as an expert on cases involving liability estimation, allocation, cost recovery and NCP (National Contingency Plan) consistency, insurance recovery valuation, disclosure, economic damages, and ability to pay. She has also worked on the evaluation of new technologies and new market opportunities often created by new environmental regulations or changing energy markets.

Examples of projects that are particularly relevant to the mass balance and allocation issues in this matter include:

- Currently working on complex allocation issues with regards to a metal production facility that operated over many decades
- Conducted a litigation risk analysis for multiple PRPs at a complex river system with PCB contamination, looking at possible regulatory action, cost, and allocation scenarios
- Critiqued an allocation prepared for a vast Superfund mining site involving multiple tributaries to a lake system
- Developed an allocation for a Superfund site involving multiple parties/operations over a lengthy period of time, requiring the re-creation of past industrial processes and waste disposal practices, including those from the manufacture of DDT
- Conducted a litigation risk analysis related to cost and allocation scenarios at a harbor site involving PCBs and metals in sediments
- As part of an insurance recovery valuation, researched allocation issues at approximately 350 sites, many with PCB and metals contamination
- Prepared an allocation related to contiguous sites with multiple oil-related activities that changed over time
- Examined allocation and NCP consistency issues as part of a cost recovery matter at a harbor with contaminated sediments
- Critiqued a proposed allocation for a multi-party landfill, examining contaminants of concern versus the composition of various waste streams
- Conducted a litigation risk analysis for an oil tanker company, including allocation, regulatory, and cost recovery issues

Ms. Koch has served as a technical contact for ASTM International (formerly the American Society of Testing and Materials) standards on environmental cost estimation, environmental disclosure, and climate change disclosure. She has participated in meetings with Commissioners of the U.S. Securities and Exchange Commission (SEC) concerning environmental cost estimation and disclosure issues. In addition, Ms. Koch served on the Standards Council of the Sustainability Accounting Standards Board (SASB).

Before co-founding Axlor Consulting, Ms. Koch led the Environmental/Mass Tort practice at The Brattle Group and worked as a consultant with Putnam, Hayes & Bartlett where she focused on environmental and toxic tort liability assessment and insurance issues. Ms. Koch also served as a manager with RCG/Hagler, Bailly & Company, where she focused on the market and economic analysis of industrial process and energy technology markets and on the management of energy and environmental R&D activities. Earlier, Ms. Koch served as a research assistant for the Sloan School of Management at the Massachusetts Institute of Technology and in several positions with E.I. du Pont de Nemours & Company.

EDUCATION

Ms. Koch received a B.S. in Chemical Engineering and a B.S. in Humanities and Engineering (in the Science, Technology and Society Program) from the Massachusetts Institute of Technology, and an M.S. in Management Science (concentrations in applied economics, corporate strategy, and management of technological innovation) from the Sloan School of Management, M.I.T.

PURPOSE

At the request of counsel on behalf of the Lower Passaic River Study Area ("LPRSA") Small Parties Group ("SPG"), I conducted research on activities of the Passaic Valley Sewer Commission ("PVSC") related to disposal of untreated waste into the Passaic River for the purpose of calculating estimated PVSC volumetric and mass flows of contaminants of concern ("COCs") related to PVSC discharges. These discharges generally fall into three categories: (1) discharge of untreated industrial and domestic waste to the river due to system breakdown, maintenance, and repair activities, (2) PVSC-controlled discharges of untreated waste to the river during high flow events such as rain storms and snow melts, and (3) automatic discharges of untreated waste from combined sewer overflow ("CSO") points. This report is based on the documentation available to date. I will continue to review information as it is made available to me. The opinions offered herein are offered to a reasonable degree of professional certainty.

SUMMARY

Table 2-1 below presents estimated bypass and CSO overflow amounts based on flow and mass information measured by a PVSC contractor in 1974-1975 , contaminant measurements taken during 1977-1986 for the COCs identified in EPA's Record of Decision ("ROD") for the lower portion of the Passaic River,[1] and documented PVSC bypasses of untreated waste to the Passaic River during 1950-1975 and 2005-2014 extrapolated to estimate for bypasses during the 1924-2016 period. Note that because they are based on measurements made after industrial waste pretreatment was starting in the late 1970s and after the phase-out of PCB sales in the mid-1970s, the COC mass estimates presented in Table 2-1 are conservatively low.

Table 2-1. Summary of Estimated PVSC Flows to the Passaic River

	Estimated Bypass Volume and Mass (1924-2016)*	Estimated CSO Automatic Overflows (1924-2016)**	Total (1924-2016)
Sewage volume	617.1 billion gallons	569.9 billion gallons	1.187 trillion gallons
Solids Mass	1.155 billion lb (577,636 tons)	0.587 billion lb (293,499 tons)	1.742 billion lb (871,135 tons)
PCBs	57,032 lb	34,781 lb	91,813 lb
Mercury	242,254 lb	205,152 lb	447,406 lb
Copper	1,015,838 lb	860,258 lb	1,876,096 lb
Lead	3,804,812 lb	3,222,088 lb	7,026,900 lb
PAHs (see Exhibit 2-6 for PAH list)	3,083,750 lb	2,611,460 lb	5,695,210 lb

* Start date is August 2, 1924; end date is September 30, 2016.

** Start date is October 1, 1924; end date is September 30, 2016.

Note: Numbers may not add to totals due to rounding.

PVSC SYSTEM

The PVSC was created by the New Jersey Legislature in 1902 for the purpose of relieving and preventing pollution in the Passaic River and its tributaries between Great Falls in Paterson, New Jersey, and Newark Bay.[2] In August 1924, the PVSC began collecting untreated sewage with a trunk line constructed along the Passaic River. This trunk line intersected municipal lines which previously discharged directly to the river. Collected wastewater was then pumped to the PVSC treatment plant at Newark Bay.[3]

Municipalities joined the PVSC over time as shown in Exhibit 2-1. As more municipalities joined and as their population grew, the flow through the PVSC treatment system expanded from 86.2

million gallons per day ("MGD") in 1924, to 201 MGD in 1950, and to approximately 250 MGD by 1976.[4]

PVSC CSOs

Some municipalities maintained combined sewer systems, in which stormwater runoff was collected in the same sewers as sanitary waste. As of 1973, a PVSC consultant reported that the municipalities of Paterson, Newark, East Newark, Harrison, Kearny, and Orange used mainly combined sewer systems.[5] These combined systems resulted in combined sewer overflows ("CSOs") of untreated waste to the Passaic River primarily during periods of rain and also occasionally during dry weather periods if the high waste levels overflowed a weir or stop logs in the overflow chambers.

A 1976 report by Killam Associates for the PVSC, *Report Upon Overflow Analysis to Passaic Valley Sewerage Commissioners: Passaic River Overflows* ("1976 Killam report"), measured one year of volumetric flows and total suspended solids ("TSS") flows to the Passaic River from 73 CSOs (located both above and below Dundee Dam) owned and operated by the PVSC.[6] Using the measured CSO flows and accompanying rainfall data, Anchor QEA correlated CSO flows to the Passaic River to rainfall amounts.[7] Anchor QEA applied this correlation to historical rainfall data to derive an estimated PVSC CSO flow of 569.9 billion gallons of untreated sewage into the Passaic River during 1924 to 2016. Applying this estimated flow to TSS data in the 1976 Killam

[7] Anchor QEA, PVSC CSO overflow and mass discharge estimates, 2017. (See Exhibit 2-8.)

report, Anchor QEA estimated that the CSOs discharged 587 million lb (293,499 tons) of solids mass to the river during this time-frame.

PVSC BYPASSES

While many PVSC CSOs discharged combined overflows to the river automatically as discussed above, some overflow chamber valves and additional separate sanitary/industrial sewer outlets were controlled manually by the PVSC. For decades, PVSC staff manually opened and closed these bypasses through chains linked to regulator valves or flaps, or through gates operated by hoists. This allowed the PVSC to choose to bypass the treatment system and discharge untreated waste directly to the river.[8] In the mid-1980s, the PVSC installed remote controls to allow control of the bypass gates from a central control facility.[9]

Seymour (Sy) Lubetkin, PVSC Assistant Chief Engineer (1950 to 1954) and Chief Engineer (1954 to 1978), who directed PVSC Bypass Crew operations (a 24-hour/7-day per week work crew), stated:

> *The PVSC bypassed waste to the River in the following instances:*
> *a. when it rained and the volume of flow in the system threatened to exceed capacity;*
> *b. when it was necessary to reduce the flow in order to repair sewer lines;*
> *c. when discharges occurred accidentally, as when the flap valves closed because the chain had broken or come unattached; and*
> d. *when a breakdown occurred at the pumping station or treatment plant and it was necessary to limit flow for repairs or to prevent further damage during repairs.*[10]

[10] Affidavit of Seymour A. Lubetkin, January 6, 1994 [846680003-846680007].

According to Mr. Lubetkin, in cases of rain, the Second River Meeting Sewer (Union Outlet) was "easy to bypass because the gates were in the line maintenance yard at Second River owned by the PVSC so they were readily accessible to PVSC personnel."[11] If extensive bypassing was needed, the "last resort" was the Yantacaw Bypass. Bypassing this part of the system, which included all waste from the northern portion of the interceptor, was referred to as "having to throw Yantacaw."[12]

The major bypasses discharged untreated waste from multiple municipalities. For example, when the Yantacaw Bypass was opened, all wastes upstream of the Third River were sent untreated to the Passaic River, including waste from the municipalities of Paterson, Haledon, Prospect Park, Hawthorne, Fair Lawn, Elmwood Park, Garfield, Clifton, Lodi, Passaic, Wallington, and East Rutherford.[13] When the Union Outlet (Second River Bypass) was opened, the entire flow of untreated sanitary, domestic, and industrial waste from Montclair, Orange, Glen Ridge, Bloomfield, and East Orange was discharged directly to the Passaic River.[14] Exhibit 2-2 shows a summary of the PVSC bypasses investigated in this report and the areas served by the sewers connected to each bypass.[15] A total of approximately 39,605 acres was served by the sewers connected to these PVSC bypasses. Exhibit 2-3 provides maps prepared for the PVSC that depict the location of the bypasses along the Passaic River, as well as maps depicting the sewer areas connected to each Newark bypass.[16]

[15] Note that there is some documentation of PVSC bypasses in Paterson. Since the available documentation covers only occasional PVSC bypasses in this area, they are not included in this report.

[16] Elson T. Killam Associates, Inc., Report Upon Overflow Analysis to Passaic Valley Sewerage Commissioners: Passaic River Overflows.

While complete documentation regarding PVSC bypasses has not been produced to date, there is extensive documentation regarding the PVSC's discharges to the Passaic River during select time periods. For example, detailed time log documentation was provided by Mr. Lubetkin for much of the period from October 1950 through December 1962. The time logs (referred to as "throw-out logs" because they depicted waste being thrown out of the PVSC system and into the river) identify the dates and times that the PVSC manually opened and closed the bypasses during rainfall and repair/maintenance events. In addition, PVSC contractor Elson T. Killam Associates, Inc. documented bypasses observed during portions of 1974 to 1975, as well as measurements of the volume of bypassed flows and total suspended solids ("TSS") concentrations.[17] The PVSC also summarized its recent annual Newark bypasses to the Passaic River in NPDES reports; to date NJDEP has made available reports for the years 2005-2014.[18]

The documented PVSC bypasses discussed above are summarized in Exhibit 2-4 for each bypass starting in October 1950. This exhibit shows the start and end times for PVSC bypasses to the Passaic River and the calculated total bypass time (in hours and minutes). For the 1974-1975 time-frame, Exhibit 2-4 also summarizes PVSC contractor measurements of bypass times, average bypass flow rates, and average storm TSS values. During the 2005-2014 time-frame, PVSC reports indicate the number of Newark bypasses and the annual elapsed time for each bypass location. Using the measured flow and TSS data from 1974-1975 for each PVSC bypass location shown in Exhibit 2-4, total bypassed volume (in million gallons/hour or "MG/hr") is calculated by summing the total measured overflow volume (elapsed time for each specific bypass event multiplied by the average flow rate for that specific bypass event). This total bypassed volume is then divided by the total bypass time to derive a bypassed volume rate (MG/hr).[19] In addition, for each bypass location in Exhibit 2-4, bypassed mass (in pounds or "lb")

---

[17] *Ibid.* Note that in this report, bypasses are indicated as "regulator closed" events, in which the regulator valve allowing waste to be transported to the PVSC Treatment Plant is closed.

[18] PVSC, NJPDES permit reports to NJDEP, CSO Regulator Events, 2008-2015, Table 1.

[19] During the 1974-1975 Killam research period, some Newark bypass regulators were inoperable or unused, preventing measurement of bypass flow. In these instances, average measured overflow data are used to calculate flow volumes as noted in Exhibit 2-4. These overflow measurements should be conservatively low compared to the flow that would be experienced when waste was bypassed. Likewise, the Yantacaw Bypass was

is calculated by multiplying average storm TSS measurements[20] by the bypassed volume. The total of bypassed mass is then divided by total bypass time to derive a mass bypass rate (lb/hr) for each location. These calculated bypass volume and mass rates are shown in Exhibit 2-4 for each bypass location.

Table 2-2 below summarizes the documented PVSC bypass times for each bypass location, using the available documentation for the 1950-1962 and 1974-1975 time periods (see Exhibit 2-4 for details). For each bypass location, average annual bypass times were calculated for 1952 to 1962, the period when there are few missing bypass logs. Bypass times for dates with missing documentation during the 1924-1974 period (see highlighted dates in Exhibit 2-4) were then estimated using the 1952-1962 average annual bypass times, adjusted downward during 1924-1950 to account for lower average daily flow rates in the PVSC system as shown in Exhibit 2-5.[21] Bypass times for dates with missing documentation during the 1975-2016 period were estimated using the more recent 2005-2014 average annual bypass times.[22] The resulting total estimated bypass times for 1924-2016 (which include the documented bypasses during this period) are shown in Table 2-2.

---

not opened during the Killam study period. However, Killam provided a measurement for the Yantacaw average flow during wet weather, which is used in this analysis. Source: Elson T. Killam Associates, Inc., Report Upon Overflow Analysis, prepared for PVSC, 1976, p. 106 [LPRSA0195596].

[20] The TSS measured during storm events was used for this analysis, since the majority of bypasses occurred during storms. Also, it is noted that TSS measurements may not measure all of the mass (such as floating solids or sludge). Therefore, this report may underestimate solids mass releases.

[21] For example, the 1925 average daily flow in the PVSC system was 100.12 MGD versus 201.02 MGD in 1950, resulting in an index adjustment of 100.12/201.02 or 0.498 for 1925 estimates. While it is possible that the 1924-1950 bypass times are similar to the 1952-1962 annual average, the lower system throughput could indicate lower bypass times and in particular, lower bypass volumes. As a conservative estimate, the times and resulting volume estimates have been adjusted downward.

[22] An EPA survey of Superfund allocators indicates that such extrapolation is often used to fill in volumetric data for non-recorded periods where waste production/disposal records are absent. In particular, existing waste production/disposal data combined with years of operation may be used to fill in missing data. In addition, typical manufacturing/production line process discharges and spills may be used to estimate disposal volumes when volumetric data are unavailable. Source: Office of Site Remediation Enforcement, EPA, *Developing Allocations Among Potentially Responsible Parties for the Costs of Superfund Site Cleanups*, October 1994, pp. 4-6.

Table 2-2. Bypass Times (hours)

Bypass	Documented Bypasses (1950-1962, 1974-1975, 2005-2014)	Total Estimated Bypasses (1924-2016)**
Yantacaw*	2,486	9,354
Union Outlet*	14,289	53,940
Verona Avenue	12,401	48,626
Herbert Place	17,804	68,521
4th Avenue	18,053	69,488
Clay Street	19,128	73,007
Rector Street	18,216	70,165

City Dock	13,075	47,656
Jackson Street	17,936	68,922
Polk Street	18,061	69,410
Freeman Street	18,180	69,874

* Projections for Yantacaw and Union Outlet bypasses are not included after 1975 due to lack of detailed bypass documentation after this date. As described in the text, anecdotal information shows that the PVSC continued to open these bypasses after 1975, making the estimates conservatively low.

** Includes documented bypasses. Start date is August 2, 1924; end date is September 30, 2016, with the exception of Yantacaw and Union Outlet where the end date is 1975 due to lack of available detailed documentation after that date.

There is evidence showing that the PVSC bypassed untreated waste to the Passaic River in time periods extending back to early operations. For example, a PVSC document summarizing flows during November 17-24, 1924 indicates that during the week, the PVSC bypassed 18.12 MGD to the Passaic River at Yantacaw, equal to 47.4% of the total Yantacaw flow for that week.[23] During the week of November 24-December 1, 1924, an additional 14.16 MGD was bypassed at Yantacaw to the Passaic River, equivalent to 46.7% of the Yantacaw flow for that week. The Union Outlet was also bypassed for several days during this week.[24]

[23] PVSC, Table No.4, Flow of Towns in Order of their Interception, Week of Nov. 17-24 [LPRSA0194301].

[24] PVSC, Table IV, Flow of Towns in the order of their Interception, November 24-December 1, 1924 [LPRSA0194291]; Table II, Weekly Record of Venturi Meters, November 26-December 3, 1924 [LPRSA0194288].

Bypasses later in time are also indicated. For example, a PVSC contractor reported that the PVSC bypassed waste to the Passaic River for several months during 1969 while pumps were being repaired.[25] The PVSC also reported that on April 16, 1973, the bypasses were opened at Yantacaw and Newark to allow for inspection of the trunk sewer line, with additional bypassing for inspections on October 14, 1973. Based on this inspection, the PVSC bypassed sewage to the Passaic River for the month of March through April 4, 1974, to allow for internal sewer repairs.[26] In June 1979, equipment repairs and breakdowns let the PVSC to bypass untreated waste to the Passaic River at Union Outlet, Herbert Place, 4th Avenue, Clay Street, Rector Street, Saybrook Place, Freeman Street, Polk Street, and Jackson Street (Newark).[27] Following primary treatment, all PVSC waste was bypassed at a PVSC outlet at Newark Bay (outlet 002) from November 9, 1979 to August 14, 1980.[28] The PVSC also bypassed waste from twenty overflow points to the Passaic River for 21 days in 1980 due to a pipeline break in Paterson. In June 1984, the PVSC bypassed approximately 12 MG of chlorinated, but otherwise untreated sewage to the Passaic River at the Wallington pumping station (including waste from Saddle Brook, Lodi, Garfield, and Wallington) due to equipment work.[29] Bypasses at Yantacaw (Third River), Union Outlet (Second River), and Clay Street (Newark) occurred during June 8-9, 1986 to allow for PVSC inspections of the main interceptor.[30] Bypasses occurred during April 17-18, 1988 at eight locations (including Verona Avenue, Herbert Place, 4th Avenue, Rector Place, and Saybrook Place in Newark as approved by NJDEP) to allow for attempted inspection of the main interceptor; toxic vapors in the sewer

[28] PVSC memo regarding discharge from PVSC to Newark Bay, July 16, 1980; NJDEP press release, August 22, 1980.

[29] R. Leith, "Effect of Sewage Flow on River Life Being Monitored," *The Record*, June 17, 1984; Letter from D.C. Hofman, NJDEP to R.D. Ricci, PVSC, May 13, 1980.

[30] Letter from J.A. Lawrence, PVSC to A. Schiffman, NJDEP, June 11, 1986. (Note that bypassed waste was disinfected with hypochlorite solution before discharge to the Passaic River.)

prevented workers from completing the inspection.[31] The Herbert Place (Newark) bypass discharged untreated sewage to the Passaic River on January 5, 1989 due to a regulator control malfunction.[32]

As indicated in the detailed bypass logs through 1962, in general the Union Outlet was used first and most frequently, followed by the Newark bypasses.[33] Yantacaw tended to be the last bypass used. As a percentage of total time, on average Union Outlet was bypassed to the Passaic River approximately 12 percent of the time, whereas Yantacaw was bypassed approximately 2 percent of the time. Bypass information for Union Outlet and Yantacaw for the 2005-2014 time-frame has not been made available; during this time the Newark bypasses were used relatively consistently and up to 62 times per year.

Table 2-3 below shows estimated bypass volume and bypass rates using the bypass flow information collected by PVSC's contractor during 1974-1975. The total bypassed volume estimate was calculated by multiplying total bypassed time by average bypass volume flow rate.[34] The estimated volume bypassed by the PVSC during 1924-2016 is approximately 617.1 billion gallons. This volume is similar in magnitude to Anchor QEA's estimated CSO automatic overflow volume of 569.9 billion gallons,[35] for a total PVSC system flow to the Passaic River of 1.187 trillion gallons of sewage.

[32] Letter from P. Habrukowich, PVSC to P. Lynch, NJDEP, January 6, 1988.

[33] While PVSC Chief Engineer Sy Lubetkin indicated in his 1994 affidavit that the Newark bypasses were usually employed first, followed by Union Outlet, the detailed bypass logs produced by Mr. Lubetkin show that Union Outlet was usually opened first, and often in concert with the Newark bypasses. As pointed out by Mr. Lubetkin, the Union Outlet bypass was located in the PVSC line maintenance yard, so it was nearby and easy to access by the bypass crew. Affidavit of Seymour A. Lubetkin, January 6, 1994 [846680003-846680007].

[34] Elson T. Killam Associates, Inc., Report Upon Overflow Analysis, Newark Area, prepared for PVSC, 1976. Note that measured stormy weather flow rates and TSS data are used from this report because a majority of the PVSC's documented bypasses cite stormy weather at the time of the bypass.

Total		**617,103**

* Start date is August 2, 1924; end date is September 30, 2016 (with the exception of Yantacaw and Union Outlet, where the end date is 1975 due to lack of available detailed documentation).
Note: Numbers may not add to totals due to rounding.

Table 2-4 below shows the estimated solids mass bypassed by the PVSC to the Passaic River. To estimate pounds of solids mass bypassed, TSS data were applied to the bypass rates discussed above for each bypass (bypass time is multiplied by mass bypass rate). For the 1924-1991 period, estimated solids mass is based on average TSS data measured for stormy weather during 1974-1975 at each bypass. Starting in 1992, these TSS data were reduced by 55 percent to track an equivalent TSS decline observed in the PVSC's influent.[36] As a result, the estimated solids mass bypassed by the PVSC to the Passaic River is 1.155 billion pounds (or 577,636 tons) as shown in Table 2-4. Anchor QEA estimated the total solids mass from automatic CSOs at 0.587 billion

[36] Hazen and Sawyer, *Maximization of the Conveyance of Wastewater: Final Report*, prepared for the PVSC, December 1996, p.2.

pounds (293,499 tons),[37] resulting in a total PVSC disposal of solids to the Passaic River of 1.742 billion pounds (871,135 tons).

According to the 2016 ROD issued by EPA for the lower 8.3 miles of the Lower Passaic River, the eight COCs that pose the highest potential risk to human health and the environment at the site are:[38]

- Dioxins and furans
- Polychlorinated biphenyls ("PCBs")
- Mercury
- Dichlorodiphenyltrichloroethane ("DDT")
- Copper

[37] Anchor QEA, PVSC CSO overflow and mass discharge estimates, 2017. (See Exhibit 2-8.)

[38] U.S. Environmental Protection Agency, Region II, Record of Decision: Lower 8.3 Miles of the Lower Passaic River, Part of the Diamond Alkali Superfund Site, March 3, 2016, pp. 14-16.

- Dieldrin (HEOD or 1,2,3,4,10,10-hexachloro-6,7-epoxy-1,4,4α,5,6,7,8,8α -octahydro-1,4-endo,exo-5,8-dimethanonaphthalene)
- Polycyclic aromatic hydrocarbons ("PAHs")
- Lead

Historical information measuring COCs in the PVSC sewage during the early decades of PVSC operation is sparse. Available studies indicate the following measurements for COCs:

- 1977 PCBs (due to the lack of PVSC sampling for PCBs during the chemicals' commercial production period of 1929 to 1976,[39] data are for influent measured at a POTW treatment facility in the City of Baltimore that is of comparable size and that treated waste from diverse PCB-using industries similar to those discharging to the PVSC)[40]

[39] Commercial production of PCBs began in the United States in 1929. A PCB ban was implemented in 1977. However, there is evidence that PCBs have been found in the PVSC system at low levels long after their phase-out. For example, PCBs were measured at 300 ng/l in PVSC influent in 1999. Sources: United Nations Environment Programme - Chemicals, *Regionally Based Assessment of Persistent Toxic Substances, North America Regional Report*, December 2002, p.32; HartCrowser, Draft Engineering and Historical Review of PVSC CSOs, Prepared for Tierra Solutions, September 12, 2002, p.7-5, Table 7-2 (based on study by Durell and Lizotta, 1999) [MAXUS2959885].

[40] EPA, *PCBs Removal in Publicly-Owned Treatment Works*, July 16, 1977, pp 1-.2, 7-8, and 59. In this report, EPA studied PCB removal at two publicly-owned treatment works ("POTWs"): a small 3.5 MGD plant in Bloomington, Indiana with one major PCB contributor (a capacitor manufacturer), and a larger, 180 MGD plant in Baltimore, Maryland where "the PCBs in the influent are more generally attributable to diverse industrial and domestic sources typical of a heavily-industrialized urban area." The average influent PCB concentrations were measured at 145 µg/l for the Bloomington facility, and at 15 µg/l for the Baltimore facility. The Baltimore concentration is used in this report due to the similarity in facility size, industrialized location, and industrial contributors (such as electric component and transformer manufacturers common to both areas as well as the common use of PCBs in hydraulic fluids, heat transfer fluids, and recycled paper) as compared to the PVSC system. The study also found a high correlation between PCB removal and TSS removal, noted as an expected result because prior studies show that "PCBs are adsorbed onto suspended solids." Note that the Baltimore POTW covers a similar size industrialized area (140 square miles) as the PVSC (150 square miles). Source: Baltimore City Department of Public Works, "Back River Wastewater Treatment Plant," accessed at http://publicworks.baltimorecity.gov/pw-bureaus/water-wastewater/wastewater/back-river. The Baltimore system also had sewer overflow and CSO overflow issues, leading to a Consent decree with EPA and DOJ in 2002 to address untreated discharges. Source: EPA, *City of Baltimore, Maryland, Sewer Overflows* Settlement, April 26, 2002 Consent Decree, accessed at https://www.epa.gov/enforcement/city-baltimore-maryland-sewer-overflows-settlement

Obtaining samples in a relevant time period is important for mass discharge estimates, as domestic PCB sales generally started around 1930, grew from the mid-1950s, and peaked in 1970, after which they dropped in half and were subsequently phased out later in the 1970s. Sources: EPA, *PCBs in the United States Industrial Use and Environmental Distribution: Task* I, February 25, 1976, pp. 198-207; Versar, Inc., *Polychlorinated Biphenyls 1929-1979: Final Report*, prepared for EPA, May 16, 1979, pp. 1-3.

- 1978 Metals in PVSC influent[41]
- 1984-86 Select PAHs in PVSC influent (see listing of PAHs in Exhibit 2-6)[42]

The sampling results from these studies are summarized in Exhibit 2-6. It is noted that sampling results are not available for each bypass, and that concentrations likely varied by bypass; however, the available sampling provides insights into an order-of-magnitude estimate for the mass of COCs bypassed by the PVSC to the Passaic River. Furthermore, the sample values in Exhibit 2-6 are expected to be low relative to earlier historical concentrations due to the imposition of industrial waste pretreatment requirements in the 1970s. In addition, the available PCB measurements do not cover the period when PCBs were in common use, prior to being phased out by the mid-1970s. Therefore, the bypassed COC estimates discussed below are likely to be low.

Using the measurements for COCs cited above, the mass of COCs bypassed by the PVSC is estimated by multiplying measured concentrations (from Exhibit 2-6) by estimated bypassed volume (summarized in Table 2-3). Starting in 1992, the concentrations are reduced by 55 percent (as discussed above for the mass calculations) to factor in a decline equivalent to the TSS decline observed in the PVSC's influent.[43] As shown in Table 2-5 below (and detailed in Exhibit 2-7), the total mass of COCs bypassed by the PVSC to the Passaic River during 1924-2016 is estimated conservatively low at 8,203,685 pounds (4,102 tons). Applying the same methodology to Anchor QEA's estimated CSO overflow volume yields an estimated 6,933,739 pounds (3,467 tons) of COCs that flowed into the Passaic River from these automatic overflows. Table 2-5 also

Lead	3,804,812	3,222,088	7,026,900	7,054,792
Select PAHs (see Exhibit 2-6)	3,083,750	2,611,460	5,695,210	903,895
Total	**8,203,685**	**6,933,739**	**15,137,424**	

* The period for PCB mass estimation is 1930-1976.
** Start date is August 2, 1924; end date is September 30, 2016 (with the exception of Yantacaw and Union Outlet, where the end date is 1975 due to lack of available detailed documentation after this date).
Note: Numbers may not add to totals due to rounding.

CONCLUSIONS

As shown in Table 2-5, the PVSC is estimated to have discharged over 15 million pounds of COCs to the Passaic River during the 1924-2016 time-frame. When comparing these estimates of PVSC-discharged COCs to those estimated by EPA as present in the sediments of the lower eight

[44] EPA, Additional Contaminant Inventory Analysis for Lower Eight Miles of the Lower Passaic River, April 2019, Table 1.

miles of the river (prior to Tierra Phase 2 Removal),[45] it is evident that the PVSC discharges alone could account for much of the mass of certain COCs[46] in OU-2.

[45] While interim activities removed some masses of COCs, for allocation purposes it is important to look at the total mass in the LPRSA driving the cleanup. Source: EPA, Additional Contaminant Inventory Analysis for Lower Eight Miles of the Lower Passaic River, April 2019, Table 1.

[46] Mass estimates are calculated for PCBs, mercury, copper, lead, and PAHs based on available historical concentration data.

EXHIBIT 2-8
ANCHOR QEA ASSESSMENT OF CSOS

Evaluation of Solids Contributions to the Passaic River from Passaic Valley Sewerage Commission Combined Sewer Overflows

Anchor QEA, LLC
123 Tice Boulevard, Suite 205
Woodcliff Lake, New Jersey 07677

Prepared for
Shook, Hardy & Bacon L.L.P.

1 Objectives

The objective of the work presented here is to evaluate the contribution of solids that the Passaic Valley Sewerage Commission (PVSC) has discharged to the Passaic River via combined sewer overflows (CSOs) and bypasses from its system during wet weather (i.e., rainfall) events. The evaluation uses PVSC flow and solids information from a comprehensive study of its collection system (Killam 1976) to estimate solids loads from the PVSC CSOs to the Passaic River. The data generated during the Killam (1976) study were used to develop an empirical relationship between rainfall and overflow volumes to estimate CSO discharges for years without overflow measurements. Estimates of solids concentrations in the overflows were applied to the overflow volumes to estimate the mass of solids discharged from the PVSC CSOs between Water Year (WY) 1924 and WY2016.

2 Methodology and Data

2.1 Methodology

Between October 1974 and September 1975 (referred to as WY1975), Elson T. Killam Associates, Inc. (Killam) conducted a comprehensive study of the PVSC interceptor and collection system to support an evaluation of alternatives aimed at eliminating overflows to the Passaic River. This study included physical characterization of the PVSC system and its components and measurement of flow and quality of the overflows over a 1-year period (Killam 1976).

This evaluation includes several parts:

1. Flow and solids concentration information collected during the WY1975 study period were used to estimate the total mass of solids (i.e., solids load) that entered the Passaic River during overflow events occurring in this WY.
2. An empirical relationship was established between total rainfall and the total overflow volume discharged from the PVSC CSOs to the Passaic River in order to estimate flow volumes and solids loads from PVSC operations from 1924 to 2016. For the period prior to the Killam study (i.e., WY1924 to WY1974), this relationship was applied to historic precipitation records from WY1924

ADR CONFIDENTIAL
PREPARED SUBJECT TO REQUIREMENTS OF AND FOR USE ONLY IN EPA ALLOCATION.
NOT BINDING OR TO BE DEEMED AN ADMISSION FOR ANY OTHER PURPOSE OR PROCEEDING.

to WY1974 to estimate the overflow volume for each year during this period. The average solids concentration measured during the WY1975 study was then applied to these overflow volumes to estimate the mass of solids discharged from the PVSC CSOs to the Passaic River for each year.

3. For the period after the Killam study (i.e., WY1976 to WY2016), the empirical relationship was applied to local precipitation records to estimate the number and magnitude of overflow events that occurred during this period. Then, average solids concentrations from the 1976 Killam study, a 2007 Hatch Mott MacDonald study, and a 2014 Newark stormwater study (Amar et al. 2014) were applied to the estimated overflow volumes to estimate the mass of solids discharged from the PVSC CSOs to the Passaic River for each year.

2.2 Data

Data from several sources were used in this evaluation, including:

- Overflow volumes and solids concentration measurements from the PVSC CSOs to the Passaic River in WY1975 (Killam 1976)
- Precipitation records from the National Oceanic and Atmospheric Administration (NOAA) weather station at Jersey City (1924 to 1948)
- Precipitation records from the NOAA weather station at Newark Liberty International Airport (Newark Airport; 1949 to 2013)
- Precipitation records from the weather station at Newark Airport, as reported by Weather Underground (www.wunderground.com) (2014 to 2016)
- Solids concentration information from the wastewater and CSO outfalls (USFWPCA 1969)
- Solids concentration information from PVSC system (Hatch Mott MacDonald 2007)
- Solids concentration information from Newark stormwater (Amar et al. 2014)

3 PVSC CSO Solids Loads

3.1 WY1975

Between October 1974 and September 1975, Killam conducted a comprehensive study of 73 CSOs (65 active, 8 inactive) within the PVSC collection system (Figure 3-1 and Table 3-1). The study focused on identifying and characterizing each CSO, and understanding the number, magnitude, and quality of observed overflows in response to measured precipitation events. To accomplish the latter objective, rainfall volume and duration were recorded for weather events occurring in the region. Dry and wet weather flow measurements were obtained from each CSO. Due to the large number of CSOs, the monitoring was conducted over variable time frames within the year; thus, no complete annual record of rainfall or overflow exists for any CSO location. In addition to overflow volume, sampling of total suspended solids (TSS), biochemical oxygen demand (BOD), and chemical oxygen demand (COD) was performed for a subset of overflow events to determine the quality of the overflows.

ADR CONFIDENTIAL
NOT BINDING OR TO BE DEEMED AN ADMISSION FOR ANY OTHER PURPOSE OR PROCEEDING

Killam reported that overflows sent approximately 7,600 million gallons (MG) of combined stormwater and sewage to the Passaic River over the monitored 1-year period. Total solids load from the CSOs was not computed in the report. This overflow volume does not include an additional 3,400 MG that were discharged from the South Side Interceptor overflows and diversions from valve closings, bypasses, the Second River Union Outlet sanitary bypass, and other sanitary system overflows (Killam 1976).

For the evaluation, measured rainfall volume, duration, intensity, and overflow volume were analyzed for each CSO location to investigate correlations that would allow one to use rainfall information to estimate overflow volume in other years (i.e., those before and after WY1975). Correlations for individual CSOs were poor due to data paucity; therefore, a system-wide relationship between rainfall and overflow volume was examined. The total daily overflow volume for each precipitation event, as reported by Killam (1976), is plotted against the daily rainfall in Figure 3-2. Reported overflow volume correlated well with daily rainfalls and a linear regression provided a good fit to the data (Figure 3-2).

The relationship shown in Figure 3-2 and precipitation records from Newark Airport for the same 1-year period were used to estimate the total overflow volume from the PVSC CSOs for comparison to that reported by Killam (1976). Because rainfall events of short duration or low intensity did not always generate runoff and overflow events during the Killam study, rainfall events less than 0.1 inch were assumed to generate no overflows and were not included in the overflow volume calculations. Using this empirical relationship and the Newark Airport precipitation records yielded an estimated overflow volume from the PVSC CSOs of 7,000 MG during WY1975. These numbers compare reasonably well with those reported by Killam (1976), providing confidence that the empirical relationship derived from the Killam study provides a reasonable tool to estimate overflow volumes in other years.

To estimate solids concentrations in the overflows, we reviewed the TSS data generated during the Killam study. Similar to the overflow monitoring, water quality monitoring was not conducted for the full year at any one station, and data exist for only a subset of the observed overflows. Additionally, sampling occurred at many CSOs during dry-weather flow to determine solids concentrations of the baseline flows to the PVSC treatment plant. Therefore, to accurately assess TSS concentrations in overflows, TSS reported by Killam (1976) when overflows were not noted were excluded from this analysis. The cumulative frequency distribution of the TSS concentrations measured by Killam is shown in Figure 3-3. Measurements range from approximately 20 milligrams per liter (mg/L) to 400 mg/L. The average TSS concentration of 147 mg/L was assumed to represent the average condition during an overflow event.

The total mass of solids discharged from the PVSC overflows for WY1975 was computed as the product of the reported total overflow volume (7,600 MG) and the average TSS concentration in the

ADR CONFIDENTIAL
NOT BINDING OR TO BE DEEMED AN ADMISSION FOR ANY OTHER PURPOSE OR PROCEEDING

overflow (147 mg/L). The calculations indicate that PVSC overflows delivered, on average, approximately 9.3 million pounds (lbs; 4,700 tons) of solids to the Passaic River during WY1975.

3.2 WY1924 to WY1974

No known regular sampling or flow measurements were conducted on CSO overflows prior to 1976. As such, impacts of infrastructure and usage changes on overflow volumes and TSS since 1924 are not known. To assess historical trends, overflow behavior and TSS levels were assumed to be similar to those observed in 1975, and the empirical overflow volume-rainfall relationship developed from the Killam study data was used to estimate overflow volumes discharged from the PVSC CSOs to the Passaic River for WY1924 to WY1974.

Rainfall data collected by NOAA at the Newark Airport weather station were used in this evaluation to forecast and hindcast overflow volumes and solids loading values from the PVSC CSOs to the Passaic River. Hourly rainfall records at Newark Airport are available for 1949 through 2013. For 2013 through 2016, daily Newark Airport rainfall records were downloaded from Weather Underground. For 1924 to 1948, rainfall data from nearby NOAA Jersey City weather station were used to calculate overflow volumes from 1924 to 1948.

The empirical overflow volume-rainfall relationship (shown in Figure 3-2) was used, along with the Jersey City/Newark Airport precipitation records, to estimate the annual volume of PVSC overflows for WY1924 to WY1974 (Figure 3-4). The average TSS concentration of 147 mg/L from the Killam study data (WY1975) was applied to the estimated overflow volumes to compute the historical solids loads from the PVSC CSOs to the Passaic River. It is likely the solids concentrations in overflows were higher in the decades before the Federal Water Pollution Control Act of 1972 than the levels measured during WY1975. However, without specific data, TSS concentration scaling assumptions could not be made. The annual solids loads estimated for WY1924 to WY1974 are shown in Figure 3-5.

3.3 WY1976 to WY2016

Similar to the WY1924 to WY1974 period, the empirical overflow volume-rainfall relationship (shown in Figure 3-2) was used along with the Newark Airport precipitation records to estimate the annual volume of PVSC overflows for WY1976 to WY2016. The estimated overflows for this period are shown in Figure 3-4.

Since 1975, the municipalities served by the PVSC have continued to develop, industrial dischargers have changed, and several federal and state regulations impacting allowable discharges were enacted (i.e., 1977 Clean Water Act, 1987 Water Quality Act, and 2004 New Jersey Stormwater Management rules). To capture the changing landscape of the PVSC system and the associated reduction in solids concentrations that resulted from best management practices (BMPs) within the

ADR CONFIDENTIAL
NOT BINDING OR TO BE DEEMED AN ADMISSION FOR ANY OTHER PURPOSE OR PROCEEDING

watershed, data collected for the PVSC and City of Newark after 1975 were used to adjust the assumed solids concentrations in overflows for WY1976 to WY2016.

In 2007, Hatch Mott MacDonald conducted a modeling study on behalf of the PVSC. The results of this modeling indicated an average TSS concentration in the PVSC overflows of approximately 90 mg/L. This value was used to represent average TSS conditions for 1988. The reduction in TSS between WY1976 and WY1988 is likely due to responses to the Clean Water and Federal Water Pollution Control acts that regulate discharges and required application of BMP technology to reduce pollutant loads to waterbodies. To reflect these changing conditions in the solids load evaluation, a linear reduction in solids concentration from 147 mg/L in WY1976 to 90 mg/L in WY1988 was assumed (Figure 3-6).

City of Newark stormwater reporting from 2014 indicates that typical stormwater TSS concentrations average 80 mg/L (Amar et al. 2014). The additional reduction in TSS concentration since 1988 is assumed to be an effect of the implementation of 2004 New Jersey Stormwater Management rules. Therefore, for this evaluation, a linear reduction in solids concentration from 90 mg/L in WY2004 to 80 mg/L in WY2014 was applied (Figure 3-6). Water quality reporting data are not currently available for individual CSOs, therefore the average of 80 mg/L was assumed to approximate contemporary TSS concentrations in overflows for WY2014 to WY2016 (Figure 3-6).

Solids loads to the Passaic River between WY1976 to WY2016 were estimated by multiplying the overflow volumes shown in Figure 3-4 and the TSS concentrations shown in Figure 3-6; results of this calculation are shown in Figure 3-5. The estimated solids loads shown in Figure 3-5 do not include the effects of significant storm events such as Hurricane Sandy, which rendered the PVSC plant inoperable for several days in 2012 (Climate Central 2013).

3.4 Summary

Based on this evaluation, the PVSC CSOs are estimated to have delivered 594 million lbs (297,000 tons) over the entire period examined (i.e., WY1924 and WY2016). This is likely an underestimate of the total solids load discharged over this period for the following reasons:

- The average solids concentration (i.e., 147 mg/L) used to represent TSS levels in historical overflows from the PVSC CSOs is likely lower than the levels in discharges occurring earlier than WY1975. This conclusion is supported by the TSS level found in a 1969 CSO study conducted by the U.S. Federal Water Pollution Control Administration (USFWPCA) and the New Jersey State Department of Health, with an average TSS of 238 mg/L from 15 CSOs, ranging from 8 to 1,230 mg/L (USFWPCA 1969).
- The Killam (1976) study identified eight inactive CSOs during their characterization of the PVSC system. These inactive CSOs were historically active and, thus, discharged combined sewage and stormwater during their active life.
- The Newark Bay treatment plant pumping facility was upgraded between 1953 and 1956, and additional upgrades were performed in 1964 (USFWPCA 1969). Overflow occurrence and

ADR CONFIDENTIAL
NOT BINDING OR TO BE DEEMED AN ADMISSION FOR ANY OTHER PURPOSE OR PROCEEDING

discharge volume may have declined as a result of these upgrades, which would indicate that the overflow volumes estimated using the empirical relationship between overflow volume and rainfall developed using the Killam (1976) measurements likely underestimate discharges from the PVSC CSOs prior to these updates.

- The estimated PVSC CSO solids loads do not include the effects of significant storm events such as Hurricane Sandy, which rendered the PVSC plant inoperable for several days in 2012 (Climate Central 2013), discharges due to maintenance or system malfunctions, or other intentional discharges that are not represented in the Killam (1976) study data.

APPENDIX B
SOURCES OF COCS TO THE LPRSA

ADR CONFIDENTIAL
NOT BINDING OR TO BE DEEMED AN ADMISSION FOR ANY OTHER PURPOSE OR PROCEEDING

Sources of COCs to the LPRSA

Available data on the historical sources for each COC in the New York/New Jersey Harbor area and the watershed including the LPRSA are summarized below. This analysis does not examine discharges from specific facilities, other than EPA conclusions regarding the Diamond Alkali facility.

Dioxins and Furans[1]

Dioxins and furans are a family of compounds with similar structure and chemical characteristics.[2] They are insoluble in water, and tend to attach to organic particles that can be transported through air, water, and land emissions. At the request of EPA, the New York Academy of Sciences ("NYAS") examined *current* sources of dioxin and furan releases in the New York/New Jersey Harbor watershed, including the Passaic River. The report was issued in 2006.[3] They concluded that a major current source of dioxin atmospheric deposition in the New York/New Jersey watershed is combustion of materials containing carbon and a chlorine source, from activities such as:

- Uncontrolled burning such as structural/building fires, open burning (*e.g.,* agricultural, residential, garbage), vehicle and tire fires, and fires at waste management facilities and dumpsters,
- Controlled combustion at incinerators such as municipal solid waste, hazardous waste, sewage sludge, crematoria, and medical waste incinerators,

---

1 The NYAS study used the term "dioxins" as shorthand for the suite of 210 polychlorinated dibenzo-p-dioxin and polychlorinated dibenzofuran compounds (PCDDs/PCDFs), including 2,3,7,8-TCDD and "dioxin-like compounds" such as coplanar PCBs, polychlorinated naphthalenes, and brominated and chlorinated/brominated dioxins. Of these, the compound 2,3,7,8-TCDD is the most toxic. The report also used "dioxins" to refer to data sets where fewer than the 210 compounds were measured. This report follows the NYAS convention and uses "dioxins" to mean 2,3,7,8-TCDD, TCDD toxic equivalents ("TEQs"), or PCDDs/PCDFs, unless otherwise noted. Source: G.R. Munoz and M.A. Panero, New York Academy of Sciences, Pollution Prevention and Management Strategies for Dioxins in the New York/New Jersey Harbor, August 2006, pp.33-34.

- Landfill gas flares, and
- Combustion of contaminated/treated/painted wood.

NYAS identified the Diamond Alkali facility as a major historical contributor of dioxins to the New York/New Jersey Harbor watershed.[4] While the focus of the NYAS study was to examine present mass flows into and out of the New York/New Jersey Harbor rather than just the Passaic River, additional research has focused more narrowly on inputs to the LPRSA. One study reconstructed historical discharges from the 2,4,5-tricholorphenol purification process at the Diamond Alkali facility, finding that the 2,3,7,8-TCDD mass discharged from this process could account for the mass of 2,3,7,8-TCDD found in the LPRSA. This finding was further supported by sediment core dating from nearby sediments.[5]

A fingerprinting study by Anchor QEA concluded that the Diamond Alkali facility was the "dominant source" of 2,3,7,8-TCDD (2,3,7,8-tetrachlorodibenzodioxin) located in River sediments in the lower 14-mile stretch of the LPRSA.[6] In the Anchor QEA study, 1,2,3,4,6,7,8-HpCDD (1,2,3,4,6,7,8-heptachlorodibenzodioxin) and OCDD (octachlorodibenzodioxin), both commonly emitted by vehicle exhaust and wood fires, with OCDD also a weathering component of pentachlorophenol, were each noted as a major component of contamination above Dundee Dam and occurring at similar levels below Dundee Dam, and were thus determined to be emissions from regional background sources. Peak 2,3,7,8-TCDD concentrations from sediment cores were found to date from the 1950s, the peak period of discharging from the Diamond Alkali facility. Secondary concentration peaks were found to coincide with a 1960 trichlorophenol autoclave explosion that occurred at the Diamond Alkali facility. Additionally, concentration

[4] G.R. Munoz and M.A. Panero, New York Academy of Sciences, Pollution Prevention and Management Strategies for Dioxins in the New York/New Jersey Harbor, August 2006, pp. 107-109 and Figure 3, p. 28.

[5] R. Parette, D.J. Velinsky, and W.N. Pearson, "Reconstruction of Historical 2,3,7,8-tetrachlorodibenzo-*p*-dioxin Discharges from a Former Pesticide Manufacturing Plant to the Lower Passaic River," *Chemosphere*, Vol. 212, 2018, pp. 1125-1132.

[6] J.D. Quadrini, W. Ku, J.P. Connolly, D.A. Chiavelli, and P.H. Israelsson, Anchor QEA, "Fingerprinting 2,3,7,8-Tetrachlorodibenzodioxin Contamination Within the Lower Passaic River, *Environmental Toxicology and Chemistry*, Vo. 34, No. 7, 2015, pp. 1485-1498.

ratios of 2,3,7,8-TCDD to total TCDD were highly correlated, with ratios from samples from the Diamond Alkali facility closely matching those found in Passaic River sediments.

The Anchor QEA researchers again found PCDD/F (polychlorinated dibenzodioxin/ polychlorinated dibenzofuran) congener composition patterns in the samples at the Diamond Alkali facility and the sediment samples from River Mile ("RM") 0 to RM 10.9 to be highly similar.[7] In the area of RM 14 to RM 17.4, the PCDD/F congener fingerprinting closely matches that from above Dundee Dam. The ratios of 2,3,7,8-TCDD to total TCDD were found to support a similarity in sources for RM 0 to RM 14, with a shift in concentration ratios from RM 14 to the Dundee Dam as more consistent with upstream sources with some tidal intrusions from below.

The findings of the Anchor QEA research (and prior research reviewed by the study) are consistent with EPA's determination in its 2014 Remedial Investigation ("Remedial Investigation") of Operable Unit 2 ("OU-2") that the measured ratios of 2,3,7,8-TCDD to Total TCDD indicates the source is "almost exclusively industrial in nature since the early 1950s."[8] EPA selected 2,3,7,8-TCDD as the indicator chemical for dioxins/furans because it comprised the largest component (about 70%) of these compounds.[9] EPA data indicate the source of 2,3,7,8-TCDD is almost completely from legacy contamination, with data linking this contamination largely to the Diamond Alkali facility for RM 0 to RM 14 of the LPRSA. Contributions to total TCDD include only a minor contribution (3 percent) from above Dundee Dam. In addition, a small contribution (3-5 percent) enters the LPRSA from tidal flow from Newark Bay, determined by EPA

[7] Anchor QEA notes that other authors identified another potential PCDD/F source at approximately RM 11 (near the Third River), but Anchor QEA determined that the Diamond Alkali facility fingerprint was the dominant source to the Passaic River from RM 0 to 14 and that the other source could not be confirmed in the sediments.

[8] The Louis Berger Group, Battelle, and HDR/HydroQual, *Lower Eight Miles of the Lower Passaic River: Remedial Investigation Report for the Focused Feasibility Study*, prepared for EPA, 2014, p. 4-38.

[9] The Louis Berger Group, Battelle, and HDR/HydroQual, *Lower Eight Miles of the Lower Passaic River: Remedial Investigation Report for the Focused Feasibility Study*, prepared for EPA, 2014, p. 4-6 and Table 4-11, Summary of Indicator Chemicals.

as likely having originated from the LPRSA.[10] **Therefore, data indicate that the major source for this COC, at least for RM 0 to RM 14, was the Diamond Alkali facility.**

DDX

DDX, including DDT and metabolites DDD and DDE, were developed as organochlorine pesticides. They tend to adsorb onto organic matter or suspended particles.[11] While NYAS did not conduct a study of DDX contamination in the New York/New Jersey Harbor, another research study examined DDX in sediment samples for Newark Bay and its tributaries, including the Passaic River. The study noted that the highest concentrations of DDX occurred in the lower Passaic River, and at depths dating from peak periods of manufacture and use of DDT, 1940 to 1970.[12]

In the Remedial Investigation, EPA examined dated sediment core profiles, using DDE as an indicator of DDX. EPA found that DDE maximum values occurred over a longer period as compared to PCBs and 2,3,7,8-TCDD, with high values in 1970, and a slow decrease of the last 25 years.[13] The Remedial Investigation estimated that 86 percent of the total DDX mass was located in the Tierra Removal (Diamond Alkali facility) area, with only 4,000 kg (out of a total of 29,000 kg) located outside of the removal area.[14]

The Remedial Investigation also noted an ongoing contribution of DDE (as a surrogate for DDX) from upstream, finding that 10 percent of DDE emanates from the Upper Passaic River, 8 percent

[13] The Louis Berger Group, Battelle, and HDR/HydroQual, *Lower Eight Miles of the Lower Passaic River: Remedial Investigation Report for the Focused Feasibility Study*, prepared for EPA, 2014, Appendix A, Data Evaluation Report No. 3: "Contaminant History as Recorded in the Sediments," pp. 3-15 to 3-16.

[14] The Louis Berger Group, Battelle, and HDR/HydroQual, *Lower Eight Miles of the Lower Passaic River: Remedial Investigation Report for the Focused Feasibility Study*, prepared for EPA, 2014, p. 4-27.

from Newark Bay, 3 percent each from tributaries and 1 percent from CSOs and stormwater, leaving 78 percent from historical legacy contamination in the lower Passaic River.[15] As discussed above, it is likely that at least 86 percent of this legacy contamination was related to the Diamond Alkali facility's historical operations.

PCBs

PCBs consist of a group of 209 compounds, known as congeners, with various chlorination patterns on a structure of two attached carbon (benzene) rings.[16] Commercial production of PCBs began in 1929. In 1971, there was a voluntary restriction of PCB sales to closed system applications. Regulations passed in 1976 under the Toxic Substances Control Act ("TSCA"), regulated PCB use and handling, subsequently prohibiting most uses except in a limited set of enclosed applications by 1977.[17]

While approximately 77 percent of PCBs were used in the production of transformers and capacitors in the U.S., PCBs were also employed in a wide variety of applications and products such as circuit breakers, heat transfer equipment, compressors, vacuum pumps, hydraulic fluids, lubricants, plastics/resins, paints and coatings, rubber, adhesives, sealants/caulks, flame-retardant materials, insulating materials, siding, shingles, flooring, dye carriers in carbonless copying paper, inks, waxes, wood preservatives, and pesticides. PCBs were also included in dust control sprays for roads, railroad yard, and utility work areas.[18] PCBs can also be generated

[15] The Louis Berger Group, Battelle, and HDR/HydroQual, *Lower Eight Miles of the Lower Passaic River: Remedial Investigation Report for the Focused Feasibility Study*, prepared for EPA, 2014, pp. 8-8 to 8-9.

[16] M. Panero, S. Boehme, and G. Munoz, New York Academy of Sciences, Pollution Prevention and Management Strategies for Polychlorinated Biphenyls in the New York/New Jersey Harbor, February 2005, p. 23.

[17] M. Panero, S. Boehme, and G. Munoz, New York Academy of Sciences, Pollution Prevention and Management Strategies for Polychlorinated Biphenyls in the New York/New Jersey Harbor, February 2005, pp. 30 and 44.

[18] M. Panero, S. Boehme, and G. Munoz, New York Academy of Sciences, Pollution Prevention and Management Strategies for Polychlorinated Biphenyls in the New York/New Jersey Harbor, February 2005, pp. 22, 29-30, 44-45, and 65.

inadvertently as part of manufacturing processes that combine carbon and chlorine at high temperature such as the production of dyes, pigments, titanium dioxide, and ferric chloride.[19]

In 2005, at the request of EPA, NYAS completed a study of the release of PCBs to the New York/New Jersey Harbor watershed.[20] This study estimated 1929-1975 PCB sales to the watershed at 33,034 metric tons.[21] The report noted that emissions of PCBs are continuing decades after production and sales ended, as products containing PCBs continue to be used, recycled, combusted, and disposed. The report concluded that, at present, most of the PCBs enter the Harbor through runoff, tributary inputs, volatilization, and deposition as well as remobilization from previously contaminated sites.[22]

The NYAS study looked broadly at the New York/New Jersey Harbor watershed, rather than more narrowly focusing on the Passaic River. In the Remedial Investigation, EPA attributed current PCB contamination in the LPRSA mostly to resuspension of historical contributions of PCBs (estimated at 81 percent of the current source), with contributions from the Upper Passaic River (11 percent), tidal flow from Newark Bay (7 percent), and tributary flows (1 percent) accounting for the remaining sources.[23] This finding is consistent with PCB testing conducted by the U.S. Geological Survey of PCB concentrations in tributaries to the Passaic River, where the Upper Passaic River and Pompton River (which enters the Passaic River above Dundee Dam) and

/[22] M. Panero, S. Boehme, and G. Munoz, New York Academy of Sciences, Pollution Prevention and Management Strategies for Polychlorinated Biphenyls in the New York/New Jersey Harbor, February 2005, p. 39.

[23] The Louis Berger Group, Battelle, and HDR/HydroQual, *Lower Eight Miles of the Lower Passaic River: Remedial Investigation Report for the Focused Feasibility Study*, prepared for EPA, 2014, pp. 5-22 to 5-23 and 8-8 to 8-9.

tributaries (particularly Saddle River) were found to contribute significant PCB loads (see Table PCB1).[24]

Table PCB1. PCB Loads (g/yr) in Passaic River Tributaries (collected 2003-2004)

Tributary	Dissolved PCB Load (g/yr)	Suspended Sediment-Bound PCB Load (g/yr)
Upper Passaic River (above confluence with Pompton River)	549	644
Pompton River	349	352
Saddle River	212	2,320
Third River	47	132
Second River	9.2	37
Comparison: Passaic River head-of-tide at Little Falls, NJ	**1,600**	**5,600**

Sediment core analyses indicate that peak PCB discharges into the Passaic River likely occurred in the late 1950s and early 1960s, with highest deposition in the 1955 to 1975 time-frame, and slowly declining thereafter.[25] Overall, the data support historical sources of PCBs consistent with the peak sales period for PCBs, with a significant portion entering the system from the Upper Passaic River, and some from tributaries.

Mercury

Mercury is another COC in the LPRSA that has had numerous historical and ongoing sources, both naturally-occurring and anthropogenic. At EPA's request, NYAS also used regional and national data to study sources of mercury to the New York/New Jersey Harbor watershed, examining air, land, and water routes as sources. This study found air discharges of mercury account for approximately 13 percent of total releases, including, for example: (1) combustion by utilities, industrial/commercial furnaces, residential furnaces, automobiles, and crematoria and (2) volatilization from fluorescent lamps, hospitals, residential thermometers, and laboratories. Wastewater disposal of mercury was found to account for 24 percent of discharges, largely caused by dental facilities and hospitals, with additional contributions by laboratories, and residential waste including thermometers. Finally, solid waste accounted for 63 percent of mercury discharges, with almost half contributed by dental facilities, followed by switches, hospital waste, thermostats, fluorescent lamps, residential thermometers, laboratory waste, and batteries.[26] While these sources account for the initial releases of mercury, the contaminant may then be redistributed through water treatment which separates the contaminant into effluent or sludge, with the sludge redistributing the contaminant through incineration, fertilizer application, or landfilling.[27]

The NYAS study largely omits historical industrial discharges of mercury. Columbia University researchers contributing to the NYAS study investigated historical sources of mercury to the Hudson-Raritan basin during 1880-2000 in their examination of mercury inputs into the New York/New Jersey Harbor.[28] They found that sediment dating of mercury showed a rapid decrease in mercury deposition at the end of the 20th century due to reduced mercury use overall, the

[26] A.L.C. de Cerreno, M. Panero, and S. Boehme, New York Academy of Sciences, Pollution Prevention and Management Strategies for Mercury in the New York/New Jersey Harbor, May 14, 2002, Table 11, p. 64.

[27] A.L.C. de Cerreno, M. Panero, and S. Boehme, New York Academy of Sciences, Pollution Prevention and Management Strategies for Mercury in the New York/New Jersey Harbor, May 14, 2002, Table 12, p. 64.

change from coal to gas as a fuel, and the change from historical incinerators to controlled waste-to-energy combustion plants.

Both production and consumption of mercury rapidly declined starting in the 1980s as regulations were implemented controlling mercury in batteries and fungicides in paints, and as producers reduced mercury use in products such as thermometers, switches, and thermostats. By the 1990s, mercury recycling regulations further reduced releases to the environment.[29] Research examining mean concentrations of mercury in Newark Bay sediments indicates some concentrations dating from before 1940, with higher concentrations dating to the 1940-1980 period (peaking in 1940) and declining significantly thereafter.[30] In the late 1980s, an EPA study of mercury releases into the New York/New Jersey Harbor estimated relative contributions of mercury at that time from the following source categories (see Table M1):[31]

Table M1. Sources of Mercury to the NY/NJ Harbor

Source	Contribution (%)
Municipal	39.59%
Industrial	0%
CSO	6.71%
Stormwater	2.69%
Tributaries	50.78%
Leachate	0.28%
Atmospheric	NA

NA = Not Available

[30] T.J. Iannuzzi and R.J. Wenning, "Distribution and Possible Sources of Total Mercury in Sediments from the Newark Bay Estuary, New Jersey," *Bulletin of Environmental Contamination and Toxicology*, Vol. 55, 1995, pp. 901-908, Figure 2.

[31] HydroQual, Inc., Task 7.1: Assessment of Pollutant Loadings to New York – New Jersey Harbor, prepared for EPA Region II, January 1991, Table 2-3, p. 8, and Figure 2-9, p. 18.

While industrial sources are not identified as contributors as of the 1980s, it is likely that a portion of the tributary (and possibly stormwater and CSO) sources are comprised of historical legacy contamination from industrial and other sources.

Looking at data more closely related to potential discharges to the LPRSA, data on mercury in the PVSC effluent shows a significant decrease in mercury concentrations over recent years, estimated at 800 kg/year in 1987 and declining to approximately 50 kg/year in 1998.[32] Likewise, influent concentrations of mercury to the PVSC showed a decline in the 1980s, from 48.0 µg/l during 1979-1980 to 5.59 µg/l during 1987/1988.[33] Analysis of sediment cores in the Passaic River dates peak concentrations of mercury to the 1950s and 1960s.

As with sediment concentrations of most other metals (with the exception of lead), the maximum concentrations for mercury were higher in the upper portion of the LPRSA (RM 11 and RM 12.6) as compared to the lower portion of the River (RM 1.4 to RM 7.8).[34] Sampling has shown elevated concentrations of mercury both above and below Dundee Dam, as shown in Table M2 below, indicating the likelihood of upstream contributions to contamination in the LPRSA.[35]

Table M2. Mercury Sediment Mean Concentrations (mg/kg) (collected 1991-1993)

Depth (cm)	Upper Passaic River (mg/kg)	Lower Passaic River (mg/kg)
Surface	2.6	3.5
20 – 80	2.8	7.5
90 – 140	3.5	7.2
> 150		5.2

The Remedial Investigation noted an ongoing contribution of mercury from upstream, finding that 11 percent of mercury still emanates from the Upper Passaic River.[36] This contribution from upstream is consistent with testing conducted by the U.S. Geological Survey of mercury concentrations in tributaries to the Passaic River, which shows that the Upper Passaic River and Pompton River (which enters the Passaic River above Dundee Dam) and other tributaries contribute significant mercury amounts both above and below Dundee Dam (see Table M3).[37]

[36] The Louis Berger Group, Battelle, and HDR/HydroQual, *Lower Eight Miles of the Lower Passaic River: Remedial Investigation Report for the Focused Feasibility Study*, prepared for EPA, 2014, pp. 8-8 to 8-9.

[37] T.P. Wilson and J.L. Bonin, U.S. Geological Survey, Occurrence of Organic Compounds and Trace Elements in the Upper Passaic and Elizabeth Rivers and Their Tributaries in New Jersey, July 2003 to February 2004: Phase II of the New Jersey Toxics Reduction Workplan for New York - New Jersey Harbor, prepared in cooperation with NJDEP, Scientific Investigations Report 2007-5136, 2008, Table 10, p. 24.

Table M3. Mercury Loads (g/yr) in Passaic River Tributaries (collected 2003-2004)

Tributary	Dissolved Mercury Load (g/yr)	Suspended Sediment Mercury Load (g/yr)
Upper Passaic River (above confluence with Pompton River)	*--	*6,500
Pompton River	*--	*3,400
Saddle River	120	4,200
Third River	46	130
Second River	*--	*1,200
Comparison: Passaic River head-of-tide at Little Falls, NJ	**1,030**	**15,000**

*Note: Dissolved concentrations were removed through blank elimination. Therefore, suspended sediment mercury load may be higher (representing both dissolved and suspended loads).

Municipality contributions of mercury to the LPRSA are also documented by mercury measurements in samples of municipality drinking water.[38]

Overall, there were significant historical contributions of mercury from municipal sources, combustion deposition, and industrial sources both above and below Dundee Dam.

Copper

Unlike some of the other COCs, NYAS did not conduct a study of copper sources to the New York/New Jersey Harbor. However, Hydroqual conducted a study for EPA examining the percentage mass flow of copper into the New York/New Jersey Harbor in the late 1980s, estimating the sources as shown in Table C1.[39]

[38] Water distribution system sampling data provided by 16 municipal water systems in the PVSC service district show varying levels of copper, lead and mercury at various times since 1983, the earliest data provided in response to New Jersey Open Public Record Act requests made in 2019.

[39] HydroQual, Inc., Task 7.1: Assessment of Pollutant Loadings to New York – New Jersey Harbor, prepared for EPA Region II, January 1991, Table 2-3, p. 8, and Figure 2-8, p. 17.

Table C1. Sources of Copper to the NY/NJ Harbor

Source	Contribution (%)
Municipal	56.97%
Industrial	0.46%
CSO	7.93%
Stormwater	7.04%
Tributaries	22.12%
Leachate	0.25%
Atmospheric	5.23%

The overwhelming current contributor is municipal wastewater discharges, followed by tributary sources. Legacy sources of copper would be a component of tributary sources, and to some extent, stormwater and CSO sources.

The 2014 Remedial Investigation evaluated dated sediment core samples for copper, finding peak concentrations during the 1950s and 1960s. Related to this time period, the Remedial Investigation also found concentrations at RM 11 and RM 12.6 that were higher than the concentrations found downstream at RM 1.4 to RM 7.7, indicating a potential upstream source during this time.[40] The Remedial Investigation also noted ongoing contributions of copper from upstream, finding that 14 percent of copper still emanates from the Upper Passaic River, with 12 percent sourced from Newark Bay, and 1 percent each from tributaries and CSOs, as shown in Table 2.[41] Municipality contributions of copper to the LPRSA are also documented by copper measurements in samples of municipality drinking water.[42] Overall, it appears that historical copper releases would have emanated largely from municipal wastewater sources, with some contribution from historical industrial sources both above and below Dundee Dam.

[40] The Louis Berger Group, Battelle, and HDR/HydroQual, *Lower Eight Miles of the Lower Passaic River: Remedial Investigation Report for the Focused Feasibility Study*, prepared for EPA, 2014, Appendix A, Data Evaluation Report No. 3: "Contaminant History as Recorded in the Sediments," pp. 3-15 to 3-17.

[41] The Louis Berger Group, Battelle, and HDR/HydroQual, *Lower Eight Miles of the Lower Passaic River: Remedial Investigation Report for the Focused Feasibility Study*, prepared for EPA, 2014, pp. 8-8 to 8-9.

[42] Water distribution system sampling data provided by 16 municipal water systems in the PVSC service district show varying levels of copper, lead and mercury at various times since 1983, the earliest data provided in response to New Jersey Open Public Record Act requests made in 2019.

Lead

NYAS did not conduct a study of lead sources to the New York/New Jersey Harbor. However, Hydroqual conducted a study for EPA examining the percentage mass flow of lead into the New York/New Jersey Harbor in the late 1980s, estimating the sources shown in Table L1.[43]

Table L1. Sources of Lead to the NY/NJ Harbor

Source	Contribution (%)
Municipal	27.40%
Industrial	0.24%
CSO	14.20%
Stormwater	5.86%
Tributaries	37.98%
Leachate	0.36%
Atmospheric	13.96%

The major sources of lead to the harbor are tributaries, municipal inputs, and atmospheric deposition.

The 2014 Remedial Investigation evaluated dated sediment core samples for lead, finding peak concentrations during the 1950s and 1960s. Related to this time period, the Remedial Investigation found the highest peak concentration at RM 7.8 followed by concentrations at RM 11 and RM 12.6, unlike the other metal COCs (which observed maximum concentration at RM 11 and RM 12.6), indicating a possibility of different sources for lead versus other metals. Lead concentrations were also different in that the peaks downstream (RM 1.4 and RM 2.2) occurred in the mid-1950s, whereas peak concentrations upstream (RM 12.6) occurred in the mid-1960s. Lead concentrations declined in sediments deposited after this time.[44]

[43] HydroQual, Inc., Task 7.1: Assessment of Pollutant Loadings to New York – New Jersey Harbor, prepared for EPA Region II, January 1991, Table 2-3, p. 8, and Figure 2-8, p. 17.

[44] The Louis Berger Group, Battelle, and HDR/HydroQual, *Lower Eight Miles of the Lower Passaic River: Remedial Investigation Report for the Focused Feasibility Study*, prepared for EPA, 2014, Appendix A, Data Evaluation Report No. 3: "Contaminant History as Recorded in the Sediments," p. 3-18.

The Remedial Investigation also noted an ongoing contribution of lead from upstream, finding that 19 percent of lead still emanates from the Upper Passaic River; an additional 7 percent comes from New Bay, and 4 percent comes from tributaries and CSOs. Only 71 percent comes from legacy contamination in the lower Passaic River.[45] This contribution from upstream is consistent with testing conducted by the U.S. Geological Survey of lead concentrations in tributaries to the Passaic River, where the Upper Passaic River and Pompton River (which enters the Passaic River above Dundee Dam) and other tributaries contribute significant lead amounts (see Table L2).[46]

Table L2. Lead Loads (g/yr) in Passaic River Tributaries (collected 2003-2004)

Tributary	Dissolved Lead Load (g/yr)	Suspended Sediment Lead Load (g/yr)
Upper Passaic River (above confluence with Pompton River)	*--	*1,040
Pompton River	*--	*310
Saddle River	*--	*1,140
Third River	2.8	89
Second River	2.1	56
Comparison: Passaic River head-of-tide at Little Falls, NJ	**320**	**2,700**

*Note: Dissolved concentrations were removed through blank elimination. Therefore, suspended sediment mercury load may be higher (representing both dissolved and suspended loads).

[45] The Louis Berger Group, Battelle, and HDR/HydroQual, *Lower Eight Miles of the Lower Passaic River: Remedial Investigation Report for the Focused Feasibility Study*, prepared for EPA, 2014, pp. 8-8 to 8-9.

[46] T.P. Wilson and J.L. Bonin, U.S. Geological Survey, Occurrence of Organic Compounds and Trace Elements in the Upper Passaic and Elizabeth Rivers and Their Tributaries in New Jersey, July 2003 to February 2004: Phase II of the New Jersey Toxics Reduction Workplan for New York - New Jersey Harbor, prepared in cooperation with NJDEP, Scientific Investigations Report 2007-5136, 2008, Table 10, p. 24.

Municipality contributions of lead to the LPRSA are also documented by lead measurements in samples of municipality drinking water.[47]

Overall, it appears that lead contamination in the LPRSA had numerous sources, including significant municipal and aerial deposition sources, as well as industrial inputs both above and below Dundee Dam.

Dieldrin

Dieldrin is an organochlorine pesticide as well as a metabolite (particularly when sunlight and bacteria are present) of the pesticide aldrin. Like DDX contaminants, dieldrin will tend to adsorb to organic matter or suspended particles.[48]

The 2014 Remedial Investigation analyzed dated sediment core samples for dieldrin, finding peak concentrations during the 1960s. Related to this time period, the Remedial Investigation also found concentrations at RM 11 and RM 12.6 that were five times the concentrations found downstream, indicating an upstream source during this time. While dieldrin concentrations declined somewhat after the 1960s, the concentrations then increased by a factor of five during the 1985 to 2007 time-frame. Further testing indicates "substantive" ongoing dieldrin sources from the Upper Passaic River, estimated to be the largest source, as well as the tributary Saddle River and Third River.[49] The Remedial Investigation concludes, "Dieldrin concentrations have been rising since reaching a minimum in the mid-1980s, and much of the dieldrin likely originates from the Upper Passaic River, with minor contributions from tributaries to the Lower Passaic

[47] Water distribution system sampling data provided by 16 municipal water systems in the PVSC service district show varying levels of copper, lead and mercury at various times since 1983, the earliest data provided in response to New Jersey Open Public Record Act requests made in 2019.

River."[50] For recently deposited sediments, the Remedial Investigation identifies the Upper Passaic River as the major source for this COC.[51]

PAHs

PAHs (polycyclic or polynuclear aromatic hydrocarbons) represent hundreds of low-to-high molecular weight compounds comprised of two or more connected aromatic rings of carbon and hydrogen. PAHs form during incomplete combustion of organic material. PAHs are hydrophobic, and tend to sorb onto organic carbon or other particles, with about two-thirds associated with particles (sediments or suspended particles) in a water system and one-third in dissolved state.[52]

In cooperation with EPA, NYAS investigated sources of PAHs to the New York/New Jersey Harbor watershed. The finding was that the vast majority of PAHs in the watershed result from aerial deposition (814,000 kg/yr or 82 percent), followed by land discharges (11,400 kg/yr or 18 percent) and water discharges (1,800 kg/yr or less than 1 percent). Results of the analysis are summarized in Figure 1 below.[53] Quantities of PAHs released to the watershed by major source are shown below in table PAH1.[54]

Figure PAH1. Relative Releases of PAHs by Primary Medium of Release

"Other" air and land releases refer to sources that individually contribute 2% or less to total releases to the respective medium. These include industrial sources, residential and commercial fossil fuel combustion, open burning of household waste and tires, other transportation-related sources (e.g., vessel and personal boats, locomotive, airplane), and PAHs in ash residue that is sequestered in a landfill.

*Average of the estimated range of releases.

Table PAH1. Estimated Ongoing PAH Releases to NY/NJ Harbor Watershed (kg/yr)[55]

Source	Mass Released (kg/yr)
Residential Fuel Combustion	341,200
Materials Containing PAHs:	
Creosote: utility poles	122,200
Creosote: railway ties	291,600
Creosote: marine pilings	1,600
Refined coal tar sealant	900-5,800
Transportation:	
Vehicle exhaust	2,800
Tire wear	91,500
Oil leaks	5,000
Improper disposal of used motor oil (down drain)	400
Nonroad internal combustion	32,500
Oil Spills and Dumping	70

[55] S. Valle, M.A. Panero, and L. Shor, New York Academy of Sciences, Pollution Prevention and Management Strategies for Polycyclic Aromatic Hydrocarbons in the New York/New Jersey Harbor, September 2007, Table 2, p.26.

Additional sources of PAHs that were not quantified in the above table include structural and vehicle fires, asphalt pavement and roofs, leaking underground storage tanks, commercial char-broilers, fireworks, and campfires.[56]

Some PAHs are the result of intentional industrial manufacture. One example is the industrial production of naphthalene, which is used in mothballs, paint thinners, solvents for metal surface preparations, as well as in processes in pharmaceuticals, photographic, soap, pigment and dye, insecticide, fungicide, plastics, and food industries. Other smaller PAH industrial products include acenaphthene (pigments), anthracene (dyes, wood preservatives), fluorene (oxidizing agent), phenanthrene (pesticides, resins), and pyrene (dyes).[57]

While NYAS examined PAH sources to the larger New York/New Jersey Watershed, EPA has examined PAH sources to the LPRSA. By examining sediment cores from the LPRSA, the 2014 Remedial Investigation determined that PAHs were present in almost all samples at all depths. While PAH concentrations increased slightly at depth, there was no decline for the deepest sediments, suggesting a fairly continuous sourcing of PAHs over time. Depth measurements of PAHs concentrations in sediment cores indicate that maximum discharges occurred prior to 1950. Heavy-molecular-weight PAHs (*e.g.,* benzo[a]pyrene, fluoranthene) comprised about 80 percent of Total PAHs, with low-molecular-weight PAHs (*e.g.*, phenanthrene) accounting for the rest.[58]

The 2014 Remedial Investigation for the LPRSA also identifies continuing loads of PAHs to the LPRSA, with sources coming from the Upper Passaic River: "PAHs contamination showed no decline with time since about 1970 and appears to be controlled by external loads originating in

the Upper Passaic River."[59] For recently deposited sediments, the Remedial Investigation identifies the Upper Passaic River as a major source for this COC.[60] The Remedial Investigation concludes: "[T]he sources of PAH contamination to the Lower Passaic River are not abating." [61]

Overall, it appears that PAH contamination in LPRSA sediments are largely from non-industrial sources. The Upper Passaic River also continues to serve as a major ongoing source of this COC.

APPENDIX C
EXAMPLES OF NON-PARTICIPATING COMPANIES THAT LIKELY DISCHARGED PCBS

ADR CONFIDENTIAL
NOT BINDING OR TO BE DEEMED AN ADMISSION FOR ANY OTHER PURPOSE OR PROCEEDING

Examples of Non-Participating PCB Parties in the Allocation

Examples of potentially major PCB-discharging facilities that are not a part of this allocation effort include (but are not limited to):

- ***Cargille Laboratories*** (aka Cargille Labs, R.P. Cargille Laboratories, Cargille & Sons, Cargille-Sacher Laboratories, Cargille Scientific) started operations in 1924 to manufacture optical fluids and immersion oils and provide products to the laboratory science industry. Operations included four facilities in Little Falls (194 Second Avenue, 9 Railroad Avenue) and Cedar Grove (33 Village Park Road, 55 Commerce Road), New Jersey, with operations presently continuing at 55 Commerce Road in Cedar Grove, New Jersey.[1] The four facilities were located in areas serviced by the Passaic Valley Sewerage Commission ("PVSC") and were located near the Passaic River or its tributaries (for example, Peckman River in Cedar Grove). Untreated wastes from these facilities would have been discharged to the Passaic River whenever the Yantacaw Bypass was opened to the river, *i.e.,* during heavy rains and maintenance/repair activities. R.P. Cargille Laboratories used PCBs as a major component of its immersion oils. When it filed for an immersion oil formulation patent in 1974, the company stated that "the vast majority of such prior art oils contain polychlorinated biphenyls (PCBs)…The prior art formulations typically contained a polychlorinated biphenyl which was blended or mixed with a mineral oil and viscosity adjusting agents to provide a good operating characteristic immersion oil…"[2] Cargille is documented as having purchased 66,662 pounds of PCBs during 1968-1972.[3] The company continues to store PCBs at its current location under a storage-and-use exemption from EPA.[4] PCBs, metals, and PAHs have been identified in site soils at

the current facility at levels exceeding New Jersey Soil Remediation Standards.[5] The facility is upgradient and adjacent to the Peckman River (tributary to the Passaic River), which has also been noted as contaminated with PCBs.[6]

- ***Hardman Inc.,*** a company that has manufactured adhesives in Belleville, New Jersey since the late 1800s, should be considered a potentially responsible party ("PRP") for PCBs in the LPRSA. By the mid-1950s, the company was located on Cortlandt Street in Belleville, and is documented at its present location of 600 Cortlandt Street by 1967. Available sales records show that the facility purchased 32,100 pounds of PCBs during 1968 to 1972. The facility is located near the Passaic River, so there was a potential for direct discharge to the river. The facility is also served by the Passaic Valley Sewer Commission ("PVSC"), which routinely discharged untreated waste directly to the river. Hardman continues to operate its facility at 600 Cortlandt Street in Belleville, and is owned by Royal Adhesives and Sealants LLC.
- ***Universal Manufacturing***, a manufacturer of fluorescent transformers, capacitors, and ballasts, operated at two facilities: (1) from 1951 to 1989 in Paterson, New Jersey (29-51 East 6th Street) near the Passaic River and the East Fifth Street and Fifth Avenue CSO, and (2) from approximately 1971 to 1989 in Totowa, New Jersey (111 Jackson Road).[7] Available PCB sales records show that Universal Manufacturing's Totowa facility received over 6 million pounds of PCB products during 1971 to 1977.[8] EPA documented that Universal Manufacturing used PCBs in its capacitors, ranking the company as the third highest user of PCBs for this purpose.[9] Universal Manufacturing's patents also indicate the use of metals throughout its operations, including solder which could be a source of lead.[10]

The company's Paterson facility was located near the Passaic River and on the East Fifth Street and Fifth Avenue CSO, which had a projection of 60-65 overflows per year in 1975.[11] According to the PVSC's 1977 Industrial Waste Survey, with a discharge of 50,000 gallons per day or more, Universal Manufacturing was classified as a major contributor of industrial waste to the sewers.[12] In addition to routine overflows of waste into the Passaic River through the CSO, Universal Manufacturing's untreated waste would have been directed to the river when (1) the City of Paterson bypassed untreated waste to the river during maintenance and storm bypass events, and (2) the PVSC bypassed untreated waste to the river during maintenance and storm bypass events, both at the Fifth Avenue CSO and at the Yantacaw Bypass. Universal Manufacturing's Paterson facility was also identified by the PVSC as having a pollution violation to the Passaic River (or its tributaries) in 1978.[13]

The Totowa facility was located on Naachtpunkt Brook, a tributary to the Passaic River, and the sewers in Totowa discharged into the PVSC main interceptor. The facility's wastes would have been discharged untreated to the Passaic River through the Yantacaw bypass when opened by the PVSC.[14] EPA also identified the Universal Manufacturing Totowa facility as directly discharging PCBs into tributaries of the Passaic River.[15] Columbus McKinnon

Corporation of Getzville, New York, appears to be the viable successor to Universal Manufacturing via its acquisition of Magnetek.[16]

Prior research indicates that there are numerous insolvent PRPs that handled PCBs in the areas served by the PVSC system, whose bypasses and CSOs discharged untreated waste to the Passaic River. Examples of such insolvent PRPs, for which the PVSC serves as the last viable allocable party through its arranger/transporter roles, include (but are not limited to) the following entities, whose PCB usage is described below:

- *Atlantic Chemical Corp.* was located at 153 Prospect Street, Passaic, N.J. (with a laboratory located at 10 Kingsland Road, Nutley, N.J.). This company researched and produced coal tar dyestuffs, organic intermediates, and fine organics.[17] The facility in Passaic purchased 24,000 pounds of PCBs (Aroclor 1248) between 1962 and 1965.[18] The Passaic and Nutley facilities were located in municipalities that joined the PVSC in 1911 and whose waste would have flowed through the Yantacaw Bypass when the PVSC bypassed untreated waste to the Passaic. Atlantic Chemical Corp. eventually became part of Chemtura (via Crompton & Knowles, Witco Corporation, Crompton Corporation, and Great Lakes Chemical Corporation), which filed for bankruptcy in 2009.[19]
- *Garden State Paper* was located at 950 River Drive in Garfield, N.J., where it recycled paper. PCBs are a common contaminant in historical paper recycling operations.[20] A

PVSC diagram identifies Garden State Paper as linked to the PVSC's Yantacaw bypass.[21] Garden State Paper filed for bankruptcy in 2001.[22]

- *Maas & Waldstein*, located at 437 Riverside Avenue, Newark, N.J. which later became 2121 McCarter Highway, in the area serviced by the Verona Avenue, Newark bypass operated by the PVSC. The company manufactured coatings, lacquers, colors, flavors, and explosives.[23] Available PCB sales records show that the facility purchased 9,380 pounds of PCBs (Aroclors 1221, 1254 and 5460 Hi Sol) between 1964 and 1971.[24] The company was dissolved in 1993.[25]
- *Marcal Paper Mills* was located at 1 Market Street in Elmwood Park, N.J., starting in 1932 as the largest paper recycler in the state. PCBs are a common contaminant in historical paper recycling operations.[26] A PVSC diagram identifies Marcal Paper as linked to the PVSC's Yantacaw bypass.[27] Marcal was the recipient of regulatory enforcement actions in 1991 and 1994 as a result of its handling of PCBs.[28] The company completed bankruptcy proceedings in 2007, committing the reorganized company to clean up onsite contamination but releasing it from contamination of the Passaic River.[29]

- *Sonneborn Chemical and Refining Corporation* was located in Belleville, N.J.,[30] a municipality that contracted to join the PVSC system in 1911. The facility purchased 975,900 pounds of PCBs (Aroclors 1242, 1248, 1254, 1260, 1262, 1268, 1268, and 5460 Hi Sol) during 1968-1971.[31] Sonneborn merged into Witco Corporation, which ultimately became part of Chemtura.[32] Chemtura filed for bankruptcy in 2009.[33]
- *U.S. Rubber* produced rubber at a facility located on Passaic and Market Streets in Passaic, N.J,[34] a municipality that joined the PVSC in 1911 and whose waste would have been discharged through the Yantacaw Bypass when the PVSC opened it. The facility purchased 20,050 pounds of PCBs (Aroclors 1232 and 1242 and Therminol FR-2) during 1962-1964.[35] U.S. Rubber changed its name to Uniroyal,[36] which sold the Passaic facility in 1977[37] and filed for bankruptcy in 2002.[38]

ADDITIONAL CONTAMINANT INVENTORY ANALYSIS FOR LOWER EIGHT MILES OF THE LOWER PASSAIC RIVER, APRIL 2019

Additional Contaminant Inventory Analysis

for

Lower Eight Miles of the Lower Passaic River

April 2019

Objective

The primary goal of this analysis is to determine the inventory of copper, lead, dieldrin, and polycyclic aromatic hydrocarbons (PAHs) in the lower 8.3 miles of the Lower Passaic River (Operable Unit 2 or OU2 of the Diamond Alkali Superfund Site). This analysis is based on the 1990-2012 data sets and statistical methods presented in Data Evaluation Report No.5 (DER No 5) of the 2014 Remedial Investigation and Focused Feasibility Study Reports (RI/FFS) (USEPA, 2014). Although the 2012 dataset is listed in Section 1.2 of the DER No 5, review of the mass inventory calculation presented in DER No 5 indicates that the 2012 data were not included in the calculation.

This analysis also updates the mass of 2,3,7,8-TCDD, Total PCBs, Total 4,4'- DDx and mercury using all data from 1990 - 2012. In addition, the updates reflect changes made for consistency with the 2016 Record of Decision (ROD) Responsiveness Summary (USEPA, 2016), as discussed below (under "Results").

Method

- Sediment chemistry data from 1990 – 2012 were used in the analysis (as listed in Section 1.2 of DER No 5 of the RI/FFS).
- PAHs and dieldrin were analyzed by both high-resolution and low-resolution methods. Comparisons of PAHs and dieldrin concentrations from high-resolution and low-resolution methods suggested that the differences were not statistically significant. Therefore, no adjustments were made to the low-resolution data. However, for sediment samples for which both high-resolution and low-resolution results were available, the high-resolution data were used.
- For PAHs, mass estimates were calculated for three different sums: high molecular weight PAHs (HMW), low molecular weight PAHs (LMW), and total PAHs (TPAH). HMW were the sum of benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(g,h,i)perylene, benzo(k)fluoranthene, chrysene, dibenzo(a,h)anthracene, fluoranthene, indeno(1,2,3-cd)pyrene, and pyrene. LMW were the sum of acenaphthene, acenaphthylene, anthracene, fluorene, naphthalene, phenanthrene and 2-methynaphthalene. And TPAH were the sum of the above 17 PAHs. The non-detect (ND) values for individual PAH were set as '0' in calculating the sums, unless all component PAHs in the sum were ND in which case half of the highest individual detection limit was used as the sum.

- For copper, lead, and dieldrin, the ND values were set as half of their reporting detection limit, consistent with how contaminants that are not sums of individual components were treated in DER No. 5.
- Average values were used for samples with field duplicates.
- Mass estimates were made for 1) the total inventory in the lower 8.3 miles of the Lower Passaic River; 2) the inventory in the Tierra Phase I removal area; and 3) the inventory that would be removed if the selected remedy were implemented as described in the 2016 ROD.

Results - Contaminant Inventory Assessment

The results obtained for the four contaminants are presented in Table 1 below. The total mass of contaminants in the fine-grained sediments of the lower 8.3 miles of the Lower Passaic River is as follows:

- Copper and lead have estimated masses of about 2,100,000 and 3,200,000 kilograms (kg), respectively, with associated relative standard errors of about 6.7 percent for copper and 6.3 percent for lead.
- Dieldrin has an estimated mass of about 390 kg, with a relative standard error of about 35 percent.
- LMW PAH and HMW PAH have estimated masses of about 170,000 kg and 240,000 kg, respectively, with associated relative standard errors of about 16 percent for LMW PAHs and 6.7 percent for HMW PAHs. The estimated mass of TPAH is about 410,000 kg, with a relative standard error of about 10 percent.

Table 1 also shows the updated mass of 2,3,7,8-TCDD, Total PCBs, Total DDx and mercury based on the 1990-2012 data sets and statistical methods presented in DER No 5. In addition, the ROD Selected Remedy mass has been updated consistent with the 2016 ROD Responsiveness Summary to reflect: 1) the final extent and depth of the navigation channel included in the ROD Selected Remedy; 2) the integration of the Tierra Removal Phase 2 area with the lower 8.3-mile remedy in a coordinated and consistent manner; and 3) the correction of an error in the PCB mass calculation performed for the Responsiveness Summary.

Table 1: Summary of Mass Estimates for RM 0 to RM 8.3. Values rounded to 2-significant figures.

Contaminant	Total Mass Prior to Phase 1 or ROD Remedy (kg)	Phase 1 Mass (kg)	ROD Selected Remedy Mass (kg)
Copper	2,100,000	12,000	570,000
Lead	3,200,000	16,000	860,000
Dieldrin	390	230	30
LMW PAH	170,000	700	64,000
HMW PAH	240,000	1,300	82,000
TPAH	410,000	2,000	150,000
2,3,7,8-TCDD	38	9.8	6.2
Total 4,4´-DDx	27,000	21,000	570
Mercury	42,000	240	11,000
Total PCB	26,000	230	7,200

CULPABILITY & COOPERATION FACTORS WORKSHEET

CONSIDERATIONS IN DETERMINING CULPABILITY & COOPERATION FACTORS

The following considerations were taken into account in determining how to assign factors for the culpability and cooperation of Allocation Parties.

In the conduct of a hazardous waste site allocation, consideration of a party's actions that exacerbate the scope of contamination requiring remediation or to cooperate with government in efforts to resolve the risk associated with such contamination are evaluated to provide equitable adjustments to the calculation of the party's share of responsibility. As noted in the foundational Gore Factors these considerations of culpability and cooperation are described as:

> The degree of care exercised by the party with respect to the hazardous substance concerned, taking into account the characteristics of such hazardous substance; and
>
> The degree of cooperation by the party with federal, state, or local officials to prevent any harm to the public health or the environment.

In the current matter, a range of actions were evaluated to establish the relative culpability and cooperation of the Allocation Parties.

The following types of considerations were evaluated in determining an appropriate facility Culpability Factor, based on available information. As noted below, given the limitations on conduct of an independent evaluation of facility operations regarding COCs, I am reviewing general facility operations where appropriate to consider the potential for activities leading to the release of the COCs.

- Whether the operations of a facility met industrial standards of environmental conduct for the era in which they occurred
- The persistent or recurring nature of sloppy or substandard industrial practices involving COCs
- Whether sloppy industrial practices or the nature of releases of other hazardous substances indicate a potential for or likelihood of releases of COCs
- Whether facility actions resulted in the issuance of NOVs or other administrative actions noting concern regarding facility operations
- The frequency or number of NOV issuance
- Whether actions resulted in the filing of civil or criminal actions to address facility operations or resulting contamination
- Whether actions were taken with apparent disregard of impact on human health or the environment or demonstrate an intentional violation of federal or state environmental authorities

The following types of considerations were evaluated in determining an appropriate negative or positive facility Cooperation Factor.

- Whether opportunities to cooperate with governmental/regulatory entities to address environmental or public harm were refused, taken under duress through compliance with a UAO, or voluntarily undertaken via an AOC/CD or independently in cooperation with such entities
- The level of participation in the activities and funding of actions by PRP Groups working in cooperation with governmental/regulatory entities to address environmental or public harm
- The extent to which an Allocation Party's efforts in cooperation with governmental/ regulatory entities to address environmental or public harm benefited other Allocation Parties by removing more contamination than they are individual responsible for having contributed to OU2
- The level of participation in the offered allocation process, including the voluntary submission of requested documents and information regarding facility operations and contaminating practices

History of Allocation Party Cooperation with Remedial Activities

A number of the Allocation Parties have cooperated with governmental/regulatory entities to address environmental or public harm caused by contamination of OU2 through individual action or participation in the activities of PRP Groups, the Cooperating Parties Group (CPG) and the Small Parties Group (SPG), formed, in part, for that purpose. The CPG was formed in February 2004 and the SPG was subsequently formed. The following is a summary of activities undertaken by Allocation Parties and the amounts of funding, if available, committed in support of EPA's remedial or removal activities in the Lower Passaic River and OU2.

2007 RI/FS ASAOC – In June 2007, members of the CPG entered into an Administrative Settlement Agreement and Order on Consent ("ASAOC") with EPA for a Remedial Investigation/Feasibility Study ("RI/FS"), in which the settling parties agreed to take over the performance of the 17-mile Lower Passaic River Study Area ("LPRSA") RI/FS from EPA. The CPG members' costs include costs of all activities required and approved by EPA, reimbursement of EPA's oversight costs, and costs for other activities in support of the RI/FS. Costs, through the end of April 2020, expended by the CPG members for such efforts amount to $124,882,811 as of that date. Occidental Chemical, an original member of the CPG, left the group in May 2012, and though continuing to pay its portion of EPA oversight costs has not contributed to RI/FS related cots since its departure from the group. Seton Tanning, likewise, left the CPG in May 2014 and ceased financial support for group activities.

Other RI/FS Costs – In 2004, the CPG members signed an ASAOC with EPA to fund EPA's work on the RI/FS for the 17-mile LPR. CPG members paid $12.64 million to EPA, excluding what was paid by OxyChem and its indemnitors. In addition to this § 122(h) Settlement, CPG members incurred other recoverable response costs in furtherance of EPA's RI/FS during the period from 2004 to 2007, totaling $3,142,680.

2012 Phase 1 Removal Action – In June 2008, EPA, OCC and Tierra signed an AOC for a non-time-critical removal action to remove 200,000 cy of contaminated sediment from the river (from RM 3.0 to RM 3.8) adjacent to the 80-120 Lister Avenue facility. This action is referred to as the "Tierra Removal." Sediment at depth adjacent to the facility has been found to have the highest levels of 2,3,7,8-TCDD measured in the river. Dredging, dewatering and transport off site of the first 40,000 cy of sediment (known as Phase 1 of the Tierra Removal) was completed in 2012. In 2015, Tierra, on behalf of OCC, collected additional samples in the Phase 2 area. Amount of funding committed to these efforts is unknown. The Phase 1 removal activities removed the following volumes of COCs determined by EPA to be located in the OU2 remedial area.

Contaminant of Concern	Total COC Mass Prior to Phase 1 or ROD Remedy (kg)	COC Mass Removed During Phase 1 (kg)
Copper	2,100,000	12,000
Lead	3,200,000	16,000
Dieldrin	390	230
LMW PAH	170,000	700
HMW PAH	240,000	1,300
TPAH	410,000	2,000
2,3,7,8-TCDD	38	9.8
Total 4,4´-DDx	27,000	21,000
Mercury	42,000	240
Total PCB	26,000	230

Activities by members of the CPG and SPG in support of EPA's actions to address OU2 remediation are ongoing in nature.
