Acronyms

BERA	baseline ecological risk assessment
DDD	dichlorodiphenyldichloroethane
DDE	dichlorodiphenyldichloroethylene
DDT	dichlorodiphenyltrichloroethane
HPAH	high-molecular-weight polycyclic aromatic hydrocarbon
LPRSA	Lower Passaic River Study Area
PAH	polycyclic aromatic hydrocarbon
PCB	polychlorinated biphenyl
PCDD	polychlorinated dibenzo-*p*-dioxin
PCDF	polychlorinated dibenzofuran
ppt	parts per thousand
SAV	submerged aquatic vegatation
SQT	sediment quality triad
TEQ	toxic equivalent
TOC	total organic carbon
Total DDx	sum of all six DDT isomers (2,4′-DDD, 4,4′-DDD, 2,4′-DDE, 4,4′-DDE, 2,4′-DDT and 4,4′-DDT)

1 Introduction

The purpose of this appendix is to provide context for the comparison of sediment toxicity and benthic invertebrate community metric data from regional estuarine (Jamaica Bay and Mullica River/Great Bay) and freshwater (Mullica River and the area above Dundee Dam) reference areas to data from the Lower Passaic River Study Area (LPRSA) made in the *Lower Passaic River Study Area Baseline Ecological Risk Assessment* (BERA). Comparisons of LPRSA sediment toxicity and benthic invertebrate community metric data are presented and discussed in Appendices B and P (and summarized in Section 6 of the BERA main text). Section 2 provides information regarding each reference area, and Section 3 provides graphical comparisons of physical sediment habitat data or chemical concentration data between reference areas and the LPRSA.

In Section 3, box plots are used to show the relative distributions of available habitat characteristic and sediment chemistry data from the reference areas as compared to the LPRSA (split into benthic salinity zones).[1] Habitat characteristic data include salinity, total organic carbon (TOC) as a percent of the total sediment weight, and the percent by weight of fine silt and clay particles (referred to herein as "fines"). TOC, fines, and salinity represent three of the more important natural environmental factors that influence benthic invertebrate community composition and function (Pearson and Rosenberg 1978; Diaz and Rosenberg 1995; Rosenberg 1977, 1976; Rosenberg et al. 1992; Rosenberg and Möller 1979; Nilsson and Rosenberg 2000; Pelletier et al. 2011; Hyland et al. 2005; Savage et al. 2002; Shin et al. 2008; Anderson 2008; Thrush et al. 2005; Cheung et al. 2008; Relyea et al. 2000, 2012; Levinton 1982), although others certainly exist;[2] this is discussed further in Section 2. Although pore water salinity data were collected in the LPRSA, such data were not available for reference area samples. Instead, co-located water column salinity data from reference areas (excepting the area above Dundee Dam and Mullica River [freshwater]) are compared with interstitial data from the LPRSA (Section 3.1). Salinity in pore water and surface water may be slightly or significantly different depending on the location, season, and/or sediment grain size. This remains a point of uncertainty for the comparisons of salinity data presented in Section 3.1 of this appendix. Salinities from the freshwater portion of the Mullica River and from above Dundee Dam are assumed to be entirely freshwater (e.g., salinity < 0.5 parts per thousand [ppt]). Data from those areas are not presented in Section 3.1.

[1] See BERA Section 2.1.1.1 for more information on benthic salinity zones.

[2] Examples of other relevant environmental factors not explicitly addressed in this appendix include seasonality (e.g., temperature and amount of precipitation and daylight hours) (Silva et al. 2006), hydrology (Walsh et al. 2005; Lake 2000), inorganic nutrients (Posey et al. 1999; Posey et al. 2002), dissolved oxygen (Belley et al. 2010; Lowell and Culp 1999), and water temperature (Haidekker 2004; Carolli et al. 2012). Sediment contamination can also drive benthic community composition and function by causing toxicity.

Although the entire suite of chemical analytes measured in LPRSA sediment quality triad (SQT) samples (in fall 2009) was also measured in samples from above Dundee Dam (in fall 2012), the analytes presented in this appendix are those that were also available from the Jamaica Bay, Mullica River (freshwater), and Mullica River/Great Bay reference areas and that were assessed as part of the background evaluation in Appendix J. Appendix J contains additional comparison between sediment chemistry data from the area above Dundee Dam and from the LPRSA.

2 Discussion of physical characteristics by area

Habitat characteristics can have a marked influence on benthic invertebrate community structure, sediment chemistry, and sediment toxicity, as well as SQT analyses. USEPA (1994) recommends that reference sites match the Superfund site, to the extent practicable, in all aspects except contamination. The comparison of LPRSA habitat to reference area habitat is, therefore, an important component of the comparison of SQT data from the LPRSA and reference areas. A comparison of the selected references areas to the LPRSA is discussed in the following subsections.

2.1 JAMAICA BAY

Jamaica Bay is a saline to brackish embayment at the southwestern end of Long Island that is influenced by a highly developed upland (e.g., Brooklyn and Queens boroughs of New York City and John F. Kennedy airport) with urban, residential, commercial, and industrial land surrounding much of the bay (USFWS 1997). Much of the area, however, lies within the federally managed Gateway National Recreation Area, which includes the Jamaica Bay Wildlife Refuge and other parks.

Sediment in Jamaica Bay is predominately fine in the eastern and northern portions, and sandier in the southern and western portions (USFWS 1997). The water body is notably impacted by anthropogenic inputs of inorganic nutrients and organic matter (e.g., sewage and TOC) (Waldman 2008; NRDC 2007), but the benthic community in the area is quite rich (USFWS 1997). Historical dredging has affected hydrology and sediment transport within Jamaica Bay (Waldman 2008). Historically, some parts of Jamaica Bay have been contaminated by polycyclic aromatic hydrocarbons (PAHs) and metals (USFWS 1997); however, samples included in the sediment toxicity (and benthic metric) datasets to be used as reference conditions for the LPRSA contained markedly lower concentrations of PAHs and metals than did samples from the upper estuarine and fluvial estuarine zones of the LPRSA (Figures 3-11, and 3-15 through 3-21).

Measured TOC from Jamaica Bay and the LPRSA were similar, although sediment grain size (as percent fine-grained material) differed somewhat between the Jamaica Bay and LPRSA datasets (Figure 3-2). Specifically, the grain size data from the upper estuary in the LPRSA differed from that of Jamaica Bay sediment, in that sediment in the estuarine zone of the LPRSA tended to be composed of more fine-grained sediment than sediment in Jamaica Bay. Conversely, the sediment grain size data from the fluvial estuary of the LPRSA was similar to the Jamaica Bay sediment grain size data.

The most apparent difference in habitat characteristics in samples from the LPRSA and Jamaica Bay is salinity (Figure 3-3), which was clearly higher throughout the Jamaica Bay dataset (approximately 25 to 30 ppt); this range is consistent with salinities reported in the literature for the area (USFWS 1997). Although the LPRSA and Jamaica Bay are both estuarine (i.e., tidally influenced), it is likely that the sampling locations in the

LPRSA receive a greater freshwater flow, as they are within the tidally influenced portion of the river, rather than a more open embayment like Jamaica Bay. It is expected that the wide range of salinities observed in the upper estuarine zone of the LPRSA has a marked influence on the composition of the benthic invertebrate communities found throughout that zone (Levinton 1982); the same is expected of communities measured throughout the fluvial estuarine zone because the range of observed salinities overlaps with the range of "critical salinities" at which estuarine benthic invertebrate communities tend to be most stressed (by salinity) and least diverse (Levinton 1982; Chapman and Wang 2001).

The dataset from Jamaica Bay was collected within the same season (July to September) but in different years (1993, 1994, 1998, and 2003). The dominant Jamaica Bay benthic community described in the literature appears to be functionally similar to that of the LPRSA, in that bivalves and polychaetes contribute substantially to the benthic biomass (USFWS 1997). This indicates that the major sources of carbon available to the benthic invertebrate community are similar, predominately organic carbon-rich sediment and particulate matter.[3]

A major difference between the LPRSA and Jamaica Bay is the availability of submerged aquatic vegetation (SAV) and salt marsh habitat in the reference area (Waldman 2008; NRDC 2007). Salt marshes and submerged vegetation provide more complex estuarine habitat for infaunal benthic and epibenthic invertebrates than might be provided by unvegetated or poorly vegetated benthic habitat (with the possible exception of productive mudflats) (Johnson et al. 2002; Orth et al. 1984; Böstrom and Bonsdorff 2000). Differences in benthic invertebrate community structure, diversity, or the presence of specific taxa between the LPRSA and Jamaica Bay may reflect this apparent difference in habitat availability.

2.2 MULLICA RIVER/GREAT BAY ESTUARY

The Mullica River and Great Bay Estuary complex is a well-mixed, semi-diurnally, tidally influenced estuary situated in southeastern New Jersey (north of Atlantic City) that receives freshwater inputs almost entirely from the central Pinelands (USFWS 1997). Salinities within Great Bay range from 14 to 30 ppt throughout the year, and decrease upstream to approximately 1 ppt below Lower Bank (13 river miles upstream of the mouth of the Mullica River) (USFWS 1997). The range in salinity is similar to that observed in the LPRSA. Approximately 22% of Great Bay is covered by mud and sand flat habitat with extensive SAV (USFWS 1997), differentiating this area from the historically dredged and channelized LPRSA. Although development is of concern for conservation in the area, very little of the total watershed is currently developed for urban land use (NOAA 2009). Median sediment TOC in the Mullica River/Great Bay

[3] The availability of organically enriched sediment and particulates is unsurprising given that Jamaica Bay receives substantial inputs of municipal sewage and other urban stormwater inputs (Waldman 2008; NRDC 2007), similar to the LPRSA.

sediment samples were generally lower than TOC measured in LPRSA sediment samples, although the range of observed values was similar to that of the LPRSA (Figure 3-2). Sediment grain size (i.e., total fines) was similar between the Mullica River/Great Bay areas and comparable salinity zones of the LPRSA (Figure 3-1).

Waters draining from the Mullica River are characteristic of Pine Barrens streams; the riverine nutrient content and pH tend to be low and organic carbon content (e.g., humic acids) tends to be high. Although the acidic waters of the Mullica River (pH 4.4 on average) (USFWS 1997) may result in the presence of a greater variety of acid-tolerant benthic species than in the LPRSA, the functional characteristics of the Mullica River/Great Bay Estuary benthic community (e.g., biomass dominated by detritus-eating taxa) (USFWS 1997) do not appear to differ from those of the estuarine portions of the LPRSA. The sediment samples from the Mullica River/Great Bay Estuary were collected entirely within late summer months but during different years (i.e., 2000–2004 and 2006).

As noted for Jamaica Bay (in Section 2.1), the presence of SAV throughout the Mullica River/Great Bay Estuary could result in differences from the LPRSA in observed benthic invertebrate community structure and diversity.

2.3 ABOVE DUNDEE DAM

Habitat observed above Dundee Dam was similar to that of the tidal freshwater zone of the LPRSA; both the percent of fine-grained sediment and TOC (Figures 3-1 and 3-2, respectively) were generally similar between the two areas. Both areas are considered freshwater environments since measured salinity was low (i.e., < 0.5 ppt).

The area above Dundee Dam is quite similar to the LPRSA tidal freshwater zone, but for the site-related source(s) of hazardous substances. Some chemical analyte concentrations (e.g., polychlorinated dibenzo-*p*-dioxins/ polychlorinated dibenzofurans [PCDD/PCDFs] and total DDx [sum of all six dichlorodiphenyltrichloroethane (DDT) isomers (2,4′-dichlorodiphenyldichloroethane [DDD], 4,4′-DDD, 2,4′-dichlorodiphenyldichloroethylene [DDE], 4,4′-DDE, 2,4′-DDT and 4,4′-DDT)]) tend to be lower above Dundee Dam compared to their concentrations just below it (Figures 3-7, 3-8,and 3-10). However, other chemicals generally associated with urban water bodies[4] (e.g., metals and PAHs) are similar between the two areas (Figures 3-11, and 3-15 through 3-21).

2.4 FRESHWATER PORTION OF THE MULLICA RIVER

The Mullica River watershed is a reference area with very few urban inputs. The area above Lower Bank (near Washington, New Jersey) is consistently freshwater, with year-round salinities < 1 ppt (USFWS 1997). Few data exist for TOC or sediment grain size distributions for the Mullica River above Lower Bank, but those few that are available

[4] Including relatively less contaminated areas like Jamaica Bay (USFWS 1997).

suggest that Mullica River sediments have fairly similar grain size and organic content to those of the tidal freshwater LPRSA (Figures 2-1 and 2-2). Because of the small sample size for the freshwater Mullica River, SQT data from that area are not used in the BERA to characterize risk. SQT data from the Mullica River are, however, used to characterize uncertainty associated with the benthic invertebrate community and sediment toxicity lines of evidence (Appendix P, Sections 2.3.4 and 3.2.5, respectively).

Sediment samples from the Mullica River freshwater reference area were collected during different seasons and years (i.e., February and March 1995, February and March 2000, November 2004, July 2005, and April 2006). Rather than pooling data from replicated sampling locations across seasons and years, each sample was treated as unique.

3 Comparisons of LPRSA and Reference Area Data

The following figures provide a comparison of the distributions of LPRSA sediment chemical and physical data to regional and upstream reference area data.[5] One or more reference area datatsets are not shown in several figures presented in this section; this is the case only when no data are available from the omitted reference area dataset for the applicable parameter. No effort was made to remove outliers or to otherwise pre-screen and remove reference area samples from the datasets described by the following figures. Therefore, the figures depict the full range of measured sediment concentrations or physical data (i.e., TOC, fines, or salinity) associated with reference conditions without the imposition of statistical or arbitrary constraints on those datasets.

3.1 PHYSICAL CHARACTERISTICS

The figures show both key differences and similarities between the LPRSA (salinity zone) and reference area data. Figures 3-1 through 3-3 show physical characeteristics; total fines and TOC appear to be generally similar (i.e., substantial overlap of distributions) across comparable datasets (Figures 3-1 and 3-2), whereas salinity appears to be quite different across datasets (Figure 3-3). For example, Jamaica Bay surface water samples have relatively stable and greater salinity relative to interstitial salinity in the LPRSA estuarine zones. Mullica River/Great Bay surface water samples have greater variability than other datasets, but they still have greater interstitial salinity than samples from comparable LPRSA zones. Comparisons of salinity between freshwater areas, although not shown, are expected to align well.

3.2 SEDIMENT CHEMISTRY

Sediment chemistry concentrations in the LPRSA generally exceed concentrations in regional reference areas (Jamaica Bay, Mullica River [freshwater], or Mullica River/Great Bay), although not always (Figures 3-4 through 3-23). Selenium is an exception; it appears to be greater in estuarine datasets (both LPRSA and reference areas) than in freshwater datasets (Figure 3-9). The urban freshwater reference area, above Dundee Dam, often has similar or slighly greater concentrations of certain contaminants (e.g., mercury, high-molecular-weight polycyclic aromatic hydrocarbons [HPAHs], and benzo[a]pyrene) than the LPRSA, downstream.

BERA Sediment Chemistry Data from Above Dundee Dam

Qualifier	Definition
J	estimated concentration
U	not detected at given concentration
N	tentative identification
EMPC	estimated maximum possible concentration
Z	estimated maximum possible concentration
R	rejected
T(#)	partial sum where the number in parentheses indicates the number of constituent parameters missing from the sum
C	data refers to the first of two or more co-eluting congeners
C###	number noted references the first of the co-eluting congeners
F	value adjusted per USEPA request
