At this facility which lies partly inside the Canal the spoils will be used to build a bulkhead inside the canal after stabilization by perhaps
mixing with cement or some other procedure. It is unclear to us whether any NLPA sediments will be treated at
the same on site facility, or whether dewatering will take place at the same facility.

We are severely opposed to these alternatives for various reasons. Depositing the stabilized materials in the canal is a
temporary measure at best. The water flow even at less than 0.5 feet per second will gradually erode and decompose
the materials and the net effect is redepositing the toxins right back in the canal. All that will be accomplished is decreasing the toxic
load in one area of the canal by increasing the toxic load in another area of the canal. Even more troublesome is that Mr
Quadrozzi's company will be given a free hand to dump the spoils back into the canal without any treatment. The lure of profit
will be too tempting and just too convenient at such a convenient location. No amount of

supervision or inspection
will be able to prevent this from happening because of the location and the fact that it may be impossible to differentiate
what has been dumped from the existing sediments. At least it will be very difficult to prove that any overnight dumping
has taken place. In essence our community will be set up to be the policemen with no enforcement capability. Furthermore
there is a general consensus in the community that Mr Quadrozzi's company has been engaged in dumping in the community
for years. We are opposed to any on site treatment of the sediments that may involve dewatering and transportation
of the sediments to any site in the Red Hook Community.

We are also concerned that the investigation of the Superfund Site although quite thorough may not be properly updated to
effects of two major hurricanes to hit NYC, and the ongoing work at the Hamilton Avenue converted Marine Transfer Station(MTS).

We understand that the ramp at the MTS site may be queuing up to 36 sanitation trucks prior to tilting for transfer of garbage
to the barges on the canal. There may be a need for a Conformity Analysis prepared for determination of Hot Spots at the site.
We have been unable to determine if one was prepared or if any review of the impact on dredging for the operation of these barges
has been completed.The converted MTS facility operated for decades as an major incinerator and this is a polluted site for the canal and adjacent area.
This site should be included in any Environmental Analysis prepared for the remediation of the canal including the taking of bores as indicated below.

The sample bores taken for analysis almost 3 years ago may not be representative after the two major hurricanes to hit NYC, most recently
Sandy. There maybe significant change in the composition of the toxic pollution of the canal. It has been reported that the Sandy surge has
been as high as 13 feet. We understand that a few bores were taken after Sandy, but these were very limited in scope.

Jesus, no - don't build this crap. Are you crazy?
Brook Shepard to: Region2 GowanusCanalComments 04/26/2013 08:02 AM

History: This message has been replied to and forwarded.

Mr. Tsiamis & Team:

Imagine my surprise when I heard about this plan and all of its options.

On the one hand I know you're all explaining highly-complex options to lay-people, and I'm sure that's hard.

On the other - the hubris of walking into a room (like you did at PS 15 in Brooklyn, a borough not known for a lack of self-regard) and saying "I was in Red Hook once for an afternoon four years ago, so I know what the community needs." Can you imagine how your neighbors would feel if I did that in their homes?

> "Oh, Greece, you've got economic problems? Well let me tell you, as a fairly-successful small-business owner I know about job creation, so here's my advice: McDonald's is hiring! Go get jobs at McDonalds! Problem Solved!"

I'd be chased off the stage, and rightfully so!

And then to make part of the plan hinge upon the enrichment of one businessman, to the possible detriment of the entire community? A businessman whose company and officers A) have plead guilty to making illegal payoffs, B) been forbidden from bidding on City contracts and C) fined millions for polluting the waters of Brooklyn?

It's insane!

I try to be polite, and I realize that you've gone out of your way to explain things to the community; but every time I think of this I get more enraged. It's mind-boggling that you could ever think any small number of people would support this plan. I try to be polite and I can't. It makes me fume.

It's crazy, and we're going to do our best to hold you to your on-record quotes saying "we heard you, we ain't gonna build it."

PRAP comment
rita miller to: Region2 GowanusCanalComments 04/26/2013 08:05 AM
Please respond to rita miller

My name is Rita Miller. I am a third generation lifelong Carroll gardens resident and property owner living just a couple of blocks away from the Gowanus Canal.

I have served on the CAG since its inception representing CoRD, an organization I co-founded several years ago. I am also a member of FROGG, the larger South Brooklyn Coalition and the 2nd Place Community Transit Garden.

Other than the two residential properties I own on Second Place, I have no other holdings or business dealings in the community. I am, however very interested in the fate and future of the Canal.

It is with a confident and enthusiastic heart that I offer my full support to your Proposed Plan. I totally approve of the Plan which accomplishes the goals we set together from the start--

---a clean and capped Canal bottom, a halt to toxic compound seepage into the water from the surrounding uplands and a solution that addresses, at their source, future chemical recontamination via the CSOs with a bonus for us to boot--since the proposed retention tank solution will alleviate the now constant unhealthy pathogen laden pollution of the canal as well.

Those tanks are the key to satisfying the community's and the CAG's well documented longing for the elimination of CSO discharges. And the proposed locations couldn't possibly be more thoughtful or logical.

I understand the need to disrupt some of the amenities offered currently at the MPG site location at Thomas Greene Park in order to accomplish the necessary upland and water remediation. I do not view this as "losing a park", as some have claimed. Instead, I see this as a positive and much needed cleanup of an unhealthy and unsafe area which unbelievably just happens to be used for recreation at the moment.

I have confidence that we, as a community, can work with EPA, NYS, NYC and National Grid to come up with first a temporary replacement and a more permanent solution later on, for the pool and whatever other amenities are necessary while the toxins are removed and the site's problems properly addressed.

As a parent myself, I find the complete and total remediation of this recreational area an absolute necessity--anything short of that--a fruitless waste of time and money. Frankly, I cannot understand anyone taking a different position. What parent is happy knowing that their child is playing somewhere that is unfit, unsafe and unhealthy? What

parent would advocate keeping that when the alternative is something so much better?

In regard to the CDF proposal, my understanding is that this one particular piece of the Proposed Plan will, as it should, be entirely up to the Red Hook Community.

In closing, I want to say that as both a CAG and individual community member I have found our EPA Region 2 team to be top notch in every way. I want to thank you for that.

So, you go Region 2--- I eagerly await the Record of Decision and look forward to the Remedial Design phase. This has been the most wonderful thing that has ever happened to our community and I want to see it through to the end. Thank you again. Let's keep moving forward!

I, the sender, vote that I do not want this project to proceed.

James Harmon to: Region2 GowanusCanalComments 04/26/2013 08:28 AM

As (one of the options above) of the community of Red Hook, I/We am/are strongly opposed to the processing of contaminated sludge dredged from the Gowanus Canal Superfund Cleanup Site at a facility at the proposed location. The cost savings are negligible, and the Red Hook Ball Fields and Pool are used in public trust. The community does not want to create more land from this contaminated sludge adjacent to one of the most heavily used recreation areas in New York City. People and organizations adversely affected include (but are not limited to!):

- Children
- Numerous public and private schools which use the fields for physical education & sports teams
- Residents of the Red Hook Houses and the surrounding neighborhood
- Soccer, softball, baseball, football, handball, basketball, track & field teams and enthusiasts
- Swimmers of all ages
- The Red Hook Food vendors and their customers
- Other visitors to our community

Further, we object to an individual (John Quadrozzi), who has incurred serious fines for environmental violations, from profiting from the project.

Revised Gowanus CAG Statement - Position #1

Jerry Armer to: Region2 GowanusCanalComments 04/26/2013 09:55 AM
Please respond to Jerry Armer

Mr. Christos Tsiamis,

The following and the attached document reflect the Gowanus CAG's Revised first comment on the Gowanus PRAP. This revised statement corrects typos that were contained in the original statement

Revised Gowanus Superfund Community Advisory Group (Gowanus GAG) Statement To The EPA

On The PRAP

The Gowanus Superfund Community Advisory Group (Gowanus CAG) would like to thank the US EPA Gowanus team at Region 2 for their leadership, transparency, timeliness and their ability to listen to the many & varied concerns, wants, desires and needs of the greater Gowanus community. Their ability to synthesize the various statements into a coherent RAP indicates their commitment to this project.

The CAG would like to remind EPA of the resolution passed unanimously by the full group in 2012. The CAG wants to make certain that the Record of Decision for the Gowanus cleanup gives the EPA sufficient authority to meet the goals of the April 5, 2012 CSO Resolution

The Gowanus Superfund Community Advisory Group fully supports the U.S. Environmental Protection Agency in its finding that New York City's Combined Sewer Overflows are a significant contributor of harmful sediment and Superfund regulated PA Hs and metals to the canal. The CAG takes the position that the total elimination of CSOs into the Gowanus Canal is the only acceptable solution to the problem. The CAG asks that the EPA, under their Superfund authority, take the necessary measures that will ensure protection of the proposed remedy from ongoing CSO sediment solids deposits and the release of PAHs and other toxins."

The CAG requests the inclusion of the entire 5th Street Basin in the EPA Superfund

Christos Tsiamis Project Manager
Central New York Remediation Section
U.S. Environmental Protection Agency
Region 2
290 Broadway, 20th floor
NY, New York 10007-1866

Mr. Tsiamis:

I am writing to register my opposition to the currently proposed location for dewatering the toxic sludge resulting from clean – up of the Gowanus Canal.

I am opposed to any solution which involves stabilizing the sludge on-site and keeping it in Red Hook in any form. I am concerned that the amount of toxicity released into the atmosphere in the dewatering process has not been studied thoroughly and that the sludge processed at this site and transformed into a concrete form (as planned) could leak toxic materials in the future. According to the EPA's own report, "Tests to assess the leachability of NAPL (toxic contaminants)... would need to be performed (on the concrete)... Permanent institutional controls would be required to ensure the long-term effectiveness of this option..." I do not want a site built with materials potentially leaching toxic contaminants near my home and requiring a permanent monitoring facility where I live and breathe. Further I seriously question why the EPA would suggest a site in a known flood zone, especially following the devastation that our neighborhood incurred from hurricane Sandy. No one can say with 100% accuracy that there would not be spillage when another flood occurs.

The estimated $37 million dollar savings for this method does not benefit the community, but rather reduces the expenses of the clean-up for the original polluters. Additionally, this proposal includes the building of additional waterfront bulkhead land for a private entity, which, by their own admission, has not been thoroughly vetted or designed. I am concerned that once this project is in motion, the requests and the needs of the community will be lost as a private developer seeks to increase profit with no benefit to the community. It appears that all parties in this plan stand to benefit in some way form storing this material in Reed Hook, with the very notable exception of the residents.

The EPA has a list of remedies that involve processing and containment of dredged material off-site for beneficial use such as the capping of landfill sites, I urge the EPA to select any option that involves off-site processing and off- site disposal.

Thank You,

Jenna John-Goodman

Comments on the Gowanus Canal Proposed Remedial Action Plan

Renee Crowley to: Region2 GowanusCanalComments 04/26/2013 12:04 PM

History: This message has been replied to and forwarded.

Mr.Christos Tsiamis -

Please accept my attached comments, for the EPA's Gowanus Canal Proposed Remedial Action Plan.

Kind regards,
Renée Crowley

r.crowley - Gowanus PRAP Comments.pdf

April 26, 2013

Christos Tsiamis, Project Manager
U.S. Environmental Protection Agency
290 Broadway, 20th floor
New York, NY 10007-1866

Dear Mr. Tsiamis,

As an individual that works and spends a significant amount of additional time in the neighborhood, please accept my comments on the EPA's Proposed Remedial Action Plan for the Gowanus Canal. My comments focus on three areas of concern:

- Minimize impacts and maximize benefits for all those that live, work and play in the area
- Conduct an Environmental Justice Assessment; identify Communities of Concern in the Gowanus area
- Incorporate climate change impacts and post Sandy mitigation measures in the ROD

Minimize impacts and maximize benefits for all those that live, work and play in the area

The EPA needs to ensure that this Superfund cleanup will minimize impacts and maximize benefits for all those that live, work and play in the area. Additionally, because of on-going gentrification and displacement pressures, which have only worsened with recent developments in the area, there will likely continue to be significant changes in the racial and ethnic make-up of the area that will disadvantage African Americans, Hispanics and Latinos and low income residents from enjoying the social and economic benefits of a clean Gowanus Canal. Since a delayed cleanup could disproportionately disadvantage these communities, we ask that the EPA do everything within its CERCLA authority to expedite a coordinated cleanup for nearby community residents, and to ensure the full and fair participation by all potentially affected communities in the ongoing decision-making processes that will occur as the design phase enfolds. The EPA also needs to take into consideration and examine the Gowanus and Red Hook communities as potential Environmental Justice (EJ) communities. To do this, the Record of Decision (ROD) needs to include an EJ assessment with a Community Involvement Plan (CIP) geared towards the needs of those communities.

As these cleanups proceed the residents that live here must be involved in the planning discussions and resource allocation decisions for the future of their neighborhoods, otherwise they suffer the health risks and cleanup burdens without any guarantees of benefits.

Conduct an Environmental Justice Assessment; identify Communities of Concern in the Gowanus area

In Gowanus, two large residential developments are located as close as 500 feet from the head of Canal. Wyckoff Gardens contains approximately 530 apartments in two, 20-story buildings located north and east of the head of the Canal. The Gowanus Houses, north and west of the Canal, contains over 1,000 apartments in a 12.57-acre complex comprising 14 buildings. Finally, a third smaller NYCHA property, the Warren Street Houses, at 572-574 Warren Street, is located across 3rd avenue from Wyckoff Gardens and comprises 200 apartments. Estimates number around 4,000 official residents in the three Gowanus NYCHA properties in the footprint of the Canal, however it may be that these numbers are low because of the overcrowding that typically takes place in low-income living situations. Furthermore, the Red Hook Houses are Brooklyn's largest public housing complex where more than 6,000 people live. The Houses are situated at the mouth of the canal, and nearby the proposed location of the canal waste facility.

Beyond the NYCHA residents of Red Hook, Gowanus Houses, Wyckoff Gardens and the Warren Street Houses, additional Communities of Concern that should be assessed include the large Hispanic and Latino populations in the Gowanus area that do not speak English that remain uninformed and uninvolved in these cleanup processes due to language barrier constraints. The EPA should assess the need for other EPA programs to take action or provide information to modify implementation of the selected remedy to minimize any disproportionately high and adverse environmental burdens impacting any potential EJ community.

Incorporate climate change impacts and post Sandy mitigation measures in the ROD
Increased flooding from the canal poses a health threat to the all residents who live in the flood zone. Increasing large scale development in the area and surrounding neighborhoods, which also contribute wastewater to the Gowanus watershed, combined with predicted average annual rainfall increases and sea level rise, all contribute to the urgency of the need to address the CSO and toxic sediments cleanups in a timely manner.

When the Gowanus Canal overflowed during Superstorm Sandy, the heavily polluted saltwater corroded two manholes covers and flooded basements in the Gowanus Houses, damaging electrical lines and fuses. As a result the Gowanus Houses were left without power for 10 days after Sandy, and forgotten by most everyone while all the focus went to waterfront areas. A broken water main along Hoyt Street, also left thousands of residents in eight of 14 buildings there without access to clean water.

In the Post-Sandy landscape it is important to consider the updated flood hazard risks. Residents remain under direct threat of exposure to the combined problems of known toxic endocrine disruptors and raw sewage exposure during any large flooding episodes. Annual rainfall and intensity in the area is increasing, presently the NYC average annual rainfall is 45 inches, while CSO abatement plans are based on 38 inches a year, and according to NYC's 2008 Sustainable storm water plan recent annual rainfall records were as high as 65 inches a year. The Gowanus community sits in the 100 year flood plain and is classified as a Zone A area by the Office of Emergency Management (OEM), facing the highest risk of flooding from coastal storms, hurricanes and storm surges. According to NYC's 2008 Sustainable storm water plan, moderate predictions for sea level rises in the city are between 4 to 7 inches by the 2020's, so the time for enforceable action for the protection of Gowanus residents presents a strong case for increased compliance and enforcement measures specific to the Clean Water Act.

As previously commented at recent EPA public meetings, the ROD should include a post Sandy assessment on the sustainability of the remedial design. Superstorm wave velocities and tidal effects on dredging / flooding should be addressed and design protections should be incorporated. Possible effects to the "armor" isolation layers from superstorm effects should also be considered. Overall, strategic flood plain management needs to designed into the ROD and the EPA should provide estimates on how much the remedy will be predicted to lower the canal water depths and incorporate as much flood protection design as the remedies will allow. For these reasons I support opening up the buried basins at First and Fifth Street to help with flood direction issues and planning.

Sincerely,

Renée Crowley

Subject: Waste to Energy Proposal - Red Hook, Brooklyn

Mr Tsiamis,

I have read the proposal for the Waste to Energy Project for Red Hook Brooklyn and am truly alarmed that the EPA would even consider such a project for the proposed site.

The proposed project site is located in a heavely populated urban area that is prone to flooding.
The proposal does not have even one example of an incinerator like the one proposed operating safely anywhere in the world. The proposal does not site even one enity anywhere in the world that successfully builds this type of incinerator. The proposal does not site even one example of incinerated waste mixed with concrete used safely as land fill. The proposal does not address what impact the placement of fill contiguous to a flood zone will have on future flood events.

I feel that this science project, written by a local university does not qualify for consideration as a viable solution for the remediation of a designated superfund site.

The people that live in Red Hook and adjoining neighborhoods should not be used as guinea pigs as the EPA, New York State, and others experiment with a "cheaper" solution to remediate the Gowanis Canal.

Edith Yates
Red Hook

Support of the PRAP and related comments

bettestoltz to: Region2 GowanusCanalComments 04/26/2013 12:33 PM

History: This message has been replied to and forwarded.

Dear Christos, Natalie, Brian, and Walter;

As someone who has been very actively involved in the Gowanus Canal Cleanup saga since way before the Superfund designation; stayed very actively involved throughout the Remedial Investigation and Feasibility Study Process as a member of the CAG and as a member of FROGG; and will remain very actively involved throughout the Remedial Design Phase as one of the administrators of the TAG Grant; I would like to express my general support for the PRAP as presented to the community and my hope that the ROD will include as many of the methodologies and techniques outlined in it as possible after consideration of community input during the comment period.

That said, I would have liked to see a few things either added or emphasized more strongly in it.

- Specifically, I fear that the size and number of CSO event holding tanks suggested will not be sufficient, especially given the huge amount of new development we will be seeing throughout the entire area that feeds into the Gowanus water treatment/sewer system. I believe that we all know that to be true but also know how politically charged the issue is - and deeply appreciate your addressing it at all in the PRAP, but I wish you could have been stronger in your recommendations.
- I wish you could have found a way to avoid re-contamination of the canal water from upland sources while still creating soft edges and wetland restoration. I know this is almost an oxymoron, but perhaps the next bullet offers a possibility.
- I wish you could have included restoration of the entire Fifth Street basin in the PRAP for two reasons: Given we are living with Climate Change and rising sea levels with the occasional storm surge, the more of the original water holding area we re-create the better our chances are to minimize flooding. Also, and this goes for both the 1st Street Basin and the 5th Street Basin, perhaps their restoration might include soft edges and wetland plantings, maybe even use of toxin removing plants as a scientific experiment.
- As I am sure you are aware, I have been, and still am among those CAG members and actively involved community members who believe that it is time to start trying to solve some of our environmental problems in the places where we made them. I strongly supported and still do, the Red Hook De-watering and CDF proposal and would deeply regret the lost opportunity, especially because it is being opposed in a "don't bother me with the facts - I have already made up my mind" oneupmanship manner. That said I would encourage EPA to continue to seek upland waterfront sites all along the canal for as much as possible of the remediation work to take place. This thought is further explained in the next bullet.
- I am concerned that whatever dewatering and/or remediation processes are used not add to the time required to complete the cleanup within your original projected time frame. I admire the fact that your team has been able to meet its own timetable thus far, and deeply appreciate your hard work. Insofar as possibly having to seek alternative methods for dealing with the dredged sediment I have the following thoughts:

  A. I don't think it should delay the design process because I believe there are plenty of sites where various other options for remediation procedures have already been used and you will not have to invent a "new" wheel, just adapt a known method to the particular site.

  B. I think it may prolong the actual, "in the mud & on the water", cleanup time it will take. When one thinks that the average large dumpster we see in the streets is 20 cubic yards, and 280.000 cubic yards need to be dredged, that is a lot of bargefuls! If we want to dredge onto barges of a size that will fit into the relatively narrow Gowanus Canal - allow the water to separate from the sediment naturally by gravity, then pipe the water onto other barges to treat it before sending c leaned water back into the canal, then get the de-watered sediment out into the harbor to go to NJ or wherever - that is a lot of maneuvering that has to be done in a very narrow waterway. The

barges will need tugs to move into place, etc. That could mean opening & closing the drawbridges at a frequency we have not seen in this generation,possibly causing massive traffic jams. It could also mean no recreational boating will be safe anywhere in the canal during the dredging period of an originally estimated 6 years, which could become much longer for the above described reasons. (No Recreational Use during the entire dredging process might already be a foregone conclusion - I'm not sure about that and would be interested to know.)

Finally, I wish to thank you all for your patience, transparency, thoroughness, and graciousness in dealing with a very diverse and often divisive community. Thank you for dealing with all our personalities, all our annoying habits, the occasional unfair (and untrue) accusations, and most of all for making science the most important part of this whole Superfund process.

Sincerely,

Bette Stoltz

Hi Berry and Natalie,

Congratulations once more on the release of the PRAP and now on the close of the comment period!

Attached you will find NYC Councilmember's comment, which we plan to share with constituents this afternoon.

Thanks again for your hard work,
Catherine

Comment on the EPA's Proposed Plan for the Gowanus Canal
New York City Councilmember Brad Lander
April 26, 2013

For many years, cleaning up the Gowanus Canal has been a high priority for our community – but one that seemed hopelessly far away. With the EPA's proposed cleanup plan, and I am thrilled to see that day getting much closer. I am enthusiastic about the EPA's Proposed Plan and believe that it puts forward the right steps:

- removing some contaminated sediment from the bottom of the canal;
- stabilizing that contaminated material off-site and identifying a beneficial use for it;
- stabilizing NAPL-contaminated sediment in place; and
- capping dredged areas with layers of clean material.

I agree with the EPA's preference for a remedy that would: restore canal bottom as a natural habitat, provide for appropriate water depths to support current navigation uses, and allow for future maintenance of the remedy and canal infrastructure, including bulkheads.

I am pleased that the EPA's Proposed Plan calls for implementing stormwater runoff control measures to significantly reduce the amount of combined sewer overflows (CSOs) deposited in the Gowanus – so that the canal is not recontaminated after dredging is complete. I share the widely-held goal of improving water quality to a standard that supports the canal's current uses, including contact recreation for children and families. We must work together to realize that goal to the greatest extent possible under CERCLA, and also through the Long Term Control Plan under the Clean Water Act.

To that end, I was encouraged to see that the EPA and DEC are "committed to work together throughout the development of the remedial design and the contemporaneous Long Term Control Plan development process to ensure that both the Superfund and CWA goals are met in a timely, cost-effective manner." I hope this spirit of collaboration can be even further extended – to include not only dredging and water quality improvements, but also bulkheads, shorelines, and wetlands restoration, and to include the City of New York, the Army Corps of Engineers, and other relevant public and private partners.

There are, of course, many important questions that will need to be answered during the three-year design phase: Where will the on-site dewatering and transfer of dredged

sediments will take place? Who will operate the facility? Where will off-site stabilization and beneficial use take place? Where will staging areas be located? Where will CSO controls (e.g. in-line storage tanks) be sited?

These decisions will have a meaningful impact on the surrounding community. I have been very encouraged by the EPA's extensive community outreach to date. The Gowanus Canal Superfund process has been one of the best examples of community engagement in public decision-making that I have seen in my time as an elected official (a remarkable feat for such a complex and technical issue). I am optimistic that the EPA will continue to work closely with, reach out regularly, and listen closely to community stakeholders as these subsequent decisions are made, and I urge them to do so.

I do not support the location of a confined disposal facility in Red Hook for the disposal of contaminated material. While I appreciate the desire to leverage the cleanup for local jobs, it appears to me that the strong majority of Red Hook residents who have engaged in this process are opposed to the proposal, and do not believe that the benefits for the community outweigh the risks. If they do not want to make this trade-off, I believe we should respect their wishes.

The users and neighbors of Thomas Greene Park and the Douglass-Degraw Pool have also expressed concern about the potential loss of this well-used community space should an in-line storage tank be sited there. Before any final decisions are made, we would need extensive conversation and further details about the proposal, the process, and the risks that would be involved.

In addition, my office is partnering with the New York City Department of Sanitation and the Gowanus Canal Conservancy, with the support of Councilmember Stephen Levin and Councilmember Sara González, to construct a community composting system on the "Salt Lot," a City-owned property located at 2nd Avenue and 5th Street—another potential location for an in-line storage tank. This innovative project won funding through the first participatory budgeting vote in District 39 and will turn one ton per day of food waste into usable compost. We are currently working with the project partners to finalize the design of the composting facility and anticipate that construction will begin this summer, pending regulatory approval. Again, before any final decisions are made about the siting of an in-line storage tank, we would need many more details about the proposal, and what the impacts would be.

In order to move forward, many different entities will need to work closely together to make the best decisions about remediation across environmental and regulatory domains, achieve the most effective use of public investments, and bring about a comprehensive cleanup. I was pleased to see the EPA's commitment in the Proposed Plan to coordinate with other government agencies to ensure the best cleanup possible. This includes working closely with the New York State Department of Environmental Conservation (DEC) on the remediation of contaminated upland sites, especially the three manufactured gas plants. There is also strong interest in how standards for bulkhead

replacement and maintenance will be promulgated, including bulkhead height and design, where soft edges are possible, and where wetlands could be restored.

This is an important moment for Gowanus – and one we need to build upon. The EPA's Proposed Plan is a major step toward a cleaner community, but there is more that needs to be done. As made painfully clear during Hurricane Sandy, we need to make difficult but important decisions about public investment in sustainable infrastructure and flood mitigation measures to protect our neighborhoods. I believe we need to move forward together, with all stakeholders at the table, to develop a comprehensive plan for the infrastructure, amenities, and land use regulations needed for a safe, vibrant, and sustainable Canal area. In the coming months, I will be working with other elected officials and reaching out to community stakeholders to begin the conversations for such a planning process.

Let me be clear: this work will not be easy. Stakeholders have different ideas for what they want to see along and around the Canal, and we will need to work through many open questions. The Gowanus future that we want will cost real money—beyond the estimated $500 million to be paid by responsible parties under the Proposed Plan—and it will not be easy to allocate those costs and raise the needed resources.

But I believe it would be a short-sighted mistake to miss this opportunity. With the great work done by the EPA leading to a real plan for cleanup, and with the clarity provided by Hurricane Sandy about the realities of climate change for our future, we have the opportunity to reclaim this toxic corner of our neighborhood, and create an innovative model for low-lying, mixed-use areas on a warming planet. Let's not let it pass us by.

Thank you to the EPA team—especially Judith Enck, Walter Mugdan, Christos Tsiamis, and Natalie Loney—for your diligent work developing this bold and important plan, to the many partners in government—including Congresswoman Nydia Velázquez, State Senator Daniel Squadron, State Senator Velmanette Montgomery, Assemblywoman Joan Millman, Councilmember Stephen Levin, and Councilmember Sara González—who have been pushing for a Gowanus cleanup, and to so many community advocates who have been working tirelessly to get to this point. I look forward to working with all of the stakeholders to see it finalized and implemented, and to build upon it toward a vibrant, sustainable future for the Gowanus in the years ahead.

Gowanus Canal Clean-Up
Triada Samaras to: Region2 GowanusCanalComments 04/26/2013 01:33 PM

History: This message has been replied to.

Dear Mr. Tsiamis,

I am in full support of yours and the EPA's plan to clean-up the Gowanus Canal. I feel very fortunate that Carroll Gardens has had such an excellent rapport with the EPA to date regarding the Gowanus Canal cleanup. Since the moment that the Gowanus Canal was declared a Federal Superfund site in my community, I have been confident, having met the EPA team, including yourself, that the EPA will do what is in the best interest of my neighborhood.

I am a firm believer in the EPA plan remedy the CSO's issue along with the rest of the Gowanus Canal cleanup. I feel very fortunate that our EPA recommended Gowanus Canal cleanup plan includes both aspects of the contamination: the chemical AND the CSO's contamination. To me it makes more than perfect sense that the CS owes become toxic when combined with other chemicals in the canal. It makes absolutely no sense to me that the EPA would clean a part of the toxins in the canal but leave the CFOs issue standing. I also feel such a move would be a giant waste of money.

Therefore I highly support the current EPA clean-up plan (the PRAP that has been featured online at the EPA website) and I hope and pray that the EPA will be able to implement this comprehensive clean-up plan.

Warm regards,
Triada Samaras

Re: Gowanus Canal Superfund Site, Brooklyn, New York (Site)
Comments on Proposed Remedial Action Plan (Proposed Plan)

Dear Mr. Tsiamis:

On behalf of the undersigned entities[1], we are providing the enclosed comments on the Proposed Plan dated December 2012, issued by Region II of the United States Environmental Protection Agency (EPA) for the above-captioned Site.

A number of the comments presented in the enclosure reflect concerns expressed previously by a group of PRPs (by June 19, 2012 letter to the National Remedy Review Board), as well as by others, with respect to the draft Feasibility Study. These comments are repeated here because they were not adequately addressed in the Proposed Plan.

The undersigned PRPs continue to believe that: (a) the conceptual site model remains incomplete; (b) continuing contamination needs to be addressed prior to implementing the Site remedy; (c) alternative remedies (e.g., capping, and monitored natural attenuation) were not evaluated or properly carried through the evaluation process; (d) the proposed remedy has been selected prematurely; and (e) the schedule of remedy implementation is unrealistic.

Our specific comments and concerns are presented in the enclosed document.

Respectfully submitted,

Beam, Inc.[2]
The Dun and Bradstreet Corporation
ExxonMobil Oil Corporation
Hauck Manufacturing Company
Hess Corporation
Honeywell International Inc.

Kings County, New York

COMMENTS ON DECEMBER 2012 PROPOSED PLAN
Prepared by the Small Parties Group

The following provides comments, prepared by the Small Parties Group (SPG),[1] on the Proposed Remedial Action Plan (Proposed Plan) for the Gowanus Canal Superfund Site (the Site) issued by the United States Environmental Protection Agency (EPA) in December 2012. Our comments also address information presented in the January 2011 Remedial Investigation (RI) report, the December 2011 Feasibility Study (FS) report and the December 2012 FS report Addendum as cited in the Proposed Plan. Our comments are organized into two general categories: (I) General Comments, and (II) Specific Comments.

I. GENERAL COMMENTS

1. EPA's Failure To Develop and Analyze Critical Data - EPA Must Develop a Conceptual Site Model That Appropriately and Fully Defines All Current and Future Source Areas Before It Can Select a Remedy

The sources of contamination to groundwater and combined sewer overflow (CSO) into the Gowanus Canal have been inadequately studied by the EPA and are not well understood. Therefore, the current and future impacts on the Site from these continuing sources have not been adequately evaluated in the Proposed Plan.

EPA's failure adequately to assess these impacts is, in part, due to the facts that: (i) the delineation of contamination at and remedial plans for the manufactured gas plant (MGP) sites are still being developed by National Grid, the party responsible for the MGP sites, in coordination with the New York State Department of Environmental Conservation (NYSDEC), and (ii) the details of New York City's plans for addressing its CSOs into the Gowanus Canal are still in flux and have not been finalized. Without these two pieces of critical

[1] Members of the SPG include, in alphabetical order, Beam, Inc.; Dun & Bradstreet, Inc.; ExxonMobil Oil Corporation; Hauck Manufacturing Company; Hess Corporation; Honeywell International, Inc.; MRC Holdings, Inc. for itself and on behalf of Citigroup, Inc.; Patterson Fuel Oil Company, Inc.; Rexam Consumer Plastics, Inc.; SPX Corporation (O-Z-Gedney); Union Oil Company of California and Verizon New York Inc.

information which, as noted above, are in the development stages, an appropriate, cost-effective remedy for the Site cannot be selected or implemented.

The missing information about the planned remediation of the MGP sites and the CSO modifications is critical to selecting an appropriate remedy for the Canal. Additional studies and modeling are necessary to characterize the flux of contaminants of potential concern, including non-aqueous phase liquid (NAPL) from, *inter alia*, the MGP sites and the CSOs. Without the supporting technical studies, it is impossible to know with any certainty how much sediment should be or can be effectively removed, or what cap design is appropriate. Moreover, without this information, the long term effectiveness (a major criterion for evaluating remedial alternatives under Superfund) of any sediment remedy cannot be determined.

2. The FS and Remedy Selection Should Emphasize Capping Over Dredging and Include Monitored Natural Attenuation

It is very unusual that the Proposed Plan carries forward only the No Action and sediment dredging alternatives, all of which are variations on the same theme (soft sediment removal), without also carrying forward a capping-only alternative with pilot scale testing. No consideration is given to dividing the remedy into Operable Units, or to first implementing any Interim Remedial Measures relating to the MGP wastes or CSO outfalls before deciding on an appropriate remedy for the remainder of the Site. Other viable alternatives, such as monitored natural attenuation, should have been but were not thoroughly evaluated.

Capping has been successfully implemented at other water bodies in New York and New Jersey, such as the Port Newark/Elizabeth project, where capping was performed in 1993 and monitoring has confirmed that the cap is stable and protective. This project was described in an EPA cap design document (Palermo, et al., 1998). In addition, capping of sediments is the approved remedial approach for the Geddes Brook and Nine Mile Creek projects located in New York. Sediment can be removed to the extent required to construct the capping system.

Therefore, existing sediment surface elevations and water depths can be maintained.

Natural Attenuation should be considered as part of the Canal remedy and is especially applicable to Reach 3 for the following reasons: (a) NAPL saturation was generally not observed in Reach 3, (b) this Reach has the lowest soft-sediment PAH concentrations relative to the other reaches, and (c) Reach 3 is subject to future maintenance dredging operations.

3. **The Effectiveness of the Selected Remedy Is in Serious Doubt**

The effectiveness and successful implementation of the proposed remedy are doubtful given the lack of adequate treatability testing to date; the ongoing sources of contamination, including mobile dense non-aqueous phase liquid (DNAPL) in the subsurface; and continuing CSO discharges. The "Adaptive Management" approach discussed in the Proposed Plan assumes that a way will somehow be found during the implementation phase of the remedy to address these ongoing sources in a timely fashion. This will require an unprecedented degree of coordination with and cooperation by the NYSDEC and National Grid with respect to abatement of upland groundwater contamination sources and DNAPL from MGP plants, and between the New York City Department of Environmental Protection (NYCDEP) and the NYSDEC with respect to the City's CSO discharge elimination. The Proposed Plan contains no contingency plan if these ongoing sources of contamination cannot be addressed in the time frame anticipated for dredging of the Canal. It should also be noted that the plans currently proposed anticipate only a 34% reduction in CSO discharges. This means that 66% of the current CSO volume will continue to be discharged for a significant period of time.

The remedy includes implementing *in-situ* soil stabilization (ISS) techniques involving delivery of stabilization material to the sediment *in situ*. EPA fails to provide any information about whether this approach has been successfully implemented at similar sites on a full scale. Ebullition of biogenic gas from

organically enriched sediments, such as the Gowanus Canal, has been demonstrated to cause migration of contaminants into the overlying water column. In particular, the migration of NAPLs from sediment to the surface of water bodies has been reported at former MGP sites elsewhere. Gas generation in sediment has the potential to cause failure of sediment caps in tidal and non-tidal rivers by way of breakthrough (channelization), or blockage of hydraulic flow. Additionally, dredging will also bring NAPL to the surface of the water, and it is expected that odorous volatile constituents will be released to the atmosphere from the water surface.

Therefore, unless the selection, design and implementation of the remedy are delayed until all ongoing sources are identified, delineated and contained, EPA's proposed remedy is potentially doomed to failure *ab initio*.

4. **The Selected PRGS Are Too Low**

The PRGs selected by EPA are artificially depressed based on Reference Area (RA) selection and the PRG development process. The PRGs are based on extremely limited sediment sampling in Gowanus Bay and Upper New York Bay. The selection of these locations as RAs reflective of background is highly questionable based on the lack of similar basin size, shape, composition, and industrial development characteristics versus the Gowanus Canal. Consequently, the PRGs selected are skewed low and are not reflective of the industrial purpose and history of the Canal. There are better RA choices for evaluation and comparison, such as the approach currently being utilized at the Newtown Creek Superfund Site, which examines a cross-section of industrial versus non-industrial, and CSO versus non-CSO, reference areas.

With respect to PRGs for protection of the ecological community, the Proposed Plan describes the PRG development process for ecological risks to be based on sediment threshold effects concentrations, arriving at 20 mg/kg Total PAH in bulk sediment. It is not stated how confounding factors, such as ammonia or sulfide toxicity, were considered. The RI data finds that amphipods had only "limited"

toxicity (no survival or growth effects) at 39 mg/kg Total PAH, which is nearly twice the selected PRG. The Proposed Plan should utilize the ESB-TU approach to develop the PRGs for sediment using measured porewater concentrations to appropriately consider PAH bioavailability.

5. **The Impact of Bulkhead Replacements and Upgrades Needs To Be Fully Evaluated Prior to Remedy Selection and Implementation**

The Proposed Plan concedes that existing bulkheads along much of the Canal are degraded and will have to be stabilized, reinforced or replaced for the remedy to be implemented and succeed. The FS Addendum assumes that as much as 80% of the bulkheads in each RTA will require replacement. However, the Proposed Plan does not specify which bulkheads need to be addressed. More importantly, it does not explain how the sediment remedy would deal with new releases of contaminants from behind the bulkheads that may occur if the sediment remedy is implemented before bulkhead replacement or repair, nor whether bulkheads are being considered in some areas as an engineered source control structure. EPA acknowledges that its sediment remedy, namely the cap, addresses only NAPL already present in the Canal sediments. It does not address NAPL entering the Canal by seepage through the bulkheads. EPA, thus, appears to have selected a remedy which relies upon an uncertain design element and thereby risks remedy failure. Bulkhead replacement/upgrade evaluation must be integrated into the Proposed Plan prior to addressing sediments in the Canal and not deferred until the design phase of the remedy, because it represents a component critical to the selection of an appropriate remedy.

6. **EPA Failed To Consider Potential Public Exposure to Airborne Pathogens During Dredging**

The Proposed Plan cites concern over odors during dredging as one reason not to drain the Canal prior to dredging activities. But there has been inadequate study and evaluation of potential odors, and migration and exposure, of airborne bacterial and chemical substances (pharmaceuticals, personal care products, etc.) during dredging under the proposed plan with the Canal not drained. NYCDEP

began oxygenation/aeration in July 2010 that will continue until the flushing tunnel is repaired, and aeration is presently being conducted at the Canal to oxidize odor-causing compounds because of the massive CSO discharges. EPA needed, but failed, to consider recent studies by Columbia University that evaluated air quality during the ongoing in-canal aeration activities by NYC at Newtown Creek. That air sampling confirmed that aeration provides "...a novel pathway of microbial exposure in densely populated urban communities containing contaminated soil and water" that have not been studied or addressed in the proposed Gowanus Canal remedy. Consequently, further study of the potential effect on public health of these impacts must be undertaken before a final decision on the ROD is made.

II. SPECIFIC COMMENTS

1. Purpose of This Proposed Plan

The Proposed Plan, at page 1, states that, "NYSDEC is currently overseeing work being performed by NYC to reduce CSOs to the canal by approximately 34 percent." Stated differently, even if NYC is successful in reaching this reduction, the CSOs will continue to contribute 66% of current loadings into the Canal, thereby resulting in significant recontamination of the post-remediation sediments. The Proposed Plan's failure to account for 2/3 of the future CSOs contribution into the Canal is untenable and demonstrates that the proposed remedy will, in fact, not remedy the targeted contamination.

2. Scope and Role of Action

The Proposed Plan, at page 2, mentions a groundwater mitigation action to be addressed as part of the upland source remediation but does not reference the plan or its timing related to sediment remediation. In fact, little information is provided in the Proposed Plan about source control plans for upland areas. As source control is required before sediment remediation can be effective to prevent recontamination (which is one of EPA's stated goals in the Proposed Plan), this gap in a significant component of the overall restoration cannot be left out of the

remedy selection scope without undermining the basis for EPA's decision. Simply put, EPA's decision to hold in abeyance the evaluation and control of upland sources until after remedy selection is inconsistent with the National Contingency Plan (NCP) and is contrary to established EPA Guidance.

3. **Discharges from Combined Sewer Overflows and Stormwater**

a. The first part of this section, at page 4, describes the current wastewater treatment plants that serve the area, as well as the active CSOs and how they have affected sediment quality. Wholly missing from this analysis is an assessment of how historical CSOs have impacted the sediment quality in the Canal.

b. Paragraph 5 on page 4 of this section states that "the cumulative impact of these projected flow reductions and flushing improvements on sediment transport and deposition throughout the canal cannot be currently predicted with a high degree of confidence." Obviously, this uncertainty has a considerable impact on recontamination potential after the proposed remedy is implemented and is likely to lead to remedy failure. EPA has to clarify whether the uncertainty is related to the reduced particulate loading resulting from the construction, or to the increase in flow that limits deposition of particulates from other sources or some other factors. Without this critical review at this stage, the uncertainty will permeate and taint the remedy selection process.

c. This section also notes on page 4 that "[n]early 250 outfalls were identified in the RI, most of which were pipes located on private property....Twenty-five of these pipe outfalls were observed to be actively discharging during dry weather..." Similar to other statements that the EPA makes throughout the Proposed Plan, this one underscores essential data gaps that, although noted by EPA, are routinely given short shrift, or rather no shrift, in the Proposed Plan. Future loadings from all of these

outfalls need to be fully evaluated and addressed before the remedy can be selected and implemented.

4. **Site Hydrology**

a. The Proposed Plan states at page 5 that "the only fresh surface water inflows to the canal are wet-weather CSO and stormwater discharges." Sheet flow off of land during rainfall and snowmelt is also likely and should have been, but was not, considered as part of the site hydrology.

b. The Proposed Plan notes at page 6 that "intermediate wells screened in the glacial deposits indicate groundwater flow upward toward the canal." What is missing from this section is any analysis of the horizontal direction (source) of the flow and what influence the marsh deposit overburden (peat, etc.) would have on the contaminant concentration in this flow (i.e., possibly to provide a contaminant migration barrier). EPA's evaluation of site hydrology is deficient without that assessment, casting doubt, again, on its ability to select a remedy at this stage of the process.

5. **Sediment Characteristics**

This section notes at page 6 that soft sediments have accumulated since Canal construction. What is missing in this section is any discussion of how the pattern/deposition rate of sediment may have changed since 1850 and the factors responsible. Understanding these factors is crucial to selection of the remedy and source control design/methodologies. EPA's failure to do so undermines the basis for its remedy evaluation and selection.

6. **Results of the Remedial Investigation**

In this section of the Proposed Plan at page 8, EPA states that additional work included "tracing outfall features to their origin." However, there is no reference in the document of where the data from this supposed additional work can be

found. As such, it cannot be evaluated or confirmed and cannot, therefore, be an appropriate underpinning for EPA's decision-making.

7. **Extent of Contamination**

a. The second paragraph of this section at page 8 states that tidal exchanges and the flushing tunnel are the only "surface water" sources. This totally ignores both the CSO discharges and sheet flow surface water sources, which are also major contributing sources.

b. Another portion of this section, also on page 8, briefly describes relative differences in PAH concentration for various sample depths/locations. It may be true that the surface sediment mainly reflects CSO discharges, but as noted in the Proposed Plan, tidal exchanges and the flushing tunnel are also sources of solids. Data on particulate loading of the various sources should be presented to support EPA's claim. Additionally, the PAH trends would be better supported by utilizing the TOC data discussed previously to normalize the data, in order to illustrate differences in loading. Relative to canal surface sediments (~90mg/kg @1% TOC), soft sediments are 3X higher (~300 mg/kg @1%TOC) but also 6X lower than native sediments (~1500 mg/kg @1% TOC). These differences in loading suggest that vastly different sources and rates are involved for each depositional layer.

8. **Groundwater**

In this section of the Proposed Plan, at page 10, EPA discusses using an ESB approach to determine toxic units in groundwater. However, scant information is provided to clarify whether measured groundwater values were used, since the referenced ESB approach uses sediment values and partitioning calculations. EPA must explain its approach in detail.

9. **Sediment Transport and Deposition**

a. This section of the Proposed Plan, at page 10, notes that the "upper canal is the reach most affected by the deposition of solids from CSO discharges." However, EPA fails to provide any explanation of this statement and why the lower reach is not similarly impacted by the CSOs.

b. Another portion of this section, at page 10, suggests that Canal sediments "may be resuspended by currents, propeller wash, dredging and other disturbances." Contrary to this claim, the Proposed Plan notes that currents in the Canal are generally weak and that dredging has not occurred in 3 decades. The Proposed Plan notes further that propeller wash may result in localized re-suspension and re-deposition but that the finest particles are transported further downstream where contamination levels are lower. There is no explanation of why the finest particles would be expected to carry a lower contaminant load, which would have to be the case in order to explain the concentration trends. Again, these internal discrepancies undercut the EPA's position on remedy selection.

10. **Solids Impacts from CSOs**

a. The Proposed Plan, at page 11, notes that the hazardous substances in shallow sediments in the upper reaches are a result of CSO and stormwater discharges, as opposed to releases from MGP sites. However, there is no definition of what is meant by "shallow sediments." Specifically, does this refer to the upper six inches of the soft sediments or some other vertical interval? This missing information is critical to a proper assessment of solid impacts.

b. The Proposed Plan, at page 11, reports that high TOC of about 6% is evidence that the surface 0-2 ft. sediment is dominated by CSO loading. However, Table 2 reports that soft sediment has a substantially higher

TOC average of 11.9%. EPA needs to clarify this section to explain whether the entire soft sediment column is primarily impacted by CSOs or is also impacted by the NAPL associated with the MGP Sites.

c. The Proposed Plan, at page 11, reports that PAH, copper and lead are similar in concentration in the surface sediment and in CSO solids. Although aluminum and iron as crustal elements are mentioned in this section, EPA fails to evaluate their likely sources.

11. **Non-aqueous Phase Liquid Fate and Transport**

a. This section, at page 12, generally describes NAPL dynamics but offers little information on the spatial distribution in the Canal. This missing data is important to EPA's fate and transport analysis.

b. The Proposed Plan, at page 12, states, "NAPL in the canal sediments can be transported upward through the sediments into the water column through several transport mechanisms, including ebullition, seep migration, sheen migration and groundwater advection." EPA needs to estimate the total mass and rate of such transport, given that the selected remedy includes an oleophilic clay treatment layer that is intended to adsorb such residual NAPL after remedy implementation. (Page 21 of the Proposed Plan indicates that the oleophilic clay layer is only 1 foot thick in RTA 1 and RTA 2 and 0.5 feet in RTA 3.) EPA also needs to conduct treatability studies to determine the specific adsorptive capacity of the clay to be used for this treatment layer so that the required depth and associated total volume (and costs) for this clay layer can be estimated. In the event that such calculations show higher NAPL residual masses and/or lower clay adsorptive capacities than envisioned in the remedy, significant modifications to the multi-layered cap design would be needed prior to implementation. Further, if the volume of clay thus estimated were significantly to increase, the entire remedy may be infeasible due either to cost increases or impact on bathymetry (thicker treatment clay layer

interfering with navigational requirements; page 21 indicates a depth of ~16 feet is needed for navigation).

12. **Summary of Remedial Alternatives**

a. This portion of the Proposed Plan, at page 19, mentions sediment disposal options but fails to consider any recommendation for a Confined Aquatic Disposal (CAD) cell. This type of remedy has been used at other Superfund sites in the region, such as Newark Bay. EPA's failure to include this option makes its remedy alternative assessment non-compliant with the NCP.

b. The Proposed Plan, at page 30, states that if the cap treatment layer proves to be inadequate over the life expectancy, then "the remedy may include the replacement of portions of the treatment layer (replacing the treatment layer would also necessitate the removal and replacement of the overlying sand and armor layers)." Although 1,356 CY of "clay import" (at a cost of $271,245/year in 2012 dollars) is included in the annual O&M, this cost does not include larger scale replacement of the clay treatment layer in the event that large areas of the clay layer reach their sorptive capacity for the residual NAPL not removed during remedy implementation. As discussed earlier, EPA has not conducted treatability studies to assess the clay sorptive capacity, nor has it attempted to estimate the total residual NAPL that will need to be treated by the clay layer. Insufficient sorptive capacity of the clay treatment layer will result in recontamination and catastrophic failure of the remedy.

13. **Basis for Remedy Preference**

Alternatives 5 and 7, discussed at page 31, involve placement of an oleophilic clay layer in the Canal. Because active vertical migration of groundwater is noted for the native layer below soft sediments, EPA should have discussed the implications of an impermeable cap that could be subjected to potential uplift,

and/or and/or whether groundwater would be redirected around the cap and result in discharge along preferential pathways, such as bulkhead interfaces.

14. Source Control Components

a. The Proposed Plan, at page 32, indicates that "EPA and NYSDEC are closely coordinating and EPA is confident that these source areas can be appropriately addressed within the anticipated remedial approach and schedule for the canal remedy." Other than to so indicate, EPA offers no tangible evidence of such coordination, such as anticipated implementation schedules for non-MGP upland cleanups, CSO control, and the sediment remedy to be implemented by NYSDEC and NYCDEP. As noted in our general comments, this crucial element--the remedies to be employed to control the CSOs and to clean up the MGP sites--cannot be left to an after-the-fact decision. Such cleanups must be conducted prior to addressing Canal sediments as there is the potential for recontamination of such sediments from these sources.

b. The Proposed Plan, at page 33, indicates that "[p]lanned development in the area has the potential to increase sewage flows further, which can contribute to increases in CSO discharges." However, what are missing from this assessment are any projections from NYCDEP for increases in CSO discharges and whether such projects have been incorporated into the projected 34% reduction of CSO discharges.

c. The Proposed Plan, at page 33, indicates that a separate groundwater remedy is not required as part of this selected remedy. This presumes that NYSDEC will implement the necessary groundwater remediation prior to construction of the sediment remedy by EPA, and that no compatibility issues with that effort (e.g., bulkhead sheet piling) will arise. Selecting the alternative prior to establishing the groundwater control plan is premature and will likely lead to conflicts between the remedies chosen by EPA and NYSDEC.

I, the sender, vote that I do not want this project to proceed.
Maureen Miller to: Region2 GowanusCanalComments 04/26/2013 02:11 PM

As (one of the options above) of the community of Red Hook, I/We am/are strongly opposed to the processing of contaminated sludge dredged from the Gowanus Canal Superfund Cleanup Site at a facility at the proposed location. The cost savings are negligible, and the Red Hook Ball Fields and Pool are used in public trust. The community does not want to create more land from this contaminated sludge adjacent to one of the most heavily used recreation areas in New York City. People and organizations adversely affected include (but are not limited to!):

- Children
- Numerous public and private schools which use the fields for physical education & sports teams
- Residents of the Red Hook Houses and the surrounding neighborhood
- Soccer, softball, baseball, football, handball, basketball, track & field teams and enthusiasts
- Swimmers of all ages
- The Red Hook Food vendors and their customers
- Other visitors to our community

Further, we object to an individual (John Quadrozzi), who has incurred serious fines for environmental violations, from profiting from the project.

Mr.Christos Tsiamis
Gowanus Remedial Project Manager
Environmental Protection Agency
GowanusCanalComments.Region2@epa.gov

Dear Mr. Christos Tsiamis:

I would like to thank you and the EPA's Gowanus Superfund Team for the leadership and commitment you have demonstrated while working in the Gowanus community during the last several years.

As a long time resident and business person living and working along the banks of the Gowanus Canal I totally support the Proposed Plan to clean up the Gowanus Canal. The EPA's proposed plan reflects careful consideration and shows commitment towards our communities concerns. I support the plans removal of contaminated sediments for the entire width and length of the Canal, to the depth of the native sediments. I support elimination the Combine Sewage Overflow as a potential source of Canal recontamination and the EPA's plans to eliminating the source of pollutants coming from upland sources.

As a member of the Gowanus Superfund Community Advisory Group I can say that our government does work for the people and that the Gowanus Remedial Team is the best example of a government that cares.

Sincerely,

Linda LaViolette

Re: Gowanus Canal Superfund Site

Dear Assistant Administrator Stanislaus:

I enclose a copy of the City of New York's ("the City's") comments on the U.S. Environmental Protection Agency's ("EPA's") proposed plan for the remedy of the Gowanus Canal under the Comprehensive Environmental Response, Compensation and Liability Act ("CERCLA" or "Superfund"), which was submitted to EPA Region 2 today. Since at least 2009, and in dozens of meetings since then, the City has been working with the EPA and stakeholders to develop and assess robust technical data and science-based strategies that will lead to sustainable improvements to the Canal. In a similar spirit, the comments submitted to Region 2 today are intended to ensure that the remedy in the Canal will work.

As you know, before the CERCLA process started the City had already made commitments to the State and the public to construct multiple projects to improve water quality, with more than $150 million invested to reduce combined sewer overflow ("CSO") discharges and to make other improvements. This year, we will be reactivating the Gowanus Flushing Tunnel to bring cleaner water from Buttermilk Channel into the Canal, and we will soon be completing upgrades to the Gowanus Pumping Station and force mains to reduce CSO discharges into the Canal. In addition, we will be constructing more than 600 bioswales in the area, which will further reduce CSO discharges and beautify the community, and will be breaking ground on a project to separate the sewer system along 3rd and 4th Avenues. As with all of our projects, the City will extensively monitor water quality to determine the effectiveness of these measures. In addition, the City has begun a pilot program to measure the volume of CSO discharges with the advice of a peer review panel of outside experts, as this is a promising but untested technology.

In light of these significant actions, we welcome the elements of the EPA's Proposed Plan that refer additional CSO control measures to the Long Term Control Plan ("LTCP") process under the oversight of the New York State Department of Conservation ("DEC"), which has delegated responsibility for implementing the Clean Water Act. We believe this is an appropriate allocation of responsibility because the State has decades of experience in

Since the designation of the Canal as a Superfund site we have shared the same ultimate goal – remediating the environmental contamination in the canal as quickly, efficiently, and cost-effectively as possible. I would like to meet with you at your earliest convenience to discuss a path forward that will lead to a feasible and complete remedy of the Gowanus Canal.

Very truly yours,

Carter H. Strickland, Jr.

Enclosure

The City of New York

The City of New York's Comments on the Proposed Plan for the Gowanus Canal Superfund Site

April 26, 2013

Table of Contents

TABLE OF CONTENTS II

INTRODUCTION 1

OVERVIEW OF COMMENTS AND RESERVATION OF RIGHTS 3

TECHNICAL REVIEW OF THE PROPOSED PLAN AND THE FS ADDENDUM 4

NYC Comment 1: There is no basis under CERCLA for requiring a 58 to 74 percent reduction in CSO discharges. The CSO reduction requirement is based on several incorrect assumptions and technically indefensible PRGs, and will fail to achieve the targeted contaminant reductions in surface sediments. 6

NYC Comment 2: CSO solids cannot be (and have not been) responsible for observed sediment contamination (PCBs, PAHs, and metals) in excess of CERCLA risk-based thresholds. 11

NYC Comment 3: EPA's risk management decision-making and remedy development is based on an underdeveloped CSM and incorrect conclusions regarding the nature and extent of the contamination, as well as contaminant fate and transport. 20

NYC Comment 4: EPA has failed to recognize the need to control upland sources adequately before implementing sediment remediation; in particular, EPA has failed to document the importance of NAPL release processes originating from MGP sites. 34

NYC Comment 5: The 2007 draft NewFields report on PAH forensics that EPA relies upon does not support EPA's conclusion that additional CSO controls are required under CERCLA. 40

NYC Comment 6: EPA's selection of reference areas is ill considered. 45

NYC Comment 7: The PAH PRG calculated by EPA is flawed 47

NYC Comment 8: PRGs stated for metals, as well as the future bioavailability analysis, are not scientifically tenable. 56

NYC Comment 9: Conceptual design parameters for the proposed remedy are unrealistic. 59

NYC Comment 10: EPA incorrectly and inappropriately relied on the article by Stein et al. (2006) regarding stormwater runoff to establish its "first flush" standard for CSO discharge capture. EPA should instead use sufficiently representative site-specific measurements to inform remedial decision-making. 65

NYC Comment 11: The proposed remedy is based on inadequate information and lacks scientific support. 69

NYC Comment 12: The cost estimates included in the FS Addendum and Proposed Plan grossly underestimate the likely project costs. 86

COMMUNITY IMPACTS 102

NYC Comment 13: The Proposed Plan does not adequately address community impacts and siting considerations of locating a CSO in-line tank at Douglass & Degraw Pool/Thomas Green Playground. 102

NYC Comment 14: The Proposed Plan does not adequately address community impacts and siting considerations of locating a CSO in-line tank at 2nd Avenue and 5th Street (Block 977, Lot 3). 103

NYC Comment 15: The Proposed Plan does not adequately address concerns related to siting of the potential Red Hook Confined Disposal Facility ("CDF"). 103

NYC Comment 16: EPA Should Consider the Land Use Impacts of Any Changes to Canal Basins 104

NYC Comment 17: The Proposed Plan should not preclude the wide variety of industrial, commercial and residential activities in the Canal's vicinity. 104

NYC Comment 18: EPA Must Ensure that the Proposed Plan Does Not Exacerbate Flooding 105

NCP COMPLIANCE 107

NYC Comment 19: EPA's failure to perform a screening evaluation and/or a detailed evaluation of source control remedies violates the mandatory remedy selection requirements of the NCP. 107

NYC Comment 20: EPA did not provide a sufficiently detailed evaluation of the remedial measures necessary to control sources from the three MGPs and other upland sites as required by 40 C.F.R. § 300.430(e)(9)(ii) and (iii). 109

NYC Comment 21: EPA did not provide an adequately detailed evaluation of the presumptive remedial measure to further control CSOs. 114

NYC Comment 22: EPA did not provide an adequate estimate of the cost of constructing two CSO storage tanks, which must include annual operations and maintenance costs pursuant to CERCLA and the cost criterion set forth in the NCP. 117

NYC Comment 23: EPA did not adequately evaluate the cost-effectiveness of the remedy, particularly the presumed construction of two CSO storage tanks. 118

NYC Comment 24: EPA's selection of a range of percentage solid reductions for CSO controls violates the NCP remedy selection requirements. 119

NYC Comment 25: EPA's determination that it will develop interim CSO controls during the remedial design phase violates the remedy selection requirements of the NCP. 119

NYC Comment 26: The Proposed MGP and upland source controls and interim control remedies are so vaguely defined that they deprive the City of a meaningful opportunity to comment. 119

NYC Comment 27: Under CERCLA, EPA cannot delegate the responsibility for remedy selection to DEC. 120

NYC Comment 28: EPA and New York State failed to identify New York State's constitutional and statutory protection of parkland as an ARAR. 121

NYC Comment 29: The Proposed Plan fails to address the cost and uncertainty related to legally alienating the Douglas and Degraw Pool/Thomas Green Playground in the cost estimates for constructing an in-line tank there and in the evaluation of its feasibility. 122

NYC Comment 30: Information contained in the City's comments requires significant changes to the Proposed Plan, and therefore EPA must issue a revised Proposed Plan, seek additional public comment on the revised Proposed Plan, and submit the revised Proposed Plan to the NRRB. 122

NYC Comment 31: The City supports EPA's decision in the Proposed Plan to wait for implementation of any additional permanent CSO controls until after currently planned infrastructure upgrades for the mid and lower reaches of the Canal are completed. 124

NYC Comment 32: The City supports EPA's decision in the Proposed Plan to evaluate any additional permanent CSO controls as part of the LTCP process. 124

NYC Comment 33: The Proposed Plan does not require any additional permanent CSO controls to be implemented prior to commencement of the preferred remedial alternative for in-Canal sediments. The City supports this approach. 124

Introduction

The City of New York ("City") appreciates the opportunity to comment on EPA's Proposed Plan for the Gowanus Canal Superfund Site (December 2012) ("Proposed Plan"). The City supports a cleaner Gowanus Canal ("Canal"), and has already expended well over $150 million under its Clean Water Act ("CWA") program to achieve this goal. Notably, the City's rehabilitation of the Gowanus Flushing Tunnel, which will bring cleaner water from Buttermilk Channel into the Canal, is slated to be completed this year. In addition, the City will be constructing a large number of "green infrastructure" projects in the neighborhoods surrounding the Canal, with the goal of further improving water quality by reducing the volume of combined sewer overflows ("CSOs").

The City strongly believes that the plan for a cleaner Canal under EPA's Superfund program must be guided by sound science and adherence to the National Contingency Plan ("NCP"). The Proposed Plan must also take into account how it will affect important City resources such as parkland and shorelines. Unfortunately, the current Proposed Plan for the Canal does not yet achieve these fundamental benchmarks. The Proposed Plan is compromised by several major technical flaws, and does not comply with the NCP. The City is concerned that, unless these significant issues are addressed by EPA before it issues its Record of Decision ("ROD"), the Proposed Plan will result in an unnecessary and onerous commitment on the part of City taxpayers and ratepayers, will result in recontamination of the Canal, and will have long-term adverse impacts on the surrounding communities. The City is very concerned that the remedy, as currently proposed, is likely to fail, as the Proposed Plan does not include adequate measures to control the significant sources of contamination (and recontamination) from groundwater contaminated with Non-Aqueous Phase Liquids ("NAPL"), originating from the properties adjacent to the Canal.

The City's primary technical concern is that EPA is proposing a remedy for the Gowanus Canal on the basis of an incomplete conceptual site model ("CSM"). Development of a reliable CSM is one of the most important objectives of a Remedial Investigation/Feasibility Study ("RI/FS") process under the Comprehensive Environmental Response, Compensation, and Liability Act ("CERCLA"). A CSM identifies sources of contamination and describes fate and transport mechanisms. Here, the absence of an adequate CSM has led EPA to overstate the impacts of CSOs on the levels of hazardous substances in sediments in the Canal. Relying on incomplete data and erroneous calculations, EPA concludes that new CSO source controls are necessary for outfalls RH-034 and OH-007 in order to prevent sediment discharged from these outfalls from re-contaminating the remedy. The City disagrees with EPA's interpretation of its limited data and furthermore has collected additional data that show conclusively that existing CSO discharges do not contribute CERCLA hazardous substances at levels that pose unacceptable risks to human health and the environment. Similarly, the City disagrees with EPA's proposed reduction targets for RH-034 and OH-007 of 58 to 74 percent. EPA has based these reduction targets on unsupported assumptions that surface sediment contamination is the result of CSO solids. The City's data demonstrate that CSOs are not the source of elevated contaminants in Canal sediments. The City's data further demonstrate that CSO solids do not exceed EPA's Preliminary Remediation Goals ("PRGs") proposed for the protection of human health and the environment, even though those goals are based on flawed science. Further, EPA's presumptive remedy for two in-line tanks to achieve this reduction is not based on site specific data or modeling, but instead on a single study examining stormwater discharges, not CSO discharges, in an

area near Los Angeles that is not comparable to New York City in terms of topography, rainfall patterns, or land use. This issue requires a site-specific technical analysis, not reliance on a single study whose author questions its applicability to the Canal (*see* Appendix B).

EPA's development of a presumed remedy to meet these flawed reduction targets also fails to comply with the NCP. EPA presumes that two in-line tanks – one for each outfall – would be necessary to achieve the proposed reduction targets, and that these tanks will cost a total of $78 million. EPA's development of this alternative fails to comply with the NCP because, among other things, it fails to properly assess this alternative individually against all nine NCP criteria and comparatively against the other alternatives that survived the screening analysis contained in the Addendum to the Feasibility Study ("FS Addendum"). As just one example, EPA, without explanation, has excluded the costs of operation and maintenance from its cost estimate – a substantial omission given that such an analysis is required by the NCP, and given the high ongoing costs of operating and maintaining these facilities. Furthermore, EPA's analysis incorrectly assumes that the tank proposed for RH-034 can be constructed and located on inalienable public parkland. This assumption not only runs contrary to applicable, relevant and appropriate New York State law, but also does not adequately consider the loss of a valuable parkland resource on the surrounding community. Moreover, EPA has significantly underestimated the capital cost of the proposed facilities.

The Proposed Plan also violates the NCP because it fails to analyze against the NCP criteria the other source control measures EPA concedes are required to implement this remedy. Notably, the Proposed Plan and underlying documents do not evaluate individually or comparatively against the nine NCP criteria the source control measures associated with groundwater contaminated with NAPL from former Manufactured Gas Plants ("MGPs"), contamination on other upland sites, or contaminated groundwater. There is no evaluation of whether the controls, which EPA assumes will take place for these sources, will be sufficient for protecting the remedy from recontamination by NAPL in groundwater and other sources. Because, as EPA agrees, these measures are essential for preventing recontamination of the Canal sediments, EPA must subject these source control measures to a full evaluation under the NCP, and not merely presume that these sources may someday be controlled under an unspecified DEC or other remedial program. Instead, EPA delegates to the State decision-making for these source control remedies, which delegation itself violates the NCP. Indeed, failure to control these sources would effectively negate the effectiveness of the Superfund cleanup, and indeed negate any source control measures related to CSOs.

Despite its deficiencies, the Proposed Plan does make some progress in moving toward a more practical framework. The City is encouraged by EPA's willingness to continue to review new data collected by the City, including data that will be collected following the completion of the current CWA upgrades. The City believes these data are essential for understanding what additional controls, if any, would be needed for CSOs to prevent recontamination of the Superfund remedy. The City is also encouraged by EPA's acknowledgment that the forthcoming Long Term Control Plan ("LTCP") process should be the predominant legal framework for planning and developing CSO control measures, in accordance with, and based upon, the appropriate criteria and schedule that apply to the LTCP process. As described more fully in the comments below, to the extent that the Proposed Plan seeks to impose additional CSO controls under CERCLA in the form of a presumed in-line tank remedy, separate and apart from the LTCP process, the City contends that EPA has not complied with CERCLA's mandatory remedy selection process for that presumed remedy. Furthermore, the City continues to urge EPA to adopt the recommendations of EPA's Contaminated Sediments Technical Advisory Group

("CSTAG"), and develop and issue an Interim ROD focused on the serious NAPL contamination currently impacting the Canal.

Overview of Comments and Reservation of Rights

The City's individual comments on the Proposed Plan and FS Addendum are consecutively numbered and generally categorized by their subject matter. The City expects that EPA will specifically respond to each individual comment, any narrative portion or annexed document elaborating on the individual comment, and to all questions or issues listed under each individual comment. In addition, any attachments to this document should be viewed as fully incorporated herein, and EPA should specifically respond to the issues raised in these attachments. The categories for the comments are for ease of reference and, thus, if an individual comment raises issues relevant to another category, EPA should respond to those issues as well.

Pursuant to 40 C.F.R. § 300.825, the City reserves the right to supplement the administrative record after the public comment period for the Proposed Plan and after the ROD has been signed. First, 40 C.F.R. § 300.825(a)(1) authorizes EPA to add documents to the administrative record after the ROD has been signed if "the documents concern a portion of a response action that the decision document does not address or reserves to be decided at a later date." The Proposed Plan expressly states that several portions of the proposed response action are reserved to be decided at a later date, including but not limited to, selection of the final remedies for the MGP sites, selection of the final remedies for the upland sites, selection of interim remedies for further CSO controls, if any, whether the presumptive remedy for further CSO controls must be implemented, selection of locations for further CSO controls, if any, and selection of the precise further percent reduction of CSOs, if any, needed to meet remedial action objectives. Any documents related to these issues submitted after the ROD is issued should be included in the administrative record.

Second, 40 C.F.R. § 300.825(c) requires EPA to consider comments submitted by interested persons after the close of the comment period to the extent "the comments contain significant information not contained elsewhere in the administrative record file which could not have been submitted during the public comment period and which substantially support the need to significantly alter the response action." As EPA is aware, the City continues to collect and analyze samples relating to current CSO discharges to the Canal and sediments in the Canal. To the extent the City receives such validated analytic data after April 28, 2013, such data may constitute "significant information not contained elsewhere in the administrative record" that "could not have been submitted before the public comment period." In addition, to the extent such data demonstrates that the concentrations of PAHs in the CSOs and/or in the sediment in the Canal do not require further control remedies as specified in the Proposed Plan, the data may "substantially support the need to significantly alter the response action" as currently proposed in the Proposed Plan.

Technical Review of the Proposed Plan And the FS Addendum

Introduction to Technical Section

Before discussing the City's concerns in detail, the City would like to outline its ongoing sampling efforts. The City has conducted an extensive sampling effort in the Canal to understand the nature of contamination in the Canal and alleged contamination in the CSOs that discharge to it. These samples are also intended to address some of the limitations of EPA's data set. In particular, the City has obtained both dissolved and suspended matter samples from each of the four major CSOs to the Canal on at least four separate occasions. These samples represent time-weighted averages of most or all of the discharge during discrete rainfall events that cause overflows at each outfall. The samples have been analyzed for an extensive set of parameters including polycyclic aromatic hydrocarbons ("PAHs"), metals, polychlorinated biphenyl ("PCB") congeners, and many supporting parameters like total suspended solids ("TSS"). Additionally, the City has sampled from the CSO pipes adjacent to National Grid's Fulton MGP facility on two separate occasions. The City has also collected surface sediment samples for use in benthic toxicity tests which the City has also conducted. Finally, the City has collected surface water from within the Canal as well as from Gowanus Bay to examine water column conditions during dry periods when the CSOs are not discharging. The City will continue these sampling programs, plans to expand its surface sediment collection effort, and will continue to provide the results of these studies to EPA. The sample results received to date provide important insights into the nature of contaminant loads to the Canal and have been used extensively in preparing the comments provided below. This document provides a summary of the results and analysis from NYC's field work that are available to date for the physical characteristics and COPC concentrations in the CSOs and WWTPs. The City is continuing the efforts described in the QAPP to further expand our understanding of these discharges. Note that the City is still awaiting additional laboratory results for certain samples obtained from the affected CSO, which will be presented in subsequent data reports.

The Canal has been extensively contaminated by discharges from upland sources. PAH contamination in the sediments of the Canal can be readily tied to the three MGP sites along its banks. However, EPA has not sufficiently quantified the magnitudes of PAH transport via direct seepage of coal tar NAPL from these facilities, PAH transport via groundwater, and PAH transport via the numerous private and unpermitted pipe discharges, to evaluate their relative importance in formulating the Proposed Plan.

Lacking information on the relative importance of the sources of contaminants to the system, EPA has resorted to speculation about the character of CSO discharges relative to surface sediment observations in the Canal. The City notes that the contaminant patterns of several chemicals in the Canal (and the magnitudes of their concentrations) simply cannot be the product of any combination of CSO discharge and harbor solids alone. Significant other sources of contamination exist and these sources must be considered before a reliable chemical mass balance can be completed. Such a mass balance is critical to understanding the role of CSO solids with respect to surface sediment chemistry in the Canal.

While EPA proceeds to remedy selection based on an inadequate CSM, the City has begun an intensive investigation of contamination in the Canal and of the City's allegedly contaminated CSO discharges, and continues to study and sample. Based on the data

developed under its investigations in concert with EPA's data, the City has demonstrated that, while EPA's low PAH cleanup goal is unjustified and technically indefensible, the CSO discharges actually meet that goal. While more work remains to be done to provide a complete understanding of all of the important sources of contamination to the Canal, the City's investigations clearly show that CSO discharges do not contribute unacceptable risk related to contaminant concentrations in the surface sediments. Taken together, the City's findings indicate that there is no technical basis for requiring CSO controls under CERCLA. It is evident from the data that all of the risk related to PAHs and PCBs that warrants CERCLA intervention is attributable to contamination from other sources (*e.g.*, adjacent MGP sites), which may not as yet be fully characterized, or in some cases may not even have been identified by EPA.

Many of the problems with the Proposed Plan that the City has identified have been the subject of ongoing discussions with EPA over the course of a year or more. In the comments below, the City presents the results of its recent sampling efforts which confirm and support the City's concerns. The City believes that the information gathered by EPA does not form a sufficient basis to make reliable decisions regarding the remediation of the Canal. As a result, the City cannot support the remedy described in the Proposed Plan.

NYC Comment 1: There is no basis under CERCLA for requiring a 58 to 74 percent reduction in CSO discharges. The CSO reduction requirement is based on several incorrect assumptions and technically indefensible PRGs, and will fail to achieve the targeted contaminant reductions in surface sediments.

In its FS Addendum, EPA derived estimates of required solids reduction for CSO outfall RH-034 on the order of 58 to 74 percent to meet its PRGs in the Upper Canal for total PCBs ("TPCBs"), total PAHs ("TPAHs"), copper, and lead. In deriving these proposed solids reductions, EPA asserts that CSOs are, and will be, the only source of surface sediment contaminant concentrations in the Upper Canal that will be controlled. Therefore, EPA incorrectly assumes that the only way for surface sediment concentrations to decline is for the CSO loads to decline.

EPA did not measure PAH concentrations on the solids from CSO discharges. Instead, EPA analyzed PAHs in whole water only. EPA then approximated PAH concentrations on the solids from CSOs using the measured whole water concentrations and TSS measurements. In this methodology, EPA simplistically (and incorrectly) assumed that the entire mass of PAHs as reported by a measured whole water concentration was carried by the solid phase and that the dissolved PAH concentration was zero.

In contrast, the City performed a more detailed and comprehensive analysis by collecting and measuring the actual PAH concentrations on the solids from CSO discharges. Based on the City's more refined data set, contaminant concentrations on CSO solids do not exceed the risk-based PRGs developed by EPA. Under CERCLA, if contaminant concentrations do not pose unacceptable risk to human health and the environment, no remedial action is required (EPA,1988; EPA 1999). EPA's preferred remedy will fail to achieve the targeted reduction in surface sediment concentrations in the Canal because EPA has failed to consider the full range of significant sources of contaminants. As discussed in NYC Comment 3, there are important sources of PAHs and PCBs that cannot be ascribed to CSOs. These sources are responsible for the elevated concentrations of PAHs and PCBs in the surface sediments of the upper and middle sections of the Canal. Additionally, the surface sediments that serve as EPA's basis to estimate the percent reductions in CSO contributions are actually more affected by other major contaminant sources that EPA has failed to quantify, or in the case of PCBs and lead, even to recognize. The failure on EPA's part to identify and quantify these additional sources properly is symptomatic of the poor CSM.(*see* NYC Comment 3).

As shown below, no reduction of CSO discharges will be sufficient to reduce surface sediment contaminant levels to the PRG since the CSOs are equivalent to or below the PRG for PAHs and PCBs. In addition, the PRGs that EPA developed for copper and lead are without merit. In preparing this analysis, the City included the reference area data for New York Harbor obtained as part of the Newtown Creek investigation. For the Newtown Creek RI/FS, an evaluation to determine appropriate background locations was conducted by collecting surface sediments at several candidate reference sites for contaminant and physical characterization. These sites were classified into four categories: industrial with CSO input, industrial with no or minimal CSO input, non-industrial with CSO input and non-industrial with no or minimal CSO input. The City determined Background Threshold Values ("BTVs") (*see* NYC Comment 6) for TPAHs, TPCBs, copper and lead (*see* Table 6-1) in each of the four categories of background areas using EPA's ProUCL Version 4.1 software (Singh et al., 2010), and then compared CSO data to the BTVs.

1) CSO solids do not exceed EPA's PRG for Total PAHs.

In the case of PAHs, recent data collected by the City on the solids fraction discharged by CSOs indicate an average TPAH concentration of 30 mg/kg, with a lower confidence limit ("LCL") of 25 mg/kg and an upper confidence limit ("UCL") of 36 mg/kg. This range is significantly lower than the TPAH concentration of 56 mg/kg and confidence bounds of 41 to 78 mg/kg used by EPA (based only on the EPA RI data) to represent CSO discharge solids in determining its proposed solids percent reduction. When the TPAH concentrations in the surface sediments of the Upper Canal are calculated using EPA RI data, EPA's Emergency Response Team ("ERT") data, and the City's data, the average TPAH concentration is 261 mg/kg (LCL 130 mg/kg, and UCL 423 mg/kg), which is significantly greater than the average TPAH concentration on CSO solids (30 mg/kg). This is more clearly demonstrated in NYC Comment 2, where the distributions in CSO solids are directly compared with solids in the Canal and the reference areas. It is clear from these observations that CSO solids are significantly less contaminated than Canal surface sediments.

When the TPAH concentrations on CSO solids are evaluated on an organic carbon-normalized basis, it is clear that these concentrations are well below EPA's PRG. The TPAH PRG set forth by EPA is 20 mg/kg for sediment exhibiting 6 percent total organic carbon ("TOC"). While the City believes that this PRG is not technically defensible, the TPAH concentrations on solids discharged by the CSOs readily meet this threshold. The average observed concentration of TOC on CSO solids is 40 percent, based on recent data collected by the City. The average TPAH concentration on the CSO solids on an equivalent 6 percent organic carbon basis is 5 mg/kg, less than one-quarter of the EPA's PRG of 20 mg/kg in sediments at 6 percent TOC. It is clear therefore that the Proposed Plan is incorrectly focused on CSOs as a substantive source of PAHs when, in fact, CSO solids are already in compliance with EPA's incorrectly calculated PRG (*see* NYC Comment 7 below for the City's major concerns with the development of the PAH PRG).

Based on this information, the City reconstructed the figure from the FS Addendum (*see* FS Addendum 7, Attachment) that EPA used to estimate the required CSO percentage reduction at RH-034 based on TPAHs. This is shown as Figure 1-1. The figure shows EPA's original calculation based on its estimate of TPAH concentrations in the surface sediments of the Upper Canal. Also shown on the diagram are two important additions. First, the TPAH concentration for CSO solids is shown, on a 6 percent TOC basis, *i.e.*, 5 mg/kg TPAH / 6 percent TOC. As noted above, this value is well below the PRG, indicating that CSO solids already satisfy the PRG value. Also shown on the diagram is the City's estimate of surface sediment concentrations in the Upper Canal. This value is more than five times greater than the estimate presented in the Proposed Plan. For the City's estimate, all data available for the Upper Canal were used, including the RI data obtained by EPA, data obtained by EPA's ERT and data obtained by the City during its own investigation of the Canal. The original EPA value was based only on the EPA's RI data, which appears biased substantially lower than the other two data sets.

This revised version of the EPA Percent Reduction Diagram yields two important conclusions. First, that CSOs are already in compliance with the proposed PAH PRG and no further CSO reduction is justified for TPAH control; and second, that surface concentrations and the source(s) of PAH contamination to the Upper Canal are indicative of a much more substantial load of PAHs to the Canal than that delivered by the CSOs, and will require a substantially greater reduction of PAH contamination (92 percent) to meet the EPA PRG than originally estimated in the Proposed Plan. The results for PCBs yield a similar conclusion and are discussed below.

As a last basis of comparison, TPAH BTVs (*see* NYC Comment 6) derived for the four categories of reference sites for Newtown Creek range from 16 to 48 mg/kg on a 6 percent TOC basis. These BTVs are higher than TPAH concentrations observed for CSO solids that discharge to the Canal on a TOC basis. From these data, it is clear that there is no combination of CSO solids and harbor solids that will yield the surface sediment concentrations observed in the Upper Canal. Taken together, these observations indicate that EPA's proposed CSO solids reduction requirement for TPAHs is not warranted.

2) CSO solids do not exceed EPA's PRG for TPCBs.

For TPCBs, recent data collected by the City on the solids fraction discharged by CSOs indicate an average TPCB concentration of 0.42 mg/kg (LCL of 0.31 mg/kg and UCL of 0.54 mg/kg). This TPCB concentration range is slightly lower than the average TPCB concentration of 0.54 mg/kg and confidence bounds of 0.42 to 0.67 mg/kg estimated by EPA to represent CSOs in determining the proposed solids percent reduction. As shown in NYC Comment 2 below, the TPCB concentrations in the surface sediments of the Upper Canal have an average of 0.96 mg/kg (LCL of 0.50 mg/kg, and UCL of 1.57 mg/kg), which is substantially greater than the TPCB concentrations on CSO solids. In the Middle Canal reach, surface sediment PCB concentrations are even greater, averaging around 5.5 mg/kg. Similar to TPAHs, the CSO discharges cannot explain the elevated PCB concentrations in surface sediments in the Canal, which means that there is a much more substantial load of PCBs to the Canal than that delivered by the CSOs. This is even more apparent when viewed on an organic carbon-normalized basis, as shown in NYC Comment 2 below, where it is observed that normalized CSO solids concentrations are more than an order of magnitude less than those for reference area samples. Therefore, it is clear that the CSO solids serve to dilute PCB concentrations delivered by other sources to the Canal. EPA's basis for reducing CSOs to meet its PRG for PCBs is flawed, and again reflects the underdeveloped CSM.

For TPCBs, the City repeated the reconstruction of the figure from the FS Addendum that EPA used to estimate the required CSO discharge percentage reduction at RH-034 (*see* FS Addendum 7, Attachment). This is shown as Figure 1-2. The figure shows EPA's original calculation based on its estimate of TPCB concentrations in the surface sediments of the Upper Canal. The City's figure has two important additions. First, the TPCB concentration for CSO solids is shown at 0.42 mg/kg. As noted above, this value is just below the PRG, indicating that again the CSO solids already satisfy the PRG value. The diagram also shows the City's estimate of surface sediment TPCB concentrations in the Upper Canal. In this instance, the City's value is twice EPA's value, at 0.96 mg/kg. This value was derived in a similar manner as for the TPAH samples, but limited to those samples with reported PCB congener results. Again, the original EPA value was based only on data collected in EPA's RI investigation; these data appear biased substantially lower than concentrations found in the other data sets.

This revised version of the EPA Percent Reduction Diagram yields the same two important conclusions as the TPAH results. First, that CSOs are already in compliance with the proposed PCB PRG and no further CSO reduction is justified for TPCBs control; and second, that surface concentrations and the source(s) of PCB contamination to the Upper Canal are substantially greater and will require a substantially greater reduction to meet the EPA PRG than originally estimated in the Proposed Plan.

The average CSO discharge for TPCBs of 0.42 mg/kg is slightly less than EPA's TPCB PRG of 0.48 mg/kg. However, as EPA's stated purpose was to define a regional signal as the TPCB PRG, it is important to consider the range of BTVs for TPCBs calculated for Newtown Creek candidate reference areas. The BTVs for TPCBs are in the range of 0.16

to 2.7 mg/kg (*see* Table 6.1), further indicating that the CSOs are not different from background. Therefore, EPA's proposed CSO solids reduction requirement is not warranted on the basis of TPCBs.

3) EPA's PRGs for metals are entirely without merit.

EPA's PRGs for copper and lead are scientifically untenable since they are based solely on background levels and not risk. By the agency's own analysis and conclusions, these metals do not pose risk and therefore no remediation is required (*see* NYC Comment 8 below). The Proposed Plan did not, and could not, present evidence of unacceptable risks to humans or the environment due to the presence of these metals in the sediments of the Canal. Although the Proposed Plan states that these metals are the most likely to cause adverse effects, there is no evidence presented to support this. Additionally, the Proposed Plan notes that metals are not bioavailable and therefore do not present toxicity in the sediments:

> "…Based on measured concentrations in sediment, copper and lead were identified as the metals most likely associated with adverse effects. However, geochemical analyses (*i.e.*, SEM/AVS) indicate that these metals currently are not bioavailable and should not cause toxicity." *See* Proposed Plan, p. 17.

Despite the observation that these metals are not bioavailable, the Proposed Plan then goes on to state:

> "However, metals may become bioavailable in the future if geochemical conditions in the canal change and do not favor the formation of insoluble sulfides. Therefore, PRGs for copper and lead are necessary in the event that metals become bioavailable and toxic in the future…." *See* Proposed Plan, p. 17.

As clearly stated here, these PRGs are based on the speculation that geochemical conditions may change in the future. As such, EPA was unable to develop toxicity-based PRGs pertaining to existing site-specific conditions. Developing a realistic understanding of future geochemical conditions posing toxicity would require estimating both the timing and the degree of geochemical changes as well as the changes in bioavailability and toxicity. No attempt has been made for purposes of the Proposed Plan to develop a model capable of predicting these changes. Instead, it is simply asserted that such a change is possible and then PRGs are proposed based on the maximum Gowanus Bay and Upper New York Bay concentrations for the reference stations that showed no overall toxicity, without any demonstration that current or future levels of these metals are toxic. In fact, as part of the Newtown Creek candidate reference area background site assessment, sediment concentrations of copper and lead in the Canal are shown to be comparable to background levels in similar settings throughout New York Harbor.

Additionally, the supposition that geochemical conditions of Canal sediments would become sufficiently oxidized so as to change the bioavailability and toxicity of these metals is without merit. Extensive studies of sediment conditions throughout New York Harbor show that sediments are reducing essentially everywhere in the harbor, with ratios of acid volatile sulfide ("AVS") to simultaneously extracted metals ("SEM") much greater than 1.0. A detailed discussion of harbor AVS and SEM levels is provided in NYC Comment 8

below. It is clear from the above discussion, and from the lack of scientific support for the toxicity of copper and lead in Canal sediments, that the PRGs for these metals do not satisfy EPA's requirements under CERCLA.

NYC Comment 1 Inquiries

The City requests that EPA respond to the following questions:

- Is EPA confident that it has sufficient information to quantitatively decide the degree of CSO reduction for the Canal when it lacks quantitative information on any of the major sources of PAHs or PCBs to the Canal? If so, please provide the technical basis for this, since the reduction analysis in the Proposed Plan for PAHs and PCBs is not valid. *See* NYC Comment 1(1) & (2) above.

- Given that concentrations of TPAHs and TPCBs on CSO solids are below EPA's PRGs for these compounds even before accounting for possible dilution by harbor suspended solids, what would be the technical basis for requiring reductions of CSO discharges?

- Why did EPA develop PRGs for copper and lead given that the agency's data indicate they do not pose risk and similar reducing conditions are characteristic of conditions essentially everywhere in the harbor?

- Why did EPA ignore its own guidance regarding AVS/SEM metal toxicity, guidance that has been extensively tested and has existed for more than 15 years? What is the technical basis that supports superseding this guidance?

- How were projections of future attainment of PRGs evaluated if quantitative models were not used? In order to support its concern about metal toxicity in the future, will EPA develop the necessary geochemical and toxicological models to estimate future conditions?

- Under what conditions does EPA estimate that Canal sediments could become sufficiently oxidized so as to consume the excess AVS and potentially free the sulfide-bound metals? How long would these conditions take to develop? Is there any evidence that these conditions exist in similar areas in the New York/New Jersey Harbor area?

NYC Comment 2: CSO solids cannot be (and have not been) responsible for observed sediment contamination (PCBs, PAHs, and metals) in excess of CERCLA risk-based thresholds.

The data set obtained in the RI process was insufficient to support the necessary analyses for remedial decision-making. A simplistic interpretation of the limited RI data set has led to a failure to recognize the major ongoing sources of the primary contaminants, *i.e.*, PAH and PCB compounds, to the sediments and water column of the Canal. Instead, the Proposed Plan has focused inordinately on the City's CSO discharges which cannot be responsible for the levels of contamination that now exist in the Canal. Failure to properly recognize and address these major sources of contamination will lead to the failure of the remedy, irrespective of any improvements or changes that may be implemented in connection with the City's CSOs since these CSOs are not responsible for this contamination.

For example, the Proposed Plan incorrectly states:

> "CSO and stormwater solids have a significantly greater influence on the quality of sediments in the 0-2-foot depth interval in the upper reach of the canal than incoming sediments from Upper New York Bay." *See* Proposed Plan, p. 11.

Several lines of evidence are cited to support this contention; each one of them is incorrect and indicates an unduly simplistic analysis of a very complex system. Based on these flawed analyses, the Proposed Plan selects a remedy that is almost certain to fail. The City notes the following flaws in the CSM developed for the site:

Throughout the Proposed Plan and FS Addendum, EPA asserts that contaminant concentrations are principally the result of CSO discharges in the upper portion of the Canal. For example:

> "CSO solids contributions dominate the canal's upper reach." *See* FS Addendum, p. 3.
>
> "However, physical and chemical characteristics of the newly deposited sediments indicate that CSO solids have a greater influence on the quality of shallow sediments in the upper reach of the canal than incoming suspended sediments from Upper New York Bay." *See* FS Addendum, p. 4.
>
> "The physical and chemical characteristics of the shallow sediments in the upper reach of the canal more closely resemble CSO solids than reference sediments from Gowanus Bay and Upper New York Bay." *See* FS Addendum, p. 5.
>
> "Multiple lines of evidence indicate that CSOs to the Gowanus Canal adversely affect canal sediment quality and are contributing to unacceptable risks that must be addressed under CERCLA." *See* FS Addendum, p. 11.

EPA based these assertions on the limited data set obtained by EPA for the RI in 2009. It did not include data obtained by EPA's ERT in 2007. Since the Proposed Plan was issued, the City has also received the results of samples (*See* Appendix A1.1 – Summary

of CSO Sampling Program) collected over the past several months from the upper reach, as well as the rest of the Canal. Inclusion of these two additional data sets yields a very different set of conditions than those initially presented by EPA. As a result, many of the assertions made by EPA in the Proposed Plan have been shown to be incorrect and should be replaced with those described in the comments to follow. Findings of the City's evaluation of all the available data relative to EPA's assertions are presented below.

1) Total organic carbon content

The Proposed Plan states:

> "CSO solids have high TOC content. The TOC content of the surface sediment is about 6 percent. Based upon the results of the RI and EPA (1998), the TOC levels in Upper New York Bay sediments are, on average, about 3 percent. Accordingly, if suspended sediments in tidal inflow or Flushing Tunnel flows from Upper New York Bay were contributing the majority of the deposited mass, the TOC of the surface sediment would be closer to 3 percent." *See* Proposed Plan, p. 11.

EPA incorrectly asserts that the 6 percent TOC content found in Upper Canal sediment is sufficiently high relative to the 3 percent TOC levels observed in the Upper New York Bay and Gowanus Bay reference areas, indicating that CSOs are contributing the majority of the sediments in the 0 to 2-foot depth interval in the upper reach of the Canal.

EPA's evaluation of the TOC data in the FS Addendum was based on:

- An assumption that the TOC concentration in the upper reach of the Canal is equivalent to the discharge from the CSO (therefore, EPA provided only a single data plot to describe CSO discharge impacts on the Canal, *i.e.*, Figure 6 in the FS Addendum, which considers only the upper reach of the Canal and the Gowanus Bay reference area); and

- A qualitative solids balance inferred from the surface sediments and the reference area sediments, without consideration of the TOC measured on the solids delivered by the CSOs.

From this limited examination, EPA reasoned that since 3 percent TOC on solids from the reference area is less than 6 percent on surface sediment in the Canal, CSO discharges must dominate the solids contribution. EPA contends that if solids from the reference area were dominating the TOC input, Canal surface sediment would necessarily contain just 3 percent TOC.

Each of these assumptions is incorrect and reflects an underdeveloped CSM, as discussed in greater detail below in NYC Comment 3. As part of the contaminant fate and transport analysis performed by the City using recent TOC data collected from the four largest CSOs, the City observes the following:

- The average concentration of organic carbon on CSO solids is 40 percent as compared to 3 percent on harbor solids (reference area, Figure 2-1) and 6 percent on sediments of the Upper Canal (Upper Reach, Figure 2-1). Thus, Upper Canal surface sediments are significantly closer in TOC content to harbor solids delivered by the Flushing Tunnel or by tidal exchange than they are to CSO solids, indicating they are primarily comprised of harbor solids.

- If an empirical mixing model with two TOC contributors consisting of the CSO solids and the sediments from the reference area is used to explain TOC content on the surface sediments of the Upper Canal (setting aside potential contributions from MGP facilities and other industrial discharges and assuming TOC to be conservative), the TOC from the CSO would have to be diluted about 9-fold with harbor solids to create surface sediments at 6 percent TOC.

- When TOC is used as a normalizer for organic compounds, the results indicate that the CSOs cannot explain the organic chemical contamination in the Canal (*see* comments on PAHs and PCBs below).

Based on these observations, if CSO solids were the dominant contributor of solids, then the TOC concentration on the surface sediments in the Upper Canal would necessarily be much greater than 6 percent.

2) Total PAH concentrations on CSO solids and Canal sediments

The Proposed Plan makes a related assertion:

> "The concentrations of PAHs, copper and lead in the surface sediment and in the CSO solids are similar. The concentrations of these chemicals are much lower in the reference sediments in the harbor; therefore, deposition of suspended sediments in harbor water (or from the Flushing Tunnel which brings in harbor water) could not be the predominant source of high concentration of PAHs, copper and lead in the canal surface sediments." *See* Proposed Plan, p. 11.

EPA incorrectly asserts that the concentrations of TPAH and selected individual PAH compounds in the CSOs are similar to concentrations in Upper Canal sediments. EPA then incorrectly concludes that the CSOs therefore have a significantly greater influence in the Upper Canal surface and soft sediments with respect to PAHs.

In the FS Addendum, EPA's evaluation of PAHs was undermined by:

- Incorrectly assuming that whole water concentrations of all PAHs compounds are entirely particle-bound. This resulted in significant overestimates of the TPAH concentrations on CSO solids and the variability of these concentrations.

- Using these incorrectly derived estimates of TPAHs, acenaphthene, benzo(b)fluoranthene, benzo(k)fluoranthene, and phenanthrene in CSO solids to assert that the CSO solids concentrations were similar to concentrations in the upper reach of the Canal, and significantly higher than reference sediments based on its very limited and apparently not representative data set (*See* Figures 8 and 9 in the FS Addendum Report).

- Conducting an analysis which excluded the data on PAHs, collected by EPA's own ERT, which includes 4 transects collected at the head of the Canal. The average concentration in the surface sediment from these transects is approximately 950 mg/kg, which is significantly higher than solids concentrations of PAHs in CSO discharges. EPA's RI sediment data in the same location as these ERT transects showed an average of 62 mg/kg.

- Basing proposed reductions for CSO RH-034 on the average TPAH value of 56 mg/kg (standard deviation of 40 mg/kg) observed in the surface sediments in the upper reach of the Canal. This value based on EPA RI data is not representative of the area since it is an order of magnitude less than the TPAH concentrations observed in the sediments collected by EPA's ERT team (average TPAH of 950 mg/kg) and also the data collected by the City during the toxicity sampling program (average TPAH of 217 mg/kg). Furthermore, the CSO solids measurements conducted by the City show that the solids from RH-034 have an average value of 30 mg/kg (standard deviation of 12 mg/kg) and hence cannot be responsible for the contamination observed in the Upper Canal since they are much too low in concentration. This is a clear indication that the basis used by EPA to derive conclusions regarding the impact of CSOs on the upper reach of the Canal is inaccurate.

- Failing to consider other sources of PAHs to the system, especially in the middle reach of the Canal, which likely impact sediments in the upper reach of the Canal.

- Incorrectly concluding that these relationships indicate that solids from CSO discharges have a greater influence on surface sediment quality in the upper reach of the Canal than suspended sediment contributions from Gowanus Bay and Upper New York Bay, when it is clear from EPA data alone that other sources of PAHs have far greater influence on Upper Canal sediments than either the CSOs or the reference area.

- Incorrectly concluding that the CSO solids which are asserted to dominate the Upper Canal exceeded the TPAH PRG.

The City collected samples of the CSO discharges and measured the particulate phase of PAHs directly, as shown in Figure 2-2a, the concentrations of TPAHs on CSO solids are substantially lower than those observed in surface sediments. This can be seen spatially in the upper diagram of Figure 2-2a. The City has analyzed the CSO data along with the available Canal sediment data and observes the following:

- Concentrations of TPAHs in CSO solids, which average 30 mg/kg, are substantially lower than surface sediment concentrations in the Upper Canal (average of 270 mg/kg) and Middle Canal (average of 920 mg/kg). Similar patterns exist for acenaphthene, benzo(b)fluoranthene, benzo(k)fluoranthene, and phenanthrene on CSO solids, relative to concentrations in the Canal (*see* Figures 2-3 to 2-6).

- In shallow sediments (0 to 2 feet), concentrations of TPAH, which average 490 mg/kg, are higher than TPAH in CSO solids (*see* Figure 2-2b). Similar patterns exist for acenaphthene, benzo(b)fluoranthene, benzo(k)fluoranthene, and phenanthrene in shallow sediments in the Upper Canal relative to CSO solids (*see* Figures 2-3b to 2-6b). This observation is contrary to the assertion in the FS Addendum that CSOs are responsible for TPAH contamination in shallow sediments.

- The substantially higher PAHs concentrations in the Canal, relative to CSO solids and the reference area, indicate that there are additional sources of PAHs to the Canal's sediments. In particular, Middle Canal sediments are substantially higher in PAH concentrations than Upper Canal sediments which, in turn, are higher than the CSO solids, especially on a TOC-normalized basis. These results demonstrate that surface sediment concentrations are not due to CSO solids

contamination, but rather that there is one or more major sources of these compounds in the Canal, particularly in the Middle Canal area. When normalized using organic carbon content, concentrations of PAHs for the CSO solids are more than an order of magnitude lower than similarly normalized concentrations in the Canal. Therefore, the concentrations of PAHs in the Canal cannot be achieved with a combination of only CSO solids and reference area sediments.

- The concentrations on the sediments of the Canal are at least an order of magnitude greater than those on the CSO solids on an organic carbon basis. The much higher concentrations of the Canal sediments are also apparent in the statistical presentations displayed in Figure 2-2b.

- As discussed in NYC Comment 1, concentrations measured directly on the CSO solids when expressed on a 6 percent TOC basis do not exceed EPA's TPAH PRG. Note that NYC Comment 7 demonstrates that the PAH PRG itself is not technically defensible because of miscalculation in the application of EPA's guidance, as well as uncertainties in the toxicity tests used to derive the PRGs.

Given these observations, the proposed reduction in CSO discharges under CERCLA is not warranted because the CSO solids do not exceed the risk-based TPAH PRG. The City believes that EPA's failure to understand and quantify the effects of other major sources of PAHs to the Canal sediment (including the three MGP sites, unpermitted pipes and groundwater) would significantly affect the performance of the preferred remedy.

3) PCB Concentrations in CSO solids and Canal sediments

The FS Addendum did not compare PCB data from CSOs to PCB concentrations found in the Canal and reference area, perhaps because PCBs were reported as non-detected in the EPA CSO data. Human exposure to PCBs via fish consumption is a significant potential risk associated with the Canal. Yet in the Proposed Plan, EPA dismisses the PCB levels found in the Canal as simply related to sediment contamination, and therefore did not investigate PCB sources. Because PCBs in the CSO solids are at levels comparable to background, EPA's hypothesis that CSOs have a significantly greater influence in the Upper Canal than the reference area and other inputs is not scientifically supported.

The City has evaluated the PCB data collected by EPA for the RI. In the process of analyzing RI PCB data for the Proposed Plan, a number of errors were made, not the least of which was to compare Aroclor results in the Canal sediments with congener results in the reference area. While this comparison is often done on PCB-contaminated sites, it is problematic in this instance due to significant differences between the results reported by EPA for each method. For example, EPA's RI data for matched pairs of Aroclor and congener analysis show the congener results to be as much as 5 times greater than the detected concentration reported by Aroclor analysis. One non-detect Aroclor result at a detection limit of 0.05 mg/kg per Aroclor had a reported congener result at 8.13 mg/kg. In the FS Addendum entitled Preliminary Estimate of Solids Reductions Needed to Achieve Remediation Goals (p. 3), EPA recognized that "PCB congener analysis is more sensitive and accurate than PCB Aroclor analysis." Yet the Proposed Plan states the highest observed PCB concentration in the Canal (3.4 mg/kg) on the basis

of its Aroclor results. The congener total for this sample was 15.1 mg/kg based on the City's review of the data, while EPA's stated congener sum total was 4.03[1] mg/kg.

The City reviewed all of the EPA congener data for comparison with its own congener analyses. In compiling these results, the City maintained consistency in the congener sums across all reported programs. With newly collected congener data on CSO solids discharge, the City has analyzed the fate and transport of TPCBs and offers the following observations:

- TPCB concentrations found in CSO solids average about 0.42 mg/kg. This average concentration is lower than the average concentration in Upper Canal surface sediments of 0.67 mg/kg and lower than EPA's PRG of 0.48 mg/kg. Notably, PCB levels on CSO solids are comparable to or lower than the reference area sediments, so the PCB source to Upper Canal sediments is unrelated to CSO discharge.

- In shallow sediments (0 to 2 feet), concentrations of TPCB, which average 3 mg/kg, are higher than TPCB in CSO solids (*see* Figure 2-7b). This observation is contrary to the assertion in the FS Addendum that CSOs are responsible for TPAH contamination in shallow sediments.

- As can be seen in Figure 2-7, PCB concentrations in the Canal are not comparable to those in EPA's reference area and are, in fact, nearly 10 times greater than the highest reference area sample. Notably, EPA dismissed its highest reference area value for TPCBs (1.7 mg/kg) so that the agency's estimate of background PCB levels based on congener analysis is 0.48 mg/kg.

- There is an as-yet unidentified PCB source in the Middle Canal area resulting in surface sediment TPCB concentrations with an average above 3 mg/kg. The presence of such high PCB levels in areas of the Canal that are depositional is clear evidence for the existence of at least one significant on-going PCB source to the surface sediments of the Canal at approximately 0.8 miles from Gowanus Bay (turning basin across from the Citizens MGP Site).

- Given the high concentrations found in the Lower Canal as well, it is likely that the source in the Middle Canal area is substantial enough to affect concentrations in both the Upper and Lower Canal as indicated in Figure 2-7.

- TOC-normalized TPCB concentrations indicate that the CSO TPCB concentration relative to TOC is more than an order of magnitude lower than in the reference area and in the surface sediments of the entire Canal.

- A principal components analysis of the PCB congener pattern shows that the highest concentrations of PCBs in sediments are associated with a unique PCB pattern, one that is unlike that of the reference area or the CSOs. This pattern is significantly heavier than that associated with CSO or reference area solids and is likely attributable to a source contributing an Aroclor 1260-like mixture. This is

[1] The City has not been able to establish why EPA's sums of PCB congeners as listed in their reports do not consistently equate to the total of the detected congeners reported in their database. However, the sums of the congeners in the EPA database closely match the congener sums of samples collected at reoccupied locations and analyzed by the City.

illustrated in Figure 2-8, which is based on the distribution of solids from CSOs, reference area solids and the surface sediments of the Canal (0-6 in).

Based on these observations, the TPCB data indicate that the existence of one or more important sources of TPCB is not accounted for in the FS Addendum. The hypothesis of a dominant CSO contribution is not supported by TPCB data. The Proposed Plan fails to estimate the needed reduction in an on-going source, whose impact on surface sediments of the Canal is clearly orders of magnitude greater than any CSO contribution. While the remedy described in the Proposed Plan may temporarily reduce surface concentrations of PCBs by dredging and capping, this on-going source of PCBs will serve to re-contaminate the sediment surface of the Canal, presumably to current levels. Failure to address this source of PCBs would be yet another basis for failure of the proposed remedy.

4) Metals concentrations in CSO solids and surface sediments in the Canal

While concentrations of copper and lead are higher in CSO solids than in the reference area, the inference by EPA that solids from CSO dominate the Canal cannot be supported given the significant dilution of harbor solids required to explain copper concentrations in the Canal, as well as the likely presence of additional sources of metals to the system, including active junkyards on the Canal that have been cited for numerous violations.

In the FS Addendum, EPA compared concentrations of copper and lead to reference area and Upper Canal concentrations. EPA also used aluminum and iron as normalizers and determined that concentrations in the Upper Canal are highly enriched with copper and lead as a basis to support its assertions that CSO discharges dominate the 0 to 2-foot (surface) sediments in the Canal. EPA did not consider the impact of other metals sources, and the effect of harbor solids in diluting the inputs of metals discharged from the CSOs. EPA also did not note that the level of enrichment of lead and copper in CSO solids are distinctly different from the enrichment levels in surface sediments of the Upper Canal.

As part of the contaminant fate and transport analysis performed by the City (*see* Appendix A3 – Chemical Concentrations and Mass Balance in Gowanus Upper Canal) using recent data collected from the four largest CSOs, the City makes the following observations regarding metals:

- CSO solids contribute substantially higher copper concentrations (average of 300 mg/kg) to the Upper Canal, but these solids must be significantly diluted by cleaner sediments to achieve an average concentration of 190 mg/kg in the Upper Canal surface sediments and 220 mg/kg in the Upper Canal shallow sediments (*see* Figure 2-9). This dilution is more pronounced when copper is normalized to aluminum (*see* Figure 2-9a).

- In the case of lead (*see* Figure 2-10), concentrations in the CSO solids (average of 295 mg/kg) compare to the surface sediment concentration in the Upper Canal (average of 350 mg/kg). This is inconsistent with the observation of copper where significant mixing of cleaner solids is required to explain Upper Canal concentrations. This indicates that another source of lead is likely contributing to the system. In shallow sediments in the Upper Canal, concentration of lead averages 450 mg/kg, slightly higher than average CSO solids concentrations.

- The likelihood of another source of lead was further explored by looking at the multivariate relationship amongst lead, copper and aluminum for the CSO solids, the reference area sediments and sediments in the Canal. Figure 2-11 presents

a ternary plot used to display three metal components. Note that in this plot each metal component is presented on a scale from 0 to 100 percent, and each sediment or solid displays their fraction of the total. This graphical procedure represents a simple, direct way to grasp the broad characteristics of the entire data set and to see the intrinsic relationships amongst the CSO solids, the Canal sediments and the reference area sediments. From the figure, it is clear that the reference area sediments, which are finer in texture, have a dominant aluminum component. The CSO solids on the other hand are dominated by copper, although they do contribute lead to some extent. However, the sediments in the Canal plot out above the CSO and reference area sediments towards the lead apex of the diagram. This characteristic strongly indicates that another source of lead is likely contributing to the lead burden in the surface sediments in the Canal.

- Three other metals of importance to understanding contaminant fate and transport are cadmium, chromium and cobalt. For all three metals, the CSO solids concentrations are, on average, 50 percent lower than concentrations in the Upper Canal. Furthermore, surface sediment concentrations in the Middle Canal and sometimes the Lower Canal are substantially higher than the CSO solids. Again if the Proposed Plan were correct and the CSO solids were the dominant input to the Canal, concentrations of these metals in the Canal would not be substantially higher than CSOs.

Based on these observations, the City concludes there are other sources of these metals to the Canal that likely also include lead and need to be considered in the selection and design of any remedy.

5) Fecal coliform concentration in surface sediments

In the Proposed Plan EPA states that, "Sewage indicators, such as fecal coliform and steroids are found consistently in surface sediment in the Canal. The highest concentrations are located in the upper portion of the Canal where most CSOs are located." To support this statement, EPA is citing the study conducted by GEI, consultant for National Grid, in 2011 where 10 sediment samples were collected in the immediate vicinity of CSO outfalls (20 – 40 feet from the outfall location). This represents a biased sample set that by its design cannot be spatially representative of the surface sediments of the Canal and thus cannot be used to draw a conclusion regarding the distribution of CSO-related impacts in the Canal.

The City also notes that fecal coliform by its nature is not persistent and therefore is not a conservative tracer for CSO solids. Moreover, modern analytical methods permit the detection of fecal coliform at extremely low levels. Thus, the mere presence of fecal coliform in the surface sediments does not at all indicate that these sediments are derived exclusively from CSOs or even from the CSOs that contribute to the Canal. The City has examined several other compounds that may serve as tracers for CSO-related solids. The results show an extensive series of contaminants whose presence cannot be explained by CSO solids. The analysis also indicates the presence of harbor solids throughout the length of the Canal.

NYC Comment 2 Inquiries

Based on the observations noted in the comments above, the City requests that EPA respond to the following:

- Given this quantitative assessment, does EPA continue to believe that CSO solids (discharged with an average TOC content of 40 percent) can be the dominant component of Canal solids with only 6 percent TOC? If so, on what basis?

- Given the importance EPA placed on TOC in inferring sediment transport in the Canal, please explain why TOC normalization was not used to understand the fate and transport of organic compounds like PAHs and PCBs?

- Please explain why the EPA ERT transect data were not used in the assessment of PAHs.

- Please explain what EPA plans to do before selecting the remedy to quantify the other major sources of PAHs to the Canal and evaluate their impacts under future conditions with respect to the proposed remedy.

- Given the TPCB data presented and the analyses showing that CSO solids have a lower TPCB concentration per unit mass of TOC or per unit mass of solids than any other source (together with other data-based observations presented), does EPA continue to believe the hypothesis that solids from the CSO have a substantially greater influence in the 0 to 2-foot interval of surface sediment in the Upper Canal than any other source? If so, on what basis?

- Does EPA plan to continue to explore metals contamination and sources given the likely presence of other metals sources even though the metals themselves are not bioavailable?

- This evidence clearly shows the processes that produce sediment contamination at the head of the Canal to be far more complicated than that suggested by hypotheses presented in the Proposed Plan. How will EPA address this complex system before selecting the remedy so as to be sure that the selected remedy is successful?

- The distributions of PAHs, PCBs, lead, and other metals indicate the presence of ongoing sources to the Canal that have not been identified or quantified by EPA. How can EPA be confident that its selected remedy will be protective in the absence of quantitative estimates of these loads and an understanding of the processes responsible for them?

- While the Proposed Plan presents only anecdotal evidence of loading from CSO compared to regional sources (*i.e.*, TOC content, copper and lead content, steroids, proximity to CSOs), how will these anecdotal sources be used to establish a quantitative evaluation in the 5-year post remedial evaluations?

NYC Comment 3: EPA's risk management decision-making and remedy development is based on an underdeveloped CSM and incorrect conclusions regarding the nature and extent of the contamination, as well as contaminant fate and transport.

1) The Proposed Plan demonstrates a lack of understanding of contaminant fate and transport and lack of a proper contaminant mass balance to support the CSM.

Development of a CSM is one of the most important objectives and requirements of a CERCLA RI/FS process (*see* EPA, 2005). The CSM should identify sources of contamination and describe fate and transport mechanisms, exposure pathways, and receptors. Contaminant sources and transport pathways are poorly characterized in the RI, FS, and Proposed Plan, and the City believes that the lack of a properly developed CSM that informs risk management decision-making will have serious consequences for the selection and future performance of EPA's proposed remedy.

The inadequate understanding of the magnitude and extent of PAH and PCB sources as presented in the Proposed Plan has led to the assumption that risk drivers can be controlled simply by dredging the Canal, controlling CSO discharges, and relying on upland investigations still underway to identify and control any remaining sources. This approach clearly conflicts with much of EPA guidance, as noted by both of EPA's advisory panels (CSTAG and NRRB). Before a complete understanding of contaminant fate and transport for the Canal can be developed, all sources of contamination must be quantified. The Canal has been extensively contaminated by discharges from upland sources. PAH contamination in Canal sediments can be readily tied to the three MGP sites along its banks. However, the magnitudes of PAH transport via direct seepage of coal tar NAPLs from these facilities, via groundwater, and via the numerous private and unpermitted pipe discharges have not been sufficiently quantified to identify their relative importance.

Lacking information on the relative importance of the sources of contaminants to the system, EPA resorted to speculation about the character of CSO discharges relative to surface sediment observations in the Canal. The City notes that the contaminant patterns of several chemicals in the Canal (and the magnitudes of their concentrations) cannot be the product of any combination of CSO discharge and harbor solids alone. Significant other sources of contamination exist and these sources must be considered before a reliable chemical mass balance can be completed. Such a mass balance is critical to understanding the role of CSO solids with respect to surface sediment chemistry in the Canal.

To improve on the understanding of the CSM that is absent from the Proposed Plan, the City conducted several analyses to assess the solids and contaminant fate and transport in the Upper Canal (*see* Appendix A3 – Chemical Concentrations and Mass Balance in Gowanus Upper Canal). The following is a summary of the City's findings.

- Because hydrophobic organic contaminants and heavy metals typically adsorb strongly to sediment particles, sediment transport is important in understanding the fate and transport of their associated contaminants. Knowledge of sediment transport can be obtained directly through observations of suspended solids, sediment bed stability and numerical modeling, or it can be inferred from a chemical mass balance of contaminant concentrations and patterns. One independent data set that can be used to understand sediment stability is

bathymetry. EPA used two single-beam bathymetric surveys conducted in 2003 and 2010 to map changes in bottom elevation. As discussed in part 6 of this comment, there are many uncertainties in the small-scale bathymetric changes estimated from these surveys. However, hypothetical calculations can be done to determine how the volume of solids from CSO discharges compare to the volume of sediment accumulated on the Canal bottom based on mean bathymetric changes over a large area. Integrating the bathymetric differences in the Upper Canal from 2003 to 2010, the average annual net deposition is estimated as 1,100 cubic yards. Assuming a typical particle density of 0.8 kilograms per cubic/cm^3, the net annual volume change is equivalent to 675 metric tons of solids per year. The total CSO discharge to the Upper Canal, from RH-034 and other CSOs, is estimated as 125 million gallons on an average annual basis. The average TSS concentration in CSO discharge is 200 mg/L (see Appendix A1-Summary of the City's CSO Sampling Program). Given this discharge volume and TSS concentration, the average CSO solids load to the Upper Canal is estimated at 95 metric tons of solids per year. This value is not directly comparable to the net accumulation, however. Before the solids load from CSOs can be compared to the estimated solids accumulation based on bathymetric change, the solids capture efficiency within the Upper Canal is needed. Based on the City's sampling program, the grain size composition of CSO discharge contained an average of 64 percent fines. The majority of these fines will likely not be captured within the Upper Canal due to their tendency to remain suspended in the water column. This is consistent with the observation of a higher sand fraction closer to the head of the Canal. Regardless of what the true capture efficiency is, the simple volume-based comparison given above (675 *vs.* 95 metric tons/yr) indicates that the solids discharge from CSOs are a small component of the estimated net accumulation of solids in the Upper Canal. By inference then, the harbor solids are likely the most significant contributor to the net accumulation of solids in the Upper Canal. While the CSOs and harbor solids are the two principal solids contributor to the canal, there are multiple sources of contaminants (including, groundwater and NAPL flowing upwards through the sediment bed) and these sources of contaminant contribute differently to risk depending on their fluxes and concentrations. Therefore, a mere ratio of solids contribution to the canal is not an appropriate means to determine contribution of risk to the Canal.

- The significant contribution of harbor solids to the Upper Canal is confirmed by TOC observations, although the City cautions that TOC is not a conservative parameter. TOC concentrations on CSO solids average about 40 percent, and a significant addition of harbor solids, which have TOC concentration of about 3 percent, is required to reduce the overall TOC found in the Upper Canal surface sediments to 6 percent.

- To further investigate the relationship between sediment transport and contaminant transport, the City developed an empirical chemical mass balance model for estimating the concentrations of chemicals in surface sediments in the Upper Canal for various hypothetical scenarios of solids contribution from CSOs, based on the enrichment of the chemicals relative to aluminum. In the model, two important solids inputs to the Canal were considered, including, the CSOs and the harbor solids. The chemical mass balance further assumed that the chemical burden on the solids from these two inputs were the only chemical contribution to the Upper Canal. Each solids contributor was represented by the average ratio of the chemical to aluminum. Aluminum was selected as a normalizer to account for differences in particle composition in the system. Using this model, the City tested EPA's assertion of a significant CSO influence by simulating surface

sediment concentrations for copper, lead, chromium, cadmium, zinc, acenaphthene, benzo(b)fluoranthene, benzo(k)fluoranthene, phenanthrene, pyrene, TPAH and TPCB for five hypothetical scenarios of CSO solids contributions: 10 percent, 30 percent, 50 percent, 70 percent and 90 percent. Figures 3-1 through 3-5 present the results of percentage deviation between the model results and observed concentrations for the Upper Canal. Note that a positive deviation indicates that the inputs to the Canal are greater than required to yield the observed surface sediment concentration, while a negative deviation indicates that significant additional sources are needed to yield the observed surface sediment concentration. For each scenario, it was impossible to simulate a mixture of the two inputs that agreed well with the observed data. For much of the time, negative deviations were obtained, indicating that sources to the system are poorly characterized. For a hypothetical scenario of 90 percent CSO contribution, for example, statistical tests of comparison confirm that the surface concentrations simulated are significantly different from the observed surface sediment concentrations, disproving the hypothesis of a dominant CSO influence. The results from this analysis highlight the uncertainties in the solids and chemical balance for the Upper Canal. Regardless of which solids contribution is assumed, the balance of several of the chemicals cannot be explained. This indicates that the process that produces the surface sediment concentration in the Upper Canal is far more complicated than is understood at the moment.

These observations, while disproving EPA's assertions on CSO contribution, provide an indication of how uncertainties in source characterization undermine the CSM and mass balance for the system. The fact that the chemical mass balance model for the Upper Canal cannot simultaneously explain all the chemicals evaluated suggests that large uncertainties exist with regard to the sources of contamination to the Canal. More importantly, it indicates that there is no correlation between sediment inputs and contaminant burden in the Canal. Therefore, any attempt to allocate responsibility for contamination in the Canal based on solids contribution will be incorrect. Failure to develop a complete and technically rigorous CSM for the Canal is inconsistent with EPA's requirements for conducting an RI/FS under CERCLA. Development of the CSM cannot be deferred to the remedial design phase. Given the unknown nature of these large contaminant loads, it is unclear that the current assemblage of upland investigation and remediation efforts will be able to control them all. The City believes that it is highly likely that, given the failure to correctly characterize these on-going sources, the proposed remedy will fail to protect human health and the environment irrespective of any actions taken to address the CSOs, and will waste the resources used in controlling CSO discharges in an attempt to address risks they are not causing.

2) **The Proposed Plan demonstrates a lack of understanding of the inextricable link between surface water and groundwater discharge, which is a critical aspect of the CSM.**

The Proposed Plan states that PAH contamination in the surface sediment in the Upper Canal is from CSO discharge and that only deeper sediments are contaminated by NAPL. The following is an excerpt:

"While the NAPL accounts for the majority of the PAH mass and the highest PAH concentrations in canal sediments, PAH concentrations in the top 6 inches of

> sediments (the bioactive zone) in the upper reach of the canal are primarily associated with contaminants introduced through CSO discharges. Existing sediments in the canal are covered by newer contaminated CSO sediments and, to a much lesser extent, solids transported from the harbor through tidal transport or through the Flushing Tunnel when it is in operation. Thus, surface sediments are newer and deeper sediments are older. The deeper sediments become more heavily contaminated over time by NAPL or NAPL-derived contaminants migrating upward from below." *See* Proposed Plan, p. 9.

This conjecture is speculative and demonstrably incorrect. EPA has not measured or estimated the rate at which NAPL or groundwater-borne contaminants are migrating upward through the sediment column, nor has EPA estimated the mass loading that occurs from the groundwater and NAPL to either the water column or the newly arrived sediment. The City strongly disagrees that CSO solids are the main constituent of surface sediment in the Canal. In fact, evaluation of sediment and surface water data collected by the City shows that discharge of contaminated groundwater and NAPL through the sediments and along the sides of the Canal continues to be the primary source of contamination to surface sediment and the water column (as well as to the deeper sediments below them). By comparison, CSO contributions are minor and inconsequential for the remediation of the Canal sediments. In the analysis below, the City presents evidence for a groundwater link based on surface water observation, and results from sediment coring data.

a. Evidence of the groundwater link from surface water observations

The City has collected dry-weather water column samples (*see* Appendix A 2.1 – Summary of the Surface Water Sampling Program) from the Canal and Gowanus Bay, which were analyzed for PAHs and other parameters during a dry weather period (three-day antecedent dry weather). Figure 3-6 shows where the surface water samples were collected. The TPAH concentrations found in the Canal under these conditions are orders of magnitude greater than those found in Gowanus Bay; the average concentration in samples collected from the Canal is about 3000 ng/L, while the average concentration found in the bay samples is just 118 ng/L.

Figures 3-7 through 3-12 show the concentrations of TPAHs (sum of 17 PAHs) and six other PAH compounds found in the Canal during the dry weather sampling. The surface water samples were collected at least three days (more than six tide cycles) after any potential CSO discharge event. Where the water was 7 feet deep or greater, samples were collected from both 2 feet above the bottom and 2 feet below the surface. Where the water was shallower, only a sample from 2 feet above the bottom was collected. Two samples per station were collected in the reference area (Gowanus Bay) from 5 locations, and from the Canal at Locations 1 through 9 and 12; only one sample per station was collected at Canal Locations 10, 11, and 13 through 15, and in the turning basins.

Note that an average CSO discharge is about 5 million gallons, while at low tide the Canal contains about 200 million gallons of water and 250 million gallons at high tide. The volume of water in the Canal is therefore about 40 to 50 times larger than a CSO discharge event, providing substantial dilution for the CSO discharge. The surface water samples collected after more than 6 tidal cycles following a CSO discharge represent Canal water impacted by contaminants from discharges other than the CSOs. Any contribution by CSOs would have been diluted more than 100 fold by tidal exchange. Rather, the high level of TPAH in the water column of the Canal can only be attributed to

the migration of contaminants with groundwater and NAPL through the Canal sediments, and discharges along the sides of the Canal.

On a simple mass basis, the standing inventory of TPAH as given by the TPAH concentrations in surface water (shown on Figure 3-7) equates to a TPAH mass of about 1.4 kg resident in the water column. Assuming these conditions are typical water column concentrations and that tidal exchange removes water at average Canal concentrations, approximately 20 to 25 percent of this inventory would be lost with each tidal cycle or 0.56 to 0.7 kg/day. This represents a substantial flux of TPAH out of the Canal, which must be regularly replaced to maintain the water column inventory. In comparison, the mass of PAHs delivered from CSOs to the Canal during a CSO discharge event is on average about 0.09 kg, or equivalent to roughly 0.017 kg/day. The elevated concentration of TPAH and corresponding resident mass in the Canal water column when the CSOs are not discharging shows there is continuing influx of PAHs to the Canal on the scale of 0.56 to 0.7 kg/day. It is clear this cannot be the result of CSO discharge and is, in fact, the result of uncontrolled discharges of groundwater and NAPL from the MGP sites. The greatest TPAH concentrations in the surface water of the Canal are found in areas adjacent to MGP plants where NAPL is known to be present in the sediment column. The predominant sources of the PAHs are groundwater discharging to the Canal and, potentially, NAPL bubbling up to the surface (ebullition).

The existence of a substantial PAH flux to the Canal unrelated to CSOs is evident even if the tidal exchange flux is ignored. The most prominent PAH compound found in the Canal surface water during the dry-weather sampling was acenaphthene (*see* Figure 3-8), which had an average whole water concentration of 1,374 ng/L (with a highest concentration of 4,420 ng/L), compared to the average acenaphthene whole water concentration in CSO discharges of 119 ng/L (and a highest concentration of 487 ng/L). Because the CSO acenaphthene concentration is a full order of magnitude less than the concentration resident in the Canal, and the approximate dilution of CSO discharge to the Canal is 40-fold (5MG to 200MG), the CSOs cannot be delivering the mass of acenaphthene found in the Canal. Again, the concentrations of acenaphthene found in the surface water of the Canal during the dry weather sampling event are most likely due to NAPL and groundwater discharge.

The observed patterns of PAHs in the surface water and CSOs further substantiates the City's assertion that the Proposed Plan has failed to identify the major source of PAHs to the entire Canal, MGP-site related groundwater and NAPL. The average mass fractions of the PAHs compounds in surface water were further compared to mass fraction of PAH in groundwater and mass fraction of PAHs in CSO discharge (Figure 3-13). These mass fraction scatter diagrams are intended to demonstrate how the composition of two inputs, groundwater and CSOs, compare to the composition observed of the surface water. In addition, the similarities or differences in PAH composition were quantitatively assessed by the coefficient of divergence ("CD"),[2] which has been used in PAH studies to compare PAH concentrations and composition at different sites (Wongphatarakul *et al.*, 1998; Zhang *et al.*, 2000) as well as in biological studies. If the PAH compositions of the compared media shown in the scatter plot are similar, the points fall close to the 1:1 line and the CD approaches zero. If PAH compositions in the media are very different, the points fall far from the line and the CD approaches one. As seen in Figure 3-13, there is close agreement between the composition in groundwater and that observed in surface

[2] $CD = \sqrt{\frac{1}{p}\sum_{i=1}^{p}\left(\frac{Xisw-Xij}{Xisw+Xij}\right)^2}$, where Xisw and Xij are the average mass fraction of the ith chemical component mass fraction for surface water, and either groundwater or CSO, respectively, and p is the number of chemical components.

water. This good agreement is validated by the low CD of 0.2. Conversely, CSO PAH composition is significantly different from groundwater or surface water composition, with a high CD of 0.71 between CSO and surface water observations. These results indicate that groundwater and surface water PAH patterns are closely linked, identifying groundwater as the major contributor of PAH contamination to the Canal.

b. Evidence of the groundwater link from sediment coring observations

In addition to incorrectly asserting that CSOs are the primary source of PAHs to the Upper Canal, the Proposed Plan also asserts that the NAPL is being buried by new sediment deposition. Due to the different fate and transport properties, mechanisms and processes for individual PAH compounds, some move more quickly through the environment than others or are degraded more quickly than others. A comparison of compounds that make up the low-molecular-weight ("LMW") PAH suite of compounds in the sediment column was conducted to test the Proposed Plan's assertion that NAPL is being isolated by sediment burial. Examination of the sediments of the Canal also shows that groundwater and NAPL are responsible for contamination of the entire sediment column, including the surficial sediment. Evaluation of the proportions of individual compounds making up LMW and high molecular weight ("HMW") PAHs in surface sediment compared to the patterns found at depth in the sediment column show that the relative percentages of the compounds remain consistent when naphthalene is excluded. Naphthalene is more biodegradable, more soluble, and more volatile than the other PAHs and is therefore not conservative in the sediments.[3] (*See* Appendix A2.2 – Evidence for degradation of Naphthalene in the Gowanus Canal System.) The consistency of the patterns of LMW and HMW suites of PAHs exclusive of naphthalene throughout the sediment column shows that sediment in the interval from 0 to 1 foot in depth is contaminated by the same source as at sediment at 8 feet in depth. These patterns are similar to those detected in NAPL samples, but are not similar to those found on CSO solids. Figures 3-14 to 3-16 show the relative proportions of 6 LMW compounds in the lower, middle and upper reaches of the Canal, respectively, while Figures 3-17 to 3-19 present the relative proportions of 10 HMW compounds for the same reaches. This assessment showed that the pattern of the main PAH constituents (except for naphthalene) remains the same from deeper sediments to the surface sediments. Note that even with the introduction of 'urban' PAHs in shallower sediments, there is little change in which PAHs dominate the patterns. The changes that are seen are attributable to variations of transport and fate processes for different compounds, which is the expected condition. This analysis further confirms that CSOs are not responsible for PAH burden in the surface sediments over background.

Given the close link of surface and deep sediment PAH patterns, an analysis was conducted to assess if the distribution of PAHs in the shallow sediments is statistically linked to the presence of NAPL in the deeper sediment. A comparison of shallow sediment (GEI samples from the 0-3 foot interval) TPAH concentration means and standard deviations to the visible presence of NAPL in the sediment column (at any depth,

[3] In environmental fate and transport, a conservative substance is one that is subject to a limited number of physical transport processes whose effects can be easily accounted for. For the purposes here, it is a substance that is strongly associated with suspended matter and sediments. The mass of a conservative substance introduced to a system must be conserved. In this context, the substance is not subject to significant losses due to biodegradation, gas exchange or other processes that significantly change the mass of the substance in the system. Thus, if a substance is introduced to the Canal via particles that originate from the harbor, the concentration of the substance per unit mass of particles remains the same unless additional particles with a different concentration of the substance or the substance itself are added directly to the Canal. Based on the degree of change or lack of change, the presence of additional sources of a substance can be inferred. If a substance is not conservative, then it may be subject to loss from the system, as is the case for naphthalene in this instance.

usually in a deeper core interval) was conducted with two categories: *i.e.*, 'Contains NAPL' in the sediment core, and 'No NAPL' present in the sediment core (the mere presence of a sheen on a sample was not considered to indicate the presence of NAPL). Figure 3-20 shows the results from this analysis. A Tukey-Kramer statistical test shows that the 'Contains NAPL' and 'No NAPL' groups represent statistically different data sets (shown by the circles on the right, representing two standard errors around each mean, having little to no overlap), with the mean of the TPAH concentrations in 'Contains NAPL' samples being significantly higher than the mean of 'No NAPL' sample TPAH concentrations. This shows that the highest concentrations of TPAH in the shallow sediments are correlated with (and most likely controlled by) the presence of NAPL in the subsurface. These processes do not appear to have been contemplated or investigated, and are not considered in the characterization of contaminant sources, FS, or Proposed Plan.

c. Summary of the groundwater link

Based on consideration of both surface water and sediment data, the rate of upward contaminant migration in the sediment and arrival at the water column is greater than the rate of sedimentation. This conclusion is contrary to the conjecture that sediment is being deposited faster than it can be contaminated by groundwater and NAPL. It also shows a significant problem with the remedial strategy described in the Proposed Plan: there is no data-based estimate of the contribution by groundwater and NAPL of contaminants to the proposed cap. Given the results of these analyses, there will be a significant amount of PAHs arriving, which has grave ramifications for the longevity of the cap. As these findings demonstrate, the Proposed Plan incorrectly attributes far more influence of the CSO discharges on surface sediment PAH concentrations than warranted, and ignores the far more critical influence of NAPL releases from adjacent upland MGP sites.

3) The Proposed Plan demonstrates inadequate characterization of CSO solids, undermining the CSM.

To characterize PAH concentrations on the solids from CSO discharges, EPA conducted an analysis of Semi Volatile Organic Compounds ("SVOCs") on a whole water basis, providing no separate information on dissolved and suspended matter concentrations. EPA then approximated PAH concentrations on the solids from CSOs using the measured whole water concentrations and TSS measurements. In this methodology, EPA simplistically (and incorrectly) assumed that the entire mass of PAHs as reported by a measured whole water concentration was carried by the solid phase and that the dissolved PAH concentration was zero. The City, in its comments to CSTAG and NRRB and in meetings with EPA, has previously raised concerns regarding this approach since the whole water data measured by EPA was dominated by LMW PAHs, which are likely to be in the dissolved phase.

The City's previously articulated concern is supported by the data that the City subsequently collected to characterize the suspended solids in CSO discharges. For this investigation, the City analyzed samples from the CSO discharges in separate dissolved and particulate phases. Figure 3-21 provides a comparison of the Total PAH concentration on CSO solids measured by the City with those estimated by EPA for the four largest CSOs. Data collected by the City show that the average TPAH concentration on CSO solids is approximately 30 mg/kg, as compared to the 60 mg/kg derived by EPA using the whole water data and assuming that all of the contaminant mass is on the solids. In addition, EPA's TPAH results show a much higher degree of variability as compared to the measured values. The coefficient of variation ("CV") for the values derived by EPA is

0.9, as compared to the CV of 0.3 on the City's measurements, representing a three-fold decrease in variance by the City's method relative to the EPA's.

This simplistic assumption used by EPA also leads to an incorrect estimate of the LMW fraction of PAHs on the CSO solids. This arises in large part because the compound naphthalene, which comprises an important fraction of the PAH mass, is nearly all in the dissolved phase, but EPA has ascribed the entire PAH mass to the solids fraction of the samples. A comparison among the different PAHs (Figure 3-22) indicates that LMW PAHs account for just 23 percent of the total PAH mass on the solids, based on direct measurements, as opposed to 40 percent calculated based on EPA's assumptions. This clearly demonstrates that the methodology used by EPA to derive TPAH concentrations on solids from CSOs produces estimates that are biased high, two times the actual measured TPAH concentrations. This is a significant flaw in EPA's characterization of CSO solids since the biased estimates are used to make inferences regarding their relationship with the surface sediments in the upper reaches of the Canal.

4) The CSM described in the Proposed Plan reflects an insufficient understanding of groundwater and NAPL transport.

As EPA points out in the Proposed Plan, NAPL exists at all depths penetrated in samples beneath the Canal, and at almost all points along the Canal's length. Given the history of the Canal and of groundwater use in Brooklyn, where saltwater intrusion was induced just as NAPL was being released to the Canal, this is to be expected. The important factor that is missed in the Proposed Plan is that this source of groundwater contamination, which is by far the greatest source, exists *beneath* the Canal, not just adjacent to it. This reservoir of contamination is not being characterized in DEC's upland investigations, and it has not been fully characterized in EPA's investigation. Not only is the NAPL itself potentially mobile, groundwater must pass through the NAPL to discharge into the Canal. EPA has not investigated the occurrence of the NAPL and the movement of groundwater in relation to it. Because of the potential for contaminated groundwater to shorten the effective lifespan of the cap included in the proposed remedy, and the virtually unlimited supply of PAHs represented by the NAPL at depth, this data gap represents a significant shortcoming in the CSM.

5) The Proposed Plan substitutes speculation in the CSM for knowledge about sediment transport processes, mechanisms and their impacts, such as propeller wash, sediment stability, erosion and deposition.

EPA did not conduct the rigorous analysis of sediment transport, deposition and erosion needed for a remedy of this scope and cost and instead provides only speculation on sediment transport mechanisms. Sediment accumulation in sheltered water bodies such as the Canal is controlled largely by tidal currents and bottom topography relative to sea level.[4] An understanding of sediment transport is essential to understanding current solids and associated contaminant loads as well as to understanding future conditions that may result from the Proposed Plan. Yet the Proposed Plan does not provide any rigorous analysis and instead speculates as to the possible causes of sediment accumulation and erosion patterns. For example, the FS Addendum p.5 states:

> "Bathymetric differences between 2003 and 2010 showed an overall lack of sediment accumulation in the middle reach of the canal, even though two major

[4] Perillo, G.M.E. (editor), 1995. Geomorphology and Sedimentology of Estuaries. Elsevier, May 16, 1995.

CSO outfalls are located in this reach (Figure 3). The lack of accumulation in this reach is most likely due to frequent resuspension of solids by vessel propeller wash and redistribution by tidal and possibly flushing tunnel currents."

The suggestion that sediment accumulation over such a large area could be controlled by propeller wash is speculative at best, and highly unlikely given the low level of boat traffic in the Middle Canal area. There is not sufficient evidence to demonstrate that boat traffic, as the Proposed Plan suggests, is truly a significant mechanism for control of sediment deposition and erosion. Net sediment accumulation is a process governed much more by the steady day-to-day tidal processes and solids loads. Thus, the analysis presented in the Proposed Plan is not supported by the data and is incorrect. This concern is symptomatic of the failure to develop a robust CSM.

6) In the Proposed Plan, EPA fails to recognize the uncertainty in its bathymetric analysis and then proposes unlikely mechanisms in its CSM to explain its observations.

The Proposed Plan makes several broad statements concerning the nature of sediment deposition in the Canal and provides very detailed maps of changes in bathymetry over time. In doing so, the Proposed Plan fails to disclose or perhaps recognize that nearly all of the surface elevations being compared are interpolated estimates of bathymetry and not direct measurements. Given the limited coverage, particularly in 2003, the real changes in elevation can only be identified by integrating over much greater distances than those shown in the plan figures. Failure to recognize this uncertainty yields many apparent changes in surface elevation that have little basis in reality.

For example, as shown in Figure 3-23, the survey lines of the 2003 and 2010 EPA bathymetric surveys do not align closely, and the 2003 survey is particularly sparse in coverage. While alignment is not a requirement for a comparison of surveys, use of unaligned surveys does introduce significant uncertainty into the analysis. Offset between survey lines means that there are few, if any, direct comparisons of elevation changes between surveyed locations. Even at this scale, the dots on the figure representing the surveyed points are much larger than the actual area surveyed at each location. Thus as noted above, the vast majority of the bottom is un-surveyed. As a result, nearly all comparisons are between interpolated locations of one survey with interpolated locations of the other. Individual survey uncertainty for a measured point is typically $\pm$3 to 6 inches vertically. However, the uncertainty of interpolated locations is much greater. Thus, given the sparse coverage of the 2003 survey and the lack of close alignment between survey lines, the estimates of changes between surveys on the small scale presented by EPA are highly uncertain and probably not meaningful below 1 to 2 feet of change and possibly more.

Yet the Proposed Plan interprets this information as if it had no uncertainty or error of any concern. For example, Area A (shown on the inset portion of Figure 3-23) indicates erosion with a bathymetric change between 1 and 2 ft. Yet there is only 2010 bathymetry data in this area. The locations where 2003 and 2010 data intersect at the boundaries of the area show no erosion between the survey events. This assertion of an erosional area is an artifact of EPA's interpolation process that fails to account for the uncertainties in the interpolation. Clearly, there is insufficient bathymetric data in this area to indicate such a level of erosion. Failure to recognize this uncertainty has led EPA to provide a highly speculative and unlikely sediment transport process.

In this area, the Proposed Plan identifies Area A and the area north of it as erosional (*see* the blue-green shaded areas in the inset of Figure 3-23) and then speculates on a possible mechanism as well as a subsequent re-deposition process:

> "Currents generated by the Flushing Tunnel apparently eroded sediments near the outlet of the tunnel, but the sediments settled out where the current velocities decreased farther down the canal between Sackett and 3rd Streets." See Proposed Plan, p. 10.

From sediment transport science, the suggestion that sediments eroded from areas near the Flushing Tunnel exit would quickly resettle downstream is without merit. If the water velocity were sufficient to scour the sediments 100 feet or more from the Tunnel outlet, it would also have been sufficient to distribute those sediments throughout the Canal and possibly out to the harbor. Fine grained sediments, which constitute the vast majority of surface sediments in the Canal, require a high shear stress (and high flow velocity) to be re-suspended due to their inter-particle attraction. Once suspended, however, they settle extremely slowly due to their small diameter. Thus, re-suspended fine-grained sediments in the Upper Canal would be widely dispersed throughout the Canal and probably the harbor as well, and not re-deposited between Sackett and 3rd Streets, as stated in the Proposed Plan.

The spatial distribution of these erosional areas in the Upper Canal are also inconsistent with any likely Flushing Tunnel flow regime (*see* Figure 3-23). The Flushing Tunnel delivers water and fine grained suspended matter from Upper New York Bay to the Canal. Given their small size, these particles are unlikely to settle near the entrance to the Canal. Even if this indication of deposition at the Tunnel discharge point is correct, if the flow from the Tunnel were sufficient to cause scour anywhere in the Canal, it would likely occur in the general vicinity of the discharge point, which is also the shallowest area of the Canal, and not hundreds of feet downstream of the discharge point where the turbulence from the Tunnel discharge would already have begun to dissipate.

This discussion highlights both the high degree of uncertainty in EPA's bathymetric analysis and its interpretation. It also points out a much more important deficiency, the lack of a quantitative basis to understand ongoing sediment transport and to predict future conditions in response to any remedial activity. The City believes that the actual nature of sediment transport in the Canal must be better understood if a successful remedy is to be selected and implemented.

7) The radionuclide profiles obtained by National Grid do not indicate a high degree of disturbances from CSOs in the Canal, and EPA's interpretation in the CSM is incorrect.

The Proposed Plan implies that the radionuclide results obtained by National Grid document frequent disturbances from CSOs when the core profiles are typical of profiles obtained elsewhere in the harbor. The profiles also document that the lead-210 result are particularly suspect, an observation EPA fails to note. As noted in FS Addendum:

> "Radioisotope profiles of Cesium-137 and Lead-210 in sediment cores collected by National Grid in the upper reach of the canal (Figure 5) do not resemble the ideal

profiles that would form in an undisturbed depositional environment such as continuous settlement of suspended sediments from the water column. The evidence of disruption in the core profiles is consistent with episodic deposition of solids from CSOs and/or other disturbances." *See* FS Addendum, p. 5.

This assertion is without merit. The City has evaluated the six radionuclide cores collected by National Grid, all from the Upper Canal, and notes that the cesium-137 results in particular are consistent with profiles obtained throughout the harbor, showing a maximum at depth and gradually decreasing in concentration to the surface. In particular, the uppermost portions of the cesium-137 profiles obtained by National Grid are fairly smooth with little layer to layer variation. More importantly, EPA provides no data on levels of cesium-137 present in CSO solids as a basis to know how such discharges would affect these profiles. Thus, the Proposed Plan provides unconfirmed speculation on the existence of disturbances due to CSOs. The lead-210 profiles are not interpretable as they show no decline over time. However, they are very typical of lead-210 profiles seen throughout the New York-New Jersey Harbor.

EPA asserts that the highly variable lead-210 profiles present in the Canal sediments can be used to calculate deposition rates for the Canal and that any inconsistencies in the profile are due to CSO discharges and episodic disturbances. This is not the case. Any episodic disturbances would also be captured in the cesium-137 profile. As an example, National Grid core 1 is shown in Figure 3-24. The "disturbances" in the lead-210 profile are not reflected in the cesium-137 curve, which is relatively smooth over the last 2 meters of deposition, unlike the lead-210. This core is located closest to RH-034 and would have been the most subject to CSO "disturbances," had they occurred. In Figure 3-25 showing National Grid core 12, the cesium-137 profile again shows the expected pattern but the lead-210 significantly increases with depth, making the lead-210 data inconsistent and difficult to interpret. These poor lead-210 profiles are not indicative of CSO events, but rather are characteristic of sediment accumulation levels in the harbor. Figure 3-26 depicts profiles of a core obtained from Newark Bay (Tierra Solutions, 2011[5]) as an example of a core from a slower deposition rate site with interpretable cesium-137 but an inconsistent lead-210 profile. Figure 3-27 presents the profile for National Grid core 88, also from the Upper Canal. This core has some consistency in its lead-210 values in that they generally decline with depth. Nonetheless, the cesium-137 and lead-210 -derived time horizons within the core are inconsistent, again indicative of issues regarding the lead-210 results.

This disagreement between the lead-210 and cesium-137 profiles suggests that it is likely that the lead-210 data in the Canal and elsewhere in the harbor do not appear to satisfy the basic requirements for interpretation, which may be indicative of poor data quality or changes in the nature of depositing solids. These concerns would result in varying levels of lead-210 that were not due to disturbances, but rather due to changes in the Canal drainage watershed and its solids load over time. The above conclusion is supported by work done in other parts of the New York/New Jersey Harbor area, such as Newark Bay. Radionuclide results obtained from cores in Newark Bay indicate that it is challenging to obtain a reliable lead-210 profile that can be used to date the sediment column. On this basis, EPA should not use the radionuclide profiles of lead-210 to infer sediment disturbances. The available cesium-137 profiles suggest typical sediment accumulation processes and do not show evidence of CSO-related disturbances.

[5] Tierra Solutions, Inc., 2011. Final Phase I and Phase II Sediment Deposition Report, Newark Bay Study Area Remedial Investigation. Revision 1. October 2011.

8) EPA's assessment of risks to human health from ingesting fish and crab fails to take into account regional sources of such contamination, which the remedy for the Canal is incapable of addressing.

The Proposed Plan states:

> "The HRRA indicated completed human risk exposure pathways with unacceptable risk levels for surface water/sediment contact and fish consumption." *See* Proposed Plan, p. 14.

However, the stated carcinogenic risks to human health from ingesting fish and crabs identified in the Proposed Plan are not driven solely by chemical quality of sediments in the Canal, but are also driven by regional sources of PCBs in fish and crabs. The regional component of the risks will not change regardless of the remedial action selected for the Canal.

NYC Comment 3 Inquiries

Given the observations above, the City requests that EPA respond to the following:

- Considering the information developed by the City as agreed upon with EPA, will EPA adjust its schedule for issuing a ROD until more data become available and a better understanding of contaminant sources fate and transport can be developed to address the uncertainties identified? If not, why not?

- Since the City's data clearly demonstrate that the Proposed Plan's focus on CSOs as the primary source of surface sediment contamination is incorrect, can EPA be confident that the other, much larger (but of indeterminate magnitude) sources of PAHs and PCBs will be sufficiently controlled by the currently proposed remedy?

- Given the City's observations that surface sediment contamination is correlated with the presence of underlying NAPL, and that surface sediment concentrations are orders of magnitude higher than concentrations on CSO solids, does EPA agree that surface concentration of PAHs are not due to CSO discharges? If not, why not?

- The City's evidence indicates that essentially all surface PAH concentrations over the PRG are due to external sources to the Canal unrelated to CSOs. Does EPA agree? If not, why not?

- Does EPA intend to investigate these PAH sources further before implementing a ROD? If not, why not?

- Given the analysis presented above, does EPA still believe that solids delivered by CSOs will yield surface sediment concentrations above the PRGs? If so, what is the basis for this belief?

- An additional source of contamination to the Canal that is not addressed in the RI/FS or Proposed Plan is direct loading of solids from eroding fill material along the shoreline through broken bulkheads. Fill is known to contain ash and other

wastes that are high in PAHs, metals and other contaminants. What is the current rate of solids and contaminant loading from eroding fill on shorelines in the Canal? How will the effect of fill from eroding shorelines be evaluated during the 5 year post-remedial evaluations?

- If EPA chooses to move forward in spite of the identified uncertainties, when does EPA estimate that conditions in the Canal will meet the PRGs, since the CSOs will clearly not be limiting?

- What are the relative sources of sediment deposition attributable to the sources identified in the Proposed Plan and from regional transport?

- If sediment transport modeling was performed to inform decision making, why was this information not reported in the RI/FS or the Proposed Plan?

- How will the new bathymetric profile to be established after the completion of the dredging component of the remedial action alter the sediment transport dynamics of the Canal and influence recontamination?

- Given the stated importance of solids sedimentation after the remedial action as a potential means to re-contaminate the Canal bottom, why didn't EPA perform sediment transport modeling and why won't this important work be done in the coming months prior to final selection of the remedial action?

- How will the Flushing Tunnel alter rates of sediment influx and loading to the Canal?

- How will the operation of the Flushing Tunnel alter the sediment transport dynamics of the Canal and influence recontamination?

- Given the concerns the City has raised regarding the uncertainties in EPA's interpretation of the bathymetric data, does the EPA plan to revise its analysis so as to obtain better estimates of sediment deposition and its associated uncertainty on a scale supported by the data?

- What are the relative sources of sediment deposition attributable to the sources identified in the Proposed Plan and from regional transport?

- How will the remedial action 5-year evaluations assess recontamination of the Canal if relative inputs of solids are not known and how will improvements be quantified if baseline loadings have not been established?

- What specific investigations will EPA perform, what data will be collected and what evaluation would be performed to verify NAPL/coal tar mobility at specific locations?

- Given that no investigations have yet been performed by EPA deeper than six feet into the native sediments, what investigation criteria will be utilized to determine the lateral and vertical dimensions of NAPL/coal tar in native deposits beneath the soft sediments?

- Without an operable sediment transport model, how can these vital questions be answered by EPA to assure the public that a proper remedial action has been

selected, that the remedial action has not been over-prescribed, or that unforeseen rates of recontamination may not occur?

NYC Comment 4: EPA has failed to recognize the need to control upland sources adequately before implementing sediment remediation; in particular, EPA has failed to document the importance of NAPL release processes originating from MGP sites.

As noted above, the Proposed Plan asserts that the current source of PAH contaminants to the surface sediments is CSO discharges and that solids from the CSOs have buried MGP-contaminated sediments and isolated them, removing them as a source. This assessment is clearly incorrect: the distribution of PAH compounds in the Canal bottom sediment, both vertically and horizontally, and the presence of PAHs at significant concentrations in dry-weather water column samples displaying similar distribution patterns, show that PAHs in the deeper subsurface sediment and groundwater continue to be the major sources of PAHs to the surface sediments. As discussed in NYC Comment 2, CSO solids do not contain PAHs at sufficiently high concentrations nor the correct mixture of PAHs to account for the PAH concentrations and patterns found in the surface sediments. These observations conclusively show that the characterization of contaminant sources presented in the Proposed Plan does not account for the major processes that are currently contaminating surface sediments. Without accurately identifying and quantifying the current PAH loading mechanisms, an appropriate remedial strategy cannot be developed and the efficacy of any proposed strategy cannot be determined with assurance.

1) Impact of groundwater on the Canal

The impact of contaminated groundwater on the Canal has not been evaluated by EPA. As described in NYC comments 3(2) and 3(4) above, EPA has underestimated the impacts of groundwater contamination and NAPL movement. EPA is relying on remedies being implemented under DEC oversight for the MGP sites adjacent to the Canal to control groundwater and NAPL. However, the DEC actions are limited and do not address the mass of NAPL and contaminated groundwater already beneath the Canal. If NAPL and groundwater from the upland sites and beneath the Canal are not adequately controlled when the remedy is implemented, they have great potential to reduce the effectiveness and sustainability of the remedy.

The extent of contamination by coal tar NAPL and its impact on the Canal, groundwater, and CSOs are not known. GEI's coring program found NAPL in the sediment or below the sediment at almost all points in the Canal, but no estimates of the existing mass and flux of contaminants from this source have been made. Anecdotal information on one of the MGP facilities indicates the presence of extensive volumes of coal tar NAPL beneath the site and is supported by observations of coal tar by the City during construction related to Gowanus facilities upgrade. In its RI/FS, EPA has not quantified the flux of contaminants via groundwater to the Canal. The City's analysis shows that the discharge of groundwater to the Canal is approximately 2 cubic feet per second ("cfs"). The concentrations of chemicals of potential concern ("COPCs"), particularly PAHs and metals, observed during the RI in the soils and sediments through which the groundwater flows are orders of magnitude higher than the concentrations observed on CSO solids, as observed both from EPA's CSO solids data and from the CSO data collected by the City. The movement of groundwater through these soils and sediments will continue to deliver these contaminants to the Canal unless measures to control groundwater are implemented. Using the estimated groundwater discharge and the concentrations of PAHs in upland groundwater areas, the City estimated potential groundwater loads of PAHs and compared to them to estimates from the CSOs. Note that the estimated

groundwater loads used are likely the minimum possible loads to the Canal, because as the groundwater is transported, additional PAHs from the NAPL already in the sediments will likely partition to the groundwater and will be transported upwards. Therefore, when the effect of NAPL on the groundwater is considered, the estimated loadings of PAHs to the Canal via groundwater may be significantly higher than the loads presented in Table 4-1.

Table 4-1. Comparison of estimated PAH loads from groundwater and CSOs

Analyte	Mean GW Concentration (ug/L)	Potential Annual Loads from GW (kg/yr)	Mean CSO Concentration (ug/L)	Potential Annual Loads from CSOs (kg/yr)
Acenaphthene	59.7	116	0.26	0.2
Acenaphthylene	10.9	21.2	0.06	0.1
Anthracene	5.9	11.4	0.17	0.1
Benzo(a)anthracene	1.47	2.9	0.46	0.4
Benzo(a)pyrene	1.34	2.6	0.51	0.4
Benzo(b)fluoranthene	0.82	1.6	0.57	0.5
Benzo(g,h,i)perylene	0.6	1.2	0.44	0.3
Benzo(j,k)fluoranthene	0.58	1.1	0.52	0.4
Chrysene	1.47	2.9	0.77	0.6
Dibenz(a,h)anthracene	0.14	0.3	0.12	0.1
Fluoranthene	3.99	7.7	1.24	1.0
Fluorene	17.6	34.2	0.17	0.1
Indeno(1,2,3-cd)pyrene	0.55	1.1	0.40	0.3
Naphthalene	1,340	2,590	1.54	1.2
Phenanthrene	33.4	64.7	0.99	0.8
Pyrene	4.95	9.6	1.2	0.9
Sum of 16 PAHs*	1,480	2,870	9.4	7.4
Sum of 15 PAHs* (excluding naphthalene)	143	278	7.9	6.2

*Data are not available for 2-methylnaphthalene

A comparison of potential PAH loads from groundwater and CSOs to the Canal demonstrates that even lower-bound estimates of the groundwater contributions are several times higher than loads from CSOs. In particular, for benzo(a)pyrene, groundwater loads to the Canal are estimated to be at least four times greater than the corresponding CSO contribution.

Although these are just first-order estimates of PAH loads to the Canal, it should be noted that the estimate of PAHs delivered by groundwater annually either with (2870 kg/yr) or without nonconservative naphthalene (278 kg/yr) identify a load that is comparable to the estimate of PAH transport out of the Canal by tidal exchange discussed in NYC Comment 3(2) (0.56 to 0.7 kg/day or 200 to 260 kg/yr). These analyses are preliminary but provide a

clear indication of the magnitude of the PAH fluxes in and out of the Canal, the dominance of the groundwater contribution to the Canal, and the de minimis contribution by CSOs.

The City also estimated potential loads for several metals from groundwater and CSOs (Table 4-2). The estimated potential groundwater loads for heavy metals are mostly higher than loads from CSOs, except for copper and lead. However, for copper the loads from CSOs will be less than or comparable to the loads from groundwater due to the reductions implemented by the City under the Water Quality Improvement Plan ("WQIP") for the Canal. Also, note that for copper and lead, CSO solids concentrations are comparable to regional background threshold values developed using the candidate reference areas selected for the Newtown Creek Superfund site.

Table 4-2. Comparison of estimated metals loads from groundwater and CSOs

Analyte	Mean GW Concentration (ug/L)	Potential Annual Loads from GW (kg/yr)	Mean CSO Aqueous Concentration (ug/L)	Potential Annual Loads from CSOs (kg/yr)
Arsenic	9	18	4	3
Barium	308	598	57	45
Cadmium	0.7	1.4	1	0.5
Chromium, Total	5	9.5	10	8
Copper	22	42	77	61
Lead	10	19	72	57
Mercury	0.10	0.2	0.23	0.2
Nickel	10	20	7	6
Silver	0.7	1.4	1	1

2) Other sources to the Canal:

The Proposed Plan is premised on a remedial investigation that lacks a complete CSM and, as a result:

- Has failed to identify several significant upland sources of contamination,
- Lacks the information needed to quantify the tentatively identified sources it has identified, and
- Incorrectly applies inadequate data to draw conclusions regarding the current nature of contaminant loads to the Canal.

EPA's Contaminated Sediment Remediation Guidance for Hazardous Waste Sites (EPA, 2005, p. 2-7[6]) states that one of the "essential elements" of the CSM is to "include information about contaminant sources." EPA should further develop the following areas.

a. Upland sources

[6] EPA, 2005. Contaminated Sediment Remediation Guidance for Hazardous Waste Sites. EPA-540-R-05-012, OSWER 9355.0-85, December 2005.

The RI does not adequately characterize current and former industrial, upland properties and processes that have historically contributed and may continue to contribute hazardous substances and petroleum contamination to the Canal. This data gap must be addressed prior to developing remedial alternatives; otherwise, loads to the Canal from these sources may ultimately undermine the remedy. This area has been extensively used by various industries for the past 140 years, but there have been relatively few cleanup activities on upland industrial properties under governmental regulatory programs. Upland sites along the Canal that are currently the subject of remedial investigation or are otherwise regulated include the three former MGP sites and over 20 other properties regulated under the New York State Brownfield Cleanup Program ("BCP"), the Voluntary Cleanup Program ("VCP"), the spill program, the Petroleum Bulk Storage ("PBS") program, the Chemical Bulk Storage ("CBS") program, and the Major Oil Storage Facility ("MOSF") program. The CSM for the Canal should provide, at a minimum, a summary of the current status of the remedial program at each of these sites, and any existing data and information about the contamination, as recommended by EPA's guidance (EPA, 2005, p. 2-7). The City's May 25, 2011 comments on the Draft Remedial Investigation ("City RI Comment Letter") describe several existing sources of information that can be used in this assessment, including a City analysis of upland properties and environmental assessments or other technical documents that were produced in response to its various 104(e) requests. The City is particularly concerned about the progress of the on- and off-site investigations at the former Fulton and Metropolitan MGPs, since full characterization of the location, magnitude, and extent of all coal tar emanating from these sites is an essential component of the investigation of the Canal.

b. Discharges from facilities with SPDES Permits

EPA's contaminated sediment guidance (EPA, 2005, p. 1-2) identifies all "direct pipeline or outfall discharges into a water body from industrial facilities" as potential sources of sediment contamination. While EPA performed sampling of the permitted CSO outfalls, the RI does not evaluate publicly-available information about other discharge points or provide a full examination of other permitted outfalls discharging to the Canal. The City's RI Comment Letter contains an analysis of the State Pollutant Discharge Elimination System ("SPDES") permits for facilities with permitted discharges to the Canal and Gowanus Bay. The City recommends that the CSM be revised to incorporate information regarding these permitted and illegal discharges, because they could contribute to recontamination.

c. Unpermitted outfalls and surface runoff

EPA's contaminated sediment guidance (EPA, 2005, p. 1-2) identifies "direct pipeline or outfall discharges into a water body from … stormwater discharges" as a potential source of contaminants in sediment. As part of the RI, EPA conducted a survey of the Canal and identified 247 outfall features (Phase 1 and Phase 2 combined, not including CSO and municipal stormwater outfalls). However, EPA only performed dry weather sampling of the discharge from 12 of the identified outfall features. As contaminated stormwater from industrial sites is likely to be discharging from these outfalls, the City recommends that EPA also collect and analyze wet weather samples from a representative number of these 247 outfalls. EPA (2005, p. 1-1) also identifies surface runoff or erosion of soil from floodplains and other contaminated sources on land, such as waste dumps, chemical storage facilities or urban areas as a potential source of sediment contamination. There are several scrap yards, bulk storage facilities, and open equipment yards along the Canal which are likely contributing contaminated overland runoff to the Canal during certain wet weather events. The City recommends that EPA attempt to quantify the loadings from contaminated runoff by conducting additional field investigations or, at a minimum,

estimate potential contaminate loadings by using existing data resources such as EPA's National Urban Runoff Program Report ("NURP"). If left unexamined, these potential sources could continue to contribute contaminated runoff into the Canal and interfere with the ultimate remedy.

EPA's contaminated sediment remediation guidance (EPA, 2005, p. 2-20) states that "controlling contaminant sources typically is critical to the effectiveness of any Superfund sediment cleanup." The above-mentioned sources of contamination, including the MGP sites, groundwater, upland sites, and unpermitted discharges, should be fully characterized and controlled.

NYC Comment 4 Inquiries

Given the observations above, the City requests that EPA respond to the following:

- Does EPA agree with the conclusions presented here that there are major sources of PAHs and PCBs that are not well characterized? Does EPA still believe these can be entirely controlled by upland activities or will the remedy for the Canal require additional in-Canal controls that will need further development?

- Does EPA intend to investigate these PAH sources further before issuing a ROD? If not, why not?

- There is almost no discussion or detail on the referenced coordinated schedule, or discussion of what occurs if National Grid does not meet EPA's expected schedule. As the upland remediation plan is essential for the successful remediation of the Canal, EPA needs to provide substantial additional detail concerning management, oversight, and coordination of this work.

- What specific upland properties other than MGP sites have been identified by EPA that are discharging, or have the potential to discharge, hazardous substances to the Canal?

- What is EPA's schedule for cleanup of upland properties that are discharging, or have the potential to discharge hazardous substances to the Canal?

- Have all upland properties with potential to discharge hazardous substances been identified or is further investigation required to identify them?

- What is this schedule for implementation of MGP cleanups?

- If MGP site cleanup is not complete in time, will the Canal remedial action be deferred until the MGP remedial actions are complete?

- If further investigation is required, when will that work be performed and who will perform it? Will this work be done before the ROD is issued?

- What are the calculated rates of discharge of contamination from upland properties other than the MGP sites in groundwater?

- Given that groundwater discharge has a high potential to re-contaminate the sediment remedy, what are EPA's goals for reduction in these rates of hazardous substance discharge to the Canal from upland properties other than MGP sites?

- How will the reduction in these rates be monitored during the post-remedial 5 year reviews?

NYC Comment 5: The 2007 draft NewFields report on PAH forensics that EPA relies upon does not support EPA's conclusion that additional CSO controls are required under CERCLA.

To support its assertion that CSO discharges have the greatest impacts on the shallow sediments in the upper reaches of the Canal near CSO outfalls RH-034 and OH-007, EPA used results of high resolution hydrocarbon fingerprints for shallow sediment samples from the 2007 draft NewFields report.[7] Section 3.5 of this section of the FS Addendum asserts:

> "A subset of sediment samples collected by National Grid in 2005 were analyzed for an expanded list of PAHs and other hydrocarbons to facilitate identification of the likely origins of PAHs in Gowanus Canal sediments (NewFields 2007). Figure 15 presents high resolution hydrocarbon fingerprints for shallow sediments in the upper reach of the canal (0 - 1.5 ft interval). The NewFields analysis concludes that the shallow sediments are dominated by an unresolved complex mixture (UCM) with multiple sources of PAHs. The UCM fingerprint is consistent with impacts from urban runoff in CSO discharges. The fingerprints of the native sediments are characteristic of coal tar." FS Addendum, p. 10.

For the following reasons, the 2007 draft NewFields report and EPA's interpretation of that report do not support EPA's conclusion that additional CSO controls are required under CERCLA:

1) **The NewFields data set is of poor quality, and is incomplete.**

NewFields did not analyze field duplicate, field blank, equipment blank and trip blank samples as part of their high resolution hydrocarbon fingerprinting analysis. While 17 of the 124 samples were analyzed twice as laboratory duplicates, laboratory duplicates are not equivalent to field duplicates. NewField's failure to analyze field duplicate, field blank, equipment blank, and trip blank samples as part of the forensic high resolution hydrocarbon evaluation conflicts with both EPA's standard data validation protocols and accepted scientific methodology for the acquisition of environmental data.

2) **Both NewFields and EPA arbitrarily selected a limited number of samples to draw their respective conclusions that CSOs contribute the bulk of PAHs to the shallow sediments in the Canal.**

Of the 124 samples analyzed by NewFields, 102 sediment samples represented the "shallow sediments (less than 2')," the "soft" sediment (between the shallow sediment and the native sediment), and the "native sediment" as referred to by EPA. NewFields' dataset also includes five soil samples from borings taken from the Canal banks, two product samples[8] from the Citizens MGP, one floating product sample, six pavement samples, and eight seep samples.

The text and illustrations in the 2007 draft NewFields report provide no justification for a limited interpretation of only a portion of the 124 samples that were analyzed. NewFields'

[7] NewFields 2007. "Environmental Forensic Investigation. Gowanus Canal, Brooklyn, New York". Draft Report. Prepared for Tracey Bell, KeySpan Corporation.

[8] In Comment 5, the word "product" is used to refer to the coal tars that were produced at the three MGP facilities.

draft report did not include the interpretation and illustration of half of the transects for the Canal sediment samples; in particular, NewFields omitted illustrations to represent most of the samples taken in proximity to National Grid's MGPs (specifically, NewFields omitted the illustration of sediment samples from transects B, E, I, J, L, M, N, P, Q, S, T, W, X, and Z). The contribution of MGPs and other sources in proximity to these transects are therefore not illustrated or otherwise discussed in the report, even though the vast majority of PAHs in Canal sediments originated in close proximity to the omitted transects.

Similarly, and even more problematic, the FS Addendum relies on only four samples identified in the 2007 draft NewFields report. In particular, EPA compared two shallow sediments (GC-SED-03 (0-1.5') and GC-SED-10 (0-1.5')) to two native sediment samples (GC-SED-01 (19-20') and GC-SED-18 (7-8')). Based on these four samples only, EPA asserts that (i) shallow sediments in the Canal are dominated by an unresolved complex mixture ("UCM"), (ii) the UCM fingerprint is consistent with impacts from urban runoff indicative of CSO discharges, and (iii) the presence of a UCM in the two shallow sediment samples and its absence in the two native sediment samples demonstrate that CSOs are contributing the bulk of PAHs in the shallow sediments in the Canal.

A review of all of the chromatograms presented in the 2007 draft NewFields report demonstrates that UCMs are common and prevalent not just in the shallow sediments, as EPA asserts, but throughout the soft sediments, the native sediments and even the soil samples taken from Canal banks. Therefore, contrary to EPA's assertion, the presence of UCM in the two shallow sediment samples EPA selectively and arbitrarily chose is not diagnostic as to the CSOs and the origins of PAHs in the shallow Canal sediments.

NewFields' and EPA's selective use of the data is not consistent with proper scientific methodology.

3) **Review of the NewFields data also shows that there is an uneven application of the assignment of UCM to the chromatograms used for illustration purposes in the report.**

At low hydrocarbon concentrations a "baseline rise" is a natural part of the chromatographic analysis. The "baseline rise" has nothing to do with the presence of petroleum but instead represents column bleed of the stationary phase from the capillary column. In the 2007 draft NewFields report, there are instances where "baseline rise" has been incorrectly attributed to the presence of a petroleum product. However, as no data have been supplied in the report to allow a determination of what proportion of UCM could be attributed to "baseline rise," the use of the presence of a "UCM" indication as support for a petroleum source in samples was not reliable science.

4) **EPA should not attribute the presence of petrogenic (petroleum-based) PAHs in the shallow sediments primarily to urban runoff associated with CSOs.**

There are multiple potential sources of petrogenic PAHs in the shallow sediments that are unrelated to CSOs, including petroleum spills (large-quantity, documented historical petroleum spills occurred at the MGPs), bulk petroleum storage, leaking underground and above ground fuel tanks, and bilge water from barges and boats. Urban runoff is only one potential source. It is therefore incorrect for EPA to determine that the primary source of petrogenic PAHs in the shallow sediments is likely the runoff from the CSOs. As shown in the ratio analysis below, the PAHs on CSO solids are not petrogenic.

5) Diagnostic PAH ratio analysis of CSO solids data collected by the City shows that CSO PAH fingerprint is different from that obtained by NewFields in Canal surface sediments.

One of the tools used by forensic scientists in understanding and distinguishing pyrogenic sources of PAH is the double ratio scatter plot (Costa and Sauer, 2005[9]). In its report, NewFields used the PAH ratios (FL0/PY0) and (BBF+BKF)/BAP[10] for the purpose of resolving the source specific differences among the pyrogenic PAHs in their field samples. Using this pair of ratios, the City re-created Figures 4f, 4e and 4d of the NewFields report with the following additions: high resolution surface sediments data collected as part of the City's toxicity test, split sediment samples collected by the City during National Grid's program to collect Canal sediments in the vicinity of CSO outfalls, and CSO solids data. The results are given in Figures 5-1 to 5-3. From this figure the City observes the following:

- Canal sediments analyzed for high resolution PAH analysis by the City plot within the cloud of Canal sediments reported by the same high resolution PAH analysis for NewFields. Therefore, both data sets can be combined for quantitative analysis.

- The CSO solids are distinct in their fingerprint compared to the surface sediments in the Canal, the heavy and middle petroleum sources, and the coal tar product used by NewFields to represent the Citizens MGP NAPL product. The same observation applies with respect to the PAH patterns in deeper accumulated sediment and native sediments in the Canal.

- The surface sediments of the Canal as well as the Citizens MGP NAPL product are consistent with the fingerprint defined by NewFields as petroleum tar. On the other hand, the CSO data is more consistent with heavy PAHs including many forms of creosote and building materials.

It is clear from the figure that the surface sediments of the Canal cannot be dominated by the discharges from the CSOs. Rather, the Canal sediments, which are classified as petroleum tars plot more closely to the Citizen MGP signature. Therefore, contrary to EPA's assertion, this plot reveals that most of the PAHs in the Canal were derived from petroleum tar dominated by the Citizen MGP product. In addition to the ratios, the concentrations from the CSO solids are substantially lower than surface sediment concentrations in the Canal, and therefore, CSO discharge cannot be responsible for the high concentrations of PAHs in the Canal.

6) The 2007 draft NewFields report relies on a deficient mixing model that does not properly account for the origin of the PAHs in the shallow sediments.

Mixing processes redistribute PAHs in the Canal both vertically (through compaction, ebullition, turbulence, bioturbation and groundwater discharge to the Canal) and horizontally (through erosion, re-suspension and re-deposition). These mixing processes result in the commingling of older and more recent sources in the Canal. Therefore, having on an accurate mixing model is imperative. As an example, since PAH concentrations in the native sediment and soft sediment attributable to the MGPs (coal tar)

[9] Costa H.J. and T.C. Sauer, 2005. "Forensic approaches and considerations in identifying PAH background." Environmental Forensics. 6: 9-16.

[10] Note: FL0 = fluoranthene; PY0 = pyrene; BBF = benzo(b)fluoranthene; BKF = benzo(k)fluoranthene; BAP = benzo(a)pyrene

are more than an order of magnitude higher than PAH concentrations in the shallow sediments, incorporation of as little as 10 percent of native or soft sediments in to the shallow sediments by mixing can explain the totality of the PAH concentrations in the shallow sediment.

NewFields acknowledges the critical importance of its mixing model in its claim that the precision of its mixing model is on the order of +/- 10 percent. NewFields' assertions regarding the precision of its mixing model have no support in scientific methodology or in the data upon which NewFields relies. In fact, for the following reasons, NewFields' mixing model biases in a way that exaggerates the asserted contribution of PAHs in CSOs to shallow sediments as opposed to PAHs from coal tar related to the MGPs and from other sources:

First, NewFields incorrectly assumes that there are only two sources of PAHs to the Canal sediments, namely the MGPs and the petroleum attributed to runoff/CSOs. The MGPs are the major contributors of PAHs to the Canal sediments; however, by considering the pavement petroleum as the only other contributor, the mixing model mischaracterizes the CSO fingerprint and exaggerates the CSO source contributions. As a threshold matter, this assumption is biased and inaccurate because it does not include many other potential PAH sources, such as fuels, coal and air emissions.

Second, NewFields assumes that the contribution of National Grid's three MGPs can be represented by two product samples collected from one of its three MGPs. This assumption is not supported by sufficient data. It is unlikely that the two selected samples would, in fact, represent the diversity of the three MGPs' contributions.

Third, NewFields assumes that pavement samples represent the petrogenic PAH contributions to the Canal sediments and that this source represents petroleum sources attributable to CSOs. Again, NewFields ignores other more logical and prevalent petroleum discharge sources to the Canal, historical and current, including known petroleum usage at the MGPs and at other petroleum storage facilities.

Fourth, in its mixing model NewFields attempted to quantify the relative contributions of petroleum and coal tar in sediment samples by using only 16 PAH compounds (EPA PAHs subset). This procedure ignores 35 of the 51 PAHs compounds that were analyzed for and are present in the Canal sediments, mostly from the MGPs. Using all 51 PAHs in the mixing model yields very different results. For example, applying the mixing model to SED-90B(6.5-7') using the 16 EPA PAHs yields a contribution of 52 percent to MGP sources compared with 82 percent if one uses the 51 PAHs that GEI actually analyzed. This demonstrates that the mixing model is biased and inaccurate.

Fifth, NewFields' mixing model produces results that allocate more than 100 percent of the PAHs in shallow sediments to one source, demonstrating that their mixing model is not scientific, and yields inaccurate and unreliable results.

The mixing model in NewFields' draft report is deficient, biased, highly uncertain, inaccurate, and therefore unreliable.

7) **A review of the NewFields sediment chemical data as a complete data set, including PAH data, alkyl homologues data and data from the transects in the Upper Canal locations (Transects A-I), the Middle Canal locations (Transects J-V) and the Lower Canal locations (Transects W-AA) demonstrates that both vertically and horizontally, coal tar related to the MGPs is the predominant source of PAHs in the Canal regardless of location.**

In locations near the three MGPs and in the turning basins, the source of PAHs is so strongly related to coal tar from the MGPs that it overwhelms all other hypothetical potential sources. While the data show some limited influence of petroleum-derived PAHs, these can be found in widely separated spots and could be attributable to multiple potential petroleum sources other than just CSOs. In fact, contrary to EPA's assertions, pavement samples were not involved in PAH source mixing within the Canal sediments. Rather, petroleum-derived PAHs appear to be more related to releases of distillate petroleum products to the Canal, in soils and on the banks of the Canal.

8) The 2007 NewFields report is in draft form.

EPA should not base significant conclusions on a draft report containing NewFields' preliminary interpretations.

NYC Comment 6: EPA's selection of reference areas is ill considered.

EPA's Gowanus Bay and Upper Hudson reference area is a poor choice as a background area for the Canal based on two important observations. First, the reference locations are open water areas that are not as protected as the Canal. As a result, the sediments that accumulate in the reference areas are likely to be different from those in the Canal. This concern was recognized as part of the Newtown Creek RI reference/background site study. In response, 14 areas around the harbor similar in hydrodynamic setting to Newtown Creek, (and effectively to the Canal) were selected for background sampling. The Canal reference areas are dissimilar to the Canal in two important respects: (i) given their lack of shelter, these areas tend not to accumulate sediment, so they experience little to no recent deposition, and (ii) these areas are subject to periodic navigational dredging, which may have removed recently accumulated material.

This concern was borne out by the surface sediment radionuclide results obtained by the City in its sediment collection program for its toxicity texts. Beryllium-7 was frequently detected in the surface sediments of the Canal, in approximately 8 of the 12 samples collected, indicating the presence of very recent deposition (less than 1 year old) in these 8 locations (see Figure 6-1). Cesium-137 was detected in 11 of the 12 locations, indicating post-1954 deposition in nearly all areas sampled (*see* Figure 6-2). This is in sharp contrast to EPA's reference areas, which only yielded one confirmed, and one marginal, detection for beryllium-7, while three samples were non-detect. Clearly, the reference areas do not have much very recent deposition. The concern is even greater for cesium-137. Three of the five reference locations were non-detect or nearly non-detect for this radionuclide as well. The absence or very low level of cesium-137 indicates the absence of deposition over the last 60 years. Thus three of the five reference area locations do not represent conditions that would be considered background for the Canal since they have not accumulated any sediment since 1954 (the year of cesium-137 appearance).

Given the lack of post-1954 deposition at three of the five reference sites, and therefore the dissimilarity to conditions in the Canal, the City recommends that EPA use the Newtown Creek reference area study as a basis to establish background concentrations and any related PRGs for the Canal.

Since the Canal is an industrially impacted site with discharges from CSOs and other sources, EPA should consider the data collected as part of the Newtown Creek RI/FS for this type of setting as candidate areas when evaluating background for the Canal. For the Newtown Creek RI/FS, an evaluation to determine appropriate background locations was conducted by collecting surface sediments at several candidate sites for contaminant and physical characterization. These waterbodies were classified into four categories including: industrial with CSO input, industrial with no or minimal CSO input, non-industrial with CSO input and non-industrial with no or minimal CSO input. The City determined BTVs (95th percentile of the upper prediction limit) for these four categories for TPAHs, TPCBs, copper, and lead.[11]

[11] In Table 6-1, data identified by Pro UCL Version 4.1 as outliers were excluded in estimating BTVs.

Table 6-1: Background Threshold Values for Candidate Reference Site in Newtown Creek Area

Chemical	Industrial, No CSOs	Industrial with CSOs	Non-Industrial No CSOs	Non-Industrial with CSOs
TPAH (mg/kg) at 6 % TOC	44	62	16	69
TPCB (mg/kg)	0.16	0.49	0.18	2.72
Copper (mg/kg)	288	388	232	182
Lead (mg/kg)	280	526	157	232

(1) Data identified by Pro UCL as outliers were excluded in estimating BTVs.

The following discusses the City's concerns regarding EPA's analysis on a contaminant-by-contaminant basis. The City performed non-parametric hypothesis testing to determine whether the Canal CSOs are statistically significantly higher than the BTVs. Figures 6-3 to 6-6 show the Canal CSO concentrations, along with concentrations in the four reference area categories for TPAH, TPCB, copper and lead. The BTV for each reference category is indicated in the figures. The following summarizes the City's observations in the Canal relative to the four categories:

- For TPAHs, on a 6-percent organic carbon basis, the CSO concentrations are lower than the BTVs from the various background areas.

- For TPCBs, the CSO median concentrations are higher than the BTVs for industrial with no or minimal CSO input and non-industrial with no or minimal CSO input. PCBs in the CSOs compare with the BTV in the industrial with CSO input category, and are significantly lower than the BTV in non-industrial with CSO input.

- For copper, the CSO median concentration is higher than the BTVs for non-industrial with no or minimal CSO input and non-industrial with CSO input. The CSO median copper concentration compares to the industrial with CSO input and industrial with no or minimal CSO input categories.

- For lead, the CSO median concentration is higher than BTVs for non-industrial with no CSOs and non-industrial with CSOs. CSO median lead concentration compares to industrial with CSO and industrial without CSO.

NYC Comment 6 Inquiries

Based on the observations above, the City requests that EPA respond to the following:

- Does EPA agree that the background sites initially selected by the EPA for the Canal are not appropriate given the differences in estuarine setting and lack of post-1954 deposition in three of the five sites? If not, why not?

- Will EPA consider substituting use of the "industrial sites with CSOs" category from the Newtown Creek site as a basis for the Canal background in lieu of the Gowanus Bay and Upper New York Bay reference areas identified in the Proposed Plan? If not, why not?

NYC Comment 7: The PAH PRG calculated by EPA is flawed.

The PRG calculated in the FS Addendum for total PAHs is undermined by:

- The failure to follow a cited method for the reference envelope approach (Ingersoll *et al.*, 2009[12]);
- The use of toxicity test data derived from samples that exceeded EPA recommended holding times for toxicity test samples by approximately 16 weeks.
- The total disregard for EPA's explicit definition of the No Observed Effect Concentration ("NOEC");
- An erroneous assumption that the variability in the NOEC is reflected in the central tendency of all measured values that are equal to or less than the No Observed Adverse Effect Concentration ("NOAEC");
- An incorrect application of the cited method (NAVFAC, 2010[13]) used recently at a Region 1 EPA Superfund site for calculating a TPAH PRG.

(*See* NYC Comment 7(6) below in which the City provides a calculation of a PRG for TPAHs based on correct application of the cited method (NAVFAC, 2010)).

1) EPA failed to follow a cited method for the reference envelope approach (Ingersoll *et al.*, 2009).

The FS Addendum (section 4.1, p. 14) states that "On each plot, a horizontal line (green) represents the lowest toxicity test result for a reference sample (considered the lower bound of the reference envelope)." This citation of the reference envelope approach derives from EPA's Ecological Risk Assessment guidance (EPA, 2011, section 5.1, p. 5-5) which states that: "Therefore, a baseline of conditions in the reference area was established using a 'reference envelope' approach (Ingersoll *et al.*, 2009) to differentiate between site- and non-site-related toxic responses." EPA applies this approach by using the station with the lowest toxic response among four reference area stations to specify toxicity (EPA, 2011; Table 6-2). EPA then extends this approach into the FS Addendum by incorporating this "lower bound of the reference envelope" into a graphical approach for which the FS Addendum provides no reference to any technical literature or EPA guidance that supports such a "graphical approach."

The method cited by EPA (Ingersoll *et al.*, 2009) uses the reference envelope approach to evaluate samples from the Ashtabula River with respect to toxicity to the amphipod *Hyalella azteca* in 28-day tests. Toxicity was established by comparing the test response (survival or length of amphipods) in site sediments to the response of amphipods exposed to reference sediments. This method designates site samples as toxic if the toxic response in those sediments is lower than the lower limit of the normal range of responses for the reference sediments. That lower limit is defined as the fifth percentile response of organisms exposed to reference sediments, not simply the lowest response value in a reference area sample. The cited method (Ingersoll *et al.*, 2009) is

[12] Ingersoll, C.G., N.E. Kemble, J.L. Kunz, W.G. Brumbaugh, D.D. Macdonald, and D. Smorong. 2009. Toxicity of Sediment Cores Collected from the Ashtabula River in Northeastern Ohio, USA, to the Amphipod *Hyalella azteca*. *Arch. Environ. Contam. Toxicol.* Vol. 57, no. 2. pp. 315–29.

[13] NAVFAC (Naval Facilities Engineering Command). 2010. Record of Decision: Site 2B – Area A Wetland, Naval Submarine Base – New London, Groton, Connecticut. August 2010.

consistent with other applications of the reference envelope approach which depend not on the lowest measured value of a toxic response among reference area samples, but depend upon the toxic threshold based on the statistical distribution of all measured samples from a reference area or reference areas (*see* Appendix A4.1 - Technical Basis for Reference Envelope Approach).

2) The FS Addendum uses toxicity test data derived from toxicity tests encumbered by significant uncertainties.

The PAH-based PRGs are based on highly uncertain toxicity tests and an incorrect application of EPA guidance in the calculation process. Among many concerns, the City notes in that the Proposed Plan EPA:

- Did not use the EPA definitions of the NOEC;
- Incompletely applied a cited method for calculating a PRG for total PAHs (NAVFAC, 2010);
- Used an averaging of the range of values among the non-toxic samples to incorrectly represent variability in the NOEC; and
- Used toxicity test data derived from samples that exceeded EPA-recommended holding times for toxicity test samples by approximately 16 weeks.

As a result, EPA's PAH PRG is not defensible. The City has repeated the toxicity tests conducted by EPA, correctly applied EPA guidance and derived a set of more accurate and supportable NOECs. The City's review of the PAH analysis presented in the FS Addendum for ecological risks uncovered many concerns with regard to the data and procedures used to derive the NOEC value that was applied as the PAH PRG (20 mg/kg on sediments at 6 percent TOC). The FS Addendum uses data derived from toxicity tests encumbered by significant uncertainties (*see* Appendix – A4.3 Critique of EPA Toxicity Test Data) including:

- Employing three "re-starts" due to poor organism health;
- Failing to describe the sample handling, distribution, and storage necessitated by these restarts;
- Exceeding recommended holding times for these toxicity tests by as many as 15 weeks; and
- Failing to address the potential uncertainties introduced into the toxicity testing due to the number of samples that were described as having "heavy" or "tar-like" sheens and odors.

A detailed description of these uncertainties is found in Appendix – A4.3 Critique of EPA Toxicity Test Data. The City was sufficiently concerned about the uncertainties introduced by these analysis issues that it conducted a separate toxicity study of its own, using sediments obtained from the same locations as originally occupied by EPA, and toxicity testing methodology prescribed by EPA in published guidance.[14] This study yielded

[14] EPA, 2001. EPA 600/R-01/020, March 2001, Method for Assessing the Chronic Toxicity of Marine and Estuarine Sediment-associated Contaminants with the Amphipod Leptocheirus plumulosus. Office of Research and Development, Western Ecology Division, U.S. Environmental Protection Agency.

PRGs based on strict adherence to the EPA guidance described in NAVFAC (2010), with values that were substantively different from those obtained by EPA; specifically 138 mg/kg TPAHs in bulk sediment assuming 6 percent TOC in the Canal for the growth endpoint; and 412 mg/kg TPAHs in bulk sediment assuming 6 percent TOC in the Canal for the survival endpoint.

3) The FS Addendum ignored EPA's explicit definition of the NOEC.

EPA's definition for the NOEC in the EPA guidance for toxicity testing using *Leptocheirus plumulosus* is:

> "The highest concentration of a toxicant to which organisms are exposed in a test that causes no observable adverse effect on the test organisms (*i.e.*, the highest concentration of a toxicant in which the value for the observed response is not statistically significantly different from the controls)." *See* EPA, 2001[15] subsection 3.1.1.1.

This definition in its characterization of the NOAEC as the highest concentration that causes no observable effect on the test organisms is consistent with EPA's definition of No Observed Adverse Effect Level (EPA, http://www.epa.gov/risk_assessment/glossary.htm) and EPA's definition of No Observed Effect Level in its Framework for Ecological Risk Assessment (EPA, 1992[16]). Explicit in all these definitions is that the no effect level is the highest concentration in an experiment that is not significantly different from an appropriate control.

For growth and reproduction, the FS Addendum used a "graphical approach." This approach estimated a NOEC by first estimating a Lowest Observed Effect Concentration ("LOEC"). This LOEC was defined as the lowest concentration at a location where the average value of an endpoint was less than the lowest response (most toxic) of that endpoint among reference area samples. The NOEC was then defined as the concentration of TPAHs in a sample that was immediately below the LOEC. This approach ignores the EPA definition of NOEC, which is the highest concentration in a sample in which the value of the observed response is not statistically different from the control. The City was unable to find prior references that employ the "graphical approach" used in the FS Addendum.

The FS Addendum selected 7.8 mg/kg TPAH as the NOEC for growth based on this non-standard definition (*i.e.*, a comparison of an average to a LOEC). This method ignores the EPA definition of a NOEC which requires that the NOEC be the highest concentration of a toxicant in which the value for the observed response is not statistically significantly different from an appropriate control.

If EPA's selection of reference station 333 as the appropriate control is accepted (*i.e.*, the reference response used in EPA's graphical method), then the NOEC (following EPA definitions) should be based on the sample that has the highest concentration of TPAHs and whose value for the growth endpoint is not significantly different from the value at

[15] EPA, 2001. EPA 600/R-01/020, March 2001, Method for Assessing the Chronic Toxicity of Marine and Estuarine Sediment-associated Contaminants with the Amphipod Leptocheirus plumulosus, Office of Research and Development, Western Ecology Division, U.S. Environmental Protection Agency.

[16] EPA, 1992. Framework for Ecological Risk Assessment, Risk Assessment Forum, EPA/630/R-92/001 February 1992.

sample 333. That sample is 303, where the concentration of TPAHs is 39 mg/kg. Note that the toxic response at station 303 is also not significantly different from laboratory controls (EPA, 2011) and is not significantly different from the pooled reference area samples (*see* FS Addendum).

Using similar methods, EPA uses the average value of the reproductive response measured at station 329 as the appropriate control to estimate a reproductive NOEC (*i.e.*, the reference response used in EPA's graphical method). If EPA's selection of reference station 329 as the appropriate control is accepted (*i.e.*, the reference response used in EPA's graphical method), then the NOEC should be based on the sample that has the highest concentration of TPAHs and whose value for the reproduction endpoint is not significantly different from the value at sample 329. That sample is 303 where the concentration of TPAHs is 39 mg/kg. Therefore, the appropriate NOEC for reproduction and growth is 39 mg/kg.

4) The FS Addendum erroneously assumes that the variability in the NOEC is reflected in the central tendency of all measured values that are equal to or less than the NOEC.

The FS Addendum incorrectly identifies the uncertainty in the NOEC as "a measure of (the) central tendency…" of all concentrations in the *L. plumulosus* toxicity testing that were equal to or less than the NOEC. This method is inherently incorrect because:

- It ignores all EPA definitions of NOEC as explained above (*See* NYC Comment 7(3)), and

- It does not address variability in the NOEC; rather it attempts to address the variability in all measured values equal to or less than the NOEC. If the FS Addendum were to address the variability in the NOAEC, it would have to measure the NOAEC in several series of toxicity tests, and calculate the appropriate statistics. The FS Addendum illogically assumes that those values that are less than a defined parameter somehow express variability in the parameter.

5) The FS Addendum incorrectly applies the cited EPA method for calculating a PRG.

The FS Addendum cites a study done in EPA Region I (NAVFAC, 2010) as an example of the method that the FS Addendum used to develop a PRG. However, the cited study used a method that adhered to the EPA definition of NOEC. Specifically, the cited study:

- Used the growth endpoint in estimating NOEC and LOEC;

- Defined toxicity based on a statistical comparison of the results at each site station to the results at combined reference area stations;

- Tabulated all non-toxic samples and their respective TPAH concentrations;

- Selected the sample with the maximum concentration in that group of non-toxic samples as the NOEC;

- Tabulated all the toxic samples and their respective PAH concentrations;

- Selected the LOEC as the lowest concentration in a toxic sample that is greater than the maximum concentration in a non-toxic sample; and

- Calculated the geometric mean of the NOEC and LOEC as the PRG.

The City notes that if the FS Addendum had followed this method:

- Among the Canal stations, the only sample that was non-toxic for growth was the sample tested from station 303, which had a total PAH concentration of 39 mg/kg;

- Therefore, the NOEC is 39 mg/kg;

- The LOEC is derived from station 310 and is 66.9 mg/kg; and

- The geometric mean of these values is 51 mg/kg, which is the PRG using the method cited by EPA in the FS Addendum.

6) The City's calculation of PRGs for TPAH based on valid toxicity test data returned a PRG of 138 mg/kg TPAH in bulk sediment assuming 6 percent TOC in the Canal for the growth endpoint and 392 mg/kg TPAH in bulk sediment assuming 6 percent TOC in the Canal for the survival endpoint.

The City has calculated PRGs based on survival and growth of *Leptocheirus plumulosus* for TPAHs in the Canal using:

- Recently obtained sediment toxicity data (*see* Table 7-1, which reproduces Table 1 from Toxicity Test Appendix A4.2 City of New York Calculation of PRGs for Total PAH) that did not require restarts and was conducted within EPA recommended holding times (2 weeks of sampling date);

- EPA definitions of NOEC and LOEC; and

- A direct application of the method cited by EPA (NAVFAC, 2010) for the calculation of PRGs.

Table 7-2 and Table 7-3 (which reproduces Table 2 from Toxicity Test A4.2 City of New York Calculation of PRGs for Total PAH) provide the estimated PRGs for TPAHs based on survival and reproduction, respectively.

(1) Maximum concentration in a non-toxic sample.

(2) Lowest concentration in a toxic sample that is greater than the maximum concentration in a non-toxic sample.

(3) Samples had zero survival and growth could not be measured.

Sources of uncertainty in development of the PRG derive from the nature of the toxicity data. Specifically, there is a small sample size to use in calculating a PRG for PAHs because:

- Most of the Canal stations (seven of 12) cannot be used to estimate a PRG for PAHs because the sample exhibited visible oil in the lab. Therefore the test organisms were potentially affected by the physical effects of oil (*e.g.*, interference with respiration, ingestion of oil) before the toxic effects of PAHs from uptake and exposure would occur;

- Among the remaining five (non-oily) stations, the low survival in the reference areas results in only one toxic sample (for survival endpoints) and only two toxic samples (for growth endpoint) in the Canal (relative to the pooled reference area sample); and

- The survival in the reference area is low and highly variable (*see* Appendix A4.4 Toxicity Tests: Summary of Methods and Results).

NYC Comment 7 Inquiries

Given the observations presented above, the City requests that EPA respond to the following:

- Please explain the ramifications of the rationale for proceeding with the development of a PRG based on toxicity data encumbered by the various uncertainties noted including: employing three “re-starts” due to poor organism health; failing to describe the sample handling, distribution, and storage necessitated by these restarts; exceeding recommended holding times for these toxicity tests by as many as 15 weeks; and failing to address the potential uncertainties introduced into the toxicity testing due to the number of samples that were described as having “heavy” or “tar-like” sheens and odors.

- Given the strict adherence to EPA guidance and the better analytical results obtained by the City, the City requests that EPA adopt the PRGs developed by the City or explain why EPA’s approach should be used instead.

- Please explain why the FS Addendum ignores the EPA definition of NOEC by employing a comparison of an average concentration in direct comparison to a LOEC, rather than using the statistical comparison to a control explicit in EPA definitions.

- Please provide technical references that support the “graphical approach” used in the FS Addendum. Is this approach a standard method employed at other EPA CERCLA sites for estimating a PRG?

- Please explain why the FS Addendum does not follow EPA definitions and select a concentration of 39 mg/kg at station 303 for the NOEC for growth. This concentration fits EPA’s definition of a NOEC based on statistical comparison to either the laboratory control, the reference area selected as the basis of comparison in EPA’s ecological risk assessment (EPA, 2011), or a comparison to pooled reference area results.

- Please explain why the FS Addendum does not follow EPA definitions and select the concentration, 39 mg/kg at station 303, for the NOEC for reproduction. This concentration fits EPA’s definition of a NOEC based on statistical comparison to the reference area selected as the basis of comparison in EPA’s ecological risk assessment (EPA, 2011).

- Please explain the logical or statistical basis upon which the FS Addendum estimates the variability in a well-defined parameter (the NOEC) by averaging a series of values that measure something other than that well-defined parameter.

- Please explain why the FS Addendum attempts to address only the uncertainty in the NOEC and does not similarly attempt to address the uncertainty in the LOEC.

- The FS Addendum ignores data from two stations, 313 and 326. What is the effect on the analysis of maintaining all stations? Specifically, what is the effect of retaining station 326 as a reference station and what is the effect on the analysis of retaining station 313 as a Canal station?

NYC Comment 8: PRGs stated for metals, as well as the future bioavailability analysis, are not scientifically tenable.

EPA should not develop a PRG for lead and copper because EPA's ecological risk characterization demonstrates no bioavailability and therefore no toxicity from benthic exposures to copper and lead. In addition, EPA's selection of PRGs for copper (80 mg/kg) and lead (94 mg/kg) in sediment is based on an assumption regarding future geochemical conditions that is not supported by the available data.

1) EPA should not develop PRGs for copper or lead.

EPA should not develop a PRG for either copper or lead because EPA's risk characterization results indicate that neither is toxic to benthic dwelling organisms. The FS Addendum (Supplemental Section 4.2 p. 17) explicitly states that metals (including copper) should not cause toxicity: "The results of the AVS and SEM analyses provided in the RI report were used to calculate SEM-AVS/f_{OC} for each toxicity test sample. The results are reported in Table 4-7. The results strongly suggest that the metals currently are not bioavailable and should not cause toxicity." The referenced table (Table 4-7) shows that, among 11 stations sampled for AVS/SEM, ten indicated toxicity was unlikely and one indicated uncertain potential for toxicity. None indicated likely toxicity. Therefore, EPA should not calculate a PRG for chemicals (copper and lead) that do not pose a risk in the baseline risk characterization.

2) EPA's development of PRGs for copper and lead is based on an unfounded assumption.

New York Harbor-specific AVS/SEM and fraction organic carbon data (EPA, 1998; NYC DEP, 1992) show that it is unlikely that future geochemical conditions in the Canal will result in exposure to metals that are toxic to benthic organisms. These data indicate that divalent metals are not bioavailable and are unlikely to cause toxicity over a broad spatial range in New York/New Jersey Harbor in general, and in Upper New York Harbor in particular. Future geochemical conditions in the Canal are likely captured by the range of geochemical conditions extant in Upper New York Harbor. (It is unreasonable to assume that future geochemical conditions in the Canal will be unique and outside the broad range of conditions currently encountered). Future geochemical conditions will result in sediments whose properties are not likely to cause toxicity to benthic organisms. Therefore, there is no reason to establish a PRG that is based on the unlikely projection in the FS Addendum that "…metals may become bioavailable in the future if geochemical conditions in the Canal change and do not favor the formation of insoluble sulfides."

a. EPA's development of PRGs for copper and lead

The FS Addendum (Supplemental Section 4.2 p. 17) provides the following rationale for the development of PRGs for metals: "The results strongly suggest that the metals currently are not bioavailable and should not cause toxicity. However, metals may become bioavailable in the future if geochemical conditions in the canal change and do not favor the formation of insoluble sulfides." EPA bases the strong suggestion that metals are "…not currently available and should not cause toxicity" on the probabilities of toxicity at different TOC normalized values of AVS-SEM demonstrated by EPA (EPA, 2005). EPA used this approach for assessing the likelihood of sediment toxicity in the Risk Assessment (EPA, 2011a), the FS (EPA, 2011a) and the FS Addendum (EPA, 2012).

Although EPA acknowledges that current geochemical conditions in the Canal strongly suggest that metals are not currently bioavailable and should not cause toxicity, they make the unsupported projection that future geochemical conditions may change in some manner that does not favor the formation of insoluble sulfides. Therefore, EPA suggests (without explanation) a PRG reflecting copper and lead concentrations in the reference area (80 mg/kg copper and 94 mg/kg lead in bulk sediment). These bulk sediment PRGs are asserted with the full and explicit knowledge that divalent metal toxicity is not dependent on bulk metal concentrations.

b. EPA's basis for predicting bioavailability and toxicity

EPA's current model to explain divalent metal bioavailability relies on equilibrium partitioning theory, which is based on the idea that divalent metals (cadmium, copper, nickel, lead, and zinc) partition in sediment among AVS (principally iron monosulfide), interstitial water, benthic organisms, and other sediment phases such as organic carbon (Di Toro *et al.*, 1990[17]). According to the theory, the availability (and hence, toxicity) of metals depends on the difference between the molar concentrations of the SEMs and AVSs in sediment ("SEM -– AVS"). The model adjusts for the fraction total organic carbon in sediment (f_{OC}) because metals also can bind to organic carbon (EPA, 2005).

This model predicts that toxicity is:

- likely when the (SEM-AVS/f_{OC}) is greater than 3,000 micromoles (µmol) per gram organic carbon (g_{OC}),
- uncertain when the concentration is between 130 and 3,000 µmol/g_{OC}; and
- not likely when the concentration is less than 130 µmol/g_{OC} (USEPA, 2005)

Obviously, the geochemical conditions in this model that predict toxicity from sediment exposures (due to divalent metals) are the various combinations of: concentrations of sulfides, concentrations of extractable metals, and the fraction of organic carbon in sediments reflected in the equation:

$$(SEM\text{-}AVS)/f_{OC} \qquad \text{(Equation 1)}$$

3) Data from New York Harbor do not support EPA's assumptions

The City makes the reasonable assumption that the future geochemical conditions in the Canal expressed as Equation 1 are likely to lie within the range of values found over the broad range of geochemical environments currently occurring in the Upper New York Harbor. That is, the future geochemical conditions in the Canal are not likely to be unique and outside the range of geochemical conditions extant in Upper New York Harbor.

EPA's Regional Environmental Monitoring and Assessment Program ("REMAP") data (EPA, 1998; Figure 8-1) and DEP's 1992 sediment sampling data (DEP, 1992; Figure 8-2) provide the information necessary to calculate (SEM-AVS)/f_{OC} at sediment sampling stations in New York/New Jersey Harbor, and in Upper New York Harbor specifically. An examination of these data demonstrates that it is unlikely that geochemical conditions (f_{OC} and SEM-AVS) will result in effects on benthic communities (as toxicity).

[17] Di Toro, D. M., J D. Mahony, D J. Hansen, K J. Scott, M B. Hicks, S M. Mayr, and M S. Redmond. "Toxicity of Cadmium in Sediments: The Role of Acid Volatile Sulfide." *Environ. Toxicol. Chem.* 9 (1990): 1487-1502.

The City evaluated data from the New York/New Jersey Harbor region (REMAP, 1998; DEP, 1992) with respect to (SEM-AVS)/f_{OC}. The REMAP program measured the parameters of interest (AVS, SEM and TOC) in 167 samples from the New York/New Jersey Harbor region (Figure 8-1). The DEP 1992 sediment sampling program measured the same parameters from 21 additional sites (Figure 8-2). These sampling sites can be viewed together in Figure 8-3. Figure 8-5 shows that the vast majority of the samples (177 of 188, or 94 percent) had (SEM-AVS)/f_{OC} ratios less than 130 umol/g_{OC}, and would therefore be considered unlikely to be toxic. Just 11 of the 188 samples, or 6 percent, had (SEM-AVS)/f_{OC} ratios greater than 130 umol/g_{OC} (toxicity uncertain), and none of the samples had (SEM-AVS)/f_{OC} ratios greater than 3000 umol/g_{OC} (likely toxic).

In Upper New York Harbor in particular, at all sampled stations, the geochemical conditions (expressed as a combination of SEM, AVS, and f_{OC}) indicate that divalent metals are not available and are unlikely to cause sediment toxicity. These stations represent a broad spatial range (Figure 8-4) covering the Hudson River, the East River from Throgs Neck to the southern tip of Manhattan, and various stations in the Upper Harbor to Verrazano Narrows. These data for Upper New York Harbor (Figure 8-5) indicate that only one of the 35 samples had an (SEM-AVS)/f_{OC} ratio greater than 130 umol/g_{OC} (at 233 umol/g_{OC}), and none of the ratios were above 3000 umol/g_{OC}, the level at which toxicity is thought to be likely.

These data demonstrate that there is no widespread combination of geochemical conditions in Upper New York Harbor that would result in the likelihood of divalent metals bioavailability and toxicity. The assumption that future conditions in the Canal will result in some geochemical conditions that are unique to the extant range of conditions is unfounded and, in fact, contradicted by these data. Therefore, EPA's rationale for asserting PRGs for the two divalent metals, lead and copper, based on the assumption that "…metals may become bioavailable in the future if geochemical conditions in the Canal change and do not favor the formation of insoluble sulfides" is not supported by regional-specific data.

NYC Comment 8 Inquiries

Given the observations noted above, the City requests that EPA respond to the following:

- On what empirical basis does EPA assume that future geochemical conditions in the Canal will result in increased bioavailability of metals, given the extensive spatially and temporally diverse data that demonstrates the non-bioavailability of metals (including copper and lead) in New York Harbor?

NYC Comment 9: Conceptual design parameters for the proposed remedy are unrealistic.

EPA's current understanding of the Canal, groundwater watershed, and related processes, as presented in the Proposed Plan, are too simplistic to support a reliable estimate of the impacts of the proposed remedy. EPA fails to incorporate in its evaluation the impact of the improvements in water and sediment quality that will result from the CSO reduction efforts and Flushing Tunnel rehabilitation that the City is undertaking pursuant to its CWA Consent Order with DEC. This failure has resulted in the use of conceptual design assumptions that are unrealistic for addressing actual site risks.

1) Contaminant transport processes identified in the Proposed Plan are too simplistic.

The Proposed Plan attributes surface sediment concentrations to contaminant sources without regard to the natural mixing and transport processes that exist in the Canal, a direct outcome of the lack of a robust CSM. The FS incorrectly identifies CSO solids as the major source of contaminants in surface sediments in the Canal. As a result, the proposed remedial actions place insufficient focus on the true major sources of PAHs to the Canal (*i.e.*, groundwater, NAPL, and seeps). This has significant ramifications for the remedy since sufficient focus will not be brought to bear on the control of the true major sources.

Based on contaminant mass balance and other analyses, the pattern of contaminants accumulating in surface sediments cannot be derived from CSOs or reference area solids and, therefore, must be due to other poorly characterized and un-quantified sources. The analyses provided by the City in these comments provide clear evidence for the existence and relative magnitude of these sources. The Proposed Plan does not consider the potential for these sources to re-contaminate the Canal after a remedy has been implemented or the consequences of implementing the proposed remedy without addressing these sources.

The impact of groundwater on water quality in the Canal has only been given cursory treatment in the FS and Proposed Plan. The FS merely acknowledges the NAPL concentrations in groundwater outside the Canal and does not consider that the groundwater must pass through NAPL at almost all points prior to discharging into the Canal. No attempt has been made to quantify the associated loading.

During construction, following the removal of the soft sediment that currently retards upward groundwater flow, gradients between the groundwater and the Canal will be at their greatest. The influx of contaminated water and NAPL has the potential to deplete the adsorptive capacity of the oleophilic clays planned to control the NAPL, even as the material is placed.

The changes in channel geometry due to deep dredging will drastically change (and likely increase) the ratio of harbor solids to CSO solids accumulating in the Canal. The plan to deepen the Canal as part of the remedy will change the dynamics of sediment accumulation. More harbor sediments will be deposited in the Canal due to the decrease in velocity associated with the deepening. For this reason, any CSO solids that settle in the Canal will be diluted to a greater extent than prior to the remedy. The Proposed Plan fails to consider this important ramification in its requirements for CSO reduction.

The Flushing Tunnel will partially offset the increase in water residence time within the Canal that will result from deepening of the Canal. The Flushing Tunnel will also distribute cleaner harbor solids throughout the length of the Canal. The Proposed Plan does not account for the changes in circulation in the Canal when the Flushing Tunnel is restored (with increased capacity). As a result of restoring the Flushing Tunnel, there will be both a continuous flow out of the Canal and delivery of additional harbor solids to the Canal. This will partially offset the increase in water residence time resulting from the Canal deepening but should still increase the overall sediment accumulation rate by delivering harbor solids to the head of the Canal, and increase the standing inventory of harbor solids in the water column. This will result in less residence time in the Canal of CSO-delivered water relative to the Canal deepening alone, and will provide additional dilution of CSO solids by harbor solids. The Proposed Plan does not acknowledge these mechanisms and outcomes and does not attempt to estimate the quality of sediments that will be deposited after the City has implemented the changes to the CSO system and the Flushing Tunnel that are currently underway. The City notes however, that since CSOs are already compliant with the PRGs for TPAHs and TPCBs, these modifications could only further reduce the already low contaminant levels on CSO solids upon deposition on the Canal bottom (assuming that the actual causes of contamination that are currently present will have otherwise been addressed).

2) Critical technology effectiveness assumptions are unrealistic.

a. Lack of understanding of the performance of oleophilic clay for use in reactive caps to NAPLs

EPA is proposing to use a layer of oleophilic clays to capture NAPL migrating from the groundwater and underlying sediments to the surface sediments above the remedy's cap. However, EPA has not conducted any studies or analyses to understand how such a layer will react under the conditions in the Canal. There is ample supply of NAPL that could quickly expend capacity of the clay to treat further releases. If the clay swells due to adsorption of NAPL (as happens when used to treat other contaminants) and blocks flow paths, contaminated groundwater and NAPL could be diverted to other locations, either in the Canal or into basements, utility corridors, or other subsurface openings around the Canal.

EPA has presented no information or analyses on how the clay will handle dissolved contaminants. Based on the surface water data discussed above (*See* NYC Comments 1 and 2), loading of dissolved PAHs is likely significant. However, because the mass of NAPL associated with the MGP sites is unknown, the required thickness of an oleophilic clay layer in a reactive cap cannot be reliably estimated and the FS did not include any estimate of the depletion rate of oleophilic clay once placed. Since there is a large amount of NAPL that will not be recovered, determining the feasibility of using oleophilic clays requires quantifying depletion rates and understanding the ramifications for costs as well as any unintended consequences that could arise from using the clays. The studies of NAPL seepage that have been done did not consider the removal of soft sediments and the conditions anticipated to prevail during construction, and therefore grossly underestimate the amount of NAPL that may discharge. The proposed replacement of the oleophilic clay layer if found to have an inadequate life is an unacceptable surrogate for knowledge and would effectively require reconstruction of a new cap as a maintenance item.

b. Lack of understanding of potential impacts from in-situ stabilization and the parameters of applicability to the entire remediation target area

EPA provides no technical justification, analytical or pilot testing results, case studies, or other studies that document the benefits of the use of in-situ solidification ("ISS") in its proposed application. Similarly EPA has not evaluated the risks posed by the widespread application of ISS in the Canal. EPA has proposed the use of ISS to stabilize low-strength, native deposits at the base of the Canal following dredging, but prior to capping. While the use of ISS in upland areas is relatively common, its use in a marine setting for the purpose of strengthening underlying soils and creating a low hydraulic conductivity barrier to NAPL migration was not documented in the FS, and the City is not aware of any precedent for such an action. The closest example of its use in a similar setting that was cited in the FS was a pilot study conducted in Newark Bay to assess whether ISS could be used to stabilize the contaminated sediment enough to minimize re-suspension of contaminants during planned dredging operations. This study was not designed to assess the factors that will be important in its proposed application in the Canal.

In Table ES-1 of the FS, EPA acknowledges the lack of technical justification for ISS, stating that "…if additional evaluations and pilot studies indicate that in situ solidification (ISS) is implementable and effective within the canal…" and "this technology is not commercially proven for application to marine environments for the control of NAPL migration.." as well as "is **expected** to provide additional protectiveness" (emphasis added). These or similar qualifiers are repeated a number of times throughout Table ES-1. In the same table EPA acknowledges that "ISS is an emerging technology" and "there are few contractors with a proven performance of ISS implementation in marine environments."

Appendix A of the FS also refers to ISS as a "promising technology" for controlling NAPL in saturated sediments and identified four ***potential benefits*** of this process as follows:

i. NAPL saturation heterogeneity would be homogenized.

This implies that NAPL concentrations, as the result of adding the reagent by mixing, would be more evenly distributed throughout the sediment bed. However, mixing technologies are not perfect in the subsurface, which can result in separation of masses or blobs of the NAPL from the stabilizing agent. Mixing, then, has the potential to mobilize the NAPL within the mixing column, releasing it to the surface water or forming isolated NAPL blobs that might not be captured by the ISS matrix. This is of particular concern in the NAPL-saturated conditions present in portions of the Canal.

ii. NAPL saturation potentially could be lowered to residual levels by ISS, preventing further NAPL migration.

This outcome might be expected where the mixing is occurring in contaminated soils above the water table, a common use for ISS. It is not clear that this would occur in the saturated native sediments present beneath the Canal. Because of the lack of historical data in a similar environmental setting, it is not possible to determine what the impact will be of a large-scale application of ISS such as envisioned in the Canal for the proposed remedy.

iii. Hydraulic conductivity of the ISS treated sediment would be greatly reduced, resulting in reduced upward groundwater velocities that can cause NAPL migration.

While it is possible that the addition of Portland cement to the material will reduce its hydraulic conductivity, the volume of Portland cement required in this setting has not been established and may vary substantially from place to place within the Canal due to variations in the native sediments. It is not proven that reducing the hydraulic conductivity across the majority of groundwater discharge zone(s) to the Canal will be an overall environmental benefit. Reducing hydraulic conductivity in one area is likely to divert groundwater flow to another location, potentially to basements and crawl spaces of houses and buildings in the area. This could distribute the contaminants in the groundwater into previously uncontaminated areas. Differential settling within the sediment could result in cracks in the ISS barrier and create preferential flow paths for contaminants, increasing the upward gradient and hence the migration of contaminant mass. The lack of geotechnical data, geotechnical analyses, and modeling results in a great deal of uncertainty regarding the potential impacts of reducing the hydraulic conductivity into the bed of the Canal.

iv. ISS has been pilot tested on soft sediment using cement deep soil mixing ("CDSM").

The referenced pilot study was conducted in Newark Bay on a small volume of material in an open setting and lasted less than six months. The intent of the program was not to improve the stability of the underlying low-strength material to allow placement of a reactive cap, rather it was intended to stabilize the soft contaminated sediment to allow dredging of the solids and their off-site disposal with minimal re-suspension of contaminants into the water column. This pilot study does not provide a true comparison for evaluating ISS in its planned application in the Canal.

While there was discussion of the potential, although unproven, benefits of the use of ISS, what the FS did not consider were the ***potential risks*** of the process.

- No field data has been gathered on the strength of the native deposits throughout the soil column; FS investigations of the native sediments stopped at a depth of approximately 5 feet. While one of the purposes of ISS is to create a layer that can support the cap, EPA has not documented any investigation as to whether the underlying sediments have the ability to support the weight not only of the cap but of the ISS layer. EPA's proposed approach may just transfer the problem of unstable soils to a greater depth in the soil column. In addition, soil borings suggest that in a number of locations, more granular soils are present at depth; compressing soils deeper in the soil column could result in spreading the groundwater contamination problem downward and outward through more porous soils.

- The justification for the ISS layer is the concern that the cap weight will mobilize the NAPL outward. It is not clear why adding the weight of a five-foot ISS layer across much of the bed of the Canal would not have the same result. In addition, as noted previously, the mixing process used has the potential to mobilize the NAPL in the sediment.

- The uncontrolled hydration of Portland cement by its incorporation into the sediment through the ISS process has the potential to release high pH leachate to the Canal containing toxic levels of heavy metals derived from the cement. The FS documents do not consider the potential risks associated with the addition of large volumes of Portland cement or similar reagents to the Canal. The bench

scale testing currently underway to identify the proposed reagent does not address this question.

- While the FS documents discuss the ISS process as creating a continuous low hydraulic conductivity layer that will prevent contaminated groundwater from entering the Canal, this seems an unlikely outcome. The underlying sediments vary in depth and material characteristics. Different portions of the underlying soils will react differently to the weight that is applied through the cap and ISS layer, resulting in differential settling and the formation of cracks in the ISS layer. These cracks may provide flow paths for contaminated groundwater and gas to enter the surface water of the Canal.

EPA needs to conduct a more complete and thorough evaluation of the ISS process in a marine environment before proposing its use in a large-scale project. This analysis should include a geotechnical evaluation of underlying soils to determine the impact of installing not only a soil cap but an ISS layer as well. This evaluation should include an assessment of the stability of the ISS layer as well as the potential for consolidation of underlying contaminated layers and the redistribution of contaminants; an assessment of the potential impact of the mixing process both on the release of chemicals from the reagent used in the ISS process and the release of NAPL in the native sediment deposits; and modeling of the local hydrogeology to determine the impact of a reduction of the hydraulic conductivity within the base of the Canal on the path of contaminant plumes.

The FS does not provide an evaluation of some of the fundamental assumptions used in the conceptual design for the recommended remedy. The approach taken in the FS to defer these and other critical evaluations until the Remedial Design phase without providing any contingency for addressing problems that will arise at that time is inconsistent with EPA's RI/FS and Contaminated Sediment Remediation guidance (EPA, 1988; EPA, 2005).

3) The conceptual design of the cap is flawed.

The Proposed Plan chose a cap design without considering its efficacy or its consequences to the groundwater system. The chosen cap design includes a 1-foot thick layer of oleophilic clay as an adsorptive barrier to NAPL discharge. The only justification for this choice is that a similar cap was used at the McCormick & Baxter Creosote Superfund Site in Portland, Oregon in 2005. While EPA correctly points out in the FS that there are important hydraulic and contaminant occurrence differences between the McCormick and Baxter site and the Canal (including large differences in the hydraulic and NAPL gradients), it does not mention the most important difference – that of scale of the capping effort. An oleophilic clay mat was used at the McCormick & Baxter site to cover an area of roughly 24,150 square feet and used 600 cubic yards of clay. In comparison, the FS indicates the remedy for the Canal will cover an area of 330,000 square feet and will require over 40,000 cubic yards of clay. The analogy between the sites is weak and does not support the proposed remedy without additional evaluation. Other detailed evaluations of cap effectiveness are needed, but were not presented in the FS. If the oleophilic clay is expended much more quickly than anticipated, removing and disposing of this NAPL-saturated material will be a significant, and expensive, undertaking.

The proposed cap does not consider lateral migration of contaminants in groundwater that discharges into the Canal. The proposed cap would be located 15 to 20 feet below the water surface in most areas of the Canal. Lateral migration of groundwater into the Canal containing NAPL from the upland sites, would be entering the surface water **above** the

reactive cap and would not be treated. This process will lead to recontamination of the cap from the surface. This issue was not addressed in the FS or Proposed Plan.

NYC Comment 9 Inquiries

Given the observations noted above, the City requests that EPA respond to the following:

- The lack of a technically supported, robust CSM for the Canal has resulted in the use of unfounded and undocumented conclusions being drawn not only about the source of the contaminants but about the long-term implications of the proposed remedy. Additional information on the fundamental processes that drive contaminant flow and contaminant deposition and control conditions in the Canal need to be provided.

- The FS and the Proposed Plan contain no evaluation of the effective life of the reactive cap or the timing or costs of its replacement. The FS does not address fundamental questions about the life of the reactive layer in the cap or the cost to replace the cap when the reactive layer fails. Under CERCLA, potential costs that will accrue during the assumed 30 year life of the remedy need to be included in the cost estimate – without an estimate of the life of the cap, this has not happened and it is not clear that enough data has been generated on NAPL flux to make this estimate.

- No consideration is given to the potential impacts associated with the use of ISS in the Canal. The use of ISS is based on unproven assumptions about its potential benefits that have not been verified based on field testing under conditions likely to exist in the Canal. Adequate testing should be conducted in the FS to assess both the potential benefits and the risks of using ISS in the Canal before it is proposed for inclusion in the recommended remedy. At this time, EPA has not established any criteria for acceptable performance of the ISS or means for evaluating lab and pilot scale testing deferred to the Remedial Design phase.

- EPA has left a number of key questions unanswered in the FS about the technical feasibility, and suitability, of the cap design. Additional study and analysis of the ability of the proposed cap design to address site conditions in a cost effective manner need to be performed before it can be included in the proposed remedy.

NYC Comment 10: EPA incorrectly and inappropriately relied on the article by Stein et al. (2006) regarding stormwater runoff to establish its "first flush" standard for CSO discharge capture. EPA should instead use sufficiently representative site-specific measurements to inform remedial decision-making.

As part of the justification for EPA's CSO reduction requirements, the Proposed Plan states:

> "Scientific literature suggests that it can be assumed that the "first flush" comprises approximately 20% of the total discharge volume and contains between 30% and 60% of the total PAH load of the discharge (Stein, 2006)." *See* Proposed Plan, p. 19.

EPA incorrectly uses this observation, which is based on storm water drainage in a western arid region, as a basis to estimate the nature of CSO in a humid, eastern setting. EPA is assuming that 20 percent of the total Canal CSO discharge volume for outfalls RH-034 and OH-007 is equivalent to a storm drainage first flush volume and includes 30 to 60 percent of the PAH loading. This assumption is based on the work of Stein *et al.* (2006).[18] The work of Stein *et al.* is not applicable to the Canal, and EPA should not have relied on it in the Proposed Plan. The work of Stein *et al.* (2006) describes conditions related to stormwater discharge in the Los Angeles area, which are significantly different from the CSO and drainage area and precipitation conditions of the Canal, and produce releases of fundamentally different character. EPA's reliance on Stein *et al*. to characterize the releases from CSOs discharging to the Canal and select remedial actions is not appropriate for the following specific reasons. *See also* Appendix B.

1) Combined sewer systems and separated storm sewer systems have fundamentally different hydrological responses

There are fundamental differences in character between the initial tipping flow for a CSO and the true "first flush" for a separated stormwater system. Typically, combined sewer systems are designed so that approximately two times the dry weather flow is captured and treated. Very often, in a combined sewer system, much of the initial rainfall runoff volume is actually captured and treated rather than released. Only when the rain is sufficiently long in duration and intensity does a CSO tipping event occur. Many smaller rain events do not yield any CSO discharge at all. This is in contrast to separated storm sewer systems, where essentially all rain events that cause surface runoff yield some storm sewer discharge.

Recognition of the capture of "first flush" for CSOs is found in *EPA's Combined Sewer Overflows Guidance for Monitoring and Modeling*, EPA/823-B-99-002 (January 1999) where it says "using overflow quantity and average concentrations, inaccuracies may result, particularly if the 'first flush' is effectively captured by the POTW or storage." Additionally, in a combined sewer system, when a portion of the "first flush" from the stormwater runoff is not captured and is released during initial tipping of the CSO, its contaminant concentrations are the result of surface runoff mixed with sanitary sewage. In contrast, a true "first flush" is released in a separated storm sewer system since there is

[18] Stein, E.D., L.L. Tiefenthaler, and K. Schiff, 2006. "Watershed-Based Sources Of Polycyclic Aromatic Hydrocarbons (PAH) In Urban Storm Water." *Environmental Toxicology and Chemistry.* 25:373–385.

typically no provision for capture or storage of flow, and its associated contaminant concentrations result exclusively from rainfall runoff.

Further, even for a given CSO location, a high level of variation in the solids and contaminant concentrations released during initial tipping of the CSO will exist, depending on storm event conditions (such as intensity, duration, and timing of peak intensity), tidal conditions and the elapsed time since the previous runoff event. These highly variable conditions would require extensive data collection for characterization and determination of the appropriate remedial action. As stated in EPA's *Combined Sewer Overflows Guidance for Long Term Control Plan* (EPA, 1995[19]):

> "Historically, the control of CSOs has proven to be extremely complex. This complexity stems partly from the difficulty in quantifying CSO impacts on receiving water quality and the site-specific variability in the volume, frequency, and characteristics of CSOs."

2) The areas drained by storm sewers in the Stein *et al.*, 2006 study are inherently different from those associated with the Canal

In addition to the fundamental hydrological differences in the highly variable properties and volumes of releases from the blended initial tipping flow from CSOs and the true "first flush" from separated storm sewer systems (especially from widely divergent climates), the stormwater drainage area considered by Stein *et al.* is very different from the Canal drainage area. The nature and volume of any first flush is highly dependent on drainage area. As stated in *EPA's Combined Sewer Overflows Guidance for Monitoring and Modeling*, (EPA, 1999[20]):

> "To characterize first flush, a sample should be collected as close to the beginning of the CSO event as feasible. Appropriate sampling intervals depend on such factors as drainage area sizes, slopes, land uses, and percent imperviousness."

Stein *et al*. considered fourteen individual events across eight stormwater in-river mass emission sites for nine storms occurring between February 2001 and February 2004. In-river mass emission sites are engineered flood control open channels or highly modified rivers that integrate runoff from all the land use types in their contributing watersheds. The in-river mass emission sites considered by Stein *et al*. included both developed and undeveloped land use sites in the arid greater Los Angeles, California region. In addition, 15 homogeneous land use sites were considered. Homogeneous land use categories considered by Stein *et al*. included high-density residential, low-density residential, commercial, industrial, agricultural, recreational, and transportation. Unlike the sites considered by Stein *et al*., the Canal's drainage area does not include in-river mass emission sites nor does it include undeveloped areas. The Canal's drainage area is largely commercial/industrial and does not include all of the land use categories considered by Stein *et al.* More importantly, unlike the sites considered by Stein *et al.*, the

[19] EPA, 1995. *Combined Sewer Overflows Guidance for Long Term Control Plan*, EPA/823-B-95-002, August 1995.
[20] EPA, 1999. *Combined Sewer Overflows Guidance for Monitoring and Modeling*, EPA/823-B-99-002, January 1999.

Canal is not in an arid region and the surrounding impervious surfaces do not accumulate large quantities of wind-blown dust, unlike the areas around Los Angeles.

The Los Angeles drainage area considered by Stein *et al.* is commonly known to be a "closed" basin subject to frequent smog, since it is surrounded by a series of mountain ranges and hills. Many of these mountains reach 10,000 feet in elevation. The hills and mountains create steep slopes and therefore generate high energy in water flowing over land to the in-river mass emission sites sampled by Stein *et al.* The high energy in overland flow has implications for mobilizing particles from the land surface and would be expected to increase particulate phase transport and associated contaminant concentrations in Los Angeles area stormwater, especially during the "first flush." The hills and mountains surrounding the Los Angeles area also have the effect of constraining aerial transport of contaminants in the atmosphere, which is particularly important for PAHs since the dominant source identified by Stein *et al*. is automobile and other vehicle emissions. In direct contrast, the drainage area of the Canal is not enclosed by hills and mountain ranges. Accordingly, unlike the drainage areas considered by Stein *et al.*, the drainage area of the Canal does not have extremely steep slopes, nor does the Canal drainage area experience any buffering or constraining of regional aerial transport of contaminants in the atmosphere. As a result CSO solids discharged to the Canal have shown relatively low variability in contaminant concentrations per unit mass of solids, typically less than $\pm$ 50 percent variability.

3) **The patterns of precipitation in the areas studied by Stein et al. (2006) are intrinsically different from those associated with the Canal, resulting in significant differences in chemical composition and concentration in Los Angeles storm water discharges relative to Canal CSO discharges**

According to Stein *et al.:*

> "The discharge of PAHs from urban watersheds is exacerbated in arid regions. … Moreover, the long antecedent periods without rain in arid regions potentially enhance the dry deposition of PAHs to urban landscapes from these atmospheric sources. When rainfall does occur, the precipitation is often short but intense. Storm flows in urban watersheds from the Los Angeles region can range from 0.5 cubic meters per second (cms) to 1,000 cms in less than 1h. Runoff from these largely impervious urban surfaces efficiently mobilizes deposited material, including PAHs, in the resulting surface runoff."

Not only were Stein *et al.* considering stormwater in an arid region (*i.e.*, just 10 to 12 precipitation events annually), but the PAH measurements in Stein *et al.* are also biased by early rainy-season storm events which emit more PAHs than later-season storm events. The bias is the result of a seasonal flushing of the land that occurs in the Los Angeles area, presumably due to the build-up of aerosol deposition on land surfaces over the dry season. Antecedent conditions for the storm events sampled by Stein *et al.* ranged from 2 to 142 days without measurable rain. As indicated by Stein *et al.*:

> "Antecedent dry period (expressed as cumulative rainfall) was strongly correlated with total PAH concentration, load, and flux in an exponentially nonlinear manner. Early-season storms have significantly higher PAH loads than late-season storms both within and between watersheds, even when rainfall quantity is similar."

For CSOs in the Canal drainage area, there is no evidence of a seasonal flush or bias and an antecedent dry period as long as 142 days would not be expected for any Canal CSO outfalls.

4) **The Stein *et al.* 2006 study has little relevance to the Canal and should not be used to support remedial decisions with regard to the Superfund site; rather, sufficiently representative site-specific measurements are needed.**

In conjunction with the City's concerns over the incorrect application of Stein *et al.* study to the Canal, the City contacted the author for his opinion. The letter from the author is provided as a separate attachment to the City's comments. *See* Appendix B. In his letter, the author confirms that his study results cannot be extrapolated to the Canal study area without substantial additional data related directly to the Canal. Therefore his study is inapplicable to the Canal.

For all of these reasons (*i.e.*, collection system, drainage area, precipitation, and PAH compound differences), the work of Stein *et al.* (2006) should not be used as the technical basis for drawing any conclusions about Canal CSOs. Rather, a statistically significant number of measurements of the discharge of Canal CSO effluent over the course of a representative number of storm events would be appropriate for determining if time-dependent phenomena, such as "first flush", are occurring. The extensive set of Canal CSO discharge measurements do not show the existence of such a phenomena and in fact show a narrow range of contaminant concentrations on CSO solids (most values fall within $\pm$ 50 percent of the mean concentration per unit mass of solids). Such Canal-specific measurements must be considered by EPA before drawing conclusions regarding the purported "first flush" from CSOs.

NYC Comment 10 Inquiries

Given these observations, the City requests that EPA respond to the following:

- Since the Stein *et al*. work clearly does not apply to Gowanus conditions, what other basis does the EPA have to supports its assertions and conclusions concerning "first flush" including the proposed sizes of in-line CSO retention tanks, or the initial tipping flow from CSOs?

- How can EPA reconcile the PAH patterns of the surface sediments of the Upper Canal with those observed in CSO discharges since they are distinctly different from each other and unlike the patterns measured by Stein *et al*.?

- What is EPA's response to the concerns expressed in Dr. Stein's letter, annexed as Appendix B?

NYC Comment 11: The proposed remedy is based on inadequate information and lacks scientific support.

1) Lack of a reliable CSM will result in a high risk of failure of remedial actions.

a. By deferring critical analyses to the remedial design stage, EPA has based its remedy selection on inaccurate and incomplete information, ultimately leading to proposal of a suboptimal alternative with a high risk of failure.

The intent of the RI/FS process is to conduct a thorough site-specific investigation to establish the nature and extent of contaminants that pose a risk to human health and/or the environment, and then to develop and evaluate potential alternatives for addressing the risk. The RI/FS does not meet this standard and is missing key components critical to the selection of an effective remedy for the Canal. The FS acknowledges a number of these significant data gaps in the Executive Summary (p. vii). At a minimum, the following data gaps exist:

- No groundwater model was prepared for the watershed. The lack of a groundwater model means that no contaminant fate and transport/particle tracking assessment of groundwater impacts from contaminated upland sites was prepared nor an assessment of the potential impacts on water quality from the upland sites; no evaluation was prepared on potential impacts to groundwater elevations from installing sheet pile walls around the majority of the Canal, disrupting normal groundwater flow patterns; no assessment was prepared on the effectiveness of the cap and ISS layer in controlling the upward flow of NAPL from contaminated groundwater under the Canal; and no assessment was prepared on the impact to groundwater elevations by installing a barrier to groundwater flow (*i.e.*, the ISS layer) in the Canal.

- No hydrodynamic model of the Canal was prepared. The lack of a hydrodynamic model of flow in the Canal means that there was no evaluation of the impact of the Flushing Tunnel (following the resumption of pumping) on the flow, sediment deposits, or water quality in the Canal; no evaluation was prepared on the impact to flow and scour rates in the Canal during construction from the dredge cell sheet pile walls (when the treatment cells are in place); and no evaluation was prepared on the armor design using flows from the Flushing Tunnel following the resumption of pumping.

- No geotechnical evaluation of conditions in the Canal was prepared. The lack of geotechnical information means that no evaluation of the design assumptions used in the conceptual design of the sheet pile walls (either as reinforcement for the failing bulkheads or for contaminant around the dredge cells) was performed; no assessment was prepared on the strength of the native sediments and the ability to support a soil cap or ISS layer; no assessment was prepared on the hydraulic conductivity of the sediments following capping and/or ISS and the impact on sediment stability; no assessment was prepared on the amount of consolidation or differential settlement in the cap/ISS layers and its impact on the overall effectiveness of the remedy; and no assessment was prepared on alternatives to ISS to stabilize the underlying sediments.

- No estimate was prepared on the flux rate of NAPL through the cap under current conditions, with a cap (sand or reactive media) by itself, or with a cap and ISS layer. No estimate was prepared on the expected effective life of the oleophilic

clay layer in containing NAPL or the estimated time until replacement will be required.

- No evaluation was performed on site-specific conditions at the proposed site for the near-shore confined disposal facility ("CDF"), to determine if the site was suitable for construction of a CDF.

- No waste characterization was conducted for treatment or disposal purposes.

The missing information is critical to evaluating the technical feasibility and constructability of the various components of the alternatives being evaluated in the RI/FS Addendum as well as in assessing the potential benefits and possible risks the technologies present. Without collecting the necessary data and performing the associated analyses, one can only guess at the implications of the planned actions. At a minimum, the lack of geotechnical data represents a serious flaw in EPA's analysis of potential alternatives. For example, without this data, the ability of the sediment to support the ISS and cap cannot be evaluated; the potential for release of NAPL from the sediment due to consolidation cannot be assessed; and the potential for differential settlement and its impact on the long-term effectiveness of the remedy cannot be evaluated. Overly optimistic assumptions about the likely outcomes can lead to the selection of inappropriate or potentially damaging systems that will exacerbate conditions in the area of the Canal not solve them.

b. EPA has not conducted an adequate technical evaluation of either the technical feasibility or implementability of disposing of sediment from RTA 3 through beneficial use or in a near-shore CDF in Gowanus Bay, with the likely result being offsite disposal in a landfill at a substantial increase in the cost compared to the estimated costs in the FS.

The Proposed Plan identifies two potential options for managing the approximately 280,000 cubic yards of sediment generated in Remediation Target Area ("RTA") 3 – either through beneficial use of the material as daily cover at a landfill or disposal in a near-shore CDF to be constructed in the Gowanus Bay area. Neither of these options was evaluated in any meaningful manner in the FS and it is unlikely that either approach could be implemented.

Beneficial Use: The availability of lightly contaminated material that could be used as landfill daily cover far exceeds the demand for the material and landfills can be very selective in choosing material for this purpose. Sediment from a highly contaminated environment such as the Canal is unlikely to be accepted at most facilities. Since daily cover takes up landfill capacity, a tipping fee is likely to be charged for the material – this cost was not included in the cost estimate.

Landfill daily cover is typically a high permeability granular material. EPA proposes to solidify/stabilize ("SS") the contaminated sediment with Portland cement or other pozzolanic material to prevent leaching of contaminants. No testing has been conducted to: 1) determine physical characteristics of the material following SS and whether it is suitable for its intended use; 2) verify mixing ratio; 3) evaluate potential interferences with contaminants in the sediment; or 4) determine hydraulic conductivity following treatment. The Canal sediment is heterogeneous and is likely to remain so following SS, making its suitability as daily cover suspect.

It is unlikely that any landfill site would commit to the use of the sediment as daily cover without extensive testing and evaluation of the final product. This type of evaluation has not been conducted. During the FS, no specific beneficial use sites were identified, no

material characterization (physical or chemical) was conducted, and no material specifications for daily cover as a beneficial use product were established.

CDF: The proposed location for the CDF is not identified in the Proposed Plan, although a location off Columbia Street is mentioned. A draft United States Army Corps of Engineers ("USACE") Technical Memorandum entitled *Gowanus Canal & Bay Navigation Analysis* (August 8, 2007) indicated that Mr. John Quadrozzi was considering developing a CDF at his industrial park at 685 Columbia Street in the Red Hook area (in the Henry Street Basin area). This site is adjacent to the Red Hook Recreational Area, a widely used public park with riparian access to the Henry Street Basin.

There is no information provided in the Proposed Plan or other documents that suggests any site evaluation work has been conducted to determine if the proposed site is suitable for construction of a CDF. At a minimum, the following analyses and studies need to be conducted to determine site suitability.

- Preliminary evaluation of soil stability, depth to bedrock, stability of bedrock, and groundwater flow.
- Bathymetric surveys of the site to assess site slope and potential obstructions.
- Evaluation of tidal impacts on contaminants in the CDF.
- Preliminary historical/archaeological investigation of the proposed area impacted by construction of the CDF. As was noted in the FS Addendum, there are a number of historical sites in the area.
- Material handling procedures of surficial materials removed during CDF construction. These materials are likely to require disposal in a CDF or confined aqueous disposal while the deeper, cleaner soils can go to the Historic Area Remediation Site.
- An Environmental Impact Statement would likely be required, adding one to two years (or more) to the project schedule.

The FS did not address any of these areas in even a peripheral manner, nor does it include the costs for conducting these studies in the cost estimates. Given the proposed location (Gowanus Bay), it is likely a limited number of sites would be available.

Construction of a CDF within Gowanus Bay presents a number of unresolved issues:

- The FS documents did not address the potential impacts of a CDF on the Bay or the surrounding property. No information is provided on the proposed end use of the CDF and its potential impacts on the surrounding land uses, such as traffic.
- The construction of a 10-acre CDF would result in the permanent loss of 10 acres of bay bottom requiring mitigation for the lost habitat at a 3:1 ratio, or 30 acres. The average cost for purchase of credits from a mitigation bank is currently approximately $700,000 per acre, or $21 million. This cost was not included in cost estimate for RTA 3.
- Removing approximately 10 acres of water surface in the Bay may increase channelization of flow within the Canal, exacerbating existing flooding problems.

- The proposed site of the Red Hook CDF is within 250-500 feet of the ball fields at Red Hook Park. The City is concerned about potential impacts from this CDF location on the park.

- The City possesses the riparian rights associated with the shorefront section of Red Hook Park along Henry Street Basin, which have been affirmed in several court rulings. *See, e.g.*, *City of New York v Gowanus Indus. Park, Inc.*, 65 A.D.3d 1071 (N.Y. App. Div. 2d Dep't 2009). Construction of the proposed Red Hook CDF includes filling a portion of Henry Street Basin, with private ownership of the filled land, thus expanding private property on the Brooklyn waterfront and substantially obstructing the City's riparian rights.

Opposition to the proposed construction of a CDF in the Gowanus Bay is likely, based on opposition to the construction of CDFs for contaminated sediment disposal at other sites in the area. Addressing these concerns is likely to increase project costs and lengthen the project schedule, none of which is discussed in the FS.

2) The lack of site specific data on geotechnical conditions and groundwater modeling in the Canal prevent a realistic assessment of bulkhead replacement requirements.

Sheet piling is proposed as a replacement for failing bulkheads around the majority of the Canal. According to Table 1 of the revised cost memorandum in the FS Addendum, in RTA 1 and 2, the costs are based on piles approximately 35 feet long, driven into the native sediment to a depth of 10 feet (including the 3 foot cap results in a total embedment of 13 feet). Slightly longer piles are used in RTA 3.

- A typical "rule of thumb" approach to estimating sheet pile design is that for every one foot of wall above the soil, two feet should be embedded in competent soil (*i.e.*, soil that is capable of supporting the design load of the sheet pile). The conceptual design in the FS inverts this ratio with one foot installed depth for two feet above the soil. No geotechnical calculations are provided to suggest that the system is capable of supporting the anticipated loads.

- No geotechnical investigations have been performed to assess whether the native sediment is even capable of supporting the proposed sheet pile wall (*i.e.*, is competent soil). The purpose of the proposed ISS layer is to strengthen the native sediment under the cap, which suggests that the native sediment is not competent, otherwise no ISS layer would be needed.

- No provisions have been made for controlling groundwater behind the wall and groundwater modeling has not been performed to assess the risk. The Canal serves as a major discharge point for area groundwater and cutting off the flow towards the Canal will result in increasing groundwater levels near the wall; the potential for contaminated groundwater to enter structures, basements, utility vaults, or other similar structures; changes in groundwater flow patterns in the area and the migration of the contaminant plume to new locations; unknown impacts to existing and proposed remediation systems in the area due to changing groundwater flow patterns; potential localized failure of the bulkhead; and other unintended consequences.

- The conceptual design assumes that the 3-foot capping layer will provide additional support to the wall. While this may be true in the long term, the critical

time for wall stability will be during excavation of the sediment when the cap will not be in place.

- The conceptual design does not consider the number of pipelines, utility crossings, and bridges in the Canal that will impact the ability to construct a bulkhead in the manner proposed.

- The conceptual design includes tiebacks to help stabilize the wall. There are a number of locations along the Canal where structures are located such that tiebacks cannot be installed. Given the lack of geotechnical sampling and analysis, the suitability of the upland soil for the use of tiebacks has not been confirmed, and the number and spacing of tiebacks has not been evaluated. Also, given the depth to groundwater in the area, it is not clear that tiebacks can be installed at a suitable depth to stabilize the wall without major excavation on adjacent properties.

- No information is provided as to whether installation would be land-based or water based.

    - If land-based, there are a number of locations where existing structures will impact access in portions of the site. In addition, it is not clear that the existing bulkheads and the material behind the bulkheads are strong enough to support the equipment loads necessary to construct a sheet pile wall. The ability of the upland soils to support the required equipment has not been assessed.

    - If water based, will equipment barges be able to access areas where sediment has accumulated to install the sheet piling. The FS repeatedly states that the reason to dredge portions of the Canal would be to allow access to the upper reaches – what assurances are there that the bulkheads can be installed without first removing the sediment, undermining the integrity of the existing bulkheads.

- The vibrations from sheet pile wall installation can destabilize or damage surrounding structures if constructed on soft materials.

- No evaluation was done assessing the potential impact of reducing the depth of dredging on the need to replace the bulkheads.

- The Proposed Plan refers to a historical and archaeological study conducted as part of the FS. (*See* Proposed Plan, p. 7.) One of the recommendations of the study was removal or stabilization of the timber cribwork bulkheads with documentation of sample bulkheads and potentially mitigation of the adverse effects of remediation. The Proposed Plan also states the following:

> "Where new bulkhead construction is required, bulkhead configurations that are in keeping with the historic character of the setting should be considered." *See* Proposed Plan, p. 8.

Sheet pile bulkheads are hardly in keeping with the historic character of the setting.

3) EPA proposes installing temporary sheet piling around dredge cells to contain contaminants disturbed by remediation activities. The lack of technical analysis in the FS raises serious questions about the effectiveness of these units.

The conceptual design calls for the construction of treatment cells by installing sheet pile walls within the Canal, to isolate areas during sediment removal, ISS (Alternative 7 only), capping, and water treatment.

- Not enough information is provided to effectively evaluate the conceptual design approach presented in Table 1 of the FS Addendum (*see* Technical memorandum – *Revised Cost Estimates for Preferred Remedial Alternatives*). If the piling length is similar to that used for the bulkheads (35 feet in RTAs 1 and 2), and the piling is embedded to a depth of 25 feet, the wall will extend approximately 10 feet above the native sediments; if the piling is embedded to a depth of 15 feet, then the piling will extend approximately 20 feet above the native sediment. (Note: these depths are based on the pricing information backup and were not described in the FS.) No stability evaluation has been prepared on the construction of the sheet pile walls for the treatment cells. As noted previously, the proposed sheet pile wall approach presented for the bulkheads inverts the standard rule of thumb for sheet pile walls and is unclear what the proposed approach will be for the treatment cells. In addition, there are numerous references in the FS regarding the low strength of the native deposits suggesting that this material may not be able to sustain the walls.

- The impact of flows from the Flushing Tunnel on the stability of the treatment cell wells has not been evaluated. No consideration has been given to the rerouting of the Flushing Tunnel around the treatment cells when working in RTA 1.

- A hydrodynamic model will be required to evaluate the potential impacts to flow within the Canal due to the construction of the treatment cells. In essence the cells will cut the width of the Canal by half, which will increase the flow rate and scour in the remaining Canal width. This will be of particular concern immediately downstream of the Flushing Tunnel. In addition, solids deposition may increase immediately upstream of the cell.

- No assessment was made on the impact to navigation in the Canal due to the installation of the treatment cells. In some locations, the width of the Canal will be reduced to less than 50 feet.

- As presented in Appendix E of the FS, the native sediment surface ranges from approximately -12 feet to -26 NAVD88 with an average depth of -19 feet NAVD88. Assuming a 35-foot pile, if embedded 25 feet into the native sediment, the piling will extend only 10 feet above the native sediments. Mean sea level is approximately 3 feet NAVD88, meaning that some of the treatment cells will be inundated the majority of the time. If the piling is embedded to a depth of 15 feet, on average, the piling will extend only 20 feet above native sediments. Approximately 42 percent of the sampling points showed that the top of the native sediments were at depths of -20 feet NAVD88 or greater, suggesting that a significant portion of the treatment cells in RTA 1 and 2 will be inundated during some portion of the tidal cycle eliminating much of the value of the walls.

- No consideration is given to pipelines, utilities, and bridges that will impact the sheet pile installation for the treatment cells.

4) EPA's ill-conceived approach to controlling contaminants during dredging and ISS operations in a treatment cell and dewatering the cell after cap installation will contaminate the cap materials during placement.

The conceptual design calls for pumping two volumes of water out of the treatment cell following dredging and cap placement with the water to be treated and discharged back to the Canal. There are several basic problems with this approach:

- This design assumes that dredge cell water would be removed ***after*** the cap is installed, meaning that the clean material used in the cap will be exposed to the contaminants (primarily NAPL) in the water column, contaminating the cap material and defeating a major purposed of the dredge cell water treatment.

- The section on the treatment cell design states:

> "Sheet piling would be used to contain turbidity and NAPL release during remedial activities but would not be designed to withstand differential head pressures created by lowering water within the cell (except for up to 5 feet differential due to tidal fluctuation). Sheet pile wall joints would not need to be completely water tight because no significant pressure differential would exist." *See* FS Addendum, Table 1, p. 4.

No stability assessment was performed on the ability of the sheet pile walls to withstand the pressure differential that would develop as water was pumped from cell. No evaluation was provided as to the effect of pumping at 750 gallons per minute ("gpm") in a confined area on the cap stability. Because the sheet pile walls will not be watertight, it is anticipated that a significant volume of the water removed from the cell will be replaced by water flowing through the sheet pile wall - no evaluation was provided or discussion on methods that would be used to prevent short circuiting during pumping.

5) Potential remedial alternatives cannot be effectively identified or evaluated based on available information.

a. Initial alternative identification and evaluation arbitrarily eliminated possible alternatives. For example, partial removal of sediment is a viable remediation alternative at a substantial savings as compared to full depth sediment removal but was not adequately evaluated during the FS process.

EPA provided very little analysis or technical justification for the elimination of the partial sediment removal alternatives (Alternatives 2 and 3) before any technical analyses were conducted. The reasoning included in Table 4-2 of the FS is vague, unsubstantiated, and inconsistent with remediation activities at other CERCLA sites. Other unsubstantiated assumptions were used to eliminate alternatives that conflicted with the presumed remedy.

i. <u>Untreated waste is left in the canal (Alternatives 2 and 3).</u>

While the preference under CERCLA is for the removal of untreated waste, this is not an absolute condition in assessing the viability of an alternative, particularly if the remaining

material can be successfully contained. Greater consideration should have been given to the partial dredging options.

ii. An armored sand cap may not be sufficient to control long term flux of contaminants (Alternative 2).

No evaluation of the anticipated flux rate of NAPL contaminants from underlying sediments was provided and no estimate was made of the required depth of the sand layer that would be necessary to provide adequate protection. Until this analysis has been completed incorporating site-specific alternatives, it is premature to eliminate a sand cap alternative.

iii. Numerous technical challenges are associated with successfully capping very soft sediments (Alternatives 2 and 3).

Capping of contaminated sediment has been successfully performed at a number of CERCLA sites as discussed in several EPA documents. No data was collected and no geotechnical evaluations were performed to assess the strength of the soft sediment and its ability to support a cap. No consideration was given to the variety of cap construction procedures that could be used to place the capping material. No consideration was given to alternatives to strengthen the underlying material to allow cap placement. While additional evaluation may have reached the conclusion that capping is impracticable, this evaluation needs to take place based on site-specific conditions.

iv. Future uses of the canal would be restricted to a greater degree by depth limitations (Alternatives 2 and 3).

The only federally authorized navigational channel is located south of Hamilton Ave. Minimal dredging would be required to maintain the authorized navigation depth. In RTAs 1 and 2, there is no navigation channel established and limited justification has been provided for the need to dredge the full depth of the soft sediment. According to a draft of a USACE memo on shipping in the Canal, limited beam at bridges poses as much of a restriction to the commercial use of the Canal as the draft. In addition, there appears to be some question as to the long term development plans for the upper reaches of the Canal, so it appears premature to extend the termination point of the navigation channel.

Although not included in Table 4-2, the justification for eliminating Alternatives 2, 3 and 4 cited in the FS text is based on the following:

> "The physical characteristics of the soft sediments in the canal suggest that they may have insufficient load bearing capacity to support a cap or could be destabilized by the uneven placement of cap material. Capping over these could destabilize any NAPL present in the soft sediments." *See* FS, p. 4-13.

This conclusion was based on very limited physical testing (grain size, bulk density) and no geotechnical analyses. EPA has based its design for the Canal on unproven assumptions that have not been confirmed by site data or analyses.

b. EPA's selection of two essentially identical alternatives for detailed evaluation represents an unwillingness to consider alternatives to site remediation that do not conform to a narrow view of possible solutions.

Two alternatives were selected for detailed evaluated (Alternatives 5 and 7). These alternatives were ranked essentially the same in the FS with the only difference being the presence or absence of the ISS layer in Alternative 7. Except for the cost of the ISS layer, the construction costs were essentially the same for the two alternatives. The Proposed Plan identifies Alternative 7 as the selected remedy for RTAs 1 and 2 because of the supposed (albeit unproven) benefits of the ISS layer. No technical justification or supporting calculations are provided.

This raises several questions and concerns regarding use of the ISS layer and its value in the design:

- If the ISS layer is a critical component of the selected remedy, its technical feasibility (constructability, effectiveness, benefits, risks) should have been assessed during the FS stage. No alternatives to the ISS layer are discussed in the FS in the event that testing does not support the use of ISS.

- If the ISS layer controls the upward migration of contaminants, as suggested in the FS, the need for a reactive layer as part of the cap is not clear – if ISS is effective, only a sand cap may be required to control the flux. However the conceptual design in the FS includes the same capping components for both Alternative 5 and 7.

- If the ISS layer stabilizes the native sediment as claimed in the FS, the cost of cap construction for Alternative 7 should be lower than for Alternative 5. However, the same construction costs are used for cap construction for both alternatives.

The volume and type of capping material are the same for both Alternative 5 and 7, and the two alternatives were ranked the same in the FS screening matrix, suggesting that there is no discernible added environmental benefit to the use of ISS in controlling the release of NAPL to the Canal. This appears contrary to Appendix A of the FS, which stated that ISS would lower the hydraulic conductivity and homogenize NAPL concentrations, both reducing the rate of flux into the cap and stabilizing the sediment. If so, it would suggest that under Alternative 7, the reactive capping requirements could be reduced or eliminated and construction costs would be reduced.

Use of ISS in the proposed remedy adds approximately $20M to the project costs with no apparent savings in other areas and no documentation as to its effectiveness. In Table ES-1, the FS acknowledges that ISS is unproven, stating “if ISS is implementable and effective.” If testing does not verify the technical feasibility and implementability, the default position appears to be to construct the cap without the ISS layer, suggesting that the ISS layer is not critical to the success of the remedy. But if it is technically feasible to construct the cap itself without the ISS layer (*i.e.*, Alternative 5) at roughly the same cost as with the ISS (*i.e.*, Alternative 7), and there are no proven environmental benefits then the value of including ISS in the selected remedy is suspect.

EPA needs to evaluate the technical feasibility of the use of ISS in this setting prior to its inclusion in the proposed remedy. This should include a combination of laboratory and field tests in a marine environment similar to the Canal. Standards for evaluating the results of the testing need to be established based on anticipated outcomes and acceptable performance. Verification that the results can be scaled up to full scale implementation needs to be documented by real world pilot testing.

Capping of sediments has been used as a remedy at numerous contaminated sediment sites and additional documentation (*e.g.* geotechnical evaluation of native sediments) should be provided as to why this approach alone is not applicable in this setting. If testing shows that some support is necessary to maintain the integrity of the cap in this setting, alternatives to ISS that may be more cost-effective than ISS should also be evaluated (*e.g.*, geogrids).

c. Dredging to the proposed depths outlined in the Proposed Plan will negatively impact dissolved oxygen concentrations in the Canal and will reduce the benefits of DEP's NYSDEC-approved Gowanus Canal Waterbody Watershed Facility Plan ("WWFP").

Dredging the Upper Canal to the proposed depths would increase the cross-sectional area of the Canal through which water must pass. This would decrease the amount of flushing that could be achieved in the Upper Canal from the Flushing Tunnel, thus increasing the residence time of pollutants in this area. As a result, organic pollutants within the Upper Canal would undergo oxidation for a longer time period, stressing dissolved oxygen concentrations beyond that planned in DEP's "WWFP".

In addition, dredging the Canal to the proposed depths would decrease the surface area-to-volume ratio, effectively reducing the ability of naturally-occurring processes, such as surface re-aeration, to replace the oxygen consumed by dissolved organic materials and/or organic matter decaying within the sediment.

The City has used the water quality model developed during the preparation of the WWFP to calculate the impacts of the proposed dredging action on Canal dissolved oxygen concentrations. The results of these analyses are provided in Figure 11-1, which supports the following conclusions:

- **Bottom Dissolved Oxygen Concentrations** – The minimum bottom layer dissolved oxygen concentration in the Canal is projected to be reduced by about 0.5 mg/L by dredging the Canal, as planned by EPA. Additionally, Figure 11-1 shows that the minimum dissolved oxygen concentration is projected to be never less than 3.0 mg/L, although it is very close in large sections of the Canal. Nevertheless, achievement of the current DEC Class SD dissolved oxygen criteria would be expected under average conditions.

- **Compliance with Dissolved Oxygen Standards** – For the design year, compliance with the current applicable Interstate Environmental Commission ("IEC") dissolved oxygen standard of 4 mg/L would be reduced about 5 percentage points. DEC has been considering upgrading the water quality classification of Gowanus Canal to Class I, which would also require a dissolved oxygen concentration of no less than 4 mg/L. The proposed dredging would further reduce compliance with the DEC's potential upgrade of the water quality classification.

In summary, the City believes that the extent of dredging proposed by EPA and the resulting water depths would prove detrimental from a dissolved oxygen standpoint, substantially reducing some of the benefits attained by the WWFP. In essence, the dredging activity would counteract the water quality benefits of DEP's current $150 million investment of rehabilitating the Gowanus Pumping Station and Flushing Tunnel.

6) The extent of the sediment removal program appears intended to fulfill other non-remediation objectives.

a. EPA has arbitrarily proposed the excavation of soil and sediment in the former 1st Street Turning Basin at a cost in excess of $20 million, based on very limited data, no evaluation of alternatives, and unrealistic cost estimates.

In the FS (*see* Appendix B, Technical Memo), EPA screened upland sites and identified seven sites that presented NAPL risks to the Canal, five of which are already in DEC-supervised remediation programs. In the FS Addendum (*see* Technical Memorandum-*Supplemental Evaluation of Upland Site*), based on the same screening process, 16 upland sites with potential water quality impacts were identified. Of these 16 sites, the former 1st Street Turning Basin was the only upland site identified proposed for remediation under CERCLA; the other upland sites have either been referred to DEC for future action, or their regulatory status is unclear based on the information provided.

The former 5th Street Basin was another of the 16 sites identified in the FS Addendum and ranked similarly to the former 1st Street Basin. The basin was filled during the same period as the former 1st Street Basin and has a number of similarities. No information is provided in the FS Addendum on the proposed plans for this basin; it was not listed as having been referred to DEC for remediation and it has not been proposed for remediation under CERCLA.

EPA based its decision to excavate the former 1st Street Basin on the analytical results of one groundwater sample collected in MW-27i with a score in excess of 100 (a limit set by EPA based on an undocumented standard) even though:

- The sample from MW-27s (*i.e.*, a sample from the same location but at a shallower depth) was ranked as "no risk";
- Groundwater sampling results from samples taken from MW-26s and MW-26i, also located within the limits of the former basin (approximately 75 feet from MW-27), were ranked as "no risk"'
- Groundwater sampling results from samples taken from MW-25s and MW-25i (located approximately 190 feet from MW-27), were ranked as "no risk." The boring log results (*see* RI Appendix D) suggest that MW-25s/i was filled at the same time as the former basin area using similar material and therefore may have been located within the limits of the basin;
- No additional investigation of the site was conducted or has been proposed to verify the nature and extent of the contamination in the former basin;
- No alternatives to excavation were identified or evaluated if remediation were determined to be necessary; and
- There is no indication that the current property owners were contacted regarding the proposed remediation activities and offered an opportunity to participate in the process.

The cost estimate prepared for the excavation significantly underestimates the remediation costs:

- The design costs are low given the complexity of the work involved.

- There are no provisions for any additional investigations of the site – it appears that EPA is planning a $20 million remediation program based on one sampling point.

- There are no costs included for geotechnical analyses required for the design of the replacement bulkheads.

- A number of costs were not addressed as part of the cost estimate, including the purchase of the land encompassing the basin.

- The former basin area is landlocked and for the construction of a proposed public access for a boat launch as mentioned in the FS Addendum, it would be necessary to purchase additional land to allow street access.

- The costs included for a permanent bulkhead around the perimeter of the basin are based on similar assumptions as the replacement bulkheads elsewhere on the Canal. As noted previously, this design is unlikely to be stable.

- As noted previously, productivity rates for the project are too high based on the limited site access in the Canal. This will be a particular issue in the former basin area where there are structures on either side of the basin and all material must be hauled to the Canal end for removal. This is likely to entail double- or triple-handling material, slowing the work and increasing the costs.

- The dredge cell dewatering costs do not include additional equipment rental time, only additional chemicals. As noted in NYC Comment 12, the dewatering schedule assumes full capacity is required to dewater the treatment cells leaving no additional time for dewatering the 1st Street Basin.

- In general, site access restrictions will increase time and costs.

- Site restoration costs are low. Given site restrictions, it will be necessary to stage some of the work on the adjacent property. These areas will need to be decontaminated and restored as part of the remediation process.

7) By its actions, EPA is proposing expansion of the existing navigation channel into the middle and upper reaches of the Canal as justification for removal of the entire soft sediment in the Canal. This expansion is not justified by current and projected navigational patterns on the Canal.

Alternatives 5 and 7 were developed based on an apparently preconceived need for a deep channel throughout the length of Canal, even though this need is not supported by current use patterns. According to information in the FS (*see* Section 1.2.2, p. 1-4), there are no federal, state, or local requirements to maintain a navigation channel of any particular depth above Hamilton Ave. Between Hamilton Ave and Sigourney Street, the federally authorized channel depth is -21 feet NAVD88; between Sigourney Street and the south end of the study area, the federally authorized depth is -33 feet NAVD88.

In the FS, EPA cites a 2007 memo, based on a 2006 study prepared by the USACE, on navigation in the Canal. (Note: only an early draft of this memo was available to the City.) Given the critical design assumptions that were made based on the information in this document, this memo needs to be provided to the City. The draft memo indicated that primary commercial usage is located south of 9th Street with no commercial navigation north of 4th Street.

- One commercial operation was located north of the 9Th Street Bridge – Ferrara Brothers; other uses were primarily recreational craft and environmental groups monitoring conditions in the Canal.

- Bridges north of 9th Street were opened less than 30 times per year.

- There has been a declining trend in vessel trips in the Canal between 1985 and 2005 with a more than 50 percent decrease in the use of the Canal even during a period when industrial activity and jobs in the area were increasing.

- The typical draft of vessels using the channel was 34 feet until 2000, since then it has generally been less than 30 feet. The typical draft of vessels in the Canal since 1990 has been 13 to 14 feet or less, consisting mostly of tug/tow barges.

- The volume of material shipped through the Canal has been on a downward trend for the last 20 years.

- While the depth of sediment in the Canal has had an impact on the size of vessels using the Canal according to some users, the allowable beam is as much a controlling factor as draft in the use of the Canal for commerce. There is a 45 foot beam limitation with economical payloads. (Note: this information was included in the draft memo available to the City but needs to be confirmed based on the final memo cited in the FS but not provided to the City).

The FS presupposes that removal of the entire column of the soft sediment is required to maintain navigation (*see* Section 2.4.3). This is based on a number of flawed assumptions:

- While maintaining navigation may be important, it is neither a legal nor regulatory requirement north of the Hamilton Ave Bridge. The Canal no longer serves as the means of transport for industries along the Canal. Bridges play a significant role in restricting the commercial use of the Canal.

- While the zoning along the Canal itself consists mostly of manufacturing districts, allowing a variety of commercial and industrial uses, there is also zoning that permits residential development. Additionally, longstanding residential districts are mapped in very close proximity to the Canal. Scattered throughout the manufacturing zoning districts are also long existing, non-conforming residential uses. Based on the historical development of the neighborhood, there are no clear functional boundaries between industrial and residential areas. The long-term development of the area as an industrial area using the Canal for large scale shipping is not supported by current land use.

- The data on the depth of the sediment in the Canal was collected along the shorelines where slow velocities would encourage settlement of solids (*see* FS Figure 3-8a-h) thereby overestimating the depth of the soft sediment in the navigational channel; no samples were collected in the navigational channel (down the center of the Canal). In fact, the bathymetric survey results (*see* FS Figure 3-1 c) for RTA 3B suggest that the depth in the channel meets the authorized depth; for RTA 3A, the depth appears to meet the navigation channel depth for the majority of the channel.

- For both RTA 3a and RTA 3b, to meet the required depth for the navigation channel, only limited dredging is required. The current plan to remove all of the

soft sediment is unnecessary to meet navigational requirements, even with allowances for a soil cap. Some dredging of individual slips may be necessary to provide deep water access.

- For RTA 2, EPA is proposing to remove all soft sediment, not only in the navigation channel but from all of the turning basins. In addition, it is proposed that the native sediment underlying the soft sediment be removed to create a **new** navigation channel with a depth of -16 feet NAVD88. Local businesses currently navigate the Canal without a maintained navigation channel. Across much of this area, the average depth of the top of the soft sediment layer is -5 to -10 feet NAVD88 (as noted above, this was measured along the shoreline and does not necessarily reflect conditions in the center of the Canal). By this action, EPA is proposing to create a navigational channel where one has not existed in the past, and which will require maintenance in the future to ensure its continued use.

- As for the need to remove all sediment in RTA 1, no justification has been provided. The City has proposed maintenance dredging of the upper 800 feet of the Canal such that the top of the cap would be 3 feet below mean lower low water at all times. This will allow recreational boating (which has a limited draft) in the upper reach of the Canal and equipment access for maintenance of the waterway. Because the width of the Canal is only 100 feet in this area, if equipment cannot access the area from the water, land-based equipment can be used for maintenance purposes if necessary.

The proposed removal of all soft sediment from the waterway has no justification based on the need to provide navigational access for the entire length of the Canal, either from a legal or regulatory requirement. From a practical standpoint, where feasible, navigation should be maintained for businesses operating in the area. However, the creation and maintenance of a 16 foot navigation channel for the entire length of the Canal is neither necessary nor warranted by the current and anticipated usage of the waterway. The FS cites two technical memoranda by the USACE to justify the navigation channel in the middle reach of the Canal. These documents are not available online and have not been made available to the City. An early draft of one of the memos does not appear to support such a wide-ranging extension of the navigation channel based on historical usage of the Canal for shipping. Will EPA make these documents available to provided full disclosure on the results of the analyses?

EPA needs to provide greater justification for the need to remove all soft sediment from the waterway along with economic justification for maintenance of a 16 foot navigational channel north of Hamilton Ave.

NYC Comment 11 Inquiries

In addition to the observations above, the City requests that EPA respond to the following:

- To finalize the FS in a technically supportable manner, the studies listed in Comment 11(1)(a) need to be completed **before** alternatives are identified and evaluated. These studies include, but are not limited to, groundwater modeling of the Canal watershed, hydrodynamic modeling of the Canal (including an assessment of the impact of the Flushing Tunnel once it is operable again), and geotechnical investigations of site conditions both in sediments underlying the Canal and in the immediately surrounding upland areas. Once this information is available, alternatives can be identified and appropriately evaluated. The current

FS screening process relied heavily on conjecture and assumptions about site specific conditions and their impact. In evaluating the technical feasibility and implementability of alternatives during the FS process, site specific information needs to be included in the process. This was not done in evaluating either of the alternatives selected for disposal of sediment from RTA3 – beneficial use or a CDF.

- No information was provided on the demand for daily cover at area landfills or the material specifications that would have to be met for its use.

- No testing was performed on the material to determine the chemical and geotechnical properties of the material following SS to verify that it can meet the required material specifications once stabilized.

- No information was provided on the proposed location, its suitability for construction of a CDF, the impacts of the site on the surrounding land use, on the Bay or Canal. No site specific studies were conducted to assess the technical feasibility of the site,

- Because of the lack of specificity in the proposed analysis of the CDF, stakeholders will not have an opportunity to provide meaningful input into the planning process.

- If, as appears likely, neither alternative can be implemented, the fall back will be off-site disposal of the material, increasing the project costs by approximately $35M.

- Both of the alternatives identified in the Proposed Plan were inadequately characterized and have substantial data gaps that need to be resolved before either can be selected.

- The implications of failure of a significant portion of the bulkheads along the Canal due to dredging operations can be catastrophic but are given little consideration in the FS.

- To realistically assess the **cost** and **technical feasibility** of installing a sheet pile bulkhead along the perimeter of the Canal, a geotechnical assessment of in-water and upland soil conditions is critical. This work has not been completed as part of the FS.

- To realistically assess the **impact** of installing a sheet pile bulkhead around the majority of the Canal, effectively cutting off much of the groundwater flow into the Canal, a groundwater model must be prepared. Without the model, the potential impact on groundwater flow patterns and contaminant transport cannot be evaluated; changes in upward migration of contaminants into the surface water cannot evaluated; and the effectiveness of the cap with or without an ISS layer cannot be evaluated.

- Site specific data on conditions in the Canal and a more complete analysis of the technical feasibility and implementability of the use of treatment cells is necessary in the FS. As currently conceived and presented in the FS, the use of treatment cells is unworkable: the system does not appear to be constructible; the length of the piling does not appear adequate to retain TSS with tidal variations in water levels; the impact of the Flushing Tunnel was not evaluated; the restriction in the

width of the Canal will increase scour and the movement of contaminated sediment; no consideration was given to other users of the Canal and their impact on operations; and no consideration was given to the impact of obstructions.

- The conceptual design presented in the FS does not consider any of the ramifications of high pumping rates in an enclosed area to dewater the treatment cells. This raises more questions as to the overall technical feasibility of the alternatives.

- As noted in NYC Comment 11(1)(a), there are significant data gaps in the FS. Only once this information is available can alternatives can be identified and appropriately evaluated. The current FS preliminary evaluation process relied heavily on conjectures and assumptions about site specific conditions and their impact on the technical feasibility and implementability of the various alternatives. Without geotechnical data and modeling results, these conclusions cannot be supported making the entire process suspect.

- The FS failed to evaluate the potential impacts of dredging alternatives on water quality. The failure to develop a hydrodynamic model of the Canal limited the ability of the EPA to effectively evaluate the impact of its proposed remedy on the Canal. The City's model of the Canal, developed as part of ongoing work to address conditions in the Canal, indicates that rather than improving conditions in the Canal dredging the Upper Canal to the depths proposed by EPA will have a detrimental impact on dissolved oxygen concentrations resulting in the inability to meet water quality standards for a SD-classified water.

- The detailed evaluation of the two "remaining" alternatives is not supported by technical data, calculations or systematic analysis. The need for the ISS layer was not evaluated in a meaningful manner in the FS, nor were alternatives to the ISS considered. To justify the inclusion of ISS in the recommended remedy, additional evaluation and testing is required. The lack of specific information on the technical feasibility and implementability of the ISS process makes its inclusion in the recommended remedy questionable.

- The remediation of the former 1st Street Basin is not supported by existing data, is impractical as currently conceived in the FS, and underestimates the project costs. Justification for this activity is weak and not consistent with the handling of other upland sites along the Canal. The decision to excavate the basin does not comply with any remedy selection requirements under CERCLA. Even if additional data supported the need to remediate the area, no alternatives to excavation were evaluated. There is no indication that property owners or neighboring landowners were contacted and offered an opportunity to participate in the process.

- The FS relies upon, and cites, two studies prepared by the USACE on the Canal. An early draft of one memo on navigation in the Canal was available for review but does not appear to support the conclusion presented in the FS. Studies conducted by the USACE on the Canal need to be made available the City for their review and comment if the information is being used to justify decisions on the proposed remedy.

- Expansion of the navigation channel beyond Hamilton Ave is not warranted based on available information. In addition, development along the Canal is in a state of flux and may not be compatible with the EPA's vision of the area. It is

important for the Proposed Plan to acknowledge the presence of residents, workers, and business patrons in close proximity to the Canal, and ensure that the remedy does not preclude the wide variety of activities that occur around the Canal.

NYC Comment 12: The cost estimates included in the FS Addendum and Proposed Plan grossly underestimate the likely project costs.

1) The dredging and sediment management costs consistently underestimate likely costs based on site-specific conditions

EPA has consistently underestimated the costs of implementing the proposed remedy. EPA has estimated that remediation costs will range from $350 to $454 million. Based on analyses by the City, the costs of implementing the proposed remedy are likely to be in a range that is twice those amounts, which is outside the acceptable tolerance for a CERCLA FS compared to the final remedy cost (*i.e.*, -30 to +50 percent). Insufficient site characterization and overly optimistic technical assumptions used to justify the design concepts have resulted in an underestimation of the probable costs for each of the alternatives.

The sections below address individual elements of the cost estimate where issues have been identified. In these paragraphs, "Table 1" refers to Table 1 in the FS Addendum (*see* Technical Memorandum – *Revised Cost Estimates for Preferred Remedial Alternatives*).

a. Institutional controls

Although Table 1 makes reference to institutional controls (maintaining fish advisory, protection of the cap and ISS layer, construction limitations within the Canal, bulkhead maintenance, and navigational dredging) no details are provided on the requirements of the controls and there is no cost estimate for the institutional controls. While some of these items will be relatively inexpensive, others – such as navigational dredging – could be significant, particularly if EPA is successful in extending the navigational channel to the head of the Canal.

b. Predesign sampling and testing

The cost estimate identifies a number of tests that will need to be conducted during the predesign investigation phase, including sediment treatability testing, waste characterization for disposal, and additional (unspecified) characterization for design. The FS assumed that all of these tests could be performed for a cost of $500,000 – ***including sample collection*** which is unrealistic. No information is provided on the number of samples to be collected, length of cores, analyses to be performed, or sampling costs, for example. No information is provided on the purpose of the geophysical testing. Geotechnical analysis is not included in the estimate, although this will be a major concern of the design process and geotechnical sample collection and analysis is substantially more expensive than for chemical analysis or treatability testing. Equipment mobilization/demobilization costs for the sample collection, bathymetry, and geophysical testing costs are not addressed in the estimate.

c. Remedial design

Remedial design costs are estimated at 4 percent of the remediation costs. Based on DEP's experience, typically, design costs range from 5 to 15 percent of the projects costs on environmental remediation projects. The estimated cost is at the low end of the scale for similar projects. According to Table 1, the remedial design budget is intended to cover the following tasks:

- Treatability studies for ex-situ treatment (including sample collection),
- Bulkhead inspection,
- Design phase activities,
- Contractor prequalification,
- Construction plans and specifications, and
- Bidding services.

The estimated cost for remedial design significantly underestimates the likely costs or does not cover the range of activities likely to be necessary.

d. Pre-remediation site work

The pre-remediation site work appears aimed at preparing the staging area, but has a number of costs that are unclear. Costs are included for constructing approximately 24,000 square yards of temporary access roads on a parcel of land near the mouth of the Canal. Given the area, the need for this amount of temporary roadwork is unclear. Streets in the area are already paved as well as many of the properties that may be available for use as a staging area. Approximately 2000 feet of temporary fencing is provided at a cost of $7.13 per linear foot (Means 01 56 26.50.0100). According to the RS Means reference number, this fencing is only six feet tall and can be installed with no equipment. Temporary fencing is typically installed in concrete supports so that it can be moved easily during construction; however, it provides little security for the job site. To allow docking at processing sites, either a temporary or permanent dock will need to be installed unless one is already available at the site. Temporary docking facilities cost upwards of $40,000 per month to rent, or almost $3 million over the life of the project.

e. Upgrading and restoration of bulkheads

Sheet piling is proposed as replacement bulkheads. According to Table 1, the costs are based on piles approximately 35 feet long, driven into the native sediment to a depth of 10 feet with a 3 foot cap (13 feet of total embedment, 22 feet above soil). Based on typical design standards, the length of embedment should be twice the amount above soil, or approximately 44 feet. This standard increases the required length of the pile to approximately 60 feet, or almost twice the current design length, adding $28 million to the sheet piling installation cost−assuming the unit price stays the same, which is unlikely. This estimate also assumes that the native sediment is competent soil.

In pricing sheet piling, no consideration was given to site access, soil stability behind the existing bulkhead, obstructions (pipeline, utilities, bridges), site restoration, or the vibration impact on adjacent older structures from driving pile. Debris removal costs were significantly underestimated based on the linear feet of bulkhead requiring replacement and information on the volume of debris as described in several reports. The cost for the crushed rock (Means 32 11 23.23.1513) placed behind the bulkhead is based on the placement of crushed rock in a large open area such as a roadway or parking lot where large equipment can quickly place and spread the material. This will not be the case in the bulkhead repair work. Smaller equipment will be required to access the site operating around numerous obstructions at each site. In addition, there is no cost estimate for processing/decontaminating or disposing of debris removed from the Canal. Compliance

with the historical and archaeological study recommendations referenced in the Proposed Plan (*see* Proposed Plan, p. 7) would further increase sheet piling costs.

f. Installation / removal of sheet pile cells

The conceptual design calls for the construction of the treatment cells using sheet pile walls within the Canal, to isolate areas during sediment removal, ISS (Alternative 7 only) capping, and water treatment.

- The estimate assumes approximately 15,000 square feet of sheet pile will be purchased and installed at a cost of $39.53 per square feet (ref: RS Means 31 41 16.10.1800). The material will then be extracted and reinstalled several times at a cost of $17.15 per square feet (ref: RS Means 31 41 16.10.1300). According to the RS Means references provided, the cost for the initial installation is based on material being driven to a depth of 25 feet and left in place; the cost for the reinstallation is based on the cost to drive the pile to a depth of 15 feet and then removed and salvaged (*i.e.*, sold for reuse). No information is provided on the planned depth of installation but the permanent bulkheads were embedded to a depth of 10 to 15 feet. These costs are inconsistent with the design concepts presented in the FS for the treatment cells.

- The per-square-foot cost for sheet pile wall installation is roughly 2/3 the cost for the sheet pile installed as the replacement bulkhead. No explanation is provided for the reduced cost for the treatment cells.

- There is no cost estimate for debris removal in the middle of the Canal prior to sheet pile wall installation, nor for processing/decontaminating or disposing of debris removed from the Canal.

g. Sediment removal

Sediment removal costs are based on a production rate of 800 to 1000 cubic yards per day. In May 2012, DEP, as part of its Consent Order with DEC, contracted with a consulting firm to prepare a Basis of Design report (BODR) for dredging the upper 825 feet of the Canal to a depth approximately five feet below mean lower low water. As part of the BODR, a cost estimate was prepared for the work. While preparing this estimate, dredging firms operating in similar canals in the City were contacted regarding equipment requirements and dredging production rates. Based on this information a maximum production rate of 45 cubic yards per hour, and approximately 30 percent down time (*i.e.*, during a 12- hour work day, approximately 8 hours of dredging could be performed) was estimated. The productivity and work schedule is due to the limited space available in the Canal for equipment storage and maneuvering, traffic restrictions based on bridge opening limitations (schedule and heights), and other obstructions in the waterway. This design did not include the use of treatment cells, as proposed in the FS, which would further restrict and slow operations. Based on the BODR, the maximum production rate that should be used in estimating the production schedule is approximately 360 cubic yards per day, or less than half the rate assumed in the FS and FS Addendum. This production rate could be even lower if consideration is given to the constraints imposed by use of the treatment cells (*e.g.*, double handling, increased traffic restrictions in the Canal).

The FS assumed that dredging operations would be performed 7 days per week, 12 hours per day. As noted previously, this does not include down times for equipment movement

or other inefficiencies from operating in a confined spaced like the Canal and does not reflect likely local opposition to the proposed 7-day per week operations. For planning purposes, a more realistic assumption in the production schedule would be 5 days per week, 12 hours per day.

No cost is provided for management (processing, decontamination if appropriate, transport or disposal) of debris removed from the Canal.

Based on a lower production rate, the dredging schedule would increase from approximately 25 months to approximately 75 months, adding a minimum of $10 to $15 million to the project cost. Debris processing and disposal costs would be in addition to this amount.

h. ISS (Alternative 7 only)

- Table 1 indicates that the "*remaining native sediment in targeted areas*" would be treated. Later in the same section, it is noted that "*[r]eagents would be delivered to a depth of 5 feet below the dredge surface.*" Numerous figures in the RI and FS show that native sediments are believed to extend to a depth of more than 40 feet below ground surface (bgs). It is not clear how injecting and mixing the reagent to a depth of 5 feet in the native sediments will treat the remaining native sediments as stated in Table 1.

- The estimate includes a cost to construct an additional 11,732 square yards (2.5 acres) of "temporary access road", in addition to the approximately 5 acres of "temporary access road" mentioned under the Pre-remediation Site Work section of the table. Given the location of the staging area, the purpose of the temporary access roads is unclear.

- The base implementation cost section includes a cost for a "temporary storage area" at a cost of $100,000 per month. For the ISS costs, there is a monthly charge for "temporary storage area" at a cost of $1,000 per month – this appears to be a typographical error since other costs in this category remain the same. For the 7.7 months required for ISS operations (based on the FS estimate), this underestimates costs by $763,000.

- The ISS process is assumed to take approximately 7.7 months based on a production rate of 1,400 square feet per day, assuming 12-hour per day operations, 7 days per week. As noted previously, this operating schedule does not reflect the operating limitations within the Canal due to site and project specific limitations. If the same reduction in productivity was applied to the ISS process as was noted for the dredging operations, productivity would be reduced by one third, to approximately 900 square feet per day, and extending the operating period from 7.7 months to 11.6 months. This would increase the ISS costs by approximately $3 million. Given the complexity of the ISS operations, space limitations, and lack of experienced contractors, this cost is likely to significantly under estimate the actual costs.

- There are a number of questions about the constructability of the ISS layer, based on the information presented in Table 1. Addressing the simple logistics questions posed by the conceptual design presented in the FS would add substantially to the cost of the project.

- According to the work sequence presented in Table 1, all work would be performed within a treatment cell until the water within the cell is pumped out and treated. Based on this approach, it is not clear how the equipment barge would get into the treatment cell to conduct ISS operations. The average width of each treatment cell will be approximately 50 feet (100 feet Canal width divided by 2). Vertical augers such as are typically used for soil mixing operations typically operate close to the equipment platform because of the torque on the drilling arm, which limits the reach of the equipment. Removing a section of the treatment cell wall to allow equipment access would defeat the purpose of the treatment cell. It is not clear that the auger would be able to reach all sections of a treatment cell from outside the cell.

- It is noted in Table 1 that the production rate was based on "two delivery platforms" working simultaneously. Since no discussion is provided suggesting that dredging would be performed in more than one cell at a time, it appears that the plan is for two ISS rigs to operate in one treatment cell at time. It is not clear that this will be feasible given the width is only 50 feet (on average). In addition to the two ISS rigs, some mechanism would be required in the cell to move the barges around as the work progresses. Having more than one rig in the cell at a time would potentially interfere with the movement of the equipment.

- The cost estimate is based on having two teams of support equipment (scow and tug) to deliver reagent to the ISS rigs. This may be adequate if the rigs are working in the same location (*i.e.*, treatment cell). However, if the work locations are separated, a second scow and potentially a second tug would be needed at each site to allow continuous operation. Otherwise, the ISS operation would need to shut down while the reagent stockpile is replenished. Given the proposed staging area (near the mouth of the Canal) and the number of obstacles between the mouth and the headwaters of the Canal (bridges), a single support scow per ISS rig could result in significant delays.

i. Sediment capping

As noted previously, the site restrictions both in working in and around the treatment cells as well as those related to the Canal, will impact the productivity in cap placement.

j. Dredge cell water treatment

- No redundancy is provided in the pumping system design and the system relies on one pump to operate continuously throughout the dewatering process.

- No down time is included for media changeout in the wastewater treatment plant, fueling of the pumping system or other routine repairs to the system.

- The water treatment plant has a capacity of 750 gpm and will be used to dewater barges containing sediment as well as the dredge cell water. To achieve the schedule in the FS, the dredge cells will need to be pumped at a rate of 750 gpm, meaning there is no excess capacity for handling water from the barges. There is no allowance for stormwater management at the staging area. It is anticipated that stormwater from a portion of the staging area will be classified as contact

water and will need to be captured and treated. There is no allowance for equipment decontamination water. There is no allowance for dewatering the former 1st Street Basin.

k. Long-term operations and maintenance cost for sediment cap

There is very little long-term monitoring of the site proposed following remediation – even though contaminants remain in the groundwater and no plan has been proposed to address the contaminant plume in the area. Monitoring is proposed to be conducted once every five years:

- Surface sampling is proposed to check if the surface soils have been re-contaminated at a frequency of one sample per acre of Canal surface.

- Biota sampling is proposed at a frequency of 1 sample per acre of Canal surface.

No monitoring of subsurface soils or porewater is proposed to check for breakthrough of NAPL (for cap replacement) or to monitor the effectiveness of the remedy in controlling the migration of NAPL from native sediment. In addition, because no baseline standards have been set, it is unclear how a determination will be made as to the remedy's effectiveness in controlling NAPL releases from groundwater adjacent to and underneath the Canal.

Essentially, the monitoring program does not address what was identified as the primary concern for the Canal – PAH contamination.

As presented in Tables 1 and 7, the remainder of the operation and maintenance ("O&M") costs is limited to maintaining cap integrity. Table 1 indicates that up to 5 percent of the cap footprint will be replaced every 10 years; the costs in Table 7 show this replacement happening every 5 years. In the cost estimate, costs are limited to the addition of new cap material to address erosion or scour issues. Given the multiple layers in the cap, how this work will be performed is unclear. As noted previously, no flux calculations are provided on the NAPL and no estimate was prepared on the anticipated life of the oleophilic clay. The FS acknowledges that replacement of the clay is likely to be required but no determination is made as to when this will happen. If breakthrough is anticipated to occur during the 30-year cost estimating period under CERCLA, the cost to remove and dispose of the existing layers of material and replace the cap needs to be included in the site maintenance costs. Because the NAPL flux rate was not estimated, the life of the reactive cap material cannot be estimated and therefore, the need to include the cost for replacing the oleophillic materials in the cap has not been addressed.

The initial cost for cap construction is approximately $20 million; the cost to replace the cap once the oleophilic clay has been expended will be many times that amount and will need to include the following costs:

- Design and Construction Oversight related to dredging of Canal and cap construction.

- Dredging of Canal to remove old cap and accumulated sediment.

- Disposal of old cap material and accumulated sediment.

- Placement of new multi-layered cap.

A rough calculation of this cost (using information from the FS) is approximately $200 million per round of replacement. This cost does not consider the potential cost/impact of dredging over the ISS layer.

l. Sediment management

No information is provided on the commercial availability of sites to treat contaminated sediment. Sites that accept this type of material (sediment) for the contaminants of potential concern should be identified. Because sampling to characterize the sediment for use in identifying sites that are permitted to treat and or disposal of the material was not conducted during the FS, it is not possible to verify the availability of potential treatment or disposal sites.

The availability of beneficial use sites is unknown. However, it is unlikely that the material would be accepted at a landfill for use as daily cover without being assessed a tipping fee. There are a large number of waste streams that have been proposed for use as daily cover at landfills. Landfills are aware of the revenue potential for accepting relatively clean material for use as daily cover and will charge accordingly. Material that presents a potential risk to the landfill is unlikely to be acceptable as daily cover at no cost.

2) EPA's approach to controlling CSO discharges to the Canal is arbitrary and does not reflect the ongoing control measures being developed. No consideration was given to the impacts associated with construction of large tanks in a highly urbanized area.

DEP has performed extensive CSO planning, design, and construction over the past several decades as part of its NYC CSO abatement program. Capital investments by the City have included the construction of CSO storage tanks with a total capacity of approximately 120 million gallons of combined sewage, resulting in the capture of more than 2.7 billion gallons in CSO discharges annually. These tanks made sense for certain locations that were either beach sensitive or connected to thousands of acres of sewer drainage areas that drained to large single outfalls and negatively impacted water quality.

DEP's approach to CSO abatement is not limited to designing tanks but includes other cost-effective and innovative grey and green infrastructure to take advantage of existing opportunities on a site-specific basis in terms of topography and infrastructure optimization. For the Canal, this includes the significant expansion of the Gowanus Canal Wastewater Pumping Station and Flushing Tunnel that will reduce CSO discharges by 34 percent from baseline conditions. This work is being performed under a Consent Order with DEC. Construction is scheduled to be completed in 2014 and water quality in the Canal is projected to improve to levels that may support upgrading the waterbody to Class I to support secondary contact recreation. Further planned investments in and around the Canal include green infrastructure for two of the largest outfalls, RH-034 and OH-007, that is projected to achieve an additional 11 percent reduction in CSO discharges. Finally, DEP is constructing high level storm sewers in two phases to reduce an additional 5 percent of CSO discharge volume.

DEP is required to develop and submit to DEC a CSO LTCP in June 2015 to quantify water quality improvements from the ongoing construction on the Gowanus Canal Wastewater Pumping Station and Flushing Tunnel, and to evaluate additional control measures that may be necessary to meet water quality standards. The LTCP process is occurring for waterbodies throughout the City and allows DEP to cost-effectively plan for additional water quality improvements as needed while also balancing the competing

needs and investments in each waterbody and across the DEP water and wastewater systems as a whole. DEP's approach to CSO reduction in the Canal is a microcosm of the City-wide approach being undertaken that includes a practical mix of cost-effective grey and green infrastructure to protect and enhance water quality throughout the City while fulfilling the fiduciary responsibility that DEP has to ensure water rate payer dollars are spent wisely.

a. The FS cost estimate significantly underestimates CSO storage tanks costs

Figure 12-1 presents the DEP's LTCP CSO tank cost curves for design and construction of CSO storage tanks. These cost curves were developed based on the DEP's experience building tanks in New York City and more accurately reflect costs in the City as compared to the estimates presented in the FS Addendum for several reasons.

The LTCP cost curve relies on actual construction costs for CSO tanks built in New York City, specifically the Paerdegat Basin, Alley Creek and Flushing Bay CSO tanks. A comparison of the actual DEP tank costs and the CH2M-HILL planning level estimates shows a wide discrepancy.

The table below shows the estimated costs of constructing the two tanks using the LTCP cost curve, with a total cost for the two tanks of $357 million. EPA estimated that the two tanks would cost $77.7 million to construct: $31.3 million for a 4-MG CSO storage tank for outfall OH-007 and $46.4 million for an 8-MG CSO storage tank for outfall RH-034 (FS Addendum, Technical memorandum *CSO Storage Tanks Draft Cost Estimates, Gowanus Canal, Brooklyn, New York* ("Tank Cost Estimates") (refer to Figure 12-1).

Project Site	NYCDEP Built Tanks Curve	Accuracy	Accuracy
	Probable Construction Cost	-50%	100%
4 MG OH-007	$129 M	$64.5 M	$258 M
8 MG RH-034	$228 M	$114 M	$456 M
Total	$357 M	$178.5 M	$714 M

Note: At this time the costs for CSO tanks at OH-007 and RH-034 are parametric, or capacity, factored estimates. Parametric or capacity factored estimates are considered Estimate Class 5 by the Association for the Advancement of Cost Engineering (AACE), with an expected level of accuracy of -50% to +100%. Based upon DEP experience in building highly complex projects within NYC, as-built project costs typically approach or exceed the higher range of preliminary project Class 5 cost estimates.

While estimated cost for the proposed 4-MG tank at outfall OH-007 is $31.3 million in the FS, the actual construction cost for a similarly-sized CSO storage tank (Alley Creek, 4.6 MG) recently constructed by DEP, was approximately $101 million.

The following is a breakdown of the Alley Creek tank costs:

- **Contract ER-AC1:** Total cost of $98 million for the construction of upstream sewers and the tank, of which approximately $43 million (40 percent) was attributable to the tank. This apportionment is based on a review of contract as-built plans in which the portion of the contract associated with the tank structures was identified; costs for sewers leading to the tank site and other upstream sewer work was removed from the total. Although this contract included considerable

construction of upstream sewers to address drainage and flooding issues, these the costs were not attributed to the Alley Creek CSO tank.

- **Contract ER- AC2**: Total cost of $38 million of which 100 percent is associated with the tank mechanical equipment and internals – screens, air handling equipment, flushing equipment, piping, instrumentation and control equipment, and improvements to the Old Doug Pumping Station for tank pump-out.

- **Contract ER-AC3**: Total $20 million for Alley Park restoration of which 100 percent of these costs are attributed to the Alley Creek tank. As experienced with all other CSO tanks constructed in the City, some level of community amenities can be expected when constructing a CSO facility.

The total construction costs directly attributable to the 4.6-MG Alley Creek CSO tank totaled $101 million ($43 million + $38 million + $20 million).

The costs for constructed projects included on Figure 12-1 were converted to September 2012 dollars so as to be in the same time frame as the costs provided in the FS Addendum. For example, for Alley Creek costs for ER-AC1 were escalated from August 2002 to September 2012; costs for ER-AC2 were escalated from August 2006 to September 2012; and costs for ER-AC3 were escalated from July 2007 to September 2012, using the escalation methodology in the DEP CSO Long Term Control Plan project.

DEP understands that cost estimates are variable but based on DEP's actual final costs of building CSO storage tanks as detailed on Figure 12-1, DEP estimates that it would cost approximately $357 million to construct a 4M-gallon tank at OH-007 and an 8M-gallon tank at RH-034. In other words, construction of both tanks is likely to cost over four times EPA's estimate of $77.7 million. Because DEP's estimate of $357 million is based on its actual experience building tanks in New York City, DEP believes they are more accurate than the estimates presented in the FS Addendum.

b. EPA's cost estimate did not include a number of costs required for construction.

EPA's capital cost estimate for the CSO storage tanks did not include a number of costs typically associated with CSO tank construction including capital cost markups and costs associated with property acquisition, demolition, rebuilding the site surfaces, addressing unknown soil conditions, staging and hauling, and heavy dewatering. In addition, the tank cost estimates did not account for New York City general conditions overhead and contractor profit; enhanced EH&S requirements; construction of appurtenant tank ventilation, flushing, and personnel facilities; site rehabilitation; and difficulty of construction.

In the FS Addendum, EPA presents estimated construction costs for tanks ranging in size from 2 to 17 MG for the RH-034 outfall, and for tanks ranging in size from 2 to 8.2 MG for the OH-007 outfall (*see* Tank Cost Estimates, p.1) assuming a Class 5 planning level estimate as defined by the AACE. The estimates include the following components in addition to the tanks themselves:

- Sewers from the outfall to the storage tanks;

- Coarse screens;

- Pump stations and force mains for tank pumpback;
- Instrumentation and SCADA;
- Odor control; and
- Brownfields remediation.

On page 15 of the Tank Cost Estimates, the Class 5 construction costs estimate assumptions state that "the construction costs accounts for excavation, sheeting and bracing, and backfill…, and dewatering," but exclude "capital cost markups, property costs, demolition, rebuilding of site surface, extra costs from unknown soil conditions, extra costs for staging and hauling, and heavy dewatering." The cost estimates (Tank Cost Estimates, p.10) are based on RS Means cost data, EPA documents and information, in-house cost databases, vendor quotes, and project bid information (such as Metropolitan Sewer District of Greater Cincinnati Engineer's Estimates in 2006). The estimated costs were converted to NYC/September 2012 dollars using the ENR construction cost indexes (*see* Tank Cost Estimate, p. 15)

Considering the significant difference between the DEP actual tank costs and those presented in the Proposed Plan, it appears that several important considerations may not be accounted for in the estimates provided in the FS Addendum.

c. EPA's cost estimate did not include O&M costs.

The CSO storage tank cost estimates in the Proposed Plan and FS Addendum do not include any estimate of O&M costs for the tanks. These costs are significant and must be taken into account. O&M costs should be taken into account for any new capital facility and must also be included in the calculation of a total present worth cost.[21]

d. The FS does not address the issue of implementability of the CSO storage tanks

DEP's years of experience with site selection, engineering, construction and operation of CSO facilities should not be overlooked by EPA. One major technical challenge the DEP has faced with CSO storage tanks is the hydraulic interaction between the existing drainage system and any new end-of-pipe facility. The conveyance of flows to, and through, the tank without impacting the surrounding drainage area is especially critical. Detailed hydraulic models and drainage plan calculations are necessary to ensure no street flooding or basement backups occur. These analyses require large investments in engineering resources to thoroughly understand the existing system and design new facilities that are hydraulically neutral or minimally impact the existing hydraulic grade line. Analyses and designs at this level of detail entail years of work at high cost. To make recommendations with regard to specific tank sizes and locations without understanding the engineering feasibility and cost of these facilities is premature. The City has faced these difficult technical issues over the history of its CSO program and this experience provides the basis for the following comments on the CSO remedy in the Proposed Plan.

e. EPA did not account for the complexities of constructing and operating two multi-million gallon CSO storage tanks in a dense urban neighborhood.

[21] *See* NYC Comment 21 regarding the NCP's requirement that O&M costs be included in cost calculations for remedies.

The Proposed Plan and FS Addendum did not account for a number of significant impediments to construction of large infrastructure works in a dense urban environment, such as: lack of sufficient laydown, staging, and parking areas; excavation/dewatering concerns; maintenance and protection of traffic; buried utilities; community impacts during construction; land use and zoning considerations; and other environmental and logistic impacts. Figures 12-2 and 12-3 depict a possible configuration of each of the proposed tanks at the suggested site, to further illustrate these difficulties described in further detail below.

i. Excavation and dewatering

The close proximity of the proposed tank sites to the Canal would add to the complexity of having to perform deep excavations adjacent to or near open water. As was the case for the Paerdegat CSO Tank, complex slurry walls would be required for construction. The two suggested sites may not afford sufficient space for this type of heavy construction. In addition, groundwater cut off systems requiring extensive dewatering and providing resistance to uplift during excavation would pose costly challenges. For example, configuring a 4-MG tank at the proposed OH-007 site would require a tank depth exceeding 30 feet to enable it to fit on the relatively narrow site while providing the needed volume.

ii. Traffic, Noise and Other Community Disruption

Use of the Douglass & DeGraw Pool/Thomas Greene Playground site for a CSO storage facility to serve outfall RH-034 would require construction of 1,700 linear feet of large combined sewer in City streets to convey the flow from outfall RH-034 to the proposed tank location. EPA's cost estimate does not appear to consider the construction of this new large sewer. This type of project would be very disruptive to traffic and the community. Pile driving, if necessary, could be highly disruptive, causing significant adverse impacts. The proximity of construction to sensitive receptors such as residences, businesses, schools, and medical facilities, would have to be carefully considered and impacts mitigated, particularly as they relate to traffic, parking, maintaining access, noise, dust, and vermin control. Similar considerations concerning traffic and community disruption during construction also apply to the DSNY truck facility site.

Operating and maintaining a CSO facility located beneath a pool would create significant challenges, as multiple access manholes and hatches to the enter the tank from the surface would be needed for O&M of the equipment within the tank. DEP would also need to place permanent above-ground facilities at this location for odor control, pumping and screening facilities, similar to those at its Paerdegat and Flushing Bay CSO tanks.

Similarly, operating and maintaining a CSO facility located beneath the triangular unimproved parcel owned by the City and managed by DSNY, located at 2nd Avenue and 5th Street (Block 977, Lot 3) adjacent to the Canal, would pose challenges. This parcel is currently being used by DSNY as an equipment and plow storage yard and seasonal salt storage location. A community composting facility, which is strongly supported by area Council members and is planned to expand in the near future, is also located here. Making the site usable for DSNY and community composting purposes following construction could also add substantial cost to the CSO structure. The structure would have to be designed with a foundation, walls and a roof capable of supporting the DSNY equipment accessing the site, as well as the weight of salt, composting equipment, and product.

iii. Interference with Underground Utilities

Installing underground tanks and associated sewers in urban areas can involve significant delays and complications relating to existing subsurface utilities. Identifying all such utilities prior to construction can be difficult, and utilities may require relocation, which may not be feasible and/or could cause further neighborhood disruption.

iv. Other Environmental Impacts

An environmental assessment will be required; a full EIS may be needed. In addition to the above issues, the EIS would examine natural and archaeological resources, hazardous materials, water and sewer infrastructure, historic and cultural resources, solid waste and sanitation services, air quality and greenhouse gases, and open space/neighborhood character. Investigation of these issues and preparation of an EIS could be a lengthy process and result in significant costs that should be considered as an additional project cost.

NYC Comment 12 Inquiries

In addition to the observations above, the City requests that EPA respond to the following issues:

The cost estimates significantly underestimate the likely remediation project costs in a number of areas:

- The estimate does not include costs for institutional controls.
- The estimate does not include the additional site investigation activities that were not addressed under the FS. This is a particular issue given the numerous data gaps remaining in the site analysis.
- The estimate does not consider the impact on productivity associated with working in the confines of the Canal.
- The estimate does not consider the reduced working hours/down time likely given the site constraints.
- The estimate does not consider the time losses cost associated with the traffic restrictions due to the low bridges crossing the Canal.
- The estimate does not consider the access restriction on upland properties in installing the bulkheads and other activities.
- The estimate does not consider the double or triple handling of material likely necessary with the use of the treatment cells and other space restrictions.
- The estimate does not consider the equipment requirements for ISS installation and the treatment cells.
- The estimate does not consider the use of unproven technology (ISS) with inexperienced contractor and the impact on the production rates.

- The estimate does not consider the space limitations and the impact on equipment staging and what this will do to the schedule.

- The estimate does not consider seasonal shutdowns due to weather and the cost for restarting construction. Even if year round operations are assumed, winter weather will result in lower productivity at times and it may not be possible to do certain activities during parts of the year.

- The project schedule is based on overly optimistic assumptions. Because a number of the costs are based on the estimated number of days/weeks/months, slippage in the schedule will significantly increase project costs.

The conceptual design presented in the FS does not consider these and other variables that will impact the project schedule and overall project costs.

EPA has significantly underestimated the cost to construct the CSO storage tanks proposed in the FS Addendum, due primarily to a failure to consider site specific conditions. In particular the following items, standard to construction in heavily developed urban areas, were not addressed:

- The Tank Cost Estimates did not include the cost of acquiring and developing property on which to build CSO storage tanks.[22]

- The Tank Cost Estimates did not include the cost of demolishing the existing swimming pool and DSNY garage. The costs of obtaining necessary permits, conducting zoning and land use review, displacement and relocation of the park and garage facilities, and site restoration must be included when estimating construction costs for the proposed tanks.

- The Tank Cost Estimates did not include the cost of rebuilding the existing swimming pool and DSNY garage. These costs should include a new pool and park on top of the proposed RH-034 tank to replace the existing public park, and a new truck garage on top of the proposed OH-007 tank that currently houses a garage.

- The Tank Cost Estimates did not include costs for handling soil and/or groundwater that contains hazardous materials. While the estimate added a 5 percent multiplier for disposal of contaminated soil (nonhazardous), it ignored the potential for hazardous constituents at the sites even though one of the sites is part of the former Fulton MGP. The Tank Cost Estimates should address the cost of properly removing and disposing of soil and groundwater containing hazardous materials, which may be required for the presumed tank locations.

- The Tank Cost Estimates did not include the cost of heavy dewatering even though the sites are located in proximity to the Canal and excavations of plus 40 feet are anticipated, indicating the likely need for heavy dewatering.

- The Tank Cost Estimates did not include New York City general conditions and contractor overhead and profit costs. Under current economic conditions, these factors include 25 percent for general conditions, 10 percent overhead, 5 percent profit, and 3 percent for bonding and insurance.

[22] *See* NYC Comment 13, regarding the reasons why a City-owned park is unavailable for use as the site of a CSO storage tank.

- The Tank Cost Estimates did not include the costs of implementing Enhanced Environmental Health and Safety requirements.

- The Tank Cost Estimates did not include costs for constructing, operating, and maintaining tank ventilation, odor, tank washdown/flushing facilities, and personnel facilities during construction.

- The Tank Cost Estimates did not include costs for handling challenging site conditions, such as existing utilities, small property lots, protection of adjacent lots/structures, poor soils, proximity to receiving waters, and depth to competent rock. For example, the proposed OH-007 tank would be constructed adjacent to Gowanus Canal where water intrusion during construction would have to be addressed and may require significant dewatering.

- The Tank Cost Estimates did not account for subsurface conditions that could entail special foundations and/or construction techniques such as slurry walls since bedrock can be up to 150 feet deep in many locations.

- The Tank Cost Estimates did not consider the additional costs of mitigating impacts to traffic, parking, and noise.

- The Tank Cost Estimates do not address the issue of interim control measures identified in the Proposed Plan as being necessary. No information is provided in the FS on the required control or the associated costs.

- The Tank Cost Estimates did not include the O&M costs for the tank facilities were completely omitted from the Tank Cost Estimates.

- The Tank Cost Estimates did not account for the costs of employing and training staff to operate the tank facilities.

- The Tank Cost Estimates did not account for the costs of preventative and corrective maintenance of the tank facilities.

- The Tank Cost Estimates did not account for the cost of electric power and other utilities necessary to operate the tank facilities.

In addition, O&M costs were not also included in the total present worth analysis for the CSO storage tanks. These costs are significant and result in a heavy burden on the City's expense budget. Over the lifetime of the tank facility, these costs would contribute significantly to the total present worth cost. For example, for the Alley Creek tank, DEP's operating costs have been approximately $1 million per year, and grit removal at the Flushing CSO storage tank facility has cost up to $2 million per year.

The FS failed to consider the technical feasibility or implementability of constructing two large CSO tanks in a highly urbanized environment. There are a significant number of factors that need to be considered, all having substantial cost implications. For example:

- The Proposed Plan does not consider the implementability of or account for the costs of installing slurry walls.

- The Proposed Plan does not consider the implementability of installing two underground tanks where existing subsurface utilities are present.

- The Proposed Plan does not consider the lack of sufficient laydown, staging, and parking areas near the construction sites.

- The Proposed Plan does not consider the implementability of extensive dewatering near the Canal.

- The Proposed Plan does not consider impact of traffic, noise, and other community disruption from installing 1,700 linear feet of large combined sewer in city streets.

- The Proposed Plan does not consider the noise disruption and potential for vibration related damage on older structures from pile driving.

- The Proposed Plan does not include the costs of conducting environmental review.

Community Impacts

.

NYC Comment 13: The Proposed Plan does not adequately address community impacts and siting considerations of locating a CSO in-line tank at Douglass & Degraw Pool/Thomas Green Playground.

As stated above, EPA's presumed remedy for CSOs includes an in-line tank on the site of the Douglass & Degraw Pool/Thomas Green Playground. *See* CH2MHILL, FS Addendum, Technologies for Combined Sewer Overflows Controls, Screening and Evaluation Using Established Criteria Gowanus Canal, Brooklyn, New York ("Technologies for CSO Screening and Evaluation") at 4 and 5; CH2MHILL, Tank Cost Estimate, p. 1. *See also* U.S. EPA Region 2, Gowanus Canal Public Meeting, Presentation, Slide 36. The City takes issue with any assumption that City parkland is available for other uses. Although EPA states its intention to confirm the availability of this location during the design phase of the project, there is no reference to the use of parkland in the Proposed Plan. The reader only finds mention of the park by name in the FS Addendum. Given the constitutional and statutory protection of parkland in New York State discussed in NYC Comment 27, this omission is highly problematic since the Proposed Plan fails to distinguish parkland in any way from other City-owned land. Important considerations for the Douglass & Degraw Pool site include:

- **Loss of Use**. The City has estimated that the construction of a storage tank at the site of Douglass & Degraw Pool would take five to six years. The extended loss of use of the Douglas & Degraw Pool site is an unacceptable burden on the public. Furthermore, there is the possibility that placement of a storage tank underneath the current site of the Douglas & Degraw Pool would effectively eliminate most park uses, including that of a pool, while the storage tank was in place. There has been no evaluation to date as to what type of land use could be located above such a storage tank.

- **Loss of Investment.** The City has invested a total of $4.1 million in recent capital improvements to public parks in this neighborhood. Adjoining the Douglass & Degraw Pool, Thomas Green Park was renovated at a cost of $1.1 million. The loss of this facility that would result from the siting of a storage tank there represents a loss of existing value that is increased by recent investment.

- **Community Need.** The Douglass & Degraw Pool is the nearest public pool for the neighborhoods of Boerum Hill, Cobble Hill and Park Slope. Significantly, 3,500 units of low- and moderate-income NYCHA housing are located nearby at the Wyckoff Gardens, Gowanus and Warren Street housing developments. Although usership statistics for the pool do not include residency information, it is likely that a large proportion of the more than 37,000 annual visitors are drawn from NYCHA housing because of their proximity. The community and local elected officials have strongly supported the pool when it was threatened with closure due to budget shortfalls in recent years. Any loss of use at this facility would be a significant loss of recreational opportunity for the surrounding community.

- **Former Fulton MGP Site.** A portion of this former MGP site coincides with the current site of the Douglass & Degraw Pool. EPA has reviewed the site investigation reports and agreed to coordinate the scheduling of clean-up efforts at this site with DEC. The City has concerns, though, that the site remediation may impact the Douglass & Degraw Pool. Neither DEC nor EPA have clarified how the on-going operation of the pool will be addressed during clean-up of the former MGP. Any plans for significant excavation work at the pool site associated with the clean-up of the former MGP site should ensure the full renovation or replacement of the pool and other recreational amenities that may be displaced. It should also be noted that there are no known health risks associated with the former MGP site that currently impact the pool or pool operations.

NYC Comment 14: The Proposed Plan does not adequately address community impacts and siting considerations of locating a CSO in-line tank at 2nd Avenue and 5th Street (Block 977, Lot 3).

EPA's presumed remedy for CSOs includes an in-line tank retention basin on a triangular unimproved parcel owned by the City and managed by DSNY, located at 2nd Avenue and 5th Street (Block 977, Lot 3). *See* Technologies for CSO Screening and Evaluation, at 4 and 5; Tank Cost Estimate, p. 1.

- **Land use impacts**. This parcel is currently being used by DSNY as an equipment and plow storage yard and seasonal salt storage location. A community composting facility, which is strongly supported by area Council members and is planned to expand in the near future, is also located here. The placement of a CSO storage tank on this site near OH-007 would normally require land use approvals, environmental review, and public review under the New York City Charter. DSNY requests that EPA engage with the City and the local communities to address concerns about potential effects on surrounding land uses and properties.

- **Loss of use**. The construction of a CSO storage tank at this location would make this facility unavailable to DSNY for an extended period of time. Since such construction would require relocation of the DSNY equipment and plow storage yard and seasonal salt storage location, a suitable alternative site must be secured and operational before construction could begin. Similar accommodations would have to be made for relocating the community composting facility, which could be relocated to a separate site.

NYC Comment 15: The Proposed Plan does not adequately address concerns related to siting of the potential Red Hook Confined Disposal Facility ("CDF").

The Proposed Plan states:

> "EPA has identified a potential CDF location on privately-owned property at the Gowanus Bay Terminal on Columbus Street in Red Hook. The CDF could be constructed within an existing slip there or within other areas of the property." Proposed Plan, p. 23.

- **Impacts on Red Hook Park:** The proposed site of the Red Hook CDF is within 250-500 feet of the ball fields at Red Hook Park. The City is concerned about potential impacts from this CDF location on the park. In particular, EPA states in the Proposed Plan that it assumes no leachate collection system will be needed as part of this disposal alternative. No rationale for the absence of either collection or monitoring of leachate is given, even though other long-term monitoring (of the surface capping) will be necessary.

- **Impact on the City's Riparian Rights:** The City asserts the riparian rights associated with the shorefront section of Red Hook Park along Henry Street Basin, and these riparian rights have been affirmed in several court rulings. *See, e.g.*, City of New York v Gowanus Indus. Park, Inc., 65 A.D.3d 1071 (N.Y. App. Div. 2d Dep't 2009). Construction of the proposed Red Hook CDF includes filling a portion of Henry Street Basin, with ownership of the filled land by a private party proposed, thus expanding private property on the Brooklyn waterfront and substantially obstructing the City's riparian rights. The City strongly opposes the siting of the CDF at this location.

NYC Comment 16: EPA Should Consider the Land Use Impacts of Any Changes to Canal Basins

The filling in of land in or near the Henry Street Basin and the excavation and restoration of the 1st Street Turning Basin (discussed in NYC Comment 11) require land use approvals, environmental review, and public review under the New York City Charter. The City requests that EPA engage with the City and the local communities to address concerns about potential effects on surrounding land uses and properties. These may include the creation of land outside the current pierhead line where no zoning district is currently designated, and changes to the ability of future developments to provide required waterfront public access. In light of these changes to the City's shoreline, EPA's engagement with the City is critical to the City's ability to coordinate with local property owners in determining the land use approvals that may be necessary to develop their property.

NYC Comment 17: The Proposed Plan should not preclude the wide variety of industrial, commercial and residential activities in the Canal's vicinity.

It should be noted that the Canal, while an industrial waterway, has significant residential populations in its immediate vicinity. In addition to the long industrial history of the Canal, there is also a long history of a mix of uses including commercial, residential and community facilities. While the zoning along the Canal itself consists mostly of manufacturing districts (which allows a variety of commercial and industrial uses), there is also zoning that permits residential development, notably the mixed-use district (M1-4/R7-2) immediately adjacent to the Canal between 2nd Street and Carroll Street. Additionally, longstanding residential districts are mapped in very close proximity to the Canal, including districts that contain NYCHA developments at the head of the Canal and residential communities to the west in Carroll Gardens and to the east in Gowanus and Park Slope. Scattered throughout the manufacturing zoning districts are also long-existing, non-conforming residential uses, including concentrations on the east side of the Canal near Carroll Street. Based on the historical development of the neighborhood, there are not clear functional boundaries between industrial and residential areas, and people living in the nearby neighborhoods cross the Canal on a daily basis for access to the MTA subway

stations and bus lines, as well as to access jobs, recreation/open space, and goods and services.

Portions of the land along the Canal have a strong industrial character. Commercial and light industrial activities are scattered through much of the area, with the greatest concentration of industrial uses in areas south of 3rd Street. These areas, on the east side of the Canal north of Hamilton Avenue and along both sides of the Canal south of Hamilton Avenue in Red Hook and Sunset Park, are within an Industrial Business Zone, wherein the City has established policies and provided assistance to support business activity.

It is important that in any final remedy for the Canal, EPA acknowledges the presence of residents, workers, and business patrons in close proximity to the Canal, and ensures that the remedy does not preclude the wide variety of activities that occur around the Canal. Specifically:

- **Shoreline Area:** Zoning requires that commercial or residential developments fronting on the Canal provide publicly accessible open space along the edge of the Canal. The remedial design should not compromise the ability of property owners to comply with these requirements.

- **Bulkhead stability:** Remedial activities should account for the need to maintain structurally sound bulkheads and avoid adverse effects on land adjacent to the Canal.

- **Impacts from Remedial Activities:** EPA has proposed to conduct dewatering on either land (in Red Hook) or on barges within the Canal. Any needs identified for localized sites for equipment staging, barge access, and processing of dredge material should be carefully considered. When requirements for on-land activities and barge docking/anchoring are finalized and sites are selected to serve these functions, EPA should work with the City and the local communities to minimize effects on traffic (including bridges), parking, air quality, open space and recreation, and other neighborhood priorities.

- **Long-term Remedial Activities**: If long-term remedial activities are planned on land near the Canal, such as continued operation of extraction wells, the scope and location of these activities should be identified as soon as possible to enable property owners and the City to incorporate them into future land use plans for the area.

- **Remedial Activity Siting**: The siting of land-based remedial operations should consider proximity of residences and open spaces, and minimize adverse effects or disruptions.

NYC Comment 18: EPA Must Ensure that the Proposed Plan Does Not Exacerbate Flooding

The Proposed Plan should take into account its potential effect on flood risk during coastal storm surge events.

- For instance, the proposed excavation of the 1st Street Basin should consider the extent to which it could subject adjacent and nearby properties to increased risks

of flooding. The possibility of excavating the 1st Street basin should also consider the effect on potential future uses of the adjacent properties, which are irregularly shaped and have limited street access.

- The interim and permanent effects of the Proposed Plan and its design should be analyzed to ensure that they do not hamper or preclude measures to reduce risks of flooding from coastal storm surge events, or storm water management measures that the City may implement in the area.

- Replacement or modification of bulkheads should take into account flood hazards and projections for sea level rise, and consider establishing appropriate shoreline elevations to reduce risks of inland flooding.

NCP Compliance

NYC Comment 19: EPA's failure to perform a screening evaluation and/or a detailed evaluation of source control remedies violates the mandatory remedy selection requirements of the NCP.

The Proposed Plan states that four separate categories of source control must be implemented to prevent recontamination of the proposed remedy for the Canal. Specifically, the Proposed Plan states that

> "the upland sources of hazardous substances, including discharges from the former manufactured gas plants (MGPs), combined sewer overflows (CSOs) to the Canal, other contaminated areas along the Canal [upland source areas] and unpermitted pipes along the Canal, *must be controlled.*" *See* Proposed Plan, p. 1 (emphasis added and footnotes omitted).

Consistent with this statement, the Proposed Plan generally discusses potential remedies for each of these four source categories.

With respect to the MGP sites, EPA chooses to rely on New York State regulations governing the State Superfund program. EPA states that those regulations require source removal or control. *See* Proposed Plan at 19, 30. EPA acknowledges that DEC has not even approved a remedy at two of the three MGP sites.[23] However, EPA concludes that it is sufficient that EPA has developed a coordinated schedule with DEC to implement cleanups at the three MGP sites consistent with the remedy for the Canal.[24] *See* Proposed Plan at 19, 30.

With respect to the other upland source areas located adjacent to the Canal, the Proposed Plan states that sites will be "referred to DEC for investigation and remediation, if necessary," under the State Superfund program. *See* Proposed Plan, pp.4, 33.[25]

With respect to CSOs, the FS Addendum screens and retains five potential CSO remedies that are in addition to the CSO controls the City is implementing pursuant to its CWA Consent Order with DEC. The Proposed Plan does not perform a detailed evaluation of each of those potential remedies. Instead, the Proposed Plan states that a reduction of CSO solids loading of between 58 and 74 percent would be required to achieve PRGs for contaminants in the Canal. To meet this percentage reduction standard, the Proposed Plan states that it is

[23] *See* NYC Comment 20 below, regarding the inadequacy of the detailed evaluation of the MGP sites remedy against the nine NCP criteria.
[24] *See* NYC Comment 27 below, which demonstrates that the NCP does not permit EPA to delegate responsibility for remedy selection to the DEC.
[25] *See* NYC Comment 20 below, regarding the inadequacy of the detailed evaluation of the upland source remedy against the nine NCP criteria.

> "presumed that in-line storage tanks would have to be constructed near outfalls RH-034 and OH-007." *See* Proposed Plan, pp.19, 30. [26]

The Proposed Plan also acknowledges, however, that during remedial design of the remedy for the Canal and the City's contemporaneous LTCP process for CSOs under the CWA,

> "these efforts may identify more efficient cost-effective and protective alternatives to achieve the remedial goals." *See* Proposed Plan, pp. 19, 30.

With respect to discharges from the unpermitted pipe outfalls along the Canal, the Proposed Plan states that EPA will work in coordination with the City and DEC to either permit or permanently seal these pipes.

The NCP provides a mandatory, specific procedure for remedy selection as part of the FS, Proposed Plan and ROD. *See* 40 C.F.R. § 300.430(e). Indeed, the "primary objective of the FS is to ensure that appropriate remedial alternatives are developed and evaluated . . ." *See* 40 C.F.R. § 300.430(e)(1). Specific to source control actions, the NCP mandates that the lead agency (here EPA, not the State) develop a range of alternatives. *See* 40 C.F.R. § 300.430(e)(3). These alternatives are then to be screened against three criteria: effectiveness, implementability, and cost. *See* 40 C.F.R. § 300.430(e)(7).

Once the alternatives are screened, EPA must perform a detailed evaluation for each alternative. On this critical requirement, the NCP states:

> *Detailed analysis of alternatives*. (i) a detailed analysis shall be conducted on the limited number of alternatives that represent viable approaches to remedial action after evaluation in the screening stage. *See* 40 C.F.R. § 300.430(e)(9)(i) (emphasis added)

The NCP defines the scope of the detailed evaluation as follows:

> (ii) The detailed analysis consists of an assessment of individual alternatives against each of the evaluation criteria and a comparative analysis that focuses upon the relative performance of each alternative against those criteria. *See* 40 C.F.R. § 300.430(e)(9)(ii) (emphasis added).[27]

EPA is then required to document this alternative evaluation in the Proposed Plan.

At a minimum, the Proposed Plan shall:

---

[26] *See* NYC Comment 21, regarding the inadequacy of the detailed evaluation of CSO remedies against the nine NCP criteria.

[27] EPA and New York State must also identify their ARARs related to specific alternatives in a timely manner and no later than the early stages of the comparative analysis. *See*, 40 C.F.R. § 430(e)(8) and (a)(9)(ii). EPA did not identify any ARARs in the FS or the FS Addendum for source control remedies.

> provide a brief summary description of the remedial alternatives evaluated in the detailed analysis established under paragraph (e)(9) of this section. *See* 40 C.F.R. § 300.430(f)(2)(i) (emphasis added).

In sum, the non-discretionary remedy selection process mandated by the NCP requires EPA to perform, at a minimum, the following actions regarding the proposed source control remedies in the Proposed Plan: (1) screening of alternatives against three criteria: effectiveness, implementability, and cost; (2) identifying ARARs for the screened alternatives; (3) performing a detailed evaluation of each of the screened alternatives against the nine NCP criteria; (4) performing a comparative analysis of the screened alternatives that focuses on the relative performance of each alternative against the nine NCP criteria; and (5) providing in the Proposed Plan a summary description of the remedial alternatives evaluated in the detailed analysis.

EPA violated the NCP by failing to follow these mandatory remedy selection procedures for each of the four categories of source controls in the Proposed Plan. For the MGPs, other upland source areas, and unpermitted pipe sources, EPA failed to screen source control remedies, failed to identify ARARs in the FS, failed to perform a sufficiently detailed evaluation of alternatives against the nine NCP criteria,[28] failed to perform a comparative analysis of alternatives relative to performance against the nine NCP criteria, and failed to provide in the Proposed Plan a summary of the remedial alternatives evaluated in the detailed analysis.

For the CSOs, EPA did issue an FS Addendum simultaneously with issuance of the Proposed Plan. The FS Addendum screened seven potential CSO remedies for effectiveness, implementability, and cost and eliminated two of the potential CSO remedies. However, EPA then failed to identify in the FS Addendum ARARs that applied to those remaining potential CSO remedies, failed to perform a detailed evaluation of those potential remedies against the nine NCP criteria, failed to perform a comparative analysis of the alternatives' relative performance against the nine NCP criteria and failed to provide in the Proposed Plan a summary of the remedial alternatives evaluated in the detailed analysis.

NYC Comment 20: EPA did not provide a sufficiently detailed evaluation of the remedial measures necessary to control sources from the three MGPs and other upland sites as required by 40 C.F.R. § 300.430(e)(9)(ii) and (iii).

As stated in NYC Comment 19 above, the NCP requires a detailed evaluation of each alternative remedy against the nine NCP criteria. The NCP requires specifically that this analysis "shall reflect the scope and complexity of site problems and alternatives evaluated and consider the relative significance of the factors within each criteria." *See* 40 C.F.R. § 300.430(e)(9)(iii). In addition to EPA's failures specified above (including failure to screen alternatives, to identify ARARs in the FS and failure to compare alternatives), EPA's evaluation of individual remedial alternatives for control of MGPs and other upland source areas against the nine NCP criteria fails to comply with 40 C.F.R. § 300.430(e)(9)(ii) and (iii).

[28] *See* NYC Comment 20 below which details why EPA's evaluation of MGP and upland remedies, which are not specified does not satisfy the requirements of 40 C.F.R. § 430(e)(9)(ii).

Instead, the Proposed Plan and FS provide only generic statements that the NAPL from the MGPs will be sufficiently controlled through ongoing State-supervised remedial actions. *See* Proposed Plan at 3 - 4. With respect to the MGPs, the Proposed Plan also acknowledges that DEC has not even completed the remedy selection process for either the Fulton or Metropolitan MGP sites. *See* Proposed Plan, at 19.

The Proposed Plan and FS are even less specific regarding source control activities at the dozens of other upland properties, even though EPA states that, based on the results of the RI, additional upland areas were found to have the potential to contribute contaminated groundwater to the Canal and were referred to DEC for investigation and, if necessary, remediation under the State Superfund program.

EPA's evaluation of remedial alternatives for these source controls was deficient for the following reasons. The City therefore requests that EPA respond to each of the following comments, separately.

1) Analysis of Overall Protection of Human Health and the Environment

This NCP criterion requires a detailed evaluation of whether the selected alternative "as a whole, achieves and maintains protection of human health and the environment." *See* Guidance for Conducting Remedial Investigations and Feasibility Studies Under CERCLA, OSWER Directive 9355.3-01, (Oct. 1988), at 6-5 ("OSWER Directive 9355.3-01"). It requires that the agency focus on whether a specific alternative achieves adequate protection, and describe how site risks posed through each pathway being addressed by the FS are eliminated, reduced, or controlled through treatment, engineering, or institutional controls." *Id*., at 6-6.

EPA's evaluation is generic, and offers no detailed analysis of whether the unspecified remedial measures on the upland parcels will be sufficient to maintain the remedy over the long term. Instead, its analysis is limited to the following:

> The upland former MGP source controls (and other upland source areas) that have been or are anticipated to be selected by NYSDEC are expected to be protective of human health and the environment by removing the primary source areas and minimizing migrations pathways to the Canal. *See* Proposed Plan, p. 25.

The City believes that this does not provide even close to enough analysis or information to ensure that the upland remedial actions will be sufficient to protect human health and/or the environment. Therefore, EPA has not provided the following information, and must do so before selecting the remedy:

- How EPA has determined that the remedial techniques EPA *assumes* will be implemented at the upland sites will be capable of achieving adequate protection of the remedy.

- How EPA has determined that the *assumed, unspecified* controls at the upland sites will prevent recontamination from contaminated groundwater or NAPL in groundwater media (a recognized source of contamination in the Canal).

2) Analysis of Long-term Effectiveness and Permanence

This criterion requires EPA to evaluate the magnitude of residual risk remaining at a site. Residual risk is typically measured by numerical standards such as cancer risk levels, or the volume or concentration of contaminants in the waste, media, or treatment residuals remaining on the site. This criterion also requires EPA to evaluate the effectiveness and reliability of controls used to manage any remaining contaminated media. Therefore, EPA has not provided the following information, and must do so before selecting the remedy:

- Whether and how EPA assessed the risk of recontamination from upland sites, including the MGPs, to ensure that residual risks are below the numerical values set forth in the Proposed Plan.

- Whether and how EPA assessed the effectiveness and reliability of controls at upland sites when there has been no evaluation of what controls will even be established on the vast majority of properties adjoining the Canal.

3) Analysis of Reduction of Toxicity, Mobility, or Volume Through Treatment

This criterion addresses "the statutory preference for selecting remedial actions that employ treatment technologies that permanently and significantly reduce toxicity, mobility, or volume of the hazardous substances as their principal element." *See* OSWER Directive 9355.3-01, at 6-6. Pursuant to EPA guidance, each remedial alternative should focus on following specific factors: (i) the treatment processes the remedy will employ; (ii) the amount of hazardous material that will be destroyed or treated, including how the principal threats will be addressed; (iii) the degree of expected reduction in toxicity, mobility, or volume measured as a percentage of reduction (or order or magnitude); (iv) the expected degree to which the treatment will be irreversible; (v) the type and quantity of treatment residuals that will remain following treatment; (vi) whether the alternative would satisfy the statutory preference for treatment as a principal element." *Id.*

EPA does not evaluate any upland site against these factors, including the assumed remedial technologies that will be necessary for preventing NAPL and contaminated groundwater from recontaminating the sediments in the Canal. By not conducting this evaluation, EPA could not have been able to determine whether the remedy satisfies the statutory preference for treatment over other remedial measures. This is particularly true with respect to EPA's presumption that barrier walls will be the primary engineering control at the upland sites. As barrier walls do not treat hazardous substances, but merely contain them, it is unlikely that EPA at this juncture can attest that the remedy has fulfilled the statutory preference for treatment. Therefore, EPA has not provided the following information and must do so before selecting a remedy:

- What treatment technologies, if any, will be employed on each upland site contributing hazardous substances to the Canal.

- The degree of groundwater and/or NAPL treatment that is necessary to prevent recontamination of the Canal remedy.

- The degree (expressed in a percentage or as an order of magnitude) that EPA expects to reduce toxicity, mobility, or volume of groundwater and/or NAPL contamination at the upland sites.

- Whether and how the barrier wall technologies presumed to be implemented for the three upland MGPs fulfill CERCLA's statutory preference for treatment technologies at Superfund sites.

- Any and all evaluations that EPA undertook to document the use of treatment technologies on the upland sites, including the three MGPs.

4) Analysis of Short-term Effectiveness

This criterion "addresses the effects of the alternative during the construction and implementation phase until … a cleanup target has been met." *See* OSWER Directive 9355.3-01, at 6-9. Among the factors that EPA should consider in the assessment of short-term effectiveness are the timing of the various remedial measures, and what environmental impacts are expected during construction and implementation of the alternative, including measures to mitigate any identified impacts.

The Proposed Plan does not provide any assessment of the overall timing of upland remediation projects, nor does the Proposed Plan assess the environmental impacts potentially arising from these actions. Given the dozens of potentially contaminated sites that could be subject to remedial action in and around the Canal, EPA needs to conduct a full evaluation of the cumulative environmental impacts of these activities, especially when combined with the potential impacts of the dredge activities proposed in the Proposed Plan. Potential environmental impacts could include, among other things:

- Traffic impacts arising from contemporaneous response actions on the upland properties, including truck traffic associated with transporting any contaminated soils and equipment;

- Potential air, dust and noise impacts associated with remedial construction at upland sites; and

- Impacts to local groundwater flow through the potential use of technologies such as barrier walls and groundwater recovery wells.

EPA has not provided the following information, and must do so before selecting the remedy:

- A detailed description of potential remedial technologies that will be employed at each parcel adjacent to the Canal, and when remedial measures will be implemented on each parcel.

- A detailed analysis of potential cumulative environmental impacts arising from the upland response actions.

If EPA has conducted this analysis, please provide the analysis in the Responsiveness Summary. If EPA has not conducted this analysis, please provide this analysis.

5) Implementability

The implementability criterion "addresses the technical and administrative feasibility of implementing an alternative and the availability of services and materials required during implementation." *See* OSWER Directive 9355.3-01, at 6-9. The implementability evaluation should include, among other things: (i) an evaluation of the uncertainties associated with constructing and operating a specific remedial technology; (ii) whether a particular technology is reliable or whether there is the potential for construction delays; (iii) the difficulty of undertaking the prescribed remedial measures; and (iv) the steps that are required to coordinate with other agencies, over the short and long term.

EPA did not evaluate the implementability of upland remedial actions, except to vaguely state that

> "[the] former MGP and upland source control actions which have been or are anticipated to be selected are expected to be implemented successfully. Excavation, capping, NAPL extraction and containment wall technologies have been successfully implemented at other MGP sites." *See* Proposed Plan, p. 29.

The Proposed Plan further states that

> "Given the number of affected former MGP and other source areas, extensive coordination among landowners, responsible parties and local, state, and federal agencies will be required." *Id.*

Yet, despite acknowledging that these required efforts will be "extensive," EPA provides no detail on what the activities will actually consist of, where these activities will be implemented, and how this extensive work will be coordinated with the in-Canal remedy. EPA's current plan for the upland sites is so lacking in detailed or specificity, it is difficult to comment on this component of the Proposed Plan.

Therefore, EPA has not provided the following information, and must do so before selecting the remedy:

- Information concerning the "other MGP sites" evaluated by EPA in assessing the implementability criteria, and an explanation of EPA's analysis regarding these sites.

- The amount and location of excavation, capping, and NAPL extraction remedial activities that will be performed at each MGP site in this response, and how EPA determined that these activities are sufficient to protect the remedy in the Canal from recontamination.

- An evaluation of the implementability criteria for each upland site where remedial activities are planned or expected.

6) Cost

The cost criterion requires an evaluation of direct capital costs and annual operation and maintenance costs associated with the remedial action. It typically includes an assessment of the accuracy of the cost estimates, a present worth analysis, and a cost sensitivity analysis. *See* 40 CFR 300.430(e)(9)(iii)(G) (requiring evaluation of capital costs, including both direct and indirect costs, annual operation and maintenance costs, and a net present value of both capital and O&M costs); *see also* OSWER Directive 9355.3-01, at 6-10 – 6-13.

EPA did not undertake any assessment of costs regarding necessary remedial actions on the non-MGP upland sites. The Proposed Plan states:

> The costs to address the other (non-MGP) upland sources will vary from parcel to parcel and will depend on the source control options that may include excavation, cutoff walls, and other measures. EPA has not estimated the costs of remediating these additional parcels as part of the FS and, thus, those costs are not included in the overall remedy costs. However, EPA believes that, in comparison to the overall anticipated canal remedy costs, the costs of addressing these parcels would be small …. *Based upon discussions with property owners willing to implement such measures for redevelopment voluntarily, such measures are likely to cost several million dollars or less per property.* See Proposed Plan, p. 20.

Excluding the MGPs, there are approximately 70 individual parcels of land along the approximately 3.6 miles of shoreline adjacent to the Canal. If the costs of remedial action could *"cost several million dollars"* per property, upland remedial costs could, by EPA's own estimate, exceed $100 million. Indeed, when this figure is combined with the $525 million that EPA estimates the MGP sites will cost, the total cost of remediating the upland sites could actually exceed the amount of the in-Canal remedy. Further, when the in-Canal remedy is combined with this figure, the total cost of the cleanup action could easily exceed $1 billion, which is double the amount that EPA has estimated for the remedy. EPA needs to provide a detailed, thorough cost analysis for each element of the remedy, including remedial actions on the upland properties, so that the total potential costs of this cleanup are fully disclosed and available for public comment.

Therefore, EPA has not provided the following information and must do so before selecting the remedy:

- An analysis of the cost of upland remedial actions necessary to protect the remedy in the Canal.
- Information on how EPA estimated that remediation will "cost several million dollars or less per property."
- Which upland properties EPA evaluated to reach its determination that each upland property would cost several million dollars or less per property.
- The total amount of capital costs and O&M costs that EPA estimates will be expended on upland remedial projects.
- Whether EPA's estimate of "several million dollars or less" included any evaluation of controls necessary to prevent recontamination of the remedy from upland sources above EPA's remedial goals.
- EPA's total estimated cost of the in-Canal remedy, upland remedies (including MGP and non-MGP remedial actions), and CSO source control actions.

NYC Comment 21: EPA did not provide an adequately detailed evaluation of the presumptive remedial measure to further control CSOs.

In addition to EPA's failures specified above (including failure to identify ARARs in the FS and failure to compare alternatives), EPA's detailed evaluation of the presumptive remedial measure for further CSO controls (in-line tanks) against the nine NCP criteria fails to comply with 40 C.F.R. § 300(e)(9)(ii) and (iii). EPA's detailed evaluation of the

presumptive remedy was deficient for the following reasons and therefore the City requests that EPA respond to each of these comments separately.

1) Analysis of Overall Protection of Human Health and the Environment

The Proposed Plan states the following with respect to this NCP criterion:

> "By reducing discharges and accumulation of CSO solids, contaminant concentrations in surface sediments after remedy implementation are expected to meet the PRGs, which are considered protective of human health and the environment." *See* Proposed Plan, p. 25.

EPA's evaluation is highly generic and offers no detailed analysis of how and why in-line tanks will maintain the remedy over the long term. *See also* NYC Comment 10. Therefore, EPA has not provided the following information:

- Why in-line tanks of this size are needed to achieve adequate protection of the remedy.
- Why in-line tanks are needed if the proposed 58 – 74 percent reduction in CSO discharges is based on incorrect assumptions and technically indefensible PRGs. (*See* NYC Comment 1.)
- Why in-line tanks are needed if CSOs are not, and have not been, responsible for observed sediment contamination (PCBs, PAHs, and metals) in excess of CERCLA risk-based methods. (*See* NYC Comment 2.)

2) Analysis of Long-Term Effectiveness and Performance

The Proposed Plan states the following with respect to this NCP criterion:

> "CSO controls can be designed and implemented to provide reliable control of discharges at the selected design criteria, thus, reducing the potential for recontamination and the residual risk after the remedy implementation. . . .
>
> The reliability of CSO solids control would require regular inspections and maintenance of controls to ensure they are operated in accordance with design criteria." *See* Proposed Plan, pp. 26-27.

EPA states that CSO remedies can be implemented to control discharges at the level of "the design criteria" and that operation and maintenance of these CSO controls is necessary. However, the Proposed Plan does not specify the design criteria. Instead, the Proposed Plan merely establishes a performance standard in the nature of a range of 58 to 74% reduction of CSO solid discharges. Moreover, the Proposed Plan specifically excludes costs for operation and maintenance of the CSO controls, while at the same time saying that such operation and maintenance is required. Therefore, EPA has not provided the following information:

- What is the cost of operation and maintenance of the CSO controls.

- What is the scope of operation and maintenance of the CSO controls.

- What are the design criteria for the CSO controls.

3) Analysis of Reduction of Toxicity, Mobility or Volume Through Treatment

The Proposed Plan states the following with respect to this NCP criterion:

> The controls would permanently reduce the mobility of contaminants by capturing and containing solids prior to being discharged to the Canal. The captured solids would then undergo appropriate treatment and/or disposal, with the specific methods to be determined during remedial design . . . CSO reductions needed to achieve the PRG's in surface sediments after remedy implementation are estimated to be in the range of 58 to 74%. *See* Proposed Plan, pp. 27-28.

On its face, the Proposed Plan concedes that EPA has only "estimated" the reduction in CSO volume. The Proposed Plan also concedes that an evaluation of the treatment methods have not been determined, but has been deferred until after issuance of the ROD. As a result, EPA cannot and has not evaluated the CSO controls against the six specific factors set forth in the OSWER Guidance at 6-6. Therefore, EPA has not provided the following information:

- What treatment technologies, if any, will be employed for the CSO controls.

- The exact degree of CSO controls necessary to prevent recontamination of the Canal remedy.

- Any and all evaluations or studies EPA undertook or relied upon to document the use of treatment technology or extent of treatment needed for the CSO controls.

4) Analysis of Short-term Effectiveness:

The Proposed Plan states the following with respect to this NCP criterion:

> "Temporary CSO control measures (*e.g.*, solids capture in upper reach with periodic removal) may be needed to maintain remedy protectiveness while the permanent CSO solids controls are being implemented." *See* Proposed Plan, p. 28.

As stated in NYC Comment 12, EPA fails to identify and evaluate in detail interim CSO controls. Further, EPA does not address the exact timing of these interim CSO controls and their respective environmental impacts, traffic impacts, and potential air, dust and noise impacts.

Therefore, EPA has not provided the following information:

- A detailed description of potential interim CSO controls and the timing for their implementation.

- Whether EPA has conducted any analysis of potential environmental impacts from these interim CSO controls. If EPA has conducted this analysis, please

provide the analysis in the Responsiveness Summary. If EPA has not conducted this analysis, please state the reason for EPA's failure to do so.

5) Implementability:

The Proposed Plan states the following with respect to this NCP criterion:

> Various approaches to CSO solids control exist and have been successfully implemented elsewhere. NYCDEP has demonstrated that CSO discharges can be reduced through successful implementation of various grey and green infrastructure techniques. *See* Proposed Plan, p. 29.

EPA failed to address this criterion at all with respect to the presumptive in-line tank remedy. In fact, the Proposed Plan refers only to the implementability of green and gray infrastructure. In addition, EPA failed to evaluate the four critical factors regarding implementability as set forth in OSWER Guidance 6-9. Furthermore, EPA's Proposed Plan fails to address issues regarding construction of in-line tanks above an existing City park. *See* NYC Comment 13. In sum, EPA's evaluation of the implementability of in-line tanks is so lacking in detail, it is not even possible to comment on this component of the Proposed Plan.

Therefore, EPA has not provided the following information:

- The other CSO controls EPA evaluated in assessing the implementability criterion, and an explanation of EPA's analysis regarding those other controls.
- The other in-line tank sites EPA evaluated in assessing the implementability criterion, and an explanation of EPA's analysis regarding those sites.
- EPA's evaluation of the implementability criterion for each potential location for the proposed in-line tanks.

6) Cost:

See NYC Comment 12.

NYC Comment 22: EPA did not provide an adequate estimate of the cost of constructing two CSO storage tanks, which must include annual operations and maintenance costs pursuant to CERCLA and the cost criterion set forth in the NCP.

CERCLA and the cost criterion of the NCP require EPA to assess the following costs: "(1) capital costs, including both direct and indirect costs; (2) annual operations and maintenance [O&M] costs; and (3) net present value of capital and O&M costs." 40 C.F.R. § 300.430(e)(9)(iii)(G); *see also* 42 U.S.C. § 9621(a) (requiring EPA to select "cost-effective" remedies taking into account short- and long-term costs "including the costs of operation and maintenance for the entire period during which such activities will be required").

EPA presumes that a 3- to 4-million gallon CSO storage tank for outfall OH-007 and a 6- to 8-million gallon CSO storage tank for outfall RH-034 will be constructed. *See* Proposed Plan, at 19. For costing purposes, EPA estimated that construction costs would be $31.3M for the 4-million gallon tank and $46.4M for the 8-million gallon tank. *See* Proposed Plan, at 19; FS Addendum, "CSO Storage Tanks Draft Cost Estimates, Gowanus Canal, Brooklyn, New York," prepared by CH2M-HILL.

However, EPA acknowledges that

> "[t]hese estimates do not include operation and maintenance costs associated with CSO controls." *See* Proposed Plan, at 19.

In the City's experience, CSO storage tanks cost approximately $1 million annually to operate. In addition, grit removal, part of the regular maintenance of a CSO storage tank, costs up to $2 million annually. *See* NYC Comment 12.

Therefore, EPA has not provided the following information and must do so before selecting the remedy:

- The total amount of O&M costs that EPA estimates will be expended to operate and maintain two CSO storage tanks.
- A detailed analysis of the cost of operating and maintaining CSO storage tanks in the present worth analysis in the Proposed Plan.

NYC Comment 23: EPA did not adequately evaluate the cost-effectiveness of the remedy, particularly the presumed construction of two CSO storage tanks.

CERCLA requires that all remedies selected by EPA must be "cost-effective." 42 U.S.C. § 9621(a). To evaluate cost-effectiveness, EPA first evaluates the "effectiveness" of the remedy by considering its long-term effectiveness and permanence; reduction of toxicity, mobility, or volume through treatment; and short-term effectiveness. Then, EPA must compare overall effectiveness to cost to ensure that the remedy is cost-effective. A remedy is "cost-effective" if its costs are proportional to its overall effectiveness. *See* 40 C.F.R. § 300.430(f)(ii)(D), 42 U.S.C. § 9621(a).

In its Proposed Plan and FS Addendum, EPA vastly underestimates the capital costs of constructing two large CSO storage tanks in dense urban neighborhoods, and completely omits any O&M costs in its cost estimate. *See* NYC Comments 12, 22.

Therefore, EPA has not provided the following information and must do so before selecting the remedy:

- An evaluation on the cost-effectiveness of the remedy, including the presumed construction of two CSO storage tanks.

NYC Comment 24: EPA's selection of a range of percentage solid reductions for CSO controls violates the NCP remedy selection requirements.

In the FS Addendum and the Proposed Plan, EPA asserts that a reduction in CSO solids of 58 to 74 percent is needed to attain PRGs for certain contaminants in the Canal. Selecting a percentage reduction as the remedial standard violates the NCP remedy selection requirements.

Specifically, without specifying what actual CSO control alternatives can meet that standard, there is simply no way to evaluate alternatives against the nine NCP criteria, either individually or comparatively. That is why the FS contains no such individual or comparative detailed analysis of further CSO control alternatives and why the Proposed Plan defines one potential alternative, in-line tanks, as only a "presumptive" remedy subject to change during the design phase and the LTCP that the City is implementing under the CWA. The NCP simply does not allow EPA to select a performance standard[29] as the remedy and allow EPA to defer detailed analysis of alternatives until after issuance of the ROD. The proper manner for EPA to deal with such uncertainties is to follow CSTAG's recommendation and, at this juncture, develop and issue an interim ROD focused on the NAPL contamination impacting the Canal.

NYC Comment 25: EPA's determination that it will develop interim CSO controls during the remedial design phase violates the remedy selection requirements of the NCP.

EPA recognizes that the planning and construction of "long term permanent Superfund controls for the Superfund remedy might not take place by the time remedial dredging is carried out." *See* Proposed Plan, at 20. Therefore, EPA states in the Proposed Plan that in consultation with DEC, EPA "would develop interim CSO solids control measures during the remedial design to control the discharges until the permanent measures are implemented." *See* Proposed Plan, at 21, 31. However, EPA does not identify any potential interim CSO solids control measures, let alone screen them, or perform a detailed individual or comparative evaluation of interim CSO solids control measures against the nine NCP criteria as required by the NCP.

NYC Comment 26: The Proposed MGP and upland source controls and interim control remedies are so vaguely defined that they deprive the City of a meaningful opportunity to comment.

The Proposed Plan fails to provide the City and other interested parties with a meaningful opportunity to comment on the controls for the MGP sites and other upland source areas. CERCLA requires that the Proposed Plan "include sufficient information as may be necessary to provide a reasonable explanation of the Proposed Plan and alternative proposals considered." 42 U.S.C. § 9617(a). Similarly, the NCP provides that the purpose of the Proposed Plan is to "provide the public with a reasonable opportunity to comment on the preferred alternative for remedial action, as well as alternative plans under consideration, and to participate in the selection of a remedial action at a site." 40 C.F.R. § 300.430(f)(2). Both of these provisions require EPA to provide the public with sufficient information so that it can intelligently comment on the matter. As a consequence, any deficiencies in EPA's notice raise due process issues.

[29] The FS and the Proposed Plan concede that even the performance standard may be revised in the design phase and in the LTCP process. *See* Proposed Plan at 19, 27-28, 33.

The adequacy of the opportunity to comment is particularly important in light of CERCLA's restrictions on the judicial review of remedies. Section 113(h) generally prohibits judicial review of remedy decisions prior to the institution of a cost recovery or civil enforcement action. *See* 42 U.S.C. § 9603(h). Furthermore, section 113 limits judicial review of remedies to the administrative record. *See id.* § 113(j)(1). Multiple courts considering due process challenges to section 113(h)'s bar on pre-enforcement review have noted that the opportunity for public comment satisfies due process concerns that might otherwise be raised by section 113(h).

The Proposed Plan does not provide the City and other interested parties with adequate notice of the control measures for the MGP sites and other upland source areas. The Proposed Plan only refers to the New York Superfund Program's requirements for "source removal or control," Proposed Plan 19, 30, but fails to discuss the methods by which these sources might be addressed. Without specifying at all how the MGP site contamination and other upland sources could be addressed, the City (and the public) do not know what alternative methods (*e.g.*, contaminant removal or engineering controls) might be used and how the surrounding area could be affected. Likewise, the Proposed Plan fails to even identify what interim CSO remedies will be evaluated. The Proposed Plan effectively requires all interested parties to guess what cleanup approach might be used at the three MGP sites, the upland sources area and as interim CSO remedies. It is precisely when the agency notice turns the comment period "into a guessing game" that agency action violates due process rights.

NYC Comment 27: Under CERCLA, EPA cannot delegate the responsibility for remedy selection to DEC.

The remedy described in the Proposed Plan provides that New York will select the precise remedial measures to be implemented for the former MGP sites and other upland source areas as part of the overall remedy for the Canal. *See* Proposed Plan at 19, 25 – 29, 32. CERCLA and the NCP, however, limit a state's role in remedy selection at EPA-lead sites. They both provide that a state may have input in the remedy selection process, but not select the actual remedy. As a consequence, the measures proposed in the Proposed Plan for the MGP sites and other upland source areas place New York in a role that is contrary to CERCLA and the NCP.

CERCLA provides for a state role in remedy selection that does not encompass actual decision-making authority. Section 121(f) sets out the ways in which states can participate in the development and selection of remedial actions. 42 U.S.C. § 9621(f). None of the ways specified in Section 121(f) include selection of a remedy. Rather, CERCLA provides states opportunities to comment, concur, or, in some instances, intervene in actions in which a consent decree has been proposed. *See*, *e.g.*, *id.* § 9621(f)(1)(E), (2)(A)-(B).

Similarly, the NCP provides that "[t]he lead agency, as specified in § 300.515(e), makes the final remedy decision, which shall be documented in the ROD." 40 C.F.R. § 300.430(f)(1)(ii). In the same subparagraph, the NCP specifies that the lead agency must "review the public comments and consult with the state." *Id.* Read together, this language contemplates EPA, as the lead agency for the Canal, selecting a remedy, while the state is limited to a consulting role, not that of the decision-maker.

The NCP further provides that for "all EPA-lead sites, EPA shall prepare the ROD and provide the state with an opportunity to concur with the recommended remedy." *Id.* § 300.515(c)(2)(i). The state's role is to concur, not develop the actual remedy. The very next subparagraph reemphasizes that the state does not make remedial decisions,

specifying that "state concurrence on a ROD is not a pre-requisite to EPA's selecting a remedy." *Id.* § 300.515(c)(2)(ii).

The preamble to the NCP states that "EPA retains the responsibility for selecting the remedy." 55 Fed. Reg. 8666, 8730 (Mar. 8, 1990). In the preamble, EPA considered the precise question of whether states could select remedies at NPL sites and answered that they could not. EPA explained "that it is not appropriate at this time to turn over final decision-making authority on remedy selection to states." *Id.* Even in those situations in which a state had already taken action under site remediation authorities, the preamble states that "EPA will not be bound by state action" on the issue of remedy selection. *Id.* In sum, EPA intended that states cannot select remedial measures for EPA-lead sites, like the Canal, under the NCP. That is what the EPA has done for the MGP sites and other upland source areas and that violates CERCLA and the NCP.

NYC Comment 28: EPA and New York State failed to identify New York State's constitutional and statutory protection of parkland as an ARAR.

The Proposed Plan does not identify New York State's public trust doctrine that limits parkland alienation as an ARAR. *See* Gowanus Canal Feasibility Study, Table 2-5 (list of location-specific ARARs). The EPA should explain why EPA and New York State did not identify New York State's restrictions on parkland alienation as an ARAR. Applicable Requirements are defined as "those cleanup standards, standards of control, and other substantive requirements, criteria, or limitations promulgated under federal environmental or state environmental or facility siting laws that specifically address a hazardous substance, pollutant, contaminant, remedial action, location, or other circumstance found at a CERCLA site. Only those state standards that are identified by a state in a timely manner and that are more stringent." 40 C.F.R. § 300.5 (2013).

In New York, the public trust doctrine restricting parkland alienation provides that dedicated parkland is "impressed with a public trust for the benefit of the people of the State. Their use for other than park purposes, either for a period of years or permanently, requires the direct and specific approval of the State Legislature, plainly conferred." *Friends of Van Cortlandt Park v. City of New York*, 95 N.Y.2d 623, 631-632 (N.Y. 2001) (internal quotation omitted). This common law public trust doctrine is also codified in state statute. General City Law provides that city-owned parklands are "inalienable" and thus require legislative approval to alienate. 1 N.Y. Gen. City Law § 20(2) (2013). EPA and New York State should identify the public trust protections for dedicated municipal parkland an ARAR because they fall within the NCP definition of ARAR as: "substantive requirements . . . or limitations promulgated under . . . state environmental . . . laws that specifically address a . . . location . . . found at a CERCLA site" and are more stringent than federal protections for municipal parkland. *See* 40 C.F.R. § 300.5 (2013). Though the NCP requires State ARARs to be timely, when the location-specific ARARs were developed for the FS, EPA had not yet developed any remedial alternatives that impacted parkland. *See* 40 C.F.R. § 300.5 (requiring State ARARs to be timely identified).

EPA's failure to identify or consider the public trust doctrine in its proposed CSO remedial components renders the analysis of this proposal flawed, incomplete, and likely to result in serious impacts to much needed community recreational facilities in this neighborhood. *See* NYC Comment 13.

NYC Comment 29: The Proposed Plan fails to address the cost and uncertainty related to legally alienating the Douglas and Degraw Pool/Thomas Green Playground in the cost estimates for constructing an in-line tank there and in the evaluation of its feasibility.

EPA should explain why it did not include the cost and uncertainty related to legally alienating the Douglas and Degraw Pool/Thomas Green Playground in the cost estimates for constructing an in-line tank there, and in the evaluation of its feasibility. It should also be noted that the approval of a City ULURP de-mapping action may be required for the construction of an in-line storage tank at the site because both the Douglass & Degraw pool are mapped parkland. This action would also require approval from the New York State legislature.

The City requests that EPA answer the following questions in the Responsiveness Summary:

- How does EPA distinguish the proposed in-line tank from the water treatment facility in *Friends of Van Cortland Park v. City of New York*, 95 N.Y.2d 623 (N.Y. 2001) given that an in-line tank is a non-park use, construction is estimated to take five to six years, and "some future uses of the land will be inhibited by the presence of the underground structure"? *See id.* at 630, 631.

- What replacement parkland does EPA expect to provide in order to secure State Legislative approval for the temporary alienation of the Douglass & Degraw Pool/Thomas Green Playground during construction and what is the estimated cost of its acquisition?

- What replacement parkland does EPA expect to provide to secure State Legislative approval for the permanent alienation of any permanent above-ground components of the in-line tank and what is the estimated cost of its acquisition?

NYC Comment 30: Information contained in the City's comments requires significant changes to the Proposed Plan, and therefore EPA must issue a revised Proposed Plan, seek additional public comment on the revised Proposed Plan, and submit the revised Proposed Plan to the NRRB.

The NCP directs EPA to issue a revised proposed plan and seek additional public comment in the following circumstances:

> (ii) After publication of the proposed plan and prior to adoption of the selected remedy in the record of decision, if new information is made available that significantly changes the basic features of the remedy with respect to scope performance, or cost, such that the remedy significantly differs from the original proposal in the proposed plan and the supporting analysis and information, the lead agency shall: . . .
>
> (B) Seek additional public comment on a revised proposed plan, when the lead agency determines the change could not have been reasonably anticipated based on the information available in the proposed plan or the supporting analysis and information in the administrative record.

> 40 C.F.R. § 300.430(f)(3)(ii).

As the City's comments demonstrate, the scope, performance and cost of the remedies identified in the Proposed Plan should change significantly. In particular, there must be significant changes to: (1) the scope and cost of the remedies for the MGP sites and upland sites (which EPA says are required for the remedy, but does not identify or evaluate specifically in the Proposed Plan); (2) the scope and cost of interim CSO controls (again, which EPA says may be required, but does not identify or evaluate specifically in the Proposed Plan); and (3) the scope, performance and costs of the CSO remedies (where EPA identified only a presumptive remedy (in-line tanks), but underestimated the capital costs of that remedy by five-fold, failed to include O&M costs for that remedy, and acknowledged that even the performance standards for that remedy, consisting of a range of 58%-74% reduction in CSO solids, may change.)

In addition, the scope of the changes in the Proposed Plan could not reasonably be anticipated pursuant to 40 C.F.R. § 300.430(f)(3)(ii)(B). As the City's comments show, there has been no detailed evaluation of any of these future remedy components. In sum, it is impossible for the public to reasonably anticipate the scope, performance and cost of a remedy component that EPA acknowledges explicitly will be determined in the future. Therefore, the NCP requires EPA to revise its Proposed Plan to include these remedy elements and allow for public comment.

Moreover, the revised Proposed Plan must be submitted to the NRRB. The NRRB review criteria state as follows:

> Board reviews will also occur for NPL sites following changes made after the release of the Proposed Plan where: A different or modified alternative (which was included in the original Proposed Plan) is selected by the region that costs more than 20 percent when compared to the original proposal and these costs trigger review criteria (even when the earlier proposed action had undergone Board review).
>
> (http://www.epa.gov/superfund/programs/nrrb/reviewcr.htm)

Therefore, NRRB review is required where the different or modified alternative will increase costs more than 20%, and that 20% increase amounts to more than $25 million (which is the dollar threshold for triggering review). The City's comments demonstrate that different or modified alternatives for source control will increase costs by more than 20% (it is a five-fold increase) and $25 million. Thus, a second NRRB review is required.

Implementation

NYC Comment 31: The City supports EPA's decision in the Proposed Plan to wait for implementation of any additional permanent CSO controls until after currently planned infrastructure upgrades for the mid and lower reaches of the Canal are completed.

NYC Comment 32: The City supports EPA's decision in the Proposed Plan to evaluate any additional permanent CSO controls as part of the LTCP process.

The Proposed Plan states:

> "EPA is committed to achieving cost savings by working closely with NYCDEP to accomplish an effective Superfund cleanup while also realizing CSO benefits through synergies and economies of scale. NYCDEP will complete full assessment of achieving CWA goals with submission of the LTCP in June 2015 pursuant to the CSO Consent Order." Proposed Plan, at 33.

The City supports evaluation of additional CSO controls, to the extent such controls are necessary to address CERCLA risks and are supported by sound science, as part of the LTCP process.

NYC Comment 33: The Proposed Plan does not require any additional permanent CSO controls to be implemented prior to commencement of the preferred remedial alternative for in-Canal sediments. The City supports this approach.

While the City takes issue with EPA's assessment and recommendation regarding permanent CSO controls related to Superfund, the City does support EPA's determination that any additional permanent controls should take place following the implementation of the in-Canal remedy. This determination is more consistent with CSTAG's recommendations concerning the timing of response actions, and it will also allow EPA to focus on the extensive, uncontrolled NAPL contamination currently impacting the Canal.

Gowanus Canal Clean Up Plan
Patrick O'Donnell to: Region2 GowanusCanalComments 04/26/2013 02:38 PM

Dear Sirs/Mesdames:

I am writing to support the current EPA proposal for clean up of the Gowanus Canal. I live in Carroll Gardens, just a few blocks from the canal, and believe the current proposal will be the best thing to happen to the Canal since it was created from the creek. Some have expressed concern about the creation of retention tanks at Thomas Greene Park, but this park has to be cleaned up anyway, and the loss of a swimming area for a season or two is a small price to pay. Please do not hesitate to contact me if you have any questions.

Sincerely,
Patrick O'Donnell

e-mail: GowanusCanalComments.Region2@epa.gov

Dear Mr. Tsiamis,

I am a long time (16 years) resident of Red Hook and I am writing to add my family to the long list of Red Hook residents who are opposed to the EPA proposal to treat and/or permanently place toxic waste in our community.

I appreciate the time you have taken to come to Red Hook and listen to our concerns. I especially appreciate the fact that the EPA made clear at the April 16 meeting in Red Hook that the CDF proposal was off the table, due to overwhelming community opposition. But, we continue to be very concerned about plans for dewatering on land or water adjacent to our homes and recreation areas.

It is difficult for those of us who are not scientists, to pick through the various aspects of an EPA clean up plan. But one thing stood out for me. At the 3 community meetings held in Red Hook, no one from the EPA was prepared to discuss risk in a mature and scientific way. For me, to hear that there is no risk in treating or storing toxic material was just astounding. We are not children who need to be told that everything safe. We know it is not. We assess risk every day in our lives - in what we eat, in raising our children, indeed, choosing to live in Red Hook carries risk. Telling us there is no risk is insulting our intelligence, and is a red flag. I hope that when the EPA presents its final proposal for the Gowanus clean up that you present a true risk assessment of all aspects

of the work.
Sincerely

John Battis

Please not in Red Hook

Jessica Lee to: Region2 GowanusCanalComments 04/26/2013 03:40 PM

History: This message has been replied to.

If there is any other location for the toxic waste processing/storage site, I hope you will consider revising the Gowanus plan to keep it out of Red Hook. The neighborhood is not in the need of another industrial site, and considering the other development options and the improvement of the neighborhood thats occurring, this would be an unwelcome addition. Its too close to the ball fields and the walkway. I am also concerned that given the flooding, this may be an unsafe location for toxic waste.

I very much want the cleanup to happen--but as it bears the risk of contributing to the industrialization and demoralization of another community, I am very concerned about the current plan. I hope you will strongly consider other options.

Thanks for your consideration,
Jessica

Friends of Douglass Greene Park

change.org

To: U.S. Environmental Protection Agency (EPA) Superfund Region 2

Subject: **make the polluters pay, not our community, save the Double "D" pool!**

Letter: Greetings,

While we, the undersigned, support a comprehensive Superfund cleanup of the Gowanus Canal that includes addressing raw sewage overflows, we also insist that Superfund follow its own principles and make the polluters pay, not our community!

For this reason, we strongly oppose the EPA's proposed placement of a raw sewage retention tank to be built beneath the Douglass and Degraw (Double D) community pool and request that an alternative location for the proposed raw sewage retention tank be identified and selected.

We also ask for guarantees to our community that any displacement or disruption to the Thomas Greene Park and Double D Pool as a result of the cleanup provide for seamless transition of the park facilities (pool, playground, skatepark, basketball courts) and services (the School Food Lunch, Learn to Swim, cooling centers, etc.) at a nearby location.

Comments

Name	Location	Date	Comment
Cathleen Bell	Brooklyn, NY	2013-04-09	We use this pool every summer, nearly every day. In a neighborhood challenged for amenities this is a HUGE bonus.
Richard Kahn	Brooklyn, NY	2013-04-09	This pool is a summer refuge for not only our kids, but for dozens or more kids from the neighboring low-income housing developments.
claudia gwardyak	Bloomfield, CT	2013-04-09	my grandchildren and I enjoy the pool every summer! Please do not transform it into sewage treatment - surely there is another place for that...
Lauri Schindler	Brooklyn, NY	2013-04-09	This is a really important community facility, providing healthy "summer in the city" activities for the residents of the nearby public housing and community at large. The pool is clean, safe, and well managed, and is a place where we all come together in a neighborhood starved for public space. Please keep looking for a more suitable location for the sewerage storage facility.
David Kraus	Brooklyn, NY	2013-04-09	Dear Sir(s) and Madame(s): The community pool is all we have to bring us all together. Without it, we have nothing but a dirty sidewalk and the corner store, nowhere for my wife and daughters to interact with our close neighbors, from different worlds, but with a lot in common. Without it, Brooklyn is dead to all of us. Seriously. Please do not hesitate to call me with any concerns or follow-up questions. I am confident we can find a suitable alternative for the water processing plant. Sincerely, David Kraus 917-301-0443
Catherine O'Malley	Brooklyn, NY	2013-04-10	The pool is an invaluable part of this community. It brings the neighborhood together in a joyful, happy way--it is essential that it remain open.
Rose Latino	Brooklyn, NY	2013-04-10	Our family visits this pool at least 2x weekly!
Atea Martin	Brooklyn, NY	2013-04-10	We need this pool in our community.
Andrea Cherrington	Brooklyn, NY	2013-04-10	We started the Facebook group! This is our neighborhood pool, and we'll fight to keep it open.
Sarah Fader	Brookyn, NY	2013-04-10	I love this pool. My kids love to swim it in every summer.
Marcia Friedland	Brooklyn, NY	2013-04-10	The pool is an important community resource.
Colleen Cruz	Brooklyn, NY	2013-04-10	It's an amazing community resource that allows for people from various walks of life to come together socially. Very few places like this exist in NYC anymore. Let's not destroy this one.
Susie Farrell	Brooklyn, NY	2013-04-10	When my children were young this was a welcome place to visit on hot summer days. I know many young families that use the pool regularly during the summer.
Maaike Bouwmeester	Brooklyn, NY	2013-04-10	My kids love this pool... it's been an incredibly important resource to connect communities with very different economic resources in this area.
gregg mitchell	brooklyn, NY	2013-04-10	i love swimming there with my child
Birgitta Rubin	Brooklyn, NY	2013-04-10	This is a fantastic neighborhood pool, teeming with children (and adults) in the summer -- a little oasis in which to cool off in, learn to swim and just have fun. What a tremendous loss if it were to close. There are no nearby pools, and to have to haul to Red Hook is not an option for most people without a car. I truly hope a closure can be prevented.

Name	Location	Date	Comment
Anne Sherman	Brooklyn, NY	2013-04-10	This is a valued community resource that improves the quality of life for local residents.
Arianne Schaeffer	New York, NY	2013-04-10	There are better locations for a raw sewage tank and pools are hard to come by in the city. Why take something away from a community when it does good like providing meals and swimming lessons. Far too many kids in the summer will open fire hydrants instead sent them to the pool to learn how to swim. NYC stop destroying communities.
Amanda Agudelo	Brooklyn, NY	2013-04-10	Help support a community
Michael DiSanto	Brooklyn, NY	2013-04-10	I'm a member of the nearby Brooklyn Boulders gym and during the summer always see tons of children and families enjoying the pool. It seems like a crime or tragedy to replace it with a sewage facility. There has to be another way.
Evan Shapiro	Brooklyn, NY	2013-04-10	Not enough community pools in NY and this is a really nice one. We use it often. Dont shut it down!
Patrick Phillips	Brooklyn, NY	2013-04-10	My kids have grown up going to this pool and we love it! Don't do this.
Jesse Groom	Brooklyn, NY	2013-04-10	Ive grown up using this pool, and if its going to be closed down 5 more need to be built. but we all know that isnt going to happen. There are already not enough ways for our communities to cool off while still being outside in that crazy nyc summer heat.
theresa jehamy	brooklyn, NY	2013-04-10	I have seen this community change for the better in the last 10 years. My children and i feel safe hear and enjoy spending several hours a week here. One of the only fun summer activity that we can do for free!!!!
Nancey Jo Tolliver	Catlett, VA	2013-04-11	This is my grandchildren's neighborhood pool. I went there with them and was blown away. It is well done and should be preserved.
Charlene Nimmons	Brooklyn, NY	2013-04-11	I don't want EPA to select Thomas Greene Park Pool as the location to install a waste tank. There are other viable sites to use that will not interfere with the summer breakfast and lunch program for our neighboring children and the only local cooling site for our local families.
Seth Harris	Brooklyn, NY	2013-04-11	What is the point in saving Gowanus if you have to destroy its best park in the process?
Tamara Greenfield	Brooklyn, NY	2013-04-11	Why take away one of the few amenities for the people who live nearby?!
Eileen Lynch	Brooklyn, NY	2013-04-11	I use this pool all summer with my family.
Marisa Schwartz	Brooklyn, NY	2013-04-11	My sons learn to swim here - water safety saves lives.
Tamar Smith	Brooklyn, NY	2013-04-11	Because the Double D pool is wonderful and so needed in the community
isak tiner	brooklyn, NY	2013-04-11	We must stand together to fight against corporate greed & planning that is inconsiderate of the needs of each community.
Manuel Carrero	Brooklyn, NY	2013-04-11	I lived my entire in Park Slope, the first 25 years of my life. Douglas pool was the only place in the neighborhood my sisters and I spent most of our summers. This was a place were friends and family go to spend quality time and beat the heat :-) Why is it that whenever there is something being built, the neighborhood children have to pay. Leave the neighborhiod pool and parks alone!
Sharon Chen	Brooklyn, NY	2013-04-12	I believe there are other ways to clean up the Gowanus Canal than taking the community pool away that many go to socialize and hang out at. What will they do once they're stripped of their favorite past time? Obesity is one of the biggest issues that we Americans are struggling to fight. You take the resource that provides and encourage physical activity away, you'll just push people to eat more and move less. You'll cause more problems than solving this one.
Mireille Mclean	Brooklyn, NY	2013-04-13	This pool is the best thing for our neighborhood kids in the summer.

Name	Location	Date	Comment
Denise Morales	Brooklyn, NY	2013-04-14	I'm signing this petition because I've used this pool since I was 13 yrs old. Now that I have my own family, we go to Douglas pool as a family. I would really hate to see this childhood place full of memories be destroyed!
Kristin Mensing	Brooklyn, NY	2013-04-15	My two daughters and I live in Park Slope and spend most of our hot days in Brooklyn at the Double "D". It is the ONLY accessible body of water for so many families, and moreso for for low income families in the community. It is a wonderful community center, where friends & family can cool off and relax during the hot summer months. PLEASE KEEP IT OPEN!!
Lorraine Le Tac	Brooklyn, NY	2013-04-15	This is a wonderful community pool that serves the immediate surroundings and beyond.
Wendy Margulies	Brooklyn, NY	2013-04-15	Great pool, serves as a necessary community resource especially for under-served children who cannot afford "camp" during the summer.
Leah Clarkson	Brooklyn, NY	2013-04-15	This pool is the only pool that can be reached on foot for a large number of Brooklynites--it is not dispensible; indeed, more resources should be devoted to improving this community treasure.
Radha Subramanyam	brooklyn, NY	2013-04-15	This is the only local pool for Park Slope, Gowanus and other neighborhoods
Kerstin Hofmann	Brooklyn, NY	2013-04-15	The children in the area NEED this pool in the summer! Please keep it open!!!
Jane Higgins	Brooklyn, NY	2013-04-15	My son (3) just saw a picture of the pool and said. "I love that cool pool." Keep it for the kids.
Katie Bednark	Brooklyn, NY	2013-04-15	This amenity serves an area where it is much needed!
Theresa Gonzalez	Brooklyn, NY	2013-04-15	Only outside recreational pool within walking distance or public transportation without having to cross a highway (ie Hamilton Ave to go into Red Hook). With little ones the travel to the pool is as big of a deal as the pool itself!
Alison Khalaf	Brooklyn, NY	2013-04-15	This pool is an important community resource.
Cathy Towle	Brooklyn, NY	2013-04-15	We use this valuable resource to beat the hot summer in the city. It's important for the community.
J. Sturm	Brooklyn, NY	2013-04-15	This pool serves a diverse group of Brooklyn residents who NEED and USE this pool all summer long.
amanda magalhaes	brooklyn, NY	2013-04-15	this is one of the best resources in our community
Jen Keiser Gordon	Brooklyn, NY	2013-04-15	My children and I love swimming in the Double D pool. It is a wonderful community resource.
Allan Scholl	Brooklyn, NY	2013-04-15	My children utilize this pool every summer with their friends. They joined the swim team and took lessons there.
Melissa Guion	Brooklyn, NY	2013-04-15	This is my local pool! My family, including my 6 year old daughter, use this pool to cool off in the summer. We can walk there. Please don't close it! It's one of the best community resources we have, and a place where all members of the community come together.
Clement Dargent	Brooklyn, NY	2013-04-15	This is the only swimming pool in the neighborhood... it's important for the community!
Jane Bliss	Brooklyn, NY	2013-04-15	While cleaning up the Gowanus Canal is great for the community, I don't support killing such a valuable community resource to do so.
patrick burns jr	Brooklyn, NY	2013-04-15	Me and my family use this pool almost every day of the summer. It would be devastating to my children, myself and the community, if this pool were to close, especially since the park was just beautifully renovated.
Sarah Lichtman	Brooklyn, NY	2013-04-15	My family uses this pool all the time in the summer. It is an important community resource where different types of people within the community can mix and enjoy spending time together.

Name	Location	Date	Comment
darian Silk	Brooklyn, NY	2013-04-15	My son learned to swim at this pool and it is a valuable community resource. Also the park was just recently re-done at much expense. As the housing increases in the Gowanus area it will be more and more important to have significant park resources available to all residents.
don sparacin	brooklyn, NY	2013-04-15	My daughter learned to swim here. There is ample space along the beautiful shores of the gowanus canal for your sewage treatment facility. Leave the community pool as is.
Bruce Hamilton	Brooklyn, NY	2013-04-15	During the spring and summer, this pool is an invaluable resource for all of the residents in the community. It is managed and maintained very well and compliments the adjoining newly renovated park. I'm pretty sure there are other locations along the canal that could support the treatment plant.
Antonia Martinelli	Brooklyn, NY	2013-04-15	This is the only walkable outdoor swimming facility in my area. The Red Hook Pool is not a pedestrian friendly option. The Double D pool makes the hot summer more tolerable and is the only opportunity my children have to learn how to swim. Why aren't we asking the Lightstone Group to put this storage facility under their buildings?
Sarah Moriarty	Brooklyn, NY	2013-04-16	Because we all deserve a place to cool off on a hot summer day. Because community is not just about working together, it is about playing together.
kathleen hackett	Brooklyn, NY	2013-04-16	The pool is just one of the things that brings people from diverse socioeconomic backgrounds together, which is essential to the health and well-being of the neighborhood and surrounding neighborhoods. It provides a healthy environment for kids in the summer --- most of whom might be left with few options.
Carolynn Di Fiore	Brooklyn, NY	2013-04-16	We have very little for our children in NYC at least let them have this pool.
Margaret O'Keefe	Brooklyn, NY	2013-04-16	We love and rely on the Double D poolas do many of our neighbors
Nancy Dodd	Brooklyn, NY	2013-04-16	My kids love to swim at the pool. It's our only community pool.
Melissa Ennen	Brooklyn, NY	2013-04-16	They are cleaning the canal in order to gentrify the neighborhood (not that it shouldn't be cleaned). Lower-income people get screwed constantly and are suffering most in this economy. Don't take the pool away, too.
Susan Boyle	Brooklyn, NY	2013-04-16	This is a necessary resource for Brooklyn families in the summer.
Louise Sloan	Brooklyn, NY	2013-04-16	I am sure there is some warehouse that could be bought and razed rather than substituting sewage for a beloved and well-used community resource.
Niamh Ring	Brooklyn, NY	2013-04-16	I've been going there for years and now take my 6-year old son there.
Christine Schwartz Hartley	Brooklyn, NY	2013-04-16	My kids and I have been going there for years. It's a great resource and wonderful space for the neighborhood's various communities to share during the summer. Taking it away would make a lot of people very angry. We need free public recreation spaces! More of them, not less!
edgar crutchfield	brooklyn, NY	2013-04-16	this is the only swimming pool in my nabe. we need it.
Boaz Weinstein	Brooklyn, NY	2013-04-16	The Double "D" pool is a valued and valuable community resource for thousands of Brooklynites, particularly in an area with limited park resources as is.
christine dappolonia	ny, NY	2013-04-16	A much used, needed and loved place for kids in the summer
Andrea Rashish	Brooklyn, NY	2013-04-16	This neighborhood deserves more services, not fewer!
patricia stegman	Brooklyn, NY	2013-04-16	Because it serves a highly populated area including large low-income apt. houses whose children need this park and pool very much!
Jennifer Bernstein	Brooklyn, NY	2013-04-16	The pool is a mainstay of our community life.
Tracey Maurer	Brooklyn, NY	2013-04-16	This pool is a vibrant part of our community

Name	Location	Date	Comment
Courtney Black	Brooklyn, NY	2013-04-16	My kids have been going to DD pool for a couple of years now. They love it. DD pool is surrounded by low-income housing. Taking the pool away means that when it comes to the summer-those kids wont have much to do since there isn't much around DD pool.
Roselyn Kopit	Brooklyn, NY	2013-04-16	This is an important resource for the entire neighborhood
Stephanie Church	Brooklyn, NY	2013-04-16	this pool is an amazing resource for the community--for kids and adults alike. a wonderful place to go in the summer.
Brooke Ferguson	Brooklyn, NY	2013-04-17	This is the only pool in our neighborhood!
Linsey Laidlaw	Brooklyn, NY	2013-04-17	Its where we swim!!!
Jessica Hartshorn	Brooklyn, NY	2013-04-17	There are plenty of other spots, you don't need to take away the place our kids go to exercise and be healthy!
Agnes Crane	Brooklyn, NY	2013-04-17	I've been going to the DD pool for 10 years and my 7-year daughters learned to swim there. With so few places to cool off in the summer, it's a terrible idea to close the pool that the whole community enjoys.
Elizabeth Williams	Brooklyn, NY	2013-04-17	This is a valuable r
Jessica Trauner	Brooklyn, NY	2013-04-17	My family and I use this pool all summer long. It is a wonderful local pool that we can walk too and it provides respite and an easy, accessible way to cool off during the hot summers. Many individuals in the community use this pool from diverse backgrounds, and many people do not have easy means to get to another pool (for example, the pool in Red Hook), if this one were to close. We ask that the EPA seek out another site in build a sewage storage facility as part of the Superfund Gowanus clean-up.
kathleen henderson	bklyn, NY	2013-04-17	Our kids need this pool to stay cool in the summer.
David Lengel	Brooklyn, NY	2013-04-17	Removing pools has a signifigant impact on the quality of life of nearby residents. Providing centres such as these are one of the many reasons New York is one of the most livable cities in the world, and pools are one of the best public services in its history. Please find another place for this facility.
Matt Polacheck	Brooklyn, NY	2013-04-17	My kids go to this pool every week with their summer camp, and it would be a shame to close such a valuable resource for our children and the community.
Kate Rope	Brooklyn, NY	2013-04-17	This pool is a valuable, well-used, and well-loved community resource that serves an economically diverse neighborhood. There is no reason the neighbors of the Gowanus canal should lose such an important part of their life in order to clean up the canal. There are many other accessible pieces of real estate to use for the same purpose. How horrible is it to take away a safe and enjoyable summertime activity from kids who need it only to replace it with raw sewage? That's a PR nightmare, EPA!
sandye renz	Brooklyn, NY	2013-04-17	We love the pool and go there often.
Jaime Brackeen	Astoria, NY	2013-04-17	A free public pool offers the potential for interaction between people of many ethnicities, social levels and walks of life to interact in a safe and fun environment. Why take that away?
Valerie Wattenberg	Brooklyn, NY	2013-04-17	This pool is an essential outlet for Brooklyn's children; how can you trash children's needs, and shift the burden from companies that poisoned the Gowanus and government that allowed it?
Isidora Finkelstein	Brooklyn, NY	2013-04-17	I love this pool! It is clean and well-managed. It is one of the most diverse places in Park Slope and the surrounding area. Plus, they just redid the park next to it.

Name	Location	Date	Comment
Jordan Green	Brooklyn, NY	2013-04-17	I live in the area- and the Double D pool is very valuable to our community. Also- when it comes to the super fund site- the polluters should be held accountable- and the community should not suffer from their actions.
Susan Kovar	BROOKLYN, NY	2013-04-17	This pool is such a neighborhood treasure! I visit regularly throughout the summer and love seeing neighbors and children enjoying the summer and taking the opportunity to cool down. Please do't take away our pool!!
Douglas Allen	Brooklyn, NY	2013-04-17	I don't want to live a block away from a raw sewage facility.
Peter Kinoy	Brooklyn, NY	2013-04-17	City pools are vital to democratic city life; the mingling of people all enjoying the same space.
Kyle Vitale	Brooklyn, NY	2013-04-17	We love this pool and swim here multiple times per week in the summer!
Isadora Reisner	New York, NY	2013-04-17	Everyone should have fun in the summer-- not just those who can afford it.
Susanna Yurick	Brooklyn, NY	2013-04-17	Think about community needs before destroying their resources.
Imanigayle Gillison	Brooklyn, NY	2013-04-17	This is important to me because Thomas Greene Park (not "Douglass/Greene" as it is being referred to) was named after my Godfather for his endless community advocacy and service to this district. He would want this park/pool/playground to remain accessible to local Gowanus Houses, Wyckoff Gardens and Warren/Turnkey Houses Community Residents.
Cricket Keys	Brooklyn, NY	2013-04-17	Public Pools are an important part of the community as much as parks. One of the few things tax payers can enjoy!
RK Dillon	Brooklyn,, NY	2013-04-17	This is a wonderful neighborhood asset & wouldn't be duplicated anywhere near if it's demolished.
RENEE FLOWERS	BROOKLYN, NY	2013-04-17	I was there and anticipation was at an all time high when this recreation area was being constructed. This pool has been the fun place to hang out for many years. What's more important is that it has drawn together the community. We live in a super diverse community and having everyone meet each other while engaging in this fun recreation has been an asset to the development of community relations (and that is awesome in itself).
Beth Frey	Brooklyn, NY	2013-04-17	It's in my community and is a wonderful resource to have in the summer for my daughter.
Katy Reitz	Brooklyn, NY	2013-04-17	There are so few places in the city for children to be able to be outside and experience the water. The DD pool is a gem that is well utilized by the community.
Mary Beth Early	Brooklyn, NY	2013-04-17	Come on! This is a great community resource for kids and families!
Greg Tiefenbrun	Brooklyn, NY	2013-04-17	I live nearby and use the pool often.
Mary Bruccoli	Brooklyn, NY	2013-04-17	This is the one amenity in the neighborhood used by everyone... young, old, black, white, rich, poor. There are plenty of open lots by the canal. Please don't take this away from the neighborhood!
Shayna Kessler	Brooklyn, NY	2013-04-17	Places for community members to exercise, play and engage in healthy activities keep communities safe and healthy by providing positive alternatives to unsafe behavior. Please don't harm our community by destroying our pool.
Julius Elinson	Brooklyn, NY	2013-04-17	This is one of the few places in the neighborhood for free and healthy fun in the summer.
Nasoan Sheftel-Gomes	Brooklyn, NY	2013-04-17	I used to live a block away and I used to take my child there. It is an extremely important part of the Park Slope community. There is a playground on the site and the community and it's children should not have to lose a vital community resource to help the Gowanus Superfund clean-up. Make the polluters pay not our community!

Name	Location	Date	Comment
Kayla Chisholm	Fanwood, NJ	2013-04-17	I grew up going to this pool, its pool that keeps kids out of trouble in the summer and gives you something to do .
Antoinette Wannebo	Brooklyn, NY	2013-04-17	It is vital to provide free opportunities for safe, healthy fun for kids and their families during the summer months. This pool severs that purpose and more -- it is well used by the community, provides a venue for free lunch and swim lessons. It is not an acceptable solution to close down a vital public community resource. I also question the environmental and social justice of siting a multimillion dollar raw sewage storage facility in the neighborhood.
J Jackson	Brooklyn, NY	2013-04-17	I frequent this pool with my son and his aunt every summer. It's a well-maintained and well-operated facility, and one of the rare places where the entire Pk Slope/Gowanus community can convene and everyone feels welcome.
Lara Holliday	Brooklyn, NY	2013-04-18	The Double D is a huge part of our community -- a place for all of the children to cool down and have fun in the summer. But more importantly, it gives city kids a chance to learn to swim -- a potentially life-saving skill that everyone deserves a chance to learn. Please save our pool!
Lisa Hickey	Brooklyn, NY	2013-04-18	my child and i use this pool regularly during the summer - the kiddy pool is wonderful and there is not another public pool in our neighborhood.
Steve de Seve	Brooklyn, NY	2013-04-18	The canal must be cleaned and the sewage must be stopped. But the city, state, and National Grid are the problem. They must pay the fll amount, including paying to make a new pool the locals can use --- otherwise it means the local families will be paying with their summer activities, for cleaning pollution others are responsible for. A new, nearby pool site must be acquired. There are a few sites nearby. But the city and the crooked bloomberg administration has to cough up the money and do the right thing.
Lisa Baker, MD	Brooklyn, NY	2013-04-18	Please don't take away community places that are used by all different members of the community. This pools draws from all around it and beyond.
sheelagh appleby	brooklyn, NY	2013-04-18	i great place to take my 3 year old when it's hot outside
Beverly J Kidd	Dayton, OH	2013-04-18	Childeren need safe, and clean places for recreation.
Taryn FitzGerald	Brooklyn, NY	2013-04-18	First the school, now the library, and next the pool? We don't have enough resources as it is, in this community. Enough! Leave our neighborhood alone!
Scott Levy	Brooklyn, NY	2013-04-18	We run a business with multiple locations in the area and this is a valued pool for our families!
Adam Witten	Brooklyn, NY	2013-04-18	This park was just renovated over the winter and the pool is in heavy use all summer. It is a true public space. Please keep this keystone of the community open.
Sergio Fanchiotti	Brooklyn NY, NY	2013-04-18	This is an important service to the neighborhood. Taking it away is really absurd.
David Locke	Cape May, NJ	2013-04-18	There are too few such amenities in this neighborhood to lose this one, even for a few years. Maybe they should put the retention tanks under that huge luxury coop about to be put up on the other side of the canal, what?
Stuart Dryburgh	Brooklyn, NY	2013-04-18	Me and my two boys swim there every day through the summer. And it is alway packed with kids from the neighborhood. Vital!
Basheba Vazquez	Brooklyn, NY	2013-04-18	This is a great community pool. We frequent this pool many times throughout the summer. It also provides free meals for those who need and a great wading pool for the little ones.

Name	Location	Date	Comment
Carolyn Pravda	Brooklyn, NY	2013-04-18	Please save the DD pool! It's an important recreation spot for two family filled neighborhoods!
Stu Anderson	Brooklyn, NY	2013-04-18	I grew up swimming in this pool and I would hate not to be able to share it with future generations. This is a Brooklyn landmark, not a disposable feature.
Henry Carrier	Brooklyn, NY	2013-04-18	I have been to the pool many times with my children. The pool is safe, clean and a welcome relief on a hot day. Public Space is a premium in Brooklyn. Do not take it away.
Deirdre Dolan	brooklyn, NY	2013-04-18	there aren't a lot of ways to entertain kids in brooklyn in the 90 degree heat.
Melissa Fitzpatrick	Brooklyn, NY	2013-04-18	This pool is an important part of an already underserved community -- why take away one of the few benefits they enjoy?
Eva Garriga	Brooklyn, NY	2013-04-18	because it is important for the community to have a place to cool off in the summer.
leslie nuchow	brooklyn, NY	2013-04-18	What would Jesus do? Take a summer pool away from inner-city kids to build a poop tank? Seriously? We need to wake UP to TRUE FAMILY VALUES. What will all of those children do in the hot summer? Do we care? Let's show the children and families that we DO CARE by stopping this closure. When will we see the value in putting our children first?
mike benson	brooklyn, NY	2013-04-18	community, health, chill out factor, connection to a natural element in an urban setting, diverse groups connecting, health and fitness, wellness, access to swimming,
Tom Lino	Brooklyn, NY	2013-04-18	Our family swims at the "Double D" pool to escape the summer heat. We love it!
gilles bransbourg	brooklyn, NY	2013-04-18	This pool serves the entire community and is a key entertainment component of what the neighborhood has to offer during summer, especially for those we don't or can't travel to nice vacation spots. Removing it would be hugely detrimental, especially to the less privileged members of our community.
Ariel Flavin	Brooklyn, NY	2013-04-18	This pool brings our often separated community together. It's a resource for everyone and kids in the city deserve a place to swim and cool off in the summer. It's one of our neighborhoods most valuable resources.
Sharon Guskin	Brooklyn, NY	2013-04-18	This pool is important for the community.
Tonya Thornton	Brooklyn, NY	2013-04-18	Summer would not be the same without the DD pool! This pool is the perfect way to cool off during the hot summer months and enjoy the water with my daughter! Please don't close the pool,
Bomee Jung	Brooklyn, NY	2013-04-18	This is a community facility beloved by families of varying economic means. There's nothing like this pool anywhere near by. Cleaning up Gowanus shouldn't place more burdens on the parents and kids of this community!
Emma Golden	New York, NY	2013-04-18	My kids use thsi pool every summer as do many kids in and around the area
Allison Conner	Brooklyn, NY	2013-04-18	Brooklyn needs it's pools. That's where my step-daughter learned to swim! It's good for the community.
Lucy McNair	Brooklyn, NY	2013-04-18	This is a fabulous small pool perfect for beginners and families and has no other one like it in the city.
Ian Dutton	New York, NY	2013-04-18	Any temporary displacement of public amenities must be rebuilt an replaced in a final state of the project with interim accommodations provided!

Name	Location	Date	Comment
Sabine Aronowsky	Brooklyn, NY	2013-04-18	Friends of Douglass Greene Park (FODGP) supports a comprehensive cleanup of the Gowanus Canal, that includes addressing Combined Sewer Overflows (CSO's) and coal tar waste entering the canal from the uplands area. We ask the EPA to make the polluters pay and not our children and our community. The potentially responsible parties (PRP's) are National Grid and the City of New York. We do not want a raw sewage tank to disrupt our Double D pool and we need clear answers about the level of toxicity of the land beneath the pool. The families that use this Park and Pool deserve remediation and not more obfuscation from the PRP's. There are other locations, closer to the CSO outfall (RH-034), where the tank can go, such as the lot on Nevins and Butler, across the street from the Pump station and the Flushing tunnel. Over $500 M will be spent on this cleanup and we want a Record of Decision that minimizes any possible disruption to the park & pool and provides for any direct costs related to that, including a nearby temporary pool and a permanent replacement, along with all the community services and other park amenities accounted for. Anything less would be considered an environmental justice issue, and there are EPA protocols for this.
Kristin Brady	Brooklyn, NY	2013-04-18	Our family relies on this pool all summer - what a fantastic community resource! We would hate to see it go.
Michelle de la Uz	Brooklyn, NY	2013-04-18	Assuming the pool needs to be disturbed to either properly remediate the Fulton MGP site or as the most appropriate location for a retention tank, then an interim location for a temporary pool MUST be found so there is no loss of access to the local community to this critical community asset AND the community must be involved in redesigning a new, replacement pool (and park if that is impacted too). The cost of the interim pool, design process that includes the community, and new pool should be born by the PRPs responsible. Thanks
Sarah Jefferys	Brooklyn, NY	2013-04-18	In summertime, my kids go to this pool almost every day. It is a life saver in hot weather and a very special spot for city kids to swim. Please save the pool!
Sheri Stein	Brooklyn, NY	2013-04-18	Please don't make local kids who have so few places to go in the summer suffer.
Jayson Haedrich	SUNNYSIDE, NY	2013-04-19	NYC Pools are important for everyone Relief from the summer heat
Anita Keire	Brooklyn, NY	2013-04-19	Love that pool in the summer time!
Michael Cosaboom	Brooklyn, NY	2013-04-19	My family uses the pool practically every day in the summer. It's the best recreational space in the neighborhood and it needs to remain open.
Geri de Seve	troy, NY	2013-04-20	My granddaughters live in the neighborhood and kenjoymthis pool in the summertime. I want to keep it open and I want it to be safe for them and the other neighborhood children who need a
Lisa Bohen	Brooklyn, NY	2013-04-20	This is a important community resource!! Please find another location for the treatment plant.
Ann Armbruster	Brooklyn, NY	2013-04-20	There are only two pools serving all of South Brooklyn. They are both packed in the summer.
Christian Fox	Brooklyn, NY	2013-04-20	The DD pool is a great resource for the community and is anything but underused. Shutting it down would remove a positive activity for many youths and families during the summer months.
Elizabeth Amon	Brooklyn, NY	2013-04-20	We love going to the pool in the summer-- it's close and a relief from the heat.

Name	Location	Date	Comment
Albert Wong	Brooklyn, NY	2013-04-20	This is the only public pool in Park Slope/ Gowanus!
Eva Radke	Brooklyn, NY	2013-04-20	This is a community resource we need preserved!
Nancy Broadway	Brooklyn, NY	2013-04-20	This is an important community resource which is utilized by people from all over the community.
Barbara Hatfield	Brooklyn, NY	2013-04-20	I use the pool and recognize its importance to the community.
David Osorio	Brooklyn, NY	2013-04-20	I owe a business on Degraw street (CrossFit South Brooklyn). Many of our parents take their kids to the pool after classes, it is a great part of our summer experience. It would be a shame to lose this pool as the entire community uses it. Please don't take more away from the housing projects too..
Andrea Lewandowski	Brooklyn, NY	2013-04-21	My kids and many of their friends depend on this using this pool every summer. It is not fair to penalize the community. We need this pool!
Paul Sonn	Brooklyn, NY	2013-04-21	Gowanus has so little park and community space already. It can't afford to lose the little that it has. The Double D Pool is a wonderful resource used by families from a wide range of neighborhoods - please find another alternative!
malcolm varon	new york, NY	2013-04-21	i use this pool often in the summer as a way to escape the heat and to get exercise and recreation. It is convenient, and provides a much needed easy to reach break from my very busy life schedule. I would find closing of this pool a severe damage to my quality of life in my neighborhood. I urge you to reconsider your proposal, and not destroy this much needed and much used pool, playground, and park facility. Yours sincerely, Malcolm Varon
Jim Brennan	Jersey City, NJ	2013-04-22	Plenty of vacant lots and vacated industrial spaces in and around that neighborhood could be used as locations - NYC residents need public pools
jennifer gandia	brooklyn, NY	2013-04-23	Brooklyn needs more, not less recreational spaces for its residents and children. This pool provides a valuable space for outdoor activity in the community. Please find another locaation for your sewage pant - yuck!
Maia Murphy	Brooklyn, NY	2013-04-23	DD pool is a rare example of a public space in a neighborhood short on green spaces. Keep it open!
Francine Pado	Brooklyn, NY	2013-04-24	My family uses the pool every day in the summer. Please don't close it!!!!!
Adria Stokes	Brooklyn, NY	2013-04-25	This is important to me because we need to keep the few neighborhood get-aways that we have.
Teddie Vietor	Brooklyn, NY	2013-04-25	My grandchildren and I frequent the pool during summers
lauren healy	brooklyn, NY	2013-04-25	We love swimming at this pool as one of our main summer activities! great for kids to have somewhere to go in the summer!
Jeannine Cooke	Brooklyn, NY	2013-04-25	Why destroy & dirty (with sewage!!!) a perfect place, to clean up a polluted one? if this happened in another country our government would protest. Everywhere in the world people replace sewage with parks & pools. Why would we do the opposite? Our park & pool are the recreation camp & summer camp for thousands of people from our community who can't go to camps outside the city. With all the unused land around this canal, why would anybody think about destroying our newly restored park & pool?
sarah crichton	brooklyn, NY	2013-04-25	This pool keeps our neighborhood healthy and happy and sane and calm!
Kathy McCullagh	Brooklyn, NY	2013-04-26	The pool keeps us sane in the summer - we can bike there - please don't destroy this pool!

Name	Location	Date	Comment
Amy Freeman	Brooklyn, NY	2013-04-26	Summers are only getting hotter in NYC and everyone needs a place nearby to cool off - especially people who can't get out of the city easily. NYC knows this better than the EPA, and can and should come up with a better, more well thought out plan. Why should the local community suffer the consequences of the polluted canal AND be the ones to pay for it??
Lisa Grocottl	Brooklyn, NY	2013-04-26	With no green space near us this is the closet thing to our local park.
ed lavelle	brooklyn, NY	2013-04-26	take a place where kids play and make it into a raw sewage tank? you're going the wrong way.

Friends of Douglass Greene Park

change.org

To: U.S. Environmental Protection Agency (EPA) Superfund Region 2

Subject: **make the polluters pay, not our community, save the Double "D" pool!**

Letter: Greetings,

While we, the undersigned, support a comprehensive Superfund cleanup of the Gowanus Canal that includes addressing raw sewage overflows, we also insist that Superfund follow its own principles and make the polluters pay, not our community!

For this reason, we strongly oppose the EPA's proposed placement of a raw sewage retention tank to be built beneath the Douglass and Degraw (Double D) community pool and request that an alternative location for the proposed raw sewage retention tank be identified and selected.

We also ask for guarantees to our community that any displacement or disruption to the Thomas Greene Park and Double D Pool as a result of the cleanup provide for seamless transition of the park facilities (pool, playground, skatepark, basketball courts) and services (the School Food Lunch, Learn to Swim, cooling centers, etc.) at a nearby location.

FRIENDS OF
DOUGLASS GREENE PARK

Petition to the EPA Region 2 Superfund regarding the Gowanus Canal Proposed Remediation Action Plan (PRAP).

Make the polluters pay, not our community!

Friends of Douglass Greene Park (FoDGP) would like to thank the EPA for it's hard work and community outreach efforts regarding the Proposed Remediation Action Plan (PRAP) for the cleanup of the Gowanus Canal. While FoDGP supports a comprehensive Superfund cleanup, we, the undersigned, strongly oppose the EPA's proposed placement of a raw sewage retention tank to be built beneath the Douglass and Degraw (Double D) community pool and request that an alternative location for the proposed raw sewage retention tank be identified and selected. We also ask for guarantees to our community that any displacement or disruption to the Thomas Greene Park and Double D Pool as a result of the EPA Gowanus Canal Superfund Cleanup provide for seamless transition of the park facilities (pool, playground, skatepark, basketball courts) and services (the School Food Lunch, Learn to Swim, cooling centers, etc.) at a nearby location.

Christos Tsiamis, Project Manager
U.S. Environmental Protection Agency
290 Broadway, 20th floor
New York, NY 10007-1866

April 26, 2013

Dear Mr. Tsiamis,

Friends of Douglass Greene Park (FODGP) would like to thank the EPA for their hard work and dedication over the past three years in support of the Superfund listing, Remedial Investigation and Feasibility Study for the cleanup of the Gowanus Canal. We greatly appreciate the EPA's efforts to clearly and openly communicate with all the varied community based organizations', groups, and concerned residents and businesses in South Brooklyn regarding the Proposed Remedial Action Plan (PRAP). We thank you for helping to restore some of the broken public trust amongst our community regarding remediation of the longtime highly polluted waterway and we support the PRAP in addressing this overdue cleanup.

FODGP is an organizational member of the Gowanus Canal Community Advisory Group (CAG) and we have limited the scope of our comments to addressing our concerns around the potential impacts to the Thomas Greene Park and Douglass and DeGraw, aka Double D Pool, along with the nearby Canal area that will comprise RTA1. As is understood by FODGP at this time, the proposed cleanup plan work to be conducted in

this northern vicinity would comprise dredging, capping and dewatering (EPA), along with a retaining wall to be built (National Grid / DEC), and a proposed raw sewage retention tank (DEP), as well as ongoing work to the Flushing Tunnel and Pump Station (DEP), plus still to be determined further excavation and removal of NAPL that would need to take place on the former Fulton MGP site (National Grid / DEC) .

In regards to all these proposed remediation's and controls, three main comments from our organization to the EPA focus on:

- **Incorporating the entire upland area of the former Fulton MGP site within the EPA Superfund cleanup.**

- **Conducting a thorough review of the Remedial Investigation results at the former Fulton MGP site and addressing new potential exposure pathways with a human health risk assessment.**

- **Providing compensation and guarantees for the potential loss or disruption of the Double D Pool.**

Incorporate the entire upland area of the former Fulton MGP site within the EPA Superfund cleanup

FODGP believes that a Record of Decision (ROD) incorporating the entire upland area of the former Fulton MGP site within the EPA Superfund cleanup will provide for the best coordination, organization, planning and design possible to minimize disruption and impacts to our community. FODGP strongly believes that not coordinating these cleanups continues to make the community pay and will continue to leave too much uncertainty regarding the fate of the Thomas Greene Park and Pool. Without specific timelines, clear communication, meaningful community participation and involvement, and clarification on what specific remedies and risks comprise the former Fulton MGP cleanup in conjunction with the Canal RTA1 site, FODGP and the community of residents that use these public resources face too many uncertainties and possible disruptions that will make any further Park designs and planning impossible.

The Thomas Greene Park and Double D Pool was formerly the site of the Fulton Manufactured Gas Plant (MGP), which National Grid and the City and State are now responsible for investigating and remediating. National Grid has a website, www.fultonmgpsite.com/, which is supposed to provide regular site news and updates, however updates have not been posted since September 2012. National Grid is also required by 6 NYCRR Part 375-1.10 NYSDEC to review and update their Citizen Participation Plan (CPP) to account for significant changes in the Fulton Municipal MGP Project's remedial program. The CPP posted online is over 5 years old and dates to when KeySpan was the responsible party for the site.

National Grid's Remedial Investigation (RI) for the former Fulton MGP site was released in July 2012 and provides detailed results of their investigations into the eight parcels of land which comprise the site. The Park and Pool comprise parcel number two, and directly beneath the Pool are old petroleum tanks from former operations. According to National Grid's summary of their RI, visible coal tar and petroleum impacts were found in soils beneath the site and in areas to the west bordering on the Canal. Subsurface migration of coal tar wastes is also so problematic that it has necessitated expedited design of an Interim Remedial Measure, consisting of a cut off wall to prevent migrating contamination from entering the Canal in support of the Superfund cleanup. A Feasibility Study (FS) to address the contamination impacts as necessary has yet to be released.

Some of the contaminants found in soil and sediment testing from National Grid's RI include benzene, toluene, ethylbenzene, and xylenes (known as BTEX) and polycyclic aromatic hydrocarbons (known as PAHs). BTEX compounds are some of the volatile organic compounds (VOCs) found in petroleum derivatives such as petrol (gasoline). Toluene, ethylbenzene, and xylenes have harmful effects on the central nervous system. PAH compounds are known carcinogens and mutagens and are also responsible for developmental toxicity, resulting in birth defects and adverse impacts to non-human life forms. When the EPA discusses these coal tar derivatives in its proposed cleanup plan, they are referred to as NAPL, non-aqueous phase liquid.

According to National Grid there is supposedly "no risk of exposure" to MGP-related contaminants at this site, unless one digs about five to seven feet down. There is also a concrete barrier at parcel number two, which is supposed to provide protection to the

user's onsite. According to the EPA and the NYS Superfund program, source removal or control for all remedies, will be necessary.

The former Fulton MGP site will require close coordination and oversight between EPA, DEC and National Grid in order to prevent NAPL migration from impacting the remedy. Furthermore, EPA has identified the Double D pool area as a potential location for a 2 to 17 million gallon in line CSO storage tank for outfall RH-034 to address the over 121 million gallons of raw sewage that are estimated to enter the Canal annually from this one outfall alone, and his could impact the integrity of the remedy.

The forthcoming Record of Decision (ROD) must reflect a comprehensive cleanup of the canal and the upland former Fulton MGP area, where all agencies and parties involved work together in a much more coordinated and timely fashion. The former Fulton MGP upland area does comprise RTA1, the first part of the Canal which will be remediated, and this will most likely set the timeline and pace for the subsequent parts of this cleanup. Furthermore, any failure to achieve the Interim Remedial Measure cut off wall would result in recontamination of the canal sediments and could potentially significantly delay the cleanup. The design and location of this interim cut off wall have yet to be presented to the public, so not only is the coordination of this remedy in question, but understanding the impacts of where this NAPL could possibly migrate to if it is prevented from entering the Canal create additional concerns for the safety and health of nearby residents, businesses and park and pool users.

More broadly, in terms of communication and transparency with residents and organizations like the Gowanus Canal Community Advisory Group (CAG); National Grid and the DEC and DEP have not responded to community concerns or public meeting requests, nor followed even the most basic parts of the Citizen Participation Plan as prescribed on the National Grid former Fulton MGP website. While National Grid continues to insist that the Park and Pool are safe, their explanations at times seem to be at odds with the EPA in terms of technical assessment, like NAPL migration for instance, where National Grid insists that coal tar waste only migrates down, yet the EPA's presentations communicate that NAPL can migrate down and up, and very importantly be transported via groundwater, not just into the Canal itself, but depositing around the neighborhood, particularly in the former MGP vicinity. This is naturally of great concern to us.

National Grid and the City of New York are potentially responsible parties (PRP's) and FODGP asks that the EPA use its Superfund authority to enforce the entire upland area cleanup in a coordinated fashion that will not cause multiple disruptions to the community and its resources.

It is for these many reasons that FODGP would like to see EPA use its vast compliance and enforcement authority under CERCLA to include the former Fulton MGP site as part of the remedy. We believe this to be the best way to guarantee source control remediation and proper agency and responsible party alignment that will ensure the protectiveness of the preferred remedy while safeguarding our community and concerns over our beloved Thomas Greene Park and Double D Pool.

Conduct a thorough review and verify remedial investigation results at the former Fulton MGP site and address new potential exposure pathways with a human health risk assessment.

For the safety of the users of the Park and Pool, FODGP insists that the EPA perform a thorough inspection of National Grid's findings regarding risks of exposure at parcel number two of the former Fulton MGP. We would like to see testing done by the EPA on the concrete barrier of parcel number two and the material of the two swimming pools onsite (the toddler pool and the regular pool) that tests for BTEX, PAH's, VOC's and NAPL. We would like to know if there is any issue with the porosity of these materials that could facilitate exposure pathways for these toxics? We would also like to see regular testing for these same chemicals done for the Pool water and the drinking and shower water at the Double D Pool facility. Finally, given the groundwater and storm water runoff contamination concerns, we would like to see groundwater testing done by the EPA onsite at the Park and Pool after wet weather events.

FODGP would also like to bring to the attention of the EPA that the Thomas Greene Park Playground was just recently redesigned and reopened this March. Over 900K in discretionary funding from City Council members was spent by NYC Parks to renovate this playground. The land was not remediated before the new playground went in. This new playground has large tree pits with a lot of exposed dirt, and a new children's sprinkler fountain, both of which should be evaluated as new dirt and groundwater sources onsite. The playground is now experiencing heavy use from neighborhood

residents and the sprinkler will surely be a very big draw for young children this summer. There are very low tree guards delineating the playground from the tree pits, but the reality is that children love to play with dirt and very young children will be digging in this dirt, and inadvertently or sometimes deliberately ingesting it. We again ask that the EPA evaluate that these new Park designs and amenities to ensure that they do not create exposure pathways that could pose health risks to the young children and families recreating onsite.

Provide compensation and guarantees for the potential loss or disruption of the Double D Pool

As part of the proposed cleanup plan, EPA is proposing potentially impacting the Double D pool area to excavate and build a 2 to 17 million gallon raw sewage storage tank. The plan obfuscates the issue in a way that residents reading the PRAP would not even realize that there is proposed threat to the pool in the proposed plan. It is for this reason that FODGP recently began a petition to inform users of the Pool.

In less than three weeks since the petition was launched, response has been tremendous. Local residents and members of FODGP trying to "Save the Pool" have been featured on Channel 12 News, DNA info, Brownstoner, the Brooklyn Paper, and in the New York Times.

The Double D pool was slated to be closed by the Mayor's office in 2010 and the neighborhood residents successfully rallied against this closure to "Save the Pool." Because the EPA understands community acceptance to be very integral to the proposed cleanup plan, FODGP is including the over 1,000 petition signatures we gathered in support of this cleanup, that includes addressing CSO's, but are against a raw sewage tank being placed beneath the Double D pool (www.change.org/petitions/epa-make-the-polluters-pay-not-our-community-save-the-double-d-pool).

We do not feel that enough information and consideration was provided to our organization and community in regards to this proposed location for us to support this proposed location in any way. Should the EPA and DEP be willing to discuss this

proposal further with FODGP and the community, and provide compensation and guarantees to the community at large, with respect to the pool, then perhaps there could be support, but at this time we resoundingly say NO to a raw sewage tank beneath the Double D pool.

The communities that use this Park and Pool also deserve clear communication on what a proposed raw sewage retention tank at this location would mean for our community. We want to see specific health risk assessments and guarantees that there would be no disruption to our facilities and services. Furthermore, FODGP understands that there are other locations, closer to the CSO outfall (RH-034), where the tank can go, such as the lot on Nevins and Butler, across the street from the Pump station and the Flushing tunnel. There are also numerous parcels of land for sale in the immediate vicinity and perhaps this might also be worthy of an eminent domain proposal.

There are hundreds of petition comments that address the communities concerns over this potential loss and demonstrate the importance of this community resource. To be clear these signatures represent that the community of residents who use this facility do not want a raw sewage tank to be built beneath the pool.

The pool primarily serves nearby public housing and neighborhood residents during the summer season, and programs provided at the Pool facility include the School Food Lunch program, which serves free breakfast and lunch while school is out, and the Learn to Swim program, which provides free swimming lessons for children. The pool also serves as a cooling center during heat waves. There is also a second pool, uniquely designed for toddlers, which some of the youngest neighborhood residents enjoy and a handicapped lift which services the main pool to allow for special needs access.

Should the ROD move forward with the retention tank location as put forward in the PRAP, what would be the exact timeline that this resource would be disabled? What compensation will be provided in the ROD for a community losing a recreational open space facility and how would the EPA enforce City open space standards for an already underserved part of the Gowanus community? New York City Planning Standards outlined in the 2010 City Environmental Quality Review Technical Manual encourage a standard of 2.5 acres of open space within half a mile for every 1000 residents. EPA and DEP will have to address what access to Parks is presently provided for in Gowanus compared with the standard requirements. Estimates from a CAG member have put

forth that Northern Gowanus residents only have access to roughly 7 acres of Parks instead of the 70 acres the standard requires.

While FODGP supports a comprehensive Superfund cleanup of the Gowanus Canal that includes addressing raw sewage overflows, we also insist that Superfund follow its own principles and make the polluters pay, not our community. The EPA's proposed placement of the raw sewage retention tank to be built beneath the Douglass and Degraw (Double D) community pool will greatly impact an already underserved community by removing a facility that serves primarily low income populations that already suffer disproportionately from the effects of obesity and lack of access to open space. Furthermore, very serious consideration should be given to what impacts could occur to our most vulnerable elderly and young populations if there is no nearby facility to provide services designed to prevent hunger, and even death during excessive heat. To prevent the denial of, reduction in, or significant delay in the receipt of benefits by minority and low-income populations would disproportionately affect communities of color and violate the U.S. EPA's environmental justice commitments.

Presently there is no specific time frame or incentives being offered in the proposed cleanup plan to the community in the regards to the potential closure of the Double D pool. It is also unclear at this time if there may be additional disruptions to the Thomas Greene Park. Also, due to the aforementioned other reasons regarding why the land in parcel two may still need to be remediated, even without the placement of the retention tank beneath the Double D Pool, it is imperative that EPA carefully consider these same reasons in their ROD before any disabling or disruption of these community resources were to occur. FODGP asks that the ROD include enforceable measures to provide for temporary and permanent relocation of services at a nearby location as needed.

Any temporary displacement or permanent disruption to the Thomas Greene Park and Double D Pool needs to be planned for with a seamless transition of services that includes an expense budget in the ROD for all the park facilities (pool, playground, skatepark, basketball courts) and services (the School Food Lunch, Learn to Swim, cooling centers, etc.) at a nearby location. FODGP would like to see an expense budget for rebuilding the Pool and Park as necessary and a budget for any interim pool and services that are needed. FODGP would also like to see enforceable measures in place

between the PRP's and the Parks Department for any necessary expenses should the new playground be disrupted.

Currently, there is much concern in the area over displacement, gentrification, affordable housing, threats to NYCHA residents housing, along with the potential closures of the Pacific library branch and Long Island College Hospital (LICH). Many longtime daycares and community centers have also lost their funding, so the threatened loss of this community resource combined with these numerous pressures adds to the burdens that neighborhood residents are already experiencing in a historically underserved area.

It is for these reasons that FODGP asks for guarantees in the ROD that minimize any possible disruption to the Double D pool and provide for any direct costs related to that, including a nearby temporary pool and a permanent replacement, along with all the community services and other park amenities accounted for.

Over $500 M will be spent on this cleanup and we want to see a Record of Decision that minimizes any possible disruption to the park & pool and provides for any direct costs related to that, including a nearby temporary pool and a permanent replacement, along with all the community services and other park amenities accounted for. Anything less would be environmentally unjust. Clean up should fall on the responsible parties, not on the backs of our children and our community.

Thank you for all your time and attention to these matters.

Sincerely,

Sue Wolfe

re Red Hook

tom lisenbee to: Region2 GowanusCanalComments 04/26/2013 04:35 PM

History: This message has been forwarded.

Dear EPA:

After carefully weighing the pros and cons, as local residents of the Hook, we must say no to your proposal to process toxic sludge dredged from the Gowanus Canal in Red Hook. The future for Hook is precarious enough as it is without dropping this toxic bombshell into our midst.

Yours,

Tom and Sharon Lisenbee

Brooklyn NY 11231

Red Hook Civic Association input re: Red Hook

rosemary mcgettrick to: Region2 GowanusCanalComments 04/26/2013 04:40 PM

History: This message has been forwarded.

Thank you for your numerous presentations to our communtiy.
Please read the attached.
Red Hook Civic Association Co-Chairs: Jay McKnight & John McGettrick

civic assos response to EPA.docx

From: **Red Hook Civic Association,**
Jay McKnight, Co-Chair, Public Housing
John McGettrick, Co-Chair, Private Housing

We greatly appreciate the three meetings that the EPA came to in Red Hook to listen to the community, concerning the proposed CDF and the most recent Agency comments indicating that the CDF would not be coming to Red Hook and that dewatering /decanting could then take place on a barge as the preferred option.

Prior to these most recent assurances, which relieved a tremendous amount of anxiety in this community, that suffered so greatly during and after *Sandy*, there had been a number of concerns, including, but not limited to:

- First and foremost, the proposal for a land-based CDF and adjacent dewatering facility at t he GBX site, within a FEMA designated flood zone, right next to the ball fields, park, track, pool and Ikea park would appear to have violated any required, unbiased, *Environmental Justice Analysis.*
  (It should be stressed that Red Hook was very involved in the establishment of these guidelines over 20 years ago – when the community was overrun with noxious uses, including a waste-transfer station, proposed sludge plants and the largest garbage processing facility on the East Coast. After years of struggle, the community prevailed in almost all of these battles.)
- Fear of noxious odors emanating from the dewatering process and the subsequent steps necessary to create the CDF that could spread to the ballfields, park and beyond,
- Concern about contaminated dust and vapors escaping during these decontamination processes and migrating beyond the GBX site, especially during the receiving and dispersal of the toxic sludge. It should also be noted that in recent years winds off the water in this area have increased substantially.
- The filling in of privately owned lands in the Gowanus Bay section of New York Harbor with partially contaminated material, used to create the CDF, could leach from the CDF

and further pollute the harbor. At the same time this action would expose adjacent lands to even greater flooding in the event of another major storm. Not "if " there is another storm, but when one occurs.

- It should be stressed that this filling-in has not been allowed in New York Harbor for more than ½ a Century and would need a full-blown EIS first, if it were ever to proceed.
- *Environmental Justice Guidelines*, in accordance with *NEPA* should prevent the siting of a land-based dewatering facility and an adjacent CDF @ the GBX site. The site is adjacent to ballfields, a popular track, park areas and an Olympic sized swimming pool all of which are frequently used by Red Hook residents and residents of neighborhoods throughout Brooklyn.
- A similar population also primarily occupies residential housing in Red Hook. In contrast, some other communities close to the contaminated canal are more affluent and in some of these areas of the Canal, efforts are underway to rezone industrial land and build mostly luxury housing.
- In addition, the owner of the property proposed for expansion vial filling-in of lands under water for the CDF is an environmental violator, and has proposed additional uses of his enlarged property such as a large concrete plant that would undermine the value of the heavily used adjacent park and recreation areas
- The process proposed for removing toxins from the contaminated sludge is not the most effective for the removal of the heavy metals that make up substantial amounts of the material.
- The composition of the sludge in the contaminated Red Hook sector of the Canal has changed in recent years and become even more toxic as the result of two hurricanes – most especially *Sandy*. This storm scoured the bed of the Canal as the surge receded.
- The ongoing construction of a large Department of Sanitation Marine Transfer Station has disturbed toxic materials deep in the bed of the canal in the same area that was once immediately adjacent to a huge NYC incinerator for years.

- Recent spillage during *Sandy* from the adjacent Hess petroleum site further polluted this area of the Canal and future storm surges are likely to further increase pollution in this area.
- Test bores previously done in this area no longer have validity for use in current analysis.
- Sixty years ago Red Hook had twice as many people and thousands of more jobs. The supporters of the current project proposal have constantly and dramatically over-stated the number of jobs involved in a CDF. They have even gone as far as suggesting that the entire Canal cleanup will not take place is there is no Red Hook CDF.
- Several thousand people have expressed their opposition via signatures on petitions and post cards or in smaller, but almost unanimous numbers showing up in opposition at the 3 meetings the EPA hosted in Red Hook. Clearly from the outset the community indicated that there was no acceptance of the CDF as set forth as a requirement by the Agency. It should be noted that others who use the ballfields and recreation areas were also opposed but did not formally object because of their pending documentation status.
- Others remain puzzled as to why if a land-based dewatering facility was needed, why was one not provided at sites closer to the most contaminated parts of the canal? This could have resulted in fewer raisings of the 9th Street & Hamilton Avenue Bridges, and therefore fewer traffic jams and less air pollution.
- In addition, there was concern that the development of luxury housing along the canal would increase pressure to push current noxious uses on the canal into Red Hook, especially if new land was being created by the proposed CDF and in turn, those uses would create even more pollution near the ballfields, park and nearby Public Housing. This would be accompanied by an increase in heavy truck traffic right through the area.
- The Red Hook Food Vendors, who have permits to sell food in Red Hook, and their customers need a pollution and odor-free environment at the ball fields.

- Asthma rates (much higher than the national average) and cancer rates are already too high in Red Hook. We do not need another potential catalyst.
- The fact that the owner of the GBX site previously had serious environmental issues and a multi-year battle with the New York City Park's Department is a continued concern.
- We were also led to believe that Thermal desorption, which, we understand is the selected treatment mechanism, is not suitable for heavy metals. According to the Federal Remediation Technologies Screening Matrix and Reference Guide (Version 4): -Thermal desorption is a physical separation process and is not designed to destroy organics. Wastes are heated to volatilize water and organic contaminants. - The limitations of the process were described in that document as:
- There are specific particle size and materials handling requirements that can impact applicability or cost at specific sites.
- Dewatering may be necessary to achieve acceptable soil moisture content levels.
- Highly abrasive feed potentially could damage the processor unit.
- Heavy metals in the feed might produce a treated solid residue that requires stabilization.
- Clay and silty soils and high humic content soils increase reaction time as a result of binding of contaminants.

This led one to wonder what was going to happen to residue? How is dewatering to be accomplished? Also - since some of the metal loading would vaporize during thermal treatment – why was there no study of possible air-pollution done first?

Statement against proposed EPA plans for Red Hook

rosemary mcgettrick to: Region2 GowanusCanalComments 04/26/2013 04:51 PM

History: This message has been forwarded.

Dear Mr. Tsiamis:
Thank you for your patient attendance and courtesy at the numerous meetings the EPA held with the Red Hook Community.
I was at them all.
I am opposed to the EPA plan for using the private property of John Quadrozzi which is in a FEMA designated flood zone for any dewatering/decanting, etc., etc purposes.
Toxic waste should not be "treated" so near ballfields, the beautiful olympic-size pool and well-used track.
This community suffered enough during and after Sandy. Please do not make it a toxic dump site.
It is a beautiful waterfront "village" and is enjoyed by so many New Yorkers.
Please use your engineering skills to accomplish the Gowanus clean-up on barges, on the site.
Thank you. Rosemary McGettrick, 178 Coffey St. (23 year homeowner here)

Give Red Hook a break

Beth K to: Region2 GowanusCanalComments 04/26/2013 05:23 PM

Christos Tsiamis
Project Manager,
Central New York Remediation Section of the U.S. Environmental Protection Agency Region 2
290 Broadway, 20th floor
NY, New York 10007-1866

Mr. Tsiamis:

I am writing to register my opposition to using Red Hook as a dumping ground from clean–up of the Gowanus Canal.

The EPA has a list of remedies that involve processing and containment of dredged material off-site for beneficial use such as the capping of landfill sites, I urge the EPA to select any option that involves off-site processing and off- site disposal.

Don't even get me started on the topic of even considering any proposal that includes a repeat environmental offender like John Quadrozzi. It's nice that he pays you hefty fines for his nefarious behavior, but that should count against him, don't you think? Or do you just like people who incur (and pay) EPA fines?

Concerned,

Beth Kaiser

Mr. Christos Tsiamis
290 Broadway, 20th Floor
New York, NY 10007-1866

Dear Mr. Tsiamis,

I totally support the EPA's plan to comprehensively clean up the Gowanus Canal.
I have 3 children and believe it's best for them and future generations of children to clean up the canal completely... dredge and remove the poisons.. Please don't build piecemeal on the coal tar and toxic sludge and leave the consequences to future generations.
Do it right on the front end.

Thank You

Blaise Corrigan

Comments to the Proposed Clean Up Plan_Natalie Weinberger.pdf

April 26, 2013

Christos Tsiamis, Project Manager
U.S. Environmental Protection Agency
290 Broadway, 20th floor
New York, NY 10007-1866

Dear Mr. Tsiamis,

I'm a young community development professional currently working in Gowanus. After learning more about the Proposed Clean Up Plan, I have determined that I am in support of the plan on the whole. In addition to the EPA's outlined plans, I would personally like to see the following find its way into the next iteration and actual cleanup plan:

- The Plan needs to link this once in a lifetime investment to workforce development opportunities, especially for local individuals facing barriers to employment.
- The EPA should enforce a more a comprehensive, coordinated and timely cleanup between all agency and responsible party stakeholders involved (EPA / DEC / DEP).
- The Plan should champion diversity and advocating for inclusion and participation for all the communities we work with in the next steps in the process - design phase and as clean up actually behind
- It is essential that the Plan advocate for local residents to be involved in the planning discussions and resource allocation decisions for the future of our neighborhoods.

Thank you for taking these comments into account as you revise the Clean Up Plan.

Sincerely,

Natalie Weinberger

I, the sender, vote that I do not want this project to proceed.

marina Pavlutskaya to: Region2 GowanusCanalComments 04/26/2013 06:32 PM

History: This message has been forwarded.

As (one of the options above) of the community of Red Hook, I/We am/are strongly opposed to the processing of contaminated sludge dredged from the Gowanus Canal Superfund Cleanup Site at a facility at the proposed location. The cost savings are negligible, and the Red Hook Ball Fields and Pool are used in public trust. The community does not want to create more land from this contaminated sludge adjacent to one of the most heavily used recreation areas in New York City. People and organizations adversely affected include (but are not limited to!):

- Children
- Numerous public and private schools which use the fields for physical education & sports teams
- Residents of the Red Hook Houses and the surrounding neighborhood
- Soccer, softball, baseball, football, handball, basketball, track & field teams and enthusiasts
- Swimmers of all ages
- The Red Hook Food vendors and their customers
- Other visitors to our community

Further, we object to an individual (John Quadrozzi), who has incurred serious fines for environmental violations, from profiting from the project.

Gowanus Canal Conservancy Superfund PRAP Comments

Hans Hesselein to: Region2 GowanusCanalComments, Natalie Loney 04/26/2013 06:33 PM

Cc: Richard Kampf, Venetia Lannon, Carter Strickland, April Dubison, askmarty, "Walsh, Daniel", Joan Millman, Sara M Gonzalez, Nydia.Velazquez, Brad Lander, Stephen Levin

History: This message has been forwarded.

Dear Mr. Tsiamis and Ms. Loney,
The Gowanus Canal Conservancy wishes to thank you for your hard work in preparing the Gowanus Canal Superfund Proposed Remedial Action Plan and for providing the community with an opportunity to review and comment on the proposed remedy. We are very excited by fact that the EPA is spearheading this important cleanup, which will address more than 150 years of contamination that has accumulated in the Canal's sediments. As a Gowanus stakeholder and watershed stewardship organization, we take our public advocacy responsibilities very seriously and have taken this opportunity to extensively review and comment on the PRAP. Please find our comments and associated figures attached to this e-mail for your review and for inclusion in the public record for this Superfund Site.

Regards,
Hans

Re: Comments on EPA's December 2012 Proposed Remedial Action Plan
Gowanus Canal Superfund Site

Dear Mr. Tsiamis,

As you know, the Gowanus Canal Conservancy is a 501(c)(3) community-based not-for-profit organization founded in 2006 in Brooklyn, New York. Our mission is to serve as the environmental steward for the Gowanus Canal and its watershed, overseeing its transformation into a system that is clean, green, and publicly accessible. As part of our efforts, we are working to improve water quality, preserve open space, and promote public access to the ecological, cultural, and recreational resources of the Gowanus Canal and its watershed.

The Gowanus Canal Conservancy has participated extensively in the Superfund process. We understand that the clean-up will take many years and that many technical questions remain unresolved at this time. Nevertheless, the Superfund clean-up represents a unique opportunity to conduct a long over-due comprehensive clean-up of the Gowanus Canal with the support of a broad coalition of stakeholders.

The Gowanus Canal Conservancy generally supports EPA's December 2012 Proposed Remedial Action Plan for cleaning up the Gowanus Canal. Our comments seek to bring attention to matters that are particularly important to our constituents as well as those that we believe require additional consideration by EPA.

Sincerely,

Hans Hesselein
Executive Director

Richard Kampf
Board Member

Clean and Green

The Gowanus Canal Conservancy is working with its many public and private partners to transform the Gowanus Canal and its watershed into a functioning urban ecosystem that is clean, green, and publicly accessible. A central part of this vision is to facilitate the creation of a functional waterfront esplanade that embraces the historic industrial character of the neighborhood while providing inspiring and accessible park space. This waterfront park aims to be integrated with a network of green infrastructure consisting of wetlands, rain gardens, and other functional green spaces existing in harmony with the city's urban infrastructure. We are working to bring cleaner water, robust vegetation, and diverse wildlife habitat to Gowanus. The restored green spaces will also buffer the community from the potential impacts of climate change, including sea level rise, storm surge, and flooding.

Today, the Conservancy is leading broad-based community stewardship activities throughout the watershed. Our flagship projects include Cleaning and Greening adjacent land, developing a state-of-the-art compost facility to help manage and reduce New York City waste, and educating young people about the pleasures of the waterfront right here in the heart of Brooklyn. Last year we shared our enjoyment of the Canal and our vision for its future with thousands of community members, volunteers, donors, voters, and fundraiser attendees. The Superfund clean-up, once complete, will provide an important foundation upon which to build in order to realize our vision of a clean, green and accessible waterfront.

The Long Term

As stewards of the watershed, the Gowanus Canal Conservancy seeks to ensure that the remedy is designed properly and functions consistently with the long-term remedial objectives contained in the National Contingency Plan. We hope to have a seat at the table with key stakeholders in the process moving forward. The following comments address ways in which the Proposed Plan may be improved in order to ensure the required long-term permanence and success of the remedy.

Watershed Perspective

One of our fundamental concerns regarding the Superfund process has been that the Remedial Investigation and Feasibility Study Reports do not accurately reflect the importance of the surrounding watershed. A complete and accurate understanding of the dynamics of the watershed, as it relates to the remedy for the Canal, is fundamental to achieving a sustainable and successful clean-up. The watershed and the surface waters of the Canal are inseparably linked through the sewer conveyance system and local and regional groundwater flow. Thus, the natural and man-made systems are interdependent. Accordingly, we request that EPA utilize a watershed-based conceptual site model (CSM) as well as a framework to managing the relevant environmental systems, and the data collected there from, that is consistent with EPA's own Watershed Approach Framework.[1]

EPA's remedial design studies and long-term monitoring programs should be used to continuously refine the watershed-based CSM as new information becomes available. EPA's use of a watershed-based CSM will assist the Agency in identifying and managing changes to the natural and man-made systems of the watershed and their potential impacts on the remedy and, ultimately, the water quality of the Canal.

Performance Monitoring

Given the reasonable likelihood of failure, shortcomings, and / or insufficiency of planned remedial measures for the Gowanus Canal, remedial design studies should fill existing data gaps in the watershed-based CSM and be used to identify potential contingencies for remedial measures that may not perform as planned. A robust plan for monitoring baseline conditions as well as the short- and long-term performance of the remedy is necessary to ensure the efficacy of the clean-up. Proper monitoring is vital to ensuring that the remedy is designed appropriately from the beginning and can adapt to the many

[1]Office of Water, (4501F), EPA-840-S-96-001, June 1996

potential changes to the natural or man-made systems of the watershed, as well as to human behavior. We understand that EPA will be developing a short- and long-term monitoring plan for Gowanus, and we look forward to learning more about the details. At this time, we seek greater clarity about EPA's plans to conduct baseline monitoring. The PRAP falls short on these details.

In addition, going forward, EPA should utilize an adaptive management approach consistent with the Adaptive Management Technical Guide published by the U.S. Department of Interior.[2] This Technical Guide describes adaptive management as an "iterative process of management, monitoring, and evaluation" that "actively engages stakeholders in all phases of a project over its timeframe, facilitating mutual learning and reinforcing the commitment to learning-based management." Adaptive management also involves "ongoing, real-time learning and knowledge creation" with the objective of achieving an "improved understanding and improved management over time." It further explains that:

> "Adaptive management [is a decision process that] promotes flexible decision making that can be adjusted in the face of uncertainties as outcomes from management actions and other events become better understood. Careful monitoring of these outcomes both advances scientific understanding and helps adjust policies or operations as part of an iterative learning process. Adaptive management also recognizes the importance of natural variability in contributing to ecological resilience and productivity. It is not a 'trial and error' process, but rather emphasizes learning while doing. Adaptive management does not represent an end in itself, but rather a means to more effective decisions and enhanced benefits. Its true measure is in how well it helps meet environmental, social, and economic goals, increases scientific knowledge, and reduces tensions among stakeholders."

As part of an adaptive management approach for the Gowanus Canal, any long-term performance monitoring plan should be closely linked to the watershed-based CSM so that the hypotheses and assumptions that led to the selected remedy can be tested and refined.

For example, it is reasonable to predict that climate change may result in sea level rise, increased frequency and intensity of storms, and increased storm surge levels. Such conditions may alter the water budget and raise the levels of both surface and ground water. Therefore, it is important that EPA further evaluate the volume and rate (flux) of groundwater discharge into the Canal. In addition, capping and installing sheet-pile walls in the Canal has the potential to significantly alter the flow of groundwater throughout the watershed, much of which currently discharges into the Canal. It is unclear where all of this water will go under future capped and bulkheaded conditions. The potential for flooding or short-circuiting through preferential pathways of least resistance between the cap and bulkheads or sheet pile walls should concern EPA. We believe that it is important that the remedial design studies acknowledge and address these uncertainties with appropriate monitoring and modeling efforts.

Finally, all data collection efforts must be transparent, with real-time sharing of information among all stakeholders. The Gowanus Canal Conservancy is developing a data clearinghouse to help facilitate the transfer of information relevant to the Gowanus Canal and its watershed. We look forward to working with EPA and other key stakeholders that are collecting data that may be used to refine and improve the remedy.

Watershed Monitoring Well Network

One way to ensure the adequate collection of remedy-relevant data would be to improve the existing monitoring well network within the watershed. A formerly extensive monitoring network has been rendered useless by lack of funding for the replacement of wells that have been destroyed over the past

[2] Williams, B. K., R. C. Szaro, and C. D. Shapiro. 2009. Adaptive Management: The U.S. Department of the Interior Technical Guide. Adaptive Management Working Group, U.S. Department of the Interior, Washington, DC.

several decades[3]. The Conservancy requests that EPA, as part of its remedial design process, improve its understanding of watershed hydrogeology in order to help ensure the efficacy of the remedy.

The United States Geological Survey (USGS) proposes to replace a number of these wells and evaluate watershed hydrology using the data it collects. Please refer to *Attachment 1* which contains the USGS Proposal. The USGS seeks to collect and evaluate data that will be used to accurately represent the present-day shallow groundwater flow system and verify groundwater-surface water interaction and related modeling efforts.

Specifically, USGS proposes to:

1. Characterize groundwater influences on increased flood potential associated with continued water-table recovery, climate change, and the proposed remedial measures;
2. More accurately estimate rates of groundwater infiltration into the groundwater system, including leakage into and out of sewers and water delivery mains;
3. More accurately estimate groundwater seepage velocities into the Gowanus Canal; and
4. More accurately estimate the direction and rate of groundwater flow as it relates to the fate and transport of dissolved phase constituents.

The field data collection objectives of the USGS proposal would be used to establish a baseline understanding of the hydrologic system of the Gowanus Canal watershed and further characterize the need for long-term monitoring. The modeling objectives would advance the understanding of the regional hydrologic processes that may affect the design of the remedy, ecological restoration, and storm water management.

The USGS proposal should be funded and implemented early in the remedial design phase. The Gowanus Canal Conservancy would be happy to help facilitate a meeting between EPA and USGS in connection with this proposal.

Improved Inter-agency Cooperation and Data Sharing

As noted above, it is extremely important to monitor baseline conditions to help evaluate the long-term effects of planned changes in order to inform future decision-making. Various parties have collected data and are preparing numerical models to simulate environmental conditions and make predictions to support future decision-making in the Gowanus watershed. These models include storm water infrastructure models prepared by NYC DEP and its consultants and hydrogeologic, hydrodynamic, and sediment transport models prepared by National Grid and its consultants. EPA should engage an independent third party to review and integrate all environmental and watershed modeling efforts that are used in refining the CSM.

The USGS has extensive experience developing, calibrating, verifying, and integrating a variety of numerical models and has the ability to help integrate these data collection and modeling efforts. The Conservancy requests that EPA consult and coordinate with USGS, or a similarly experienced entity, to utilize its expertise in reviewing and helping to integrate these models into a single, peer-reviewed, publicly available resource that would be used and refined throughout the clean-up process.

---

[3] Groundwater monitoring efforts in the Gowanus watershed have declined significantly since the mid-20th century. During the first half of the 20th century, groundwater in Brooklyn was used for drinking water and industrial purposes. Hundreds of monitoring wells were located throughout Brooklyn, including dozens in the Gowanus watershed, to monitor water levels and water quality. Since the 1940s, when groundwater use began to decline, the monitoring well network slowly has been destroyed. Today, there is a single USGS monitoring well located in the Gowanus watershed.

The Gowanus Community

Conservancy Activities at the Salt Lot

One aspect of the proposed clean-up affects a parcel of property located adjacent to the Canal, an underutilized road-salt storage facility at 2 Second Avenue, Brooklyn, 11215, the Salt Lot. This parcel is critical to our community and to Conservancy members and volunteers. Our vision for the Salt Lot is rooted in our strong partnership with the community, the City, and local small businesses and organizations and is consistent with the objectives of the Brownfield Opportunity Area (BOA) program. The site is currently used by the New York City Department of Sanitation (DSNY) to store road-salt.

Through a partnership with DSNY, the Gowanus Canal Conservancy has transformed a portion of the Salt Lot into the focal point for efforts of the Conservancy's robust volunteer gardening, composting, community nursery, and environmental education programs, including our highly successful volunteer neighborhood greening programs. Through this volunteer program, we enable community members to plant and maintain street trees and street side gardens installed in partnership with neighborhood property owners, businesses, and the City. The Conservancy currently maintains Canal-side gardens on the lot and a street-end rain garden at the end of Second Avenue. In 2012, the Conservancy hosted more than 700 volunteers who logged over 3500 hours of service to the community.

The Conservancy also operates a composting facility, which produces high quality compost that is used in parks, gardens, planters, and tree pits throughout the City. In 2012, about a dozen volunteers each month worked to build each windrow by hand, while 3-4 volunteers turned the piles on a weekly basis. Using this manual approach, we processed approximately 100 tons of organic material into usable compost. To date, the Conservancy's compost program has received approximately $400K in capital funding to expand the physical facility.[4] The expanded composting facility will be capable of processing up to 400 tons of organic matter per year, representing the largest community-based facility of its type in Brooklyn. Our volunteer participation in the composting program is projected to double. The compost we produce will be available to the community for use in local landscaping, tree planting, and green infrastructure construction projects. *Attachment 2* presents a schematic drawing of the proposed compost facility.

Our experience at the Salt Lot suggests that industrial operations and ecological improvements are compatible. Our vision for the future of the property includes transformation into a clean, green, and publicly accessible component of a contiguous waterfront park. In our vision, road de-icing and compost waste management activities will serve as points of interest to be observed and learned from by community members. These operations would be surrounded and buffered by extensive Canal-side plantings, providing beauty, habitat, stormwater retention and cleansing functions. A clean, green, and publicly accessible Salt Lot will help us to highlight the importance of industrial operations to the character and economy of the neighborhood and represent a major step toward creating a resilient and healthy watershed and publicly accessible Canal for generations to come. This public space will become a key centerpiece to a contiguous, functional, accessible waterfront park along the Canal. These characteristics have also brought the Salt Lot to the attention of New York State Department of State as well as the Brownfield Opportunity Area (BOA) program.

Proposed CSO Retention Tank at the Salt Lot

EPA, in its Proposed Remedial Action Plan, proposes to install a 4 million gallon underground CSO

[4] The initial grant was provided by Councilmember Brad Lander's Participatory Budgeting initiative that crowd-sourced neighborhood improvement initiatives from community members. In March 2012, District 39 residents voted, as part of this process, to award $165,000 in capital funds to expand the Conservancy's compost facility at the Salt Lot. The project was second in popularity, with 919 votes. Building on the success and popularity of the participatory budgeting initiative, City Council Members Steve Levin and Sara Gonzalez matched District 39's commitment with a combined contribution of $131,000. Brooklyn Borough President Marty Markowitz has pledged $100,000 in additional funding.

retention tank at the Salt Lot. We understand that EPA also proposes to install an 8 million gallon CSO retention tank at the Thomas Greene Park. Both of these spaces are extremely valuable to the community. We understand, however, the importance of finding the appropriate strategic sites for installing these retention tanks to reduce CSOs, which include hazardous materials regulated under CERCLA as well as pathogenic bacteria, suspended solids, nutrients and other water quality impairments. Therefore, we support EPA's conceptual approach in this regard.

It is our understanding that the proposed CSO retention tank would not be constructed in the northwest corner of the Salt Lot because of the unusual shape and dimensions of this portion of the property. As such, we request that EPA consider the plans of the Conservancy and our community partners and design and construct the proposed CSO retention tank such that the Conservancy's community programming, including our composting program in particular, may be allowed to safely continue to operate during construction of the CSO tank.

Further, we request that EPA work with the Conservancy and our community partners to ensure that the Salt Lot is restored to its current use as a shared-space for the ecological and industrial activities of the Conservancy and DSNY after the proposed CSO retention tanks are installed.

Economic Benefits

Community members should be given the opportunity to participate in the economic benefits of the remedy. The clean-up is an opportunity to create blue, green, and white collar jobs in fields such as construction, engineering, and research. There are also significant environmental education opportunities for the community. We are concerned, however, that the Agency's traditional procurement process will result in the hiring of out-of-town and out-of-state firms and workers to conduct much of the work. We are hopeful that the regulatory agencies, elected officials, and PRPs will work with local economic development advocates to develop hiring criteria that will help to ensure that local firms and workers are given preference for contracts related to the clean-up.

Sediment Management

EPA has a unique opportunity to provide leadership on the management of contaminated sediments on a regional scale. We support the use of ecologically sensitive, equitable, and cost-beneficial disposal alternatives that promote local economic and workforce development. Therefore, we reiterate that EPA needs to take a closer look at all opportunities to implement sustainable regional sediment management solutions that involve using contaminated sediments as a resource rather than as a waste.

The Gowanus Canal is one of several contaminated sediment sites in the New York metropolitan region. Others include Newtown Creek, Hudson River, Passaic River, Hackensack River, and New York Harbor. These sites are expected to generate 15 – 20 million cubic yards of contaminated sediment over the next 15 to 20 years. There are potential economies of scale associated with these concurrent remediation projects. Off-site transport, processing and disposal / destruction of contaminated sediments not only is unsustainable, it is also uneconomical. Much progress has already been made in developing viable, cost-beneficial technologies to treat and beneficially re-use these sediments. Further, the opportunity to handle, treat, and re-use these sediments presents a significant economic development opportunity for Brooklyn, the City, and / or the tri-state region. Therefore, we request that EPA keep all potentially viable options for sediment decontamination and beneficial re-use on the table at this stage of the process.

Sediment Barging

Multiple bridges along several highly travelled east-west streets cross the Gowanus Canal. These bridges support significant vehicle, bicycle, and pedestrian traffic and are typically opened just a few times each year. The Gowanus community is concerned that barging sediments to a treatment facility, which will require that the bridges be opened much more frequently, will cause business disruptions and social and economic hardship throughout the community.

The Conservancy request that EPA and National Grid re-consider the use of hydraulic pumping to move the contaminated sediment as a slurry from the point of dredging to the point of treatment. This technology has been used with great success at the Lower Passaic River Superfund Site at which contaminated sediments were hydraulically pumped approximately one mile. In Gowanus, the sediments could be pumped to a treatment facility anywhere in New York Harbor. Any additional costs related to screening out debris may be offset by the absence of any disruption to the community from the opening and closing of bridges. Further, this process may help limit complaints of noise and nuisance odors.

Noise and Odors

Our community has expressed concern about noise and nuisance odors. The community demands that odors as well as volatile organic compounds (VOCs), dust, and particulates, be carefully managed and should be given additional guidance regarding what to expect during the clean-up in this regard. The Conservancy would be happy to assist key stakeholders in the development of a Community Air Monitoring Plan as early in the process as possible.

After the Clean-Up

Clean Water

It is highly unfortunate that the Gowanus Canal has been used as part of the City's sewer system for almost 150 years. This antiquated system has resulted in unacceptable environmental health and safety conditions for the entire community. The vitality of the watershed and community depends on cessation of combined sewer discharges to the Canal and an enhanced, environmentally sustainable, stormwater / wastewater system. The Gowanus Canal Conservancy supports community efforts to achieve total elimination of combined sewer overflows (CSOs). The only practical means of achieving a remedy that is comprehensive, permanent, and sustainable is to address CSO discharge concerns within the duration of the Superfund clean-up. Therefore, we support EPA's efforts to require CSO reduction to the maximum extent allowable, consistent with its authority under CERCLA, and we believe that the CSOs and the hazardous wastes they contain are inseparable. Accordingly, we support EPA's suggested use of CSO retention tanks at the previously noted locations along the Canal to reduce CSOs from discharging at two outfalls, OH-007 and RH-034. We welcome the concomitant reduction of harmful pathogens, and other water quality impairments that are also present in these CSOs.

We understand that the City may retain flexibility in how it meets the remedial objectives specified by EPA. Should the City seek an alternative to the proposed CSO retention tanks to meet EPA's remedial objectives, we are concerned that the CSOs may not be adequately reduced as part of the Superfund clean-up. Further, NYCDEP's August 2008 Waterbody / Watershed Facility Plan for the Gowanus Canal indicates that the upgrades that are presently being made to the Gowanus Pumping Station and Flushing Tunnel will still allow the discharge of 69 million gallons of CSOs every year at outfall OH-007 and 127 million gallons every year at outfall RH-034. In total, over 250 million gallons of CSOs would still be released into the Canal every year, even after the City completes its upgrades. While this is an improvement from the baseline condition of 372 million gallons of CSOs discharging into this water body each year, much more work needs to be done. Further, according to EPA's December 2012 Feasibility Study Addendum, "the CSO reductions planned under the Facility Plan will not reduce the CSO solids that are primarily responsible for sediment accumulation and chemical contamination in the surface sediment in the upper reach of the canal." As a result, EPA states that "additional CSO reductions of 58 to 74 percent should be sufficient to achieve the PRGs [Preliminary Remediation Goals] for the PAHs and for lead, copper and PCBs. Accordingly, the Conservancy supports EPA's plan to require additional CSO reductions at outfalls OH-007 and RH-034.

Regardless of the volume of CSO reduction that is achieved by Superfund, EPA's Office of Water should provide sufficient funding to ensure proper compliance with the Clean Water Act, such that the remaining CSO discharges to the Gowanus Canal are eliminated within the duration of the Superfund clean-up. We

encourage all stakeholders, especially our elected officials, to join us in helping New York City support the Gowanus community in its desire to meet the requirements of the 1973 Clean Water Act by 2023.

Bulkhead Reconstruction

EPA's proposed plan for "bulkhead stabilization throughout the entire canal" has the potential to impair the unique and historic character of the Gowanus Canal and reduce opportunities for ecological restoration. The Canal's shoreline is composed of a mixture of bulkhead types, including cast-in-place concrete walls, stone rip rap, wooden crib-walls, steel sheet piles and others. The wooden crib-walls are of unique historical character and should be protected and / or restored to the degree practicable. They also provide habitat to some aquatic organisms, such as mussels. In contrast, steel sheet-pile walls offer the least ecological value and aesthetic appeal of any edge condition currently in the Canal. We understand that dredging activities may cause dilapidated bulkheads to further weaken and collapse during remedy construction and that the installation of temporary sheet-pile walls during remedy construction may be unavoidable. However, the wholesale reconstruction / replacement of existing bulkheads with steel or wooden bulkheads throughout the Canal is not consistent with the Conservancy's vision for the Canal, nor is it an acceptable remedy.

Any plan to reconstruct bulkheads must consider access, aesthetics, and habitat value. As such, any temporary steel sheet-pile walls must not be allowed to become permanent except, and only to the extent required, as part of the necessary remedial measures at the three upland manufactured gas plant (MGP) sites. Accordingly, the Conservancy requests that EPA require that any permanent bulkhead reconstruction that is implemented as part of the Superfund remedy be conducted consistent with the desires of the community and design parameters set forth by the New York City Department of City Planning. The Conservancy looks forward to participating as a partner with a variety of stakeholders in the bulkhead design process, and integrating this with ecological restoration efforts, as described below.

Ecological Restoration

The Gowanus Canal is mapped by NYSDEC as a tidal wetland. The Gowanus Canal Conservancy supports a remedy that is consistent with, and does not preclude, any and all efforts to restore and enhance the ecological function of the tidal wetland system. The Conservancy strongly supports EPA's plans for dredging and restoring the First Street Turning Basin as described in its Feasibility Study Addendum. We are pleased that the final design of the First Street Turning Basin will include a 30 ft wide central channel sloping up at a 4:1 (horizontal to vertical) ratio on the sides at a 6:1 ratio on the southeastern end. We are also pleased that the Proposed Plan indicates that this approach will accommodate water habitat restoration along the shoreline and a boat launch at its southeastern end. The Conservancy looks forward to working with key stakeholders to help bring this outcome to fruition.

Nevertheless, EPA can and should do much more to support the ecological restoration of the Canal within the Superfund framework. The Gowanus Canal Conservancy is working to plan, design, and build wetlands, consistent with current and future industrial and recreational uses, throughout the Canal and its turning basins, once the remediation is complete. The remedial design process should examine ecological restoration efforts throughout the Canal and its turning basins including, at a minimum, shoreline softening, improving riparian buffers, creating and expanding wetlands, restoring habitat, re-introducing native species, and ensuring no-net loss to existing wetlands. These efforts should also consider NYC's design recommendations for softer edge conditions. Finally, the remedy should be performed in a manner that is consistent with potential future ecological restoration projects and would allow them to proceed unencumbered, and without the need for any additional clean-up activities.

The Conservancy has prepared the drawings and renderings described below to further support our vision for a clean, green, and publicly accessible Gowanus Canal.

Attachment 3 presents the Conservancy's vision for the optimal location of three different shoreline treatments, including: hard bulkheads with ecological adaptation, stepped, or terraced bulkheads, and soft shorelines. Each proposed shoreline condition supports different degrees of ecological restoration, while

allowing for the continued human and industrial use of important commercial activity zones. The Conservancy understands that existing and future commercial use of the waterway requires that specific areas maintain navigable depths and armored bulkheads for the passage and mooring of vessels, while other areas no longer require the same degree of infrastructure and water depth to support these activities. Building on this, the 3 proposed shoreline conditions support different usages in different areas.

Attachment 4 offers the Conservancy's vision for an ecologically supportive, hard bulkhead. These bulkheads consist of a sheet-pile wall that can support barging activities, with a resilient material applied to the surface, which can support greater ecological colonization than a steel-faced sheetpile. Materials that can support ecological activity and withstand barge traffic might include specialized concrete or wood products, either of which provide significantly more habitat value than a steel-face. This bulkhead type has been proposed for locations that continue to receive water-based industrial traffic and in locations where concerns of contaminant transport through groundwater migration require the installation of sealed bulkheads (former MGP sites, for example).

Attachment 5 offers a rendering of a stepped, or terraced, bulkhead. Stepped bulkheads could accommodate tidal wetland or other native plant community and habitat restoration efforts, while offering aesthetic benefits and get-down opportunities in residential areas, especially along the future waterfront park. Terraced bulkheads are also designed to withstand wave action and barge transportation, but are not suitable for large-vessel mooring.

Attachment 6 reflects the Conservancy's vision for the creation of soft shorelines within all of the turning basins along the canal, as well as at the head of the canal, wherever practicable. Soft shorelines offer the greatest habitat value and ecological restoration potential, but should not be sited in areas where heavy shipping traffic is anticipated. The Conservancy proposes locating the soft shorelines in areas that are protected or will receive no water-based industrial traffic.

Attachment 7 identifies salt marsh and mudflat restoration opportunities throughout the Canal, specifically the 4th / 5th Street Basin, 6th Street Basin, 7th Street basin, and 11th Street (Lowe's) Turning Basins. These proposed locations should be used to offer public access and wildlife observation opportunities. The Conservancy requests that EPA modify the Proposed Remedial Action Plan to require that ecological restoration be conducted at all of the Gowanus Canal Turning Basins as well as at the head of the Canal.

In addition, we understand that the United States Army Corps of Engineers conducted a series of studies between 2003 and 2005 as part of its Gowanus Canal and Bay Ecosystem Restoration Project[5]. These studies contemplated various components of ecological restoration including restoration of water flow to enhance aquatic habitat and water quality, integration of ecosystem restoration with local plans, re-establishment of greenway and buffer areas, re-contouring of the Canal bottom to create natural creek depths, and habitat creation and restoration. The findings of these studies, including, but not limited to, its July 2004 Wetland Creation and General Investigation Report, should be considered during the remedial design process and the reports included in the Administrative Record. We look forward to seeing increased EPA coordination with the Army Corps of Engineers in this regard.

The Conservancy also requests that EPA increase its coordination with the appropriate state and federal Natural Resource Trustees for the Gowanus Canal from this point forward. If it has not already done so, we request that EPA formally notify the Trustees of potential injuries to natural resources from releases under investigation in connection with the Gowanus Canal and coordinate its assessments, investigations, and planning with the Trustees as required under CERCLA. We request that EPA's remedial design phase include studies to establish baseline ecological conditions against which to base future ecological restoration requirements. We hope that such coordination will increase the likelihood that selected response actions and settlement agreements will include measures to protect and restore

[5] For examples of potential ecological restoration projects for the Gowanus Canal, please refer to the U.S. Army Corps of Engineers "Gowanus Canal and Bay Ecosystem Restoration Project: Wetland Creation General Investigation Report," 2004.

the natural resources of the Canal. Finally, we hope that our request for Natural Resource Trustee coordination will result in a process that moves forward in a timely manner, is completed within a reasonable timeframe, and involves community input.

Funding

Multiple sources of funding from various levels of government will be required to fund the ecological restoration efforts that will be necessary after the Superfund cleanup has been completed. The Conservancy reiterates its request that EPA continue to work closely with New York State, New York City, our elected officials, and other stakeholders to identify opportunities and sources of funding outside the traditional Superfund PRP framework to support a comprehensive clean-up and restoration of the Gowanus Canal.

The Great Lakes Legacy Act (GLLA) and the Great Lakes Restoration Initiative (GLRI) should be considered as a model for the funding, cleanup, and restoration of the Gowanus Canal as well as other contaminated sediment sites within the New York-New Jersey Harbor Complex. The Great Lakes initiatives have resulted in the development of public-private partnerships among federal, state, and local government, communities, and industry. The Gowanus community should receive similar benefits from such cooperation and funding.

The Conservancy looks forward to working in partnership with EPA to integrate the Gowanus Canal Superfund process with other federal environmental and sustainability programs and initiatives. We also look forward to working with key stakeholders to undertake the necessary acquisition of open space that will support the development of the high quality ecological habitat that Gowanus desperately needs, as well as the installation of green infrastructure and tree planting, that will help reduce CSO and improve air quality throughout the Gowanus Canal watershed.

Concluding Remarks

The Gowanus Canal Conservancy respectfully submits these comments to EPA. A successful clean-up must take into account the function and interaction of the natural and man-made systems that exist within the Gowanus watershed. With this perspective in mind, the Conservancy supports a clean-up that not only considers EPA's nine criteria for remedy selection but that is also consistent with the goals and objectives that have been set forth in New York City's Comprehensive Waterfront Plan, the Hudson-Raritan Estuary Restoration Plan, and New York City's waterfront zoning efforts.

In summary, we request that EPA:

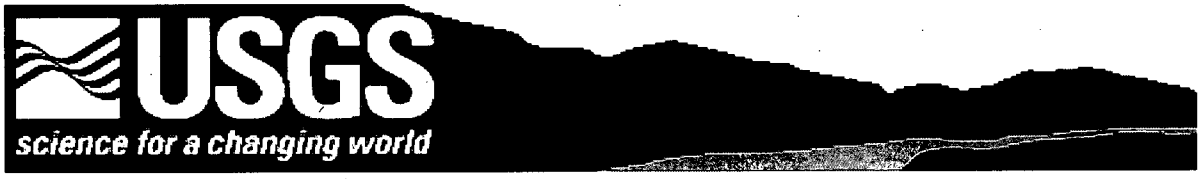
- Utilize a watershed-based conceptual site model,
- Ensure a robust baseline and long-term monitoring program and transparent data sharing as part of an adaptive management process,
- Coordinate with USGS regarding its proposal for data collection and evaluation and to oversee and integrate environmental modeling efforts,
- Consider all potential viable regional sediment management solutions that may utilize contaminated sediments as a resource rather than as a waste,
- Consider access, aesthetics, and habitat value of bulkheads and not allow any unnecessary installation of permanent sheet-pile walls,
- Utilize sediment pumping rather than barging,
- Engage the community regarding potential noise and nuisance odor concerns,
- Fund and enforce the Clean Water Act,

- Explore additional opportunities for ecological restoration and ensure that the clean-up is consistent with future ecological restoration efforts,
- Coordinate with Natural Resource Trustees, and
- Assist the community in obtaining the necessary funding to support the comprehensive clean-up and restoration of the Gowanus Canal.

Finally, we ask that EPA include this letter, and any response from EPA, in the Administrative Record for the Gowanus Canal Superfund Site.

We look forward to receiving the Agency's response to these and other comments. The Conservancy reserves the right, and hopes to continue, to share information on the proposed clean-up plans with EPA and the public and to facilitate public involvement in the process.

Attachment 1



Factors Affecting Groundwater Discharge to Gowanus Canal, Brooklyn, New York

by Paul Misut and William Capurso
USGS New York Water Science Center, Coram N.Y.

U.S. Geological Survey Proposal
June 2012

Introduction: The Gowanus Canal is a tidal creek located on the western end of the New York City Borough of Brooklyn, and discharges to Gowanus Bay. During the first half of the 20th century, local groundwater levels showed severe declines resulting from heavy pumping and loss of recharge. As groundwater supplies became impaired by saltwater intrusion and surface-derived contamination, pumping ceased and the water table partially recovered.

Industrial releases have resulted in significant contamination of the Gowanus Canal and its groundwater-contributing area. The Canal continues to receive contaminated groundwater, storm water, and permitted and unpermitted effluent including combined sewer overflows (CSOs) during wet weather events. Flooding is also a significant problem in parts of the watershed.

On March 4, 2010, the U.S. Environmental Protection Agency (EPA) announced that it had placed the Gowanus Canal on its Superfund National Priorities List. The Superfund remedy may include a combination of sediment dredging, capping, and source control and involve significant bulkhead repair and (or) reconstruction. The Superfund remedial measures are scheduled to be implemented beginning in 2015. In addition, a flushing tunnel that connects the inner Gowanus Canal to the Upper New York Bay is scheduled to be reactivated in spring 2013 to improve water quality of the canal. The remedial measures along with infrastructure improvements and land use planning initiatives for the Canal and its watershed may result in significant changes to the natural and engineered systems. In addition, climate change may result in accelerated sea level rise, increased frequency and intensity of storm events, and higher storm-tides during coastal storms. Baseline and long-term monitoring of groundwater and surface-water levels in the Gowanus watershed is necessary to help evaluate the effects of planned and anticipated changes and inform the decision-making processes going forward.

Problem Statement: A lack of understanding and field monitoring of the hydrologic system surrounding the Gowanus Canal has prompted questions about environmental remediation and land-use planning for the area, including the following:

1. inadequate characterization of groundwater influences on increased flood potential associated with continued water-table recovery and (or) effects of climate change, and with proposed remedial measures and potential future ecological restoration projects that may include constructed wetlands and other open spaces;
2. lack of accuracy in estimates of groundwater infiltration into sewers, and leakage from sewers and water-supply mains into the groundwater system;
3. lack of accuracy of the groundwater-discharge component of surface-water hydrodynamic models; and
4. lack of accuracy in estimating fate, transport, and remediation of contaminants traveling along groundwater-flow paths.

Objective: The first objective (phase 1) is to apply standard USGS field-data collection methods to map the water table and local groundwater divides that define the source area of groundwater discharging to the Canal.

The second objective (phase 2) is to apply USGS numerical-flow simulation methods to represent the shallow groundwater-flow system, and to evaluate planned management alternatives identified in the EPA Feasibility Study dated December 2011 (U. S. Environmental Protection Agency, 2011).

Relevance and Benefits: Various parties have prepared, and will continue to refine hydrologic, hydrogeologic, surface-water, and sediment-transport models of both the natural and engineered systems. The field-data collection objective (phase 1) of this project will advance knowledge of the regional-hydrologic system. At present, knowledge of the Gowanus Canal system is limited due to lack of data. The collected data will be part of a nationally consistent unbiased data set that follows USGS techniques and procedures. This data will be used to form a baseline understanding of the hydrologic system and further characterize the need for long-term monitoring.

The modeling objective (in phase 2) of this project will advance the understanding of hydrologic processes that affect the design of constructed wetlands, tidal-flushing systems, calibration and verification of surface-water hydrodynamic models, and efforts to remediate groundwater plumes.

Approach: The USGS currently monitors two groundwater-observation wells within 2 miles of the Gowanus Canal. These wells are monitored for water levels on a monthly basis by the USGS as part of a cooperative program with New York City Environmental Protection. However, the source area of groundwater discharging to the Gowanus Canal may extend several miles inland from the Canal itself.

Thus, to help adequately define the groundwater basin, up to four additional monitoring wells will be installed and monitored monthly by the USGS at selected locations and depths to further characterize local groundwater conditions.

Additional wells within 100 ft of the Canal are currently monitored by other parties, but provide data that likely do not adhere to USGS data-collection procedures and standards. The USGS would request permission to monitor up to five of these wells for synoptic water-level measurements. Field reconnaissance and accurate well-head surveying would be necessary at these wells and the four new USGS wells.

Effects of tidal fluctuations on the local groundwater system are not known; therefore, a continuous groundwater recorder would be installed at some of the wells on a temporary basis. Data would be collected on 15-minute increments or shorter to document changes in water levels due to the tides, as well as the effects of precipitation, and leaking storm sewers and water-distribution pipes.

Water-Table Delineation (phase 1): A baseline characterization of groundwater conditions would be generated by mapping the present configuration of the water table using a 1-ft contour interval. Starting from a previously developed conceptual model of the hydrogeologic framework of the area, groundwater divides and directions and magnitudes of groundwater flow would be generated based on standard assumptions (for example, Freeze and Cherry, 1979) such as that groundwater flowpaths are orthogonal to water-table contour lines. A water budget for the groundwatershed would also be generated. Maps of the surfacewatershed and groundwatershed of the Gowanus Canal will also be developed and compared.

Groundwater Modeling (phase 2): The USGS conducts research in the development and coding of numerical groundwater-model programs and has a long history of applying models to groundwater issues on Long Island. The USGS modular groundwater-flow model MODFLOW would be applied in this approach. A previous application of MODFLOW to the Kings/Queens area (Misut and Monti, 1999) will provide a starting point. The hydrogeologic framework of the groundwater system is represented in this previous model at a coarse scale and would be refined based on analysis of new data collected since the previous model was developed (about 10 years ago), including driller's and geophysical logs. Other sources of new data include recently drilled wells and improved land-surface digital-elevation models. The well-pumping boundary conditions simulated in the model will be updated with the latest New York State Department of Environmental Conservation (NYSDEC) data on pumpage. Groundwater recharge, discharge, and storage processes would be carefully considered in the modeling effort, which would likely contribute to our understanding of the effects of groundwater on stormwater-management systems—including the proposed construction of wetlands.

Expected responses to climate-change factors including sea-level rise and increased precipitation intensity may be evaluated. A detailed water budget would be generated using the computer model and include categories for leakages associated with combined-sewer lines, direct groundwater discharge to the Canal seafloor, groundwater evapotranspiration, and movement of groundwater across deep clay layers. Finally, the USGS particle tracker MODPATH (Pollock, 1994) would be used to delineate recharge-

contributing areas to Canal reaches and the Superfund-related pump and treat operations. The MODFLOW model will be calibrated to match field-measured heads, by varying parameter values, boundary conditions, and the model discretization. Starting from a no-change condition, hypothetical scenarios will be simulated to explore questions about environmental remediation and utility of further data-collection and analysis activities.

Products: Groundwater-level data collected during the course of the investigation will be distributed online annually in the USGS Water-Data Report for Long Island, and through the USGS National Water Information System: Web Interface (NWISWeb) at http://waterdata.usgs.gov/ny/nwis/.

Additionally, the results of the field investigation and phase 1 delineation of the water table and surface-water and groundwatersheds would be disseminated through a short report adhering to the standards of the USGS Scientific Investigations Map (SIM) series.

The results of the modeling investigation (phase 2) would be disseminated through a final report adhering to the standards of the USGS Scientific Investigations Report (SIR) series. The report will help guide decision making. Oral presentations of interim results would also be given to interested parties.

Budget: Estimated costs for the cooperative program are shown below. All costs are estimates and assume a USGS matching contribution of 20% (based on availability of funds when the agreement is signed), and a 3-percent annual inflationary increase. During the course of the agreement, internal adjustments may be made to the funding levels assigned to each work item upon mutual agreement between the USGS and the cooperator. If matching funds are not available, or are available at a reduced level, the funding and extent of effort devoted to each work item will be evaluated and revised in consultation with the cooperator. Work for phase 1 of the proposal would begin in October 2012; phase 2 work would begin in July 2013.

Item	2012	2013
Water-Table Delineation (phase 1):		
Budget for field reconnaissance, well installation, water-level monitoring, baseline characterization of groundwater conditions (water budget), and report production.	$30,430	$58,230
USGS Matching Sub-total	$6,090	$11,650
Cooperator(s) Sub-total	**$24,340**	**$46,580**
Groundwater Modeling (phase 2):		
Budget for development and calibration of groundwater-flow model and report production.	$0	$78,830
USGS Matching Sub-total	$0	$15,760
Cooperator(s) Sub-total	**$0**	**$63,070**
Program Total	$30,430	$137,060
USGS Matching Total	$6,090	$27,410
Cooperator(s) Total	**$24,340**	**$109,650**

Schedule:

Phase 1a:

1. Develop a set of working GIS maps including surfacewatershed, previous water-table delineations, hydrogeologic framework, engineered structures, and all existing wells.

2. Field reconnaissance and selection of existing well sites for monthly and synoptic monitoring; identify proposed drilling sites.

3. Produce a preliminary water-table map from field-reconnaissance data.

4. Surveying of existing wells.

Phase 1b:

1. Drilling of new wells.

2. Surveying of new wells and collection of final data.

3. Produce a final water-table map; delineate flow directions and groundwater contributing areas.

Phase 2:

1. Assemble new model-input data.

2. Rediscretization and calibration of model.

3. Sensitivity analysis of model hydraulic properties.

5. Particle-tracking analysis of recharge-contributing areas.

6. Produce first draft of model report.

7. Publish model report.

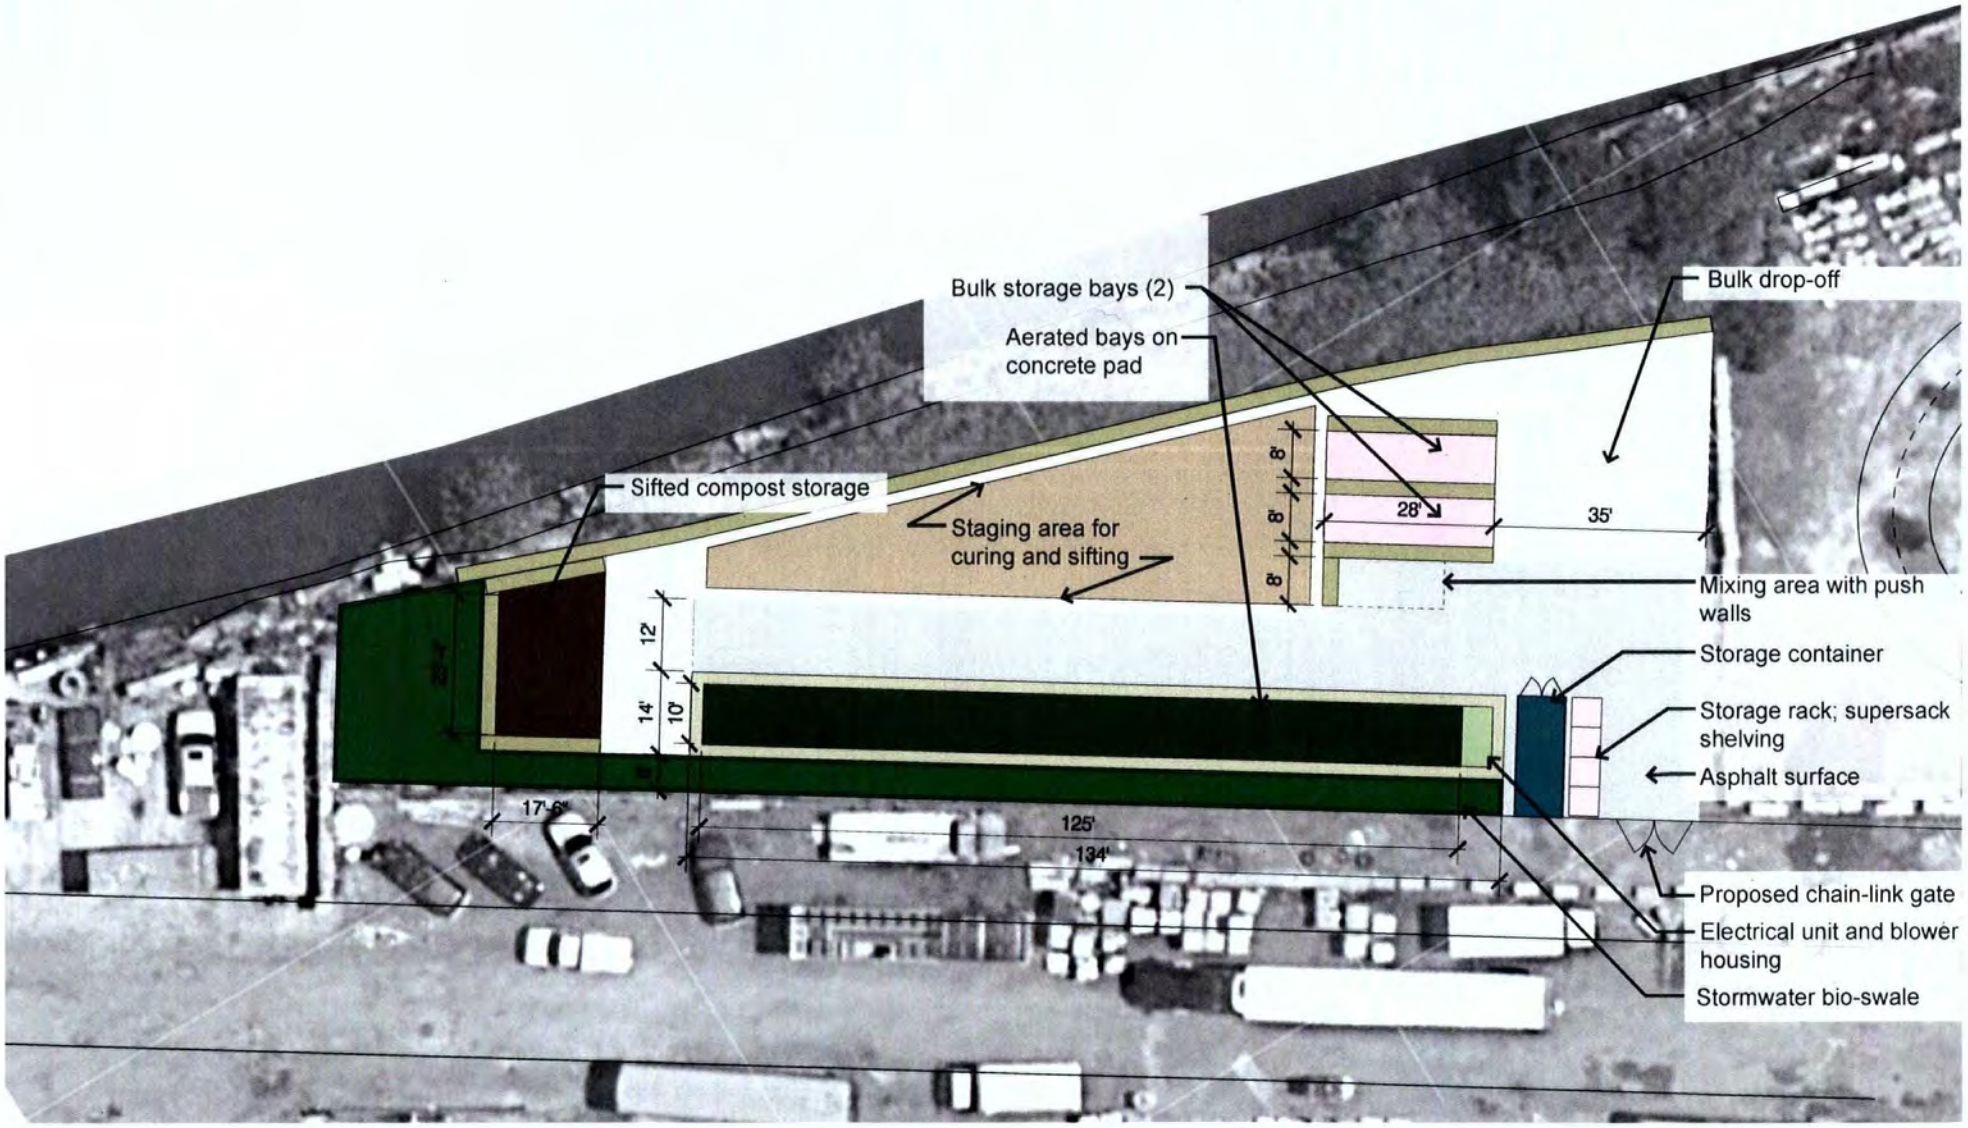
As the nation's largest water, earth, and biological science and civilian mapping agency, the USGS works in cooperation with more than 2000 organizations across the country to provide reliable, impartial, scientific information to resource managers, planners, and other customers. This information is gathered in every state by USGS scientists to: minimize the loss of life and property from natural disasters; contribute to the conservation and the sound economic and physical development of the nation's natural resources; and enhance the quality of life by monitoring water, biological, energy and mineral resources.



ATTACHMENT 2 This option utilizes a bay system and an aerated floor on a concrete pad. Each bay can accomodate an 8 ton batch held statically for 5 weeks. Every week a new bay is filled and after week 5 the first bay is emptied and windrowed for 3-4 weeks. The curing windrow is sifted and stockpiled for distribution. This technology is used at St. John's university where the school processes 40 tons of greens per year in a similar configuration.

Re: Sediment Management Work Group's Comments on the Proposed Plan for the Gowanus Canal Superfund Site, December 2012

Dear Mr. Tsiamis,

The Sediment Management Work Group ("SMWG")[1] is an ad hoc group of industry and government parties actively involved in the evaluation and management of contaminated sediments on a nationwide basis. The SMWG has long advocated a national policy addressing contaminated sediment issues that is founded on sound science and risk-based evaluation of contaminated sediment management options. The SMWG recognizes that the management of sites involving contaminated sediments frequently involves unique and complex scientific and technical issues, including assessment methodologies and evaluation of risk and risk reduction options. As an active participant in the national discussions on sediment management issues, the SMWG welcomes the opportunity to offer comments on the United States Environmental Protection Agency's ("U.S. EPA") Proposed Plan for the Gowanus Canal Superfund Site, located in Brooklyn, New York.

The SMWG previously submitted comments to the National Remedy Review Board on the Gowanus Canal Feasibility Study ("FS"). Those comments are attached (Attachment B) and incorporated by reference here. The Proposed Plan is similar to the FS in that both documents did not provide a meaningful evaluation of a full range of remedial alternatives, which is contrary to the National Contingency Plan ("NCP"). Moreover, like the FS, the Proposed Plan does not comport with the *11 Risk Management Principles for Contaminated Sediment Sites* (U.S. EPA 2002)[2] and the *Contaminated Sediment Remediation Guidance for Hazardous Waste*

---

[1] Please see Attachment A for a list of SMWG members.

[2] United States Environmental Protection Agency. 2002. Principles for Managing Contaminated Sediment Risks at Hazardous Waste Sites. OSWER Directive 9285.9-08.

Sites (U.S. EPA 2005)[3] (the "Sediment Guidance"). The Proposed Plan's inconsistency with the NCP and national sediment policy, as embodied in the Sediment Guidance, concerns the SMWG because these regulations and policies are in place to assist in the development, evaluation, and selection of remedial alternatives that effectively protect human health and the environment.

The SMWG understands that the Gowanus Canal is a highly complex urban waterbody with multiple sources of impacts – both historical and ongoing – that presents unique and complicated challenges. Moreover, the SMWG recognizes U.S. EPA's attempt to navigate the intersection of the Comprehensive Environmental Response, Compensation, and Liability Act ("CERCLA") with the Clean Water Act ("CWA"); however, there are certain fundamental principles of the remediation process that have not been followed in arriving at the Proposed Plan. These principles are in place to ensure that the site is fully understood, that the remedy selected is effective, implementable, sustainable, cost-effective, and most importantly, that the remedy selected protects human health and the environment. The NCP requires no less.

Unfortunately, the Proposed Plan does not adhere to these principles in a number of ways. There are three areas of specific concern to the SMWG that will be addressed in more detail below: (1) the need to control sources prior to implementation of the remedy; (2) the important steps of the CERCLA investigation process that have been skipped, resulting in an unrealistic design and remediation schedule; and (3) the role of cost in selecting and implementing the remedy.

I. The Proposed Plan fails to adequately address U.S. EPA's long-standing priority to control sources early, thereby posing a significant risk of recontamination.

Despite U.S. EPA's long-standing priority to control sources early, the Proposed Plan does not adequately address either the source control issue or the associated sequencing of remedial activities issue. Source control prior to remediation is essential to successful remedies. Unfortunately, the Proposed Plan fails to adequately address the significant source control needs at the Gowanus Canal.

A. U.S. EPA's national policy emphasizes the importance of controlling sources prior to remediation.

In its Contaminated Sediment Management Strategy (1998), U.S. EPA stated that "before initiating any remediation, active or natural, it is important that point and nonpoint sources of contamination be identified and controlled." This strategy identified specific point sources as potential contaminant sources, including "combined sewer overflows ("CSOs"), storm water discharges from municipal and industrial facilities, direct industrial discharges of process waste, ... runoff from industrial manufacturing and storage sites, atmospheric deposition of contaminants, and contaminated groundwater discharges to surface water."

---

[3] United States Environmental Protection Agency. 2005. Contaminated Sediment Remediation Guidance for Hazardous Waste Sites. OSWER 9355.0-85.

The need to control sources early is further emphasized in the Sediment Guidance, which provides:

> Identifying and controlling contaminant sources typically is critical to the effectiveness of any Superfund sediment cleanup. Source control generally is defined for the purposes of this guidance as those efforts [that] are taken to eliminate or reduce, to the extent practicable, the release of contaminants from direct and indirect continuing sources to the water body under investigation. (p. 2-20.)

The Sediment Guidance, therefore, calls for identification of these potential continuing sources and for the development of a source control strategy before sediment remediation begins.

B. Source control at the Gowanus Canal is challenging and the Proposed Plan does not adequately address the significant issues with the timing and sequencing of sediment remediation and source control efforts.

The Gowanus Canal is especially challenging from a source control perspective. There are nearly 250 unpermitted discharge pipes, 10 CSOs, 3 storm sewer outfalls ("SSOs"), and 5 other permitted discharges into the Gowanus Canal. These are on-going sources of contaminants, with the CSOs and SSOs alone discharging almost 400 million gallons of untreated sewage and runoff per year. These CSO and SSO discharges contain petrogenic and pyrogenic polycyclic aromatic hydrocarbons ("PAHs"), polychlorinated biphenyls ("PCBs"), metals, pesticides, and pathogens all of which contribute significantly to the risk profile of the Gowanus Canal. Unless these numerous sources are controlled before remedial action is taken in the Gowanus Canal, recontamination is a virtual certainty.

As noted by the Contaminated Sediments Technical Advisory Group ("CSTAG"):

> [T]here are long-term plans to reduce releases from lateral inputs and from major CSOs, but...it may be many years if not decades before contaminant releases are reduced to levels that would not present unacceptable risks to human health and the environment. Of specific concern are releases of copper, PCBs, and PAHs from the outfalls and discharge pipes and the non-point releases of PAHs typical of heavily developed urban areas bordering the canal ... CSTAG anticipates there would be significant recontamination of the surface sediment after any sediment remedy is implemented before the needed source control actions for other releases are completed. (CSTAG Recommendations, p. 3.)

Recontamination, therefore, is a significant concern if any remedial action is undertaken before these numerous sources are controlled. This significant likelihood of recontamination should be seriously considered and factored into planning for any sediment remediation. In particular, this consideration should include an evaluation of the impact of recontamination (via ongoing sources such as the CSOs) on the development and achievement of performance

standards. Remedy performance cannot be fairly evaluated without accounting for ongoing sources of contamination.

Moreover, the Proposed Plan does not adequately address either the source control issue or the related sequencing issue (i.e., the timing of sediment remediation versus the timing of source control activities). With regard to the CSOs, the Proposed Plan proposes the installation of large retention tanks to intercept some portion of the CSO discharges during storm events to alleviate some overflows into the Gowanus Canal. While retention tanks may be an appropriate control as a general matter, it is unclear whether they will be sufficient to appreciably reduce the contaminant loadings to the Gowanus Canal from the CSOs. The Proposed Plan recognizes that such retention tanks will take time to design and install and, therefore, proposes to use unidentified interim CSO controls. These interim controls are not identified and other critical information, such as when they will be implemented and their anticipated level of CSO reductions, are not addressed in the Proposed Plan. Given the CSOs' significant contribution to the contamination of the Gowanus Canal on an ongoing basis, this lack of specificity for the interim controls is troubling. Implementation of the sediment remedy prior to control of the CSOs – interim or otherwise – puts the success of the remedy in serious jeopardy.[4] The SMWG believes that the Record of Decision ("ROD") must clearly require implementation of controls for CSOs and other source controls before a sediment remedy is implemented.

II. The accelerated process used to investigate sediment impacts at the Gowanus Canal and to develop remedial alternatives resulted in a Proposed Plan that has inappropriately deferred key issues to the remedial design phase.

The accelerated pace of the Superfund process at the Gowanus Canal is unprecedented, but unfortunately has resulted in an inadequately characterized site with significant unknowns that impacted development and evaluation of remedial alternatives and selection of the remedy. For context on the pace, the Gowanus Canal was listed on the National Priorities List in March 2010. The Remedial Investigation ("RI") was completed in February 2011, and the FS was completed in December 2011. The Proposed Plan was released in December 2012. This accelerated process failed to provide adequate time for key data to be collected and used to develop a comprehensive conceptual site model ("CSM"). CSMs are crucial to the development and evaluation of remedial alternatives and failure to develop an adequate CSM prior to selecting a remedy will create delays in designing and implementing a remedy that is protective of human health and the environment. Additional data collection and refinement of the CSM during remedial design is no substitute for collecting the appropriate information prior to selecting a remedy.

[4] Please see, e.g., Nadeau, S., Skaggs, Jr., M. (2007). Analysis of Recontamination of Completed Sediment Remedial Projects. Proceedings of the Fourth International Conference on Remediation of Contaminated Sediments, Savannah, Georgia. ISBN 978-1-57477-159-6. Battelle Press, Columbus, OH. January 2007.

A. Contrary to the NCP's RI/FS process, key information required to evaluate and select a protective remedy has not been developed yet.

The RI/FS process is intended to result in a full characterization of the site, a pre-requisite to developing and evaluating remedial alternatives, and ultimately, to selecting a remedy. When this RI/FS process is incomplete, additional characterization must take place during the design phase. Deferring collection of key characterization data until remedial design is inappropriate because it is too late in the process to be used to develop and evaluate other potential remedial alternatives. Due to the pace of the RI/FS process at the Gowanus Canal, key information that should have been collected during the RI/FS must now be collected during the remedial design phase in order to fully develop and refine the CSM as well as to design and implement an effective, sustainable remedy. Either the development of the Final Plan should be postponed until this information is collected and used to develop and evaluate the full suite of remedial alternatives or the ROD must include sufficient flexibility to allow for incorporation of the information derived from this additional study. The first option is clearly better because deferring several critical components to the post-ROD design phase side steps the public review and comment required by the NCP and places inappropriate uncertainty and risk on potentially responsible parties who will need to decide whether to implement such an ill-defined remedy with undefined costs and significant consequences for planning.

Key information that will need to be more fully developed during the design phase includes:

- Evaluation of on-going contaminant and particulate loading from the CSOs, SSOs, and other discharge points;
- Assessment of sediment stability and contaminant fate and transport; at a highly complex site, a comprehensive understanding of contaminant fate and transport under current and proposed post-remedy conditions is a necessity;
- Further refinement of a hydrodynamic and sediment transport model, including a more detailed evaluation of the likely effects of wet weather events and the operation of the upgraded Flushing Tunnel (engineered to move over 200 million gallons of water per day) on any potential cap, as well as the chemistry and biology of the Gowanus Canal;
- Evaluation of in-situ solidification technologies;
- Evaluation of alternative approaches to the lower reach of the Gowanus Canal, particularly RTA3b, where sediment removal may be limited to "hot spots;"
- Evaluation of capping technologies; and
- Evaluation of navigational needs and the potential for vessel impacts to the remedy performance following implementation.

This information is critical to completing the CSM, filling in the data gaps left by the accelerated RI/FS process, and ultimately designing a successful remedy. The schedule to design and

implement the remedy should provide adequate time to address outstanding issues from the RI/FS as well to address more typical design-level issues.

Similar to the accelerated schedule for the RI/FS process, the Proposed Plan indicates that the remedial design and implementation will progress similarly quickly. While the SMWG understands U.S. EPA's and other stakeholders' desire in this respect, the efficacy and sustainability of the remedy should not be sacrificed in the name of speed.

The design and implementation schedule established in the ROD must realistically take into account the need for additional study, as described above. Modeling, pilot tests, and sampling all take time to be performed correctly, and are, in the end, necessary for the design of the remedy. In addition, the implementation of this remedy – once designed – must be properly sequenced to account for the unique challenges presented by the Gowanus Canal's urban setting and on-going sources. The limited access to the Gowanus Canal, lack of open space for staging, loading/off-loading, and treatment, tight clearances and space for work within the waterbody, and potential for community disruption will all likely slow the speed of implementation. The schedule established by the ROD should take these implementation challenges into account and set realistic expectations for all stakeholders.

III. The Proposed Plan is inconsistent with the NCP.

The NCP requires that the selected remedial action be cost-effective by having a proportionality between the effectiveness of each remedial alternative in relation to their respective costs: "Each remedial action selected shall be cost-effective" (40 CFR §300.430(f)(1)(ii)(D)). Cost-effectiveness is defined as "costs are proportional to its overall effectiveness." (40 CFR §300.430(f)(1)(ii)(D)). Per the U.S. EPA's 1999 guidance, *A Guide to Preparing Proposed Plans, Records of Decision, and Other Remedy Selection Documents*,[5] "cost-effectiveness is concerned with the reasonableness of the relationship between the effectiveness afforded by each alternative and its costs compared to other available options." Moreover, "if the difference in effectiveness is small but the difference in cost is very large, a proportional relationship between the alternatives does not exist" (Preamble to NCP).[6] These proportionality requirements were reiterated by U.S. EPA in the Sediment Guidance.

The Proposed Plan violates the NCP's cost-effectiveness requirement because it did not engage in an evaluation of cost-effectiveness. For example, CSTAG had recommended that "the Region evaluate the expected limited effectiveness of dredging based on the relatively large amount of debris in the canal and the fact that the deeper sediments are much more contaminated than the surface sediments. Alternatives that focus on capping and minimize removal of sediments may be more effective." (CSTAG Recommendations, p. 5-6.)

Despite this recommendation, the Proposed Plan calls for a significant – and costly – amount of dredging activities, without a real assessment of whether there will be a

---

[5] United States Environmental Protection Agency. 1999. A Guide to Preparing Proposed Plans, Records of Decision, and Other Remedy Selection Documents. OSWER 9200.1-23P. EPA 540-R-98-031.

[6] United States Environmental Protection Agency. 55 Federal Register 8728. March 8, 1990.

commensurate level of risk reduction. For example, the Proposed Plan proposes dredging and removal of all soft sediments, ignoring the potential for capping or in-situ stabilization of the soft sediments. These approaches are likely to effectively reduce risk while reducing impacts to the surrounding community and minimizing costs. Relatedly, CSTAG also suggested evaluating the use of monitored natural recovery in the lower reach of the Canal. Such a remedial approach may be highly effective, resulting in significantly decreased disruption to the community. Moreover, it has fewer short term risks, it is effective in the long term and it is cost effective because by incorporating MNR, there would be a significant decrease in the amount of sediment handling and transportation. RTA 3b is a particularly good candidate for this approach, especially when combined with targeted removal. Thus, to adequately evaluate remedial alternatives, including an evaluation of their cost-effectiveness, U.S. EPA should evaluate this alternative and others and compare their cost-effectiveness prior to finalizing the Plan and drafting the ROD.

In addition, the Proposed Plan does not acknowledge the link between a failure to control all sources and increased remedial costs. As noted above, a failure to control sources – including CSOs – prior to the implementation of the sediment remedy virtually guarantees recontamination of the Gowanus Canal. That recontamination may require additional remedial expenditures that could have been avoided by controlling sources prior to implementing the remedial action.

Moreover, the failure to properly characterize and understand the complex dynamics of the Gowanus Canal during the RI/FS will lead to unnecessarily increased costs. Without the development of all necessary information, the design and implementation process will be impeded and will likely require a number of iterations to get to the right approach. An iterative evaluation process should take place during the design phase, not during remedy implementation. This back-tracking and re-doing will cost both time and money.

Finally, the Proposed Plan significantly underestimates the cost of actually constructing the proposed remedy. For example, the FS assumes a work schedule that is not feasible to implement. The FS also fails to account for the volume of wastes requiring disposal as hazardous waste, thereby underestimating the disposal costs.

IV. The process at the Gowanus Canal deviates from the appropriate CERCLA process in key ways that profoundly affect the selection, design, and implementation of the remedy and the resulting issues should be addressed prior to finalizing the Plan and drafting the ROD.

The CERCLA process is intended to provide a scientifically sound, risk-based approach to addressing contaminated sediment sites. Sediment sites present challenging problems, but following this process is necessary to ensure that the selected remedy will reduce risk to human health and the environment and be cost-effective. Thus far, the regulatory actions at the Gowanus Canal deviate from this process in several critical ways, including inadequately addressing the significant source control issues, incompletely characterizing the site, failing to develop adequate information to evaluate all remedial alternatives, and insufficiently considering the cost-effectiveness of the proposed remedy. U.S. EPA should address these issues prior to finalizing the Plan and drafting the ROD. Moreover, the ROD should provide enough flexibility

and time to properly design, sequence, and implement the remedy after sources have been controlled. Without properly sequencing source control efforts and remediation, the site will be recontaminated.

***

The SMWG would be pleased to answer any questions about its comments on the Proposed Plan for the Gowanus Canal Superfund Site. Re: Sediment Management Work Group's Comments on the Draft Feasibility Study for the Gowanus Canal

Dear Ms. Legare,

The Sediment Management Work Group ("SMWG")[1] is an ad hoc group of industry and government parties actively involved in the evaluation and management of contaminated sediments on a nationwide basis. The SMWG has long advocated a national policy addressing contaminated sediment issues that is founded on sound science and risk-based evaluation of contaminated sediment management options. The SMWG recognizes that the management of sites involving contaminated sediments frequently involves unique and complex scientific and technical issues, including assessment methodologies and evaluation of risk and risk reduction options. As an active participant in the national discussions on sediment management issues, the SMWG welcomes the opportunity to offer observations and comments on the draft *Feasibility Study* ("FS") for the Gowanus Canal.

The SMWG's review of the Gowanus Canal Draft FS has identified a number of critical areas where the draft FS does not comport with the *11 Risk Management Principles for Contaminated Sediment Sites* (U.S. EPA 2002)[2] and the *Contaminated Sediment Remediation Guidance for Hazardous Waste Sites* (U.S. EPA 2005)[3] ("Guidance"). In particular, the draft FS

---

[1] See Exhibit "A" for a list of its Members.

[2] United States Environmental Protection Agency. 2002. Principles for Managing Contaminated Sediment Risks at Hazardous Waste Sites. OSWER Directive 9285.6-08.

[3] United States Environmental Protection Agency. 2005. Contaminated Sediment Remediation Guidance for Hazardous Waste Sites. OSWER 9355.0-85.

does not adequately consider the presence and contributions of significant on-going sources, completely characterize the site, or provide all of the information essential to support development of a full suite of remedial alternatives. Without source controls, any remediated area will be recontaminated and the public will not be protected from pathogens in the water.

The comments below offer more discussion of the significant limitations of the draft FS. Unless these limitations are addressed before a proposed plan is issued, the remedy that ultimately is selected for the Gowanus Canal is unlikely to achieve U.S. EPA's objectives.

I. U.S. EPA's National Contaminated Sediment Policy Is Embodied In The Contaminated Sediment Remediation Guidance For Hazardous Waste Sites.

In December 2005, U.S. EPA issued the *Contaminated Sediment Remediation Guidance for Hazardous Waste Sites*. This Guidance embodies national policy on contaminated sediment and should be followed at all contaminated sediment sites. The Guidance was issued for use "by federal and state project managers considering remedial response actions or non-time-critical removal actions" under CERCLA (p. 1-1). The Guidance provides a risk management decision-making framework to assist with selecting appropriate remedies.

There are at least seven key remedy selection principles in the Guidance:

1) Confirming that the site is ready for remediation by controlling sources to the greatest extent practical before commencing remediation (p. 2-20, 7-17).
2) The focus of remediation should be on risk reduction, not simply on contaminant removal or on the number of cubic yards of dredged sediment (p. 7-1, 7-16).
3) A realistic, site-specific evaluation of the potential effectiveness of each sediment management option, including dredging, capping, and monitored natural recovery, should be incorporated into the selection of remedies at a site (p. 7-3).
4) An appropriate evaluation of the comparative net risk reduction potential of the various sediment management options, including a realistic evaluation of their respective advantages and site-specific limitations should be conducted (p. 7-13, 7-14).
5) At large and/or complex sites, consideration of the use of combinations of remedies may be appropriate (p. 7-3).
6) Adaptive management concepts, which recognize the need for reconsideration of the original remedy chosen where new data and/or results of pilots suggest the appropriateness of revising the original approach, should be applied (p. 2-22, 3-1, 7-16).
7) Comparing and contrasting the costs and benefits of the various remedies is part of the risk management decision-making framework (p. 7-1).

These principles all focus on risk reduction. If applied appropriately, they will lead to a protective remedy that is also cost effective, as required by CERCLA and the National Contingency Plan ("NCP").

In order to comply with these principles of remedy selection and ultimately reduce risk, the Guidance emphasizes the importance of thorough site characterization. Site characterization includes collecting data to develop a conceptual site model, conducting risk assessments, understanding sediment and contaminant fate and transport, and identifying sources (Section 2.1). These data necessarily form the basis of the feasibility study, which subsequently informs the remedial decision (Sections 3 and 7). Thorough site characterization and developing a good understanding of what is driving the risk at the site via development of a conceptual site model are keys to informed decision-making at contaminated sediment sites.

II. The FS Deviates From U.S. EPA's National Contaminated Sediment Policy.

The draft FS deviates from the Guidance in a number of critical areas. These comments highlight some, but not all, of the many areas where the FS deviates from U.S. EPA's national contaminated sediment policy as embodied in the Guidance.

A. Source Control Is A Prerequisite But Has Not Been Adequately Addressed At The Site

Early control of sources has long been a U.S. EPA priority and is essential to successful remedies at contaminated sediment sites. In its *Contaminated Sediment Management Strategy* (1998)[4], the U.S. EPA stated that "before initiating any remediation, active or natural, it is important that point and nonpoint sources of contamination be identified and controlled." This strategy identified specific point sources as potential contaminant sources, including "municipal treatment plants, combined sewer overflows ("CSOs"), storm water discharges from municipal and industrial facilities, direct industrial discharges of process waste, runoff and leachate from hazardous and solid waste sites, agricultural runoff, runoff from mining operations, runoff from industrial manufacturing and storage sites, atmospheric deposition of contaminants, and contaminated groundwater discharges to surface water."

The need to control sources early is emphasized in the Guidance (as well as in the 2002 OSWER Directive 9285.6-08). The Guidance provides:

> "Identifying and controlling contaminant sources typically is critical to the effectiveness of any Superfund sediment cleanup. Source control generally is defined for the purposes of this guidance as those efforts [that] are taken to eliminate or reduce, to the extent practicable, the release of contaminants from direct and indirect continuing sources to the water body under investigation." (p. 2-20). ...

---

[4] United States Environmental Protection Agency. 1998. EPA's Contaminated Sediment Management Strategy. EPA-823-R-98-001.

> [S]ignificant upland sources (including ground water, NAPL, or upgradient water releases) should be controlled to the greatest extent possible before sediment cleanup." (p. 2-21).

The Guidance, therefore, calls for these potential continuing sources to be identified (see Highlight 2-2) and for a source control strategy to be developed before sediment cleanup begins.

Although the FS acknowledges that addressing "contaminant contributions to the canal from upland properties, combined sewer overflows (CSOs) and other pipe outfalls is a prerequisite to a sustainable remedy for canal sediments," the draft FS does not satisfy that prerequisite (FS, p. 1-1). There are over 200 non-permitted discharge pipes, 10 CSOs, 3 storm sewer outfalls ("SSOs"), and 5 other permitted discharges into the Gowanus Canal. These are likely on-going sources of contaminants, with the CSOs and SSOs alone discharging almost 400 million gallons of untreated sewage and runoff per year. Moreover, investigation and remediation activities are underway at three upland former manufactured gas plant sites. Unless these numerous sources are controlled before remedial action is taken in the Canal, recontamination is a virtual certainty.

As noted by the Contaminated Sediments Technical Advisory Group ("CSTAG"):

> "there are long-term plans to reduce releases from lateral inputs and from major CSOs, but ... it may be many years if not decades before contaminant releases are reduced to levels that would not present unacceptable risks to human health and the environment. Of specific concern are releases of copper, PCBs, and PAHs from the outfalls and discharge pipes and the non-point releases of PAHs typical of heavily developed urban areas bordering the canal. ... CSTAG anticipates there would be significant recontamination of the surface sediment after any sediment remedy is implemented before the needed source control actions for other releases are completed" (*CSTAG Recommendations*, p. 3).

Recontamination, therefore, is a significant concern if any remedial action is undertaken before these numerous sources are controlled. This significant probability of recontamination should be seriously considered and factored into any planning for sediment response actions. Developing and evaluating alternatives for sediment remediation prior to implementation of source control activities and understanding their effects on improving sediment and water quality is premature.

B. Site Characterization Is Inadequate.

Sediment site characterization activities are intended to provide the information necessary to permit effective remedial alternatives to be developed, evaluated, and selected. Site characterization is performed through the Remedial Investigation ("RI"). The Guidance specifies that a sediment site RI should accomplish the following goals:

- Identify and quantify the contaminants present in sediment, surface water, biota, and in some cases, ground water;

- Understand the vertical and horizontal distribution of the contaminants within the sediment;
- Identify the sources of historical contamination and quantify any continuing sources;
- Understand the geomorphological setting and processes (e.g., resuspension, transport, deposition, weathering) affecting the stability of sediment;
- Understand the key chemical and biological processes affecting the fate, transport, and bioavailability of contaminants;
- Identify the complete or potentially complete human and ecological exposure pathways for the contaminants;
- Identify current and potential future human and ecological risks posed by the contaminants;
- Collect data necessary to evaluate the potential effectiveness of natural recovery, in-situ capping, sediment removal, and promising innovative technologies; and
- Provide a baseline of data that can be used to monitor remedy effectiveness in all appropriate media (generally sediment, water, and biota). (p. 2-1, 2-2).

To aid in accomplishing these goals, the Guidance provides, as an example, a list of sediment site characterization data that should be collected during the RI. (Highlight 2-1, page 2-5). The data gathered during the RI is then used in a feasibility study, which develops and evaluates alternative methods for achieving the remedial action objectives for the site (p. 3-1).

In contrast to the policy set forth in the Guidance, a complete remedial investigation has not been conducted and site characterization is incomplete at the Gowanus Canal. As a result, few of the data necessary for a feasibility study to develop and evaluate remedial alternatives are available. Collection of these data during design is not a substitute for collection and incorporation of these data into the draft FS.[5]

The significance of the missing information can be illustrated through a few examples where additional information is needed to develop and screen remedial alternatives. These examples are discussed below.

[5] Even if an accelerated approach is viewed as necessary, proceeding with an early action without adequate data also would be inconsistent with the Guidance. Based on the site description and circumstances as described in the FS, however, there appears to be no justification to rush to conduct an early action in the absence of source control and adequate data to evaluate the appropriate early action.

1. Information Required To Adequately Characterize The Site.

In addition to the need to identify and further characterize historic and on-going sources, other key issues that need additional study in order to fully develop and refine the conceptual site model ("CSM"), which will aid in the development and evaluation of a full suite of remedial alternatives, include:

- Evaluation of on-going contaminant and particulate loading
- Assessment of sediment stability and contaminant fate and transport
- Development of a hydrodynamic and sediment transport model, which can evaluate the likely effects of wet weather events and the operation of the upgraded Flushing Tunnel (engineered to move over 200 million gallons of water per day)
- Development of a groundwater model to understand and predict discharges to the canal
- Evaluation of in-situ solidification technologies (bench-scale and field pilot study)
- Bulkhead stability analysis

This information is key to developing an accurate, comprehensive CSM that can be used to develop and evaluate a full suite of remedial alternatives. Without such a CSM, the effectiveness of remedial alternatives cannot be understood or evaluated.

2. Fate And Transport Modeling Suitable To The Site Is Essential To Develop An Effective Remedy.

The Guidance emphasizes the importance of assessing the fate and transport of sediment and contaminants at sediment sites (Section 2.8). Such information is necessary to assess the exposure and risk associated with the contaminants and to evaluate the protectiveness of remedial alternatives (p. 2-23, 2-32). To assess sediment and contaminant fate and transport, modeling is required (p. 2-25). At large or complex sites, the Guidance emphasizes the importance of using mathematical modeling:

> "Mathematical modeling generally is recommended for large or complex sites, especially where it is necessary to predict contaminant transport and fate over extended periods of time to evaluate relative differences among possible remedial approaches" (p. 2-36).

Developing a robust hydrodynamic and sediment transport model is critical to the development of an effective remedy, but it has not been done for the Gowanus Canal. CSOs and SSOs are responsible for a significant portion of the flow in the Canal. Upgrades to the Flushing Tunnel will be coming on-line in the near future and will increase the flow in the Canal. Understanding the effects of wet weather events and additional flows from the Flushing Tunnel is key to developing remedial alternatives and to evaluating their anticipated effects. Without this tool, the analysis of alternatives in the draft FS is incomplete.

The failure to provide appropriate modeling for the site in the draft FS, coupled with the absence of site characterization data, precludes an effective remedial alternatives evaluation process as required by the Guidance. At a highly complex site, a comprehensive understanding of contaminant fate and transport under current and proposed post-remedy conditions is a necessity. More discussion of remedial alternatives development is included below.

C. Inadequate Development Of Remedial Alternatives.

Adequate development and analysis of remedial alternatives cannot be completed without proper site characterization. The Guidance's requirement of collecting and evaluating sufficient baseline data to support a realistic evaluation of remedial alternatives, the remedy's likely ability to reduce risk on a site-specific basis, and to provide realistic cost comparisons was not followed in developing the draft FS (see Sections 2.1, 2.3, 3.1, 3.4, and 3.5 of the Guidance). For these reasons, the draft FS fails to support the development and analysis of robust remedial alternatives.

First, as described above, the current level of site characterization is wholly inadequate to support the remedial alternative selection process under the Guidance. Proper site characterization and completion of necessary data collection tasks is a prerequisite to the development and analysis of a robust suite of remedial alternatives.

Second, the alternatives developed and evaluated in the draft FS did not follow CSTAG's appropriate recommendation that "the Region evaluate the expected limited effectiveness of dredging based on the relatively large amount of debris in the canal and the fact that the deeper sediments are much more contaminated than the surface sediments. Alternatives that focus on capping and minimize removal of sediments may be more effective" (*CSTAG Recommendations*, p. 5-6).

Third, the draft FS did not follow an additional CSTAG recommendation that "the Region consider developing and evaluating a range of remedial alternatives in the FS that include the following additional remedial alternatives:

- Use of a low permeability, reactive capping material to control NAPL migration. Gas ebullition from under the cap that can facilitate NAPL transport through the cap can be addressed with vents and activated carbon to treat gas
- Temporarily draining the canal and redirecting the water flow to allow sediments to consolidate before placing a cap or dredging, this should include consideration of installing a passive French-drain style NAPL collection system under a cap as part of a capping alternative
- Monitored natural recovery (MNR) as a remedial alternative for the lower reach
- For areas where maintaining a minimum navigational water depth is not an issue, evaluate further if a cap can be placed without pre-dredging. Based upon experiences at other sites with soft sediment and low bearing strength, a cap can

be placed by using several thin lifts of sand, allowing time for consolidation between placing lifts

- Retain one or more capping-only remedies that may use different in-situ amendments such as activated carbon or ograno-clays within the cap
- Consider use of in-situ amendments to reduce bioavailability of surface contaminants for other areas of the site." (*CSTAG Recommendations*, p. 6).

Rather than developing and evaluating a full suite of remedial alternatives, only a limited suite of remedial alternatives was developed. The draft FS failed to develop or evaluate any capping-only remedial alternatives.

Finally, the draft FS also failed to quantify risk reduction expectations or to estimate the levels of recontamination that are expected to occur. As such, the draft FS is incomplete and cannot serve as the basis to select a cost-effective remedy that will protect human health and the environment, as required by the NCP.

D. Procedure For Addressing Contaminated Sediment Sites.

USEPA's Sediment Management Principles (2002) and the Guidance state that remedies are to be selected based on site-specific information. This information will not exist until the site is well characterized. Principle 7 of Principles for Managing Contaminated Sediment Risks At Hazardous Waste Sites (OSWER Directive 9285.6-08, February 12, 2002) states:

> "Select Site-specific, Project-specific, and Sediment-specific Risk Management Approaches that will Achieve Risk-based Goals.
>
> EPA's policy has been and continues to be that there is no presumptive remedy for any contaminated sediment site, regardless of the contaminant or level of risk. ... At Superfund sites, for example, the most appropriate remedy should be chosen after considering site-specific data and the NCP's nine remedy selection criteria. All remedies that may potentially meet the removal or remedial action objectives (e.g., dredging or excavation, in-situ capping, in-situ treatment, monitored natural recovery) should be evaluated prior to selecting the remedy. This evaluation should be conducted on a comparable basis, considering all components of the remedies, the temporal and spatial aspects of the sites, and the overall risk reduction potentially achieved under each option." (Guidance, p. A-7).

The Gowanus Canal draft FS does not satisfy this principle.

Moreover, characterization of the dozens of on-going sources that are known to exist in this waterway has yet to be performed. Limited samples were taken prior to the preparation of the draft FS, and the draft FS omitted much of the modeling and analysis traditionally relied on in sediment site remedial decision-making. Further, the draft FS specified that the following studies be undertaken in the remedial design phase:

- Development of a groundwater model for the entire project area
- Additional data collection and analysis to determine NAPL seepage rates
- Additional evaluation of in-situ solidification or other developing technologies that could increase the overall protection and permanence of the remedy
- Additional evaluation and analysis of the sustainability impacts of the selected remedy
- Other data collection activities and surveys such as a bulkhead stability evaluation, bathymetric and sediment-probing surveys to refine volumes and establish baseline conditions prior to remedial action, and sediment chemistry surveys to establish baseline, or pre-remedy, conditions
- Additional bench-scale testing to support disposal options
- Hydrodynamic modeling to support cap design

It seems apparent that much of this work is necessary due to the incomplete site characterization when the draft FS was prepared. It is inappropriate to defer these critical components of site-specific information to the remedial design phase. Much of this information is critical to the remedial alternative development and analysis phases, and could result in selection of a very different remedy than could occur at this time. These significant shortcomings are further examples of inconsistency with the Guidance.

III. Conclusion.

The Guidance provides a scientifically sound, risk-based approach to addressing contaminated sediment sites. Sediment sites present challenging problems, but following the policy and procedures in the Guidance is necessary to assure that the selected remedy will reduce risk and be cost-effective. The draft FS for the Gowanus Canal deviates from the Guidance in several critical ways, including lack of source control, incomplete site characterization, and inadequate information to support development of a full suite of remedial alternatives. As a consequence, the remedial alternatives proposed in the draft FS are not likely to reduce risks to human health and the environment to any significant extent. Rather, significant recontamination of the surface sediment is a virtual certainty. Accordingly, the current draft FS should be withdrawn until sufficient information is developed to prepare a FS that can adequately address the issues presented at the Gowanus Canal.

Moving forward with the draft FS and issuance of a proposed plan in the absence of essential information is premature. Numerous uncontrolled sources pose a significant recontamination risk. It would, therefore, be ineffective to try to address all sediment-related risks at this time. The next step should be to identify and control sources to the greatest extent possible in accordance with the Guidance (Section 2.6). During this important activity, the work

necessary to properly develop site-specific risk management approaches that will achieve risk-based goals under the Guidance should be undertaken and completed.

History: This message has been forwarded.

As (one of the options above) of the community of Red Hook, I/We am/are strongly opposed to the processing of contaminated sludge dredged from the Gowanus Canal Superfund Cleanup Site at a facility at the proposed location. The cost savings are negligible, and the Red Hook Ball Fields and Pool are used in public trust. The community does not want to create more land from this contaminated sludge adjacent to one of the most heavily used recreation areas in New York City. People and organizations adversely affected include (but are not limited to!):

- Children
- Numerous public and private schools which use the fields for physical education & sports teams
- Residents of the Red Hook Houses and the surrounding neighborhood
- Soccer, softball, baseball, football, handball, basketball, track & field teams and enthusiasts
- Swimmers of all ages
- The Red Hook Food vendors and their customers
- Other visitors to our community

Further, we object to an individual (John Quadrozzi), who has incurred serious fines for environmental violations, from profiting from the project.

Re: ***Superfund Proposed Plan***
Gowanus Canal Superfund Site
Kings County, New York

Dear Mr. Tsiamis:

These comments on the "*Superfund Proposed Plan*, Gowanus Canal Superfund Site, Kings County, New York" (SPP) issued by the U.S. Environmental Protection Agency (EPA) in December 2012 are submitted on behalf of Consolidated Edison Company of New York, Inc. (Con Edison).

Introduction and Summary of EPA's Preferred Remedy

The Gowanus Canal is a man-made canal located in Brooklyn, New York, that was added to the National Priorities List in early 2010.[1] EPA conducted a remedial investigation of the sediments in the canal, and a feasibility study of remedial alternatives, with the goal of developing a response action that would "reduce or eliminate unacceptable human health and ecological risks from exposure to the contaminated sediments and to prevent recontamination of the sediments after the remedy is implemented."[2] The SPP describes the remedial alternatives that were considered for the site, identifies EPA's preferred remedy, and provides EPA's rationale for that preference.[3]

The principal focus of EPA's preferred remedy is on the contamination of Gowanus Canal sediments by polycyclic aromatic hydrocarbons (PAHs) and by non-aqueous phase liquid

[1] 75 *Fed. Reg.* 9790 (Mar. 4, 2010).
[2] SPP (at 2).
[3] The administrative record in support of the SPP includes a draft Remedial Investigation Report (RI) dated January 2011; a draft Feasibility Study (FS) dated December 2011; and a Feasibility Study Report Addendum (FS Addendum) dated December 2012. Appendices to the RI include a Human Health Risk Assessment (HHRA) and an Ecological Risk Assessment (ERA).

(NAPL). EPA has established six Remedial Action Objectives (RAOs) to be achieved by the preferred remedy, and five of them address either PAHs or NAPL. Three risk-based RAOs for PAHs were developed based on EPA's conclusion that the PAH contamination presents unacceptable risks to human health and to ecological receptors. Two other RAOs were developed to address potential recontamination by NAPL, either from ongoing sources, or from the residual NAPL that will remain at the site because it is too deep to be practically removed.

To address the human health and ecological risks from PAH contamination identified by EPA, the preferred remedy requires the removal of all soft sediments along the entire length of the canal. EPA also determined that ongoing sources of PAH and NAPL contamination, primarily from the three former manufactured gas plants that were located along the Gowanus Canal, must be controlled in order for the proposed remedy to be effective. And to prevent the residual NAPL remaining in the canal after the remedy is implemented from releasing additional PAHs into the canal sediments, EPA determined that a three-layer cap with a treatment layer will be constructed, and that in-situ stabilization of native sediment will be required in some areas with high levels of NAPL contamination.

The SPP also includes proposed actions to reduce combined sewer overflows from the City of New York's sewer system; the excavation and restoration of a lateral extension of the canal that has been filled in; institutional controls to incorporate an existing fish consumption advisory and to protect the integrity of the cap; and a possible on-site disposal facility. EPA states that it will coordinate with State and local authorities to control ongoing discharges from upland contaminated areas and from unpermitted pipe outfalls.

Overview of Comments

The SPP suggests that, in addition to the PAH and NAPL contamination, concentrations of polychlorinated biphenyls (PCBs) in Gowanus Canal sediments are contributing to unacceptable human health and ecological risks. Consequently, PCBs are identified in two of the six RAOs. However, as discussed in detail in these comments, the underlying analyses used to support those risk-based conclusions are flawed. Thus, EPA's conclusions regarding the risks presented by PCBs in Gowanus Canal sediments, and regarding the need to address those purported risks in the preferred remedy, are not supported in the administrative record.

With respect to human health risks, EPA has not supported its assertion that PCB levels in fish taken from the Gowanus Canal are "about two times higher" than PCB levels in fish taken from the reference area. In addition, the HHRA uses overly conservative and unrealistic assumptions about fish consumption rates, and about the species that are consumed. Further, EPA has not demonstrated that PCBs in Gowanus Canal surface sediments actually contribute to PCBs in fish tissue, or that the proposed remedy will reduce fish tissue concentrations of PCBs.

Moreover, the RAO addressing human health risks is based on the assumption that concentrations of PCBs in Gowanus Canal surface sediments are significantly higher than in reference area surface sediments, when in fact there is no statistically significant difference

between them. And EPA acknowledges that even if the proposed remedy were to be implemented and the RAO were to be achieved, human health risks from fish consumption would not be reduced to acceptable levels, because PCB concentrations in fish and shellfish are and will remain a regional problem. Those risks are currently being addressed by institutional controls, and the same institutional controls would be required even if this remedy were to be implemented. In short, the administrative record does not support the assertion that PCB concentrations in Gowanus Canal surface sediments present human health risks that must be addressed by the preferred remedy.

With respect to ecological risks, EPA's assertion that PCB concentrations in Gowanus Canal surface sediments are statistically higher than in reference area surface sediments disregards the PCB congener data in the administrative record. The environmental consulting firm ENVIRON conducted an analysis using those congener data, and it shows that there is no statistically significant difference between PCB concentrations in Gowanus Canal surface sediments and in reference area surface sediments.

More importantly, EPA's conclusion that PCBs in Gowanus Canal surface sediments are contributing to benthic toxicity is based solely on a comparison of sediment concentrations to a screening value. But screening values are merely tools to determine whether more refined analyses are required; they cannot be used to determine toxicity, because they do not take into account site-specific conditions that affect bioavailability.

EPA apparently found it unnecessary to develop a site-specific risk-based value for PCBs, based on its reasoning that the remediation that is necessary to address benthic toxicity from PAHs in Gowanus Canal surface sediments will also remove the PCBs that "co-occur" with those PAHs. But that begs the question of whether the PCBs in Gowanus Canal surface sediments are, or are not, toxic to benthic organisms. In order to answer that question, ENVIRON relied on several lines of evidence derived from the scientific literature to develop a site-specific risk-based criterion for Gowanus Canal surface sediments based on cause-effect, concentration-response relationships. The PCB concentrations in Gowanus Canal surface sediments are all well below that site-specific risk-based criterion.

Moreover, EPA did not comply with the requirements of the National Contingency Plan (NCP) in its development of the two RAOs that are intended to address human health and ecological risks from PCB concentrations in Gowanus Canal sediments. The RI lacks sufficient data to adequately characterize risks attributable to PCBs, or to support the development of appropriate response actions based on those risks, both of which are required under the NCP. In addition, the FS does not contain remediation goals that "establish acceptable exposure levels that are protective of human health and the environment," also as required by the NCP.

For all of these reasons, Con Edison respectfully submits that the RAOs identified in the SPP should be modified in the Record of Decision (ROD). Specifically, the RAO addressing PCB levels in fish and shellfish should be eliminated in its entirety, and the RAO addressing toxicity to benthic organisms should be revised to eliminate any reference to PCBs.

Comments

I. Statements in the SPP that PCBs in Gowanus Canal Sediments Present Unacceptable Risks to Human Health are Not Supported by the Record, and the Proposed Remedial Action Would be Unnecessary and Ineffectual

The SPP states that human consumption of fish and crabs taken from the Gowanus Canal presents unacceptable health risks, due to the levels of PCBs in edible tissues.[4] EPA also implies, without further support, that PCBs in Gowanus Canal surface sediments have contributed to those tissue levels. EPA thus derived the following RAO:

> Reduce the contribution of polychlorinated biphenyls (PCBs) from the Gowanus Canal to fish and shellfish by reducing the concentrations of PCBs in Gowanus Canal sediments to levels that are within the range of Gowanus Bay and Upper New York Bay reference concentrations.[5]

EPA also established a PRG of 0.48 mg/kg total PCB congeners, which it described as the "maximum concentration in reference area surface sediment."[6]

EPA's analyses and conclusions regarding human health risks from PCBs in Gowanus Canal sediment are flawed. First, the administrative record does not support EPA's characterization of PCB levels in Gowanus Canal fish as "about two times higher" than PCB levels in reference area fish. Second, the HHRA uses overly conservative and unrealistic assumptions regarding fish consumption rates and the species that are consumed. Third, EPA fails to quantify the extent to which PCBs in Gowanus Canal surface sediments contribute – if at all – to PCB levels in fish tissue, and fails to quantify the reduction in PCBs in fish tissue – if any – that would result from achieving the RAO. Fourth, there is no statistically significant difference between total PCB congener concentrations in Gowanus Canal surface sediments and total PCB congener concentrations in reference area surface sediments.

The RAO and PRG are thus based on certain assumptions that are not supported in the administrative record. More importantly, the SPP notes that "game fish and blue crabs do not forage solely in the canal and the PCB concentrations in their tissues reflect cumulative uptake from all of the areas that they inhabit."[7] EPA further acknowledges that consumption of fish and crabs taken from the reference area also present unacceptable human health risks.[8] Consequently, "because of the anticipated unacceptable human health risk associated with the consumption of PCB-contaminated fish and shellfish *after the remedy is implemented,*"[9] the SPP incorporates the existing fish consumption advisory as an institutional control.

[7] *Id.* (at 16).
[8] *Id.* (at 14).
[9] SPP (at 31, emphasis added).

In other words, according to EPA, even if the RAO is achieved, it will not reduce to acceptable levels the human health risks from consumption of fish and shellfish. Thus, any remedial action intended to achieve that RAO would not meet the effectiveness criterion of the NCP. Continuation of the existing institutional control is both necessary and sufficient to address the risk pathway from fish consumption, and nothing in the administrative record demonstrates that the proposed response action is required or would be effective. Accordingly, the RAO based on human health risks from PCBs in Gowanus Canal sediments should not be included in the ROD for this site.

A. EPA has not properly compared PCB levels in fish taken from the Gowanus Canal to PCB levels in fish taken from the reference area

The SPP states that the "average concentrations of PCBs in the canal fish and crab samples were about two times higher than the average PCB concentrations in the reference area samples collected from Gowanus Bay and Upper New York Bay."[10] Although the SPP does not provide a reference for that assertion, it appears to come from a statement in the HHRA that "[r]eference area average PCB fish concentrations are about one half the average concentrations identified in canal fish."[11] However, that comparison is neither accurate nor complete.

Table 2-5 of the RI provides a summary of the total number of samples collected for blue crabs and for larger fish species. In the Gowanus Canal, there were 12 blue crab samples (edible tissue), 2 blue crab samples (hepatopancreas), 6 American eel samples, 5 striped bass samples, and 2 white perch samples. In the reference area, there were 8 blue crab samples (edible tissue) and 1 blue crab sample (hepatopancreas), but only 1 American eel sample, and no striped bass or white perch samples. In other words, although blue crabs are represented by data from both the Gowanus Canal and the reference area, American eel is the only fish species represented by data from both the Gowanus Canal and the reference area, and the data used to characterize PCB concentrations in American eel in the reference area were based on a single sample.

The comparisons of average concentrations for PCBs in crab and fish tissue are found in Table 7-3 of the HHRA, for three groupings of PCB congeners used in the risk calculations (dioxin-like, non-dioxin-like, and total PCB congeners), and show the following:

- The comparisons for blue crabs show that the reference area averages range from 61 to 77 percent of the Gowanus Canal averages, which is considerably greater than one half.[12]

---

[10] SPP (at 14; at 15).
[11] HHRA (at 9-3).
[12] These percentages are based on the averages reported for the edible tissue and hepatopancreas samples, which were analyzed for PCB congeners. The data reported for "whole body" crabs were calculated from the edible and hepatopancreas data, and were not measured directly. RI (at 4-45).

- The comparisons for fish show that for American eel, the concentrations in the sole reference area sample taken ranged from 54 to 83 percent of the Gowanus Canal averages, which is also considerably greater than one half. And even though concentrations are presented for striped bass and white perch in the Gowanus Canal, it is not possible to make comparisons to concentrations in reference area samples of those fish species, because such data do not exist in the administrative record.

The extremely limited sample size of comparable fish data (*i.e.*, one sample for one species), and the magnitude of the actual percentage comparisons for both fish and crabs, are insufficient support for the blanket statement in the SPP that average PCB concentrations measured in fish and crabs collected from the Gowanus Canal were "about two times higher" than average PCB concentrations in the reference area samples.

B. The HHRA uses inadequately supported assumptions about overall fish consumption rates and about species-specific consumption rates

The HHRA relies on a number of highly conservative upper-bound exposure assumptions to estimate potential risks for reasonable maximum exposure (RME) scenarios. Some of these exposure assumptions appear to be inconsistent with USEPA's definition of an RME scenario as "the highest exposure that is reasonably expected to occur at a site."[13] Such overly conservative assumptions may be appropriate for use in screening-level risk assessments; if the risks estimated in a screening-level assessment are below levels of concern, then further refinement is not warranted. However, when the screening-level risk estimates exceed levels of concern (as in the case of the Gowanus Canal HHRA), it is appropriate to examine the underlying assumptions to identify those that warrant further refinement.

In fact, the SPP acknowledges that the HHRA "assumed fishing/crabbing and ingestion of the fish/crab from the canal at typical recreational angler fish/crab consumption rates, *which is very conservative given the nature of the canal.*"[14] But a thorough review of the HHRA suggests that little effort was made to refine the initial assessment in order to incorporate more reasonable assumptions.[15] Further, while the Uncertainty Assessment section of the HHRA acknowledges that "the resulting risks are likely overestimates,"[16] it does not appear that any effort was made to characterize the degree of overestimation. Thus, the HHRA presents an overly conservative RME scenario that is inappropriate for a CERCLA baseline risk assessment.

[15] The only significant modification to the exposure scenarios in the HHRA was the addition of a subsistence fisherman scenario in the *Supplemental Evaluation of Remediation Goals* section of the FS Addendum.

[16] HHRA (at 8-2)

1. The consumption rates for Gowanus Canal fish and crabs are unrealistic

The HHRA risk calculations are based on the assumption that all of the fish and crabs consumed by an individual angler are taken from the Gowanus Canal. Considering the frequency of CSO discharges to the Gowanus Canal, the poor water quality in the Gowanus Canal (characteristics unrelated to PCBs), and the current and anticipated future fish consumption advisory, this assumption is unrealistic and highly unlikely to occur.[17]

Section 2.5 of the RI Report indicates that it was necessary to set traps at multiple locations and to combine samples from multiple reaches in order to obtain adequate tissue mass for analysis, due to the paucity of fish and crabs in the Gowanus Canal. In light of the limited number of locations offering public access to the Gowanus Canal, and the proximity of other fishable water bodies that have a greater abundance of fish and crabs than the Gowanus Canal, it would be appropriate to use an adjustment factor – to reduce the anglers' assumed consumption of fish and crabs taken from the Gowanus Canal and to account for their consumption of fish and crabs taken from other surface water bodies in the area.

2. The species-specific consumption rates used in the HHRA are not properly supported

The HHRA is not consistent in its statements regarding the percentages of total fish consumption assigned to each species taken from the Gowanus Canal, nor are those percentages properly supported. At one point, the HHRA indicates that striped bass represent top-level predators, white perch represent mid-level predators, and that "[t]he midlevel predator represents species most frequently harvested and consumed by anglers."[18] Elsewhere, however, the HHRA states that "eel represent bottom feeders with 44 percent of the total fish consumption, striped bass represent the intermediate level with 47 percent consumption, and white perch represent the remaining 9 percent."[19]

These statements are inconsistent regarding the predator level represented by striped bass (top-level vs. intermediate level). More significantly, because the PCB exposure point concentrations in American eel samples from the Gowanus Canal are nearly three times higher than the corresponding concentrations in white perch samples, assignment of 44 percent of total consumption to that bottom-feeding species is inappropriate in light of the statement that mid-level predator species are most frequently harvested and consumed by anglers.

Further, the HHRA indicates that the percentages assigned to those three species are based on a publication that presents data collected by a survey of licensed anglers in New York State conducted more than 20 years ago.[20] These data are unlikely to represent the practices of

---

[17] A report by the New York City Department of Environmental Protection (NYCDEP) states that the NYSDEC listed the Gowanus Canal as a high-priority water body in 1998, noting that the levels of dissolved oxygen in the Gowanus Canal were severe enough to prevent fish propagation. This listing is still in effect. NYCDEP. 2008. *Gowanus Canal Waterbody/Watershed Facility Plan Report* (at 1-6).

[18] HHRA (at 4-3).

[19] HHRA (at 5-6).

[20] *Id.*, citing Connelly et al., 1992.

anglers who currently consume fish from the Gowanus Canal, because no license is required to collect fish and crabs from the Gowanus Canal.[21] Instead, the data most likely represent the practices of fresh-water fishermen, not those of Gowanus Canal anglers. Thus, the species-specific consumption rates and the angler practices assumed in the HHRA are unlikely to be representative of those actually occurring in the Gowanus Canal.

C. EPA has not demonstrated that PCBs in Gowanus Canal surface sediments contribute to PCBs in fish tissue or that the proposed remedy will reduce tissue concentrations of PCBs

It is well-established EPA policy that risks associated with background conditions must be properly assessed and taken into account in the development and selection of a proposed remedy, because "the CERCLA program, generally, does not clean up to concentrations below natural or anthropogenic background levels."[22] In the context of the HHRA for PCBs in Gowanus Canal sediments, this means two things: first, that EPA must consider whether, and to what extent, background conditions contribute to the PCB levels found in fish tissue; and second, that EPA must evaluate whether, and to what extent, PCBs in Gowanus Canal surface sediments contribute to the PCB levels found in fish tissue in excess of those background levels.

Although EPA implicitly assumes that PCBs in Gowanus Canal sediments contribute to the PCB levels in fish tissue, there are absolutely no data, analyses, studies or other information in the administrative record that support that key assumption. To the contrary, EPA acknowledges that it has not established any causal link between PCBs in Gowanus Canal sediments and PCBs in fish tissue:

> Additionally, the species targeted in the HHRA (striped bass, white perch, American eel and blue crab) inhabit areas that are larger than the Gowanus Canal, and the PCB concentrations in their tissue reflect contributions from all of the areas in which they forage. Therefore, *the PCB concentrations in fish and shellfish caught in the canal cannot be directly linked to PCB concentrations in the canal sediments alone. . . .PCB concentrations in [canal] sediment cannot be directly linked to the target species that were caught in the canal.*[23]

And even if such linkage could be established from studies or other information not in the administrative record, EPA acknowledges that the amount of any such contribution is uncertain at best:

> [T]he home ranges of the fish and shellfish species evaluated in the HHRA are not restricted to the Gowanus Canal, and the contaminant concentrations in tissue reflect contributions from all of the areas in which they forage. Additionally, the

---

[21] HHRA (at 2-1). New York State does not require a license for fishing from marine, coastal district, and tidal waters for "migratory fish from the sea." http://www.dec.ny.gov/permits/6091.html.
[22] USEPA 2002, *Role of Background in the CERCLA Cleanup Program.* OSWER 9285.6-07P.
[23] FS Addendum, *Supplemental Evaluation of Remediation Goals* (at 4, emphasis added).

> ingestion of some fish and shellfish species from the reference area in Upper New York Bay also poses an unacceptable risk. *Therefore, reductions in contaminant concentrations in canal sediments will not necessarily result in reductions in tissue concentrations to levels that do not pose a risk.*[24]

In short, EPA has assumed, but has not demonstrated in the administrative record, that PCBs in Gowanus Canal surface sediments actually contribute to PCB concentrations in fish tissue. And even if such a demonstration could be made, the fact remains – as discussed below – that, according to EPA, background concentrations of PCBs in fish tissue are already unacceptably high, and will not be reduced to acceptable levels by the proposed remedial action. Under these circumstances, any incremental risk reduction that could hypothetically be achieved by reducing PCB concentrations in Gowanus Canal surface sediments cannot be justified under EPA policy, or under the effectiveness criterion of the NCP.

D. The RAO and PRG have been set arbitrarily and will not reduce human health risks to acceptable levels

The RAO to address human health risks from consumption of PCBs in edible fish and shellfish tissues is as follows:

> Reduce the contribution of polychlorinated biphenyls (PCBs) from the Gowanus Canal to fish and shellfish by reducing the concentrations of PCBs in Gowanus Canal sediments to levels that are within the range of Gowanus Bay and Upper New York Bay reference concentrations. [25]

Implicit in this formulation are the assumptions (i) that PCBs from Gowanus Canal surface sediments are in fact contributing to PCB levels in fish and shellfish tissues, and (ii) that reducing PCB concentrations in Gowanus Canal surface sediments will reduce PCB levels in fish and shellfish tissues. But as discussed above, there is no support in the administrative record for either of those assumptions. The RAO has thus been set arbitrarily.

Moreover, there is another embedded assumption in the RAO – namely, that the concentrations of PCBs in Gowanus Canal surface sediments are statistically significantly higher than the reference area concentrations. But that is not the case. As discussed in detail below in Section II.A. of these comments, there is no statistically significant difference between total PCB congener concentrations in Gowanus Canal surface sediments and total PCB congener concentrations in reference area surface sediments, which renders the RAO essentially meaningless.

---

[24] *Responses to National Remedy Review Board and Contaminated Sediments Technical Advisory Group Recommendations for the Gowanus Canal Superfund Site, Brooklyn, New York* (Responses to NRRB/CSTAG), Region 2, Dec. 28, 2012 (at 11, emphasis added).

[25] FS Addendum, *Supplemental Evaluation of Remediation Goals* (at 3).

More importantly, even if there were supporting documentation for this formulation of the RAO, EPA acknowledges that achieving the RAO – *i.e.*, reducing concentrations of PCBs in Gowanus Canal surface sediment to levels within the range of Gowanus Bay and Upper New York Bay reference concentrations – will not reduce human health risks from fish consumption to acceptable levels:

> [H]owever, *the PCB concentrations in the reference area samples also result in carcinogenic risks and non-carcinogenic hazards that exceed acceptable levels.* The New York State Department of Health (NYSDOH) has fish consumption advisories for Gowanus Bay and Upper New York Bay that identify PCBs as a COC in fish (NYSDOH, 2010). Because PCB contamination in fish is a regional problem, remediation of the sediments in the canal is unlikely to reduce PCB concentrations in fish tissue to acceptable levels.[26]

> Under current conditions, the PCB concentrations in reference area fish tissue pose a risk. *If the canal is cleaned up to similar concentrations as the reference area, the fish tissue will still pose a risk. While the concentration may not be protective*, it is the best that can be achieved.[27]

Under these circumstances, the RAO for human health risks from PCB contamination in Gowanus Canal sediments cannot be used as a criterion in support of, or to justify, the preferred remedy. Indeed, any RAO that has the sole purpose of reducing PCB concentrations in Gowanus Canal sediments, in the expectation of reducing fish tissue concentrations to acceptable levels of risk, would be futile and would result in remedial action for the sake of remedial action.

The PRG suffers from the same deficiencies, as it is nothing more than a numerical target for achieving the RAO, and it is not derived from any consideration of risk reduction:

> Site-specific risk-based PRGs were not developed for PCBs in sediment or tissue because it is unlikely that the canal remedy will reduce risk from ingesting PCB-contaminated fish and shellfish to acceptable levels. . ..[28]

Instead, the "maximum Gowanus Bay and Upper New York Bay reference area concentration for PCBs in sediment was selected as the PRG. This PRG is 0.48 mg/kg [total PCB congeners]."[29] However, as noted above, this PRG is essentially meaningless, because there is no statistically significant difference between total PCB congener concentrations in Gowanus Canal surface sediments and total PCB congener concentrations in reference area surface sediments.

[29] *Id.*

E. Existing institutional controls are the best method to address any human health risks that may be presented by PCBs in Gowanus Canal surface sediments

As discussed above, the administrative record does not support the threshold assertion that PCBs in Gowanus Canal surface sediments contribute to unacceptable human health risks. As EPA has acknowledged, PCB contamination in fish is a regional problem and even fish in the reference area have unacceptably high levels of PCBs in their edible tissue.

This regional problem is currently being addressed by a NYSDOH fish consumption advisory. Not surprisingly, the SPP incorporates that institutional control as part of the preferred remedy. However, EPA's statement in support of that action is highly significant:

> The existing fish consumption advisory would be included because of the anticipated unacceptable human health risk associated with the consumption of PCB-contaminated fish and shellfish *after the remedy is implemented.*[30]

In other words, EPA acknowledges that the proposed remedial action will not be an effective means of addressing human health risks (if any) presented by PCBs in Gowanus Canal surface sediments. Continuation of the existing institutional controls (*i.e.*, the fish consumption advisory) will still be required, and nothing in the administrative record demonstrates that any additional response would be necessary, appropriate, or effective in addressing that exposure pathway.

* * *

For all of the foregoing reasons, the RAO based on human health risks from PCBs in Gowanus Canal surface sediments should not be included in the ROD for this site.

II. PCBs in Gowanus Canal Surface Sediments Do Not Present An Unacceptable Toxicity Risk to Benthic Organisms

As part of the RI, EPA conducted an ERA to determine whether contaminant concentrations in Gowanus Canal surface sediments present a risk to ecological receptors. Risks to benthic macroinvertebrate communities were evaluated primarily through the use of laboratory-based sediment bioassays (i.e., toxicity tests), and through comparison of sediment chemical concentrations to literature-based screening benchmarks.[31]

The sediment bioassays indicated "a site-related potential for adverse effects to benthic communities from chemicals in sediment."[32] Because PAHs were "consistently detected in sediment at the highest concentrations relative to their ecological screening benchmarks,"[33] EPA

---

[30] SPP (at 31, emphasis added).
[31] SPP (at 14).
[32] *Ibid.*
[33] *Ibid.*

concluded that PAHs "represent the greatest site-related risk to the benthic community"[34] and are "the most likely cause of the toxicity observed in laboratory tests."[35]

Other contaminants were also identified as potential contributors to the observed toxicity to benthic organisms, based on two criteria: they were present in Gowanus Canal surface sediments at concentrations that "exceeded both risk-based screening levels and were statistically higher than reference area concentrations."[36] Based on those two criteria, PCBs and seven metals were designated as COCs with respect to "*potential* site-related risk to the benthic community."[37] Based on the same two criteria, but without further analysis, EPA concluded that the ERA had found that PCBs and the seven metals "*are* toxic to benthic organisms."[38]

EPA thus developed the following RAO for benthic toxicity:

> Reduce the risks to benthic organisms in the canal from direct contact with PAHs, PCBs, and metals in sediment by reducing sediment toxicity to levels that are comparable to reference conditions in Gowanus Bay and Upper New York Bay.[39]

However, a site-specific risk-based PRG was "developed for PAHs only[,] because PAHs are most likely causing the toxicity in the sediments."[40] With respect to PCBs, EPA specifically noted that although concentrations exceeded sediment quality screening values, "the magnitude of exceedances was low. Therefore, the potential contribution of PCBs to observed toxicity relative to PAHs is considered to be low. PCBs co-occur with PAHs and therefore will be addressed through the remediation of the PAHs."[41]

EPA's conclusion that PCBs are contributing to benthic toxicity of Gowanus Canal surface sediment is unsupported. EPA based that conclusion on a simple comparison of sediment concentrations to a screening value. But screening values are merely tools to decide whether more refined analyses are required; they cannot be used to make determinations about cause-effect, concentration-response relationships, because they do not take into account site-specific conditions that affect bioavailability, nor other confounding factors. The mere circumstance that PCB concentrations in Gowanus Canal surface sediments exceed a screening value does not establish that those PCBs are toxic to benthic invertebrate organisms.

In order to make a determination regarding benthic toxicity, it would first be necessary to develop a site-specific risk-based criterion for Gowanus Canal surface sediments, and then to compare the PCB concentrations in Gowanus Canal surface sediments to that site-specific risk-

---

[34] *Ibid.*
[35] FS Addendum, *Supplemental Evaluation of Remediation Goals* (at 5).
[36] *Ibid.*
[37] SPP (at 14, emphasis added).
[38] *Id.* (at 15, emphasis added).
[39] FS Addendum, *Supplemental Evaluation of Remediation Goals* (at 4).
[40] Responses to NRRB/CSTAG (at 13).
[41] FS Addendum, *Supplemental Evaluation of Remediation Goals* (at 5). A PRG was not established for either of the two metals of concern (copper and lead) because they "are not likely to be bioavailable." *Ibid.*

based criterion. EPA did not develop such a site-specific risk-based criterion, and therefore cannot properly conclude that PCB concentrations in Gowanus Canal surface sediments are toxic to benthic organisms.

EPA found it unnecessary to reach a definitive conclusion about the benthic toxicity of PCBs in Gowanus Canal surface sediments, as reflected in its statement that the remediation it selected to address benthic toxicity from PAHs in Gowanus Canal surface sediments will also remove the PCBs that "co-occur" with those PAHs. Under EPA's reasoning, the issue of whether those PCBs are toxic to benthic organisms is moot, because they will be "along for the ride" during the remediation that EPA has determined is necessary to address the PAH contamination.

Whether or not this issue is moot, the assertion in the SPP that those PCBs "are toxic to benthic organisms" is wholly unfounded, and finds no support in the ERA or elsewhere in the administrative record. Nor does the administrative record contain a site-specific risk-based criterion for determining the benthic toxicity of PCBs in Gowanus Canal surface sediments.

In order to make a definitive determination as to the matter of benthic toxicity of PCBs in Gowanus Canal surface sediments, ENVIRON developed a site-specific risk-based criterion based on three lines of evidence from the scientific literature. As discussed in detail below in Section II.C. of these comments, ENVIRON derived a value of 41 mg/kg. Because PCB concentrations in all Gowanus Canal surface sediments sampled in the RI are well below that level, the RAO for benthic toxicity should be revised in the ROD to eliminate any reference to PCBs.

A. PCB concentrations in Gowanus Canal surface sediments are not statistically higher than in reference area surface sediments

As a threshold issue, not only is EPA's characterization of the PCB concentrations in Gowanus Canal surface sediments as "statistically higher than reference area concentrations"[42] incorrect, but it is also based on an inaccurate and inconsistent value for PCB concentrations in reference area surface sediments.

Specifically, Table 6-1 of the ERA is entitled "Comparison of Detected Constituents in Reference Sediment Samples to Criteria." Under the heading "Pesticides/PCBs (ug/kg)," the only entry is "*None detected.*"

But "none detected" is inconsistent with the analytical results from the RI and with the statement in the FS Addendum that the "maximum Gowanus Bay and Upper New York Bay

[42] *Ibid.*

reference area concentration for PCBs in sediment" is 0.48 mg/kg.[43] That same value is also reflected in Table 1 of the SPP, "Average Contaminant Concentrations at Reference Stations."[44]

It is likely that the "none detected" entry in Table 6-1 of the ERA was based on analysis for PCB Aroclors, rather than PCB congeners, even though the ERA itself states that "congener-specific data offers a more comprehensive representation of the total PCB concentrations in a medium."[45] Indeed, there are congener data in the RI for three of the five reference area stations that are shown in Table 6-1; instead of "none detected," the total PCB values reported for those three stations are 0.341 mg/kg, 0.466 mg/kg, and 0.476 mg/kg.[46]

The last of those three congener values would be rounded to 0.48 mg/kg, which is the value used in the SPP and the FS Addendum as the maximum concentration in the reference area. The same congener value is established as the PRG for the RAO addressing human health risks, and EPA also used congener data to perform the risk calculations presented in the HHRA and the ERA. Accordingly, instead of the "none detected" value from Aroclor data, congener data should have been used to investigate the potential differences in total PCB concentrations between the Gowanus Canal surface sediments and the reference area surface sediments.

Appendix A to these comments, "Comparison of PCB Congener Concentrations in Surface Sediments in Gowanus Canal and in Reference Area," was prepared by ENVIRON and shows that there is no statistically significant difference between total PCB congener concentrations in the Gowanus Canal surface sediments and total PCB congener concentrations in reference area surface sediments. In support of that analysis, Appendix A also contains a detailed description of the available data sets, and discusses inconsistencies both in those data sets, and in certain analyses in the RI and the SPP.

B. Toxicity determinations cannot be based on comparisons to screening levels

EPA has used a screening value as the sole determinant of the benthic toxicity of PCBs in Gowanus Canal surface sediments. But screening levels are just that – thresholds below which no further analysis is warranted, and above which more refined assessments are required. By their very nature, screening values cannot be used to make determinations about cause-effect, concentration-response relationships, because they do not take into account site-specific conditions that affect bioavailability, nor other confounding factors.

---

[43] *Id.* (at 4).

[44] Table 1 shows a "Reference Average" of 0.47 mg/kg, and a "Reference Range" of 0.47-0.48 mg/kg, for "Total PCBs."

[45] "There are 209 individual PCB congeners (compounds), but there are nine Aroclors (Aroclors 1016, 1221, 1232, 1242, 1248, 1254, 1260, 1262, and 1268). . . .Aroclors consist of a mixture of PCB congeners. Since not all congeners are represented in Aroclor mixtures, congener-specific data offers a more comprehensive representation of the total PCB concentrations in a medium." ERA (at 7-4).

[46] The PCB congener data are found in Table I-5A of the RI.

Indeed, EPA acknowledges in the SPP that screening criteria are not determinative of toxicity, and cannot be used to establish target cleanup levels. The SPP includes the following quotation, selected by EPA, from NYSDEC's *Technical Guidance for Screening Contaminated Sediments*:

> Sediments with contaminant concentrations that exceed the criteria listed in this document are considered to be contaminated and *potentially* causing harmful impacts to marine and aquatic ecosystems. *These criteria do not necessarily represent the final concentrations that must be achieved through sediment remediation.* Comprehensive sediment testing and risk management are necessary to establish when remediation is appropriate and what final contaminant concentrations the sediment remediation efforts should achieve.[47]

The screening value used to evaluate benthic toxicity was 0.0598 mg/kg,[48] which is found in the Screening-Level Ecological Risk Assessment (SLERA). As indicated in Table 3-5 of the ERA, "Medium-Specific SLERA Screening Values – Sediment and Surface Water," that value is for total PCB congeners, and the source is identified as MacDonald et al. (2000).[49] That table also references a screening value of 0.0227 mg/kg for individual PCB Aroclors, and total PCB Aroclors, and the source is identified as NYSDEC (1999),[50] although those screening values were based on an earlier publication by Long et al. (1995).[51]

It is widely accepted that empirical sediment quality guidelines (SQGs) such as those presented by Long et al. (1995) and by MacDonald et al. (2000) do not necessarily represent cause-effect, concentration-response relationships between chemical concentrations and biological effects.[52] Rather, their purpose is to provide an indication of whether more detailed analyses (for example, sediment toxicity tests) should be conducted to determine whether sediments are actually toxic. And in sediments contaminated by multiple chemicals, additional information would be needed to determine which chemicals are responsible for any observed toxicity.

The SQGs for PCBs presented in Long et al. (1995) were derived using an empirical approach that relied upon a large database of paired sediment chemistry and biological data collected from sites contaminated by multiple chemicals. There are several limitations to this

database. *First*, the specific chemicals that caused the toxicity observed in laboratory tests were not identified; multiple chemicals were present at most sites and may have contributed to the toxicity of the sediments. *Second*, the bioavailability of the chemicals detected in the sediment from each site was not determined; this matters, because site-to-site variation in bioavailability causes site-to-site variation in the levels of PCBs that are toxic to benthic organisms. *Third*, there was substantial variation in sediments from various sites in geochemical characteristics that are known to influence bioavailability (e.g., organic carbon content, and sulfide concentration); this suggests that there was substantial site-to-site variability in the levels of PCBs that would be toxic to benthic organisms.

In addition, a critical evaluation of the "consensus" screening values for PCBs developed by MacDonald et al. (2000) found that those screening values were unreliable in identifying PCB toxicity and suffered from the same limitations noted above.[53] Key deficiencies include: inability to isolate effects caused by PCBs due to the co-occurrence of multiple contaminants in underlying data; inability to distinguish non-causal correlations from cause-effect, concentration-response relationships between chemical concentrations and biological effects; and derivation methods that are influenced by the distribution of concentrations in the underlying data set (regardless of relationship to toxicity) and are thus biased toward background and low PCB concentrations.[54]

Furthermore, the reliability of SQGs for predicting the toxicity of PCBs in sediments has been repeatedly demonstrated to be less than 60%.[55,56,57,58] Because of these limitations, the critical evaluation states that any conclusion regarding the cause of observed toxicity in sediment contaminated by multiple chemicals should be based on site-specific assessments of bioavailability and concentration-response relationships, as well as laboratory determination of causality with spiked sediment studies.[59]

C. The PCB concentrations in Gowanus Canal surface sediments are not toxic to benthic organisms

Screening values are useful as the first step in identifying COCs, but they cannot be used as the sole criterion to conclude that PCBs in Gowanus Canal surface sediments are toxic to

benthic organisms. Screening values do not represent proof of a causal relationship between sediment concentrations and benthic toxicity, primarily because they do not take into account site-specific conditions that affect bioavailability. However, using multiple lines of evidence derived from the scientific literature, it is possible to develop a site-specific criterion based on cause-effect, concentration-response relationships between PCB concentrations in Gowanus Canal surface sediments and their potential effects on benthic invertebrates.

Appendix B to these comments, "Development of a Site-Specific Risk-Based Criterion for PCBs in Gowanus Canal Surface Sediments," was prepared by ENVIRON and describes that approach. The site-specific risk-based criterion was derived from application of the equilibrium partitioning method, from review of spiked sediment toxicity test results, and from analysis of biological data from contaminated sediment sites where PCBs are the primary contaminant of concern. It also used site-specific data from the RI regarding PCB homologue distributions and total organic carbon (TOC) concentrations.

The value derived in Appendix B as the site-specific risk-based criterion for PCB toxicity to benthic invertebrates is 41 mg/kg total PCB concentration, regardless of whether the concentration is generated from congener analysis or from Aroclor analysis. A review of the RI data indicates that all concentrations of PCBs in Gowanus Canal surface sediments are well below 41 mg/kg – the highest reported surface sediment concentration of total PCB congeners was 8.13 mg/kg at location 313,[60] and the highest reported surface sediment concentration of total PCB Aroclors was 3.4 mg/kg at location 314.[61]

Based on the comparison of PCB concentrations in Gowanus Canal surface sediments to the site-specific risk-based criterion determined by ENVIRON, it is clear that PCB concentrations in the Gowanus Canal are not toxic to benthic organisms. The RAO for benthic toxicity should therefore be revised in the ROD to eliminate any reference to PCBs.

III. EPA Did Not Comply with the Requirements of the NCP in its Development of the RAOs for PCBs

The NCP[62] is the blueprint for remedial actions under CERCLA, providing both a framework and specific provisions for responding to releases of hazardous substances. It establishes procedures and standards for conducting the investigation, study, and remediation of such releases. The framework emphasizes a measured process of: characterizing the nature and extent of the hazardous substance releases; assessing the risks posed by such releases, and the

[60] RI, Table I-5A. Table 5-5 of the ERA erroneously indicates that the maximum concentration of total PCB congeners was 15.1 mg/kg, reported at location 314. However, Table I-5A of the RI shows that the concentration of total PCB congeners in duplicate samples at location 314 were 4.03 mg/kg and 6.8 mg/kg, respectively. In any event, the erroneously reported value of 15.1 mg/kg for location 314 is still well below the site-specific criterion of 41 mg/kg.

[61] RI, Table I-4A; ERA, Table 5-5.

[62] 40 CFR Part 300.

need for response; and developing and selecting a remedy to address those hazardous substances that pose an unacceptable risk to human health or the environment.

The NCP sets forth the requirements that govern the conduct of the remedial investigation, the conduct of the feasibility study, and the selection of the remedy. However, EPA did not follow those requirements in its development of the RAOs for PCBs at this site. Accordingly, those RAOs should not be included in the ROD.

A. EPA did not comply with the NCP requirements for remedial investigations

The NCP sets out the purpose and requirements for the conduct of the remedial investigation, and provides in pertinent part as follows:

> The purpose of the remedial investigation (RI) is to collect data necessary to adequately characterize the site for the purpose of developing and evaluating effective remedial alternatives.. . .The RI provides information to assess the risks to human health and the environment and to support the development, evaluation, and selection of appropriate response alternatives.. . .The lead agency shall. . .gather data necessary to assess the extent to which the release poses a threat to human health or the environment.[63]

The NCP also contemplates that "estimates of actual or potential exposures and associated impacts on human and environmental receptors may be refined throughout the phases of the RI."[64]

Neither the SPP nor any of the underlying documents in the administrative record – either individually or in the aggregate – appropriately completed this process in order to support the development of the two RAOs for PCBs. In particular, and as discussed in detail above, the deficiencies include the following:

- EPA failed to collect sufficient information regarding PCB concentrations in fish tissues.
- EPA failed to refine its exposure estimates to reflect more realistic assumptions regarding both overall, and species-specific, fish and shellfish consumption rates.
- EPA failed to properly assess the risks to human health posed by consumption of fish and crabs from the Gowanus Canal.
- EPA failed to demonstrate a nexus between PCB concentrations in Gowanus Canal surface sediments and PCB concentrations in fish tissue.
- EPA failed to show that reductions in PCB concentrations in Gowanus Canal surface sediments will result in reductions in fish tissue concentrations.
- EPA failed to show that PCB concentrations in Gowanus Canal surface sediments are statistically higher than in reference area surface sediments.

---

[63] 40 CFR § 300.430(d)(1) and (2).
[64] 40 CFR § 300.430(d)(1).

- EPA failed to refine its initial determination of potential impacts on benthic toxicity that were based only on a screening value for PCBs.
- EPA failed to determine whether PCB concentrations in Gowanus Canal surface sediments are, or are not, toxic to benthic organisms.

In short, it is clear that EPA did not "collect data necessary to adequately characterize the site" with respect to PCB concentrations in Gowanus Canal surface sediments, nor did it "gather data necessary to assess" the extent to which those PCB concentrations pose a threat to human health or the environment. Further, the information in the RI is clearly not sufficient "to support the development, evaluation, and selection of appropriate response alternatives" that are based on a proper assessment of risks posed by PCB concentrations in Gowanus Canal surface sediments. Because of these shortcomings, the two RAOs for PCBs should not be included in the ROD for this site.

B. EPA did not comply with the NCP requirements for feasibility studies

The NCP establishes requirements for the feasibility study, and states that its primary objective is "to ensure that appropriate remedial alternatives are developed and evaluated such that relevant information concerning the remedial action options can be presented to a decision-maker and an appropriate remedy selected."[65] In support of that effort, the NCP directs the lead agency to:

> Establish remedial action objectives specifying contaminants and media of concern, potential exposure pathways, and remediation goals. . . . Remediation goals shall establish acceptable exposure levels that are protective of human health and the environment.[66]

The NCP also provides that "preliminary remediation goals" (PRGs) should be developed based on readily available information and then "modified, as necessary, as more information becomes available during the RI/FS."[67] In addition, the development and screening of remedial alternatives are to be guided by three criteria: effectiveness, implementability, and cost.[68]

As with the RI, EPA did not follow the requirements of the NCP for a feasibility study in its development of the two RAOs for PCBs.

With respect to the RAO based on health risks from PCBs, EPA has not established a PRG with "acceptable exposure levels that are protective of human health." Indeed, EPA has admitted that it is impossible to do so, because PCB contamination in fish is a regional problem, reflecting cumulative uptake from a broad foraging area: "If the canal is cleaned up to similar concentrations as the reference area, the fish tissue will still pose a risk. While *the concentration*

---

[65] 40 CFR § 300.430(e)(1).
[66] 40 CFR § 300.430(e)(2)(i).
[67] *Ibid.*
[68] 40 CFR § 300.430(e)(7).

may not be protective, it is the best that can be achieved."[69] This falls far short of meeting the effectiveness criterion of the NCP.

Because EPA anticipates that the preferred remedy will be ineffective and that there will continue to be "unacceptable human health risk associated with the consumption of PCB-contaminated fish and shellfish after the remedy is implemented,"[70] the SPP retains the current, long-standing fish advisory as an institutional control. Clearly, that is the only response action that will effectively address this exposure pathway, and nothing in the administrative record suggests that any other remedial alternative would meet the effectiveness criterion of the NCP.

With respect to the RAO based on ecological risks of PCBs at this site, the deficiency is even more glaring. EPA did not establish any PRG that would "establish acceptable exposure levels that are protective" of benthic organisms. EPA essentially takes the position that it doesn't have to do so, because all of the soft sediment will be removed to address the benthic toxicity of PAHs – and since the PCBs "co-occur" in the soft sediment with PAHs, they will be removed as well. While this "along for the ride" rationale may be appealing, it is an insufficient basis for establishing an RAO under the NCP, particularly where EPA has failed to address the threshold issue of whether PCB concentrations in Gowanus Canal sediments are, or are not, toxic to benthic organisms. PCBs therefore must not be included in the RAO that addresses benthic toxicity.

* * *

In summary, EPA has failed to comply with the requirements of the NCP for remedial investigations, and for feasibility studies, in its development of the RAOs for PCBs at the Gowanus Canal site. Consequently, the RAOs for PCBs should not be included in the ROD.

Conclusion

Nothing in the administrative record supports the assertion that the low levels of PCBs in Gowanus Canal surface sediments are in any way risk drivers for the preferred remedy, which addresses PAH and NAPL contamination. There is no statistically significant difference between total PCB congener concentrations in Gowanus Canal surface sediments and total PCB congener concentrations in reference area surface sediments, and the PCB concentrations in Gowanus Canal surface sediments have not been shown to be toxic to benthic organisms.

Nevertheless, EPA proposes two remedial action objectives based on PCB concentrations in Gowanus Canal surface sediments. The first RAO addresses the potential contribution of PCBs to fish and shellfish that may forage in the Gowanus Canal, and states that the goal is to reduce PCB concentrations in Gowanus Canal sediments to levels "within the range" of reference area concentrations. There are several problems with this approach. EPA has not demonstrated that PCBs in Gowanus Canal surface sediments actually contribute to PCBs in fish tissue, or that reducing surface sediment concentrations of PCBs will reduce tissue

---

[69] Responses to NRRB/CSTAG (at 14, emphasis added).
[70] SPP (at 31).

concentrations of PCBs. Moreover, even if those assumptions were correct, no action would be required to achieve EPA's stated goal, because there is no statistically significant difference between the PCB concentrations in Gowanus Canal surface sediments and in reference area surface sediments.

More importantly, EPA indicates that even if the preferred remedy achieves the RAO, it will not reduce to acceptable levels the risks from consumption of PCB-contaminated fish and shellfish. Indeed, because concentrations of PCBs in fish tissue reflect cumulative uptake from a broad foraging area, no remedy addressing Gowanus Canal surface sediments would be effective at doing so; reference area fish and shellfish would continue to have unacceptably high levels of PCBs in their edible tissues following any such action. The only measure that would effectively address the exposure pathway from fish consumption, and the only measure that is needed, is continuation of the existing institutional control.

In these circumstances, the RAO based on this exposure pathway is not well conceived. Many of its underlying assumptions are not supported in the administrative record, and the RAO was not developed in compliance with the requirements of the NCP. For all of these reasons, that RAO should not be included in the ROD for this site.

The second RAO addresses the potential benthic toxicity of PCBs. EPA's development of that RAO began with an incorrect assumption, and ended prematurely without proper analysis. At the outset, EPA used two criteria to identify contaminants as potential contributors to benthic toxicity. The first criterion was whether concentrations of a contaminant in Gowanus Canal surface sediments "were statistically higher than reference area concentrations." EPA concluded that PCBs met that criterion, when in fact there is no statistically significant difference between total PCB congener concentrations in Gowanus Canal surface sediments and total PCB congener concentrations in reference area surface sediments.

The second criterion used to identify PCBs as a COC for benthic toxicity was the fact that the PCB concentrations in Gowanus Canal surface sediments slightly exceeded a risk-based screening level. However, instead of taking the scientifically-required next step – namely, conducting more refined analyses to determine, on a site-specific basis, whether the PCB concentrations in Gowanus Canal surface sediments were in fact toxic to the benthic community found there – EPA stopped the process. Without any further support, EPA simply concluded that benthic toxicity due to PCBs had already been established, when in fact it had not been. Indeed, had EPA evaluated the scientific literature and the available site-specific data regarding PCB homologues and TOC concentrations, it would have reached the opposite conclusion.

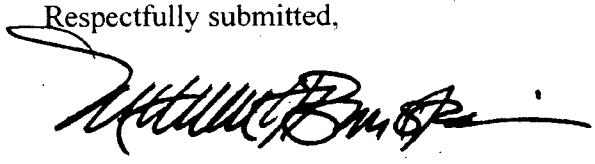
EPA glosses over these shortcomings by saying, in effect, that it doesn't really matter – all of the soft sediments will be removed to address EPA's concerns about the benthic toxicity of PAHs, and since the PCBs "co-occur" with the PAHs, they will be removed as well. But under that reasoning, where the PCBs are merely "along for the ride," they cannot be fairly characterized as a risk driver for the remedial element that will address benthic toxicity. EPA cannot have it both ways: either it must make an affirmative determination about the site-

specific benthic toxicity of the low levels of PCBs in Gowanus Canal surface sediments, or it must delete any reference to PCBs in the RAO. Because there is nothing in the administrative record that would support a finding of site-specific benthic toxicity, the RAO should therefore be revised to eliminate the reference to PCBs.

* * *

For all of the reasons set out in these comments, Con Edison respectfully submits that the RAOs identified in the SPP should be modified in the ROD. Specifically, the RAO addressing PCB levels in fish and shellfish should be eliminated in its entirety, and the RAO addressing toxicity to benthic organisms should be revised to eliminate any reference to PCBs.

Respectfully submitted,



Mitchell H. Bernstein

Comparison of PCB Congener Concentrations in Surface Sediments in Gowanus Canal and in Reference Area

ENVIRON

Appendix A – Comparison of PCB Congener Concentrations in Surface Sediments in Gowanus Canal and in Reference Area

Description of the available data sets

The RI Report provides concentration data for PCBs in surface sediments within the Gowanus Canal and in the reference area; PCB data from both areas were generated by two different laboratory methods.[1] All of the surface sediment samples collected by USEPA in 2010 (31 samples collected at 27 locations in the Gowanus Canal and 10 samples collected at 10 locations in the reference area) were analyzed for PCB Aroclors. In addition, 23 of the Gowanus Canal surface sediment samples (collected at 19 of the 27 locations) and 3 of the reference area surface sediment samples (collected at 3 of the 10 locations) were analyzed for PCB congeners. The RI report does not identify any earlier investigations of conditions in the Gowanus Canal and reference area that involved analysis of surface sediment samples for PCB Aroclors and congeners.

PCB Aroclors were detected in only 13 surface sediment samples collected at Gowanus Canal locations (at 10 of the 27 locations), and PCB Aroclors were not detected in any of the surface sediment samples collected at the 10 reference area locations. Thus, the available data set for PCB Aroclors in surface sediments in the Gowanus Canal and the reference area is composed primarily of non-detects (i.e., heavily censored[2]); actual measurements of the levels of PCBs in surface sediments are available for only 13 of the total of 41 samples, taken from only 10 of the total of 37 sampling locations. The results of the Aroclor analysis for the other 28 samples collected at the remaining 27 locations were all non-detects. The reported detection limits (which vary from sample to sample) should be interpreted as upper limits on the actual PCB

---

[1] Table I-4A of the RI Report lists data obtained by analyzing surface sediment samples for PCB Aroclors, and Table I-5A of the RI Report lists data obtained by analyzing surface sediment samples for PCB congeners.

[2] Page 130 of the USEPA guidance document titled *Data Quality Assessment: Statistical Methods for Practitioners* (EPA/240/B-06/003, USEPA 2006) says "Data that includes both detected and non-detected results are called censored data in the statistical literature."

concentrations in these samples, which were too low to be measured accurately by the method used to analyze these samples for PCB Aroclors.

By contrast, PCB congeners were detected in all 26 of the surface sediment samples that were analyzed for PCB congeners (23 from the Gowanus Canal and 3 from the reference area), although not all congeners were detected in each sample. The 26 samples analyzed for congeners were collected at 19 of the 27 Gowanus Canal surface sediment sampling locations and at 3 of the 10 reference area surface sediment sampling locations. Thus, compared to the Aroclor analysis, the PCB congener analysis provides measured values for a larger number of sampling locations both in the Gowanus Canal and in the reference area.

The RI Report does not explain why only 3 of the 10 reference area surface sediment samples were analyzed for PCB congeners. Although the field documentation provided in Appendix D-02 of the RI Report indicates that samples for PCB congener analysis were collected at 1 additional location in the Gowanus Canal and 5 additional locations in the reference area, the RI Report does not provide congener data for those samples or explain why they were not analyzed for PCB congeners.

A review of the quality of the PCB congener data is provided in Appendix H of the RI Report. This review says 22 results (of a total of 4,394 results[3]) were rejected by the data validator due to serious QA/QC problems and are not usable as detects or non-detects for any purpose. These 22 rejected results are identified by an "R" flag in the table that presents the complete results of the PCB congener analysis (i.e., Table I-5A in Appendix I of the RI Report). The 22 R-flagged results occur in a total of 7 surface sediment samples, all collected from the Gowanus Canal.[4] Table I-5A provides 169 results for each sample,[5] including results for each of nine homologue parameters and a parameter identified as "Total PCB (Lab)". None of the 22 R-flags in Table I-5A are applied to results reported for the homologue parameters or the Total PCB (Lab) parameter; this indicates that all of the results reported for these parameters are usable.

---

[3] The total number of results reported by the laboratory (4,394) is equal to 26 (the number of samples analyzed for PCB congeners) times 169 (the number of parameters addressed by the PCB congener analysis).

[4] The 7 samples qualified with R-flags for one or more PCB congeners are identified in Table 1.

[5] Although there are 209 PCB congeners, some results were reported for groups of congeners that co-elute in the laboratory procedure (e.g., PCB 12/13, PCB 40/41/71, etc.) rather than for individual congeners. All 209 PCB congeners are represented in the 169 results reported for each sample.

Inconsistencies in the data sets and analyses in the RI Report and the SPP

1. Although the results reported for the Total PCB (Lab) parameter in Table I-5A are usable, USEPA apparently calculated and used different values to represent total PCB congeners in some of the surface sediment samples. This is indicated on a page titled "Notes for Statistical Summary Tables" that follows RI Table 4-3. A note at the bottom of that page concerning calculation of total concentrations says, "Total PCB was calculated by summing either detected concentrations of PCB Aroclors, or detected concentrations of PCB congeners. If any constituent had a rejected, or "R"-flagged, result, a total value was not calculated for the sample."

As noted above, 7 of the 23 Gowanus Canal surface sediment samples had at least one R-flagged concentration; this suggests that USEPA calculated total PCB concentrations for the other 19 surface sediment samples (16 from the Gowanus Canal and 3 from the reference area) by "summing. . .detected concentrations of PCB congeners". Table 2.12 Supplement a (which is presented in an attachment to the HHRA) lists congener data and provides sums of the detected congeners for each of the 26 surface sediment samples analyzed for PCB congeners, but that table shows 43 R-flagged results affecting 8 samples; this is not consistent with Table I-5A or the information in Appendix H of the RI Report, which identify only 22 R-flagged results affecting 7 samples. Section 5.3.1 of the HHRA indicates that non-detected congeners and B-flagged congeners[6] were not included in the sums shown in Table 2.12 Supplement a, but no B-flagged results were listed in that table or in RI Table I-5A. In addition, the highest sum shown in Table 2.12 Supplement a (which is equivalent to 10.1 mg/kg[7]) does not match the maximum value of 15.1 mg/kg shown in some of the other tables in the RI Report (e.g., Table H-3.1 and H-3.12 of the attachment to the HHRA, and Table 3-2 and Table 5-5 of the ERA).

Because of these discrepancies, ENVIRON re-calculated the sum of the detected congeners for each surface sediment sample. The R-flagged results identified in Table I-5A were excluded from these calculations; the sums produced by these calculations are provided in Table 1. In addition, the statement that a total value was not calculated for the samples with at least one R-flagged concentration suggests that USEPA used the results reported in Table I-5A for the Total

---

[6] Although B-flags are not discussed or applied to the PCB congener data in the Data Quality Evaluation presented in Appendix H of the RI Report, a B-flag is generally used to identify analytical results that are similar to the level of a chemical detected in related quality control blanks.

[7] The values reported in Table I-5A and some of the other tables discussed in this appendix are expressed in ng/kg. To simplify this appendix, all of these values are expressed in mg/kg in this discussion.

PCB (Lab) parameter to represent the total PCB concentrations in those 7 samples; those concentrations are also shown in Table 1.

2. The RI Report does not clearly identify the data that were used to represent total PCB congeners in each of the various analyses and tables presented in the body and appendices of that report. For example, the RI says "Data for PCB congeners that were used in support of the human health and ecological risk assessments are provided in Appendix I, Table I-5" (page 4-5). This statement suggests that USEPA used the results reported for the Total PCB (Lab) parameter in that table to represent the total PCB congener concentrations in surface sediments in the risk assessments. However, Table 5-5 of the ERA indicates that the maximum value for total PCB congeners is 15.1 mg/kg. This maximum value does not appear in Table I-5A; the highest concentration in that table is 8.13 mg/kg, reported for the Total PCB (Lab) parameter for the sample collected at station 313.

Although this discrepancy is not explained in the RI, ENVIRON has determined that the value of 15.1 mg/kg reported in ERA Table 5-5 is the sum of the detected congeners for one of the two samples collected at station 314. Rather than averaging the values for the two duplicate samples, USEPA apparently used only the maximum value in analyses of the total congener values. As a result, the maximum value reported for total PCB congeners in ERA Table 5-5 is nearly twice as high as the maximum concentration reported in Table I-5A, and is also associated with a different sampling location.[8]

3. For some of the surface sediment samples, the total PCB congener values calculated by summing the detected concentrations of congeners are considerably different from the values reported in Table I-5A for the Total PCB (Lab) parameter. Ratios that reflect this difference (calculated as the sum of congeners divided by the Total PCB (Lab) value) are nearly equal to 1 for 12 of the samples and less than 2 for all but 4 of the 26 samples; but the ratios for those 4 samples are much higher (9.8 for the sample collected at station 307A, 5.8 for the sample collected at station 319, 5.1 for the sample collected at station 326, and 3.7 for one of the two duplicate samples collected at station 314). Thus, the difference between the total PCB values calculated by summing the detected concentrations of congeners and the values reported for the Total PCB (Lab) parameter varies substantially from sample to sample.

---

[8] Station 313 is in the middle reach of the Gowanus Canal, while station 314 is at the eastern end of the Sixth Street turning basin.

In light of this variation, it is not appropriate to represent the total PCB concentrations in the sediments of interest by the sum of the detected congeners at some locations and by the Total PCB (Lab) values at other locations.

4. Table 1 of the SPP indicates that one station with a total PCB level of 1.7 mg/kg was excluded in determining the range of total PCB levels in the reference area. Although not explained in the RI or in the SPP, ENVIRON has determined that this value is the sum of the detected congeners in the surface sediment sample collected at station 326; the Total PCB (Lab) parameter value reported in Table I-5A for this sample is 0.34 mg/kg. The FS Addendum reports (page 4 in *Supplemental Evaluation of Remediation Goals, Gowanus Canal, Brooklyn, New York*) "The sample from station 326 was not included in the reference area data set because the total PCB congener concentration was more than three times higher than the concentrations in the other reference area samples." Exclusion of valid data merely because the value is substantially higher than other values considered representative of the same area is contrary to USEPA guidance documents (e.g., USEPA 2006, *Data Quality Assessment: Statistical Methods for Practitioners*, QA/G-9S, EPA/240/B-06/003). In this particular case, there are only three samples available to represent the reference area; exclusion of the value for station 326 suggests that conditions throughout the reference area can be adequately represented by the values at the two remaining locations. But the value of 1.7 mg/kg calculated for station 326 is valid, and should not have been excluded from the reference area data set.

Methods and data sets used to compare total PCB levels (Gowanus Canal to Reference Area)

The RI Report indicates that total PCB concentrations in surface sediment in the Gowanus Canal are significantly higher than in surface sediment in the reference area. This conclusion is based on statistical analysis of the data produced by the Aroclor analysis. Table 4-5 of the RI Report shows the results of comparisons of levels in the Gowanus Canal surface sediments to levels in the reference area surface sediments performed using data for three Aroclors and total PCBs (by Aroclor analysis). According to that table, the statistical method used for all four comparisons is Gehan's test, rather than the Wilcoxon Rank Sum (WRS) test; as explained in the RI Report, "The WRS test was used when the detection frequency in each data set was at least 60 percent; otherwise, Gehan's test was used" (page 4-6). Based on these tests, USEPA concludes that the levels of Aroclor 1260 and total PCBs in the Gowanus Canal surface sediment are significantly higher than in the reference area surface sediment (RI page 4-6).

The total PCB levels in surface sediments in the Gowanus Canal and reference area can also be compared using the PCB congener data, which USEPA has acknowledged are superior to Aroclor data. For example, USEPA describes congener data as "more sensitive and accurate" than Aroclor data in the FS Addendum *(Preliminary Estimate of Solids Reduction Needed to Achieve Remediation Goals,* page 3); elsewhere, EPA explains that "congener-specific data offers a more comprehensive representation of the total PCB concentrations in a medium" than do Aroclor data (ERA, page 7-4).

Nevertheless, the congener data are not used in the RI Report to compare the total PCB levels in the Gowanus Canal surface sediments to levels in the reference area surface sediments. Congener data are available for 19 Gowanus Canal locations and 3 reference area locations, which compares favorably to the number of locations represented by measured values (i.e., uncensored data) in the Aroclor data set (only 10 in the Gowanus Canal and none in the reference area). Moreover, USEPA's failure to use congener data for that purpose is inconsistent with its reliance on congener data for the risk calculations presented in the HHRA and the ERA. Accordingly, the congener data also should have been used to investigate the potential differences in total PCB concentrations between the Gowanus Canal and the reference area.

Because the total PCB congener data are not censored, the comparison between PCB levels in the Gowanus Canal and the reference area can be performed using the WRS test as described in the USEPA guidance document named above (EPA QA/G-9S), rather than using Gehan's version of this test method. The earlier sections of this appendix describe several data sets that could be used to compare the total PCB congener levels in the Gowanus Canal to the levels in the reference area, and another data set is suggested by Appendix C to these comments. The three data sets used in this appendix are:

1. The laboratory data set: This data set is based on the values reported in Table I-5A for the Total PCB (Lab) parameter. To provide the best estimate of the total PCB concentration at each location, the locations with duplicate samples are represented in the WRS tests by the averages of the two values reported for the Total PCB (Lab) parameter.
2. The combination data set: Even though ENVIRON does not believe that it is appropriate to use combined data sets in the statistical comparisons, this data set was developed to be consistent with the page titled "Notes for Statistical Summary

Tables" that follows RI Table 4-3. It includes the values reported for the Total PCB (Lab) parameter for the 7 samples with R-flagged congener data; for all other samples, it includes the values calculated as the sums of detected congeners. Because USEPA apparently used the higher of each pair of duplicate sample results in some analyses (e.g., RI Table 6-1 and ERA Table 5-5), the locations with duplicate samples are represented in the WRS tests by the higher of the two sample values.

3. The normalized data set: As explained in Appendix C to these comments, the toxicity of PCBs in sediments to benthic organisms is determined in part by their bioavailability, which is closely related to the level of TOC in the sediments. The normalized data set was developed to represent the level of total PCBs per gram of organic carbon in the sediments at each location. These normalized values were calculated by dividing the values in the laboratory data set (i.e., the values for the Total PCB (Lab) parameter) by the total organic carbon (TOC) values provided for each location in RI Table I-7. To provide the best estimate of the normalized PCB concentration at each location, the locations with duplicate samples are represented in the WRS tests by the averages of the two normalized values.

Only the values in the laboratory data set were found in the RI Report, so the remaining values used for the combination data set were calculated by ENVIRON by summing the results reported for the congeners and co-eluting groups in Table I-5A. The values used to prepare all three data sets are provided in Table 1.

This appendix presents the comparisons performed using the WRS test with all three data sets. As explained above, USEPA excluded the total PCB congener value for station 326 from the data used to represent conditions in the reference area without sufficient justification. Nevertheless, each of the three data sets (the laboratory data set, the combination data set, and the normalized data set) was analyzed both with and without station 326. Thus, six WRS tests are shown in Table 2. Each test was performed at a 5% level of significance with a one-sided region of rejection. The notation and nomenclature used in Table 2 are consistent with the USEPA guidance document cited previously (EPA QA/G-9S).

Results of the comparisons

All six of the WRS tests summarized in the attached table show that there is no statistically significant difference between the mean values of the populations represented by the data.

Contrary to the characterization presented in the RI Report, this shows that the average concentration of total PCBs in the Gowanus Canal surface sediments is not significantly higher than the average concentration of total PCBs in the reference area surface sediments. The RI conclusion was based on a heavily-censored Aroclor data set that does not include any actual measurements in the reference area sediment samples, whereas the conclusion drawn here is based on a congener data set that provides actual measurements for both the Gowanus Canal sediment samples and the reference area sediment samples.

In addition, the comparisons using the normalized data set demonstrate that much of the apparent difference in total PCB levels in surface sediments between the Gowanus Canal and the reference area is due to differences in the levels of organic carbon. Application of the WRS test to the TOC data in Table I-7 of the RI indicates that there is a statistically significant difference between the average TOC level in the Gowanus Canal surface sediments and the average TOC level in the reference area surface sediments. The normalized total PCB concentrations account for this difference in TOC, and the results of the WRS tests performed with the normalized data set indicate that the normalized concentrations of PCBs in the Gowanus Canal surface sediments are not significantly higher than the normalized concentrations in the reference area.

Finally, the same conclusion is supported by analyzing the normalized data set using rank as the metric. When the normalized total PCB concentrations in Table 1 are ranked from lowest to highest, the ranks assigned to the normalized PCB concentrations for the three reference area locations are 3, 10, and 13 (out of 22) when station 326 is included; without that station, the two reference area ranks are 9 and 12 (out of 21). These ranks are not distinctly different than the ranks assigned to the Gowanus Canal locations.

Appendix B

Development of a Site-Specific Risk-Based Criterion for PCBs in Gowanus Canal Surface Sediments

ENVIRON

Appendix B – Development of a Site-Specific Risk-Based Criterion for PCBs in Gowanus Canal Surface Sediments

Introduction

The Superfund Proposed Plan (SPP) for the Gowanus Canal Superfund Site includes the following Remedial Action Objective (RAO) related to PCBs in sediments:

> "Reduce the risks to benthic organisms in the canal from direct contact with PAHs, PCBs and metals in the sediments by reducing sediment toxicity to levels that are comparable to reference conditions in Gowanus Bay and Upper New York Bay."

PCBs are included in this RAO because the Ecological Risk Assessment (ERA) suggests that PCBs in Gowanus Canal surface sediments may contribute to adverse effects on the benthic community. This suggestion is based on a comparison of the concentrations of PCBs in Gowanus Canal surface sediment samples to screening values reported in the scientific literature.

The ERA indicates that the levels of PCBs in the Gowanus Canal surface sediments were evaluated by comparing the total PCB concentrations measured in samples of those sediments to two sets of screening criteria. In the first (screening-level) comparison, total PCB concentrations determined by congener analysis (total PCB congeners) were compared to a criterion of 0.0598 mg/kg attributed to MacDonald et al. (2000).[1] The criteria provided in MacDonald et al. (2000) were developed for freshwater ecosystems, not for estuarine waterways such as the Gowanus Canal, and are not specific to either Aroclor or congener data. The concentrations of each of four individual Aroclors and total PCBs determined by Aroclor analysis were compared to a criterion of 0.0227 mg/kg established by the New York State

[1] The criterion applied to the total PCB congener data is listed in Table 3-5 of the ERA as 59800 ng/kg (which is equivalent to 0.0598 mg/kg) and that table lists "MacDonald et al. (2000)" as the source of this criterion. The ERA reference list does not include an entry that corresponds to MacDonald et al. (2000). The source publication for the 59800 ng/kg criterion is listed as MacDonald, Ingersoll, and Berger (2000) in the reference section of this appendix.

Department of Environmental Conservation (NYSDEC) for total PCBs.[2] Table 3-2 of the ERA indicates that these initial screening-level criteria for both congeners and Aroclors were exceeded by the total PCB concentrations in the Gowanus Canal surface sediment samples, and section 4.1.1 of the ERA (page 4-1) indicates that PCB congeners and three PCB Aroclors were identified as chemicals of potential concern (COPCs) on the basis of this screening-level comparison.

According to section 5.2.1 of the ERA (pages 5-6 and 5-7), the PCB concentrations in the Gowanus Canal surface sediments were evaluated further by a two-step process. The first step involved calculating and comparing the 95% upper confidence limits for the mean concentrations to the screening-level criteria (0.0598 mg/kg for total PCB congeners and 0.0227 mg/kg for total PCBs by Aroclor analysis). Chemicals that were identified as chemicals of concern (COCs) by this step are identified in ERA Table 5-5, which lists four PCB Aroclors, total PCBs, and total PCB congeners as COCs. These COCs were evaluated further by comparing the reported concentrations to less conservative baseline criteria, which are listed in Table 5-6 of the ERA (0.676 mg/kg for total PCB congeners and 0.180 mg/kg for total PCBs by Aroclor analysis). Based on this comparison, the ERA includes PCBs in the following statement (page 6-5) "Chemical analysis indicates the presence of organic chemicals (primarily PAHs and PCBs) and metals in sediment at concentrations that are likely to be causing the adverse effects observed in the sediment bioassays."[3]

Because none of the screening values for PCBs used in the ERA account for site-specific conditions, PCB concentrations that exceed those screening values do not establish that the levels of PCBs in the Gowanus Canal sediments are toxic to benthic invertebrates. The purpose of this paper is therefore to develop a site-specific risk-based criterion that can be used to make such a determination.

The site-specific risk-based criterion derived in this appendix is applicable to total PCB concentration data generated by either congener analysis or Aroclor analysis. Congener and Aroclor analyses are different ways of measuring the levels of the same chemical compounds (i.e., the 209 PCB congeners). Differences in total PCB concentrations determined by these

---

[2] The criterion applied to the PCB Aroclor data and attributed to NYSDEC (1999) in Table 3-5 of the ERA corresponds to the ER-L ("Effects Range – Low") value for marine and estuarine sediments published in Long et al. (1995).

[3] Note, however, that Table 7 of the SPP indicates that USEPA considers the screening-level criterion of 0.0598 mg/kg for total PCB congeners to be the critical criterion for protection of the benthic community. As indicated earlier, this criterion was developed for protection of freshwater ecosystems.

methods reflect uncertainty (imprecision) in the analytical measurements. The site-specific risk-based criterion is based on the organic carbon content of the Gowanus Canal surface sediments and the PCB composition of those sediments as determined by the distribution of congener homologues, and it can therefore be used to evaluate data generated by either congener or Aroclor analysis.

Basis for the site-specific risk-based criterion for PCBs

The site-specific risk-based criterion for evaluating potential PCB risks to the benthic invertebrate community in the Gowanus Canal is based on analysis described by Fuchsman et al. (2006). These authors identified and reviewed the types of evidence that can be used to characterize cause-effect, concentration-response relationships between PCB concentrations in sediment and effects on benthic invertebrates. The three lines of evidence used to derive the site-specific risk-based criterion for the Gowanus Canal involve application of the equilibrium partitioning method, spiked sediment toxicity test results, and biological data from contaminated sediment sites where PCBs are the primary chemicals of interest.

Equilibrium partitioning

The equilibrium partitioning analysis described by Fuchsman et al. (2006) involved (1) characterizing aquatic (water-only) toxicity of PCBs based on data from extensive controlled experiments, (2) characterizing partitioning of PCBs between sediment particles and pore water, and (3) identifying sediment concentrations that would correspond to safe concentrations of PCBs in sediment pore water. A number of publications have demonstrated that pore water concentrations of hydrophobic organic compounds provide substantially better predictions of sediment toxicity than bulk sediment concentrations (USEPA 2003, Di Toro et al. 1991, Kraaij et al. 2003, McDonough et al. 2010). Fuchsman et al. (2006) proposed alternative sediment quality benchmarks based on this approach. These benchmarks range from 210 to 5,300 micrograms of PCBs per gram organic carbon (µg/gOC), depending on the composition of the PCB mixture, with more highly chlorinated mixtures being less bioavailable and having higher sediment benchmarks. The range of the benchmark values corresponds to PCB concentration ranges of 2.1 to 53 mg/kg dry weight for sediment containing 1% organic carbon, and 12.6 to 318 mg/kg dry weight for sediment containing 6% organic carbon. According to Table 3-1 of the draft Remedial Investigation (RI) Report, the average total organic carbon content of the Gowanus Canal surface sediments is 6.4%.

Spiked sediment toxicity tests

Spiked sediment toxicity tests are controlled experiments that provide direct measurements of chemical toxicity in sediment. Such studies provide valuable cause-effect data, although toxicity thresholds may be unrealistically low (overly conservative) due to slow sorption processes, especially if the study design does not incorporate a stabilization period to allow chemical partitioning to approach equilibrium. Of nine spiked sediment studies with PCBs, most showed no adverse effects at any test concentration, with no-effect concentrations ranging from 81 to 2,560 µg/gOC for PCB mixtures and up to 50,000 µg/gOC for individual PCB congeners. These concentrations correspond to PCB concentrations ranging from 0.81 to 25.6 mg/kg dry weight assuming 1% organic carbon, or from 4.9 to 154 mg/kg dry weight assuming 6% organic carbon. Toxicity was only observed in certain studies that did not incorporate a sediment equilibration period. The lowest PCB concentration associated with toxicity was from DiPinto et al. (1993), who observed reduced copepod reproduction at 100 µg/gOC; this result was not reproducible in a duplicate experiment, however, and the study did not incorporate an equilibration period. The available results of spiked sediment toxicity tests with PCBs are thus generally consistent with the equilibrium partitioning benchmarks described above.

Biological data from contaminated sediment sites

Fuchsman et al. (2006) also reviewed sediment toxicity test and benthic invertebrate community studies for eight contaminated sediment sites where PCBs were the major contaminants of concern. This review provided a "reality check" for the equilibrium partitioning evaluation developed in that paper, and for published sediment screening values. The results were generally consistent with the equilibrium partitioning benchmarks for PCBs and inconsistent with the various sediment screening values used in the Gowanus Canal ERA. Specifically, no-effect concentrations for benthic invertebrates at "PCB sites" generally ranged from 70 to 1,000 µg/gOC, with a lack of toxicity observed at even higher PCB concentrations at one site contaminated with unusually highly chlorinated PCBs. These concentrations correspond to PCB concentrations ranging from 0.70 to 10 mg/kg dry weight assuming 1% organic carbon. By comparison, Table 7 of the SPP indicates that the critical criterion for protection of the benthic community in the Gowanus Canal is 0.0598 mg/kg for total PCBs. Thus, even assuming an organic carbon content that is much lower than the average for surface sediments in the Gowanus Canal, the concentrations associated with no toxicity at PCB sites are more than an order of magnitude higher than the screening criterion considered critical by USEPA.

Derivation of the site-specific risk-based criterion for PCBs

The equilibrium partitioning approach (DiToro et al. 1991) uses the sediment-specific mass fraction of organic carbon content (f_{oc}) and the chemical-specific partitioning coefficient between water and organic carbon (K_{oc}) to calculate equilibrium-partitioning sediment-quality benchmarks (ESBs) from water quality values (WQVs) as follows:

$$\text{ESB (mg/kg)} = \text{WQV (mg/L)} \times K_{oc}\text{ (L/kgOC)} \times f_{oc}\text{ (kgOC/kg sediment)}$$

Dividing both sides of this equation by f_{oc} expresses the ESB in units of milligrams per kilogram organic carbon (mg/kgOC), which are equivalent to micrograms per gram organic carbon (µg/gOC):

$$\text{ESB (µg/gOC)} = \text{ESB (mg/kgOC)} = \text{WQV (mg/L)} \times K_{oc}\text{ (L/kgOC)}$$

Fuchsman et al. (2006) developed a water quality value for total PCBs of 0.54 µg/L (equal to 0.00054 mg/L) using USEPA methodology for developing chronic aquatic life water quality criteria. This water quality value is based on acute (i.e., short term) aquatic toxicity data for 21 invertebrate species and acute-to-chronic ratios (to estimate long-term toxicity thresholds) for 3 invertebrate species. These data represented a comprehensive literature review for Aroclor 1254 toxicity to aquatic and benthic invertebrates (Fuchsman et al. 2006). The invertebrate water quality value is higher than USEPA's ambient water quality criterion of 0.014 µg/L because the USEPA criterion is calculated from a fish tissue PCB concentration for the protection of wildlife, whereas the invertebrate water quality value is based on aquatic toxicity data (USEPA 1980).

The K_{oc} value for total PCBs in Gowanus Canal surface sediments depends on the site-specific composition of PCB mixtures in the sediments. Fuchsman et al. (2006) provide a methodology to estimate the total PCB K_{oc} value based on the distribution of PCB concentrations among different levels of chlorination (homologues). The K_{oc} value for each homologue is assumed to be approximately equal to the octanol-water partition coefficient (K_{ow}); for reasons explained by Fuchsman et al. (2006), this is generally a conservative assumption.[4] The K_{ow} value for the PCB mixture can be calculated based on the distribution of PCB concentrations among different levels of chlorination (homologues) as follows:

[4] A more conservative approach to estimating K_{oc} will result in a lower site-specific risk-based criterion.

$$K_{ow-\text{Total PCB}} = \frac{1}{\sum_{n=1}^{i} \frac{f_{\text{homologue i}}}{K_{ow-\text{homologue i}}}}$$

where $K_{ow\text{-Total PCB}}$ represents the overall K_{ow} for the PCB mixture, $f_{\text{homologue i}}$ represents the fraction of PCB mixture consisting of homologue *i*, and $K_{ow\text{-homologue i}}$ is the K_{ow} for homologue *i*.

The derivation of the site-specific risk-based criterion for PCBs from the relative proportion of the total PCB concentration represented by each PCB homologue in Gowanus Canal surface sediment (as identified in the RI Report, Table I-5A) is shown in Table 1. The PCB composition of Gowanus Canal surface sediments results in a site-specific sediment ESB of 641 µg/gOC. This site-specific benchmark lies near the high end of the range of default benchmarks developed by Fuchsman et al. (2006) because the PCBs in Gowanus Canal surface sediments are relatively highly chlorinated. Based on an average total organic carbon concentration of 6.4% in the Gowanus Canal surface sediments, the site-specific risk-based criterion for PCBs in those sediments is 41 mg/kg. Because this criterion was derived from the proportion of total PCBs found in each homologue group in the Gowanus Canal surface sediments, it is applicable to total PCB concentration data generated either by congener analysis or by Aroclor analysis.

TABLE 1

Calculation of a site-specific risk-based criterion for PCB toxicity to benthic organisms in surface sediments in the Gowanus Canal

PCB homologue	average percentage of total PCBs in sediments (100 x $f_{homologue}$)	homologue $\log_{(10)} K_{ow}$	homologue K_{ow}	ratio ($f_{homologue}$ / K_{ow})

			site-specific criterion for total PCBs (mg/kg):	**41**

notes:

1. Methodology, homologue log(10) Kow values, and Water Quality Value are from Fuchsman et al. (2006)
2. The average percentage of total PCBs for each homologue is calculated from the the homologue concentrations in Table I-5A of the Remedial Investigation report
3. Total organic carbon is the average for Gowanus Canal surface sediments as reported in Table 3-1 of the Remedial Investigation Report

Comparison of total PCB data for surface sediments to the site-specific criterion

The total PCB measurements generated by both Aroclor and congener analyses of surface sediment samples collected in the Gowanus Canal and the reference area are listed in Table 2. Values are provided for each sampling location for which a measured value is available; locations at which the only analytical results are non-detects are not shown. The values reported for locations with duplicate samples are averages of the results from each analysis. The values for total PCB congeners are the "Total PCB (Lab)" values in Table I-5A of the RI Report; for locations with duplicate samples, the "Total PCB (Lab)" values were averaged. The levels of total organic carbon (TOC) reported for each location are from Table I-7 of the RI Report.

The total PCB concentrations for each analysis are shown in mg/kg units; these values are all well below the site-specific risk-based criterion of 41 mg/kg. In fact, the maximum reported value (8.13 mg/kg total PCBs by congener analysis at station 313) is only 20% of the site-specific risk-based criterion.

A comparison can also be made to the site-specific sediment quality benchmark (ESB) of 641 µg/gOC that was used to derive the site-specific risk-based screening criterion, by normalizing the total PCB concentrations to account for the variation of TOC from one location to another. The normalized concentrations were calculated by dividing the total PCB concentrations determined by congener analysis by the TOC levels, then multiplying by 1,000 to convert to µg/gOC units, as shown in Table 2. The highest normalized concentration in the surface sediment samples collected in the Gowanus Canal and the reference area is 62.3 µg/gOC at station 315 (in the middle reach of the canal). This is an order of magnitude lower than the site-specific ESB of 641 µg/gOC.

Please respond to Benjamin Ellis

Apr 26, 2013

Mr. Christos Tsiamis
290 Broadway, 20th Floor
New York, NY 10007-1866

Dear Mr. Tsiamis,

For 20 years I have lived and worked within half a block of the Gowanus and I am writing to support the EPA's proposed plan to clean up the Gowanus Canal Superfund site. After 150 years of pollution a comprehensive plan that addresses the toxic sludge at the bottom of the canal and ongoing pollution from CSOs and upland contamination is critically important to returning this long neglected waterway to the community.

While the EPA's plan takes the critical step of calling for CSO retention for two of the Canal's worst outfalls many details will not be solidified until New York City submits their CSO Long Term Control Plan in 2015. It is critical for the EPA to stand firm on requiring retention tanks to control CSOs and to work with New York City towards the eventual goal of 100% elimination of CSOs from the Canal.

I support the EPA's commitment to dredge as much as 10 feet of contaminated sediment from the entire length of the canal, build a multi-layer cap on the bottom, and treat and dispose of this contaminated sediment offsite. I also believe that the EPA should listen to the wishes of the community in Red Hook who oppose the building of a CDF on the Red Hook waterfront to dispose of the least contaminated sediment.

Sincerely,

Mr. Benjamin Ellis

RE: Riverkeeper, Inc. Comments on Gowanus Canal Superfund Site, Brooklyn, NY (EPA ID#: NYN000206222) Proposed Remedial Action Plan.

Dear Mr. Tsiamis,

Riverkeeper, Inc. ("Riverkeeper") respectfully submits the following comments on the Proposed Remedial Action Plan ("PRAP") for the Gowanus Canal Superfund Site, Brooklyn, NY (EPA ID#: NYN000206222) which was released for comment on December 27, 2012[1].

Organizational Background and Involvement with Gowanus Cleanup

Riverkeeper is a member-supported, not-for-profit organization, dedicated to protecting the Hudson River and its tributaries, and to safeguarding the drinking water supply for New York City. Since 1966, Riverkeeper has used litigation, science, advocacy, and public education to end pollution, restore ecological health, and revitalize waterfront use and access.[2] Many of

[1] EPA press release announcing availability of Gowanus PRAP and establishing comment period, *available at:* *http://yosemite.epa.gov/opa/admpress.nsf/d10ed0d99d826b068525735900400c2a/40b44a89e9d3b36885257ae100707518!OpenDocument*

[2] For additional information on Riverkeeper's mission and work, go to www.riverkeeper.org.

Riverkeeper's members live in the communities surrounding the Canal including members of the Brooklyn Riverkeeper Action Group ("BRAG").

The Gowanus Canal, located in Brooklyn, NY is one of the most heavily contaminated water bodies in the nation. This 1.8 mile long, 100 foot wide, canal was built in the 19th century and historically was home to many industries including manufactured gas plants, cement factories, oil refineries, tanneries, and chemical plants. After nearly 150 years of use, the canal has become heavily contaminated with PCBs, heavy metals, pesticides, volatile organic compounds, sewage solids from combined sewer overflows, and polycyclic aromatic hydrocarbons ("PAHs").

Riverkeeper is an organizational member of the Gowanus Canal Superfund Community Advisory Group (CAG) and has been actively involved with the Gowanus Canal Superfund site since the Canal was nominated for inclusion on the National Priorities List ("NPL") in 2009. Riverkeeper supported the listing of the Canal and called upon the EPA to undertake a comprehensive cleanup to address the decades of historic contamination in the Canal, ongoing sources of pollution from properties upland of the Canal, and discharges from Combined Sewer Overflows ("CSOs") following the Canal's NPL listing proposal.[3]

In addition to Riverkeeper's involvement with the CAG our Water Quality testing program conducts regular sampling of the Gowanus Canal[4] and our Gowanus Canal Pollution Enforcement Initiative has worked with the New York State Department of Environmental

Conservation as well as other federal, state, and local agencies to bring environmental law breakers to justice.[5]

Comments on Gowanus Canal Proposed Remedial Action Plan

Riverkeeper supports the PRAP issued by the EPA for the Gowanus Canal Superfund site and commends the Agency for putting forth a comprehensive plan to address multiple sources of legacy and ongoing pollution. The PRAP addresses the many decades' worth of toxic sludge at the Canal's bottom, ongoing pollution from upland sites, and toxic discharges from CSOs. Also critically important to the success of the cleanup is ongoing coordination with the New York State supervised cleanups of the Fulton, Citizen's, and Metropolitan Manufactured Gas Plant ("MGP") sites and other contaminated properties along the canal, coordination with the United States Army Corps on shoreline and bulkhead restoration post cleanup, and Citywide CSO control efforts under the Clean Water Act and the 2012 CSO administrative consent order ("CSO Order") between New York City and the New York State Department of Environmental Conservation ("DEC").

While the EPA's plan takes the critical step of calling for CSO retention for two of the Canal's worst outfalls, many details will not be solidified until the design phase of the Superfund Cleanup and when New York City submits their CSO Long Term Control Plan ("LTCP") in 2015.[6] It is critical for the EPA, New York State, and New York City to work together towards the eventual goal of 100% elimination of CSOs from the Canal and for the EPA to require

[5] http://www.riverkeeper.org/news-events/news/stop-polluters/pollution-enforcement/victory-in-gowanus-canal/
[6] Gowanus Canal Proposed Remedial Action Plan (herein after "PRAP") at 19-20.

sufficient interim CSO control measures to protect the Superfund Remedy once construction begins if prior to implementation of the LTCP.

Since the EPA proposed the Canal for listing on the NPL in 2009 Riverkeeper has been gratified by the Agency's extraordinary level of engagement with the community. Over the course of the past four years the staff of EPA Region 2 has gone to great lengths to work with and educate the community on the Superfund process, while responding to community concerns and desire for a comprehensive cleanup that fully addresses not only legacy contamination, but ongoing discharges from CSOs. The comprehensive nature of the remediation plan set forth in the PRAP reflects this level of engagement. Riverkeeper is also gratified to see the Agency adhere to the timeline for conducting the RI/FS and issuance of a PRAP that was promised to the community when the Canal was added to the NPL in 2010. Riverkeeper looks forward to continuing to work closely with the Agency and other members of the Gowanus CAG during the upcoming Remedial Design and the implementation of the Remedy.

The PRAP addresses contamination of the bottom of the Canal, ongoing contamination from upland sources of pollution, and discusses disposal options for the dredged material. Riverkeeper's comments on each element of the PRAP follow.

1. Remediation of Historic contamination within the Canal

During ongoing patrols of the Gowanus Canal conducted between 2009 and 2012 Riverkeeper staff has documented the extent of ongoing and historic pollution of the canal. Aerial patrols have revealed oil sheens near the canal's head, floating debris, and patches of floating coal tar wastes. Boat patrols have confirmed that the water in the canal is often a toxic cocktail of sewage, coal tar waste, and other pollutants. Furthermore boat patrols have yielded

evidence of collapsing bulkheads, ongoing dumping of waste and debris, and the continued leaching of pollutants from sediments and the canal's bulkheads.

Through the studies conducted as part of the RI/FS the EPA has confirmed high levels of toxic contamination permeating the length and depth of the Canal from historic and ongoing sources of pollution. The FS presented seven alternatives for remediation of the sediment and fully analyzed the Agency's two preferred alternatives, both of which require the dredging of the entire soft layer of sediment in the bottom of the Canal and the construction of a multi-layered and armored cap.[7]

The PRAP proposes the use of Alternative 7 for the Upper and Middle sections of the Canal (labeled as Remediation Target Areas ("RTA") 1 and 2[8]). This alternative involves dredging of the soft sediment column, targeted use of in-situ stabilization ("ISS") of native sediment in areas with potential for upward nonaqueous phase liquid ("NAPL") migration, and construction of a cap with treatment, isolation and armor layers. The EPA is proposing Alternative 5 (dredge entire soft sediment column and cap with treatment, isolation and armor layers) for the Lower Reach of the Canal (RTA 3).[9]

Given the extent and pervasive nature of the contamination in the bottom of the Canal, Riverkeeper supports the EPA's determination to dredge the entire layer of accumulated "soft sediments" which have built up to as much as 10 feet thick on top of the native sediments that formed the original Gowanus Creek. PAHs, metals and PCBs are only found in the soft sediment at concentrations that pose a threat to human health and the environment.[10] In addition

[7] PRAP at 18.
[8] *Id.* at 30.
[9] *Id.*
[10] *Id.* at 31.

given that the NAPL contamination extends into the native sediment to a depth of 100 feet in certain areas the total remediation of the historic NAPL contamination is not technically feasible.

The PRAP will remove the pervasive and highly contaminated soft sediment layer and will prevent future NAPL recontamination through the use of stabilization agents and a multilayer armored cap. In conjunction with long term monitoring to ensure that the integrity of the cap is maintained and the permanent measures to protect the remedy from recontamination from upland sources and CSOs (as discussed below), the Remedy proposed by the EPA in the PRAP will be effective in meeting the goals of remediating the 150 years of historic and ongoing contamination in the Canal and returning this long neglected waterway to the community.

2. Control of Upland sources of pollution

The long term success of the Remedy set forth in the PRAP is closely tied with efforts to halt ongoing sources of contamination that have the potential to recontaminate the Canal. The RI/FS found that the greatest sources of ongoing contamination are the three former Manufactured Gas Plant ("MGP") sites, toxic discharges from CSOs, leaching of contamination from other properties along the Canal, and unpermitted discharge pipes.[11]

a. Remediation of the Manufactured Gas Plant Sites

Riverkeeper has been encouraged by the efforts that the DEC and National Grid have made to coordinate the remediation schedules and work at the three MGP sites with the Superfund cleanup. Many details are still in development regarding interim pollution control measures and the long term cleanup of these sites so it is crucial for the EPA to take the lead on continued coordination between the federal and state cleanups as Remedial Design progresses. The EPA must also reserve all rights to add the MGP cleanups under the umbrella of the

[11] *Id.* at 19.

Superfund cleanup if progress on these sites begins to lag behind what is needed to achieve the full timely implementation of the Superfund Remedy.

b. Combined Sewer Overflows

Riverkeeper along with our partners such as the Natural Resources Defense Council and the SWIM Coalition have been involved for many years in citywide efforts to ensure that New York City lives up to the requirements of the Clean Water Act and takes critical measures to reduce the more than 30 billion gallons per year of sewage that overflows into waterways that surround the City. Riverkeeper supports to 2012 CSO administrative consent order ("CSO Order") between New York City and DEC which mandates the development of the LTCPs as well as specific requirements for grey and green infrastructure projects.[12] Riverkeeper strongly believes that nothing in the CSO order precludes New York City from implementing additional CSO controls beyond what is mandated through the LTCP development process or in any way diminishes EPA's authority under Superfund to address toxics being discharged to the Canal and protect the long term viability of the selected Remedy.

The PRAP and Feasibility Study Report addendum present scientifically and legally sound reasoning for why it is crucial for the Superfund Remedy to include measures to reduce toxic CSO discharges from outfalls RH-034 and OH-007 (which represent 97% of overall CSO discharges into the Canal[13]). When combined with CSO reductions and infrastructure upgrades required under the CSO LTCP the overall reductions in CSOs are projected to be significant (approximately 58 – 74%).[14]

---

[12] *See*, www.riverkeeper.org/news-events/news/stop-polluters/nyc-cso-order-1203/

[13] Currently 4 CSOs contribute 95% of all discharges to the Canal. Following the infrastructure upgrades required under the Gowanus Canal Waterbody Watershed Plan OH-007 and RH-034 will account for 97% of all discharges. PRAP at 4.

[14] PRAP at 30-31

The studies conducted as part of the Remedial Investigation and Feasibility Study (RI/FS) found that wet weather CSO discharges contained VOCs, PAHs, PCBs, pesticides and metals. In addition residual sediment samples collected from the CSO pipes contained VOCs, PAHs, PCBs, pesticides and metals that could be mobilized and discharged to the canal during CSO overflow events.[15] The two outfalls identified by the EPA for the installation of control measures also contribute significantly to the sedimentation of the Canal.[16] Significant reductions in discharges from these outfalls are crucial to ensuring the integrity of the remedy.

Riverkeeper strongly supports the EPA's continued position that controlling CSOs is an essential part of the Gowanus canal cleanup. Development of the additional controls that would reduce CSOs by 58 – 74% is a significant step forward, but many details are still unknown and it is essential for the EPA to insist upon retention as the primary means of meeting the EPAs defined remedial performance goals[17] during the Remedial Design and the development of the Gowanus LTCP.

As detailed in the PRAP the Agency screened out various CSO control measures for CSOs OH-007 and RH-034 (including no action; optimization of existing trap chamber in CSO OH-007; constructing a CSO sediment trap at CSO RH-034; silt curtains and/or netting facilities, maintenance dredging; sewer cleaning and CSO storage[18]). The PRAP concluded that to ensure continued protection of the Superfund Remedy that permanent CSO sediment controls would be required to capture twice the amount of the "first flush".[19] It is estimated that this would capture 40% of the overall discharge volume and 60%-120% of the PAH load of the baseline storm event.

---

[15] PRAP at 9
[16] *Id.* at 11.
[17] *Id.* at 20.
[18] *Id.* at 19.
[19] *Id.*

Although the PRAP details the PAH load reductions that would be achieved through the capture of twice the "first flush" there are no estimates of reductions in the other contaminants contained in the discharge such as VOCs, PAHs, PCBs, pesticides and metals. Riverkeeper suggests that the EPA quantify the reductions in these additional contaminants and analyze whether additional CSO capture may be required to fully protect the remedy from discharges of these toxics.

In the PRAP that EPA has committed to work with New York City and the DEC as part of the development of the LTCP to achieve remedial goals in a cost-effective manner that is both protective of the Superfund Remedy and the Clean Water Act's requirement to meet Water Quality Standards for the waterbody's "highest attainable use." With the implementation of the Superfund Remedy it is anticipated that greater recreational and ecological uses of the Canal will be attainable beyond the current classification under the State's water quality classification system.

Riverkeeper commends the EPA for their stated commitment to require significant CSO reductions that will be protective of the Superfund Remedy while working with NYC and the DEC to integrate Remedy design and planning with the development of the LTCP.

3. Proposed Confined Disposal Facility and other disposal issues

Because of the varying levels of contamination within the sediments proposed to be dredged from the Canal, the PRAP proposes the use of several methods to treat and dispose of contaminated sediments from RTAs 1-3.

a. Proposed Red Hook CDF

One of the options that the Agency has proposed is for the least contaminated sediments from RTA 3 to be treated and disposed of utilizing a Confined Disposal Facility ("CDF") constructed in Red Hook. The EPA has stated that any proposal to utilize such a facility would be subject to acceptance by the community.[20] Although it appears that the construction of a CDF would be technically feasible and likely protective of the environment the EPA has not presented enough detailed information on the design of any potential CDF for Riverkeeper to fully evaluate any potential impacts. In addition many members of the Red Hook community have expressed opposition to the proposed CDF and significant concern regarding potential impacts to the community.

Although there has been some support within Red Hook for the CDF, with a significant level of opposition it cannot be said that the community accepts this proposal. The EPA should not construct the CDF given the lack of community acceptance.

b. Dewatering and offsite treatment and disposal of dredge material

The PRAP proposes offsite incineration (thermal desorption) and beneficial reuse for NAPL impacted sediments from RTAs 1 and 2 and offsite stabilization and beneficial reuse for non-NAPL impacted sediments from RTA 1 and 3 (if no CDF is constructed).[21] For all options dredge material would need to be dewatered prior to disposal.

EPA staff has stated during public meetings that the details of any required dredge material dewatering will be addressed during Remedial Design. Riverkeeper looks forward to engaging with EPA staff during the Remedial Design to further define how this will be

[20] PRAP at 30.
[21] *Id.*

accomplished in a way that achieves design goals while minimizing community impact, and addressing community concerns.

Conclusion

As set forth in the comments above Riverkeeper supports that EPA's plan to remediate the historic contamination in the Canal's sediments, and proposed measures to halt ongoing pollution from upland sources, and significantly reduce toxic CSO overflows.

Riverkeeper appreciates this opportunity to submit comments. If I may provide any clarification regarding the above, or additional information, please contact me at jverleun@riverkeeper.org or 914-478-4501 x 247.

Respectfully Submitted,

IU_Letter_to_EPA_April_26 - Copy.doc

Fifth Avenue Committee
Our Community. Our Future.

April 26, 2013

Christos Tsiamis, Project Manager
U.S. Environmental Protection Agency
290 Broadway, 20th floor
New York, NY 10007-1866

Dear Mr. Tsiamis,

I am the Director of Organizing and Advocacy at the Fifth Avenue Committee (FAC) and I am writing today in my capacity as a tenant advocate who works with Latino residents from all over South Brooklyn who have their own group called Inquilinos Unidos (IU), which translates in English to Tenant's United. IU are primarily Spanish speakers and longtime renters in the Gowanus / Park Slope neighborhoods and they work with FAC in organizing to strengthen tenant protections and Rent Stabilization laws.

IU holds monthly meetings at our FAC offices and recently we held a workshop on the Gowanus Canal cleanup. Most of the membership had previously not been aware of the proposed cleanup plan or even that the levels of toxicity in the canal posed serious health risks. After the discussion on the cleanup, IU requested that FAC send a letter on behalf of their membership expressing their deepest support for the cleanup.

FAC would like to remind the EPA of the large Latino population that lives in the Gowanus area and that many, like IU's membership, do not speak English. Despite FAC's efforts, we strongly believe that due to language barrier constraints the Hispanic and Latino populations in the area remain mostly uninformed and uninvolved in this cleanup process.

IU and FAC would like to see the EPA ensure that the residents and businesses that will be directly impacted by these cleanups have equal opportunity and access to information about the Superfund public processes happening locally and the opportunity to participate in the planning discussions and meetings involving the future of our neighborhood. Along these lines, we would like to see more direct outreach and engagement done to promote diversity, inclusion and participation amongst our communities as the clean-up moves to the design and implementation phases.

We also encourage the EPA to maximize benefits for the local low and moderate income residents, especially for local individuals facing barriers to employment., so that they can benefit from the nearly $500 million investment in cleaning up our Gowanus Canal.

Sincerely,

Jackie Del Valle

Director of Organizing and Advocacy

Support for Gowanus Canal PRAP
CYNOCK to: Region2 GowanusCanalComments 04/26/2013 10:44 PM

History: This message has been forwarded.

I support the proposed plan for the long-overdue cleanup of the Gowanus. The people in the nearby neighborhoods deserve no less. Furthermore, all of us in Brooklyn, not just in the nearby neighborhoods, will benefit from being able to walk through that area and enjoy the waterway without being nauseated by its current aromatic and unsafe condition.

The plan will provide significant cleanup and help to protect against re-contamination. I am grateful to EPA for preparing the proposed plan, and for standing firm against New York City's regrettable efforts to weaken the cleanup.

Cynthia Nockold

Re: Gowanus Canal Superfund Proposed Plan
Response to EPA Region 2 Proposed Remedial Action Plan (PRAP)

Dear Christos:

Thank you and the entire Region 2 Gowanus Canal Superfund Team for the opportunity to comment on the Proposed Remedial Action Plan (PRAP) for the Canal Cleanup.

As you know, the Gowanus Green team has been designated by the New York City Department of Housing Preservation and Development (HPD) to re-develop the Public Place site once National Grid, under NYS Department of Environmental Conservation's (DEC) oversight, has completed the remediation of the former Manufactured Gas Plant (MGP) site. Gowanus Green is an affordable, mixed income, mixed use development whose design includes public open space, and over 770 units of housing, 70% of which will be subsidized and affordable to families at a range of incomes. Our team has extensive experience redeveloping brownfield sites to the highest sustainability standards while also creating much needed affordable and mixed income housing.

The Gowanus Green team appreciates the time that you and members of the US EPA Region 2 team have spent with us discussing the proposed remedial action plan (PRAP) and how it may impact on the design of our project. It is clear from our discussions that EPA's detailed oversight of the Gowanus Canal cleanup and review of plans for the remediation of the former MGP sites which are contributing to the contamination of the Canal has resulted in a more thorough draft remedy for the former Citizens site, in particular. Our team is hopeful that the final remedy for the Citizens site will be meaningfully improved as a result, leading to a significantly less contaminated parcel that is ultimately to everyone's – the community, National Grid and Gowanus Green's - benefit.

As the Record of Decision (ROD) is finalized and plans move into design, Gowanus Green would like to be substantively involved in discussions with US EPA and NYS DEC about the designs for the Public Place/former Citizens MGP site. Specifically, we'd like to discuss excavation depths, barrier materials, barrier wall and its final location and the location of tie backs for the barrier wall, location of collection wells and any other facility or access connected to the remediation which might ultimately be located on the current

GOWANUS green

The Bluestone Organization
Fifth Avenue Committee
The Hudson Companies
Jonathan Rose Companies

Public Place site. We look forward to working closely with all the stakeholders involved to coordinate Gowanus Green's design and construction.

Finally, Gowanus Green continues to be concerned about additional delays. Though the EPA has kept to its word on the timing of the Remedial Investigation and PRAP, NYS DEC has not been as diligent and ultimately their delays will impact the entire Gowanus Canal cleanup timetable. We respectfully request that EPA consider a Gowanus Canal cleanup timetable that accelerates the design and remediation of the MGP sites. Ultimately, the Gowanus Green team would like the EPA to utilize its authority to advance the most coordinated and timely cleanup of the Gowanus Canal possible.

Our proposal for the Public Place site will provide much needed affordable housing and public open space long sought by the adjacent community. We submit these comments on the PRAP with a strong desire to advance the remediation of the Public Place site and the Canal and its environs which has long been awaited by this community.

Thank you for the opportunity to comment on the PRAP. We look forward to continued work with the EPA as the Canal cleanup moves forward.

RE: Gowanus Canal Superfund Operations in Red Hook, Brooklyn

Dear Mr. Tsiamis,

Brooklyn's waterfront development historically favored industrial interests over those of the community. In fact, the Gowanus Canal has been an industrial waterway since the Dutch. The toxic waste characterizing it and the failed attempts to take corrective action reflect a lack of concerted community involvement together with an appreciation for the benefits of industry. After all, the Gowanus has been a source of employment for nearly 150 years.

Today, we promote recreation on waterfront that had been the exclusive preserve of industry along with the benefits of recycling. The Gowanus Bay Terminal's Red Hook Option's novel approach combines state-of-the-art hazardous waste recycling with Brooklyn's own prestigious heritage of concrete production. The execution of this alternative will be under intense scrutiny by federal, state and local government enhanced by an actively engaged neighborhood. It's difficult to imagine a project of this magnitude with more attention paid to it.

Brooklyn's tradition of concrete innovation goes back to the Gilded Age and the Coignet Stone Company with offices - not coincidentally - in Gowanus. Quadrozzi Concrete continues this tradition with the building of prominent New York City skyscrapers. That Quadrozzi's high-strength concrete is used to construct the Freedom Tower is a source of pride for many.

Rather than dismiss the Red Hook Option and the role of Quadrozzi Concrete outright, Brooklynites would do well to take an active role in collaborating with all parties for the sake of our community. This is an unprecedented opportunity for Brooklynites to positively influence the development of our waterfront.

Sincerely,

Dom Gervasi, Owner & Producer

Attn: Christos Tsiamis

I fully support and encourage this dredging operation of the Gowanus Canal and use of the Gowanus Bay Terminal in the Red Hook Option for dewatering and construction of a CDF.

As a marine operator of a tug boat company for nearly a decade, I have see a lot of things change. Mainly and sadly, the deterioration of what were operable maritime facilities and/or transition of them to residential development. As a result, it is becoming more and more difficult to find industrial waterfront property to operate a maritime business like ours.

My tug boats have moved several hundred thousand tons of rock salt by barge into GBX under contract for International Salt Company. Because I'm in and out of marine terminals all the time, there was no question when first seeing this terminal reactivated, that there was enormous potential for rock salt and other maritime bulk materials. Wide open land for bulk materials is at a premium in the bulk industry.

Cleanup of the Gowanus Canal would help make the marine environment cleaner and expansion of GBX would make a more viable industrial waterfront that which we need so desperately to maintain a working waterfront infrastructure for the city overall.

Very respectfully yours,

Michael Vinik

Re: Gowanus Canal Superfund, Red Hook Option

Sirs,

We are writing to support the EPA Red Hook Option.

We are a scrap metal processing company that occupies space at Gowanus Bay Terminal. The Terminal provides our business with an ideal place to operate. It is logistically advantageous to reach our market, is easy to access with clear and wide truck routes directly off the BQE, Battery Tunnel and Hamilton Avenue, is secure from outside elements and is managed in an organized, clean and safe manner working in concert with the local community.

We are also planning an expansion of our own at the Terminal, and plan to utilize their docks and waterborne commerce to reach our end users.

It is critical that facilities like Gowanus Bay Terminal are encouraged to grow to ensure small businesses like ours have a proper and viable place to exist.

Please approve this important plan for the better of Red Hook and Brooklyn overall.

Regards,

Tom Petrosino

Benson Metals

I support the Red Hook Option of the EPA Gowanus Canal Superfund cleanup.

The improvement to an active local maritime industrial business, the economic benefits it will bring, the jobs that it will create, are all important to me and what I believe is best for the majority of the community of Red Hook.

Further, I am confident that any necessary safeguards will be incorporated into the work, monitored and maintained, to ensure the workers and the community are without harm or risk of such.

Please approve the Red Hook option.

The improvement to an active local maritime industrial business, the economic benefits it will bring, the jobs that it will create, are all important to me and what I believe is best for the majority of the community of Red Hook.

Further, I am confident that any necessary safeguards will be incorporated into the work, monitored and maintained, to ensure the workers and the community are without harm or risk of such.

Please approve the Red Hook option.

IMPORTANT- MUST BE SUBMITTED BEFORE *APRIL 26th, 2013* *DEADLINE!*

Rec'd 4/29/13

I support the Red Hook Option of the EPA Gowanus Canal Superfund cleanup.

The improvement to an active local maritime industrial business, the economic benefits it will bring, the jobs that it will create, are all important to me and what I believe is best for the majority of the community of Red Hook.

Further, I am confident that any necessary safeguards will be incorporated into the work, monitored and maintained, to ensure the workers and the community are without harm or risk of such.

Please approve the Red Hook option.

Comments on Gowanus Canal Proposed Plan

Margaret Maugenest to: Region2 GowanusCanalComments 04/27/2013 12:16 AM

Sent by: **Riverkeeper <info@Riverkeeper.org>**

Please respond to Margaret Maugenest

History: This message has been forwarded.

Apr 26, 2013

Mr. Christos Tsiamis
290 Broadway, 20th Floor
New York, NY 10007-1866

Dear Mr. Tsiamis,

I am writing in full support of your proposed plan to clean up the Gowanus Canal.

I have lived along the canal since 1984 in an artists in residence building. Superfund designation is the best things that has happened to our neighborhood. I also live a block away from the De Graw pool where you might place a retention pool. I understand that some voices and forces in my community are saying that they do not want to see that happen - but please bear in mind that these voices are coming from ignorance or hidden agendas. I swam in that pool also once, long ago - until the tenants in my building ordered an environmental report from Toxic Targeting and we found out about the migrating coal tar plume from the former coal gasification plant that had been at the site where the pool is now. I have not been back to the pool since, nor should anyone in their right mind. All this hoopla about trying to save the pool is manipulation. If people were really informed about the facts, they would not argue against the retention pool.

And they would not be arguing for keeping the swimming pool.

I am presenting my support as a Gowanus resident. I have no opinion about the EPA's plan for Red Hook except that I hope the EPA will listen to the community there.

Thank you for giving us hope, and for all you have done for us.

I am a co-founder of FROGG and also a CAG member.

Sincerely,

Ms. Margaret Maugenest
280 Nevins St
Brooklyn, NY 11217-3028

Comments on Gowanus Canal Proposed Plan

daniel cohen to: Region2 GowanusCanalComments 04/27/2013 12:16 AM

Sent by: **Riverkeeper <info@Riverkeeper.org>**

Please respond to daniel cohen

Apr 26, 2013

Mr. Christos Tsiamis
290 Broadway, 20th Floor
New York, NY 10007-1866

Dear Mr. Tsiamis,

I am writing to support the EPA's proposed plan to clean up the Gowanus Canal Superfund site. After 150 years of pollution a comprehensive plan that addresses the toxic sludge at the bottom of the canal and ongoing pollution from CSOs and upland contamination is critically important to returning this long neglected waterway to the community.

While the EPA's plan takes the critical step of calling for CSO retention for two of the Canal's worst outfalls many details will not be solidified until New York City submits their CSO Long Term Control Plan in 2015. It is critical for the EPA to stand firm on requiring retention tanks to control CSOs and to work with New York City towards the eventual goal of 100% elimination of CSOs from the Canal.

I support the EPA's commitment to dredge as much as 10 feet of contaminated sediment from the entire length of the canal, build a multi-layer cap on the bottom, and treat and dispose of this contaminated sediment offsite. I also believe that the EPA should listen to the wishes of the community in Red Hook who oppose the building of a CDF on the Red Hook waterfront to dispose of the least contaminated sediment.

Sincerely,

Dr. daniel cohen
20983 18th Ave
Bayside, NY 11360-1444

I, the sender, vote that I do not want this project to proceed.

Joy Ferguson to: Region2 GowanusCanalComments 04/27/2013 08:12 AM

As (one of the options above) of the community of Red Hook, I/We am/are strongly opposed to the processing of contaminated sludge dredged from the Gowanus Canal Superfund Cleanup Site at a facility at the proposed location. The cost savings are negligible, and the Red Hook Ball Fields and Pool are used in public trust. The community does not want to create more land from this contaminated sludge adjacent to one of the most heavily used recreation areas in New York City. People and organizations adversely affected include (but are not limited to!):

- Children
- Numerous public and private schools which use the fields for physical education & sports teams
- Residents of the Red Hook Houses and the surrounding neighborhood
- Soccer, softball, baseball, football, handball, basketball, track & field teams and enthusiasts
- Swimmers of all ages
- The Red Hook Food vendors and their customers
- Other visitors to our community

Further, we object to an individual (John Quadrozzi), who has incurred serious fines for environmental violations, from profiting from the project.

Comments regarding EPA with regard to clean up and Douglass Greene Park

LBlyer to: Region2 GowanusCanalComments 04/27/2013 12:58 PM
Cc: Sabine13

Please consider the three main comments outlined by the letter from Friends of Douglass Greene Park in a letter they submitted which 3 areas of focus (below) as you move forward in cleaning up the canal and surrounding areas:

□

* Incorporating the entire upland area of the former Fulton MGP site within the EPA Superfund cleanup.
* Conducting a thorough review of the Remedial Investigation results at the former Fulton MGP site and addressing new potential exposure pathways with a human health risk assessment.
* Providing compensation and guarantees for the potential loss or disruption of the Double D Pool.

Thanks
Linda Blyer
Cobble Hill

Comments on Gowanus Canal Proposed Plan

Lizzie Olesker to: Region2 GowanusCanalComments 04/27/2013 01:07 PM

Sent by: **Riverkeeper <info@Riverkeeper.org>**

Please respond to Lizzie Olesker

Apr 27, 2013

Mr. Christos Tsiamis
290 Broadway, 20th Floor
New York, NY 10007-1866

Dear Mr. Tsiamis,

I am a Gowanus homeowner, residing with my family on First Street, one block from the Gowanus Canal. I have spent over 15 years in this neighborhood, smelling the canal and watching its fetid, oil slicked and sewage strewn waters lie tragically unaddressed. My children and I have walked over the Carroll Street Bridge countless times on their way to school, wondering how our powerful city could continually ignore this highly toxic waterway. Now with the historic designation of the Gowanus Canal as a Superfund site, our community has finally been given the hope and possibility for real change concerning this environmental disaster.

I strongly support the EPA's proposed plan to clean up the Gowanus Canal Superfund site. After 150 years of pollution, we finally are being given a comprehensive plan that addresses the toxic sludge at the bottom of the canal and ongoing pollution from CSOs. The comprehensive clean up of the canal by the EPA is the only way that we might return this egregiously neglected waterway to the community, benefitting the health and well-being of all.

While the EPA's plan takes the critical step of calling for CSO retention for two of the Canal's worst outfalls many details will not be solidified until New York City submits their CSO Long Term Control Plan in 2015. It is critical for the EPA to stand firm on requiring retention tanks to control CSOs and to work with New York City towards the eventual goal of 100% elimination of CSOs from the Canal.

I support the EPA's commitment to dredge as much as 10 feet of contaminated sediment from the entire length of the canal, build a multi-layer cap on the bottom, and treat and dispose of this contaminated sediment offsite. Though I personally support the building of a CDF on the Red Hook waterfront to dispose of the least contaminated sediment as the most environmentally safe and efficient method of disposal, I also believe that the EPA should listen to the wishes of the Red Hook community itself. If the majority of those who live and work in Red Hook oppose the building of a CDF, their demands must be addressed, and an alternative disposal plan pursued.

Sincerely,

Ms. Lizzie Olesker

Gowanus Canal Comment
Christie Leece to: Region2 GowanusCanalComments 04/27/2013 01:47 PM

Dear Mr. Tsiamis,

I am a resident of Brooklyn, and in recent months have attended several community meetings concerning the proposal for cleaning up the Gowanus Canal. The meetings have been very informative and your team of EPA representatives has taken great pains to explain the particulars of the site and the options for dredging and dewatering.

My concerns with the proposal are not related to the dredging or dewatering, but rather the approach to dealing with the contaminated sediment. The residents of Red Hook have spoken against the onsite CDF, and it is my understanding that this means the sediment will be moved offsite after being stabilized with Portland cement. From there, the sediment may or may not end up at the CESP in Morrisville, Pennsylvania, a co-gen plant in Pennsylvania, an unidentified treatment plant or an unidentified landfill. These treatments, based in adding cement fixers or heat-treating at best, do not seem to truly remediate the soil. What happens when the cement begins to break down? The McCormick and Baxter Superfund site plan is lauded for being designed for a hundred years, as if a hundred years is a long time.

According to myriad studies, including several conducted by the EPAthrough the Superfund Innovative Technology Evaluation Program[i] , more permanent remediation strategies to address the contaminated sediment exist that aren't being addressed in this proposal: phytoremediation and mycoremediation. Fungi have been show to break down the same PCBS and PAHs found in the Gowanus.[ii] They also have the proven ability to accumulate heavy metals in the fruiting body (mushroom caps), and can easily be harvested from the site.[iii] The metals in these mushrooms can then be extracted for new uses. Safety surrounding the treatment of this sediment is of the utmost concern, but it is important to think in the long term to avoid revisiting the Gowanus cleanup down the line. Heavy metals, once extracted with mushrooms or other bioaccumulators do not pose the risk of leaching. Mycoremediation is also significantly less environmentally taxing than heat-treating to rid the soil of PCBs and PAHs.

All of the possible plans described in the Feasibility Study relating to a CDF required extensive monitoring scheduled for years to come. Rather than monitoring a "fixed" system for errors and leaching, why not monitor a living system for remediation markers? If the EPA were to isolate a small portion of the Gowanus sediment, treat it using mycoremediation technologies, and monitor extensively for changes, this study could not only inform future superfund cleanups of this magnitude, but also serve to promote ecologically and economically effective practices. It may take more time than the standard methods to be rid of the toxins, but we would actually be remediating them, not just suspending them for a period of time.

In the course of researching the plans for the Gowanus, I have spent a good amount of

time reading through the Feasibility Study and Remedial Investigation Report. The study is heavy on charts, and while it is wonderful that a digital version of the records is available, I urge you to offer the data in CSV or XML format. Doing any analysis of the data requires parsing the PDF into a usable format, which can be time consuming and inevitably increases the likelihood of transcription errors.

Thank you for your time and consideration on this matter.

Sincerely,

Christie Leece

Volcano Partners Comments on Gowanus PRAP (Dec. 2012)

Robert Fabricant to: Region2 GowanusCanalComments 04/27/2013 01:51 PM

Mr. Tsiamis, thank you for the opportunity to submit comments regarding the USEPA Gowanus PRAP issued in December, 2012. I have attached hereto our Gowanus PRAP comments dated 4-27-2013. Also attached is a second document referenced by our comments that was submitted to USEPA as part of the Lower Passaic River Superfund site process. Please also include this document into the record for the Gowanus PRAP as it provides important information and updates regarding our Cement-Lock manufacturing technology. Do not hesitate to call if you have any questions regarding this submission. Thanks. Bob Fabricant, Volcano Partners (908) 370-8063.

Re: Comments to United States Environmental Protection Agency Regarding the Proposed Plan for the Gowanus Canal Superfund Site

Dear Mr. Tsiamis:

Volcano Partners, LLC (Volcano Partners) appreciates the opportunity to provide comments on the Superfund Proposed Plan for the Gowanus Canal Superfund Site, Kings County, New York (PRAP) published by the United States Environmental Protection Agency (USEPA), Region 2 in December 2012.

Volcano Partners supports the selection of thermal processing as a treatment/disposal option in the PRAP. However, we are now seeking a clarification of the available thermal treatment options discussed in the PRAP. Specifically, we are requesting that EPA identify high temperature thermo-chemical processing of sediments in the production of cement admixtures as an available treatment/disposal option in the Record of Decision (ROD). As discussed in more detail below, this type of thermal treatment meets the evaluation criteria of the Feasibility Study and PRAP and would be an effective and cost-competitive treatment/disposal alternative for inclusion in the ROD.

I. Volcano Partners Requests High Temperature Thermo-Chemical Processing of Sediments in the Production of Cement Admixtures as a Treatment/Disposal Option in the Record of Decision

Volcano Partners is the owner of the patented Cement-Lock• manufacturing process. Cement-Lock• uses a high temperature thermo-chemical process that effectively destroys organic contaminants in dredged sediments, including petroleum aromatic hydrocarbons (PAHs) and polychlorinated biphenyls (PCBs), and immobilizes any remaining metals in a beneficial use product, Ecomelt•, that serves a substitute for portland cement in the production of concrete. The Cement-Lock• manufacturing facility also captures waste heat from the manufacturing process to generate electricity for use by the facility and for export to the grid.

The contaminants of concern (COCs) to human and ecological health in the sediments at the Gowanus Canal Superfund Site include PAHs, volatile organic compounds (VOCs), particularly benzene, toluene, ethyl benzene and xylene (BTEX), PCBs and seven metals (barium, cadmium, copper, lead, mercury, nickel and silver). According to the PRAP, portions of the site contain concentrations of these constituents, particularly PCBs and lead, that may exceed the capabilities of thermal desorption as a suitable treatment technology. The PRAP acknowledges that treatability testing will be required to identify appropriate handling and disposal options for sediments from those portions of the site. The Cement-Lock• manufacturing process would effectively destroy, immobilize in a beneficial use product, or capture in air pollution control (APC) equipment any and all of these identified COCs without the need for additional treatability testing.

Finally, as discussed in more detail below, the use of the Cement-Lock• manufacturing process would have additional benefits when compared to other thermal treatment options reviewed by EPA in the PRAP. For example, the use of the Cement-Lock• manufacturing process would dramatically reduce the number of truck trips required by the use of technology Option A (thermal desorption). The use of Option A requires:

- Barge transport of approximately 284,000 cubic yards of dredged material to a processing facility where the sediment is amended by portland cement increasing the volume by 7.5 percent.
- Transport of the approximately 307,000 cubic yards of amended material by truck to a thermal desorption facility. Approximately 35,000 truck trips[1] will be required.
- Transport of the approximately 203,000 cubic yards of processed sediment[2] plus treatment process waste materials to a landfill(s), requiring approximately 20,000 additional truck trips.

We believe that the Cement-Lock• manufacturing process is an effective and cost-competitive treatment/disposal alternative for the Gowanus Canal Superfund Site. Therefore, we are requesting

---

[1] Assumes a 20 cubic yard-capacity truck travels to or from the destination.

[2] Thermal desorption typically reduces the volume by two-thirds plus baghouse waste. Source: J. Blanchard and Stamnes, R., 1997. *Engineering Forum Issue Paper: Thermal Desorption Implementation Issues*. United States Environmental Protection Agency Office of Emergency and Remedial Response Publication 9200.5-224FS EPA 540/F-95/031 PB95-963315 January 1997.

that USEPA identify high temperature thermo-chemical processing of sediments in the production of cement admixtures as an available treatment/disposal option in the ROD.

II. Cement-Lock• Manufacturing Technology Delivers Sustainable, Integrated Sediment Management

The Cement-Lock• manufacturing technology is a sustainable, integrated sediment management system that supports Remedial Action Objectives (RAOs) for the Gowanus Canal Superfund Site and USEPA guidance supporting the use of innovative, sustainable technology. USEPA guidance[3] urges project managers to utilize innovative technology when such technology offers the potential for comparable or superior treatment performance or implementability, fewer or lesser adverse impacts than other available approaches, or lower costs for similar levels of performance than demonstrated technologies. Additionally, in the course of manufacturing products for which there is a market demand, the Cement-Lock• process meets USEPA treatment criteria for PCBs and dioxins/furans.

Cement-Lock• is a thermo-chemical manufacturing process that produces a high quality pozzolanic material, called Ecomelt•, by using contaminated sediment as a manufacturing process feedstock. Ecomelt• can replace up to 40 percent of portland cement in concrete production. Blended cement composed of Ecomelt• and portland cement is suitable for general construction purposes at lower costs than portland cement alone.

The Cement-Lock• manufacturing process was developed by the Gas Technology Institute, Des Plains, IL, (GTI) under a contract with Brookhaven National Laboratory (BNL), funded by the federal Water Resources Development Act (WRDA) and the USEPA Region 2 Superfund program. Additional funding and project management support was provided by the New Jersey Department of Transportation, Office of Maritime Resources and the Gas Research Institute, Des Plaines, IL (GRI). A demonstration plant was constructed at the International Matex Tank Terminal, Bayonne, New Jersey. Demonstration tests conducted in 2005 through 2007 successfully produced Ecomelt• from sediment from the Lower Passaic River, New Jersey, Newtown Creek, New York and Detroit River, Michigan Superfund sites.

The Cement-Lock• manufacturing process is specifically designed to use contaminated dredged materials as a feedstock raw material for the production of Ecomelt•. After dewatering, the sediments are processed into a homogeneous "filter cake". The patented technology combines the "filter cake" with calcium, aluminum and silica additives necessary for production of a pozzolanic cementitious material. The mix is then run through a high temperature manufacturing process (a natural gas-fired slagging rotary kiln). This process produces a molten mixture that is then quenched in a water bath to create a beneficial use product, Ecomelt•.

The high temperature (2400° to 2600° F) involved in the manufacturing process to create Ecomelt• has the benefit of destroying organic contaminants present in the feedstock, achieving DRE's of 99.9999+ for

---

[3] United States Environmental Protection Agency. 2005. *Contaminated Sediment Remediation Guidance for Hazardous Waste Sites*. OSWER 9355.0-85.

compounds such as PAHs, PCBs and dioxin/furans. The thermo-chemical manufacturing process also effectively immobilizes inorganic contaminants, such as metals, in the pozzolanic matrix found in Ecomelt•. Mercury, lead and other volatilized metals are captured in the APC system, as designed by Foster Wheeler Corporation and described in detail in the attached Memorandum, dated November 30, 2011, from TetraTech EC. Ecomelt• is collected from the kiln as vitreous pellets and milled for blending with portland cement for use in concrete.

As described in detail by the 2008 WRDA final report[4], leaching tests conducted during the course of the demonstration project concluded that Ecomelt• readily passed USEPA Toxicity Characteristic Leaching Procedure (TCLP). Ecomelt• can be blended with ordinary portland cement at a 40:60 (Ecomelt• to portland cement) weight ratio.[5] This use is consistent with ASTM C595 (Standard Specification for Blended Hydraulic Cements) and confirmed by the pilot and demonstration project test results. In 2008, a batch of concrete using Ecomelt•, made from Passaic River sediments, was used for a length of sidewalk at Montclair State University, Montclair, New Jersey.[6]

Under this technology option, the dredged material would be screened, dewatered and processed at a single site located in New York-New Jersey harbor complex. Sediment would be offloaded from barges and mechanically screened for debris and oversized material. Debris would be washed and disposed in a landfill. Screened sediment would be run through hydrocyclones to remove sand for recycling. The fine material would be dewatered using membrane filter presses. Ecomelt• would be manufactured from the resulting "filter cake". Finally, the Cement-Lock• manufacturing facility captures waste heat from the manufacturing process to generate electricity for use by the facility and for export to the grid.

III. Cement-Lock• Manufacturing Technology Meets the Evaluation Criteria for Treatment/Disposal Established in the Feasibility Study and PRAP

As discussed above, the use of Cement-Lock• manufacturing technology supports the RAOs established for the Gowanus Canal Superfund Site including the protection of overall human health and the environment and the achievement of applicable or relevant and appropriate standards (ARARs). Cement-Lock• also meets the additional evaluation criteria set forth in the Feasibility Study and PRAP, including short-term effectiveness, long-term effectiveness and permanence, reduction of toxicity, mobility or volume through treatment, implementability, cost, acceptance and sustainability.

[6] Mensinger, M.,2008. *Cement-Lock® Technology for Decontominating Dredged Estuarine Sediments Topical Report on Beneficial Use of Ecomelt• from Passaic River Sediment* at Montclair State University, New Jersey. Gas Technology institute, Des Plains, IL., 2008.

A. Short-Term Effectiveness

Cement-Lock• manufacturing technology would centralize processing and treatment of the Gowanus Canal dredged material into a single location, minimizing handling and transportation, as well reducing the risk of releases. While meeting required performance specifications, this approach reduces potential impacts to the community, including the reduction of noise and levels of traffic, and dust and odors during the handling, processing and disposal of contaminated sediment. The APC equipment and monitoring instrumentation for lime injection, carbon absorption, NOx capture and stack emissions control have been demonstrated to be fully compliant with all applicable APC standards.

Specifically, the Cement-Lock• manufacturing technology can simplify the remedy and improve the short-term effectiveness of the remedy as follows:

- Because the preparation of dredged material for the Cement-Lock• manufacturing process involves sand separation as part of the dewatering process, the volume of dredged material requiring thermal treatment would be reduced by at least one-third based on the average sand content described in the Remedial Investigation. The treatment of dredged material would not require amendment by portland cement, avoiding the 7.5 percent increase in volume imposed solely to reduce moisture content for transport to the thermal desorption facility.
- The dredged material would be offloaded directly to the manufacturing facility from the barge, eliminating the repeated material handling required by the technology Option A (thermal desorption). Over 35,000 truck trips required to convey material from the processing facility to the treatment facility are eliminated, together with the associated truck traffic impacts to local highways and communities
- Truck trips between the treatment facility and the end use would be reduced because of the comparatively lower volume of material that must be transported.
- Approximately 20,000 truck trips to import portland cement to amend the dredged sediment for the transportation to the treatment facility would be eliminated.
- Because Ecomelt•, the end product of the Cement-Lock• manufacturing process, is a replacement for portland cement that would be used locally, truck trips associated with the mining, processing and transport of raw materials for cement manufacturing of an equivalent volume of Ecomelt• for local construction would be eliminated.
- The eliminated truck traffic would sharply reduce traffic impacts, noise and greenhouse gas emissions associated with the remedy.
- The reduced handing of the dredged material could reduce the volatilization of BTEX and associated risks to workers and the community.
- Process heat from the Cement-Lock• manufacturing process can be captured and used to co-generate electricity to run the facility with a balance available for export to the grid.

B. Long-term Effectiveness and Permanence

The very nature of the higher temperatures involved by the Cement-Lock• manufacturing process, as demonstrated in the WRDA Demonstration Project by the USEPA Region 2, in conjunction with BNL, can improve the long-term effectiveness and permanence of the remedy, minimizing potential exposure pathways and long-term risks. Specifically,

- The Cement-Lock• manufacturing process uses high temperatures that effectively destroy all organic constituents, including PAHs, PCBs and dioxins.
- The unvolatilized metals are immobilized within the Ecomelt• matrix. TCLP test results have demonstrated the immobility of metals in Ecomelt•.[7]
- Lead and other metals volatilized by the high temperature process would be captured by the APC system.
- The mass of contaminants transferred from Gowanus Canal to landfills would be sharply reduced. Only residual material recovered from the baghouse of the APC system, containing a small fraction of original contaminant load found in the in situ volume of dredged sediments would require landfilling. Volcano Partners is actively reviewing recycling options that would eliminate the need to landfill even this small fraction of contaminants found in APC residual.

C. Reduction of Toxicity, Mobility, or Volume Through Treatment

The ability to destroy organics and immobilize metals in the course of manufacturing marketable products from dredged material is the strength of this alternative treatment option. Specifically,

- The high temperatures involved in the manufacturing process irreversibly destroy all organic contaminants, achieving 99.9999+ percent DREs for PAHs, PCBs and dioxins;
- Metals are immobilized in the Ecomelt• pozzolanic matrix. TCLP analyses on Ecomelt• meet EPA and State standards;
- The material dredged from the Gowanus Canal would be used as a feedstock to produce Ecomelt• for use as a portland cement replacement;
- All sediment recommended to be dredged by the PRAP, regardless of COC concentrations, is acceptable feedstock for the Cement-Lock® process for manufacturing Ecomelt•; and
- Volcano Partners is actively reviewing recycling options that would eliminate the need to landfill even the small fraction of contaminants remaining in APC system residual.

D. Implementability

After the successful manufacture of Ecomelt• from Passaic River, New Jersey, Newtown Creek, New York and Detroit River, Michigan Superfund sites was demonstrated during the WRDA Demonstration Project by the USEPA Region 2, BNL and the GTI, operational enhancements were made to the feedstock

[7] Mensinger, M, 2008. *Op.cit.*

delivery and APC systems by Foster Wheeler Corporation (see attached Memorandum dated November 30, 2011, from Tetra Tech EC). Foster Wheeler specializes in the design of high temperature rotary kilns and has over nine facilities currently active in the United States, including the Aragonite, Utah facility that successfully treated dredged material from the Passaic River Phase 1 Removal Project last year.

Cement-Lock• utilizes established technology comprised of components whose efficacy and reliability has been proved by more than 20 years of operational experience. The uniqueness of the Cement-Lock• manufacturing process lies in the additives, the mixture ratios and residence times used to manufacture Ecomelt®, rather than in the thermo-chemical processing equipment. All mechanical systems are "off-the-shelf" and in widespread use worldwide. Foster Wheeler's proprietary rotary kiln designs readily scale-up to meet the removal requirements of the Gowanus Canal Superfund Site. Our engineers estimate that a full-scale manufacturing facility can be operational in 18 months after delivery of a contract guaranteeing a minimum volume of material for processing at a proposed Cement-Lock• manufacturing facility. Based on our preliminary analysis, the amount of dredged material from RTA 1 and RTA 2 (284,000 in situ cubic yards) recommended by the USEPA in the PRAP for treatment by technology Option A (thermal desorption) would be sufficient to support the development of a minimum commercial-scale Cement-Lock• manufacturing facility.

As we outlined above, all dredged material from the Gowanus Canal is suitable for the Cement-Lock• manufacturing process. Therefore, the uncertainties arising from the potential suitability of the dredged material, given the limitations of thermal desorption, are eliminated. Finally, processing and treating the dredged material in a single off-site location would reduce the impacts to the affected community resulting from implementation of the remedy.

E. Cost

The PRAP estimated approximately $365 per cubic yard for treatment and disposal using technology Option A (thermal desorption) for RTA 1 and RTA 2. However, the actual cost may be higher when the full cost to design and implement the proposed technology option and long-term costs to operate and maintain the remedy are considered. For comparison, a recent estimate of approximately $350 per in situ ton for implementation of Cement-Lock• technology for the Passaic River Superfund sediments was submitted to the USEPA (see attached Memorandum, dated November 30, 2011, from Tetra Tech EC). This cost estimate for the Passaic River sediment included material management after barge offloading at site, sand removal, dewatering, water treatment and processing by a Cement-Lock• manufacturing facility. Without providing a specific cost estimate, Volcano Partners' preliminary analysis for processing Gowanus Canal sediment confirms that the use of the Cement-Lock• manufacturing process would be cost-competitive with technology Option A (thermal desorption) based on a contract to process the minimum amount of dredged material identified in Section IIID above.

The use of the Cement-Lock• manufacturing technology reduces overall implementation and long-term costs in several ways:

- The costs for identifying and implementing alternative treatment or placement technologies for material unsuitable for thermal desorption are avoided. All organic COCs can be treated to 99.9999+ percent DREs and remaining metals would be immobilized in the end product, eliminating the need and costs to investigate and utilize additional treatment/disposal technologies for material unsuitable for thermal desorption.
- Costs for transportation from a dewatering facility to a treatment facility would be avoided as the material would be dewatered and processed at a single location. Cost for transportation from the processing facility to a landfill would be sharply reduced.
- Long-term liability costs are sharply reduced or eliminated. As the volume of material requiring placement in a landfill would not be increased by the addition of portland cement for dewatering, the long-term insurance, monitoring, bonding and other costs associated with placement in a landfill would be nearly eliminated.

F. Acceptance

The Cement-Lock• manufacturing process is recommended by the National Advisory Council for Environmental Policy and Technology (NACEPT) as a technology for environmental justice communities and other vulnerable populations.[8] Volcano Partners is committed to developing and implementing a community education and outreach program to keep communities informed and engaged.

G. Sustainability

The Cement-Lock• manufacturing process is consistent with USEPA Region 2 Clean and Green Policy that promotes a more sustainable approach to remediation. The Cement-Lock• manufacturing process is the result of the unprecedented 20-year effort by USEPA Region 2 and public and private stakeholders to identify and deploy a sustainable, green technology capable of producing a beneficial use product from contaminated dredged sediments. Specifically,

- The Cement-Lock• facility uses natural gas for the manufacturing process and waste heat for cogeneration. Coal would not be used as required by technology Option C- Cogeneration;
- Energy used in the manufacturing process would be captured through cogeneration to run the manufacturing facility and exported to the electrical grid;
- The end product of the manufacturing process would be a high quality pozzolanic material that would be beneficially used as a cement admixture to substitute with a portion of portland cement in the production of concrete for construction projects. This process virtually eliminates any need for landfilling of contaminants. Nearly the entire volume of contaminated dredged material would be used in the production of non-hazardous building materials, including sand and Ecomelt•, a pozzolanic cement admixture, for local construction use; and
- Greenhouse gas emissions would be reduced by the elimination of truck transport and by the offset of CO_2 emissions resulting from the beneficial use production of a portland cement

[8] NACEPT, *Technologies for Environmental Justice Communities and Other Vulnerable Populations*, February 15, 2012

replacement and electricity associated with the Cement-Lock• facility. For each ton of Ecomelt• produced, a Cement-Lock• facility eliminates one ton of CO_2 produced by the portland cement industry.

We look forward to working with you and your staff, and the PRPs and other stakeholders, to establish an effective and cost competitive treatment/disposal plan for the Gowanus Canal Superfund Site. We would be happy to provide any additional information you may need regarding the Cement-Lock• manufacturing process, or to meet with you or your staff to answer any questions.

Sincerely,

Al Hendricks

GENERAL NOTES:
PRELIMINARY
10/25/11
FOSTER WHEELER USA CORP.

7. Induced Draft Fan, Stack and Continuous Emission Monitoring System

The entire thermal processing and gas cleaning system operates under slight negative draft pressure provided by the induced draft fan which pulls the flue gas through the system and pushes it up the stack where the cleaned gas is vented to the atmosphere. The negative draft pressure ensures that any system leaks will allow ambient air into the system rather than allowing untreated or partially treated flue gas to escape to the atmosphere. The stack will provide adequate lift to the gases to allow for proper dispersion of the cleaned flue gas into the atmosphere. A proven CEMS will be provided to monitor the stack gases to ensure that the thermal processing and gas cleaning system are operating efficiently and within the constraints of the regulations and operating permit requirements for all pollutants.

occurs by selective non-catalytic reduction (SNCR) in the Waste Heat Boiler (WHB) where urea is injected into the flue gases in the zone where the temperature is about 1,800° to 1,700°F. At this temperature the urea reacts to reduce the NOx to N_2 without a catalyst. A reduction of 50 to 70 percent of NOx has been demonstrated in Foster Wheeler's systems. The gas is cooled to about 650°F in the WHB as steam is generated.

- The gas is then further quenched, to a temperature of about 375°F, by spraying a lime solution into a spray dryer absorber. The aqueous lime droplets absorb and react with the acid gas components (HCl , SOx, etc.) to form calcium salts (such as $CaCl_2$ and $CaSO_4$) which are dried and removed from the gas stream in a baghouse. A removal efficiency of 99.9% for HCl and 98% for SO_2 has been demonstrated.

- Fine particulate will be collected in the baghouse together with the lime and salts to achieve maximum achievable control of particulate emissions. Volatile and semi-volatile metals and metal compounds (such as Pb, $PbCl_2$, and PbO) will condense on the powdered lime and salt particles and will also be captured in the baghouse. The vapor pressures of Pb, $PbCl_2$ and PbO at 375 °F (which is the baghouse operating temperature) are less than 10^{-8}, 10^{-7} and 10^{-8} mm Hg, respectively (less than 1 ppm in the vapor phase). The fine particulate, lime, salts, and condensed compounds will be removed from the flue gas stream at over 99.9% efficiency by the bags. Based on Foster Wheeler's experience, the elevated Pb emissions from the demonstration tests were probably due to a damaged bag in the baghouse[13].

- Powdered activated carbon is also injected into the gas stream ahead of the baghouse to remove dioxins or furans (that may be generated in the boiler) and mercury compounds. The baghouse is maintained at a temperature sufficiently above the acid gas dew point to prevent any condensation and consequent plugging of the bags, and corrosion. ADA/Norit Americas expects that a reduction of 90 to 95% of the Hg in the flue gas stream can be achieved in this stage.

- The final step in the gas cleaning system is another partial quench, to a temperature of about 250 °F, by spraying water into the gas and then passing the gases through a packed bed absorber filled with carbon to absorb any mercury (Hg) or mercury compounds still present as vapor. ADA/Norit Americas expects that this Hg removal polishing step is capable of removing an additional 90+% of the Hg compounds. An Hg continuous emission monitoring system (CEMS) will be provided before the guard section of the packed bed to signal when the carbon packing needs to be replaced.

Each of these process components has been demonstrated successfully for the application described in numerous projects and can be provided by several reliable equipment suppliers.

[13] Gas Technology Institute, 2008. Cement-Lock® Technology for Decontaminating Dredged Estuarine Sediments Final Project. Gas Technology Institute, Des Plains, IL., November 2008.

production of thermal NOx at a minimum. A minimum of two burners will be provided in the SCC. They will be arranged to promote turbulence and eliminate dead spaces and/or short circuits within the SCC.

To achieve the required Destruction and Removal Efficiency (DRE) for the thermal processor, Foster Wheeler uses proven guidelines combining residence time, temperature, turbulence, physical arrangement of the secondary combustion chamber (SCC), and type and arrangement of the burners. By following these guidelines all Foster Wheeler designs have surpassed the DRE requirements, as demonstrated, before being placed in service, for all organic components present in the feed, including dioxin and PCBs, whether the DRE is four nines (99.99 percent) or six nines (99.9999 percent). This operating experience demonstrates their capability of exceeding the DRE requirement of the project for any organic components present in Passaic River sediment.

5. Waste Heat Boiler

After the SCC, the hot flue gases enter a Waste Heat Boiler (WHB). The WHB will have a radiant section, designed with wide passes and slag/ash build-up removal capability, followed by a convection section with soot blowing. An aqueous urea solution will be sprayed into the WHB in the proper temperature zone (about 1,800° to 1,700°F) to allow selective non-catalytic reduction (SNCR) of most of the NOx in the flue gas to elemental nitrogen.

6. Flue Gas Cleaning System

The flue gas cleaning system will use proven components for any applicable state or federal air pollution control standards, including Maximum Achievable Control Technology (MACT) or New Jersey SOTA (State of the Art) requirements, for all regulated pollutants, including:

- Acid gases: SOx, HCl/Cl_2, and other halogen species,
- Fine particulate including volatile and semi-volatile metals,
- Mercury,
- Lead,
- NOx (as required), and
- Dioxins and Furans

Each component in the gas cleaning system will be designed to handle the maximum loading of contaminants and maximum flow rates for the process to ensure that all emission standards are met or exceeded.

The system will be a multi-step process and will provide a dry discharge with no waste water to treat. The treatment steps are as follows:

- The generation of fuel NOx in the system will be low due to the small amount of nitrogen in the feed. Thermal NOx will be minimized by the use of low-NOx burners. Further reduction of NOx

2. Feed System

The dewatered sediments that have been mixed with feed additives (slag modifiers) are placed in a feed hopper at the front wall of the rotary kiln. A double screw feeder conveyor (redesigned to address issues raised by the demonstration project) or ram feeder will be used to feed this material through an opening in the stationary front wall of the kiln on a continuous basis. The double screw conveyor creates a seal and restricts the in-leakage of air to the kiln. The heat for processing the sediments is provided by burning natural gas in a low-NOx burner also mounted on the stationary front wall of the rotary kiln. A combustion air fan will provide the proper ratio of air to fuel for efficient combustion.

Foster Wheeler rotary kilns are used routinely to treat widely heterogeneous materials that are often fed in batch mode (drums, boxes, etc.). It is much simpler to handle a single waste stream that will be somewhat homogeneous and fed continuously as is planned for this project. For example, Clean Harbors operates three 4.4 meter diameter x 12 meter long Foster Wheeler slagging rotary kilns at two locations. These kilns average over 10 tons/hour of feed to each one and have obtained onstream factors in excess of 85%.

The operating experience of these kilns demonstrates that the processing of 6-9 tons/hour of sediment modifier mix is well within their capability; especially considering the feed will be relatively homogeneous in nature and fed continuously to the kiln with a vast majority of the heat release from burning natural gas.

3. Wet Deslagger

To handle the slag discharge from the rotary kilns, a wet deslagger is employed. The molten slag falls from the discharge of the kiln and the walls of the secondary combustion chamber into a pool of water where it is quenched and cooled. The design of this slag drop area is extremely important. The proper openings and slopes are critical to the operability of the system. Foster Wheeler has gained this know-how through numerous applications. The slag is carried from the pool with a drag flight or plate-type conveyor. These wet deslaggers have been used on all of the slagging rotary kilns designed with Foster Wheeler technology and have provided excellent, reliable service thereby demonstrating that the removal of quenched slag will not be an issue with this design. Additional natural gas lances can be mounted at the kiln discharge to assist in melting any slag that may solidify and begin to build up in this area.

4. Secondary Combustion Chamber

The SCC must supply additional heat to the process to account for SCC heat losses, air in-leakage, and to heat the water vapor (steam) generated in the wet deslagger to temperatures necessary to obtain the designed DRE for the facility. Low-NOx burners are used in the SCC, as well as the kiln to keep the

1. Rotary Slagging Kiln

The rotary kiln thermal processing technology provided by Foster Wheeler has been used to treat a wide variety of contaminated soils, sediments, sludges, and debris fed through both continuous feeders and in bulk containers (drums). These kilns are routinely operated in slagging mode to ensure that desorption, volatilization and required carbon burn-out of organic contaminants in the solids feed is achieved and maximized. The feed materials, feed additives (slag modifiers), auxiliary fuel(s) and oxygen content are carefully planned and regulated to control the slagging conditions in the kiln. The internal diameter and length of the kiln are carefully chosen to stay within our proven limits for volumetric heat release, kiln gas velocity (to minimize ash carry-over to the secondary combustion chamber (SCC) and waste heat boiler), solids filling factor and residence time. Carefully selecting these design features is important to ensure the feed sediment is heated thoroughly, to completely volatilize organic contaminants that are then oxidized in the Secondary Combustion Chamber (SCC).

Foster Wheeler's thermal treatment technology, experience and know-how was obtained and demonstrated on multiple projects dating back to 1986. Their rotary kiln projects in North America include 13 designed, 12 built and operated, 9 currently operating, including several currently operating units that were designed and demonstrated to meet 99.9999+ percent DRE. Several other facilities were taken to various stages of design but not built for a variety of reasons. A partial list of their completed rotary kiln thermal treatment projects is provided below. We would be happy to provide additional examples of Foster Wheeler's relevant projects upon request.

containing sediments is thermal treatment, such as the thermo-chemical process employed by Cement-Lock Technology in the manufacture of Ecomelt®. Thermal destruction has also been demonstrated to destroy organic contaminants such as PCDD/F, PCB, and PAH.

Off-site thermal treatment options are also limited. Only a few facilities in the United States (primarily in Texas, Utah, Nebraska and other western states) and Canada are permitted to treat such materials. All require transport over long distances and considerable material handling. Importantly, residue ash from these facilities all contain mobile metals that requires placement in a hazardous waste landfill, while the Cement-Lock® Technology manufacturing process creates a beneficial use product that immobilizes metals in a pozzolanic matrix.

E. Design Updates for Cement-Lock® Technology Manufacturing Plant.

As discussed above, the efficacy and feasibility of the Cement-Lock® manufacturing process was proved by the 2006 demonstration project in Bayonne, New Jersey that produced Ecomelt® from approximately 500 cubic yards of Passaic River sediment[10]. The demonstration project used a medical waste kiln modified to treat sediment. The demonstration yielded considerable operational data that has been used to refine the engineering design for a commercial-scale manufacturing facility specifically designed for the use of dredged sediments as a feedstock.

This section summarizes the key design developments since that demonstration, including any engineering modifications to address issues encountered in the demonstration project and advances proposed in the APC equipment for the commercial-scale facility.

The Cement-Lock 2006 demonstration identified a number of plant equipment-related problems, including: 1) inconsistent feeding of sediment to the demonstration plant system, and 2) discharging of slag from the drop-out box. Principal among these problems was the inability of the Ecomelt® Generator to continuously discharge slag from the rotary kiln. Slag accumulated in the drop-out box instead of falling into the granulator to be quenched[11]. In part, these problems were the result of the adaptation of a kiln designed for medical waste processing. The subsequent equipment modification design study as part of the New Jersey Department of Transportation/Office of Maritime Resources project[12] recommended modifications that were largely implemented and tested. The recommendations of that study and test results have been reviewed. The current design addresses these issues, as described in more detail below.

[11] ENDESCO Clean Harbors, Inc., 2006. Sediment Decontamination Demonstration Program: Cement-Lock® Technology Phase I Pilot Test Final Report. August 2006

[12] ENDESCO Clean Harbors, Inc., 2006. Sediment Decontamination Demonstration Program: Cement-Lock® Technology Report on Task 6 – Equipment Modification Design Study. July 2006

D. Design Specifications for Passaic River Sediments

Cement-Lock® Technology is the first sustainable thermo-chemical manufacturing process specifically designed to manufacture a construction-grade, cementitious building material (Ecomelt®) from contaminated dredged sediments. USEPA has identified Cement-Lock® technology as a potential early action treatment process for contaminated sediments found at the Lower Passaic River Superfund Site. In addition to producing a beneficial use product, the Cement-Lock® Technology manufacturing process employs a thermo-chemical process that is highly effective for the destruction of organic contaminants, such as dioxin and PCBs, and the treatment and immobilization of inorganic contaminants, such as metals, found in dredged sediments.

Volcano Partners is proposing the construction of a 50,000 ton per year Cement-Lock® Technology manufacturing plant in the vicinity of the Lower Passaic River Study Area in New Jersey. The plant design will accommodate additional capacity expansion as needed and will be constructed on a timeline necessary, under an early action plan, to accept contaminated dredged sediments as a manufacturing feedstock for Ecomelt® production. This facility will be dedicated to the treatment of contaminated dredged sediment unsuitable for ocean or upland disposal.

The Passaic River and Newark Bay superfund sites contain an estimated 11 million cubic yards of sediments determined by the USEPA and the state of New Jersey to contain elevated levels of various constituents (including dioxin, PCBs, metals and organics and pesticides)[7]. Concentrations of 2,3,7,8-TCDD in these sediments exceed 5 parts per million (ppm); chromium (363 ppm, average concentration), lead (555 ppm, average concentration) and mercury (7.78 ppm, average concentration) are also detected at elevated levels[8].

Silt and clay are the primary sediment size encountered in this area of the Passaic River. The primary assumptions made for the sediment are "in-situ" solids content of 35 percent. The assumption made for debris, oversize screenings, and sand removal is 17 percent of the mass prior to dewatering. We have utilized a density of 1.21 tons per "in-situ" cubic yard. These assumptions are based upon information received regarding the Phase I early action removal. The financial model for the project is based upon receipts using these assumptions.

The USEPA guidance[9] indicates that, to the extent practicable, clean-up project alternatives should consider the CERCLA preference for treatment over containment or land disposal. The only on-site potential treatment technology applicable for treatment of UTS (Universal Treatment Standard) dioxin

[9] USEPA. 1993. Guidance on Conducting Non-Time-Critical Removal Actions Under CERCLA. EPA540-R-93-057. August

Rotary Kiln Design /Build - For more than 25 years the Foster Wheeler team, and its predecessor companies, has designed and built slagging rotary kiln technology to treat a wide variety of contaminated materials, including soils, sludges, and debris, fed through both continuous feeders and in bulk containers (drums). Foster Wheeler's design handles the slag discharge from rotary kilns by the use of a wet deslagger. The wet slag falls from the discharge of the kiln and the walls of the secondary combustion chamber into a pool of water where it is quenched and cooled. The slag is carried from the pool with a drag flight or plate-type conveyor.

Ecomelt® Production – The cooled slag is our beneficial use product, Ecomelt®. The use of additives and the control of mixture ratios and residence times used to manufacture Ecomelt® will require simple operational and design modifications to Foster Wheeler's slagging rotary kiln design. As set forth in Section IV below, we are currently working with Foster Wheeler to finalize revisions to its standard slagging rotary kiln design for the production of Ecomelt®. The thermo-chemical process used to produce Ecomelt® has an additional benefit by effectively destroying organic contaminants, including dioxins/furans, PCBs and pesticides/herbicides, found in the feedstock. This thermo-chemical manufacturing process also effectively immobilizes inorganic contaminants, such as metals, in the pozzolanic matrix found in Ecomelt®. Leaching tests have demonstrated that the Ecomelt® product meets TCLP criteria[6].

Air Pollution Control Systems (APC) – Foster Wheeler's slagging rotary kiln designs are fully compliant with all applicable air pollution control standards. ABB and ADA/Norit Americas will assist with the development of APC equipment and monitoring instrumentation for lime injection, carbon absorption, NOx capture, and stack emissions control. Independent companies will be used to conduct air monitoring.

Beneficial Use Product – The primary beneficial use product is Ecomelt® , a glassy, pozzolanic material, which when dried and finely ground, can be used as a partial replacement for Portland cement in the production of concrete. The Cement-Lock manufacturing process is specifically designed to use contaminated dredged materials as a feedstock or raw material for the production of Ecomelt®. Volcano Partners has determined that a market exists for sale of Ecomelt®. Volcano Partners has entered into a letter of intent with U.S. Concrete, a major domestic Redi-Mix concrete manufacturer, to purchase construction-grade Ecomelt® from the Cement-Lock plant.

C. Project Layout Schematic

The proposed project layout as designed by Foster Wheeler is attached hereto in Appendix A. The thermo-chemical processing and APC systems set forth in the schematic are described in more detail in Section IV E. below.

---

[6] Gas Technology Institute, 2008. Cement-Lock® Technology for Decontaminating Dredged Estuarine Sediments Final Project. Gas Technology Institute, Des Plains, IL., November 2008.

build basis. In 2011, the Company revenues were $2.6 billion and there are currently over 13,000 employees. Tetra Tech will leverage their successful approach on the $700 million Fox River project to deliver a potential early action for the Lower Passaic River Study Area within the budget and schedule commitments.

Foster Wheeler Corporation -- Tetra Tech EC, Inc. has hired Foster-Wheeler to perform the design engineering. There are nine rotary kilns commercially operating in the United States designed by Foster-Wheeler. These kilns have an exceptional, long-term operating and compliance history. In addition to the rotary kiln and processing facilities, Foster Wheeler design systems include secondary combustion chambers and flue gas cleaning systems.

ABB -- Global leader ABB will be contracted to provide the integrated process controls, instrumentation, and monitoring systems required for plant operation. They presently operate in 200 countries and have over 100,000 employees.

ADA/NORIT Americas JV -- The ADA/NORIT Americas JV will provide the equipment and technology for the capture of trace metals from the flue gas. These firms provide the majority of these systems to the power generation and cement manufacturing industries around the world.

U.S. Concrete -- U.S. Concrete services the United State construction market through two primary business segments. These are Ready-Mix concrete and precast concrete products. The Company has 101 fixed-base facilities and 11 portable Ready-Mix plants. These facilities produced over 4 million cubic yards of Ready-Mix concrete last year. Volcano Partners has entered into a letter of intent with U.S. Concrete to purchase construction-grade Ecomelt® from the Cement-Lock plant.

B. Updated Scope of Project

As set forth above, Volcano Partners has asked us to commence design, permitting and cost evaluation in support of a "project-based" 50,000 ton per year Cement-Lock manufacturing plant. As discussed above, all mechanical systems are "off-the-shelf" and in widespread use worldwide. The permitting, design and construction timeline for such a plant is projected at 18 months.

As proposed, the Cement-Lock Technology manufacturing process involves the following key components:

Front End Materials Handling - Dredged sediments that serve as our manufacturing feedstock will arrive at our site by barge. This material will be offloaded by excavator and conveyed to the processing train. All free carriage water will be pumped directly to the water treatment plant for processing prior to and during sediment off-loading. Our materials management and dewatering vendor will conduct debris separation and dewatering to 50 percent solids content. We are currently evaluating the membrane filter press design for dewatering. Our vendor will then deliver the dewatered sediment to the kiln site. Cement-Lock Technology additives are dry and will be blended with the sediment filter cake to reduce moisture content to 40 percent or below.

We have commenced pre-permitting meetings with NJDEP regarding the proposed 50,000 ton per year plant. The projected permitting timeline is a 6-month period. Design and construction for this proposed plant is projected to require an 18-month period, with some overlap between permitting and design expected.

III. Scalability of Cement-Lock® Technology Manufacturing Plant

As you are aware, the uniqueness of the Cement-Lock process lies in the additives, the mixture ratios and residence times used to manufacture Ecomelt®, rather than in the thermo-chemical processing equipment. All mechanical systems are "off-the-shelf" and in widespread use worldwide. As set forth below, Foster Wheeler's proprietary rotary kiln designs readily scale up from your demonstration scale system to your proposed 50,000 ton per year project capacity requirements. Any of these components can be obtained within a 6 to 9 month lead time. Consequently, the ability to enlarge the facility from the 10,000 cubic yards per year 2006 demonstration facility to a full commercial facility consisting of multiple processing trains is not limited by mechanical considerations.

An increase in production or processing volume could be accomplished through the parallel deployment of additional rotary kiln trains. The base model evaluated by the 2008 Report was for a 125,000 ton per year plant, with the possible addition of three additional 125,000 ton kilns, for a total processing capacity of 500,000 tons per year. As per your direction, the current focus of our efforts has been an economic evaluation of a single 50,000 ton per year plant, but we would be happy to further discuss the cost efficiencies associated with a scaled up plant that would be possible with the dedication of additional feedstock.

IV. Description of Cement-Lock® Technology Design Updates

Please find below a detailed description of Cement-Lock® technology design updates. This description includes: 1) project management and design team, 2) updated scope of project, 3) project layout schematic, 4) design specifications for Passaic River sediments, and 5) design updates for Cement-Lock Technology manufacturing plant.

A. Project Management and Design Team

Volcano Partners, LLC -- Volcano Partners owns the patent to utilize the Cement-Lock Technology for the manufacture of Ecomelt, a Portland cement replacement. They have organized a project team which consists of firms with global experience.

Gas Technology Institute (GTI) -- Volcano Partners is collaborating with the GTI as the inventor of Cement-Lock. GTI is a world leader in the development and deployment of innovative technology solutions, and were the project managers of the original demonstration-scale Cement-Lock field pilots performed from 2005-2008 on contaminated dredged sediment that included Passaic River sediment.

Tetra Tech EC, Inc. --Tetra Tech EC, Inc. is the Program Manager and General Contractor, and will perform the facility Operations & Maintenance. They will implement the project on a fast track, design-

pozzolanic matrix found in Ecomelt®. As set forth in detail by the 2008 Final Report, leaching tests[2] conducted during the course of the demonstration project concluded that Ecomelt® readily passed the U.S. Environmental Protection Agency (USEPA) Toxicity Characteristic Leaching Procedure (TCLP) testing criteria[3]. Ecomelt® can be blended with ordinary Portland cement at a 40:60 Ecomelt®/Portland cement weight ratio[4]. The use is consistent with ASTM C 595 (Standard Specification for Blended Hydraulic Cements) and confirmed by the pilot and demonstration project testing results.

In addition, we have an example of the use of Ecomelt® as a partial replacement for Portland cement. In 2008, the production of a batch of concrete using Ecomelt® was used to pour a length of sidewalk (165 feet long by 6 feet wide) at Montclair State University, Montclair, New Jersey. The pour is readily available for inspection by interested stakeholders.

Finally, Volcano Partners has determined that a market exists for the sale of Ecomelt®. Volcano Partners has entered into a letter of intent with U.S. Concrete, a major domestic Redi-Mix concrete manufacturer, to purchase construction-grade Ecomelt® from the Cement-Lock plant. Based on information received from GTI, a 50,000 ton per year facility will yield more than 20,000 tons/year of Ecomelt® for incorporation in construction-grade cement[5] As a point of comparison, the current price of Portland cement is about $105 per ton.

II. Summary of Proposed Project and Cost Evaluation

We have conducted a preliminary economic project analysis using information provided by F&G, Chicago supporting Volcano Partners determination that a commercial-scale plant is feasible under the following conditions. The plant requires the dedication of a minimum of 300,000 cubic yards of "in-situ" contaminated sediments, with a processing fee of $350.00 for each "in-situ" ton of sediment. With projected process treatments and volume reductions for the contaminated dredged sediment, the resulting "filter cake" and combined process additives requires a minimum plant capacity of 50,000 tons per year. This "project-based" 50,000 ton per year plant is the minimum necessary for a commercial-scale Cement-Lock plant. Notably, as compared to past economic analysis, the proposed project scope includes all costs post barge delivery, including materials management, storage and dewatering costs. As the volume of dedicated "in-situ" contaminated sediments increases, we would expect a decrease in the fee per "in-situ" ton. However, the scope of our current evaluation focuses on the costs related to a 50,000 ton per year plant.

---

[2] Toxicity Characteristic Leaching Procedure, EPA Method 1311

[3] Rehmat, A., A. Lee, A. Goyal, and M. C. Mensinger, 1999. Construction-Grade Cement Production from Contaminated Sediments Using Cement-Lock™ Technology . http://www.bnl.gov/wrdadcon/publications/reports/igt-weda-5-99.pdf

[4] Mensinger, M.C., 2008. Cement-Lock® Technology for Decontaminating Dredged Estuarine Sediments Topical Report on Beneficial Use of Ecomelt from Passaic River Sediment at Montclair State University, New Jersey. Gas Technology institute, Des Plains, IL., 2008.

[5] Gas Technology Institute, 2008. Cement-Lock® Technology for Decontaminating Dredged Estuarine Sediments Final Project. Gas Technology Institute, Des Plains, IL., November 2008.

We have also conducted a preliminary economic project analysis supporting Volcano Partners determination that a commercial-scale plant is feasible with the dedication of a minimum of 300,000 cubic yards of "in-situ" contaminated sediments. With a conversion to "in-situ" tons, a minimum "project-based" commercial-scale Cement Lock® manufacturing plant is projected to require a processing fee of $350.00 per "in-situ" ton of sediment. This manufacturing plant would utilize a 4.4 meter rotary kiln operating at 6-9 tons per hour with a projected average capacity of 50,000 tons per year. This facility is projected to require 4 to 5 years to process 300,000 "in-situ" cubic yards of sediment as feedstock. The permitting, design and construction timeline for such a plant is projected at 18 months.

Finally, two important aspects of scalability are addressed by this report. First, as you are aware, the uniqueness of the Cement Lock manufacturing process lies in the additives, the mixture ratios and residence times used to manufacture Ecomelt®, rather than in the thermo-chemical processing equipment. All mechanical systems are "off-the-shelf" and in widespread use worldwide. As set forth below, Foster Wheeler's proprietary rotary kiln designs readily scale up from your demonstration scale system to your proposed 50,000 ton per year project capacity requirements. Second, we are also designing the facility to allow future expansion through the addition of 1-3 rotary kilns and associated equipment placed in a parallel configuration. This would permit the plant to expand if additional feedstock becomes available.

I. Summary of Cement-Lock® Technology Manufacturing Process

According to the inventor, GTI, Cement-Lock technology is the first sustainable thermo-chemical manufacturing process specifically designed to manufacture a construction-grade, cementitious building material (Ecomelt®) from contaminated dredged sediments. The development of a commercial-scale Cement-Lock plant would be the final step in the unprecedented 20-year effort by public and private stakeholders to identify and deploy a sustainable, green technology capable of producing a beneficial use product from contaminated dredged sediments. The primary beneficial use product is Ecomelt®, a glassy, pozzolanic material, which when dried and finely ground, can be used as a partial replacement for Portland cement in the production of concrete. The Cement-Lock manufacturing process is specifically designed to use contaminated dredged materials as a feedstock or raw material for the production of Ecomelt®. After dewatering, these sediments are processed into a homogenous "filter cake." The patented technology then combines the "filter cake" with additives necessary for production of a pozzolanic, cementitious material. The mix is then run through a high temperature manufacturing process (slagging rotary kiln). This process produces a molten mixture that is then quenched in a water bath to create a beneficial use product, Ecomelt®.

The high temperature (2400° to 2600°F) involved in the manufacturing process to create Ecomelt® has the benefit of destroying organic contaminates present in the feedstock. This thermo-chemical manufacturing process also effectively immobilizes inorganic contaminants, such as metals, in the

RE: Summary of Project and Design Updates for Cement-Lock Technology Manufacturing Plant

As requested by Volcano Partners, LLC, please find below a response to several questions raised by Mr. Scott Thompson, Louis Berger Group, regarding Cement-Lock® technologies. Mr. Thompson requested additional information on the Cement-Lock® process design and an update on our plans for the development of a commercial-scale Cement-Lock manufacturing plant. Specifically, Mr. Thompson requested an update regarding our cost evaluation, scalability of the system and any additional updates for process design, including air emissions control systems modifications.

As Program Manager for this project, Tetra Tech is pleased to provide a response to the above questions. We have worked closely with our highly experienced team members to prepare this memorandum. In particular, Foster Wheeler Corporation (Foster Wheeler), with a highly experienced team and recognized 25-year track record in the design and construction of slagging rotary kilns, provided key input into design revisions for a commercial-scale Cement-Lock plant. As requested by Mr. Thompson, we are including below a detailed description of the Foster Wheeler design revisions with a particular focus on the engineering and air pollution control (APC) issues presented in the November 2008 Final Project Report (2008 Final Report) [1].

In addition, as per your request, we have incorporated material handling and dewatering components into the front end of our proposed project scope in order to provide turn key management of the project commencing with the barge delivery of our process feedstock, contaminated dredged sediments, to our proposed waterfront facility. We are currently assessing siting feasibility at several waterfront sites in the New York/New Jersey harbor area. As you know, TetraTech has operated in a similar Program Manager capacity at the Lower Fox River Superfund site where material management and dewatering technologies were designed and deployed for the management of more than four million cubic yards of contaminated dredged sediments. Working with input from experienced vendors, we are providing a more detailed description of our proposed materials management and dewatering facilities for this project.

Please respond to Nancy Alexandru

Apr 27, 2013

Mr. Christos Tsiamis
290 Broadway, 20th Floor
New York, NY 10007-1866

Dear Mr. Tsiamis,

I am writing to support the EPA's proposed plan to clean up the Gowanus Canal Superfund site. After 150 years of pollution a comprehensive plan that addresses the toxic sludge at the bottom of the canal and ongoing pollution from CSOs and upland contamination is critically important to returning this long neglected waterway to the community.

While the EPA's plan takes the critical step of calling for CSO retention for two of the Canal's worst outfalls many details will not be solidified until New York City submits their CSO Long Term Control Plan in 2015. It is critical for the EPA to stand firm on requiring retention tanks to control CSOs and to work with New York City towards the eventual goal of 100% elimination of CSOs from the Canal.

I support the EPA's commitment to dredge as much as 10 feet of contaminated sediment from the entire length of the canal, build a multi-layer cap on the bottom, and treat and dispose of this contaminated sediment offsite. I also believe that the EPA should listen to the wishes of the community in Red Hook who oppose the building of a CDF on the Red Hook waterfront to dispose of the least contaminated sediment.

Sincerely,

Ms. Nancy Alexandru

Re: Proposed Remedial Action Plan for the Gowanus Canal Superfund Site

Dear Mr. Tsiamos:

I am writing today to offer my support for the Proposed Remedial Action Plan developed by the EPA for the treatment of the Gowanus Canal Superfund site in my District. I offer my support with several concerns, very similar to those ably presented by Community Board 6, which I will explain below.

But first I would like to offer my thanks for everything the EPA has accomplished to date. You have given this community hope that the Gowanus Canal, which all of us living here suspected was incredibly polluted, could actually be brought back from the brink. Your thorough and methodic studies documented for us the actual shocking state of the Canal and now you offer us a plan that will not only clean the Canal, but protect it from further pollution from Combined Sewage Overflows. For all of this, you have my deepest thanks.

The major questions about the course of remediation seem to center on the disposal of contaminated material, particularly the possible use of Treatment Disposal Options E, F, or G.

I appreciate that these are not simple decisions. While we cannot be callous about the creation of possible jobs, we must balance these possibilities against the concerns of residents who are envisioning the future character of Red Hook. I support the creation of jobs; I have worked for years to bring employment opportunities to my District. And while the entrance to the Bay is a working waterfront and should remain a working waterfront, there are serious questions about what will happen to a treatment facility and stabilized sediment in the face of another Sandy, or an even greater storm. Onsite treatment and use of stabilized sediment seems to potentially risk further degradation of the environment.

Red Hook has a large and growing residential community, and we must be concerned with what an on-site disposal solution will mean to the current residents and those who are certain to follow. My observation is that there is considerable opposition to the placement of an onsite treatment and storage facility. I am certain you will fully and sensitively consider the opinions of the community residents in your deliberations.

Once again, I thank you for your efforts and look forward to working with you however I can to accomplish the work ahead in finally cleaning the Gowanus Canal.

Sincerely,

Senator Velmanette Montgomery
25th Senate District

History: This message has been replied to.

Ladies and Gentlemen of the EPA:

Your care and consideration for the Carroll Gardens neighborhood's issues surrounding the Gowanus Canal cleanup has been exemplary. While I have attended more meetings as a "charter" CAG member than for, perhaps any other public/civic interest in my life, I have never failed to be impressed and elevated by the intelligent consideration and active problem-solving presented by the three GrimeFighters, aka, Christos Tsianis, Natalie Loney and Brian Carr.

All levity aside, this project has generated an extraordinary synergy, and I have appreciated every minute of the time and dedication on the part of both the professional and residential members. This has been an extraordinary exercise in civic engagement, with exciting results. Recognizing your standards of excellence, talent and professionalism, I thank you for the opportunity to engage. It is startling, on a personal level.

Knowing that you have provided what looks to be a state-of-the art, thorough scientific remediation, going far beyond the initial parameter (water cleaning only), I will only ask that you get the cleanup going ASAP.

I do have concerns, which have been voiced by several others; I want to make certain that the same level of problem-solving effort is applied to incorporating the "northern Gowanus" neighborhood surrounding the top of the canal and the southern-most neighborhood, Red Hook, into equally viable solutions unique to their neighborhoods.

The canal runs thru all our neighborhoods- and offers a unique opportunity to unite our communities, which is a terrific side benefit of the sanitary remediation.

We are all part of South Brooklyn,linked by the now fetid canal. We're looking to you to turn the "lavender lake" into a blue highway linking our neighborhoods for the benefit of all.

Sincerely,
Maria Pagano

WE LOVE YOUR PLAN, EPA.....JUST DO IT!"

Gowanus Canal Cleanup Comments, due 4/27/13
steve deSeve to: Region2 GowanusCanalComments 04/27/2013 04:21 PM
Please respond to steve deSeve

To:
Christos Tsiamis, Project Manager
U.S. Environmental Protection Agency
290 Broadway, 20th floor
New York, NY 10007-1866

From:
Stephen de Seve
111 Court St. #3L
Brooklyn, NY 11201

I support the Superfund cleanup of the Gowanus canal with certain reservations. My comments address a number of points, and include very specific questions; which must be answered thoroughly in order to have a transparent and fair process.

While it is clear that book toxic waste in the canal must be cleaned up, and that the combined sewer overflow's must be dealt with; especially the one that dumps 80% of the sewage into the canal which is located on Butler Street at the head of the canal, there are issues both with the EPA's Plan and its approach at deriving the plan.

Two major PRP's are the City of New York,and the National Grid company which owns the gas monopoly. These two parties have been bad citizens when it comes to their track record regarding voluntary cleanup of their messes.

It is common knowledge that the EPA met with officials from the Bloomberg administration, both here, and in Washington, and that those meetings influenced the plan. But the details of these meetings have not been shared with the public.

This is akin to a judge meeting with a murderer and asking the murderer how he would like to be dealt with by the law, and then not telling the jury the process has been so influenced. It is collusion, it is inappropriate, and it is unproductive. It must now be corrected.

Question one: please list each meeting, formal and informal, with the city of New York and the EPA. Please detail who attended each meeting, the dates of each meeting, and what was discussed. Please list any aspect of the cleanup plan that may have been influenced by these discussions. Please list any alternative approaches that could have been taken. A refusal to answer this question fully would show that the PRP counts far more than the public, and that the EPA protects secret negotiations and resists transparency - that its duty to the public is secondary to its protection of the concerned party with which it held meetings.

Question two: please list each meeting, formal and informal, with national grid and the EPA. Please detail who attended each meeting, the dates of each meeting, and what was discussed. Please list any aspect of the cleanup plan that may have been influenced by these discussions. Please list any alternative approaches that could have been taken instead. A refusal to answer this question fully would show that the PRP counts far more than the public, and that the EPA protects secret negotiations and

resists transparency - that its duty to the public is secondary to its protection of the concerned party with which it held meetings.

The City of New York, and National Grid can never be trusted to do a proper cleanup. I understand the EPA can use eminent domain to seize their properties that are involved in the Superfund cleanup, and take over the cleanup, while making National Grid and the cCity of New York pay the EPA to do this. This is the only appropriate approach to take, given the track record of the entities involved. But, if the EPA feels it can show the National Grid and NYC have done a stellar job of removing toxins from the concerned area, then please convince the public of this.

Question three: did the city of New York at any time request the EPA not take over all superfund related sites by the canal and caused the city to pay while EPA managed the cleanup?

Question four: will the EPA now please take over all lab and waterways associated with the cleanup, disregard any side deals made with the city of New York and national grid, and simply force the city of New York and national grid to pay money to the EPA so that the EPA itself, and not either the city or the gas monopoly, will supervise the cleanup.

Question five: please evaluate New York City's track record of toxic cleanup of the go honest canal since pollution began in the canal. Does the EPA concur that New York City has done a less than optimal job keeping the canal clean? Or, does the EPA belief, from this track record, that the city is flawless and it's taking responsibility and performing adequate cleanups? In other words, is the canal clean now? Since it was the city's responsibility to clean it, one would have to say the canal is clean to say the city is a good bet to clean it.

Question six: for the record, does the EPA have the legal right to take over the entire cleanup site, perform the cleanup, and make the City and National Grid pay? It would seem from the Superfund law that the EPA does have such a right.

My next question has to do with the parcel of land also known as Thomas Green Park and double D pool. This land is so toxic that a retaining wall is slated to be put in, not to protect the park's land from the toxins in the canal, but to protect the canals water from the toxins in the park's land.

Question seven: does the Thomas GreenPark and Double D pool combination constitute enough legally required green space and recreational space as required by any applicable laws, to cover the population that surrounds it? It is my understanding that there is a 90% deficit are required to green space to serve the population of Gowanus. How will the EPA remediate this environmental injustice, or, whether or not an environmental injustice is technically present, how with the EPA protect residents from temporarily or permanently losing their green and recreation space? Will the EPA require a new parcel of land be procured for the duration of the clean-up so that the same meager amount of green space is provided during the cleanup? Or will the EPA clean-up result in the loss, temporarily or permanently, of the green space available to the residents? if not, then please explain why?

Question eight: it is an environmental injustice what is being done to the people in the area that's around the upland section of the canal? Where are the environmental overlays for this environmental justice zone?

Question nine: any shutting down of the double the pool, even temporarily, would

deprive residents of green space and recreation space. How will the EPA protect the jobs of those who work at the pool and park, and protect the rights of the local people to have daily use of their park and facilities?

The City of New York has repeatedly tried to close the so-called Double D pool. The EPAs plan to place a massive sewage tank under the pool will disrupt services of the pool, and could likely lead to the pool never reopening, especially if the project is left in The city's hands. The city has been scofflaw for over a century. It is imperative that the EPA use eminent domain to take over enough land to build a new pool before any cleanup of the land of the pool currently is on begins. Failure to do that would create a new environmental injustice upon the people in that neighborhood. This is not allowed under Superfund regulations. And under other laws.

This next section has to do with the CDF and Redhook. It is not fair or appropriate under any circumstances for the EPA to build a shipping facility that benefits just one person. This would be what would happen if the CDF was built and used to make deep water piers for Mr. Quadrozzi.

Requirement that the new peers and the work on the CDF employ local residents are very difficult to enforce. And, as is usually the case in these situations, a document will be drawn up that will have no economic value to the local residents, save for one resident, named Quadrozzi.

Question 10: Can the EPA use eminent domain to take the land, and underwater land, from Mr. Quadrozzi or any other owner, to place the CDF on it?

Question 11: once the EPA took over ownership of the land associated with the CDF and the CDF itself, can the EPA cede such land to some type of public or private entity to manage it? to own it?

Question 12: can all the residents of Redhook be given shares in the corporation that would own Quadrozzi's former land and the new pier capable waterfront built by the EPA which would include the CDF?

What I am getting at is this: rather than build a deep water potential pier area for one person in Redhook, when all residents of Redhook would share the burden, and one alone will get the benefit; Why not make the new land a collectively held entity so that all residents of Redhook be given ownership in the new peer so that their economic benefit is assured? A precedent for this would be England's discovery of oil in the North Sea and their profit-sharing scheme for North Sea oil with all residents of Scotland.

I have no objection to the CDF, other then the objection that one person would be benefited and others would receive empty promises. Removing the land from its owner, building the CDF, building the piers, and ceding ownership of the land with the piers to public housing residents in Redhook would solve this problem. Will the EPA now do this?

In conclusion, I commend the EPA on its Gowanus Canal cleanup plan. But we need details. The plan needs to have exposition of the players involved in shaping it. We need to know anything that happened behind any door that was open or closed, that influenced the plan. I trust that the answers to my questions will be thorough and complete. The public has been left in the dark far too long on any collusion or co-influencing that may have happened between the EPA and representatives of the

city government.

New York City is incredibly corrupt! This corruption can be seen in its failure to ever have cleaned up the canal. And because of this corruption it should not be involved in any aspect of the Canal cleanup except for handing the EPA the cash to do it.

Without a gun, of some metaphorical kind of course, to the head of New York City officials, they will wriggle and squirm and fail to do anything. This has been their track record for 150 years. That portions of the EPA plan that are invested in the fantasy that the city will do anything at all, will fail. Then, the further environmental injustices perpetrated by the city in the name of attempting to fulfill the EPA plan will be on the EPA's head. The EPA has no business trusting and an entity that has shown itself to be completely useless when it comes to cleaning up the canal. Please present a full Evaluation, going back 150 years, of the city's successes in cleaning the canal. If the state of the canal currently is an indication of these successes, then it is criminal for the E PA to allow the city to do anything but pay.

The same goes double for the gas monopoly, which is now under the umbrella of the National Grid Corporation. Have they been successful at cleaning the land and canals the monopoly polluted? If the current state of the land and the canal are an indication of their success, then it is, once again, criminal for EPA to rely on the gas monopoly to do anything except pay for the cleanup. They will wriggle and squirm and fail. And the resulting environmental injustices and disaster will be on the E PA's head. The EPA has no business dealing with these scofflaws, except to make them hand the EPA cash.

In the EPA Superfund zone around the canal, there are brownfields that house tens of thousands of lower income residents. There are brownfields that are the land parks and recreational facilities are built on. The whole canal is incredibly polluted, and this has continued specifically because of neglect by the City of New York, and by the gas monopoly. And also by other PRP's. How this has not been treated with the full environmental justice zone overlays is beyond comprehension. The canal was DESIGNED to be a sewer and a trench for toxic waste -- and then it was BUILT to fulfill those purposes. All landscaping around it was done to make the Gowanus Canal the lowest point. It has not even been dredged for decades --- leaving residents with a bio-hazard and toxic waste sickness zone-- just to save a little money.

Many business have made unreasonably large profits by polluting and neglecting the canal and the brownfields around it. The City has made a lot of money from the economic benefits of such behavior -- and it has saved a lot of money turning its back on this area and its (mostly poor, mostly black and brown) people. When it came time to build public housing, the housing was built on the toxic land. When it came time to make green space, the same thing happened. This is shirkmanship at its highest level. If the city officials from a hundred years ago could be dug up and imprisoned, then that would be one step in a reasonable treatment of the environmental criminals who profited by doing what they did to the canal. But you have to go after their successors instead. But treat them like crooks, murders, con-men, and poisoners. Don't sit down to meals with them. Don't treat them like professionals, or even as humans. I realize there is a temptation to do so --- but no! These are the bad guys. If you can't lynch them, then charge them -- either with crimes, or with a big fat bill to pay for the clean-up. And don't let them play broke! Make them pay for a pool. Make them pay for hotels for area residents if the clean-up is smelly. These people are responsible for

some horrific stuff.

I feel the EPA forgets, sometimes, how foul and subhuman the things that have been done here, and in other superfund sites, are. I feel the EPA does not go after the lowest of low-lifes with an appropriate attitude. Make the polluters pay. Make the innocent victims of pollution-for-profit get some fair treatment, and not have to beg to be treated with dignity.

Let us know, fully, what the PRPs discussed with you. Reneg on any deals the EPA made with them, and stand up for the non-polluting public.

In Redhook, the problem is that a burden will be shared by many and I benefit will accrue to one person. Only eminent domain seizure of the properties of the one person, which is an appropriate way to obtain the land and waterfronts to build the CDF, must result in shared ownership, not unenforceable Job promises; so that all those who share the burden of the cleanup benefit equally from any and all results of the cleanup. Each resident of Redhook must be a shareholder in the CDF and in the improved waterfront property and commercial ability it represents. Otherwise, there is an appearance of impropriety, with the EP a acting to benefit a very rich land owner. This appearance of impropriety and corruption is enough Reason to prevent VE PA from building the CDF, on its own. Only a shared ownership of the CDF would make it clear that there is no corruption, and there is an equal and real benefit to each and every resident.

One final question:

Question 13: Since the Gowanus Canal and surrounding land parcels contain both chemical and biological pollutants, and since the City continues to dump both into the canal at the Butler St. CSO, will the EPA treat the clean-up of biological toxins the same way as the clean-up of chemical toxins? Will the EPA stop the city from using the CSOs that are continuing pollution to this day?

Please stop treating polluters like kings and the public like beggars, and make a clean canal and area that benefits all residents equally, and treats polluters appropriately.

Thank you.

April 26, 2013

Dear Mr. Tsiamis,

Friends of Douglass Greene Park (FODGP) would like to thank the EPA for their hard work and dedication over the past three years in support of the Superfund listing, Remedial Investigation and Feasibility Study for the cleanup of the Gowanus Canal. We greatly appreciate the EPA's efforts to clearly and openly communicate with all the varied community based organizations', groups, and concerned residents and businesses in South Brooklyn regarding the Proposed Remedial Action Plan (PRAP). We thank you for helping to restore some of the broken public trust amongst our community regarding remediation of the longtime highly polluted waterway and we support the PRAP in addressing this overdue cleanup.

FODGP is an organizational member of the Gowanus Canal Community Advisory Group (CAG) and we have limited the scope of our comments to addressing our concerns around the potential impacts to the Thomas Greene Park and Douglass and DeGraw, aka Double D Pool, along with the nearby Canal area that will comprise RTA1. As is understood by FODGP at this time, the proposed cleanup plan work to be conducted in

this northern vicinity would comprise dredging, capping and dewatering (EPA), along with a retaining wall to be built (National Grid / DEC), and a proposed raw sewage retention tank (DEP), as well as ongoing work to the Flushing Tunnel and Pump Station (DEP), plus still to be determined further excavation and removal of NAPL that would need to take place on the former Fulton MGP site (National Grid / DEC) .

In regards to all these proposed remediation's and controls, three main comments from our organization to the EPA focus on:

- **Incorporating the entire upland area of the former Fulton MGP site within the EPA Superfund cleanup.**

- **Conducting a thorough review of the Remedial Investigation results at the former Fulton MGP site and addressing new potential exposure pathways with a human health risk assessment.**

- **Providing compensation and guarantees for the potential loss or disruption of the Double D Pool.**

Incorporate the entire upland area of the former Fulton MGP site within the EPA Superfund cleanup

FODGP believes that a Record of Decision (ROD) incorporating the entire upland area of the former Fulton MGP site within the EPA Superfund cleanup will provide for the best coordination, organization, planning and design possible to minimize disruption and impacts to our community. FODGP strongly believes that not coordinating these cleanups continues to make the community pay and will continue to leave too much uncertainty regarding the fate of the Thomas Greene Park and Pool. Without specific timelines, clear communication, meaningful community participation and involvement, and clarification on what specific remedies and risks comprise the former Fulton MGP cleanup in conjunction with the Canal RTA1 site, FODGP and the community of residents that use these public resources face too many uncertainties and possible disruptions that will make any further Park designs and planning impossible.

The Thomas Greene Park and Double D Pool was formerly the site of the Fulton Manufactured Gas Plant (MGP), which National Grid and the City and State are now responsible for investigating and remediating. National Grid has a website, www.fultonmgpsite.com/, which is supposed to provide regular site news and updates, however updates have not been posted since September 2012. National Grid is also required by 6 NYCRR Part 375-1.10 NYSDEC to review and update their Citizen Participation Plan (CPP) to account for significant changes in the Fulton Municipal MGP Project's remedial program. The CPP posted online is over 5 years old and dates to when KeySpan was the responsible party for the site.

National Grid's Remedial Investigation (RI) for the former Fulton MGP site was released in July 2012 and provides detailed results of their investigations into the eight parcels of land which comprise the site. The Park and Pool comprise parcel number two, and directly beneath the Pool are old petroleum tanks from former operations. According to National Grid's summary of their RI, visible coal tar and petroleum impacts were found in soils beneath the site and in areas to the west bordering on the Canal. Subsurface migration of coal tar wastes is also so problematic that it has necessitated expedited design of an Interim Remedial Measure, consisting of a cut off wall to prevent migrating contamination from entering the Canal in support of the Superfund cleanup. A Feasibility Study (FS) to address the contamination impacts as necessary has yet to be released.

Some of the contaminants found in soil and sediment testing from National Grid's RI include benzene, toluene, ethylbenzene, and xylenes (known as BTEX) and polycyclic aromatic hydrocarbons (known as PAHs). BTEX compounds are some of the volatile organic compounds (VOCs) found in petroleum derivatives such as petrol (gasoline). Toluene, ethylbenzene, and xylenes have harmful effects on the central nervous system. PAH compounds are known carcinogens and mutagens and are also responsible for developmental toxicity, resulting in birth defects and adverse impacts to non-human life forms. When the EPA discusses these coal tar derivatives in its proposed cleanup plan, they are referred to as NAPL, non-aqueous phase liquid.

According to National Grid there is supposedly "no risk of exposure" to MGP-related contaminants at this site, unless one digs about five to seven feet down. There is also a concrete barrier at parcel number two, which is supposed to provide protection to the

user's onsite. According to the EPA and the NYS Superfund program, source removal or control for all remedies, will be necessary.

The former Fulton MGP site will require close coordination and oversight between EPA, DEC and National Grid in order to prevent NAPL migration from impacting the remedy. Furthermore, EPA has identified the Double D pool area as a potential location for a 2 to 17 million gallon in line CSO storage tank for outfall RH-034 to address the over 121 million gallons of raw sewage that are estimated to enter the Canal annually from this one outfall alone, and his could impact the integrity of the remedy.

The forthcoming Record of Decision (ROD) must reflect a comprehensive cleanup of the canal and the upland former Fulton MGP area, where all agencies and parties involved work together in a much more coordinated and timely fashion. The former Fulton MGP upland area does comprise RTA1, the first part of the Canal which will be remediated, and this will most likely set the timeline and pace for the subsequent parts of this cleanup. Furthermore, any failure to achieve the Interim Remedial Measure cut off wall would result in recontamination of the canal sediments and could potentially significantly delay the cleanup. The design and location of this interim cut off wall have yet to be presented to the public, so not only is the coordination of this remedy in question, but understanding the impacts of where this NAPL could possibly migrate to if it is prevented from entering the Canal create additional concerns for the safety and health of nearby residents, businesses and park and pool users.

More broadly, in terms of communication and transparency with residents and organizations like the Gowanus Canal Community Advisory Group (CAG); National Grid and the DEC and DEP have not responded to community concerns or public meeting requests, nor followed even the most basic parts of the Citizen Participation Plan as prescribed on the National Grid former Fulton MGP website. While National Grid continues to insist that the Park and Pool are safe, their explanations at times seem to be at odds with the EPA in terms of technical assessment, like NAPL migration for instance, where National Grid insists that coal tar waste only migrates down, yet the EPA's presentations communicate that NAPL can migrate down and up, and very importantly be transported via groundwater, not just into the Canal itself, but depositing around the neighborhood, particularly in the former MGP vicinity. This is naturally of great concern to us.

National Grid and the City of New York are potentially responsible parties (PRP's) and FODGP asks that the EPA use its Superfund authority to enforce the entire upland area cleanup in a coordinated fashion that will not cause multiple disruptions to the community and its resources.

It is for these many reasons that FODGP would like to see EPA use its vast compliance and enforcement authority under CERCLA to include the former Fulton MGP site as part of the remedy. We believe this to be the best way to guarantee source control remediation and proper agency and responsible party alignment that will ensure the protectiveness of the preferred remedy while safeguarding our community and concerns over our beloved Thomas Greene Park and Double D Pool.

Conduct a thorough review and verify remedial investigation results at the former Fulton MGP site and address new potential exposure pathways with a human health risk assessment.

For the safety of the users of the Park and Pool, FODGP insists that the EPA perform a thorough inspection of National Grid's findings regarding risks of exposure at parcel number two of the former Fulton MGP. We would like to see testing done by the EPA on the concrete barrier of parcel number two and the material of the two swimming pools onsite (the toddler pool and the regular pool) that tests for BTEX, PAH's, VOC's and NAPL. We would like to know if there is any issue with the porosity of these materials that could facilitate exposure pathways for these toxics? We would also like to see regular testing for these same chemicals done for the Pool water and the drinking and shower water at the Double D Pool facility. Finally, given the groundwater and storm water runoff contamination concerns, we would like to see groundwater testing done by the EPA onsite at the Park and Pool after wet weather events.

FODGP would also like to bring to the attention of the EPA that the Thomas Greene Park Playground was just recently redesigned and reopened this March. Over 900K in discretionary funding from City Council members was spent by NYC Parks to renovate this playground. The land was not remediated before the new playground went in. This new playground has large tree pits with a lot of exposed dirt, and a new children's sprinkler fountain, both of which should be evaluated as new dirt and groundwater sources onsite. The playground is now experiencing heavy use from neighborhood

residents and the sprinkler will surely be a very big draw for young children this summer. There are very low tree guards delineating the playground from the tree pits, but the reality is that children love to play with dirt and very young children will be digging in this dirt, and inadvertently or sometimes deliberately ingesting it. We again ask that the EPA evaluate that these new Park designs and amenities to ensure that they do not create exposure pathways that could pose health risks to the young children and families recreating onsite.

Provide compensation and guarantees for the potential loss or disruption of the Double D Pool

As part of the proposed cleanup plan, EPA is proposing potentially impacting the Double D pool area to excavate and build a 2 to 17 million gallon raw sewage storage tank. The plan obfuscates the issue in a way that residents reading the PRAP would not even realize that there is proposed threat to the pool in the proposed plan. It is for this reason that FODGP recently began a petition to inform users of the Pool.

In less than three weeks since the petition was launched, response has been tremendous. Local residents and members of FODGP trying to "Save the Pool" have been featured on Channel 12 News, DNA info, Brownstoner, the Brooklyn Paper, and in the New York Times.

The Double D pool was slated to be closed by the Mayor's office in 2010 and the neighborhood residents successfully rallied against this closure to "Save the Pool." Because the EPA understands community acceptance to be very integral to the proposed cleanup plan, FODGP is including the over 1,000 petition signatures we gathered in support of this cleanup, that includes addressing CSO's, but are against a raw sewage tank being placed beneath the Double D pool (www.change.org/petitions/epa-make-the-polluters-pay-not-our-community-save-the-double-d-pool).

We do not feel that enough information and consideration was provided to our organization and community in regards to this proposed location for us to support this proposed location in any way. Should the EPA and DEP be willing to discuss this

proposal further with FODGP and the community, and provide compensation and guarantees to the community at large, with respect to the pool, then perhaps there could be support, but at this time we resoundingly say NO to a raw sewage tank beneath the Double D pool.

The communities that use this Park and Pool also deserve clear communication on what a proposed raw sewage retention tank at this location would mean for our community. We want to see specific health risk assessments and guarantees that there would be no disruption to our facilities and services. Furthermore, FODGP understands that there are other locations, closer to the CSO outfall (RH-034), where the tank can go, such as the lot on Nevins and Butler, across the street from the Pump station and the Flushing tunnel. There are also numerous parcels of land for sale in the immediate vicinity and perhaps this might also be worthy of an eminent domain proposal.

There are hundreds of petition comments that address the communities concerns over this potential loss and demonstrate the importance of this community resource. To be clear these signatures represent that the community of residents who use this facility do not want a raw sewage tank to be built beneath the pool.

The pool primarily serves nearby public housing and neighborhood residents during the summer season, and programs provided at the Pool facility include the School Food Lunch program, which serves free breakfast and lunch while school is out, and the Learn to Swim program, which provides free swimming lessons for children. The pool also serves as a cooling center during heat waves. There is also a second pool, uniquely designed for toddlers, which some of the youngest neighborhood residents enjoy and a handicapped lift which services the main pool to allow for special needs access.

Should the ROD move forward with the retention tank location as put forward in the PRAP, what would be the exact timeline that this resource would be disabled? What compensation will be provided in the ROD for a community losing a recreational open space facility and how would the EPA enforce City open space standards for an already underserved part of the Gowanus community? New York City Planning Standards outlined in the 2010 City Environmental Quality Review Technical Manual encourage a standard of 2.5 acres of open space within half a mile for every 1000 residents. EPA and DEP will have to address what access to Parks is presently provided for in Gowanus compared with the standard requirements. Estimates from a CAG member have put

forth that Northern Gowanus residents only have access to roughly 7 acres of Parks instead of the 70 acres the standard requires.

While FODGP supports a comprehensive Superfund cleanup of the Gowanus Canal that includes addressing raw sewage overflows, we also insist that Superfund follow its own principles and make the polluters pay, not our community. The EPA's proposed placement of the raw sewage retention tank to be built beneath the Douglass and Degraw (Double D) community pool will greatly impact an already underserved community by removing a facility that serves primarily low income populations that already suffer disproportionately from the effects of obesity and lack of access to open space. Furthermore, very serious consideration should be given to what impacts could occur to our most vulnerable elderly and young populations if there is no nearby facility to provide services designed to prevent hunger, and even death during excessive heat. To prevent the denial of, reduction in, or significant delay in the receipt of benefits by minority and low-income populations would disproportionately affect communities of color and violate the U.S. EPA's environmental justice commitments.

Presently there is no specific time frame or incentives being offered in the proposed cleanup plan to the community in the regards to the potential closure of the Double D pool. It is also unclear at this time if there may be additional disruptions to the Thomas Greene Park. Also, due to the aforementioned other reasons regarding why the land in parcel two may still need to be remediated, even without the placement of the retention tank beneath the Double D Pool, it is imperative that EPA carefully consider these same reasons in their ROD before any disabling or disruption of these community resources were to occur. FODGP asks that the ROD include enforceable measures to provide for temporary and permanent relocation of services at a nearby location as needed.

Any temporary displacement or permanent disruption to the Thomas Greene Park and Double D Pool needs to be planned for with a seamless transition of services that includes an expense budget in the ROD for all the park facilities (pool, playground, skatepark, basketball courts) and services (the School Food Lunch, Learn to Swim, cooling centers, etc.) at a nearby location. FODGP would like to see an expense budget for rebuilding the Pool and Park as necessary and a budget for any interim pool and services that are needed. FODGP would also like to see enforceable measures in place

between the PRP's and the Parks Department for any necessary expenses should the new playground be disrupted.

Currently, there is much concern in the area over displacement, gentrification, affordable housing, threats to NYCHA residents housing, along with the potential closures of the Pacific library branch and Long Island College Hospital (LICH). Many longtime daycares and community centers have also lost their funding, so the threatened loss of this community resource combined with these numerous pressures adds to the burdens that neighborhood residents are already experiencing in a historically underserved area.

It is for these reasons that FODGP asks for guarantees in the ROD that minimize any possible disruption to the Double D pool and provide for any direct costs related to that, including a nearby temporary pool and a permanent replacement, along with all the community services and other park amenities accounted for.

Over $500 M will be spent on this cleanup and we want to see a Record of Decision that minimizes any possible disruption to the park & pool and provides for any direct costs related to that, including a nearby temporary pool and a permanent replacement, along with all the community services and other park amenities accounted for. Anything less would be environmentally unjust. Clean up should fall on the responsible parties, not on the backs of our children and our community.

Thank you for all your time and attention to these matters.

Sincerely,

Sue Wolfe

Mr. Christos Tsiamis
290 Broadway, 20th Floor
New York, NY 10007-1866

Dear Mr. Tsiamis,

I am writing to support the EPA's proposed plan to clean up the Gowanus Canal Superfund site. After 150 years of pollution a comprehensive plan that addresses the toxic sludge at the bottom of the canal and ongoing pollution from CSOs and upland contamination is critically important to returning this long neglected waterway to the community.

While the EPA's plan takes the critical step of calling for CSO retention for two of the Canal's worst outfalls many details will not be solidified until New York City submits their CSO Long Term Control Plan in 2015. It is critical for the EPA to stand firm on requiring retention tanks to control CSOs and to work with New York City towards the eventual goal of 100% elimination of CSOs from the Canal.

I support the EPA's commitment to dredge as much as 10 feet of contaminated sediment from the entire length of the canal, build a multi-layer cap on the bottom, and treat and dispose of this contaminated sediment offsite. I also believe that the EPA should listen to the wishes of the community in Red Hook who oppose the building of a CDF on the Red Hook waterfront to dispose of the least contaminated sediment.

Sincerely,

Ms. Rosemary Moore

The importance of the Douglass Greene Park and DD Pool

Hollister White to: Region2 GowanusCanalComments 04/27/2013 05:06 PM

To whom it may concern,

My family uses the The Douglass Greene Park and the DD Pool. Please find another spot to put the waste. I am all for the clean up, but don't want this vital neighborhood resource taken away for years. By the time they put the pool back my now young children will be teenagers.

If the only place you can put the sewage is under our DD pool, with an impact and possible closing of our newly renovated Douglass Greene Park, please put a temporary pool and playground up within walking distance of the current neighborhood park and pool BEFORE closing our much used Douglass Greene Park and DD Pool.

Please allocate funds for this new temporary pool and park, build it, employ it, and open it before breaking ground on our current public pool and park. Please also put specific funds aside for the rebuilding of our DD Pool at the completion of the construction, and monies to beautify our park. Please take into account inflation and how the Gowanus Canal will be lovely based on your efforts and the DD Pool and Douglass Greene Park will be a lovely extension of everyone's best efforts, only a few short blocks from the end of the Canal.

Your goal to make the Gowanus Canal both clean and a place for the community is wonderful. Please make sure that in the process something that is highly valued by the community, our Park and Pool, won't be interrupted or destroyed to make another clean green space for our Brooklyn community. These two important areas should be complimenting each other, a clean canal with a park and pool.

I feel confident that you can see the importance of protecting a public pool and park, while helping to clean another important resource for our community.

Thank you for your time and consideration.

Best,

Hollister White
Brooklyn

Dear Christos,
I wanted to thank the EPA so much for coming to meet in Red Hook and for acknowledging that our community does not want the CDF in our neighborhood. For your records I am sending a link to a video of the entire meeting.
Thank you again,
Alexandra

Gowanus Canal Superfund PRAP Comment
Phaedra Thomas to: Region2 GowanusCanalComments 04/27/2013 07:12 PM

To: Whom It May Concern

I am writing in support of the EPA's PRAP for the Gowanus Canal Superfund, and specifically in strong favor of the "Red Hook Option" including Dewatering and construction of a Confined Disposal Facility (CDF) at GBX • Gowanus Bay Terminal in Red Hook. I own a 2 family home at 213 Van Brunt Street, where I resided from 2001 – 2010, and have worked in the Red Hook community, primarily in the nonprofit sector in community and economic development, for over a decade.

While I am employed as a consultant to the owner of GBX • Gowanus Bay Terminal, I am writing to you in the capacity of a Red Hook stakeholder, that cares deeply about this community, especially the residents of Red Hook Houses. Even when I was not employed at the South Brooklyn LDC or Southwest Brooklyn IDC, I have always volunteered (and continue to do so) for community initiatives that benefit the residents of Red Hook Houses, and know intimately the needs of this community. I have worked very closely with the leadership of the Houses, and the general public there, for 13 years.

I became involved in the Red Hook Option of the Gowanus Canal Superfund, because I knew from the moment I heard about the proposal, that it was the perfect fit for Red Hook. Because GBX is located in a THOUROUGHLY industrial section of Red Hook, zoned M-3, an active marine terminal, next to the largest Bargeport in our region, within NYC's Industrial Business Zone, I thought that expanding industry here would be a no-brainer for All of Red Hook. I have known and worked with the owner of GBX for over 10 years, which is why I knew I could stand by him, and strongly advocate for this project. I met John Quadrozzi, Jr. in 2000 when we started an Illegal Dumping Taskforce together. I was running the Red Hook office of the South Brooklyn Local Development Corporation and was the Administrator of the Red Hook Gowanus Chamber of Commerce.

We began the process of planning for the Red Hook Option by attempting to facilitate a transparent, open, communication forum for residents in both the 'Back' (primarily affluent property owners) and the 'Front" (Red Hook Houses) to discuss the project, and any concerns or questions residents might have had about the project. People were open to the idea, many were optimistic about the Job Training Initiative and job opportunities that would come from the EPA work, and all were invited to engage with us in a visioning process that would plan the new uses that could be placed on the CDF once it was completed.

We met with Mr. McGettrick and Lou Sones repeatedly. All of a sudden the discussions were about 'zero expansion of industrial land in Red Hook' versus whether the project was going to be safe or beneficial to the Red Hook community. Then, prior to the EPA presentation at PS 15, bright orange signs saying "Toxic Sludge Coming To Red Hook" went up on every door in Red Hook Houses, with no organizational affiliation and with no permission from NYCHA or the Resident Associations. Residents who were typically part of Red Hook's anti-industry clique had obviously prepped their cronies to disrupt the meeting and worse, instilled fear into residents of both the "back" and "front" of Red Hook. All people heard was scary, false terminology and all they saw was fear and anger on people's faces. We were victims of sabotage. Red Hook Houses residents were again victims of a Great Social Injustice, and it was brought against them by their own neighbors. The whole experience has been extremely

disheartening and sad. I too was a victim of Sandy, and had been experiencing great personal tragedy in my own family, but I stayed with this project because it's the right thing to do. Now it is not only the right project for the right community, the Red Hook Houses community and their local employers, it is a matter of JUSTICE.

I am not in this for myself, and never was. Red Hook deserves this project to happen, please have the courage to fight for it with us.

Yours Truly,

Phaedra Thomas, Owner
213 Van Brunt Street
Brooklyn, New York 11231

Written comments on the proposed plan
Josh Skaller to: Region2 GowanusCanalComments 04/27/2013 07:44 PM

Christos Tsiamis
Project Manager
Central New York Remediation Section
U.S. Environmental Protection Agency
290 Broadway, 20th Floor
New York, New York 10007-1866

My Name is Josh Skaller, I live in Park Slope, and I have been actively participating in the discussion surrounding the cleanup of the Gowanus Canal for many years now.

I strongly support the proposed plan, and look forward to continuing with the EPA to make sure all of our community concerns continue to be addressed.

When the EPA first began looking into designating the canal as a Superfund site, there was both a great deal of excitement from the community at the prospect of a real clean up, and of course many questions about what to expect during the process, and what the final cleanup would entail. In addressing these concerns, the region 2 team of the EPA has been a model of good government, and truly a joy to work with.

As a parent in the neighborhood, I look forward to having a clean and safe waterway - what parent wouldn't. The proposed plan is to be commended not only on the thoroughness of the cleanup, but also for the proactive approach towards keeping the canal clean for the future.

In particular addressing the combined sewage overflow issues and committing to deep and meaningful cuts in discharge levels will have a real impact on residents and should remain a high priority in the plan. I urge the EPA to continue to work with the city towards finding ways to minimize or eliminate where possible the short term impacts any work might have in pursuing the needed discharge remediation.

I also believe that any processing as a result from dredging, including dewatering, be done in a fair and open manner, that no community should be unfairly burdened with the clean-up, and that all remediation efforts go forward only with continued community input. In the case where there is widespread opposition to processing, the epa should either find alternative means to address the issue, or find a more suitable, remote location.

In closing I would like to reiterate both my support of the plan, and my appreciation for the fantastic job the Region 2 team has done thus far. I look forward to the Record of Decision, the Remedial Design Phase, and ultimately, a clean, safe waterway that has been transformed from albatross to asset.

Support for the Red Hook Option of the Gowanus Canal Superfund Cleanup Plan

Ray Hall to: Region2 GowanusCanalComments 04/27/2013 07:48 PM

RED HOOK HOUSES COMMUNITY ACTION COALITION

RED HOOK RISE ORGANIZATION, RED HOOK EAST & WEST RESIDENT ASSOCIATIONS

April 25, 2013

Christos Tsiamis, Project Manager
Central New York Remediation Section
U.S. Environmental Protection Agency
290 Broadway, 20th Floor
New York, New York 10007-1866

Dear Mr. Tsiamis:

We are writing to you in support of the Environmental Protection Agency's Proposed Plan for the Gowanus Canal Superfund, and in particular, in strong support of stabilizing Red Hook dredge (RTA-3a&3b) on-site, and subsequently placing it in an on-site Confined Disposal Facility at Gowanus Bay Terminal in Red Hook (the "Red Hook Option"). We truly appreciate the Red Hook Option, as our community is ready to play our part in the long-awaited cleanup of the Canal, and our residents would glean great benefit from the Job Training Initiative and Superfund employment opportunities.

Our organizations have joined together in an act of solidarity to fight for the Red Hook Option because people from the 'back' of Red Hook, many of whom own their own homes, have organized an outspoken and misguided campaign against it. This group Does Not represent the majority of Red Hook, and to the contrary, represents the minority. Their campaign has involved misrepresentations and lies about the nature and safety of the Red Hook Option. The 'No Toxic Red Hook' literature and website have robbed many of our residents' right to factual information, self-determination and the pursuit of bettering their own community. There was a bright orange sign Illegally posted on every one of our buildings' doors saying "Toxic Sludge Coming to Red Hook?". At public meetings where residents came to hear your Agency's proposal, hecklers and ill-mannered speakers scared our residents away from even daring to ask any normal questions about the activities that will be involved in the Red Hook Option.

We IMPLORE you not to allow this small, yet politically savvy, overly empowered elitist group to dictate the future of our community. Some people have just joined into the mob mentality, lighting the torches out of misplaced fear. But the *leaders*, who know the project is perfectly safe, but are using this as an opportunity to get renewed name recognition and to stop ANY growth of industry and the jobs industry provides, are guilty of orchestrating a great social injustice on a community that desperately needs the real opportunities that a project like this would afford our residents.

As you may know Red Hook Houses is the 2nd largest Housing development in NYC. Census 2010 counted our unemployment rate at about 23%. We believe it to be over 30%. Red Hook Houses wants a seat at the Superfund table to begin real dialogue with the EPA, Responsible Parties, elected officials and other government agencies on how we will be able to shape the JTI program and maximize the amount of local residents that can get Superfund related jobs; in Red Hook for Red Hook Houses residents, and in the rest of the Canal area for Red Hook and Gowanus/Wyckoff residents.

There has been a deliberate attack on John Quadrozzi, Jr.'s character which has also been appalling. We have known and worked with John for over 10 years. We know him to be an active Advocate for a cleaner environment, not an environmental criminal. Not only did he clean up his own property (which was the center of all negative activity in Red Hook in the 80's and 90's), he has always worked on improving and cleaning ALL of Red Hook. He has sponsored greening initiatives, fought illegal dumping with a personal partnership with the NYC Department of Sanitation Police, and insists on impeccable cleanliness from his tenants at the Terminal. John has Always delivered on his word including delivering turkeys on thanksgiving, presents on Christmas, horses on National Night Out Against Crime, basketballs and books for Summer programs, and countless other acts of charity and partnership. John always hires Red Hook Houses residents, and prides himself on providing opportunities for people to better their lives through honest work. We look forward to working with Mr. Quadrozzi on this exciting project and know that you can have full confidence that he will continue his stellar record of being a great neighbor and friend to all of Red Hook's residents.

It is of NO small significance that our groups have joined as one. We, as a group, represent Red Hook Houses. We all live here, or have spent the vast majority of our lives here. Red Hook East and West Resident Association Officers were elected by Red Hook Houses residents to represent them. Red Hook Rise has held the confidence of thousands of young people and their families for well over a decade now, touching countless lives through youth programming, and through fighting for local employment opportunities for residents. We represent Red Hook Houses, and we support the Red Hook Option.

Thank you Mr. Tsiamis for proposing the Red Hook Option. Rest assured you did the right thing. We will stand with you, Natalie and Brian proudly. We expect to accomplish many great things, together.

Yours Truly,

Drinking water concerns

Sabine Aronowsky to: Region2 GowanusCanalComments 04/27/2013 08:41 PM

History: This message has been forwarded.

Hello,

Given that the levels of bacterial and industrial contamination are so high in the Gowanus canal, have there been or can there be any testing by the EPA into nearby residents and businesses tap water for cross-contamination?

I am a Gowanus resident, and a renter, and I have tested my own tap water with the hardware store water testing kits and my building tap water has tested high for pesticides and bacteria.

Please test local residents, especially renters, tap water and the nearby public water supply system around the Gowanus Canal Pump station, former MGP sites and major CSO outfalls, to ensure Is there is no potential exposure pathway being generated from local contaminated groundwater impacting our drinking water supply.

Thank you.

History: This message has been replied to.

Dear Mr. Tsiamis,
The EPA has done an amazing job advocating a comprehensive clean up for the Gowanus Canal. I have been very impressed to see the remedy of the CSOs in your plan. I support the current EPA Plan wholeheartedly.
Sincerely,
Susan Handler

New York, NY 10007-1866

April 27, 2013

Dear Christos,

I would like to thank the EPA Region 2 team for their hard work and dedication over the past four years in support of the Superfund listing, Remedial Investigation, Feasibility Study, and Proposed Remedial Action Plan (PRAP) for the cleanup of the Gowanus Canal. I sincerely appreciate the EPA's efforts to openly communicate and support dialogue with all the varied community based organizations', groups, and concerned residents and businesses in Southwest Brooklyn and beyond. Thank you to Region 2 for helping to restore some of the broken public trust amongst our community regarding remediation of this longtime highly polluted waterway and I support the PRAP in addressing this overdue cleanup.

My comments regarding this cleanup are driven from multiple community based perspectives and active participation in this process. I am a videographer who produces original content, independent media and television shows for my own media program called Freddy's Brooklyn Roundhouse (FBR), which broadcasts on Brooklyn Community Access Television (BCAT) and on Youtube. In 2009, I produced several videos featuring Friends and Residents of Greater Gowanus (FROGG) efforts to bring attention to the issue of the Gowanus Canal cleanup in support of the EPA Superfund designation. Walter Mugdan, the EPA Region 2 Director of the Division of Environmental Planning

and Protection (DEPP), credited FROGG's video campaign with generating public attention and support for the 2010 National Priority Listing (NPL). A Brooklyn College professor teaching and researching Environmental Sciences commented that "Superfund Gowanus" was one of the best persuasive videos he and his class had seen.

When the EPA's Superfund designation of the Gowanus Canal became official, I joined the EPA CAG (Community Advisory Group) as an at-large member to discuss pertinent issues in this EPA cleanup process and to offer my media services to continue to bring attention to this very necessary cleanup. Beyond the over 150 years of contaminated industrial wastes deposited at the bottom of the canal, I became quite distressed to learn that three former Manufactured Gas Plant (MGP) sites were still discharging toxics into the Canal, and that close to 500 million gallons of Combined Sewer Overflows, CSO's, were also entering the Canal annually.

As the EPA Gowanus Canal Remedial Investigation results were being released and discussed, I entered school to obtain my Masters in Public Administration and Nonprofit Management from CUNY Baruch. I spent time in academic circles researching and discussing Superfund and the Clean Water Act, water quality standards and classifications, the State Pollutant Discharge Elimination System, combined sewer systems, and how the Gowanus Canal cleanup exemplifies a paradox of loopholes where the City, State and Federal accountability for the level of high concentrations of bacteria, pathogens and toxics that pose significant public health risks can continue almost unabated despite decades of environmental protections and regulations in place.

At Baruch, I also focused on community development issues and environmental justice concerns specific to the demographic populations that live in the Gowanus Canal area. As this cleanup proceeds I believe a new Environmental Justice assessment for Red Hook and Gowanus will be necessary. I think Communities of Concern should be reevaluated in the overall Record of Decision (ROD) to ensure a Community Involvement Plan (CIP) is specifically geared towards the needs and input from those communities. Additional Communities of Concern that should be assessed include the large Hispanic and Latino populations in the Gowanus area that do not speak English that remain uninformed and uninvolved in these cleanup processes due to language barrier constraints. The EPA should assess the need for other EPA programs to take action or provide information to modify implementation of

the selected remedy to minimize any disproportionately high and adverse environmental burdens impacting any potential EJ community.

Southwest Brooklyn also represents my hometown. I was born and raised in Park Slope, and my stepfather has had a stained glass studio business in Gowanus for over 30 years. My mother and stepfather have lived for the same amount of time in Gowanus, right near the former Metropolitan MGP site. I am also the mother of a 21 month old toddler and now a Gowanus resident for 9 years, who lives within 4 blocks of the head of the Canal on Butler Street, which is also near the former Fulton MGP site. As such, my family and I are very personally invested in making sure this cleanup happens in a coordinated and timely manner that safeguards our health, minimizes impacts to our daily lives and business and also benefits and considers those of us that presently live here along the polluted waterway.

As these cleanups proceed the residents that live here must be involved in the planning discussions and resource allocation decisions for the future of our neighborhoods, otherwise we suffer the health risks and cleanup burdens without any guarantees of benefits. I am including a demographic breakdown of the Gowanus area produced by the CAG Outreach and Engagement Committee to show some of the 2011 ACS census information that highlights the demographic details of the communities that live in the census tracks immediately surrounding the canal. Around 80% of the populations, in the immediate canal area are renters; about 40% of the total population in the Gowanus Canal area speaks English less than very well. Simply put, issues of affordable housing and displacement, along with communication, will grow for the majority of the populations in the area, alongside this cleanup. I want my family and neighbors to be able to afford to live and work here once this cleanup is complete and to understand that there are real opportunities for participation in planning discussions and resource allocation decisions for the future of our neighborhoods happening now. I believe there should be some Federal monitoring of the demographic shifts that will take place along side this cleanup and support for a broader community involvement plan that can focus on these issues.

At the beginning of this year, when the CAG charter decreed that there could be no dual representation amongst organizations on the CAG, I transitioned from an at-large member to an organizational representative for Friends of Douglass Greene Park (FODGP). FODGP has found itself in the difficult place of

being an advocate for the Superfund cleanup while still learning the level of detail in which the Thomas Greene Park and Douglass and Degraw Pool could be impacted by this cleanup.

It is therefore from all these personal and community based perspectives that my comments to the EPA Superfund are based. I also just recently began employment with the Fifth Avenue Committee (FAC), a nonprofit community development corporation that is also involved on the CAG and with community development throughout South Brooklyn. I hope the EPA Region 2 and whomever else decides to read these comments will strongly consider these comments, not just from a single individual perspective, but from a CAG member who has tried to be as informed as possible on the PRAP, while authentically attempting to engage and solicit input from all the varied constituencies and interests in this cleanup process.

In regards to the PRAP's proposed remediation's and controls, my main comments ask the EPA to consider the following within the forthcoming Record of Decision:

1) Incorporate the entire upland area of the former Fulton MGP site within the EPA Superfund cleanup.

I support FODGP's position that a Record of Decision (ROD) incorporating the entire upland area of the former Fulton MGP site within the EPA Superfund cleanup will provide for the best coordination, organization, planning and design possible to minimize disruption and impacts to our community. I agree that not coordinating these cleanups continues to make the community pay and will continue to leave too much uncertainty regarding the fate of the Thomas Greene Park and Douglass and Degraw Pool. Without specific timelines, clear communication, meaningful community participation and involvement, and clarification on what specific remedies and risks comprise the former Fulton MGP cleanup in conjunction with the Canal RTA1 site, the vast community of residents that use these public resources face too many uncertainties and possible disruptions that will make any further Park designs and planning impossible.

The Thomas Greene Park and Double D Pool was formerly the site of the Fulton Manufactured Gas Plant (MGP), which National Grid and the City and State are now responsible for investigating and remediating. National Grid has a website,

www.fultonmgpsite.com/, which is supposed to provide regular site news and updates, however updates have not been posted since September 2012. National Grid is also required by 6 NYCRR Part 375-1.10 NYSDEC to review and update their Citizen Participation Plan (CPP) to account for significant changes in the Fulton Municipal MGP Project's remedial program. The CPP posted online is over 5 years old and dates to when KeySpan was the responsible party for the site.

National Grid's Remedial Investigation (RI) for the former Fulton MGP site was released in July 2012 and provides detailed results of their investigations into the eight parcels of land which comprise the site. The Park and Pool comprise parcel number two, and directly beneath the Pool are old petroleum tanks from former operations. According to National Grid's summary of their RI, visible coal tar and petroleum impacts were found in soils beneath the site and in areas to the west bordering on the Canal. Subsurface migration of coal tar wastes is also so problematic that it has necessitated expedited design of an Interim Remedial Measure, consisting of a cut off wall to prevent migrating contamination from entering the Canal in support of the Superfund cleanup. A Feasibility Study (FS) to address the contamination impacts as necessary has yet to be released.

Some of the contaminants found in soil and sediment testing from National Grid's RI include benzene, toluene, ethylbenzene, and xylenes (known as BTEX) and polycyclic aromatic hydrocarbons (known as PAHs). BTEX compounds are some of the volatile organic compounds (VOCs) found in petroleum derivatives such as petrol (gasoline). Toluene, ethylbenzene, and xylenes have harmful effects on the central nervous system. PAH compounds are known carcinogens and mutagens and are also responsible for developmental toxicity, resulting in birth defects and adverse impacts to non-human life forms. When the EPA discusses these coal tar derivatives in its proposed cleanup plan, they are referred to as NAPL, non-aqueous phase liquid.

According to National Grid there is supposedly "no risk of exposure" to MGP-related contaminants at this site, unless one digs about five to seven feet down. There is also a concrete barrier at parcel number two, which is supposed to provide protection to the user's onsite. According to the EPA and the NYS Superfund program, source removal or control for all remedies, will be necessary.

The former Fulton MGP site will require close coordination and oversight between EPA, DEC and National Grid in order to prevent NAPL migration from impacting the remedy. Furthermore, EPA has identified the Double D pool area as a potential location for a 2 to 17 million gallon in line CSO storage tank for outfall RH-034 to address the over 121 million gallons of raw sewage that are estimated to enter the Canal annually from this one outfall alone, and this could impact the integrity of the remedy.

The forthcoming Record of Decision (ROD) must reflect a comprehensive cleanup of the canal and the upland former Fulton MGP area, where all agencies and parties involved work together in a much more coordinated and timely fashion. The former Fulton MGP upland area does comprise RTA1, the first part of the Canal which will be remediated, and this will most likely set the timeline and pace for the subsequent parts of this cleanup. Furthermore, any failure to achieve the Interim Remedial Measure cut off wall would result in recontamination of the canal sediments and could potentially significantly delay the cleanup. The design and location of this interim cut off wall have yet to be presented to the public, so not only is the coordination of this remedy in question, but understanding the impacts of where this NAPL could possibly migrate to if it is prevented from entering the Canal create additional concerns for the safety and health of nearby residents, businesses and park and pool users.

More broadly, in terms of communication and transparency with residents and organizations like the Gowanus Canal Community Advisory Group (CAG); National Grid and the DEC and DEP have not responded to community concerns or public meeting requests, nor followed even the most basic parts of the Citizen Participation Plan as prescribed on the National Grid former Fulton MGP website. While National Grid continues to insist that the Park and Pool are safe, their explanations at times seem to be at odds with the EPA in terms of technical assessment, like NAPL migration for instance, where National Grid insists that coal tar waste only migrates down, yet the EPA's presentations communicate that NAPL can migrate down and up, and very importantly be transported via groundwater, not just into the Canal itself, but depositing around the neighborhood, particularly in the former MGP vicinity.

National Grid and the City of New York are potentially responsible parties (PRP's) and the EPA should use its Superfund authority to enforce the entire

upland area cleanup in a coordinated fashion that will not cause multiple disruptions to the community and its resources. These are just some of the reasons why I believe the EPA should use its vast compliance and enforcement authority under CERCLA to include the former Fulton MGP site as part of the remedy. I believe this to be the best way to guarantee source control remediation and proper agency and responsible party alignment that will ensure the protectiveness of the preferred remedy while safeguarding our residents and concerns over our community resources.

2) Conduct a thorough review of the Remedial Investigation results at the former Fulton MGP site and address new potential exposure pathways with a human health risk assessment.

For the safety of the users of the Park and Pool, and residents in the nearby vicinity, the EPA should perform a thorough inspection of National Grid's findings regarding risks of exposure at all parcels of the former Fulton MGP. In particular, at parcel 2, testing should be done by the EPA on the concrete barrier and the material of the two swimming pools onsite (the toddler pool and the regular pool) that tests for BTEX, PAH's, VOC's and NAPL. The EPA should determine if there is any issue with the porosity of these materials that could facilitate exposure pathways for these toxics? Regular testing for these same chemicals should also be performed regularly for the Pool water and the drinking and shower water at the Double D Pool facility. Finally, given the groundwater and storm water runoff contamination concerns, additional groundwater testing should be conducted by the EPA onsite after wet weather events.

The Thomas Greene Park Playground that is part of parcel number 2 was just recently redesigned and reopened this March. Over 900K in discretionary funding from City Council members was spent by NYC Parks to renovate this playground. The land was not remediated before the new playground went in. This new playground has large tree pits with a lot of exposed dirt, and a new children's sprinkler fountain, both of which should be evaluated as new dirt and groundwater sources onsite. The playground is now experiencing heavy use from neighborhood residents and the sprinkler will surely be a very big draw for young children this summer. There are very low tree guards delineating the playground from the tree pits, but the reality is that children love to play with dirt and very young children will be digging in this dirt, and inadvertently or sometimes deliberately ingesting it. The EPA should also evaluate that these new Park designs and amenities to ensure that they do not create exposure

pathways that could pose health risks to the young children and families recreating onsite.

3) **Ensure that if a combined sewer overflow (CSO) retention tank is ultimately placed in Thomas Greene Park under the D&D pool, that the pool and any park must be replaced, at the cost of the responsible party; the design of the replacement pool and/or park must meaningfully involve the local community and, finally, that interim pool and park uses must be provided for the entire time that there is disruption to this critical community resource.**

As part of the proposed cleanup plan, EPA is proposing potentially impacting the Double D pool area to excavate and build a 2 to 17 million gallon raw sewage storage tank. The plan obfuscates the issue in a way that residents reading the PRAP would not even realize that there is proposed threat to the pool in the proposed plan. It is for this reason that a petition campaign was started very recently to inform users of the Pool about the potential I disruption to this valuable community resource.

In less than three weeks since the petition was launched, over 1,000 petition signatures gathered online and offline in support of this cleanup, but against the disabling of the Double D pool (www.change.org/petitions/epa-make-the-polluters-pay-not-our-community-save-the-double-d-pool). Because the EPA understands community acceptance to be very integral to the proposed cleanup plan, the EPA should read the hundreds of petition comments that address the communities concerns over this potential loss and demonstrate the importance of this community resource. To be clear these signatures represent that the community of residents who use this facility do not want a raw sewage tank to be built beneath the pool.

While a lot of questions were raised with the EPA and the PRP's in regards to the potential impacts to the community as to the proposed siting of the CSO retention tank for outfall RH-034, not enough information and consideration was provided in support of this proposed location. Should the EPA, DEC and DEP be willing to discuss this proposal further with the community, in the context of the overall cleanup, and provide compensation and guarantees to the community at large, with respect to the pool, then perhaps there could be

support, but at this time residents have resoundingly said NO to a raw sewage tank beneath the Double D pool.

As part of that discussion, communities that use this Park and Pool also deserve clear communication on what a proposed raw sewage retention tank at this location would mean for our community. It is important to see specific health risk assessments and designs that demonstrate how this CSO remedy would be protective of human health, along with guarantees that there would be no disruption to the facilities and services provided. Furthermore, why aren't other locations, closer to the CSO outfall (RH-034), being considered either for the siting of the raw sewage tank or as a site for relocation of the Pool and services? The empty Con-Ed lot on Nevins and Butler, across the street from the Pump station and the Flushing tunnel is a prime example. There are also numerous parcels of land for sale in the immediate vicinity and perhaps this might also be worthy of an eminent domain proposal.

The pool primarily serves nearby public housing and neighborhood residents during the summer season, and programs provided at the Pool facility include the School Food Lunch program, which serves free breakfast and lunch while school is out, and the Learn to Swim program, which provides free swimming lessons for children. The pool also serves as a cooling center during heat waves. There is also a second pool, uniquely designed for toddlers, which some of the youngest neighborhood residents enjoy and a handicapped lift which services the main pool to allow for special needs access.

Should the ROD move forward with the retention tank location as put forward in the PRAP, what would be the exact timeline that this resource would be disabled? What compensation will be provided in the ROD for a community losing a recreational open space facility and how would the EPA enforce City open space standards for an already underserved part of the Gowanus community? New York City Planning Standards outlined in the 2010 City Environmental Quality Review Technical Manual encourage a standard of 2.5 acres of open space within half a mile for every 1000 residents. EPA and DEP will have to address what access to Parks is presently provided for in Gowanus compared with the standard requirements. Estimates from a CAG member have put forth that Northern Gowanus residents only have access to roughly 7 acres of Parks instead of the 70 acres the standard requires.

While there is large community support for a comprehensive Superfund cleanup of the Gowanus Canal that includes addressing raw sewage overflows, Superfund must follow its own principles and make the polluters pay, not our community. Furthermore, to prevent the denial of, reduction in, or significant delay in the receipt of benefits by minority and low-income populations would disproportionately affect communities of color and violate the U.S. EPA's environmental justice commitments.

Presently there is no specific time frame or incentives being offered in the proposed cleanup plan to the community in the regards to the potential closure of the Double D pool. It is also unclear at this time if there may be additional disruptions to the Thomas Greene Park. Also, due to the aforementioned other reasons regarding why the land in parcel two may still need to be remediated, even without the placement of the retention tank beneath the Double D Pool, it is imperative that EPA carefully consider these same reasons in their ROD before any disabling or disruption of these community resources were to occur. The ROD should include enforceable measures to provide for temporary and permanent relocation of services at a nearby location as needed.

4) Incorporate climate change impacts and post Sandy mitigation measures in the ROD.

Increased flooding from the canal poses a health threat to the all residents who live in the flood zone. Increasing large scale development in the area and surrounding neighborhoods, which also contribute wastewater to the Gowanus watershed, combined with predicted average annual rainfall increases and sea level rise, all contribute to the urgency of the need to address the CSO and toxic sediments cleanups in a timely manner.

When the Gowanus Canal overflowed during Superstorm Sandy, the heavily polluted saltwater corroded two manholes covers and flooded basements in the NYCHA Gowanus Houses, damaging electrical lines and fuses. As a result the Gowanus Houses were left without power for 10 days after Sandy, and forgotten by most everyone while all the focus went to waterfront areas. A broken water main along Hoyt Street, also left thousands of residents in eight of 14 buildings there without access to clean water.

In the Post-Sandy landscape it is important to consider the updated flood hazard risks. Residents remain under direct threat of exposure to the combined

problems of known toxic endocrine disruptors and raw sewage exposure during any large flooding episodes. Annual rainfall and intensity in the area is increasing, presently the NYC average annual rainfall is 45 inches, while CSO abatement plans are based on 38 inches a year, and according to NYC's 2008 Sustainable storm water plan recent annual rainfall records were as high as 65 inches a year. The Gowanus community sits in the 100 year flood plain and is classified as a Zone A area by the Office of Emergency Management (OEM), facing the highest risk of flooding from coastal storms, hurricanes and storm surges. According to NYC's 2008 Sustainable storm water plan, moderate predictions for sea level rises in the city are between 4 to 7 inches by the 2020's, so the time for enforceable action for the protection of Gowanus residents presents a strong case for increased compliance and enforcement measures specific to the Clean Water Act.

As previously commented at recent EPA public meetings, the ROD should include a post Sandy assessment on the sustainability of the remedial design. Superstorm wave velocities and tidal effects on dredging / flooding should be addressed and design protections should be incorporated. Possible effects to the "armor" isolation layers from superstorm effects should also be considered. Overall, strategic flood plain management needs to designed into the ROD and the EPA should provide estimates on how much the remedy will be predicted to lower the canal water depths and incorporate as much flood protection design as the remedies will allow. For these reasons I support opening up the buried basins at First and Fifth Street to help with flood direction issues and planning.

5) Conduct a new Environmental Justice Assessment; reevaluate Communities of Concern in the Gowanus area based on the Record of Decision (ROD) and ensure a Community Involvement Plan (CIP) is specifically geared towards the needs and input from those communities.

In Gowanus, two large NYCHA residential developments are located as close as 500 feet from the head of Canal. Wyckoff Gardens contains approximately 530 apartments in three, 21-story buildings located north and east of the head of the Canal. The Gowanus Houses, north and west of the Canal, contains over 1,000 apartments in a 12.57-acre complex comprising 14 buildings. Finally, a third smaller NYCHA property, the Warren Street Houses, at 572-574 Warren Street, is located across 3rd avenue from Wyckoff Gardens and comprises 200 apartments. Estimates number around 4,000 official residents in the three

Gowanus NYCHA properties in the footprint of the Canal, however it may be that these numbers are low because of the overcrowding that typically takes place in low-income living situations. Furthermore, the Red Hook Houses are Brooklyn's largest public housing complex where more than 6,000 people live. The Red Hook Houses are situated at the mouth of the canal, and nearby the proposed location of the proposed Confined Disposal Facility (CDF).

I believe the EPA should conduct a new EJ analysis that includes a preliminary burden analysis with respect to the raw sewage tank and disruption to the Park and Pool services, as well as the CDF, and the environmental burdens that would result to the particular Communities of Concern (COC).

Beyond the NYCHA residents of Red Hook, Gowanus Houses, Wyckoff Gardens and the Warren Street Houses, additional COC's that should be assessed include the large Hispanic and Latino populations in the Gowanus area that do not speak English that remain uninformed and uninvolved in these cleanup processes due to language barrier constraints. The EPA should assess the need for other EPA programs to take action or provide information to modify implementation of the selected remedy to minimize any disproportionately high and adverse environmental burdens impacting any potential EJ community.

6) Continue to support the Gowanus Canal Community Advisory Group (CAG) and facilitation at the general and committee levels.

As mentioned previously, I am an organization representative on the CAG and I participate in the Outreach and Engagement (O&E) committee. The Gowanus Canal CAG is now the largest Superfund CAG in the nation and I believe that this is justified to adequately reflect the diversity of community interests regarding site cleanup and reuse. As a member of the O&E committee., I primarily view my role within the CAG to expand public participation and to the extent possible, to ensure that the membership of the CAG reflect the composition of the community near the site and the diversity of racial, ethnic, and economic interests in the community.

As part of the Superfund process, the EPA presented a choice of neutral facilitators, and Jeff Edelstein was selected as the Gowanus Canal CAG facilitator. The role of neutral facilitator has been a critical component to ensuring the equal opportunity for participation, process and dialogue amongst such a large group. Previously, the facilitator was engaged in all CAG meetings,

down to the Committee level, but has since scaled back his facilitation to General CAG meetings, at the request of the EPA.

I strongly support full CAG facilitation, down to the Committee level, to be supported by the EPA. The reasons for this are because historically, minorities have been absent from the rank and file membership of mainstream environmental associations, and the Gowanus Canal CAG is no exception. Compositionally, the CAG is primarily representative of Environmentalists and home owners, from the middle and upper class, geographically situated in Carroll Gardens. Ideologically, intentional or not, this creates barriers to more demographically representative and diverse participation. To engage more environmental justice communities and ensure meaningful public involvement from all segments of society impacted by the continuing phases of cleanup of the site, strong facilitation that promotes inclusivity and equal access and participation is needed.

7) Carefully review the potential siting of the CDF – disposal facility – in Red Hook and let the Red Hook Community decide.

Since the EPA has repeatedly stated that community acceptance would drive the remedy, treatment and disposal selection process, I do believe that in regard to the CDF proposal, the decision should be entirely up to the Red Hook Community.

As a CAG member who attended the meetings in Red Hook, I have definitely witnessed the vocal and contentious opposition to the construction of a CDF for beneficial use onsite at the privately-owned Gowanus Bay Terminal (GBX). With this in mind, I have also heard complaints from Red Hook Rises that encapsulate the crux of the argument that fair participation by all potentially affected communities in the treatment and disposal decision-making process has not been achieved.

Since the potential siting of the CDF pertains to the last part of the remedy, namely RTA3a and 3b, I believe there is enough time to postpone a specific decision on this remedy, while still moving forward with the ROD. In this manner there would be no delays in the forthcoming remedial designs for RTA1 and 2 and there would still be an opportunity for all concerned parties to meaningfully engage on this matter, hopefully, in a non confrontational setting.

From an Environmental Justice perspective, historically supporters of economic growth have taken advantage of environmentalists' neglect of minorities and at times they have convinced minority leaders looking to improve their communities that the economic benefits of industrial facility and the increase in the number of jobs are worth the health risks. Although, this may not be the situation in regards to the safety of the remediated sediments for the CDF, this certainly represented the overall opinion of some of the Red Hook community, as they galvanized around the "No Toxic Red Hook" campaign.

With this in mind I believe that any future remediation proposals in particular communities of concern should be as transparent as possible and engage from the onset Community Benefits Agreements that represent equitable distribution of the benefits, along with the community burdens of the cleanup.

For example, since close to 60% of the Red Hook population lives in public housing, and John Quadrozzi Jr. of GBX is only one person, delivering a result of the cleanup that only benefits Mr. Quadrozzi clearly would not represent equitable distribution of the benefits. If the EPA could first and foremost gain public acceptance that this process is safe, they could negotiate a MOU or establishment of Corporation to share ownership of the deep sea port that the CDF would facilitate being built, (reasons for this are the shore line is a public good and using the EPA to change the shoreline is an end run around public processes). Then perhaps the Red Hook residents might consider the proposal. Also, a promise of jobs is not assured and in my opinion, not a compelling enough community benefit to justify support. Community members might not have proper qualifications, and elderly or special needs populations could not be considered, plus community job numbers are usually lower than forecasted. While workforce development, through the JTI, should absolutely be an integral part of the Superfund cleanup and jobs should be written into a CBA, the best way to share the proceeds of any public good resulting from the EPA cleanup would be collaborative ownership and dividend payments associated with the public good.

8) RTA 1 and RTA 2 - Treatment and Disposal Options

Given the high level of toxicity in the sediments of RTA1 and RTA2, only options A, B or C, as laid out in the evaluation criteria of the PRAP, would prove a viable remedy in terms of long term effectiveness and

implementability. I support the selection of whichever of these three options gains widest community acceptance for overall sustainability.

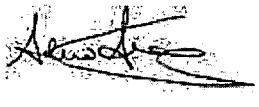
Since all of these treatment/disposal options include barging of the dredged sediment to a local, onsite dewatering and transfer facility, I believe the acquisition of critical parcels both for cleanup and dewatering staging operations should have been more directly addressed within the PRAP and must be clearly presented in the ROD.

9) Utilize Notify NYC procedures for public notification and Emergency Management.

Finally, I would like to see the ROD adopt the "Notify NYC" system to quickly notify the public of any potential health and safety concerns regarding the Gowanus Canal cleanup, including but not limited to, flooding, air quality, accidents and spills that may occur under any of the responsible parties or agencies involved in the cleanup.

Thank you for all your time and attention to these matters. I hope Region 2 recognizes the importance of their role in delivering a just, cooperative, enforceable and accountable ROD that will allow for the most protective and comprehensive cleanup moving forward. In line with the EPA's plans to address this cleanup of the toxic sediments and raw sewage in the canal and upland areas I look forward to the continued building momentum that will minimize impacts and maximize benefits for the communities that live, work and play in the area.

Sincerely,



Sabine Aronowsky

Re: *Civilian Environmental Corps (CEC) – The Brooklyn Brigade - and its Coalition Partner's Comments to EPA Gowanus Remediation Plan*

Dear Mr. Tsiamis:

On behalf of the Civilian Environmental Corps (CEC) – "the Brooklyn Brigade" - and our coalition partners, I submit the following comment letter concerning the remediation of the Gowanus Canal. The CEC, is a not-for-profit environmental organization formed by concerned civilian community members in response to the proposed remediation of the Gowanus Canal and the contributing upland sites.

The CEC has formed a coalition with other concerned groups such as the Gowanus Community Development Corp., numerous residents of the Gowanus, Wyckoff and Red Hook Public Housing Projects, numerous residents and property owners residing along the banks of the Gowanus Canal and the contributing upland sites and numerous individual residents and business owners within the broader neighborhoods that will be negatively impacted by the remediation if our concerns are confirmed.

Other individuals, community groups, business owners and organizations have expressed interest in joining this letter but have not had the opportunity to review its contents as of this date. It is anticipated that these groups will submit their own letters joining in this comment letter within the coming days

Our comments first focus on air pathway issues associated with the Gowanus Canal remediation as well as the issues associated with the treatment of the waste material at a proposed waste treatment facility we believe is planned for banks of the Red Hook shore in proximity to residents and businesses in Red Hook and Sunset Park.

If our concerns are not taken into account we fear that there will be disastrous and acute health impacts upon an unsuspecting community that has not been adequately informed of such risks.

We are also very concerned with the legal and technical responses/denials that have recently been made in connection with a similar ongoing, highly contentious Onandaga Lake remediation in upstate New York, in which there are issues and circumstances very similar to those surrounding the Gowanus Canal remediation. We strongly believe that the situation (as well as the legal/technical denials) taking place in the Onondaga Lake remediation is proof positive of what will happen if our concerns are not taken seriously here – except on a far greater scale.

There is a highly relevant pending lawsuit in connection with the Onondaga Lake remediation in which numerous people are suffering serious health effects. Media reports confirm that there is no doubt that people are getting sick in the Camillus community in a remediation that pales in scope, toxic acuity and urban density to the Gowanus area.

So far the responses and denials from responsible parties – including the very government agency charged with overseeing and protecting public health – has been inadequate and defensive at best.

Indeed, there has been virtually no expression of concern for the health of the community. The only expressed concern is supposedly meeting statutory requirements, the very purpose of which is to protect human health. We see the situation rapidly degenerating into litigation to mitigate liability – rather than protect human health and life – which is and should be the overarching purpose of any remediation and the applicable federal, state and local laws and regulations concerning same. If these don't achieve their only purpose, they are of little to no utility in our democratic society.

We hope to avoid this unnecessary dialogue by participating in the process. We believe there are easy, cost-effective solutions to all of our concerns – but given the large degree of skepticism and mistrust, our informed input to the process is essential.

The Onondaga Lake Remediation

On March 18, 2013, the Camillus Clean Air Coalition (CCAC) filed a Complaint seeking a temporary injunction against Honeywell International in connection with Honeywell's remediation of Onondaga Lake, a Superfund site near Syracuse, New York. The injunction seeks to stop the piping of highly contaminated, dredged lake-bottom sediments for treatment and disposal in the nearby Town of Camillus (**Exhibit A**).

The Complaint, based on numerous incidences of adverse health effects consistent with acute exposure to toxic airborne contaminants, cites an April 18 report prepared jointly for the Town of Camillus and CCAC by their consultant (**Exhibit B**). This report shows that air toxic concentrations are pervasive throughout the local community, far exceeding long-term and especially short-term safe levels.

The report also provides irrefutable proof that EPA's 2010 Supplemental Human Health Risk Assessment (HHRA) prepared at the request of Senator Charles Schumer and Congressman Daniel Maffei prior to remediation start-up, is severely flawed (**Exhibit C**). The HHRA erroneously concluded that residential risks associated with the treatment and disposal of the contaminated sediments in Camillus would be well within acceptable ranges when, as it would later be shown, quite the opposite was true. Still, the local community and elected officials, satisfied at the time with EPA's conclusions, offered no further

resistance to the dredged-sediment piping until residents began to suffer intense odors and symptoms of acute airborne exposure coinciding with remediation start-up last July.

One reason that EPA was asked to perform the HHRA is that an air pathway analysis (APA) was never performed for this remediation, even though: (a) detailed project planning documents specified an APA (**Exhibit C, Appendix C**); and (b) an APA is required under Superfund.

On April 4, Honeywell filed a Motion to Dismiss the CCAC Complaint (**Exhibit D**). In its Preliminary Statement, Honeywell argued that the Court is without subject matter jurisdiction to hear the CCAC claims, and that these claims must be dismissed pursuant to Federal Rule of Civil Procedure 12(b)(1). Honeywell argued that Congress has expressly removed jurisdiction from courts to hear such challenges prior to completion of the cleanup, owing to the serious impediment to cleaning up contaminated sites brought about by the "never-ending litigation by third parties challenging EPA's remedial decisions. . ." Honeywell further argued that such challenges must be raised during the Public Comment period. And therein is the Catch-22 for the Camillus residents. The Complaint is scheduled to be heard in U.S. District Court, Northern District of New York, on May 15.

The Gowanus Canal Remediation

CEC is fiercely committed that the situation occurring in Camillus is not repeated here in Brooklyn, especially since the Canal wastes are at least equally toxic and the residents are in much closer proximity to this hazardous toxic site.

The EPA has failed to perform an APA for the Gowanus Canal Remediation

Based on extensive review of available project documents, be advised that CEC hereby asserts that: (a) EPA has failed to perform an APA for the Gowanus Canal Remediation; (b) the selected remedy for this site (and the upland sites) is, therefore, not in accordance with the law; and (c) if an APA were to be performed, it would clearly show unacceptable risks to nearby residents owing to very high predicted levels of airborne exposure.

A Waste Treatment Facility Poses a Threat to the Residents of Red Hook

Although contradictory and confusing information has been disseminated by the EPA with respect to a planned construction of a waste treatment/sludge dewatering facility (the "Proposed Facility") on the banks of the shore of Red Hook, we are against such construction for numerous reasons: (a) the Proposed Facility would be at great risk of spreading contaminated sludge through the streets of Red Hook in the event of a storm surge like the one that has occurred in Red Hook during Hurricane Sandy; and (b) it is not clear what impact the dewatering of contaminated material will have on the air quality, because, as with the Gowanus remediation itself, no APA has been performed in connection with such Proposed Facility.

Risks to Human Life and Health in the Adjoining Communities Are Paramount

The potential disastrous effect of proceeding with a remediation and treatment of the Gowanus Canal site are enormous – not only to the immediately communities of the Gowanus basin, Red Hook, Carroll Gardens, Cobble Hill, Park Slope and Sunset Park – but also to any community within a reasonable up or downwind distance of the contaminants that may be released during the process. We recall with distress the distance that particulate matter and gaseous vapors travelled in the wake of 911 – reaching distances as far as Staten Island and Coney Island and farther. Unlike Camillus, Brooklyn is a dense urban environment with nearly three million residents all easily within range of a release of a

contaminated release from Gowanus. The risk of exposure warrants extreme caution, concern and scrutiny, and every potentially affected individual has a right to protect the health of their family and community.

The Legal and Technical Responses to the Camillus' Complaint are Inadequate and Similar Responses Will Not Be Accepted by the Communities Affected Here

As the Complaint alleges, numerous people are suffering serious physical effects from a poorly planned and executed cleanup of the same contaminants in a far less contaminated site in a far less densely populated area.

The Motion to Dismiss the Complaint interposed by Honeywell can be summed up as: (a) we did everything the EPA required; and (b) Federal environmental law limits and actually prohibits the federal courts from exercising jurisdiction once a cleanup of superfund site is already underway. This position is deeply troubling and will not be accepted by families who experience serious health effects like those currently impacting the Camillus' cleanup area.

Similarly, the New York State Department of Environmental Conservation (the "DEC"), has submitted a response to the Air Exposure Study that the Town of Camillus commissioned **(Exhibit B)** that consists of meritless denials, demurrer's and mischaracterizations of fact in response thereto. A copy of the DEC's Response is attached hereto as **Exhibit E.** Nowhere in the DEC's Response is any hint at concern or sensitivity to the legitimate health concerns raised in the Air Exposure Study and the Complaint. This is simply government at its insensitive worst and it will not be tolerated by the CEC and its coalition partners in connection with the Gowanus Remediation.

Proven Solutions Exist

The CEC has identified some extremely cost-effective and technically persuasive approaches to the remediation that we would like to share with appropriate EPA personnel at the earliest possible date. The CEC has consulted with numerous domestic and international experts in a variety of highly relevant industries and believe that there are solutions that can minimize the potential risks to public health and actually reduce the overall time and cost of the remediation.

The CEC and its partners support the Gowanus remediation and commend the EPA for its hard work. But we believe that the community has a right to raise its concerns, to consult with proven experts for a second and third opinion, and to have its suggestions taken into account in solving what we believe to be very soluble concerns. We therefore implore EPA to perform an APA and, based on its results, re-evaluate the selected remedy for the remediation of the Gowanus Canal with our input.

Thank you for the opportunity to submit these comments.

Kristian Karl Larsen, Esq.

Complete cleanup of Gowanus desperately needed

Jessica Weiss to: Region2 GowanusCanalComments 04/27/2013 09:51 PM

Dear EPA-

As a home owner in Brooklyn living one block from the Gowanus Canal I support a comprehensive clean up of the Canal with the reduction of Combined Sewer Overflows into the Canal.

Thank you.

Jessica Weiss
374 Bond Street
Brooklyn, NY 11231

Comments from Victoria Hagman - CAG member and Red Hook resident

Victoria Hagman to: Region2 GowanusCanalComments 04/27/2013 10:07 PM
Please respond to victoria.hagman

Dear EPA,
Thank you for the time and energy you have invested in the clean up of the Gowanus Canal.
Recommendations:
- the 5th street basin should be included in the clean up
- I support the CDF and dewatering facility being located in Red Hook
- the EPA should mandate that with any addition of new housing in the area that those new developments not add to to the cso over flows and that waste should be handled on site and not contribute to the gowanus canal cso pollution.
- new developments should take extensive flood precautions that boarder the canal

Thanks you
Victoria Hagman

Re: Gowanus Canal Superfund Proposed Plan
Response to EPA Region 2 Proposed Remedial Action Plan (PRAP)

Dear Christos:

Thank you and the entire Region 2 Gowanus Canal Superfund Team for the opportunity to comment on the Proposed Remedial Action Plan (PRAP) for the Canal Cleanup.

As you know, Fifth Avenue Committee (FAC) is a 35 year old nonprofit comprehensive community development corporation in South Brooklyn that advances economic and social justice by building vibrant, diverse communities where residents have genuine opportunities to achieve their goals as well as the power to shape the community's future.
FAC is a nationally recognized nonprofit community development corporation formed in 1978 that works to transform the lives of over 5,500 low and moderate income New Yorkers annually so that we can all live and work with dignity and respect while making our community more equitable, sustainable, inclusive and just.

To achieve our mission, FAC develops and manages affordable housing and community facilities, creates economic opportunities and ensures access to economic stability, organizes residents and workers, offers student-centered adult education and combats displacement caused by gentrification. FAC has built over 800 units of affordable housing in neighborhoods surrounding the Gowanus Canal; built Brooklyn's largest LEED Gold affordable housing building and New York State's first LEED Platinum supportive housing project and remediated a brownfield site in the process.
As you know, FAC was also designated with our three partners, Hudson Companies, Jonathan Rose Companies and the Bluestone Organization, to develop Gowanus Green on the Public Place site along the Canal. Gowanus Green will create over 700 units of much needed housing, 70% of which will be subsidized and affordable to families at a range of incomes and includes plans for significant public open space. This *LEED neighborhood* development will help to fulfill some of the overwhelming demand for affordable, mixed income housing and open space in an environmentally sustainable manner. Finally, FAC will be responsible for the marketing and lease up of the affordable housing at the Lightstone project, also along the Gowanus Canal.

FAC's involvement with the Gowanus Canal and surrounding area dates back more than 20 years. FAC's main office is in Gowanus on the same block as part of the former Fulton MGP site and over

150 of the 600 units of affordable housing that we manage are just blocks from the Gowanus Canal. We've been an active participant in the Community Advisory Group (CAG) and have been active in both the CAG Outreach and Engagement and Real Estate Committees. FAC has been engaged with its own constituencies to ensure that local residents who will be directly impacted by the cleanup have equal opportunity and access to information about the Superfund and NYS DEC public processes happening locally and the opportunity to participate in the planning discussions and processes involving the future of our neighborhood.

FAC supports the EPA's overall remediation plan for the Gowanus Canal that includes removal and capping of toxic sediments within the Canal while addressing the upland and CSO discharges into the Canal.

FAC would like to thank the EPA Gowanus team at Region 2 for their leadership, transparency, accessibility, timeliness and their ability to listen to the many varied concerns, wants, desires and needs of the greater Gowanus community. FAC supports the overall PRAP vision to provide a coordinated and comprehensive clean up that includes the removal and capping of toxic sediments within the Canal while also addressing the upland and combined sewer overflow (CSO) discharges into the Canal.

FAC does want to share some additional, overlapping concerns and areas of focus that we believe the EPA should turn their attention to as the ROD is finalized and the next phases of the Canal cleanup are undertaken. Specifically;

Minimize impacts and maximize benefits especially for low and moderate income residents of color immediately surrounding the Gowanus Canal, many of who have been living with the Canal's impacts for generations

In line with FAC's mission, FAC wants to ensure that the Gowanus Canal Superfund cleanup will minimize impacts and maximize benefits for the surrounding communities, most especially for local low and moderate income residents, the majority of whom are Latino and African American, who have been living with the effects of the Canal for generations. Many FAC participants and residents in the area have lived with the foul odor and other impacts of the Canal and the surrounding area's lack of sewer infrastructure for generations. Yet it appears that just as government is finally turning its attention to the community's long-standing environmental issues, the displacement pressures for long-time mostly poor and working class residents are at an all time high.

Due to these displacement pressures, there will likely continue to be significant changes in the racial, ethnic and economic make-up of the area that will disadvantage low and moderate income residents from enjoying the benefits of a clean Gowanus Canal. Since a delayed cleanup could disproportionately disadvantage these communities, we ask that the EPA do everything within its CERCLA authority to expedite a coordinated cleanup for nearby community residents, and to ensure the full and fair participation by all potentially affected communities in the ongoing decision-making processes that will occur as the next phases unfold.

FAC views the Gowanus and Red Hook communities as Environmental Justice (EJ) communities, and requests both that the EPA's Gowanus Canal EJ Assessment and Community Involvement Plan (CIP) be shared formally with the CAG (specifically the Outreach and Engagement Committee) prior to the Record of Decision (ROD) being finalized to ensure the current and upcoming community needs are addressed..

As the EPA knows, approximately 75% of Red Hook's population lives in Red Hook East and West and the median income in the NYCHA properties, according to recent US Census data, is less than $20,000 annually for a family of four and the unemployment rate is more than double the national average. Red Hook East and West are the 2nd largest NYCHA developments in all of New York City and the largest in Brooklyn with a population of nearly 7,000 residents. In Gowanus, two large public housing developments are located as close as 500 feet from the head of Canal. Wyckoff Gardens contains approximately 530 apartments in two, 21-story buildings home to over 1,200 residents. The Gowanus Houses, north and west of the Canal, has a population of just less than 3,000 residents in 14 buildings. Finally, a third smaller NYCHA property, the Warren Street Houses, at 572-574 Warren Street, is located across 3rd avenue from Wyckoff Gardens and comprises 200 apartments. Estimates number around 4,000 official residents in the three Gowanus NYCHA properties adjacent to the Canal, however, based on reports, these numbers are low compared with unofficial residents. Finally, Sunset Park, though not immediately adjacent to the Canal may be impacted by the cleanup if dewatering is sited there. Sunset Park is a working class immigrant community home to New York's largest Mexican-American population, third largest Chinese population as well as a large Arab population. Additionally, there is a large Latino, Spanish dominate population that lives in the areas adjacent to the Canal that would benefit from additional outreach and engagement.

The EPA should consider updating its EJ Assessment and CIP as part of the ROD to ensure that a preliminary burden analysis is done that takes into account the impact of the retention tank(s) as well as the possible Confined Disposal Facility (CDF) or dewatering in Red Hook or Sunset Park, and the environmental burdens that could result to these particular communities.

The EPA should assess the need for other EPA programs to take action or provide information to modify implementation of the selected remedy to minimize any disproportionately high and adverse environmental burdens impacting any potential EJ community.

Leverage the approximate $500m investment in cleaning up the Canal by PRP's to benefit local low and moderate income residents with barriers to employment.

FAC believes the EPA's Gowanus Canal cleanup plan should specifically commit to this goal through its Superfund Job Training Initiative (SJTI).

Fifth Avenue Committee and its workforce development affiliate, Brooklyn Workforce Innovations (BWI) and its temporary staffing company, First Source Staffing, together placed over 1,100 individuals with barriers to employment into decent jobs in the last year alone. BWI trains and places low and moderate income individuals through 6 sector based training programs including our

Red Hook on the Road commercial drivers license training program, *Brooklyn Woods* woodworking training program , *Brooklyn Networks* cable installation training program, *Made in New York* TV and Film Production Assistant Training program and *NYCHA Academy* which trains and places public housing residents into caretaker and pest control positions. Our sector based training programs consistently have the highest graduation and job placement rates in New York City.

Local low and moderate income residents have actually been harmed as a result of the recent private investment in the area due to increased gentrification and displacement pressures. It is imperative that the $500m invested to clean-up the Gowanus Canal, which will unlock tremendous land value and lead to unprecedented displacement pressures, results in some direct benefit to local low and moderate income residents.

Enforce the most comprehensive, coordinated and timely cleanup of the Gowanus Canal Possible

Not only does FAC serve a diverse constituency, and provide comprehensive community development programs in the greater Gowanus Canal area, but as was mentioned, our offices are also located a mere two blocks away from the northern end of the Canal, where the dredging cleanup work will begin and we manage over 150 units of affordable housing within blocks of the Canal and our affordable housing pipeline includes an additional 600+ units of affordable housing immediately adjacent to the Gowanus Canal

Thousands of program participants, tenants in FAC managed properties and future residents of affordable housing projects FAC is involved in are relying on the most comprehensive, coordinated and timely cleanup of the Gowanus Canal possible. As you know, the cleanup of the Gowanus Canal though overseen by US EPA involves three levels of government and a number of responsible parties. Any one of these parties could contribute to a delay or issue which could impact on the surrounding communities in unacceptable ways including leading to a delay in the provision of much needed affordable housing or access to public open space at the future Gowanus Green project on the Public Place site.

FAC believes that the forthcoming ROD must reflect a comprehensive cleanup of the Canal and the upland areas where all agencies and parties involved work together in a coordinated and timely fashion. As is understood by FAC at this time, the proposed cleanup plan work to be conducted in the northern portion of the Canal alone would comprise dredging, capping and dewatering (EPA), along with a retaining wall to be built (National Grid / DEC), and the proposed retention tank (DEP), as well as ongoing work to the Flushing Tunnel and Pump Station (DEP), plus still to be determined further excavation and removal of NAPL that would need to take place on the former Fulton MGP site (National Grid / DEC) .

This work comprises the first part of the Canal to be remediated, and therefore will most likely set the timeline and pace for the subsequent parts of this cleanup. Furthermore, any failure by NYS DEC to achieve the Interim Remedial Measure cut off wall would result in recontamination of the Canal sediments and could potentially significantly delay the cleanup. It is for these reasons that

FAC believes that a ROD incorporating terms of enforcement and compliance must be put forward for the former MGP sites to provide for the best coordination, organization, planning and design to minimize disruption and impacts to the community.

Finally, given the number of PRPs and government agencies at all levels involved, FAC asks that the EPA use its Superfund authority to ensure the upland area cleanups move forward in a coordinated fashion that will not cause disruptions or delay to the community and its resources and which result in cleanups that are appropriate for the end use on the site. FAC believes that not effectively coordinating these cleanups would cause an adverse burden upon the community and, in the case of the Citizens MGP site, would further delay the Gowanus Green project which will provide significant affordable housing, with a preference for Community Board 6 residents, and open space

Ensure full cost of temporary and permanent replacement of public park spaces and uses and the community's meaningful involvement in the plans involving Thomas Greene Park.

The EPA has identified the Double D pool parcel in Thomas Greene Park as a potential location for an 8 million gallon in line CSO storage tank for outfall RH-034 to address the over 100 million gallons of raw sewage that are estimated to enter the Canal annually from this one outfall alone, which could also impact the integrity of the remedy.

The pool primarily serves the nearby New York City Public Housing Authority (NYCHA) and neighborhood residents during the summer season, and programs provided at the pool facility include the School Food Lunch program, which serves free breakfast and lunch while school is out, and the Learn to Swim program, which provides free swimming lessons. The pool also serves as a cooling center during heat waves. There is also a second pool, uniquely designed for toddlers, which some of the youngest neighborhood residents enjoy and a handicapped lift which services the main pool to allow for special needs access.

Should the ROD move forward with the retention tank location as put forward in the PRAP, what would be the exact timeline that this resource would be disabled? What compensation will be provided for a community losing a recreational open space facility and how would the EPA enforce City open space standards for an already underserved part of the Gowanus community? New York City Planning Standards outlined in the 2010 City Environmental Quality Review Technical Manual (CEQRA) encourage a standard of 2.5 acres of open space within half a mile for every 1000 residents. Presently, Northern Gowanus residents only have access to roughly 7 acres of Parks instead of the 70 acres the standard requires.

While FAC supports a comprehensive Superfund cleanup of the Gowanus Canal that includes addressing CSOs, we also insist that Superfund follow its own principles and make the polluters pay, not our community. The EPA's proposed placement of the retention tank to be built beneath the Douglass and DeGraw (Double D) community pool will greatly impact an already underserved community by potentially removing a facility that serves primarily low income populations that already suffer disproportionately from a number of health issues and lack of access to open space.

Furthermore, very serious consideration should be given to what impacts could occur to our most vulnerable elderly and young populations if there is no nearby facility to provide services designed to prevent hunger, and even death during excessive heat. FAC believes any public decision which contributes to the denial of, reduction or significant delay in the benefits associated with the facilities and programs at Thomas Green Park benefitting local minority and low income families would constitute environmental discrimination in FAC's opinion.

Presently there is no specific time frame or incentives being offered in the proposed cleanup plan to the community in the regards to the potential closure of the Double D pool. It is also unclear at this time if there may be additional disruptions to the Thomas Greene Park. With this in mind, FAC asks that the ROD include enforceable measures to provide for temporary and permanent relocation of services at an immediately nearby location as needed.

Any temporary displacement or permanent disruption to the Thomas Greene Park and Double D Pool should be planned for with a seamless transition of services for all the park facilities (pool, playground, skatepark, basketball courts) and services (the School Food Lunch, Learn to Swim, cooling centers, etc.) at a nearby location and the additional costs associated with the temporary disruption and replacement should be borne by the PRPs. The costs of replacing facilities and services during a temporary disruption and permanently following the NYS DEC clean-up and/or NYC DEP's installation of the retention tank, should be fully disclosed as part of the ROD.

There is much concern in the area over displacement caused by gentrification, lack of affordable housing, threats to NYCHA residents' housing, along with the potential closures of the Pacific Branch Library and Long Island College Hospital (LICH). Many longtime daycares and community centers have also lost their funding, so the threatened loss of this community resource combined with these numerous pressures adds to the burdens that neighborhood residents are already experiencing in a historically underserved area.

It is for these reasons that FAC would like for the ROD to outline how the least possible disruption to the Double D pool and Thomas Greene Park could be achieved while also meeting EPA's other goals related to re-contamination of the Canal. Moreover, if a retention tank is ultimately placed in Thomas Greene Park under the Double D pool, the pool (and any park) must be replaced, at the cost of the responsible party; the design of the replacement pool (and/or park) must meaningfully involve the local community and, finally, a temporary pool (and park) use must be provided for the entire time that there is disruption to this critical community resource.

Thoroughly review and verify remedial investigation results at the Former Fulton MGP site and address new exposure pathways as appropriate

A number of community residents have expressed concern over potential exposure pathways connected to the uses at Thomas Greene Park, including new exposure pathways that may have resulted from recent renovations of the park that include installation of tree pits and sprinklers which will be used for the first time this summer since the park renovation was just recently

completed without any remedial action being taken. As more attention is being focused on the contamination beneath the Thomas Greene Park and the risks that that contamination may pose to the public, FAC asks that EPA does everything within its power to ensure NYS DEC fully discloses these risks and ensures the public's health is protected at all times. Finally, EPA's consistently thoughtful and transparent approach in engaging the surrounding community in the cleanup of the Gowanus Canal has established a new benchmark by which other government agencies involved in the Gowanus Canal and upland MGP sites are being measured.

Adhere to the Community Acceptance Principle in Weighing the Siting of the Confined Disposal Facility (CDF) in Red Hook.

FAC appreciates the EPA's attention in holding additional meetings in Red Hook to ensure participation by all potentially affected communities in the siting and handling of dredged material from the Canal. Unfortunately, these efforts may have come too late. Red Hook residents have not had significant involvement in the Gowanus Canal Superfund process or CAG until very recently; have had limited opportunity to develop a trusting relationship with the EPA, and therefore were surprised to learn their community may be a site for a CDF. These are an unfortunate set of circumstances, since together with Red Hook's history, they may ultimately undermine 'community acceptance' of *any* proposal involving the neighborhood.

Despite EPA's clear efforts to describe the ability to develop a Confined Disposal Facility (CDF) in an environmentally safe manner, many local residents remain skeptical primarily due to Red Hook's long history of being a repository for waste transfer facilities, recent issues with the ball fields needing to be remediated which caused a delay in the baseball season and, of course, due to concerns raised about siting such a facility on the waterfront given the community's recent experience with Superstorm Sandy. These are all valid and understandable reasons why a community would be skeptical of an proposal to handle or treat contaminated dredged materials.

FAC believes that economic and workforce development opportunities, responsible environmental stewardship and environmental justice can be simultaneously pursued but adequate time, financial resources and trust must be present to work through real and/or perceived trade offs. Historically in these kinds of situations, communities – especially marginalized ones - are presented with false choices by dubious or self-interested actors. The EPA made an effort to share an evidenced based approach to help inform the community's opinion on the CDF and will now be hearing directly from Red Hook stakeholders on this matter. FAC believes that the EPA should strictly adhere to its principal of community acceptance as it weighs input on the CDF.

Continue to support the Gowanus Canal Community Advisory Group (CAG) and return to full facilitation at both the general and committee levels.

FAC is represented as an organization on the CAG and participates in the Outreach and Engagement (O&E) and Real Estate committees. We regularly offer our space for a number of CAG committees and trainings at our 621 DeGraw Street location. FAC recognizes that the

Gowanus Canal CAG is currently the largest Superfund CAG in the nation and that this is necessary to adequately reflect the diversity of community interests regarding site cleanup and reuse. FAC primarily views it's role within the CAG as promoting and protecting the interests of low and moderate income residents; promoting meaningful public participation of local low and moderate income residents and to the extent possible, also promoting membership in the CAG of underrepresented groups so that it better reflects the composition of the communities surrounding the Canal.

The role of neutral facilitator has been a critical component to ensuring equal opportunity for participation, process and dialogue amongst such a large and diverse group. Previously, the facilitator was engaged in all CAG meetings, including the Committee level, but has since had to scale back his facilitation to just General CAG meetings, at the request of the EPA. FAC feels strongly that full CAG facilitation, including Committees, should continue to be supported by the EPA. It is only *very* recently that CAG membership has become a bit more racially and socio-economically diverse, largely due to FAC's outreach efforts, but the CAG remains primarily a white, middle to upper middle income, English dominate, homeowner organization.

To engage more racially and socio-economically diverse stakeholders and ensure meaningful public involvement from all segments of society impacted by the continuing phases of cleanup of the Canal, strong facilitation that promotes inclusivity is needed for both the full CAG and CAG Committee meetings.

Incorporate climate change impacts and post Sandy mitigation measures in the ROD

Increased flooding from the Canal poses a health threat to the all residents who live in the flood zone. Increasing development without sufficient investment in public infrastructure in the surrounding area, combined with increases in predicted average annual rainfall and sea level rise, all contribute to the urgency of the need to address the CSO and toxic sediments cleanups in a timely manner.

When the Gowanus Canal overflowed during Superstorm Sandy, the heavily polluted saltwater corroded two manholes covers and flooded basements in the Gowanus Houses, damaging electrical lines and fuses and also damaged boiler and electrical panels in two FAC managed properties on Butler and Baltic Streets. As a result the Gowanus Houses and FAC managed properties were left without power for weeks after Sandy, and forgotten by most everyone while all the focus went to more traditional 'waterfront' areas. A broken water main along Hoyt Street, also left thousands of residents in eight of 14 buildings in Gowanus Houses without access to clean water.

Post Sandy it is important to consider the updated flood hazard risks. Residents remain under direct threat of exposure to the combined problems of known toxic endocrine disruptors and raw sewage during any large flooding episodes. Annual rainfall and intensity in the area is increasing, presently the NYC average annual rainfall is 45 inches, while CSO abatement plans are based on 38 inches a year, and according to NYC's 2008 Sustainable Storm Water Plan recent annual rainfall records were

as high as 65 inches a year. The Gowanus community sits in the 100 year flood plain and is classified as a Zone A area by the Office of Emergency Management (OEM), facing the highest risk of flooding from coastal storms, hurricanes and storm surges. According to NYC's 2008 Sustainable Storm Water Plan, moderate predictions for sea level rises in the city are between 4 to 7 inches by the 2020's, which presents a strong case for increased compliance and enforcement measures specific to the Clean Water Act to protect residents.

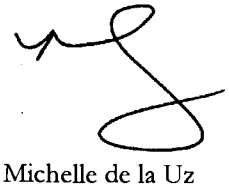
As previously commented at recent EPA public meetings, FAC agrees that the ROD should include a post Sandy assessment on the sustainability of the remedial design. Superstorm wave velocities and tidal effects on dredging / flooding should be addressed and design protections should be incorporated. Possible effects to the "armor" isolation layers from superstorm effects should also be considered. Overall, strategic flood plain management needs to designed into the ROD and the EPA should provide estimates on how much the remedy will be predicted to lower the Canal water depths and incorporate as much flood protection design as the remedies will allow. For these reason's FAC supports opening up the buried basins at First Street to help with flood direction issues and planning and believes further testing should be done at the Fifth Street basin to justify why it *shouldn't* be included in the Superfund clean-up.

Utilize Notify NYC procedures for public notification and Emergency Management

Finally, FAC would like to join others in recommend that as we move into actual implementation of a remedy that the EPA and the agencies and PRPs it is working with as part of the Canal cleanup, adopt the "Notify NYC" system to quickly notify the public of any potential health and safety concerns regarding the Gowanus Canal cleanup, including but not limited to, flooding, air quality, and accidents and spills that may occur under any of the responsible parties or agencies involved in the cleanup.

Thank you again to the entire Region 2 Gowanus Canal Superfund team for your efforts to comprehensively address the cleanup of the Gowanus Canal and the upland and CSO discharges which impact it and for the opportunity to participate in this process.

Sincerely,



Michelle de la Uz

RE: Proposed Remedial Action Plan for the Gowanus Canal

Dear Mr. Tsiamis:

Thank you for this opportunity to offer comment on the EPA's Proposed Remedial Action Plan (PRAP) for the Gowanus Canal. I congratulate you and your colleagues with the EPA on your extensive engagement of the community in a transparent, conscientious and timely manner. The community has benefitted greatly from the agency's patience and dedication in educating us all about these complex and confounding issues as we seek to attain our mutual goal of cleaning up the Gowanus Canal.

To that end, I am generally supportive of the PRAP and its remedy preferences, but it is clear to me from the many community meetings and conversations that there remain unanswered questions and concerns regarding (a) opportunities for recontamination (as particularly seems to be the problem near the Manufactured Gas Plant sites and attendant the Fifth Street Basin); (b) the movement of Non Aqueous Phase Liquids (NAPLs) and those that are less dense than water (LNAPLs); (c) the maximization of community benefits including workforce development and the minimization of negative impacts such as disruptions to local businesses; (d) the improved coordination of the relevant agencies, responsible parties and stakeholders involved; (e) the increased opportunities for inclusion of diversity and greater participation of all the affected communities in the next steps (both design phase and actual clean-up) and (f) resource allocation decisions.

I support the vast majority of the comments made by Community Board Six and share its concerns about responsible development in the area and support fully its concerns and request for competent and independent technical advice. While the process has been a fine example of community engagement, and community members gone above and beyond in their efforts to educate themselves, the quantity and complexity of information to be digested alone argues forcefully for strong community technical assistance. This has been painfully highlighted by Hurricane Sandy and its aftermath.

In addition, I respect the widely held preference of the Red Hook community that a confined disposal facility not be located in Red Hook.

I also share the concerns expressed by the Friends of Douglass/Greene Park regarding the clean-up of the former Fulton MGP site which sits below the Thomas Greene Park and Douglass and DeGraw ("Double D") Pool, the outstanding questions about the remediation of this site, and the wisdom and necessity of locating a raw sewage overflow collection tank beneath what is now the pool area. I ask that the EPA engage in serious dialogue with the community and adjacent property owners regarding the temporary location of a replacement park and pool during the period of time when the pool and/or park would be undergoing remediation, or the use of the lot on Nevins and Butler, across the street from the Pump station and the Flushing tunnel for the overflow retention tank instead. Should this not be possible, it would seem that the use of eminent domain be carefully considered. Surely, such a use would be a classic example of "public use."

The water quality in the canal must be improved to the greatest extent possible by drastically reducing Combined Sewer Overflows with vigorous enforcement under CERCLA and all available mechanisms under the Clean Water Act.

This is an important once-in-a-lifetime opportunity; we must exercise care and we must get it right. I look forward to continuing to work with the EPA, the City and the State, the responsible parties and the community and local business stakeholders to replace toxicity with a vibrant, clean, and sustainable Gowanus Canal that will bring pleasure and prosperity to the area.

Very truly yours,

Jo Anne Simon

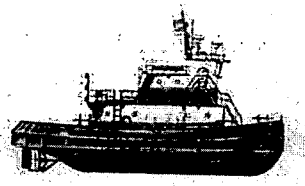
Gowanus Canal Superfund Red Hook Option support letters

Gowanus Bay Terminal to: Region2 GowanusCanalComments 04/28/2013 12:02 AM

History: This message has been forwarded.

Red Hook Option letters of support.pdf



VANE BROTHERS

25April 2013

GBX Gowanus Bay Terminal
699 Columbia Street
Brooklyn, NY 11231

Attn: John Quadrozzi Jr.
Re: Red Hook CDF

Gentlemen:

As the current tenant of the west dock of the GBX Facility, Vane Line Bunkering would like to add our support for the proposed future expansion of the terminal by way of the Red Hook Option of the EPA Gowanus Canal Superfund cleanup. The GBX pier has become a significant asset to our New York Harbor operations by providing layberthing area for our barges during non-operational periods. At the present time we are in the final stages of preparation for an expansion of additional mooring structures to the end of the pier that will allow us to double the available dock space for barges awaiting assignment.

The availability of adequate commercial dock space in New York Harbor for vessels that are of the size and type of our barge fleet is extremely limited. GBX has been advantageous to our operations not only for its current and future dock space, but also because of its location within the area of our marine related business activities. Our impact on the terminal and the surrounding community is limited to primarily waterborne activity only. As such we would have littler interface with the remediation process or project itself, but maintain a long term interest in the development of the terminal for current and expanded commercial maritime interest that would result from the successful completion of this endeavor.

As a maritime operator within the immediate geographic area, we support both the cleanup efforts of the Gowanus Canal as well as future expansion of GBX.

Sincerely,

D. Michael Barr
Property Manager

Att: Christos Tsiamis

Best Trails & Travel have been at GBX since approx year 2001. We currently employ about 55 people.
Out of the 55 employee we have approx 45% of them are local residents.
GBX is an ideal location and environment for our business in that it is self governing and maintains a clean, safe and secure terminal.
I am fully familiar with the EPA Gowanus Canal Superfund - Red Hook Option for a CDF which creates an increased footprint at the facility
and support such an endeavor completely. As less and less industrial land is available in Brooklyn, it gives us hope that we will have places
like GBX which are enclosed industrial incubators to house our operations.

Please approve this important plan.

Aly Goldenberg

EPA Division 2

Manhattan, NY
Att: Christos Tsiamis, Project Manger

EPA- Gowanus Canal Superfund, Red Hook Option

Dear Sir,
I'm writing to support the EPA Red Hook Option.
My business is a trucking company which transports food and beverage products into the metro NY and Long Island areas.
We have been tenants of Gowanus Bay Terminal since 1995 and have over 75 employees of which 70 operate regularly at GBX.
The facility is in an ideal location for us to service two important customers, Snapple and Arizona Ice Tea located nearby in Red Hook, where we exchange full length box trailer every day/all day/day and night. It is easily accessible due to wide truck routes and its close proximity to major thoroughfares.
The use of this facility has allowed us to greatly reduce the amount of trucks operating during peak rush hour on RT 278 and RT 495 as well as all the local bridges. By staging trailers at night at the Gowanus Bay Terminal we minimize our impact on to local areas during peak day time hours. We modified our operation to maximize after hours transit at the request of the TBTA and Port Authority.
The terminal is managed well, kept clean and run in a safe and respectful manner.
We feel it essential for Gowanus Bay Terminal to grow so industries like ours have a place exist.

Kindly approve the EPA Superfund - Red Hook Option.

Please contact me if you have any questions.

Sincerely,
John Vaccaro
Senior Vice President

GBX John Quadrozzi Jr

Mr. Christos Tsiamis, Project Manager
Gowanus Canal Superfund Project
U.S. EPA – Region 2
290 Broadway , 20thfloor
New York, NY 10007-1866

Dear Mr. Tsiamis,

As an advocate for the business community of South Brooklyn, retail, industrial, and commercial, a role the South Brooklyn Local Development Corporation has played since 1987, we wish to add our voice to those who favor the siting of a de-watering facility at GBX, and are supportive of the innovative way in which the EPA and GBX propose to handle the far less contaminated sediments culled from the Red Hook one third of the canal. We believe in the science and the global citizenship of that response and trust the EPA team to do this and do it right.

Moreover, when the Gowanus Superfund project is completed and gone - the benefits of having begun a green 21st Century ECO Industry Park at that site, with as many local residents trained to work in that field as is feasible, will still be there. Green industry will be happy to have another welcoming home and will fill the space with jobs. If we build it they will come.

In our work in Red Hook and Gowanus over the years we have seen the same anti-industry "community" responses as you and your team were subjected to used over and over again to promote the real estate interests of the few, and sadly to try to manipulate the many into being afraid. The tactics being used, the alliances being formed, and the scheming way of thinking is more reminiscent of a reality TV show than of an informed democracy.

Additionally, in our business advocacy role let us give you our opinion of the alternative proposal to do all the work on a series of small barges here and there in the canal. IMPENDING DISASTER FOR BUSINESSES!! The need to open and close the drawbridges as frequently as would be needed to treat the dredged sediment on the northern side of the Hamilton Avenue Bridge will cause huge traffic jams, make deliveries and shipments extremely difficult, discourage customers from coming to our retail businesses and in short will be a loss of jobs and vitality from Red Hook to 4th Avenue, from Atlantic Avenue to the Gowanus Bay.

I know I have sent in a personal comment already, but this is an organizational one so I hope both can be counted:

Sincerely yours,
Bette Stoltz for South Brooklyn Local Development Corporation

RE: Gowanus Canal Superfund Operations in Red Hook, Brooklyn

Dear Mr. Tsiamis,

Brooklyn's waterfront development historically favored industrial interests over those of the community. In fact, the Gowanus Canal has been an industrial waterway since the the Dutch. The toxic waste characterizing it and the failed attempts to take corrective action reflect a lack of concerted community involvement together with an appreciation for the benefits of industry. After all, the Gowanus has been a source of employment for nearly 150 years.

Today, we promote recreation on waterfront that had been the exclusive preserve of industry along with the benefits of recycling. The Gowanus Bay Terminal's Red Hook Option's novel approach combines state-of-the-art hazardous waste recycling with Brooklyn's own prestigious heritage of concrete production. The execution of this alternative will be under intense scrutiny by federal, state and local government enhanced by an actively engaged neighborhood. It's difficult to imagine a project of this magnitude with more attention paid to it.

Brooklyn's tradition of concrete innovation goes back to the Gilded Age and the Coignet Stone Company with offices - not coincidentally - in Gowanus. Quadrozzi Concrete continues this tradition with the building of prominent New York City skyscrapers. That Quadrozzi's high-strength concrete is used to construct the Freedom Tower is a source of pride for many.

Rather than dismiss the Red Hook Option and the role of Quadrozzi Concrete outright, Brooklynites would do well to take an active role in collaborating with all parties for the sake of our community. This is an unprecedented opportunity for Brooklynites to positively influence the development of our waterfront.

Sincerely,

Dom Gervasi, Owner & Producer

Christos Tsiamis
Project Manager
Central New York Remediation Section
U.S. Environmental Protection Agency
290 Broadway, 20th Floor
New York, New York 10007-1866

Dear Mr. Tsiamas:

On behalf of Brooklyn Economic Development Corporation (BEDC), I am writing to support the GBX/Gowanus Bay Terminal proposal for treating and disposing of the sludge removed from the Gowanus Canal.

When the determination of the Canal as a Superfund site was first promulgated, I had deep concerns on many levels. While I know and understand that toxicity that the Canal in it current form poses to the community, I also feared that the designation would halt any kind of redevelopment efforts for many years as the logistical questions of how to clean the canal and where to dump the sludge were negotiated. I know that there are few places left in the US that willingly accept toxic sludge and I understand why; as communities all over the country try to clean up and reuse brownfield sites for purposes of job creation and community revitalization, who would want to *add* contaminants to the soil where they might leach and contaminate adjacent sites and aquifers?

The GBX Terminal solves this problem in a very elegant and prudent way! It dramatically reduces the potential truck trips to and from the site, carrying their toxic cargo – this benefits the community not only from a noise and congestion standpoint, but as a way to avoid truck exhaust that has led to asthma and other respiratory problems in the Red Hook community.

Secondly, the end result is a community amenity – a waterfront park will further add to the livability of this community, which is so congested with high-rise housing and closely built industrial plants. As the Greenway project grows and expends in Brooklyn, this park will add another link to the green "necklace" that the Brooklyn waterfront can become.

Third, it helps preserve jobs and industry in a community that desperately needs them. So many "economic development" projects in Red Hook have had disappointing results – the Cruise Ship Terminal that created few jobs, the IKEA that created part-time retail jobs. Certainly, these projects have enhanced the Red Hook community, but their impact has been muted.

The Gowanus Bay terminal has been a presence in Red Hook for many years. The product they provide is *essential* to the continue rebuilding of New York City. There are few options for them to relocate to if Red Hook completely de-industrializes. That is not a desired outcome in the continuing redevelopment of Red Hook! The most vibrant communities in NYC support jobs and industries of many types. BED has been an advocate for industrial uses, *where appropriate*, in Brooklyn for our entire 34-year history. This is an appropriate use, and the GBX Terminal will not only allow The Gowanus Terminal to stay and grow, but benefit the community in terms of jobs and amenities.

If this plan is implemented, the clean-up of the Gowanus Canal can begin sooner rather than alter and the community can begin planning for a future without a toxic gash running through it. That dream has been a long time on coming, and this project helps move it closer to reality.

I have been an advocate of community-based brownfield clean-ups for many years. I was part of the original Pocantico Roundtable which advocated for better Brownfield clean-up regulations in New York State. I currently serve as Vice Chair of the Board of New Partners for Community Revitalization, a non-profit organization well known to your agency, which is in the forefront of environmental solutions to brownfield issues.. [Note: I write as an individual and not on behalf of New Partners.] Certainly the Gowanus Canal rises to a higher threat level than a typical brownfield, but as governments across New York State avoid clean-ups because they know there are no easy solutions to where to put the waste and what to do with the remediated land, we in Brooklyn are not subject to that same dilemma. We have a sound clean-up solution and we have a community that is desirable and ready to react to the positive change that a cleaner Gowanus Canal can bring.

The people of Red Hook, the residents of Public Housing, who have stuck it out for many years amidst decay, crime, being ignored and being dumped on, support this project. They see its intrinsic value. They do not support it based on whether or not the value of their houses will go up or down – they understand that it is about the long-term future for ALL Red Hook residents.

Based on the soundness of the science, the positive economic development impacts, and the faith of the people of Red Hook, BEDC endorses this project and urge you to move it forward.

Sincerely,

Joan Bartolomeo
President, BEDC

I fully support and encourage this dredging operation of the Gowanus Canal and use of the Gowanus Bay Terminal in the Red Hook Option for dewatering and construction of a CDF.

As a marine operator of a tug boat company for nearly a decade, I have see a lot of things change. Mainly and sadly, the deterioration of what were operable maritime facilities and/or transition of them to residential development. As a result, it is becoming more and more difficult to find industrial waterfront property to operate a maritime business like ours.

Cleanup of the Gowanus Canal would help make the marine environment cleaner and expansion of GBX would make a more viable industrial waterfront that which we need so desperately to maintain a working waterfront infrastructure for the city overall.

Very respectfully yours,

Michael Vinik

Re: Gowanus Canal Superfund, Red Hook Option

Sirs,

We are writing to support the EPA Red Hook Option.

We are a scrap metal processing company that occupies space at Gowanus Bay Terminal. The Terminal provides our business with an ideal place to operate. It is logistically advantageous to reach our market, is easy to access with clear and wide truck routes directly off the BQE, Battery Tunnel and Hamilton Avenue, is secure from outside elements and is managed in an organized, clean and safe manner working in concert with the local community.

We are also planning an expansion of our own at the Terminal, and plan to utilize their docks and waterborne commerce to reach our end users.

It is critical that facilities like Gowanus Bay Terminal are encouraged to grow to ensure small businesses like ours have a proper and viable place to exist.

Please approve this important plan for the better of Red Hook and Brooklyn overall.

Regards,

Tom Petrosino

Dear Mr. Tsiamis,

THE FOLLOWING IS IN REGARDS TO THE PROJECT THAT IS IN QUESTION, WE AT THE ABOVE MENTIONED COMPANY ARE APPOSE TO DESTROYING OUR NATURAL RESOURCES AND THAT INCLUDES OUR WATER CANALS.

We've been at GBX since 2012 and we have only the highest of respect for the company, at the present time we employ 6 drivers who are just delighted and joyful with the care and dedication that GBX employees entrust in the preservation and commitment that goes on in the everyday activity in the cleaning of their lot.

Approx. 90% of our employees are local residents, GBX is an ideal location and environmentally safe for your business in that it is self-governing and maintains a clean, safe & secure terminal. I am fully familiar with the EPA Gowanus Canal Superfund - Red Hook Option for a CDF which creates an increased footprint at the facility and support such an endeavor completely.

As less and less industrial land is available in Brooklyn, NY it gives us hope that we will have places like GBX which are enclosed industrial incubators to house our operations.

Please approve this important plan and thank you in advance for your cooperation

Re: Gowanus Canal Superfund Operations in Red Hook, Brooklyn

Dear Mr. Tsiamis:

I am writing to you to express our support for GBX's proposal to create a new public waterfront park and Maritime Center on its property as part of the Superfund remediation activities under consideration in Red Hook at this site.

Brooklyn Greenway Initiative (BGI) is a 501(c) (3) non-profit organization planning the Brooklyn Waterfront Greenway; a 14-mile, off street, landscaped, bicycle, pedestrian and running facility from Greenpoint to Bay Ridge We are also leading the development of neighborhood parks and open spaces along the route of the Greenway.

One of these spaces now in conceptual planning is the "Columbia Street Connector" project which runs adjacent to the GBX-Gowanus Bay Terminal. The objective of this project is to improve the pedestrian experience between the Red Hook Houses and the Columbia Street Esplanade, Red Hook Park and the route of the Brooklyn Waterfront Greenway. This stretch of Columbia Street has low traffic and wide sidewalks. The land uses in the northern three blocks are mostly industrial and commercial and the pedestrian experience there and on the Esplanade could be improved significantly with vegetation and other treatments. The esplanade itself is currently barren, with no vegetation or shade, but it could become a more attractive destination with some trees and landscaping.

The addition of new public open space at the GBX facility fits well with our mission of creating and expanding public access to the waterfront.

Sincerely,

Brian McCormick, Co-founder

Re: Gowanus Canal Superfund Operations in Red Hook, Brooklyn

Dear Mr. Tsiamis:

The following is a follow-up correction to my letter to you dated May 17, 2012.

The Gowanus Canal Community Development Corporation enthusiastically supports the creation of a Confined Disposal Facility (CDF) at GBX-Gowanus Bay Terminal proposed by GBX President John Quadrozzi, Jr. In my opinion this will hasten the Gowanus Canal remediation by eliminating lengthily transport of wet waste along with cost containment.

The creation of the CDF at the GBX would also eliminate the need to fill the Fourth Street Turn Basin on the Gowanus Canal as a proposed site for treated disposal. As the majority of Brooklyn (Gowanus) residents were led to believe in the year long lead up to Superfund designation, the EPA was coming in to "oversee the clean-up of the entire water body" and not segmented portions.

However, the most exciting aspect of establishing a CDF at GBX is the "green" jobs training and employment opportunities it will create for Red Hook residents. I like to think we are in the business of creating responsible tax payers helping to *sustain* this great city.

We at the GCCDC look forward to the creation of this model project which we hope can be replicated throughout our city. We also look forward to the Gowanus Canal clean-up which will allow for responsible development both commercial and residential on the east and west banks and throughout the uplands of our canal. Please feel free to call if you have any questions.

Sincerely yours,

Bill Appel
Executive Director

Via email to tsiamis.christos@epa.gov

Dear Mr. Tsiamis:

PortSide NewYork is a 501(c)(3) non-profit organization. PortSide NewYork's mission is focused on NYC's waterfront and relative to Red Hook, to foster community revitalization along a water theme.

On behalf of the board of PortSide NewYork, I would like to express support for EPA Superfund activities to be based at GBX. We understand those Superfund activities to include three possible layers of use of the GBX site in relation to the dredging of the Gowanus Canal:

1. as a staging area for the dredging equipment and a dewatering site,
2. as potential site for remediating the dredge spoils,
3. as a Confined Disposal Facility (CDF) which would contain the processed spoils by filling the Henry Street Basin and a large portion of the GBX property lying underwater to the east of Columbia Street, leaving space for a deep water berth in the Gowanus Bay and creating new public space.

We think it essential that a community benefits agreement be established and that community involvement with the EPA and GBX be an ongoing process. If those two conditions can be met, PortSide NewYork finds ample reason to support all three stages of the proposed Superfund activities at GBX for the following reasons.

PortSide mission is to activate NYC's BlueSpace, or water part of the waterfront, and to breathe life into the relationship between Red Hook's landside community and the maritime sector—to the advantage of both. Our approach is to create activities and spaces that benefit both groups, nurture economic connections between the two, foster their mutual appreciation, and make the waterfront neighborhood they share a better place to live, work and visit. PortSide NewYork manifests a new vision for how to revitalize New York City's waterfront and create waterside public spaces without displacing the maritime functions essential to the city's transportation infrastructure.

PortSide NewYork, aboard the tanker MARY A. WHALEN
P.O. Box 195, Red Hook Station, Brooklyn, NY 11231
917-414-0565, portsidenewyork@gmail.com, www.portsidenewyork.org

PortSide has continually advocated that maritime facilities are essential to the city and should not be displaced, but that they could be turned into centers of economic activity, job training opportunities, and neighborhood attractions via cultural tourism (interpretation). The proposed uses of GBX satisfy all those goals, given the addition of the maritime park in the GBX proposal to the community. Additionally, we think that the creation of new land providing both a community amenity and a new deep water berth, is a win-win of significant dimensions.

This proposal builds on the existing assets of the GBX site, whose recent uses include maritime hub, center for land-based transportation, center for delivery and storage of bulk materials, D&C rubble processing, and more.

It is our hope that the GBX Superfund proposals could give Red Hook a facility of the quality of the DEP's Newtown Wastewater Treatment Plant, where "dirty work" is being conducted in a facility with great architecture and landscape design, a nature walk, interpretation of local history, a free community room and an educational center where the work of sewage processing is interpreted and open to school groups and the general public. That DEP facility has made sewage processing a destination. OHNY tours of the plant book up rapidly. We would like to encourage the EPA and GBX to use this welcome clean-up of a toxic canal as a means to create a similar quality destination in Red Hook.

We also understand that the EPA could establish a Job Training Institute (JTI) in the neighborhood to train potential employees of the dredge remediation processing plant. We firmly support this.

We would like to emphasize the need for local jobs and for the proposed training center for local residents. There is terribly high unemployment in Red Hook, mostly concentrated in the Red Hook Houses. Though larger Red Hook has recently rebounded, the residents of the Houses still face high levels of unemployment and low income.

We at PortSide believe that having EPA Gowanus Canal Superfund remediation activities centered in Red Hook at GBX, if done properly, could be a good thing for a community concerned with being socially and environmentally responsible. We see this project as an opportunity for federal investment in the community, potential employment for local residents, increased industrial land, and increased public open space.

Thank you for your consideration. I can be reached at (917) 414-0565.

Sincerely,

Carolina Salguero
Director
PortSide NewYork

Christos Tsamios

US EPA

New York New York

Dear Mr. Tsamios,

This letter is in support of the GBX proposal for a confined disposal site beneath the Gowanus Canal for the disposition of contaminated dredged material that now exists on the surface of the canal. I think the alternative of filling a turning basin is not acceptable because it would destroy existing and future habitat.

I support the use of a CDF because I am aware that such an approach is effective in Newark Bay. I speak with a certain amount of knowledge of the options for disposition of dredged material. While I was in New York State Department of Environmental Conservation as Special Assistant to the Commissioner for New York Harbor Environmental issues, my portfolio had dredging and dredged material disposal as a major factor. During that time I co-chaired dredging conferences dedicated to finding innovative sustainable ways to deal with dredged material. In addition I made a presentation about dredged material disposal before the New York Academy of

Sciences. I continued to follow the dredging issue while I was at New York City Economic Development Corporation as Director of Port and Intermodal Planning, as consultant to the Gowanus Canal Community Development Corporation in developing its conceptual plan for redevelopment, and continue to do so as a member of the Steering Committee of the Harbor Operations Committee.

Although my words of support are few they are based on a great depth of knowledge and experience.

Very truly yours,

Roberta Weisbrod, Ph.D.

Dear Mr. Tsiamis:

I am writing to support creating a Confined Disposal Facility (CDF) at GBX-Gowanus Bay Terminal in Red Hook as part of the Gowanus Superfund project. My family and I live in Red Hook, and my business; Movers Not Shakers! is located here as well.

There are many reasons why constructing a CDF in Red Hook is the right thing to do. I am part of a Red Hook community that prides itself on being socially and environmentally responsible. We do not want to export local contaminated sludge to some other community, as it is in our backyard, and therefore should remain here, and not be trucked to a different location to be treated. We want to retain as much of this tremendous federal investment in our community, and create the maximum amount of employment opportunities for local residents. We do not want to waste our tax dollars by spending millions of dollars more to export dredge to some distant facility, nor do we want to create the exponentially larger amount of pollution that distance would create because of the associated increase in transportation.

I know GBX's owner, John Quadrozzi, Jr. to be a good corporate citizen who, like me, utilizes bio-diesel in company vehicles and equipment, hires locally whenever possible and gives back to local causes. I look forward to working with fellow community stakeholders and John to develop a Community Benefits Agreement where we can ensure the community gets the most out of the Superfund investment, creating new eco-economic development opportunities and a Job Training Institute that will live beyond the Superfund, and in creating new open space for Red Hook.

Obviously, we want to know that our community will be protected from *any* environmental health hazards that could arise from work done at GBX and want the EPA to give us a clear understanding of what we can expect from this process. I do feel there are more questions that need to be answered, and look forward to having an open, clear communication process, and a productive

Re: Gowanus Canal Super Fund Operations – Red Hook, Brooklyn

Dear Mr. Tsiamis,

We thank you for taking the time to come to Red Hook to give our community a great presentation. We are excited about working together to bring positive change to a very deserving neighborhood. We have worked with John Quadrozzi, Jr., owner of GBX Gowanus Bay Terminal for over ten years. He has always supported community initiatives and always hires people from the neighborhood and Red Hook Rise has been extremely instrumental in the hiring process. We are very optimistic the Super Fund project will begin a new era for green industry and jobs that will be a model for all to replicate.

Working with GBX to craft a community benefits agreement will put to words Mr. Quadrozzi's dedication to hiring locally while utilizing environmentally responsible business practices like fueling equipment and trucks with biodiesel and building a waterfront park in Maritime Center. We were proud to assist Fairway, IKEA, and the Brooklyn Cruise Terminal with job placement/training in Red Hook and know we can be an asset to this great project at GBX. As a result of their success, we would welcome the opportunity to work with your agency to set up a job training program that will prepare local residents for what is to come while fulfilling the hiring needs for GBX.

Red Hook Rise has provided community based programs for Red Hook residents of all ages since 1994. The violence that has plagued the neighborhood for many years coupled with astounding unemployment rates is a recipe for disaster. Super Fund related job opportunities resulting from a larger GBX site will increase employment and decrease violent activity and that is our ultimate goal. That is why we also support Option G in the feasibility study for the Gowanus Canal Super Fund in hopes that the EPA will choose Red Hook to create a confined disposal facility at GBX Gowanus Bay Terminal. GBX's quest to maintain the industrial fabric of our working waterfront and repeat history by expanding upland property while simultaneously creating greener collar job opportunities is a win win situation for

all involved. Furthermore we would like to ask the agency to consider remediation for both light and heavy contaminants which will also maximize employment opportunities.

We know your agency will keep us informed about Super Fund activities in Red Hook including any associated risks to site workers, local residents, and the general public. We are happy to spread the word about relevant meetings and other information that needs to be disseminated within the community. We hope you will let us assist you in your efforts to bring prosperity to a place that so desperately needs it.

For more information on our background and any other information you may need, we can be reached at (917) 560-7226 and we thank you so very much for your consideration.

Sincerely,

Ray and Earl Hall

Re: Gowanus Canal Superfund Operations in Redhook , Brooklyn

Dear Mr. Tsiamis,

We appreciate your informative and understandable presentation you made in Redhook. We truly thank you for taking the time out to meet with our community members, moreover, thank you for considering us to take part in this monumental initiative. We trust that the Superfund Project will serve as a great springboard to continue to propel Redhook into a sustainable and job-rich future. We are proud to have Redhook restored as a haven for industry, shipping and very high quality jobs.

I represent Redhook West Residents in support of Option G in the study for the Gowanus Canal Superfund, in hopes that EPA will choose Redhook for creating a Confined Disposal Facility at GBX-Gowanus Bay Terminal. We support GBX's quest to maintain the industrial fabric of our working waterfront and repeat history by expanding upland property more job opportunities for our community.

Redhook Houses is the 2nd largest public housing complex in the City of New York, with over 7,000 residents facing an unemployment rate of 23.4% (as per census 2010) compared with 8.4% in the Borough of Brooklyn. We face tremendous obstacles to employment, and so we welcome the opportunity to have a Job Training Institute set up here. The owner of GBX has always hired employees from Redhook, and will be working with current and future tenants. We are looking forward to the development opportunities that will arise out of the expansion of upland space at GBX. We will work with the owner to ensure all resulting new economic activity will generate jobs for the residents of Redhook.

We feel that EPA has the community's best interest at heart and will keep us informed about the work process while ensuring that environmental hazards are controlled for the safety of our workers, families , friends and visitors of Redhook.

Redhook is proud of its rich tradition in industrial job creation. We are looking forward to growing green, sustainable industrial businesses and employment going forward. Conducting Superfund remediation activities in Redhook is the right choice for the

environment and for our residents; for us it will be a sad loss not to have this great investment in our community.

I can be reached at (718 755-5027). I do appreciate your attention to this very important matter.

Sincerely,

RE: Gowanus Canal Superfund Operations in Red Hook, Brooklyn

Dear Mr. Tsiamis:

We enjoyed you and your team's presentation made to our community and thank you so much for your time. I am writing to express Red Hook East Resident Association's support of creating a Confined Disposal Facility at GBX-Gowanus Bay Terminal as part of the Gowanus Canal Superfund project. I have worked with GBX and its President John Quadrozzi, Jr. for many years and support expanding its upland property so that new business development can flourish there and more Red Hook residents can be put back to work. I also ask that your agency consider conducting remediation for both light and heavy contaminants in Red Hook so that our community can reap the most benefit out of this substantial investment.

As you know Red Hook Houses has a very high unemployment rate (23%) and so would be a prime candidate to create a model Superfund Job Training Institute. We will work with Mr. Quadrozzi on creating a Community Benefits Agreement to formalize his commitment to Red Hook by ensuring new job opportunities go to local residents first, to establish a new public waterfront park and Maritime Center, and to growing his industrial park sustainably, in harmony with the interests of local residents.

We look forward to working with the EPA to ensure all Superfund activities are safe for local residents and employees. We hope to be informed about all actions being considered for our neighborhood, and any associated risks to the public's health. We welcome the continuance of EPA community outreach efforts.

Red Hook is proud of its rich tradition in industrial job creation. We look forward to growing green, sustainable industrial business and employment going forward so that more high quality jobs can be created. Conducting Superfund remediation activities in Red Hook is the right choice for the environment and will help propel Red Hook into a job-rich and sustainable future. I know we can do great things together and hope we can look back on these times as the beginning to something truly special.

I can be reached at 718-522-1452. Thank you for your attention to this very important matter.

Sincerely Mrs. Dorothy Shields, President Resident Association

Re: EPA Gowanus Superfund PRAP

Dear Christos:

The work that the EPA has undertaken on the Feasibility Study, Remedial Investigation and Proposed Remedial Action Plan (PRAP) to clean up the Gowanus Canal has been well-considered, timely and thorough. Throughout the entire process, the EPA in general, and your team in particular, have made an exemplary effort to present detailed information to the community and respond to community input and concerns. This project has earned the EPA the trust of our community, and renewed my own faith in our federal government.

Following are comments on three PRAP issues which I present as both, a community stakeholder and an organizational CAG member representing more than 300 persons working at The Old American Can Factory.

I urge you to consider the following comments and requests as you prepare the Record of Decision:

1.0 CONFINED DISPOSAL FACILITY
We support keeping "Option G: On-site stabilization and disposal in an on-site CDF for RTA 3" as a viable option.

2.0 BULKHEADS
We request that any bulkhead replacement not infringe at all on the existing width of the canal waterway. Furthermore, all efforts should be made to restore the historical width of the Canal where and when bulkheads are replaced.

3.0 FIFTH STREET BASIN
We request the inclusion of the Fifth Street Basin in the Superfund Proposed Remediation Plan and in the Record of Decision for the following reasons:

3.1 BACKGROUND
The Fifth St Basin was built as a primary segment of the Gowanus Canal, not just as a 'turning' basin. At 100' wide and appx 565' long, it represented appx 10% of the entire Canal area north of Hamilton Avenue. This Basin, which was actively used for barging to at least two large coal yards and a 200,000 SF factory on its north side, was filled in the 1950's with unknown material. It was contiguous with the Fourth St Basin during the peak period of Canal pollution and EPA soil and groundwater samples contained high levels of VOCs, SVOCs and metals.

In 2004, the US Army Corp of Engineer Study noted "the sites of the filled First St and Fifth St Basins are part of the historic district" and in 2011, the EPA included the Fifth St Basin in its Archeological Sensitivity Study. In 2008, NYC Dept of Transportation rebuilt the entire Third Ave Bridge that spans the basins over water still present beneath the bridge. Many city, state and federal maps still represent the Fifth St Basin as being in existence.

3.2 REASONS, USES & BENEFITS TO REMEDIATING & RESTORING THE FIFTH ST BASIN

3.2.1 It is contaminated at levels comparable to other portions of the Canal.
3.2.2 Possible CSO retention tank location.

3.2.3 Stormwater retention area for the Gowanus watershed that includes Prospect Heights, Park Slope and Boerum Hill.
3.2.4 Flood water mitigation.
3.2.5 Wetlands restoration and parkland.
3.2.6 Re-establish access for commercial barging.
3.2.7 Re-establish the Gowanus Canal's original form and preserve area's historic relevancy.

3.3 EPA CRITERIA FOR EXCLUSION IN SUPERFUND BOUNDARY

From the announcement of the Superfund designation until the PRAP was presented, the boundary of the Gowanus Superfund Site excluded the Fifth St Basin along with the First St Basin. EPA explained that though both Basins may be contaminated the criteria was established that only the existing body of 'water' was defined as 'Canal', and since the Basins were filled, both were considered 'upland', and any remediation of those Basins were to be administered by NYS Dept of Environmental Conservation (NYCDEC). However, since the First St Basin was indeed included in the PRAP, that is no longer the criteria and therefore not a valid explanation.

3.4 EPA REASONS FOR EXCLUSION IN SUPERFUND PRAP

While acknowledging that the Fifth Street Basin is contaminated but perhaps not contaminated 'enough', the EPA has cited a few 'complications' as to why it exclude it from the PRAP, including, land "ownership" issues and structures built on the Basin:.

3.4.1 STRUCTURES CURRENTLY ON THE FIFTH ST BASIN

The current structures that encroach into the Fifth St Basin's edge, include a portion of a one-story metal shed attached to the U-Haul building, and a portion of a concrete pad and perimeter retaining walls currently being used as a school yard. None of these conditions are insurmountable obstructions to remediating and restoring the Basin.

3.4.2 OWNERSHIP

NYC Dept of Finance show several privately-owned tax lots on the fill of the Fifth St Basin. There are questions about the legal private ownership of these lots on what was a public waterway, along with evidentiary material that support the challenge to the legal acquisition of those tax lots. The EPA can work with the City of New York to establish ownership and to clear the way for the EPA to do its remediation work.

3.5 PERCEPTIONS

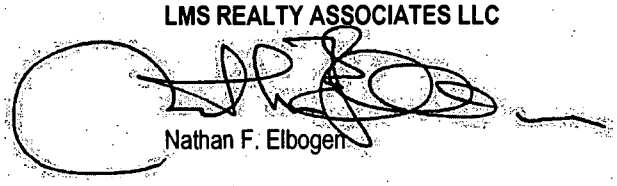
Some in the community have noted that the EPA may have reversed its original exclusion of the First St Basin and included it in the PRAP for remediation and restoration only because it sits at the heart of prime developable real estate that has been slated by NYC Dept of City Planning for rezoning.

As the EPA suggested for the Fifth St Basin, a barrier wall can be installed across the 75' width of the First St Basin to keep it from re-contaminating the Canal, and let New York City, a PRP and the owner of the Basin, to remediate it just as all other uplands under NYS DEC's Brownfield Remediation Program.

Thank you kindly for you terrific service to our community and to our nation.

Sincerely,

LMS REALTY ASSOCIATES LLC



Nathan F. Elbogen

I, the sender, vote that I do not want this project to proceed.

Karly Smelson to: Region2 GowanusCanalComments 04/28/2013 10:16 AM

As Parks User of the community of Red Hook, I strongly opposed to the processing of contaminated sludge dredged from the Gowanus Canal Superfund Cleanup Site at a facility at the proposed location. The cost savings are negligible, and the Red Hook Ball Fields and Pool are used in public trust. The community does not want to create more land from this contaminated sludge adjacent to one of the most heavily used recreation areas in New York City. People and organizations adversely affected include (but are not limited to!):

- Children
- Numerous public and private schools which use the fields for physical education & sports teams
- Residents of the Red Hook Houses and the surrounding neighborhood
- Soccer, softball, baseball, football, handball, basketball, track & field teams and enthusiasts
- Swimmers of all ages
- The Red Hook Food vendors and their customers
- Other visitors to our community

Further, we object to an individual (John Quadrozzi), who has incurred serious fines for environmental violations, from profiting from the project.

New York, New York 10007-1866

Dear Christos Tsiamis

I am writing to provide my support in favor of the EPA PRAP (Proposed Remedial Action Plan) for the Gowanus Canal. As the Proposed Plan establishes methods for removal of contaminated sediments for the entire width of the canal to the depth of native sediment and to permanently and impermeably cover whatever might remain, and has identified ways to prevent re-contamination and halt future toxic inputs; I strongly support the EPA Proposed Plan to clean the Gowanus Superfund site.

Although I do not live near the Canal, I am aware of the issues and support the EPA's plan to clean it up.

Sincerely,

Abby Krumholz

COMMENTS REGARDING THE ENVIRONMENTAL PROTECTION AGENCY'S PROPOSED REMEDIAL ACTION PLAN FOR THE GOWANUS CANAL

Submitted by R. Frank Eadie
April 26, 2013

I write as a very concerned citizen and resident of New York City and former Water and Oceans Committee Chairperson of the Sierra Club's New York City Group to thank your agency for your conscientious and timely actions in designating the Gowanus Canal as a Super Fund Site and in developing the Proposed Remedial Action Plan (PRAP).

As one who has been concerned about and communicated with city officials regarding the Canal for more than two decades, I greatly appreciate your Agency's willingness, initiative and persistence in dealing with those officials and with pressures from other sources with interests in the area. You also deserve much praise for your patient and consistent efforts to include residents of the area in the entire process. In educating, listening and negotiating modes your performance has been outstanding.

Thank you, thank you, thank you!

Now I look forward, hopefully, to a similarly fine performance in the implementation phases.

Comments and Questions

I very strongly support almost all aspects of the PRAP and urge that implementation begin as soon as possible.

I do have some concerns and suggestions regarding aspects of the PRAP, however:

CSO Solids Control Measures and Costs

Would the proposed 8 million and 4 million gallon storage tanks retain 40% of the discharge volume of a Sandy-sized or an Irene-sized storm directly over NYC? Is even 40% truly adequate to protect the many improvements promised by the PRAP?

Twelve million gallons is only enough water to hyrofrack an average well two to four times.

Will Region 2 continue to review and critique NYC's performance as "Current and future high density residential redevelopment along the banks of the canal and within the sewershed," which "should be consistent with recently adopted NYC criteria for on-site storm water control and green infrastructure ... so as to not contribute discharges to the canal that would result in compromising the remedy"?

Is it possible that EPA could even suggest that high density residential redevelopment may not be the appropriate form of development along the banks, given what it knows about environmental impacts and potential meteorological changes? Just asking.

Dredging, Capping and Treatment/Disposal

For RTA 3: Option G does seem to make sense if the suggested criteria are met, but I would add another, critical one:

Option G would be used only if there is at least one very experienced, reputable, reliable contractor available that has used the appropriate procedures under similar conditions without serious misadventures.

If otherwise appropriate, Option G might also be used in dealing with the 1st Street Basin spoils, as well.

Community Outreach Considerations

Local residents and other stakeholders would greatly appreciate receiving notification of EPA's expected timeline for the project and of potential meeting and feedback opportunities.

Re: Gowanus Canal Superfund Proposed Plan
Response to EPA Region 2 Proposed Remedial Action Plan (PRAP)

Dear Christos:

Thank you and the entire Region 2 Gowanus Canal Superfund Team for the opportunity to comment on the Proposed Remedial Action Plan (PRAP) for the Canal Cleanup.

As you know, the Gowanus Green team has been designated by the New York City Department of Housing Preservation and Development (HPD) to re-develop the Public Place site once National Grid, under NYS Department of Environmental Conservation's (DEC) oversight, has completed the remediation of the former Manufactured Gas Plant (MGP) site. Gowanus Green is an affordable, mixed income, mixed use development whose design includes public open space, and over 770 units of housing, 70% of which will be subsidized and affordable to families at a range of incomes. Our team has extensive experience redeveloping brownfield sites to the highest sustainability standards while also creating much needed affordable and mixed income housing.

The Gowanus Green team appreciates the time that you and members of the US EPA Region 2 team have spent with us discussing the proposed remedial action plan (PRAP) and how it may impact on the design of our project. It is clear from our discussions that EPA's detailed oversight of the Gowanus Canal cleanup and review of plans for the remediation of the former MGP sites which are contributing to the contamination of the Canal has resulted in a more thorough draft remedy for the former Citizens site, in particular. Our team is hopeful that the final remedy for the Citizens site will be meaningfully improved as a result, leading to a significantly less contaminated parcel that is ultimately to everyone's – the community, National Grid and Gowanus Green's - benefit.

As the Record of Decision (ROD) is finalized and plans move into design, Gowanus Green would like to be substantively involved in discussions with US EPA and NYS DEC about the designs for the Public Place/former Citizens MGP site. Specifically, we'd like to discuss excavation depths, barrier materials, barrier wall and its final location and the location of tie backs for the barrier wall, location of collection wells, and any other facility or access connected to the remediation which might ultimately be located on the current

GOWANUS green

The Bluestone Organization
Fifth Avenue Committee
The Hudson Companies
Jonathan Rose Companies

Public Place site. We look forward to working closely with all the stakeholders involved to coordinate Gowanus Green's design and construction as needed.

Finally, Gowanus Green continues to be concerned about additional delays. Though the EPA has kept to its word on the timing of the Remedial Investigation and PRAP, NYS DEC has not been as diligent and ultimately their delays will impact the entire Gowanus Canal cleanup timetable. We respectfully request that EPA consider a Gowanus Canal cleanup timetable that accelerates the design and remediation of the MGP sites. Ultimately, the Gowanus Green team would like the EPA to utilize its authority to advance the most coordinated and timely cleanup of the Gowanus Canal possible.

Our proposal for the Public Place site will provide much needed affordable housing and public open space long sought by the adjacent community. We submit these comments on the PRAP with a strong desire to advance the remediation of the Public Place site and the Canal and its environs which has long been awaited by this community.

Thank you for the opportunity to comment on the PRAP. We look forward to continued work with the EPA as the Canal cleanup moves forward.

Sincerely,

Att: Christos Tsiamis

Dear Mr. Tsiamis,

Biehl & Co., LP is a marine agent in the Port of New York & New Jersey that coordinates the docking and undocking of marine ships with a focus on Bulk Carriers/Cargo.

We have reviewed the EPA Gowanus Canal Superfund Red Hook Proposal and think it would be beneficial to the port. As agents we often struggle with the lack of docking space for full sized ships, whether lack of deep water, inadequate upland or failing marine structures, it is a battle to keep ship owners happy and wanting to return to the port. Further, the lack of infrastructure in the port drives many maritime opportunities to other states.

The expansion of the GBX terminal not only adds capacity to the port, but sends the right message to importer/exporter's and ship owners from around the world that NYC is coming back.

I have worked with John Quadrozzi, Jr.'s cement company, NYCEMCO, for over two decades. I know him to be a hard worker sometimes spending several days without sleep to efficiently unload his cargos. I am confident that John will make GBX a viable location as he had done over these many years in the cement importing business.

We request you approve the Red Hook Option.

Thank you for allowing us to provide our input in this important matter.

Sincerely,

Joe Maranzani

May 17, 2012 (originally written)

Christos Tsamios
US EPA
New York New York

Dear Mr. Tsamios,

This letter is in support of the GBX proposal for a confined disposal site beneath the Gowanus Canal for the disposition of contaminated dredged material that now exists on the surface of the canal. I think the alternative of filling a turning basin is not acceptable because it would destroy existing and future habitat.

I support the use of a CDF because I am aware that such an approach is effective in Newark Bay. I speak with a certain amount of knowledge of the options for disposition of dredged material. While I was in New York State Department of Environmental Conservation as Special Assistant to the Commissioner for New York Harbor Environmental issues, my portfolio had dredging and dredged material disposal as a major factor. During that time I co-chaired dredging conferences dedicated to finding innovative sustainable ways to deal with dredged material. In addition I made a presentation about dredged material disposal before the New York Academy of Sciences. I continued to follow the dredging issue while I was at New York City Economic Development Corporation as Director of Port and Intermodal Planning, as consultant to the Gowanus Canal Community Development Corporation in developing its conceptual plan for redevelopment, and continue to do so as a member of the Steering Committee of the Harbor Operations Committee.

Although my words of support are few they are based on a great depth of knowledge and experience.

Very truly yours,

Roberta Weisbrod

Mr. Christos Tsiamis
Project Manager
Central New York Remediation Section
U.S. Environmental Protection Agency
290 Broadway 20th Floor
New York, New York 10007-1866

Dear Mr. Tsiamis,

First of all, I wish to convey my appreciation to you and the Agency for listening to my community's concerns regarding the possible creation of the CDF and de-watering facility in Red Hook.

My name is Allyn Bacher, I live at 83 Dikeman Street in Red Hook. I am a mother of a 15 year old boy and a small business owner. For the first time in the 35 years I've lived in New York City, I have found a real home in the special community of Red Hook. And more importantly, my husband and son share these feelings.

I am writing to you today to express my family's concerns relating to the EPA's Gowanus Superfund proposal, speficially options E,F & G. I attended the public meeting in February at PS 15. Since that time I have dedicated many hours toward educating myself and the Red Hook community on the choice we are being asked to make by the EPA. When the community became aware of the EPA's proposal it was crystal clear that options E,F & G were not acceptable to our community – as your team witnessed on April 16th at the meeting at South Brooklyn Community High School. We support the proposal mentioned at that meeting, by Walter Mugden, that the sludge de-watering take place on barges located within the area where dredging is occurring, and thank him for his repeated statement that the CDF and de-watering facility will not come to Red Hook.

My family is not opposed to the cleaning of the canal but we are strongly opposed to the currently proposed location within the bounds of Red Hook – especially so close to our community Ball Fields and the adjacent public housing residences – for dewatering the toxic sludge, any solution which involves stabilizing the sludge on-site (in Red Hook), and storing it in Red Hook in any form within a CDF. We are also troubled that the testing to measure toxicity and determine the composition of the sludge in the Gowanus Canal was done prior to Hurricane Sandy and now that data is no longer valid. How can the EPA move forward with the Gowanus Canal clean-up without current and accurate data?

We urge the EPA to hold the immediate and long term health effects of person and property above all else. Regardless of the venetual outcome, we expect the EPA to use all means necessary to monitor any particles released into the atmosphere during all stages of this process, collecting real time data throughout, and make to that data public knowledge.

We are hopeful that the EPA will be sensitive to our concerns and those of the residents who live within the neighborhoods bounded by the Gowanus Canal Superfund Site and that their final decision will be an amenable solution to the concerns presented.

Thank you,

allyn Bacher
Jeffrey Chong

postmarked 4/29/13
Recd 4/4/13

To whom it may concern:

I live in Red Hook, Brooklyn with my husband and two small children and I am writing to inform you that I am absolutely opposed to the EPA's latest plan to clean up the Gowanus Canal., as this plan involves storing the contaminated dredged materials from the canal in the waters surrounding my beloved neighborhood, Red Hook. I am convinced that these stored materials would cause serious health risks to my family and my neighbors, many of whom are elderly and many of whom have small children, like myself. I understand that the Gowanus Canal needs to be cleaned and I am in favor of doing so, but I will not stand to have Red Hook become a depository for the Canals' contaminants.

Thank you.

Sincerely Yours,
Jessica Sheehan
