IMPORTANT- MUST BE SUBMITTED BEFORE *APRIL 26th, 2013* *DEADLINE!*

I support the Red Hook Option of the EPA Gowanus Canal Superfund cleanup.

The improvement to an active local maritime industrial business, the economic benefits it will bring, the jobs that it will create, are all important to me and what I believe is best for the majority of the community of Red Hook.

Further, I am confident that any necessary safeguards will be incorporated into the work, monitored and maintained, to ensure the workers and the community are without harm or risk of such.

Please approve the Red Hook option.

IMPORTANT- MUST BE SUBMITTED BEFORE *APRIL 26th, 2013* *DEADLINE!*

I support the Red Hook Option of the EPA Gowanus Canal Superfund cleanup.

The improvement to an active local maritime industrial business, the economic benefits it will bring, the jobs that it will create, are all important to me and what I believe is best for the majority of the community of Red Hook.

Further, I am confident that any necessary safeguards will be incorporated into the work, monitored and maintained, to ensure the workers and the community are without harm or risk of such.

Please approve the Red Hook option.

IMPORTANT- MUST BE SUBMITTED BEFORE *APRIL 26th, 2013* *DEADLINE!*

I support the Red Hook Option of the EPA Gowanus Canal Superfund cleanup.

The improvement to an active local maritime industrial business, the economic benefits it will bring, the jobs that it will create, are all important to me and what I believe is best for the majority of the community of Red Hook.

Further, I am confident that any necessary safeguards will be incorporated into the work, monitored and maintained, to ensure the workers and the community are without harm or risk of such.

Please approve the Red Hook option.

I support the Red Hook Option of the EPA Gowanus Canal Superfund cleanup. Recd 4/25/13

The improvement to an active local maritime industrial business, the economic benefits it will bring, the jobs that it will create, are all important to me and what I believe is best for the majority of the community of Red Hook.

Further, I am confident that any necessary safeguards will be incorporated into the work, monitored and maintained, to ensure the workers and the community are without harm or risk of such.

Please approve the Red Hook option.

Comments on Gowanus Canal Proposed Plan

Diane McMillian to: Region2 GowanusCanalComments 04/25/2013 07:13 AM

Sent by: **Riverkeeper <info@Riverkeeper.org>**

Please respond to Diane McMillian

Apr 25, 2013

Mr. Christos Tsiamis
290 Broadway, 20th Floor
New York, NY 10007-1866

Dear Mr. Tsiamis,

I am writing to support the EPA's proposed plan to clean up the Gowanus Canal Superfund site. After 150 years of pollution a comprehensive plan that addresses the toxic sludge at the bottom of the canal and ongoing pollution from CSOs and upland contamination is critically important to returning this long neglected waterway to the community.

While the EPA's plan takes the critical step of calling for CSO retention for two of the Canal's worst outfalls many details will not be solidified until New York City submits their CSO Long Term Control Plan in 2015. It is critical for the EPA to stand firm on requiring retention tanks to control CSOs and to work with New York City towards the eventual goal of 100% elimination of CSOs from the Canal.

I support the EPA's commitment to dredge as much as 10 feet of contaminated sediment from the entire length of the canal, build a multi-layer cap on the bottom, and treat and dispose of this contaminated sediment offsite. I also believe that the EPA should listen to the wishes of the community in Red Hook who oppose the building of a CDF on the Red Hook waterfront to dispose of the least contaminated sediment.

Sincerely,

Ms. Diane McMillian
PO Box 50443

I, the sender, vote that I do not want this project to proceed.

Yeshwant Chitalkar to: Region2 GowanusCanalComments 04/25/2013 07:53 AM

I do not see any benefit to the community in building the CDF in Red Hook and only see potential problems down the road that were either not transparently disclosed or foreseen.
Therefore, why am I being asked support the CDF?

Daniel Genova to: Region2 GowanusCanalComments 04/25/2013 08:41 AM

As (one of the options above) of the community of Red Hook, I/We am/are strongly opposed to the processing of contaminated sludge dredged from the Gowanus Canal Superfund Cleanup Site at a facility at the proposed location. The cost savings are negligible, and the Red Hook Ball Fields and Pool are used in public trust. The community does not want to create more land from this contaminated sludge adjacent to one of the most heavily used recreation areas in New York City. People and organizations adversely affected include (but are not limited to!):

- Children
- Numerous public and private schools which use the fields for physical education & sports teams
- Residents of the Red Hook Houses and the surrounding neighborhood
- Soccer, softball, baseball, football, handball, basketball, track & field teams and enthusiasts
- Swimmers of all ages
- The Red Hook Food vendors and their customers
- Other visitors to our community

Further, we object to an individual (John Quadrozzi), who has incurred serious fines for environmental violations, from profiting from the project.

Gowanus CAG PRAP Position #1
Jerry Armer to: Region2 GowanusCanalComments 04/25/2013 09:39 AM
Please respond to Jerry Armer

Mr. Christos Tsiamis,
The following and the attached document reflect the Gowanus CAG's first comment on the Gowanus PRAP

The Gowanus Superfund Community Advisory Group (Gowanus GAG)
Statement To The EPA
On The PRAP

The Gowanus Superfund Community Advisory Group (Gowanus CAG) would like to thank the US EPA Gowanus team at Region 2 for their leadership, transparency, timeliness and their ability to listen to the many & varied concerns, wants, desires and needs of the greater Gowanus community. Their ability to synthesize the various statements into a coherent RAP indicates their commitment to this project.

The CAG would like to remind EPA of the resolution passed unanimously by the full group in 2012. The CAG wants to make certain that the Record of Decision for the Gowanus cleanup gives the EPA sufficient authority to meet the goals of the April 5, 2012 CSO Resolution

The Gowanus Superfund Community Advisory Group fully supports the U.S. Environmental Protection Agency in its finding that New York City's Combined Sevier Overflows are a significant contributor of harmful sediment and Superfund regulated PA Hs and metals to the canal. The CAG takes the position that the total elimination of CSOs into the Gowanus Canal is the only acceptable solution to the problem. The CAG asks that the EPA, under their Superfund authority, take the necessary measures that will ensure protection of the proposed remedy from ongoing CSO sediment solids deposits and the release of PAHs and other toxins."

The CAG requests the inclusion of the entire 5th Street Basin in the EPA Superfund

Remediation Plan CAG Position #1.doc.docx

ATSDR
Suzie Stempel to: Region2 GowanusCanalComments 04/25/2013 10:21 AM

To Whom it May Concern:

I see no mention of the ATSDR findings in the Human Health Risks section of this plan. Upon further investigation, it looks as if this report has not yet been completed. This process has already been completed for Newtown Creek, which was listed as a Superfund site well after the Gowanus. Will the ATSDR be completed for the Gowanus Canal? If so, when will these findings be made public, and how will they be incorporated into the remediation plan?

Thank You,

Suzie Stempel

Gowanus CAG Position #2 Statement on the Gowanus PRAP

Jerry Armer to: Region2 GowanusCanalComments 04/25/2013 10:44 AM

Please respond to Jerry Armer

History: This message has been forwarded.

Mr.Christos Tsiamis
Gowanus Remedial Project Manager

The following & attached is the Position #2 statement from the Gowanus Canal CAG on the Gowanus PRAP

Gowanus Community Advisory Group's (CAG) Statement #2 on the PRAP
Approved at its April 23, 2013 meeting.

In addition to the comments submitted earlier, (please see attached Position #1) the Gowanus Community Advisory Group (CAG) submits the following statements as their public comment on the PRAP.

The Gowanus Canal Community Advisory Group, comprised of fifty plus (50+) members representing over thirty organizations and 20 non organizational members, wishes to thank the EPA Region 2 Gowanus Team for their transparency, dedication and true to their word timeliness during these first phases of the Superfund process.

You came to us faced with a Herculean task and we knew it. We are appreciative of your continued commitment to community, and in particular, to CAG involvement. We want to thank you for your willingness to reach out to the various communities surrounding the Gowanus Canal and being responsive to their concerns. We know that it was precisely this respectful collaborative spirit, the constant exchange of information, sharing of concerns, ideas, hopes and possibilities which led us to the Proposed Plan before us today.

We are in support of the Proposed Plan which:

---cleans and caps the bottom of the Canal

---prevents recontamination from the uplands and

---effectively addresses the known toxic compounds contributed by the Combined Sewer Overflow (CSO) at their source, while simultaneously helping us get closer to our goal of CSO elimination in the Canal

We move forward with confidence in the knowledge that we have been heard.

As the Proposed Plan establishes methods for removal of contaminated sediments for the entire width and length of the Canal, to the depth of the native sediment, and has identified ways to prevent re-contamination and halt future toxic inputs; the Gowanus CAG supports the EPA Proposed Plan to clean the Gowanus Superfund site.

The CAG looks forward to continued open discussions with the EPA as project design details are developed.

Comments on Gowanus Canal Proposed Remedial Action Plan

Roy Sloane to: Region2 GowanusCanalComments 04/25/2013 11:19 AM

History: This message has been forwarded.

Dear Mr. Tsiamis,

Attached please find the comments prepared by the Cobble Hill Association's CAG representative Jerry Armer. Our executive board has reviewed and voted unanimously to support these comments. We support and deeply appreciate all the efforts by the EPA to clean up the Gowanus Canal. Thank you on behalf of all of the members of the Cobble Hill community.

Sincerely,
Roy Sloane, President
Cobble Hill Association, Inc.
P.O. Box 376
Brooklyn, NY 11201

GowanusPRAPcomments.pdf

COBBLE HILL ASSOCIATION•P.O. BOX 376•BROOKLYN•NY 11201

Comments on Gowanus Canal Proposed Remedial Action Plan

The Cobble Hill Association (CHA) would like to commend the US EPA and the local Region 2 staff that has worked cooperatively with the Gowanus Community Advisory Group (CAG) over these last two and one half years in understanding the various desires of the communities surrounding the Gowanus Canal Superfund site.

The CHA generally concurs with the EPA's Remedial Action Objectives as outlined in PRAP and looks forward to a positive working relationship with the EPA Region 2 staff in the next phases(s) of the Superfund Clean-up of the Gowanus Canal.

The CHA through the Gowanus CAG has supported Gowanus Canal water quality improvements to SC (secondary Contact) standards with regular pathogen monitoring. We would like to see a stronger commitment from the City, State and Federal governments that standard would be achieved.

We are concerned how the future elimination of the migration of Nonaqueous Phase Liquids (NAPL) will be achieved, since two of the three Manufactured Gas Plant (MGP) sites do not have remedial plan commitments in place.

We support the integration of soft edges as an alternative to metal bulkheads wherever practicable, and the introduction of flora and fauna appropriate for the control and absorption of water runoff and the natural treatment of contaminants that may be present.

The proposal for the placing of a Confined Disposal Facility (CDF) in Red Hook has generated a significant level of negative comments in Red Hook and has managed to divide the Red Hook community and to pit one community against another community. Since the EPA has not stated the methodology as to how they will "measure the Red Hook community's acceptance" of the CDF in Red Hook, the CHA cannot support this option.

The CHA is totally committed to the full and complete elimination of CSOs into the Gowanus Canal. This must be achieved not in the distant future, but must be accomplished within the EPA's time frame of cleaning up the Gowanus Canal with all proven and accepted techniques.

Though some questions remain, overall, the CHA as a member of the Gowanus CAG supports the PRAP.

History: This message has been forwarded.

To whom it may concern:

I live in Red Hook, Brooklyn with my husband and two small children and I am writing to inform you that I am absolutely opposed to the EPA's latest plan to clean up the Gowanus Canal., as this plan involves storing the contaminated dredged materials from the canal in the waters surrounding my beloved neighborhood, Red Hook. I am convinced that these stored materials would cause serious health risks to my family and my neighbors, many of whom are elderly and many of whom have small children, like myself. I understand that the Gowanus Canal needs to be cleaned and I am in favor of doing so, but I will not stand to have Red Hook become a depository for the Canals' contaminants.

Thank you.

Sincerely Yours,

Jessica Sheehan

Subject: Opposition to EPA's Plan to CDF Plan for Gowanus Canal

Dear Ms. Loney,

I am resident of Red Hook and I am writing to share my opposition to the EPA's current plan to build a confided disposal facility with the purpose of remediating toxic materials and mixing them with cement.
As a resident, I think this plan will be harmful to our community and furthermore, I do not believe John Quadrozzi, whose company has polluted the Gowanus for years, should benefit from the EPA plan. I hope that you see our community is clearly not in favor of this plan and further does not trust Mr. Quadrozzi.

Best,

As (one of the options above) of the community of Red Hook, I/We am/are strongly opposed to the processing of contaminated sludge dredged from the Gowanus Canal Superfund Cleanup Site at a facility at the proposed location. The cost savings are negligible, and the Red Hook Ball Fields and Pool are used in public trust. The community does not want to create more land from this contaminated sludge adjacent to one of the most heavily used recreation areas in New York City. People and organizations adversely affected include (but are not limited to!):

- Children
- Numerous public and private schools which use the fields for physical education & sports teams
- Residents of the Red Hook Houses and the surrounding neighborhood
- Soccer, softball, baseball, football, handball, basketball, track & field teams and enthusiasts
- Swimmers of all ages
- The Red Hook Food vendors and their customers
- Other visitors to our community

Further, we object to an individual (John Quadrozzi), who has incurred serious fines for environmental violations, from profiting from the project.

Email: GowanusCanalComments.Region2@epa.gov

Mr. Tsiamis,

My name is Carly Yates, I live at 25 Dikeman Street in Red Hook, Brooklyn. I am writing to you today to express my deepest concern to the EPA's Gowanus Superfund proposal in relation to the community of Red Hook.

I am a mother and small business owner. My business is 8.8 Design LLC an Interior Design studio located in Red Hook. I am an informed and protective member of this community. When hurricane Sandy hit, one third of my house was devastated and every physical aspect of my business was destroyed, Gone. This is unfortunately the common story for residents and business owners in our beloved village. In the time spanning from the storm Oct 31st until the last EPA meeting at P.S-15, February 15th my full time job was recovery. That focus shifted upon learning of the EPA's proposal option for Red Hook. I heard a brief of the proposal from my neighbor as he was walking to that meeting and I was in disbelief. How could such an impactful proposition be put to this community yet I hadn't heard anything of it? That reason is that I like my neighbors were focused on the crisis and recovery.

Since that time I have dedicated many hours a day to educating myself on this topic, researching and discussing information with my neighbors; a well educated, passionate and diverse group of caring individuals to inform this community of the choice they are being asked to make. That 1st week after I learned of the Red Hook options E,F & G. I started asking everyone I knew in this community if they had heard about it and only 1/10 had. That was a shocking and unacceptable ratio when compared to the magnitude the impact of those options could have on this community.

When the community did become aware of these options through our efforts it was outstanding that E, F or G options are not welcome in our community as your team witnessed on April 16th at South Brooklyn Community High School. This is also evident via the petitions, letters and postcards you have received.

Mr. Tsiamis there is much I could say regarding the private party this proposal, proposes to be engaged with but that point has been made and displayed. I will say on that topic that I am surprised that a man of your obvious intelligence would not have immediately discarded such a party. This is because these options were presented to us in the format of trust. *Trust* that the CDF would be safe, and *Trust* that the air quality and environmental impact would be fine. When your office does not support those assurances with scientific studies and data you are asking us to TRUST you and the proposed entity. When we are told those studies are done after the proposal stage that is asking too much of this historically dumped upon and now storm damaged community.

My family and I are not opposed to the cleaning of the canal but are strongly opposed to any option that would expect Red Hook to shoulder the burdens of that clean up. Building a CDF or a "de-watering facility and/or remediation facility" within red hook and/or options E, F & G is unacceptable. I expect the EPA to design a process that shares all burdens equally while holding the immediate and long-term health effects of person and property above all else. Especially held above any cost savings to the polluters. I also expect the EPA to use any means necessary to ensure that real time data be used to monitor particles released into the atmosphere during all stages of this process and make that data public knowledge.

The EPA's proposal and studies were done in a pre-sandy condition, I strongly urge you to re-test the sediments at the bottom of the canal in the Red Hook portion to make sure that the composition of the sediment is of the same make up. Your proposal plan is based upon this composition and thus re-testing is prudent. I worry that the EPA's stated "lesser contaminated" material in that portion of the canal has changed to higher toxicity levels. I also worry that another storm surge could devastate the clean up procedures causing short and long-term health problems from spilled material. I expect that all possible engineering technologies be used and all precautions taken to ensure the health and safety of all communities should another storm surge happen during the cleanup, sparing no expense.

I thank you and your team for coming back to Red Hook to hear the community once our storm ravaged and recovery focused community really did have your attention. Thank you for stating over and over that the CDF would not be built and confirming that dewatering on barges along the canal is a plausible and a likely alternative to a facility in Red Hook. I / We will of course be paying very close attention that these options are discounted in the design phase as stated. We were asked to give support to or reject these options and rejection is well proven and documented.
I will consider the issue of trust re-set but will be watching closely.

Unwaveringly,
Carly Yates

I. INTRODUCTION

National Grid commends the Environmental Protection Agency (EPA) for its significant efforts in addressing the challenges posed by remediation of the Gowanus Canal. In addition to decades worth of contamination from hundreds of industrial sources, the Canal is impacted by significant contamination from municipal combined sewer overflows (CSOs), storm water outfalls, and other direct outfalls that continue to this day. Addressing the environmental state of the Canal became all the more challenging when the complexity of the waterbody and the community desire for a speedy remediation were added. Commendably, the EPA has worked extremely hard and has strived to satisfy community expectations by expediting the Remedial Investigation (RI) and Feasibility Study (FS), and issuing a Proposed Remedial Action Plan (PRAP) within two years.

For its part, National Grid quickly recognized the challenge posed by the Gowanus Canal and has stepped up to be part of the solution. After it acquired the companies that held responsibility for the manufactured gas plant (MGP) sites in Brooklyn, National Grid moved expeditiously and used significant resources to remediate the legacy MGP sites, which are located along the Canal. National Grid immediately began and continues to participate in community meetings, communicating with citizens groups, and working with community officials and representatives. In addition, National Grid has collaborated closely with the EPA and conducted a number of essential studies, which it has shared with EPA.[1] Lastly, National Grid assembled experienced, nationally recognized experts to assist in reviewing the technical aspects of the FS Addendum and the PRAP, and to offer expert insights to assist the EPA. All of these efforts are aimed at making the remedy one that is appropriate, sustainable and, most important, successful.

The EPA's understandably fast tracking of the RI / FS, however, did not come without consequences. The record pace to select the final remedy this year has left insufficient time to fully understand the Gowanus Canal eco-system and to evaluate how a proposed remedy will perform under future conditions. Indeed, the Contaminated Sediment Technical Advisory Group (CSTAG) recognized this challenge when it warned that the EPA was proceeding without a complete understanding of all of the Canal elements (EPA 2012a). National Grid's experts have echoed this concern and agree that significant design studies, flexibility, and adaptive management are needed to increase the probability of success.

Nonetheless, the PRAP is a bold first step toward proposing a remedy that, if designed based on good science and implemented under a flexible Record of Decision (ROD), can achieve meaningful remediation. Seeking to align the Clean Water Act (CWA) with the Comprehensive Environmental Response, Compensation and Liability Act (CERCLA or Superfund), the EPA has set out a blueprint to address our national problem of ongoing combined and sanitary sewer discharges to urban water systems. The PRAP correctly proposes that the CSOs be addressed now with a combination of interim and long-term controls. The EPA, however, needs to go further because the proposed CSO storage tanks may not capture a sufficient volume of the

[1] A list of the studies and other documents that National Grid has submitted to EPA for inclusion in the Gowanus Administrative Record is attached as Appendix A.

contamination, including petrogenic and pyrogenic polycyclic aromatic hydrocarbons (PAHs), metals, pesticides, and other contaminants associated with fine particles discharged from the CSOs during the total duration of CSO events. This issue, plus specific identification of interim controls, must be addressed in the ROD. If they are not addressed and the much needed CSO controls are postponed until after the remainder of the Canal remedy is implemented, recontamination will occur quickly, wasting not only time and resources, but also resulting in an inability to meet water quality objectives and to attain sustained sediment improvements, needless and substantial disruption, and significant disappointment to the community.[2]

That being said, National Grid recognizes CSO control poses a difficult challenge. Like the decades old contamination left over from the industry of another era that poses its own challenges, the CSO system is dated and its infrastructure is complex. Improving the CSO system is not easy and certainly cannot be done overnight. Any improvements will be very expensive and pose unique technical challenges. To the extent complete CSO control proves to be infeasible and continuing discharges of polluted water are not fully addressed, it will be impossible to effectively remediate the Canal. In addition to adequately controlling the inflow of sediments and contaminants from the CSOs and storm water discharges, other industrial sources need to be identified and controlled. Accordingly, the EPA must be prepared to set in the ROD realistic remedial action objectives (RAOs) and performance standards which recognize and are calibrated to the level of control that is achievable in the near term. Due to remaining uncertainties regarding the appropriateness and specific design requirements for remedy components like dredging, capping, and sediment disposal, the ROD should contain language that allows for the application of alternative methods and techniques that are acceptable to EPA.

Equally important to source control, the EPA needs to work with all parties to study and design remedy components like dredging, capping, and sediment disposal, refine the conceptual site model that evaluates all potential current and future exposure pathways, collect additional data to understand sediment and contaminant transport, and then clarify RAOs and performance standards. Along the way, the design process should not be blind to the potential for equally effective and more efficient alternatives. As a result, the ROD should be flexible enough to allow application of such potential alternatives and allow for real-time modification of the remedy even while it is being implemented. Such an adaptive management approach will enable the parties to work together to design an appropriate and sustainable remedy that will need to be done only once.

[2]Careful consideration of the remedial evaluation factors set forth in the National Contingency Plan (NCP) is also critical in developing the ROD. Those factors – overall protection of human health and the environment, compliance with Applicable or Relevant and Appropriate Requirements (ARARs), long-term effectiveness and permanence, reduction of toxicity, mobility, or volume, short-term effectiveness, implementability, cost, and state and community acceptance – are markers against which the remedy should be measured. A remedy that allows for recontamination fails to meet those measures.

The comments that follow outline many of the important design tasks in more detail and propose specific and practical recommendations in the Conclusion. National Grid has been and continues to be prepared to do its part in these efforts. For the remedy to succeed, all stakeholders must keep an open mind and accept the realities that the Canal is an extremely difficult setting, there will likely be delays, and there needs to be an honest discussion about real need for CSO control and best practices for dredge and cap design. If we work together and do the right thing, then together we can work to restore the Gowanus Canal and achieve the clean waterway that all stakeholders desire.

II. EXECUTIVE SUMMARY

The PRAP's plan to mesh the requirements of the CWA and CERCLA establishes the Gowanus Canal as a significant opportunity to chart a new course in urban waterway remediation. If design of the remedy is undertaken with appropriate planning, flexibility, and adaptive management, the EPA will not only be in a position to make significant positive strides toward addressing CSOs and perfecting innovative technologies that can have benefit around the nation, but it will have done a great service to the Gowanus community.

In order to reach those accomplishments, the EPA must move from the concepts contained in the PRAP to specifics in the ROD. The EPA must now work with all parties to create a detailed plan that will control sources to the maximum achievable level, while simultaneously maintaining flexibility and employing an adaptive management approach to designing the rest of the remedy. Once the impacts of source controls are known, the EPA and the parties should reevaluate matters in light of this newly developed information and move in the appropriate direction. To the extent sources cannot be controlled fully, the Canal cannot be cleaned to the extent all would like. Hard choices about the use and ecological recovery will need to be made. These choices must be fully vetted during the design process, so that all parties, including the community, know what the future vision of the Canal is. Only with such vision, known and acknowledged by all stakeholders, can a cooperative effort be had that will make this project a success.

The experts brought together by National Grid will benefit the EPA and the community, as their experience-based recommendations will facilitate creation of the needed vision and plan. They stand ready to assist in the significant efforts that lie ahead, and if afforded the needed flexibility, will help fill in data gaps and help design a remedy that will be the most successful and, therefore, only need to be performed once.

The Gowanus Canal system and the performance of the proposed remedy under future conditions remain largely unexplored. Indeed, as made clear in the accompanying comments by Michael Palermo, P.E., Ph.D. and Alex Brunton, Ph.D. of Baird & Associates, the proposed dredge and cap remedy not only requires evaluation of a host of issues that are not considered in the PRAP, but modeling results raise questions about whether the remedy, as proposed, can meet its objectives. For example, once the flushing tunnel is operational, the increased flow will adversely affect the proposed sand benthic layer and possibly wash it downstream. Continued commercial navigation similar to what is conducted now could also compromise any cap due to

propeller induced scouring, which alone could negate the benefits intended from all capping. There may also be periods of hypoxia in remediation target area (RTA) 2 due to reduction in flow caused by an increased depth resulting from dredging.

On the other hand, and contrary to the EPA's PRAP assumptions, testing by Danny Reible, Ph.D. has found no evidence that non-aqueous phase liquid (NAPL) will be mobilized by the weight of a sediment cap; Drs. Palermo and Reible advise that soft sediment can be capped successfully; and early field work indicates that In-Situ Stabilization (ISS) may very well be suitable as well.

The following is a summary of key observations that have been raised by experts retained by National Grid, which are attached as Appendices B through G:

- **Professor Danny Reible, Ph.D.** is a nationally recognized expert on capping technologies, including geotechnical issues and constraints for capping, cap design, evaluating recontamination, cap performance, and long term protectiveness. Dr. Reible's observations are provided as Appendix B and include:

    - Capping of soft sediments should not be ruled out as a potential technique for isolating deeper contaminants. Soft sediment capping has been conducted successfully at other contaminated sites.

    - Initial testing has not observed NAPL mobility in the soft sediments, which may simplify capping and may allow capped soft sediments to be left in place to stabilize NAPL in deeper native sediments (Appendix K).

    - Cap requirements will vary along the length of the Canal depending on sediment conditions, presence of NAPL, groundwater expression, ebullition and navigational requirements. The cap should be designed for specific conditions to optimize placement, functionality, and long term operational costs.

- **Michael Palermo, Ph.D., P.E.** was a Director of the United States Army Corps of Engineers Center for Contaminated Sediments and is an expert in evaluating capping and dredging, including among other things, feasibility, planning, overall coordination and sequencing, volume and production rates, costs, and effectiveness. Dr. Palermo's observations are provided as Appendix C and include:

    - Dredging to the native sand layer may needlessly compromise the existing bulkheads along many parts of the Canal, resulting in potential failure of the cap.

    - Capping soft sediments in select areas of the Canal should not be discounted, but rather should be evaluated during the design process.

    - Commercial navigation in the upper portions of the Canal (RTA 1 and RTA 2) will be interrupted during construction of the remedy. After construction, commercial navigation is likely to cause severe stress on any cap. Given the limited water-dependent industry currently in the upper reaches and the

significant interruption of commerce that will occur during construction of the remedy, serious consideration should be given to the extent of commercial tug and barge navigation permanently allowed in these reaches.

- Significant additional studies will be required to fully define and design the remedy. The full implications of the site conditions, the need for some of the proposed remedy components, the potential negative impacts of some proposed actions, the effectiveness of some components, and the practicability of implementing some of the components must be fully evaluated.

- Flexibility, within the bounds of meeting remediation goals, is essential for addressing complex sites like the Gowanus Canal.

- **Baird & Associates** are experts in marine engineering, hydrodynamic and sediment transport modeling and water quality modeling and navigation studies. Baird has developed a calibrated model of the Gowanus Canal, and performed a vessel impacts study, numerical modeling, modeling of CSO flow and sediment inputs, historical analysis of Canal sediment and contaminant dynamics, and modeling of water quality and contaminant transport (Appendix D). Dr. Brunton, who performed the modeling, offers the following conclusions:

  - Sediments entering the Canal through the existing CSO discharges are deposited near the CSO outfalls and comprise the existing soft sediment layer. This condition will continue even after the flushing tunnel is reactivated. Sand deposition near the outfalls will continue (depending upon their location in the Canal) under flushing tunnel flow. Fine sediment (silts and clays) will be redistributed through the Canal and end up in deeper areas of the Canal.

  - The elevations selected for the final cap remedy will determine where ongoing solids in the CSO discharges will collect in the Canal. Deep dredging in the upper reaches of the Canal will result in low water velocities and settling of solids onto the bottom of the Canal, as well as lower dissolved oxygen (DO) levels in the water column. The resulting Canal will at times fail to meet CWA requirements, even with the flushing tunnel active, if the design does not account for these considerations.

  - Bed sheer stresses associated with current Canal tug and barge traffic will destroy the benthic zone in areas with shallow (less than 30 feet deep) water. Baird & Associates believes commercial navigation creates formidable challenges to maintaining cap integrity and ecological recovery in RTAs 1, 2, and 3a.

  - Continued accumulation of CSO sediments above the cap is expected to occur under the proposed remedy conditions. This accumulation may compromise ecological recovery.

  - Higher flow velocities are likely to result, at least locally, during the implementation of some components of the remedy. These include use of sheet

piling, or silt fences which may restrict flow in the channel, operation of barges and tugs, and normal navigation activities. Any of these operations may result in velocities that scour contaminated sediment from the bottom of the Canal and redistribute it downstream. The remedial design will need to account for potentially damaging flow velocities.

- **Exponent** has performed an analysis of sediment chemistry data and an evaluation of sources, risk, and dredging risks and effects (Appendix E). Paul Boehm, Ph.D. and Tarek Saba, Ph.D., who performed the analysis, offer the following conclusions:

    - Shallow accumulated sediments and associated contaminants in the Canal likely originated from the CSOs and other upland sources of sedimentation. The sources of sediments are ongoing and will continue unless the CSOs, storm sewers and other upland sources are addressed.

    - Following review and analysis of work performed by GEI, Exponent confirmed that accumulated sediments have elevated levels of a variety of pathogens and pharmaceuticals and personal care products (PPCPs) that are similar to those found in CSO discharges. These compounds will continue to accumulate and cause toxicity in the shallow sediments until CSO and other upland discharges are addressed.

    - PAH distribution in the sediments occurs at different depths. The lower depths are largely attributable to, among other things, the MGPs. PAH distribution in the accumulated shallower sediments point to a range of potential sources including petroleum spills, road runoff, and other materials which likely enter the Canal through the CSOs, storm sewers, and direct groundwater discharges. These sources will need to be addressed in addition to the MGPs to lower future PAH levels in post remediation surface sediments.

    - In RTA 3b, elevated contaminants are present in limited areas ("hot spots") and should be addressed using a targeted approach as opposed to the proposed remedy of dredging the entirety of RTA 3b.

- **Mutch Associates, LLC**. and GEI Consultants, Inc. (GEI) have developed a groundwater model for the Gowanus watershed. The model suggests the following conclusions:

    - Groundwater flows into the Canal, primarily in its upper reaches (RTA 1 and RTA 2). Groundwater flow rates in RTA 3b are significantly lower.

    - Introduction of impermeable barriers along the sides of the Canal will deflect groundwater flow toward New York Harbor. The groundwater table will tend to mound behind impermeable barriers, potentially resulting in localized flooding.

- **Marc Wilkenfeld, M.D.,** a Board Certified Occupational Physician and GEI have analyzed Canal-related pathogen and public health issues. Dr. Wilkenfeld's curriculum

vitae is attached as Appendix F. Dr. Wilkenfeld and GEI have made the following observations:

- The CSOs are releasing a broad range of pathogens and PPCPs. The potential for these compounds, which are not addressed in the FS for the Gowanus Canal, to pose a health threat to those who come into contact with Canal waters should be carefully evaluated by the appropriate public health and environmental regulatory authorities.

- **Woodard & Curran**, an environmental engineering firm with sewer design expertise, has evaluated CSO data and cap recontamination by ongoing sources. Janet Robinson and Vincent Spada, P.E., have evaluated the proposed remedy and the presumed upgrades to the CSOs (Appendix G) and offer the following observations:

  - EPA's observation that the CSOs have been and will continue to be a significant source of sediments and contaminants to the Canal is well founded. The CSOs are widely documented to contribute the levels and types of contaminants seen in the accumulated Canal sediments.

  - The City of New York has indicated that its Waterbody / Watershed Facility Plan (WWFP) is essentially going to be the City's long term control plan (LTCP), which is due in June 2015. The WWFP, as written with the addition of some planned sewer separation and green infrastructure, will not offer the same level of CSO control that is recommended in the PRAP.

  - The PRAP proposed CSO controls of an eight million gallon storage tank and a four million gallon storage tank is an accepted and proven CSO control technology that will provide CSO control for low intensity storm events.

  - EPA suggests that capturing the first 40 percent of the total discharge volume of each storm will likely capture the storms first flush, which is needed to ensure protectiveness of the proposed remedy. There is not sufficient characterization of the Gowanus CSO discharges during storm events to support this conclusion.

  - The EPA's proposed remedy includes storage tanks to capture about 65 percent of the total annual CSO discharge volume to the Canal. To better ensure that the protectiveness of the remedy is maintained, EPA should consider using the CSO presumptive level of 85 percent capture of annual CSO discharge volume as a criterion, the standard set forth in EPA's CSO Policy.

  - Another approach to reducing CSO loading may be to establish a total maximum daily load (TMDL) for total suspended solids (TSS) in the CSO discharge. The CWA requires establishment of TMDLs for water bodies that do not meet water quality standards after application of technology-based effluent limits, which will likely be the case in the Canal post-remedy.

- The proposed CSO control improvements discussed in the PRAP (including installation of tanks to capture first flush) are based on planning level design information (less than two percent complete) and numerous assumptions, including CSO discharge volumes and volume of first flush. Flow monitoring and hydraulic modeling and post construction monitoring must be conducted for the Gowanus system and may result in the requirement of additional CSO controls beyond the proposed storage tanks. Planning and design of the CSO controls must be flexible and include contingencies to expand CSO controls to account for this outcome.

GEI, an environmental engineering firm with remediation expertise, has performed the following studies:

- ISS may be a feasible technology for stabilization of Canal sediments, even though this technology was ruled out as a feasible technology during the FS. More recent bench scale ISS treatability studies conducted by GEI and Geo-Con (Appendix H) indicate that a number of additives and mixtures of soft and native sediments achieved typical performance standards for strength and permeability.

- GEI has performed repeated, seasonal sampling of surface sediments to evaluate toxicity, chemistry, and the benthic community condition throughout the Canal (GEI 2011a, 2012a, 2012b). Results of this sampling provide the following conclusions:

  - Toxicity and poor benthic community conditions are the result of a wide variety of contaminants and non-contaminant stressors. Chemical contaminants contributing to toxicity include PAHs, polychlorinated biphenyls (PCBs), metals, pathogens, and PPCPs. Non-chemical stressors that strongly impair the benthic community include low DO and poor sediment substrate conditions that result from the organic enrichment caused by CSO discharges. Therefore, control of ongoing sources of non-contaminant stressors (e.g., from CSOs and other urban runoff by way of storm water outfalls) will be needed to ensure that a sediment remedy based on reducing toxicity is successful and that full ecological recovery is achieved.

  - After the installation of the cap, exposure to NAPL associated with the former MGPs and other upland sources will be effectively eliminated, and will no longer contribute to toxicity in the Canal. Toxicity will be dominated by a number of other factors, including PAHs, PCBs, and metals derived from the CSOs, storm drains, and road runoff. Performance standards too narrowly focused on existing conditions, specifically on PAH associated with NAPL, may not provide sufficient protection to ensure ecological recovery. While remedy performance initially should be judged based on the physical integrity of the cap, longer term performance should be established following an evaluation of causes and sources of any toxicity that might remain in sediments deposited after completion of the remedy.

- The benthic community in RTA 3b is significantly healthier, and appears to be less impacted by chemical contamination, low DO stress, and poor substrate condition in comparison to the rest of the Canal. In RTA 3b, greater benthic species diversity and density were observed consistently, even to the point of including commercially important species such as blue mussels (*Mytilus edulus*). Combined with only limited hot spot areas in RTA 3b, this argues strongly for a different and less disruptive remedy in this reach. The relative lack of impacts in RTA 3b is wholly inconsistent with a remedy in which nearly 50 percent of all the sediment slated for dredging in the PRAP is found in this area.

III. COMMENTS ON THE GOWANUS CANAL PROPOSED REMEDIAL ACTION PLAN

A. Optimize the Remedy with Vision, Flexibility, and Adaptive Management

National Grid is not just a service provider to the Gowanus Canal communities, but is an active community member and supporter that has embraced the Superfund process. National Grid is well known among community officials, representatives, and groups and participates regularly with the public at Gowanus Superfund meetings. National Grid has offered to fund the Community Advisory Group Facilitator, offered technical support to citizen groups, and has supported EPA jobs programs, among many other actions. We have listened to the community and submit that the Canal remediation is not just about technical processes, studies, and data. Make no mistake, those are critical and will be discussed at length herein, but community concerns must also be considered.

This is all the more important given that implementation of the remedy, no matter what the form, is likely to have significant ramifications such as noise, odor, inconvenience, and disruption to local businesses. With its lack of detail, the PRAP inadvertently presents an overly optimistic picture and schedule. Contrary to some of the language in the PRAP, the large dredging, sheet piling, and removal / treatment components will certainly cause disruption and the enormity of the tasks that lay ahead will require careful collaborative and time consuming logistical planning.

The foregoing issues require realistic thought, serious discussion, and real understanding. Surely, everyone wants a clean Canal, while at the same time minimizing disruption and leaving neighborhoods intact, but the Gowanus remediation is so immense and complex that the EPA, no matter how well intentioned, cannot simply order it to happen. Rather, the EPA must first come to a vision of the future of the Canal. Once that vision is reached, an adaptive management approach that encourages identification and study of innovative solutions, allows for modification of such solutions to fit different areas of the Canal, and facilitates resolution of the technical contradictions in the proposed remedy (i.e., continued commercial navigation versus ecological restoration), must follow.

While National Grid is not supporting any specific future use for the Canal, there are various and competing interests that will need to be resolved in the final design of the remedy.

For example: Will the Canal be remediated for recreation or dredged for commercial navigation? How important is benthic recovery, especially given that the Canal may very well never be swimmable and fishable? What is to be done with the flushing tunnel, the CSOs, and other discharge pipes? Will the CSOs and pipes truly be controlled or is that simply unrealistic given technical limitations, costs, and politics? If they are not controlled fully, real remediation of the Canal will not be achieved. Should this scenario come to pass, background levels of contaminant concentrations that are anticipated post-remedy should be established. The community must then recognize that years of disruption will achieve only a limited improvement in water quality.

National Grid believes strongly that the EPA must supplement technical considerations in the ROD with a mixed dose of reality and "vision" of the future of the Canal. The community must not only know what it will face during the years of construction, but it must understand that due to technical realities, it is simply not possible for the remedy to accomplish all things for all parties. Stakeholders will have to compromise during the design of the remedy. The remedy can neither be dictated as it is in the PRAP, nor should remedial technologies be applied rigidly throughout the Canal length; rather, the approaches need to be tailored to specific reaches. National Grid is committed to a flexible approach and will work in good faith with all stakeholders to tailor the design so that future use of the Canal can be optimized along its entire length.

Analysis of the complex Canal hydrodynamics in conjunction with external factors like the flushing tunnel, sediment disruption by vessels and barges, and CSO flows highlights significant problems with the remedy as presently set forth in the PRAP. For example, in order for the flushing tunnel to move sediment (and contamination) under design conditions, there must be a gradually sloped, relatively shallow bed elevation throughout the Canal. Dredging RTA 2, as called for in the PRAP, will thus hamper the performance of the flushing tunnel and lead to dramatic re-sedimentation in the middle of the Canal (Appendix D) that will require routine maintenance dredging. Sedimentation will also bring additional organic matter which can increase oxygen demand as bacteria and other organisms feed on it, thus starving the water and sediments within the Canal of DO.

At first glance, it would seem that re-thinking the dredge depth in RTA 2 is in order to help achieve the intended workings of the flushing tunnel. That, however, could hamper commercial navigation. To the extent commercial navigation is desired and must be retained, ecological restoration (needed to meet the RAO of reducing risk to the benthic community) will be impeded. Commercial navigation could also frustrate several of the expressed desires of certain stakeholders within the community, including soft siding along the Canal, wetlands mitigation, public access, recreational use, and shallow benches or sponge parks. Continued commercial navigation affects another critical component of the remedy – the cap. Propeller scour will require that much larger stone be used to create the armor layer. Even then, vessel traffic would still destroy the benthic layer.

In RTA 1, where there is no commercial navigation, the flushing tunnel will do exactly what it is intended to do – refresh water quality in an otherwise stagnant water body. This is achieved by flushing sediments (in particular organic sediments) down the Canal and into

Gowanus Bay. This, however, will also push the critical sand benthic layer down the Canal, thus defeating the ecological goal of the remedy.[3]

Flexibility in the ROD that allows the use of a range of demonstrated techniques is the lynchpin that will optimize the remedy throughout the Canal.[4] The geometry of the Canal should be designed according to modeling that suggests shallower depths at the head of the Canal with gradual deepening along the length optimize flow, maximize DO levels, and move sediments out to the Bay. Soft sediment capping in RTA 1 and RTA 2 is another optimization technique because less dredging means less need for bulkhead replacement and sheet piling, less disruption to the community, and a shorter overall implementation schedule.

Capping may also be optimized to provide a substrate for the benthic community, while still containing deeper contaminants. Solidified material, reactive layers, and various armoring layers must all be explored, and even then, they may be appropriate in different amounts and configurations depending upon location within the Canal. Wetlands plantings (requiring shallower channel depths) and public access points could be located in the turning basins where flow velocities will be lower. Soft siding of the Canal would have to be balanced with the need to maintain proper hydraulics.

Within this scheme of optimization, National Grid's experts suggest that deep draft commercial navigation may best be limited to the lower portions of the Canal (RTA 3b). This is the area where most shipping currently occurs and is also the area maintained by the Army Corps as a federal shipping channel. Navigation above RTA 3b could be limited to recreational and shallow draft, low horsepower or mechanically towed vessels that will cause minimal disturbance to the benthic sand cap.

---

[3]Further complicating matters is the lack of available information on the schedule, sequencing, and future operational conditions associated with the flushing tunnel upgrades. The design of the cap and dredge remedy must take the flushing tunnel operation into account to allow both the CWA and CERCLA objectives to be achieved. In view of the fact that the City of New York has agreed to provide its hydraulic model for CSOs on Newtown Creek, similar information should certainly be made available for use during the Gowanus remedy design, including identification and design of both the interim and long term CSO controls described in the PRAP.

[4]The cost estimates contained in the PRAP may very well be underestimated. For example, the FS speaks of an unrealistic seven day per week, 12-hour per day work schedule and too small sheet piles. On the other hand, the FS leaves open the volume of wastes requiring disposal as hazardous waste. This could be a high potential cost differential. Even the cost for long term operation and maintenance of the remedy cited in the FS is an extremely low two million dollars over 30 years (present value). Given the data gaps and implementability issues which have not yet been addressed, it is difficult, if not impossible, to compare the costs of remedial options in the manner required by the NCP.

B. CONTROL ALL SOURCES

The EPA Principles for Managing Contaminated Sediment Risks at Hazardous Waste Sites, Principle One is "control sources early." The Principles go on to instruct, "[a]s early in the process as possible, site managers should try to identify all direct and indirect continuing sources of significant contamination to the sediments under investigation."

The historical industrial nature of the Gowanus area and its long and complex history of industrial uses are well known. Those uses have impacted the Canal in a variety of ways, leaving a number of contaminant sources and potential migration pathways that must be addressed. National Grid's MGPs formerly located along the Gowanus Canal are identified in the PRAP as a source and National Grid accepts responsibility for this historical contamination by its predecessor companies. National Grid is committing a substantial investment of time, energy, and financial resources to ensure that all three MGPs are being properly addressed to control potential sources to the Canal. National Grid simply seeks to have other sources treated in the same way.

The key sources of contamination are identified in the PRAP, and each one must be defined and controlled early:

- MGPs and other upland industrial sources
- CSO discharges
- Other pipes discharging to the Canal.

The ultimate remedy for the Canal should address both historical and ongoing sources. Identification and investigation of sources, and the design and installation of a remedy are complex engineering and regulatory challenges. The ROD should establish a sequence of the Canal remedy that controls all ongoing sources first, and then moves on to the active sediment remedy.[5]

(1) MGPs and Other Upland Industrial Sources

National Grid is already working with the New York State Department of Environmental Conservation (DEC) and the EPA to remediate the former MGPs. National Grid recognizes the importance of eliminating past sources of contamination to the Canal first and will continue to do its part. A remedy for the former Citizens Gas Works MGP (a/k/a Carroll Gardens/Public Place) that includes soil removal, a barrier wall and NAPL collection system designed to prevent future potential migration of coal tar has been approved by the DEC. National Grid is moving forward with this upland remedy and is hopeful that potential sources from Citizens will be controlled prior to initiation of remedial construction in RTA 2 on the Gowanus Canal.

[5]Proper sequencing of source control and remedial implementation will also facilitate both short-term and long-term effectiveness of the remedy, primary factors in determining consistency with the NCP. *See* 40 C.F.R. § 300.430(f)(1)(i)(B).

Similarly, at the former Fulton MGP site, National Grid is working on the FS with the DEC. Simultaneously, National Grid is working with the DEC to prioritize as an Interim Remedial Measure a barrier wall and NAPL collection system to effectively prevent future potential migration of NAPL from the site. National Grid anticipates that the barrier system will be completed in conjunction with the schedule proposed by the EPA, so that potential sources from Fulton will be controlled prior to initiation of remedial construction on RTA 1 on the Gowanus Canal.

Finally, at the former Metropolitan MGP site, National Grid is completing the RI report and will be starting on the FS for the site, which will include a source control barrier/collection system. Again, National Grid expects that the Metropolitan barrier system will be constructed in keeping with EPA's schedule so that potential sources from Metropolitan will be controlled prior to initiation of remedial construction on RTA 2 on the Gowanus Canal.

The MGPs, however, are by no means the only potential sources of uplands contamination, including coal tar. Various environmental databases and historical records (EDR 2009) have identified thousands of other contaminated or potentially contaminated sites within the Canal sewer shed / water shed that may cause the remedy to fail in achieving sustainable water quality improvement due to direct and / or indirect groundwater discharge to sewers and then to the Canal by the CSOs. Historical operations along the Canal include approximately 80 parcels directly adjacent to the Canal that may be responsible for groundwater impacts (including the former MGP sites along the Canal).

The RI relied heavily on data collected by National Grid from its upland MGP sites to define potential upland sources to the Canal. Additional work performed by the EPA to identify and quantify additional upland sources led to the conclusion that "[w]ith the exception of PCBs, all classes of contaminants that were sampled (for VOCs, SVOCs, PCBs, pesticides and metals) were detected in samples from both the shallow and intermediate groundwater throughout the length of the [C]anal." The PRAP fails to address the identification and interception/remediation of any of the sources (with the exception of the MGPs), except to say that upland sites will be addressed by DEC. All of these sources of contamination must also be identified and controlled first and all parties must cooperate in the same fashion that National Grid is. Failure to address all upland sources will compromise the success of the remedy.

(2) CSOs

(i) Introduction

The CSOs are one of the most, if not the most, vexing problems of the Gowanus project. While the most significant ongoing and future source of sediments and contaminants to the Canal, the CSOs are also the mainstay of the Gowanus water shed / sewer shed system. Having been put in place over a century ago, the CSOs cannot just be replaced, shut down or separated. On the other hand, if the CSOs continue to operate, the Gowanus Canal will continue to receive more than 350 million gallons of raw sewage from CSO discharges every year (New York City Department of Environmental Protection (DEP) 2008) and the soft sediments and their

associated contaminants that are attributable to storm water and CSO discharges will continue to accumulate.[6] Under such circumstances, the question is not whether the CSOs should be addressed, but rather, to what extent the CSOs can be addressed given the urban and technical realities.

(ii) Human Health and Success of the Remedy

There is evidence that the most significant source of new contaminants to the soft sediments is in fact the CSOs. Sampling of water discharged from the CSOs during a storm event in September 2012 contained suspended and dissolved solids as well as the range of contamination and foreign constituents found throughout the Canal sediments, including PAHs, PCBs, metals, pathogens, and PPCPs (Appendix J).7 This mix of contaminants threatens the success of any remedy and is set forth in the following table:

[6]Geochronology age-dating of the sediments using ^{137}Cesium and ^{210}Lead (performed by Battelle on behalf of NewFields Environmental Forensics Practice) revealed that the top four feet of soft sediments, with accumulated high organic carbon, post-date the 1950s when the MGPs were shut down. The deeper (native) sediments, on the other hand, are much older (NewFields 2007) and reflect contaminants from MGPs and other historical sources. Similarly, comparison of bathymetry data collected from 2010 through 2012 confirm that soft sediment continues to collect in the Canal (GEI 2011a, 2012a, 2012b), while modeling of sediment fate and transport demonstrates that sediments discharged from the CSOs are deposited along the bed of the Canal (Appendix D). Lastly, sampling of the top four feet of the soft sediment layer in the vicinity of the CSOs confirms the presence of CSO derived chemicals throughout the soft sediment. These chemicals include caffeine, hormones, pathogens, and a variety of PPCPs associated with CSO discharges (Appendix I).

[7]Discharge of sedimentation from the CSOs – as opposed to transportation into the Canal from New York Harbor via tidal action – is supported by multiple lines of evidence. The notion that the Harbor is the source of sedimentation is counter-intuitive based on the presence of CSO sediment mounds above low tide elevation. The DEC Consent Order (signed by New York City) that mandates dredging of these mounds to mitigate CSO "nuisance odors" (Gowanus Canal Waterbody / Watershed Facility Plan Report (DEP 2008). If tidal action was truly moving sediments and water up the entire length of the Canal, tidal flushing would be much greater than has been documented. Furthermore, the flushing tunnel, whose very purpose is to flush stagnant sewage from the Canal, would not be needed. Surficial sediment data demonstrate the presence of pathogens (e.g. fecal coliform) and PPCP compounds in the sediments that are only associated with CSO effluent. Indeed, triclosan and estradiol have both been found in shallow sediments in the Canal (GEI 2011a, 2012a, 2012b). Finally, bathymetric surveys illustrate that discharges from the CSO outfalls cause scour immediately in front of the pipes, as well as deposition of sediments just outside of these localized scour zones.

Pathogens	**Endocrine Disrupting Compounds (EDCs) and PPCPs (continued)**	**Metals**
C. perfringens	Methadone	Cobalt
Coliphage, Male Specific	Naproxen	Copper
Coliphage, Somatic	Nonylphenol	Iron
E.Coli	Nonylphenol Diethoxylate	Lead
Enterococci	Nonylphenol Monoethoxylate	Magnesium
Fecal Coliform	Oxybenzone	Manganese
Giardia	Phenytoin (5,5-Diphenylhydantion/Dilantin)	Mercury
EDCs and PPCPs		Nickel
Acetaminophen	Progesterone	Potassium
alpha-Estradiol	Salicylic Acid	Selenium
Androstenedione	Sulfamethoxazole	Silver
Bisphenol A	Testosterone	Sodium
Caffeine	Trimethoprim	Vanadium
Carbamazepine	**Pesticides**	Zinc
Diazepam	gamma-Chlordane	**Other**
Diclofenac	**Herbicides**	VOCs, including BTEX
Estradiol	2,2-Dichloropropionic acid	SVOCs, including PAHs
Estriol	**Metals**	Total Petroleum Hydrocarbons
Estrone	Aluminum	PCBs
Fluoxetine	Antimony	Free Cyanide
Gemfibrozil	Arsenic	Ammonia
Hydrocodone	Barium	Dissolved Organic Carbon

Pathogens	Endocrine Disrupting Compounds (EDCs) and PPCPs (continued)	Metals
Ibuprofen	Cadmium	Total Dissolved Solids
Iopromide	Calcium	Total Suspended Solids
Meprobamate	Chromium	Total Organic Carbon

Needless to say, the continuing discharges from the CSOs pose an ongoing risk to both human health and the environment and must therefore be a primary target of any remedy.[8] The EPA human health risk assessment (EPA, 2011) concluded that there is a significant risk to human health from incidental ingestion of and dermal exposure to carcinogenic PAHs and PCBs in Canal surface sediment. The presence of these contaminants in Canal surface sediment is primarily attributable to storm water and continuing CSO discharges.

National Grid's human health risk assessment also concluded that there is significant risk to human health from exposure to pathogens and PPCPs (GEI; 2011a, 2012a, 2012b), which EPA did not evaluate. Pathogen and PPCP contamination has been detected throughout the Canal surface sediment. Dr. Wilkenfeld has reviewed the status of the Canal and advises that currently there is a risk of disease including gastroenteritis and other infectious disease from exposure to the sewage in the Canal. Other documented health effects from exposure to sewage include irritation (burning eyes, sore throat, cough); an odor response (headache, nausea, vomiting); and toxic effects (skin disorders, fatigue) (Bridges, 2003; Thorn and Kerekes, 2001). Epidemiological studies also indicate an increased risk of cancer and liver disease from exposure to sewage (Thorn and Kerekes, 2001; Wild et al. 2005; Pizzo et al. 2011).

Dr. Wilkenfeld also notes that pathogens and PPCPs, including EDCs such as estrone and beta-estradiol -- which were also detected in Canal surface water and surface sediment -- contribute to significant human health risk. Exposure to these EDCs in Canal surface water and surface sediment can result in increased cancer and non-cancer risks to human health due to their estrogenic mode of action and resulting increased toxicity.

The PRAP identifies the need for CSO controls and assumes that reduction of solids discharge in the range of only 58 to 74 percent will achieve the preliminary remediation goals (PRGs). Given the ongoing and expected future recreation activity in the Canal, and the recent Hurricane Sandy experience where CSO contaminated Canal water actually invaded homes, clearly more control of CSO contaminants are needed if this issue is to truly be addressed.

In addition to protecting health, the CSOs must be controlled lest they defeat any remedy. Analytical data collected near the outfalls (Appendix I) and sediment transport modeling (Appendix D) support the conclusion that at least the upper four feet of accumulated sediment is

[8]In fact, the NCP identifies the overall protection of human health and the environment as a threshold criterion in selecting a remedy. *See* 40 C.F.R. § 300.430(f)(1)(i)(A).

comprised of highly organic soft sediments and are not derived from the former MGPs. In other words, the age of the shallow sediments is very recent, substantially post-dating MGP operations. Although the PRAP acknowledges the proposed Gowanus system upgrades by the City of New York will achieve some level of CSO source reduction, it is far short of what is necessary to meet RAOs. The PRAP goes on to state that, "[t]he cumulative impact of these projected flow reductions and flushing improvements on sediment transport and deposition cannot currently be predicted with a high degree of confidence." Still other City proposed improvements are even less certain because they rely on the implementation of LTCP improvements that have not even been conceived.

The PRAP proposed CSO storage tank improvements will yield some improvements to water quality. However, even under the best case scenario – assuming all of the improvements are actually implemented and achieve the desired results – the remaining 26 percent to 42 percent of the load of contaminants from the CSOs as estimated by EPA will continue to enter the Canal.[9] Furthermore, hydrodynamic and transport modeling indicates that this sediment will settle out and re-contaminate the surface of the Canal bed, even with the flushing tunnel operational.

The storage tanks may not have enough storage volume to reduce CSO solids and contaminants to levels necessary to be protective of the remedy. Contrary to the conclusions of Stein (2006), which are relied upon in the FS to calculate tank size, TSS data collected during a CSO discharge event, indicates that TSS is not concentrated during the first flush (Appendix G). Indeed, as Woodard & Curran explain, the potential exists for a continued discharge of contaminants to the Canal during rain events that produce a flow volume in excess of the capacity of both the tanks and the conveyance system (Appendix G).[10] While these data are not conclusive, they make clear that potential frequency and volume of storm water that may be discharged needs to be studied further, especially in light of climate change predictions that storm events will be more frequent and severe.

(iii) If CSO Control is Infeasible, the RAOs Must be Modified and the Canal Conditions Must Become the Background

Failure to stop discharges from the CSOs will have significant ramifications for everything from the most fundamental success / failure of the remedy to accomplishing the RAOs of reducing human health and ecological risks. Current plans by the City of New York

[9]Dr. Brunton of Baird notes that the PRAP appears to underestimate the full extent of sediment discharge from the CSOs. A mass balance for the upper Canal suggests that the one to two inches per year of sedimentation noted in the PRAP could be understated by as much as five to ten times.

[10]Woodard & Curran explained, "The scientific literature suggests that the potential for continued discharge of PAHs and metals to the Canal during storm events that produce a flow volume in excess of the capacity of both the tanks and the sewer system, still exists." This is so because "the first flush tends to include a larger proportion of coarse particulate matter. Since PAH concentrations tend to be higher on finer particulates, PAHs in the CSO flow may continue to be discharged to the Canal later in a storm event, after the CSO tanks are full." (Appendix G).

will not stop contamination from the CSOs. To the extent the City cannot reach full CSO control because it is technically infeasible or prohibitively costly or both, then the EPA, and the City should strive to implement the maximum achievable CSO reductions before the remedy is implemented. The extent of CSO reductions should then be carefully evaluated. Only after understanding the continued loadings into the Canal, can a cap be implemented with any chance of success.

Under current circumstances, the initial step of establishing performance standards in the PRAP is premature since the major ongoing source of contamination will not be controlled. To the extent infeasible or cost prohibitive to fully control CSO discharges any ongoing contribution should be considered background for the Canal and the remedy design should factor in those ongoing sources. Once the background loading to the Canal is understood, future uses of the Canal should be tailored to be protective of human health, as determined appropriate by the relevant public health agencies. Depending on the extent and success of CSO controls, future use may still include some public access restrictions.

Finally, and regardless of the remedy that is ultimately decided upon for the CSOs, the EPA should create and implement a program to measure baseline pathogen levels prior to initiation of any remedy, and this program must be ongoing since pathogen levels do not remain static. Samples must be continuously collected over the course of months and testing must follow remediation to confirm a reduction in pathogens. Parameters for pathogen levels protective of all populations, including pathogen RAOs and risk based PRGs that consider water quality criteria for recreation, must all be established and even then, additional studies may be required as action is taken in the Canal.

(3) Non-CSO Pipes

Other sources in addition to the CSOs, such as roadway runoff, petroleum facilities, and the hundreds of non-CSO pipes, likely account for significant PAH and other loadings to the Canal surface sediment. National Grid understands the importance of controlling potential sources and has implemented serious efforts to clean up legacy MGP sites. However, there are other non-CSO sources that require examination. Accidental releases of contaminants around the Canal occur frequently and impact the Canal through sewers, permitted, and non-permitted discharge points. The DEC has extensive documentation of such contaminant releases to the Canal. Some of these accidental spills included diesel fuels and waste oils with sheens visible on Canal surface water. Petroleum products, oils containing PCBs, and dielectric fluids were also found to be impacting manholes around the Canal at numerous locations. Many other spills were reported in the DEC files to be of unknown sources, some of which were reported to be an "ongoing problem" directly impacting the Canal. This is in addition to the hundreds of thousands of gallons of raw sewage that impacted the Canal over the past 20 years from pump and gate failures, as documented by DEC (Appendix E).

The RI documented almost 250 pipes that are discharging to the Canal. The RI did not evaluate wet weather discharges from any of these pipes. As a result, the chemical loading from these unpermitted discharges is unknown. Even though wet weather sampling of these discharges was not undertaken, the RI did evaluate dry-weather discharges from 12 pipes and identified 18 VOCs, 21 SVOCs, and 18 metals, and cyanide in the dry weather unpermitted

discharges. The RI report concluded that flow rates of less than one liter per minute were inconsequential and hence were not sampled under dry flow conditions. However, one liter per minute is the equivalent of 0.264 gallons per minute or 380 gallons per day or 138,700 gallons per year. Furthermore, that is for only a single pipe. Thus, loading from the over 200 unpermitted pipes could be a significant factor in evaluation of a site remedy. At the very least, good science requires that it be explored.

Approximately 14 of the pipes have state pollutant discharge elimination system permits. These include both industrial discharges and storm sewer discharges. All of these sources must be identified, quantified, and controlled before implementing the sediment remedy. Seventy-four million gallons of storm water and roadway runoff are discharged to the Canal each year through storm sewers and overland runoff (DEP 2008). The PRAP characterizes these pipes as "insignificant" and the cost to address them as "minimal" with little, if any, support and without any regard to how the pipes will be addressed by DEC or how making required adjustments will affect permit holders. Exponent has noted that the EPA's investigations of unpermitted pipes is more of a "snapshot" and does not provide the entire story because they were not conducted concurrent with releases of contaminants from upland sources. "Surface sediments adjacent to these pipe outfalls are far more representative of cumulative and time-integrated inputs of contaminants from the upland sources." (Appendix E).

(4) Conclusion: Control All Sources First

Since data from the Canal sediments makes clear that CSO and other outfall inputs of contaminants are continuing, the EPA, consistent with the CSTAG recommendations, must make controlling all contamination sources around the Canal a priority in the ROD. Otherwise, any dredging will be a wasteful use of resources and the Canal sediment will be recontaminated.[11] Only then, when all sources of contamination to the Canal are addressed to the degree practicable using sound science and engineering, proven technologies, a background level of ongoing

[11]In 2007, the Sediment Management Work Group presented to the Battelle Conference the results of, "[a] survey of recently completed contaminated sediment remedial actions [which] identified a total of twenty sites in which sediment had become recontaminated" (Nadeau and Skaggs). All had become recontaminated largely because of no assessment or incomplete assessment prior to remedy selection of the risk of recontamination by continuing sources. CSOs and storm sewer outfalls were listed among the "dominant" sources that may lead to the recontamination. At one site, the Anacostia River, sediments covered the cap near to and downstream of an active CSO. Monitoring results after only 18 months indicated that the cap was containing the targeted contaminated sediments, but new sediments containing elevated PAHs from urban sources were accumulating on top of the cap. Sites like Anacostia, and by implication the Gowanus Canal, are important because they make clear that when sediment response actions are planned in areas receiving urban discharges, steps to ensure source control prior to implementing sediment cleanups must be taken. To avoid recontamination, careful study is necessary and source control must be of an equal or greater priority than the sediment response action itself.

contribution is established, and a control plan with specific steps and schedules is in place – can the parties begin their work to implement a successful and sustainable remedy.

C. THE CANAL MUST BE THOROUGHLY CHARACTERIZED BEFORE ANY EFFECTIVE REMEDY CAN BE DESIGNED

The PRAP is largely focused on a one-size-fits all remedy of dredge and cap across the entire Canal. This approach is based on assumptions and does not take into account the myriad of variation in conditions along and within the Canal. Successful design and completion of the work requires that all of the variations be considered in the remedy selection process.

(1) Sediment Variation

Sampling results for sediments along the Canal show variation in characteristics, including contaminant levels, chemical properties, geotechnical properties, and mobility (Appendix K). Design of the remedy must accommodate the variations in sediment characteristics to protect existing bulkheads and provide future stability for the cap.

(2) Operational Variation

The PRAP views the Canal as static and thus does not fully consider how the Canal will operate in the future. As a result, the remedy is focused on containment of historical releases. Although important, controlling such releases is only one part of a very complex system. The ROD must consider the impacts and need to control all significant releases, future operations, and the full range of complicating variables.

The PRAP acknowledges that the conditions in the Canal are likely to change as a result of upgrades to the CSO system related to the New York City WWFP. There will be additional changes in the future as a result of the yet-to-be-written New York City LTCP. These changes can have significant implications for the design and performance of the remedy. Furthermore, climate change, and the potential for sea level rise, present issues that were not discussed in the PRAP and will pose challenges during the design. As stated by the New York City Panel on Climate Change (New York City 2010), "[c]limate change poses challenges to planning for coastal waterfront development in New York City, given the uncertain but significant risks of progressive sea level rise and enhanced flooding of low-lying neighborhoods and infrastructure, increased transportation disruptions, increased structural damage, impaired operations, increased beach and shorefront erosion, and loss of wetlands." All of these risks apply to the Gowanus Canal, the Harbor, and surrounding neighborhoods. The final remedy must consider the hydrodynamics of the Canal given rising sea levels and potential for greater storm surges. The design should evaluate the potential for continued and possibly more frequent flooding in the surrounding neighborhoods. The proposed work on the CSO and storm sewer systems must consider the potential for larger and more frequent discharges to the Canal. Finally, these considerations underscore the need for the remedy that will need to be adaptable as conditions change into the future.

There is also the flushing tunnel, which is set to be re-activated in 2014. In an effort to assess the effects of the City's actions, National Grid undertook sediment transport and hydrodynamic modeling of the Canal. These studies demonstrate that increased flow from the flushing tunnel will have a variety of effects on future conditions in the Canal including, bed shear and sediment transport, scour of finer bottom material, and changes in water chemistry and biological conditions such as the reintroduction of marine borers affecting the integrity of timber bulkheads / pilings.

As explained by Drs. Palermo and Brunton, when moored barges and sheet pile enclosures are coupled with the flushing tunnel, flow velocities in the Canal will increase even more, which will increase scour (Appendices C and D). All of this must be carefully evaluated as a part of the remedial design effort.

DO must be maintained to support benthic invertebrate communities and other aquatic life. In accordance with the New York State Water Quality Standards, as a Class SD saline waterbody, the DO in the Canal should never be less than the acute criterion of 3.0 mg/L. However, during the summer of 2012, DO concentrations were less than 3.0 at 28 of 29 sampling stations in RTA 1 and RTA 2 (GEI 2012a). Although the flushing tunnel was not operational during that sampling event, the aeration system in RTA 1 was operating. Testing has shown it was insufficient to maintain DO levels to support aquatic life. Furthermore, 11 of the 29 stations in RTA 1 and RTA 2 had zero benthic invertebrates and most other stations had fewer than 100 organisms per square meter. During other sampling events (GEI 2011a, 2012b), all but two of these sampling stations had hundreds to thousands of invertebrates per square meter. This is strong evidence that lack of DO, even more so than chemical concentrations, will limit the benthic community in the Canal. For the remedy to be successful, and for the Canal to support a healthy benthic community, DO must be addressed as the primary consideration in the RAOs and performance metrics, rather than simply focusing on mitigation of chemical toxicity as do the current RAOs. Modeling of DO levels in the Canal with the flushing tunnel reactivated projects that DO levels are not expected to meet CWA requirements in RTA 2 (Appendix D). The Baird results for DO have identified periods of hypoxia in RTA 2 following large CSO events.

Lastly, even if the volume of solids entering the Canal is reduced, the deposition of potentially toxic sediments from ongoing point sources is not expected to stop. National Grid's hydrodynamic model indicates that solids will continue to settle out in the Canal even with the proposed increased flow generated by the flushing tunnel. According to EPA's proposed remedy, routine maintenance dredging of solids will be required for the life of the Canal. In addition, the full impact of the flushing tunnel still remains unknown. Sediment transport and hydrodynamic modeling has revealed that sediments are likely to come out of suspension in areas of the Canal where there is a significant decrease in velocities. Deeper dredging in RTA 1 and RTA 2 could thus result in settling of sediments with the return of sediment mounds and associated odor and contamination over the long term (Appendix D). Modeling has also identified parameters that have yet to be addressed, including flow conditions, flux of suspended sediment and contaminants, bed shear, and sediment transport and fate.

In summary, the success of the remedy depends primarily on short and long term CSO controls. The FS and PRAP do not include sufficient evaluation of the effects of these controls on the remedy. The evaluation performed by National Grid raises a wide variety of issues concerning the implementability and long term performance of the remedy under the proposed conditions.

(3) Groundwater Flow Variation

Transport mechanisms, including movement of NAPL and dissolved phase constituents in groundwater (leading to discharge of NAPL and groundwater to the Canal), need to be better understood in order to achieve a successful remedial design.

Groundwater modeling and NAPL mobility testing performed by National Grid indicate that contaminant fate and transport vary along the Canal and may require different controls in different reaches and sub-reaches (GEI 2011b and Appendix B). This is especially important given that the majority of the Canal bulkheads are highly permeable timber cribbing structures that allow groundwater to migrate into the Canal. The proposed remedy, however, may require impermeable bulkheads (like those being designed by National Grid for the MGP sites), to stop groundwater migration and thus mitigate the discharge of contaminants to the Canal from other responsible party sites. Groundwater modeling shows that impervious bulkheads will cause groundwater to deflect in different directions and to mound behind the bulkheads. To resolve this issue at the MGP sites, where barrier walls are planned, National Grid is exploring installing liners throughout the sites to minimize infiltration and consequently mounding behind the barrier walls. Under drain systems to collect ground water may also be needed should it rise above an unacceptable level.

There is a high potential for deflection and mounding to flood basements and properties. The effects of the remedy on groundwater flow thus may require responsible parties to explore groundwater controls. This should include a comprehensive groundwater modeling review of each system and how each interrelates. This would be performed in conjunction with the design of the remedy.

Modeling also demonstrates that the majority of groundwater discharge to the Canal (approximately 70 percent) in RTA 1 comes through the Canal floor (GEI 2011b). Design of the cap in this area in particular will require significant pre-design studies, including studies to identify discharge areas and to estimate flow rates.

D. CONSTRUCTION, ENGINEERING, AND FUTURE USE CONSIDERATIONS

(1) Dredging and Capping

As explained by Dr. Palermo, all dredging projects are unique because each must address specific site conditions and objectives, not to mention deal with specific unforeseen conditions. There is no doubt that the Gowanus Canal will offer up its own challenges that will result in delays and setbacks. The PRAP does not appear to consider this or the varying site conditions

and sediment characteristics throughout the Canal. Matters are further complicated in the Canal because of components, like the CSO system, that are in motion and ongoing and subject to change when the flushing tunnel is reactivated. Armed with experience, Dr. Palermo has recognized these unknown variables and how they reduce the dredge remedy proposed in the PRAP to "little more than a concept." (Appendix C).

Given the conceptual nature of the PRAP, much time must be afforded for extensive study and work to design the dredging portion of the remedy. Basic physical characteristics of the Canal such as water depths, bathymetry, currents, wave energies, the presence and nature of infrastructure and debris, and geotechnical conditions must all be considered. After evaluating the physical setting, dredging allowances, sediment re-suspension, and total volume must be calculated. Finally, the limited access to the Canal, lack of open space for staging, loading / off-loading, and treatment, and tight clearances and space for work within the waterbody must be resolved.[12]

With all of the unknowns outlined above, the very specific remedy components that are set forth in the PRAP are ill-advised and could be counter-productive. This approach cannot be justified given the present preliminary knowledge about the site and sediment conditions and the limited state of technical evaluations conducted to date. Once again, flexibility and adaptive management are essential to design this part of the remedy and to ensure its success. To that end, Drs. Palermo and Reible have identified several studies that, if performed, would help in remedy design:

- **Remedial Design Field Investigations**. Data gaps regarding sediment transport; hydrodynamics associated with ever changing Canal conditions due to the CSOs, the flushing tunnel, other pipes, and flow variations during construction; groundwater flows (lateral and vertical); geotechnical conditions of the soft and native sediments; and bulkhead conditions, and near shore building foundation conditions should receive additional study.

- **Cap Design and Performance Studies**. This would include evaluation of the basic issues such as the need for an armor layer, performance of armoring layers, and in situ stabilization (ISS) to stabilize both soft and native sediments.

- **Performance Standards Evaluation**. Performance standards are a touchstone of the remedial design and are needed for sediment re-suspension, contaminant release to water and air, and dredging production and timeline for completion of dredging.

- **Dredging Production and Throughput Evaluation**. An evaluation of dredging production and sediment throughput from dredging to final disposal should be conducted.

[12]These challenges all affect the implementability and cost of the remedy, important factors identified by the NCP. *See* 40 C.F.R. § 300.430(f)(1)(i)(B).

- **Contaminant Release Studies**. Sediment characteristics coupled with high concentrations of contaminants and the presence of NAPL in some areas raise the potential for contaminant release. A study of sediment re-suspension potential, contaminant release potential to water and air, and residual sediments due to dredging should be conducted.

- **Sediment Re-suspension and Contaminant Release Control Evaluations**. The PRAP calls for the most stringent and aggressive form of engineered re-suspension control -- a sheet pile enclosure. More technical evaluation is needed to determine either the need for such control or the potential impact of such control on sediment erosion and the contaminant releases that will follow. Use of hard enclosures may actually result in higher contaminant releases to the Bay as compared to dredging without enclosures.

- **Operations Plan**. The PRAP includes a proposed sequence of work. However, a more comprehensive evaluation of operational aspects is needed to fully assess the practicality and community impacts associated with implementing the remedy. By way of example, the PRAP does not address the feasibility of removing the significant amount of buried debris in the Canal which in itself is an enormous and complex undertaking.

- **Monitoring and Management Plan**. Similarly, a more comprehensive evaluation of monitoring aspects is needed to more fully assess the effectiveness of the remedy.

- **Field Pilot Studies**. Field pilot studies will also be needed to confirm the effectiveness of some remedy components. Pilot studies may include dredging an area to assess sediment re-suspension, contaminant release, and source strengths; as well as cap placement to verify the ability to place caps in both the soft and native sediment layers.

- **Re-handling and Transport Study**. Careful planning of re-handling and transport of sediments is the key to compatibility. Areas for staging and offloading, and sediment treatment must be identified.

- **Sediment Treatability Studies**. The FS and the PRAP identify either stabilization and / or thermal desorption as the treatment and disposal options. Additional treatment studies would help uncover additional options and find a disposal approach.

- **Beneficial Use Studies**. The PRAP identifies beneficial use as the option for all dredged sediment. This may be difficult to implement given the volumes of sediments involved and the lack of a market for sediments with properties as found in the Canal.

- **Landfill Investigation**. Although the PRAP calls for beneficial use of all the dredged sediments, placement in landfills should also be investigated. Evaluations should be conducted to determine required pre-treatment or treatment, logistics of re-handling and transport to the landfills, capacity of landfills that may be considered and the acceptability of the Canal sediments for placement at those landfills from the standpoint of dewatering and workability.

- **Confined Disposal Investigation**. The PRAP includes potential use of a combined disposal facility (CDF) for sediment disposal. Acknowledging the apparent opposition to a CDF and taking no position on it, National Grid submits that if the EPA decides to move forward, more comprehensive studies are needed. Indeed, perhaps a contained aquatic disposal site is an option or a CDF outside the project footprint which could offer true community benefit such as waterfront park land. Initial investigation should focus on possible sites within the basins and Gowanus Bay, and consider volume, site bathymetry, and compatibility for future landside development. Engineering, contaminant pathway, and pathway control should also be evaluated.

The expedited schedule has made it challenging to get to the full range of studies National Grid believes are important (including the list above). Many of these studies would support the development of a more robust conceptual site model that fully identifies sources of contamination and describes fate and transport mechanisms. Such a model is a cornerstone of the CERCLA process and is integral to designing a remedy. As a result, for the remedy concepts outlined in the PRAP to be successful, National Grid believes the ROD should provide for additional time and flexibility for all of the required work to be planned, coordinated, and performed. Data will have to be analyzed, changes in courses of action may have to be made, and new steps may have to be planned. All the while, residents, public officials, and community groups will need to be kept informed.

(2) Navigation

Although the Canal is no longer the heavily trafficked industrial channel it once was, current commercial navigation has a significant impact on remedy design for the Gowanus Canal. The Baird Vessel Impact Study (VIS) Report, submitted to EPA on December 14, 2012 and summarized in Appendix D, found continued deep draft commercial navigation on the Canal could present a serious challenge to the restoration of a benthic habitat layer atop the cap as proposed in the PRAP. If allowed to continue post-remedy, impacts from commercial vessels (notably tugs and barges) that currently mobilize, transport, and redistribute sediments and contaminants in RTA 2 and other shallow portions of the Canal, would likely destroy any habitat.

The Baird VIS provided an analysis of propeller wash calculations to determine the potential for bed sediment mobilization. This coupled with three-dimensional numerical modeling (including flow around moored barges and propeller scour of the Canal bed by vessels underway) from the Baird Sediment Transport Modeling Study, highlights the extensive work and analysis that is required before a final remedy is chosen.

The Baird VIS report documented that despite the continued decline in commercial navigation, vessels and barges nevertheless impact the Canal bed in the following ways:

- Changes to local flow patterns;

- Tugs and barges are a direct and significant influence on flow velocities (and therefore sediment movement) in the Canal;

- Flow velocities increased by at least 600-800 percent ; and

- Vessel contact (or "grounding") with the Canal bed in RTA 2.

A detailed vessel traffic analysis using Automated Identification System (AIS) vessel tracking data identified five active docks located in the Canal between 3rd Street and the Gowanus Expressway. The present-day operations include tug and barge activities for two steel recyclers, two aggregate importers, and one fuel oil importer. Tugs make up over 99 percent of the vessel trips. Over half of all the trips are to the Bayside Fuel Oil Depot located next to Smith Street (at the lower reach of RTA 2).

While the trips to destinations above 9th Street are fewer than trips to the lower Canal, they may be more significant for sediment mobilization due to shallower water depths in the middle and upper Canal. The shallow sediments in RTA 2 show direct evidence of repeated barge groundings. Multi-beam bathymetric surveys very clearly show sediment bed scour caused by barges.

The barge and tug transits not only occur at high water as suggested in the FS (CH2M Hill 2011), but at all stages of tide (including low waters), demonstrating that the FS may have underestimated the potential for commercial vessel traffic to mobilize Canal sediments and contaminants as well as the potential to impact the viability of the future remedy. It is clear that the current vessel traffic in the Canal not only mobilizes and redistributes sediment and contaminants, but propeller wash can mobilize sediments as large as cobbles and boulders – materials much larger than those observed in the Canal bed or proposed for the benthic layer of the cap. Given this fact, it is reasonable to conclude that bed sediments are regularly mobilized into the water column by vessel activity.

For the remedy to succeed, National Grid's experts suggest that allowing commercial navigation in the Canal in RTA 1 and RTA 2 should be carefully considered. While one answer would be to dredge deeper, this will create a different set of problems. The increased depths proposed in the PRAP will decrease water velocity and DO levels in the Canal. This will compromise the ability of the flushing tunnel upgrades to achieve DO standards that satisfy CWA requirements. In addition lower velocities will lead to deposition of CSO solids and sediment on the cap, in turn further reducing DO concentrations and compromising the integrity of the remedy.

Because there is no current commercial navigation in RTA 1, alternative dredging depths should be explored. It is important to note that none of these options would preclude recreational boating from shallow draft boats that are regularly used in the Canal.

Navigation depths proposed for RTA 2 that would leave the cap surface only 16 feet below the water surface at slack tide are a concern. At this depth, the benthic sand cover would likely be continuously disturbed by tug prop wash and scour. This problem and the fact that access to dock facilities in RTA 2 will be lost for extended periods of time during construction of the remedy, speak in favor of additional discussion about supporting commercial navigation in RTA 2.

In RTA 3, sediment depths at the mouth of the Canal reflect current navigational activities. Dredging to greater depths will potentially interrupt navigation dependent businesses and likely result in slower velocities and deposition of fine sediments coming from the Canal, compromising the integrity of the remedy.

E. THE FULL RANGE OF POTENTIAL TECHNOLOGIES SHOULD BE AVAILABLE FOR USE IN THE REMEDY

The FS evaluated a broad range of proven and potential technologies for use in the Canal. Yet, many were eliminated by the EPA during the screening process. Studies performed by National Grid indicate that a variety of techniques eliminated during screening may actually be useful in the final Canal remedy. The ROD should allow further testing and possible use of any viable technique for dredging and/or isolation of sediments.

It is National Grid's belief that sediment removal requirements set in the PRAP still need further evaluation. There is a much wider range of potential technologies that could be employed to achieve RAOs than those included in the PRAP. Maximum flexibility is needed to optimize the use of any or all of these technologies during the design process. Processes like ISS, capping soft sediments without pre-dredging, capping-only remedies, in-situ amendments to reduce bioavailability of contaminants, and alternate approaches in RTA 3 should all be explored. Treatment and disposal also need to be given a hard look.

(1) ISS

The PRAP does identify ISS as a means to mitigate NAPL release in native sediment. However, it does not recommend ISS of soft sediment because the FS considered it technically infeasible, though no performance studies were undertaken. National Grid has undertaken bench scale ISS testing of Canal soft sediment, and the data suggests it may very well be a viable approach (Appendix H). Soft sediment samples from RTA 2 and Turning Basin 1 were successfully solidified in a preliminary round of testing. This work was performed on "worst-case scenario" samples of 100 percent soft sediment. A second round of testing investigated the benefits of mixing the soft sediment with native sediment during solidification. This mimics the blending that could occur as the mixing auger moves up and down the soft and native sediment column to incorporate cement grout. Mixtures of native and soft sediments solidify with less cement than if they are treated separately because of the higher sand and gravel content and lower moisture content of the native sediment.

The effect on groundwater flow patterns resulting from sediment ISS was also noted as a concern. Rather than discounting ISS's potential use as a blanket approach, it would be preferable to better understand groundwater flow dynamics and design accordingly. For example, a portion of the Canal could be solidified, and an adjacent portion left unsolidified as a hydraulic release point topped with a permeable reactive cap like that proposed in the PRAP. Including soft sediment solidification as an option in the ROD will preserve flexibility to combine several appropriate technologies to create a complete and sustainable remedy.

The FS noted potential issues with ebullition and methane upwelling resulting in potential cap uplift. Solidification of the soft sediments and the NAPL-impacted native sediments could inhibit these phenomena. Solidified sediments could also improve bulkhead toe stability and potentially eliminate or reduce the loading to support sheeting, simplifying the design.

In summary, while the PRAP acknowledges ISS may be a useful technology for treating NAPL in native sediments, testing performed by National Grid indicates that both native and soft sediments are promising candidates for solidification. Depending on the final design of the remedy, solidification could be used to help control NAPL in deeper sediments, assist in stabilizing soft sediments to shore up bulkheads (in lieu of or in conjunction with using sheet piles), as a treatment to improve the handling characteristics of sediments used to form the base for soft siding, or to improve the handling of sediments prior to transport offsite or placement in a CDF. While any of these uses may be applicable, the actual use of ISS should be determined based on performance and cost evaluations during the design process. Bench scale tests performed to date (Attachment H) show sufficient promise to include ISS as a potential component of any remedy developed for the Canal.

(2) Capping soft sediments without pre-dredging

The soft sediment layers are heterogeneous throughout the Canal. As summarized in Table 2 of the PRAP, the soft sediments average 54 percent solids with a 35 percent sand fraction. As noted by Drs. Palermo and Reible, caps have been installed successfully at sites with softer and more challenging sediments. Based on field observations of sediment cores, the sand fraction of the soft sediments in some areas of the Canal increases with depth (GEI 2009 and Appendix I). Accordingly, partial dredging of the soft sediments may be best in some areas because it will expose material even better suited for supporting a cap.

To the extent there is concern that soft sediments and any NAPL held therein might be destabilized by uneven placement of cap material, the cap may be placed in thin lifts to avoid point loading. Field observations of sediment cores and the data summarized in the sediment physical characteristics table (PRAP Table 2) suggest that the soft sediments in some reaches of the Canal may have sufficient bearing capacity that could very well do away with special cap placement techniques.

With regard to releasing NAPL, Dr. Reible points out that residual NAPL is unlikely to be mobilized by the weight of a sediment cap. Preliminary testing of sediment samples near the soft-native interface and with vertical loading equivalent to 10 feet of sand showed only trace amounts of NAPL expressed (Appendix B). Finally, NAPL impacts in soft sediment are generally lower than in native sediment (Appendix B). Removal of the soft sediment could actually promote upward migration from the native sediment.

In summary, the EPA should weigh the benefits of removing categories of contaminants (e.g., PCBs and metals) via complete removal of soft sediments against the cost of complete soft sediment removal, the likelihood of cap failure (low), and the fact that native sediments contain higher concentrations of some contaminants than do soft sediments (Appendix B). Flexibility is critical to designing and implementing a successful and sustainable remedy.

(3) RTA 3 Should be Approached Differently

RTA 3b is dissimilar from the other RTAs in terms of size, depth, navigational requirements, hydrology, benthic community characteristics, and level of impacts. Whereas RTAs 1 and 2 are narrow and relatively uniform in width, RTA 3 widens and is more irregular in shape and is also deeper. In fact, RTA 3b is three to five times as wide and, generally one and a half to two times as deep as the rest of the Canal. Also, RTA 3b has the most commercial navigation, but the least concentrations of constituents within soft sediments, including NAPL (saturated impacts are limited to one, western area).

The shape, location and dimensional differences affect a number of other characteristics which can have significant influence on the remedy from upwelling rates of groundwater to sediment flux. Yet, despite these significant differences, the PRAP selects virtually the same remedial approach for RTA 3b as the remainder of the Canal. The Draft FS (CH2M Hill, 2012) appears to over-generalize the nature and extent of impacts within the Canal soft sediments, when in fact this RTA warrants a different approach.

As it stands now, the proposed remedy will result in high costs, level of effort, and disruption to navigation and business that are out of proportion with the low levels of reduction (if any) of risk to human health and the environment that would be gained. A remedial approach that is modified to meet the specific characteristics of RTA 3b makes much more sense. Such an approach could not only decrease the overall level of complexity in the implementation of the remedy, but it could decrease the level of business interruption to nearby commercial facilities, lower resource consumption and decrease the overall cost of construction while still achieving the RAOs outlined in the PRAP.

(i) The Hydrology and NAPL Impacts are Different

Section 4.3.1 of the FS discusses screening of dredging and capping as a remedial technology. This section states "although little NAPL is present in RTA 3, groundwater upwelling through PAH-contaminated sediments in some portions of RTA 3 may pose a concern" (CH2M Hill, 2011). Groundwater modeling demonstrates that the preferential pathways for upwelling follow the alignment of the original Gowanus Creek, with most upwelling occurring further up the Canal in RTAs 1 and 2. The amount of upwelling in RTA 3 (3a and 3b combined) represents only 12 percent of the total groundwater upwelling spread over half of the area of the Canal. This discharge represents roughly 12 percent of the total groundwater upwelling in the Canal (GEI 2011b). This relatively small flux indicates that groundwater velocities are much lower in RTA 3 (and especially the much wider RTA 3b) than RTAs 1 and 2. The results of the quantitative analyses of groundwater (GEI 2011b) should quell the theoretical concern that NAPL could migrate upward in RTA 3b due to groundwater velocity.

Alternative 5 (as opposed to Alternative 7 which was selected for the remainder of the Canal (EPA, 2012b)), was selected for RTA 3b in part because "NAPL impacts in the southern portion of the project area are much less significant and less pervasive than those observed in the upper reaches of the canal" (CH2M Hill, 2011). Further investigation should be undertaken to identify impacted portions of RTA 3b that may then be specifically targeted for remediation. Such a more targeted approach makes much more sense than simply applying Alternative 5 to the entire area.

(ii) The Sediment Chemistry is Different

Although fewer sediment samples have been collected in RTA 3b than in the rest of the Canal (GEI 2009, 2011a, 2012a, 2012b; EPA 2011), it is nonetheless clear that sediments in RTA 3b contain lower concentrations of potentially toxic chemicals than much of the rest of the Canal. Statistical analyses, conducted to evaluate differences in chemical concentrations among and between RTAs (shown graphically in Figures 1 through 6 of Appendix L), indicated that for each of the chemical constituents and constituent groups discussed below, there are relatively lower risks of effects from other chemical contaminants in the soft sediments of RTA 3b.

Total PAH16 in surficial (zero to six inch depth) sediments, measured as the sum of the 16 EPA priority pollutant PAHs, was greatest in RTA 2 and the least in RTA 1 and RTA 3b (Figure 1 of Appendix L). Statistical analysis indicated significant pairwise differences between RTA 3b and all other areas, though RTA 3b is most similar to RTA 1. Concentrations ranges of total PAH16 in subsurface samples in each RTA generally overlap with those of surficial concentrations (Figure 2 of Appendix L). However, the noticeably lower concentrations of total PAH16 within RTA 3b surficial sediment may be the result of natural recovery processes.

Total PAH34 in surface sediment pore water (i.e. interstitial water), measured as the sum of parent and alkylated PAHs using solid phase micro-extraction (SPME), was consistent with bulk surface sediment PAH16 results: Concentration was greatest in RTA 2 and the least in RTA 1 and RTA 3b (Figure 3 of Appendix L). The median PAH34 concentration in pore water was the least in RTA 3b, which may at least partially explain the benthic community results discussed in the next section.

Estimation of PAH pore water toxic units (IWTU) from PAH concentrations measured in pore water using SPME is the most reliable method to estimate the toxicity of PAHs to benthic invertebrates in sediments (EPA 2003, Hawthorne et al, 2005, 2007). IWTU in surficial samples in RTA 3b were less than 10, indicating toxicity resulting from PAHs would likely be minimal. This is in contrast to RTA 2, in which the median IWTU was greater than 10 (Figure 4 of Appendix L). Statistical test results for IWTU were similar to those described for PAH34 in pore water.

Total PCBs concentrations, measured as the sum of PCB aroclors, in Canal sediments followed a very similar spatial pattern to that of PAH16, with surface concentrations in RTA 3b being similar to RTA 1 and significantly less than RTA 2 (Figure 5 of Appendix L). Patterns in subsurface PCB concentrations were similar but less distinct than the surficial concentrations.

Concentrations of lead in surficial samples in RTA 3b were significantly less than those in RTA 1, 2, and 3a (Figure 6 of Appendix L). Consistent with other analytes, subsurface patterns were similar to surficial patterns, but variability was greater.

What is more, the highest PAH concentrations in RTA 3b are localized in sediment abutting the boundaries of this RTA. In contrast, the top four feet of soft sediment in the remainder of RTA 3b contains much lower PAH concentrations. Figure 7 of Appendix L shows this pattern of PAH concentrations in sediment cores located within RTA 3b. The “Alternative Remedial Approaches” section below describes in more detail how the distinctive sediment

impacts at the edges of RTA 3b ("hot spots") influence the mean concentrations of impacts when the location of the impacts is taken into account.

(iii) Sediment Toxicity and Benthic Community Health are Different

GEI performed three rounds of benthic sampling concurrent with chemistry and toxicity samples in the Canal between January 2011 and May 2012. Sediment toxicity was variable within each RTA, indicating that location-specific factors are important. However, in general median survival in laboratory toxicity tests was greater in RTA 3b than in RTA 2 and 3a (Figure 8 of Appendix L). These results support the concept that only impacted portions of RTA 3b need be identified and specifically targeted for remediation.

In general, the benthic invertebrate community observed in the Canal represents an estuarine community adapted to soft substrate habitat and that is highly tolerant to disturbed conditions including organic enrichment and low DO (GEI 2011a, 2012a, 2012b). Stress-tolerant annelid worms, specifically of the classes *Polychaeta* and *Oligochaeta*, are the dominant invertebrates, representing greater that 50 percent of the benthic invertebrate community.

Despite the relatively homogenous invertebrate community throughout the Canal, several patterns in the benthic invertebrate community in RTA 3b are clear that further distinguish this RTA from the rest of the Canal:

- The greatest number of taxa was observed within RTA 3b where the Canal opens into Gowanus Bay (Figure 9 of Appendix L). Fifty-six of the 86 taxa (70 percent) identified in all the sampling events were observed in RTA 3b.

- RTAs 3a and 3b were the only areas where Mollusca were observed consistently in samples collected during all events (winter, summer, and spring). Additionally *Mytilus edulus* (blue mussel), a commercially important invertebrate species with known sensitivity to environmental stressors, were observed at two locations in RTA 3b during the spring sampling event.

- RTA 3b maintained a more consistent and stable benthic community across two years and three seasons of sampling. Patterns of number of taxa (Figure 9 of Appendix L), benthic density (Figure 10 of Appendix L), and benthic species diversity (Figure 11 of Appendix L) measured between seasonal events, indicate that the severe benthic community stress that occurred during the summer in most of the Canal had little effect in RTA 3b.

In summary, more hospitable conditions exist for the benthic community in RTA 3b. While toxicity was observed in some locations, the toxicity was not uniform throughout RTA 3b. The physical habitat conditions and DO stress that, in combination with chemical toxicity, severely limit the benthic community in most of the Canal, appear to be significantly improved in RTA 3b, facilitating the observed significant improvement in benthic community health and stability.

(iv) Issues with the Proposed Alternative for RTA 3b

According to Table F-3 of the FS, the combined estimated dredging volumes of RTAs 1 and 2 is 307,000 cubic yards (CY). The estimated volume of RTA 3b alone is 257,000 CY. Thus, under the currently selected alternative, slightly less than half of the dredging work for the entire remediation will be performed in what is accepted to be the least impacted portion of the Canal. Dredging all of the soft sediment in RTA 3b, as called for in the PRAP, will bring disruptions, expense, worker and public risk, resuspension of contaminants within the water column, increased levels of dissolved contaminants, and an extended period of construction,[13] while obtaining minimal, if any, improvements in risk reduction.

As noted in the FS, RTA 3b is used for commercial navigation. Removing all of the soft sediment from EPA will no doubt disrupt those businesses. RTA 3b is also larger and deeper and would invariably take longer to remediate as compared to the narrower areas of the Canal, further protracting business interruptions. Additionally, due to the width, barge traffic would be crossing the channel frequently to unload the dredged sediment for dewatering. There would also be disruption to benthic community.

(v) Alternative Remedial Approaches for RTA 3b

Based on the available information, the proposed remedy for RTA 3b could be altered to reduce construction time, business interruption, and costs, while at the same time comply with all RAOs. This can be done by combining multiple approaches, including dredging only those areas of RTA 3b that contain the most significant impacts (i.e. "hot spots"), allowing natural recovery processes currently taking place to continue, and employing adaptive management as new data becomes available.

To illustrate the importance of addressing sediment hot spots, as opposed to dredging the entire soft sediment, the Table 1 in Appendix L compares the average PAH16 concentrations in the hot spots versus the remainder of RTA 3b. Identification of the hot spots in RTA 3b is presented in Figure 7 of Appendix L. PAH16 concentration in the top two feet of hot spots is an average of 808 mg/kg, as compared to 31 mg/kg in other locations. For the two to four feet range in the soft sediment, the PAH16 concentrations averaged 828 mg/kg for the hot spots, versus 23 mg/kg in other locations. This contrast in concentrations calls for defining and addressing hot spots, as opposed to dredging the entire soft sediment.

In areas outside the hotspots, the accumulation of sediment with relatively low PAH concentrations has been occurring (e.g., core 142 has 9.4 and 6.7 mg/kg PAH16 in the 0-2' and 2-3.8' of sediment, respectively). Certainly, PAH levels at this location suggest that this and other similar locations do not need to be dredged.

[13]Production rate estimates for remedial dredging from contractors for recent similar projects indicate that removal of the large amount of sediment targeted for RTA 3b could take as long as two years.

Based on these results, the RTA 3b remedial action should include identifying the extent of hotspots in RTA 3b and addressing them, as opposed to dredging the entire area in which large volumes of clean sediment has been accumulating. Indeed, this approach has been adopted in other Superfund Sites (e.g., the Hylebos waterway), and has been effective in addressing risks.

Over time, natural recovery processes will also improve the quality of the sediment. A sediment transport and deposition model would provide a quantitative basis and provide certainty in the effectiveness of the natural recovery processes to address contamination in-situ. Areas where the soft sediments are removed could be capped with the treatment, isolation, and armor layered cap as outlined in the PRAP, while areas dredged for navigation could be left at depth with no cap. To the extent there is concern that NAPL in adjacent soft sediments may be destabilized, as noted above, the level of NAPL impacts in RTA 3b are minimal with the only NAPL saturation limited to a single location.

The required exploration and analytical data needed to define remedial action levels and the RTA 3b hot spot areas to be dredged would be collected as part of the predesign investigation. Although there is currently not enough data to compare dredging volumes of the currently selected remedial alternative and alternative proposed herein, given the size of RTA 3b, the reduction in total dredging volume by targeting hot spots could be significant.

Additionally, adaptive management should be considered for any remedy selected. Additional data will be collected from RTA 3b for remedial design, and the selected remedy should be flexible enough to incorporate the more refined understanding of the soft sediment present that the additional data will provide.

Finally, as discussed in the hydrology section of this report, the available data indicates that a comparatively small amount of groundwater is upwelling in RTA 3b, which may negate the need for the treatment layer as currently proposed.

(vi) Conclusion

RTA 3b is a unique portion of the Canal that requires consideration of a different remedial approach. Disproportionate levels of dredging within RTA 3b (slightly less than half of all soft sediments are contained within this RTA), the level of construction, sediment handling, and disruption all contrast starkly with the localized nature of the impacts. The alternative currently proposed in the PRAP does not perform as well for the nine NCP factors (listed in footnote two) when compared to other targeted remedial approaches leading to the need for reexamination of the approach in RTA3. A different, more targeted approach would be as effective, more implementable, result in significant savings in time and cost, minimize resusupension and minimize impact to the community (e.g., less sediment handling, traffic, and odor). The NCP requires that EPA weigh all of these factors when selecting a remedy.

(4) Tailored Design for Optimal Cap Performance

The quality of the sediments, potential for groundwater discharge, current bulkhead conditions, and navigational requirements vary significantly along the length of the Canal. Additional modeling, design studies, and pilot tests are needed to evaluate optimal cap configuration and NAPL control measures. The ROD should acknowledge the need for such

additional studies, allow for flexibility in design of the cap to meet RAOs, and provide a full palette of potential capping technologies for use in constructing the final remedy.

A cap with treatment, isolation, and armor layers, like that proposed in the PRAP, may be appropriate for some portions of the Canal. However, the dimensions and compositions of these layers will require a substantial design effort, and therefore should not be prescribed in the ROD. Also, different areas of the Canal will require different cap configurations. At least three categories of caps, consisting of variations of treatment, isolation, armor, sand, and impermeable layers, may be required to optimize the final remedy. The type of cap required will also vary with underlying sediment characteristics, potential for groundwater discharge, amount of NAPL present, potential for methane gas production and ebullition, Canal depth, and navigational requirements.

The PRAP specified a single cap design of a one and a half foot armor layer of stone, a one foot isolation layer of sand and gravel, and a six inch to one foot treatment layer of clay. As noted, the cap design will need to be variable based on specific needs within each reach of the Canal. For example, oil-absorbing material like oleophilic clay, should be targeted where it provides the greatest benefit, can be monitored, and can be replaced at the end of its design life. If relatively impermeable zones of solidified sediment are to be created, oleophilic clay should be deployed elsewhere and only in zones where groundwater communicates freely with surface water. A broadly applied single-design cap of the type designated in the PRAP will be difficult to monitor and evaluate.

A treatment layer of oleophilic clay like that proposed in the PRAP is likely not needed over solidified sediment since the solidification process dramatically reduces contaminant mobility, the very thing that a reactive cap is intended to treat. These technologies are simply redundant. An armor layer is also likely not needed over solidified sediments since the sediments are less susceptible to scour. A benthic habitat layer could be installed over the ISS matrix to facilitate habitat restoration.

A thinner benthic cap offers the advantage of reducing dredge volumes and thereby minimizing waste. Prop wash calculations are needed to determine sizing and thickness of the benthic supporting sand and gravel layer. The calculations would evaluate the type of vessel and draft for the specific portion of the Canal to provide the grain size (armor) and thickness of benthic cover to protect against prop wash. This was similarly completed in Appendix D of the FS and in models completed more recently for the Canal (Appendix D).

Finally, an impermeable cap may be useful for portions of the Canal in conjunction with adjacent areas of benthic or treatment (PRAP-style) caps. Impermeable cap areas (and solidified sediments) will force ground water to discharge through permeable cap areas, where treatment layers could be employed to intercept contaminants. This would be similar to a “funnel and gate” system and may provide a more practicable approach than a treatment layer across the entire Canal. It would also better facilitate monitoring for cap effectiveness. If replacement of a treatment zone is required, it could be more targeted and would not require a widespread dredge effort.

The FS expressed concern that methane gas "may be generated beneath the cap, causing potential uplift and deformation without special design considerations" (CH2M Hill, 2011). National Grid believes it is premature to eliminate the option of a low permeable cap before the design process identifies potentially appropriate technologies to address this concern. Gas venting can be managed, and the generation of gas in a low oxygen environment at the base of the cap may not be as severe as anticipated (Appendix B).

Additional modeling, design studies, and pilot tests are needed to evaluate optimal cap configuration and NAPL control measures. Therefore, the type of cap(s) to be installed should be determined during the design process, which requires flexibility to accomplish this in the ROD.

(5) PRGs and Performance Goals

The remedy will be manageable only if reasonable performance standards are put in place. As such, a proper understanding of the final remedial conditions and the future operating conditions in the Canal must be considered in light of establishing measurable and meaningful performance standards. The following discusses the issues involved.

The PRAP specifies that PRGs for protection of the ecological community be used as performance standards to evaluate the effectiveness of the post-remedy "clean surface." The PRAP identifies three PRGs / performance standards: PAHs (20 mg/kg), Copper (80 mg/kg), and lead (94 mg/kg) [EPA 2012b]. These PRGs were developed to support RAOs to reduce risks to benthic organisms and herbivorous birds in the Canal from direct contact with PAHs, PCBs, and metals in the sediments as well as from dietary exposure, respectively.

National Grid agrees that establishing a "clean surface" cap following remedial construction will accomplish the RAOs of reducing risk to benthic organisms and herbivorous birds because any remaining sediment contaminants will be isolated from exposure to post-remedy benthic organisms and birds. However, the PRAP approach toward establishing performance standards is not sustainable. While the remedy recommended in the PRAP will result in a "clean surface," the PRAP specifically acknowledges that additional ongoing sources of contamination will continue to discharge to the Canal. In other words, PAHs, copper, lead, and other contaminants will all continue to be transported to the Canal via storm water discharges, CSO overflow events, and via the other 200+ outfalls that have not yet been quantified from a contaminant of concern (COC) loading perspective.[14] Given these other ongoing sources from CSO discharges and various other undefined upland discharges, the

[14]PAHs in particular have a multitude of origins that will be carried via storm and sanitary discharges to the Canal including roadway runoff, rooftop drainages, and overland flow from paved surfaces. It has been extensively documented (Menzie 2002) that roadway runoff contains PAHs originating from crankcase motor oils, asphalt particulates, abraded tire particulates, and combustion fallout (e.g. diesel soot). These ubiquitous urban sources of PAHs along with roofing tar PAH sources have chemical forensic fingerprint signatures (pyrogenic) that are similar to other sources of PAHs related to tar that would be isolated beneath the proposed cap (Boehm 2006, Yang 2010, Valle 2007, and Yunker 2002).

concept of a "clean surface" in the Canal is not likely to persist for very long following implementation of the sediment remedy.

Further, the DEP has stated that as part of its LTCP for the Canal, it intends to implement a high-level sewer separation for some of the largest CSO outfalls on the Canal. The intent is to further reduce future sanitary discharges, but with that comes the unintended consequence of bringing roadway runoff contaminants directly into the Canal. This runoff also contains significant loads of COCs, and thus likely will increase the likelihood that the sediment remedy will fail to meet the PRGs due to recontamination.

(6) Background Reference Conditions are Not Currently Defined

The PRAP states that background concentrations of COCs in the Canal, "after all of the major canal-related sources of contamination have been reduced or controlled is likely to be at the upper end of the range of reference concentrations in the Upper New York Bay sediments, i.e., 14 mg/kg PAHs, because of ongoing contributions from uncontrolled surface water runoff and storm water discharges" [EPA 2012b]. The basis for this statement is that,

> [t]he canal . . . is a water body contained in a constructed confined space of relatively regular geometry and shallow depth. Its only natural surface water inputs are from the New York Harbor through tidal exchanges from the south end of the canal and through Flushing Tunnel flow at the northern end. Deposition of solids in the canal from these two main sources and small amounts of exposed soil, historic fill, and rooftop and surface drainage would constitute the background level (i.e. regional) level of contamination[.]

This characterization of the Canal, although accurate, does not fully acknowledge that the post-remedy environment of the Canal will continue to concentrate and receive storm water and overland flow discharges from the heavily urbanized and industrialized properties and uses that surround the Canal and that the high-level sewer separation will in fact increase roadway runoff into the Canal. In addition, the CSO controls that will be implemented likely will not completely stop ongoing discharges of raw sewage into the Canal, and the residual amount that cannot be controlled must be factored into any assessment of future background conditions. Lastly, the conclusion that background levels would be reflective of the reference concentrations in Upper New York Bay sediments (14 mg/kg PAHs) is not accurate. There is no physical mechanism that would account for the Upper Bay sediments to have similar background concentrations to the future sediments in the confined Gowanus that will continue to receive discharges from the surrounding industrial areas.

(7) Selection of Appropriate Performance Measures and Monitoring Programs

Given the containment type remedy using a combination of cap and cutoff measures proposed in the PRAP, ecological risk will primarily be reduced by minimizing migration of COCs through the cap into the surface sediments where the benthic community will re-establish itself. However, as discussed above, the ongoing source discharges to the top of the "clean surface" cap will make it difficult to determine whether the constructed remedy is effective at

achieving this objective. Therefore, effective performance monitoring must be able to differentiate contaminants that are migrating through the cap and / or associated sidewall containment systems, from the contaminants being discharged on top of the cap from ongoing sources.

The PRAP makes reference to chemical analyses of PAHs to evaluate the origins of the PAHs that will find their way atop the cap, post-remedy. Presumably, the intent is to distinguish petrogenic (petroleum related) PAHs from pyrogenic PAHs, such as MGP tars. However, there are many current-day sources of pyrogenic PAHs that will continue to be discharged to the Canal (crank-case oils, combustion particulate fallout, boiler exhaust soots, roofing tars, road sealants, etc.) making the sources of PAHs from ongoing storm and CSO discharge difficult to distinguish from sources of legacy PAHs that may migrate up through the cap.

Therefore, until such time as the ongoing discharges from CSOs, storm water outfalls, roadway, parking lot, and roof drain runoff are controlled, National Grid believes that the performance standards proposed in the PRAP cannot differentiate between performance of the remedy and ongoing source loading to the Canal.

With regard to monitoring the effectiveness of the constructed remedy both in the near-term (prior to comprehensive source controls in place) and in the long-term (after source controls are in place), an adaptive management approach is suggested to address the performance of the remedy. This means that performance standards should be developed for the monitoring of cap integrity and a separate plan should be developed for monitoring ongoing discharges to the Canal and the effect of any COC loading to the surface of the cap. To accomplish this:

- A physical cap integrity standard should be implemented by monitoring for the observation of sheen and or NAPL migration through the cap. The details of the monitoring program can be worked out in the design of the actual remedy. However, a simple approach (that has been implemented at other sediment cap sites) would be to periodically use a probe in a regular grid pattern to check for potential sheen generation through the upper armoring and sand layers of the cap.

- Depending on the specific construction of the cap, monitoring for COC migration through the cap should be specified in the cap monitoring plan. Such monitoring could be achieved through the use of probes, coring or passive sampling devices. Final selection of a cap monitoring approach should be based on the final design of the cap.

- During the design of the remedy, data also should be collected on the range and rate of discharge of various COCs and other stressors associated with ongoing CSO and storm sewer discharges. These data should be used to establish an interim baseline condition for expected background levels of COC concentrations that would provide a more realistic sense of what levels of contamination are anticipated post-remedy.

- Finally, similar to recommendations made in the PRAP, toxicity to benthic organisms in the Canal will need to be evaluated post-remedy to confirm that benthic toxicity is indeed being reduced as intended in the RAOs. The goals for this post-remedy evaluation of benthic toxicity should be twofold: First, it is important to determine whether ongoing

sources of COC recontamination of the "clean surface" will cause the remedy to fail by introducing toxic concentrations of COCs. Second, the numeric PRGs selected in the PRAP are likely to need adjustments post-remedy because they are based on current numeric relationships between sediment COC concentrations and toxicity. Because such correlations will change substantially following the generation of the "clean surface," strict adherence to the existing PRGs post-remedy cannot help determine whether RAOs are being achieved.

- During the interim period between the construction of the cap and the elimination of ongoing discharges, the cap monitoring program and the benthic toxicity evaluation should be implemented to assess the performance of the remedy.

Following implementation of the CSO and other direct discharge effluent controls, National Grid recommends that the performance standards should be re-evaluated to determine appropriate toxicity-based performance standards that would be protective of the benthic community. Under this adaptive management approach, following comprehensive source controls, a thorough evaluation of the remaining urban background toxicity to benthic organisms should be performed.

This adaptive management approach to modify the standards and monitoring programs as conditions change in the Canal is warranted for evaluating the performance of the remedy.

IV. CONCLUSION

As is common during this type of complex remediation project, there are many open questions that have yet to be answered. All of them, however, are manageable so long as the EPA works with the responsible parties to provide the additional time and flexibility to do all the required work that remains outstanding. That being said, there is one thing that is immediately critical to the ultimate success of any remedy: First, all sources must be controlled to the maximum extent practicable. National Grid is actively addressing its MGP sites along the Canal. This first and most basic principle of remediation requires that the CSOs, all other discharge pipes, and all uplands sources be identified and characterized and that a long-term plan be put in place that will finally end these sources of contamination.

To succeed, these controls must be implemented before any remedy construction work begins. The critical source control plan must be designed around control measures that have been demonstrated to be effective. To the extent interim controls are required, they too must be identified and their efficacy clearly documented. If the EPA and the City of New York determine that CSO discharges cannot be fully controlled, then we must understand the extent to which these discharges will continue as ongoing sources of contamination. The remedy must be designed to accommodate those influences and the performance standards measuring success of the remedy must realistically account for these ongoing sources. Lastly, the final depths of the Canal needs to be optimized to the ultimate operation and flow rates of the flushing tunnel to ensure both cap stability and to maximize the ability of the flushing tunnel to remove sediments and maintain acceptable DO levels.

Once source control is accomplished, sediment remediation work can go forward: In those areas requiring a bank to bank dredge, private parties who own bulkheads and who allowed them to decay must bring their property up to code; the various sediments and areas of the Canal with their differing characteristics, must all be evaluated and accounted for; and future use of the Canal must be considered and perhaps re-visited. As discussed previously, the final design of the cap will need to balance a number of competing priorities including optimal geometry to avoid sediment deposition and recontamination of the cap, operation of the flushing tunnel to avoid destruction of the benthic sand layer and t commercial navigation in the upper reaches of the Canal.

Finally, there are the "nuts and bolts." The remedy, in whatever form it eventually takes, is going to be a challenge for this community for years with, among other things, dislocation, odors, and noise. Controls for these challenges need to be worked into the final remedy. Basic construction components must also be more fully fleshed out. National Grid's experts explain that sheet pile enclosures, underwater debris removal, groundwater deflection and mounding, dredge production and throughput, treatment, and disposal all pose serious challenges that need better planning and coordination. Given the highly congested, urban environment, even things like simple physical access to the Canal and the availability of nearby land for staging and treatment still need to be evaluated carefully.

All of the issues outlined in these comments must be the subject of many good faith conversations among all of the stakeholders and parties. National Grid started the conversation long ago by cooperating with EPA and other authorities to address its upland MGPs (currently a work in progress) and to undertake informative studies. National Grid is continuing the conversation with these comments and with the expert comments that are attached. It is our hope that EPA will reply with a concerted effort to control all sources, a planning approach that allows sufficient flexibility and timing to allow National Grid and other responsible parties to continue the needed work, and with an open mind to let available experts assist in designing the remedy.

To that end, National Grid requests that EPA incorporate the following concepts into the ROD:

- The ROD should acknowledge that the operational status of the Canal will change dramatically over the next decade in ways that are not fully predictable, and allow flexibility in the design and implementation of the remedy to accommodate these changes.

- The ROD should require an assessment of navigational uses of the Canal with the aim of striking the proper balance between commercial traffic and restoration of ecological conditions. Baird & Associates believes deep draft commercial navigation creates formidable challenges to maintaining cap integrity and ecological recovery in RTAs 1, 2, and 3a.

- The ROD should allow flexibility to incorporate soft sediment capping, ISS of soft and native sediments, different types of capping in different areas of the Canal, and other similar technologies, all based on evaluations during the remedy design.

- The ROD should provide a framework and reasonable schedule for coordinating the regulatory programs responsible for upland site remediation with the CERCLA remedy proposed for the Canal to ensure that, to the maximum extent practicable, upland sources are controlled before construction begins on the remedy.

- The ROD should provide a framework and approach to mitigate and control potential contaminant discharge to the Canal of all permitted and unpermitted pipe discharges including storm sewers to avoid failure of the remedy to achieve sustainable water quality improvement.

- Since remedy success is dependent on the implementation of CSO controls, the ROD should clearly show how a reduction in volume and toxicity from the CSO discharges will be achieved. The ROD should present clear calculations on the future projected volume of contaminants entering the Canal, address the uncertainty associated with the "presumed" future scenarios, and provide estimates of contaminant loading under interim and long term sediment control measures.

- Control of all sources, including the CSOs, should be implemented to the maximum extent practicable prior to the Canal-wide remedy, to prevent recontamination of the "clean surface."

- The ROD should acknowledge the use of modeling – both hydrodynamic and groundwater – during the design to optimize the remedy based on variations in different segments of the Canal and flow conditions after the re-start of the flushing tunnel.

- The ROD should acknowledge the chemical, structural and ecological differences in RTA 3b. The remedy for RTA 3b should be re-evaluated and less-intrusive alternative approaches including hot spot removal and monitored natural attenuation should be considered, especially given that RTA 3b represents nearly 50 percent of all sediments slated for removal in the PRAP.

- The ROD should specify that the performance of the remedy will be based on the post-remedy operation of the Canal. Post-remedy ongoing discharges of pollutants must be realistically accounted for. Performance standards for the remedy should be developed for both the remedial systems designed to control and isolate releases from historical sources, and the impacts from ongoing discharges associated with CSOs and storm sewers. Performance standards should be adapted as conditions in the Canal change.

The Gowanus Canal remedy presents an opportunity to address an age-old problem of our urban waterways. The EPA has seized this opportunity with the Gowanus PRAP and started the much needed dialogue. Now, the EPA must start the hard work that could very well shape a new direction for sediment sites. Given the significance of the Gowanus, EPA and the parties must work together to control sources, plan, and study. This work, however, must be grounded in sound science and engineering practicality and follow a common vision with stakeholders finding areas of compromise to achieve a successful result.

In addition, if all sources are able to be controlled in true working fashion, the EPA should pursue all means to make that happen and National Grid will certainly do its part. If, however, full source control is not practical, alternative means must be taken to arrive at the best solution possible. Under either scenario, the ROD must employ an adaptive management approach that will identify interim and long range controls that are realistic, allow sufficient time and flexibility to analyze the effects of such controls while at the same time planning out the rest of the remedy, and encourage equally effective and more efficient alternatives in order to optimize the remedy that is ultimately selected.

National Grid thanks the EPA for their consideration.

LIST OF ACRONYMS

AIS	Automated Identification System
ARAR	Applicable or Relevant and Appropriate Requirements
BTEX	Benzene, Toluene, Ethylbenzene, Xylene
CDF	Combined Disposal Facility

Re: **Gowanus Canal Superfund Site Proposed Remedial Action Plan**

I submit the following comments on the United States Environmental Protection Agency (EPA) Proposed Remedial Action Plan (PRAP) for the Gowanus Canal.

I am a Board Certified Environmental Engineer with a Bachelor of Science in Chemical Engineering from Lamar University, and a Master of Science and Doctorate in Chemical Engineering from the California Institute of Technology. I am a Fellow of the American Institute of Chemical Engineers and the American Association for the Advancement of Science. In 2005, I was elected to the National Academy of Engineering for "the development of widely used means of managing contaminated sediments"

I am the Bettie Margaret Smith Chair of Environmental Health Engineering in the Department of Civil, Architectural and Environmental Engineering and Director of the Center for Research in Water Resources at the University of Texas.

I have coauthored four National Research Council committee reports on risk assessment and remediation of contaminated sites and have written two textbooks, Fundamentals of Environmental Engineering and Diffusion Models of Environmental Transport, and edited four other texts including one focused specifically on the management of contaminated sediments. I have published more than 150 journal papers and chapters in books.

Within the area of contaminated sediments I am most recognized for my work on the design and assessment of sediment capping alternatives.

I have reviewed the PRAP and agree with my colleague, Dr. Michael Palermo, that more study and work remains to be done before a final alternative is selected. Based on my experience, capping options exist (i.e., capping soft sediment) that have not been adequately considered by the EPA.

(1) Alternatives were ruled out prematurely

Although the PRAP proposes seven alternative remedial plans, only two, alternatives five and seven, were retained. Alternatives two and three involved partial sediment removal and a conventional cap (alternative two) or a treatment layer with a conventional cap (alternative three). Alternatives four and six involved dredging of the entire soft sediment column and conventional capping (alternative four) or stabilization (alternative six). Alternatives two and three were rejected

because of concerns about the technical challenges of capping over low strength sediments, and possible destabilization of non-aqueous phase liquid (NAPL). Alternatives four and six were rejected because they did not include a treatment layer.

I believe these alternatives were screened out prematurely. Capping is the primary means of achieving remediation of the Canal, but the specific form of capping that is most appropriate and effective is not yet clear based on the currently available site data. Accordingly, those options that have been screened out should not have been. For example, in portions of the Canal it is likely that even alternative two (conventional capping) will be effective. It is also unclear if any of the remedial alternatives that focused solely on the sediment will achieve the desired risk reduction in the Canal. Passive or active management of groundwater contamination may be required to achieve a lasting sediment remedy. More site-specific information needs to be obtained and more analysis needs to be performed before creating and selecting among the various alternatives.

Lastly, to the extent the PRAP cities my own work (Reible, 2005) as a basis for screening out alternatives, I respectfully submit that my work suggests only that the alternatives that were screened out might require additional assessment and/or modified construction methods for successful implementation.

Although the PRAP is correct that the low bearing capacity of soft, fine-grained sediment with high water content makes capping difficult, it by no means makes it impossible. The soft sediments in the Gowanus Canal that we have examined often contain significant quantities of sand and exhibit water contents of less than 50% (total sample basis). This does not suggest that the sediments are particularly soft and unlikely to be successfully capped. Caps have been placed on sediments with essentially no sand content and far higher moisture contents. Conventional techniques (bucket placement) were used on soft sediments in the Anacostia River (Reible, Lampert et al. 2006). Slurry placement has also been used at a number of sites where soft sediments were of concern (e.g. Silver Lake, Massachusetts; Soda Lake, Wyoming; Roxana Marsh, Indiana; Onondaga Lake, New York). Special techniques have also been adapted for sediments that have had no measurable shear stress or bearing capacity. Low density material and placement using minimum disturbance approaches were used in Welch Creek in North Carolina over exceedingly soft and weak contaminated sediments.

To the extent there is concern that capping the soft sediment could destabilize NAPL present in the sediment, such concern is over-emphasized. Past experience at a variety of contaminated sediment sites suggests that NAPL has often weathered prior to remedial evaluation such that it is largely immobile due to loss of more mobile, lower viscosity constituents as well as loss of any NAPL greater than residual saturations. "Could destabilize" is not “will destabilize" and NAPL mobility and expression as a result of capping should have been assessed.

To the extent that alternatives two, four, and six were rejected because “an armored sand cap is not sufficient to control the long-term flux of NAPL and dissolved-phase contaminants,” alternative six includes stabilization of the top three to five feet of native sediment. Such treatment has the potential to eliminate long-term flux of NAPL and substantially reduce the flux of dissolved-

phase contaminants. Furthermore, I am unaware of any definitive analysis that suggests that such a cap would not work in at least portions of the Gowanus Canal. To the contrary, in the Pine Street Canal (Burlington, Vermont) a sand cap was placed over very soft NAPL contaminated sludges and with the exception of a single location where the sludges were the weakest and thickest, the cap has been effective. As an added precaution, organophilic clay was added to contain the NAPL where the sand cap was not effective. At the Gowanus Canal, it is certainly possible, if not likely, that an armored sand cap may be effective over at least portions of the Canal and that amendments to manage NAPL or dissolved contaminant flux may be needed only in portions of the Canal. This was apparently not quantitatively assessed prior to the screening out of such remedies from the Canal. A proper evaluation of NAPL mobility via in situ and laboratory testing in conjunction with groundwater modeling will be required to make informed decisions on cap components.

(2) Cap integrity

Ensuring cap integrity is a key component of cap design and construction. Without detailed assessment of the potential risks of cap failure and the resulting contaminant exposure, it is difficult to evaluate the different alternatives. Again, the decision to rule out alternatives appears to have been made prematurely without assessment of the variations in effects along the length of the Canal of reactivation of the flushing tunnel, combined sewer overflows, and continued navigation in the Canal. Stormwater flows may cause sediment resuspension and the contaminant loads associated with such flows may lead to substantial recontamination of sediments. Current commercial navigation in portions of the Canal likely cause substantial sediment and contaminant resuspension. It is unclear if continued commercial navigation in the upper 2/3 of the Canal is consistent with long-term sediment remedial goals under any of the PRAP alternatives. The flushing tunnel will also likely necessitate substantive differences in remedial design in the upper reaches of the Canal compared to the rest of the Canal.

(3) Required studies and work

The following data collection approaches, which are well known and have become standard since 1998 when they were outlined in the EPA Capping Guidance (Palermo, Maynord et al. 1998), are critical to selection, design, and implementation of any capping remedy, and should be followed here:

(a) Identify the remedial objective. The Canal faces multiple inputs including uncontrolled groundwater, combined sewer overflows, stormwater, and releases from sediment. Moreover, current plans for the Canal include reactivation of the flushing tunnel and continued navigation that could lead to erosion and thus undermine the remedy. Evaluation of the hydrodynamics of the Canal under future use and operating scenarios (e.g. flushing tunnel and commercial navigation) is needed to effectively address these questions.

(b) Identify the geotechnical characteristics of the sediment layer to be capped. The degree to which the soft sediments can form a foundation for a cap, the ability to stabilize and solidify these sediments in-place, and their stability under flushing tunnel and commercial navigation operations, is

unknown. Variation in these properties over the length of the Canal and how that variation might affect remedial designs is also unknown. Among the testing required to address these questions are geotechnical testing (strength, consolidation, NAPL and contaminant expression) (Erten, Gilbert et al. 2011) over the length of the Canal and solidification testing of particular Canal sediments for strength and contaminant control.

(c) Identify contaminant physical characteristics, concentrations, and fluxes. Although sampling to date has identified contaminant concentrations in sediments and confirmed the presence of NAPL, additional testing is needed to evaluate mobile phases (dissolved or NAPL), mobile phase concentration (porewater or mobile NAPL concentration), and fluxes (groundwater and contaminant fluxes). Since the phase of concern and fluxes are expected to vary widely over the length of the Canal and with depth into the sediments, characterization is critical at those portions of the Canal and at depth horizons that might contribute to surface fluxes after partial implementation of a remedy. Until studied and known, these issues pose significant uncertainties for cap design and could ultimately determine whether sediment remediation in any form should be pursued,

(d) Identify potential capping materials and their characteristics, including any amendments that might be necessary to effectively contain contaminants. The characteristics of a cap (stability, chemical containment) are a strong function of the available capping materials. The need for any amendment material to enhance performance of a cap also depends upon the foundation cap materials and their characteristics. Lastly, the performance of many specific cap amendments, including organophilic clay for NAPL containment and carbon (manufactured or natural carbons) for dissolved contaminant mitigation are strongly site dependent and require site specific testing to evaluate their expected performance and feasibility.

(e) Design cap thickness and composition. The information outlined above will help inform a cap design. The selection of cap materials and conceptual design, however, also require modeling of consolidation and NAPL expression during cap loading and modeling of chemical migration through specific cap compositions to identify potentially effective caps and their viability in the Canal. Key questions that remain are whether a cap can be effective in the environment of the Canal or whether any sediment remedy may achieve remedial goals given ongoing sources and the potential for recontamination.

(f) Evaluate potential erosive forces that might impact a cap and the resulting impacts on cap design. A critical component of the design of a cap in the Gowanus Canal is the integration into future uses and operation of the Canal. The ability to cap the Canal is dependent upon the erosive forces generated by future commercial navigation and the operation of the flushing tunnel and is a strong function of water depth. It is far from clear that the proposed sediment remedy can work in conjunction with the current plans for the flushing tunnel and continued navigation. The evaluation of future use and operating scenarios must be coupled with analysis of potential cap designs.

(g) Evaluate appropriate equipment and placement techniques. The Canal currently poses significant logistical challenges to a large-scale sediment remedial project. All of the challenges

identified, such as access, open space for staging, and clearances and space for work, will also make it difficult to cap as desired.

(h) Iterate as necessary to finalize the design. It is to be expected that the analysis outlined above, will result in design requirements that are incompatible with the proposed plan, and thus iteration will be required, which will require more analysis, and which will require more time.

(i) Implement the design. Regardless of repeated iteration and analysis, significant uncertainties will remain that can only be managed during implementation so long as flexibility and adaptive management are allowed.

(j) Monitor performance and apply adaptive management as necessary to achieve remedial goals. Given the uncertain status and effects of components like control of ongoing sources, reactivation of the flushing tunnel, and future navigation within the Canal, adaptive management becomes even more critical to evaluate cap performance. In general, the focus should be on measures of available and mobile contaminants rather than bulk solids, which is not particularly useful to address cap performance (e.g .Lampert, Lu et al. 2013).

Conclusions

My review of the PRAP and my knowledge and experience with contaminated sediment management suggests the following

- The PRAP prematurely rejects capping upon soft sediments and sediments containing NAPL, and arbitrarily removes from consideration alternatives that involve capping directly on soft sediments or after partial dredging of the soft sediments.
- The PRAP focuses on the sediments rather than on potential sources of recontamination such as combined sewer overflows, stormwater, groundwater, and sediment resuspension due to commercial navigation and the flushing tunnel. Failure to consider these effects may limit the ultimate success of any remedial alternative. The PRAP does not recognize the critical importance of groundwater on long-term effectiveness of any sediment remedy and the need to integrate groundwater management with in-Canal remedies.
- The PRAP does not recognize that there exists a variety of different conditions within the Canal that may encourage selection of one or more of the alternatives screened out.
- Further assessment and evaluation is required before I could recommend any particular remedial approach and have any confidence in its appropriateness and effectiveness.

Re: **Geotechnical Investigation of Gowanus Canal Sediments: NAPL Expression**

Summary

Selected sediments samples from the Gowanus Canal were subjected to geotechnical testing for potential NAPL expression. The testing followed the methodology of Erten et al. (2011)[1]. The samples were selected on the basis of measurable NAPL content (based upon PID readings from sonic cores in the same interval) and location near the interface of the "soft" and "native" sediments in the Canal. The sediments that may be exposed after dredging and that will require capping to contain sediment contaminants. The purpose of the testing was to determine the potential for NAPL expression.

Of the three samples, two samples were fine-grained material containing 9-15% hexane extractible material (HEM, EPA Method 9071B) divided by total sample weight) or 20-32% HEM per dry solids, and one was more sandy material containing approximately 3% HEM (total basis), 4% HEM (dry solids basis). HEM is used here as a surrogate for NAPL content although HEM may overpredict NAPL content if there is significant extractible organic material in the samples. All samples were subjected to loadings equivalent to up to 10 feet of sand in five stages. No samples released meaningful quantities of NAPL as a result of this loading. One sample with a higher content of NAPL did release a non-measurable trace quantity of NAPL during loading. Significantly, no substantial NAPL was expressed even though the samples were subjected to volumetric strains (volume reduction during consolidation) of 16-18% of the fine-grained samples and 2.5-5% of the coarser samples.

This testing indicates that the methodology of Erten et al. (2011) may be used for NAPL expression testing in these sediments and that the NAPL present in the sediment samples is at a residual saturation that is unlikely to be mobilized by loading with the weight of a sediment cap. The trace amounts of NAPL expressed in one sample suggests that disturbance can release small amounts of material that could ultimately lead to sheens. Further testing is required to confirm whether these conclusions are generally applicable in the Canal.

[1] Erten, M.B., R. Gilbert, C.S. El Mohtar, D.D. Reible, Development of a laboratory procedure to evaluate the consolidation potential of soft contaminated sediments, *Geotechnical Testing Journal, 34*, 5, September (2011)

Methodology and Results

Selected sediments samples from the Gowanus Canal were subjected to geotechnical testing for potential NAPL expression. The testing followed the methodology of Erten et al. (2011)[1] which is designed to evaluate the potential for NAPL expression under loadings typical of placement of a sediment cap. Three samples were taken and designated:

- GC-B-002
- GC-B-004
- GC-B-005

These samples were selected based on testing of samples with tar impacts or elevated PID readings in sonic cores over the same tube sample interval and location near the interface of accumulated "soft" sediments and alluvial/sand "native" deposits.

Three eight-inch-long sections were cut from the bottom of each sample core and tested at the University of Texas at Austin. Four triaxial consolidation tests were performed on samples obtained from the three Shelby tubes. Iit should be noted that the tubes were subjected to some disturbance during shipping as a result of shipping while horizontal. As a result, the samples were likely to be less consolidated and the NAPL more mobile than in undisturbed cores.

Characterization of the samples included

- Density and estimated mass of dry solids based on NAPL and Water content
- NAPL, mobile organic contaminant content- Measured via EPA 9071B, Hexane Extractible Material
- Water Content- Measured by drying overnight at 105 C

Measurements were conducted on pre-consolidated samples as well as at the top, middle and bottom of consolidated cores. All measurements were conducted in triplicate although occasional samples were lost or invalidated.

Typically a Ko consolidation test is run to simulate field conditions. In a Ko consolidation test, the vertical and horizontal principle effective stresses are not equal and the ratio between the two is chosen to insure that the specimen consolidates only vertically (no lateral strains). For the soft sediments, the vertical effective stresses are usually higher than the normal effective stresses to insure Ko conditions. With only three samples it was not possible to determine the appropriate Ko value and a value of 0.7 (horizontal to vertical effective stress) was used based on previous results on soft sediment testing. This was likely lower than optimum and one sample (GC-B-005) failed horizontally during testing. Volumetric strain and NAPL displacement can still be determined although other consolidation parameters would not be estimated accurately. These parameters were estimated as part of other geotechnical testing and so this was not considered a serious limitation for the current testing.

The samples were first removed from the tube and trimmed down to the testing diameter of two inches. Figure 1 below shows the early stages of trimming on specimen GC-B-004(p1) obtained from tube GC-B-004. Note the limited presence of contaminants in samples from this tube and the heterogeneity of their distribution. Figure 2 shows specimens GCB-004(P1) and GC-B-002 after being trimmed down to testing diameter. The specimens were then placed in a second

trimming device to cut off the top and bottom to insure they were parallel and perpendicular to the heigh of the specimen (Figure 3).

After trimming, the specimens were placed in the triaxial setup through a split mold (Figure 4a). Before the cell is assembled and testing begins (Figure 4b), bladder accumulaters were used to collect the effluent. General comments about the specimens and consolidation testing performed are as follows:

1) The samples cannot be considered undisturbed since they were not stored and shipped properly. Specimen GC-B-002 had traces of contaminents that were already expelled from the specimen due to disturbance during shipping. Since they were not undistubed, there is a higher likelihood that contaminants would be mobile.
2) Samples GC-B-002 and GC-B-005 appeared more contaminated (Figure 2b and 3). Sample GC-B-005 had more "roots" and other debris that made trimming more challenging and eventually resulted in the specimen failing during consolidation.
3) The soil in sample GC-B-004 was light brown with occasional non-uniform pockets of NAPL or other organic rich material (Figure 1). The soil was coarser than that of the other two samples, with a higher sand content.
4) Sample GC-B-002 was tested first. Due to a transducer failure, high precision consolidation information was not recorded although volume changes due to consolidation at regular intervals were recorded manually and analyzed herein.
5) With the limited number of samples, Ko could not be identified and therefore the results reported here should be used with caution as they do not reflect true Ko conditions. Additional tests are needed to determine Ko for these sediments before a true Ko consolidation can be run.

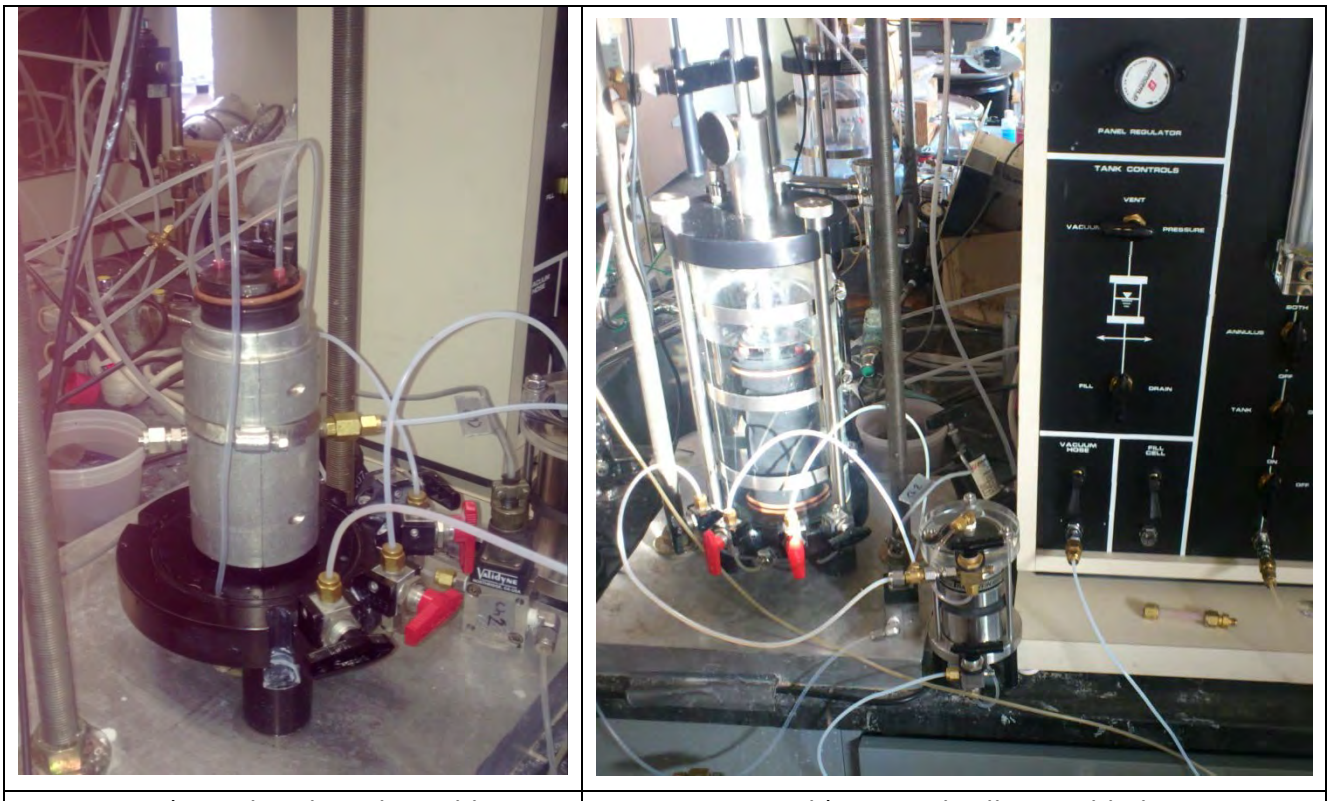
Figure 2: specimens trimmed to final diameter of 2”

Figure 3: trimming top and bottom of specimen GC-B-002.



a) Within the split mold | b) Triaxial cell assembled

Figure 4: specimen setup in the triaxial cell.

Consolidation was conducted in five stages as shown in Table 1, exposed sediment and then capped with the equivalent of up to 10 feet of sand in 2.5 foot stages. Water depth (to set hydrostatic pressures) was assumed to be 10 ft. Table 1 summarizes the stresses used for the testing and the equivalent field conditions.

Table 1: lab stresses and equivalent field conditions

Depth to top of specimen (ft)	Thickness of sand cap (ft)	Depth of water to top of specimen (ft)	Horizontal Effective Stress (psi)	Vertical Effective Stress (psi)	Back Pressure (psi)	Horizontal Total Stress (psi)	Vertical Total Stress (psi)
2.5	-	10	0.47	0.68	5.5	5.97	6.18
2.5	2.5	10	1.31	1.88	5.5	6.81	7.38
2.5	5.0	10	2.16	3.09	5.5	7.66	8.59
2.5	7.5	10	2.95	4.21	5.5	8.45	9.71
2.5	10.0	10	3.82	5.45	5.5	9.32	10.95

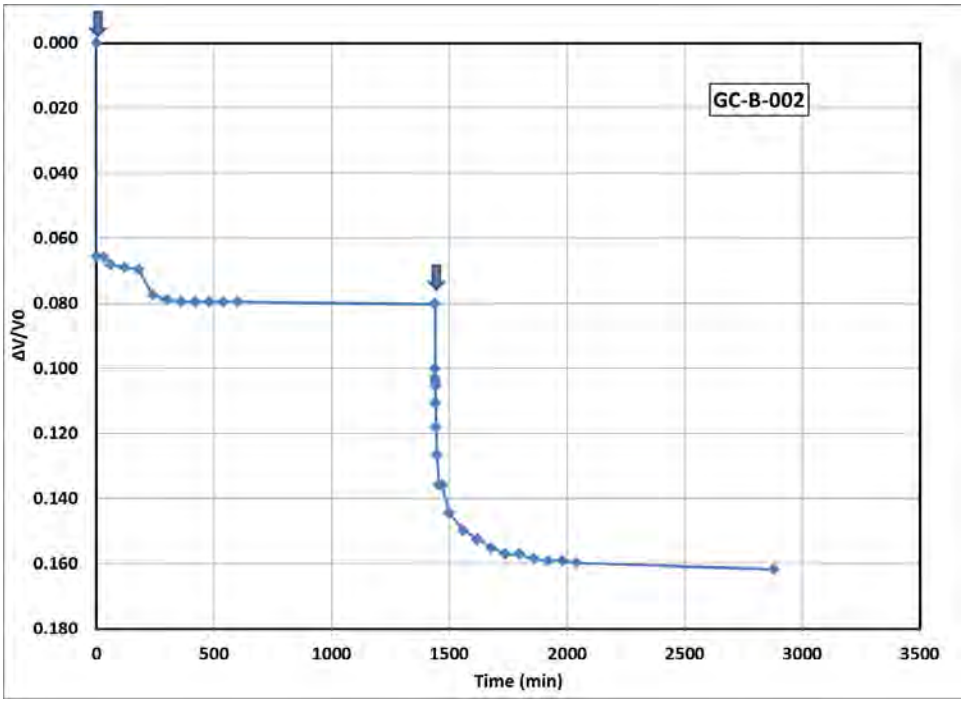
The volumetric strains versus time for each of the specimens and estimated NAPL (as measured by HEM) and water contents are shown in Figures 4-7. In each figure the placement of additional load on the sample is shown by the vertical arrows. For Sample GC-B-002, the maximum load was placed in two steps while for other samples, the load was applied in 5 steps. The fine-grained sediment samples GC-B-002 and GC-B-005 showed >20% initial NAPL contents and water contents in the 70-100% range (mass NAPL or water per mass dry solids). The coarse grained sediment sample GC-B-004-1 and GC-B-004-2 showed initial oil contents of less than 5% and a water content of 25%. There was similar variability as measured by absolute standard deviation between replicates of all samples which meant that the lower NAPL content

of sample GC-B-004 samples exhibited a relatively high relative standard deviation (+/- ~100%). Samples GC-B-002 and GC-B-005 samples showed similar absolute variability but much lower relative variability due to the higher NAPL/HEM contents. The fine grained samples consolidated approximately 16-18% with the loading of the equivalent of 10 feet of sand. The coarser sample consolidated <5%. None of the samples expressed meaningful amounts of NAPL. Trace observations of expressed NAPL however indicate that the sediments could lead to transient sheens if disturbed.

Post-consolidation sampling showed that some redistribution of NAPL and water had occurred in the samples despite negligible NAPL release. Water mobilized to the near surface and water was expressed from the top of the sediment during the consolidation process. NAPL, however, had apparently replaced water at the bottom of the sample. Samples collected post-consolidation from the top of the specimens showed elevated water contents and depleted NAPL levels (as measured by HEM) while bottom samples showed the reverse trends.

Although this testing was preliminary in nature, it suggests that the NAPL currently present in sediments in the Gowanus Canal is unlikely to be mobilized by capping. Further testing is required to confirm whether these conclusions are generally applicable in the Canal.

Figure 5: Sample GC-B-002 consolidation profile and water/NAPL content statistics pre and post consolidation. The full load of the equivalent of 10 foot of cap was placed in two steps with rapid sample consolidation immediately after application. Total sample strain was 16%. No meaningful NAPL was displaced, only water. NAPL redistributed slightly through the sample with some movement to the bottom of the sample as water was displaced.



Core GC-B-002			Post Consolidation		
		Undisturbed	Bottom	Middle	Top
Density of sample	(kg/m3)wet sample	1.31	1.33	1.40	1.32
SD	+-	0.10	0.09	0.09	0.04
Water Content	g water/g sample	48.56%	37.79%	38.76%	42.27%
SD	+-	0.65%	6.97%	2.21%	1.29%
% HEM	g HEM/g sample	9.09%	13.55%	11.17%	9.61%
SD	+-	1.99%	1.91%	2.29%	0.28%
Water Content	g water/g dry solid	114.69%	77.67%	77.40%	87.86%
SD	+-	2.19%	10.05%	3.87	1.85
% HEM	g HEM/g dry solid	21.47%	27.86%	22.30%	19.97%

National Grid has retained Dr. Michael R. Palermo, Mike Palermo Consulting, with expertise in environmental dredging and dredged sediment treatment and disposal, to evaluate the feasibility and practicality of environmental dredging and dredged sediment treatment and disposal as proposed in the United States Environmental Protection Agency (EPA) Proposed Remedial Action Plan (PRAP) for the Gowanus Canal.

I. Qualifications

I have been an engineer concentrating on dredging, dredged material management, and contaminated sediment remediation for almost 40 years, since 1974. I have extensive experience in both design and technical oversight of navigation dredging and contaminated sediment remediation. I have supported government agencies and responsible parties on a number of large-scale sediment remediation projects, including Hudson River (New York), Housatonic River (Massachusetts), Fox River, (Wisconsin), Onondaga Lake (New York), and Portland Harbor (Oregon).

I hold Bachelors and Masters degrees in Civil Engineering from Mississippi State University and a Ph.D. in Environmental and Water Resources Engineering from Vanderbilt University. I have served with the United States Army Corps of Engineers (the Army Corps) as a Research Civil Engineer and Director of the Center for Contaminated Sediments at the Engineer Research and Development Center at the Waterways Experiment Station, where I managed and conducted both research and applied studies for the Army Corps, the EPA, the Department of Justice, the National Oceanic and Atmospheric Administration, and the United States Navy, among others.

In addition to being a member of the Western Dredging Association (WEDA), the International Navigation Association, and the American Society of Civil Engineers, I have served as an Adjunct Professor of Engineering at Texas A&M University and Mississippi State University. I am also an Associate Editor for the WEDA Journal of Dredging Engineering and have served on numerous national and international workgroups and peer-review panels.

I have written a number of articles and guidance documents on dredging, dredged material disposal technology, and contaminated sediments remediation. I have been the lead author of Army Corps, EPA, and international guidance documents pertaining to contaminated sediments, including the Army Corps / EPA 2008 Technical Guidelines for Environmental Dredging of

Contaminated Sediments, the EPA 2005 Contaminated Sediment Remediation Guidance for Hazardous Waste Sites, and the EPA 1998 Guidance for In-Situ Subaqueous Capping of Contaminated Sediment.

II. Introduction

Dredging projects require a specific expertise, and even then, much hands-on experience. These comments are offered in a spirit of cooperation and support to provide recommendations that have been informed by my work on a number of real dredging projects and that will hopefully not just improve the PRAP, but also lead to a workable and successful remedy for the Gowanus Canal.

EPA has completed a Remedial Investigation (RI) and a Feasibility Study (FS) and I have reviewed both, along with numerous other documents, as part of this evaluation. Although my evaluation focuses on dredging, dredged sediment treatment and disposal, and post-dredging cap design and implementation, other components of the PRAP are also considered because they relate to dredging. Compatibility of dredging, in-situ stabilization, capping, and sediment treatment and disposal are extremely important and must be evaluated in order to design any remedy.

The RI identified two major sediment layers in the Canal: A surficial layer of "soft" sediments which have accumulated since the Canal and bulkheads were constructed, and an underlying layer of "native" sediment which dates back to the time when the Canal was in its natural state. Both layers are contaminated, but NAPL impacts are more severe in the native sediment, presenting challenges with respect to dredging in this layer. Further, exposing the native sediment will make it harder for the post-dredging cap to be effective. The two-layer stratigraphy in the Canal therefore plays an important role in defining dredging elevations and has significant effect upon the scale and complexity of the dredging remedy put forward in the PRAP.

The RI also identified three Remediation Target Areas (RTAs) corresponding to the upper (RTA 1), middle (RTA 2), and lower (RTA 3) reaches of the Canal. Conditions and sediment characteristics unique to each RTA have bearing upon how dredging may differ in each RTA. In other words, the one remedy outlined in the PRAP does not necessarily fit all three areas. This then adds yet another dimension to the Canal that must be evaluated.

The FS set forth seven remedial alternatives, ranging from "No Action" to active remediation with dredging the soft and native sediment layers, followed by capping. Only two alternatives were evaluated in detail: Alternative 5 which calls for complete dredging of the soft sediment layer, followed by capping; and Alternative 7 which calls for complete dredging of the soft layer, followed by in situ stabilization (ISS) of the surficial native sediment layer in areas of active NAPL migration, followed by capping.

The PRAP follows closely the findings described in the FS. The PRAP calls for application of Alternative 5 to RTA 3 and application of Alternative 7 to RTA 1 and RTA 2. The PRAP, however, neither builds upon nor explains the descriptions of Alternatives 5 and 7 beyond the

limited information presented in Table 4-4 of the FS (for purposes of this memo, the PRAP is assumed to incorporate the concepts provided in Table 4-4).

The comments that follow focus primarily on the steps needed to get from the PRAP to an implementable remedy. Based on my experience, I submit there is still much study and work to be done during the design phase. The Record of Decision for the Canal must provide flexibility to incorporate the results of these important studies and to allow time to shape new plans and work into the ultimate remedy. Based on my experience as well as my work with Dr. Danny Reible, who has also reviewed the PRAP and is commenting on it, I believe that capping soft sediments in select areas of the Canal should not be discounted, but rather should be evaluated during the design process.

III. The ROD Should Include Flexibility and a Realistic Timeline

The PRAP calls for application of remedy components in a very specific manner with little appearance of flexibility. In my experience, flexibility, within the bounds of meeting remediation goals, is essential to address complex sites like the Gowanus Canal. There are numerous components to even the simplest environmental dredging project that require extensive advance study and planning. I have found that as each dredging projects unfolds, unforeseen conditions and events arise that not only create delay, but may mandate overhaul of the entire project. The PRAP appears to make no accounting for this reality. To the contrary, significant components of the PRAP appear to have been based on limited, if any, information and evaluations. As a result, critical issues like the need for some components of the PRAP, the effectiveness of certain proposed actions, the potential negative impacts of other proposed actions, and the ability to implement the proposed plan all remain unknown to a large degree.

With the need for flexibility comes the need for sufficient time, especially with the type of involved dredge and cap remedy called for in the PRAP. The PRAP targets five years for project completion, but offers few details on the sequencing, coordination, and production rates, to name a few of the things required to meet this goal. By way of example, production rates must be calculated at the conceptual level based on conservative assumptions for operating production rates and operational and quality of life constraints. During remedial design, these rates will be refined as the unique constraints presented by the Canal geometry and the requirements for compatibility with transport, re-handling, and disposal become known. Likewise, the type, size and availability of treatment and staging areas will impact the time-line.

In short, based on my experience with these types of dredging projects, and given the need for advance thinking, planning, and coordination, as well as the unforeseen conditions, delays, and setbacks that are always inevitable, setting a target time as the PRAP does, is not prudent. It will only lead to disappointment and, worse, resentment. The ROD should omit the five year target and wait until a more realistic time frame can be set depending upon the outcome of the remedial design efforts.

IV. Capping Soft Sediments Should be Evaluated

Much of the proposed plan appears to have been shaped by the notion that soft sediment cannot support a cap. Apart from the fact that removal of all soft sediments — a mass removal

approach — and removal of more sediment "in case of cap failure" are wholly inconsistent with EPA guidance, there is no evidence in the PRAP that supports this notion.

The "golden rule" of capping is to place the cap in thin layers over large areas, gradually building up thickness. If this rule is followed, a cap can be constructed on the Canal soft sediment layer. At Gowanus, the soft sediment layer contains a significant fraction of sand size particles, while the solids content averages 51% by weight, a value higher than the average for many contaminated sediment sites. Plasticity is also low. Also, the cap can be designed more easily if founded on the soft sediment where NAPL migration will not easily occur. The higher PAH concentrations and NAPL with depth strongly favor a combined remedy approach with limited sediment removal followed by engineered capping. This approach will also reduce contaminant releases during implementation and increase long term effectiveness.

Shear strength (the strength of the sediments to resist a bearing or sliding failure) also plays a role in supporting a cap over the soft sediment. Shear strength increases as you move down deeper into a sediment column. This is so because the pressure of the sediment column increases as you move down, thus consolidating (compacting and compressing) the deeper sediment. Under such circumstances, dredging of even a few feet of the soft sediment in the Canal will leave a surface with a higher shear strength than the original soft sediment surface. This new and stronger "pre-consolidated" soft sediment surface may very well support a cap. However, much geotechnical evaluation coupled with time and flexibility to review and digest evaluation data will be necessary to establish whether or not this will be the case.

The geometry of the Canal also lends itself to capping the soft sediment. Mud waves, which are a risk with any soft sediment occur when sediment squeezes out laterally as the cap is placed. This leads to an uneven surface, which makes capping much more complicated and less effective. The Canal bulkheads (and bulkhead reinforcements) provide lateral containment for cap placement, reducing the potential for mud waves. Placing the cap in thin layers across the full width of the Canal to build up the cap will reduce the risk of mud waves. And, the geometry of the Canal is suited for placement of geotextiles, if needed, for increasing the strength of the sediments to support a cap.

Finally and perhaps most important, the EPA's misguided notion that soft sediment cannot be capped is contradicted by the fact that caps have been placed successfully on soft sediment at a number of sites:

- Soda Lake (Wyoming) - Capping materials were mixed with water to form a slurry which was pumped through four inch pipe to a spreader barge, where it was distributed using an eight foot wide diffuser box. The pipeline discharge entered the diffuser box in a way that sprayed the slurry upward against a baffled surface. This surface distributed the slurry in a lateral fashion less than one foot above the water column and promoted uniform distribution. In shallower areas, the cap was placed using an aerial disbursement method.

•Fox River (Wisconsin) – Cap material was placed using hydraulic slurry conveyed by pipeline to a floating mechanical spreader with a spreader wheel, similar to those that spread salt on roadways.

•Silver Lake (Massachusetts) - A dissipater/spreader assembly (spreader box) consisting of a 20 foot wide perforated diffuser pipe extended across the top of the spreader box, with an angled steel plate was mounted on a barge. The angled plate dissipated energy while directing and spreading sand. The same equipment was used for a phase of the Fox River project.

•St. Louis River (Minnesota) - A sand sub-cap was placed hydraulically using a barge with a spreader box fed by a dredge pump. As the barge advanced using a cable system, the spreader box dissipated energy to allow the sand to settle gently as a uniform layer.

•Mocks Pond (Indiana) – Cap material slurry was pumped to a spreader barge through eight inch pipe, where it was distributed using a 16footwide diffuser plate. The plate distributed the slurry in a lateral fashion less than one foot above the water column and promoted uniform material distribution.

•Ward Cove (Alaska) –A sand cap was placed by using an eight and one-half cubic yard bucket that was welded to hold an amount of material equivalent to a six inch placement over the 300 square foot arc of the bucket swing. The material was released below the water surface within 10 to 20 feet of the bottom.

•Onondaga Lake (New York) – A large spreader plate system, similar to the one used at Silver Lake, was used. Cap material slurry was conveyed by pipeline to the spreader using a 12 inch pipeline.

Photos of the equipment used at these projects are attached.

The foregoing shows the wide variety of equipment designs and placement techniques that have been utilized around the nation to resolve the challenge of capping soft sediment. Clearly then, the option of capping the soft sediment layer should not be dismissed out of hand as in the PRAP, but should be evaluated as part of the remedial design.

V. The PRAP Fails to Consider the Practicalities of Dredging

Implementing dredging as part of the remedy for major sites like the Gowanus Canal is a complex undertaking, involving a range of issues. Some issues can be addressed in design, but others relate directly to the practicality of dredging and the ability to effectively implement a remedy. The EPA Office of Emergency Response recognized the complexity of such projects as early as 2002, and engaged the Army Corps to develop guidelines for environmental dredging for sediment remediation. I was the lead author of those guidelines, published by the Corps as the Technical Guidelines for Environmental Dredging of Contaminated Sediments (Palermo et.

al. 2008) (the Guidelines). EPA identified the Guidelines as a supporting document for the EPA Contaminated Sediment Remediation Guidance for Hazardous Waste Sites (EPA 2005), commonly called the "Superfund Sediment Guidance." The Guidelines and the Superfund Sediment Guidance provide the framework for designing, implementing, and monitoring environmental dredging projects.

(a) Dredging Operations

The PRAP does not consider how dredging operations should be conducted in view of the challenges presented by the Canal site conditions. Site conditions and sediment characteristics are of particular importance when planning dredging, treatment, and disposal. These components are challenging at the Gowanus Canal because they vary throughout the water body, are in perpetual motion because of the ongoing nature of sources like the combined sewer overflows (CSOs), and are subject to dramatic change in the near and distant future. One significant change in the Canal will occur when the flushing tunnel is reactivated. Increased flow from the tunnel coupled with CSO inputs and natural tidal and river flow fluctuations will make for a very active system that will mobilize sediment and contamination. Dredging and capping actions, if done strictly in accordance with the PRAP, will further stir things up by exacerbating the flow. This will cause sediment scouring during and immediately following dredging operations. The PRAP addresses none of this, and as a result the dredge and cap remedy as proposed therein is little more than a concept.

In addition, basic physical characteristics of the Canal must be evaluated because any one by itself has the potential to undermine the dredge and cap remedy. As with the active and changing components of the Canal, the PRAP contains little or no discussion of how site conditions such as water depths, bathymetry (especially slopes), currents, wave energies, the presence and nature of major infrastructure (i.e., bulkheads, piers, abandoned pilings, bridges, utility crossings, pipelines), the presence and nature of debris in Canal sediments, and geotechnical conditions (i.e., stratification of underlying sediment layers, depth to bedrock, physical properties of foundation layers) will impact the dredging operations. All of these things must also be considered as part of the remedial design.

Consideration of over dredging allowances, potential for sediment resuspension, and behavior related to removal, post-dredging treatment, and disposal — all very necessary parts of any dredge design — are essentially absent in the PRAP. The remedial design must account for overdredging (additional dredging depth to account for equipment inaccuracies) and must evaluate the allowable tolerances around target elevations. Other operational factors such as ability to dredge along a sloping bottom and limits on precision of removal must also be considered in defining the total volume of material to be dredged. None of these dredging design specifics were considered in the PRAP, and this has resulted in an underestimation of the dredging volumes, operational challenges, and timelines required to implement the PRAP remedy.

Future use of the Canal should also be considered. One of the most basic and important questions asked when designing a remedy is, "What do we want this site to look like post-remedy?" Underlying the answer to this question for the Gowanus Canal are issues like

commercial versus recreational navigation use, habitat restoration / enhancement, future shoreline and adjacent upland development, and engineering practicalities associated with shoreline stability. All of these issues must be addressed in the remedial design. Especially critical among these issues is re-thinking of Canal uses that require greater water depth. Given that the Canal has seen limited use (as revealed by the present state of sediment accumulation) and the plans for residential / recreational development along the Canal, it is unlikely that there will be a need for deeper navigation depths. At the very least, it appears that the upper portion of the Canal will eventually be limited to recreational traffic, which reduces any requirement for depth and thus reduces the need for dredging.

Finally, simple access to the waterbody is extremely critical when it comes to dredging. In addition to the need for open space for staging, loading / off-loading, and treatment, clearances and space for work within the waterbody determine equipment and operational approaches for both dredging and capping. For example, in the Gowanus Canal, horizontal clearances at bridges in RTA 3 constrain access from the bay. The narrow channel width of 40 feet between abutments, at several other bridges constrain ability to work in the Canal. Similarly, land-side access is limited by the dense development along both sides of the Canal. As a result, there are few, if any, areas adjacent to the Canal suitable for staging, re-handling, and treatment. These constraints, plus the narrow width of the Canal for most of its length will limit the size and operation of dredge barges, sediment transport barges, and tugs. Not only are none of these things mentioned in the PRAP, but certain components recommended in the PRAP like the enclosures to control resuspension, which will reduce the Canal width by half, actually magnify the already significant constraints that are sure to hamper a dredge operation and increase the time required to complete a remedy.

(b) Impacts of Dredging

In addition to the site characteristics and operational specifics that are not considered in the PRAP, the consequences of the remedial actions proposed are also not included. This is a fundamental mistake that often arises because of single focus on “how to do the dredging.” After the dredging is undertaken, it often becomes clear that insufficient provision was made for how to handle the impacts of the dredging, with disastrous results.

All dredges stir up (resuspend) some sediment into the water column during the dredging operation, and resuspension results in release of contaminants in dissolved form to the water and as a volatile release to the air. Resuspension evaluations with appropriate modeling are needed to predict suspended solids concentrations as a function of distance and time and related potential for contaminant release to water and air. These estimates can be based on field experience or empirical or analytical models (e.g., the Army Corps DREDGE model or more sophisticated numerical sediment transport models). Results are then compared to performance standards for resuspension or water quality standards for suspended sediments or turbidity. The need for control measures (such as restrictions on the rate and timing of operations or deployment of silt curtain or hard containments) can then be determined. No such evaluations were conducted or even considered in developing the PRAP.

At the Gowanus, site-specific estimates of resuspension rates need to be performed before any design is put in place. Estimates should be based on procedures provided in the Army Corps Guidelines, considering the site specific sediment characteristics of the Canal (both for the soft and native sediments) and the anticipated dredge types and sizes. The resuspension estimates will inform the subsequent estimates of contaminant release rates for water and air.

Lastly, the PRAP fails to account for "residual sediments," sediments found at the post-dredge surface either within or adjacent to the dredging footprint that contain contaminants at concentrations above the action level. Residual sediments can be generated and left behind by the digging action of the dredge or can be missed by the dredging operation due to poor characterization of the sediments. Residual sediments pose a significant risk because they result in contaminant releases from the dredged surface prior to cap placement. This was a real problem at the Hudson River Superfund Site, where scour of loose residual sediments at the new, post-dredge surface, resulted in a high degree of contaminant release. This problem may even be worse in the Gowanus Canal due to the higher concentrations of contaminants of concern and the PRAP plan to dredge to the native sediment where NAPL is much more concentrated.

(c) Resuspension Controls

Evaluation results for sediment resuspension, contaminant release, and residual sediments should be compared with performance standards to determine if operational and engineering controls are needed during dredging, and if so, whether they will be effective. Operational controls are those associated with dredging, such as adjustment of dredge type or size, bucket wash tanks, changes in the rate of operation or advancement of the dredge. Engineering controls include structural containments such as sheet pile enclosures or silt curtains to control sediment resuspension. Controls for resuspension also help control contaminant release to water and air.

Operational and engineered controls, however, are not only expensive, but they can significantly limit the amount of material that can be dredged at any one time and therefore reduce efficiency. Further, the improper use of controls can have significant negative impacts like increasing sediment resuspension and / or the time needed to complete the project.

The FS requires that sheetpile enclosures be used. Furthermore, it assumes that all dredging and capping will be conducted within the enclosures, the enclosures will capture all resuspended sediment, and overlying water from the enclosures will be treated prior to opening the enclosures. These assumptions were included in the PRAP without the benefit of any technical evaluations and without consideration of the potential negative impacts of implementing such controls.

Sheetpile enclosures will significantly narrow the Canal. My construction experience shows that once the bulkheads are reinforced, the enclosures could reduce the width of the Canal by more than half. This will increase flow velocities around the enclosure, which will increase shear (force on the bottom sediment), which will increase erosion (movement of the bottom sediment). This will become even worse once the flushing tunnel is turned back on and transport barges appear. Lastly, modeling indicates that moored barges will also cause an increase in scour. Transport barges will have the same effect. It is possible that sediment erosion and related

contaminant release could be greater with enclosures, as opposed to dredging without enclosures. These issues were not addressed in the PRAP and directly relate to the ability to implement the remedy.

Sheetpile enclosures, if used, will also concentrate resuspension of sediments within the enclosures. The enclosure will thus turn into a concentrated source for more releases to air, which will mean significant odor throughout the community. Although resuspension within the enclosure may stop once dredging is complete and suspended sediment may settle out, significant dissolved concentrations will remain in the water column. To remedy this unwanted situation, EPA proposes dilution-based flushing by treating two volumes of water from the enclosure prior to opening them. This, however, is a waste of resources because groundwater will continue to discharge laterally and from below into the enclosure, and leakages through the sheetpiles will occur. As a result, EPA's dilution-based flushing will not treat the enclosure water sufficiently, and once the enclosure is opened, a sudden pulse release will occur. Also, treating the water and then discharging it outside the enclosure into the dirtier Canal makes no sense. It may be better to discharge the treated water inside the enclosure, which will reduce contaminant concentrations in the slug of water released when the enclosure is moved.

If the need for enclosures is established in the design, an alternative to the sheetpile enclosure chosen by EPA may be reinforced silt curtains. In fact, this very design worked well at the Bangor (Maine) site, a site along the Penobscot River with significant NAPL, flow variability, and a 14 foot tidal fluctuation. The silt curtains were attached to spaced anchor piles with mesh reinforcement to reduce curtain sailing and tears. A baffle configuration was used to allow for exchange of water from the large tidal fluctuation. The mesh was cyclone fencing material, but other mesh materials such as hardware cloth are also effective. Although the Penobscot River bank had an inset that saved the curtain from being directly exposed to river current / flow, the same could be accomplished in the Gowanus Canal by installing a short sheetpile deflector wall at the upstream end, which would also shield the curtain from direct flow. Construction of this alternative design would take less time, be less intrusive to the community with respect to noise and emissions, and would allow for greater flexibility in alternating the enclosure from side to side and along longitudinal reaches of the Canal.

The foregoing makes clear that the degree of controls needed is site-specific and should only be applied when conditions clearly dictate. They should not be set, as they are in the PRAP, solely because they can be (EPA 2005). Indeed, operational controls such as fixed arm equipment, enclosed buckets, operation of the dredge within a primary oil boom and silt curtain Moon Pool, secondary oil booms, and bucket washing and catch pans may very well be more effective than enclosures in maintaining an acceptable level of releases during dredging and capping in the Canal. A site-specific evaluation should be conducted for the remedial design to first establish the need to control sediment re-suspension, and second if needed, an evaluation should be conducted to evaluate the type of controls that should be used, whether they will be effective, and whether such controls could also have negative impacts.

(d) Material Re-handling

Another key issue not considered in the PRAP is the compatibility of the dredging, treatment, and disposal or reuse of the dredged sediments. Careful planning and design of rehandling and transport is critical because rehandling operations should be limited as much as possible to minimize the risk of spills and releases. Community intrusions (e.g., odor, noise, lighting, traffic and other issues) should also be considered, and health and safety plans should address both workers and community members. In order to reducing bottlenecks and maintaining throughput of material from the dredge to transport to treatment to disposal, transport and rehandling must be associated with dredge operations very closely, generally in the form of a detailed Operations Plan. The PRAP does none of this and all of this will take time.

With mechanical dredging, multiple re-handling steps between the dredge and disposal of sediments are usually required. Material is usually placed directly into barges for transport to an offloading or staging area where the dredged sediments undergo dewatering and / or treatment. The dewatered / treated sediments are then rehandled to trucks or barges for transport to the disposal site. Neither the FS nor the PRAP discuss this in any detail. Rather, EPA simply says all treatment / disposal options will include barging dredged sediment to a "local on-site dewatering and transfer facility." Again, the PRAP does not account for inevitable delays due to things like public concern and releases, not to mention the very real challenges to re-handling and transport posed by the limited access to the Canal, the Canal geometry, and the lack of space for staging and operations. Accordingly, refined studies and evaluations are required for purposes of remedial design and siting specific areas for staging and offloading, and sediment treatment.

(e) Transport and treatment of Dredged Sediments

The narrow width of the Canal will hamper placement of dredged sediments into transport barges. As explained above, bulkhead reinforcement and construction coupled with the use of control enclosures, will cut the width of the Canal by more than half. Such narrow confines will limit barge traffic to one way only, will not allow for barge turning, and will slow ingress / egress for barge rotations. Further, the small width will effectively eliminate navigation upstream of the active working area and will likely limit the project to use of a single operating dredge. These issues need to be evaluated in light of the required dredge sizes and dredging barge dimensions as well as the likely dimensions of transport barges.

The PRAP suggests that dewatering be done at an on-site staging area, followed by treatment of the water. It is quite possible that no acceptable offloading or treatment / re-handling sites can be located along the Canal because such arrangement requires not only space on land for a treatment plant, but also space in the Canal to moor multiple barges and to allow time for settling and generation of free decant water.

Location of such a transfer / dewatering facility may not even be the best approach from a public acceptance standpoint. Such a facility will be another source for emissions and noise and light. Such a facility will also create an offloading / re-handling step that may not be necessary.

Finally, an on-site area with limited space is not likely to allow for docking or offloading of multiple barges, which will possibly cause delays.

To the extent facilities off-site will be considered, that will affect the dredging operations in proportion to the distance away from the Canal. Transit times will directly influence the required number of transport barges and the size of the barges so as to avoid dredging delays. Although experience with a number of projects has shown that redundancy in equipment and operations can reduce down time and allow for continuing throughput of materials, this must be studied.

(f) Sediment Treatment and Beneficial Use

The treatment and disposal options in the FS and PRAP involve stabilization and / or thermal desorption, but do not provide any technical evaluations regarding the necessity or effectiveness of this approach. Thermal desorption will not reduce the concentrations of metal contaminants in the sediments. Sediments will therefore still be required to be placed in a landfill. EPA selected these approaches without the benefit of any treatability studies and without considering whether a specific treatment approach is workable or optimal for the Canal sediments.

A major consideration is the need or benefit of a sediment treatment approach. Stabilization may be needed for meeting the "paint filter test" so the material may be accepted for landfill disposal. However, the need for thermal desorption should be fully established. If the material would be acceptable for landfill placement without thermal desorption, there is no justification for requiring that treatment.

Furthermore, most sediment treatment technologies have not seen wide use because of high unit costs and difficulties treating sediments at the rate at which they are removed. Particle size separation and solidification / stabilization have comparatively lower unit costs and are more commonly implemented. Treatment of sediment solids to reduce toxicity or mobility of contaminants may be considered, but are not commonly used because of high cost and the need for permanent disposal of the treated sediment.

Beneficial use of sediments is also limited by the lack of cost-effective uses (EPA 2005). Landfill cover and construction fill are two uses that have worked, but the potential treatment requirements, levels of residual contamination following treatment, and physical nature of the fine-grained sediments normally associated with remediation sites present significant challenges to most beneficial uses. Beneficial use will be especially difficult for Non-NAPL impacted sediments from RTA 1 and for all sediments from RTA 3 because of the volumes of sediments involved and the lack of a market for sediments with the properties found in the Canal.

Several technical / logistical evaluations are needed to determine if beneficial use for Canal sediments is practical. Landfill cover is the best possibility, but agreements will be needed with landfills regarding the rate of throughput that can be accepted and total volume requirements. In general, total volumes of material needed for landfill cover are far less than the capacity of most landfills. Use as construction fill is also a possibility, but specific projects must be identified that will match the timeline for generation of material from the Canal as well as the properties of the material generated. These issues are real impediments to application of large volumes of

material from a remediation project for beneficial use, and they cannot be merely assumed to be workable.

(g) Landfill Disposal

Off-site disposal of sediments in licensed landfills is an option that is common to most remediation projects, and the Gowanus Canal project should be no different. This is so because on-site disposal is limited in the New York City region. However, there are a number of issues that can complicate landfill disposal. These are requirements for pre-treatment or treatment, logistics of rehandling and transport to the landfill, capacity of the landfill, and acceptability of the sediments for the landfill.

The PRAP assumes that sediments will be stabilized to the degree needed to pass the paint filter test, and that the sediments will be transported by truck from the processing facility to a Subtitle D landfill. The PRAP, however, makes no mention of the degree of dewatering needed for landfill placement and the workability of sediments for landfill placement, even if they pass the paint filter test. Indeed, at the Fox River site, some landfills required a higher tipping fee for dewatered sediments that had poor workability. Furthermore, agreements will be needed with specific landfills regarding the rate of throughput that will be accepted and the total capacity for sediments that will be handled over the total timeline of the project.

(h) CDF Option

The PRAP includes a confined disposal facility (CDF) option for one of the turning basins that will contain sediments from RTA 3 only because those sediments are the least contaminated. To the extent the Region pursues a CDF, the more contaminated sediments from RTAs 1 and 2 should not be precluded. There are no technical constraints (or to my knowledge regulatory constraints) limiting use of a CDF based on contaminant concentrations. CDFs can be designed with contaminant pathway controls that are as effective as any in hazardous waste landfills. Similarly, the PRAP requirement that only solidified material may be placed in a CDF is also unfounded. This requirement is not based on any technical evaluation. The CDF option, should it move forward, must, like all other components of the proposed remedy, be better planned and studied and afforded flexibility in design to meet performance standards.

VI. Conclusions

(a) Dredging Feasibility and Practicalities

The conclusions regarding the feasibility and practicality of the dredging and sediment treatment / disposal remedy set forth in the Gowanus Canal PRAP are summarized as follows:

- The PRAP calls for application of remedy components in a very specific manner with little or no flexibility. This approach is neither supported by the present level of knowledge about the site and sediment conditions, nor is it supported by the level of technical evaluations conducted to date. Experience has shown that flexibility, within the

bounds of meeting remediation goals, is essential for addressing complex sites like the Gowanus Canal.

- The feasibility of implementing several of the specific components of the proposed plan as described in the PRAP is questionable, considering the site conditions, physical constraints, the nature of the sediments, and the potential for stringent performance standards. The limited geometries of the Canal, potential for bulkhead instability and need for reinforcements, future operation of the flushing tunnel, presence of significant debris, and the presence of NAPL and contaminants of concern at high concentrations, all point to difficulties with dredging.

- Many components of the proposed plan were based on limited information and evaluations. Many technical evaluations and studies are needed to determine the full implications of the site conditions, the need for some of the proposed components, the potential negative impacts of some proposed actions, the effectiveness of some components, and the practicability of implementing some of the components.

(b) Summary of Required Evaluations and Studies

A significant technical effort will be required to fully determine feasibility, practicality, and effectiveness of the remedy and then to optimize the remedy ultimately chosen. This effort should include laboratory testing studies, hydrodynamic / sediment transport modeling studies, groundwater modeling, bench treatability studies, contaminant pathway testing, field investigations, and pilot studies. Such a comprehensive and complex effort will require close coordination among the various parties and significant time.

Required evaluations and studies pertaining to the dredging component are as follows:

- **Remedial Design Field Investigations.** Important data gaps exist for basic processes such as sediment transport, hydrodynamics resulting from changing conditions, groundwater flow conditions, geotechnical conditions, and bulkhead condition mapping and sampling. These aspects have not been characterized to the extent necessary for comparison of the remedial options and for remedial design. The gaps should be addressed with a coordinated series of remedial design field investigations.

- **Navigation Study.** Future navigation needs as well as future maintenance should be assessed. This assessment should include both commercial and residential / recreational potential.

- **Performance Standards Evaluation.** Performance standards (numeric limits or criteria related to the dredging operation) are a touchstone of remedial design. Categories of performance standards may include those related to sediment resuspension, water quality or air quality standards for contaminant release to water and air, and dredging production and timeline for completion of dredging. The specifics of meeting ARARs should be established using an effects-based approach and should consider the background concentrations and potential for recontamination of the Canal. Similar considerations apply to performance standards for the capping and sediment treatment and disposal

components. Evaluations of performance standards should be discussed with the agencies in the early stages of the remedial design, not later.

- **Dredging Production and Throughput Evaluation.** An evaluation of dredging production and sediment throughput from dredging to final disposal should be conducted. Mechanical dredging is the approach most suited for the Canal, but specifics like the size and numbers of dredges as well as redundancy and flexibility of use of equipment to avoid delays and bottlenecks must be determined. This will inform the desired timeline for completion of the remedy, which at this juncture is unrealistic. A production and throughput evaluation should also be performed to identify potential constraints resulting from control measures and the interface between the dredging and subsequent transport and rehandling components of the remedy.

- **Contaminant Release Studies.** Sediment characteristics for the Canal, high concentrations of contaminants, including NAPL in some areas and sediment layers, create a potential for contaminant release. A study of sediment resuspension potential, contaminant release potential to water and air, and residual sediments should be conducted. This effort would include laboratory testing for source strengths, and near field and far field modeling of release behaviors. This study is critical in determining the potential short-term effectiveness and long-term effectiveness of environmental dredging for the site, and the potential need for control measures. The potential contaminant releases due to a dredging operation should be compared with releases due to sediment erosion in the Canal with and without the use of controls such as sheetpile enclosures.

- **Sediment Resuspension and Contaminant Release Control Evaluations.** The PRAP calls for the most stringent and intrusive form of engineered resuspension control -- a sheetpile enclosure. No technical evaluations were conducted to determine either the need for such control or the potential impact of such control on sediment erosion and contaminant release. Considering the geometry of the Canal and the potential influence of the flushing tunnel, the use of hard enclosures may actually result in higher contaminant releases as compared to dredging without enclosures. A site-specific evaluation should be conducted to establish the need for engineered controls. If controls are needed, options must be evaluated to determine the most appropriate and effective control for the Canal, as well as the potential for negative impacts.

- **Operations Plan.** The PRAP's limited sequence of work is inadequate and a more comprehensive evaluation of operational aspects is needed to assess more fully the practicality of implementing the remedy. Among other things, an Operations Plan with detailed dredging prisms; delineation of dredging management units; description of dredge cuts, layback slopes, and box cuts; a sequence of operations; detailed mobilization and demobilization and construction timelines, complete descriptions of all equipment to be used; design and use of control measures; and methods for monitoring progress must be developed. This, however, can only be developed after all of the studies outlined in these comments are completed.

- **Monitoring and Management Plan.** Although these comments focus on dredging planning, design, and implementation, it cannot be forgotten that monitoring will be required to ensure the various performance standards are met. A Monitoring Plan should be developed during the remedial design and agreed to by all parties. This plan should include the monitoring equipment and techniques to be used (e.g. specific instruments, sampling devices, coring equipment); the protocols for sampling, handling and testing of samples (e.g. numbers and locations for sampling, compositing schemes, and testing procedures); and a description of how the monitoring data will be interpreted. Monitoring baseline conditions is critical during the remedial design phase for purposes of comparing conditions prior to, and immediately following, reactivation of the flushing tunnel.

- **Field Pilot Studies.** Field pilot studies will be needed to demonstrate the effectiveness at full scale for some remedy components. The pilot studies could include full scale dredging to assess sediment resuspension and contaminant release source strengths as well as full scale cap placement operations to field verify the ability to place caps on both the soft and native sediment. Specific objectives of the pilot studies will require an assessment of the needs based on the results of earlier investigations.

Required evaluations and studies pertaining to the sediment treatment/ disposal components of the Canal remedy are:

- **Rehandling and Transport Study.** Careful planning and design of the rehandling and transport components of the remedy is the key to compatibility. Areas for staging, offloading, and sediment treatment must be identified; and dredge to transport barge issues need to be evaluated in light of the required dredge sizes and dredging barge dimensions as well as the likely dimensions of transport barges. In-barge stabilization, including both treatability and operations, should be evaluated as part of the remedial design studies.

- **Sediment Treatability Studies.** EPA has identified treatment and disposal options in the FS and PRAP that involve either stabilization and / or thermal desorption. However, it appears EPA selected these approaches without the benefit of any treatability studies and without considering whether a specific treatment approach is workable or optimal for Canal sediments. A full bench-scale treatability study should be conducted to evaluate solidification / stabilization, thermal desorption, ISS, and treatment related to potential beneficial uses and potential landfill placement. The testing for ISS should be conducted on both the soft and native sediments.

- **Beneficial Use Studies.** Beneficial use will be difficult to implement considering the volumes of sediments involved and the market for sediments with the properties found in the Canal. A marketing study, aimed at identifying the potential demand for use of the Canal sediments, should be conducted to determine if there is any real potential for this option.

- **Landfill Investigation.** Although the proposed plan calls for beneficial use of all dredged sediments, placement in landfills should be investigated as one aspect of remedy optimization. Evaluations should be conducted to determine required pre-treatment or treatment, logistics of rehandling and transport, capacity of landfills that will be under consideration, and the acceptability of sediments from the Canal for placement in those landfills from the standpoint of dewatering and workability.

- **Confined Disposal Investigation.** To the extent EPA pursues use of a CDF, more comprehensive studies should be conducted. In addition to a CDF, a Contained Aquatic Disposal (CAD) may be considered. The initial investigation should focus on possible sites within the basins and Gowanus Bay, considering volumes, site bathymetry, and compatibility for future landside development. The more comprehensive studies would include the engineering design aspects as well as contaminant pathway testing and pathway control evaluations.

I. Introduction

Hydrodynamic characteristics, sediment and contaminant transport, re-suspension, and deposition in the Gowanus Canal have not been assessed in sufficient detail in the United States Environmental Protection Agency (EPA) Proposed Remedial Action Plan (PRAP). Consequently, there are several shortcomings of the proposed remedy with respect to long-term sustainability and ecological functionality of the Canal, not to mention basic feasibility of the EPA's proposed plans and actions.

EPA's discussion of sediment and contaminant transport and deposition through the Canal is anecdotal and not quantified. This is not surprising because the patterns of sediment and contaminant movement in the Canal are far more complex than anticipated by EPA and require the use of a numerical model to appreciate the full impacts of all of the processes involved. To that end, flow patterns, sediment and contaminant transport, and water quality issues in the Canal have been evaluated by Baird.

The performance of the EPA proposed remedy was examined with an eye toward four key areas:

- Surface water and sediment contributions to the Canal under existing conditions and under the EPA proposed remedy;
- Performance of the EPA proposed remedy;
- Feasibility of construction; and
- Transport and fate of contaminants of potential concern (COPCs).

The model results presented below demonstrate the complex interaction between factors like the flushing tunnel, vessels and barges, combined sewer outfall (CSO) flows, and tidal-driven currents, which together control flow patterns in the Canal. These in turn affect scour, and transport and deposition of sediments in the Canal.

Baird

II. CSO Contributions

Particle tracking and sediment transport model analysis to assess the potential fate of sediments from CSOs suggests that the particles found in the sediment mounds come from the outfall in the immediate vicinity of the mound. A two-week simulation from 23 August to 6 September 2011 tracked particles from CSOs RH-034, OH-007, and RH-031. The particles tracked were clays, medium silt and sand. This time period was chosen as it represents an extreme condition (it includes the Hurricane Irene surge and rainfall), giving an indication of the farthest distance that sediments may travel when the flushing tunnel is inactive. The model results (Figure 1) show that even under extreme conditions, sands and silts settle in the vicinity of the mounds, with clays being dispersed around the mounds. Under less extreme conditions, sediments are deposited even closer to the CSO outfalls.

Although the PRAP correctly recognizes that discharge from CSO RH-034 is the dominant source of sedimentation in the upper Canal when the flushing tunnel is inactive, the PRAP underestimates the full extent of the problem. So far, long-term sediment discharge from the CSOs has been predicted based only on flows from the New York City InfoWorks model. This model, however, is uncalibrated and unvalidated for sediment discharge from the CSOs. As a result, the PRAP does not account for the actual sediment discharge from the CSOs, which must be greater than is presently estimated. Indeed, although section 2/p. 2 of the Feasibility Study (FS) Addendum notes that CSO loading is estimated by DEP to be 259,000 pounds per year, a mass balance for the upper Canal suggests that this is five to ten times **less** than the amount of sediment that would generate the one to two inches per year of sedimentation noted in the PRAP (column 2, p. 10).

Given the likely underestimation of the amount and type of sediment discharged to the Canal from the CSOs,[1] the CSO storage tanks will need to be much larger to achieve the EPA desired reductions in solids. Absent this, the bed morphology of the restored Canal will need to be optimized to allow for greater throughput of sediment to New York Harbor. Lastly, percentage reductions in target flows for sediment from any remaining outfalls in the remedial design must be replaced by absolute targets so that these volumes can be accounted for in the remedial design.

III. Sediment Transport Analysis Summary

Monitoring of CSO sediment loads is required prior to selection of a final remedial alternative, and the Record of Decision (ROD) must be flexible enough to adapt any remedial design accordingly. Given that data and model predictions of flow and sediment load inputs from the CSOs and other outfalls is limited, longer-term inflows

[1]Given that parts of the Canal are accumulating at rates greater than two inches per year, the underestimation of the CSO sediment loading is in all likelihood even more than a factor of five to ten.

Baird

were derived from a basic watershed hydrologic model. With this in mind, the Delftl3D water quality, sediment and contaminant transport model was set up to evaluate the transport and fate of sediments under different events and Canal configurations. In addition to using the model to examine event-based sediment and contaminant transport, the hydrodynamic and water quality model results were applied along with particle tracking to determine likely pathways of sediments over longer time periods.

When sediments are represented in the Delftl3D morphological model, we find that they enter the Canal from CSO RH-034 and are initially transported by the momentum of the CSO flow. As coarse sediments settle out in the vicinity of the CSO outfall, the finer sediments move downstream by tidal currents (and diffusion). With the flushing tunnel inactive, the finer particles remain within the upper area of the Canal where they mostly settled out within two tidal cycles. A sediment budget for the CSO sediments introduced to the Canal from RH-034 with the flushing tunnel inactive (Figure 2) shows that most of the sediments settle to the bed of the Canal upstream from 3rd Street, and all of the sand settles out above Carroll Street, while the clays and silts are transported further downstream. The sediment budget highlights the ability of the model to reproduce the general patterns of sediment movement in the Canal under existing conditions, which form a baseline against which the performance of a remedial design (or series of designs) can be evaluated.

The PRAP asserts correctly that CSOs dominate sedimentation in the Canal, and that this sedimentation is most apparent in RTA 1 and the "surface" layer (the top two feet) of the soft sediment. The basis for this assertion are the five bullets ("multiple lines of evidence") in column two of the table on page 11 of the PRAP and column one of the table on page 12 of the PRAP, which are repeated below:

- CSO solids have high TOC content. The TOC content of the surface sediment is about 6 percent. Based upon the results of the RI and EPA (1998), the TOC levels in Upper New York Bay sediments are, on average, about 3 percent. Accordingly, if suspended sediments in tidal inflow or Flushing Tunnel flows from Upper New York Bay were contributing the majority of the deposited mass, the TOC of the surface sediment would be closer to 3 percent.
- The concentrations of PAHs, copper and lead in the surface sediment and in the CSO solids are similar. The concentrations of these chemicals are much lower in the reference sediments in the harbor; therefore, deposition of suspended sediments in harbor water (or from the Flushing Tunnel which brings in harbor water) could not be the predominant source of high concentration of PAHs, copper and lead in the Canal surface sediments. Aluminum and iron are not good indicators of CSO solids since they are "crustal" elements, i.e., they are very common in soils and sediments and are not COCs at this site.

Baird

- Sewage indicators, such as fecal coliform (GEI, 2011) and steroids (Kruge et al., 2007), are found consistently in the surface sediment in the Canal. The highest concentrations are located in the upper portion of the Canal where most of the CSOs are located.
- EPA's bathymetric study shows that most of the accumulation of sediment coincides with the Canal location (upper reach) where most of the CSOs are located and the highest CSO volumetric discharges take place. It has been reported and visually noted that CSOs discharge heavier mass solids. These heavier solids are typically expected to settle to the bottom of the Canal within a short distance from the point of discharge unless high horizontal velocities disperse the solids downstream.
- Overall, the surface sediments in the upper Canal have higher sand content and lower silt and clay content than the Harbor reference locations. The sediments in the lower Canal, closer to the Harbor, have similar silt and clay content to the reference stations. This indicates that the upper Canal surface sediment is more influenced by the deposition of CSO solids than the area near the mouth of the Canal. This is consistent with NYCDEP's conclusion that CSOs predominately contribute heavy grain sediments, while fine grain sediments are a mixture of CSO discharges and Flushing Tunnel and harbor tidal contributions.

(EPA, 2012)

While these bullets certainly indicate that the CSOs are the primary / dominant source of sediment to the Canal, the bullets by no means indicate that the role of the CSOs stops there. There is no evidence that discharges from the CSOs are limited to the surface layer and upper part of the Canal. We contend that the limits of CSO influence to surface sediments and the upper reach of the Canal are not supported by the sedimentary evidence. The CSO influence is likely to be dominant in all areas of soft sediment accumulation, and not just in the top 2 feet (it is highly unlikely that any other sediment source has been dominant in the past). In areas of propeller scour and remobilization of bed materials (particularly in RTA 2), it is also likely that CSO sediments have become mixed with native materials due to the regular turbation of bed materials. A more thorough analysis of this factor needs to be included in the PRAP design. We recommend that the ROD clarify this:

First, bullet number 1 suggests there is no difference between total organic carbon (TOC) in sediments found in the surface and sediments found lower in the bed. This does not indicate that discharges from the CSOs are limited to the surface layer and upper part of the Canal.

Second, bullet number 3 states that sewage indicators are highest in the upper part of the Canal. Although this is the case, it does not prove that discharges from the CSOs are limited to the surface layer and upper part of the Canal. NYCDEP (2008; Figure 4-18) states soft sediments are found throughout the Canal, suggesting that soft

sediments will accumulate wherever CSO sediment inflows occur, and not just in the upper Canal.

Baird

Third, bullet number 4 suggests that the location of recent accumulation can be determined by a bathymetric survey. Such survey is by no means representative of long-term depositional patterns throughout the Canal, and regular, repeated bathymetric surveys are required to monitor the depositional characteristics of the Canal. In addition, the notion that CSO sediments are coarser in general is only true in the sense that they feature a sand fraction. They also feature high silt and clay fractions. Consequently the idea that CSO sediments are heavier and settle closer to their discharge point is misleading.

Fourth and last, bullet number 5 identifies that surface sediments in the upper Canal have higher sand content. This suggests that a signature of the CSO solids is sand, which may imply incorrectly that silts and clays are not derived from CSOs. Rather, it is simply unclear.

IV. The Proposed Remedy Will Not Meet Objectives

Model runs of sediment and contaminant transport show that the proposed remedial design is incompatible with the habitat and water quality goals of the project because particle tracking and sediment transport simulations confirm that trapping of sediments will increase, especially in RTA 2. Figure 3 shows a comparison of sediment deposition rates between existing conditions and the EPA remedial design, using the November 2010-November 2011 boundary conditions. Sediment deposition rates increase by up to 300 % in RTA 2, showing that any sediment still entering the Canal will be trapped in the deeper channel in RTA 2.

Background suspended sediments present in Buttermilk Channel will be introduced to the Canal through the flushing tunnel (FT) upon its reactivation. Figure 4 shows when the flushing tunnel is active, with the existing Canal bed configuration, sediments from the tunnel are deposited primarily in the central, deeper section of the Canal (RTA 2). This is so because flow slows down due to the increase in channel depth. Dredging in RTA 2 to an even greater depth, with a target evelation of -16 feet further reduces the ability of the flushing tunnel to move sediments and contaminants through the Canal to the Harbor, as the flow speed in RTA2 decreases due to the proposed increase in depth (Figure 3).

Even with the Flushing Tunnel flow, the USEPA Feasibility Study alternative reduces the ability of the Canal to transport sediment in the section between 3rd Street and the Expressway. In contrast to Existing Conditions with the FT inactive (Figure 2), where most of the sediment is trapped in the upper reach of the Canal, under the Remedial Design conditions the major area of sediment trapping is now the deeper section between 3rd Street and 9th Street. This demonstrates the general incompatibility

between the effectiveness of the Flushing Tunnel (requiring a relatively uniform bed elevation throughout the Canal), and the deep dredge to accommodate commercial vessel navigation.

The model study has identified other complex interactions that will occur in the Canal and that also need to be considered in order to develop a design that meets the water quality and ecological restoration objectives in a sustainable manner:

- **Reactivation of the flushing tunnel will have significant adverse effects.** The sand "benthic layer" in RTA 1 will require ongoing maintenance as flow from the flushing tunnel pushes the benthic layer downstream. This points to the issue that design of RTA1 will be more complex and challenging than is presented in the PRAP, and that flexibility to alter the design to be resilient to the driving forces in the Canal is imperative.

- **Varying depths in the Canal must be considered.** Figure 5 shows when the flushing tunnel is active, sediments from the flushing tunnel are deposited primarily in the central, deeper section of the Canal (RTA 2). This is so because flow slows down (and it is exclusive of the influence of commercial navigation, which will cause sediments to be regularly resuspended and deposited). Deep dredging in RTA 2, however, will reduce the ability of the flushing tunnel to move sediments and contaminants through the Canal to the Harbor. Similarly, the -16 feet target elevation for RTA 2 is not realistic, given ongoing commercial navigation in this section of the Canal. Propeller scour will require an armor layer consisting of large cobbles to boulders to prevent damage to the cap. Sediments deposited above the armor layer would be subject to regular remobilization and redepostion under the influence of vessel traffic. Lastly, the transition from "shallow" (-9 feet) in RTA 1 to "deep" (-16 feet) in RTA 2 leads to deposition in RTA 2 of CSO sediments and contaminants, sediments from the flushing tunnel, and sediments remobilized from the sand benthic layer in RTA 1. These sediments will be subject to remobilization by vessel activity. If this section of the Canal is made deeper to accommodate commercial vessel navigation, conditions may be significantly worse. Given these scenarios, all commercial navigation should be stopped.

- Even at a Canal depth of 30 feet, which would be necessary for a gravel armor layer to survive the presence of commercial vessel traffic, the sand benthic layer would still be subject to re-suspension by propeller wash. Once re-suspended, there would be a net downstream movement of this sand due to the flow from the flushing tunnel.

Baird

- At a proposed elevation of -16 feet, dissolved oxygen levels in the middle reach (RTA 2) of the Canal may border on hypoxic conditions at times of high CSO flow inputs, even with the flushing tunnel active. If this section of the Canal is made deeper to accommodate commercial vessel navigation, conditions may be significantly worse following major CSO flow events, as the flushing tunnel flow becomes less effective at flushing the Canal in deeper scenarios. Sediment transport simulations confirm that the Remedial Design configuration will increase trapping of sediments in the Canal, especially in RTA2. Organic matter and organic substances adsorbed to suspended sediment may also settle in the Canal, which may lead to development of a layer of anoxic sediment in RTA2. Deposition of this organic material could increase the sediment oxygen demand as bacteria and other organisms feed on it, starving the Canal of oxygen. This process would considerably reduce the effectiveness of any remediation measures for the Canal.

V. Evaluation of Water Quality Performance of EPA proposed Remedial Design: Dissolved Oxygen

Delft3D-WAQ is a three dimensional water quality model which solves advection-diffusion-reaction equations for various substances on a predefined computational grid.[2] It is not a hydrodynamic model. It was coupled with the Delftl3D hydrodynamic model to evaluate the impacts of the reactivated flushing tunnel, CSOs, vessel traffic, tidal flushing, hydrodynamics and sediment transport, re-suspension, and sediment-related contaminant transport on the water quality in the Canal under existing and remedial design conditions.[3] None of these issues have been assessed in the FS Report, the FS Addendum or the PRAP. Consequently, the effects of these

[2]Baird simulated the influence of freshwater inputs on water quality and sediment transport processes in the Canal through the inclusion of CSO flows in the model. The water quality model includes tidal flows, CSO flows, flushing tunnel flow (when applicable), temperature and salinity (heat flux model), dissolved oxygen (a function of: biochemical oxygen demand, sediment oxygen demand, and chemical oxygen demand; nitrification and denitrification; photosynthesis and respiration), sedimentation and resuspension, re-aeration of oxygen.

[3]Prior to water quality modeling, the hydrodynamics model was updated to include temperature and salinity processes. The ocean heat flux model, which represents back radiation and heat losses due to evaporation and convection using air temperature, cloud cover, and relative humidity, was used. The model boundary was forced with water level (tide/surge), water temperature, and salinity at the Harbor boundary. Wind measurements, air temperature, relative humidity, and cloud cover were applied over the full model domain.

processes on Canal water quality have not been fully considered. This is an essential step towards evaluating the existing and historic behavior of contaminants in the Canal, and in determining the likely effectiveness of any remedial activities.

A long-term simulation of dissolved oxygen (DO) levels in the Canal was completed for the time period from 1 November 2010 to 31 October 2011. CSO flows from the watershed hydrologic and sediment supply model were included in the WQ model. Observed and predicted hypoxia and anoxia from the long-term validation runs are shown in Figures 6 and 7. The results show that predicted DO levels agree well with observed values throughout the year, and also spatially throughout the model domain. Throughout the model year, the Canal was repeatedly subjected to hypoxic and anoxic conditions as a result of CSO flows during storm events and the limited flushing capability of the Canal without the flushing tunnel. The DO model results also suggest there may be periods of hypoxia in RTA 2, even when the flushing tunnel is active (Figure 8).

While the flushing tunnel flow is generally effective in improving DO conditions in the Canal, it's effectiveness is reduced in the deep dredge area in RTA 2. The reduced flushing and increased sedimentation in RTA 2 could lead to development of a layer of anoxic sediment. Further, deposition of organic material could increase the sediment oxygen demand as bacteria and other organisms feed on it, starving the Canal of oxygen. Decay of this material also uses up oxygen and generates methane gas. These processes could reduce the effectiveness of any remediation measures for the Canal in considerable fashion.

The results of our initial DO modeling also suggest that water quality goals may not be met with a deep dredge approach. Sediment deposited in the deeper middle section of the Canal is likely to impair water quality, especially when remobilized by vessels and barges. A thorough water quality assessment due to the possibility of developing hypoxic or anoxic conditions in the lower part of the water column in deeper areas is necessary prior to selection of a remedial alternative.

The bottom line of this modeling is that regardless of how much the water quality of CSO discharges is improved, there will likely always be fine organic sediments delivered to the Canal (from storm water, direct surface runoff, flushing tunnel flow), and the ROD should recognized that due to these on-going discharges from the CSO system, the post-remedy ecological diversity and populations likely will not re-establish to the same degree as one may expect devoid of the on-going CSO releases.

We contend that there is an opportunity during the remedial design of the Canal to adjust the Canal bed configuration and flushing tunnel flow so that there is a 'balance' or equilibrium in sediment transport over the long term. However, in the proposed design, the flushing tunnel flow that would prevent sedimentation in the deeper downstream areas may be too high in the shallower upstream area. Accordingly, detailed predictive model transport runs incorporating validated CSO

flows and sediment and contaminant inputs need to be completed prior to selecting a remedy. In addition, the potential to use the flushing tunnel flow in an adaptive capacity to maximize the water quality in the Canal (such as by increasing flushing flow after a CSO event) should be recognized as a possible way to provide active management of water quality and sediment transport in the proposed remediation scheme.

VI. Evaluation of Water Quality Performance of EPA proposed Remedial Design: Contaminants of Potential Concern

While the PRAP includes provisions for improved source control through the implementation of CSO flow retention tanks, it does not consider the transport and fate of contaminants that may still enter the Canal from the CSOs under the proposed remedial alternative. Baird developed a three-dimensional numerical contaminant transport model for Gowanus Canal using the Delft3D model suite. The Delft3D-WAQ model allows for the tracking of contaminants, their retention time and deposition in the Canal under existing and remedial design configurations. The following four contaminants of potential concern were evaluated:

- Polycyclic Aromatic Hydrocarbons (PAHs)
- Polychlorinated Biphenyls (PCBs)
- Copper (Cu)
- Lead (Pb)

The concentrations of the COPCs entering the Canal through the CSOs were estimated from results of the CSO flow event sampling undertaken during two wet weather events on 18th and 28th September 2012. During the event on September 18th 2012, samples were collected at OH-007, and on September 28th 2012, samples were collected at OH-007, RH-031, RH-034 and RH-035. The average values of these samples were used to define the COPC concentrations from the CSOs for inclusion in the model. Further details on the setup of the COPC model will be made available in the water quality modeling report for this study (in preparation).

The results of the COPC model runs show broadly similar patterns to those of the sediment transport runs. Figures 9 to 12 show the differences in deposition rates between existing conditions and the EPA remedial alternative bed configuration for copper, lead, PAHs (benzo[a]pyrene) and PCB-153. The figures compare the existing conditions with the remedial alternative, assuming the same CSO and tidal flows, based on the 2010-2011 time period. The remedial alternative includes the flushing tunnel flow. The figures show that heavy metals entering the Canal through the CSOs tend to settle in the dredged portion of the Canal, particularly in RTA 2, as this is the main receiving area for material from RH-034 and OH-007. This highlights the

incompatibility of deepening the Canal to accommodate commercial navigation, while trying to reduce deposition of sediment and contaminants in the Canal to reach an ecologically-sustainable outcome.

Further model scenario results for varying depth configurations show that if RTA 2 was to become even deeper to accommodate vessel navigation, more accumulation occurs. This is simply because the deeper water decreases the velocity in the Canal, which allows more sediment and contaminants to drop out of suspension and accumulate in these areas. Sediment and contaminants also tend to accumulate in the quiescent waters of the turning basins.

In order to assess and optimize the remedial design, the accumulation rates for the COPCs should be evaluated in detail to determine whether the ecological goals of the remediation can be met, given that the deeper water in RTA 2 leads to reduced flushing tunnel effectiveness and deposition of contaminants on the benthic layer in this reach. While maintenance dredging will be needed to maintain the required depths in the deep section of the remedial design, it may also be necessary to remove contaminated sediments caused by deposition where depths are necessary to accommodate navigation. This would appear to be contrary to the EPA goals of sustainable benthic habitat in the restored Canal.

VII. Construction

In order to prevent bed sediments from being disturbed during construction, which can lead to remobilization of the contaminants therein, the United States Environmental Protection Agency (EPA) has proposed that dredging be conducted within sheet pile cells (EPA Proposed Remedial Action Plan (PRAP), Table 9; FS Addendum, Table 1), that would be blocked off from the surrounding water body. The dredge cells will span half of the width of the Canal at any given time. This approach, simply cannot be employed while the flushing tunnel is operating. Accordingly, the flushing tunnel will need to be shut down for the entire time that the dredge cells are in the Canal.

Baird simulated hydrodynamic flow patterns and sediment transport potential in the vicinity of a dredge cell using the Delftl3D model.[4] Model results show an increased rate of erosion for the portion of the Canal next to the dredge cell, as a result of reduced cross-sectional area. When the discharge that normally passes through the entire width of the Canal, is forced through an area half as large, flow speeds double and scour of sediment increases accordingly. This presents a problem in terms of implementation: the existing contaminated sediments alongside the dredge cell (not contained within the cell) will be subject to scour and remobilization. In this way, the

[4]Three bed elevation configurations were considered for RTA 1, each representing a range of different dredging scenarios: -7, -12, and -17 feet.

dredge cell system proposed by the EPA, rather than containing contamination, will actually facilitate its redistribution throughout the Canal. It may also damage portions of the newly constructed cap – if one side of the Canal cap is constructed, and the dredge cells are in place on the opposite side of the newly-built cap, damage could result from the increase in velocity and propeller scour caused by the presence of the dredge cell. We therefore agree with Dr. Palermo's assertion that the EPA's dredge cell approach would increase erosion rates in uncontained areas (Palermo, 2013).

Next, Baird looked at a "worst-case" scenario by adding a moored barge alongside the dredge cell. Conditions worsened as the presence of the barge further constricted the area and increased flow velocities five-fold. This in turn increased scour potential of contaminated materials in the uncontained section of the Canal. Similarly, a vessel operating (as opposed to being moored) alongside the dredge cell also increases bed scour. Lastly, the effects of propeller scour increased (Schokking, 2002), to the point where the depth of disturbance may be even higher than the estimated values provided in our Vessel Impacts Analysis (see section VII).

Given the findings outlined above and in the Baird Vessel Impacts Analysis, the work sequence proposed by EPA is unlikely to be practical. If tugs are used to move barges to and from the dredge cell locations, it is likely that previously-remediated downstream sections will be damaged by grounding and propeller scour.

Based on this, we recommend that the ROD require that the flushing tunnel be shut down while (or if) dredge cells are employed; that the related negative impacts to water quality must be accounted for; and that all navigation alongside the dredge cells in RTAs 1 and 2 be stopped for the full period of construction.

VII. Vessel Impacts Analysis

In the PRAP, a navigation depth of -16 feet (NAVD88) was assumed in RTA 2 based on existing commercial navigational needs. Baird tested this with a vessel impact analysis.[5] Modeling revealed that the PRAP does not account for the full range of vessel impacts, such as vessel grounding and propeller scour, which cause remobilization and redistribution of bed sediments. This has significant implications

[5]The analysis in Baird's 2012 Vessel Impact Study included: quantification of commercial vessel traffic using Automated Information System vessel tracking data; examination of Acoustic Doppler Current Profiler data collected in the Canal to determine the impacts of vessels underway on flow in the Canal; analysis of multibeam bathymetric data for evidence of propeller scour and vessel grounding; analytical propeller wash calculations to determine the potential for bed sediment mobilization under existing and remedial design conditions; and three-dimensional numerical modeling, including flow around moored barges and prediction of the fate of sediments mobilized by propeller scour of the Canal bed by vessels underway.

for depth and cap / armor layer designs, namely with the continued presence of commercial navigation in RTA 2, the depths prescribed in the PRAP are not practical. In order for a remedy to continue in place and have positive effects, it must take into account the impacts identified through this study, incorporate them into the ROD, and account for them during the remedial design. The findings that must be considered are as follows:

- Contrary to the EPA's assumption, vessels do not only move at high tide;
- Several instances of propeller wash close to the Canal bed and of vessel groundings (vessel contact with the Canal bed) have been identified and they both disturb and redistribute bed sediments. In fact, vessel traffic cannot only mobilize and redistribute sediments (and thus contaminants), but propeller wash can mobilize sediments as large as cobbles and boulders – materials much larger than those observed in the Canal bed. Given this fact, it can be concluded that bed sediments are regularly mobilized into the water column by vessel activity;
- Flow speeds in the Canal increased by at least 600 to 800 percent as a result of vessel passage and propeller wash;
- Scour of the Canal bed is induced by propeller wash, causing resuspension and redistribution of bed sediments and contaminants;
- A significantly deeper dredge depth will be required to accommodate commercial vessel traffic in RTA 2;
- The cap armor layer material size for the proposed elevation of the bed in RTA 2 is significantly underestimated in the PRAP, and as a result, for example, a single trip by a commercial vessel may be sufficient to irrevocably damage the armor layer and underlying cap;
- A sand benthic layer will be unsustainable under the combined effects of propeller wash and flushing tunnel flow at depths as deep as 30 feet. However, a deeper dredge depth will compromise the ability of the flushing tunnel to prevent water quality issues in the Canal.

As noted above, the sand benthic layer will be disturbed. Published methods were used to determine if a benthic sand layer could be stable given the presence of tug activity in the Canal. Based on the methods provided by Hamill et al. (1999) and Ryan and Hamill (2012), the depth of sand disturbance will be significant. In the case of the -16 foot target elevation in RTA 2, disturbance to a depth of more than five feet in the sand benthic layer is possible assuming a fixed tug with full power. At the 30 foot depth, the predicted disturbance of the sand benthic layer is approximately two to six inches. A confined flow case (such as against a quay wall) will produce higher

bed velocities (Schokking, 2002), and the depth of disturbance may be higher than the estimated values provided.

Baird

In some sections of the Canal under existing conditions, the bed materials are similar to a sandy benthic layer. Accordingly, the potential for tug-induced disturbance expected in the benthic sand layer was checked against observations made in the Canal. Bathymetry surveys in 2010 and 2011 were completed. During the period between surveys, AIS data suggests that tug / barge activity in towards the Dorann dock (but never beyond or from the opposite direction) disturbed the bed (Baird, 2012). In this area of tug activity and maneuvering, erosion / scour on the order of four to seven feet is observed in the bathymetric data, supporting the view that disturbance of the Canal bed can occur to a significant depth, and that a sand benthic layer will be subject to remobilization and redeposition on a regular basis unless commercial navigation is removed from RTA 2.

The effects of mobilizing sands and silts into the water column in the Canal were evaluated using the numerical flow and sediment transport model (Baird, 2012). Fine sediments and contaminants mobilized through propeller action can migrate away from the point of scour due to tidal and / or flushing tunnel activity. Regular tug activity in the Canal causes fine sediments in the bed to regularly move around and mix throughout the area. The movement of sands and gravels is likely less dramatic within a single event, however repeated erosion and deposition of sandy materials could result in gradual offshore migration through the study area. This also indicates the potential for fine sediments to be "winnowed" out of the bed – that is fine sediments are mobilized while leaving behind the coarse sediments. Since tug operators mostly travel in the Canal during higher tides, there is potential for a net asymmetry in the movement of fine bed sediments as they remain in suspension over the ebb tide. This effect is magnified during operation of the flushing tunnel since flow in the Canal becomes unidirectional towards the outlet at all states of the tide. The significance of this in terms of ongoing maintenance and nourishment of a depleting benthic layer needs to be considered as part of the analysis of the potential impacts of the remedial design.

Given the foregoing issues, the ecological and water quality objectives of the Canal remediation effort are incompatible with ongoing commercial navigation in RTA 2, the ROD should call for an end to commercial navigation in RTA 2. This is especially so in view of the facts that vessel traffic analysis identified a total of only five active docks limited to the southern portion of the Canal between 3rd Street and the Gowanus Expressway, on average there is only a single commercial vessel trip per day, and the typical trip is approximately only a single hour in duration.

VIII. Conclusions

RTA 2 is unlikely to remain stable with ongoing commercial navigation, even at the EPA recommended bed elevation of -16 feet. A deeper bed configuration is similarly

Baird

ineffective because it will not only increase sediment and contaminant accumulation, but it will also lessen the ability of the flushing tunnel to address water quality issues in this section of the Canal. Given that the environmental goals of the proposed remedy are not achievable with commercial navigation in RTA 2, removing commercial navigation in RTA 2 must be evaluated. This should be done with a numerical flow and sediment transport model prior to development of the final remedy.

In the event that the prudent strategy of eliminating commercial vessel traffic is not pursued as part of remediation of the Canal, there must be flexibility within the PRAP to be able to evaluate bed elevations and the configuration of any proposed cap and armor layer in light of detailed vessel impacts.

The results demonstrate that if RTA 2 is dredged to accommodate navigation by commercial vessels, RTA 2 will suffer ongoing accumulation of sediment and contaminants. This is so even if the CSOs are controlled. In order to meet the primary goal of the restoration of benthic macroinvertebrate communities, a solution that minimizes sedimentation, erosion, and maintenance dredging is required.

1 Comments on Upland Source Control and the Potential for Canal Recontamination

In its comments regarding the Gowanus Canal (the Canal), the Contaminated Sediment Technical Advisory Group (CSTAG) made clear that control of upland sources of contamination (such as combined sewer overflows [CSOs]) should be made a priority before any remedy is implemented (CSTAG 2012). CSTAG added that a final Record of Decision (ROD) should be issued "after the CSOs, ground-water, permitted and unpermitted discharges have been further controlled and their impacts on reducing risks are better understood" (CSTAG 2012). Otherwise, "there would be significant recontamination of the surface sediment after any sediment remedy" because "it may be many years if not decades before contaminant releases are reduced." (CSTAG 2012).

The United States Environmental Protection Agency (EPA) Region 2 (the Region) responded that a detailed working schedule had been developed "for the control of major contaminant sources and the entity responsible for each activity." The Region added that although it "has not yet achieved a consensus with the [New York City Department of Environmental Protection] [DEP] on the various issues relating to the CSOs," the Region believes that CSO controls will be constructed in a "time frame not inconsistent with the remaining remedial work." (EPA 2012).

However, the Region's plan to reduce CSO discharges to the Canal, while a good first step, will not eliminate ongoing and future contamination from reaching the Canal. This is because CSOs, even at lower flow rates, will continue to discharge contaminants from historical and ongoing accidental spills of hazardous wastes that occur frequently around the Canal. Indeed, the recent chemical data obtained in 2012 from sediment mounds located near CSO outfalls confirmed that hazardous wastes are continuing to be conveyed to the Canal.

Storm water outfalls and other permitted and unpermitted outfalls also need to be addressed prior to any remedy implementation because they convey significant amounts of contamination to the Canal. For example, in Canal turning basins, accidental releases of waste oils from properties abutting the Canal have resulted in sheens on Canal surface water (e.g., NYDEC spill number 0800421, further discussed below). These impacts to the Canal were likely conveyed through permitted and non-permitted outfalls. Accidental releases of wastes will continue to occur in the future as they are part and parcel of industrial operations around the Canal. Although the Region's investigations of unpermitted pipes identified only "minor releases from a handful" of pipes, those "snapshot" investigations are not representative because they were not conducted concurrent with releases of contaminants from upland sources. Indeed, the actual data from the Canal sediments suggests continuing CSO and other outfall inputs of contaminants.

Consistent with the CSTAG recommendations, we recommend that controlling all contamination sources around the Canal should be made a priority in the ROD. Otherwise, any dredging will be a wasteful use of resources and the Canal sediment will be recontaminated. As discussed below, such recontamination has occurred at many sites throughout the country where source control was either neglected or was conducted during remedy implementation. The

Proposed Remedial Action Plan (PRAP) does not provide a clear plan to address upland sources. Our comments on the PRAP with regard to controlling upland sources are presented below.

1.1 Comment 1: The recent (2012) CSO sediment mound data show that CSOs are conveying contamination from upland areas to the Canal. The proposed plan to reduce CSO flow rates will not eliminate Canal recontamination.

The 2012 core samples from sediment mounds along the Canal bottom confirm that CSOs continue to discharge contamination from historical and current upland sources. Direct discharges via seeps from upland sources also account for some of the contamination in the mounds. It is not clear how flow reductions will eliminate CSOs from conveying contaminants to the Canal.

GEI 2012 sampling event

Bathymetric surveys conducted between 2003 and 2010 showed that sediment was accumulating below and in the vicinity of CSO outfalls. Some of these CSO sediment mounds were up to five feet thick (bathymetric survey results were presented in the 2011 Remedial Investigation Report; EPA 2011). In 2012, GEI Consultants, Inc. collected four feet sediment cores from these sediment mounds. See Figure 1 for sediment core locations. The sediment cores, which were sliced every six inches, were analyzed for VOCs, SVOCs, TPH, metals, PCBs, PPCPs and pathogens[1], pesticides, and herbicides. Analytical results are presented in Appendix I. Below is an evaluation of these results.

Analytical results for sediment samples from mounds near CSO RH-031/OH-602 (see Figure 1)

Total polycyclic aromatic hydrocarbons (tPAH) concentrations in this sediment mound were as high as 3,581 mg/kg (as the sum of the 16 priority pollutant compounds– $tPAH_{16}$). With the exception of just one sample containing PAHs that originated from a tar-like source, PAHs in the sediment mound originated from petroleum sources, such as waste oils. Figure 2 presents example PAH and gas chromatogram profiles for a sediment sample that is consistent with waste oils. The figure also presents similar information for the one sediment sample with a PAH profile with a dominant pyrogenic (e.g., tar) signature. Figure 3 presents the ratio $tPAHs_{44}/TPH$[2] for all the sediment samples. This shows that the PAHs in the sediment mound at RH-031/OH-602 originated predominantly from petroleum sources, consistent with waste oils.

The presence of tar in the CSO mound is consistent with the use of tar at the former Honeywell tar felt plant. The Honeywell plant had coal tar and petroleum in its soil, with PAHs up to 473,000 mg/kg (Fleming 2005). The presence of waste oils in the mound appears to be

[1] Volatile organic compounds (VOCs), semivolatile organic compounds (SVOCs), total petroleum hydrocarbons (TPH), metals, polychlorinated biphenyls (PCBs), pharmaceuticals, and personal care products (PPCPs).

[2] $tPAH_{44}$ is the sum of 44 parent and alkylated PAH compounds. TPH is total petroleum hydrocarbons in the sediment sample.

consistent with contamination at the Witco Site, where PCBs and light non-aqueous phase liquid (LNAPL) were found in groundwater (WSP 2009). Indeed, PCBs were found in the sediment mound at concentrations up to 92 mg/kg; a concentration higher than any previously reported value in the Canal. It is clear that the CSO continues to convey contamination from historical upland sources to the Canal, including the last 10 years. Other example compounds in the CSO mound at high concentrations included DDT up to 1 mg/kg, lead up to 2,900 mg/kg, copper up to 1,200 mg/kg, the CSO marker *Clostridium perifringens* up to 410,000 cfu/mg, among other compounds exceeding their respective screening values (see Appendix I for details).

During the remedial investigation, a sediment sample was collected from RH-031 (EPA 2011). During dry weather, total PAH_{16} concentration in the CSO solids was 18 mg/kg and PCBs were not detected. These CSO sampling results are not representative of the contamination that has been discharging from RH-031, as the results are inconsistent with the CSO mound data. We believe that the CSO sediment mound data more accurately reflect the cumulative and time-integrated contamination that is being episodically discharged to the Canal.

The 2008 NYCDEP waterbody/watershed facility plan (NYCDEP 2008) for RH-031 is to reduce its flow rate by upgrading the Gowanus pump station. It is not clear how a 70% reduction in the flow from RH-031 will stop the conveyance of historical tars, waste oils, and PCBs to the Canal (in addition to future upland spills). As noted above, the CSO discharge concentration and volumes have not been adequately characterized. Furthermore, it has not been demonstrated and may be unlikely that a reduction in flow will reduce the concentration of contaminants in the discharge. The 2012 sediment mound core data showed that contamination discharged by CSOs to the Canal is variable in nature (e.g., core SED-522: tar impacts in a layer from 2.5-3 feet, with waste oils above and below the tar layer; see Figures 2 and 3). It is not clear if this variability is a function of CSO flow rates or other factors; such as direct discharges. This situation warrants additional investigation to understand how contaminants are being conveyed to the Canal through CSOs. Clearly, controlling the historical upland sources and future activities along the Canal before any remedy implementation should be made a priority in the ROD.

Results for CSO RH-035/OH-007 sediment samples (see Figure 1)

Total PAH concentrations in these sediment mound samples ($tPAH_{16}$) ranged from 16 to 647 mg/kg and originated predominantly from petroleum sources, consistent with mid- to heavy-range fuel oils, transmission oils, and other waste oils. The gas chromatograms in Figure 4 show clear evidence of petroleum and petroleum-related PAH in sediment samples from the mound. Figure 5 shows that the mound samples have ratios of $tPAH_{44}$/TPH that resemble petroleum sources.

Most likely, these petroleum and waste oil impacts resulted from frequent and recent upland spills. For example, near RH-035, recent spills that impacted the Canal include fuel oil spills (New York State Department of Environmental Conservation (DEC) spill number 9301903 (1993)), and diesel spills into sewers (DEC spill number 9401648 (1994)). This is in addition to several hundred thousand gallons of sewage that were discharged in 1997 to the Canal at the OH-007 location (e.g., DEC spill numbers 9710741 and 9706778, 263,000 and 12,750 gallons of sewage discharge, respectively).

In addition to PAHs, other compounds in the CSO mounds include PCBs up to 23 mg/kg, DDT up to 0.5 mg/kg, lead up to 1,400 mg/kg, and copper up to 3,200 mg/kg among other compounds.

The Region's plan for OH-007 is to construct a 3-4 million gallon in-line storage tanks to reduce the discharge, with no further information available. The tanks are anticipated to capture approximately two times the amount of first flush during wet weather events. However, the Region has not provided any evidence that the proposed in-line tanks will result in the 74% reduction of solids, which was noted in the Feasibility Study as required to meet the preliminary remediation goal (PRG) for PAH, PCBs, copper, and lead (CH2MHill 2012). (See additional comments on the Region's plan for OH-007 in Appendix G by Woodard and Curran).

For RH-035, the 2008 NYCDEP waterbody/watershed facility plan (NYCDEP 2008) is to reduce the flow rate by upgrading the Gowanus pump station. Conveyance of contaminants, however, will continue to occur even at the lower flows, unless protective measures are taken to control the flow from Bond Street to the catch basins or to redirect the flow from the outfall. Any of these alternatives will be time consuming. As it stands, the PRAP does not have a clear plan to control Canal recontamination in the RH-035/OH-007 area.

Results for sediment mounds at the northern reach of the Canal (see Figure 1)

Total PAH concentrations in these sediment mounds ($tPAH_{16}$) ranged from 5 to 1,508 mg/kg and originated from a mix of petrogenic and pyrogenic sources. Figure 6 presents exemplar sediment samples from the mounds with petrogenic and pyrogenic PAH/Gas chromatogram signatures. Figure 7 shows that the mound samples have ratios of $tPAH_{44}$/TPH that resemble a mix of sources. This mix is indicative of multiple ongoing upland sources along the Canal. Other contaminants included PCBs up to 3.5 mg/kg, DDT up to 0.099 mg/kg, and metals (lead up to 1,300 mg/kg, copper up to 740 mg/kg) among other contaminants.

The Region's plan to control the discharge from RH-034 is to install a 6-8 million gallon in-line storage tank for a 58% reduction of solids to meet the PRG for PAH, PCBs, copper, and lead. Again, the Region has not provided any evidence that the proposed in-line tanks would result in a 58% reduction of solids (See additional comments on the Region's plan for RH-034 in Appendix G by Woodard and Curran).

In summary, the 2012 sediment mound data confirmed that CSOs are conveying contaminants at concentrations much higher than characterized during the Remedial Investigation. The Region has failed to demonstrate that its plans to control CSOs and stop contaminants from reaching the Canal will be successful. This is a critical shortcoming. The proposed remedy for the Gowanus Canal is extensive and will be an engineering challenge. There must be assurance that this proposed massive cleanup will not be immediately reversed because of lack of CSO control measures.

1.2 Comment 2: Hazardous wastes from accidental spills are conveyed to the Canal through stormwater and non-permitted outfalls. These spills and transport routes must be recognized and addressed prior to any remedy selection.

Accidental releases of contaminants occur frequently around the Canal and impact the Canal through sewers, permitted discharge points, and non-permitted discharge points. DEC has extensive documentation of such contaminant releases to the Canal. Some examples are presented in Table 1 (which is by no means exhaustive and which does not cover all segments of the Canal) and Figure 8.

Among the accidental spills were releases of diesel fuels and waste oils that led to visible sheens on Canal surface water. Petroleum products, oils containing PCBs, and dielectric fluids were also found in manholes around the Canal at numerous locations. On some occasions, retaining walls collapsed into the Canal (e.g., location 204 in Table 1). Many other spills were reported in the DEC files to be of unknown sources, some of which were reported to be an "ongoing problem" of directly impacting the Canal (e.g., location 293 in Table 1). This is in addition to the hundreds of thousands of gallons of raw sewage that impacted the Canal over the past 20 years from pump and gate failures, as documented by the DEC.

This documentation of releases is important because it illustrates the nature of industrial operations around the Canal -- leaking underground storage tanks (USTs), truck and bus yards, salvage yards, and manholes with PCB filled transformers, among other sources. Clearly, controlling these hundreds of sources prior to any remedy selection must be made a priority in the ROD.

1.3 Comment 3: The effectiveness of upland source control measures must be demonstrated as effective prior to any remedy implementation.

In the past few years, many sediment remediation sites that included both dredging and capping have been recontaminated after implementation of remedial measures. Examples of these sites are included in Table 2. This fact underscores the importance of demonstrating that sources have been controlled prior to embarking on dredging or other sediment management activities.

In its *Contaminated Sediment Management Strategy* (EPA 1998), the EPA stated that "before initiating any remediation, active or natural, it is important that point and nonpoint sources of contamination be identified and controlled." EPA site managers were advised to adopt a phased approach towards site remediation where the effectiveness of source control is in doubt (EPA 2005). Such instruction holds true for the Gowanus Canal. The Region must "phase" its next steps by identifying and controlling all sources of contamination first including discharges from adjacent upland sites, and discharges from the combined sewer system. Only after this is done may the Region move on to the second phase of designing the remedy.

As highlighted in Table 2, sources of recontamination include point sources (e.g., public sources like CSOs, storm sewer outfalls, and industrial discharges), and non-point sources (groundwater advection spills, runoff, adjacent upland contamination). As the data in Table 2 show, these sites became recontaminated relatively quickly after the completion of remedial actions.

Relevant to the setting of the canal, sources of recontamination included both storm sewer discharges (e.g., Thea Foss Waterway in Tacoma, Washington) and discharges from contaminated upland sites into existing storm sewer systems that subsequently impacted sediments around outfalls (St. Clair Shores, MI). Additional documentation on the extent of this problem and the costs associated with addressing recontamination is presented in the recently published Sediment Remedy Effectiveness and Recontamination: Selected Case Studies (ASTSWMO 2013). Notably, this document about recontamination was prepared with assistance from the EPA.

Based on experience from other sites around the country, source control at the Gowanus Canal must be in place and demonstrated to be effective prior to remedy selection. This is consistent with EPA's sediment strategy, policies, guidance, and prior experience.

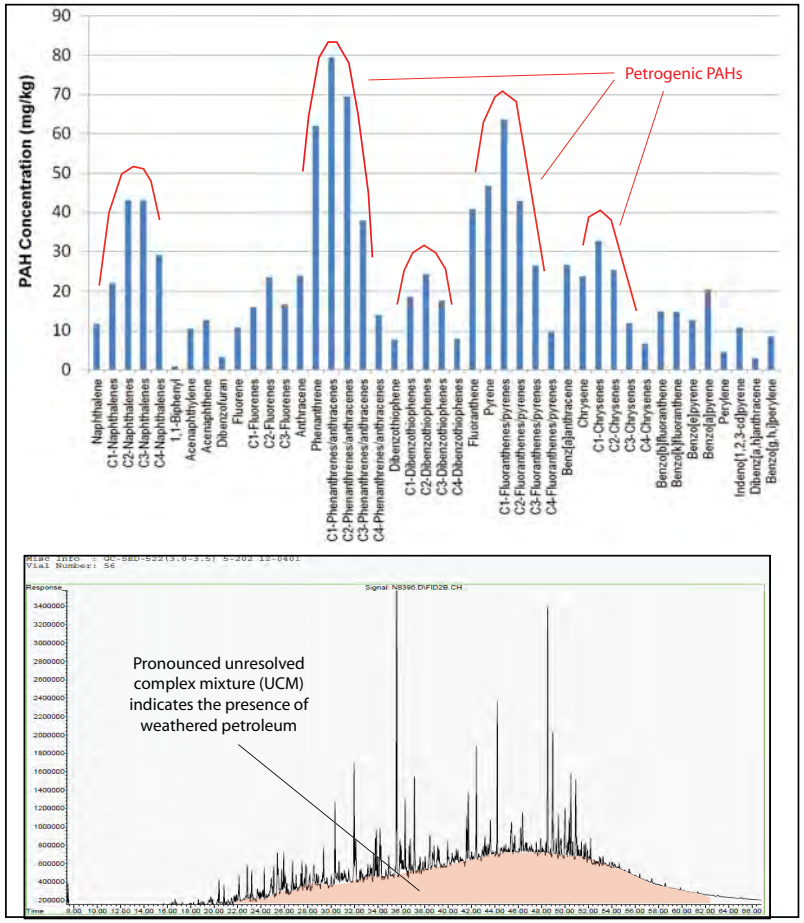
Figures

Figure 1. CSO Sediment Core Locations
(Collected August 2012 by GEI)

PAH profile consistent with petrogenic (e.g., waste oil) source.

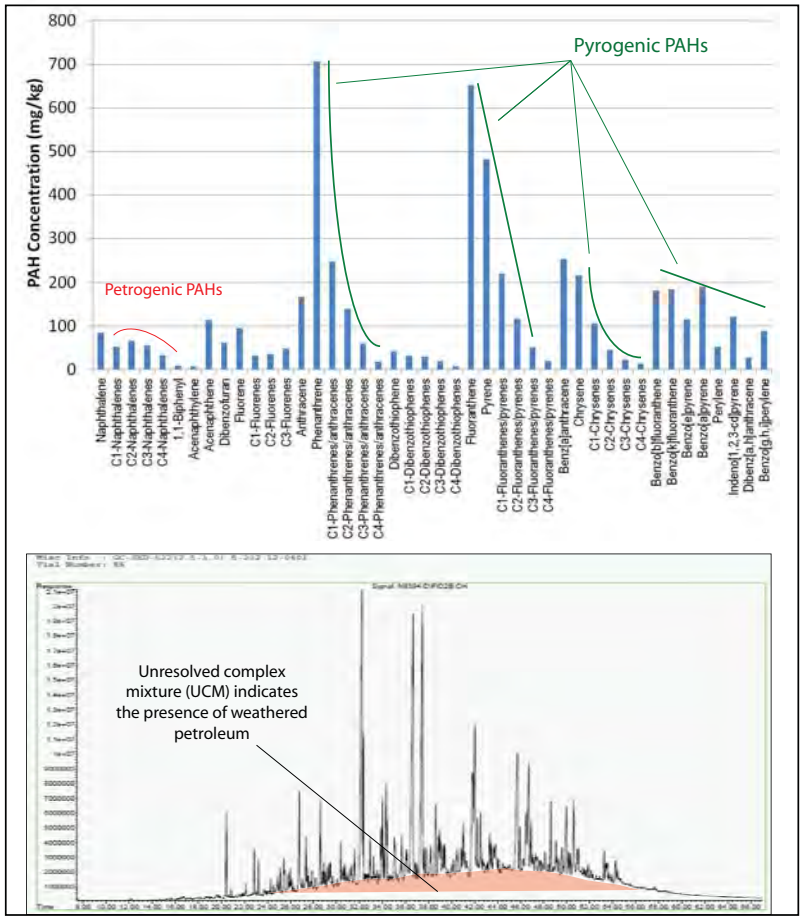
GC Chromatogram indicates petroleum source such as waste oil.

SED-522 (3-3.5 ft); tPAHs16 = 3,580 mg/kg



Consistent with Petrogenic Sources

SED-522 (2.5-3 ft); tPAHs16 = 3,580 mg/kg



Consistent with Pyrogenic Sources

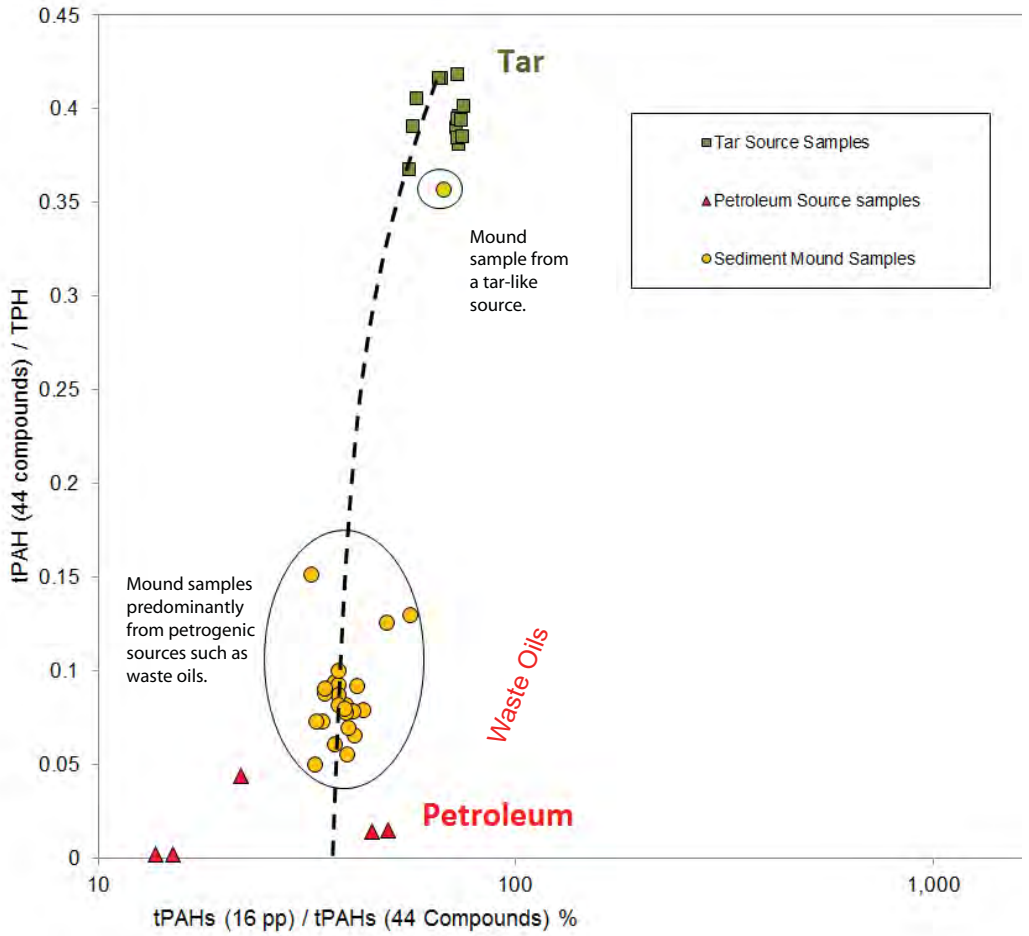
PAH profile consistent with pyro-genic (e.g., coal tar) source.

GC Chromato-gram indicates a minor petro-leum input to sample SED-522 (2.5 - 3 ft)

Figure 2. Example PAH and gas chromatogram profiles for samples from the RH-031/OH-602 sediment mound.

Exponent

Sediment mound sample locations. (tPAH/TPH analysis results are presented on the adjacent graph)

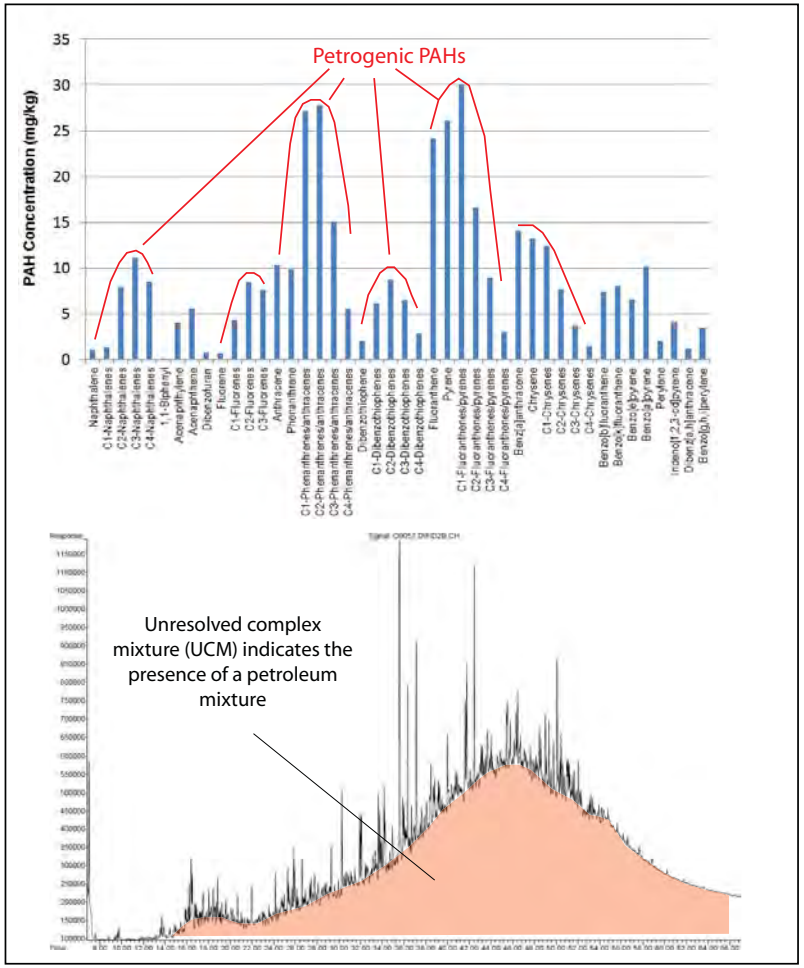


tPAH 44 is the sum of 44 parent and alkylated compounds, tPAH 11 is the sum of the 16 priority pollutant compounds. TPH is total petroleum hydrocarbons in the sediment sample

Figure 3. PAHs in the RH-031/OH-602 sediment mound originated predominantly from petroleum sources, consistent with waste oils, with PAHs in one sample originating from a tar-like source.

Exponent

SED-519 (1 - 1.5 ft); tPAHs16 = 3,580 mg/kg



SED-512 (3.5 - 4 ft); tPAHs16 = 117 mg/kg

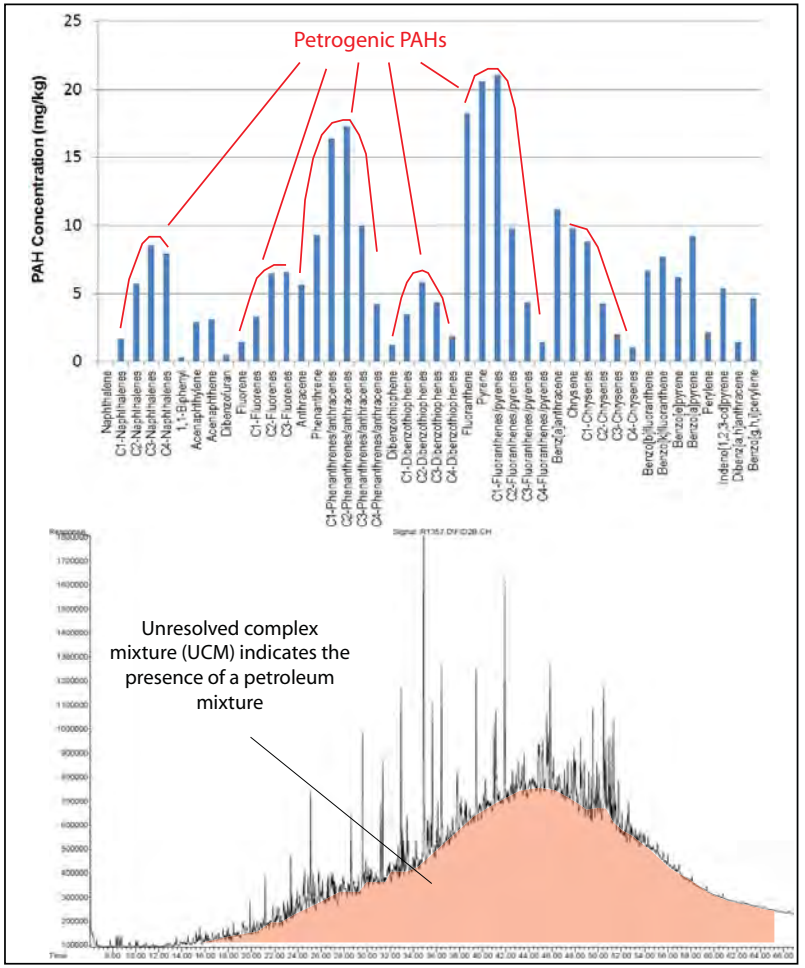


Figure 4. Example PAH and gas chromatogram profiles for samples from the RH-035/OH-007 sediment mound showing a mix of petroleum hydrocarbons in the samples, consistent with mid- to heavy-range fuel oils, transmission oils, and other waste oils

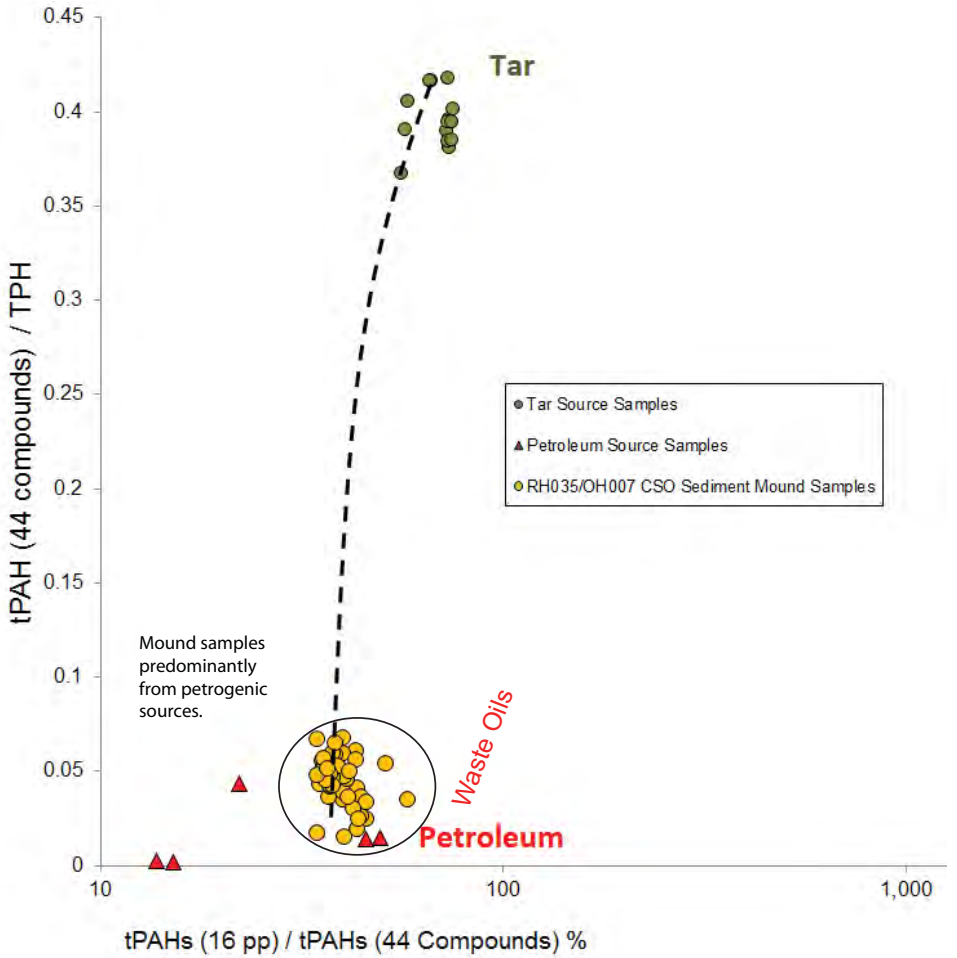
Exponent

Sediment mound sample locations.
(tPAH/TPH analysis results are presented on the adjacent graph)



tPAH 44 is the sum of 44 parent and alkylated compounds, tPAH 16 is the sum of the 16 priority pollutant compounds. TPH is total petroleum hydrocarbons in the sediment sample

Figure 5. PAHs in the RH-035/OH-007 sediment mound originated predominantly from petroleum sources.

Exponent

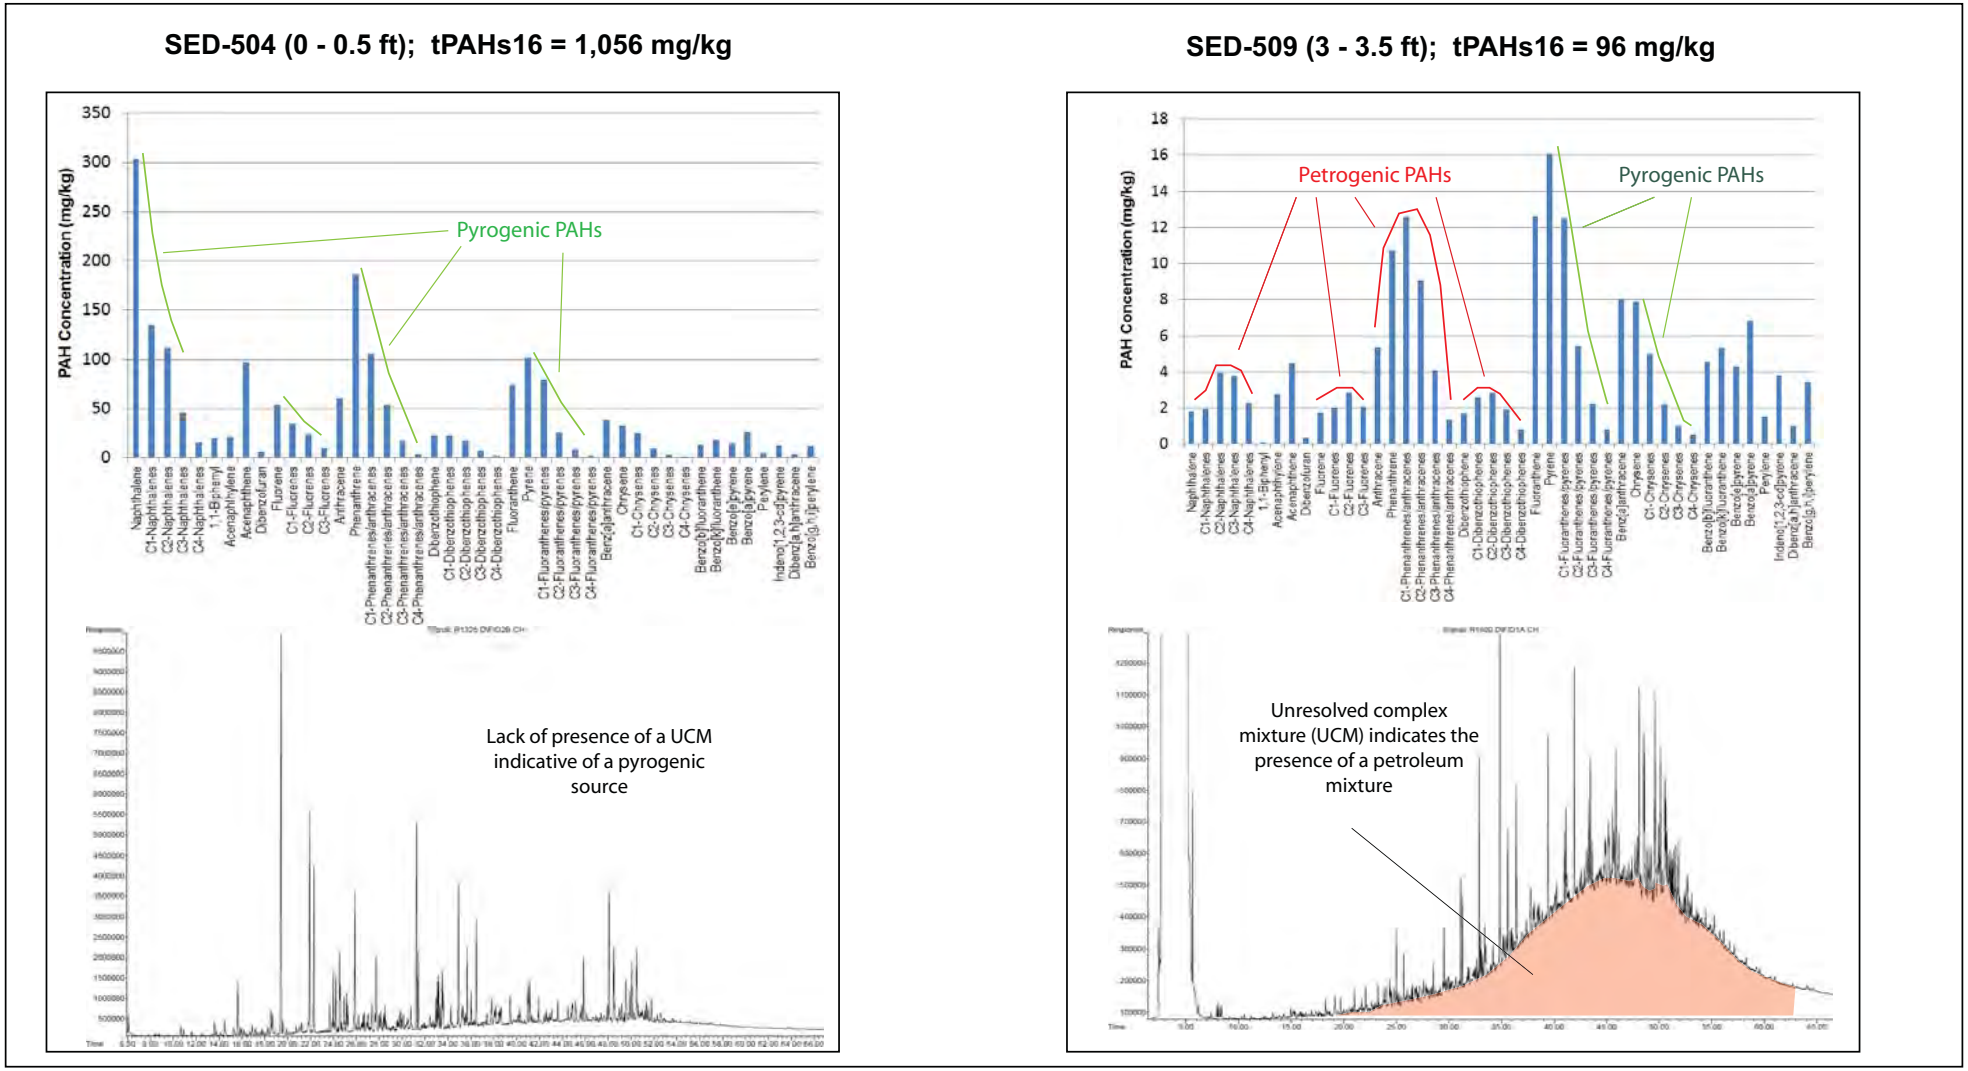


Figure 6. Example PAH/gas chromatogram profiles with petrogenic and pyrogenic signatures (samples from the sediment mounds at the northern reach of the Canal).

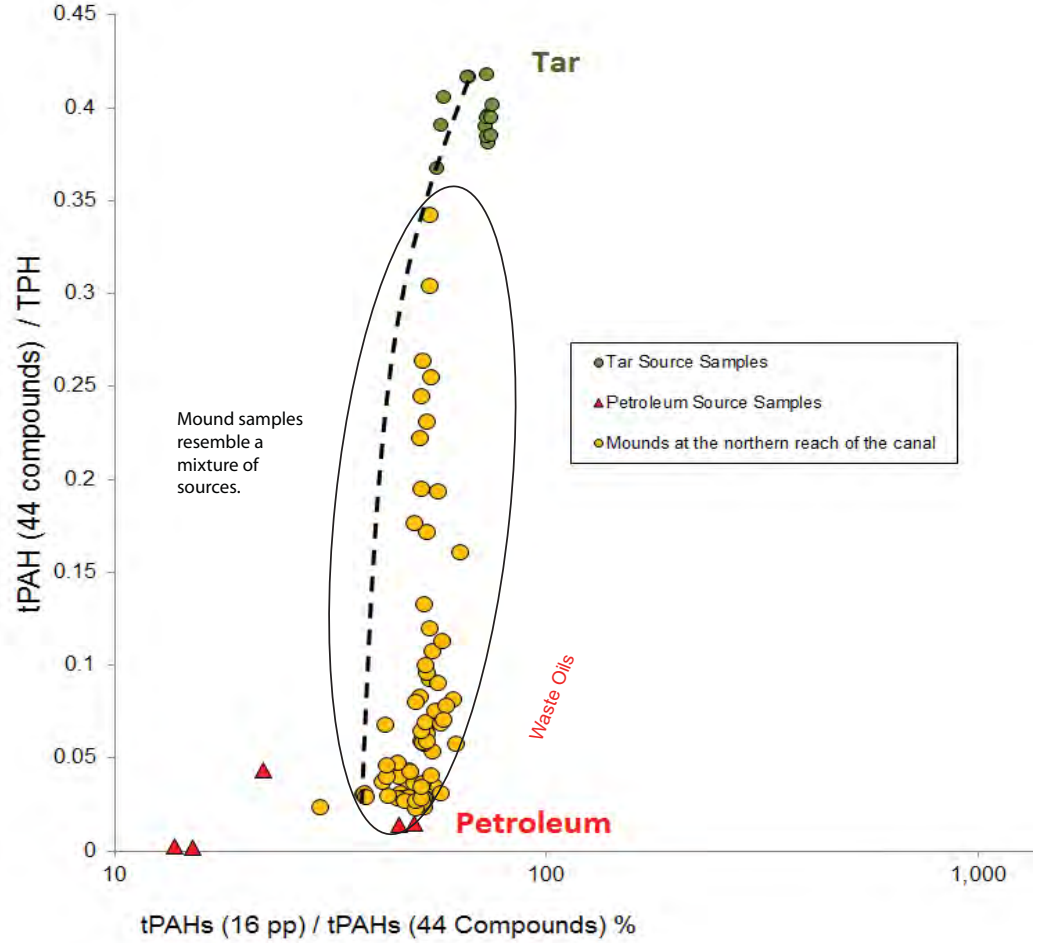
Exponent

Sediment mound sample locations. (tPAH/TPH analysis results are presented on the adjacent graph)



tPAH 44 is the sum of 44 parent and alkylated compounds, tPAH 16 is the sum of the 16 priority pollutant compounds. TPH is total petroleum hydrocarbons in the sediment sample

Figure 7. PAHs in the sediment mounds at the northern reach of the Canal originated from a mix of petrogenic and pyrogenic sources indicative of multiple ongoing upland sources along the Canal.

Exponent

Figure 8. Example spill locations in upland areas around the Canal.

Tables

Table 1. Example Spills in the Vicinity of Gowanus Canal

Map Identification Number	Spill Date	NYDEC Spill Number	Spill Description	Comments	Page in Document
171	7/15/1992	9204442	200 gallons diesel spill directly next to the Gowanus Canal.		286
172	5/10/1993	9301903	250 gallons of #4 fuel oil spill, impacting the sewers.		287
164	4/10/2008	0800421	Petroleum spill, releasing petroleum products in sewers and the Gowanus Canal	From DEC investigator remarks: MCIZ CORP site is used for bus maintenance and parking. One Bus was in accident with two cars on the lot releasing sewage, waste oil, and motor oil. Sewers were affected. Remarks discussed continual problem of discharge to the Gowanus Canal.	275
336	9/7/1997	9706778	12,750 gallons of raw sewage discharged to Gowanus Canal	Nonchlorinated sewage discharge due to pump failure. Entered the Canal around 2nd Ave and 5th Street.	460
337	2/20/2007	0612588	100 gallons of diesel in a truck yard. Spill went into sewer.	Six drums of contaminated snow were hauled off the Williams Construction Site.	461
167	9/18/2004	0406715	Unknown amount of raw sewage discharged into the Gowanus Canal	Ongoing due to rain	282
168	7/10/2004	0403825	Wastewater release impacted groundwater	Caller remarks: "Fire in area. Fire hydrant water and wastewater flowing into Gowanus Canal".	283
169	3/31/200	031433	Unknown petroleum containing PCBs on 500	DEC investigator remarks: "there is smoke in MH-5389 due to burning wires, 1-sample	284

Table 1. (cont.)

Map Identification Number	Spill Date	NYDEC Spill Number	Spill Description	Comments	Page in Document
	4	3	gallons of water and mud in manhole (MH-5389).	taken envir tag #33745 placed". Lab results received 3/31/04 Lab ID: 04-02439 results: 135 ppm PCBs…Tanker drained 31 hundred gallons of liquid from structure"	
170	10/8/2000	0008008	Unknown oil on 1,000 gallons of water in manhole with transformer that historically contained PCBs.	Liquids and solids removed from manhole.	286
335	12/19/1997	9710741	263,000 gallons of raw sewage discharged into Gowanus Canal.	Caller Remarks: "Malfunction of tide gate. DDC Emergency sewer lining malfunction"	459
334	5/4/1994	9401648	125 gallons of diesel spilled into sewer.	DEC Investigator remarks: "ON SCENE: SADDLE TANK RUPTURE, OIL RAN DOWN STREET INTOGOWANUS CANAL, KTL IS SPILLER, FDNY RECOVERED 1-DRUM FROM TANK, LIGHT SHEEN IN CANAL"	458
114	6/3/1986	8601502	Unknown petroleum product released in Gowanus Canal	Caller Remarks: "OIL SHEEN ABOVE SHORE LINE & SHEEN IN WATER"	203
115	1/25/2010	0911434	200 gallons of dielectric fluid spilled in manhole.	DEC Investigator Remarks: "Spill contained and cleaned up by Con Edison"	204
333	9/8/1997	9706833	100 gallons of waste oil impacted sewers	DEC Investigator Remarks: "THREE CATCH BASINS STARTING AT 3RD STREET WERE OPENED AND CLEANED BY FLUSH AT THE REQUEST OF DEP".	457
176	5/30/200	050241	Unknown petroleum release	Caller Remarks: "unknown substance on	292

Table 1. (cont.)

Map Identification Number	Spill Date	NYDEC Spill Number	Spill Description	Comments	Page in Document
	5	6	affecting surface water	body of water of union st west side of Canal"	
177	7/1/2009	0914289	Unknown petroleum release in the vicinity of the Canal		293
179	11/4/2004	0408640	1/2 Pint of oil on 400 gallons of water.	DEC investigation remarks: "Approximately 600 gallons of liquid was removed by tanker"	295
78, 185	9/25/2001 9/12/2001	0106619 0106920	Unknown amount of #2 fuel oil leaked into the environment	Cause of spill was reported as "Tank Test Failure". DEC Investigator remarks included: "Consolidating open spills on property. Spill closed and cross referenced to spill #0106920. Additional remarks included: "DR. YOUSSEFNIA STATED THAT THERE IS A 275 OR 550 UST AT SAID SPILL LOCATION THAT FAILED ATANK TEST. THE UST LEAKED FUEL OIL OVER AN UNKNOWN PEROID OF TIME."	159, 301
184	9/20/2000	0007226	Unknown oil bubbling to surface of Canal		300

Table 1. (cont.)

Map Identification Number	Spill Date	NYDEC Spill Number	Spill Description	Comments	Page in Document
201	12/11/2001	0109040	Oil leaks from trucks impacting sewer during rain events	DEC remarks: "in alleyway between 6th and 7th Street on 2nd Ave there are 3 sets of double parked unused oil delivery trucks in front of GEMTEC owned by T&S Trucking (718)499-2900. The rear of the two rear trucks were underlain by used speedy dry which was leaking sheen into the nearby sewer during rain events. The sewer appears to be connected to the Gowanus Canal on 7ths Street east of 2nd Ave. A large 300' x 100' sheen was present on the Canal. T&S responded by sweeping used speedy dry and spreading new speedy dry. Coast Guard 718-354-4121 was notified regarding sheen on12/14/2001. DEP (Andrew Kelley 718-595-6700) was notified on 12/14/2001 regarding illegal sewer discharge. Spill will be referred to Environmental Conservation Officers to see if trucks can be stored in alley and to determine if the alley is a public street. Spill closed 12/17/2001"	323
204	11/13/2000	0030027	Unknown petroleum spill impacting the Gowanus Canal.	Spill Caller remarks: NOTICED SHEEN ON GOWANUS CANAL POSSIBLY COMING FROM SPILL LOCATION. WALL COLLAPSE INTO GOWANUS CANAL. POSSIBLE FORMERPBS FACILITY.	326

Table 1. (cont.)

Map Identification Number	Spill Date	NYDEC Spill Number	Spill Description	Comments	Page in Document
205	2/17/2005	0412308	One gallon of unknown oil on 100 gallons of water in a sump near the Canal.	DEC Investigator remarks: FOUND ONE GALLON OF UNKNOWN OIL ON 100 GALLONS OF WATER IN MH5436...CAN NOT VERIFY IF THERE IS ANY OTHER OIL FILLED EQUIPMENT IN HOLE. ENV STOP TAG# 11976 WAS PLACED.ALSO CAN NOT VERIFY IF THERE IS ANY SEWER CONNECTIONS OR SUMPS.	327
72	5/31/1995	9502574	Four abandoned barrels, possibly containing hazardous material	Cause of spill was reported as "Tank Failure"	153
269	11/24/1997	9709837	20 gallons diesel spill.	Caller Remarks: Spill from a truck saddle tank.	395
293	8/18/1999	9905930	Unknown oil spill impacting Gowanus Canal	Caller stated that this is an ongoing problem. No DEC remarks for this spill.	420
294	7/21/1999	9904739	Unknown oil spill impacting Gowanus Canal	Caller stated that sheen was covering most of the Canal.	420
297	7/30/2007	0704871	Milky substance bubbling up into Gowanus Canal water	DEC Investigator Remarks: Unknown material dissipated.	423
122	7/10/2000	0004300	1 gallon of unknown petroleum	"1qt unknown oil on floor of manhole. 3" inactive drain exists in manhole... Adjacent sewer checked and found 4" pipe in the direction of manhole. There is product dripping onto floor. No free flowing water involved. 2gal product removed from	211

Table 1. (cont.)

Map Identification Number	Spill Date	NYDEC Spill Number	Spill Description	Comments	Page in Document
				structure."	
137	2/14/2000	9912931	2 gallons of hydraulic oil to sewer	"Caller Remarks: rain did cause some to go into sewer…"	243
141	5/14/1998	9801934	4 gallons of unknown material spilled to sewer	"Product similar to dielectric fluid (< 1ppm PCB); vendor's dumpster overflowed the liquid…" Additional remarks included: "GAL OF UNKNOWN OIL ON PAVEMENT. AREA IS NOT CONTAINED, & SEWERS ARE AFFECTED."	247
149	2/8/1996	9514237	2 gallons of diesel discharged into sewer	"Caller Remarks: crew found a trail of diesel that leads to a storm drain." Additional remarks include: "2 gallons spilled by pumps, slight sheen through cable yard to drain... Unsure when it occurred... Later determined none in drain."	256
214	6/25/2002	0203199	3 gallons of unknown petroleum spilled on soil.	DEC Investigator Remarks: "FOUND APPROX 3-GALLONS OF UNKNOWN OIL ON 500 GALLONS OF WATER IN MH-55750. IT APPEARS TO BE CONTAINED AT THIS TIME NO SEWERS OR WATERWAYS EFFECTED."	337

Table 1. (cont.)

Map Identification Number	Spill Date	NYDEC Spill Number	Spill Description	Comments	Page in Document
229	7/10/2004	0403837	200 gallons of gasoline discharged to sewer.	DEC Investigator Remarks: "Spill was called in by Fire Department Owner was not aware of an open spill violation at this site. The site had a waste oil tank when the factory was hit by fire... the spill was washed away when FD injected water to put down fire."	353
250	6/30/1999	9903695	3 gallons of unknown petroleum spilled in a manhole	DEC Investigator Remarks: "discovered approx. 2800 gallons of water and 3 gallons of oil in MH 65436." Apparently, spill was contained in the manhole, and did not impact sewers or waterways.	375
251	3/3/1999	9814432	5 gallons of unknown petroleum in a manhole.	Caller Remarks: "5 GALLONS OF UNK OIL ON TOP OF 7000 GALLONS OF WATER - CONTAINE DIN MANHOLE."	377
253	5/23/2005	0502141	4 gallons of unknown petroleum in a manhole.	DEC Investigator Remarks: "WHILE ON LOCATION TO INSPECT M65434 FOR AN ABATENENT JOB... FOUND: APPROX. 4 GALS OF UNKNOWN OIL ON APPROX. 75 GAL'S OF WATER. NO SEWERS OR WATERWAYS APPEAR TO BE AFFECTED."	379
255	1/1/1996	9515448	Unknown petroleum	Caller Remarks: "caller complained to sewer dept because she was getting a fuel smell from sewer... possibly underground spill from a nearby gas station and oil company"	381

Table 1. (cont.)

Map Identification Number	Spill Date	NYDEC Spill Number	Spill Description	Comments	Page in Document
286	3/5/2003	0211997	5 gallons of unknown petroleum in a manhole.	Caller Remarks: "UNKNOWN FOUND FLOATING ON WATER IN THE ABOVE MANHOLE." DEC Investigator Remarks: "5 gallons of oil on top of approximately 2500 gallons of water in Manhole 70465, Feeder 41/42. The spill is contained in the manhole."	410
306	11/11/1994	9410709	Unknown petroleum in sewer.	Caller Remarks: "OIL SMELL COMING FROM SEWERAGE VENT."	431

Toxics Targeting, Inc. 2011. Phase I Environmental Database Report, Carroll Street, Brooklyn, NY 11215. March 15.

Table 2. Sediment sites with reported recontamination

Site	Response Measure(s)	Recontamination Information	References
Anacostia River, DC	2004 Cap	2006 Urban sources, upstream sources	USEPA 2006
Bloomington, IN (3 creeks)	1987 Sediment Removal	1992 All sources unclear – point source discharge included	ATSDR 1992
Bremerton Naval Complex, WA	2000 Dredge	2000 Losses from CAD placement	SPI 2002, DNO 2002
Convair Lagoon, CA	1998 Cap	2002 Public storm drain discharges	Zeng 2002, Carlisle 2002
Denny Way Site, WA	1990 Cap	1993 CSO point source discharges	Palermo 2002, NRC 2001, Romberg 2005, WDNR 2002
Duwamish Norfolk CSO, WA	1999 Dredge-Cap	2001 CSO point source discharges; unremediated adjacent contaminated sediment	WDE 2003, USEPA 2003
Duwamish River Diagonal, WA	2004 Dredge	2005 Sewage system discharges	SPI 2005
Eagle Harbor Site, WA	1994 Cap	1999 “Surface sources”, “offsite sources”	USEPA 1999, Palermo 2002
Ford Outfall/River Raisin, MI	1997 Dredge	2001 Unremediated upstream sediments and/or upland sources; sediments sloughed from adjacent navigational channel	Cieniewski 2003, Bergeron 2000, Cleland 2000, Cleland 2001, Weston 2004
Housatonic River, MA	2002 Dredge-Cap	2005 Upstream sediments, CSO and SSO point source discharges	Boston Globe 2005
Lauritzen Canal, CA	1996 Dredge-Cap	1998 Undetected point source(s); incomplete remediation near margins of site	USEPA 2001, Weston 2002, USEPA 2004a
Long Beach North Energy Island	2001 Cap	2004 “Deposition from the surrounding harbor”	USACE 2005

Table 2. (cont.)

Site	Response Measure(s)	Recontamination Information	References
Borrow Pit (NEIBP), CA			
Pier 51 Ferry Terminal, WA	1989 Cap	1990 PAHs due to pile pulling; metals from “new sediment deposition”	HSRC
Pier 53-55, WA	1992 Cap	2002 Prop wash resuspension near edges; PAHs due to pile removal	Romberg 2005
Pier 64-65, WA	1994 Cap	2002 Piling repair work released creosote	Romberg 2005
St. Clair Shores, MI	2002 Dredge	2003 Recontamination from PCBs in the sewer pipes	TMD 2006
Thea Foss Waterway, WA	2002 Dredge-Cap	2006 City storm drain discharges	TNT 2006a, TNT 2006b

EDUCATION

MT. SINAI SCHOOL OF MEDICINE, New York, NY
M.P.H. Equivalent, 6/89

UNIVERSITY OF VERMONT COLLEGE OF MEDICINE, Burlington, VT
M.D. 5/85

McGill UNIVERSITY, Montreal, Canada
B.S. 6/81, Physiology

PROFESSIONAL TRAINING

7/87 – 6/89 Mt. Sinai Medical Center**,** New York, NY
Resident in Occupational/Environmental Medicine

Screened and treated cases of occupational illness including exposure to asbestos, heavy metals, solvents, and other hazardous substances. Examined patients, read X-rays for evidence of change secondary to exposure and educated patients on hazardous exposure. Developed medical programs for workers and their families. Served on advisory committee to major occupational medicine screening program. Carried out research activities. Taught medical students. Also provided urgent and primary care to Mt. Sinai Hospital employees both years.

7/85 – 6/86 Roosevelt Hospital, New York, NY
Intern – Department of Internal Medicine

CERTIFICATIONS Board Certified in Occupational Medicine, 2011
ACLS Certification, 2011
Certified by NIOSH as an "A" Reader, 1990

LICENSURE New York, Florida, New Jersey and Missouri (Active)

Environmental Disaster Management:

2004 – 2005	Member/Expert Technical Panel for evaluation of 9/11-related health and environmental effects formed by Senators Hillary Clinton and Joseph Lieberman in conjunction with White Council on Environmental Quality
2003 – 2009	Medical Consultant for deconstruction of 130 Liberty Street
2002 – 2008	Member/Medical Working Group, Mt Sinai Medical Center World Trade Center (WTC) Worker and Volunteer Screening Program. Assisted in development of protocols for screening individuals with exposure at the WTC site.
2001 – 2008	Evaluated environmental data from the WTC site. Presented to community boards and tenant groups about the potential health effects 9/11. Assisted in implementation/interpretation of independent testing in Lower Manhattan. Developed and moderated major health effects forum in September 2002.

Clinical/Health Management:

2010-Present	Chief, Division of Occupational Medicine Winthrop University Hospital, Mineola NY
2007-2010	Physician Specialist-WTC Environmental Health Center-Gouverneur Health Care Services
9/2005-10/2007	Medical Director-Arbor We Care Brooklyn New York-Supervised Primary Care specialists and specialist performing fitness for duty Evaluations
5/1997 – 2010	Consultant in Occupational Medicine - Columbia University Health Science Division, New York, NY
9/1993 – Present	Founding Partner, Medlantic LLC, New York, NY Consulting firm specializing in occupational and environmental medical issues.
10/1991 – 10/1997	Staff Physician (PT), Bristol Myers Squibb Employee Health,
10/1991 – 4/1997	Medical Director (PT**),** Barnert Occupational Health Center,

11/1986 – 5/1987 Primary Care Physician, Executive Health Examiners, New York, NY. Provided walk-in medical care, pre-employment physicals, and periodic examinations to employees of contracted companies

ACADEMIC AND HOSPITAL APPOINTMENTS

10/2010-Present Winthrop University Hospital, Mineola NY
Chief, Division of Occupational Medicine

12/2007 – Present: New York University Medical Center, New York, NY
Clinical Assistant Professor in Medicine

9/2007 – Present: Gouverneur Health Care Services, New York, NY
Attending Physician

5/1997 – Present: Columbia University Medical Center, New York, NY
Assistant Professor in Clinical Medicine and Environmental Sciences

NEW YORK PRESBYTERIAN HOSPITAL, New York, NY
Assistant's Attending

10/1989-Present BETH ISRAEL HOSPITAL, New York, NY
Attending Physician, Staff Member

10/1989-9/2005 BARNERT HOSPITAL, Patterson, NJ
Consulting Physician, Staff Member

PROFESSIONAL AND ACADEMIC PANELS

- Member –NY State Task on Toll Plaza Air Quality 2009-Present
- Past President – New York Occupational Medicine Association, 1997
- Co-Chair Environmental Health Section ,ACOEM 2010-2011
- Medical Advisory Committee NYS Workers Compensation Board 2011
- Member (Representative of Assembly Speaker Silver) – NY Health Sciences Research Board, 2004 – Present

PRESENTATIONS

Multiple presentations since 1988 to:

- White Lung Association of New Jersey
- Asbestos Environmental Institute of New York

- Environmental/Occupational Safety at Health Institute of New Jersey
- National Safety Council
- American Society of Safety Engineers
- American Industrial Hygiene Association

Occupational Liver Disease – Presented to the American Liver Foundation, January 1998

Diagnosis and Management of Tight Building Syndrome, Indoor Air, Toronto, Canada, 1990

Environmental Medicine in Primary Care – Presented to the American Cancer Society, 1990

Health Promotion in the Workplace – Presented at the American Society of Safety Engineers, Washington, D.C. 1990

Indoor Air Pollution – Presented at the Annual Meeting of the Medical Society of the State of New York, 1989

Cholesterol Determination by a Corporate Medical Department – Presented to the AOHC in Boston, May 1989. Awarded resident research award by American College of Occupational Medicine.

Gowanus Canal: Response to NYDEC Approach for Stormwater Control, prepared for National Grid by Woodard & Curran, Inc.

GOWANUS CANAL: RESPONSE TO NYDEC APPROACH FOR STORMWATER CONTROL

Woodard & Curran Inc.
April 23, 2013

The United States Environmental Protection Agency (EPA) Proposed Remedial Action Plan (PRAP) for the Gowanus Canal proposes that two large capacity storm water storage tanks be installed to accept overflow from combined sewer outfalls (CSOs) RH-034 and OH-007 during high-flow storm conditions. The tank for CSO RH-034 is to be six to eight million gallons and the tank for CSO OH-007 is to be three to four million gallons in size. As indicated in note 14 (page 19) of the PRAP, storm water flow that exceeds the capacity of the sewer system would be diverted to and stored in these tanks until storm conditions subside. At that point the storm water flow would be directed to the wastewater treatment plant.

The size of the two tanks is based in part on data presented in Stein et al (2006), which indicates that the "first flush" of storm water comprises approximately 20% of the total discharge volume and contains between 30% and 60% of the total PAH load of the total storm discharge. According to the PRAP, "capturing approximately twice the amount of the 'first flush' of the design storm water event from CSO outfalls...would ensure that the protectiveness of the remedy is maintained." This statement suggests that the tanks will be designed to accommodate in excess of 40% of the design storm discharge (assuming a portion continues to be conveyed to treatment through the CSOs).

Although the approach set forth in the PRAP will capture a large portion of the sediment and pollutant mass, the scientific literature suggests that the potential still exists for the continued discharge of PAHs and metals to the Canal during storm events that produce a flow volume in excess of the capacity of both the tanks and the sewer system. This is due to the different flow behaviors of various particles sizes in storm water runoff, and the well-documented association of PAHs with the finer fraction of storm water particles. As summarized below, the first flush tends to include a larger proportion of coarse particulate matter. Since PAH concentrations tend to be higher on finer particulates, PAHs in the CSO flow may continue to be discharged to the Canal later in a storm event, after the CSO tanks are full.

I. Summary of Issue

Contaminants in storm water exist both in dissolved form and bound to particles. Contaminants bound to particles are of primary interest because of their ability to be deposited in the sediment of receiving waters such as the Gowanus Canal. The mass-based "first flush" phenomenon of storm water discharges occurs when the early stages of a storm contain a disproportionately large amount of the total particulate mass. Because PAHs are typically associated with particulates, the mass of PAHs is related to the size and number of particulates. However, PAHs have been shown to be distributed unevenly across size classes. Because of the presence of total organic carbon (TOC) in silt and other fine material, PAH concentrations tend to be higher on fine particulate matter than on coarse particulates. In a typical mass-based first flush of storm water, a

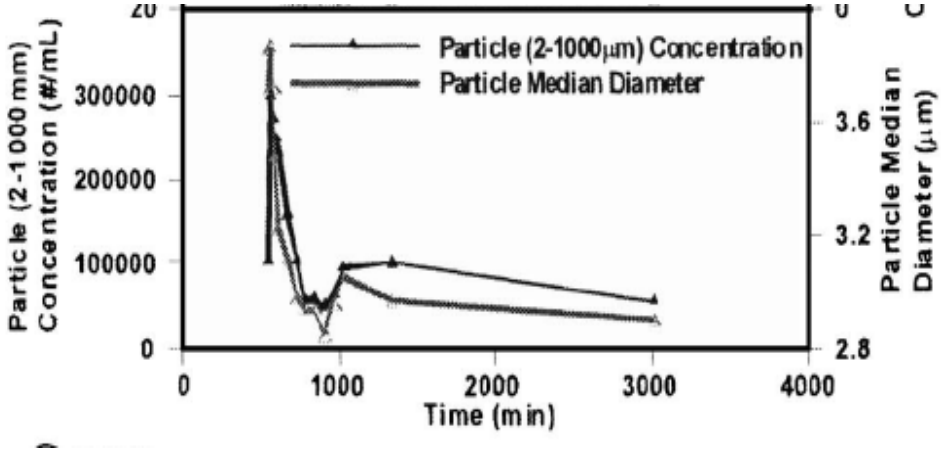
large proportion of the particulate material consists of coarse material transported by the high energy of the larger flows produced by intense rainfall. Transport of the coarse fraction is flow-dependent and so tends to decrease rapidly as the flows in the storm decrease. In contrast, the fraction of fine material remains elevated throughout the entire duration of a storm. Thus, PAHs bound to fine particulates may continue to be discharged to the Canal during late stages of storm events, when runoff volume exceeds conveyance capacity and the proposed storage tanks are full.

II. Scientific Literature

Review of the scientific literature on storm water composition and management supports the foregoing view. The key studies and sources are described below.

(a) Discharge of Fine Particulates. The differing discharge patterns of coarse and fine particulates in storm water has been documented by several researchers (Furumai et al. (2004), Crista and Sansalone (2003), Hergen et al. (2003), Li et al. (2005)). The sustained nature of fine particulate discharge is illustrated in the following figure from Li et al (2005), who studied roadway runoff patterns from two heavily traveled urban highways in Los Angeles. In this study, the highest concentration of particles of all sizes combined occurred within the first hour of the storm and declined rapidly. However, the discharge of very fine particles continued for the duration of the storm, with a steady decline in the median size of particles.

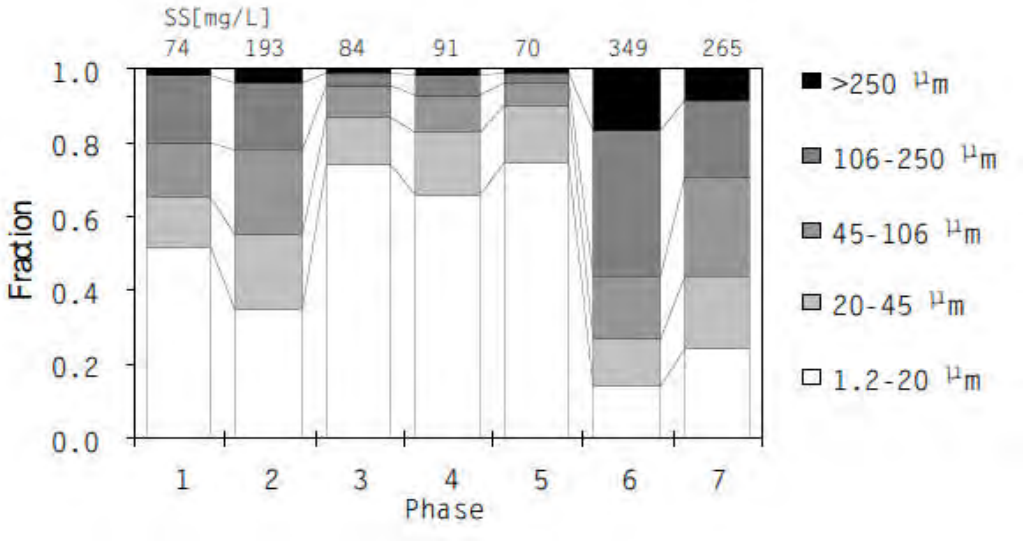
Figure 1. Relationship of Particle Size and Storm Duration (from Li et al. (2005))



Source: Li et al. (2005).

The predominance of coarse particulates is associated with high intensity flows, which may occur at multiple times during a storm event. The effect of later flow peaks is illustrated by data from Furumai et al. (2004), which describes storm water runoff from a highway system in Switzerland. In this event, a small spike in precipitation occurred in the early part of the storm (Phase 2), but heavy precipitation arrived at the end of the storm (Phase 6). The effect of these flow increases on storm water particle size and suspended solids concentrations is shown in Figure 2.

Figure 2. Changes in Particle Size and Suspended Solids with Increased Flow (Phases 1 and 6) (Furumai et al. (2004))



As the data from this study shows, particles less than 45 µm in diameter comprised over half of the particulate fraction, except following the intense precipitation at the end of the storm. The discharge of fine particulates occurs in all flow stages, but dominates during low flow conditions and tends to decline in later stages of the storm, as the surface is essentially washed free of movable particulates (Mitsova et al. (2011), Li et al. (2005), Furumai et al. (2004), Cristina and Sansalone (2003).

Throughout a typical storm, fine particulates comprise a small to moderate percentage of the total mass of storm water discharge, but dominate the composition numerically. Yun et al. (2010) found that particles less than five µm in diameter accounted for more than 80% of the number fraction while their mass was about 12%. Particles with a diameter of 50 µm or less comprised over 99% of the number fraction, and 59% of the mass throughout the storm event. Herngren et al.(2012) found up to 85% of the total particle volume was in the 0.45 – 75 µm size fraction, and Li et al (2005) found that while 97% of the particles were less than 30 µm, particles smaller than 50 µm accounted for 30% - 60% of the total mass.

While the concentration of all particulates decreases significantly after periods of intense precipitation, these values indicate the importance of the fine particulate fraction in the transport and distribution of storm water contaminants during all stages of a storm. Fine suspended particulates from storm water have been found to contribute to lethal and sub-lethal toxicity due to their ability to stay suspended in the water column. Suspended fine particles with size ranges less than 25 µm are easily trapped by gill tissue and once trapped, interfere with gill function of fish (Liu and Sansalone 2007).

(b) Association of PAHs with Fine Particulates. Numerous studies have documented the association of PAHs with the fine particulate fraction of storm water

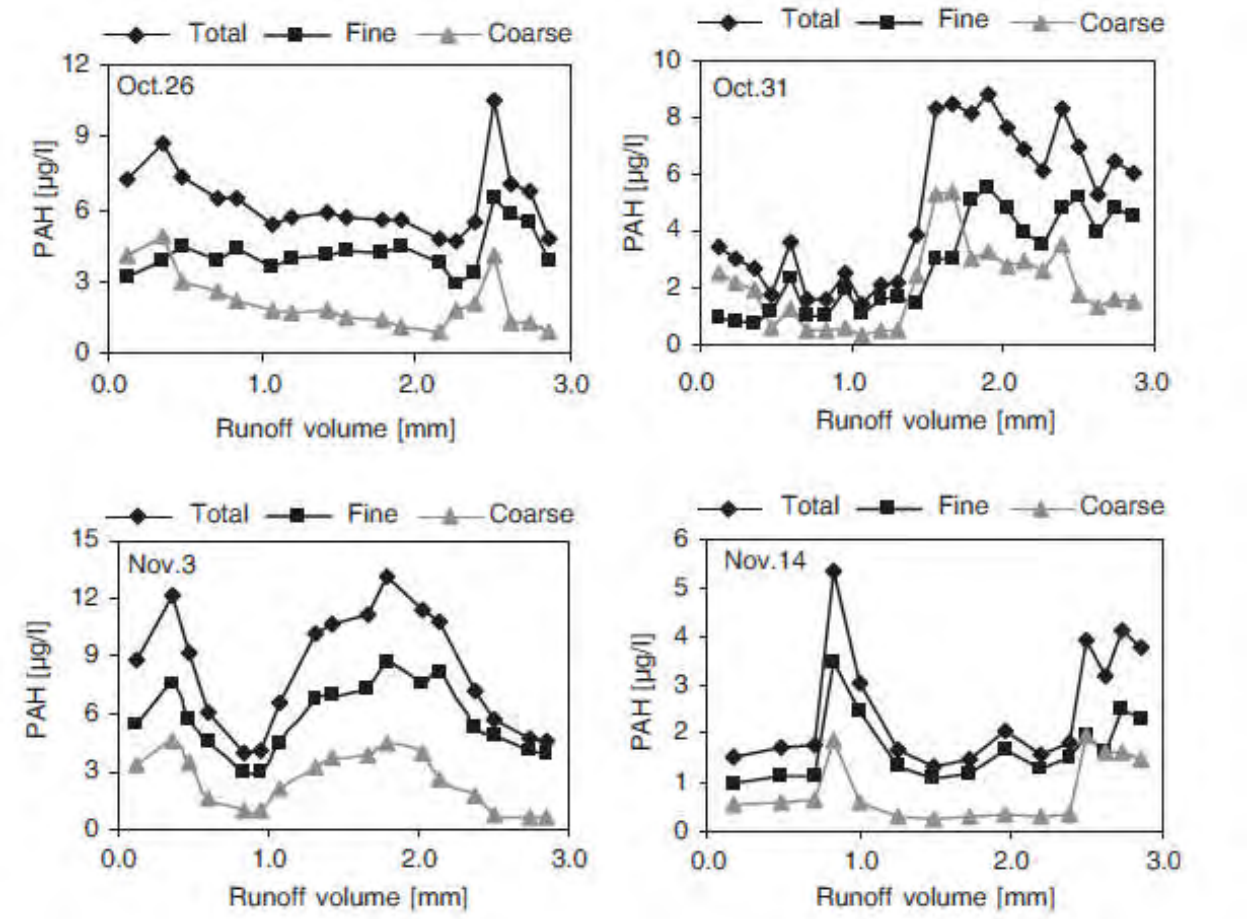
runoff, an association attributed largely to the higher surface area and TOC content of fine particulates. Results from Lee et al. (2005) illustrate this association with data from a study of urban street particulates, which form the fine fraction of surface runoff. As shown in Table 1, below, both TOC and PAH increase with decreasing particle size.

Table 1. Association of PAHs with TOC and Particle Size in Street Sweepings in Japan (Lee et al. 2005)

Size Fraction:	<20 um	20-53 um	53-106 um	106-250 um	250-500 um	500-1000 um	1000-2000 um
Wt (%)	0.5	2.6	5.1	13.9	24.1	29.2	24.6
TOC mg/kg	0.81	0.32	0.17	0.11	0.08	0.06	0.04
TPAH (24 PAHs) mg/kg	4.740	4.017	4.268	3.883	1.790	0.922	0.493

Likewise, Herngren et al (2012) found that runoff particles in the 0.45 µm – 75 µm size range exhibited the highest PAH concentrations in runoff from industrial, commercial, and parking lot areas, and also contributed the highest volume of particles (up to 85%). Aryal et al. (2005) studied the relationship of particulate size and PAH composition in runoff collected in the first three mm of precipitation (the first flush period) and found concentrations higher in the smaller fraction (< 45 µm) during all storm events studied, as illustrated in Figure 3.

Figure 3. Size-fractionated PAH Concentrations in Initial 3 mm of Storm Runoff (Aryala et al (2005))



Because of the association of PAHs with fine particulates, the continuing discharge of fine particulates during the later phases of large or long storms remains a concern. PAHs in the particulate fraction of storm water runoff can lead to elevated concentrations in receiving streams (Bathiet al (2012), Mahler and Metre (2003)).

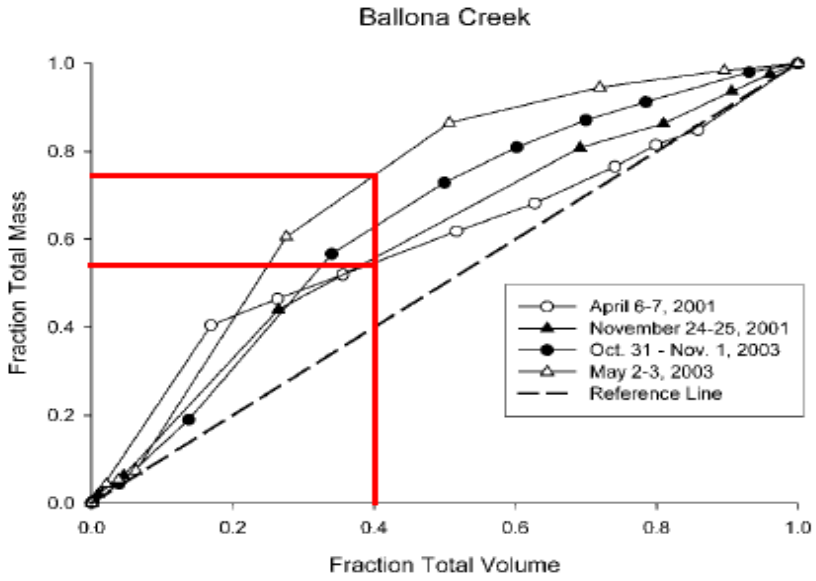
III. Potential for effects on the Gowanus Canal

Although the proposed storage tanks will capture the early discharge from CSOs RH-034 and OH-007, further evaluation is needed to determine if the volume of the tanks will be sufficient to capture enough of the particulate mass throughout the storm to prevent recontamination of the Canal. In particular, the dependence on an early-stage mass first-flush event to deliver most of the contaminant load to the storage tank merits further examination. Stormwater discharge patterns vary widely, and are influenced by watershed and conveyance characteristics, storm hydrography, type of impervious surfaces, number of preceding dry days, and other characteristics (Hergren et al. (2012), Mitsova (2011), Stein et al. (2006)).

Many studies are conducted in arid environments such as Los Angeles, where the long dry period combined with intense rainfall typically produce distinct mass-based first-flush effects. See for example, Stein et al. (2006). Data from other areas suggest that the first flush effect is less pronounced in areas that receive rainfall frequently, or in cases where fewer dry days precede storm events (Mitsova (2011), Zhang et al (2008)). The first flush effect itself has been shown to vary in both flow and concentration (Sansalone and Cristina (2004)).

Even in events where a first flush is evident, a large proportion of the particulate mass may still discharge late in the storm. Figure 4, below, shows the cumulative mass versus volume data from Stein et al. (2006), which illustrates the increase in PAH mass in this urban watershed in the early stages of the storm. Additional lines (red) have been added to Figure 4 to reflect the 40% cumulative volume value (twice the "first flush" volume of 20%) used in the sizing of the storage tanks at CSOs RH-034 and OH-007. On this data set, a 40% capture rate would contain approximately 55% to 75% of the storm water volume (depending on the storm event), but would still allow between 25% and 45% of the volume to bypass the system. The particulates in this portion are expected to be largely fine particulates, with relatively elevated PAH concentrations. This fraction would either remain in the conveyance, if flow is low enough, or be discharged to the Canal.

Figure 4. Fraction of PAH Mass Associated with 40% of Cumulative Flow (Stein et al. 2006)

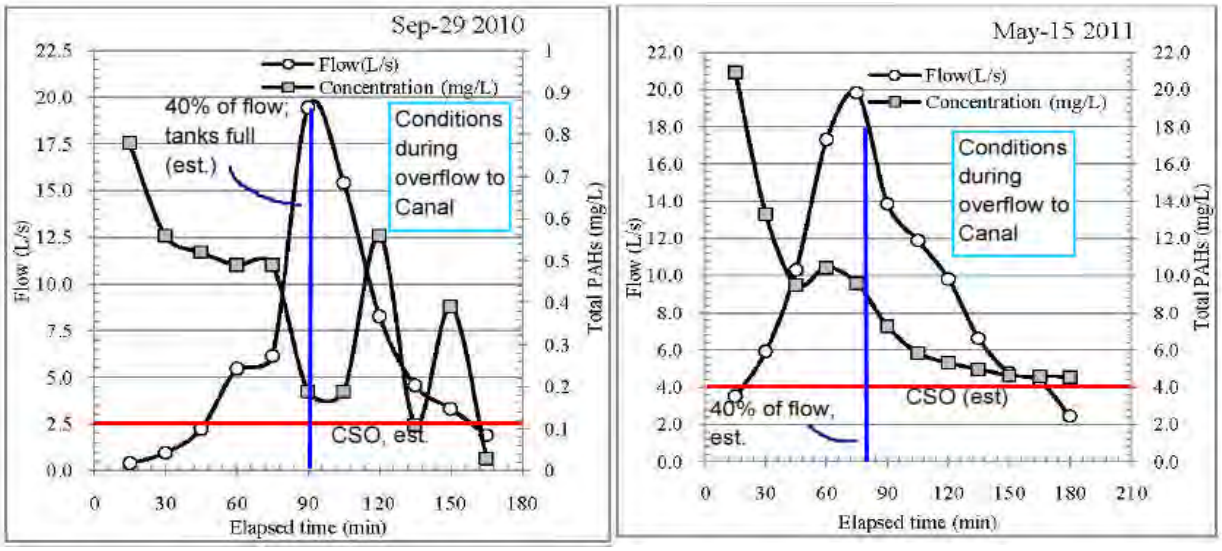


The portion of a storm event that may be released by the system in overflow conditions is better visualized with a so-called "pollutograph," which illustrates changes in volume and runoff concentration throughout the duration of a storm. Such visuals do not clearly reveal the first flush phenomena, but do illustrate runoff composition at different

points in a storm. Typically concentrations are low during peaks flows, as a result of dilution.

Figure 5 shows pollutographs from two storms in a highly urbanized area near Biscayne Bay, Florida (Mitsova et al (2011)). These depict changes in road runoff PAH concentration and flow as a function of time for storms two to three hours in length. To illustrate conceptually how the proposed tank system might affect discharges, we have overlaid lines that represent the boundary conditions that would affect the potential for overflow to the Canal: namely, the flow capacity of the sewer system (in L/s) and the capacity of the tanks, estimated at 40% of total storm flow volume. Since the total flow volume is the area under the flow curve, 40% of flow occurs somewhere near peak intensity. In these figures, storm water that would be contained by the tanks is represented by the area on the left of the vertical blue line (which represents tank capacity), while the storm water potentially discharging to the Canal is represented by the area to the right of the blue line and above the red line (which represents CSO capacity).

Figure 5. Estimated Gowanus BMP Boundary Conditions on Urban Stormwater Flow Data (data from Mitsova 2011)



As illustrated, potential overflow to the Canal could occur during conditions when both flow rate and PAH concentrations are declining, but still variable and high. Variability is shown by the figure on the left, for September 2010, which reflects pulses in rainfall intensity that occurred late in the storm and mobilized additional particles. The figure on the right shows conditions under more steadily declining precipitation intensity (Mitsova et al (2011)). Both cases illustrate the potential for continuing PAH discharges even after a significant volume of storm water has been contained.

As noted previously, the size and presence of a first-flush phenomenon is dependent on an array of site and storm specific factors. The selection of best management practices (BMPs) to capture first flush storm water flow is often based on precipitation guidelines applied to the unit watershed area. However, a study of four such state and literature

guidelines used to size hypothetical BMPs for using runoff data from an interstate highway in Cincinnati found that BMPs designed according to the guidelines (which ranged one-half to one inch of rainfall per specific area) experienced bypass in from one to four of eight storm events studied. For this dataset, the total mass of sediment bypassing the BMPs ranged from 0.02 to 0.59 kg per storm for a 300 m^2 (57 x 57 ft) study area (Sansalone and Cristina (2004)). While these data do not necessarily reflect the conditions in the watershed surrounding the Gowanus Canal, they do indicate the magnitude of particle bypass that can occur when units are designed based on first flush characteristics.

IV. Conclusion

Numerous studies indicate that PAHs on fine particulates are present in storm water throughout the entire storm event. Review of proposed BMPs for Gowanus storm water suggests that the potential exists for PAHs to be discharged to the Canal during periods of high and extended flow, when the capacity of both the sewer system and the storage tanks are exceeded. We suggest that the combined capacity of the storage tanks and the sewer conveyance be examined further, using hydraulic modeling and historical precipitation data as appropriate, to obtain additional information about the potential frequency and volume of storm water that may be discharged from the system. Without this analysis, the actual effectiveness of the proposed CSO remedy cannot be evaluated.

1. Introduction

The Gowanus Canal (the Canal or the Site) sediments contain or have been impacted by non-aqueous phase liquids (NAPLs) that are a complex hydrocarbon mixture including polycyclic aromatic hydrocarbons (PAHs). The NAPL contains petrogenic and pyrogenic hydrocarbons, as well as other types of chemicals. The oil refineries, petrochemical plants, manufactured gas plant (MGP) facilities, fertilizer and glue factories, coal yards, and other industrial and urban discharges along the Canal are all potential sources of NAPL. These industrial land uses and discharges have likely contributed petroleum, heavy metals, pesticides, herbicides, polychlorinated biphenyls and/or other chemicals to the sediments. Many of these compounds are the same as or difficult to distinguish from compounds also associated with former MGP operations.

In support of the development of a remedial design focused on an effective, sustainable remedy, with overall containment for all sources of contaminants present in the Canal, a number of investigative efforts are planned under the general categories as follows:

- Cap stability and components
- In situ solidification
- Upland and underlying sediments loading (hydraulic and chemical)
- Hydrodynamic modeling

On behalf of National Grid, GEI Consultants, Inc. (GEI) has prepared this *In Situ Solidification Treatability Study Status Report*. This document provides interim data from preliminary solidification testing and two rounds of optimization testing and provides preliminary conclusions based on those data. This is an interim report pending the final results and analysis of leachability testing.

2. Purpose and Objectives

In situ solidification (ISS) was selected as a potential treatment technology to address NAPL in sediments in the Canal. As stated in the ISS Treatability Study Work Plan (ISSTWP), the remedial objectives of ISS are to:

- Prevent direct human or ecological contact with NAPL-contaminated sediments
- Prevent the migration of NAPL into the Canal after the remedial action is completed
- Prevent NAPL from acting as a continuing source of contaminants to groundwater discharging to the Canal

The purpose of the treatability study is to determine the effectiveness of ISS as a treatment technology for the Canal sediments. The primary objective of the treatability study is to determine whether solidification of the Canal "native sediment" is possible and cost-effective using typical ISS reagents. If this primary objective is achieved, then the secondary objectives are to:

- Determine whether the Canal "soft sediment" can also be solidified
- Optimize the reagent content of ISS grout mixes for native and soft sediments
- Evaluate the performance of beneficial admixtures such as anti-washout additives
- Measure the leaching behavior of successfully solidified sediments
- Investigate whether native sediment mixed with soft sediment can be solidified

Although the Feasibility Study (FS) does not propose ISS in the soft sediment for any Remediation Target Area (RTA), or in the native sediment at RTA 3, GEI included soft sediments from each RTA where they are present as well as native sediment from RTA 3 in the ISSTWP. GEI chose to include these sediments in order to provide as much information as possible and allow for flexibility in considering ISS wherever it might be effective in the Canal sediment.

3. Materials and Methods

The treatability study was divided into four phases:

1. Collection and characterization of sediment samples
2. Preliminary solidification testing
3. First-round optimization testing
4. Second-round optimization testing

This document is an interim status report on the ISS treatability testing. Phases 1 through 4 have been completed and are addressed in this document, although leachability samples associated with phases 2 and 4 are still being collected and analyzed. The results of all ISS treatability testing will be included in a final report.

3.1 Phase 1: Collection and Characterization of Sediment Samples

GEI performed sediment sampling at a total of five locations within the three RTAs and one Turning Basin (TBN). These locations are shown in Figure 1. The naming convention selected by GEI to distinguish soft and native sediment samples places either an "S" or an "N" at the end of the sample name. Therefore, RTA-1N is the native sediment sample at that location, and RTA-1S is the soft sediment sample. The only exception to this nomenclature is the sample named RTA3, which is a native sediment sample (no soft sediment sample was collected at RTA3).

- RTA 1 – Upper Canal, from head of Canal to 3rd Street. In this area, NAPL is present in native sediment, with some evidence of NAPL in soft sediment. One sampling location was selected, north of the Union Street Bridge. Soft sediment and native sediment samples were collected at this location. These samples are identified as RTA-1S (soft) and RTA-1N (native).
- RTA 2 – Middle Canal, between 3rd and Creamer Streets. In this area, NAPL is present in both native and soft sediments. Two sampling locations (A and B) were selected. Soft sediment and native sediment samples were collected at each location. Samples from the first location, north of the Ninth Street Bridge, are identified as RTA-2AS (soft) and RTA-2AN (native). Samples from the second location, south of the Ninth Street Bridge, are identified as RTA-2BS (soft) and RTA-2BN (native).

- TBN 1 – The Fourth Street Turning Basin. In this area, NAPL is present in both native and soft sediments. One sampling location was selected. Soft sediment and native sediment samples were collected at this location. These samples are identified as TBN-1S (soft) and TBN-1N (native).
- RTA 3 – Lower Canal, Sigourney Street to Redhook Channel. In this area, NAPL impacts in soft sediment are infrequent, and some NAPL is present in native sediment. One sampling location was selected, south of the Gowanus Expressway. Only a native sediment sample was collected at this location. This sample is identified as RTA-3.

3.1.1 Sample Collection and Screening

Sample collection was performed in accordance with the GEI Quality Assurance Project Plan. GEI oversaw the collection of sediment samples by Ocean Surveys, Inc. (OSI), of Old Saybrook, Connecticut, from August 16 to 20, 2012. OSI advanced vibratory sediment cores using a pneumatic hammer with a 20-foot long, 3.625-inch diameter hard polycarbonate liner within a steel casing. The cores were collected from an aluminum research vessel (boat). Liners were extracted and cut into approximately 5-foot sections on the research vessel and then brought to land for processing. The cores were evaluated by a GEI geologist to determine soil type and log visual contamination.

The GEI geologist continuously logged the cores in a manner consistent with previous investigations at the site. The core logs are presented in Appendix A. OSI collected multiple cores at each sampling location to generate sufficient sample volume (approximately 5 gallons). All cores were collected within a 7 foot radius of the sample locations shown in Figure 1. Core recoveries were generally very good, averaging greater than 90 percent recovery for cores retained for processing. Cores with poor recoveries or those that refused before reaching target depths were not retained for processing.

The GEI geologist estimated the interface of the accumulated (or “soft”) and native sediments in the field: soft sediment samples were collected from the interface to 5 feet above the interface and native sediment samples were collected from the interface to 5 feet below the interface. Field observations indicate that the soft sediments generally become less soft and more dense with increasing depth. The top of the soft sediment column near the sediment-water interface (what might be called the “softest” sediments) was excluded from the composite samples.

GEI personnel screened the sediment for volatile organic compounds (VOCs) using a photoionization detector (PID) and collected grab samples for laboratory analysis of VOCs and semi-volatile organic compounds (SVOCs) from the interval of the core with the highest PID readings. The rest of the cores were composited into either native or soft sediment

samples and placed in sealed 5-gallon plastic buckets and stored on ice. Geo-Con picked up the treatability sample buckets and the VOC/SVOC samples at the Site on August 20, 2012, and transported them to the Geo-Con treatability laboratory in Pittsburgh, Pennsylvania.

3.1.2 Sample Analysis and Characterization

Immediately upon receipt, Geo-Con shipped the VOC/SVOC samples collected by GEI in the field to Pace Analytical Laboratories in Greensburgh, Pennsylvania, for analysis of VOCs including benzene, toluene, ethylbenzene, and xylene (BTEX) by United States Environmental Protection Agency (EPA) Method 8260 and SVOCs including PAHs by EPA Method 8270. These analyses were intended to measure the baseline concentration of volatile and semi-volatile constituents of interest (COI) in the sediment samples prior to solidification testing, for comparison to leach test results.

After the first round of leach testing was completed in March 2013, GEI decided to submit the composited sediment samples for analysis of VOCs and SVOCs. The composited samples had been held in refrigerated storage at the Geo-Con treatability laboratory since they were received from GEI in August 2012. Whereas the baseline VOC/SVOC samples submitted in August 2012 were collected as grab samples from the sediment core interval with the highest PID readings, the ISS treatability work was performed on the composited sediment core samples. This second set of laboratory analyses was performed because GEI suspected that the grab samples from August 2012 might not accurately reflect the COI concentrations in the composited sediment samples.

The results of each of these analyses are summarized in Table 1, with the grab and composite sample results presented side-by-side for comparison. The laboratory data reports will be included in the ISS treatability study final report.

Geo-Con maintained the treatability samples in refrigerated storage at a temperature of 4 degrees Celsius (^{o}C) in the laboratory facilities of Geotechnics, Inc., located in East Pittsburgh, Pennsylvania. Geo-Con used stainless steel tools to homogenize each sediment sample and to remove particles larger than 0.5 inches in diameter. This work was performed in a refrigerated space to minimize volatilization of organic compounds. Geo-Con submitted aliquots of the homogenized, untreated samples to Geotechnics for analysis of the following parameters:

- Moisture Content by American Society for Testing and Materials (ASTM) D 2216
- Unit Weight by ASTM D 7263
- Grain Size Distribution (with hydrometer) by ASTM D 422
- Loss-on-ignition by ASTM D 2974

The results of these analyses are summarized in Table 2. The laboratory data reports will be included in the ISS treatability study final report.

3.2 Phase 2: Preliminary Solidification Testing

3.2.1 Treatability Sample Preparation

GEI selected three percentages of Portland cement addition for preliminary solidification testing: 10, 15, and 20 percent. GEI also decided to test each of these mix designs with and without a 1 percent bentonite addition, yielding a total of six different mix designs. Percent reagent addition is measured as weight of dry reagent per weight of wet sediment.

Geo-Con performed treatability testing using these six mix designs on each of the nine sediment samples collected from the Canal, yielding a total of 54 treatability samples for preliminary solidification testing. Treatability samples were prepared between September 13 and 16, 2012.

Geo-Con prepared each treatability sample by mixing the solidification reagents (Portland cement and bentonite) with tap water to create a cement grout. The ratio of water mass to reagent mass in the grout mixes was approximately 1:1. Then Geo-Con mixed the grout into weighed aliquots of the sediment samples until the target percentage of reagent to sample was achieved. Bulking was measured by comparing the volume of the sample prior to grout addition to the volume of the sample after grout addition. Geo-Con mechanically mixed the sediment and grout until it was homogeneous, placed the mixture into 2-inch diameter by 4-inch tall cylindrical plastic molds (except for permeability molds, which were 3-inch diameter by 3-inch tall), tamped and rodded the molds to remove air voids, covered the cylinders with plastic caps and cured the cylinders at room temperature in a sealed curing box with a shallow water bath to maintain 100 percent relative humidity levels.

3.2.2 Physical Performance Criteria Evaluation

Geotechnics performed pocket penetrometer testing at 1, 3, and 7 days of curing to estimate the rate of strength development for the treatability samples. Shrinkage of the samples was estimated by measuring the depth of “bleed water” present on top of the cylinders. One cylinder from each treatability sample set was immersed in water after 7 days of curing to test for the presence of sheen or disintegration of the sample.

Geotechnics tested the unconfined compressive strength (UCS) of the treatability samples at 7 days and 28 days using the ASTM method D 1633. Cylinders subjected to UCS testing (a destructive test in which the cylinder is broken, typically into several pieces) were examined for the presence of free NAPL.

Geotechnics tested the hydraulic conductivity (K) of the treatability samples at 28 days using the test method ASTM D 5084 (flexible wall permeameter, constant head).

Physical performance data for preliminary solidification testing are summarized in Table 3.

3.2.3 Leachability Evaluation

GEI identified five treatability mixes to be further evaluated for leaching behavior: mixes 2, 18, 19, 37, and 49 (see Table 3). They include four native sediment samples and one soft sediment sample, and span the range of reagent additions from 10 to 20 percent Portland cement and zero to 1 percent bentonite. GEI chose to use the leach test method EPA 1315, for which the cylinders are submerged for nine time intervals (for varying durations per the method) over 63 days with testing of leachate at the conclusion of each interval. EPA 1315 is the leach method proposed by the EPA for proposed ISS treatability work described by CH2M HILL in the draft *Technical Plan for Pre-design Bench Scale Testing of In-situ Stabilization of Native Sediments,* dated October 2012.

3.3 Phase 3: First-Round Optimization Testing

After reviewing the preliminary results from Phase 2, and in consultation with National Grid, GEI directed Geo-Con to perform additional treatability testing. This additional testing started the process of optimizing reagent doses and types, and improving the solidification performance of the soft sediments.

GEI's strategy for optimization testing of native sediment samples was to decrease the total reagent addition below 10 percent, and to substitute ground granulated blast furnace slag (GGBS) cement for Portland cement at a ratio of 60:40. First-round optimization testing was performed on native sediment samples from each of the five sampling locations in Canal, with a total reagent addition rate of 7 percent, composed of 4.2% GGBS cement and 2.8 percent Portland cement.

GEI's strategy for optimization testing of soft sediment samples was to maintain a 20 percent reagent rate but to substitute GGBS cement for Portland cement at a ratio of 60:40. First-round optimization testing was performed on soft sediments from two sampling locations (RTA-2AS and TBN-1S), with a total reagent addition rate of 20 percent, composed of 12% GGBS cement and 8 percent Portland cement.

Bentonite was not included in the first-round optimization mix designs for either native or soft sediments.

GEI decided to evaluate the addition of a liquid cellulose-based anti-washout admixture (RHEOMAC® UW 450) in anticipation of the need to control turbidity in the water column during pilot and full-scale implementation of ISS in the Canal. Each of the first-round optimization treatability samples was performed with and without the anti-washout additive (added at 1.5% by weight of reagent).

Geo-Con prepared the first-round optimization treatability samples between November 19 and 21, 2012. The samples were prepared and handled according to the methods described above in Section 3.2.1 for preliminary solidification samples. The water to reagent mass ratio for the cement grout was increased to 1.4:1 for this set of treatability samples. GEI chose to eliminate pocket penetrometer testing at one, three, and seven days for these samples, as well as seven-day UCS testing in order to minimize the amount of sediment sample used and to preserve sample volume for future optimization testing. Geotechnics performed 28-day UCS testing and hydraulic conductivity testing on the cured samples.

The physical performance data for all Phase 2 and 3 treatability samples are summarized in Table 3.

Geo-Con submitted a sample of GGBS cement for metals analysis; those data will be included in the ISS treatability study final report.

3.4 Phase 4: Second-Round Optimization Testing

After reviewing the results from Phase 3, and in consultation with National Grid, GEI directed Geo-Con to perform a second round of optimization testing, aimed at investigating the effectiveness of solidification when soft sediment and native sediment are mixed.

Phases 1 through 3 of ISS treatability testing kept native and soft sediments separated, and treated them with different cement grout mixes. This strategy makes sense if the pilot- or full-scale ISS implementations are restricted to either of these two scenarios:

1. Only native sediment is allowed to be solidified, in which case soft sediment would have to be removed prior to solidification, or
2. Soft and native sediments are solidified separately, with deliberate efforts not to mix them during the solidification process.

A third option would be to encourage, rather than to minimize, mixing of the native and soft sediment layers. Mixing is facilitated by the vertical auger installation method typical of ISS implementations, which results in a homogeneous mixture of cement grout, sediment and impacts throughout the column.

GEI hypothesized that mixing the native sediment with the soft sediment would improve the strength and permeability performance of the soft sediments. The total reagent addition rate might be higher than what is required for solidification of native sediments alone, but ISS of soft sediment in this manner would likely be more cost effective than dredging, handling, transportation, and disposal.

GEI's strategy for mixed sediment optimization testing was to mix soft and native sediment samples in a volumetric ratio of 1:1 (50 percent soft, 50 percent native). This represents a scenario in which equal depths of native and soft sediments are solidified together (e.g. 5-feet of soft sediment and 5-feet of native sediment). Mixed samples were solidified with total reagent addition rates of 9, 12, and 15 percent. In cases where sufficient sample volume was available, some other variations were also tested:

- Three sample locations tested mixes of 2:1 soft-to-native sediment (67 percent soft, 33 percent native)
- One sample location tested a mix of 90 percent soft and 10 percent native sediment (this mix was solidified with 17 percent total reagent)
- Two sample locations tested mixes of 1:1 soft-to-native sediment with a reagent ratio of 60 percent Portland cement to 40 percent GGBS (versus the typical mix of 40 percent Portland to 60 percent GGBS)

Bentonite was not included in the second-round optimization mix designs. Anti-washout admixture (RHEOMAC® UW 450) was added to each of the second-round optimization treatability samples at 1.0% by weight of reagent.

Geo-Con prepared the second-round optimization treatability samples between February 9 and 11, 2013. The samples were prepared and handled according to the methods described above in Section 3.2.1 for preliminary solidification samples. The water to reagent mass ratio for the cement grout was decreased to 0.8:1 for this set of treatability samples. GEI chose to eliminate seven-day UCS testing due to the dwindling supply of sediment sample remaining for some sample locations. Geotechnics performed 28-day UCS testing and hydraulic conductivity testing on the cured samples.

The mix design and physical performance data for the second-round treatability samples are summarized in Table 4.

GEI will select a subset of second-round optimization testing samples to be further evaluated for leaching behavior. These samples will be evaluated as described above in Section 3.2.3, and the results of leaching analysis will be included in the final ISS treatability study report.

4. Results and Discussion

4.1 Phase 1: Collection and Characterization of Sediment Samples

Physical characterization of the sediment samples is important to ensure that the materials evaluated in the treatability testing are similar to those expected at the site. Chemical characterization is important because it provides a baseline for leach testing to evaluate the effectiveness of the solidification treatment. These physical and chemical evaluations also give an indication of how variations in sediment composition and NAPL may affect ISS performance.

Table 1 summarizes the results of chemical analysis of the untreated samples for BTEX and PAHs. The results from grab samples collected immediately after the cores were recovered in the field are presented side-by-side with the results of composite samples submitted in March 2013. PAHs and VOCs were generally detected in all of the samples; the measured concentrations vary widely among locations and do not show a consistent trend between sediment types.

Table 2 summarizes the physical characterization results of the untreated sediment samples. The soft sediments generally have a higher water content (from 49.2 to 149.1 percent, expressed as mass of water divided by mass of solids) than the native sediments (17.0 to 57.3 percent). In every case, the soft sediments have a lower density (77.5 to 98.5 pounds per cubic foot) than the native sediments (102.9 to 119.7 pounds per cubic foot). The higher water content and lower densities of the soft sediments are their most distinguishing physical characteristics versus the native sediments.

Particle size distribution data show substantial variations in the composition of both soft sediments and native sediments. Although the solids fraction for all but one of the samples is composed primarily of sand, the sand fraction in native sediments varies from 38 to 91 percent, and the sand fraction in soft sediments varies from 64 to 77 percent. Three of the four soft sediment samples have a fines (clay and silt) fraction of more than 20 percent, but none are above 30 percent. By comparison, three of the five native sediment samples have a fines fraction of less than 10 percent, but the other two native sediment samples are 35 and 62 percent fines, respectively.

Loss-on-ignition data further illustrate the difference between soft and native sediments: soft sediments have an organic fraction (dry weight basis) that ranges from 13.6 to 28.1 percent, versus just 1.0 to 6.0 percent for native sediments.

In general, the heterogeneity of both the soft and native sediments suggests that optimal ISS mix designs may vary with material composition between sediment layers and in different RTAs. Additional sediment sampling and ISS treatability testing will be required prior to full-scale implementation of ISS, in order to optimize the mix design to the varying sediment characteristics along the length of the Canal.

4.2 Phase 2: Preliminary Solidification Testing

Six mix designs were evaluated in the preliminary solidification testing on five native sediment samples and four soft sediment samples, for a total of 54 mixes. Native and soft sediment sample mixes are evaluated separately below. The physical performance data for Phase 2 treatability samples are summarized in Table 3.

4.2.1 Native Sediment Mixes

All of the treatability mixes performed with native sediment samples developed strength quickly. The average UCS value for 28-day tests on native sediment mixes was 231 pounds per square inch (psi).

Native sediment mixes with the lowest level of reagent addition (10 percent Portland cement) had 28-day UCS values that ranged from 61.9 to 236.8 psi (without bentonite) and 115.4 to 231.3 psi (with 1 percent bentonite). No free NAPL was noted in any of the native sediment mixes during UCS testing.

All of the native sediment mixes had hydraulic permeability values of less than $1x10^{-6}$ centimeters per second (cm/sec). The average K value for native soil mixes was $3.23x10^{-7}$ cm/sec.

4.2.2 Soft Sediment Mixes

Soft sediment mixes with the highest level of reagent addition (20 percent Portland cement) had 28-day UCS values that ranged from 17.4 to 39.8 psi (without bentonite) and 8.3 to 52.6 psi (with 1 percent bentonite). No free NAPL was noted in any of the soft sediment mixes during UCS testing.

The average hydraulic conductivity for soft sediment mixes was $3.23x10^{-6}$ cm/sec, with most of the mixes falling into the range of $1x10^{-5}$ to $1x10^{-6}$ cm/sec. The best-performing mix was the same one that achieved the highest UCS value of 52.6 psi: RTA-2AS, at 20 percent reagent and 1 percent bentonite. RTA-2AS also had the highest sand fraction and lowest fines fraction among the soft sediment samples, and a relatively low water content of 74.8 percent.

4.2.3 Leachability Results

As described in Section 3.2.3, GEI selected five mixes (four native sediment samples and one soft sediment sample) to be evaluated for leaching behavior. GEI is still analyzing the leach test results, so they are not yet available for inclusion in this interim report. Those data will be included and discussed in the ISS treatability study final report.

4.3 Phase 3: First-Round Optimization Testing

One mix design (7 percent reagent: 4.2 percent GGBS cement, 2.8 percent Portland cement) was evaluated for five native sediment samples, with and without anti-washout additive, for a total of 10 native sediment mixes. A different mix design (20 percent reagent: 12 percent GGBS cement, 8 percent Portland cement) was evaluated for two soft sediment samples, with and without anti-washout additive, for a total of 4 soft sediment mixes. Native and soft sediment mix results are discussed separately below. The performance criteria for UCS and hydraulic conductivity are as described above in Section 3.2.2. The physical performance data for Phase 3 treatability samples are summarized in Table 3.

4.3.1 Native Sediment Mixes

All of the treatability mixes performed with native sediment had 28-day UCS values of greater than 100 psi, and four of the ten mixes had strengths of greater than 200 psi. The average UCS value for 28-day tests on native sediment mixes was 181 psi. By comparison, the average UCS value for 28-day tests on the ten native sediment mixes from Phase 2 with 10 percent Portland cement, (with or without 1 percent bentonite) was 146 psi. This suggests that the substitution of GGBS cement for some of the Portland cement had the expected result of generating strength gains even though the total reagent addition was decreased from 10 percent in Phase 2 to 7 percent in Phase 3. No free NAPL was noted in any of the native sediment mixes during UCS testing.

The average K value for native sediment mixes was 8.8×10^{-8} cm/sec. This is an improvement versus the average hydraulic conductivity values for native sediment mixes in Phase 2.

4.3.2 Soft Sediment Mixes

Soft sediment mixes in the first round of optimization testing (using 60 percent GGBS and 40 percent Portland cement, at a total reagent addition rate of 20 percent) performed better than in preliminary solidification testing (Phase 2). The average UCS value for 28-day tests on soft sediment mixes during the first round of optimization testing was 104 psi. By comparison, the average UCS value for 28-day tests on these same two soft sediment samples in Phase 2 treated with 20 percent Portland cement (with or without 1 percent

bentonite) was 44.8 psi. This suggests that substitution of GGBS cement for some of the Portland cement resulted in strength gains for soft sediment mixes, just like it did for the native sediment mixes. No free NAPL was noted in any of the soft sediment mixes during UCS testing.

The average K value for soft sediment mixes during first-round optimization testing was $2.6x10^{-7}$ cm/sec. By comparison, the average hydraulic conductivity value of these same two soft sediment samples in Phase 2 treated with 20 percent Portland cement (with or without 1 percent bentonite) was $2.3x10^{-6}$ cm/sec. As with the native sediment mixes in Phase 3, hydraulic conductivity performance for the soft sediment mixes improved with the substitution of GGBS cement for some of the Portland cement.

4.3.3 Anti-washout additive performance

Geo-Con qualitatively evaluated the performance of the anti-washout additive by placing aliquots of the uncured mixes with and without the additive into 5-gallon buckets of tap water and observing the relative increases in turbidity. Mixes with the anti-washout additive had clearly observable better turbidity performance versus the mixes without the additive. The anti-washout additive did not have a discernible effect on either the strength or permeability results of the mixes. All future optimization mixes will likely incorporate the anti-washout additive, since it is anticipated to be necessary for pilot- and full-scale implementation of ISS in the Canal.

4.3.4 Leachability Results

GEI does not plan to perform leachability testing for any of the Phase 3 mixes.

4.4 Phase 4: Second-Round Optimization Testing

The primary objective of second-round optimization testing was to evaluate whether mixing the soft and native sediments had any effect on their solidification behavior. Each of the sample locations where both soft and native sediments were collected in August 2012 were included in the Phase 4 work (RTA-1, RTA-2A, RTA-2B, and TBN-1). As described above in Section 3.4, the variables evaluated during this phase of testing were:

1. Ratio of soft sediment to native sediment
2. Total reagent addition rates
3. Ratio of Portland cement to GGBS

The mix designs and physical performance data for second-round optimization testing are summarized in Table 4.

4.4.1 Soft and Native Sediment Mixes

With respect to sediment mix ratios, 14 of the 18 mixes were tested at a 1:1 ratio of soft sediment to native sediment (by volume). Three of four locations had one mix tested at 2:1 soft-to-native, and one location had a mix tested at 9:1 soft-to-native. As described in Section 3.4, GEI hypothesized that mixing the native sediment with the soft sediment would improve the strength and permeability performance of the soft sediments. The purpose of the four mixes at higher ratios of soft to native material was to investigate how much benefit might result from the incorporation of a relatively small amount of native material in a predominantly soft sediment mix.

The 1:1 soft-to-native sediment mixes were tested at total reagent addition rates of 9, 12, and 15 percent. The reagent blend used in these mixes was 40 percent Portland cement and 60 percent GGBS. Due to dwindling sample volumes from prior testing, sample location RTA-2A was only tested at 12 and 15 percent reagent addition rates. The three 1:1 mixes tested at 9 percent total reagent addition had 28-day UCS values of 7.3, 14.2, and 97 psi (average of 39.5 psi). The four 1:1 mixes tested at 12 percent total reagent addition had 28-day UCS values of 25.8, 107.7, and 73.3 psi (average of 68.9 psi). The four 1:1 mixes tested at 15 percent total reagent addition had 28-day UCS values of 77.4, 141, 108.2, and 157.6 psi (average of 121 psi).

The 2:1 soft-to-native sediment mixes were tested at a total reagent addition rate of 15 percent. The reagent blend used in these mixes was 40 percent Portland cement and 60 percent GGBS. Due to dwindling sample volumes from prior testing, sample location RTA-2A was not tested at a 2:1 mix ratio. The three 2:1 mixes tested at 15 percent total reagent addition had 28-day UCS values of 22.0, 176, and 75.9 psi (average of 91.3 psi). This is a lower average strength than the 1:1 mixes at 15% total reagent addition for these same three sample locations (114.4 psi).

The 9:1 soft-to-native sediment mix was tested at a total reagent addition rate of 17 percent. The reagent blend used in this mix was 40 percent Portland cement and 60 percent GGBS. RTA-1 was the only sample location tested at a 9:1 ratio. The 28-day UCS value for this test was 24.5 psi. This result is comparable to what was observed for this sample location in the 2:1 mix at 15 percent reagent addition (22.0 psi) but lower than the 1:1 mix at 15 percent reagent addition (77.4 psi).

The Portland cement to GGBS ratio was flipped for two sample locations tested at 1:1 soft-to-native sediment and 12 percent total reagent addition. The reagent blend used in these mixes was 60 percent Portland cement and 40 percent GGBS. At RTA-1, the mix with more

Portland cement had a greater 28-day UCS value (43.6 versus 25.8 psi) but at TBN-1, the opposite was true (28.7 versus 73.3 psi).
GEI identified eleven mixes for measurement of permeability, based on good performance with respect to UCS testing. The measured K values ranged from $4.1x10^{-6}$ cm/sec to $6.6x10^{-8}$ cm/sec, with an average value of $7.6x10^{-7}$ cm/sec.

4.4.2 Leachability Results

GEI will perform leachability testing on several of the Phase 4 mixes. These data will be included in the ISS treatability study final report.

5. Preliminary Conclusions

1. Solidification of native sediment is possible with typical ISS reagents at cost-effective reagent addition rates. Substantial performance gains for strength and hydraulic permeability were achieved using a mixture of GGBS cement and Portland cement at a 7 percent total reagent addition rate.

2. Solidification of soft sediment is possible with typical ISS reagents. Solidification of soft sediments requires more total reagent addition to achieve strength and permeability gains compared to native sediments.

3. ISS of a mixture of native and soft sediments can result in cost reduction and performance gains as compared to separate treatment. At a constant reagent addition rate, strength and permeability gains increase as the ratio of native to soft sediment is increased (this effect is most pronounced for strength results). The amount of reagent necessary for ISS decreases as the ratio of native to soft sediment increases. These results are likely due to the properties of the native sediments such as lower water content (greater solids fraction) and lower organic content compared to the soft sediments.

4. Based on GEI's past experience, strength and permeability gains correlate well to reduced leachability. We expect that ISS in native, soft, and mixtures of native and soft sediments will physically immobilize contaminants and reduce the risk of contaminant availability in sediment. Leach testing and analysis is ongoing.

5. Based on test results for native sediments, soft sediments, and mixtures of native and soft sediments, GEI expects that ISS can achieve strength gains sufficient to support an engineered cap. Cap design and geotechnical evaluation will be required to confirm this assumption.

6. A mixture of GGBS cement and Portland cement yields strength and permeability performance gains in solidified native and soft sediments equal to or greater than Portland cement alone, which may allow for a more cost effective ISS design mix.

7. The use of bentonite is not necessary for strength and permeability gains in Gowanus Canal sediments.

8. The use of an anti-washout additive is likely to substantially improve the turbidity performance of ISS mixes, pilot- and full-scale ISS implementation in a marine environment.

Notes:
Data provided by Pace Analytical Services on September 7, 2012.
"U" = The analyte was not detected at a concentration above the specified laboratory reporting limit.
µg/kg = micrograms per kilogram.
BTEX = benzene, toluene, ethylbenzene, xylene.
NR = not reported
The composite sample date represents the date that the sample aliquot was collected from sediment held in refrigerated storage at Geo-Con. The composite sample is sediment that was originally collected in the field in August 2012.
Due to lack of sufficient sample volume, composite sample RTA2AS is ISS Mix 13 and 16, and composite sample TBN1S is Mix 43 and 46. This represents a COI dilution (due to solidification reagent addition) of approximately 20 percent.
Therefore, the composite sample COI concentrations for RTA2AS and TBN1S shown on this table should be multiplied by a factor of 1.25 to estimate the concentrations of COI in the untreated sediment.

NOTES:
ft = feet.
pcf = pounds per cubic feet.
Sample depth interval is feet below the interface of sediment and surface water.
Particle size distribution data are expressed as percent of total solids in the sample in each classification (gravel, sand, or fines).
Water content is expressed as weight of water in the sample divided by the weight of dry solids in the sample.
Percent solids is calculated as (10,000 / (100 + water content)) where water content is expressed in percent.
Loss on ignition is the weight of sample lost upon combustion in a 440 degree Celsius furnace, compared to the weight of the dry sample prior to combustion.

Mixes 82 through 86 required additional water to mix due to sediment cohesiveness, which increased the water : reagent ratio

Figure

NOTES:

1. MULTIPLE SEDIMENT CORES WERE COLLECTED FROM EACH SAMPLE LOCATION TO FUFILL VOLUME REQUIREMENTS. CORES WERE COLLECTED WITHIN A 7' RADIUS OF LOCATIONS SHOWN.

1.0 Introduction

This Data Report contains validated analytical results from sediment core samples collected in the vicinity of combined sewer overflow (CSO) discharge locations in the Gowanus Canal, located in Brooklyn, New York. This report will be expanded with additional results from these sediment cores when they are available.

The CSO Investigation Work Plan, which describes sediment core collection, was developed by Woodard and Curran and is dated June 5, 2012. It was approved by the United States Environmental Protection Agency (USEPA) on July 6, 2012.

2.0 Sampling Methods

Sediment cores (GC-SED-501 through CG-SED-523) were collected at twenty-three locations in the Gowanus Canal, as shown in Figure 1. The sampling event took place between August 2 and August 15, 2012.

The cores were advanced within sediment to a depth of four feet using vibracore methods. Multiple cores were collected at each sample location to provide the required sample volume. The cores for each sample location were collected within six lateral feet of the designated coordinates.

Sediment cores were transferred to the landside for processing. The cores were logged and analytically sampled based on sample recovery. If a core had been advanced four feet but generated only three feet of intact material, the sample was logged as 3.0 feet (as opposed to interpolation that "stretches" the material over 4.0 feet). A Petite ponar sampler was occasionally used to augment sample volume for the uppermost (surficial) 6-inch core sections.

Each core was divided into 6-inch sections, starting at the top of the core, with each section designated as a separate sample for analysis. All sections were screened with a photoionization detector (PID) to assist in selecting sediment analytical samples most likely to have the highest volatile organic compound (VOC) concentrations. For each 6-inch interval, a sample for VOC analysis was collected from the core with the highest PID reading. The remaining samples were collected from a composite of each 6-inch sample interval from each of the cores. Each core was also digitally photographed. The core logs are provided in Appendix A. A table summarizing the PID readings for each sample core is also provided in Appendix A.

Ocean Surveys, Inc. provided the sampling boat, vibracoring services, and GPS location mapping. Where multiple cores were required at one location, the sample location coordinates were averaged to generate single locations as presented in Figure 1.

3.0 Analytical Regime

Table 1 summarizes the complete list of analytical parameters applied to each sediment sample. The analytical results are presented in Tables 2 and 3.

Tables

Table 1
CSO Sediment and Sediment-fraction Target Analytes
Phase I Sediment Cores
Gowanus Canal
Brooklyn, New York

Conventional Parameters	EDC/PPCP
Particle Size	Bisphenol A
TOC	Nonylphenol
Organics	Nonylphenol Diethoxylate
	Nonylphenol Monoethoxylate
VOCs	4-tert-Octylphenol
SVOCs	Acetominophen
TPH (whole sample)	alpha-Estradiol
PAH Fingerprint Analysis (whole sample)	Androstenedione
TPH (by grain size)	Atrazine
PAH Fingerprint Analysis (by grain size)	Bisphenol A
Pesticides/Herbicides	Caffeine
Total PCBs	Carbamazepine
Pathogens	Diazepam
	Diclofenac
Clostridium perfringens	Diethylstilbestrol
Coliphages	Phenytoin
Enterococcus	Estradiol
Fecal coliforms	Estriol
E. coli	Estrone
Enteroviruses	Ethinyl
Giardia	Estradiol
Cryptosporidium	Fluoxetine
Metals	Gemfibrozil
	Hydrocodone
Aluminum (Al)	Ibuprofen
Antimony (Sb)	Iopromide
Arsenic (As)	Meprobamate
Barium (Ba)	Methadone
Beryllium (Be)	Naproxen
Calcium (Ca)	DEET
Cadmium (Cd)	Oxybenzone
Chromium (Cr)	Pentoxifylline
Cobalt (Co)	Progesterone
Copper (Cu)	Salicylic Acid
Iron (Fe)	Sulfamethoxazole
Lead (Pb)	Testosterone
Magnesium (Mg)	Triclosan
Manganese (Mn)	Trimethoprim
Mercury (Hg)	
Nickel (Ni)	
Potassium (K)	
Selenium (Se)	
Silver (Ag)	
Sodium (Na)	
Thallium (Tl)	
Vanadium (V)	
Zinc (Zn)	

TOC = Total Organic Carbon
VOCs = Volatile Organic Compounds
SVOCs = Semi-volatile Organic Compounds
TPH = Total Petroleum Hydrocarbons
PAH = Polycyclic Aromatic Hydrocarbons
PCB = Polychlorinated Biphenyls
EDC = endocrine disrupting compounds
PPCP = pharmaceutical and personal care products

Table 2
Summary of Sediment Analytical Results
Phase I Sediment Cores
Gowanus Canal
Brooklyn, New York

Notes:

mg/kg - milligrams/kilogram or parts per million (ppm)
cfu/g - colony forming units per gram
pfu/g - plaque forming units per gram
Oocysts/g - Oocysts per gram
mpn/g - most probable number per gram
BTEX - benzene, toluene, ethylbenzene, and xylenes
VOCs - volatile organic compounds
PAHs - polycyclic aromatic hydrocarbons
SVOCs - semi-volatile organic compounds
PCBs - polychlorinated biphenyls
EDCs - endocrine disruptor compounds
PPCPs - pharmaceuticals and personal care products
Total BTEX and Total PAHs are calculated using detects only
Total PAHs are calculated using the EPA16 list of analytes (Acenaphthene, Acenaphthylene, Anthracene, Benz[a]anthracene, Benzo[a]pyrene, Benzo[b]fluoranthene, Benzo[g,h,i]perylene, Benzo[k]fluoranthene, Chrysene, Dibenz[a,h]anthracene, Fluoranthene, Fluorene, Indeno[1,2,3-cd]pyrene, Naphthalene, Phenanthrene, and Pyrene) plus 2-Methylnaphthalene

ND - not detected; total concentrations are listed as ND because no analytes are detected in the group
NA - not analyzed

Bolding indicates a detected concentration
Analytes in blue are not detected in any sample

Validation Qualifiers:

J - estimated value
JN - analyte is presumptively present at an approximated quantity
R - rejected
U - indicates not detected to the reporting limit
UJ - not detected at or above the reporting limit shown and the reporting limit is estimated

Validated

Table 3
Summary of Analytical Fractionated Results
Phase I Sediment Cores
Gowanus Canal
Brooklyn, New York

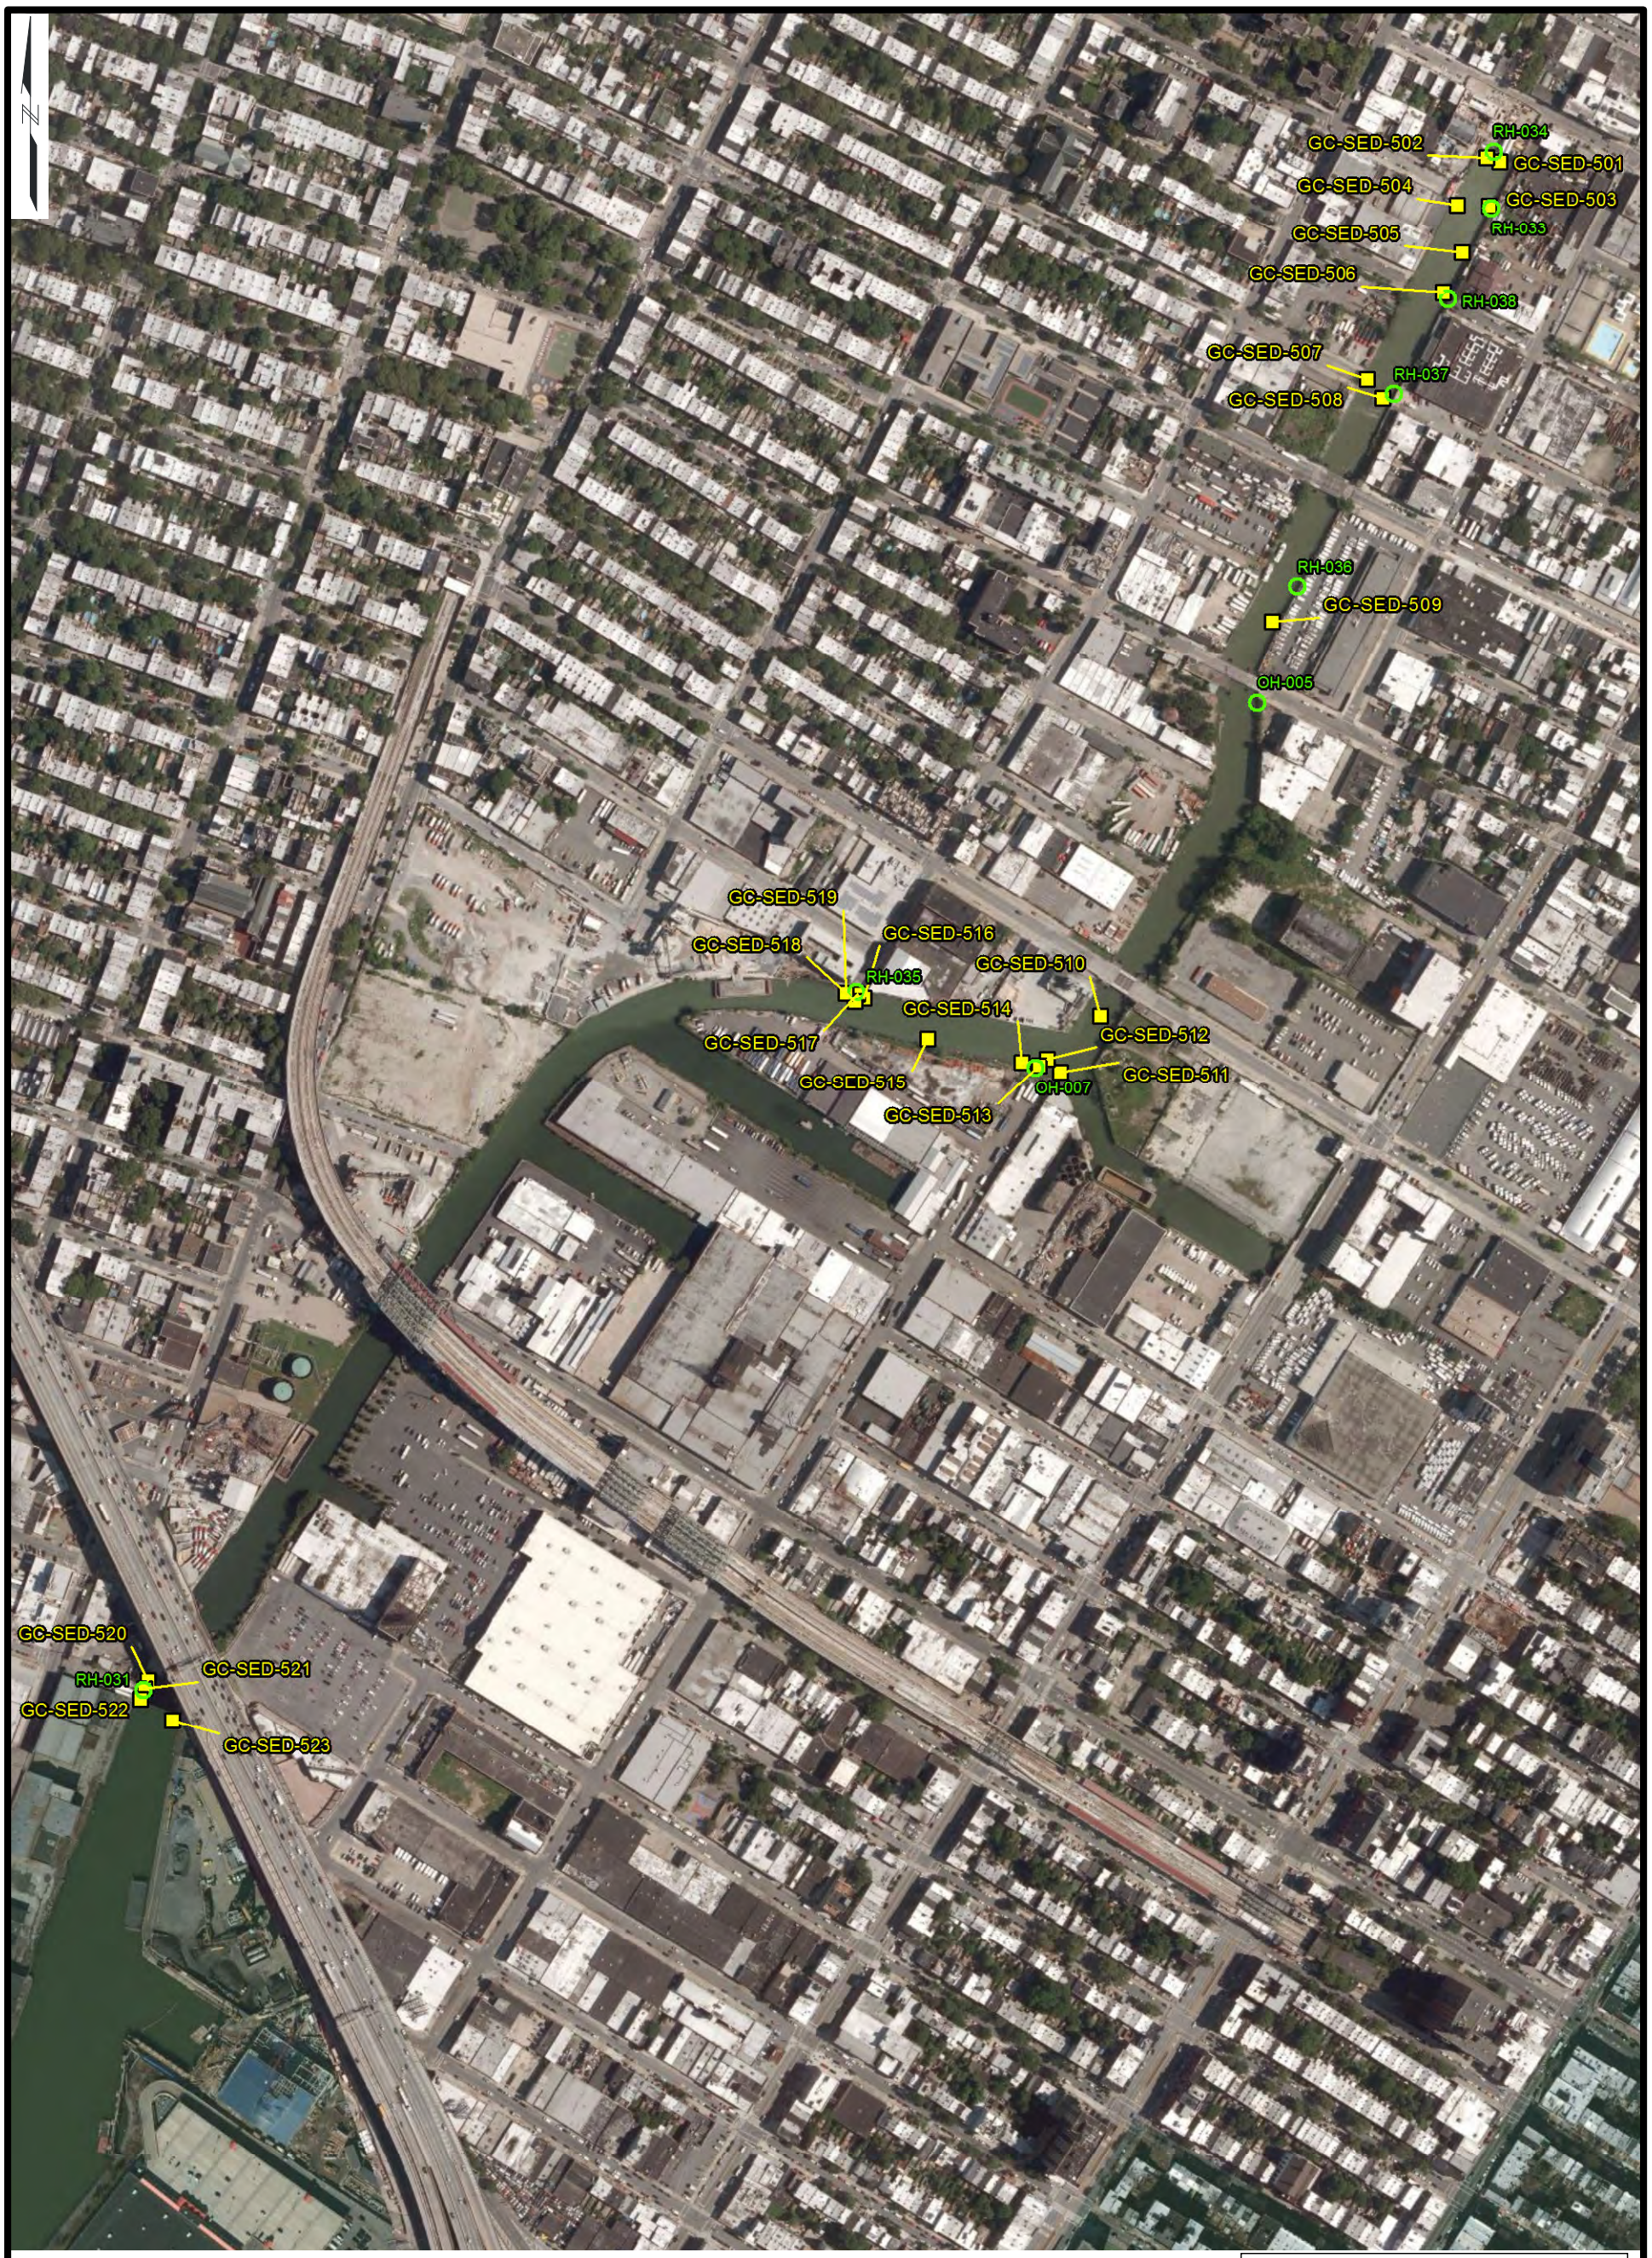
Notes:

mg/kg - milligrams/kilogram or parts per million (ppm)
PAHs - polycyclic aromatic hydrocarbons

Bolding indicates a detected concentration

Validation Qualifiers:
J - estimated value
U - indicates not detected to the reporting limit

Figure



NOTES:

1. MULTIPLE SEDIMENT CORES WERE COLLECTED FROM EACH SAMPLE LOCATION TO FUFILL VOLUME REQUIREMENTS. CORES WERE COLLECTED WITHIN A 6' RADIUS OF LOCATIONS SHOWN.

SOURCES:

Notes.
ft - feet
PID - Photoionization Detector
ppm - parts per million
PID measurements were collected from cores to a maximum depth of 4 feet.
-- no recovery, no measurement
NA - not available

Bolding indicates the highest PID measurement and the core from which the VOC samples were collected at that interval.

a. GC-SED-502 A-3 was cut into two sections prior to receiving it from the boat.

b. There was not enough volume for the full suite of analyses from cores GC-SED-517 A-1 and A-3 collected on 8/2/2012. Therefore, the A-4 core was collected on 8/13/2012 and sampled for the remaining analyses. The VOC samples were collected from the initial cores even though the PID measurements were higher in the A-4 core on 8/13/2012.

c. There was not enough volume for the full suite of analyses from cores GC-SED-518 A-1, A-2, and A-3 collected on 8/2/2012. Therefore, the A-4 core was collected on 8/16/2012 and sampled for the remaining analyses. The VOC samples were collected from the initial cores.

1. Introduction

This Data Report contains validated analytical results for water samples collected in September 2012 and from combined-sewer overflows (CSOs) that discharge during storm events into the Gowanus Canal in Brooklyn, New York.

The CSO Investigation Work Plan, which describes CSO sampling, was developed by Woodard and Curran and is dated June 5, 2012. It was approved by the United States Environmental Protection Agency (USEPA) on July 6, 2012.

2. Sampling Methods

Water samples were collected during storm events from four CSO locations (RH-031, RH-034, RH-035, and OH-007), as shown in Figure 1. The first sampling event was attempted on September 18, 2012; however, rain was light or intermittent and did not produce the required conditions for a full suite of sampling. A baseline sample was collected at OH-007. A full sampling event took place on September 28, 2012. Samples were collected from RH-031, RH-034, RH-035, and OH-007. A portion of the sample collected at RH-035 was collected after the rain began, but before overflow conditions occurred.

Samples were collected at select locations during the second and third events on January 11 and 16, 2013. Samples were collected at RH-035 and OH-007 during the second event and OH-007 and the Owl's Head Treatment Plant during the third event. During the third event, total suspended solid (TSS) samples were collected every 15 minutes during overflow conditions at RH-035.

The fourth sampling event was a full sampling event on January 21, 2013. Samples were collected from RH-031, RH-034, RH-035, OH-007, and the Owl's Head and Red Hook Treatment Plants. TSS samples were collected every 15 minutes during overflow conditions at RH-035 and OH-007.

The samples from locations RH-031, RH-035, and OH-007 were collected by lowering two sets of polyethylene tubing into the designated manholes and pumping through peristaltic pumps. RH-034 is located within an active construction site with limited access and space constraints. Four in-situ chemical oxidation (ISCO) automated samplers were used to collect samples at this location. The ISCO samplers were programmed prior to each sampling event to reflect expected storm conditions. Installation of tubing was performed by Louis Berger Group at all four locations. Tubing was dedicated to each location and was removed and replaced between each event.

Four types of samples were collected from the CSOs:

- Baseline whole water
- Baseline lab filtered
- Discharge whole water
- Discharge lab filtered

A baseline sample was collected at the start of rain. Baseline samples were not collected from the RH-034 location due to space and access limitations. A discharge sample was collected after the CSOs began to overflow and was composited in intervals representing conditions over the duration of the storm event. Unfiltered CSO discharge water (storm water with suspended particulates) and filtered CSO discharge water (storm water that was passed through a 1.2 micrometer (µm) filter in the laboratory to remove settleable solids) were submitted for both baseline and discharge samples. Filtered and unfiltered samples were collected simultaneously. A description of sample collection including sample IDs, sample type, times collected, and CSO overflow times are included in Table 1.

Sample volume was limited in some cases due to storm duration and flow patterns. Priority of analysis was assigned to samples with limited volume in the following order:

Contaminants:

1. Polycyclic Aromatic Hydrocarbon (PAH) 34 list
2. Total Petroleum Hydrocarbon (TPH)
3. Metals
4. Semivolatile Organic Compounds (SVOCs) and Volatile Organic Compounds (VOCs)
5. Polychlorinated Biphenyls (PCBs)
6. Pesticides and herbicides
7. Pathogens, Endocrine Disrupting Compounds (EDCs), Pharmaceutical and Personal Care Products (PPCPs)

Conventional parameters – aqueous samples

1. Total Suspended Solids (TSS), Total Dissolved Solids (TDS), Suspended Sediment Concentration (SSC), turbidity
2. Total Organic Carbon (TOC), Dissolved Organic Carbon (DOC)
3. Hardness, pH, conductivity, free cyanide, ammonia

3. Analytical Regime

Table 2 summarizes the complete list of analytical parameters applied to each water sample. The analytical results are presented in Tables 3 and 4.

MH-RH-035E	Grab	2:10	
MH-RH-035F	Grab	2:25	
MH-RH-035G	Grab	2:40	
MH-RH-035H	Grab	2:55	
MH-RH-035I	Grab	3:10	
MH-RH-035J	Grab	3:40	
MH-RH-035K	Grab	4:10	
MH-OH-007-LFB4	Baseline	1:00 - 1:40	2:30 - Still flowing at completion of sample collection
MH-OH-007-WWB4			
MH-OH-007-LFD4	Discharge	2:30, 3:30, 4:30, 5:30	
MH-OH-007-WWD4			
MH-OH-007A	Grab	2:30	
MH-OH-007B	Grab	2:45	
MH-OH-007C	Grab	3:00	
MH-OH-007D	Grab	3:15	
MH-OH-007E	Grab	3:30	
MH-OH-007F	Grab	3:45	
MH-OH-007G	Grab	4:00	
MH-OH-007H	Grab	4:15	
MH-OH-007I	Grab	4:30	
MH-OH-007J	Grab	5:00	
MH-OH-007K	Grab	5:30	
MH-OH-007L	Grab	6:00	
MH-RH-034-LFD4	Discharge	Programmed to collect 2.5 L every hour	Trigger set to collect sample when both of the following conditions are met: 1. water rises above the weir 2. tide gate is open
MH-RH-034-WWD4			
WTP-OH-LFD4	Discharge	2:40, 3:40, 4:40, 5:40	Collection start time based on overflow at OH-007
WTP-OH-WWD4			
WTP-RH-LFD4	Discharge	2:45, 3:45, 4:45, 5:45	Collection start time begins 2 hours after the beginning of the rain event
WTP-RH-WWD4			

Notes:
* Sample was collected after rainfall began, but before overflow conditions were observed.
L - Liter

Table 2
CSO Water Target Analytes
Gowanus Canal
Brooklyn, New York

Conventional Parameters	EDC/PPCP *
Total Suspended Solids (TSS)	Bisphenol A
Total Dissolved Solids (TDS)	Nonylphenol
Suspended Sediment Concentration (SSC) Turbidity	Nonylphenol Diethoxylate
Total Organic Carbon (TOC)	Nonylphenol Monoethoxylate
pH Hardness Conductivity Free Cyanide Ammonia	4-tert-Octylphenol
Total Organic Carbon (TOC)	Acetominophen alpha-Estradiol
Dissolved organic carbon (DOC	Androstenedione
	Atrazine
Organics	Bisphenol A
Volatile Organic Compounds (VOCs)	Caffeine
Semivolatile Organic Compounds (SVOCs)	Carbamazepine
Total Petroleum Hydrocarbons (TPH)	Diazepam
PAH Fingerprint Analysis	Diclofenac
Pesticides/Herbicides	Diethylstilbestro
Total PCBs	l Phenytoin
PCB Congeners	Estradiol
	Estriol
Pathogens	Estrone
Clostridium perfringens	Ethinyl
Coliphages Enterococcus	Estradiol
Fecal coliforms	Fluoxetine
E. coli	Gemfibrozil
Enteroviruses Giardia	Hydrocodone
Cryptosporidium	Ibuprofen
	Iopromide
Metals, Total and Dissolved	Meprobamate
Antimony (Sb)	Methadone
Arsenic (As)	Naproxen
Barium (Ba)	DEET
Beryllium (Be)	Oxybenzone
Cadmium (Cd)	Pentoxifylline
Chromium (Cr)	Progesterone
Cobalt (Co)	Salicylic Acid
Copper (Cu)	Sulfamethoxazole
Lead (Pb)	Testosterone
Mercury (Hg)	Triclosan
Molybdenum (Mo)	Trimethoprim
Nickel (Ni)	
Selenium (Se)	
Thallium (Tl)	
Vanadium (V)	
Zinc (Zn)	

*EDC = endocrine disrupting compounds

PPCP = pharmaceutical and personal care products

Table 3
Summary of Storm Water Analytical Results
Gowanus Canal
Brooklyn, New York

Notes:
Analytes in blue are not detected in any sample
ntu - nephelometric turbidity units
oocyst/L - oocyst per liter
pfu/mL - plaque forming units per 1 milliliter
S.U. - standard units
umhos/cm - micromhos per centimeter

BTEX - benzene, toluene, ethylbenzene, and xylenes
VOCs - volatile organic compounds
PAHs - polycyclic aromatic hydrocarbons
PCBs - polychlorinated biphenyls
SVOCs - semivolatile organic compounds
EDCs - endocrine disruptor compounds
PPCPs - pharmaceuticals and personal care products

Total BTEX, Total VOCs, Total PAHs, Total SVOCs, and Total PCBs are calculated using detects only.
Total PAH16 is calculated using the EPA16 list of analytes: Acenaphthene, Acenaphthylene, Anthracene, Benz[a]anthracene, Benzo[a]pyrene, Benzo[b]fluoranthene, Benzo[g,h,i]perylene, Benzo[k]fluoranthene, Chrysene, Dibenz[a,h]anthracene, Fluoranthene, Fluorene, Indeno[1,2,3-cd]pyrene, Naphthalene, Phenanthrene, and Pyrene
Total PAH17 is calculated using the EPA16 list of analytes plus 2-Methylnaphthalene

NE - not established
NA - not analyzed
ND - not detected; total concentration is listed as ND because no compounds were detected in the group

Bolding indicates a detected concentration
Gray shading indicates that the detected result value exceeds NYS AWQS

Validation Qualifiers:
J - estimated value
R - rejected
U - indicates not detected to the reporting limit
UJ - not detected at or above the reporting limit shown and the reporting limit is estimated

Validated

Executive Summary

GEI Consultants, Inc. (GEI) was retained by National Grid to conduct a geotechnical investigation along the Gowanus Canal in support of a United States Environmental Protection Agency (USEPA) proposed remedial design that may include dredging and/or capping of impacted sediments within the Canal. The environmental impacts detected within the Canal sediments have been identified as a complex mixture of petrogenic and pyrogenic hydrocarbons, as well as heavy metals, pesticides, herbicides, polychlorinated biphenyls (PCBs) and other types of chemicals.

The purpose of this initial investigation was to obtain geotechnical strength parameters of the native sediments to gain a better understanding of the sediments' bearing and shear load capacities in addition to the sediments' compressibility characteristics along the Canal. Findings from this investigation will be used to guide future design investigations.

This geotechnical investigation included performing 19 cone penetration tests (CPTUs), 5 test borings, and a laboratory testing program that included geotechnical index testing (grain size distribution, unit weight, specific gravity, moisture content, organic content, and Atterberg limits), unconsolidated-undrained compression (UUC) and isotropically-consolidated undrained compression (CIUC) strength testing, and incremental consolidation testing. In addition, bulk sediments samples were collected with the intention of conducting Dredging Elutriate Testing (DRET); however, this part of the program was deferred to a later date.

In addition to the Standard Penetration Tests (SPTs) and CPTU field tests, nine sediments samples were retained and evaluated for sediment engineering properties from the five test borings that were performed within the Canal. Samples were collected within the upper 15 feet of soil deposits below the mudline of the Canal.

Based on the results of the SPT, CPTU, and geotechnical laboratory testing programs, sediments within the upper 3 to 12 feet of soil deposits below the mudline of the Canal were characterized as accumulated or "soft" sediments. The soft sediments are collectively described as a mixture of mainly grayish-black soft organic silt (OH) with varying amounts of loose inorganic silty clay (CL-ML) with some areas of intermixed gravel present in thin deposits. In general, only slight to moderate "organic-like" and/or petroleum-like odors were evident in these shallow sediments with very few obvious visual signs of tar impacts.

The SPT results (N-values) recorded in the soft sediment layer ranged from Weight-of-Hammer (WOH) to 3 blows per foot. Undrained shear strengths (S_u) within the organic layer (OH) ranged from less than 65 pounds per square foot (psf) for UUC tests to less than 530 psf for the CIUC tests. Medium dense silty clay (CL-ML) yielded S_u values of 2,370 psf for

the UUC test. A thin sand layer (SM) was observed in one boring a foot below the mudline and a CIUC test on this layer yielded a S_u value of 16,490 psf.

The compressive properties of the shallow sediments yielded a relatively low compression index (C_c) given the range of organic sediments present. The C_c for the OH materials ranged from 0.6 to 1.0 and only 0.1 for the CL-ML materials for sediments tested within the upper 3 feet. Based on the estimated pre-consolidation stresses, it appears that these shallow soft sediments are over consolidated.

Underlying the soft sediments layer, a mixture of alluvial sandy-silt and some organic silt deposits or "native" sediments were generally encountered within all the borings performed in the Canal. The native sediments layer consisted mainly of loose to medium dense widely graded sand with silt (SW-SM); and the intermixed organic silt (OL-OH) deposit was described as a soft, black, organic silt with tar present.

SPT N-values for the native sediments from 5 to 15 feet ranged from 5 to 14 blows per foot. Visual and olfactory inspection of these soils indicated mild to strong petroleum odors and signs of tar impacts present at various intervals to a depth of approximately 24 feet. Undrained shear strengths of the soft organic soils yielded S_u of less than 85 psf for UUC tests and less than 270 psf for the CICU test.

1. Introduction

1.1 Scope and Purpose of the Investigation

The Gowanus Canal sediments contain or have been impacted by non-aqueous phase liquids (NAPLs) that are a complex hydrocarbon mixture including polycyclic aromatic hydrocarbons (PAHs). The NAPL contains petrogenic and pyrogenic hydrocarbons, as well as other types of chemicals. The oil refineries, petrochemical plants, Manufactured Gas Plant (MGP) facilities, fertilizer and glue factories, coal yards, and other industrial and urban discharges along the Canal are all potential sources of NAPL. These industrial land uses and discharges have likely contributed petroleum, heavy metals, pesticides, herbicides, polychlorinated biphenyls (PCBs) and/or other chemicals to the sediments. Many of these compounds are the same as or difficult to distinguish from compounds also associated with former MGP operations.

In support of the development of a remedial design focused on an effective, sustainable remedy, with overall containment for all sources of contaminants present in the Gowanus Canal, a number of investigative efforts are planned under the general categories as follows:

- Cap stability and components
- In-situ solidification
- Upland and underlying sediments loading (hydraulic and chemical)
- Hydrodynamic modeling

On behalf of National Grid, GEI Consultants, Inc. (GEI) has prepared this Data Report to present the findings from an initial geotechnical investigation conducted to support the design of a cap in the Gowanus Canal. This report provides laboratory data and field observations collected during the field investigation conducted by National Grid. This Data Report documents the investigation methods, findings, and results from the sediments investigation.

The general scope of the investigation was to obtain geotechnical strength parameters of the native sediments to gain a better understanding of the sediments' bearing and shear load capacities in addition to the sediments' compressibility characteristics along the Canal. Findings from this investigation will be used to guide future design investigations.

This investigation was performed with the intent of providing supplemental data in support of the United States Environmental Protection Agency's (USEPA) draft Feasibility Study (FS) with specific regards to an evaluation of cap stability and dredge design for the Gowanus Canal. USEPA has outlined a potential remedy for the Canal that included dredging of soft sediments and placement of a protective cap over the subgrade (native

sediments). This investigation focused on developing preliminary engineering properties of the soft and native sediments to evaluate the feasibility of related elements of the approach and consider alternatives to the USEPA approach. One alternative would be the placement of a cap on or some depth into the soft sediments rather than fully dredging to the native sediments for cap placement.

The scope of this investigation included the installation of 19 cone penetrometer tests (CPTUs) that provided continuous resistance profiles through the sediments at various locations within the Canal. Cone Penetrometer Test (CPT) data includes typical cone plots, in addition to 10 pore water dissipation tests, interpretation of soil behavior types (SBT) classifications, as well as interpretations of geotechnical parameters based on published CPT correlations[1]. In addition, five test borings were performed using a sonic drill rig that had the capability of performing Standard Penetration Tests (SPTs) as well as collecting standard Shelby tube samples for laboratory analyses. Subsurface exploration data are summarized in Table 1

The laboratory testing program included geotechnical index testing (grain size distribution, unit weight, specific gravity, moisture content, organic content, and Atterberg limits), unconsolidated-undrained compression (UUC) and isotropically-consolidated undrained compression (CIUC) strength testing, and incremental consolidation testing. Geotechnical laboratory testing data are summarized in Table 2.

1.2 Air Monitoring

Work zone air monitoring was implemented during the sampling activities in accordance with the Geotechnical Investigation Work Plan for Cap Design, dated April 24, 2012. Concentrations of volatile organic compounds (VOCs), hydrogen cyanide, hydrogen sulfide, combustible gas, oxygen, and particulate matter less than 10 microns in size (PM-10) were monitored in accordance with the Health and Safety Plan (HASP).

There were no exceedances of the particulate matter action level related to sampling activities. Measured exceedances that occurred throughout the work were considered due to exhaust fumes from the boat engine or spud movement. There was no visible dust observed in the work area. There were no exceedances of VOCs, hydrogen cyanide, hydrogen sulfide, combustible gas, or oxygen action levels related to sampling activities. Exceedances of hydrogen cyanide and VOCs action levels that occurred throughout the work were considered due to exhaust fumes from the boat engine and spud movement.

[1] CPT correlations are subject to change to reflect the current state of practice. The interpreted values are not considered valid for all soil types. The interpretations are presented only as a guide for geotechnical use and should be carefully scrutinized for consideration in any geotechnical design.

High temperatures and humidity potentially interfered with the instruments creating false elevated readings. Odors were not observed in the work area.

1.3 Exploration Locations and Canal Access

The Gowanus Canal is located in an industrial section of South Brooklyn, New York. It roughly includes 2 miles of man-made canal that extends from Butler Street to the southwest past the Gowanus Expressway and into the Gowanus Bay. Several barge basins are connected to the main channel at the eastern side of the canal at 7th Street, 6th Street, 5th, and 4th Streets. The study area encompasses the entire main Canal; excluding the barge basins. The explorations for this initial geotechnical investigation were spaced approximately 400 feet apart from each other. Figure 1 summarizes the study area and the specific locations of the CPTUs and test borings.

Notification to the US Coast Guard to gain access to the Canal was made by Millers Launch, the local barge contractor hired by the driller.

1.4 Limitations

The engineering review, associated data collection, and preparation of documents related to this report have been performed in accordance with the standard of care commonly used as the state-of-practice in the engineering profession. Standard of care is defined as the ordinary diligence exercised by fellow practitioners in the profession performing the same services under similar circumstances during the same period.

The geotechnical information presented in this report is based on a limited number of explorations and tests performed by GEI. Subsurface conditions and material properties presented in this report may vary significantly between borings and locations. The nature and extent of the variations may not become evident until subsequent phases of investigation or future construction. Therefore, this study may not have revealed all adverse conditions present at the Site.

Our work was performed in accordance with generally accepted engineering practices. No warranty, expressed or implied, is made that the actual encountered subsurface and site conditions will conform exactly to the conditions described herein, or that this report's interpretations will be applicable to, or sufficient for, all future work planned at the subject site. GEI does not attest to the accuracy, completeness, or reliability of geotechnical borings and other subsurface data by others that are included in this report. GEI did not perform independent validation or verification of data provided by others.

This report was prepared for use by and the benefit of National Grid. Use by any other party is at its own discretion and risk.

2. Sediments Exploration

2.1 Piezocone Penetrometer Testing (CPTU)

This section presents the results of a CPTU exploration program carried out on the Canal. The work was performed by ConeTec, Inc. of West Berlin, New Jersey under contract with GEI. ConeTec performed CPTUs between August 21 and August 29, 2012.

A total of 19 CPTU soundings were completed at 19 different locations as depicted in Figure 1. The CPTU testing was performed to evaluate in-situ geotechnical criteria of the soils. The CPTUs ranged in depth from 25 to 35 feet below the mudline (with an average depth of 27 feet). The CPTU logs are provided in Appendix A.

In addition, flow penetrometer testing (BCPT) soundings were completed at 10 of the 19 CPTU locations. BCPT soundings were performed to evaluate undrained shear strengths of the soft to medium strength sediments where the CPTU soundings were not sufficiently accurate to assess the lower soil strengths of those layers. CPTU sounding locations were selected and numbered under the direction and supervision of GEI personnel.

The specific procedures for the CPTU soundings, BCPT soundings, and method of evaluation of the in-situ geotechnical properties are described in ConeTec's Field Report, dated October 3, 2012, which is included in Appendix A of this Data Report.

The CPTU sounding method provides continuous interpretive information about soil types and relative strengths; the test consists of advancing (or pushing) a steel cone penetrometer into the ground using a small mini-sonic rig. The tip of the cone is equipped with sensors that collect information about the tip and sleeve friction resistance encountered in the soil as the probe is advanced. This information can then be used to classify the strata using empirical correlations. The interpreted logs are also included in Appendix A and the CPT locations are shown in Figure 1.

Interpretation of sediments/soils encountered on the project was carried out using correlations developed by Robertson (1992). Interpretations of cone data is based on the relationship between tip resistance (qc), sleeve friction (fs), penetration resistance, and high friction pore water measurements (u). Generally, saturated cohesive soils (clays and slits) have low tip ratios and generate large excess pore water pressures. Cohesionless soils (sands

and gravel) have higher tip resistances, lower friction ratios, and do not generate significant excess pore water pressure.[2]

Based on the normalized CPTU graphs prepared by ConeTec, classifications of certain soil types were estimated using charts that plot ranges of normalized cone resistance versus friction ratio. These charts are referred to as "Normalized Behavior Type Classifications" and are used to identify the stratigraphy at the test sounding locations.

The CPTU interpretations generally identified a mixture of soft alluvial silt/sand sediments deposit within the upper 2 to 12.5 feet. The soundings also showed a relatively distinct transition to a mixture of coarser medium-dense sand below the finer grained softer sediments layer. This transition was observed at almost all the CPTU locations with the only exception being GC-CPT-015, which appeared to represent a more continuous silty soft material all the way to the bottom of the CPTU sounding (approximately 30 feet below the mudline).

The CPTU interpretations identified that the soft sediments layer was found to be thicker (up to 12.5 feet thick) near the head of the Canal and appears to thin out to less than 6 feet thick towards the southern end of Remediation Target Area (RTA) 2 and the mouth of the Canal (RTA 3). The average soft sediment thickness found in the CPTU's was 6.3 feet. Based on an estimation of the over consolidation ratio (OCR), it appears that a majority of the shallow sediments along the northern portion of the Canal appear to be over consolidated. This indicates that the shallow sediments may have experienced a greater load at some time in the past and possibly have been historically dredged. However, CPTU sounding GC-CPT-018 indicated a deeper compressible (under consolidated) organic layer at a depth of 11 to 18 feet below the mudline.

Undrained shear strengths (S_u) were estimated using BCPT sounding methods at 10 of the CPTU sounding locations. The BCPT soundings were mainly performed within the upper 10 to 15 feet of the soft sediments. Based on the BCPT sounding interpretations, undrained shear strengths within the upper 2 to 5 feet of the sediments were estimated to be relatively weak at S_u values between 41 to 125 pounds per square foot (psf). Table 3 summarizes the estimated S_u at these shallow depths, and the complete BCPT soundings are presented in Appendix A.

[2] Interpretations of soil types from CPTU data is entirely performed by ConeTec, Inc., and any explanations of the technical methods used by ConeTec are presented in the text for convenience to the reader only. A copy of the complete CPTU Data Report is included in Appendix A.

2.2 Test Borings

Five Test borings were performed using roto-sonic drilling methods. The boring logs are included in Appendix B and the boring locations are shown in Figure 1.

The borings were performed by Boart Longyear of Northborough, Massachusetts. Boart Longyear, in turn, contracted directly with Miller's Launch of Staten Island, New York whom facilitated access to the Canal and provided the barge for the drilling work. The borings were performed using roto-sonic drilling methods with SPT performed at approximately 5-foot intervals. The borings were drilled between August 14 and August 20, 2012 using a track-mounted mini-sonic LS600 drill rig that was barge-mounted. The borings were drilled to depths ranging from 25 to 35 feet below the existing mudline. Water depth ranged from 7.5 feet to about 18 feet at the time of drilling. The total drilled length was approximately 137 feet.

Undisturbed Shelby tubes were collected with a hydraulically-activated piston sampler in the soft sediments at four of the five test boring locations and retained for laboratory strength and consolidation analyses. At GC-B-003, sediment deposits that were conducive for undisturbed sampling were not encountered. A total of 17 Shelby tubes were pushed in the soft and native sediments deposits with 9 of those tubes having limited or no sample recovery. There were eight undisturbed tube samples collected that retained enough soil for further laboratory strength and consolidation analyses, of which seven were actually submitted for testing. These eight tubes were collected at depth intervals of 0 to 2, 2 to 4, 10 to 12, and 15 to 17 feet below the mudline.

A photoionization detector (PID) was used to screen the levels of VOCs present along the length of each sample. Jar headspace analyses were performed on 5-foot intervals at each boring location. A GEI field representative was on site full time to observe and document the borings and to collect the samples.

After each boring was completed, Boart Longyear tremie grouted the boreholes with a grout mixture suitable for saltwater. The mixture is intended to prevent platelet flocculation and was mixed in the following proportions: 1 pint LIQUI-TROL™, 16 pounds ZEOGEL®, 5 pounds powdered bentonite, and 40 gallons potable water. A 4.5-inch casing was used to advance the borehole, which was extracted at completion. A GEI field representative observed the grouting of all boreholes.

2.3 Laboratory Testing Program

Representative soil samples were selected and tested in the laboratory to substantiate visual classifications and to aid in the determination of pertinent engineering properties. The laboratory testing program included:

- Natural Moisture Content Tests (American Society of Testing and Materials [ASTM] D2216)
- Organic Content Tests (ASTM D2974)
- Grain Size Distribution Tests (ASTM D422)
- Unit Weight Tests (ASTM D7263)
- Atterberg Limits Tests (ASTM D4318)
- UUC Triaxial Tests (ASTM D2850)
- CIUC Triaxial Tests (with pore water pressures) (ASTM D4767)
- One-Dimensional Consolidation Tests (ASTM D-2435)

The laboratory testing results are included in Appendix C of this report and a summary table of results are presented in Table 2.

Select sediment samples from the Gowanus Canal were also submitted to the University of Texas at Austin for geotechnical testing to evaluate the potential for NAPL expression. The sediment samples selected for analysis were at intervals that may be exposed during dredging activities. The samples were limited due to the difficulty of collecting undisturbed tube samples and were selected based on potential NAPL presence (based upon field PID readings) and from locations near the interface of the soft and native sediments. A summary of the NAPL expression testing prepared by Dr. Danny Reible of the University of Texas is provided in Appendix D.

An experienced GEI engineer visually classified each soil sample on the basis of texture and plasticity (ASTM D2488) and identified each soil sample using the classification group symbols and names in general accordance with the Unified Soil Classification System (USCS) (ASTM D2487). A brief explanation of the USCS is included with this report in Appendix B.

3. Sediments Stratigraphy and Characteristics

3.1 Sediments Stratigraphy

The subsurface soil conditions encountered in the explorations performed by GEI were similar to the expected conditions based on our review of previous investigations conducted by the USEPA. In general, two distinct soil units with inter-bedding organic marsh deposits are identified within the Canal that are relevant to the dredge and cap system design. These two stratums are[3] accumulated or "soft" sediments and alluvial/sand deposits or "native" sediments and are further described in the paragraphs below.

Soft Sediments – Soft sediments are the soils present at the sediments-water interface (mudline) within the Canal that appears to range in thickness from about 2 to possibly 12.5 feet. A clear interface between the soft and native sediments was difficult to estimate due to the intermixed deposits of sands, silts, and clays, with deposits of organics present at various depth intervals. In general, soft sediments were described as consisting of a mixture of grayish-black, soft organic silt (OH), intermixed with leaves, roots, wood, and other debris with varying amounts of inorganic silty clay (CL-ML) with some gravel also intermixed.

Mild to strong "organic-like" and petroleum odors were evident in most of the recovered samples, but few obvious visual NAPL impacts were observed. The SPT results (N-values) recorded within this layer ranged from Weight-of-Hammer (WOH) to 3 blows per foot. A rough estimation of the soft sediments thickness is presented on the cross sections in Figures 2 through 4.

Native Sediments – underlying the soft sediments layer, a mixture of alluvial/sand and lenses of lean clay and silt was generally encountered within all the borings performed in the Canal. The native sediments typically consisted of tan fine to coarse widely graded sand with silt (SW-SM), and were generally loose with N-values ranging from 5 to 14 blows per foot. Mild to strong petroleum odors were observed in all five borings ranging in depths from 16 to 25 feet below the mudline. Visual impacts were also observed within all soil borings mainly ranging from petroleum sheen/staining, tar coating, and some thin zones of tar saturation. A depth profile and locations of the visual impacts observed within the borings are presented on the cross sections in Figures 2 through 4.

[3] The subsurface conditions are known only at the exploration locations. The subsurface conditions between exploration locations may differ from those described below and/or depicted in the subsurface profiles.

3.2 Estimated Sediments Engineering Properties

Laboratory strength and consolidation testing was performed on shallow and deeper sediments to gain a general understanding of engineering properties of the sediments within the Gowanus Canal.

A total of seven undisturbed Shelby tube samples and six disturbed jar samples were retained for laboratory testing from the five test borings that were performed within the Canal. The testing program focused on characterization of sediments from 0 to 15 feet below the mudline.

Upper 3 feet of Soft Sediments

Based on the laboratory results, shallow sediments (0 to 3 feet) consisted mainly of a mixture of organic and inorganic silts (OL-OH), silty sands (SM), and silty clays (CL-ML); the presence of gravel was also observed within boring GC-B-003. In general, these shallow sediments are characterized as soft highly plastic active[4] silts, which is typical for this type of deposit. No visual signs of NAPL impacts were observed within these shallow soils.

UUC tests indicate that the organic sediments are relatively weak with shear strengths ranging between 30 to 65 psf. The CIUC tests on these organic silts indicated shear strength ranging from 160 to 530 psf using a 250 psf confining pressure.

Test results on the silty clay material indicated higher strengths than the organic sediments. A UUC test performed on the silty clay material indicates undrained shear strength of 2,370 psf.

A CIUC test performed on the silty sand material in GC-B-004 yielded undrained shear strength of 16,490 psf using a 250 psf confining pressure, with an estimate effective friction angle of 37.7 degrees.

Consolidation tests performed on the OH taken from the upper 3 feet resulted in a Compression Index (C_c) that ranged between 0.64 and 1.00, which is relatively low[5] for this type of material. Void ratios ranged between 2.02 and 2.96. Based on an estimation of the pre-consolidated stress, sediments in this area appear to be over consolidated (OCR > 1). This estimation of the OCR on the shallow sediments was also estimated within the CPTU testing program (see Section 2.1.1).

[4] Skempton (1953) defined the activity of clays as the plasticity index divided by the clay fraction of specimen finer than 0.002 mm. (Das 1999, Principals of Foundation Engineering, Fourth Edition)
[5] Typical values of C_c presented by Holtz and Kovacs (1981) as presented in Table 9-7 FHWA (1997).

Native Sediments and Soft Sediments between 5 and 15 feet

Soil deposits between the 5- and 15-foot-depth range appear to be a transitional zone of the soft sediments to the native sediments layer. In general, the sandy silt layer was found within four of the five test borings and began at about 5 to 6 feet beneath the mudline.

At GC-B-005, the OH layers (soft sediments layer) appear to extent to about 15 feet. Tar impact and distinct petroleum-like odor and sheens were reported within all borings at this depth interval, with the only exception being GC-B-005, where no impacts or odors were observed until below 15 feet.

Strength testing was performed for the OH material (at GC-B-005) at depths of 10.95 and 11.45 feet deep. A UUC test indicates that the OH material is relatively weak with shear strengths estimated at only 85 psf. A CIUC test performed on the OH material yielded undrained shear strength of 270 psf using a 500 psf confining pressure. An effective friction angle of 31.3 degrees was estimated based on one sample tested[6].

Although no laboratory strength or consolidation tests were performed for the SM-SW material, geotechnical index properties can be estimated based on SPT N-values. Based on N-values between 5 and 14 blows per foot, a wet unit weight of approximately 106 to 116 pound per cubic foot (pcf), an effective friction angle of between 27 and 32 degrees can be assumed[7].

[6] a strength envelope was not developed to more accurately determine a friction angle or cohesion (c) for this material

Notes:

1 - Italics indicate that mutliple tests were performed from one sample interval and that the values have been averaged.

2 - Organic Content determined by burning off the organic matter in the soil sample and recording the change in soil matter after this process.

3 - Silt particle size is defined as between 0.074 and 0.002 mm; Clay particle size is smaller than 0.002 mm. If only silt value shown then this indicates percent fines.

4 - Type of Strength Test: (see Appendix C for stress-strain plots and detailed testing information)
UUC = Unconsolidated, undrained triaxial compression
CIUC = Consolidated isotropically, undrained triaxial compression (with pore pressure measurements)

5 - Consolidation test performed. See Appendix C for compression curves and detailed testing information.

1.0 INTRODUCTION

This report presents the results of a piezocone penetrometer testing (CPTU) and flow penetrometer testing (BCPT) programs carried out on the Gowanus Canal Site located in Brooklyn, New York. The work was performed under subcontract to GEI Consultants of Glastonbury, Connecticut. The CPTU & BCPT programs took place from August 21st through August 28th, 2012.

A total of nineteen CPTU soundings were completed at nineteen different sounding locations. The CPT testing was performed to evaluate insitu geotechnical criteria of the soils.

A total of ten BCPT soundings were completed at ten of the above CPTU locations. BCPT soundings were performed to evaluate the undrained shear strengths of the soil.

CPT sounding locations were selected and numbered under the direction and supervision of GEI personnel.

2.0 FIELD EQUIPMENT AND PROCEDURES

2.1 CONE PENETRATION TESTING

The cone penetrometer tests were carried out using an integrated electronic piezocone manufactured by ConeTec in Vancouver, Canada. The piezocone used for the CPTu's was a compression model cone penetrometer with a 15 cm^2 tip and a 225 cm^2 friction sleeve. The cone is designed with an equal end area friction sleeve and a tip end area ratio of 0.80. The piezocone dimensions and the operating procedure were in accordance with ASTM Standard D-5778-07. A diagram of the cone penetrometer used for this project is shown as Figure 1.

Pore pressure filter elements, made of porous plastic, were saturated under a vacuum using silicone as the saturating fluid. The pore pressure element was six millimeters thick and was located immediately behind the tip (the u_2 location) for all soundings.

The cone was advanced using Boart Longyear's Drill Rig mounted on a spud barge. The following data were recorded onto magnetic media every five centimeters (approximately every two inches) as the cone was advanced into the ground:

- Tip Resistance (qc)
- Sleeve Friction (fs)
- Dynamic Pore Pressure (u_t)

Before each sounding a complete set of analog baseline readings are taken with a multi-meter and compared with the digitized value on the computer screen. This provides a check on the analog to digital conversion board.

Evaluation of the analog baselines is key to consistent readings. The baseline data should be stable and should not wander excessively during the course of a sounding. Baseline data can be used to apply corrections to the cone data where necessary. For this project, the baseline shift from sounding to sounding was small, typically less than 0.1% of full scale, and no data corrections were applied.

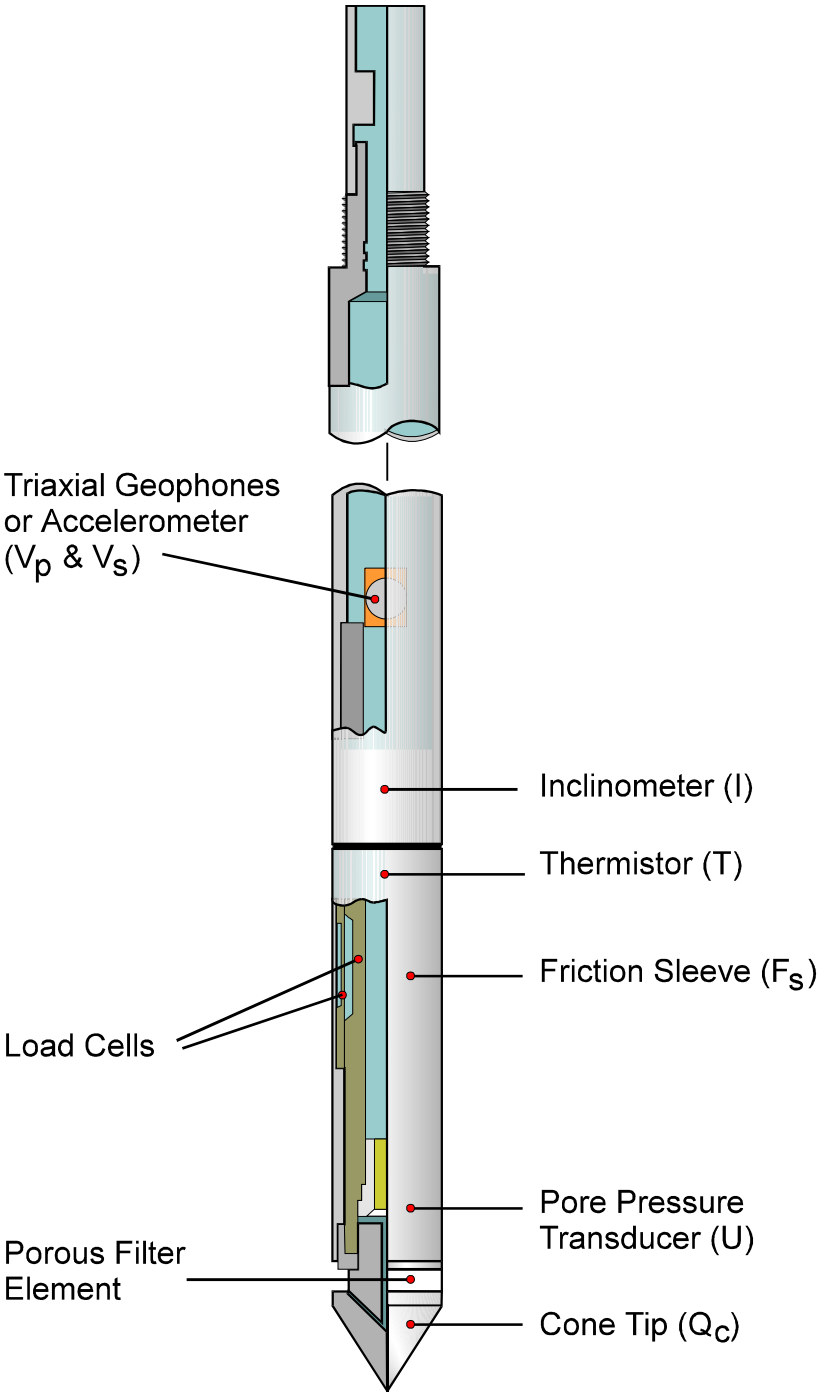

FIGURE 1 - TYPICAL CONE PENETROMETER

2.2 PORE PRESSURE DISSIPATION TESTS

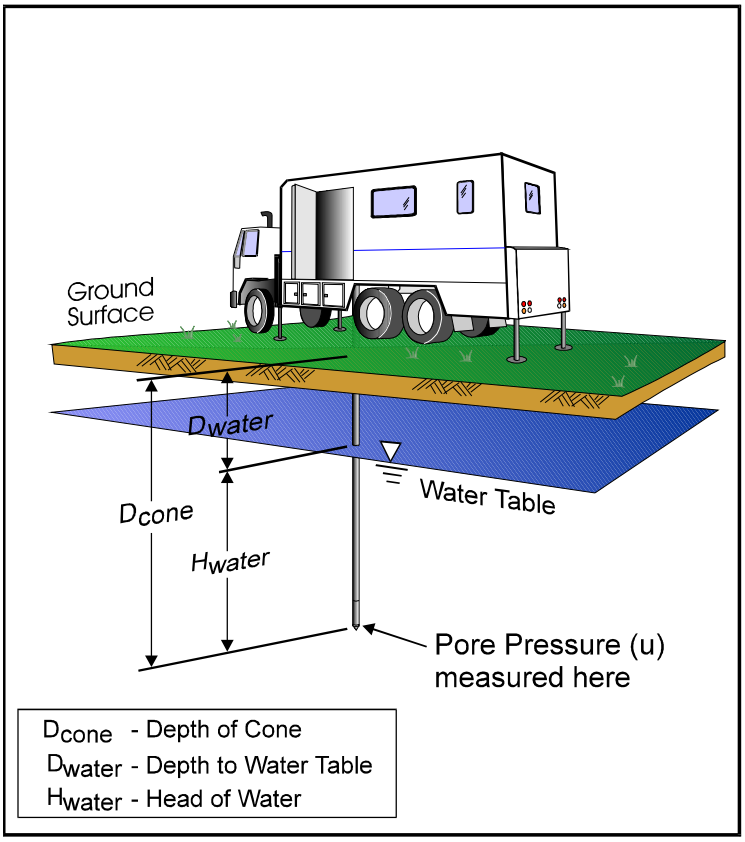
When cone penetration is stopped, the piezocone essentially becomes a piezometer. While stopped, pore water pressures are automatically recorded at five-second intervals and the readings are stored in a dissipation file (.ppd). Dissipation data can then be plotted onto a dissipation curve consisting of pore water pressure (u) verses time (t). The shapes of dissipation curves are very useful in evaluating soil type, drainage and in situ static water level.

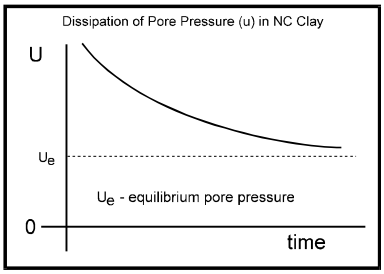
A flat curve that stabilizes quickly (i.e. less than 30 seconds) is typical of a free draining sand. In this case, the final measured pore water pressure is the static in situ water pressure.

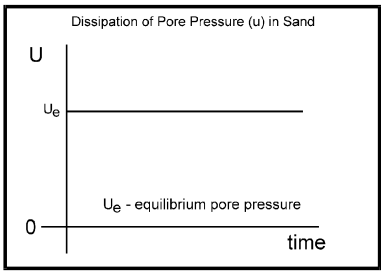
Soils that generate excess dynamic pore water pressure during penetration will dissipate this excess pressure when penetration stops. The shape of the dissipation curve and the time of dissipation can be used to estimate C_h, the coefficient of consolidation that can in turn be used to calculate K_h, the horizontal permeability.

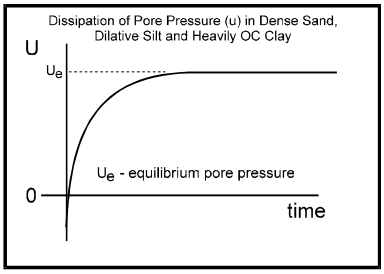
Figure 2 shows some idealized shapes of various pore water pressure dissipation curves. The reader is referred Robertson et. al., 1990 to reference dissipation test data analytical techniques.

Estimation of Ground Water Table from CPT Dissipation Tests









Water Table Calculation

$$D_{water} = D_{cone} - H_{water}$$

where $H_{water} = U_e$ (depth units)

Useful Conversion Factors: 1psi = 0.704m = 2.31 feet (water)
1tsf = 0.958 bar = 13.9 psi
1m = 3.28 feet

FIGURE 2 - TYPICAL DISSIPATION TESTS

2.3 FLOW PENETROMETER PROCEDURES

Full flow penetrometer testing is used for assessing the undrained shear strength (S_u) of low to medium strength soils. The test incorporates a standard cone penetrometer body (typically 10 cm^2 plan area) and a spherical attachment that replaces the standard 60 degree conical tip, as shown in Figure 4.

During penetration soil is able to flow around the penetrometer, significantly reducing the influence of overburden stress as compared to the cone penetration test (CPT). The undrained shear strength derived from the full flow penetration test is related to the net penetration resistance using the following relationship:

$$S_u = q_{net} / N \quad \text{where N typically varies between 10.0 and 11.0}$$

Although the N factor is generally considered to be unique across soil deposits, experience has shown that some minor variation does exist. However this variation is generally less compared to the N_{kt} factor for the standard CPT. Data is recorded continuously and the test is performed in the same manner as the CPT. Because of the subdued sleeve and pore pressure response full flow penetration test results are not used for the interpretation of other geotechnical parameters or for soil classification. The test may be interrupted at selected depths to cycle the probe up and down to in order to achieve a completely remolded soil state to provide an indication of sensitivity in soft soils. For the calculations to be valid, full flow of soil around the probe must be assumed.

A standard 10 ton, 10 cm^2 cone penetrometer body was used with a spherical attachment resulting in a projected area of (A_b) 60 cm^2.

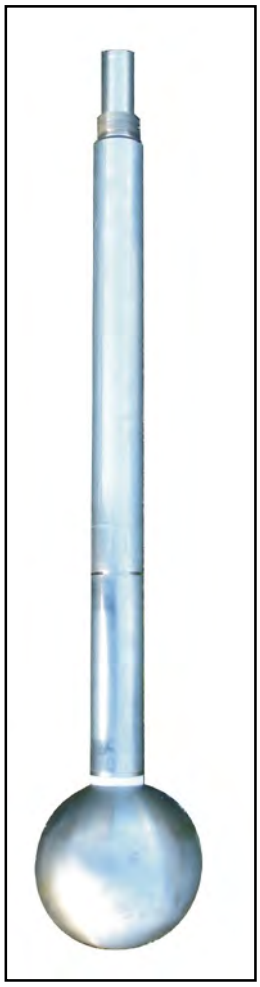


FIGURE 3 - TYPICAL FLOW PENETROMETER

2.4 FLOW PENETROMETER RESULTS

Continuous and cycling profiles of undrained shear strength (Su) from the ball penetrometer tests for this project are presented in Appendix D. The unit weights used for calculating the undrained shear strength were based on assigned unit weights from SBT zones of the adjacent CPT soundings. The plots presented shows the initial ball penetration, cycling and undrained shear strength results from the vane tests. Cycling data allows for an easy comparison of the initial strength to the residual or post peak strength, and finally to the completely remolded strength of the soil.

3.0 CONE PENETRATION TEST DATA AND INTERPRETATION

3.1 ANALYSIS OF PIEZOCONE DATA - GENERAL

A total of nineteen CPT & BCPT soundings, involving 806.26 feet of testing, were completed.

The interpretation of cone data is based on the relationship between cone bearing, qc, sleeve friction, fs, and penetration resistance, high friction pore water pressure, u. The friction ratio, Rf , (sleeve friction divided by cone bearing) is a calculated parameter which is used to infer soil behavior type. Generally, saturated cohesive soils have low tip ratios and generate large excess pore water pressures. Cohesionless soils have higher tip resistances, lower friction ratios and do not generate significant excess pore water pressure.

The interpretation of soils encountered on this project was carried out using correlations developed by Robertson et al., 1992. It should be noted that it is not always possible to clearly identify a soil type based on qc, fs and u. Occasionally soils will fall within different soil categories on the classification charts. In these situations, experience and judgment and an assessment of the pore pressure dissipation data should be used to infer the soil behavior type. Computer tabulations of the interpreted soil types along with certain other geotechnical parameters for each cone hole is presented in Appendix B.

Each of the parameters measured in the sounding is discussed briefly below. A detailed explanation of CPTU testing and interpretation of the results can be found in Robertson, 1989.

TIP RESISTANCE (q_c): The resistance to penetration, measured at the cone tip, provides an accurate profile of subsurface strata. The recorded tip resistance is a composite of the penetration resistance of the soils located five to ten cone diameters (7 to 14 inches) in front of and behind the tip. The actual resistance "sensed" by the tip depends on the soil properties and on the relative stiffness of the layers encountered. Tip resistance is often corrected for pore pressure effects when testing in soft saturated cohesive soils.

For this project the correction was made and the tip resistance shown, q_t is the corrected tip resistance.

The correction used is: $q_t = q_c + (1\text{-}a)u$

Where: q_t = corrected tip resistance
q_c = measured tip resistance
a = net area ratio for cone (0.80 for this project)
u = dynamic pore water pressure measured behind tip

SLEEVE FRICTION (f_s) The resistance recorded on the friction sleeve, is a measure of the remolded strength of the soil. Values of sleeve friction in very soft soils (such as peat) may fluctuate due to the measured force being small relative to the capacity of the measuring load cell.

FRICTION RATIO (R_f) The ratio of sleeve friction to tip resistance expressed as a percentage, is an indicator of soil type. Cohesive soils generally have friction ratios that are greater than two, while sands and non-plastic silts have friction ratios that are lower than two.

PORE PRESSURE (u*)* Dynamic pore water pressure is measured during penetration. (dynamic pore water pressure data can be found in the .cor, and .xls files. Static pore water pressure is measured when cone penetration is stopped (static pore water pressure data can be found in the .ppd files). The measured dynamic pore water pressure changes with the location of the porous filter and negative readings are possible when the filter is located behind the tip.

It is important to note that the CPT classifies soil by physical behavior, not by grain size; therefore, the CPT classification should be verified against samples obtained from a conventional drilling program. While the CPT soil classification may not always be accurate in terms of the actual label it applies to a particular soil, it is very accurate in grouping soils with similar mechanical properties.

3.2 CONE PLOTS

The data from each sounding was plotted using the computer program SCREENzW. The plots are included in Appendix A. SCREENzW was developed by ConeTec Inc. and it incorporates soil behavior type (SBT) classification as part of the plot. The soil classification is based on the classification chart reproduced chart in Appendix B.

3.3 PORE PRESSURE DISSIPATION TEST RESULTS

Pore water pressure dissipation data are collected and automatically recorded during pauses in penetration. The pore water pressure data is recorded at five second intervals. No pore water pressure dissipation tests were performed on this project.

3.4 CPT DATA PROCESSING

The electronic data files were processed using the program SCREENzW. SCREENzW is a program developed by ConeTec to calculate common engineering parameters from CPT data. The processed data file summery sheet is attached in Appendix B. The files (.xls) are also included in the CDS package. The calculations used are summarized in the table at the front of the Appendix. Each calculation is derived according to the referenced article.

For this project, the depth to ground water used was determined to be the canal surface. The exact depth used is noted in the header of each ifi.xls file.

3.5 ELECTRONIC DATA FILES

Along with the report, all of the project data can be downloaded from ConeTec's "ConeTec Data Services" (CDS) website (www.conetecdataservices.com) using a secure, project-specific user name and password. These electronic files contain all important project information including tabular data (.xls and ASCII formats), GPS coordinates of approximate sounding locations, dynamic and static pore water pressure and some basic interpretation files in Microsoft™ Excel format (.xls). Information regarding the digital file formats of the electronic files is included in Appendix E.

CONETEC INTERPRETATION METHODS

A Detailed Description of the Methods Used in ConeTec's CPT Interpretation and Plotting Software

Revision SZW-Rev 05
January 16, 2011

Prepared by Jim Greig

CONETEC

ConeTec Interpretations as of January 16, 2011

ConeTec's interpretation routine provides a tabular output of geotechnical parameters based on current published CPT correlations and is subject to change to reflect the current state of practice. The interpreted values are not considered valid for all soil types. The interpretations are presented only as a guide for geotechnical use and should be carefully scrutinized for consideration in any geotechnical design. Reference to current literature is strongly recommended. ConeTec does not warranty the correctness or the applicability of any of the geotechnical parameters interpreted by the program and does not assume liability for any use of the results in any design or review. Representative hand calculations should be made for any parameter that is critical for design purposes. The end user of the interpreted output should also be fully aware of the techniques and the limitations of any method used in this program. The purpose of this document is to inform the user as to which methods were used and what the appropriate papers and/or publications are for further reference.

The CPT interpretations are based on values of tip, sleeve friction and pore pressure averaged over a user specified interval (e.g. 0.20m). Note that q_t is the tip resistance corrected for pore pressure effects and q_c is the recorded tip resistance. Since all ConeTec cones have equal end area friction sleeves, pore pressure corrections to sleeve friction, f_s, are not required.

The tip correction is: $q_t = q_c + (1-a) \cdot u_2$

where: q_t is the corrected tip resistance
q_c is the recorded tip resistance
u_2 is the recorded dynamic pore pressure behind the tip (u_2 position)
a is the Net Area Ratio for the cone (typically 0.80 for ConeTec cones)

The total stress calculations are based on soil unit weights that have been assigned to the Soil Behavior Type zones, from a user defined unit weight profile or by using a single value throughout the profile.

Effective vertical overburden stresses are calculated based on a hydrostatic distribution of equilibrium pore pressures below the water table or from a user defined equilibrium pore pressure profile (this can be obtained from CPT dissipation tests). For over water projects the effects of the column of water have been taken into account as has the appropriate unit weight of water. How this is done depends on where the instruments were zeroed (i.e. on deck or at mud line).

Details regarding the interpretation methods for all of the interpreted parameters are provided in Table 1. The appropriate references cited in Table 1 are listed in Table 2. Where methods are based on charts or techniques that are too complex to describe in this summary the user should refer to the cited material.

The estimated Soil Behavior Types (normalized and non-normalized) are based on the charts developed by Robertson and Campanella shown in Figures 1 and 2. Alternate classification charts, such as the Bq SBTcharts, are shown in Figure 3.

Where the results of a calculation/interpretation are declared *'invalid'* the value will be represented by the text strings "-9999" or "-9999.0". In some cases the value 0 will be used. Invalid results will occur because of (and not limited to) one or a combination of:

1. Invalid or undefined CPT data (e.g. drilled out section or data gap).

2. Where the interpretation method is inappropriate, for example, drained parameters in an undrained material (and vice versa).

3. Where interpretation input values are beyond the range of the referenced charts or specified limitations of the interpretation method.

4. Where pre-requisite or intermediate interpretation calculations are invalid.

The parameters selected for output from the program are often specific to a particular project. As such, not all of the interpreted parameters listed in Table 1 may be included in the output files delivered with this report.

The output files are provided in Microsoft Excel XLS format. The ConeTec software has several options for output depending on the number or types of interpreted parameters desired. Each output file will be named using the original COR file basename followed by a three or four letter indicator of the interpretation set selected (e.g. BSC, TBL, NLI or IFI) and possibly followed by an operator selected suffix identifying the characteristics of the particular interpretation run.

Table 1
CPT Interpretation Methods

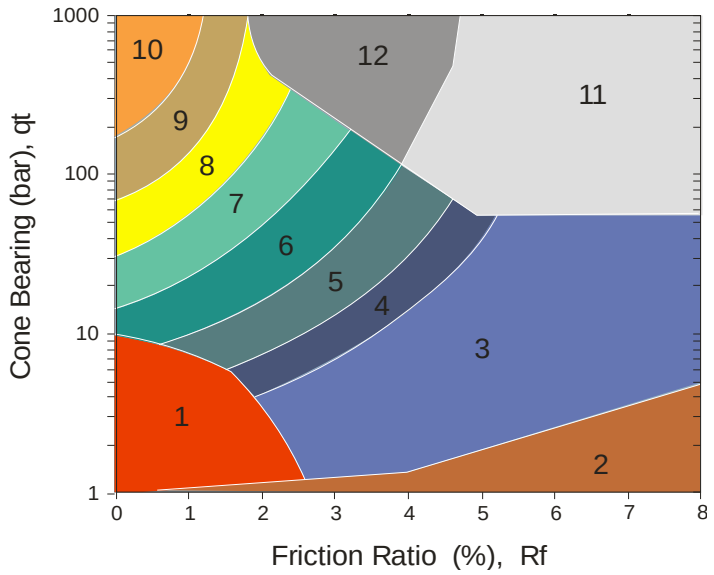
Interpreted Parameter	Description	Equation	Ref
Depth	Mid Layer Depth *(where interpretations are done at each point then Mid Layer Depth = Recorded Depth)*	*Depth (Layer Top) + Depth (Layer Bottom) / 2.0*	
Elevation	Elevation of Mid Layer based on sounding collar elevation supplied by client	Elevation = Collar Elevation - Depth	
Avgqc	Averaged recorded tip value (q_c)	$Avgqc = \frac{1}{n}\sum_{i=1}^{n} q_c$ *n=1 when interpretations are done at each point*	
Avgqt	Averaged corrected tip (q_t) where: $q_t = q_c + (1-a) \bullet u$	$Avgqt = \frac{1}{n}\sum_{i=1}^{n} q_t$ *n=1 when interpretations are done at each point*	
Avgfs	Averaged sleeve friction (f_s)	$Avgfs = \frac{1}{n}\sum_{i=1}^{n} fs$ *n=1 when interpretations are done at each point*	
AvgRf	Averaged friction ratio (Rf) where friction ratio is defined as: $Rf = 100\% \bullet \frac{fs}{qt}$	$AvgRf = 100\% \cdot \frac{Avgfs}{Avgqt}$ *n=1 when interpretations are done at each point*	
Avgu	Averaged dynamic pore pressure *(u)*	$Avgu = \frac{1}{n}\sum_{i=1}^{n} u_i$ *n=1 when interpretations are done at each point*	
AvgRes	Averaged Resistivity (this data is not always available since it is a specialized test requiring an additional module)	$Avgu = \frac{1}{n}\sum_{i=1}^{n} RESISTIVITY_i$ *n=1 when interpretations are done at each point*	
AvgUVIF	Averaged UVIF ultra-violet induced fluorescence (this data is not always available since it is a specialized test requiring an additional module)	$Avgu = \frac{1}{n}\sum_{i=1}^{n} UVIF_i$ *n=1 when interpretations are done at each point*	
AvgTemp	Averaged Temperature (this data is not always available since it is a specialized test)	$Avgu = \frac{1}{n}\sum_{i=1}^{n} TEMPERATURE_i$ *n=1 when interpretations are done at each point*	
AvgGamma	Averaged Gamma Counts (this data is not always available since it is a specialized test requiring an additional module)	$Avgu = \frac{1}{n}\sum_{i=1}^{n} GAMMA_i$ *n=1 when interpretations are done at each point*	
SBT	Soil Behavior Type as defined by Robertson and Campanella	See Figure 1	2, 5

Interpreted Parameter	Description	Equation	Ref
U.Wt.	Unit Weight of soil determined from one of the following user selectable options: 1) uniform value 2) value assigned to each SBT zone 3) user supplied unit weight profile	See references	5
T. Stress σ_v	Total vertical overburden stress at Mid Layer Depth. *A layer is defined as the averaging interval specified by the user. For data interpreted at each point the Mid Layer Depth is the same as the recorded depth.*	$TStress = \sum_{i=1}^{n} \gamma_i h_i$ *where* γ_i is layer unit weight h_i is layer thickness	
E. Stress σ_v'	Effective vertical overburden stress at Mid Layer Depth	*Estress = Tstress - u_{eq}*	
Ueq	Equilibrium pore pressure determined from one of the following user selectable options: 1) hydrostatic from water table depth 2) user supplied profile	For hydrostatic option: $u_{eq} = \gamma_w \cdot (D - D_{wt})$ where u_{eq} is equilibrium pore pressure γ_w is unit weight of water D is the current depth D_{wt} is the depth to the water table	
Cn	SPT N_{60} overburden correction factor	*$Cn=(\sigma_v')^{-0.5}$* where *σ_v' is in tsf* *$0.5 < C_n < 2.0$*	
N_{60}	SPT N value at 60% energy calculated from qt/N ratios assigned to each SBT zone. This method has abrupt N value changes at zone boundaries.	*See Figure 1*	4, 5
$(N_1)_{60}$	SPT N_{60} value corrected for overburden pressure	*$(N_1)_{60} = Cn \cdot N_{60}$*	4
$N_{60}I_c$	SPT N_{60} values based on the Ic parameter	(qt/pa)/ N_{60} = 8.5 (1 – Ic/4.6)	5
$(N_1)_{60}$Ic	SPT N_{60} value corrected for overburden pressure (using N_{60} $I_{c)}$. User has 2 options.	*1) $(N_1)_{60}Ic = Cn \cdot (N_{60}\, Ic)$* 2) q_{c1n}/ *$(N_1)_{60}Ic$* = 8.5 (1 – Ic/4.6)	4 5
$(N_1)_{60cs}$Ic	Clean sand equivalent SPT $(N_1)_{60}$Ic. User has 3 options.	1) $(N_1)_{60cs}Ic = \alpha + \beta((N_1)_{60}Ic)$ 2) $(N_1)_{60cs}Ic = K_{SPT} * ((N_1)_{60}Ic)$ 3) q_{c1ncs}/ $(N_1)_{60cs}Ic$ = 8.5 (1 – Ic/4.6) FC ≤ 5%: α = 0, β=1.0 FC ≥ 35% α = 5.0, β=1.2 5% < FC < 35% α = exp[1.76 – (190/FC^2)] β = [0.99 + ($FC^{1.5}$/1000)]	10 10 5
Su	Undrained shear strength based on q_t Su factor N_{kt} is user selectable	$Su = \frac{qt - \sigma_v}{N_{kt}}$	1, 5
Su	Undrained shear strength based on pore pressure Su factor $N_{\Delta u}$ is user selectable	$Su = \frac{u_2 - u_{eq}}{N_{\Delta u}}$	1, 5
k	Coefficient of permeability (assigned to each SBT zone)		5
Bq	Pore pressure parameter	$Bq = \frac{\Delta u}{qt - \sigma_v}$ *where:* $\Delta u = u - u_{eq}$ *and u = dynamic pore pressure* *u_{eq} = equilibrium pore pressure*	1, 5

Interpreted Parameter	Description	Equation	Ref
Q_t	Normalized q_t for Soil Behavior Type classification as defined by Robertson, 1990	$Qt = \frac{qt - \sigma_v}{\sigma'_v}$	2, 5
F_r	Normalized Friction Ratio for Soil Behavior Type classification as defined by Robertson, 1990	$Fr = 100\% \cdot \frac{fs}{qt - \sigma_v}$	2, 5
Net qt	Net tip resistance	$qt - \sigma_v$	
qe	Effective tip resistance	$qt - u_2$	
qeNorm	Normalized effective tip resistance	$\frac{qt - u_2}{\sigma'_v}$	
SBTn	Normalized Soil Behavior Type as defined by Robertson and Campanella	See Figure 2	2, 5
SBT-BQ	Non-normalized Soil Behavior type based on the Bq parameter	See Figure 3	2, 5
SBT-BQn	Normalized Soil Behavior based on the Bq parameter	See Figure 3	2, 5
SBT-JandD	Soil Behaviour Type as defined by Jeffries and Davies	See Figure 3	7
SBT-BQn	Normalized Soil Behavior base on the Bq parameter	See Figure 3	2, 5
I_c	Soil index for estimating grain characteristics	$Ic = [(3.47 - \log_{10}Q)^2 + (\log_{10} Fr + 1.22)^2]^{0.5}$ *Where:* $Q = \left(\frac{qt - \sigma_v}{P_{a2}}\right)\left(\frac{P_a}{\sigma'_v}\right)^n$ *And* *Fr is in percent* P_a *= atmospheric pressure* P_{a2} *= atmospheric pressure* *n varies from 0.5 to 1.0 and is selected in an iterative manner based on the resulting* I_c	3, 8
FC	Apparent fines content (%)	$FC=1.75(Ic^{3.25}) - 3.7$ $FC=100$ *for* $Ic > 3.5$ $FC=0$ *for* $Ic < 1.26$ $FC = 5\%$ *if* $1.64 < Ic < 2.6$ *AND* $F_r<0.5$	3
Ic Zone	This parameter is the Soil Behavior Type zone based on the Ic parameter (valid for zones 2 through 7 on SBTn chart)	Ic < 1.31 Zone = 7 1.31 < Ic < 2.05 Zone = 6 2.05 < Ic < 2.60 Zone = 5 2.60 < Ic < 2.95 Zone = 4 2.95 < Ic < 3.60 Zone = 3 Ic > 3.60 Zone = 2	3
PHI ϕ	Friction Angle determined from one of the following user selectable options: a) Campanella and Robertson b) Durgunoglu and Mitchel c) Janbu d) Kulhawy and Mayne	See reference	5 5 5 11
Dr	Relative Density determined from one of the following user selectable options: a) Ticino Sand b) Hokksund Sand c) Schmertmann 1976 d) Jamiolkowski - All Sands	See reference	5

Interpreted Parameter	Description	Equation	Ref
OCR	Over Consolidation Ratio	a) Based on Schmertmann's method involving a plot of S_u/σ_v' /($S_u/\sigma_v')_{NC}$ and OCR where the Su/p' ratio for NC clay is user selectable	9
State Parameter	The state parameter is used to describe whether a soil is contractive (SP is positive) or dilative (SP is negative) at large strains based on the work by Been and Jefferies	See reference	8, 6, 5
Es/qt	Intermediate parameter for calculating Young's Modulus, E, in sands. It is the Y axis of the reference chart.	Based on Figure 5.59 in the reference	5
Young's Modulus E	Young's Modulus based on the work done in Italy. There are three types of sands considered in this technique. The user selects the appropriate type for the site from: a) OC Sands b) Aged NC Sands c) Recent NC Sands Each sand type has a family of curves that depend on mean normal stress. The program calculates mean normal stress and linearly interpolates between the two extremes provided in the Es/qt chart.	Mean normal stress is evaluated from: $\sigma_m' = \frac{1}{3}\left(\sigma_v' + \sigma_h' + \sigma_h'\right)^3$ where σ_v'= vertical effective stress σ_h'= horizontal effective stress and $\sigma_h = K_o \cdot \sigma_v'$ with Ko assumed to be 0.5	5
q_{c1}	q_t normalized for overburden stress used for seismic analysis	$q_{c1} = q_t \cdot (Pa/\sigma_v')^{0.5}$ where: Pa = atm. Pressure q_t is in MPa	3
q_{c1n}	q_{c1} in dimensionless form used for seismic analysis	$q_{c1n} = (q_{c1} / Pa)(Pa/\sigma_v')^n$ where: Pa = atm. Pressure and n ranges from 0.5 to 0.75 based on Ic.	3
K_{SPT}	Equivalent clean sand factor for $(N_1)60$	$K_{SPT} = 1 + ((0.75/30) \cdot (FC - 5))$	10
K_{CPT}	Equivalent clean sand correction for q_{c1N}	$K_{cpt} = 1.0$ for $I_c \leq 1.64$ $K_{cpt} = f(I_c)$ for $I_c > 1.64$ (see reference)	10
q_{c1ncs}	Clean sand equivalent q_{c1n}	$q_{c1ncs} = q_{c1n} \cdot K_{cpt}$	3
CRR	Cyclic Resistance Ratio (for Magnitude 7.5)	$q_{c1ncs} < 50$: $CRR_{7.5} = 0.833\ [(q_{c1ncs}/1000] + 0.05$ $50 \leq q_{c1ncs} < 160$: $CRR_{7.5} = 93\ [(q_{c1ncs}/1000]^3 + 0.08$	10
CSR	Cyclic Stress Ratio	$CSR = (\tau_{av}/\sigma_v') = 0.65\ (a_{max} / g)\ (\sigma_v/ \sigma_v')\ r_d$ $r_d = 1.0 - 0.00765\ z$ $z \leq 9.15$m $r_d = 1.174 - 0.0267\ z$ $9.15 < z \leq 23$m $r_d = 0.744 - 0.008\ z$ $23 < z \leq 30$m $r_d = 0.50$ $z > 30$m	10

Interpreted Parameter	Description	Equation	Ref
MSF	Magnitude Scaling Factor	See Reference	10
FofS	Factor of Safety against Liquefaction	FS = ($CRR_{7.5}$ / CSR) MSF	10
Liquefaction Status	Statement indicating possible liquefaction	Takes into account FofS and limitations based on I_c and q_{c1ncs}.	10
Cont/Dilat Tip	Contractive / Dilative qc1 Boundary based on $(N_1)_{60}$	$(\sigma_v')_{boundary} = 9.58 \times 10^{-4} [(N_1)_{60}]^{-4.79}$ qc1 is calculated from specified qt(MPa)/N ratio	11
Su(Liq)/s'v	Liquefied Shear Strength Ratio	$\frac{Su(Liq)}{\sigma_v'} = 0.03 + 0.0143(q_{c1})$	12



Zone	qt / N	Soil Behavior Type
1	2	sensitive fine grained
2	1	organic material
3	1	clay
4	1.5	silty clay to clay
5	2	clayey silt to silty clay
6	2.5	sandy silt to clayey silt
7	3	silty sand to sandy silt
8	4	sand to silty sand
9	5	sand
10	6	gravelly sand to sand
11	1	very stiff fine grained *
12	2	sand to clayey sand *

* overconsolidated or cemented

Appendix E

Electronic Data Files

The released data contains the following folders:

1. CPT Data - .cor files in ASCII format, and or .xls files.
2. Pore Pressure Dissipation Data - .ppd files in Excel format
3. CPT Plots - .pdf files
4. Data Interpretation - .xls files contain common engineering values

ConeTec Digital File Formats

CPT Data Files (COR Extension)

ConeTec data files are stored in ASCII text files that are readable by almost any text editor. ConeTec CPT data files are named such that the first 3 characters contain the job number, the next two characters are CP followed by two characters indicating the sounding number. The last 8th character position is reserved for the letters a, b, c, d etc to uniquely identify multiple soundings at the same location. The CPT sounding file has the extension COR, and pore pressure dissipation files have the extension PPD or PPF. As an example, for job number 06-127 the first sounding will have file names 127CP01.COR and 127CP01.PPD.

The sounding (COR) file consists of the following components:

1. Two lines of header information
2. Data records
3. End of data marker
4. Units information

Header Lines

Line 1: Columns 1-6 may be blank or may indicate the version number of the recording software
Columns 7-21 contain the sounding Date and Time
Columns 22-36 contain the sounding Operator

Line 2: Columns 1-16 contain the Job Location
Columns 17-31 contain the Cone ID
Columns 32-47 contain the sounding number

Data Records

The data records contain 4 or more columns of data in floating point format. A comma (and spaces) separates each data item:

Column 1: Sounding Depth (meters)
Column 2: Tip (q_c) data uncorrected for pore pressure effects. Recorded in units selected by the operator.
Column 3: Sleeve (f_s) data. Recorded in units selected by the operator
Column 4: Dynamic pore pressure readings. Recorded in units selected by the operator
Column 5: Empty, Resistivity, UVIF or Gamma data

End of Data Marker

After the last line of data there will be a line containing ASCII 26 (CTL-Z) and a newline (carriage return/ line feed) character. This is used to mark the end of data.

Units Information

The last section of the file contains information about the units that were selected for the sounding. A separator bar makes up the first line. The second line contains the type of units used for depth, q_c, f_s and u. The third line contains the conversion values required for ConeTec's software to convert the recorded data to an internal set of base units (bar for q_c, bar for f_s and meters for u).

CPT Dissipation Files (PPx Extension)

CPT Dissipation files have the same naming convention as the CPT sounding files and have the extension PPD, PPF or PPM. PPF (PPM and PPD) files consist of the following components:

1. Two lines of header information
2. Data records

Header Lines (same as COR file):

Line 1: Columns 1-6 may be blank or may indicate the version number of the recording software
Columns 7-21 contain the sounding Date and Time
Columns 22-36 contain the sounding Operator

Line 2: Columns 1-16 contain the Job Location
Columns 17-31 contain the Cone ID
Columns 32-47 contain the sounding number

Data Records

The data records immediately follow the header lines. Each data record can occupy several lines in the file and is a complete record of a dissipation test at a particular depth. Each data record starts with a line containing two values separated by spaces; the first value being an index number (not currently used by the Software) and the second being the dissipation test depth in meters. Following this line are the dissipation pore pressure values stored at 5 second intervals with a maximum of 12 entries per line. The last line of the dissipation record may not contain a full 12 entries. The data record is terminated with an ASCII 30 character (appears as a triangle in some editors).

This sequence is repeated for every dissipation test in the sounding. No marker is used to indicate end of file. Units information is not stored in this file. Users need to check the CPT file for the units that were used.

CPT Basic Interpretations (TBL Extension)

ConeTec's basic CPT interpretation output files are generally delivered in text files with a TBL extension. The root file name is the same as the COR files. A number of calculated geotechnical parameters are presented in these files. The files are stored as ASCII text files that can be viewed using any text editor such as Notepad or Wordpad. The files do not contain any page formatting. These files are not distributed if the enhanced interpretation files are provided.

CPT Enhanced Interpretations (IFI, IFP, XLS Extension)

ConeTec's enhanced CPT interpretation output files are delivered in several formats, each file type containing the exact same information but formatted slightly differently. The files typically have any of the following file extensions:

1. IFI — an importable TAB delimited ASCII text file containing approximately 47 data columns of geotechnical interpretations. The file is designed for easy import to Excel. A companion document describes the techniques used for the interpretations (usually reproduced at the beginning of the Interpretation Appendix). Text editors can be used to view the file contents, however, they may remove the tabs or replace the tabs with spaces upon saving the file destroying the feature that makes them easy to import into Excel.

   Because Excel imports the data as text and the sheet is protected two steps may be necessary to modify the data or use the values in certain Excel functions:

   a) Under Tools (Excel 2000) Select the Protection Option and then Unprotect the sheet
   b) Select the entire sheet, copy and then use Paste Special to paste as values to a second sheet.

   Future versions of our interpretation routine will address these inconveniences.

2. IFP — a printable ASCII text file containing the same 47 columns of geotechnical interpretations as the IFI file. This file type has been formatted as a multi-page document with up to 132 characters per line and up to 68 lines per page. Each page has been separated into multiple sections to accommodate all the data fields. Each physical page has a header section and a page/section number. The file is designed for direct printing to laser printers set into compressed font mode. This output is typically provided in the Interpretation Appendix.

   An abbreviated set of interpretations (containing 36 columns of output) may be generated instead. These files usually have the extensions NLI and NLP. XLS files can be generated from these as well.

3. XLS — an Excel format file that has been generated directly from the corresponding IFI file. IFI and IFP files are not distributed if the XLS files are generated. The XLS files may have been generated from abbreviated NLI interpretation files.

In each case root file name is the same as the COR files.

CPT Interpretations (Excel Format)

ConeTec's latest software (September 2007) outputs CPT interpretations directly to Excel format (XLS extension) without creating intermediate ASCII files. Because of the desires of various clients, there are several different configurations of output parameters in ConeTec's interpretation files. Since the Excel format file must have the XLS extension a suffix is used after the basename of the source CPT data file (COR) to identify the format of the file. The configurations still follow the formats described above and use the same extensions but now as suffixes. To allow for various runs (e.g. using a different water table, or user supplied equilibrium profile, or different methods for a particular parameter) of the same data an additional suffix may be specified by the engineer post processing the data to identify each particular run. This suffix will follow the one used to identify the format of the file.

For example:

If the selected format is ConeTec's TBL configuration and each run is identified by a run number. The resultant files generated for 278CP01.COR would be:

78CP01-TBL-RUN01.XLS
78CP01-TBL-RUN02.XLS
78CP01-TBL-RUN03.XLS

CPT Data in Excel Format

ConeTec can now provide the equivalent of the ASCII COR files in Excel Format. These files will have the same basename as the COR files and an XLS extension.

Pore Pressure Dissipation Data in Excel Format

ConeTec can now provide the equivalent of the ASCII PPD format files in Excel format. These files will contain each dissipation trace that exceeds a minimum duration (selected by the engineer during post-processing) in a particular Excel spreadsheet column. The first column (Column A) will contain the time in seconds and the second column (Column B) will contain the time in minutes. Subsequent columns will contain dissipation trace data. The time columns will extend to the longest trace of the data set.

Detailed header information is provided at the top of the spreadsheet. The test depth in meters and feet, the number of points in the trace and the particular units are identified at the top of each trace column.

The Excel format file names will have the same basename as the original PPD format file followed by the suffix -PPD and then followed by a second suffix that the engineer doing the post processing can specify. Because the engineer can select various types of units for the dissipation data output (which can be different from the units used in the original recording) the secondary suffix is often used to identify the units in the XLS file, however, the original recorded units and the output units are clearly identified within the XLS spreadsheet file.

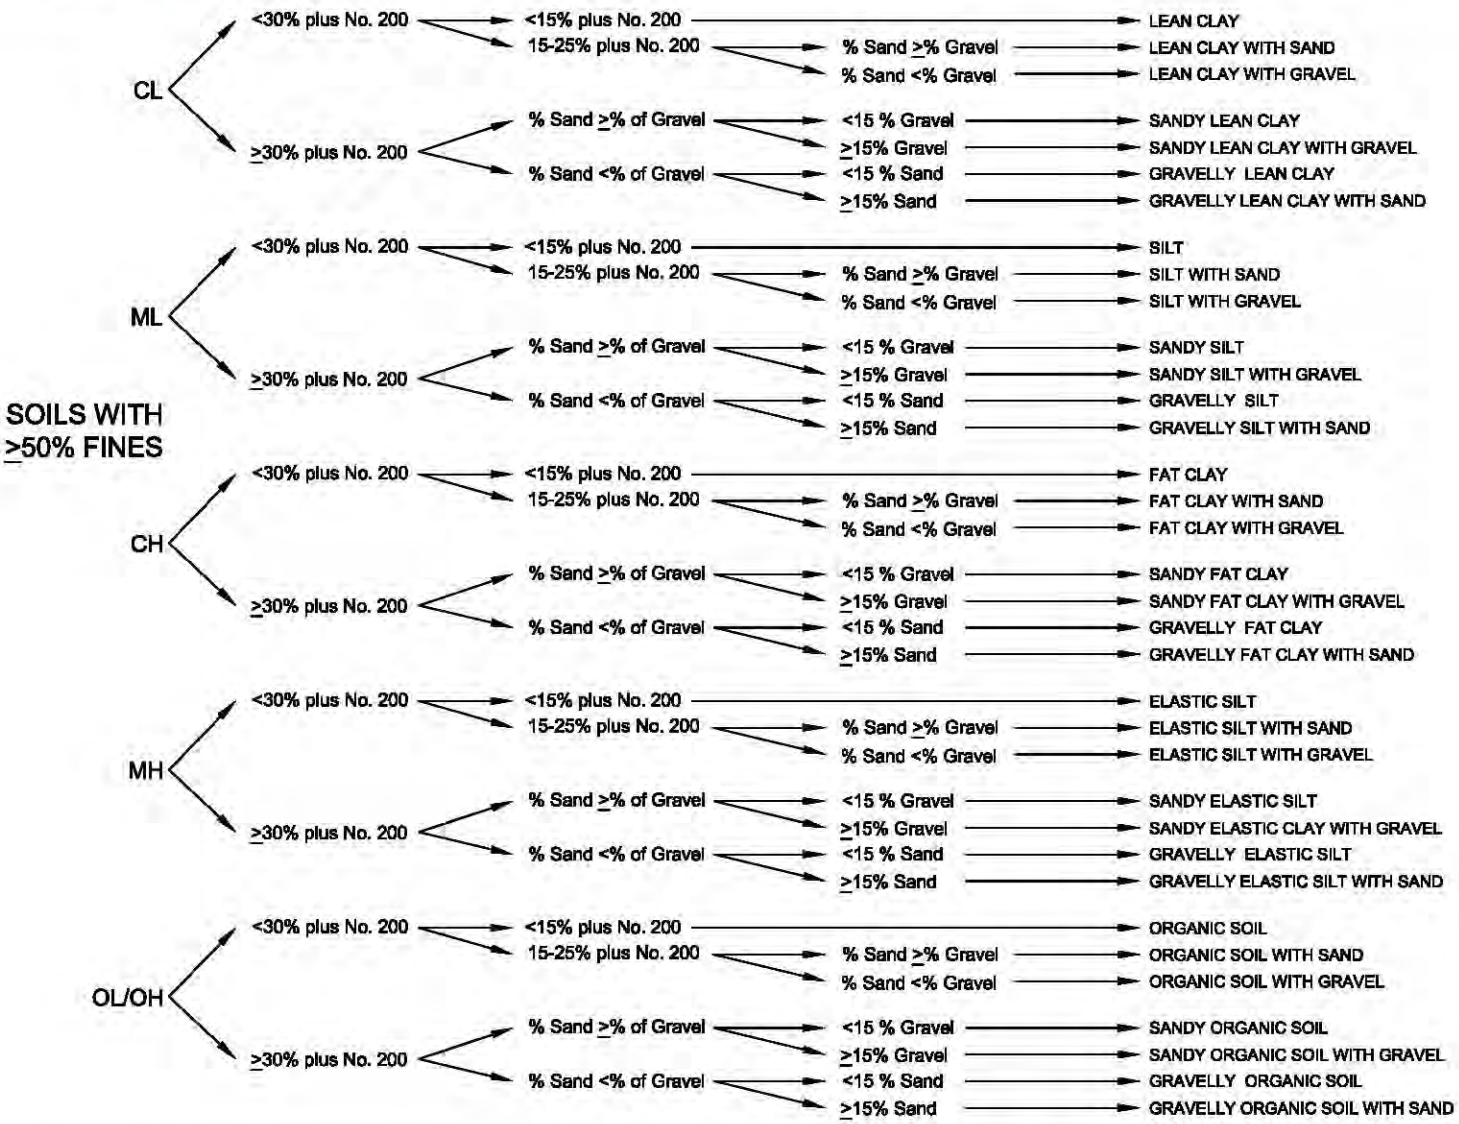
FINE-GRAINED SOILS
VISUAL-MANUAL DESCRIPTIONS



ID OF INORGANIC FINE SOILS FROM MANUAL TESTS

Symbol	Name	Dry Strength	Dilatancy	Toughness*
ML	Silt	None to low	Slow to rapid	Low or thread cannot be formed
CL	Lean Clay	Medium to high	None to slow	Medium
MH	Elastic Silt	Low to medium	None to slow	Low to medium
CH	Fat Clay	High to very high	None	High

1. GROUP NAME and (SYMBOL)
2. Describe fines, sand, and gravel components, in order of predominance. Include plasticity of fines. Include percentages of sand and gravel.
3. Color
4. Sheen, odor, roots, ash, brick, cementation, torvane and penetrometer results, etc.
5. "Fill," local name or geologic name, if known

PEAT

Peat refers to a sample composed primarily of vegetable matter in varying stages of decomposition. The description should begin: PEAT (PT) and need not include percentages of sand, gravel or fines.

CRITERIA FOR DESCRIBING PLASTICITY

Description	Criteria
Nonplastic ML	A 1/8-in. (3 -mm) thread cannot be rolled at any water content
Low Plasticity ML, MH	The thread can barely be rolled and the lump cannot be formed when drier than the plastic limit *
Medium Plasticity MH, CL	The thread is easy to roll and not much time is required to reach the plastic limit. The thread cannot be rerolled after reaching the plastic limit. The lump crumbles when drier than the plastic limit
High Plasticity CH	It takes considerable time rolling and kneading to reach the plastic limit. The thread can be rerolled several times after reaching the plastic limit. The lump can be formed without crumbling when drier than the plastic limit

* Toughness refers to the strength of the thread near plastic limit. The lump refers to a lump of soil drier than the plastic, similar to dry strength.

EXAMPLE SOIL DESCRIPTIONS

SANDY SILT (ML) ~60% slightly plastic fines, ~40% mostly fine sand, 1" thick layer of fine to medium sand with <20% fines, gray.

LEAN CLAY (CL) ~90% moderately plastic fines, ~10% fine sand, olive. Boston Blue Clay. Sv = 0.5, 0.5, 0.8 tsf, Qp = 1.0, 1.5, 1.6 tsf

Stratified CLAYEY SAND (SC) and WIDELY GRADED SAND (SW) SC layers 1 to 2 inches thick consist of fine sand with ~30% moderately plastic fines, gray. SW layers 1 to 4 inches thick consist of fine to coarse sand, ~10% gravel to 1/2 inch, <5% fines, brown. Hydraulic Fill.

EXAMPLE ROCK DESCRIPTIONS

(0-9"): GRANITE, hard, one piece, joint surface slightly weathered, pink.
(6-60"): PHYLLITE, joints ~ 45° generally parallel to foliation, 9" to 44" moderate to severe jointing and joint weathering. 44" to 60" single piece, green-gray.

ARGILLITE, medium hard, moderately weathered joints, gray. Cambridge Argillite.

GEOPROBE AND ROTOSONIC

When SPTs are not performed, note sample density (sands) or stiffness (clays) in description.

CRITERIA FOR DESCRIBING DILATANCY OF FINE-GRAINED SOILS

Description	Criteria
None	No visible change in the specimen
Slow	Water appears slowly on the surface of the specimen during shaking and does not disappear or disappears slowly upon squeezing.
Rapid	Water appears quickly on the surface of the specimen during shaking and disappears quickly upon squeezing.

SPT: Standard Penetration Test

30-inch drop with 140-lb hammer
1 3/4 to 2 1/4 turns around cathead
2-inch O.D. split spoon sampler

ENV'L TERMINOLOGY FOR SOIL DESCRIPTIONS

- **Ash** - Typically silt-size to medium sand-size.
- Do not use the term "cinders." This is not a technical term. Instead, use "ash," "burnt wood," "burnt material," or a similar term.
- **Coal-like material** - If it looks like coal but you aren't sure.
- **Clinker** - Vitrified (glass-like) or heat-fused material. Often burned impurities in coal. Often looks like pumice, but heavier.
- **Slag** - Similar to clinker, but normally refers to residue from metal ore processing.

- **Sheen** - Iridescent petroleum-like sheen. Not to be used for a "bacterial sheen," which can be distinguished by its tendency to break up on the water surface at angles. Petroleum sheen will be continuous and will not break up.
- **Stained** - Use with a color ("brown-stained") to indicate that the soil is stained a color other than its natural (unimpacted) color.
- **Coated** - Soil grains are coated with NAPL (oil, tar, etc.). There is not enough NAPL to saturate the pore spaces. ("Split spoon sampler coated with brown oil." "Soil grains coated with gray substance with slight gasoline-like odor.")
- **Saturated** - The entire sample pore space is saturated with NAPL. If you use this term, be sure it is not water saturating the pore spaces. Depending on viscosity, the NAPL may drain from a soil sample. ("Sample saturated with green, sticky substance.")
- **Blebs** - Discrete sphericals of NAPL in a soil matrix that was not visibly coated or saturated. ("Occasional blebs of reddish-brown tar.")
- **Oil** - Exhibits a petroleum odor, different from MGP odors.
- **Tar** - Exhibits an MGP odor (e.g. naphthalene-like odor).

- **Odors** - Use terms such as "naphthalene-like odor" or "petroleum-like odor." Use modifiers (strong, moderate, slight) to indicate odor intensity.

Re: **Geotechnical Investigation of Gowanus Canal Sediments: NAPL Expression**

Summary

Selected sediments samples from the Gowanus Canal were subjected to geotechnical testing for potential NAPL expression. The testing followed the methodology of Erten et al. (2011)[1]. The samples were selected on the basis of measurable NAPL content (based upon PID readings from sonic cores in the same interval) and location near the interface of the "soft" and "native" sediments in the Canal. The sediments that may be exposed after dredging and that will require capping to contain sediment contaminants. The purpose of the testing was to determine the potential for NAPL expression.

Of the three samples, two samples were fine-grained material containing 9-15% hexane extractible material (HEM, EPA Method 9071B) divided by total sample weight) or 20-32% HEM per dry solids, and one was more sandy material containing approximately 3% HEM (total basis), 4% HEM (dry solids basis). HEM is used here as a surrogate for NAPL content although HEM may overpredict NAPL content if there is significant extractible organic material in the samples. All samples were subjected to loadings equivalent to up to 10 feet of sand in five stages. No samples released meaningful quantities of NAPL as a result of this loading. One sample with a higher content of NAPL did release a non-measurable trace quantity of NAPL during loading. Significantly, no substantial NAPL was expressed even though the samples were subjected to volumetric strains (volume reduction during consolidation) of 16-18% of the fine-grained samples and 2.5-5% of the coarser samples.

This testing indicates that the methodology of Erten et al. (2011) may be used for NAPL expression testing in these sediments and that the NAPL present in the sediment samples is at a residual saturation that is unlikely to be mobilized by loading with the weight of a sediment cap. The trace amounts of NAPL expressed in one sample suggests that disturbance can release small amounts of material that could ultimately lead to sheens. Further testing is required to confirm whether these conclusions are generally applicable in the Canal.

[1] Erten, M.B., R. Gilbert, C.S. El Mohtar, D.D. Reible, Development of a laboratory procedure to evaluate the consolidation potential of soft contaminated sediments, *Geotechnical Testing Journal, 34*, 5, September (2011)

Methodology and Results

Selected sediments samples from the Gowanus Canal were subjected to geotechnical testing for potential NAPL expression. The testing followed the methodology of Erten et al. (2011)[1] which is designed to evaluate the potential for NAPL expression under loadings typical of placement of a sediment cap. Three samples were taken and designated:

- GC-B-002
- GC-B-004
- GC-B-005

These samples were selected based on testing of samples with tar impacts or elevated PID readings in sonic cores over the same tube sample interval and location near the interface of accumulated "soft" sediments and alluvial/sand "native" deposits.

Three eight-inch-long sections were cut from the bottom of each sample core and tested at the University of Texas at Austin. Four triaxial consolidation tests were performed on samples obtained from the three Shelby tubes. Iit should be noted that the tubes were subjected to some disturbance during shipping as a result of shipping while horizontal. As a result, the samples were likely to be less consolidated and the NAPL more mobile than in undisturbed cores.

Characterization of the samples included

- Density and estimated mass of dry solids based on NAPL and Water content
- NAPL, mobile organic contaminant content- Measured via EPA 9071B, Hexane Extractible Material
- Water Content- Measured by drying overnight at 105 C

Measurements were conducted on pre-consolidated samples as well as at the top, middle and bottom of consolidated cores. All measurements were conducted in triplicate although occasional samples were lost or invalidated.

Typically a Ko consolidation test is run to simulate field conditions. In a Ko consolidation test, the vertical and horizontal principle effective stresses are not equal and the ratio between the two is chosen to insure that the specimen consolidates only vertically (no lateral strains). For the soft sediments, the vertical effective stresses are usually higher than the normal effective stresses to insure Ko conditions. With only three samples it was not possible to determine the appropriate Ko value and a value of 0.7 (horizontal to vertical effective stress) was used based on previous results on soft sediment testing. This was likely lower than optimum and one sample (GC-B-005) failed horizontally during testing. Volumetric strain and NAPL displacement can still be determined although other consolidation parameters would not be estimated accurately. These parameters were estimated as part of other geotechnical testing and so this was not considered a serious limitation for the current testing.

The samples were first removed from the tube and trimmed down to the testing diameter of two inches. Figure 1 below shows the early stages of trimming on specimen GC-B-004(p1) obtained from tube GC-B-004. Note the limited presence of contaminants in samples from this tube and the heterogeneity of their distribution. Figure 2 shows specimens GCB-004(P1) and GC-B-002 after being trimmed down to testing diameter. The specimens were then placed in a second

trimming device to cut off the top and bottom to insure they were parallel and perpendicular to the heigh of the specimen (Figure 3).

After trimming, the specimens were placed in the triaxial setup through a split mold (Figure 4a). Before the cell is assembled and testing begins (Figure 4b), bladder accumulaters were used to collect the effluent. General comments about the specimens and consolidation testing performed are as follows:

1) The samples cannot be considered undisturbed since they were not stored and shipped properly. Specimen GC-B-002 had traces of contaminents that were already expelled from the specimen due to disturbance during shipping. Since they were not undistubed, there is a higher likelihood that contaminants would be mobile.
2) Samples GC-B-002 and GC-B-005 appeared more contaminated (Figure 2b and 3). Sample GC-B-005 had more "roots" and other debris that made trimming more challenging and eventually resulted in the specimen failing during consolidation.
3) The soil in sample GC-B-004 was light brown with occasional non-uniform pockets of NAPL or other organic rich material (Figure 1). The soil was coarser than that of the other two samples, with a higher sand content.
4) Sample GC-B-002 was tested first. Due to a transducer failure, high precision consolidation information was not recorded although volume changes due to consolidation at regular intervals were recorded manually and analyzed herein.
5) With the limited number of samples, Ko could not be identified and therefore the results reported here should be used with caution as they do not reflect true Ko conditions. Additional tests are needed to determine Ko for these sediments before a true Ko consolidation can be run.

Figure 4: specimen setup in the triaxial cell.

Consolidation was conducted in five stages as shown in Table 1, exposed sediment and then capped with the equivalent of up to 10 feet of sand in 2.5 foot stages. Water depth (to set hydrostatic pressures) was assumed to be 10 ft. Table 1 summarizes the stresses used for the testing and the equivalent field conditions.

Table 1: lab stresses and equivalent field conditions

Depth to top of specimen (ft)	Thickness of sand cap (ft)	Depth of water to top of specimen (ft)	Horizontal Effective Stress (psi)	Vertical Effective Stress (psi)	Back Pressure (psi)	Horizontal Total Stress (psi)	Vertical Total Stress (psi)
2.5	-	10	0.47	0.68	5.5	5.97	6.18
2.5	2.5	10	1.31	1.88	5.5	6.81	7.38
2.5	5.0	10	2.16	3.09	5.5	7.66	8.59
2.5	7.5	10	2.95	4.21	5.5	8.45	9.71
2.5	10.0	10	3.82	5.45	5.5	9.32	10.95

The volumetric strains versus time for each of the specimens and estimated NAPL (as measured by HEM) and water contents are shown in Figures 4-7. In each figure the placement of additional load on the sample is shown by the vertical arrows. For Sample GC-B-002, the maximum load was placed in two steps while for other samples, the load was applied in 5 steps. The fine-grained sediment samples GC-B-002 and GC-B-005 showed >20% initial NAPL contents and water contents in the 70-100% range (mass NAPL or water per mass dry solids). The coarse grained sediment sample GC-B-004-1 and GC-B-004-2 showed initial oil contents of less than 5% and a water content of 25%. There was similar variability as measured by absolute standard deviation between replicates of all samples which meant that the lower NAPL content

of sample GC-B-004 samples exhibited a relatively high relative standard deviation (+/- ~100%). Samples GC-B-002 and GC-B-005 samples showed similar absolute variability but much lower relative variability due to the higher NAPL/HEM contents. The fine grained samples consolidated approximately 16-18% with the loading of the equivalent of 10 feet of sand. The coarser sample consolidated <5%. None of the samples expressed meaningful amounts of NAPL. Trace observations of expressed NAPL however indicate that the sediments could lead to transient sheens if disturbed.

Post-consolidation sampling showed that some redistribution of NAPL and water had occurred in the samples despite negligible NAPL release. Water mobilized to the near surface and water was expressed from the top of the sediment during the consolidation process. NAPL, however, had apparently replaced water at the bottom of the sample. Samples collected post-consolidation from the top of the specimens showed elevated water contents and depleted NAPL levels (as measured by HEM) while bottom samples showed the reverse trends.

Although this testing was preliminary in nature, it suggests that the NAPL currently present in sediments in the Gowanus Canal is unlikely to be mobilized by capping. Further testing is required to confirm whether these conclusions are generally applicable in the Canal.

Figure 5: Sample GC-B-002 consolidation profile and water/NAPL content statistics pre and post consolidation. The full load of the equivalent of 10 foot of cap was placed in two steps with rapid sample consolidation immediately after application. Total sample strain was 16%. No meaningful NAPL was displaced, only water. NAPL redistributed slightly through the sample with some movement to the bottom of the sample as water was displaced.

I, the sender, vote that I do not want this project to proceed.

Robert Goldberg to: Region2 GowanusCanalComments 04/25/2013 06:23 PM

History: This message has been forwarded.

As (one of the options above) of the community of Red Hook, I/We am/are strongly opposed to the processing of contaminated sludge dredged from the Gowanus Canal Superfund Cleanup Site at a facility at the proposed location. The cost savings are negligible, and the Red Hook Ball Fields and Pool are used in public trust. The community does not want to create more land from this contaminated sludge adjacent to one of the most heavily used recreation areas in New York City. People and organizations adversely affected include (but are not limited to!):

- Children
- Numerous public and private schools which use the fields for physical education & sports teams
- Residents of the Red Hook Houses and the surrounding neighborhood
- Soccer, softball, baseball, football, handball, basketball, track & field teams and enthusiasts
- Swimmers of all ages
- The Red Hook Food vendors and their customers
- Other visitors to our community

Further, we object to an individual (John Quadrozzi), who has incurred serious fines for environmental violations, from profiting from the project.

Carlos Slinger to: Region2 GowanusCanalComments 04/25/2013 06:40 PM

I'm here registering my opposition to the toxic waste processing center and/or placement of toxic waste in red hook,as proposed in the EPA Gowanus clean up plan. The neighborhood is potentially one of the next great place to live,visit,and shop if the plan goes ahead,mostly all of us will not only be severely affected by the processing center,and also all business
Thank you

I, the sender, vote that I do not want this project to proceed.

Irene Shen to: Region2 GowanusCanalComments 04/25/2013 06:45 PM

As (one of the options above) of the community of Red Hook, I/We am/are strongly opposed to the processing of contaminated sludge dredged from the Gowanus Canal Superfund Cleanup Site at a facility at the proposed location. The cost savings are negligible, and the Red Hook Ball Fields and Pool are used in public trust. The community does not want to create more land from this contaminated sludge adjacent to one of the most heavily used recreation areas in New York City. People and organizations adversely affected include (but are not limited to!):

- Children
- Numerous public and private schools which use the fields for physical education & sports teams
- Residents of the Red Hook Houses and the surrounding neighborhood
- Soccer, softball, baseball, football, handball, basketball, track & field teams and enthusiasts
- Swimmers of all ages
- The Red Hook Food vendors and their customers
- Other visitors to our community

Further, we object to an individual (John Quadrozzi), who has incurred serious fines for environmental violations, from profiting from the project.

re: EPA's plan for Gowanus Canal

Taryn FitzGerald to: Region2 GowanusCanalComments 04/25/2013 08:09 PM

Hello,

We are residents in the community and understand that the Douglas Degraw Pool is in jeopardy of being destroyed to create an underground sewage system. This pool serves many old and new residents of a growing, thriving community that has been targeted lately by the Bloomberg administration. While we are all for cleanup of the area, the pool must remain for the community and should NOT be considered as a site for such storage.

Thank you very much.

Sincerely,
Taryn FitzGerald, Sergio Fanchiotti and Ryan Fanchiotti

My comments

Warren Cohen to: Region2 GowanusCanalComments, Natalie Loney 04/25/2013 09:53 PM

Please respond to Warren Cohen

To the EPA:

I am a resident of the Gowanus who lives a block and a half from the canal (44 1st Street.)

I supported the initial listing of the canal as a Superfund candidate and now I support nearly all of your proposed methods for cleaning up the Canal via the Superfund process.

I was very pleased to note that along with chemical contaminants, you plan to clean up the biological contaminants as well. Not only to clean the canal but to protect it against future contaminants. My neighbors support this as well .

On that end, I wish the EPA were actually more aggressive, encompassing the canal's bulkheads and the land that is leaching toxic materials into the canal. I don't understand why there isn't a more comprehensive approach by the EPA. I also wish the EPA was more actively considering the impact of cleanup change that will affect the region after its remedy is complete. I also oppose the EPA granting special endorsements to projects like Lightstone's 700 apartment building on the canal which I think will have a negative impact on our local environment.

I do hope the EPA can work around disruption at the Double D pool, which is a community resource.

But overall and on the plus side, I do appreciate the EPA wanting to minimize the carbon footprint. I do hope the clean up itself is done in ways that minimize disruption to the local neighborhoods. I support barge transport for the toxic materials (not trucks or truck traffic.)

I am excited to see the Gowanus Canal finally cleaned via the Superfund Process. Thank you.

Best,

Warren Cohen

Re: Gowanus Canal Superfund Site – Proposed Plan

Dear Mr. Tsiamis:

On behalf of Natural Resources Defense Council ("NRDC") and its 1.3 million members and activists, I write to submit comments in support of the Environmental Protection Agency's ("EPA") December 2012 "Proposed Plan" for the Gowanus Canal Superfund Site.[1] NRDC commends EPA for focusing its attention on this long-neglected, highly polluted, urban waterway and for developing a plan intended to remove from the canal, and/or permanently sequester from potential routes of human and ecological exposure, the most significant toxic contamination in the canal. We express our support for community efforts to ensure that the cleanup is completed both expeditiously and safely.

We submit this letter to emphasize our support for EPA's proposal to address ongoing sources of contamination as part of the Superfund remedy, particularly combined sewage overflows ("CSOs") near the head of the canal, which threaten to recontaminate areas targeted for intensive cleanup.

NRDC has been involved for decades in efforts to ensure that New York City solves its 30 billion-gallon-per-year sewage overflow problem, consistent with the requirements of the federal Clean Water Act. We support the 2012 CSO administrative consent order ("CSO Order") between New York City and the New York State Department of Environmental Conservation ("NYSDEC"), which commits the city to (i) implement specific "gray" infrastructure projects in particular drainage areas, (ii) meet targets for green infrastructure implementation citywide, and (iii) critically, to develop Long Term Control Plans ("LTCPs")

[1] http://www.epa.gov/region2/superfund/npl/gowanus/pdf/gowanus_prap.pdf

that build upon the gray and green projects specified in the AOC to identify *additional* CSO reduction projects necessary to achieve compliance with state water quality standards.

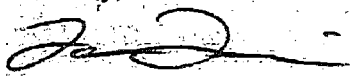
The CSO Order makes clear that the City's CSO reduction obligations in the Gowanus Canal are not limited to the specific projects identified in the CSO Order itself. Rather, under the CSO Order, the City, through the LTCP, must achieve any additional reductions necessary to meet not only existing water quality standards, which correspond to the canal's current "designated uses," but also any higher standards corresponding to the canal's "highest attainable use." We fully expect that, following the Superfund cleanup, more extensive recreational and ecological uses will be attainable in the canal than are reflected in the canal's current designated uses under state law. It is critical to ensure that ongoing CSO discharges do not preclude such uses or otherwise undermine the remedial goals of the Superfund cleanup.

EPA's Proposed Plan rightly concludes that the City's LTCP for the Gowanus Canal, which is due for submission to NYSDEC in June 2015, should be required to achieve CSO reductions at a level necessary to prevent recontamination of the Superfund site and to ensure the long-term integrity of the Superfund remedy. We applaud NYSDEC for concurring in this determination, and for committing to coordinate with EPA to ensure the Gowanus LTCP achieves this goal.

We also look forward to participating in the City's process of developing LTCPs for the Gowanus Canal and waterbodies throughout the city. We stand ready to support the City's efforts to identify the most cost-effective combinations of green and gray infrastructure to meet the requirements of both the CSO Order and the Gowanus Canal Superfund remedy.

Thank you for your consideration of these comments.

Sincerely,



Lawrence M. Levine
Senior Attorney

I support the Red Hook Option of the EPA Gowanus Canal Superfund cleanup.

The improvement to an active local maritime industrial business, the economic benefits it will bring, the jobs that it will create, are all important to me and what I believe is best for the majority of the community of Red Hook.

Further, I am confident that any necessary safeguards will be incorporated into the work, monitored and maintained, to ensure the workers and the community are without harm or risk of such.

Please approve the Red Hook option.

IMPORTANT- MUST BE SUBMITTED BEFORE *APRIL 26th, 2013* *DEADLINE!*

I support the EPA Gowanus Canal Superfund - Red Hook option.

The improvement to an active local maritime industrial business, the economic benefits it will bring, the jobs that it will create, are all important to me and what I believe is best for the majority of the community of Red Hook.

Further, I am confident that any necessary safeguards will be incorporated into the work, monitored and maintained, to ensure the workers and the community are without harm or risk of such.

Please approve the Red Hook option.

IMPORTANT- MUST BE SUBMITTED BEFORE *APRIL 26th, 2013* *DEADLINE!*

I support the Red Hook Option of the EPA Gowanus Canal Superfund cleanup.

The improvement to an active local maritime industrial business, the economic benefits it will bring, the jobs that it will create, are all important to me and what I believe is best for the majority of the community of Red Hook.

Further, I am confident that any necessary safeguards will be incorporated into the work, monitored and maintained, to ensure the workers and the community are without harm or risk of such.

Please approve the Red Hook option.

IMPORTANT- MUST BE SUBMITTED BEFORE *APRIL 26th, 2013* *DEADLINE!*

I support the Red Hook Option of the EPA Gowanus Canal Superfund cleanup.

The improvement to an active local maritime industrial business, the economic benefits it will bring, the jobs that it will create, are all important to me and what I believe is best for the majority of the community of Red Hook.

Further, I am confident that any necessary safeguards will be incorporated into the work, monitored and maintained, to ensure the workers and the community are without harm or risk of such.

Please approve the Red Hook option.

T S Valvanis

I, the sender, vote that I do not want this project to proceed.

Tiziana Mazziotto to: Region2 GowanusCanalComments 04/26/2013 05:29 AM

History: This message has been replied to.

As (one of the options above) of the community of Red Hook, I/We am/are strongly opposed to the processing of contaminated sludge dredged from the Gowanus Canal Superfund Cleanup Site at a facility at the proposed location. The cost savings are negligible, and the Red Hook Ball Fields and Pool are used in public trust. The community does not want to create more land from this contaminated sludge adjacent to one of the most heavily used recreation areas in New York City. People and organizations adversely affected include (but are not limited to!):

- Children
- Numerous public and private schools which use the fields for physical education & sports teams
- Residents of the Red Hook Houses and the surrounding neighborhood
- Soccer, softball, baseball, football, handball, basketball, track & field teams and enthusiasts
- Swimmers of all ages
- The Red Hook Food vendors and their customers
- Other visitors to our community

Further, we object to an individual (John Quadrozzi), who has incurred serious fines for environmental violations, from profiting from the project.

Gowanus Canal
Dena Schultz to: Region2 GowanusCanalComments 04/26/2013 07:40 AM

Christos Tsiamis
Project Manager,
Central New York Remediation Section of the U.S. Environmental Protection Agency
Region 2
290 Broadway, 20th floor
NY, New York 10007-1866

Mr. Tsiamis:

I am writing to register my opposition to the currently proposed location for dewatering the toxic sludge resulting from clean – up of the Gowanus Canal.

I am opposed to any solution which involves stabilizing the sludge on-site and keeping it in Red Hook in any form.

I am concerned that the amount of toxicity released into the atmosphere in the dewatering process has not been studied thoroughly and that the sludge processed at this site and transformed into a concrete form (as planned) could leak toxic materials in the future. According to the EPA's own report, "Tests to assess the leachability of NAPL (toxic contaminants)... would need to be performed (on the concrete)... Permanent institutional controls would be required to ensure the long-term effectiveness of this option..." I do not want a site built with materials potentially leaching toxic contaminants near my home and requiring a permanent monitoring facility where I live and breathe.

The estimated $37 million dollar savings for this method does not benefit the community, but rather reduces the expenses of the clean-up for the original polluters. Additionally, this proposal includes the building of additional waterfront bulkhead land for a private entity, which, by their own admission, has not been thoroughly vetted or designed. I am concerned that once this project is in motion, the requests and the needs of the community will be lost as a private developer seeks to increase profit with no benefit to the community. It appears that all parties in this plan stand to benefit in some way form storing this material in Reed Hook, with the very notable exception of the residents.

The EPA has a list of remedies that involve processing and containment of dredged material off-site for beneficial use such as the capping of landfill sites, I urge the EPA to select any option that involves off-site processing and offsite disposal.

Thank You,

Dena Schultz
44 Coffey Street
Brooklyn, NY 11231

I, the sender, vote that I do not want this project to proceed.

From: luis sturla <lsturla730@gmail.com>
Subject: email to USEPA

Mr Christos Tsiamis
Project Manager
Central New York Remediation Section
US Environmental Protection Agency
290 Broadway 20th Floor
New York, New York 10007-1866
e-mail: GowanusCanalComments.Region2@epa.gov

Dear Mr Tsiamis

Our community is very alarmed about proposals for the selection of site for processing and disposal of toxic sediments
extracted from the canal, as part of the preferred remedy. We respectfully request that these proposals not be included
in the final rule for reasons explained below.

The Red Hook Community is opposed to the proposed Alternatives E,F,and G These alternatives variously involve on or off
site stabilization and disposal in on site constructed facility. We understand that this involves transporting the non-NAPL dredging
of sediments to a facility owned by Mr Quadrozzi directly adjacent to the Red Hook Park and Playground(a NYC designated Landmark).
