> <u>Clarification of Field Investigation Activities</u> <u>Remedial Investigation/Feasibility Study</u> <u>Work Plan Addendum</u> <u>Allegan, Michigan Facility</u>

Dear Ms. Sikora:

As you requested on Thursday, November 12, 1992, Remcor, Inc. (Remcor) has prepared this letter to clarify Remcor's position regarding the use of photoionziation detectors (PIDs) for field screening of soils and the deletion of headspace screening from the field investigation of the above-captioned project.

It was Remcor's intent to use only HNu[™] PIDs during this field investigation in accordance with the U.S. Environmental Protection Agency- (EPA-) approved Quality Assurance Project Plan (QAPP) (Section 6, Page 2 of 2). Representatives of Rockwell International Corporation (Rockwell) expressed some concern over the absence of a Photovac[™] PID for this portion of the investigation as such equipment had been used in conjunction with HNUs[™] during the 1990 field investigation work; hence, this issue was brought to your attention. The EPA agreed that the use of the Photovac[™] PID was not necessary based on the fact that the Photovac[™] was of limited use during the 1990 investigation (due to its sensitivity to weather conditions which greatly decreased its value), and because the HNu[™], only, was specified in the QAPP.

Within the Remedial Investigation/Feasibility Study Work Plan Addendum, Remcor stated that field screening, to be performed with an HNu^m PID would be used to select samples not otherwise specified for laboratory analyses. As this procedure was identified for sample selection in lieu of the headspace analyses used during the 1990 field investigation, Remcor did not, therefore, also intend to perform headspace analyses. The use of headspace analyses can be problematic due to limited recovery of soils from each sample interval and the need for separate samples from a given interval for both laboratory analyses and headspace screening. In addition, the quality of the data generated from headspace analyses is largely

dependent upon the ambient temperature at the time of sample collection and the temperature of the room/area where the samples are stored prior to screening. And, because field screening of split-spoon samples typically generate data that are similar to headspace screening the performance of both evaluations is redundant. Based on this discussion, the EPA concurred that headspace screening was not necessary.

On November 12, 1992, the EPA requested that the proposed locations for the cyanide pot test pits, TP-8 and TP-9, be modified. The enclosed Field Change Request Form reflects this modification and the justification for the final field procedures. Please sign each of the three enclosed copies and forward them to Mr. Tom DeFouw for his signature; one signed copy will then distributed to each of the signing parties.

In addition to the clarification/changes discussed above, Remcor requested several minor field changes from your on-site representative. It is our understanding that you gave verbal approval for these changes to your on-site representative. Documentation of these changes will be forwarded to your office following the return of Remcor field personnel from the site.

Very truly yours,

Martha E. Fleming, C.P.G Project Geologist

Lawrence M. Martin, P.E. Project Manager

"REALISTIC SOLUTIONS FOR HAZARDOUS WASTE PROBLEMS"

FIELD CHANGE REQUEST FORM

Rockwell International Corporation Allegan, Michigan Site

PART I - INITIATION

Modification Requested:

EPA requested that the locations of the cyanide test pits, TP-8 and TP-9 be moved approximately 60 feet south of the locations shown in Figure 2, Drawing 92192-E5, of the Work Plan Addendum. To accomodate this request, one of the approved test pits (TP-9) was omitted from the Work Plan addendum scope. In addition, EPA stand that it was not necessary to extend the test pit to a depth below 10 feet in attempting to reach the water table (saturated soils). EPA recommended that if there is no evidence of cyanide pots, samples will be collected from 0 to 0.5 feet and 5 to 7 feet. If cyanide pots are present, samples are to be collected at 0 to 0.5 feet and the most impacted interval based on field screening, or if the screening does not indicate impact the sample is to be collected from immediately adjacent to the pot. The third sample will be collected from two feet lower in the soil column unless the interval is greater than 10 feet below ground surface or in a saturated interval. The new test pit location is shown in revised Figure 2, Drawing 92192-E6.

Justification:

EPA believes that if cyanide pots are present it is most likely that they will be relatively close to the loading dock doors at the north end of the former drive-line assembly building, hence the relocation nearer these doors. Due to limited access in the area of the new test pit location and the potential for structural damage/failure of the adjacent buildings, the EPA agreed to the completion one large test pit (TP-8) in lieu of the two approved test pits. In addition, the EPA stated that it would not be necessary to excavate the test pit to the water table if such excavation would required removal of materials below 10 feet; this was in response to the nature of the underlying materials which are believed to be comprised of loose, well-sorted, fine sand.
