EXECUTIVE SUMMARY

1.0 INTRODUCTION

This document is the final baseline human heath risk assessment (BHHRA) for the Omaha Lead Site (OLS) located in Omaha, Nebraska. The purpose of this document is to characterize the risks to area residents, both now and in the future, from site-related contaminants present in environmental media, assuming that no steps are taken to remediate the environment or to reduce human contact with contaminated environmental media. The results of this assessment are intended to help inform risk managers and the public about potential human risks attributable to site-related contaminants and to help determine where there is a need for action at the site.

2.0 SITE CHARACTERIZATION

Site Location and Description

The OLS is located in Omaha, Nebraska. The site is approximately 27 square miles in size, and includes most of the eastern portion of the greater Omaha metropolitan area (Figure ES-1). It includes all residential properties, child-care facilities, vacant lots, and other residential-type properties (schools, churches, parks) that have been contaminated as a result of historic air emissions from lead smelting/refining operations. There are more than 39,000 residential properties and vacant lots located within the Final Focus Area (Figure ES-1). Commercial and industrial properties are not included in the site.

Basis for Concern

In the past, two lead smelters operated in the eastern part of the OLS. Historical smelting, refining, and recycling activities that occurred at these smelters resulted in the release of lead and other smelter-related metals into air in the form of particulate matter. These particulates in the air were transported by wind and deposited onto soil in the vicinity of the site. Humans may be exposed to lead and other smelter-related metals in soil by a number of pathways, and adverse health effects may occur if concentrations and exposure levels are high enough.

One measure of human exposure to lead is the concentration of lead in the blood, generally expressed in units of micrograms of lead per deciliter of blood (µg/dL). Concentration values above 10 µg/dL are generally considered to be elevated and of potential health concern. The Douglas County Health Department has been monitoring lead levels in the blood of children living in Douglas County for a number of years. Figure ES-2 shows the percentage of children with elevated blood leads (> 10 µg/dL) in the area of the site compared with State and national data. As shown, the frequency of elevated blood lead values in the area of the OLS have been consistently higher than elsewhere. This indicates that children living in the area of the site are

being exposed to lead in the environment at levels that exceed other locations, and which may be of potential health concern to some children.

3.0 SITE CONCEPTUAL MODEL

Exposure Media and Pathways of Potential Concern

Figure ES-3 presents a general conceptual model of how smelter-related contaminants that have been released to the environment at the OLS might result in exposure of humans. The environmental medium of chief concern is surface soil that has been impacted by the wet or dry deposition of metal-containing airborne particulates released from the smelters. The human population of chief concern is residents in the area of the site, now or in the future, including both children and adults. Residents might be exposed to smelter-related contaminants in site soils by a number of different pathways, including ingestion, inhalation, and dermal contact with contaminated soil or dust. Other pathways (ingestion of home-grown produce that may have taken up contaminants from the soil, ingestion of contaminated drinking water, and contact with contaminated surface water or sediment) are likely to be minor sources of exposure.

Selection of Chemicals of Potential Concern

Chemicals of Potential Concern (COPCs) are chemicals which exist in the environment at concentration levels that might be of potential health concern to humans and which are or might be derived, at least in part, from site-related sources. The chief COPC at this site is lead. However, several other chemicals were identified that might also be of potential concern to humans, including the following:

Chemicals of Potential Concern	
Aluminum	Iron
Antimony	Lead
Arsenic	Manganese
Cadmium	Mercury
Chromium	Thallium
Cobalt	Vanadium
Copper	Zinc

4.0 EVALUATION OF RISK ASSOCIATED WITH EXPOSURE TO LEAD

4.1 Exposure Assessment

Population of Chief Concern

The population of chief concern for lead exposure is young children (age 0-84 months of age). This is because young children tend to have higher intakes of lead than adults, tend to absorb more lead than adults, and are inherently more sensitive to lead than adults. If environmental exposures to lead in a residential area are below a level of health concern for young children, exposures are usually also below a level of health concern for older children and adults, including pregnant women.

Exposure Pathways of Chief Concern

Young children can be exposed to lead from a variety of sources. At this site, the environmental medium of chief concern to EPA is outdoor soil that became contaminated with lead released from historic smelter operations. Exposure to smelter-contaminated soil may occur through ingestion of soil or dust, or through inhalation. Dermal absorption of lead from soil or dust is considered to be very minor, as is uptake of lead from soil into home-grown produce.

In addition to these exposures to smelter-related releases of lead, children may also be exposed to lead from other sources as well. This includes lead in drinking water and in food bought from grocery stores. Because risk from lead depends on exposure from all of these sources, these exposure pathways are also included in the risk evaluation for lead.

Another source of lead exposure is lead-based paint. To the extent that lead-based paint has contributed to lead levels in soil or dust at the site, the risks are included in the evaluation of risks from ingestion of these media. Risk from direct ingestion of lead-based paint chips is also of substantial concern, but this exposure pathway is not evaluated in this assessment.

4.2 Toxicity Assessment

Non-Cancer Effects

Excess exposure to lead can result in a wide variety of adverse effects in children. The most important effect is on the nervous system. The effects of chronic low-level exposure on the nervous system include decreased performance in various types of tests of intelligence, attention span, hand-eye coordination, etc. The overall weight of the available evidence provides clear evidence of nervous system effects in young children occurring at blood lead levels in the range of 5-10 µg/dL, and possibly lower. Such effects on the nervous system are long-lasting and may be permanent.

Cancer Effects

Studies in animals indicate that chronic oral exposure to very high doses of lead salts may cause an increased frequency of tumors of the kidney. However, there is only limited evidence suggesting that lead may be carcinogenic in humans, and the non-carcinogenic effects on the nervous system are usually considered to be the most important and sensitive endpoints of lead toxicity.

Current Guidelines for Protecting Children from Lead

The USEPA identifies 10 µg/dL as the blood lead concentration level at which adverse effects begin to occur that warrant avoidance. For convenience, the probability that an observed blood lead value will exceed 10 µg/dL is referred to as P10. The EPA has established a health-based goal that there should be no more than a 5% chance that a child will have a blood lead value above 10 µg/dL (USEPA 1994b,1998b). That is, the health-based goal is to ensure that P10 does not exceed 5%.

4.3 Overview of the IEUBK Model

The USEPA has developed a mathematical model for evaluating lead risks to residential children. This model is referred to as the Integrated Exposure Uptake Biokinetic (IEUBK) model. This model requires, as input, data on the levels of lead in all potentially contaminated environmental media (soil, dust, water, air, diet) at a specific location, and an estimate of the amount of these media taken in (by ingestion or inhalation) by a child living at that location. Given these inputs, the model calculates an estimate of the distribution of blood lead values that might occur in a population of children exposed to the specified conditions, including the value of P10.

4.4 Inputs to the IEUBK Model

For most IEUBK model exposure parameters, the default values recommended by current EPA guidance were used. Data from the site were used to estimate:

- The average concentration of lead in outdoor surface soil at each property
- The average concentration of lead in indoor dust at each property
- The average concentration of lead in air (site-wide)
- The average concentration of lead in drinking water (site-wide)
- The relative bioavailability (absorbability) of lead in soil and dust

These data were then used to calculate the value of P10 at each property inside the final focus area that has not already been remediated by USEPA.

4.5 Results

The results of the lead risk evaluation are presented in Table ES-1 and in Figure ES-4. Key points to note include the following:

- Of the 28,478 properties evaluated, a total of 19,445 homes (68%) are predicted to have P10 values at or below the health-based goal of 5%, and 9,033 properties (32%) have values that exceed the goal.
- Of these 9,033 properties, 3,177 have P10 values between 5% and 10%, 3,051 properties have P10 values between 10% and 20%, and 2,805 properties have P10 values greater than 20%.
- The locations of properties with P10 values greater than the health-based goal of 5% were widespread across the OLS final focus area and were found within all zip codes with the exception of 68117 (which only had 2 properties).

These results indicate that a number of homes or parcels within the final focus area have soil lead levels that are of potential health concern to children who may reside there, now or in the future.

4.6 Uncertainties in the Evaluation of Risk Associated with Exposure to Lead

It is important to recognize that the exposure and risk calculations for lead presented in this section are subject to uncertainty that arises from a number of different sources. This includes:

- Uncertainty in measured lead concentrations in soil
- Uncertainty in estimated lead concentrations in indoor dust
- Uncertainty in the estimate of lead absorption from soil and dust
- Uncertainty in the IEUBK model calculations and predictions

Because of these uncertainties, risk predictions for lead may not be highly accurate for every property, and risk managers and the public should take these uncertainties into account when interpreting the risk conclusions for lead at this site.

5.0 EVALUATION OF RISK ASSOCIATED WITH EXPOSURE TO NON-LEAD CONTAMINANTS

Although lead was the primary contaminant released to the environment from the historic operation of the smelters in the OLS, other metal and metalloid contaminants may also have been released. The purpose of this section is to provide an evaluation of the risks to area residents from these chemicals.

5.1 Exposure Assessment

The risk assessment focused on potential health risks to residents (both children and adults) from incidental ingestion of surface soil and indoor dust, as well as dermal contact with soil and indoor dust (when data permitted). Other pathways were judged to be sufficiently minor that quantitative evaluation was not warranted.

Exposure of residents (adults and children) to non-lead chemicals of potential concern in site soils and dusts was quantified on a property-by-property basis. Exposure was calculated in accord with standard equations recommended by USEPA. In brief, the amount of chemical ingested or absorbed per day from each medium was calculated from information on the concentration of the chemical in the medium and the amount of medium that is ingested or contacted. Because there are usually differences between individuals in the level of exposure due to differences in intake rates, body weights, exposure frequencies, and exposure durations, calculations were performed for individuals that are "average" or are otherwise near the central portion of the range, and on intakes that are near the upper end of the range (e.g., the 95th percentile). These two exposure estimates are referred to as Central Tendency Exposure (CTE) and Reasonable Maximum Exposure (RME), respectively. Values of CTE and RME parameters for soil and dust were in accord with standard default values recommended by USEPA for evaluation of residents. Because only limited data were available on the concentration of non-lead COPCs in residential yards, each yard was evaluated using the highest detected concentration of each chemical. This approach is expected to tend to overestimate actual exposure levels.

5.2 Toxicity Assessment

A toxicity assessment is usually divided into two parts: the first characterizes and quantifies the non-cancer effects of the chemical, while the second addresses the cancer effects of the chemical. This two-part approach is employed because there are typically major differences in the time-course of action and the shape of the dose-response curve for cancer and non-cancer effects.

Non-cancer effects of an ingested chemical are usually described in terms of a Reference Dose (RfD). An RfD is an estimate (with uncertainty spanning perhaps an order of magnitude) of a daily exposure to the human population (including sensitive subgroups) that is likely to be without an appreciable risk of deleterious effects during a lifetime.

For cancer effects of ingested chemicals, toxicity is usually expressed in terms of the Slope Factor (SF). At this site, arsenic is the only chemical of potential concern that is known to cause cancer effects when ingested.

Toxicity values (RfD and SF values) for each non-lead COPC evaluated in this assessment were selected from EPA's database of toxicity factors or other sources in accordance with USEPA

guidance. In the absence of site-specific data, the relative bioavailability (RBA) for all non-lead chemicals in all media was assumed to be 1.0. This is expected to be a conservative assumption, tending to overestimate the true degree of absorption and risk.

5.3 Risk Characterization

5.3.1 Basic Methods

Non-Cancer Effects

The potential for non-cancer effects is evaluated by comparing the estimated daily intake of the chemical over a specific time period with the RfD for that chemical derived for a similar exposure period. This comparison results in a non-cancer Hazard Quotient (HQ), as follows:

$$HQ = DI / RfD$$

where:

HQ = Hazard Quotient
DI = Daily Intake (mg/kg-day)
RfD = Reference Dose (mg/kg-day)

If the HQ for a chemical is equal to or less than one (1E+00), it is believed that there is no appreciable risk that non-cancer health effects will occur. If an HQ exceeds 1E+00, there is some possibility that non-cancer effects may occur, although an HQ above 1E+00 does not indicate an effect will definitely occur. This is because of the margin of safety inherent in the derivation of all RfD values. However, the larger the HQ value, the more likely it is that an adverse effect may occur.

If an individual is exposed to more than one chemical, a screening-level estimate of the total non-cancer risk is derived simply by summing the HQ values for that individual. This total is referred to as the Hazard Index (HI). If the HI value is less than 1E+00, non-cancer risks are not expected from any chemical, alone or in combination with others. If the screening level HI exceeds 1E+00, it may be appropriate to perform a follow-on evaluation in which HQ values are added only if they affect the same target tissue or organ system (e.g., the liver). This is because chemicals which do not cause toxicity in the same tissues are not likely to cause additive effects.

Cancer Effects

The excess risk of cancer from exposure to a chemical is described in terms of the probability that an exposed individual will develop cancer because of that exposure. For each chemical of

concern, this value is calculated from the daily intake of the chemical from the site, averaged over a lifetime (DI_L), and the slope factor (SF) for the chemical, as follows:

$$\text{Excess Cancer Risk} = 1 - \exp(-DI_L * SF)$$

Excess cancer risks are summed across all chemicals of concern and all exposure pathways that contribute to exposure of an individual in a given population.

The level of total cancer risk that is of concern is a matter of personal, community, and regulatory judgment. In general, the USEPA considers excess cancer risks that are below about 1 in one million (1E-06) to be so small as to be negligible, and risks above 1 in 10,000 (1E-04) to be sufficiently large that some sort of remediation is desirable. Excess cancer risks that range between 1E-04 and 1E-06 are generally considered to be acceptable, although this is evaluated on a case by case basis, and USEPA may determine that risks lower than 1E-04 are not sufficiently protective and warrant remedial action.

5.3.2 Results

Non-Cancer Risks

Table ES-2 shows the estimated non-cancer HQ values for residential CTE (Panel A) and RME (Panel B) scenarios, including both children (age 0-6 years) and adults (age 7-30 years). As shown, risks from most COPCs in surface soil are below a level of potential concern (HQ = 1) for both child and adult residents with CTE and RME scenarios. An exception is arsenic, which results in an HQ > 1 at about 10% of the properties. In addition, there are a small number of properties (< 1% of the total) where antimony, mercury and/or thallium yield HQ values above 1. Summation of non-cancer HQ values for chemicals that act on the same target tissue does not result in a substantial increase in non-cancer risk at most properties.

Cancer Risks

The only COPC at this site that is carcinogenic by the oral or dermal route is arsenic. Excess cancer risks were estimated at each property within the final focus area where data on arsenic concentrations in soil were available. Table ES-3 presents a summary of the estimated cancer risks to CTE residents and RME residents from arsenic in soil, including both the ingestion and dermal pathways. As seen, estimated cancer risks to CTE residents are within USEPA's target risk range (1E-06 to 1E-04) at all properties. Estimated risks to RME residents are also within USEPA's target risk range at most properties, although risks exceed 1E-04 at 141 locations (5% of the properties with data). The excess individual lifetime cancer risks at these 141 properties range from 2E-04 to 1E-03.

Summary of Risks from Non-Lead COPCs

Based on the evaluations described above, the frequency of properties with chemical-specific HQ values or organ-specific HI values above 1 is very low except for arsenic. At some properties, the concentrations of arsenic are sufficient that, if the soil is ingested by child and/or adult residents over a long period of time, the risk of both cancer and adverse non-cancer effects would be higher than normally considered acceptable by USEPA.

5.5 Uncertainties in Risk Estimates for Non-Lead Chemicals

Quantitative evaluation of the risks to humans from environmental contamination is frequently limited by uncertainty regarding a number of key data items, including the true mean concentration of contaminants at individual properties, the true level of human contact with contaminated media, the true extent of absorption of metals from ingested soil and dust, and the true relationship between exposure and response in humans. This uncertainty is usually addressed by making assumptions or estimates for uncertain parameters based on whatever limited data are available. In general, the assumptions are intentionally conservative, such that risk calculations based on the assumptions are more likely to overestimate than underestimate actual human exposure and risk. It is important for risk managers and the public to keep this in mind when interpreting the results of this risk assessment.

1.0 INTRODUCTION

1.1 Purpose

This document is the final baseline human heath risk assessment (BHHRA) for the Omaha Lead Site (OLS) located in Omaha, Nebraska (CERCLIS ID NESFN0703481). The purpose of this document is to assess the potential risks to humans, both now and in the future, from site-related contaminants present in environmental media, assuming that no steps are taken to remediate the environment or to reduce human contact with contaminated environmental media.

This final risk assessment is an extension and update of an interim risk assessment that was previously performed at the site (NHHSS 2004). This final risk assessment incorporates additional data that were not available at the time of the interim assessment.

The results of this final assessment are intended to help inform risk managers and the public about potential human risks attributable to site-related contaminants under current site conditions and to help determine where there is a need for action at the site. The overall management goal is to ensure protection of humans from deleterious effects of exposures to site-related contaminants for both current and future land uses.

The methods used to evaluate risk in this assessment are consistent with current United States Environmental Protection Agency (USEPA) guidelines for human health risk assessment (USEPA 1989a, 1991a, 1991b, 1992a, 1997a, 2001a, 2002a, 2002b, 2004a) provided by the USEPA for use at Superfund sites.

1.2 Organization

In addition to this introduction, this report is organized into the following sections:

Section 2 This section provides a description of the site and a review of data that are available to characterize the nature and extent of environmental contamination at the site.

Section 3 This section provides a Site Conceptual Model that summarizes how people may be exposed to site-related contaminants in the environment at the site, and identifies chemicals of potential concern (COPCs) in soil that warrant quantitative evaluation of exposure and risk.

Section 4 This section evaluates exposure and potential risk to residential children from lead in soil and dust.

Section 5 This section evaluates exposure and potential risk to area residents (adults and children) from non-lead chemicals of potential concern.

Section 6 This section provides full citations for USEPA guidance documents, site-related documents, and scientific publications referenced in the baseline risk assessment.

2.0 SITE CHARACTERIZATION

A detailed description of the site is provided in the Remedial Investigation (RI) report for the site (Black and Veatch 2009). A summary of information that is needed for the evaluation of human exposure and risk from lead and other site-related contaminants is provided below.

2.1 Site Location and Description

The OLS is located in Omaha, Nebraska. As shown in Figure 2-1, it encompasses the eastern portion of the greater metropolitan area, excluding Omaha's Central Business District (USEPA 2005a). It includes residential properties, child-care facilities, vacant lots, and other types of properties used by area residents (schools, churches, parks) that have been contaminated as a result of historic air emissions from lead smelting/refining operations. Figure 2-2 illustrates the levels of lead that have been observed in yard soils in residential properties at the site.

2.2 Focus Area Boundary

Under Superfund, one important objective of the RI is to characterize the nature and extent of site-related contamination. In performing an RI, the most common approach is to establish an initial focus area to guide initial sampling efforts, and then to expand this focus area as needed based on the results that are obtained.

For the OLS, the original boundary of the focus area was established at the time the site was added to the National Priorities List (NPL) by establishing a perimeter surrounding properties that had been determined at the time to have a soil lead concentration that exceeded 1,200 milligrams per kilogram (mg/kg) (USEPA 2005a). This area encompassed approximately 13.8 square miles.

As RI sampling continued, the focus area was expanded to include a total of about 20 square miles, bounded by Ames Avenue to the north, L Street to the south, 45th Street to the west, and the Missouri River to the east (USEPA 2005a). In 2004, the focus area was further expanded to include a portion of the area bounded by Redick Street to the north, Harrison Street to the south and 52nd Street to the west. This expanded focus area is shown by the grey area in Figure 2-3.

Most recently, the focus area has been expanded again to include additional areas to the west and north. The final focus area is shown in Figure 2-3 by the purple line. The final focus area is based on a geospatial analysis of lead in surface soil that is described in Appendix A. In brief, the approach is based on evaluating the density (frequency) of properties within a neighborhood (a circle with a radius of 500 meters) that have a mean soil lead concentration above 400 mg/kg (the default level of concern and soil screening level for residential properties). The density is expected to be highest near former smelters, and to decrease as a function of distance away from

the smelters. When the density decreases to 5% or less, the occurrence of properties above 400 mg/kg is expected to be infrequent, and the relative contribution of the smelter to the soil lead level is expected to be low. On this basis, the final focus area boundary is defined as a line that encloses properties located in neighborhoods where the density of properties with mean soil concentrations of 400 mg/kg or higher exceeds 5%.

Based on this approach, the final focus area encompasses all or part of the following 13 zip codes: 68102, 68104, 68105, 68106, 68107, 68108, 68110, 68111, 68112, 68117, 68131, 68132, 68198. It includes a total of 39,305 properties that are classified as residential or vacant (see Table 2-1).

2.3 Topography

The topography of the Omaha metropolitan area is characterized by a hilly upland in the western portion of the city and the Missouri River floodplain area to the east. The altitude at the OLS ranges from approximately 1,030 to 1,200 feet above mean sea level (Black and Veatch 2001).

2.4 Meteorology

Omaha has a climate that is continental in character, with contrasts in both temperature and precipitation. Seasons typically consist of severe winters, wet springs, and warm summers with moderate thunderstorm activity. The normal annual total precipitation in the area is approximately 28 to 30 inches, and the mean annual lake evaporation is 28 inches, resulting in a net precipitation of 0-2 inches (Black and Veatch 2009). The prevailing winds are from the south/southeast and from the north/northwest, along the river valley (see Figure 2-4).

2.5 Surface Water

The Missouri River is the predominant surface water feature near the OLS, located immediately east of the site. It supports recreational fishing and boating. The OLS is located outside of the 500 year floodplain of the Missouri River (Black and Veatch 2009).

Surface water runoff from the OLS flows easterly towards the Missouri River, and this is a potential pathway by which smelter-related contaminants deposited to soil could enter the river. Based on air transport modeling, the furthest north that site-related impacts to the Missouri River might be expected is about river mile 629 (Black and Veatch 2001). Direct surface water runoff from the Final Focus Area is expected to occur from Read Street (approximately river mile 624) to the Douglas County Line (approximately river mile 609).

2.6 Land Use

Current land use at the OLS consists of a mixture of residential, industrial, and commercial uses (Black and Veatch 2001). Future land use at the OLS is reasonably expected to remain approximately similar to current land use patterns, with a mixture of residential, industrial and commercial properties. However, land use at individual properties may change over time. That is, some residential properties could be converted to non-residential use in the future, and current non-residential properties located within the OLS could be converted into residential properties in the future, particularly into multi-unit dwellings (USEPA 2005a).

2.7 Drinking Water

Residences located within the OLS focus area receive their drinking water from the municipal water supply (USEPA 2005a). The Metropolitan Utilities District (MUD) provides drinking water to Omaha and Papillion, Nebraska, and Carter Lake, Iowa, from 52 municipal wells and one surface water intake. The 52 municipal wells are all located outside of a 4-mile radius of the OLS. The surface water intake is located north of the OLS at river mile 623, which is within the zone that might be influenced by runoff of contaminated surface water (see Section 2.5). Council Bluffs Waterworks (CBW) provides drinking water to Council Bluffs, Crescent and Underwood, Iowa, and operates 2 municipal wells and one surface water intake. The municipal wells and surface water inlet are located approximately 2-3 miles east-northeast of the site, approximately 2,000 feet downstream of river mile 619 (Black and Veatch 2001).

2.8 Basis for Concern

Two lead processing facilities conducted operations within the boundary of the OLS. The locations of these two facilities are shown in Figure 2-5.

The American Smelting and Refining Company, Inc. (ASARCO) operated a lead refinery for a period of more than 120 years (early 1870s to 1997) at 500 Douglas Street. This facility processed lead bullion containing gold, silver, antimony, and bismuth. The ASARCO facility was closed in 1997. The property is currently owned by the City of Omaha and has been reutilized for both commercial and public purposes (Black and Veatch 2009).

A secondary lead smelter and a lead battery recycling plant operated from the early 1950s until 1982 at 555 Farnam Street. Two different owners operated this facility: Aaron Ferer and Sons Co., and Gould Electronics, Inc. (Gould). Douglas County purchased the property in the early 1980s. The property has been remediated and developed into a county park (Black and Veatch 2009).

Historical smelting, refining, and recycling activities at these two former smelters resulted in the release of lead and other smelter-related metals into air in the form of particulate matter. These

particulates in the air were transported by wind and deposited onto soil in the vicinity of the site. Humans may be exposed to lead and other smelter-related metals in soil by a number of pathways, and adverse health effects may occur if concentrations and exposures are high enough.

One way to evaluate the level of human exposure to lead is to measure the concentration of lead in the blood, generally expressed in units of micrograms of lead per deciliter of blood (µg/dL). As discussed in greater detail in Section 4.1, concentration values above 10 µg/dL are generally considered to be elevated and of potential health concern. The Douglas County Health Department (DCHD) has been monitoring lead levels in the blood of children living in Douglas County for a number of years. Figure 2-6 shows the percentage of children with elevated blood lead levels (> 10 µg/dL) in the area of the site compared with State and national data. As shown, the frequency of elevated blood lead values in the area of the site has been consistently higher than elsewhere (USEPA 2005a). This indicates that children living in the area of the site are being exposed to lead in the environment at levels that exceed other locations, and which may be of potential health concern to some children.

2.9 Potential Sources

There are a number of potential sources of lead in the environment. This includes naturally-occurring lead in soil, lead released from anthropogenic sources such as leaded gasoline and leaded paint, as well as lead released from smelter emissions.

The USEPA conducted an apportionment investigation to determine the sources of lead contamination found in the soil of residential properties at the site. Soil samples were collected from the former ASARCO refinery property, the former Gould property and residential properties. These soil samples were examined using an electron microprobe to characterize the chemical form of the lead that was present and to compare the types of lead found in soil samples at the smelter areas to that found in residential properties. More than 90 percent of the community soils studied contained lead in a form that was characterized as pyrometallurgical (i.e., smelter-related) (Black and Veatch 2009). Based on this, the study concluded that the ASARCO and Gould facilities are significant sources of the lead at the OLS (USEPA 2005a).

2.10 Response Actions to Date

Time-Critical Removal Action

USEPA initiated two time-critical removal actions at the OLS site (USEPA 1999, 2001b, 2002c, 2003a) to eliminate or reduce ingestion exposure to lead in soil. In 2004, the two removal actions were combined into a single response action that encompassed residential properties with soil lead concentrations equal to or greater than 1,200 mg/kg and properties (childcare facilities or residential properties) where there were one or more children with elevated blood lead levels

(above10 µg/dL) and with soil lead concentrations greater than 400 mg/kg (Black and Veatch 2009, USEPA 2005a).

Remedial Action

An Interim Record of Decision (ROD) was signed in 2004 (USEPA 2005a) that included the following remedial actions to address site risks:

- Excavation and removal of lead-contaminated soils at properties with the greatest human health risk. These generally include:
  - A residential property where at least one non-foundation sample exceeds 800 mg/kg for lead.
  - Residences where a child with an elevated blood lead level (>10 µg/dL) resides and with any non-foundation sample exceeding 400 mg/kg lead.
  - Child-care facilities and other high-child impact areas with any non-foundation sample exceeding 400 mg/kg lead.
- Stabilization of loose and flaking exterior lead-based paint, in cases where it threatens the protectiveness of the soil remedy implemented at a property.
- High-efficiency interior cleaning at properties where soil cleanup actions are conducted and lead in interior dust exceeds Housing and Urban Development (HUD) standards.
- Participation in a comprehensive program with other public and private entities to characterize and address all potential lead sources.
- Health education for the Omaha community and medical professionals to support public awareness, exposure prevention programs, in-home assessments, blood-lead screening programs and diagnosis, treatment, and surveillance programs.

As of September 2008, a total of 36,000 properties (residential, commercial, other, etc.) have been investigated, and USEPA has remediated 4,100 properties.

2.11 Site Investigations

Several investigations have collected data on the levels of environmental contamination at the OLS. The available data are summarized in Tables 2-2 through 2-3 and are briefly described below.

2.11.1 Surface Soil

Table 2-2 presents a summary of three soil investigations conducted at or in the vicinity of the OLS. Each investigation is summarized in the following sections. Electronic data are provided in Appendix B and summary statistics are provided in Tables 2-4 and 2-5.

Preliminary Assessment/Site Inspection

A Preliminary Assessment/Site Investigation (PA/SI) was conducted from 1998 to April 2001 to support removal action and remedial action at the Omaha Lead Site (Black and Veatch 2001). Soil samples were collected from childcare facilities and from properties where children with elevated blood lead levels resided in order to evaluate the properties for potential removal action. Soil samples were also collected from other residential properties to identify the extent of lead contamination from the industrial emission sources in downtown Omaha. These samples were collected along four sampling corridors that extended from downtown Omaha to the north, south, east and west. Along a sampling corridor, surface soil samples were collected from approximately eight properties, every tenth of a mile until the soil lead concentrations were consistently found to be below 400 mg/kg. Additionally, grab samples of subsurface soil were collected at every other property within the sampling corridor. Sample depths were 0-8 inches below ground surface (bgs), 8-16 inches bgs, and 16-24 inches bgs (Black and Veatch 2001).

At all properties, a minimum of five surface soil samples were collected: four from the yard and one from the drip zone (within 3 feet of the house foundation). Surface soil samples consisted of five-point composite samples of the top one inch of soil (0-1" bgs). Yard sample locations were generally determined by dividing the property into four quadrants of approximately equal areas and collecting one composite sample from each quadrant (Black and Veatch 2001). Surface and subsurface soil samples were homogenized and sieved with a number 10 (2 mm) mesh sieve prior to analysis. All samples were analyzed using X-Ray Fluorescence (XRF) and approximately 10% of all field samples were analyzed for the 23 metals on the Target Analyte List (TAL) using Inductively Coupled Plasma Atomic Emission Spectroscopy (ICP-AES) and Cold Vapor Atomic Absorption (CVAA) for mercury (Black and Veatch 2001).

Background Summary Report

In November of 1999, a total of thirty soil samples were collected approximately 8 miles north of the former ASARCO facility to determine background concentrations of metals. The samples consisted of 23 surface soil (0-1" bgs) samples and 7 subsurface soil samples (0-8", 8-16" and 16-24" bgs). Surface soil samples consisted of 5-point composite samples, whereas subsurface samples were collected as grab samples. Soil samples were homogenized and sieved through a number 10 mesh sieve (2 mm). The samples were analyzed by XRF for 15 of the 23 TAL Metals (arsenic, lead, zinc, silver, barium, cadmium, cobalt, chromium, copper, iron, mercury, nickel, manganese, antimony, and selenium) as well as 7 additional analytes (molybdenum, rubidium, tin, strontium, titanium, uranium, and zirconium). Twenty-nine of the soil samples were also analyzed for 23 metals by ICP-AES (the 23 TAL Metals (except for mercury) and bismuth) (Jacob 2000).

Remedial Investigation/Feasibility Study

From May 2001 to May 2008, USEPA collected surface soil samples to support site characterization, remedial investigation and risk assessment activities. At residential properties, the yard was divided into 4 quadrants of approximately equal size. At most properties this consisted of 2 quadrants in the front yard and 2 quadrants in the backyard. A 5-point composite surface soil (0-1 inches in depth) sample was collected from each quadrant. Surface soil samples were also collected from play areas, gardens, and the drip zone around each residence (the area within 6-30 inches of the foundation of a residence) in the same manner. Surface soil samples were homogenized and sieved prior to analysis. Surface soil samples collected from March 1999 to May 2000 were sieved through a number 60 mesh sieve (250 µm), whereas surface soil samples collected thereafter were sieved through a number 10 mesh sieve (2 mm) (Black and Veatch 2009).

All surface soil samples were analyzed by XRF and approximately 5% of all field samples were analyzed for the 23 TAL Metals using ICP-AES and CVAA for mercury (Black and Veatch 2009).

2.11.2 Paired Indoor Dust-Outdoor Soil Samples

Two investigations have collected paired outdoor soil-indoor dust samples at the site. Each data set is briefly described below and summarized in Table 2-3. Electronic data are provided in Appendix B.

2003-2004 Remedial Investigation

During 2003-2004, paired outdoor soil and indoor dust samples were collected from 159 homes located within the OLS. These homes were selected by dividing the site into four-acre parcels, each of which was assigned a random number. Starting with number 1, the parcels were selected in order for collection of data. Within each parcel, only properties that had not already had soil samples collected were included in the property lists eligible for sampling (approximately 6,000 of the 40,000 residential properties located within the site). The homes within the selected parcels were randomly ordered. The field teams used this order to contact the property owners for permission to collect indoor dust samples. Permission to sample was granted at only 330 properties in spite of extensive efforts by access personnel. From the 330 properties, only 159 allowed the collection of indoor dust samples (Black and Veatch 2009).

At each of these 159 properties, several yard soil and indoor dust samples were collected. For yard soil, one five-point composite of surface soil (0-1" bgs) was collected in each quadrant of the yard. All soil samples were sieved using a number 10 mesh screen (2 mm) and analyzed by XRF and by ICP-AES. For indoor dust, samples were collected from three locations in the house, including: (1) entryway, (2) windowsill, and (3) floor. Samples were collected in

accordance with the Field Sampling Plan (Black and Veatch 2009) using a High Volume Small Surface Sampler (HVS3) vacuum. Dust samples were sieved using a number 100 sieve (150 µm) and analyzed for lead (only) using ICP.

2007 Supplemental Data Collection Activities

In the fall of 2007, paired outdoor soil-indoor dust samples were collected from 98 properties in accordance with the Field Sampling Plan (Black and Veatch 2007) to address some of the limitations identified in the existing outdoor soil-indoor dust dataset (see Black and Veatch 2007 for details). The properties for sampling were selected based on the concentration of lead in yard soil measured in previous investigations, seeking to ensure that a wide range of concentration levels were included. Collecting samples from a range of lead concentrations increases the confidence of the best fit line through the data that defines the outdoor soil to indoor dust relationship. In addition, an effort was made to sample properties at which children currently reside.

For soil, one 20-point composite sample of surface soil (0-1 inches bgs) was collected from each participating property. The composite sample was collected by dividing up the property into 4 quadrants and collecting five grab samples from each quadrant (e.g., from the four corners away from drip zones and the center of each quadrant). The composite soil sample was sieved in the field, using a number 60 mesh screen to isolate the soil particles in the fine fraction (< 250 µm). The fine fraction of the soil samples were submitted to the USEPA Region 7 laboratory for analysis of the 23 TAL Metals using SW846 6010 and SW 846 7471 (mercury). Three additional analytes were added to the analytical suite: silicon, titanium and zirconium. These chemicals are thought to be good indicator chemicals for deriving an outdoor soil to indoor dust relationship because they are present in both media and are not thought to have significant alternative indoor sources (Black and Veatch 2007).

For indoor dust, one composite sample was collected from each participating property. The composite consisted of sub-samples from 3 locations in the home including: (1) entryway; (2) living area; and (3) bedroom. Samples were collected in accordance with the Field Sampling Plan (Black and Veatch 2007) using an HVS3 vacuum. The composite dust samples were sieved in the field using a number 60 mesh screen to isolate the dust particles in the fine fraction (250 µm). The fine fraction dust samples were submitted to the EPA Region 7 laboratory for analysis of the 23 TAL Metals and silicon, titanium, and zirconium by Method SW846 6010 and SW846 7471 (mercury) (Black and Veatch 2007). Summary statistics for indoor dust samples collected in 2007 are presented in Table 2-6.

2.11.3 Tap Water

In December 2007, a total of 154 tap water samples were collected from 77 residences to support the final human health risk assessment. A total of two tap water samples were collected at each

home: a "first-flush" sample and a "post-flush" sample. The first-flush sample represents a water sample that is collected first thing in the morning, before any household use of water (e.g., running the shower, flushing the toilet, running the sink). The post-flush sample represents a water sample that is collected after allowing the tap to run for approximately 5 minutes. Both samples were collected from the kitchen sink in accordance with the Field Sampling Plan (Black and Veatch 2007) using 1 liter, high density polyethylene sample bottles. Both the first-flush and post-flush samples were collected by residents. Field personnel added 1 milliliter of nitric acid to the sample containers to preserve the samples. Water samples were analyzed for lead by the USEPA Region 7 laboratory in Kansas City, KS, using EPA Method 200.8 (Black and Veatch 2007). These data are provided electronically in Appendix B and are summarized in Table 2-7.

2.11.4 Ambient Air

Concentrations of lead in ambient air were obtained from USEPA's Air Quality System (AQS) database (USEPA 2008b). This database contains ambient air monitoring results for contaminants that are considered hazardous air pollutants or criteria air pollutants by the Clean Air Act, including lead. The database contains annual summaries of the data for the current year and ten previous years. As shown in Figure 2-7, 11 of the 14 monitoring stations in Douglas County are located within the Omaha Lead Site. Table 2-8 presents details on the location of each station and the time period(s) when lead measurements were collected at each station. Table 2-9 presents the mean concentration of lead measured from 1997 (the year ASARCO ceased operations) to 2002 (the most current data available).

2.12 Data Useability Assessment

In accord with guidelines for assessing data quality (USEPA 1989a, 1992b), the available data were reviewed to determine if they were appropriate for use in the risk assessment. The following sections describe the data useability findings.

2.12.1 Review Against Data Useability Criteria

The soil, dust, and tap water data were reviewed in accord with USEPA's (1992b) Guidance for Data Useability in Risk Assessment. Detailed data useability worksheets are presented in Appendix H. The results of the review are briefly presented below:

- Data Sources: the sampling and analytical methods used in the PA/SI and RI are comparable and appropriate to combine across data sets, with the exception of the indoor dust. For indoor dust, different sieve sizes were used to prepare samples collected in 2003-2004 (Number 100 mesh screen, 150 µm) and 2007 (Number 50 mesh screen (250 µm). Thus, these datasets should not be combined together for use in the risk assessment.

- Documentation: field documentation was appropriate, and no deviations from the Sampling and Analysis Plan (SAP) were reported.
- Analytical Methods and Detection Limits: the analytical methods used to quantify metals in soil, dust and tap water are appropriate for use in risk assessment. The detection limits were found to be adequate for all chemicals, in all media, with the exception of thallium in soil[1].
- Data Quality Indicators: Data quality indicators (completeness, comparability, representativeness, precision and accuracy) were met for soil, dust, and tap water.
- Data Review: Laboratory data were reviewed by the USEPA Region 7 Laboratory. XRF data were reviewed by the field contractor. Data were qualified accordingly.
- Reports to Risk Assessor: All USEPA (1992b) recommended data and documentation were made available for use in the preparation of this risk assessment.

Based on this evaluation, USEPA's data useability criteria have been satisfied for surface soil, indoor dust, and tap water data collected at the site.

Detailed data quality information was not readily available for the ambient air data collected at the air monitoring stations in Douglas County. However, most data of this type are collected and reported in accord with the monitoring requirements specified in the National Ambient Air Quality Standard for Lead (40 CFR 50, 53 and 58), and the database indicates that all data considered for use in this risk assessment were collected in accord with an approved quality assurance project plan. Based on this, all of the ambient air data for lead collected within the OLS were considered appropriate for use in this risk assessment.

2.12.2 XRF vs. ICP

As described above, the concentrations of lead and other metals in soil have been analyzed by two different methods (XRF and ICP). In some cases, XRF data may be less accurate than ICP data due mainly to interferences between different chemicals and because of effects of the soil matrix. Thus, whenever ICP data were available at a sampling location, these data were preferred over XRF data from the same sampling location, and only the ICP data were included in the risk assessment. If only XRF data were available for a sampling location, then the XRF results were included if they were determined to be adequate for use in risk assessment.

The adequacy of XRF data were determined by conducting a Data Quality Assessment (DQA) of XRF data sets. This assessment is presented in Appendix C. In brief, the first step was to evaluate the XRF detection limit of the analyte in soil. If the XRF detection frequency was high (>80%), the detection limit was considered adequate. If the detection frequency was < 80%, the XRF detection limit was compared to the level needed for risk assessment purposes. If the detection limit was below the level needed for risk assessment purposes, the detection limit was

[1] The detection limit for thallium in soil was about 7 mg/kg, which is slightly higher than the risk-based concentration of 5 mg/kg.

considered adequate. If the detection limit (evaluated as described above) was not adequate, the data were deemed to be inappropriate for risk assessment purposes. If the detection limit was adequate, then the strength of the correlation between paired XRF and ICP results was evaluated. If the strength of the correlation was good ($R^2 > 0.7$), the data were considered to be adequate for use in risk assessment. Otherwise, the XRF data were not considered to be adequate. Based on the DQA in Appendix C, only the XRF data for lead and zinc were determined to be adequate for use in the risk assessment. Consequently, XRF data for other metals were not used.

For lead and zinc, all XRF data were adjusted to estimate the ICP-equivalent concentrations, using the chemical-specific parameters from the ICP/XRF regressions (see Appendix C for details):

$$[\text{ICP-equivalent concentration}] = a_i + b_i * [\text{XRF concentration}]$$

where:

a_i = intercept from the ICP/XRF regression line for chemical "i"
b_i = slope from the ICP/XRF regression line for chemical "i"

2.12.3 Current *vs.* Historic Site Conditions

As mentioned above, USEPA has remediated yard soil at a number of residences in the OLS that meet the response action criteria described in the interim ROD (see Section 2.10). Properties that have already been remediated by USEPA were not evaluated in this risk assessment.

2.12.4 Data Qualifiers

Data qualifiers assigned by the laboratory were reviewed in order to determine if individual measurements were reliable and appropriate for use. All data points were considered appropriate for use in the risk assessment except for soil samples that were qualified by the laboratory as "R" (rejected for not meeting quality control requirements), "0" (no results reported), or "N/A-I" (no results reported).

3.0 SITE CONCEPTUAL MODEL

3.1 Scope of the Baseline Risk Assessment

This risk assessment evaluates the potential risks to residents at current residential properties (including child-care facilities) and at properties that could be converted to residential land use in the future (vacant lots). Properties that are currently commercial, schools, parks, or churches were not evaluated by this risk assessment.

3.2 Exposure Media and Pathways of Potential Concern

Figure 3-1 presents a conceptual model of how smelter-related contaminants that have been released to the environment at the OLS might result in exposure of residents, including both children and adults. The environmental medium of chief concern is surface soil that has been impacted by the wet or dry deposition of metal-containing airborne particulates released from the smelters. Residents might be exposed to smelter-related contaminants in site soils by a number of different pathways, including ingestion, inhalation, and dermal contact with contaminated soil or dust, and ingestion of home-grown produce that may have taken up contaminants from the soil. In addition, contaminated soil might be carried to the Missouri River by surface water runoff, potentially leading to contamination of surface water, sediment, fish, and drinking water. However, not all of these are likely to be of equal concern for all contaminants. Section 4.1 describes the exposure pathways that are of chief concern for lead, and Section 5.1 describes the exposure pathways that are of chief concern for other (non-lead) contaminants.

3.3 Selection of Chemicals of Potential Concern

Chemicals of Potential Concern (COPCs) are chemicals which exist in the environment at concentrations that might be of potential health concern to humans and which are or might be derived, at least in part, from site-related sources.

The chief COPC at this site is lead. The procedure used to identify other (non-lead) COPCs for the evaluation of risks to residents is shown in Figure 3-2. Chemicals that are not likely to contribute significant risks to humans are eliminated, while chemicals that might be of potential concern are retained for either quantitative or qualitative evaluation, depending on the availability of data. It is important to note that this COPC selection procedure is intended to be conservative. Thus, it is expected that some chemicals will be identified as COPCs that are actually of little or no concern, but that no chemicals of authentic concern will be overlooked.

The steps in the COPC selection process are described below.

Step 1: Eliminate chemicals for which no toxicity values are available

If a chemical does not have a toxicity value, it is generally not possible to evaluate whether site-related exposure is of potential health concern or not. Therefore, all chemicals that were detected at the site and which had no appropriate toxicity value were identified as a source of uncertainty, unless the chemical is a beneficial nutrient (e.g., calcium, magnesium, potassium and sodium).

Step 2: Eliminate chemicals never detected

In this risk assessment, chemicals that were analyzed for but never detected were excluded from quantitative evaluation. However, if the analytical detection limit exceeded a level of health concern for a chemical that was never detected, that chemical was identified as a source of uncertainty.

Step 3: Eliminate chemicals detected, but whose maximum value is below a level of concern

If a chemical is detected at least once, but the maximum detected concentration is below a level of health concern, that chemical may be eliminated from further consideration. The level of health concern used in this evaluation is based on Regional Screening Levels for residential exposure to soil (USEPA 2008c). With the exception of lead, which is assessed differently, the target risk levels were set to a non-cancer hazard quotient (HQ) equal to 0.1 and an excess cancer risk equal to 1E-06 (1 in 1,000,000) for residential exposure.

Appendix E presents detailed results of the COPC selection process. Table 3-1 lists the COPCs identified for quantitative evaluation.

4.0 EVALUATION OF RISK FROM LEAD

Lead is the contaminant of primary human health concern at the OLS. This section describes the toxicity of lead and the approach that the USEPA uses to evaluate risk to humans from exposure to lead, and applies that method to characterize the level of risk that would exist if no further action is taken to reduce human exposure to lead at the site.

4.1 Exposure Assessment

4.1.1 Population of Chief Concern

For residential land use, young children (age 0-84 months) are the sub-population of chief concern for exposure to lead. This is because young children (1) tend to have more hand-to-mouth behavior which leads to higher intakes (expressed in terms of mg/kg-day) of lead-contaminated environmental media such as soil, dust, and paint, (2) tend to absorb ingested lead more readily than adults, and (3) are more sensitive to the toxic effects of lead than are older children or adults. If the risk associated with environmental exposure to lead in a residential area is found to be below a level of concern for young children, then the risk for older children and adults, including pregnant women, would also be below a level of concern.

4.1.2 Exposure Pathways of Chief Concern

A generalized site conceptual model (SCM) for exposure of residents to smelter-related contaminants was presented previously in Figure 3-1. The detailed SCM for exposure of residents to lead is presented in Figure 4-1. The following sections describe which of these pathways are likely to be potentially significant for residents (children) and that have been included in the quantitative evaluation of the total exposure to lead in the risk assessment.

Ingestion of Lead in Soil or Dust

Although few children intentionally ingest large amounts of soil, many children ingest small quantities as a consequence of normal hand-to-mouth activities while playing outside. In addition, soil may be tracked into indoor living spaces where it becomes mixed into indoor dust, which may also be ingested as a result of indoor hand-to-mouth activities. Because these exposure pathways are often among the most important sources of lead exposure in children, both are evaluated quantitatively in this risk assessment.

Note that lead in soil and dust may arise from a number of different sources, including not only deposition from historic smelter emissions but also releases from indoor and outdoor lead-based paint, historic releases from vehicles using leaded gasoline, and others. In accord with EPA guidance (USEPA 2003c), the risk assessment is based on the total level of lead in soil and dust.

Inhalation of Lead in Suspended Soil Particulates

Release of soil particles into air can occur from wind or other disturbances (e.g., digging in soil), and children can be exposed to lead in the soil particles by breathing the air. Although lead exposure by this pathway is usually small compared to the ingestion pathway, it is evaluated quantitatively in this risk assessment.

Dermal Contact with Lead in Soil and Dust

Dermal contact with soil or dust may also occur, but dermal absorption of lead from soil or dust is generally considered to be a minor pathway compared to exposure from ingestion pathways. Consequently, these pathways are not evaluated quantitatively in this risk assessment.

Ingestion of Lead in Drinking Water

Lead may occur in drinking water either because the source water is contaminated, or because lead enters the water from pipes or plumbing fixtures. This pathway may be significant in some cases, and is evaluated quantitatively in this risk assessment.

Ingestion of Lead in Home-Grown Vegetables

At locations where a resident maintains a home garden, exposure to lead may occur via ingestion of home-grown garden vegetables. However, uptake of lead from soil into plants is usually not extensive, and ingestion from this source is not evaluated quantitatively in this risk assessment.

Ingestion of Lead in Purchased Food

Lead is present in low levels in many types of food purchased from stores, and exposure by this pathway is evaluated quantitatively in this risk assessment.

Ingestion of Lead in Surface Water and Sediment

Exposures of children to lead in surface water or sediment along the Missouri River (e.g., during recreational visits to the river) are likely to be much smaller than exposures at the residence, and these pathways are not evaluated quantitatively in this risk assessment.

Ingestion of Lead in Paint Chips

When lead-based paint is in poor condition (i.e., peeling and chipping), a child can directly ingest flakes or chips of the paint. In accord with EPA recommendations (USEPA 1994a), this exposure pathway is not evaluated in this assessment because data on the amount of paint chips

ingested are not available and the amount is highly uncertain. However, direct ingestion of lead-based paint chips is generally recognized as being a serious health threat.

4.2 Toxicity Assessment

Excess exposure to lead can result in a wide variety of adverse effects in children. The following sections summarize the most characteristic and significant of the adverse effects of lead on children, and highlights current guidelines for protecting children from exposure to lead.

Neurological Effects

The effect of lead that is usually considered to be of greatest concern in children is impairment of the nervous system. Many studies have shown that animals and humans are most sensitive to the effects of lead during the time of nervous system development, and because of this, the fetus, infants and young children (0-6 years of age) are particularly vulnerable. The effects of chronic low-level exposure on the nervous system are subtle, and normally cannot be detected in individuals, but only in studies of groups of children. Common measurement endpoints include various types of tests of intelligence, attention span, hand-eye coordination, etc. The overall weight of the available evidence provides clear evidence of neurocognitive effects in young children occurring at blood lead levels in the range of 5-10 µg/dL, and possibly lower (USEPA 2006). Such effects on the nervous system are long-lasting and may be permanent.

Effects on Heme Synthesis

A characteristic effect of chronic lead exposure is anemia stemming from lead-induced inhibition of the synthesis of heme (the oxygen-binding component of hemoglobin) and a decrease in red blood cell life span. Lead interferes with heme synthesis by inhibiting the enzymes ALA-D and ferrochelatase (USEPA 2007a). Decreases in ALA-D activity can be detected at blood lead levels below 10 µg/dL in children and adults (ACGIH 1995, USEPA 2006). At concentrations of 20-30 µg/dL, ferrochelatase is also inhibited (USEPA 2006). Heme synthesis is inhibited not only in red blood cells but in other tissues. Several key enzymes that contain heme, including those needed to form vitamin D, also show decreased activity following lead exposure (USEPA 1986). The Centers for Disease Control (CDC) (1991) reviewed studies on the synthesis of an active metabolite of vitamin D and found that impairment was detectable at blood lead levels of 10-15 µg/dL.

Cardiovascular Effects

Both human and animal studies support the conclusion that lead exposure increases the risk of cardiovascular effects, including increased blood pressure, increased incidence of hypertension, cardiovascular morbidity, and mortality (USEPA 2006). Epidemiological studies reported an association of increased systolic blood pressure and decreased diastolic pressure with increased

blood lead levels, including levels below 10 µg/dL (USEPA 2006, 2007a). This finding is supported by studies in animals that demonstrate blood lead levels of 20-30 µg/dL for long periods result in hypertension, with one study reporting blood pressure increases in animals at blood lead levels as low as 2 µg/dL (USEPA 2006, 2007a).

Renal Effects

In adults, reduced renal function (measured by decreased renal clearance of creatinine) has been observed in adults at blood lead levels below 10 µg/dL. Low levels of lead can also act as a co-factor with other risk factors to increase the risk for renal dysfunction, increasing the susceptibility of sensitive populations such as those with diabetes, hypertension and chronic renal insufficiency for adverse renal effects (USPEA 2006). Individuals with chronic, high level exposure to lead (40-100 µg/dL), such as occupationally exposed adults, have an increased risk for lead nephropathy which can result in small, fibrotic kidneys and ultimately kidney failure (USEPA 1986, 2006). The renal effects of lead exposure in children are difficult to access, as most studies only measured early biological effect markers which have unknown clinical significance (USEPA 2006).

Immune System Effects

The main immune system targets of lead are macrophages and T lymphocytes, leading to a potential for increased tissue inflammation, reduced cell-mediated immunity, and increased risk of autoimmunity (USEPA 2006 and 2007a). Additionally, studies of lead exposure in both animals and humans have found an association between increased production of IgE (an immunoglobulin involved in allergic responses and asthma) and blood lead concentrations. In children, significant associations between serum IgE levels and increasing blood lead levels were observed at blood lead levels of less than 10 µg/dL (USEPA 2006 and 2007a). In animals, neonatal exposure to lead resulting in blood lead levels less than 10 µg/dL was found to produce persistent later-life immunotoxicity (USEPA 2006).

Cancer

Studies in animals indicate that chronic oral exposure to very high doses of lead salts may cause an increased frequency of tumors of the kidney (USEPA 1989b, ACGIH 1995). In humans, evidence of lead carcinogenicity is limited (USEPA 2006). Based on the available data, lead has been classified as a probable human carcinogen by the International Agency for Research on Cancer (IARC) (IARC 2005), and is reasonably anticipated to be a human carcinogen by the National Toxicology Program (NTP) (NTP 2003, 2004). USEPA classifies lead as a probable human carcinogen (USEPA 2008d). Nevertheless, the non-carcinogenic effects on the nervous system are usually considered to be the most important and sensitive endpoints of lead toxicity (USEPA 1986, 2006, 2007a).

Current Guidelines for Protecting Children from Lead

It is currently difficult to identify what degree of lead exposure, if any, can be considered safe for infants and children. As discussed above, some studies report lead-induced effects in children and adults beginning at around 5-10 µg/dL or even lower. Of special concern is the fact that many researchers have concluded the effects of lead on neurobehavioral performance, heme synthesis, the immune system, and fetal development may not have a threshold value, and that the effects are long-lasting (USEPA 1986, 2006).

After a thorough review of all the data, the USEPA currently identifies 10 µg/dL as the concentration level at which effects begin to occur that warrant avoidance. Likewise, the CDC has established a guideline of 10 µg/dL in preschool children which is believed to prevent or minimize lead-associated cognitive deficits (CDC 1991, 2005). For convenience, the probability that an observed blood lead value will exceed 10 µg/dL is referred to as P10. The USEPA has established a health-based goal that there should be no more than a 5% chance that a child will have a blood lead value above 10 µg/dL (USEPA 1994b,1998a). That is, the health-based goal is to ensure that P10 does not exceed 5%.

It is important to note that USEPA seeks to apply this goal at the level of individual properties, rather than at the level of a community. To understand the distinction, consider a community of 1,000 properties. Assume that 960 of these properties have a P10 value of 2%, while 40 of the properties have a P10 value of 20%. When studied at the community level, the expected value of P10 would be about 2.7%, suggesting that lead exposures do not exceed USEPA's health-based goal. However, lead exposures substantially exceed the health-based goal at the 40 properties with P10 = 20%. By achieving the P10 goal at every property, the community-level frequency of elevated blood lead values will automatically achieve the health-based goal.

4.3 Overview of the IEUBK Model

The USEPA has developed a standard approach for evaluating the risks of lead exposure in residential children (USEPA 1994a, 2001c). This approach employs a set of mathematical equations and calculations to predict the likely distribution of blood lead values in a population of children exposed to a specified set of environmental lead levels. This model is referred to as the Integrated Exposure Uptake Biokinetic (IEUBK) model. This model requires, as input, data on the levels of lead in all potentially contaminated environmental media (soil, dust, water, air, diet) at a specific location, and on the amount of these media taken in (by ingestion or inhalation) by a child living at that location. As noted above, dermal exposure to lead is considered to be a minor source of exposure and is not included in the model.

The inputs to the IEUBK model are selected to reflect estimates of central tendency values (i.e., arithmetic means or medians). These estimated inputs are used to calculate an estimate of the central tendency (the geometric mean (GM)) of the distribution of blood lead values that might

occur in a population of children exposed to the specified conditions. Assuming the distribution is lognormal, and given (as input) an estimate of the variability between different children (this is specified by the geometric standard deviation or GSD), the model calculates the expected distribution of blood lead values, and estimates the value of P10. This value may be compared to the EPA health-based goal (P10 = 5%) in order to determine if environmental contamination levels at that location are of concern or not.

4.4 Inputs to the IEUBK Model

Table 4-1 presents the IEUBK model inputs used in the risk assessment. For most parameters, the default values recommended by the guidance for the model were used (USEPA 2004a, 2008a). Details on site-specific model inputs used in the risk assessment are described below.

4.4.1 Environmental Concentration Data

USEPA guidance (USEPA 1994a) specifies that environmental concentration values provided to the IEUBK model should generally be the best estimates of the arithmetic mean concentration in a medium, averaged over the exposure unit of concern (a property). The following sections describe the derivation of these input values for each environmental medium included in the IEUBK model calculations.

Residential Yard Soil

For yard soil, the exposure point concentration (EPC) for each property was calculated as the mean of all surface soil (0-2 inch) samples collected at that property from locations where children may be regularly exposed to soil (USEPA 2007b). At most residences, this was usually the mean of four composite surface soil samples collected from 4 quadrants of the yard (2 samples from the front yard and 2 samples from the back yard). If more than one estimate was available for a quadrant, these were averaged within the quadrant before averaging across the quadrants. At some properties, additional composite samples were collected from garden areas, play areas, and drip zones. In these cases, samples from garden areas and play areas were included in calculating the yard-wide average lead concentration for the property. Soil samples from the drip zone were excluded from the yard-wide average lead concentration, because the drip zone is not thought to be an area where children are likely to play on a regular basis. In addition, the drip zone may contain chips of lead-based paint which could significantly overestimate exposure from soil if included in estimating EPCs for soil.

As discussed previously (see Section 2.11.1), most measures of lead in yard soil are obtained using XRF analysis of "coarse" soils (i.e., < 2 mm). However, the ideal measure would be lead measured in the fine fraction (< 250 µm) using ICP. This is because it is considered likely that children are exposed mainly to the fine faction, and because ICP measurements are considered to be more accurate than XRF measurements. Therefore, each XRF measurement of lead in coarse

soil was converted to an estimate of the concentration that would be expected had the fine fraction been analyzed by ICP. Appendix F presents the details of how this conversion is achieved. In brief, the calculation is as follows:

Fine ICP = Coarse XRF * 1.16 * 1.04

where:

1.16 = Conversion factor from coarse XRF to coarse ICP
1.04 = Conversion factor from coarse ICP to fine ICP

Appendix G presents the EPCs for lead in soil calculated in this way for each property evaluated in the risk assessment.

Indoor Dust

Indoor dust is a medium that is composed in part of outdoor soil and in part of material derived from other sources. Soil can be a dominant source of lead in indoor dust at residences. The IEUBK model incorporates a soil-to-dust transfer factor to describe the potential for lead in soil to be transported indoors and contribute to the concentration of lead in dust. This transfer factor is called M_{sd} and it is defined as the mass fraction of soil-derived particles in indoor dust (gram soil/gram dust) (USEPA 1998b). The M_{sd} is used to estimate the concentration in dust as follows:

$$Pb_{dust} = D0 + M_{sd} * Pb_{soil}$$

where:

Pb_{dust} = concentration of lead in indoor dust (µg Pb/g dust)
D0 = The concentration of lead in dust (µg Pb/g dust) that is not attributable to soil
M_{sd} = mass fraction of soil in dust (g soil/g dust)
Pb_{soil} = concentration of lead in outdoor soil (µg Pb/g soil)

M_{sd} values can range from 0 to 1, with low values indicating that the contribution of outdoor soil to indoor dust is minimal, and high values indicating that soil is the predominant source of indoor dust. The USEPA default assumption for M_{sd} is 0.70. That is, the default assumption is that 70% (by mass) of indoor dust is derived from outdoor soil (USEPA 1994a). However, the average fraction of dust derived from soil is likely to vary between sites, so USEPA Region 7 has obtained data to derive a site-specific equation that relates the concentration of lead in dust to that in soil for the OLS. The data and the analysis are presented in Appendix F. The resulting equation is:

$$C_{dust} = 42 + 0.74*C_{soil}$$

With regard to this equation, it is important to note several items:

- There is substantial variability of individual data points around the best-fit linear regression (see Figure F-11 in Appendix F). This is expected because of the many factors that determine the transfer of soil into indoor dust in each individual home (e.g., number of children and pets, extent of vegetative cover, frequency of cleaning, etc.). However, the slope of the line is highly significant ($p<0.001$), indicating that the regression model is a good predictor of the average contribution of soil to indoor dust.
- The intercept term (42 ppm) is relatively low. This indicates that although there may be a few individual homes with high indoor dust derived from indoor lead-based paint or other indoor sources (e.g., see Figure F-11 in Appendix F), on average it appears that indoor lead-based paint is not the dominant source of lead in indoor dust.
- The slope term (0.74 grams of soil per gram of dust) is relatively high, indicating that outdoor soil is, on average, the dominant source of material in indoor dust.

This equation was used to calculate the concentration of lead in dust at each property, based on the mean concentration of lead in outdoor soil at the property (excluding drip zone samples). Based on measured soil levels, estimated dust concentrations ranged from 51 mg/kg to 4,269 mg/kg (see Appendix G, Table G-1 for property-by-property estimates). Note that this equation is used to estimate the dust concentration even in cases where a measured value for dust was available (N = 98). This is because the measured value in dust is conditional on the current conditions at the property (percent grass cover in the yard, number of people and pets residing at the property, frequency of house cleaning, etc.), while the goal is to perform a generic assessment that includes expected values for all future as well as current residents.

Drinking Water

Data on the concentration of lead in tap water at 98 properties in the Final Focus Area were collected in 2007 and 2008 (Black and Veatch 2008a, 2008b). Samples of two types were collected at each residence: "first-flush" samples (i.e., the water that emerges when the water is first turned on after standing overnight) and "post-flush" samples (i.e., water that emerges after the standing water has been fully flushed from the pipes). This is potentially important because lead levels in first-flush water tends to be higher than in post-flush samples in homes where lead is present in pipes, soldered joints, or plumbing fixtures.

In the original data set (Black and Veatch 2008a), one location (property ID 29349) yielded values of 48.8 µg/L for first-flush water and 635 µg/L for post-flush water. These values were considered unusual for two reasons: 1) the values were much higher than any other samples collected, and 2) the post-flush sample was much higher than the first-flush sample. Because these levels (if actual) would be of acute health concern to residents at the location, USEPA re-sampled the tap water at this residence and found the levels of lead to be considerably lower that

the initial estimates, with both values below the national drinking water standard (15 µg/L). Because the high concentrations of lead were not confirmed by the second set of tap water samples, the first tap water results collected at this residence are considered invalid and were excluded from the risk assessment, and only the results from the second round of sampling at this property were used.

The resulting data are shown in Table 2-7. The average concentration in water ingested by residents was calculated by assuming that 50% of the water ingested is first-flush and 50% is post-flush (USEPA 1994a). Based on this assumption, the mean concentration of lead in tap water at the OLS is 1.36 µg/L.

Outdoor Air

Data on the mean concentration of lead in outdoor ambient air in the vicinity of the site was obtained from USEPA's AQS database (USEPA 2008b). This database contains ambient air monitoring results for contaminants that are considered hazardous air pollutants or criteria air pollutants by the Clean Air Act, including lead. Table 2-8 lists 14 stations located within Douglas County, and the availability of lead data from each station. As shown in Figure 2-7, 11 of these stations are located within the Final Focus Area of the OLS. Table 2-9 presents the annual average lead concentrations measured at these stations for the years 1997 to 2002. As seen, data are only available at 5 of the 11 stations (0011, 0041, 0042, 0046, 0049) during this time period.

Inspection of the data in Table 2-9 reveals that lead levels in ambient air have tended to decline over the time interval from 1997 to 2002. The reason for the decline is not certain, but one factor that is likely to be important is the cessation of ASARCO smelter operations in 1997. Because the goal of the risk assessment is to evaluate risks under current site conditions, only the most recent data were used in calculating the EPC for air. The available data are not adequate to determine with confidence if downward trends are continuing in the time frame of 2000 or later, so all data from 2000-2002 were used. If downward trends are still continuing, this approach could lead to an overestimate of lead exposure from ambient air under current site conditions.

It should be noted that the five stations for which data are available are all located in central Omaha, relatively near the former smelter site. The data are not adequate to reveal if there is a tendency for air concentrations to decrease as a function of distance from the former smelter site, so these data were used to represent all locations within the Final Focus Area. If there is a tendency for lead concentrations to decrease as a function of distance from the smelter, it is possible that the use of these data may tend to overestimate exposure from ambient air at locations that are furthest away from the former smelters.

Based on these considerations, the concentration value selected to represent lead in ambient air in the Final Focus Area is 0.036 µg/m^3. This concentration is the average lead concentration measured at 5 monitoring stations at the OLS from 2000 – 2002.

Purchased Food Items

For food items purchased from a grocery store, estimates of the average daily intake of lead were based on measured concentration values in food reported by the Food and Drug Administration's (FDA) Total Diet Study (FDA 2006), combined with typical dietary intake data from the National Health and Nutrition Examination Survey (NHANES III) (CDC 1997). These intake values are shown in Table 4-1 (Panel B).

Exposure of area residents by ingestion of lead taken up from soil into home-grown garden vegetables was not evaluated in this risk assessment because no site-specific data were available on the concentration of lead in home grown produce. This is not considered to be a substantial source of uncertainty because data from other sites indicate that lead does not tend to strongly accumulate in home grown garden vegetables (Life Systems 1995, USEPA 2001d).

4.4.2 Lead Bioavailability

Accurate assessment of the human health risks resulting from oral exposure to lead requires knowledge of the amount of lead absorbed from the gastrointestinal tract into the body. This information on gastrointestinal absorption may be described either in absolute or relative terms:

> *Absolute Bioavailability (ABA)* is the ratio of the amount of lead absorbed to the amount ingested:
>
> ABA = (Absorbed Dose) / (Ingested Dose)
>
> This ratio is also referred to as the oral absorption fraction (AFo).
>
> *Relative Bioavailability (RBA)* is the ratio of the absolute bioavailability of lead in a test material compared to the absolute bioavailability of lead in an appropriate reference material:
>
> RBA = ABA(test) / ABA(reference)
>
> Usually the form of lead used as the reference material is a compound that is readily soluble in water (e.g., lead acetate) and that is expected to readily dissolve in gastrointestinal fluids when ingested.

For example, if 100 µg of lead dissolved in drinking water were ingested and a total of 50 µg were absorbed into the body, the ABA would be 0.50 (50%). Likewise, if 100 µg of lead contained in soil were ingested and 30 µg were absorbed into the body, the ABA for soil would

be 0.30 (30%). If the lead dissolved in water were used as the frame of reference for describing the relative amount of lead absorbed from soil, the RBA would be 0.30/0.50, or 0.60 (60%).

Site-specific estimates of RBA of lead in soil may be obtained from either *in vivo* or *in vitro* methods. The *in vivo* approach measures the gastrointestinal absorption of lead in animals dosed with site soils compared to that for lead acetate. This ratio is the RBA for lead. The *in vitro* approach measures the fraction of lead that is solubilized from soil into an extraction fluid that simulates natural gastrointestinal conditions. The fraction solubilized is referred to as the *in vitro* bioaccessibility (IVBA). For lead, IVBA results are well correlated with the *in vivo* RBA results, and USEPA has determined that IVBA values measured using an approved method are appropriate for estimating the RBA for lead (USEPA 2007a). The relationship between a measured IVBA value and the corresponding RBA value is given by the following equation (USEPA 2007b):

$$RBA = 0.878 * IVBA - 0.028$$

USEPA Region 7 conducted both *in vivo* and IVBA testing on soil samples collected from the OLS, and IVBA testing was conducted on indoor dust samples (see Table 4-2). The results are presented in the following sections.

4.4.2.1 Lead RBA in Soil

In Vivo Results

USEPA measured the RBA of lead in juvenile swine using two test soils collected from the OLS (Casteel *et al.* 2004). Juvenile swine are used because they are believed to be a good model for the gastrointestinal absorption of lead in children. The amount of lead absorbed by each animal was estimated based on measurements of lead concentration in four different tissues (blood, liver, kidney, and bone) during or following exposure.

Each test soil consisted of a composite sample of surface soil collected from 2 residential yards. These materials were sieved before testing to isolate the fine fraction (< 250 µm). This is because the fine fraction is generally considered to be more likely to adhere to the hands and be ingested than coarse soil particles. The original report of the *in vivo* study is provided in Appendix B, and the resulting RBA values are shown in Panel A of Table 4-3. As seen, the suggested point estimate and the plausible range of RBA of lead measured in these two surface soils was 1.01 (1.01-1.03) and 0.74 (0.68-0.76).

More recently, USEPA (2007b) described a new statistical approach for estimating the RBA of lead in soil from *in vivo* studies. In accord with this guidance, the RBA data were reanalyzed using USEPA's new recommended statistical method. In addition, the concentrations of lead in the two test soils were revised based on quintuplicate measurements of each soil. The revised

results are provided in Appendix B and are summarized in Panel B of Table 4-3. As seen, the new statistical method yields point estimates and 90% confidence intervals for RBA of 0.96 (0.64 – 1.29) and 0.83 (0.58 – 1.10) for Test Materials 1 and 2, respectively.

IVBA Results

USEPA measured the IVBA of lead in the fine fraction (< 250 µm) of 47 different surface soil samples collected at the OLS (Drexler 2004, 2008a). These data are provided in Appendix B. Table 4-4 presents the IVBA results[2] and the estimated RBA values derived from the IVBA results using the equation presented above. As seen, the estimated RBA values range from 0.27 to 0.95, with a mean of 0.68. Figure 4-2 plots the estimated RBA values as a function of soil concentration. This plot indicates there are two data points with estimated RBA values that are considerably lower than the rest of the results. These two data points were identified as outliers using Rosner's Test (Gilbert 1987), and were excluded from the data set. The relationship between soil concentration and estimated RBA (excluding outliers) was examined using linear regression and the slope of the line was not statistically different from zero ($p = 0.45$). Based on this, it is concluded that the RBA of lead in soil is independent of concentration, and the best estimate of RBA based on the IVBA approach is equal to the mean of the estimated RBA values (outliers excluded). The resulting value is 0.70.

Correlation Between RBA and IVBA

The two test materials used in the *in vivo* RBA study (Test Material 1 and Test Material 2) were also analyzed by IVBA (Drexler 2008a). Table 4-5 compares the RBA values derived from the IVBA results and from the *in vivo* study. For both test materials, the RBA values estimated from the *in vivo* test were somewhat higher than estimated using the IVBA approach, although the uncertainty bounds of the estimates overlapped in both cases.

In making this comparison, it should be recognized that a) *in vivo* RBA values are generally subject to more measurement error than IVBA values, and b) that extrapolation from IVBA to RBA yields the average RBA value associated with that IVBA, and that actual RBA values may be either higher or lower than the calculated mean. Thus, exact agreement is not expected.

Selection of Weight-of-Evidence RBA Value for Soil

Both the *in vivo* results for two samples and the *in vitro* results for 47 samples clearly indicate that the RBA of lead in soil at the site is higher than the USEPA default value of 0.60. The *in vitro* data suggest a mean value of about 0.70, while the two *in vivo* values are 0.83 and 0.96. In

[2] Note: The values shown in this table are different than originally reported in Drexler (2004). This is because the 2004 report was published before the ICP results for the concentrations of lead in the fine fraction (<250 µm) were available, so the initial IVBA estimates presented in Drexler (2004) were based on XRF estimates of lead in the bulk fraction (<2 mm) (Drexler 2008a, personal communication). The values shown in Table 4-4 are based on the concentration of lead in the fine fraction measured by ICP.

general, greatest weight is placed on the *in vivo* data, suggesting a point estimate of about 0.9. However, as noted above, *in vivo* values are more difficult to measure and have wider uncertainty than *in vitro* values, and in this case, there are 47 *in vitro* values compared to only two *in vivo* values. Based on the weight of evidence, a point estimate of 0.8 is selected to represent the mean RBA of lead in soil at the site. This value is slightly above the average for the *in vitro* estimates, is approximately equal to the *in vivo* point estimate for Test Material 2, and is only somewhat lower than the *in vivo* point estimate for Test Material 1.

4.4.2.2 Lead RBA in Indoor Dust

IVBA Results

USEPA measured the IVBA of lead in the fine fraction (< 250 µm) of 94 different indoor dust samples collected at the OLS in 2007 (Drexler 2008b). Table 4-6 presents the IVBA results and the estimated RBA values derived from the IVBA results. As seen in Table 4-6, the estimated RBA values for indoor dust range from 0.32 – 4.44, with a mean of 0.79. Figure 4-3 presents the estimated RBA values plotted as a function of the dust concentration. As seen, there are three data points with estimated RBA values that were considerably higher than the rest of the results (RBA > 1.5), and one data point has an estimated RBA that is considerable lower (RBA < 0.3). These four data points were identified as outliers using Rosner's Test (Gilbert 1987), and were excluded from the data set. The relationship between indoor dust and estimated RBA (excluding outliers) was examined using linear regression and the slope of the line was not statistically different from zero ($p = 0.18$). Based on this, it is concluded that the RBA of lead in indoor dust is independent of concentration, and the best estimate is given by the average of the values (outliers excluded). The resulting value is 0.73.

Selection of Weight-of-Evidence RBA Value for Dust

In the case of soil, two data sets were available for consideration: two *in vivo* RBA values and 47 IVBA values. As discussed above, the two *in vivo* values tended to be somewhat higher than the corresponding RBA values computed for those samples using the IVBA results, and were also higher than the average of the other IVBA-based RBA values. On this basis, the RBA for soil was set to a value somewhat higher than the mean IVBA-based RBA. In the case of dust, only IVBA-based RBA estimates are available, and there are no direct *in vivo* measurements. However, there is no reason to expect that the RBA for dust should be lower than for soil. To the contrary, because dust particles tend to be smaller than some soil particles, it is expected that RBA in dust should be the same or higher than in soil. On this basis, and by extension of the rationale used for soil, the RBA value selected to represent the mean for dust is 0.8.

4.4.3 Age

When the IEUBK model is run for a particular property, the resulting output is intended to represent the distribution of long-term average (0-84 month) blood lead values in a population of children exposed at that location. When the IEUBK model must be run for a large number of properties (approximately 40,000 at the OLS), calculations are not run one by one, but are performed using a "batch mode". In the batch mode, the output is the blood lead level for a child of a specific age, which must be specified as input. In order to ensure that the output of the batch run is comparable to that of a single property run, an age of 50 months was selected for use. This is because the blood lead at age 50 months is nearly the same as the average blood from 0-84 months.

4.5 Results

The IEUBK model was run in batch mode to calculate the probability that a child would have a blood lead level over 10 µg/dL at each property in the OLS for which data are available and which has not yet undergone soil cleanup activities. The results are summarized in Table 4-7, stratified by zip code.

Inspection of Table 4-7 and Figure 4-4 reveals the following main findings:

- Of the 28,478 properties evaluated, a total of 19,445 homes (68%) are predicted to have P10 values at or below the health-based goal of 5%, and 9,033 properties (32%) have values that exceed the goal.
- Of these 9,033 properties, 3,177 have P10 values between 5% and 10%, 3,051 properties have P10 values between 10% and 20%, and 2,805 properties have P10 values greater than 20%.
- The location of properties with P10 values greater than the health-based goal of 5% were widespread across the OLS final focus area and were found within all zip codes with the exception of 68117 (which only had 2 properties).

These results indicate that a number of homes or parcels within the final focus area have soil lead levels that are of potential health concern to children who may reside there, now or in the future.

4.6 Uncertainties

It is important to recognize that the exposure and risk calculations for lead presented in this section are subject to uncertainty that arises from a number of different sources. Each of the major sources of uncertainty in the lead risk assessment are discussed below. It is important for risk managers and the public to take these uncertainties into account when interpreting the risk conclusions for lead at this site.

4.6.1 Uncertainty in Lead Concentration Estimates

Evaluation of human health risk from lead at any particular location (property) requires accurate information on the average concentration level of lead in each environmental medium at that location.

Uncertainty in Soil Concentration Values

For soil, lead concentrations were usually measured using XRF for four or more composite samples representing different areas of the residential property. Each measured XRF value is uncertain, due both to analytical error and to sampling variability. Consequently, the mean across the multiple values is also uncertain. The effect of analytical error is likely to be relatively small. The effect of sampling error is somewhat larger than the effect of analytical error, but is still relatively small because most samples are a composite of 5 sub-samples. That is, the variability in the mean of five samples is smaller than the variability in each of the individual samples.

Additional uncertainty in the measured concentration of lead in soil arises from two adjustments to the measured data that are needed. First, XRF values of lead in soil at this site tend to be biased somewhat low compared to paired ICP measures (see Appendix C), so it was necessary to adjust for this bias using a factor of 1.16. This adjustment factor itself is uncertain (see Appendix F), so corrected values may be either higher or lower than the true mean. Second, XRF measures of lead were performed on "bulk" soils (< 2 mm) while human exposure is believed to be primarily to "fine" soils (< 250 µm). At some sites, the concentration of lead in the fine fraction can be up to 30% or more higher than in the bulk fraction, which would result in an underestimate of exposure if not accounted for. However, at this site, the ratio of the concentration of lead in the fine fraction to that in the bulk fraction is only slightly higher than 1 (1.04). Thus, although this adjustment is a source of uncertainty, the magnitude of the uncertainty is small.

Uncertainty in Dust Concentration Values

Lead in soil may serve as a source of contamination of indoor dust. The USEPA generally assumes that 70% of dust is derived from soil (i.e., $C_{dust} = 0.7 \cdot C_{soil}$). At this site, data on the relationship between lead levels in soil and dust were collected at 98 different properties in order to support the derivation of a site-specific equation to relate lead levels in dust to those in soil. These data and the resulting equation are detailed in Appendix F.

As discussed in Appendix F, quantification of the relationship is complicated by the fact that there is measurement and sampling error in both the soil and the dust values, and that both errors tend to increase as the concentration of lead increases. A number of different statistical strategies were investigated to determine which best accounted for the errors, and the resulting

equation utilizes the most successful method. However, the parameters of the regression equation are uncertain, and dust levels at any given property may be either higher or lower than computed using the equation.

4.6.2 Uncertainty in Lead Absorption from Soil and Dust

Another important source of uncertainty regarding the risk from lead in soil and dust is the degree of absorption (RBA) of lead within the gastrointestinal tract. For this risk assessment, a site-specific relative bioavailability factor for lead of 0.80 has been applied to both soil and dust. This value is based on two types of site-specific data: *in vivo* estimates derived by dosing an appropriate animal model (juvenile swine) with two different site soils, and *in vitro* measures of bioaccessibility (IVBA) derived for 47 soils and 94 dust samples. This is a very substantial data set upon which to estimate a site-specific RBA value, and the data are in general agreement that the value is higher than the default. However, there remains some difference between the *in vivo* and the IVBA estimates, and although the value selected for use reflects a weight-of evidence consideration of both types of data, the selected value is uncertain, and might be either higher or lower than the true value.

4.6.3 Uncertainty in the IEUBK Model

All predictive models, including the IEUBK model, are subject to a number of limitations. First, there is inherent difficulty in providing the model with reliable estimates of human exposure to lead-contaminated media. For example, exposure to soil and dust is difficult to quantify because human intake of these media is likely to be highly variable, and it is very difficult to derive accurate measurements of actual intake rates. Second, it is often difficult to obtain reliable estimates of key biokinetic parameters in humans (e.g., absorption rates, distribution and clearance rates from various tissues), since direct observations in humans are limited. Finally, the absorption, distribution, and clearance of lead in the human body is an extremely complicated process, and any mathematical model intended to simulate the actual processes is likely to be an over-simplification. Consequently, model calculations and predictions are uncertain.

A second source of uncertainty arises from the approached used by the IEUBK model to estimate the probability of a random child at a property having a blood level above 10 µg/dL (P10). As discussed in Section 4.3, the IEUBK model estimates this value by assuming that the distribution of blood lead values at a location is lognormal with a specified geometric standard deviation (GSD). The value of P10 is quite sensitive to the assumed value of GSD, with P10 increasing rapidly as GSD increases. The true value of GSD at the OLS is not known, and the lead risk calculations are based on a default value of 1.6, which is estimated from blood lead data studies at three lead sites around the country (USEPA 1994a). Use of this assumed GSD is an important source of uncertainty, and actual P10 values might be either higher or lower than calculated.

5.0 EVALUATION OF RISKS FROM NON-LEAD CONTAMINANTS

Although lead was the primary contaminant released to the environment from the historic operation of the smelters in the OLS, other metal and metalloid contaminants may also have been released. The Interim Risk Assessment (NHHSS 2004) included an initial evaluation of the risks from non-lead contaminants, and concluded that adverse non-cancer effects and unacceptable excess cancer risks were not anticipated as a result of incidental ingestion of soil (NHHSS 2004). The purpose of this section is to provide an updated evaluation of the risks from non-lead contaminants utilizing new data that have been collected since the date of the Interim Risk Assessment.

In accord with USEPA guidance (USEPA 1989a), risks from non-lead contaminants are evaluated using a four-step process:

- Data collection and evaluation involves gathering and analyzing the site data relevant to the human health risk assessment, as well as identifying the contaminants present at the site that are the focus of the risk assessment process.
- Exposure Assessment is conducted to identify the pathways by which humans may potentially be exposed, and to estimate the magnitude, frequency, and duration of actual and/or potential human exposures by those pathways.
- Toxicity Assessment characterizes the nature of the adverse effects caused by each chemical and a description of how the frequency or severity of effects depends on exposure level.
- Risk Characterization combines the information from the exposure assessment and the toxicity assessment to predict the nature, frequency and/or severity of adverse effects in humans exposed at the site. This final step also discusses the uncertainties of each step of the risk assessment and their impact on the risk estimates.

The data collection and evaluation step was described previously in Sections 2 and 3. The following sections summarize the exposure assessment, toxicity assessment, and risk characterization steps.

5.1 Exposure Assessment

5.1.1 Site Conceptual Model

The generalized site conceptual model for exposure of residents to smelter-related contaminants was presented previously in Figure 3-1. The detailed site conceptual model for exposure of residents to non-lead COPCs is presented in Figure 5-1. The following sections describe which of these pathways are likely to be potentially significant and that have been selected for quantitative evaluation in the risk assessment.

Sources of Contamination

The principal source of smelter-related contamination with non-lead COPCs is wet or dry deposition of metal-containing particles from historic smelter mission to area soils. However, it should be noted that metals and metalloids released from the smelter also occur naturally in soil and other environmental media, and may also be released to soil from other (non-smelter) sources.

Incidental Ingestion of Surface Soil and Indoor Dust

Even though few people intentionally ingest soil, residents (especially children) who have direct contact with soil at the site might ingest small amounts that adhere to their hands during outdoor activities. In addition, soil can be brought into residences by direct transport on shoes, clothing, pets, etc., or may be deposited in residence by airborne dust where it becomes mixed into indoor dust, which may also be ingested by hand to mouth activities. Incidental ingestion of outdoor soil and indoor dust are often the most important routes of human exposure at a site, so these exposure pathways are evaluated quantitatively in this risk assessment.

Dermal Contact with Soil and Indoor Dust

Residents may get soil on their skin during outdoor activities involving direct contact with soil. Although most metals do not readily cross the skin into the body, dermal exposure to soil is a complete exposure pathway and is evaluated quantitatively in the risk assessment when data are sufficient. Little is known about dermal contact with indoor dust while in a residence, but it is generally assumed this is minor compared to dermal contact with soil. Therefore, dermal contact with dust is not evaluated quantitatively in this risk assessment.

Inhalation of Airborne Soil Particulates

Whenever contaminated soil is exposed at the surface, particles of contaminated surface soil may become suspended in outdoor air by wind disturbance, and humans in the area could inhale those particles. Screening level calculations (see Appendix D) indicate that exposure to particulates suspended in outdoor air is very small compared to oral exposure, so this pathway is evaluated qualitatively rather than quantitatively in this risk assessment.

Ingestion of Homegrown Produce Items

Area residents may grow garden vegetables or fruit in smelter-impacted soil, and some contaminants in the soil may be taken up by the vegetables or fruit and ingested. Because no data are available on the levels of metals in locally grown vegetables or fruit, this exposure pathway cannot be evaluated quantitatively in this risk assessment. However, uptake of metals

into plants is usually not extensive, so omission of this pathway is not likely to be a major source of uncertainty.

Exposure to Surface Water and Sediment

Smelter-related contaminants in soil may be eroded into the Missouri River from surface runoff events, and area residents who have contact with the river during recreational visits might be exposed by incidental ingestion or dermal contact with surface water or sediment. However, sampling results of water and sediment in the Missouri River immediately adjacent to the ASARCO and Gould facilities did not detect elevated levels of lead or any other smelter-related contamination (Black and Veatch 2009). This is not unexpected because the amount of dilution provided by the flow of the Missouri River is expected to reduce any potential release of transported site contaminants to very low levels (USEPA 2005a). Therefore, exposures of area residents to surface water and sediment are not evaluated quantitatively in this assessment.

Exposure to Groundwater

In some cases, smelting-related releases to soil may lead to increased levels of contaminants in groundwater due to infiltration of the contaminants from rain and snow-melt. If the groundwater were used for drinking, area residents could be exposed by ingestion of the contaminants. However, at the OLS site, area residents receive their drinking water from the municipal public water system, so it is not believed that the groundwater pathway is complete at present.

Exposure to Drinking Water

Although drinking water at the site is derived in part from the Missouri River, this exposure pathway is not considered to be of significant concern because no significant increases in metal concentrations have been observed in the river near the site, and because the water is treated in accord with the requirements of the Safe Drinking Water Act before distribution to homes. Therefore, exposure from drinking water is not evaluated quantitatively in this risk assessment.

Exposure to Fish Tissue

Area residents who ingest fish caught in the Missouri River near the site might be exposed to site-related contaminants taken up into the edible fish tissues from contaminants in surface water and/or sediments. However, because metals in surface water and sediment samples collected from the Missouri River were not elevated, and because the dilution factor of the Missouri River is so great (Black and Veatch 2009), site-related contaminants are not expected to accumulate in fish tissue. Thus, this exposure pathway is not evaluated quantitatively in this risk assessment.

Summary of Exposure Pathways for Quantitative Assessment

Based on the evaluation of potential exposure pathways presented above, the following exposure pathways to non-lead contaminants are evaluated quantitatively in this risk assessment:

Population	**Exposure Pathway**
Residents	Ingestion of outdoor soil Ingestion of indoor dust Dermal contact with outdoor soil

5.1.2 Quantification of Human Exposure

5.1.2.1 Basic Equations

Quantification of Oral Exposure

The amount of a chemical which is ingested from an environmental medium (dose) is quantified in terms of the average daily intake (DI, expressed in units of mg/kg-day), calculated using an equation of the following form:

$$DI = C * (IR / BW) * (EF * ED / AT)$$

where:

DI = Daily intake of chemical (mg of chemical per kg of body weight per day).
C = Concentration of the chemical in the contaminated environmental medium to which the person is exposed. The units are mg/kg for soil and dust.
IR = Intake rate of the contaminated environmental medium. The units are kg/day for soil and dust.
BW = Body weight of the exposed person (kg).
EF = Exposure frequency (days/year). This describes how often a person is likely to be exposed to the contaminated medium over the course of a typical year.
ED = Exposure duration (years). This describes how long a person is likely to be exposed to the contaminated medium during their lifetime.
AT = Averaging time (days). This term specifies the length of time over which the average intake or dose is calculated. Usually, two different averaging times are considered:

"Chronic" exposure includes averaging times on the scale of years (typically ranging from 7 to 30 years). This exposure duration is used when assessing the non-cancer risks from chemicals of potential concern.

"Lifetime" exposure employs an averaging time of 70 years. This exposure interval is selected when evaluating cancer risks.

Note that the factors EF, ED, and AT combine to yield a factor between zero and one. Values near 1.0 indicate that exposure is nearly continuous over the specified averaging period, while values near zero indicate that exposure occurs only rarely.

For mathematical convenience, the general equation for calculating the daily intake (or dose) can be written as:

$$DI = C * HIF$$

where:

HIF = Human Intake Factor. This term describes the average amount of an environmental medium contacted by the exposed person each day. The value of HIF is typically given by:

$$HIF = (IR / BW) * (EF * ED / AT)$$

The units of HIF are kg/kg-day for soil and dust.

Because one or more exposure parameters (e.g., intake rates, body weight, and exposure frequency) may change as a function of age, exposure calculations are often performed separately for children and adults. In the case of site residents, non-cancer risks were calculated separately for a child resident and an adult resident. However, for estimating excess cancer risks from exposure to a chemical, because the same individual may be exposed beginning as a child and extending into adulthood, exposure is calculated as the time-weighted average (TWA) exposure:

$$TWA\ DI = C *[(IRc / BWc) * (EFc * EDc / AT) + [(IRa / BWa) * (EFa * EDa / AT)]$$

where the subscripts "c" and "a" refer to child and adult, respectively.

Quantification of Dermal Exposure

The amount of a chemical which is absorbed across the skin is referred to as the dermal absorbed dose (DAD). Procedures for estimation of the DAD as outlined in USEPA (2004a) were used in this assessment and are described below. For chemicals except lead (which is evaluated as described in Sections 4.3 and 4.4), exposure is quantified using an equation of the following general form:

$$DAD = DA_{event} * EF * ED * EV * SA / (BW * AT)$$

where:

DAD = Dermal absorbed dose (mg of chemical per kg of body weight per day).

DA_{event} = Absorbed dose per event (mg of chemical per square centimeter of skin surface area per event). This is media-specific and is further described below.

EF = Exposure frequency (days/year). This describes how often a person is likely to be exposed to the contaminated medium over the course of a typical year.

ED = Exposure duration (years). This describes how long a person is likely to be exposed to the contaminated medium during their lifetime.

EV = Event frequency (events/day). This describes the number of times per day a person comes in contact with a contaminant in soil.

SA = Surface area (cm^2). This describes the amount of skin exposed to the contaminated media.

BW = Body weight of the exposed person (kg).

AT = Averaging time (days). This term specifies the length of time over which the average dose is calculated.

For contaminants in soil, DA_{event} is estimated as follows:

$$DA_{event} = C_{soil} * CF * AF * ABS_d$$

where:

C_{soil} = Chemical concentration in soil (mg of chemical per kg of soil).

CF = Conversion factor (10^{-6} kg/mg).

AF = Adherence factor (mg of soil per cm^2 of skin surface area per event). This describes the amount of soil that adheres to the skin per unit of surface area.

ABS_d = Dermal absorption fraction (unitless). This value is chemical-specific and represents the contribution of absorption of a chemical across a person's skin from soil to the systemic dose.

Combining these equations yields the following:

$$DAD = C_{soil} * CF * AF * ABS_d * EF * ED * EV * SA / (BW * AT)$$

For mathematical convenience, the general equation for calculating DAD can be written as:

$$DAD = C_{soil} * ABS_d * HIF_{soil}$$

where:

$$HIF_{soil} = (SA * AF * EF * ED * EV * CF) / (BW * AT)$$

The units of HIF_{soil} are kg/kg-day.

As described above, in the case of residents, because the same individual may be exposed beginning as a child and extending into adulthood, exposure is calculated as the time-weighted average (TWA) exposure for evaluating cancer risks. For non-cancer risks, children and adults were evaluated separately.

5.1.2.2 Human Exposure Parameters

For every exposure pathway of potential concern, it is expected that there will be differences between individuals in their level of exposure at a specific location due to differences in intake rates, body weights, exposure frequencies, and exposure durations. Thus, there is normally a wide range of average daily intakes between different members of an exposed population. Typically, attention is focused on intakes that are "average" or are otherwise near the central portion of the range, and on intakes that are near the upper end of the range (e.g., the 95th percentile). These two exposure estimates are referred to as Central Tendency Exposure (CTE) and Reasonable Maximum Exposure (RME), respectively.

The USEPA has collected a wide variety of data and has performed a number of studies to help establish default values for most residential exposure parameters. The chief sources of these standard default values are the following documents:

1. Risk Assessment Guidance for Superfund (RAGS). Volume I. Human Health Evaluation Manual (Part A). USEPA 1989a.

2. Human Health Evaluation Manual, Supplemental Guidance: "Standard Default Exposure Factors." USEPA 1991a.

3. Exposure Factors Handbook. USEPA 1997a.

4. Supplemental Guidance for Developing Soil Screening Levels for Superfund Sites. USEPA 2002a.

5. Risk Assessment Guidance for Superfund (RAGS). Volume I. Human Health Evaluation Manual (Part E, Supplemental Guidance for Dermal Risk Assessment). USEPA 2004a.

Exposure parameters used in this risk assessment for evaluation of area residents are summarized in Table 5-1 and are described below.

Body Weight. For children, a body weight of 15 kg was assumed for a CTE and RME resident (USEPA 1991a). This value is the average body weight for young children (boys and girls combined) under the age of 6 years. For adults, a body weight of 70 kg was assumed for a CTE and RME resident. This value is the average body weight for adult men and women (USEPA 1991a, 1997a). These body weights are USEPA (1991a) recommended default values.

Exposure Frequency. For both children and adult residents, a CTE exposure frequency of 245 days per year and an RME exposure frequency of 350 days per year were assumed. The CTE value is based on the mean percent of time men and women spend at home (67%) reported in Table 15A-3 of the Exposure Factors Handbook (USEPA 1997a). The RME value is the USEPA (1991a) recommended default value for exposure frequency for a resident.

Exposure Duration. For both children and adult residents, a CTE exposure duration of 9 years and an RME exposure duration of 30 years were used. The CTE value is based on the average residency occupancy of a home, as reported in EPA's Exposure Factors Handbook (USEPA 1997a). Of the 9 years of exposure, it is assumed that 2 years of exposure occur as a child and that 7 years of exposure occur as an adult, based on professional judgment. The RME value is the USEPA (1991a) recommended default value for a resident. This value represents the 90th percentile for time spent at one residence (USEPA 1991a).

Averaging Time. As recommended by USEPA (1989a), an averaging time of 70 years (25,550 days) is used for assessing excess lifetime cancer risk for both CTE and RME residents. For assessing adverse non-cancer effects, the averaging time was set equal to the exposure duration (expressed in days) (USEPA 1989a).

Soil and Dust Ingestion Rate. For children, an intake rate of 200 mg/day of soil plus dust (combined) was used for an RME individual (USEPA 1991a), and an intake rate of 100 mg/day

was used for a CTE individual (USEPA 1997a). For adults, the USEPA (1991a) recommended default intake rate of 100 mg/day was used for an RME individual and an intake rate of 50 mg/day was used for a CTE individual.

Exposed Surface Area. USEPA (2004a) recommended default values for both child and adult residents were used for the exposed surface area. An exposed surface area of 2,800 cm^2 was used for both the CTE and RME child resident and an exposed surface area of 5,700 cm^2 was used for the CTE and RME adult resident. The values assume that the exposed skin surface includes the head, hands, forearms, and lower legs. The exposed surface area for children also assumes exposure of the feet.

Soil Adherence Factor. USEPA (2004a) recommended default values for child and adult residents were used for the soil adherence factor exposure parameter. For children, the CTE adherence factor of 0.04 mg/cm^2 is the geometric mean of children playing with dry soil. The RME adherence factor of 0.2 mg/cm^2 for a child resident represents the high end (95th percentile) of a typical soil contact activity (children playing at a day care center) and the central tendency estimate (50th percentile) of a high-end soil contact activity (children playing with wet soil). For adults, the CTE adherence factor of 0.01 mg/cm^2 represents the geometric mean adherence factor for a low-end soil contact activity (grounds keepers). The RME adherence factor of 0.07 mg/cm^2 is based on the 50th percentile of a high-end soil contact activity (gardening) (USEPA 2004a).

Dermal Absorption Fraction. USEPA (2004a) recommended default values are available for 2 of the 11 COPCs (arsenic and cadmium). The values used in the risk assessment were 0.03 for arsenic and 0.001 for cadmium (USEPA 2004a).

5.1.2.3 Selection of Exposure Points

An exposure point (also referred to as an exposure unit or exposure area) is an area where a human receptor is likely to be exposed to a contaminated environmental medium. A key feature of an exposure point is that a receptor is assumed to move about within the exposure point at random.

Selection of the bounds of an exposure point is based mainly on a consideration of the likely activity patterns of the exposed receptors. For exposure of residents to outdoor soil, it is expected that most contact will occur when a resident is working or playing in their own yard. Likewise, exposure to indoor dust is expected to occur mainly within the home of the resident. For these reasons, the exposure point selected for evaluation of residents is the property where the resident lives.

5.1.2.4 Exposure Point Concentrations

Because of the assumption of random exposure over an exposure area, risk from a chemical is related to the arithmetic mean concentration of that chemical averaged over the entire exposure area. Since the true arithmetic mean concentration cannot be calculated with certainty from a limited number of measurements, the USEPA recommends that the upper confidence limit (UCL) of the arithmetic mean at each exposure point be used when calculating exposure and risk at that location (USEPA 1992a). The approach that is most appropriate for computing the UCL of a data set depends on a number of factors, including the number of data points available, the shape of the distribution of the values, and the degree of censoring (i.e., samples below the detection limit) (USEPA 2002b). To facilitate this process, the USEPA has developed a specialized software package (ProUCL v4.0) that calculates UCLs for a data set using several different strategies and recommends which UCL is considered preferable based on the properties of the data set (USEPA 2007c).

Exposure Point Concentrations for Soil

At this site, reliable data for all non-lead COPCs except zinc in soil are restricted to measurements performed by ICP (see Section 2.12.2). Because ICP measurements were performed on only about 5% of all soil samples, many properties have no reliable measurements, and when a value is available, there is usually only one (maximum = 2) per property. Because it is not possible to compute a reliable UCL with only one or two samples, the maximum concentration value for each property was used as the exposure point concentration.

For zinc, because reliable XRF data are available in addition to the ICP data, there are usually 4-6 measurements of soil per property. While ProUCL can compute a UCL based on 4-6 samples, it is generally recognized that a UCL based on a sample set of this relatively small size is statistically unstable, and it is expected that the majority of UCL values would exceed the maximum detected value. For this reason, the exposure point concentration for zinc was also based on the maximum concentration at each property.

For chromium, toxicity depends upon valence state (Cr^{+3} vs. Cr^{+6}), but data are available only for total chromium (Cr^{+3} + Cr^{+6}) in soil. Based on data on chromium speciation in soil summarized in ATSDR (2000), USEPA (1998c) and USEPA (1998d), the fraction of total chromium in each valence state in soil was estimated to be 86% for Cr^{+3} and 14% for Cr^{+6}.

Exposure Point Concentrations for Indoor Dust

The relationship between outdoor soil and indoor dust for a number of non-lead analytes is summarized in Appendix I. As indicated, indoor dust concentrations tend to be lower than outdoor soil for some analytes (e.g., arsenic), but for many analytes the concentration in indoor

dust is similar to or sometimes even higher than outdoor soil. Based on this, the EPC for indoor dust was assumed to be equal to the EPC for outdoor soil for all non-lead COPCs.

Detailed Calculations

Detailed exposure point concentrations for all non-lead COPCs are provided in Appendix G.

5.1.2.5 Exposure Calculations

Detailed exposure calculations are provided in Appendix H.

5.2 Toxicity Assessment

The objective of a toxicity assessment is to identify what adverse health effects a chemical may cause, and how the appearance of these adverse effects depends upon the level of exposure, the route of exposure (ingestion, inhalation, dermal contact, etc.) and the duration of exposure (subchronic, chronic, or lifetime).

5.2.1 Basic Methods

The toxicity assessment process is usually divided into two parts: the first characterizes and quantifies the adverse non-cancer effects that may be associated with exposure to the chemical, while the second addresses the excess cancer risk that may be associated with exposure to the chemical. This two-part approach is employed because there are typically major differences in the time-course of action and the shape of the dose-response curve for cancer and for adverse non-cancer effects.

Non-Cancer Effects

Essentially all chemicals can cause adverse health effects if given at a high enough dose. However, when the dose is sufficiently low, typically no adverse effect is observed. Thus, in characterizing the adverse non-cancer effects of a chemical, the key parameter is the threshold dose at which an adverse effect first becomes evident.

The threshold dose is typically estimated from toxicological data (derived from studies of humans and/or animals) by finding the highest dose that does not produce an observable adverse effect, and the lowest dose which does produce an adverse effect. These are referred to as the "No-observed-adverse-effect-level" (NOAEL) and the "Lowest-observed-adverse-effect-level" (LOAEL), respectively. The threshold is presumed to lie in the interval between the NOAEL and the LOAEL. However, in order to be conservative (protective), non-cancer risk evaluations are not based directly on the threshold exposure level, but on a value referred to as the Reference Dose (RfD). The RfD is an estimate (with uncertainty spanning perhaps an order of magnitude)

of a daily exposure to the human population (including sensitive subgroups) that is likely to be without an appreciable risk of deleterious effects during a lifetime.

The RfD is derived from the NOAEL, LOAEL or threshold dose by dividing by one or more uncertainty and/or modifying factors to account for limitations in the data used. Each uncertainty and/or modifying factor is normally 3 to 10, and the combined product can be quite large (up to 3,000) if the data are limited. If the data are from high quality studies in humans, the factor may be as small as 1.0.

The effect of dividing the NOAEL, LOAEL, or threshold by these uncertainty/modifying factors is to ensure that the RfD is not higher than the true (but uncertain) threshold level for adverse non-cancer effects. Thus, there is always a "margin of safety" built into an RfD, and doses equal to or less than the RfD are not likely to be associated with adverse effects. Doses higher than the RfD may carry some risk, but because of the margin of safety, an intake or dose above the RfD does not mean that an effect will necessarily occur.

Cancer Effects

For cancer or carcinogenic effects, the toxicity assessment process has two components. The first is a qualitative evaluation of the weight of evidence (WOE) that the chemical does or does not cause cancer in humans. In the past, this evaluation was performed by the using the system summarized below (USEPA 1986):

WOE Group	Meaning	Description
A	Known human carcinogen	Sufficient evidence of cancer in humans.
B1	Probable human carcinogen	Suggestive evidence of cancer incidence in humans.
B2	Probable human carcinogen	Sufficient evidence of cancer in animals, but lack of data or insufficient data in humans.
C	Possible human carcinogen	Suggestive evidence of carcinogenicity in animals.
D	Cannot be evaluated	No evidence or inadequate evidence of cancer in animals or humans.
E	Not carcinogenic to humans	Strong evidence that it does not cause cancer in humans.

More recently, USEPA has revised the weight of evidence descriptions and its approach for evaluating the carcinogenic potential of environmental contaminants (USEPA 2005b). However, because EPA has not yet applied this new procedure to all carcinogenic chemicals, the new procedure was not used in this risk assessment.

For chemicals which are classified using the 1986 guidelines in Group A, B1, B2, or C, the second part of the toxicity assessment is to describe the carcinogenic potency of the chemical. This is done by quantifying how the number of cancers observed in exposed animals or humans increases as the dose increases. Typically, it is assumed that the dose-response curve for cancer has no threshold, and is linear in the low dose range. Thus, the most convenient descriptor of cancer potency is the slope of the dose-response curve at low doses. This is referred to as the Slope Factor (SF). The units of SF are risk of cancer per unit dose [$(mg/kg\text{-}d)^{-1}$].

Estimating the cancer SF is often complicated by the fact that observable increases in cancer incidence usually occur only at relatively high doses, frequently in a part of the dose-response curve that is no longer linear. Thus, it is necessary to use mathematical models to extrapolate from the observed high dose data to the desired (but unmeasurable) slope at low dose. In order to account for the uncertainty in this extrapolation process, USEPA typically chooses to employ the upper 95th confidence limit of the slope as the Slope Factor. That is, there is a 95 percent probability that the true SF is lower than the value chosen as an estimate of the SF. This approach helps ensure that cancer risk estimates are unlikely to underestimate true excess cancer risk.

5.2.2 Toxicity Values

Toxicity values (RfD and SF values) are often estimated by a number of different groups or agencies. USEPA (2003b) identifies a recommended hierarchy for selecting toxicity values for use in human health risk assessment at Superfund sites. The first preference is for USEPA consensus values listed in the Integrated Risk Information System (IRIS), an electronic database containing human health assessments for various chemicals (available online at http://www.epa.gov/iris/). If values are not available from IRIS, the next preference is to seek Provisional Peer Reviewed Toxicity Values for Superfund (PPRTVs) developed by USEPA's Superfund Health Risk Technical Support Center (STSC). If PPRTVs are not available, toxicity values may be obtained from other sources, such as the Agency for Toxic Substances and Disease Registry's (ATSDR) Minimal Risk Levels (MRLs) (available online at http://www.atsdr.cdc.gov/mrls.html), California EPA's Toxicity Criteria Database (available online at http://www.oehha.ca.gov/risk/ChemicalDB/index.asp), and USEPA's Health Effects Assessment Summary Tables (HEAST) (USEPA 1997b). Most of these values are also compiled in the Regional Screening Level Tables developed and maintained by USEPA (USEPA 2008c).

Table 5-2 summarizes the toxicity values used for quantitative evaluation of human health risks from COPCs at this site. Values were selected in accordance with USEPA (2003b). Points to note regarding the data in this table are listed below:

- Two oral RfD values are available for cadmium, depending on exposure medium (water, food). The value for food is assumed to apply to soil.

- The RfD for manganese (0.023 mg/kg-day) is based on the oral RfD of 1.4E-01 mg/kg-day in the diet. In accord with recommendations in IRIS, this value is adjusted by dividing by a Modifying Factor of 3 for application to exposure from soil.

- The RfD for thallium (6.5E-05 mg/kg-day) is based on the oral RfD for thallium sulfate of 8E-05 mg/kg-day. As recommended by USEPA (2008c), this value is adjusted to factor out the molecular weight of the sulfate ion by multiplying by the percent thallium in thallium sulfate (81%).

- The RfD for vanadium (5E-03 mg/kg-day) is based on the oral RfD for vanadium pentoxide of 9E-03 mg/kg-day. As recommended by USEPA (2008c), this value is adjusted to factor out the molecular weight of the oxide ion by multiplying by the percent vanadium in vanadium pentoxide (56%).

5.2.3 Adjustments for Relative Bioavailability

As discussed above for lead, accurate assessment of human exposure to metals in soil and dust requires knowledge of the amount of metal absorbed into the organism following contact with a contaminated medium.

No site-specific data were available on the relative bioavailability of any non-lead COPCs in soil or dust. In the absence of site-specific data, the RBA for all non-lead chemicals in all media was assumed to be 1.0 (USEPA 1989a). This is expected to be a conservative (health-protective) assumption, tending to overestimate the true degree of absorption and risk.

5.2.4 Adjustments for Evaluating Dermal Exposures

In the absence of dermal toxicity factors, USEPA (1989a, 2004a) recommends that dermal toxicity factors be estimated by extrapolation from oral toxicity factors. Because dermal exposures are expressed in terms of absorbed dose, while oral exposures are expressed in terms of ingested dose, this requires an adjustment of each oral toxicity factor as follows:

$$SF_{ABS} = SFo / ABS_{GI}$$
$$RfD_{ABS} = RfD_o * ABS_{GI}$$

where:

SF_o	=	Oral slope factor based on ingested dose $(mg/kg\text{-}day)^{-1}$
SF_{ABS}	=	Dermal slope factor based on absorbed dose $(mg/kg\text{-}day)^{-1}$
RfD_o	=	Oral reference dose based in ingested dose (mg/kg-day)
RfD_{ABS}	=	Dermal reference dose based on absorbed dose (mg/kg-day)
ABS_{GI}	=	Fraction of contaminant absorbed in gastrointestinal tract (dimensionless) in the critical toxicity study

USEPA (2004a) provides recommended ABS_{GI} values for a number of chemicals, and these values were used when available. In accord with USEPA (2004a) guidance, if no ABS_{GI} value was recommended, a factor of 1.0 was used. Table 5-2 presents the dermal toxicity values (SF_{ABS} and RfD_{ABS}) used in the risk assessment and the values used in their derivation.

5.3 Risk Characterization

5.3.1 Basic Methods

Non-Cancer Effects

The potential for adverse non-cancer effects is evaluated by comparing the estimated average daily intake of the chemical over a specific time period with the RfD for that chemical derived for a similar exposed period. This comparison results in a non-cancer Hazard Quotient (HQ), as follows (USEPA 1989a):

$$HQ = DI / RfD$$

where:

HQ	=	Hazard Quotient
DI	=	Daily Intake (mg/kg-day)
RfD	=	Reference Dose (mg/kg-day)

If the HQ for a chemical is equal to or less than 1 (1E+00), it is believed that there is no appreciable risk that non-cancer health effects will occur. If an HQ exceeds 1E+00, there is some possibility that non-cancer effects may occur, although an HQ above 1E+00 does not indicate an effect will definitely occur. This is because of the margin of safety inherent in the derivation of all RfD values. However, the larger the HQ value, the more likely it is that an adverse effect may occur.

If an individual is exposed to more than one chemical, a screening-level estimate of the total non-cancer risk is derived simply by summing the HQ values for that individual. This total is

referred to as the Hazard Index (HI). If the HI value is less than 1E+00, non-cancer risks are not expected from any chemical, alone or in combination with others. If the screening level HI exceeds 1E+00, it may be appropriate to perform a follow-on evaluation in which HQ values are added only if they affect the same target tissue or organ system (e.g., the liver). This is because chemicals which do not cause toxicity in the same tissues are not likely to cause additive effects.

Cancer Effects

The excess risk of cancer from exposure to a site-related chemical is described in terms of the probability that an exposed individual will develop cancer because of that exposure. For each chemical of concern, this value is calculated from the daily average intake of the chemical from the site, averaged over a lifetime (DI_L), and the slope factor (SF) for the chemical, as follows (USEPA 1989a):

$$\text{Excess Cancer Risk} = 1 - \exp(-DI_L * SF)$$

In most cases (except when the product of $DI_L \cdot SF$ is larger than about 0.01), this equation may be accurately approximated by the following:

$$\text{Excess Cancer Risk} = DI_L * SF$$

Excess cancer risks are summed across all chemicals of concern and all exposure pathways that contribute to exposure of an individual in a given population.

The level of total cancer risk that is of concern is a matter of personal, community, and regulatory judgment. In general, the USEPA considers excess cancer risks that are below about 1E-06 to be so small as to be negligible, and risks above 1E-04 to be sufficiently large that some sort of response action is desirable. Excess cancer risks that range between 1E-04 and 1E-06 are generally considered to be acceptable (USEPA 1991b), although this is evaluated on a case by case basis, and USEPA may determine that risks lower than 1E-04 are not sufficiently protective and warrant remedial action.

5.3.2 Results: Estimated Risks to Residents from Non-Lead COPCs

Detailed cancer and non-cancer risk calculations for non-lead COPCs are provided in Appendix H, and the results are summarized in Tables 5-3 to 5-6. All results are expressed to one significant figure (USEPA 1989a). As mentioned above, not all of the 13 non-lead COPCs were analyzed in every soil sample, so risk estimates are not available for every COPC at every residential property.

Estimated Excess Cancer Risks

The only COPC at this site that is carcinogenic by the oral or dermal route is arsenic. Table 5-3 presents a summary of the excess cancer risk estimates for CTE and RME residents from exposure to arsenic in soil, including both the ingestion and dermal pathways. As seen, estimated excess cancer risks to CTE residents are within USEPA's target risk range (1E-06 to 1E-04) at all properties. Estimated risks to RME residents are also within USEPA's target risk range at most properties, although risks exceed 1E-04 at 141 locations (5% of the properties with data). The estimated excess lifetime cancer risks at these 141 properties range from 2E-04 to 1E-03.

Estimated Non-Cancer Risks

Evaluation of Risk By Chemical

Table 5-4 shows the chemical-specific non-cancer Hazard Quotients (HQs) for residential CTE (Panel A) and RME (Panel B) scenarios, including both children (age 0-6 years) and adults (age 7-30 years). As shown, HQs for most COPCs detected in surface soil are less than 1 for all receptors (CTE and RME children and adults). An exception is arsenic, which results in an HQ > 1 for a RME child at about 10% of the properties. Some HQ values greater than 1 also occur for antimony, mercury, and/or thallium, although the frequency is quite low (< 0.6% of the properties). Maximum HQ values are summarized below:

COPC	Maximum HQ			
	CTE Child	RME Child	CTE Adult	RME Adult
Antimony	0.9	**2**	0.09	0.3
Arsenic	**8**	**24**	0.8	**3**
Mercury	**6**	**17**	0.6	**2**
Thallium	**4**	**11**	0.4	1

Screening-Level Evaluation of Combined Non-Cancer Risk

To evaluate the potential additive non-cancer effects of exposure to more than one non-lead COPC in soil, the chemical-specific non-cancer HQs were summed to estimate the total non-cancer HI for each property. Based on data availability, the number of COPC HQs included in the HI calculations for each property varied from 7 to 13. The results are detailed in Appendix H and are summarized in Table 5-5. For a CTE child, screening-level HI values are below 1 at most (96-97%) of all properties. However, for an RME child, screening-level HIs exceed 1 at 11-97% of all locations, depending on the number of COPCs for which data are available. These risks are attributed primarily to the ingestion of arsenic in surface soil and from the ingestion of thallium in surface soil at a few locations. For adults, screening-level HIs values are below 1 at

all locations for CTE receptors, and at most locations (>99%) for RME receptors. This exceedance is due mainly to the ingestion of arsenic.

Organ-Specific Combined Non-Cancer Risk

It is important to recognize that HI estimates derived by summing HQs across all chemicals is a screening-level approach that tends to overestimate the potential of adverse non-cancer effects that may be occurring. This is because not all chemicals act on the same target tissues or through the same mode of action, so not all HQ values are actually additive.

Therefore, in cases where screening-level HI values exceed 1E+00, it is appropriate to segregate HQ values according to target organ, and compute organ-specific HI values (USEPA 1989a).

Table 5-6 presents target organ-specific HI values based on the critical target organs identified in Table 5-2. As seen, for most of the target organs evaluated (nervous system, kidney, GI tract, blood, thyroid), estimated HIs do not exceed 1 for any receptor (CTE and RME children and adults). However, estimated HI values exceed 1 at a small number of locations (<1% of the total) for effects on liver, and at up to 10% of the properties for effects on skin. These risks are due to the ingestion of arsenic in soil.

Summary of Risks from Non-Lead COPCs

Based on the evaluations described above, the frequency of properties with chemical-specific HQ values or organ-specific HI values above 1E+00 is very low except for arsenic. At some properties, the concentrations of arsenic are sufficient that, if the soil is ingested by children and/or adults over a long period of time, the excess cancer risk and potential for adverse non-cancer effects would be higher than normally considered acceptable by EPA.

5.4 Uncertainty Assessment

Quantitative evaluation of the risks to humans from environmental contamination is frequently limited by uncertainty regarding a number of key data items, including concentration levels in the environment, the true level of human contact with contaminated media, the true absorption of contaminants from environmental media, and the true dose-response curves for adverse non-cancer and cancer effects in humans. This uncertainty is usually addressed by making assumptions or estimates for uncertain parameters based on whatever limited data are available. Because of these assumptions and estimates, the results of risk calculations are themselves uncertain, and it is important for risk managers and the public to keep this in mind when interpreting the results of a risk assessment. The following sections review the main sources of uncertainty in the risk calculations performed at this site.

5.4.1 Uncertainties in Exposure Assessment

As described above, the risk assessment process begins with estimation of human exposure to potentially toxic chemicals in environmental media. There are multiple sources of uncertainty in these exposure estimates, as discussed below.

Uncertainties from Exposure Pathways Not Evaluated

As discussed in Section 3, humans may be exposed to site-related chemicals by a number of pathways, but not all of these pathways were evaluated quantitatively in this risk assessment. For example, at this site, inhalation of dust in air and ingestion of contaminants taken up from soil into home-grown garden vegetables were not included in this risk assessment.

In the case of inhalation of dust in air, omission of this pathway will result in a small underestimation of exposure and risk, but the magnitude of this underestimation is not expected to be significant. This is because the amount of soil inhaled from air is much smaller than the amount ingested.

With regard to exposure from home-grown vegetables, data are available that show that lead and cadmium are taken up from soils into vegetables (Hemphill *et al.* 1973, Finster *et al.* 2003, Samsoe-Peterson *et al.* 2002). However, risk assessments at other mining, milling and smelting sites indicate that exposure from ingestion of washed garden vegetables is likely to be a minor source of exposure compared with direct ingestion of soil. For example, a 1995 study at the Kennecott Mining site found no significant uptake of lead and arsenic into fruit or leafy and root vegetables (Life Systems 1995). At the Murray Smelter site in Utah, estimated exposure to arsenic from leafy and root vegetables, legumes, and garden fruits was two orders of magnitude less than that from soil and indoor dust (Weston 1997). Additionally, there was no statistically significant relationship between the concentration of lead in garden soil and the concentration of lead in garden vegetables collected at the Vasquez Boulevard and Interstate 70 Site in Colorado (USEPA 2001d). Based on this, it is concluded that omission of the home grown garden vegetable pathway is not likely to result in a significant underestimation of exposure and risk from metal contaminants in soil.

Uncertainties From Chemicals Not Evaluated

As discussed in Section 3.3, exposure and risk were quantified only for a selected subset (the COPCs) of chemicals detected in environmental media. In most cases, omission of other (non-COPC) chemicals is likely to be a minor source of uncertainty because the highest level of the chemical detected did not exceed a level of potential concern. For chemicals for which toxicity data are not available, (e.g., bismuth), omission of the chemical may tend to underestimate total risk, but it is not possible to estimate the magnitude of the risk.

Uncertainties in Exposure Point Concentrations

In all exposure calculations, the desired input parameter is the true arithmetic mean concentration of a contaminant within a medium, averaged over the area where random exposure occurs (the exposure point). However, because the true mean can not be calculated based on a limited set of measurements, the USEPA (1989a, 1992a) recommends that the exposure estimate for non-lead COPCs be based on the upper confidence limit (UCL) of the mean. If the UCL exceeds the maximum value, the maximum value is used.

At this site, data from only 1-2 samples were available for most non-lead COPCs in surface soil at residential properties, except for zinc, which usually had 4-6 soil samples per property. Because of these small data sizes, the maximum concentration was used as the EPC for soil in all cases. Use of the maximum value to characterize risk at a residence will usually tend to overestimate risk. However, when the data set is small (1-2 samples) the maximum value may not exceed the true mean, and risks might be underestimated in some cases.

For exposure to non-lead COPCs in dust, the concentration at each home was assumed to be equal to the concentration in outdoor soil at that home. This approach may tend to be conservative in some cases (e.g., arsenic; see Appendix I), but may be approximately correct for a number of other COPCs.

Uncertainties in Human Exposure Parameters

Accurate calculation of risk values requires accurate estimates of the level of human exposure that is occurring now or may occur in the future. The exposure parameters used in this risk assessment are all default values recommended for use by USEPA at residential locations. In general, these exposure parameters are based on national data and are usually chosen in a way that was intended to be conservative or health-protective. Therefore, the values selected are thought to more likely overestimate than underestimate actual exposure and risk.

Uncertainties in Chemical Absorption (RBA)

The risk from an ingested chemical depends on how much of the ingested chemical is absorbed from the gastrointestinal tract into the body. This issue is especially important for metals in soil, because some of the metals may exist in poorly absorbable forms, and failure to account for this may result in a substantial overestimation of exposure and risk.

In the absence of data for non-lead COPCs, the approach followed in this document is to assume that the RBA is 100%. Use of this default assumption is likely to overestimate the true risk, with the magnitude of the error depending on the true RBA value. For example, studies at other sites (Weston 1997, USEPA 2001d) suggest the RBA for arsenic in soil is often about 20-40% when measured in young swine. Similarly, the RBA of arsenic in 14 soil samples from 12 different

sites ranged from 0.05 to 0.31 (5-31%) when measured in monkeys (Roberts *et al.* 2007). Assuming the RBA of arsenic in soil at this site might be in the range of 10-30%, the calculations presented in this assessment could be overestimating both the estimated excess cancer risk and the potential for adverse non-cancer effects by a factor of 3-10.

5.4.2 Uncertainties in Toxicity Values

Toxicity information for many chemicals is limited or lacking, and uncertainty in toxicity factors is one of the largest sources of uncertainty in risk estimates at a site. For example, uncertainties can arise from extrapolation from animal studies to humans, extrapolation from high dose to low dose, and extrapolation from continuous exposure to intermittent exposure. In addition, in some cases, only a few studies are available to characterize the toxicity of a chemical, and uncertainties exist not only in the dose-response curve, but also in the nature and severity of the adverse effects which the chemical may cause.

For adverse non-cancer effects, USEPA typically deals with this uncertainty by applying an uncertainty factor to account for limitations in the database. For carcinogens, this is accounted for by using the upper bound on the slope factor. Because the USEPA seeks to be conservative in the development of both cancer and non-cancer toxicity values, risk estimates based on these values are more likely to be high than low.

In this document, adverse non-cancer risks to child residents were quantified using chronic oral RfDs. This is conservative because the exposure duration of a child resident (6 years) is considered a subchronic exposure. Thus, using chronic RfDs to evaluate subchronic exposures may tend to overestimate adverse non-cancer risks to child residents for some COPCs.

5.4.3 Uncertainties in Risk Characterization

A number of uncertainties occur in the risk characterization approach for adverse non-cancer health effects and excess cancer risk.

First, because adverse non-cancer effects and excess cancer risk estimates for a chemical are derived by combining uncertain estimates of exposure and toxicity (see above), the risk estimates for each chemical are more uncertain than either the exposure estimate or the toxicity estimate alone. However, even if the risk estimates for individual chemicals were quite certain, there is considerable uncertainty in how to combine risk estimates for different chemicals. In some cases, the effects caused by one chemical do not influence the effects caused by other chemicals. In other cases, the effects of one chemical may interact with effects of other chemicals, causing responses that are greater than additive (synergistic), or less than additive (antagonistic). In most cases, available toxicity data are not sufficient to define what type of interaction is expected. In the absence of chemical-specific information to the contrary, USEPA generally assumes that non-cancer risks are additive if the chemicals act on the same target tissue, while cancer risks are

additive regardless of the target tissue. Because documented cases of significant synergistic or antagonistic interactions between chemicals are relatively uncommon, this approach is likely to be reasonable for most chemicals.

TABLE 2-1. RESIDENTIAL-TYPE PROPERTIES IN THE FINAL FOCUS AREA

CURRENT LAND USE		NUMBER OF PROPERTIES
RESIDENTIAL[1]	single family	32,121
	multi-family	3,172
VACANT LOTS		4,012
RESIDENTIAL AND VACANT LOTS		**39,305**

[1] Includes child-care facilities.

Table 2-2. Summary of Available Soil Data

Investigation	Date	Medium	Sample Description	Analytes
PA/SI (Black and Veatch 2001)	1998 - April 2001	Surface Soil	Five-point composite samples from yards, gardens, play areas and drip zones; collected from 0-1 inches bgs and sieved through number 10 (2 mm) or number 60 (250 um) mesh sieve. Composite drip zone sample, consisting of four aliquots (one from each side of the house), collected from 0-6 inches bgs and sieved through number 10 (2 mm) mesh sieve.	XRF: XRF metals ICP: TAL metals
		Subsurface Soil	Grab samples collected at every other property along the North/South/East/West sampling corridors at depths of 0-8" bgs, 8-16" bgs, and 16-24" bgs.	
RI/FS (Black and Veatch 2009)	May 2001 - September 2008	Surface Soil	Five-point composite samples from yards, gardens, play areas and drip zones; collected from 0-1 inches bgs and sieved through number 10 (2 mm) or number 60 (250 um) mesh sieve. Composite drip zone sample, consisting of four aliquots (one from each side of the house), collected from 0-6 inches bgs and sieved through number 10 (2 mm) mesh sieve.	XRF: XRF metals ICP: TAL metals
Omaha Lead Site Investigatoin Background Summary Report (Jacobs 2000).	November 1999	Surface Soil	5-point composite samples collected from 0-1 inches bgs and sieved through number 10 (2mm) mesh sieve.	XRF: XRF metals ICP: TAL metals (excluding mercury) bismuth
		Subsurface Soil	Grab samples collected at 2 properties at depths 0-8" bgs (2 samples), 8-16" bgs (3 samples), and 16-24" bgs (2 samples) and sieved through a number 10 (2mm) mesh sieve.	

bgs = below ground surface

bulk = bulk fraction of soil (sieved to 2 mm, using a number 10 sieve).

fine = fine fraction of soil (sieved to 250 µm using a number 60 sieve).

XRF = X-Ray Fluorescence

ICP-AES = Inductively Coupled Plasma Atomic Emission Spectroscopy

TAL (Target Analyte List) Metals: aluminum (Al), antimony (Sb), arsenic (As), barium (Ba), beryllium (Be), cadmium (Cd), calcium (Ca), chromium (Cr), cobalt (Co), copper (Cu), iron (Fe), lead (Pb), magnesium (Mg), manganese (Mn), mercury (Hg), nickel (Ni), potassium (K), selenium (Se), silver (Ag), sodium (Na), thallium (Th), vanadium (V), zinc (Zn).

XRF Metals: antimony (Sb), arsenic (As), cadmium (Cd), chromium (Cr), cobalt (Co) copper (Cu), iron (Fe), lead (Pb), manganese (Mn), mercury (Hg), molybdenum (Mo), nickel (Ni), rubidium (Rb), selenium (Se), silver (Ag), strontium (Sr), tin (Sn), titanium (Ti), uranium (U), Zinc (Zn), zirconium (Zr).

Table 2-3. Summary of Available Indoor Dust, Tap Water and Ambient Air Data

Data Type	Investigation	Medium	Date	Number of Stations	Number of Field Samples	Sample Description	Analyses	Analytes	Sieved
Indoor Dust (Paired with outdoor soil)	Remedial Investigation (Black and Veatch 2009)	Surface Soil	December 2003 - January 2004	159	636	Five-point composite samples from yards, gardens, play areas and drip zones; collected from 0-1 inches bgs and sieved through number 10 (2 mm) or number 60 (250 µm) mesh sieve. Composite drip zone sample, consisting of four aliquots (one from each side of the house), collected from 0-6 inches bgs and sieved through number 10 (2 mm) mesh sieve.	XRF - 100% (159)	XRF: XRF Metals	bulk - 100% (636)
		Indoor Dust	December 2003 - January 2004	159	475	Up to 3 samples collected at each property from entryways, living areas and windowsills. Samples sieved using a number 100 mesh screen (150 µm).	ICP - 100% (477)	Lead (Pb)	fine[1] - 100% (477)
	Omaha Lead Site OU2 Field Investigation (Black and Veatch 2007)	Surface Soil	October - December 2007	98	98	One 20-point composite surface soil (0-1 inches bgs) sample was collected from each property, collected by dividing up the property into 4 quadrants and collecting five grab samples from each quadrant (e.g., from the four corners and a center of each quadrant). Samples were sieved using a number 60 mesh screen (250 µm).	ICP - 100% (98)	23 TAL Metals, with the addition of titanium, silicon and zirconium	fine - 100% (98)
		Indoor Dust	October - December 2007	98	98	One composite dust sample was collected from each property, comprised of dust collected from 3 locations in the home: entryway, living area and bedroom. Samples were sieved using a number 60 mesh screen (250 µm).	ICP - 100% (98)	23 TAL Metals, with the addition of titanium, silicon and zirconium	fine - 100% (98)
Tap Water	Omaha Lead Site OU2 Field Investigation (Black and Veatch 2007)	Tap Water	December 2007	77	154	Grab samples from residential taps. Two grabs were collected at each residence: a first-flush sample and a post-flush sample.	ICP - 100%	Lead (Pb)	--
Ambient Air	USEPA Air Quality Database	Ambient Air	1997 - 2002	11	24	Mean ambient air concentration in total suspended particulates recorded at a monitoring station.	NA	Lead (Pb)	--

-- = Not applicable.
bgs = below ground surface.
bulk = bulk fraction of soil (sieved to 2 mm, using a number 10 sieve).
fine = fine fraction of soil (sieved to 250 µm using a number 60 sieve).
First - flush = tap water sample collected first thing in the morning, after water has set in pipes overnight.
ICP-AES = Inductively Coupled Plasma Atomic Emission Spectroscopy
NA = Not available.
Post-flush = tap water sample collected after runing the tap for at least 5 minutes.
XRF = X-Ray Florescence

TAL (Target Analyte List) Metals: aluminum (Al), antimony (Sb), arsenic (As), barium (Ba), beryllium (Be), cadmium (Cd), calcium (Ca), chromium (Cr), cobalt (Co), copper (Cu), iron (Fe), lead (Pb), magnesium (Mg), manganese (Mn), mercury (Hg), nickel (Ni), potassium (K), selenium (Se), silver (Ag), sodium (Na), thallium (Th), vanadium (V), zinc (Zn).

XRF Metals: antimony (Sb), arsenic (As), cadmium (Cd), chromium (Cr), cobalt (Co) copper (Cu), iron (Fe), lead (Pb), manganese (Mn), mercury (Hg), molybdenum (Mo), nickel (Ni), rubidium (Rb), selenium (Se), silver (Ag), strontium (Sr), tin (Sn), titanium (Ti), uranium (U), Zinc (Zn), zirconium (Zr).

[1] Fine fraction in this investigation is < 150 µm.

Table 2-4. Summary Statistics for Metals in Residential Soil

ANALYTE	SOIL CONCENTRATION (mg/kg)[1]				
	Detection Frequency		Minimum	Maximum	Average
ANTIMONY	320 / 89,605	0.4%	9	2,142	45
ARSENIC	56,882 / 162,903	35%	1.9	4,107	21
BARIUM	14,563 / 89,580	16%	66.3	6,896	332
CADMIUM	6,351 / 89,838	7%	2	1,057	24
CHROMIUM	2,951 / 116,450	3%	4.9	1,602,400	154
COBALT	38,764 / 111,330	35%	23	8,867	162
COPPER	55,200 / 111,243	50%	1.7	17,783	33
IRON	111,894 / 111,899	100%	1,155	2,211,200	19,982
LEAD	166,661 / 168,076	99%	3	54,219	337
MANGANESE	95,095 / 111,895	85%	30	103,900	497
MERCURY	2,136 / 116,493	2%	1	6,746	9
MOLYBDENUM	5,180 / 107,386	5%	1	17,245	5
NICKEL	19,107 / 110,518	17%	7	599,650	77
RUBIDIUM	111,706 / 111,878	100%	4	415	72
SELENIUM	225 / 116,112	0.2%	1	833	3
SILVER	104 / 89,600	0.1%	2.4	2,718	21
STRONTIUM	111,861 / 111,878	100%	5	3,224	138
TIN	18,687 / 89,526	21%	0.3	1,604.0	50
TITANIUM	89,845 / 90,250	100%	155.7	44,045	3,090
URANIUM	19 / 2,226	1%	4	68	14
ZINC	160,422 / 163,401	98%	6.6	4,444,444	436.1
ZIRCONIUM	111,881 / 111,896	100%	4	3,240	251

[1] Results for samples analyzed by XRF are presented. Concentrations qualified as not detected were adjusted to 1/2 of the quantitation limit.

Table 2-5. Summary Statistics for Metals in Background Soil

ANALYTE	SOIL CONCENTRATION (mg/kg)[1]																			
	Surface Soil (0-2" bgs)					Subsurface Soil (0-8" bgs)					Subsurface Soil (8-16" bgs)					Subsurface Soil (16-24" bgs)

Table 3-1. Summary of Quantitative COPCs in Surface Soil

CHEMICALS OF POTENTIAL CONCERN	
Aluminum	Iron
Antimony	Lead
Arsenic	Manganese
Cadmium	Mercury
Chromium	Thallium
Cobalt	Vanadium
Copper	Zinc

Table 4-1 IEUBK Model Inputs

A. AGE-INDEPENDENT MODEL INPUTS:

PARAMETER	VALUE	BASIS
Soil concentration (mg/kg)	Property-specific	Yard-wide average concentration[1] (excluding drip zone samples)
Indoor dust concentration (mg/kg)	Property-specific	Calculated using site-specific M_{sd} equation: $C_{dust} = 42 + 0.74 \cdot C_{soil}$
Air concentration ($\mu g/m^3$)	0.036	Average concentration in air at the Site (2000 – 2002) (USEPA 2008b)
Indoor air concentration ($\mu g/m^3$)	30% of outdoors	USEPA (1994a) default
Drinking water concentration (µg/L)	1.36	Average concentration in tap water at the Site. Assumes water consumed is 50% first draw and 50% post flush
Absorption Fractions: Air Diet Water Soil Dust	 32% 50% 50% 40% 40%	 USEPA (1994a) default USEPA (1994a) default USEPA (1994a) default Site-specific value Site-specific value
Fraction soil	45%	USEPA (1994a) default
GSD	1.6	USEPA (1994a) default

B. AGE-DEPENDENT MODEL INPUTS:

	AIR		DIET	WATER	SOIL
Age	Time Outdoors (hrs)	Ventilation Rate (m^3/day)	Dietary Intake [2] (µg Pb/day)	Intake (L/day)	Intake (mg/day)
0-1	1.0	2.0	2.26	0.20	85
1-2	2.0	3.0	1.96	0.50	135
2-3	3.0	5.0	2.13	0.52	135
3-4	4.0	5.0	2.04	0.53	135
4-5	4.0	5.0	1.95	0.55	100
5-6	4.0	7.0	2.05	0.58	90
6-7	4.0	7.0	2.22	0.59	85

Source: USEPA (1994a) recommended default values, unless noted otherwise.

[1] Fine fraction, ICP-equivalent concentration of lead in soil (see Section 3.4.1):
Fine ICP = Coarse XRF · 1.16 · 1.04

[2] Revised USEPA (2008a) recommended dietary intake parameters, based on updated dietary lead estimates from the Food and Drug Administration's Total Diet Study (FDA 2006) and food consumption data from NHANES III (CDC 1997) .

Table 4-2. Summary of Lead Relative Bioavailability (RBA) Data

Medium	Estimation Method	Reference	Date	Number of Field Samples	Sample Description	Soil Fraction
Surface Soil	*In Vivo*	Casteel *et al.* (2004)	2004	2	Two test materials consisted of 2 surface soil samples collected from residential yards at the site	fine
	IVBA	Drexler (2004)	2002	28	Composite surface soil samples collected from residential yards	fine
			2004	19	Composite surface soil samples collected from residential yards	fine
		Drexler (2008a)	2004	2	Samples consisted of the 2 *in vivo* test materials evaluated by Casteel *et al.* (2004)	fine
Indoor Dust	IVBA	Drexler (2008b)	2008	94	Composite indoor dust samples collected in 2007	fine

IVBA = In Vitro Bioaccessibility

Table 4-3. *In Vivo* RBA Results for Lead in Soil

A. ORIGINAL RESULTS

Measurement Endpoint	Estimated Soil RBA	
	Test Material 1	Test Material 2
Blood Lead AUC	1.01	0.76
Liver Lead	1.07	0.74
Kidney Lead	1.04	0.66
Bone Lead	0.98	0.64

Uncertainty Range	Estimated Soil RBA	
	Test Material 1	Test Material 2
Plausible Range	1.01 - 1.03	0.68 - 0.76
Preferred Range	1.01 - 1.02	0.72 - 0.76
Suggested Point Estimate	1.01	0.74

Source: Casteel *et al.* (2004)
AUC = Area Under Curve (AUC) for blood lead vs time (days 0-15), a standard pharmacokinetic index of lead uptake into blood.
RBA = Relative Bioavailability

B. REANALYSIS USING EPA 2007 METHOD

Measurement Endpoint	Estimated Soil RBA (90% Confidence Interval)	
	Test Material 1	Test Material 2
Blood Lead AUC	1.04 (0.58 - 1.43)	0.87 (0.57 - 1.24)
Liver Lead (a)	0.91 (0.62 - 1.36)	0.82 (0.55 - 1.22)
Kidney Lead	0.83 (0.62 - 1.10)	0.75 (0.56 - 1.00)
Bone Lead	1.07 (0.85 - 1.37)	0.89 (0.70 - 1.15)
Combined	0.96 (0.64 - 1.29)	0.83 (0.58 - 1.10)

(a) Results exclude one outlier data point

AUC = Area Under Curve (AUC) for blood lead vs time (days 0-15), a standard pharmacokinetic index of lead uptake into blood.
RBA = Relative Bioavailability

Table 4-4. IVBA Results for Lead in Soil

A. IVBA AND ESTIMATED RBA RESULTS:

Index	Sample ID	Concentration (Fine Fraction) (mg/kg) [2]	IVBA [1]	Estimated RBA [1,2]	Outlier? [3]

Source: Drexler (2004 and 2008a).

IVBA = *In vitro* bioaccessibility

RBA = Relative bioavailability

B. SUMMARY STATISTICS:

DATA SET	NUMBER OF SAMPLES	MEAN (RANGE)	
		IVBA	RBA
All	46	81% (34% - 112%)	68% (27% - 95%)
Outliers Excluded	45	83% (63% - 112%)	70% (53% - 95%)

[1] Note: The values shown in this table are different than originally reported in Drexler (2004). This is because the 2004 report was published before the ICP results for the concentrations of lead in the fine fraction (<250 µm) were available, so the initial IVBA estimates were based on XRF estimates of lead in the bulk fraction (<2 mm) (Drexler 2008a, personal communication).

[2] RBA estimated in accord with USEPA (2007a): $[RBA] = 0.878 \cdot [IVBA] - 0.028$

[3] Identified using Rosner's Test for Outliers (Gilbert 1987).

[4] Corrected value, based on personal communication with Drexler (2008a).

Table 4-5

***In Vivo* and *In Vitro* RBA Estimates for Lead in Soil**

Soil	Concentration (mg/kg)	IVBA mean (range)	RBA point estimate (range)	
			estimated from IVBA	measured *In Vivo*
Test Material 1	2,003	0.90 (0.88 - 0.92)	0.76 (0.74 - 0.78)	0.96 (0.64 - 1.29)
Test Material 2	1,613	0.84 (0.83 - 0.85)	0.71 (0.70 - 0.72)	0.83 (0.58 - 1.10)

IVBA = *In vitro* bioaccessibility

RBA = Relative bioavailability

Table 4-6. IVBA Results for Lead in Indoor Dust

A. IVBA AND ESTIMATED RBA RESULTS:

Index	Sample ID	Concentration (fine fraction) (mg/kg)	IVBA	RBA [1]	Outlier? [2]

B. SUMMARY STATISTICS:

DATA SET	NUMBER OF SAMPLES	MEAN (RANGE)	
		IVBA	RBA
All	94	94% (40% - 509%)	79% (32% - 444%)
Outliers Excluded	90	87% (64% - 117%)	73% (53% - 100%)

[1] RBA estimated in accord with USEPA (2007): [*RBA] = 0.878 · [IVBA] - 0.028*

[2] Identified using Rosner's Test for Outliers (Gilbert 1987).

IVBA = *In vitro* bioaccessibility

RBA = Relative bioavailability

Table 5-5. Screening-Level Non-Cancer HI Values for Ingestion and Dermal Exposure to Surface Soil

Zip Codes	Chemical-Specific HQs Included in the HI Calculations[1]			Number of Properties Evaluated[2]	Number and Percent of Properties with Non-Cancer HI > 1				Primary Contributor(s) to Estimated Risks
					CHILD		ADULT		
	Number	Chemical Names			CTE	RME	CTE	RME	
ALL	13	aluminum antimony arsenic cadmium chromium III chromium VI cobalt	copper iron manganese thallium vanadium zinc	213	7 (3%)	207 (97%)	0 (0%)	2 (0.9%)	Arsenic and/or Thallium (ingestion)
	8	antimony arsenic cadmium chromium III chromium VI	mercury thallium zinc	2,630	104 (4%)	1,412 (53%)	0 (0%)	8 (<0.3%)	Arsenic and/or Thallium (ingestion)
	7	arsenic cadmium chromium III chromium VI	mercury thallium zinc	202	7 (4%)	23 (11%)	0 (0%)	1 (0.5%)	Arsenic (ingestion)

[1] The number of chemicals that could be summed across properties varies from chemical-to-chemical and property to property, based on the available data used in the risk assessment.

[2] Total number of properties with data available for all chemicals included in the HI calculations (e.g., n=7, n=8 or n=13).

CTE = Central Tendency Exposure
HI = Hazard Index
HQ = Hazard Quotient
RME = Reasonable Maximum Exposure

Table 5-6. Target Organ-Specific Non-Cancer HI Values for Ingestion and Dermal Exposure to Surface Soil

Target Organ	Chemicals Evaluated	Number of Properties Evaluated[1]	Number of Properties with Target Organ Non-Cancer HI > 1			
			CHILD		ADULT	
			CTE	RME	CTE	RME
Central Nervous Sysem	aluminum, manganese	214	0	0	0	0
Kidney	cadmium, mercury, vanadium	0	--	--	--	--
Gastrointestinal Tract	chromium VI, copper, iron	214	0	0	0	0
Liver	antimony, thallium	2,843	6 (0.2%)	26 (0.9%)	0	0
Blood	zinc	27,737	0	0	0	0
Thyroid	cobalt	214	0	0	0	0
Skin	arsenic	3,046	76 (2.5%)	310 (10.2%)	0	8 (0.3%)

[1] Properties were evaluated only if HQ values were available for all of the chemicals listed

-- = Could not be quantified. No residential properties had results for all 3 chemicals (cadmium, mercury and vanadium).

CTE = Central Tendency Exposure

RME = Reasonable Maximum Exposure

APPENDIX A

DERIVATION OF THE FINAL FOCUS AREA BOUNDARY USING GEOSPATIAL ANALYSIS

APPENDIX A
DERIVATION OF THE FINAL FOCUS AREA BOUNDARY USING GEOSPATIAL ANALYSIS

1.0 INTRODUCTION

As discussed in the risk assessment, when there has been a release of a hazardous substance at a Superfund site, the EPA seeks to define the nature and extent of the environmental contamination by performing a Remedial Investigation (RI). The spatial bounds of the RI are not set by any *a priori* definition, but are determined by the results of the RI.

At the Omaha Lead Site (OLS), the original boundary of the focus area was established at the time the site was added to the National Priorities List by establishing a perimeter surrounding properties that had been determined at the time to have a soil lead concentration that exceeded 1,200 milligrams per kilogram (mg/kg). This area encompassed approximately 13.8 square miles. As RI sampling continued, the focus area was expanded to include a total of about 20 square miles, bounded by Ames Avenue to the north, L Street to the south, 45th Street to the west, and the Missouri River to the. In 2004, the focus area was further expanded to include a portion of the area bounded by Redick Street to the north, Harrison Street to the south and 52nd Street to the west. This Expanded Focus Area is shown in Figure A-1.

As a final step in the delineation of the focus area, geospatial analysis of available data on lead levels in soils was performed in order to determine if the Expanded Focus Area was sufficient, or if a final expansion was needed. The purpose of this Appendix is to describe this geospatial analysis and the delineation of the Final Focus Area Boundary.

2.0 OVERVIEW OF THE STRATEGY

EPA considered two strategies for the geospatial analysis. In the first approach, the goal of the analysis would be to identify a boundary beyond which the increase in soil lead concentrations due to lead emissions from the former smelters was sufficiently small (e.g., < 10 mg/kg) that it would be negligible compared to naturally occurring levels of lead in soil. This approach is very difficult to implement, however, because of the inherent variability in lead levels in soil from naturally occurring and other non-smelter sources. For this reason, EPA chose to implement a second approach that focused on whether or not the average concentration of lead in soil at a property is above 400 mg/kg (the default level of concern and soil screening level for residential properties). If a property has a mean concentration in yard soil above 400 mg/kg, it is considered likely that deposition from historic smelter releases is a significant contributing factor, although other sources of lead (naturally occurring background levels, releases from paint, automobile exhaust, etc.) may also contribute in some cases.

Ideally, the boundary would be selected to include every property with a mean soil concentration above 400 mg/kg. However, since it would not be possible to identify such properties without testing, this would, in essence, extend the study boundary indefinitely. However, the area requiring investigation can be limited by focusing on the density (frequency) of properties above 400 mg/kg. That is, it is expected that the density of impacted properties will be highest near the former smelters, and then tend to decrease as a function of distance away from the smelters. Based on this, the goal of the geospatial analysis was to identify a boundary such that the density of properties with mean concentrations above 400 mg/kg drops below 5% outside the boundary.

This analysis is performed to assure that there are no neighborhoods excluded from the Final Focus Area where the frequency of properties with average mid-yard soil lead levels exceeding 400 ppm is greater than 5%. This analysis is not intended to exclude properties with soil lead levels exceeding 400 ppm in areas outside of the 5% boundary which have been significantly impacted from former lead smelting/refining operations. Rather, the geospatial analysis assures that no significantly impacted neighborhoods are overlooked. EPA believes that it is necessary and justified for protection of human health to include the properties within the 2004 Expanded Focus Area and newly identified properties resulting from the geospatial analysis within the Final Focus Area.

EPA recognizes that a limited number of properties beyond the Final Focus Area boundary may have concentrations above 400 mg/kg, and that smelter releases may be a contributing factor in some cases. Such properties are expected to be infrequent. In most cases the average soil lead levels at properties outside the Final Focus Area will be below a level of health concern, and the contribution of former smelter/refinery releases to soil lead will usually tend to be decreased..

3.0 MATHEMATICAL METHODS

3.1 Calculating the Mean Concentration at Each Property

The mean concentration of lead at each property was computed as detailed in Appendix B and Section 4.4.1. In brief, the mean was computed as the average of all surface soil (0-1 inch) composite samples from the yard, garden, or play area. Samples from the drip zone were not included.

3.2 Calculating the Density of Properties Above 400 mg/kg

The density, or percentage, of properties with mean concentrations above 400 mg/kg was calculated on a *neighborhood* basis. The *neighborhood* of a given property consists of all other properties that are located within 500 meters of the property. This calculation was implemented using the *neighborhood statistics* function of ESRI's Spatial Analyst extension with a 500 meter radius moving circular window. The result is that each property is assigned a value that

represents the density (frequency) of properties in the *neighborhood* of that property (including the property itself) with a mean soil lead concentration above 400 mg/kg. The interpolation function of the Spatial Analyst extension was then used with this grid of values to generate a contour line that connected points on the grid with values of 5%.

4.0 RESULTS

The resulting geospatial contour is indicated by the green line shown in Figure A-2. The green line includes all properties that are located in *neighborhoods* in which 5% or more of the properties have a mean concentration exceeding 400 mg/kg.

The isolated shapes or "islands" which can be found northwest and southwest of the estimated site boundary are artifacts that occur when the number of properties in a neighborhood is small, or there is a large gap between sampled parcels (or both). For example, the crescent-shaped island that is between Highway 6 and Highway 275 is due to the combination of the isolated parcels that are located near the crescent shape and the two parcels located closest to, but outside of, the estimated site boundary, which have mean concentrations exceeding 400 mg/kg. The neighborhoods of these isolated parcels include one or both of the parcels with mean concentrations exceeding 400 mg/kg. However, the combination of the gap between these isolated parcels, and the isolation of the two parcels with mean concentrations greater than 400 mg/kg (relative to other parcels with mean concentrations greater than 400 mg/kg), provides insufficient evidence to conclude that the neighborhoods located within the crescent are actually impacted by smelter releases. Similar arguments can be made for the other isolated shapes that are present in the map. While the algorithm could have been modified to eliminate neighborhoods with less than a selected minimum number of parcels, and those that included isolated parcels with mean concentrations exceeding 400 mg/kg, the selection of the criteria that excluded neighborhoods would have been arbitrary. It seemed more transparent to include all neighborhoods in the estimation of the boundary location and then consider how the boundary was estimated when interpreting the results.

5.0 FINAL FOCUS AREA BOUNDARY

As indicated in Figure A-2, most of the boundary determined by the geospatial analysis is included within the Expanded Focus Area boundary. However, portions of the geospatial boundary extended outside Expanded Focus Area on the western and northern edges. Consequently, the focus area was expanded to include these additional areas, as shown by the purple line in Figure A-3. The resulting boundary is referred to as the Final Focus Area.

6.0 UNCERTAINTY

The large amount of data that are available at this site to estimate the location of the study area boundary provides a generally high level of confidence in the results. However, several sections

of boundary along the western edge are located near the geographic extent of the available data, which increases the uncertainty somewhat in that area. The uncertainty in the location of the boundary along the western edge of the site may be lessened by the collection of additional data in this portion of the Final Focus Area.

APPENDIX B

ELECTRONIC DATA AND DATABASE QUERIES

B-1. Omaha Database
B-2. Omaha Database Query Summary
B-3. *In Vivo* Relative Bioavailability of Lead in Soil
B-4. *In Vitro* Bioaccessibility of Lead in Soil and Dust

B-1. OMAHA DATABASE

The database is a Microsoft Access Database file entitled, *OmahaleadData.mdb.*

The database is provided as an attachment to this pdf file.

To access the database, first click on the gray tab entitled, "attachments" in the far left side of this .pdf file. Then, double click on the file, *OmahaleadData.mdb,* in the attachment window to open the database. Note this requires having Microsoft Access installed on your computer.

Due to the large size of the database, please allow a few minutes for the *OmahaleadData.mbd* file to open.

B-2. OMAHA DATABASE QUERY SUMMARY

This document provides a description of a number of database queries that were used in the preparation and analysis of the soil database for the Omaha Lead Site. This electronic database and all of the queries described below are provided electronically as part of this Appendix.

For each query, the following sections describe the purpose of the query, the name of the query, and the SQL code that implements the query. This information is provided to help reviewers of this risk assessment understand, repeat and verify all of the data operations that have been performed during the risk assessment.

1.0 Pre-Queries

The purpose of the pre-queries is to format the data so that it is usable in later queries.

PreQuery1_XRF_Null Records_ID

Purpose: Identify XRF records for which the results are not populated. A column was manually inserted in Btbl_ASSESSMENT_SAMPLING_DETAIL and was labeled "NULL" then the query was run.

SQL Code:
```
UPDATE Btbl_ASSESSMENT_SAMPLING_DETAIL SET
Btbl_ASSESSMENT_SAMPLING_DETAIL.[NULL] = "X"
WHERE ((([Btbl_ASSESSMENT_SAMPLING_DETAIL]![FINAL_RESULTS]) Is Null) AND
(([Btbl_ASSESSMENT_SAMPLING_DETAIL]![QLIMIT]) Is Null));
```

PreQuery1b_XRF_Null Records_Make Table of Null

Purpose: Create a new table containing records XRF records for which the results are not populated.

SQL Code:
```
SELECT Btbl_ASSESSMENT_SAMPLING_DETAIL.* INTO
Btbl_ASSESSMENT_SAMPLING_DETAIL_NULL
FROM Btbl_ASSESSMENT_SAMPLING_DETAIL
WHERE (((Btbl_ASSESSMENT_SAMPLING_DETAIL.[NULL])="X"));
```

PreQuery1c_XRF_Null Records_Delete Null

Purpose: Remove records from XRF table that do not contain results.

SQL Code:
```
DELETE Btbl_ASSESSMENT_SAMPLING_DETAIL.[NULL]
FROM Btbl_ASSESSMENT_SAMPLING_DETAIL
WHERE (((Btbl_ASSESSMENT_SAMPLING_DETAIL.[NULL])="X"));
```

PreQuery2a_XRF_populate ND_VALUE

Purpose: Create a column that is equal to the "ND" column but is formatted to contain numbers not text. A column was manually inserted in Btbl_ASSESSMENT_SAMPLING_DETAIL and was labeled "ND_VALUE" then the query was run.

SQL Code:
```
UPDATE Btbl_ASSESSMENT_SAMPLING_DETAIL SET
Btbl_ASSESSMENT_SAMPLING_DETAIL.ND_VALUE =
Btbl_ASSESSMENT_SAMPLING_DETAIL!ND;
```

PreQuery2b_XRF_populate QLIMIT_VALUE

Purpose: Create a column that is equal to the "QLIMIT" column but is formatted to contain numbers not text. A column was manually inserted in Btbl_ASSESSMENT_SAMPLING_DETAIL and was labeled "QLIMIT_VALUE" then the query was run.

SQL Code:
```
UPDATE Btbl_ASSESSMENT_SAMPLING_DETAIL SET
Btbl_ASSESSMENT_SAMPLING_DETAIL.[QLIMIT VALUE] =
Btbl_ASSESSMENT_SAMPLING_DETAIL!QLIMIT;
```

PreQuery3a_XRF_SRC Exclude 3 cat 0

Purpose: Create a column labeled "SRC EXCLUDE" that will identify a set of records SRC chose to exclude from the dataset. A column was manually inserted then the query was run.

SQL Code:
```
UPDATE Btbl_ASSESSMENT_SAMPLING_DETAIL SET
Btbl_ASSESSMENT_SAMPLING_DETAIL.[SRC EXCLUDE] = "X"
```

WHERE (((Btbl_ASSESSMENT_SAMPLING_DETAIL.ND_VALUE)=0) AND ((Btbl_ASSESSMENT_SAMPLING_DETAIL.FINAL_RESULTS)=0) AND ((Btbl_ASSESSMENT_SAMPLING_DETAIL.[QLIMIT VALUE])=0));

PreQuery3b_XRF_SRC Exclude nd1, result null, q 0

Purpose: Identify an additional set of records SRC chose to exclude from the dataset.

SQL Code:
```
UPDATE Btbl_ASSESSMENT_SAMPLING_DETAIL SET
Btbl_ASSESSMENT_SAMPLING_DETAIL.[SRC EXCLUDE] = "X"
WHERE (((Btbl_ASSESSMENT_SAMPLING_DETAIL.ND_VALUE)=1) AND
((Btbl_ASSESSMENT_SAMPLING_DETAIL.FINAL_RESULTS) Is Null) AND
((Btbl_ASSESSMENT_SAMPLING_DETAIL.[QLIMIT VALUE])=0));
```

PreQuery3c_XRF_SRC Exclude nd0, result neg

Purpose: Identify an additional set of records SRC chose to exclude from the dataset.

SQL Code:
```
UPDATE Btbl_ASSESSMENT_SAMPLING_DETAIL SET
Btbl_ASSESSMENT_SAMPLING_DETAIL.[SRC EXCLUDE] = "X"
WHERE (((Btbl_ASSESSMENT_SAMPLING_DETAIL.ND_VALUE)=0) AND
((Btbl_ASSESSMENT_SAMPLING_DETAIL.FINAL_RESULTS)<0));
```

PreQuery4a_XRF_Populate Results Rev

Purpose: Create a column labeled “FINAL_RESULTS REV” that is the same as “FINAL_RESULTS” and will later be modified when results are non-detect. This column was manually added and then the query was run.

SQL Code:
```
UPDATE Btbl_ASSESSMENT_SAMPLING_DETAIL SET
Btbl_ASSESSMENT_SAMPLING_DETAIL.[FINAL_RESULTS REV] =
[Btbl_ASSESSMENT_SAMPLING_DETAIL]![FINAL_RESULTS]
WHERE (((Btbl_ASSESSMENT_SAMPLING_DETAIL.ND_VALUE)=0) AND
((Btbl_ASSESSMENT_SAMPLING_DETAIL.[SRC EXCLUDE]) Is Null));
```

PreQuery4b_XRF_Populate Results Rev ND Adj

Purpose: Adjust non-detect results to be one-half the QLIMIT.

SQL Code:
```
UPDATE Btbl_ASSESSMENT_SAMPLING_DETAIL SET
Btbl_ASSESSMENT_SAMPLING_DETAIL.[FINAL_RESULTS REV] =
[Btbl_ASSESSMENT_SAMPLING_DETAIL]![QLIMIT VALUE]/2
WHERE (((Btbl_ASSESSMENT_SAMPLING_DETAIL.ND_VALUE)=1) AND
((Btbl_ASSESSMENT_SAMPLING_DETAIL.[SRC EXCLUDE]) Is Null));
```

PreQuery5a_ICP_Populate Results Value

Purpose: Create a column similar to “FINAL_RESULT”, but format the data to be a number. “FINAL RESULT_VALUE” was manually added to the table and the query was run.

SQL Code:
```
UPDATE Btbl_ICP_ASSESSMENT_SAMPLING_EPA SET
Btbl_ICP_ASSESSMENT_SAMPLING_EPA.[FINAL RESULT_VALUE] =
Btbl_ICP_ASSESSMENT_SAMPLING_EPA!FINAL_RESULT;
```

PreQuery5b_ICP_Populate QLIMT Value

Purpose: Create a column that is equal to the “QLIMIT” column but is formatted to contain numbers not text. A column was manually inserted in Btbl_ASSESSMENT_SAMPLING_DETAIL and was labeled “QLIMIT_VALUE” then the query was run.

SQL Code:
```
UPDATE Btbl_ICP_ASSESSMENT_SAMPLING_EPA SET
Btbl_ICP_ASSESSMENT_SAMPLING_EPA.QLIMIT_VALUE =
Btbl_ICP_ASSESSMENT_SAMPLING_EPA!QLIMIT;
```

PreQuery6a_ICP_Populate ND_Value w 0

Purpose: Populate the “ND_VALUE” column with “0”

SQL Code:
```
UPDATE Btbl_ICP_ASSESSMENT_SAMPLING_EPA SET
Btbl_ICP_ASSESSMENT_SAMPLING_EPA.ND_VALUE = 0;
```

PreQuery6b_ICP_Populate ND_Value w 1

Purpose: Revise the “ND_VALUE” column to be “1” when the “DETCTION_ID” is “U” or “UJ”.

SQL Code:
```
UPDATE Btbl_ICP_ASSESSMENT_SAMPLING_EPA SET
Btbl_ICP_ASSESSMENT_SAMPLING_EPA.ND_VALUE = 1
WHERE (((Btbl_ICP_ASSESSMENT_SAMPLING_EPA.DETECTION_ID)="U" Or
(Btbl_ICP_ASSESSMENT_SAMPLING_EPA.DETECTION_ID)="UJ"));
```

PreQuery7a_ICP_SRC Exclude result and Qlimit null

Purpose: Populate the “EXCLUDE” column with an “X” when both the “FINAL_RESULT” and “QLIMIT” are null.

SQL Code:
```
UPDATE Btbl_ICP_ASSESSMENT_SAMPLING_EPA SET
Btbl_ICP_ASSESSMENT_SAMPLING_EPA.[SRC EXCLUDE] = "X"
WHERE (((Btbl_ICP_ASSESSMENT_SAMPLING_EPA.FINAL_RESULT) Is Null) AND
((Btbl_ICP_ASSESSMENT_SAMPLING_EPA.QLIMIT) Is Null));
```

PreQuery7b_ICP_SRC Exclude Detect ID R

Purpose: Populate the “EXCLUDE” column with an “X” when the “DETECTION_ID” is an “R”.

SQL Code:
```
UPDATE Btbl_ICP_ASSESSMENT_SAMPLING_EPA SET
Btbl_ICP_ASSESSMENT_SAMPLING_EPA.[SRC EXCLUDE] = "X"
WHERE (((Btbl_ICP_ASSESSMENT_SAMPLING_EPA.DETECTION_ID)="R"));
```

PreQuery7c_ICP_SRC Exclude result and Qlimit 0

Purpose: Populate the “EXCLUDE” column with an “X” when the “FINAL_RESULT” and the “QLIMIT” are zero.

SQL Code:
```
UPDATE Btbl_ICP_ASSESSMENT_SAMPLING_EPA SET
Btbl_ICP_ASSESSMENT_SAMPLING_EPA.[SRC EXCLUDE] = "X"
WHERE (((Btbl_ICP_ASSESSMENT_SAMPLING_EPA.FINAL_RESULT)="0") AND
((Btbl_ICP_ASSESSMENT_SAMPLING_EPA.QLIMIT)="0"));
```

PreQuery8a_ICP_Populate Results Rev

Purpose: Populate “FINAL RESULT_REV” with what is contained in “FINAL RESULT_VALUE” when the result was detected and not excluded.

SQL Code:
```
UPDATE Btbl_ICP_ASSESSMENT_SAMPLING_EPA SET
Btbl_ICP_ASSESSMENT_SAMPLING_EPA.[FINAL RESULT REV] =
Btbl_ICP_ASSESSMENT_SAMPLING_EPA![FINAL RESULT_VALUE]
WHERE (((Btbl_ICP_ASSESSMENT_SAMPLING_EPA.ND_VALUE)=0) AND
((Btbl_ICP_ASSESSMENT_SAMPLING_EPA.[SRC EXCLUDE]) Is Null));
```

PreQuery8b_ICP_Populate Results Rev ND Adj

Purpose: Populate the result in “FINAL RESULT_REV” to be one-half the “QLIMIT_VALUE” when the result is indicated to be non-detect (“ND_VALUE” is 1).

SQL Code:
```
UPDATE Btbl_ICP_ASSESSMENT_SAMPLING_EPA SET
Btbl_ICP_ASSESSMENT_SAMPLING_EPA.[FINAL RESULT REV] =
Btbl_ICP_ASSESSMENT_SAMPLING_EPA!QLIMIT_VALUE/2
WHERE (((Btbl_ICP_ASSESSMENT_SAMPLING_EPA.ND_VALUE)=1) AND
((Btbl_ICP_ASSESSMENT_SAMPLING_EPA.[SRC EXCLUDE]) Is Null));
```

PreQuery8c_ICP_Populate Results Rev ND Adj no Qlimit but result

Purpose: Populate the result in “FINAL RESULT_REV” to be one-half the “FINAL RESULT_VALUE” when the result is indicated to be non-detect (“ND_VALUE” is 1) and the QLIMIT is not available.

SQL Code:
```
UPDATE Btbl_ICP_ASSESSMENT_SAMPLING_EPA SET
Btbl_ICP_ASSESSMENT_SAMPLING_EPA.[FINAL RESULT REV] =
Btbl_ICP_ASSESSMENT_SAMPLING_EPA![FINAL RESULT_VALUE]/2
```

WHERE (((Btbl_ICP_ASSESSMENT_SAMPLING_EPA.ND_VALUE)=1) AND ((Btbl_ICP_ASSESSMENT_SAMPLING_EPA.QLIMIT_VALUE) Is Null) AND ((Btbl_ICP_ASSESSMENT_SAMPLING_EPA.[SRC EXCLUDE]) Is Null));

PreQuery8d_ICP_Populate Results Rev ND Adj detect but result 0

Purpose: Populate the result in "FINAL RESULT_REV" to be one-half the "QLIMIT_VALUE" when the result is "0" and not indicated to be non-detect ("ND_VALUE" is "0").

SQL Code: UPDATE Btbl_ICP_ASSESSMENT_SAMPLING_EPA SET Btbl_ICP_ASSESSMENT_SAMPLING_EPA.[FINAL RESULT REV] = Btbl_ICP_ASSESSMENT_SAMPLING_EPA!QLIMIT_VALUE/2
WHERE (((Btbl_ICP_ASSESSMENT_SAMPLING_EPA.[FINAL RESULT_VALUE])=0) AND ((Btbl_ICP_ASSESSMENT_SAMPLING_EPA.ND_VALUE)=0) AND ((Btbl_ICP_ASSESSMENT_SAMPLING_EPA.[SRC EXCLUDE]) Is Null));

PreQuery8e_ICP_Populate Results Rev ND Adj detect but result nul

Purpose: Populate the result in "FINAL RESULT_REV" to be one-half the "QLIMIT_VALUE" when the result is null and not indicated to be non-detect ("ND_VALUE" is "0").

SQL Code: UPDATE Btbl_ICP_ASSESSMENT_SAMPLING_EPA SET Btbl_ICP_ASSESSMENT_SAMPLING_EPA.[FINAL RESULT REV] = Btbl_ICP_ASSESSMENT_SAMPLING_EPA!QLIMIT_VALUE/2
WHERE (((Btbl_ICP_ASSESSMENT_SAMPLING_EPA.[FINAL RESULT_VALUE]) Is Null) AND ((Btbl_ICP_ASSESSMENT_SAMPLING_EPA.ND_VALUE)=0) AND ((Btbl_ICP_ASSESSMENT_SAMPLING_EPA.[SRC EXCLUDE]) Is Null));

PreQuery9a_Populate Zip in new FFA

Purpose: Populate the Zip Code in table FFA_091808.

SQL Code: UPDATE FFA_091808 INNER JOIN [FFAprop_5-27-08] ON FFA_091808.SAMPLE_AREA_ID = [FFAprop_5-27-08].SAMPLE_ARE SET FFA_091808.[Zip Code] = [FFAprop_5-27-08]!ZIP;

Note: 5 properties needed manual entry of zip (propertyid is null). This information was provided via email correspondence.

PreQuery9b_Populate Property ID in new FFA

Purpose: Populate the PROPERTY_ID in table FFA_091808.

SQL Code: UPDATE FFA_091808 INNER JOIN [FFAprop_5-27-08] ON FFA_091808.SAMPLE_AREA_ID = [FFAprop_5-27-08].SAMPLE_ARE SET FFA_091808.PROPERTY_ID = [FFAprop_5-27-08]!PROPERTY_I;

2.0 Main Queries

The purpose of the main queries is to create summaries of the data by property.

Step00_XRF_SCPXA id

Purpose: Identify samples for use in the risk assessment. These sample contain "scpxa" in the "SAMPLE_ID", where:
S = soil
C = Composite
P = Primary
X = XRF
A = sampled at 0-2 inches

SQL Code: UPDATE [Btbl_ASSESSMENT_SAMPLING-xrf] SET [Btbl_ASSESSMENT_SAMPLING-xrf].lcw_SCPXA = "X"
WHERE ((([Btbl_ASSESSMENT_SAMPLING-xrf].SAMPLE_ID) Like "*scpxa*"));

Step01_ICP_create full sample list

Purpose: Create a table of the ICP samples with additional columns (“lcw_SCPLA”, “lcw_Dripline”, and “lcw_ICPwoXRF”).

SQL Code:
```
SELECT Btbl_ICP_ASSESSMENT_SAMPLING_EPA.SAMPLE_ID,
Btbl_ICP_ASSESSMENT_SAMPLING_EPA.SAMPLE_DATE,
Btbl_ICP_ASSESSMENT_SAMPLING_EPA.SAMPLE_AREA_ID, "" AS lcw_SCPLA, "" AS
lcw_Dripline, "" AS lcw_ICPwoXRF INTO [Btbl_ASSESSMENT_SAMPLING-icp]
FROM Btbl_ICP_ASSESSMENT_SAMPLING_EPA
GROUP BY Btbl_ICP_ASSESSMENT_SAMPLING_EPA.SAMPLE_ID,
Btbl_ICP_ASSESSMENT_SAMPLING_EPA.SAMPLE_DATE,
Btbl_ICP_ASSESSMENT_SAMPLING_EPA.SAMPLE_AREA_ID, "", "", "";
```

Step02_ICP_SCPLA id

Purpose: Populate “lcw_SCPLA” with an “X” if “SCPLA” is contained in the”SAMPLE_ID” column where:
S = soil
C = Composite
P = Primary
L = Laboratory
A = sampled at 0-2 inches

SQL Code:
```
UPDATE [Btbl_ASSESSMENT_SAMPLING-icp] SET [Btbl_ASSESSMENT_SAMPLING-
icp].lcw_SCPLA = "X"
WHERE ((([Btbl_ASSESSMENT_SAMPLING-icp].SAMPLE_ID) Like "*SCPLA*"));
```

Step03a_XRF_dripline id

Purpose: Populate “lcw_Dripline” with an “X” if the “SAMPLE_ID” contained a “D” to indicate it is a dripline sample.

SQL Code:
```
UPDATE [Btbl_ASSESSMENT_SAMPLING-xrf] SET [Btbl_ASSESSMENT_SAMPLING-
xrf].lcw_Dripline = "X"
WHERE ((([Btbl_ASSESSMENT_SAMPLING-xrf].SAMPLE_ID) Like "?D*"));
```

Step03b_ICP_dripline id

Purpose: Populate “lcw_Dripline” with an “X” if the “SAMPLE_ID” contained a “D” to indicate it is a dripline sample.

SQL Code:
```
UPDATE [Btbl_ASSESSMENT_SAMPLING-icp] SET [Btbl_ASSESSMENT_SAMPLING-
icp].lcw_Dripline = "X"
WHERE ((([Btbl_ASSESSMENT_SAMPLING-icp].SAMPLE_ID) Like "?D*"));
```

Step04_assign remed status

Purpose: Assign the remediation status to the “SAMPLE_AREA_ID” according to the “CONTRACTOR_ID” and “EXCAVATION_END_DATE”.

SQL Code:
```
UPDATE FFA_091808 INNER JOIN OMAHALEAD_SOIL_REMEDIATION ON
FFA_091808.SAMPLE_AREA_ID =
OMAHALEAD_SOIL_REMEDIATION.SAMPLE_AREA_ID SET FFA_091808.lcw_Remed =
"X"
WHERE (((OMAHALEAD_SOIL_REMEDIATION.CONTRACTOR_ID)<22) AND
((OMAHALEAD_SOIL_REMEDIATION.EXCAVATION_END_DATE) Is Not Null));
```

Step05_QUERY NO LONGER NEEDED

Note: This query is no longer needed, however, renaming downstream queries would require revision if removed and other queries were renamed.

Step06a_XRF_sample subset

Purpose: Select the XRF results that meet the sample type criteria.

SQL Code: SELECT FFA_091808.PROPERTY_ID, FFA_091808.SAMPLE_AREA_ID, FFA_091808.[Zip Code], Left([SAMPLE_ID],3) AS LocationDecode, [Btbl_ASSESSMENT_SAMPLING-xrf].SAMPLE_ID
FROM FFA_091808 INNER JOIN [Btbl_ASSESSMENT_SAMPLING-xrf] ON FFA_091808.SAMPLE_AREA_ID = [Btbl_ASSESSMENT_SAMPLING-xrf].SAMPLE_AREA_ID
WHERE ((([Btbl_ASSESSMENT_SAMPLING-xrf].lcw_SCPXA)="X") AND (([Btbl_ASSESSMENT_SAMPLING-xrf].lcw_Dripline) Is Null) AND (([Btbl_ASSESSMENT_SAMPLING-xrf].INVALID) Is Null) AND ((FFA_091808.lcw_Remed) Is Null))
GROUP BY FFA_091808.PROPERTY_ID, FFA_091808.SAMPLE_AREA_ID, FFA_091808.[Zip Code], [Btbl_ASSESSMENT_SAMPLING-xrf].SAMPLE_ID;

Step06b_ICP_sample subset

Purpose: Select the ICP results that meet the sample type criteria.

SQL Code: SELECT FFA_091808.PROPERTY_ID, FFA_091808.SAMPLE_AREA_ID, FFA_091808.[Zip Code], Left([SAMPLE_ID],3) AS LocationDecode, [Btbl_ASSESSMENT_SAMPLING-icp].SAMPLE_ID
FROM FFA_091808 INNER JOIN [Btbl_ASSESSMENT_SAMPLING-icp] ON FFA_091808.SAMPLE_AREA_ID = [Btbl_ASSESSMENT_SAMPLING-icp].SAMPLE_AREA_ID
WHERE ((([Btbl_ASSESSMENT_SAMPLING-icp].lcw_SCPLA)="X") AND (([Btbl_ASSESSMENT_SAMPLING-icp].lcw_Dripline) Is Null) AND ((FFA_091808.lcw_Remed) Is Null))
GROUP BY FFA_091808.PROPERTY_ID, FFA_091808.SAMPLE_AREA_ID, FFA_091808.[Zip Code], [Btbl_ASSESSMENT_SAMPLING-icp].SAMPLE_ID;

Step07_ICP wo XRF

Purpose: Create a table that contains the Sample Area IDs that have ICP results without paired XRF results.

SQL Code: SELECT [Step06a_XRF_sample subset].PROPERTY_ID AS Expr1, [Step06a_XRF_sample subset].SAMPLE_AREA_ID AS Expr2, [Step06a_XRF_sample subset].LocationDecode, [Step06a_XRF_sample subset].SAMPLE_ID AS XRF_SAMPLE_ID, [Step06b_ICP_sample subset].SAMPLE_ID AS ICP_SAMPLE_ID INTO [temp_ICP wo XRF]
FROM [Step06a_XRF_sample subset] INNER JOIN [Step06b_ICP_sample subset] ON ([Step06b_ICP_sample subset].PROPERTY_ID = [Step06a_XRF_sample subset].PROPERTY_ID) AND ([Step06b_ICP_sample subset].SAMPLE_AREA_ID = [Step06a_XRF_sample subset].SAMPLE_AREA_ID) AND ([Step06a_XRF_sample subset].LocationDecode = [Step06b_ICP_sample subset].LocationDecode)
WHERE ((([Step06a_XRF_sample subset].SAMPLE_ID) Is Null));

Step08_exclude ICP wo XRF

Purpose: Update the ICP table of results to identify those that do not have paired XRF results.

SQL Code: UPDATE [temp_ICP wo XRF] INNER JOIN [Btbl_ASSESSMENT_SAMPLING-icp] ON [temp_ICP wo XRF].ICP_SAMPLE_ID = [Btbl_ASSESSMENT_SAMPLING-icp].SAMPLE_ID
SET [Btbl_ASSESSMENT_SAMPLING-icp].lcw_ICPwoXRF = "X";

Step09a_XRF and ICP id summary

Purpose: Create a summary table of the property information and the paired XRF and ICP “SAMPLE_ID”s.

SQL Code: SELECT [Step06a_XRF_sample subset].PROPERTY_ID, [Step06a_XRF_sample subset].SAMPLE_AREA_ID, [Step06a_XRF_sample subset].LocationDecode, "" AS AreaType, [Step06a_XRF_sample subset].[Zip Code], [Step06a_XRF_sample subset].SAMPLE_ID AS XRF_SAMPLE_ID, [Step06b_ICP_sample subset].SAMPLE_ID AS ICP_SAMPLE_ID INTO [temp_XRF and ICP id summary]
FROM [Step06a_XRF_sample subset] LEFT JOIN [Step06b_ICP_sample subset] ON ([Step06a_XRF_sample subset].LocationDecode = [Step06b_ICP_sample subset].LocationDecode) AND ([Step06a_XRF_sample subset].PROPERTY_ID =

[Step06b_ICP_sample subset].PROPERTY_ID) AND ([Step06a_XRF_sample subset].SAMPLE_AREA_ID = [Step06b_ICP_sample subset].SAMPLE_AREA_ID);

Step09b_area type = garden

Purpose: Add the column AreaType and populate it with “garden” if the sample was indicated to be collected there.

SQL Code: UPDATE [temp_XRF and ICP id summary] SET [temp_XRF and ICP id summary].AreaType = "Garden"
WHERE ((([temp_XRF and ICP id summary].LocationDecode) Like "?G?"));

Step09c_area type = play

Purpose: Populate the column AreaType with “Play” if the sample was indicated to be collected in the play area.

SQL Code: UPDATE [temp_XRF and ICP id summary] SET [temp_XRF and ICP id summary].AreaType = "Play"
WHERE ((([temp_XRF and ICP id summary].LocationDecode) Like "?P?"));

Step09d_area type = yard A

Purpose: Populate the column AreaType with “Yard A” if the sample was indicated to be collected in the there.

SQL Code: UPDATE [temp_XRF and ICP id summary] SET [temp_XRF and ICP id summary].AreaType = "Yard A"
WHERE ((([temp_XRF and ICP id summary].LocationDecode) Like "?YA"));

Step09e_area type = yard B

Purpose: Populate the column AreaType with “Yard B” if the sample was indicated to be collected in the there.

SQL Code: UPDATE [temp_XRF and ICP id summary] SET [temp_XRF and ICP id summary].AreaType = "Yard B"
WHERE ((([temp_XRF and ICP id summary].LocationDecode) Like "?YB"));

Step09f_area type = yard C

Purpose: Populate the column AreaType with “Yard C” if the sample was indicated to be collected in the there.

SQL Code: UPDATE [temp_XRF and ICP id summary] SET [temp_XRF and ICP id summary].AreaType = "Yard C"
WHERE ((([temp_XRF and ICP id summary].LocationDecode) Like "?YC"));

Step09g_area type = yard D

Purpose: Populate the column AreaType with “Yard D” if the sample was indicated to be collected in the there.

SQL Code: UPDATE [temp_XRF and ICP id summary] SET [temp_XRF and ICP id summary].AreaType = "Yard D"
WHERE ((([temp_XRF and ICP id summary].LocationDecode) Like "?YD"));

Step10a_ICP Zn sample results_avg by area type

Purpose: Calculate the average ICP zinc concentration by area type.

SQL Code: SELECT [temp_XRF and ICP id summary].PROPERTY_ID, [temp_XRF and ICP id summary].SAMPLE_AREA_ID, [temp_XRF and ICP id summary].AreaType, [temp_XRF and ICP id summary].[Zip Code], Btbl_ICP_ASSESSMENT_SAMPLING_EPA.ANALYTE_NAME, Btbl_ICP_ASSESSMENT_SAMPLING_EPA.UNITS, Count(Btbl_ICP_ASSESSMENT_SAMPLING_EPA.[FINAL RESULT REV]) AS [ICP_N Results], Sum(Btbl_ICP_ASSESSMENT_SAMPLING_EPA.ND_VALUE) AS [ICP_N Detect Results], Avg(Btbl_ICP_ASSESSMENT_SAMPLING_EPA.[FINAL RESULT REV]) AS [ICP_Avg Result], Max(Btbl_ICP_ASSESSMENT_SAMPLING_EPA.[FINAL RESULT REV]) AS [ICP_Max Result]

FROM [temp_XRF and ICP id summary] INNER JOIN Btbl_ICP_ASSESSMENT_SAMPLING_EPA ON [temp_XRF and ICP id summary].ICP_SAMPLE_ID = Btbl_ICP_ASSESSMENT_SAMPLING_EPA.SAMPLE_ID
WHERE (((Btbl_ICP_ASSESSMENT_SAMPLING_EPA.INVALID) Is Null) AND ((Btbl_ICP_ASSESSMENT_SAMPLING_EPA.[SRC EXCLUDE]) Is Null)) OR (((Btbl_ICP_ASSESSMENT_SAMPLING_EPA.INVALID) Is Null) AND ((Btbl_ICP_ASSESSMENT_SAMPLING_EPA.[SRC EXCLUDE]) Is Null))
GROUP BY [temp_XRF and ICP id summary].PROPERTY_ID, [temp_XRF and ICP id summary].SAMPLE_AREA_ID, [temp_XRF and ICP id summary].AreaType, [temp_XRF and ICP id summary].[Zip Code], Btbl_ICP_ASSESSMENT_SAMPLING_EPA.ANALYTE_NAME, Btbl_ICP_ASSESSMENT_SAMPLING_EPA.UNITS
HAVING (((Btbl_ICP_ASSESSMENT_SAMPLING_EPA.ANALYTE_NAME)="ZINC"));

Step10b_ICP Pb sample results_avg by area type

Purpose: Calculate the average ICP lead concentration by area type.

SQL Code: SELECT [temp_XRF and ICP id summary].PROPERTY_ID, [temp_XRF and ICP id summary].SAMPLE_AREA_ID, [temp_XRF and ICP id summary].AreaType, [temp_XRF and ICP id summary].[Zip Code], Btbl_ICP_ASSESSMENT_SAMPLING_EPA.ANALYTE_NAME, Btbl_ICP_ASSESSMENT_SAMPLING_EPA.UNITS,
Count(Btbl_ICP_ASSESSMENT_SAMPLING_EPA.[FINAL RESULT REV]) AS [ICP_N Results], Sum(Btbl_ICP_ASSESSMENT_SAMPLING_EPA.ND_VALUE) AS [ICP_N Detect Results], Avg(Btbl_ICP_ASSESSMENT_SAMPLING_EPA.[FINAL RESULT REV]) AS [ICP_Avg Result], Max(Btbl_ICP_ASSESSMENT_SAMPLING_EPA.[FINAL RESULT REV]) AS [ICP_Max Result]
FROM [temp_XRF and ICP id summary] INNER JOIN Btbl_ICP_ASSESSMENT_SAMPLING_EPA ON [temp_XRF and ICP id summary].ICP_SAMPLE_ID = Btbl_ICP_ASSESSMENT_SAMPLING_EPA.SAMPLE_ID
WHERE (((Btbl_ICP_ASSESSMENT_SAMPLING_EPA.INVALID) Is Null) AND ((Btbl_ICP_ASSESSMENT_SAMPLING_EPA.[SRC EXCLUDE]) Is Null)) OR (((Btbl_ICP_ASSESSMENT_SAMPLING_EPA.INVALID) Is Null) AND ((Btbl_ICP_ASSESSMENT_SAMPLING_EPA.[SRC EXCLUDE]) Is Null))
GROUP BY [temp_XRF and ICP id summary].PROPERTY_ID, [temp_XRF and ICP id summary].SAMPLE_AREA_ID, [temp_XRF and ICP id summary].AreaType, [temp_XRF and ICP id summary].[Zip Code], Btbl_ICP_ASSESSMENT_SAMPLING_EPA.ANALYTE_NAME, Btbl_ICP_ASSESSMENT_SAMPLING_EPA.UNITS
HAVING (((Btbl_ICP_ASSESSMENT_SAMPLING_EPA.ANALYTE_NAME)="LEAD"));

Step10c_ICP non-Pb&Zn sample results_avg by area type

Purpose: Calculate the average ICP non-lead and non-zinc concentration by area type.

SQL Code: SELECT [temp_XRF and ICP id summary].PROPERTY_ID, [temp_XRF and ICP id summary].SAMPLE_AREA_ID, [temp_XRF and ICP id summary].AreaType, [temp_XRF and ICP id summary].[Zip Code], Btbl_ICP_ASSESSMENT_SAMPLING_EPA.ANALYTE_NAME, Btbl_ICP_ASSESSMENT_SAMPLING_EPA.UNITS,
Count(Btbl_ICP_ASSESSMENT_SAMPLING_EPA.[FINAL RESULT REV]) AS [ICP_N Results], Sum(Btbl_ICP_ASSESSMENT_SAMPLING_EPA.ND_VALUE) AS [ICP_N Detect Results], Avg(Btbl_ICP_ASSESSMENT_SAMPLING_EPA.[FINAL RESULT REV]) AS [ICP_Avg Result], Max(Btbl_ICP_ASSESSMENT_SAMPLING_EPA.[FINAL RESULT REV]) AS [ICP_Max Result]
FROM [temp_XRF and ICP id summary] INNER JOIN Btbl_ICP_ASSESSMENT_SAMPLING_EPA ON [temp_XRF and ICP id summary].ICP_SAMPLE_ID = Btbl_ICP_ASSESSMENT_SAMPLING_EPA.SAMPLE_ID
WHERE (((Btbl_ICP_ASSESSMENT_SAMPLING_EPA.INVALID) Is Null) AND ((Btbl_ICP_ASSESSMENT_SAMPLING_EPA.[SRC EXCLUDE]) Is Null)) OR (((Btbl_ICP_ASSESSMENT_SAMPLING_EPA.INVALID) Is Null) AND ((Btbl_ICP_ASSESSMENT_SAMPLING_EPA.[SRC EXCLUDE]) Is Null))

GROUP BY [temp_XRF and ICP id summary].PROPERTY_ID, [temp_XRF and ICP id summary].SAMPLE_AREA_ID, [temp_XRF and ICP id summary].AreaType, [temp_XRF and ICP id summary].[Zip Code], Btbl_ICP_ASSESSMENT_SAMPLING_EPA.ANALYTE_NAME, Btbl_ICP_ASSESSMENT_SAMPLING_EPA.UNITS
HAVING (((Btbl_ICP_ASSESSMENT_SAMPLING_EPA.ANALYTE_NAME) Not Like "LEAD" And (Btbl_ICP_ASSESSMENT_SAMPLING_EPA.ANALYTE_NAME) Not Like "ZINC"));

Step11a_XRF Pb sample results

Purpose: Summarize lead XRF results and calculate estimated fine fraction ICP lead results.

SQL Code:
SELECT [temp_XRF and ICP id summary].PROPERTY_ID, [temp_XRF and ICP id summary].SAMPLE_AREA_ID, [temp_XRF and ICP id summary].LocationDecode, [temp_XRF and ICP id summary].AreaType, [temp_XRF and ICP id summary].[Zip Code], [temp_XRF and ICP id summary].XRF_SAMPLE_ID, [temp_XRF and ICP id summary].ICP_SAMPLE_ID, Btbl_ASSESSMENT_SAMPLING_DETAIL.ANALYTE_NAME, Btbl_ASSESSMENT_SAMPLING_DETAIL.UNITS, Btbl_ASSESSMENT_SAMPLING_DETAIL.[FINAL_RESULTS REV] AS [XRF_Pb Result], Btbl_ASSESSMENT_SAMPLING_DETAIL.ND_VALUE, [XRF_Pb Result]*1.04 AS [XRF_Pb Fine_Adj], [XRF_Pb Fine_Adj]*1.16 AS [XRF_Pb ICPest_adj]
FROM [temp_XRF and ICP id summary] INNER JOIN Btbl_ASSESSMENT_SAMPLING_DETAIL ON [temp_XRF and ICP id summary].XRF_SAMPLE_ID = Btbl_ASSESSMENT_SAMPLING_DETAIL.SAMPLE_ID
WHERE (((Btbl_ASSESSMENT_SAMPLING_DETAIL.ANALYTE_NAME)="LEAD"));

Step11b_XRF Pb sample results_avg by area type

Purpose: Calculate the average measured XRF and estimated ICP lead concentration by area type.

SQL Code:
SELECT [Step11a_XRF Pb sample results].PROPERTY_ID, [Step11a_XRF Pb sample results].SAMPLE_AREA_ID, [Step11a_XRF Pb sample results].AreaType, [Step11a_XRF Pb sample results].[Zip Code], [Step11a_XRF Pb sample results].ANALYTE_NAME, [Step11a_XRF Pb sample results].UNITS, Count([Step11a_XRF Pb sample results].[XRF_Pb ICPest_adj]) AS [CountOfXRF_Pb ICPest_adj], Avg([Step11a_XRF Pb sample results].[XRF_Pb Result]) AS [AvgOfXRF_Pb Result], Avg([Step11a_XRF Pb sample results].[XRF_Pb ICPest_adj]) AS [AvgOfXRF_Pb ICPest_adj], Max([Step11a_XRF Pb sample results].[XRF_Pb ICPest_adj]) AS [MaxOfXRF_Pb ICPest_adj]
FROM [Step11a_XRF Pb sample results]
GROUP BY [Step11a_XRF Pb sample results].PROPERTY_ID, [Step11a_XRF Pb sample results].SAMPLE_AREA_ID, [Step11a_XRF Pb sample results].AreaType, [Step11a_XRF Pb sample results].[Zip Code], [Step11a_XRF Pb sample results].ANALYTE_NAME, [Step11a_XRF Pb sample results].UNITS;

Step12a_XRF Zn sample results

Purpose: Summarize zinc XRF results and calculate estimated fine fraction ICP zinc results.

SQL Code:
SELECT [temp_XRF and ICP id summary].PROPERTY_ID, [temp_XRF and ICP id summary].SAMPLE_AREA_ID, [temp_XRF and ICP id summary].LocationDecode, [temp_XRF and ICP id summary].AreaType, [temp_XRF and ICP id summary].[Zip Code], [temp_XRF and ICP id summary].XRF_SAMPLE_ID, [temp_XRF and ICP id summary].ICP_SAMPLE_ID, Btbl_ASSESSMENT_SAMPLING_DETAIL.ANALYTE_NAME, Btbl_ASSESSMENT_SAMPLING_DETAIL.UNITS, Btbl_ASSESSMENT_SAMPLING_DETAIL.[FINAL_RESULTS REV] AS [XRF_Zn Result], Btbl_ASSESSMENT_SAMPLING_DETAIL.ND_VALUE, 23+[XRF_Zn Result]*0.89 AS [XRF_Zn ICPest_adj]
FROM [temp_XRF and ICP id summary] INNER JOIN Btbl_ASSESSMENT_SAMPLING_DETAIL ON [temp_XRF and ICP id summary].XRF_SAMPLE_ID = Btbl_ASSESSMENT_SAMPLING_DETAIL.SAMPLE_ID
WHERE (((Btbl_ASSESSMENT_SAMPLING_DETAIL.ANALYTE_NAME)="ZINC"));

Step12b_XRF Zn sample results_avg by area type

Purpose: Calculate the average measured XRF and estimated ICP zinc concentration by area type.

SQL Code:
```
SELECT [Step12a_XRF Zn sample results].PROPERTY_ID, [Step12a_XRF Zn sample results].SAMPLE_AREA_ID, [Step12a_XRF Zn sample results].AreaType, [Step12a_XRF Zn sample results].[Zip Code], [Step12a_XRF Zn sample results].ANALYTE_NAME, [Step12a_XRF Zn sample results].UNITS, Count([Step12a_XRF Zn sample results].[XRF_Zn ICPest_adj]) AS [CountOfXRF_Zn ICPest_adj], Avg([Step12a_XRF Zn sample results].[XRF_Zn Result]) AS [AvgOfXRF_Zn Result], Avg([Step12a_XRF Zn sample results].[XRF_Zn ICPest_adj]) AS [AvgOfXRF_Zn ICPest_adj], Max([Step12a_XRF Zn sample results].[XRF_Zn ICPest_adj]) AS [MaxOfXRF_Zn ICPest_adj]
FROM [Step12a_XRF Zn sample results]
GROUP BY [Step12a_XRF Zn sample results].PROPERTY_ID, [Step12a_XRF Zn sample results].SAMPLE_AREA_ID, [Step12a_XRF Zn sample results].AreaType, [Step12a_XRF Zn sample results].[Zip Code], [Step12a_XRF Zn sample results].ANALYTE_NAME, [Step12a_XRF Zn sample results].UNITS;
```

Step13_create Pb XRF-ICP summary

Purpose: Create a summary table of the lead XRF and ICP average by area results where the ICP result is preferred over the XRF result.

SQL Code:
```
SELECT [Step11b_XRF Pb sample results_avg by area type].PROPERTY_ID, [Step11b_XRF Pb sample results_avg by area type].SAMPLE_AREA_ID, [Step11b_XRF Pb sample results_avg by area type].AreaType, [Step11b_XRF Pb sample results_avg by area type].[Zip Code], [Step11b_XRF Pb sample results_avg by area type].ANALYTE_NAME, [Step11b_XRF Pb sample results_avg by area type].UNITS, [Step11b_XRF Pb sample results_avg by area type].[CountOfXRF_Pb ICPest_adj], [Step11b_XRF Pb sample results_avg by area type].[AvgOfXRF_Pb Result], [Step11b_XRF Pb sample results_avg by area type].[AvgOfXRF_Pb ICPest_adj], [Step11b_XRF Pb sample results_avg by area type].[MaxOfXRF_Pb ICPest_adj], [Step10b_ICP Pb sample results_avg by area type].[ICP_N Results], [Step10b_ICP Pb sample results_avg by area type].[ICP_N Detect Results], [Step10b_ICP Pb sample results_avg by area type]![ICP_Avg Result]*1.04 AS [ICP_Fine_Avg Result], [Step10b_ICP Pb sample results_avg by area type]![ICP_Max Result]*1.04 AS [ICP_Fine_Max Result], IIf([ICP_FIne_Avg Result] Is Null,[AvgOfXRF_Pb ICPest_adj],[ICP_Fine_Avg Result]) AS [Final_Pb Result] INTO [temp_Pb XRF & ICP Summary]
FROM [Step11b_XRF Pb sample results_avg by area type] LEFT JOIN [Step10b_ICP Pb sample results_avg by area type] ON ([Step11b_XRF Pb sample results_avg by area type].AreaType = [Step10b_ICP Pb sample results_avg by area type].AreaType) AND ([Step11b_XRF Pb sample results_avg by area type].SAMPLE_AREA_ID = [Step10b_ICP Pb sample results_avg by area type].SAMPLE_AREA_ID)
WHERE ((([Step11b_XRF Pb sample results_avg by area type].AreaType) Is Not Null) AND (([Step10b_ICP Pb sample results_avg by area type].ANALYTE_NAME) Is Null Or ([Step10b_ICP Pb sample results_avg by area type].ANALYTE_NAME) Like "LEAD"));
```

Step14_create Zn XRF-ICP summary

Purpose: Create a summary table of the zinc XRF and ICP average by area results where the ICP result is preferred over the XRF result.

SQL Code:
```
SELECT [Step12b_XRF Zn sample results_avg by area type].PROPERTY_ID, [Step12b_XRF Zn sample results_avg by area type].SAMPLE_AREA_ID, [Step12b_XRF Zn sample results_avg by area type].AreaType, [Step12b_XRF Zn sample results_avg by area type].[Zip Code], [Step12b_XRF Zn sample results_avg by area type].ANALYTE_NAME, [Step12b_XRF Zn sample results_avg by area type].UNITS, [Step12b_XRF Zn sample results_avg by area type].[CountOfXRF_Zn ICPest_adj], [Step12b_XRF Zn sample results_avg by area type].[AvgOfXRF_Zn Result], [Step12b_XRF Zn sample results_avg by area type].[AvgOfXRF_Zn ICPest_adj], [Step12b_XRF Zn sample results_avg by area type].[MaxOfXRF_Zn ICPest_adj], [Step10a_ICP Zn sample results_avg by area type].[ICP_N Results], [Step10a_ICP Zn sample results_avg by area type].[ICP_N Detect Results],
```

[Step10a_ICP Zn sample results_avg by area type].[ICP_Avg Result], [Step10a_ICP Zn sample results_avg by area type].[ICP_Max Result], IIf([ICP_Avg Result] Is Null,[AvgOfXRF_Zn ICPest_adj],[ICP_Avg Result]) AS [Final_Zn Result] INTO [temp_Zn XRF & ICP Summary]
FROM [Step12b_XRF Zn sample results_avg by area type] LEFT JOIN [Step10a_ICP Zn sample results_avg by area type] ON ([Step12b_XRF Zn sample results_avg by area type].AreaType = [Step10a_ICP Zn sample results_avg by area type].AreaType) AND ([Step12b_XRF Zn sample results_avg by area type].SAMPLE_AREA_ID = [Step10a_ICP Zn sample results_avg by area type].SAMPLE_AREA_ID)
WHERE ((([Step12b_XRF Zn sample results_avg by area type].AreaType) Is Not Null) AND (([Step10a_ICP Zn sample results_avg by area type].ANALYTE_NAME) Is Null Or ([Step10a_ICP Zn sample results_avg by area type].ANALYTE_NAME) Like "ZINC"));

3.0 Statistical Queries

Step15a_Pb Summary Stats

Purpose: Calculate yard-wide summary statistics of the lead results.

SQL Code:
```
SELECT [temp_Pb XRF & ICP Summary].SAMPLE_AREA_ID, [temp_Pb XRF & ICP Summary].[Zip Code], [temp_Pb XRF & ICP Summary].ANALYTE_NAME, [temp_Pb XRF & ICP Summary].UNITS, Count([temp_Pb XRF & ICP Summary].AreaType) AS CountOfAreaType, Avg([temp_Pb XRF & ICP Summary].[Final_Pb Result]) AS [AvgOfFinal_Pb Result], StDev([temp_Pb XRF & ICP Summary].[Final_Pb Result]) AS [StDevOfFinal_Pb Result], Max([temp_Pb XRF & ICP Summary].[Final_Pb Result]) AS [MaxOfFinal_Pb Result]
FROM [temp_Pb XRF & ICP Summary]
WHERE ((([temp_Pb XRF & ICP Summary].AreaType) Like "Yard*" Or ([temp_Pb XRF & ICP Summary].AreaType) Like "Garden" Or ([temp_Pb XRF & ICP Summary].AreaType) Like "Play"))
GROUP BY [temp_Pb XRF & ICP Summary].SAMPLE_AREA_ID, [temp_Pb XRF & ICP Summary].[Zip Code], [temp_Pb XRF & ICP Summary].ANALYTE_NAME, [temp_Pb XRF & ICP Summary].UNITS;
```

Step15b_Pb Summary Stats_w dust

Purpose: Add summary statistics of estimated dust concentrations based on formulas derived on the relationship between soil and dust concentrations of lead.

SQL Code:
```
SELECT [Step15a_Pb Summary Stats].SAMPLE_AREA_ID, [Step15a_Pb Summary Stats].[Zip Code], [Step15a_Pb Summary Stats].ANALYTE_NAME, [Step15a_Pb Summary Stats].UNITS, [Step15a_Pb Summary Stats].[AvgOfFinal_Pb Result], [Step15a_Pb Summary Stats].[MaxOfFinal_Pb Result], 42+[AvgOfFinal_Pb Result]*0.74 AS [Avg Pb Dust], 42+[MaxOfFinal_Pb Result]*0.74 AS [Max Pb Dust]
FROM [Step15a_Pb Summary Stats];
```

Step16_Zn Summary Stats

Purpose: Calculate yard-wide summary statistics of the zinc results.

SQL Code:
```
SELECT [temp_Zn XRF & ICP Summary].SAMPLE_AREA_ID, [temp_Zn XRF & ICP Summary].[Zip Code], [temp_Zn XRF & ICP Summary].ANALYTE_NAME, [temp_Zn XRF & ICP Summary].UNITS, Count([temp_Zn XRF & ICP Summary].AreaType) AS CountOfAreaType, Avg([temp_Zn XRF & ICP Summary].[Final_Zn Result]) AS [AvgOfFinal_Zn Result], StDev([temp_Zn XRF & ICP Summary].[Final_Zn Result]) AS [StDevOfFinal_Zn Result], Max([temp_Zn XRF & ICP Summary].[Final_Zn Result]) AS [MaxOfFinal_Zn Result]
FROM [temp_Zn XRF & ICP Summary]
WHERE ((([temp_Zn XRF & ICP Summary].AreaType) Like "Yard*" Or ([temp_Zn XRF & ICP Summary].AreaType) Like "Garden" Or ([temp_Zn XRF & ICP Summary].AreaType) Like "Play"))
GROUP BY [temp_Zn XRF & ICP Summary].SAMPLE_AREA_ID, [temp_Zn XRF & ICP Summary].[Zip Code], [temp_Zn XRF & ICP Summary].ANALYTE_NAME, [temp_Zn XRF & ICP Summary].UNITS;
```

Step17_non-Pb&Zn Summary Stats

Purpose: Calculate summary statistics for non-lead and non-zinc chemicals.

SQL Code:

```
SELECT [Step10c_ICP non-Pb&Zn sample results_avg by area type].SAMPLE_AREA_ID,
[Step10c_ICP non-Pb&Zn sample results_avg by area type].[Zip Code], [Step10c_ICP non-
Pb&Zn sample results_avg by area type].ANALYTE_NAME, [Step10c_ICP non-Pb&Zn sample
results_avg by area type].UNITS, Avg([Step10c_ICP non-Pb&Zn sample results_avg by area
type].[ICP_Avg Result]) AS [AvgOfICP_Avg Result], Max([Step10c_ICP non-Pb&Zn sample
results_avg by area type].[ICP_Avg Result]) AS [MaxOfICP_Avg Result]
FROM [Step10c_ICP non-Pb&Zn sample results_avg by area type]
WHERE ((([Step10c_ICP non-Pb&Zn sample results_avg by area type].AreaType) Like "Yard*"
Or ([Step10c_ICP non-Pb&Zn sample results_avg by area type].AreaType) Like "Garden" Or
([Step10c_ICP non-Pb&Zn sample results_avg by area type].AreaType) Like "Play"))
GROUP BY [Step10c_ICP non-Pb&Zn sample results_avg by area type].SAMPLE_AREA_ID,
[Step10c_ICP non-Pb&Zn sample results_avg by area type].[Zip Code], [Step10c_ICP non-
Pb&Zn sample results_avg by area type].ANALYTE_NAME, [Step10c_ICP non-Pb&Zn sample
results_avg by area type].UNITS;
```

ACKNOWLEDGEMENTS

The work described in this report is the product of a team effort involving a number of people. In particular, the authors would like to acknowledge the efforts and support of the following:

- Margaret E. Dunsmore, BS, who helped with all aspects of animal handling and dosing, sample collection and preparation, and chemical analysis of all biological samples for total lead concentrations.

- Dr. Edward Hinderberger of L.E.T., Inc., Columbia, Missouri, who provided prompt and reliable chemical analysis of test materials and feed and water samples for total lead concentrations.

EXECUTIVE SUMMARY

A study using juvenile swine as test animals was performed to measure the gastrointestinal absorption of lead from two test materials (Test Material 1 and Test Material 2) from a Superfund site in Omaha, Nebraska. The relative bioavailability of lead was assessed by comparing the absorption of lead from the test materials to that of a reference material (lead acetate). The lead concentrations of Test Material 1 and Test Material 2 were 1650 ug/g and 1630 ug/g, respectively. Groups of five swine were given oral doses of lead acetate or a test material twice a day for 15 days. The amount of lead absorbed by each animal was evaluated by measuring the amount of lead in the blood (measured on days 0, 1, 2, 3, 5, 7, 9, 12, and 15) and the amount of lead in liver, kidney, and bone (measured on day 15 at study termination). The amount of lead present in blood or tissues of animals exposed to test materials was compared to that for animals exposed to lead acetate, and the results were expressed as relative bioavailability (RBA).

The RBA results for the two samples in this study are summarized below:

Measurement Endpoint	Estimated RBA	
	Test Material 1	Test Material 2
Blood Lead AUC	1.01	0.76
Liver Lead	1.07	0.74
Kidney Lead	1.04	0.66
Bone Lead	0.98	0.64

Because the estimates of RBA based on blood, liver, kidney, and bone do not agree in all cases, judgment must be used in interpreting the data. In general, USEPA recommends greatest emphasis be placed on the RBA estimates derived from the blood lead data. This is because blood lead data are more robust and less susceptible to random errors than the tissue lead data, so there is greater confidence in RBA estimates based on blood lead. In addition, absorption into the central compartment is an early indicator of lead exposure, is the most relevant index of central nervous system exposure, and is the standard measurement endpoint in investigations of this sort. However, data from the tissue endpoints (liver, kidney, and bone) also provide valuable information. USEPA considers the plausible range to extend from the RBA based on blood AUC to the mean of the other three tissues (liver, kidney, and bone). The preferred range is the interval from the RBA based on blood to the mean of the blood RBA and the tissue mean RBA. Our suggested point estimate is the mid-point of the preferred range. These values are presented below:

Relative Bioavailability of Lead	Test Material	
	Test Material 1	Test Material 2
Plausible Range	1.01 - 1.03	0.68 - 0.76
Preferred Range	1.01 - 1.02	0.72-0.76
Suggested Point Estimate	1.01	0.74

These RBA estimates may be used to help assess lead risk at this site by refining the estimate of absolute bioavailability (ABA) of lead in soil, as follows:

$$ABA_{soil} = ABA_{soluble} \cdot RBA_{soil}$$

Available data indicate that fully soluble forms of lead are about 50% absorbed by a child. Thus, the estimated absolute bioavailability of lead in the site samples is as follows:

Absolute Bioavailability of Lead	Test Material	
	Test Material 1	Test Material 2
Plausible Range	0.50 - 0.52	0.34 - 0.38
Preferred Range	0.50 - 0.51	0.36 - 0.38
Suggested Point Estimate	0.51	0.37

These absolute bioavailability estimates are appropriate for site-specific use in EPA's IEUBK model, although it is clear that there is both natural variability and uncertainty associated with these estimates. This variability and uncertainty arises from several sources, including: 1) the inherent variability in the responses of different individual animals to lead exposure, 2) uncertainty in the relative accuracy and applicability of the different measurement endpoints, 3) the extrapolation of measured RBA values in swine to young children, and 4) the potential effect of food in the stomach on lead absorption. Thus, the values reported above are judged to be reasonable estimates of typical lead absorption by children at this site, but should be interpreted with the understanding that the values are not certain.

RELATIVE BIOAVAILABILITY OF LEAD IN TEST MATERIALS FROM A SUPERFUND SITE IN OMAHA, NEBRASKA

1.0 INTRODUCTION

1.1 Absolute and Relative Bioavailability

Bioavailability is a concept that relates to the absorption of chemicals and how absorption depends upon the physical-chemical properties of the chemical and its medium (e.g., dust, soil, rock, food, water) and the physiology of the exposed receptor. Bioavailability is normally described as the fraction (or percentage) of a chemical which enters into the blood following an exposure of some specified amount, duration, and route (usually oral). In some cases, bioavailability may be measured using chemical levels in peripheral tissues such as liver, kidney, and bone, rather than blood. The fraction or percentage absorbed may be expressed either in absolute terms (absolute bioavailability, ABA) or relative terms (relative bioavailability, RBA). **Absolute bioavailability** is measured by comparing the amount of chemical entering the blood (or other tissue) following oral exposure to a test material with the amount entering the blood (or other tissue) following intravenous exposure to an equal amount of some dissolved form of the chemical. Similarly, **relative bioavailability** is measured by comparing oral absorption of a test material to oral absorption of some fully soluble form of the chemical (e.g., either the chemical dissolved in water, or a solid form that is expected to fully dissolve in the stomach). For example, if 100 ug of dissolved lead were administered in drinking water and a total of 50 ug entered the blood, the ABA would be 0.50 (50%). Likewise, if a total of 100 ug of lead contained in soil was ingested and 30 ug entered the blood, the ABA for soil would be 0.30 (30%). If the lead dissolved in water was used as the reference substance for describing the relative amount of lead absorbed from soil, the RBA would be 0.30/0.50, or 0.60 (60%). These values (50% absolute bioavailability of dissolved lead and 30% absolute absorption of lead in soil) are the values currently employed as defaults in USEPA's IEUBK model.

It is important to recognize that simple *solubility* of a test material in water or some other fluid (e.g., a weak acid intended to mimic the gastric contents of a child) may not be a reliable estimator of bioavailability due to the non-equilibrium nature of the dissolution and transport processes that occur in the gastrointestinal tract (Mushak, 1991). For example, fluid volume and pH are likely to be changing as a function of time, and transport of lead across the gut will prevent an approach to equilibrium concentrations, especially for poorly soluble lead compounds. However, information on the solubility of lead in different materials is useful in interpreting the importance of solubility as a determinant of bioavailability. To avoid confusion, the term “bioaccessibility” is used to refer to the relative amount of lead that dissolves under a specified set of test conditions.

For additional discussion about the concept and application of bioavailability see Goodman et al. (1990), Klaassen et al. (1996), and Gibaldi and Perrier (1982).

1.2 Using Bioavailability Data to Improve Exposure Calculations for Lead

When data are available on the bioavailability of lead in soil, dust, or other soil-like waste materials at a site, this information can often be used to improve the accuracy of exposure and risk calculations at that site. The basic equation for estimating the site-specific ABA of a test soil is as follows:

$$ABA_{soil} = ABA_{soluble} \cdot RBA_{soil}$$

where:

ABA_{soil}	=	Absolute bioavailability of lead in soil ingested by a child
$ABA_{soluble}$	=	Absolute bioavailability in children of some dissolved or fully soluble form of lead
RBA_{soil}	=	RBA for soil measured in swine

Based on available information on lead absorption in humans and animals, the USEPA estimates that the absolute bioavailability of lead from water and other fully soluble forms of lead is usually about 50% in children. Thus, when a reliable site-specific RBA value for soil is available, it may be used to estimate a site-specific absolute bioavailability as follows:

$$ABA_{soil} = 50\% \cdot RBA_{soil}$$

In the absence of site-specific data, the absolute absorption of lead from soil, dust, and other similar media is estimated by USEPA to be about 30%. Thus, the default RBA used by USEPA for lead in soil and dust compared to lead in water is 30%/50%, or 60%. When the measured RBA in soil or dust at a site is found to be less than 60% compared to some fully soluble form of lead, it may be concluded that exposures to and risks from lead in these media at that site are probably lower than the typical default assumptions. If the measured RBA is higher than 60%, absorption of and risks from lead in these media may be higher than usually assumed.

1.3 Purpose of This Study

The objective of this study was to use juvenile swine as a test system in order to determine the oral bioavailability of lead in two soil samples from a Superfund site in Omaha, Nebraska, relative to the bioavailability of a soluble form of lead. The relative bioavailability estimates may be used to improve accuracy and decrease uncertainty in estimating exposures to lead in soil in human health risk assessments for these test materials.

2.0 STUDY DESIGN

A standardized study protocol for measuring absolute and relative bioavailability of lead was developed based upon previous study designs and investigations that characterized the juvenile swine model (Weis et al., 1995). A detailed study schedule is presented in Appendix A, Table A-1. The study was performed as nearly as possible within the spirit and guidelines of Good Laboratory Practices (GLP: 40 CFR 792).

2.1 Test Materials

2.1.1 Sample Description

Two samples (Test Material 1 and Test Material 2) were collected from a Superfund site in Omaha, Nebraska. No further information on the samples was provided.

2.1.2 Sample Preparation

No information on sample preparation was provided.

2.1.3 Lead Concentration

The concentration of lead in the test materials was measured by inductively coupled plasma atomic emission spectroscopy (ICP-AES). The resulting lead values were 1650 ug/g for Test Material 1 (TM1) (measured in duplicate) and 1630 ug/g for Test Material 2 (TM2) (measured in singlicate).

2.2 Experimental Animals

Juvenile swine were selected for use in this study because they are considered to be a good physiological model for gastrointestinal absorption in children (Weis and LaVelle, 1991). The animals were intact males of the Pig Improvement Corporation (PIC) genetically defined Line 26, and were purchased from Chinn Farms, Clarence, MO.

The number of animals purchased for the study was several more than required by the protocol. These animals were purchased at an age of about 4-5 weeks (weaning occurs at age 3 weeks) and housed in individual lead-free stainless steel cages. The animals were then held under quarantine for one week to observe their health before beginning exposure to test materials. Each animal was examined by a certified veterinary clinician (swine specialist) and any animals that appeared to be in poor health during this quarantine period were excluded from the study. To minimize weight variations among animals and groups, extra animals most different in body weight (either heavier or lighter) four days prior to exposure (day -4) were also excluded from the study. The remaining animals were assigned to dose groups at random (group assignments are presented in Appendix A, Table A-2). When exposure began (day zero), the animals were about 5-6 weeks old and weighed an average of about 10.3 kg. The animals were weighed every three days during the course of the study. On average, animals gained about 0.35 kg/day and the rate of weight gain was comparable in all groups, ranging from 0.29 to 0.39 kg/day. These body weight

data are summarized in Figure 2-1 and are also presented in Appendix A, Table A-3. All animals were examined daily by an attending veterinarian while on study.

2.3 Diet

Animals were weaned onto standard pig chow (purchased from MFA Inc., Columbia, MO) by the supplier. In order to minimize lead exposure from the diet, the animals were gradually transitioned from the MFA feed to a special low-lead feed (guaranteed less than 0.2 ppm lead, purchased from Zeigler Brothers, Inc., Gardners, PA), and this feed was maintained for the duration of the study. The feed was nutritionally complete and met all requirements of the National Institutes of Health–National Research Council. The typical nutritional components and chemical analysis of the feed is presented in Table 2-1. Each day every animal was given an amount of feed equal to 4% of the mean body weight of all animals on study. Feed amounts were adjusted every three days, when pigs were weighed. Feed was administered in two equal portions at 11:00 AM and 5:00 PM daily. Analysis of random feed samples indicated that the lead level was typically below 0.2 ug/g.

Drinking water was provided *ad libitum* via self-activated watering nozzles within each cage. Analysis of samples from randomly selected drinking water nozzles indicated the lead concentration was less than 2 ug/L.

2.4 Dosing

The protocol for exposing animals to lead is shown in Table 2-2. The dose levels for lead acetate were based on experience from previous swine investigations that showed that lead doses of 25-225 ug/kg-day resulted in clear and measurable increases in lead levels in all endpoints measured (blood, liver, kidney, and bone). The doses of test materials were set at the same level as lead acetate, with one higher dose (400 ug/kg-day) included in case the test materials were found to yield very low responses. The dose levels administered were calculated based on the lead content of the test material and the measured group mean body weights. Specifically, doses of lead for the three days following each weighing were based on the group mean body weight adjusted by the addition of 1 kg to account for the expected weight gain over the time interval. After completion of the study, body weights were estimated by interpolation for those days when measurements were not collected and the actual administered doses were calculated for each day and then averaged across all days. The actual mean doses for each dosing group are included in Table 2-2; the actual lead doses administered to each pig are presented in Appendix A, Table A-3.

Animals were exposed to lead acetate or a test material for 15 days, with the dose for each day being administered in two equal portions beginning at 9:00 AM and 3:00 PM (two hours before feeding), with two minute intervals allowed for individual pig dosing. Dose material was placed in the center of a small portion (about 5 grams) of moistened feed (this is referred to as a "doughball"), and this was administered to the animals by hand[1]. If uneaten portions of doughballs were discovered, these were retrieved and offered again for consumption. Occasionally, some animals did not consume some or all of their dose. In these instances, the

[1] The lot of low-lead feed used in this study was unusually sticky, requiring the addition of cornstarch to the feed (about 1 part cornstarch to four parts feed) in order to achieve the desired consistency.

missed doses were estimated and recorded and the time-weighted average dose calculation for each animal was adjusted downward accordingly (see Appendix A, Table A-3).

2.5 Collection of Biological Samples

Samples of blood were collected from each animal on the first day of exposure (day zero) and on days 1, 2, 3, 5, 7, 9, 12, and 15 following the start of exposure. All blood samples were collected by vena-puncture of the anterior vena cava, and samples were immediately placed in purple-top Vacutainer® tubes containing EDTA as anticoagulant. Although EDTA is a chelator of metals, its presence in the sampling tubes will not impact the analytical results for lead. This is because the nitric acid digest used in the analysis destroys the organic constituents in the blood, thereby freeing all lead for analysis. Blood samples were collected each sampling day beginning at 8:00 AM, approximately one hour before the first of the two daily exposures to lead on the sampling day and 17 hours after the last lead exposure the previous day. This blood collection time was selected because the rate of change in blood lead resulting from the preceding exposures is expected to be relatively small after this interval (LaVelle et al., 1991; Weis et al., 1993), so the exact timing of sample collection relative to the last dosing is not likely to be critical.

Following collection of the final blood sample at 8:00 AM on day 15, all animals were humanely euthanized and samples of liver, kidney, and bone (the right femur) were removed and stored in lead-free plastic bags for lead analysis.

Samples of all biological samples collected were archived in order to allow for reanalysis and verification of lead levels, if needed. All animals were also subjected to detailed examination at necropsy by a certified veterinary pathologist in order to assess overall animal health.

2.6 Preparation of Biological Samples for Analysis

Blood

One mL of whole blood was removed from the purple-top Vacutainer® tube and added to 9.0 mL of "matrix modifier", a solution recommended by the Centers for Disease Control and Prevention (CDCP) for analysis of blood samples for lead. The composition of matrix modifier is 0.2% (v/v) ultrapure nitric acid, 0.75% (v/v) Triton X-100, and 0.2% (w/v) dibasic ammonium phosphate in deionized and ultrafiltered water. Samples of the matrix modifier were routinely analyzed for lead to ensure the absence of lead contamination.

Liver and Kidney

One gram of soft tissue (liver or kidney) was placed in a lead-free screw-cap teflon container with 2 mL of concentrated (70%) nitric acid and heated in an oven to 90°C overnight. After cooling, the digestate was transferred to a clean lead-free 10 mL volumetric flask and diluted to volume with deionized and ultrafiltered water.

Bone

The right femur of each animal was removed and defleshed, and dried at 100°C overnight. The dried bones were then placed in a muffle furnace and dry-ashed at 450°C for 48 hours.

Following dry ashing, the bone was ground to a fine powder using a lead-free mortar and pestle, and 200 mg was removed and dissolved in 10.0 mL of 1:1 (v:v) concentrated nitric acid/water. After the powdered bone was dissolved and mixed, 1.0 mL of the acid solution was removed and diluted to 10.0 mL by addition of 0.1% (w/v) lanthanum oxide (La_2O_3) in deionized and ultrafiltered water.

2.7 Lead Analysis

Samples of biological tissue (blood, liver, kidney, and bone) and other materials (e.g., food, water, reagents, solutions) were assigned random chain-of-custody tag numbers prior to lead analysis. Each sample was analyzed for lead using a Perkin Elmer Model 5100 graphite furnace atomic absorption spectrophotometer. Internal quality assurance samples were run every tenth sample, and the instrument was recalibrated every 15th sample. A blank, duplicate, and spiked sample were run every 20th sample.

All results from the analytical laboratory were reported in units of ug Pb/L (ng/mL) of prepared sample. The quantitation limit was defined as three-times the standard deviation of a set of seven replicates of a low-lead sample (typically about 2-5 ug/L). The standard deviation was usually about 0.3 ug/L, so the quantitation limit was usually about 0.9-1.0 ug/L. For prepared blood samples (diluted 1/10), this corresponds to a quantitation limit of 10 ug/L (1 ug/dL). For soft tissues (liver and kidney, diluted 1/10), this corresponds to a quantitation limit of 10 ug/kg (ng/g) wet weight, and for bone (final dilution = 1/500) the corresponding quantitation limit is 0.5 ug/g (ng/g) ashed weight. All responses below the quantitation limit were evaluated at one-half the quantitation limit.

Lead analytical results for study samples are presented in Appendix A, Table A-4.

2.8 Quality Assurance

A number of quality assurance (QA) steps were taken during this project to evaluate the accuracy of the analytical procedures.

2.8.1 Laboratory Quality Assurance

Steps performed by the analytical laboratory included:

Spike Recovery

Randomly selected urine samples were spiked with known amounts of lead (6 - 10 ug, as lead acetate) and the recovery of the added lead was measured. Recovery for individual samples ranged from 75% to 113%, with an average across all analyses of 97 ± 9% (N = 31).

Duplicate Analysis

The laboratory analyst selected random lead samples for duplicate analysis. Duplicate results for blood samples were within 1 ug/L (N = 42). Duplicate results for femur samples were all within 2 ug/L, with a relative percent differences (RPD) up to 13% (N = 4). Duplicate results for liver

and kidney samples had a relative percent difference (RPD) of 0% to 10%, with an average of 4.7% ± 4.0% (N = 9).

Laboratory Control Standards

Three different laboratory control standards were tested periodically during the analysis. These are samples for which a certified concentration of lead has been established. Results for these standards are summarized below:

Standard	Target Value	Acceptable Range	Mean	Range	Standard Deviation	Mean % Recovery	N
Perkin Elmer Quality Control Standard	10 ug/L	+/-10% (9.0 - 11.0 ug/L)	10.2	9 - 11	0.6	101.9%	80
Perkin Elmer Quality Control Standard	25 ug/L	+/-10% (22.5 - 27.5 ug/L)	24.6	23 - 26	0.9	98.4%	17
CDC BLLRS 592 (blood)	13.9 ug/dL	[no range provided]	13.3	12 - 15	1.0	95.6%	24

As seen, recovery of lead from these standards was generally good and within the acceptable ranges.

Blanks

Blank samples run along with each batch of samples never yielded a measurable level of lead, with all values being reported as less than 0.1 ug/L.

2.8.2 Blind Quality Assurance

In addition to these laboratory-sponsored QA samples, an additional series of QA samples were submitted to the laboratory in a blind fashion. This included a number of blood lead check samples and blind duplicates.

Blood Lead Check Samples

The Centers for Disease Control and Prevention (CDCP) provides a variety of blood lead "check samples" for use in quality assurance programs for blood lead studies. Each time a group of blood samples was prepared and sent to the laboratory for analysis, several CDCP check samples of different concentrations were included in random order and in a blind fashion.

The results for the samples submitted during this study are summarized in Figure 2-2; detailed results are presented in Appendix A, Table A-5. As seen, the results for the high and low standards (nominal values of 1.9 ug/dL and 13.9 ug/dL, respectively) tend to cluster around the line of equality as expected. The results of the middle standard (nominal value of 4.8 ug.dL) tend to be lower than expected, with one result much higher than expected. The reason for this is not known.

Duplicates

A randomly selected set of about 10% of all samples generated during the study were submitted to the laboratory in a blind fashion for duplicate analysis. The results for these duplicates are summarized in Figure 2-3; detailed results are presented in Appendix A, Table A-6. As seen, the duplicate blood data (Panel A of Figure 2-3) tend to follow the line of equality indicating that the duplicate pairs are generally in good agreement, although there is some variability for individual samples. The absolute difference between duplicate pairs of blood samples ranged from 0 to 4.1 ug/dL with an average of 1.12 ug/dL (N = 27). As seen, there was good reproducibility between duplicate samples for tissues (Panel B of Figure 2-3). The absolute difference between duplicate pairs of tissue samples ranged from 0.06 to 3.40 ug/g with an average of 0.95 ug/g (N = 9).

Based on the results of all of the quality assurance samples and steps described above, it is concluded that the analytical results are of suitable for derivation of reliable estimates of lead absorption from test materials.

3.0 DATA ANALYSIS

3.1 Overview

Studies on the absorption of lead are often complicated because some biological responses to lead exposure may be non-linear functions of dose (i.e., tending to flatten out or plateau as dose increases). The cause of this non-linearity is uncertain but might be due either to non-linear **absorption kinetics** and/or to non-linear **biological response** per unit dose absorbed. When the dose-response curve for either the reference material (lead acetate) and/or the test material is non-linear, RBA is equal to the ratio of doses that produce equal responses (not the ratio of responses at equal doses). This is based on the simple but biologically plausible assumption that equal absorbed doses yield equal biological responses. Applying this assumption leads to the following general methods for calculating RBA from a set of non-linear experimental data:

1. Plot the biological responses of individual animals exposed to a series of oral doses of soluble lead (e.g., lead acetate). Fit an equation that gives a smooth line through the observed data points.

2. Plot the biological responses of individual animals exposed to a series of doses of test material. Fit an equation that gives a smooth line through the observed data.

3. Using the best fit equations for reference material and test material, calculate RBA as the ratio of doses of test material and reference material that yield equal biological responses. Depending on the relative shape of the best-fit lines through the lead acetate and test material dose response curves, RBA may either be constant (dose-independent) or variable (dose-dependent).

The principal advantage of this approach is that it is not necessary to understand the basis for a non-linear dose response curve (non-linear absorption and/or non-linear biological response) in order to derive valid RBA estimates. Also, it is important to realize that this method is very general, as it will yield correct results even if one or both of the dose-response curves are linear. In the case where both curves are linear, RBA is dose-independent and is simply equal to the ratio of the slopes of the best-fit linear equations.

3.2 Fitting the Curves

<u>Blood Lead Data</u>

The measurement endpoint used to quantify the blood lead response was the area under the curve (AUC) for blood lead vs. time (days 0-15). AUC was selected because it is the standard pharmacokinetic index of chemical uptake into the blood compartment, and is relatively insensitive to small variations in blood lead level by day. The AUC was calculated using the trapezoidal rule to estimate the AUC between each time point that a blood lead value was measured (days 0, 1, 2, 3, 5, 7, 9, 12, and 15):

$$AUC(d_i \text{ to } d_j) = 0.5 \cdot (r_i + r_j) \cdot (d_j - d_i)$$

where:

d = day number

r = response (blood lead value) on day i (r_i) or day j (r_j)

The areas were then summed across all time intervals in the study to yield the final AUC for each animal.

Basic Equations

Based on the experience from many lead studies, it is known that blood lead AUC data are best characterized by a nonlinear (exponential) equation and tissue (bone, liver, and kidney) lead data are best characterized by a linear equation, as follow:

Linear (LIN): $\text{Response} = a + b \cdot \text{Dose}$

Exponential (EXP): $\text{Response} = a + c \cdot (1-\exp(-d \cdot \text{Dose}))$

A commercial curve-fitting program (TableCurve 2D version 5.0) which utilizes a least squares regression method was used to derive best fit equations for each of the individual dose-response data sets from this study. The exponential equation was used for all blood lead AUC data and the linear equation was used for all tissue lead data.

Constraints

In the process of finding the best fit equations to the data, the values of the parameters (*a*, *b*, *c*, and *d*) were subjected to some constraints, as follow:

- Parameter *a* (the intercept, equal to the baseline or control value of the measurement endpoint) was constrained to be non-negative and was forced in all cases to be the same for the reference material (lead acetate) and the test materials. This is because, by definition, all dose-response curves for groups of animals exposed to different materials must arise from the same value at zero dose.

- Parameter *b* (the slope of the linear dose-response line) was constrained to non-negative values, since all of the measurement endpoints evaluated are observed to increase, not decrease, as a function of lead exposure.

- Parameter *c* (the plateau value of the exponential curve) was constrained to be non-negative, and was forced to be the same for the reference material (lead acetate) and the test material. This is because: 1) it is expected on theoretical grounds that the plateau (saturation level) should be the same regardless of the source of lead, and 2) curve-fitting of individual curves tends to yield values of *c* that are close to each other and not statistically different.

- Parameter *d* was unconstrained.

Outlier Identification

Upon fitting all raw data to the appropriate equation (exponential for blood data or linear for tissue data), any data points that fell outside the 95% prediction limits were considered to be outliers and were excluded from further analyses. After excluding these points (if any), a new best fit equation was obtained. In some cases, data points originally inside the 95% prediction limits were now outside the limits. However, further iterative cycles of data point exclusion were not performed, and the fit was considered final.

4.0 RESULTS

4.1 Clinical Signs

The doses of lead administered in this study are below a level that is expected to cause toxicological responses in swine, and no clinical signs of lead-induced toxicity were noted in any of the animals used in the study.

4.2 Blood Lead vs. Time

Figure 4-1 shows the group mean blood lead values as a function of time during the study; blood lead data for individual animals are shown in Appendix A, Figure A-1. As seen, blood lead values began at or below quantitation limits (about 1 ug/dL) in all groups, and remained at or below quantitation limits in control animals (Group 10). In animals given repeated oral doses of lead acetate (Groups 1-3), Test Material 1 (Groups 4-6), or Test Material 2 (Groups 7-9), blood levels began to rise within 1-2 days, and tended to plateau by the end of the study (day 15).

4.3 Dose-Response Patterns

Blood Lead AUC

As discussed in section 3.2, the measurement endpoint used to quantify the blood lead response was the area under the curve (AUC) for blood lead vs. time (days 0-15). The AUC was calculated using the trapezoidal rule to estimate the AUC between each time point that a blood lead value was measured (days 0, 1, 2, 3, 5, 7, 9, 12, and 15) and the areas were then summed across all time intervals in the study to yield the final AUC for each animal. The AUC determinations are presented in Appendix A, Table A-7.

Curve Fit Results

As discussed in section 3.2, best fit curves for blood lead AUC dose-response data were obtained using an exponential equation, and best fit curves for all tissue dose-response data were obtained using a linear equation. The parameters of the resulting best fit equations are presented in Appendix A, Table A-8.

Blood Lead

The dose-response data for blood lead AUC results are summarized in Figure 4-2. Each data point reflects the group mean exposure and group mean response, with the variability in dose and response shown by standard error bars. The figure also shows the best-fit equation through each data set.

As seen, the dose response pattern is non-linear for both the soluble reference material (lead acetate), and for each of the two test materials. The dose response curve for TM1 appears to be very similar to that for lead acetate, while the curve for TM2 is slightly lower.

Tissue Lead

The dose-response data for lead levels in bone, liver, and kidney (measured at sacrifice on day 15) are summarized in Figures 4-3, 4-4, and 4-5, respectively. As seen, all of these dose response curves for tissues are fit by linear equations, both for lead acetate and each of the two test materials.

4.4 Calculated RBA Values

Relative bioavailability values were calculated for each test material for each measurement endpoint (blood AUC, bone, liver, kidney) using the method described in Section 3.0. The results are shown below:

Measurement Endpoint	Estimated RBA	
	Test Material 1	Test Material 2
Blood Lead AUC	1.01	0.76
Liver Lead	1.07	0.74
Kidney Lead	1.04	0.66
Bone Lead	0.98	0.64

Recommended RBA Values

For each test material, the estimates of RBA based on blood, liver, kidney, and bone are generally similar, but do not agree exactly in all cases. In general, we recommend greatest emphasis be placed on the RBA estimates derived from the blood lead data. There are several reasons for this recommendation, including the following:

1. Blood lead calculations are based on multiple measurements over time, and so are statistically more robust than the single measurements available for tissue concentrations. Further, blood is a homogeneous medium, and is easier to sample than complex tissues such as liver, kidney, and bone. Consequently, the AUC endpoint is less susceptible to random measurement errors, and RBA values calculated from AUC data are less uncertain.

2. Blood is the central compartment and one of the first compartments to be affected by absorbed lead. In contrast, uptake of lead into peripheral compartments (liver, kidney, and bone) depends on transfer from blood to the tissue, and may be subject to a variety of toxicokinetic factors that could make bioavailability determinations more complicated.

3. The dose-response curve for blood lead is non-linear, similar to the non-linear dose-response curve observed in children (e.g., see Sherlock and Quinn, 1986). Thus, the response of this endpoint is known to behave similarly in swine as in children, and it is not known if the same is true for the tissue endpoints.

4. Blood lead is the classical measurement endpoint for evaluating exposure and health effects in humans, and the health effects of lead are believed to be proportional to blood lead levels.

However, data from the tissue endpoints (liver, kidney, and bone) also provide valuable information. We consider the plausible range to extend from the RBA based on blood AUC to the mean of the RBA based on the other three tissues (liver, kidney, and bone). The preferred range is the interval from the RBA based on blood to the mean of the blood RBA and the tissue mean RBA. Our suggested point estimate is the mid-point of the preferred range. These values are presented below:

Relative Bioavailability of Lead	Test Material	
	Test Material 1	Test Material 2
Plausible Range	1.01 - 1.03	0.68 - 0.76
Preferred Range	1.01 - 1.02	0.72-0.76
Suggested Point Estimate	1.01	0.74

4.5 Estimated Absolute Bioavailability in Children

These RBA estimates may be used to help assess lead risk at this site by refining the estimate of absolute bioavailability (ABA) of lead in soil, as follows:

$$ABA_{soil} = ABA_{soluble} \cdot RBA_{soil}$$

Available data indicate that fully soluble forms of lead are about 50% absorbed by a child (USEPA 1991, 1994). Thus, the estimated absolute bioavailability of lead in the site samples is calculated as follows:

$$ABA_{Site} = 50\% \cdot RBA_{Site}$$

Based on the RBA values shown above, the estimated absolute bioavailability in children is as follows:

Absolute Bioavailability of Lead	Test Material	
	Test Material 1	Test Material 2
Plausible Range	0.50 - 0.52	0.34 - 0.38
Preferred Range	0.50 - 0.51	0.36 - 0.38
Suggested Point Estimate	0.51	0.37

4.6 Uncertainty

The bioavailability estimates above are subject to uncertainty that arises from several different sources. First, differences in physiological and pharmacokinetic parameters between individual animals leads to variability in response, even when exposure is the same. Because of this inter-animal variability in the responses of different animals to lead exposure, there is mathematical uncertainty in the best fit dose-response curves for both lead acetate and test material. This in turn leads to uncertainty in the calculated values of RBA, because these are derived from the two best-fit equations. Second, there is uncertainty in how to weight the RBA values based on the different endpoints, and how to select a point estimate for RBA that is applicable to typical site-specific exposure levels. Third, there is uncertainty in the quantitative extrapolation of measured RBA values in swine to young children. Even though the immature swine is believed to be a useful and meaningful animal model for gastrointestinal absorption in children, it is possible that differences in stomach pH, stomach emptying time, and other physiological parameters may exist and that RBA values in swine may not be precisely equal to values in children. Finally, studies in humans reveal that lead absorption is not constant even within an individual, but varies as a function of many factors (e.g., mineral intake, health status). One factor that may be of special importance is time after the last meal, with the presence of food tending to reduce lead absorption. The values of RBA measured in this study are intended to estimate the maximum uptake that occurs when lead is ingested in the absence of food. Thus, these values may be somewhat conservative for children who ingest lead along with food. The magnitude of this bias is not known.

TABLE 2-2 DOSING PROTOCOL

Group	Number of Animals	Dose Material Administered	Lead Dose (ug/kg-day)	
			Target	Actual [a]
1	5	Lead Acetate	25	25.8
2	5	Lead Acetate	75	77.7
3	5	Lead Acetate	225	234.0
4	5	Test Material 1	75	77.6
5	5	Test Material 1	225	230.8
6	5	Test Material 1	400	409.7
7	5	Test Material 2	75	77.7
8	5	Test Material 2	225	230.4
9	5	Test Material 2	400	406.4
10	3	Control	0	0

[a] Calculated as the administered daily dose divided by the measured or extrapolated daily body weight, averaged over days 0-14 for each animal and each group.

Doses were administered in two equal portions given at 9:00 AM and 3:00 PM each day. Doses were based on the mean weight of the animals in each group, and were adjusted every three days to account for weight gain.

Missed Doses:

Day 0 - Pig 265 did not eat entire AM dose (ate approximately 25%). Daily dose adjusted to 62.5%.
Day 1 - Pig 259 did not eat entire PM dose (ate approximately 90%). Daily dose adjusted to 95%.
Day 2 - Pig 260 did not eat entire PM dose (ate approximately 50%). Daily dose adjusted to 75%.
Day 2 - Pig 269 did not eat entire PM dose (ate approximately 50%). Daily dose adjusted to 75%.
Day 5 - Pig 231 did not eat entire PM dose (ate approximately 90%). Daily dose adjusted to 95%.
Day 5 - Pig 434 did not eat entire PM dose (ate approximately 60%). Daily dose adjusted to 80%.
Day 7 - Pig 233 did not eat entire PM dose (ate approximately 50%). Daily dose adjusted to 75%.
Day 8 - Pig 232 did not eat entire PM dose (ate approximately 95%). Daily dose adjusted to 97.5%.
Day 8 - Pig 261 did not eat entire PM dose (ate approximately 95%). Daily dose adjusted to 97.5%.
Day 8 - Pig 233 did not eat entire PM dose (ate approximately 90%). Daily dose adjusted to 95%.
Day 9 - Pig 232 did not eat entire PM dose (ate approximately 90%). Daily dose adjusted to 95%.
Day 10 - Pig 261 did not eat entire PM dose (ate approximately 95%). Daily dose adjusted to 97.5%.
Day 11 - Pig 227 did not eat entire PM dose (ate approximately 50%). Daily dose adjusted to 75%.

Laboratory Report: Results and QA/QC For In Vitro Bioassay Results using the Relative Bioavailability Leaching Procedure (RBLP)

Omaha Lead Site

For
USEPA Region 7

By
Dr John W. Drexler
Department of Geological Sciences
University of Colorado
Boulder, CO 80309

1.0 Introduction

In February, 2004 Black and Vetch, Inc., on behalf of U.S. Environmental Protection Agency (USEPA) shipped the Laboratory for Environmental and Geological Studies (LEGS), at the University of Colorado soils from the Omaha Lead Site to undertake a bioavailability study. In response to this an in vitro bioassay was conducted to determine relative lead bioavailability . Samples were acquired from the community by representatives of Black and Vetch on behalf of the USEPA. Results of that study are summarized in Table 1.1 and all raw data are supplied.

In addition, a set of 61 samples from the EPA speciation report entitled "THE SOURCE OF ANOMALOUS LEAD CONCENTRATIONS IN SOILS FROM THE OMAHA COMMUNITY--- OMAHA, NEBRASKA, September 22, 2002 are included in Table 1. 2 to provide a more comprehensive estimate of relative bioavailability across the site.

2.0 In Vitro Standard Operating Procedure

2.1 Background

An increasingly important property of contaminated media found at environmental sites is the bioavailabilty of individual contaminants. Bioavailability is the fraction of a contaminant that is absorbed by an organism via a specific exposure route. Many animal studies have been conducted to experimentally determine oral bioavailability of individual metals, particularly lead and arsenic. During the period 1989-97, a juvenile swine model developed by USEPA Region VIII was used to predict the relative bioavailability of lead and arsenic in approximately 20 substrates (Weis and LaVelle 1991; Weis et al. 1994). The bioavailability determined was relative to that of a soluble salt (i.e. lead acetate trihydrate). The tested media had a wide range of mineralogy, and produced a range of lead and arsenic bioavailabilty values. In addition to the swine studies, other animal models (e.g. rats and monkeys) have been used for measuring the bioavailabilty of lead and arsenic from soils and paint.

Several researchers have developed in vitro tests to measure the fraction of a chemical solubilized from a soil sample under simulated gastrointestinal conditions. The in vitro tests consist of an aqueous fluid, into which the contaminant is introduced. The solution than solubilizes the media under simulated gastric conditions. Once this procedure is complete, the solution is analyzed for lead concentrations. The mass of the lead found in the filtered extract is compared to the mass introduced into the test. The fraction liberated into the aqueous phase is defined as the bioavailable fraction of lead or arsenic in that media. To date, for lead-bearing materials tested in the USEPA swine studies, this in vitro assay has correlated well ($R^2 = 0.93$, $p = .0001$), Figure 2.1.1, with relative bioavailability. Arsenic results are still in review and data should be considered for screening purposes only at this time.

Further background on the development and validation of in vitro test systems for estimating lead and arsenic bioaccessibility can be found in; Ruby et al. (1993, 1996); Medlin (1972); Medlin and Drexler, 1997; Drexler, 1998; and Drexler et al., 2004. Background information for the USEPA swine studies may be found in (Weis and LaVelle, 1991; Weis et al. 1994; and Casteel et al., 1997) and in the USEPA Region VIII Center in Denver, Colorado.

2.2 Sample Preparation

All media were prepared for the in vitro assay by first drying (<40 °C) all samples and then sieving to < 250 m. The <250 micron size fraction was used because this particle size is representative of that which adheres to children's hands. Samples were thoroughly mixed prior to use to ensure homogenization. Samples were archived after the study completion and retained for further analysis for a period of six months unless otherwise requested. Prior to obtaining a subsample for testing in this procedure, each sample was homogenized in its sample container by end-over-end mixing.

2.3 Apparatus and Materials

2.3.1 Equipment

The main piece of equipment required for this procedure is the extraction device. The device holds ten; 125 ml, wide-mouth, high-density polyethylene (HDPE) bottles. These were rotated within a Plexiglas tank by a TCLP extractor motor with a modified flywheel. The water bath must be filled such that the extraction bottles remained immersed. Temperature in the water bath was maintained at 37 +/- 2 °C using an immersion circulator heater (Fisher Scientific Model 730). The 125-ml HDPE bottles had an airtight screw-cap seal (Fisher Scientific #02-893-5C), and care was taken to ensure that the bottles did not leak during the extraction procedure.

2.3.2 Standards and Reagents

The leaching procedure for this method used an aqueous extraction fluid at a pH value of 1.5. The pH 1.5 fluid was prepared as follows:

Two liters of aqueous extraction fluid were prepared using ASTM Type II deionized (DI) water. The buffer was made up in the following manner. To 1.9 L of DI water, 60.06 g glycine (free base, reagent grade), were added bringing the solution volume to 2 L (0.4M glycine). The mixture was placed in the water bath at 37 °C until the extraction fluid reached 37 °C. The pH meter (using both a 2.0 and a 4.0 pH buffer for standardization) was standardized using temperature compensation at 37 °C or buffers maintained at 37 °C in the water bath. Trace metal grade, concentrated hydrochloric acid (12.1N) was added until the solution pH reached a value of 1.50 +/_ 0.05 (approximately 60 mL).

All reagents were free of lead and arseic, and the final fluid was tested to confirm that lead and arsenic concentrations were less than one-fourth the project required detection limit (PRDL) of 100 (less than 25 µg/L lead 5µg/L arsenic) in the final fluid.

Cleanliness of all materials used to prepare and/or store the extraction fluid and buffer is essential. All glassware and equipment used to prepare standards and reagents were properly cleaned, acid washed, and finally, triple-rinsed with deionized water prior to use. When possible, disposable "poly" tubes were used.

2.4 Leaching Procedure

100 +/- 0.5 mL of the extraction fluid was measured, using a graduated cylinder, and transfered to a 125 mL wide-mouth HPDE bottle. 1.00 +/- 0.5 g of test substrate (<250 m) was added to the bottle, ensuring that static electricity did not cause soil particles to adhere to the lip or outside threads of the bottle. If necessary, an antistatic brush was used to eliminate static electricity prior to adding the media. The mass of substrate added to the bottle was recorded. Each bottle top was hand tightened and shaken/inverted to ensure that no leakage occurred, and that no media was caked on the bottom of the bottle.

The bottle was placed into the modified TCLP extractor, making sure each bottle was secure and the lid(s) were tightly fastened. The extractor was filled with 125 mL bottles containing test material or QA samples.

The temperature of the water bath was 37 +/- 2 °C.

The extractor was turned on and rotated end-over-end at 30 +/- 2 rpm for 1 hour. The start time of rotation was recorded.

When extraction (rotation) was complete, the extractor rotation was immediately stopped and the bottles were removed. They were then wiped dry and placed upright on the bench top.

Extract was removed directly from the reaction vessel into a disposable 20 cc syringe with a Luer-Lok attachment. A 0.45 µm cellulose acetate disk filter (25 mm diameter) was attached to the syringe, and the extract was filtered into a clean 15 mL polypropylene centrifuge tube (labeled with sample ID) or other appropriate sample vial for analysis.

The time that the extract was filtered was recorded (i.e. extraction was stopped). If the total time elapsed was greater than 1 hour 30 minutes, the test was repeated.

The pH of the remaining fluid was measured in the extraction bottle. If the fluid pH was not within +/- 0.5 pH units of the starting pH, the test was discarded and the sample reanalyzed as follows:

If the pH had changed more than 0.5 units, the test was re-run in an identical fashion. If the second test also resulted in a decrease in pH of greater than 0.5 s.u. this was recorded, and the extract filtered for analysis. If the pH had increased by 0.5 s.u. or more, the test was repeated, but the extractor stopped at specific intervals and the pH manually adjusted down to pH of 1.5 with dropwise addition of HCl (adjustments at 5, 10, 15, and 30 minutes into the extraction, and upon final removal from the water bath { 60 min}). Samples with rising pH values might better be run following the method of Medlin, 1997.

Filtered samples were stored in a refrigerator at 4 °C until analyzed. Analysis for lead and arsenic concentrations occurred within 1 week of extraction for each sample.

In general, extracts were analyzed for lead and arsenic, following EPA methods 6010B, 6020, or 7061A.

2.5 Quality Control/Quality Assurance

Quality Assurance for the extraction procedure consisted of a series of quality control samples. Controls, control limits and corrective actions are listed in Table 2.5.1 .

Table 2.5.1.

	Analysis Frequency	Control Limits	Corrective Actions
Reagent Blank	once per batch	< 25 Φg/L lead	Make new fluid and re-run all analyses.
Bottle blank	1 in 10	<50 Φg/L lead	Check calibration and re-analyze as necessary.
Blank spike*	1 in 10	85-115% recovery	Check calibration and/or source of contamination and re-analyze.
Matrix spike*	1 in 20	75-125% recovery	Flag
Duplicate sample	1 in 20	+/- 20% RPD**	Flag
Control soil***	1 in 25	+/- 10% RPD	Flag

- Spikes contained 10 mg/L lead . ** RPD= relative percent difference.
- *** The National Institute of Standards and Technology (NIST) Standard Reference Material (SRM) RPD is based upon mean RBA-lead values of 84% and 75% for MS2711 and MS2710, respectively.

3.0 Bulk Soil Analyses

Analysis of the <250 μ soil sample was carried out using Good Laboratory Practice (GLP) protocols. Samples were digested following EPA Method 3050B. Analysis of the digest was similar to EPA Methods 6020 A or B, but with somewhat reduced QA/QC. Controls, control limits and corrective actions are listed in Table 3.0.1. Initial calibration was based on a 4- point calibration curve with a minimum 0.999 R^2 value.

	Analysis Frequency	Control Limits	Corrective Actions
Method Blank	once per run	25 Φg/L lead	Check calibration and/or source of contamination and re-analyze all samples.
IVC Initial Calibration Verification	once per run	90-110% recovery	Check calibration and start run over.
Interference Check	once per run	90-110% recovery	Flag
Matrix spike*	1 in 20	75-125% recovery	Flag
CCV Continuing Calibration Verification	1 in 10	90-110% recovery	Check calibration and re-analyze preceding samples.
Duplicate sample	1 in 20	+/- 20% RPD	Flag

* Spikes contained 500 mg/L lead

4.0 Chain-of-Custody Procedures

All media once received by the Laboratory were maintained under standard chain-of-custody. Samples were maintained within secured facilities, with limited access, for 60 days post laboratories final report.

5.0 Data Handling and Verification

All sample and fluid preparation calculations and operations were recorded on data sheets. Finally, all key data were entered into EXCEL spreadsheets for final delivery and calculation of percent relative bioavailability.

6.0 Data Evaluation

Data evaluation is based on in vitro analyses from the current set of samples, not historical samples that have been added to this report for comprehensiveness. Bulk soil analyses met or exceeded all required QA/QC and therefore no corrective action was necessary. Results are summarized below.

3050B	**Analysis Frequency**	**Control Limits**	**Corrective Actions**
Method Blank	1 Method blank run	<3 Φg/L lead no values above limit.	None
IVC Initial Calibration Verification	once per run	99% recovery	None
Interference Check	once per run	99% recovery	None
CCV Continuing Calibration Verification	2 CCV run	98-99% recovery	None
Matrix spike	2 matrix spike run	98-99% recovery-Pb	None
Duplicate sample	2 duplicates run	3-9% RPD-Pb	None

RBLP analyses did meet all QA/QC and no corrective action is suggested.

RBLP	Analysis Frequency	Control Limits	Corrective Actions
Reagent Blank	0ne Reagent Blank	<1 Φg/L lead	None
Bottle blank	1 blank run	<1 Φg/L lead	None
Blank spike	2 blank spikes run	98-99% recovery	None
Matrix spike	2 matrix spikes run	96-97% recovery	None
Duplicate sample	2 duplicates run	1-2% RPD	None
Control soil	1 control run	4% RPD	None

IVBA = *In vitro* bioaccessibility

RBA = Relative bioavailability

[1] Note: The values shown in this table are different than originally reported in Drexler (2004). This is because the 2004 report was published before the ICP results for the concentrations of lead in the fine fraction (<250 µm) were available, so the initial IVBA estimates were based on XRF estimates of lead in the bulk fraction (<2 mm) (Drexler 2008a, personal communication).

[2] RBA estimated in accord with USEPA (2007a): $[RBA] = 0.878 \cdot [IVBA] - 0.028$

[3] Identified using Rosner's Test for Outliers (Gilbert 1987).

[4] Corrected value, based on personal communication with Drexler (2008a).

APPENDIX C
XRF Data Adequacy Evaluation

1.0 OVERVIEW

Soil samples collected from the Omaha Lead Site (OLS) were analyzed for lead and other metals using X-ray Fluorescence Spectroscopy (XRF). Approximately 5% of these soil samples were also analyzed by Inductively Coupled Plasma Spectroscopy (ICP). Of these two methods, ICP is considered to be the most reliable, while XRF may be prone to measurement error and/or bias for some analytes.

In order to determine if the data obtained by XRF are reliable for use in the risk assessment, a data quality assessment of the XRF data was conducted. The evaluation approaches and the results are presented in the following sections.

2.0 METHODS FOR EVALUATING DATA QUALITY

The data adequacy evaluation approach is presented in Figure C-1, and is discussed below.

2.1 Detection Limit Evaluation

The first step in the data adequacy evaluation was to evaluate whether the XRF detection limit was adequate. In order for a detection limit to be considered adequate, either (1) the detection frequency had to be high (>80%), or (2) the detection limit had to be less than the concentration of potential concern to humans. The concentration of potential concern to humans is referred to as the Risk Based Concentration (RBC) or Preliminary Remediation Goal (PRG). RBC values were based on the Regional Screening Tables USEPA for residential soil screening levels (USEPA 2008), using a cancer risk of 1E-06 or a non-cancer Hazard Quotient (HQ) of 0.1, whichever was lower.

2.2 Correlation with ICP

If the XRF detection limit was considered adequate, the XRF data were then evaluated by assessing the strength of the correlation between the XRF values and the paired ICP values. If either the XRF or the ICP value was non-detect, the data pair was excluded from the correlation analysis. A minimum of 10 pairs of ICP/XRF data were required to perform the analysis.

The strength of the correlation was based on the R^2 value for the best fit straight line derived using ordinary linear regression. If the R^2 value was less than 0.7, it was concluded that the precision of the XRF method for analysis of that chemical was unacceptably low. The value of 0.7 is based on the USEPA Region VIII Superfund Technical Assessment and Response Team (START) Generic Quality Assurance Project Plan (QAPP) which specifies that XRF is usually considered adequate when the coefficient of determination is above 0.70 (UOS 1999).

3.0 RESULTS

Results presented in this section are based on the OLS soil database as it existed on 06/21/2007.

Table C-1 presents summary statistics for soil samples analyzed by XRF. As seen, there are XRF data for 22 different metals, although not all metals were analyzed in every sample. The most data are available for lead (N = 160,035), arsenic (N = 155,366) and zinc (N = 155,882).

Table C-2 shows summary statistics for soil samples analyzed by ICP. As seen, data are available for 25 different metals. As above, not all metals were analyzed in every sample. The most data are available for lead (N = 8099), with over 4000 samples for 11 other metals.

Table C-3 presents the list of metals evaluated by both XRF and ICP. Note that there are a number of metals evaluated by XRF that were not evaluated by ICP (rubidium, strontium, tin, titanium, uranium, and zirconium), and that there were a number of metals analyzed by ICP that were not evaluated by XRF (aluminum, beryllium, bismuth, calcium, magnesium, potassium, sodium, thallium, and vanadium).

3.1 Detection Frequency Evaluation

Table C-4 presents an evaluation of the XRF detection frequencies. Of the 22 chemicals analyzed by XRF, the detection frequency was considered adequate for only 9 analytes: iron, lead, manganese, rubidium, strontium, tin, titanium, zinc, and zirconium.

3.2 Correlation with ICP Concentrations

Figures C-2 through C-5 present the correlation of XRF and ICP concentrations for four of these chemicals (iron, lead, manganese, and zinc). As noted above, ICP analysis was not performed for the other 5 chemicals (rubidium, strontium, tin, titanium, and zirconium), so no correlation analysis can be performed for these analytes.

Table C-5 summarizes the results. The correlation of the XRF to the ICP data was first evaluated using the full data set. Based on this, data points whose studentized residual was more than 3 standard deviations were identified as potential outliers (Canavos 1984), and the analysis was repeated after exclusion of these data pairs. Examination of Table C-4 indicates that, of the 5 chemicals evaluated, two (lead and zinc) yielded R^2 value > 0.7.

3.3 Data Adequacy and Useability

Table C-6 combines the results of these three data quality evaluations and provides a conclusion of the overall adequacy of the XRF data. As shown, the results for only 2

analytes (lead and zinc) met the specified data quality criteria and are considered reliable for use in the risk assessment.

3.4 Adjustment of Useable XRF Data

Although the XRF data for lead and zinc are considered adequate for use, it is still necessary to adjust each XRF value to an estimated ICP-equivalent concentration to account for biases in the XRF data:

$$\text{ICP-equivalent} = a + b \cdot \text{XRF}$$

For lead, a detailed evaluation was performed to identify the best way to estimate the parameters for this adjustment. This evaluation is presented in Appendix F. In brief, the parameters were derived using the One Group (zero intercept approach) for a sub-set of the data where the concentration by ICP was = 1000 mg/kg). The results are presented in Figure C-6.

For zinc, data were not available to support an assessment similar to that performed for lead in Appendix F, so the parameters were derived using ordinary linear regression.

Table C-7 summarizes the parameters used to adjust XRF values to ICP-equivalent concentrations for lead and zinc.

Uranium	19 / 2,261	1%	4.4 - 68	23	[5]	No
Zinc	151,663 / 155,882	97%	6.6 - 520	2,300		**Yes**
Zirconium	99,870 / 99,885	100%	3.9 - 160	--		**Yes**

-- = A soil screening level was not available for this chemical.

NOTES:

[1] USEPA. 2008c. Regional Screening Level Tables for Residential Soil. Values are based on a target cancer risk of 1E-06 or a noncancer HI of 0.1, whichever value is lower.

[2] RBC is based on Cr (VI), the most conservative screening level for chromium.

[3] Value is from IRIS and is based on the oral RfD of 1.4E-01 mg/kg-day in the diet. In accord with recommendations in IRIS, this value is modified by dividing by a Modifying Factor of 3 for application to exposures from soil or water.

[4] Merchloric chloride and inorganic salts.

[5] RBC is for insoluble salts.

Table C-5. Summary of XRF/ICP Correlation

Analyte	Outliers	Number of Data Pairs	R^2	Correlation Adequate?[1]
Iron	Included	401	0.19	No
	Excluded	397	0.22	No
Lead	Included	7,094	0.52	No
	Excluded	7,041	**0.87**	**Yes**
Manganese	Included	227	0.002	No
	Excluded	224	0.006	No
Rhubidium	Included	0	--	cannot be evaluated
	Excluded			
Strontium	Included	0	--	cannot be evaluated
	Excluded			
Tin	Included	0	--	cannot be evaluated
	Excluded			
Titanium	Included	0	--	cannot be evaluated
	Excluded			
Zinc	Included	3,959	**0.84**	**Yes**
	Excluded	3,896	**0.93**	**Yes**
Zirconium	Included	0	--	cannot be evaluated
	Excluded			

Boldface indicates analyte with an adequate XRF/ICP correlation ($R^2 > 0.7$).

ABBREVIATIONS:

XRF = X-Ray Fluorescence

-- = Not evaluated. A minimum of 10 data pairs are required for correlation analysis.

NOTES:

[1] Data are considered adequate if $R^2 > 0.70$.

Table C-6. XRF Data Quality Evaluation Summary

Analyte	Detection Frequency Adequate?	Correlation Adequate?	XRF Dataset Reliable?
Antimony	No	--	No
Arsenic	No	--	No
Barium	No	--	No
Cadmium	No	--	No
Chromium	No	No	No
Cobalt	No	--	No
Copper	No	--	No
Iron	Yes	No	No
Lead	Yes	Yes	Yes
Manganese	Yes	No	No
Mercury	No	--	No
Molybdenum	No	--	No
Nickel	No	--	No
Rubidium	Yes	unknown	--
Selenium	No	--	No
Silver	No	--	No
Strontium	Yes	unknown	--
Tin	Yes	unknown	--
Titanium	Yes	unknown	--
Uranium	No	--	No
Zinc	Yes	Yes	Yes
Zirconium	Yes	unknown	--

Boldface indicates an analyte that is considered adequate, and that is retained for further evaluation.

-- = Not evaluated.

Table C-7. Estimation of ICP-Equivalent Concentrations
from XRF Data

Equation for Estimating ICP-Equivalent Concentrations:

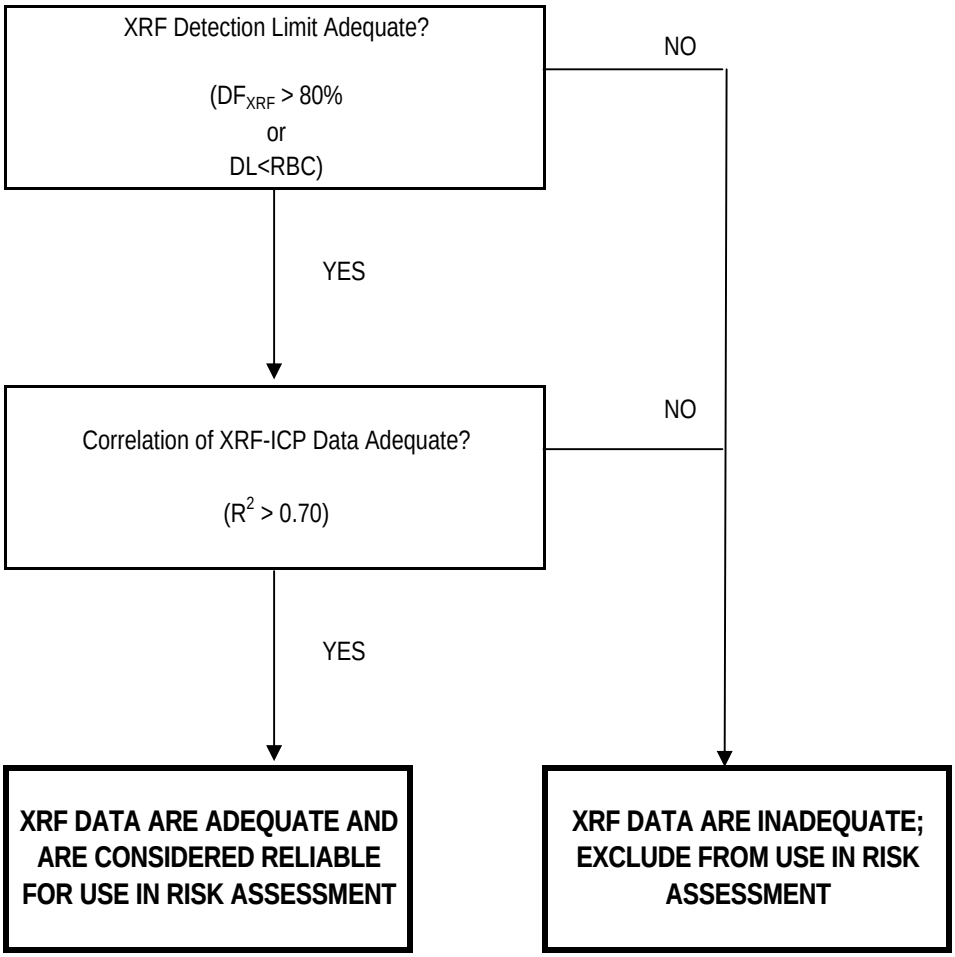
[ICP-equivalent concentration] = a + b * [XRF Concentration]

Parameters:

Analyte	Data Set	Outliers	Intercept (a)	Slope (b)
Lead	Full (all data)	Included	-3	1.47
		Excluded	-25	1.40
	Restricted (0 -1,000 mg/kg)	Included	0	1.14
		Excluded	**0**	**1.16**
Zinc	Full (all data)	Included	27	0.89
		Excluded	**23**	**0.89**

Boldface indicates parameters used to estimate ICP-equivalent concentrations in the risk assessment.

Figure C-1. Procedure for Evaluating the Adequacy of XRF Data for Use in the Risk Assessment



ABBREVIATIONS:

CV = Coefficient of Variation
DF = Detection Frequency
DL = Detection Limit
ICP = Inductively Coupled Plasma Atomic Emission Spectroscopy
RBC = Risk-Based Concentration
XRF = X-Ray Fluorescence

APPENDIX D

SCREENING LEVEL EVALUATION OF INHALATION OF DUST EXPOSURE PATHWAY

APPENDIX D
Screening Level Evaluation of the Inhalation of Dust Exposure Pathway

1.0 INTRODUCTION

This appendix presents a screening level evaluation of the inhalation of particulates from the air exposure pathway identified in the conceptual site model to determine if this pathway requires further evaluation in the risk assessment.

The screening level approach quantifies the dose of metals inhaled from particulates in air relative to the dose of metals ingested from soil.

The basic equation recommended by EPA (1989) for evaluation of inhalation exposure is:

$$DI_{air} = C_a \times BR_a \times EF \times ED/(BW \times AT)$$

where:

DI_{air}	=	Daily intake from air (mg/kg-d)
C_a	=	Concentration of substance in air (mg/m^3)
BR_a	=	Breathing rate of air (m^3/day)
EF	=	Exposure frequency (days/yr)
ED	=	Exposure duration (yrs)
BW	=	Body weight (kg)
AT	=	Averaging time (days)

and

$$C_a = PEF \times C_{soil}$$

where:

C_{soil}	=	Concentration of substance in soil (mg/kg)
PEF	=	Particulate Emission Factor (PEF), or soil to air transfer factor (kg/m^3)

The basic equation recommended by EPA (1989) for evaluation of soil ingestion is given by:

$$DI_{soil} = C_s \times IR_s \times EF \times ED/(BW \times AT)$$

where:

DI_{soil}	=	Daily intake from soil (mg/kg-d)
C_s	=	Concentration of substance in soil (mg/kg)
IR_s	=	Ingestion rate for soil (kg/day)
EF	=	Exposure frequency (days/yr)
ED	=	Exposure duration (yrs)
BW	=	Body weight (kg)
AT	=	Averaging time (days)

Based on the above equations, the relative magnitude of the inhaled dose of a COPC from air can be compared to the ingested dose from soil as follows:

Ratio (inhalation / ingestion) = PEF ⊗ BR_a / IR_s

Values for these parameters for each of the receptors identified in the conceptual model are summarized in Table D-1.

2.0 RESULTS

Table D-1 summarizes the ratio of the mass of soil inhaled to that ingested for each of the receptors identified in the conceptual model. As seen, the inhaled dose of soil from wind erosion is very small (<<1%) compared to the ingested dose, so the wind erosion pathway is not considered significant at this site.

TABLE D-1.
PATHWAY SCREENING INHALATION OF PARTICULATES RELATIVE TO SOIL INGESTION

Basic Equation: $DI_{air}/DI_{soil} = PEF \bullet BR_d/IR_s$

Air Source	Receptor	Input Parameters			Ratio	
		PEF[1] (kg/m^3)	BR_d[2] (m^3/day)	IR_s[3] (kg/day)	DI_{air}/DI_{soil}	DI_{air}/DI_{soil} (%)
wind erosion	Adult Resident	8E-10	20	1E-04	2E-04	0.015%
	Child Resident	8E-10	10	2E-04	4E-05	0.0038%

Note: RME exposure parameters are used in the calculations

PEF = Particulate Emission Factor (see Appendix F for derivation)
BR_d = Breathing rate of dust
IR_s = Soil Ingestion Rate
DI = Daily Intake (mg/kg-day)

[1] USEPA (1996) default PEF of 1.32E+09 m^3/kg, expressed as kg/m^3.
[2] USEPA (1991) recommended default inhalation rate for adults; USEPA (1997) recommended inhalation rate for children 6-8 years.
[3] USEPA (1991) recommended default soil ingestion rate for residents.

[1] Surface soil samples collected from resdiential properties (single family, multi-family and vacant lots) within the final focus area, excluding remediated properties. Data include all ICP results and XRF results for lead and zinc that have been adjusted, according to the XRF-ICP relationships presented in Appendix C.

[2] Based on USEPA (1994), Table 1. Chemicals identified by USEPA as beneficial nutrients for which toxicity data were not available were assigned a value of "Yes". All other chemicals were assigned values of "No".

[3] Maximum expected dose for the maximally exposed receptor (child resident), see Table E-2 for calculations.

[4] Values are either Reference Daily Intake (RDI) or Daily Reference Value (DRV). RDIs replace the term "U. S. Recommended Daily Allowances" (introduced in 1973 as a reference value for vitamins, minerals, and protein). DRVs are for nutrients for which no set of standards previously existed. Values obtained from http://www.fda.gov/fdac/special/foodlabel/dvs.html.

[5] USEPA (2008) default soil screening level for residential soil, based on a target cancer risk of 1E-06 and a target noncancer Hazard Quotient of 0.1 .

Table E-2. Evaluation of Beneficial Nutrients

Media	Maximally Exposed Receptor	Essential Nutrient	Maximum Concentration (C_{max})		RME Intake Rate (IR)		Maximum Daily Intake [1] (mg/day)	Accepted Daily Intake [2] (mg/day)		Ratio
			Value	Units	Value	Units		value	Source	
Residential Soil	Resident (child)	Calcium	75,400	mg/kg	200	mg/day	15.08	1,000	RDI	0.015
		Magnesium	10,600	mg/kg	200	mg/day	2.12	400	RDI	0.0053
		Potassium	3,710	mg/kg	200	mg/day	0.74	3,500	DRV	0.00021
		Sodium	1,430	mg/kg	200	mg/day	0.29	2,400	DRV	0.00012

[1] Calculated from maximum concentration and RME intake rate for the maximally exposed receptor (highest intake rate).
Max Daily Intake = C_{max} * IR. Conversion factors applied (as necessary) to yield daily intake in units of mg/day. Phosphorus in environmental media assumed to be present as phosphate. Maximum site concentration converted to phosphorus by multiplying by 0.316 (mass phosphorus/mass of phosphate).

[2] Valies are Reference Daily Intake (RDI) or Daily Reference Value (DRV). RDIs replace the term "U. S. Recommended Daily Allowances" (introduced in 1973 as a reference value for vitamins, minerals, and protein). DRVs are for nutrients for which no set of standards previously existed. Values obtained from http://www.fda.gov/fdac/special/foodlabel/dvs.html.

APPENDIX F

STATISTICAL METHODS USED TO FIT LINEAR MODELS FOR LEAD DATA

APPENDIX F
STATISTICAL METHODS USED TO FIT LINEAR MODELS FOR LEAD DATA

1.0 OVERVIEW

At the OLS site, data have been collected to evaluate three site-specific relationships that are needed for use in the lead risk assessment:

- The concentration of lead in soil when measured by XRF compared to that when measured by ICP ("XRF vs ICP")
- The concentration of lead in the fine fraction (< 250 µm) of soil compared to that in the bulk (< 2 mm) fraction ("Bulk vs Fine")
- The concentration of lead in indoor dust at a property compared to the average level in soil for that property ("Soil vs Dust")

At the level of individual sample pairs, all three of these relationships are rather variable. However, in all cases the average relationship appears to be adequately characterized by a linear equation:

- $ICP = a1 + b1 \cdot XRF$
- $Fine = a2 + b2 \cdot Bulk$
- $Dust = a3 + b3 \cdot Soil$

The parameters (slope and intercept) for linear models of this type are often estimated using ordinary linear regression (OLR). Use of OLR assumes that two conditions are satisfied: 1) the errors in y are normal and independent of the value of y (or x) (i.e., y is homoscedastic), and 2) there are no errors in the x variable. However, neither of these assumptions is likely to be true for the three data sets considered here. That is, the magnitude of the errors in y are likely to depend on the value of y (i.e., y is heteroscedastic), and there are likely to be errors in the value of x (measurement error). The occurrence of measurement error in x is especially important, because application of OLR to data sets that include measurement error will generally tend to underestimate the slope and overestimate the intercept.

There are a number of statistical methods that have been developed to deal with data that are either heteroscedastic and/or that include measurement error in x. These methods differ from each other in the degree to which they are statistically rigorous or are simplifications and approximations, and in the amount of information that is needed to implement the methods. The purpose of this appendix is to describe a set of seven alternative methods that were considered for use, describe an approach that was followed to evaluate which method was best for each data

set, and give the results of the application of the selected method to each of the three data sets described above.

2.0 DESCRIPTION OF METHODS EVALUATED

A total of seven different methods were considered in this evaluation, as described below.

2.1 Ordinary Linear Regression (OLR)

The parameters of the best fit OLR line to a data set are obtained by computing the squared error for each data pair and minimizing the sum of the squared errors. The solution for the intercept and slope are given by:

Slope = S_{xy} / S_{xx}

Intercept = $\overline{Y} - slope \cdot \overline{X}$

where:

$$S_{xy} = \sum_{i=1}^{N} \left(X_i - \overline{X}\right)\left(Y_i - \overline{Y}\right)$$

$$S_{xx} = \sum_{i=1}^{N} \left(X_i - \overline{X}\right)^2$$

$$\overline{Y} = \frac{\sum_{i=1}^{N} Y_i}{N}$$

$$\overline{X} = = \frac{\sum_{i=1}^{N} X_i}{N}$$

As noted above, while easy to implement, OLR is expected to yield slope estimates that are too low and intercepts that are too high when there is significant measurement error in x.

2.2 95% UCL on the OLR Slope

As described in (USEPA 1998), one potential method for mitigating the tendency of OLR to underestimate slope is to use the 95% Upper Confidence Limit (95% UCL) on the OLR slope rather than the best estimate. The 95% UCL on the slope is given by:

$$95\%UCL(slope) = Slope(best\ est) + t_{n-2,0.95} \cdot (MSE / S_{xx})^{0.5}$$

where:

$$MSE = \frac{\sum_{i-1}^{N} \left(y_i - a - b \cdot x_i\right)^2}{N-2}$$

The intercept is then computed as follows:

$$Intercept = \overline{Y} - slope \cdot \overline{X}$$

2.3 Chi-Square Merit Function

The most rigorous method for dealing with data sets that may be either heteroscedastic and/or have measurement error in x is the Chi-Square Merit Function (Press *et al.* 1992):

$$C_i^2 = \frac{(y_i - a - b \cdot x_i)^2}{s_{yi}^2 + b^2 \cdot s_{xi}^2}$$

This approach weights the squared error for each data pair (i) in inverse proportion to the magnitude of the errors in both x(i) and y(i). The parameters of the regression line (slope, intercept) are found by minimizing the sum of the C_i^2 terms.

The difficulty in implementing this method is the requirement for the $s^2(x_i)$ and $s^2(y_i)$ terms. Ideally, these would be derived by multiple measures of x(i) and y(i) in each sample "i". For example, this would involve collecting multiple rounds of indoor dust and outdoor soil samples at each of the study properties. However, such replicate measures are rarely performed at a property, and no data of this type are available for the three data sets of interest from the OLS site. Therefore, to implement the Chi-Square Merit Function approach, it is necessary to estimate the values of $s^2(x_i)$ and $s^2(y_i)$, as follows.

For all three data sets, the error in x was modeled as:

$$s_{x(i)} = MAX\left[s_x \min,\ k1 + k2 \cdot x(i)\right]$$

Note that, in this error model, the value of $s_{x(i)}$ can not be smaller than $s_x$min. This is important because true values of $s_{x(i)}$ are unlikely to approach zero as the value of x approaches zero, and because the merit function would assign unreasonably high weights to data pairs with small x if $s_{x(i)}$ were allowed to approach zero.

For the first two data sets (XRF vs ICP and Bulk vs Fine), the errors in x are simply the measurement errors of lead in soil when measured by XRF. The values of k1 and k2 were estimated from a data set of triplicate XRF measures of 6128 soil samples from a different site (Madison County Mines Site in Missouri). For each sample, the standard error of the mean of the three replicates is given by:

SEM(i) = Stdev(i) / sqrt(3)

A plot of SEM(i) vs Mean(i) is shown in Figure F-1. As seen, the data are clearly heteroscedastic (i.e., the error in x increases as a function of x), and the relationship is well characterized by a straight line with parameters:

k1 = 2.7
k2 = 0.0063

Based on this, the value of $s_x$min is also set to 2.7.

For the third data set (Dust vs Soil), the errors in x arise both from measurement error and also from sampling error. The values of k1 and k2 were estimated from the OLS data set as follows. For each property that had four or more 5-point composite soil samples available, the mean and standard deviation were computed from the composite values. The standard deviation of the 5-point composites was adjusted by multiplying by the square root of 5/20 = 0.5 to account for the fact that the error being modeled is based on a 20-point composite rather than on 5-point composites. A plot of this estimated sampling/measurement error in the 20-point composite as a function of the mean soil level is shown in Figure F-2. As seen, there is a clear tendency towards heteroscedasticity, with a slope of about 0.28. However, the intercept based on the data is negative (an impossibility), so the intercept term was set to a value of 5 mg/kg. This is approximately the SEM that would be expected for a composite of 20 samples drawn from a lognormal distribution with a GSD of about 2. Based on this intercept, the slope is 0.22.

In all three cases, the error in y was modeled as follows:

$$s_{y(i)} = MAX[s_y \text{min}, k3 + k4 \cdot y(i)]$$

As above, the error in y is limited by the value $s_y$min to avoid unreasonable values of $s_{y(i)}$ and to prevent inappropriate weights for low values of y.

The parameters k3 and k4 were estimated by dividing the data into a series of bins based on the value of x, with approximately 10 data pairs in each bin. For each bin, the standard deviation of the y values was computed and plotted as a function of the mean value of y for the bin.

These data points were then fit to a linear model to estimate the values of k3 and k4.

stdev y = k3 + k4· $\bar{y}$

The value of $s_y$min is set to 5 for XRF-ICP, 1 for Bulk-Fine, and 5 for Soil-Dust.

2.4 Geometric Mean Functional Relationship (GMFR)

Draper and Smith (1998) discuss the problem of fitting linear regression lines in the face of measurement error, and recommend an approach referred to as the geometric mean functional relationship. In this approach, the slope of the line is computed as:

Slope = sqrt(S_{yy}/S_{xx})

where:

$$S_{yy} = \sum_{i=1}^{N} \left(Y_i - \overline{Y}\right)^2$$

$$S_{xx} = \sum_{i=1}^{N} \left(X_i - \overline{X}\right)^2$$

Values of S_{xx} and S_{yy} are derived from the data. Note that this approach assumes homoscedasticity in both x and y.

2.5 Three-Group Approach

Draper and Smith (1998) also describe a simple alternative approximation method for estimation of the slope, as follows:

1. Divide the data into three groups of approximately equal number of samples, based on the values of x (low, medium, high).
2. Compute the center of mass (defined as $\overline{Y_i}, \overline{X_i}$) for both the first group) (i = 1) and the third group (i = 3).
3. Compute the slope of the line by drawing a line through these two centers of mass:
   $$slope = \left(\overline{Y}_3 - \overline{Y}_1\right) / \left(\overline{X}_3 - \overline{X}_1\right)$$
4. Calculate the intercept by requiring the line to pass through the overall center of mass $\left(\overline{Y}, \overline{X}\right)$:
   $$Intercept = \overline{Y} - Slope \cdot \overline{X}$$

2.6 One-Group Approach (zero intercept)

This approach is suggested by EPA Region 8 (USEPA 1995). This approach assumes the intercept is zero, and defines the slope as the line that passes through the overall center of mass:

$$slope = \frac{\overline{Y}}{\overline{X}}$$

2.7 One-Group Approach (non-zero intercept)

This approach, also identified as an alternative by Region 8 (USEPA 1995), first estimates the intercept by finding the average value of y for the first 10% of the x values:

$$Intercept = \frac{10}{N}\sum_{i=1}^{N/10} y_i$$

The slope is the found by requiring the line to pass through the overall center of mass $\left(\overline{Y}, \overline{X}\right)$:

$$Slope = \frac{\overline{Y} - Intercept}{\overline{X}}$$

3.0 EVALUATION OF METHOD PERFORMANCE

In order to evaluate which of these methods was most appropriate for evaluating the three data sets from the OLS, Monte Carlo simulations were performed as follows.

1. For each data set, define a set of assumed "true" values for N (number of data pairs), slope, intercept, and error terms in x and y that are selected to be similar to the actual site data set.
2. Draw a random data set of size N, and compute the slope using each of the 7 methods above. Divide the estimated slope by the "true" slope to obtain the "slope ratio" for that simulated data set.
3. Repeat step 2 many times, and plot the distribution of slope ratios for each of the methods.

The preferred method is the method that yields a distribution of slope ratios most nearly centered on 1.0, and that has the narrowest distribution.

3.1 Monte Carlo Simulation of ICP vs XRF Data Sets

For the ICP vs XRF data set, the Monte Carlo simulation was based on the following model of "truth":

$Csoil_{true} \sim LN(\mu, s)$
$IPC_{true} = Csoil_{true}$
$ICP_{true} = a + b \cdot XRF_{true}$
$XRF_{true} = (ICP_{true} - a) / b$
$XRF_{obs} \sim XRF_{true} + N(0, s_x)$
$ICP_{obs} = ICP_{true} + N(0, s_y)$
$s_x = k1 + k2 \cdot x_{true}$
$s_y = k3 + k4 \cdot y_{true}$

Values for use in the Monte Carlo simulation were selected to be similar to the authentic site data set as follows:

Parameters	Values	Basis
N	9072	Number of paired XRF vs ICP data set for lead in soil at the OLS
a, b	0, 1.47	OLR parameters of the XRF vs ICP data set at the OLS
μ,s	5.3, 1.29	Log-probability regression coefficients of the lead in soil data set for ICP samples with matching XRF values.
k1, k2	2.7, 0.0063	Parameter estimates for the Standard Error of the Mean (SEM) of lead measured by XRF, based on triplicate XRF analyses of soil at the Madison County Mines Site (see Figure F-1).
k3, k4	0, 0.1	Parameter estimates for the Standard Deviation of lead measured by ICP, based on Matrix Spike/Matrix Spike Duplicate (MS/MSD) analysis of lead in soil at the Omaha Lead Site (see Figure F-3).

3.2 Monte Carlo Simulation of Fine vs Bulk Data Sets

For the Fine vs Bulk data set, the Monte Carlo simulation was based on the following model of "truth":

$Csoil_{true} \sim LN(\mu, s)$
$Bulk_{true} = Csoil_{true}$
$Fine_{true} = a + b \cdot Bulk_{true}$
$Bulk_{obs} \sim Bulk_{true} + N(0, s_x)$
$Fine_{obs} = Fine_{true} + N(0, s_y)$
$s_x = k1 + k2 \cdot x_{true}$
$s_y = k3 + k4 \cdot y_{true}$

Values were selected to be generally similar to the authentic site data as follows:

Parameters	Values	Basis
N	380	Number of paired Bulk vs Fine data set for lead in soil at the OLS.
a, b	0, 1.08	OLR parameters of the Bulk vs Fine data set at the OLS.
μ,s	5.3, 0.96	Log-probability regression coefficients of the lead in soil data set measured by XRF for bulk samples with matching fine values.
k1, k2	2.7, 0.0063	Parameter estimates for the Standard Error of the Mean (SEM) of lead measured by XRF, based on triplicate XRF analyses of soil at the Madison County Mines Site (see Figure F-1).
k3, k4	2.7, 0.0063	Parameter estimates for the Standard Error of the Mean (SEM) of lead measured by XRF, based on triplicate XRF analyses of soil at the Madison County Mines Site (see Figure F-1).

3.3 Monte Carlo Simulation of Dust vs Soil Data Sets

For the Indoor Dust vs Outdoor Soil data set, the Monte Carlo simulation was based on the following model of "truth":

$Csoil_{true} \sim UNIFORM(min, max)$
$Cdust_{true} = a + b \cdot Csoil_{true}$
$a \sim LN(\mu, s)$
$b \sim BETA(p1, p2)$
$Csoil_{obs} \sim Csoil_{true} + N(0, s_x)$
$Cdust_{obs} = Cdust_{true} + N(0, s_y)$
$s_x = k1 + k2 \cdot x_{true}$
$s_y = k3 + k4 \cdot y_{true}$

Values were selected to be generally similar to the authentic site data as follows:

Parameters	Values	Basis
N	98	Number of paired Soil vs Dust data set for lead in soil at the OLS
min, max	50, 2000	Minimum and maximum XRF concentration of lead in soil in the soil-dust data set at the OLS
μ,s	4.62, 0.57	Lognormal distribution parameters for the intercept parameter (a) at the soil-indoor dust relationship at the OLS. Values are based on professional judgment and correspond to linear space values of 120 and 75.
p1, p2	4, 3	Beta distribution parameters for the b parameter in the soil-indoor dust relationship at the OLS. Values are based on professional judgment and yield a distribution with mean = 0.57 and 90% of values between 0.27 and 0.85.

k1, k2	5, 0.22	Parameter estimates for the Standard Error of the Mean (SEM) of lead in soil. Estimated from OLS soil dataset from the yard-wide average concentration of lead in soil vs the SEM of lead in soil (see Figure F-2).
k3, k4	5, 0.36	Parameter estimates for the SEM lead in indoor dust. Estimated from OLS indoor dust dataset (see Figure F-4)

4.0 RESULTS

4.1 Preferred Method and Parameter Estimates for ICP vs XRF Data Set

Figure F-5 plots the distribution of slope ratios for each of the seven alternative statistical methods applied to data sets that are similar to the site-specific ICP vs XRF data set. As seen, Method 6 (one group, zero intercept) yields the best results, although Method 5 (Three Group) is also reasonable.

Based on this, the authentic ICP vs XRF data from the OLS site were fit using Method 6. The results are shown in Figure F-6. Based on the best fit, data points whose studentized residual was larger than 3 or less than -3 were identified as potential outliers (Canavos 1984), and the analysis was repeated after exclusion of these data pairs. The resulting equation after exclusion of outliers is:

ICP-Equivalent = 1.46·XRF

This process was then repeated for a sub-set of the data where the concentration of lead in soil as measured by ICP was = 1000 mg/kg). This evaluation was performed because this is the range of soil lead concentrations of primary concern for decision-making at the site. That is, soil concentrations > 1000 mg/kg (whether by XRF or ICP) are above a level of concern for residential exposures and will be remediated. Thus, it is most important to accurately characterize the correlation in the range of 0-1000 mg/kg. These results are shown in Figure F-7.

As seen, after exclusion of outliers, the best fit equation is:

ICP-Equivalent = 1.16·XRF

This equation is selected for use in this risk assessment.

4.2 Preferred Method and Parameter Estimates for Bulk vs. Fine Data Set

Figure F-8 (Panel A) plots the distribution of slope ratios for each of the seven alternative statistical methods applied to data sets that are similar to the site-specific Bulk vs. Fine data set. An expanded view is provided in Panel B. As seen, Method 6 (one group, zero intercept) yields the best results, although Method 5 (Three Group) is also reasonable.

Based on this, the authentic Bulk vs. Fine data from the OLS site were fit using Method 6. The results are shown in Figure F-9. Based on the best fit, data points whose studentized residual was larger than 3 or less than -3 were identified as potential outliers (Canavos 1984), and the analysis was repeated after exclusion of these data pairs. The resulting equation after exclusion of outliers is:

Fine = 1.04·Bulk

4.3 Preferred Method and Parameter Estimates for Soil vs. Dust Data Set

Figure F-10 plots the distribution of slope ratios for each of the seven alternative statistical methods applied to data sets that are similar to the site-specific Dust vs. Soil data set. As seen, none of the methods yield totally un-biased results, but the best result is achieved using Method 2 (95% UCL of the OLR slope).

Figure F-10 plots the distribution of slope ratios for each of the seven alternative statistical methods applied to data sets that are similar to the site-specific Dust vs. Soil data set. As seen, none of the methods yield totally un-biased results, but the best result is achieved using Method 2 (95% UCL of the OLR slope).

Based on this, the authentic soil vs. dust data from the OLS site (N = 98) were fit using OLR and Method 2 (95% UCL on the OLR slope). The results are as follows:

All Data (N=98)

Best Estimate:	Dust = 121 + 0.65·Soil
95% UCL on Slope:	Dust = 34 + 0.86·Soil

Based on the 95% UCL equation, three data points whose studentized residual was larger than 3 or less than -3 were identified as potential outliers (Canavos 1984), and the analysis was repeated after exclusion of these three data pairs. The resulting equations (best estimate and 95% UCL) after exclusion of the outliers is:

Outliers Excluded (N = 95)

Best Estimate:	Dust = 42 + 0.74·Soil
95% UCL on Slope:	Dust = -8 + 0.87·Soil

In concept, the final equation (95% UCL after exclusion of outliers) would be selected as the preferred model. However, this fit is problematic because the true intercept can not be less than zero, and a value somewhat above zero is expected because it is considered likely that there are one or more non-soil sources of lead in indoor dust at many homes. Based on this, it appears that

this method is over-correcting for measurement error, and hence the equation adjusted by the 95% UCL method was judged to be inappropriate for use.

Consequently, each of the other alternative strategies for correcting the data for measurement error were investigated, with the results shown below:

Method	Slope	Intercept
Chi Square Merit Function	1.04	-200
GMFR	1.07	-83
Three-Group	0.52	126
One-group (zero intercept)	0.85	0
One-group (non-zero intercept)	0.68	65

As seen, the results vary substantially between different methods used to adjust for measurement error. Based on this strong dependence of the model coefficients on the statistical method used, it is concluded that attempts to adjust this particular data set for measurement error are likely either tending to either over-correct or under-correct, and that the most reasonable estimate of the relationship is based on OLR (unadjusted):

$$\text{Dust} = 42 + 0.74 \cdot \text{Soil} \quad (R^2 = 0.48)$$

These coefficients are in the central portion of the range of values generated by the various statistical methods, and therefore are considered to be reasonable estimates. In this regard, it should be noted that these values are not too far removed from the values derived using OLR in the interim risk assessment (NHHSS 1994):

Parameter	NHHSS 2004	This Study
N	159	95
Slope	0.79	0.74
Intercept	139	42
R^2	0.19	0.48

This leads to greater confidence in the use of this model, although it is still considered possible that the slope is too low and the intercept is too high as a consequence of measurement error in the soil values.

[1] Soil concentrations adjusted to represent the concentration of lead in the fine fraction, analyzed by ICP (see Section 4.4.1).

[2] Estimated concentration of lead in indoor dust (see Section 4.4.1)

Area Type = Yard soil (Quadrant 1, Quadrant 2, Quadrant 3, and/or Quadrant 4), Play Area Soil, and/or Garden Soil.
