Energy*Solutions* is authorized to dispose of waste containing both friable and non-friable asbestos. The asbestos waste must be described in the Radioactive Waste Profile Record and packaged, marked, and labeled in accordance with applicable federal regulations. Friable asbestos must not be packaged in bulk containers unless approved in writing by Energy*Solutions*.

Asbestos waste that requires wetting to prevent dispersion must be inspected to minimize free liquids. However, unless the waste is to be solidified at the Treatment Facility, the free liquid may not exceed one percent of the waste volume. Absorbent material must be added to containers when free liquids are present. Waste streams containing greater than one percent free liquid by waste volume may be shipped to Energy*Solutions*' Treatment Facility for solidification prior to disposal. Contact Energy*Solutions* prior to shipping waste streams that contain free liquids.

Waste containing other potential inhalation hazards such as beryllium must be described in the Waste Profile and documented on the 5 Working-Day Advanced Shipment Notification form. A quantitative description of potential beryllium surface contamination and air monitoring measurements both before and after any fixatives or wrapping are applied should be included in the Waste Profile for beryllium contaminated waste. The description should also include information about the current management of the beryllium contaminated waste including specific work control procedures in handling and packaging the waste for shipment, details of the beryllium protection program as applicable, and air monitoring measurements, etc. Beryllium contaminated waste must be packaged in 55-gallon or smaller drums unless approved in writing by Energy*Solutions*.

3.1.10 Lab Packs

Lab packs are described as small containers of liquid with varying hazardous waste codes that are placed in a larger shipping or storage container. Energy*Solutions* is authorized to receive lab packs in which all of the contents are known and acceptable for treatment or disposal. Lab packs require a specific Waste Profile that must be approved by Energy*Solutions* prior to shipment. Generators must provide a description of unused chemicals within containers with the shipping paperwork.

3.2 ACCEPTABLE FORMS OF RADIOACTIVE WASTE

Energy*Solutions*' Radioactive Material License authorizes the receipt of radioactive waste in the form of liquids and solids. Solid radioactive waste must contain less than one percent free liquid by waste volume. Generators shipping solid waste must minimize free liquid to the maximum extent practicable. Conversely, liquid radioactive wastes contain greater than one percent free liquid by waste volume (e.g., sludge, wastewater, evaporator bottoms, etc.). Energy*Solutions* will determine if a waste contains free liquids by either visual inspection or by performing the Paint Filter Liquid Test (EPA SW-846 Method 9095). Liquid radioactive waste is solidified at Energy*Solutions*' Treatment Facility prior to disposal.

Solid waste includes, but is not limited to, the following forms of waste: soil, sludge, dry active waste, metal, concrete, wood, glass, resin, etc. For simplicity, these waste forms are categorized into either soil or debris waste streams due to the placement criteria specified in the license.

3.2.1 Soil or Soil-Like Wastes

Energy*Solutions* constructs the disposal embankment by achieving specified compaction criteria and minimizing void spaces in the disposal lift. Construction of the disposal embankment in this manner ensures long-term integrity of the disposal facility. Soil and soil-like waste material are placed in the disposal embankment and compacted in 12-inch soil lifts. The license requires these soil lifts to be compacted to greater than 90 percent of optimum density and at a moisture content not to exceed three percentage points above optimum moisture as determined by the Standard Proctor Method (ASTM D-698). Consequently, soil or soil-like waste must have soil-like properties and conform to the following specifications. Otherwise, the waste material will be considered debris and managed for disposal as described in Section 3.2.2.

Soil/Soil-Like Properties

- Greater than 70 percent by weight compactable material less than 3/4" particle size and 100 percent compactable material less than 4" particle size
- Maximum dry density greater than 70 pounds per cubic foot (dry weight basis)
- Moisture content of the soil or soil-like waste must not exceed three percentage points above optimum moisture upon receipt at Energy*Solutions*
- Maximum dry density and optimum moisture must be determined by Standard Proctor Method ASTM D-698

Energy*Solutions* may request a preshipment sample to perform an independent compaction test using Standard Proctor Method ASTM D-698. Generators must include their compaction test results as part of the waste profile submittal.

Shipments of soil or soil-like waste streams may contain some standard size debris in waste packages. The percentage of allowable debris in the waste stream must be listed in the waste profile. Soil or soil-like waste streams with moisture content exceeding three percentage points above optimum moisture are acceptable by Energy*Solutions* and require additional handling prior to disposal. Contact Energy*Solutions*' Customer Service representatives prior to shipping soil or soil-like waste streams with elevated moisture content.

3.2.2 Debris

Waste material not meeting the specified soil or soil-like properties is considered debris by Energy*Solutions*. Debris includes both decommissioning and routinely generated operational waste including, but not limited to, radiologically contaminated paper, piping, rocks, glass, metal, concrete, wood, bricks, resins, sludge, tailings, slag, residues, and personal protective equipment (PPE) that conforms to the debris size requirements.

3.2.2.1 Standard Size Debris

Debris is defined into two broad categories based on size. The first category is standard debris and includes materials that are less than 10 inches in at least one dimension and no longer than 12 feet in any dimension. Debris that does not meet this size criterion is categorized as oversize debris.

Standard size debris is uniformly distributed throughout the 12-inch soil lifts. Energy*Solutions* adds either native clay or radioactive soil to the debris. Each soil lift is limited to the amount of debris that may be placed with soil to achieve the required compaction criteria. Depending upon the conditions of the disposal agreement, some generators that have both soil and debris may be able to achieve cost savings by delivering these materials together such that the shipping package contains enough soil to mix with the debris to achieve compaction requirements. All debris must be placed in such a way to minimize void space in the soil lift.

3.2.2.2 Oversize Debris and Large Components

Waste material is considered oversize debris if the debris has at one dimension greater than 12 feet or does not have one dimension less than 10 inches. Since oversize debris cannot be compacted directly into the soil lifts, this material is placed in different areas of the disposal embankment where void spaces are minimized to the maximum extent practicable both in and around the debris.

Bulk oversize debris, such as a large component, is also disposed of using this alternative disposal process. Energy*Solutions* has received and disposed of several large components over 250 tons including steam generators, reactor heads, turbine components, and other large equipment as illustrated in Figure 3-2. Generators should identify these types of materials as part of the waste profiling process. This will allow Energy*Solutions* to evaluate the off-loading and placement of the large component prior to shipment.

Generally, single items over 20,000 pounds are considered large components and require special handling and engineering reviews prior to placement. The type of information required for large components includes drawings, photographs, weight, dimensions, description of enclosed voids, packaging configuration, rigging and loading plan, identification of lifting points, transportation mode, and radiological characterization and survey documentation. Void spaces within large components must be made accessible via a minimum of two access ports to allow grout in-fill during disposal operations at the Clive disposal facility. Access ports must be at least four inches in diameter unless approved in writing by Energy*Solutions*. Containers of oversize debris must exclude soil or soil-like waste due to placement criteria.

Energy*Solutions* may also elect to dispose of dispersible waste forms (e.g., filtercake, dusty material, etc.) or waste with elevated dose rates by not emptying the waste from the container. Although ion-exchange media (resin) meets the standard size debris criteria, resins are not emptied from the container but grouted to minimize void spaces. Consequently, resin waste streams must be shipped under a resin specific waste profile unless approved in writing by Energy*Solutions*. Void spaces in and around the containers are minimized to the maximum extent practicable.

Figure 3-2. Large Component Disposal

3.2.3 Gaseous Waste

Energy*Solutions* is authorized to receive gaseous waste in accordance with Utah Administrative Code R313-15-1008(2)(a)(viii). Gaseous waste must be packaged at an absolute pressure that does not exceed 1.5 atmospheres at a temperature of 20 degrees Celsius and the total activity of any container shall not exceed 100 Curies. This information must be identified in the Radioactive Waste Profile Record.

3.2.4 Waste Containing Free Liquids

Wastes containing free liquids greater than one percent by volume are considered liquid waste streams. Generators may use visual inspection of the waste or the Paint Filter Liquids Test to determine if the waste contains free liquids. The Radioactive Waste Profile Record must describe the physical, chemical, and radiological characteristics of the liquid waste. Energy*Solutions* received approval from the Utah DRC to receive radioactive liquid wastes that are aqueous based. Non-aqueous radioactive liquids require case-by-case approval from the Utah DRC.

Energy*Solutions* will perform a solidification study on a sample of the liquid waste prior to authorizing shipments. Liquid waste must be solidified and disposed at the Mixed Waste Facility. Energy*Solutions* has permitted liquid storage tanks to accommodate liquids delivered in tankers and other DOT approved bulk containers.

For generators with waste streams that may contain free liquids, the process by which the liquid will be minimized to less than one percent of the waste volume must be documented in the Radioactive Waste Profile Record. Approval of these waste streams would be considered authorized free liquids.

The presence of unauthorized free liquid within a package or shipment is a significant cause of non-compliance. Each incoming shipment will be tested for free liquids in accordance with Energy*Solutions*' Waste Characterization Plan using visual inspection of the waste or the Paint Filter Liquids Test.

If a solid waste shipment is found to contain unauthorized free liquids greater than one percent of the waste volume in any manifested container, Energy*Solutions* is required to promptly notify the generator and the Utah DRC. Energy*Solutions* may stop shipments of waste material until the cause of the problem is identified and corrected. The Waste Characterization Plan requires that the generator submit a quality control program that identifies the root cause of the problem and outlines corrective actions that will be taken to correct the problem and the quality control measures that will be implemented to prevent recurrence. Until this corrective action plan has been submitted, reviewed, and approved by Energy*Solutions*' Quality Assurance Manager, no further shipments may be permitted from the waste generator's site.

In order to control free liquid within the waste material, the use of absorbent materials is strongly recommended. Sufficient absorbent material to absorb twice the volume of the potential liquid should be used. Experience has shown that some soil matrices actually 'bleed' moisture out during transport due to vibration. If testing indicates that the waste material, as shipped, could exceed the optimum moisture content (as determined by the Standard Proctor Test) and that a risk of waste form separation exists while the shipment is en route, the precautionary addition of absorbents prior to shipment is strongly advised. To ensure that adequate absorbents are added, generators should also consider testing the moisture content of each shipment.

Although uncommon, in some cases it is possible for precipitation to enter the package resulting in free liquids. Detailed inspections should be completed before waste is placed in transit to ensure the package meets strong-tight criteria and that water cannot enter. Energy*Solutions* does not maintain a list of approved absorbents or manufacturers. If absorbents are added to the waste, the specific absorbent must be identified in the Radioactive Waste Profile Record (Section B.5).

3.3 PROHIBITED RADIOACTIVE AND MIXED WASTE

Condition 16 of the Radioactive Material License prohibits receipt of the following wastes:

- Sealed sources defined in UAC R313-12 as "radioactive material that is permanently bonded or fixed in a capsule or matrix designed to prevent release and dispersal of the radioactive material under the most severe conditions which are likely to be encountered in normal use and handling" (e.g., instrument calibration check sources, smoke detectors, nuclear density gauges, etc.).
- Radioactive waste which is classified as Class B, Class C, or Greater Than Class C waste.
- Solid waste containing unauthorized free liquids.
- Waste material that is readily capable of detonation, of explosive decomposition, reactive at normal pressure and temperature, or reactive with water or air.
- Waste materials that contain or are capable of generating quantities of toxic gases, vapors, or fumes harmful to persons transporting, handling, or disposing of the waste.
- Waste materials that are pyrophoric. Pyrophoric materials contained in wastes must be treated, prepared, and packaged to be nonflammable.
- Waste materials containing untreated biological, pathogenic, or infectious material including contaminated laboratory research animals. Generators desiring to ship this type of waste must document in the Radioactive Waste Profile Record the process used to treat the potential non-radiological hazard. Sharps including needles, scalpels, knives, syringes, pipettes, and similar items having a point or sharp edge or that are likely to break during transportation must not be packaged in bulk containers unless written approval is given by Energy*Solutions*. When these items are used in the medical industry or related research, they must be treated to remove the biohazard. Documentation of such treatment must be included in the Waste Profile.

The following Mixed Wastes are not acceptable for treatment or disposal at the Mixed Waste facility:

- Hazardous waste that is not also a radioactive waste
- Wastes that react violently or form explosive reactions with air or water
- Pyrophoric wastes and materials
- DOT Forbidden, Class 1.1, Class 1.2 and Class 1.3 explosives
- Shock sensitive wastes and materials
- Compressed gas cylinders, unless they meet the definition of empty containers
- Utah waste codes F999 and P999

SECTION 4

WASTE ACCEPTANCE PROCESS

4.1 WASTE PROFILING PROCESS

This section details Energy*Solutions*' waste characterization and profiling process. Profiling a waste stream involves collecting samples and obtaining analytical results for the parameters specified on Energy*Solutions*' Radioactive Waste Profile Record (Waste Profile). The Waste Profile serves the following functions: (1) enables Energy*Solutions* to evaluate wastes for acceptance, (2) maintains an operating record for the material during acceptance, storage, treatment, if applicable, and disposal of waste shipments, (3) provides a historical record of the waste project for each waste stream, and (4) ensures compliance with Energy*Solutions*' licenses and permits. The Waste Profile and related instructions can be downloaded from Energy*Solutions*' web site at www.energysolutions.com. An Energy*Solutions* Technical Services Representative is also available to assist in the waste profiling process.

The waste profiling process consists of the following steps as illustrated in Figure 4-1:

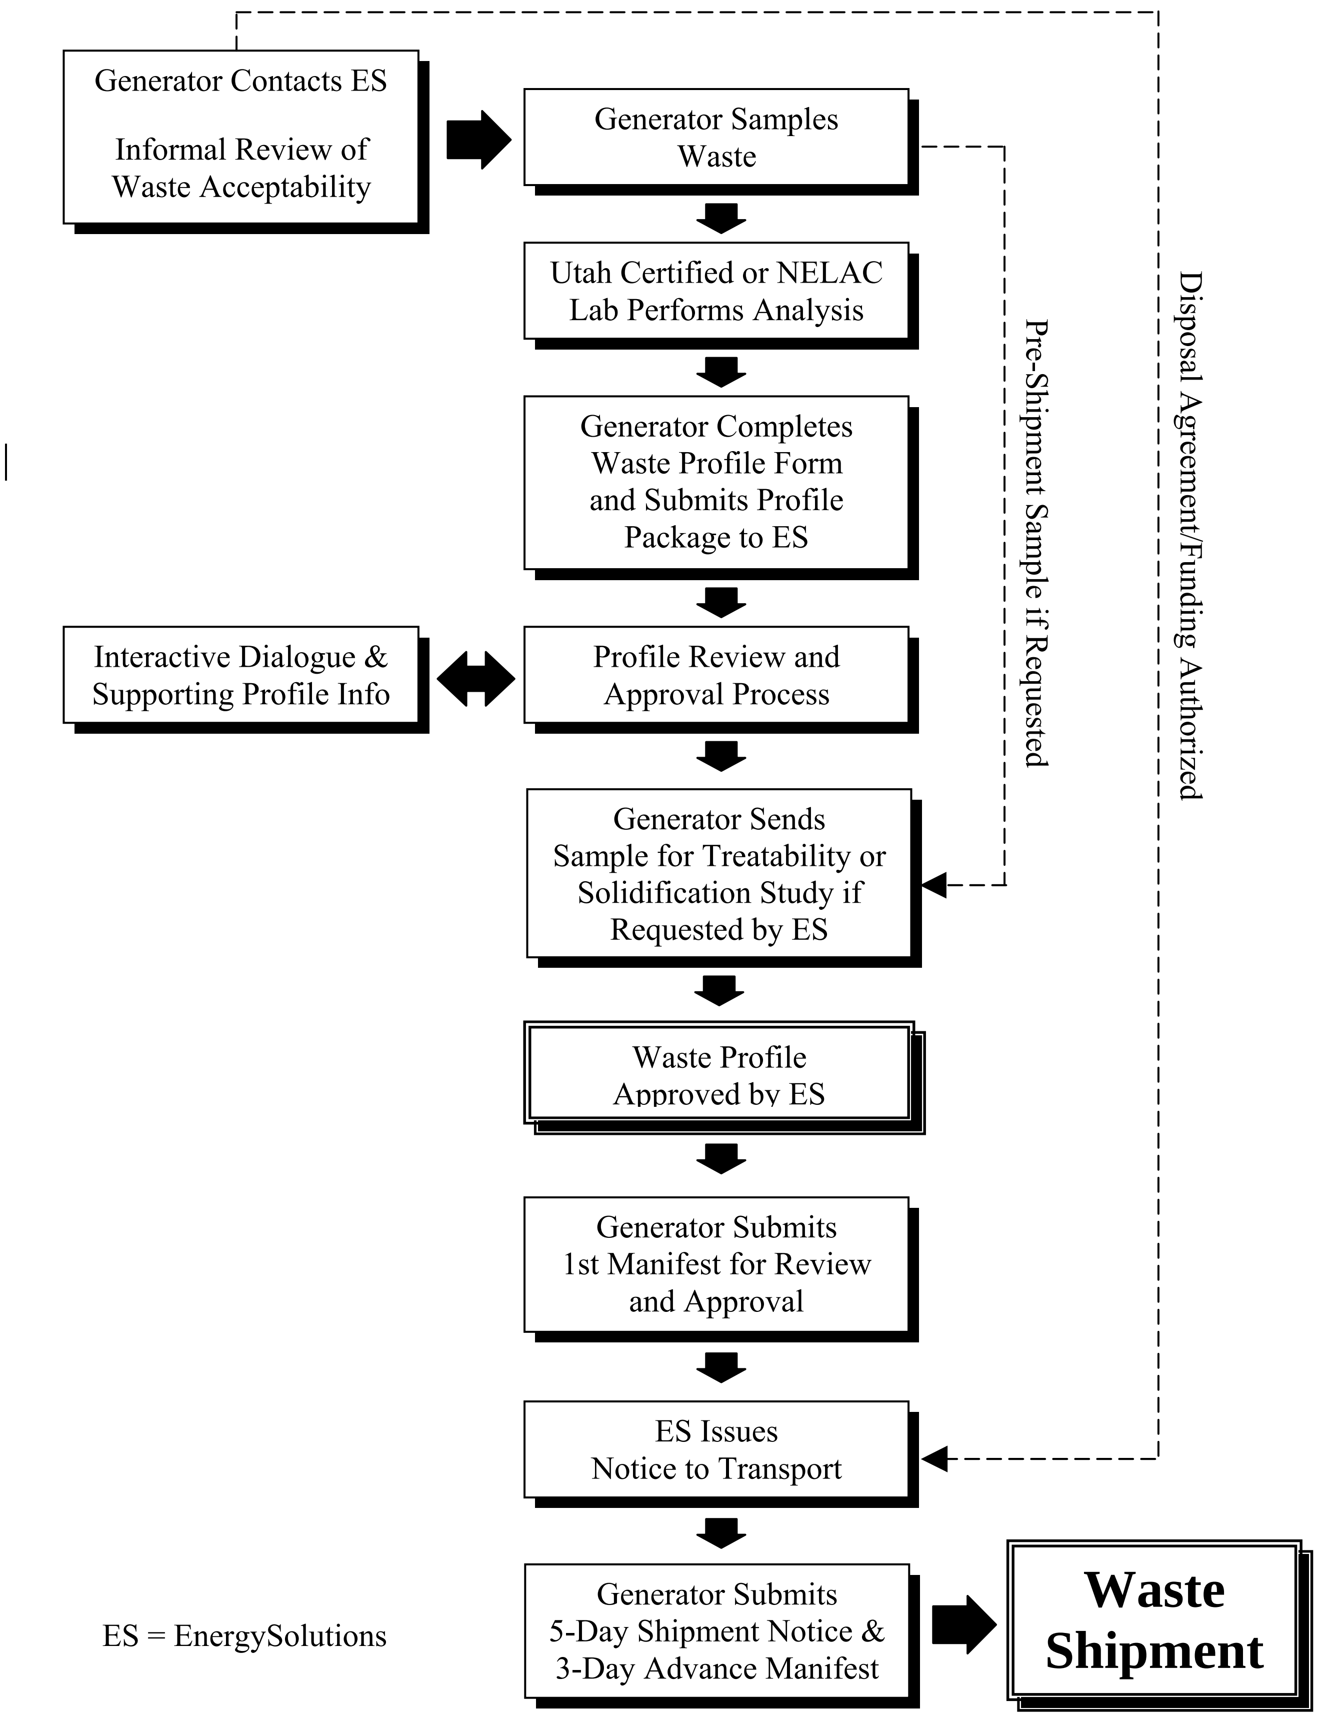
- Initial discussions
- Waste characterization
- Waste Profile Record completion and submittal
- Treatability and/or solidification study sample submitted, if requested
- Profile review and approval
- Notice to Transport

Initial discussions of the waste stream are critical in ensuring that the waste profiling process is accurate and efficient. Technical Services representatives are a resource to the generator in completing this process.

4.2 WASTE CHARACTERIZATION

Early in the process, the generator samples the waste stream where applicable and begins to accumulate the analytical data required in the waste profile record described below. It is critical that chemical analyses are performed by laboratories certified by either the State of Utah or the National Environmental Laboratory Accreditation Conference (NELAC). Generators may contact the Utah Department of Health at (801) 584-8501 or visit their website at http://health.utah.gov to obtain information on the Utah Laboratory certification requirements. Laboratories certified by NELAC are listed on the US EPA's website at www.epa.gov/nerlesd1/land-sci/nelac/accreditlabs.html. Technical Services representatives can also provide current laboratory certification information. Once the analytical support data is available, the generator completes the Waste Profile record as described in the following section.

Figure 4-1. Waste Acceptance Process



4.3 RADIOACTIVE WASTE PROFILE RECORD

The waste profile record is a document required by Energy*Solutions*' licenses and permits. It provides information in the following areas:

- Generator and waste stream information
- Physical properties and packaging
- Radiological information
- Chemical composition and hazard evaluation

Waste generators must complete a Radioactive Waste Profile Record for every waste stream shipped to Energy*Solutions*. To complete this form, the generator should use process knowledge along with analytical laboratory results. The form contains the following sections.

- Generator and Waste Stream Information
  These sections request generator contact information and general overview of the type of waste material, physical characteristics, transportation and package modes, identification of specific radionucildes, and the average and range of radionuclide concentrations.

- Chemical and Hazardous Waste Characteristics (LLRW or MW)
  The generator selects the applicable attachment for describing the chemical properties for either LLRW or Mixed Waste. These attachments request the chemical information to evaluate the waste relative to RCRA regulations. Only one of these attachments is required to be signed and submitted to Energy*Solutions* with the Waste Profile.

- SNM Exemption Certification
  This form requests the radiological information to evaluate waste containing SNM with respect to the SNM Exemption issued by the NRC and incorporated into Energy*Solutions*' license. Condition 3 of the SNM Exemption Certification form requests specific information to be included with the narrative of the Waste Profile.

- PCB Waste Certification
  This form requests information about the type of Polychlorinated Biphenyls (PCBs) waste included with the waste stream. PCB waste streams must be profiled separately from non-PCB waste streams. Energy*Solutions* uses this form and supporting information to evaluate PCB waste streams with respect to Energy*Solutions*' permits and TSCA regulations in 40 CFR 761.

4.3.1 Generator and Waste Stream Information

This section includes contact information for generators, including addresses and responsible parties. The contact information is required for the generator's representative as well as for the individual completing the Waste Profile. The generator must answer a series of questions designed to categorize the waste material that is profiled. The generator identifies the following:

- If the waste is hazardous, and whether it has been treated or requires treatment at Energy*Solutions*
- If the waste is Low-Level Radioactive Waste and subject to LLRW Compact Export approval
- If the waste contains Special Nuclear Materials, PCBs, or asbestos

4.3.2 Waste Physical Properties and Packaging

The physical and geotechnical properties of the waste include gradation of the material, density range, a full description of the physical composition and characteristics of the waste, moisture content, optimum moisture, and maximum dry density determined by the Standard Proctor Method (for soil or soil-like materials).

The purpose of the physical and geotechnical testing requirements is to demonstrate that the material can be managed at Energy*Solutions* under existing license/permit requirements and in accordance with Energy*Solutions*' waste disposal placement methods.

The gradation of the waste may be determined through analysis or waste process knowledge. After an assessment of the entire waste stream, the generator is expected to estimate the amount of material that would pass through the various screens indicated. This information is necessary to determine the method of waste placement.

In this section, the generator addresses questions regarding free liquids. If the waste contains free liquids, the Waste Profile requires a description including the quantity and nature (aqueous or non-aqueous) of the liquid. Solid waste profiled to contain free liquids must be minimized to the maximum extent practical but in no case shall the free liquid exceed one percent of the waste volume upon arrival and inspection at the Energy*Solutions* disposal site. Waste streams containing PCBs must not contain any free liquids unless shipped for VTD treatment.

The waste description is continued by addressing several items in a narrative description and history of the waste provided by the generator as an attachment, referred to as Attachment B.5. The narrative should include the following items as applicable:

- The process that generated the waste
- Waste material physical composition and characteristics
- Radiological and chemical characterization method
- Information requested on the SNM Exemption Certification form, if applicable
- The type and description of PCB waste, if applicable
- Basis for determining manifested radionuclide concentrations
- Description and amounts of absorbents, if applicable
- Basis of non-hazardous or hazardous waste determinations
- Treatment processes, if applicable
- Product information or Material Safety Data Sheets associated with the waste as applicable
- Information requested in other sections of the Waste Profile

4.3.3 Radiological Information

All waste streams must be analyzed to determine the radionuclide concentrations in the waste. The waste must be characterized via gamma spectroscopy, liquid scintillation, or other standard radiochemistry methods to determine the radionuclide concentrations in the waste. Indirect measurements such as dose-to-curie or use of scaling factors may also be used if the process has been validated with direct measurements. Radiological analysis does not need to be performed by a Utah-Certified laboratory. Non-gamma emitting radionuclides such as Fe-55 and Ni-63, may be scaled from the gamma spectral analysis obtained from testing the material if the waste generator has specific process knowledge of the material being profiled (10 CFR Part 61 analyses).

Please note that discrepancies between radiological information, particularly concentration ranges, and waste manifest documents could delay or prevent acceptance of a shipment. The Waste Profile must always be reviewed with the waste manifest documents prior to shipping waste to Energy*Solutions*. In the event that radiological, physical, or chemical properties of a profiled waste stream have changed, an update to the Waste Profile must be submitted and approved before such waste can be shipped to Energy*Solutions*.

Energy*Solutions* requires that generators evaluate the maximum dose rates and contamination levels anticipated in each waste stream. In the radiological section of Waste Profile, the generator indicates whether or not the maximum dose rate on accessible surfaces exceeds the ALARA Criteria as described in Section 2.3.1.

While Energy*Solutions* is permitted to receive Class A LLRW, certain radionuclides are subject to additional controls established by the Utah DRC. For example, Radium-226 is limited to 10,000 pCi/g. In addition, the Utah DRC regulates the following radionuclides under Condition 29E of Energy*Solutions*' Radioactive Materials License:

- Aluminum-26
- Berkelium-247
- Calcium-41
- Californium-250
- Chlorine-36
- Rhenium-187
- Terbium-157
- Terbium-158

Energy*Solutions* is required to provide a one-time notice for each generator shipping one of these radionuclides to the Class A disposal embankment. For waste shipped for disposal at the Mixed Waste disposal embankment, Energy*Solutions* must provide a one-time notification for each generator shipping waste containing Chlorine-36 and Berkelium-247. The generator includes the anticipated presence of these nuclides in the radiological information provided in the Waste Profile.

Finally, the generator lists the radionuclides present in the waste stream in conjunction with the expected maximum manifested concentration and the weighted average concentrations expected for each radionuclide. The generator is expected to manifest values for each shipment that are within the maximum values stated in this section of the Waste Profile. In the event that a generator needs to ship waste to Energy*Solutions* that exceeds the limits in the radiological information section of the Waste Profile, the generator may submit a revised Waste Profile to Energy*Solutions* for review and approval.

Any additional information including laboratory results for gamma spectroscopy or radiochemistry analysis must be attached to the Waste Profile. Radiological characterization methods and the basis for determining manifested radionuclide concentrations should be included in Attachment B.5 as described above.

4.3.4 Chemical Composition and Hazardous Waste Evaluation

In accordance with the response to the hazardous waste question posed in the generator and waste stream information section, the generator provides one of two attachments with the Waste Profile addressing the chemical composition of the waste.

For hazardous wastes, the generator provides a completed and signed copy of the Hazardous Waste Analysis Certification Attachment. The chemical and hazardous characteristics of the waste stream must be provided in extensive detail. The purposes of chemical testing are to (1) demonstrate that the waste meets specific waste acceptance chemical requirements; and (2) demonstrate that the waste is either non-hazardous, compliant with RCRA treatment standards, or will require treatment prior to disposal. In addition, analysis is required to qualify wastes that may contain other specific regulated constituents.

Energy*Solutions*' licenses and permits require the results of the following minimum analyses be provided with the Waste Profile:

Analysis	EPA SW-846 Method(s)
pH (liquids only)	Method 9045
PFLT (solid waste only)	Method 9095
Organics (Totals)	Method 8260 & 8270
Results from applicable concentration based treatment standards	

The results of these analyses are documented on the Hazardous Waste Analysis Certification Attachment and attached to the Waste Profile.

The Hazardous Waste Analysis Certification Attachment also includes waste codes applicable to the waste stream with corresponding treatment standards or technology codes and worst case concentrations. This information is critical in evaluating wastes for treatment at Energy*Solutions*.

Applicable Underlying Hazardous Constituents (as defined in 40 CFR 268.48) and other chemicals present are identified at the end of the attachment.

For non-hazardous waste streams, the generator provides a signed copy of the Low-Level Radioactive Waste Certification Attachment. Energy*Solutions*' licenses and permits require the results of the following analyses be provided with the Waste Profile:

Analysis	EPA SW-846 Method
pH (liquids only)	Method 9045
TCLP Metals	Method 6010/7470
TCLP Herbicides	Method 8151
TCLP Pesticides	Method 8081
TCLP Semi-volatiles	Method 8270
TCLP Volatiles	Method 8260

The individual chemical compounds required for these analyses are listed on the Low-Level Radioactive Waste Certification Attachment and correspond to the characteristic D-list constituents (D004 through D043) identified in 40 CFR 261.24 Table 1 as shown below.

40 CFR 261.24 Table 1

TABLE 1—MAXIMUM CONCENTRATION OF CONTAMINANTS FOR THE TOXICITY CHARACTERISTIC

EPA HW No.[1]	Contaminant	CAS No.[2]	Regulatory Level (mg/L)
D004	Arsenic	7440–38–2	5.0
D005	Barium	7440–39–3	100.0
D018	Benzene	71–43–2	0.5
D006	Cadmium	7440–43–9	1.0
D019	Carbon tetrachloride	56–23–5	0.5
D020	Chlordane	57–74–9	0.03
D021	Chlorobenzene	108–90–7	100.0
D022	Chloroform	67–66–3	6.0
D007	Chromium	7440–47–3	5.0
D023	o-Cresol	95–48–7	[4] 200.0
D024	m-Cresol	108–39–4	[4] 200.0
D025	p-Cresol	106–44–5	[4] 200.0
D026	Cresol	....	[4] 200.0
D016	2,4-D	94–75–7	10.0
D027	1,4-Dichlorobenzene	106–46–7	7.5
D028	1,2-Dichloroethane	107–06–2	0.5
D029	1,1-Dichloroethylene	75–35–4	0.7
D030	2,4-Dinitrotoluene	121–14–2	[3] 0.13
D012	Endrin	72–20–8	0.02
D031	Heptachlor (and its epoxide).	76–44–8	0.008
D032	Hexachlorobenzene	118–74–1	[3] 0.13
D033	Hexachlorobutadiene	87–68–3	0.5
D034	Hexachloroethane	67–72–1	3.0
D008	Lead	7439–92–1	5.0
D013	Lindane	58–89–9	0.4
D009	Mercury	7439–97–6	0.2
D014	Methoxychlor	72–43–5	10.0
D035	Methyl ethyl ketone	78–93–3	200.0
D036	Nitrobenzene	98–95–3	2.0
D037	Pentrachlorophenol	87–86–5	100.0
D038	Pyridine	110–86–1	[3] 5.0
D010	Selenium	7782–49–2	1.0
D011	Silver	7440–22–4	5.0
D039	Tetrachloroethylene	127–18–4	0.7
D015	Toxaphene	8001–35–2	0.5
D040	Trichloroethylene	79–01–6	0.5
D041	2,4,5-Trichlorophenol	95–95–4	400.0
D042	2,4,6-Trichlorophenol	88–06–2	2.0
D017	2,4,5-TP (Silvex)	93–72–1	1.0
D043	Vinyl chloride	75–01–4	0.2

[1] Hazardous waste number.
[2] Chemical abstracts service number.
[3] Quantitation limit is greater than the calculated regulatory level. The quantitation limit therefore becomes the regulatory level.
[4] If o-, m-, and p-Cresol concentrations cannot be differentiated, the total cresol (D026) concentration is used. The regulatory level of total cresol is 200 mg/l.

The attachment also includes a question as to whether or not the waste was at the point of generation of a hazardous waste, and a section to address former hazardous waste codes and additional chemical constituents.

As stated previously, the chemical analysis must be performed by a laboratory holding a NELAC or State of Utah certification. Data provided to the generator prior to any discussions of waste characterization with Energy*Solutions* may be acceptable for waste profiling purposes upon investigation of associated quality control sample data.

Energy*Solutions* may waive the chemical laboratory analyses if the material is not amenable to chemical sampling and analysis (e.g., debris items including metal pieces, concrete, plastic, etc.). Justification for waiving the chemical analyses must be provided in the narrative in Attachment B.5. Technical Service representatives can provide direction in cases where the waste meets such a description.

4.3.5 Special Nuclear Material Exemption Certification Form

Waste containing Special Nuclear Material (SNM) must comply with the SNM requirements for concentration, spatial distribution, chemical mixture, solubility and chemical composition of SNM isotopes as described in Section 3.1.5 of the BWF WAC. The SNM Exemption Certification form guides the generator through the supporting information that must accompany the Waste Profile and each shipment of waste containing SNM. In addition to answering the questions on the form, the generator includes descriptions in Attachment B.5 for the requirements listed in items 3(a) through 3(d) of the SNM form. A completed and signed copy of the SNM Exemption Certification form must accompany the shipping paperwork for waste shipments containing Special Nuclear Material.

4.3.6 PCB Waste Certification Form

Energy*Solutions*' Statue-Issued Part B Permit and Groundwater Quality Discharge Permit include the authorizations and requirements for Energy*Solutions* to receive PCB waste regulated for disposal under 40 CFR 761. The PCB waste types acceptable at Energy*Solutions* are listed in Section 3.1.6 of the BWF WAC. The generator must include a description of the type of PCB waste in the narrative of Attachment B.5. The PCB Waste Certification form does not need to accompany the waste shipment unless requested by Energy*Solutions* during the Waste Profile approval process.

4.4 TREATABILITY AND SOLIDIFICATION STUDY SAMPLES

For waste streams requiring treatment or solidification, Energy*Solutions* will request a preshipment sample to perform a treatability and/or solidification study during the waste profiling approval process. This allows Energy*Solutions* to develop the necessary treatment and solidification formula prior to receipt of the waste. Preshipment samples are not required for waste streams requiring treatment via macroencapsulation. Energy*Solutions* may request additional preshipment samples during the waste profiling process to evaluate the waste material prior to receipt.

Preshipment samples should represent the waste material destined for shipment to Energy*Solutions*. Representative sampling techniques appropriate to radiological and hazardous wastes should be employed in obtaining these samples. Treatability study samples should represent the "worst case" for a waste stream destined for treatment at Energy*Solutions*. The samples should contain the highest anticipated levels of chemical contaminants in the waste steam to ensure that Energy*Solutions* can develop a treatment formula that is adequate for the entire waste stream. Energy*Solutions* may be required to perform additional treatability studies if the waste shipments contain chemical constituents of concern at concentrations that are higher than the treatability study sample.

Preshipment samples may not be shipped to Energy*Solutions* without prior authorization. At a minimum, a preliminary Waste Profile will need to be created that describes the waste and its generation. This preliminary Waste Profile must include both chemical and radiological assessments and must be approved by Energy*Solutions* prior to shipment of the sample. When approved for shipment, Energy*Solutions* will provide a Preshipment Sample Authorization Record to the generator.

Samples should be packaged into one or more sealed containers in such a manner that the sample container will not break during normal shipping conditions. Generally, the volume of sample requested will be less than 5 gallons. Sample containers should be labeled with the waste stream number, date, and a sample ID number. Sample closure devices should also be sealed with a custody or anti-tamper seal to ensure sample integrity.

Preshipment samples sent to Energy*Solutions* must be properly classed, described, packaged, marked, labeled, and in condition for transport as required by the DOT Hazardous Materials Regulations (HMR) contained in 49 CFR Parts 171 through 180. The Preshipment Sample Authorization forms must be completed and attached to the outside of the shipping package. A Uniform LLRW Manifest (Forms 540/541) must also accompany the shipping paperwork. The manifest number for the shipping paperwork is the Waste Stream ID number (e.g., XXXX-YY). The samples must be sent to the following address:

Energy*Solutions*
Attention: Sample Control
US I-80, Exit 49
Tooele County
Clive, UT 84029 (84083 if using Fed Ex)
Phone: (435) 884-0155

Treatability studies normally require 30 to 45 days to complete. Please keep this in mind when planning the first shipment of waste. Rush treatability studies are possible; however, there are higher costs for this service. Please contact Energy*Solutions* if a rush treatability study is required to meet a disposal schedule.

4.5 WASTE PROFILE REVIEW AND APPROVAL

Energy*Solutions* will assist waste generators throughout the waste profiling process to ensure shipping and acceptance of the waste can be accomplished within the desired timeframe. In order to facilitate timely shipment and receipt of waste materials, Energy*Solutions* requests that the Waste Profile forms and analytical reports be provided as far in advance of the anticipated shipping date as possible. Upon receipt, Energy*Solutions* will complete a preliminary review of the waste profile information provided. Comments concerning the Waste Profile will usually be provided within two weeks of Energy*Solutions*' receipt of the profile information. If additional information is required for pre-acceptance, Energy*Solutions* will specify the information needed and communicate this to the generator. A comprehensive internal review is completed once all information has been submitted.

In order to assist each generator and accomplish the profile review and approval process as quickly as possible, Energy*Solutions* has developed a two-phase review process. During the first phase, an Energy*Solutions* Technical Services Representative will review and assess the Waste Profile, accompanying documentation, and analytical data for acceptability. If necessary, Energy*Solutions* will provide comments that delineate additional information needed for approval. This process typically takes one to two weeks. Once the additional information or revisions have been received by Energy*Solutions* and found to be satisfactory, phase 2 of the process begins.

The second phase involves and independent evaluation of the Waste Profile by Energy*Solutions*' Compliance and Operations representatives. Energy*Solutions* will notify the generator as soon as the review and approval process is completed.

At this point, the waste stream has been "pre-approved" for management at Energy*Solutions*, since the waste has been shown to be in compliance with all waste acceptance criteria. Energy*Solutions* will issue a Notice to Transport once the Waste Profile has been approved and a contractual disposal agreement or necessary funding is authorized for the waste stream.

4.6 NOTICE TO TRANSPORT

Energy*Solutions* will issue a Notice to Transport to the generator that authorizes subsequent waste shipments. The Notice to Transport is completed and issued once the Waste Profile is completed and approved by Energy*Solutions*. A Notice to Transport is also issued in the following situations:

- The Waste Profile is revised in such a way that additional evaluations are required (radiological, chemical, or physical properties change significantly)
- An annual update letter is received for Mixed Waste streams
- The approval to ship is restored after the Notice to Transport is revoked

In the event that the Notice to Transport is revoked, customers will not be able to schedule shipments until the approval to ship is restored and a new Notice to Transport is issued.

SECTION 5

SHIPMENT SCHEDULING AND MANIFESTING

5.1 GENERATOR SITE ACCESS PERMIT

Prior to the first shipment of waste material to Energy*Solutions*' disposal site, generators must receive a Generator Site Access Permit (GSAP) issued by the Utah DRC. Utah Administrative Code R313-26 establishes the terms for a Generator Site Access Permit Program that authorizes waste generators, waste processors, and waste collectors to deliver radioactive wastes to a disposal facility within Utah. Generators may apply for the GSAP on-line at the Utah DRC's website at www.radiationcontrol.utah.gov/DRC_prmt.htm.

The GSAP number must be listed in Block 5 of the Uniform LLRW Manifest Form 540 and correspond to the shipper's name and facility. Shippers must ensure the GSAP is renewed annually with the Utah DRC.

Shippers are subject to the provisions contained in the "Generator Site Access Permit Enforcement Policy" as amended, UAC R313-14, and UAC R313-19-100 for violations of state rules or requirements in the current land disposal facility operating license regarding radioactive waste packaging, transportation, labeling, notification, classification, marking, or manifesting requirements.

5.2 SHIPPING CHECKLIST

To assist generators with shipments to Energy*Solutions*, the "Shipping Checklist" shown below in Figure 5-1 provides general contact, scheduling, and manifesting information. Generators and shippers should use this checklist in conjunction with their shipping procedures to ensure compliance with Energy*Solutions*' waste acceptance process. Energy*Solutions*' Technical Service Representatives are available to assist generators and shippers during the shipment scheduling and transportation process.

5.3 5 WORKING-DAY ADVANCED SHIPMENT NOTIFICATION

Generators must schedule the shipment to arrive at the facility a minimum of five working days prior to the requested shipment arrival date. Energy*Solutions* strongly encourages generators to submit the 5 Working-Day Advanced Shipment Notification form prior to the shipment departing from the generator's site. A completed copy of the 5 Working-Day Advanced Shipment Notification form must be sent to the attention of Energy*Solutions* Scheduling Department to establish an arrival date for each shipment. This form may be downloaded from Energy*Solutions*' website at www.energysolutions.com. This form must be completed and either emailed to scheduling@energysolutions.com or faxed to the site at (435) 884-3549. Once this form has been received, the Scheduling Department will confirm the shipment's arrival date with the shipper. If all required information is not available at the time of submission, updates may be provided as the information becomes available. The Scheduling Department must be informed in the event that there are delays in the shipment scheduled arrival date.

Scheduling: Must be established at least 5 working days in advance of requested arrival date

- ☐ A "Notice to Transport" has been issued by Energy*Solutions* for the Waste Profile.
- ☐ **Submitted "5 Working Day Advanced Shipment Notification" form to request shipping schedule. Email form to scheduling@energysolutions.com or fax to (435) 884-3549.**
- ☐ Shipping schedule has been confirmed by Energy*Solutions*.
  Energy*Solutions*' Shipping & Receiving Scheduler: (435) 884-0155.

Advanced Manifesting: Must be submitted prior to releasing each shipment/conveyance

- ☐ Manifested information is consistent with the approved Waste Profile.
  Verify that all manifested radionuclides are listed in the approved Waste Profile and that manifested concentrations do not exceed the approved ranges.
- ☐ Verified consignee information on manifests (see below).
  Consignee: Energy*Solutions*, LLC, Clive Disposal Site, Interstate 80, Exit 49, Clive, UT 84029
  Contact: Shipping and Receiving
  Phone: (435) 884-0155
- ☐ Verified Shipment ID/Manifest Number (XXXX-YY-ZZZZ)
  XXXX is the generator number, YY is the waste stream number, and ZZZZ is the shipment number (starting with 0001 for the first shipment/conveyance and incrementing by one for each additional shipment/conveyance). If a Hazardous Waste Manifest is submitted, include the Shipment ID Number in Block 15.
- ☐ Verified valid Utah Site Access Permit number in Block 5 on Form 540. Generators must apply for the permit with the Utah Division of Radiation Control (DRC). The Shipper Name and Facility must be consistent with the Utah Site Access Permit number.
- ☐ Verified that Block 9 of Form 540 specifies Energy*Solutions*' "Treatment Facility" or "Bulk Waste Facility". Enter "Bulk Waste Facility" for LLRW, 11e.(2) Byproduct Material, and Mixed Waste shipped for direct disposal or enter "Treatment Facility" for waste streams requiring treatment by Energy*Solutions* prior to disposal.
- ☐ Submitted manifests to Energy*Solutions* **<u>at least three working days</u>** prior to the shipment arrival date. If possible, please export the manifests and send electronically via email to manifest@energysolutions.com. Otherwise, fax manifests to "Shipping and Receiving – Manifest" at (801) 413-5643. If applicable, include the LDR Notification/Certification forms, Hazardous Waste Manifest, and SNM Exemption Certification form.

Shipment Paperwork and Inspection

- ☐ The original shipping paperwork/manifests accompany each shipment (conveyance). If applicable, include the LDR Notification/Certification forms and Hazardous Waste Manifest for each shipment.
- ☐ If applicable, **a completed and signed copy of the SNM Exemption Certification form and DOE/NRC form 741** has been included with the shipping papers.
- ☐ If applicable, the Uniform Hazardous Waste Manifest lists all hazardous waste codes associated with the shipment.
- ☐ Containers have been inspected and comply with DOT packaging requirements. Waste must be packaged in a strong, tight container at a minimum.
- ☐ **Containers do not contain unauthorized free standing liquids.**
- ☐ If applicable, containers are labeled **"Class A Unstable" or "Class AU"**. Refer to Block 16 of NRC Form 541.

Figure 5-1. Shipping Checklist

Shipments containing radionuclides with total activities exceeding the limits listed below must be specified on the 5 Working-Day Shipment Notification form and approved prior to waste shipment.

- Californium-252 (in excess of 5.4 Ci)
- Co-60 (in excess of 8.1 Ci)
- Cs-137 (in excess of 27 Ci)
- Gd-153 (in excess of 270 Ci)
- Ir-192 (in excess of 22 Ci)
- Pm-147 (in excess of 11,000 Ci)
- Se-75 (in excess of 54 Ci)
- Tm-170 (in excess of 5,400 Ci)
- Yb-169 (in excess of 81 Ci)

5.4 SHIPPING PAPERWORK

Advance copies of the Uniform Low-Level Radioactive Waste Manifest (Forms 540/541, and 542 if applicable) are required to be sent to Energy*Solutions* **at least three working days** prior to the shipment arrival date. Shippers must submit the shipping paperwork electronically via email to **manifest@energysolutions.com** or fax to "Shipping and Receiving – Manifest" at (801) 413-5643. Energy*Solutions* encourages submittal of the Uniform LLRW Manifest electronically by exporting the manifest information to a specified file format as discussed below. The advance manifest must include the Uniform LLRW Manifest, and if applicable, LDR Notification/Certification forms, Uniform Hazardous Waste Manifest, and SNM Exemption Certification form.

Additional shipping paperwork may be required depending on the type of waste being shipped to Energy*Solutions*. Multiple waste streams on a single conveyance must include a unique set of shipping paperwork for each manifested shipment. The following paperwork may also need to accompany the shipping paperwork as applicable:

- SNM Exemption Certification form. This form must be completed, signed, and included with the shipping paperwork for shipments containing Special Nuclear Material.

- LDR Certification and/or Notification form must contain the information required in 40 CFR 268.7. Energy*Solutions* requires that this information be provided with each shipment of Mixed Waste or waste that has been treated to meet 40 CFR 268 treatment standards.

- Uniform Hazardous Waste Manifest must be included with the shipping paperwork for waste shipments of Mixed Waste. As applicable, Energy*Solutions* requests that shippers list the gross weight on the manifest.

5.4.1 Instructions for the Uniform LLRW Manifest Forms 540, 541, and 542

The NRC's guidance document "Instructions for Completing the NRC's Uniform Low-Level Radioactive Waste Manifest" (NUREG/BR-0204, Rev. 2, July 1998) should be used by shippers when preparing the shipping paperwork. Energy*Solutions* requires shippers to include information in both metric units and English units following the International Standard of Units (SI). Additionally, Energy*Solutions* has specific information that should also be included on the Uniform LLRW Manifest.

Form 540

- Block 5, "Shipper" must list the shipper's company name and facility that corresponds to the Utah Generator Site Access Permit (GSAP) number. Shippers shipping on behalf of the generator and using their GSAP number should list "(shipper's company name) on behalf of (generator's name)".

- Block 5, "Shipment Number" and "Shipment ID Number" may be used by the shipper for their own tracking purposes. In most cases, shippers use the "Manifest Number" in Block 8 as the "Shipment ID Number".

- Block 8, "Manifest Number" must list the Energy*Solutions* shipment number in the following format: (XXXX-YY-ZZZZ) where XXXX is the generator number, YY is the waste stream number, and ZZZZ is the shipment number (starting with 0001 for the first shipment and incrementing by one for each additional shipment).

- Block 9, "Consignee" must list Energy*Solutions*' disposal site address as shown below, contact name and telephone number. The address must specify Energy*Solutions*' "Treatment Facility" or "Bulk Waste Facility". List "Bulk Waste Facility" for LLRW, 11e.(2) Byproduct Material, and Mixed Waste shipped for direct disposal or list "Treatment Facility" for waste streams requiring treatment by Energy*Solutions* prior to disposal.

  Energy*Solutions*, LLC
  Clive Disposal Site – Bulk Waste Facility
  Interstate 80, Exit 49
  Clive, UT 84029

Form 541

- Block 6, "Container Description" specifically applies to the disposal container. For bulk shipments (e.g., gondola railcars, intermodals, etc.), list "11" for "Bulk, Unpackaged Waste" along with the bulk packaging descriptor if the bulk package does not contain other manifested packages inside. For example, a gondola railcar with a super-load wrapper would be listed as "11A" in Block 6.

- Blocks 7 and 8, "Volume" and "Waste and Container Weight" must list the gross volume and weight of the disposal container and contents. For bulk, unpackaged waste where the waste package will not be disposed (e.g., gondola railcar, intermodal, etc.), list the weight and volume of the waste.

- Block 15, "Radiological Description" must also include a column for the radionuclide concentration expressed in units of pCi/g.

- Block 16, "Waste Classification" must list "AU" for Class A Unstable LLRW. Waste packages must also be labeled either "Class A Unstable" or "Class AU". For NORM or 11e.(2) waste material, enter "N/A" since the waste classification requirements are not applicable.

Form 542

Form 542, "Manifest Index and Regional Compact Tabulation) is required for processors and collectors of LLRW who are shipping LLRW attributed to others for ultimate disposal at Energy*Solutions*. Energy*Solutions* requires that processors or collectors submitting the Form 542 do so electronically using the file transfer protocol described in Section 5.4.2 due to the size of the manifest.

5.4.2 Electronic Submittal of the Uniform LLRW Manifest

Energy*Solutions* developed a document titled "Electronic Submittal of the Uniform Low-Level Radioactive Waste Manifest" to assist generators with the electronic submittal of the Uniform Low-Level Radioactive Waste Manifest (Forms 540, 541 and 542). Generators are able to submit their manifests electronically in a comma-delimited file format to the Energy*Solutions* disposal facility for review and distribution. Upon arrival, manifests are imported directly into Energy*Solutions*' waste tracking system. Manifest information is checked against the information contained in the generators Waste Profile. Any discrepancy will be automatically flagged, allowing potential problems to be fixed well in advance of shipment arrival.

Electronic manifest submittal has numerous benefits for both the generator and Energy*Solutions* which include:

- Generators are able to e-mail their shipping manifests directly to the site, reducing the time and expense of express mailing or faxing copies to the disposal facility.
- The generator can use the electronic signature feature, eliminating the need for any advance hard copies to be sent to Energy*Solutions*.
- Energy*Solutions* personnel can print the required copies of the manifest, including electronic signature, and distribute for proper review.
- The import of manifest information directly to Energy*Solutions*' waste tracking system will eliminate manual data entry.
- Electronic submittal will significantly reduce the time it takes Energy*Solutions* personnel to process the advanced paperwork.

5.5 90-DAY SHIPPING FORECAST

The 90-Day Shipping Forecast is used by Energy*Solutions* to properly staff and ensure adequate resources are available to ensure efficient and timely management of waste shipments. Generators are strongly encouraged to provide Energy*Solutions* with a 90-Day Shipping Forecast for all upcoming shipments. Current shippers will receive a fax or email from Energy*Solutions* every month and are requested to return the shipping forecast to Energy*Solutions* within three working days of receipt. The forecast can also be emailed to the appropriate Client Service Manager.

SECTION 6

PACKAGING AND TRANSPORTATION

6.1 COMPLIANCE WITH TRANSPORTATION REGULATIONS

Each shipment of waste material sent to Energy*Solutions* for disposal must be properly classed, described, packaged, marked, labeled, and in condition for transport as required by the Department of Transportation (DOT) Hazardous Materials Regulations (HMR) contained in 49 CFR Parts 171 through 180. Shipments of radioactive waste that are exempt from DOT regulations must be shipped to Energy*Solutions*' disposal site in packages that prevent release of the waste during transit. Specifically, all waste packages must be secure to 1) prevent rain or snow from entering the manifested waste package and 2) prevent waste from being exposed to the environment at any time during transit. Shippers should review NRC IE Bulletin No. 79-19 for training requirements applicable to radioactive waste management.

Energy*Solutions* will inspect each shipment arriving at its disposal facility for compliance with the applicable licenses and/or permits including compliance with DOT HMR requirements. Energy*Solutions* will notify the generator of a non-compliant shipment and determine the best course of action to resolve the discrepancy in a safe, compliant, and timely manner.

6.2 WASTE PACKAGING GUIDELINES

Energy*Solutions* receives waste for disposal either in bulk or in non-bulk packages. The packaging used must be authorized for the specific material being shipped by the HMR. Each generator is responsible for ensuring that the packaging used meets the appropriate regulations. The shipper of waste material is responsible for the certification of the packaging as meeting the DOT requirements. The DOT and NRC have published a joint guidance document to assist shippers of LSA and SOC material. The title of this document is "Categorizing and Transporting Low Specific Activity Materials and Surface Contaminated Objects" (NUREG-1608 or RSPA Advisory Guidance 97-005). The document is available from either agency. The following minimum packaging requirements must be met for all packages received at Energy*Solutions*.

6.2.1 Bulk Packaging

Generators are able to minimize packaging and transportation costs by utilizing bulk packages that are intended for re-use. Energy*Solutions* receives various bulk packages illustrated in Figure 6-1 which include gondola railcars with either hard-top lids or super-load wrappers, intermodals, sealands, cargo containers, roll-offs, etc. Bulk packages are unloaded at Energy*Solutions* and then decontaminated, surveyed, and returned in accordance with the requested radiological release criteria specified in Section 6.5. Bulk packaging must conform to the following requirements:

- Bulk packaging must, at a minimum, meet the applicable requirements contained in 49 CFR 173.24, General Requirements for Packagings and Packages and in 49 CFR 173.410, General Design Requirements.
- Bulk packaging must be covered. The top must be completely enclosed with no opening along the sides or openings in the top.

- Bulk packaging (e.g., railcars, trucks, trailers, etc.) must also be tightly sealed to prevent waste from leaking out or water from leaking in to the package. Packages containing unauthorized free liquids will be considered non-compliant.
- Bulk packaging must be clean. It must not have any waste material, or other material that could be mistaken for waste material, on the outer surface. Energy*Solutions* will perform contamination surveys on suspect areas of the package to ensure compliance with DOT regulations.
- Bottom dump railcars and end-dump trucks are not permitted unless approved in writing by Energy*Solutions*.
- Bulk packaging in intermodals, sealands, cargo containers, roll-offs, etc. must have ISO connectors on the top corners as illustrated in Figure 6-1 to allow the containers to be lifted from the top unless approved in writing by Energy*Solutions*.
- Friable asbestos is prohibited in bulk packages unless approved in writing by Energy*Solutions*.
- Each bulk container, which requires marking, will be properly marked in accordance with 49 CFR 172 Subpart D.
- Bulk packaging may not contain a mixture of bulk, unpackaged waste and manifested packaged waste (e.g., an intermodal containing loose unpackaged soil with manifested disposal containers within the same intermodal).

6.2.2 Non-Bulk Packaging (Disposal Containers)

Energy*Solutions* receives non-bulk packages (disposal containers) including boxes, drums, super sacks, etc. The disposal container is generally disposed of with the waste contents and will not be returned to the generator. Energy*Solutions* recommends drums be palletized to reduce the amount of time required to offload drum shipments. Palletized drums are also safer to manage at the disposal site. Generators may be charged extra for shipments containing non-palletized drums. Drums on one pallet must be from the same waste stream unless approved in writing by Energy*Solutions*. Contact Energy*Solutions* to request approval to ship non-palletized drums prior to shipment. Non-Bulk packaging must conform to the following requirements:

- Non-Bulk packaging must, at a minimum, meet the applicable requirements contained in 49 CFR 173.24, General Requirements for Packagings and Packages and in 49 CFR 173.410, General Design Requirements.
- Containers must be properly sealed to prevent load movement from "pumping" dust-laden air out of the container.
- Containers must be clean. They must not have any waste material, or other material, which could be mistake for waste material, on the outer surface. Energy*Solutions* will perform contamination surveys on suspect areas of the package to ensure compliance with DOT regulations.
- Containers in a shipment must be properly loaded and blocked and braced securely to prevent shifting and damage during transport. The specific transport loading requirements contained in 49 CFR 174 for rail and 49 CFR 177 for highway should be examined as well as 49 CFR 393 Subpart I, Protection Against Shifting and Falling Cargo.
- Although preferred, containerized rail shipments are not required to be enclosed or covered.
- Do not have unnecessary container closures; e.g., welding of drum rings or box lids.
- Non-bulk packages will not be returned to the generator.
- Overpack containers only when necessary (e.g., to meet DOT requirements) for shipment.
- Energy*Solutions* prefers drums to be palletized to reduce the amount of time required to offload drum shipments. Palletized drums are also safer to manage at the disposal site. The pallets must

be strong enough to withstand collapse during transit. The drums should be securely banded to the pallet.

- Truck or railcar beds used to transport containers must be free of all loose material, waste or otherwise.
- Each container that is required to be labeled will be properly labeled in accordance with the requirements of 49 CFR 172 Subpart E and UAC R313-15-1008.

Each container that is required to be marked will be properly marked in accordance with the requirements of 49 CFR 172 Subpart D and/or 49 CFR 173.421 and Subpart 425.

Figure 6-1. Bulk Shipping Containers

6.3 HIGHWAY TRANSPORTATION

For highway shipments (Figure 6-2), Energy*Solutions* is located just three miles south of Interstate 80 at the Clive Exit (Exit 49). Highway shipments should arrive for receipt and acceptance between 7:00 AM to 12:00 PM MST, Monday through Friday only. Shipments that arrive after 12:00 PM may not be accepted until the next day unless special handling arrangements have been previously approved.

Figure 6-2. Truck Highway Shipments

Shipments are generally unloaded on a first-come, first-served basis. Non-compliant shipments may result in unexpected delays. Shipments may take up to four hours to be checked in, inspected, surveyed, evaluated, and unloaded. Consequently, drivers should be informed that there are no eating facilities within the vicinity of the site.

6.4 RAIL TRANSPORTATION

Rail shipments will be delivered to the Energy*Solutions*' rail siding by the Union Pacific railroad on a predetermined schedule (Figure 6-3). Once at Energy*Solutions*' siding, they will be moved into the disposal site by Energy*Solutions*' equipment.

Figure 6-3. Rail Shipments

Since the signed copies of the Uniformed Low-Level Radioactive Waste Manifest or Uniform Hazardous Waste Manifest forms do not travel with the railcars during transport, the original signed manifest must be mailed or electronically transferred to the Clive Disposal Facility. The documents must arrive at the Clive Disposal Facility a minimum of 3 working days prior to the receipt of the rail shipment.

6.5 RELEASE OF SHIPPING CONVEYANCES

The timeframe for the release of shipping conveyances (e.g., trucks, intermodal containers, railcars, etc.) is based on the specific contractual arrangements that have been established between each generator and Energy*Solutions*. Generators must request the type of radiological release prior to the shipment's arrival and must be allowed under the Terms and Conditions of the disposal agreement. The requested release types must be authorized by Energy*Solutions*' Business Development Department. Containers released to the Unrestricted Use criteria require significantly more time and expense due to the resources needed to meet these release criteria. Energy*Solutions* performs the following types of radiological releases as listed in the following table.

Energy*Solutions* Radiological Release Criteria

Release Type	Criteria	Reference
Unrestricted Use	Removable and fixed surface contamination levels are isotope specific. The most restrictive isotopic removable surface contamination levels are less than 20 dpm α/100 cm^2 and 200 dpm β-γ/100 cm^2. The most restrictive isotopic total surface contamination levels are less than 100 dpm α/100 cm^2 and 1,000 dpm β-γ/100 cm^2. The contamination levels apply to all internal and external surfaces. Contact Energy*Solutions*' Business Development Department to make contractual arrangements for this type of release.	US NRC Regulatory Guide 1.86, June 1974 (Consistent with Energy*Solutions*' RML Condition 27)
Return to Service	Removable surface contamination levels must be less than 220 dpm α/100 cm^2 and 2,200 dpm β-γ/100 cm^2. The radiation dose rate at each accessible surface must be less than 0.5 mrem/hr. The contamination levels apply to all internal and external surfaces of the transport vehicle.	49 CFR 173.443(c)
DOT Empty	Removable surface contamination levels on the outside of the package must be less than 220 dpm α/100 cm^2 and 2,200 dpm β-γ/100 cm^2. Removable surface contamination levels on the inside of the package must be less than 22,000 dpm α/100 cm^2 and 220,000 dpm β-γ/100 cm^2. The package must be emptied of contents to the extent practical.	49 CFR 173.428
Sole Use	Removable surface contamination levels on the outside of the transport vehicle must be less than 220 dpm α/100 cm^2 and 2,200 dpm β-γ/100 cm^2. The radiation dose rate on the internal surfaces must be less than 10 mrem/hr or 2 mrem/hr at one meter from the surface.	49 CFR 173.443(d)

Clean Harbors, Inc. – Deer Trail, Colorado

Clean Harbors Deer Trail NORM Waste Acceptance

Facility Permitting

Clean Harbors Deer Trail (CHDT) operates a treatment, storage and land disposal facility near Last Chance, Colorado. The Deer Trail facility operates under Colorado RCRA Permit CO-05-12-21-01, and Colorado Radioactive Materials License CO-1102. The permit and license allows for treatment, storage and landfill disposal of liquid and solid NORM wastes less than 2000 pCi/g total radionuclide activity. Additionally, our permits allow us to accept landfillable mixtures of RCRA and NORM wastes.

Waste Pre-Acceptance Process

To evaluate a NORM waste stream for facility acceptance, each Generator must submit a **Material Profile Sheet, Supplemental Radioactive Questionnaire and Laboratory Analysis.** Required lab analysis are listed below. CHDT evaluates the information to determine if the waste meets the acceptance criteria for land disposal at CHDT. After the waste is approved to come to CHDT, an **Application for Waste Impor**t must be made to the Rocky Mountain Low-Level Radioactive Waste Board (Compact) and an application fee must be sent with the application. (An import application is not required for wastes from the States of CO, NM and NV.) A sample Import Application is included. Import Application Requests are normally approved and processed within two weeks. If waste is generated from a one-time site or process, a new profile and analysis must be completed each time. If the waste is produced by an ongoing process from one site, the profile and import application can be approved such that only periodic analysis is needed for repeat waste shipments.

On-Site Waste Acceptance

Bulk waste shipments of radioactive material must be scheduled in advance. All shipments must be documented using a manifest. Once a shipment arrives at CHDT, it is weighed and the external dose rate of the vehicle is measured. The waste is analyzed using a portable gamma spectrum analyzer and the truck is surveyed for removable radioactive contamination. After testing is complete, the vehicle/container will either be dumped in the landfill or, if it requires solidification/treatment, will be dumped in the treatment area. After dumping, the inside and outside of the container will be surveyed for radioactive contamination. If necessary, the container will be decontaminated. CHDT's permit requires us not to release any container or vehicle above the allowed permit limits. Shippers of solid radioactive material are encouraged to line the beds of roll-off containers or dump trucks with plastic in order to prevent incurring the costs of vehicle washouts and decontamination fees.

Deer Trail Minimum Analytical Requirements

1. Total Uranium (mg/kg) by ICP; alternate Isotopic Uranium by Alpha Spec.
2. Total Thorium (mg/kg) by ICP; Alternate Isotopic Thorium by Alpha Spec.
3. Gamma spectrum analysis with Peak identification and Ra-226 quantitation pCi/g
4. Gross alpha (pCi/g)
5. Gross beta (pCi/g)
6. Pb-210 if applicable (pCi/g) (Natural Gas Processing Waste Only)

Deer Trail NORM Acceptance Limits

1. Must be Classified NORM or TENORM by CO Regulations
2. Must be less than 2000 pCi/g total activity
3. Must be less than 500mg/kg total Uranium and Thorium
4. Ra-226 must be less than 222pCi/g if only primary radionuclide present
5. Pb-210 must be less than 666pCi/g if only primary radionuclide present
6. Gamma dose rate must be less than 116 μRoentgens/hr at the surface of the container.

Other Requirements

1. Wastes containing free liquids must contain less than 500ppm VOC's (Volatile Organic Compounds)
2. Waste containing free liquids must have a flash point greater than 140F
3. Wastes containing greater than 500ppm reactive sulfides require special treatment.
4. RCRA/NORM wastes are acceptable but may require additional testing.

Clean Harbors Environmental Services
108555 East Highway 36, Deer Trail, CO 80105
Office: 970.386.2293

Transportation & Disposal

Deer Trail, Colorado Facility Facts

Colorado Radioactive Materials License Issued on December 21, 2005

The Deer Trail facility is a fully permitted Subtitle C landfill authorized to treat, store and dispose of a wide variety of hazardous and industrial wastes, including RCRA, TSCA (megarule) and debris for encapsulation.

As of December 21, 2005, Deer Trail is now licensed to dispose of Naturally Occurring Radioactive Material (**NORM**) and Technologically Enhanced Radioactive Material (**TENORM**) wastes. This license was issued by the State of Colorado, Department of Public Health and Environment. Deer Trail can accept NORM and TENORM wastes containing radionuclides (in the decay series of U-238, U-235 and Th-232) up to 2000 pCi/gram. The Rocky Mountain Low Level Radioactive Waste Compact has designated Deer Trail as the Low Level Waste Facility for Colorado, New Mexico and Nevada.

Deer Trail is located 75 miles east of Denver, CO. The facility can store, treat and dispose of wastes in bulk and containerized quantities. Deer Trail receives waste by truck and also by rail from a trans-loading point located in Sterling, Colorado.

Permits

- Colorado Radioactive Materials License Number Colo. 1101-01, CDPHE
- RCRA Part B Permit renewed 2005, No. CO-05-12-21-01, CDPHE
- EPA ID No COD991300484, USEPA
- Certificate of Designation, No. 147-82-C-CD, Adams County
- Colorado Wastewater Discharge Permit, No. CO-0042064, CDPHE
- Colorado Air Emissions No. 01AD0713

Facility Description & General Information

- Permit issued - 1987, first waste received - 1991
- 325 acres of permitted facility surrounded by 5760 acres of Clean Harbors owned buffer zone
- Rural location
- 2.5 million cubic yards of permitted cell space
- Sited on the impermeable Pierre Shale formation

Services Provided:

- Storage, final treatment and landfill disposal
- Stabilization treatment of toxic metal wastes
- Custom treatment of organic wastes
- Chemical reduction
- Solidification of liquid wastes
- Deactivation and neutralization
- Micro encapsulation
- Macro encapsulation
- Direct landfill

Typical Customers: Customers include, but are not limited to, remediation sites, chemical facilities, manufacturers, refineries, mines, plating facilities, and brokers.

Typical Waste Streams: Typical waste streams accepted include, but are not limited to, NORM and TENORM wastes, industrial metal bearing wastes, contaminated process wastewaters, refinery wastes, inorganic cleaning solutions, plating wastes, paint residues, debris from toxic or reactive chemical cleanups, off-spec commercial products.

Treatment, Storage and Disposal Capabilities

- Totally enclosed waste treatment building with dual emission control systems
- Drum Storage Building with capacity for 600 x 55-gallon drums or 33,000 gallons
- Bulk Container Storage Area A: 2000 cubic yards of bulk solids
- Bulk Container Storage Area B: 1000 cubic yards of bulk solids
- Wide range of permitted waste codes

Waste Disposal Services

NORM and TENORM Waste Management Fact Sheet

NORM and TENORM Waste Management

Clean Harbors provides disposal for Naturally Occurring Radioactive Material (NORM) and Technologically Enhanced Naturally Occurring Radioactive Material (TENORM) wastes at our Deer Trail, Colorado and Buttonwillow, California facilities.

Deer Trail and Buttonwillow are fully permitted Subtitle C landfills authorized to accept NORM and TENORM wastes containing radionuclides (in the decay series of U-238, U-235 and Th-232) up to 2000 pCi/gram for Deer Trail and up to 1800 pCi/gram for Buttonwillow.

Typical sources of NORM and TENORM wastes include

- Oil and gas industry
- Geothermal energy production
- Coal combustion
- Mining of uranium and metals
- Phosphate production
- Municipal water treatment
- Abandoned mines and processing facilities
- General manufacturing

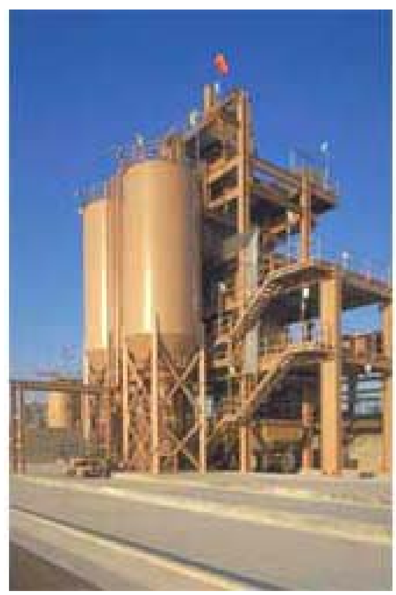
Deer Trail, Colorado Facility

The Rocky Mountain Low Level Radioactive Waste Compact has designated the Deer Trail facility as the low level waste facility for Colorado, New Mexico, and Nevada. The facility is located 75 miles east of Denver, Colorado, and can store, treat and dispose of wastes in bulk and containerized quantities. Deer Trail receives waste by truck and also by rail from a trans-loading point located in Sterling, Colorado.

The Deer Trail facility is also authorized to treat, store, and dispose of a wide variety of hazardous and industrial wastes including RCRA, TSCA (megarule), and debris for encapsulation.

Buttonwillow, California Facility

Located in central California, the Buttonwillow facility is also fully permitted to manage a large number of RCRA hazardous wastes, California hazardous waste, and non-hazardous waste for stabilization treatment, solidification, and landfill. It can handle waste in bulk (solids and liquids) and in containers.



This facility operates a permitted drum handling and storage area, which can store and/or transfer up to 1,500 drums. Permitted landfill capacity is in excess of 10 million cubic yards.

Re: License Amendment
Colorado Radioactive Materials License Number Colo. 1102-01

Enclosed is Radioactive Materials License Number Colo. 1102-01, Amendment No. 6, which has been amended as requested in your letter dated March 18, 2009. Please review this document thoroughly.

This amendment was necessary because of a change to the definitions in the Colorado Rules and Regulations that caused radium contaminated debris to no longer fall under the definition of TENORM. It is now defined as a "new" type of byproduct material. Because the license restricted Clean Harbors to only NORM and TENORM, the amendment is necessary to retain Clean Harbors' ability to take radium contaminated debris and soil. This amendment does not expand the scope of the material that Clean Harbors is allowed to accept for disposal.

Please note that the mailing address, use location(s), maximum quantities of radioactive materials, and the radiation safety officer are specific conditions of your license. If you have questions about making changes to your licensed activities, please contact the Radiation Management Unit to discuss the requirements for an amendment of your license.

If you have any questions regarding this letter or your license please contact Jennifer Opila at 303-692-3403 or jennifer.opila@state.co.us. Additional questions or comments can be directed to me at 303-692-3423 or steve.tarlton@state.co.us.

Radiation Management Unit
Hazardous Materials and Waste Management Division

Enclosure: Colo. 1102-01, Amendment No. 6

State of Colorado
Department of Public Health and Environment

RADIOACTIVE MATERIALS LICENSE

Pursuant to the *Radiation Control Act* Title 25, Article 11, *Colorado Revised Statutes*, and the State of Colorado *Rules and Regulations Pertaining to Radiation Control* and in reliance on statements and representations heretofore made by the licensee designated below; a license is hereby issued authorizing such licensee to receive, possess, analyze, store, process and dispose the radioactive material(s) designated below; and to use such radioactive material(s) for the purpose(s) and at the place(s) designated below. This license is subject to all applicable rules, regulations, and orders now or hereafter in effect of the Colorado Department of Public Health and Environment (CDPHE) and to any conditions specified below.

1. Licensee: Clean Harbors Deer Trail, LLC
2. Address: 108555 East US Highway 36, Deer Trail, CO 80105-9611
3. License Number Colo. 1102-01, Amendment Number 06
4. Expiration date: December 31, 2010
5. Reference Number: Fee Category: 4.A

6. **Authorized Radioactive Material and Uses**

A. The licensee is authorized to receive, possess, analyze, store, process, and dispose of waste materials containing naturally occurring radioactive material (NORM), technologically enhanced naturally occurring radioactive material (TENORM), and radium contamination resulting from activities involving purposefully concentrated radium-226. The specific radionuclides are limited to K-40 and all of the radionuclides in the decay series for U-238, U-235 and Th-232. The summed activity of all radionuclides per gram contained in such waste materials shall not exceed 2000 pCi (74 Bq). Additionally, the Ra-226 activity per gram shall not exceed 400 pCi (14.8 Bq). The physical form of the material includes but is not limited to soils, sludges, process residues, resins, and filters that are compatible with the design and operational criteria required by the CHWA permit.

B. In addition to the limits established in items 6.A the total uranium and thorium content shall be less than 0.05% by weight (500 μg per gram) of the materials received for disposal.

C. In addition to the limits established in items 6.A and 6.B the licensee shall limit the total of all waste materials containing radioactive material to a total volume not to exceed 510,440 cubic yards. Of this amount, at least 16,000 cubic yards shall be set aside for radium processing wastes.

State of Colorado
Department of Public Health and Environment

RADIOACTIVE MATERIALS LICENSE

Conditions

7. The licensee shall comply with the provisions of the State of Colorado *Rules and Regulations Pertaining to Radiation Control*: Part 3, "Licensing of Radioactive Material"; Part 4, "Standards for Protection Against Radiation"; Part 10, "Notices, Instructions and Reports to Workers: Inspections"; Part 11, "Special Land Ownership Requirements"; Part 14, "Licensing Requirements for Land Disposal of Low Level Radioactive Wastes"; Part 15, "Colorado Low-Level Radioactive Waste Rate Regulations"; and Part 17, "Transportation of Radioactive Material."

8. Radioactive materials may be received, stored, handled, processed and disposed only at the Clean Harbors Deer Trail facility, 108555 East US Highway 36, Deer Trail, CO 80105-9611.

9. The licensee is prohibited from receiving low-level wastes, as defined by the Rocky Mountain Low Level Waste Compact Board, from outside the Compact Region without written authorization from the Rocky Mountain Low Level Waste Compact Board.

10. For the purposes of this license and as used in the application, regulated waste refers to any waste received, handled, processed or disposed of at the site containing radioactive material including: a) NORM/TENORM radionuclides in solid waste; b) NORM/TENORM radionuclides in material licensed by CDPHE; c) NORM/TENORM radionuclides mixed with Colorado Hazardous Waste Act (CHWA) hazardous wastes; d) radium processing wastes; and e) radium contamination resulting from activities involving purposely concentrated radium-226.

11. Pursuant to its authority over all radioactive materials at the facility, the Department may at any time impose additional requirements and/or license conditions regarding the receipt, processing, analysis, storage or disposal of these materials as may be necessary to ensure health and safety of workers, protection of the environment and compliance with any applicable rules, regulations and statutes.

12. Should the licensee become aware of radioactive materials that were not identified in any waste characterization or manifest that are present in waste materials received or buried at the site, the licensee shall maintain a record of these and shall provide immediate notification to the Department for any materials that are not specifically authorized on the license.

13. The designated Radiation Safety Officer (RSO) is Scott Zoller, CHP.

14. The designated Alternate Radiation Safety Officer (RSO) is Tracy A. Ikenberry, CHP.

15. The Radiation Safety Officer shall be on-site sufficient to ensure protection of workers and compliance with this license and the Rules and Regulations.

16. Radioactive material authorized in License Conditions 6.A. through 6.C. shall only be received, stored, handled, analyzed, processed or disposed by or under the supervision of John Kehoe, Michael Webb, Ismael Hernandez, Randall Musgrave, Daniel O'Brien, Leresa Wilson, Joseph Sanchez, or Terry Musgrave.

State of Colorado
Department of Public Health and Environment

RADIOACTIVE MATERIALS LICENSE

17. One or more authorized users identified in Condition 16 of this license shall be physically present at the facility at all times when radioactive materials are being received, stored, handled, analyzed, processed or disposed. The number of authorized users present on site at any one time shall be sufficient to ensure adequate supervision of all persons within the restricted area.

18. Temporary contract laborers and members of the public shall be escorted throughout the restricted area under the direct supervision and in the physical presence of an authorized user listed in License Condition 16. Temporary contract laborers shall sign in and out of the facility each day. The sign-in, sign-out logs for the facility shall be maintained in the Operating Record.

19. Contract laborers and consultants who have successfully completed the radiation safety training as described in the Radiation Protection Program may work throughout the restricted area without continuous direct supervision by Clean Harbors personnel.

20. The Radiation Safety Officer, Alternate Radiation Safety Officer, or persons specifically listed in License Condition 16 shall physically observe the day-to-day activities of contract laborers and consultants who work without constant supervision. The extent of these observations shall be sufficient to ensure that contract laborers and consultants are complying with established procedures and the requirements of this license.

21. Each person receiving an occupational dose at the facility is deemed to require monitoring pursuant to Section 4.18 of the Regulations.

22. The Radiation Safety Officer shall maintain training and dose monitoring records for each worker at the site who receives an occupational dose. These records shall show the initial hire date, the specific training received, the date training was successfully completed, the date when dose monitoring was initiated, the date when employment terminated, and a copy of the annual total dose assessment for each year the individual works at the site.

23. The licensee shall determine occupational doses on a quarterly basis, with the final determination being completed within 60 days from the end of each quarter.

24. The licensee shall determine occupational doses (total effective dose equivalent (TEDE), committed effective dose equivalent (CEDE), and deep dose equivalent (DDE)) within 90 days from the end of each calendar year.

State of Colorado
Department of Public Health and Environment

RADIOACTIVE MATERIALS LICENSE

25. The licensee shall not make any substantial modification to the facility, equipment, process, or procedures used in the receipt, storage, handling, processing or disposal of waste containing radioactive materials without first evaluating and documenting the impact of such changes to workers, the environment, and members of the public. The licensee shall obtain written authorization from the Department, including a license amendment, if deemed necessary by the Department prior implementing the proposed changes. The Radiation Safety Officer shall maintain documentation of all such evaluations for review by the Department.

26. Characterization and approval of regulated waste streams shall be performed in accordance with the Waste Acceptance SOP 15.W.01 dated April 19, 2006. All records of characterization and approval of regulated waste streams shall be maintained by the licensee for review by the department.

27. The licensee shall collect a random sample from 1 shipment out of every 20 shipments from each waste stream from each generator as described in the Waste Acceptance SOP 15.W.01 dated April 19, 2006. The random sample shall be sent to an off-site laboratory for analysis including: Gamma Spectrum, Gross Alpha Activity/g, Gross Beta Activity/g, Total Uranium Mass/g, Total Thorium Mass/g and Total Radium Activity/g. The results of this analysis shall be compared to the initial characterization data for the waste stream. If the results differ significantly from the profile, the RSO, general manager, compliance manager, or their designee shall contact the waste generator and attempt to resolve the discrepancy. If the results cannot be reconciled, the waste stream shall be deactivated until it can be resolved. All records from the random sampling program shall be maintained for review by the Department.

28. The licensee shall implement and maintain Department-approved controls for limiting the release of radon and radioactive particulates from all waste repositories and processing facilities.

29. The licensee shall conduct an air sampling program sufficient to demonstrate compliance with the public and occupational dose limits specified in Part 4 of the Regulations.

30. The licensee shall continue collecting monthly samples of groundwater, leachate and air for the purposes of establishing baseline environmental data for radionuclides until the Department approves an alternate sampling frequency.

31. Samples collected for the assessment of doses to members of the public, occupational doses, and samples collected for verification of characterization of wastes or environmental contamination levels shall be analyzed by radiochemistry laboratory that is appropriately licensed for the type of analysis being performed.

32. The licensee shall conduct sufficient radiation surveys on materials and equipment to ensure that contamination levels do not exceed Department-approved criteria prior to release to unrestricted areas or for unrestricted use. The results of each survey shall be recorded and maintained on file for review by the Department for three (3) years after the record is made in accordance with RH 4.42.

State of Colorado
Department of Public Health and Environment

RADIOACTIVE MATERIALS LICENSE

33. The licensee shall maintain all equipment and facilities, essential to operations governed by this license, in good working condition. This includes but is not limited to process equipment, process tanks, dust suppression equipment, air sampling equipment, water monitoring wells, radiation detection equipment, survey instruments, gates, fences, waste impoundments, security systems, safety equipment, and emergency systems and equipment.

34. The licensee's management and radiation safety officer shall take prompt and appropriate action to correct known deficiencies in the facility's procedures, processes, equipment, and site conditions. These deficiencies and the corrective actions shall be documented and records maintained for review by the Department for three (3) years.

35. The licensee shall document and implement a system of routine preventive maintenance so that safety equipment is checked for proper working order according to a regular schedule.

36. The license shall post individual areas of the facility and the entrances to each building or room that contains radioactive materials, with a conspicuous sign bearing the radiation symbol and the words, "Caution – Radioactive Materials".

37. The licensee shall maintain security measures to prevent unauthorized access to the site's facilities and radioactive materials.

38. Prior to closure of each landfill cell, the licensee shall submit an analysis of the adequacy of the cap design to the Department for approval. The cap design must provide reasonable assurance of control of radiological hazards to be effective for 1,000 years, to the extent reasonably achievable, and, in any case, for at least 200 years. Additionally, the cap design must be sufficient such that the release of Radon-222 does not exceed 20 pCi per square meter per second averaged over the surface area of the cell. This analysis shall include radon flux measurements and an analysis of the amount and concentration of radon producing materials disposed in the cell.

39. Upon closure of each landfill cell containing radioactive material, the licensee shall record with the Adams County clerk and recorder a deed annotation as required in Section 11.3.5.

40. Following the construction of a new landfill liner system or a landfill final cover system, the licensee shall provide the Department with "as-built" drawings of the landfill liner system or final cover system.

State of Colorado
Department of Public Health and Environment

RADIOACTIVE MATERIALS LICENSE

41. The licensee shall provide the Department with an annual report by April 1 of each calendar year. That report shall contain the following items:

A. specification of each quantity of radioactive contaminants released to unrestricted areas in liquid and in airborne effluents;

B. the results of the environmental monitoring program;

C. a summary of licensee disposal unit radiation survey and maintenance activities;

D. a summary of activities and quantities of radionuclides disposed of;

E. any instances in which the observed site characteristics were significantly different from those described in the application for a license;

F. estimated doses to members of the public from the licensee's activities. This includes TEDE (total effective dose equivalent) and TODE (total organ dose equivalent) for both the nearest resident and the maximally exposed member of the public (if they are not the same person). The calculation of public doses shall be in accordance with Department approved methods, sampling frequencies, and dose modeling assumptions. Dose estimates shall be accompanied by appropriate supporting data including an electronic copy of the lab results, spreadsheets, computer model inputs, and modeling results/outputs;

G. a summary of Occupational Doses (total effective dose equivalent (TEDE), committed effective dose equivalent (CEDE), and deep dose equivalent (DDE));

H. a copy of the annual ALARA program audit;

I. a summary of anticipated activities for coming year;

J. an evaluation of the existing decommissioning warranty to ensure that the available funds are sufficient to account for inflation, current site conditions, and projected activities for the coming year; and

K. an evaluation of the existing decommissioning funding plan to ensure that the licensee will have sufficient funds for the licensee to complete site decommissioning activities.

State of Colorado
Department of Public Health and Environment

RADIOACTIVE MATERIALS LICENSE

License conditions 42 and 43 only apply to wastes under the jurisdiction of the Rocky Mountain Low-Level Radioactive Waste Board

42. Two (2) years after the facility has been licensed, the licensee shall petition the Board of Health of the State of Colorado to determine the rates using a historic test period of no less than twelve (12) continuous months, adjusted for known and certain future expenditures that will be incurred by the licensee which are reasonable and necessary for the operation of the facility.

43. The licensee shall provide rate review documentation to the Department pursuant to Sections 15.16, 15.17, 15.18 and 15.19.

    A. Semiannual reports shall be submitted by July 31st and January 31st of each year.

    B. Annual reports shall be submitted by April 1st of each year.

44. Records of waste disposal shall be maintained in accordance with Section 4.48.

45. The licensee's facility management and the radiation safety officer shall thoroughly review the content and requirements of this license. The licensee shall promptly notify the Department whenever it identifies an error in license authorizations or it has identified a specific license condition or technical requirement established in this license that is not achievable given the current state of technology or site conditions.

46. If statements in referenced documents conflict, the most recent document listed below shall prevail unless otherwise specified in this license.

47. The State of Colorado Rules and Regulations Pertaining to Radiation Control and the *Radiation Control Act* Title 25, Article 11, *Colorado Revised Statutes*, shall govern the licensee, unless the conditions of this license or the licensee's statements, representations, or procedures contained in applications or other documents submitted to the Department are more restrictive than the Regulations. Except as specifically provided otherwise by this license, the licensee shall possess and use radioactive material described in Item 6 of this license in accordance with statements, representations, and procedures contained in:

    A. the application and attachments received January 31, 2005; and

    B. the CHWA Subtitle C Permit dated December 2005; and

    C. financial assurance arrangements for decommissioning and long term care (Steadfast Insurance Policy Number ENC 5254333-02); and

    D. the decommissioning funding plan dated December 20, 2005; and

State of Colorado
Department of Public Health and Environment

RADIOACTIVE MATERIALS LICENSE

E. the Rocky Mountain Low-Level Radioactive Waste Board Designation as a Limited Regional Disposal Facility, as amended; and

F. the Radiation Protection Plan dated October 4, 2005; and

G. the Standard Operating Procedures as follows:

Waste Disposal Services

Truck-to-Rail Transloading Fact Sheet

Truck-to-Rail Transloading

Clean Harbors portable truck-to-rail transloading solution provides the most economical and safest method of overland transportation of bulk waste material. Our truck-to-rail transloading ramps offer you a significant advantage when managing the shipment of material from your project site to one of Clean Harbors rail served treatment and disposal facilities, including our incinerators and landfills. Even if your project location does not have rail on-site or the rail is at the opposite side of a property, you can still benefit from the economies of rail shipping by utilizing our truck-to-rail transloading solution.

- We provide a total solution
- Railroad approved & specifically designed
- Gain high throughput rates
- Minimal site requirements

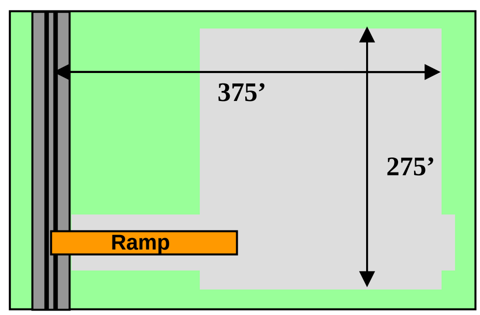
We Provide a Total Solution - Clean Harbors will set up and operate portable truck-to-rail ramps on your project site. We can also provide the trucks to move materials to the rail cars as well as manage the rail shipments to the end disposal facility.

Railroad Approved & Specifically Designed - These ramps are railroad approved and specifically designed for transloading activity involving transferring bulk loads of soils and small debris from dump trailers and roll-offs into 90-100 ton gondola rail cars.

Auto-leveling hoppers distribute the bulk wastes evenly throughout the length of the railcar. The ramps are configured for "back-on" use and can handle most any conventional dump trailer or the higher model roll-off frames. To maximize railcar payload, our ramp system is compatible for use with 53-foot, 90-100-ton gondola railcars.

Gain High Throughput Rates - When transloading operating conditions are optimal, approximately 92 tons (four trailer loads) can be transloaded per 1½ hours.

Minimal Site Requirements - We require a non-shared dedicated rail spur or siding. The transload ramp will be set-up at approximately the mid-point of the siding. The siding must have sufficient length to accommodate a full days/shifts production of railcars on both sides of the transload ramp. A minimum of 375 feet of perpendicular approach to the inside rail and approximately 275 feet of truck/trailer maneuvering area is necessary. Since our equipment is a back-on ramp, we do not require any additional area or accommodations on the opposite side of the rail.



Typical Site Layout – perpendicular approach to the rail supported by a load bearing improved surface, without overhead obstacles, shallow buried conveyances and/or highly irregular angles of approach.

Summary - Understanding and appreciating the complexities of remedial and project site activities and knowing the nuts and bolts of railroad service, Clean Harbors is able to provide a unique value-added service that makes transportation and disposal economical and as seamless and uncomplicated as ever.

1. INTRODUCTION

This report presents an evaluation of the potential application of apatite and/or phosphate solutions for possible treatment of waste materials and/or groundwater for the remedial action for Operable Unit-1 (OU-1) of the West Lake Landfill Superfund Site (the Site). The evaluation presented in this report was prepared in accordance with the Revised Work Plan – Evaluation of the Use of Apatite/Phosphate Treatment Technologies (Work Plan) dated October 31, 2013 (EMSI, 2013) that was approved by the U.S. Environmental Protection Agency (EPA) on March 20, 2015.

1.1 Summary

An extensive review of the literature regarding the use of apatite and/or other phosphate-based materials for treatment of radionuclides and metals in water, soil, sediments, tailings and landfill leachate was performed. No literature or case studies were identified relative to use of apatite or phosphate-based materials for treatment of radium or thorium in soil or MSW.

No applications of apatite or phosphate-based treatment of any type were identified relative to MSW. Uncertainty exists as to whether apatite formation can be initiated synthetically under field conditions associated with MSW, including whether apatite solids or solutions can be delivered and homogeneously distributed within an overall heterogeneous matrix of MSW. DOE technical representatives with extensive experience with bench- and pilot-testing of apatite under various geochemical conditions have expressed concerns about unintended consequences such as a potential for increased mobility that could result from physical disturbance or modification of the geochemical conditions within the landfill from application of apatite based treatment technologies (Thompson and Wellman, 2012).

Applications of apatite/phosphate-based treatment of groundwater containing strontium, uranium, and some metals were identified. However, no known applications for treatment of radium or thorium in groundwater were identified.

Given the lack of demonstrated application of this technology for either radium or MSW, implementation uncertainties, and the potential for adverse effects, this technology is not considered appropriate for treatment of OU-1 soil/waste material. Therefore, it is recommended that this technology be eliminated from further consideration relative to treatment of OU-1 soil/waste. EPA has indicated that groundwater conditions will be addressed in a separate operable unit. Therefore, further evaluations of potential application of apatite/phosphate-based or other treatment technologies may be evaluated as part of the RI/FS for a groundwater OU.

1.2 Background

In an October 12, 2012 letter (EPA, 2012), EPA Region 7 indicated that the National Remedy Review Board (NRRB) recommended that more detailed evaluations of potential treatment technologies be conducted as part of a Supplement to the Supplemental Feasibility Study (SFS) (EMSI, 2011). EPA Region 7 requested in the letter that the OU-1 Respondents, among other things, evaluate potential applications of apatite and/or phosphate solutions for possible treatment of waste materials and/or groundwater at a level of detail comparable to that used to evaluate the treatment technologies previously analyzed in the SFS.

In its email approving the Revised Work Plan (EPA, 2015), EPA recommended that

> *"additional literature research be undertaken to identify all relevant literature pertaining to the reduction in mobility of Radiologically Impacted Material (RIM) in landfill environments of appropriate geochemical conditions (solubility and sorption). More specifically, the additional literature research should include various stabilization agents, for example, but not limited to (phosphates, carbonates, sulfates, sulfides) under current and projected subsurface geochemical conditions of pH and Eh at the West Lake landfill. The identified site conditions should dictate the best chemical treatment options based on waste, RIM and geochemical conditions to achieve minimum RIM component mobility.*

1.3 Apatite/Phosphate-Based Treatment

Apatite is an isomorphic mineral. More specifically, apatite is a group of crystalline phosphate mineral compounds that have different chemical compositions, but identical crystalline structures. Consequently, precipitation of apatite can result in incorporation of other elements into the mineral's crystalline structure. In an isomorphic mineral, certain ions or molecules will enter into the crystal-lattice of a mineral solid without causing any marked change in the crystal morphology or other physical properties of the mineral. For simplicity, this process reflects two ions having similar but not equal atomic radii and the same charge, with the smaller ion being preferentially concentrated in the early formed specimens of a crystallizing mineral series.

Application of apatite/phosphate-based treatment agents was considered as a possible in situ stabilization method. Stabilization refers to processes that involve chemical reactions that reduce the leachability of a waste (EPA, 2000). Stabilization is performed to chemically immobilize hazardous materials or to reduce their solubility through a chemical reaction (EPA, 2000).

Relative to the radionuclides at West Lake Landfill, apatite or other phosphate-based materials or solutions possibly could be added in situ to the solid waste materials containing the radionuclides to reduce potential leaching of the radionuclides. The apatite or other phosphate-based material would be added in sufficient quantities and under appropriate geochemical conditions necessary to promote apatite crystallization. Such crystallization may result in incorporation of Site-related radionuclides such as thorium, radium and uranium into the apatite crystals. Incorporation of radionuclides into the crystalline matrix would reduce the potential for leaching of such radionuclides. Alternatively, apatite or phosphate based solutions could be physically placed (*e.g.,* permeable reactive barrier) or injected into groundwater containing radionuclides with the goal of precipitating and thereby immobilizing radionuclides contained in groundwater.

Radium and thorium, and to a lesser extent uranium, are the major radionuclides of concern at the Site relative to potential leaching to groundwater. Thorium is known to be highly insoluble and uranium is relatively insoluble under reducing conditions such as those that occur at municipal solid waste (MSW) landfills. Neither of these radionuclides has been detected in groundwater at the Site at levels above background. Therefore, radium would be the key constituent for treatment using apatite materials.

1.4 Approach

Typically, the first step in the identification of potentially applicable remedial technologies is to evaluate general response actions that, based on site conditions and media of concern, could address the remedial action objectives (RAOs) at a site. The RAOs developed for OU-1 do not include direct treatment of the waste materials or treatment of groundwater. Consequently, potential remedial technologies related to these response actions were not evaluated in the FS (EMSI, 2006) or the SFS (EMSI, 2011). Therefore, as discussed in the Work Plan, for purposes of conducting an evaluation of potential apatite/phosphate-based treatment technologies, this initial step (evaluation of general response actions based on site conditions and media of concern) was omitted. Instead, to comply with EPA's direction, the evaluation was based on a hypothetical scenario where treatment of the waste/source materials and/or treatment of groundwater have been deemed appropriate response actions relative to the site conditions and media of concern. In the event that an apatite/phosphate-based treatment technology is determined to potentially be applicable to OU-1, it may be necessary to revisit the evaluation of general response actions and the identification of other potentially applicable remedial technologies.

Evaluation of the potential applicability of apatite or other phosphate-based treatment technologies for direct treatment of waste/source materials or for treatment of impacted groundwater was performed using the same approach used to evaluate other potential remedial technologies under a Feasibility Study level of effort. The first step was to identify potential apatite/phosphate-based treatment technologies and perform an initial screening of the technical implementability of such technologies relative to the waste and site conditions. The approach to evaluating the potential application of apatite/phosphate-based treatment technology was based on the following:

1. Review of available published literature; and
2. Discussions with DOE individuals with knowledge of the use and applicability of apatite injection technology.

If the initial screening of potential apatite/phosphate-based treatment technologies indicates that such technologies may potentially be applicable to the site and waste conditions in OU-1, these technologies are subjected to further evaluations, including potential effectiveness, implementability, and cost, in accordance with the procedures prescribed in EPA's *Guidance for Conducting Remedial Investigations and Feasibility Studies Under CERCLA* (EPA, 1988).

2. RESULTS OF INITIAL SCREENING

A search of available published technical literature was conducted as an initial screening of the technical implementability of apatite or other phosphate treatment technologies for the direct treatment of waste/source materials associated with West Lake Landfill OU-1 Areas 1 and 2 or for treatment of impacted groundwater. The results of the search are presented in Table 1. For each of the 72 references identified, Table 1 includes the name of the principal author; date of publication; the radioactive or other metal elements addressed; the nature of the media evaluated; and the scale of study conducted. A brief summary of the technical information/conclusions from each reference is also provided in Table 1.

Following is a summary of the radionuclide or metal elements addressed in the references:

Element(s)	Number of References
Radium	11
Thorium	3
Uranium	42
Other radionuclides	22
Metals (*e.g.*, lead, cadmium, zinc)	21

The types of liquid or solid media used in the various evaluations described in the literature include:

Media	Number of References
Water (groundwater, mine water, or synthetic water spiked with radionuclides and/or metals)	51
Soil	16
Sediments	9
Tailings	7
Landfill Leachate	1

The scale of the studies conducted in the literature is as follows:

Scale of Study	Number of References
Literature/Summary Review	18
Theoretical	4
Bench-scale	42

Pilot-scale	10
Full-scale	10

Application of apatite, other phosphate, or other treatment technologies to a source material composed of municipal solid waste such as the RIM present in OU-1 was not found in the literature. Also, a discussion with Department of Energy (DOE) personnel familiar with the use of apatite/phosphate-based treatment technologies at the Hanford Site indicated that because of the potential disruption in chemical equilibrium within the solid waste matrix, application of an apatite/phosphate media could result in an *increase* in the leaching potential of radionuclides instead of the reduction in leaching potential that would be intended by such an application.

3. APPLICATION OF APATITE TO SOLID MEDIA

The application of apatite or other treatment technologies to a material composed of municipal solid waste such as the RIM present in OU-1 was not found in the references reviewed. With respect to the 32 references where there was theoretical discussion of, or testing using, solid media (*i.e.*, soil, sediments, and tailings), a summary of the applications found in the literature that considered use of apatite or other technologies for removal from or immobilization of radionuclides or other metals within solid media is provided below.

- Several references (Bostick, undated; Conca and Wright, undated; Conca et al., 2000; CRC Press, 2000; Francis and Nancharaiah, 2014; Martinez et al., 2014; Raicevic et al., 2006; Shoesmith, 1984; Washington Department of Ecology, 2007; Wright and Conca, 2003; and Wright et al., 2004) were a literature or summary review or theoretical discussion of the potential applications of the use of apatite for removal of metals and radionuclides in groundwater and soil;

- Misra (2001) conducted bench-scale testing for removal of radium from soil using chemical washing followed by flotation;

- Arey et al. (1999) performed batch studies to assess the ability of hydroxyapatite to immobilize uranium in sediments;

- Burnett (1987) evaluated leaching of radium, uranium, radon, and polonium from phosphate mineral samples that contained radionuclides;

- Chen et al. (1997) conducted bench studies of sorption and desorption of lead, cadmium, and zinc from a contaminated soil reacted with apatite;

- Dacheux et al. (2000) performed bench studies of the behavior of thorium phosphate diphosphate (TPD) during acid leaching;

- Fyfe et al. (1981) showed in bench studies that collophanitic apatite removed uranium, thorium and barium from a synthetic solution and fixation of radium with potassium phosphate solutions using dry and wet tailings;

- Kanai (2003) conducted chemical leaching of uranium-series radionuclides in apatite-bearing sediments in bench-scale tests;

- Morrison and Spangler (1992) evaluated various industrial materials, including calcium phosphate, in bench tests for use as a chemical barrier for uranium and molybdenum under a uranium mill tailings repository in Monticello, UT;

- Murray et al. (1983) evaluated adsorption of radium, thorium, and uranium in mine water from tailings onto apatite in bench tests;

- Schumacher (1993) referenced bench mineralogical studies that showed much of the uranium in sediments from the Weldon Spring raffinate pits is associated with apatite;

- Wellman, Pierce, et al. (2008) conducted bench studies to optimize polyphosphate amendment within the Hanford 300 Area sediments vadose zone and capillary fringe to stabilize uranium; and

- Wellman et al. (2007) completed saturated and unsaturated column studies using sediment from the Hanford 300 Area N Process Pond and soluble sodium tripolyphosphate amendments to assess uranium removal.

None of these references involved pilot- or full-scale testing or mention of conditions similar to those requested by EPA in their approval of the Work Plan (*i.e, "…current and projected subsurface geochemical conditions of pH and Eh at the West Lake landfill.").* The materials employed in several of the studies might be considered for stabilization/immobilization of the soil component of the RIM present in OU-1, but the caution expressed by DOE personnel in use of apatite/phosphate-based treatment technologies with a solid waste matrix needs to be considered.

In addition to the above list, phosphate-based treatment has been used to stabilize lead-impacted soils (ITRC, 2010 and EPA, 1997). Chemical stabilization using phosphate for treatment of mining wastes has proven effective at reducing the mobility of divalent heavy metals both ex situ and in situ (ITRC, 2010). Ex situ treatment has been much more widely used than in situ and is usually used in conjunction with off-site disposal (ITRC, 2010). In situ phosphate treatment has been tested and proven effective but not widely implemented at stabilizing lead-contaminated soil in residential settings (ITRC, 2010).

4. APPLICATION OF APATITE TO GROUNDWATER

With respect to the potential application of apatite or other phosphate-based treatment technologies to groundwater, nine references provide information regarding full-scale operation of systems where apatite is employed to remove or sorb/sequester radionuclides and/or metals from groundwater or mining waters. Uranium and strontium-90 are the radionuclides being removed via these full-scale groundwater systems; there is no mention of radium and thorium, the predominant radionuclides associated with West Lake Landfill OU-1. The full-scale systems include:

- CETCO manufactures a permeable composite of geotextiles and apatite (Reactive Core Mat ™) that can be used as a subaqueous cap for sediments or for embankment seepage control to control leaching of certain metals;
- Conca and Wright (2006) describe a permeable reactive barrier (PRB) filled with Apatite II™ that removes zinc, lead, and cadmium from mine drainage in shallow alluvial groundwater in Idaho;
- A PRB with bone char apatite removes uranium from groundwater in Fry Canyon, UT (EPA, 2000). Fuller et al. (2003) conducted x-ray analysis of apatite samples from this PRB to determine the method of uranium sequestration within the PRB;
- A zeolite media PRB in groundwater at the DOE West Valley, NY site removes 77% of strontium-90 (DOE, 2013);
- DOE (2012) reported that apatite was injected into wells to expand a groundwater barrier in soil at the DOE Hanford facility, although the location and the nature of the contaminant(s) removed by the barrier were not specified in the reference; and
- The Washington Department of Ecology (2010 and undated), Heart of America NW (2010), and Vermeul et al. (2009) describe injection of apatite or apatite-forming minerals into the saturated and unsaturated zones of the Hanford N-100 Area plume along the shoreline of the Columbia River, forming a PRB that removes strontium-90.

Although no applications of removal of radium from groundwater were identified in the literature, at least two of the papers explicitly address sequestration of radium by apatite/phosphate in mine wastes based on the results of bench tests including:

> Fyfe W.S., Brown, J.R., Kronberg, E.I, and Murray, F., 1981, Immobilization of U-Th-Ra in Mine Wastes by Mineralization, Ontario Geological Survey Open-File Report 5366, Grant #28; and

Murray, F.H., Brown, J.R., Fyfe, W.S., and Kronberg, B.I., 1983, Immobilization of U-Th-Ra in Mine Wastes by Phosphate Mineralization. *Canadian Mineralogist*, Vol. 21, pp. 607-610.

It is also important to note that radium is an alkaline earth element. As such, it is in the same group as two other metals (strontium and barium). As an alkaline earth element, radium shares many geochemical properties with other elements of that group. It substitutes for/co-precipitates with strontium and barium in carbonates and sulfates, and it has a strong affinity for adsorption to various mineral surfaces because of its charge-to-ionic radius ratio. With regard to the alkaline earth elements, Kathren (1984) shows the cation exchange sequence for soils as follows:

$$Sr^{2+} < Ra^{2+} < Ca^{2+} < Mg^{2+}$$

There is no reason to expect that radium reacts unlike other alkaline earth elements in either surface-water or groundwater systems. Clearly, the two papers by Fyfe and others (1981) and Murray and others (1983) underscore the strong sorption affinity of radium for apatite-phosphate surfaces.

Removal of radionuclides from water is typically performed using ex situ techniques such as ion exchange or precipitation for radium removal, ion exchange for uranium removal, or air stripping/granular activated carbon for radon removal. EPA recently indicated that groundwater conditions at West Lake Landfill will be addressed in a separate operable unit (OU-3). Therefore, further evaluations of potential application of apatite/phosphate-based or other treatment technologies may be evaluated as part of the RI/FS for a groundwater OU.

5. CONCLUSIONS AND RECOMMENDATIONS

An extensive review of literature on the application and case studies of apatite/phosphate based technology, including applications for treatment of radionuclides, did not identify any known application of such technologies for immobilization of radium or radionuclide occurrences in a MSW matrix. Several theoretical/literature reviews and bench-scale study references relative to use of apatite/phosphate-based treatment for removal/immobilization of radionuclides and/or metals in solid media were identified; however, no studies were identified relative to immobilization of radium or relative to stabilization of radionuclides in MSW or under geochemical conditions similar to those present in an MSW landfill.

The effectiveness or potential effectiveness of in situ application of apatite/phosphate-based treatment technology for stabilization of radium or stabilization of radionuclides in MSW has not been demonstrated. Application of this technology also requires efficient delivery methods to control the effectiveness, implementability and cost of such an in situ treatment technique (EPA, 1993). The highly heterogeneous nature of the composition, chemistry and particle size of MSW would greatly affect the delivery of any injected liquid or mixing of any solid material. The variable organic content of MSW would also affect the binding ability and long-term stability of any stabilization/solidification technique. Therefore, large uncertainties exist with respect to the potential implementability of in situ stabilization using apatite/phosphate-based materials. In addition, questions have been raised regarding potential adverse effects of the application of such a technology to MSW, including a potential to increase the solubility of chemicals and/or radionuclides.

Given the lack of demonstrated application of this technology for either radium or MSW, implementation uncertainties and the potential for adverse effects, this technology is not considered appropriate for treatment of OU-1 soil/waste material. Therefore, it is recommended that this technology be eliminated from further consideration relative to treatment of OU-1 soil/waste. Since the results of this initial technical implementability screening indicate that apatite/phosphate-based treatment technologies are not applicable to the waste/source materials associated with OU-1, the further evaluations of the application of such technologies to MSW with respect to effectiveness, implementability, and cost prescribed in EPA's *Guidance for Conducting Remedial Investigations and Feasibility Studies Under CERCLA* (EPA, 1988) were not conducted.

Literature reports of several full-scale projects where apatite/phosphate-based treatment was used for removing/immobilization of uranium and strontium-90 in groundwater were identified. However, no case studies, testing or evaluations of such technologies for removal of radium or thorium from groundwater were identified. However, because it is an alkaline earth element, radium shares similar geochemical properties with other alkaline earth elements that are readily sequestered by various apatite-phosphate technologies. The absence of citations about radium sequestration from groundwater should be balanced by consideration of what is known about the geochemical properties of radium and other alkaline earth elements. EPA has indicated that groundwater conditions will be addressed in a separate operable unit. Therefore, further evaluations of potential application of apatite/phosphate-based or other treatment technologies may be evaluated as part of the RI/FS for a groundwater OU.

Technical Memorandum: Evaluation of Potential "Hot Spot" Occurrences and Removal of Radiologically-Impacted Soil

Technical Memorandum:
Evaluation of Potential "Hot Spot" Occurrences and Removal
For Radiologically Impacted Soil
West Lake Landfill OU-1

INTRODUCTION

The West Lake Landfill Superfund Site consists of two Operable Units (OUs). OU-1 includes two areas, Areas 1 and 2, where radiologically impacted soil was mixed with municipal solid waste and construction debris. A Remedial Investigation report was previously completed for OU-1 (EMSI, 2000). A draft Feasibility Study (FS) for OU-1 was developed to identify and evaluate potential remedial alternatives for the radiological impacted soils present in Areas 1 and 2 of the West Lake Landfill (EMSI, 2000).

During the development of remedial alternatives in the FS, the Respondents considered the potential presence of "hot spots" and evaluated the potential need for consideration of hot spot removal as part of the remedial alternative evaluation for OU-1. For CERCLA municipal landfills such as the West Lake Landfill, EPA guidance indicates that "hot spots consist of highly toxic and/or highly mobile material and present a potential principal threat to human health and the environment." (EPA, 1993). EPA guidance further states that "Hot spots at CERCLA municipal landfills typically consist of liquids, buried drums or other highly mobile and toxic wastes that are present in a discreet area or portion of the landfill." As discussed further below, the FS concluded that there are no "hot spots" in the West Lake Landfill, and that implementation of hot spot removal as part of the remedial actions that may be undertaken for OU-1 is not warranted based on EPA guidance. Moreover, it is not practical and could potentially result in unacceptable risks to remediation workers. The additional risks involved in a hot spot removal significantly exceed the risks of leaving the waste in place as proposed in the FS.

The EPA Remedial Project Manager (RPM) requested at a June 14, 2000 meeting that the OU-1 Respondents prepare a separate technical memorandum addressing the evaluation of potential hot spots and possible removal of such hot spots. Specifically, at the June 14, 2000 meeting among EPA, a representative of the Missouri Department of Natural Resources (MDNR) and the Respondents, the EPA RPM requested the Respondents to submit a technical memorandum to evaluate potential "hot spot" removal of radiologically impacted soil present in Areas 1 and 2 of OU – 1. This memorandum responds to that request. A quantitative evaluation of the costs and risks associated with hot spot removal, however, requires that the Respondents proceed on the basis of an assumed volume of hot spot material. Because there are no "hot spots" at the West Lake Landfill, no basis exists to make such an assumption. Therefore, any such assumption would be arbitrary and the estimated costs would not be meaningful. Accordingly, the analysis that follows is primarily a qualitative analysis.

In evaluating the applicability of hot spot removal for OU-1, this memorandum summarizes the applicability to OU-1 of the use of the presumptive remedy of containment for municipal landfill sites; provides a discussion from EPA guidance regarding how "hot spots" should be addressed; includes a quantitative discussion of potential risks to workers and the public associated with excavation of filled material and removal of radionuclides within Areas 1 and 2 that are dispersed within soil material that is further dispersed throughout the overall, heterogeneous matrix of municipal refuse, construction and demolition debris and other, non-impacted soil materials; and concludes that hot spot removal for OU-1 at the West Lake Landfill is not appropriate based on EPA guidance documents.

APPLICATION OF THE PRESUMPTIVE REMEDY TO OU-1 AT THE WEST LAKE LANDFILL

Section 300.430(a)(iii)(B) of the NCP contains the expectation that engineering controls, such as containment, will be used for waste that poses a relatively low long-term threat or where treatment is impracticable (USEPA, 1990). The preamble to the NCP identifies municipal landfills as a type of site where treatment of the waste may be impracticable because of the size and heterogeneity of the contents (55 FR 8704). Waste in CERCLA landfills usually is present in large volumes and is a heterogeneous mixture of municipal waste frequently co-disposed with industrial and/or hazardous waste. Because treatment is usually impracticable, EPA generally considers containment to be the appropriate response action, or the "presumptive remedy" for the source areas of municipal landfill sites (USEPA, 1993).

Based upon EPA experiences at numerous CERCLA municipal landfill sites and as a result of the initiatives undertaken as part of the Superfund Accelerated Cleanup Model, EPA has initiated use of and developed presumptive remedies for specific types of sites, contaminants, or both, including CERCLA municipal landfill sites. Based upon its experience, EPA has identified the following components for consideration in applying the presumptive remedy approach for source area containment at CERCLA municipal landfills:

- Landfill cap;
- Source area ground-water control to contain plume;
- Leachate collection and treatment;
- Landfill gas collection and treatment, and/or
- Institutional controls to supplement engineering controls.

EPA's Remedial Project Manager (RPM) has previously indicated that the presumptive remedy for CERCLA municipal landfills should be considered in the development and evaluation of potential remedial alternatives for the West Lake Landfill. Occurrences of radionuclides within Areas 1 and 2 are dispersed within soil material that is further dispersed throughout the overall, heterogeneous matrix of municipal refuse, construction and demolition debris and other, non-impacted soil materials. Consequently, excavation of the radiologically impacted materials for possible ex situ treatment techniques or possible offsite disposal is impracticable.

Of the source containment options identified by EPA as part of the presumptive remedy approach, the landfill cap and institutional control actions are considered applicable to Areas 1 and 2. As there is no plume of groundwater contamination associated with Areas 1 and 2, source area ground-water control is not applicable to Areas 1 and 2. With the possible exception of the intermittent and highly localized seep in the southwestern portion of Area 2, no leachate discharge has been identified from Areas 1 and 2. Based on the results of the radon monitoring conducted during the RI, collection or control of radon gas is not considered necessary.

The West Lake Landfill site had been used for waste disposal and other industrial activities for approximately 50 years and will remain a waste disposal site forever regardless of any remedial actions that may be taken with respect to OU-1. As discussed in the FS, existing institutional controls will continue to be used to control current and future use of the entire West Lake Landfill and Areas 1 and 2 in particular. Institutional controls along with the existing landfill fencing are used to control and restrict access to Areas 1 and 2. The existing institutional controls consist of a deed restriction recorded in June 1997 against the entire landfill prohibiting residential use and groundwater use. An additional deed restriction was recorded in January 1998 restricting construction of buildings and underground utilities and pipes within Areas 1 and 2. These deed restrictions cannot be terminated without the written approval of the current owners, EPA, and MDNR. Also, as part of all alternatives in the FS except the No Action alternative, additional institutional controls in the form of additional deed restrictions would be implemented to prevent or control potential future uses of Areas 1 and 2 not currently expressly restricted. For example, construction of office buildings or other commercial or industrial structures could be performed in areas adjacent to Areas 1 and 2 in the future. As part of this type of development, there may be an expectation of using Areas 1 and 2 for ancillary uses such as landscaping, parking lots, or open storage. An additional deed restriction would be implemented to prevent use of Areas 1 and 2 for parking lots, employee recreation, open storage or other similar uses that may be ancillary to future commercial/industrial development of the landfill areas outside of Areas 1 and 2.

In addition, irrespective of the radiologically impacted soil present in Areas 1 and 2 of OU – 1, the entire West Lake Landfill Superfund Site is a landfill and will remain a landfill. The Missouri Solid Waste Rules (10 CSR 80) require owners of solid waste disposal areas, as part of closure of the solid waste disposal area to "Submit evidence to the department that a notice and covenant running with the land has been recorded with the recorder of deeds in the county where the sanitary landfill is located. The notice and covenant shall specify ….. that the use of the land in any manner which interferes with closure plans, and post-closure plans filed with the department, is prohibited."

EPA GUIDANCE ON "HOT SPOTS" RELATIVE TO RADIOLOGICALLY IMPACTED SOIL AT THE WEST LAKE LANDFILL

EPA's guidance for presumptive remedies at CERCLA municipal landfill sites also describes issues to be addressed related to the characterization and possible treatment of "hot spots". Hot spots consist of highly toxic and/or highly mobile material and present a potential principal threat to human health or the environment (EPA, 1993). EPA guidance (EPA, 1993) states that "The overriding question is whether the combination of the waste's physical and chemical characteristics and volume is such that the integrity of the new containment system will be threatened if the waste is left in place." Neither the physical nor chemical characteristics of the radiologically impacted materials in OU-1 will affect the integrity of a containment system (landfill cover). Consequently, the answer to the overriding question in determining whether hot spot removal is appropriate is that the integrity of the containment remedy presumed by EPA for CERCLA municipal landfill sites would not be threatened if the radiologically impacted soil is left in place. Hot spot removal is not considered appropriate for OU-1.

Excavation or treatment of hot spots is generally practicable where the waste type or mixture of wastes is in a discrete, accessible location of a landfill. EPA guidance provides that a hot spot should be large enough that its remediation would significantly reduce the risk posed by the overall site, but small enough that it is reasonable to consider removal or treatment.

EPA guidance identifies four questions to be addressed to determine whether characterization and/or treatment of hot spots are warranted. All four of these questions must be answered in the affirmative to support a decision to characterize and treat hot spots. These four questions are as follows:

- Does evidence exist to indicate the presence and approximate location of waste?
- Is the hot spot known to be principal threat waste?
- Is the waste in a discrete accessible part of the landfill?
- Is the hot spot known to be large enough that its remediation will reduce the threat posed by the overall site but small enough that it is reasonable to consider removal (e.g., 100,000 cubic yards or less)?

As to the first question, reliable historic information regarding the location of the radionuclide materials does not exist. Surveys and sampling conducted as part of the RI have identified the general locations of the occurrences of the radiologically impacted materials within Areas 1 and 2. Results of the RI investigations indicate that the radiologically impacted soil material is dispersed both laterally and vertically throughout the overall, heterogeneous matrix of municipal refuse, construction and demolition debris, and unimpacted soil cover material. Therefore, the exact location, boundaries and extent of the radiologically impacted materials cannot be precisely located and can only be approximately estimated. The answer to the first question is no.

Principal threat wastes addressed by the presumptive remedy guidance for which hot spot remediation is most likely to be appropriate include liquids, areas contaminated with high concentrations of toxic compounds, and highly mobile material. As defined in A Guide to Principal Threat and Low Level Threat Wastes (USEPA, 1991), principal threat wastes are "those source materials considered to be highly toxic or highly mobile that generally cannot be reliably contained or would present a significant risk to human health or the environment should exposure occur." "Source material" is defined in the principal threat guidance as material that includes or contains hazardous substances, pollutants or contaminants that act as a reservoir for migration of contamination to groundwater, to surface water, to air, or act as a source for direct exposure. The guidance also states that no threshold level of toxicity/risk has been established to equate to a "principal threat", but that where toxicity and mobility of source material combine to pose a potential risk of 1×10^{-3} or greater, generally treatment alternatives should be considered.

Radiologically impacted materials at the West Lake Landfill occur in soil material, not liquids. The radionuclides are not present in a discrete area, unit, or zone of the landfill. Specifically the radiologically impacted soils are interspersed within the overall landfill matrix at depths ranging from the ground surface to over 20 feet below ground surface, making retrieval of the impacted materials impracticable. Similarly, the types of radionuclides, and the presence of the radionuclides in soil material, result in the radionuclide occurrences at the West Lake Landfill being generally immobile. Therefore, in accordance with the guidance, the radiologically impacted materials are not considered a source material or principal threat waste. The answer to the second question is no.

As the radionuclides are not located in a discrete area, the answer to the third question is no and hot spot removal is not appropriate. This conclusion is further supported by answering the "overriding question" of "whether the combination of the waste's physical and chemical characteristics and volume is such that the integrity of the new containment system will be threatened if the waste is left in place." (EPA, 1993) As discussed in the OU-1 Feasibility Study (EMSI, 2000), no significant risk to human health or the environment would occur if a containment remedy were implemented at the Site. There is no indication of widespread or even significant groundwater contamination from the radionuclides at the site and evaluations conducted as part of the RI report indicate that potential future migration is limited and should not significantly affect the underlying or downgradient groundwater quality. The only significant exposure pathways identified by the Baseline Risk Assessment (BRA) entailed gamma radiation from or direct contact with radiologically impacted soil. Both of these exposure pathways could be addressed through installation of a containment (landfill cover) system, supplemented with institutional controls. Radiologically impacted soil at the West Lake Site can easily and effectively be isolated through installation of a cover system. Neither the physical nor chemical characteristics of the radiologically impacted materials will affect the integrity of the landfill cover. Consequently, the answer to the overriding question in determining whether hot spot removal is appropriate is that the integrity of the containment remedy presumed by EPA for CERCLA municipal landfill sites would not be threatened if the radiologically impacted soil is left in place, and hot spot removal is not appropriate.

As to the fourth question, removal of the radionuclides would require excavation of approximately 130,000 cubic yards of refuse containing radiologically impacted soil plus an additional approximately 120,000 cubic yards of refuse present as overburden that is not expected to contain radiologically impacted soil. This combined volume of over approximately 250,000 cubic yards is substantially greater than the volume of 100,000 cubic yards or less that is considered by the guidance to be reasonable for removal. Therefore, excavation and offsite disposal of refuse containing radiologically impacted soil is not reasonable and not warranted.

As stated above, EPA guidance identifies four questions to be addressed to determine whether characterization and/or treatment of hot spots are warranted and all four of these questions must be answered in the affirmative to support a decision to characterize and treat hot spots. None of the four questions can be answered in the affirmative. Therefore, hot spot removal is not appropriate and not warranted. This conclusion is consistent with the evaluation of the overriding question of whether hot spot removal is necessary to protect the integrity of the containment remedy presumed by EPA for CERCLA municipal landfill sites.

THEORETICAL LIMITATIONS TO REMOVAL AND OFFSITE DISPOSAL OF RADIOLOGICALLY IMPACTED SOIL

As previously discussed, the radiologically impacted materials are present in soil material contained within the overall matrix of municipal refuse, construction and demolition debris and unimpacted soil, making retrieval of the impacted materials impracticable. Despite the conclusion that hot spot removal is not necessary, and to address EPA's request that hot spot removal scenarios be discussed, the following paragraphs present theoretical limitations to removal and off-site disposal of radiologically impacted soils. Excavation and offsite disposal of radiologically impacted soil would require either:

1. Excavation, loading, offsite transport via truck, offloading and transfer to railcars, and subsequent transport to an out-of-state facility for disposal of large volumes of municipal solid waste and debris that contains both radiologically impacted and non-impacted soil; or alternatively

2. Excavation of the solid waste and soil followed by screening or other physical separation of the radiologically impacted soil from the solid waste followed by loading, offsite transport via truck, off-loading and transfer to railcars, and

subsequent transport to an out-of-state facility for disposal of the soil fraction along with re-disposal onsite of the excavated refuse and debris.

If the first option were to be selected, a large volume, greater than the 100,000 cubic yard upper limit suggested in EPA's CERCLA Municipal Landfill guidance document as reasonable to consider for removal, would need to be excavated and sent for offsite disposal. This transportation would likely involve highway trucks travelling approximately 20 miles one-way or more on local roads and highways involving approximately 5,000 to 10,000 truck trips. The material would subsequently be transferred from the trucks to railcars at a truck/rail car transfer facility that would need to be built in the St. Louis area, and subsequent rail transport to an out-of-state disposal facility located in Utah, Texas, Washington or elsewhere. The rail distance to the Utah facility would be approximately 1,600 miles.

Under the second option, the radiologically impacted soil fraction would, to the maximum extent possible, initially be separated from the excavated refuse to reduce the total volume of material to be disposed offsite. Separation of the soil from the refuse and debris would be performed using a grizzly and/or vibrating screen. The act of screening would result in mixing of the more highly impacted soil with less impacted and unimpacted soil. After screening, the impacted soil would be loaded into trucks for transport to the rail transfer facility and subsequent rail transport to an out-of-state disposal facility as described above.

Removal of the highest levels of radionuclide occurrences from Area 2 would not eliminate the need for or reduce the scope of potential containment measures. It is unrealistic to assume that all of the radiologically impacted soil could be removed as portions of this soil occur at depths of 10 to 20 feet below ground surface. Consequently, there would still exist a need for implementation of a containment system. Furthermore, even if excavation of the refuse, debris and soil with attendant offsite disposal of impacted soil and refuse were to occur, it would not alleviate the need for installation of a cover system, as the site would still remain a municipal solid waste landfill. After completion of the excavation activities, the excavations would have to be filled and/or graded out, the surface of the landfill would have to be graded and contoured and a new cover system would have to be installed. Consequently, excavation of the radiologically impacted soil does not eliminate the need for or reduce the scope of installation of a new landfill cover system.

In contrast, containment measures, such as capping, can effectively address both the potential areas of higher levels of radionuclides as well as the overall extent of radionuclides in Areas 1 and 2 and the adjacent solid wastes.

POTENTIAL RISKS ASSOCIATED WITH REMOVAL OF RADIONUCLIDES

Excavation and offsite disposal of radiologically impacted soil pose potential risks to both remediation workers and other onsite workers as well as to the public at large.

Screening of the refuse to separate out the soil material would be a difficult, time- and labor-consuming and potentially hazardous activity. Screening of refuse material would necessitate use of personnel to remove plastic, wood and other material that would otherwise clog or foul the screens. In addition to the physical hazards associated with such activities (i.e., slip, trip and fall, crushing or laceration from contact with moving machinery, etc.) such workers would also be exposed to elevated levels of gamma radiation for which practical, effective protection could not be readily and/or effectively implemented.

Regardless of which two options for removal and offsite disposal of radiologically impacted soil might be considered, extensive amounts of earth and waste moving activity would be required with the attendant potential for accidents between equipment and/or between equipment and workers. Transport of wastes by such a large number of truck and railcar trips poses real and potentially severe potential for additional accidents or possibly deaths. Moving any material across the country increases the amount of traffic on public roads and railways.

It is estimated that approximately 130,000 cubic yards of material would have to be removed from the site if off-site disposal is implemented. Assuming 20 cubic yards per truckload, moving this volume of material would require approximately 6,500 trips by heavy trucks on public roads. If the distance to the railhead were 20 miles, then the total round trip distance by the hauling fleet on public roads would be about 260,000 miles. Data collected between 1988 and 1997 by the National Highway Traffic Safety Administration demonstrates that, on average, for every 1,168,310 miles a heavy truck travels on public roads, there is a chance of an accident involving injury or death (NHTSA, 1998). This implies that the risk of an injury or fatality from hauling materials to a railhead from the site is about 2×10^{-1}.

Using the same volume assumptions discussed above, it would require about 1,300 gondola railcar loads of material, or approximately 13 100-car trainloads. If the round trip rail distance to a disposal facility is about 3,200 miles, the total rail distance for off-site disposal is about 42,000 miles. Data collected by the Federal Railroad Administration shows that between 1994 and 1998, for every 42,720 miles traveled by rail, an accident involving an injury or death occurred (USDOT), 1999). This implies that the risk of injury or death for the rail transport portion of the alternative is approximately 1.0.

The combined transportation risk for this alternative is on the order of 1.0, indicating that there is a real risk of injuring or killing someone every time off-site disposal is selected as an option. This combined transportation risk is in contrast with the current no-action risk from the Baseline Risk Assessment (Auxier, 2000) of 4×10^{-5} to the groundskeeper. Future risks to a hypothetical storage yard worker, assuming no engineered controls were placed on the site were calculated to be 4×10^{-4}. Thus, the combined transportation risk of disposing the material offsite is between 2,500 and 25,000 times greater than the calculated risk associated with leaving the material in place under a no-action scenario. Implementation of a capping alternative would reduce the onsite risk and therefore further increase the difference in risks associated with offsite disposal compared to an onsite remedy.

Furthermore, due to the nature of the loading and transfer activities, it is expected that the truck and train transport would occur using covered loads; however, in the event of an accident, a real possibility exists that soil and refuse material could be exposed or possibly spilled on the roadways or rail lines.

The West Lake Landfill, as with all municipal landfills, also contains methane gas. Consequently, excavation of refuse at the landfill poses a potential risk for explosion hazard and creation of a landfill fire. In addition to potential physical and radiological hazards posed by excavation, regardless of the approach selected, removal of the impacted soil would require excavation of large volumes of the landfill and handling of large volumes of partially decomposed refuse with the attendant odor emissions. Although there are techniques that can be considered to reduce odor emissions, it unrealistic to assume that all of the odors that would emanate from decades-old refuse could be controlled. Consequently, it is highly likely that odor emissions would affect nearby properties and be a source of nuisance, discomfort and possibly even illness to adjacent receptors.

CONCLUSION

The overriding question posed by EPA guidance regarding potential hot spot removal is whether the combination of the waste's physical and chemical characteristics and volume is such that the integrity of the new containment system will be threatened if the waste is left in place. Neither the physical nor chemical characteristics of the radiologically impacted materials will affect the integrity of the landfill cover. Consequently, the answer to the overriding question in determining whether hot spot removal is appropriate is that the integrity of the containment remedy presumed by EPA for CERCLA municipal landfill sites would not be threatened if the radiologically impacted soil is left in place, and hot spot removal is not appropriate.

Further characterization, evaluation, and excavation/offsite disposal of potential "hot spots" within Areas 1 and 2 is not warranted. The radiologically impacted materials in Areas 1 and 2 are dispersed throughout the soil material contained within the overall matrix of municipal refuse, construction and demolition debris and unimpacted soil, cannot be classified as a "hot spot" as defined in EPA guidance, and are not known to be a principal threat waste as defined by EPA. The chemical and physical characteristics of the impacted material will not adversely affect the cap called for by the presumptive remedy. Furthermore, based on the evaluation of the four factors identified by EPA, implementation of "hot spot" removal as part of the remedial actions that may be undertaken for OU-1 at the West Lake Landfill is not considered practical. In addition, as discussed above, excavation and subsequent screening of the refuse containing the soils with the elevated levels of radionuclides could potentially:

1. Expose remediation workers to physical hazards, gamma exposure and other unacceptable risks which, in the case of gamma exposure, could not easily or possibly effectively be mitigated with standard protective equipment;

2. Expose remediation workers, other onsite employees, offsite workers, and possible other nearby receptors to nuisance or noxious odor emissions; and

3. Expose remediation workers, onsite employees and the public to increased risks associated with potential accidents and possible spills associated with transportation by truck and rail of the excavated material to a distant offsite facility.

Consequently, excavation and offsite disposal of "hot spot" material is not considered practical, effective, beneficial or safe for Operable Unit 1 at the West Lake Landfill. Furthermore, excavation and offsite disposal of the radiologically impacted soil is inconsistent with EPA's established approach for CERCLA Municipal Landfill Sites, published EPA guidance and the National Contingency Plan.

Quick Reference Fact Sheet

Since Superfund's inception in 1980, the remedial and removal programs have found that certain categories of sites have similar characteristics, such as types of contaminants present, types of disposal practices, or how environmental media are affected. Based on information acquired from evaluating and cleaning up these sites, the Superfund program is undertaking an initiative to develop presumptive remedies to accelerate future cleanups at these types of sites. The presumptive remedy approach is one tool of acceleration within the **Superfund Accelerated Cleanup Model (SACM).**

Presumptive remedies are preferred technologies for common categories of sites, based on historical patterns of remedy selection and EPA's scientific and engineering evaluation of performance data on technology implementation. The objective of the presumptive remedies initiative is to use the program's past experience to streamline site investigation and speed up selection of cleanup actions. Over time presumptive remedies are expected to ensure consistency in remedy selection and reduce the cost and time required to clean up similar types of sites. Presumptive remedies are expected to be used at all appropriate sites except under unusual site-specific circumstances.

This directive establishes **containment** as the presumptive remedy for CERCLA municipal landfills. The framework for the presumptive remedy for these sites is presented in a streamlining manual entitled *Conducting Remedial Investigations/Feasibility Studies for CERCLA Municipal Landfill Sites,* February 1991 (OSWER Directive 9355. 3-11). This directive highlights and emphasizes the importance of certain streamlining principles related to the scoping (planning) stages of the remedial investigation/feasibility study (RI/FS) that were identified in the manual. The directive also provides clarification of and additional guidance in the following areas: (1) the level of detail appropriate for risk assessment of source areas at municipal landfills and (2) the characterization of hot spots.

BACKGROUND

Superfund has conducted pilot projects at four municipal landfill sites[1] on the National Priorities List (NPL) to evaluate the effectiveness of the manual *Conducting Remedial Investigations/Feasibility Studies for CERCLA Municipal Landfill Sites* (hereafter referred to as "the manual") as a streamlining tool and as the framework for the municipal landfill presumptive remedy. Consistent with the National Oil and Hazardous Substances Pollution Contingency Plan (or NCP), EPA's expectation was that containment technologies generally would be appropriate for municipal landfill waste because the volume and heterogeneity of the waste generally make treatment impracticable. The results of the pilots support this expectation and demonstrate that the manual is an effective tool for streamlining the RI/FS process for municipal landfills.

Since the manual's development, the expectation to contain wastes at municipal landfills has evolved into a presumptive remedy for these sites.[2] Implementation of the streamlining principles outlined in the manual at the four pilot sites helped to highlight issues requiring further clarification, such as the degree to which risk assessments can be streamlined for source areas and the characterization and remediation of hot spots. The pilots also demonstrated the value of focusing streamlining efforts at the scoping stage, recognizing that the biggest savings in time and money can be realized if streamlining is incorporated at the beginning of the RI/FS process. Accordingly, this directive addresses those issues identified during the pilots and highlights streamlining opportunities to be considered during the scoping component of the RI/FS.

[1] Municipal landfill sites typically contain a combination of principally municipal and to a lesser extent hazardous wastes.

[2] See EPA Publication 9203.1-021, SACM Bulletins, *Presumptive Remedies for Municipal Landfill Sites,* April 1992, Vol. 1, No. 1, and February 1993, Vol. 2, No. 1, and SACM Bulletin *Presumptive Remedies,* August 1992, Vol. 1, No. 3.

Finally, while the primary focus of the municipal landfill manual is on streamlining the RI/FS, Superfund's goal under SACM is to accelerate the entire cleanup process. Other guidance issued under the municipal landfill presumptive remedy initiative identifies design data that may be collected during the RI/FS to streamline the overall response process for these sites (see Publication No. 9355.3-18FS, *Presumptive Remedies: CERCLA Landfill Caps Data Collection Guide*, to be published in October 1993).

CONTAINMENT AS A PRESUMPTIVE REMEDY

Section 300.430(a)(iii)(B) of the NCP contains the expectation that engineering controls, such as containment, will be used for waste that poses a relatively low long-term threat where treatment is impracticable. The preamble to the NCP identifies municipal landfills as a type of site where treatment of the waste may be impracticable because of the size and heterogeneity of the contents (55 FR 8704). Waste in CERCLA landfills usually is present in large volumes and is a heterogeneous mixture of municipal waste frequently co-disposed with industrial and/or hazardous waste. Because treatment usually is impracticable, EPA generally considers containment to be the appropriate response action, or the "presumptive remedy," for the source areas of municipal landfill sites.

The presumptive remedy for CERCLA municipal landfill sites relates primarily to containment of the landfill mass and collection and/or treatment of landfill gas. In addition, measures to control landfill leachate, affected ground water at the perimeter of the landfill, and/or upgradient ground-water that is causing saturation of the landfill mass may be implemented as part of the presumptive remedy.

The presumptive remedy does not address exposure pathways outside the source area (landfill), nor does it include the long-term ground-water response action. Additional RI/FS activities, including a risk assessment, will need to be performed, as appropriate, to address those exposure pathways outside the source area. It is expected that RI/FS activities addressing exposure pathways outside the source generally will reconducted concurrently with the streamlined RI/FS for the landfill source presumptive remedy. A response action for exposure pathways outside the source (if any) may be selected together with the presumptive remedy (thereby developing a comprehensive site response) or as an operable unit separate from the presumptive remedy.

Highlight 1 identifies the components of the presumptive remedy. Response actions selected for individual sites will include only those components that are necessary, based on site-specific conditions.

Highlight 1: Components of the Presumptive Remedy: Source Containment

- Landfill cap;
- Source area ground-water control to contain plume;
- Leachate collection and treatment;
- Landfill gas collection and treatment; and/or
- Institutional controls to supplement engineering controls.

The EPA (or State) site manager will make the initial decision of whether a particular municipal landfill site is suitable for the presumptive remedy or whether a more comprehensive RI/FS is required. Generally, this determination will depend on whether the site is suitable for a streamlined risk evaluation, as described on page 4. The community, state, and potentially responsible parties (PRPs) should be notified that a presumptive remedy is being considered for the site before work on the RI/FS work plan is initiated. The notification may take the form of a fact sheet, a notice in a local newspaper, and/or a public meeting.

Use of the presumptive remedy eliminates the need for the initial identification and screening of alternatives during the feasibility study (FS). Section 300.430(e)(1) of the NCP states that, "... the lead agency shall include an alternatives screening step, <u>when needed</u>, (emphasis added) to select a reasonable number of alternatives for detailed analysis."

EPA conducted an analysis of potentially available technologies for municipal landfills and found that certain technologies are routinely and appropriately screened out on the basis of effectiveness, feasibility, or cost (NCP Section 300.430(e)(7)). (See Appendix A to this directive and "Feasibility Study Analysis for CERCLA Municipal Landfills," September 1993 available at EPA Headquarters and Regional Offices.) Based on this analysis, the universe of alternatives that will be analyzed in detail may be limited to the components of the containment remedy identified in Highlight 1, unless site-specific conditions dictate otherwise or alternatives are considered that were not addressed in the FS analysis. The FS analysis document, together with this directive, must be included in the administrative record for each municipal landfill presumptive remedy site to support elimination of the initial identification and screening of site-specific alternatives. Further detailed and comprehensive supporting materials (e.g., FS reports included in analysis, technical reports) can be provided by Headquarters, as needed.

While the universe of alternatives to address the landfill source will be limited to those component identified in Highlight 1, potential alternatives that may exist for each component or combinations of components may be evaluated in the detailed analysis. For example, one component of the presumptive remedy is source area ground-water control. If appropriate, this component may be accomplished in a number of ways, including pump and treat, slurry walls, etc. These potential alternatives may then be combined with other components of the presumptive remedy to develop a range of containment alternatives suitable for site-specific conditions. Response alternatives must then be evaluated in detail against the nine criteria identified in Section 300.430(e)(9) of the NCP. The detailed analysis will identify site-specific ARARs and develop costs on the basis of the particular size and volume of the landfill.

EARLY ACTION AT MUNICIPAL LANDFILLS

EPA has identifies the presumptive remedy site categories as good candidates for early action under SACM. At municipal landfills, the upfront knowledge that the source area will be contained may facilitate such early actions as installation of a landfill cap or a ground-water containment system. Depending on the circumstances, early actions may be accomplished using either removal authority (e.g., non-time-critical removal actions) or remedial authority. In some cases, it may be appropriate for an Engineering Evaluation/Cost Analysis to replace part or all of the RI/FS if the source control component will be a non-time-critical removal action. Some factors may affect whether a specific response action would be better accomplished as a removal or remedial action including the size of the action, the associated state cost share, and/or the scope of O&M. A discussion of these factors is contained in *Early Action and Long-term Action Under SACM- Interim Guidance* Publication No. 9203.1-05I, December 1992.

SCOPING A STREAMLINED RI/FS UNDER THE PRESUMPTIVE REMEDY FRAMEWORK

The goal of an RI/FS is to provide the information necessary to: (1) adequately characterize the site; (2) define site dynamics; (3) define risks; and (4) develop the response action. As discussed in the following sections, the process for achieving each of these goals can be streamlined for CERCLA municipal landfill sites because of the upfront presumption that landfill contents will be contained. The strategy for streamlining each of these areas should be developed early (i.e., during the scoping phase of the RI/FS).

1. Characterizing the Site

The use of existing data is especially important in conducting a streamlined RI/FS for municipal landfills. Characterization of a landfill's contents is not necessary or appropriate for selecting a response action for these sites except in limited cases; rather, existing data are used to determine whether the containment presumption is appropriate. Subsequent sampling efforts should focus on characterizing areas where contaminant migration is suspected, such as leachate discharge areas or areas where surface water runoff has caused erosion. It is important to note that the decision to characterize hot spots should also be based on existing information, such as reliable anecdotal information, documentation, and/or physical evidence (see page 6).

In those limited cases where no information is available for a site, it may not be advisable to initiate use of the presumptive remedy until some data are collected. For example, if there is extensive migration of contaminants from a site located in an area with several sources, it will be necessary to have some information about the landfill source in order to make an association between on-site and off-site contamination.

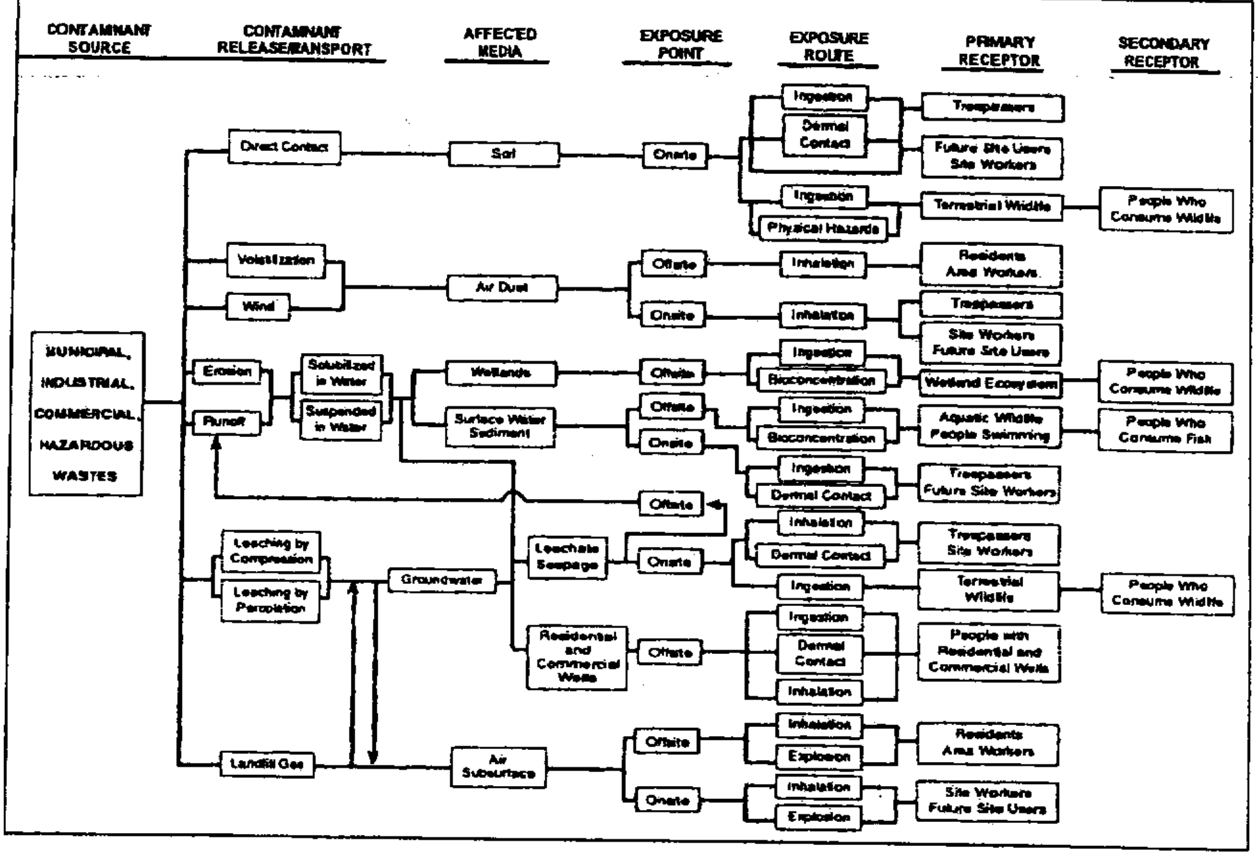
Sources of information of particular interest during scoping include records of previous ownership, state files, closure plans, etc., which may help to determine types and sources of hazardous materials present. In addition, a site visit is appropriate for several reasons, including the verification of existing data, the identification of existing site remediation systems, and to visually characterize wastes (e.g., leachate seeps). Specific information to be collected is provided in Sections 2.1 through 2.4 of the municipal landfill manual.

2. Defining Site Dynamics

The collected data are used to develop a conceptual site model, which is the key component of a streamlined RI/FS. The conceptual site model is an effective tool for defining the site dynamics, streamlining the risk evaluation, and developing the response action. Highlight 2 presents a generic conceptual site model for municipal landfill. The model is developed before any RI field activities are conducted, and its purpose is to aid in understanding and describing the site and to present hypotheses regarding:

- The suspected sources and types of contaminants present;
- Contaminant release and transport mechanisms;

Highlight 2: Generic Conceptual Site Model



- Rate of contaminant release and transport (where possible);
- Affected media;
- Known and potential routes of migration; and
- Known and potential human and environmental receptors.

After the data are evaluated and a site visit is completed, the contaminant release and transport mechanisms relevant to the site should be determined. The key element in developing the conceptual site model is to identify those aspects of the model that require more information to make a decision about response measures. Because containment of the landfill's contents is the presumed response action, the conceptual site model will be of most use in identifying areas beyond the landfill source itself that will require further study, thereby focusing site characterization away from the source area and on areas of potential contaminant migration (e.g., ground water or contaminated sediments).

3. Defining Risks

The municipal landfill manual states that a streamlined or limited baseline risk assessment will be sufficient to initiate response action on the most obvious problems at a municipal landfill (e.g., ground water, leachate, landfill contents, and landfill gas). One method for establishing risk using a streamlined approach is to compare contaminant concentration levels (if available) to standards that are potential chemical-specific applicable or relevant and appropriate requirements (ARARs) for the action. The manual states that where established standards for one or more contaminants in a given medium are clearly exceeded, remedial action generally is warranted[3]

It is important to note, however, that based on site-specific conditions, an active response is not required if ground-water contaminant concentrations exceed chemical-specific standards but the site risk is within the Agency's acceptable risk range (10^{-4} to 10^{-6}). For example, if it is determined that the release of

[3]See also OSWER Directive 9355.0-30, *Role of the Baseline Risk Assessment in Superfund Remedy Selection Decisions*, April 22, 1991, which states that if MCLs or non-zero MCLGs are exceeded, [a response] action generally is warranted.

contaminants from a particular landfill is declining, and concentrations of one or more ground-water contaminants are at or barely exceed chemical-specific standards, the Agency may decide not to implement an active response. Such a decision might be based on the understanding that the landfill is no longer acting as a source of ground-water contamination, and that the landfill does not present an unacceptable risk from any other exposure pathway.

A site generally will not be eligible for a streamlined risk evaluation if ground-water contaminant concentrations do not clearly exceed chemical-specific standards or the Agency's accepted level of risk, or other conditions do not exist that provide a clear justification for action (e.g., direct contact with landfill contents resulting from unstable slopes). Under these circumstances, a quantitative risk assessment that addresses all exposure pathways will be necessary to determine whether action is needed.

Ultimately, it is necessary to demonstrate that the final remedy addresses all pathways and contaminants of concern, not just those that triggered the remedial action. As described in the following sections, the conceptual site model is an effective tool for identifying those pathways and illustrating that they have been addressed by the containment remedy.

Streamlined Risk Evaluation Of The Landfill Source

Experience from the presumptive remedy pilots supports the usefulness of a streamlined risk evaluation to initiate an early response action under certain circumstances. As a matter of policy, <u>for the source area</u> of municipal landfills, a quantitative risk assessment that considers all chemicals, their potential additive effects, etc., is not necessary to establish a basis for action if ground-water data are available to demonstrate that contaminants clearly exceed established standards or if other conditions exist that provide a clear justification for action.

A quantitative risk assessment also is not necessary to evaluate whether the containment remedy addresses all pathways and contaminants of concern associated with the source. Rather, all potential exposure pathways can be identified <u>using the conceptual site model and compared to the pathways addressed by the containment presumptive remedy.</u> Highlight 3 illustrates that the containment remedy addresses all exposure pathways associated with the source at municipal landfill sites.

Finally, a quantitative risk assessment is not required to determine clean-up levels because the type of cap will be determined by closure ARARs, and ground water that is extracted as a component of the presumptive remedy will be required to meet discharge limits, or other standards for its disposal. Calculation of cleanup levels for ground-water contamination that has migrated away from the source will not be accomplished under the presumptive remedy, since such contamination will require a conventional investigation and a risk assessment.

Highlight 3: Source Contaminant Exposure Pathways Addressed by Presumptive Remedy

1. Direct contact with soil and/or debris prevented by landfill cap;
2. Exposure to contaminated ground water within the landfill area prevented by ground-water control;
3. Exposure to contaminated leachate prevented by leachate collection and treatment; and
4. Exposure to landfill gas addressed by gas collection and treatment, as appropriate.

Streamlining the risk assessment of the source area eliminates the need for sampling and analysis to support the calculation of current or potential future risk associated with direct contact. It is important to note that because the continued effectiveness of the containment remedy depends on the integrity of the containment system, it is likely that institutional controls will be necessary to restrict future activities at a CERCLA municipal landfill after construction of the cap and associated systems. EPA has thus determined that it is not appropriate or necessary to estimate the risk associated with future residential use of the landfill source, as such use would be incompatible with the need to maintain the integrity of the containment system. (Long-term waste management areas, such as municipal landfills, may be appropriate, however, for recreational or other limited uses on a site-specific basis.) The availability and efficacy of institutional controls should be evaluated in the FS. Decision documents should include measures such as institutional controls to ensure the continued integrity of such containment systems whenever possible.

Areas of Contaminant Migration

Almost every municipal landfill site has some characteristic that may require additional study, such as leachate discharge to a wetland or significant surface water run-off caused by drainage problems. These migration pathways, as well as ground-water contamination that has migrated away from the source, generally will require characterization and a more comprehensive risk assessment to determine whether action is warranted beyond the source area and, if so, the type of action that is appropriate.

While future residential use of the landfill source area itself is not considered appropriate, the land adjacent to landfills is frequently used for residential purposes. Therefore, based on site-specific circumstances, it may be appropriate to consider future residential use for ground water and other exposure pathways when assessing risk from areas of contaminant migration.

4. Developing the Response Action

As a first step in developing containment alternatives, response action objectives should be developed on the basis of the pathways identified for action in the conceptual site model. Typically, the primary response action objectives for municipal landfill sites include:

<u>Presumptive Remedy</u>

- Preventing direct contact with landfill contents;
- Minimizing infiltration and resulting contaminant leaching to ground water;
- Controlling surface water runoff and erosion;
- Collecting and treating contaminated ground water and leachate to contain the contaminant plume and prevent further migration from source area; and
- Controlling and treating landfill gas.

<u>Non-Presumptive Remedy</u>

- Remediating ground water;
- Remediating contaminated surface water and sediments; and
- Remediating contaminated wetland areas.

As discussed in Section 3, "Defining Risks," the containment presumptive remedy accomplishes all but the last three of these objectives by addressing all pathways associated with the source. Therefore, the focus of the RI/FS can be shifted to characterizing the media addressed in the last three objectives (contaminated ground water, surface water and sediments, and wetland areas) and on collecting data to support design of the containment remedy.

Treatment of Hot Spots

The decision to characterize and/or treat hot spots is a site-specific judgement that should be based on the consideration of a standard set of factors. Highlight 4 lists questions that should be answered before making the decision to characterize and/or treat hot spots. The overriding question is whether the combination of the waste's physical and chemical characteristics and volume is such that the integrity of the new containment system will be threatened if the waste is left in place. This question should be answered on the basis of what is <u>known</u> about a site (e.g., from operating records or other reliable information). An answer in the affirmative to all of the questions listed in Highlight 4 would indicate that it is likely that the integrity of the containment system would be threatened, or that excavation and treatment of hot spots would be practicable, and that a significant reduction in risk at the site would occur as a result of treating hot spots. EPA expects that few CERCLA municipal landfills will fall into this category; rather, based on the Agency's experience, the majority of sites are expected to be suitable for containment only, based on the heterogeneity of the waste, the lack of reliable information concerning disposal history, and the problems associated with excavating through refuse.

The volume of industrial and/or hazardous waste co-disposed with municipal waste at CERCLA municipal landfills varies from site to site, as does the amount of information available concerning disposal history. It is impossible to fully characterize, excavate, and/or treat the source area of municipal landfills, so uncertainty about the landfill contents is expected. Uncertainty by itself does not call into question the containment approach. However, containment remedies must be designed to take into account the possibility that hot spots are present in addition to those that have been identified and characterized. The presumptive remedy must be relied upon to contain landfill contents and prevent migration of contaminants. This is accomplished by a combination of measures, such as a landfill cap combined with a leachate collection system. Monitoring will further ensure the continued effectiveness of the remedy.

The following examples illustrate site-specific decision making and show how these factors affect the decision whether to characterize and/or treat hot spots.

Examples of Site-Specific Decision Making Concerning Hot Spot Characterization/ Treatment

<u>Site A</u>

There is anecdotal information that approximately 200 drums of hazardous waste were disposed of at this 70-acre former municipal landfill, but their location and contents are unknown. The remedy includes a landfill cap and ground-water and landfill gas treatment.

A search for and characterization of hot spots is not supported at Site A based on the questions listed in

Highlight 4: Characterization of Hot Spots

If all of the following questions can be answered in the affirmative, it is likely that characterization and/or treatment of hot spots is warranted:

1. Does evidence exist to indicate the presence and approximate location of waste?
2. Is the hot spot known to be principal threat waste?*
3. Is the waste in a discrete, accessible part of the landfill?
4. Is the hot spot known to be large enough that its remediation will reduce the threat posed by the overall site but small enough that it is reasonable to consider removal (e.g., 100,000 cubic yards or less)?

*See *A Guide to Principal Threat and Low Level Threat Wastes*, November 1991, Superfund Publication No. 9380.3-06FS.

Highlight 4: (1) no reliable information exists to indicate the location of the waste; (2) the determination of whether the waste is principal threat waste cannot be made since the physical/chemical characteristics of the wastes are unknown; (3) since the location of the waste is unknown, the determination of whether the waste is in a discrete accessible location cannot be made; (4) in this case, the presence of 200 drums in a 70-acre landfill is not considered to significantly affect the threat posed by the overall site. Rather, the containment system will include measures to ensure its continued effectiveness (e.g., monitoring and/or leachate collection) given the uncertainty associated with the landfill contents and suspected drums.

__Site B__

Approximately 35,000 drums, many containing hazardous wastes, were disposed of in two drum disposal units at this privately owned 80-acre inactive landfill, which was licensed to receive general refuse. The site is divided into two operable units. The remedy for Operable Unit 1 (OU 1) is incineration of drummed wastes in the two drum disposal units. The remedy for OU2 consists of treatment of contaminated ground water and leachate and containment of treatment residuals (from OU 1) and remaining landfill contents, including passive gas collection and flaring.

Treatment of landfill contents is supported at Site B because all of the questions in Highlight 4 can be answered in the affirmative: (1) existing evidence from previous investigations and sampling conducted by the state (prior to the RI) indicated the presence and approximate location of wastes; (2) the wastes were considered principal threat wastes because they were liquids and (based on sampling) were believed to contain contaminants of concern; (3) the waste is located in discrete accessible parts of the landfill; and (4) the waste volume is large enough that its remediaton will significantly reduce the threat posed by the overall site.

CLOSURE REQUIREMENTS

Subtitle D

In the absence of Federal Subtitle D closure regulations, State Subtitle D closure requirements generally have governed CERCLA response actions at municipal landfills as applicable or relevant and appropriate requirements (ARARs). New Federal Subtitle D closure and post-closure care regulations will be in effect on October 9, 1993 (56 FR 50978 and 40 CFR 258)[1] State closure requirements that are ARARs and that are more stringent than the Federal requirements must be attained or waived

The new Federal regulations contain requirements related to construction and maintenance of the final cover, and leachate collection, ground-water monitoring, and gas monitoring systems. The __final cover__ regulations will be __applicable__ requirements for landfills that received household waste after October 9, 1991. EPA expects that the final cover requirements will be applicable to few, if any, CERCLA municipal landfills, since the receipt of household wastes ceased at most CERCLA landfills before October 1991. Rather, the substantive requirements of the new Subtitle D regulations generally will be considered __relevant and appropriate__ requirements for CERCLA response actions that occur after the effective date.

Subtitle C

RCRA Subtitle C closure requirements may be applicable or relevant and appropriate in certain circumstances. RCRA Subtitle C is __applicable__ if the landfill received waste that is a listed or characteristic waste under RCRA, __and:__

1. The waste was disposed of after November 19, 1980 (effective date of RCRA), or

[1] An extension of the effective date has been proposed but not finalized at this time.

2. The new response action constitutes disposal under RCRA (i.e., disposal back into the original landfill).[7]

The decision about whether a Subtitle C closure requirement is <u>relevant and appropriate</u> is based on a variety of factors, including the nature of the waste and its hazardous properties, the date on which it was disposed, and the nature of the requirement itself. For more information on RCRA Subtitle C closure requirements, see *RCRA ARARs: Focus on Closure Requirements* Directive No. 9234.2-04FS, October 1989.

---

[7]Note that disposal of only small quantity hazardous waste and household hazardous waste does not make Subtitle C applicable.

Notice:

The policies set out in this document are intended solely as guidance to the U.S. Environmental Protection Agency (EPA) personnel; they are not final EPA actions and do not constitute rulemaking. These policies are not intended, nor can they be relied upon, to create any rights enforceable by any party in litigation with the United States. EPA officials may decide to follow the guidance provided in this document, or to act at variance with the guidance, based on an analysis of specific site circumstances. EPA also reserves the right to change the guidance at any time without public notice.

APPENDIX A
TECHNICAL BASIS FOR PRESUMPTIVE REMEDIES

This Appendix summaizes the analysis that EPA conducted of feasibilty study (FS) and Record of Decision (ROD) data from CERCLA municipal landfill sites which led to the establishment of containment as the presumptive remedy for these sites. The objectve of the study was to idenffy those technologies that are consistently included in the remedies selected, those that are consistently screened out, and to identify the basis for their elimination. Results of this analysis support the decision to eliminate the initial technology identification and screening steps on a site-specific basis for this site type. The technical review found that certain technologies are appropriately screened out based on effectiveness, implementability, or excessive costs.

The methodology for this analysis entailed reviewing the technology identification and screening components of the remedy selection process for a representative sample of municipal landfill sites. The number of times each technology was either screened out or selected in each remedy was compiled. A detailed discussion of the methodology used is provided below.

METHODOLOGY

<u>Identification of Sites for Feasibility Study Analysis</u>

Of the 230 municipal landfill sites on the NPL, 149 sites have had a remedy selected for at least one operable unit. Of the 149 sites, 30 were selected for this study on a random basis, or slightly greater than 20 percent. The sites range in size from 8.5 acres to over 200 acres and are located primarily in Regions 1,2,3, and 5. This geographical distribution approximates the distribution of municipal landfills on the NPL.

<u>Technology Secrning and Remedial Alternative Analysis</u>

The FS analysis involved a review of the technology identification and screening phase, including any pre-screening steps, followed by a review of the detailed analysis and comparative analysis phases. Information derived from each review was documented on site-specific data collection forms, which are available for evaluation as part of the Administrative Record for this presumptive remedy directive. The review focused on the landfill source contamination only; ground-water technologies and alternatives were not included in the analysis.

For the screening phase, the full range of technologies considered was listed on the data collection forms, along with the key reasons given for eliminating technologies from further consideration. These reasons were categorized according to the screening criteria: cost, effectiveness, or implementability. The frequency with which specific reasons were given for eliminating a technology from further consideration was then tallied and compiled into a screening phase summary table.

For the detailed analysis and comparative analysis, information on the relative performance of each technology/alternative with respect to the seven NCP criteria was documented on the site-specific data collection forms. The advantages and disadvantages associated with each clean-up option were highlighted. In some cases, a technology was combined with one or more technologies into one or more alternatives. The disadvantages of a technology/alternative were then compiled into a detailed analysis/comparative analysis summary table, under the assumption that these disadvantages contributed to non-selection. All summary tables are available for review as part of the Administrative Record.

APPENDIX A
TECHNICAL BASIS FOR PRESUMPTIVE REMEDIES (continued)

RESULTS

The information from the technology screening and remedial alternative analyses is provided in Table 1. It demonstrates that containment (the presumptive remedy), was chosen as a component of the selected remedy at all thirty of the sites analyzed. No other technologies or treatments were consistently selected as a remedy or retained for consideration in a remedial alternative. However, at eight of the thirty sites, there were circumstances where technologies were included in the selected remedy to address a site-specific concern, such as principal threat wastes. These technologies are included in the column entitled "Tech. Not Primary Component of Alternative"[1] in Table 1 and include incineration at two sites, waste removal and off-site disposal at two sites, soil vapor extraction at two sites, and bioreclamation at one site.

Leachate collection and gas collection systems were also tracked as part of the detailed analysis and comparison of remedial alternatives. These types of systems generally were not considered as remediation technologies during the screening phases. At fifteen sites, leachate collection was selected as part of the overall containment remedy. At seventeen sites, gas collection systems were selected as part of the overall containment remedy.

This analysis supports the decision to eliminate the initial technology identification and screening step for municipal landfill sites. On a site-specific basis, consideration of remediation technologies may be retained as needed.

[1] This column title is used for record-keeping purposes only and is not meant to imply that these treatment technologies are not considered important components of the selected remedies.

[1] The study was conducted on 30 RODs and their corresponding FSs.
[2] This does not include the no-action or institutional control only alternatives. No RODs selected either of these as remedies.
[3] FSs and RODs may contain more than one criterion for screening or non-selection of technology. Also, some FSs did not fully explain the criteria for screening out a technology. Thus, the totals for screening and non-selection criteria are not equal to the number of FSs and RODs considered.
[4] Information on State and community concerns was not included in this analysis because FSs do not contain this information and RODs generally only reference supporting documentation (i.e., State concurrence letter and responsiveness summary).

EPA

A Guide to Principal Threat and Low Level Threat Wastes

Office of Emergency and Remedial Response
Hazardous Site Control Division OS-220W

Quick Reference Fact Sheet

The National Oil and Hazardous Substances Pollution Contingency Plan (NCP) promulgated on March 8, 1990 states that EPA expects to use "treatment to address the principal threats posed by a site, wherever practicable" and "engineering controls, such as containment, for waste that poses a relatively low long-term threat." (40 CFR Section 300.430(a)(1)(iii).) These expectations, derived from the mandates of CERCLA §121 and based on previous Superfund experience, were developed as guidelines to communicate the types of remedies that the EPA generally anticipates to find appropriate for specific types of wastes. Although remedy selection decisions are ultimately site-specific determinations based on an analysis of remedial alternatives using the nine evaluation criteria, these expectations help to streamline and focus the remedial investigation/feasibility study (RI/FS) on appropriate waste management options. **This guide explains considerations that should be taken into account in categorizing waste for which treatment or containment generally will be suitable and provides definitions, examples, and ROD documentation requirements related to waste that constitute a principal or low level threat.** EPA makes this categorization of waste as principal or low level threat waste after deciding whether to take remedial action at a site. The "Interim Final Guidance on Preparing Superfund Decision Documents," (EPA/624/1-87/90, October 1990) and "A Guide to Developing Superfund Records of Decision" (Publication 9335.3-02FS-1, May 1990) provide additional information on ROD documentation.

NCP Expectations

EPA established general expectations in the NCP (40 CFR 300.430(a)(1)(iii)) to inform the public of the types of remedies that EPA has found to be appropriate for certain types of waste in the past and anticipates selecting in the future. These expectations (see Highlight 1) provide a means of sharing collected experience to guide the development of cleanup options. They reflect EPA's belief that certain source materials are addressed best through treatment because of technical limitations to the long-term reliability of containment technologies, or the serious consequences of exposure should a release occur. Conversely, these expectations also reflect the fact that other source materials can be safely contained and that treatment for all waste will not be appropriate or necessary to ensure protection of human health and the environment, nor cost effective.

Identifying Principal and Low Level Threat Wastes

The concept of principal threat waste and low level threat waste as developed by EPA in the NCP is to be applied on a site-specific basis when characterizing source material. "Source material" is defined as material that includes or contains hazardous substances, pollutants or contaminants that act as a reservoir for migration of contamination to ground water, to surface water, to air, or acts as a source for direct exposure.

HIGHLIGHT 1: NCP Expectations Involving Principal and Low Level Threat Wastes

EPA expects to:

1. Use treatment to address the principal threats posed by a site, wherever practicable.
2. Use engineering controls, such as containment, for wastes that pose a relatively low long-term threat or where treatment is impracticable.
3. Use a combination of methods, as appropriate, to achieve protection of human health and the environment. In appropriate site situations, treatment of principal threats posed by a site, with priority placed on treating waste that is liquid, highly toxic or highly mobile, will be combined with engineering controls (such as containment) and institutional controls, as appropriate, for treatment residuals and untreated waste.
4. Use institutional controls such as water use and deed restrictions to supplement engineering controls as appropriate for short- and long-term management to prevent or limit exposure to hazardous substances.

Printed on Recycled Paper

Contaminated ground water generally is not considered to be a source material although non-aqueous phase liquids (NAPLs) may be viewed as source materials. The NCP establishes a different expectation for remediating contaminated ground water (i.e., to return usable ground waters to their beneficial uses in a time frame that is reasonable given the particular circumstances of the site). Examples of source and non-source materials are provided in Highlight 2.

> **HIGHLIGHT 2: Examples of Source and Non-Source Materials**
>
> **Source Materials**
>
> - Drummed wastes
> - Contaminated soil and debris
> - "Pools" of dense non-aqueous phase liquids (NAPLs) submerged beneath ground water or in fractured bedrock
> - NAPLs floating on ground water
> - Contaminated sediments and sludges
>
> **Non-Source Materials**
>
> - Ground water
> - Surface water
> - Residuals resulting from treatment of site materials

Principal threat wastes are those source materials considered to be highly toxic or highly mobile that generally cannot be reliably contained or would present a significant risk to human health or the environment should exposure occur. They include liquids and other highly mobile materials (e.g., solvents) or materials having high concentrations of toxic compounds. No "threshold level" of toxicity/risk has been established to equate to "principal threat." However, where toxicity and mobility of source material combine to pose a potential risk of 10^{-3} or greater, generally treatment alternatives should be evaluated.

Low level threat wastes are those source materials that generally can be reliably contained and that would present only a low risk in the event of release. They include source materials that exhibit low toxicity, low mobility in the environment, or are near health-based levels.

Determinations as to whether a source material is a principal or low level threat waste should be based on the inherent toxicity as well as a consideration of the physical state of the material (e.g., liquid), the potential mobility of the wastes in the particular environmental setting, and the lability and degradation products of the material. However, this concept of principal and low level threat waste should not necessarily be equated with the risks posed by site contaminants via various exposure pathways. Although the characterization of some material as principal or low level threats takes into account toxicity (and is thus related to degree of risk posed assuming exposure occurs), characterizing a waste as a principal threat does not mean that the waste poses the primary risk at the site. For example, buried drums leaking solvents into ground water would be considered a principal threat waste, yet the primary risk at the site (assuming little or no direct contact threat) could be ingestion of contaminated ground water, which as discussed above is not considered to be a source material, and thus would not be categorized as a principal threat.

The identification of principal and low level threats is made on a site-specific basis. In some situations site wastes will not be readily classifiable as either a principal or low level threat waste, and thus no general expectations on how best to manage these source materials of moderate toxicity and mobility will necessarily apply. [NOTE: In these situations wastes do not have to be characterized as either one or the other. The principal threat/low level threat waste concept and the NCP expectations were established to help streamline and focus the remedy selection process, not as a mandatory waste classification requirement.]

> **HIGHLIGHT 3: Examples of Principal and Low Level Threat Wastes**
>
> Wastes that generally will be considered to constitute principal threats include, but are not limited to:
>
> - Liquids - waste contained in drums, lagoons or tanks, free product (NAPLs) floating on or under ground water (generally excluding ground water) containing contaminants of concern.
> - Mobile source material - surface soil or subsurface soil containing high concentrations of contaminants of concern that are (or potentially are) mobile due to wind entrainment, volatilization (e.g., VOCs), surface runoff, or sub-surface transport.
> - Highly-toxic source material - buried drummed non-liquid wastes, buried tanks containing non-liquid wastes, or soils containing significant concentrations of highly toxic materials.
>
> Waste that generally will be considered to constitute low level threat wastes include, but are not limited to:
>
> - Non-mobile contaminated source material of low to moderate toxicity - Surface soil containing contaminants of concern that generally are relatively immobile in air or ground water (i.e., non-liquid, low volatility, low leachability contaminants such as high molecular weight compounds) in the specific environmental setting.
> - Low toxicity source material - soil and subsurface soil concentrations not greatly above reference dose levels or that present an excess cancer risk near the acceptable risk range.

Examples of principal and low level threat wastes are provided in Highlight 3.

Risk Management Decisions fo. Principal and Low Level Threat Wastes

The categorization of source material as a principal threat or low level threat waste, and the expectations regarding the use of treatment and containment technologies follows the fundamental decision as to whether any remedial action is required at a site. These determinations, and the application of the expectations, serve as general guidelines and do not dictate the selection of a particular remedial alternative. For example, EPA's experience has demonstrated that highly mobile wastes (e.g., liquids) are difficult to reliably contain and thus generally need to be treated. As such, EPA expects alternatives developed to address highly mobile material to focus on treatment options rather that containment approaches.

However, as stated in the preamble to the NCP (55 FR at 8703, March 8, 1990), there may be situations where wastes identified as constituting a principal threat may be contained rather than treated due to difficulties in treating the wastes. Specific situations that may limit the use of treatment include:

- Treatment technologies are not technically feasible or are not available within a reasonable time frame;
- The extraordinary volume of materials or complexity of the site make implementation of treatment technologies impracticable;
- Implementation of a treatment-based remedy would result in greater overall risk to human health and the environment due to risks posed to workers or the surrounding community during implementation; or.
- Severe effects across environmental media resulting from implementation would occur.

Conversely, there may be situations where treatment will be selected for both principal threat wastes and low level threat wastes. For example, once a decision has been made to treat some wastes (e.g., in an onsite incinerator) economies of scale may make it cost effective to treat all materials including low level threat wastes to alleviate or minimize the need for engineering/institutional controls.

While these expectations may guide the development of appropriate alternatives, the fact that a remedy is consistent with the expectations does not constitute sufficient grounds for the selection of that remedial alternative. The selection of an appropriate waste management strategy is determined solely through the remedy selection process outlined in the NCP (i.e., all remedy selection decisions are site-specific and must be based on a comparative analysis of the alternatives using the nine criteria in accordance with the NCP). Independent of the expectations, selected remedies must be protective, ARAR-compliant, cost-effective, and use permanent solutions or treatment to the maximum extent practicable. Once the final remedy is selected, consistency with the NCP expectations should be discussed as part of the documented rationale for the decision.

ROD Documentation

Declaration

The "Description of the Selected Remedy" section should note whether the remedy is addressing any source materials that constitute "principal" or "low level" threat wastes, or both.

The "Statutory Determinations" section should discuss how the selected remedy satisfies the statutory preference stated in CERCLA §121 to select remedial actions "in which treatment which permanently and significantly reduces the volume, toxicity or mobility of the hazardous substances, pollutants, and contaminants is a principal element." In evaluating this statutory preference, the site manager needs to decide whether treatment selected in the ROD constitutes treatment as a major component of the remedy for that site. Remedies which involve treatment of principal threat wastes likely will satisfy the statutory preference for treatment as a principal element, although this will not necessarily be true in all cases (e.g., when principal threat wastes that are treated represent only a small fraction of the wastes managed through containment). Ground water treatment remedies also may satisfy the statutory preference, even though contaminated ground water is not considered a principal threat waste and even though principal threat source material may not be treated.

Decision Summary

The "Decision Summary" of the ROD should identify those source materials that have been identified as principal threat and/or low level threat wastes, and the basis for these designations. These designations should be provided in the "Summary of Site Characteristics" section as part of the discussion focusing on these source materials that pose or potentially pose a risk to human health and the environment. In addition, the "Description of Alternatives" and the "Selection of Remedy" sections should briefly note how principal and/or low level threat wastes that may have been identified are being managed.

The "Statutory Determinations" section of the ROD should include a discussion of how the statutory preference for treatment as a principal element is satisfied or explain why it is not satisfied, stating reasons in terms of the nine evaluation criteria.

NOTICE: The policies set out in this memorandum are intended solely as guidance. They are not intended, nor can they be relied upon, to create any rights enforceable by any party in litigation with the United States. EPA officials may decide to follow the guidance provided in this memorandum, or to act at variance with the guidance, based on an analysis of specific site circumstances. The Agency also reserves the right to change this guidance at any time without public notice.

TABLE OF CONTENTS

LIST OF TABLES

LIST OF FIGURES

1 REQUIREMENTS DETERMINING COVER THICKNESS

This appendix reviews the basis for the cover design proposed for the three remedial alternatives that leave RIM in place and assesses the theoretical ability of those cover designs to attenuate radon emissions and gamma radiation. The five proposed alternatives listed in the Final Feasibility Study (FFS) are:

- **No Action Alternative –** Required by the National Contingency Plan (NCP) and RI/FS guidance to provide a baseline against which all of the other remedial alternatives are evaluated.
- **The 2008 Record of Decision (ROD)-Selected Remedy**: This remedy would require grading parts of Operable Unit 1 (OU-1) before leaving all radiological-impacted material (RIM) in place. In this remedy, OU-1 would be covered by an engineered cover.
- **Partial Excavation 1,000 pCi/g Alternative**: This remedial alternative would leave residual RIM containing less than 1,000 pCi/g of radium-226 + radium-228 or 1,000 pCi/g of thorium-232 + thorium-230 beneath an engineered cover.
- **Partial Excavation 52.9 pCi/g Alternative**: This remedial alternative would excavate all soil/waste containing combined radium (radium-226 plus radium-228) or combined thorium (thorium-230 plus thorium-232) with activity levels greater than 52.9 pCi/g down to a total depth of 16 feet beneath the 2005 topographic surface.
- **Full Excavation with Off-site Disposal Alternative**: This remedy involves the excavation of all soil containing more than 7.9 pCi/g of radium-226 + radium-228 or 7.9 pCi/g of thorium-232 + thorium-230 and installing an engineered cover over the remaining soil (the "complete rad removal" alternative).

Three of the remedial alternatives evaluated in this FFS involve leaving at least some of the RIM identified at OU-1 in place, and covering OU-1 with an enhanced cover that takes into consideration the presence of radionuclides.

The cover thicknesses of all four remedial alternatives are governed, in part, by the Missouri Department of Natural Resources (MDNR) Solid Waste Regulations and the Uranium Mill Tailings Radiation Control Act (UMTRCA). In particular, the final cover system designs should:

1. Consider the requirements of Missouri's 10 Code of State Regulations (CSR) 80-3.010, to the extent that such additional requirements do not compromise or diminish the performance of appropriate components of the UMTRCA regulations; and,
2. Provide assurance that the design will limit radon emissions consistent with the standards set forth in 40 Code of Federal Regulations (CFR) Part 192 – "Health and Environmental Protection Standards for Uranium and Thorium Mill Tailings," as required by UMTRCA.

The “complete rad removal” remedial alternative involves the complete removal of the RIM from OU-1, eliminating the need for a radiological performance evaluation of its final configuration (Item 2, above).

The analysis described in this appendix first identifies the minimum thickness required to satisfy the MDNR Solid Waste regulations applicable to all remedial alternatives. The resulting MDNR cover and RIM configurations are then evaluated to determine if they will meet the UMTRCA design requirements.

1.1 MDNR DESIGN REQUIREMENTS FOR LANDFILL COVERS

The MDNR Solid Waste regulation 10 CSR 80-3.010(17)(C)(4)(A) is an applicable or relevant and appropriate requirement which mandates that the final cover of existing sanitary landfills without composite liners to include at least two feet (2’) of compacted clay with a coefficient of permeability of 1×10^{-05} centimeters per second) cm/s or less, and be overlaid by at least one foot (1’) of soil capable of sustaining vegetative growth.

Areas 1 and 2 are pre-existing landfills that do not have composite liners. The MDNR has requested the inclusion of a bio-intrusion layer be incorporated in any remedial alternative leaving residual RIM. To accommodate this request, a bio-intrusion layer of rock has been incorporated into the remedy designs of any alternative where RIM is left in place. This rock layer is included in the table of MDNR-based design criteria and discussed in more detail in the following section.

1.2 UMTRCA REQUIREMENTS

Standards for UMTRCA remedial cell performance have been established by the U.S. Environmental Protection Agency (EPA) in 40 CFR Part 192, Subpart A - Standards for the Control of Residual Radioactive Materials from Inactive Uranium Processing Sites and Subpart B - Standards for Cleanup of Land and Buildings Contaminated with Residual Radioactive Materials from Inactive Uranium Processing Sites (collectively, the UMTRCA standards). These standards require that final cover designs limit exposures to radiation and radioactive materials, provide long-term stability, and require minimal maintenance to assure performance standards are met in the future. Control measures would be designed to be effective for up to 1,000 years (to the extent reasonably achievable) and, in any case, for at least 200 years.

The control measures must provide reasonable assurance that releases of radon-222 from residual radioactive material to the atmosphere will not exceed an average release rate of 20 picocuries per square meter per second ($pCi/m^2/s$) averaged over the entire disposal site and over a one-year period or increase the average concentration of radon-222 in air by more than 0.5 picoCuries per liter (pCi/L).

2 DESCRIPTION OF COVER DESIGNS EVALUATED

2.1 GEOMETRY OF COVER AND RIM USED IN SIMULATIONS

The physical dimensions of the cover layers effect both radon flux and gamma emissions from the ground surface. The thickness of the component layers that will make up the proposed final cover systems are listed in Table 1.

2.2 RADIOACTIVE SOURCE LAYER

The minimum cover thicknesses required to meet the UMTRCA standards (as stated above) is directly related to the concentrations of the radionuclides present within the RIM. Radioactive decay of some radionuclides and the subsequent in-growth of others is expected to change the concentrations of the radionuclides within the RIM during the evaluation period. This change must be quantitatively estimated in order to determine the cover thickness required during the period of maximum radioactivity. In particular, the concentration of radium-226 must be estimated before radon emanation or gamma shielding calculations can be made. Table 2 presents the concentrations of thorium-230 and radium-226 in Areas 1 and 2 at one year and 1,000 years after construction of a particular remedial alternative.

3 COVER PERFORMANCE EVALUATION

The updated Baseline Risk Assessment (BRA) (Auxier 2016), which represents the no action alternative, identified direct exposure to gamma radiation as the only viable exposure pathway from OU-1 producing hypothetical risks to receptors that exceed the risk range used by EPA at Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) sites. The ability of the different covers to reduce the amount of gamma radiation passing through them is therefore of interest when evaluating the long-term effectiveness of each assessed remedial alternative.

The updated BRA determined that modeled current and future radon exposures from OU-1 are not expected to result in risks to hypothetical receptors that exceed the CERCLA risk range. However, the effectiveness of each remedial alternative's cover in reducing radon flux levels has been estimated in this appendix to demonstrate compliance with the UMTRCA standard in Section 1.2.

3.1 PERFORMANCE COMPARED TO EXPOSURE RATE CONSTRAINTS

Exposure rates are influenced by time, distance and shielding. The values used to represent each of these parameters and the reasons for their selection are presented below:

Time: The exposure time used to estimate the exposure rates from OU-1 after construction of a given remedial alternative was 52.7 h/y (8.5 h/d x 6.2 d/y). This is the same exposure time used in the updated BRA (Auxier 2016) to describe the portion of time the reasonably maximally exposed (RME) individual, a grounds keeper, who spends time maintaining the surface of OU-1 each year.

Distance: Exposure rates are typically assessed at one meter above the ground's surface, and the exposure rates evaluated in this evaluation were all calculated at this height. This reflects the observation that the majority of the body's blood forming and filtering organs (marrow, liver and spleen) are typically located near this height in adult humans.

Shielding: In this case, shielding will be afforded by engineered covers placed over any residual RIM remaining within OU-1. The amount of shielding will depend on the thickness of those covers. The total thicknesses of the different covers are presented in Table 1. An aggregate density of 1.6 grams per cubic centimeter was used for all covers.

The exposure rates for the cover design evaluated were calculated using a computer program called MicroShield® produced by Grove Engineering. These calculations were performed as part of the human health risk assessment presented in Appendix H to the FFS. The exposure rates from that evaluation are reproduced in Table 3.

3.2 COVER PERFORMANCE COMPARED TO RADON-222 FLUX CONSTRAINTS

While some radon-222 gas (radon) produced by radioactive decay of radium-226 in soil are typically released to the atmosphere, recent radon flux measurements in OU-1 indicate radon fluxes from OU-1 currently meet UMTRCA standards. These fluxes can be further reduced by placing a cover over the radium-bearing materials. Such a cover will slow the escape of free radon, allowing its rapid decay rate[1] to deplete the amount of activity that reaches the surface. The percent reduction in radon emissions achieved by each remedial alternative's cover was calculated using the approach described in NUREG/CR-3533[2]. This handbook (NUREG/CR-3533) offers a set of one-dimensional, steady-state radon diffusion calculations to determine radon concentrations and fluxes in a multi-layer system. These equations form the basis of the computer program RAECOM (Radiation Attenuation Effectiveness and Cover Optimization with Moisture effects). A copy of this program has been modified to run as a web-based calculator.[3] The RAECOM web-based calculator requires user input that describes the physical and radiological characteristics of the source and overlying cover layers. Specific types of information required include:

- radon emanation coefficient of material in the source layer,
- porosity and moisture content of materials in the source and each layer of the cover (see Table 4), and
- thicknesses of the source layer and the overlying cover layers (see Table 1).

Site-specific values for many of these variables were not available when the 2011 Supplemental Feasibility Study (SFS) (EMSI 2011) was prepared. The calculations have been updated in this appendix using recently available data and field observations.

---

1 The half-life of radon-222 is 3.8 days (Kocher 1981). Only half of the produced radon-222 remains after 3.8 days. After 7.6 days, a quarter of the original radon-222 remains. Delaying its emergence by 30 days reduces the radon to just 0.4% of its original concentration.

2 "Radon Attenuation Handbook for Uranium-Mill Tailings Cover Design, NUREG/CR-3533." Battelle Pacific Northwest Labs., Richland, WA. April 1984.

3 The RAECOM web calculator used in this evaluation is hosted at http://www.wise-uranium.org/ctc.html.

3.2.1 Determination of Site-Specific Radon Emanation Coefficient

Most of the radon-222 produced by radium-226 in a particle of soil remains captured within that particle. A small fraction of the produced radon escapes into the void space surrounding the particle, and this radon emanation fraction is called the radon emanation coefficient in this evaluation. A site-specific value for this fraction was not determined in 2011, but it was assumed to be similar to uranium mill tailings based on its origin and processing history.

After submittal of the 2011 SFS, EPA Region 7 commissioned the Southwest Research Institute to perform radon emanation tests on six soil samples collected at the West Lake Landfill Site in Bridgeton, Missouri. In April 2016, Tetra Tech, Inc. submitted an analytical report produced by Southwest Research Institute and a Level IV Data Validation Report to EPA Region 7 containing radon emanation results from the six samples (Tetra Tech 2016). These six samples were exposed to a variety of thermal conditions where samples were heated to different temperatures for various durations and then subjected to radon-222 emanation tests. After careful homogenization, sample aliquots of approximately 50 grams were analyzed via gamma spectrometry (Tetra Tech 2016).

Radon emanation results from the six samples in the Southwest Research Institute and accompanying laboratory report are presented in Table 5, along with their associated statistics. Column headers in Table 5 include the thermal test conditions evaluated. The radon emanation results in the "None, As Received" column of Table 5 were selected to determine a representative radon emanation coefficient because the samples were not heated prior to analyses and therefore most closely resembled the "in-situ" condition of RIM in OU-1. The arithmetic mean of the emanation coefficients reported for the six unheated samples in the "None, As Received" column is 0.18, which is slightly less than the value of 0.2 used in the 2011 SFS. It is comparable to emanation coefficients reported in other studies (Sakoda, et al. 2011). The RAECOM default value for emanation fraction of 0.2 was used on all cover layers.

3.2.2 Porosity and Moisture Content of Soil

The values for soil porosity and percent moisture used to represent the source layer and various components of the cover layers required by the evaluated remedial alternatives are presented in Table 4. These are consistent with those used in the cover evaluations presented in the 2011 SFS, with one exception. The porosity of the source layer was reduced from the original value of 0.671 to 0.4 to reflect observations made in the field regarding the effect that more than 30 years of decomposition and settling has had on the municipal solid waste in the landfill.

3.2.3 Cover Thicknesses over RIM in Areas 1 and 2

The cover for the three remedial alternatives that leave some residual RIM in OU-1 is made up of three layers: soil, clay, and rock; while the cover in the "complete rad removal" alternative is thinner and composed only of soil and clay. Table 1 lists the dimensions of these covers and their component layers.

3.2.4 Reduction in Radon Fluxes as Calculated Using NUREG/CR-3533 (RAECOM)

The radon attenuation characteristics of the cover design described in the previous subsection was evaluated for the RIM in Areas 1 and 2 using a source layer concentration of 1 pCi/g. Using 1 pCi/g will provide a unit value that can be used to test the effectiveness of the cover. The percent reduction of radon flux can then be applied to existing measured radon flux values. The percent reduction of radon flux is listed as the last line of the output file. For these simulations, the average thickness of the RIM layer of 1.3 meters (m) in Area 1 and 2.2 m in Area 2 were taken from Section 6.4 of the RI Addendum (EMSI 2016).

The outputs from these simulations are reproduced in Figure 1 and Figure 2. In these figures, the case name and case-specific input values are listed at the top of each output file and the results of the calculations for the different layers follow the input values.

3.3 MEASURED RADON FLUXES FROM THE BARE SURFACE OF OU-1

In June 2016, radon flux was measured at 124 locations within OU-1, including 35 positions within Area 1 and 76 positions within Area 2.[4] Section 4.13.2.3 of the Remedial Investigation Addendum (RI) (EMSI 2016) contains a description of the collection of the 2016 radon measurements and Section 7.1.1.1 of the RI for a full discussion of the results. Table 6 contains summary statistics for the analytical results, in units of activity flux ($pCi/m^2/s$), as reported by a Multi-Agency Radiological Laboratory Analytical Protocol (MARLAP) compliant analytical lab (Eberline Services). Radon was detected in 68 of the 124 samples collected in 2016. Fluxes ranged from 0 to 1.5 $pCi/m^2/s$, with an arithmetic mean value of approximately 0.06 $pCi/m^2/s$, which is far below the UMTRCA standard of 20 $pCi/m^2/s$.

[4] Thirteen additional, duplicate samples were collected for QA purposes, bringing the total to 124 locations.

3.4 CALCULATION OF RADON FLUXES THROUGH THE COVER AFTER 1,000 YEARS

The maximum theoretical radon fluxes in the first 1,000 years were estimated by dividing the 95% UCL radon fluxes for Areas 1 and 2 (Q), in pCi/m^2/s by the concentrations of radium-226 in Area 1 and 2 soils (C). These ratios of flux per unit of activity were then used to estimate the radon emission from an uncovered source layer in the future assuming radium ingrowth had occurred:

$$Q_{Rn222,1000y,uncovered}\left(\frac{pCi}{m^2 \cdot s}\right) = C_{Ra226,1000y}\left(\frac{pCi}{g}\right) \times \frac{Q_{Rn222,current}\left(\frac{pCi}{m^2 \cdot s}\right)}{C_{Ra226,current}\left(\frac{pCi}{g}\right)}$$

The reduction of radon flux produced by the cover was then calculated using the estimated radon flux in the future and the percent reduction in radon flux as calculated using RAECOM as described in Section 3.2.4:

$$Q_{Rn222,1000y,covered}\left(\frac{pCi}{m^2 \cdot s}\right) = Q_{Rn222,1000y,uncovered}\left(\frac{pCi}{m^2 \cdot s}\right) \times \left(1 - \frac{\%Reduction}{100\%}\right)$$

The results of these calculations are summarized in Table 3. The results indicate that the cover for the three proposed remedial alternatives that leave RIM in place is sufficient to meet the 20 pCi/m^2/s radon flux UMTRCA standard for the RIM in OU-1.

3.5 SUMMARY

The cover proposed as part of the remedial alternatives where RIM is left in place and assessed in this Appendix meet the design requirements of 10 CSR 80-3.010(17)(C)(4)(A). In addition, the cover's ability to attenuate radon flux from any residual RIM left by a particular remedial alternative meets the performance requirements of 40 CFR 192 (UMTRCA).

1 INTRODUCTION

The West Lake Landfill OU-1 Superfund Site (the Site) is a former solid waste landfill that consists of various contiguous and discrete areas historically used for disposal of municipal solid wastes and construction and demolition debris. During past operations at the Site, radiologically-impacted materials (RIM) were placed in two areas (now known as Area 1 and Area 2). The Site also includes the Buffer Zone/Crossroads property. No occupied structures are currently located on Areas 1 and 2.

Land use surrounding the Site is primarily commercial and industrial. A small population of individuals works in the area primarily during the daytime. A few occupied buildings are currently located on the Site, and the Spanish Village residential subdivision is located less than a mile to the south of Area 1 (Figure 1-1).

EPA determined that additional work is necessary to accomplish the objectives of the Remedial Investigation/Feasibility Study (RI/FS) for the OU-1 of the West Lake Landfill. Specifically, Region 7's Statement of Work (SOW) for the RI Addendum and Final Feasibility Study (FFS) identifies the following five alternatives:

> **No Action Alternative–** Required by the National Contingency Plan (NCP) and RI/FS guidance to provide a baseline against which all of the other alternatives are evaluated[1]. This alternative is considered the baseline condition, and theoretical risks associated with this alternative are discussed in detail in the updated Baseline Risk Assessment (BRA) (Auxier 2016);
>
> **Partial Excavation 1,000 pCi/g Alternative –** Excavation of all soil/waste containing combined radium (radium-226 plus radium-228) or combined thorium (thorium-230 plus thorium-232) with activity levels greater than 1,000 pCi/g[2];
>
> **Partial Excavation 52.9 pCi/g Alternative–** Excavation of all soil/waste containing combined radium (radium-226 plus radium-228) or combined thorium (thorium 230 plus thorium-232) with activity levels greater than 52.9 pCi/g down to a total depth of 16 feet beneath the 2005 topographic surface;

---

[1] The SOW identifies an alternative no. 3 "Leaving all RIM in place on-site." Subsequent discussions with EPA indicated that this alternative was the No Action Alternative.

[2] In all cases evaluated in the baseline, thorium-230 and radium-226 (plus decay products) accounted for more than 95% of the risk to the target receptors. Other radionuclides are co-located with radium-226 and thorium-230 and are projected to produce risks to the future groundskeeper of $< 10^{-7}$. Remediation of the thorium-230 and radium-226, by themselves, would reduce the total risks from RIM to below 10^{-4}. Any remediation of radium-226 and thorium-226 would also lower the negligible risks from these ancillary radionuclides still further.

Full Excavation with Off-site Disposal Alternative – Excavation of all soil/waste containing combined radium (radium-226 plus radium-228) or combined thorium (thorium-230 plus thorium-232) with activity levels greater than 7.9 pCi/g (the "complete rad removal" alternative); and

2008 ROD-Selected Remedy – A containment remedy that consists of regrading and installation of a new landfill cover and other remedial components for Area 1 and 2, as well as the consolidation of any radiologically-impacted soil that may remain on the former Ford property (now known as the Buffer Zone and Crossroad Lot 2A2) into the containment areas in Area 1 and 2 prior to placement of additional fill and construction of the new landfill cover.

Each of these alternatives would include monitoring activities that would be performed both during and after construction. This Appendix G was prepared only for purposes of developing cost estimates for the FFS. Therefore, the exact scope and detailed plans of this monitoring would be developed as part of the alternative design effort, but a generic, preliminary description of the scope of potential monitoring activities is necessary to assess the anticipated effectiveness of a monitoring system, as well as to provide the bases for estimated monitoring costs. Actual monitoring networks, locations, analytical parameters, specific instrumentation, and sampling frequencies would be determined during remedial design (RD) of the EPA-selected alternative.

Monitoring activities associated with the four remedial alternatives were divided into three groups for this evaluation: pre-construction baseline monitoring, monitoring activities with a limited duration that would be performed during construction (short-term monitoring), and longer duration monitoring activities performed after alternative construction is complete (long-term monitoring). These three groups of monitoring activities are discussed separately in this evaluation.

The remainder of this Appendix provides a description of the monitoring systems proposed for each alternative. Section 2 contains a description of the pre-construction baseline environmental monitoring program. Section 3 provides a description of short-term monitoring during construction. Section 4 presents a description of the long-term monitoring systems. Section 5 provides a summary of monitoring activities and systems for each alternative.

2 PRE-CONSTRUCTION BASELINE AIR MONITORING

An integrated system of 13 air monitoring stations has been installed at the Site in accordance with EPA guidance. Air monitoring activities began in May 2015 and continue to date. The purpose of the air monitoring program is to provide baseline data regarding air quality prior to implementation of remedial actions. Ultimately, baseline data will be compared to future data obtained during implementation of remedial actions to assess whether such actions contribute to any release of radionuclides or volatile organic compound (VOCs). Twelve of these stations are located around the perimeters of Areas 1 and 2, with two located close to the nearest onsite buildings (the landfill office and the transfer station building). The thirteenth station is located in the southwest corner of the Site, the farthest distance onsite from Areas 1 and 2. These 13 locations were selected to ensure that the monitoring network encompassed Areas 1 and 2, including the Site entrance road and the road through the center of the Site (see Figure 2-1).

An on-site meteorological station (the "met station") measures and logs temperature, barometric pressure, relative humidity, wind speed and direction. The station is located adjacent to the landfill office building (13570 St. Charles Rock Road). Details regarding both the configuration and installation of the air monitoring stations and met station can be found in the RI Addendum and EPA-approved Air Monitoring, Sampling, and QA/QC Plan (EMSI 2016 and A&A 2014).

The monitoring network shown in Figure 2-1 provides coverage around Areas 1 and 2 under all wind direction conditions. The air monitoring and sampling locations near the center of the Site are arranged in a broad line oriented approximately southeast to northwest and parallel to the predominant wind directions. Additional stations are located transverse to this orientation, parallel to the less dominant southwest and northeast wind directions. Stations A1-A6 and A9 bound the perimeter of Area 2. Stations A5, A7, A8, A10 and 11 bound Area 1. Station 12 is located at the southern boundary of the North Quarry pit area. Station A13 is at the southern boundary of the South Quarry pit area, and is located upwind of Areas 1 and 2 (A&A 2014).

Table 2-1 lists the types and quantities of environmental monitoring equipment for the different monitoring stations depicted in Figure 2-1. The table also lists the COPCs measured by the equipment housed at each station.

The sampling and sensor equipment in each monitoring station enclosure operates continuously. The equipment in these stations consists of a high volume air sampler for airborne particulates, a continuous radon monitor (alpha track etch), and an environmental radiation detector called a thermoluminescent dosimeter (TLD). Alpha track etch monitors provide a cumulative measure of radon gas present and allow determination of average radon levels for the sampling period. TLDs measure ambient gamma radiation levels.

Particulates gathered on air sample filters are collected every four weeks (28 days) and analyzed for alpha and beta emitters. Radiation dosimeters and alpha track etch detectors are exchanged and sent for analysis every calendar quarter.

Five of the monitoring stations house continuous passive samplers to monitor for VOCs. VOC monitoring is performed using the Radiello RAD130 chemical adsorbing cartridge diffusion samplers that are left in place for a period of 14 days. The Radiello RAD130 cartridges consist of a stainless steel net cylinder with 100 mesh grid openings and a 5.8 mm diameter, packed with approximately 530 milligrams of activated charcoal. VOCs are trapped by adsorption and recovered by carbon disulfide displacement.

A summary of the types of measurements and frequency is shown in Table 2-2. A summary of the results can be found in the air monitoring quarterly reports (A&A 2015-2016).

3 SHORT-TERM MONITORING

Short-term monitoring activities that would be performed during construction of the alternatives were divided into two categories for this evaluation: (1) health-based monitoring and (2) remediation control monitoring. Data quality objectives are different for each category of short-term monitoring activity. Health-based monitoring activities would be designed to evaluate potential human exposures during construction of a given alternative. Remediation control monitoring would be designed to guide the construction contractor during excavation of the RIM, to ensure that equipment and materials remain free of residual radioactive materials, to characterize excavated material prior to transport and disposal, and to perform final status surveys. Both of these categories of monitoring and survey activities would be limited to the period of construction and are therefore called "short-term monitoring" in this evaluation. Health-based monitoring activities will mirror the EPA-approved monitoring activities performed during Phase I investigations. Plans for these activities will be developed during remedial design and will include procedures for data validation, recordkeeping and QA/QC.

In addition to the short-term monitoring program descriptions, this section also includes a discussion regarding the utility of providing an onsite radiological analytical laboratory for the partial or full excavation alternatives.

3.1 Short-Term Health-Based Monitoring

Potential emissions that might affect the health of workers or the public would be monitored using a combination of fixed and mobile monitors. After potential emissions, exposures, and receptors associated with construction of each alternative were identified, the type and number of fixed and mobile monitors were estimated for each alternative.

Among all four of the remedial alternatives, RIM would be encountered in the same locations in Areas 1 and 2 and similar general construction techniques would be used (See Appendix B). Similar emissions and types of exposure pathways would be produced during construction of all four remedial alternatives. Therefore, the same types of emissions and exposures would be measured by the short-term monitoring programs for all four remedial alternatives. The major difference in monitoring among the four remedial alternatives would be relative differences in the alternative construction duration and resulting magnitude of emissions and exposures that might be generated during implementation of the different alternatives. For example, workers would be required to be in close proximity to the RIM at some point during excavation and/or grading operations for each alternative. While the potential exposure pathways would be the same for each alternative, the amount of time spent near the RIM and the degree to which the RIM would be disturbed would vary. For the ROD-selected remedy, the amount of time spent near the RIM and the degree to which the RIM would be disturbed would be minimal. The amount of time spent near the RIM and the degree to which the RIM would be disturbed would be significant for the two "partial excavation" alternatives. The "complete rad removal" alternative would result in the highest disturbance and amount of time spent near the RIM (See Appendix H).

An evaluation of populations in the area concluded that during construction, each of the four remedial alternatives had the potential to impact similar groups and types of receptors. One group of potential receptors common to all alternatives is remediation workers. Remediation workers could potentially encounter RIM directly or indirectly as part of their duties and would be subject to the project medical monitoring and health and safety programs. A second group of potential receptors common to all alternatives is members of the public (i.e., workers in nearby businesses, Site visitors, and off-property residents) (see Appendix H).

Table 3-1 contains a list of potential exposure pathways and receptors considered for the remedial alternatives. These short-term exposures and associated monitoring efforts are grouped by the program under which they would likely be monitored - either the Occupational Health and Safety Program or the Environmental Monitoring Program. The list of receptors and the types and nature of potential exposures discussed in this Appendix is based on current knowledge of the Site and may change in response to additional information collected during remedial design or construction (see Appendix H).

3.1.1 Health-Based Monitoring During Construction of ROD-Selected Remedy

During construction of the ROD-selected remedy, it is anticipated that most of the RIM would remain covered throughout the construction phase. A smaller volume of radiologically-impacted soil is anticipated to be relocated from the Buffer Zone/Crossroad Property to Area 2. Additionally, some RIM located near the surface of Areas 1 and 2 might be disturbed during cut-and-fill activities associated with regrading of Areas 1 and 2 to achieve final surface slopes. Direct contact with exposed RIM would be expected to be limited to remediation workers in a few areas.

Remediation workers might walk over or operate equipment on the RIM during construction of the ROD-selected remedy, but most of the RIM would remain covered so repeated contact during construction is expected to be limited. Some remediation workers performing activities close to the RIM may encounter elevated radiation levels. Radiation survey technicians and other health and safety personnel would be expected to spend the most time near the RIM and therefore have the greatest risk for exposure. Because only a minimal volume of RIM is anticipated to be disturbed, it was assumed that minimal, if any, measureable airborne exposure levels would be experienced during construction of the ROD-selected remedy (See Appendix H).

It is possible that non-remediation workers would be present in buildings near the Site during construction of the ROD-selected remedy. The nearest residential community is located about 1,000 meters to the south of the portion of the Site where RIM in Areas 1 and 2 might be exposed. It is assumed that these two groups of potential receptors (i.e., non-remediation workers and offsite residents) would not be exposed to radiation directly from the RIM, but might be subject to airborne exposure. Airborne radiological and chemical constituent exposures to these receptors, if any, would be expected to be transient and small. Use of dust control measures at the Site and the distance between the potential receptors and the Site reduces the potential for dust generation and exposure to dust, thereby lessening risk of ingestion or inhalation by on-site or off-property receptors. Specific detailed plans for minimizing fugitive dust during alternative implementation will be generated during remedial design.

Due to operational procedures and engineering controls, any ponding of surface water from precipitation would be expected to be localized and limited in size during construction of this alternative. Any surface water contacting exposed RIM during construction would be collected, sampled, and treated or discharged. Workers handling collected surface water would be required to wear personal protective equipment (PPE) and use appropriate tools and techniques to minimize exposures and risks.

3.1.1.1 Occupational Health and Safety Monitoring

Because exposures to remediation workers are assumed to be much greater than exposures to other individuals, these workers would be subject to more rigorous monitoring than other potential receptors (e.g., continuous monitoring of environmental conditions and dosimetry). If monitoring can demonstrate that risks to remediation workers from radiological and other hazardous constituents are within acceptable levels, then it is safe to assume that risks to less-exposed receptors would also be within acceptable levels.

Airborne emissions from construction activities would be monitored on a daily basis as part of the Occupational Health and Safety Program and in accordance with the existing Radiation Safety Plan for Invasive Subsurface Activities in place at the Site (Auxier 2013). Portable air samplers would be set up in the area of construction and moved as necessary to provide representative samples of air in the breathing zone of workers. These samples would be collected at the end of each work day and checked for total alpha and total beta radiation. In some cases, continuous radon monitors may be included to monitor occupational radon exposures.

Radiation exposure rates in work areas would be periodically monitored with hand-held instrumentation. Any cumulative radiation exposures would be tracked using personal dosimetry badges or electronic dosimeters.

The anticipated types of health and safety monitors (as well as proposed and projected quantities) are presented in Table 3-2. This table also lists the current constituents of potential concern with the understanding that the list may change if new information becomes available during remedy design.

3.1.1.2 Air Monitoring

An integrated system of 13 air monitoring stations (as described in Section 2) has been established around the perimeters of Areas 1 and 2, and near the closest occupied building onsite (Figure 2-1). Air samples collected in the stations would be analyzed for particulates and gases that may be emitted during cut and fill operations, grading for the final cover, and movement of any RIM from the Buffer Zone/Crossroad Property onto Area 2.

The types and quantities of equipment in each weatherproof monitoring station enclosure are listed in Table 2-1. The types of measurements and frequency of collection are summarized in Table 2-2. The table also lists the current constituents of potential concern, with the understanding that this list may change if new information becomes available during remedy design.

These air monitoring stations would be maintained by the onsite radiological protection group (health physics personnel). Buried or overhead electrical power service has already been established at all air monitoring station locations.

3.1.2 Health-Based Monitoring During the "Partial Excavation to 1,000 pCi/g", "Partial Excavation to 52.9 pCi/g", and "Complete Rad Removal" Alternatives

These alternatives would involve partial or complete removal of the RIM in Areas 1 and 2. In all cases, overburden would be excavated and stockpiled onsite, and RIM in Areas 1 and 2 would be excavated and transported to a permitted off-site disposal facility. A smaller volume of RIM would also be excavated from the Buffer Zone/Crossroad Property (Figure 1-1), consolidated with the RIM from Areas 1 and 2, and then transported and disposed at the off-site facility. It is anticipated that only a portion of the RIM would be uncovered at any one time, and the remaining RIM would be covered until it was scheduled to be excavated.

In the analysis of the three excavation alternatives, it was assumed that individuals working near the RIM for a protracted period of time would encounter elevated radiation levels. During construction, remediation workers could walk over RIM or operate equipment on RIM. Other remediation workers would be close to the RIM while surveying. If RIM were to be transported via truck to a truck-to-intermodal trans-loading facility, remediation workers sealing the RIM-filled intermodal containers on the semi-trailers would be close to the RIM during the sealing activity. Dust control measures, along with routine contamination control surveys and air monitoring, would be implemented to keep exposures to airborne radioactive material as low as reasonably achievable.

Of all the potential receptors evaluated, radiation survey technicians and other health and safety personnel are assumed to encounter the highest risk from radioactive and chemical exposures because they would spend the most time near the RIM and would therefore receive the highest potential doses. Highway semi-truck drivers who would routinely haul RIM could potentially accrue a small but measureable dose, as they are assumed to spend a part of their workday near the RIM when loaded semi-trailers are hauled to the truck-to-rail trans-loading facility. Exposures to the public from covered trucks hauling RIM are expected to be transitory and therefore minimal.

Due to operational procedures and engineering controls, any ponding of surface water from precipitation is expected to be localized and limited in size during construction of these alternatives. Any surface water contacting exposed RIM during construction would be collected, sampled, and treated or discharged. Workers handling collected surface water would be required to wear PPE and use appropriate tools and techniques to minimize exposures and risks.

3.1.2.1 Occupational Health and Safety Monitoring

Because exposures to remediation workers are assumed to be expected to be much greater than exposures to other individuals, these workers would be subject to more rigorous monitoring than other potential receptors (e.g., continuous monitoring of environmental conditions and dosimetry). If monitoring can demonstrate that risks to remediation workers from radiological and other hazardous constituents are within acceptable levels, then it is safe to assume that risks to less exposed receptors would also be within safe levels.

Airborne emissions from construction activities would be monitored on a daily basis as part of the Occupational Health and Safety Program. Portable air samplers would be set up in the area of construction and moved as necessary to provide representative samples of air in the breathing zone of workers. These samples would be collected at the end of each work day and checked for total alpha and total beta radiation. In some cases continuous radon monitors may be included to monitor occupational radon exposures.

Ambient radiation levels would be monitored in real time with hand-held instrumentation. Any cumulative radiation exposures would be tracked using personal dosimetry badges or electronic dosimeters.

It would be likely that some surface water from precipitation would be collected, sampled, and treated or discharged during remediation. Workers handling this water would be required to wear PPE and use appropriate tools and techniques to minimize exposures and risks.

The anticipated types of health and safety monitors (as well as proposed and projected quantities) are presented in Table 3-2. This table also lists the current constituents of potential concern, with the understanding that the list may change if new information becomes available during remedy design.

3.1.2.2 Air Monitoring

Similar to the ROD-selected remedy, for the “partial excavation to 1,000 pCi/g”, “partial excavation to 52.9 pCi/g”, and “complete rad removal” alternatives, the integrated system of air monitoring stations will continue to operate during construction. See Section 2 and 3.1.1.2 for a complete description.

3.2 Short-Term Remediation Monitoring

Short-term remediation control monitoring would include remediation control surveys to guide cut and fill operations, guide overburden and RIM excavation activities, verify that cover thickness would be sufficient under the ROD-selected remedy, and verify that RIM from the Buffer Zone/Crossroad Property and from Areas 1 and 2 had been removed both during and after RIM excavation. Remediation control monitoring would also include waste characterization surveys and sampling.

3.2.1 Remediation Control Monitoring During Construction of the ROD-Selected Remedy

Disturbance of RIM during construction of the ROD-selected remedy would be minimal. Some RIM might be moved during cut and fill operations that would be necessary for regrading of the surfaces of Areas 1 and 2. Other deposits of RIM may be inadvertently uncovered during grading in preparation for placement of the cover over Areas 1 and 2. Other than the RIM that would be relocated from the Buffer Zone/Crossroad Property onto Area 2 or Area 1, no RIM would be excavated and relocated or disposed off-site.

3.2.1.1 Remediation Control Surveys

Four types of radiological surveys would be conducted to guide the minor cut and fill operations in Areas 1 and 2, to guide the excavation and relocation of RIM from the Buffer Zone/Crossroad Property onto other parts of OU-1 (Area 1 or Area 2), and to confirm that final cover placement over Areas 1 and 2 would meet design criteria:

- Surveys conducted to identify and delineate any exposed RIM at the Buffer Zone/Crossroad Property;
- Quality Control (QC) walkover surveys of areas after final cover grading operations have ceased, but before the cover would be released for final status survey;
- Final Status Surveys for each covered (capped) area; and
- Final Status Surveys for areas on the Site adjacent to the final-covered Areas 1 and 2.

Following is a description of each of the remediation control survey types:

<u>Surveys conducted to locate and delineate any exposed RIM at the Buffer Zone/Crossroad Property.</u> These surveys would be conducted to locate areas where RIM is exposed or close to the surface at the Buffer Zone/Crossroad Property. Due to the complexity of surveying in unconsolidated material, the care that survey technicians would need to exhibit during the survey, and the need to communicate potentially complex instructions to the excavator operator, this process would reduce the excavator

efficiency. In order to calculate estimated survey costs, a 50 percent reduction in excavation production was assumed.

Samples of RIM and surrounding materials would be collected during any activity where RIM would be exposed or moved. These samples would require rapid analysis by field or on-site or off-site laboratory equipment to support decisions by the survey technicians to continue or cease handling materials on the current working face.

QC walkover surveys conducted after final cover grading and capping in an area has ceased. This type of survey would involve a systematic walkover survey of the final cover areas of Areas 1 and 2 after construction has ended. The intent of this type of survey is to provide reasonable assurance that recently disturbed or capped areas have a high likelihood of passing a final survey.[3] These surveys would follow MARSSIM guidance and established procedures. This survey would be conducted with hand-held gamma survey equipment. Soil samples would likely be collected if areas of higher gamma activity were identified during the scan. Any areas where soil concentrations above the remediation goals are identified would be marked and referred to engineering construction management personnel for potential RIM relocation or covering. These areas would then be resurveyed. This process would repeated until the entire covered area of Areas 1 and 2 meets the surface soil concentration criteria and cover design requirements. This level of effort would likely require two or three survey technicians equipped with hand held survey meters and soil sampling equipment. The survey team should be able to complete a survey of 1,000 square meters (m^2) in 4 to 8 man-hours. Some of these survey and sampling activities could potentially be conducted as areas of the final cover are being completed and prior to the entire cover surface being completed.

3.2.1.2 Final Status Surveys

Final Status Surveys for each covered area. These surveys, which are required to demonstrate compliance with cleanup standards and ARARs will be performed in order to confirm that the covered areas in Areas 1 and 2 meet the release criteria.[4] The exact method used to perform the Final Status Survey will be submitted for approval by EPA and other stakeholders (as applicable) prior to remedy construction. For example, on other sites impacted with similar radionuclides, walkover surveys have been conducted using a 2” x 2” sodium iodide detector coupled to a meter and a GeoPositioning System (GPS). The surveys were conducted by walking across the site in a systematic pattern at a rate of one meter per second with the detector held as close to the ground as practical.

---

[3] During the remedy design and planning phase, remediation goals will be established. While the proposed remediation goals would include area and depth averaging criteria, the intent of this post-excavation QC survey would be to remediate to a “not-to-exceed” number. The averaging criteria would be used during the subsequent final status survey, but they would not be considered during this phase of the remediation.

[4] These numerical criteria will be established and implemented during the during the remedy design phase.

The results of these surveys were plotted on site maps or aerial photos and examined for anomalies. If no anomalies were identified, a reference grid was staked out on the remediated area and samples were taken at regular intervals as specified in the Final Status Survey Plan. Note that if the preceding QC walkover survey did not identify locations of elevated radioactivity in an area during the first pass over the area, that QC walkover survey was used to satisfy the walkover requirement of the Final Status Survey. The same approach would be proposed in the Final Status Survey Plan for the excavation remedial alternatives.

For planning purposes, the level of effort for this Final Status Survey would likely require three or four survey technicians as well as a health physics supervisor. For purposes of estimating costs in this FFS, it is assumed that the survey team would complete a survey of 1,000 m^2 in 4 to 8 man-hours, and 10 samples every 1,000 m^2 would be collected for laboratory analysis. Samples would be subject to gamma spectroscopy analysis and alpha spectroscopy analysis for isotopic thorium and isotopic uranium. A final survey report for both Areas 1 and 2 would be prepared and submitted for approval to EPA. When accepted, these surveys will serve as the baseline gamma surveys for these areas.

Final Status Surveys for areas on the Site adjacent to the final-covered Areas 1 and 2. A final survey of the surface of the property would also be required for areas traversed by vehicles containing RIM and where overburden was stored. These surveys would be identical to the final status surveys conducted for covered/capped areas. For purposes of estimating costs in this FFS, it is assumed that the survey team would complete a survey of 1,000 m^2 in 4 to 8 man-hours, and 10 samples every 1,000 m^2 would be collected for laboratory analysis. When accepted by EPA, these surveys will serve as the baseline gamma survey for these areas.

3.2.1.3 Waste Characterization Surveys and Sampling

Since disturbance of RIM in Areas 1 and 2 during construction of the ROD-selected remedy would be minimal and no areas of RIM in Areas 1 and 2 would be targeted for excavation and disposal, no formal waste characterization sampling would be necessary. A small volume of soil containing RIM would be relocated from the Buffer Zone/Crossroad Property onto Area 1 or Area 2. Waste characterization of this soil would involve collection and analysis of samples for radiological parameters at a frequency to be determined during remedial design.

3.2.2 Remediation Control Monitoring during Partial Excavation to 1,000 pCi/g", "Partial Excavation to 52.9 pCi/g", and "Complete Rad Removal" Alternatives

Disturbance of RIM during the alternatives that involve excavation activities would be significant. Remediation control monitoring would be crucial in assuring (1) that excavated overburden debris from Areas 1 and 2 would not contain any RIM, and (2) that all RIM has been removed from Areas 1 and 2 as well as from the Buffer Zone/Crossroad Property. Remediation control monitoring would be used to selectively excavate RIM while leaving non-impacted materials behind.

3.2.2.1 Remediation Control Surveys

Seven types of radiological surveys would be conducted to guide excavation of RIM in Areas 1 and 2 and from the Buffer Zone/Crossroad Property under the excavation remedial alternatives:

- Surveys of overburden known or suspected to be above an area of RIM;
- Surveys conducted to identify and delineate any exposed RIM;
- Surveys conducted to guide selective excavation of RIM;
- Surveys conducted on trucks leaving the Site;
- QC walkover surveys of an excavated area after excavation has ceased but before the area would be released for Final Status Survey;
- Final Status Surveys for each completed excavation of a RIM area; and
- Final Status Surveys for the unexcavated areas involved with the movement and handling the RIM, overburden storage locations, and Subtitle D capped areas over Areas 1 and 2.

Following is a description of each of the remediation control survey types:

<u>Surveys conducted to support removal of overburden from above the RIM</u>. This type of survey would be designed to assure that RIM would not be intermingled with the uncontaminated debris overburden being excavated. The survey would be conducted on the uncontaminated waste as it was moved by the excavator. The level of effort would likely require one full-time survey technician with each excavator.

<u>Surveys conducted to locate and delineate any exposed RIM.</u> These surveys would be conducted to locate areas where RIM is exposed or close to the surface. These surveys would likely require two or three full-time survey technicians with survey instruments to accompany each excavator. Due to the complexity of surveying in unconsolidated material, the care that survey technicians would need to exhibit during the survey, and the need to communicate potentially complex instructions to the excavator operator, this process would reduce the excavator efficiency. In order to estimate survey costs, a 50 percent reduction in excavation production was assumed.

Samples of RIM and surrounding materials would be collected during any activity where RIM would be exposed or moved. These samples would require rapid analysis by field or on-site or off-site laboratory equipment to support decisions by the survey technicians to continue or cease handling materials on the current working face.

<u>Surveys conducted to guide selective excavation of RIM.</u> The purpose of these real-time surveys would be to guide the excavator operators to deposits of RIM. These surveys

would likely require two or three full-time survey technicians with survey instruments to accompany each excavator. Due to the complexity of surveying in unconsolidated material, the care that survey technicians would need to exhibit during the survey and the need to communicate potentially complex instructions to the excavator operator, this process would reduce the efficiency of excavation. In order to calculate estimated survey costs, a 50 percent reduction in excavation production was assumed.

Samples of RIM and surrounding materials would be collected during any excavation involving RIM or overburden. These samples would require rapid analysis by laboratory equipment to support decisions by the survey technicians to continue or cease excavation on the current working face.

Surveys conducted on trucks leaving the Site. These surveys would be conducted on the tires of the highway trucks prior to the trucks leaving the Site. If radiological material were to be identified as a result of the survey, the truck would be directed to a decontamination pad where the radiological material would be removed and the truck resurveyed.

QC walkover surveys of an excavated area after excavation has ceased but before the area was released for Final Status Survey. This type of survey would involve a systematic walkover survey of the entire excavated area after excavation has ceased but before the excavator is released from the area. The intent of this type of post-excavation survey is to provide reasonable assurance that the recently excavated area has a high likelihood of passing a Final Status Survey.[5] QC walkover surveys would be conducted with hand-held gamma survey equipment. Soil samples would likely be collected if areas of higher gamma activity were identified during the scan. If any areas where soil concentrations above the remediation goals are identified, these areas would be subject to focused excavation and resurveyed until the entire area meets the soil concentration criteria established for each alternative. Extensive QC surveying and sampling is anticipated, and it is expected that this QC sampling would be supplemented by some boring or excavation to provide reasonable assurance that another layer of RIM does not exist below the newly exposed uncontaminated surface. A small excavator or backhoe (with an operator) might be necessary to assist the survey technicians. The level of effort would likely require two or three survey technicians equipped with hand-held survey meters and soil sampling equipment. After RIM excavation is completed in a particular area, it is estimated that the survey team would be able to complete a QC walkover survey of a 1,000 m^2 area in 4 to 8 man-hours. Some of the survey and sampling work would be on-going as excavation was being completed.

[5] During the remedy design and planning phase, remediation goals will be established. While the proposed remediation goals would include area and depth averaging criteria, the intent of this post-excavation survey would be to remediate to a "not-to-exceed" number. The averaging criteria would be used during the subsequent final status survey, but they would not be considered during this phase of the remediation.

3.2.2.2 Final Status Surveys

Final Status Surveys for completed RIM excavation areas. These surveys are conducted to confirm that the excavated area meets the release criteria. The exact method used to perform the Final Status Survey will be submitted for approval prior to remedy construction. Walkover surveys will be conducted using a 2” x 2” sodium iodide detector coupled to a meter and a GeoPositioning System (GPS), or equivalent. The surveys would be conducted by walking across the Site in a systematic pattern at a rate of one meter per second with the detector held as close to the ground as practical. The results of these surveys will be plotted on Site maps or aerial photos and examined for anomalies. If no anomalies are identified, a reference grid will be laid out on the remediated area and samples will be taken at regular intervals as specified in an approved Final Status Survey Plan. Note that if areas of elevated radioactivity are not identified during the first pass of the preceding QC survey, that QC walkover survey will be used to satisfy the area survey component of the Final Status Survey. The same successful approach would be proposed in the Final Status Survey Plan for these alternatives.

The level of effort for this Final Status Survey would likely require three or four survey technicians, as well as a health physics supervisor. For purposes of estimating costs in this FFS, it is assumed that the survey team would complete a survey of 1,000 m^2 in 4 to 8 man-hours, and 10 samples every 1,000 m^2 would be collected for laboratory analysis. A final survey report for each RIM excavation area would be prepared and submitted for approval to EPA. When accepted, these surveys will serve as the baseline gamma surveys for the excavated areas.

Final Status Surveys for the unexcavated areas involved with the movement and handling the RIM and overburden storage locations. Final Status Surveys would be conducted of the surface of the property traversed by vehicles containing RIM (i.e., the areas between where trucks would be loaded and the transfer station) and the area between any RIM excavations and the overburden staging area and the surface of the property where overburden would be stored. These surveys would be identical to the Final Status Surveys conducted for excavated areas.

For purposes of estimating costs in this FFS, it is assumed that the survey team would complete a survey of 1,000 m^2 in 4 to 8 man-hours and 10 samples every 1,000 m^2 would be collected for laboratory analysis. When accepted by EPA, these surveys will serve as the baseline gamma survey for the completed remedy in these locations.

3.2.2.3 Waste Characterization Sampling and Analyses

Off-site disposal facilities require that incoming waste meet certain acceptance criteria. Prior to being transported off-site, waste would be sampled as determined by the disposal facility waste acceptance criteria, and analyzed by the on-site laboratory to determine that the material meets the waste acceptance criteria of the receiving facility.

3.3 Utility of an On-site Laboratory during Construction of the "Partial Excavation to 1,000 pCi/g", "Partial Excavation to 52.9 pCi/g", and "Complete Rad Removal" Alternatives

A large number of air and soil samples would be generated by the Occupational Health and Safety and air monitoring programs discussed previously in this section for the partial and full excavation alternatives. The estimated cost for analysis of these samples in an off-site commercial analytical laboratory would be substantial. To significantly decrease the turnaround time on key samples, as well as to reduce project costs, estimated costs associated with siting and operating/maintaining an on-site laboratory containing a low-background alpha-beta counter and gamma and alpha spectroscopy systems are included in the cost estimates presented in Appendix K of the FFS for the excavation alternatives.

Significantly fewer samples for radiological parameter analysis would be generated during implementation of the ROD-selected remedy because only a minor amount of RIM, if any, would be disturbed during cut/fill activities associated with regrading the surfaces of Areas 1 and 2 prior to cap placement. Therefore, use of an on-site laboratory was not considered in the cost estimates for the ROD-selected remedy.[6]

3.3.1 Radiological Analysis of Air Samples

As discussed above, the proposed air monitoring systems would be designed to capture information regarding potential emissions during alternative implementation activities. A large number of air samples requiring radiological analysis would be generated over the duration of construction. Due to the volume of samples expected, an on-site laboratory would be proposed to reduce response times and overall analytical costs.

Any radioanalytical equipment used on-site would be required to have the capability to reliably measure radionuclide concentrations in air that were at or below health-based standards. A very conservative detection goal for air samples was set in this analysis to evaluate the feasibility of an on-site laboratory and to estimate the total counter time required to perform the analyses.

The required radionuclide detection limit for on-site radioanalytical equipment was calculated by assuming that thorium-230 would be the only alpha emitter in the sampled air. Thorium-230 was chosen because it has the most restrictive allowable limit for air (and therefore would provide the most conservative, or protective, results), and it produces Radium-226, whose daughters are the most radiotoxic radionuclides at the Site. The assumption that thorium-230 is the only alpha emitter is very health-protective,

[6] The cost estimates provided in Appendix I for the ROD-Selected remedy do assume the on-site use of a low-background counter during the cut/fill and surface regrading activities.

because some of the alpha emissions in air would actually be produced by less-radiotoxic radionuclides.

In 10 CFR Part 20 Appendix B, Annual Limits on Intake (ALI) and Derived Air Concentration of Radionuclides for Occupational Exposure; Effluent Concentrations; Concentrations for Release to Sewerage, the NRC limits the acceptable airborne concentration of thorium-230 in areas accessible to the public to 2×10^{-14} microCuries per milliliter (µCi/mL). Assuming all alpha emissions in air were from thorium-230 (a gross overestimation), the detection limit for this equipment would be set at the NRC limit of 2×10^{-14} µCi/mL, after correcting for interferences from radon daughters.

For the purpose of estimating operation costs for an on-site laboratory, it assumed that each air sample would require two separate 15 minute analyses on a state-of-the-art low-background counter.[7] Approximately 30 samples per day could be counted (including sample loading, unloading and counter maintenance) with one gas proportional counter. Based on this evaluation, one gas proportional counter was assumed to be included in an on-site laboratory in the cost estimates for each of the partial and full excavation alternatives in Appendix K of the FFS. This assumption may be revised after preparation of the Construction Sampling and Analysis Plan during remedial design to include two counters to provide redundancy and excess capacity for smear and occupational health and safety samples.

3.3.2 Non-radiological Analysis of Particulate Air Samples

For the purpose of estimating costs, it was assumed that two air sample filters per week would be submitted for chemical analysis. The number of samples per week may increase depending on the nature of the activities being conducted.

Chemical analyses of air samples would not be considered for an on-site laboratory because of the significant cost of analytical equipment and QA/QC requirements for a laboratory conducting chemical analyses. The detection limits for the analytical methods used would allow direct comparison to the air quality objectives established for the project during alternative design.

3.3.3 Radiological Analysis of Soil and Waste Samples

Because of the anticipated significant number of soil and RIM waste samples that would require analysis for the excavation alternatives, it is anticipated that on-site gamma spectroscopy and alpha spectroscopy systems would be installed. As compared to shipping samples to an off-site commercial laboratory for analytical services, use of an on-site system would afford a rapid turnaround time between sample collection and

---

[7] This would allow interferences from radon daughter build-up on the filters to be estimated and removed from the final gross alpha measurement used to determine compliance with the 2×10^{-14} µCi/mL thorium-230 limit in air.

analytical reporting, thereby allowing excavation decisions to be made quickly (thus reducing both standby time for construction equipment and the overall alternative implementation schedule). A secondary consideration is the reduction in the analytical cost per sample that would be provided by on-site gamma spectroscopy and alpha spectroscopy systems.

3.3.4 Non-radiological Analysis of Soil and Waste Samples

After the nondestructive radiological analysis of an individual soil or waste sample is completed, and depending on the characteristics of the sample (e.g., chemical toxicity, matrix interference, etc.), it may be sent to an off-site commercial analytical laboratory for analysis of organic and/or inorganic parameters. The laboratory manager would likely make this determination.

4 POST-CONSTRUCTION MONITORING

Post-construction radiological monitoring would be conducted to confirm that the remedial action has been completed as designed and to provide initial post-construction values that could be compared to long-term monitoring results.

4.1 Post-Construction Monitoring Following Construction of the ROD-Selected Remedy, the "Partial Excavation to 1,000 pCi/g", and "Partial Excavation to 52.9 pCi/g" Alternatives

Post-construction monitoring performed following completion of construction of the ROD-selected remedy and the two partial excavation alternatives would be used to assess whether any radon gas is emanating from or around the cover over Areas 1 and 2. Monitoring activities would include:

- Measurement of radon flux emanating from the cover over Areas 1 and 2; and
- Measurement of radon in subsurface landfill gas.

4.1.1 Radon Flux Measurement

A one-time radon flux monitoring campaign would be performed after the final cover is completed over Areas 1 and 2. The purpose of this monitoring is to assess surface emissions of radon from the final cover over Areas 1 and 2 in order to demonstrate compliance with the radon flux emission standard established under 40 CFR § 192.02(b).

Radon flux would be measured using the Large Area Activated Charcoal Canisters (LAACC) method presented in Method 115, Appendix B, 40 CFR Part 61. The protocols used for the LAACC radon flux measurement program and calculations are contained in the USEPA report "Radon Flux Measurements on Gardinier and Royster Phosphogypsum Piles near Tampa and Mulberry, Florida" (USEPA, 1986).

For purposes of costing, it was assumed that approximately 50 LAACC samplers would be placed on the surface of Areas 1 and 2. The LAACC samplers would be distributed to provide coverage similar to the spacing in the 2016 sampling event. This proposed measurement campaign may vary depending upon the alternative chosen.

4.1.2 Sub-surface Landfill Gas Monitoring

A landfill gas monitoring program would be developed and implemented as part of the long-term monitoring program. The need for and scope of the landfill gas monitoring program, including the exact number and locations of gas monitoring points and measurement frequency, would be determined in the remedial design documents for the selected alternative for OU-1. Final landfill gas monitoring well locations and spacing would be based on geologic conditions and proximity to property boundaries and adjacent features. Gas monitoring wells would be designed and constructed in accordance with the MDNR Solid Waste Management Program (SWMP) fact sheet *Design and Construction of Landfill Gas Monitoring Wells* (MDNR, 2007). This guidance indicates that monitoring locations be spaced 100 to 500 feet apart, depending on the ground permeability and the number of nearby features that could be potentially damaged from landfill gas.

For purposes of this FFS, it is assumed that 2-inch diameter "Code Wells" (see MDNR, 2007) would be installed to a depth of approximately 10 feet for the subsurface gas monitoring program. The inner casing of each well would be sealed with a bushing and a sampling port consisting of a shutoff valve and hose barb fitting. For purposes of preparing cost estimates for the ROD-selected remedy and the two partial excavation alternatives, it is assumed that approximately 16 monitoring wells would be installed along the boundary of Area 1 and approximately 15 wells along the boundary of Area 2 (Figure 4-1). A more frequent spacing was assumed for the wells around Area 1 because of the proximity of Area 1 to the Site entrance road and St. Charles Rock Road. Because of the lack of significant features near the boundaries of Area 2, a greater spacing was assumed for the Area 2 gas monitoring wells.

For the post-construction radiological monitoring program, only radon gas would be monitored in the gas wells. Landfill gas (i.e., lower explosive limit [LEL] for methane) would be monitored as part of the Long-Term Monitoring Program (see discussion in Section 5). Gas samples would be collected from each well and the radon content of the gas would be measured using a radon gas monitor and detector (e.g., Pylon Instrument Manufacturing Model AB-5R monitor and Pylon Model 300A detector).

4.2 Post-Construction Monitoring Following Construction of the "Complete Rad Removal" Alternative

Since all RIM will have been removed under this alternative as confirmed by the Final Status Surveys discussed in Section 3.2.2.2, the only monitoring that would be conducted under the full excavation remedial alternative would be measurement of radon gas in landfill gas wells installed along the boundaries of Areas 1 and 2. For purposes of preparing cost estimates for this "complete rad removal" alternative, it is assumed that the same locations and type and number of gas monitoring wells as those assumed for the ROD-selected remedy (Figure 4-1) would be monitored. Gas samples would be collected from each well and the radon content of the gas would be measured using a radon gas monitor and detector.

4.3 Gamma Radiation

As discussed in Sections 3.2.1.2, and 3.2.2.2, the Final Status Surveys will serve as the post-construction survey of gamma radiation after remedy construction is complete.

5 LONG-TERM MONITORING

Long-term monitoring of landfill gas, groundwater, and surface water, as well as annual post-construction Site inspections, would be conducted after the selected remedial alternative is constructed to verify that the constructed remedy is performing as designed. Long-term air monitoring would not be necessary, as after construction of the engineered cap, the potential for windborne transport of RIM containing gases and dust would be eliminated. Detailed plans would be generated during remedy design.

This section provides a conceptual overview of the types of systems and equipment that would be used to monitor potential exposure and emissions after remedy construction is complete. For purposes of preparing a monitoring plan for the FFS, it is assumed that the level of potential exposure is low for the four remedial alternatives under consideration and that the constructed remedy has reduced potential exposures to the point that they would be indistinguishable from background levels using current technology. A detailed long-term monitoring plan would be developed as part of the remedial design for the selected alternative.

5.1 Long-term Monitoring Following Construction of the ROD-Selected Remedy, the "Partial Excavation to 1,000 pCi/g", and "Partial Excavation to 52.9 pCi/g" Alternatives

5.1.1 Long-term Landfill Gas Monitoring

Landfill gas would be monitored following construction of the cover over Areas 1 and 2 as part of the Long-Term Monitoring Program for the ROD-selected remedy and the two partial excavation alternatives using the approximately 31 subsurface gas monitoring wells discussed in Section 4.1.2. Gas samples would be analyzed for methane (as a percentage of total air volume or as a percentage of LEL) and percent volume of oxygen using a multi-gas detector (e.g., Industrial Scientific iBrid™ MX6). The radon content of each gas sample would also be measured using a radon gas monitor and detector. In addition, the barometric pressure at the time of gas sample collection would be recorded.

In accordance with the MDNR Solid Waste Management Program technical bulletin *Sampling of Landfill Gas Monitoring Wells* (MDNR, 2006), landfill gas monitoring would be conducted quarterly during the months of February, May, August, and November. Depending on weather conditions, consideration would also be given to sampling at those times when landfill gas would be most likely to migrate (i.e., when barometric pressure is low and soils are saturated, when snow cover is just beginning to melt, and/or when the ground is frozen or ice covered).

5.1.2 Long-term Groundwater Monitoring

One of the primary objectives of the ROD-selected remedy and the two partial excavation alternatives is to protect groundwater from any ongoing or future impacts from Areas 1 and 2. The landfill cover over Areas 1 and 2 would be designed and constructed to shed water and minimize the potential for precipitation to infiltrate waste materials. Therefore, the cover is expected to further reduce the potential for migration of contaminants from Areas 1 and 2 to the shallow groundwater underlying the Site.

A long-term groundwater monitoring program would be established to demonstrate that the ROD-selected remedy or the two partial excavation alternatives perform as required over the post-closure period. Also, as requested in the EPA Office of Superfund Remediation and Technology Innovation (OSRTI) memorandum of May 21, 2009 to EPA Region 7, the groundwater monitoring program would be designed so that it can be determined whether contaminants from the Site have migrated across the waste management unit boundary in concentrations that exceed drinking water Maximum Contaminant Levels (MCLs). Statistical evaluation of groundwater data would be used to assess groundwater quality and identify long-term trends.

The exact scope and requirements for the long-term groundwater monitoring component of the selected alternative would be set forth in the remedial design documents. Any design and implementation of a long-term groundwater monitoring program would be expected to meet the substantive requirements of the UMTRCA groundwater protection and monitoring requirements and the MDNR post-closure regulations for closed solid waste landfills.

A conceptual groundwater monitoring plan for the ROD-selected remedy and the two partial excavation alternatives was developed as part of the FFS (EMSI, 2016). For purposes of estimating monitoring costs for this FFS, the point of compliance for groundwater monitoring is assumed to consist of those portions of the boundaries of Areas 1 and 2 that would be coincident with the boundary of the West Lake Landfill. Specifically, this would include the northeastern boundary of Area 1 and the northeastern, northern, northwestern and western boundaries of Area 2. The point of compliance used for this evaluation does not include the other boundaries of Areas 1 and 2, as these boundaries would be located internal to and within the overall boundary of the Site and therefore would be adjacent to areas containing other landfill wastes, making compliance monitoring along these boundaries impractical.

In this FFS evaluation it was assumed for purposes of monitoring the point of compliance that 24 groundwater monitoring wells would monitored. The specific wells to be monitored would be determined during remedial design. It is anticipated that the wells to be monitored would consist of a combination of existing well clusters (Figure 5-1) and new wells that would be constructed (the costs for 12 new groundwater monitoring wells were included in the capital cost estimates for the ROD-selected and excavation alternatives). The wells would be sampled twice per year for the first five years to characterize baseline conditions and annually thereafter.

Groundwater samples would be analyzed for gross alpha and beta, uranium and radium isotopes, volatile organic compounds (VOCs), semi-volatile organic compounds (SVOCs), trace metals, mercury, total organic carbon (TOC), major anions and cations, phosphorus, and ammonia as required by the UMTRCA groundwater protection standards and the MDNR regulations. During the sample collection process, water level elevations and field parameters (e.g., pH, specific conductance, turbidity, temperature, and redox potential) would be recorded. Also, as requested in the EPA OSRTI memorandum of May 21, 2009 to EPA Region 7, broader water quality parameter indicators (e.g., alkalinity, carbonates, and sulfates/sulfides) would analyzed in the collected samples. Both filtered and unfiltered samples would be collected in the field and analyzed in the laboratory.

As with any alternative, the exact number and locations of the wells to be monitored, the parameters for which they would be monitored, and the frequency at which they would be monitored would be determined as part of the remedial design activities. In addition, EPA had determined that an additional operable unit (OU-3) will be created and investigations to address groundwater may affect cost estimates. The description of the wells to be monitored, analyte list, and monitoring frequency presented above is intended solely to provide a basis for developing an estimated cost for long-term groundwater monitoring following construction of the ROD-selected remedy or the either of the partial excavation alternatives.

5.1.3 Annual Post Construction Site Inspections

Every year the surface of the cover constructed over Areas 1 and 2 would be inspected to assess whether any significant changes have occurred.

Annual long-term monitoring results would be validated and compiled along with air monitoring results from previous years in a database and archived in a secure, accessible location. Monitoring results would be made available to the regulatory agency team conducting the Comprehensive Five-Year Reviews of the alternative (OSWER Directive 9355.7-03B-P). The frequency and extent of post-construction site inspections would be subject to reassessment as a result of each Five-Year Review. Estimated costs for compiling, reporting, and maintaining monitoring results are included in the long-term monitoring costs provided in Appendix K of the FFS for the ROD-selected remedy and the two partial excavation alternatives.

5.2 Long-term Monitoring Following Construction of the "Complete Rad Removal" Alternative

5.2.1 Long-term Landfill Gas Monitoring

Under the "complete rad removal" alternative, all RIM will have been removed from Areas 1 and 2. Therefore, samples from subsurface gas wells installed around Areas 1 and 2 would only be analyzed for methane and percent volume of oxygen. It is assumed for purposes of this FFS that the same number of subsurface gas monitoring wells would be installed and monitored as those for the other alternatives discussed in Section 5.1 (Figure 3-1).

5.2.2 Long-term Groundwater Monitoring

Although under the “complete rad removal” alternative, RIM will have been removed from the Site, it is assumed for purposes of this FFS that the same number of groundwater monitoring wells discussed in Section 5.1.2 would be monitored. Further, it is assumed that the frequency of monitoring and parameters analyzed would also be the same as those described previously for the other alternatives in Section 5.1.2.

5.2.3 Annual Post Construction Site Inspections

Every year, the surface of the Subtitle D cover constructed over Areas 1 and 2 after the RIM has been removed would be inspected to assess whether any significant changes have occurred.

Annual long-term monitoring results would be compiled along with environmental monitoring results from previous years and archived in a secure, accessible location. Long-term monitoring results would be made available to the regulatory agency team conducting the Five-Year Reviews of this alternative. The estimated costs for compiling, reporting, and maintaining monitoring results are included in the long-term monitoring costs provided in Appendix I of the FFS for the “complete rad removal” alternative.

6 SUMMARY OF MONITORING FOR EACH ALTERNATIVE

A summary table listing the types of monitoring assumed for the purpose of generating estimated costs is provided in Table 6-1. Specific types of monitors and the number of monitor types would likely change to some degree during remedy design and construction.

EXECUTIVE SUMMARY

Auxier & Associates, Inc. (Auxier) has prepared this Evaluation of Potential Risks Associated with the Proposed Remedial Alternatives (the Remedial Risk Assessment) to support the Final Feasibility Study (FFS) for OU-1 of the West Lake Landfill Superfund Site (the Site) in Bridgeton, Missouri. The purpose of the Remedial Risk Assessment is to calculate a conservative assessment of the potential short-term and long-term risks associated with each remedial alternative. The results of the Remedial Risk Assessment show that the overall risks of the ROD-selected remedy are less than any other remedial alternative. In fact, the short-term and long-term risks from the ROD-selected remedy are the only set of risks that are less than the upper bound of EPA's acceptable risk range. The risks for the off-property resident for all remedial alternatives are less than 10^{-07}, well below EPA's acceptable risk range for CERCLA sites.

ES1. Methods

The risk evaluations in this Remedial Risk Assessment build on the updated Baseline Risk Assessment (Auxier 2016) (BRA) for OU-1, which modeled hypothetical current and future risks to potential receptors at and near the Site, conservatively assuming that no corrective action would occur in OU-1 (i.e., assuming implementation of the No Action alternative). This Remedial Risk Assessment models hypothetical current and future risks to potential receptors at and near the Site for each of the remedial alternatives proposed by EPA in its December 9, 2015 RI/FS Statement of Work:

- 2008 ROD-selected remedy, which involves installing an enhanced cover over Areas 1 and 2 of OU-1, among other remedial components;
- Excavation and off-site disposal of all soil/waste containing combined radium or combined thorium with activity levels greater than 52.9 picoCuries per gram (pCi/g) down to a total depth of 16 feet beneath the 2005 topographic surface;
- Excavation and off-site disposal of all soil/waste containing combined radium or combined thorium with activity levels greater than 1,000 pCi/g;
- Excavation and off-site disposal of all soil/waste containing combined radium or combined thorium with activity levels greater than 7.9 pCi/g.

Potential risks associated with each of these remedial alternatives were modeled by conducting a human health risk assessment (HHRA) in accordance with CERCLA regulations and guidance. The HHRA characterizes potential risks posed by radioactive or chemical constituents to hypothetical humans assumed to live or work at or near the Site. It consists of the following steps:

- *Identification of constituents of potential concern (COPCs):* OU-1 of the West Lake Landfill contains both radiological and chemical (non-radiological) constituents of potential concern (COPCs). The concentrations and toxicity of these constituents were identified and used in the updated BRA to focus the risk assessment on the chemicals and radionuclides most likely to produce risks above the 10^{-06} cancer risk point of departure. These risk-driving constituents were defined as COPCs and are used in this Remedial Risk Assessment to evaluate the effectiveness of each remedial alternative to reduce risks.

- *Exposure assessment:* This step calculates the ways in which humans may be exposed to the constituents in OU-1. For example, humans may be exposed to OU-1 constituents by breathing, touching, or consuming contaminated air, water, or soil. These exposure routes are referred to in the BRA as "pathways," and pathway exposure assessments take into account how long, how often, and how many ways in which certain types of people may be exposed. The types of people who are hypothetically assumed to be exposed are defined by their physical characteristics and behaviors and are called "receptors" in this Remedial Risk Assessment. Potential exposure pathways were qualitatively evaluated in this Remedial Risk Assessment for each remedial alternative in order to identify receptors with the greatest potential for exposure. The receptor with greatest exposure potential is called the "reasonably maximally exposed" individual (RME individual).

- *Toxicity assessment:* This step evaluates the potential health effects that exposure to constituents found in OU-1 may cause. It includes an assessment of the increased risk of cancer, as well as non-carcinogenic effects. The chemicals and radionuclides selected for evaluation are the same as those listed as COPCs in the updated BRA.

- *Risk characterization:* This final step combines the results of the first three steps to identify the largest sources of risk that may be posed by COPCs in OU-1 and determine whether these risks exceed the acceptable risk range of 10^{-06} to 10^{-04} required by EPA under CERCLA.

ES2. Modeling Risks

Among other risks, this Remedial Risk Assessment evaluates what are called "cancer risks." It is well established that humans are exposed to a wide variety of carcinogens on a daily basis (for example, secondhand smoke, cosmic and solar radiation from the sun, and air pollution, among others). Therefore, the risks described in this Remedial Risk Assessment are expressed numerically as the incremental increase to lifetime risk of cancer due to a human's exposure to a particular constituent under a certain prescribed scenario. Stated another way, an incremental cancer risk of 10^{-06} is equivalent to a 0.0001% increase in the chance that a particular person may get cancer as a result of the assumed exposure scenario. The EPA has previously determined that exposures resulting in an incremental cancer risk of no more than one instance in ten thousand – that is, 10^{-04}, or a 0.01% chance increase – to the hypothetical receptor are acceptable for purposes of CERCLA risk assessment. Because risk is calculated as a probability, a finding of risk associated with a particular constituent does not necessarily mean that a person will actually develop cancer as a result of exposure to that constituent.

The purpose of this Remedial Risk Assessment is to undertake an evaluation of the potential short-term and long-term risks associated with each remedial alternative. Short-term risks are risks that are associated with the process of implementing a particular remedial alternative. Long-term risks are risks that remain after the remedial work is complete. This evaluation is designed to be conservative in that it is intended to *overstate* potential risk. In order to accomplish this, risks are evaluated based upon a hypothetical RME individual – that is, the person who is assumed to have the greatest exposure to COPCs at the Site with respect to the remedial alternatives. In this Remedial Risk Assessment, the RME individual for short-term risk associated with all remedial alternatives is the radiation control technician working on remedial alternative implementation. The RME individual for the long-term risk associated with all remedial alternatives is a grounds keeper working on the OU-1 areas.

ES3. Results

This Remedial Risk Assessment concludes that:

- The calculated short-term risks associated with implementation of the ROD-selected remedy are substantially lower than the potential short-term risks associated with the remedial alternatives (the full excavation and both partial remedial alternatives) in all risk categories evaluated.
- The calculated short-term risks to the RME individual (the radiation control technician) during implementation of the ROD-selected remedy are within EPA's generally acceptable risk range at CERCLA sites. The risks associated with the other remedial alternatives are up to an order of magnitude greater than EPA's generally accepted risk range at CERCLA sites.
- The calculated short-term risks to the off-property resident for all remedial alternatives are less than 10^{-07}.
- Construction and industrial accident forecasts for all remedial alternatives were higher than the construction and industrial accident forecasts for the ROD-selected remedy.
- The estimated short-term radiation dose to the RME individual for the ROD-selected remedy is also the lowest of all the remedial alternatives.
- All calculated long-term risks are well below EPA's maximum acceptable risk of 10^{-04}, and are in fact below 10^{-08}. The predicted radiation doses to the RME individual (the landfill grounds keeper) for all remedial alternatives are also well below the occupational exposure limit of 5,000 millirem per year (mrem/yr).
- The short-term risks from the ROD-selected remedy are the only set of risks that are less than the upper bound of EPA's acceptable risk range.

Table ES-1 Compilation of Calculated Short-term and Long-term Hazards and Risks

	Category of Hazard or Risk	Partial Excavation to 1,000 pCi/g Alternative	Partial Excavation to 52.9 pCi/g Alternative	Full Excavation with Off-Site Disposal Alternative	ROD-Selected Remedy
Short-term	Projected Incidence of Transportation Accidents [a]	1.66E+01	1.06E+01	3.49E+01	6.14E-01
	Projected Incidence of Industrial Accidents [b]	1.17E+01	8.47E+00	1.78E+01	2.76E+00
	Carcinogenic Risk to Reasonably Maximally-Exposed RadCon Tech during Construction [c]	2.38E-03	1.18E-03	2.19E-03	9.23E-05
	Hazard Index for Reasonably Maximally-Exposed RadCon Tech during Construction [c]	1.22E+00	1.22E+00	1.22E+00	1.22E+00
	Carcinogenic Risk to Reasonably Maximally-Exposed Off-property Resident during Construction [c]	5.26E-08	4.17E-08	5.17E-08	3.37E-08
	Hazard Index for Reasonably Maximally-Exposed Off-property Resident during Construction [c]	4.12E-04	4.12E-04	4.12E-04	4.12E-04
	Dose (TEDE) to Qualified Radiation Remediation Worker (mrem/y) [d]	8.67E+02	7.20E+02	4.05E+02	1.87E+02
Long-term	Carcinogenic Risk to Reasonably Maximally-Exposed Individual after Construction [e]	3.63E-10	1.90E-11	1.48E-09	1.01E-09
	Dose (TEDE) to Reasonably Maximally-Exposed Individual after Construction (mrem/y) [d]	2.89E-04	1.51E-05	1.71E-04	4.23E-04

[a] Dependent on mileage on public roads.
[b] Dependent on man-hours worked.
[c] Dependent on man-hours worked while RIM exposed and will vary depending on length of project. Note systemic effects from lead were evaluated separately from other non-carcinogens; no unacceptable risks were predicted for lead.
[d] Annual dose limited by concentration and 1 year reporting period.
[e] Highest risks are in year 1,000 at Area 1.

1 INTRODUCTION

Operable Unit 1 (OU-1) of the West Lake Landfill (the "Site") is currently the subject of a Remedial Investigation /Feasibility Study (RI/FS) pursuant to the Comprehensive Environmental Response, Compensation & Liability Act (CERCLA or "Superfund Act"). As part of the RI/FS process, numerous reports presenting Site investigation data and evaluations have been submitted to the United States Environmental Protection Agency (EPA) Region 7. This Appendix contains evaluations of potential human health risks associated with the remedial alternatives proposed by EPA and thus is a companion document to the Final Feasibility Study (FFS), which was prepared to fulfill EPA's December 9, 2015 Statement of Work (SOW). Consistent with the SOW, the FFS evaluates the following five potential remedial alternatives:

No Action Alternative – Required by the National Contingency Plan (NCP) and RI/FS guidance to provide a baseline against which all of the other remedial alternatives are evaluated[1]. This alternative is considered the baseline condition, and modeled risks associated with this alternative are discussed in detail in the updated Baseline Risk Assessment (BRA) (Auxier 2016);

Partial Excavation 1,000 pCi/g Alternative – Excavation and off-site disposal of all soil/waste containing combined radium (radium-226 plus radium-228) or combined thorium (thorium-230 plus thorium-232) with activity levels greater than 1,000 picoCuries per gram (pCi/g)[2];

Partial Excavation 52.9 pCi/g Alternative– Excavation and off-site disposal of all soil/waste containing combined radium (radium-226 plus radium-228) or combined thorium (thorium-230 plus thorium-232) with activity levels greater than 52.9 pCi/g down to a total depth of 16 feet beneath the 2005 topographic surface;

Full Excavation with Off-site Disposal Alternative– Excavation and off-site disposal of all soil/waste containing combined radium (radium-226 plus radium-228) or combined thorium (thorium-230 plus thorium-232) with activity levels greater than 7.9 pCi/g (the "complete rad removal" alternative); and

2008 ROD-Selected Remedy – This alternative is the remedy selected pursuant to EPA's 2008 Record of Decision (ROD) for the Site. It is a containment remedy consisting of regrading and installation of a new landfill cover and other remedial components for the Site, including consolidation of any radiologically-impacted soil that may remain on the former Ford property (now known as the Buffer Zone and Crossroad Lot 2A2) into the containment areas in Area 1 and 2 prior to placement of additional fill and construction of the new landfill cover.

---

[1] The SOW identifies an alternative no. 3: "Leaving all RIM in place on-site." Subsequent discussions with EPA indicated that this alternative was the No Action Alternative.

[2] In all cases evaluated in the baseline, thorium-230 and radium-226 (plus decay products) accounted for more than 95% of the risk to the target receptors. Other radionuclides are co-located with radium-226 and thorium-230 and are projected to produce risks to the future groundskeeper of $< 10^{-7}$. Remediation of the thorium-230 and radium-226, by themselves, would reduce the total risks from RIM to below 10^{-4}. Any remediation of radium -226 and thorium-226 would also lower the negligible risks from these ancillary radionuclides still further.

The FFS comparatively evaluates these remedial alternatives based on nine criteria set forth in the National Contingency Plan (NCP): (i) overall protection of human health and the environment; (ii) compliance with Applicable or Relevant and Appropriate Requirements (ARARs); (iii) long-term effectiveness; (iv) reduction of toxicity, mobility, or volume; (v) short-term effectiveness; (vi) implementability; (vii) cost; (viii) state acceptance; and (ix) community acceptance. In support of evaluating protectiveness of human health and the environment, this Appendix contains evaluations of potential short-term and long-term risks associated with soil and air for each remedial alternative and the methods used to identify and quantify those risks. Note that groundwater risks are not evaluated herein because (i) under current and anticipated future conditions, there are no known completed exposure pathways and (ii) groundwater at the Site is being evaluated as a separate operable unit (OU-3).

This Appendix has been prepared consistent with guidance provided in Risk Assessment Guidance for Superfund (RAGS) Volume 1 Human Health Evaluation Manual(EPA 1989). This Appendix also contains information on projected remedial alternative-specific industrial hazards, such as construction and traffic accidents, for the four remedial alternatives.

1.1 OBJECTIVES

The specific objectives of this evaluation are:

- Estimate the magnitude of potential short-term health risks associated with activities involved with implementation of each remedial alternative; and
- Estimate the magnitude of potential long-term health risks that may be posed by the Site after implementation of each remedial alternative is complete.

For the purposes of this evaluation, "short-term" is defined as the period during which a given remedial alternative is being implemented and "long-term" is defined as the post-remediation period (whether 1 year or 1,000 years later). Risks were grouped into the following categories for this report:

- Short-term risks to human health from short-duration exposures to radio-carcinogenic, chemical-carcinogenic, and systemic (non-carcinogenic) constituents;
- Short-term risks of injury or fatalities from industrial and construction accidents, which are collectively referred to herein as "industrial hazards";
- Short-term occupational doses to radiation workers; and
- Long-term risks to human health from exposures to radio-carcinogenic constituents of potential concern (COPCs).

Potential short-term and long-term human health risks for each of the four remedial alternatives are evaluated in this Appendix. The modeled risks associated with the No Action alternative are detailed in the updated BRA (Auxier 2016).

1.2 INCORPORATION OF UPDATED INFORMATION

In conjunction with the RI Addendum and FFS, Auxier & Associates, Inc. completed an update to the BRA that was previously prepared in 2000 for OU-1 of the West Lake Landfill (Auxier 2000). The updated BRA builds upon the information, evaluations and data collected prior to and as part of the RI (EMSI 2000), the FS (EMSI 2006), the ROD (EPA 2008a), the

Supplemental Feasibility Study (SFS) (EMSI 2011), and the RI Addendum (EMSI 2016). The BRA was updated to reflect the latest physical changes (installation of the non-combustible cover over radiologically-impacted material (RIM) on the surface of the Site) to Areas 1 and 2 and the latest efforts to characterize the nature and extent of the RIM. The BRA used EPA methodology to model hypothetical current and future risks to a variety of potential receptors, conservatively assuming that no corrective action would occur in Area 1, Area 2, and/or the Buffer Zone.

The risk evaluations in this FFS build on the updated BRA (Auxier 2016) for OU-1 of the West Lake Landfill. Updated information regarding toxicity, dose conversion factors, and toxicity values gathered from EPA's Integrated Risk Information System (IRIS) database and risk assessment websites were incorporated in the updated BRA and in this evaluation.

1.3 ORGANIZATION OF APPENDIX

An introduction to the human health risk assessment methods and general risk assessment information that applies to both short-term and long-term COPC risks is presented in Section 2. Short-term risk methods common to all remedial alternatives are presented in Section 3. Short-term assessments for the individual alternatives are presented in Sections 4 through 7. Sections 8 through 12 present the long-term risks calculated for each of the four alternatives. A summary of the findings presented in this Appendix are presented in Section 13. References are listed in Section 14.

2 COPC HUMAN HEALTH RISK ASSESSMENT METHODOLOGY

2.1 INTRODUCTION

Modeled theoretical risk estimates from potential exposure to COPCs in environmental media for the four remedial alternatives are evaluated in this Appendix. The theoretical risks associated with the No Action Alternative are detailed in the updated BRA (Auxier 2016). The subsections that follow present the methods used herein to evaluate potential radiocarcinogenic, chemical-carcinogenic, and systemic (non-carcinogenic) risks associated with each of the four remedial alternatives.

2.2 RISK ASSESSMENT PARAMETERS

Short-term and long-term risks from exposure to radiological and chemical constituents are evaluated using standard EPA methodology for conducting human health risk assessments (HHRAs), which includes the following four components: selection of COPCs, exposure assessment, toxicity assessment, and risk characterization. Elements of these components that are common to all alternatives under short-term and long-term scenarios are discussed below; elements specific to a timeframe or an alternative are described in greater detail, as appropriate, in Sections 3 through 12.

2.2.1 **Identification of Constituents of Potential Concern**

OU-1 of the West Lake Landfill contains both radiological and chemical (non-radiological) COPCs. The concentrations and toxicity of these constituents were identified and used in the updated BRA to focus the risk assessment on the chemicals and radionuclides most likely to produce risks above the 10^{-06} cancer risk point of departure. These risk-driving constituents were defined as COPCs and are used to evaluate the effectiveness of each remedial alternative to reduce risks. The COPCs identified in Table 2-1 and Table 2-2 are applicable to short-term and long-term risks; however, note that under future scenarios, exposure pathways for non-radiological COPCs are assumed to be incomplete due to cap/cover installation.

2.2.1.1 Radionuclides of Potential Concern

The updated BRA identified as constituents of interest the radionuclides associated with the naturally occurring uranium-238, uranium-235, and thorium-232 decay series. Soil samples from various sampling events in and around OU-1 were compiled into one data set. A series of screening evaluations were performed on these data to focus attention on those detected analytes that are (1) believed to be associated with RIM at the Site, and (2) may be important contributors to human health risk. Table 2-1 presents the radionuclides that were evaluated in the updated BRA risk characterization process. Calculated BRA risks for many of the radionuclide COPCs did not exceed the 10^{-06} cancer risk point of departure; however, in consideration of the potential for in-growth and therefore changing activity levels, all radionuclide COPCs from the updated BRA were retained for evaluation herein.

Table 2-1 Radionuclide COPCs in Soil at the West Lake Landfill

	Frequency Screen			Background Screen		
Analyte	**Detection Frequency**	**Detection Rate**	**Maximum Screening Concentration**	**Background Concentration [a]**	**Background Comparison**	**Screen Results**
Radionuclides	**(hits/analyses)**	**(< 5% ?)**	**(pCi/g)**	**(pCi/g)**	**(< 2 x BKG)**	
Uranium Series						
Uranium-238	300/308	No	1823	1.33	No	Pass
Thorium-234	109/326	No	1166	1.18	No	Pass
Uranium-234	298/308	No	1711	1.47	No	Pass
Thorium-230	305/326	No	57300	1.51	No	Pass
Radium-226	261/326	No	4926	1.06	No	Pass
Lead-214	289/326	No	4578	1.01	No	Pass
Bismuth-214	237/326	No	3690	0.72	No	Pass
Lead-210	158/326	No	1370	2.08	No	Pass
Actinium Series						
Uranium-235	267/308	No	774	0.33	No	Pass
Protactinium-231	55/326	No	2030	2.19	No	Pass
Actinium-227	160/308	No	1320	0.45	No	Pass
Thorium Series						
Thorium-232	292/308	No	515	0.90	No	Pass
Radium-228	184/326	No	31.8	1.12	No	Pass
Actinium-228	147/326	No	31.8	ND	No	Pass
Thorium-228	176/308	No	16.9	0.68	No	Pass
Radium-224	47/326	No	6580	1.93	No	Pass
Lead-212	262/326	No	800	1.29	No	Pass
Thallium-208	221/326	No	23.5	0.44	No	Pass

[a] Background values are based on four site samples taken by McLaren/Hart in 1995. Analytical suites differed between sample groups and a background screen was only performed on analytes where background values were reported.

2.2.1.2 Chemicals of Potential Concern

The updated BRA included a series of screening tests on the chemicals that were reported at the Site. Table 2-2 presents the concentrations used in the screening evaluation and the results; a “pass” flag in the screening results column indicates that the chemical was identified as a COPC for further evaluation in the BRA risk characterization.

Table 2-2 Summary of Chemical Toxicity Screen in All Soil at the West Lake Landfill

		Frequency Screen			Nutrient Screen		Toxicity Screen [b]					
Analyte	CAS Number	Detection Frequency	Detection Rate	Maximum Screening Concentration [a]	Nutrient Screening Value	Essential Nutrient?	Ingestion Screening Value	Dermal Screening Value	Inhalation Screening Value	Target Screening Value	Toxicity Comparison	Screen Results
Inorganic Chemicals		(hits/analyses)	(< 5% ?)	(mg/kg)			(mg/kg)	(mg/kg)	(mg/kg)	(mg/kg)	(< Criterion)	
Antimony	7440-36-0	63/131	No	54		No	47			47	No	Pass
Arsenic	7440-38-2	112/134	No	610		No	3.6	17	3900	3	No	Pass
Chromium, Total	18540-29-9	130/134	No	890		No	6.5		200	6.3	No	Pass
Cobalt	7440-48-4	99/100	No	2700	7.82	No	35		1900	35	No	Pass
Lead	7439-92-1	132/134	No	13000		No				800	No	Pass
Mercury	7439-97-6	92/134	No	12		No			4.6	4.6	No	Pass
Nickel	7440-02-0	134/134	No	3600		No	2300		54000	2200	No	Pass
Vanadium	7440-62-2	79/100	No	1800		No	590		60000	580	No	Pass
Uranium	7440-61-1	300/308	No	5457		No	350		24000	NA	No	Pass
Pesticides/Polychlorinated Biphenyls (PCBs)												
Aroclor 1242	53469-21-9	5/44	No	2.60		No	1.6	2.8	13	0.95	No	Pass
Aroclor 1254	11097-69-1	4/44	No	1.6		No	1.6	2.8	18	0.97	No	Pass
Volatile Organic Compounds												
1,4-Dichlorobenzene	106-46-7	10/36	No	2100		No	610		12	11	No	Pass
Chlorobenzene	108-90-7	8/37	No	180		No	2300		140	130	No	Pass

[a] Screening concentrations are maximum detected concentrations. Note that sample WL-208-U was an anomalous sample where the drillers went through a paint can. This sample is not thought to be representative of the entire landfill, therefore the sample was removed for the purposes of this screening table.

[b] Unless otherwise noted, screening values are from EPA Regional Risk-Based Screening Levels (EPA 2016a)

2.2.2 Exposure Assessment

The purpose of an exposure assessment is to estimate the nature and magnitude of exposures from a site under current and plausible future conditions. An exposure assessment consists of the following steps:

- Characterization of the exposure setting during remedy implementation (i.e., the short-term);
- Quantification of exposure point concentrations;
- Identification of receptors with potentially complete exposure pathways and selection of representative receptors for use in the FFS comparative analysis; and
- Quantification of receptor-specific intake/exposure.

Components of the exposure assessment that are specific to an alternative are discussed in Section 4 through Section 7 in the short-term, and Section 9 through Section 12, in the long-term. The subsections that follow present those components that are broadly applicable to the COPC risk characterization.

2.2.3 Exposure Point Concentrations in Soil

2.2.3.1 Short-term

The calculated risks published in the updated BRA indicate that radio-carcinogenic risks to receptors associated with Area 2 were consistently higher than risks to the same receptors in Area 1. Therefore, this assessment uses the radionuclide concentrations associated with Area 2 to provide a conservative estimate of the risk to hypothetical receptors (i.e., receptors in other areas will be exposed to lower concentrations of the constituents producing the greatest human health effects).

The 95% upper confidence limit on the mean (UCL) for all radionuclide COPCs were calculated from sample results using methods described in the updated BRA. Subsequently, the average concentrations of Ra-226 and Th-230 based on the volume of soil excavated for each remedial alternative were calculated using the methods described in Appendix L. The exposure point concentration for other radionuclide COPCs were estimated by establishing the ratio of the average and 95% UCL for Ra-226 and Th-230 (average concentration / 95% UCL). Those two ratios were averaged and then multiplied by the 95% UCL to scale the other radionuclide COPCs and establish their exposure point concentrations.

A smaller number of samples were tested for chemical analytes rather than for radionuclides. As a result, all chemical sample results from OU-1 were combined into one data set. The 95% UCL was calculated from this data set and used as representative chemical exposure point concentrations. This approach is reasonable due to the limited number of chemical samples and because not all chemical analytes were found in one area. The identified chemical analytes are associated with general landfill materials; therefore, this assessment conservatively assumes that the identified chemical analytes could be detected in either Area 1 or Area 2, even if they were not detected in one of the areas.

Because the remaining and excavated soil volumes for each of the remedial alternatives will result in differing soil concentrations in the short-term, Sections 4 through 7 will present each remedial alternative's specific exposure point concentrations.

2.2.3.2 Long-term

In the long-term (post-construction), the identification of remedial alternative-specific remediation criteria will result in remedial alternative-specific exposure point concentrations (EPCs). Only constituents that produce indirect exposures that would emanate through the cap need to be considered, as there is no means of direct contact with RIM under any of the four remedial alternatives in the long term. The chemical COPCs were screened out of the long-term assessment because the landfill cap contemplated under all four remedial alternatives will prevent direct contact with these COPCs, and their lack of volatility prevents their emission in gaseous form. Representative concentrations for each COPC will be presented in each of the remedial alternative-specific long-term risk sections.

2.2.4 **Exposure Point Concentrations in Air**

2.2.4.1 Short-term

Occurrences of RIM within Areas 1 and 2 are dispersed within landfilled material that is further dispersed throughout portions of the overall, heterogeneous matrix of municipal refuse, construction and demolition debris, and soil materials. As such, material that will be disturbed during remedial alternative implementation is not just soil. Rather, the material likely consists of a mixture of paper, rags, plastic, bottles and cans, lumber and pipe, old food and refuse, with some soil mixed into the matrix. It is likely that the trash/debris will have a much lower resuspension rate than soil undergoing similar processes.

Thus there are two competing considerations when modeling air concentrations at OU-1: construction activities would be expected to raise dust levels, but given the nature of the materials being handled, substantial dust would not be expected. In addition, dust suppression measures, partial excavation of areas, and a properly managed health and safety monitoring program will further reduce dust emissions within the working areas. For this evaluation, it was conservatively assumed that the material was "true" soil and would be dispersed and transported as such.

The air transport model AERMOD-View^{TM} v 9.1 was used to simulate aerial transport of respirable particulate matter (PM 2.5) and radon. AERMOD-View^{TM} v 9.1 is a commercially available application which features a user-friendly interface on the EPA-approved air dispersion modeling code known as AERMOD (EPA 2004), version 15181 (EPA 2015). Radon flux values were measured on OU-1 after the non-combustible cover was installed in 2016. Since radon is a gas it is minimally impacted by the non-combustible cover. Those measured radon flux values were then modelled using AERMOD to obtain the projected radon concentrations at the specific receptor sites. Since radon exposure is from all of OU-1, the maximum concentration does not change based on the remedial alternative chosen. Table 2-3 presents the projected radon concentrations at both an on-property and off-property receptor location; these locations were selected based on the results presented in the updated BRA (Auxier 2016). The particulate concentrations, however, vary with the volume of soil excavated and therefore are specific to each remedial alternative. The specific concentrations will be presented in each short-term risk section.

Table 2-3 Projected Radon Concentrations at Selected Locations

Analyte	Off-Property, Southeast (722898 E 4293620 N)	On-Site, Area 2 (721720 E 4294785 N)
Flight distance(m)	1090	440
Flight time(min) [a]	4.40	1.80
Current		
Rn-222 (pCi/m^3)	2.3 E-2	2.2 E+0
Po-218 (pCi/m^3)	1.5 E-2	7.1 E-1
Pb-214(pCi/m^3)	9.3 E-4	1.7 E-2
Bi-214 + 1 dtr (pCi/m^3)	5.0 E-5	3.6 E-4

[a] Average flight time to a location is estimated as a quotient of the location's distance from the center of the domain and 4.1 m/s, the average annual wind speed (Dist(m)/Speed(m/s/60s/min).

2.2.4.2 Long-term

Each remedial alternative includes a landfill cover as a remedial component, thereby eliminating the potential for fugitive dust emissions from any remaining RIM. Therefore, for the long-term AERMOD was used to simulate aerial transport of only radon from Area 1 and 2. Representative radon concentrations for each remedial alternative will be presented in each of the remedial alternative-specific long-term risk sections.

2.2.5 **Potential Receptors**

In the short-term, the activities expected to occur during construction of each of the remedial alternatives were examined to identify potential receptors. Most of the tasks and activities are common to all four remedial alternatives. Other activities would be limited to the specific remedial alternatives. Each short-term remedial alternative-specific evaluation in Sections 4 through 7 contains a list of hypothetical receptors considered for that particular risk assessment. As detailed in Section 3, the On-Property RadCon Tech Worker and Off-Property Resident were selected as representative receptors for the short-term evaluation.

The long-term post-construction receptor chosen for evaluation was the hypothetical grounds keeper, who was the reasonably maximally exposed (RME) individual, as determined in the updated BRA.

2.2.6 **Exposure Pathways**

Exposure pathways are discussed in length in Section 3.1.3 of the updated BRA. The six plausible exposure pathways are: inhalation of fugitive dust, inhalation of radon, direct radiation from soil, direct radiation from submersion in air, incidental soil ingestion, and dermal contact. In the short term, RIM will be disturbed by grading or excavation during construction of each of the four remedial alternatives. In the long term, the presence of the cover and/or the extent of RIM removal will affect the plausible exposure pathways.

There are currently no private wells used to provide domestic or community (potable) water supplies within a 2-mile radius of the West Lake Landfill. The Landfill and surrounding areas are projected to continue to receive potable water from the municipal supply system for the foreseeable future. Due to the limited potential for leaching of the principal constituents , the deed restrictions that prohibit use of wells for drinking water at the Site, and the lack of potable groundwater wells, direct exposure to groundwater at the West Lake Landfill and surrounding areas represents an incomplete exposure pathway and was not considered for quantitative evaluation.

2.2.7 Toxicity Assessment

The chemicals and radionuclides selected for evaluation are the same as those listed as COPCs in the updated BRA. The toxicity values used in the updated BRA were also used herein for both short-term and long-term risk evaluations. Further discussion regarding the carcinogenic and systemic effects of the COPCs can be found in the updated BRA.

2.2.7.1 Blood Lead Levels of Workers During Construction

EPA's Adult Lead Methodology (2003, 2007, 2009a, and 2009b) and the EPA Adult Lead Methodology (ALM) spreadsheet[3] were used to calculate blood levels for the RadCon Tech providing health physics services in the field during construction. This receptor could potentially have years of regular direct contact with OU-1 soils while they are exposed during construction. The potential exposures for other occupational receptors will be more limited due to (1) lack of direct access to RIM, (2) exposure to more limited quantities of RIM, or (3) shorter and/or intermittent exposure to RIM.

The EPA methodology recommends using the average concentration of lead in soil to calculate blood lead levels in adults (EPA 2007). The average current concentrations for Area 1 and Area 2 surface soil, as presented in Section 2.6 of the updated BRA, are 85.5 mg/kg and 555 mg/kg, respectively. These average current concentrations were used to calculate blood lead levels in two hypothetical adult populations. The calculated blood levels in those two populations effectively describe the upper and lower ranges of the measured blood levels in U.S. women aged 17-45, monitored as part of the NHANES III study.[4]

Using the average surface soil lead concentrations and an exposure duration of 225 days yields adult blood lead levels of 1.1 µg/dL to 1.8 µg/dL for the RadCon Tech exposed to Area 1 and Area 2 soil, respectively, as presented in Table 2-4. EPA guidance is pending on the potential impacts of low blood lead level concentrations on public health, but these calculated levels are less than the EPA's 5-10 µg/dL levels discussed as potential benchmarks in EPA's OSWER Directive 9200.2-82 (EPA 2009a). The ALM also predicts an unlikely probability that blood lead levels in a fetus will exceed these acceptable benchmark levels; EPA has set a goal that there should be no more than a 5% chance that a child will have a blood lead level above 10 µg/dL. Results of the blood lead modeling are evaluated based on comparisons to these benchmarks.

---

[3] From https://www.epa.gov/sites/production/files/2015-09/alm_2009.xls (Aug 25, 2016).

[4] For more information about these two test populations and the default parameters used in the calculation, see EPA 2002, CDC 2005a, CDC 2005b, and CDC 2005c.

It should be noted that proper use of standard personal protective equipment such as gloves, the use of heavy equipment for most jobs requiring direct handing of RIM, and active dust suppression measures all would likely result in actual soil ingestion rates that are less than those used in the calculations. Any reduction of soil ingestion rates would, in turn, reduce calculated blood lead levels, suggesting that the calculated blood lead levels published here overestimate what can be expected during remedial alternative construction.

It should be noted that proper use of standard personal protective equipment such as gloves, the use of heavy equipment for most jobs requiring direct handing of RIM, and active dust suppression measures all would likely result in actual soil ingestion rates that are less than those used in the calculations. Any reduction of soil ingestion rates would, in turn, reduce calculated blood lead levels, suggesting that the calculated blood lead levels published here overestimate what can be expected during remedial alternative construction.

Table 2-4 Projected Blood Levels in Workers Exposed to Current Concentrations of Lead in Surface Soil

Variable	Description of Variable	Units	Area 1		Area 2	
			EPA 2009 [a]	EPA 2002 [b]	EPA 2009 [a]	EPA 2002 [b]
PbS	Soil lead concentration	mg/kg	86	86	555	555
$R_{fetal/maternal}$	Fetal/maternal PbB ratio	unitless	0.9	0.9	0.9	0.9
BKSF	Biokinetic Slope Factor	µg•d/dL•µg	0.4	0.4	0.4	0.4
GSD_i	Geometric standard deviation PbB	unitless	1.8	2.1	1.8	2.1
PbB_0	Baseline PbB	µg/dL	1.0	1.5	1.0	1.5
IR_{S+D}	Ingestion rate, soil + indoor dust	g/d	0.050	0.050	0.050	0.050
$AF_{S, D}$	Absorption fraction (soil and dust)	unitless	0.12	0.12	0.12	0.12
$EF_{S, D}$	Exposure frequency (soil and dust)	d/y	225	225	225	225
$AT_{S, D}$	Averaging time (soil and dust)	d/y	365	365	365	365
PbB_{adult}	**PbB of adult worker, geomean**	**µg/dL**	**1.1**	**1.6**	**1.8**	**2.3**
$PbB_{fetal, 0.95}$	95th %tile PbB among worker's fetuses	µg/dL	2.7	5.0	4.3	7.1
PbB_t	Target PbB benchmark	µg/dL	**10.0**	**10.0**	**10.0**	**10.0**

[a] More homogeneous, GSD_i and PbB_o from NHANES 1999-2004. Recommended by EPA 2009.

[b] Reflects an earlier evaluation of a more homogeneous population, GSD_i and PbB_o from NHANES III (Phases 1&2)

2.2.8 **Exposure Setting and Risk Characterization Methods**

Potential exposure media, receptors, and exposure points are typically identified in an HHRA based on site conditions, including current and future land use. In the short-term, general land use at and surrounding West Lake Landfill is expected to remain unchanged – the Site will continue operating within an industrial setting. As such, many of the receptors identified in the updated BRA are also relevant to the evaluation of short-term COPC exposure risks (e.g., nearby workers, off-property residents). Several additional receptors are expected be present at OU-1 during remedial alternative implementation – some of which are expected to be in close proximity to RIM. Therefore, in the short term, the anticipated activities are the key aspect of the exposure setting considered in this evaluation.

The construction phase of all remedial alternatives considered in this study is expected to produce direct exposure to RIM and chemical COPCs, and all but one ("complete rad removal") will leave some RIM in place at the West Lake Landfill. The post-construction surface of OU-1 for all the remedial alternatives will be covered by a RCRA Subtitle D solid waste landfill cover designed to comply with structural and performance standards associated with the closure and post-closure requirement of the Missouri solid waste regulations. Under the ROD-selected remedy and the two remedial alternatives that leave concentrations of RIM above 7.9 pCi/g, the solid waste landfill cover would also include a rock/concrete rubble bio-intrusion/marker layer pursuant to Uranium Mill Tailings Radiation Control Act (UMTRCA) requirements.

Potential human health effects resulting from exposure to COPCs are estimated using methods established by the EPA. These methods are published in a series of guidance documents including the Risk Assessment Guidance for Superfund, Volume 1, Human Health Evaluation Manual (EPA 1989a) (RAGS) and integrated into web-based calculators hosted by the Oak Ridge National Laboratory (ORNL) and EPA.[5]

Other tools used in the COPC risk assessment process include AERMOD, which was used to estimate the air concentration of COPCs at receptor locations, MicroShield, which was used to calculate the Total Effective Dose Equivalent (TEDE), and EPA's Adult Lead Model (short-term only). These are described in more detail in the following subsections.

2.2.8.1 EPAs PRG and RSL Calculators to Assess Risks

Radio-and chemo-carcinogenic risks involving contact with surface and subsurface soils (inhalation, ingestion, direct radiation, and submersion) and from inhalation (fugitive dust, radon and radon daughters) were calculated using the EPA's web-based preliminary remediation goal (PRG) calculator[6] or the Regional Screening Level (RSL) calculator[7]. These calculators provide PRGs for radionuclides or RSLs for chemicals for each exposure route. Using a target risk (TR) of 10^{-06} and the EPA web calculator's default or site-specific parameters for a particular type of worker or resident, the "unit PRG (or RSL)" or the PRG associated with 1 pCi/g (or mg/kg or $\mu g/m^3$) can be determined. This method results in an effective and efficient means of calculating

[5] https://epa-prgs.ornl.gov/cgi-bin/radionuclides/rprg_search and https://www.epa.gov/risk/regional-screening-levels-rsls-generic-tables-may-2016

[6] http://epa-prgs.ornl.gov/cgi-bin/radionuclides/rprg_search

[7] http://www.epa.gov/reg3hwmd/risk/human/rb-concentration_table/Generic_Tables/

the risk associated with any concentration of a COPC. The risk is calculated by dividing 10^{-06} by the unit PRG (or RSL), and then multiplying by the concentration (soil or air depending on the application) of the COPC. For example, the default unit PRG for outdoor worker exposures for radium-226 and its short-lived daughters in soil from all exposure routes is 2.33 x 10^{-02} pCi/g. The incremental risk associated with each additional pCi/g of radium-226 is 4.292 x 10^{-05} (10^{-06} / 2.33 x 10^{-02}). This ratio can be multiplied by the applicable concentration to determine the risk associated with exposure to the COPC.

In the FFS, risks to specific workers from soil and air are evaluated using the method illustrated above. However, assessment of carcinogenic risks to individual types of workers identified during the scheduling and manpower evaluation stages of this study may require job-specific changes in parameters used to calculate the unit PRG, such as exposure time and duration. Therefore, a combination of site- and receptor-specific parameters and default values from the EPA calculators were used during risk calculation. Changes in these parameters and their justifications are presented as part of the risk evaluation in each remedial alternative specific section. Because the relationship between risk and exposure is linear, the risk results will change linearly with changes in either exposure times or durations. For example, if the calculated risk from 45,000 hours[8] of exposure to soil containing 1 pCi/g of radium-226 is 4.0 x 10^{-05}, then exposure to the same soil for only one hour will be 1/45,000th of that risk or 8.9 x 10^{-10} per pCi/g per hour and a 1,000 hour exposure would yield a calculated risk of 8.9 x 10^{-07}.

2.2.8.2 MicroShield

Dose rates to the short-term and long-term occupationally exposed individuals, in units of millirem/year (mrem/y), were calculated using MicroShield® software. MicroShield® is a comprehensive photon/gamma ray shielding and dose assessment program that is widely used for designing shields, estimating source strength from radiation measurements, minimizing exposure to people, and teaching shielding principles.

The TEDE was calculated by multiplying the time spent exposed to RIM in a year by the dose rate in mrem/y as calculated by MicroShield (given the soil concentration of COPCs and a cover thickness where applicable). To provide a preliminary evaluation of potential risk, these dose rates were compared to the default occupational exposure limit of 5,000 mrem/y.

2.2.8.3 AERMOD

Air exposure point concentrations at selected receptor exposure points were estimated using AERMOD. AERMOD is an EPA-approved, steady-state Gaussian dispersion model. BREEZE AERMOD is an enhanced version of AERMOD that provides modelers with the tools and functionality required to perform air quality analyses to address both permitting, regulatory, and nuisance issues as well as to perform academic research.

Radio-carcinogenic risk from radon and radon daughters was calculated by dividing 10^{-06} by the "Air" unit PRG and then multiplying by the estimated air concentration as modeled using AERMOD (given the soil concentration of COPCs and a cover thickness where applicable).

---

[8] http://epa-prgs.ornl.gov/cgi-bin/radionuclides/rprg_search. EPA's outdoor worker receptor assumes the worker is present for 8 hours a day, 225 days/year for 25 years, or 25 years x 225 days/year x 8 hour/day = 45,000 hours of exposure.

2.2.8.4 EPAs RSL Calculator to Assess Hazard Indices

The effects associated with exposures to non-carcinogenic chemicals are evaluated differently from the approach used to evaluate carcinogens. Intakes are compared to a reference quantity that represents a safe level of exposure. The ratio of a receptors intake over the reference quantity is termed the Hazard Quotient (HQ) for that chemical in a given exposure scenario. If the HQ exceeds 1, there may a risk of potential health effects. In the case where a receptor receives simultaneous exposures to several chemicals, a Hazard Index (HI) is calculated as the sum of the HQ. Table 2-2 presents the non-carcinogenic COPCs that were considered in this FFS and in this evaluation.

2.3 SHORT-TERM RISK ASSESSMENTS FOR PROPOSED REMEDIAL ALTERNATIVE

Short-term risks were grouped into two major categories in this report: risks to human health from exposures to RIM and COPCs present in OU-1; and, risks of injury or fatalities from industrial and construction accidents in conjunction with implementation of the remedial alternatives. These risks are evaluated for both on- and off-property individuals. Human health risks include carcinogenic and non-carcinogenic effects from exposure to any RIM and COPCs that might be uncovered, excavated, transported or handled while on the Site or during transportation from the Site. The risks from construction, material handling, and transportation accidents have been grouped together under “industrial hazards”. Specifics risks for each remedial alternative are found in Sections 3 through 7.

2.4 LONG-TERM RISK ASSESSMENTS FOR PROPOSED REMEDIAL ALTERNATIVE

Long-term human health risk assessments for each of the four remedial alternatives are also presented. These risks are presented in Sections 8 through 12. Each of the remedial alternative-specific risk assessments identify the source and inventory of RIM constituents, lists exposure pathways, identifies the RME individual(s) and presents remedial alternative-specific details about the methods and data used to assess potential risks at year 1 after construction and over the next 1,000 years after implementation of a remedial alternative.

3 SHORT-TERM RISK EXPOSURE ASSESSMENT

This section presents the short-term exposure assessment, which consists of the following steps:

- Characterization of the exposure setting during remedy implementation (i.e., the short-term);
- Quantification of exposure point concentrations;
- Identification of receptors with potentially complete exposure pathways and selection of representative receptors for use in the FFS comparative analysis; and
- Quantification of receptor-specific intake/exposure.

This exposure assessment supports the evaluation of short-term COPC exposure risks. Information presented in this section, unless otherwise noted, is applicable to each "action" alternative (i.e., the two partial excavation remedial alternatives, the full excavation remedial alternative, and the ROD-selected remedy).

3.1 CHARACTERIZATION OF EXPOSURE SETTING

Potential exposure media, receptors, and exposure points are typically identified in an HHRA based on site conditions, including current and future land use. In the short-term, general land use at and surrounding West Lake Landfill is expected to remain unchanged – the Site will continue operating within an industrial setting. As such, many of the receptors identified in the BRA are also relevant to the evaluation of short-term COPC exposure risks (e.g., nearby workers, off-property residents). Several additional receptors are expected be present at OU-1 during remedy implementation, some of whom will be in close proximity to RIM. Therefore, in the short term, the anticipated activities are the key aspect of the exposure setting considered in this evaluation.

Activities anticipated in conjunction with the remedial alternatives may include:

- move contaminated materials from the Buffer Zone onto Area 2;
- excavate RIM from Areas 1 and 2 (not applicable to the ROD-selected remedy);
- move excavated material around OU-1(not applicable to the ROD-selected remedy);
- ship excavated RIM to an off-site location(not applicable to the ROD-selected remedy);
- ship cover materials into OU-1;
- grade the landfill surface; and
- construct a multilayer, vegetated cover over Areas 1 and 2.

3.2 EXPOSURE POINT CONCENTRATIONS

The short-term exposure point concentrations for both soil and air were introduced in Sections 2.2.3.1 and 2.2.4.1, respectively. Remedial alternative-specific exposure point concentrations are presented in Sections 4 through 7.

3.3 POTENTIAL RECEPTORS

The activities expected to occur during construction of each of the remedial alternatives were examined to identify potential receptors. Some of the tasks and activities are common to all four remedial alternatives. Other activities would be limited to specific remedial alternatives. Potential receptors identified include:

- **<u>Radiation Survey/Radiation Control Technicians (RadCon Techs)</u>** – One or more RadCon Techs were assumed to be involved in identifying areas of soil containing RIM, directing the excavation and movement of RIM on the Site, and surveying the equipment that has to move into and out of the exclusion zones set up around work areas. These receptors will spend most of their work day standing on or next to areas containing RIM. They will likely be exposed to higher concentrations of RIM for longer periods of time than any other potential receptor identified.

- **<u>Heavy Equipment Operator</u>** – One or more heavy equipment operators were assumed to be involved in excavating the RIM, loading this material into trucks, spreading any fill or cover materials placed on the excavated areas, and regrading the surface of OU-1. These workers are assumed to be riding above the surface of the RIM in an enclosed cab with portions of the vehicle, thereby shielding them from the underlying RIM.

- **<u>Truck to Rail Transfer Facility Operators</u>** – One or more qualified radiation workers may be involved with material handling operations at a waste transfer facility. Activities might include operating heavy equipment, inspecting trucks and railcars, spill cleanup, waste sampling, and general housekeeping. These workers would be partially shielded by the sides of the trucks and the railcars and would often be working at some distance from the RIM. Note: this receptor is potentially relevant to the partial and full excavation remedial alternatives, but not the ROD-selected remedy.

- **<u>Truck Drivers</u>** – One or more truck drivers were assumed to be involved with hauling any RIM from OU-1 to a transfer station. This driver is also assumed to haul fill material and cover material into OU-1 during construction of a cover. The driver would remain seated in his truck during the majority of his work shift. Note: receptors hauling RIM off-site are potentially relevant to the partial and full excavation remedial alternatives, but not the ROD-selected remedy.

- **<u>Laborers</u>** – One or more qualified radiation workers may perform manual labor within the OU-1 as part of the remediation. Activities could range from carrying equipment to cleaning equipment. It is expected that the exposure times required to perform these activities will be shorter that the exposure times of the RadCon Techs.

- **<u>Engineers/Management</u>** – This group of receptors include qualified radiation workers who direct operations and respond to atypical occurrences but typically spend limited time in close proximity to exposed RIM.

- **<u>Nearby Workers</u>** – Businesses located near the Site employ workers who may be exposed to transient plumes of dust transported from the Site by wind. The average exposure concentrations in air (if any) would be lower than those encountered by RadCon Techs because exposures to a given receptor will only occur during times when the wind blows in their direction. Further, when the wind does blow in the direction of the workers, near ground turbulence will mix the particulates into a larger volume of air, lowering their concentrations.

- **<u>Off-Property Residents</u>** – One or more off-property residents may be exposed to fugitive dust and/or gases during the construction of the remedial alternative.

- **Highway Users** – If RIM is shipped on public roads, the trucks containing the RIM would pass near members of the public on those same roads. The RIM on the trucks would be placed in strong-tight packaging, and any radiation from the RIM would be partially shielded by the body of the truck. Trucks will be inspected for loose contamination before being allowed to leave the Site. In the event of an accident, any spillage would be removed from the road as part of incident response. Any routine or accidental exposures would be transitory and receptors would be separated from the truck carrying the RIM by at least two to three meters. Note: this receptor is potentially relevant to the partial and full excavation remedial alternatives, but not the ROD-selected remedy.

- **Transients/Visitors** – Individuals may visit the Site to service or repair equipment, deliver items or inspect operations. Exposures to these individuals are expected to be transitory. Note: if visitors are present on a more frequent basis, *e.g.*, such as a local delivery driver, risks calculated for laborers would be applicable to these receptors.

- **Rail Users** – If RIM is shipped by rail, the trains containing the RIM could pass near members of the public adjacent to the rail line. The RIM in the railcars would be contained in super sacks, and any radiation from the RIM would be partially shielded by the body of the railcar. Any exposures would be transitory and receptors would be separated from the train carrying the RIM by at least three to five meters. Note: this receptor is potentially relevant to the partial and full excavation remedial alternatives, but not the ROD-selected remedy.

- **Rail Workers** – One or more rail workers were assumed to be involved with hauling any RIM from the Site to the disposal site. These workers would be shielded from the RIM in the railcars by at least one diesel engine and separated from the RIM by many meters of distance. Note: this receptor is potentially relevant to the partial and full excavation remedial alternatives, but not the ROD-selected remedy.

Potential exposure pathways for each of these receptors were qualitatively evaluated to identify receptors with the greatest potential for exposure that were relevant to each of the action remedial alternatives. Consistent with the conclusions of the updated BRA (Auxier 2016), the RME individual is anticipated to be an on-property receptor. This reflects the dominance of the gamma exposure pathway in the risk assessment calculations. Off-property receptors would not be exposed to direct gamma from the soil and the primary pathway for those receptors would be potential inhalation of airborne emissions from the Site. Based on these considerations, the On-Property RadCon Tech Worker and Off-Property Resident were selected for quantitative evaluation herein. These potential and selected receptors are listed in Table 3-1.

Table 3-1 Potential Short-Term Receptors Identified During Remedial Alternative Implementation

Receptors Identified	[a] Scenario Applicability (P/F/R)	Exposure Route: Inhalation of Fugitive Dust	Inhalation of Radon	Direct Radiation from Soil	Direct Radiation from Submersion in Air	Incidental Soil Ingestion	Dermal Contact	Selected for Quantitative Evaluation?
RadCon Techs	**P/F/R**	●	●	●	●	●	●	**Yes**
Heavy Equipment Operators	**P/F/R**	{O}	{O}	{O}	{O}	{O}	{O}	No
Truck to Rail Transfer Facility Operators	**P/F**	{O}	{O}	{O}	{O}	{O}	{O}	No
Truck Drivers	**P/F/R**	{O}	{O}	{O}	{O}			No
Laborers	**P/F/R**	{O}	{O}	{O}	{O}			No
Engineers/Management	**P/F/R**	{O}	{O}	{O}	{O}			No
Nearby Workers	**P/F/R**	{O}	{O}	{O}	{O}			No
Off-Property Residents	**P/F/R**	●	●		●			**Yes**
Highway Users	**P/F**			{S}				No
Transients/Visitors	**P/F/R**	{O}	{O}					No
Rail Users	**P/F**			{O}	{O}			No
Rail Workers	**P/F**			{O}	{O}			No

[a] An exposure scenario was considered if it included a source, a means of moving constituents of concern to a location of interest, and a receptor at that location. All receptor scenarios listed in the table are applicable to the partial ("P") and full ("F") excavation alternatives; however, only a subset are applicable to the ROD-selected ("R") remedy.

●	Exposure route selected for detailed analysis
(shaded box)	A shaded box indicates that the receptor/exposure route combination was not selected for quantitative analysis.
{O}	Not quantified because other receptors identified for this scenario have higher intake rates and longer exposure times.
{S}	Scoping level analysis of possible spillage of RIM performed using MicroShield indicates doses < 1 mrem/y. Source evaluated was 1 mm thick soil containing 338 pCi Ra-226/g (Area 2 conc.) spread across one 100 ft. long lane (16 ft. wide). Dose point 3 feet over road through 2 mm iron (car floor).

3.4 EXPOSURE PATHWAYS

The following potentially complete exposure pathways were identified for the selected representative receptors:

- **On-Property RadCon Tech Workers** – These on-property workers are potentially exposed to COPCs via inhalation of fugitive dust, inhalation of radon gas, direct radiation from soil, direct radiation from submersion in air, incidental ingestion of soil, and dermal contact with soil.
- **Off-Property Residents** – These receptors are potentially exposed to COPCs via inhalation of fugitive dust, inhalation of radon, and direct radiation from submersion in air.

The details of these exposures (e.g., exposure time and duration) are remedial alternative-specific and are addressed in the short-term evaluations for each remedial alternative presented in Sections 4 through 7.

4 SHORT-TERM RISKS FOR THE "PARTIAL EXCAVATION TO 1,000 PCI/G" ALTERNATIVE

4.1 ALTERNATIVE DESCRIPTION

In this remedial alternative, RIM with activity levels above 1,000 pCi/g will be excavated and shipped to an approved out-of-state disposal facility. This remedial alternative is intended to protect human health by removing the RIM above the established criterion and placing an engineered cap over all of OU-1. This cap design provides a physical barrier that isolates the remaining RIM from surface receptors.

This risk analysis identifies and evaluates the major short-term hazards and exposures from the construction and transportation activities during excavation, capping, and restoration of Areas 1 and 2 that would occur during construction of the "partial excavation to 1,000 pCi/g" alternative. It also evaluates the human health risks from exposure to chemicals and radionuclides that may occur during remedial alternative construction.

4.2 QUANTIFICATION OF SHORT-TERM COPC EXPOSURE RISKS

As discussed in Section 2, a human health assessment considers the following components: COPC selection, exposure assessment (exposure point concentrations, potential receptors, and exposure pathways), toxicity assessment, and risk characterization. This section combines the first three components to characterize risks to both on-property and off-property receptors from exposure to COPCs. The following sections combine information from Section 3 with remedial alternative-specific information and present the calculations specific to the "partial excavation to 1,000 pCi/g" alternative.

4.2.1 Exposure Point Concentrations in Soil

The exposure point concentration is the concentration of a contaminant in an exposure medium that may be contacted by a real or hypothetical receptor. As previously discussed in Section 2.2.1.1, the average concentration of radionuclides in the total volume of excavated materials was calculated and used for radionuclide exposure point concentrations. Radionuclide concentrations in Area 2 were selected to evaluate human health effects because the radionuclide concentrations with the greatest impact on health (Ra-226 and Th-230) are in Area 2.

Chemical exposure point concentrations were calculated from combined OU-1data as described in Section 2.2.1.2. Table 4-1presents the representative concentrations of radionuclides and chemicals in soil used in this short-term risk assessment.

Table 4-1 Short-term Soil Exposure Point Concentrations for the "Partial Excavation to 1,000 pCi/g" Alternative

Analyte	Soil Exposure Point Concentrations	Units
Radionuclides [a]		
Uranium Series		
Uranium-238 + 3 dtrs	47.33	pCi/g
Uranium-234	49.6	pCi/g
Thorium-230	694.09	pCi/g
Radium-226 + 8 dtrs	241.2	pCi/g
Lead-210 + 2 dtrs	52.63	pCi/g
Actinium Series		
Uranium-235 + 1 dtr	2.42	pCi/g
Protactinium-231	68.91	pCi/g
Actinium-227 + 9 dtrs	46.57	pCi/g
Thorium Series		
Thorium-232 + 10 dtrs	8.33	pCi/g
Inorganic Chemicals [b]		
Antimony (metallic)	5.97	mg/kg
Arsenic, Inorganic	40.18	mg/kg
Chromium, total) [c]	64.87	mg/kg
Cobalt	349.00	mg/kg
Lead and Compounds	785.80	mg/kg
Mercury [c]	0.70	mg/kg
Nickel Soluble Salts	432.40	mg/kg
Uranium (Soluble Salts)	156.00 [d]	mg/kg
Vanadium and Compounds	158.00	mg/kg
Pesticides/PCBs [b]		
Aroclor 1242	0.43	mg/kg
Aroclor 1254	0.40	mg/kg
Volatile Organic Compounds (VOCs) [b]		
Dichlorobenzene, 1,4-	312.79	mg/kg
Chlorobenzene	26.45	mg/kg

[a] Based on average concentration of excavated material in Area 2 only..
[b] Based on 95% UCLs of sample results for all OU-1 soils combined.
[c] The names listed reflect the lab chemical designation. There are no RSL values within the EPA calculator for these laboratory chemical names. As such, risk is calculated using the RSL values within the EPA calculator for related chemicals (i.e., chromium (VI) for chromium, total, and mercury (elemental) for mercury.
[d] Of the isotopes of natural uranium, uranium-238 accounts for more than 99 percent of the mass of uranium. The 95% UCL mass concentration of uranium-238 for all OU-1 soils of 52.3 pCi/g was divided by the specific activity of 0.336 pCi/µg, resulting in a mass concentration of 156 mg of uranium (soluble salts) per kg of soil (mg/kg).

4.2.2 **Exposure Point Concentrations in Air**

As previously discussed in Section 2.2.8.3, AERMOD was used to simulate aerial transport of both fugitive dust and radon. Radon concentrations in the short-term are derived from measured values, are the same values as presented in the updated BRA, and are presented in Table 2-3. Particulate air concentrations for selected locations are dependent on soil concentrations and are presented in Table 4-2 below.

Table 4-2 Short-term Air Exposure Point Concentrations for the "Partial Excavation to 1,000 pCi/g" Alternative

Analyte	Off-Property, Southeast (722898 E 4293620 N)	On-site, Area 2 (721720 E 4294785 N)
Uranium Series (pCi/m^3)		
Uranium-238 + D	2.84E-07	3.45E-04
Uranium-234	2.97E-07	3.62E-04
Thorium-230	4.16E-06	5.06E-03
Radium-226 + D	1.45E-06	1.76E-03
Lead-210 + D	3.16E-07	3.84E-04
Actinium Series (pCi/m^3)		
Uranium-235 + 1 D	1.45E-08	1.76E-05
Protactinium-231 + D	4.13E-07	5.02E-04
Actinium-227 + D	2.79E-07	3.40E-04

4.2.3 Exposure Pathways

During remedial alternative construction, the RIM and chemicals will be disturbed by excavation and loading into open-topped trucks for on-property transport. The receptors identified in Section 3.3 could be exposed to this material by inhalation of fugitive dust, inhalation of radon, incidental ingestion of soil, direct exposure to radiation from soil, direct exposure to radiation and chemicals from submersion in air, or dermal contact, depending on the receptor and their locations.

4.2.4 Quantification of Human Health COPC Exposure Risks

4.2.4.1 Calculation of Carcinogenic Risk to Selected Receptors

Calculations of carcinogenic risks to potential receptors were based on the relationships between risk and concentration produced by Site-specific scenario descriptions input into EPA's PRG and RSL calculators. The major differences between the default parameter values used by EPA to calculate health effects to default receptors and the values used to describe Site-specific receptors at this Site are the times the receptors are assumed to spend exposed to RIM. For example, EPA's PRG calculations for an outdoor worker assume the workers spends 5,625 days on the Site[9] during a 25 year period, and scheduling information suggests the worker will be exposed to RIM for 8 hours a day over a 1,468 day period[10] during the excavation of the RIM from the three areas where RIM has been identified (Areas 1 and 2 and the Buffer Zone).

The work is scheduled to be performed over 6.5 years, and the period of exposure was allocated equally between the 6.5 years. The RadCon Tech was assumed to be exposed for 225 days a year over the duration of the construction. The off-property resident may also be exposed for a longer period while the RIM is exposed but no work is ongoing (nights, weekends, etc.). Therefore, the default EPA annual exposure frequency of 350 days a year was used.

Table 4-3 and Table 4-5 provide the input parameters for EPA's Soil and Air PRG and RSL Calculators for outdoor workers and off-property residents. Table 4-4 and Table 4-6 provide the results of the calculations using these parameters.

Table 4-3 Input for EPA's Soil and Air PRG and RSL Calculators, RadCon Tech, "Partial Excavation to 1,000 pCi/g" Alternative

Variable	Radionuclide PRG Calculator Value	Chemical RSL Calculator Value
Slab size for ACF (area correction factor) m^2	2000	NA
t_{ow} (time – outdoor worker) yr	6.5	NA
ED_{ow} (exposure duration – outdoor worker) yr	6.5	6.5
ET_{ow} (exposure time – outdoor worker) hr/day	8	8
EF_{ow} (exposure frequency - outdoor worker) day/yr	225	225

Note: Other parameters were left at their default values.

[9] Total days = Exposure Duration 25 (y/lifetime) x 225 (d/y) = 5,625 (d/lifetime)

[10] Derived from project schedule provided by Feezor Engineering, Inc., dated September 27, 2016.

The calculated lifetime risk to the hypothetical RadCon Tech on Area 2 is 2.38 x 10^{-03}. The risks to a hypothetical receptor living at the location identified in the updated BRA as "Off-Property, Southeast"[11] were calculated as 5.26 x 10^{-08}.

[11] The updated BRA (Auxier 2016) identified the "Off-Property, Southeast" receptor as the RME receptor of the two residents assessed.

4.2.4.2 Calculation of Non-Carcinogenic Effects to Selected Receptors

Site-specific parameters listed in Table 4-3 and Table 4-5 were used in the EPA RSL calculator to calculate the hazard quotients to the RadCon Tech and off-property resident, respectively. The results for the hypothetical RadCon Tech are presented in Table 4-7. Table 4-8 presents the hazard quotients calculated for the off-property resident.

The calculated HI for the hypothetical RadCon Tech located on Area 2 is 1.22. The HI for a receptor living at the location identified in the updated BRA as "Off-Property, Southeast" was calculated as 4.12×10^{-04}. The EPA has previously determined that an HI of greater than one (1) for a particular COPC may represent a potential health risk.

4.3 QUANTIFICATION OF INDUSTRIAL INCIDENT RISK

There is a risk of occupational and traffic accidents during earthmoving or transportation of materials on public roads. Generally, the risk of occurrence is time dependent, increasing as the duration of the activity lengthens. The severity of the accident depends, in part, on the activity itself.

In order to assess the likelihood and severity of possible accidents, Occupational Safety and Health Administration (OSHA) and National Highway Traffic Safety Administration (NHTSA) statistics for workers in different occupations and transportation records were used in conjunction with manpower and resource projections from remedial alternative construction schedules to calculate the risks for accidents.

4.3.1 **Transportation Hazards**

Table 4-9 lists statistics on the rate that traffic accidents involving heavy trucks occurred in 2012 (NHTSA 2014). The projection for heavy truck use on public roads during construction of the "partial excavation to 1,000 pCi/g" alternative is 3,290,000 miles. Multiplying this mileage by the injury and fatality rates in Table 4-9 yields the transportation incident forecast presented Table 4-10.

Table 4-9 Accident Incident Rate for Trucks on Public Roads

Incident	Published rate [a]	Per mile rate [b]
Injury Crashes	2.90E+01	2.90E-07
Fatal Crashes	1.42E+00	1.42E-08

[a] Rate per 100 million miles (NHTSA 2014).
[b] Derived from rate (incidents/100,000,000 mile)

Table 4-10 Traffic Injury and Fatality Forecast for the "Partial Excavation to 1,000 pCi/g" Alternative

Parameter	Value
Total miles for all hauling on public roads [a]	3.29E+06
Injury risk for the project	9.54E-01
Fatality risk for the project	4.67E-02
Forecast of accidents involving injuries or fatalities	**1.00E+00**

[a] Estimate provided by Feezor Engineering, Inc., September 27, 2016, "Total Delivery Miles (Totals)"

Hazards from transporting the RIM by rail from the local railhead to the off-site destination can be similarly assessed (Table 4-11 and Table 4-12).

Table 4-11 Accident Incident Rate for Railroads

Incident	Published Per Mile Rate [a]
Injury Rate	1.20E-05
Fatality Rate	1.04E-06

[a] Rate per mile (FRAOSA 2016).

Table 4-12 Railroad Injury and Fatality Forecast for the "Partial Excavation to 1,000 pCi/g" Alternative

Parameter	Value
Rail mile [a]	1.20E+06
Injury risk for the project	1.44E+01
Fatality risk for the project	1.24E+00
Forecast of rail accidents involving injuries or fatalities	**1.56E+01**

[a] Rail distance calculated as 374 trains x 3,200 miles round trip

The projected number of on-site and off-site transportation accidents involving injury or death during construction of the "partial excavation to 1,000 pCi/g" alternative of 16.6 is related primarily to the number of trucks hauling materials onto the Site and transporting the RIM via rail to an off-site disposal facility. It should be noted that this projection includes injuries and deaths of people other than the truck occupants. In 2012, 3% of the injuries and 10% of the fatalities from traffic accidents on public roads were to people not riding in the truck involved in the incident (NHTSA 2014).

4.3.2 Industrial Hazards

As in the previous assessment, the workers involved with remedial alternative construction have been divided into two groups: general construction and driver/operators. The Bureau of Labor Statistics (BLS) maintains historical information on the rate that accidents occur in the U.S. These statistics are available grouped by job description, and Table 4-13 and Table 4-14 list accident statistics for general construction and off-road drivers, respectively.

Table 4-13 Accident Rate for General Construction and Support Workers

Parameter	Value
Injury accident rate per 100 full-time workers [a]	2.90E+00
Accident rate per man-hour worked	1.45E-05
Accident rate per man-day worked	1.16E-04
Number of general construction + support man-days worked [b]	7.38E+04
Number of Accidents Forecast	**8.56E+00**

[a] Bureau of Labor Statistics News Release, October 29, 2014 "Employer-Reported Workplace Injuries and Illnesses – 2014" for Heavy and civil engineering construction (237). (BLS 2015)
[b] Estimate provided by Feezor Engineering, Inc., September 27, 2016, "Crew Man-Days Overall"

Table 4-14 Occupational Accident Rate for Truck Drivers

Parameter	Value
Injury accident rate per 100 full-time workers [a]	4.40E+00
Accident rate per hour worked	2.20E-05
Hours spent driving [b]	1.19E+05
Other transportation activities (hrs) [c]	2.38E+04
Total transportation man-hours worked	1.43E+05
Number of Accidents Forecast [d]	**3.15E+00**

[a] Bureau of Labor Statistics News Release, October 29, 2014 "Employer-Reported Workplace Injuries and Illnesses – 2014" for Heavy and civil engineering construction (484). (BLS 2015)

[b] Estimate provided by Feezor Engineering, Inc., September 27, 2016, "Crew Man-Days On-site Haul Trucks" x 8 h/d

[c] Hours assumed - Driving hours x 0.2.

[d] Accident Rate per hour x Total Transportation Man-hours

Table 4-13 and Table 4-14 also list the remedial alternative construction time in either man-days or man-hours that can be grouped into each of those broad labor categories. Multiplying the total time by the appropriate accident rate will yield an accident forecast for this group's activities during this project. The number of accidents forecast for the general construction and off-road drivers are presented in bold on the last line of Table 4-13 and Table 4-14, respectively. Summing the number of accidents forecast for both labor groups yields the total accident projection for the project.

For example, it is estimated that it will require 73,800 man-days of general construction and support labor to construct the "partial excavation to 1,000 pCi/g" alternative. Multiplying this duration by the injury and fatality rate of 1.16×10^{-04} accidents per man-day in Table 4-13 yields the construction incident forecast of 8.56 accidents. Adding this to the project risk of non-traffic accidents for truck drivers in Table 4-14 yields a total accident projection for general construction and off-road activities of 11.71.

4.4 QUANTIFICATION OF OCCUPATIONAL EXTERNAL RADIATION EXPOSURE

Remedial workers were assumed to be classified as radiation workers in this assessment. As such, the RadCon Tech is expected to be the RME individual in the short-term. Unit doses factors to those workers were calculated using MicroShield 9.02. The current exposure point concentrations from Table 4-1 were multiplied by the unit dose rate to calculate the average dose rate for the worker. Multiplying the average of these dose rates and the total projected time spent exposed to RIM yields the estimated annual TEDE to RadCon Techs on the project (Table 4-15).

Table 4-15 Radiation Dose to RadCon Tech

	Area 2
Days per Project	1468
Average TEDE on surface (mrem/hour)	4.81E-01
Hours spent exposed to RIM (per year)	1.80E+03 [b]
TEDE for Reasonably Maximally-Exposed Individual (mrem/y)	**8.67E+02**

[a] Calculated by MicroShield.
[b] 1,468 worker exposure days / 6.5 year project duration= 225 days/year x 8 hours/day = 1,800 hours/year

The calculated average exposure rate to the hypothetical RadCon Tech would be approximately 0.481 mrem/hr. If the RadCon Tech spent 1,800 hours per year working on the RIM, the TEDE would be 867 mrem/y. To put this in perspective, according to 10 CFR § 20.1201, a radiation worker has an occupational exposure limit of 5,000 mrem/y, assuming no administrative limits are imposed for the Site (NRC 1991).

4.5 SUMMARY

The short-term human health risks and hazard projections are summarized in Table 4-16.

Table 4-16 Summary of Short-Term Hazards and Risks Associated with "Partial Excavation to 1,000 pCi/g" Alternative

Category of Hazard or Risk	Value
Projected Incidence of Transportation Accidents	1.66E+01
Projected Incidence of Industrial Accidents	1.17E+01
Carcinogenic Risk to RadCon Tech	2.38E-03
Carcinogenic Risk to Off-Property Resident	5.26E-08
HI to RadCon Tech	1.22E+00
HI to Off-Property Resident	4.12E-04
TEDE to Reasonably Maximally-Exposed Individual	8.67E+02

It is projected that 16.6 individuals could be injured or killed on public roads during implementation of the "partial excavation to 1,000 pCi/g" alternative, and 11.7 injuries or deaths are projected to be related to industrial activities. There is also a 4.7% chance of a fatal transportation accident and a 95% chance that a person will be injured as a result of a transportation accident.

Carcinogenic risks from exposure to COPCs, including RIM, encountered during construction are expected to be no greater than the risk calculated for the RadCon Tech. The lifetime risk to the RadCon Tech for the "partial excavation to 1,000 pCi/g" alternative was calculated to be 2.38 x 10^{-03}. This calculated risk exceeds EPA's acceptable risk range of 10^{-06} to 10^{-04}. The most important single contributor to this risk is the gamma radiation from RIM on and near the surface of the contamination area. Note that the carcinogenic risk to the off-property resident is less than 10^{-06}.

5 SHORT-TERM RISKS FOR THE "PARTIAL EXCAVATION TO 52.9 PCI/G" ALTERNATIVE

5.1 ALTERNATIVE DESCRIPTION

In this remedial alternative, RIM with activity levels above 52.9 pCi/g would be excavated and shipped to an approved out-of-state disposal facility. This remedial alternative is intended to protect human health by removing the RIM above the established criterion and placing an engineered cap over all of OU-1. This cap will provide a physical barrier that isolates the remaining RIM from surface receptors.

This risk analysis identifies and evaluates the major short-term hazards and exposures from the construction and transportation activities during excavation, capping, and restoration of Areas 1 and 2 that would occur during construction of the "partial excavation to 52.9 pCi/g" alternative. It also evaluates the human health risks from exposure to chemicals and radionuclides that may occur during remedial alternative construction.

5.2 QUANTIFICATION OF SHORT-TERM COPC EXPOSURE RISKS

As discussed in Section 2, a human health assessment considers the following components: COPC selection, exposure assessment (exposure point concentrations, potential receptors, and exposure pathways), toxicity assessment, and risk characterization. This section combines the first three components to characterize risks to both on-property and off-property receptors from exposure to COPCs. The following subsections combine information from Section 3 with remedial alternative-specific information and present the calculations specific to the "partial excavation to 52.9 pCi/g" alternative.

5.2.1 Exposure Point Concentrations in Soil

The exposure point concentration is the concentration of a contaminant in an exposure medium that may be contacted by a real or hypothetical receptor. As previously discussed in Section 2.2.1.1, the average concentration of radionuclides in the total volume of excavated materials was calculated and used for radionuclide exposure point concentrations. Radionuclide concentrations in Area 2 were selected to evaluate human health effects because the radionuclide concentrations with the greatest impact on health (Ra-226 and Th-230) are in Area 2.

Chemical exposure point concentrations were calculated from combined OU-1data as described in Section 2.2.1.2. Table 5-1presents the representative concentrations of radionuclides and chemicals in soil used in this short-term risk assessment.

Table 5-1 Short-Term Soil Exposure Point Concentrations for the "Partial Excavation to 52.9 pCi/g" Alternative

Analyte	Soil Exposure Point Concentrations	Units
Radionuclides [a]		
Uranium Series		
Uranium-238 + 3 dtrs	43.21	pCi/g
Uranium-234	45.28	pCi/g
Thorium-230	529.37	pCi/g
Radium-226 + 8 dtrs	228.90	pCi/g
Lead-210 + 2 dtrs	48.05	pCi/g
Actinium Series		
Uranium-235 + 1 dtr	2.21	pCi/g
Protactinium-231	62.91	pCi/g
Actinium-227 + 9 dtrs	42.52	pCi/g
Thorium Series		
Thorium-232 + 10 dtrs	7.60	pCi/g
Inorganic Chemicals [b]		
Antimony (metallic)	5.97	mg/kg
Arsenic, Inorganic	40.18	mg/kg
Chromium, total	64.87	mg/kg
Cobalt	349.00	mg/kg
Lead and Compounds	785.80	mg/kg
Mercury	0.70	mg/kg
Nickel Soluble Salts	432.40	mg/kg
Uranium (Soluble Salts)	156.00 [c]	mg/kg
Vanadium and Compounds	158.00	mg/kg
Pesticides/PCBs [b]		
Aroclor 1242	0.43	mg/kg
Aroclor 1254	0.40	mg/kg
Volatile Organic Compounds [b]		
Dichlorobenzene, 1,4-	312.79	mg/kg
Chlorobenzene	26.45	mg/kg

[a] Based on average concentration of excavated material in Area 2 only..
[b] Based on 95% UCLs of sample results for all OU-1 soils combined.
[c] The names listed reflect the lab chemical designation. There are no RSL values within the EPA calculator for these laboratory chemical names. As such, risk is calculated using the RSL values within the EPA calculator for related chemicals (i.e., chromium (VI) for chromium, total, and mercury (elemental) for mercury.
[d] Of the isotopes of natural uranium, uranium-238 accounts for more than 99 percent of the mass of uranium. The 95% UCL mass concentration of uranium-238 for all OU-1 soils of 52.3 pCi/g was divided by the specific activity of 0.336 pCi/µg, resulting in a mass concentration of 156 mg of uranium (soluble salts) per kg of soil (mg/kg).

5.2.2 Exposure Point Concentrations in Air

As previously discussed in Section 2.2.8.3, AERMOD was used to simulate aerial transport of both fugitive dust and radon. Radon concentrations in the short-term are the same values as presented in the updated BRA, and are presented in Table 2-3. Particulate air concentrations for selected locations are dependent on soil concentrations and are presented in Table 5-2 below.

Table 5-2 Short-Term Air Exposure Point Concentrations for the "Partial Excavation to 52.9 pCi/g" Alternative

Analyte	Off-Property, Southeast (722898 E 4293620 N)	On-site, Area 2 (721720 E 4294785 N)

1,4-Dichlorobenzene	1.88E-06	2.28E-03
Chlorobenzene	1.59E-07	1.93E-04

5.2.3 Exposure Pathways

During remedial alternative construction, the RIM and chemicals will be disturbed by excavation and loading into open-topped trucks for on-property transport. The receptors identified in Section 3.3 could be exposed to this material by inhalation of fugitive dust, inhalation of radon, incidental ingestion of soil, direct exposure to radiation from soil, direct exposure to radiation and chemicals from submersion in air, or dermal contact, depending on the receptor and their locations.

5.2.4 Quantification of Human Health COPC Exposure Risks

5.2.4.1 Calculation of Carcinogenic Risk to Selected Receptors

Calculations of carcinogenic risks to potential receptors were based on the relationships between risk and concentration produced by Site-specific scenario descriptions input into EPA's PRG and RSL calculators. The major difference between the default parameter values used by EPA to calculate health effects to default receptors and the values used to describe Site-specific receptors at this Site is the amount of time the receptors are assumed to spend exposed to RIM. For example, EPA's PRG calculations for an outdoor worker assume the workers spends 5,625 days on the site[12] during a 25-year period, and scheduling information suggests the worker will be exposed to RIM for 8 hours a day over a 762 day period[13] during the excavation of the RIM from the three areas where RIM has been identified (Areas 1 and 2 and the Buffer Zone).

The work is scheduled to be performed over 3.4 years, and the period of exposure was allocated equally between the 3.4 years. The timeframe is a shorter duration because of the depth limitation written into the remedial alternative design. The RadCon Tech was assumed to be exposed for 225 days a year over the duration of the construction. The off-property resident may also be exposed for a longer period while the RIM is exposed but no work is ongoing (nights, weekends, etc.). Therefore, the default EPA annual exposure frequency of 350 days a year was used.

Table 5-3 and Table 5-5 provide the input parameters for EPA's Soil and Air PRG and RSL Calculators for outdoor workers and off-property residents. Table 5-4 and Table 5-6 provide the results of the calculations using these parameters.

Table 5-3 Input for EPA's Soil and Air PRG and RSL Calculators, RadCon Tech, "Partial Excavation to 52.9 pCi/g" Alternative

Variable	Radionuclide PRG Calculator Value	Chemical RSL Calculator Value
Slab size for ACF (area correction factor) m^2	2000	NA
t_{ow} (time – outdoor worker) yr	3.4	NA
ED_{ow} (exposure duration – outdoor worker) yr	3.4	3.4
ET_{ow} (exposure time – outdoor worker) hr/day	8	8
EF_{ow} (exposure frequency - outdoor worker) day/yr	225	225

Note: Other parameters were left at their default values.

[12] Total days = Exposure Duration 25 (y/lifetime) x 225 (d/y) = 5,625 (d/lifetime)

[13] Derived from project schedule provided by Feezor Engineering, Inc., dated September 27, 2016.

The calculated lifetime risk to the hypothetical RadCon Tech on Area 2 is 1.18 x 10^{-03}. The risks to a hypothetical receptor living at the location identified in the updated BRA as "Off-Property, Southeast"[14] were calculated as 4.17 x 10^{-08}.

5.2.4.2 Calculation of Non-Carcinogenic Effects to Selected Receptors

Site-specific parameters listed in Table 5-3 and Table 5-5 were used in the EPA RSL calculator to calculate the hazard quotients to the RadCon Tech and off-property resident, respectively. The results for the hypothetical RadCon Tech are presented in Table 5-7. Table 5-8 presents the hazard quotients calculated for the off-property resident.

			Total Hazard Index (HI)	**4.12E-04**

NA - Not applicable
"-" indicates no PRG or RSL.

The calculated HI for the hypothetical RadCon Tech located on Area 2 is 1.22. The HI for a receptor living at the location identified in the updated BRA as "Off-Property, Southeast" was calculated as 4.12 x 10^{-04}. The EPA has previously determined that an HI of greater than one (1) for a particular COPC may represent a potential health risk.

5.3 QUANTIFICATION OF INDUSTRIAL INCIDENT RISKS

There is a risk of occupational and traffic accidents during earthmoving or transportation of materials on public roads. Generally, the risk of occurrence is time dependent, increasing as the duration of the activity lengthens. The severity of the accident depends, in part, on the activity itself.

In order to assess the likelihood and severity of possible accidents, OSHA and NHTSA statistics for workers in different occupations and transportation records were used in conjunction with manpower and resource projections from remedial alternative construction schedules to calculate the risks for accidents.

5.3.1 **Transportation Hazards**

Table 5-9 lists statistics on the rate that traffic accidents involving heavy trucks occurred in 2012 (NHTSA 2014). The projection for heavy truck use on public roads during construction of the "partial excavation to 52.9 pCi/g" alternative is 3,600,000 miles. Multiplying this mileage by the injury and fatality rates in Table 5-9 yields the transportation incident forecast presented Table 5-10.

Table 5-9 Accident Incident Rate for Trucks on Public Roads

Incident	Published rate [a]	Per mile rate [b]
Injury Crashes	2.90E+01	2.90E-07
Fatal Crashes	1.42E+00	1.42E-08

[a] Rate per 100 million miles (NHTSA 2014).
[b] Derived from rate (incidents/100,000,000 mile)

Table 5-10 Traffic Injury and Fatality Forecast for the "Partial Excavation to 52.9 pCi/g" Alternative

Parameter	Value
Total miles for all hauling on public roads [a]	3.60E+06
Injury risk for the project	1.04E+00
Fatality risk for the project	5.11E-02
Forecast of accidents involving injuries or fatalities	**1.10E+00**

[a] Estimate provided by Feezor Engineering, Inc., September 27, 2016, "Total Delivery Miles (Totals)"

Hazards from transporting the RIM by rail from the local railhead to the off-site destination can be similarly assessed (Table 5-11 and Table 5-12).

Table 5-11 Accident Incident Rate for Railroads

Incident	Published Per Mile Rate [a]
Injury Rate	1.20E-05
Fatality Rate	1.04E-06

[a] Rate per mile (FRAOSA 2016).

Table 5-12 Railroad Injury and Fatality Forecast for the "Partial Excavation to 52.9 pCi/g" Alternative

Parameter	Value
Rail mile [a]	7.26E+05
Injury risk for the project	8.71E+00
Fatality risk for the project	7.57E-01
Forecast of rail accidents involving injuries or fatalities	**9.46E+00**

[a] Rail distance calculated as 227 trains x 3,200 miles round trip

The projected number of on-site and off-site transportation accidents involving injury or death during construction of the "partial excavation to 52.9 pCi/g" alternative of 10.56 is related primarily to the number of trucks hauling materials onto the site and transporting the RIM via rail to an off-site disposal facility. It should be noted that this projection includes injuries and deaths of people other than the truck occupants. In 2012, 3% of the injuries and 10% of the fatalities from traffic accidents on public roads were to people not riding in the truck involved in the incident (NHTSA 2014).

5.3.2 Industrial Hazards

As in the previous assessment, the workers involved with remedial alternative construction have been divided into two groups: general construction and driver/operators. The BLS maintains historical information on the rate that accidents occur in the U.S. These statistics are available grouped by job description, and Table 5-13 and Table 5-14 list accident statistics for general construction and off-road drivers, respectively.

Table 5-13 Accident Rate for General Construction and Support Workers

Parameter	Value
Injury accident rate per 100 full-time workers [a]	2.90E+00
Accident rate per man-hour worked	1.45E-05
Accident rate per man-day worked	1.16E-04
Number of general construction + support man-days worked [b]	5.98E+04
Number of Accidents Forecast	**6.94E+00**

[a] Bureau of Labor Statistics News Release, October 29, 2014 "Employer-Reported Workplace Injuries and Illnesses – 2014" for Heavy and civil engineering construction (237). (BLS 2015)
[b] Estimate provided by Feezor Engineering, Inc., September 27, 2016, "Crew Man-Days Overall"

Table 5-14 Occupational Accident Rate for Truck Drivers

Parameter	Value
Injury accident rate per 100 full-time workers [a]	4.40E+00
Accident rate per hour worked	2.20E-05
Hours spent driving [b]	5.81E+04
Other transportation activities (hrs) [c]	1.16E+04
Total transportation man-hours worked	6.97E+04
Number of Accidents Forecast [d]	**1.53E+00**

[a] Bureau of Labor Statistics News Release, October 29, 2014 "Employer-Reported Workplace Injuries and Illnesses – 2014" for Heavy and civil engineering construction (484). (BLS 2015)

[b] Estimate provided by Feezor Engineering, Inc., September 27, 2016, "Crew Man-Days On-site Haul Trucks" x 8 h/d

[c] Hours assumed - Driving hours x 0.2.

[d] Accident Rate per hour x Total Transportation Man-hours

Table 5-13 and Table 5-14 also list the remedial alternative construction time in either man-days or man-hours that can be grouped into each of those broad labor categories. Multiplying the total time by the appropriate accident rate will yield an accident forecast for this group's activities during this project. The number of accidents forecast for the general construction and off-road drivers are presented in bold on the last line of Table 5-13 and Table 5-14, respectively. Summing the number of accidents forecast for both labor groups yields the total accident projection for the project.

For example, it is estimated that it will require 59,800 man-days of general construction and support labor to construct the "partial excavation to 52.9 pCi/g" alternative. Multiplying this duration by the injury and fatality rate of 1.16 x 10^{-04} accidents per man-day in Table 5-13 yields the construction incident forecast of 6.94 accidents. Adding this to the project risk of non-traffic accidents for truck drivers in Table 5-14 yields a total accident projection for general construction and off-road activities of 8.47.

5.4 QUANTIFICATION OF OCCUPATIONAL EXTERNAL RADIATION EXPOSURE

Remedial workers were assumed to be classified as radiation workers in this assessment. As such, the RadCon Tech is expected to be the RME individual in the short-term. Unit dose factors to those workers were calculated using MicroShield 9.02[15]. The current exposure point concentrations from Table 5-1 were multiplied by the unit dose rate to calculate the average dose rate for the worker. Multiplying the average of these dose rates and the total projected time spent exposed to RIM yields the estimated annual TEDE to RadCon Techs on the project (Table 5-15).

Table 5-15 Radiation Dose to RadCon Tech

	Area 2
Days per Project	762
Average TEDE on surface (mrem/hour)	4.00E-01
Hours spent exposed to RIM (per year)	1.80E+03 [b]
TEDE for Reasonably Maximally-Exposed Individual (mrem/y)	**7.20E+02**

[a] Calculated by MicroShield.
[b] 762 worker exposure days / 3.4 year project duration= 225 days/year x 8 hours/day = 1,800 hours/year

The calculated average exposure rate to the hypothetical RadCon Tech would be approximately 0.4 mrem/hr. If the RadCon Tech spent 1,800 hours per year working on the RIM, the TEDE would be 720 mrem/y. To put this in perspective, according to 10 CFR § 20.1201, a radiation worker has an occupational exposure limit of 5,000 mrem/y, assuming no administrative limits are imposed for the Site (NRC 1991).

5.5 SUMMARY

The short-term human health risks and hazard projections are summarized in Table 5-16.

[15] Grove Software

Table 5-16 Summary of Short-Term Hazards and Risks Associated with "Partial Excavation to 52.9 pCi/g" Alternative

Category of Hazard or Risk	Value
Projected Incidence of Transportation Accidents	1.06E+01
Projected Incidence of Industrial Accidents	8.47E+00
Carcinogenic Risk to Rad Con Tec	1.18E-03
Carcinogenic Risk to Off-Property Resident	4.17E-08
HI to RadCon Tech	1.22E+00
HI to Off-Property Resident	4.12E-04
TEDE to Reasonably Maximally-Exposed Individual	7.20E+02

It is projected that 10.6 individuals could be injured or killed on public roads during implementation of the "partial excavation to 52.9 pCi/g" alternative, and 8.47 injuries or deaths are projected to be related to industrial activities. There is also a 5.1% chance of a fatal transportation accident and a 104% chance that a person will be injured as a result of a transportation accident.

Carcinogenic risks from exposure to RIM encountered during construction are expected to be no greater than the risk calculated for the RadCon Tech. The lifetime risk to the RadCon Tech was calculated to be 1.18 x 10^{-03}. This calculated risk exceeds EPA's acceptable risk range of 10^{-06} to 10^{-04}. The most important single contributor to this risk is the gamma radiation from RIM on and near the surface of the contamination area. Note that the carcinogenic risk to the off-property resident is less than 10^{-06}.

6 SHORT-TERM RISKS FOR THE "COMPLETE RAD REMOVAL" ALTERNATIVE

6.1 ALTERNATIVE DESCRIPTION

In this remedial alternative, the RIM above 7.9 pCi/g would be excavated and shipped to an out-of-state disposal facility. Areas 1 and 2 would be regraded and capped as part of the overall Site closure plan. The overburden and final cap will provide a physical barrier for other non-RIM landfill wastes and will incidentally isolate surface receptors from any RIM below cleanup levels that remains in place at the Site. Controls intended to address radiological occurrences would no longer be required under this remedial alternative, but the same or similar controls would still be required because the Site will remain an inactive municipal waste landfill.

This risk analysis identifies and evaluates the major short-term hazards and exposures from the construction and transportation activities during excavation, capping, and restoration of Areas 1 and 2 that would occur during construction of the "complete rad removal" alternative. It also evaluates the human health risks from exposure to chemicals and radionuclides that may occur during remedial alternative construction.

6.2 QUANTIFICATION OF SHORT-TERM COPC EXPOSURE RISKS

As discussed in Section 2, a human health assessment considers the following components: COPC selection, exposure assessment (exposure point concentrations, potential receptors, and exposure pathways), toxicity assessment, and risk characterization. This section combines the three components to characterize health risks to both on-property and off-property receptors from exposure to COPCs. The following sections combine information from Section 3 with remedial alternative-specific information and present the calculations specific to the "complete rad removal" alternative.

6.2.1 **Exposure Point Concentrations in Soil**

The exposure point concentration is the concentration of a contaminant in an exposure medium that may be contacted by a real or hypothetical receptor. As previously discussed in 2.2.1.1, the average concentration of radionuclides in the total volume of excavated materials was calculated and used for radionuclide exposure point concentrations. Radionuclide concentrations in Area 2 were selected to evaluate human health effects because the radionuclide concentrations with the greatest impact on health (Ra-226 and Th-230) are in Area 2.

Chemical exposure point concentrations were calculated from combined OU-1data as described in Section 2.2.1.2. Table 6-1presents the representative concentrations of radionuclides and chemicals in soil used in this short-term risk assessment.

Table 6-1 Short-Term Soil Exposure Point Concentrations for the "Complete Rad Removal" Alternative

Analyte	Soil Exposure Point Concentrations	Units
Radionuclides [a]		
Uranium Series		
Uranium-238 + 3 dtrs	24.35	pCi/g
Uranium-234	25.52	pCi/g
Thorium-230	300.33	pCi/g
Radium-226 + 8 dtrs	128.83	pCi/g
Lead-210 + 2 dtrs	27.08	pCi/g
Actinium Series		
Uranium-235 + 1 dtr	1.24	pCi/g
Protactinium-231	35.46	pCi/g
Actinium-227 + 9 dtrs	23.96	pCi/g
Thorium Series		
Thorium-232 + 10 dtrs	4.29	pCi/g
Inorganic Chemicals [b]		
Antimony (metallic)	5.97	mg/kg
Arsenic, Inorganic	40.18	mg/kg
Chromium, total	64.87	mg/kg
Cobalt	349.00	mg/kg
Lead and Compounds	785.80	mg/kg
Mercury	0.70	mg/kg
Nickel Soluble Salts	432.40	mg/kg
Uranium (Soluble Salts)	156.00 [c]	mg/kg
Vanadium and Compounds	158.00	mg/kg
Pesticides/PCBs [b]		
Aroclor 1242	0.43	mg/kg
Aroclor 1254	0.40	mg/kg
Volatile Organic Compounds [b]		
Dichlorobenzene, 1,4-	312.79	mg/kg
Chlorobenzene	26.45	mg/kg

[a] Based on average concentration of excavated material in Area 2 only..
[b] Based on 95% UCLs of sample results for all OU-1 soils combined.
[c] The names listed reflect the lab chemical designation. There are no RSL values within the EPA calculator for these laboratory chemical names. As such, risk is calculated using the RSL values within the EPA calculator for related chemicals (i.e., chromium (VI) for chromium, total, and mercury (elemental) for mercury.
[d] Of the isotopes of natural uranium, uranium-238 accounts for more than 99 percent of the mass of uranium. The 95% UCL mass concentration of uranium-238 for all OU-1 soils of 52.3 pCi/g was divided by the specific activity of 0.336 pCi/µg, resulting in a mass concentration of 156 mg of uranium (soluble salts) per kg of soil (mg/kg).

6.2.2 **Exposure Point Concentrations in Air**

As previously discussed in Section 2.2.8.3, AERMOD was used to simulate aerial transport of both fugitive dust and radon. Radon concentrations in the short-term are the same values as presented in the updated BRA, and are presented in Table 2-3. Particulate air concentrations for selected locations are dependent on soil concentrations and are presented in Table 6-2 below.

Table 6-2 Short-Term Air Exposure Point Concentrations for the "Complete Rad Removal" Alternative

Analyte	Off-Property, Southeast (722898 E 4293620 N)	On-site, Area 2 (721720 E 4294785 N)

Chlorobenzene	1.59E-07	1.93E-04

6.2.3 Exposure Pathways

During remedial alternative construction, the RIM and chemicals will be disturbed by excavation and loading into open-topped trucks for on-property transport. The receptors identified in Section 3.3 could be exposed to this material by inhalation of fugitive dust, inhalation of radon, incidental ingestion of soil, direct exposure to radiation from soil, direct exposure to radiation and chemicals from submersion in air, or dermal contact, depending on the receptor and their locations.

6.2.4 **Quantification of Human Health COPC Exposure Risks**

6.2.4.1 Calculation of Carcinogenic Risk to Selected Receptors

Calculations of carcinogenic risks to potential receptors were based on the relationships between risk and concentration produced by Site-specific scenario descriptions input into EPA's PRG and RSL calculators. The major difference between the default parameter values used by EPA to calculate health effects to default receptors and the values used to describe Site-specific receptors at this Site is the amount of time that the receptors are assumed to spend exposed to RIM. For example, EPA's PRG calculations for an outdoor worker assume the workers spends 5,625 days on the Site[16] during a 25 year period, and scheduling information suggests the worker will be exposed to RIM for 8 hours a day over a 2,531 day period[17] during the excavation from the three areas where RIM has been identified (Areas 1 and 2 and the Buffer Zone).

The work is scheduled to be performed over 11.2 years, and the period of exposure was allocated equally between the 11.2 years. The RadCon Tech was assumed to be exposed for 225 days a year over the duration of the construction. The off-property resident may also be exposed for a longer period while the RIM is exposed but no work is ongoing (nights, weekends, etc.). Therefore, the default EPA annual exposure frequency of 350 days a year was used.

Table 6-3 and Table 6-5 provide the input parameters for EPA's Soil and Air PRG and RSL Calculators for outdoor workers and off-property residents. Table 6-4 and Table 6-6 provide the results of the calculations using these parameters.

Table 6-3 Input for EPA's Soil and Air PRG and RSL Calculators, RadCon Tech, "Complete Rad Removal" Alternative

Variable	Radionuclide PRG Calculator Value	Chemical RSL Calculator Value
Slab size for ACF (area correction factor) m^2	2000	NA
t_{ow} (time – outdoor worker) yr	11.2	NA
ED_{ow} (exposure duration – outdoor worker) yr	11.2	11.2
ET_{ow} (exposure time – outdoor worker) hr/day	8	8
EF_{ow} (exposure frequency - outdoor worker) day/yr	225	225

Note: Other parameters were left at their default values.

[16] Total days = Exposure Duration 25 (y/lifetime) x 225 (d/y) = 5,625 (d/lifetime)

			Total Hazard Index (HI)	**4.12E-04**

NA - Not applicable
"-" indicates no PRG or RSL.

The calculated HI for the hypothetical RadCon Tech located on Area 2 is 1.22. The HI for a receptor living at the location identified in the updated BRA as "Off-Property, Southeast" was calculated as 4.12 x 10^{-04}. The EPA has previously determined that an HI of greater than one (1) for a particular COPC may represent a potential health risk.

6.3 QUANTIFICATION OF INDUSTRIAL INCIDENT RISKS

There is a risk of occupational and traffic accidents during earthmoving or transportation of materials on public roads. Generally, the risk of occurrence is time dependent, increasing as the duration of the activity lengthens. The severity of the accident depends, in part, on the activity itself.

In order to assess the likelihood and severity of possible accidents, OSHA and NHTSA statistics for workers in different occupations and transportation records were used in conjunction with manpower and resource projections from remedial alternative construction schedules to calculate the risks for accidents.

6.3.1 Transportation Hazards

Table 6-9 lists statistics on the rate that traffic accidents involving heavy trucks occurred in 2012 (NHTSA 2014). The projection for heavy truck use on public roads during construction of the "complete rad removal" alternative is 4,990,000 miles. Multiplying this mileage by the injury and fatality rates in Table 6-9 yields the transportation incident forecast presented Table 6-10.

Table 6-9 Accident Incident Rate for Trucks on Public Roads

Incident	Published rate [a]	Per mile rate [b]
Injury Crashes	2.90E+01	2.90E-07
Fatal Crashes	1.42E+00	1.42E-08

[a] Rate per 100 million miles (NHTSA 2014).
[b] Derived from rate (incidents/100,000,000 mile)

Table 6-10 Traffic Injury and Fatality Forecast for the "Complete Rad Removal" Alternative

Parameter	Value
Total miles for all hauling on public roads [a]	4.99E+06
Injury risk for the project	1.45E+00
Fatality risk for the project	7.09E-02
Forecast of accidents involving injuries or fatalities	**1.52E+00**

[a] Estimate provided by Feezor Engineering, Inc., September 27, 2016, "Total Delivery Miles (Totals)"

Hazards from transporting the RIM by rail from the local railhead to the off-site destination can be similarly assessed (Table 6-11 and Table 6-12).

Table 6-11 Accident Incident Rate for Railroads

Incident	Published Per Mile Rate [a]
Injury Rate	1.20E-05
Fatality Rate	1.04E-06

[a] Rate per mile (FRAOSA 2016).

Table 6-12 Railroad Injury and Fatality Forecast for the "Complete Rad Removal" Alternative

Parameter	Value
Rail mile [a]	2.56E+06
Injury risk for the project	3.07E+01
Fatality risk for the project	2.66E+00
Forecast of rail accidents involving injuries or fatalities	**3.33E+01**

[a] Rail distance calculated as 783 trains x 3,200 miles round trip

The projected number of on-site and off-site transportation accidents involving injury or death during construction of the "complete rad removal" alternative of 34.86 is related primarily to the number of trucks hauling materials onto the site and transporting the RIM via rail to an off-site disposal facility. It should be noted that this projection includes injuries and deaths of people other than the truck occupants. In 2012, 3% of the injuries and 10% of the fatalities from traffic accidents on public roads were to people not riding in the truck involved in the incident (NHTSA 2014).

6.3.2 Industrial Hazards

As in the previous assessment, the workers involved with remedial alternative construction have been divided into two groups: general construction and driver/operators. The Bureau of Labor Statistics (BLS) maintains historical information on the rate that accidents occur in the U.S. These statistics are available grouped by job description, and Table 6-13 and Table 6-14 list accident statistics for general construction and off-road drivers, respectively.

Table 6-13 Accident Rate for General Construction and Support Workers

Parameter	Value
Injury accident rate per 100 full-time workers [a]	2.90E+00
Accident rate per man-hour worked	1.45E-05
Accident rate per man-day worked	1.16E-04
Number of general construction + support man-days worked [b]	1.18E+05
Number of Accidents Forecast	**1.37E+01**

[a] Bureau of Labor Statistics News Release, October 29, 2014 "Employer-Reported Workplace Injuries and Illnesses – 2014" for Heavy and civil engineering construction (237). (BLS 2015)
[b] Estimate provided by Feezor Engineering, Inc., September 27, 2016, "Crew Man-Days Overall"

Table 6-14 Occupational Accident Rate for Truck Drivers

Parameter	Value
Injury accident rate per 100 full-time workers [a]	4.40E+00
Accident rate per hour worked	2.20E-05
Hours spent driving [b]	1.55E+05
Other transportation activities (hrs) [c]	3.10E+04
Total transportation man-hours worked	1.86E+05
Number of Accidents Forecast [d]	**4.10E+00**

[a] Bureau of Labor Statistics News Release, October 29, 2014 "Employer-Reported Workplace Injuries and Illnesses – 2014" for Heavy and civil engineering construction (484). (BLS 2015)

[b] Estimate provided by Feezor Engineering, Inc., September 27, 2016, "Crew Man-Days On-site Haul Trucks" x 8 h/d

[c] Hours assumed - Driving hours x 0.2.

[d] Accident Rate per hour x Total Transportation Man-hours

Table 6-13 and Table 6-14 also list the remedial alternative construction time in either man-days or man-hours that can be grouped into each of those broad labor categories. Multiplying the total time by the appropriate accident rate will yield an accident forecast for this group's activities during this project. The number of accidents forecast for the general construction and off-road drivers are presented in bold on the last line of Table 6-13 and Table 6-14, respectively. Summing the number of accidents forecast for both labor groups yields the total accident projection for the project.

For example, it is estimated that it will require 118,000 man-days of general construction and support labor to construct the "complete rad removal" alternative. Multiplying this duration by the injury and fatality rate of 1.16×10^{-04} accidents per man-day in Table 6-13 yields the construction incident forecast of 13.7 accidents. Adding this to the project risk of non-traffic accidents for truck drivers in Table 6-14 yields a total accident projection for general construction and off-road activities of 17.78.

6.4 QUANTIFICATION OF OCCUPATIONAL EXTERNAL RADIATION EXPOSURE

Remedial workers were assumed to be classified as radiation workers in this assessment. As such, the RadCon Tech is expected to be the RME individual in the short-term. Unit dose factors to those workers were calculated using MicroShield 9.02[19]. The current exposure point concentrations from Table 6-1 were multiplied by the unit dose rate to calculate the average dose rate for the worker. Multiplying the average of these dose rates and the total projected time spent exposed to RIM yields the estimated annual TEDE to RadCon Techs on the project (Table 6-15).

Table 6-15 Radiation Dose to RadCon Tech

	Area 2
Days per Project	2531
Average TEDE on surface (mrem/hour)	2.25E-01
Hours spent exposed to RIM (per year)	1.80E+03 [b]
TEDE for Reasonably Maximally-Exposed Individual (mrem/y)	**4.05E+02**

[a] Calculated by MicroShield.
[b] 2,531 worker exposure days / 11.2 year project duration= 225 days/year x 8 hours/day = 1,800 hours/year

The calculated average exposure rate to the hypothetical RadCon Tech would be approximately 0.225 mrem/hr. If the RadCon Tech spent 1,800 hours per year working on the RIM, the TEDE would be 405 mrem/y. To put this in perspective, according to 10 CFR § 20.1201, a radiation worker has an occupational exposure limit of 5,000 mrem/y, assuming no administrative limits are imposed for the Site (NRC 1991).

6.5 SUMMARY

The short-term human health risks and hazard projections are summarized in Table 6-16.

Table 6-16 Summary of Short-Term Hazards and Risks Associated with "Complete Rad Removal" Alternative

Category of Hazard or Risk	Value
Projected Incidence of Transportation Accidents	3.49E+01
Projected Incidence of Industrial Accidents	1.78E+01
Carcinogenic Risk to Rad Con Tech	2.19E-03
Carcinogenic Risk to Off-Property Residents	5.17E-08
HI to RadCon Tech	1.22E+00
HI to Off-Property Resident	4.12E-04
TEDE to Reasonably Maximally-Exposed Individual	4.05E+02

It is projected that 34.9 individuals could be injured or killed on public roads during implementation of the "complete rad removal" alternative, and 17.8 injuries or deaths are projected to be related to industrial activities. There is also a 7.1% chance of a fatal

[19] Grove Software

transportation accident and a 145% chance that a person will be injured as a result of a transportation accident.

Carcinogenic risks from exposure to RIM encountered during construction are expected to be no greater than the risk calculated for the RadCon Tech. The lifetime risk to the RadCon Tech was calculated to be 2.19×10^{-03}. This calculated risk exceeds EPA's acceptable risk range of 10^{-06} to 10^{-04}. The most important single contributor to this risk is the gamma radiation from RIM on and near the surface of the contamination area. Note that the carcinogenic risk to the off-property resident is less than 10^{-06}.

7 SHORT-TERM RISKS FOR THE ROD-SELECTED REMEDY

7.1 ALTERNATIVE DESCRIPTION

In this alternative, the RIM will remain in place with Site improvements to meet the stated goals of the ROD. This remedy is a containment remedy for OU-1 intended to protect human health by regrading part of the Site and placing an engineered cap over all of OU-1. This will provide a physical barrier that isolates the RIM from surface receptors.

Field investigations indicate that RIM is present at or near the surface in Areas 1 and 2. The ROD-selected remedy requires recontouring the surface of OU-1 and installing a cover designed to meet Missouri Department of Natural Resources (MDNR) landfill closure requirements. The design also includes an underlying rock/concrete rubble layer to enhance long-term stability, protect the RIM from bio- or human intrusion, and prevent erosion of the underlying waste materials. These Site improvements will bring the upper surface to an acceptable slope and improve surface drainage of Areas 1 and 2.

This risk analysis identifies and evaluates the major short-term hazards and exposures from the construction and transportation activities during grading and capping of Areas 1 and 2 under the ROD-selected remedy. It also evaluates the human health risks from exposure to chemicals and radionuclides that may occur during the construction of the remedy.

7.2 QUANTIFICATION OF SHORT-TERM COPC EXPOSURE RISKS

As discussed in Section 2, a human health assessment considers the following components: COPC selection, exposure assessment (exposure point concentrations, potential receptors, and exposure pathways), toxicity assessment, and risk characterization. This section combines the first three components to characterize risks to both on-property and off-property receptors from exposure to COPCs. The following sections combine information from Section 3 with alternative-specific information and present the calculations specific to the ROD-selected remedy.

7.2.1 **Exposure Point Concentrations in Soil**

The exposure point concentration is the concentration of a contaminant in an exposure medium that may be contacted by a real or hypothetical receptor. As previously discussed in Section 2.2.1.1, the average concentration of radionuclides in the total volume of excavated materials was calculated and used for radionuclide exposure point concentrations. Radionuclide concentrations in Area 2 were selected to evaluate human health effects because the radionuclide concentrations with the greatest impact on health (Ra-226 and Th-230) are greater in Area 2.

Chemical exposure point concentrations were calculated from combined OU-1data as described in Section 2.2.1.2. Table 7-1 presents the representative concentrations of radionuclides and chemicals in soil used in this short-term risk assessment.

Table 7-1 Short-term Soil Exposure Point Concentrations for the ROD-Selected Remedy

Analyte	Soil Exposure Point Concentrations	Units
Radionuclides [a]		
Uranium Series		
Uranium-238 + 3 dtrs	11.47	pCi/g
Uranium-234	12.03	pCi/g
Thorium-230	150.00	pCi/g
Radium-226 + 8 dtrs	60.00	pCi/g
Lead-210 + 2 dtrs	12.76	pCi/g
Actinium Series		
Uranium-235 + 1 dtr	0.59	pCi/g
Protactinium-231	16.71	pCi/g
Actinium-227 + 9 dtrs	11.29	pCi/g
Thorium Series		
Thorium-232 + 10 dtrs	2.02	pCi/g
Inorganic Chemicals [b]		
Antimony (metallic)	5.97	mg/kg
Arsenic, Inorganic	40.18	mg/kg
Chromium, total	64.87	mg/kg
Cobalt	349.00	mg/kg
Lead and Compounds	785.80	mg/kg
Mercury	0.70	mg/kg
Nickel Soluble Salts	432.40	mg/kg
Uranium (Soluble Salts)	156.00 [c]	mg/kg
Vanadium and Compounds	158.00	mg/kg
Pesticides/PCBs [b]		
Aroclor 1242	0.43	mg/kg
Aroclor 1254	0.40	mg/kg
Volatile Organic Compounds [b]		
Dichlorobenzene, 1,4-	312.79	mg/kg
Chlorobenzene	26.45	mg/kg

[a] Based on average concentration of excavated material in Area 2 only..
[b] Based on 95% UCLs of sample results for all OU-1 soils combined.
[c] The names listed reflect the lab chemical designation. There are no RSL values within the EPA calculator for these laboratory chemical names. As such, risk is calculated using the RSL values within the EPA calculator for related chemicals (i.e., chromium (VI) for chromium, total, and mercury (elemental) for mercury.
[d] Of the isotopes of natural uranium, uranium-238 accounts for more than 99 percent of the mass of uranium. The 95% UCL mass concentration of uranium-238 for all OU-1 soils of 52.3 pCi/g was divided by the specific activity of 0.336 pCi/µg, resulting in a mass concentration of 156 mg of uranium (soluble salts) per kg of soil (mg/kg).

7.2.2 **Exposure Point Concentrations in Air**

As previously discussed in Section 2.2.8.3, AERMOD was used to simulate aerial transport of both fugitive dust and radon. Radon concentrations in the short-term are the same values as presented in the updated BRA, and are presented in Table 2-3. Particulate air concentrations for selected locations are dependent on soil concentrations and are presented in Table 7-2 below.

Table 7-2 Short-term Air Exposure Point Concentrations for the ROD-Selected Remedy

Analyte	Off-Property, Southeast (722898 E 4293620 N)	On-site, Area 2 (721720 E 4294785 N)
Uranium Series (pCi/m^3)

1,4-Dichlorobenzene	1.88E-06	2.28E-03
Chlorobenzene	1.59E-07	1.93E-04

7.2.3 Exposure Pathways

During remedy construction, the RIM and chemicals will be disturbed by grading and limited excavation, for example from the Buffer Zone. The receptors identified in Section 3.3 could be exposed to this material by inhalation of fugitive dust, inhalation of radon, incidental ingestion of soil, direct exposure to radiation from soil, direct exposure to radiation and chemicals from submersion in air, or dermal contact, depending on the receptor and their locations.

7.2.4 Quantification of Human Health COPC Exposure Risks

7.2.4.1 Calculation of Carcinogenic Risk to Selected Receptors

Calculations of carcinogenic risks to potential receptors were based on the relationships between risk and concentration produced by Site-specific scenario descriptions input into EPA's PRG and RSL calculators. The major difference between the default parameter values used by EPA to calculate health effects to default receptors and the values used to describe Site-specific receptors at this Site is the amount of time that the receptors are assumed to spend exposed to RIM. For example, EPA's PRG calculations for an outdoor worker assume the worker spends 5,625 days on a generic Site[20] during a 25 year period, and scheduling information suggests a West Lake Landfill remediation worker would be exposed to RIM for 8 hours a day over 223 days[21] during the relocation of the RIM from the Buffer Zone and grading of Areas 1 and 2.

The RadCon Tech was assumed to be exposed for 225 days a year over the 1 year of construction. The off-property resident may be exposed for a longer period but no work is ongoing (nights, weekends, etc.). Therefore, the default EPA annual exposure frequency of 350 days a year was used over the 1 year of construction.

Table 7-3 and Table 7-5 provide the input parameters for EPA's Soil and Air PRG and RSL Calculators for outdoor workers and off-property residents. Table 7-4 and Table 7-6 provide the results of the calculations using these parameters.

Table 7-3 Input for EPA's Soil and Air PRG and RSL Calculators, RadCon Tech, ROD-Selected Remedy

Variable	Radionuclide PRG Calculator Value	Chemical RSL Calculator Value
Slab size for ACF (area correction factor) m^2	2,000	NA
t_{ow} (time - outdoor worker) yr	1	NA
ED_{ow} (exposure duration - worker) yr	1	1
ET_{ow} (exposure time - worker) hr/day	8	8
EF_{ow} (exposure frequency - worker) day/yr	225	225

Note: Other parameters were left at default values.

[20] Total days = Exposure Duration 25 (y/lifetime) x 225 (d/y) = 5,625 (d/lifetime)

[21] Derived from project schedule provided by Feezor Engineering, Inc., dated October 20, 2016.

[22] The updated BRA (Auxier 2016) identified the "Off-Property, Southeast" receptor as the RME receptor of the two residents assessed.

Table 7-8 Hazard Index Calculated for the Off-Property Resident During Construction of the ROD-Selected Remedy

COC	Resident RSL, HQ = 1, Inhalation of Dust	Resident RSL, HQ = 1, Inhalation of Radon	Resident RSL, HQ = 1, Inhalation of Radon	Calculated HQ to Resident, All Pathways
Inorganic Chemicals				
Antimony (metallic)	-	NA	NA	0.00E+00
Arsenic, Inorganic	1.54E-05	NA	NA	1.54E-05
Chromium(VI)	3.74E-06	NA	NA	3.74E-06
Cobalt	3.34E-04	NA	NA	3.34E-04
Lead and Compounds	-	NA	NA	0.00E+00
Mercury (elemental)	1.34E-08	NA	NA	1.34E-08
Nickel Oxide	2.76E-05	NA	NA	2.76E-05
Uranium (Soluble Salts)	2.24E-05	NA	NA	2.24E-05
Vanadium and compounds	9.08E-06	NA	NA	9.08E-06
Pesticides/PCBs				
Aroclor 1242	-	NA	NA	0.00E+00
Aroclor 1254	-	NA	NA	0.00E+00
Volatile Organic Compounds				
Dichlorobenzene, 1,4-	2.25E-09	NA	NA	2.25E-09
Chlorobenzene	3.04E-09	NA	NA	3.04E-09
			Total Hazard Index (HI)	**4.12E-04**

NA - Not applicable
"-" indicates no PRG or RSL.

The calculated HI for the hypothetical RadCon Tech located on Area 2 is 1.22. The HI for a receptor living at the location identified in the updated BRA as "Off-Property, Southeast" was calculated as 4.12×10^{-04}. The EPA has previously determined that an HI of greater than one (1) for a particular COPC may represent a potential health risk.

7.3 QUANTIFICATION OF INDUSTRIAL INCIDENT RISKS

There is a risk of occupational and traffic accidents during earthmoving or transportation of materials on public roads. Generally, the risk of occurrence is time dependent, increasing as the duration of the activity lengthens. The severity of the accident depends, in part, on the activity itself.

To assess the likelihood and severity of possible accidents, OSHA and NHTSA statistics for workers in different occupations and transportation records were used in conjunction with manpower and resource projections from remedy construction schedules to calculate the risks for accidents.

7.3.1 Transportation Hazards

Table 7-9 lists statistics on the rate that traffic accidents involving heavy trucks occurred in 2012 (NCSA 2014). The projection for heavy truck use on public roads during construction of the ROD-selected Remedy is 2,020,000 miles. Multiplying this mileage by the injury and fatality rates in Table 7-9 yields the transportation incident forecast presented Table 7-10.

Table 7-9 Accident Incident Rate for Trucks on Public Roads

Incident	Published rate [a]	Per mile rate [b]
Injury Crashes	2.90E+01	2.90E-07
Fatal Crashes	1.42E+00	1.42E-08

[a] Rate per 100 million miles (NHTSA 2014).
[b] Derived from rate (incidents/100,000,000 mile)

Table 7-10 Traffic Injury and Fatality Forecast for the ROD-Selected Remedy

Parameter	Value
Total miles for all hauling on public roads [a]	2.02E+06
Injury risk for the project	5.86E-01
Fatality risk for the project	2.87E-02
Forecast of accidents involving injuries or fatalities	**6.14E-01**

[a] Estimate provided by Feezor Engineering, Inc., October 20, 2016, "Total Delivery Miles (Totals)"

The projected number of transportation accidents involving injury or death of 0.61 is related primarily to the number of trucks hauling materials to the site.

7.3.2 Industrial Hazards

As in the previous assessments, the workers involved with remedy construction have been divided into two groups: general construction and driver/operators. The BLS maintains historical information on the rate that accidents occur in the U.S. These statistics are available grouped by job description, and Table 7-11 and Table 7-12 list occupational statistics for general construction and off-road drivers, respectively.

Table 7-11 Accident Rate for General Construction and Support Workers

Parameter	Value
Injury accident rate per 100 full-time workers [a]	2.90E+00
Accident rate per man-hour worked	1.45E-05
Accident rate per man-day worked	1.16E-04
Number of general construction + support man-days worked [b]	2.11E+04
Number of Accidents Forecast	**2.45E+00**

[a] Bureau of Labor Statistics News Release, October 29, 2014 "Employer-Reported Workplace Injuries and Illnesses – 2014" for Heavy and civil engineering construction (237). (BLS 2015)
[b] Estimate provided by Feezor Engineering, Inc., September 27, 2016, "Crew Man-Days Overall"

Table 7-12 Occupational Accident Rate for Truck Drivers

Parameter	Value
Injury accident rate per 100 full-time workers [a]	4.40E+00
Accident rate per hour worked	2.20E-05
Hours spent driving [b]	1.18E+04
Other transportation activities (hrs) [c]	2.35E+03
Total transportation man-hours worked	1.41E+04
Number of Accidents Forecast [d]	**3.10E-01**

[a] Bureau of Labor Statistics News Release, October 29, 2014 "Employer-Reported Workplace Injuries and Illnesses – 2014" for Heavy and civil engineering construction (484). (BLS 2015)

[b] Estimate provided by Feezor Engineering, Inc., September 27, 2016, "Crew Man-Days On-site Haul Trucks" x 8 h/d

[c] Hours assumed - Driving hours x 0.2.

[d] Accident Rate per hour x Total Transportation Man-hours

Table 7-11 and Table 7-12 also list the remedy construction time in either man-days or man-hours that can be grouped into each of those broad labor categories. Multiplying the total time by the appropriate accident rate will yield an accident forecast for this group's activities during this project. The number of accidents forecast for the general construction and off-road drivers are presented in bold on the last line of Table 7-11 and Table 7-12, respectively. Summing the number of accidents forecast for both labor groups yields the total accident projection for the project.

For example, it is estimated that it will require 21,100 man-days of general construction and support labor to construct the ROD-selected remedy. Multiplying this duration by the injury and fatality rate of 1.16 x 10^{-04} accidents per man-day in Table 7-11 yields the construction incident forecast of 2.45 in Table 7-11. Adding this to the projected risk of non-traffic accidents for truck drivers in Table 7-12 yields a total injury accident projection for general construction and off-road activities of 2.76.

7.4 QUANTIFICATION OF OCCUPATIONAL EXTERNAL RADIATION EXPOSURE

Remedial workers were assumed to be classified as radiation workers in this assessment. Unit dose factors to those workers were calculated using MicroShield 9.02[23]. The current exposure point concentrations from Table 7-1 were multiplied by the unit dose rate to calculate the average dose rate for the worker. Multiplying the average of these dose rates and the total projected time spent exposed to RIM yields the estimated annual TEDE to RadCon Techs on the project (Table 7-13).

[23] Grove Software

Table 7-13 Radiation Dose to RadCon Tech

	Area 2
Days per Project	223
Average TEDE on surface (mrem/hour)	1.05E-01
Hours spent exposed to RIM (per year)	1.78E+03 [b]
TEDE for Reasonably Maximally-Exposed Individual (mrem/y)	**1.87E+02**

[a] Calculated by MicroShield.
[b] 223 worker exposure days x 8 hours/day = 1,780 hours/year

The calculated average exposure rate to the hypothetical RadCon Tech would be approximately 0.105 mrem/hr. If the RadCon Tech spent 1,780 hours per year working on the RIM, the TEDE would be 187 mrem/y. To put this in perspective, according to 10 CFR § 20.1201, a radiation worker has an occupational exposure limit of 5,000 mrem/y, assuming no administrative limits are imposed for the Site (NRC 1991).

7.5 SUMMARY

The short-term human health risks and hazard projections are summarized in Table 7-14.

Table 7-14 Summary of Short-Term Hazards and Risks Associated with ROD-Selected Remedy

Category of Hazard or Risk	Value
Projected Incidence of Transportation Accidents	6.14E-01
Projected Incidence of Industrial Accidents	2.76E+00
Carcinogenic Risk to RadCon Tech	9.23E-05
Carcinogenic Risks to Off-Property Residents	3.37E-08
HI to RadCon Tech	1.22E+00
HI to Off-Property Resident	4.12E-04
TEDE to Reasonably Maximally-Exposed Individual	1.87E+02

It is projected that 0.614 individuals could be injured or killed on public roads during implementation of the ROD-selected remedy, and 2.76 injuries or deaths are projected to be related to industrial activities are projected to occur. There is also a 3% chance of a fatal transportation accident and a 59% chance that a person will be injured as a result of a transportation accident.

Carcinogenic risks from exposure to RIM encountered during construction are expected to be no greater than the risk calculated for the RadCon Tech. The lifetime risk to the RadCon Tech was calculated to be 9.23×10^{-05}. This calculated risk is within EPA's acceptable risk range of 10^{-06} to 10^{-04}. The most important single contributor to this risk is the gamma radiation from RIM on and near the surface of the contamination area. Note that the carcinogenic risk to the off-property resident is less than 10^{-06}.

8 LONG-TERM RISK EXPOSURE ASSESSMENT

This section presents the long-term exposure assessment, which consists of the following steps:

- Characterization of the post-remedy exposure setting (i.e., in the long-term);
- Quantification of exposure point concentrations one year post-remedy and 1,000 years post-remedy;
- Identification of receptors with potentially complete exposure pathways and selection of representative receptors for use in the FFS comparative analysis; and
- Quantification of receptor-specific intake/exposure.

This exposure assessment supports the evaluation of long-term COPC exposure risks. Information presented in this section, unless otherwise noted, is applicable to each "action" alternative (i.e., the two partial excavation alternatives, the full excavation alternative, and the ROD-selected remedy).

8.1 CHARACTERIZATION OF EXPOSURE SETTING

Under each of the OU-1 "action" alternatives, Site improvements include elimination of exposure to RIM at the surface, installation of a cap or cover, and institutional controls. Similar receptors are expected under each alternative. The post-remedy physical configuration is the key component of the exposure setting that affects the overall exposure assessment (i.e., exposure point concentration). Physical attributes of the waste and cover are described on an alternative-specific basis in Sections 9 through 12.

8.2 EXPOSURE POINT CONCENTRATIONS

Section 2.2.1 lists the OU-1 COPCs. Under future conditions, the cap or cover will prevent direct contact with RIM; potentially complete exposure pathways only exist for constituents that produce indirect exposures through the cap via gas, vapor, or radiation transport. Inorganic chemical COPCs are excluded from future exposure scenario evaluations because of their lack of volatility. Organic chemical COPCs are excluded from future exposure scenario evaluations because of their limited extent and risk under current conditions and because biological and chemical degradation is anticipated to further reduce concentrations through time. Therefore, long-term exposures are limited to radionuclides. Long-term risks were calculated based on radionuclide concentrations one year post-remedy and 1,000 years post-remedy. Long-term risks are presented separately for Area 1 and Area 2 exposures.

8.2.1 **Exposure Point Concentrations in Soil at 1 Year after Construction**

For the partial and full excavation alternatives, radionuclides at OU-1 will be excavated until residual concentrations of thorium-232 plus thorium-230, or radium-226 plus radium-228, are equal to or less than the alternative-specific criterion (i.e., 1,000, 52.9, or 7.9 pCi/g). For this evaluation, future exposure point concentrations were estimated by (i) calculating the ratio of the alternative-specific criterion to the baseline 95% UCL for thorium-230 and (ii) multiplying baseline 95% UCL concentrations for other radiological COPCs by this ratio. Thorium-230 was used because the radium 95% UCL concentrations for OU-1 were less than the target remediation goal.

For the ROD-selected remedy, the baseline 95% UCL for concentrations across all depths was used to represent radionuclide concentrations in Areas 1 and 2 immediately after remedy construction. These concentrations were assumed to be representative of the material underlying the proposed cover.[24]

8.2.2 Exposure Point Concentrations in Soil 1,000 Years after Construction

The concentrations of the radionuclides are expected to change over the course of 1,000 years due to radiological decay and in-growth[25]. For each alternative, future concentrations over the next 1,000 years were calculated using the following assumptions:

- The future RIM is unaffected by chemical degradation during the study period of 1,000 years; and
- Radiological decay and associated daughter in-growth over 1,000 years will change the concentrations of the radionuclides in a predictable manner.

The representative concentrations used in this risk assessment are listed in each alternative-specific long-term risk section.

8.3 TOXICITY ASSESSMENT

Construction of this alternative will not change the toxicity of the contaminants in the RIM. The purpose of the alternative is to eliminate unacceptable risks through the removal of potential exposure pathways to be protective of human health and the environment. The toxicity values used in the updated BRA were also used herein.

8.4 POTENTIAL RECEPTORS

The Site has historically been used as a landfill, and most property surrounding the Site is currently used for commercial or industrial purposes. Deed restrictions on the West Lake Landfill prohibit on-site residential use. A deed restriction on Areas 1 and 2 prohibits construction of buildings, installation of underground utilities or pipes, and further future excavation; these restrictions are expected to preclude workers from being present full-time at OU-1, but full-time workers will likely be employed at the Landfill and some may periodically be on OU-1. Therefore, plausible future on-property receptors are limited to workers and transient users. Future surrounding land use 1,000 years in the future is uncertain and could hypothetically include farming or residential uses. Potential on-property and off-property receptors are identified in Table 8-1.

Because potential exposures are dependent on close proximity to radionuclides, individuals with the highest potential for exposure would be the people spending the most time on or near OU-1. Based on these considerations, the future receptor with the greatest potential for exposure is the landfill grounds keeper who works outdoors on the West Lake Landfill property and will work periodically directly on and adjacent to Area 1 or Area 2 soils.

[24] Soil removed from the Crossroads Property and Buffer Zone during an interim remedial action will be added to Area 2 during remedy construction. This material contains lower concentrations of RIM and adding it to the material in Area 2 would lower the average concentration in Area 2.

[25] A 1,000-year study period was selected based on design requirements of 40 CFR Part 192.

8.5 EXPOSURE PATHWAYS

Each of the "action" alternatives would eliminate exposure via incidental ingestion, dermal contact, and inhalation of fugitive dust. Therefore, potentially complete exposure pathways evaluated for the future landfill grounds keeper are: direct radiation from soil, inhalation of radon emanating through the cover, and direct radiation from submersion in air.

Table 8-1 List of Potential Future Receptors

Receptors Identified	Scenario Considered? [a]	Exposure Route: Inhalation of Fugitive Dust	Exposure Route: Inhalation of Radon	Exposure Route: Direct Radiation from Soil	Exposure Route: Direct Radiation from Submersion in Air	Exposure Route: Incidental Soil Ingestion	Exposure Route: Dermal Contact	Selected for Quantitative Evaluation?
Landfill Farmer	No							No
Landfill Resident	No							No
Landfill Outdoor Storage Yard Worker	**Yes**		{O}	{O}	{O}			No
Landfill Commercial Building User	**Yes**		{O}	{O}	{O}			No
Landfill Construction Worker	**Yes**		{O}	{O}	{O}			No
Landfill Trespasser	**Yes**		{O}	{O}	{O}			No
Landfill Recreational/Intermittent User	**Yes**		{O}	{O}	{O}			No
Landfill Grounds Keeper	**Yes**		•	•	•			**Yes**
Off-Property Farmer	**Yes**		{O}	{O}	{O}			No
Off-Property Resident	**Yes**		{O}	{O}	{O}			No
Off-Property Commercial Building User	**Yes**		{O}	{O}	{O}			No
Off-Property Recreational/Intermittent User	**Yes**		{O}	{O}	{O}			No
Off-Property Grounds Keeper	**Yes**		{O}	{O}	{O}			No

[a] An exposure scenario was considered if it included a source, a means of moving constituents of concern to a location of interest, and a receptor at that location.

Symbol	Meaning
•	Exposure route selected for detailed analysis
(shaded box)	A shaded box indicates that the receptor/exposure route combination was not selected for quantitative analysis.
{O}	Not quantified because other receptors identified for this scenario have higher intake rates and longer exposure times.

8.6 SCENARIO-SPECIFIC ASSUMPTIONS AND EXPOSURE PARAMETERS

Some exposure parameters are dependent on receptor-specific behavior patterns and vary from receptor scenario to receptor scenario. This assessment of each alternative assumed the same receptor parameters as the hypothetical landfill grounds keeper in the updated BRA. The exposure factors listed in Table 8-2 provide a description of this receptor's projected behavior. Only Site-specific parameters are shown in the table; other input parameters are default values from ORNL or EPA.

Table 8-2 Input for EPA's Air PRG Calculator, Grounds Keeper

Variable	Radionuclide PRG Calculator Value
t_{ow} (time - outdoor worker) yr	25
ED_{ow} (exposure duration - worker) yr	25
ET_{ow} (exposure time - worker) hr/day	8.5
EF_{ow} (exposure frequency - worker) day/yr	17.6

Note: Other parameters were left at default values.

8.7 UMTRCA REQUIREMENTS

Standards for UMTRCA remedial cell performance have been established by the EPA in 40 CFR Part 192, Subpart A - Standards for the Control of Residual Radioactive Materials from Inactive Uranium Processing (UMTRCA 1983). These standards require that final cover designs limit exposures to radiation and radioactive materials, provide long-term stability, and require minimal maintenance to assure performance standards are met in the future. Control measures are to be designed to be effective for up to 1,000 years (to the extent reasonably achievable) and, in any case, for at least 200 years. The rate at which radon escapes the cover surface (the radon flux rate) is measured in picocuries per square meter per second ($pCi/m^2/s$). The control measures must provide reasonable assurance that releases of radon-222 from radioactive material to the atmosphere would not exceed an average release rate of 20 $pCi/m^2/s$ (averaged over the entire site and over a one year period) and radiation exposure rates should be limited to 20 microroentgens per hour above background.

The clay and soil cover would slow the movement of radon gas. This is important because delaying radon's arrival at the surface allows radioactive decay to reduce the amount of radon emerging from the soil's surface. The radon flux through the cover was evaluated using RAECOM for the ROD-selected remedy which leaves all RIM in Areas 1 and 2 (See the cover design description in Appendix F for details on this model and its use).

These calculations predict that very little radon-222 for each alternative would reach the surface of the cover (< 1 $pCi/m^2/s$).

9 LONG-TERM RISKS FOR THE "PARTIAL EXCAVATION TO 1,000 PCI/G" ALTERNATIVE

9.1 ALTERNATIVE DESCRIPTION

In this alternative, RIM above 1,000 pCi/g will be excavated and transported to an approved out-of-state disposal facility. This alternative is intended to protect human health by removing RIM above the established criterion and placing an engineered cap over all of OU-1. This cap design provides a physical barrier that isolates the remaining RIM from surface receptors.

This section evaluates long-term residual COPC exposure risks to human health using standard EPA methodology for conducting HHRAs, which includes the following four components: selection of constituents COPCs, exposure assessment, toxicity assessment, and risk characterization. COPC selection, portions of the exposure assessment, and the toxicity assessment were presented in Section 8. This section focuses on the alternative-specific components: exposure setting, residual exposure point concentrations, and the risk characterization. Additionally, this section evaluates remedial alternative performance relative to Standards for the Control of Residual Radioactive Materials from Inactive Uranium Processing, which were established by the EPA in 40 CFR Part 192, Subpart A ("UMTRCA Requirements").

9.2 EXPOSURE SETTING

This alternative requires excavation of RIM, re-contouring the surface of OU-1, and installation of a cover designed to meet MDNR landfill closure requirements. The design also includes an underlying rock/concrete rubble layer to enhance long-term stability, protect the remaining RIM from bio- or human intrusion, and prevent erosion of the underlying waste materials. These Site improvements will bring the upper surface to an acceptable slope and improve surface drainage of Areas 1 and 2.

9.2.1 **Physical Setting**

The physical configuration of OU-1 after completion of the alternative is summarized below:

- A portion of the RIM in Areas 1 and 2 will have been removed, leaving a layer of RIM at concentrations below criteria, and non-RIM wastes.
- Areas 1 and 2 will be graded to improve the drainage characteristics of the final cover.
- A two-foot (0.6 m) thick rock and/or concrete rubble bio-intrusion layer would be placed over the RIM in Areas 1 and 2.
- A two-foot (0.6 m) thick clay cap would be placed over the rock/rubble layer to minimize precipitation infiltration into the underlying waste materials and to attenuate radon emissions from the RIM. The permeability of this clay will be a minimum of 10^{-07} m/s (10^{-05} cm/s).
- The clay layer will be covered with one foot (0.3 m) of soil and a vegetative cover (grass) will be established on the cap. This vegetative cover is assumed to be maintained to prevent depletion of the cap.

Figure 9-1 depicts the cap design for Areas 1 and 2.

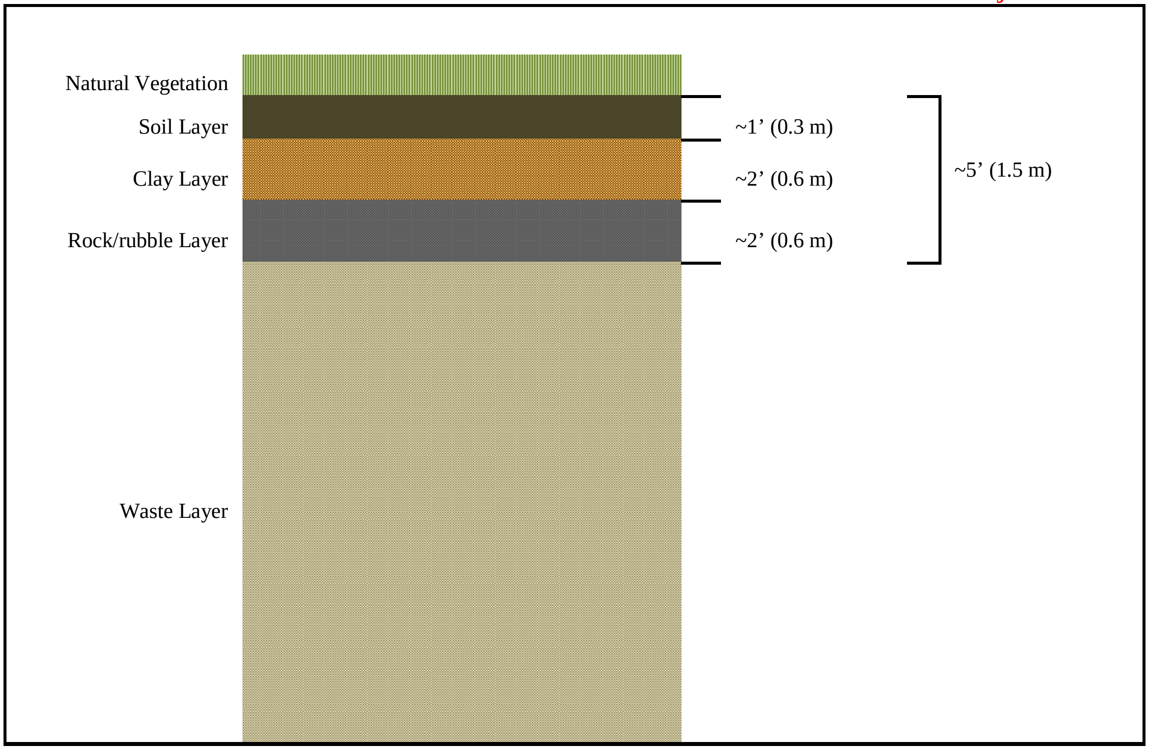

Figure 9-1 Stylized Cross-Section of RIM and Cover for the "Partial Excavation to 1,000 pCi/g" Alternative

9.2.2 Physical Attributes of the Waste and Cover

The physical properties of the remaining RIM and cover components are presented in Table 9-1. The erosion rate of the cover layer reflects the effects of maintenance and the rock/rubble layer.

Table 9-1 Physical Properties of RIM Below Criteria and Cover

Parameter	Area 1	Area 2
Contamination Zone (RIM)		
Area (m^2)	25,217	98,515
Erosion Rate (m/y)	0.001	0.001
Total Porosity (dry wt_%)	0.3	0.3
Field Capacity (vol/vol)	0.292	0.292
Hydraulic Conductivity (m/y)	5.26	5.26
Radon Diffusion Coefficient (m^2/s)	$1.806x10^{-09}$	$1.806x10^{-09}$
Cover		
Thickness (m)	1.5	1.5
Erosion Rate (m/y)	0.0001	0.0001
Total Porosity (vol/vol)	0.427	0.427
Volumetric Water Content (vol/vol)	0.367	0.367
Hydraulic Conductivity (m/y)	0.000526	0.000526

9.3 EXPOSURE POINT CONCENTRATIONS

As discussed in Section 8, the evaluation of future risks focuses on radiological COPCs. Placing the engineered cover over OU-1 will block almost all of the direct radiation exposure from the remaining RIM. Exposures from the small fraction of direct gamma radiation predicted to penetrate the cover were quantified in this assessment. This cover will also attenuate almost all of the radon-222 produced in the underlying RIM below the 1,000 pc/g excavation limit. Radium-226 in the remaining RIM will decay to radon-222, which is a noble gas. About 20% of radon gas is released to interstitial air and water in the pore spaces of the residual radium and surrounding soils, while the other 80% remains within the solid matrix of the soil particles. Once in the pore space, radon gas is free to move in the soil. The distance that radon can travel is greatly limited by its 3.8-day half-life. Covering the remaining RIM with low permeability soil/clay increases the time required for the radon to reach the ground surface. This increased travel time allows almost all of the radon to decay before it reaches the surface. Risks from residual radon gas and the risks associated with direct radiation from radon daughters if submerged in air were quantified in this assessment.

Calculated exposure point concentrations 1 year and 1,000 years post- remedial alternative are discussed below. The representative concentrations used in this risk assessment are listed in Table 9-2.

9.3.1.1 Exposure Point Concentrations in Soil at 1 Year after Construction

The RIM in each area would be removed until residual concentrations of thorium-232 plus thorium-230, or radium-226 plus radium-228, were equal to or less than 1,000 pCi/g. Beginning with the initial RIM concentrations in Area 1 and Area 2 listed in the updated BRA, and for the purposes of these calculations, the concentrations of the all radionuclides were reduced proportionally until the total thorium-230 concentration in the remaining RIM equaled 1,000 pCi/g. For example, the current 95% UCL concentration of Th-230 in Area 2 is 4,732 pCi/g and the remedial alternative-specific criterion is 1,000 pCi/g; 1,000 pCi/g divided by 4,732 pCi/g results in a ratio of 0.2113. All other current exposure point concentrations for radiological COPCs were multiplied by this ratio to reflect the approximate concentrations post- remedial alternative. Thorium-230 was used because the radium 95% UCL concentrations for OU-1 were less than the target remediation goal.

9.3.1.2 Exposure Point Concentrations in Soil at 1,000 Years after Construction

The concentrations of the radionuclides in the RIM below the remedial alternative-specific criterion are expected to change over the course of 1,000 years due to radiological decay and in-growth[26]. The 1,000 year values include the effects of radioactive in-growth and decay.

[26] A 1,000 year study period was selected based on design requirements of 40 CFR Part 192.

Table 9-2 COPC Concentrations in Areas 1 and 2, "Partial Excavation to 1,000 pCi/g" Alternative

	1 Year Post-Construction		1,000 Years Post-Construction		
COPC	**Area 1** [a]	**Area 2** [a]	**Area 1**	**Area 2**	**Units**
Uranium Series					
Uranium-238 + 3 dtrs	1.50E+01	2.64E+01	1.50E+01	2.64E+01	pCi/g
Uranium-234	1.65E+01	2.77E+01	1.65E+01	2.76E+01	pCi/g
Thorium-230	1.00E+03	1.00E+03	9.91E+02	9.91E+02	pCi/g
Radium-226 + 8 dtrs	1.69E+02	8.35E+01	4.59E+02 [b]	4.04E+02 [b]	pCi/g
Lead-210 + 2 dtrs	4.95E+01	2.94E+01	4.59E+02 [c]	4.04E+02 [c]	pCi/g
Actinium Series					
Uranium-235 + 1 dtr [d]	7.86E-01	1.35E+00	7.86E-01	1.35E+00	pCi/g
Protactinium-231	4.01E+01	3.85E+01	3.93E+01	3.77E+01	pCi/g
Actinium-227 + 9 dtrs	1.18E+01	2.60E+01	3.93E+01	3.77E+01	pCi/g
Thorium Series					
Thorium-232 + 10 dtrs	1.57E+01	4.65E+00	1.57E+01	4.65E+00	pCi/g

[a] One year after construction ceases.
[b] Includes in-growth from the decay of thorium-230.
[c] Assumed to be in secular equilibrium with radium-226.
[d] Due to the uncertainty of the uranium-235 results, these values were calculated using the more reliable uranium-238 and uranium-234 results and the expected relative abundance of uranium-235 in natural uranium.

9.3.1.3 Exposure Point Concentrations in Air at 1 and 1,000 years

Radon concentrations were also generated for the residual concentration of RIM left below 1,000 pCi/g at 1 and 1,000 years. These concentrations were generated at the same locations as the updated BRA. As the hypothetical grounds keeper will be located atop Area 1 and Area 2, those two locations were chosen and are presented in Table 9-3.

Table 9-3 Radon-222 Concentrations in Air at Exposure Point Concentrations for the "Partial Excavation to 1,000 pCi/g" Alternative

Analyte	On-site, Area 1 (722130 E 4294400 N)	On-site, Area 2 (721720 E 4294785 N)
Flight distance(m)	250	440
Flight time(min) [a]	1.0	1.8
At 1 Year

9.4 RISK CHARACTERIZATION

The long-term risk characterization quantitatively evaluated potential risks to a landfill grounds keeper who works outdoors at the West Lake Landfill property, adjacent to and on Area 1 or Area 2. This receptor is assumed to be exposed to radiological COPCs via inhalation of radon, direct radiation from submersion in air, and exposure to direct radiation from soil. Results of the risk characterization are presented below. Potential risks are quantified using EPA RAGS methodology and based on a comparison of radiation dose rates to acceptable occupational exposure limits.

9.4.1 Risks from Inhalation of Radon and Submersion in Air

The EPA PRG calculator for air does not provide the ability to estimate air concentrations emitted from subsurface contaminants. AERMOD (see Section 2.2.8.3) was used to calculate the concentration of radon-222 and daughters at the RME receptor site with a 1.5 m cover. Radon flux as measured on OU-1 was used in conjunction with AERMOD to establish the radon and radon daughter concentrations at receptor locations. The risk was calculated for that concentration by dividing 10^{-06} by the sum of the PRGs and then multiplying by the estimated concentration of radon-222 and daughters (see Attachment A to the updated BRA).

For example, for the Area 2 "partial excavation to 1,000 pCi/g" alternative, the radon-222 concentration (4.2 x 10^{-03} pCi/m^3 from Table 9-3) at the receptor emanating from the 1.5 m cover at 1,000 years was calculated using AERMOD software and the 1,000 year post- remedial alternative concentration of radium-226 (404 pCi/g). The 10^{-06} risk was then calculated by dividing 10^{-06} by the PRG for inhalation of radon while outdoors ($3.34 \times 10^{+00}$ pCi/m^3), then multiplying by the concentration at the receptor site of 4.2×10^{-03} pCi/m^3. The risk value for radon-222 was further modified by multiplying the risk by 0.095, a factor that is described in footnote (a) of the updated BRA, Table 26. This factor was applied to account for the incorrect slope factor used in the EPA PRG calculator for radon-222. This equates to a total risk for radon-222 of 1.21×10^{-10}.

The same method was used to calculate the risks associated with submersion in air; however, because similar information does not exist to calculate an immersion slope factor, no further adjustment was made.

9.4.2 **Exposure from Direct Radiation**

In both Areas 1 and 2, the landfill cover design greatly reduces the amount of direct radiation that reaches the ground surface above the cover. This shielding increases as the thickness or density of intervening material increases.

The EPA PRG calculator was used to quantify carcinogenic risks from this remedial alternative; however, the PRG calculator does not provide the option to select the engineered cover design thickness of 1.5 meters. PRGs for a 1 pCi/g concentration associated with a 1.5 meter (150 cm) cover were established by generating PRGs for 50, 60, 70, 80, 90, 100, 200, and 300 cm covers. Scatter plots for each COPC were generated with the PRG plotted on the Y axis and the cover thickness plotted on the X axis. The equation associated with the highest correlation coefficient was then used to calculate the 1.5 meter PRGs for each COPC.

The risk was calculated by dividing 10^{-06} by the calculated 1.5 meter PRG, and then multiplying by the concentration of the COPC at 1 and 1,000 years. For example, the 1.5 meter PRG for radium-226 was calculated at $1.99 \times 10^{+06}$ pCi/g, and the radium-226 1,000 year concentration in Area 2 is 404 pCi/g. The resulting risk is calculated as 10^{-06} / ($1.99 \times 10^{+06}$ pCi/g x 404 pCi/g) $=2.03 \times 10^{-10}$.

9.4.3 **Doses from Direct Radiation**

Dose to the RME individual in mrem/h was calculated using MicroShield® software (see Section 2.2.8.2). Using the software, a unit dose rate associated with 1 pCi/g concentration, a 1.5 meter cover, 1-meter above the surface was calculated for each COPC. The 1,000 year concentrations listed in Table 9-2 were then multiplied by the unit dose rate to calculate the dose associated with the 1,000 year concentration. For example, the unit dose rate associated with 1 pCi/g of radium-226 above a 1.5 m cover and 1 m above the surface was calculated to be 8.86×10^{-09} mrem/hr. The 1,000 year radium-226 concentration in Area 2 associated with this remedial alternative is 404 pCi/g. The resulting exposure rate equals 3.58×10^{-06} mrem/hr for radium-226 (8.86×10^{-09} mrem/hr x 404 pCi/g = 3.58×10^{-06} mrem/hr). This same method was then applied to all COPCs. It is estimated that the grounds keeper will spend 52.7 hours[27] each year outdoors. Multiplying the total hours each year by the sum of the exposure rates for all the COPCs combined results in a TEDE of 2.11×10^{-04} mrem/yr.

[27] 6.2 days per year exposed to soil x 8.5 hours per day.

9.4.4 **Risk Summary**

The parameters set forth in Table 8-2 were used to calculate long-term risks. Table 9-4 and Table 9-6 contain long-term risks at year 1 and year 1,000. Table 9-5 and Table 9-7 present calculated doses to the receptor during those same time periods.

9.5 SUMMARY

Risk and dose estimates for the RME individual on Areas 1 and 2 in the first year after remedial alternative construction and 1,000 years after remedial alternative completion are listed in Table 9-8. Calculated exposures to the hypothetical grounds keeper receptor were dominated by exposures from radon daughters produced by decay of radium-226 in any remaining RIM.

Table 9-8 Long-term Risks and Doses to the Grounds Keeper for the "Partial Excavation to 1,000 pCi/g" Alternative

	Area 1	Area 2	Total
Risk at 1 year	1.32E-10	7.01E-11	2.02E-10
Risk a 1,000 years	3.63E-10	3.37E-10	7.00E-10
Dose at 1 year (mrem/y)	1.53E-04	6.10E-05	2.14E-04
Dose at 1,000 years (mrem/y)	2.89E-04	2.11E-04	4.99E-04

The cancer risk estimate for the RME individual under this remedial alternative at 1,000 years after remedial alternative construction is complete is 7.00×10^{-10} for Area 1 and Area 2 combined. This risk is well-below EPA's acceptable risk range. The greatest risk to on-site workers after the cap is applied is direct exposure to ionizing gamma radiation. Risks for external exposure to ionizing gamma radiation are driven by radium-226 concentrations. Originally, radium-226 concentrations in Area 2 were greater than those in Area 1; therefore, one would expect the risk to be higher for Area 2. The concentration of radium-226 was normalized for each area based on thorium-230 concentrations. After normalization, Area 2 radium-226 concentrations were less than the concentrations in Area 1; therefore, the risks are higher in Area 1. The predicted radiation doses are also well below the occupational exposure limit of 5,000 mrem/y. Therefore, the "partial excavation to 1,000 pCi/g" alternative satisfies the threshold criterion for the protection of human health.

10 LONG-TERM RISK FOR THE "PARTIAL EXCAVATION TO 52.9 PCI/G" ALTERNATIVE

10.1 ALTERNATIVE DESCRIPTION

In this remedial alternative the RIM above 52.9 pCi/g will be excavated and transported to an approved out-of-state disposal facility. This remedial alternative is intended to protect human health by removing RIM above the established criterion and placing an engineered cap over all of OU-1. This cap design provides a physical barrier that isolates the remaining RIM from surface receptors.

This section evaluates long-term residual COPC exposure risks to human health using standard EPA methodology for conducting HHRAs, which includes the following four components: selection of constituents COPCs, exposure assessment, toxicity assessment, and risk characterization. COPC selection, portions of the exposure assessment, and the toxicity assessment were presented in previous sections. This section focuses on the remedial alternative-specific components: exposure setting, residual exposure point concentrations, and the risk characterization. Additionally, this section evaluates remedial alternative performance relative to the UMTRCA requirements.

10.2 EXPOSURE SETTING

This remedial alternative requires excavation of RIM to 52.9 pCi/g, re-contouring the surface of OU-1, and installation of a cover designed to meet MDNR landfill closure requirements. The design also includes an underlying rock/concrete rubble layer to enhance long-term stability, protect remaining RIM from bio- or human intrusion, and prevent erosion of the underlying waste materials. These Site improvements will bring the upper surface to an acceptable slope and improve surface drainage of Areas 1 and 2.

10.2.1 Physical Setting

The physical configuration of OU-1 after completion of the remedial alternative is summarized below:

- A portion of the RIM in Areas 1 and 2 will have been removed, leaving a layer of RIM at concentrations below criteria, and non-RIM wastes.
- Areas 1 and 2 will be graded to improve the drainage characteristics of the final cover.
- A two-foot (0.6 m) thick rock and/or concrete rubble bio-intrusion layer will be placed over the RIM in Areas 1 and 2.
- A two-foot (0.6 m) thick clay cap will be placed over the rock/rubble layer to minimize precipitation infiltration into the underlying waste materials and to attenuate radon emissions from the RIM. The permeability of this clay will be a minimum of 10^{-07} m/s (10^{-05} cm/s).
- The clay layer will be covered with one foot (0.3 m) of soil and a vegetative cover (grass) will be established on the cap. This vegetative cover is assumed to be maintained to prevent depletion of the cap.

Figure 10-1 depicts the cap design for Areas 1 and 2.

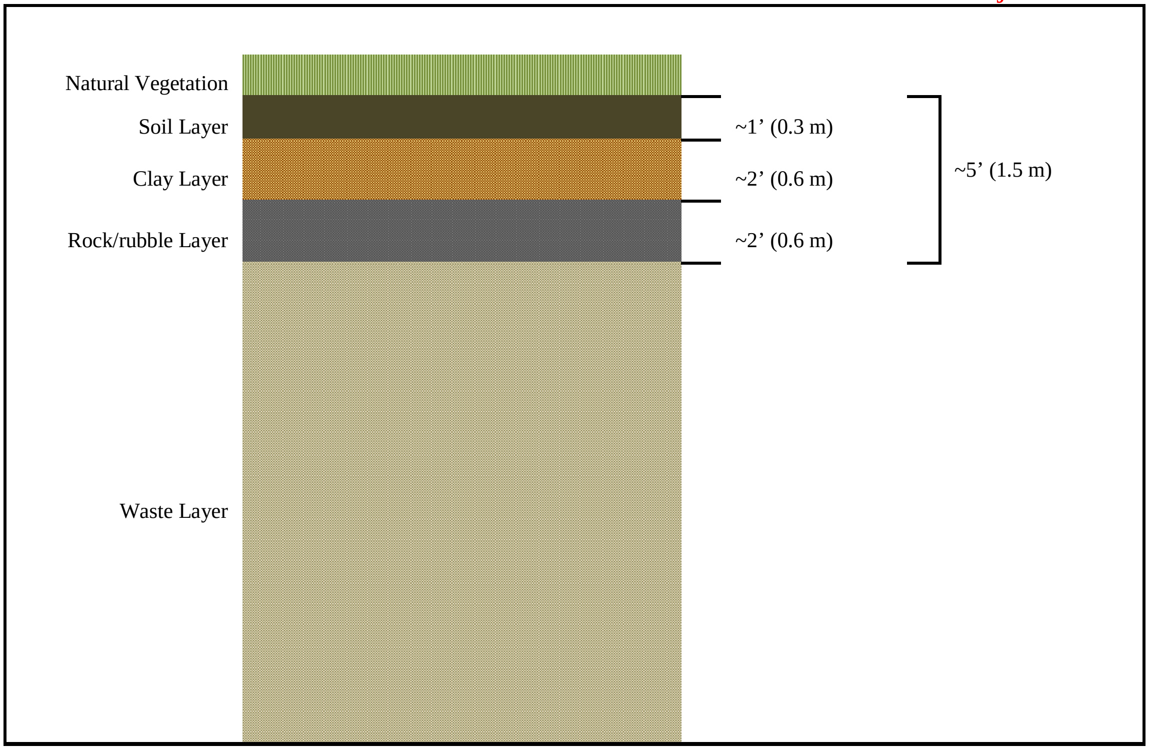

Figure 10-1 Stylized Cross-Section of RIM and Cover for the "Partial Excavation to 52.9 pCi/g" Alternative

10.2.2 **Physical Attributes of the Waste and Cover**

The physical properties of the remaining RIM and cover components are presented in Table 10-1. The erosion rate of the cover layer reflects the effects of maintenance and the rock/rubble layer.

Table 10-1 Physical Properties of RIM Below Criteria and Cover

Parameter	Area 1	Area 2
Contamination Zone (RIM)		
Area (m^2)	25,217	98,515
Erosion Rate (m/y)	0.001	0.001
Total Porosity (dry wt_%)	0.3	0.3
Field Capacity (vol/vol)	0.292	0.292
Hydraulic Conductivity (m/y)	5.26	5.26
Radon Diffusion Coefficient (m^2/s)	1.806×10^{-09}	1.806×10^{-09}
Cover		
Thickness (m)	1.5	1.5
Erosion Rate (m/y)	0.0001	0.0001
Total Porosity (vol/vol)	0.427	0.427
Volumetric Water Content (vol/vol)	0.367	0.367
Hydraulic Conductivity (m/y)	0.000526	0.000526

10.3 EXPOSURE POINT CONCENTRATIONS

As discussed in Section 8, the evaluation of future risks focuses on radiological COPCs. Placing the engineered cover over OU-1 will block almost all of the direct radiation exposure from the remaining RIM. Exposures from the small fraction of radiation predicted to penetrate the cover were quantified in this assessment. This cover will also attenuate almost all of the radon-222 produced in the underlying RIM below 52.9 pCi/g. Radium-226 in the remaining RIM will decay to radon-222, which is a noble gas. About 20% of radon gas is released to interstitial air and water in the pore spaces of the residual radium and surrounding soils, while the other 80% remains within the solid matrix of the soil particles. Once in the pore space, radon gas is free to move in the soil. The distance that radon can travel is greatly limited by its 3.8-day half-life. Covering the remaining RIM with low permeability soil/clay increases the time required for the radon to reach the ground surface. This increased travel time allows almost all of the radon to decay before it reaches the surface. Risks from residual radon gas and the risks associated with direct radiation from radon daughters if submerged in air were quantified in this assessment.

Calculated exposure point concentrations 1 year and 1,000 years post- remedial alternative are discussed below. The representative concentrations used in this risk assessment are listed in Table 10-2.

10.3.1 **Exposure Point Concentrations in Soil at 1 Year after Construction**

Under this remedial alternative, the RIM in each area would be removed until residual concentrations of thorium-232 plus thorium-230, or radium-226 plus radium-228, were equal to or less than 52.9 pCi/g. Beginning with the initial RIM concentrations in Area 1 and Area 2 listed in the updated BRA, and for the purposes of these calculations, the concentrations of the radionuclides were reduced proportionally until the total thorium-230 concentration in the remaining RIM equaled 52.9 pCi/g. For example, the current 95% UCL concentration of Th-230 in Area 2 is 4,732 pCi/g and the remedial alternative-specific concentration is 52.9 pCi/g; 52.9 pCi/g divided by 4,732 pCi/g results in a ratio of 0.0112. All other current radiological COPCs were multiplied by this ratio to reflect the approximate concentrations post- remedial alternative. Thorium-230 was used because the radium 95% UCL concentrations for OU-1 were less than the target remediation goal.

10.3.2 **Exposure Point Concentrations in Soil at 1,000 Years after Construction**

The concentrations of the radionuclides in the RIM below criteria are expected to change over the course of 1,000 years due to radiological decay and in-growth[28]. The 1,000-year values include the effects of radioactive in-growth and decay.

Table 10-2 COPC Concentrations in Areas 1 and 2, "Partial Excavation to 52.9 pCi/g" Alternative

[a] One year after construction ceases.
[b] Includes in-growth from the decay of thorium-230.
[c] Assumed to be in secular equilibrium with radium-226.
[d] Due to the uncertainty of the uranium-235 results, these values were calculated using the more reliable uranium-238 and uranium-234 results and the expected relative abundance of uranium-235 in natural uranium.

10.3.3 **Exposure Point Concentrations in Air at 1 and 1,000 years**

Radon concentrations were also generated for the residual concentration of RIM left below 52.9 pCi/g at 1 and 1,000 years. These concentrations were generated at the same locations as the updated BRA. As the hypothetical grounds keeper will be located atop Area 1 and Area 2, those two locations were chosen and are presented in Table 10-3.

[28] A 1,000-year study period was selected based on design requirements of 40 CFR Part 192.

10.4 RISK CHARACTERIZATION

The long-term risk characterization quantitatively evaluated potential risks to a landfill grounds keeper who works outdoors at the West Lake Landfill property, adjacent to and on Area 1 or Area 2. This receptor is assumed to be exposed to radiological COPCs via inhalation of radon, direct radiation from submersion in air, and exposure to direct radiation from soil. Results of the risk characterization are presented below. Potential risks are quantified using EPA RAGS methodology and based on a comparison of radiation dose rates to acceptable occupational exposure limits.

10.4.1 Risks from Inhalation of Radon and Submersion in Air

The EPA PRG calculator for air does not provide the ability to estimate air concentrations emitted from subsurface contaminants. AERMOD (see Section 2.2.8.3) was used to calculate the concentration of radon-222 and daughters in on-property air, assuming a 1.5 m cover. The risk was calculated for that concentration by dividing 10^{-06} by the sum of the PRGs and then multiplying by the estimated concentration of radon-222 and daughters.

For example, for the Area 2 "partial excavation to 52.9 pCi/g" alternative, the radon-222 concentration (2.2×10^{-04} pCi/m^3 from Table 10-3) at the receptor emanating from the 1.5 m cover at 1,000 years was calculated using AERMOD software and the 1,000 year post- remedial alternative concentration of radium-226 (21 pCi/g). The risk was then calculated by dividing 10^{-06} by the PRG for inhalation of radon while outdoors ($3.34 \times 10^{+00}$ pCi/m^3), then multiplying by the concentration at the receptor site of 2.2×10^{-04} pCi/m^3. The risk value for radon-222 was further modified by multiplying the risk by 0.095, a factor that is described in footnote (a) of the updated BRA, Table 26. This factor was applied to account for the incorrect slope factor used in the EPA PRG calculator for radon-222. This equates to a total risk for radon-222 of 6.27 x 10^{-12}.

The same method was used to calculate the risks associated with submersion in air; however, because similar information does not exist to calculate an immersion slope factor, no further adjustment was made.

10.4.2 **Exposure from Direct Radiation**

In both Areas 1 and 2, the landfill cover design greatly reduces the amount of direct radiation that reaches the ground surface above the cover. This shielding increases as the thickness or density of intervening material increases.

The EPA PRG calculator was used to quantify carcinogenic risks from this remedial alternative; however, the PRG calculator does not provide the option to select the engineered cover design thickness of 1.5 meters. PRGs for a 1 pCi/g concentration associated with a 1.5 meter (150 cm) cover were established by generating PRGs for 50, 60, 70, 80, 90, 100, 200, and 300 cm covers. Scatter plots for each COPC were generated with the PRG plotted on the Y axis and the cover thickness plotted on the X axis. The equation associated with the highest correlation coefficient was then used to calculate the 1.5 meter PRGs for each COPC.

The risk was calculated by dividing 10^{-06} by the calculated 1.5 meter PRG, and then multiplying by the concentration of the COPC at 1 and 1,000 years. For example, the 1.5 meter PRG for radium-226 was calculated at 1.99 x 10^{+06} pCi/g, and the radium-226 1,000 year concentration in Area 2 is 21 pCi/g. The resulting risk is calculated as 10^{-06}/1.99 x 10^{+06} pCi/g x 21 pCi/g =1.06 x 10^{-11}.

10.4.3 **Doses from Direct Radiation**

Dose to the RME individual in mrem/h was calculated using MicroShield® software (see Section 2.2.8.2). Using the software, a unit dose rate associated with 1 pCi/g concentration, a 1.5 meter cover, 1-meter above the surface was calculated for each COPC. The 1,000 year concentrations listed in Table 10-2 were then multiplied by the unit dose rate to calculate the dose associated with the 1,000 year concentration. For example, the unit dose rate associated with 1 pCi/g of radium-226 above a 1.5 m cover and 1 m above the surface was calculated to be 8.86 x 10^{-09} mrem/hr. The 1,000 year radium-226 concentration in Area 2 associated with this remedial alternative is 21 pCi/g. The resulting exposure rate equals 1.86 x 10^{-07} mrem/hr for radium-226 (8.86 x 10^{-09} mrem/hr x 21 pCi/g = 1.86 x 10^{-07} mrem/hr). This same method was then applied to all COPCs. It is estimated that the grounds keeper will spend 52.7 hours[29] each year outdoors. Multiplying the total hours each year by the sum of the exposure rates for all the COPCs combined results in a TEDE of 1.1 x 10^{-05} mrem/yr.

10.4.4 **Risk Summary**

Long-term risks and doses are presented in Table 10-4 through Table 10-7. Table 10-4 and Table 10-6 contain excerpts of the output files generated by EPA PRG calculators for long-term risks at year 1 and year 1,000. Table 10-5 and Table 10-7 present calculated doses to the receptor during those same time periods.

[29] 6.2 days per year exposed to soil x 8.5 hours per day.

Grounds Keeper (52.7 h/y)	3.23E-06	1.10E-05

10.5 SUMMARY

Risk and dose estimates for the RME individual on Areas 1 and 2 in the first year after remedial alternative construction and 1,000 years after remedial alternative completion are listed in Table 10-8. Calculated exposures to the hypothetical grounds keeper receptor were dominated by exposures from radon daughters produced by decay of radium-226 in any remaining RIM.

Table 10-8 Long-term Risks and Doses to the Grounds Keeper for the "Partial Excavation to 52.9 pCi/g" Alternative

	Area 1	Area 2	Total
Risk at 1 year	6.97E-12	3.71E-12	1.07E-11
Risk a 1,000 years	1.90E-11	1.75E-11	3.65E-11
Dose at 1 year (mrem/y)	8.10E-06	3.23E-06	1.13E-05
Dose at 1,000 years (mrem/y)	1.51E-05	1.10E-05	2.61E-05

The cancer risk estimate for the RME individual under this remedial alternative at 1,000 years after remedial alternative construction is complete is 3.65×10^{-11} for Area 1 and Area 2 combined. This risk is well-below EPA's acceptable risk range. The greatest risk to on-site workers after the cap is applied is direct exposure to ionizing gamma radiation. Risks for external exposure to ionizing gamma radiation are driven by radium-226 concentrations. Originally, radium-226 concentrations in Area 2 were greater than those in Area 1; therefore, one would expect the risk to be higher for Area 2. The concentration of radium-226 was normalized for each area based on thorium-230 concentrations. After normalization, Area 2 radium-226 concentrations were less than the concentrations in Area 1; therefore, the risks are higher in Area 1. The predicted radiation doses are also well below the occupational exposure limit of 5,000 mrem/y. Therefore, the "partial excavation to 52.9 pCi/g" alternative satisfies the threshold criterion for the protection of human health.

11 LONG-TERM RISKS FOR THE "COMPLETE RAD REMOVAL" ALTERNATIVE

11.1 ALTERNATIVE DESCRIPTION

In this remedial alternative RIM above 7.9 pCi/g will be excavated and transported to an out-of-state disposal facility. This remedial alternative is intended to protect human health by removing RIM above the established criterion and placing an engineered cap over all of Areas 1 and 2 as part of the overall landfill closure plan. The overburden and final cap will provide a physical barrier for other non-RIM landfill wastes and will incidentally isolate surface receptors from any remaining RIM below cleanup levels which remains in place at the Site. Controls intended to address radiological occurrences would no longer be required under this remedial alternative, but the same or similar controls would still be required because the Site will remain an inactive municipal waste landfill.

This section evaluates long-term residual COPC exposure risks to human health using standard EPA methodology for conducting HHRAs, which includes the following four components: selection of constituents COPCs, exposure assessment, toxicity assessment, and risk characterization. COPC selection, portions of the exposure assessment, and the toxicity assessment were presented in previous sections. This section focuses on the remedial alternative-specific components: exposure setting, residual exposure point concentrations, and the risk characterization. Additionally, this section evaluates remedial alternative performance relative to the UMTRCA requirements.

11.2 EXPOSURE SETTING

This remedial alternative requires excavation of RIM, re-contouring the surface of OU-1, and installation of a cover designed to meet MDNR landfill closure requirements. These improvements will bring the upper surface to an acceptable slope and improve surface drainage of Areas 1 and 2.

11.2.1 **Physical Setting**

The physical configuration of OU-1 after completion of the remedy is summarized below:

- The bulk of the RIM in Areas 1 and 2 will have been removed, leaving both a layer of RIM at concentrations below criteria and non-RIM wastes.
- A two foot (0.6 m) thick layer of clay would be placed over the waste materials in Areas 1 and 2. The permeability of this clay would be a minimum of 10^{-07} m/s (10^{-05} cm/s).
- Areas 1 and 2 would be covered with one foot (0.3 m) of soil and a vegetative cover will be established on the cap. This vegetative cover is assumed to be maintained to prevent depletion of the cap.

Figure 11-1 depicts the cap design for Areas 1 and 2.

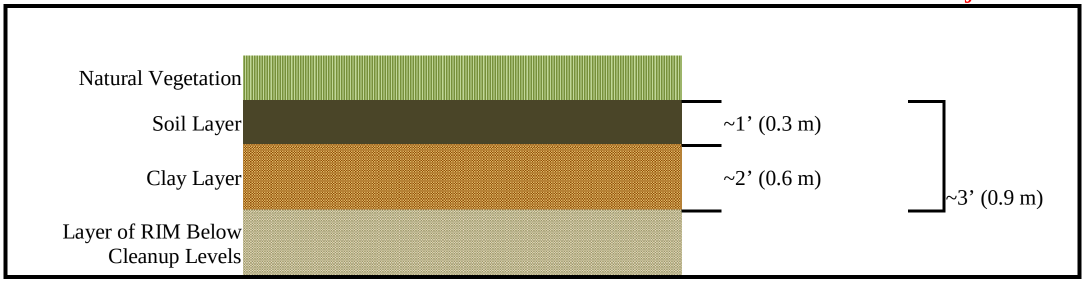

Figure 11-1 Stylized Cross-Section of RIM and Cover for the "Complete Rad Removal" Alternative

11.2.2 **Physical Attributes of the Waste and Cover**

The physical properties of the remaining RIM and cover components are presented in Table 11-1. The erosion rate of the cover layer reflects the effects of maintenance.

Table 11-1 Physical Properties of RIM Below Cleanup Levels and Cover

Parameter	Area 1	Area 2
Contamination Zone (RIM)		
Area (m^2)	25,217	98,515
Erosion Rate (m/y)	0.001	0.001
Total Porosity (dry wt_%)	0.3	0.3
Field Capacity (vol/vol)	0.292	0.292
Hydraulic Conductivity (m/y)	5.26	5.26
Radon Diffusion Coefficient (m^2/s)	1.806×10^{-09}	1.806×10^{-09}
Cover		
Thickness (m)	0.9	0.9
Erosion Rate (m/y)	0.0001	0.0001
Total Porosity (vol/vol)	0.427	0.427
Volumetric Water Content (vol/vol)	0.367	0.367
Hydraulic Conductivity (m/y)	0.000526	0.000526

11.3 EXPOSURE POINT CONCENTRATIONS

As discussed in Section 8, the evaluation of future risks focuses on radiological COPCs. Placing the engineered cover over OU-1 will block almost all of the direct radiation exposure from the remaining RIM. Exposures from the small fraction of radiation predicted to penetrate the cover were quantified in this assessment. This cover will also attenuate almost all of the radon-222 produced in the underlying RIM below 7.9 pCi/g. Radium-226 in the remaining RIM will decay to radon-222, which is a noble gas. About 20% of radon gas is released to interstitial air and water in the pore spaces of the residual radium and surrounding soils, while the other 80% remains within the solid matrix of the soil particles. Once in the pore space, radon gas is free to move in the soil. The distance that radon can travel is greatly limited by its 3.8-day half-life. Covering the remaining RIM with low permeability soil/clay increases the time required for the radon to reach the ground surface. This increased travel time allows almost all of the radon to decay before it reaches the surface. Risks from residual radon gas and the risks associated with direct radiation from radon daughters if submerged in air were quantified in this assessment.

Calculated exposure point concentrations 1 year and 1,000 years post- remedial alternative are discussed below. The representative concentrations used in this risk assessment are listed in Table 11-2.

11.3.1 Exposure Point Concentrations in Soil at 1 Year after Construction

Under this remedial alternative, the RIM in each area would be removed until residual concentrations of thorium-232 plus thorium-230, or radium-226 plus radium-228, were equal to or less than 7.9 pCi/g. Beginning with the initial RIM concentrations in Area 1 and Area 2 listed in the updated BRA, and for the purposes of these calculations, the concentrations of the radionuclides were reduced proportionally until the total thorium-230 concentration in the remaining RIM equaled 7.9 pCi/g. For example, the current 95% UCL concentration of Th-230 in Area 2 is 4,732 pCi/g and the remedial alternative-specific concentration is 7.9 pCi/g; 7.9 pCi/g divided by 4,732 pCi/g results in a ratio of 0.0017. All other current radiological COPCs were multiplied by this ratio to reflect the approximate concentrations post- remedial alternative. Thorium-230 was used because the radium 95% UCL concentrations for OU-1 were less than the target remediation goal.

11.3.2 Exposure Point Concentrations in Soil at 1,000 Years after Construction

The concentrations of the radionuclides in the RIM below criteria are expected to change over the course of 1,000 years due to radiological decay and in-growth[30]. The 1,000-year values include the effects of radioactive in-growth and decay.

[30] A 1,000-year study period was selected based on design requirements of 40 CFR Part 192.

Table 11-2 COPC Concentrations in Areas 1 and 2, "Complete Rad Removal" Alternative

COPC	1 Year Post-Construction Area 1 [a]	1 Year Post-Construction Area 2 [a]	1,000 Year Area 1	1,000 Year Area 2	Units

[a] One year after construction ceases.
[b] Includes in-growth from the decay of thorium-230.
[c] Assumed to be in secular equilibrium with radium-226.
[d] Due to the uncertainty of the uranium-235 results, these values were calculated using the more reliable uranium-238 and uranium-234 results and the expected relative abundance of uranium-235 in natural uranium.

11.3.3 **Exposure Point Concentrations in Air at 1 and 1,000 years**

Radon concentrations were also generated for the residual concentration of any residual materials at 1 and 1,000 years. These concentrations were generated at the same locations as the updated BRA. As the hypothetical grounds keeper will be located atop Area 1 and Area 2, those two locations were chosen and are presented in Table 11-3.

Table 11-3 Radon-222 Concentrations in Air at Exposure Point Concentrations for the "Complete Rad Removal Option" Alternative

Bi-214 + 1 dtr (pCi/m^3)	3.5 E-9	1.5 E-8

11.4 RECEPTOR BEHAVIOR

This assessment of the remedial alternative assumed the same receptor parameters as the hypothetical grounds keeper in the updated BRA. The cover for the "complete rad removal" alternative is a 0.9 m cap. This is different than the other remedial alternatives that all have a 1.5 m cover. As a result of this different cover, the receptor in this remedial alternative would have both soil and air EPA PRG's obtained directly from the EPA calculator (as opposed to the other remedial alternatives in which the PRG's for the 1.5 m cover had to be calculated). The air assumptions and parameters for air are the same as previously discussed in Section 8.6. In addition to those parameters, however, Table 11-4 provides a description of this receptor's projected behavior on soil.

Table 11-4 Input for EPA's Soil PRG Calculator, Grounds Keeper, "Complete Rad Removal" Alternative

Variable	PRG Calculator Value
Slab size for ACF (area correction factor) m^2	2,000
EF_{ow} Soil (exposure frequency - worker) day/yr	6.2

Note: Other parameters were left at default values.

11.5 RISK CHARACTERIZATION

The long-term risk characterization quantitatively evaluated potential risks to a landfill grounds keeper who works outdoors at the West Lake Landfill property, adjacent to and on Area 1 or Area 2. This receptor is assumed to be exposed to radiological COPCs via inhalation of radon, direct radiation from submersion in air, and exposure to direct radiation from soil. Results of the risk characterization are presented below. Potential risks are quantified using EPA RAGS methodology and based on a comparison of radiation dose rates to acceptable occupational exposure limits.

11.5.1 **Risks from Inhalation of Radon and Submersion in Air**

The EPA PRG calculator for air does not provide the ability to estimate air concentrations emitted from subsurface contaminants. AERMOD (see Section 2.2.8.3) was used to calculate the concentration of radon-222 and daughters in on-property air, assuming a 0.9 m cover. The risk was calculated for that concentration by dividing 10^{-06} by the sum of the PRGs and then multiplying by the estimated concentration of radon-222 and daughters.

For example, for the Area 2 "complete rad removal" alternative, the radon-222 concentration (9.1×10^{-05} pCi/m^3) at the receptor emanating from the 0.9 m cover at 1,000 years was calculated using AERMOD software and the 1,000 year post- remedial alternative concentration of radium-226 (3 pCi/g). The risk was then calculated by dividing 10^{-06} by the PRG for inhalation of radon while outdoors ($3.34 \times 10^{+00}$ pCi/m^3) then multiplying by the concentration at the receptor site of 9.1×10^{-05}pCi/m^3. The risk value for radon-222 was further modified by multiplying the risk by 0.095, a factor that is described in footnote (a) of the updated BRA, Table 26. This factor was applied to account for the incorrect slope factor used in the EPA PRG calculator for radon-222. This equates to a total risk for radon-222 of 2.6×10^{-12}.

The same method was used to calculate the risks associated with submersion in air, however because similar information does not exist to calculate an immersion slope factor, no further adjustment was made.

11.5.2 **Exposure from Direct Radiation**

In both Areas 1 and 2, the landfill cover design greatly reduces the amount of direct radiation that reaches the ground surface above the cover. This shielding increases as the thickness or density of intervening material increases.

Unlike the other remedial alternatives, the EPA PRG calculator was used to quantify carcinogenic risks. The risk was calculated by dividing 10^{-06} by the calculated 0.9 m PRG, and then multiplying by the concentration of the COPC at 1 and 1,000 years. For example, the 0.9 m PRG for radium-226 was calculated at $2.72 \times 10^{+03}$ pCi/g, and the radium-226 1,000 year concentration in Area 2 is 3 pCi/g. The resulting risk is calculated as $10^{-06}/ (2.72 \times 10^{+03}$ pCi/g x 3 pCi/g) $=1.10 \times 10^{-09}$.

11.5.3 **Doses from Direct Radiation**

Dose to the RME individual in mrem/h was calculated using MicroShield® software (see Section 2.2.8.2). Using the software, a unit dose rate associated with 1 pCi/g concentration, a 0.9 meter cover, 1-meter above the surface was calculated for each COPC. The 1,000 year concentrations listed in Table 11-2 were then multiplied by the unit dose rate to calculate the dose associated with the 1,000 year concentration. For example, the unit dose rate associated with 1 pCi/g of radium-226 above a 0.9 m cover and 1 m above the surface was calculated to be 7.11×10^{-07} mrem/hr. The 1,000 year radium-226 concentration in Area 2 associated with this remedial alternative is 3 pCi/g. The resulting exposure rate equals 2.13×10^{-06} mrem/hr for radium-226 (7.11×10^{-07} mrem/hr x 3 pCi/g = 2.13×10^{-06} mrem/hr). This same method was then applied to all COPCs. It is estimated that the grounds keeper will spend 52.7 hours[31] each year outdoors. Multiplying the total hours each year by the sum of the exposure rates for all the COPCs combined results in a TEDE of 1.19 x 10^{-04} mrem/yr.

11.5.4 **Risk Summary**

Long-term risks and doses are presented in Table 11-5 through Table 11-8. Table 11-5 and Table 11-7 contain excerpts of the output files generated by EPA PRG calculators for long-term risks at year 1 and year 1,000. Table 11-6 and Table 11-8 present calculated doses to the receptor during those same time periods.

[31] 6.2 days per year exposed to soil x 8.5 hours per day.

Grounds Keeper (52.7 h/y)	3.09E-05	1.19E-04

11.6 SUMMARY

Risk and dose estimates for the RME individual on Areas 1 and 2 in the first year after remedial alternative construction and 1,000 years after remedial alternative completion are listed in Table 11-9. Calculated exposures to the hypothetical grounds keeper receptor were dominated by exposures from radon daughters produced by decay of radium-226 in any remaining RIM.

Table 11-9 Long-term Risks and Doses to the Grounds Keeper for the "Complete Rad Removal" Alternative

	Area 1	Area 2	Total
Risk at 1 year	5.00E-10	2.46E-10	7.46E-10
Risk a 1,000 years	1.48E-09	1.11E-09	2.59E-09
Dose at 1 year (mrem/y)	7.06E-05	3.09E-05	1.01E-04
Dose at 1,000 years (mrem/y)	1.71E-04	1.19E-04	2.89E-04

The cancer risk estimate for the RME individual under this remedial alternative at 1,000 years after remedial alternative construction is complete is 2.59 x 10^{-09} for Area 1 and Area 2 combined. This risk is well-below EPA's acceptable risk range. The greatest risk to on-site workers after the cap is applied is direct exposure to ionizing gamma radiation. Risks for external exposure to ionizing gamma radiation are driven by radium-226 concentrations. Originally, radium-226 concentrations in Area 2 were greater than those in Area 1; therefore, one would expect the risk to be higher for Area 2. The concentration of radium-226 was normalized for each area based on thorium-230 concentrations. After normalization, Area 2 radium-226 concentrations were less than the concentrations in Area 1; therefore, the risks are higher in Area 1. The predicted radiation doses are also well below the occupational exposure limit of 5,000 mrem/y. Therefore, the "complete rad removal" alternative satisfies the threshold criterion for the protection of human health.

12 LONG-TERM RISKS FOR THE ROD-SELECTED REMEDY

12.1 ALTERNATIVE DESCRIPTION

In this alternative, RIM will remain in place with Site improvements to meet the stated goals of the ROD. This remedy is a containment remedy for OU-1 intended to protect human health by regrading part of the Site and placing an engineered cap over all of OU-1, including the RIM. This will provide a physical barrier above the RIM that isolates the RIM from surface receptors.

Field investigations indicate that RIM is present at or near the surface in Areas 1 and 2. The ROD-selected remedy requires recontouring the surface of OU-1 and installing a cover designed to meet MDNR landfill closure requirements. The design also includes an underlying rock/concrete rubble layer to enhance long-term stability, protects the RIM from bio- or human intrusion, and prevents erosion of the underlying waste materials. These Site improvements will bring the upper surface to an acceptable slope and improve surface drainage of Areas 1 and 2.

This section evaluates long-term residual COPC exposure risks to human health using standard EPA methodology for conducting HHRAs, which includes the following four components: selection of constituents COPCs, exposure assessment, toxicity assessment, and risk characterization. COPC selection, portions of the exposure assessment, and the toxicity assessment were presented in previous sections. This section focuses on the alternative-specific components: exposure setting, residual exposure point concentrations, and the risk characterization. Additionally, this section evaluates remedial alternative performance relative to the UMTRCA Requirements.

12.2 EXPOSURE SETTING

Under this alternative, OU-1 would be graded and covered with an engineered cap consisting of two feet of rock, two feet of soil/clay and a one foot topsoil layer that would support vegetation for the final cover. These improvements would eliminate the exposed RIM at the surface of Areas 1 and 2 and constitute a physical barrier between the RIM and the ground surface.

12.2.1 **Physical Setting**

The physical configuration of OU-1 after completion of the remedy is summarized below:

- The contaminated material in Area 1 remains the same as in the description published in the updated BRA (Auxier 2016). The contaminated material from the Crossroads Property and Buffer Zone will have been consolidated into Area 2, below the cap. This will add approximately 3,500 cubic yards of RIM to Area 2.
- Areas 1 and 2 will be graded to improve the drainage characteristics of the final cover.
- A two-foot (0.6 m) thick rock and/or concrete rubble layer will have been placed over the RIM in Areas 1 and 2.
- A two-foot (0.6 m) thick clay cap will have been placed over the rock/rubble layer to minimize precipitation infiltration into the underlying waste materials and to attenuate radon emissions from the RIM. The permeability of this clay will be a minimum of 10^{-07} m/s (10^{-05} cm/s).

- The clay layer will have been covered with one foot (0.3 m) of soil and a vegetative cover will be established on the cap. This vegetative cover is assumed to be maintained to prevent depletion of the cap.

Figure 12-1 depicts the cap design for Areas 1 and 2.

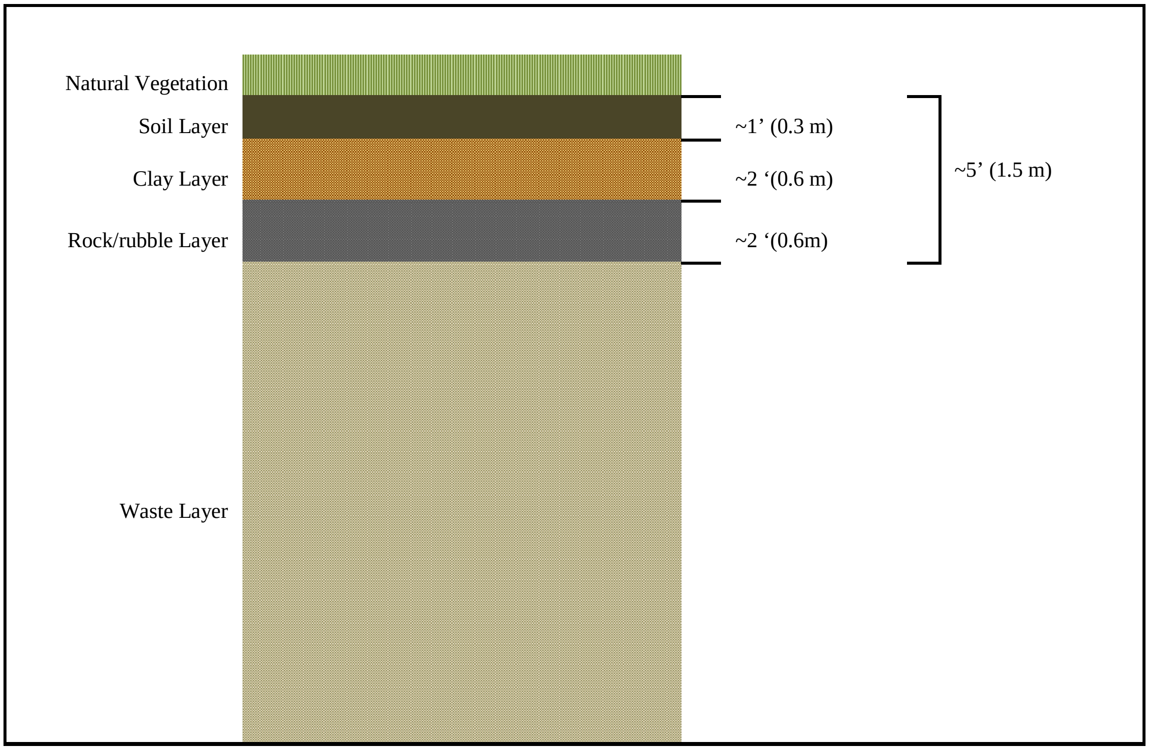

Figure 12-1 Stylized Cross-Section of RIM and Cover for the ROD-Selected Remedy

12.2.1.1 Physical Attributes of the Waste and Cover

The physical properties of the remaining RIM and cover components are presented in Table 12-1. The erosion rate of the cover layer reflects the effects of maintenance and the rock/rubble layer.

Table 12-1 Physical Properties of RIM and Cover

Parameter	Area 1	Area 2
Contamination Zone (RIM)		
Area (m^2)	25,217	98,515
Erosion Rate (m/y)	0.001	0.001
Total Porosity (dry wt_%)	0.3	0.3
Field Capacity (vol/vol)	0.292	0.292
Hydraulic Conductivity (m/y)	5.26	5.26
Radon Diffusion Coefficient (m^2/s)	1.806×10^{-09}	1.806×10^{-09}
Cover		
Thickness (m)	1.5	1.5
Erosion Rate (m/y)	0.0001	0.0001
Total Porosity (vol/vol)	0.427	0.427
Volumetric Water Content (vol/vol)	0.367	0.367
Hydraulic Conductivity (m/y)	0.000526	0.000526

12.3 EXPOSURE POINT CONCENTRATIONS

As discussed in Section 8, the evaluation of future risks focuses on radiological COPCs. Placing the engineered cover over OU-1 will block almost all of the direct radiation exposure from the RIM. Exposures from the small fraction of radiation predicted to penetrate the cover were quantified in this assessment. This cover will also attenuate almost all of the radon-222 produced in the underlying RIM. Radium-226 in the RIM will decay to radon-222, which is a noble gas. About 20% of radon gas is released to interstitial air and water in the pore spaces of the radium and surrounding soils, while the other 80% remains within the solid matrix of the soil particles. Once in the pore space, radon gas is free to move in the soil. The distance that radon can travel is greatly limited by its 3.8-day half-life. Covering the RIM with low permeability soil/clay increases the time required for the radon to reach the ground surface. This increased travel time allows almost all of the radon to decay before it reaches the surface. Risks from residual radon gas and the risks associated with direct radiation from radon daughters if submerged in air were quantified in this assessment.

Calculated exposure point concentrations 1 year and 1,000 years post-remedy are discussed below. The representative concentrations used in this risk assessment are listed in Table 12-2.

12.3.1 **Exposure Point Concentrations in Soil at 1 Year after Construction**

The current 95% UCL for concentrations across all depths was used to represent RIM concentrations in Areas 1 and 2 immediately after remedy construction. These concentrations were assumed to be representative of the entire volume of RIM in the respective areas underlying the proposed cover.[32]

[32] Soil removed from the Crossroads Property and Buffer Zone during an interim remedial action will be added to Area 2 during remedy construction. This material contains lower concentrations of RIM and adding it to the material in Area 2 would lower the average concentration in Area 2.

12.3.2 **Exposure Point Concentrations in Soil at 1,000 Years after Construction**

The concentrations of the radionuclides in the RIM are expected to change over the course of 1,000 years due to radiological decay and in-growth[33]. The 1,000-year values include the effects of radioactive in-growth and decay for radionuclides.

Table 12-2 Characterization of RIM in Areas 1 and 2, ROD-Selected Remedy

[a] One year after construction ceases.
[b] Includes in-growth from the decay of thorium-230.
[c] Assumed to be in secular equilibrium with radium-226.
[d] Due to the uncertainty of the uranium-235 results, these values were calculated using the more reliable uranium-238 and uranium-234 results and the expected relative abundance of uranium-235 in natural uranium.

12.3.3 **Exposure Point Concentrations in Air at 1 and 1,000 years**

Radon concentrations were also generated for the concentration of RIM at 1 and 1,000 years. These concentrations were generated at the same locations as the updated BRA. As the hypothetical grounds keeper will be located atop Area 1 and Area 2, those two locations were chosen and are presented in Table 12-3.

[33] A 1,000-year study period was selected based on design requirements of 40 CFR Part 192.

Table 12-3 Radon-222 Concentrations in Air at Exposure Point Concentrations for the ROD-Selected Remedy

Analyte	On-site, Area 1 (722130 E 4294400 N)	On-site, Area 2 (721720 E 4294785 N)

Bi-214 + 1 dtr (pCi/m^3)	7.1 E-7	9.6 E-6

12.4 RISK CHARACTERIZATION

The long-term risk characterization quantitatively evaluated potential risks to a landfill grounds keeper who works outdoors at the West Lake Landfill property, adjacent to and on Area 1 or Area 2. This receptor is assumed to be exposed to radiological COPCs via inhalation of radon, direct radiation from submersion in air, and exposure to direct radiation from soil. Results of the risk characterization are presented below. Potential risks are quantified using EPA RAGS methodology and based on a comparison of radiation dose rates to acceptable occupational exposure limits.

12.4.1 Risks from Inhalation of Radon and Submersion in Air

The EPA PRG calculator for air does not provide the ability to estimate air concentrations emitted from subsurface contaminants. AERMOD (see Section 2.2.8.3) was used to calculate the concentration of radon-222 and daughters in on-property air, assuming a 1.5 m cover. The risk was calculated for that concentration by dividing 10^{-06} by the sum of the PRGs and then multiplying by the estimated concentration of radon-222 and daughters.

For example, for the Area 2 ROD-selected remedy, the radon-222 concentration (5.7×10^{-02} pCi/m^3 from Table 12-3) at the receptor emanating from the 1.5 m cover at 1,000 years was calculated using AERMOD software and the 1,000 year post-alternative concentration of radium-226 (1,910 pCi/g). The risk was then calculated by dividing 10^{-06} by the PRG for inhalation of radon while outdoors ($3.34 \times 10^{+00}$ pCi/m^3), then multiplying by the concentration at the receptor site of 5.7×10^{-02} pCi/m^3. The risk value for radon-222 was further modified by multiplying the risk by 0.095, a factor that is described in footnote (a) of the updated BRA, Table

26. This factor was applied to account for the incorrect slope factor used in the EPA PRG calculator for radon-222. This equates to a total risk for radon-222 of 1.62 x 10^{-09}.

The same method was used to calculate the risks associated with submersion in air; however, because similar information does not exist to calculate an immersion slope factor, no further adjustment was made.

12.4.2 **Exposure from Direct Radiation**

In both Areas 1 and 2, the landfill cover design greatly reduces the amount of direct radiation that reaches the ground surface above the cover. This shielding increases as the thickness or density of intervening material increases.

The EPA PRG calculator was used to quantify carcinogenic risks from this remedy; however, the PRG calculator does not provide the option to select the engineered cover design thickness of 1.5 meters. PRGs for a 1 pCi/g concentration associated with a 1.5 meter (150 cm) cover were established by generating PRGs for 50, 60, 70, 80, 90, 100, 200, and 300 cm covers. Scatter plots for each COPC were generated with the PRG plotted on the Y axis and the cover thickness plotted on the X axis. The equation associated with the highest correlation coefficient was then used to calculate the 1.5 meter PRGs for each COPC.

The risk was calculated by dividing 10^{-06} by the calculated 1.5 meter PRG, and then multiplying by the concentration of the COPC at 1 and 1,000 years. For example, the 1.5 meter PRG for radium-226 was calculated at 1.99 x 10^{+06} pCi/g, and the radium-226 1,000 year concentration in Area 2 is 1,910 pCi/g. The resulting risk is calculated as 10^{-06}/ (1.99 x 10^{+06} pCi/g x 1,910 pCi/g) = 9.60x 10^{-10}.

12.4.3 **Doses from Direct Radiation**

Dose to the RME individual in mrem/h was calculated using MicroShield® software (see Section 2.2.8.2). Using the software, a unit dose rate associated with 1 pCi/g concentration, a 1.5 meter cover, 1-meter above the surface was calculated for each COPC. The 1,000 year concentrations listed in Table 12-2were then multiplied by the unit dose rate to calculate the dose associated with the 1,000 year concentration. For example, the unit dose rate associated with 1 pCi/g of radium-226 above a 1.5 m cover and 1 m above the surface was calculated to be 8.86 x 10^{-09} mrem/hr. The 1,000 year radium-226 concentration in Area 2 associated with this alternative is 1,910 pCi/g. The resulting exposure rate equals 1.69 x 10^{-05} mrem/hr for radium-226 (8.86 x 10^{-09} mrem/hr x 1,910pCi/g = 1.69 x 10^{-05} mrem/hr). This same method was then applied to all COPCs. It is estimated that the grounds keeper will spend 52.7 hours[34] each year outdoors. Multiplying the total hours each year by the sum of the exposure rates for all the COPCs combined results in a TEDE of 9.96 x 10^{-04} mrem/yr.

12.4.4 **Risk Summary**

Long-term risks and doses are presented in Table 12-4 through Table 12-7. Table 12-4 and Table 12-6 contain excerpts of the output files generated by EPA PRG calculators for long-term risks at year 1 and year 1,000. Table 12-5 and Table 12-7 present calculated doses to the receptor during those same time periods.

---

[b] Radon source term includes emissions from all OU-1 areas.

Table 12-7 Doses from Area 2 to the Grounds Keeper for the ROD-Selected Remedy

Receptor	Dose (mrem/y) Year 1	Dose (mrem/y) Year 1,000
Grounds Keeper (52.7 h/y)	2.89E-04	9.96E-04

12.5 SUMMARY

Risk and dose estimates for the RME individual on Areas 1 and 2 in the first year after alternative construction and 1,000 years after remedy completion are listed in Table 11-9. Calculated exposures to the hypothetical grounds keeper receptor were dominated by exposures from radon daughters produced by decay of radium-226.

Table 12-8 Long-term Risks and Doses to the Grounds Keeper for the ROD-Selected Remedy Alternative

	Area 1	Area 2	Total
Risk at 1 year	3.45E-10	5.73E-10	9.18E-10
Risk a 1,000 years	1.01E-09	2.76E-09	3.76E-09
Dose at 1 year (mrem/y)	2.24E-04	2.89E-04	5.13E-04
Dose at 1,000 years (mrem/y)	4.23E-04	9.96E-04	1.42E-03

The cancer risk estimate for the RME individual under this remedy at 1,000 years after construction is complete is 3.76×10^{-09} for Area 1 and Area 2 combined. This risk is well-below EPA's acceptable risk range. The greatest risk to on-site workers after the cap is applied is direct exposure to ionizing gamma radiation. Risks for external exposure to ionizing gamma radiation are driven by radium-226 concentrations. Originally, radium-226 concentrations in Area 2 were greater than those in Area 1; therefore, one would expect the risk to be higher for Area 2. The concentration of radium-226 was normalized for each area based on thorium-230 concentrations. After normalization, Area 2 radium-226 concentrations were less than the concentrations in Area 1; therefore, the risks are higher in Area 1. The predicted radiation doses are also well below the occupational exposure limit of 5,000 mrem/y. Therefore, the ROD-selected remedy satisfies the threshold criterion for the protection of human health.

13 SUMMARY

13.1 PRESENTATION OF CALCULATED RESULTS

A compilation of short-term and long-term risks calculated during this risk assessment is presented in Table 13-1.

Table 13-1 Compilation of Calculated Short-term and Long-term Hazards and Risks

	Category of Hazard or Risk	Partial Excavation to 1,000 pCi/g Alternative	Partial Excavation to 52.9 pCi/g Alternative	Full Excavation with Off-Site Disposal Alternative	ROD-Selected Remedy
Short-term	Projected Incidence of Transportation Accidents [a]	1.66E+01	1.06E+01	3.49E+01	6.14E-01
	Projected Incidence of Industrial Accidents [b]	1.17E+01	8.47E+00	1.78E+01	2.76E+00
	Carcinogenic Risk to Reasonably Maximally-Exposed RadCon Tech during Construction [c]	2.38E-03	1.18E-03	2.19E-03	9.23E-05
	Hazard Index for Reasonably Maximally-Exposed RadCon Tech during Construction [c]	1.22E+00	1.22E+00	1.22E+00	1.22E+00
	Carcinogenic Risk to Reasonably Maximally-Exposed Off-property Resident during Construction [c]	5.26E-08	4.17E-08	5.17E-08	3.37E-08
	Hazard Index for Reasonably Maximally-Exposed Off-property Resident during Construction [c]	4.12E-04	4.12E-04	4.12E-04	4.12E-04
	Dose (TEDE) to Qualified Radiation Remediation Worker (mrem/y) [d]	8.67E+02	7.20E+02	4.05E+02	1.87E+02
Long-term	Carcinogenic Risk to Reasonably Maximally-Exposed Individual after Construction [e]	3.63E-10	1.90E-11	1.48E-09	1.01E-09
	Dose (TEDE) to Reasonably Maximally-Exposed Individual after Construction (mrem/y) [d]	2.89E-04	1.51E-05	1.71E-04	4.23E-04

[a] Dependent on mileage on public roads.
[b] Dependent on man-hours worked.
[c] Dependent on man-hours worked while RIM exposed and will vary depending on length of project. Note systemic effects from lead were evaluated separately from other non-carcinogens; no unacceptable risks were predicted for lead.
[d] Annual dose limited by concentration and 1 year reporting period.
[e] Highest risks are in year 1,000 at Area 1.

13.2 UNCERTAINTIES ASSOCIATED WITH HUMAN HEALTH EFFECTS AND ACCIDENT PROJECTIONS

A risk assessment contains uncertainties associated with measured or estimated quantities and uncertainties associated with a lack of information.

To compensate for these data uncertainties, risk assessors often use numerical values that are in the higher range of the distribution of data to ensure that the result of any single step is not underestimated. When this is done repeatedly for many parameters, the compound effect is to elevate the calculated risk well above what individuals would likely encounter. Although it is possible that such an exposure involving the highest possible value at each step in the evaluation process can occur, the probability of an individual actually being exposed to this combination of events and conditions is considered low. The human health results of the risk assessments for the four OU-1 remedial alternatives presented in this Appendix are based on such conservatism.

Because this evaluation is intended to provide a comparative rather than absolute evaluation of hazards/risks and similar conservative assumptions were made for each alternative, these uncertainties are unlikely to have affected the conclusions of this evaluation.

Traffic and industrial accident predictions for the remedial alternatives are based on observed incident rates among the American population. There are uncertainties associated with these predictions, but given enough operational time, the injury and fatality rate of any remediation project (or collection of projects) is expected to approach industry norms.

13.3 COMPARISON OF ALTERNATIVE RESULTS

Short-term risks to the RME individual (the Radiation Control Technician) associated with implementation of the ROD-selected remedy are substantially lower than those associated with the two partial and the full excavation alternatives in all on-property risk categories evaluated. In fact, only the risks associated with the RME individual during implementation of the ROD-selected remedy are within the EPA's generally acceptable risk range at CERCLA sites. The risks associated with the other alternatives are up to an order of magnitude greater than EPA's generally accepted risk range at CERCLA sites. The risks for the off-property resident for all alternatives are less than 10^{-07}. Construction and industrial accident forecasts for all excavation alternatives were higher than the ROD-selected remedy. The estimated short-term radiation dose to the RME individual for the ROD-selected remedy is also the least of all the alternatives.

A large contributor to risk is time. When analyzing short-term risks, it should be noted that "complete rad removal" alternative has the highest risk. This is due to the 11.2 year duration of the remedial alternative construction. The next longest duration is the "partial excavation to 1,000 pCi/g" alternative (6.5 years); therefore, its risk, in the short-term, is the second highest. The "partial excavations to 52.9 pCi/g" alternative (3.4 years due to the limited excavation depth) and the ROD-selected remedy (1 year) follow in descending order of risk.

All long-term risks are well below EPA's maximum acceptable risk of 10^{-04} (and are in fact below 10^{-08}). The predicted radiation doses to the landfill grounds keeper for all alternatives are also several orders of magnitude below the occupational exposure limit of 5,000 mrem/y.

The short-term risks from the ROD-selected remedy are the only set of risks that are less than the upper bound of EPA's acceptable risk range.

13.4 COMPARISON OF RADIOCARCINOGENIC RISKS WITH RISKS FROM OTHER RADIATION SOURCES

The long-term and short-term human health risks are dominated by radiological exposures. These calculated long-term and short-term risks can be compared to radiological risks from other commonly encountered radiation sources to provide perspective on the numerical results. For example, the long-term radiological risks from any of the alternatives are all less than the radiological risk associated with one transcontinental airplane flight. Table 13-2 presents a comparison of the relative risks associated with the long- and short-term risks for the four alternatives.

Table 13-2 Comparison of Risks from a Variety of Radiation Sources

Activity/Exposure	Risk (___ x 10^{-6})
Long-term risk to West Lake RME Individual (Grounds Keeper), "Partial Excavation to 52.9 pCi/g" Alternative at 1 year post-construction	**0.000011[a]**
Long-term risk to West Lake RME Individual (Grounds Keeper), "Partial Excavation to 52.9 pCi/g" Alternative at 1,000 years post-construction	**0.000036[a]**
Long-term risk to West Lake RME Individual (Grounds Keeper), "Partial Excavation to 1,000 pCi/g" Alternative at 1 year post-construction	**0.00020 [a]**
Long-term risk to West Lake RME Individual (Grounds Keeper), "Partial Excavation to 1,000 pCi/g" Alternative at 1,000 years post-construction	**0.00070[a]**
Long-term risk to West Lake RME Individual (Grounds Keeper), "Full Excavation with Off-site Disposal" Alternative at 1 year post-construction	**0.00075 [a]**
Long-term risk to West Lake RME Individual (Grounds Keeper), ROD-Selected Remedy at 1 year post-construction	**0.00092[a]**
Long-term risk to West Lake RME Individual (Grounds Keeper), "Full Excavation with Off-site Disposal" Alternative at 1,000 years post-construction	**0.0026[a]**
Long-term risk to West Lake RME Individual (Grounds Keeper), ROD-Selected Remedy at 1,000 years post-excavation	**0.0038 [a]**
Point of departure for EPA's generally acceptable risk range at CERCLA Sites	**1**
Radiation from a transcontinental plane flight, one-way	2 [b]
Cooking or heating with natural gas (radon in the gas)	5 [b]
Radiation from one routine chest X-ray	6 [b]
Annual radiation exposure to cosmic rays at sea level	18 [b]
Watching a cathode-ray TV or computer screen	18 [b]
Annual radiation exposure from internal exposure to naturally-occurring radionuclides in the human body (such as potassium-40)	23 [b]
Annual radiation exposure from cosmic rays in Denver	30 [b]
Living in a brick house	45 [b]
Short-term risk to West Lake RME Individual (RadCon Tech) during construction of ROD-Selected Remedy	**92.3 [a]**
Top of EPA's generally acceptable risk range at CERCLA Sites	**100**
Annual exposure to naturally occurring radon in air	120 [b]
Nuclear medicine bone scan (Tc-99)	258 [b]
EPA published value for acceptable risk from 20 pCi/m^2/s radon emitted by tailings piles (preamble to NESHAPS)	300 [c]
Annual radiation exposure from smoking a pack and a half of cigarettes a day	780 [b]
Short-term risk to West Lake RME Individual (RadCon Tech) during construction of the "Partial Excavation to 52.9 pCi/g" Alternative	**1,200 [a]**
Short-term risk to West Lake RME Individual (RadCon Tech) during construction of the "Complete Rad Removal" Alternative	**2,400 [a]**
Short-term risk to West Lake RME Individual (RadCon Tech) during construction of the "Partial Excavation to 1,000 pCi/g" Alternative	**2,200 [a]**

[a] Calculated in this report and values greater than 10^{-7} rounded to two (2) significant figures.

[b] Calculated using the dose to risk conversion factor of 6×10^{-04} per rem Total Effective Dose Equivalent (TEDE) recommended by EPA (ISCORS, 2003) (http://homer.ornl.gov/oepa/guidance/risk/iscors.pdf).

Appendix I:

Estimated Greenhouse Gas Emissions Associated with the Alternatives

Prepared by:

Engineering Management Support, Inc.
7220 West Jefferson Avenue, Suite 406
Lakewood, Colorado 80235

Appendix I

Estimated Greenhouse Gas Emissions Associated with the Alternatives

Introduction

This appendix presents the results of calculations to estimate the quantity of carbon dioxide equivalent (CO2e) greenhouse gas emissions predicted for each remedial alternative. Each alternative will involve the use of various types of vehicles and heavy equipment to implement the remedy, resulting in the combustion of diesel fuel and subsequent emission of greenhouse gas into the atmosphere. Gasoline will also be consumed by the vehicles of workers when the workers commute to and from the Site during construction of the remedy. The estimated volume of diesel fuel and gasoline that would be consumed, number of vehicle-miles, and number of ton-miles (for rail transport) were calculated for each remedy alternative for the construction heavy equipment and vehicles anticipated to be used onsite during construction; for trucks transporting materials, equipment, and supplies to the West Lake Landfill site; for truck and rail transport of RIM to an off-site disposal facility (for the "complete rad removal" and partial excavation alternatives only); and for vehicles transporting workers, supervisory and support personnel, and regulatory agency personnel commuting to/from the Site during remedy implementation. The total volume of fuel, number of vehicle miles, and number of ton-miles were converted to equivalent tons of CO2e using the Emission Factors for Greenhouse Gas Inventories published by EPA at https://www.epa.gov/sites/production/files/2015-07/documents/emission-factors_2014.pdf (EPA, 2014d) and in EPA's "Emissions Facts: Calculating Emissions of Greenhouse Gases - Key Facts and Figures", Office of Transportation and Air Quality, EPA 420-F-05-003, February 2005

Recent guidance indicates that total CO2e greenhouse gas emissions is comprised of the total of CO_2, CH_4 and N_2O. Initial calculations to estimate the total CO2e greenhouse gas emissions were conducted using the Emission Factors in Tables 2, 4, 5, 7, and 8 found in https://www.epa.gov/sites/production/files/2015-07/documents/emission-factors_2014.pdf for the three emission components (CO_2, CH_4 and N_2O) for the various vehicles (light duty pickup trucks, heavy-duty diesel dump and semi-trucks, on-site construction heavy equipment and vehicles, and diesel locomotives [rail]) assumed to be used during implementation of a remedy at the Site. The result from the initial calculations indicated that a very minor amount of CO2e emissions were contributed by the CH_4 and N_2O components; therefore, the estimates provided in this Appendix are comprised of only the CO_2 component.

Step 1) Calculate Fuel Consumption

Diesel fuel and gasoline consumption for construction heavy equipment used on-site, for trucks delivering materials/equipment to the Site, for transporting RIM to an off-site disposal facility, and for workers commuting to and from the Site was calculated as outlined below.

Construction Heavy Equipment Used On-site

The "Construction Cost Worksheet" pages for each of the remedial alternatives (Appendix K) list the estimated Crew Type (from RS Means), daily construction rate, and crew man-days for each construction step/task.

- The Crew Type assigned to each line item in the construction cost worksheet was assessed for the type, size, and quantity of construction equipment used.

- To the extent practicable, the type and size of each piece of construction equipment was then equated to a Caterpillar® construction equipment model number and the hourly fuel consumption rate for that equipment model was estimated using fuel consumption tables and load factor guidelines provided in the Caterpillar® Performance Handbook, Edition 46 (Caterpillar, 2016). A "medium" load factor was considered in most cases. For equipment where Caterpillar®-equivalents could not be determined, such as flatbed trucks and general service vehicles and tools, professional judgment was applied in estimating an hourly diesel fuel consumption rate. Table I-1 provides the unit fuel consumption estimated for each Crew Type.

- The hourly fuel consumption rates were then multiplied by the Time of Construction (*i.e.*, the number of crew-days worked) times 9 hours per crew-day. The product was gallons of diesel fuel burned for each construction task in the cost estimate.

Trucks Delivering Material/Equipment to the Site

- The number of "Delivery Truckloads" for those tasks in the Construction Cost Worksheet involving delivery of materials and/or equipment were multiplied by the Delivery Distances (round-trip) provided in Appendix K-1 (Costing Assumptions) for the respective material/equipment to derive the Total Miles for Delivery.

- The Total Miles for Delivery were then divided by an average diesel fuel consumption rate of 4 miles per gallon (mpg) for a double-axle dump truck; end-, side-, or belly-dump semi-truck; or flatbed semi-truck to obtain the estimated gallons of diesel fuel consumed.

Rail Transport of RIM to an Off-site Disposal Facility

For transporting radiologically-impacted material (RIM) to an off-site disposal facility in intermodal containers via railcar, the distance between a leased rail spur in the St. Louis area near the Site and the US Ecology-Idaho rail/truck transloading facility in Grandview, ID is 1,600 miles via the route shown on Figure 4-3 of the FFS text. A rail fuel consumption rate of 408 ton-miles per gallon of diesel fuel (UPRR, 2007) was used to estimate the diesel fuel consumption for delivery of the intermodals containing RIM to Idaho. For purposes of preparing the emissions estimates, for the 1,600 mile return of the empty intermodals from Idaho to St. Louis, a rail fuel consumption rate of one-half of the 408 ton-miles per gallon of diesel fuel (*i.e.*, 204 ton miles per gallon of diesel) was used. Therefore, a total rail fuel consumption rate of 612 ton-miles per gallon of diesel fuel was estimated for the 3,200 mile round-trip. Assuming a unit weight for RIM of 1,000 lbs per lcy (0.5 tons per lcy), the rail diesel fuel consumption unit rate was calculated to be 2.61 gallons per lcy of RIM. For the alternatives that involve excavation and off-site disposal of RIM, the total lcy of RIM estimated to be hauled off-site for disposal were multiplied by 2.61 gallons of diesel fuel per lcy to provide an estimate of the volume of diesel fuel that would be consumed in transporting RIM via rail to an off-site facility.

Gasoline Consumed by Worker Vehicles

To estimate the volume of gasoline fuel consumed by the vehicles of workers commuting to and from the Site during construction of each of the remedial alternatives, an estimated average roundtrip commute distance of 20 miles was multiplied by the number of crew man-days in the Construction Cost Worksheet, and divided by the average fuel economy of 17.4 mpg for a light duty pickup truck (EPA, 2005b).

Step 2) Conversion of Fuel Consumption to CO_2 Factor Component of CO2e Emissions

One gallon of burned diesel fuel yields the equivalent of 22.2 pounds of the CO_2 component of the total CO2e greenhouse gas emissions and one gallon of gasoline yields the equivalent of 19.4 pounds of the CO_2 component of the total CO2e greenhouse gas emissions (EPA, 2005b). Accordingly, the estimated gallons of diesel fuel and gasoline consumed for each alternative were converted to the equivalent tons of the CO_2 component of the total CO2e greenhouse gas emissions.

The total estimated mass of greenhouse gas emissions for each alternative are provided in the text of Section 6 and on Table 7-1 (Summary of Comparative Analysis of Alternatives). Tables I-2 (ROD-Selected Remedy), I-3 (52.9 pCi/g Partial Excavation), I-4 (1,000 pCi/g Partial Excavation), and I-5 ("Complete Rad Removal") provide detail for the greenhouse gas emissions estimates.

Table I-1: Unit Fuel Consumption Rates

DRAFT

Crew Type	Equipment	Fuel (diesel) consumption (gph) a/	Fuel (diesel) consumption (gal/crew day) b/
A2	Flatbed truck (1.5 ton) (professional judgement)		10

E8	1 lattice boom crane, 90 ton (Use Cat 587T) + 4 welders, 300 amp (prof jdgmt)	4	36
Transport via Railcar to USE-Idaho Offload Spur	Use 408 ton miles/gal for rail transport (UPRR Env facts, 2007) between Missouri and Idaho. Assume 50% of this rate for return trip empty. Therefore, use average of 612 ton miles/gal for R/T of 3,200 miles. Use 1,000 lbs/lcy = 0.5 tons/lcy.	2.61	gal/lcy

a/ From Caterpillar Performance Handbook, Edition 46. Assumes medium fuel consumption factor.
b/ Assumes 9 hr/day

Shaded cells indicate fuel consumption for transport to Idaho at unit rates of gallons of diesel per loose cubic yard of RIM material

APPENDIX J:

Estimated Project Schedules for the Remedial Alternatives

Estimated Schedule

ROD-Selected Remedy

OVERVIEW OF ROD CONSTRUCTION SCHEDULE

Final Feasibility Study, West Lake Landfill

OVERALL PROJECT: *MARCH 2018 – OCTOBER 2019 (1.7 YEARS)*

Site-wide Preparations – *MARCH - APRIL 2018*

- Mobilization, Construction Trailers, Project Infrastructure

Area 2 – *MARCH 2018 – OCTOBER 2019*

- Site Preparations – *MARCH - APRIL 2018*
- Waste Regrading – *APRIL - SEPTEMBER 2018*
    - Including Buffer Zone
- Final Cover – *SEPTEMBER 2018 - SEPTEMBER 2019*
    - Limited by material delivery rate and coordination with Area 1
- Stormwater Controls and Site Completion – *THROUGH OCTOBER 2019*

In parallel:

Area 1 – *APRIL 2018 - APRIL 2019*

- Site Preparations – *APRIL 2018*
- Waste Regrading – *MAY - JUNE 2018*
- Final Cover – *JUNE 2018 - APRIL 2019*
- Stormwater Controls and Site Completion – *THROUGH APRIL 2019*

West Lake FFS - ROD Remedy

DRAFT

ID	Task Name	Estimated Duration	Start	Finish
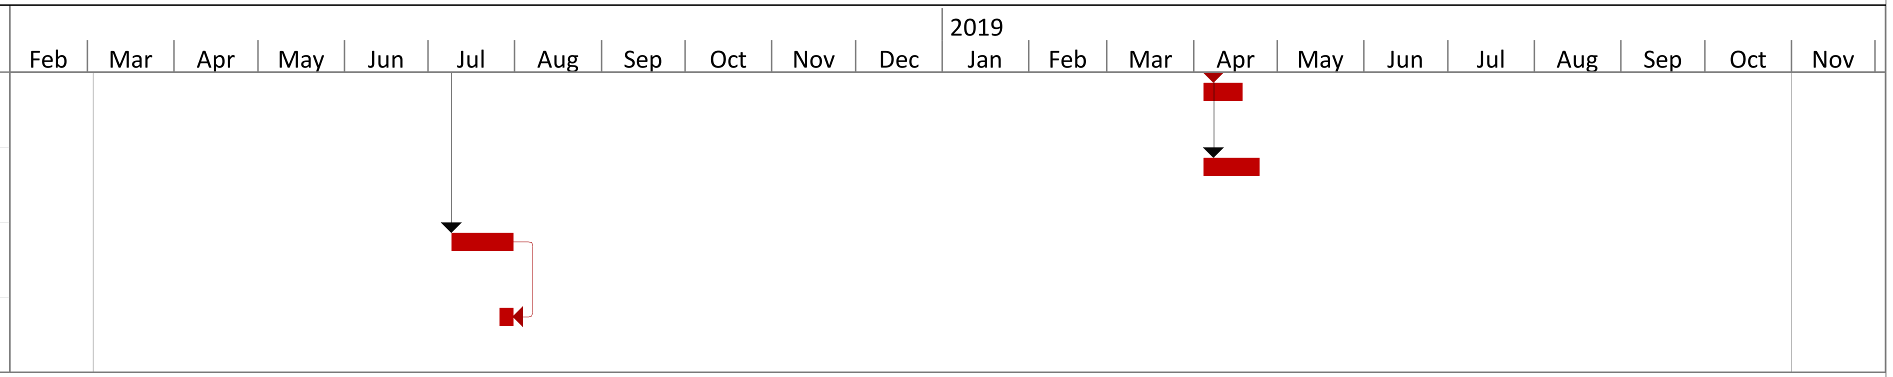
199	Apply seeding to cover	9 days	Thu 4/4/19	Thu 4/18/19
200	Install Fencing	14 days	Thu 4/4/19	Wed 4/24/19
201	Clean Leachate Frac Tanks	16 days	Mon 7/9/18	Tue 7/31/18
202	Remove Leachate Frac Tanks	3 days	Thu 7/26/18	Tue 7/31/18



Note: All dates are for planning purposes only - not actual dates.

Estimated Schedule

"Complete Rad Removal" with Off-Site Disposal Alternative

OVERVIEW OF "COMPLETE RAD REMOVAL" (>7.9 PCI/G) CONSTRUCTION SCHEDULE

Final Feasibility Study, West Lake Landfill

OVERALL PROJECT: *MARCH 2018 – APRIL 2030 (12.1 YEARS)*

Site-wide Preparations – *MARCH - AUGUST 2018*

- Mobilization, Construction Trailers, Project Infrastructure, RIM Loading Station

Area 1 – *MARCH 2018 – JUNE 2024*

- Site Preparations – *MARCH - APRIL 2018*
- Waste Excavation – *AUGUST 2018 – MARCH 2021*
    - Ship RIM offsite, stockpile overburden
- Waste Backfilling and Regrading – *MARCH 2021 – FEBRUARY 2024*
    - Backfill excavation, regrade other waste as necessary
- Final Cover – *FEBRUARY - MAY 2024*
- Stormwater Controls and Site Completion – *MAY - JUNE 2024*

Partially overlapping:

Area 2 – *FEBRUARY 2021 – JANUARY 2030*

- Site Preparations – *FEBRUARY – MARCH 2021*
- Waste Excavation – *MARCH 2021 – OCTOBER 2026*
    - Ship RIM offsite, stockpile overburden, backfill where possible
    - Including Buffer Zone
- Remaining Waste Backfilling and Regrading – *OCTOBER 2026– MAY 2029*
    - Backfill excavation, regrade other waste as necessary
- Additional Fill – *MAY 2029*
- Final Cover – *MAY - DECEMBER 2029*
- Stormwater Controls and Site Completion – *THROUGH JANUARY 2030*

Clean-up and Demolition –*ENDING APRIL 2030*

- Takes place as appropriate throughout project

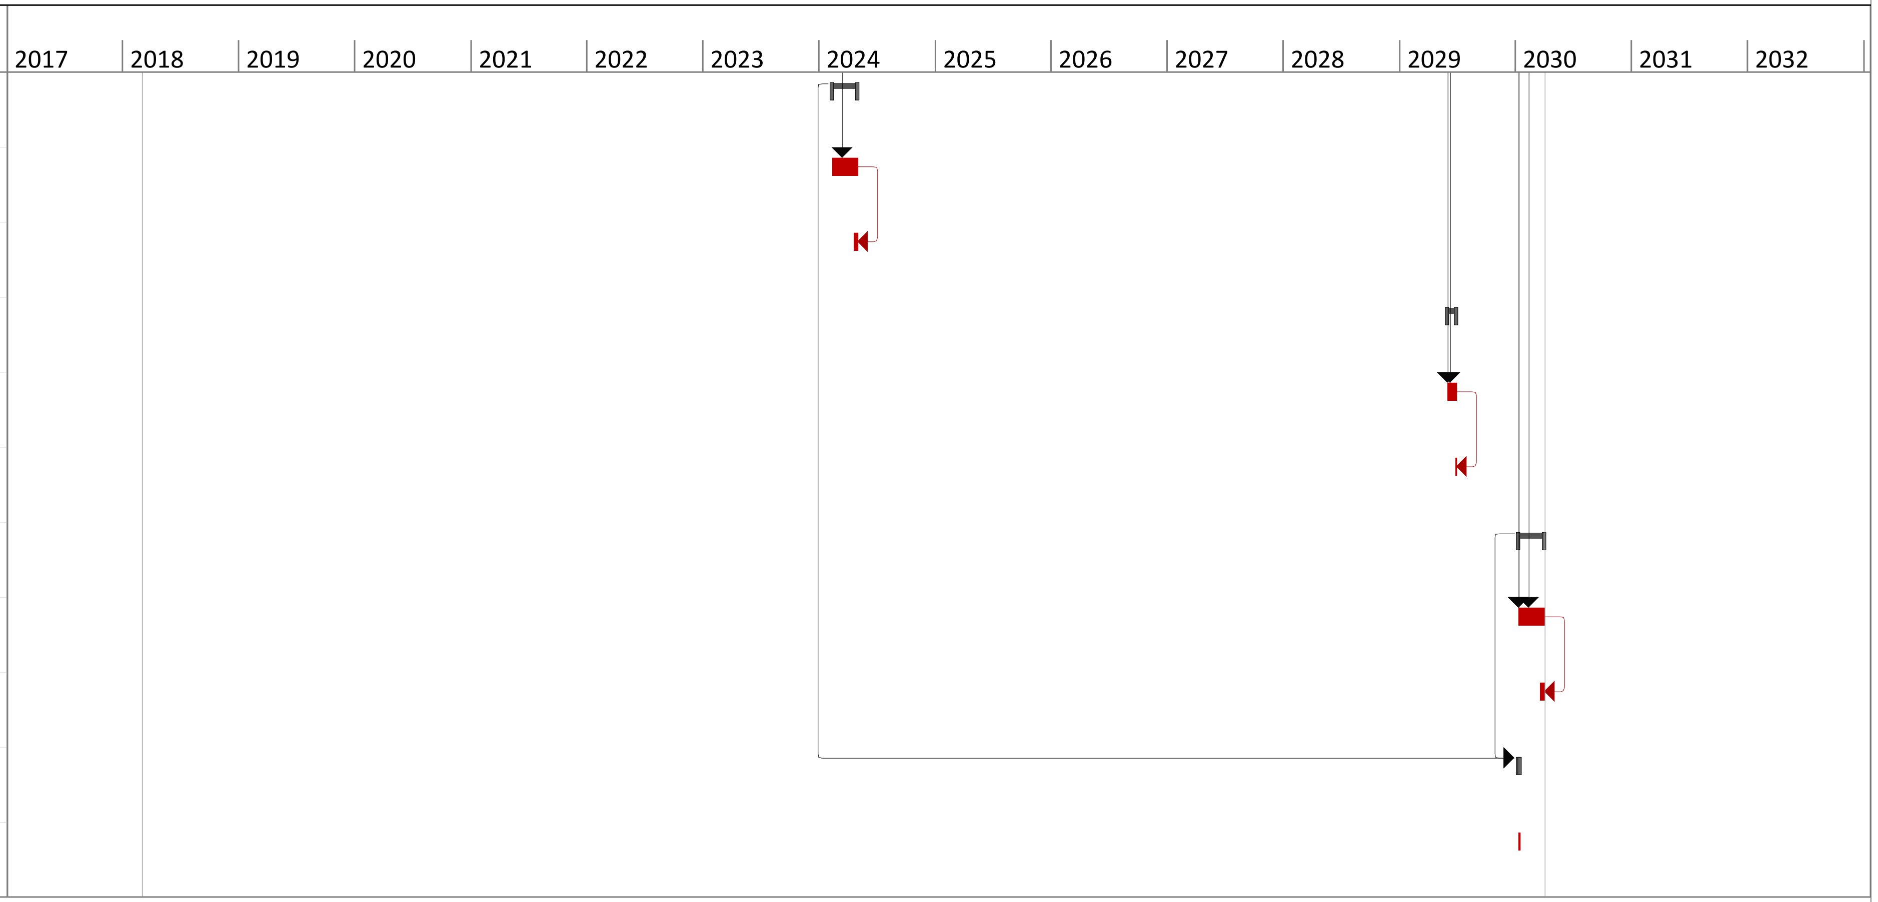
335	Clean Leachate Frac Tanks	20 days	Fri 6/1/29	Fri 6/29/29
336	Remove Leachate Frac Tanks	3 days	Tue 6/26/29	Fri 6/29/29
337	**Area 2 Stormwater Frac Tanks**	**58 days**	**Fri 1/11/30**	**Tue 4/2/30**
338	Clean Frac Tanks	58 days	Fri 1/11/30	Tue 4/2/30
339	Remove Frac Tanks	10 days	Wed 3/20/30	Tue 4/2/30
340	**Stormwater Treatment Facility**	**2 days**	**Fri 1/11/30**	**Tue 1/15/30**
341	Demolition	2 days	Fri 1/11/30	Tue 1/15/30



Estimated Schedule

“Partial Rad Removal, >52.9 pCi/g and <16 ft.” with Off-Site Disposal Alternative

OVERVIEW OF PARTIAL EXCAVATION >52.9 PCI/G AND <16 FT. CONSTRUCTION SCHEDULE

Final Feasibility Study, West Lake Landfill

OVERALL PROJECT: *MARCH 2018 – SEPTEMBER 2022 (4.6 YEARS)*

Site-wide Preparations – *MARCH - AUGUST 2018*

- Mobilization, Construction Trailers, Project Infrastructure, RIM Loading Station

Area 1 – *MARCH 2018 – JUNE 2020*

- Site Preparations – *MARCH - APRIL 2018*
- Waste Excavation – *AUGUST - DECEMBER 2018*
  - Ship RIM offsite, stockpile overburden
- Waste Backfilling and Regrading – *DECEMBER 2018 - OCTOBER 2019*
  - Backfill excavation, regrade other waste as necessary
- Final Cover – *OCTOBER 2019 – MAY 2020*
- Stormwater Controls and Site Completion – *MAY – JUNE 2020*

Partially overlapping:

Area 2 – *NOVEMBER 2018 – JULY 2022*

- Site Preparations – *NOVEMBER - DECEMBER 2018*
- Waste Excavation – *DECEMBER 2018 - APRIL 2020*
  - Ship RIM offsite, stockpile overburden, backfill where possible
  - Including Buffer Zone
- Remaining Waste Backfilling and Regrading – *MAY 2020 - FEBRUARY 2021*
  - Backfill excavation, regrade other waste as necessary
- Additional Fill – *FEBRUARY - JULY 2021*
- Final Cover – *JULY 2021 - JUNE 2022*
- Stormwater Controls and Site Completion – *THROUGH JULY 2022*

Clean-up and Demolition – *ENDING SEPTEMBER 2022*

- Takes place as appropriate throughout project

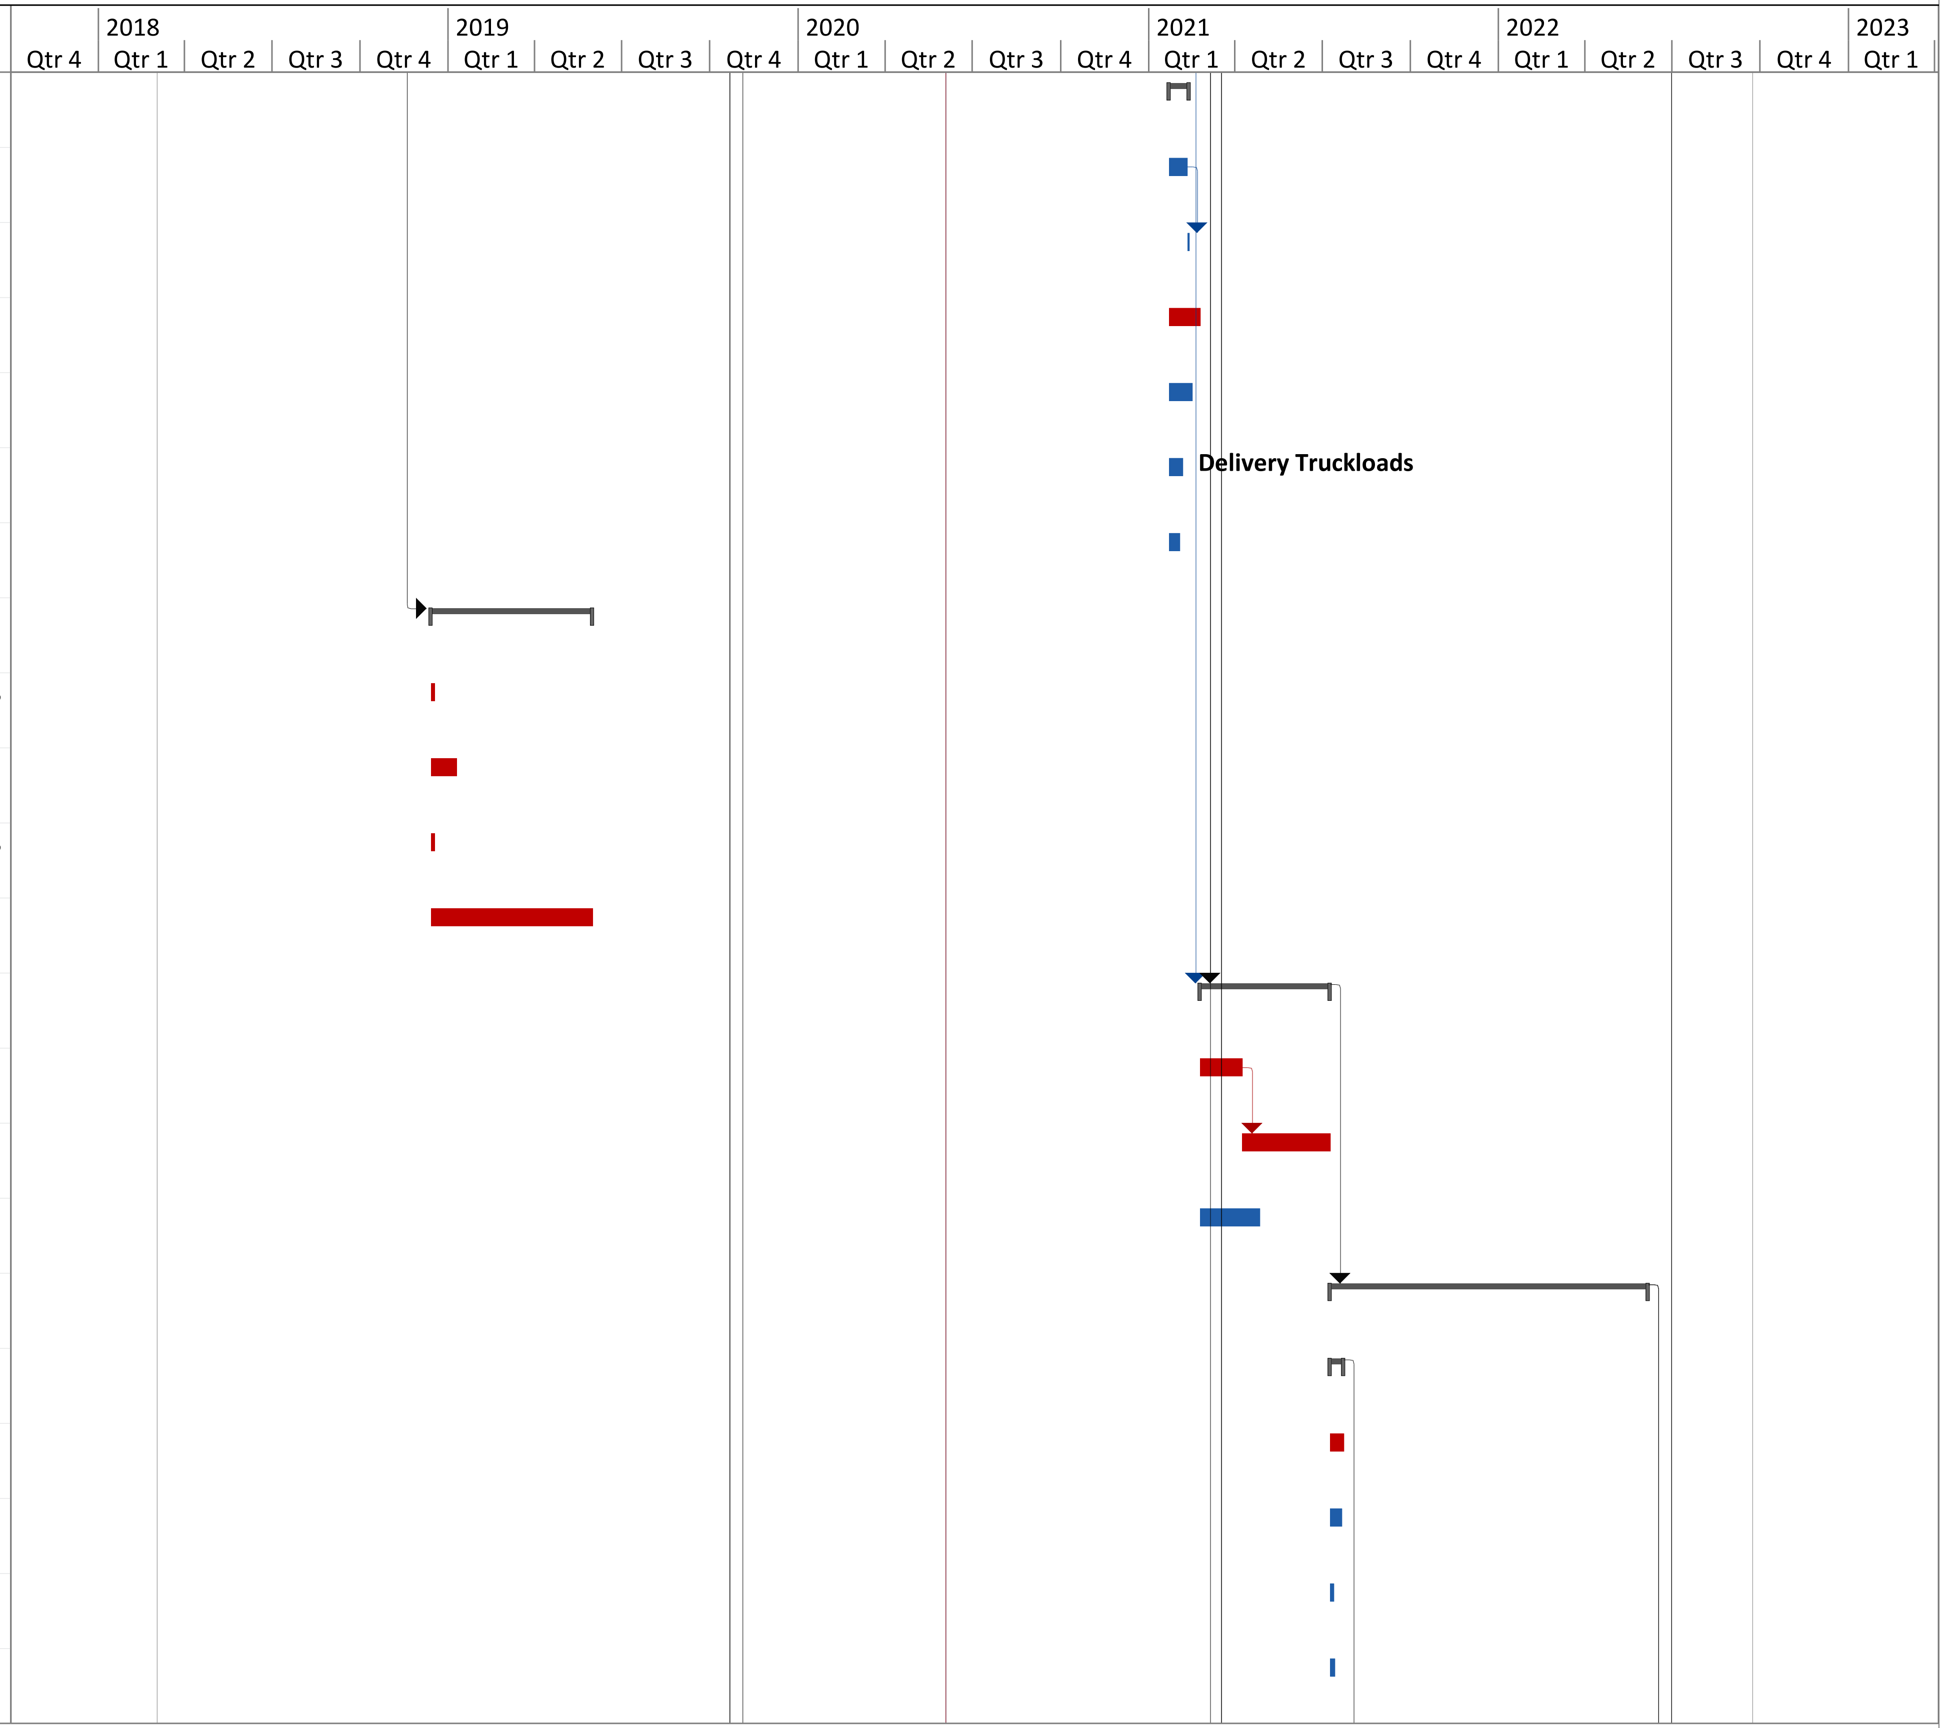
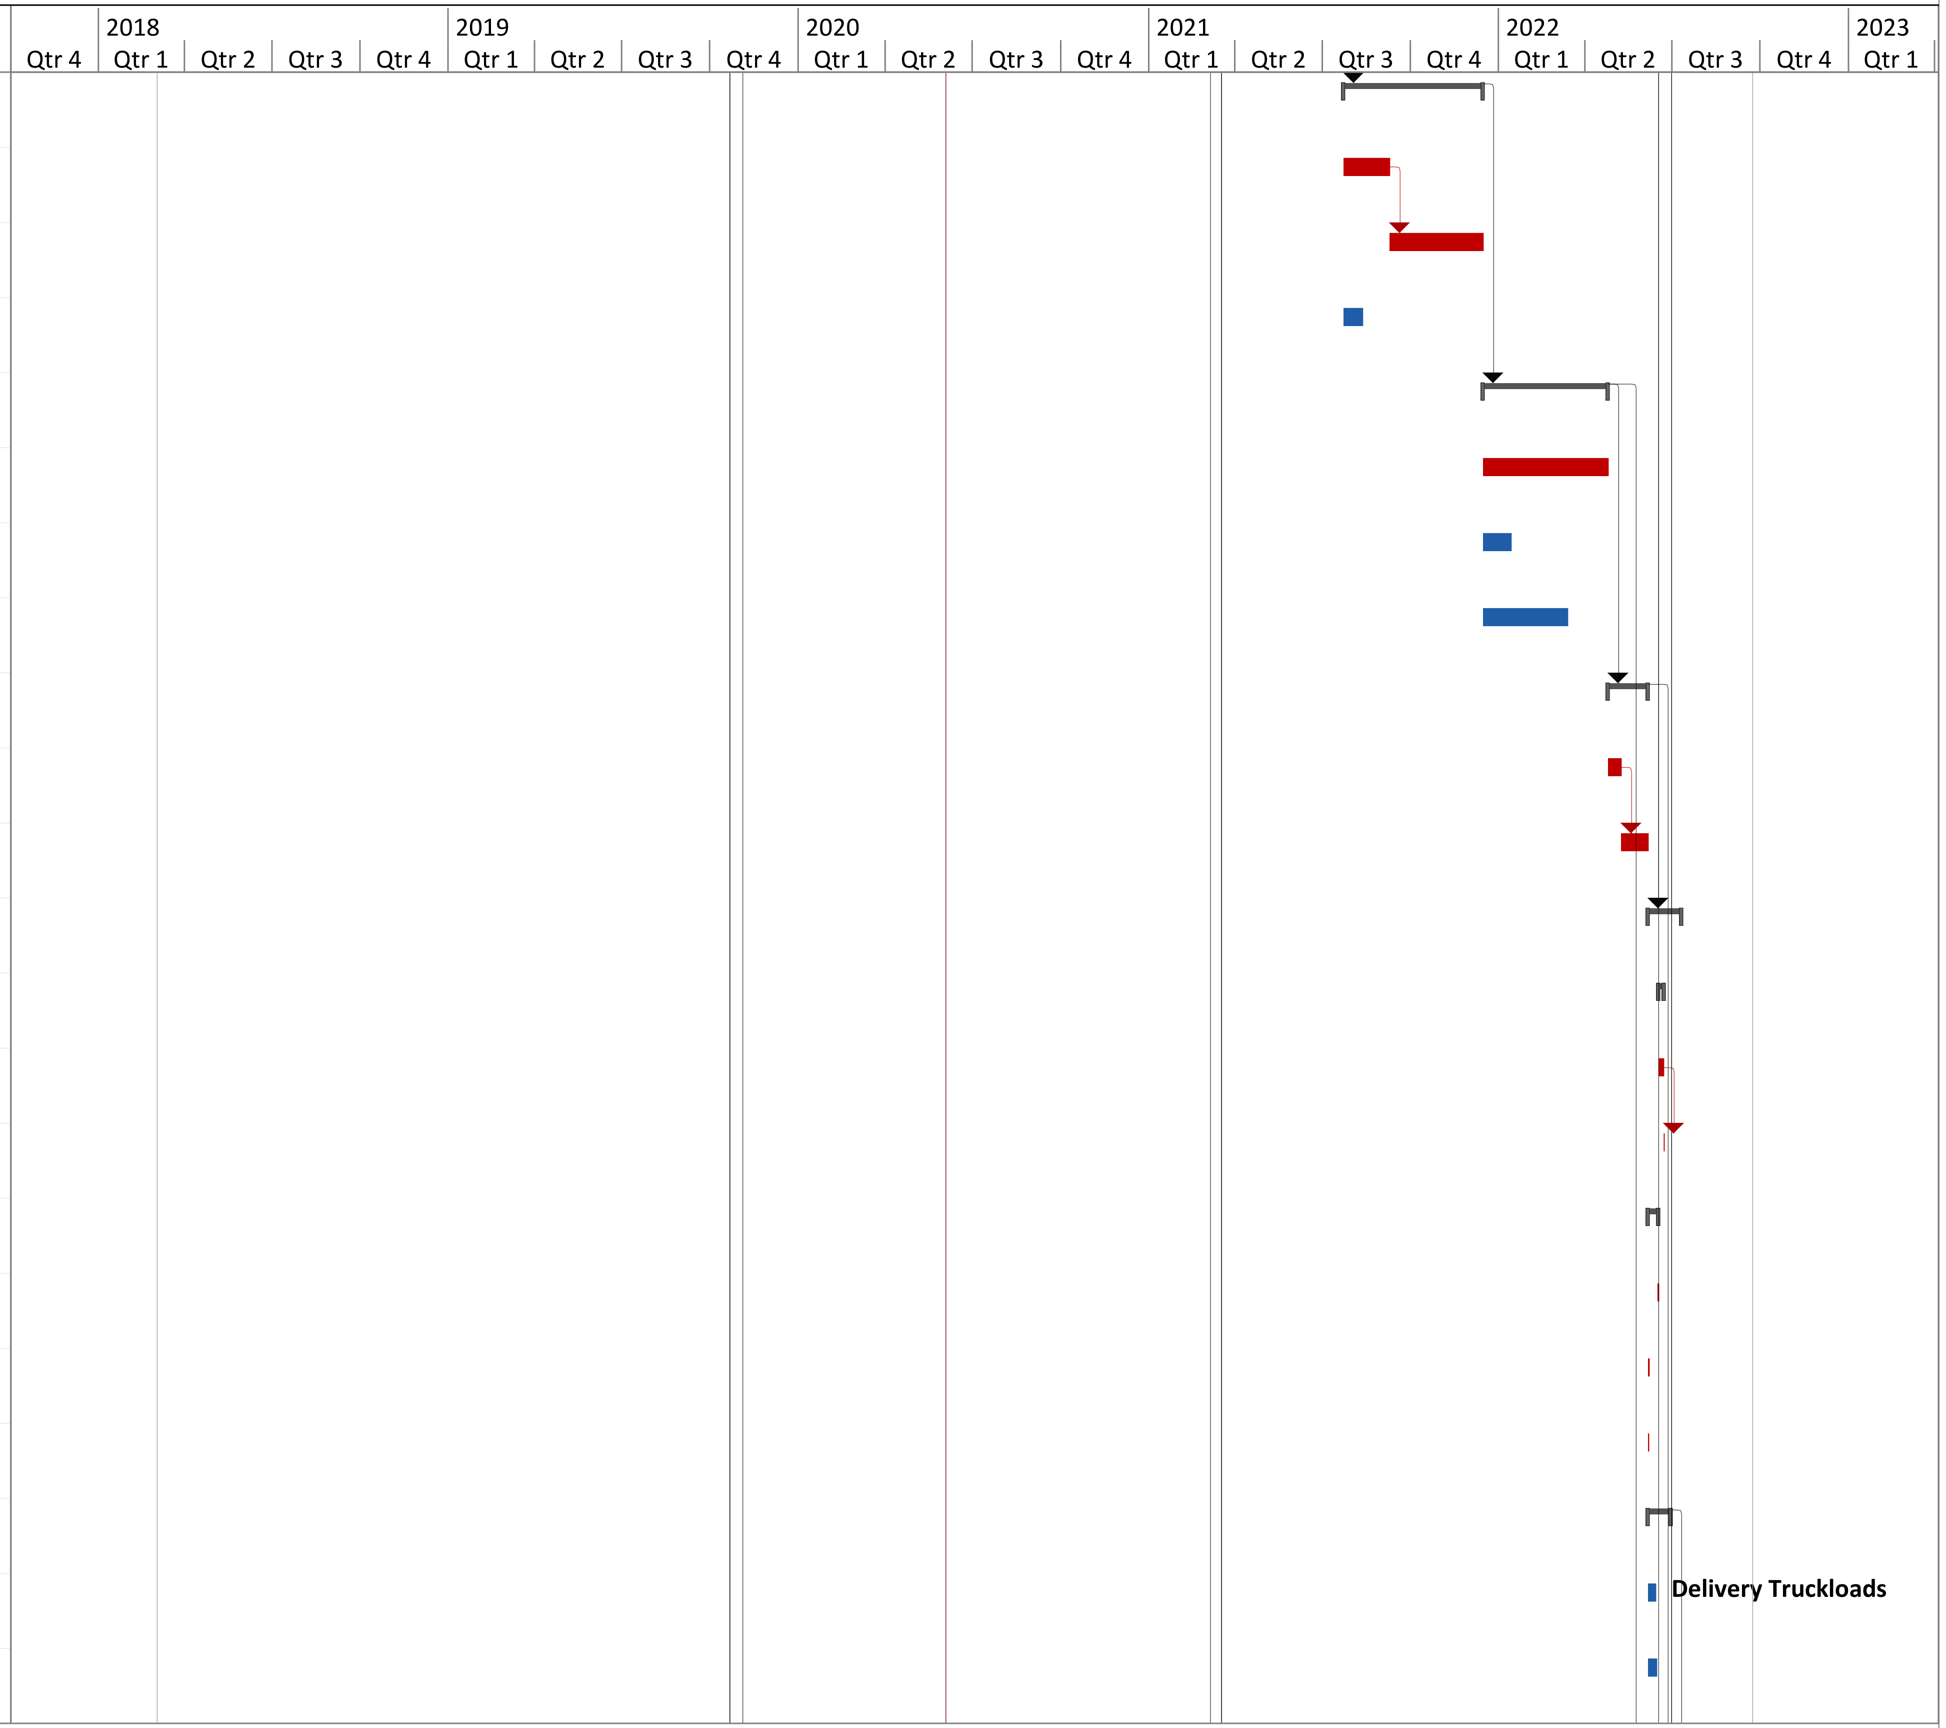
258	Compact material	44 days	Tue 2/23/21	Mon 4/26/21
259	**Final Cover**	**228 days**	**Fri 7/9/21**	**Mon 6/6/22**
260	**Starter Berms**	**10 days**	**Fri 7/9/21**	**Fri 7/23/21**
261	Purchase and deliver material	10 days	Fri 7/9/21	Fri 7/23/21
262	Spread loose lift before compacti	8 days	Fri 7/9/21	Wed 7/21/21
263	Special grading for steep slopes	2 days	Fri 7/9/21	Tue 7/13/21
264	Compact starter berms	3 days	Fri 7/9/21	Wed 7/14/21



ID	Task Name	Estimated Duration	Start	Finish
265	**Bio-Intrusion**	**100 days**	**Fri 7/23/21**	**Thu 12/16/21**
266	Purchase and Spread Bio-Intrusion Layer Material	34 days	Fri 7/23/21	Thu 9/9/21
267	Deliver Bio-Intrusion Layer Mater	67 days	Thu 9/9/21	Thu 12/16/21
268	Compact Bio-Intrusion Layer Mat	14 days	Fri 7/23/21	Thu 8/12/21
269	**Clay**	**89 days**	**Thu 12/16/21**	**Mon 4/25/22**
270	Purchase and deliver clay materia	89 days	Thu 12/16/21	Mon 4/25/22
271	Spread loose lift before compacti	18 days	Thu 12/16/21	Fri 1/14/22
272	Compact Clay (Final Cover)	59 days	Thu 12/16/21	Mon 3/14/22
273	**Top Soil**	**29 days**	**Mon 4/25/22**	**Mon 6/6/22**
274	Purchase and place Topsoil	10 days	Mon 4/25/22	Mon 5/9/22
275	Addition for Delivery Distance	19 days	Mon 5/9/22	Mon 6/6/22
276	**Post-Construction Stormwater Contro**	**24 days**	**Mon 6/6/22**	**Mon 7/11/22**
277	**Install Terraces**	**4 days**	**Fri 6/17/22**	**Thu 6/23/22**
278	Purchase and place Topsoil	3 days	Fri 6/17/22	Wed 6/22/22
279	Addition for Delivery Distance	1 day	Wed 6/22/22	Thu 6/23/22
280	**Diversion Berms**	**9 days**	**Mon 6/6/22**	**Fri 6/17/22**
281	Purchase and deliver clay materia	1 day	Thu 6/16/22	Fri 6/17/22
282	Spread loose lift before compacti	1 day	Mon 6/6/22	Tue 6/7/22
283	Compact berms	0 days	Mon 6/6/22	Mon 6/6/22
284	**Pond**	**18 days**	**Mon 6/6/22**	**Thu 6/30/22**
285	Purchase and deliver liner & berm	6 days	Mon 6/6/22	Tue 6/14/22
286	Spread loose lift before compacti	7 days	Mon 6/6/22	Wed 6/15/22



West Lake FFS - Partial Excavation 52.9/16'

DRAFT - Subject to Revision

ID	Task Name	Estimated Duration	Start	Finish
287	Compact Liner & Berm	4 days	Mon 6/6/22	Fri 6/10/22
288	Perimeter Berm Structural Rock	18 days	Mon 6/6/22	Thu 6/30/22
289	Perimeter Road Stormwater Crossin	2 days	Thu 6/30/22	Mon 7/4/22
290	Final Stormwater Controls	4 days	Mon 7/4/22	Mon 7/11/22
291	**Site Completion**	**38 days**	**Tue 5/24/22**	**Fri 7/15/22**
292	Install temporary irrigation system	9 days	Tue 5/24/22	Mon 6/6/22
293	Apply seeding to cover	28 days	Mon 6/6/22	Fri 7/15/22
294	Install Fencing	19 days	Mon 6/6/22	Fri 7/1/22
295				
296	**Clean-up and Demolition**	**742 days**	**Fri 10/11/19**	**Thu 9/22/22**
297	**RIM Loading Station**	**15 days**	**Wed 6/3/20**	**Tue 6/23/20**
298	Demolition	15 days	Wed 6/3/20	Tue 6/23/20
299	Air Treatment Demobilization	12 days	Wed 6/3/20	Thu 6/18/20
300	**Haul Road between Areas and Loadin**	**346 days**	**Fri 10/11/19**	**Tue 3/2/21**

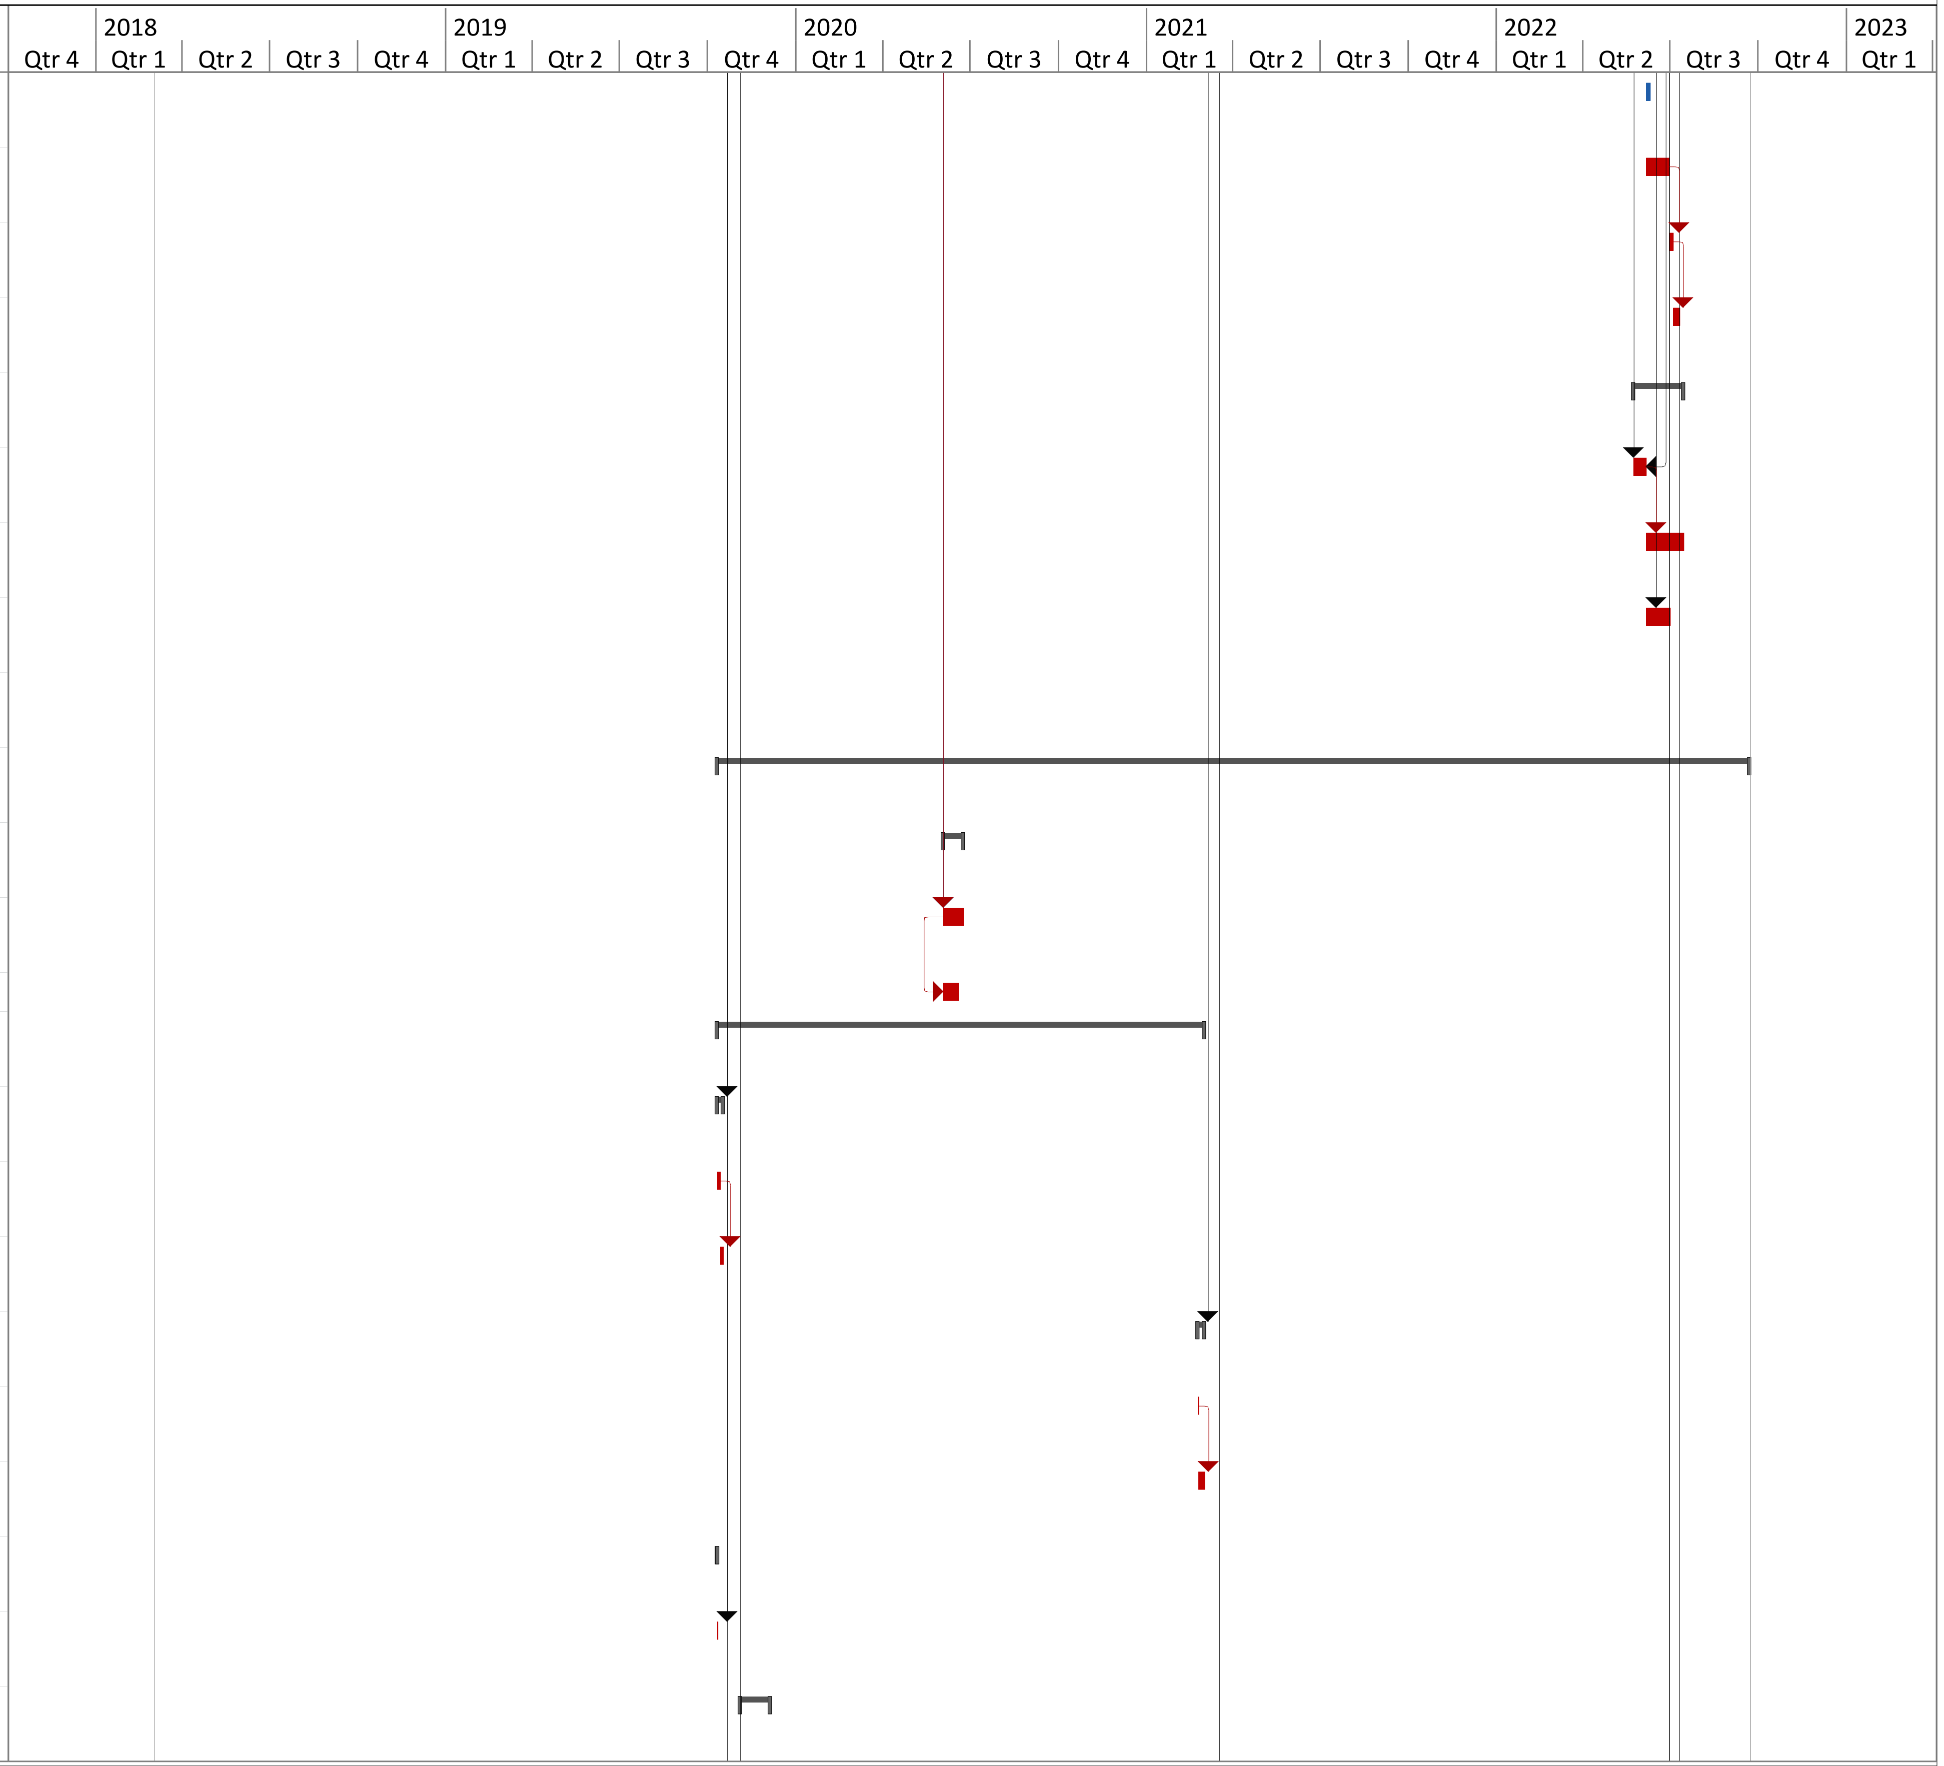
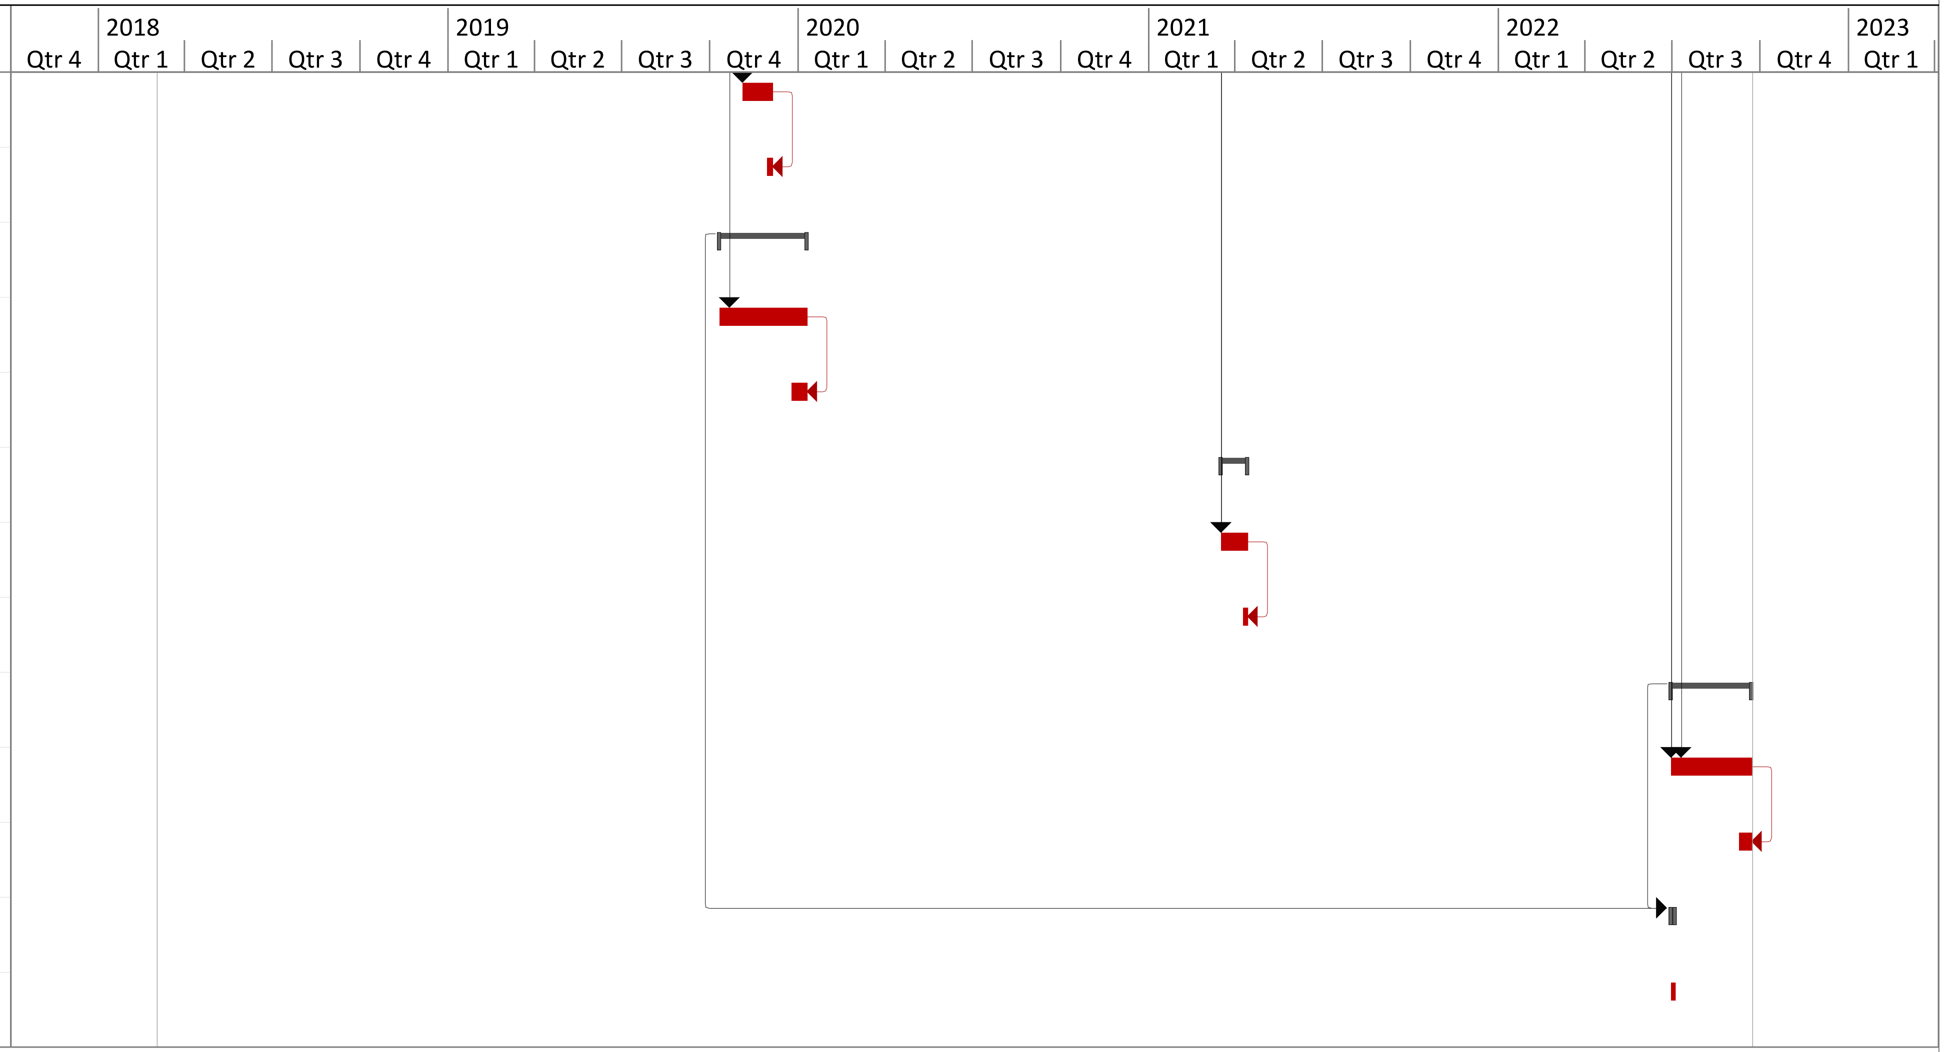
302	Remove potential contamination	1 day	Fri 10/11/19	Mon 10/14/19
303	Repairs for use during Capping Ph	4 days	Mon 10/14/19	Thu 10/17/19
304	**Area 2**	**5 days**	**Tue 2/23/21**	**Tue 3/2/21**
305	Remove potential contamination	1 day	Tue 2/23/21	Wed 2/24/21
306	Repairs for use during Capping Ph	4 days	Wed 2/24/21	Tue 3/2/21
307	**Bridge**	**1 day**	**Fri 10/11/19**	**Fri 10/11/19**
308	Demolition	1 day	Fri 10/11/19	Fri 10/11/19
309	**Area 1 Leachate Frac Tanks**	**20 days**	**Mon 11/4/19**	**Thu 12/5/19**



ID	Task Name	Estimated Duration	Start	Finish
310	Clean Leachate Frac Tanks	20 days	Mon 11/4/19	Thu 12/5/19
311	Remove Leachate Frac Tanks	3 days	Fri 11/29/19	Thu 12/5/19
312	**Area 1 Stormwater Frac Tanks**	**58 days**	**Fri 10/11/19**	**Fri 1/10/20**
313	Clean Frac Tanks	58 days	Fri 10/11/19	Fri 1/10/20
314	Remove Frac Tanks	10 days	Wed 12/25/19	Fri 1/10/20
315	**Area 2 Leachate Frac Tanks**	**20 days**	**Wed 3/17/21**	**Wed 4/14/21**
316	Clean Leachate Frac Tanks	20 days	Wed 3/17/21	Wed 4/14/21
317	Remove Leachate Frac Tanks	3 days	Fri 4/9/21	Wed 4/14/21
318	**Area 2 Stormwater Frac Tanks**	**58 days**	**Thu 6/30/22**	**Thu 9/22/22**
319	Clean Frac Tanks	58 days	Thu 6/30/22	Thu 9/22/22
320	Remove Frac Tanks	10 days	Fri 9/9/22	Thu 9/22/22
321	**Stormwater Treatment Facility**	**2 days**	**Thu 6/30/22**	**Mon 7/4/22**
322	Demolition	2 days	Thu 6/30/22	Mon 7/4/22



Estimated Schedule

“Partial Rad Removal, >1000 pCi/g” with Off-Site Disposal Alternative

Overview of Partial Excavation >1000 pCi/g Construction Schedule

Final Feasibility Study, West Lake Landfill

Overall Project: *March 2018 – November 2025 (7.7 years)*

Site-wide Preparations – *March - August 2018*

- Mobilization, Construction Trailers, Project Infrastructure, RIM Loading Station

Area 1 – *March 2018 – April 2022*

- Site Preparations – *March - April 2018*
- Waste Excavation – *August 2018 - January 2020*
  - Ship RIM offsite, stockpile overburden
- Waste Backfilling and Regrading – *February 2020 - April 2021*
  - Backfill excavation, regrade other waste as necessary
- Final Cover – *April 2021 – March 2022*
- Stormwater Controls and Site Completion – *March – April 2022*

Partially overlapping:

Area 2 – *December 2019 – September 2025*

- Site Preparations – *December 2019 - February 2020*
- Waste Excavation – *February 2020 - October 2022*
  - Ship RIM offsite, stockpile overburden, backfill where possible
  - Including Buffer Zone
- Remaining Waste Backfilling and Regrading – *October 2022 - August 2024*
  - Backfill excavation, regrade other waste as necessary
- Final Cover – *August 2024 - July 2025*
- Stormwater Controls and Site Completion – *through September 2025*

Clean-up and Demolition – *Ending November 2025*

- Takes place as appropriate throughout project

West Lake FFS - Partial Excavation 1000

Appendix K-1

Costing Assumptions

Swell and Recompaction Factors	Swell (Load Factor =1/[1+Swell])		Recompaction (over 100% means higher compaction in new location)	
Material	Factor	Units	Factor	Units
Clay	140%	lcy/bcy	110%	bcy/ccy
Bio-Intrusion Rock	165%	lcy/bcy	105%	bcy/ccy
Top Soil	125%	lcy/bcy	NA	bcy/ccy
General Fill Material	165%	lcy/bcy	105%	bcy/ccy
Starter Berm Riprap	120%	lcy/bcy	105%	bcy/ccy
General Refuse	150%	lcy/bcy	110%	bcy/ccy
C&D Stockpiled Refuse	120%	lcy/bcy	110%	bcy/ccy

Material Densities (placed)	Value	Units
Density Clay	125	pcf
Density Bio-Intrusion Rock	135	pcf
Density Top Soil	105	pcf
Density Daily Cover	110	pcf
Density Starter Berm Riprap	2.0	ton/bcy

Delivery Distances (Round Trips)	Distance	Units	Basis	Calculation of Additional Delivery Distance Factor		
				Hauling Increment	*Increment Basis*	*Hauling Increment Multiplier*
Clay Delivery Round Trip	40	miles	RS Means 354113200040 (max haul is 20 mi [40 RT])	NA		
Topsoil Round Trip	15	miles	Radius for possible sites is intermediate between Fred Weber (8.5 mi RT) and Central Stone (33 mi RT). Assumption is based on the "average load", if there were multiple sources.	10	RS Means 310513100900 (assume 5 mi haul = 10 round trip)	1.3
Bio-Intrusion Rock, Round Trip	15	miles		10	RS Means 310513100900 (assume 5 mi haul = 10 round trip)	1.3
Daily Cover, Round Trip	15	miles		10	RS Means 310513100900 (assume 5 mi haul = 10 round trip)	1.3
General Fill, Round Trip	15	miles		10	RS Means 310513100900 (assume 5 mi haul = 10 round trip)	1.3
Round Trip Miles to Rail Spur	20	miles	US Ecology estimate	NA		NA
Miscellaneous Deliveries Distance Round Trip	20	miles		NA		NA

Delivery Truck Traffic	Value	Units
Maximum Daily Delivery Truckloads to Site	200	truckloads
Assume no constraints on material availability		

Daily Cover

Assuming that daily cover material will be purchased, and delivered to the location needed just a few days in advance

Operation	RS Means Item	Description	Units	Crew	Source	Production Rate	Crew Size	Unit Costs: Ext. Mat, O&P	Unit Costs: Ext. Labor, O&P	Unit Costs: Ext. Equip, O&P	Unit Costs: Ext. Total, O&P
Purchase material and spread	310513100200	Soils for earthwork, common borrow, spread with 200 H.P. dozer, includes load at pit and haul, 2 miles round trip, excludes compaction	C.Y.	B15	RS Means, Year 2016 Quarter 1	600	3.5	$ 12.63	$ 3.02	$ 5.76	$ 21.41
Additional delivery distance	310513100900	Soils for earthwork, borrow, spread with 200 HP dozer, includes load at pit and haul, round trip, excludes compaction, for 5 mile haul, add	C.Y.	B34B	RS Means, Year 2016 Quarter 1	200	1	$ -	$ 2.50	$ 4.29	$ 6.79
Total per unit for additional delivery	Multiplier (add'l mileage increments needed) = 1.3					154	1	$ -	$ 3.25	$ 5.58	$ 8.83
What size haul crew is needed to match the production rate of material spreading?		*Production Rate to match:*		600	*Calculated Crew Size:*		3.9				
Total		**Common borrow, spread w/ dozer, includes load at pit & haul, excl. compaction (see Assumptions)**	**B.C.Y.**	**B15/B34B**	**RS Means, Year 2016 Quarter 1**	**600**	**7.4**	**$ 12.63**	**$ 6.27**	**$ 11.34**	**$ 30.24**
						Total number of truck drivers in crew:	**5.9**				

Dust Control	Quantity	Units	Notes
Water Truck Capital Expense	$ 55,000	each	Assumed depreciation between purchase and resale. (Based on SFS, plus inflation)
Average Days per Month Requiring Dust Control	30.4	days/month	Work days plus holidays and weekends
Water Truck Average Hours per Day	12	hours/day	Average hours of daylight
Water Truck Operation	$ 19,800	per month	Estimate of operator, fuel, maintenance. (Based on SFS, plus inflation)
Water Use (per water truck)	1,250	gallons/hour	
which is	*457,000*	*gallons/month per truck*	
Water Cost	$ 0.0034	per gallon	Missouri American Water Company, 7/19/2016
Water Truck Crew Size	1	workers per truck	

Bird Mitigation	Quantity	Units
Estimate of Annual Cost	$ 400,000	
Estimated Monthly Cost	$ 33,000	
Crew Size	2	workers
Estimate of Crew Labor	$ 18,300	per month

Based on conversation with LGL Limited, 9/19/2016

Tree Removal

Estimating the number of trees to be removed in OU-1, based upon site experience with the 2016 Non-Combustible Cover (NCC) project.

- *Assuming that tree density in early NCC construction (Area 2) is representative of the rest of Area 2*
- *Assuming that tree density in early NCC construction (Area 2) is representative of Area 1*

Item	Quantity	Units
Preliminary NCC coverage (Area 2)	15.22	acres
NCC buttress area	1.75	acres
Total initial NCC cleared Area 2 area (partial project)	*16.97*	*acres*
Trees with diameter 12-24 inches, within initial NCC progress	174	trees
Average Trees (12-24 inches) per acre	***10.3***	***trees/acre***
Trees with diameter >24 inches, within initial NCC progress	48	trees
Average Trees (>24 inches) per acre	***2.8***	***trees/acre***

Construction Trailers

Capital Costs	**RS Means Reference #**	**Description**	**Cost**	**Source**	**Crew Type**	**Crew Size**	**Daily Rate**	**Days**	**Man-days**
Trailer Purchase	015213200300	Office trailer, furnished, buy, 32' x 8', excl. hookups	$ 19,571	RS Means, Year 2016 Quarter 1	2 Skwk	2	0.7	1.4	2.9
Trailer Delivery, per mile	015213200800	Office trailer, delivery, add per mile	$ 12	RS Means, Year 2016 Quarter 1			0		
Delivery Distance (Round Trip)		Delivery Distance (miles)	20	Estimate					
Trailer Delivery (each)			*$ 244*						
Electrical Connection	015113500890	Temporary electrical power equipment (pro-rated per job), connections, office trailer, 200 amp	$ 711	RS Means, Year 2016 Quarter 1	1 Elec	1	2	0.5	0.5
Total per Trailer			*$ 20,526*					*1.9*	*3.4*
Number of Site Trailers		Contractor, Engineering, Reg. Oversight, Decon building, Lab	5

Leachate Handling				
Assume that a portion of excavated waste will be saturated, and that pockets of this leachate will be encountered occassionally				
	Quantity	**Units**	**Source**	**Notes**
Percentage of Waste with Leachate Saturation	10%			
Drainability Factor	20%			
Average Leachate Production Rate	*28*	*cy/day*		
which is	*5,655*	*gal/day*		
Safety Factor (accounts for continuous pockets of leachate)	3.0			Safety factor on volume within the time window
Frac Tank Capacity	20,000	gal		Assume 21k tanks are useable to 20k
Leachate Storage Days for Testing	14	days		Test by on-site lab, turn around could be shorter depending on priority
Leachate Storage Days to Coordinate Hauling	2	days		
Leachate Storage Days for Upcoming Excavation	7	days		
Days of Leachate Storage Needed	*23*	*days*		
Volume of Storage Needed	*390,000*	*gal*		Volume (with safety factor) that could be encountered in the time window
Frac Tanks Needed for Leachate Storage (time-based)	*20*	*tanks*		This many tanks needed for the specified time window
Leachate Hauling and Disposal Cost	$ 0.57	per gallon	Heritage Environmental estimate, 8/3/2016	
Disposal Distance (round trip)	600	miles (round trip)		
Tank Truck Capacity	5,000	gal	Heritage Environmental estimate, 8/3/2016	
Disposal Truck Crew (approximation)	B34B			

Leachate Tank Costs			
	Quantity	**Units**	**Source**
Rent	$ 28	per day	Rain for Rent, 7/22/2016
Purchase	$ 30,000	per tank	
Delivery	$ 200	per tank	Rain for Rent, 7/22/2016
Pickup	$ 200	per tank	Rain for Rent, 7/22/2016
Reposition Onsite (both directions)	$ 140	per tank	Based on Delivery cost and distance
Cleaning	$ 1,500	per tank	Estimated by Rain for Rent, 7/22/2016
Delivery distance	60	miles (round trip)	
Budget for prevention (or remediation) of stormwater contamination	$ 10,000	per month	

Secondary Containment			
Assume that tanks are lined up side to side, placed on clay liner and surrounded by berms			
	Quantity	**Units**	**Notes**
Liner Area qty per frac tank	700	sf	Assume 102" wide x 560" long, with 60" between tanks
Liner Thickness	2	ft	
Berm length per frac tank	27	lf	Assume 102" wide + 60" between x 2 sides
Additional berm length for 1st tank	103	lf	Assume 560" long + 60" x 2 sides
Berm Cross-section	16	sf	Triangular berm, 2' tall, 2:1 sides. 2' floor beneath.
Clay per additional Frac Tank	*68*	*cy*	
Clay for initial berm	*61*	*cy*	

Assumptions:

Perched Leachate is encountered in proportion to excavation

Leachate is held for lab testing, then hauled offsite for disposal

Leachate is Non-Hazardous

Assume one tank to be located near excavation, then moved to tank farm

Gas System for Overburden Stockpile

Based on system estimate by Environmental Information Logistics, July 2016

			Material		Installation			
Installation Costs	**Units**	**Qty**	**Unit Cost**	**Extended**	**Unit Cost**	**Extended**	**Total**	**Note**
4 inch perforated channel flow single wall ADS w/ 3 holes in 120 degrees	lf	20550	$ 1.50	$ 30,825	$ 10.00	$ 205,500	$ 236,000	
Misc. Fittings for 4 inch pipe				$ 3,083		$ 20,550	$ 24,000	10% of pipe costs
6" HDPE SDR 17 manifold system	lf	1000	$ 6.00	$ 6,000	$ 10.00	$ 10,000	$ 16,000	
Misc. Fittings for 6 inch pipe				$ 1,200		$ 2,000	$ 3,000	20% of pipe costs
Installation Totals				$ 41,108		$ 238,050	**$ 279,000**	
Est. Labor (at $80/hr)							**2,980**	**man-hours**

Monthly Costs	**Units**	**Qty**	**Unit Cost**	**Extended**	**Monthly**
Vacuum System rental	per month	1	$3,000.00	$ 3,000	$ 3,000
Carbon Treatment System rental	per month	1	$2,600.00	$ 2,600	$ 2,600
Power	per year	1	$3,500.00	$ 3,500	$ 290
Condensate Disposal	gallons/day	13	$ 0.14	$ 1.82	$ 55
Operational Labor	hours/week	2	$ 80.00	$ 160	$ 700
Monthly Total					**$ 6,600**
Monthly Labor Hours					9

Road Extension to New Transfer Station

Estimate of unit cost for road extension	$ 1,000,000	per mile
Estimated unit cost per foot	*$ 190*	per foot
Estimate distance of Road Extension	2,000	feet
Budget for Road Extension to New Transfer Station	*$ 380,000*	
RS Means Crew Estimate	B25	*Asphalt paver, tandem roller, pneumatic wheel loader, foreman, 3 equipment operators, 7 laborers*
Daily Cost	$ 6,500	
Production Estimate	*34*	ft/day

Calculated values shown in italics

RIM Loading Station		
Based on estimates from two companies, a projected budget was determined for a clear-span fabric structure for managing and loading RIM for transportation off-site.		
	Budget	
Structure and Other Non-Itemized Construction*	$ 2,300,000	
Sitework	$ 330,000	
Slab on Grade (6" concrete)	$ 480,000	
HVAC	$ 400,000	
Fire Suppression (and needed water/sewer)	$ 250,000	
Misting System	$ 180,000	
Internal Furnishings (Jersery Barriers, Scaffolding, etc.)	$ 80,000	
Truck Scale	$ 120,000	
Contractor's Construction Management	$ 300,000	
Overhead, Profit, Insurance	$ 320,000	
**Air treatment (carbon filtering, odor mitigation) are estimated separately*		
Total Construction Budget (rounded)	**$ 4,800,000**	
Demolition Budget	**$ 160,000**	
Construction Duration	22	weeks
Demolition Duration	3	weeks
Estimated Construction Crew (average workers per day)	30	workers

Estimated Costs for Internal Furnishings

Item	Qty	Cost	Total	Note	RS Means Item	RS Means Description
Jersey Barriers	36	$ 887	$ 31,920	3 bays x 2 row x 6 per row	347113171900	Security vehicle barriers, concrete barrier, jersey, 20' L x 2' by 6" W x 32" H, 10 or more same site
Scaffolding Sections	32	$ 174	$ 5,575	Need qty 4, each 25' x 15' tall total	015423701350	Scaffolding, steel tubular, regular, frame, buy, 7'-6" high x 6' wide
Scaffolding Stairs	8	$ 317	$ 2,538	2 per assembly	015423701900	Scaffolding, steel tubular, regular, accessory, stairway section, buy
Misc Furnishings			$ 40,000	Allotment for various smaller items		
Total			**$ 80,000**			

Air Treatment System

Based on information from Carbonair to EMSI (July 2016), with additional assumptions for sitework

System would use (9) 22,000 cfm contactors (3 in parallel at 3 locations somewhere around the bldg), each loaded with 10,000 lb of Darco H2S media and 10,000 lb of vapor phase granular activated carbon (VPGAC). Vessels would be rented. Carbonair would supply 480v/3 ph blower packages (w/ controls) at each location.

Capital Expenses

Project Startup	Cost	Est. Taxable	Man-Days	Notes
Installation	$ 332,800	$ 332,800	5	Initial media, installation labor, initialization
Vessel and Media Mobilization	$ 40,000	$ 40,000	23.4	Each vessel requires a dedicated semi (1040 miles RT)
Startup Capital Subtotal	$ 372,800	$ 372,800	28	
Sitework	$ 136,000	$ 13,400	43	*See Site Work Details*
Total	**$ 508,800**	**$ 386,200**	**71**	
Average Crew Size	7.1			
Project Wrapup	Cost	Est. Taxable	Man-Days	Notes
Media Disposal	$ 45,000	$ 45,000	5	
Vessel and Media Demobilization	$ 40,000	$ 40,000	23.4	
Wrapup Capital Subtotal	$ 85,000	$ 85,000	28	
Sitework (Demolition)	$ 36,000	$ -	13	*See Site Work Details*
Total	**$ 121,000**	**$ 85,000**	**41**	
Average Crew Size	3.5			

Recurring Costs

Media Replacement & Change-out	7.9	52.9	1000
Total Excavation (months, active excavation only)	61.1	16.7	26.3
Number of Media Cycles	5.1	1.4	2.2
Estimated Number of Media Change-outs	5	1	2
Media Replacement Cost	**$ 2,160,000**	**$ 432,000**	**$ 864,000**
Media Replacement Man-days	150	30	60
Rental Fees			
Expected Excavation Duration (months, including breaks)	96	23	50
Vessel Rental costs over expected duration	$ 3,168,000	$ 956,000	$ 1,768,000
Blower Rental Costs, capped by Purchase Cost	$ 975,000	$ 709,000	$ 975,000
Average Monthly System (given expected duration)	**$ 43,000**	**$ 73,600**	**$ 55,200**

Summary

	Estimated Cost (after taxes)		
Remediation Alternative	**7.9**	**52.9**	**1000**
Startup Capital Expenses	$ 541,000	$ 541,000	$ 541,000
Rental Costs (Project Total)	$ 4,492,000	$ 1,805,000	$ 2,973,000
Media Replacement (Project Total)	$ 2,341,000	$ 468,000	$ 936,000
Wrapup & Demobilization	$ 128,000	$ 128,000	$ 128,000
Total	**$ 7,500,000**	**$ 2,940,000**	**$ 4,580,000**

Assumption Details for Air Treatment System

Rental Fees	First 12 months	Next 6	>18 months	Purchase Outright
Vessels (3 groups of 3)	$ 48,600	$ 38,880	$ 30,000	N/A
Blower Packages (3)	$ 36,745	$ 27,600	$ 22,000	$ 975,000
Subtotal	**$ 85,345**	**$ 66,480**	**$ 52,000**	

Media Replacement Costs	Quantity	Notes
Replacement Cost	$ 432,000	For all 9 vessesls
Assumed Average Frequency	12	months
Crew Man-Days	30	4 workers x 2.5 days per 3 vessels
Crew Size	4	

Site Work Details				**Installation**		**Demolition**		
Item	Unit Cost	Units	Qty	Cost	Man-Days	Cost	Man-Days	Notes
Concrete slabs for vessels	$ 7,067	each	3	$ 21,200	12.75	$ 21,200	12.75	Based on RS Means Data. Assume demolition is similar to construction.

Stormwater Treatment Plant

Based on information from Carbonair to EMSI (August 2016), with additional assumptions for sitework

System would include 2 treatment trains, each handling 120 gpm. (Second train is for redundancy, or for extra capacity in an emergency.) Consist of duplex bag filter skid, LPGAC adsorbers, transfer pump, interconnecting piping, flow meter, pressure gauges. To be housed in pre-engineered slab on grade metal building.

Capital Expenses

Project Startup	Cost	Est. Taxable	Man-Days	Notes
System shipping & installation, initial media	$ 10,267	$ 10,267	3.6	Initial media, installation labor, initialization
Transfer Pumps	$ 54,254	$ 54,254	1	2 pumps, delivered & installed
Startup Capital Subtotal	$ 64,521	$ 64,521	5	
Sitework	$ 37,000	$ 6,700	25	*See Site Work Details*

Total						**$ 86,297**	**$ 35,337**							**6.4**	**42.0**

Other Note and Assumptions

Clearing

- Any existing geomembrane liner requiring demolition is assumed to be added to the overburden waste, consuming an insignificant volume.
- Tree density of the early Non-Combustible Cover construction (Area 2) is assumed to be representative of the rest of Area 2, and of Area 1.
- Disposal of stumps is assumed to be as normal waste (RS Means rate), not as a special waste. Stumps are not included in the truckload estimate.

C&D Rubble Stockpiles

- It is assumed that all construction & demolition material can be used without crushing or other means of processing for size reduction.

Air Treatment System (RIM Loading Station)

- Media replacement frequency for the Air Treatment System is a significant risk item. In addition to being a sizeable expense, its effectiveness is not yet known.
  -- The media replacement frequency could be significantly shorter than assumed, perhaps prohibitively so.
- Depending on the final project scheduling, it may be advantageous to demobilize and remobilize the Air Treatment System components rather than maintain continuous rental for long gaps between RIM excavation phases.

Stormwater and Leachate

- Stormwater design is conceptual in nature.
- It is assumed that solids from stormwater retention can be returned to the landfill.
- Preliminary locations for frac tanks have been identified and it assumed that the design phase will either confirm these locations or identify alternates within a reasonable distance.

Landfill Gas System

- A longer-term gas system may be required in Area 2 if a significant volume of waste is permanently relocated from the North Quarry.

Material Delivery

- No traffic study has been conducted as a part of this feasibility-level estimate.
- Final cover materials, daily cover, and clean fill are assumed to be delivered to the locations needed, 3 days in advance. Thus double-handling will be minimized but a buffer of material will still be available in case of disruption.

Schedule Estimates

- Construction schedules assume that replacement of the existing Transfer Station is completed before excavation begins. This includes design, permitting, construction of the new, and demolition of the old.
- Schedules account for weather delays, but not any seasonal stoppages.
- Schedules do not relect any delays (or costs) of work stoppages or standby time due to odor issues, regulatory requests, etc.
- The construction rate is assumed to be limited by the on-site hauling rate, with the contractor furnishing equipment for other operations as needed to meet this rate.
- Inefficiency factors due to radiological materials are applied primarily to excavation and loading operations. It is assumed that space will allow assigning additional crews to these operations so that the on-site hauling rate is maintained.

Additional Assumptions	**Quantity**	**Units**	**Notes**
On-site Transportation Rate (per each Contractor's Operation)	2,100	lcy/day	
Work Days per Year	250	days	
Traffic Improvements (TBD), Area 1	10	days	
Traffic Improvements (TBD), Area 2	10	days	
Radiological Survey following final excavation in an area	7	days	
Taxes for Bridgeton, MO	8.363%		http://dor.mo.gov/pdf/rates/2016/jul2016.pdf
Construction Inflation Rate			
RS Means Historical Cost Index for 2011	191.2		
RS Means Historical Cost Index for 2016	207.2		For January 2016, estimated
Construction Inflation Multiplier from SFS to FFS	*1.084*		

Construction Assumptions for ROD Remedy

Estimated Non-discounted Capital Costs: 0

Estimated Non-discounted Total Costs: 210,000

Estimated 30-year Present Worth Costs: 82,000

Note: For purposes of costing, it is assumed that the 5-year Review periodic costs would be the same as for the ROD-selected Remedy

The information in this cost estimate summary is based on the best available information regarding the anticipated scope of the remedial alternative. Changes in the cost elements are likely to occur as a result of new information and da collected during the engineering design of the remedial alternative. In accordance with USEPA Guidance, this is a order-of-magnitude engineering estimate that is expected to be within -30 to +50 percent of the actual project cos

DRAFT

Capital Cost Estimate - Long-Term Monitoring
FFS ROD Remedy Alternative

Description	Quantity	Units	Unit Rate	Estimated Cost ($)
Secure easements	1	LS	5,000	5,000
Landfill Gas:				
Driller: Install radon/landfill gas monitoring probes, MDNR "Code Wells"; 10' deep	31	each	2,000	62,000
Misc. wellhead sampling fittings and locks	31	each	40	1,200
Field technician observation during drilling and construction of probes (4/day)	64	hour	90	5,800
Mileage for field technician during probe construction	400	mile	0.54	200
Multi-gas detector (e.g., Industrial Scientific iBrid™ MX6), incl regulator, tubing, calbrtn gas	1	LS	4,806	4,800
Portable radon gas monitor and detector (e.g., Pylon AB6 monitor w/ 300A detector)	1	LS	9,075	9,100
Groundwater:				
Construction of new groundwater monitoring wells	12	each	10,000	120,000
Flat-bottom polyethylene tank to store purge water prior to disposal	1,500	gallon	2	3,000
Estimated Long-term Monitoring Capital Costs - Total				**211,000**

DRAFT

Post-Construction Radon Flux Monitoring Cost Estimate
FFS ROD Remedy Alternative

Description	Quantity	Units	Unit Rate	Estimated Cost ($)
Radon Flux (once after cover construction is complete):				
Number of Monitoring Locatons (assume same as post-NCC program):	*130*			
Surveying of locations	1	day	1,500	1,500
Auxier labor	1	LS	6,345	6,350
Per diem	2	each	1,190	2,380
Airfare and vehicle rental	2	each	1,000	2,000
Overnight shipping to lab	1	LS	1,200	1,200
Lab analysis (Eberline)	1	LS	11,050	11,050
Data validation and management	1	each	1,000	1,000
Reporting	4	hour	150	600
Estimated Post-Construction Radon Flux Monitoring Costs - Total				**26,000**

Stormwater and Air Monitoring During Construction Cost Estimates
FFS ROD Remedy Alternative

Description	Quantity	Units	Unit Rate ($)	Estimated Cost ($)
Stormwater Monitoring and Inspection (Quarterly - only during remedy construction)				
4 sampling locations				
1 field duplicate				
5 total samples				
Sampling and Inspection (Feezor Engineering estimate)	1	LS	5,000	5,000
Laboratory Analysis:				
Eberline (T-uranium, iso-uranium, iso-thorium, gross alpha/beta, Ra-226, Ra-228)	1	LS	2,325	2,330
TekLab (all other parameters)	1	LS	2,743	2,740
Data validation and management	1	LS	1,500	1,500
Reporting	4	hour	150	600
Estimated Quarterly Stormwater Monitoring and Inspection Costs - Total				**12,000**
Air Monitoring during Construction				
13 air monitoring stations and one MET station				
Auxier & Associates FY2016 Air Monitoring Program Estimate (minus contingency)	1	LS	172,852	172,900
Data validation	1	LS	6,800	6,800
Power costs (13 stations plus one MET station; $10/month per station)	12	months	140	1,700
Estimated Air Monitoring during Construction Costs - Annual Total				181,000
Estimated Quarterly Air Monitoring Costs during Construction (assuming annual costs divided by 4)				**45,000**

DRAFT

Capital Cost Estimate - Amend Existing/Additional Institutional Controls
FFS ROD Remedy Alternative

Description	Quantity	Units	Unit Rate	Estimated Cost
Prepare Institutional Controls planning documents	1	LS	10,000	10,000
Attorney labor: prepare draft amended existing and additional ICs	1	LS	20,000	20,000
Review of draft documents	1	LS	5,000	5,000
Revise amended and additional Institutional Controls documents	1	LS	10,000	10,000
Filings and registrations	1	LS	5,000	5,000
Estimated Institutional Controls Capital Costs - Total				**50,000**

DRAFT

Long-Term Post-Construction Monitoring (per event) Cost Estimate
FFS ROD Remedy Alternative

(Landfill Gas/Radon, Groundwater Monitoring and Annual Post-Construction Site Inspections)

Description	Analytical Method	Quantity	Units	Unit Rate ($)	Estimated Cost ($)
Landfill Gas/Radon (quarterly after contruction complete):					
Number of Landfill Gas/Radon Monitoring Wells		*31*			
Labor - field technician		9	hour	90	810
Field vehicle		1	day	120	120
Replacement radon detector (Pylon 300A)		1	each	550	550
Calibration gas for multi-gas detector		1	each	449	450
Data management		2	hour	100	200
Reporting		8	hour	150	1,200
Estimated Landfill Gas/Radon Monitoring Costs - Subtotal					3,300
Contingency			*%*	*20*	*700*
Estimated Landfill Gas/Radon Monitoring Costs - Total (per Event)					**4,000**

Description	Analytical Method	Quantity	Units	Unit Rate ($)	Estimated Cost ($)
Groundwater (semi-annual first 5 years after construction; annually thereafter):					
Number of Samples:			*For VOCs*		
Investigative Groundwater (5, 3-wells clusters in Area 2; 3, 3-well clusters in Area 1)		*24*	*24*		
Field Duplicates (one per every 10 investigative samples)		*3*	*3*		
Trip blank (one per day per cooler)			*15*		
Matrix Spike			*1*		
Matrix Spike Duplicate			*1*		
Sub-total number of unfiltered samples:		*27*	*44*		
Sub-total number of filtered samples for radionuclide and metals analyses:		*27*			
Total number of samples:		*54*	*44*		
Labor:					
Labor - field technicians (assume 2 people, 5 days, 10-hr days)		100	hour	90	9,000
Materials and equipment:					
Sample kits, incl. filters		24	each	50	1,200
Field instrumentation and flowcell rental - groundwater		5	day	100	500
Field Vehicle		5	day	120	600
Overnight shipping of sample coolers (assume 1 per day to rad lab)		5	coolers	100	500
Delivery of sample coolers to local lab (2 to 3 coolers per day)		5	hour	90	450
Disposal of purge water (assumes PE tank previously purchased is onsite):					
Vacuum truck		4	hour	200	800
Transportation and disposal (assumes approx 25 gal per well per event)		600	gallon	2.00	1,200
Laboratory Sample Analysis:	*Analytical Method:*				
Gross alpha and beta	EPA 900.0	54	each	50	2,700
Total Uranium		54	each	65	3,510

Operation and Maintenance Cost Estimate - Annual Cover System Maintenance
FFS ROD Remedy Alternative

Description	Quantity	Units	Unit Rate	Estimated Cost
Mowing; tractor w/ rotary mower (once/year)	55.3	acre	40.00	2,200
Fill depressions in cover w/ topsoil, assume 1% of area; 6 inches deep	446	bcy	37.53	16,700
Seeding of filled area	24.1	M.S.F.	66.04	1,600
Estimated Cover System O&M Costs - Subtotal				20,500
Contingency		*%*	*20*	*4,100*
Estimated Annual Cover Maintenance O&M Costs - Total				**25,000**

M.S.F. = 1,000 square feet

DRAFT

Periodic Cost Estimate - 5 year Review
FFS ROD Remedy Alternative

Description	Quantity	Units	Unit Rate	Estimated Cost ($)
Access Restrictions (inspect/repair fencing and signage)	16	hours	150	2,400
Institutional Controls verification	8	hours	150	1,200
Document that landfill cover is effective	8	hours	150	1,200
Assemble Monitoring Data (landfill gas/radon, groundwater, surface water)	40	hours	150	6,000
Summarize Annual Post-Construction Site Inspections	8	hours	150	1,200
Summarize Annual Cover Maintenance Documentation	8	hours	150	1,200
Water supply well inventory review	8	hours	150	1,200
Document any changes in Land Use at and around West Lake Landfill	16	hours	150	2,400
Prepare Summary Report	80	hours	150	12,000
Estimated 5-year Maint/Review O&M Costs - Subtotal				**29,000**
Contingency		*%*	*20*	*6,000*
Estimated 5-year Maintenance O&M Costs - Total				**35,000**

		Estimated Non-discounted Capital Costs:		67,000,000					Estimated Non-discounted Total Costs:	73,000,000		
											Estimated 30-year Present Worth Costs:	64,000,000

The information in this cost estimate summary is based on the best available information regarding the anticipated scope of the remedial alternative. Changes in the cost elements are likely to occur as a result of new information and data collected during the engineering design of the remedial alternative. In accordance with USEPA Guidance, this is an order-of-magnitude engineering estimate that is expected to be within -30 to +50 percent of the actual project cost.

										Estimated 200-year Present Worth Costs:		64,000,000

The information in this cost estimate summary is based on the best available information regarding the anticipated scope of the remedial alternative. Changes in the cost elements are likely to occur as a result of new information and data collected during the engineering design of the remedial alternative. In accordance with USEPA Guidance, this is an order-of-magnitude engineering estimate that is expected to be within -30 to +50 percent of the actual project cost.

	Estimated Non-discounted Capital Costs:			67,000,000			Estimated Non-discounted Total Costs:			241,000,000		
									Estimated 1,000-year Present Worth Costs:			78,000,000

The information in this cost estimate summary is based on the best available information regarding the anticipated scope of the remedial alternative. Changes in the cost elements are likely to occur as a result of new information and data collected during the engineering design of the remedial alternative. In accordance with USEPA Guidance, this is an order-of-magnitude engineering estimate that is expected to be within -30 to +50 percent of the actual project cost.

Appendix K-4

Cost Estimates for the “Complete Rad Removal” with Off-site Disposal Alternative

DRAFT

Preliminary Estimated Capital Costs
Complete Rad Removal (7.9 pCi/g) Remedy Alternative

Cost Item			Estimated Capital Costs
Construction Costs		$	162,800,000
Radiological Survey/H&S Support Costs		$	62,292,000
On-site Rad Laboratory		$	1,144,000
Long-Term Monitoring Facilities		$	211,000
Post Construction Radon Flux Monitoring		$	26,000
Stormwater Monitoring during Construction		$	588,000
Air Monitoring during Construction		$	2,205,000
Institutional Controls		$	50,000
Subtotal		$	229,316,000
Project Management	5%	$	11,466,000
Engineering Design	6%	$	13,759,000
Construction Management	6%	$	13,759,000
Subtotal - Construction On-Site		$	268,300,000
Off-site Transportation and Disposal (@229/lcy)		$	102,000,000
Subtotal - Transport/Disposal Off-site		$	102,000,000
Contingencies:			
Scope (construction onsite)	55%	$	147,565,000
Scope (transport/disposal offsite)	15%	$	15,300,000
Bid (all activities)	20%	$	74,060,000
Subtotal - Contingency		$	236,930,000
Other Requirements:			
Buy-out Asphalt Plant Lease		$	3,200,000
Permitting for Relocation of Transfer Station		$	500,000
Relocate Transfer Station		$	5,260,000
Subtotal - Other Requirements		$	8,960,000
Total: Complete Rad Removal (7.9 pCi/g)	Remedy	$	616,000,000

Estimated Length Construction	3/5/18	start
	4/2/30	end
	4,411	no. Days
	12.1	no. Years
	49	no. Quarters

Capital Cost Estimate - Long-Term Monitoring
Complete Rad Removal (7.9 pCi/g) Remedy Alternative

Description	Quantity	Units	Unit Rate	Estimated Cost ($)
Secure easements	1	LS	5,000	5,000
Landfill Gas:				
Driller: Install radon/landfill gas monitoring probes, MDNR "Code Wells"; 10' deep	31	each	2,000	62,000
Misc. wellhead sampling fittings and locks	31	each	40	1,200
Field technician observation during drilling and construction of probes (4/day)	64	hour	90	5,800
Mileage for field technician during probe construction	400	mile	0.54	200
Multi-gas detector (e.g., Industrial Scientific iBrid ™ MX6), incl regulator, tubing, calbrtn gas	1	LS	4,806	4,800
Portable radon gas monitor and detector (e.g., Pylon AB6 monitor w/ 300A detector)	1	LS	9,075	9,100
Groundwater:				
Construction of new groundwater monitoring wells	12	each	10,000	120,000
Flat-bottom polyethylene tank to store purge water prior to disposal	1,500	gallon	2	3,000
Estimated Long-term Monitoring Capital Costs - Total				**211,000**

Post-Construction Radon Flux Monitoring Cost Estimate
Complete Rad Removal (7.9 pCi/g) Remedy Alternative

Description	Quantity	Units	Unit Rate	Estimated Cost ($)
Radon Flux (once after cover construction is complete):				
Number of Monitoring Locatons (assume same as post-NCC program):	*130*			
Surveying of locations	1	day	1,500	1,500
Auxier labor	1	LS	6,345	6,350
Per diem	2	each	1,190	2,380
Airfare and vehicle rental	2	each	1,000	2,000
Overnight shipping to lab	1	LS	1,200	1,200
Lab analysis (Eberline)	1	LS	11,050	11,050
Data validation and management	1	each	1,000	1,000
Reporting	4	hour	150	600
Estimated Post-Construction Radon Flux Monitoring Costs - Total				**26,000**

Stormwater and Air Monitoring During Construction Cost Estimates
Complete Rad Removal (7.9 pCi/g) Remedy Alternative

Description	Analytical Methc	Quantity	Units	Unit Rate ($)	Estimated Cost ($)
Stormwater Monitoring and Inspection (Quarterly - only during remedy construction					
4 sampling locations					
1 field duplicate					
5 total samples					
Sampling and Inspection (Feezor Engineering estimate)		1	LS	5,000	5,000
Laboratory Analysis:					
Eberline (T-uranium, iso-uranium, iso-thorium, gross alpha/beta, Ra-226, Ra-228)		1	LS	2,325	2,330
TekLab (all other parameters)		1	LS	2,743	2,740
Data validation and management		1	LS	1,500	1,500
Reporting		4	hour	150	600
Estimated Quarterly Stormwater Monitoring and Inspection Costs - Total					**12,000**
Air Monitoring during Construction					
13 air monitoring stations and one MET station					
Auxier & Associates FY2016 Air Monitoring Program Estimate (minus contingency)		1	LS	172,852	172,900
Data validation		1	LS	6,800	6,800
Power costs (13 stations plus one MET station; $10/month per station)		12	months	140	1,700
Estimated Air Monitoring during Construction Costs - Annual Total					181,000
Estimated Quarterly Air Monitoring Costs during Construction (assuming annual costs divided by 4					**45,000**

Capital Cost Estimate - Amend Existing/Additional Institutional Controls
Complete Rad Removal (7.9 pCi/g) Remedy Alternative

Description	Quantity	Units	Unit Rate	Estimated Cost
Prepare Institutional Controls planning documents	1	LS	10,000	10,000
Attorney labor: prepare draft amended existing and additional ICs	1	LS	20,000	20,000
Review of draft documents	1	LS	5,000	5,000
Revise amended and additional Institutional Controls documents	1	LS	10,000	10,000
Filings and registrations	1	LS	5,000	5,000
Estimated Institutional Controls Capital Costs - Total				**50,000**

Long-Term Post-Construction Monitoring (per event) Cost Estimate
Complete Rad Removal (7.9 pCi/g) Remedy Alternative

(Landfill Gas/Radon, Groundwater Monitoring and Annual Post-Construction Site Inspections)

Description	Analytical Method	Quantity	Units	Unit Rate ($)	Estimated Cost ($)
Landfill Gas/Radon (quarterly after contruction complete):					
Number of Landfill Gas/Radon Monitoring Wells		*31*			
Labor - field technician		9	hour	90	810
Field vehicle		1	day	120	120
Replacement radon detector (Pylon 300A)		1	each	550	550
Calibration gas for multi-gas detector		1	each	449	450
Data management		2	hour	100	200
Reporting		8	hour	150	1,200
Estimated Landfill Gas/Radon Monitoring Costs - Subtotal					3,300
Contingency			*%*	*20*	*700*
Estimated Landfill Gas/Radon Monitoring Costs - Total (per Event)					**4,000**

Description	Analytical Method	Quantity	Units	Unit Rate ($)	Estimated Cost ($)
Groundwater (semi-annual first 5 years after construction; annually thereafter):					
Number of Samples:			*For VOCs*		
Investigative Groundwater (5, 3-wells clusters in Area 2; 3, 3-well clusters in Area 1)		*24*	*24*		
Field Duplicates (one per every 10 investigative samples)		*3*	*3*		
Trip blank (one per day per cooler)			*15*		
Matrix Spike			*1*		
Matrix Spike Duplicate			*1*		
Sub-total number of unfiltered samples:		*27*	*44*		
Sub-total number of filtered samples for radionuclide and metals analyses:		*27*			
Total number of samples:		*54*	*44*		
Labor:					
Labor - field technicians (assume 2 people, 5 days, 10-hr days)		100	hour	90	9,000
Materials and equipment:					
Sample kits, incl. filters		24	each	50	1,200
Field instrumentation and flowcell rental - groundwater		5	day	100	500
Field Vehicle		5	day	120	600
Overnight shipping of sample coolers (assume 1 per day to rad lab)		5	coolers	100	500
Delivery of sample coolers to local lab (2 to 3 coolers per day)		5	hour	90	450
Disposal of purge water (assumes PE tank previously purchased is onsite):					
Vacuum truck		4	hour	200	800
Transportation and disposal (assumes approx 25 gal per well per event)		600	gallon	2.00	1,200
Laboratory Sample Analysis:	*Analytical Method:*				
Gross alpha and beta	EPA 900.0	54	each	50	2,700
Total Uranium		54	each	65	3,510

Estimated Non-discounted Capital Costs: 616,000,000

Estimated Non-discounted Total Costs: 619,000,000

Estimated 30-year Present Worth Costs: 420,000,000

The information in this cost estimate summary is based on the best available information regarding the anticipated scope of the remedial alternative. Changes in the cost elements are likely to occur as a result of new information and data collected during the engineering design of the remedial alternative. In accordance with USEPA Guidance, this is an order-of-magnitude engineering estimate that is expected to be within -30 to +50 percent of the actual project cost.

Estimated Non-discounted Capital Costs: 616,000,000

Estimated Non-discounted Total Costs: 649,000,000

Estimated 200-year Present Worth Costs: 573,000,000

The information in this cost estimate summary is based on the best available information regarding the anticipated scope of the remedial alternative. Changes in the cost elements are likely to occur as a result of new information and data collected during the engineering design of the remedial alternative. In accordance with USEPA Guidance, this is an order-of-magnitude engineering estimate that is expected to be within -30 to +50 percent of the actual project cost.

Estimated Non-discounted Capital Costs: 616,000,000

Estimated Non-discounted Total Costs: 788,000,000

Estimated 1,000-year Present Worth Costs: 573,000,000

The information in this cost estimate summary is based on the best available information regarding the anticipated scope of the remedial alternative. Changes in the cost elements are likely to occur as a result of new information and data collected during the engineering design of the remedial alternative. In accordance with USEPA Guidance, this is an order-of-magnitude engineering estimate that is expected to be within -30 to +50 percent of the actual project cost.

Appendix K-5

Cost Estimates for the Partial Excavation of Shallow RIM with Activities above 52.9 pCi/g Alternative

DRAFT

Preliminary Estimated Capital Costs
Complete Rad Removal (52.9 pCi/g) Remedy Alternative

Cost Item		Estimated Capital Costs
Construction Costs		$ 89,520,000
Radiological Survey/H&S Support Costs		$ 19,439,000
On-site Rad Laboratory		$ 596,000
Long-Term Monitoring Facilities		$ 211,000
Post Construction Radon Flux Monitoring		$ 26,000
Stormwater Monitoring during Construction		$ 228,000
Air Monitoring during Construction		$ 855,000
Institutional Controls		$ 50,000
Subtotal		$ 110,925,000
Project Management	5%	$ 5,546,000
Engineering Design	6%	$ 6,656,000
Construction Management	6%	$ 6,656,000
Subtotal - Construction On-Site		$ 129,780,000
Off-site Transportation and Disposal (@229/lcy)		$ 56,900,000
Subtotal - Transport/Disposal Off-site		$ 56,900,000
Contingencies:		
Scope (construction onsite)	55%	$ 71,379,000
Scope (transport/disposal offsite)	15%	$ 8,535,000
Bid (all activities)	20%	$ 37,336,000
Subtotal - Contingency		$ 117,250,000
Other Requirements:		
Buy-out Asphalt Plant Lease		$ 3,200,000
Permitting for Relocation of Transfer Station		$ 500,000
Relocate Transfer Station		$ 5,260,000
Subtotal - Other Requirements		$ 8,960,000
Total: 52.9 pCi/g Partial Excavation Remedy		$ 313,000,000

Estimated Length Construction	3/5/18	start
	9/22/22	end
	1,662	no. Days
	4.6	no. Years
	19	no. Quarters

DRAFT

Capital Cost Estimate - Long-Term Monitoring
Complete Rad Removal (52.9 pCi/g) Remedy Alternative

Description	Quantity	Units	Unit Rate	Estimated Cost ($)
Secure easements	1	LS	5,000	5,000
Landfill Gas:				
Driller: Install radon/landfill gas monitoring probes, MDNR "Code Wells"; 10' deep	31	each	2,000	62,000
Misc. wellhead sampling fittings and locks	31	each	40	1,200
Field technician observation during drilling and construction of probes (4/day)	64	hour	90	5,800
Mileage for field technician during probe construction	400	mile	0.54	200
Multi-gas detector (e.g., Industrial Scientific iBrid™ MX6), incl regulator, tubing, calbrtn gas	1	LS	4,806	4,800
Portable radon gas monitor and detector (e.g., Pylon AB6 monitor w/ 300A detector	1	LS	9,075	9,100
Groundwater:				
Construction of new groundwater monitoring wells	12	each	10,000	120,000
Flat-bottom polyethylene tank to store purge water prior to disposa	1,500	gallon	2	3,000
Estimated Long-term Monitoring Capital Costs - Total				**211,000**

DRAFT

Post-Construction Radon Flux Monitoring Cost Estimate
Complete Rad Removal (52.9 pCi/g) Remedy Alternative

Description	Quantity	Units	Unit Rate	Estimated Cost ($)
Radon Flux (once after cover construction is complete):				
Number of Monitoring Locatons (assume same as post-NCC program):	*130*			
Surveying of locations	1	day	1,500	1,500
Auxier labor	1	LS	6,345	6,350
Per diem	2	each	1,190	2,380
Airfare and vehicle rental	2	each	1,000	2,000
Overnight shipping to lab	1	LS	1,200	1,200
Lab analysis (Eberline)	1	LS	11,050	11,050
Data validation and management	1	each	1,000	1,000
Reporting	4	hour	150	600
Estimated Post-Construction Radon Flux Monitoring Costs - Total				**26,000**

Stormwater and Air Monitoring During Construction Cost Estimates
Complete Rad Removal (52.9 pCi/g) Remedy Alternative

Description	Quantity	Units	Unit Rate ($)	Estimated Cost ($)
Stormwater Monitoring and Inspection (Quarterly - only during remedy construction				
4 sampling locations				
1 field duplicate				
5 total samples				
Sampling and Inspection (Feezor Engineering estimate)	1	LS	5,000	5,000
Laboratory Analysis:				
Eberline (T-uranium, iso-uranium, iso-thorium, gross alpha/beta, Ra-226, Ra-228)	1	LS	2,325	2,330
TekLab (all other parameters)	1	LS	2,743	2,740
Data validation and management	1	LS	1,500	1,500
Reporting	4	hour	150	600
Estimated Quarterly Stormwater Monitoring and Inspection Costs - Total				**12,000**
Air Monitoring during Construction				
13 air monitoring stations and one MET station				
Auxier & Associates FY2016 Air Monitoring Program Estimate (minus contingency)	1	LS	172,852	172,900
Data validation	1	LS	6,800	6,800
Power costs (13 stations plus one MET station; $10/month per station)	12	months	140	1,700
Estimated Air Monitoring during Construction Costs - Annual Total				181,000
Estimated Quarterly Air Monitoring Costs during Construction (assuming annual costs divided by 4				**45,000**

DRAFT

Capital Cost Estimate - Amend Existing/Additional Institutional Controls
Complete Rad Removal (52.9 pCi/g) Remedy Alternative

Description	Quantity	Units	Unit Rate	Estimated Cost
Prepare Institutional Controls planning documents	1	LS	10,000	10,000
Attorney labor: prepare draft amended existing and additional ICs	1	LS	20,000	20,000
Review of draft documents	1	LS	5,000	5,000
Revise amended and additional Institutional Controls documents	1	LS	10,000	10,000
Filings and registrations	1	LS	5,000	5,000
Estimated Institutional Controls Capital Costs - Total				**50,000**

DRAFT

Long-Term Post-Construction Monitoring (per event) Cost Estimate
Complete Rad Removal (52.9 pCi/g) Remedy Alternative

(Landfill Gas/Radon, Groundwater Monitoring and Annual Post-Construction Site Inspections)

Description	Analytical Method	Quantity	Units	Unit Rate ($)	Estimated Cost ($)
Landfill Gas/Radon (quarterly after contruction complete):					
Number of Landfill Gas/Radon Monitoring Wells		*31*			
Labor - field technician		9	hour	90	810
Field vehicle		1	day	120	120
Replacement radon detector (Pylon 300A)		1	each	550	550
Calibration gas for multi-gas detector		1	each	449	450
Data management		2	hour	100	200
Reporting		8	hour	150	1,200
Estimated Landfill Gas/Radon Monitoring Costs - Subtotal					3,300
Contingency			*%*	*20*	*700*
Estimated Landfill Gas/Radon Monitoring Costs - Total (per Event)					**4,000**

Description	Analytical Method	Quantity	Units	Unit Rate ($)	Estimated Cost ($)
Groundwater (semi-annual first 5 years after construction; annually thereafter):					
Number of Samples:			*For VOCs*		
Investigative Groundwater (5, 3-wells clusters in Area 2; 3, 3-well clusters in Area 1)		*24*	*24*		
Field Duplicates (one per every 10 investigative samples)		*3*	*3*		
Trip blank (one per day per cooler)			*15*		
Matrix Spike			*1*		
Matrix Spike Duplicate			*1*		
Sub-total number of unfiltered samples:		*27*	*44*		
Sub-total number of filtered samples for radionuclide and metals analyses:		*27*			
Total number of samples:		*54*	*44*		
Labor:					
Labor - field technicians (assume 2 people, 5 days, 10-hr days)		100	hour	90	9,000
Materials and equipment:					
Sample kits, incl. filters		24	each	50	1,200
Field instrumentation and flowcell rental - groundwater		5	day	100	500
Field Vehicle		5	day	120	600
Overnight shipping of sample coolers (assume 1 per day to rad lab)		5	coolers	100	500
Delivery of sample coolers to local lab (2 to 3 coolers per day)		5	hour	90	450
Disposal of purge water (assumes PE tank previously purchased is onsite):					
Vacuum truck		4	hour	200	800
Transportation and disposal (assumes approx 25 gal per well per event)		600	gallon	2.00	1,200
Laboratory Sample Analysis:	*Analytical Method:*				
Gross alpha and beta	EPA 900.0	54	each	50	2,700
Total Uranium		54	each	65	3,510

Estimated Non-discounted Capital Costs: 313,000,000

Estimated Non-discounted Total Costs: 318,000,000

Estimated 30-year Present Worth Costs: 265,000,000

The information in this cost estimate summary is based on the best available information regarding the anticipated scope of the remedial alternative. Changes in the cost elements are likely to occur as a result of new information and data collected during the engineering design of the remedial alternative. In accordance with USEPA Guidance, this is an order-of-magnitude engineering estimate that is expected to be within -30 to +50 percent of the actual project cost.

Estimated Non-discounted Capital Costs: 313,000,000

Estimated Non-discounted Total Costs: 348,000,000

Estimated 200-year Present Worth Costs: 265,000,000

The information in this cost estimate summary is based on the best available information regarding the anticipated scope of the remedial alternative. Changes in the cost elements are likely to occur as a result of new information and data collected during the engineering design of the remedial alternative. In accordance with USEPA Guidance, this is an order-of-magnitude engineering estimate that is expected to be within -30 to +50 percent of the actual project cost.

Estimated Non-discounted Capital Costs: 313,000,000

Estimated Non-discounted Total Costs: 487,000,000

Estimated 1,000-year Present Worth Costs: 312,000,000

The information in this cost estimate summary is based on the best available information regarding the anticipated scope of the remedial alternative. Changes in the cost elements are likely to occur as a result of new information and data collected during the engineering design of the remedial alternative. In accordance with USEPA Guidance, this is an order-of-magnitude engineering estimate that is expected to be within -30 to +50 percent of the actual project cost.

Appendix K-6

Cost Estimates for the Partial Excavation of RIM with Activities above 1,000 pCi/g Alternative

DRAFT

Preliminary Estimated Capital Costs
1,000 pCi/g Remedy Alternative

Cost Item			Estimated Capital Costs
Construction Costs		$	123,260,000
Radiological Survey/H&S Support Costs		$	36,121,000
On-site Rad Laboratory		$	857,000
Long-Term Monitoring Facilities		$	211,000
Post Construction Radon Flux Monitoring		$	26,000
Stormwater Monitoring during Construction		$	372,000
Air Monitoring during Construction		$	1,395,000
Institutional Controls		$	50,000
Subtotal		$	162,292,000
Project Management	5%	$	8,115,000
Engineering Design	6%	$	9,738,000
Construction Management	6%	$	9,738,000
Subtotal - Construction On-Site		$	189,880,000
Off-site Transportation and Disposal (@229/lcy)		$	14,400,000
Subtotal - Transport/Disposal Off-site		$	14,400,000
Contingencies:			
Scope (construction onsite)	55%	$	104,434,000
Scope (transport/disposal offsite)	15%	$	2,160,000
Bid (all activities)	20%	$	40,856,000
Subtotal - Contingency		$	147,450,000
Other Requirements:			
Buy-out Asphalt Plant Lease		$	3,200,000
Permitting for Relocation of Transfer Station		$	500,000
Relocate Transfer Station		$	5,260,000
Subtotal - Other Requirements		$	8,960,000
Total: Complete Rad Removal (7.9 pCi/g) Remedy		$	361,000,000

Estimated Length Construction	3/5/18	start
	11/6/25	end
	2,803	no. Days
	7.7	no. Years
	31	no. Quarters

DRAFT

Capital Cost Estimate - Long-Term Monitoring
1,000 pCi/g Remedy Alternative

Description	Quantity	Units	Unit Rate	Estimated Cost ($)
Secure easements	1	LS	5,000	5,000
Landfill Gas:				
Driller: Install radon/landfill gas monitoring probes, MDNR "Code Wells"; 10' deep	31	each	2,000	62,000
Misc. wellhead sampling fittings and locks	31	each	40	1,200
Field technician observation during drilling and construction of probes (4/day)	64	hour	90	5,800
Mileage for field technician during probe construction	400	mile	0.54	200
Multi-gas detector (e.g., Industrial Scientific iBrid™ MX6), incl regulator, tubing, calbrtn gas	1	LS	4,806	4,800
Portable radon gas monitor and detector (e.g., Pylon AB6 monitor w/ 300A detector)	1	LS	9,075	9,100
Groundwater:				
Construction of new groundwater monitoring wells	12	each	10,000	120,000
Flat-bottom polyethylene tank to store purge water prior to disposal	1,500	gallon	2	3,000
Estimated Long-term Monitoring Capital Costs - Total				**211,000**

DRAFT

Post-Construction Radon Flux Monitoring Cost Estimate
1,000 pCi/g Remedy Alternative

Description	Quantity	Units	Unit Rate	Estimated Cost ($)
Radon Flux (once after cover construction is complete):				
Number of Monitoring Locatons (assume same as post-NCC program):	*130*			
Surveying of locations	1	day	1,500	1,500
Auxier labor	1	LS	6,345	6,350
Per diem	2	each	1,190	2,380
Airfare and vehicle rental	2	each	1,000	2,000
Overnight shipping to lab	1	LS	1,200	1,200
Lab analysis (Eberline)	1	LS	11,050	11,050
Data validation and management	1	each	1,000	1,000
Reporting	4	hour	150	600
Estimated Post-Construction Radon Flux Monitoring Costs - Total				**26,000**

DRAFT

Stormwater and Air Monitoring During Construction Cost Estimates
1,000 pCi/g Remedy Alternative

Description	Analytical Method	Quantity	Units	Unit Rate ($)	Estimated Cost ($)
Stormwater Monitoring and Inspection (Quarterly - only during remedy construction)					
4 sampling locations					
1 field duplicate					
5 total samples					
Sampling and Inspection (Feezor Engineering estimate)		1	LS	5,000	5,000
Laboratory Analysis:					
Eberline (T-uranium, iso-uranium, iso-thorium, gross alpha/beta, Ra-226, Ra-228)		1	LS	2,325	2,330
TekLab (all other parameters)		1	LS	2,743	2,740
Data validation and management		1	LS	1,500	1,500
Reporting		4	hour	150	600
Estimated Quarterly Stormwater Monitoring and Inspection Costs - Total					**12,000**
Air Monitoring during Construction					
13 air monitoring stations and one MET station					
Auxier & Associates FY2016 Air Monitoring Program Estimate (minus contingency)		1	LS	172,852	172,900
Data validation		1	LS	6,800	6,800
Power costs (13 stations plus one MET station; $10/month per station)		12	months	140	1,700
Estimated Air Monitoring during Construction Costs - Annual Total					181,000
Estimated Quarterly Air Monitoring Costs during Construction (assuming annual costs divided by 4)					**45,000**

DRAFT

Capital Cost Estimate - Amend Existing/Additional Institutional Controls
1,000 pCi/g Remedy Alternative

Description	Quantity	Units	Unit Rate	Estimated Cost
Prepare Institutional Controls planning documents	1	LS	10,000	10,000
Attorney labor: prepare draft amended existing and additional ICs	1	LS	20,000	20,000
Review of draft documents	1	LS	5,000	5,000
Revise amended and additional Institutional Controls documents	1	LS	10,000	10,000
Filings and registrations	1	LS	5,000	5,000
Estimated Institutional Controls Capital Costs - Total				**50,000**

DRAFT

Long-Term Post-Construction Monitoring (per event) Cost Estimate
1,000 pCi/g Remedy Alternative

(Landfill Gas/Radon, Groundwater Monitoring and Annual Post-Construction Site Inspections)

Description	Analytical Method	Quantity	Units	Unit Rate ($)	Estimated Cost ($)
Landfill Gas/Radon (quarterly after contruction complete):					
Number of Landfill Gas/Radon Monitoring Wells		*31*			
Labor - field technician		9	hour	90	810
Field vehicle		1	day	120	120
Replacement radon detector (Pylon 300A)		1	each	550	550
Calibration gas for multi-gas detector		1	each	449	450
Data management		2	hour	100	200
Reporting		8	hour	150	1,200
Estimated Landfill Gas/Radon Monitoring Costs - Subtotal					3,300
Contingency			*%*	*20*	*700*
Estimated Landfill Gas/Radon Monitoring Costs - Total (per Event)					**4,000**

Description	Analytical Method	Quantity	Units	Unit Rate ($)	Estimated Cost ($)
Groundwater (semi-annual first 5 years after construction; annually thereafter):					
Number of Samples:			*For VOCs*		
Investigative Groundwater (5, 3-wells clusters in Area 2; 3, 3-well clusters in Area 1)		*24*	*24*		
Field Duplicates (one per every 10 investigative samples)		*3*	*3*		
Trip blank (one per day per cooler)			*15*		
Matrix Spike			*1*		
Matrix Spike Duplicate			*1*		
Sub-total number of unfiltered samples:		*27*	*44*		
Sub-total number of filtered samples for radionuclide and metals analyses:		*27*			
Total number of samples:		*54*	*44*		
Labor:					
Labor - field technicians (assume 2 people, 5 days, 10-hr days)		100	hour	90	9,000
Materials and equipment:					
Sample kits, incl. filters		24	each	50	1,200
Field instrumentation and flowcell rental - groundwater		5	day	100	500
Field Vehicle		5	day	120	600
Overnight shipping of sample coolers (assume 1 per day to rad lab)		5	coolers	100	500
Delivery of sample coolers to local lab (2 to 3 coolers per day)		5	hour	90	450
Disposal of purge water (assumes PE tank previously purchased is onsite):					
Vacuum truck		4	hour	200	800
Transportation and disposal (assumes approx 25 gal per well per event)		600	gallon	2.00	1,200
Laboratory Sample Analysis:	*Analytical Method:*				
Gross alpha and beta	EPA 900.0	54	each	50	2,700
Total Uranium		54	each	65	3,510
Iso-Uranium-234, 235, 238	EML U-02 Mod	54	each	100	5,400
Iso-Thorium-228, 230, 232	EML Th-01 Mod	54	each	100	5,400
Radium 228	EPA 904.0	54	each	75	4,050
Radium 226	EPA 903.0 Mod	54	each	75	4,050
Radon 222 - 72 hr hold time	SM 20th ED 7500-Rn B	54	each	85	4,590
Volatile Organic Compounds [VOCs] (GC/MS)	8260B	44	each	110	4,840
Semivolatile Organic Compounds [SVOCs] (GC/MS)	8270C	54	each	220	11,880
22 Metals Target Analyte List (ICP/AES)	6010B	54	each	115	6,210
Mercury (CVAA)	7470A	54	each	35	1,890
4 Anions (IC) - Bromide, Chloride, Fluoride, Sulfate	300.0	54	each	72	3,890
2 Anions (IC) - Nitrate, Nitrite - 48 hr hold time	300.0	54	each	36	1,940
Sulfide, Total	SM 4500 S2 D	54	each	35	1,890
Phosphorus, Total	365.1	54	each	40	2,160
Organic carbon, Total (TOC)	SM 5310B	54	each	40	2,160
Total Alkalinity, Carbonate, Bicarbonate	SM 2320B	54	each	20	1,080
Nitrogen, Ammonia	350.1	54	each	25	1,350
Level IV data deliverable		$ 68,990	%	10%	6,900
Data validation (assumes validation of 100% of Level IV data will be required)		1	LS	6,600	6,600
Data management		7	SDG	100	700
Reporting		40	hour	150	6,000
Estimated Groundwater Monitoring Costs - Subtotal					103,400
Contingency			*%*	*20*	*20,700*
Estimated Groundwater Monitoring Costs - Total (per Event)					**124,000**

DVR = data validation report
SDG = sample delivery group

Description	Analytical Method	Quantity	Units	Unit Rate ($)	Estimated Cost ($)
Annual Post-Construction Site Inspections					
Labor - Engineer		9	hour	130	1,170
Field vehicle		1	day	120	120
Site Inspection Report		4	hour	130	520
Estimated Annual Post-Construction Site Inspections Costs - Subtotal					1,800
Contingency			*%*	*20*	*400*
Estimated Annual Post-Construction Site Inspections Costs - Total					**2,200**

DRAFT

Operation and Maintenance Cost Estimate - Annual Cover System Maintenance
1,000 pCi/g Remedy Alternative

Description	Quantity	Units	Unit Rate	Estimated Cost
Mowing; tractor w/ rotary mower (once/year)	55.3	acre	40.00	2,200
Fill depressions in cover w/ topsoil, assume 1% of area; 6 inches deep	446	bcy	37.53	16,700
Seeding of filled area	24.1	M.S.F.	66.04	1,600
Estimated Cover System O&M Costs - Subtotal				20,500
Contingency		*%*	*20*	*4,100*
Estimated Annual Cover Maintenance O&M Costs - Total				**25,000**

M.S.F. = 1,000 square feet

DRAFT

Periodic Cost Estimate - 5 year Review
1,000 pCi/g Remedy Alternative

Description	Quantity	Units	Unit Rate	Estimated Cost ($)
Access Restrictions (inspect/repair fencing and signage)	16	hours	150	2,400
Institutional Controls verification	8	hours	150	1,200
Document that landfill cover is effective	8	hours	150	1,200
Assemble Monitoring Data (landfill gas/radon, groundwater, surface water)	40	hours	150	6,000
Summarize Annual Post-Construction Site Inspections	8	hours	150	1,200
Summarize Annual Cover Maintenance Documentation	8	hours	150	1,200
Water supply well inventory review	8	hours	150	1,200
Document any changes in Land Use at and around West Lake Landfill	16	hours	150	2,400
Prepare Summary Report	80	hours	150	12,000
Estimated 5-year Maint/Review O&M Costs - Subtotal				**29,000**
Contingency		*%*	*20*	*6,000*
Estimated 5-year Maintenance O&M Costs - Total				**35,000**

Estimated Non-discounted Capital Costs: 361,000,000

Estimated Non-discounted Total Costs: 365,000,000

Estimated 30-year Present Worth Costs: 275,000,000

The information in this cost estimate summary is based on the best available information regarding the anticipated scope of the remedial alternative. Changes in the cost elements are likely to occur as a result of new information and data collected during the engineering design of the remedial alternative. In accordance with USEPA Guidance, this is an order-of-magnitude engineering estimate that is expected to be within -30 to +50 percent of the actual project cost.

The information in this cost estimate summary is based on the best available information regarding the anticipated scope of the remedial alternative. Changes in the cost elements are likely to occur as a result of new information and data collected during the engineering design of the remedial alternative. In accordance with USEPA Guidance, this is an order-of-magnitude engineering estimate that is expected to be within -30 to +50 percent of the actual project cost.

Estimated Non-discounted Capital Costs: 361,000,000

Estimated Non-discounted Total Costs: 534,000,000

Estimated 1,000-year Present Worth Costs: 350,000,000

The information in this cost estimate summary is based on the best available information regarding the anticipated scope of the remedial alternative. Changes in the cost elements are likely to occur as a result of new information and data collected during the engineering design of the remedial alternative. In accordance with USEPA Guidance, this is an order-of-magnitude engineering estimate that is expected to be within -30 to +50 percent of the actual project cost.

Memorandum

Date: December 15, 2016

From: Matthew J. Tonkin, SSP&A

To: Paul Rosasco, EMSI

Subject: Estimates of Average Combined Radium and Combined Thorium Concentrations

In support of the risk assessment (FFS Appendix H) and comparison of radiologically impacted material (RIM) activity levels to the Waste Acceptance Criteria (WAC) of the various off-site disposal facilities, estimates were required of the average concentrations of combined Radium and of combined Thorium in landfilled material in OU-1 Areas 1 and 2 that would need to be handled or disposed of under the various remedy alternatives considered. These averages were estimated by post-processing the results of the previously-completed three-dimensional (3D) indicator kriging (IK) that is detailed in the report "*Estimated Three-Dimensional Extent of Radiologically Impacted Material, West Lake Landfill, Operable Unit 1, Bridgeton, Missouri*" ("RIM mapping report", SSP&A, September 2016: FFS Appendix B). The materials that would need to be handled under the various remedy alternatives include RIM and any associated landfill material together with overburden and any additional material removed as required for safe setback during excavation. Estimates of average concentrations were required for:

1. All materials that would be handled (*i.e.*, RIM with associated landfill materials, vertical overburden and setback), in consideration of the risk posed to workers during remedy implementation ("all material").
2. RIM only, to evaluate estimated activity levels relative to the WAC of the various disposal facilities ("RIM only").

The 3D IK calculations described in the RIM mapping report were completed to estimate the extent of landfill material that would exceed four concentration thresholds (*i.e.*, 7.9, 52.9, 500 and 1,000 pCi/g) for combined Thorium *or* combined Radium. Calculations of "all material" and "RIM only" averages presented here were made for the following five potential remedy alternatives:

1. Excavation of Areas 1 and 2 to remove RIM exhibiting combined Radium *or* combined Thorium concentrations greater than 7.9 pCi/g (the "complete rad removal" alternative);
2. Partial excavation of Areas 1 and 2 to remove RIM exhibiting combined Radium *or* combined Thorium concentrations greater than 52.9 pCi/g present within 16 feet of the 2005 ground surface;
3. Partial excavation of Areas 1 and 2 to remove RIM exhibiting combined Radium *or* combined Thorium concentrations greater than 500 pCi/g;
4. Partial excavation of Areas 1 and 2 to remove RIM exhibiting combined Radium *or* combined Thorium concentrations greater than 1,000 pCi/g; and

5. The ROD-selected remedy, which would involve regrading of Areas 1 and 2, thus necessitating handling of some RIM and some non-RIM.

Alternative (3) is an intermediate between (2) and (4) that was not specifically evaluated in the FFS or risk assessment, but is included here for completeness and consistency with the results presented in the RIM mapping report.

Output files from the 3D IK calculations do not specifically list concentrations of combined Thorium or combined Radium; rather, they list probabilities as to whether the concentration thresholds are or are not exceeded, from which concentrations can be estimated. For each OU-1 Area, two sets of outputs from the 3D IK RIM mapping were used to estimate average concentrations for the potential alternatives listed above. The first group of outputs comprises two files: one file for combined Radium and one file for combined Thorium. Each of these files lists, for each location in the 3D grid, a conditional cumulative density function (CCDF) describing the probability of non-exceedance for each concentration threshold. An example CCDF is shown below:

Threshold (pCi/g)	Non-Exceedance Probability
7.9	0.49
52.9	0.96
500	0.98
1,000	0.99

The interpolated values between 0 and 1 can be interpreted as probabilities. In the simplest case of a single concentration threshold, the value of 0.50 is then often used distinguish between regions that likely exceed the concentration threshold of interest (i.e., the interpolated probability is >0.50) or fall below that threshold (i.e., the interpolated probability is <0.50). In the case of multiple concentration thresholds, if the 0.50 probability lies between two thresholds, the likely concentration is constrained and can be estimated using the non-exceedance probabilities for the two thresholds that bound the 0.50 probability. In this example, the concentration likely lies above 7.9 and below 52.9 pCi/g, and can be estimated assuming a linear or a semi-logarithmic relation between concentration and probability. In this case, the difference in the concentration estimates is small (8.6 pCi/g, assuming a linear relation versus 8.2 pCi/g assuming a semi-logarithmic relation), because one of the two non-exceedance probabilities is very close to 0.50. If the 0.50 probability lies below the lowest threshold or above the highest threshold, the likely concentration lies outside these thresholds and estimation requires interpolation bounds at these "tails" (*e.g.*, Goovaerts, 1997; Pyrcz and Deutsch, 2014). In all calculations here, the lower interpolation bound was set at 0.1 pCi/g and the upper interpolation bound was set at the median value of the sample concentrations that exceed the upper threshold, which reduces the leverage of the small number of very high concentration sample results when estimating averages. In all cases, concentration was assumed to vary linearly with probability between concentration thresholds or interpolation bounds.

The above calculations provide estimates of the combined Radium and combined Thorium concentrations for each 3D IK grid block. To obtain the average concentration for "all material" that would be handled and for the "RIM only" material that would be handled under each of the five potential alternatives, each 3D IK grid block must be identified as either RIM, vertical overburden or setback. This was accomplished using the second group of 3D IK output files, comprising four files - one for each concentration threshold. This set of files contains integers (i.e., numeric flags) that identify whether each grid block is (a) RIM, (b) vertical overburden or (c) setback material assuming excavation of RIM at the corresponding concentration threshold. Any non-zero entry in any of these integer files represents a 3D IK block that would need to be removed under the corresponding alternative. For the first four potential remedy alternatives, the average concentration of combined Radium and combined Thorium was determined for each area by summing the concentrations estimated for all non-zero IK 3D blocks and dividing by the number of non-zero blocks. For the ROD remedy alternative, the average concentration of combined Radium and combined Thorium was determined for each Area by making the same calculation using only 3D IK blocks that lie above the corresponding ROD remedy top-of-waste elevation surface (provided by Feezor Engineering, Inc., in files "*SRF_ROD A1 top of waste.tif*" and "*SRF_ROD A2 top of waste.tif*" for Areas 1 and 2, respectively).

The average concentrations of combined Radium and combined Thorium estimated using this procedure for each of Area 1 and Area 2 for the five potential remedial alternatives are provided in Table L-1 ("All Material") and Table L-2 ("RIM Only"). The estimates obtained for the ROD remedy alternative – in particular for the "RIM only" scenario listed in Table L-2 – are subject to greater uncertainty than the estimates obtained for the other potential alternatives, because the ROD remedy alternative requires the handling of substantially (orders of magnitude) less material, much of which is at or close to the land surface and for which relatively few samples were available when the 3D IK RIM mapping was undertaken.

Table L-1 Summary of Average Concentrations (pCi/g): "All Material"

OU-1 Area	Constituent	*Linear Averages using Median Value for Upper Tail*				
		>7.9	**>52.9**	**>500**	**>1,000**	**ROD Remedy**
Area 1	Combined Thorium	52	250	65	76	5
Area 2	Combined Thorium	300	529	574	694	150
Area 1	Combined Radium	33	157	41	43	5
Area 2	Combined Radium	129	229	232	241	60

Table L-2 Summary of Average Concentrations (pCi/g): "RIM Only"

OU-1 Area	Constituent	*Linear Averages using Median Value for Upper Tail*				
		>7.9	**>52.9**	**>500**	**>1,000**	**ROD Remedy[1]**
Area 1	Combined Thorium	662	847	1,487	2,661	100
Area 2	Combined Thorium	856	1,184	2,191	4,111	750
Area 1	Combined Radium	401	526	841	1,192	100
Area 2	Combined Radium	362	507	807	1,025	310

Notes:

1 Estimates of the average concentration of combined Radium and combined Thorium for the ROD remedy alternative are subject to substantial uncertainty. See text for explanation.
