January 4, 2017

EXECUTIVE SUMMARY

This Final Feasibility Study (FFS) for Operable Unit-1 (OU-1) of the West Lake Landfill (the Site) was prepared at the direction of the U.S. Environmental Protection Agency (EPA) to present further evaluations of potential remedial alternatives to address the presence of radiologically impacted materials (RIM) contained within portions of some of the landfill units at the Site. This FFS was prepared in accordance with the requirements of the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), the National Oil and Hazardous Substances Pollution Contingency Plan (NCP), relevant EPA guidance documents (including, but not limited to, EPA's 1988 Guidance for Conducting Remedial Investigations and Feasibility Studies under CERCLA), the EPA's December 9, 2015 Statement of Work (SOW) for the RI Addendum and FFS, and the May 6, 2016 Abbreviated Work Plan for the RI Addendum and FFS.

The Site is a 200-acre, inactive solid waste disposal facility that accepted wastes for on-site landfilling from approximately the 1950s through 2005. OU-1 consists of two landfill disposal areas (Areas 1 and 2) and a 1.78-acre parcel of land known as the Buffer Zone/Crossroad Property where radionuclides have been identified within the soil and solid waste materials. Operable Unit-2 (OU-2) consists of the remainder of the Site, including areas never used for landfilling, several inactive fill areas containing sanitary waste or demolition debris (which were closed prior to state regulation), and a permitted, inactive sanitary landfill (the Bridgeton Landfill). This FFS does not address remedial options for the portions of the Site that comprise OU-2.

RIM at the Site consists of soils containing radium and thorium isotopes intermixed with and interspersed within an overall matrix of municipal solid waste (MSW) and non-radionuclide bearing soil in portions of two areas of the West Lake Landfill. These two areas have been identified as Areas 1 and 2 (Figure ES-1). Disposal of MSW within these areas ended in 1974, at which time MSW disposal was shifted to other portions of the Site. The original discontinuous nature of the placement of soil cover over the top of the uneven surface of the landfill waste during the period of active operations, the use of Site soil and quarry spoil material that did not contain radionuclides above background levels as cover material during the same period of time, and the waste decomposition, consolidation and differential settlement that occurred over the subsequent 40 years has resulted in the occurrences of radionuclides in soil being interspersed and intermixed within portions of the MSW in Areas 1 and 2. In addition, although the Buffer Zone/Crossroad property was never used for landfilling, radionuclides have been documented as being present on this portion of the Site – likely as a result of historical soil erosion from adjacent, sloped portions of Area 2. Additional information regarding the nature and extent of the occurrences of radionuclides and other aspects of the surface and subsurface conditions at the Site can be found in the 2000 Remedial Investigation (RI) and the 2016 RI Addendum.

Consistent with the NCP, a Remedial Investigation (RI) and Feasibility Study (FS) were previously completed for OU-1 and approved by the EPA in 2006. Based on those reports, EPA developed a Proposed Plan for OU-1 and, after an extended public comment process including three public meetings, issued a Record of Decision (ROD) in 2008. The ROD-selected remedy called for containment of the RIM and solid waste materials within a new multi-layered engineered landfill cover system, long-term operation and maintenance and environmental monitoring, and land use controls (including deed restrictions).

In January 2010, EPA directed Respondents to prepare a Supplemental Feasibility Study (SFS) for OU-1 to evaluate two additional potential remedial alternatives. Specifically, EPA directed the OU-1 Respondents to perform an updated engineering and cost analysis of the ROD-selected remedy, and to also conduct a similar analysis of two new alternatives to excavate all RIM in excess of a specified cleanup level from OU-1 and either send the excavated materials to a permitted, out-of-state landfill for disposal ("complete rad removal" with off-site disposal), or re-dispose of the excavated material in a new engineered landfill cell to be built within the boundaries of the Site ("complete rad removal" with on-site disposal)[1].

In December 2015, EPA directed Respondents to perform additional investigation and monitoring and to prepare an addendum to the RI, as well as this FFS, which expands on and augments the prior Supplemental Feasibility Study (SFS) completed in 2011 and the original Feasibility Study (FS) completed in 2006 (both of which were previously reviewed and approved by EPA) and evaluates additional remedial alternatives identified by EPA. Specifically, this FFS provides further evaluation of the containment remedy that was previously evaluated in the original FS and subsequently selected by EPA in 2008 as the remedial action for OU-1, as documented in the ROD (ROD-selected remedy). This FFS also presents additional evaluations of (1) the "complete rad removal" with off-site disposal alternative, which was one of two "complete rad removal" alternatives previously evaluated in the 2011 SFS; (2) a partial excavation alternative that would remove material containing either combined radium or combined thorium activities above 52.9 pCi/g and located within 16 feet of the 2005 topographic surface; and (3) a partial excavation alternative that would remove material containing either combined radium or combined thorium above 1,000 pCi/g, regardless of depth. The option to re-dispose the excavated material in an on-site engineered cell was previously removed from consideration by EPA, and therefore was not presented in the FFS. In accordance with the NCP, this FFS also includes discussion of a No Action Alternative (which operates as a baseline against which all the remedial alternatives are evaluated).

In this FFS, the remedial alternatives are evaluated using the nine criteria set forth in CERCLA and the NCP: two threshold criteria (1) overall protection of human health and the environment and; (2) compliance with applicable or relevant and appropriate requirements of other environmental regulations (ARARs); and five primary balancing criteria including (3) long-term effectiveness and permanence; (4) reduction of toxicity, mobility or volume through treatment; (5) short-term effectiveness; (6) implementability; and (7) cost. The two remaining criteria – State and community acceptance – will be evaluated by EPA as part of any future decision

[1] Although a "complete rad removal" with on-site disposal alternative was evaluated in the SFS, EPA did not require this alternative to be further evaluated in the FFS.

process. In addition to the nine CERCLA/NCP criteria, at EPA's direction the long-term effectiveness and permanence of each remedial alternative was evaluated relative to potential effects of climate change, potential impacts of a tornado, the potential impacts of a subsurface reaction, and potential construction of a thermal isolation barrier. At EPA's direction, environmental justice considerations relative to the long-term effectiveness and permanence of each alternative and potential short-term impacts associated with each remedial alternative were also evaluated.

Overall, the results of the FFS evaluations indicate the following:

1. Protection of Public Health and the Environment

   - All of the remedial alternatives -- the ROD-selected remedy, the "complete rad removal" with offsite disposal alternative, and the two partial excavation alternatives meet EPA's criteria for overall protection of human health and the environment.

   - The No Action alternative is not protective of human health and the environment (see the updated Baseline Risk Assessment (Auxier, 2016)).

2. Compliance with ARARs

   - All of the alternatives, except No Action, would comply with ARARs.

Because the No Action Alternative did not meet the threshold criteria of protection of public health and the environment and compliance with ARARs, it is not discussed as part of the evaluation of the primary balancing criteria below.

3. Long-Term Effectiveness and Permanence

   - With the exception of No Action, all of the remedial alternatives would result in long-term risks below the health risk range that EPA uses to assess the protectiveness of remedial alternatives at Superfund sites (see Table ES-1 and Appendix H).

   - All of the alternatives would rely on engineering measures and institutional controls that have been used and demonstrated as being effective and permanent at numerous municipal solid waste sites and other Superfund sites.

   - The effectiveness of the remedial alternatives is not expected to be significantly impacted by possible climate change or a tornado, and none of the remedial alternatives present adverse impacts or risks if a subsurface heating event were to occur or would be impacted by installation of a thermal isolation barrier, provided that such a barrier was installed prior to or concurrent with implementation of a remedial action.

   - A screening-level analysis did not identify any environmental justice concerns relative to the Site.

4. Reduction in Toxicity, Mobility or Volume Through Treatment

   - Because radionuclides are naturally-occurring elements that cannot be fully modified or destroyed by physical, chemical, or thermal processes, none of the alternatives include treatment technologies that would reduce the toxicity, mobility or volume through treatment as a primary component.

   - The excavation alternatives would reduce the volume of the materials left onsite.

   - All of the alternatives would reduce the mobility of the radionuclides.

5. Short-Term Effectiveness

   - None of the remedial alternatives are expected to pose risks to the general public above EPA's accepted risk range during remedy implementation (Table ES-1).

   - The short-term risks to on-site workers associated with the "complete rad removal" and partial excavation alternatives are projected to exceed EPA's acceptable risk range.

   - The ROD-selected remedy is not expected to pose risks to workers above EPA's generally accepted risk range, whereas, all of the excavation alternatives are projected to expose workers to unacceptable risks from exposure to chemicals; however, these risks may be mitigated through use of personal protective equipment and appropriate health and safety procedures.

   - None of the alternatives are expected to result in radiation doses to workers above the limits established by OSHA and NRC.

   - None of the alternatives are expected to result in measurable, long-term impacts to plants or animals.

   - The time required to achieve the RAOs would be shortest for the ROD-selected remedy, would take twice as long for the 52.9 partial excavation alternative compared to the ROD-selected remedy, three times as long for the 1,000 partial excavation alternative and five times longer for the "complete rad removal" with off-site disposal alternative compared to the ROD-selected remedy.

6. Implementability

   - All of the remedial alternatives are considered to be implementable.

   - The "complete rad removal" and partial excavation alternatives likely will pose a greater potential bird or other wildlife hazard to aircraft and airport facilities than the ROD-selected remedy, because performing the excavation remedies would (1) open up larger areas of the landfilled waste to excavation; (2) require the excavation, handling, and relocation of larger volumes of waste material; and (3) take significantly longer to complete than the ROD-selected remedy.

- The “complete rad removal” and the partial excavation alternatives would require the existing MSW transfer station building to be relocated due to the potential for impact to the structural integrity of the building from excavation of material near the foundation of the building. Relocation of the existing transfer station would require buyout of the asphalt plant lease in order to provide space for the relocated transfer station building

7. Cost

- Of the four remedial alternatives (excluding the No-Action alternative), the cost estimate for the ROD-selected remedy is the lowest, followed by the partial excavation alternatives and then the “complete rad removal” with off-site disposal alternative (Table ES-1).

Table ES-1 summarizes in numerical format the results of the FFS evaluation of long-term risks, short-term risks, time to achieve the remedial action objectives, and the estimated costs of each of the alternatives.

Table ES-1: SUMMARY OF POTENTIAL RISKS, IMPLEMENTATION SCHEDULES AND ESTIMATED COSTS WEST LAKE LANDFILL FFS REMEDIAL ALTERNATIVES

	ROD-Selected Remedy	**52.9 pCi/g to a 16-ft depth Partial Excavation Alternative**	**1,000 pCi/g Partial Excavation Alternative**	**"Complete Rad Removal" with Off-Site Disposal**

1 INTRODUCTION

In an October 9, 2015 letter to Cotter Corporation (N.S.L.), Laidlaw Waste Systems (Bridgeton) (n/k/a Bridgeton Landfill, LLC) and Rock Road Industries and the U.S. Department of Energy (Federal Respondent), collectively, the West Lake Landfill Operable Unit-1 (OU-1) Respondents ("Respondents" or "OU-1 Respondents"), the United States Environmental Protection Agency (EPA) informed Respondents that additional work was necessary to accomplish the objectives of the Remedial Investigation/Feasibility Study for OU-1 (EPA, 2015a). EPA also provided a Statement of Work (subsequently revised on December 9, 2015) (EPA SOW) (EPA, 2015b) that identified the additional work that needed to be performed, including preparation of a Final Feasibility Study (Final FS or FFS). In accordance with the EPA SOW, the OU-1 Respondents prepared an Abbreviated Work Plan for a Remedial Investigation Addendum and Final Feasibility Study (RI Addendum/FFS Work Plan) (EMSI, 2016a) that was approved by EPA on May 18, 2016 (EPA, 2016a). On behalf of the OU-1 Respondents, Engineering Management Support, Inc. (EMSI) has prepared this FFS to address the requirements set forth in the EPA SOW as further described in the RI Addendum/FFS Work Plan.

1.1 Background

The West Lake Landfill Site (the Site) is located within the western portion of the St. Louis metropolitan area on the east side of the Missouri River. The Site has an address of 13570 St. Charles Rock Road, Bridgeton Missouri. The Site consists of an approximately 200-acre parcel of land that includes six identified waste disposal areas or units, including Radiological Area 1 (Area 1), Radiological Area 2 (Area 2), a closed demolition landfill, an inactive sanitary landfill, and the North Quarry and South Quarry portions of the permitted Bridgeton Landfill. These six identified areas were used for solid and industrial waste disposal from approximately the 1950s through 2004.

The areas of the West Lake Landfill where radiologically-impacted materials (RIM) are present have been designated by EPA as OU-1. The radionuclides within OU-1 include materials generated by the Manhattan Engineering District (MED) and Atomic Energy Commission (AEC) activities resulting from extraction and concentration of uranium from various ores, as further described in the RI Addendum (EMSI, 2016b). OU-1 comprises Radiological Area 1 and Radiological Area 2 (or more simply as Area 1 and Area 2). In addition to RIM, these two areas also contain municipal solid waste (MSW), industrial waste and construction and demolition (C&D) debris, which may contain other non-radionuclide constituents such as trace metals and volatile organic compounds (VOCs) typically found in MSW landfills. OU-1 also includes a 1.78-acre parcel of land adjacent to Area 2 known as the Buffer Zone. Although the Buffer Zone has never been used for landfilling, RIM has been documented to be present on this parcel of land as well. Investigations and evaluations of non-radioactive constituents in other parts of the Site outside of Areas 1 and 2 are being performed by Bridgeton Landfill, LLC under a separate operable unit (OU-2) RI/FS.

In 1990, EPA listed the Site on the National Priorities List (NPL) under the Comprehensive Environmental, Response, Compensation and Liability Act of 1980 (CERCLA). EPA designated Areas 1 and 2 as OU-1 and the remainder of the Site as OU-2. In 2016, EPA publicly announced that it will be designating a third operable unit, OU-3, to address groundwater conditions at the Site.

In accordance with a 1993 Administrative Order on Consent (AOC) (EPA, 1993a), and over the period from 1994 to 2008, the OU-1 Respondents conducted numerous Site investigations that included the collection and analysis of waste/soil samples and monitoring of the quality of surface water, sediment, groundwater and air at the Site. During this same time period, the OU-1 Respondents also performed numerous evaluations and prepared various comprehensive reports, including a Remedial Investigation (RI) report (EMSI, 2000), a Baseline Risk Assessment (BRA) report (Auxier & Associates, Inc. 2000), and a Feasibility Study (FS) report (EMSI, 2006). These studies and evaluations were considered by EPA in the development of a Proposed Plan for OU-1 (EPA, 2006a) and the subsequent selection of a remedial action as described in the Record of Decision (ROD) for OU-1 (EPA, 2008).

After issuance of the ROD, and as a result of internal deliberations and further consideration of certain comments provided by interested community members, EPA determined in 2010 that additional investigation was warranted, and instructed the OU-1 Respondents to perform a Supplemental Feasibility Study (SFS) (EPA, 2010). Work on the implementation of the ROD Remedial Design Work Plan and negotiation of the associated Consent Decree was accordingly suspended while the OU-1 Respondents performed the necessary evaluations and prepared the SFS report (EMSI et al., 2011) to assess potential remedial alternatives for removal of the RIM from the Site. EPA also requested, and the OU-1 Respondents performed, additional environmental monitoring of groundwater (EMSI, 2012a, 2013a, 2013b and 2014a) and air quality (Auxier and EMSI, 2016a, 2016b, and 2016c), as well as additional characterization of Areas 1 and 2 (including additional drilling, logging, sampling and laboratory analyses). The additional site data were incorporated into an RI Addendum (EMSI, 2016b) and updated BRA (Auxier & Associates, Inc. 2016a).

In the EPA SOW, EPA stated that the FFS shall be a comprehensive document incorporating the elements of and updating as appropriate the June 2006 FS (EMSI, 2006) and the 2011 SFS (EMSI et al., 2011). The FS evaluated six containment (capping) alternatives that were considered in EPA's selection of a containment remedy for OU-1 as documented in the OU-1 ROD (EPA, 2008). The SFS evaluated two "complete rad removal" alternatives: excavation of the RIM and offsite disposal, and excavation and disposal of the RIM in a new engineered landfill cell at the Site. The SFS also included additional evaluation of the ROD-selected remedy, including more detailed estimates of the potential risks, costs, and schedule commensurate with the level of additional detail developed for the excavation alternatives.

1.2 ROD-Selected Remedy

A description of and reasons for selection of the final remedy for the Site are presented in EPA's ROD for OU-1 (EPA, 2008). In particular, EPA reached the following conclusions:

- The ROD-selected containment remedy for OU-1 would protect human health and the environment by providing source control and institutional controls for the landfilled waste materials.

- The source control and institutional control methods would prevent human receptors from contacting the waste material.

- The source control method would mitigate contaminant migration to air and restrict infiltration of precipitation into the landfill, which contributes to protection of groundwater quality.

The components of the ROD-selected remedy include the following:

1. Installation of landfill cover meeting the Missouri closure and post-closure care requirements for sanitary landfills, including enhancements consistent with the standards for uranium mill tailing sites, *i.e.*, armoring layer and radon barrier;
2. Consolidation of radiologically contaminated surface soil from the Buffer Zone/Crossroads Property to the containment area;
3. Application of groundwater monitoring and protection standards consistent with requirements for uranium mill tailing sites and sanitary landfills;
4. Surface water runoff control;
5. Gas monitoring and control, including radon and decomposition gas as necessary;
6. Institutional controls to prevent land and resource uses that are inconsistent with a closed sanitary landfill site containing long-lived radionuclides; and
7. Long-term surveillance and maintenance of the remedy.

Performance standards for each of the remedy components are described in Section 12 of the ROD.

Subsequent discussions between EPA Region 7 and EPA's Office of Superfund Remediation and Technology Innovation (OSRTI) identified the following additional performance standards for the ROD-selected remedy:

- The proposed cover should meet Uranium Mill Tailings Remediation Control Act (UMTRCA) guidance for a 1,000-year design period including an additional thickness as necessary to prevent radiation emissions.

- Air monitoring stations for radioactive materials should be installed at both on-site and off-site locations.

- Groundwater monitoring should be implemented at the waste management unit boundary and also at off-site locations. The groundwater monitoring program needs to be designed so that it can be determined whether contaminants from the Site have migrated across the waste management unit boundary (i.e., the boundary of OU-1) in concentrations that exceed drinking water Maximum Contaminant Levels (MCLs). The groundwater monitoring program needs to measure for both contaminants that have historically been detected in concentrations above MCLs (e.g., benzene, chlorobenzene, dissolved lead, total lead, dissolved arsenic, total arsenic, dissolved radium and total radium) and broader indicators of contamination (*e.g.*, redox potential, alkalinity, carbonates, pH and sulfates/sulfides).

- Flood control measures at the Site should meet or exceed design standards for a 500-year storm event under the assumption that the existing levee system is breached.

These items were addressed through performance of additional evaluations and additional monitoring as described below.

The SFS analysis incorporated these additional performance standards and refined the description and evaluation of the containment remedy that was selected in the ROD to document that the proposed measures were designed to be protective for projected increases in both gamma radiation and radon emissions anticipated to occur over the next 1,000 years.
EPA implemented a program of offsite air quality monitoring in 2014 and 2015 (TetraTech, 2014, 2015a, 2015b, 2015c, 2015d and 2015e). A comprehensive program for monitoring air quality around the perimeter of Areas 1 and 2 was implemented in 2015 (Auxier and EMSI, 2014) and continues to be conducted through the date of this FFS. The results of this air monitoring are presented in various quarterly monitoring reports (Auxier and EMSI, 2016a, 2016b, and 2016c) and were described in the RI Addendum (EMSI, 2016b).

Four comprehensive, Site-wide groundwater monitoring events were conducted in 2012-2013. The results of the additional groundwater monitoring activities are presented in various monitoring reports (EMSI, 2012a, 2013a, 2013b and 2014a) and also in the RI Addendum (EMSI, 2016b).

Additional measures to prevent impacts in the unlikely event of flooding were also included as part of the additional evaluation of the ROD-selected remedy; however, it should be noted that subsequent evaluations by the Federal Emergency Management Agency (FEMA) have determined that Areas 1 and 2 are located outside of the Missouri River floodplain.

1.3 Scope of the FFS

This FFS has been prepared to provide additional evaluation of a select group of potential remedial alternatives for OU-1 specified by EPA in the SOW, as described below. The FFS also addresses various additional evaluations identified by EPA in the EPA SOW, and which are further set forth in the RI/FFS Work Plan.

1.3.1 Remedial Alternatives

The EPA SOW and the RI/FFS Work Plan identified six remedial alternatives to be evaluated in the FFS:

1. No Action (2006 FS Former Alternative L1)– Required by the National Oil and Hazardous Substances Pollution Contingency Plan (NCP) and RI/FS guidance to provide a baseline against which all of the other alternatives are evaluated;

2. Partial Excavation 1,000 picoCuries/gram (pCi/g) (2006 FS Former Alternative L6 and Alternative F4) – Excavation of all soil/waste containing combined radium (radium-226 plus radium-228) or combined thorium (thorium-230 plus thorium-232) with activity levels greater than 1,000 pCi/g;

3. Partial Excavation 52.9 pCi/g to 16 feet bgs – Excavation of all soil/waste containing combined radium or combined thorium with activity levels greater than 52.9 pCi/g down to a total depth of 16 feet beneath the 2005 topographic surface;

4. Partial Excavation Based on Expected Land Use – Partial excavation of all soil/waste containing combined radium or combined thorium with activity levels greater than a risk-based level to be developed based on the reasonably anticipated future land use of the Site;

5. Full Excavation with Offsite Disposal ("complete rad removal") – Excavation of all soil/waste containing combined radium or combined thorium with activity levels greater than 7.9 pCi/g; and

6. 2008 ROD-Selected Remedy (2006 FS Former Alternative L4 and Alternative F4) – Containment consisting of regrading and installation of a new landfill cover and other remedial components for the landfill, as described in Section 1.2, and consolidation of any radiologically-impacted soil that may remain on the former Ford Property (now known as the Buffer Zone and Crossroads Lot 2A2) into the containment areas in Area 1 and 2 prior to placement of additional fill and construction of the new landfill cover.

The EPA definition (EPA, 2010) of the "complete rad removal" alternative is based on the unrestricted land use criteria for combined radium and combined thorium activities as specified in OSWER Directives No. 9200-4.18 and 9200-4.25 (EPA, 1997a and 1998). Although uranium is a contaminant of concern at the Site, uranium was not found to be a driver for identification of RIM, because any locations/depth intervals that contained uranium above its criterion for "complete rad removal" (54.5 pCi/g) also contained radium and/or thorium activity levels greater than their respective criteria for unrestricted land use. In addition, no uranium equivalent criteria were identified by EPA for the partial excavation alternatives. Therefore, these alternatives are based solely on the combined radium and combined thorium activity levels. As noted above, use of the combined radium and combined thorium activity levels to define the materials to be included in the scope of the partial excavation alternatives should also result in inclusion of any materials with commensurate uranium activity.

1.3.2 Additional Evaluations Required by the SOW

The EPA SOW required (and the RI/FFS Work Plan describes) various additional engineering and other types of evaluations to be performed as part of the FFS.

1.3.2.1 Additional Technology Evaluations

The EPA SOW requires additional evaluations of several technologies, including:

- Volume separation techniques and other physical and/or chemical treatment technologies as they relate to partial and full excavation alternatives;
- Evaluation of the long-term effectiveness of proposed landfill caps/covers in addressing both humid region conditions and long-term shielding of the RIM;
- Evaluation of the long-term effectiveness of a landfill cap/cover on potential migration of chemicals-of-concern (COCs) to leachate and groundwater;
- Evaluation of apatite/phosphate based treatment technologies as appropriate to solid matrices[1]; and
- Additional evaluation of potential technologies to control bird populations based on the methods described in the draft Bird Mitigation Plan (LGL, Ltd., 2015) as part of the Isolation Barrier Alternatives Assessment (EMSI et. al., 2014a and EMSI, 2015a).

1.3.2.2 Other Additional Evaluations

The EPA SOW required several other additional evaluations to be performed as part of the FFS, including the following:

[1] Evaluation of these technologies relative to possible groundwater applications may be further considered and/or implemented under the pending new operable unit, OU-3.

- Discussion and consideration of the occurrence of an exothermic subsurface reaction (SSR)[2] and evaluation of an Isolation Barrier (IB), including a brief discussion of pending/ongoing IB-related design and field work;

- Acknowledgement of any environmental justice concerns;

- Updates to the evaluation of potentially applicable or relevant and appropriate requirements of other environmental regulations (ARARs), and in particular, additional detailed assessment of the requirements associated with the UMTRCA and the Resource Conservation and Recovery Act (RCRA) Subtitle C landfill cover design requirements as appropriate;

- Discussion of climate change and vulnerabilities associated with extreme weather events (such as potential impacts associated with possible flooding or tornadoes) and any system vulnerabilities to potential climate change in accordance with EPA's "Climate Change Adaptation Technical Fact Sheet: Landfills and Containment as an Element of Site Remediation (EPA, 2014a) and the EPA Region 7 Climate Change Adaption Implementation Plan (EPA, 2014b); and

- Potential impacts of an SSE within OU-1 and the effects of an IB on the remedial alternatives presented in this FFS.

The EPA SOW also requires the FFS to include information associated with (and results of) the following studies that have been performed by the Respondents since 2006 (including revisions made to these documents based upon EPA comments):

- Supplemental Feasibility Study (EMSI et al., 2011);

- Discount Rates and Cost Estimates Evaluation (EMSI, 2014b and 2013c);

- Phase 1 RIM Investigation (EMSI et al., 2016a);

- Area 1 and Area 2 Additional Characterization (EMSI, 2015b);

- Alternate Cover Designs Evaluation (EMSI, 2015c and 2014c);

- Partial Excavation Alternatives (EMSI, 2014d, 2015d, and 2015e);

- Evaluation of the Use of Apatite/Phosphate Treatment Technology (EMSI, 2013d);

[2] This reaction has previously been called a "subsurface smoldering event" (SSE). However, the current understanding of the reaction is that it is occurring within saturated landfill materials in the absence of oxygen, which indicates that it is not the result of a fire or smoldering (combustion). Accordingly, current references are to an "SSR," or subsurface reaction, rather than the prior SSE terminology.

- Evaluation of Possible Effects of a Tornado on Integrity of the ROD Selected Remedy (EMSI, 2013e and 2013f);
- Evaluation of Risks Associated with Subsurface Smoldering Events (EMSI, 2014d and 2013g);
- Radon Flux Calculations (Auxier and EMSI, 2016d); and
- Bird Mitigation Analysis (LGL, Ltd, 2015).

1.3.3 NCP Required Evaluations of Remedial Alternatives

All of the remedial alternatives are to be evaluated using the threshold and primary balancing criteria set forth in the NCP, 40 CFR § 300.430 (EPA, 2009a). These criteria include the following:

- Threshold Criteria:
  - Overall Protection of Human Health and the Environment; and
  - Compliance with ARARs.
- Primary Balancing Criteria:
  - Long-term Effectiveness and Permanence;
  - Reduction of Toxicity, Mobility, or Volume through Treatment;
  - Short-term Effectiveness;
  - Implementability; and
  - Cost.

These evaluations have been performed in this FFS consistent with the requirements set forth in the NCP and EPA's RI/FS guidance (EPA, 1988a) using the same methodologies that were previously used and described in the SFS and FS reports (EMSI et al., 2011 and EMSI, 2006). Additional descriptions of these criteria are presented in Section 6 of this FFS.

The NCP also requires remedial alternatives to be evaluated in terms of "Modifying Criteria," which include State and community acceptance. State acceptance will be evaluated by EPA based on comments and feedback provided by the Missouri Department of Natural Resources (MDNR) on the FFS and subsequent Proposed Plan. State and community acceptance will be evaluated by EPA as part of any decision process that may be undertaken by EPA after completion of the FFS and are not considered in this document.

A comparative analysis of the results of the evaluations of the alternatives against the No Action alternative was also performed. The relative performance of each of the alternatives was evaluated against the performance of the other alternatives for each of the threshold and primary balancing criteria during the comparative analysis. This comparative analysis is intended to identify the advantages and disadvantages of each alternative.

1.4 FFS Approach

This FFS has been developed pursuant to a October 9, 2015 letter from EPA to the OU-1 Respondents (EPA, 2015a), the EPA SOW (EPA, 2015b), and the EPA-approved Abbreviated Work Plan for an RI Addendum and FFS (EMSI, 2016a). This report has been prepared to address the requirements of the EPA SOW, EPA-approved Work Plan, and the NCP, in accordance with EPA's Guidance for Conducting Remedial Investigations and Feasibility Studies Under CERCLA, OSWER Directive 9355.3-01 (EPA, 1988a), "Guidance for Data Useability in Risk Assessment", OSWER Directive 9285.7-09A (April 1992) (EPA, 1992a), "Establishment of Cleanup Levels for CERCLA Sites with Radioactive Contamination," OSWER Directive 9200.4-18, (August 1997) (EPA, 1997a), "Clarification of the Role of Applicable, or Relevant and Appropriate Requirements in Establishing Preliminary Remediation Goals under CERCLA," OSWER Directive 9200.4-23, (August 1997) (EPA, 1997b), "Use of Soil Cleanup Criteria in 40 CFR Part 192 as Remediation Goals for CERCLA Sites," OSWER Directive 9200.4-25 (February 1998) (EPA, 1998), "Remediation Goals for Radioactively Contaminated CERCLA Sites Using the Benchmark Dose Cleanup Criteria in 10 CFR Part 40 Appendix A, I, Criterion 6(6)," OSWER Directive 9200.4-35P (April 2000) (EPA, 2000a), and other EPA FS-related guidance documents (*e.g.*, EPA, 1991a and EPA, 2000b).

This FFS includes:

- A summary discussion of Site conditions and other information presented in the RI Addendum for OU-1 (EMSI, 2016b), including addressing the findings in United States Nuclear Regulatory Commission (NRC) reports (NRC, 1988 and RMC, 1982 and 1981) that evaluated the radiological disposal areas at the West Lake Landfill Site;

- The nature and extent of RIM in Areas 1 and 2 and the Buffer Zone/Crossroads Property and information regarding the occurrence of non-radiological hazardous substances in Areas 1 and 2;

- A summary of the characterization of potential Site risks presented in the updated BRA for OU-1 (Auxier, 2016a);

- Further information and evaluation pertaining to a negative easement on the property held by the City of St. Louis, and its potential impacts on remedy implementation for OU-1;

- Additional information about environmental monitoring during remedy implementation and long-term maintenance and operations;

- Evaluation of potential treatment technologies for the RIM; and

- Evaluation of potential ARARs and remedial technologies, descriptions of the six remedial alternatives to be evaluated, evaluation of the six alternatives using the threshold and primary balancing criteria, and a comparative analysis of the alternatives.

Where necessary for the evaluation of the alternatives, or as otherwise appropriate for completion of the FFS, brief summaries or tabulations of the results of prior Site evaluations are provided; however, the prior reports should be reviewed or consulted for additional details and specific information relative to those evaluations.

1.5 Report Organization

This report is organized as follows:

Section 1: Introduction – Presents information regarding the scope and approach used to complete the FFS.

Section 2: Site Conditions – Summarizes information regarding Site conditions as they relate to the alternatives evaluated in the FFS. Detailed information about Site conditions was presented in the [draft] RI Addendum report for OU-1 (EMSI, 2016b) and a summary discussion of Site conditions related to the development and evaluation of remedial alternatives was presented in the FS and SFS reports for OU-1 (EMSI, 2006 and EMSI et al., 2011). This section provides a description of occurrences of radionuclides in soil/waste, air, surface water, sediment, and groundwater at the Site. In addition, this section describes the nature, general locations, and overall lateral and vertical extent of RIM. This section also provides a summary of the occurrences of chemical constituents in soil/waste and groundwater. Finally, this section provides a brief summary of the results of the updated BRA (Auxier, 2016a).

Section 3: ARARs – Summarizes information regarding potential ARARs and remedial action objectives (RAOs) as they relate to the remedial alternatives evaluated in the FFS. Additional, detailed information about potential ARARs and RAOs was presented in the FS and SFS reports (EMSI, 2006 and EMSI et al., 2011).

Section 4: Remedial Technologies – Summarizes information regarding additional remedial technologies that may be potentially applicable to the partial excavation and “complete rad removal” alternatives evaluated in the FFS. Additional, detailed information about potentially applicable technologies was presented in the FS and SFS reports (EMSI, 2006 and EMSI et al., 2011).

Section 5: Remedial Alternatives – Provides descriptions of the partial excavation alternatives, the “complete rad removal” with off-site disposal alternative, and the ROD-selected remedy alternative that are the subject of the detailed evaluations presented in Sections 6 and 7. Descriptions of other remedial alternatives previously developed and evaluated for OU-1 that were not included in the list of alternatives identified by EPA for evaluation in this FFS were presented in the FS and SFS reports (EMSI, 2006 and EMSI et al., 2011) and are not repeated in this FFS report.

Section 6: Detailed Analysis of Alternatives – Presents a detailed analysis of the six remedial alternatives relative to the threshold and balancing criteria defined by the NCP.

Section 7: Comparative Analysis of Alternatives – Presents a summary comparison of the six remedial alternatives in terms of the threshold and balancing criteria defined by the NCP.

Section 8: References – Provides a list of references cited in this report.

This FFS also includes the following appendices:

Appendix A: Existing Institutional Controls, City of St. Louis Negative Easement and Restrictive Covenant on West Lake Landfill, and FAA ROD, MOU and Advisories
Appendix B: Estimated Three-Dimensional Extent of Radiologically Impacted Material
Appendix C: Off-site Disposal Facilities – Waste Acceptance Criteria
Appendix D: Evaluation of the Use of Apatite/Phosphate Treatment Technologies
Appendix E: Technical Memorandum: Evaluation of Potential "Hot Spot" Occurrences and Removal of Radiologically-Impacted Soil
Appendix F: Cover Thickness Calculations
Appendix G: Conceptual Bases for Costs of Occupational and Environmental Monitoring Associated with Each Remedial Alternative
Appendix H: Evaluation of Potential Risks Associated with the Proposed Remedial Alternatives
Appendix I: Estimated Greenhouse Gas Emissions Associated with the Alternatives
Appendix J: Estimated Project Schedules for the Remedial Alternatives
Appendix K: Estimated Costs for the Remedial Alternatives
Appendix L: RIM Average Activity Levels
Appendix M: Excavation and Final Grading Plans.

2 SITE CONDITIONS

The purpose of this Section 2 is to provide information necessary to support the evaluation of remedial technologies and alternatives presented in Sections 4, 6, and 7. This section summarizes the site conditions at the West Lake Landfill. It is divided into five subsections:

- Section 2.1 provides information regarding the Site and the surrounding area, including discussions and/or descriptions of historical landfill operations and disposal areas; Superfund Operable Units (OUs) on the Site; current Site uses; Site zoning, use restrictions and easements; surrounding land uses; and proximity to the Missouri River floodplain.

- The nature and extent of radionuclide occurrences in OU-1 are discussed in Section 2.2, including the source of the radionuclides; general locations of RIM in Areas 1, 2, and the Buffer Zone/Crossroads Property; lateral and vertical extent of RIM; estimated volume of RIM; radiological characterization of the RIM in Areas 1 and 2; projected radionuclide decay and in-growth of the RIM; and the evaluation of principal threat wastes. Section 2.2 also includes information regarding the occurrence of non-radiological hazardous substances (trace metals, petroleum hydrocarbons, volatile and semi-volatile organics, pesticides and PCBs) in soil samples collected from Areas 1 and 2, as well as discussions regarding the potential for occurrences of hazardous wastes and asbestos-containing materials in the landfill matrix.

- The presence of radionuclides in air is discussed in Section 2.3.

- Occurrences of radionuclides in stormwater, surface water and sediment are discussed in Section 2.4.

- Brief descriptions of the Site geology and hydrogeology and the nature and extent of radionuclide and chemical occurrences in groundwater near Areas 1 and 2 are provided in Section 2.5.

- Finally, Section 2.6 includes summaries and conclusions from the baseline human health and screening-level ecological risk assessments.

2.1 Site Location and Surrounding Area

The West Lake Landfill Superfund Site is located within the western portion of the St. Louis metropolitan area on the east side of the Missouri River (Figure 2-1). The Site is located approximately one mile north of the intersection of Interstate 70 and Interstate 270 within the city limits of the City of Bridgeton in northwestern St. Louis County. The Site has an address of 13570 St. Charles Rock Road, Bridgeton, Missouri.

The Site is bounded to the north and east by St. Charles Rock Road (State Highway 180) and by the Crossroads Industrial Park to the northwest (Figures 2-2 and 2-3). Taussig Road, commercial properties, and agricultural land are located to the southeast. The Site is bounded to the southwest by Old St. Charles Rock Road (now vacated) and the Earth City Industrial Park (Earth City) stormwater/flood control pond. The Earth City commercial and industrial complex continues to the west and north of the flood control pond and extends from the Site to the Missouri River. Earth City is separated from the river by an engineered levee system owned and maintained by the Earth City Flood Control District.

The Site is divided into six areas:

- Radiological Area 1, which is adjacent to (and in part overlain by) waste material within the North Quarry portion of the Bridgeton Landfill;
- Radiological Area 2;
- The Closed Demolition Landfill;
- The Inactive Sanitary Landfill;
- The Bridgeton Landfill (including the North Quarry portion and the South Quarry portion); and
- The Buffer Zone.

These areas are discussed further below.

2.1.1 Historic Landfill Operations and Disposal Areas

The West Lake Landfill Superfund Site is an approximately 200-acre parcel of land containing multiple areas of differing past operations. The Site was used agriculturally until a limestone quarrying and crushing operation began in 1939. The quarrying operation continued until 1988 and resulted in shallow excavation areas and two quarry pits, the North Quarry Pit and the South Quarry Pit (Figure 2-3), which were excavated to maximum depth of 240 feet below ground surface (bgs) (Herst & Associates, 2005). The relationship between the quarries and Area 1 is shown on Figure 2-3.

The Site contains several areas where solid wastes have been disposed. The date on which landfilling activities started at the West Lake Landfill is not known with certainty and has been variously cited as beginning in or around the early 1950s (EMSI, 2000), or as starting in 1952 or possibly 1962 (Herst & Associates, 2005). The Site was not officially permitted for use as a sanitary landfill until 1952. EPA has reported that "from 1941 through 1953 it appeared that limestone extraction was the prime activity at the facility; however, as time passed the focus of the activity appeared to shift to waste disposal" (EPA, 1989). EPA has reported that historical aerial photography from 1953 indicates use of a landfill had commenced (EPA, 1989). Mine spoils from quarrying operations were deposited on adjacent land immediately to the west of the quarry (Herst & Associates, 2005). Portions of the quarried areas and adjacent areas were subsequently used for landfilling municipal refuse, industrial solid wastes and construction and demolition debris. EPA has reported that liquid wastes and sludges were also disposed of at the

Site (EPA, 1989). These operations, which predated state and federal laws and regulations governing such operations, occurred in areas that subsequently have been identified as Area 1, Area 2, the Closed Demolition Landfill, and the Inactive Sanitary Landfill (Figure 2-3).

The early landfilling activities at the Site (prior to 1974) were not subject to state permitting (although they were still subject to an authorization issued by the county), and the portion of the Site where these activities occurred has been referred to as the "unregulated landfill." Waste disposal in St. Louis County was regulated solely by county authorities until 1974, when the Missouri Department of Natural Resources (MDNR) was formed. Landfill activities conducted after 1974 were subject to permits obtained from the Missouri Department of Natural Resources (MDNR).

Additional discussion of the history of landfill operations, including a discussion of permitted disposal operations at the Site, is presented in Section 3.3 of the RI Addendum (EMSI, 2016b).

2.1.2 Superfund Operable Units

Superfund-program remedial action at the Site is currently divided into two operable units (OUs). OU-1 includes the solid wastes and RIM disposed in Areas 1 and 2. Area 1, which encompasses approximately 17.6 acres, is located immediately to the southeast of the Site entrance. Area 2, which encompasses approximately 47.8 acres, is located in the northwestern part of the Site. On the west side of Area 2 is the property referred to in the OU-1 RI (EMSI, 2000) as the Ford Property because it was previously owned by Ford Motor Credit, Inc. In 1998, the majority of the Ford Property was sold to Crossroad Properties, LLC and has since been developed into the Crossroads Industrial Park. Ford initially retained the 1.78 acres immediately adjacent to the western boundary of Area 2, but subsequently transferred ownership of this parcel of land to Rock Road Industries, Inc. in order to provide a buffer between the Site and the adjacent property, and therefore this parcel has been identified as the Buffer Zone (Figure 2-3). Due to the presence of radionuclides in surface soils, the Buffer Zone is also included as part of OU-1.

OU-2 consists of the other landfill areas at the Site that are not impacted by radionuclides, including the Inactive Sanitary Landfill located adjacent to Area 2, the Closed Demolition Landfill, and North and South Quarry portions of the Bridgeton Landfill. OU-2 also includes a surface water retention pond, abandoned leachate lagoons, a closed leachate retention pond, a former soil borrow area, a current soil stock pile area, a current stormwater retention basin, and an active leachate treatment facility associated with the Bridgeton Landfill. The Closed Demolition Landfill and the Bridgeton Landfill, while designated as part of OU-2, are regulated by the MDNR pursuant to State of Missouri solid waste regulations and are not being actively addressed by EPA. To the extent that the presence of, or activities associated with, these OU-2 areas potentially impact OU-1 and the remedial alternatives considered by this FFS, those impacts are discussed in the appropriate FFS sections.

OU-1 Area 1 is situated on the northern and western slopes of a topographic high within the overall Site. Ground surface elevation in Area 1 varies from 490 feet above mean sea level (AMSL) on the south side of Area 1 to 452 feet AMSL at the roadway near the Site access road along the north side of Area 1 (Figure 2-4). OU-1 Area 2 is situated between a topographic high of landfilled materials to the south and east, and the Buffer Zone/Crossroads Property to the west. The highest topographic level in Area 2 is about 500 feet AMSL on the southwest side of Area 2, sloping to approximately 470 feet AMSL near the top of the landfill berm (Figure 2-4). The upper surface of the berm along the western edge of Area 2 is located approximately 20 to 30 feet above the adjacent Buffer Zone/Crossroads Property and approximately 30 to 40 feet higher than the water surface in the flood control channel located to the southwest of Area 2. A berm on the northern portions of Area 2 controls runoff to the adjacent properties.

2.1.3 Current Site Uses

The Site is located in a predominantly industrial area. The entire Site area, including the areas investigated as part of OU-1 and OU-2, has been the site of historic limestone quarrying operations, as well as landfill operations. Other activities on the OU-2 portion of the property currently include a solid waste transfer facility, a leachate treatment facility, and an asphalt batch plant operation (Figure 2-3).

With the exception of the Buffer Zone, all of the Site has previously been developed and has been used for, or in conjunction with, disposal of solid wastes at the Site or is currently being used in conjunction with the various industrial operations conducted at the Site. Areas 1 and 2, the Closed Demolition Landfill, the Inactive Sanitary Landfill, and the North and South Quarry portions of the Bridgeton Landfill (Figure 2-3) were all used for disposal of solid wastes. Current activities in these areas consist of maintenance of the landfill covers and environmental monitoring. Extraction of groundwater/leachate continues to be performed on an ongoing basis from the North and South Quarry portions of the Bridgeton Landfill.

In addition to the area containing the Site access road and an office trailer/weigh station, there are areas located outside of the solid waste disposal units in which industrial activities are conducted at the Site. These include the area in the central portion of the Site where the solid waste transfer station, leachate treatment facility, and the asphalt batch plant are located (Figure 2-3). The asphalt batch plant operates at the Site pursuant to a long-term (99-year) lease. The OU-2 stormwater retention pond and OU-2 on-site soil borrow and stockpile area are also located at the Site (Figure 2-3).

2.1.4 Site Zoning, Use Restrictions, and Easements

Current owners of the land encompassed by the Site and of adjacent properties are shown on Figure 2-5. The land use zoning for the Site and adjacent properties is shown on Figure 2-6. The southern portion of the Site is zoned M-1 (manufacturing district, limited). Although the northern portion of the Site is zoned R-1 (one family dwelling district), this area has never been used for residential purposes, is bounded on all sides by industrial and commercial uses, and has been used for industrial purposes for more than 50 years.

In addition, various restrictions on land use have been implemented at the Site (Figure 2-7) to reflect: (1) use of the Site as a solid waste disposal facility; (2) the presence of radiologically-impacted materials in Areas 1 and 2; and (3) the proximity of the Site to the Lambert-St. Louis International Airport. In particular, residential land use has been precluded at the West Lake Landfill (including Areas 1 and 2) by restrictive covenants recorded in May 1997 by each of the fee owners against their respective parcels. These restrictive covenants also prohibit use of groundwater from beneath the Site. Construction activities and commercial and industrial uses have also been precluded on Areas 1 and 2 by a Supplemental Declaration of Covenants and Restrictions recorded by Rock Road Industries, Inc. in January 1998, prohibiting the placement of buildings and restricting the installation of underground utilities, pipes, and/or excavation upon its property. These covenants automatically renew fifty (50) years from the date first recorded and every twenty five (25) years thereafter. The covenants grant EPA, the MDNR, and the owners the right to enforce the covenants' restrictions and cannot be terminated without written approval of their respective owners, MDNR and EPA. Copies of these land use covenants are included in Appendix A to this report. Consequently, even though a portion of the Site is zoned residential, as a practical matter, the only reasonable future use of the Site is commercial-industrial, not residential.

The Site is located northwest of the Lambert-St. Louis International Airport (Lambert Field). Much of the Site, including more than half of Area 1, is located at its closest point within approximately 9,166 feet of the start of Runway 11 (end of Runway 29), which is less than the FAA siting guidance of a 10,000-foot separation radius (Figure 2-8). Numerous flight tracks pass over the West Lake Landfill Site (Figure 2-8). In 2005, the City of St. Louis entered into an Negative Easement and Declaration of Restrictive Covenants Agreement with Bridgeton Landfill, LLC (among other entities) to prohibit depositing or dumping of new or additional putrescible waste on the entirety of the Bridgeton Landfill after August 1, 2005 (City of St. Louis, 2005). This negative easement stemmed in part from an earlier determination by the Federal Aviation Administration (FAA) and the United States Department of Agriculture, Animal and Plant Health Inspection Service (USDA) that the Site was a hazardous wildlife attractant for the Lambert-St. Louis International Airport (City of St. Louis, 2010). In particular, the proximity of the airport to the Site presents a risk of bird strikes. Certain types of scavenging birds (e.g., gulls, crows) are attracted to exposed putrescible wastes at landfills, and accordingly can present a bird strike risk to passing aircraft. Similarly, bird flocks also pose a serious risk to aircraft (by, e.g., being sucked into the jet engines of commercial aircraft, thereby causing complete engine failure).

2.1.5 Surrounding Land Uses

Land use in the area surrounding the Site is commercial and industrial. The Crossroads Industrial Park is located on the north and west of the Site. The property to the north and east of the Site, across St. Charles Rock Road, is moderately developed with commercial, retail and manufacturing operations. The Earth City Industrial Park is located adjacent to the Site on the south and west, across Old St. Charles Rock Road. Various manufacturing facilities are located to the east of the Site, across St. Charles Rock Road. The Republic Services area office and refuse collection vehicle parking and repair facilities are located on the southeast side of the Site and the Boenker farm (agricultural property) is located to the south of the Site.

Two residential communities are present within approximately one mile of the Site. The Terrisan Reste mobile home park is located on the east side of St. Charles Rock Road approximately one-half mile to the southeast of Area 1 and nearly one mile to the southeast of Area 2 (near the intersection of St. Charles Rock Road and Interstate 270) (Figure 2-2). The Spanish Village neighborhood, which contains mixed single and multi-family residential units as well as commercial and industrial facilities, is located to the south of the Site just north of I-70, approximately one mile from Areas 1 and Area 2 (Figure 2-2).

2.1.6 Missouri River Floodplain

The limits of the geomorphic floodplain of the Missouri River were delineated based on information obtained from the MDNR, as further described in the RI Addendum (EMSI, 2016b). Portions of the Site, including all of Area 2 and much of Area 1, are located within the geomorphic floodplain of the Missouri River.

The topography of the Site area has been significantly altered by quarry activities and by placement of quarry spoils and landfill materials. Consequently, although portions of the Site were built over the historic (geomorphic) floodplain, landfilling activities have significantly increased the topographic elevation of much of the Site (Figure 2-4) such that with the exception of the stormwater retention basin and the soil borrow and stockpile area (Figure 2-3), the entire Site is now located above and outside of the 500-year floodplain of the Missouri River (Figure 2-9).[3]

The Earth City Flood Control and Levee District operates and maintains a levee and stormwater management system in order to protect the Earth City development from Missouri River floods with a recurrence interval greater than 500 years (commonly referred to as a 500-year flood). As the Earth City levee system is located between the Missouri River and the Site, this levee system also acts to protect the Site from a 500-year flood. No flooding of the Site or the adjacent Crossroads Property occurred in 1993 or 1995 during the 500- and 300-year flood events that occurred in those years, respectively.

[3] The Federal Emergency Management Agency (FEMA) prepares Flood Insurance Rate Maps (FIRM) for many portions of the country. These maps are available online through FEMA's Map Service Center site (http://msc.fema.gov). The area of the West Lake Landfill is on FIRM Map Number 29189C0039K dated February 4, 2015 (FEMA, 2015). The FIRM map (Figure 2-9) indicates that the entire West Lake Landfill Site is outside the 0.2-percent annual chance (500-year) floodplain.

2.2 Nature and Extent of Radionuclide and Chemical Occurrences in OU-1

This section summarizes the origin and general nature and extent of occurrences of RIM in waste materials in Areas 1 and 2 and the Buffer Zone/Crossroads Property. The occurrence, distribution and volume of RIM in Areas 1 and 2 has been the subject of extensive field investigations, sampling and laboratory analyses, and engineering evaluations, as summarized in the OU-1 Soil Boring/Surface Soil Investigation Report (McLaren/Hart, 1996a), the OU-1 Remedial Investigation Report (EMSI, 2000), the OU-1 Feasibility Study (EMSI, 2006), EPA's Record of Decision for OU-1 (EPA, 2008), the Supplemental Feasibility Study (EMSI et al., 2011), the Bridgeton Landfill Thermal Isolation Barrier Investigation Phase 1 Report (FEI et al., 2014), the Comprehensive Phase 1 Report (EMSI et al., 2016a), and the RI Addendum (EMSI, 2016b). Information regarding the nature and extent of non-radionuclide chemical occurrences in soil/waste material in OU-1 is also presented to assess the potential for occurrences of hazardous waste within the landfill materials.

2.2.1 Occurrences of Radionuclides in Areas 1 and 2

Radiological constituents in OU-1 Areas 1 and 2 occur in soil materials that are intermixed with and interspersed within portions of the overall matrix of landfilled refuse, debris and fill materials and unimpacted soil and quarry spoils in Area 1 and Area 2. In some portions of Areas 1 and 2, radiologically-impacted materials are present at the surface; however, the majority of the radiological occurrences are present in the subsurface beneath these two areas. At the Buffer Zone/Crossroads Property, the radiologically-impacted materials are found in surface soil believed to have been carried by erosion from the Area 2 berm prior to growth of the current onsite vegetation. See additional discussion in Section 2.2.5, below.

In general, the primary radionuclides detected at levels above background concentrations at the Site are part of the uranium-238 decay series. Thorium-232 and radium-224 isotopes from the thorium-232 decay series are also present above background levels but at a lesser frequency and at much lower activity levels.

2.2.2 Source of the Radionuclides

The NRC reported (1976, 1988) that disposal of radioactive materials mixed with soil occurred at the West Lake Landfill in 1973. Reportedly, approximately 8,700 tons of leached barium sulfate residues (LBSR) were mixed with approximately 39,000 tons of topsoil from a site located at 9200 Latty Avenue in Hazelwood, MO (the Latty Avenue Site) and transported to the West Lake Landfill over a three-month period from July 16 through October 9, 1973 (EPA, 2008; NRC, 1976 and 1988; and RMC, 1982). The LBSR was derived from uranium ore processing for the production of uranium metal from 1942 to 1957 under contracts with the Manhattan Engineering District (MED) and the Atomic Energy Commission (AEC) at the Mallinckrodt Chemical Works facility in St. Louis, known today as the St. Louis Downtown Site (SLDS).

Prior to 1966, these materials were stored by the AEC on a 21.7-acre tract of land (now known as the St. Louis Airport Site or SLAPS) in what was then an undeveloped area of north St. Louis County (EPA, 2008, NRC, 1988, and RMC, 1982). The LBSR, along with certain uranium processing residuals, reportedly were moved from SLAPS to the nearby Latty Avenue Site in 1966 (NRC, 1988). Most of the uranium and radium had previously been removed from the LBSR in multiple extraction steps (EPA, 2008 and NRC, 1988), and the LBSR reportedly contained only approximately 0.05% to 0.1% of uranium (NRC, 1976 at page 2).

Over time, the radiologically-impacted materials within Areas 1 and 2 have been intermixed within portions of the overall matrix of landfilled solid waste materials, debris and fill materials, and unimpacted soil and quarry spoils in portions of Area 1 and Area 2. Use of soil mixed with LBSR as landfill cover, combined with the placement and compaction of additional MSW and other soil material both during and after placement of RIM-containing materials, and the subsequent natural decomposition, consolidation, and settlement of the MSW over the years, have also resulted in RIM being dispersed and intermixed within portions of the overall matrix of MSW in Areas 1 and 2. As a result, the Site contains areas comprised of both radiologically-impacted and non-radiologically-impacted materials that cannot be visually distinguished, and both of which are intermixed with solid waste materials.

2.2.3 Criteria for Defining RIM Occurrences

EPA previously determined for purposes of evaluating “complete rad removal” alternatives (EPA, 2010) that RIM would be defined based on the criteria set forth in EPA’s regulations (40 CFR Part 192) promulgated pursuant to the Uranium Mill Tailings Radiation Control Act of 1978 (UMTRCA) as modified by subsequent EPA guidance on the use of these regulations at CERCLA sites. Specifically, EPA’s Scope of Work for the Supplemental Feasibility Study (EPA, 2010) indicated that “complete rad removal” was defined to mean attainment of risk-based radiological cleanup levels specified in OSWER Directives 9200.4-25 and 9200.4-18 (EPA, 1998 and 1997a). These directives provide guidance as to the use of the UMTRCA soil cleanup criteria as remediation goals at CERCLA sites.

Based on these criteria, EPA has established a conservative definition of RIM at the Site based on the application of criteria for unrestricted (*i.e.*, residential) land use.[4] In particular, EPA has determined that RIM at the Site will be defined as any material containing combined Ra-226 plus Ra-228 or combined Th-230 plus Th-232 at levels greater than 5 pCi/g above background (EPA, 2010). The EPA previously identified that this criterion would allow for unrestricted (*i.e.*, residential) use of the Site relative to radionuclide occurrences for purposes of identifying RIM at the Site. Based on the uranium remediation goal of 50 pCi/g established for the SLDS and SLAPS in the RODs for those sites (USACOE, 1998, and EPA, 2005, respectively), for purposes

[4] As noted in Section 2.1.4, above, use of the Site for residential purposes is inconsistent with the presence of municipal solid wastes within a landfill, regardless of the presence (or absence) of radionuclides within those wastes.

of identifying RIM at the Site, the criteria of 50 pCi/g plus background total uranium will be used to identify RIM. Evaluation of background levels and the associated criteria that would allow for unrestricted use was previously performed for the SFS (EMSI et al., 2011) and was also discussed in detail in the RI Addendum (EMSI, 2016b).

Based on the Site background values presented in the RI Addendum and the SFS, the criteria to be used to identify RIM are as follows:

- Ra-226 plus Ra-228 = 7.9 pCi/g[5]
- Th-230 plus Th-232 = 7.9 pCi/g
- Combined uranium (U-234 plus U-235 plus U-238) = 54.5 pCi/g

These values were used to identify the Site soil/waste that would be included within the definition of RIM for purposes of the FFS, and in particular, for the purpose of identifying the materials included within the scope of the “complete rad removal” alternative.

2.2.4 Occurrences of RIM in Areas 1 and 2

Radionuclides (specifically, Th-230, Ra-226, and U-238) have been identified as primarily present in soils at two distinct and separate areas at the Site. These two areas have been designated by EPA as Radiological Area 1 (Area 1) and Radiological Area 2 (Area 2) (Figure 2-3). Area 1 encompasses an approximately 17.6-acre portion of the Site located immediately to the southeast of the main access road to the Site. Area 2 encompasses an approximately 47.8-acre portion of the Site along the northern boundary of the West Lake Landfill property (Figure 2-3).

Procedures used to identify RIM occurrences based on the results of the field investigations and laboratory testing are detailed in Section 6.3 of the RI Addendum (EMSI, 2016b). The RIM occurrences in Areas 1 and 2 are provided in Tables 2-1 and 2-2, respectively.

The minimum, average and maximum identified thickness of the RIM intervals in Areas 1 and 2 based on the results of the field investigations and laboratory testing were as follows:

	Area 1	Area 2
Minimum RIM thickness (ft)	0.2	1
Average RIM thickness (ft)	4.3	7.4
Maximum RIM thickness (ft)	19	25

[5] Total radium Derived Concentration Guideline Level (DCGL) = 1.3 pCi/g Ra-226 + 1.6 pCi/g Ra-228 + 5 pCi/g radium cleanup level = 7.9 pCi/g total radium

The depths to the top of the identified intervals containing RIM in Area 1 average approximately 28 ft bgs (average elevation of 450.0 ft amsl), ranging from 0 (at the surface) to 89 ft bgs (elevations ranged from 425.4 to 470.5 amsl)[6]. The base of the RIM intervals occurs at an average depth of 32 ft bgs (average elevation of 446.0 amsl), ranging from 5 to 96 ft bgs (elevations ranging from 420.3 to 462.3 amsl). Part of the reason for these depths is that the landfill materials in the southern portion of Area 1 were buried beneath additional landfilled waste that was placed in that area in approximately 2002-2003 in conjunction with disposal in the above-grade portion of the North Quarry portion of the Bridgeton Landfill.

The average depth to the top of the intervals identified as containing RIM in Area 2 ranges from 0 (at the surface) to 42.5 ft bgs (elevations ranged from 434.9 to 486.5 ft amsl). The base of the RIM intervals occurs at depths ranging from 1 to 49.5 ft bgs (elevations from 428.3 to 484.5 ft amsl).

2.2.5 Estimated Volume of RIM and Overburden Material

A geostatistical evaluation of the extent and volume of RIM using an IK approach was performed by S.S. Papadopoulos & Associates (SSPA). Specifically, the extent of RIM within OU-1 Areas 1 and 2 was estimated in three dimensions (3D) using indicator kriging (IK). The IK method is commonly used to identify regions of the subsurface that exhibit properties that exceed one (or more) defined threshold criterion – typically a concentration – and as such, is well-suited to delineating RIM. In the case of a single threshold, sample results are indexed according to whether they exceed (index=1) or fall below (index=0) the threshold value. The transformed indicators are interpolated using kriging, resulting in a continuous 3D distribution of values ranging between zero and one that, in the simplest case, reflect the probability that the criterion is exceeded at the corresponding location. All indicator kriging calculations were completed using a recent release of the Fortran-based Geostatistical Library (GSLIB: Deutsch and Journel, 1992) program IK3D, compiled with dynamic memory allocation. A more complete description of the methods and results obtained by the IK evaluations is included in Appendix B.

The data available to estimate the extent of RIM include (a) thorium and radium obtained from laboratory analysis of landfill materials; and (b) a comparatively larger number of vertically continuous gamma and alpha recordings obtained during downhole logging or logging of drill core sample material. The reported values of thorium and of radium comprise direct measurements of the quantity of interest, and as such are referred to here as “hard” data. In contrast, measurements of gamma and alpha radiation are indirect indicators of the presence, and likely relative concentration of, radiological constituents including (but not limited to) thorium and radium: as such, radioactivity counts are referred to here as “soft” data. Indicator kriging

[6] Note that the borings used to define RIM were drilled before construction of the Non-Combustible Cover removal action construction activities, and therefore the reported depth intervals discussed in this section do not reflect placement of an additional eight (8) inches (or in some areas, an even greater thickness) of material over portions of Areas 1 and 2 in 2016.

enables such "soft" data to be incorporated in the estimate of the primary "hard" variable under the assumption that the "soft" quantity exhibits a correlation with the "hard" quantity.

The interpolation grid used for the kriging was defined to provide estimates of the presence or absence of RIM on a vertical and horizontal discretization suitable for evaluating combined Ra-226 plus Ra-228 or combined Th-230 plus Th-232 values greater than 7.9 pCi/g (the EPA defined value for identification of RIM). The grid size was selected based upon UMTRCA regulations, resulting in a grid defined by square blocks of side-length 10 meters (32.8 feet) and thickness 0.15 meters (0.5 feet) consistent with the criteria specified in 40 CFR § 192.12a for cleanup of land containing residual radioactive materials.

The areal extent of RIM (*i.e.,* material containing combined radium or combined thorium activities greater than 7.9 pCi/g) based on results of the IK for Area 1 is 6.4 acres (Figure 2-10). The estimated extent of RIM in Area 2 is 22.9 acres (Figure 2-11). Details regarding the methods used to perform the IK and the results obtained are presented in Appendix B.

In order to meet the schedule for preparation of the FFS, SSPA provided results of the IK in May 2016 (referred to in the SSPA report contained in Appendix B as "Initial Best-Estimates"). These results were used for characterization of the extent and volume of RIM in the RI Addendum. The results of these evaluations were also used to develop excavation and grading plans (Appendix M), cost and schedule estimates, and risk evaluations for the complete and partial excavation alternatives for the FFS. After further review of the initial IK results, SSPA revised its analyses to better reflect the Site data, which resulted in slight modifications to the estimated RIM volumes (SSPA, 2016a). Specifically, the updated best-estimates were 4.3% larger for Area 1, 3.2% lower for Area 2, and 1.9% lower overall compared to the initial best-estimates. Given the timing of these revisions and the schedule constraints associated with preparation of the draft FFS, these revised values of the RIM volumes (referred to in the SSPA report contained in Appendix B as "Updated Best-Estimates") have not been incorporated into the evaluations contained in this draft FFS. Moreover, these variations are within the estimate level of precision of the volume calculations.

Based on the geostatistical evaluations, the initial best-estimate total volumes of RIM contained in Areas 1 and 2 were estimated to be as follows:

Area 1 RIM	46,200 bank cubic yards (bcy)
Area 2 RIM	220,000 bcy
Total RIM	266,200 bcy

A "bank cubic yard" refers to the volume of an in-place, undisturbed material such as soil or refuse. Conversely, a "loose cubic yard" refers to a volumetric measurement of material when it is in a loose state after it has been excavated. When material is excavated, it typically swells relative to its in-place volume. For example, a "loose cubic yard" of soil will typically occupy 20 to 30 percent more volume than a "bank cubic yard" of soil, and a "loose cubic yard" of refuse may occupy up to 60 percent more volume than a "bank cubic yard" of refuse. For purposes of estimating quantities in the SFS, it was assumed that a "loose cubic yard" of combined overburden and RIM (matrix of soil and refuse) in Areas 1 and 2 would occupy 50 percent more volume than a "bank cubic yard".

Based on the geostatistical estimate of the depths and extent of RIM in Areas 1 and 2, the volume of non-radiological overburden soil and waste materials (including material directly above the RIM plus material that would need to be removed to lay back the excavation sidewalls) that would have to be removed to allow for excavation of the RIM was estimated to be as follows:

Area 1 overburden	702,000 bcy
Area 2 overburden	493,000 bcy
Total overburden	1,195,000 bcy

Additional information and supporting calculations used to estimate the extent and volumes of RIM above levels that would allow for unrestricted use, as well as the uncertainties associated with the estimates, are presented in Appendix B and discussed in Section 5.

2.2.6 Radiological Characterization of the RIM

The primary radionuclides detected in Areas 1 and 2 at levels above background concentrations are part of the U-238 decay series. The uranium decay series includes Th-230, Ra-226, and Rn-222, which are the primary radionuclides of concern at the Site. Th-232 and Ra-228 isotopes from the thorium decay series were also present above background levels but at a lesser frequency and relatively lower activity levels than the radionuclides in the U-238 decay series. A total of 218 radium analyses and 213 thorium analyses (including investigative samples, field duplicate samples, and laboratory duplicate analyses) are available for Area 1, and 144 radium and thorium results are available for Area 2, from the OU-1 RI, Phase 1, and Additional Characterization investigations. Table 2-3 summarizes the radium, thorium and uranium results for samples obtained from Area 1 while Table 2-4 summarizes the results for samples obtained from Area 2.[7]

[7] Although the analytical results from the additional samples collected by Cotter are included on Tables 2-3 and 2-4, these data have not been included in the evaluation of the statistical estimates of radium and thorium levels in Areas 1 and 2, as certain of those samples are still being analyzed. The Cotter data were collected in part to "help determine the presence of radiological materials with chemical compositions diagnostically different from LBSR." (Arcadis, 2015a and b). Consequently, collection of samples by Cotter was heavily biased toward collection of samples with the highest levels of radium and thorium at the Site with the goal of "identification and evaluation of any non-LBSR material[.]" (Arcadis, 2015a and b). Furthermore, in response to some questions from EPA with regard to the ratio of the Th-230 and Ra-226 reported for several of the Cotter samples, EPA has requested that the remaining materials associated with these samples be provided to EPA for re-analysis to verify the results (EPA, 2016b). Therefore, until this issue is resolved, the Cotter data will be reported but not integrated into the overall evaluations of the nature of the radiological occurrences in RIM.

The total number of results, and the average, maximum, and estimated 95% UCL values (based on results for a non-parametric distribution as calculated using ProUCL 5.0 – see additional discussion below) for the radium and thorium data sets are provided on Table 2-5. For purposes of these calculations, only the original sample results have been used, and therefore field duplicate results and lab duplicate results were not considered in these calculations.

It should be noted that although an average value is presented in Table 2-5, the data sets were not normally distributed and therefore, an arithmetic average is not an appropriate measure of central tendency of the data sets. Similarly, the 95% UCL values listed on Table 2-5, although based on a non-parametric distribution and estimation technique, are also not considered to be appropriate based on the distribution of the data sets.

Review of the data sets indicates that these data represent two separate populations (that is, the data represent a bimodal distribution) that have a small degree of overlap. As discussed in the RI Addendum (EMSI, 2016b), weighted mean values and weighted 95% upper confidence limits were calculated based on the percentages of data values contained within each subpopulation. The resultant values are provided on Table 2-5.

Regardless of whether the data are treated as a single population or as bimodal mixture of two populations, the values provided on Table 2-5 support the conclusion that the RIM is primarily characterized by elevated levels of Th-230 and Ra-226, and that, with the exception of a few values, most of the Th-232 and Ra-228 values are close to or similar to background values. There is also a relatively close correlation between the Ra-226 and Th-230 results obtained from each area. Furthermore, review of the data indicates that for all of the results that are greater than the unrestricted use criteria (*i.e.*, 7.9 pCi/g combined Ra-226 + 228 or combined Th-230 + 232), the Th-230 activities are greater than the Ra-226 activities.

2.2.7 Radionuclide Decay and In-Growth

Review of the data indicated that for all of the results that are greater than the unrestricted use criteria (*i.e.*, 7.9 pCi/g combined Ra-226 + Ra-228 or combined Th-230 + Th-232), the Th-230 activities are greater than the Ra-226 activities. These analytical data indicate that the Ra-226 activities are not in equilibrium with the Th-230 activity levels and consequently the levels of Ra-226 at the Site will increase over time. Over time, the activity concentrations of Ra-226 will grow into that of its parent, Th-230.

The arithmetic average values of the Th-230 and Ra-226 data for the Area 1 and Area 2 soil/waste samples (see Section 2.2.6) were used to estimate the anticipated in-growth of Ra-226 from decay of Th-230 over time. These values were used to estimate the average amount of Ra-226 that would be present in Area 1 and Area 2 in 1,000 years. Accounting for the in-growth of Ra-226 due to the decay of Th-230 results in an estimated average Ra-226 activity level of 1,337 pCi/g in Area 1 and 6,882 pCi/g in Area 2 in 1,000 years (Tables 2-6 and 2-7). The expected increases in the Ra-226 levels in Areas 1 and 2 owing to decay of Th-230 over time are graphically presented on Figures 2-12 and 2-13.

The projected increase in Ra-226 levels over time will result in both increased radiation levels and increased radon gas generation over time. Design of a landfill cover included within the scope of the ROD-selected remedy, or a cover associated with any of the other remedial alternatives, will need to consider the projected increase in radium over time and the associated increases in gamma radiation and radon emanation that will also occur over time. The projected increase in radiation and radon levels over time was addressed as part of the risk characterization included in the Baseline Risk Assessment and Updated Baseline Risk Assessment (Auxier & Associates, 2000 and 2016a), and was considered as part of the conceptual design of the remedial alternatives and potential long-term risks evaluated in the prior SFS and in this FFS, as described further in Sections 5 and 6.

2.2.8 Principal Threat Wastes

In accordance with the NCP, EPA expects that treatment will be the preferred means by which to address the principal threats posed by a site, wherever practicable. Because one of the purposes of the FFS is to provide a thorough evaluation of potential “complete rad removal” and partial excavation alternatives relative to the ROD-selected remedy, it is conservatively assumed that principal threat wastes may be present within OU-1. Therefore, potential treatment technologies are evaluated in Section 4 of this FFS. As discussed in Section 4, the evaluation of potential treatment technologies takes into account both the presence of the RIM and the expected further in-growth of radionuclides in the RIM due to radioactive decay and disequilibrium.

2.2.9 Radiological Occurrences on the Buffer Zone and Crossroads Property

During the RI (EMSI, 2000), radionuclide occurrences in surface soil were identified in the southern portion of what at that time was property owned by Ford Motor Credit (referred to in the RI as the Ford Property and now known as the Buffer Zone), located immediately to the west of Area 2 (Figure 2-3).

Reportedly, after completion of landfilling activities in Area 2, but prior to establishment of a vegetative cover over the landfill berm, erosion of soil from the landfill berm resulted in the transport of radiologically-impacted materials from Area 2 onto the adjacent former Ford Property (EMSI, 2000). The landfill berm and the adjacent properties were subsequently re-vegetated by natural processes such that no evidence of subsequent erosion or other failures were present at the time of the RI. Based on the results of sampling performed during the RI, occurrences of radionuclides were found in surficial (6 to 12 inches or less) soil at the toe and immediately adjacent to the landfill berm. The overall distribution and surficial nature of the occurrences of radiologically-impacted soil on the former Ford Property was determined to be consistent with historic, erosional transport of soil from the Area 2 slope onto the surface of the former Ford Property.

Based on an estimated areal extent of 196,000 square feet and a presumed 6-inch thickness, the volume of radiologically-impacted materials located on the former Ford Property was estimated to be 3,600 cubic yards (EMSI, 2000 and 2006a).

In November 1999, third parties scraped the vegetation and surface soil on Crossroads Lot 2A2 and the Buffer Zone to a depth of approximately 2 to 6 inches. These areas were covered with gravel to allow for parking of tractor-trailers. The removed materials were piled in a berm along the southern boundary of the Buffer Zone, adjacent to the northwestern boundary of the Site. A small amount of removed materials was also placed in a small pile on the Crossroads Property near the base of the landfill berm along the east side of Lot 2A1 (Figure 2-14).

In February 2000, additional surface soil samples were collected from the disturbed area and submitted for laboratory testing. Only one sample (RC-02) obtained from the Buffer Zone, below and adjacent to the area of the former landfill berm slope failure, contained radionuclides (Th-230) above levels that would allow for unrestricted use (Table 2-8). The remainder of the samples contained either background levels of radionuclides or levels above background but within levels that would allow for unrestricted use. The results of the additional soil sampling indicated that most of the radiologically-impacted soil that had previously been present on the Buffer Zone and Lot 2A2 of the Crossroads Property had been removed and placed in the stockpiles. Evaluation of the soil sampling results obtained prior to and after the 1999 disturbance indicates that approximately one acre of the Buffer Zone still contained some radionuclides above unrestricted use levels. Inspection of the area in May 2000 indicated that native vegetation had been re-established over both the disturbed area and the stockpiled materials. The presence of native vegetation over these materials was determined to be sufficient to prevent windblown or rainwater runoff of these materials.

A 2004 inspection of this area indicated that additional soil removal/regrading had been performed on the remaining portion of the Crossroads Property and the adjacent Buffer Zone property. These activities appear to have resulted in removal of the soil stockpiles created during the previous regrading activity, removal of any remaining soil on Lot 2A2 and the Buffer Zone not scraped up during the 1999 event, and placement of gravel over the entirety of Lot 2A2 and much of the Buffer Zone. According to AAA Trailer, all of the soil removed during the July 1999 grading work and the May 2003 gravel layer installation was placed in the northeastern corner of the Buffer Zone (terra technologies, 2004). Respondents installed a fence between the Buffer Zone and Crossroads Property to prevent any future disruption of the Buffer Zone by AAA Trailer or any other party.

Because no sampling has been performed since the most recent (May 2003) grading work conducted by AAA Trailer, the levels and extent of radionuclides, if any, that may remain in the soil at the Buffer Zone and Crossroads Property are unknown. Additional soil sampling to determine current conditions with respect to radionuclide occurrences in the Buffer Zone and Crossroads Property soil will be conducted as part of implementation of the selected remedy for this area.

2.2.10 Occurrences of Non-Radiological Chemical Constituents in Soil/Waste

Although the primary focus of the OU-1 RI field and laboratory investigations was on radionuclide occurrences, investigation of occurrences of non-radiological, chemical constituents was also performed during the RI. The soil/waste samples collected by McLaren/Hart as part of the soil boring program (McLaren/Hart, 1996a) were analyzed for the following non-radiological constituents:

- Priority pollutant metals and cyanide;
- Total petroleum hydrocarbons (TPH);
- Volatile Organic Compounds (VOCs);
- Semi-Volatile Organic Compounds (SVOCs); and
- Pesticides and poly-chlorinated biphenyls (PCBs).

As part of the OU-1 RI field investigation and laboratory analyses, 43 soil samples from 28 borings were analyzed for VOCs, SVOCs, pesticides and PCBs, and TPH. Twelve of these borings were located in Area 1 and 16 were located in Area 2. Seventeen of the soil samples analyzed for organic compounds were collected from Area 1 borings and 23 were collected from Area 2 borings. There were also three field duplicates, for a total of 43 soil samples analyzed for organic compounds. Of the 43 samples collected and analyzed for non-radiological constituents, 15 were of surface soils, including five from Area 1 and 10 from Area 2.

In addition, 37 soil samples from 25 borings were analyzed for the 12 priority pollutant metals: antimony, arsenic, beryllium, cadmium, chromium, copper, lead, mercury, nickel, selenium, thallium, and zinc. Cyanide analyses were also performed on these samples. Nine of these borings were located in Area 1 and 16 were located in Area 2. Eleven of the soil samples analyzed for trace metals were collected from Area 1 borings and 23 were collected from Area 2 borings. There were also three field duplicates for a total of 37 soil samples analyzed for trace metals. Additional detailed information is contained in the Soil Boring/Surface Soil Investigation Report (McLaren/Hart, 1996a).

The only other non-radiological results are for samples collected during the Phase 1D investigation of Area 1, the Additional Characterization of Areas 1 and 2, and the Cotter investigation.[8] These samples were analyzed for Target Analyte List (TAL) trace metals, inorganic parameters including pH, calcium, magnesium, sodium, potassium, alkalinity, chloride, fluoride and sulfate, and three transition metals: scandium, niobium and tantalum. A total of 138 soil samples were collected by these investigations, including 69 samples plus seven duplicate samples from Area 1 and 54 samples plus eight duplicate samples from Area 2.

---

[8] As described further in Sections 4.4.8 and 4.5.6 of the RI Addendum, Cotter conducted additional investigations in Areas 1 and 2 as part of the Phase 1 and Additional Characterization sampling efforts.

A summary of the results of the non-radiological analyses (both organic and non-organic) are presented in Section 8 of the RI Addendum (EMSI, 2016b). Overall, the occurrences and concentrations of the various chemical constituents are consistent with the disposal of MSW. Disposal operations at the West Lake Landfill date back to the 1950s and predate the adoption of federal or state regulations prohibiting the disposal of hazardous wastes in solid waste landfills. In addition, during the time period in which wastes were disposed of at the Site, certain household products frequently contained substances that are now regulated as hazardous waste. Accordingly, there is a potential that some of the waste materials at the Site could display the characteristics of hazardous wastes.

The potential for occurrences of hazardous wastes within Areas 1 and 2 exhibiting the toxicity characteristic (TC) was evaluated by comparing the maximum levels of the 40 designated chemical constituents detected in any of the RI or subsequent investigation (Phase 1D, Additional Characterization or Cotter Investigation) soil/waste samples to the maximum concentration of contaminants using the Toxicity Characteristic Leaching Procedure (TCLP) established under the Resource Conservation and Recovery Act (RCRA) (40 CFR Part 261.24) and the Missouri state hazardous waste regulations (10 CSR 25-4.261). Section 1.2 of the TCLP provides that if the total analysis of a waste demonstrates that toxic characteristics are present only at concentrations below their respective regulatory levels, the TCLP need not be run. For wastes with no free liquids, this is accomplished by multiplying the TC regulatory limit by 20 (to reflect the 20x weight ratio of extraction fluid to solid in the TCLP protocol) for comparison to the respective constituent concentrations. The results of these comparisons are presented on Table 2-9.

Based on these comparisons, the possibility exists that some of the waste materials contained in Areas 1 and 2 could be classified as hazardous wastes based upon the presence of TC metals, or their benzene, chloroform, or 1-4 dichlorobenzene concentrations. However, this possibility can only be verified by subjecting representative samples to the TCLP for those constituents, since the screening was compared to the highest single value (not necessarily the representative concentration), and the chemical form and/or attenuation by the solid matrix may preclude significant leachability under the procedure. RCRA regulatory authorities do not apply to wastes legally placed into a disposal unit prior to RCRA's effective date unless the wastes are excavated or removed from the disposal unit. Further waste classification is not necessary unless and until such excavation occurs.

2.2.11 Asbestos Containing Materials in Soil/Waste

Identification of, or testing for, regulated asbestos containing materials (RACM) was not included in the scope of the RI field investigations or the subsequent investigations. Review of the RI soil boring logs (Appendix B-1 of the RI Addendum) does not indicate that pipe insulation, transite panels or other materials that may represent RACM were encountered during drilling; however, as stated above, identification of such materials was not part of the scope of the RI field investigations. Individuals responsible for performance of the Phase 1C, Phase 1D, Additional Characterization and Cotter investigations were required to complete asbestos awareness training and were therefore conscious of the potential for asbestos. No indications of potential RACM were noted during these field investigations. However, because the RI field investigations did not include procedures to identify the presence of RACM, no definitive information exists from the RI investigations regarding the presence of RACM in Areas 1 and 2.

2.3 Radionuclide Occurrences in Air

Radionuclides can be transported to the atmosphere either as a gas (in the case of the various radon isotopes) or as fugitive dust (in the case of the other radionuclides). This section summarizes the results of radon flux measurements from the surfaces of Areas 1 and 2 and measurements of radon levels in air along the perimeters of Areas 1 and 2. It also summarizes the results of radionuclide analyses of fugitive dust samples collected from Areas 1 and 2 during the OU-1 RI and from along the perimeters of Areas 1 and 2 during 2015-2016.

2.3.1 Radon Flux and Radon in Atmospheric Air

Radon gas is discharged into the atmosphere as a result of the decay of radium. No standard for radon emissions directly applicable to the Site have been established. In 40 CFR Part 61, EPA established a standard of an average of 20 pCi/m^2s for radon emissions from uranium mill tailings from a number of samples (generally 100) collected from the surface of the tailings in a statistically unbiased fashion. Although this standard is directly applicable only to uranium mill tailings, it does represent a health-based standard derived by EPA.

Radon flux measurements were conducted at the Site during the RI investigation using the Large Area Activated Charcoal Canisters (LAACC) method presented in Method 115, Appendix B, 40 CFR Part 61 (EMSI, 1997a). The LAACC method involves placing a canister on the surface of the Site in a designated area and then allowing radon to collect on charcoal within the canisters for a period of 24 hours. Based on the radon flux measurements obtained during the RI[9], the average radon flux from Area 1 is 13 pCi/m^2s, which is below the EPA standard for uranium mill tailings. The average radon flux for Area 2 is 28 pCi/m^2s. This average is above the EPA uranium mill tailings standard; however, this value is due solely to the results obtained from two locations (WL-209 and WL-223). The results obtained from these two locations represented the vast majority of the radon flux found in Area 2 during the OU-1 RI. The average flux for all other portions of Area 2, excluding these two locations, was only 0.94 pCi/m^2s, which is approximately 5% of the allowable flux for uranium mill tailings piles.

Radon flux emissions from the surfaces of Areas 1 and 2 were also measured in 2016 after completion of construction of the non-combustible cover over those portions of Areas 1 and 2

[9] Radon flux was measured rather than concentration because no structures are present in either Area 1 or Area 2 that would result in the buildup of radon concentrations. Instead, the potential transport pathway is the migration of the gas from the Site to the atmosphere.

where RIM previously existed at the ground surface. The arithmetic mean value of the results was 0.061 pCi/m^{2}s, which is far below the UMTRCA standard of 20 pCi/m^{2}s.

Radon that is emitted from the surface of Areas 1 and 2 is subject to natural dilution and dispersion processes active in the atmosphere. As noted above, radon flux measurements were taken directly at the ground surface and within the confined space of each LAACC. Under natural conditions, radon emissions from the Site are immediately dispersed by atmospheric movement as the gas migrates from the ground surface, resulting in far less exposure to the potential receptors than was measured using the LAACCs. Measurement of radon levels in atmospheric air were conducted at the 13 air monitoring stations installed in 2015 and operated to obtain baseline air monitoring data for the Site (Auxier and EMSI, 2014 2016a, 2016b, and 2016c). Recorded radon concentrations were all less than 0.4 pCi/L during the first quarterly (12-week) monitoring event (May through August 2015), ranged from less than 0.4 up to 0.7 pCi/L in the second quarterly event (September through November 2015), and ranged from less than 0.4 up to 0.6 pCi/L during the third quarterly event (October 2015 through January 2016). Table 2-10 presents a summary of the perimeter air monitoring results for radon obtained through January 2016.

EPA has established a standard under UMTRCA (40 CFR § 192.02 (b)(2)) for radon outside an UMTRCA-regulated disposal facility. The standard specifies that control of residual radioactive materials shall be designed to provide reasonable assurances that releases of Rn-222 from residual radioactive material to the atmosphere will not increase the annual average concentration of Rn-222 in air at or above any location outside the disposal site by more than one-half picocurie per liter (0.5 pCi/L). The radon levels measured at the Site (Table 2-10) meet this standard.

EPA also performed air monitoring at five off-site stations, four of which were located in the vicinity of the West Lake Landfill and one (EPA station 5) that was located in St. Charles, MO. EPA designated station 5 as a reference (or background) station, because it is frequently upwind of the Site and was located further away from the Site than the other stations but still within the general vicinity so as to be representative of the North St. Louis County and east St. Charles County area (TetraTech, 2016 and 2015b). For the period from April 25, 2015 through February 17, 2015, EPA reported radon levels at its reference (background) station ranging from 0.11 to 1.45 pCi/L, with a median value of 0.30 pCi/L (TetraTech, 2015e). The values measured at the 13 perimeter air monitoring stations are similar to the levels obtained from the EPA reference (background) station, and if the 0.3 pCi/L median value from the EPA reference station was considered to be background (instead of the 0.4 pCi/L value EPA has indicated is typically present in outdoor air), the results from 13 perimeter air monitoring stations at the Site are all within 0.5 pCi/L of the median result obtained by EPA at its reference station.

2.3.2 Fugitive Dust Sampling

Fugitive dust monitoring was conducted at one location in Area 1 and one location in Area 2 during the OU-1 RI field investigations. Sampling for fugitive dust was performed at locations that contained some of the highest radionuclide concentrations in surface soil samples. Based on the monitoring results, as well as the presence of the prior vegetative cover and the subsequent rock cover over Areas 1 and 2, atmospheric transport of radionuclides in fugitive dust does not appear to have been, or currently be, a significant pathway for offsite migration (EMSI, 2000).

After the OU-1 RI sampling in 1996, the surface areas of Areas 1 and 2 became heavily vegetated, and inert fill was placed over portions of the surface, thereby reducing the potential for fugitive dust emissions at the Site. This reduction is confirmed by the absence of increased levels of radionuclides in the fugitive dust samples collected from around the perimeters of Areas 1 and 2 in 2015 and 2016, as described below. In addition, those portions of Areas 1 and 2 where RIM was previously present at the ground surface were covered in 2016 (after development of the most recent air monitoring results available) with rock/roadbase material as part of the construction of the non-combustible cover over these areas, thereby further reducing the potential for emissions of radionuclides in fugitive dust.

Measurements of radionuclides in fugitive dust (particulate samples) have been obtained at the 13 air monitoring stations installed in 2015 and operated to collect baseline air monitoring data for the Site (Auxier and EMSI, 2014, 2016a, b and c). Air particulate samples are collected every 28 days and submitted for analysis. Each sample is analyzed for Gross Alpha and Gross Beta levels. The results of the first three quarters (May 2015 through January 2016) of on-site monitoring for gross alpha and gross beta are summarized on Tables 2-11 and 2-12. The results obtained during the first three quarters of operation of the perimeter air monitoring program were compared to the results obtained from the EPA off-site monitoring program over the period from May 2014 through February 2015 (Auxier and EMSI, 2016a, b, and c). Overall, the gross alpha results obtained from the 13 on-site stations are similar to or slightly higher than the results obtained from EPA's five off-site stations.[10] The gross beta results obtained from the 13 on-site stations are similar to the gross beta results obtained from the EPA off-site monitoring locations.

For the first quarter of sampling (May through July 2015), the May and June 2015 particulate samples were analyzed for isotopic thorium, uranium, and by gamma spectroscopy. Particulate results from September and December 2015 (the middle of each respective three-month monitoring period) were also submitted for isotopic analysis and gamma spectroscopy. As expected, the isotopic and the gamma spectroscopy results demonstrate only naturally-occurring radioactive materials. Statistics for Th-230, U-238, and combined radium results (the sum of actinium-228 [for Ra-228] and Bi-214 [for Ra-226] from gamma spectrometry) for each station in pCi/m^3 for May, June, September, and December 2015 are presented on Tables 2-13, 2-14, and 2-15. The results of on-site monitoring for U-238, Th-230, and combined radium were also compared to the results obtained from the EPA off-site monitoring program over the period from May 2014 through February 2015 (Table 2-16).

---

[10] Whether this difference is statistically significant cannot be determined until additional on-site data are obtained (sampling is ongoing at this time). The differences may reflect dust levels, seasonal conditions (pollen levels), differences in precipitation (*i.e.*, soil moisture), or differences in the total particulate levels between the period covered by EPA's air monitoring program and the period covered by the on-site air monitoring program.

In almost all cases, the isotopic uranium and thorium and combined radium results obtained from the 13 on-site stations are lower than the results obtained from EPA's five off-site stations. The isotopic results were converted to µCi/ml and compared to 10 CFR 20 Appendix B Effluent Limits. The results are well below the applicable effluent limits (Auxier and EMSI, 2016a, b, and c).

2.4 Radionuclides in Stormwater, Surface Water and Sediment

Radionuclides present in Areas 1 and 2 could potentially be transported to other portions of the Site or to offsite areas via precipitation runoff from the Site. Transport via rainwater runoff could include both dissolved phase transport and suspended phase transport within the flowing runoff water. Potential impacts to permanent surface water bodies, as well as the actual or potential receptors of any offsite migration of radionuclides, are summarized below. A more detailed discussion can be found in Section 7.2 of the RI Addendum (EMSI, 2016b).

It should be noted that this section discusses sampling results performed in 1995-1997 as part of the OU-1 field investigations – before inert fill material was placed on the surface of Areas 1 and 2, and before the recent (2016) installation of a non-combustible cover over areas where RIM is present at the ground surface. All of these actions would serve to greatly reduce and, ultimately, likely eliminate the potential for radionuclide transport in surface water. This conclusion is supported by results of the recent stormwater monitoring activities (discussed below) conducted in conjunction with installation of the non-combustible cover.

Current surface water runoff patterns for Areas 1 and 2 are presented on Figure 2-15. All runoff from Area 1 ultimately flows into the perimeter drainage ditch located along the northeast side of the landfill adjacent to St. Charles Rock Road (the Northeast Perimeter Drainage Ditch), which then flows into the surface water body located north of Area 2 (the North Surface Water Body).

Runoff from the northern (majority) portion of Area 2 flows into one of two closed topographic depressions created by the presence of the perimeter berm located at the top of the landfill slope. Runoff from the southeastern portion of Area 2 flows to the northeast where it enters the Northeast Perimeter Drainage Ditch and subsequently flows into the North Surface Water Body. Runoff from the southernmost portion of Area 2 eventually flows to the southeast along the internal road that provides access to Area 2 and down to the drainage ditch located on the north side of the Site access road, from where it also flows to the Northeast Perimeter Drainage Ditch. Runoff from the southwestern portion of Area 2 flows as overland flow onto the Buffer Zone where it ponds, unless sufficient water accumulates such that the water reaches the western portion of the Buffer Zone where it can flow overland into a culvert that conveys stormwater to the large Earth City stormwater basin located adjacent to Area 2 and the AAA Trailer property.

Rainwater runoff (stormwater) samples were collected in 1995 by McLaren/Hart and in 1997 by EMSI during the OU-1 RI field investigations at four locations in Area 1 and six locations in Area 2 (Weirs 1 through 10, as depicted on Figure 2-15). Review of the rainwater runoff results indicates that radium levels above the drinking water standard were only present in the sample from Weir 9. Specifically, the Ra-226 level detected in the unfiltered sample obtained in April 1996 from this location was 8.85 pCi/L compared to the drinking water standard of 5 pCi/L.[11] Subsequent sampling of rainwater runoff from this location in May 1997 indicated that the combined Ra-226 (0.32 pCi/L) and Ra-228 (<0.87 pCi/L) did not exceed or even come close to the drinking water standard of 5 pCi/L.

Stormwater samples were also collected in 2016 during construction of the non-combustible cover over surface RIM in Areas 1 and 2. With one possible exception, all of these samples contained only background levels of radium and uranium. The reported activity concentrations of combined Ra-226 plus Ra-228 for these samples were all less than the radium drinking water standard of 5 pCi/L. Total uranium results were all less than 20 pCi/L (estimated equivalency to 30 µg/L drinking water standard), except for one sample from NCC-002 obtained on April 13, 2016, which was reported to contain 30 pCi/L of combined uranium isotopes. Subsequent stormwater samples were analyzed for total uranium as a metal and were below the 30 µg/L standard.

During the OU-1 RI field investigations, McLaren/Hart in 1995 and EMSI in 1997 collected samples of permanent surface water adjacent to the Site into which runoff from the Site may flow. The two surface water bodies adjacent to the Site are the North Surface Water Body[12] and the Earth City Flood Control Channel.[13] The surface water sampling locations associated with these two water bodies are shown on Figure 2-15. Analytical results for these samples did not exceed the drinking water MCL of 5 pCi/L for gross alpha. Further, none of the radium sample results exceeded the radium drinking water MCL of 5 pCi/L.

Sediment sampling was conducted in 1995, 1997, and 2016 at locations depicted on Figure 2-15. Results of the 1995 and 1997 sediment sampling and analysis indicated that Th-230, Ra-226 and Pb-210 were present in sediments above EPA Preliminary Remediation Goals (PRG) at Weirs 1, 2 and 3 in Area 1 and at Weirs 5, 6, 7 and 9 in Area 2.

Additional sediment samples were obtained from SED-1, SED-2 and SED-4 in 2016 in conjunction with the Additional Characterization of Areas 1 and 2. Only Th-230 (14.7 pCi/g) in the sample from SED-4 exceeded the unrestricted use standards; however, radionuclides were not detected in these samples at levels above the EPA PRGs for outdoor workers (19.8 pCi/g for Th-230). In response, additional sediment samples were also obtained in 2016 from the

[11] However, the filtered sample obtained from this location during the same sampling event contained only 0.80 pCi/L, indicating that the majority of the Ra-226 detected in the unfiltered sample was present as suspended sediment. Due to high MDA levels, the Ra-228 results for this sampling event did not provide any meaningful data (for purposes of comparison to the MCL).

[12] The North Surface Water Body is currently located partially onsite and partially on offsite property owned by STL Properties LLC (the former Emerson Electric property), and its composition has changed over time. During the RI investigations, the North Surface Water Body was located primarily onsite. Subsequently, the portion that is located on the Site became overgrown and silted and is now primarily swamp, except during periods of rainfall, when water ponds in this area.

[13] Based on topographic conditions, it does not appear that runoff from Areas 1 or 2 could enter the Flood Control Channel.

Northeast Perimeter Drainage Ditch at the location of SED-4 and at approximately 100-foot increments 100, 200 and 300 feet to the north of SED-4. Analytical results for these samples did not detect the presence of any radionuclides at levels above the unrestricted use criteria.

The northern portion of Area 2 is characterized by a landfill slope/berm of approximately 20 to 30 feet average height. Scouring and erosional transport of soil via rainwater runoff from the landfill berm slope down onto the adjacent former Ford Property reportedly occurred a year or two after disposal activities in Area 2 ceased. This historic erosional scour resulted in transport of soil, some of which contained radionuclides, from Area 2 down onto the adjacent former Ford Property where it meets the toe of the landfill berm. This runoff and erosion was subsequently stopped through the construction of runoff diversion berms and natural re-vegetation of the landfill slope.

Analytical results from soil samples collected from the former Ford Property during the OU-1 RI field investigation indicated that past transport of radionuclides onto the former Ford Property was limited to the upper 6 inches of soil. The current extent of radionuclide occurrences on the former Ford Property (now the Buffer Zone and Crossroads Lots 2A1 and 2A2) are unknown because these areas were graded after the most recent samples were collected from these areas; however, all of these areas are currently covered with rock and or pavement. (See prior discussion in Section 2.2.9).

2.5 Groundwater Conditions

This section briefly summarizes the results of the most recent groundwater sampling events at the Site as of the writing of this FFS.

Sampling of all of the groundwater monitoring wells at the Site (up to 85 wells per event) was conducted as part of four comprehensive groundwater sampling events performed in 2012-2013. The following results were obtained:

- Generally, only background levels of uranium and thorium were detected in groundwater during these events.
- Certain wells at the Site contained combined total radium at levels greater than the MCL (5 pCi/L) during all four of the 2012-2013 sampling events.
- Overall, no spatial correlation between occurrences of radium at levels greater than the MCL and Areas 1 and 2 could be identified.
- No contiguous area of radium occurrences indicative of a plume of groundwater contamination was present.
- The most probable source of the radium occurrences in bedrock groundwater around the North and South Quarry portions of the Bridgeton Landfill is release of naturally-

occurring radium in the bedrock units, or release of radium that was adsorbed onto iron and manganese oxides and hydroxides which have become soluble under reducing conditions associated with anaerobic (oxygen-deficient) decomposition of the MSW in the landfill.

- Based on the relatively low solubility of radionuclides in water and their affinity to adsorb onto the soil matrix, leaching of radionuclides into groundwater and subsequent transport in groundwater to off-site areas does not appear to be a significant migration pathway.

Additional evaluations of the potential for leaching and vertical transport of radionuclides in the landfill mass are currently being conducted.

Brief descriptions of the geology and hydrogeology of the Site are provided in subsections 2.5.1 and 2.5.2. More detailed information on the geology and hydrogeology is set forth in the RI Addendum (EMSI, 2016b) and the OU-1 and OU-2 RI reports (EMSI, 2000 and Herst & Associates, 2005).

The nature and extent of radiological and chemical constituent occurrences in groundwater near Areas 1 and 2 are described in Sections 2.5.3 and 2.5.4 below. Additional information regarding the nature and extent of contamination associated with Areas 1 and 2 is presented in the OU-1 RI Addendum report (EMSI, 2016b).

EPA has previously indicated that groundwater conditions at the Site will be separately characterized as part of a new Operable Unit (OU-3).

2.5.1 Geology

The bedrock geology of the Site area consists of Paleozoic-age sedimentary rocks overlying Precambrian age igneous and metamorphic rocks (EMSI, 2000). The Paleozoic bedrock is overlain by unconsolidated alluvial and loess deposits of recent (Holocene) age (EMSI, 2000).

The depth to bedrock and the thickness of the alluvial deposits increases to the west of the Site where the thickness of alluvium (depth to bedrock) was reported to be 120 feet (Herst & Associates, 2005).

2.5.2 Hydrogeology

Alluvial deposits of varying thickness are present beneath Areas 1 and 2 (See Section 5.5.1 of the RI Addendum, EMSI 2016b). The landfill debris varies in thickness from 5 to 56 feet in Areas 1 and 2, with an average thickness of approximately 36 feet in Area 1 and approximately 30 feet in Area 2. The underlying alluvium increases in thickness from east to west beneath Area 1. The alluvial thickness beneath the southeastern portion of Area 1 is less than 5 feet (bottom elevation of 420 feet AMSL), while the thickness along the northwestern edge of Area 1 is approximately 80 feet (bottom elevation of 370 feet AMSL). The thickness of the alluvial deposits beneath Area 2 is fairly uniform at approximately 100 feet (bottom elevation of 335 feet AMSL). Water level measurements performed during the RI indicated that the water level elevations beneath, and adjacent to, Areas 1 and 2 were consistent with only approximately one-half foot of variability in the water levels beneath these areas during any given set of measurements. Seasonally, the water levels varied by approximately 5 feet beneath and adjacent to Areas 1 and 2 from approximately 429 feet AMSL in April 1995 to 434 feet AMSL in July 1995. These water level elevations corresponded to depth-to-groundwater in these areas of at least 35-40 feet bgs and generally nearer to 50 feet bgs beneath Areas 1 and 2. Consequently, groundwater was generally encountered beneath Areas 1 and 2 in the underlying alluvium near or below the base of the landfill debris.

The regional direction of groundwater flow is generally northward within the Missouri River alluvial valley, parallel or sub-parallel to the river alignment. The RI data indicate that only a very small amount of difference (less than one foot) exists in the water table surface beneath the Site, making interpretations of the directions of groundwater flow based only on water level data difficult. Based on the water level data, the direction of groundwater flow beneath Area 1 during the RI appeared to be generally to the south toward the Bridgeton Landfill. Water level elevations beneath Area 2 displayed areal differences of less than one foot indicating the presence of a relatively flat water table. Based on the groundwater levels, the direction of groundwater flow beneath Area 2 is expected to be to the west/northwest toward the Missouri River.

There are no public water supply wells near the Site. Well inventories presented in the RI report (EMSI, 2000) and in the RI for OU-2 (Herst & Associates, 2005) indicate that the nearest private well reportedly used as a drinking water source is located one mile to the north of the Site (Foth & Van Dyke, 1989), and that the closest registered well is located approximately one mile northeast of the Site. This well was reportedly drilled to a depth of 245 feet, which indicates a bedrock completion. Regional groundwater flow in the bedrock near the Site is to the northwest, towards the Missouri River. Accordingly, the nearest registered well is not downgradient of the Site. The closest registered well that appears to be completed in alluvium is approximately 2.5 miles south (upgradient) of the Site.

An updated evaluation of the locations of water supply wells was performed by USGS during the performance of the 2012-2013 comprehensive groundwater sampling events. Information regarding the locations of water supply wells is provided in the RI Addendum and the associated figures. Overall, the wells located to the north and west of the Site (*i.e.*, downgradient) are used for industrial and commercial purposes such as irrigation, construction, and dewatering (levee system operations). None of the wells are used to provide domestic or community (potable) water supplies.

Detailed discussions of the hydrogeology of the alluvial groundwater and bedrock groundwater are presented in the RI Addendum (EMSI, 2016b) and the OU-1 and OU-2 RI reports (EMSI, 2000 and Herst & Associates, 2005).

2.5.3 Occurrences of Radionuclides in Groundwater

Groundwater sampling and analysis was performed during 1995, 1996 and 1997 as part of the 2000 RI and during 2004 in conjunction with the FS. To date, the most comprehensive groundwater data sets for the Site were developed during the site-wide groundwater sampling events conducted in August 2012 and April, July, October, and November 2013.[14] The focus of the discussions presented in this section is largely on the results obtained from the 2012/2013 comprehensive groundwater sampling events. A comparison of the results obtained by the 2012/2013 events to results obtained during the earlier RI and FS events is presented in the RI Addendum (EMSI, 2016b).

Radionuclide water quality results are discussed in terms of radium isotopes, thorium isotopes, and uranium isotopes. Because radium isotopes are the primary radionuclides of concern (in terms of general occurrences in groundwater, mobility, and potential health risks), the majority of the discussion of the radionuclide water quality results is focused on occurrences of radium in groundwater.

It should be noted that both Ra-226 and Ra-228 are naturally occurring (EPA, 2006b and 2002 and Focazio, et al., 2000). Background levels of naturally-occurring Ra-226 in groundwater are expected to range from 1 to 5 pCi/L, and background levels of naturally-occurring Ra-228 in groundwater are expected to range from 1 to 7 pCi/L. However, Ra-226 levels as high as 35 pCi/L and Ra-228 levels as high as 26 pCi/L have been reported for samples obtained from wells located to the south (upgradient) and away from the disposal units at the Site, and more particularly upgradient of Areas 1 and 2.

EPA has established (40 CFR Part 141) an MCL of 5 pCi/L for combined Ra-226 plus Ra-228 in drinking water supplies. Although this standard is not applicable to groundwater that is not used for drinking water, it was determined by EPA (2008a) to be a potentially relevant and appropriate requirement for evaluation of groundwater quality. Therefore, the combined radium results from the recent groundwater monitoring events have been compared to 5 pCi/L.

A graphical display of the results of the comparisons of the combined total (unfiltered samples) radium results to the radium MCL is shown on Figure 2-16. A graphical display of the results of the comparisons of the combined dissolved (filtered samples) radium results to the MCL is shown on Figure 2-17. The overall distribution of wells that contain combined total and/or combined dissolved radium levels greater than the MCL indicates that a mechanism other than leaching to and migration within groundwater from Areas 1 and 2 is responsible for these radium occurrences.

---

[14] In addition to the four events requested by EPA, two additional sampling events were conducted to obtain samples from eight new monitoring wells that were installed by Bridgeton Landfill, LLC in October 2013. These eight wells were sampled in November 2013 and February 2014.

2.5.4 Occurrences of Chemical Constituents in Groundwater

The most extensive program of groundwater sampling and chemical analyses conducted were those associated with the four comprehensive groundwater sampling events conducted in August 2012 and April, July and October 2013. During these events, up to 85 monitoring wells located throughout the entire Site were sampled and submitted for chemical analyses, including VOCs, trace metals, inorganic parameters and during the first event, SVOCs.

2.5.4.1 Volatile Organic Compounds in Groundwater

The groundwater samples collected from all of the Site wells during the 2012 – 2013 comprehensive groundwater monitoring events were analyzed for 49 different VOCs. Most of these VOCs were not detected in any of the groundwater samples. The primary VOCs that were detected in some of the groundwater monitoring wells included benzene and related hydrocarbon compounds (toluene, ethyl benzene, xylenes, methyl tert-butyl ether, and cumene), chlorobenzene and other chlorinated benzenes (1,4-dichlorobenzene), and vinyl chloride and related chlorinated solvents (1,2-dichloroethene). Of these, only benzene, chlorobenzene and vinyl chloride were detected at concentrations above their respective groundwater standards (5 µg/L for benzene, 100 µg/L for chlorobenzene and 2 µg/L for vinyl chloride).

Benzene was the most commonly detected VOC. Benzene has been detected at concentrations greater than its MCL of 5 µg/L in three distinct areas of the Site, as shown on Figure 2-18.

Chlorobenzene was detected in 24 to 25 monitoring wells during each of the 2012 – 2013 groundwater monitoring events (Figure 2-19). Chlorobenzene was detected in only two monitoring wells (PZ-112-AS and LR-105) at concentrations greater than its MCL of 100 µg/L (Figure 2-19).

Vinyl chloride was detected in 4 to 10 wells during each event (Figure 2-20). Vinyl chloride was detected in only four monitoring wells at concentrations greater than its MCL of 2 µg/L during some but not all of the 2012 – 2013 groundwater monitoring events (Figure 2-20).

Overall, VOC occurrences in groundwater at the Site are isolated and do not indicate the presence of an extensive area or plume of VOC contamination. Most of the benzene in the groundwater is near the South Quarry portion of the Bridgeton Landfill and the southern portion of the Inactive Sanitary Landfill.

2.5.4.2 Semivolatile Organic Compounds in Groundwater

The August 2012 groundwater samples were analyzed for SVOCs. Very few SVOCs were detected. The most commonly detected SVOC was 1,4-dichlorobenzene, which was detected in

11 of the 73 monitoring wells that were sampled and analyzed for SVOCs. The highest detected concentration of 1,4-dichlorobenzene was 19 µg/L in LR-105, which is less than the corresponding Missouri water quality standard of 75 µg/L. Overall, SVOCs were detected in only a few groundwater samples from the Site and generally at levels below their respective drinking water standards.

2.5.4.3 Trace Metals

Most of the trace metals were detected in most of the groundwater samples; however, many of the trace metals were not detected at concentrations greater than their respective MCLs or were only detected in the total fraction samples at concentrations above the MCLs, possibly indicating that their presence is due to inclusion of suspended sediment/colloidal matter in the unfiltered samples. The primary trace metals of interest that were detected in the groundwater monitoring wells include arsenic, iron, manganese, and barium.

2.5.4.3.1 Arsenic

Figure 2-21 presents a graphical summary of the locations where total (unfiltered) arsenic was detected above its MCL of 10 µg/L. The highest levels of total arsenic were reported for samples obtained from wells PZ-114-AS and S-82 near Area 1 and in wells PZ-302-AS and PZ-304-AS located on the west side of the Inactive Sanitary Landfill.

Figure 2-22 presents a graphical summary of the locations where dissolved arsenic was detected above its MCL of 10 µg/L. The highest levels of dissolved arsenic were reported for samples obtained from the same wells as those that contained high concentrations of total arsenic (*e.g.*, PZ-114-AS, PZ-302-AS, PZ-304-AS, and S-82).

2.5.4.3.2 Iron

Occurrences of total and dissolved iron at levels above its MCL (300 µg/L) were found throughout the Site area (Figures 2-23 and 2-24). The highest levels of iron were generally detected near the Inactive Sanitary Landfill and Area 1. The iron in the groundwater at the Site is consistent with the presence of reducing conditions associated with MSW decomposition in landfill settings.

2.5.4.3.3 Manganese

Occurrences of total and dissolved manganese at levels above its MCL (50 µg/L) were found throughout the Site area (Figures 2-25 and 2-26). The highest levels of manganese were generally detected near the Inactive Sanitary Landfill, between the Closed Demolition Landfill and Area 2, near Area 1, beneath the hauling company yard to the east of the North Quarry portion of the Bridgeton Landfill, and near the southern corner of the South Quarry portion of the Bridgeton Landfill.

The occurrences of manganese in groundwater at the Site are, similar to iron, consistent with the presence of reducing conditions associated with decomposition of MSW.

2.5.4.3.4 Barium

Occurrences of total and dissolved barium at levels above its MCL (2,000 µg/L) are summarized on Figures 2-27 and 2-28.

As shown, three wells (D-3, D-85, and PZ-113-AD) contained barium in the total fraction (unfiltered) samples at concentrations greater than its MCL of 2,000 µg/L during the 2012-2014 events. All three of these wells are near Area 1. Three other wells (PZ-112-AS, I-73, and PZ-304-AS) contained total barium above its MCL during some, but not all, of the 2012-2013 monitoring events. No other wells displayed total barium levels above its MCL.

Six wells contained dissolved barium levels above its MCL during some, but not all four, of the 2012-2013 monitoring events, including D-3, PZ-113-AD and PZ-112-AS near Area 1; I-73 and MW-1204 near the South Quarry portion of the Bridgeton Landfill; and PZ-304-AS along the west side of the Inactive Sanitary Landfill.

None of the groundwater samples obtained from wells located around Area 2 ever detected barium at concentrations greater than its MCL.

2.5.4.4 Inorganic Constituents

Results obtained for two inorganic constituents, sulfate and chloride are summarized in this section. Additional information regarding occurrences of inorganic constituents is presented in the RI Addendum (EMSI, 2016b).

2.5.4.4.1 Sulfate

Only four wells contained sulfate at concentrations above its MCL (250 µg/L): wells D-12 and S-10 in Area 2, well MW-102 on the west side of Area 2, and well PZ-204A-SS on the southwest side of the South Quarry portion of the Bridgeton Landfill (Figure 2-29). Of these, sulfate was reported at concentrations above its MCL during all 2012-2013 events for wells S-10 and D-12 and during the last two 2013 events for wells MW-102 and PZ-204A-SS.

2.5.4.4.2 Chloride

Chloride is a common constituent of landfill leachate. The highest levels of chloride were detected in wells I-73 (1,700 mg/L in July 2013), MW-1204 (1,400 mg/L in October 2013), and LR-105 (930 mg/L in April 2013). Occurrences of chloride at concentrations greater than its MCL of 250 mg/L were detected in nine of the 85 wells sampled during all 2012-2013 events (Figure 2-30). Chloride was detected at concentrations greater than its MCL during one or more, but not all four, events in 14 additional wells (Figure 2-30). Occurrences of chloride above the MCL were generally found in wells located around the South Quarry portion of the Bridgeton Landfill, the west side of the Inactive Sanitary Landfill, around Area 1, and along the east and south sides of Area 2 (Figure 2-30).

2.5.5 Possible Radionuclide and Chemical Contributions to Groundwater from Areas 1 and 2

The results of the 2012–2013 groundwater monitoring activities clearly indicate that Areas 1 and 2 are not contributing either uranium or thorium to the groundwater. This is not unexpected given the very low solubility of thorium and the low solubility of uranium, especially under reducing conditions, which often occur in and around MSW landfills.

Evaluation of potential radium contributions to groundwater from Areas 1 and 2 is influenced by the presence of higher levels of radium in upgradient bedrock wells. All of the radium results obtained from alluvial monitoring wells located within or downgradient of Areas 1 and 2 were less than or similar to the radium levels observed in bedrock and alluvial monitoring wells located upgradient or upgradient/cross-gradient from Areas 1 and 2. This observation is consistent with the conclusion offered by the USGS that "there is not a strong spatial association of monitoring wells surrounding or downgradient of RIM areas with elevated radium concentrations as might be expected if RIM areas were releasing substantial quantities of radium to the groundwater." (USGS, 2014, p. 43).

With the possible exception of benzene occurrences in the southwestern portion of Area 1 (*i.e.*, wells D-14, I-4, and PZ-112-AS), chlorobenzene in PZ-112-AS, and vinyl chloride occurrences in the southwestern portion of Area 2 (*i.e.*, wells I-9 and D-93), there are no VOC impacts to groundwater beneath or immediately downgradient of Areas 1 and 2. The majority of wells in or around Areas 1 and 2 were either non-detect for VOCs or contained trace levels of VOCs (less than their respective MCLs).

Occurrences of arsenic, iron, manganese, barium and sulfate were detected in groundwater throughout the Site and reflect dissolution of these substances from the landfilled wastes and/or possibly enhanced dissolution of these substances from naturally-occurring minerals within the alluvial and bedrock units due to the presence of reducing conditions associated with waste decomposition within the landfills. The monitoring data do not indicate that Areas 1 and 2 are contributing significantly greater amounts of trace metals or inorganic constituents than occur in other landfill areas at the Site, or at other offsite landfills.

2.6 Baseline Risk Assessment

To be provided in a subsequent submittal.

3 POTENTIAL ARARS AND REMEDIAL ACTION OBJECTIVES

This section of the FFS describes environmental laws which may represent potentially applicable or relevant and appropriate requirements (ARARs) for remedial actions for OU-1. This section also describes additional requirements associated with offsite disposal. Remedial action objectives (RAOs) to be addressed by the remedial alternatives are also presented in this section. Cleanup levels that would allow for unrestricted use of the Site relative to radionuclide occurrences are developed in this section based on EPA's directives regarding chemical-specific ARARs and Site-specific risk-related factors. Cleanup levels associated with partial excavation alternatives identified by EPA (EPA, 2015a) are also discussed.

3.1 Potentially Applicable or Relevant and Appropriate Requirements

CERCLA remedial actions must be analyzed for compliance with ARARs. ARARs are divided into three categories (EPA, 1988):

- Chemical-specific ARARs;
- Location-specific ARARs; and
- Action-specific ARARs.

Compliance with ARARs is one of the criteria used to evaluate potential remedial alternatives in an FS. Descriptions of ARARs, the criteria used to identify whether a regulation contains potentially applicable or relevant and appropriate requirements for remedial actions for OU-1, and identification of potential ARARs for OU-1 are provided in the FS and SFS reports (EMSI, 2006 and EMSI et al., 2011). The following sections provide additional evaluation of ARARs as they relate to the ROD-selected remedy, the "complete rad removal" and the partial excavation alternatives. In addition, this section addresses additional ARARs evaluation specified by EPA in the SOW.

3.1.1 Potential Chemical-Specific ARARs

Chemical-specific ARARs include those laws and requirements that regulate the release to the environment of materials possessing certain chemical or physical characteristics, or containing specified chemical compounds. Evaluations of potential chemical-specific ARARs for West Lake Landfill OU-1 are presented in the FS and SFS reports (EMSI, 2006 and EMSI et al., 2011). The results of these evaluations are summarized on Table 3-1 and are discussed below. No additional chemical-specific ARARs have been identified as a result of work performed for this FFS or relative to the additional evaluations of the "complete rad removal" and partial excavation alternatives.

3.1.1.1 Health and Environmental Protection Standards for Uranium and Thorium Mill Tailings

The FS report (EMSI, 2006) includes an evaluation of the health and environmental protection standards promulgated under the Uranium Mill Tailings Radiation Control Act (UMTRCA) (40 CFR Part 192) for potential chemical- and action-specific requirements. Because the UMTRCA standards only apply to certain designated uranium mill tailings sites, they are not applicable to the Site. The UMTRCA standards may nonetheless represent potentially relevant and appropriate requirements for remedial actions at the Site.

The UMTRCA regulations establish specific standards for waste disposal units containing residual radioactive material and for land outside of such waste disposal units that has been contaminated with radionuclides as a result of uranium processing or waste disposal activities. Standards associated with management of a tailing pond or waste disposal unit are evaluated for potential relevance with respect to the solid waste disposal units in Areas 1 and 2, while standards associated with occurrences of radionuclides in land outside of a waste disposal unit (such as the Buffer Zone and Crossroads Industrial Park) are evaluated relative to areas outside of the Areas 1 and 2.

Specifically, the FS and SFS addressed requirements relative to the standards for radon emissions from closed tailing impoundments (40 CFR Part 192 Subpart A), standards for cleanup of contaminated land and buildings (40 CFR Part 192 Subpart B), and groundwater protection standards (40 CFR Part 192 Subparts A and B). Additional discussion of these standards as they relate to the ROD-selected remedy and the “complete rad removal” and partial excavation alternatives is presented below.

3.1.1.1.1 Radon Emissions Standards – 40 CFR § 192.02(b)

The UMTRCA regulations establish standards of release of radon to the atmosphere from residual radioactive material (40 CFR § 192.02(b)). Specifically, these standards state that control of residual radioactive materials and their listed constituents shall be designed to:

> (b) Provide reasonable assurance that releases of radon-222 from residual radioactive material to the atmosphere will not:
>
> (1) Exceed an average release rate of 20 picocuries per square meter per second, or
>
> (2) Increase the annual average concentration of radon-222 in air at or above any location outside the disposal site by more than one-half picocurie per liter.

Section 192.02(b)(1) further states that the average release rate specified therein “ shall apply over the entire surface of the disposal site and over at least a one-year period.”

These standards may potentially be relevant and appropriate chemical-specific criteria for radon emissions from Areas 1 and 2, and also represent potential performance criteria for the design of a cover system for Areas 1 and 2 included in the ROD-selected remedy and the partial excavation alternatives.

Radon monitoring was performed as part of the RI for OU-1 (see prior discussion in Section 2.3.1). These results indicate that the overall radon emission from Areas 1 and 2 (21.8 pCi/m^2/s based on the average of 50 test locations) slightly exceeded the 20 pCi/m^2/s radon emission flux standard as a result of the presence of three high value samples. Additional radon flux monitoring was performed as part of the construction of a non-combustible cover over Areas 1 and 2 and demonstrated that the average radon flux from these areas both individually and collectively meets the UMTRCA radon emission standard. In addition, monitoring performed along the margins of Areas 1 and 2 has demonstrated that under current conditions the radon emission rate from these areas meets the UMTRCA standard of no more than 0.5 pCi/L increase in radon levels in air outside of Areas 1 and 2 (see prior discussion in Section 2.3.1). Furthermore, an evaluation of the design and thickness of a landfill cover associated with the ROD-selected remedy and the partial excavation alternatives necessary to meet the 20 pCi/L and 0.5 pCi/L standards in the future based on the anticipated level of radium in-growth over time has been performed as part of the evaluation of potential remedial alternatives as discussed in Section 6 of this FFS.

Remedial actions involving placement of an engineered cover pursuant to the ROD-selected remedy or the partial excavation alternatives should be designed to meet the radon emission standard promulgated under UMTRCA. Because this standard applies to design, monitoring after disposal is not required to demonstrate compliance with this standard. However, due to the anticipated increase in radium expected to occur over time from decay of thorium, the design of an engineered cover should be based on projected future radium activity levels and associated radon generation instead of the currently observed radon flux levels.

The UMTRCA radon standards relative to any occupied or habitable building (40 CFR § 192.12(b)(1)) represent potentially relevant and appropriate requirements for radon monitoring relative to occupied buildings. Specifically, the objective of the remedial action shall be, and reasonable effort shall be made to achieve, an annual average (or equivalent) radon decay product concentration (including background) not to exceed a 0.02 Working Level (WL) (40 CFR § 192.12(b)(1)). In any case, the radon decay product concentration (including background) shall not exceed a 0.03 WL (40 CFR § 192.12(b)(1)). A Working Level is a unit of measure for documenting exposure to radon decay products, which are termed "daughter products" or simply "daughters." One Working Level is defined as any combination of short-lived daughters in one liter of air which will ultimately release 1.3 x10^5 MeV (million electron volts) of alpha by decay through polonium-214. One Working Level is equal to approximately 200 pCi/L.

3.1.1.1.2 Standards for Cleanup of Contaminated Land – 40 CFR § 192.12(a)

Requirements relative to standards for cleanup of land contaminated with residual radioactive materials from an inactive uranium processing site (40 CFR § 192.12(a)) are evaluated as potentially relevant and appropriate chemical-specific ARARs in the FS (EMSI, 2006). These standards state that:

> Remedial actions shall be conducted so as to provide reasonable assurance that, as a result of residual radioactive materials from any designated processing site:
>
> (a) The concentration of radium-226 in land averaged over any area of 100 square meters shall not exceed the background level by more than—
>
> (1) 5 pCi/g, average over the first 15 cm of soil below the surface, and
> (2) 15 pCi/g, averaged over 15 cm thick layers of soil more than 15 cm below the surface.

OSWER Directive 9200.4-25, titled "Use of Soil Cleanup Criteria in 40 CFR Part 192 as Remediation Goals for CERCLA Sites" (EPA, 1998a) (the CERCLA UMTRCA guidance) discusses the potential applicability, relevance and appropriateness, and use of the soil cleanup standards established pursuant to UMTRCA at CERCLA sites. Pursuant to the CERCLA UMTRCA guidance, EPA has determined that the surface soil standard for cleanup of soil at UMTRCA sites (5 pCi/g plus background for combined Ra-226 plus Ra-228 or combined Th-230 plus Th-232) would only be applicable to cleanup of uranium mill tailings at the 24 uranium mill tailing sites designated under Section 102(a)(1) of UMTRCA (Title I sites). The West Lake Landfill Superfund Site is not a Title I site and therefore these standards are not applicable to any remedial actions at the Site. In addition, the UMTRCA standards apply to "land," which is defined in the regulations as any surface or subsurface land that is not part of a disposal site and is not covered by an occupiable building (40 CFR § 192.11(b)). Therefore, these requirements are not relevant or appropriate to the solid waste disposal units within OU-1 Areas 1 and 2.

Further, the UMTRCA standards are not relevant and appropriate requirements for remedial actions related to Areas 1 and 2 because they do not address specific conditions which are sufficiently similar to conditions at the Site. The UMTRCA mine tailings standards for cleanup of land and buildings contaminated with residual radioactive materials established pursuant to 40 CFR § 192.12(a) were not developed or intended to address conditions at solid waste disposal units. As indicated in the CERCLA UMTRCA guidance, "[t]he purpose of these standards [is] to limit the risk from inhalation of radon decay products in houses built on land contaminated with tailings, and to limit gamma radiation exposure of people using contaminated land." The Site is a solid waste landfill that is subject to controls on future land use which will prevent the construction of houses or other inhabitable structures over the waste materials within Areas 1 and 2, regardless of whether radiologically-impacted materials are present or not. Institutional controls to restrict residential use of the property have previously been developed and implemented by the owners of the various parcels of land that comprise the Site, including OU-1, OU-2 and other portions of the Site. In addition, implementation of institutional controls to restrict future use of solid waste disposal sites is required by the Missouri Solid Waste Regulations (10 CSR 80-3.010(20)(C)2.C.II). Further, even if a "complete rad removal" alternative were to be implemented, non-radiological waste materials would still remain onsite, thereby requiring institutional controls as required for RCRA Subtitle D landfills which would prevent construction of houses or other inhabitable structures on the Site (EPA SOW, 2010b). Therefore, the standards established pursuant to 40 CFR § 192.12(a) do not address situations sufficiently similar to those present within the solid waste management units at the Site, so the standards are neither relevant nor appropriate. However, the FS concluded that the portion of these regulations addressing cleanup levels for offsite impacted soil may be potentially relevant and appropriate criteria for remedial action, if any, involving excavation of radiologically-impacted soil on the Buffer Zone/Crossroads Property.

The CERCLA UMTRCA guidance further indicates that for CERCLA sites where subsurface contamination exists at a level between 5 pCi/g and 15 pCi/g averaged over areas of 100 square meters, conditions are not considered to be sufficiently similar to an UMTRCA site to warrant use of the UMTRCA subsurface soil standard of 15 pCi/g over background as a relevant and appropriate requirement. Instead, EPA recommends 5 pCi/g as a suitable subsurface cleanup level so long as a site-specific risk assessment demonstrates that 5 pCi/g is protective. EPA further notes that when the UMTRCA subsurface cleanup standards are found to be relevant and appropriate requirements for a CERCLA site, the 5 pCi/g standard should be applied to both the combined levels of radium-226 and radium-228, and to the combined level of thorium-230 and thorium-232, in order to provide reasonable assurance that the preceding radionuclides in the series would not be left behind at levels that would permit the combined radium activity to build up to levels exceeding 5 pCi/g after completion of the response action.

Finally, and as stated in the CERCLA UMTRCA guidance, the standards established pursuant to 40 CFR § 192.12(a) do address cleanup of so-called "vicinity" sites at which cleanup to unrestricted use is authorized for specified off-site properties. Because these "vicinity" sites are related solely to the 24 UMTRCA Title I sites, the standards established for vicinity sites are not applicable to any remedial actions at the West Lake Landfill. Overland gamma surveys and surface soil sampling of Area 2 indicated that soil containing radionuclides eroded from the surface of Area 2 and was deposited on the surface of the adjacent Buffer Zone and a portion of the Crossroads Industrial Park. Subsequent site development of the Crossroads Industrial Park resulted in regrading and placement of surface soil previously located on Lots 2A1 and 2A2, which are owned by Crossroad Properties, LLC (Crossroad), onto the Buffer Zone. Current conditions relative to occurrences of radionuclides at the Buffer Zone and Crossroad Lots 2A1 and 2A2 are unknown but are to be the subject of additional investigation and sampling as part of the ROD-selected remedy for OU-1. Remaining occurrences of radionuclides, if present, on these properties would represent a condition that may be sufficiently similar to the conditions associated with the "vicinity" sites addressed by the UMTRCA regulations. Therefore, the standards established pursuant to 40 CFR § 192.12(a) potentially may represent relevant and appropriate requirements for remedial actions that may be taken to address radionuclides in soil at the Buffer Zone/Crossroads Property.

3.1.1.1.3 Groundwater Protection Standards – 40 CFR 192 Subparts A and B

The concentration limits established under the groundwater protection standard of the UMTRCA regulations (40 CFR § 192.02(c)(3)) present potentially relevant and appropriate standards for groundwater quality at the Site. With only two exceptions, none of the hundreds of measurements of uranium concentrations in groundwater obtained during the 1995 – 1997 RI, 2004 FS and the 2012-2013 groundwater sampling events approached the UMTRCA standard of 30 pCi/L for uranium. The first exception was the total fraction uranium result from well S-53 obtained in April 2013, after a long period over which this well had not been sampled. Neither the associated dissolved sample nor the subsequent two (July 2013 and October 2013) total and dissolved samples from this well contained uranium activities close to the UMTRCA standard. The other exception was the first total fraction sample obtained from newly installed well PZ-211-SD in November 2013. Again, neither the contemporaneous dissolved fraction sample nor the subsequent total or dissolved fraction samples from this well in February 2014 displayed uranium activities levels near the UMTRCA standard. The groundwater monitoring data indicate that upon proper development and continued sampling of the monitoring wells, the uranium levels in groundwater at the Site meet the UMTRCA standard.

As previously discussed in Section 2.5.3 and in more detail in the RI Addendum, wells containing total (unfiltered samples) and dissolved (filtered samples) combined radium (Ra-226 plus Ra-228) levels greater than the UMTRCA standard were identified throughout the Site including at locations upgradient and distant from Areas 1 and 2. The overall broad distribution of wells containing combined total and dissolved radium levels greater than the MCL, including occurrences in areas of the Site that are upgradient or cross-gradient of Area 1 and 2, indicates that another mechanism, beyond leaching to and migration in groundwater from Areas 1 and 2, is responsible for these radium occurrences. The most likely mechanism responsible for the broad distribution of radium at the site is mobilization of naturally-occurring radium from the soil and rock in response to the presence of reducing conditions associated with decomposition of the landfilled wastes.

Concentrations of trace metals in groundwater were previously discussed in Section 2.5.4. Occurrences of arsenic, iron, manganese, barium and sulfate were detected throughout the Site and reflect dissolution of these substances from the landfilled wastes and/or possibly enhanced dissolution of these substances from naturally-occurring minerals within the alluvial and bedrock units due to the presence of reducing conditions associated with waste decomposition within the landfills. The monitoring data do not indicate that Areas 1 and 2 are contributing significantly greater amounts of trace metals or inorganic constituents than occur in other landfill areas onsite or at other offsite landfills.

Based on the presence of radioactive materials at OU-1 and the potential for leaching trace metals to groundwater, the groundwater protection standards (40 CFR §§ 192.02(c)(3) and (4)) and monitoring requirements (40 CFR § 192.03) of the UMTRCA regulations are potentially relevant and appropriate to the ROD-selected remedy and the partial excavation alternatives.

3.1.1.2 Other Potential Chemical-Specific ARARs

Other potential chemical-specific ARARs are identified and evaluated in the FS (EMSI, 2006) and are summarized on Table 3-1. Some of these ARARs were determined to be potentially applicable or relevant and appropriate to OU-1, and in particular to the ROD-selected remedy and partial excavation alternatives. These include the following:

- The National Emissions Standards for Hazardous Air Pollutants (NESHAPs) standards for radon-222 emissions (40 CFR Part 61 Subpart T);

- The Missouri Radiation Regulations for Protection Against Ionizing Radiation (19 CSR 20-10.040); and

- Missouri Maximum Contaminant Levels (10 CSR Division 60 Chapter 4)

3.1.1.2.1 National Emissions Standards for Hazardous Air Pollutants

The NESHAPs include standards for radon-222 emissions to ambient air from designated uranium mill tailings piles that are no longer operational. Specifically, these standards provide that radon-222 emissions from inactive uranium mill tailings piles should not exceed 20 $pCi/m^2/s$ (40 CFR Part 61 Subpart T). Because West Lake Landfill OU-1 is not a designated uranium mill tailings site, this requirement is not applicable. Insofar as a portion of the waste materials in West Lake Landfill OU-1 do emit radon, however, the NESHAP standards are potentially relevant and appropriate to the ROD-selected remedy and the partial excavation alternatives.

The “complete rad removal” with off-site disposal alternative includes removal of all RIM above the cleanup standards from Areas 1 and 2 and from the Buffer Zone/Crossroads Property, if necessary, such that additional engineering and institutional controls would not be required due to the radiological content of Areas 1 and 2. As the RIM would be disposed offsite, there would be no RIM left at the Site above the cleanup standards. Therefore, the radon NESHAP is not considered to be a relevant and appropriate requirement for this alternative.

3.1.1.2.2 Nuclear Regulatory Commission Standards for Protection Against Radiation

The Nuclear Regulatory Commission (NRC) Standards for Protection Against Radiation (10 CFR Part 20) apply only to persons licensed by the NRC to use or handle nuclear materials under certain, defined circumstances. *See* 10 CFR § 20.1002. Since no licenses have been issued by NRC for the West Lake Landfill, Part 20 is not applicable.

However, Part 20 contains standards for protection against radiation, certain subparts of which may, under certain circumstances, represent potentially relevant and appropriate requirements for OU-1.

Subpart D to Part 20 contains radiation dose limits for members of the public, who are located beyond the licensee's restricted area. Because there is no license for the West Lake Landfill, there is no restricted area. Therefore, the limits in Subpart D are not generally relevant or appropriate. However, if one were to consider the Site boundary for OU-1 as a surrogate for the restricted area, then the limits in Subpart D might be viewed as relevant and appropriate during the course of a remedial action for purposes of identifying non-occupational radiation dose limits.

Subpart C to Part 20 contains occupational radiation dose limits. Occupational doses are defined as the dose received by an individual in the course of employment in which the individual's assigned duties involve exposure to radiation. Occupational doses do not include doses received as a member of the public (i.e., people in locations beyond the restricted area, or people within the restricted area whose jobs do not involve exposure to radiation). Because there is no license for the West Lake Landfill, there is no restricted area. Therefore, the limits in Subpart C are not generally relevant or appropriate. However, if one were to view the Site boundary for OU-1 as a surrogate for the restricted area, then the limits in Subpart C might be viewed as relevant and appropriate during the course of a remedial action for purposes of identifying occupational radiation dose limits. In such case, various protective measures required by Part 20 and NRC guidance may also apply, such as establishment of radiation monitoring and protection programs to control occupational doses within limits. *See, e.g.*, 10 CFR 20 Subpart F (survey and monitoring requirements for individual exposures), Subpart H (respiratory protection and controls), and Subpart J (caution signs and other warning labels). As a precaution, these protective measures previously have been implemented at the Site, and will be continue to be performed as part of the ROD remedy phase.

Finally, depending on the nature of the remedy, the waste disposal requirements set forth in 10 CFR Subpart K may be relevant and appropriate (if, for example, certain treatment methods are used to address the radionuclides within OU-1, or if radionuclide-impacted soils are shipped offsite for treatment or disposal).

3.1.1.2.3 Missouri Maximum Contaminant Levels

EPA has established MCLs and Maximum Contaminant Level Goals (MCLGs) pursuant to the Safe Drinking Water Act (40 CFR Part 141, Subparts F and G). Implementation of the requirements of the Safe Drinking Water Act in Missouri has been delegated to the State of Missouri and is the subject of regulations promulgated by the MDNR.

These regulations (10 CSR Division 60 Chapter 4) establish MCLs for public drinking water systems. Because the Site does not operate a public drinking water system, these regulations are not applicable to the remedial actions under consideration for OU-1. Because groundwater beneath the Site is part of a larger alluvial aquifer which could potentially be used for drinking water by private and/or public wells outside of the Site, these regulations, while not directly applicable, are potentially relevant to the remedial actions evaluated under this FFS. These regulations are potentially relevant and appropriate for remedial actions for OU-1 insofar as they identify MCLs for certain chemicals in drinking water, and some of the chemical constituents that are the subject of these regulations have been detected in one or more groundwater monitoring wells located within or adjacent to Areas 1 and 2. The MCLs provide numerical standards against which the groundwater monitoring results obtained as part of the remedial action can be evaluated to assess the overall protectiveness of the remedy and the effectiveness of the various remedy components.

3.1.2 Potential Location-Specific ARARs

Location-specific ARARs are those requirements that relate to the geographical or physical location of the site or remedial action rather than the nature of the contaminants or the actions being taken. The FS (EMSI, 2006) includes evaluations of potential location-specific ARARs. The results of these evaluations are summarized on Table 3-2. The significant location-specific ARARs identified in the FS are those related to floodplain management and the site selection standards of the Missouri Solid Waste Management regulations regarding proximity to airport runways and floodplains. The requirements of these regulations are discussed below.

3.1.2.1 Floodplain Management

Executive Order 11,988, 40 CFR § 6.302(b), and the Missouri Governor's Order 82-19 relative to floodplain management are identified in the FS (EMSI, 2006) as potential location-specific ARARs relative to floodplain management (Table 3-2 in the FS). The Buffer Zone and Crossroads Property are located within the historic floodplain of the Missouri River. These areas are currently protected by the engineered Earth City levee and flood control system. As discussed in Section 2.1.6 and shown on Figure 2-9, other than the OU-2 stormwater retention basin and on-site soil borrow and stockpile area, the entire West Lake Landfill site (including all of the disposal areas) is outside the 0.2-percent annual chance (500-year) floodplain.

The goal of floodplain mitigation is to lessen the potential impact floods have on people, property and the environment. Impacts can occur due to forces of water causing damage to location-specific or project-specific structures and/or to the overall functions of the floodplain, which may include the flood-holding capacity of the floodplain, fish and wildlife habitat values of the floodplain, water quality functions of the floodplain, or other hydrological processes (*e.g.*, groundwater recharge). The nature of potential mitigative measures depends on the nature of the potential impacts that could occur. For example, with respect to location- or project-specific structures, flood-protection techniques such as elevation of critical structures, application of rip-rap armoring, or other measures to reduce impacts of flooding on project structures may be appropriate mitigation measures. Mitigation of potential impacts to the overall functions of a floodplain could also include construction and operation of stormwater detention basins to offset reductions in flood-holding capacity or water quality functions of a floodplain, or designation of open/natural areas to offset habitat loss from construction in a floodplain.

Because the Site is located outside of the 0.2-percent annual chance (500-year) floodplain, no mitigative actions would be required unless the remedial action (1) impacts the base floodplain, (2) indirectly supports floodplain development, or (3) is a critical action. Critical actions are those for which even a slight chance of flooding would be too great. Remedial actions for OU-1 are not expected to impact the base floodplain or indirectly support floodplain development. In the event of a failure of the Earth City Levee system (which provides protection from flood events with a recurrence interval greater than 500 years), floodwaters could reach the Buffer Zone and Crossroads Property[15]. Due to the distance from the river, such floodwaters would not be expected to be high energy, but instead would be nearly stagnant and without the velocity and energy capable of resulting in significant erosion of these areas.

3.1.2.2 Missouri Solid Waste Management Regulations – Site Selection

The Missouri Solid Waste Regulations contain site selection standards that apply to new or operating landfills (10 CSR 80.3.010(4)). Some of the site-selection standards also apply to horizontal expansions of existing landfills. The solid waste site-selection standards address landfills located in proximity to airports, within 100-year floodplains, within wetlands, within seismic impact zones, and within unstable areas. The site selection criteria also specify site condition information required for design and operation plan submittals and requirements relative to the base elevation of a landfill liner to the depth of groundwater.

Because Areas 1 and 2 are neither new nor operating landfills, these requirements are not considered applicable to remediation of Areas 1 and 2. Although these standards are not applicable to Areas 1 and 2, certain of them are considered to be potentially relevant and appropriate to Areas 1 and 2. In particular, the regulatory requirements relating to airport safety and floodplains are potential ARARs for the ROD-selected remedy, the partial excavation alternatives, and the “complete rad” removal alternatives because regrading or excavation of wastes within Areas 1 and 2 is a component of each of these alternatives. These potential ARARs are described below.

3.1.2.3 Missouri Solid Waste Management Regulations – Floodplains

The Missouri Solid Waste Regulations contain requirements for landfills located within floodplains (10 CSR 80-3.010(4)(B)2). Specifically, owners/operators of sanitary landfills located in 100-year floodplains must demonstrate to MDNR that the sanitary landfill would not restrict the flow of the 100-year flood, reduce temporary water storage capacity of the floodplain, or result in washout of solid waste so as to pose a hazard to public health or the environment. Areas 1 and 2 are not within the 100-year floodplain, and therefore this standard is not applicable and neither relevant nor appropriate to actions taken in Areas 1 and 2.

---

[15] It is expected that any radiologically-impacted soil that may remain on these properties would be removed as part of the implementation of any remedial action taken for OU-1.

3.1.2.4 Missouri Solid Waste Management Regulations – Seismic Impact Zones

The solid waste regulations require that sanitary landfills located in seismic impact zones shall generally not be located within 200 feet of a fault that has had displacement in Holocene time (10 CSR 80-3.010(4)B.4). Landfills located within seismic impact zones must demonstrate that all containment structures (e.g., liners, final covers, leachate collection systems and surface water control systems) are designed to resist permanent cumulative earthquake displacements greater than 6 inches resulting from the maximum credible Holocene time earthquake event's acceleration versus time history (10 CSR 80-3.010(4)B.5).

The St. Louis area is part of the New Madrid Seismic Impact Zone and therefore these requirements are potentially applicable to the design of the final cover system for Areas 1 and 2 under all of the alternatives. There is no indication that any Holocene-age faults are present at the Site. Extensive geologic mapping of the quarry walls in the area of the inactive Bridgeton Sanitary Landfill did not identify the presence of any faults in that area.

3.1.2.5 Missouri Solid Waste Management Regulations – Unstable Areas

The Missouri solid waste regulations require that sanitary landfills located in unstable areas demonstrate that the landfill design ensures that the integrity of the structural components of the sanitary landfill will not be disrupted (10 CSR 80-3.010(4)B.6). Minimum factors to be considered in determining whether an area is unstable include the following:

- areas where on-site or local rock or soil conditions may result in failure or significant differential settlement;
- on-site or local geologic or geomorphologic features; and
- on-site or local human-made features or events (both surface and subsurface).

None of these features are known or currently expected to be present in the area. Therefore this requirement is not applicable, relevant or appropriate.

3.1.2.6 Missouri Solid Waste Management Regulations – Plans

The Missouri solid waste regulations require that design and operations plans for new sanitary landfills include maps showing initial and proposed topographies at specified scales and contour intervals, and maps showing land use and zoning within one quarter mile including specific features listed in the regulations (10 CSR 80-3.010(4)B.7). The regulations also require a description of project post-closure land use and evaluations of the characteristics and quantity of available on-site soil with respect to its suitability for sanitary landfill operations. Because these regulations address new sanitary landfills, they are not applicable to the existing Areas 1 and 2, nor are they relevant or appropriate for the remedial alternatives.

3.1.2.7 Missouri Solid Waste Regulations – Airport Safety

The Missouri Solid Waste Regulation requirements for airport safety apply to new or existing municipal solid waste landfills or lateral expansions that are located within 10,000 feet of the end of any airport runway used by turbojet aircraft or within 5,000 feet of any airport runway end used by only piston-type aircraft (10 CSR 80-3.010(4)(B)1). Landfills or landfill expansions located within these areas must demonstrate that the units are designed and operated so as to pose no bird hazards to aircraft.

Portions of the Site, including a portion of Area 1, are located within approximately 9,166 feet of the end of Lambert-St. Louis International Airport's Runway 11-29 (Figure 2-8). Because Area 1 is located in an inactive/closed portion of the Site, these requirements are not applicable. Insofar as the intent of the regulations is to control bird hazards, however, these requirements potentially may be relevant to remedial activities that could result in the exposure of previously placed refuse which could attract birds and therefore present a potential hazard to aircraft. Consequently, these regulations potentially may be relevant and appropriate to excavation and regrading activities that may be performed in Area 1 under the ROD-selected remedy, and for the excavation and regrading activities required for the "complete rad removal" and partial excavation alternatives.

3.1.2.8 FAA Guidance

The Federal Aviation Administration (FAA) has developed guidance to address safety issues associated with aircraft bird strikes (Appendix A). The FAA also issued a Record of Decision (the Lambert Airport ROD) (FAA, 1998) (Appendix A) for federal actions related to improvements at Lambert-St. Louis International Airport (Lambert), including construction and operation of a new air carrier length runway (then designated 12W/30W, now known as Runway 11/29). The FAA ROD included requirements relative to proximity of the proposed new runway to the existing Bridgeton Sanitary Landfill. In 2003, the FAA, EPA and other agencies also entered into a Memorandum of Understanding (the FAA MOU) (Appendix A) addressing aircraft-wildlife strikes. These advisories, decision document, and memorandum are not cleanup standards, standards of control, or other substantive environmental protection requirements, criteria, or limitations promulgated under Federal or State law and therefore are not ARARs. Likewise, because the FAA guidance, Lambert Airport ROD, and FAA MOU are not legally binding, they therefore are not potential ARARs. They do, however, represent to-be-considered (TBC) criteria relative to the potential remedial actions at the Site.

In its Lambert Airport ROD (Appendix A), the FAA noted that the end of the proposed runway would be located within 10,000 feet of a then-existing active landfill (the Bridgeton Landfill) and therefore would not be consistent with FAA's current runway siting guidelines without mitigation. The decision document indicated that at its closest point, the Bridgeton Landfill is located approximately 9,166 feet west of the northwest end of proposed Runway 12W/30W.

This is not consistent with FAA's runway siting guideline of 10,000 feet, which was developed to protect aircraft from potential bird strikes.

The FAA decision document states:

> "STLAA will attempt to develop an agreement with the operator of the landfill to implement one of the following options:
>
> - Re-prioritize the landfill utilization plan so that the subject portion (i.e., that portion within the FAA's 10,000-foot radius of incompatibility) of the landfill is utilized first;
>
> - Require that STLAA be able to direct available fill that cannot be reasonably recycled from the construction projects to the subject portions of the landfill;
>
> - Require that organic waste be capped in the landfill before the new runway is opened and that only clean fill (such as construction materials) be placed in the subject portions of the landfill once the runway is operational.
>
> Should it not be practical to completely fill the subject landfill through the above measures, the STLAA will purchase an easement from the landfill operator which will provide the operator compensation for any lost revenue associated with the unused excess capacity. Any plan to convert or close the landfill must provide for a one-year bird-repelling program. Repelling efforts will begin 6 months before opening of the new runway and continue for a minimum of 6 months thereafter. The program will be in effect from dawn until dusk.
>
> (FAA ROD, September 30, 1998, pp 42 – 43).

Pursuant to an agreement between Bridgeton Landfill, LLC and the City of St. Louis (among other parties) on behalf of the STLAA, the Bridgeton Landfill ceased accepting waste materials prior to the opening of Runway 11/29.

FAA Advisory Circular AC 150/5200-34A dated January 26, 2006, "Construction or Establishment of Landfills Near Public Airports," contains guidance on complying with Federal statutory requirements regarding the construction or establishment of a new municipal solid waste landfill (MSWLF) near public airports (Appendix A). This advisory only applies to a new MSWLF constructed or established after April 5, 2000, near an airport that received Federal grants (under the Airport and Airway Improvement Act of 1982 as amended, 49 U.S.C. § 47101, et seq.) and primarily serves general aviation aircraft and scheduled air carrier operations using aircraft with fewer than 60 passenger seats. This advisory requires a minimum separation distances of six statute miles between a new MSWLF and a public airport as measured from the closest point of the airport property boundary to the closest point of the MSWLF property boundary. Because no new landfill cells are included within the scope of the remedial alternatives considered in this FFS, this guidance does not provide any criteria that would affect any of the anticipated remedial actions.

FAA Advisory Circular AC 150/5200-33B, dated August 28, 2007, "Hazardous Wildlife Attractants On or Near Airports," provides guidance on certain land uses that have the potential to attract hazardous wildlife on or near public-use airports (Appendix A). This circular recommends against locating a MSWLF within the separation distances identified below:

1. Airports serving piston-powered aircraft – 5,000 feet
2. Airports serving turbine-powered (jet) aircraft – 10,000 feet
3. Protection of approach, departure and circling airspace – 5 statute miles

These separation distances are to be maintained between the Air Operations Area (AOA) and the nearest point to the hazardous wildlife attractant. The AOA is defined as any area of an airport used or intended to be used for landing, takeoff, or surface maneuvering of aircraft which includes such paved or unpaved areas that are used or intended to be used for the unobstructed movement of aircraft in addition to its associated runway, taxiways, or apron. With respect to landfills, the separation distances should be measured from the closest point of the AOA to the closest planned MSWLF cell (AC 150/5200-33B, p. 4). The FAA strongly recommends against allowing a waste disposal operation to be located within 10,000 feet of a jet aircraft runway if the material contains putrescible waste or has the potential to attract wildlife that could threaten air traffic.

The FAA, EPA, and other agencies developed and signed the FAA MOU to address risks that aircraft-wildlife strikes pose to safe aviation (Appendix A). Because this MOU is not a standard, requirement, criteria or limitation under Federal or State environmental laws, it does not represent a potential applicable or a potentially relevant and appropriate requirement; however, it may represent a "to be considered" criterion (TBCs). Specific aspects of this MOU that could be considered as part of potential remedial actions at the Site include the following:

Paragraph M – Agree to cooperate with the airport operator to develop a specific wildlife hazard management plan for a given location when a potential wildlife hazard is identified.

Paragraph O - Agree that information and analyses relating to mitigation that could cause or contribute to aircraft-wildlife strikes should, whenever possible, be included in documents prepared to satisfy the National Environmental Policy Act (NEPA).

EPA and representatives of Bridgeton Landfill, LLC previously met with the STLAA to discuss the remedial actions at the Site and to obtain STLAA input on the remedial alternatives included in the SFS. The STLAA sent a letter to EPA regarding the potential remedial actions under consideration for the Site (included in Appendix A). It is anticipated that additional meetings with the STLAA will occur as the project progresses. It is also anticipated that any remedial work plan would require development of a plan to mitigate hazards to aircraft operations that may be posed by bird populations at the Site during implementation of remedial actions, and that such a plan will be provided to the STLAA for review and input. These actions should meet the objectives of Paragraph M of the FAA MOU. Evaluation of potential risks associated with bird hazards to aircraft and evaluation of potential mitigation measures for aircraft-bird hazards as part of the detailed analysis of alternatives in the FFS addresses the objectives of Paragraph O of the FAA MOU.

3.1.2.9 Airport Negative Easement and Restrictive Covenants

Although not part of a promulgated Federal or State standard and therefore by definition not an ARAR or a TBC standard or criteria, use of the Site is subject to additional constraints relative to airport safety. As previously discussed, in August 2005, the Bridgeton Sanitary Landfill stopped receiving waste pursuant to an agreement with the airport owner, the City of St. Louis, to reduce the potential for birds to interfere with airport operations. As part of this closure plan, a Negative Easement and Declaration of Restrictive Covenants Agreement (Restrictive Covenant) (Appendix A) was recorded against the majority of the West Lake Landfill Site, including all of Area 1, most of Area 2, and all of the soil borrow/stockpile area (Appendix A). Paragraph 1 of the Restrictive Covenant imposes the following restrictions upon the Site:

> There shall be no new or additional depositing or dumping of municipal waste, organic waste, and/or putrescible waste (municipal waste, organic waste and putrescible waste hereinafter collectively referred to as “Putrescible Waste”) above, upon, on, or under the Property beginning as of August 1, 2005 and continuing in perpetuity, unless and until such time as this Agreement is terminated or canceled by St. Louis in accordance with the terms set out in paragraph 3 below. For purposes of this Agreement, “Putrescible Waste” shall mean solid waste that contains organic matter capable of being decomposed by micro-organisms and of such a character and proportion as to be capable of attracting or providing food for birds. For purposes of this Agreement, “Putrescible Waste” shall not include construction waste or demolition waste.

Section 4 of the Restrictive Covenant states that the agreement shall end only if and when the City of St. Louis chooses in its sole and absolute discretion to abandon its negative easement. Consequently, although the Restrictive Covenant is not an ARAR, construction and operation of any new engineered disposal cell would violate the terms of this recorded land use covenant.

On September 7, 2010, representatives of Bridgeton Landfill, LLC and the EPA met with representatives of the St. Louis Airport Authority and the U.S. Department of Agriculture to follow up on concerns raised that the Restrictive Covenant entered into between landfill owners and STLAA would prohibit construction of the “on-site cell” evaluated as part of the SFS. The EPA provided a summary of the alternatives considered in the SFS. STLAA and USDA stated that an excavation remedy would create risks that they could not even calculate, and that monitoring and management of risks created by wildlife would be impossible. STLAA noted that under the ROD-selected remedy, the Site will present no risk to human health or the environment and said that creating new risks by implementing an excavation remedy did not seem advisable. STLAA further stated that an excavation remedy would necessitate FAA review and likely result in objections from airlines as well as the FAA. STLAA was particularly concerned that either excavation alternative would take years to perform.

The EPA asked whether the airport's concerns would be alleviated by excavation of only Area 2 (outside the 10,000-foot range). STLAA's response was no: the entire area is within the Restrictive Covenant and subject to FAA review if "new landfilling operations" were to occur. In particular, STLAA explained that construction of an on-site disposal cell would not qualify as an expansion or change to an existing landfill because the Bridgeton Sanitary Landfill was already in closure mode, but would instead constitute "new operations" at the Site and therefore would trigger FAA review. STLAA stated that it could not predict the changes that any excavation activities would cause to the migratory patterns of birds and could not take the risk that such changes would increase the local bird population. STLAA stated that its 2006 letter, submitted during the public comment period on the ROD for Operable Unit I, still reflected its position.

Notes of this 2010 meeting were provided to the EPA and are included in Appendix A.

By letter dated September 20, 2010 (Appendix A), the City of St. Louis provided written comments on the SFS Work Plan. The letter identified the Site as a hazardous wildlife attractant for the airport. The City stated that the excavation ("complete rad removal") alternatives would adversely affect wildlife mitigation measures taken by the airport to protect aircraft from bird strikes, thereby placing the City in violation of the FAA ROD and its requirement that such mitigation efforts be undertaken and maintained. The City also stated that implementation of the excavation alternatives would violate the Restrictive Covenant.

3.1.3 Potential Action-Specific ARARs

Action-specific ARARs are technology-based requirements that define handling, treatment, disposal, and other procedures triggered by the type of remedial action under consideration. These requirements generally set performance or design standards for specific activities related to the management of wastes. Evaluations of potential action-specific ARARs are presented in the FS report (EMSI, 2006) and are summarized on Table 3-3. Table 3-3 also lists additional potential action-specific ARARs related to the "complete rad removal" and partial excavation alternatives. The potential action-specific ARARs associated with the ROD-selected remedy and the "complete rad removal" and partial excavation alternatives are discussed below.

3.1.3.1 Health and Environmental Protection Standards for Uranium and Thorium Mill Tailings

Part 192 of Title 40 of the Code of Federal Regulations provides for Health and Environmental Protection Standards for Uranium and Thorium Mill Tailings pursuant to UMTRCA. Subpart A of these UMTRCA regulations contains standards for the control of residual radioactive materials from inactive uranium processing sites. As previously discussed, the UMTRCA regulations only apply to designated Title I sites and therefore are not applicable to West Lake Landfill. However, those portions of these regulations that provide for closure performance standards may potentially be relevant and appropriate to remedial actions for OU-1. Specifically, 40 CFR § 192.02 states that "[c]ontrol of residual radioactive materials and their listed constituents shall be designed to: (a) be effective for up to one thousand years, to the extent reasonably achievable, and, in any case, for at least 200 years[.]" In addition, 40 CFR § 192.02(d) requires that "[e]ach site on which disposal occurs shall be designed and stabilized in a manner that minimizes the need for future maintenance." For UMTRCA tailings piles, the longevity consideration is typically addressed through use of natural materials for construction and often includes placement of a rock armoring layer over the upper surface of the tailings pile capping system to reduce the potential for erosion.

In developing this requirement, EPA was concerned with long-term hazards relating to misuse by humans or disruption by natural phenomena. While large volumes of uniform sand-like tailings from uranium mining activities piled on the ground or in impoundments may be of concern due to misuse by humans (for example, use of tailings as construction or fill material), Areas 1 and 2 contain radiological contamination mixed with solid waste, construction and demolition debris and other wastes contained within an even larger volume of solid waste. It is highly unlikely that old garbage and debris of these types would be misused by humans. Furthermore, the solid waste regulations require the upper portion of a landfill cover system consist of a vegetative layer that supports grass that through evapotranspiration can intercept and reduce potential for infiltration of precipitation. A grass cover also can be periodically mowed to prevent establishment of woody vegetation that could damage or otherwise reduce the functionality of the landfill cover system.

Therefore, the ultimate question is which type of capping system – UMTRCA or solid waste – is the more appropriate for Site conditions. Areas 1 and 2 each consist of over a million yards of MSW – within which exists a smaller amount of MSW mixed with radionuclide-containing material. The fact that the majority of the materials are solid waste, including the RIM itself, suggests that the more appropriate cap design would reflect the solid waste closure criteria. However, the presence of RIM and its unique (relative to the overall MSW) characteristics of emitting gamma radiation and radon, indicate that additional measures, such as those developed for UMTRCA tailing piles, could also be appropriate. The approach included in the ROD-selected remedy reflects the key design components of both sets of regulations. Specifically, the ROD-selected remedy includes a hybrid cover system that is based on the MSW design criteria but incorporates additional measures to address gamma emissions and radon generation, including the projected emissions that will occur as a result of radium ingrowth over time from decay of thorium. By their very nature, MSW landfills require long-term inspection, maintenance and monitoring. To further address longevity considerations and long-term hazards relating to potential disruption of the disposal Site by natural phenomena, the ROD-selected remedy incorporates a concrete debris or a rock material layer to restrict bio-intrusion and erosion into the underlying landfilled materials, to act as a marker layer indicating the presence of human-derived, non-natural materials, and to increase the overall longevity of the landfill cover.

3.1.3.2 Missouri Solid Waste Management Regulations

The ROD-selected remedy was developed and selected to provide engineered containment of the solid wastes and RIM contained in Areas 1 and 2. Because these areas contain solid wastes, the RCRA Subtitle D regulations and the MDNR Solid Waste Management Regulations represent the primary standards for design and implementation of a containment remedy. Specifically, the landfill cover design, gas control measures, maintenance, groundwater monitoring, and corrective action criteria of these regulations are potentially relevant and appropriate.

Evaluation of these solid waste management criteria as potential ARARs relative to the evaluation of remedial alternatives for OU-1, including the remedial alternative that ultimately became the ROD-selected remedy, is presented in the FS report (EMSI, 2006). In particular, the FS report presents an extensive discussion of the final grading and cover requirements for solid waste landfills as potentially relevant and appropriate requirements for construction of new landfill covers over Areas 1 and 2. In the ROD (EPA, 2008a), EPA provided an evaluation of solid waste regulations as potential ARARs, including how they would apply to the ROD-selected remedy. These evaluations will not be repeated in this FFS.

The final grading and final cover requirements of the Missouri Solid Waste regulations are not applicable to remedial alternatives for OU-1, because they apply only to existing sanitary landfills that are closed after October 9, 1991. However, the Solid Waste regulations would be relevant and appropriate to regrading and design and construction of final cover over Areas 1 and 2 as part of the ROD-selected remedy or the partial excavation and “complete rad removal” alternatives. EPA determined that the 5% minimum sloping requirement under the Solid Waste regulations was not appropriate for the ROD-selected remedy (see ROD at p. 50). The ROD required the selected remedy to include final grades of at least 2% and less than 25% (unless a stability analysis is performed to support inclusion of steeper slopes, but in no event shall the final slopes exceed 33 1/3%) and final cover of at least two feet (2’) of compacted clay with a coefficient of permeability of 1 x 10^{-5} cm/sec or less overlaid by at least one foot (1’) of soil capable of sustaining vegetative growth (10 CSR 80-3.010(17)(C)(4)). Analysis of these requirements and the basis for use of a minimum slope of 2% for the ROD-selected remedy is provided in the ROD (EPA, 2008a) and the FS (EMSI, 2006). For the partial excavation and “complete rad removal” alternatives, the final grading and cover requirements will likely need to include final grades of at least 5% and less than 25% (unless a stability analysis is performed to support inclusion of steeper slopes, but in no event shall the final slopes exceed 33 1/3%) and final cover of at least two feet (2’) of compacted clay with a coefficient of permeability of 1 x 10^{-5} cm/sec or less overlaid by at least one foot (1’) of soil capable of sustaining vegetative growth (10 CSR 80-3.010(17)(C)(4)).

3.1.3.3 RCRA Subtitle C Regulations

The RCRA Subtitle C requirements relative to identification of hazardous wastes (40 CFR Part 261), packaging, temporary storage, offsite transportation of hazardous wastes (40 CFR Parts 262 and 263), and treatment and disposal of hazardous wastes (40 CFR Part 268), are potentially applicable requirements in the event that hazardous wastes are encountered during implementation of any remedy at the Site.

The RCRA Subtitle C landfill closure design criteria were also evaluated as potential action-specific ARARs for closure of Areas 1 and 2. RCRA landfill closure regulations (40 CFR § 264.310) specify that at final closure of a landfill or cell, the landfill or cell must be covered with a final cover designed and constructed to:

1. Provide long-term minimization of migration of liquids through the closed landfill;
2. Function with minimum maintenance;
3. Promote drainage and minimize erosion or abrasion of the cover;
4. Accommodate settling and subsidence so that the cover's integrity is maintained; and
5. Have a permeability less than or equal to the permeability of any bottom liner system or natural subsoils present.

Per EPA guidance (EPA, 1988 and 1989), RCRA Subtitle C requirements, including closure requirements, are applicable to a Superfund remedial action if the following conditions are met:

- The waste is a RCRA hazardous waste, and either:

- The waste was initially treated, stored, or disposed of after November 19, 1980 (the date upon which the RCRA Subtitle C requirements became effective), or

- The activity at the CERCLA site constitutes treatment, storage, or disposal, as defined by RCRA.

As discussed in Section 2.5.4, the waste materials in Area 1 and 2 are typical MSW and do not contain confirmed amounts of hazardous waste. Regardless, the wastes in Area 1 and 2 were disposed of prior to November 19, 1980 and therefore do not meet the second criterion listed above. To the extent that the remedial actions being considered for Areas 1 and 2 entail consolidation, regrading and capping of the waste within Areas 1 and 2, these actions should not constitute treatment, storage or disposal. Therefore, the RCRA regulations, including the closure requirements, would not be applicable to remedial actions for Areas 1 and 2.

RCRA requirements that are not applicable may nonetheless be relevant and appropriate, based on site-specific circumstances (EPA, 1988 and 1989). The determination of relevance and appropriateness of RCRA requirements is based on the circumstances of the release, including the hazardous properties of the waste, its composition and matrix, the characteristics of the site, the nature of the release or threatened release from the site, and the nature and purpose of the requirement itself. Because the waste materials in Areas 1 and 2 are primarily MSW, there currently is no basis to conclude that these wastes are hazardous or similar to hazardous wastes. Therefore, the RCRA closure requirements would not be relevant. Furthermore, the intent of the RCRA Subtitle C regulations is to minimize migration of liquids through the closed landfill. Requirements to minimize migration of liquids through a closed landfill are also addressed by the RCRA Subtitle D regulations for MSW landfills, which, based on the nature of the materials in Areas 1 and 2, are considered more appropriate requirements than the RCRA Subtitle C regulations. In addition, the primary constituents of concern in Areas 1 and 2 are radionuclides, principally thorium and radium, which are relatively insoluble and therefore relatively immobile as compared to solvents or other types of more mobile constituents addressed by the RCRA Subtitle C regulations. The RCRA Subtitle C regulations are also intended to address closure of smaller areas containing high concentration (hazardous) wastes, and are not considered appropriate for closure of larger, dispersed areas of lower level contamination associated with a MSW landfill (EPA, 1988b). EPA (1988b) has indicated that RCRA covers are generally not appropriate for large municipal landfills where the waste is generally of a lower toxicity, and the Site encompasses an area that bears little resemblance to the discrete units regulated under RCRA Subtitle C. Therefore, the RCRA Subtitle C regulations are not considered to be relevant and appropriate requirements for design and construction of a final landfill cover over Areas 1 and 2.

Furthermore, EPA has indicated that designing closure through the use of a hybrid approach may be more appropriate (EPA, 1989). Hybrid landfill closure is used when residual contamination poses a direct contact threat, but does not pose a groundwater threat. Although EPA has determined that additional evaluations of groundwater conditions will be conducted as part of OU-3, as previously discussed in Sections 2.5.3 and 2.5.4, the groundwater monitoring performed to date has not identified the presence of a plume or contiguous area of groundwater contamination originating from Areas 1 or 2. Hybrid landfill closure entails use of covers, which may be permeable, to address direct contact threat with limited long-term management involving site and cover maintenance and minimal groundwater monitoring coupled with institutional controls (*e.g.*, land-use restrictions or deed notices) as necessary. EPA has directed the FFS consider alternative landfill cover designs. In addition, the landfill cover design included in the ROD-selected remedy is a hybrid MSW cover that has been modified to provide sufficient thickness to protect against gamma radiation and radon emissions.

3.1.4 Additional Requirements Associated with Off-site Disposal

This section discusses additional requirements that would apply to the “complete rad removal” with off-site disposal or partial excavation alternatives. The requirements under CERCLA for compliance with other laws differ for on-site and off-site actions. Importantly, the ARARs provision applies only to on-site actions; off-site actions need only comply with any laws that apply to such an action. In other words, off-site actions need only comply with “applicable” requirements, not with “relevant and appropriate” requirements. Consequently, CERCLA actions involving the transfer of hazardous substances, pollutants or contaminants off-site must comply with applicable Federal and State requirements and are not exempt from formal administrative permitting requirements.

The primary requirements affecting off-site disposal are the CERCLA Off-Site Rule (OSR), requirements associated with transportation of the RIM to an off-site disposal facility, and the waste acceptance criteria associated with each potential off-site disposal facility. These requirements are described below.

3.1.4.1 CERCLA Off-site Rule

Section 121(d)(3) of CERCLA (42 U.S.C.§ 9621(d)(3)) applies to any CERCLA response action involving the off-site transfer of any hazardous substance, pollutant or contaminant (*i.e.*, CERCLA wastes). These principles are interpreted in the off-site rule (OSR) set forth in the NCP at 40 CFR § 300.440. The OSR requires that CERCLA wastes be placed only in a facility operating in compliance with RCRA or other applicable Federal or State requirements. The OSR prohibits the transfer of CERCLA wastes to a land disposal facility that is releasing contaminants into the environment, and requires that any releases from other waste management units at the disposal facility be controlled. The purpose of the OSR is to avoid having CERCLA wastes from site response actions authorized or funded under CERCLA contribute to present or future environmental problems by directing these wastes to management units determined to be environmentally sound (preamble to final OSR, 58 Fed. Reg. 49,200, 49,201, Sept. 22, 1993).

The OSR establishes the criteria and procedures for determining whether facilities are acceptable for the receipt of CERCLA wastes from response actions authorized or funded under CERCLA. The OSR establishes both compliance and release criteria, and establishes a process for determining whether facilities are acceptable based on those criteria. The OSR also establishes procedures for notification of unacceptability, reconsideration of unacceptability determinations, and re-evaluation of unacceptability determinations.

EPA verifies the acceptability of off-site treatment, storage, and disposal facilities (TSDFs) on a frequent basis. Consequently, before any off-site shipment occurs, a verification of current acceptability (VCA) must be obtained from EPA certifying that the proposed receiving facility is operating in compliance with the requirements of CERCLA Section 121(d)(3) and 40 CFR § 300.440. EPA (usually the applicable EPA Regional Office) will determine the acceptability under this section of any facility selected for the treatment, storage, or disposal of CERCLA waste. EPA will determine if there are relevant releases or relevant violations at a facility prior to the facility's initial receipt of CERCLA waste. A facility which has previously been evaluated and found acceptable under this rule is acceptable until the EPA Regional Office notifies the facility otherwise pursuant to § 300.440(d).

3.1.4.2 Off-site Transportation Requirements

Under the "complete rad removal" or partial excavation alternatives, RIM would be excavated and shipped for off-site disposal. It is currently anticipated that the excavated RIM would be loaded directly into intermodal containers which would be hauled by trucks to a local off-site rail loading facility where they would be loaded on rail cars. Once loaded on rail cars, the intermodal containers containing RIM would be shipped via rail directly to the off-site disposal facility or to a rail unloading facility located near the off-site disposal facility, where the containers would be loaded onto trucks and taken to the off-site disposal facility.

Because transportation to an off-site disposal location would constitute an off-site action, the transportation activities would need to comply with both the substantive and administrative requirements of any regulations applicable to transportation of radiologically-contaminated materials. The U.S. Department of Transportation (DOT) has developed regulations for transport of hazardous materials (49 CFR Parts 100 – 178), including specific regulations related to transport of radioactive materials (49 CFR Parts 171 – 180). These include regulations on hazardous materials communications, emergency response information, training requirements and security plans (49 CFR Part 172) which address special provisions, preparation and retention of shipping papers, packaging and container marking, emergency response, security and planning. The regulations contain specific requirements associated with shipment of radioactive materials (e.g., 49 CFR §§ 172.310, 172.436-440, and 172.556). Other regulations (49 CFR Part 173) describe requirements for shipment and packaging that are applicable to shippers, including specific requirements for shipment of radioactive materials. Regulations set forth in 49 CFR Part 174 address shipment by rail and include special handling requirements for radioactive materials (49 CFR § 174.700). Required emergency response information is described in 49 CFR Subpart G (49 CFR § 173.602). The NRC, through a Memorandum of Understanding with DOT, also has promulgated regulations related to transport of radioactive materials (10 CFR Part 71).

Requirements established by rail carriers relative to transport of waste materials or radioactive wastes would also be applicable to the “complete rad removal” and partial excavation with off-site disposal alternatives. Because the specific carriers that might be used to transport the wastes under these alternatives cannot be identified at this time, identification and evaluation of the carrier-specific requirements has not been performed. This evaluation would be completed if necessary as part of design of the “complete rad removal” or partial excavation alternatives that include off-site disposal.
State requirements and fees, including Missouri fees for transport of the RIM (Section 260.392 RSMo), would also potentially be applicable to the “complete rad removal” or partial excavation with off-site disposal alternatives. Review, description and detailed evaluation of these requirements is beyond the scope of this FFS, but would be addressed in detail in planning documents in the event the “complete rad removal” or partial excavation with off-site disposal alternatives were to be implemented.

As of the writing of this draft FFS, four disposal facilities have been identified that could potentially accept RIM from the Site for off-site disposal:

- U.S. Ecology's facility in Grandview, Idaho,
- U.S. Ecology's facility in Wayne, Michigan,
- Energy*Solutions* facility in Clive, Utah, and
- Clean Harbors' Deer Trail facility in Last Chance, Colorado.

Discussions with representatives of potential off-site disposal facilities in conjunction with preparation of the SFS (EMSI et al., 2011) indicated that most of the facilities would provide a turnkey service that includes transport of the RIM from the Site and disposal. These companies provided unit costs for complete turnkey services for waste profiling and acceptance testing, waste transportation (including all related fees and taxes), and waste disposal services (including all related fees and taxes). Under a turnkey service, the disposal company would be responsible for arranging for transport, preparation of waste/shipping manifests, testing the RIM after they are loaded into transportation vehicles/containers, securing vehicles/containers, unloading vehicles/containers, safety and emergency response plans, and all other aspects associated with transport of RIM from the Site to an off-site disposal facility. Additional discussion with U.S. Ecology in conjunction with preparation of this FFS indicated that they would provide turnkey. U.S. Ecology provided updated unit costs for these services for use in preparing this FFS.

3.1.4.3 Waste Acceptance Criteria for Off-site Disposal

Waste Acceptance Criteria (WAC) are established pursuant to the specific permit or license issued to each waste disposal facility and consequently are different for each facility. As part of the evaluation of potential remedial technologies for the "complete rad removal" and the partial excavation alternatives that include off-site disposal, potential off-site disposal facilities were identified. The WAC for the off-site disposal facilities were reviewed as part of the prior SFS evaluation and re-examined as part of the FFS to assess the ability of each facility to accept the RIM. Summaries of the WAC for each off-site disposal facility are presented below. Copies of the WAC provided by each of the facilities are contained in Appendix C.

3.1.4.3.1 U.S. Ecology, Grandview, Idaho

U.S. Ecology - Idaho (USEI) has a RCRA Part B Permit that contains waste acceptance criteria relative to radionuclide levels (Appendix C-1). USEI's WAC are listed in the tables below:

USEI Table C.1: Unimportant Quantities of Source Material Uniformly Dispersed in Soil or Other Media

Status of Equilibrium	Maximum Concentration of Source Material	Sum of Concentrations Parent(s) and All Progeny Present
Natural uranium in equilibrium with progeny	<500 ppm / 167 pCi/g (^{238}U activity)	≤ 3000 pCi/g
Refined natural uranium (^{238}U, ^{235}U, ^{234}U, ^{234}Th, ^{234m}Pa, ^{231}Th,	<500 ppm / 333 pCi/g	≤ 2000 pCi/g
Depleted Uranium (^{234}Th, ^{234m}Pa)	<500 ppm / 169 pCi/g	≤ 2000 pCi/g
Natural Thorium (^{232}Th, ^{228}Th)	<500 ppm / 110 pCi/g	≤ 2000 pCi/g
^{230}Th in equilibrium with progeny	<0.01 ppm / 200 pCi/g	≤ 2000 pCi/g
^{230}Th (with no progeny)	<0.1 ppm / ≤ 2000 pCi/g	
Any mixture of Thorium and Uranium	Sum of ratios <1	≤ 2000 pCi/g

USEI Table C.2: Naturally Occurring Radioactive Material (NORM) Other Than Uranium and Thorium Uniformly Dispersed in Soil or Other Media

Status of Equilibrium	Maximum Concentration of Parent Nuclide	Sum of Concentrations of Parent and All Progeny Present
^{226}Ra or ^{228}Ra with progeny in bulk form	500 pCi/g	≤ 4500 pCi/g
^{226}Ra or ^{228}Ra with progeny in reinforced 1P-1 containers	1500 pCi/g	13,500 pCi/g
^{210}Pb with progeny (Bi & ^{210}Po)	1500 pCi/g	4500 pCi/g
^{40}K	818 pCi/g	N/A
Any other NORM		≤ 3000 pCi/g

USEI is also permitted to accept 11e.(2) mixed waste (Appendix C-1).

3.1.4.3.2 U.S. Ecology, Wayne, Michigan

The US Ecology Michigan facility in Belleville, Michigan (also known as Wayne Disposal), is permitted to accept solid waste, hazardous waste and Naturally Occurring Radioactive Material (NORM) and Technologically Enhanced Radioactive Material (TENORM) waste. US Ecology Michigan has a RCRA Part B Permit that contains waste acceptance criteria relative to hazardous wastes and a NORM/TENORM Waste Addendum that identifies waste acceptance criteria relative to radionuclides (Appendix C-2).

Based on the NORM/TENORM Waste Addendum criteria, US Ecology Michigan can accept generally exempt unimportant quantities (as that term is defined in NRC regulations) of source material uniformly distributed in soil or other media provided the total percentage of uranium and/or thorium (Th-232) is less than 0.05% by weight. US Ecology Michigan can accept source material containing natural uranium and thorium (Th-232) provided the sum of the fractions is less than 1. US Ecology Michigan can accept NORM/TENORM waste that contains less than 50 pCi/g Ra-226 and less than 260 pCi/g Pb-210 or that after treatment or blending meets these criteria.

3.1.4.3.3 Clean Harbors, Deer Trail, Colorado

The Clean Harbors Deer Trail, Colorado facility can only accept materials classified by Colorado Regulations as NORM and TENORM (Appendix C-3). This facility can only accept materials with total activity levels less than 2,000 pCi/g and with total uranium and thorium content less than 500 mg/kg. Ra-226 must be less than 222 pCi/g if it is the only primary radionuclide present. Lead-210 must be less than 666 pCi/g if it is the only primary radionuclide present. In addition, the gamma dose rate must be less than 116 microRoentgens/hour (uR/hr) at the surface of the container. The Deer Trail facility can accept mixed RCRA/NORM wastes, but additional testing of such wastes may be required.

3.1.4.3.4 Energy*Solutions*, Clive, Utah

Energy*Solutions* has an Agreement State Radioactive Materials License issued by the State of Utah that authorizes Energy*Solutions* to receive Class A Low Level Radioactive Waste (LLRW), NORM and Accelerator-Produced Radioactive Material (NARM) waste. Energy*Solutions* also has a separate license to receive and dispose of uranium and thorium mill tailings byproduct material as defined by Section 11e(2) of the Atomic Energy Act, as amended.

Energy*Solutions*' Radioactive Material License allows receipt and disposal of NORM or NARM. NORM/NARM does not include byproduct, source, or special nuclear material and generally contains radionuclides in the uranium and thorium decay series. Because NORM/NARM waste is not considered LLRW, the waste classification regulations do not apply.

The generator or owner must attach to the certification a list of all radiological and non-radiological constituents in the waste and the maximum and average concentrations of such constituents.

3.1.4.3.5 Other Off-site Disposal Facilities

Several other off-site disposal facilities were identified, including the US Ecology facility in Robstown, Texas; the Waste Control Specialists facility in Andrews, Texas; and the Chem-Nuclear Systems facility in Barnwell, South Carolina. Based on the results of the prior EPA evaluation (TetraTech, 2009), subsequent discussions with representatives of these facilities, and review of the permit limitations or WAC for these facilities, it was determined that disposal of RIM from the Site at these facilities was not likely to be acceptable. Factors anticipated to limit acceptance of RIM from the Site include prohibitions on landfilling of radioactive wastes mixed with other materials, limits on the total or specific radionuclide activity levels, and prohibitions on acceptance of wastes generated outside of particular low-level radioactive waste regional compact areas.

Although disposal of soil containing radionuclides may be acceptable at the US Ecology facility in Richland, Washington (Hanford Nuclear Reservation area), disposal of mixed refuse and soil was not likely to be acceptable at this facility. In addition, as this facility was designed to accept higher activity wastes, disposal fees at the Richland facility are substantially higher than those charged by US Ecology at its Grandview, Idaho or Michigan facilities or at the Energy*Solutions* Clive, Utah facility. Both the prior EPA evaluation (TetraTech, 2009) and evaluations made for the SFS determined that disposal of RIM from the Site at the Richland, WA facility would be substantially more expensive than disposal at US Ecology's Grandview, Idaho facility.

3.2 Remedial Action Objectives

RAOs are developed based on contaminants, media of interest, and exposure pathways that permit a range of containment and treatment alternatives to be developed. RAOs are developed based on chemical-specific ARARs and site-specific risk-related factors.

The NCP sets forth a requirement to "establish remedial action objectives specifying contaminants and media of concern, potential exposure pathways, and remediation goals" [40 CFR § 300.430 (e)(2)(i)]. The remedial action objectives (RAOs) are developed based on chemical-specific ARARs and site-specific risk-based cleanup levels, serve as a basis for developing and assessing remedial action alternatives, and describe what the remedial alternatives need to accomplish in order to be protective of human health and the environment. In particular, the development of the RAOs is based on contaminants, media of interest, and exposure pathways that permit a range of containment and treatment alternatives to be developed. Specific remediation goals (RGs) are developed consistent with protective ARARs. If ARARs are not available or are not sufficiently protective due to multiple contaminants or multiple pathways, then RGs are based on site-specific risk-based cleanup levels.

The following RAOs are identified for West Lake Landfill OU-1:

<u>RAOs for Areas 1 and 2</u>

1. Prevent direct contact with landfill contents, including exposure to external radiation;
2. Minimize infiltration and any resulting contaminant leaching to groundwater;
3. Control surface water runoff of contaminants of concern and minimize erosion; and
4. Control and treat landfill gas emissions including radon.

<u>RAO for the Buffer Zone/Crossroads Property:</u>

5. Prevent direct contact with contaminated surface soils or ensure contaminant levels are low enough to allow for unlimited use and unrestricted exposure.

Because the RI/FS, SFS and RI Addendum do not identify groundwater contamination issues associated with the Site, and because neither the ROD-selected remedy nor the excavation options for OU-1 include groundwater remediation, no groundwater RAO is identified or required at this time. Groundwater will be further evaluated separately as part of the anticipated "OU-3" investigations directed by EPA.

3.2.1 Cleanup Levels

This section describes the preliminary remediation goals (PRGs) or "cleanup levels" that are used to define the various remedial alternatives evaluated in the FFS.

3.2.1.1 ROD-Selected Remedy Cleanup Levels

Because the ROD-selected remedy is a containment remedy, no specific cleanup levels would apply. However, for purposes of defining the extent of the engineered landfill cover that would be installed under the ROD-selected remedy, the EPA criteria for unrestricted use (see discussion below) would be used.

3.2.1.2 "Complete Rad Removal" Alternative

EPA has defined (EPA, 2010a) "complete rad removal" to mean attainment of the risk-based radiological cleanup levels specified in OSWER directives 9200.4-25 and 9200.4-18 (EPA, 1998a and 1997a). These criteria are based on the UMTRCA standards (40 CFR Part 192 Subpart B) for cleanup of so-called "vicinity properties" (as opposed to the actual waste disposal units). Although the UMTRCA standards are neither applicable nor relevant and appropriate to the solid waste disposal units at the Site, they do represent standards that have been established by EPA for remediating radionuclide occurrences so as to allow for unrestricted use. EPA has indicated that "[o]ne intent of the 'complete rad removal' alternatives, if implemented, would be to leave disposal areas 1 and 2 in a condition that would not require additional engineering and institutional controls due to their radiological content, if feasible." (EPA, 2010b). The standards established pursuant to 40 CFR Part 192 Subpart B are intended to allow for unrestricted use of land relative to radionuclide occurrences. Although removal of all radionuclides above the UMTRCA standards (as modified by the OSWER Directives) would allow for unrestricted (*e.g.*, residential) use of the Site relative to the presence of radionuclides, the Site would still contain MSW and would still be subject to the solid waste regulations requirements including installation of an engineered landfill cover and institutional controls that prohibit residential land use on an MSW landfill.

The radiological cleanup levels specified in OSWER directive 9200.4-25 are total Ra-226 + Ra-228 greater than 5 pCi/g (above background) and total Th-230 + Th-232 greater than 5 pCi/g (above background). For purposes of performing the evaluations in this FFS for the "complete rad removal" alternative, a cleanup level of 54.5 pCi/g was used for uranium based on the approach established by EPA for development of the uranium remediation goals for the St. Louis Downtown Site (SLDS) [EPA, 1998b] and the St. Louis Airport Site (SLAPS) (EPA, 2005a). Additional discussion regarding the approach used for development of the uranium remediation level is presented in the EPA-approved SFS Work Plan (EMSI, 2010) and in Section 2.8.2.1 of the Record of Decision for SLAPS (EPA, 2005a).

Based on these cleanup levels, the so-called "complete rad removal" alternative would not result in complete removal of all radionuclides from the Site. Rather, this alternative is intended to result in removal of radionuclides to a level such that engineering measures and institutional controls intended to address radionuclide occurrences would no longer be required. EPA's policies pursuant to CERCLA and the NCP do not require removal of all radionuclides. The radionuclide levels that would remain within Areas 1 and 2 under the "complete rad removal" alternative would allow for unrestricted use of the Site and therefore would be protective of human health for reasonably expected future exposure scenarios.

EPA has defined the "complete rad removal" alternative to mean attainment of the risk-based radiological cleanup levels specified in OSWER directives 9200.4-25 and 9200.4-18. These directives provide guidance for establishing protective cleanup levels for radioactive contamination at CERCLA (Superfund) sites. In particular, these directives provide clarification as to the use of the UMTRCA soil cleanup criteria as remediation goals at CERCLA sites. The UMTRCA soil cleanup criteria are based on concentrations above background levels. Similarly, EPA has stated elsewhere that CERCLA cleanup levels are not set at concentrations below natural background levels (EPA, 2002). As a result, the cleanup standards to be used for the development and evaluation of the "complete rad removal" alternative are background-based standards. Determination of background levels is an important part of the development of the soil cleanup levels for the "complete rad removal" alternative.

As with any set of data, background values are subject to variability. By definition, the mean background value represents the central tendency of the background data set, but does not incorporate any measure of the variability of the background data set. Values greater than the mean value may nonetheless be representative of background conditions. Therefore, some measure of the variability of the background data is necessary to define the uncertainty associated with the mean of the background values. A common type of value for the interval around an estimate is a "confidence interval." A confidence interval may be regarded as combining an interval around an estimate with a probabilistic statement about the unknown parameter. Confidence intervals are based on the standard deviation of the data set and published statistical values defining population distributions.

Background concentrations of the various isotopes of radium, thorium and uranium are presented in Section 6.2 of the RI report (EMSI, 2000). These background concentrations were determined using analytical results from samples collected at four background locations. In order to account for the variability in the background results, the representative background values used in the RI are the mean values of the four results plus two standard deviations. Use of two standard deviations reflects the critical value of 1.96 used to calculate the 95% confidence limit for a normally distributed population with a large number (greater than 30) of sample results. Specifically, through repeated sampling, the true mean value is expected to fall within a range defined by two times the standard deviation 95% of the time. For smaller sample sizes, the critical values are larger. In the case of a sample set consisting of four data values, the critical value would be 2.35. Therefore, use of a value of two is a reasonable, yet slightly conservative (more protective), method of estimating the variability of the background values.

The mean background concentrations and the mean background concentrations plus two standard deviations were presented in the RI report (EMSI, 2000) and are listed below:

Parameter	Mean of the background sample results	Standard deviation of the background sample results	Mean value plus two standard deviations
Radium-226	1.06	0.12	1.30
Radium-228	1.65	0.36	2.37
Thorium-230	1.51	0.47	2.45
Thorium-232	0.90	0.33	1.55
Uranium-238	1.33	0.46	2.24
Uranium-235	0.39	0.38	1.15
Uranium-234	1.47	0.63	2.73

All values reported as pCi/g

Collection of additional background samples to provide a larger data set for use in estimating background values, or incorporation or use of background values obtained from other studies conducted in the general area of the Site (such as SLAPS) may provide a better estimate of the background values, but these efforts are outside the scope of – and are not necessary for – completion of this FFS.

Each of these radionuclides is a member of either the U-238 or the Th-232 decay chains. The short-lived members of these chains normally are in equilibrium with longer-lived progenitors in the same chain. For example, Th-232 and Ra-228 are members of the Th-232 decay series and should be in equilibrium with each other. Examining the results listed above, it can be seen that they are noticeably different. These differences likely result from variations in the analytical results obtained from the four samples, combined with the effects of averaging the results and incorporation of two standard deviations about the results to address the overall variability of the sample results.

In order to address the difference in activity levels of the parent and daughter radionuclides for purposes of the FFS, the representative background concentration for all short-lived members of a decay chain were set to the lowest value calculated for any member in the chain. This is a small adjustment that results in a slightly lower derived concentration guideline (DCGL). In the case of the Th-232 series, the background concentration of all members of the Th-232 series was set to 1.55 pCi/g for this FFS. Applying this same logic to the remaining radionuclides, the background values to be used for series nuclides in this evaluation are as follows:

- Radium-226 = 1.3 pCi/g
- Radium-228 = 1.55 pCi/g
- Thorium 232 = 1.55 pCi/g (parent of Ra-228)
- Thorium-230 = 1.3 pCi/g (parent of Ra-226)
- Uranium-238 = 2.24 pCi/g (parent of U-234)
- Uranium 234 = 2.24 pCi/g (parent of Th-230)

These values are comparable to the following background values identified for SLAPS (EPA, 1998b):

- Radium-226 = 2.8 pCi/g
- Radium-228 = not identified
- Thorium 232 = not identified
- Thorium-230 = 1.9 pCi/g
- Uranium-238 = 1.4 pCi/g
- Uranium 234 = not identified

The resultant cleanup levels are the sum of the representative background concentrations and the appropriate risk-based remediation concentrations listed in the OSWER directives (*i.e.*, 5 pCi/g plus background). Based on the Site background values presented in the RI and RI Addendum (EMSI, 2000 and 2016a), the Site cleanup values would be as follows:

- Radium-226+228 = 7.9 pCi/g[16]
- Thorium-230+232 = 7.9 pCi/g

[16] Total radium DCGL = 1.3 pCi/g radium-226 + 1.6 pCi/g radium-228 + 5 pCi/g radium cleanup level = 7.9 pCi/g total radium

- Total uranium = 54.5 pCi/g

These cleanup values were used to identify the Site soils that would be included with the scope of the "complete rad removal" alternative and that would otherwise be used to define the extent of any hybrid landfill cover that may be included within the scope of the ROD-selected remedy or the partial excavation alternatives.

A uranium remediation goal of 50 pCi/g is equivalent to a mass-based uranium concentration of 71 mg/kg. EPA's current non-carcinogenic screening level for uranium is 3,500 mg/kg for commercial/industrial uses and 230 mg/kg for residential exposures (https://www.epa.gov/risk/regional-screening-levels-rsls-generic-tables-may-2016). Consequently, cleanup of uranium to 50 pCi/g plus background should not pose any non-carcinogenic risks. Therefore, the cleanup level (54.5 pCi/g) derived for the West Lake Landfill OU-1 by use of the same approach used for the SLAPS, which is part of the North St. Louis sites, for potential carcinogenic risks should not present unacceptable non-carcinogenic risks and represents the more conservative cleanup target.

3.2.1.3 Partial Excavation Alternatives Cleanup Levels

EPA directed three potential partial excavation alternatives for evaluation in the FFS (EPA, 2015a):

1. Partial Excavation 1,000 pCi/g – Excavation of all soil/waste containing combined radium (radium-226 plus radium-228) or combined thorium (thorium-230 plus thorium-232) with activity levels greater than 1,000 pCi/g;

2. Partial Excavation 52.9 pCi/g – Excavation of all soil/waste containing combined radium or combined thorium with activity levels greater than 52.9 pCi/g down to a total depth of 16 feet beneath the 2005 topographic surface; and

3. Partial Excavation Based on Expected Land Use – Partial excavation of all soil/waste containing combined radium or combined thorium with activity levels greater than a risk-based level to be developed based on the reasonably anticipated future land use of the Site.

The 1,000 pCi/g value is based in part on the criterion used in the original 2006 FS to define potential "hot spots." It is also the risk-based level associated with commercial/industrial land use, which is the reasonably anticipated future land use of the Site (Auxier & Associates, 2016b).

EPA did not provide a rationale for the 52.9 pCi/g or the 16-foot depth below the 2005 topographic surface criterion in the SOW (EPA, 2015a).

4 TECHNOLOGY SCREENING

The technology screening process in a CERCLA FS involves identifying General Response Actions (GRAs) that may be applicable for development of remedial alternatives based on the site characterization results and the RAOs established for the site or the operable unit. Potential remedial action technologies associated with each GRA that may be applicable to addressing the site characterization results and satisfying the RAOs are first identified and screened based on technical implementability. The resultant technologies are then evaluated based on anticipated effectiveness, implementability, and relative cost to identify the most applicable technologies. These technologies are then combined to develop remedial action alternatives for the FS.

In identifying potential GRAs and technologies, EPA's expectations with respect to developing appropriate remedial alternatives should be considered. These expectations are included in the National Contingency Plan (NCP) at 40 CFR §300.430(a)(iii), specifically:

- EPA expects to use treatment to address the principal threats posed by a site, wherever practicable. Principal threats for which treatment is most likely to be appropriate include liquids, areas contaminated with high concentrations of toxic compounds, and highly mobile materials;

- EPA expects to use engineering controls, such as containment, for waste that poses a relatively low long-term threat or where treatment is impracticable;

- EPA expects to use a combination of methods, as appropriate, to achieve protection of human health and the environment. In appropriate site situations, treatment of the principal threats posed by a site, with priority placed on treating waste that is liquid, highly toxic or highly mobile, will be combined with engineering controls, as appropriate, for treatment residuals and untreated waste;

- EPA expects to use institutional controls such as water use and deed restrictions to supplement engineering controls as appropriate for short- and long-term management to prevent or limit exposure to hazardous substances, pollutants, or contaminants;

- EPA expects to consider using innovative technology when such technology offers the potential for comparable or superior treatment performance or implementability, fewer or lesser adverse impacts than other available approaches, or lower costs for similar levels of performance than demonstrated technologies; and

- EPA expects to return usable ground waters to their beneficial uses wherever practicable, within a timeframe that is reasonable given the particular circumstances of the site.

Because of the presence of radionuclides in the waste material in Areas 1 and 2 of OU-1 at the West Lake Landfill Superfund Site, EPA's Technology Reference Guide for Radioactively Contaminated Media (EPA, 2007) is used as a reference for technologies that can effectively treat environmental media at radioactively contaminated sites. This guidance document states that the special characteristics of radioactive material in a waste constrain the technologies available to address site characterization results and satisfy RAOs. These special characteristics should be considered in light of the NCP's preference for treatment. The Technology Reference Guide for Radioactively Contaminated Media states:

> [U]nlike non-radioactive hazardous waste, which contains chemicals alterable by physical, chemical, or biological processes to reduce or destroy the hazard, radioactive waste cannot be similarly altered or destroyed. Since destruction of radioactivity is not an option, response actions at radioactively contaminated sites must rely on measures that prevent or reduce exposure to radiation.
>
> The concepts of "Time, Distance and Shielding" are used in radiation protection. Increasing the distance from radioactive material, increasing the shielding between the radioactive material and the point of exposure, and/or decreasing the time of exposure to radioactive material will rapidly reduce the risk from all forms of radiation. The concept of time as used in waste stream management and remediation has an additional meaning. Time allows the natural radioactive decay of the radionuclide to take place, resulting in reduction in risk to human health and the environment. Therefore all remediation solutions involve either removing and disposing of radioactive waste, or immobilizing and isolating radioactive material to protect human health and the environment.

EPA's reference guide includes 13 treatment technologies that can potentially be applied to radioactively-contaminated solid media. Descriptions of these technologies are included in Section 4.3.

Previously, GRAs were identified and technologies were screened and evaluated and used to develop the remedial alternatives in the FS (EMSI, 2006). To address the two "complete rad removal" alternatives evaluated in the Supplemental Feasibility Study (SFS) (EMSI et al., 2011) some technologies that were screened-out or not retained in the FS were revisited, and additional technologies from the Technology Reference Guide for Radioactively Contaminated Media (EPA, 2007) were evaluated relative to the development of the two "complete rad removal" alternatives. Because EPA has eliminated the "complete rad removal" with on-site disposal alternative from further consideration and added partial excavation alternatives for the FFS evaluations, the technologies that were previously evaluated in the FS (EMSI, 2006) and the SFS (EMSI et al., 2011) were re-examined. EPA also identified additional technologies for consideration in the FFS (EMSI, 2016a) such as volume separation/volume reduction techniques and apatite/phosphate-based treatment, which are also evaluated in this section.

4.1 Technologies Evaluated in the FS Report

The results of the technical implementability screening and evaluation of technologies previously conducted for the Site are presented in Figures 4-1 and 4-2 of the FS (EMSI, 2006). GRAs and retained technologies and process options within the technologies included:

General Response Action	Remedial Technology	Process Options
No Action		
Institutional Controls	Access Restrictions	• Fences and guards
	Proprietary Controls	• Deed restrictions • Deed notices • Easements • Covenants • Groundwater use restrictions
Monitoring	Long-term Performance Monitoring	• Groundwater, surface water, and sediment monitoring
Containment	Surface Controls/Diversions	• Diversion/collection, grading, swales and berms, and vegetation to isolate storm water from Areas 1 and 2
	Surface Water/ Sediment Control Barriers	• Sediment traps, sedimentation basins
	Dust Controls	• Revegetation, capping
	Capping and Covers	• Soil, clay, and vegetation; asphalt or concrete; synthetic membrane material; and multilayer, multimedia material
Physical Treatment/Pre-Treatment following Removal	Solids Separation	• Soil sorting and screening
Removal	Excavation	• Backhoe, bulldozer, scraper, and front-end loader
	Disposal	• Off-site disposal in licensed facility • On-site disposal on Area 2 (for surface soil from Buffer Zone/Crossroad property)

4.2 Additional Technology Evaluations/Revisit Previously Eliminated Technologies

In its January 11, 2010 letter and accompanying Statement of Work (SOW) for the SFS (EPA, 2010), EPA identified two "complete rad removal" alternatives to be developed and evaluated in the SFS:

- Excavation of radioactive materials with off-site commercial disposal of the excavated materials ("complete rad removal" with off-site disposal alternative); and

- Excavation of radioactive materials with on-site disposal of the excavated materials in an on-site engineered disposal cell with a liner and cap if a suitable location outside the geomorphic flood plain can be identified ("complete rad removal" with on-site disposal alternative).

Development and evaluation of the "complete rad removal" alternatives required amendment of several remedial technologies and process options included in the FS, and inclusion in the SFS of a few technologies that were screened out in the FS. These technologies and process options are listed below and presented on Figure 4-1.

Figure 4-1 is a graphical presentation of the technical implementability screening of remediation technologies and process options and provides a brief description for each of the potential technologies. In addition to the volume separation/volume reduction techniques and apatite/phosphate-based treatment volume/size reduction technology, the following technologies and process options were added to the technical implementability screening in this FFS to potentially be considered as components of the "complete rad removal" and partial excavation alternatives. Long-term performance monitoring and short-term monitoring during construction – two specific process options under the "monitoring" GRA that were discussed in general in the FS – are described in more detail in this section. Technical implementability screening comments are also included for each technology on Figure 4-1.

General Response Action	Remedial Technology	Process Options
Monitoring	Long-term performance monitoring Short-term monitoring during construction	• Landfill and radon gas monitoring • Perimeter environmental media air monitoring • Work zone monitoring • Excavation guidance/ clearance monitoring • Waste acceptance monitoring • Post cover construction radon flux monitoring
Containment	Land encapsulation	• On-site: new cell • Off-site licensed facility
	Cryogenic Barriers	• Subsurface cryogenic barrier
	Vertical Barriers	• Slurry wall

General Response Action	Remedial Technology	Process Options
		• Grout curtain • Sheet pile cutoff wall
Physical/Chemical Treatment	Solidification/ Stabilization	• Cement solidification / stabilization • Chemical solidification / stabilization
	Chemical Separation	• Solvent/chemical extraction
	Physical Separation	• Dry soil separation • Soil washing • Flotation
	Vitrification	• In-situ vitrification • Ex-situ vitrification
	Apatite/Phosphate-Based Treatment	• Mixing/injection of crystalline minerals with wastes or groundwater
Biological Treatment	Phytoremediation	• Phytoextraction • Phytostabilization
Removal	Physical Separation	• Dry soil separation • Rotating screen – Trommel • Radiological Segregation/Separation
	Transportation (hauling of wastes and construction material)	• On-site off-road trucks • Off-site on-road trucks • Rail
	Disposal	• Off-site disposal in a licensed facility
Nuisance Control Technologies	Storm Water Management	• Best Management Practices (BMPs) to route runon around working areas • BMPs to minimize waste exposure to direct precipitation • Enclose excavation with temporary structure • BMPs to collect, detain, treat, and release runoff
	Bird Nuisance Mitigation	• BMPs: excavation, staging, soil/tarp covers • Enclose excavation with temporary structure • Grids over exposed refuse • Visual deterrents

General Response Action	Remedial Technology	Process Options
		• Auditory frightening devices • Chemical frightening agents or toxicants
	Fugitive Dust/Odor Control	• Best management practices to cover excavation and stockpile areas during non-working periods • Use of water spray/misting, foam or chemical agents to minimize dust generation and control odors • Use of a temporary building over excavation or waste sorting/loading areas

4.3 Descriptions of Additional Technologies

The technologies and process options that were added in the SFS or the FFS to be considered as potential components of the “complete rad removal” and partial excavation alternatives are described and discussed in the following subsections.

4.3.1 Monitoring

Environmental monitoring is a technology used to assess the levels of chemical or radiological constituents in environmental media at a site.

4.3.1.1 Long-term Performance Monitoring

In addition to long-term groundwater and surface water monitoring, samples of landfill gas and radon could be collected at landfill gas monitoring probes installed around the periphery of those areas where solid waste and radionuclides would still be present after implementation of the remedy. Landfill gas monitoring is a potential component of the ROD-selected remedy and the complete and partial excavation alternatives if sufficient landfill gas is expected to be generated post-remediation to require such monitoring.

4.3.1.2 Short-term Monitoring During Construction

Short-term monitoring activities that might be required during implementation of any of the alternatives could include perimeter environmental media air monitoring, work zone monitoring, excavation guidance/clearance monitoring, waste acceptance monitoring, and post-cover construction radon flux monitoring. A detailed monitoring plan would be developed as part of RD of the selected remedy.

Perimeter and local area environmental media air monitoring would use fixed monitoring stations containing low volume air samplers to collect airborne particulates and organic vapor samples for analysis of VOCs and radionuclide activity; continuous radon monitors; and radiation dosimeters. Air quality would be monitored during construction of the remedy. Concentrations of chemicals and radionuclides would be measured in areas where non-remediation workers might congregate and at the fence line. These measured air concentrations would be compared to air quality objectives for the remedy to assure that non-remediation workers who might be present in other portions of the Site, as well as members of the general public, would not be exposed to radiation from the remediation activities. It is anticipated that the air quality objectives for the remedy would be health-based standards designed to satisfy State (10 CSR, Chapter 6) and Federal (40 CFR Part 61) requirements.

Regarding remediation workers, work zone monitoring activities would involve surveillance of working conditions during remediation. Air quality would be monitored in work areas and the breathing zone surrounding individual workers using fixed and portable air samplers. Air samples would be analyzed for a variety of potential RIM constituents, including radionuclides in particulate form, radon, radon daughters, along with asbestos, selected metals such as arsenic, lead and chromium, and explosive gases. Ambient radiation would be monitored using hand-held radiation detectors and personal dosimeters issued to individual workers. Remediation workers would participate in a medical monitoring program.

Excavation guidance/clearance monitoring would involve the use of walkover field radiological survey equipment and solids sampling to identify impacted materials above cleanup levels and to guide excavation equipment. To document that RIM has been removed, clearance monitoring would include final walkover radiological scans of exposed faces and bases of excavated areas as well as sampling of soil/MSW at the base of excavations.

If excavated RIM would be disposed off-site, waste acceptance monitoring would entail scanning each load of material removed from the Site to verify that the radiological waste acceptance criteria of the facility where the RIM would be disposed is met. The material would also be inspected and tested as necessary to determine whether the waste materials contain or could be classified as hazardous wastes or contain asbestos. Discussions with potential disposal facilities indicate that the facilities would conduct these inspections and testing, including providing the necessary personnel and equipment, as such testing is a requirement of their RCRA permits.

After construction is complete for the final cover systems associated with the ROD-selected remedy or the partial excavation alternatives, Large Area Activated Charcoal Canisters would be used to measure radon flux of the cover surface.

4.3.2 Containment

Because most radionuclides require long-term management, remedies for radioactively-contaminated sites usually employ containment technologies. Containment technologies are designed to isolate contaminated materials to prevent exposure to humans and the environment. Some containment technologies are designed to prevent horizontal contaminant migration, some to prevent vertical migration, and others to prevent any form of migration. Four containment technologies are included in the Technology Reference Guide for Radioactively Contaminated Media: capping and covers (containment in place); land encapsulation (excavation and disposal, on-site or off-site); cryogenic barriers (containment in place); and vertical barriers (containment in place) (EPA, 2007).

4.3.2.1 Capping and Covers

A contaminated area can be capped by placing low permeability surface seal barriers such as caps and covers on top of the area. Capping of soil and waste could effectively limit airborne emissions and reduce precipitation-enhanced percolation, infiltration, and leaching. An engineered landfill cover consisting of natural materials such as soil, clay and vegetation layers is the primary type of landfill cap considered for OU-1. The description and discussion of this technology were included in the FS (EMSI, 2006).

The standard RCRA Subtitle D (solid waste) landfill cover system may need to be enhanced as necessary to provide additional thickness for gamma shielding and/or radon attenuation, to prevent bio-intrusion by burrowing animals, and to provide some type of marker layer to identify the presence of waste materials. In addition, a geosynthetic liner such as a geosynthetic clay liner (GCL) may be incorporated into the cover design if needed, to provide for an even lower permeability layer to further reduce radon emissions and further restrict precipitation infiltration.

4.3.2.2 Land Encapsulation: New On-Site Cell

Land encapsulation is a well-proven and readily implementable containment technology that is generally used at the disposal stage of radioactive waste management. Land encapsulation can either occur on-site or off-site if the waste is transported to an off-site land encapsulation facility (EPA, 2007).

This technology was described in the SFS in conjunction with evaluation of the “complete rad removal” with on-site disposal alternative; however, at the direction of EPA, an alternative consisting of on-site disposal in a new engineered cell is no longer being considered for the Site.

Therefore, technologies that were associated solely with this alternative that were presented, described and evaluated in the SFS are not discussed in this FFS.

4.3.2.3 Cryogenic Barriers

Cryogenic barriers provide containment and reduce the mobility of radionuclide contaminants by freezing contaminated subsurface soils to create an ice barrier around a contaminated zone. Rows of freeze pipes are inserted in an array outside and beneath the contaminated zone and the array of pipes connected to a refrigeration plant. Coolants typically consist of salt water, propylene glycol or calcium chloride. Cryogenic barriers are considered a good application for the containment of short-lived radionuclides such as tritium. Both a full-scale field test and full-scale demonstration project of this technology have been performed in the Oak Ridge, TN area (EPA, 2007a).

4.3.2.4 Vertical Barriers

A vertical barrier is a containment technology that is installed around a contaminated zone to assist in confining radioactive waste and any contaminated groundwater that might otherwise flow from a site. To be effective, vertical barriers should be constructed such that the bottom of the barrier is keyed into a relatively impermeable natural horizontal barrier (i.e., a groundwater aquitard), such as a clay zone or bedrock, to limit groundwater flow. The vertical barrier technology is often used where the waste mass is too large to practically treat and where soluble and mobile constituents pose an imminent threat to a drinking water source (EPA, 1992b). Vertical barriers are frequently used in conjunction with a surface cap to produce an above- and below-grade containment structure (EPA, 1988b). Vertical barriers can include slurry walls, grout curtains, and sheet pile cutoff walls.

4.3.2.4.1 Slurry Wall

Slurry walls consist of a vertically excavated trench filled with a slurry mix of soil, bentonite and water, or cement, bentonite and water. The slurry is pumped into the trench as the trench materials are being excavated, which provides short-term stability of the trench to prevent collapse of the side walls during excavation and, once completed, provides a barrier to groundwater flow. Soil-bentonite slurry walls have a wider range of chemical compatibility and a lower permeability than cement-bentonite slurry walls or walls with other slurry compositions, but soil-bentonite slurry walls have lower shear strength and are subject to more settlement over time.

4.3.2.4.2 Grout Curtain

Grout curtains are thin vertical grout walls constructed by pressure-injecting grout directly into the soil at closely-spaced intervals around the waste mass. The spacing is designed so that each "pillar" of grout intersects the next, thus forming a continuous wall or curtain (EPA, 1988b). Grout curtains are generally used at shallow depths (*i.e.*, less than 30 to 40 feet). Grouting materials can include hydraulic cements, clays, bentonite, silicates, and polymers (sometimes preferable because they are impermeable to gases and liquids, resist radiation, and perform well in acidic and alkaline environments).

4.3.2.4.3 Sheet Pile Cutoff Wall

Sheet pile cutoff walls are used for excavation stability and to control groundwater flow. Sheet pile cutoff walls are constructed by driving interlocking steel or high density polyethylene (HDPE) sheets into the ground. The joints between individual sheets are typically plugged with clay slurry for steel sheets or an expanding gasket for HDPE sheets. Sheet pile cutoff walls have not been demonstrated as a containment barrier at a radionuclide-contaminated site (EPA, 2007).

Although the use of sheet piling to stabilize excavation side slopes could potentially reduce the amount of material that may need to be removed, obstructions and uncertain geotechnical properties within the waste mass could greatly impact the implementability of this technology. In addition, even if it were implementable, the use of sheet piling is expected to increase the overall construction schedule and add significant costs. Consequently, the potential benefit of using sheet piling does not appear to be commensurate with the additional construction risks, cost, and schedule extension. Application of the sheet pile technology for excavation stabilization is not considered to be implementable or cost effective for Areas 1 and 2.

4.3.3 Physical/Chemical Treatment

The Technology Reference Guide for Radioactively Contaminated Media (EPA, 2007) includes six physical and chemical treatment technologies that can potentially be used to effectively treat wastes from radioactively-contaminated sites: solidification/stabilization, chemical separation, physical separation, vitrification, soil washing, and column and centrifugal flotation. Physical separation is discussed in Section 4.3.5.2 in conjunction with other physical removal related technologies. In addition, per the SOW for the FFS, apatite/phosphate based treatment technologies are also reviewed in this section.

4.3.3.1 Solidification/Stabilization

Solidification/stabilization technologies reduce the mobility of hazardous and radioactive contaminants in the environment through both physical and chemical processes. The goal of the solidification/stabilization process is to limit the spread of radioactive material via leaching, and to "trap" and contain radionuclides within a densified and hardened soil mass that has a high structural integrity. In stabilization, chemical reactions are induced between the stabilizing agent and contaminants. Solidification does not involve chemical interaction or chemical bonding between the contaminants and the solidification agent, but bonds them mechanically.

Solidification/stabilization can be employed in-situ or ex-situ. In-situ techniques use auger/caisson and injector head systems to apply agents to soils in-place, while ex-situ techniques involve excavating the contaminated materials and machine-mixing them with the solidifying agent. Ex-situ processes typically involve disposal of the resultant materials.

Solidification/stabilization techniques can involve either microencapsulation or macroencapsulation. Microencapsulation involves thorough and homogeneous mixing of small waste particles (typically 0.08 inches or less) with a liquid binder that then solidifies to form a solid, monolithic final waste form. Individual waste particles are coated and surrounded by the solidified binder to provide mechanical integrity and act as a barrier against leaching of contaminants. Macroencapsulation involves packaging large pieces of waste or containers of waste not suitable for processing by microencapsulation and surrounding the package with a layer of clean binder material. The binder forms a protective layer around the waste that provides structural support, prevents dispersion, and helps reduce migration of contaminants. EPA defines macroencapsulation as being appropriate for immobilizing low-level radioactive debris waste with dimensions greater than or equal to 2.5 inches (EPA, 2007).

Cement solidification/stabilization processes involve the addition of cement or a cement-based mixture, while chemical solidification/stabilization involves adding chemical reagents including thermoplastic polymers (asphalt bitumen, paraffin, polyethylene, polypropylene, modified sulfur cement), thermosetting polymers (vinyl ester monomers, urea formaldehyde, epoxy polymers), and other proprietary additives. Cement solidification/stabilization is best suited to highly porous, coarse-grained, low-level radioactive waste in permeable matrices, while chemical solidification/stabilization is better suited to fine-grained soil with small pores (EPA, 2007). After an extensive search of the literature, EMSI could not find an application of the solidification/stabilization technology to MSW.

4.3.3.2 Chemical Separation

Chemical separation using solvent/chemical extraction is an ex-situ chemical separation technology that separates hazardous contaminants from soils, sludges, and sediments to reduce the volume of hazardous waste that must be treated. The resulting process residuals require further treatment, storage, or disposal. Solvent/chemical extraction involves excavation and transferring soil to equipment that mixes the soil with a solvent. Solvents that have been used to remove radionuclide contaminants include complexing agents such as ethylenediaminetetraacetic acid (EDTA); inorganic salts; organic solvents; and sulfuric, hydrochloric, and nitric mineral acids. Use of water alone as the solvent is referred to as soil washing – see Section 4.3.3.3.

Solvent/chemical extraction equipment processes contaminated soil either in batches for dry soil or as a continuous flow for pumpable waste. When the contaminants have been sufficiently extracted, the solvent is separated from the soil and is either distilled in an evaporator or column or removed from the leachate by precipitation. Distilled vapor consists of relatively pure solvent that is recycled into the extraction process. The liquid residue, which contains concentrated contaminants, undergoes further treatment or disposal. If the contaminants are precipitated, the sludge is dewatered with a filter press.

Not all radionuclides and solvent will be removed from the contaminated soil during the chemical extraction process, requiring further processing if the remaining concentrations are not below levels such that the soil can be returned to its original location. Results from 22 studies indicate contaminant removal rates using the solvent/chemical extraction process of 13% to 100% for soils contaminated with radioactive waste and heavy metals (EPA, 2007). Two studies (one pilot-scale and one full-scale) using sodium carbonate/sodium bicarbonate solution for uranium extraction achieved removal efficiencies of between 75% and 90% (EPA, 2007). A solvent/chemical extraction field demonstration project treating soil containing Ra-226 and Th-232 showed removals of 60% to 67% and 73% to 76%, respectively (EPA, 2007).

Soil properties such as particle size, pH, partition coefficient, ion exchange capacity, organic content, moisture content, and contaminant concentrations and solubilities are factors that affect the efficiency and the operability of solvent/chemical extraction (FRTR, 2002). Bench-scale testing is required. Soils with high clay, silt, or organic content might cause dewatering problems in the contaminated waste stream. Debris greater than 2.4 inches in diameter typically must be removed prior to processing, and chemical extraction is not practical for soil with more than 6.7% organic material. If multiple radionuclides or metals are targeted for removal, multiple solvent extraction steps may be required using multiple solvents. Interference from thorium could limit the application of EDTA in removing radium when both radionuclides are present (EPA, 1995).

4.3.3.3 Soil Washing

Soil washing is a process in which water, with or without surfactants, is mixed with contaminated soil and debris to produce a slurry feed. This slurry feed flows through a scrubbing process to segregate contaminated fine soil particles (silts and clays) from granular soil particles. Contaminants are generally bound more tightly to the fine soil particles and not to larger-grained sand and gravel. Separation processes such as mechanical screening are needed to divide excavated soils into the coarse- and fine-grained fractions, and for dissolving or suspending contaminants in the slurry feed wash. The sand and gravel fraction is generally passed through an abrasive scouring or scrubbing action to remove surface contamination. The fine fraction can be separated further in a sedimentation tank, sometimes with the help of a flocculating agent. The output streams of these processes consist of clean granular soil particles, contaminated soil fines, and process/wash water, all of which need to be tested for contamination. Soil washing is effective only if the process transfers the radionuclides to the wash fluids or concentrates them in a fraction of the original soil volume. In either case, soil washing must be used with other treatment technologies, such as precipitation, filtration and/or ion exchange, to recover the radionuclides. Clean soil (sands and gravels) can be returned to the excavation area, while the contaminated soil fines and process water are further treated and/or disposed.

Soil washing is most effective when the contaminated soil consists of less than 25% silt and clay and at least 50% sand and gravel; soil particles should be between 0.01 to 0.08 inches in diameter for optimum performance (EPA, 2007). Soil characteristics including particle size distribution, moisture content, ion exchange capacity, and contaminant concentrations and solubilities are factors that impact the efficiency and operation of the soil washing process. Despite many bench- and pilot-scale tests, soil washing has not been fully demonstrated as a technology for reducing the volume of radionuclide-contaminated soil (EPA, 2007). There also are no known treatability tests or applications of this technology to MSW.

4.3.3.4 Flotation

Flotation separates the radionuclide-contaminated soil fraction (usually the fine soil particles such as silts and clays) from the clean soil fractions (usually the large granular soil particles and gravel) in order to reduce the volume of soil requiring treatment or disposal. During flotation, radionuclide-contaminated soil is pretreated to remove coarse material and then mixed with water to form a slurry. A flotation agent (a chemical that binds to the surface of the contaminated soil particles to form a water repellant surface) is then added to the solution. Small air bubbles are then passed through the slurry. These air bubbles adhere to the floating particles, transport them to the surface, and produce a foam containing the radionuclide-contaminated soil particles. The foam is mechanically skimmed from the surface or allowed to overflow into another vessel. Residual radionuclide-contaminated soil fines and foam require further testing and treatment and/or disposal. After dewatering and drying, the clean soil can then be returned to the excavation area (EPA, 2007).

Soil-specific site considerations such as particle size and shape distribution, radionuclide distribution, soil characteristics (clay, sand, silt, and organic content), specific gravity, chemical composition and mineralogical composition can impact the effectiveness of flotation. Flotation is most effective at separating soil particles in the 0.0004 to 0.004 inch size range. For soils that include a wider range of particle sizes, flotation can sometimes be part of a treatment train (e.g., soil washing). Although mining industry operations have consistently and successfully segregated metal-containing fines from soil using this process, the flotation technology has not been fully demonstrated for reducing the volume of radionuclide-contaminated soil (EPA, 2007). The effectiveness of floatation technology is dependent upon the degree to which the technology concentrates the radionuclide-contaminated soil/waste fraction.

4.3.3.5 Vitrification

Vitrification involves heating contaminated media to extremely high temperatures, then cooling them to form a solid mass. Upon cooling, a dense glassified mass remains, trapping the radioactive contaminants in a solid, inert form. The process can be applied to contaminated soil, sediment, sludge, mine tailings, buried waste, and metal combustibles. Although mobility is greatly reduced for contaminants trapped within the vitrified mass, the radioactivity of the radionuclide contaminants is not reduced. EPA has designated vitrification as a Best Demonstrated Available Technology (BDAT) for high level radioactive waste (EPA, 2007).

Vitrification can be performed both in-situ and ex-situ. Traditional in-situ vitrification uses a square array of four graphite electrodes that allows a melt width of approximately 20 to 40 feet and a potential treatment depth of up to 20 feet. Multiple locations, referred to as settings, can be used for remediation of a larger contaminated area. The electrode array is lowered progressively, as the melt grows, to the desired treatment depth. Depending on the amount and types of organics and metals (*e.g.*, mercury, lead, and cadmium) present in the soil or waste mass which may volatilize, offgas treatment may be required.

In the ex-situ configuration, waste is fed to a furnace (*e.g.*, joule-process heating; plasma; electric arc; microwave; and coal-, gas- or oil-fired cyclone furnace) on either a batch or continuous feed basis. The ex-situ vitrified mass is then disposed off-site or returned to the area where the waste was excavated.

In-situ vitrification should generally not be used on waste or contaminated soils with organic contents higher than 10 percent by weight or highly reactive materials. To effectively immobilize radionuclides and heavy metals, soils should have greater that 30 percent glass-forming materials (*i.e.*, SiO_2). The waste and/or contaminated media must have sufficient alkali content (*i.e.*, Na_2O, Li_2O, and K_2O) to ensure the proper balance between electrical conductivity and melting temperature. Void volumes and percentages of metals, rubble, and combustible organics (*e.g.*, methane in landfill gas) need to be considered, as soils and waste that contain greater than 55 percent inorganic debris and/or rubble are difficult to treat with in-situ vitrification (EPA, 1997). The process is also not applicable to soils or waste containing sealed containers such as drums, tanks, or paint cans since pressurized gases will be released and may disrupt the melt (EPA, 2007). No information was identified regarding the potential applicability or previous application of this technology to MSW.

4.3.3.6 Apatite/Phosphate-Based Treatment

The EPA SOW (EPA, 2015b) required an evaluation of the potential feasibility of using apatite/phosphate-based treatment technologies for treatment of radionuclides in soil or groundwater. This section presents a summary of the evaluation of the apatite treatment technology. Additional details regarding this evaluation are presented in Appendix D.

Apatite is an isomorphic mineral. Specifically, apatite is a group of crystalline mineral compounds that have different chemical compositions but identical crystalline structures. Consequently, precipitation of apatite can result in incorporation of other elements into the mineral's crystalline structure. In an isomorphic mineral, certain ions or molecules will enter into the crystal-lattice of a mineral solid without causing any marked change in the crystal morphology or other physical properties of the mineral. For simplicity, this process reflects two ions having similar but not equal atomic radii and the same charge, with the smaller ion being preferentially concentrated in the early formed specimens of a crystallizing mineral series.

Relative to the radionuclides at the Site, apatite or other phosphate-based materials or solutions would be added to groundwater containing radionuclides or to the solid phase materials containing the radionuclides in sufficient quantities and under appropriate geochemical conditions necessary to promote apatite crystallization. Such crystallization may result in incorporation of Site-related radionuclides such as thorium, radium and uranium into the apatite crystals. Incorporation of radionuclides into the crystalline matrix would reduce the potential for leaching of such radionuclides.

Radium and thorium, and to a lesser extent uranium, are the major radionuclides of concern at the Site relative to potential leaching to groundwater. Thorium is known to be highly insoluble and uranium is relatively insoluble under reducing conditions such as those that occur at MSW landfills. Neither of these radionuclides has been detected in dissolved-phase groundwater at levels above background. Therefore, radium would be the key constituent for treatment using apatite materials. Based on an extensive review of the literature regarding the use of apatite and/or other phosphate-based materials for treatment of radionuclides and metals in water, soil, sediments, tailings and landfill leachate (EMSI, 2016c), there is known applicability for treatment of groundwater containing strontium, uranium, and some metals, but no known applications for treatment of radium or thorium in groundwater.

There is no demonstrated application of use of apatite and/or other phosphate-based materials for treatment of MSW. Uncertainty exists as to whether apatite formation can be initiated synthetically under field conditions associated with MSW, including whether apatite solids or solutions can be delivered and homogeneously distributed within an overall heterogeneous matrix of MSW, which in the case of Areas 1 and 2 have been shown to be in generally unsaturated conditions (EMSI, 2016b and EMSI, 2000). DOE technical representatives with extensive experience with bench- and pilot-testing of apatite under various geochemical conditions have expressed concerns about unintended consequences that could result from physical disturbance or modification of the geochemical conditions within the Site from application of apatite-based treatment technologies (Thompson and Wellman, 2012).

4.3.4 Biological Treatment

Biological treatment of radioactively-contaminated soils, sediments, and sludges involves stabilization of the contaminants in-place and/or removal via plant root systems. Phytoremediation is the use of plant systems to remove, transfer, stabilize, or destroy contaminants in soils, sediments and sludges. The contaminants are transferred to various parts of the plant, including the shoots and leaves, where they can be harvested. The mechanisms of phytoremediation applicable to solid media include enhanced rhizosphere biodegradation, phytoextraction, phytodegradation and phytostabilization.

Because radionuclides do not biodegrade, the mechanisms applicable to remediation of radionuclides are phytoextraction and phytostabilization (FRTR, 2002). Phytoremediation is limited to shallow soils and sediments. Because growth of plants can be affected by climatic or seasonal conditions, this technology may not be applicable in areas with cold climates and short growing seasons.

Phytoextraction (also known as phytoaccumulation), is the uptake of contaminants by plant roots and the translocation/accumulation of contaminants into plant shoots and leaves. Phytoextraction will produce a harvested biomass residual waste that must be further treated and/or disposed as a radioactive waste. For phytoextraction to be effective, the root system of the selected plants should be able to penetrate the entire contaminated zone, and to be cost-effective, the rate of plant uptake must be greater than one percent of the plant's weight per harvest and the time to complete the remediation process must be between two and 10 years. Phytoextraction has been pilot-tested to remove low levels of cesium and strontium from contaminated soils and sediments (EPA, 2007). EPA (2007) indicated that phytoremediation is applicable to uranium, cesium, strontium and cobalt in solids but that application of this technology is limited to shallow soils, that this technology is best suited to sites with lower levels of contamination only slightly above cleanup levels, and that this process can take several years or more for implementation. EPA (2007) further indicated that this technology has not been fully demonstrated for radioactive contamination in solids. EPA identified a bench scale demonstration for removal of thorium from soil but indicated that based on testing and field trials, the most promising candidates for phytoextraction appeared to be cesium-137 and strontium-90 (EPA, 2007). No information was identified regarding the potential applicability or prior application of this technology for removal of radium (EPA, 2007).

Phytostabilization is the production of chemical compounds by plants to immobilize contaminants at the interface of roots and soil. Contaminant transport in soil, sediments, or sludges can be reduced through absorption and accumulation by roots; adsorption onto roots; precipitation, complexation, metal valence reduction in soil within the root zone; or binding into organic humic matter through the process of humification. Although considerable research has been conducted on phytostabilization of metals, little research or field testing has been performed regarding phytostabilization of radionuclides (Pivetz, 2001).

Phytoextraction and phytostabilization all require the root systems of the plants to extend down through the zone of contamination. RIM in Areas 1 and 2 occurs at depths ranging 0 to 89 feet bgs in Area 1 and 0 to 42.5 feet bgs in Area 2. Therefore, application of phytoremediation technologies would require growing large trees on the surface of Areas 1 and 2 which is inconsistent with the objectives of the recently implemented non-combustible cover and would also be inconsistent with the ARARs associated with the Missouri solid waste regulations which require development of grasses and shallow rooted vegetation as part of a landfill cover.

4.3.5 Removal

Several removal technologies may be considered as components of alternatives to address the site characterization results, as well as to satisfy the RAOs associated with OU-1 at the West Lake Landfill. Removal technologies considered include excavation, physical separation, transportation, off-site disposal, and stormwater management.

4.3.5.1 Excavation

Excavation construction equipment includes back- and track-hoes, bulldozers, scrapers, and front-end loaders. This equipment would be used for cutting and filling of waste and fill materials to achieve surface grades, to excavate and move filled waste material, and to construct new site features such as stormwater retention/conveyance and cover systems.

4.3.5.2 Physical Separation

Physical separation technologies are a class of treatment in which radionuclide-contaminated media are separated into clean and contaminated fractions by taking advantage of the physical properties of the contaminants. These technologies work on the principle that radionuclides are associated with a particular fraction of a media which can be separated based on size and other physical attributes. In solid media such as soil or sediment, most radioactive contaminants are associated with smaller particles, known as soil fines (*i.e.*, clays and silts). Physical separation of the contaminated media into clean and contaminated fractions could potentially reduce the volume of contaminated media requiring further treatment and/or disposal.

4.3.5.2.1 Dry Soil Separation

Dry soil separation segregates radioactive particles from clean soil particles. The simplest application involves screening and sieving soils to separate finer fractions, such as silt and clay, from coarser fractions of the soil. Since most contaminants tend to bind to the fine fraction of a soil either chemically or physically, separating the finer portion of the soil can concentrate the contaminants to a smaller volume of soil for subsequent treatment or disposal (FRTR, 2002).

Radiological constituents at OU-1 Areas 1 and 2 occur in soil materials that are intermixed with and interspersed within the overall matrix of landfilled refuse, debris, fill materials, and soil and quarry spoils. Therefore, before a dry soil separation process could be considered, the interstitial soil materials would need to be separated from the other landfilled materials using a solids separation process. Solids separation processes can include hand picking for large bulky items and hazardous materials such as propane tanks; magnetic separation for ferrous metals and contaminants associated with ferrous metals; eddy current separation for non-ferrous metals (*e.g.*, inducing an electric current to separate aluminum cans from other recyclables); air classification for papers and plastics; and various fixed, vibrating, or rotating screens.

4.3.5.2.2 Rotating Screen – Trommel

Trommel (revolving cylindrical sieve) screens are commonly used during landfill mining and reclamation (LFMR) projects to separate materials by size, with the soil fraction passing through the screen. Metal conveyor flights on the inside surface of the screen direct the non-soil fraction to the discharge end of the rotating cylinder. The size and type of screen used depends on the end use of the recovered material.

During LFMR projects, trommel screens are typically used downstream in series with a shear shredder with the recovered soil fraction directed to one side of the trommel. If the radiologically-impacted soil were to be separated from the landfilled waste materials, one or more mobile diesel-driven trommels would be used downstream of a shear shredder. A 1 to 1½-inch trommel screen size would likely be chosen to recover the most soil while passing through small pieces of metal, plastic, glass, and paper. This configuration of shear shredder and trommel in an LFMR pilot-test application is shown in Figure 4-2.

A comb and shaft shear shredder uses counter-rotating multi-edged knives or hooks rotating at a slow speed with high torque to shred materials fed into the inlet hopper. Shear shredders are employed prior to trommel screens in LFMR projects for three primary reasons:

- An approximate 30 percent volume reduction in waste material is achieved by shredding all filled material to a uniform 6 to 8-inch minus size. Separated material that is returned to the landfill is more easily compacted and takes up less volume than the original in-place waste material. It should be noted that very large landfilled objects such as white goods and steel beams, etc. are “hand-picked” from the waste stream prior to shredding.

- Shredding pretreatment breaks up pockets and clumps of organic and matted materials and soil; dislodges smaller materials that may be ‘hidden” in among the larger materials; and pulverizes materials such as brick, concrete block, large chunks of concrete that contain rebar, and mattresses to provide a stream of more uniformly-sized material such that fines and the soil fraction of the waste can be more easily separated.

- Shear shredding reduces the size of materials (primarily from construction/remodeling and demolition of utilities, structures, and roads, including rebar and other pieces of steel, dimensional lumber and columns/beams, plumbing fixtures and piping, recycled asphalt, and electrical wiring and components) that would tend to clog, get hung up in, and increase the wear on the trommel screen and flights.

The benefits or impacts of using a shear shredder prior to a trommel screen relative to maximizing separation of radiologically-impacted soil from solid wastes typically is evaluated as part of a pilot test during RD prior to full-scale implementation. A pilot-test would require at least seven to nine months to perform, including at least three months to develop, review, approve, and finalize a work plan, one to two months for equipment mobilization and field testing, two months for lab testing, and one to two months for data evaluation and reporting.

4.3.5.2.3 Radiological Segregation/Separation

A refinement of the dry soil separation process uses radiation detectors to further separate materials (EPA, 2001, Patteson, 2000, Patteson, Maynor and Callan, 2000, Thermo Nutech,1998, and Cummings and Booth, 1996). For this method, radionuclide-contaminated soil is first excavated and screened to remove large rocks and debris. Large rocks are crushed and placed with soil on a conveyor belt, which carries the soil under radiation detectors that measure and record the level of radiation in the material. Radioactive batches of material on the conveyor belt are tracked and mechanically diverted through automated gates, which separate the soil into contaminated and clean segments. The radioactive materials then receive further treatment and/or disposal. This technology would require extensive pilot-testing to determine the appropriate screening criteria to be used to segregate the material, and to demonstrate the implementability, cost, and potential effectiveness of the technique.

This system is best suited to sort any dry host matrix that can be transported by conveyor belts (EPA, 2003) and which is contaminated with no more than two radionuclides with different gamma energies (DOE, 1998). Large debris should be removed before processing the soil and large rocks, concrete, or asphalt must be crushed before being placed on the conveyor belt. Screening to size the feed material to diameters of less than 0.5 inches is desirable and material greater than approximately 1.5 inches in diameter cannot be processed without crushing. Optimal soil moisture content is between 5 and 15 percent (DOE, 1999).

Several case studies of application of this technology are available (EPA, 2001, Patteson, 2000, Patteson, Maynor and Callan, 2000, Thermo Nutech, 1998, and Cummings and Booth, 1996). Review of these case studies indicates that applications of this technology have been used for sorting of soil containing depleted uranium, natural uranium, plutonium or Cesium-137. Most of these applications involved use of the ThermoRetec (formerly Thermo Nutech) segmented gate system (SGS) which consists of a mobile, radiological soil assay system with motorized conveyor belts, a variable belt speed motor controller, air actuated segmented gates, a radionuclide assay computer system and two sets of radiation detector arrays, deployed across a 32-inch wide assay conveyor. Contaminated soil is fed into the SGS processing plant where oversized material (typically 1.5 inches) is removed. The remaining soil is conveyed at a constant speed beneath the detector arrays that are linked to a control computer which toggles pneumatic diversion gates located at the end of the sorting conveyor. Contaminated material that exceeds the criteria for radioactive materials is diverted to a separate conveyor from that used to convey non-contaminated material. The SGS is designed for detection of gamma-ray emitting radionuclides using NaI detectors; however, it can also be modified to detect some beta-emitting radionuclides (Patteson, 2000).

Advantages of the SGS are that it physically surveys the entire volume of soil processed and typically reduces the volume of soil requiring treatment or disposal by 50% to 90% (Patteson, 2000). Dry decontamination has been proven effective for free release of the system so generation of secondary waste is limited to personnel protective equipment (Patteson, 2000). A disadvantage of the SGS is that it is limited to gamma -emitting radionuclides. It is also limited to analyses of a maximum of two radionuclides with different gamma energies at a time (Patteson, 2000). Soil cannot be sorted for unknown radionuclides, so prior knowledge of the primary radioactive contaminants is required (Patteson, 2000). Material greater than 1.5 inches cannot be processed without pre-crushing (Patteson, 2000). The radioactive contaminants must also be heterogeneously distributed within the suspect soil.

A detailed summary of several case studies is presented in Patteson (2000). The SGS has been used at Sandia National Laboratories where, through initial processing and subsequent reprocessing, it was used to sort 662 cubic yards of soil contaminated with depleted uranium with a resulting volume reduction of 99% relative to a cleanup criteria of 540 pCi/g. Soil processed through the SGS was separated into contaminated (average uranium activity of 406.5 pCi/gm) and uncontaminated soil (average activity of 4.2 pCi/g). At the Pantex Plant in Amarillo, Texas, the SGS system was also tested for use in processing soil containing depleted uranium. A total of 294 cubic yards were processed through the SGS with a resultant volume reduction of only 38.5% relative to a cleanup criteria of 50 pCi/g. The SGS system was tested for sorting 333 cubic yards of plutonium contaminated soil at the Tonopah Test Range in Nevada using varying set-point values to activate the sorting gates with results ranging from 4% to 99% reduction. The SGS was used to process 2,526 cubic yards of soil containing natural uranium at the Los Alamos National Laboratory where it achieved separation efficiencies ranging from 75% to over 99% for separation points of 50 to 65 pCi/g. The SGS was also used at the Idaho National Engineering and Environmental Laboratory (INEEL) to process soil containing cesium-137. Only 442 cubic yards were processed before the project was terminated because it did not achieve the expected volume reduction. EPA reports that the system only achieved a 3% volume reduction (EPA, 2001).

As discussed above, the SGS is designed for detection and sorting of gamma-emitting radionuclides. A soil sorter process such as the segmented gate system that uses gamma radiation to identify contaminated soil is likely to have difficulty identifying soil with a Th-230 concentration that would allow for unrestricted use (*e.g.*, 5 pCi/g plus background) due to the lower gamma emissions associated with thorium decay. Experience gained through investigations (EMSI, 2016b) and the non-combustible cover removal actions indicate that Th-230 is the dominant and most widespread radionuclide at the Site. The NRC (1988) stated that "[b]ecause the controlling radionuclide (Th-230) has no characteristics that make it easy to measure quantitatively in place, as can be done for Ra-226 with its decay products, the large but variable ratio of Th-230 to Ra-226 and its decay products makes the delineation of cleanup more difficult." The presence and overall dominance of Th-230 in the waste material greatly restricts the use of gamma radiation detection-based systems for automatically or even manually sorting RIM from non-RIM waste containing low levels of primarily non-gamma-emitting radionuclides. Therefore, it is likely this technology will not be effective for the "complete rad removal" or possibly even the 52.9 pCi/g criteria partial excavation alternative. Due to the general correlation between radium and thorium occurrences at higher levels (EMSI, 2016b), this technology may have some application relative to the partial excavation alternative based on the 1,000 pCi/g criteria.

4.3.5.3 Transportation

Hauling of waste material on- and off-site would be conducted using on-road and off-road trucks, rail, or a combination of trucks and rail. Delivery of clean fill, liner and cover materials, and other materials and equipment associated with construction of the selected remedy also would be accomplished with a variety of trucks.

4.3.5.3.1 Hauling of Wastes and Construction Materials – On-site, Off-road and Off-site, On-road Trucks

Hauling of waste material by truck would be conducted off-site with on-road trucks and on-site with off-road trucks. Various off-site, on-road "highway" trucks would be used to haul clean fill material to the Site, haul waste material from the Site directly to a waste disposal facility, or haul waste material to a truck-to-rail transloading location where it would be transferred from the trucks to rail cars for subsequent rail hauling. If hauled off-site via trucks, wastes with radionuclides must be placed in appropriate containers and USDOT requirements for shipping must be met.

Highway trucks are equipped with tires suitable for long distances on flat surfaces and are used for transporting loose material such as sand, gravel, rock, asphalt, soil or waste materials on roads and highways to and from construction sites, quarries, borrow pits, landfills, and waste disposal facilities. Typical configurations include the standard dump truck (truck chassis with dump body mounted to the truck frame); the semi-trailer or tractor-trailer equipped with flat-bed and bottom-, end-, and side-dump cargo trailers; and the transfer dump truck that pulls a separate dump (or "pup") trailer. Semi-trailer trucks equipped with flatbed or end-dump trailers as well as transfer trucks with pup trailers are typically used to haul waste material from a site to a truck-to-rail transloading operation at a rail spur location. Hauling of waste to a transloading facility can also be performed using 32 cubic yard (20 ton) capacity DOT Industrial Packaging (IP)-1 metal intermodal containers (see 49 CFR Subparts A and B and 49 CFR § 173.410 for IP design requirements for low specific activity (LSA) materials) that can be placed on a flatbed truck, which can be hauled directly to a waste disposal facility via truck or taken to a rail loading facility and transferred directly to flatbed railcars.

On-site, off-road dump trucks or "haul trucks" resemble heavy construction equipment and are used strictly off-road for mining and heavy dirt or other construction materials hauling projects. These vehicles employ large diameter off-road patterned rubber tires and can have large payload capacities. There are two primary forms: the rigid frame and the articulated frame or "Yuke."

4.3.5.3.2 Hauling of Waste Material - Rail

Hauling of waste material via rail is typically accomplished with 110-ton capacity gondola cars (railroad car with an open top but enclosed sides and ends, for transporting bulk commodities) or with DOT IP-1 intermodal containers that can be stacked onto flatbed railcars. Wastes hauled off-site to an off-site licensed facility via rail must be shipped in appropriate containers and USDOT requirements for shipping must be met.

If waste material is loaded directly into gondola cars, rigid lids are locked onto the open top prior to transport. Waste material can also be placed into 10 or 35 cubic yard IP-1 soft-sided shipping containers (bags), with the bags then loaded onto flatbed semi-trailers and trucked to a truck-to-rail transloading operation at a rail spur location where the containers are off-loaded from the flatbed into gondola cars. Nine to ten 10 cubic yard bags will fit in a standard sidewall height (5½ feet) gondola car. Four 35 cubic yard bags can be loaded into a larger volume 148 cubic yard gondola. After the gondola cars are filled with soft-sided shipping containers, rigid lids or secured tarps are placed over the top of the car prior to shipment. After the railcars arrive at an off-site disposal facility, the contents are either discharged directly at the facility using a rotary car dumper or “excavated” from the gondolas and transferred to trucks at a rail transfer facility and subsequently hauled to the disposal facility.

Metal intermodal containers have a hinged top and one end of the container is also hinged. After a liner has been placed in the container, the waste material is loaded into the top of the container, the top is secured and the container is lifted onto a flatbed trailer and hauled to a truck-to-rail transloading operation at a rail spur location, where the container is lifted off of the flatbed and stacked with other intermodals onto a flat railcar. At the off-site disposal facility, intermodal containers are lifted off of the railcar onto a truck, transported to the disposal cell, and the contents are discharged into the disposal cell through the hinged end of the container.

4.3.5.4 Disposal at an Off-Site Licensed Facility

The SFS evaluation included contacting low-level radioactive waste disposal facilities that could potentially accept the bulk debris-type of waste material to be excavated from the West Lake Landfill OU-1 areas. These facilities include the Energy Solutions facility in Clive, Utah; the US Ecology facilities in Grand View, Idaho and Robstown, Texas; the Waste Control Specialists facility near Andrews, Texas; and the Clean Harbors Deer Trail facility near Last Chance, Colorado. After the SFS was completed, US Ecology opened an additional facility in Wayne, Michigan and therefore US Ecology was also contacted regarding this facility.

As discussed in Section 3, prior to disposal, the waste material excavated from the Site would have to meet the waste acceptance criteria (WAC) of the respective disposal facility. A preliminary evaluation of the WAC for the various facilities relative to the activity of the RIM material indicates that only four – the US Ecology, Grand View, ID; US Ecology, Wayne, MI; Energy Solutions, Clive, UT; and Clean Harbors Deer Trail, CO facilities – could accept waste material from the Site. The locations of these facilities relative to the St. Louis, Missouri area are shown on Figure 4-3. Figure 4-3 also includes the various railroad lines that serve the areas where the various off-site disposal facilities are located. Because of the long distances between the facilities and the Site, rail transfer would be the most likely method of transporting waste materials for the "complete rad removal" with off-site disposal alternative; however, hauling by truck is also a potentially viable method for transportation of waste to the US Ecology, Wayne, MI facility (Figure 4-3).

Descriptions of these disposal facilities and the proposed methods of transportation of waste material from the Site are provided below. In addition to being permitted to accept low-level radioactive waste, each of these facilities is permitted to accept hazardous waste and low-level radioactive/hazardous mixed wastes if these wastes are encountered in Areas 1 and 2.

US Ecology: Grand View, Idaho. This 160-acre disposal facility (included within a 1,000 acre privately-owned buffer zone) is located 70 miles southeast of Boise in the Owyhee Desert, approximately 10 miles northwest of Grand View, ID. It has a permit from the State of Idaho to accept RCRA, NORM, TENORM, NRC, and mixed waste (Part B Permit # IDD073114654). Information for the facility can be found at http://www.americanecology.com/grand_view.htm. The link to a photo gallery showing the facilities and nearby rail transfer facility is: http://www.americanecology.com/grand_view_photo_gallery.htm.

Wastes are received at the US Ecology-Idaho facility by truck directly and by rail via their 130-car rail transfer facility located in Simco, Idaho, 36 miles from the disposal facility. Wastes shipped by rail are trucked from the rail transfer facility to the disposal facility. US Ecology has indicated that excavated material from the Site would be either: (1) loaded directly into bag-lined gondola cars if a rail spur could be extended across St. Charles Rock Road onto the Site; or (2) loaded into 35 cubic yard IP-1 DOT bags or 32 cubic yard IP-1 metal intermodal containers that would be placed on a semi-trailer, transported to a truck-to-rail transloading operation at a potential future leased rail spur located near the Site (assuming one could be located), and then loaded into gondola or flatbed rail cars in the case of the intermodal containers. Under either a direct-to-rail or truck-to-rail loading procedure in St. Louis, the bagged, excavated material in the gondola cars would be hauled by rail to the rail transfer facility east of Grand View, ID, then transferred from the gondola cars to transfer trucks with pup trailers and trucked the final 36 miles to the US Ecology facility for disposal.

The specific rail routes that would be followed from a potential future rail spur extended onto the Site or a truck-to-rail transloading operation at a potential future leased rail spur located near the Site to the US Ecology Grand View, ID facility are as follows: Burlington Northern Santa Fe (BNSF) from Bridgeton, MO to Kansas City, MO; then the Union Pacific from Kansas City, MO to Simco, ID. This route transits through the major cities of Bridgeton, MO, Kansas City, MO, Atchison, KS, Marysville, KS, Hastings, NE, North Platte, NE, Cheyenne, WY, Green River, WY, Salt Lake City, UT, Pocatello, ID, and Nampa, ID.

Approximately 2.5 million tons of waste material containing radionuclides, including 2 million tons of USACE FUSRAP waste containing uranium, radium, and thorium soils and debris, have been disposed at the Grand View, ID facility. Material containing radionuclides from SLAPS

[634,000 tons], Latty Avenue [69,000 tons], and Denver Radium OU-8 (Shattuck Chemical) [243,000 tons] sites have also been disposed at this facility.

The WAC and RCRA Part B permit for this facility are included in Appendix C-1.

US Ecology: Wayne, Michigan. This 450-acre treatment and disposal facility is located approximately 30 miles west of downtown Detroit adjacent to Interstate 94 in Van Buren Township, Wayne County, MI (just northwest of Belleview, MI): 49350 N I-94 Service Drive, Belleville, MI 48111. US Ecology-Michigan operates the largest (by volume) stabilization and treatment facility in North America with the ability to process hazardous and non-hazardous materials through stabilization, chemical oxidation/reduction, deactivation, microencapsulation and other permitted technologies. The facility manages more than 600 federal and state waste codes, employs a Regenerative Thermal Oxidation (RTO) system, and is the only commercial hazardous waste landfill in Michigan and the only landfill in EPA Region V with a TSCA approval to accept PCB contaminated wastes. It is permitted to accept solid waste, RCRA hazardous waste, and NORM and TENORM wastes under RCRA permits EPAID#MID000724831 (Treatment) and EPAID#MID048090633 (Landfill), which contain waste acceptance criteria relative to hazardous wastes. The NORM/TENORM Waste Addendum identifies waste acceptance criteria relative to radionuclides. The co-located solid waste transfer facility and processing plant (Michigan Disposal Waste Treatment Plant [MDWTP]) operates under the Michigan Department of Environmental Quality license number 9411. Information for the facility can be found at: https://www.usecology.com/Locations/All-Locations/US-Ecology-Michigan.aspx

Wastes are received at the US Ecology-Michigan facility by truck directly (lined and covered end/side-dump semi trailers or 32 cubic yard IP-1 metal intermodal containers placed on a semi-trailer) and indirectly by rail. Wastes shipped by rail are transported in intermodal containers placed on flatbed railcars to a spur location near the US Ecology-Michigan facility (e.g., in Romulus, MI or the large switching yard in Melvindale, MI). At the spur location, the intermodals are transferred from the railcars onto semi-trailers and trucked from the rail spur transfer location to the disposal facility.

Because the US Ecology-Michigan facility is only 520 miles from the Site, US Ecology has indicated that wastes from the Site would most likely be transported by truck to this facility. The specific truck route that would be followed from the West Lake site to the US Ecology-Michigan would most likely be: Interstate 270, then Interstate 70 from Bridgeton, MO to Dayton, OH, then Interstate 75 from Dayton, OH to the intersection with Interstate 275 just north of Monroe, MI, then Interstate 275 to Interstate 94 at Romulus, MI, then Interstate 94 to Van Buren Township, MI. This route transits through the major cities of Bridgeton, MO, St. Louis, MO, Terre Haute, IN, Indianapolis, IN, Dayton, OH, and Toledo, OH.

The specific rail routes that would be followed from a truck-to-rail transloading operation at a potential future leased rail spur located near the Site (assuming one could be located) to the US Ecology-Michigan facility would be: Norfolk Southern from Bridgeton, MO to St. Louis, MO; then CSX from St. Louis, MO to a spur location near the US Ecology-Michigan facility. This route transits through the major cities of Bridgeton, MO, Saint Louis, MO, Terre Haute, IN, Indianapolis, IN, Sidney, OH, Toledo, OH, and Wayne, MI.

The WAC and RCRA Part B permit for this facility are included in Appendix C-2.

Energy Solutions: Clive, Utah. The 439-acre Energy Solutions Clive site is located in Utah's West Desert, approximately 75 miles west of Salt Lake City and about three miles south of Interstate 80, Exit 49. Information for the facility can be found at http://www.energysolutions.com/?id=OTkw. A video of the facilities at the Clive site can be found under the Media Room tab at this website. The facility is authorized to receive Class A LLRW, NORM/NARM, Class A Mixed LLRW (i.e., radioactive and hazardous), 11e.(2) Byproduct Material, and Special Nuclear Material based on concentration limits under Radioactive Material License (RML) Number UT 2300249, as amended, and 11e.(2) Byproduct Material License Number UT 2300478, as amended. The facility has a separate license to receive and dispose of uranium and thorium mill tailings byproduct material as defined by section 11e.(2) of the Atomic Energy Act of 1954, as amended.

The Clive, UT facility receives waste shipped via bulk truck, containerized truck, enclosed truck, bulk railcars, rail boxcars, and rail intermodals. The disposal site is accessed year-round by the Union Pacific Railroad at Energy Solutions' 10 miles of private siding. A covered railcar rotary dumper and covered railcar decontamination facilities are also located at the disposal facility.

Energy Solutions has indicated that excavated material from the Site would be either: (1) loaded directly into gondola cars if a potential future rail spur could be extended across St. Charles Rock Road onto the Site; (2) loaded into 10 cubic yard IP-1 DOT bags, with the bags placed on a flat bed semi-trailer and transported to a truck-to-rail transloading operation at a potential future leased rail spur located near the Site (assuming one could be located), and then loaded into gondola rail cars; or (3) bulk loaded into 25 cubic yard intermodal containers, with the intermodal containers then placed on a flat bed semi-trailer and transported to a truck-to-rail transloading operation and multiple intermodal containers stacked onto flat railcars. The gondolas or intermodal containers would be transported via rail directly to the Clive, UT facility for disposal at the Energy Solutions facility.

The specific rail routes that would be followed from a potential future rail spur extended onto the Site or a truck-to-rail transloading operation at a potential future leased rail spur located near the Site to the Energy Solutions Clive, UT facility are as follows: Norfolk Southern (NS) from Bridgeton, MO to Kansas City, MO; then the Union Pacific from Kansas City, MO to Clive, UT. This route transits the major cities of Bridgeton, MO, Kansas City, MO, Atchison, KS, Marysville, KS, Hastings, NE, North Platte, NE, Cheyenne, WY, Green River, WY, Ogden, UT, Salt Lake City, UT, West Wendover, NV, and Clive, UT. Note that Energy Solutions uses a different rail route from Bridgeton, MO to Kansas City, MO than US Ecology.

Large volumes of soil and waste materials with low-levels of radionuclides have been disposed at the Clive facility from the following projects: DOE – Fernald, OH Closure; DOE – Rocky Flats, CO Closure; DOE – Mound, OH OU-1 Landfill Closure; DOE Columbus Closure;

USACE Maywood, NJ FUSRAP sites; USACE St. Louis FUSRAP sites; and Denver Radium, CO CERCLA site.

The WAC for this facility is included in Appendix C-3.

Clean Harbors (Deer Trail) – Last Chance, Colorado. This 325-acre treatment, storage, and land disposal facility is located in a rural area approximately 75 miles east of Denver and is licensed to accept NORM and TENORM wastes and debris, as well as landfillable mixtures of RCRA and NORM wastes under Colorado Department of Public Health and Environment Radioactive Materials License Number Colo. 1101-01 and Colorado RCRA Part B Permit renewed 2005, No. CO-05-12-21-01. A Fact Sheet for this facility can be downloaded from the Clean Harbors website at the following link: http://cleanharbors.com/locations/index.asp?id=55.

Wastes are received at the facility by truck directly and by rail via a trans-loading point located in Sterling, Colorado, approximately 73 miles from the disposal facility. Clean Harbors has indicated that Site wastes would be either: (1) loaded directly into lined gondola cars if a potential future rail spur could be extended across St. Charles Rock Road onto the Site, or (2) loaded into end-dump semi-trailers, transported to a truck-to-rail transloading operation at a potential future leased rail spur located near the Site (assuming one could be located), and discharged from the end-dump semi-trailers into lined gondola cars. The gondola cars would be hauled by rail to the trans-loading point in Sterling, transferred from the gondola cars to semi-trailer trucks, and trucked the 73 miles to the Deer Trail facility for disposal.

The specific rail routes that would be followed from a potential future rail spur extended onto the Site or a truck-to-rail transloading operation at a potential future leased rail spur located near the Site to the trans-loading point located in Sterling, CO for the Clean Harbors (Deer Trail) facility are as follows: NS or BNSF from Bridgeton, MO to Kansas City, MO; then the Union Pacific from Kansas City, MO to Sterling, CO. This route transits through the major cities of Bridgeton, MO, Kansas City, MO, Atchison, KS, Marysville, KS, Hastings, NE, North Platte, NE, Julesburg, CO, and Sterling, CO.

The Rocky Mountain Low Level Radioactive Waste Compact has designated Deer Trail as the Low Level Waste Facility for Colorado, New Mexico, and Nevada. Wastes from other states may be disposed at Deer Trail but an Application for Waste Import must be made to the Rocky Mountain Low Level Radioactive Waste Board and an application fee paid. DOE FUSRAP wastes have been disposed at the Deer Trail facility.

The WAC for this facility is included in Appendix C-4.

4.3.6 Nuisance Control Technologies

Technologies for stormwater management, bird nuisance and fugitive dust and odor emissions mitigation were also screened. These technologies are discussed further below.

4.3.6.1 Storm Water Management

During construction of the selected remedy, storm water management will be addressed by minimizing storm water flow into the working areas (also referred to as run-on); by minimizing the surface area of disturbed ground that is exposed to direct precipitation; and by properly detaining and treating, if necessary, runoff that has contacted the working areas. A Storm Water Management Plan that incorporates appropriate diversion, conveyance, detention, and treatment measures would be prepared as part of the remedial design and implemented during the remedial action to ensure that appropriate effective measures are taken to limit run-on, minimize waste contact with precipitation, and manage and monitor runoff in accordance with applicable regulations and a stormwater management plan (as necessary).

Applicable technologies that could be employed for storm water management include:

- Use of Best Management Practices (BMPs) such as diversion ditches, earthen berms, and culverts to divert storm water around the disturbed or working areas so as to prevent its contact with exposed waste material.

- Use of BMPs such as selective excavation, staging, daily soil cover or tarps, and covering truck loads during transportation to minimize the area of waste exposed to direct precipitation. In some cases, temporary sumps and pumps may also be used to augment conveyance of direct precipitation into run-on diversion ditches.

- Use of temporary structures (*e.g.*, a tensioned fabric frame structure) erected above and around excavation and/or waste sorting/loading areas to shield waste from contact with direct precipitation. A temporary enclosed structure would require construction of a relatively flat foundation system (e.g., spread footings, drilled piers, driven piles, or grade beams) to support the predicted loads. The maximum width of commercially-available structures is approximately 200 feet, with a typical maximum width of 160 feet due to the significant increase in the size of the trusses and other structural components required for spans greater than 160 feet and the commensurate increase (approximately 50%) in the unit costs for larger spans. Therefore, for excavations with widths greater than 140 feet, a temporary structure would need to be moved multiple times, with each move involving excavation and earthwork to prepare the next area and install a new foundation prior to disassembling and reassembling the structure. The geotechnical properties of buried refuse in Areas 1 and 2 would likely not support the loads induced by a temporary structure without an elaborate foundation system or localized ground improvement to strengthen the foundation materials. Concerns about relocating such a structure would not apply to its potential use for shielding of waste sorting/loading activities as these activities could be established in a single central area that would be used throughout implementation of potential remedial actions.

- Use of BMPs to collect, detain, treat, and release runoff as required by Missouri storm water regulations. These BMPs would include the use of sumps, pumps, pipelines, lined impoundments and/or temporary storage tanks to collect, convey, and detain stormwater that has contacted waste material. If treatment is necessary, any radionuclides would likely be precipitated with the particulates in the storm water and would be removed via gravity settling within a detention or stormwater pond or tanks and filtration to meet direct or indirect (*i.e.*, to a Publically-Owned Treatment Works [POTW]) discharge limits. Radon gas would be removed via liquid-phase granular activated carbon (LPGAC) adsorption, if necessary. In addition, conventional flow control devices such as a morning-glory spillway within, or fixed weir at, an outlet of a detention pond could be used to limit discharge rates to those of the design storm[17] or as allowed by State regulations.

4.3.6.2 Bird Nuisance Mitigation

Because the waste materials in Areas 1 and 2 would be regraded as part of the ROD-selected remedy or subjected to excavation under either the partial or "complete rad removal" alternatives, the nuisance attraction to and congregation by birds at and above the affected areas could be problematic unless effectively controlled. The main concern would be the potential for increased bird strikes to aircraft approaching and departing from Lambert-St. Louis International Airport.

Ongoing research by the US Department of Agriculture Animal and Plant Health Inspection Service (USDA, 2008) and the National Wildlife Research Center (NWRC, 2008) into bird control mechanisms at landfills, as well as practical experience by landfill operators, offer control strategies that may help mitigate bird congregation above and within excavation areas. If needed, an avian management plan that incorporates appropriate measures would be prepared by a qualified wildlife expert as part of the remedial design process to ensure that appropriate effective measures are taken during excavation to cost-effectively limit bird congregation in order to protect approaching and departing aircraft from increased risk of bird-strikes. Potential control strategies include:

- Use of BMPs based on practical experience by landfill operators. These BMPs would include the use of selective excavation and staging of waste material to minimize the area of exposed waste at any given time, and using daily cover consisting of soil or a tarp placed over the exposed waste.

- Removal of food sources by covering exposed refuse with a temporary structure (e.g., a tensioned fabric frame structure).

- Erecting grids over exposed refuse to prevent bird access using stainless steel wire, monofilament, or Kevlar line placed above the working area in parallel lines or in spoke configurations. Parallel spacings of between 10 and 50 feet have been effective for most gulls such as those that nest in Missouri. Lines would be placed above the maximum height of working equipment, which would be approximately 15 feet above the original ground elevations for Areas 1 and 2, assuming scrapers and/or bulldozers are initially used. Lines

---

[17] The design storm represents the maximum rate at which stormwater can be discharged from the Site.

would need to be placed at higher levels when excavators and loaders are employed. Line length would depend on the strength of the wire/filament used and available space for support poles. The size of open excavations may limit the constructability of wire or monofilament grids.

- Use of predator birds such as falcons or visual deterrents such as effigies of predator birds.

- Use of auditory "frightening" devices such as pyrotechnics, propane exploders, bird alarm calls, or sound generators that produce noise that is irritating to birds.

- Use of chemical frightening agents or toxicants such as the EPA-registered gull toxicant DRC-1339 and/or Avitrol®. Effective full-scale and long term application information regarding either chemical on gulls at landfills is not available in the literature. Use of chemical frightening agents or toxicants does not address the concern regarding congregating birds within the flight path of aircraft.

4.3.6.3 Fugitive Dust and Odor Control

Waste materials in OU-1 would be regraded during construction of the cover components under the ROD-selected remedy and excavated under the partial excavation or "complete rad removal" alternatives. Fugitive dust and odor could be generated during excavation, regrading, and final cover construction; as a result of construction vehicles or trucks operating on or traversing the Site; and from the staging of wastes and other construction materials. Methods for control of fugitive dust could include implementation of BMPs; misting/spraying of water or foams on exposed excavation surfaces, staged materials, and roads; enclosing the areas of excavation within a temporary structure; and enclosing excavated waste within a temporary structure during waste sorting and loading prior to transporting of waste off-site, as discussed further below.

- Use of BMPs based on practical experience of landfill operators and construction contractors. These would include the use of selective excavation and staging of waste material to minimize the area of exposed waste at any given time, temporary staging excavated waste in as small an area as practicable, daily covering of exposed waste using soil or tarps, and rapid re-covering of exposed waste whenever practicable.

- Fugitive dust, and to some extent odor, can be controlled through misting and spraying of exposed and staged wastes and permanent and temporary construction roads at the Site with water. Temporary misting systems would be set up above and around staged wastes. Water would be sprayed on exposed waste if the waste is dry and dust is generated during excavation. Water trucks with spray applicators would be used to spray roads to minimize dust generation. Viscous water-based non-hardening foams would be sprayed on exposed and staged waste to suppress fugitive dust and odor. Acrylic copolymer resin foams that penetrate the road surface to eliminate or reduce repeated watering can be applied to roads for dust and erosion protection.

- A temporary structure (see description and discussion above in Section 4.3.6.1 and in Section 4.4.1.1 below) could be erected above and around an excavation and/or waste staging area such that any fugitive dust or odor would be contained within the structure.

- For the partial excavation and "complete rad removal" alternatives, excavated waste that would be staged and sorted prior to shipment off-site for disposal could be enclosed within a temporary structure (*e.g.*, a tensioned fabric frame structure). Loading of trucks or intermodal containers for transport of RIM to the off-site disposal facility would also be performed in this structure. The structure would include a concrete floor working surface and be sized to house an appropriate volume of staged RIM to allow an uninterrupted rail transportation schedule. The structure would include ventilation and emissions control facilities to reduce/eliminate fugitive dust and odor concerns associated with staged waste. Workers inside the structure would wear appropriate PPE.

4.4 Implementability Screening of Remediation Technologies and Process Options

Potential remedial action technologies and process options that may be applicable to address the Site characterization results and satisfy the RAOs are described in Section 4.3 and are also summarized in Figure 4-1. The technologies are screened based on technical implementability in Figure 4-1. The following remedial technologies and process options were eliminated from further consideration based on the rationale discussed in the Implementability Screening Comments column in Figure 4-1.

General Response Action	Remedial Technology	Process Options
Containment	Land Encapsulation Cryogenic Barriers Vertical Barriers	• On-site: New cell • Subsurface cryogenic barrier • Slurry wall • Grout curtain • Sheet pile cutoff wall
Physical/Chemical Treatment	Chemical Separation	• Solvent/chemical extraction
	Physical Separation	• Soil washing • Flotation
	Vitrification	• In-situ vitrification • Ex-situ vitrification
Biological Treatment	Phytoremediation	• Phytoextraction • Phytostabilization
Removal	Storm Water Management Bird Nuisance Mitigation	• Enclose excavation with temporary structure • Enclose excavation with temporary structure

General Response Action	Remedial Technology	Process Options
		• Chemical frightening agents or toxicants

Implementability screening comments in addition to those provided on Figure 4-1 for the use of a temporary structure to enclose an excavation for stormwater management or bird nuisance mitigation and the dry soil separation physical treatment process are provided below.

4.4.1 Implementability Comments: Temporary Structure and Dry Soil Separation Process

Discussions of additional factors affecting the potential implementability of temporary structures and physical separation technologies are provided below.

4.4.1.1 Temporary Structure

Use of a temporary enclosure to protect an exposed excavation from contact with stormwater or for a potential bird mitigation strategy was eliminated because the other potential process options would provide adequate stormwater controls or bird nuisance mitigation without the significant disadvantages (summarized below) of using a temporary enclosure. A temporary enclosed structure would require construction of a foundation system (e.g., spread footings, drilled piers, driven piles, or grade beams) to support the predicted loads (in particular, wind loads) on the structure. The foundation alignment must also be relatively flat from side-to-side and end-to-end. Because the topography of the Site is variable, with slopes for drainage control, considerable earthwork would be necessary to prepare an area for foundation construction in advance of erecting the enclosed structure. This would likely include over-excavation for the foundation system that would support the structure. All of this earthwork would be performed without protective cover. In addition, the maximum width of commercially-available structures is approximately 250 feet, with a reasonable maximum width of only 160 feet. The width of RIM areas to be excavated, plus layback for overburden, is estimated to range from 250 feet to 1,050 feet. Thus, temporary structures would need to be moved many times, with each move involving excavation and earthwork to prepare the next area and installation of a new foundation prior to disassembling and reassembling the structure. Finally, the geotechnical properties of the buried refuse would likely not support the loads induced by the structure without an elaborate foundation system or localized ground improvement to strengthen the foundation materials.

Beyond the construction difficulties, other complications would include (1) provision of proper ventilation inside the structure to protect workers from potential accumulation of radon, methane, hydrogen sulfide, heavy equipment exhaust, dust, and ambient heat, (2) provision of "explosion-proof" electrical conduit and fixtures within the structure because of the potential presence of landfill gas when wastes are excavated, (3) worker safety risk from assembling, disassembling, lifting, then reassembling the 30-40 foot tall structures, (4) durability of the structure for multiple moves, and wear and tear on the components causing the likelihood for ongoing replacements, maintenance and repair of the structure and associated construction delays, and (5) the need for construction of temporary drainage controls around the structure each time it is moved.

Overall, use of enclosed structures over the excavation areas, where they can be applied, would add considerable time to the remediation schedule because each move would necessitate a new foundation, removal of fabric, disassembly of the structure, crane lifts, reassembly, demobilization and remobilization of electrical and ventilation equipment, removal of old foundations, and construction of new drainage controls. Capital and O&M costs associated with the structures, mobilizing them to the Site, assembly/disassembly/reassembly, demobilizing them from the Site, foundations, capital and operating costs for electrical and ventilation equipment, and the additional carrying costs for the project due to schedule delays would be prohibitive.

Use of a temporary rigid frame fabric structure erected in a fixed location for use as a facility within which excavated RIM would be staged prior to being transported to a licensed off-site disposal facility was retained as a remedial technology/process option for fugitive dust and odor control. RIM excavated from Areas 1 and 2 would be trucked from the excavation into one side of the “RIM staging/loading” building via articulated on-site construction trucks and be staged in the middle of the building for potential blending and subsequent loading into intermodals for transportation off-site. Lined intermodals transported on flat-bed highway trucks would be loaded with RIM and tarped/covered on the opposite side (“intermodal loading” side) of the RIM staging/loading building. Staging and loading of RIM in an enclosed structure would prevent precipitation from contacting excavated RIM, prevent bird access, and contain odor that would be associated with excavated MSW. Based on the estimated volumes of RIM to be excavated under the complete rad removal and partial excavation alternatives (see discussion in Section 5), for costing purposes it is assumed that a 200 ft by 400 ft building would be constructed on approximately four acres of land within the Site on an area that has not been landfilled (i.e., within OU-2). The building would be equipped with an air emissions/odor control system. For costing purposes, it is reasonably assumed (based on professional judgment) that between three and four building volume air changes per hour would be necessary and that emissions control would include vessels filled with activated carbon specifically developed to remove hydrogen sulfide as well as activated carbon developed to remove volatile organic compounds.

4.4.1.2 Dry Soil Separation

Although it is expected that use of the shear shredder/trommel equipment would be effective at separating the majority of soil from the non-soil solid waste, the degree of separation that may be achieved by this technology is uncertain. Prior applications of this technology have been focused on separating the bulk of the soil volume from an overall matrix of landfill wastes in order to implement waste-to-energy or waste composting operations or to recover the soil for reuse. These applications were not designed or expected to recover 100% of all of the soil in a landfill and were not concerned with the fractions of soil that were contained in or adhered to the segregated refuse. These applications also were not concerned with the creation of additional fine-grained fractions that would become mixed with the recovered soil as a result of use of a shear-shredder prior to a trommel. Consequently, the effectiveness of this technology at separating RIM (and only RIM) from the overall mass of solid wastes could not be determined without performance of a full-scale pilot-test.

In Areas 1 and 2 of the Site, residual soil containing radionuclides that adheres to or is otherwise contained in the refuse after performance of waste segregation using a trommel screen could still produce processed waste exceeding the levels that would allow for unrestricted use. As a result, the effectiveness of this technology cannot be determined without performing a pilot-test. . Furthermore, although a trommel includes an exterior brush (Figure 4-2) to remove debris that may otherwise become entangled in the rotating screen, there would still be instances in which laborers would have to enter the screen and physically remove wire, rebar, plastic, wood, or other entangled debris. During these events, workers would be exposed to increased radiation emitted by RIM that adheres to or otherwise remains in the trommel. The frequency and duration of physical removal of debris cannot be estimated at this time; however, it is clear that use of a trommel would create an additional mechanism for worker exposures to the RIM. Consequently, the potential effectiveness and implementability of this technology relative to segregation of RIM from non-RIM cannot be assessed without performing a pilot test.

Depending upon the production rate and dependability of the solids separation equipment, inclusion of a solids separation step as part of a process used for excavation and disposal of the RIM could become a factor relative to the daily production rates and project duration. In addition to the additional activities requiring workers and resultant exposures, use of such equipment is expected to extend the overall project schedule and increase the potential or amounts of stormwater accumulation, airborne emissions, bird or other vector impacts due to a possible increase in the overall schedule.

In order to evaluate this technology, full-scale pilot testing of the shear shredder/trommel screen solids separation equipment for volume reduction would be required using representative material from Areas 1 and/or 2. Pilot testing is typically performed prior to LFMR projects in order to assess screening and trommel equipment sizing, estimate production rates, determine the fraction of soil that can be separated from the filled material using varying trommel screen opening sizes (and therefore maximizing the amount of soil that can be removed), and obtain an indication of the type of material that was filled (*e.g.*, construction and demolition debris such as bricks, concrete and rebar, dimensional lumber and/or MSW). Of particular interest in conducting pilot testing of material from Areas 1 and 2 would be obtaining an estimate of the degree of RIM volume reduction that could be achieved, assessing the moisture content of the filled material, and determining the fraction of soil that would be contained in or adhered to the segregated refuse.

Assuming pilot test results show that the radiologically-impacted soil fraction of RIM could be separated from the overall matrix of landfilled refuse, debris and fill materials, and unimpacted soil and quarry spoils using the revolving cylindrical sieve trommel technology, then additional dry soil separation technologies might be considered to further reduce the volume of radiologically-impacted soil. However, if results of pilot-testing indicate that the non-soil fraction of RIM that would be discharged out the end of the trommel exhibited radionuclide concentrations greater that those that would allow for unrestricted use, then the soils separation process would not be effective in reducing the volume of RIM that would be addressed under the "complete rad removal" alternative.

This technology, alone or possibly in combination with an SGS, may be effective for the partial excavation alternative based on the 1,000 pCi/g criterion. However, the additional costs required to implement this technology may not be supported by the overall lower volume of RIM to be excavated and disposed off-site under this alternative. The effectiveness of this technology relative to the partial excavation alternative based on the 52.9 pCi/g and 16-ft depth criteria cannot be ascertained from the available information and would require pilot-testing to determine the degree of separation that could be achieved.

4.5 Evaluation of Remediation Technologies and Process Options

Potential remedial action technologies that may be applicable to address the Site characterization results and satisfy the RAOs are described in Section 4.3 and are also summarized in Figure 4-1. The technologies are screened based on technical implementability in Figure 4-1. The resultant technologies are then evaluated in Figure 4-4 based on anticipated effectiveness, implementability, and relative cost to identify applicable technologies that might be used as components of the remedial action alternatives.

Ordinarily in the CERCLA FS process, technologies identified in the technology screening step as being potentially applicable to site characterization results and RAOs are combined to develop remedial alternatives. The remedial alternatives are then screened, if necessary, and subjected to a detailed analysis using nine prescribed evaluation criteria. In the case of this FFS, EPA stipulated the alternatives to be developed and evaluated (EPA, 2015b). Therefore, the step of combining technologies to develop alternatives and screening the alternatives is unnecessary and could result in the elimination of one or more of the alternatives that EPA determined must be evaluated in this FFS.

In addition to the technologies identified in the original FS report (EMSI, 2006) as being potentially applicable to the media and contaminants at the Site, the various technologies identified in this section as potentially applicable have been included as appropriate within the alternatives specified by EPA (2015b) for this FFS. Specifically, the following additional technologies or process options were included: short- and long-term monitoring; capping and covers; disposal in an off-site licensed facility; physical/chemical treatment including solidification/stabilization and soil separation; excavation; temporary structure to enclose a material handling area; storm water management; fugitive dust/odor control, bird nuisance mitigation; and truck and truck and rail transportation.

5 REMEDIAL ACTION ALTERNATIVES

This section provides descriptions of the remedial alternatives evaluated in this FFS, including the ROD-selected remedy, the "complete rad removal" alternative, and two partial excavation alternatives. As part of preparation of this FFS, preliminary, conceptual-level designs were developed for each of the alternatives in order to prepare estimates of the costs of construction, operation, maintenance and monitoring; construction schedules for each alternative; and to evaluate the alternatives relative to the criteria specified in the NCP as described in Section 6. In addition to the conceptual designs of the alternatives, general procedures to be used for materials handling, surface water control, and methane gas management were also developed and are described in this section of the FFS.

5.1 Remedial Alternatives Previously Evaluated

This is the third evaluation of potential remedial alternatives for OU-1 of the Site. Prior evaluations of remedial alternatives were performed for the FS (EMSI, 2006) and SFS (EMSI et al., 2011).

5.1.1 Remedial Alternatives Evaluated in the FS

A range of remedial alternatives addressing waste materials and contaminated soil present in OU-1 was developed for, and evaluated in, the FS (EMSI, 2006). These alternatives were developed in accordance with EPA's guidance on Presumptive Remedy for CERCLA Municipal Landfill Sites (EPA, 1993b) and "Conducting Remedial Investigations/Feasibility Studies for CERCLA Municipal Landfill Sites" (EPA, 1991b). These guidance documents establish containment as the presumptive remedy for CERCLA municipal landfills. Part of the presumptive remedy approach for CERCLA municipal landfills includes a decision with respect to characterization and/or treatment of "hot spots," which represent discrete, accessible areas within the overall landfill that contain principal threat wastes which are large enough such that remediation would reduce the threat posed by the overall site but small enough that it is reasonable to consider removal (EPA, 1993b). An evaluation of potential occurrences of "hot spots" in Areas 1 and 2 was performed as part of the original (2006) FS and is included as Appendix E to this FFS. Based on the nature and extent of the radiological materials present within OU-1, the evaluation concludes that the additional risks involved with a hot spot removal significantly exceed the risks of leaving the waste in place per the ROD-selected remedy.

The remedial alternatives developed in the FS address containment of the wastes (landfill alternatives) and management of radiologically-impacted soil on the Buffer Zone/Crossroad property (former Ford property). Detailed descriptions of the six landfill and four Buffer Zone/Crossroad property alternatives are presented in the FS report (EMSI, 2006).

The remedial alternatives developed and evaluated in the FS (EMSI, 2006) to address containment of the waste materials present in Areas 1 and 2 consisted of the following:

Areas 1 and 2 Landfill Alternatives

- Alternative L1 – No Action
- Alternative L2 – Cover Repair and Maintenance, Additional Access Restrictions, Additional Institutional Controls, and Monitoring
- Alternative L3 – Soil cover to address gamma exposure and erosion potential
- Alternative L4 –Regrading of Areas 1 and 2 (minimum slope of 2%) and installation of a Subtitle D cover system
- Alternative L5 – Regrading of Areas 1 and 2 (minimum slope of 5%) and installation of a Subtitle D cover system
- Alternative L6 – Excavation of material with higher levels of radioactivity from Area 2 and regrading and installation of a Subtitle D cover system

EPA (2008a) determined that all of the landfill alternatives except the No Action Alternative (Alternative L1) would protect human health and the environment by limiting exposure to the Site's contaminants through engineering means and land use controls. Due to the inclusion of engineering controls, EPA (2008a) determined that the landfill cover alternatives (Alternatives L3, L4, L5 and L6) offer much more reliable protection than Alternative L2, which is more reliant on land use controls. EPA (2008a) also determined that the more sophisticated design of a multi-layer landfill cover with infiltration barrier (Alternatives L4, L5 and L6) would provide greater overall protection than the soil cover (Alternative L3). In addition, EPA (2008a) determined that Alternatives L4, L5 and L6 comply with all ARARs while alternatives L2 and L3 do not meet the basic cover design requirements found in the Missouri Solid Waste Rules for sanitary landfills (10 CSR 80-3.010) and therefore do not meet the NCP threshold criterion of compliance with ARARs.

In addition to the presence of RIM in Areas 1 and 2, the FS also developed remedial alternatives to address historic erosion of the landfill berm along the west side of Area 2 and the resultant deposition of radiologically-impacted soil on the surface of the Buffer Zone/Crossroad property (formerly termed the Ford property). The remedial alternatives developed in the FS (EMSI, 2006) to address management of contaminated soil on the Buffer Zone/Crossroad property are as follows:

Buffer Zone/Crossroad Property (former Ford property) Remedial Alternatives

- Alternative F1 – No Action
- Alternative F2 – Institutional and Access Controls

- Alternative F3 – Capping and Institutional and Access Controls

- Alternative F4 – Soil Excavation and Consolidation in Area 2

EPA (2008a) determined that all of the alternatives for the Buffer Zone/Crossroad property, except Alternative F1 (No Action), are protective of human health and the environment and would comply with ARARs.

Detailed evaluations of the six landfill and four Buffer Zone/Crossroad property alternatives relative to the nine criteria specified in the NCP are presented in the FS report (EMSI, 2006).

EPA subsequently issued a Proposed Plan that identified alternatives L4 and F4 as the preferred alternatives. After holding several public meetings and obtaining public comments, EPA selected these alternatives, with the addition of rock armoring along the toe of the north and northwest boundaries of Area 2 to protect against potential erosion in the event of flooding from failure of the Earth City flood control system (levees and pumping) as the remedy for OU-1.

5.1.2 Remedial Alternatives Evaluated in the SFS

In a January 11, 2010, letter (EPA, 2010) and accompanying SOW, EPA requested that the Respondents prepare an SFS to evaluate two complete rad removal alternatives. For purposes of the SFS, EPA identified two "complete rad removal" alternatives that EPA directed be developed and evaluated in addition to the ROD-selected remedy:

1. Excavation of radioactive materials with off-site commercial disposal of the excavated materials (referred to as "complete rad removal" with off-site disposal alternative in the SFS); and

2. Excavation of radioactive materials with on-site disposal of the excavated materials in an on-site engineered disposal cell with a liner and cap if a suitable location outside the geomorphic flood plain could be identified (referred to as "complete rad removal" with on-site disposal alternative in the SFS).

EPA indicated (EPA, 2010) that "complete rad removal" was defined to mean attainment of risk-based radiological cleanup levels specified in OSWER Directives 9200.4-25 and 9200.4-18.

These three alternatives (ROD-selected remedy plus two "complete rad removal" alternatives) were evaluated in the SFS (EMSI et al., 2011).

5.1.3 Remedial Alternatives Evaluated in the Final FS

EPA's SOW for the RI Addendum and FFS identifies three partial excavation alternatives and two other remedial alternatives which, in addition to the No Action Alternative, results in the following six remedial alternatives to be evaluated in the FFS:

1. 2008 ROD-Selected Remedy (Former Alternative L4 and Alternative F4) – Containment consisting of regrading and installation of a new landfill cover and other remedial components for the landfill, and consolidation of any radiologically-impacted soil that may remain on the former Ford property (now known as the Buffer Zone and Crossroads Lot 2A2) into the containment areas in Area 1 and 2 prior to placement of additional fill and construction of the new landfill cover.

2. No Action – Required by the National Contingency Plan (NCP) and RI/FS guidance to provide a baseline against which all of the other alternatives are evaluated[18];

3. Partial Excavation 1,000 pCi/g – Excavation of all soil/waste containing combined radium (Ra-226 plus Ra-228) or combined thorium (Th-230 plus Th-232) with activity levels greater than 1,000 pCi/g[19];

4. Partial Excavation 52.9 pCi/g – Excavation of all soil/waste containing combined radium (Ra-226 plus Ra-228) or combined thorium (Th-230 plus Th-232) with activity levels greater than 52.9 pCi/g down to a total depth of 16 feet beneath the 2005 topographic surface[20];

5. Partial Excavation Based on Expected Land Use – Partial excavation of all soil/waste containing combined radium (Ra-226 plus Ra-228) or combined thorium (Th-230 plus Th-232) with activity levels greater than a risk-based level to be developed based on the reasonably anticipated future land use of the Site;[21] and

---

[18] The SOW identifies an alternative No. 3 "Leaving all RIM in place on-site." Subsequent discussions with EPA indicated that this alternative was the No Action Alternative.

[19] In all cases evaluated in the Baseline Risk Assessment, Th-230 and Ra-226 (plus decay products) accounted for more than 95% of the risk to the target receptors. Other radionuclides are co-located with Ra-226 and Th-230 and are projected to produce risks to the future groundskeeper receptor of $<10^{-7}$. Remediation of the Th-230 and Ra-226, by themselves, would reduce the total risks from RIM to below 10^{-4}. Any remediation of Ra-226 and thorium-226 would also lower the negligible risks from these ancillary radionuclides still further.

[20] The SOW indicates that the Respondents have the ability to propose in the Work Plan for the RI Addendum and Final FS a different depth to be used for this alternative. However, it is premature to propose an alternative depth at this time. In the event that an alternative depth interval reflective of the actual site data is identified during evaluation of the data during preparation of the RI Addendum and FFS reports, the Respondents will seek concurrence from EPA at that time.

[21] The evaluation performed by Auxier (as set forth in the June 2016 "Risk to Industrial user of Operable Unit 1 prepared by Auxier & Associates, Inc.") identified an industrial-risk-based level of approximately 1,000 pCi/g (after rounding). Alternatives No. 2 and No. 4 are therefore, for all intents and purposes, currently the same alternative.

6. Full Excavation with Offsite Disposal – Excavation of all soil/waste containing combined radium (Ra-226 plus Ra-228) or combined thorium (Th-230 plus Th-232) with activity levels greater than 7.9 pCi/g;

The EPA definition of the "complete rad removal" alternative is based on combined radium and combined thorium activities as specified in OSWER Directive No. 9200-4.18 and 9200-4.25. In addition to combined radium and combined thorium, the combined uranium activity will also be considered as appropriate. However, based on the prior SFS evaluations of the "complete rad removal" alternatives, uranium was not found to be a driver for identification of RIM because any locations/depth intervals that contained uranium above its criteria for "complete rad removal" (54.5 pCi/g) also contained radium and/or thorium activity levels greater than their respective criteria for unrestricted land use. In addition, no uranium equivalent criteria were identified by EPA for the partial excavation alternatives; therefore, these alternatives are based solely on the combined radium and combined thorium activity levels. As noted above, use of the combined radium and combined thorium activity levels to define the materials to be included in the scope of the partial excavation alternatives should also result in inclusion of any materials with commensurate uranium activity.

5.2 No Action Alternative

No additional engineering or institutional controls would be implemented under the no action alternative and no monitoring would be performed. Per the NCP, a no action alternative is required and serves as a baseline for evaluation of the other alternatives.

5.3 ROD-Selected Remedy

Upon completion and EPA acceptance of the FS (EMSI, 2006) in June 2006, EPA developed a Proposed Plan (EPA, 2006a) and initiated a public comment period that opened on June 14, 2006 and remained open until December 29, 2006 (EPA, 2008). EPA subsequently re-opened the public comment period in March 2008 and closed this additional public comment period on April 9, 2008 (EPA, 2008). During these periods, EPA held three separate public meetings on June 26, 2006, September 14, 2006, and March 27, 2008 (EPA, 2008).

Based on the results of the RI and FS evaluations and the comments received during the various public meetings and comment periods, EPA prepared a Record of Decision (ROD) that identified the remedial actions that EPA selected for OU-1 (EPA, 2008).

The major components of the ROD-selected remedy for OU-1 (EPA, 2008) are as follows:

- Installation of a landfill cover meeting the Missouri closure and post-closure care requirements for sanitary landfills, including enhancements consistent with the standards for uranium mill tailing sites (*i.e.*, armoring layer and radon barrier);

- Consolidation of radiologically-contaminated surface soil from the Buffer Zone/Crossroad Property to the containment area;
- Application of groundwater monitoring and protection standards consistent with requirements for uranium mill tailing sites and sanitary landfills;
- Control of surface water runoff;
- Gas monitoring and control including radon and decomposition gas as necessary;
- Institutional controls to prevent land and resource uses that are inconsistent with a closed sanitary landfill site containing long-lived radionuclides; and
- Long-term surveillance and maintenance of the remedy.

Prior to construction of the landfill cover, the areas will be brought up to grade using placement of inert fill and regrading of existing material as determined in the RD. Final grades will achieve a minimum slope of two percent.

The ROD (EPA, 2008) indicated that the landfill berm around Area 2 would be regraded through placement of additional clean fill prior to placement of the landfill cover, resulting in an estimated 100 lateral feet of additional material between the current landfill toe and the toe at completion of the RA. The ROD (EPA, 2008) indicated that in this area, the landfill is built over the geomorphic flood plain that is now protected by the Earth City Levee.[22] In the unlikely event of levee failure during a 500-year flood event, the lowermost two feet of the toe of the landfill cover at the northwestern end of the Site could be impacted by the water. The Site is more than a mile from the river and no high-energy water would be expected. The flood protection needs of the toe of the landfill will be evaluated in design and appropriate bank protection methods will be used, *e.g.*, rock rip rap apron. The vertical height of the flood protection feature will include a margin of safety over the 1993 (500-year) flood level. Figure 12-1 in the ROD displays a conceptual cross-section of the Selected Remedy and indicates the approximate flood level at the toe of the landfill.

The ROD requires any radiologically-contaminated soil on the Buffer Zone/Crossroad Property to be consolidated in the area of containment (Areas 1 or 2) prior to placement of fill material or construction of the cover. It is anticipated that construction of the landfill cover will require the toe of the landfill berm to be regraded and extended over the impacted area on the Buffer Zone/Crossroad Property. The precise nature and extent of contaminated soil is uncertain because grading of the Buffer Zone/Crossroad Property occurred after collection of the most recent set of soil sample data.[23] Gamma scans and soil sampling will be used to support the RD

---

[22] These areas were subsequently filled such that the surface elevations of these areas are now located outside of the 500-year flood plain (FEMA, 2015).

[23] Sampling conducted on the Buffer Zone/Crossroad Property in February 2000 (after site soils had been scraped to a depth of approximately 1 to 2 feet) indicated that with the exception of a single sample, all of the samples

and document the existing conditions. Any soil outside the footprint of the landfill will meet remediation goals that support unlimited use and unrestricted exposure and will be subject to verification sampling. Any excavation of contaminated material will include dust suppression and work place monitoring to ensure there is no release of fugitive dust.

The ROD requires landfill cover, gas control, runoff control, long-term groundwater monitoring, and post-closure inspection and maintenance to meet (at a minimum) the relevant and appropriate requirements found in the Missouri Solid Waste Rules for sanitary landfills. Consistent with the requirements for uranium mill tailing sites, the ROD requires the proposed landfill cover to incorporate a rubble or rock armoring layer to minimize the potential for biointrusion and erosion and increase longevity. The landfill cover will also be designed to provide protection from radioactive emissions, *i.e.*, gamma radiation and radon. Figure 12-2 of the ROD shows a conceptual cross-section of a sanitary landfill cover that has been augmented to include a crushed concrete or rock biointrusion layer. Figure 12-3 of the ROD plots the cover thickness necessary to shield a person on the surface of the cover from gamma exposure.

The ROD requires surface drainage diversions, controls, and structures to be designed and constructed to expeditiously route stormwater runoff to the water drainage systems, which are presently subject to state National Pollution Discharge Elimination System permits.

Landfill gas characterization during the RI indicated the sporadic presence of decomposition gases, *e.g.*, methane, and radon. Radon gas needs only to be detained for a few days until it decays to its solid progeny, and a landfill cover designed to act as a diffusion barrier is generally sufficient to control radon. However, decomposition gases must be handled differently. Typically, gas generation in municipal solid waste increases for the first five or six years after placement in the landfill and then declines thereafter. Because these areas have been inactive for at least 30 years[24], decomposition gas generation is relatively low and expected to decline. However, even at low generation rates, placement of the landfill cover creates the potential for these gases to be trapped and accumulate under the cover. To prevent pressure build up under the landfill cover and/or lateral migration, the ROD states that gas control systems may be required. Gas control measures may involve passive venting or active collection. The need for and nature of the gas control measures will be evaluated and defined as part of the RD. The plans for the control and/or treatment of landfill gas will consider the presence of radon and be developed accordingly.

The ROD requires the landfill cover system to be routinely inspected and maintained to ensure the integrity of the remedy over time. In addition to surveillance of the physical remedy, the periodic site inspections will include administrative functions such as monitoring of institutional

---

displayed radionuclide levels of less than 5 pCi/g above background. Based on these data, the total extent of the area on the Buffer Zone/Crossroad property that may still contain radionuclides at levels greater than 5 pCi/g above background in February 2000 was estimated to be approximately one acre. For evaluation of remedial alternatives in the FS, it was assumed that soil containing radionuclides at levels above those suitable for unrestricted use remained on the Buffer Zone/Crossroad property.

[24] In light of the passage of time since issuance of the ROD, these areas have now been inactive for an even longer period of time.

controls and coordination with key stakeholders, including the Earth City Levee District regarding management of the flood control system. See Section 5.1 of the ROD (EPA, 2008) for a description of the levee maintenance program.

The ROD requires the O&M Plan[25] to be developed and submitted for approval as part of the RD/RA process. The O&M Plan is to cover all the long-term remedy management functions including groundwater monitoring plans, site inspection, maintenance and repair, institutional control monitoring and enforcement, five-year reviews, notification and coordination, community relations, health and safety, emergency planning, activity schedules, reporting, etc.

The detailed descriptions of the engineering components, groundwater monitoring objectives and institutional controls components of the ROD-selected remedy are summarized below along with additional information and details developed during preparation of this FFS.

5.3.1 Engineering Components of the ROD-Selected Remedy

The ROD-selected remedy includes both engineered and non-engineered components. The engineered components of the ROD-selected remedy include:

- Regrading of the existing landfill surface to comply with minimum and maximum slope angles pursuant to the Missouri Solid Waste Rules;
- Surveying and removal of radiologically-impacted soil from the Buffer Zone/Crossroad Property;
- Construction of a multi-layered, engineered landfill cover over Areas 1 and 2;
- Installation of rock armoring for flood protection along the toe of the northern portion of Area 2;
- Installation of stormwater/surface water runoff management structures;
- Landfill gas monitoring and, if needed, installation and operation of a landfill gas control system;
- Long term inspection and maintenance of the engineered components of the remedy; and
- Environmental monitoring during and after construction of the remedy.

[25] Operations and Maintenance (O&M) Plan is referred to elsewhere in this report as the OM&M (Operations, Maintenance and Monitoring) Plan.

5.3.1.1 Regrading of the Landfill Surface for the ROD-Selected Remedy

Prior to construction of the landfill cover, the surfaces of Areas 1 and 2 would be recontoured to meet the applicable slope requirements using placement of inert fill and regrading of existing material as determined in the RD. Final grades would achieve a minimum slope of two percent (2%) and a maximum slope of twenty-five percent (25%). Final grades would be achieved through placement of additional material, regrading of existing waste materials or a combination of the two. The specific procedures to be used would be determined as part of RD based on site constraints, minimization of the amount of material to be moved or placed, other design requirements, health and safety considerations, cost and other factors as appropriate.

As part of the development of the SFS, a preliminary evaluation of potential alternative regrading designs was developed and evaluated. The specific options examined included:

1. Use of a fill-only approach to regrading the interior portions of Areas 1 and 2;

2. Elimination of the stormwater basins in the northern corner of Area 1 and in the Buffer Zone that were included in the scope of the ROD-selected remedy described in the Remedial Design Work Plan (RDWP);

3. Construction of a 10-ft-high perimeter earthen berm/access road embankment (*i.e.* starter berm) with an external slope angle of 40 degrees along the northern (adjacent to the landfill access road), eastern (adjacent to St. Charles Rock Road) and western (adjacent to the transfer station) portions of Area 1 and the northern (adjacent to Crossroads property and St. Charles Rock Road) and western (adjacent to Crossroads property, Buffer Zone, and Old St. Charles Rock Road) portions of Area 2 so as to reduce the amount of waste excavation required for these areas; and

4. Use of a 3:1 (33⅓ %) slope for that portion of the final landfill cover along the perimeter of Area 2. This would require the completion of a detailed slope stability analysis (as discussed in Section 6.2.1.2.1).

Evaluation of these options as part of preparation of the SFS (EMSI et al., 2011) indicated that excavation of portions of the toe of the landfill in Areas 1 and 2 and construction of a perimeter (starter) berm composed of clean fill material (Option 3 above) is the best approach for achieving the required surface grades while minimizing the amount of waste regrading that needs to be performed. Additional details regarding the various grading options and the results of the prior evaluations are presented in Section 5.2.1.1 and Appendix E of the SFS (EMSI et al., 2011). Based on these evaluations and discussion with EPA, it was determined that the starter-berm (Option 3) would be used for purposes of the SFS evaluations.

Under this approach an approximately ten-foot-high starter berm would be constructed along portions of the outer boundaries of Areas 1 and 2. Construction of the starter berm would require excavation of waste materials present at the toe of the landfill in these areas. These materials would be replaced by earthen material that would provide the base for a perimeter access road and perimeter drainage features, incorporate rock armoring for flood control to the extent required, and through use of steeper side slopes for the soil/rock material (in contrast to those allowed for waste materials) would result in greatly reducing the amount of waste material that would need to be regraded under the ROD-selected remedy. Detailed design and agency approval of the starter berm approach would be performed as part of the RD phase; however, based on initial agency comments, it was determined that incorporation and use of the starter berm approach for the ROD-selected remedy was appropriate for the SFS evaluations.

Based on the results of the SFS evaluations, the use of a starter berm has been incorporated into the evaluation of the ROD-selected remedy in the FFS.

5.3.1.2 Management of Materials During Recontouring

It is anticipated that any waste that is excavated (cut) to create space for construction of the starter berm or as needed to regrade the surface of Areas 1 and 2 to meet the minimum and maximum slope requirements would immediately be placed in another portion of Area 1 or 2 and therefore no temporary stockpiling of excavated waste would be required for implementation of the ROD-selected remedy. In the event that temporary stock-piling of some of the regraded waste material is necessary, it is anticipated that such stockpiling would be performed on other portions of Areas 1 and 2.

The amount and duration of any waste material stockpiling would be minimized. Any stockpiled waste material would be managed to control odors. For example, these materials would be covered with tarps, soil cover or foams/chemical agents to suppress odor emissions and reduce the potential for windblown debris and dust, vectors (*e.g.*, rodents and birds), and precipitation infiltration. All stockpiles of waste materials or imported construction materials would be managed to prevent dust emissions and stormwater impacts. They could be covered with tarps and would be located away from drainage courses and stormwater drop inlets so as to reduce windblown erosion and sediment runoff. Sediment netting, berms, straw bales, or equivalent measures would be employed to reduce sediment runoff from the stockpile(s) to the adjacent areas, as well as to prevent run-on contact with exposed waste. Water, tarps or other forms of dust suppression would be used to prevent wind erosion of soil stockpiles. The construction contractor would be responsible for ensuring that the stockpiles are stabilized from wind erosion at night and during non-construction days. A plan for stockpiling of waste materials including identification of actual or potential areas for temporary stockpiles, temporary covers, runon-runoff controls, ongoing inspection and maintenance requirements, and other factors would be developed as part of the RD. A Stormwater Pollution Prevention Plan (SWPP) would be prepared prior to commencement of construction activities and would provide a detailed plan for the location and maintenance of the stockpiles.

Application of a temporary cover (*e.g.*, clean soil or other means) to the landfill surfaces being regraded at the end of each workday would help to mitigate odors during non-working periods. This would also reduce radiological exposures to potentially exposed non-radiological workers in the vicinity, and would reduce the attractiveness of the exposed waste to birds and vermin. As such, the conceptual design of the ROD-selected remedy includes application of daily cover and the volume of additional soil to be added as a result of placement of daily cover has been incorporated into design of the grading plans and cost estimates for the ROD-selected remedy (Appendices M and K).

Much of the area requiring re-contouring is outside the area covered by the Negative Easement. Even in those portions subject to the Negative Easement, the re-contouring activity would not be prohibited since the Negative Easement mandates that the facility at all times "comply with all applicable federal, state and local laws and regulations regarding proper landfill cover." Because the re-contouring is necessary to comply with the slope requirements of the Missouri Solid Waste regulations, it is consistent with the terms of the Negative Easement.

The nuisance attraction to and congregation by birds at and above the Site if its contents are exposed could be problematic unless effectively controlled. If necessary, an avian management plan that incorporates best management practices (BMPs) such as daily soil cover and/or tarping, visual and auditory frightening devices, or wire or monofilament grids positioned over exposed refuse to prevent bird access, could be prepared and implemented prior to and during regrading of waste containing municipal refuse. In addition, for regrading required for the ROD-selected remedy, the area of regrading will be minimized and immediate replacement utilized as much as possible in order to minimize potential exposure of waste.

5.3.1.3 Removal of Radiologically-Impacted Soil from the Buffer Zone/Crossroads Property

A design-phase investigation would be performed to evaluate the nature and extent of occurrences of radionuclides beneath Lot 2A2 of the Crossroads property and the Buffer Zone (Figure 2-14). This design-phase survey would only apply to the Buffer Zone/Crossroads Property and would be performed in accordance with the requirements of the Multi-Agency Radiation Survey and Site Investigation Manual (MARSSIM) (EPA, DOE, NRC, DOD, 1997). The remediation control and waste characterization surveys for the Buffer Zone/Crossroads property are discussed in Section 3.2.1.1 of Appendix G.

Any radiologically contaminated soil on the Buffer Zone/Crossroads Property would be removed and consolidated in the area of containment (Areas 1 or 2) prior to placement of fill material or construction of the cover over that portion of the Site. The precise nature and extent of contaminated soil on the Buffer Zone/Crossroads Property is uncertain due to grading activities conducted in these areas after the latest set of samples were obtained. Any soil outside the boundaries of the Site would need to meet remediation goals that support unlimited use and unrestricted exposure and would be subject to verification sampling. Excavation of contaminated material would include dust suppression and monitoring (see Appendix G) to ensure there is no release of fugitive dust.

5.3.1.4 Engineered Landfill Cover for the ROD-Selected Remedy

The extent of the new engineered landfill cover included as part of the ROD-selected remedy is presented on Figure 5-1. Figure 5-2 presents a profile of the new engineered landfill cover that would be installed under the ROD-selected remedy and would consist of the following layers (from top to bottom):

- A one-foot thick layer of soil capable of sustaining vegetative growth;
- A two-foot thick infiltration layer of compacted USCS CL, CH, ML, MH, or SC soil-type with a coefficient of permeability of 1 x 10^{-5} cm/sec or less; and
- A two-foot thick bio-intrusion/marker layer consisting of well-graded rock or concrete/asphaltic concrete rubble.

Specifically, the landfill cover to be installed over Areas 1 and 2 would consist of (from bottom to top): 2 feet of rock consisting of well-graded pit run rock and/or concrete/asphaltic rubble ranging from sand sized up to 6 inches such that upon placement would contain minimal void spaces; 2 feet of compacted clay or silt that when compacted at optimum moisture content possesses a coefficient of permeability of 1 x 10^{-5} cm/sec or less; and 1 foot of soil suitable of supporting vegetative growth. The thicknesses of these layers are based on the requirements of the Missouri Solid Waste Rules and the description of the cover system included in the ROD.

In accordance with direction from EPA on October 12, 2012 (EPA, 2012), December 9, 2015 (EPA, 2015c), and August 4, 2016 (EPA, 2016c), the FFS is to include an evaluation of an alternative landfill cover design as set forth in the Revised Work Plan for Alternative Cover Design (EMSI, 2014c), which EPA approved on September 9, 2014. An evaluation of alternative landfill cover design was performed and documented in the January 27, 2015 "Evaluation of Alternative Landfill Cover designs (EMSI, 2015c), which indicated that, as a substitute for the 2-foot compacted clay/silt liner (CCL) included in the ROD-selected remedy cover description, a geosynthetic clay liner (GCL) could instead be implemented at the Site and could provide greater effectiveness at minimizing infiltration at comparable cost. EPA indicated (EPA, 2016c) that this option should be included in the FFS. Therefore, evaluation of the ROD-selected remedy includes both a 2-foot CCL and a 2-foot soil layer that incorporates a GCL (Figure 5-2).

Additionally, as part of this FFS, detailed calculations were performed to select a design cover thickness that meets the remedial action objective for control of radon gas and to ensure that the cover provides sufficient shielding from gamma radiation (Appendix F). Consistent with the UMTRCA requirements and EPA's Office of Superfund Remediation and Technology Innovation (OSRTI) May 2009 memorandum (EPA, 2009b), these evaluations were performed using the updated radium-226 and thorium-230 concentrations and the results of radon flux testing recently completed as part of the construction of the non-combustible cover over portions of Areas 1 and 2 to predict the expected levels of radon, radium and thorium that would result from 1,000 years of thorium and radium decay, radium ingrowth and radon generation.

Measured radon flux values indicate current radium-226 concentrations produce radon-222 emanations that are currently less than 10% of the regulatory limit of 20 $pCi/m^2/s$, averaged across OU-1 (EMSI, 2016b). Using standard ingrowth equations, it was determined that the average future concentration of radium-226 after 1,000 years of ingrowth would not increase radon-222 emissions above the 20 $pCi/m^2/s$ mark, regardless of cover design. From this it was concluded that a cover over the affected soil is not needed to meet radon-222 criteria. Placing any cover, such as the one required during landfill closure by MDNR, would reduce already acceptable radon-222 emanations further, making the considered designs insensitive to radon-222 radon emission criteria.

Since radon-222 emission criteria would be satisfied by all cap designs, the cap thickness will be governed by surface exposures from gamma radiation penetrating the cap. These calculations were performed on the aged radium-226 inventory using the gamma pathway in EPA's web-based risk calculator for radionuclides[26], and the design specified in the ROD,[27] which is based on the Missouri Solid Waste Regulations (CSR 80-3.010(17)(C)(4)(A)) cover design requirements for closure of unlined solid waste landfills, with the additional enhancement of a 2-ft concrete rubble/rock layer, as described above. This cap design was found to provide sufficient protection from surface radiation exposures throughout the 1,000 simulation.

Results of these evaluations indicated that the ROD-specified cover design would have sufficient thickness and characteristics to be protective against gamma radiation and radon emissions in both Areas 1 and 2 (Appendix F). Additional evaluations of the cover design may be performed during the RD phase to further verify that the design of the landfill cover complies with the applicable and relevant and appropriate requirements of other environmental regulations. The design of the landfill cover, as well as the gas control, runoff control, long-term groundwater monitoring, and post-closure inspection and maintenance components, would at a minimum meet the relevant and appropriate requirements found in the Missouri Solid Waste Rules for sanitary landfills. Consistent with the requirements for uranium mill tailing sites, the landfill cover would also incorporate a rubble or rock armoring layer to minimize the potential for biointrusion and erosion and increase the overall longevity of the cover. The landfill cover would also be designed to provide protection from radioactive emissions (*i.e.*, gamma radiation and radon). Figure 5-2 shows a conceptual cross-section of a sanitary landfill cover that has been augmented to include a crushed concrete or rock biointrusion layer.

A significant amount of earthen material would need to be obtained from an off-site source and delivered to the Site for use in constructing the new landfill cover. Specifically, it is anticipated that all of the final cover system components, materials for construction of the bio-intrusion layer, low permeability soil (clay) layer, and vegetative layer, will need to be purchased and delivered to the Site. FS level design projections determined that approximately 820,000 loose cubic yards of soil material will be required from off-site sources for implementation of the ROD-selected remedy.

---

[26] Provided on https://epa-prgs.ornl.gov/cgi-bin/radionuclides/rprg_search.

[27] A minimum thickness of 2 feet of compacted clay with a coefficient of permeability of 10^{-5} cm/sec. or less, overlain by a soil layer (minimum thickness of 1 foot) capable of sustaining vegetative growth.

There are several options for how this material could be managed. Depending upon the relative rates of landfill cover construction compared to the anticipated rate of delivery of the various soil materials, the required materials could be delivered directly to the work area and incorporated into cover construction, thereby avoiding the need to stockpile the materials. If the rate of material delivery does not match the rate of material required for landfill cover construction, then stockpiling may be necessary or advantageous to help prevent construction delays. The time required to deliver the necessary materials needed for construction of the new landfill cover represents a significant portion of the anticipated total construction schedule (Appendix J). As such, in order to shorten the anticipated duration of construction activities for the ROD-selected remedy, it may be advantageous to import and stockpile the required materials in advance of the time they are needed for cover construction. Subject to Site owner/operator approval, these materials could be stockpiled on inactive portions of the Site such as the on-site soil borrow stockpile area (subject to requirements associated with OU-2 construction schedules), the Closed Demolition Landfill, and/or on portions of Areas 1 and 2 not contemporaneously subject to regrading (Figure 5-3). The feasibility, implementability, costs, and impacts to construction schedules associated with stockpiling of materials are addressed as part of the detailed evaluation of the ROD-selected remedy.

5.3.1.5 Rock Armoring/Flood Protection of the Toe of the Landfill

Portions of the Site were developed over the geomorphic flood plain, but these areas were subsequently filled such that the surface elevations of these areas are now located outside of the 500-year flood plain (FEMA, 2015). These areas are further protected by the presence of the 500-year levee and supporting flood control system of the Earth City Levee District. In the unlikely event of levee failure during a 500-year flood event, it is possible that flood waters could reach the lowermost approximately two feet of the toe of the landfill cover at the northwestern edge of Area 2. Because the Site is located more than 1.3 miles from the Missouri River, no high energy water flows would be expected if flood waters reached the Site. The flood protection needs of the toe of the landfill would be evaluated in more detail in the RD, and appropriate bank protection methods would be incorporated as necessary (*e.g.*, a rock rip-rap apron). The vertical height of the flood protection feature would be a subject of design phase evaluations but is expected to include a margin of safety over the 1993 (500-year) flood level. As indicated in the May 2009 memorandum from EPA's Office of Superfund Remediation and Technology Innovation (EPA, 2009b), flood control measures should meet or exceed design standards for a 500-year storm event under the assumption that the existing levee system is breached.

5.3.1.6 Stormwater Management/Surface Water Runoff Control

Management of stormwater during and after construction would be addressed in the Storm Water Pollution Prevention Plan (SWPP) that would be prepared during RD of the selected remedy. During construction, it is anticipated that:

- Temporary berms and/or ditches would be constructed as needed at the downstream edge of the existing landfill cover or the edges of any interim daily cover in excavation areas, to direct stormwater away from open excavations;

- Other practices may include installation of silt fencing and sedimentation barriers; slope minimization; stabilization of temporary waste stockpiles; use of plastic tarps, mulching, or hydro-seeding on areas not being actively graded or completed and that would be exposed for extended periods (*i.e.*, longer than 45 days); construction and stabilization of stormwater ditches and down chutes; and planting of permanent native vegetative cover when construction is complete. Additional prevention measures would include performing heavy equipment fueling and storing any hazardous materials in designated areas, as well as parking vehicles and locating waste stockpiles away from stormwater drainage points;

- Stormwater that contacts the existing surfaces of Areas 1 and 2, daily cover soil during regrading or excavation in Areas 1 and 2, and the surfaces of cover material as the covers over Areas 1 and 2 are being constructed would be managed as non-contact stormwater and directed off-site via the existing stormwater drainage system; and

- Stormwater that contacts exposed waste during regrading activities would be considered contact stormwater, requiring treatment and/or disposal as discussed below. Any accumulated contact stormwater would be pumped out of the low points in depressions created by the excavation and backfilling activities using portable pumps and directed via a new pipeline to a series of tanks (*e.g.*, frac tanks).

The stormwater tank farm would be sized to accommodate the maximum historical 24-hour rainfall over the anticipated maximum area of exposed waste. Accumulated stormwater would be pumped out of the tanks at a steady flow rate and directed to treatment equipment prior to discharge to the Metropolitan St. Louis Sewer District (MSD) in accordance with MSD procedures and discharge limitations. It is assumed that treated stormwater could be introduced to the MSD sanitary sewer system using the force main that is currently used to convey leachate from the Bridgeton Landfill or via tie-in to an MSD manhole in the vicinity of the West Lake Landfill. Representatives of MSD were contacted during preparation of the SFS, at which time they indicated a willingness to accept perched water/leachate encountered during construction, and stormwater generated during construction, subject to their standard approval procedures and discharge limitations. MSD has in the past accepted or is currently accepting similar waters from the Weldon Springs, SLAPS, and SLDS sites.

Given the variability of the waste, it is not possible to predict the quality of the stormwater that could come in contact with exposed waste during regrading at this time. It is anticipated that any radionuclides would be associated with particulates in the stormwater and might include isotopes of uranium and radium, radon-222 and various radon decay products, and potassium-40. It is not anticipated that there would be a significant amount of alpha activity actually dissolved in the stormwater, and as such removal of particulates should be sufficient for treatment of the stormwater.

For purposes of preparing cost estimates for the alternatives in this FFS, it is assumed that 0.2 acres of exposed waste (based on an assumption that the total area of exposed waste at any given time would be approximately 20 acres and that the majority [99%] if this area would be covered by tarps, daily cover or other means) would be subjected to an 8.8 inch rainfall (maximum 24-hour rainfall for August 1946; NOAA, 2011) over a 24-hour period and that this stormwater would be pumped to the stormwater tank farm. This volume of stormwater would be pumped out of the tank farm, treated, and discharged to the MSD sanitary sewer system. Treatment would consist of bag filtration to remove particulates and liquid-phase granular activated carbon (LPGAC) to polish the filtered stormwater and remove any remaining radon and organics. Because any radionuclides that may be present in stormwater would most likely be associated with suspended sediment, it is assumed that these treatment processes would be sufficient to meet the discharge criteria. Two treatment trains would be provided for redundancy and in order to have a back-up system available at all times. It is anticipated that the treatment facilities would be located in a building adjacent to the tank farm. Used filter bags and exhausted LPGAC would be tested and disposed at the appropriate facility according to the analytical test results.

5.3.1.7 Landfill Gas Monitoring and Control

The presence and levels of landfill gas would be monitored both during and after construction of the ROD-selected remedy. Measures to control potential accumulations and/or migration of explosive or toxic gases would be taken as needed both during and after construction.

As part of RD, specifications for a Methane Gas Emergency Monitoring and Action Plan would be prepared. The contractor selected to perform the remediation would be required to provide a detailed plan that meets those specifications and they would be required to incorporate both methane gas monitoring procedures and emergency response actions into their operational Health and Safety Plan. Methane gas monitoring would be performed in any and all areas where waste materials are exposed or where methane could potentially occur or accumulate. In the event that methane monitoring indicated the presence of methane concentrations which exceed the standard permitted by the Plan in any of the work areas, all work in that area would be immediately stopped and all personnel and equipment would be immediately withdrawn from the area. Methane monitoring would continue to be performed along the margins of the subject area to identify the extent of the area containing the methane exceedance and to assess changes in methane levels over time. In the event that the methane levels declined to below the clearance level of the Plan, work in the area could proceed subject to the results of ongoing and continuous methane monitoring demonstrating that the results remain at the acceptable level. In the event that methane levels again rose above the trigger level, work would again be stopped until the levels declined at which point one or more of the following mitigation procedures could be deployed:

- Work in the subject area could be delayed until methane levels dissipate on their own;

- Equipment could be used to remotely open up and aerate the waste materials to enhance dissipation of the methane; and/or

- Industrial fans could be brought to the work area to dissipate any methane occurrences.

A post-construction landfill gas monitoring program would be developed during the RD phase and implemented as part of the long-term monitoring program. The need for and scope of the landfill gas monitoring program, including the exact number and locations of gas monitoring points and measurement frequency, would be determined in the RD documents for the selected remedy for OU-1. Final landfill gas monitoring well locations and spacing would be based on geologic conditions and proximity to property boundaries and adjacent features. Section 3.1.2 in Appendix G discusses the assumed number and location of sub-surface landfill gas monitoring probes to be installed as part of the post-construction baseline monitoring program for the ROD-selected remedy. Long-term landfill gas monitoring is described in Section 4.1.2 of Appendix G.

Installation and operation of a landfill gas extraction system is included as a contingent action for the ROD remedy, in the event that the perimeter landfill gas or radon monitoring indicate that lateral migration of either explosive gases or radon is occurring along the Site boundary. This would be evaluated by comparing the landfill gas or radon levels at the perimeter of Areas 1 and 2 under the ROD-selected remedy, to the appropriate performance standards. Due to the overall age of the landfill waste, along with the relatively low levels of methane detected during the RI (EMSI, 2000), high levels of methane are not expected to occur in Areas 1 and 2.

If it is determined that a contingent landfill gas control system is necessary, it is expected that such a system would consist of either passive or active gas control wells, and in the event that an active gas control system is determined to be necessary, a gas extraction blower and offgas treatment system (a landfill gas flare or granular activated carbon adsorption in the case of radon) would also be required. A contingent landfill gas control system would be implemented in accordance with the substantive requirements standards established by the MDNR Solid Waste Management regulations (10 CSR 80-3(14)(C)(5)), the Missouri Statutes (Chapter 643 RSMo) and corresponding rules and regulations governing air quality, and the UMTRCA regulations (40 CFR Part 192). Operation of a landfill gas extraction and treatment system would include monitoring of the emissions from any vents, pipes, or flares that discharge to the atmosphere. Results of this monitoring would be compared to the substantive requirements of the above-cited regulations and/or to a site-specific risk-based value.

5.3.1.8 Management of Subsurface Liquids During Construction

It is not anticipated that groundwater will be encountered during regrading of the waste materials under the ROD-selected remedy. The potential does exist that perched layers/lenses of leachate may be encountered during waste regrading; however, the additional investigations conducted in 2013 – 2015 did not encounter any leachate or perched water in Area 1 or 2. Any perched liquid that may be encountered during implementation of the ROD-selected remedy would be pumped into temporary holding tanks (*e.g.,* frac tanks), tested to determine whether treatment or pre-approval by MSD prior to discharge is required, and then would be discharged to MSD after authorization is granted. In the event that this liquid cannot be discharged to MSD, it would be hauled to an offsite disposal facility.

5.3.1.9 Regulated Materials Management During Construction

As part of RD, a regulated materials identification and classification plan would be developed to address procedures to be employed in the event that suspected hazardous wastes or regulated asbestos containing material (RACM) are encountered during implementation of the ROD-selected remedy. Components of this plan would include training of the Site health physicists in procedures and criteria to be used to identify potential hazardous wastes or RACM that may be encountered during waste regrading. The contractor's construction manager (CM), health physicist (HP), and construction quality assurance officer (CQAO) would be instructed on the requirements for compliance with 40 CFR Part 61.154(j), 10 CSR 10-6.241, and St. Louis County Ordinance 612.530, all of which pertain to excavating/disturbing asbestos. Specifically, the HP and/or CQAO would complete the required MDNR Certification; Missouri State Certificate for Asbestos-Related Occupations. The materials identification plan would also address procedures to be used for segregation, stockpiling and testing of possible hazardous wastes or RACM and procedures to be used for on-site or off-site disposal of the materials based on the results of the testing.

In the event testing of suspected hazardous wastes indicates that such materials are hazardous waste, these materials would need to be identified, classified, manifested and shipped to an off-site hazardous waste facility for treatment (*e.g.*, solidification, stabilization, micro- or macro-encapsulation, incineration, etc.) in accordance with the Land Disposal Restrictions and associated Universal Treatment Standards of the RCRA Hazardous Waste regulations, and corresponding Missouri regulations. If any identified hazardous wastes also include radionuclides above levels that would allow for unrestricted use, these waste materials would need to be treated and disposed of as "Mixed Wastes" in a RCRA permitted disposal cell at one of the radioactive waste disposal facilities identified in Section 4.3.5.4 of this FFS (U.S. Ecology Idaho, U.S. Ecology Michigan, Energy*Solutions*, or Clean Harbors-Deer Trail). In the event that RACM is encountered during remedy implementation, this material would need to be managed and disposed in accordance with applicable state regulations (see discussion in Section 3).

5.3.1.10 Long-Term Operations, Maintenance and Monitoring for the ROD-Selected Remedy

Long-term operations, maintenance and monitoring (OM&M) activities would be performed upon completion of the remedy construction. An operations, maintenance and monitoring plan (OM&M Plan) would be developed and submitted for approval as part of the RD/RA process. The OM&M Plan would cover all the long-term remedy management and monitoring functions including groundwater monitoring plans; site inspection, maintenance and repair; notification and coordination; community relations; health and safety; emergency planning; activity schedules; reporting; etc. In practice, the OM&M Plan may be developed as a compilation of more focused plans.

Under the ROD-selected remedy, RIM would remain on-site, and accordingly, the post-closure operations, maintenance and monitoring period would likely exceed the 30-year period specified in the Missouri Solid Waste Rules for a solid waste landfill. For purposes of this FFS, cost estimates for both 30 years and 1,000 years of OM&M have been developed as part of the detailed analysis of alternatives (Section 6).

The final landfill cover system would be routinely inspected and maintained to ensure the integrity of the remedy over time. The inspections would focus on identifying any erosion of the landfill cover, the condition and coverage of vegetation on the landfill cover, the presence of material, vehicle, or equipment storage, vehicle tracks, burrowing animals, or any other activities that could affect the integrity of the landfill cover. Periodic mowing or brush-hogging of the vegetative cover would also be performed as part of long-term OM&M in order to control weed and woody plant growth on the landfill cover and to provide for an aesthetically pleasing appearance of the landfill area.

Inspections would also be performed to assess the integrity and overall condition of the perimeter security fencing around Areas 1 and 2. Any impacts to the integrity of the fence caused by activities on adjacent properties, snow accumulation, or other factors would be repaired. Any trash, debris, or woody vegetation that may accumulate along the fence would also be removed.

The various stormwater management structures (detention and sedimentation basins, diversion berms and ditches, runoff ditches and let-down structures, etc.) would be inspected for damage or the presence of erosional features or excessive sediment accumulation. Repairs to these features would be made as necessary.

In addition to surveillance of the physical remedy, the periodic site inspections would include administrative functions such as monitoring of institutional controls and coordination with key stakeholders, including the Earth City Levee District regarding management of the flood control system.

5.3.1.11 Environmental Monitoring for the ROD-Selected Remedy

The ROD-selected remedy would include monitoring activities that would be performed during and after construction of the remedy. The exact scope of this monitoring would be developed as part of the RD effort, but a preliminary description of the scope of potential monitoring activities was necessary to assess the anticipated effectiveness of a monitoring system as well as to provide the bases for estimated monitoring costs. The scope of potential monitoring activities is provided as Appendix G (Conceptual Bases for Costs of Occupational and Environmental Monitoring Associated with each Remedial Alternative) and includes monitoring activities with a limited duration that would be performed during construction (short-term monitoring), post-construction baseline monitoring, and longer duration monitoring activities performed following remedy construction (long-term monitoring).

Short-term monitoring activities that would be performed during construction of the ROD-selected remedy (and the other remedial alternatives) were divided into two categories: (1) health-based monitoring; and (2) remediation control monitoring. Data quality objectives (DQOs) would be different for each category of short-term monitoring activity. Health-based monitoring activities would be designed to evaluate potential emissions and human exposures that may occur during construction of a given alternative. The remediation control monitoring program would be designed to guide the construction contractor during construction of the ROD-selected remedy. Both of these categories of monitoring and survey activities would be limited to the period of construction. Short-term monitoring activities are described in Section 3 of Appendix G.

Post-construction baseline monitoring would be conducted to confirm that the remedial action was completed as designed and to provide initial post-construction values that could be compared to long-term monitoring results. Post-construction baseline monitoring activities are described in Section 4 of Appendix G.

Long-term monitoring activities are described in Section 5 of Appendix G and include landfill gas, groundwater, and surface water as well as annual post-construction site inspections that would be conducted after remedy construction to verify that the constructed remedy was performing as designed.

Four types of radiological surveys would be conducted to guide the minor cut and fill operations in Areas 1 and 2, to guide the excavation and relocation of RIM from the Buffer Zone/Crossroad Property onto Area 2, and to obtain regulatory approval that final cover placement over Areas 1 and 2 would meet design criteria. These methods of remediation control monitoring for the ROD-selected remedy are described in Section 3.2.1 in Appendix G.

5.3.2 Non-Engineered Components of the ROD-Selected Remedy

In addition to the various engineered components of the ROD-selected remedy, non-engineered activities including implementation, maintenance and monitoring of institutional controls and periodic reviews by EPA and MDNR of the effectiveness and protectiveness of the remedy would be performed.

5.3.2.1 Institutional Controls Included in the ROD-Selected Remedy

Land use restrictions would be maintained and/or implemented for OU-1 to limit future uses and to prevent any allowable future uses from impacting the effectiveness or integrity of the remedial action, taking into consideration the presence of long-lived radionuclides. The restrictions must be maintained until the remaining hazardous substances are at levels allowing for unlimited use and unrestricted exposure. Due to the presence of long-lived radionuclides at OU-1, the restrictions would need to be maintained indefinitely. The existing Negative Easement and Restrictive Covenants on the West Lake Landfill (Appendix A) would also remain applicable as institutional controls.

The following long-term use restrictions would potentially apply within the boundary of the cover systems for Areas 1 and 2:

- Prevent development and use for residential housing, schools, childcare facilities, or playgrounds;
- Prevent development and use for industrial or commercial purposes such as manufacturing, offices, storage units, parking lots, or other facilities that are incompatible with the function or maintenance of the landfill cover;
- Prevent construction activities involving drilling, boring, digging, or other use of heavy equipment that could disturb vegetation, disrupt grading or drainage patterns, cause erosion, or otherwise compromise the integrity of the landfill cover or manage these activities such that any damage to the cover is avoided or repaired;
- Prevent use of groundwater under these areas (for any purpose other than monitoring); and
- Provide for access necessary for continued maintenance, monitoring, inspections, and repair.

Property use restrictions have already been implemented at the Site through the placement of institutional controls on the individual parcels as discussed in Section 2.1.4. Design and implementation of any additional institutional controls that may be necessary would be addressed as a component of the RD planning process. Where appropriate, multiple mechanisms or a layered approach would be used to enhance the effectiveness of the institutional control strategy. Access controls such as fences and gates would also be used to support the use restrictions.

At the Site, the affected properties are privately owned and the use restrictions must be maintained for an indefinite period of time. Therefore, recorded covenants would be used because they generally run with the land and are enforceable. The Missouri Environmental Covenants Act (MECA), Mo. Rev. Stat.§ 260.1012, et seq., specifically authorizes environmental covenants and authorizes the State to acquire property interests for the purpose of ensuring long term compliance with such covenants. An environmental covenant pursuant to MECA is a potential instrument for use at the Site because such covenants are specifically designed to support use restrictions at contaminated sites.

The Site has been listed by MDNR on the State's Registry of Confirmed, Abandoned, or Uncontrolled Hazardous Waste Disposal Sites in Missouri (Uncontrolled Sites Registry). The registry is maintained by MDNR pursuant to the Missouri Hazardous Waste Management Law (Mo. Rev. Stat. § 260.440). Sites listed on the registry appear on a publicly-available list. A notice is filed with the County Recorder of Deeds and notice must be provided by the seller to any potential buyers of the property. Parties are not permitted to change the use of a listed site without approval of MDNR.

The OM&M Plan would contain procedures for surveillance, monitoring, and maintenance of the institutional controls. The OM&M Plan would provide for notice to EPA and the State of any institutional control violations, planned or actual land use changes, and any planned or actual transfers, sales, or leases of property subject to the use restrictions.

EPA has stated that financial assurance will be required to provide for operation, maintenance and monitoring of the remedy after construction.

5.3.2.2 Five Year Reviews

The ROD-selected remedy would also include performance of a 5-year review by EPA as required by Section 121 of CERCLA and the NCP. The specific questions to be addressed by each Five Year Review include the following:

1. Is the remedy functioning as intended by the decision documents?

2. Are the exposure assumptions, toxicity data, cleanup levels, and RAOs used at the time of remedy selection still valid?

3. Has any other information come to light that could call into question the protectiveness of the remedy?

EPA and/or the State would perform a Five Year Review at a minimum of every five years after completion of the Record of Decision for the Site or, if determined by EPA to be necessary, at more frequent intervals. The Five Year review would include an overall statement regarding the protectiveness of the remedy.

5.4 "Complete Rad Removal" Remedial Action Alternative

This section of the FFS describes the RIM volumes to be addressed under the "complete rad removal alternative, RIM excavation procedures and associated activities; short-term, post-construction, and long-term monitoring associated with the "complete rad removal" alternative; and describes the specific components of the "complete rad removal" with off-site disposal alternative. Final grading, capping and closure of Areas 1 and 2 after RIM removal are also described.

Activities associated with the "complete rad removal" alternative would include the following components:

- Excavation and stockpiling of overburden in OU-1 Areas 1 and 2 in order to access the RIM;
- Excavation of RIM from the OU-1 Areas 1 and 2 that contains radionuclides above levels that would allow for unrestricted use relative to the presence of radionuclides;
- Survey and identification of the presence and extent of radiologically-impacted soil on the Buffer Zone and Crossroad property;
- Excavation of any soil from the Buffer Zone and/or Crossroad property that contains radionuclides at levels greater than those that would allow for unrestricted use;
- Loading, transport, and disposal of the RIM and impacted soil at an off-site disposal facility;
- Regrading of the remaining solid waste materials within Areas 1 and 2 to meet the minimum (5%) and maximum (25%) slope criteria;
- Installation of a landfill cover meeting the Missouri closure and post-closure care requirements for sanitary landfills over Areas 1 and 2;
- Design, installation and maintenance of surface water runoff controls;
- Groundwater monitoring consistent with the requirements for sanitary landfills;
- Landfill gas monitoring and control, as necessary;

- Institutional controls to prevent land and resource uses that are inconsistent with a closed sanitary landfill site; and

- Long-term surveillance and maintenance of the landfill cover in Areas 1 and 2.

Per EPA's December 9, 2015 letter and attached SOW (EPA, 2015a), the FFS is to include a "complete rad removal" alternative consisting of excavation of RIM with off-site commercial disposal of the excavated materials. EPA previously indicated (EPA, 2010) that "complete rad removal" was defined to mean attainment of risk-based radiological cleanup levels specified in OSWER Directives 9200.4-25 and 9200.4-18.

Although this alternative has been termed "complete rad removal," it must be recognized that implementation of this alternative would not result in complete removal of all radionuclides from the Site, but instead would remove radionuclides from Areas 1 and 2 to the degree feasible such that additional engineering and institutional controls would not be required based on the radiological content of these areas. Because these areas would still contain solid wastes after removal of the radiologically-impacted materials, regrading, capping and establishment of institutional controls related to the presence of solid wastes would still be required.

Several components of this alternative have been addressed above in the ROD-selected remedy and will not be repeated here. The following subsections address excavation, loading and transport of RIM and impacted soil for disposal at an off-site facility.

5.4.1 RIM Volumes for the "Complete Rad Removal" Alternative

As previously discussed in Section 2.2.5, the total volumes of RIM contained in Areas 1 and 2 were estimated based on geostatistical evaluations (Appendix B) as follows:

Area 1 RIM (7.9 pCi/g criteria)	46,200 bank cubic yards (bcy)
Area 2 RIM (7.9 pCi/g criteria)	220,000 bcy
Total RIM (7.9 pCi/g criteria)	266,200 bcy

The volumes of non-radiological overburden soil and waste materials that would have to be removed to allow for excavation of the RIM were estimated to be as follows:

Area 1 overburden (7.9 pCi/g criteria)	702,500 bcy
Area 2 overburden (7.9 pCi/g criteria)	493,200 bcy
Total overburden (7.9 pCi/g criteria)	1,195,700 bcy

Figures 5-4 and 5-5 display the extent of RIM that would be excavated from Areas 1 and 2 under the "complete rad removal" alternative.

Removal of all of the RIM containing combined radium or combined thorium levels greater than 7.9 pCi/g would require removal, stockpiling and ultimately replacement of a large part of the above-grade mass of the North Quarry portion of the Bridgeton Landfill in order to access the RIM in that portion of Area 1 that lies beneath the above-grade portion of the North Quarry (*e.g.*, RIM in the vicinity of boring 1D-7). In addition, the Bridgeton Transfer Station, LLC solid waste transfer station building would need to be relocated to allow for removal of RIM located in close proximity to the transfer station (*e.g.*, GCPT 1-2, GCPT 1C-2R, and GCPT 1C-6, GCPT 1C-6T, GCPT 1C-6T1, and boring 1C-6). The only usable space for relocation of the transfer station is the area currently occupied by Simpson Asphalt pursuant to a 99-year lease, which would require buyout of the Simpson lease.

A discussion of the methods and supporting calculations used to estimate the extent and volumes of RIM above levels that would allow for unrestricted use, as well as the non-radiological overburden soil and waste materials that would have to be removed to allow for excavation of the RIM, is included in Section 2.2.5 and is further described in Appendix B.

It should be recognized that the RIM and overburden volume estimates were performed to a feasibility-study level of accuracy, and there is a high degree of uncertainty in these quantities. The levels and distribution of radionuclide activity within the RIM is known to be highly variable due to the inherent heterogeneity of the waste as well as the variable locations where RIM is concentrated. Uncertainty also arises from the limits on the accuracy of the existing site topographic mapping, which is based on aerial photogrammetry without ground control, producing, at best, a topographic surface with a tolerance of approximately one foot. In addition, past subsurface investigations of the Site were focused on providing information on the general nature and extent of occurrences of RIM. This site characterization information was determined to be sufficient to characterize the potential risks posed by the Site and to identify and evaluate potential remedial alternatives (EMSI et al., 2011). However, the intent of the prior investigations was not to accurately define the three-dimensional extent of the RIM for detailed quantity estimates. Consequently, precise estimates of the amounts and volumes of overburden materials that would need to be removed to access the RIM, the actual volumes and configurations of the RIM, and the relative amounts and distributions of soil and waste materials within the RIM cannot be made at this time. For purposes of this FFS evaluation, the estimated volume of RIM is the single largest uncertainty affecting the estimated costs and schedule for the "complete rad removal" alternative.

5.4.2 RIM Excavation and Associated Activities

This section describes the various activities associated with the "complete rad removal" alternative. Activities associated with regrading and installation of a new landfill cover over Areas 1 and 2 after removal and off-site or on-site disposal of the radioactively-impacted materials in Areas 1 and 2 are described in Section 5.3.5.

5.4.2.1 RIM Excavation Procedure and Sequencing

The RIM excavation process would be performed in a systematic manner in order to allow for efficient removal of the RIM and to minimize excavation quantities to the extent practicable. The remainder of this subsection describes the RIM excavation process. The logistics of RIM excavation sequencing in an affected area is illustrated on Figure 5-6. As shown, a grid-system would be marked in the field in an affected area. Using field radiological monitoring supplemented by on-site laboratory and/or off-site laboratory data, health physics (HP) technicians would guide the excavator operator where to remove materials in a progressive manner from grid-to-grid, removing a specified layer thickness from each grid. The radiological surveys that would be conducted to guide excavation of RIM are described in Section 3.2.2.1 of Appendix G.

As thin layer excavation progresses within the affected area, the HP technicians would follow the excavator at a close but safe distance to survey the surface. It is assumed that Ra-226 and its radioactive progeny will serve as a suitable surrogate for the activity for the initial excavation activities because the survey equipment would be able to detect < 3 pCi/g in the top few centimeters. The excavation would continue across the edge of the suspected RIM zone as guided by the radiation surveyors. It is anticipated that HP technicians could conduct periodic small-scale hand excavations when measurements indicated the presence of RIM just beneath the surface. If the RIM zone was judged to be relatively thin, these hand excavations could be used to attempt to verify the RIM thickness.

If overburden material is present, the excavator would remove the overburden and the survey technicians would screen the material to ensure no RIM was present. If no RIM is present, an additional layer of material would be removed and the area resurveyed. If additional RIM is encountered, field gamma surveys would be used to guide the removal of RIM. If the survey does not identify gamma signatures indicative of radioactivity above levels that would allow for unrestricted use in a particular excavation area where RIM is anticipated to occur, the survey technicians would direct the excavation to continue to another grid width while the analytical results of soil/waste samples are obtained to determine if all of the RIM above unrestricted use criteria has been removed.

During the excavation and surveying in the RIM zones, some soil or soil/debris could be collected and analyzed in an on-site or off-site analytical laboratory to validate the field survey measurements. Determination of whether to use an on-site laboratory, off-site laboratory, or both to support RIM excavation activities would be evaluated as part of RD based on analytical detection limits, turnaround time for lab results, cost and other factors. Regardless of which method is used to guide the excavation activities, samples would be collected from any areas of RIM excavation that are determined in the field to contain radionuclide activities below those that would allow for unrestricted use, for laboratory confirmation. If an on-site laboratory is used to make this determination, a specified percentage of the samples would also be sent to an off-site laboratory to independently verify the results obtained by the on-site laboratory.

As stated above, field surveys and measurements would need to be augmented with laboratory analyses from an on-site or off-site laboratory in order to verify that thorium levels were below the unrestricted use criteria. As noted by the NRC (1988), thorium does not possess characteristics that make it easy to measure quantitatively in place, as can be done for Ra-226 and associated decay products that have an identifiable gamma signature. Therefore, laboratory analyses are the only method for determining thorium levels. Because Th-230 is the controlling radionuclide at the Site, guidance of the excavation activities for the "complete rad removal" alternative can be generally guided by field measurements but ultimately will be directed by the results of laboratory analyses which will increase both the time required for and cost of excavation activities.

The shaded area in Figure 5-6 is a hypothetical scenario that portrays the zone of RIM and the potential approach to excavation along the edge of the RIM zone. Ideally, the excavation would continue along the edges of the RIM zone until the extent of the zone was delineated and the uncontaminated soil/debris on top of it removed. Conditions of the materials surrounding the RIM might limit how to proceed once the RIM zone was identified. The decision as to how to proceed would be made by the construction manager with input from the HP technicians.

The process of excavating the RIM would continue laterally and with depth, following a similar procedure as described above. If possible, the excavator would remain outside the RIM zone and reach into the RIM zone to lift out the RIM. The excavator would still remain on the uncontaminated surface reaching out with the bucket to excavate RIM soil/debris. HP technicians would follow the excavation to verify the absence of radioactivity above levels that would allow for unrestricted use.

For areas where RIM may be present in a thicker or deeper band, it could be necessary to move the excavator into the RIM zone. Efforts would be undertaken to limit direct contact between the RIM and the excavator. A set of wooden tracks or construction mats placed in front of the excavator tracks or a platform for the tracks would be considered.

As RIM is excavated, the nuisance attraction to, and congregation by birds at and above the excavation could be problematic unless effectively controlled. An avian management plan that incorporates use of excavation BMPs such as daily soil cover and/or tarping, visual and auditory frightening devices, or wire or monofilament grids positioned over exposed refuse to prevent bird access, would be prepared prior to and implemented during excavation of the RIM.

5.4.2.2 Material Handling

It has been estimated that approximately 46,200 and 220,000 bank cubic yards of RIM would be excavated from Area 1 and Area 2, respectively, under the "complete rad removal" alternative. In addition, it is estimated that approximately 702,500 and 493,200 bank cubic yards of non-RIM waste overburden would require excavation from Area 1 and Area 2, respectively, to access the RIM waste for the "complete rad removal" alternative. In order to access the underlying RIM waste, this non-RIM overburden material would be removed and temporarily stockpiled at the Site.

Characterization data generated during the RI and supplemental investigation phases of this project (EMSI, 2016b) indicated that the materials expected to be encountered during the excavation would consist of:

- Solid waste consisting of varying amounts of household wastes, commercial/industrial wastes, and construction and demolition debris;
- Daily/intermediate soil cover, including some soil that has been mixed with leached barium-sulfate residues; and
- Final soil cover, possibly including some soil that has been mixed with leached barium-sulfate residues.

The levels and distribution of radionuclide activity within the RIM is known to be highly variable. Consequently, precise estimates of the amounts and volumes of overburden materials that would need to be removed to access the RIM, the actual volumes and configurations of the RIM, and the relative amounts and distributions of soil and waste materials within the RIM cannot be made at this time. Until actual excavation were to commence and field screening and visual observation begin, the extent and volume of overburden and RIM that would be removed under the "complete rad removal" alternative can only be estimated using the available data.

As discussed in Section 4, physical separation of the soil and solid waste is a technology that can potentially reduce the amount of waste material that would have to be transported and disposed off-site under the "complete rad removal" with off-site disposal alternative. As discussed in Section 4, although physical separation has been used to separate soil from refuse in old landfills, it has never been used to separate radiologically-impacted material from solid waste. Consequently, the degree to which this technology could effectively separate all or most of the soil, such that the remaining solid waste materials would not contain radionuclides at levels greater than those that would allow for unrestricted use, is unknown. Therefore, this technology, although a proven application for "mining" of old landfills, has never been applied and its performance has never been tested or demonstrated for the type of application associated with the "complete rad removal" alternative. Pilot-scale testing of the degree of separation and resultant radionuclide activity levels within the separated fractions (*i.e.*, garbage and soil) as well as other factors such as dust generation and air quality of the generated dust, worker maintenance activities and resultant radionuclide exposure levels to workers and the community, among others, would need to be evaluated through performance of a pilot-scale test as part of RD activities before a determination of the potential applicability, effectiveness, impacts and costs of this technology could be made. Pilot testing would include mobilizing a trommel unit to the Site, excavating several test tracts, and performing physical separation using the trommel and testing the result separated materials for radioactivity levels. Particulate samples would also be collected in order to examine potential dust emissions. Performance of a pilot test, evaluation of the test results, and, if appropriate, integration of this technology as part of the remedial action would therefore increase the time and cost required for completion of the RD phase for this alternative.

5.4.2.3 Material Stockpiling

As previously noted, excavation of the RIM under the “complete rad removal” alternative would require removal and stockpiling of non-RIM waste materials that overlie the RIM (overburden wastes). For the “complete rad removal” alternative, excavated non-RIM overburden waste would be temporarily stockpiled adjacent to the excavation(s) or elsewhere on-site until areas containing RIM had been completely excavated and cleared of radiation, and final samples confirm that all materials with radionuclide activities above levels that would allow for unrestricted use had been removed. Subsequently, the non-RIM overburden waste would be placed back into the excavations upon completion of the RIM removal activities. As discussed previously, approximately 702,500 and 493,200 bank cubic yards of non-RIM waste overburden would need to be excavated from Area 1 and Area 2, respectively, in order to implement the “complete rad removal” alternative.

For the “complete rad removal” alternative, a significant amount of earthen material would also need to be delivered on-site and stockpiled for use in construction of the final landfill cover over Areas 1 and 2 once the RIM were removed. The overall preference would be to stockpile the required construction materials on portions of Areas 1 and 2 that would not be subject to excavation or that would not be contemporaneously subject to excavation activities. However, due to the limited size of Areas 1 and 2 and the extensive amount of excavation associated with the “complete rad removal” alternative, it is likely that implementation of the “complete rad removal” alternative would require some stockpiling of materials (non-RIM waste and/or cover construction materials) outside of Areas 1 and 2. Figure 5-3 illustrates potential locations where stockpiles could be established. These locations potentially include the surface of the northern portion of Area 2 (during performance of excavation in Area 1) and on top of the Closed Demolition Landfill. These locations appear viable for this preliminary feasibility-level evaluation, but their actual locations would vary depending on the results of the detailed design and in consideration of issues such as the final excavation layouts, limits, and procedures; discussions/agreement with the Site owner and operator; and potential interference with existing utilities, roads, vehicular traffic patterns, or structures.

The low permeability soil and vegetative cover material for the cover to be placed over Areas 1 and 2 after RIM removal would be purchased and delivered to the Site. A portion of this soil would be stockpiled to avoid delay in construction activities. A bio-intrusion layer is not included as part of the cover for the “complete rad removal” with off-site disposal alternative. FS-level design projections determined that approximately 1,280,000 loose cubic yards of soil material would be required from outside sources. These materials could be stockpiled on the Closed Demolition Landfill, on portions of Areas 1 and 2 not contemporaneously subject to RIM excavation, and/or the current on-site soil stockpile area (subject to requirements associated with implementation of the OU-2 remedy). Potential stockpile areas are shown on Figure 5-3.

Stockpiled non-RIM waste material would be managed to control odors. For example, these materials would be covered with tarps, soil cover or foams/chemical agents to suppress odor emissions and reduce the potential for windblown debris and dust, vectors, and precipitation infiltration. The stockpiles would be managed to prevent dust emissions and stormwater impacts; for example, by applying water or other dust suppressants, and by strategically locating the stockpiles away from Site drainage features to the extent possible. A plan for stockpiling of waste materials including identification of actual or potential areas for temporary stockpiles, temporary covers, runon-runoff controls, ongoing inspection and maintenance requirements, and other factors would be developed as part of the RD. A Storm Water Pollution Prevention Plan (SWPPP) would be prepared prior to commencement of construction activities and would provide a detailed plan for the location and maintenance of the stockpiles.

While the non-RIM overburden waste is excavated and stored on-site, the nuisance attraction to, and congregation by birds at and above, the excavation and non-RIM overburden waste stockpiles could be problematic unless effectively controlled. An avian management plan that incorporates use of excavation BMPs such as daily soil cover and/or tarping, visual and auditory frightening devices, or wire or monofilament grids positioned over exposed refuse to prevent bird access, would be prepared prior to and implemented during excavation of the non-RIM overburden waste.

5.4.2.4 Radiological Surveys during RIM Excavation

Based on evaluations conducted in preparation of the prior SFS, it is expected that eight types of radiological surveys would be conducted to guide the excavation and verify that the RIM had been removed during and after the RIM excavation process. These surveys are described in detail in Section 3.2.2.1 of Appendix G. Excavation surveys and verification sampling would be performed during and upon completion of excavation activities in each area, as described in Section 5.4.2.1 and Appendix G.

5.4.2.5 Application of Daily Soil Cover

In order to minimize odors, vectors, windblown debris, and precipitation infiltration, a nominal thickness of six (6) inches of soil would be applied as daily cover over grading, excavation, waste stockpile, and waste placement areas. Daily cover would be applied to the stockpiles of non-RIM waste overburden material as well as the RIM excavation areas.

For cost purposes, the daily cover is assumed to be soil because it is the most conventional and widely used material for this purpose. The amount of daily cover included for each of these activities was estimated to be equal to 10% of the volume of the waste materials subject to daily cover. This value is based on professional experience with the development of design and operations plans for solid waste landfills and monitoring of in-place waste and soil volumes during landfill development. The actual amount of soil required for use as daily cover would be a function of the size and configuration of the various cut and fill areas, waste excavation areas, and overburden stockpiles that would be subject to daily cover under each of the remedial alternatives addressed by the FFS as well as the physical configuration of the material to be covered. The amount of soil required for daily cover is also a function of equipment operator expertise, and desired production rates. Considering all of these factors, the actual amount of soil required could be slightly less (as low as 8%) than the 10% estimated in this FFS or substantially more (as much as 20%) than the amount included in this FFS.

Application of daily cover to the waste excavation areas would increase the volumes and mass of the RIM-impacted waste materials to be addressed in the “complete rad removal” and partial excavation alternatives. Daily cover placed over the RIM excavation areas would mix with and become part of the volume of RIM, therefore increasing the volume and mass of RIM that would be sent for off-site disposal.

It may be possible to place tarps or foam over the non-RIM and RIM excavation areas and non-RIM overburden stockpiles under the “complete rad removal” and partial excavation alternatives in lieu of using soil as the daily cover material. The ability to use tarps or foam in place of soil as a daily cover material would be a function of the size and configuration of the various areas requiring cover, the ability of the tarps and foam to withstand wind loads, potential worker exposures during placement and removal of the tarps and/or foam, and various other factors that can only be evaluated and/or tested during design or possibly during the initial stages of implementation of a remedial action at the Site.

To the extent that application of daily soil cover alone proves insufficient to address the nuisance attraction to and congregation by birds at and above the excavation, additional measures may need to be taken. These measures could include some or all of the technologies identified in Section 4, including minimization of areas of exposed wastes, use of tarps or additional thickness of daily cover material over areas of exposed waste, placement of wire or monofilament grids positioned over exposed refuse to prevent bird access, and/or implementation of visual deterrents (simulated predators) or frightening devices (noise makers) to deter bird activity.

5.4.2.6 Removal of Radiologically-Impacted Soil from the Buffer Zone/Crossroad Property

With the exception of the ultimate disposition of such soil, identification, characterization and removal of soil on the Buffer Zone or Crossroad Property that contains radionuclide levels above those that would allow for unrestricted use would be performed in the same manner as was previously described for the ROD-selected remedy (see Section 5.2.1.2). Under the “complete rad removal” with off-site disposal alternative, any such soil would be disposed off-site.

5.4.2.7 Management of Subsurface Liquids During RIM Excavation

It is not anticipated that groundwater would be encountered during excavation of RIM. Pockets of perched leachate present in the waste mass may be encountered during implementation based on the extent and depths of excavation associated with the “complete rad removal” and partial excavation alternatives. Leachate, if any, that may be encountered during remedy implementation would be pumped into temporary holding tanks (*e.g.*, frac tanks), tested to determine treatment requirements, if any, with the test results submitted to MSD for approval for discharge to MSD, and subsequently treated, if and as necessary, prior to discharge to MSD. In the event that this liquid cannot be discharged to MSD, it would be hauled to an offsite disposal facility.

It is not expected that groundwater will be encountered during RIM excavation, based on a comparison of typical measured Site groundwater elevations to the anticipated bottom of the anticipated excavations for Areas 1 and 2.

5.4.2.8 Regulated Materials Management During RIM Excavation

Management of suspected hazardous wastes or RACM encountered during implementation of the "complete rad removal" and partial excavation alternatives would be conducted in the same manner described in Section 5.2.1.8 for the ROD-selected remedy.

5.4.2.9 Radiological Surveys after RIM Excavation

Final status surveys that would be conducted for completed RIM excavation areas and for the unexcavated areas involved with the movement and handling the RIM and overburden storage locations are described in Section 3.2.2.2 of Appendix G.

5.4.3 Loading and Transportation of RIM to an Offsite Disposal Facility

RIM that would be excavated from Areas 1 and 2 and the Buffer Zone/Crossroad property under the "complete rad removal" alternative would be hauled to one of the off-site disposal facilities described in Section 4.3.7. Because of the long distances between the Site and any off-site disposal facility, the large volume of RIM estimated to be excavated under the "complete rad removal" alternative, and considerations related to effectiveness, safety, and cost, direct hauling of RIM to the disposal facility using trucks was eliminated as a transportation technology for all of the offsite disposal facilities with the possible exception of U.S. Ecology's Wayne Disposal facility in Michigan. For all of the offsite disposal facilities, with the possible exception of U.S. Ecology Michigan, RIM would be hauled to the disposal facilities via rail.

As described in Section 4.3.5, there are several methods for containment of waste material for rail transport, including:

- RIM loaded directly into gondola cars, if a potential future rail spur could be extended onto the Site;

- RIM loaded into an open 35 cubic yard soft-sided U.S. DOT Industrial Packaging (IP)-1 shipping container bag that had been placed in an end-dump semi-trailer, the bag closed and trucked to a truck-to-rail transloading operation at a leased rail spur location near the Site (assuming a location could be identified during the design phase), the trailer backed onto a transload ramp, and the bag dumped into the gondola car;

- RIM could be placed into 10 cubic yard soft-sided IP-1 shipping container bags located near the excavation area, the bags loaded onto flatbed semi-trailers with a forklift or crane and trucked to a truck-to-rail transloading operation at a leased rail spur location near the Site; and the containers off-loaded from the flatbed and into gondola cars with a forklift or crane; or

- RIM could be loaded into a lined metal intermodal container with a secured lid and the intermodal container would be lifted onto a flatbed trailer and hauled to a truck-to-rail transloading operation at a leased rail spur location where the containers would be lifted off of the flatbed and stacked with other intermodals onto a flat railcar.

Loading of the intermodal containers at the Site would occur within an enclosed structure equipped with dust, odor and vapor emission control equipment (Figure 5-7). Conceptually, the RIM staging and loading building is anticipated to be constructed in the current Bridgeton Landfill surplus/reclaimed material and equipment storage ("boneyard") area (Figure 5-8). Trucks arriving at the Site carrying empty intermodal containers would be first weighed and then would enter one (the "intermodal loading") side of the building. A liner would be placed in the intermodal container and the truck would pull forward to the center of the building where RIM would be placed in the lined intermodal container by a front-end loader. The loading of RIM would be supervised by a representative of the disposal facility to ensure that the material meets the disposal facility's waste acceptance criteria. Upon completion of the RIM loading, the truck would pull to the far end of the "intermodal loading" side of the building where the outer portions of the liner would be placed over the top of the RIM and the container would either be covered with a tarp or alternatively if equipped with a metal lid, the lid would be placed over the top and sealed before the truck exits the building. The truck would then exit the building where it would be scanned for radioactivity and decontaminated if necessary. The truck would then proceed to the scale to be weighed and the waste manifest would be completed prior to leaving the Site. The truck would then transport the intermodal containers of RIM to a truck/rail transloading facility where the intermodal containers would be loaded onto flat rail cars for transport to the waste disposal facility. The RIM staging and loading building would be equipped with air emissions controls consisting of exhaust blowers that would discharge air through sulfur dioxide odor control media and vapor phase granular activated carbon media (Figure 5-7).

For the "complete rad removal" with off-site disposal alternative, determination of the containment method for rail transport would be made as part of the RD effort. Extending a rail spur onto the Site, if possible, and loading RIM material directly onto railcars would reduce material handling steps, reduce risks associated with the intermediate step of transporting RIM via trucks to a leased rail spur location near the Site, and probably reduce transportation costs.

Extending a spur would likely require the following activities and facilities, as shown on Figure 5-8:

- Purchase or long-term lease of portions of the PM Resources, Inc. and CP III Properties, LLC properties located across St. Charles Rock Road from the Site entrance (Figure 5-8);
- Approvals to construct a rail spur across private property located to the east of St. Charles Rock Road, across St. Charles Rock Road, and along the access roads to the existing solid waste transfer station and asphalt plant operations at the Site;
- A new switch and tie-in to the existing spur located on CP III Properties, LLC property;
- Removal of trees and brush in the wooded area between the tie-in and St. Charles Rock Road;
- Assessment of whether the wooded area is a designated wetlands and, if so, obtaining approvals and potential wetlands mitigation;
- Laying of flat track in the cleared area between the tie-in and St. Charles Rock Road;
- Installation of an electrically-gated and signed crossing and flat track across St. Charles Rock Road (Missouri State Highway 180) including appropriate coordination with and approval from local and state authorities;
- Installation of flat track on the Site on surfaces that have not been landfilled, including north of and along the Site access road, between the OU-2 Closed Demolition and Inactive Sanitary Landfills to OU-1 Area 1, and parallel tracks to the west of the asphalt plant area[28];
- Two switches on the tracking within the Site;
- Renegotiation of the long-term lease for the asphalt plant, which leases land south of the solid waste transfer facility and whose property would be impacted by the on-site spur;
- Installation of a reinforced concrete (estimated as at least a 100 ft by 100 ft area) loading platform at the edge of Area 2 where excavated RIM would be placed by articulated trucks and then loaded into gondola rail cars with front-end loaders.[29]

---

[28] It is assumed that two sets of tracks would extend onto the Site to provide enough room for switching and staging of empty gondola cars during simultaneous loading of gondola cars, to maximize the volume of RIM that could be removed per day.

[29] It is anticipated that the loading platform would be placed in one permanent location adjacent to Area 2 and the smaller volume of RIM from Area 1 would be transported via articulated on-site trucks to the loading platform.

- Installation of a tensioned fabric frame structure over the loading platform such that loading of rail cars can be performed regardless of weather conditions;

- Installation of a scale within the loading platform structure; and

- Purchase of a "trackmobile" (small rail locomotive) to be used to move empty and loaded gondola rail cars around on-site.

A detailed evaluation of the above issues (including whether an on-site rail spur extension is technically or economically feasible) is beyond the scope of this FFS, and would need to be conducted during the RD phase.

Based on discussions with U.S. Ecology, it was decided that for the purposes of FFS evaluations of the "complete rad removal alternative" it would be assumed that excavated RIM would be loaded into 30 cubic yard lined metal intermodal containers. The intermodal containers would be hauled via flatbed truck to a truck-to-rail transloading operation at a rail spur location within a 10-mile radius of the Site. The intermodal containers would be loaded onto flatbed rail cars at the transloading facility for shipment to one the off-site disposal facilities described in Section 4.3.7.

5.4.4 Stormwater and Landfill Gas Monitoring and Control

In addition to the surfaces that stormwater could contact under the ROD-selected remedy, stormwater under the "complete rad removal" alternative could contact: (1) exposed waste during excavation of overburden and RIM from Areas 1 and 2; (2) daily cover soil that has been placed over areas of exposed overburden or RIM after excavation; and (3) surfaces of cover material as the covers over Areas 1 and 2 are being constructed.

Stormwater management for the "complete rad removal" alternative would be performed in the same manner as was described in Section 5.3.1.6 for the ROD-selected remedy except for possible variations in the locations and size of the stormwater control structures owing to the greater area of disturbance and creation of topographic depressions during construction of the "complete rad removal" alternative and the greater period of stormwater management resulting from the longer duration required for implementation of the "complete rad removal" alternative.

Landfill gas monitoring and control during construction would be performed in the same manner as was described in Section 5.3.1.7 for the ROD-selected remedy. Long-term monitoring of landfill gas monitoring along the perimeters of Areas 1 and 2 would performed in the same manner as was described in Section 5.3.1.7 for the ROD-selected remedy except that radon monitoring would not be required.

Installation and operation of a landfill gas extraction system as described above for the ROD-selected remedy is also included as a contingent action under the "complete rad removal" alternative in the event that the perimeter landfill gas monitoring indicates that lateral migration of explosive gases is occurring along the Site boundary. This would be evaluated by comparing the landfill gas levels at the perimeter of Areas 1 and 2 under the "complete rad removal" alternative to the appropriate performance standards. Due to the overall age of the landfill waste, along with the relatively low levels of methane detected during the RI (EMSI, 2000), high levels of methane are not expected to occur in Areas 1 and 2.

5.4.5 Final Grading and Engineered Landfill Cover

As only the RIM would be removed, waste materials would still remain on-site in Areas 1 and 2. Regrading and construction of a final cover would be performed for Areas 1 and 2 as described in Section 5.3.1.4 above with the exception that the final grades would be a minimum of 5% and the final cover installed for the "complete rad removal" alternative would not include the additional two-foot thick rock/rubble biointrusion layer. Long-term inspection and maintenance of the final cover would be required.

After RIM had been removed from Areas 1 and 2, only waste materials below the appropriate rad screening level would remain in these areas. The presence of waste materials would require a final RCRA Subtitle D cover to be constructed over these areas. MDNR regulations (and in particular, 10 CSR 80-3.010(17)(C)(4)(A)) would govern the requirements for the landfill cover over Areas 1 and 2.

In order to safely access and remove RIM as described previously, it would be necessary to temporarily excavate and stockpile solid wastes (overburden wastes) that currently lie on top of the RIM. Once removal of RIM over the levels permitted for unrestricted use has been verified, this overburden waste material would be returned to the excavated areas. These wastes would then be graded and a new Subtitle D landfill cover installed. It is envisioned that the overburden wastes would be suitable for backfilling into the excavations of Areas 1 and/or 2, which would aid in the proper regrading of the excavations and promote positive drainage from the two areas. The design criteria specified for MSW landfills (*e.g.*, minimum 5% and maximum 25% slopes) would also apply to design of the final grades for any waste materials that would remain after excavation of the RIM.

Consistent with MDNR regulations for existing solid waste landfills without liners (10 CSR 80-3.010(17)(C)(4)(A)), the cover for Areas 1 and 2 would consist of the following layers (from top to bottom):

- 1-ft vegetative soil; and
- 2-ft compacted clay layer (10^{-5} cm/sec).

The uppermost one (1) ft soil layer would have to be capable of sustaining vegetative growth. It would typically be composed of a soil with sufficient organic content and permeability to allow vegetative growth. USCS soil types such as OH and OL are often found suitable for this end use. The United States Department of Agriculture (USDA) soil taxonomy system would also be referenced and used to aid in identifying suitable vegetative layer soils.

The two (2) ft compacted clay layer would consist of a USCS CL, CH, ML, MH, or SC soil-type with characteristics such that a compacted permeability 1 x 10^{-5} cm/sec or less could be achieved during construction.

5.4.6 Long-Term Operations, Maintenance and Monitoring and Non-Engineered Components

Long-term OM&M activities and the non-engineered components for the "complete rad removal" alternative would still require post-closure care activities associated with a closed MSW landfill, which would generally be the same as those described in Sections 5.3.1.10 and 5.3.2 for the ROD-selected remedy and described in Section 5.2 of Appendix G for the "complete rad removal" alternative. Because all of the RIM containing radionuclides above levels that would allow for unrestricted use would have been removed from Areas 1 and 2 under the "complete rad removal" alternative, some of the long-term OM&M activities and institutional controls included as part of the ROD-selected remedy should not be necessary for Areas 1 and 2, including:

- Long-term OM&M of Areas 1 and 2 would only need to be performed for a 30-year period;
- Institutional controls required solely for the presence of radionuclides in Areas 1 and 2 would no longer be necessary;
- Monitoring of radon occurrences in landfill gas around Areas 1 and 2 should not be necessary; and
- Performance of five-year reviews.

Financial assurance would be required to provide for operation, maintenance and monitoring of the remedy. Because radionuclides above levels that would allow for unrestricted use would be removed under this alternative, five-year regulatory reviews, as described in Section 5.2.2.2, should not be required for the "complete rad removal" alternative.

Groundwater and landfill gas monitoring of Areas 1 and 2 would also be mandated for a period of 30 years, consistent with the post-closure monitoring requirements for solid waste landfills (10 CSR 80-2.030(4)(A)3.E(I)). Maintenance and monitoring of institutional controls would also be necessary, similar to the requirements described above for the ROD-selected remedy.

5.5 Partial Excavation – Removal of RIM Greater than 52.9 pCi/g within 16-foot Depth

This section describes the partial excavation alternative that includes removal of RIM containing combined radium or combined thorium activities greater than 52.9 pCi/g that is located within 16 feet of the topographic elevation of the 2005 ground surface of Areas 1 and 2. This alternative consists of many of the same components as were previously discussed for the “complete rad removal” alternative, including:

- Excavation and stockpiling of overburden in OU-1 Areas 1 and 2 in order to access the RIM;
- Excavation of RIM from the OU-1 Areas 1 and 2 that contains combined radium or combined thorium activities greater than 52.9 pCi/g that is located within 16 feet of the 2005 topographic surface;
- Survey and identification of the presence and extent of radiologically-impacted soil on the Buffer Zone and Crossroad property;
- Excavation of any soil from the Buffer Zone and/or Crossroad property that contains radionuclides at levels greater than those that would allow for unrestricted use;
- Loading, transport, and disposal of the RIM and impacted soil at an off-site disposal facility;
- Regrading of the remaining solid waste materials within Areas 1 and 2 to meet the minimum (5%) and maximum (25%) slope criteria;
- Installation of a landfill cover meeting the Missouri closure and post-closure care requirements for sanitary landfills over Areas 1 and 2;
- Design, installation and maintenance of surface water runoff controls;
- Groundwater monitoring consistent with the requirements for sanitary landfills;
- Landfill gas and radon monitoring and control, as necessary;
- Institutional controls to prevent land and resource uses that are inconsistent with a closed sanitary landfill site containing radiological materials; and
- Long-term surveillance and maintenance of the landfill cover in Areas 1 and 2.

The primary differences between the 52.9 pCi/g partial excavation alternative and the “complete rad removal” alternative are the higher criteria for excavation of RIM under the 52.9 pCi/g partial excavation alternative (52.9 pCi/g of combined radium or combined thorium as compared to 7.9 pCi/g for the “complete rad removal” alternative) and the imposition of a maximum depth of excavation for the 52.9 pCi/g partial excavation alternative. These differences result in significantly lower volumes of RIM and overburden material to be excavated under the 52.9 pCi/g partial excavation alternative as compared to the “complete rad removal” alternative, and accordingly, a remedy that (comparatively speaking) may be implemented more readily.

5.5.1 RIM Volumes for the 52.9 pCi/g Partial Excavation Alternative

The total volumes of RIM containing combined radium or combined thorium activities greater than 52.9 pCi/g in Areas 1 and 2 that were located within 16 feet of the 2005 topographic surface were estimated based on geostatistical evaluations (Appendix B) and are as follows:

Area 1 RIM (52.9 pCi/g criteria)	20,800 bank cubic yards (bcy)
Area 2 RIM (52.9 pCi/g criteria)	130,000 bcy
Total RIM (52.9 pCi/g criteria)	150,800 bcy

The volumes of non-radiological overburden soil and waste materials that would have to be removed to allow for excavation of the RIM above the 52.9 pCi/g criteria were estimated to be as follows:

Area 1 overburden (52.9 pCi/g criteria)	52,800 bcy
Area 2 overburden (52.9 pCi/g critiera)	198,700 bcy
Total overburden (52.9 pCi/g criteria)	251,500 bcy

Figures 5-9 and 5-10 display the extent of RIM that would be excavated from Areas 1 and 2 under the 52.9 pCi/g partial excavation alternative.

In contrast to the "complete rad removal" alternative, removal of all of the RIM containing combined radium or combined thorium levels greater than 52.9 pCi/g down to a depth of 16 feet below the 2005 topographic elevations would not require removal of the above-grade mass of the North Quarry portion of the Bridgeton Landfill, because RIM within the portion of Area 1 that is located beneath the above-grade portion of the North Quarry is located deeper than 16 feet below the 2005 topographic surface. However, removal of RIM greater than 52.9 pCi/g would require relocation of the Allied Waste solid waste transfer station building to allow for removal of RIM located in close proximity to the transfer station (*e.g.*, GCPT 1-2, GCPT 1C-2R, and GCPT 1C-6, GCPT 1C-6T, GCPT 1C-6T1, and boring 1C-6), as that excavation would affect the stability of the transfer station (Figure 5-9). As previously discussed in Section 5.4.1 relative to the "complete rad removal" alternative, the only usable space for relocation of the transfer station is the area currently occupied by Simpson Asphalt pursuant to a 99-year lease, which would require buyout of the Simpson lease.

A discussion of the methods and supporting calculations used to estimate the extent and volumes of RIM containing combined radium or combined thorium activities greater than 52.9 pCi/g in Areas 1 and 2 that were located within 16 feet of the 2005 topographic surface, as well as the non-radiological overburden soil and waste materials that would have to be removed to allow for excavation of the RIM is further described in Appendix B.

As previously discussed in Section 5.4.1 relative to the “complete rad removal” alternative, the estimates of the RIM and overburden volume associated with the 52.9 pCi/g alternative were developed to a feasibility-study level of accuracy. Therefore, a high degree of uncertainty exists relative to the above-listed estimates for the same reasons cited in Section 5.4.1 relative to the “complete rad removal” alternative. For purposes of this FFS evaluation, the estimated volume of RIM is the single largest uncertainty affecting the estimated costs for all of the excavation alternatives.

All other aspects of the 52.9 pCi/g partial excavation alternative would generally be the same as those previously described for the “complete rad removal” alternative, except that because RIM would be left on-site, the enhanced cap included under the ROD-selected remedy (e.g. the biointrusion/marker layer) would also be included as part of 52.9 pCi/g alternative. The 52.9 pCi/g alternative would require a lesser amount of soil material (1,060,000 loose cubic yards) to be purchased and delivered to the Site for construction of this alternative. In addition, because radionuclides above the unrestricted use criteria would still remain at the Site, five-year review evaluations, groundwater monitoring for radionuclides, and radon gas monitoring would be required for the 52.9 pCi/g partial excavation alternative. Baseline monitoring for measurement of radon gas in landfill gas wells for the partial excavation alternatives is described in Section 4.1.2 of Appendix G and includes measurement of radon gas in landfill gas wells installed along the boundaries of Areas 1 and 2.

5.6 Partial Excavation – Removal of RIM Greater than 1,000 pCi/g

This section provides a description of the partial excavation alternative that includes removal of RIM containing combined radium or combined thorium activities greater than 1,000 pCi/g. As with the 52.9 pCi/g partial excavation alternative, this alternative consists of many of the same components as were previously discussed for the “complete rad removal” alternative including:

- Excavation and stockpiling of overburden in OU-1 Areas 1 and 2 in order to access the RIM;
- Excavation of RIM from the OU-1 Areas 1 and 2 that contains combined radium or combined thorium activities greater than 1,000 pCi/g;
- Survey and identification of the presence and extent of radiologically-impacted soil on the Buffer Zone and Crossroad property;
- Excavation of any soil from the Buffer Zone and/or Crossroad property that contains radionuclides at levels greater than those that would allow for unrestricted use;
- Loading, transport, and disposal of the RIM and impacted soil at an off-site disposal facility;

- Regrading of the remaining solid waste materials within Areas 1 and 2 to meet the minimum (5%) and maximum (25%) slope criteria;
- Installation of a landfill cover meeting the Missouri closure and post-closure care requirements for sanitary landfills over Areas 1 and 2;
- Design, installation and maintenance of surface water runoff controls;
- Groundwater monitoring consistent with the requirements for sanitary landfills;
- Landfill and radon gas monitoring and control, as necessary;
- Institutional controls to prevent land and resource uses that are inconsistent with a closed sanitary landfill site containing radionuclides; and
- Long-term surveillance and maintenance of the landfill cover in Areas 1 and 2.

The primary difference between the 1,000 pCi/g partial excavation alternative and the 52.9 pCi/g partial excavation and the "complete rad removal" alternatives is the higher criteria for excavation of RIM associated with this partial excavation alternative (1,000 pCi/g of combined radium or combined thorium as compared to 7.9 pCi/g for the "complete rad removal" alternative and 52.9 pCi/g for the other partial excavation alternative). The higher criteria associated with the 1,000 pCi/g partial excavation alternative results in a lower volume of RIM to be excavated. However, in contrast to the 52.9 pCi/g partial excavation alternative, which also includes a maximum depth of excavation limited to 16 feet below the 2005 ground surface, the 1,000 pCi/g partial excavation alternative does not include any depth limitation. Therefore, even though the RIM volume associated with this alternative is smaller, the volume of overburden that would need to be removed to allow for removal of RIM greater than 1,000 pCi/g is significantly greater than the volume of overburden associated with the 52.9 pCi/g partial excavation alternative.

5.6.1 RIM Volumes for the 1,000 pCi/g Partial Excavation Alternative

The total volumes of RIM containing combined radium or combined thorium activities greater than 1,000 pCi/g in Areas 1 and 2 were estimated based on geostatistical evaluations (Appendix B) and are as follows:

Area 1 RIM (1,000 pCi/g criteria)	7,100 bcy
Area 2 RIM (1,000 pCi/g criteria)	31,100 bcy
Total RIM (1,000 pCi/g criteria)	38,200 bcy

The volumes of non-radiological overburden soil and waste materials that would have to be removed to allow for excavation of the RIM above the 1,000 pCi/g criteria were estimated to be as follows:

Area 1 overburden (1,000 pCi/g criteria)	387,000 bcy
Area 2 overburden (1,000 pCi/g critiera)	213,600 bcy
Total overburden (1,000 pCi/g criteria)	600,600 bcy

Figures 5-11 and 5-12 display the extent of RIM that would be excavated from Areas 1 and 2 under the 1,000 pCi/g partial excavation alternative.

Similar to the "complete rad removal" alternative, removal of all of the RIM containing combined radium or combined thorium levels greater than 1,000 pCi/g would require removal, stockpiling, and ultimately replacement of a large part of the above-grade mass of the North Quarry portion of the Bridgeton Landfill. However, removal of RIM greater than 1,000 pCi/g is not expected to require relocation of the Allied Waste solid waste transfer station building.

The methods and supporting calculations used to estimate the extent and volumes of RIM above the 1,000 pCi/g criteria, as well as the non-radiological overburden soil and waste materials that would have to be removed to allow for excavation of the RIM, are further described in Appendix B.

Similar to the discussion in Section 5.4.1 relative to the "complete rad removal" alternative, the estimates of the RIM and overburden volume associated with the 1,000 pCi/g alternative were developed to a feasibility-study level of accuracy. Therefore, a high degree of uncertainty exists relative to the above-listed quantities for the same reasons cited in Section 5.4.1 relative to the "complete rad removal" alternative. For purposes of this FFS evaluation, the estimated volume of RIM is the single largest uncertainty affecting the estimated costs for all of the excavation alternatives.

All other aspects of the 1,000 pCi/g partial excavation alternative would generally be the same as those previously described for the 52.9 pCi/g partial excavation alternatives. The 1,000 pCi/g alternative would require the greatest amount of soil material (1,290,000 loose cubic yards) to be purchased and delivered to the Site for construction of this alternative. Ongoing monitoring for radionuclide occurrences in groundwater and potentially measurement of radon gas in landfill gas wells installed along the boundaries of Areas 1 and 2 could be required as part of this alternative. Because this alternative only entails removal of radionuclides above 1,000 pCi/g, radionuclides would still remain at the Site at levels above the unrestricted use criteria. Therefore, five-year review evaluations and radon gas monitoring would be required for the 1,000 pCi/g partial excavation alternative.

6 DETAILED ANALYSIS OF ALTERNATIVES

This section provides a detailed analysis of the No Action alternative, the ROD-selected remedy, the “complete rad removal” alternative, and the two partial excavation alternatives developed in Section 5. The purpose of this detailed analysis is to provide sufficient information to allow for comparisons among the alternatives based on the nine evaluation criteria specified in the National Contingency Plan (NCP) (40 CFR § 300.430).

The detailed evaluation of final alternatives for a remedial action is a two-stage process. This section presents the first stage of evaluation, in which each of the alternatives is assessed against the nine evaluation criteria prescribed by the NCP. This evaluation is based on the conceptual descriptions of the alternatives provided in Sections 5.2 through 5.6.

Section 7 will set out the second stage of the evaluation process, in which the alternatives are compared against each other to identify relative advantages, disadvantages and trade-offs using the nine NCP evaluation criteria. The purpose of the comparative analysis is to provide information for a balanced remedy selection.

The NCP categorizes these nine evaluation criteria into three groups: threshold criteria, primary balancing criteria, and modifying criteria. The evaluation criteria consist of:

Threshold Criteria:

- Overall Protection of Human Health and the Environment
- Compliance with ARARs

Primary Balancing Criteria:

- Long-Term Effectiveness and Permanence
- Reduction of Toxicity, Mobility, or Volume through Treatment
- Short-Term Effectiveness
- Implementability
- Cost

Modifying Criteria:

- State Acceptance
- Community Acceptance

Each criterion has its own weight when it is evaluated.

- Threshold criteria are requirements that each alternative must meet to be eligible for selection as the preferred alternative, and include overall protection of human health and the environment and compliance with ARARs (unless a waiver is obtained).[30]

[30] Section 121(d)(4) of CERCLA identifies six circumstances under which ARARs may be waived. An ARARs waivers analysis is outside the scope of this FFS.

- Primary balancing criteria are used to weigh effectiveness and tradeoffs among alternatives. The primary balancing criteria include long-term effectiveness and permanence; reduction of toxicity, mobility, or volume through treatment; short-term effectiveness; implementability; and cost. The primary balancing criteria represent the main technical criteria upon which the evaluation of alternatives is based.

- Modifying criteria include State acceptance and community acceptance. These criteria are evaluated and applied by EPA as part of any decision process that may be undertaken by EPA after completion of the FFS. Accordingly, only the seven threshold and primary balancing criteria are applied in the detailed analysis phase of this section.

6.1 Description of Evaluation Criteria

Specific elements to be considered in the evaluation of the nine NCP criteria are discussed below.

6.1.1 Overall Protection of Human Health and the Environment

This criterion assesses how each alternative provides and maintains adequate protection of human health and the environment. Alternatives are assessed to determine whether they can adequately protect human health and the environment from unacceptable risks posed by contaminants present at the Site, in both the short and long term. This criterion is also used to evaluate how risks would be eliminated, reduced, or controlled through implementation of the remedial activities. Overall protection of human health and the environment draws on the assessments of other evaluation criteria, especially long-term effectiveness and permanence, short-term effectiveness, and compliance with ARARs.

6.1.2 Compliance with ARARs

This evaluation criterion is used to evaluate whether each alternative would comply with federal and State ARARs, or, if not, whether invoking waivers to one or more specific ARARs is adequately justified. Other information, such as advisories, criteria or guidance, is considered during the ARARs analysis as “to be considered” elements (TBCs). The considerations evaluated during the analysis of the ARARs applicable to each alternative are presented below. Potential chemical-, location-, and action-specific ARARs for West Lake Landfill OU-1 are discussed in detail in Subsection 3.1.

Chemical-specific ARARs:

- Likelihood that the alternative will achieve compliance with chemical-specific ARARs within a reasonable period of time.
- If it appears that compliance with chemical-specific ARARs will not be achieved, then evaluation of whether a waiver is appropriate.

Location-specific ARARs:

- Determination of whether any location-specific ARARs apply to the alternative.
- Likelihood that the alternative will achieve compliance with the location-specific ARAR.
- Evaluation of whether a waiver is appropriate if the location-specific ARAR cannot be met.

Action-specific ARARs:

- Likelihood that the alternative will achieve compliance with action-specific ARARs.
- Evaluation of whether a waiver is appropriate if the action-specific ARAR cannot be met.

Other criteria and guidance:

- Likelihood that the alternative will achieve compliance with other criteria, such as risk-based criteria.

6.1.3 Long-Term Effectiveness and Permanence

Alternatives are to be assessed for the long-term effectiveness and permanence that they afford, along with the degree of certainty that the alternative will prove successful. The primary components of this criterion are the magnitude of residual risk remaining at the Site after remedial objectives have been met, and the adequacy and reliability of controls (such as containment systems or institutional controls) that may be required to manage that risk. The analysis of each alternative for long-term effectiveness and permanence is presented below.

<u>Magnitude of residual risks</u>:

- Identify remaining risks from treatment residuals and untreated contamination.
- Magnitude of the remaining risks.

The magnitude of residual risk at the completion of remedial activities is evaluated against numerical standards (e.g., cleanup levels or chemical-specific ARARs), or the volume or concentration of contaminants remaining. The characteristics of the residuals remaining are also evaluated, considering their volume, toxicity, mobility, and propensity to bioaccumulate.

Adequacy and reliability of controls:

This criterion requires evaluation of the adequacy and reliability of controls that are used to manage either treatment residuals or untreated materials that remain after attaining remediation goals. This evaluation includes an assessment of containment systems and institutional controls to assess the degree of confidence that they will adequately handle potential problems and provide sufficient protection. Factors to be considered are:

- Likelihood that the technologies will meet required process efficiencies or performance specifications.
- Type and degree of long-term management required.
- Long-term monitoring requirements.
- Operations, Maintenance and Monitoring (OM&M) functions that must be performed.
- Difficulties and uncertainties associated with long-term OM&M functions.
- Potential need to replace technical components of the remedial action.
- Magnitude of threats or risks should the remedial action need replacement.
- Degree of confidence that controls can adequately handle potential problems.
- Uncertainties associated with land disposal of residuals and untreated wastes.

At EPA's direction (EPA, 2015b), the evaluation of long-term effectiveness for the West Lake Landfill Superfund Site also includes evaluation of potential impacts to the alternatives if a tornado were to occur at the Site, the potential effects of climate change, and potential impacts if a subsurface reaction (SSR) were to occur within Area 1 or 2.

6.1.4 Reduction of Toxicity, Mobility or Volume through Treatment

This criterion addresses the anticipated performance of the treatment technologies employed by each alternative in permanently and significantly reducing toxicity, mobility, or volume of hazardous substances. The NCP expresses a preference for remedial actions in which treatment is used to reduce the principal threats at a site through destruction of toxic contaminants, irreversible reduction in contaminant mobility, or reduction of total volume of contaminated media. The considerations evaluated during the analysis of each alternative for reduction of toxicity, mobility, or volume of contaminants are presented below:

(1) Treatment process and remedy:

- Likelihood that the treatment processes address the principal threat, including the materials to be treated.
- Special requirements for the treatment processes.

(2) Amount of hazardous material destroyed or treated:

- Portion (mass) of constituents of potential concern (COPC) that is destroyed.
- Portion (mass) of COPC that is treated.

(3) Reduction in toxicity, mobility, or volume through treatment:

- Degree of expected reduction in the total mass, mobility, volume, or toxicity of contaminants (measured as a percentage of reduction or order of magnitude).

(4) Irreversibility of treatment:

- Degree to which the effects of the treatment are irreversible.

(5) Type and quantity of residuals remaining following treatment:

- Residuals that will remain.
- Quantities and characteristics of the residuals, including persistence, toxicity, mobility, and propensity to bioaccumulate.
- Risk posed by the treatment residuals.

(6) Statutory preference for treatment as a principal element:

- Extent to which treatment addresses the principal threats.
- Extent to which treatment reduces the inherent hazards posed by the principal threats at the site, including the extent to which toxicity, mobility, or volume are reduced either alone or in combination.

6.1.5 Short-Term Effectiveness

Short-term effectiveness considers the ability of each remedial alternative to protect human health and the environment during the construction and implementation phase. The short-term effectiveness evaluation addresses protection prior to meeting the RAOs. The considerations evaluated during the analysis are presented below.

(1) Protection of the community during any remedial action:

- Short-term risks that might be posed to the community during the implementation of an alternative.
- How these risks will be addressed and mitigated.
- Remaining risks, if any, that cannot be readily controlled.

(2) Protection of workers during remedial actions:

- Potential risks to the workers that must be addressed.
- How these risks will be addressed and mitigated and the effectiveness and reliability of measures to be taken.
- Remaining risks, if any, that cannot be readily controlled.

(3) Environmental impacts of any remedial action:

- Potential environmental impacts that are expected as a result of the construction and implementation of the alternative.
- Available mitigation measures, as well as their effectiveness and reliability in minimizing potential impacts.
- Impacts that cannot be avoided, should the alternative be implemented.

(4) Time until RAOs are achieved:

- Time to achieve protection against the threats being addressed.
- Time until any remaining threats are addressed.
- Time until RAOs are achieved.

At EPA's direction (EPA, 2015b), the evaluation of short-term impacts also includes an evaluation of environmental justice considerations.

6.1.6 Implementability

Implementability evaluates the technical and administrative feasibility (i.e., the ease or difficulty) of implementing each alternative, as well as the availability of required services and materials during remedy implementation. The following considerations are evaluated for implementability:

<u>Technical Feasibility</u>

(1) Ability to construct and operate the technology:

- Difficulties associated with the construction.
- Uncertainties associated with the construction.

(2) Reliability of the technology:

- Likelihood that technical problems will lead to schedule delays.

(3) Ease of undertaking additional remedial actions:

- Likely future remedial actions that may be anticipated.
- Difficulty implementing additional remedial actions.

(4) Monitoring considerations with respect to effectiveness of the remedy:

- Migration or exposure pathways that cannot be monitored adequately.
- Risks of exposure, should the monitoring be insufficient to detect failure.

Administrative Feasibility

Coordination with other agencies:

- Steps required to coordinate with regulatory agencies other than EPA to implement the remedy.
- Steps required to establish long-term or future coordination among agencies.
- Ease of obtaining permits for off-site activities, if required.

Availability of Services and Materials

(1) Availability of adequate treatment, storage capacity, and disposal services:

- Availability of adequate off-site treatment, storage capacity, and disposal services.
- Additional capacity that is necessary.
- Whether lack of capacity prevents implementation.
- Additional provisions required to ensure that additional capacity is available.

(2) Availability of necessary and adequate equipment and specialists:

- Availability of necessary equipment and specialists.
- Additional equipment or specialists required.
- Whether there is a lack of equipment or specialists that would prevent implementation.
- Additional provisions required to ensure that equipment and specialists are available.

(3) Availability of prospective technologies:

- Whether technologies under consideration are generally available and sufficiently demonstrated.
- Further field applications needed to demonstrate that the technologies may be used full-scale to treat contaminants.
- When the technology would be available for full-scale use.
- Whether more than one vendor would be available to provide a competitive bid.

6.1.7 Cost

In accordance with the NCP, as well as the "Guidance for Conducting Remedial Investigations and Feasibility Studies under CERCLA" (EPA, 1988a) and "A Guide to Developing and Documenting Cost Estimates During the Feasibility Study" (EPA, 2000c), estimated capital costs, annual OM&M costs, periodic costs, and present worth costs have been prepared for the ROD-selected remedy, the "complete rad removal" alternative, and the partial excavation alternatives. As specified in the RI/FS guidance (EPA, 1988a), the estimated costs were developed to provide a level of accuracy of +50/-30 percent – that is, the actual costs may be up to 50% higher or 30% lower than the estimated costs.

6.1.7.1 Capital and Operation, Maintenance, and Monitoring Costs

Capital costs include (1) direct costs for labor, equipment, materials, subcontractors, contractor markups such as overhead and profit, and professional/technical services that are necessary to support construction of the remedial action; and (2) indirect capital costs that are not part of the actual construction but are necessary to implement the remedial action (e.g., engineering, legal, construction management, and other technical and professional services). Operation, maintenance, and monitoring (OM&M) costs include annual post-construction costs for labor, equipment, materials, subcontractors, and contractor markups such as overhead and profit associated with activities such as monitoring and maintaining the components of the remedial action. Annual OM&M costs also include expenditures for professional/technical services necessary to support OM&M activities. Periodic costs are those that might occur only once every few years (e.g., five-year reviews, cap/cover repair, and equipment replacement), or expenditures that would occur only once during the entire OM&M period or remedial timeframe (e.g., well abandonment, update of the Institutional Controls (ICs) Plan, and site closeout).

In preparing the cost estimates used in this FFS, quantities for labor, equipment, and materials were developed as discussed in Sections 2 and 5 of this report. Cost data were obtained from a variety of sources including cost estimating guides and references such as unit prices in the latest RS Means Heavy Construction and Sitework & Landscaping Cost Data, RS Means CostWorks First Quarter 2016 digital cost data, site-specific vendor and contractor quotes and discussions, experience with actual costs from similar projects, other historical project costs updated to 2016 costs using the Engineering News Record Construction Cost Index (ENR CCI), and engineering judgment.

As discussed in Section 4, only four disposal facilities (US Ecology's facility in Grandview, Idaho; US Ecology's facility in Wayne, Michigan; the Energy*Solutions* facility in Clive, Utah; and Clean Harbors' Deer Trail facility in Last Chance, Colorado), have been identified that could accept RIM from the West Lake Landfill for off-site disposal.

All of the disposal companies considered in Section 4 of the FFS have experience performing the type of services that would be necessary for implementation of a "complete rad removal" or partial excavation alternative. In particular, US Ecology's Idaho facility has experience relative to excavation, transport and off-site disposal of radiologically-impacted soils from the St. Louis Airport Site (SLAPS), which is geographically close to the West Lake Landfill. The other two disposal facilities have performed similar services for Formally Utilized Sites Remedial Action Program (FUSRAP) and DOE sites, as well as for remedial actions at other Superfund sites that contained radioactively-impacted materials.

Because these turnkey disposal firms performed removal, transportation and off-site disposal services for SLAPS and DOE FUSRAP sites, estimates of the expected costs for transport and disposal of the West Lake Landfill RIM are considered appropriate for preparation of FS-level cost estimates. Each of the identified contractors could provide all coordination involved with leasing a nearby rail spur, waste profiling and acceptance testing, loading and manifesting each truck that leaves the Site, and scheduling gondola car transportation with the respective railroads who own the track along the rail routes between the West Lake Landfill and the disposal facility location. Solely for purposes of preparing the cost estimates for the FFS, the unit costs for the complete "turnkey" services provided by US Ecology were used. For the "complete rad removal" and partial excavation alternatives, this FFS considered unit costs for complete ("turnkey") services for waste classification, transportation, and disposal provided by US Ecology for its Grandview, Idaho facility. Contacting trucking and rail companies to obtain independent estimates of the potential costs of transportation separate from the potential costs for disposal is beyond the scope and level of detail required to prepare FS-level cost estimates. Furthermore, it would be difficult to ascertain the degree of qualifications, capabilities and understanding such transportation firms might have regarding the licensing, permitting, applicable fees, manifesting, placarding, health and safety monitoring, and other aspects of interstate transportation of radioactive wastes. US Ecology provided unit costs for complete turnkey services for waste profiling and acceptance testing, waste transportation (including all related fees and taxes), and waste disposal services (including all related fees and taxes). The information provided by US Ecology is considered appropriate for an FS-level evaluation of potential alternatives. The possible cost impacts of using the Energy*Solutions* facility were previously evaluated as part of the sensitivity evaluation of the cost estimates performed for the SFS (EMSI et al., 2011) and it was determined that use of the Energy*Solutions* facility would result in significantly greater costs.

Estimates for professional/technical services cost elements (project management, RD, construction management, and technical support) were based on the example percentages provided in "A Guide to Developing and Documenting Cost Estimates During the Feasibility Study" (EPA, 2000c) for construction of remedies greater than $10 million. These percentages of total construction cost are 5%, 6%, and 6%, respectively, for project management, remedial design (RD), and construction management. Costs for regulatory oversight were estimated at 5% of the capital costs (exclusive of off-site transportation and disposal costs and contingency costs), and 5% of the long-term OM&M costs.

The factors (*e.g.*, total number of acres to be regraded under the ROD-selected remedy, the volume of RIM to be excavated under the "complete rad removal" and partial excavation alternatives, the total length of fencing, etc.) and the assumptions (e.g., material densities and swell factors, volume of leachate encountered or stormwater generated during construction, excavation efficiency factors, etc.) used to prepare the cost estimates are presented in Appendix K-1.

6.1.7.2 Contingency Costs

A contingency was added as a percentage of the total capital, annual OM&M, and periodic costs to cover unknowns, unforeseen circumstances, or unanticipated conditions that are not possible to evaluate from the data on hand at the time the FS-level cost estimates were prepared. Contingency is composed of two elements: scope and bid.

Scope contingency covers unknown costs due to scope changes that may occur during RD and represents project risks associated with an incomplete design, because design concepts are not typically developed enough during preparation of an FS to identify all project components or quantities. This type of contingency represents costs unforeseeable at the time of the preparation of the FS, as well as conceptual design cost estimate preparation, both of which are likely to become better known as the RD phase progresses. For this reason, scope contingency is sometimes referred to as "design" contingency. In general, scope contingency should decrease as RD progresses and should be near 0% at the 100% design stage. At the early stages of RD (*e.g.*, during the FS stage, which represents 0% to 10% design completion), concepts are not typically developed enough to identify all project components or quantities. Higher scope contingency values may be justified for alternatives with greater levels of cost growth potential. A low percentage for scope contingency indicates an opinion that the project scope would undergo minimal change during design. A high percentage indicates an opinion that the project scope may change considerably between the FS and final design. In accordance with EPA guidance (EPA, 2000c), engineering judgment was used whenever selecting a scope contingency percentage, and the value used was clearly identified in the cost estimate.

For this FFS, scope contingency factors ranged from 10% to 55%, depending upon the degree of certainty or uncertainty associated with each alternative and the remedial technologies that comprise each alternative, and taking into consideration the ranges in FS-level scope contingency percentages listed in Exhibit 5-6 of "A Guide to Developing and Documenting Cost Estimates During the Feasibility Study" (EPA, 2000c). Exhibit 5-6 of that guidance provides a range of scope contingencies to consider for various remedial technologies. As examples, the following ranges from Exhibit 5-6 were considered and selected for this FFS.

Remedial Technology	Scope Contingency Range from Exhibit 5-6 (%)	Selected Scope Contingency for SFS (%)
Soil excavation	15 – 55	55
Off-site disposal	5 – 15	15
Clay cap	5 - 10	10

The uppermost values for these remedial technologies were selected for use in this FFS due to the high level of uncertainty associated with the scope of each of the remedial alternatives. Factors contributing to the high level of uncertainty for the ROD-selected remedy and the "complete rad removal" and partial excavation alternatives include the following:

- The estimated volume of RIM to be removed under the "complete rad removal" and partial excavation alternatives. As presented in Appendix B of the FFS, the RI data and various interpolation techniques were used to estimate the volume of waste material that might need to be removed, and those estimated volumes then served as the basis for the cost estimates. Costs for excavation and off-site transportation and disposal are directly proportional to the estimated volume of RIM to be excavated, removed or disposed off-site. The data quality objectives (DQOs) for the RI were to develop site characterization data, not to estimate volumes of waste material for RD.

- The assumed unit weight of the existing in-place filled material in Areas 1 and 2 and the assumed waste volume expansion or "swell" factor for the filled material after excavation: Based on experience from other sites and engineering judgment, a unit weight of 1,500 pounds per cubic foot (lbs/cf) and a swell factor of 1.5 were used in this FFS. Swell factors reported for the CERCLA landfill excavation remedial action for OU-1 at the Mound (Miamisburg, OH) site varied from 1.2 to 1.6 (Lee, 2010), while a swell factor of 2 was experienced during excavation of the Tulalip Landfill CERCLA site near Marysville, WA (Richtel, 2010). Assuming a swell factor of 1.3 instead of the 1.5 used in this FFS would result in 13% less volume of RIM that would be disposed off-site under the "complete rad removal" or partial excavation alternatives, while a swell factor of 2.0 would result in 33% more RIM volume than the amount estimated using the 1.5 swell factor.

- The uncertain level of effort for radiation surveying and confirmatory laboratory sample turnaround time and analysis required to guide the excavation of RIM, and the effect of such uncertainties on excavation progress.

- The ability and level of effort required to excavate deeper occurrences of RIM in Area 1 and 2.

- The methods assumed to handle overburden materials so as to minimize "double handling" of the materials during excavation and subsequent replacement have not been fully developed or designed.

- The actual equipment production rates for regrading or excavation of the landfilled wastes in Areas 1 and 2 are uncertain at this time.

- It was not possible to estimate precise volumes of precipitation and resultant contact stormwater that might be generated when precipitation is exposed to waste during regrading activities under the ROD-selected remedy or to waste and RIM during excavation of overburden and to RIM from Areas 1 and 2 under the "complete rad removal" and partial excavation alternatives. Detailed design would be conducted during RD to address management of the types and quantities of stormwater that might be generated during construction of the selected remedy. For purposes of preparing cost estimates for the alternatives evaluated in this FFS, it is assumed that precipitation that contacts wastes and/or RIM during regrading, excavation, or waste re-placement and accumulates in the low point of an excavation or fill would be pumped to a series of storage tanks. Stormwater would be pumped from the tanks to a treatment building, subjected to filtration and liquid phase granular activated carbon (LPGAC) treatment processes, and discharged to the Metropolitan Sewer District (MSD) in accordance with MSD procedures and discharge limitations. Capital and OM&M costs for stormwater collection and on-site treatment are included for each of the alternatives assuming a maximum historical 24-hour rainfall over an anticipated maximum area of exposed waste at any one time of 4 acres, resulting in an estimated stormwater volume of 608,000 gallons. This value is based on an assumption that the majority of the work area would be covered with tarps or other means to reduce the amount of precipitation which comes into contact with the overburden, waste or RIM. Although the same storm event and exposed area were assumed for all of the alternatives, the estimated OM&M costs vary among the alternatives as a result of differences in the estimated construction schedules (*i.e.*, the estimated duration that areas being excavated might be exposed to precipitation) for each alternative.

- Uncertainties regarding the rates at which cover construction materials could be delivered from off-site sources.

- Uncertainties regarding the actual type of materials to be used for cover construction (*e.g.*, the use of "shot rock" from a nearby quarry was assumed for the materials for the biointrusion layer rather than more uniformly sized large rip-rap).

- For the "complete rad removal" and partial excavation alternatives, uncertainties exist regarding: (1) the methods and effectiveness of physically separating the radiological and non-radiological materials during excavation activities; (2) transport relative to the availability and location of a truck/rail transloading facility; (3) the amount of handling of material at a truck/rail transloading facility; (4) which off-site disposal facilities are able to accept the RIM at the time of removal and the capacities and waste acceptance criteria of such facilities at the time of remedy implementation[31]; (5) and the overall validity, duration, and reliability of the verbal quotes received from disposal facility representatives.

Bid contingency represents costs, unforeseeable at the time of estimate preparation, which are likely to become known as the remedial action construction or OM&M proceeds. Bid contingency accounts for changes that occur after a construction or OM&M contract is awarded and represents a reserve for quantity overruns, modifications, change orders, or claims during construction or OM&M. Examples include changes due to adverse weather, material or supply

[31] Although potential disposal facilities were contacted during preparation of the SFS and again during preparation of the FFS with regard to available capacity for municipal solid waste mixed with soil containing radionuclides and their specific Waste Acceptance Criteria (WAC), there is no way to ensure that these facilities would still have sufficient capacity for such material or that such materials would meet the WAC that may be in effect in the future when a remedy for OU-1 may be implemented.

shortages, or new regulations. A bid contingency of 20% was included for all of the alternatives in this FFS, in accordance with the range of bid contingency factors from "A Guide to Developing and Documenting Cost Estimates during the Feasibility Study" (EPA, 2000c).

6.1.7.3 Present Worth and Non-Discounted Constant Dollar Costs

A present worth analysis has been prepared to allow comparison of the estimated costs of each alternative on the basis of a single figure – i.e., a single dollar amount that, if invested in the base year and disbursed as needed, would be sufficient to cover all costs associated with the remedial action over its planned life. In accordance with EPA's "Guidance for Conducting Remedial Investigations and Feasibility Studies Under CERCLA" (EPA, 1988a), a 30-year period of performance was used in the development of the present worth analysis. The use of a 30-year period for the present worth analysis is not intended to imply or otherwise provide a basis to limit future site maintenance and monitoring activities to 30 years. The need for, and scope of, continued monitoring and maintenance both within and beyond 30 years would be subject to ongoing evaluation as part of the five-year review process for the Site. For some of the alternatives, radioactively-impacted materials would remain on-site and active beyond 30 years, and monitoring and maintenance activities would likely be required beyond the 30-year period used in the cost estimates. Therefore, for the alternatives in which radioactively-impacted materials would remain on-site, OM&M cost estimates and present worth estimates were prepared for 30-year, 200-year, and 1,000-year periods in accordance with the criteria set forth under the NCP and the UMTRCA regulations.

While the "Guidance for Conducting Remedial Investigations and Feasibility Studies Under CERCLA" (EPA, 1988a) recommends the general use of a 30-year period of analysis for estimating present worth costs during a FS, more recent EPA guidance ("A Guide to Developing and Documenting Cost Estimates During the Feasibility Study" (EPA, 2000c) (FS Costing Guidance)), recommends that for projects with durations exceeding 30 years, the FS should prepare both a present worth analysis using the project duration and a non-discounted constant dollar cash flow over time scenario. In this FFS, both present worth and non-discounted constant dollar cash flow analyses have been developed for all of the alternatives. It should be noted that the 2000 guidance states that "non-discounted constant dollar costs are presented for comparison purposes only and should not be used in place of present value costs in the Superfund remedy selection process."

EPA policy on the use of discount rates for RI/FS present worth cost analyses is stated in the preamble to the NCP (55 Fed. Reg. 8722), in the Office of Solid Waste and Emergency Response (OSWER) Directive 9355.3-20 entitled "Revisions to OMB Circular A-94 on Guidelines and Discount Rates for Benefit-Cost Analysis" (EPA, 1993a). Based on the NCP and the OSWER directive, a discount rate of 7% should be used in developing present value cost estimates for remedial action alternatives during the FS (EPA, 2000c). According to the FS Costing Guidance: "This specified rate of 7% represents a 'real' discount rate in that it approximates the marginal pretax rate of return on an average investment in the private sector in recent years and has been adjusted to eliminate the effect of expected inflation." It should be noted that the “recent years” cited in EPA’s 2000 guidance appear to refer to pre-NCP timeframe, which would place this period in the 1970s, or, alternatively, prior to issuance of OSWER Directive 9355.3-20 in 1993. Although OMB Circular A-94 is updated on an annual basis, the 7% discount rate contained in the main portion of the circular is not updated on an annual basis (EPA, 2000c). The 7% discount rate has been in use since the initial Superfund legislation was passed in 1980 and likely does not reflect current pre-tax return on an average private sector investment. Regardless, the 7% discount rate has been used in the calculation of present worth costs for the remedial alternatives for purposes of this FFS.

The FS Costing Guidance states that there may be circumstances in which it would be appropriate to consider the use of a lower or higher discount rate than 7% for the FS present value analysis if an explanation for use of the different rate is provided. The U.S. Securities and Exchange Commission (SEC) has determined that the appropriate discount rate to be applied to an environmental remediation liability should be the rate that would produce an amount at which the environmental liability could be settled in an arms-length transaction with a third party (SEC Codification of Staff Accounting Bulletins Topic 5 Miscellaneous Accounting – Y. Accounting and Disclosures Relating to Loss Contingencies Question 1). The SEC further states that the discount rate used to discount cash payments should not exceed the interest rate on monetary assets that are essentially risk-free and have maturities comparable to that of the environmental liability (SEC Codification of Staff Accounting Bulletins Topic 5 Miscellaneous Accounting – Y. Accounting and Disclosures Relating to Loss Contingencies Question 1). Treasury bills are a primary investment tool that is essentially risk-free. According to the latest (February 12, 2016) Office of Management and Budget (OMB) Circular A-94 Appendix C 30-year, the Real Interest Rates on Treasury Notes and Bonds for a 30-year period is 1.5 percent. This rate has also been applied to the present worth analyses.

6.1.8 State Acceptance

This criterion involves technical and administrative concerns that the state may communicate in its comments concerning the alternatives addressed in an FS. State acceptance will initially be evaluated based on comments provided by MDNR on this FFS. A final evaluation of state acceptance will be performed by EPA as part of any decision process that may be undertaken by EPA after completion of the FFS.

6.1.9 Community Acceptance

Community acceptance will be evaluated by EPA as part of any decision process that may be undertaken by EPA after completion of the FFS.

6.2 Detailed Analysis of Alternatives

This section provides a detailed analysis of five potential alternative remedies for the Site: (1) No Action alternative; (2) the ROD-Selected Remedy (regrading and enhanced capping); (3) "complete rad removal"; (4) partial excavation of RIM with activity levels above 52.9 pCi/g located within 16 feet of the 2005 topographic surface; and (5) partial excavation of RIM with activity levels greater than 1,000 pCi/g.[32] Each of these alternatives is assessed against the nine NCP evaluation criteria described above.

6.2.1 No Action Alternative

This section presents the description and detailed analysis of the No Action alternative. Under the No Action alternative, no additional engineering measures[33] would be implemented to reduce potential exposures or control potential migration of COPCs from Areas 1 and 2 and no maintenance would be performed to ensure the integrity of the existing measures. Similarly, no additional institutional controls would be imposed beyond those already in place at the Site, and no additional fencing would be implemented to control land use, access, or potential future exposures to potential receptors at or near Areas 1 and 2. Because the existing institutional controls cannot be removed or modified without the approval of the land owner(s), EPA and MDNR, the existing institutional controls are assumed to remain in effect as part of the No Action alternative. The Site continues to be an active industrial facility to which access is controlled (including fencing and 24-hour security). It is anticipated that the industrial uses currently ongoing at the Site would continue into the future, and it is assumed that the existing fencing and access controls would remain in effect for the No Action alternative. It is also assumed that no monitoring would be conducted under the No Action alternative to identify or evaluate any potential changes that may occur to conditions at Areas 1 and 2 or to contaminant levels or occurrences. As RIM and other wastes would remain on-site, a five-year review would be performed by EPA as part of the implementation of the No Action alternative.

Because the No Action alternative does not include any active engineering measures, this alternative is not consistent with the NCP expectation that engineering controls, such as containment, should be used for waste that poses a relatively low long-term threat or where treatment is impracticable. The No Action alternative serves as the baseline for comparison of the effectiveness of the other alternatives and is therefore evaluated in this FFS, as required by the NCP, EPA's SOW for the RI Addendum and FFS (EPA, 2015b), and EPA's RI/FS guidance documents (EPA, 1988a and 1993b).

---

[32] Initial evaluation of a risk-based criterion reflective of the industrial land use at the Site was previously performed (Auxier & Associates, 2016b) and resulted in a criterion of 1,000 pCi/g. Because this value was the same as the value selected by EPA for one of the partial excavation alternatives (EPA, 2015b), a separate alternative was not developed. EPA has indicated that it would like additional evaluations of the industrial risk-based level to be performed. If such evaluations result in identification of a value other than 1,000 pCi/g, an additional partial excavation alternative may be developed and evaluated in a subsequent draft of the FFS.

[33] Prior actions include installation of the non-combustible cover, fencing and signage on Areas 1 and 2.

6.2.1.1 Overall Protection of Human Health and the Environment

Based on the results of the BRA evaluations (Auxier, 2000 and 2016a), conditions associated with OU-1 do not currently pose an unacceptable risk to on-site workers or the off-site community, assuming the existing institutional controls are maintained, monitored and enforced. The BRA analyses indicated that the potential risks posed to a future groundskeeper[34] working in Areas 1 and 2 could be above the generally accepted risk range used by EPA. The BRA evaluations were dependent on the assumed frequency and duration that potential future on-site workers would be present in Areas 1 and 2 at some point in the future. Potential future risks to other on-site workers, off-site commercial building users, a hypothetical off-site farmer, and off-site residents and the general public were within EPA's accepted risk range. As the surface of Areas 1 and 2 is not currently covered by a landfill cover meeting the requirements of the MDNR solid waste regulations, infiltration into and erosion of these areas poses a potential risk to human health and the environment in the future.

The No Action alternative does not provide for monitoring and enforcement of institutional controls which are necessary to ensure overall protection. Additionally, this alternative does not provide for monitoring and maintenance of Areas 1 and 2, which would also be necessary to ensure overall protection. Lastly, this alternative does not address all the pathways identified by the RAOs. Therefore, the No Action alternative is not considered to be protective of human health and, absent appropriate response actions, the Site poses an unacceptable risk over the long term.

6.2.1.2 Compliance with ARARs

Chemical-specific ARARs that may potentially be applicable or relevant and appropriate to OU-1 are the UMTRCA radon emission and groundwater protection standards; the radon NESHAP; the NRC standards for protection against radiation; and the Missouri MCLs for radionuclides, VOCs, inorganic chemicals and other parameters (Table 3-1). The No Action alternative is expected to meet some but not all of these potential chemical-specific ARARs. Overall radon emissions for Areas 1 and 2 were measured and found to be well below the UMTRCA standard and radon NESHAP of 20 pCi/m^2s and the radon standard outside of the Area 1 and 2 disposal areas (see RI Addendum Section 7.1.1.1). Although individual groundwater wells have shown some isolated occurrences of chemical or radiological constituents (*e.g.*, radium) at levels slightly above the UMTRCA groundwater protection standards and the Missouri MCLs, many of these occurrences, including the highest radium activities found in groundwater beneath the Site, were reported in monitoring wells located upgradient of Areas 1 and 2. In addition, the USGS (2014) concluded that that there is not a strong spatial association of monitoring wells surrounding or downgradient of RIM areas with elevated radium concentrations, as might be expected if RIM areas were releasing substantial quantities of radium to the groundwater. EPA has indicated that additional evaluations of groundwater will be conducted in the future as part of the OU-3 RI/FS. Current air monitoring (Auxier and EMSI, 2015a, 2016b and 2016c) and health

---

[34] The updated Baseline Risk Assessment (Auxier, 2016a) concluded that a future groundskeeper was the potential receptor with the reasonably-maximum exposure.

and safety monitoring performed during the Phase 1 and additional characterization investigations conducted in 2013, 2014 and 2015 indicate that the conditions in and around Areas 1 and 2 meet the NRC standards for protection against radiation. Although conditions associated with Areas 1 and 2 currently meet all of these chemical-specific ARARs, without installation and maintenance of additional engineering controls, continued compliance with these standards cannot be ensured.

The No Action alternative is expected to meet all of the location-specific ARARs identified in Section 3.1.2 of this FFS.

Because there are no active engineering measures or waste handling, treatment, or disposal activities associated with the No Action alternative, there are no action-specific ARARs for this alternative.

6.2.1.3 Long-Term Effectiveness and Permanence

All current and potential future risks would remain under the No Action alternative. Without monitoring and maintenance of Areas 1 and 2, the No Action alternative would not be effective in meeting the RAOs. As indicated above, future activities such as groundskeeping that may be performed in Areas 1 and 2 could result in potential risk levels to on-site workers above the generally accepted risk range used by EPA for CERCLA actions. Because the surfaces of Areas 1 and 2 do not currently meet the MDNR cover requirements for inactive solid waste landfills, infiltration into, and erosion off of, these areas poses an overall potential risk to human health and the environment in the future.

The existing institutional controls cannot be changed without the agreement of EPA and MDNR; however, by their nature, institutional controls are not considered to be permanent. The No Action alternative does not provide the same degree of long-term effectiveness as would be achieved by active engineered measures. The No Action alternative contains no provisions to stabilize or maintain the physical integrity of the disposal units in Areas 1 and 2, and there are no provisions to monitor and maintain existing institutional or access controls. Therefore, the No Action alternative may not be effective over the long-term at reducing risks to potential future receptors.

6.2.1.4 Reduction of Toxicity, Mobility, and Volume through Treatment

The No Action alternative does not include any treatment measures and therefore there would be no reduction in contaminant toxicity, mobility or volume through treatment associated with this alternative. Similarly, no treatment residuals would be generated by this alternative.

6.2.1.5 Short-Term Effectiveness

Because there are no active remediation measures included in the No Action alternative, it does not pose any unacceptable short-term risks or other adverse impacts. Because no remedial action would be taken under the No Action alternative, no short-term risks to the community or to workers from implementation of this action would occur. Similarly, no environmental impact from construction activities would occur.

The RAOs of (1) preventing direct contact with landfill contents and exposure to radiation; (2) minimizing infiltration and any resulting contaminant leaching to groundwater; (3) controlling surface water runoff and erosion and decreasing the potential for erosion and subsequent transport of RIM; and (4) controlling radon and landfill gas emissions from Areas 1 and 2 would not be met by the No Action alternative.

6.2.1.6 Implementability

Because no active or passive remedial technologies would be implemented under the No Action alternative, there are no technical implementability concerns or issues associated with the No Action alternative. There are no engineering or administrative impediments to implementation of the No Action alternative for Areas 1 and 2.

6.2.1.7 Costs

Because no active or passive engineering measures or monitoring would be performed, the only costs anticipated to be associated with the No Action alternative are costs associated with performance of five-year reviews. A periodic (every 5 years) cost of $35,000 is estimated to perform the activities that would be associated with a five-year review. The estimated present worth costs under the 7% discount rate scenario for performance of five-year reviews over periods of 30 years, 200 years and 1,000 years are estimated to be $82,000, $94,000 and $94,000, respectively. Under the 1.5% discount rate scenario, the 30-, 200-, and 1,000-year present worth costs are estimated to be $165,000, $437,000, and $456,000, respectively. Present worth calculations for the No Action alternative are provided in Appendix K-2.

6.2.2 Regrading and Enhanced Capping (ROD-Selected Remedy)

As discussed in Section 5.3, the ROD-selected remedy consists of the following components:

- Installation of a landfill cover meeting the Missouri closure and post-closure care requirements for sanitary landfills, including enhancements consistent with the standards for uranium mill tailing sites (*i.e.*, armoring layer and radon barrier), and inclusion of flood protection measures along the toe of Area 2.

- Survey and identification of the presence and extent of radiologically-impacted soil on the Buffer Zone and Crossroads Property.

- Excavation of any soil containing radionuclides above levels that would allow for unrestricted use from the Buffer Zone and/or Crossroads Property and consolidation of the excavated soil within Areas 1 or 2.

- Application of groundwater monitoring and protection standards consistent with requirements for uranium mill tailing sites and sanitary landfills.

- Design, installation and maintenance of surface water runoff controls.

- Gas monitoring and control, including radon and decomposition gas as necessary.

- Institutional controls to prevent land and resource uses that are inconsistent with a closed sanitary landfill site containing long-lived radionuclides.

- Long-term surveillance and maintenance of the remedy.

The ROD-selected remedy consists of regrading (cutting and filling) the existing landfill materials along with placement of additional soil or clean fill material (as defined in the Missouri solid waste regulations [10 CSR 80-2.010(11)]) over Areas 1 and 2 to adjust the final grades to achieve minimum slope angles of 2% and maximum angles of 25%. Portions of the landfill berm that contain slopes greater than 25% would be regraded through construction of a perimeter "starter" berm, regrading the existing landfill materials, and/or placing additional material to reduce the slope angles to 25% or less. The method used to regrade the perimeter portions of Areas 1 and 2 would be subject to physical constraints associated with the location of the toe of the landfill relative to the property boundary or adjacent Site features (*e.g.*, the solid waste transfer station access road).

Upon completion of the landfill regrading, a new RCRA Subtitle D-equivalent landfill cover would be constructed over Areas 1 and 2 consistent with the MDNR final cover requirements for operating sanitary landfills without composite liners. The final cover system would encompass approximately 24 acres for Area 1 and 51 acres for Area 2. Although not required for a Subtitle D cover, a layer of well-graded rock or concrete/asphaltic-concrete rubble would be installed immediately beneath the clay layer to minimize the potential for bio-intrusion and erosion, increase the longevity of the landfill cover, and enhance the radon attenuation capability of the cover system. Surface drainage diversions, controls and structures would also be designed and constructed on the surface of or adjacent to the landfill cover as necessary to route non-impacted, uncontaminated stormwater (stormwater that has not contacted the underlying waste materials) off of Areas 1 and 2 onto the adjacent areas of the Site or into off-site storm water drainage systems.

The cover system under the ROD-selected remedy would consist of the following layers (from top to bottom):

- A one-foot-thick layer of soil capable of sustaining vegetative growth;

- A two-foot-thick infiltration layer of compacted, low-permeability clay soil with a permeability coefficient of 1 x 10^{-5} cm/sec or less; and

- A two-foot-thick bio-intrusion/erosion protection layer consisting of well-graded rock or concrete/asphaltic concrete rubble consisting of pieces up to 8 inches in size.

A geosynthetic clay liner (GCL) could be added to or used as a replacement for the two-foot-thick compacted clay layer (CCL). Because installation of a GCL would require placement of a bedding layer and an overlying protective or drainage layer, it has been assumed for purposes of the FFS that the thickness of the infiltration layer would be two feet with or without inclusion of a GCL.

Sampling would be performed to evaluate the presence and extent of radiologically-impacted soil that may still be present on the Buffer Zone/Crossroads Property. To the extent that soil containing radionuclides at levels greater than those which would allow for unrestricted use are present on these areas, this soil would be removed and placed into Area 1 or 2. Based on sampling performed during the RI prior to subsequent regrading and placement of gravel cover by the adjacent property occupant in these areas, it was estimated that radionuclides may be present on approximately 1.78 acres to a depth of one foot, resulting in approximately 2,900 bank cubic yards (bcy) of potentially impacted soil.

The existing institutional controls on Areas 1 and 2 and the Buffer Zone would be maintained, and any modifications or additions to these that EPA determines are necessary would be implemented as needed as part of the ROD-selected remedy. The institutional controls are necessary to ensure that residential uses do not occur at the Site, and that commercial and industrial uses or ancillary uses that could result in unacceptable risks do not occur on Areas 1 and 2 or the Buffer Zone. In addition to prohibiting land uses that could result in potential exposure to waste materials or contaminants in the Site, institutional controls would also limit or prohibit land uses or activities that could disrupt the integrity, performance or longevity of the new landfill cover or other components of the remedy. Landfill gas and groundwater monitoring, as described in Sections 5.3.1.6 and 5.3.1.9, respectively, are also included as part of the ROD-selected remedy. Finally, the ROD-selected remedy calls for long-term inspections and maintenance activities of the engineered components (Section 5.3.1.9) and enforcement of the institutional controls (Section 5.3.2.1).

6.2.2.1 Overall Protection of Human Health and the Environment

The ROD-selected remedy would protect human health and the environment through the use of engineered containment, long-term surveillance and maintenance, and institutional controls on land and resource use. The landfill cover would reduce potential risks from exposure to external gamma radiation or radon gas emissions, and eliminate potential risks associated with inhalation or ingestion of contaminated soils or other wastes, dermal contact with contaminated soils or other wastes, and wind dispersal of fugitive dust.

The cover would prevent users of the Site from exposure to external gamma radiation, primarily through shielding and increasing the distance to the radiation source (*i.e.*, the cover materials would be of sufficient thickness and design to attenuate gamma radiation). For the types of clay soils used for infiltration protection in the construction of final covers, the depth of cover required for gamma radiation shielding is on the order of two feet (60 cm). The total thickness of the final cover required by the ROD-selected remedy would be a minimum of five feet (two feet of biointrusion rock/rubble, two feet of clay soil, and one foot of vegetative soil).

The cover materials would also be of sufficient thickness and design to retard or divert the vertical upward migration of radon. The landfill cover would act as a diffusion barrier, allowing time for the decay of the relatively short-lived radon-222 gas (the half-life for radon-222 is 3.8 days) during migration through the pore spaces of the cover soil. Radon needs only to be detained in the cover materials for a few days in order to decay to its non-radiological progeny, thereby eliminating any significant radon emissions. The radon may also be intentionally vented or diverted to a gas control system. Calculations presented in Appendix F indicate that a clay layer thickness of two feet, combined with a two-foot thick rock/rubble layer and a one-foot thick vegetative layer, would provide sufficient radon attenuation to meet the radon emissions ARAR of 20 picocuries per square meter per second (pCi/m^2s). As discussed in Appendix F, these calculations were based on the increased levels of radium expected to be present at the Site after 1,000 years of in-growth of radium from decay of thorium.

The potential for direct contact with waste materials would be eliminated by placing a barrier (multi-layer landfill cover including bio-intrusion layer) between the waste materials and any potential receptors. Likewise, there would be no potential for the generation of fugitive dust from the waste material as long as the barrier remains in place.

The multi-layer cover would also be designed to minimize infiltration of surface water through the wastes, thereby reducing the potential for leaching of contaminants to the groundwater. This is typically accomplished by promoting surface drainage and using a hydraulic barrier (e.g., a compacted clay layer meeting the specified permeability requirements). These are all conventional functions for landfill cover technologies and are widely used by government and industry to address similar circumstances where contaminated materials must be encapsulated to protect against future potential contact. Long-term maintenance of the cover and monitoring of the groundwater would ensure that the ROD-selected remedy functions as intended.

The ROD-selected remedy also requires monitoring of groundwater quality to ensure that groundwater quality at the perimeter of the Site meets state standards or other ARARs.[35] Monitoring of subsurface occurrences of landfill gas and radon and, if necessary, implementation of contingent landfill gas extraction along the perimeter of Areas 1 and 2 would be performed to ensure that gas migration above regulatory thresholds does not occur beyond the Site perimeter.

Institutional controls (as described above) would ensure that land and resource uses are consistent with permanent waste disposal. The use restrictions reflect the presence of radionuclides at the Site.

6.2.2.2 Compliance with ARARs

The ROD-selected remedy would comply with all ARARs, as explained below.

6.2.2.2.1 Missouri Solid Waste Rules for Sanitary Landfills

Under RCRA Subtitle D, a state may promulgate more stringent regulations for landfills, provided that EPA approves them. Missouri is an approved state for regulating landfills. Missouri's solid waste regulations became effective July 1, 1997 (see 22 Mo. Reg. 1008, June 2, 1997) (the Solid Waste Rules). The Solid Waste Rules establish closure and post-closure requirements for existing sanitary landfills that are closed after October 9, 1991. Although not applicable to the closure of Areas 1 and 2, the Missouri Solid Waste Rules described below are considered relevant and appropriate. The ROD-selected remedy meets these ARARs.

The Solid Waste Rules require cover to be applied to minimize fire hazards, precipitation infiltration, and odors and blowing litter, as well as to control gas venting and vectors, discourage scavenging, and provide a pleasing appearance (10 CSR 80-3.010(17)(A)). Final cover is to consist of at least two feet of compacted clay with a coefficient of permeability of 1×10^{-5} cm/sec or less, overlaid by at least one foot of soil capable of sustaining vegetative growth (10 CSR 80-3.010(17)(C)(4)). Placement of soil cover addresses the requirements for minimization of fire hazards, odors, blowing litter, control of gas venting, and scavenging. Placement of clay meeting the permeability requirement addresses the requirement for minimizing precipitation infiltration. Placement of soil and establishment of a vegetative cover meet the requirement of providing a pleasing appearance. The final cover would prevent Site users from coming into contact with the waste material.

The Solid Waste Rules also contain minimum and maximum slope requirements. Specifically, these regulations require the final slope of the top of the sanitary landfill to have a minimum slope of 5% (10 CSR 80-3.010(17)(B)(7)). MDNR regulations also require that the maximum slopes be less than 25%, unless it has been demonstrated in a detailed slope stability analysis that steeper slopes can be constructed and maintained throughout the entire operational life and post-

[35] After issuance of the ROD in 2008, EPA announced its intention to address groundwater at the Site as part of an entirely separate operable unit (OU-3).

closure period of the landfill. Even with such a demonstration, no active, intermediate, or final slope may exceed 33.33%.

The objective of these requirements is to promote maximum runoff without excessive erosion and to account for potential differential settlement. Because landfilling of Areas 1 and 2 was completed approximately 30 years ago, most compaction of the refuse has taken place and differential settlement is no longer a significant concern. The 5% minimum sloping requirement is greater than necessary and may not be optimal in this case. Therefore, the 5% minimum sloping requirement is not considered appropriate. Sloping specifications would be designed to promote drainage and reduce infiltration of precipitation while minimizing the potential for erosion. It is anticipated that a 2% slope would be sufficient to meet drainage requirements while resulting in a lower potential for erosion. This approach should increase the life of the cover and overall longevity of the remedy compared to a steeper slope, which would be subject to increased erosion potential. The maximum sloping requirements would be met.

The requirements for decomposition gas monitoring and control in 10 CSR 80-3.010(14) are considered relevant and appropriate (Section 3.1.3.2) and would be met. The number and locations of gas monitoring points and the frequency of measurement would be established in RD submittals to be approved by EPA and MDNR. In the event landfill gas is detected at the Site boundaries above the regulatory thresholds, appropriate gas controls would be implemented.

The requirements for a groundwater monitoring program in 10 CSR 80-3.010(11) are considered relevant and appropriate (Section 3.1.3.2.1). The monitoring program must be capable of monitoring any potential impact of the Site on underlying groundwater. The monitoring program would enable the regulatory agencies to evaluate the need for any additional requirements.

The substantive MDNR landfill requirements for post-closure care and corrective action found in 10 CSR 80-2.030 are also considered relevant and appropriate. These provisions provide a useful framework for OM&M and corrective action plans. They require post-closure plans describing the necessary maintenance and monitoring activities and schedules. These requirements would be used in addition to EPA CERCLA policy and guidance on developing robust OM&M and long-term monitoring plans.

6.2.2.2.2 Environmental Protection Standards for Uranium and Thorium Mill Tailings

The Health and Environmental Protection Standards for Uranium and Thorium Mill Tailings (40 CFR 192 Subpart B) provide standards for land and buildings contaminated with residual radioactive materials from inactive uranium processing sites. The standards were developed pursuant to the Uranium Mill Tailings Radiation Control Act of 1978 (UMTRCA) (42 U.S.C. § 2022 et. seq.,). Although not applicable, some of the regulations that provide for closure performance standards are considered potentially relevant and appropriate to the ROD-selected remedy for OU-1. Specifically, to address longevity considerations, 40 CFR § 192.02(d) requires that each disposal site "be designed and stabilized in a manner that minimizes the need for future maintenance." For UMTRCA tailings piles, the longevity consideration has often been addressed through placement of a rock armoring layer over the upper surface of the tailings pile capping system. To address longevity considerations for OU-1 and long-term hazards relating to disruption of the disposal site by natural phenomena, the ROD-selected remedy would use a hybridized cover system which incorporates a rock or concrete rubble layer under the clay soil layer to restrict biointrusion and erosion into the underlying landfilled materials.

Three chemical-specific standards of the UMTRCA regulations are considered potentially relevant and appropriate (although not applicable) to OU-1. In particular, the radon emission and groundwater protection standards for closed uranium tailing units are considered to be potentially relevant and appropriate standards for Areas 1 and 2. The unrestricted use standards for soil on vicinity properties are considered to be potentially relevant and appropriate for the evaluation and remediation of any remaining radionuclide occurrences on the Buffer Zone or Crossroads Property. The applicability of these chemical-specific standards to the ROD-selected remedy is discussed further below.

First, Subpart A of the UMTRCA standards provides that control of residual radioactive materials (defined to mean waste in the form of tailings resulting from the processing of ores for the extraction of uranium and other valuable constituents) and their listed constituents shall be designed to provide reasonable assurance that the release of radon-222 from residual radioactive materials to the atmosphere will not exceed an average release rate of 20 pCi/m^2s (40 CFR §192.02 (b)(1)). For inactive sites, this standard can be satisfied by providing reasonable assurance that releases of radon-222 from residual radioactive materials to the atmosphere will not increase the annual average concentration of radon-222 in air at or above any location outside the disposal site by more than one-half of a picocurie per liter (0.5 pCi/L) (40 CFR § 192.02(b)(2)). As discussed in Section 7.1.1.1 of the RI Addendum (EMSI, 2016b), radon flux measurements performed in 2016 demonstrate that Areas 1 and 2 currently meet this standard. The ROD-selected remedy would ensure that the radon emission standard promulgated under UMTRCA continues to be met in the future through placement of clean fill material and construction of the landfill cover. The landfill cover system would be designed appropriately to take into consideration future radon generation resulting from increased radium levels owing to the decay of thorium over time. Evaluations presented in Appendix F indicate that the landfill cover included in the ROD-selected remedy would provide sufficient radon attenuation to ensure such that future surface emissions from Areas 1 and 2 would meet the UMTRCA radon standard.

Second, the UMTRCA regulations establish concentration limits for groundwater protection (see discussion in Section 3.1.1.4). Based on the presence of radioactive materials in OU-1, the groundwater protection standards (40 CFR § 192.02(c)(3) and (4)) and monitoring requirements (40 CFR § 192.03) are relevant and appropriate and would be met. Specifically, regrading of the landfill surface to promote stormwater drainage and installation of an engineered landfill cover under the ROD-selected remedy would greatly reduce the potential for infiltration through, and generation of leachate within, the landfill mass in Areas 1 and 2, thereby preventing infiltration of radionuclides to groundwater.

Third, the standards for cleanup of land and buildings contaminated with residual radioactive materials in Subpart B of the UMTRCA regulations are potentially relevant and appropriate requirements for the remediation of any radiologically-impacted soil that may be present outside of Areas 1 and 2 (*e.g.*, on the Buffer Zone/Crossroads Property). UMTRCA defines "land" to mean any surface or subsurface land that is not part of a disposal site and is not covered by an occupiable building. These soil standards address the remediation of soil contaminated with radium. Specifically, 40 CFR § 192.12(a) states:

> The concentration of Ra-226 in land averaged over any area of 100 square meters shall not exceed the background level by more than:
>
> 1. 5 pCi/g, averaged over the first 15 centimeters of soil below the surface; and
>
> 2. 15 pCi/g, averaged over 15-centimeter-thick layers of soil more than 15 centimeters below the surface.

The EPA has promulgated guidance on the use of these UMTRCA soil standards for CERCLA site cleanups ("Use of Soil Cleanup Criteria in 40 CFR Part 192 as Remediation Goals for CERCLA Sites," OSWER Directive 9200.4-25, February 12, 1998 (the UMTRCA Guidance)). This guidance document was discussed in detail in Section 3.1.1.3 of this FFS. In brief, the UMTRCA Guidance states that the subsurface concentration criterion (15 pCi/g) is not a health-based standard; rather, it was developed for use in limited circumstances that, for most CERCLA sites, are not considered sufficiently similar to UMTRCA sites to warrant use of the 15 pCi/g standard for subsurface soil (EPA, 1998). EPA also determined that although the UMTRCA soil standards were developed for Ra-226, they are also suitable for Ra-228. EPA further determined that the soil standards should be applied to both the combined level of Ra-226 and Ra-228 and the combined level of Th-230 and Th-232. These UMTRCA soil cleanup standards for vicinity properties, as modified by the UMTRCA Guidance, are considered potentially relevant and appropriate criteria for evaluation and cleanup of radionuclides in soil on the Buffer Zone and Crossroads Property. The ROD-selected remedy would satisfy the UMTRCA soil standards through further investigation of radionuclide occurrences in soil outside of Areas 1 and 2 and removal of soil that exceeds these standards, including removal of soil on the Buffer Zone and the adjacent Crossroads Property and consolidation of such soil in Areas 1 and 2.

6.2.2.2.3 National Emissions Standards for Hazardous Air Pollutants (NESHAPs)

EPA's National Emissions Standards for Hazardous Air Pollutants (NESHAPs) include standards for radon-222 emissions to ambient air from designated uranium mill tailings piles that are no longer operational. As discussed in Section 3, the radon-222 NESHAP is considered to be potentially relevant and appropriate. As discussed in Section 7.1.1.1 of the RI Addendum (EMSI, 2016b), radon flux measurements performed in 2016 demonstrate that Areas 1 and 2 currently meet the NESHAP radon standard. The ROD-selected remedy would ensure the radon emission standard continues to be met, through placement of clean fill material and construction of the landfill cover. Evaluations presented in Appendix F indicate that the landfill cover system included as part of the ROD-selected remedy would provide sufficient radon attenuation to ensure that the radon NESHAP standard is met in the future, accounting for future radon generation resulting from increased radium levels owing to the decay of thorium over time.

Additional evaluations to demonstrate the ability of the landfill cover to meet the radon NESHAP may be performed as part of the remedial design.

6.2.2.2.4 Safe Drinking Water Act

40 CFR Part 141 establishes primary drinking water regulations, including maximum contaminant levels (MCLs) pursuant to Section 1412 of the Public Health Service Act, as amended by the Safe Drinking Water Act (SDWA), and related regulations applicable to public water systems. These MCLs apply to public drinking water systems. Missouri regulations (10 CSR 60-4.010 et seq.) also establish MCLs for public drinking water systems (Table 3-1). Consistent with the NCP, MCLs and non-zero Maximum Contaminant Level Goals (MCLGs) are considered potentially relevant and appropriate to all potentially usable groundwater. Regardless of whether groundwater beneath the Site is subsequently determined to be usable for drinking water, regrading of the landfill surface to promote stormwater drainage and installation of an engineered landfill cover under the ROD-selected remedy would greatly reduce the potential for infiltration through, and generation of leachate within, the landfill mass in Areas 1 and 2, thereby preventing infiltration of radionuclides to groundwater.

6.2.2.2.5 NRC Standards for Protection Against Radiation

The NRC Standards for Protection Against Radiation (10 CFR Part 20) contain chemical-specific standards that address radiation protection. These regulations establish dose limits for individual members of the public and for radiation workers and define maximum permissible exposure limits for specific radionuclides in air at levels above background inside and outside of controlled areas. These requirements are considered potentially applicable during implementation of any remedial action. Specifically, to meet these regulations, perimeter air monitoring would be conducted during remedy implementation. Site health and safety plans would address worker protection consistent with these requirements (including perimeter air monitoring); therefore, the ROD-selected remedy would meet this ARAR.

6.2.2.2.6 Missouri Well Construction Code

MDNR has promulgated regulations pertaining to the location and construction of water wells. The Well Construction Code (10 CSR 23-3.010) prohibits the placement of a well within 300 feet of a landfill. These rules should provide protection against the placement of wells on or near the Site. The regulations on monitoring well construction (10 CSR 23-4) would apply to the construction of new or replacement monitoring wells. The ROD-selected remedy would meet this ARAR through enforcement of the existing institutional controls[36] and by adhering to the Well Construction Code requirements for installation of new monitoring wells or abandonment of existing monitoring wells.

---

[36] In addition, the deed restrictions currently in place on Areas 1 and 2 and the Buffer Zone (and which are to be maintained in perpetuity as part of the ROD-selected remedy) prohibit the placement of water wells for drinking water or agricultural purposes.

6.2.2.2.7 Missouri Storm Water Regulations

The Missouri regulations governing storm water management at construction sites are set out in 10 CSR 20-6.200 (Table 3-3). A disturbance of greater than one acre or the creation of a storm water point source during construction of the remedy would trigger these requirements. The ROD-selected remedy would meet these requirements through implementation of a Stormwater Pollution Prevention Plan (SWPPP), use of Best Management Practices (BMPs) during construction, installation and maintenance of an engineered landfill cover to prevent stormwater from contacting the waste materials, and construction and maintenance of stormwater diversion and control structures to control runon and runoff and reduced erosion potential as part of the design of the engineered landfill cover.

6.2.2.3 Long-Term Effectiveness and Permanence

These criteria refer to expected residual risk and the ability of a remedy to maintain reliable protection of human health and the environment over time. The ROD-selected remedy provides engineered containment in conjunction with long-term monitoring, maintenance, and land use controls designed to be effective over the long term. Because RIM would remain on-site under this remedy alternative, potential risks associated with the RIM would remain. Construction of an engineered cover for Areas 1 and 2 would reduce the potential for exposure from the following potential pathways: external gamma exposure; inhalation of radon gas or dust containing radionuclides or other constituents; dermal contact with impacted materials; and incidental ingestion of soil containing radionuclides or other chemicals. Maintaining the integrity of the engineered cover would protect the underlying RIM from erosion and intrusion. An intact cover provides a reliable method to control exposure of the RIM to surface receptors and mitigates potential migration of radionuclides or chemicals from the covered waste materials.

Long-term site management plans and institutional controls would be robust and durable. Long-term groundwater monitoring (as required under the ROD-selected remedy) would be effective in verifying the remedy is performing as required and groundwater is protected. While not anticipated, even with the loss of institutional controls and long-term management, the landfill cover would still act to passively prevent potential contaminant migration and human exposures for an indefinite period.

By moving the radiologically-impacted soil from the Buffer Zone/Crossroads Property to the Site (and thereby subjecting it to the remedial measures and controls described above), the ROD-selected remedy provides long-term effectiveness and permanence relative to the Buffer Zone/Crossroads Property.

6.2.2.3.1 Magnitude of Residual Risks

The calculated lifetime risks to the reasonably maximally-exposed individual (an on-site groundskeeper) from Areas 1 and 2 after the ROD-selected remedy has been implemented (Appendix H) are as follows:

- Area 1: <1 x 10^{-7} for year 1 and <1 x 10^{-7} for year 1,000; and
- Area 2: <1 x 10^{-7} for year 1 and <1 x 10^{-6} for year 1,000.

These calculated risks are attributable to gamma radiation and radon emissions from the RIM that would remain at the Site after implementation of the ROD-selected containment remedy. Given that the RIM would be capped and thus rendered inaccessible, along with the use of access restrictions and institutional controls, direct contact with RIM and exposure from ingestion, inhalation, or dermal contact with the waste materials would not be expected to occur. Ingestion, inhalation or dermal contact are the primary exposure pathways for any non-radiological COPCs that may also be present in Areas 1 and 2. Because no complete exposure pathway would exist for such materials after completion of the cap construction, the landfill waste materials would not be expected to produce non-carcinogenic effects or carcinogenic risks from non-radiological COPCs.

The calculated risk levels are below EPA's target risk range of 1 x 10^{-6} to 1 x 10^{-4}, and therefore the magnitude of the radiological carcinogenic risk from capped RIM in these two remediated areas is acceptable. These risks do not specifically include potential exposures from non-radiological landfill waste after construction is complete; however, those wastes would also be covered by a cap which would prevent exposures. Additional information regarding the risk assessment calculations is presented in Appendix H.

After soils containing radionuclide concentrations above the cleanup levels are removed from the Buffer Zone/Crossroads Property, residual risks posed by the remaining radionuclide-impacted soil on these properties, if any, should be indistinguishable from variations in background levels.

6.2.2.3.2 Adequacy and Reliability of Controls

The conceptual design of the engineered cover has been developed to provide protection against all potential exposure pathways. Cover construction is based on and relies upon the use of natural materials that would be expected to remain in place and meet performance criteria for at least 200 years, as required by the UMTRCA ARARs. Post-closure inspection and maintenance of the cover, as required by the solid waste regulation ARARs and as routinely performed at thousands of landfills across the country, also would ensure long-term reliability of the landfill cover.

Currently the surfaces of Areas 1 and 2 are not graded to promote drainage of stormwater, but instead are generally flat with several surface depressions which act to increase precipitation accumulation and infiltration through the waste mass. In addition, no engineered landfill cover exists over these areas. Although the non-combustible cover installed over portions of Areas 1 and 2 in 2016 does reduce the potential for erosion of the waste and soil, reduce radon emissions and gamma radiation, and prevent direct contact with the waste and RIM, it does not promote stormwater drainage or reduce the potential for infiltration of precipitation. Even with these limitations, infiltration of precipitation has not resulted in discernible leaching of radionuclides or other chemicals to groundwater. Regrading to promote drainage and installation of the engineered landfill cover included in the ROD-selected remedy would significantly reduce infiltration of precipitation and potential for leaching, providing further protection against potential impacts to groundwater. Modeling of potential landfill covers conducted as part of the Fate and Transport Evaluations (SSPA, 2016b) indicated that inclusion of a GCL would further reduce the potential for infiltration and therefore provide a greater degree of protection against precipitation infiltration and leaching to groundwater. Although a GCL includes synthetic components which may degrade over time, studies of the projected life of geomembranes exposed to air, water and leachate have indicated that the service life of a geomembrane is on the order of hundreds of years, may exceed 700 years, and would probably be on the order of 1,000 years or longer (Marr and Christopher, 2003; Kavazanjian et al., 2006; National Research Council, 2007; Rowe, Rimal, and Sangam, 2009; Rowe and Rimal, 2008; Rowe and Islam, 2009; Rowe and Jones, 2015; and Benson, 2016). The service life of a GCL is influenced by a variety of factors (Rowe and Jones, 2015), including:

1. Loss of bentonite during placement;
2. Lateral movement;
3. Assumption that the geosynthetic component of the GCL is not critical to long-term performance of the bentonite component;
4. Proper installation performance of the seams;
5. No significant long-term loss of bentonite due to internal erosion through the GCL under hydraulic gradients that may occur;
6. Interaction (e.g., cation exchange) with the adjacent soil impact on hydraulic conductivity.

Temperature is an additional factor affecting the service life of a GCL (Stark, Jafari and Rowe, 2012). Inclusion of a GCL in the engineered cover could also create a potential slip surface that could result in a failure (movement or displacement of portions of the cover material) on steeper slopes. This potential could be addressed by limiting use of a GCL to the upper, flatter (2%) slopes of the final grades of Areas 1 and 2 or potentially through inclusion of a drainage layer above the GCL; however, this approach would need to be evaluated during remedial design.

Long-term OM&M would include routine cover and storm water ditch inspection and service, if necessary, to mitigate erosion and, if a landfill gas collection and treatment system is needed, OM&M of such a system. Long-term monitoring would also be implemented to assess compliance with groundwater standards. The performance of these engineering controls would also be re-evaluated during statutory five-year reviews.

Covenant restrictions (Appendix A) have been recorded by each of the West Lake Landfill property owners against their respective parcels and the entire West Lake Landfill (including

Areas 1 and 2) prohibiting residential use (including use as a day care, preschool, or other educational use) and use of groundwater for drinking water. With respect to the parcels of land that comprise OU-1 (including the Buffer Zone), restated and amended restrictive covenants filed in 2016 (Appendix A) also prohibit (1) the installation and use of wells for drinking water; (2) the construction of buildings or other habitable structures for any purpose; (3) the construction of underground pipes/utilities and excavation work (except in conjunction with approved remedial activities); and (4) use of the property for commercial or industrial purposes, including as a storage yard (whether indoor or outdoor).[37] Covenant restrictions cannot be terminated without the written approval of the parcel owners, MDNR, and EPA.

The current covenants and restrictions for Areas 1 and 2 and the Buffer Zone would be adequate to provide protection to human health under the ROD-selected remedy. Permanence of these restrictions is assumed to be adequate for the foreseeable future, as both EPA and MDNR approval are required to remove or modify the restrictions. The adequacy of the restrictions would be continually evaluated during the statutorily-required five-year reviews.

6.2.2.3.3 Climate Change and Potential Impacts of a Tornado

Per EPA's SOW, the FFS is to include a discussion of climate change and vulnerabilities associated with extreme weather events – such as possible flooding or tornadoes – as part of the evaluation of long-term effectiveness. This evaluation should consider any system vulnerabilities to potential climate change in accordance with EPA's "Climate Change Adaptation Technical Fact Sheet: Landfills and Containment as an Element of Site Remediation (EPA, 2014a) and the EPA Region 7 Climate Change Adaption Implementation Plan (EPA, 2014b). EPA also required the FFS to include information and results from the "Evaluation of Possible Effects of a Tornado on the Integrity of the ROD-Selected Remedy" (EMSI, 2013f).

The ROD-selected remedy includes an engineered landfill cover that would be classified as in-situ containment system (EPA, 2014a). Climate change adaptation for a containment system focuses on evaluating the vulnerability of the system to climate change and implementing adaptation measures, when warranted, to ensure the remedy continues to prevent human or environmental exposure to contaminants of concern (EPA, 2014a).

Evaluation of the vulnerability of a containment system to climate change may involve:

- Identifying climate change hazards of concern;
- Characterizing the system's exposure to those hazards of concern;
- Characterizing the system's sensitivity to the hazards of concern; and
- Considering factors that may exacerbate system exposure and sensitivity.

---

[37] Construction work and commercial and industrial uses were also previously precluded on Areas 1 and 2 by a Supplemental Declaration of Covenants and Restrictions recorded by Rock Road Industries, Inc. in January 1998 prohibiting the placement of buildings and restricting the installation of underground utilities, pipes and/or excavation upon its property. The 2016 Declaration of Covenants amends and restates the requirements of the May 1997 and January 1998 covenants but otherwise does not alter them.

A climate change exposure assessment identifies climate change hazards of concern for a remediation system in light of a range of potential climate and weather scenarios (EPA, 2014a). EPA identified the following potential climate change impacts for landfills and containment remedies:

- Increased occurrence of extreme temperatures;
- Sustained changes in average temperatures;
- Decreased precipitation and increasing drought;
- Increased heavy precipitation events;
- Increased flood risk; and
- Increased intensity of tornadoes.

EPA indicated that precipitation changes that could degrade cover systems is a specific climate change hazard relative to landfills and containment systems.

A climate change sensitivity assessment evaluates the likelihood for the climate change hazards of concern to reduce the effectiveness of a landfill/containment system. Damage to cover materials and a potential washout of contaminated contents, as well as unexpected and additional costs for repairing or replacing a cover system, are particular concerns for a landfill containment system. Specific containment system components included in the ROD-selected remedy that could be affected by climate change include:

- Physical and water damage to the vegetative layer overlying the low-permeability cover layer;
- Physical and water damage to a GCL layer if such a layer were to be included in the cover system;
- Physical or water damage and reduced access to surface water drainage systems and structures; and
- Physical damage or reduced access to groundwater and landfill gas monitoring wells.

In particular, the vegetative layer could be vulnerable to increased occurrences of extreme temperatures, sustained changes in average temperatures, decreased precipitation, and increases in drought occurrences. Increased temperatures or decreased precipitation/drought could affect the viability of the vegetation (*e.g.*, grasses) on the surface of the landfill cover. Any changes to the overall health of the vegetative cover would be readily identifiable by visual inspection. Therefore, although the vegetative cover may be vulnerable to potentially increased temperatures or drought conditions, the potential for impacts to the vegetative layer could be anticipated and readily identified in advance of any such occurrence.

The CCL – or a GCL layer if such material is included in the design of the landfill cover – could be damaged by periods of extended extreme temperatures or prolonged drought. Potential impacts could include desiccation of the low permeability materials (CCL or GCL) with a resultant increase in permeability, which could lead to increased infiltration of precipitation or increased radon emissions. Such impacts are not considered to be significant because the Site has existed for over 40 years with essentially flat (no grade) surfaces and minimal cover material, thereby maximizing precipitation infiltration. Even with this increased potential for infiltration of precipitation through Areas 1 and 2, the USGS (2014) concluded that that there is not a strong spatial association of monitoring wells surrounding or downgradient of RIM areas with elevated radium concentrations, as might be expected if RIM areas were releasing substantial quantities of radium to the groundwater. EPA has indicated that additional evaluations of groundwater would be conducted in the future as part of the OU-3 RI/FS. In addition, even without significant cover material, the radon emissions from the surfaces of Areas 1 and 2 are far below the UMTRCA and NESHAP standards and are projected to remain below these standards in the future (see prior discussion in Section 2.3.1 and also in RI Addendum Section 7.1.1.1). Therefore, even if desiccation of the low-permeability layer were to occur, the impacts to groundwater quality or radon emissions are not expected to be significant. More importantly, the vegetative layer would show significant signs of stress from increased temperatures/drought prior to the occurrence of any impacts to the underlying low-permeability layer, thereby providing advance notice of a potential impact to the CCL/GCL. Therefore, although the low-permeability layer could potentially be vulnerable to effects of increased temperature or drought, the potential for any impacts could be anticipated and readily identified in advance of any such occurrence. In the event that such impacts were to occur, additional maintenance activities such as temporary irrigation to maintain the grass cover, overseeding with grasses that required less water, placement of additional soil to repair erosion, or other typical cover repair measures would be implemented. Further, such impacts are not expected to result in release of contamination.

Increased heavy precipitation events could result in erosion of the vegetation layer and, if left untended, could result in erosion of the underlying low-permeability layer. Any erosion of the landfill cover would be readily identifiable by visual inspection. Given the overall 5-foot thickness of the landfill cover and the inclusion of the 2-foot thick rock layer in the base of the cover system, stormwater erosion – even under the most severe storm event – is not anticipated to result in erosion down through the entire landfill cover. Heavy precipitation events could impact the integrity or performance of stormwater drainage conveyance structures, including erosion of drainage channels, damage to or bypassing of let-down and erosion control structures and features, or damage to stormwater detention structures. Heavy precipitation events could also temporarily restrict access to portions of the landfill cover, stormwater control structures, and environmental monitoring points, thereby causing delays in implementation of repairs (if any are needed). Therefore, the vegetation layer and stormwater controls are potentially vulnerable to impacts from heavy precipitation events; however, due to the overall thickness and design of the landfill cover, any potential impacts are not expected to result in exposure of the waste material or release of contamination. Furthermore, any impacts that occur could be readily addressed as part of normal maintenance and repair of the landfill cover, including localized regrading, repair and replacement of cover material in response to any damage that may occur.

The ROD-selected remedy is not anticipated to be impacted by flooding that may occur in the area of the Site. As previously discussed in Section 2.1.6, FEMA has determined that, with the exception of the easternmost portions of Areas 1 and 2 (which do not contain waste materials), Areas 1 and 2 are located outside of the 500-year floodplain. In addition, areas to the north and west of Area 2 (*e.g.,* Crossroads Industrial Park and Earth City Industrial Park) that potentially could be subject to flooding by the Missouri River are protected by the engineered levee and stormwater and flood control systems installed to protect the Earth City Industrial Park. Further, the conceptual design for the ROD-selected remedy includes construction of a perimeter (starter) berm along the toe of the entire northern boundary of Area 2 that would result in placement of approximately 25 feet of rock and soil between any possible floodwaters and the landfilled waste. This perimeter berm may be further protected from flooding by placement of rip-rap along the base of the berm. Therefore, although increased occurrences of flooding in the area of the Site may be a potential impact of climate change, the ROD-selected remedy is not expected to be vulnerable to flooding.

An evaluation of the potential impacts of a tornado on the ROD-selected remedy was previously performed and submitted to EPA (EMSI, 2013f). This evaluation concluded that the ROD-selected remedy was not vulnerable to impacts from a tornado. Specifically, a tornado is not expected to damage the vegetative layer, and, even if it did, such an impact is not considered to be significant because it could be easily identified. Further, due to the design and thickness of the engineered cover, any impacts from a tornado are not expected to result in exposure of the underlying waste or release of contamination. A tornado could damage or destroy above-ground infrastructure such as signage, fencing or environmental monitoring equipment; however, such impacts are not expected to be significant because they would be readily identified and easily repaired or replaced. Therefore, the ROD-selected remedy is not considered to be vulnerable to impacts from a tornado.

Although the ROD-selected remedy is not considered to be vulnerable to climate change, implementation of adaptation measures could nevertheless be considered during remedial design. Several aspects of the conceptual design of the ROD-selected remedy already provide a degree of adaptation for climate change. For example, regrading of the surface of Areas 1 and 2 to a 2% slope would reduce the velocity of runoff across these areas. Installation of runoff collection and diversion systems along the base of the above-grade portion of the North Quarry part of the Bridgeton Landfill adjacent to Area 1, as well as along the north sides of the Closed Demolition Landfill and the Inactive Sanitary Landfill adjacent to Area 2, would divert runoff from these areas around Areas 1 and 2 to reduce the potential for impacts from heavy precipitation events. Identification and evaluation of additional adaptation measures can be addressed as part of the design of the engineered landfill cover and stormwater controls in order to increase the overall resilience of these features to heavy precipitation events. For example, use of grass-seed mixtures that are more tolerant of long-term changes in precipitation or temperature, and/or additional soil to increase water storage capacity, could be evaluated as part of the design. Similarly, inclusion of geotextile at the base of the vegetative layer could be considered to minimize the potential for water or wind erosion extending down into the underlying low-permeability layer of the cap. The design grades of the stormwater conveyance structures could be evaluated to provide a balance between the ability to quickly route stormwater away from Areas 1 and 2 while minimizing the stormwater velocity and the associated potential for erosion of the stormwater conveyance structures. Continuous re-evaluation of potential vulnerabilities, system resilience and possible adaptation measures can be included as part of the ongoing inspection and maintenance program.

6.2.2.3.4 Potential Impacts of a Subsurface Heating Event

In December 2010, Bridgeton Landfill, LLC detected elevated temperatures and carbon monoxide levels in the landfill gas extraction system (Bridgeton Landfill, LLC, 2013). Further investigation indicated that the South Quarry portion of the Bridgeton Landfill (which is located within OU-2) was experiencing an exothermic (heat-generating) subsurface reaction or event (Bridgeton Landfill, LLC, 2013). A discussion of this subsurface reaction (SSR)[38] is included in Section 5.7 of the RI Addendum.

Per EPA's SOW, the FFS is to include a discussion of the potential impacts of a subsurface smoldering event (SSE) or other type of subsurface heating event, if one were to occur within (or migrate to) OU-1. A qualitative assessment of the potential impacts of a subsurface heating event on the occurrences of RIM in Areas 1 and 2 and potential impacts on the ROD-selected remedy was previously prepared, submitted to EPA, and revised in response to EPA comments (EMSI, 2014e) (the SSE Impact Study). In addition, the potential for increased release of radionuclides – including via radon and fugitive dust – were further addressed as part of the Isolation Barrier Alternatives Analysis (IBAA) (EMSI, et al., 2014) and as part of the responses to EPA and MDNR comments on this analysis (EMSI, 2015a), both of which were prepared for Bridgeton Landfill LLC. Finally, quantitative calculations and modeling of potential radon and fugitive dust emissions performed on behalf of Bridgeton Landfill LLC were completed in 2016 as part of additional evaluations of a potential isolation barrier (Auxier and EMSI, 2016d and 2016e).

Based on consideration of the conditions and processes known to be associated with subsurface heating events at landfills and the remedy selected by EPA in the 2008 ROD, the following conclusions were reached in the SSE Impact Study as part of the initial qualitative evaluation (EMSI, 2014e):

- The RIM disposed of in West Lake Areas 1 and 2 would not become more or less radioactive in the presence of heat. Likewise, the RIM is not explosive and would not become explosive in the presence of heat.

- An SSE[39] does not create conditions that could carry RIM particles or dust off-site. The heat of an SSE is not high enough to ignite non-RIM wastes or chemical compounds or to cause them to explode.

---

[38] This reaction has previously been called a "subsurface smoldering event" (SSE) or by some as a fire. The current understanding of the nature of the reaction, however, is that it is occurring within saturated landfill materials in the absence of oxygen, which indicates that it is not a result of fire or smoldering (i.e., combustion). Accordingly, current references are to a "subsurface reaction," or SSR, rather than using the prior SSE terminology. Unlike a fire, the SSR has not produced visible smoke or flames.

[39] As noted in the SSE Impact Study, subsurface heating events are described in the literature using many terms, including subsurface fire, smoldering fire, slow pyrolysis, glowing combustion, subsurface oxidation, and subsurface reaction. For purposes of the SSE Impact Study, a "subsurface heating event" was considered to include any and all of these differing heating events.

- An increase in subsurface temperatures may allow radon gas to more easily rise through the ground and reach the surface of the landfill than would otherwise occur, because heat reduces the amount of moisture in the buried solid waste (trash), thereby increasing the amount of air between the soil particles and thus limiting the ability of the buried solid waste to retain radon below-ground. Any radon gas that does make it to the surface would dissipate quickly in open air. This potential increase in the rate of release of radon gas at the surface of the landfill would be limited to the area of the SSE and would stop when the SSE ends.

- In the unlikely event that increased subsurface temperatures were to occur in West Lake Area 1 or 2, such an event would create no long-term additional risks to people or the environment.

- Any short-term risks would be associated with the temporary increase in radon gas coming from the surface of Areas 1 and 2 if no cap is installed, or if the cap called for by the 2008 ROD was not properly maintained.

- These short-term risks can be addressed by designing, building, and maintaining the landfill cap called for by the 2008 ROD, and by maintaining the land use restrictions already in place on the entire Site, which prevent certain land uses.

- There are no additional ARARs associated with an SSE.

As part of the IBAA, the projected increase in radon emissions if a heating event were to enter Area 1, or in the unlikely event that an independent heating event were to otherwise occur in Area 1, were estimated based on examination of three potential conditions associated with radon emissions under elevated temperatures and occurrence of a SSE in Area 1:

- Initial thermal expansion of landfill gas due to increased temperature as a hypothetical heating event approaches and enters into Area 1, resulting in exhalation (emission at the ground surface) of the incremental increase in the volume of landfill/soil gas due to expansion of the gas volume in response to an increase in subsurface temperature;

- Subsequent increase in radon emissions due to increased soil gas permeability resulting from vaporization of soil moisture in response to increased temperature; and

- Subsequent destruction (pyrolysis) of a portion of the waste mass and associated loss of pore space, resulting in further displacement and resultant emission of an additional portion of the landfill/soil gas.

Results of these calculations indicated that even if these conditions were to occur, the radon emission rate from Area 1 would still be less than the standard established by the radon NESHAP, and if such a release were to occur, risks at or beyond the fenceline would be below the acceptable risk levels established by EPA.

Additional evaluations performed in 2016 on behalf of Bridgeton Landfill, LLC and Rock Road Industries, Inc., further examined potential increases in radon emissions in the event that a heating event were to occur in the southern portion of Area 1, outside of a potential isolation barrier (Auxier and EMSI, 2016d) (the Supplemental Radon Flux Analysis). The Supplemental Radon Flux Analysis evaluated potential radionuclide emissions – primarily radon – if an SSR were to reach isolated RIM deposits on the south side of a hypothetical isolation barrier in the southern portion of Area 1. Specifically, evaluations were performed on potential radon-222 emissions from three sources: (1) Area 1 during a hypothetical, progressive SSR crossing the study area; (2) a postulated release of radon-222 gas by way of a hypothetical event, such as a cover surface crack that exposes a portion of deep RIM after the occurrence of an SSR; and (3) a hypothetical release of RIM-derived soil gas to the landfill gas collection and flare system. In each of these hypothetical situations, the performed calculations estimated the expected surface radon flux generated by diffusion from the RIM combined with advective flux produced by thermal and physical changes associated with the passage of the postulated SSR.

The Supplemental Radon Flux Analysis concluded that largest single contributor to radon emissions under the conditions assumed in the assessment is the area source[40] used to represent Area 1 during a theoretical SSR passing through the area, followed by radon emitted from the flare stack. The calculated flux emissions were compared to permissible radon flux levels for radium storage and disposal facilities set forth at 40 CFR § 61.192. The Supplemental Radon Flux Analysis concludes that the area weighted average radon flux in Area 1 is less than the radon flux standard of 20 pCi/m^2s.

The Supplemental Radon Flux Analysis also assessed potential risks to receptors beyond the Site fenceline under modeled conditions.[41] In particular, concentrations of radon-222 gas and its progeny were projected in air at four locations: the closest occupied structure, the closest boundary fence (along St. Charles Rock Road), and at the two closest communities (Spanish Village and the Terrisan Reste mobile home community). The highest combined radon concentration at the Area 1 fenceline from all sources – 0.013 pCi/L – was projected to occur at the fence line next to the Site office. This is less than the 0.5 pCi/L alternative radon air concentration limit published in 40 CFR § 192.02(b)(2).

Potential risks to one of three different receptor types were evaluated at each of these locations of interest: indoor workers at the Site office building, outdoor workers at the closest boundary fence, and residential receptors at the two closest communities. The highest theoretical risk identified in the Supplemental Radon Flux Analysis – 2×10^{-6} – was calculated to occur to EPA's default indoor worker inside the closest occupied structure. This theoretical risk is well within EPA's acceptable risk range of 1×10^{-4} to 1×10^{-6} for CERCLA sites. Risks to off-site

[40] The Supplemental Radon Flux Analysis defined the term "area source" as the size of the area affected by a heating event at any given point in time.

[41] Potential risks were calculated by entering calculated concentrations of radon progeny into EPA's Preliminary Remediation Goals for Radionuclides (PRG) calculator, which is a web-based tool developed by EPA pursuant to the Risk Assessment Guidance (RAGS) guidance.

residential communities were all projected to be below 1 x 10^{-7}, which is below EPA's acceptable risk range.

The potential for release of particulate matter containing radionuclides was also evaluated in a second report submitted on behalf of Bridgeton Landfill, LLC and Rock Road Industries, Inc., in 2016 (Auxier and EMSI, 2016e) (the Final Particulate Emission Analysis). The purpose of the Final Particulate Emission Analysis was to estimate hypothetical risks to potential receptors if particulates from deeply buried RIM on the south side of an assumed isolation barrier in Area 1 were to somehow be brought to the surface and become airborne. Few (if any) viable mechanisms could actually cause such an occurrence on a large scale; however, a review of non-routine practices or events was conducted to determine whether any could actually produce an event where particulates from deep RIM could be released. Based on this review, the Final Particulate Emission Analysis postulated that a theoretical subsurface drilling event in Area 1 south of a proposed isolation barrier brought a mixture of landfill waste and subsurface soil to the surface, where it was then deposited on the ground surface around the drilled hole. If this material were to be left unattended, dry particulates within it could become suspended via wind erosion and carried to off-site locations.[42]

Based on the calculated results, the Final Particulate Emission Analysis concluded that even with very conservative (worst-case) assumptions, the highest risk identified in the study – 2 x 10^{-6} – was calculated to occur to EPA's default indoor worker inside the closest occupied structure. This calculated risk is within EPA's acceptable risk range of 1 x 10^{-4} to 1 x 10^{-6} for CERCLA sites. Further, risks to off-site receptors at the closest boundary fence and at the two closest communities produced risks below 1 x 10^{-7}, far below EPA's acceptable risk range of 10^{-4} to 10^{-6}.

EPA recently asked that the evaluations of potential radon and fugitive dust emissions be updated to include same exposure factors as were used in the recently completed updated Baseline Risk Assessment (Auxier & Associates, 2016a). These evaluations are currently being performed and will be incorporated into the revised draft or final version of this FFS.

6.2.2.3.5 Effects of an Isolation Barrier

In 2013, Bridgeton Landfill, LLC began evaluation of potential engineering measures that might be implemented to isolate the RIM in Area 1 from a heating event should such an event either

[42] The conclusion that dry particulates could become airborne was based in part on several very conservative assumptions about drilling procedures and soil/waste conditions. In particular, the mixture was assumed to remain uncovered on the ground surface; it was assumed to be dry and friable, with the consistency of coal dust; all precipitation events were ignored; and all particulates produced were assumed to be respirable. These assumptions are in contrast to/not representative of conditions much more likely to occur in such a drilling event, namely: (1) much or all of the soil mixture would be covered or removed promptly in accordance with standard drilling procedures; (2) the mixture would be moist, not dry, when it was first brought to the surface; (3) precipitation would periodically wet the mixture, thereby reducing emissions and promoting the formation of a surface crust; and (4) a sizeable portion of the particulates produced would be too large to be entrained by the wind or ever become respirable.

migrate from the South Quarry portion of the Bridgeton Landfill or otherwise originate in the North Quarry portion of the Bridgeton Landfill. Extensive investigations (Feezor Engineering, Inc. et al., 2014) were performed as part of this evaluation. Contemporaneously, the USACE, on behalf of EPA, prepared an Isolation Barrier Alignment Alternatives Assessment (USACE, 2014). EPA subsequently requested that Bridgeton Landfill, LLC prepare the IBAA, which was completed in 2014 (EMSI et al., 2014). Agency comments (EPA, 2015d and MDNR, 2014) were received and responded to in 2015 (EMSI, 2015a). Evaluation of potential isolation barrier alignment alternatives was conducted by the USACE in 2015 (USACE, 2015). Additional evaluations were undertaken by Bridgeton Landfill, LLC in 2016 (Auxier and EMSI, 2016d and 2016e). In April 2016, EPA issued an Administrative Settlement Agreement and Order on Consent (ASAOC) requiring Bridgeton Landfill, LLC to install a heat extraction barrier (HEB) in the “neck” area between the South and North Quarry portions of the Bridgeton Landfill, to install additional temperature monitoring probes, and to develop and implement other plans relative to mitigation of a possible migration of the SSR in the South Quarry into the North Quarry portion of the Bridgeton Landfill, or the potential origination of a new SSR or SSE in the North Quarry portion of the Bridgeton Landfill. At the time this draft FFS was prepared, evaluation of potential alignments and technologies for implementation of an isolation barrier were still ongoing, and no specific alignment or technology (*e.g.*, physical or heat extraction barrier) has been chosen. In 2015, Bridgeton Landfill, LLC conducted technical evaluations of potential heat extraction technologies to halt any potential movement of the heating event in the South Quarry portion of the Bridgeton Landfill (Feezor Engineering, Inc., 2015 and MDNR, 2015). In 2016, EPA issued an Administrative Settlement Agreement and Order on Consent (ASAOC) to Bridgeton Landfill, LLC that required, among other things, installation of a heat extraction barrier (HEB) in the “neck” area between the North and South Quarry portions of the Bridgeton Landfill (EPA, 2016c). The HEB was installed in the summer of 2016 and began operating in October 2016.

EPA’s SOW for the RI Addendum and FFS (EPA, 2015b) requires an evaluation of the effects of an isolation barrier to be included in the FFS. As discussed in the previous subsection, no adverse impacts or unacceptable risks are expected to result if an SSR or SSE were to extend into Area 1. Therefore, regardless of the location or type of isolation barrier that may be installed, or even if no barrier is installed, no unacceptable risks are expected to occur. Installation of a heat extraction barrier consisting of various heat extraction points (regardless of location) would not have any impact on the protectiveness, long-term effectiveness, short-term effectiveness, implementability or cost of the ROD-selected remedy. Installation of a physical barrier, such as a vertical wall of inert material, would require excavation and regrading of the above-grade portion of the North Quarry part of the Bridgeton Landfill located over the southern portion of Area 1. If such a barrier were to be installed prior to implementation of the ROD-selected remedy, the design of the engineered cover included in the ROD-selected remedy would need to account for any changes in the surface grades, stormwater drainage system, and the presence of any above-grade features (*e.g.*, heat extraction points, temperature monitoring probes, or additional gas extraction wells) that may be installed in conjunction with a physical barrier. In contrast, if a physical barrier were installed after construction of the engineered cover included in the ROD-selected remedy, that portion of the engineered landfill cover that extended over the area of an isolation barrier and the associated revised landfill grades would need to be removed as part of construction of an isolation barrier.

6.2.2.3.6 Environmental Justice Considerations

EPA's SOW (EPA, 2015b) requires the FFS to include an acknowledgement of any environmental justice concerns to be included in both the short-term and long-term effectiveness sections of the alternatives analysis. Executive Order (E.O.) 12898, entitled "Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations," calls on each covered Federal agency to make achieving environmental justice part of its mission "by identifying and addressing, as appropriate, disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minority populations and low-income populations" (EPA, 2016d). EPA defines environmental justice (EJ) as the fair treatment and meaningful involvement of all people regardless of race, color, national origin, or income with respect to the development, implementation, and enforcement of environmental laws, regulations, and policies. EPA further defines the term *fair treatment* to mean that "no group of people should bear a disproportionate burden of environmental harms and risks, including those resulting from the negative environmental consequences of industrial, governmental, and commercial operations or programs and policies" (EPA, 2011). EPA defines meaningful involvement as, "1) potentially affected populations have an appropriate opportunity to participate in decisions about a proposed activity [i.e., rulemaking] that will affect their environment and/or health; 2) the population's contribution can influence [the EPA's] rulemaking decisions; 3) the concerns of all participants involved will be considered in the decision-making process; and 4) [the EPA will] seek out and facilitate the involvement of population's potentially affected by EPA's rulemaking process" (EPA, 2015e). EPA defines a potential EJ concern as "the actual or potential lack of fair treatment or meaningful involvement of minority populations, low-income populations, tribes, and indigenous peoples in the development, implementation and enforcement of environmental laws, regulations and policies" (EPA, 2015e).

E.O. 12898 identifies a number of population groups of concern in considering potential EJ implications of a regulatory action. These include: minority populations, low-income populations, and indigenous peoples. For purposes of E.O. 12898, the term "minority" means "individual(s) who are members of the following population groups: American Indian or Alaskan Native; Asian or Pacific Islander; Black, not of Hispanic origin; or Hispanic" (CEQ, 1997). A population is identified as minority in an area affected by the policy action if "either (a) the minority population of the affected area exceeds 50 percent or (b) the minority population percentage of the affected area is meaningfully greater than the minority population percentage in the general population or other appropriate unit of geographic analysis" (CEQ, 1997). EPA has indicated that low-income populations may include families whose income is above the poverty threshold but still below the average household income for the United States (EPA, 2016d and 2015e). EPA Policy on Environmental Justice for Working with Federally Recognized Tribes and Indigenous Peoples (EPA, 2014c) defines "indigenous people" to include state-recognized tribes; indigenous and tribal community-based organizations; individual members of federally recognized tribes, including those living on a different reservation or living outside Indian country; individual members of state-recognized tribes; Native Hawaiians; Native Pacific Islanders; and individual Native Americans.

EPA's "Technical Guidance for Assessing Environmental Justice in Regulatory Analysis" (EPA, 2016d) (referred to as the EJ Technical Guidance) and EPA's Guidance on Considering Environmental Justice During the Development of Regulatory Actions (EPA, 2015e) (referred to as the EJ Process Guidance) were used to evaluate potential environmental justice concerns that may exist in the vicinity of the West Lake Landfill. The EJ Technical Guidance states that the analysis of potential EJ concerns for regulatory actions should address three questions:

- Are there potential EJ concerns associated with environmental stressors affected by the regulatory action for population groups of concern in the baseline?[43]

- Are there potential EJ concerns associated with environmental stressors affected by the regulatory action for population groups of concern for the regulatory option(s) under consideration?

- For the regulatory option(s) under consideration, are potential EJ concerns created or mitigated compared to the baseline?

Both the EJ Process Guidance and the EJ Technical Guidance recommend the use of a screening-level analysis to identify the extent to which a regulatory action may raise potential EJ concerns that need further evaluation, and what level of analysis is feasible and appropriate for that further evaluation. EPA's EJSCREEN: Environmental Justice Screening and Mapping Tool (EPA, 2015f) was used to perform a screening-level analysis to identify any potential environmental justice concerns that may exist in the vicinity of the Site. The EJ Technical Guidance indicates that when using EJSCREEN, the 80th percentile is a suggested starting point for the purpose of identifying geographic areas in the United States that may warrant further consideration, analysis, or outreach. That is, if any of the EJ Indexes for the areas under consideration are at or above the 80th percentile nationally, then further review may be appropriate (EPA, 2016d).

Areas 1 and 2 of the West Lake Landfill were identified on EJSCREEN, and a one-mile radius around these areas was created (Figure 6-1). EJSCREEN Indexes for the census blocks that intersected this one-mile radius were evaluated. The EJSCREEN Demographic Index, which is a combination of percent low-income and percent minority, was less than 80th percentile for all of the census blocks within the bounds of the one-mile radius (Figure 6-2). The individual EJSCREEN minority population (Figure 6-3), low income (Figure 6-4), and linguistically isolated (Figure 6-5) indexes were also below the 80th percentile; although the census block immediately to the east of Interstate 270, which is along the margin of the one-mile radius, was

[43] Per EPA's EJ Technical Guidance, this question asks whether there are discernible differences in impacts or risks to minority populations, low-income populations, or indigenous peoples that exist prior to or that may be created by the proposed regulatory action and that are extensive enough that they may merit Agency action. Differences in impacts or risks may include differential exposures, differential health and environmental outcomes, or other relevant effects. The subsequent analytic questions here are intended to prompt assessment of differences in anticipated impacts across population groups of concern for the baseline and proposed regulatory options, and to prompt the presentation of these results to decision makers to support their determinations regarding potentially actionable disproportionate impacts.

identified as a low-income population (Figure 6-4). The only EJSCREEN index that was greater than the 80th percentile for the area within the one-mile radius was the percentage of the population greater than 64 years of age, for which the EJSCREEN index was in the 95th percentile of the national rates (Figure 6-6). This indicates that a significant portion of the population living in the immediate area of the Site is elderly.

The EJSCREEN analyses did not identify any environmental justice concerns in the vicinity of the Site. Discussions with EPA Region 7 personnel on August 1, 2016 indicated that EPA had not identified any environmental justice concerns in the vicinity of the West Lake Landfill; however, EPA did indicate that interviews with the residents of the Terrisan Reste mobile home park suggested that more traditional methods of communication, such as U.S. mail, would be more appropriate than electronic methods for providing information to this group of residents.

Region 7 personnel did indicate that a few block groups[44] located within three miles of the Site were identified as being above the 80th percentile for low income. EPA Region 7 also indicated that it conducted visual inspections and community surveys in the area of the Site, and, based on this work, did identify the Terrisan Reste mobile home park, which is located approximately three-quarters of mile to the southeast of Area 1, as potentially being low income and potentially having a high proportion of elderly and disabled residents. Based on information obtained from its community survey, EPA indicated that the mobile home park residents faced communication challenges due to limited computer access. Consequently, communication by U.S. Postal Service mail is an important method for communication with these residents in order to ensure meaningful involvement.

6.2.2.4 Reduction of Toxicity, Mobility or Volume through Treatment

Reduction of toxicity, mobility, or volume through treatment refers to the anticipated performance of the treatment technologies that may be included as part of a remedy. Overall, the ROD-selected remedy is a containment remedy and therefore generally would not result in any reduction in the toxicity, mobility, or volume of the waste material through treatment.

As discussed in Section 4, radionuclides are naturally-occurring elements which cannot be fully neutralized or destroyed by treatment. Occurrences of radionuclides within Areas 1 and 2 are dispersed within soil material that is further dispersed throughout portions of the overall, heterogeneous matrix of municipal refuse, construction and demolition debris, and other non-impacted soil materials in Areas 1 and 2. Consequently, ex-situ treatment techniques are considered impracticable. In addition, the heterogeneous nature of the solid waste materials and the dispersed nature of the radionuclide occurrences within the overall solid waste matrix in portions of Areas 1 and 2 make in-situ treatment techniques impracticable. The ROD-selected

[44] A Census Block Group is a geographical unit used by the United States Census Bureau and is generally defined to contain between 600 and 3,000 people. It is the smallest geographical unit for which the Bureau publishes sample data.

remedy for the Buffer Zone/Crossroads Property also would not reduce toxicity, mobility, or volume through treatment because it consists of moving radiologically-impacted soil from the Buffer Zone/Crossroads Property to Area 1 or 2, where it would be consolidated with the RIM.

In the event that hazardous wastes are encountered during implementation of the remedy, such materials would be separated from the other solid wastes and subjected to waste profiling to determine the appropriate treatment and disposal requirements. Suspect material would initially be stored on-site while test results were obtained to verify the presence, if any, and type of hazardous wastes encountered. Storage would be conducted in accordance with RCRA and State hazardous waste regulation requirements for storage containers or units and limitations on the duration of storage (90 days if the amount of hazardous waste exceeds 2,200 lbs in a month or 270 days if the amount is less than 2,200 lbs a month).[45] Procedures to be used for testing, storage, management, treatment and disposal of any hazardous wastes or mixed wastes that could be encountered during implementation of the alternative would be documented as part of the RD activities.

To the extent that hazardous wastes or mixed wastes are encountered, they would be shipped off-site and would be treated at the disposal facility in accordance with the hazardous waste regulations (e.g., EPA's Land Disposal Restrictions (LDR) program and Universal Treatment Standards (UTS)) and in accordance with the permits and standard operating procedures of the receiving facility. Examples of treatment processes include stabilization of soil and micro- or macro-encapsulation of debris. To the extent that treatment of the hazardous waste or mixed waste would be required for off-site disposal, stabilization or encapsulation treatment would result in a reduction of the mobility of the hazardous waste or the radiologically-impacted components of the mixed waste. Toxicity and volume would not be reduced by these technologies but may be reduced by other technologies potentially applicable to hazardous wastes that do not contain RIM, if such wastes were encountered during implementation of the remedial action at the Site.

As the expected volume of waste material that would be disturbed during landfill regrading is relatively small, the amount of hazardous waste that may be encountered, if any, during implementation of the ROD-selected remedy is also expected to be relatively small. Therefore, it is anticipated that any hazardous waste that may be encountered during implementation of the ROD-selected remedy would be shipped to an off-site disposal facility by truck.

6.2.2.5 Short-Term Effectiveness

During the construction period, the ROD-selected remedy could pose radiation exposure and physical hazards for workers and result in additional local truck traffic. The ROD-selected remedy for the Buffer Zone/Crossroads Property would be effective over the short term and the

[45] These storage limitations assume that the off-site facility is located more than 200 miles from the Site. This distance is assumed based on the expectation that any identified hazardous waste would also be rad-contaminated and therefore shipped to one of the four off-site disposal facilities identified in Section 4.3.5.4.

relatively short duration required to remove the small amount of impacted soil should result in no significant adverse impacts.

The ROD-selected remedy would entail some excavation, handling, loading and transport of RIM within the Site associated with re-contouring to achieve slope requirements, and therefore would pose some short-term exposure risks to on-site workers. The number of truck trips required to import construction materials to the Site would also result in additional physical risks to the community and/or workers due to the potential for traffic accidents.

Potential short-term risks to the community and workers would be addressed through monitoring and dust control and other mitigative measures to assess and limit worker and community exposures during construction. Adherence to OSHA practices would be necessary to limit worker exposures and accidents.

6.2.2.5.1 Protectiveness of the Community During Remedial Actions

The projected carcinogenic risks that may be posed to off-site residents by this alternative would be less than 1×10^{-7}, which is substantially below EPA's accepted risk levels (Appendix H). No non-carcinogenic risks are expected to occur.

In order to further ensure that construction activities do not pose unacceptable risks, effective dust control measures would be implemented from the start of the project. An extensive perimeter environmental monitoring system has already been installed at the Site. Results of monitoring along the perimeter of Areas 1 and 2, combined with monitoring performed in the work zone during various investigative activities, have indicated that no significant airborne migration of radionuclides is occurring and that workers and the general public are not being exposed to radionuclides above background levels. Continued monitoring during construction would identify any potential for releases that could impact the area outside the work location.

The risk assessment (Appendix H) includes an estimate of the projected incidence of transportation accidents associated with each alternative. For the ROD-selected remedy, the projected incidence of transportation accidents associated with importing of materials for construction of the multi-layer landfill cover is 0.61, meaning that there would be a 61% probability of at least one transportation-related accident occurring during implementation of the remedy. To address this risk, traffic control for the incoming shipment of the materials would be implemented from the project start. All drivers would be cautioned about the normal congestion existing on St. Charles Rock Road. Routing of trucks, safety briefings, and adherence to traffic laws would reduce but not necessarily eliminate the potential for accidents. To the extent possible, shipments would be scheduled to avoid the highest traffic times.

Vehicle operations for importing the materials to be used to construct the multilayer landfill cover and during landfill regrading and cover construction are projected to emit 19,000 tons of carbon dioxide equivalent emissions to the atmosphere (Appendix I, Table I-2).

As Areas 1 and 2 are regraded during cap installation, the nuisance attraction to and congregation by birds at and above the affected areas could be problematic unless effectively controlled. Concerns include odor management, vector control, and the potential for increased bird strikes to aircraft approaching and departing from the Lambert-St. Louis International Airport. Excavation best management practices – including immediate re-deposition of cut material, limiting the area of excavation, and application of daily soil cover – are included in the ROD-selected remedy, and, if necessary, mitigation measures such as tarps, visual and auditory frightening devices, or wire or monofilament grids strung over exposed refuse to prevent bird access, could be implemented to minimize bird attraction to and congregation at and above the disturbed areas.

As Areas 1 and 2 are regraded during cap installation, stormwater controls would be implemented in accordance with Missouri Storm Water regulations 10 CSR 20-6.200.

6.2.2.5.2 Environmental Justice Concerns

As was previously discussed in Section 6.2.1.3.6, as part of the evaluation of long-term effectiveness, a screening-level analysis did not identify any environmental justice concerns. EPA did identify a need for implementation of more traditional (non-electronic) communication methods to inform and ensure meaningful involvement of residents in the Terrisan Reste mobile home community.

6.2.2.5.3 Protectiveness of Workers During Remedial Actions

The risk assessment (Appendix H) presents an evaluation of potential risks to Site workers that may occur for each alternative. These include risks from industrial accidents, exposure to carcinogenic substances, and projected radiation exposures. For the ROD-selected remedy, the projected incidence of industrial accidents is 2.76 over the life of the project (Appendix H). The projected carcinogenic risk to the maximally-exposed individual (field radiation technician) is estimated to be 9.2×10^{-5} and the projected radiation dose to a remediation worker is 187 millirems/year (mrem/yr) [Appendix H)].

A complete and comprehensive Health and Safety Program would form the core of worker protectiveness measures. The program would direct protective actions of all personnel on the Site. All workers at the Site would be trained to handle both radioactive materials (Rad Worker Training) and hazardous materials (HAZMAT Training). Protective clothing and equipment and constant monitoring for toxic hazards and radioactive emissions would be mandated. All workers on the project would be required to adhere to the project safety requirements, including any sub-contractors or vendors who are at the Site for an extended period of time.

6.2.2.5.4 Environmental Impacts

No measurable long-term impacts to plants or animals in surrounding ecosystems are expected from implementation of the ROD-selected remedy. A screening-level ecological assessment was performed as part of the original BRA (Auxier, 2000) and was updated as part of the updated BRA (Auxier, 2016a). The results of that assessment are presented in Section 7 of the BRA (Auxier, 2000) and Appendix B of the updated BRA (Auxier, 2016a). No wetlands are located within the on-site construction footprint of this alternative and no endangered species were identified.

The activities to be conducted during Site regrading and cover construction would affect wildlife and plant life on Areas 1 and 2 and possibly adjacent portions of the Site. This disruption would be temporary and would last for the period of active construction. Much of the habitat on Areas 1 and 2 was removed in 2016 in conjunction with construction of the non-combustible cover. Regrading of Areas 1 and 2 and construction of the engineered landfill cover included in the ROD-selected remedy would destroy the remaining portions of the habitats that currently exist on the surface of Areas 1 and 2, forcing wildlife to migrate to other areas. Vegetative cover would be placed on the Site as a part of the final cover, and the landfill would be allowed to return to an early-stage field ecosystem with periodic mowing and maintenance.

6.2.2.5.5 Ability to Monitor Effectiveness

Measurement of gamma radiation and radon flux through the newly constructed landfill cover would be conducted on Areas 1 and 2 after construction is complete. Regular monitoring of groundwater quality would be performed at appropriate locations around Areas 1 and 2. Measurements of subsurface occurrences of landfill gas and radon levels would be conducted along the property boundaries adjacent to Areas 1 and 2 to verify that off-site gas migration above regulatory thresholds does not occur.

6.2.2.5.6 Time Until Remedial Action Objectives Are Achieved

The RAO of (1) preventing direct contact with the landfill contents and exposure to external radiation would be met upon installation of an engineered landfill cover. The RAOs of: (2) minimizing infiltration and any resulting contaminant leaching to groundwater; (3) controlling surface water runoff and erosion and decreasing the potential for erosion and subsequent transport of RIM; and (4) controlling radon and landfill gas emissions from Areas 1 and 2 all would be met once construction of the new landfill cover over Areas 1 and 2 is completed. The RAO related to the Buffer Zone and Crossroads Property soil would be met upon removal of any remaining soil containing radionuclides above unrestricted levels from these areas.

Construction is estimated to require approximately 1.7 years after approval of the RD. Preparation of the RD should be completed within approximately one year of authorization to proceed with the RD. Therefore, the remedial action objectives should be achieved within approximately 2.7 years of authorization to begin (Appendix J).

6.2.2.6 Implementability

The design and construction of a landfill cover, with subsequent monitoring and maintenance as specified for the ROD-selected remedy, is not expected to pose any significant implementability challenges. Materials and services necessary for the regrading and construction of the final landfill covers over Areas 1 and 2 are readily available and the technologies have been proven through application at other landfills. Monitoring of the cover surfaces, landfill gas, groundwater, and surface water are proven methods for demonstrating the long-term effectiveness of landfill covers, and are easily implemented.

6.2.2.6.1 Ability to Construct and Operate the Technology

It is technically feasible to regrade existing materials and install a starter berm and/or place additional soil in order to achieve minimum and maximum slopes of 2% and 25% respectively. It is also technically feasible to construct an upgraded landfill cover over Areas 1 and 2. Regrading of existing landfills through placement of additional soil or regrading of existing materials is a common remedial action that has been implemented at many other CERCLA landfill sites as well as at RCRA corrective action sites.

Because of the configuration and location of Areas 1 and 2 within the overall existing larger Site footprint and the existing relatively steep side slopes on portions of the northern and eastern edges of Area 1 and the northern and western edges of Area 2, achieving the required maximum slope grades along the entire margin of Areas 1 and 2 cannot be achieved by placement of additional fill material alone. The toe of the landfill in the northern portion of Area 2 is located near or coincident with the property boundary/fence line, and therefore placement of additional soil or fill material is not an option to reduce the slope angle of the landfill berm in this area. Similar grading constraints exist for portions of the landfill in Area 1 due to the presence of the solid waste transfer station access road located along the northern toe of the landfill berm in Area 1, and the presence of the property/fence line along the eastern toe of the landfill. An existing drainage ditch located along the St. Charles Rock Road immediately outside of the fence line would also pose grading restraints around Area 1. For these areas, re-contouring the waste materials is a viable option to achieve the proper slope for construction of the cover. Re-contouring can be greatly reduced through use of a starter berm, as discussed elsewhere in this FFS report and in more detail in the prior SFS report (EMSI et al., 2011).

Bird nuisance mitigation measures such as best management practices (including, but not limited to, selective excavation, daily soil cover, and tarping of exposed wastes), visual and auditory frightening devices, and use of wire or monofilament grids strung over exposed refuse to prevent bird access, are demonstrated technologies that can be readily constructed and operated as part of the ROD-selected remedy.

Effective storm water controls can be readily implemented using conventional construction equipment, materials and best management practices.

6.2.2.6.2 Reliability of the Technology

Landfill cover systems that are designed and constructed consistent with State and Federal regulations and with post-closure care implemented in accordance with current regulatory guidance have been demonstrated to be reliable at: 1) minimizing percolation and infiltration of precipitation; 2) minimizing leachate generation; 3) minimizing impacts to groundwater quality; 4) minimizing impacts to surface water quality and quantity; 5) minimizing erosion of cover material; and 6) minimizing uncontrolled releases of landfill gas. In addition, existing security systems (*e.g.*, gates and fencing, signage, site surveillance, etc.) would be evaluated and enhanced, if necessary. These are reliable mechanisms to prevent unauthorized access to the Site.

Bird nuisance mitigation measures such as best management practices (including, but not limited to, selective excavation, daily soil cover, and tarps), visual and auditory frightening devices, and wire or monofilament grids strung over exposed refuse to prevent bird access, are demonstrated reliable technologies. However, while visual or auditory frightening devices can be effective in the short-term, birds tend to habituate to deterrents over time, causing the deterrent to lose effectiveness. Frequent relocation of predator birds and predator effigies and/or altering the timing of auditory activation may help, but long-term effectiveness is not assured. The FAA has stated that "[t]o date, no . . . [putrescible waste] facility has been able to demonstrate an ability to reduce and sustain hazardous wildlife [birds] to levels that existed before the putrescible-waste landfill operations began operating." (FAA, 2007).

Storm water controls are also well-established technologies that have been implemented and proven reliable at most landfill sites.

6.2.2.6.3 Ease of Undertaking Additional Remedial Actions, if Necessary

The only potential additional remedial actions that may need to be taken for the ROD-selected remedy would be maintenance activities to sustain the cover system, repair areas of differential settlement or erosion, or possible implementation of a contingent landfill gas control system. Regrading and contouring the existing waste materials to achieve final grades would require re-compaction of the regraded waste materials in order to minimize the potential for compaction or differential settlement over time that could affect the integrity of the landfill cover. Placement of additional fill material to achieve the final slope requirements and for construction of the landfill cover may result in differential compaction of the waste materials, depending upon the nature, age and amount of prior degradation of the waste materials. Runoff of stormwater can result in formation of erosional rills. Depressions caused by differential settlement of the wastes or erosional features can easily be (and commonly are) addressed at landfill sites through placement of additional soil material to fill such features.

In the event that monitoring of subsurface landfill gas and radon detects the presence of gas levels above regulatory thresholds along the perimeter of the Site, a landfill gas control system could be implemented as an additional remedial action. Implementation of a contingent landfill gas control system would entail drilling and installation of gas extraction wells, installation of conveyance piping, installation and operation of landfill gas extraction blowers and a landfill gas treatment (flare) system, and/or possible use of a carbon adsorption system to remove radon from the extracted gas stream. Installation of a contingent gas system can easily be performed as a future action. Any disruption to the final landfill cover resulting from the installation of a contingent gas extraction system would need to be repaired. Such activities are commonly and routinely undertaken at solid waste disposal sites.

Long-term monitoring and maintenance of the landfill covers at other Superfund sites and at non-Superfund site solid waste landfills is typically required to assess whether differential settlement or surface erosion of the cover has occurred over time. Long-term maintenance, including cover inspection and repair, would be part of this alternative. Cover repair, if necessary, would be straightforward, primarily entailing placement of additional fill, regrading, and re-vegetation of the repaired area.

Storm water management measures other than those using conventional earth-moving equipment, piping, pumps, liners, filtration and carbon adsorption water treatment equipment, rip-rap, and pond outlet structures are not anticipated.

6.2.2.6.4 Ability to Monitor Effectiveness of Remedy

One purpose of installing a landfill cover would be to prevent direct contact with the waste materials. The integrity of a landfill cover relative to protection from direct contact can easily be monitored through visual inspection to identify the presence of exposed waste or the existence of erosional features that could impact the landfill cover.

Another long-term goal of constructing new landfill covers over the surfaces of Areas 1 and 2 would be to minimize percolation and infiltration of precipitation with subsequent leachate generation and potential impacts to groundwater. Visual inspection of the cover integrity relative to the potential for erosion and infiltration impacts to the landfill cover can be easily performed. Groundwater monitoring to detect the presence of, or verify the absence of, impacts to groundwater is a standard technology that also can easily be performed at the Site.

Demonstrating the effectiveness of the cover systems would be accomplished by implementing the monitoring programs required by the ROD-selected remedy, including programs for the cover surface, landfill gas system, groundwater, and surface water (as previously described in Section 5.3.1). These types of monitoring programs are proven at demonstrating cover effectiveness and can be easily implemented.

6.2.2.6.5 Ability to Obtain Approvals from Other Agencies

No approvals by other agencies would be required to implement the ROD-selected remedy. The potential for increased bird strikes to aircraft approaching and departing the Lambert-St. Louis International Airport is a major concern of the Federal Aviation Administration (FAA) and the St. Louis Airport Authority (STLAA or Airport Authority). The effectiveness of best management practices and proposed bird nuisance mitigation measures would be of interest to the FAA and the Airport Authority.

6.2.2.6.6 Coordination with Other Agencies

Other than coordination with the STLAA regarding the bird hazard mitigation measures and effectiveness, coordination with other agencies would not be necessary to implement the ROD-selected remedy.

Although they would not be considered "agencies," coordination with the landfill owner and operator, the owners of the various parcels that comprise the West Lake Landfill property, and the asphalt batch plant tenant would be required during regrading and installation of an upgraded landfill cover under the ROD-selected remedy. Coordination would be necessary because:

- Access to operations conducted on other portions the Site would need to be maintained;
- Areas 1 and 2 are within a larger existing Site footprint, and use of areas on the West Lake Landfill property outside of Areas 1 and 2 might be necessary to stockpile cover materials or otherwise to facilitate cover construction; and
- For the time period during construction when trucks would be delivering rock, clay, and soil materials for cover construction, the flow of vehicles associated with remedy construction would need to be coordinated with the traffic patterns of vehicles associated with the on-site solid waste transfer station and asphalt plant.

The owners of all of the various parcels that comprise the West Lake Landfill are participating PRPs and given this, coordination with owners is expected to be feasible.

Coordination with other agencies including the Earth City Flood Control District and MSD and the Missouri Department of Transportation (MDOT), as well as the adjacent property owners and businesses (*i.e.*, Crossroads Property/AAA Trailer) would also be necessary to:

- Coordinate with the Earth City Flood Control District regarding the design of non-contact stormwater management and discharge facilities both during and after completion of construction;
- Coordinate with MSD regarding permitting and design of leachate/contact stormwater discharge during construction;
- Coordinate with MDOT for access to areas along St. Charles Rock Road (MO Route 180) and for any traffic control or ingress and egress additions along St. Charles Rock Road in the vicinity of the Site entrance; and
- Obtaining legal and physical access from Crossroad Properties, LLC and AAA Trailer for testing and, if necessary, remediation of the Crossroads Property and for implementation of remedial actions that may need to be performed along the property boundary (*e.g.* regrading, fencing, etc.).

6.2.2.6.7 Availability of Offsite Treatment, Storage and Disposal Services and Capacity

No off-site treatment, storage or disposal services are envisioned as part of the direct implementation of the ROD-selected remedy. Off-site treatment, storage and disposal may be required in the event that hazardous wastes or regulated asbestos-containing materials (RACM) are encountered during re-contouring Areas 1 and 2. Additionally, the four off-site disposal facilities identified for the "complete rad removal" and partial excavation alternatives are permitted to accept liquid, hazardous, and mixed wastes and asbestos, as well as to treat soil and/or debris that contain hazardous or mixed waste.

Offsite treatment and discharge of any leachate that may be encountered or stormwater that may contact waste materials during the landfill re-contouring activities could also be required. Off-site treatment and discharge of any leachate that may be encountered or stormwater that may contact RIM during the landfill excavation activities could also be required. Initial discussions with MSD indicated that they are willing to accept leachate and contact stormwater and initial discussions with the Earth City Flood Control District indicated a willingness to accept stormwater, subject to installation of additional stormwater detention/retention capacity.

6.2.2.6.8 Availability of Necessary Equipment and Specialists

Personnel, equipment, and materials are readily available to implement the cover systems, institutional controls, and monitoring components of this alternative. The implementability and potential cost of this alternative would be influenced by the availability and location of clean fill materials and/or off-site soil borrow sources at the time this alternative is implemented. Potential vendors of rock, clay and soil were contacted during the development of the FS (EMSI, 2006), during preparation of the Remedial Design Work Plan for the ROD-selected remedy (EMSI et al., 2008), and during preparation of the SFS (EMSI, et al., 2011). These vendors indicated that rock, clay and clean fill material were readily available from sources located near the Site at the time these inquiries were made. If these local sources of cover materials become exhausted prior to remedy implementation, cover materials would have to be obtained from suppliers at greater distances from the Site; however, all of the materials are expected to be available.

The necessary materials, equipment and personnel required for assessment and removal of radiologically-impacted soil that may be present at the Buffer Zone/Crossroads Property are also readily available.

6.2.2.6.9 Availability of Prospective Technologies

The ROD-selected remedy is based on proven, established, commonly used technologies. Use of prospective technologies is not anticipated to be part of the ROD-selected remedy.

6.2.2.7 Cost

Estimated capital, annual OM&M, and 30-year present worth costs for the ROD-selected remedy are included in Appendix K-3 and summarized on Table 6-1. Conceptual bottom and top of final cover grading plans and stormwater control features used as the basis for the ROD-selected remedy capital cost estimate are provided in Appendix M. The estimated costs to construct the ROD-selected remedy (i.e., design costs, capital costs, and costs for monitoring during the construction period) are $67 million. The estimated annual OM&M costs range from $167,000 to $326,000 per year depending upon the specific activities that occur each year (e.g., higher costs for years with additional environmental monitoring, years when landfill cover repairs may occur, and years when five year reviews are conducted). The cost estimates provided in this FFS are feasibility-level cost estimates; that is, they were developed to a level of accuracy such that the actual costs incurred to implement this alternative are anticipated to fall within a range bounded by 50% above and 30% below these estimates.

The present-worth costs of the ROD-selected remedy are projected to be $64 million over a 30-year period based on a discount rate of 7%. Based on the current OMB rate of 1.5%, the present worth costs would be $70 million. The total non-discounted costs for the ROD-selected remedy over 30 years are projected to be $73 million. Given the long life of the radionuclides present at OU-1, the costs for the ROD-selected remedy were also evaluated for 200- and 1,000-year periods (without consideration of any constraints on annual expenditures). The total non-discounted costs of the ROD-selected remedy are projected to be $102 million over a 200-year period. The total present-worth costs of the ROD-selected remedy are projected to be $64 million based on a 7% discount rate or $77 million based on a 1.5% discount rate, respectively, over a 200-year period. The total non-discounted and present worth costs of the ROD-selected remedy are projected to be $241 million over a 1,000-year period. The present worth costs over a 1,000-year period are projected to be $64 million based on a 7% discount rate or $78 million based on a 1.5% discount rate.

For purposes of demonstrating the extent to which shipping of mixed waste could influence costs, it was assumed that mixed waste would represent 0.5% of the total mass of the relocated volume for the ROD-selected remedy. The added costs for handling, sampling/analysis, shipping, treating, and disposing of mixed waste under the ROD-selected remedy are estimated to range from $240,000 to $450,000 depending upon the nature of the hazardous wastes (*i.e.,* metals or organics) that may be encountered. The range of costs primarily results from variations in the fees charged by the off-site disposal facilities and uncertainties associated with the nature of such wastes and the required method of treatment. If the volume of mixed waste is higher than the 0.5% of total mass assumption, the added costs would be higher as well.

6.2.3 "Complete Rad Removal" with Off-site Disposal Alternative

This section presents the detailed analysis of the "complete rad removal" alternative. As previously described in Section 5.4, this alternative consists of the following components:

- Removal of the asphalt plant and relocation of the Bridgeton Transfer Station, LLC building to provide access to RIM located adjacent to the building and construction of an overpass over the Site access road;

- Excavation and stockpiling of overburden from OU-1 Areas 1 and 2 in order to access the RIM;

- Excavation of RIM from OU-1 Areas 1 and 2 that contains radionuclides above levels that would allow for unrestricted use as defined by the UMTRCA standards in 40 CFR 192.12 as modified by EPA's 1997 and 1998 OSWER guidance (EPA, 1997a and 1998);

- Loading, transport, and disposal of the RIM at an off-site disposal facility;

- Survey and identification of the presence and extent of radiologically-impacted soil on the Buffer Zone and Crossroads Property;

- Excavation of any soil from the Buffer Zone and/or Crossroads Property that contains radionuclides at levels greater than those that would allow for unrestricted use and shipment of such soil to an off-site disposal facility;

- Regrading of the remaining solid waste materials within Areas 1 and 2 to meet the minimum (5%) and maximum (25%) slope criteria;

- Installation of a landfill cover meeting the Missouri closure and post-closure care requirements for sanitary landfills over Areas 1 and 2;

- Design, installation and maintenance of storm water runoff controls;

- Groundwater monitoring consistent with the requirements for sanitary landfills;

- Landfill gas monitoring and control, as necessary;

- Institutional controls to prevent land and resource uses that are inconsistent with a closed sanitary landfill site; and

- Long-term surveillance and maintenance of the landfill cover in Areas 1 and 2.

Under this alternative, an estimated 266,000 bank cubic yards (bcy) of RIM and impacted soils would be excavated for off-site disposal from Areas 1 and 2, and an additional approximately 2,900 bcy of impacted soil from the Buffer Zone/Crossroads Property would be excavated for off-site disposal under this alternative. However, the volume of material would increase upon excavation due to swelling, handling and loading for off-site transport. Applying an assumed swell factor of 1.5 and accounting for daily cover, it is estimated that approximately 444,000 loose cubic yards (lcy) would be transported off-site for disposal at a permitted disposal facility.

As indicated in Section 5.4.3, it is unknown whether extending a rail spur onto the Site would be feasible. If feasible, loading RIM material directly onto railcars on-site would reduce material handling steps and probably reduce transportation costs. Based on information provided by US Ecology for turnkey transportation and off-site disposal, transportation costs might be reduced as much as $35 per lcy of RIM if a rail spur of sufficient length could be extended onto the West Lake Landfill Site; however, this estimate does not take into account the costs of property acquisition, regulatory approval, or capital construction associated with an on-site rail spur, so the true cost reduction, if any, is unknown. Preparation of an engineering feasibility evaluation and a conceptual design to potentially extend a rail spur onto the Site is outside the scope of this FFS.

Therefore, based on discussions with US Ecology, for purposes of preparing a cost estimate for this alternative in this FFS it was assumed that excavated RIM would be loaded into 30-cubic-yard metal DOT IP intermodal (IM) containers, which would then be loaded onto and hauled by trucks to a truck-to-rail transloading operation at a rail spur location within a 10-mile radius of the West Lake Landfill Site, where the containers would be placed onto flatbed rail cars for shipment to one of the off-site disposal facilities described in Section 4.3.5.4.

For purposes of this FFS, it has been assumed that the RIM would be shipped for disposal at the US Ecology, Inc. facility in Grandview, Idaho. US Ecology provided the most complete information regarding transportation mechanisms and transportation and disposal costs. US Ecology has prior experience with transport and disposal of radioactive materials from SLAPS and other DOE/FUSRAP sites (Latty Avenue and Denver Radium Site Operable Unit 8).

Once all of the RIM above levels which would allow for unrestricted use has been removed from each area, the remaining solid waste materials in Areas 1 and 2 would be regraded to meet the final closure standards for sanitary landfills and a final sanitary landfill cover would be constructed over Areas 1 and 2. This cover would not include the additional hybrid components included in the ROD-selected remedy to address the UMTRCA requirements, because the RIM above unrestricted use levels would have been removed under this alternative.

However, because solid wastes would still be present in Areas 1 and 2, this alternative includes installation and maintenance of storm water runon and runoff controls, groundwater and landfill gas monitoring, and institutional controls, as described for the ROD-selected remedy. Environmental monitoring of groundwater quality would be performed to ensure that groundwater quality at the perimeter of the Site met UMTRCA and State groundwater standards or other ARARs. Monitoring of subsurface occurrences of landfill gas and, if necessary, implementation of contingent landfill gas extraction along the perimeter of Areas 1 and 2 would be performed to ensure that migration of landfill gas above regulatory thresholds does not occur beyond the Site perimeter.

Institutional controls would ensure that land and resource uses are consistent with permanent waste disposal.

6.2.3.1 Overall Protection of Human Health and the Environment

Conditions at the Site would be protective of human health and the environment after completion of construction of this alternative. This alternative would protect human health and the environment by limiting potential exposure to the Site contaminants through the removal and off-site disposal of RIM and implementation of engineering methods and land use controls to address the remaining solid wastes.

6.2.3.2 Compliance with ARARs

The "complete rad removal" alternative would comply with the ARARs discussed below.

6.2.3.2.1 UMTRCA

Removal of any soil containing radionuclides from the Buffer Zone and Crossroads Property would be done in a manner that meets the UMTRCA soil cleanup standards (40 CFR Part 192 Subpart B) as modified by the EPA guidance on the use of UMTRCA for cleanup at CERCLA sites (EPA, 1998 and 1997a). Although the UMTRCA standard is only intended to apply to land (which is defined to include any surface or subsurface land that is not part of a disposal site and is not covered by an occupiable building) and therefore is not considered to be an ARAR for Areas 1 and 2, removal of RIM from Areas 1 and 2 as specified by EPA (EPA, 2015b and 2010a) would also be conducted in a manner that achieved the UMTRCA standard as modified by the EPA guidance.

6.2.3.2.2 CERCLA Off-site Rule

Section 121(d)(3) of CERCLA (42 U.S.C. § 9621(d)(3)) applies to any CERCLA response action involving the off-site transfer of any hazardous substance, pollutant or contaminant (CERCLA wastes). These principles are stated in the Off-Site Rule (OSR) set forth in the NCP at 40 CFR § 300.440. The OSR requires that CERCLA wastes only be placed in a facility operating in compliance with RCRA or other applicable Federal or State requirements. The OSR prohibits the transfer of CERCLA wastes to a land disposal facility that is releasing contaminants into the environment, and requires that any releases from other waste management units at the disposal facility must be controlled.

The OSR establishes the criteria and procedures for determining whether facilities are acceptable for the receipt of CERCLA wastes from response actions authorized or funded under CERCLA. The OSR establishes both compliance and release criteria, and also establishes a process for determining whether facilities are acceptable based on those criteria. The OSR also establishes procedures for notification of unacceptability, reconsideration of unacceptability determinations, and re-evaluation of unacceptability determinations.

EPA verifies the acceptability of off-site treatment, storage, and disposal facilities (TSDFs) on a frequent basis. Consequently, before any off-site shipment occurs, a verification of current acceptability (VCA) must be obtained from EPA certifying that the proposed receiving facility is operating in compliance with the requirements of CERCLA Section 121(d)(3) and 40 CFR § 300.440. EPA (usually the EPA Regional Office) would determine the acceptability under this section of any facility selected for the treatment, storage, or disposal of CERCLA waste. EPA would determine if there are relevant releases or relevant violations at a facility prior to the facility's initial receipt of CERCLA waste. EPA typically makes such determinations every 60 days. The compliance status of an off-site disposal facility would need to be evaluated during RD and would need to be regularly evaluated and updated during remedy implementation.

6.2.3.2.3 Off-site Transportation Requirements

Transportation to an off-site disposal location would need to comply with both the substantive and administrative requirements of any regulations applicable to transportation of radiologically-contaminated materials. These would include U.S. Department of Transportation (DOT) regulations for transport of hazardous materials (49 CFR Parts 100 – 178), and specific regulations related to transport of radioactive materials (49 CFR Parts 171 – 180). These include regulations governing hazardous materials communications, emergency response information, training requirements and security plans (49 CFR Part 172) which address special provisions, preparation and retention of shipping papers, packaging and container marking, emergency response, security and planning. The regulations contain specific requirements associated with shipment of radioactive materials (*e.g.*, 49 CFR §§ 172.310, 172.436-440, and 172.556). Other regulations (49 CFR Part 173) describe requirements for shipment and packaging that are applicable to shippers and again include specific requirements for shipment of radioactive materials. Regulations set forth in 49 CFR Part 174 address shipment by rail and include special handling requirements for radioactive materials (49 CFR § 174.700). Required emergency response information is described in 49 CFR Subpart G (49 CFR § 173.602). The NRC, through a Memorandum of Understanding with DOT, also has promulgated regulations regarding transport of radioactive materials (10 CFR Part 71).

Requirements established by common carriers (including rail carriers) for transport of waste materials or radioactive wastes would also be applicable to this alternative. Because the specific carriers that might be used to transport the wastes under the "complete rad removal" alternative cannot be identified at this time, identification and evaluation of the carrier-specific requirements has not been performed.

Discussions with representatives of potential off-site disposal facilities indicate that most of the facilities would provide a turnkey service that includes transport of the RIM from the West Lake Site and subsequent treatment and disposal. As such, the disposal company would be responsible for arranging for transport, preparation of waste/shipping manifests, testing of RIM materials after they are loaded into transportation vehicles/containers, securing of vehicles/containers, unloading of vehicles/containers, safety and emergency response plans, and all other aspects associated with transport of RIM from the West Lake Site to an off-site disposal facility.

6.2.3.2.4 Waste Acceptance Criteria (WAC) for Off-site Disposal

WAC are established pursuant to the specific permit or license issued to each waste disposal facility, and consequently are different for each facility. Summaries of the WAC for each off-site disposal facility were presented in Section 3.2.3 of this FFS and would be complied with, as appropriate. Copies of the WAC provided by each of the facilities are contained in Appendix C. A comparison of RIM activity levels relative to the US Ecology WAC is presented on Table 6-2.

6.2.3.2.5 Missouri Solid Waste Rules for Sanitary Landfills

Regrading, cover and closure of the remaining solid waste at OU-1 Areas 1 and 2 after RIM removal would need to comply with the MDNR regulations described in Section 6.2.1.2.1 of this FFS. The only difference between the "complete rad removal" and the ROD-selected remedy would be that regrading Areas 1 and 2 after removal of the RIM under the "complete rad removal" alternative would need to meet a minimum slope angle of 5% instead of the 2% permitted for the ROD-selected remedy. The increased surface slope would be necessary to account for the increased risk of differential settlement resulting from the greater extent of excavation and material disturbance caused by the RIM removal including excavation, stockpiling, and relocation of relatively younger waste contained in the above-grade portion of the North Quarry part of the Bridgeton Landfill that overlies the southern portion of Area 1.

6.2.3.2.6 Safe Drinking Water Act

40 CFR Part 141 establishes primary drinking water regulations including maximum contaminant limits (MCLs) pursuant to section 1412 of the Public Health Service Act, as amended by the Safe Drinking Water Act (Public Law 93-523), and related regulations applicable to public water systems. These MCLs apply to public drinking water systems. Missouri regulations (10 CSR 60-4.010, et seq.) also establish MCLs for public drinking water systems. MCLs are considered relevant and appropriate to all potentially usable groundwater. As set forth in the NCP, non-zero maximum contaminant level goals (MCLGs) are also potentially relevant and appropriate to potentially usable groundwater. Regrading of the landfill surface and installation of an engineered landfill cover to promote runoff and minimize infiltration are included as part of this alternative. These measures should ensure groundwater quality that meets the MCLs and non-zero MCLGs.

6.2.3.2.7 NRC Standards for Protection Against Radiation

The NRC Standards for Protection Against Radiation (10 CFR Part 20) contain chemical-specific standards that address radiation protection. These regulations establish dose limits for individual members of the public and radiation workers, and define maximum permissible exposure limits for specific radionuclides in air and water at levels above background inside and outside of controlled areas. These requirements are considered applicable during implementation of any remedial action. Specifically, these regulations would require perimeter air monitoring during implementation of the "complete rad removal" alternative. In addition, Site health and safety plans would address worker protection consistent with these requirements.

6.2.3.2.8 Missouri Well Construction Code

MDNR has promulgated regulations pertaining to the location and construction of water wells. The Well Construction Code (10 CSR 23-3.010) prohibits the placement of a well within 300 feet of a landfill. These rules would provide protection against the placement of wells on or near the Site. The regulations on monitoring well construction (10 CSR 23-4) would apply to the construction of new or replacement monitoring wells. The "complete rad removal" alternative would meet these requirements through enforcement of the existing Institutional Controls[46] and adherence to the Well Construction Code requirements for installation of new monitoring wells or abandonment of existing monitoring wells.

6.2.3.2.9 Missouri Stormwater Regulations

The Missouri regulations governing stormwater management at construction sites are set out in 10 CSR 20-6.200 (Table 3-3). A disturbance of greater than one acre or the creation of a storm water point source during construction of the remedy would trigger these requirements. The "complete rad removal" alternative would meet these requirements through implementation of a SWPPP, use of BMPs during construction, installation and maintenance of an engineered landfill cover to prevent stormwater from contacting the waste materials, and construction and maintenance of stormwater diversion and control structures to control runon and runoff and reduce erosion potential as part of the design of the engineered landfill cover.

6.2.3.3 Long-Term Effectiveness and Permanence

Because the "complete rad removal" alternative is defined by EPA to result in removal of RIM containing radionuclides above unrestricted use levels from the Site, this alternative would provide permanent protection against exposures to radionuclides. This conclusion assumes there would be no long-term impacts to the environment in the vicinity of the off-site disposal facility or to any communities along the transport route from transport to and disposal of RIM at the off-site disposal facility.

RIM containing radionuclides at levels above those that would allow for unrestricted use would be removed from the Site under this alternative; however, other solid wastes would still remain at the Site, and it would still remain a landfill subject to the applicable requirements for closed solid waste landfills. Therefore, a new landfill cover would need to be installed over the remaining solid wastes after removal of the RIM above cleanup levels. Groundwater monitoring would need to be performed consistent with the applicable or relevant and appropriate requirements for a solid waste landfill. Institutional controls would also be required to ensure that future land uses at the Site would be compatible with the presence of a solid waste landfill and to prevent intrusion into the waste materials, disruption of the landfill cover, monitoring points, or other aspects of the solid waste landfill containment system.

6.2.3.3.1 Magnitude of residual risk

The calculated lifetime risks from radiological materials that would remain in Areas 1 and 2 after implementation of the "complete rad removal" alternative are as follows:

- Area 1: $<1 \times 10^{-7}$ for year 1 and $<1 \times 10^{-7}$ for year 1,000.

[46] In addition, the deed restrictions currently in place on Areas 1 and 2 and the Buffer Zone (and which are to be maintained in perpetuity) prohibit the placement of water wells for drinking water or agricultural purposes.

- Area 2: <1 x 10^{-7} for year 1 and <1 x 10^{-7} for year 1,000.

These calculated risks are attributable to gamma radiation and radon emissions from the radionuclide occurrences that would remain after implementation of the "complete rad removal" alternative. Any such residual materials would be present at levels which do not require further remediation. The calculated risk levels are below EPA's target risk range of 1 x 10^{-6} to 1 x 10^{-4} and the magnitude of the radiological carcinogenic risk from residual RIM in these two remediated areas is acceptable. These risks do not specifically include potential exposures from non-radiological landfill waste after construction is complete; however, those wastes would also be covered by a cap which would prevent exposures. Additional information regarding the risk assessment calculations is presented in Appendix H.

Additionally, the remaining landfill wastes, including any residual radionuclides below unrestricted use levels, would be capped with access to and future use of the capped waste disposal areas limited by Site access restrictions and institutional controls. Direct contact with residual RIM under the cap, or ingestion, inhalation, or dermal contact with such materials, is not expected to occur. These also are the primary exposure pathways for any non-radiological COPCs which may be present in the landfill wastes remaining in Areas 1 and 2 after removal of the RIM. Because no complete exposure pathway would exist for such materials after completion of the cap construction, the landfill waste materials would not be expected to produce non-carcinogenic effects or carcinogenic risks.

After soils containing radionuclide concentrations above the cleanup levels are removed from the Buffer Zone/Crossroads Property, residual risks posed by the remaining radionuclide-impacted soils on these properties, if any, are expected to be indistinguishable from variations in background levels.

6.2.3.3.2 Adequacy and reliability of controls

Although the "complete rad removal" alternative as defined by EPA (2015b and 2010a) is presumed to result in removal of RIM such that the remaining materials would allow for unrestricted use relative to the presence of radionuclides, there is uncertainty as to whether all of the RIM above cleanup levels could be removed. There are several areas where RIM is located at substantial depth. In addition, some of the RIM in OU-1 Area 1 is located adjacent to or beneath the above-grade portion of the North Quarry part of the Bridgeton Landfill and some of the RIM in OU-1 Area 2 is located very close to the adjacent Closed Demolition Landfill or the Inactive Sanitary Landfill, which are not known to contain radionuclides and are therefore part of OU-2. The proximity of these adjacent landfills greatly increases the level of difficulty and the amount of overburden material that would have to be moved to access and remove some of the RIM. These conditions would increase the potential for failure of the adjacent landfill units during implementation of the OU-2 remedy and the potential that all of the RIM above cleanup levels may not be able to be removed from Areas 1 and 2.

There are a very limited number of possible off-site facilities where the RIM could be disposed, and therefore there are uncertainties regarding land disposal. There also are uncertainties regarding the acceptability of the wastes at some of the facilities, further limiting the number of facilities that could accept the wastes. At this time, only four facilities have been identified that might be able to accept these wastes. See the discussion in Section 3.2.3 for a description of these facilities and their capabilities.

The engineered measures and institutional controls that would be implemented for Areas 1 and 2 under the "complete rad removal" alternative (landfill cover, groundwater and landfill gas monitoring, and institutional controls), are considered to be adequate and reliable. OM&M requirements for the "complete rad removal" alternative would be the same as those included in the ROD-selected remedy. No difficulties or uncertainties or potential need to replace significant components are envisioned for the long-term OM&M functions for the "complete rad removal" alternative.

Because the "complete rad removal" alternative entails removal of all RIM above the criteria that would allow for unrestricted use relative to radionuclide occurrences, the remedial actions included in this alternative are expected to be a final action for OU-1, and it is assumed that no components of the remedy would need to be replaced in the future. The landfill cap would need to be maintained but because it would be composed of natural materials (*e.g.*, soil) it should not need to be replaced. However, in the unlikely case that components of the remedy need replacement in the future, unacceptable risks are not expected to occur because the Site presents only slight risks under current conditions. Moreover, given that the components of the final covers at Areas 1 and 2 would be constructed from natural materials with properties that limit migration potential of any residual radionuclides below unrestricted levels or solid waste constituents, there is a high degree of confidence that the engineered controls would prevent or otherwise address potential problems.

6.2.3.3.3 Climate Changes and Potential Impacts of a Tornado

Because municipal solid waste would still remain in Areas 1 and 2, a new engineered landfill cover would be installed over these areas. Because radionuclides above unrestricted use levels would be removed from the Site under this alternative, the engineered landfill cover to be installed under this alternative would not include the 2-foot thick rock/rubble biointrusion layer. Instead, the engineered cover would consist of a standard landfill cover for a Subtitle D MSW landfill without a liner system, which would consist of a 2-foot-thick low-permeability layer and a 1-foot-thick vegetative layer. This engineered landfill cover would be classified as an in-situ containment system (EPA, 2014a).

Because of the general similarity between the engineered landfill cover to be installed over Areas 1 and 2 under the "complete rad removal" alternative with the landfill cover to be installed under the ROD-selected remedy, the analysis of the potential effects of climate change or impacts of a tornado are essentially the same for both alternatives. These effects were previously discussed in Section 6.2.1.3.3 for the ROD-selected remedy and therefore the overall evaluation of climate change effects and potential impacts from a tornado will not be repeated again here.

Similar to the ROD-selected remedy, the vegetative layer of the landfill cover to be installed under the "complete rad removal" alternative could be vulnerable to increased occurrences of extreme temperatures, sustained changes in average temperatures, decreased precipitation and increase in drought occurrences. Increased temperatures or decreased precipitation/drought could affect the viability of the vegetation (*e.g.*, grasses) on the surface of the landfill cover. Any changes to the overall health of the vegetative cover would be readily identifiable by visual inspection. Therefore, although the vegetative cover may be vulnerable to potential increased temperatures or drought conditions, the potential for impacts to the vegetative layer could be anticipated and readily identified in advance of any such occurrence.

The low permeability layer (CCL) could be damaged by periods of extended extreme temperatures or prolonged drought. Potential impacts could include the desiccation of the CCL, which could increase the CCL's permeability and therefore also increase the potential for precipitation infiltration. These potential impacts are not considered to be significant because the Site has existed for over 40 years with essentially flat (no grade) surfaces and minimal cover material, thereby maximizing precipitation infiltration. Even with this increased potential for infiltration of precipitation through Areas 1 and 2, the USGS (2014) concluded that that there is not a strong spatial association of monitoring wells surrounding or downgradient of RIM areas with elevated radium concentrations, as might be expected if RIM areas were releasing substantial quantities of radium to the groundwater. EPA has indicated that additional evaluations of groundwater will be conducted in the future as part of the OU-3 RI/FS. Therefore, even if desiccation of the low-permeability layer were to occur, the impacts to groundwater quality are not expected to be significant. More importantly, the vegetative layer would likely show significant signs of stress from increased temperatures/drought prior to the occurrence of any impacts to the underlying low-permeability layer and thereby provide advance notice of a potential impact to the CCL. Accordingly, although the low-permeability layer could potentially be vulnerable to effects of increased temperature or drought, the potential for any impacts could be anticipated and readily identified in advance of any such occurrence. For these reasons, potential degradation of the CCL due to extreme temperatures or drought is not expected to result in release of contamination.

Increased heavy precipitation events could result in erosion of the vegetation layer and, if left untended, could result in erosion of the underlying low permeability layer. Any erosion of the landfill cover would be readily identifiable by visual inspection. Given that the landfill cover under the "complete rad removal" alternative would not include the 2-foot thick rock layer in the base of the cover system, stormwater erosion under a severe storm event could potentially erode down through the entire landfill cover, resulting in temporary exposure of waste materials. Heavy precipitation events could impact the integrity or performance of stormwater drainage conveyance structures, including the erosion of drainage channels, damage to or bypassing of let-down and erosion control structures and features, or damage to stormwater detention structures. Heavy precipitation events could also temporarily restrict access to portions of the landfill cover, stormwater control structures, and environmental monitoring points, thereby causing delays in implementation of repairs (if any are needed). Therefore, the vegetation layer and stormwater controls are potentially vulnerable to impacts from heavy precipitation events. This could result in exposure of the waste material or release of contamination; however, because under the "complete rad removal" alternative it is presumed that all RIM above unrestricted use levels would be removed, such impacts would not result in release of radionuclides above risk-based levels. Furthermore, any impacts that occur could be readily addressed as part of normal maintenance and repair of the landfill cover, including localized regrading, repair and replacement of cover material in response to any damage that may occur.

The "complete rad removal" alternative is not anticipated to be impacted by flooding that may occur in the area of the Site. As previously discussed in Section 2.1.6, FEMA has determined that Areas 1 and 2 are located outside of the 500-year floodplain. In addition, the area to the north and west of Area 2 (*e.g.,* Crossroads Industrial Park and Earth City Industrial Park) that potentially could be subject to flooding by the Missouri River, are protected by the engineered levee and stormwater and flood control systems installed to protect the Earth City Industrial Park.

Similar to the ROD-selected remedy as discussed in Section 6.2.1.3.3, the "complete rad removal" alternative is not vulnerable to impacts from a tornado. Specifically, a tornado is not expected to damage the vegetative layer, and even if it did, such an impact would not be significant because it could be easily identified and, due to the design and thickness of the engineered cover, would not result in exposure of the underlying waste or release of contamination. A tornado could damage or destroy aboveground infrastructure such as signage, fencing or environmental monitoring equipment; however, such impacts are not expected to be significant because they would be readily identified and easily repaired or replaced. Therefore, the "complete rad removal" alternative is not considered to be vulnerable to potential impacts from a tornado.

Although the "complete rad removal" alternative is not considered to be vulnerable to climate change, implementation of adaptation measures could be considered during remedial design to provide a degree of adaptation for climate change. For example, regrading of the surface of Areas 1 and 2 to a 2% slope instead of a 5% slope could be considered to reduce the velocity of runoff across the surface of Areas 1 and 2 and thereby reduce erosion and soil loss potential under extreme precipitation events. Installation of runoff collection and diversion systems along the base of the above-grade portion of the North Quarry part of the Bridgeton Landfill adjacent to Area 1 and along the north sides of the Closed Demolition Landfill and the Inactive Sanitary Landfill adjacent to Area 2 could be installed in order to divert runoff from these areas around Areas 1 and 2 to reduce the potential for impacts from heavy precipitation events. Use of grass seed mixtures that are more tolerant of long-term changes in precipitation or temperature and/or soil addition to increase water storage capacity could be evaluated as part of the design. Similarly, inclusion of a geotextile at the base of the vegetative layer could be considered to minimize the potential for water or wind erosion extending down into the underlying low permeability layer. The design grades of the stormwater conveyance structures could be evaluated to provide a balance between the ability to quickly route stormwater away from Areas 1 and 2 while minimizing the stormwater velocity and the associated potential for erosion of the stormwater conveyance structures. Identification and evaluation of additional adaptation measures can be addressed as part of the design of the engineered landfill cover and stormwater controls to increase the overall resilience of these features to heavy precipitation events. Continuous re-evaluation of potential vulnerabilities, system resilience and possible adaptation measures would be included as part of the ongoing inspection and maintenance program.

6.2.3.3.4 Potential Impacts of a Subsurface Heating Event

Because it is presumed that all radionuclides above unrestricted use levels would be removed from the Site under the "complete rad removal" alternative, no radionuclide-related impacts would occur if an SSE or SSR were to occur in Areas 1 or 2. Odor emissions, ground settlement, and other impacts associated with a heating event could potentially still occur under the "complete rad removal" alternative. These would be addressed as part of OM&M activities including activities such as placement of additional soil to fill areas of subsidence, repair the landfill cover, and reduce odor emissions.

6.2.3.3.5 Effects of an Isolation Barrier

Because it is presumed that all of the radionuclides above unrestricted levels would be removed under the "complete rad removal" alternative, there would be no need for installation of an isolation barrier. If an isolation barrier were installed prior to implementation of a "complete rad removal" alternative, large portions of such a barrier would need to be removed and hence destroyed in order to gain access to RIM located in the subsurface in the vicinity of a barrier.

6.2.3.3.6 Environmental Justice Considerations

As was previously discussed in Section 6.2.1.3.6 as part of the evaluation of long-term effectiveness of the ROD-selected remedy, a screening level analysis did not identify any environmental justice concerns relative to the Site. EPA did identify a need for implementation of more traditional (non-electronic) communication methods to inform and ensure meaningful involvement of residents in the Terrisan Reste mobile home community.

6.2.3.4 Reduction of Toxicity, Mobility or Volume through Treatment

Reduction of toxicity, mobility, or volume through treatment refers to the anticipated performance of the treatment technologies that may be included as part of a remedy. The "complete rad removal" alternative is an off-site disposal action that does not include treatment as a primary component.

As discussed in Section 4, radionuclides are naturally-occurring elements which cannot be neutralized or destroyed by treatment. Occurrences of radionuclides within Areas 1 and 2 are dispersed within soil material that is further dispersed throughout portions of the overall, heterogeneous matrix of municipal refuse, construction and demolition debris, and other non-impacted soil materials in Areas 1 and 2. Consequently, ex-situ treatment techniques are considered impracticable. In addition, the heterogeneous nature of the solid waste materials and the dispersed nature of the radionuclide occurrences within the overall solid waste matrix in portions of Areas 1 and 2 make in-situ treatment techniques equally impracticable. The remedy for the Buffer Zone/Crossroads Property also would not reduce toxicity, mobility, or volume through treatment because it consists of removing radiologically-impacted soil from the Buffer Zone/Crossroads Property and shipping it off-site for disposal.

An on-site technology that may potentially be applicable to the "complete rad removal" alternative is physical separation of impacted soil from the solid wastes by using solids separation techniques such as hand-picking for large bulky items and various fixed, vibrating, or rotating screens, among others (see discussion in Section 4.3.5.2). Physical separation would not decrease the mobility or toxicity of the radiologically-impacted materials, but has the potential to separate existing RIM from non-radiologically-impacted materials. As previously discussed, any solids separation techniques would need to be pilot-tested at full-scale using materials from Areas 1 and 2 during remedial design to ascertain the potential effectiveness, implementability, and cost of this technology. Of particular interest in conducting pilot-testing with material from Areas 1 and 2 would be obtaining an estimate of the degree of RIM volume reduction that could be achieved, assessing the moisture content of the filled material, determining the fraction of soil that would be contained in or adhered to the segregated refuse, and determining the residual levels of radioactivity that would be present in the non-soil refuse after screening out the soil fraction. Assuming that solids separation could prove to be an effective and implementable technology (that is, it could effectively separate the radiologically-impacted soil from the other landfilled waste materials such that the other landfilled wastes would contain radionuclide activities below the levels that would allow for unrestricted use), it has the potential to reduce the volume of radiologically-impacted material that would need to be transported to an off-site disposal facility. However, little is known about the potential application of a soils separation technology to this situation, and it is possible that pilot-testing could demonstrate that physical separation would not be effective at separating RIM from non-radiologically-impacted materials, in which case, the non-radiologically-impacted materials would also need to be shipped off-site for disposal. At this stage of analysis, neither the estimated costs nor the estimated schedules in this FFS include any allowance for solids separation pilot-testing or implementation.

In the event that hazardous wastes are encountered during implementation of the remedy, such materials would be separated from the other solid wastes and subjected to waste profiling to determine the appropriate treatment and disposal requirements. To the extent that hazardous wastes or mixed wastes are encountered, they would be shipped off-site and would be treated at the disposal facility in accordance with the hazardous waste regulations (e.g., EPA's Land Disposal Restrictions (LDR) program and Universal Treatment Standards (UTS)) and in accordance with the permits and standard operating procedures of the receiving facility. After arriving at an off-site disposal facility and undergoing a waste receipt analysis, RCRA soil/debris and RCRA soil/debris with radionuclide material would be stabilized prior to placement in a disposal cell. Depending on its physical characteristics, RCRA debris and RCRA debris with radionuclide material would undergo either micro- or macro-encapsulation prior to placement in a disposal cell. To the extent that treatment of the hazardous waste or mixed waste would be required for off-site disposal, stabilization or encapsulation treatment would result in a reduction of the mobility of the hazardous waste and radiologically-impacted components of the mixed waste. Toxicity and volume would not be reduced by these technologies but may be reduced by other technologies potentially applicable to hazardous wastes that do not contain RIM, if such wastes were encountered during implementation of the remedial action at the Site.

For the “complete rad removal” alternative, any hazardous waste or mixed waste would be shipped to the off-site disposal facility either separately by truck or, depending upon the volume, possibly by rail in conjunction with shipment of the RIM. If the volume is small, the material may be placed in drums, metal boxes or other containers and shipped by truck, although if the volume is sufficient to fill an IM container, it may be shipped by rail. Shipment of mixed waste to an off-site disposal facility by rail would not be significantly different than shipment of RIM. Like the RIM, the mixed waste would be loaded into 30-cubic yard metal DOT intermodal containers and hauled by truck to a truck-to-rail transloading station. The IM containers would be placed on flatbed rail cars and transported via rail to one of the off-site disposal facilities described in Section 4.3.5.4. Either way, any material that is identified as hazardous would be handled and shipped as discrete material and not mixed with a larger volume of RIM. Both types of materials would be subjected to a radiation survey and classification in accordance with DOT requirements; however, the shipping documentation would be slightly different. While the RIM would be shipped under a bill of lading with appropriate placarding identifying the material as radioactive, the mixed waste would require use of a uniform hazardous waste manifest and specific placards and markings on the semi-trucks and rail cars identifying the material as hazardous waste in addition to being radioactive.

Beyond the shipping aspect, the hazardous component of any mixed waste would present additional issues with respect to waste segregation, sampling/analysis, and ultimate disposition at the off-site disposal facility. During excavation, any suspected hazardous or mixed waste would be segregated from the waste containing only overburden material or RIM, stockpiled in a separate area, sampled and analyzed for toxic characteristic leaching procedure (TCLP) parameters, and covered with a tarp or other cover material until analytical results were available. Sampling procedures and analytical methods would be addressed in a Remedial Action Sampling and Analysis Plan to be developed during the remedial design phase.

Based on analytical results, segregated materials would be assigned a waste profile of non-RCRA soil and debris, non-RCRA soil and debris with radionuclide material, RCRA soil, RCRA soil with radionuclide material, RCRA debris, or RCRA debris with radionuclide material. The non-RCRA soil and debris would be relocated with the overburden stockpile; the non-RCRA soil and debris with radionuclide material would be managed along with the RIM; and the RCRA soil, RCRA soil with radionuclide material, RCRA debris, and RCRA debris with radionuclide material would be packaged and shipped to the off-site disposal facility in containers separate from the RIM with appropriate marking/placarding under a unique manifest. In order to comply with the RCRA waste storage limitations, stockpiled RCRA soil, RCRA soil with radionuclide material, RCRA debris, and RCRA debris with radionuclide material would not be stored on-site beyond the RCRA specified maximum accumulation periods prior to shipment to the off-site disposal facility.

The four off-site disposal facilities identified and discussed in Section 4.3.5.4 are all permitted to accept RCRA wastes and mixed wastes (Section 3.2.3) subject to their WAC (Appendix C).

After arriving at the selected off-site disposal facility and undergoing a waste receipt analysis, RCRA waste/soil and RCRA waste/soil with radionuclide material would be stabilized prior to placement in a disposal cell. Depending on the physical characteristics of the debris, RCRA debris and RCRA debris with radionuclide material would undergo either micro- or macro-encapsulation prior to placement in a disposal cell.

6.2.3.5 Short-Term Effectiveness

The "complete rad removal" alternative poses significant potential short-term risks, as described below. During a public meeting held as part of the ROD-selected remedy process, EPA identified and discussed the following short-term risk issues for waste excavation: waste handling, sorting and stockpiling; water management; noise, odor and windblown trash; worker health and safety (PPE, gamma exposure, physical stress, physical hazards, workplace monitoring); contaminant migration/spreading (fugitive dust and airborne migration, fugitive dust control and water application, leachate generation, equipment decontamination water, and water from open excavations); and waste hauling and transportation/truck decontamination issues (transfer facilities, increased local traffic, waste handling on public roads, interstate transport by rail, DOT requirements, safety issues).

6.2.3.5.1 Protection of the Community During Remedial Actions

The projected carcinogenic risks that may be posed to off-site residents by this alternative are expected to be less than 1×10^{-7}, which is within EPA's acceptable risk range. No non-carcinogenic risks are expected to occur.

Unless a rail spur is extended onto the West Lake Landfill Site (the feasibility of which, as discussed in Section 5.4.3, is currently uncertain), significant additional local truck traffic would occur during the construction period for the "complete rad removal" alternative, in order to implement the transfer of the excavated RIM to a local off-site truck-to-rail transloading location. It is estimated that nearly 29,500 round trips of semi-trucks would be required to truck the excavated RIM from the Site to a rail spur location in the vicinity of the Site and from a rail spur transloading location near the off-site disposal facility to that facility. These additional truck trips would result in additional physical risk to the local communities and truck drivers due to potential traffic accidents. Transfer of RIM from the Site by truck to an off-site rail transloading facility, by rail to the general geographic area of the disposal facility, and off-loading and transfer by truck to the actual off-site disposal facility location would be required, all of which would result in the increased potential for release of RIM as a result of traffic or train accidents and the extensive amount of additional handling of the RIM required for this alternative.

The risk assessment (Appendix H) includes an estimate of the projected incidence of transportation accidents associated with each FFS alternative. For the "complete rad removal" alternative, the projected incidence of transportation accidents associated with removal of RIM, regrading of the landfill, and importing of materials for construction of the multi-layer landfill cover is 34.9, meaning that approximately 35 accidents are projected to occur if this option were implemented.

The excavated waste to be shipped off-site would be placed in sealed metal containers (sealed DOT Industrial Packaging [IP] intermodal [IM] containers) before leaving the Site, so there should not be any spillage or other release of RIM from the containers during transport unless a major vehicular accident occurs that results in significant damage to both the transport vehicle (truck trailer or railroad car) and the DOT IP container. Notwithstanding the implementation of appropriate protective measures, a potential does exist for loose debris that may contain RIM to adhere to the wheels, under-carriage, or sides of the transport vehicles. All vehicles leaving the Site would be subject to screening for potential radioactivity and cleaning as necessary to remove any debris that may contain radioactivity prior to leaving the Site. In the event that such material is not identified during screening or removed during cleaning, a potential exists for this material to be released along the route of transport from the Site to the off-site disposal facility. If such releases were to occur, members of the public that traverse the same roads or that trespass onto the railroad tracks could potentially be exposed to RIM that may be released. Such exposures are not expected to pose a significant risk due to the anticipated small amounts of material that potentially could be released, the distance between such materials and possible receptors, the limited duration of exposure, and the presence of shielding associated with vehicular use of the roads or limited trespass onto the rail lines (see Appendix H).

Disturbing the waste material during implementation of the “complete rad removal” alternative may expose the community to radioactive waste, methane and radon gas and other contaminants, and cause a release of undesirable odors. Excavation of existing waste materials would undoubtedly result in odor emissions during the period of time that existing wastes may be handled or exposed. Mitigation of odors through engineering means is limited.

The “complete rad removal” alternative would contribute significant carbon dioxide equivalent emissions as a result of ongoing vehicle operations associated with remedial work. In particular, approximately 83,000 tons of carbon dioxide equivalent emissions are projected to be emitted to the atmosphere as a result of landfill regrading work, construction of the landfill cover, the excavation, loading, and transport of the RIM to an off-site disposal facility, and the importation of materials used to construct the multilayer landfill cover (Appendix I, Table I-5).

Because RIM in Areas 1 and 2 would be excavated under this alternative, overburden containing putrescible wastes would be stockpiled and stored and RIM would be loaded into transport containers. During these activities, the nuisance attraction to and congregation by birds at and above the affected areas would be problematic unless effectively controlled. The FAA has stated that “[t]o date, no . . . [putrescible waste] facility has been able to demonstrate an ability to reduce and sustain hazardous wildlife [birds] to levels that existed before the putrescible-waste landfill operations began operating.” (FAA, 2007). The main concern would be the potential for increased bird strikes to aircraft approaching and departing from the Lambert-St. Louis International Airport. For the “complete rad removal” alternative, an enclosed waste staging and loading structure would be constructed to minimize the outdoor handling of waste and associated attraction of birds or other vectors. Additional mitigation measures (such as excavation best management practices, which include application of daily soil cover and/or tarping of exposed waste, visual and auditory frightening devices, or use of wire or monofilament grids positioned over exposed refuse to prevent bird access) could be implemented to attempt to minimize bird attraction to and congregation at and above the disturbed areas.

Excavation of waste materials from Areas 1 and 2 would require removal of the existing landfill cover and overburden from Areas 1 and 2 and portions of adjacent areas of OU-2. Excavation of overburden and RIM would create depressions in the landfill area during the period of time required to remove the RIM and regrade and cover the remaining landfill wastes. Precipitation that falls on the landfill while such depressions are open would potentially flow into and accumulate in the depressions. Any accumulation of precipitation[47] in depressions created during waste excavation could result in increased infiltration of precipitation runoff through the underlying waste materials, which could result in increased leaching of volatile organic compounds (VOCs) or other soluble contaminants from the waste materials.

Because Areas 1 and 2 would be excavated and RIM loaded into transport containers, storm water controls would be implemented in accordance with the Missouri Storm Water regulations 10 CSR 20-6.200 to protect the community. During construction, consideration would be given to minimizing the areas of excavation that would be open and the areas of exposed waste materials at any given time. Temporary diversion berms would also be constructed above the open excavation areas and any previously excavated (and temporarily covered) surfaces in order to divert precipitation runoff around the open excavation to prevent the runoff from contacting uncovered waste materials. Precipitation that would contact uncovered waste materials would flow into the low point of the excavation and be pumped out into temporary storage tanks using portable gas-driven pumps. Samples would be collected from the tanks and sent to a laboratory for analysis. The stored water would be directly discharged or treated and disposed appropriately based on the analytical results.

6.2.3.5.2 Environmental Justice Concerns

As was previously discussed in Section 6.2.1.5.1 as part of the evaluation of short-term impacts associated with the ROD-selected remedy, a screening level analysis did not identify any environmental justice concerns. EPA did identify a need for implementation of more traditional (non-electronic) communication methods to inform and ensure meaningful involvement of residents in the Terrisan Reste mobile home community.

6.2.3.5.3 Protection of Workers During Remedial Actions

The "complete rad removal" alternative would entail significant excavation, handling, loading and transport of RIM at the Site and therefore would pose both significantly increased radiological exposure risks as well as construction safety risks to on-site workers. The risk assessment (Appendix H) presents an evaluation of potential risks to Site workers that may occur

---

[47] Accumulation could be significant during a heavy rainstorm insofar as the maximum historical 24-hour rainfall for the St. Louis area ranges from a low of 3.7 inches in November to a high of 8.8 inches in August (NOAA, 2011).

for each alternative. These include risks from industrial accidents, exposure to carcinogenic substances, and projected radiation exposures. For the “complete rad removal” alternative, the projected incidence of industrial accidents is 17.8 over the life of the project. The projected carcinogenic risk to the maximally exposed individual (radiation field technician) is 2.2 x 10^{-3}, and the projected radiation dose to a remediation worker is 405 mrem/yr (Appendix H).

Workers involved in the excavation activities may be subject to potential short-term risks associated with excavation of the waste materials, including exposure to contaminated waste; excavation/trenching instability; stormwater runoff entering areas where waste is exposed, resulting in the exposure to contact storm water; odor emissions; and other aesthetic issues (*e.g.*, windblown trash) arising from exposed waste. Worker exposures would be addressed through development and implementation of a site safety plan, use of personal protective equipment, and performance of personnel and environmental monitoring during implementation of remedial action. Workers would be protected during construction by adhering to OSHA practices; however, as this alternative entails extensive excavation, handling and transportation of RIM, OSHA work practices and personal protective equipment may not provide full protection against exposure to external gamma radiation.

Excavation would require construction workers and equipment that would initially disturb the overburden soil and underlying waste materials. Dust control measures would be required to limit worker exposure to fugitive dust during construction. As discussed in Section 6.2.2.4 above, the separation of radiologically-impacted soil from solid wastes and construction/ demolition debris may (if feasible) be a potential means of reducing the overall volume of material and resultant cost of off-site transport and disposal; however, this action would increase short-term exposures and risks to remediation workers because the screens or other equipment used to segregate large items and debris from the soil become fouled with plastic, wood, and other debris that potentially would need to be physically removed by workers. Such activities would require workers to be in close proximity to the RIM, thereby increasing their short-term exposure risks. The risk assessment conducted for this FFS does not account for such increased physical separation/segregation exposures to workers.

6.2.3.5.4 Environmental Impacts

No measurable long-term impacts to plants or animals in surrounding ecosystems are expected from this alternative. As noted in the original and updated BRA (Auxier & Associates, 2000 and 2016a), some of the ecosystems present at the Site are the result of existing institutional controls and other limitations on land use within or adjacent to OU-1 that have allowed field succession to take place. Much of the habitat on Areas 1 and 2 was removed in 2016 in conjunction with construction of the non-combustible cover. Excavation of RIM, regrading of Areas 1 and 2, and construction of the engineered landfill cover under the “complete rad removal” alternative would destroy the remaining portions of the habitats that currently exist on the surface of Areas 1 and 2, forcing wildlife to migrate to other areas. Vegetative cover would be placed on the Site as a part of the final cover, and the landfill would be allowed to return to an early-stage field ecosystem with periodic mowing and maintenance.

6.2.3.5.5 Ability to Monitor Effectiveness

Regular monitoring of groundwater quality would be performed at appropriate locations around Areas 1 and 2 to assess the effectiveness of this alternative.

6.2.3.5.6 Time Until Remedial Action Objectives Are Achieved

The RAO related to the Buffer Zone and Crossroads Property soil would be met upon removal of any remaining soil containing radionuclides above unrestricted levels from these areas. The RAOs related to Areas 1 and 2 would be met once the RIM excavation and construction of the new landfill cover over Areas 1 and 2 were completed. Excavation and off-site disposal of RIM makes achievement of these RAOs post-excavation more certain because the "complete rad removal" alternative is predicated on the assumption that all RIM above unrestricted use levels would be removed from the Site, thereby greatly reducing the RIM source term and the magnitude of potential exposures to radionuclides, potential future radon emissions, and potential leaching of radionuclide constituents in the unlikely event that the landfill cover or institutional controls were to fail.

Initiation of this alternative would require significant planning and permitting due to the limited number of off-site disposal facilities capable of taking RIM and the extensive logistics associated with identifying, handling, classifying and loading the materials for transport to the selected off-site facility. Preparation of the remedial design should be completed within approximately 15 months of authorization to proceed with the RD. RD could take significantly longer if full-scale pilot-testing of solids separation equipment were to be performed. The RAOs would be achieved upon completion of construction, which is estimated to be finished within approximately 12.1 years after approval of the RD. Therefore, the remedial action objectives should be achieved within 13.35 years of approval to proceed with the RD (Appendix J). This schedule estimate assumes that the buyout of the asphalt company lease and potential permitting for and subsequent relocation of the solid waste transfer station occurs during the remedial design phase; otherwise, the schedule would be longer.

The projected construction schedule and the cost estimate for the "complete rad removal" alternative are highly dependent on the waste material swell factor; that is, the amount the in-place waste volume expands as it is excavated, handled and loaded for transport to an off-site disposal facility. For purposes of this FFS, a swell factor of 1.5 has been assumed. A swell factor greater than 1.5 would result in an increase to the overall construction schedule and the estimated costs. The projected construction schedule and the cost estimate for the "complete rad removal" alternative also are highly dependent on the number of rail cars that could be loaded and shipped per day. The schedule and cost estimate developed in this FFS for this alternative are based on an assumption that a sufficient number of IM containers and rail cars can be made available, loaded, switched out and replaced every day. The schedule is also based on (1) a "fleet" (*e.g.*, approximately 20) of flat railcars being dedicated to the project that would be continuously cycled between the off-site disposal facility and the St. Louis area during the period of time required to transport RIM to the off-site disposal facility and (2) the RIM loading operation being performed in a relatively continuous manner with a constant volume of RIM being transport off-site per day. If the actual rate is less than the projected rates of RIM excavation used to develop the construction schedule or if the RIM loading and transport operation is not relatively continuous, the time required to complete construction and the costs for the "complete rad removal" alternative would increase.

6.2.3.6 Implementability

This alternative would involve excavation and off-site disposal of RIM in Areas 1 and 2, repair and restoration of the disturbed portions of the OU-2 landfill units adjacent to Areas 1 and 2, grading of the surfaces and installation of upgraded landfill covers over the excavated areas of Areas 1 and 2, long-term monitoring and maintenance of the covers, and long-term monitoring of landfill gas and groundwater and surface water quality.

Excavation of RIM would require removal of substantial amounts of overburden and material from the sidewalls of the excavations in order to maintain stability of the excavation areas. Overburden removal would entail removing and temporarily relocating a large amount of the above-grade portion of the North Quarry part of the Bridgeton Landfill in order to access the underlying RIM in OU-1 Area 1. The total amount of non-RIM waste required to be removed is estimated to be approximately 1,300,000 bcy, which, based on an expansion factor of 1.5, would result in the need to handle, stockpile and replace 1,950,000 lcy of waste. Management of such a large amount of exposed waste in both the excavation areas and the stockpiles (including management of stockpiles, stormwater runon and runoff, odor emissions, attraction to birds and other vectors, and litter control) would be a significant undertaking. The amount of space available for stockpiling the overburden material is limited, and therefore overburden material from Area 1 would need to be transported to Area 2 for temporary stockpiling while waiting for final placement and capping. Similarly, the total volume of RIM that would be excavated under this alternative is estimated to be 269,000 bcy, equivalent to approximately 400,000 lcy. Due to the double-handling (at a minimum) of the overburden material plus the RIM handling, it is anticipated that more than 4,700,000 lcy of waste would be handled under this alternative.

An additional complication arises from the proximity of the Bridgeton Transfer Station. In order to access the RIM in the southwest portion of Area 1, the solid waste transfer station would need to be relocated, as removal of waste material would extend up to and along the base of the transfer station such that the integrity of the transfer station building foundation and above-grade structure would be compromised. The only available space for relocation of the transfer station is the area currently occupied by Simpson Asphalt Company, which holds a long-term (99-year) lease on this area. This lease would have to be bought out and the asphalt company would need to be relocated before the transfer station could be relocated to this area. The estimated construction schedule (Appendix J) and costs (Appendix K-4) for this alternative are predicated on the solid waste transfer station being relocated prior the start of RIM excavation and transport.

It is anticipated that a new structure would be constructed to shelter the RIM staging and loading operations in order to minimize stormwater contact, odor emissions and bird attraction and to allow RIM loading for off-site disposal would occur on a relatively continuous basis. Such a structure would likely be constructed along the north side of the Site access road in the area that is currently being used to store new, reclaimed and surplus equipment and materials associated with ongoing operation and maintenance and closure activities for the Bridgeton Landfill. These materials would need to be relocated to another portion of the Site prior to construction of such a structure.

In order to minimize potential vehicle interactions between normal traffic to and from the re-located solid waste transfer station and the construction operations associated with this alternative, a temporary overpass would likely need to be constructed over the Site access road to allow for uninterrupted movement of construction traffic between Areas 1 and 2 and uninterrupted traffic of refuse trucks to/from the relocated solid waste transfer station. An overpass is considered the most efficient and safest means for transfer of overburden waste from Area 1 to stockpile locations in Area 2 and then back to Area 1. In addition, as discussed above, a single RIM staging and loading building would be constructed and operated as part of this alternative. RIM removed from Area 1 would need to be transferred over the Site access road to the RIM staging and loading building. Installation of an overpass would eliminate the potential for RIM material to be tracked across the Site access road and potentially tracked off-site. An overpass would also eliminate the need for traffic control and potential for accidents that would be associated with an intersection of the solid waste transfer station access road and the temporary construction traffic road between Area 1 and Area 2.

While excavation with subsequent off-site transportation and disposal have been implemented at other sites containing radioactively-impacted materials, materials from these other sites have not included significant amounts of landfill solid wastes and debris, and it is expected that these landfill wastes could complicate the implementation of any RIM removal. Significant technical and administrative implementability issues are also associated with excavating the RIM and loading it into IM containers for transportation if this alternative were to be implemented. These include the following:

- Reduced excavation production rates and increased volume of RIM ultimately subject to excavation and disposal resulting from application of daily cover over an extended excavation schedule;

- Ability to locate and obtain a lease to an off-site rail spur for use as a truck-to-rail transfer facility, or alternatively, the ability to construct an on-site rail spur and rail loading facility;

- Increased potential over an extended period of time for bird strikes to aircraft as a result of excavation of putrescible or organic solid waste overburden waste from the North Quarry portion of the Bridgeton Landfill and Areas 1 and 2 and excavation RIM contaminated waste from Areas 1 and 2, all of which are located within flight paths of Lambert–St. Louis International Airport;

- Ability to remove all of the RIM due to the close proximity of some of the deeper RIM in OU-1 Area 1 beneath and adjacent to the above-grade portion of North Quarry part of the

Bridgeton Landfill and in OU-1 Area 2 adjacent to other landfill units (*e.g.*, Closed Demolition Landfill and Inactive Sanitary Landfill); and

- Impacts to other Site operations and traffic on surrounding roads from additional truck traffic used to haul wastes to an off-site truck-to-rail transfer facility and to haul earthen materials to the Site for daily cover, stockpile covers, and construction of the final cover.

Design and construction of post-RIM-excavation landfill covers over Areas 1 and 2, with subsequent monitoring and maintenance, are not expected to pose any implementability challenges. Materials and services necessary for the regrading and construction of the final landfill covers over Areas 1 and 2 after RIM removal are available, and the technologies have been proven through application at other landfills.

The actions included for the Buffer Zone/Crossroads Property – that is, the testing and excavation of surface soil – are regularly and easily implementable.

Monitoring of the cover surfaces, landfill gas, groundwater, and surface water are proven methods for demonstrating the long-term effectiveness of the covers placed over Areas 1 and 2 and are easily implemented.

6.2.3.6.1 Ability to Construct and Operate the Technology

In general, excavation and off-site disposal are standard technologies. However, there are unique circumstances associated with excavation of RIM in Areas 1 and 2, located as Areas 1 and 2 are within an overall larger closed/inactive landfill site, which would complicate implementation of standard excavation technologies.

There are questions regarding the ability to remove all of the RIM from Area 1 and Area 2 due to the depth of some of the RIM and/or the proximity of OU-1 Areas 1 and 2 to the OU-2 landfill units such as the North Quarry portion of the Bridgeton Landfill, closed construction and demolition waste landfill (the C&D landfill) and the OU-2 inactive solid waste landfill. RIM is not present in these other landfill units, but it would be necessary to excavate into these OU-2 units in order to access some of the RIM in OU-1. Although sheet piling as a Site-wide replacement for excavation sidewall sloping was evaluated as part of the SFS and found not to save costs or time compared to sloping the sidewalls, small areas of sheet piling where the OU-1 RIM is closest to the adjacent OU-2 landfill units may prevent or minimize encroachment of excavation slopes into the OU-2 units and therefore prove economical for the “complete rad removal” alternative. Such targeted use of sheet piling could be further evaluated during remedial design.

Upon completion of removal of the RIM from OU-1, disturbed portions of the adjacent landfill units in OU-2 would need to be repaired and restored to a condition that meets or exceeds existing closure conditions prior to implementation of this alternative and subject to the requirements of any additional remedial actions required for either of these areas as part of implementation of the OU-2 remedy.

RIM excavation and placement in IM containers and hauling of the containers by truck for subsequent transfer to rail is also expected to present implementability concerns, challenges, and risks, specifically those associated with the following:

- Excavation and handling of contaminated materials;
- Safety risks associated with encountering methane gas during excavation;
- Management of fugitive dust and potential odors;
- Mitigation of bird hazards;
- Management and treatment of stormwater exposed to RIM during excavation; and
- Identifying, segregating, and disposing off-site of any hazardous wastes, polychlorinated biphenyls (PCBs) or RACM that may be encountered during RIM excavation.

If hazardous wastes, PCBs, or RACM are encountered during excavation of RIM, these materials would need to be segregated from the other waste materials, characterized, and transported to an off-site disposal facility in containers separate from the other RIM. Additional health and safety procedures would be required during excavation of these materials. These materials would require separate handling at the off-site disposal facility and could require treatment prior to disposal. Depending on the characteristics of any hazardous waste encountered during excavation, the hazardous waste could need to be transported to a different off-site facility for treatment and disposal in accordance with RCRA.

Directing and controlling the RIM excavation process using radiological scanning and sampling techniques would significantly impact overburden and RIM excavation production rates. Based on experience in excavation of radiologically-impacted waste at other sites, a reduction in efficiency is expected for overburden excavation and a greater reduction is expected for RIM excavation. Because thorium-230 is a primary radionuclide of concern with regard to a "complete rad removal" alternative, even greater reductions in efficiency and increased time may be required for RIM excavation. Thorium-230 cannot be detected using field survey instruments, and therefore excavation activities would have to rely on collection and laboratory analyses of samples for guidance. In order to minimize the potential impacts on the excavation schedule, it is assumed that an on-site laboratory would be set up and operated to provide quick analyses of samples to guide excavation activities and initial confirmation that all of the RIM had been removed. A percentage of such samples would also be sent to an off-site laboratory for verification of the on-site laboratory results. Samples obtained for final confirmation that all RIM has been removed from a particular area would also be subjected to off-site laboratory analyses and data validation. All of these activities would undoubtedly impact the rate of RIM excavation and the duration over which excavation areas need to remain open.

Daily soil cover and tarps would need to be placed over open excavation areas and stockpiled overburden to minimize dust, odor, and the attraction of birds and other wildlife. The proximity of Areas 1 and 2 to Lambert-St. Louis International Airport poses a potential risk to aviation operations. The St. Louis Airport Authority and the U.S. Department of Agriculture have identified as a problem the potential for increased bird activity in conjunction with waste excavation at the Site and the resultant increased risk of aviation bird strikes. Bird nuisance mitigation measures such as best management practices (including, but not limited to, daily soil cover and tarps over exposed overburden and wastes), visual and auditory frightening devices, and wire or monofilament grids strung over exposed refuse to prevent bird access, could be evaluated for use at Areas 1 and 2. The size of open excavations may limit the constructability of wire or monofilament grids. Careful evaluation of material properties would be necessary during remedial design to assure that the appropriate strength and elasticity of materials are considered, that the materials are available, and that grids can be reasonably constructed.

Effective storm water controls could be readily implemented using conventional construction equipment and materials. Temporary berms to direct stormwater away from open excavations would need to be constructed, and precipitation accumulation in depressions created by the excavation activities would need to be pumped out and managed. Direct precipitation or runoff that may contact waste material could become contaminated with soils or wastes containing thorium or radium. These elements would be entrained in colloidal material that would readily settle in low areas or in the tanks used to collect and store stormwater prior to treatment and discharge. At the end of excavation activities, accumulated sediment in any low areas or the tanks would also be removed and, depending upon the activity levels, either placed in Area 1 or 2 or transported to the off-site disposal facility.

Excavated RIM exposed to precipitation would be subject to the paint filter liquids test (PFLT) as necessary to determine if free liquids exist prior to being loaded for off-site disposal. If the excavated material to be hauled off-site does not pass the PFLT, a dewatering area would need to be staged and collected water treated and/or disposed, potentially through off-site disposal. The current estimated costs and schedules do not address any dewatering activities. Should such activities be necessary, a suitable area would have to be identified within the Site.

Truck hauling of IM containers of RIM to a truck-to-rail transloading facility and transferring the RIM to railcars is technically implementable. Loading RIM directly into railcars on-site if a rail spur could be extended onto the West Lake Landfill property is theoretically implementable; however, it is not known whether extension of a spur onto the property is actually feasible. If construction of an on-site rail spur were to be considered, an engineering study and development of a detailed design would be necessary to determine the feasibility and implementability. As previously discussed in Section 5.4.3 and as further discussed in Sections 6.2.3.6.5 and 6.2.3.6.6 below, construction of an on-site rail spur would also require coordination with a number of local and state regulatory authorities as well as private landowners.

An initial comparison of the US Ecology Grand View facility WAC to estimated activity levels in the OU-1 RIM under the “complete rad removal” alternative is presented on Table 6-2. Although a representative of the turnkey contractor would be on-site during RIM excavation to coordinate loading of containers, there is a potential that one or more shipping containers could contain activity levels that exceed the WAC and may have to be unloaded and re-distributed prior to shipment or, in the worst case, returned to the Site by the disposal facility and/or sent to a different disposal facility. These additional activities could result in additional worker exposures, additional time to complete the project, and potentially additional costs.

Regrading the landfills and placement of final cover is implementable and has been performed at other landfills, including CERCLA sites. Environmental monitoring is routinely performed at most sites and is not expected to present any feasibility challenges.

6.2.3.6.2 Reliability of the Technology

Excavation and off-site disposal of radioactively-impacted material generally is a reliable technology, and has been implemented at a number of FUSRAP sites. Notably, waste deemed “inaccessible” has generally been allowed to remain in place, including in the case of the St. Louis North County Sites, which were successfully remediated to conditions that pose no risk to human health and the environment under any future use scenarios. It should be noted, however, that none of these FUSRAP sites involved radiological materials commingled with municipal solid waste and disposed in a landfill setting. The reliability associated with disposal in an off-site facility would be dependent on the integrity of the liner and cover systems at the off-site facility being maintained, as well as the effectiveness of the various off-site facility monitoring programs.

Landfill cover systems such as those that would be implemented over Areas 1 and 2 after RIM removal, and which are designed and constructed consistent with State and Federal regulations and with post-closure care implemented in accordance with current regulatory guidance, have been demonstrated to be reliable at: (1) minimizing percolation and infiltration of precipitation; (2) minimizing leachate generation; (3) minimizing impacts to groundwater quality; (4) minimizing impacts to surface water quality and quantity; (5) minimizing erosion of cover material; and (6) minimizing uncontrolled releases of landfill gas. Landfill cover systems have been demonstrated to be reliable methods for isolating waste materials. Similarly, access restriction measures have been demonstrated to be reliable mechanisms to prevent unauthorized access to a site.

Bird nuisance mitigation measures such as best management practices (including, but not limited to daily soil cover and tarps over exposed RIM and waste), visual and auditory frightening devices, and wire or monofilament grids strung over exposed refuse to prevent bird access, are demonstrated reliable technologies under proper operating and excavating conditions. However, while visual or auditory frightening devices can be effective in the short-term, birds tend to habituate to deterrents over time, causing the deterrent to lose effectiveness. Frequent relocation of predator birds and predator effigies and/or altering the timing of auditory activation may help, but long-term effectiveness is not assured. In addition, the FAA has stated that “[t]o date, no . . . [putrescible waste] facility has been able to demonstrate an ability to reduce and sustain hazardous wildlife [birds] to levels that existed before the putrescible-waste landfill operations began operating.” (FAA, 2007).

Storm water controls are well-established technologies that are implemented at most landfill sites. For this alternative, gravity settling of suspended solids potentially containing radionuclides is a well-established and reliable technology.

6.2.3.6.3 Ease of Undertaking Additional Remedial Actions, if Necessary

It is possible that all of the RIM may not be removed during implementation of the "complete rad removal' alternative. In accordance with the Supplemental Standards provision of UMTRCA (40 CFR § 192.21), a decision could be made by EPA to leave some RIM at the Site. EPA could determine that RIM that is deeply buried beneath large volumes of waste or that is located adjacent to buildings (*e.g.*, adjacent to the solid waste transfer station) such that removal could impair/ undermine the integrity of those structures, would be better left at the Site. If this were to occur after completion of the "complete rad removal" alternative, regrading of the landfill, and construction of a new engineered landfill cover, performance of additional remedial action in the future to remove such materials would be very difficult and costly.

The only anticipated additional remedial actions that may need to be taken for the "complete rad removal" alternative would be maintenance activities needed to sustain the cover system, repair areas of differential settlement or address erosion, or possible implementation of a contingent landfill gas control system. Differential settlement or compaction of the underlying remaining waste materials after RIM excavation could necessitate placement of additional soil over all or portions of Areas 1 or 2 to maintain the required final grades. Long-term monitoring and maintenance of the landfill covers at other Superfund sites and at non-Superfund solid waste landfills is typically required to assess whether differential settlement or surface erosion of the cover has occurred over time. Long-term monitoring and maintenance including cover inspection and repair would be part of this alternative. Cover repair, if necessary, would involve placement of additional fill, regrading, and revegetation of the repaired area.

In the event that monitoring of subsurface landfill gas detects the presence of gas levels above regulatory thresholds along the perimeter of the landfill, a landfill gas control system could be implemented as an additional remedial action. Implementation of a contingent landfill gas control system would entail drilling and installation of gas extraction wells, installation of conveyance piping, installation and operation of landfill gas extraction blowers and a landfill gas treatment (flare) system. Installation of a contingent gas system could be performed as a future action. Any disruption to the final landfill cover resulting from the installation of a contingent gas extraction system would need to be repaired. Such activities are commonly and routinely undertaken at solid waste disposal sites.

Bird nuisance mitigation measures such as best management practices (including, but not limited to daily soil cover and tarps over exposed waste), visual and auditory frightening devices, and wire or monofilament grids strung over exposed refuse to prevent bird access, could be applied to additional excavated area in the event that additional waste volume is encountered.

Storm water management measures, other than those using conventional earth-moving equipment, piping, pumps, liners, filtration and carbon adsorption water treatment equipment, rip-rap, and pond outlet structures, are not anticipated to be necessary to support implementation of the "complete rad removal" alternative.

6.2.3.6.4 Ability to Monitor Effectiveness of Remedy

Demonstrating the effectiveness of the cover systems constructed over Areas 1 and 2 after RIM removal above unrestricted use levels would be accomplished by implementing monitoring programs for the cover surface, landfill gas system, groundwater and surface water programs as previously described in Section 5.4.4. These types of monitoring programs have been proven at demonstrating cover effectiveness and are easily implemented.

6.2.3.6.5 Ability to Obtain Approvals from Other Agencies

Implementation of the "complete rad removal" alternative would require approvals from other agencies, including the following:

- Approval from the FAA to conduct waste excavation activities within 10,000 feet of an active airport runway. FAA Advisory Circular AC 150/5200-33B, dated August 28, 2007, "Hazardous Wildlife Attractants On or Near Airports," recommends "against locating a MSWLF [municipal solid waste landfill] within the separation distances identified in Sections 1-2 through 1-4. The separation distances should be measured from the closest point of the airport's AOA [airport operations area] to the closest planned MSWLF cell." AC 150/5200-33B, p. 4. The separation distances referenced are 5,000 feet from the end of a runway for airports serving piston-powered (propeller) aircraft; 10,000 feet for airports serving turbine-powered (jet) aircraft; and 5 miles of protection from hazardous wildlife movement for approach, departure and circling airspace. The FAA strongly recommends against allowing a waste disposal operation within 10,000 feet of a jet aircraft runway if the material contains putrescible waste and so has the potential to attract wildlife that could threaten air traffic. The excavation of RIM material containing putrescible waste within 10,000 feet of the westernmost runway (11/29, formerly known as 12W/30W) at Lambert-St. Louis International Airport, as would occur during excavation of the RIM in Areas 1 and 2, is limited by the need to mitigate potential bird activity during excavation to address the requirements of the FAA Advisory Circular and to comply with the same prohibitions in the Missouri solid waste regulations. It may be necessary to work directly with the FAA and MDNR to identify specific bird mitigation measures during implementation.

- Approval of St. Louis Airport Authority (STLAA) relative to obtaining a release for the Negative Easement and Declaration of Restrictive Covenants Agreement (Appendix A-2). Excavation of RIM from Areas 1 and 2 poses a potential to increase the bird populations at the Site if mitigation procedures are not employed or prove ineffective. An increase in bird populations presents a greater potential for aircraft-bird strikes. The STLAA and USDA have identified this as a concern relative to construction and operation of a new on-site disposal cell that was included in the “complete rad removal” with on-site disposal alternative evaluated in the SFS. Based on the STLAA’s position stated in the STLAA’s September 20, 2010 letter to EPA (Appendix A-5), STLAA acceptance of RIM waste excavation would not be likely if bird activity were to increase. It may be necessary to work directly with the FAA and the STLAA to address these concerns, either by amending the FAA ROD, amending the Negative Easement, requiring specific bird mitigation measures during implementation, or making other changes to secure STLAA’s cooperation.

- Location of an off-site truck-to-rail loading facility. At a discussion held in September 2010, the STLAA indicated that they would not allow the use of the existing SLAPS truck-to-rail transloading facility for loading waste from the West Lake Landfill into railcars (see Appendix A-4). The SLAPS rail spur is reportedly owned by the U.S. Army Corps of Engineers and the land upon which the rail spur is built is owned by the City of St. Louis. It is not clear that the STLAA could prevent use of the SLAPS rail spur for loading and shipping via contractual means; however, as the STLAA is the owner of the property, their concurrence must be considered. Therefore, it appears unlikely that the rail spur at the airport would be available for implementation of a remedial action for West Lake Landfill. No other nearby off-site truck-to-rail loading facilities have been identified. Discussions with US Ecology have indicated that as part of the transportation and disposal activities, US Ecology would locate and lease an existing rail spur in the area or otherwise construct a rail spur somewhere in the area that could serve as a transloading facility.

- Approval for construction of on-site rail spur. If a rail spur were to be extended onto the West Lake Landfill Site, necessary permitting and approval to construct a rail spur across St. Charles Rock Road (Missouri Route 180) and associated rail crossing traffic control facilities would need to be obtained from the Missouri Department of Transportation, St. Louis County and/or the City of Bridgeton.

- Compliance with EPA’s Off-Site Rule (OSR). The EPA Region where the off-site disposal facility is located would need to be contacted every 60 days during the period of off-site waste shipments to obtain a compliance determination as to whether the disposal facility currently meets the criteria under the OSR to accept CERCLA waste. If, during RIM excavation, the contracted off-site disposal facility was to fall out of compliance for a period of time, excavation and transportation would either need to cease until the facility becomes compliant again, or RIM would need to be transported to another facility that is determined to be in compliance with the OSR. Besides schedule delays, temporary stoppage of construction would present significant technical implementability concerns regarding open excavation areas.

- Rocky Mountain Low Level Radioactive Waste Compact Consent. If RIM were to be disposed at the Clean Harbors Deer Trail, CO facility, an application would have to be submitted to and accepted by the Rocky Mountain Low Level Radioactive Waste

Compact. Disposal at the US Ecology Grand View, ID or Wayne, MI facilities, and Energy*Solutions* Clive, UT facility would not be subject to a Waste Compact consent.

6.2.3.6.6 Coordination with Other Agencies

Coordination with many entities would be necessary to implement the "complete rad removal" alternative (although not all of them are considered "agencies"). Coordination with the Site owner and operator and owners or occupants of the various parcels that comprise the West Lake Landfill Site would be necessary because of the following:

- Termination of the asphalt company lease and removal of the asphalt plant followed by relocation of the Bridgeton solid waste transfer facility and construction of an overpass between Areas 1 and 2 over the Site access road would need to occur prior to the start of RIM excavation;

- Access to operations conducted on other portions of the Site would need to be maintained.

- Areas 1 and 2 are within a larger existing Site footprint, and use of areas on the West Lake Landfill Site outside of Areas 1 and 2 might be necessary to stockpile cover materials or otherwise to facilitate cover construction.

- Implementation of this alternative would require excavation of portions of landfill units located outside of OU-1. Upon completion of removal of the RIM, disturbed portions of the adjacent landfill units would need to be repaired and restored, and regrading and installation of a replacement landfill cover over areas outside of OU-1 would need to be performed. Coordination would also be required relative to integration of the slopes and grading for adjacent landfill areas and routing and design of stormwater diversion and conveyance structures between OU-1 and other landfill areas.

- Use of other areas of the West Lake Landfill Site that may be necessary for stockpiling of overburden and staging or routing of trucks or rail cars used to haul the excavated RIM off-site.

- Implementation of any additional institutional controls or modifications of any of the existing institutional controls that EPA may require would need to be approved and accepted by the individual entities that own the various parcels that compose the Site.

For the duration of excavation, off-site transport, and import of cover materials, the flow of vehicles associated with remedy construction would need to be coordinated with the traffic patterns of vehicles associated with the current on-site solid waste transfer station and other Site tenants.

If a truck-to-rail transloading facility at an off-site rail spur location were to be used, a suitable location would need to be identified and a lease secured with the land/rail spur owner for the duration of the RIM loading and transport operations. As noted above, it does not appear that the existing SLAPS truck-to-rail transloading facility would be available, so costs for establishing a new facility would need to be considered[48].

If a rail spur were to be extended onto the West Lake Landfill Site:

- Land located across St. Charles Rock Road would either need to be purchased or long-term leases would be needed with landowners;
- State and local government, private landowner, facility occupant and community approval would need to be obtained in order to construction of a rail spur across private property located to the east of St. Charles Rock Road, across St. Charles Rock Road, and along the access roads which serve the existing solid waste transfer station and asphalt plant operations located at the Site;
- Appropriate safety measures for the crossing at St. Charles Rock Road would have to be installed, consistent with requirements of state and local governments;
- The long-term lease of the asphalt plant for land south of the solid waste transfer station, would need to be bought out or otherwise acquired; and
- Because of the high traffic volume on St. Charles Rock Road during the day, dropping off empty and picking up loaded railcars would likely be possible only during late nighttime and early morning hours.

Provision and switching of gondola railcars either at a truck-to-rail transloading facility spur or an on-site rail spur would need to be coordinated with the railroad company that would be hauling the railcars to the off-site disposal facility.

Future groundwater monitoring activities could require obtaining and maintaining access to off-site properties if off-site groundwater monitoring were required as part of the remedy.

The potential for increased bird strikes to aircraft approaching and departing the Lambert-St. Louis International Airport is a major concern of the FAA and St. Louis Airport Authority. The effectiveness of proposed bird nuisance mitigation measures would be of interest to the FAA and Airport Authority. Consequently, the FAA and Airport Authority would need to be involved in the remedial planning process.

Coordination with other agencies, including the Earth City Flood Control District, MSD and MDOT, as well as adjacent property owners and businesses (for example, the Crossroads Property/AAA Trailer) would also be necessary to:

---

[48] The unit cost estimates provided by US Ecology for purposes of this FFS include costs to secure an off-site rail spur for a truck-to-rail transloading facility.

- Coordinate with the Earth City Flood Control District regarding the design of non-contact stormwater management and discharge facilities both during and after completion of construction;

- Coordinate with MSD regarding permitting and design of leachate/contact stormwater discharge during construction;

- Coordinate with MDOT for access to areas along St. Charles Rock Road and for any traffic control or ingress and egress additions along St. Charles Rock Road in the vicinity of the Site entrance; and

- Obtain legal and physical access from AAA Trailer for testing and, if necessary, remediation of the Crossroads Property and possibly for implementation of remedial actions that may need to be performed along the property boundary (e.g. regrading, fencing, etc. in Area 2).

As discussed at the beginning of this section (6.2.3.6), in order to access RIM in Area 1, the Bridgeton Transfer Station LLC building would need to be relocated. The only suitable area for relocation of the solid waste transfer station is the area currently under lease and occupied by Simpson Asphalt Company. The asphalt company lease would need to be bought out and their equipment removed from the Site before the transfer station could be relocated. Relocation of the transfer station would normally be subject to permitting by the City of Bridgeton and St. Louis County; however, because relocation of the transfer station would be performed as part of a Superfund remedial action and the transfer station would remain on-site, additional permitting is not anticipated to be required. However, it is likely that public meetings and hearings may be necessary, which would require coordination with the City of Bridgeton and St. Louis County and could impact the timing for the start of construction of a "complete rad removal" alternative.

6.2.3.6.7 Availability of Off-site Treatment, Storage and Disposal Services and Capacity

As discussed in Section 4.3.5.4., four off-site disposal facilities that could accept excavated RIM from the West Lake Landfill OU-1 have been identified. At least three of these facilities (located in Idaho, Utah and Colorado) have accepted radiologically-impacted soil from projects or sites in the United States, although none of them have previously accepted radiologically-impacted soil mixed with solid waste. All four of the identified facilities have available capacity to accept the estimated volume of RIM from the Site. The volumetric rate of acceptance for all facilities would be limited by the number of IM containers and railcars that could be provided and loaded at or near the Site, as well as the number that could be unloaded at or near the disposal facility. Off-site treatment, storage and disposal may be required in the event that hazardous wastes or regulated asbestos-containing materials (RACM) are encountered in the overburden or RIM excavated from Areas 1 and 2.

The identified off-site disposal facilities are also permitted to: (1) accept liquid wastes, should any stormwater that may accumulate in excavations during RIM excavation become contaminated and require disposal off-site; (2) accept mixed wastes, if mixed wastes are encountered during excavation; and (3) treat soil and/or debris that contains hazardous waste or mixed waste.

As discussed in Section 3.2.1, the CERCLA Off-Site Rule requires that waste materials removed from a CERCLA site only be placed in a facility operating in compliance with RCRA or other applicable Federal or State requirements. EPA makes such determinations every 60 days. The compliance status of an off-site disposal facility would need to be evaluated during remedial design and would need to be regularly evaluated and updated during remedy implementation.

Off-site treatment and discharge of any leachate that may be encountered or stormwater that may contact RIM during the landfill excavation activities could also be required. Initial discussions with MSD indicated that they are willing to accept leachate and contact stormwater and initial discussions with the Earth City Flood Control District indicated a willingness to accept stormwater, subject to installation of additional stormwater detention/retention capacity.

6.2.3.6.8 Availability of Necessary Equipment and Specialists

Materials, equipment and personnel required for excavation and transport of RIM to an off-site disposal facility are readily available. Trained health physics technicians and specialized equipment required to monitor personnel and environmental conditions, as well as to assist in directing the RIM excavation sequencing, are also available.

As discussed above, there are a limited number of disposal facilities that can accept these types of wastes, and most of these have stringent waste acceptance criteria which may limit the ability of some of the facilities to receive the wastes.

Availability of rail service, particularly the number of rail cars that can be made available and switched daily by the railroad, would also affect the production rate of RIM excavation and disposal and therefore the cost.

All of the materials, equipment and personnel needed to construct the covers over Areas 1 and 2 after RIM removal are readily available and the technologies have been generally proven through application at other landfills. The implementability and potential cost of the covers would be influenced by the availability and location of clean cover materials and/or off-site borrow sources at the time this alternative would be implemented. Potential vendors of rock, clay and soil were contacted during the development of the FS (EMSI, 2006) and during preparation of the Remedial Design Work Plan for the ROD-selected remedy (EMSI, 2008). Information obtained from the vendors at these times indicated that rock, clay and clean fill material were readily available from sources located near the Site. If these local sources of cover materials become exhausted prior to or during remedy implementation, cover materials would have to be obtained from suppliers at greater distances from the Site.

The necessary materials, equipment and personnel required for assessment and removal of RIM that may be present at the Buffer Zone/Crossroads Property to unrestricted use levels and to implement the institutional controls and monitoring components of this alternative are also readily available.

6.2.3.6.9 Availability of Prospective Technologies

The “complete rad removal” alternative is based on proven, established, and commonly used technologies. Use of prospective technologies is not currently envisioned to be part of this alternative.

6.2.3.7 Cost

Estimated capital, annual OM&M, and 30-year present worth costs for the “complete rad removal” alternative are included in Appendix K-4 and summarized on Table 6-1. Conceptual excavation, backfill, and bottom and top of final cover grading plans as well as stormwater control features used as the basis for the “complete rad removal” alternative capital cost estimate are provided in Appendix M. The estimated cost to conduct the “complete rad removal” remedy (i.e., design costs, capital costs, and costs for monitoring during the construction period) is $616,000,000 based in part on unit costs provided by US Ecology. These costs do not include costs to conduct full-scale pilot-testing of solids separation equipment, which is beyond the scope of the FFS. The estimated annual OM&M costs range from $167,000 to $326,000 per year depending upon the specific activities that occur each year (e.g., higher costs for years with additional environmental monitoring and years when landfill cover repairs may occur). The cost estimates provided in this FFS are feasibility-level cost estimates which were developed to a level of accuracy such that the actual costs incurred to implement this alternative are expected to fall within a range bounded by 50% above and 30% below these estimates.

The present-worth costs of the “complete rad removal” alternative are projected to be $420 million over a 30-year period based on a discount rate of 7%. Based on the current OMB rate of 1.5%, the present worth costs would be $566 million. The total non-discounted costs for the “complete rad removal” alternative over 30 years are projected to be $6190 million. Present-worth cost estimates were also calculated for 200-years and 1,000-years (Table 6-1), similar to what was done for the other alternatives.

Unit costs associated with transportation by rail and disposal of RCRA soil, RCRA soil with radionuclide material, RCRA debris, and RCRA debris with radionuclide material would have added treatment costs in order to meet the Land Disposal Restrictions (LDRs) and Universal Treatment Standards (UTS). Based on discussions with representatives of the disposal facilities during preparation of the SFS (EMSI et al., 2011), the additional costs for treatment at these facilities are estimated to range from $45 to $150 per ton for RCRA metals or $400 to $500 per ton for organics, depending on the type of treatment.

Since the amount of mixed waste that might be excavated along with the RIM is unknown, and because of the RCRA restrictions on waste accumulation amounts and timeframes and limited storage space on-site, it is unclear if volumes would support shipment by rail. As such, the mixed waste would likely be shipped to the off-site disposal facility directly via truck. For truck hauling to the off-site disposal facility, the interior of the semi-trailer would be lined with a disposable polyethylene slip liner and after the waste was loaded the trailer would be covered and the cover securely strapped down. The capacity of each truckload would be 22 tons or 17 cubic yards, depending on the weight of the material. Current trucking costs range from $4.70 to $5.10 per loaded mile. Road mileage from the West Lake Landfill to the US Ecology Wayne Disposal, Michigan; Clean Harbors Deer Trail, Colorado; Energy Solutions Clive, Utah; and US Ecology Grandview, Idaho facilities are 520, 720, 1,340, and 1,580 miles, respectively. Therefore, RCRA or mixed-waste truck transportation costs to an off-site facility could range from $145 to $470 per cubic yard or $110 to $370 per ton, depending on where the material is ultimately disposed.

For purposes of demonstrating how much shipping of mixed waste could influence costs, it was assumed that mixed waste would represent 0.5% of the sum of the volumes of overburden wastes and RIM for the "complete rad removal" with off-site disposal alternative. The added costs for handling, sampling/analysis, shipping, treating, and disposing of mixed waste for this alternative are estimated to range from $3 to $5.6 million. This cost range primarily results from variations in the fees charged by the off-site disposal facilities, as well as uncertainties associated with the nature of such wastes and the required method of treatment. If the volume of mixed waste is higher than the 0.5% of total mass assumption, the added costs would be higher.

6.2.4 Partial Excavation of Shallow RIM with Activities Above 52.9 pCi/g

This section presents the detailed analysis of a partial excavation alternative consisting of removal of RIM with combined radium and/or combined thorium activities greater than 52.9 pCi/g that is located within 16 feet of the 2005 topographic (ground) surface and subsequent regrading and capping of the remaining waste (hereafter referred to as the "52.9 Partial Excavation Alternative"). As previously described in Section 5.5, this alternative consists of the following components:

- Removal of the asphalt plant and relocation of the Bridgeton Transfer Station, LLC building to provide access to RIM located adjacent to the building and construction of an overpass over the Site access road;

- Excavation and stockpiling of overburden from OU-1 Areas 1 and 2 in order to access the RIM;

- Excavation of RIM from the OU-1 Areas 1 and 2 that contains combined radium or combined thorium activities greater than 52.9 pCi/g that is located within 16 feet of the 2005 topographic surface;

- Loading, transport, and disposal of the RIM and impacted soil at an off-site disposal facility;

- Survey and identification of the presence and extent of radiologically-impacted soil on the Buffer Zone and Crossroads Property;
- Excavation of any soil from the Buffer Zone and/or Crossroads Property that contains radionuclides at levels greater than those that would allow for unrestricted use and, depending upon activity levels, placement of such soil in Area 1 or 2 or alternatively transport of such soil that contains combined radium or combined thorium levels greater than 52.9 pCi/g to an off-site disposal facility;
- Regrading of the remaining solid waste materials within Areas 1 and 2 to meet the minimum (5%) and maximum (25%) slope criteria;
- Installation of a landfill cover meeting the Missouri closure and post-closure care requirements for sanitary landfills over Areas 1 and 2;
- Design, installation and maintenance of surface water runoff controls;
- Groundwater monitoring consistent with the requirements for sanitary landfills;
- Landfill gas and radon monitoring and control, as necessary;
- Institutional controls (currently in place) to prevent land and resource uses that are inconsistent with a closed sanitary landfill site containing radionuclides; and
- Long-term surveillance and maintenance of the landfill cover in Areas 1 and 2.

Under this alternative, an estimated 151,000 bcy of RIM would be excavated from Areas 1 and 2 for off-site disposal. The volume of material would increase upon excavation due to swelling, handling and loading for transport to an off-site disposal facility. Applying the swell factor of 1.5 and accounting for daily cover, it is estimated that approximately 249,000 lcy would be transported to and disposed off-site. Under this alternative an additional approximately 2,900 bcy of impacted soil would be excavated from the Buffer Zone/Crossroads Property and, depending upon activity levels, would either be placed in Area 1 or 2 or transported to the off-site disposal facility.

Once all of the material containing combined radium or combined thorium activities greater than 52.9 pCi/g that is located within 16 feet of the 2005 ground (topographic surface) has been removed from Areas 1 and 2, the remaining solid waste materials in Areas 1 and 2 would be regraded to meet the final closure standards for sanitary landfills and a final sanitary landfill cover would be constructed over Areas 1 and 2. Because waste containing radionuclides above unrestricted use standards would still remain in Areas 1 and 2, this cover would include the additional hybrid components included in the ROD-selected remedy to address the UMTRCA requirements.

This alternative also includes installation and maintenance of surface water runon and runoff controls, groundwater and landfill gas monitoring, and institutional controls for Areas 1 and 2 and the Buffer Zone. Environmental monitoring of groundwater quality would be performed to ensure that groundwater quality at the perimeter of the Site met State standards or other ARARs or risk-based levels. Monitoring of subsurface occurrences of landfill gas and radon and, if necessary, implementation of contingent landfill gas extraction would be performed to ensure that gas migration above regulatory thresholds does not occur beyond the perimeter of Areas 1 or 2. Landfill gas and groundwater monitoring as described in Sections 5.3.1.6 and 5.3.1.10, respectively, are also included as part of the 52.9 Partial Excavation Alternative.

Existing institutional controls would be maintained and enforced, and any additional controls or modifications to the existing controls that EPA determines are necessary would also be implemented. These institutional controls are necessary to ensure that residential uses do not occur at the Site, and that commercial and industrial uses or ancillary uses that could result in unacceptable risks do not occur on Areas 1 and 2 or the Buffer Zone. In addition to prohibiting land uses that could result in potential exposure to waste materials or contaminants at the Site, these institutional controls would also limit or prohibit land uses or activities that could disrupt the integrity, performance or longevity of the new landfill cover or other components of the remedy.

Long-term inspections and maintenance activities of the engineered components similar to those described for the ROD-selected remedy (Section 5.3.1.9) would also be required.

6.2.4.1 Overall Protection of Human Health and the Environment

The 52.9 Partial Excavation Alternative would protect human health and the environment through (1) removal and off-site disposal of a large portion (50% or more) of the RIM; and (2) engineered containment, long-term surveillance and maintenance, and institutional controls on land and resource use. The landfill cover would reduce potential risks from exposure to external gamma radiation or radon gas emissions, and eliminate potential risks associated with inhalation or ingestion of contaminated soils or other wastes, dermal contact with contaminated soils or other wastes, and wind dispersal of fugitive dust.

The presence of an engineered landfill cover would prevent users of the Site from exposure to external gamma radiation, primarily through shielding and increasing the distance to the radiation source (i.e., the cover materials would be of sufficient thickness and design to attenuate gamma radiation). For the types of clay soils used for infiltration protection in the construction of final covers, the depth of cover required for gamma radiation shielding is on the order of two feet (60 cm). The total thickness of the final cover for the 52.9 Partial Excavation Alternative would be a minimum of five feet (two feet of biointrusion rock/rubble, two feet of clay soil, and one foot of vegetative soil).

The cover materials would also be of sufficient thickness and design to retard or divert the vertical upward migration of radon. The landfill cover would act as a diffusion barrier, thereby allowing time for the decay of the relatively short-lived radon-222 gas (the half-life for radon-222 is 3.8 days) during migration through the pore spaces of the cover soil. Radon is continually produced from the radium source, but need only be detained in the cover materials for a few days to decay to its non-radiological progeny, thereby eliminating any significant radon emissions. The radon may also be intentionally vented or diverted to a landfill gas control system. Calculations presented in Appendix F indicate that a clay layer thickness of two feet, combined with a two-foot thick rock/rubble layer and a one-foot thick vegetative layer, would provide sufficient radon attenuation to meet the radon emissions ARAR of 20 pCi/m^2s. As discussed in Appendix F, these calculations were based on the increased levels of radium expected to be present at the Site after 1,000 years of in-growth of radium from decay of thorium.

The potential for direct contact with waste materials is eliminated by partial removal of RIM and by placing a barrier (multi-layer landfill cover including bio-intrusion layer) between the remaining RIM/waste materials and any potential receptors. There is no potential for the generation of fugitive dust from the waste material as long as the barrier remains in place.

The multi-layer cover would also be designed to minimize infiltration of surface water through the wastes, thereby reducing the potential for leaching of contaminants to the groundwater. This is typically accomplished by promoting surface drainage and using a hydraulic barrier (e.g., a compacted clay layer meeting the specified permeability requirements). These are all conventional functions for landfill cover technologies and are widely used by government and industry to address similar circumstances where contaminated materials must be encapsulated to protect against future potential contact. Long-term maintenance of the cover and monitoring of the groundwater would ensure that the 52.9 Partial Excavation Alternative functions as intended.

Environmental monitoring of groundwater quality would be performed to ensure that groundwater quality at the perimeter of the Site meets state standards or other ARARs. Monitoring of subsurface occurrences of landfill gas and radon and, if necessary, implementation of contingent landfill gas extraction along the perimeter of Areas 1 and 2 would be performed to ensure that gas migration above regulatory thresholds does not occur beyond the Site perimeter.

Institutional controls would ensure that land and resource uses are consistent with permanent waste disposal. The use restrictions would reflect the presence of radionuclides at the Site.

6.2.4.2 Compliance with ARARs

Insofar as the 52.9 Partial Excavation Alternative includes excavation and off-site disposal of a large portion of the RIM and regrading of the remaining solid wastes and installation of a new landfill cover over Areas 1 and 2, the Missouri solid waste rules for sanitary landfills would be relevant and appropriate to this alternative. Upon completion of RIM excavation, the remaining RIM and solid waste in Areas 1 and 2 would be regraded to achieve minimum 5% and maximum 25% slopes and an engineered cover consistent with the cover requirements for a solid waste landfill without a liner. Because all of the RIM above unrestricted use levels would not be removed from Areas 1 and 2, the UMTRCA standards would be relevant and appropriate for

Areas 1 and 2. Therefore, the landfill cover under this alternative would also include the 2-foot-thick rock biointrusion layer. Sections 6.2.2.2.1 and 6.2.2.2.2 contain full discussions of the MDNR solid waste regulations and the UMTRCA standards.

The 52.9 Partial Excavation Alternative would also need to comply with the applicable or relevant and appropriate requirements of NESHAPs, the Safe Drinking Water Act, Missouri Radiation Regulations for Protection Against Ionizing Radiation, the Missouri Well Construction Code, and the Missouri Storm Water Regulations. Sections 6.2.2.2.3 through 6.2.2.2.8 contain full discussions of these regulatory requirements. These requirements would be met or achieved using the same methods as previously described in Sections 6.2.3.2.3 through 6.2.3.2.8 with respect to the "complete rad removal" alternative.

6.2.4.3 Long-Term Effectiveness and Permanence

These criteria refer to expected residual risk and the ability of a remedy to maintain reliable protection of human health and the environment over time. The 52.9 Partial Excavation Alternative would reduce risk through removal of a portion of the RIM and provide engineered containment in conjunction with long-term monitoring, maintenance, and land use control designed to be effective over the long term for the remaining RIM. Removal of a large portion of the RIM, combined with installation of an engineered landfill cover, would essentially eliminate the potential for gamma exposure, inhalation of radon gas or dust containing radionuclides or other constituents, dermal contact with impacted materials, and incidental ingestion of soil containing radionuclides or other chemicals and leaching of radionuclides or chemicals to the underlying groundwater. Maintaining the integrity of the engineered cover would protect the underlying RIM from erosion and intrusion. An UMTRCA-compliant cover would provide a reliable method to control exposure of the RIM to surface receptors and mitigate potential migration of the covered materials.

Long-term site management plans and institutional controls would be made as robust and durable as possible. Long-term groundwater monitoring would be effective in verifying that the remedy is performing as required and groundwater is protected. The landfill cover would also passively prevent potential contaminant migration and human exposures for an indefinite period in the unlikely event that institutional controls were compromised.

By moving the contamination from the Buffer Zone/Crossroads Property back on to Area 1 or 2 or, if the activity levels are high enough, shipping it to the off-site disposal facility in conjunction with shipping of the RIM with activity levels above 52.9 pCi/g, this alternative would provide long-term effectiveness and permanence relative to the Buffer Zone/Crossroads Property.

6.2.4.3.1 Magnitude of residual risk

The calculated lifetime risks following the exposure scenarios in the risk assessment after a portion of the RIM had been removed from Areas 1 and 2, an engineered landfill cover has been installed, and the remainder of this remedial alternative has been implemented (Appendix H) are as follows:

- Area 1: <1 x 10^{-7} for year 1 and <1 x 10^{-7} for year 1,000.
- Area 2: <1 x 10^{-7} for year 1 and <1 x 10^{-7} for year 1,000.

The calculated risk levels are below EPA's target risk range of 1 x 10^{-6} to 1 x 10^{-4}, and the magnitude of residual risk in Areas 1 and 2 is acceptable. These risk levels are attributable to gamma radiation and radon emissions from any radionuclide occurrences that would remain in Areas 1 and 2 after removal of RIM containing combined radium and/or combined thorium activities greater than 52.9 pCi/g, but take into consideration the installation of the new engineered cover and access restrictions and institutional controls. They do not specifically include potential exposures from non-radiological landfill wastes after construction is complete; however, those wastes would also be covered by caps which would prevent exposures. Additional information regarding the risk assessment calculations is presented in Appendix H.

Direct contact with the remaining RIM under the cap at Areas 1 and 2, and exposure by ingestion, inhalation, or dermal contact with such materials, is not expected to occur. These are the primary exposure pathways for any non-radiological COPCs which may be mixed with the RIM and landfill wastes that would remain in Areas 1 and 2 after partial excavation. Because no complete exposure pathway would exist for such materials after completion of the partial excavation and cap construction in Areas 1 and 2, the landfill waste materials would not be expected to produce non-carcinogenic effects or carcinogenic risks.

After soils containing radionuclide concentrations above unrestricted use levels are removed from the Buffer Zone/Crossroads Property, residual risks posed by the remaining radionuclide-impacted material on these properties, if any, should be indistinguishable from variations in background levels.

6.2.4.3.2 Adequacy and reliability of controls

The conceptual design of the engineered cover has been developed to provide protection against all potential exposure pathways. Cover construction is based on and relies upon the use of natural materials that would be expected to remain in place and meet performance criteria for at least 200 years, as required by the UMTRCA ARARs. Post-closure inspection and maintenance of the cover as required by the solid waste regulation ARARs, and as routinely performed at thousands of landfills across the country, also would ensure long-term reliability of the landfill cover.

The surfaces of Areas 1 and 2 are not currently graded to promote drainage of stormwater, but instead, are generally flat with several surface depressions which act to increase precipitation accumulation and infiltration through the waste mass. In addition, no engineered landfill cover exists over these areas. Even with these limitations, infiltration of precipitation has not resulted in discernible leaching of radionuclides or other chemicals to groundwater. Removal of a portion of the RIM, regrading Areas 1 and 2 to promote drainage, and installation of the engineered landfill cover included as part of the 52.9 Partial Excavation Alternative would significantly reduce infiltration of precipitation and potential for leaching, thereby providing further protection against potential impacts to groundwater.

Long-term OM&M would include routine cover and stormwater ditch inspection and service, if necessary, to mitigate erosion, and if such a system is necessary, OM&M of a landfill gas collection and treatment system. Long-term monitoring would also be implemented to assess compliance with environmental performance standards. The performance of these engineering controls would also be re-evaluated during statutory five-year reviews.

The current Covenants and Restrictions for Areas 1 and 2 would be adequate to protect human health. The permanence of these restrictions is assumed to be adequate for the foreseeable future, as both EPA and MDNR approval are required to remove or modify the restrictions. The adequacy of the restrictions would be continually evaluated during the statutory-required five-year reviews.

6.2.4.3.3 Climate Change and Potential Impacts of a Tornado

Because RIM and municipal solid waste would still remain in Areas 1 and 2 after implementation of the 52.9 Partial Excavation Alternative, a new engineered landfill cover would be installed over these areas. Because radionuclides above unrestricted use levels would remain in Areas 1 and 2, this engineered landfill cover would include the 2-foot-thick rock/rubble biointrusion layer along with the 2-foot-thick low-permeability and 1-foot thick vegetative layers as previously described for the ROD-selected remedy (Sections 5.3.1.4 and 6.2.2). This engineered landfill cover would be classified as in-situ containment system (EPA, 2014a).

Because the engineered landfill cover to be installed over Areas 1 and 2 under the 52.9 Partial Excavation Alternative is substantially similar to the landfill cover to be installed under the ROD-selected remedy, the analysis of the potential effects of climate change or impacts of a tornado are essentially the same for both alternatives. These effects were previously discussed in Section 6.2.2.3.3 for the ROD-selected remedy and therefore will not be repeated again here. The results of those evaluations (as discussed in Section 6.2.2.3.3) relevant to the landfill cover system for the 52.9 Partial Excavation Alternative are summarized below.

Similar to the ROD-selected remedy, the vegetative layer of the landfill cover to be installed under the 52.9 Partial Excavation Alternative could be vulnerable to increased occurrences of extreme temperatures, sustained changes in average temperatures, decreased precipitation and increase in drought occurrences. Increased temperatures or decreased precipitation/drought could affect the viability of the vegetation (*e.g.*, grasses) on the surface of the landfill cover. Any changes to the overall health of the vegetative cover would be readily identifiable by visual inspection. Therefore, although the vegetative cover may be vulnerable to potential increased temperatures or drought conditions, the potential for impacts to the vegetative layer could be anticipated and readily identified in advance of any such occurrence.

The low-permeability layer (CCL) could be damaged by periods of extended extreme temperatures or prolonged drought. Potential impacts could include desiccation of the CCL, with a resultant increase in permeability that in turn could lead to increased precipitation infiltration. Such impacts are not considered to be significant because the Site has existed for over 40 years with essentially flat (no grade) surfaces and minimal cover material, thereby maximizing precipitation infiltration without generation of currently identifiable impacts to underlying groundwater quality[49]. Therefore, even if desiccation of the low-permeability layer were to occur, the impacts to groundwater quality are not expected to be significant. More importantly, the vegetative layer would show significant signs of stress from increased temperatures/drought prior to the occurrence of any impacts to the underlying low permeability layer and thereby provide advance notice of a potential impact to the CCL. Therefore, although the low permeability layer could potentially be vulnerable to effects of increased temperature or drought, the potential for any impacts could be anticipated and readily identified in advance of any such occurrence and such impacts are not expected to result in release of contamination.

Increased heavy precipitation events could result in erosion of the vegetation layer, which, if left untended, could result in erosion of the underlying low-permeability layer. Any erosion of the landfill cover would be readily identifiable by visual inspection. Given the overall 5-foot thickness of the landfill cover and the inclusion of the 2-foot-thick rock layer in the base of the cover system, stormwater erosion, even under the most severe storm event, is not anticipated to result in erosion down through the entire landfill cover. Heavy precipitation events could impact the integrity or performance of stormwater drainage conveyance structures, including erosion of drainage channels, damage to or bypassing of let-down and erosion control structures and features, or damage to stormwater detention structures. Heavy precipitation events could also temporarily restrict access to portions of the landfill cover, stormwater control structures, and environmental monitoring points thereby causing delays in implementation of repairs if any are needed. Therefore, the vegetation layer and stormwater controls are potentially vulnerable to impacts from heavy precipitation events. However, due to the overall thickness and design of the landfill cover, any potential impacts are not expected to result in exposure of the waste material or release of contamination. Furthermore, any impacts that occur could be readily addressed as part of normal maintenance and repair of the landfill cover, including localized regarding, repair and replacement of cover material in response to any damage that may occur.

The 52.9 Partial Excavation Alternative is not anticipated to be impacted by flooding that may occur in the area of the Site. As previously discussed in Section 2.1.6, FEMA has determined that, with the exception of the easternmost portions of Areas 1 and 2, which do not contain waste materials, Areas 1 and 2 are located outside of the 500-year floodplain. In addition, the area to the north and west of Area 2 (*e.g.*, Crossroads Industrial Park and Earth City Industrial Park) that potentially could be subject to flooding by the Missouri River, are protected by the engineered

---

[49] EPA has indicated that additional evaluations of groundwater will be conducted in the future as part of the OU-3 RI/FS.

levee and stormwater and flood control systems installed to protect the Earth City Industrial Park.

As previously discussed in Section 6.2.2.3.3 in connection with the ROD-selected remedy, an evaluation of potential impacts associated with a tornado was previously performed and submitted to EPA (EMSI, 2013f). Similar to the ROD-selected remedy, the 52.9 Partial Excavation Alternative is not vulnerable to impacts from a tornado. Specifically, a tornado is not expected to damage the vegetative layer and even if it did, such an impact is not considered to be significant because it could be easily identified and due to the design and thickness of the engineered cover, would not result in exposure of the underlying waste or release of contamination. A tornado could damage or destroy aboveground infrastructure such as signage, fencing or environmental monitoring equipment; however, such impacts are not expected to be significant because they would be readily identified and easily repaired or replaced. Therefore, the 52.9 Partial Excavation Alternative is not considered to be vulnerable to impacts from a tornado.

Although the 52.9 Partial Excavation Alternative is not considered to be vulnerable to climate change, implementation of adaptation measures could be considered during remedial design to provide a degree of adaptation for climate change. For example, regrading of the surface of Areas 1 and 2 to a 2% slope instead of a 5% slope could be considered to reduce the velocity of runoff across the surface of Areas and 1 and 2 and thereby reduce erosion and soil loss potential under extreme precipitation events. Installation of runoff collection and diversion systems along the base of the above-grade portion of the North Quarry part of the Bridgeton Landfill adjacent to Area 1 and along the north sides of the Closed Demolition Landfill and the Inactive Sanitary Landfill adjacent to Area 2 could be included in order to divert runoff from these areas around Areas 1 and 2 to reduce the potential for impacts from heavy precipitation events. Use of grass seed mixtures that are more tolerant of long-term changes in precipitation or temperature, and/or soil addition to increase water storage capacity, could be evaluated as part of the design. Similarly, inclusion of a geotextile at the base of the vegetative layer could be considered to minimize the potential for water or wind erosion extending down into the underlying low-permeability layer. The design grades of the stormwater conveyance structures could be evaluated to provide a balance between the ability to quickly route stormwater away from Areas 1 and 2 while minimizing the stormwater velocity and the associated potential for erosion of the stormwater conveyance structures. Identification and evaluation of additional adaptation measures can be addressed as part of the design of the engineered landfill cover and stormwater controls to increase the overall resilience of these features to heavy precipitation events. Continuous re-evaluation of potential vulnerabilities, system resilience, and possible adaptation measures would be included as part of the ongoing inspection and maintenance program.

6.2.4.3.4 Potential Impacts of a Subsurface Heating Event

Because radionuclides above unrestricted use levels would still remain at the Site under the 52.9 Partial Excavation Alternative, radionuclide-related impacts similar to those described in Section 6.2.2.3.4 for the ROD-selected remedy could potentially occur if an SSE or SSR were to occur in Areas 1 or 2. Specifically, a localized, temporary increase in radon emissions from the ground surface could occur. However, as discussed for the ROD-selected remedy, even if such an event were to occur, the radon emission rate would still be less than the standard established by the radon NESHAP. Additionally, if such a release were to occur, risks at or beyond the fence line are expected to be below the acceptable risk levels established by EPA.

6.2.4.3.5 Effects of an Isolation Barrier

As discussed in the previous subsection, no adverse impacts or unacceptable risks are expected to result if an SSR or SSE were to extend into Area 1. Therefore, regardless of the location or type of isolation barrier that may be installed, or even if no barrier is installed, no unacceptable risks are expected to occur. Installation of a heat extraction barrier consisting of various heat extraction points, regardless of location, would not have any impact on the protectiveness, long-term effectiveness, short-term effectiveness, implementability or cost of the 52.9 Partial Excavation Alternative. Installation of a physical barrier, such as a vertical wall of inert material, would require excavation and regrading of the above-grade portion of the North Quarry part of the Bridgeton Landfill wastes located over the southern portion of Area 1. If such a barrier were to be installed prior to implementation of the 52.9 Partial Excavation Alternative, portions of the barrier would need to be removed in conjunction with removal of RIM in the southwestern portion of Area 1. In addition, the design of the engineered cover included in this alternative would need to account for any changes in the surface grades, the stormwater drainage system, and the presence of any above-grade features (*e.g.,* heat extraction points, temperature monitoring probes, or additional gas extraction wells) that may be installed in conjunction with a barrier. In contrast, if a physical barrier were installed after RIM removal and construction of the engineered cover included in the 52.9 Partial Excavation Alternative, that portion of the engineered landfill cover that extended over the construction area of an isolation barrier and the associated revised landfill grades would need to be removed as part of construction of an isolation barrier. The potential alignment of a potential isolation barrier may also need to be revised to reflect the removal of some of the RIM from the southwestern portion of Area 1, assuming that the barrier is designed before the RIM removal and regrading occurs.

6.2.4.3.6 Environmental Justice Considerations

As was previously discussed in Section 6.2.2.3.6 as part of the evaluation of long-term effectiveness of the ROD-selected remedy, a screening-level analysis did not identify any environmental justice concerns relative to the Site. EPA did identify a need for implementation of more traditional (non-electronic) communication methods to inform and ensure meaningful involvement of residents in the Terrisan Reste mobile home community.

6.2.4.4 Reduction of Toxicity, Mobility or Volume through Treatment

Reduction of toxicity, mobility, or volume through treatment refers to the anticipated performance of the treatment technologies that may be included as part of a remedy. Although a portion of the RIM would be removed, the 52.9 Partial Excavation Alternative is overall a containment remedy and therefore generally would not reduce the toxicity, mobility, or volume of the waste material through treatment.

As discussed in Section 4, radionuclides are naturally-occurring elements which cannot be fully neutralized or destroyed by treatment. Occurrences of radionuclides within Areas 1 and 2 are dispersed within soil material that is further dispersed throughout portions of the overall, heterogeneous matrix of municipal refuse, construction and demolition debris, and other non-impacted soil materials in Areas 1 and 2. Consequently, ex-situ treatment techniques are considered impracticable. In addition, the heterogeneous nature of the solid waste materials and the dispersed nature of the radionuclide occurrences within the overall solid waste matrix in portions of Areas 1 and 2 make in-situ treatment techniques equally impracticable. The remedy for the Buffer Zone/Crossroads Property also would not reduce toxicity, mobility, or volume through treatment because it consists of moving radiologically-impacted soil from the Buffer Zone/Crossroads Property to Area 1 or 2, where it would either be shipped off-site for disposal or consolidated with the RIM in Areas 1 and 2.

An on-site technology that may potentially be applicable to this alternative is ex-situ physical separation of impacted soil from the solid wastes by using solids separation techniques such as hand picking for large bulky items and various fixed, vibrating, or rotating screens, among others (see prior discussion in Section 4.3.5.2). Physical separation would not decrease the mobility or toxicity of the radiologically-impacted materials, but has the potential to separate existing RIM from non-radiologically-impacted materials. As previously discussed, any solids separation techniques would need to be pilot-tested at full-scale using materials from Areas 1 and 2 during remedial design to ascertain the potential effectiveness, implementability, and cost of this technology. Of particular interest in conducting pilot-testing with material from Areas 1 and 2 would be obtaining an estimate of the degree of RIM volume reduction that could be achieved, assessing the moisture content of the filled material, determining the fraction of soil that would be contained in or adhered to the segregated refuse, and determining the residual levels of radioactivity that would be present in the non-soil refuse after screening out the soil fraction. Assuming that solids separation could prove to be an effective and implementable technology (that is, it could effectively separate the radiologically-impacted soil from the other landfilled waste materials such that the other landfilled wastes would contain radionuclide activities below the levels that would allow for unrestricted use), it has the potential to reduce the volume of radiologically-impacted material that would need to be transported to and disposed at an off-site disposal facility. However, little is known about the potential application of a soils separation technology to this situation, and it is possible that pilot-testing could demonstrate that physical separation would not be effective at separating RIM from non-radiologically-impacted materials, in which case the non-radiologically-impacted materials would need to also be shipped off-site for disposal. At this stage of analysis, neither the estimated costs nor the estimated schedules for this FFS include any allowance for solids separation pilot-testing or implementation.

In the event that hazardous wastes are encountered during implementation of the remedy, such materials would be separated from the other solid wastes and subjected to waste profiling to determine the appropriate treatment and disposal requirements. To the extent that hazardous wastes or mixed wastes are encountered, they would be shipped off-site and would be treated at the disposal facility in accordance with the hazardous waste regulations (e.g., EPA's LDR program and UTS) and in accordance with the permits and standard operating procedures of the receiving facility. After arriving at an off-site disposal facility and undergoing a waste receipt analysis, RCRA soil/debris and RCRA soil/debris with radionuclide material would be stabilized prior to placement in a disposal cell. Depending on its physical characteristics, RCRA debris and RCRA debris with radionuclide material would undergo either micro- or macro-encapsulation prior to placement in a disposal cell. To the extent that treatment of the hazardous waste or mixed waste would be required for off-site disposal, stabilization or encapsulation treatment would result in a reduction of the mobility of the hazardous waste and radiologically-impacted components of the mixed waste. Toxicity and volume would not be reduced by these technologies but may be reduced by other technologies potentially applicable to hazardous wastes that do not contain RIM, if such wastes were encountered during implementation of the remedial action at the Site.

Section 6.2.2.4 contains a full discussion of the procedures, protocols and concerns associated with the off-site shipment of hazardous wastes or mixed wastes.

6.2.4.5 Short-Term Effectiveness

This alternative poses significant potential short-term risks as described below. During a public meeting held as part of the ROD-selected remedy process, EPA identified and discussed the following short-term risk issues for waste excavation: waste handling, sorting and stockpiling; water management; noise, odor and windblown trash; worker health and safety (PPE, gamma exposure, physical stress, physical hazards, workplace monitoring); contaminant migration/spreading (fugitive dust and airborne migration, fugitive dust control and water application, leachate generation, equipment decontamination water, and water from open excavations); and waste hauling and transportation issues/truck decontamination (transfer facilities, increased local traffic, waste handling on public roads, interstate transport by rail, DOT requirements, safety issues).

6.2.4.5.1 Protection of the Community During Remedial Actions

The projected carcinogenic risks that may be posed to off-site residents by this alternative would be less than 1×10^{-7}. No non-carcinogenic risks are expected to occur.

The risk assessment (Appendix H) includes an estimate of the projected incidence of transportation accidents associated with each FFS alternative. For the 52.9 Partial Excavation Alternative, the projected incidence of transportation accidents associated with shipping of RIM for off-site disposal and importing of materials for construction of the multi-layer landfill cover is 10.6, meaning that approximately 11 transportation-related accidents are project to occur if this alternative were implemented. This risk is associated with transportation of excavated RIM from the Site to the rail transloading facility, hauling by rail, and transport of the RIM from the destination rail offloading facility to the disposal site, plus truck traffic associated with delivery of construction materials to be used for construction of the new engineered landfill cover on Areas 1 and 2.

Disturbing the waste material may expose the community to radioactive waste, methane and radon gas, dust and particulates and cause an undesirable release of odors. Excavation of existing waste materials would undoubtedly result in odor emissions during the period of time that existing wastes may be handled or exposed. Mitigation of odors through engineering means is limited.

The 52.9 Partial Excavation Alternative would contribute significant carbon dioxide equivalent emissions to the atmosphere as a result of vehicle operations associated with the remedial work. In particular, approximately 43,000 tons of carbon dioxide equivalent emissions are projected to be emitted to the atmosphere as a result of landfill regrading and cover construction in Areas 1 and 2, the excavation, loading, and transport of the RIM to an off-site disposal facility, and the importation of materials used to construct the multilayer landfill cover for Areas 1 and 2 (Appendix I, Table I-3).

Because RIM in Areas 1 and 2 would be excavated under this alternative, overburden would be stockpiled and stored, and RIM would be staged and loaded for off-site disposal. During these activities, the nuisance attraction to and congregation by birds at and above the affected areas could be problematic unless effectively controlled. The main concern would be the potential for increased bird strikes to aircraft approaching and departing from the Lambert-St. Louis International Airport. For the 52.9 Partial Excavation Alternative, an enclosed waste staging and loading structure would be constructed to minimize the outdoor handling of waste and associated attraction of birds or other vectors. Additional mitigation measures such as excavation best management practices, which include application of daily soil cover and/or placement of tarps over areas of exposed waste, visual and auditory frightening devices, or wire or monofilament grids positioned over exposed refuse to prevent bird access, could be implemented to minimize bird attraction to and congregation at and above the disturbed areas.

Excavation of waste materials from Areas 1 and 2 would require removal of the existing landfill cover and overburden from Areas 1 and 2 and portions of adjacent areas of OU-2. Excavation of overburden and RIM would create depressions in the landfill area during the period of time required to remove the RIM and regrade and cover the remaining landfill wastes. Precipitation that falls on the landfill while such depressions are open would potentially flow into and accumulate in the depressions. Any increased accumulation of precipitation[50] in depressions created during waste excavation could result in increased infiltration of precipitation runoff through the underlying waste materials, which could result in leaching of VOCs or other soluble contaminants from the waste materials.

Because Areas 1 and 2 would be excavated and RIM loaded into transport containers, storm water controls would be implemented in accordance with the Missouri Storm Water regulations

[50] Accumulation could be significant during a heavy rainstorm as the maximum historical 24-hour rainfall for the St. Louis area ranges from a low of 3.7 inches in November to a high of 8.8 inches in August (NOAA, 2011).

10 CSR 20-6.200 to protect the community. During construction, consideration would be given to minimizing the areas of excavation that would be open and exposed to waste materials at any given time. Temporary diversion berms using daily cover material would also be constructed above the open excavation areas on the previously excavated (and temporarily covered) surface of any excavation depressions in order to divert precipitation runoff around the open excavation to prevent the runoff from contacting uncovered waste materials. Precipitation that would contact uncovered waste materials would flow into the low point of the excavation and be pumped out into temporary storage tanks using portable gas-driven pumps. Samples from each tank would be collected and sent to a laboratory for analysis. The stored water would be directly discharged or treated and disposed appropriately based on the analytical results.

6.2.4.5.2 Environmental Justice Concerns

As was previously discussed in Section 6.2.2.5.1 as part of the evaluation of short-term impacts associated with the ROD-selected remedy, a screening-level analysis did not identify any environmental justice concerns. EPA did identify a need for implementation of more traditional (non-electronic) communication methods to inform and ensure meaningful involvement of residents in the Terrisan Reste mobile home community.

6.2.4.5.3 Protection of Workers During Remedial Actions

This alternative would entail significant excavation, handling, loading and transport of RIM at the Site and therefore would pose both significantly increased radiological exposure risks as well as construction safety risks to on-site workers.

Workers involved in the excavation activities would be subject to potential short-term risks. Possible short-term impacts associated with excavation and regrading of the RIM include the following potential risks: exposure of workers to contaminated waste; excavation/trenching instability; stormwater runoff entering areas where waste is exposed resulting in the exposure of workers to contact storm water; and odor emissions or other aesthetic issues arising from exposed waste. Worker exposures would be addressed through development and implementation of a Site safety plan, use of personal protective equipment, and performance of personnel and environmental monitoring during implementation of remedial action. Workers would be protected during construction by adhering to OSHA practices; however, as this alternative entails extensive excavation, handling and transportation of radiologically-impacted materials, OSHA work practices and personal protective equipment may not provide full protection against exposure to external gamma radiation.

The risk assessment (Appendix H) presents an evaluation of potential risks to Site workers that may occur for each alternative. These include risks from industrial accidents, exposure to carcinogenic substances, and projected radiation exposures. For the 52.9 Partial Excavation Alternative, the projected incidence of industrial accidents is 8.5 over the life of the project. The projected carcinogenic risk to the maximally exposed individual is 1.18×10^{-3} and the projected radiation dose to a remediation worker is 720 mrem/yr (Appendix H).

Excavation would require construction workers and equipment that would disturb the overburden soil and underlying waste materials. Dust control measures would be required to limit worker exposure to fugitive dust during construction.

6.2.4.5.4 Environmental Impacts

No measurable long-term impacts to plants or animals in surrounding ecosystems are expected from this alternative. As noted in the BRA (Auxier, 2000) and the updated BRA (Auxier, 2016a), some of the ecosystems present at the landfill are the result of existing institutional controls and other limitations on land use within or adjacent to OU-1 that have allowed field succession to take place. Much of the habitat on Areas 1 and 2 was removed in 2016 in conjunction with construction of the non-combustible cover. Excavation of RIM, regrading of Areas 1 and 2, and construction of the engineered landfill cover under the 52.9 Partial Excavation Alternative would destroy the remaining portions of the habitats that currently exist on the surface of Areas 1 and 2, forcing wildlife to migrate to other areas. Vegetative cover would be placed on the Site as a part of the final cover, and the landfill would be allowed to return to an early-stage field ecosystem with periodic mowing and maintenance.

6.2.4.5.5 Ability to Monitor Effectiveness

Measurement of gamma radiation and radon flux through the newly constructed landfill cover would be conducted on Areas 1 and 2 after construction is complete. Regular monitoring of groundwater quality would be performed at appropriate locations around Areas 1 and 2. Measurements of subsurface occurrences of landfill gas and radon levels would be conducted along the property boundaries adjacent to Areas 1 and 2 to verify that off-site gas migration above regulatory thresholds does not occur.

6.2.4.5.6 Time Until Remedial Action Objectives Are Achieved

The RAO of (1) preventing exposure to radionuclides or waste at concentrations above ARARs or risk levels would be met immediately upon completion of construction of a new engineered landfill cover. The RAOs of: (2) minimizing infiltration and any resulting contaminant leaching to groundwater; (3) controlling surface water runoff and erosion and decreasing the potential for erosion and subsequent transport of RIM; and (4) controlling radon and landfill gas emissions from Areas 1 and 2 would also be met once construction of the new landfill cover over Areas 1 and 2 is completed. The RAO related to the Buffer Zone and Crossroads Property soil would be met upon removal of any remaining soil containing radionuclides above unrestricted levels from these areas.

Initiation of this alternative would require significant planning and permitting due to the limited number of off-site disposal facilities capable of taking this material and the extensive logistics associated with identifying, handling, classifying and loading the materials for transport to the selected off-site facility. Preparation of the remedial design should be completed within approximately 15 months of authorization to proceed with the RD. RD could take significantly longer if full-scale pilot-testing of solids separation equipment were to be performed. The RAOs would be achieved upon completion of construction which is estimated to be finished within approximately 4.6 years after approval of the RD. Therefore, the remedial action objectives should be achieved within 5.9 years of approval to proceed with the RD (Appendix J). This schedule estimate assumes that the buyout of the asphalt company lease and relocation of the solid waste transfer station occurs during the remedial design phase; otherwise, the schedule would be longer.

The projected construction schedule and the cost estimate for the 52.9 Partial Excavation Alternative are highly dependent on the waste material swell factor; that is, the amount the in-place waste volume expands as it is excavated, handled and loaded for transport to an off-site disposal facility. For purposes of this FFS, a swell factor of 1.5 has been assumed. A swell factor greater than 1.5 would result in an increase to the overall construction schedule and the estimated costs. The projected construction schedule and the cost estimate for the 52.9 Partial Excavation Alternative also are highly dependent on the number of rail cars that could be loaded and shipped per day. The schedule and cost estimate developed in this FFS for this alternative are based on an assumption that a sufficient number of IM containers and rail cars can be made available, loaded, switched out and replaced every day. If the actual rate is less than the projected rates of RIM excavation used to develop the construction schedules, the time required to complete construction and consequently the costs for 52.9 Partial Excavation Alternative would increase.

6.2.4.6 Implementability

This alternative would involve excavation and off-site disposal of a portion of the RIM in Areas 1 and 2, repair and restoration of the disturbed portions of the OU-2 landfill units adjacent to Areas 1 and 2, grading of the surfaces and installation of upgraded landfill covers over the areas of Areas 1 and 2, long-term monitoring and maintenance of the covers, and long-term monitoring of landfill gas and groundwater and surface water quality.

Excavation of RIM would require removal of substantial amounts of overburden and material from the sidewalls of the excavations in order to maintain stability of the excavation areas. Overburden removal would entail removing and temporarily relocating part of the above-grade portion of the North Quarry part of the Bridgeton Landfill in order to access the underlying RIM in Area 1 of OU-1. The total amount of non-RIM waste required to be removed under this alternative is estimated to be approximately 350,000 bcy, which, based on an expansion factor of 1.5, would result in the need to handle, stockpile and replace 525,000 lcy of waste. Management of exposed waste in both the excavation areas and the stockpiles – including management of stockpiles, stormwater runon and runoff, odor emissions, attraction to birds and other vectors, and litter control – would be a significant undertaking. The amount of space available for stockpiling the overburden material is limited, and therefore overburden material from Area 1 would likely need to be transported to Area 2 for temporary stockpiling while waiting for final placement and capping. Similarly, the total volume of RIM that would be excavated under this alternative is estimated to be 151,000 bcy, equivalent to 226,000 lcy. Due to the double-handling (at a minimum) of the overburden material plus the RIM handling, it is anticipated that more than 1,100,000 lcy of waste would be handled under this alternative.

An additional complication arises from the proximity of the Bridgeton Transfer Station. In order to access the RIM in the southwest portion of Area 1, the solid waste transfer station would need to be relocated, as removal of waste material would extend up to and along the base of the solid waste transfer station such that the integrity of the solid waste transfer station building foundation and above-grade structure would be compromised. The only available space for relocation of the transfer station is the area currently occupied by Simpson Asphalt Company, which holds a long-term (99-year) lease on this area. This lease would have to be bought out and the asphalt company would need to be relocated before the transfer station could be relocated to this area.

It is anticipated that a new structure would be constructed to shelter the RIM staging and loading operations in order to minimize stormwater contact, odor emissions and bird attraction. It is anticipated that such a structure would be constructed along the north side of the Site access road in the area that is currently being used to store new, reclaimed and surplus equipment and materials associated with ongoing operation and maintenance and closure activities for the Bridgeton Landfill. These materials would need to be relocated to another portion of the Site prior to construction of such a structure.

In order to minimize potential vehicle interactions between normal traffic to and from the solid waste transfer station and the construction operations associated with this alternative, a temporary overpass would likely need to be constructed over the Site access road to allow for uninterrupted movement of construction traffic between Areas 1 and 2. An overpass is considered the most efficient and safest means for transfer of overburden waste from Area 1 to stockpile locations in Area 2 and then back to Area 1. In addition, as discussed above, a single RIM staging and loading building would be constructed and operated as part of this alternative. RIM removed from Area 1 would need to be transferred over the Site access road. Installation of an overpass would eliminate the potential for RIM to be tracked across the Site access road and potentially tracked off-site.

While excavation with subsequent off-site transportation and disposal have been implemented at other sites containing radioactively-impacted materials, materials from these other sites have not included significant amounts of landfill solid wastes. Significant technical and administrative implementability issues are associated with excavating the RIM and loading it into IM containers for transportation if this alternative were to be implemented. These include the following:

- Reduced excavation production rates and increased volume of RIM subject to excavation resulting from application of daily cover over an extended excavation schedule;
- Ability to locate and obtain a lease to an off-site rail spur for use as a truck-to-rail transfer facility, or alternatively the ability to construct an on-site rail spur and rail loading facility;
- Increased potential for bird strikes to aircraft as a result of excavation of putrescible or organic solid waste overburden waste from the North Quarry portion of the Bridgeton

Landfill and Areas 1 and 2 and excavation of RIM-contaminated waste from Areas 1 and 2, all of which are located within flight paths of Lambert–St. Louis International Airport;

- Impacts to other Site operations and traffic on surrounding roads from additional truck traffic used to haul wastes to an off-site truck-to-rail transfer facility and to haul earthen materials to the Site for daily cover, stockpile covers, and construction of the final cover.

Design and construction of post-RIM-excavation landfill covers over Areas 1 and 2, with subsequent monitoring and maintenance, are not expected to pose any implementability challenges. Materials and services necessary for the regrading and construction of the final landfill covers over Areas 1 and 2 after RIM removal are available and the technologies have been proven through application at other landfills. Design and construction of landfill covers over Areas 1 and 2 after RIM removal are not expected to pose any significant implementability challenges.

The actions included for the Buffer Zone/Crossroads Property – that is, testing and excavation of surface soil – are regularly and easily implementable.

Monitoring of the cover surfaces, landfill gas, groundwater, and surface water are proven methods for demonstrating the long-term effectiveness of the engineered landfill cover that would be placed over Areas 1 and 2 and are easily implemented.

6.2.4.6.1 Ability to Construct and Operate the Technology

In general, excavation and off-site disposal are standard technologies. However, there are unique circumstances associated with excavation of RIM in Areas 1 and 2, located as they are within an overall larger closed/inactive landfill site, which would complicate implementation of standard excavation technologies.

RIM excavation and placement in IM containers and hauling of the containers by truck for subsequent transfer to rail is also expected to present implementability concerns, challenges, and risks, specifically those associated with the following:

- Excavation and handling of contaminated materials;
- Safety risks associated with encountering methane gas during excavation;
- Management of fugitive dust and potential odors;
- Mitigation of bird hazards;
- Management and treatment of stormwater exposed to RIM during excavation; and
- Identifying, segregating, and disposing off-site any hazardous wastes, PCBs or RACM that may be encountered during RIM excavation.

If hazardous wastes, PCBs, or RACM are encountered during excavation of RIM, these materials would need to be segregated from the other waste materials, characterized, and transported to an off-site disposal facility in containers separate from the other RIM. Additional health and safety procedures would be required during excavation of these materials. These materials would require separate handling at the off-site disposal facility and could require treatment prior to disposal. Depending on the characteristics of any hazardous waste encountered during excavation, the hazardous waste could need to be transported to a different off-site facility for treatment and disposal in accordance with RCRA.

Directing and controlling the RIM excavation process using radiological scanning and sampling techniques would significantly impact overburden and RIM excavation production rates. Based on experience in excavation of radiologically-impacted waste at other sites, a reduction in efficiency is expected for overburden excavation and a greater reduction is expected for RIM excavation. Because thorium-230 is a primary radionuclide of concern relative to any excavation alternative that may be considered for the Site, even greater reductions in efficiency and increased time may be required for RIM excavation. Thorium-230 cannot be detected using field survey instruments, and therefore excavation guidance would have to rely on collection and laboratory analyses of samples. In order to minimize the potential impacts on the excavation schedule, it is assumed that an on-site laboratory would be set up and operated to provide quick analyses of samples to guide excavation activities and initial confirmation that all RIM had been removed. A percentage of such samples would also be sent to an off-site laboratory for verification of the on-site laboratory results. Samples obtained for final confirmation that all RIM has been removed from a particular area would also be subjected to off-site laboratory analyses and data validation. All of these activities would undoubtedly impact the rate of RIM excavation and the duration over which excavation areas need to remain open.

Daily soil cover and tarps would need to be placed over open excavation areas and stockpiled overburden to minimize dust, odor, and the attraction of birds and other wildlife. The proximity of Areas 1 and 2 to Lambert-St. Louis International Airport poses a potential risk to aviation operations. The St. Louis Airport Authority and the U.S. Department of Agriculture have identified as a problem the potential for increased bird activity in conjunction with waste excavation at the Site and the resultant increased risk of bird strikes to aircraft. Bird nuisance mitigation measures such as best management practices (including, but not limited to, daily soil cover and tarps over exposed overburden and wastes), visual and auditory frightening devices, and wire or monofilament grids strung over exposed refuse to prevent bird access, could be evaluated for use at Areas 1 and 2. The size of open excavations may limit the constructability of wire or monofilament grids. Careful evaluation of material properties would be necessary during remedial design to assure that the appropriate strength and elasticity of materials are considered, that the materials are available, and that grids can be reasonably constructed.

Effective storm water controls could be readily implemented using conventional construction equipment and materials. Temporary berms to direct stormwater away from open excavations would need to be constructed, and precipitation accumulation in depressions created by the excavation activities would need to be pumped out and managed. Direct precipitation or runoff that may contact waste material could become contaminated with soils or wastes containing thorium or radium. These elements would be entrained in colloidal material that would readily settle in low areas or in the tanks used to collect and store stormwater prior to treatment and discharge. At the end of excavation activities, after all RIM above cleanup levels would have been removed, accumulated sediment in any low areas or the tanks would also be removed and, depending upon activity levels, either placed in Area 1 or 2 or transported to the off-site disposal facility.

Excavated RIM exposed to precipitation would be subject to the paint filter liquids test (PFLT) as necessary to determine if free liquids exist prior to being loaded for off-site disposal. If the excavated material to be hauled off-site does not pass the PFLT, a dewatering area would need to be staged and collected water treated and/or disposed, potentially through off-site disposal. The current costs and schedules do not address any dewatering activities. Should such activities be necessary, a suitable area would have to be identified within the Site.

Truck hauling of IM containers of RIM to a truck-to-rail transloading facility and transferring the RIM to railcars is technically implementable. Loading RIM directly into railcars on-site if a rail spur could be extended onto the West Lake Landfill property is theoretically implementable; however, it is not known whether extension of a spur onto the property is actually feasible. If construction of an on-site rail spur were to be considered, an engineering study and development of a detailed design would be necessary to determine the feasibility and implementability. As discussed in detail in Sections 6.2.3.6.5 and 6.2.3.6.6 above, construction of an on-site rail spur would also require coordination with a number of local and state regulatory authorities as well as private landowners.

An initial comparison of the US Ecology Grand View facility WAC to estimated activity levels in the OU-1 RIM under the 52.9 Partial Excavation Alternative is presented on Table 6-3. Although a representative of the turnkey contractor would be on site during RIM excavation to coordinate loading of containers, there is a potential that one or more shipping containers could contain activity levels that exceed the WAC and may have to be unloaded and re-distributed prior to shipment or, in the worst case, returned to the Site by the disposal facility and/or sent to a different disposal facility. These additional activities could result in additional worker exposures, additional time to complete the project, and potentially additional costs.

Regrading the remaining landfills and placement of final cover is implementable and has been performed at other landfills, including CERCLA sites. Environmental monitoring is routinely performed at most sites and is not expected to present any feasibility challenges.

6.2.4.6.2 Reliability of the Technology

Excavation and off-site disposal of radioactively-impacted material has been performed at number of FUSRAP facilities and is a reliable technology. It should be noted, however, that none of these FUSRAP sites involved radiological materials commingled with municipal solid waste and disposed in a landfill setting. The reliability associated with disposal in an off-site facility would be dependent on the integrity of the liner and cover systems at the off-site facility being maintained, as well as the effectiveness of the various off-site facility monitoring programs.

Landfill cover systems such as those that would be implemented over Areas 1 and 2 after partial removal of RIM, and which are designed and constructed consistent with State and Federal regulations and with post-closure care implemented in accordance with current regulatory guidance, have been demonstrated to be reliable at: (1) minimizing percolation and infiltration of precipitation; (2) minimizing leachate generation; (3) minimizing impacts to groundwater quality; (4) minimizing impacts to surface water quality and quantity; (5) minimizing erosion of cover material; and (6) minimizing uncontrolled releases of landfill gas. Landfill cover systems have been demonstrated to be reliable methods for isolating waste materials. Similarly, access restriction measures have been demonstrated to be reliable mechanisms to prevent unauthorized access to a site.

Bird nuisance mitigation measures such as best management practices (including, but not limited to daily soil cover and tarps over exposed RIM and waste), visual and auditory frightening devices, and wire or monofilament grids strung over exposed refuse to prevent bird access, are demonstrated reliable technologies under proper operating and excavating conditions. However, while visual or auditory frightening devices can be effective in the short-term, birds tend to habituate to deterrents over time, causing the deterrent to lose effectiveness. Frequent relocation of predator birds and predator effigies and/or altering the timing of auditory activation may help, but long-term effectiveness is not assured. In addition, the FAA has stated that “[t]o date, no . . . [putrescible waste] facility has been able to demonstrate an ability to reduce and sustain hazardous wildlife [birds] to levels that existed before the putrescible-waste landfill operations began operating.” (FAA, 2007).

Stormwater controls are well-established technologies that are implemented at most landfill sites. For this alternative, gravity settling of suspended solids potentially containing radionuclides is a well-established and reliable technology.

6.2.4.6.3 Ease of Undertaking Additional Remedial Actions, if Necessary

Because all of the RIM would not be removed during implementation of this partial excavation alternative, it is possible that EPA could later require removal of additional RIM. If such a decision were to occur after construction completion of this alternative, performance of any such additional remedial action in the future would be very difficult and costly. Such actions would require removal of the newly constructed engineered landfill cover and re-excavation of materials previously removed and replaced as part of this partial excavation alternative.

Other than the possibility of additional excavation in the future, the only potential additional remedial actions that may need to be taken for the 52.9 Partial Excavation Alternative would be maintenance activities to sustain the cover system, repair areas of differential settlement or erosion, or possible implementation of a contingent landfill gas control system. Regrading and contouring the existing waste materials to achieve final grades would require re-compaction of the regraded waste materials in order to minimize the potential for compaction or differential settlement over time that could affect the integrity of the landfill cover. Placement of additional fill material to achieve the final slope requirements and for construction of the landfill cover may result in differential compaction of the waste materials, depending upon the nature, age and amount of prior degradation of the waste materials. Runoff of stormwater can result in formation of erosional rills. Depressions caused by differential settlement of the wastes or erosional features can easily be (and commonly are) addressed at landfill sites through placement of additional soil material to fill such features.

In the event that monitoring of subsurface landfill gas and radon detects the presence of gas levels above regulatory thresholds along the perimeter of the Site, a landfill gas control system could be implemented as an additional remedial action. Implementation of a contingent landfill gas control system would entail drilling and installation of gas extraction wells, installation of conveyance piping, installation and operation of landfill gas extraction blowers and a landfill gas treatment (flare) system, and/or possible use of a carbon adsorption system to remove radon from the extracted gas stream. Installation of a contingent gas system could be performed as a future action. Any disruption to the final landfill cover resulting from the installation of a contingent gas extraction system would need to be repaired. Such activities are commonly and routinely undertaken at solid waste disposal sites.

Long-term monitoring and maintenance of the landfill covers at other Superfund sites and at non-Superfund solid waste landfills is typically required to assess whether differential settlement or surface erosion of the cover has occurred over time. Long-term maintenance, including cover inspection and repair, would be part of this alternative. Cover repair, if necessary, would be straightforward, primarily entailing placement of additional fill, regrading, and revegetation of the repaired area.

Bird nuisance mitigation measures such as best management practices (including, but not limited to, selective excavation, daily soil cover, and tarps), visual and auditory frightening devices, and wire or monofilament grids strung over exposed refuse to prevent bird access, are demonstrated to be readily implementable at landfill sites.

Storm water management measures other than those using conventional earth-moving equipment, piping, pumps, liners, filtration and carbon adsorption water treatment equipment, rip-rap, and pond outlet structures are not anticipated.

6.2.4.6.4   Ability to Monitor Effectiveness of Remedy

Demonstrating the effectiveness of the cover systems constructed over Areas 1 and 2 after partial excavation of RIM would be accomplished by implementing monitoring programs for the cover surface, landfill gas system, groundwater and surface water programs, as previously described in Section 5.4.4. These types of monitoring programs have been proven at demonstrating cover effectiveness and are easily implemented.

6.2.4.6.5 Ability to Obtain Approvals from Other Agencies

Implementation of the 52.9 Partial Excavation Alternative would require approvals from other agencies, including the following:

- Approval from the FAA to conduct waste excavation activities within 10,000 feet of an active airport runway. FAA Advisory Circular AC 150/5200-33B, dated August 28, 2007, "Hazardous Wildlife Attractants On or Near Airports," recommends "against locating a MSWLF [municipal solid waste landfill] within the separation distances identified in Sections 1-2 through 1-4. The separation distances should be measured from the closest point of the airport's AOA [airport operations area] to the closest planned MSWLF cell." AC 150/5200-33B, p. 4. The separation distances referenced are 5,000 feet from the end of a runway for airports serving piston-powered (propeller) aircraft; 10,000 feet for airports serving turbine-powered (jet) aircraft; and 5 miles of protection from hazardous wildlife movement for approach, departure and circling airspace. The FAA strongly recommends against allowing a waste disposal operation within 10,000 feet of a jet aircraft runway if the material contains putrescible waste and so has the potential to attract wildlife that could threaten air traffic. The excavation of RIM containing putrescible waste within 10,000 feet of the westernmost runway (11/29, formerly known as 12W/30W) at Lambert-St. Louis International Airport, as would occur during excavation of the RIM in Areas 1 and 2, is limited by the need to mitigate potential bird activity during excavation to address the requirements of the FAA Advisory Circular and to comply with the same prohibitions in the Missouri solid waste regulations. It may be necessary to work directly with the FAA and MDNR to identify specific bird mitigation measures during implementation.

- Approval of St. Louis Airport Authority (STLAA) relative to obtaining a release for the Negative Easement and Declaration of Restrictive Covenants Agreement. Excavation of RIM from Areas 1 and 2 poses a potential to increase the bird populations at the Site if mitigation procedures are not employed or prove ineffective. An increase in bird populations presents a greater potential for aircraft-bird strikes. The STLAA and USDA have identified this as a concern relative to construction and operation of a new on-site disposal cell that was included in the "complete rad removal" with on-site disposal alternative evaluated in the SFS. Based on the STLAA's position stated in the STLAA's September 20, 2010 letter to EPA, STLAA acceptance of RIM waste excavation would not be likely if bird activity were to increase. It may be necessary to work directly with the FAA and the STLAA to address these concerns, either by amending the FAA ROD, amending the Negative Easement, requiring specific bird mitigation measures during implementation, or making other changes to secure STLAA's cooperation.

- Location of an off-site truck-to-rail loading facility. At the discussion held in September 2010, the STLAA indicated that they would not allow the use of the existing SLAPS truck-to-rail transloading facility for loading waste from the West Lake Landfill into railcars (Appendix A-4). The SLAPS rail spur is reportedly owned by the U.S. Army Corps of Engineers and the land upon which the rail spur is built is owned by the City of

St. Louis. It is not clear that the STLAA could prevent use of the SLAPS rail spur for loading and shipping via contractual means; however, as the STLAA is the owner of the property, their concurrence must be considered. Therefore, it appears unlikely that the SLAPS rail spur would be available for implementation of a remedial action for West Lake Landfill. No other nearby off-site truck-to-rail loading facilities have been identified. Discussions with US Ecology have indicated that as part of the transportation and disposal activities, US Ecology would locate and lease an existing rail spur in the area or otherwise construct a rail spur somewhere in the area that could serve as a transloading facility.

- Compliance with EPA's OSR. The EPA Region where the off-site disposal facility is located would need to be contacted every 60 days during the period of off-site waste shipments to obtain a compliance determination as to whether the disposal facility currently meets the criteria under the OSR to accept CERCLA waste. If, during RIM excavation, the contracted off-site disposal facility was to be out of compliance for a period of time, excavation and transportation would need to cease until the facility becomes compliant or RIM would need to be transported to another facility that is determined to be in compliance with the OSR. Besides schedule delays, temporary stoppage of construction would present significant technical implementability concerns regarding open excavation areas.

- Rocky Mountain Low Level Radioactive Waste Compact Consent. If RIM were to be disposed at the Clean Harbors Deer Trail, CO facility, an application would have to be submitted to and accepted by the Rocky Mountain Low Level Radioactive Waste Compact. Disposal at the US Ecology Grand View, ID, US Ecology Wayne, MI, and Energy*Solutions* Clive, UT facilities would not be subject to a Waste Compact consent.

6.2.4.6.6 Coordination with Other Agencies

Although not all would be considered "agencies," coordination with many entities would be necessary to implement the 52.9 Partial Excavation Alternative. Coordination with the landfill owner and operator and owners or occupants of the various parcels that comprise the West Lake Landfill Site would be necessary because of the following:

- Termination of the asphalt company lease and removal of the asphalt plant followed by relocation of the Bridgeton solid waste transfer facility and construction of an overpass between Areas 1 and 2 over the Site access road would need to occur prior to the start of RIM excavation;

- Access to operations conducted on other portions the Site would need to be maintained.

- Areas 1 and 2 are within a larger existing Site footprint, and use of areas on the Site outside of Areas 1 and 2 might be necessary to stockpile cover materials or otherwise to facilitate cover construction.

- Implementation of this alternative would require excavation of portions of landfill units located outside of OU-1. Upon completion of removal of the RIM, disturbed portions of the adjacent landfill units would need to be repaired and restored, and regrading and installation of a replacement landfill cover over areas outside of OU-1 would need to be performed. Coordination would also be required relative to integration of the slopes and grading for adjacent landfill areas and routing and design of stormwater diversion and conveyance structures between OU-1 and other landfill areas.

- Use of other areas of the West Lake Landfill Site that may be necessary for stockpiling of overburden and staging or routing of trucks or rail cars used to haul the excavated RIM off-site.

- Implementation of any additional institutional controls or modifications to existing institutional controls that EPA may require would need to be approved and accepted by the individual entities that own the various parcels that compose the Site.

For the duration of excavation, off-site transport, and import of cover materials, the flow of vehicles associated with remedy construction would need to be coordinated with the traffic patterns of vehicles associated with the current on-site solid waste transfer station and other Site tenants.

If a truck-to-rail transloading facility at an off-site rail spur location were to be used, a suitable location would need to be identified and a lease secured with the land/rail spur owner for the duration of the RIM loading and transport operations. As noted above, it does not appear that the existing SLAPS truck-to-rail transloading facility would be available, so costs for establishing a new facility would need to be considered[51].

If a rail spur were to be extended onto the West Lake Landfill Site:

- Land located across St. Charles Rock Road would either need to be purchased or long-term leases would be needed with landowners;

- State and local government, private landowner, facility occupant and community approval would need to be obtained in order to construct a rail spur across private property located to the east of St. Charles Rock Road, across St. Charles Rock Road, and along the access roads which serve the existing solid waste transfer station and asphalt plant operations located at the Site;

- Appropriate safety measures for the crossing at St. Charles Rock Road would have to be installed, consistent with requirements of state and local governments;

---

[51] The unit cost estimates provided by US Ecology for purposes of this FFS include costs to secure an off-site rail spur for a truck-to-rail transloading facility.

- The long-term lease of the asphalt plant for land south of the solid waste transfer station, would need to be bought out or otherwise acquired; and

- Because of the high traffic volume on St. Charles Rock Road during the day, dropping off empty and picking-up loaded railcars would likely be possible only during late nighttime and early morning hours.

Provision of and switching of gondola railcars either at a truck-to-rail transloading facility spur or an on-site rail spur would need to be coordinated with the railroad company that would be hauling the railcars to the off-site disposal facility.

Future groundwater monitoring activities could require obtaining and maintaining access to off-site properties if off-site groundwater monitoring were required as part of the remedy.

The potential for increased bird strikes to aircraft approaching and departing the Lambert-St. Louis International Airport is a major concern of the FAA and St. Louis Airport Authority. The effectiveness of proposed bird nuisance mitigation measures would be of interest to the FAA and STLAA. Consequently, the FAA and STLAA would need to be involved in the remedial planning process.

Coordination with other agencies, including the Earth City Flood Control District, MSD and MDOT, as well as the adjacent property owners and businesses (for example, the Crossroads Property/AAA Trailer) would also be necessary to:

- Coordinate with the Earth City Flood Control District regarding the design of non-contact stormwater management and discharge facilities both during and after completion of construction;

- Coordinate with MSD regarding permitting and design of leachate/contact stormwater discharge during construction;

- Coordinate with MDOT for access to areas along St. Charles Rock Road and for any traffic control or ingress and egress additions along St. Charles Rock Road in the vicinity of the Site entrance; and

- Obtain legal and physical access from AAA Trailer for testing and if necessary remediation of the Crossroads Property and possibly for implementation of remedial actions that may need to be performed along the property boundary (e.g., regrading, fencing, etc. in Area 2).

As discussed at the beginning of this section (6.2.3.6), in order to access RIM in Area 1, the solid waste transfer station facility would need to be relocated. The only suitable area for relocation of the transfer station is currently under lease and occupied by Simpson Asphalt Company. The asphalt company lease would need to be bought out and their equipment removed from the Site before the transfer station could be relocated. Relocation of the transfer station would normally be subject to permitting by the City of Bridgeton and St. Louis County; however, because relocation of the transfer station would be performed as part of a Superfund remedial action and the transfer station would remain on-site, additional permitting is not anticipated to be required. However, it is likely that public meetings and hearings may be necessary, which would require coordination with the City of Bridgeton and St. Louis County and could impact the timing for the start of construction of a 52.9 Partial Excavation Alternative.

6.2.4.6.7 Availability of Off-site Treatment, Storage and Disposal Services and Capacity

As discussed in Section 4.3.5.4, four off-site disposal facilities that could accept excavated RIM from the West Lake Landfill OU-1 have been identified. At least three of these facilities (located in Idaho, Utah and Colorado) have accepted radiologically-impacted soil from projects or sites in the United States, although none of them have previously accepted radiologically-impacted soil mixed with solid waste. All four of the identified facilities have available capacity to accept the estimated volume of RIM from the Site. The volumetric rate of acceptance for all facilities would be limited by the number of IM containers and railcars that could be provided and loaded at or near the Site, as well as the number that could be unloaded at or near the disposal facility. Off-site treatment, storage and disposal may be required in the event that hazardous wastes or RACM are encountered in the overburden or RIM excavated from Areas 1 and 2.

The identified facilities are also permitted to: (1) accept liquid wastes, should any stormwater that may accumulate in excavations during RIM excavation become contaminated and require disposal off-site; (2) accept mixed wastes if mixed wastes are encountered during excavation; and (3) treat soil and/or debris that contains hazardous waste or mixed waste.

As discussed in Section 3.2.1, the CERCLA OSR requires that waste materials removed from a CERCLA site be placed only in a facility operating in compliance with RCRA or other applicable Federal or State requirements. EPA makes such determinations every 60 days. The compliance status of an off-site disposal facility would need to be evaluated during remedial design and would need to be regularly evaluated and updated during remedy implementation.

Offsite treatment and discharge of any leachate that may be encountered or stormwater that may contact waste materials during the landfill re-contouring activities could also be required. Off-site treatment and discharge of any leachate that may be encountered or stormwater that may contact RIM during the landfill excavation activities could also be required. Initial discussions with MSD indicated that they are willing to accept leachate and contact stormwater and initial discussions with the Earth City Flood Control District indicated a willingness to accept stormwater, subject to installation of additional stormwater detention/retention capacity.

6.2.4.6.8 Availability of Necessary Equipment and Specialists

Materials, equipment and personnel required for excavation and transport of RIM to an off-site disposal facility are readily available. Trained health physics technicians and specialized equipment required to monitor personnel and environmental conditions, as well as to assist in directing the RIM excavation sequencing, are also available.

As discussed above, there are a limited number of disposal facilities that can accept these types of wastes, and most of these have stringent waste acceptance criteria which may limit the ability of some of the facilities to receive the wastes.

Availability of rail service, particularly the number of rail cars that can be made available and switched daily by the railroad, would also affect the production rate of RIM excavation and disposal and therefore the cost.

All of the materials, equipment and personnel necessary to remove the designated portion of the RIM and to regrade and construct the engineered landfill cover over Areas 1 and 2 after the designated portion of the RIM (*i.e.*, greater than 52.9 pCi/g) has been removed are readily available and the technologies have been generally proven through application at other landfills. The implementability and potential cost of the covers would be influenced by the availability and location of clean cover materials and/or off-site borrow sources at the time this alternative would be implemented. Potential vendors of rock, clay and soil were contacted during the development of the FS (EMSI, 2006) and during preparation of the Remedial Design Work Plan for the ROD-selected remedy (EMSI, 2008) regarding availability, and the availability of some of the materials was verified in conjunction with construction of the NCC. Information obtained from the vendors at these times indicated that rock, clay and clean cover material were readily available from sources located near the Site. If these local sources of cover materials become exhausted prior to or during remedy implementation, cover materials would have to be obtained from suppliers at greater distances from the Site.

The necessary materials, equipment and personnel required for assessment and removal of RIM that may be present at the Buffer Zone/Crossroads Property above unrestricted use levels and to implement the institutional controls and monitoring components of this alternative are also readily available.

6.2.4.6.9 Availability of Prospective Technologies

The 52.9 Partial Excavation Alternative is based on proven, established, and commonly used technologies. Use of prospective technologies is not currently envisioned to be part of this alternative.

6.2.4.7 Cost

Estimated capital, annual OM&M, and 30-year present worth costs for the 52.9 Partial Excavation Alternative are included in Appendix K-5 and summarized on Table 6-1. Conceptual excavation, backfill, and bottom and top of final cover grading plans as well as stormwater control features used as the basis for the 52.9 Partial Excavation Alternative capital cost estimate are provided in Appendix M. The estimated cost to conduct the 52.9 Partial Excavation Alternative (i.e., design costs, capital costs, and costs for monitoring during the construction period) is $313,000,000 based in part on unit costs provided by US Ecology. These costs do not include costs to conduct full-scale pilot-testing of solids separation equipment. The estimated annual OM&M costs range from $159,000 to $326,000 per year depending upon the specific activities that occur each year (e.g., higher costs for years with additional environmental monitoring and years when landfill cover repairs and five year reviews may occur). The cost estimates provided in this FFS are feasibility-level cost estimates which were developed to a level of accuracy such that the actual costs incurred to implement this alternative are expected to fall within a range bounded by 50% above and 30% below these estimates.

The present-worth costs of the 52.9 Partial Excavation Alternative are projected to be $265 million over a 30-year period based on a discount rate of 7%. Based on the current OMB rate of 1.5%, the present worth costs would be $305 million. The total non-discounted costs for the 52.9 Partial Excavation Alternative over 30 years are projected to be $318 million.

Given the long life of the radionuclides present at OU-1, the costs for the 52.9 Partial Excavation Alternative were also evaluated for 200- and 1,000-year periods (without consideration of any constraints on annual expenditures). The total non-discounted costs of the 52.9 Partial Excavation Alternative are projected to be $348 million over a 200-year period. The total present-worth costs of the 52.9 Partial Excavation Alternative are projected to be $265 million based on a 7% discount rate or $312 million based on a 1.5% discount rate, respectively, over a 200-year period. The total non-discounted costs of the 52.9 Partial Excavation Alternative are projected to be $487 million over a 1,000-year period. The present-worth costs over a 1,000-year period are projected to be $265 million based on a 7% discount rate or $312 million based on a 1.5% discount rate.

Unit costs associated with transportation by rail and disposal of RCRA soil, RCRA soil with radionuclide material, RCRA debris, and RCRA debris with radionuclide material would have added treatment costs in order to meet the LDRs and UTS. Based on discussions with representatives of the disposal facilities during preparation of the SFS (EMSI et al., 2011), the additional costs for treatment at their facilities are estimated to range from $45 to $150 per ton for RCRA metals or $400 to $500 per ton for organics, depending on the type of treatment.

Since the amount of mixed waste, if any, that might be excavated along with the RIM is unknown, and because of the RCRA restrictions on waste accumulation amounts and timeframes and limited storage space on-site, it is unclear if volumes would support shipment by rail. As such, the mixed waste would likely be shipped to the off-site disposal facility directly via truck. For truck hauling to the off-site disposal facility, the interior of the semi-trailer would be lined with a disposable polyethylene slip liner and, after the waste was loaded the trailer, would be covered and the cover securely strapped down. The capacity of each truckload would be 22 tons or 17 cubic yards, depending on the weight of the material. Current trucking costs range from $4.70 to $5.10 per loaded mile. Road mileage from the West Lake Landfill to the US Ecology Wayne Disposal, Michigan, Clean Harbors Deer Trail, Colorado; Energy Solutions Clive, Utah; and US Ecology Grandview, Idaho facilities are 520, 720, 1,340, and 1,580 miles, respectively. Therefore, RCRA or mixed-waste truck transportation costs to an off-site facility could range from $145 to $470 per cubic yard or $110 to $370 per ton, depending on where the material is ultimately disposed.

For purposes of demonstrating how much shipping of mixed waste could influence costs, it was assumed that mixed waste would represent 0.5% of the sum of the volumes of overburden wastes and RIM for the 52.9 Partial Excavation Alternative. The added costs for handling, sampling/analysis, shipping, treating, and disposing of mixed waste for this alternative are estimated to range from $950,000 to $1.8 million. The range of costs primarily results from variations in the fees charged by the off-site disposal facilities and uncertainties associated with the nature of such wastes and the required method of treatment. If the volume of mixed waste is higher than the 0.5% of total mass assumption, the added costs would be higher.

6.2.5 Partial Excavation of RIM with Activities Above 1,000 pCi/g

This section presents the detailed analysis of a partial excavation alternative consisting of removal of RIM with combined radium and/or combined thorium activities greater than 1,000 pCi/g and subsequent regrading and capping of the remaining waste (hereafter referred to as the "1,000 Partial Excavation Alternative"). As previously described in Section 5.6, this alternative consists of the following components:

- Removal of the asphalt plant and relocation of the Bridgeton Transfer Station, LLC building to provide access to RIM located adjacent to the building and construction of an overpass over the Site access road;
- Excavation and stockpiling of overburden from OU-1 Areas 1 and 2 in order to access the RIM;
- Excavation of RIM from the OU-1 Areas 1 and 2 that contains combined radium or combined thorium activities greater than 1,000 pCi/g;
- Loading, transport, and disposal of the RIM at an off-site disposal facility;
- Survey and identification of the presence and extent or radiologically-impacted soil on the Buffer Zone and Crossroads Property;
- Excavation of any soil from the Buffer Zone and/or Crossroads Property that contains radionuclides at levels greater than those that would allow for unrestricted use and placement of such soil in Area 1 or 2;
- Regrading of the remaining solid waste materials within Areas 1 and 2 to meet the minimum (5%) and maximum (25%) slope criteria;
- Installation of a landfill cover meeting the Missouri closure and post-closure care requirements for sanitary landfills over Areas 1 and 2;

- Design, installation and maintenance of surface water runoff controls;
- Groundwater monitoring consistent with the requirements for sanitary landfills;
- Landfill gas and radon monitoring and control, as necessary;
- Institutional controls to prevent land and resource uses that are inconsistent with a closed sanitary landfill site containing radionuclides; and
- Long-term surveillance and maintenance of the landfill cover in Areas 1 and 2.

Under this alternative, an estimated 38,200 bcy of RIM would be excavated from Areas 1 and 2 for off-site disposal. The volume of material would increase upon excavation due to swelling, handling and loading for transport to an off-site disposal facility. Applying the swell factor of 1.5 and accounting for daily cover, it is estimated that approximately 63,100 lcy would be transported to and disposed off-site. An additional approximately 2,900 bcy of impacted soil would be excavated from the Buffer Zone/Crossroads Property and placed in either Area 1 or 2 under this alternative.

Once all of the material containing combined radium or combined thorium activities greater than 1,000 pCi/g has been removed from Areas 1 and 2, the remaining solid waste materials in Areas 1 and 2 would be regraded to meet the final closure standards for sanitary landfills and a final sanitary landfill cover would be constructed over Areas 1 and 2. Because waste containing radionuclides above unrestricted use standards would still remain in Areas 1 and 2, this cover would include the additional hybrid components included in the ROD-selected remedy to address the UMTRCA requirements.

This alternative also includes installation and maintenance of surface water runon and runoff controls, groundwater and landfill gas monitoring, and institutional controls for Areas 1 and 2 and the Buffer Zone. Environmental monitoring of groundwater quality would be performed to ensure that groundwater quality at the perimeter of the Site met State standards or other ARARs. Monitoring of subsurface occurrences of landfill gas and radon and, if necessary, implementation of contingent landfill gas extraction would be performed to ensure that gas migration above regulatory thresholds does not occur beyond the perimeter of Areas 1 or 2. Landfill gas and groundwater monitoring as described in Sections 5.3.1.6 and 5.3.1.10, respectively, are also included as part of the 1,000 Partial Excavation Alternative.

Existing institutional controls would be maintained and enforced as previously described in Section 5.3.2.1 for the ROD-selected remedy to ensure that land and resource uses are consistent with permanent waste disposal. These institutional controls are necessary to ensure that residential uses do not occur at the landfill and that commercial and industrial uses or ancillary uses that could result in unacceptable risks do not occur on Areas 1 and 2 or the Buffer Zone. In addition to prohibiting land uses that could result in potential exposure to waste materials or contaminants at the Site, these institutional controls would also limit or prohibit land uses or activities that could disrupt the integrity, performance or longevity of the new landfill cover or other components of the remedy. Any modifications to the existing institutional controls or any additional controls that EPA may determine are necessary would be implemented as part of remedial design.

Long-term inspections and maintenance activities of the engineered components, similar to that described for the ROD-selected remedy (Section 5.3.1.9) and enforcement of the institutional controls (Section 5.3.2.1) would also be required.

6.2.5.1 Overall Protection of Human Health and the Environment

The 1,000 Partial Excavation Alternative would protect human health and the environment through (1) removal and off-site disposal of RIM above industrial use risk-based levels which also possess the highest activity levels found at the Site, and (2) engineered containment, long-term surveillance and maintenance, and institutional controls on land and resource use. The landfill cover would reduce potential risks from exposure to external gamma radiation or radon gas emissions and eliminate potential risks associated with inhalation or ingestion of contaminated soils or other wastes, dermal contact with contaminated soils or other wastes, and wind dispersal of fugitive dust.

The presence of an engineered landfill cover would prevent users of the Site from exposure to external gamma radiation primarily through shielding and increasing the distance to the radiation source (i.e., the cover materials would be of sufficient thickness and design to attenuate gamma radiation). For the types of clay soils used for infiltration protection in the construction of final covers, the depth of cover required for gamma radiation shielding is on the order of two feet (60 cm). The total thickness of the final cover for the 1,000 Partial Excavation Alternative would be a minimum of five feet (two feet of biointrusion rock/rubble, two feet of clay soil, and one foot of vegetative soil).

The cover materials would also be of sufficient thickness and design to retard or divert the vertical upward migration of radon. The landfill cover acts as a diffusion barrier, allowing time for the decay of the relatively short-lived radon-222 gas (the half-life for radon-222 is 3.8 days) during migration through the pore spaces of the cover soil. Radon is continually produced from the radium source, but need only be detained in the cover materials for a few days to decay to its non-radiological progeny, thereby eliminating any significant radon emissions. The radon may also be intentionally vented or diverted to a landfill gas control system. Calculations presented in Appendix F indicate that a clay layer thickness of two feet, combined with a two-foot-thick rock/rubble layer and a one-foot-thick vegetative layer, would provide sufficient radon attenuation to meet the radon emissions ARAR of 20 pCi/m^2s. As discussed in Appendix F, these calculations were based on the increased levels of radium expected to be present at the Site after 1,000 years of in-growth of radium from decay of thorium.

The potential for direct contact with waste materials is eliminated by partial removal of RIM and by placing a barrier (multi-layer landfill cover including bio-intrusion layer) between the remaining RIM/waste materials and any potential receptors. Likewise, there is no potential for the generation of fugitive dust from the waste material as long as the barrier remains in place.

The multi-layer cover would also be designed to minimize infiltration of surface water through the wastes, thereby reducing the potential for leaching of contaminants to the groundwater. This is typically accomplished by promoting surface drainage and using a hydraulic barrier (e.g., a compacted clay layer meeting the specified permeability requirements). These are all conventional functions for landfill cover technologies and are widely used by government and industry to address similar circumstances where contaminated materials must be encapsulated to protect against future potential contact. Long-term maintenance of the cover and monitoring of the groundwater would ensure that the 1,000 Partial Excavation Alternative functions as intended.

Environmental monitoring of groundwater quality would be performed to ensure that groundwater quality at the perimeter of the Site meets state standards or other ARARs. Monitoring of subsurface occurrences of landfill gas and radon and, if necessary, implementation of contingent landfill gas extraction along the perimeter of Areas 1 and 2, would be performed to ensure that gas migration above regulatory thresholds does not occur beyond the Site perimeter.

Institutional controls would ensure that land and resource uses are consistent with permanent waste disposal. The use restrictions would reflect the presence of radionuclides at the Site.

6.2.5.2 Compliance with ARARs

Insofar as the 1,000 Partial Excavation Alternative includes excavation and off-site disposal of a large portion of the RIM, regrading of the remaining solid wastes, and installation of a new landfill cover over Areas 1 and 2, the Missouri solid waste rules for sanitary landfills would be relevant and appropriate to this alternative. Upon completion of RIM excavation, the remaining RIM and solid waste in Areas 1 and 2 would be regraded to achieve minimum 5% and maximum 25% slopes, and an engineered cover consistent with the cover requirements for a solid waste landfill without a liner would be installed. These actions would result in this alternative meeting the MDNR solid waste rules. Because some RIM above unrestricted use levels would remain in Areas 1 and 2, the UMTRCA standards for gamma and radon emissions in 40 CFR 192.02 are potentially relevant and appropriate for Areas 1 and 2. Therefore, the landfill cover under this alternative would also include the 2-foot thick rock biointrusion layer and the cover would be designed to meet the radiation exposure and radon emission requirements of UMTRCA. Sections 6.2.2.2.1 and 6.2.2.2.2 contain full discussions of the MDNR solid waste regulations and the UMTRCA standards. The design of the landfill cover would meet these requirements.

The 1,000 Partial Excavation Alternative would also need to comply with the applicable or relevant and appropriate requirements of NESHAPs, the Safe Drinking Water Act, the NRC Standards for Protection Against Radiation, the Missouri Well Construction Code, the Missouri Storm Water Regulations, and the Clean Water Act (for stormwater runoff). These requirements would be met or achieved using the same methods as previously described in Sections 6.2.3.2.3 through 6.2.3.2.8 with respect to the "complete rad removal" alternative.

6.2.5.3 Long-Term Effectiveness and Permanence

These criteria refer to expected residual risk and the ability of a remedy to maintain reliable protection of human health and the environment over time. The 1,000 Partial Excavation Alternative would reduce risk through removal of a portion of the RIM and provide engineered containment in conjunction with long-term monitoring, maintenance, and land use control designed to be effective over the long term for the remaining RIM. Removal of a portion of the RIM, combined with installation of an engineered landfill cover, would essentially eliminate the potential for gamma exposure, inhalation of radon gas or dust containing radionuclides or other constituents, dermal contact with impacted materials, and incidental ingestion of soil containing radionuclides or other chemicals and leaching of radionuclides or chemicals to the underlying groundwater. Maintaining the integrity of the engineered cover would protect the underlying RIM from erosion and intrusion. An UMTRCA-compliant cover would provide a reliable method to control exposure of the RIM to surface receptors and mitigate potential migration of the covered materials.

Long-term site management plans and institutional controls would be made as robust and durable as possible. Long-term groundwater monitoring would be effective in verifying a remedy is performing as required and groundwater is protected. The landfill cover would also passively prevent potential contaminant migration and human exposures for an indefinite period in the unlikely event of a loss of institutional controls.

By moving the contamination from the Buffer Zone/Crossroads Property to either Areas 1 or 2, the remedy would provide long-term effectiveness and permanence relative to the Buffer Zone/Crossroads Property.

6.2.5.3.1 Magnitude of residual risk

The calculated lifetime risks following the exposure scenarios in the risk assessment after removal from Areas 1 and 2 of RIM with combined radium and/or combined thorium activities greater than 1,000 pCi/g, an engineered landfill cover has been installed, and the remainder of this remedial alternative has been implemented (Appendix H) are as follows:

- Area 1: <1 x 10^{-7} for year 1 and <1 x 10^{-7} for year 1,000.
- Area 2: <1 x 10^{-7} for year 1 and <1 x 10^{-7} for year 1,000.

These calculated risk levels are below EPA's target risk range of 1 x 10^{-6} to 1 x 10^{-4}, and the magnitude of residual risk in Areas 1 and 2 is acceptable. These calculated risk levels are attributable to gamma radiation and radon emissions from any radionuclide occurrences that would remain in Areas 1 and 2 after removal of RIM containing combined radium and/or combined thorium activities greater than 1,000 pCi/g and the new engineered cover had been installed, and are also reflective of access restrictions and institutional controls. They do not specifically include potential exposures from non-radiological landfill wastes after construction is complete; however, those wastes would also be covered by caps which would prevent exposures. Additional information regarding the risk assessment calculations is presented in Appendix H.

Direct contact with the remaining RIM under the cap at Areas 1 and 2, and exposure by ingestion, inhalation, or dermal contact with such materials, is not expected to occur. These are the primary exposure pathways for any non-radiological COPCs which may be mixed with the RIM and landfill wastes that would remain in Areas 1 and 2 after partial excavation. Because no complete exposure pathway would exist for such materials after completion of the partial excavation and cap construction in Areas 1 and 2, the landfill waste materials would not be expected to produce non-carcinogenic effects or carcinogenic risks.

After soils containing radionuclide concentrations above unrestricted use levels are removed from the Buffer Zone/Crossroads Property, residual risks posed by the remaining radionuclide-impacted soil on these properties, if any, should be indistinguishable from variations in background levels.

6.2.5.3.2 Adequacy and reliability of controls

The conceptual design of the engineered cover has been developed to provide protection against all potential exposure pathways. Cover construction is based on and relies upon the use of natural materials that would be expected to remain in place and meet performance criteria for at least 200 years, as required by the UMTRCA ARARs. Post-closure inspection and maintenance of the cover – as required by the solid waste regulation ARARs, and as routinely performed at thousands of landfills across the country – also would ensure long-term reliability of the landfill cover.

The surfaces of Areas 1 and 2 are not currently graded to promote drainage of stormwater, but instead are generally flat with several surface depressions which act to increase precipitation accumulation and infiltration through the waste mass. In addition, no engineered landfill cover exists over these areas. Even with these limitations, infiltration of precipitation has not resulted in discernible leaching of radionuclides or other chemicals to groundwater. Removal of a portion of the RIM, regrading Areas 1 and 2 to promote drainage, and installation of the engineered landfill cover included as part of the 1,000 Partial Excavation Alternative would significantly reduce infiltration of precipitation and potential for leaching, thereby providing further protection against potential impacts to groundwater.

Long-term OM&M would include routine cover and stormwater ditch inspection and service to mitigate erosion, and OM&M of a landfill gas collection and treatment system if such a system is needed. Long-term monitoring would also be implemented to assess compliance with environmental performance standards. The performance of these engineering controls would also be re-evaluated during statutory five-year reviews.

The current Covenants and Restrictions for Areas 1 and 2 would be adequate to provide protection to human health. The permanence of these restrictions is assumed to be adequate for the foreseeable future, as both EPA and MDNR approval are required to remove or modify the restrictions. The adequacy of the restrictions would be continually evaluated during the statutorily-required five-year reviews.

6.2.5.3.3 Climate Changes and Potential Impacts of a Tornado

Because RIM and municipal solid waste would still remain in Areas 1 and 2 after the 1,000 Partial Excavation Alternative is implemented, a new engineered landfill cover would be installed over these areas. Because radionuclides above unrestricted use levels would remain in Areas 1 and 2, the engineered landfill cover that would be installed under this alternative would include the 2-foot-thick rock/rubble biointrusion layer along with the 2-foot-thick low permeability and 1-foot-thick vegetative layers as previously described for the ROD-selected remedy (Sections 5.3.1.4 and 6.2.2). This engineered landfill cover would be classified as an in-situ containment system (EPA, 2014a).

Because of the similarity between the engineered landfill cover to be installed over Areas 1 and 2 under the 1,000 Partial Excavation Alternative with the landfill cover to be installed under the ROD-selected remedy, the analysis of the potential effects of climate change or impacts of a tornado are essentially the same for both alternatives. These effects were previously discussed in Section 6.2.2.3.3 for the ROD-selected remedy and therefore will not be fully repeated here. The results of those evaluations (as discussed in Section 6.2.2.3.3) with regard to the landfill cover system for the 1,000 Partial Excavation Alternative are summarized below.

Similar to the ROD-selected remedy, the vegetative layer of the landfill cover to be installed under the 1,000 Partial Excavation Alternative could be vulnerable to increased occurrences of extreme temperatures, sustained changes in average temperatures, decreased precipitation and increase in drought occurrences. Increased temperatures or decreased precipitation/drought could affect the viability of the vegetation (*e.g.,* grasses) on the surface of the landfill cover. Any changes to the overall health and voracity of the vegetative cover would be readily identifiable by visual inspection. Therefore, although the vegetative cover may be vulnerable to potential increased temperatures or drought conditions, the potential for impacts to the vegetative layer could be anticipated and readily identified in advance of any such occurrence.

The low-permeability layer (CCL) could be damaged by periods of extended extreme temperatures or prolonged drought. Potential impacts could include desiccation of the CCL, with a resultant increase in permeability that could lead to increased precipitation infiltration. Such impacts are not considered to be significant because Areas 1 and 2 have existed for over 40 years with essentially flat (no grade) surfaces and minimal cover material, thereby maximizing precipitation infiltration without generation of currently identifiable impacts to underlying groundwater quality[52]. Therefore, even if desiccation of the low-permeability layer were to occur, the impacts to groundwater quality are not expected to be significant. More importantly, the vegetative layer would show significant signs of stress from increased temperatures/drought prior to the occurrence of any impacts to the underlying low permeability layer and thereby provide advance notice of a potential impact to the CCL. Therefore, although the low-permeability layer could potentially be vulnerable to effects of increased temperature or drought, the potential for any impacts could be anticipated and readily identified in advance of any such occurrence, and therefore are not expected to result in release of contamination.

Increased heavy precipitation events could result in erosion of the vegetation layer and, if left untended, could result in erosion of the underlying low-permeability layer. Any erosion of the landfill cover would be readily identifiable by visual inspection. Given the overall 5-foot thickness of the landfill cover and the inclusion of the 2-foot-thick rock layer in the base of the cover system, stormwater erosion, even under the most severe storm event, is not anticipated to result in erosion down through the entire landfill cover. Heavy precipitation events could impact the integrity or performance of stormwater drainage conveyance structures, including erosion of drainage channels, damage to or bypassing of let-down and erosion control structures, and features, or damage to stormwater detention structures. Heavy precipitation events could also temporarily restrict access to portions of the landfill cover, stormwater control structures, and environmental monitoring points, thereby causing delays in implementation of repairs if any are needed. Therefore, the vegetation layer and stormwater controls are potentially vulnerable to impacts from heavy precipitation events. However, due to the overall thickness and design of the landfill cover, any potential impacts are not expected to result in exposure of the waste material or release of contamination. Furthermore, any impacts that occur could be readily addressed as part of normal maintenance and repair of the landfill cover, including localized regrading, repair and replacement of cover material in response to any damage that may occur.

The 1,000 Partial Excavation Alternative is not anticipated to be impacted by flooding that may occur in the area of the Site. As previously discussed in Section 2.1.6, FEMA has determined that with the exception of the easternmost portions of Areas 1 and 2, which do not contain waste materials, Areas 1 and 2 are located outside of the 500-year floodplain. In addition, the areas to the north and west of Area 2 (*e.g.*, Crossroads Industrial Park and Earth City Industrial Park) that potentially could be subject to flooding by the Missouri River are protected by the engineered levee and stormwater and flood control systems installed to protect the Earth City Industrial Park.

As previously discussed in Section 6.2.2.3.3 relative to the ROD-selected remedy, an evaluation of potential impacts associated with a tornado was previously performed and submitted to EPA (EMSI, 2013f). Similar to the ROD-selected remedy, the 1,000 Partial Excavation Alternative is not vulnerable to impacts from a tornado. Specifically, a tornado is not expected to damage the vegetative layer and even if it did, such an impact is not considered to be significant because it could be easily identified and, due to the design and thickness of the engineered cover, would not

[52] EPA has indicated that additional evaluations of groundwater will be conducted in the future as part of the OU-3 RI/FS.

result in exposure of the underlying waste or release of contamination. A tornado could damage or destroy aboveground infrastructure such as signage, fencing or environmental monitoring equipment; however, such impacts are not expected to be significant because they would be readily identified and easily repaired or replaced. Therefore, the 1,000 Partial Excavation Alternative is not considered to be vulnerable to impacts from a tornado.

Although the 1,000 Partial Excavation Alternative is not considered to be vulnerable to climate change, implementation of adaptation measures could be considered during remedial design to provide a degree of adaptation for climate change. For example, regrading of the surface of Areas 1 and 2 to a 2% slope instead of a 5% slope could be considered to reduce the velocity of runoff across the surface of Areas and 1 and 2 and thereby reduce erosion and soil loss potential under extreme precipitation events. Installation of a runoff collection and diversion system along the base of the above-grade portion of the North Quarry part of the Bridgeton Landfill adjacent to Area 1 and along the north sides of the Closed Demolition Landfill and the Inactive Sanitary Landfill adjacent to Area 2 could be included to divert runoff from these areas around Areas 1 and 2 to reduce the potential for impacts from heavy precipitation events. Use of grass seed mixtures that are more tolerant of long-term changes in precipitation or temperature and/or soil addition to increase water storage capacity could be evaluated as part of the design. Similarly, inclusion of a geotextile at the base of the vegetative layer could be considered to minimize the potential for water or wind erosion extending down into the underlying low permeability layer. The design grades of the stormwater conveyance structures could be evaluated to provide a balance between the ability to quickly route stormwater away from Areas 1 and 2 while minimizing the stormwater velocity and the associated potential for erosion of the stormwater conveyance structures. Identification and evaluation of additional adaptation measures can be addressed as part of the design of the engineered landfill cover and stormwater controls to increase the overall resilience of these features to heavy precipitation events. Continuous re-evaluation of potential vulnerabilities, system resilience, and possible adaptation measures should be included as part of the ongoing inspection and maintenance program.

6.2.5.3.4 Potential Impacts of a Subsurface Heating Event

Because radionuclides above unrestricted use levels would still remain at the Site under the 1,000 Partial Excavation Alternative, radionuclide-related impacts similar to those described in Section 6.2.2.3.4 for the ROD-selected remedy could potentially occur if an SSE or SSR were to occur in Areas 1 or 2. Specifically, a localized, temporary increase in radon emissions from the ground surface could occur. However, as discussed for the ROD-selected remedy, even if such an event were to occur, the radon emission rate would still be less than the standard established by the radon NESHAP. Additionally, if such a release were to occur, risks at or beyond the fence line are expected to be below the acceptable risk levels established by EPA.

6.2.5.3.5 Effects of an Isolation Barrier

As discussed in the previous subsection, no adverse impacts or unacceptable risks are expected to result if an SSR or SSE were to extend into in Area 1. Therefore, regardless of the location or type of isolation barrier that may be installed, or even if no barrier is installed, no unacceptable risks are expected to occur. Installation of a heat extraction barrier consisting of various heat extraction points would not have any impact on the protectiveness, long-term effectiveness, short-term effectiveness, implementability or cost of the 1,000 Partial Excavation Alternative, regardless of barrier location. Installation of a physical barrier, such as a vertical wall of inert material, would require excavation and regrading of the above-grade portion of the North Quarry part of the Bridgeton Landfill wastes located over the southern portion of Area 1. If such a barrier were to be installed prior to implementation of the 1,000 Partial Excavation Alternative, portions of the barrier would need to be removed in conjunction with removal of RIM in the southwestern portion of Area 1. In addition, the design of the engineered cover included in this alternative would need to account for any changes in the surface grades, stormwater drainage system and the presence of any above-grade features (*e.g.,* heat extraction points, temperature monitoring probes, or additional gas extraction wells) that may be installed in conjunction with a barrier. In contrast, if a physical barrier were installed after RIM removal and construction of the engineered cover included in the 1,000 Partial Excavation Alternative, that portion of the engineered landfill cover that extended over the area of an isolation barrier and the associated revised landfill grades would need to be removed as part of the construction of an isolation barrier. The alignment of a potential isolation barrier may also need to be revised to reflect the removal of some of the RIM from the southwestern portion of Area 1 assuming that it is designed before the RIM removal and regrading occurs.

6.2.5.3.6 Environmental Justice Considerations

As was previously discussed in Section 6.2.2.3.6 as part of the evaluation of long-term effectiveness of the ROD-selected remedy, a screening-level analysis did not identify any environmental justice concerns relative to the Site. EPA did identify a need for implementation of more traditional (non-electronic) communication methods to inform and ensure meaningful involvement of residents in the Terrisan Reste mobile home community.

6.2.5.4 Reduction of Toxicity, Mobility or Volume through Treatment

Reduction of toxicity, mobility, or volume through treatment refers to the anticipated performance of the treatment technologies that may be included as part of a remedy. Although a portion of the RIM would be removed, the 1,000 Partial Excavation Alternative is overall a containment remedy and therefore generally would not reduce the toxicity, mobility, or volume of the waste material through treatment.

As discussed in Section 4, radionuclides are naturally-occurring elements which cannot be neutralized or destroyed by treatment. Occurrences of radionuclides within Areas 1 and 2 are dispersed within soil material that is further dispersed throughout portions of the overall, heterogeneous matrix of municipal refuse, construction and demolition debris, and other non-impacted soil materials in Areas 1 and 2. Consequently, ex-situ treatment techniques are considered impracticable. In addition, the heterogeneous nature of the solid waste materials and the dispersed nature of the radionuclide occurrences within the overall solid waste matrix in portions of areas 1 and 2 make in-situ treatment techniques equally impracticable. The remedy for the Buffer Zone/Crossroads Property also would not reduce toxicity, mobility, or volume through treatment because it consists of moving radiologically-impacted soil from the Buffer Zone/Crossroads Property to Area 1 or 2, where it would either be shipped off-site for disposal or consolidated with the RIM in Areas 1 and 2.

An on-site technology that may potentially be applicable to this alternative is ex-situ physical separation of impacted soil from the solid wastes by using solids separation techniques such as hand picking for large bulky items and various fixed, vibrating, or rotating screens, among others (see prior discussion in Section 4.3.5.2). Physical separation would not decrease the mobility or toxicity of the radiologically-impacted materials, but has the potential to separate existing RIM from non-radiologically-impacted materials. As previously discussed, any solids separation techniques would need to be pilot-tested at full-scale using materials from Areas 1 and 2 during remedial design to ascertain the potential effectiveness, implementability, and cost of this technology. Of particular interest in conducting pilot-testing with material from Areas 1 and 2 would be obtaining an estimate of the degree of RIM volume reduction that could be achieved, assessing the moisture content of the filled material, determining the fraction of soil that would be contained in or adhered to the segregated refuse, and determining the residual levels of radioactivity that would be present in the non-soil refuse after screening out the soil fraction. Assuming that solids separation could prove to be an effective and implementable technology (that is, it could effectively separate the radiologically-impacted soil from the other landfilled waste materials such that the other landfilled wastes would contain radionuclide activities below the levels that would allow for unrestricted use), it has the potential to reduce the volume of radiologically-impacted material that would need to be transported to and disposed at an off-site disposal facility. However, little is known about the potential application of a soils separation technology to this situation, and it is possible that pilot-testing could demonstrate that physical separation would not be effective at separating RIM from non-radiologically-impacted materials, in which case the non-radiologically-impacted materials would need to also be shipped off-site for disposal. At this stage of analysis, neither the estimated costs nor the estimated schedules for this FFS include any allowance for solids separation pilot-testing or implementation.

In the event that hazardous wastes are encountered during implementation of the remedy, such materials would be separated from the other solid wastes and subjected to waste profiling to determine the appropriate treatment and disposal requirements. To the extent that hazardous wastes or mixed wastes are encountered, they would be shipped off-site and would be treated at the disposal facility in accordance with the hazardous waste regulations (*e.g.*, EPA's LDR program and UTS) and in accordance with the permits and standard operating procedures of the receiving facility. After arriving at an off-site disposal facility and undergoing a waste receipt analysis, RCRA soil/debris and RCRA soil/debris with radionuclide material would be stabilized prior to placement in a disposal cell. Depending on its physical characteristics, RCRA debris and RCRA debris with radionuclide material would undergo either micro- or macro-encapsulation prior to placement in a disposal cell. To the extent that treatment of the hazardous waste or mixed waste would be required for off-site disposal, stabilization or encapsulation treatment would result in a reduction of the mobility of the hazardous waste and radiologically-impacted components of the mixed waste. Toxicity and volume would not be reduced by these technologies, but may be reduced by other technologies potentially applicable to hazardous wastes that do not contain RIM, if such wastes were encountered during implementation of the remedial action at the Site.

Section 6.2.3.4 contains a full discussion of the procedures, protocols and concerns associated with the off-site shipment of hazardous wastes or mixed wastes.

6.2.5.5 Short-Term Effectiveness

This alternative poses significant potential short-term risks, as described below. During a public meeting held as part of the ROD-selected remedy process, EPA identified and discussed the following short-term risk issues for waste excavation: waste handling, sorting and stockpiling; water management; noise, odor and windblown trash; worker health and safety (PPE, gamma exposure, physical stress, physical hazards, workplace monitoring); contaminant migration/spreading (fugitive dust and airborne migration, fugitive dust control and water application, leachate generation, equipment decontamination water, and water from open excavations); and waste hauling and transportation issues/truck decontamination (transfer facilities, increased local traffic, waste handling on public roads, interstate transport by rail, DOT requirements, safety issues).

6.2.5.5.1 Protection of the Community During Remedial Actions

The projected carcinogenic risks that may be posed to off-site residents by this alternative would be less than 1×10^{-7} (see Appendix H). No non-carcinogenic risks are expected to occur.

The risk assessment (Appendix H) includes an estimate of the projected incidence of transportation accidents associated with each FFS alternative. For the 1,000 Partial Excavation Alternative, the projected incidence of transportation accidents associated with shipping of RIM for off-site disposal and importing of materials for construction of the multi-layer landfill cover is 16.6, meaning that approximately 17 transportation-related accidents are projected to occur if this alternative were implemented. The risk of an increased number of transportation-related accidents is associated with the transport of excavated RIM from the Site, and in particular: (1) transport from the Site to the rail transloading facility; (2) hauling by rail of the RIM to the disposal site; (3) transport of the RIM from the destination rail offloading facility to the disposal site; and (4) truck traffic associated with delivery of construction materials to be used for construction of the new engineered landfill cover on Areas 1 and 2.

Disturbing the waste material may expose the community to radioactive waste, methane and radon gas, dust and particulates. Excavation of existing waste materials would also undoubtedly result in undesirable odor emissions during the period of time that existing wastes may be handled or exposed. Mitigation of odors through engineering means is limited.

The 1,000 Partial Excavation Alternative would contribute significant carbon dioxide equivalent emissions to the atmosphere as a result of ongoing, vehicle operations associated with remedial work. In particular, approximately 53,000 tons of carbon dioxide equivalent emissions are projected to be emitted to the atmosphere as a result of the excavation, loading, and transport of the RIM to an off-site disposal facility, landfill regrading and cover construction work in Areas 1 and 2, and the importation of materials used to construct the multilayer landfill cover for Areas 1 and 2 (Appendix I, Table I-4).

Because RIM in Areas 1 and 2 would be excavated under this alternative, overburden would be stockpiled and stored, and RIM would be staged and loaded for off-site disposal. During these activities, the nuisance attraction to and congregation by birds at and above the affected areas could be problematic unless effectively controlled. The main concern would be the potential for increased bird strikes to aircraft approaching and departing from the Lambert-St. Louis International Airport. For the 1,000 Partial Excavation Alternative, an enclosed waste staging and loading structure would be constructed to minimize the outdoor handling of waste and associated attraction of birds or other vectors. Additional mitigation measures such as excavation best management practices, which include application of daily soil cover and/or placement of tarps over areas of exposed waste, visual and auditory frightening devices, or wire or monofilament grids positioned over exposed refuse to prevent bird access, could be implemented to minimize bird attraction to and congregation at and above the disturbed areas.

Excavation of waste materials from Areas 1 and 2 would require removal of the existing landfill cover and overburden from Areas 1 and 2 and portions of adjacent areas of OU-2. Excavation of overburden and RIM would create depressions in the landfill area during the period of time required to remove the RIM and regrade and cover the remaining landfill wastes. Precipitation that falls on the Site while such depressions are open would potentially flow into and accumulate in the depressions. Any accumulation of precipitation in depressions created during waste excavation could result in increased infiltration of precipitation runoff through the underlying waste materials, which could result in increased leaching of VOCs or other soluble contaminants from the waste materials. Such leaching potentially could contaminate the underlying groundwater if not adequately controlled.

Because Areas 1 and 2 would be excavated and RIM loaded into transport containers, stormwater controls would be implemented in accordance with the Missouri Storm Water regulations 10 CSR 20-6.200 to protect the community. During construction, consideration would be given to minimizing the areas of excavation that would be open and exposed to waste materials at any given time. Temporary diversion berms using daily cover material would also be constructed above the open excavation areas on the previously excavated (and temporarily covered) surface of any excavation depressions in order to divert precipitation runoff around the open excavation to prevent the runoff from contacting uncovered waste materials. Precipitation that contacts uncovered waste materials would flow into the low point of the excavation and be pumped out into temporary storage tanks using portable gas-driven pumps. Samples from each tank would be collected and sent to a laboratory for analysis. The stored water would be either directly discharged or treated and disposed appropriately based on the analytical results.

6.2.5.5.2 Environmental Justice Concerns

As was previously discussed in Section 6.2.2.5.1 as part of the evaluation of short-term impacts associated with the ROD-selected remedy, a screening-level analysis did not identify any environmental justice concerns. EPA did identify a need for implementation of more traditional (non-electronic) communication methods to inform and ensure meaningful involvement of residents in the Terrisan Reste mobile home community.

6.2.5.5.3 Protection of Workers During Remedial Actions

The 1,000 Partial Excavation Alternative would entail significant excavation, handling, loading and transport of RIM at the Site and therefore would pose both significantly increased radiological exposure risks as well as construction safety risks to on-site workers.

Workers involved in excavation and regrading of the RIM would be subject to potential short-term risks, including: exposure of workers to contaminated waste; excavation/trenching instability; stormwater runoff entering areas where waste is exposed, resulting in the exposure of workers to contact stormwater; and odor emissions or other aesthetic issues arising from exposed waste. Worker exposures would be addressed through development and implementation of a site safety plan, use of personal protective equipment, and performance of personnel and environmental monitoring during implementation of remedial action. Workers would be protected during construction by adhering to OSHA practices; however, as this alternative entails extensive excavation, handling and transportation of radiologically-impacted materials, OSHA work practices and personal protective equipment may not provide full protection against exposure to external gamma radiation.

The risk assessment (Appendix H) presents an evaluation of potential risks to Site workers that may occur for each alternative. These include risks from industrial accidents, exposure to carcinogenic substances, and projected radiation exposures. For the 1,000 Partial Excavation Alternative, the projected incidence of industrial accidents is 11.7 over the life of the project. The projected carcinogenic risk to the reasonably maximally exposed individual, a radiation technician, is 2.37×10^{-3}, which exceeds EPA's generally accepted risk range of 10^{-4} to 10^{-6}. The projected radiation dose to a remediation worker is 867 mrem/yr (Appendix H).

Excavation would necessarily entail disturbance of the overburden soil and underlying waste materials by construction workers and equipment. Dust control measures would be required in order to limit worker exposure to fugitive dust during construction.

6.2.5.5.4 Environmental Impacts

No measurable long-term impacts to plants or animals in surrounding ecosystems are expected from the 1,000 Partial Excavation Alternative. As noted in the BRA (Auxier, 2000) and the updated BRA (Auxier, 2016a), some of the ecosystems present at the Site are the result of existing institutional controls and other limitations on land use within or adjacent to OU-1 that have allowed field succession to take place. Much of the habitat on Areas 1 and 2 was removed in 2016 in conjunction with construction of the non-combustible cover. Excavation of RIM, regrading of Areas 1 and 2, and construction of the engineered landfill cover under the 1,000 Partial Excavation Alternative would destroy the remaining portions of the habitats that currently exist on the surface of Areas 1 and 2, forcing wildlife to migrate to other areas. Vegetative cover would be placed on the Site as a part of the final cover, and the Site would be allowed to return to an early-stage field ecosystem with periodic mowing and maintenance.

6.2.5.5.5 Ability to Monitor Effectiveness

Measurement of gamma radiation and radon flux through the newly constructed landfill cover would be conducted on Areas 1 and 2 after construction is complete. Regular monitoring of groundwater quality would be performed at appropriate locations around Areas 1 and 2. Measurements of subsurface occurrences of landfill gas and radon levels would be conducted along the property boundaries adjacent to Areas 1 and 2 to verify that off-site gas migration above regulatory thresholds does not occur.

6.2.5.5.6 Time Until Remedial Action Objectives are Achieved

The RAO of (1) preventing exposure to radionuclides or waste at concentrations above ARARs or risk levels would be met immediately upon construction of a new engineered landfill cover. The RAOs of: (2) minimizing infiltration and any resulting contaminant leaching to groundwater; (3) controlling surface water runoff and erosion and decreasing the potential for erosion and subsequent transport of RIM; and (4) controlling radon and landfill gas emissions from Areas 1 and 2 would also be met once construction of the new landfill cover over Areas 1 and 2 is completed. The RAO related to the Buffer Zone and Crossroads Property soil would be met upon removal of any remaining soil containing radionuclides above unrestricted levels from these areas.

Initiation of this alternative would require significant planning and permitting due to the limited number of off-site disposal facilities capable of taking this material and the extensive logistics associated with identifying, handling, classifying and loading the materials for transport to the selected off-site facility. Preparation of the remedial design should be completed within approximately 15 months of authorization to proceed with the RD. RD could take significantly longer if full-scale pilot-testing of solids separation equipment were to be performed. The RAOs would be achieved upon completion of construction, which is estimated to be finished within approximately 7.7 years after approval of the RD. Therefore, the remedial action objectives should be achieved within 9 years of approval to proceed with the RD (Appendix J). This schedule estimate assumes that the buyout of the asphalt company lease and relocation of the solid waste transfer station occurs during the remedial design phase; otherwise, the schedule would be longer.

The projected construction schedule and the cost estimate for the 1,000 Partial Excavation Alternative are highly dependent on the waste material swell factor; that is, the amount the in-place waste volume expands as it is excavated, handled and loaded for transport to an off-site disposal facility. For purposes of this FFS, a swell factor of 1.5 has been assumed. A swell factor greater than 1.5 would result in an increase to the overall construction schedule and the estimated costs. The projected construction schedule and the cost estimate for the 1,000 Partial Excavation Alternative also are highly dependent on the number of rail cars that could be loaded and shipped per day. The schedule and cost estimate developed in this FFS for this alternative are based on an assumption that a sufficient number of IM containers and rail cars can be made available, loaded, switched out and replaced every day. If the actual rate is less than the projected rates of RIM excavation used to develop the construction schedule, the time required to complete construction and consequently the costs for the 1,000 Partial Excavation Alternative would increase.

6.2.5.6 Implementability

The 1,000 Partial Excavation Alternative would involve excavation and off-site disposal of a portion of the RIM in Areas 1 and 2, repair and restoration of the disturbed portions of the OU-2 landfill units adjacent to Areas 1 and 2, surface grading and installation of upgraded landfill covers over the areas of Areas 1 and 2, long-term monitoring and maintenance of the covers, and long-term monitoring of landfill gas and groundwater and surface water quality.

Excavation of RIM would require removal of substantial amounts of overburden and material from the sidewalls of the excavations in order to maintain stability of the excavation areas. Overburden removal would entail removing and temporarily relocating part of the above-grade portion of the North Quarry part of the Bridgeton Landfill in order to access the underlying RIM in Area 1 of OU-1. The total amount of non-RIM waste required to be removed under this alternative is estimated to be 787,000 bcy, which – based on an expansion factor of 1.5 – would result in the need to handle, stockpile and replace approximately 1,200,000 lcy of waste. Management of exposed waste in both the excavation areas and the stockpiles, including management of stockpiles, stormwater runon and runoff, odor emissions, attraction to birds and other vectors, and litter control, would be a significant undertaking. The amount of space available for stockpiling the overburden material is limited, and therefore overburden material from Area 1 would likely need to be transported to Area 2 while waiting for final placement and capping. Similarly, the total volume of RIM that would be excavated under this alternative is estimated to be 38,200 bcy, which is equivalent to 57,300 lcy. Accounting for the excavation and handling of overburden, side slope cut material, and RIM, a total of approximately 3.4 million cubic yards of waste would be handled under this alternative.

An additional complication arises from the proximity of the Bridgeton Transfer Station. In order to access the RIM in the southwest portion of Area 1, the solid waste transfer station would need to be relocated, as removal of waste material would extend up to and along the base of the transfer station such that the integrity of the transfer station building foundation and above-grade structure would be compromised. The only available space for relocation of the solid waste transfer station is the area currently occupied by Simpson Asphalt Company, which holds a long-term (99-year) lease on this area. This lease would have to be bought out and the asphalt company would need to be relocated before the solid waste transfer station could be relocated to this area.

It is anticipated that a new structure would be constructed to shelter the RIM staging and loading operations in order to minimize stormwater contact, odor emissions and bird attraction. It is anticipated that such a structure would be constructed along the north side of the Site access road in the area that is currently being used to store new, reclaimed and surplus equipment and materials associated with ongoing operation and maintenance and closure activities for the Bridgeton Landfill. These materials would need to be relocated to another portion of the Site prior to construction of such a structure.

In order to minimize potential vehicle interactions between normal traffic to and from the solid waste transfer station and the construction operations associated with this alternative, a temporary overpass would likely need to be constructed over the Site access road to allow for uninterrupted movement of construction traffic between Areas 1 and 2. An overpass is considered the most efficient and safest means for transfer of overburden waste from Area 1 to stockpile locations in Area 2 and then back to Area 1. In addition, as discussed above, a single RIM staging and loading building would be constructed and operated as part of this alternative. RIM removed from Area 1 would need to be transferred over the Site access road. Installation of an overpass would eliminate the potential for RIM to be tracked across the Site access road and potentially tracked off-site.

While excavation with subsequent off-site transportation and disposal have been implemented at other sites containing radioactively-impacted materials, materials from these other sites have not included significant amounts of landfill solid wastes. Significant technical and administrative implementability issues are associated with excavating the RIM and loading it into IM containers for transportation if this alternative was to be implemented. These include the following:

- Reduced excavation production rates and increased volume of RIM subject to excavation resulting from application of daily cover over an extended excavation schedule;

- Ability to locate and obtain a lease to an off-site rail spur for use as a truck-to-rail transfer facility, or alternatively the ability to construct an on-site rail spur and rail loading facility;

- Increased potential for bird strikes to aircraft as a result of excavation of putrescible or organic solid waste overburden waste from the North Quarry portion of the Bridgeton Landfill and Areas 1 and 2 and excavation of RIM contaminated waste from Areas 1 and 2, all of which are located within flight paths of Lambert–St. Louis International Airport; and

- Impacts to other Site operations and traffic on surrounding roads from additional truck traffic used to haul wastes to an off-site truck-to-rail transfer facility and to haul earthen materials to the Site for daily cover, stockpile covers, and construction of the final cover.

Design and construction of post-RIM-excavation landfill covers over Areas 1 and 2, with subsequent monitoring and maintenance, are not expected to pose any implementability challenges. Materials and services necessary for the regrading and construction of the final landfill covers over Areas 1 and 2 after RIM removal are available and the technologies have been proven through application at other landfills. Design and construction of landfill covers post RIM removal over Areas 1 and 2 are not expected to pose any significant implementability challenges.

The actions included for the Buffer Zone/Crossroads Property – that is, testing and excavation of surface soil – are regularly and easily implementable.

Monitoring of the cover surfaces, landfill gas, groundwater, and surface water are proven methods for demonstrating the long-term effectiveness of the engineered landfill cover that would be placed over Areas 1 and 2 and are easily implemented.

6.2.5.6.1 Ability to Construct and Operate the Technology

In general, excavation and off-site disposal are standard technologies. However, there are unique circumstances associated with excavation of RIM in Areas 1 and 2, located as they are within an overall larger closed/inactive landfill site, which would complicate implementation of standard excavation technologies.

RIM excavation and placement in IM containers and hauling of the containers by truck for subsequent transfer to rail is also expected to present implementability concerns, challenges, and risks, specifically those associated with the following:

- Excavation and handling of contaminated materials;
- Safety risks associated with encountering methane gas during excavation;
- Management of fugitive dust and potential odors;
- Mitigation of bird hazards;
- Management and treatment of stormwater exposed to RIM during excavation; and
- Identifying, segregating, and disposing off-site any hazardous wastes, PCBs or RACM that may be encountered during RIM excavation.

If hazardous wastes, PCBs, or RACM are encountered during excavation of RIM, these materials would need to be segregated from the other waste materials, characterized, and transported to an off-site disposal facility in containers separate from the other RIM. Additional health and safety procedures would be required during excavation of these materials. These materials would require separate handling at the off-site disposal facility and could require treatment prior to disposal. Depending on the characteristics of any hazardous waste encountered during excavation, the hazardous waste could need to be transported to a different off-site facility for treatment and disposal in accordance with RCRA.

Directing and controlling the RIM excavation process using radiological scanning and sampling techniques would significantly impact overburden and RIM excavation production rates. Based on experience in excavation of radiologically-impacted waste at other sites, a reduction in efficiency is expected for overburden excavation and a greater reduction is expected for RIM excavation. Because thorium-230 is a primary radionuclide of concern relative to any excavation alternative that may be considered for the Site, even greater reductions in efficiency and increased time may be required for RIM excavation. Thorium-230 cannot be detected using field survey instruments, and therefore excavation guidance would have to rely on collection and laboratory analyses of samples. In order to minimize the potential impacts on the excavation schedule, it is assumed that an on-site laboratory would be set up and operated to provide quick analyses of samples to guide excavation activities and initial confirmation that all RIM had been removed. A percentage of such samples would also be sent to an off-site laboratory for verification of the on-site laboratory results. Samples obtained for final confirmation that RIM has been removed from a particular area would also be subjected to off-site laboratory analyses and data validation. All of these activities would undoubtedly impact the rate of RIM excavation and the duration over which excavation areas need to remain open.

Daily soil cover and tarps would need to be placed over open excavation areas and stockpiled overburden to minimize dust, odor, and the attraction of birds and other wildlife. The proximity of Areas 1 and 2 to Lambert-St. Louis International Airport poses a potential risk to aviation operations. The St. Louis Airport Authority and the U.S. Department of Agriculture have identified as a problem the potential for increased bird activity in conjunction with waste excavation at the Site and the resultant increased risk of aviation bird strikes. Bird nuisance mitigation measures such as best management practices (including, but not limited to, daily soil cover and tarps over exposed overburden and wastes), visual and auditory frightening devices, and wire or monofilament grids strung over exposed refuse to prevent bird access, could be evaluated for use at Areas 1 and 2. The size of open excavations may limit the constructability of wire or monofilament grids. Careful evaluation of material properties would be necessary during remedial design to assure that the appropriate strength and elasticity of materials are considered, that the materials are available, and that grids can be reasonably constructed.

Effective stormwater controls could be readily implemented using conventional construction equipment and materials. Temporary berms to direct stormwater away from open excavations would need to be constructed and precipitation accumulation in depressions created by the excavation activities would need to be pumped out and managed. Direct precipitation or runoff that may contact waste material could become contaminated with soils or wastes containing thorium or radium. These elements would be entrained in colloidal material that would readily settle in low areas or in the tanks used to collect and store stormwater prior to treatment and discharge. At the end of excavation activities, after all RIM above cleanup levels would have been removed, accumulated sediment in any low areas or the tanks would also be removed and, depending upon activity levels, either placed in Area 1 or 2 or transported to the off-site disposal facility.

Excavated RIM exposed to precipitation would be subject to the PFLT as necessary to determine if free liquids exist prior to being loaded for off-site disposal. If the excavated material to be hauled off-site does not pass the PFLT, a dewatering area would need to be staged and collected water treated and/or disposed, potentially through off-site disposal. The current costs and schedules do not address any dewatering activities. Should such activities be necessary, a suitable area would have to be identified within the Site.

Truck hauling of IM containers of RIM to a truck-to-rail transloading facility and transferring the RIM to railcars is technically implementable. Loading RIM directly into railcars on-site if a rail spur could be extended onto the West Lake Landfill Site is theoretically implementable; however, it is not known whether extension of a spur onto the property is actually feasible. If construction of an on-site rail spur were to be considered, an engineering study and development of a detailed design would be necessary to determine the feasibility and implementability. As discussed in detail in Sections 6.2.3.6.5 and 6.2.3.6.6 above, construction of an on-site rail spur would also require coordination with a number of local and state regulatory authorities as well as private landowners.

An initial comparison of the US Ecology Grand View facility WAC to estimated activity levels in the OU-1 RIM under the 1,000 Partial Excavation Alternative is presented on Table 6-4. Although a representative of the turnkey contractor would be on-site during RIM excavation to coordinate loading of containers, there is a potential that one or more shipping containers could contain activity levels that exceed the WAC and may have to be unloaded and re-distributed prior to shipment or, in the worst case, returned to the Site by the disposal facility and/or sent to a different disposal facility. These additional activities could result in additional worker exposures, additional time to complete the project, and potentially additional costs.

Regrading the landfill surface and placement of final cover is implementable and has been performed at other landfills, including CERCLA sites. Environmental monitoring is routinely performed at most sites and is not expected to present any feasibility challenges.

6.2.5.6.2 Reliability of the Technology

Excavation and off-site disposal of radioactively-impacted material has been performed at FUSRAP facilities and is generally a reliable technology. It should be noted, however, that none of these FUSRAP sites involved radiological materials commingled with municipal solid waste and disposed in a landfill setting. The reliability associated with disposal in an off-site facility would be dependent on the integrity of the liner and cover systems at the off-site facility being maintained, as well as the effectiveness of the various off-site facility monitoring programs.

Landfill cover systems such as those that would be implemented over Areas 1 and 2 after partial removal of RIM, and which are designed and constructed consistent with State and Federal regulations and with post-closure care implemented in accordance with current regulatory guidance, have been demonstrated to be reliable at: (1) minimizing percolation and infiltration of precipitation; (2) minimizing leachate generation; (3) minimizing impacts to groundwater quality; (4) minimizing impacts to surface water quality and quantity; (5) minimizing erosion of cover material; and (6) minimizing uncontrolled releases of landfill gas. Landfill cover systems have been demonstrated to be reliable methods for isolating waste materials. Similarly, access restriction measures have been demonstrated to be reliable mechanisms to prevent unauthorized access to a site.

Bird nuisance mitigation measures such as best management practices (including, but not limited to daily soil cover and tarps over exposed RIM and waste), visual and auditory frightening devices, and wire or monofilament grids strung over exposed refuse to prevent bird access, are demonstrated reliable technologies under proper operating and excavating conditions. While visual or auditory frightening devices can be effective in the short-term, birds tend to habituate to deterrents over time, causing the deterrent to lose effectiveness. Frequent relocation of predator birds and predator effigies and/or altering the timing of auditory activation may help, but long-term effectiveness in not assured. In addition, the FAA has stated that "[t]o date, no . . . [putrescible waste] facility has been able to demonstrate an ability to reduce and sustain hazardous wildlife [birds] to levels that existed before the putrescible-waste landfill operations began operating." (FAA, 2007).

Stormwater controls are well-established technologies that are implemented at most landfill sites. For this alternative, gravity settling of suspended solids potentially containing radionuclides is a well-established and reliable technology.

6.2.5.6.3 Ease of Undertaking Additional Remedial Actions, if Necessary

Because all of the RIM would not be removed during implementation of this partial excavation alternative, it is possible that EPA could later require removal of additional RIM. If such a decision were to occur after construction completion of this alternative, performance of any such additional remedial action in the future would be very difficult and costly. Such actions would require removal of the newly constructed engineered landfill cover and re-excavation of materials previously removed and replaced as part of this partial excavation alternative.

The only other potential additional remedial actions that may need to be taken for the 1,000 Partial Excavation Alternative would be maintenance activities to sustain the cover system, repair areas of differential settlement or erosion, or possible implementation of a contingent landfill gas control system. Regrading and contouring the existing waste materials to achieve final grades would require re-compaction of the regraded waste materials in order to minimize the potential for compaction or differential settlement over time that could affect the integrity of the landfill cover. Placement of additional fill material to achieve the final slope requirements and for construction of the landfill cover may result in differential compaction of the waste materials dependent upon the nature, age and amount of prior degradation of the waste materials. Runoff of stormwater can result in formation of erosional rills. Depressions caused by differential settlement of the wastes or erosional features can easily be (and commonly are) addressed at landfill sites through placement of additional soil material to fill such features.

In the event that monitoring of subsurface landfill gas and radon detects the presence of gas levels above regulatory thresholds along the perimeter of the landfill, a landfill gas control system could be implemented as an additional remedial action. Implementation of a contingent landfill gas control system would entail drilling and installation of gas extraction wells, installation of conveyance piping, installation and operation of landfill gas extraction blowers and a landfill gas treatment (flare) system, and/or possible use of a carbon adsorption system to remove radon from the extracted gas stream. Installation of a contingent gas system can easily be performed as a future action. Any disruption to the final landfill cover resulting from the installation of a contingent gas extraction system would need to be repaired. Such activities are commonly and routinely undertaken at solid waste disposal sites.

Long-term monitoring and maintenance of the landfill covers at other Superfund sites and at non-Superfund site solid waste landfills is typically required to assess whether differential settlement or surface erosion of the cover has occurred over time. Long-term maintenance, including cover inspection and repair, would be part of this alternative. Cover repair, if necessary, would be straightforward, primarily entailing placement of additional fill, regrading, and revegetation of the repaired area.

Bird nuisance mitigation measures such as best management practices (including, but not limited to, selective excavation, daily soil cover, and tarps), visual and auditory frightening devices, and wire or monofilament grids strung over exposed refuse to prevent bird access, are demonstrated to be readily implementable at landfill sites.

Storm water management measures other than those using conventional earth-moving equipment, piping, pumps, liners, filtration and carbon adsorption water treatment equipment, rip-rap, and pond outlet structures are not anticipated.

6.2.5.6.4 Ability to Monitor Effectiveness of Remedy

Demonstrating the effectiveness of the cover systems constructed over Areas 1 and 2 after partial excavation of RIM would be accomplished by implementing monitoring programs for the cover surface, landfill gas system, groundwater and surface water programs as previously described in Section 5.4.4. These types of monitoring programs are easily implemented and have been proven to be successful at demonstrating cover effectiveness in landfill settings.

6.2.5.6.5 Ability to Obtain Approvals from Other Agencies

Implementation of the 1,000 Partial Excavation Alternative would require approvals from other agencies, including the following:

- Approval from the FAA to conduct waste excavation activities within 10,000 feet of an active airport runway. FAA Advisory Circular AC 150/5200-33B, dated August 28, 2007, "Hazardous Wildlife Attractants On or Near Airports," recommends "against locating a MSWLF [municipal solid waste landfill] within the separation distances identified in Sections 1-2 through 1-4. The separation distances should be measured from the closest point of the airport's AOA [airport operations area] to the closest planned MSWLF cell." AC 150/5200-33B, p. 4. The separation distances referenced are 5,000 feet from the end of a runway for airports serving piston-powered (propeller) aircraft; 10,000 feet for airports serving turbine-powered (jet) aircraft; and 5 miles of protection from hazardous wildlife movement for approach, departure and circling airspace. The FAA strongly recommends against allowing a waste disposal operation within 10,000 feet of a jet aircraft runway if the material contains putrescible waste and so has the potential to attract wildlife that could threaten air traffic. The excavation of RIM material containing putrescible waste within 10,000 feet of the westernmost runway (11/29, formerly known as 12W/30W) at Lambert-St. Louis International Airport, as would occur during excavation of the RIM in Areas 1 and 2, is limited by the need to mitigate potential bird activity during excavation to address the requirements of the FAA Advisory Circular and to comply with the same prohibitions in the Missouri solid waste regulations. It may be necessary to work directly with the FAA and MDNR to identify specific bird mitigation measures during implementation.

- Approval of St. Louis Airport Authority with regard to obtaining a release for the Negative Easement and Declaration of Restrictive Covenants Agreement. Excavation of RIM from Areas 1 and 2 poses a potential to increase the bird populations at the Site if mitigation procedures are not employed or prove ineffective. An increase in bird populations presents a greater potential for aircraft bird strikes. It may be necessary to work directly with the FAA and the Airport Authority to address these concerns, either by amending the FAA ROD, amending the Negative Easement, requiring specific bird mitigation measures during implementation, or making other changes to secure STLAA's cooperation.

- Location of an off-site truck-to-rail loading facility. At the discussion held in September 2010, the STLAA indicated that they would not allow the use of the existing SLAPS truck-to-rail transloading facility for loading waste from the West Lake Landfill into railcars. The SLAPS rail spur is reportedly owned by the U.S. Army Corps of Engineers and the land upon which the rail spur is built is owned by the City of St. Louis. It is not clear that the STLAA could prevent use of the SLAPS rail spur for loading and shipping via contractual means; however, as the STLAA is the owner of the property, their concurrence must be considered. No other nearby off-site truck-to-rail loading facilities have been identified.

- Compliance with EPA's Off-Site Rule. The EPA Region where the off-site disposal facility is located would need to be contacted every 60 days during the period of off-site waste shipments to obtain a compliance determination as to whether the disposal facility currently meets the criteria under the OSR to accept CERCLA waste. If during RIM excavation the contracted off-site disposal facility were to be out of compliance for a period of time, excavation and transportation would need to cease until the facility becomes compliant or RIM would need to be transported to another facility that is determined to be in compliance with the OSR. Besides schedule delays, temporary stoppage of construction would present significant technical implementability concerns regarding open excavation areas.

- Rocky Mountain Low Level Radioactive Waste Compact Consent. If RIM were to be disposed at the Clean Harbors Deer Trail, CO facility, an application would have to be submitted to and accepted by the Rocky Mountain Low Level Radioactive Waste Compact. Disposal at the US Ecology Grand View, ID, US Ecology Wayne, MI, and Energy*Solutions* Clive, UT facilities would not be subject to a Waste Compact consent.

6.2.5.6.6 Coordination with Other Agencies

Although not all would be considered "agencies," coordination with many entities would be necessary to implement the 1,000 Partial Excavation Alternative. Coordination with the landfill owner and operator and owners or occupants of the various parcels that comprise the West Lake Landfill Site would be necessary because of the following:

- Termination of the asphalt company lease and removal of the asphalt plant followed by relocation of the Bridgeton solid waste transfer facility and construction of an overpass between Areas 1 and 2 over the Site access road would need to occur prior to the start of RIM excavation;

- Access to operations conducted on other portions the Site would need to be maintained.

- Areas 1 and 2 are within a larger existing landfill footprint and use of areas on the West Lake Landfill Site outside of Areas 1 and 2 might be necessary to stockpile cover materials or otherwise to facilitate cover construction.

- Implementation of this alternative would require excavation of portions of landfill units located outside of OU-1. Upon completion of removal of the RIM, disturbed portions of the adjacent landfill units would need to be repaired and restored, and regrading and installation of a replacement landfill cover over areas outside of OU-1 would need to be performed. Coordination would also be required relative to integration of the slopes and grading for adjacent landfill areas and routing and design of stormwater diversion and conveyance structures between OU-1 and other landfill areas.

- Use of other areas of the West Lake Landfill Site that may be necessary for stockpiling of overburden and staging or routing of trucks or rail cars used to haul the excavated RIM off-site.

For the duration of excavation, off-site transport, and import of cover materials, the flow of vehicles associated with remedy construction would need to be coordinated with the traffic patterns of vehicles associated with the current on-site solid waste transfer station and other Site tenants.

If a truck-to-rail transloading facility at an off-site rail spur location were to be used, a suitable location would need to be identified and a lease secured with the land/rail spur owner for the duration of the RIM loading and transport operations. As noted above, it does not appear that the existing SLAPS truck-to-rail transloading facility would be available, so costs for establishing a new facility would need to be considered[53].

If a rail spur were to be extended onto the West Lake Landfill Site:

- Land located across St. Charles Rock Road would either need to be purchased or long-term leases would be needed with landowners;

- State and local government, private landowner, facility occupant and community approval to construct a rail spur across private property located to the east of St. Charles Rock Road, across St. Charles Rock Road, and along the access roads which serve the existing solid waste transfer station and asphalt plant operations located at the Site would need to be obtained;

- Appropriate safety measures for the crossing at St. Charles Rock Road would have to be installed, consistent with requirements of state and local governments;

- The long-term lease of the asphalt plant for land south of the solid waste transfer station, would need to be bought out or otherwise acquired; and

- Because of the high traffic volume on St. Charles Rock Road during the day, dropping off empty and picking up loaded railcars would likely be possible only during late nighttime and early morning hours.

Provision of and switching of gondola railcars either at a truck-to-rail transloading facility spur or an on-site rail spur would need to be coordinated with the railroad company that would be hauling the railcars to the off-site disposal facility.

Future groundwater monitoring activities could require obtaining and maintaining access to off-site properties if off-site groundwater monitoring were required as part of the remedy.

The potential for increased bird strikes to aircraft approaching and departing the Lambert-St. Louis International Airport is a major concern of the FAA and St. Louis Airport Authority. The effectiveness of proposed bird nuisance mitigation measures would be of interest to the FAA and Airport Authority. Consequently, the FAA and Airport Authority would need to be involved in the remedial planning process.

Coordination with other agencies including the Earth City Flood Control District, MSD and MDOT, as well as the adjacent property owners and businesses (for example, the Crossroads Property/AAA Trailer) would also be necessary to:

[53] The unit cost estimates provided by US Ecology for purposes of this FFS include costs to secure an off-site rail spur for a truck-to-rail transloading facility.

- Coordinate with the Earth City Flood Control District regarding the design of non-contact stormwater management and discharge facilities both during and after completion of construction;

- Coordinate with MSD regarding permitting and design of leachate/contact stormwater discharge during construction;

- Coordinate with MDOT for access to areas along St. Charles Rock Road and for any traffic control or ingress and egress additions along St. Charles Rock Road in the vicinity of the Site entrance; and

- Obtain legal and physical access from AAA Trailer for testing and, if necessary, remediation of the Crossroads Property and possibly for implementation of remedial actions that may need to be performed along the property boundary (e.g., regrading, fencing, etc. in Area 2).

As discussed at the beginning of this section (6.2.3.6), in order to access RIM in Area 1, the Bridgeton Transfer Station would need to be relocated. The only suitable area for relocation of the solid waste transfer station is the area currently under lease and occupied by Simpson Asphalt Company. The asphalt company lease would need to be bought out and their equipment removed from the Site before the transfer station could be relocated. Relocation of the transfer station would normally be subject to permitting by the City of Bridgeton and St. Louis County; however, because relocation of the transfer station would be performed as part of a Superfund remedial action and the transfer station would remain on-site, additional permitting is not anticipated to be required. However, it is likely that public meetings and hearings may be necessary, which would require coordination with the City of Bridgeton and St. Louis County and could impact the timing for the start of construction of a 1,000 Partial Excavation Alternative.

6.2.5.6.7 Availability of Off-site Treatment, Storage and Disposal Services and Capacity

As discussed in Section 4.3.5.4., four off-site disposal facilities that could accept excavated RIM from the West Lake Landfill OU-1 have been identified. At least three of these facilities (located in Idaho, Utah and Colorado) have accepted radiologically-impacted soil from projects or sites in the United States, although none of them have previously accepted radiologically-impacted materials mixed with solid waste. All four of the identified facilities have available capacity to accept the estimated volume of RIM from the Site. The volumetric rate of acceptance for all facilities would be limited by the number of IM containers and railcars that could be provided and loaded at or near the Site, as well as the number that could be unloaded at or near the disposal facility. Off-site treatment, storage and disposal may be required in the event that hazardous wastes or regulated asbestos-containing materials (RACM) are encountered in the overburden or RIM excavated from Areas 1 and 2.

The identified facilities are also permitted to: (1) accept liquid wastes, should any stormwater that may accumulate in excavations during RIM excavation become contaminated and require disposal off-site; (2) accept mixed wastes if mixed wastes are encountered during excavation; and (3) treat soil and/or debris that contains hazardous waste or mixed waste.

As discussed in Section 3.2.1, the CERCLA OSR requires that waste materials removed from a CERCLA site only be placed in a facility operating in compliance with RCRA or other applicable Federal or State requirements. EPA makes such determinations every 60 days. The compliance status of an off-site disposal facility would need to be evaluated during remedial design and would need to be regularly evaluated and updated during remedy implementation.

Offsite treatment and discharge of any leachate that may be encountered or stormwater that may contact waste materials during the landfill re-contouring activities could also be required. Off-site treatment and discharge of any leachate that may be encountered or stormwater that may contact RIM during the landfill excavation activities could also be required. Initial discussions with MSD indicated that they are willing to accept leachate and contact stormwater and initial discussions with the Earth City Flood Control District indicated a willingness to accept stormwater, subject to installation of additional stormwater detention/retention capacity.

6.2.5.6.8 Availability of Necessary Equipment and Specialists

Materials, equipment and personnel required for excavation and transport of RIM to an off-site disposal facility are readily available. Trained health physics technicians and specialized equipment required to monitor personnel and environmental conditions, as well as to assist in directing the RIM excavation sequencing, are also available.

As discussed above, there are a limited number of disposal facilities that can accept these types of wastes, and most of these have stringent waste acceptance criteria which may limit the ability of some of the facilities to receive the wastes.

Availability of rail service, particularly the number of rail cars that can be made available and switched daily by the railroad, would also affect the production rate of RIM excavation and disposal and therefore the cost.

All of the materials, equipment and personnel to remove the designated portion of the RIM and to construct the engineered landfill cover over Areas 1 and 2 are readily available, and the technologies have been generally proven through application at other landfills. The implementability and potential cost of the covers would be influenced by the availability and location of clean cover materials and/or off-site borrow sources at the time this alternative would be implemented. Potential vendors of rock, clay and soil were contacted during the development of the FS (EMSI, 2006) and during preparation of the Remedial Design Work Plan for the ROD-selected remedy (EMSI, 2008). Information obtained from the vendors at these times indicated that rock, clay and clean cover material were readily available from sources located near the Site. If these local sources of cover materials become exhausted prior to and during remedy implementation, cover materials would have to be obtained from suppliers at greater distances from the Site.

The necessary materials, equipment and personnel required for assessment and removal of RIM that may be present at the Buffer Zone/Crossroads Property above unrestricted use levels and to implement the institutional controls and monitoring components of this alternative are also readily available.

6.2.5.6.9 Availability of Prospective Technologies

The 1,000 Partial Excavation Alternative is based on proven, established, and commonly used technologies. Use of prospective technologies is not currently envisioned to be part of this alternative.

6.2.5.7 Cost

Estimated capital, annual OM&M, and 30-year present worth costs for the 1,000 Partial Excavation Alternative are included in Appendix K-6 and summarized on Table 6-1. Conceptual excavation, backfill, and bottom and top of final cover grading plans as well as stormwater control features used as the basis for the 1,000 Partial Excavation Alternative capital cost estimate are provided in Appendix M. The estimated cost to conduct the 1,000 Partial Excavation Alternative (i.e., design costs, capital costs, and costs for monitoring during the construction period) is $361,000,000 based in part on unit costs provided by US Ecology. These costs do not include costs to conduct full-scale pilot-testing of solids separation equipment. The estimated annual OM&M costs range from $167,000 to $326,000 per year depending upon the specific activities that occur each year (e.g., higher costs for years with additional environmental monitoring and years when landfill cover repairs and five year reviews may occur). The cost estimates provided in this FFS are feasibility-level cost estimates which were developed to a level of accuracy such that the actual costs incurred to implement this alternative are expected to fall within a range bounded by 50% above and 30% below these estimates.

The present-worth costs of a 1,000 Partial Excavation Alternative are projected to be $275 million over a 30-year period based on a discount rate of 7%. Based on the current OMB rate of 1.5%, the present worth costs would be $342 million. The total non-discounted costs for the 1,000 Partial Excavation Alternative over 30 years are projected to be $365 million.

Given the long life of the radionuclides present at OU-1, the costs for the 1,000 Partial Excavation Alternative were also evaluated for 200 and 1,000 year periods (without consideration of any constraints on annual expenditures). The total non-discounted costs of the 1,000 Partial Excavation Alternative are projected to be $395 million over a 200-year period. The total present-worth costs of the 1,000 Partial Excavation Alternative are projected to be $276 million based on a 7% discount rate or $349 million based on a 1.5% discount rate, respectively, over a 200-year period. The total non-discounted costs of the 1,000 Partial Excavation Alternative are projected to be $534 million over a 1,000-year period. The present-worth costs over a 1,000-year period are projected to be $276 million based on a 7% discount rate or $350 million based on a 1.5% discount rate.

Unit costs associated with transportation by rail and disposal of RCRA soil, RCRA soil with radionuclide material, RCRA debris, and RCRA debris with radionuclide material would have added treatment costs in order to meet the LDRs and UTS. Based on discussions with representatives of the disposal facilities during preparation of the SFS (EMSI et al., 2011), the additional costs for treatment at their facilities are estimated to range from $45 to $150 per ton for RCRA metals or $400 to $500 per ton for organics, depending on the type of treatment.

Since the amount of mixed waste that might be excavated along with the RIM is unknown, and because of the RCRA restrictions on waste accumulation amounts and timeframes and limited storage space on-site, it is unclear if volumes would support shipment by rail. As such, the mixed waste would likely be shipped to the off-site disposal facility directly via truck. For truck hauling to the off-site disposal facility, the interior of the semi-trailer would be lined with a disposable polyethylene slip liner and after the waste was loaded the trailer would be covered and the cover securely strapped down. The capacity of each truckload would be 22 tons or 17 cubic yards, depending on the weight of the material. Current trucking costs range from $4.70 to $5.10 per loaded mile. Road mileage from the West Lake Landfill to the US Ecology Wayne Disposal, MI, Clean Harbors Deer Trail, Colorado; Energy Solutions Clive, Utah; and US Ecology Grandview, Idaho facilities are 520, 720, 1,340, and 1,580 miles, respectively. Therefore, RCRA or mixed-waste truck transportation costs to an off-site facility could range from $145 to $470 per cubic yard or $110 to $370 per ton, depending on where the material is ultimately disposed.

For purposes of demonstrating how much shipping of mixed waste could influence costs, it was assumed that mixed waste would represent 0.5% of the sum of the volumes of overburden wastes and RIM for the 1,000 Partial Excavation Alternative. The added costs for handling, sampling/analysis, shipping, treating, and disposing of mixed waste for this alternative are estimated to range from $1.6 to $3 million. The range of costs primarily results from variations in the fees charged by the off-site disposal facilities and uncertainties associated with the nature of such wastes and the required method of treatment. If the volume of mixed waste is higher than the 0.5% of total mass assumption, the added costs would be higher.

7 COMPARATIVE ANALYSIS OF ALTERNATIVES

This section presents a comparative analysis of the No Action alternative, the ROD-selected remedy, the "complete rad removal," and the partial excavation alternatives evaluated in Section 6. The relative performance of each alternative, including advantages and disadvantages, is compared to the performance of the other alternatives for each of the threshold (subsection 7.1) and primary balancing (subsection 7.2) criteria prescribed in the NCP, as previously discussed in Section 6 and summarized below.

Threshold Criteria:

- Overall Protection of Human Health and the Environment
- Compliance with ARARs

Primary Balancing Criteria:

- Long-Term Effectiveness and Permanence
- Reduction of Toxicity, Mobility, or Volume through Treatment
- Short-Term Effectiveness
- Implementability
- Cost

As discussed in Section 6, the NCP "modifying criteria" (state acceptance and community acceptance) will be evaluated by EPA as part of any decision process that may be undertaken by EPA after completion of the FFS. Therefore, a comparison of alternatives using the modifying criteria is beyond the scope of this FFS, and is not undertaken here.

The comparative analysis identifies the general similarities and differences between the alternatives, the relative advantages and disadvantages of each alternative, and trade-offs among the alternatives in terms of the NCP criteria. The purpose of the comparative analysis is to provide information for a balanced remedy selection. The results of this comparative analysis are discussed below and summarized on Table 7-1.

7.1 Threshold Criteria

Two of the nine criteria specified in the NCP relate directly to statutory findings that must ultimately be made in the ROD. These two criteria are (1) overall protection of human health and the environment, and (2) compliance with ARARs. They are classified as threshold criteria, as each alternative must meet both of these two criteria.

7.1.1 Overall Protection of Human Health and the Environment

This criterion addresses how risks would be eliminated, reduced, or controlled by each remedial alternative to provide short- and long-term protection of human health and the environment from unacceptable risks posed by contaminants present at the Site.

Based on the results of the updated BRA evaluations (Auxier, 2016a), conditions associated with OU-1 do not currently pose an unacceptable risk to on-site workers or the off-site community as long as the existing institutional controls are maintained, monitored and enforced and Areas 1 and 2 are monitored and maintained. These analyses indicated that the potential risks posed to a future groundskeeper working in Areas 1 and 2 could be above the generally accepted risk range used by EPA. Therefore, the No Action alternative would not be adequately protective of human health. The potential for future leaching to groundwater or erosion and transport of waste or radionuclides by stormwater indicates that the No Action alternative would not be protective of the environment.

All of the other alternatives are expected to be protective of human health and the environment through the use of engineered containment, long-term surveillance and maintenance, and institutional controls on land and resource use. Installation of a new multi-layer landfill cover under the ROD-selected remedy and two partial excavation alternatives, and excavation of RIM under the "complete rad removal" and partial excavation alternatives, would all serve to reduce potential risks from exposure to external gamma radiation or radon gas emissions from the RIM in Areas 1 and 2. Installation of a new multi-layer landfill cover over Areas 1 and 2 is included as part of all of the remedial alternatives. This cover would eliminate potential risks associated with inhalation or ingestion of contaminated soils or wastes, dermal contact with contaminated soils or wastes, and wind dispersal of fugitive dust. Installation of a cover over Areas 1 and 2 also would greatly reduce the potential for infiltration of precipitation and thus the potential for leaching of contaminants from wastes into groundwater.

Long-term maintenance of the cover under each remedial alternative, as well as monitoring of the groundwater and subsurface occurrences of landfill gas and radon, would ensure that each remedial action functions as intended and remains protective. The institutional controls included as part of each remedial alternative would ensure that land and resource uses are consistent with permanent waste disposal. These use restrictions address the presence of radionuclides and chemical constituents within the waste mass under the ROD-selected remedy and partial excavation alternatives, as well as the presence of chemical constituents under the "complete rad removal" alternative.

7.1.2 Compliance with ARARs

An alternative must comply with ARARs in order to be selected as a remedy, unless a waiver is obtained for any particular ARAR. ARARs that may be potentially applicable or relevant and appropriate to the remedial alternatives are summarized on Tables 3-1, 3-2, and 3-3.

7.1.2.1 Chemical-Specific ARARs

As discussed in Section 6.2.1.2, the No Action alternative is expected to meet some but not all of the potentially applicable chemical-specific ARARs. All of the other remedial alternatives will meet the chemical-specific ARARs. These include the UMTRCA and NESHAP standards for radon emissions; the UMTRCA standards for cleanup of contaminated land (Buffer Zone and Crossroad Property), as modified by the EPA OSWER Directives regarding use of these standards at Superfund sites; Nuclear Regulatory Commission (NRC) radiation protection standards; the maximum concentrations for groundwater protection under the UMTRCA standards; and the Missouri maximum contaminant levels (MCLs).

7.1.2.2 Location-Specific ARARs

All of the alternatives (including the No Action alternative) would meet the location-specific ARARs found in the Missouri solid waste regulations standards for landfills located within the 100-year floodplain or within 10,000 feet of an airport runway. As discussed in Section 2.1.6, evaluations of the floodplain by FEMA indicate that with the exception of the easternmost portions of Areas 1 and 2 (which do not contain waste materials), Areas 1 and 2 are located outside of the 500-year floodplain.

The Missouri Solid Waste Management regulations require owners or operators of sanitary landfills located within 10,000 feet of an airport runway end used by turbojet aircraft to demonstrate to MDNR that the landfill is designed and operated such that it does not pose a bird hazard to aircraft. Portions of the Site are located within 10,000 feet of the end of the westernmost runway at Lambert-St. Louis International Airport; however, none of the alternatives evaluated in this FFS entail construction of new disposal cells or new solid waste disposal activities. Waste excavation under the complete and partial excavation alternatives and waste regrading activities under all of the remedial alternatives (except for No Action Alternative) would need to be performed in a manner that minimizes attractions for birds. Specifically, an avian management plan that incorporates the various techniques described in Section 4.3.6.2 of this FFS would need to be developed and approved by EPA and MDNR. Such a plan would also be of interest to the FAA and the Airport Authority. The FAA has stated, "[t]o date, no [landfill] facility has been able to demonstrate an ability to reduce and sustain hazardous wildlife to levels that existed before the putrescible-waste landfill began operating." (FAA Advisory Circular 150/5200-33B at page 16, August 2007).

7.1.2.3 Action-Specific ARARs

Because there are no active engineering measures or waste handling, treatment, or disposal activities associated with the No Action alternative, there are no action-specific ARARs for the No Action alternative. All of the other remedial alternatives would meet the requirements of the action-specific ARARs. In particular, all of the remedial alternatives would meet the Missouri closure and post-closure standards of the solid waste regulations, the NRC radiation protection standards, and the noise protection standards during implementation of a remedial action and closure of Areas 1 and 2.

Design of the final cover for Areas 1 and 2 under the ROD-selected remedy and the partial excavation alternatives would meet the design standards for landfill covers established by the Missouri solid waste management regulations and the substantive relevant and appropriate requirements of the UMTRCA regulations. Although design of the final cover for these alternatives would primarily be based on the design standards of the solid waste regulations, additional components would be included to address the presence of radionuclides and the requirements of the UMTRCA regulations. Specifically, the design of the final cover would need to be thick enough to shield against gamma radiation and attenuate radon emissions under both current and future conditions (including projected ingrowth of radium from thorium decay over time). A rock layer within the landfill cover would be included to address the longevity criteria of the UMTRCA standards. Under the “complete rad removal” alternative, all of the material containing radium and/or thorium levels above those that would allow for unrestricted use is assumed to have been removed; therefore, the design of the final cover system for this alternative is based solely on the design standards of the solid waste regulations.

The off-site disposal component of the partial excavation and the “complete rad removal” alternatives would also need to be designed and implemented to meet the requirements of the CERCLA Off-Site Rule, DOT and NRC requirements for transport of radioactive materials/wastes, and the waste acceptance criteria (WAC) of any off-site disposal facility.

7.2 Primary Balancing Criteria

The five NCP primary balancing criteria are: (1) long-term effectiveness and permanence; (2) reduction of toxicity, mobility and volume through treatment; (3) short-term effectiveness; (4) implementability; and (5) cost. Primary balancing criteria are used to weigh effectiveness and cost tradeoffs among alternatives. The primary balancing criteria represent the main technical criteria upon which the alternatives evaluation is based, and provide the primary basis for differentiation among the various alternatives.

Since the No Action Alternative does not meet the threshold criteria it is not included in the evaluation of the primary balancing criteria. Therefore, the discussion of the primary balancing criteria only considers the other four alternatives (*i.e.*, ROD-selected remedy, “complete rad removal’”, and the 52.9 and 1,000 partial excavation alternatives).

7.2.1 Long-Term Effectiveness and Permanence

This criterion addresses the risks that may remain at a site after the remedial action objectives have been met. The primary focus of this evaluation is the extent and effectiveness of the controls that may be required to manage the risk posed by the wastes that remain at the site.

Although conditions associated with OU-1 currently do not pose an unacceptable risk to on-site workers or the off-site community, the BRA analyses indicated that the potential risks posed to a future groundskeeper working in Areas 1 and 2 could pose a risk above the generally accepted risk range used by EPA in CERCLA actions (Auxier, 2016a) if no remedial action is taken at the Site. None of the remedial alternatives pose significant radiological or chemical exposure-related risks to on-site workers or the general public. The long-term risks associated with each of the alternatives are essentially the same, and the residual cancer risks posed to a potential future groundskeeper at the Site under all four remedial alternatives are below EPA's target risk range of 1×10^{-6} to 1×10^{-4}. Projected radiation doses after 1,000 years of radium ingrowth for all four remedial alternatives are far below the limit of 100 mrem per year established by NRC for the general public. The estimated long-term risks associated with each alternative are listed on Table 7-1. Detailed information regarding the estimated potential long-term risks and estimated radiation doses relative to a future on-site groundskeeper associated with each remedial alternative is provided as part of the assessment of risks included as Appendix H.

All of the remedial alternatives result in some amount of waste materials remaining on-site, thereby necessitating installation, maintenance and monitoring of engineered containment structures and institutional controls. Engineering measures are the primary method that would be used to control waste materials that remain on-site. The primary engineering measures included in the ROD-selected remedy and the partial excavation alternatives are the construction, inspection and maintenance of multilayer engineered landfill cover systems over Areas 1 and 2 that are designed to reduce potential exposures to gamma radiation and reduce radon emissions, including increased levels of gamma radiation and radon emissions occurring after 1,000 years of radioactive decay of thorium. The "complete rad removal" and partial excavation alternatives include excavation and off-site disposal of at least a portion of the RIM. In addition, the partial excavation alternatives include construction, inspection and maintenance of multilayer engineered landfill cover systems over Areas 1 and 2 designed to reduce potential exposures to gamma radiation and reduce radon emissions, including increased levels of gamma radiation and radon emissions occurring after 1,000 years of radioactive decay. The "complete rad removal" alternative entails removal and off-site disposal of all RIM containing radionuclides at levels above those that would allow for unrestricted use. Therefore, this alternative would not need to address potential gamma exposures or radon emissions and would not include the rock/rubble layer that would be part of the landfill cover system included under the ROD-selected remedy and the partial excavation alternatives.

Although the RIM and other wastes have been present in Areas 1 and 2 for many decades without grading to promote runoff or an engineered landfill cover to minimize infiltration and leachate production, the USGS (2014) concluded that that there is not a strong spatial association of monitoring wells surrounding or downgradient of RIM areas with elevated radium concentrations, as might be expected if RIM areas were releasing substantial quantities of radium to the groundwater. EPA has indicated that additional evaluations of groundwater will be conducted in the future as part of the OU-3 RI/FS. All of the remedial alternatives rely on the construction, inspection and maintenance of multilayer covers to prevent or reduce the potential for infiltration of precipitation and resultant leaching to groundwater. The "complete rad removal" alternative (as well as the partial excavation alternatives) includes removal of at least some of the RIM from the Site, thus providing a corresponding additional level of effectiveness and permanence relative to potential leaching of radionuclides to groundwater.

The performance and effectiveness of the engineered measures for each of the remedial alternatives is primarily based on the durability of natural earthen materials used to construct these measures. Natural earthen materials such as clay and rock are extremely durable and, with minimal maintenance and repair over time, are expected to remain effective for decades or centuries. The design of the cover systems for the ROD-selected remedy and the partial excavation alternatives has been determined to be effective at limiting exposures to projected gamma radiation and radon levels after 1,000 years of radioactive decay using only the performance of those natural earthen components. The potential effects of erosion of the landfill cover by precipitation, disruption of the landfill cover by possible intrusion by woody vegetation, or potential human actions that could affect the cover system would necessitate regular and ongoing inspections and maintenance (O&M) to ensure that the cover system continues to remain effective over time.

The engineering measures implemented under each remedial alternative would be augmented and supported by maintenance of the existing institutional controls at the Site and implementation of additional institutional controls, as necessary. Institutional controls would limit future uses of the land and resources at the Site so as to eliminate or restrict potential exposure to the wastes or contaminated media and to reduce the potential for future land uses to impact or reduce the effectiveness of the engineered measures. Areas 1 and 2 currently are solid waste disposal units and would remain as such under all of the remedial alternatives. Institutional controls would be necessary to restrict future land uses that could interfere with the landfill closure at Areas 1 and 2 for all alternatives, regardless of the presence of RIM.

7.2.1.1 Climate Change Considerations

Potential effects of climate change were evaluated in Section 6 for each of the alternatives; pertinent considerations are briefly discussed below.

The vegetative layer included in the landfill covers for all of the alternatives could be vulnerable to increased occurrences of extreme temperatures, sustained changes in average temperatures, decreased precipitation, and an increase in drought occurrences. Increased temperatures or decreased precipitation/drought could affect the viability of the vegetation (*e.g.*, grasses) on the surface of the landfill cover. Any changes to the overall health and voracity of the vegetative cover would be readily identifiable by visual inspection. Therefore, although the vegetative cover may be vulnerable to potentially increased temperatures or drought conditions, the potential for impacts to the vegetative layer could be anticipated and readily identified in advance of any such occurrence.

The low permeability layer included as part of the landfill cover for all of the remedial alternatives could be damaged by periods of extended extreme temperatures or prolonged drought. Potential impacts could include drying out of the low-permeability materials (CCL or

GCL) with a resultant increase in permeability, which could lead to increased infiltration of precipitation. Such potential impacts are not considered to be significant because the landfill has existed for over 40 years with minimal cover material and essentially flat (no grade) surfaces with low spots that collect and pond water, thereby maximizing precipitation infiltration. Even with this increased potential for infiltration of precipitation through Areas 1 and 2, the USGS (2014) concluded that that there is not a strong spatial association of monitoring wells surrounding or downgradient of RIM areas with elevated radium concentrations, as might be expected if RIM areas were releasing substantial quantities of radium to the groundwater. However, EPA has indicated that additional evaluations of groundwater will be conducted in the future as part of the OU-3 RI/FS. Drying of the low-permeability layer could also result in an increase in radon emissions for all of the alternatives except for the “complete rad removal” alternative; however, even without significant cover material, the radon emissions from the surfaces of Areas 1 and 2 are far below the UMTRCA and NESHAP standards (see Section 2.3.1 of this FFS and Section 7.1.1.1 of the RI Addendum) and are projected to remain below these standards in the future (Appendix F). Therefore, even if drying of the low-permeability layer was to occur, the impacts to groundwater quality or radon emissions are not expected to be significant. More importantly, the vegetative layer would show significant signs of stress from increased temperatures/drought prior to the occurrence of any impacts to the underlying low-permeability layer, thereby providing advance notice of a potential impact to the CCL/GCL. Therefore, the potential for any impacts could be anticipated and readily identified in advance of any such occurrence and such impacts are not expected to result in release of contamination

Increased heavy precipitation events could result in erosion of the vegetation layer and, if left untended, could result in erosion of the underlying low-permeability layer. Any erosion of the landfill cover would be readily identifiable by visual inspection. Given the overall 5-foot thickness of the landfill cover and the inclusion of the 2-foot-thick rock layer in the base of the cover system for the ROD-selected remedy and the two partial excavation alternatives, stormwater erosion, even under the most severe storm events, is not anticipated to result in erosion down through the entire landfill cover. Since the landfill cover under the “complete rad removal” alternative would not include that 2-foot-thick rock layer in the base of the cover system, stormwater erosion under a severe storm event could potentially erode down through the entire landfill cover, resulting in temporary exposure of non-radiological waste materials.

Heavy precipitation events could also impact the integrity or performance of stormwater drainage conveyance structures, including erosion of drainage channels, damage to or bypassing of let-down and erosion control structures and features, or damage to stormwater detention structures. Heavy precipitation events could also temporarily restrict access to portions of the landfill cover, stormwater control structures, and environmental monitoring points, thereby causing delays in implementation of repairs (if any are needed). The vegetation layer and stormwater controls are therefore potentially vulnerable to impacts from heavy precipitation events; however, due to the overall thickness and design of the landfill cover, any potential impacts are not expect to result in exposure of the waste material or release of contamination. Further, any impacts that occur could be readily addressed as part of normal maintenance and repair of the landfill cover, including localized regrading, repair and replacement of cover material, and repair or implementation of stormwater controls in response to any damage that may occur.

None of the alternatives are expected to be impacted by flooding that may occur in the area of the Site. As previously discussed in Section 2.1.6, recent updates to the flood insurance rate map (FIRM) by FEMA indicate that, with the exception of the easternmost portions of Areas 1 and 2 (which do not contain waste materials), Areas 1 and 2 are located outside of the 500-year floodplain. In addition, the area to the north and west of Area 2 (*e.g.,* Crossroads Industrial Park and Earth City Industrial Park) that potentially could be subject to flooding by the Missouri River is protected by the engineered levee and stormwater and flood control systems installed to protect the Earth City Industrial Park. Further, the conceptual design for the ROD-selected remedy includes construction of a perimeter (starter) berm along the toe of the entire northern boundary of Area 2, which would result in placement of approximately 25 feet of rock and soil between any possible floodwaters and the landfilled waste. This perimeter berm may be further protected from flooding by placement of rip-rap along the base of the berm. Therefore, although increased occurrences of flooding in the area of the Site may be a potential impact of climate change, the ROD-selected remedy and the other alternatives are not expected to be vulnerable to flooding.

An evaluation of the potential impacts of a tornado was included as part of the evaluation of the long-term effectiveness of each of the alternatives in Section 6 and concluded that none of the alternatives are vulnerable to such impacts. Specifically, a tornado is not expected to damage the vegetative layer, and even if it did, such an impact is not considered to be significant because it could be easily identified and, due to the design and thickness of the engineered cover, would not result in exposure of the underlying waste or release of contamination. A tornado could damage or destroy above-ground infrastructure such as signage, fencing or environmental monitoring equipment; however, such impacts are not considered to be significant because they would be readily identified and easily repaired or replaced. Therefore, none of the alternatives are considered to be vulnerable to impacts from a tornado.

Although the remedial alternatives are not considered to be vulnerable to effects of climate change, implementation of adaptive measures (discussed in Section 6) could be considered during remedial design to minimize any potential impacts from future climate change. For example, consideration could be given to reducing the final grades of the landfill surface under the complete and partial excavation alternatives from 5% to 2% to reduce the potential for erosion of the cover soil.

7.2.1.2 Subsurface Heating Event and Thermal Isolation Barrier

At EPA's request, a qualitative evaluation of the conditions and processes known to be associated with subsurface heating events at landfills was previously completed by the Respondents (EMSI, 2014e). This evaluation reached the following conclusions:

- The RIM disposed of in West Lake Areas 1 and 2 would not become more or less radioactive in the presence of heat. Likewise, the RIM is not explosive and would not become explosive in the presence of heat.

- A subsurface heating event does not create conditions that could carry RIM particles or dust off the Site. The heat generated by such an event is not high enough to ignite non-RIM wastes or chemical compounds or to cause them to explode.

- An increase in subsurface temperatures may allow radon gas to more easily rise through the ground and reach the surface of the landfill than would otherwise occur, because heat would reduce the amount of moisture in the buried solid waste (trash), thereby increasing the amount of air between the soil particles and thus reducing the ability of the buried solid waste to retain radon below ground. Any radon gas that does make it to the surface would dissipate quickly in open air. This potential increase in the rate of release of radon gas at the surface of the landfill would be limited to the area of increased temperature and would quickly reach an equilibrium at a lower rate reflective of the rate of radon emanation.

- In the unlikely event that an increased subsurface temperature were to occur in West Lake Area 1 or 2, it would not result in any additional long-term risks to people or the environment.

- Any short-term risks associated with increased subsurface temperatures would result from the temporary increase in radon gas coming from the surface of Areas 1 and 2 if no cover is installed, or if the cover was not properly maintained.

- These short-term risks can be addressed by designing, constructing, and maintaining the landfill cover required under all of the remedial alternatives and by the Missouri landfill closure regulations, and by maintaining the land use restrictions already in place on the entire Site that prevent certain land uses.

Based on the foregoing conclusions, the only potential impact that may occur as a result of a subsurface heating event would be a temporary, localized increase in radon emissions. Because it is expected that all of the RIM above unrestricted levels would be removed under the "complete rad removal" alternative, any potential short-term increase in radon emissions as a result of a heating event would only be associated with the two partial excavation alternatives and the ROD-selected remedy.

Quantitative evaluations of the potential magnitude of an increase in radon emissions were performed on behalf of the Respondents in 2014 (EMSI et al., 2014e). Quantitative evaluations of potential increases in radon emissions were performed as part of evaluations of a potential thermal isolation barrier on behalf of Bridgeton Landfill, LLC and Rock Road Industries in 2014, 2015 and 2016 (EMSI et al., 2014, EMSI, 2015f, and Auxier and EMSI, 2016d). Three potential conditions associated with radon emissions under elevated temperatures and occurrence of a heating event in Area 1 were examined:

- Initial thermal expansion of landfill gas due to increased temperature as a hypothetical heating event approaches and enters into Area 1, resulting in exhalation (emission at the ground surface) of the incremental increase in the volume of landfill/soil gas due to expansion of the gas volume in response to an increase in subsurface temperature;

- Subsequent increase in radon emissions due to increased soil gas permeability resulting from vaporization of soil moisture in response to increased temperature; and

- Subsequent destruction (pyrolysis) of a portion of the waste mass and associated loss of pore space resulting in further displacement and resultant emission of an additional portion of the landfill/soil gas.

Results of these calculations indicated that even if these conditions were to occur, the radon emission rate from Area 1 would still be less than the standard established by the radon NESHAP, and if such a release were to occur, risks at or beyond the fence line would be below the acceptable risk levels established by EPA.

The potential for a hypothetical release of particulate matter containing radionuclides was also evaluated on behalf of Bridgeton Landfill, LLC and Rock Road Industries in 2016 (Auxier and EMSI, 2016e). This evaluation concluded that even with very conservative (worst-case) assumptions, the projected air concentrations at the closest occupied structure, the closest boundary fence, and at the two closest communities produced risks on the order of 10^{-8}, far below EPA's acceptable risk range of 10^{-4} to 10^{-6}.

7.2.1.3 Environmental Justice Considerations

As discussed in Section 6.2.2.3.6, a screening-level analysis did not identify any environmental justice concerns relative to the Site. EPA did identify a need for implementation of more traditional (non-electronic) communication methods to inform and ensure meaningful involvement of residents in the Terrisan Reste mobile home community.

7.2.2 Reduction of Toxicity, Mobility or Volume through Treatment

This criterion addresses the statutory preference to select remedial actions that employ treatment technologies which permanently and significantly reduce toxicity, mobility, or volume of hazardous substances as their principal element.

None of the alternatives include treatment technologies that would reduce the toxicity, mobility, or volume of the waste material through treatment. Treatment technologies are generally not applicable to solid waste landfills due to the overall large volume and heterogeneity of the wastes, which make treatment impracticable (EPA, 1991b and 1993b). For the RIM interspersed within portions of the solid waste in Areas 1 and 2, the radionuclides are naturally-occurring elements which cannot be fully neutralized or destroyed by treatment. Occurrences of radionuclides are dispersed within soil material that is further dispersed throughout portions of the overall heterogeneous matrix of municipal refuse, construction and demolition debris, and other non-impacted landfill materials within portions of Areas 1 and 2. Consequently, ex-situ treatment techniques are considered impracticable. In addition, the heterogeneous nature of the solid waste materials and the dispersed nature of the radionuclide occurrences within the overall solid waste matrix in portions of Areas 1 and 2 make in-situ treatment techniques equally impracticable.

Accordingly, under all of the alternatives, no treatment processes would be employed on-site or at an off-site disposal facility for soil or debris containing only RIM. Therefore, there would not be any reduction in toxicity, mobility, or volume through treatment for RIM under any alternative.

The potential exists to reduce the volume of materials handled as RIM (but not the overall total volume of waste materials in Areas 1 and 2) through use of ex-situ physical separation processes to separate impacted soil from solid wastes such as hand-picking of large, bulky items, shredding and physical sorting with various fixed, vibrating, or rotating screens. For example, revolving cylindrical Trommel sieve screens have been used in conjunction with landfill mining and reclamation (LFMR) projects to separate materials by size, with the soil fraction passing through the screen. While not a "treatment" process, this physical separation process could potentially be employed to reduce the volume of excavated RIM that would be transported to an off-site disposal facility under the "complete rad removal" or the partial excavation alternatives. Because such processes have not been applied to a solid waste matrix that contains radiologically-impacted materials, no data exist regarding the potential effectiveness, implementability or cost of such technologies in this context. Therefore, though the potential exists as part of the "complete rad removal" or partial excavation alternatives to reduce the volume of RIM (but not the overall volume of waste materials at the Site), the potential viability of any physical separation technology cannot be determined based on existing information. Full-scale pilot-testing of such a physical separation process during remedial design, using excavated materials from Area 1 and/or Area 2, would be necessary in order to evaluate the reduction in volume of RIM, as well as the effectiveness, implementability, and cost of the technology. Additional evaluation would be necessary to assess the potential for increased short-term risk to workers and off-site receptors due to additional materials handling associated with pilot-testing, or full-scale operation of any physical separation process.

To the extent that hazardous wastes or mixed wastes are encountered under any of the alternatives, such wastes would be shipped off-site and would be treated at the disposal facility in accordance with the hazardous waste regulations (e.g., EPA's LDR program and UTS) and in accordance with the permits and standard operating procedures of the receiving facility. Examples of treatment processes for hazardous wastes or mixed wastes include solidification/stabilization of soil and micro- or macro-encapsulation of debris. To the extent that treatment of any hazardous waste or mixed waste would be required for off-site disposal, stabilization or encapsulation treatment would result in a reduction of the mobility of the hazardous constituents or the radiological components of the waste. Toxicity and volume would not be reduced by these technologies but may be reduced by other technologies potentially applicable to hazardous wastes that do not contain RIM, if such wastes were encountered during implementation of remedial action at the Site.

7.2.3 Short-Term Effectiveness

This criterion addresses the effects that would occur during construction and implementation of the alternatives prior to achievement of the Site RAOs. Factors considered in the evaluation of this criterion include protection of the community during the remedial action, protection of workers, environmental impacts, and the time until the RAOs are met. Environmental justice considerations that may occur during implementation of the alternatives are also discussed in this section. Severity of impacts among the excavation and disposal alternatives corresponds to the duration and extent (volume, area) of the remedial action. Because the "complete rad removal" alternative is of significantly longer duration and requires contact with a substantially greater volume of the RIM than the partial excavation alternatives, it has significantly greater short-term impacts.

7.2.3.1 Protection of the Community

None of the remedial alternatives pose significant radiological or chemical exposure-related risks to the general public during remedy implementation. Potential exposures to area residents that may occur during construction of each and all of the alternatives were projected to pose total radiocarcinogenic and chemocarcinogenic risks that are less than 10^{-7}, which is below EPA's target risk range of 10^{-4} to 10^{-6}. Projected non-carcinogenic hazard indices for all of the alternatives were projected to be less than 0.0001, far below a hazard index of 1.0 used by EPA to identify unacceptable toxic effects.

The greatest potential risks to the community are associated with the off-site disposal components of the "complete rad removal" and partial excavation alternatives, with the "complete rad removal" alternative posing the greatest risk. These risks arise largely from the much greater number of truck trips associated with off-site disposal, resulting in greater traffic congestion on St. Charles Rock Road and other nearby highways, as well as the associated potential for traffic accidents and fatalities, greater greenhouse gas emissions, and greater noise impacts. The projected incidence of transportation-related accidents (Table 7-1) is 34.9 for the "complete rad removal" alternative, compared to 16.6 for the 1,000 pCi/g partial excavation alternative, 10.6 for the 52.9 pCi/g partial excavation alternative, and 0.61 for the ROD-selected remedy, respectively[54]. The off-site disposal components of the complete and partial excavation

---

[54] If it were feasible to extend a rail spur onto to the West Lake Landfill Site such that RIM could be directly loaded into rail cars for transport to an off-site disposal facility, the projected incidence of traffic accidents for the "complete rad removal" or partial excavation alternatives may be reduced; however, even if the trains were only

alternatives pose the potential for an off-site release resulting from potential vehicle accidents or other losses of vehicle or container integrity during material handling and transfer activities and transport to an off-site disposal facility. Projected carbon dioxide equivalent (greenhouse gas) emissions are also substantially greater for the "complete rad removal" alternative, at 83,000 tons of carbon dioxide equivalent emissions, compared to 43,000 tons and 53,000 tons for the 52.9 and 1,000 partial excavation alternatives, respectively, and 19,000 tons for the ROD-selected remedy (Table 7-1).

In contrast to the ROD-selected remedy, which only includes regrading of existing landfill surfaces, the "complete rad removal" and partial excavation alternatives require excavation of large portions of Areas 1 and 2. Excavation of RIM from Areas 1 and 2 would require removal of (1) the existing landfill cover; (2) non-RIM overburden over Areas 1 and 2; (3) RIM above cleanup levels in Areas 1 and 2; and (4) portions of adjacent areas of landfill at OU-2. The "complete rad removal" and 1,000 pCi/g partial excavation alternatives also would require removal, temporary relocation and subsequent replacement of a large amount of the above-ground portion of the North Quarry part of the Bridgeton Landfill that overlies the southwestern portion of Area 1. Excavation, handling, stockpiling and replacement of overburden is likely to result in generation of significant amounts of odor. The total amount of waste material to be relocated as part of the regrading process under the ROD-selected remedy is estimated to be approximately 130,000 bank cubic yards (bcy). In contrast, the total volume of waste that would need to be excavated under the "complete rad removal" alternative is estimated to be nearly 1,600,000 bcy, much of which would be associated with younger, and therefore more putrescible, wastes contained in the above-grade portion of the North Quarry part of the Bridgeton Landfill. Similarly, the 1,000 pCi/g partial excavation alternative would require removal of approximately 820,000 bcy of waste, while the 52.9 pCi/g partial excavation alternative would require removal of approximately 500,000 bcy. Both of these partial excavation alternatives also require removal of significant portions of North Quarry waste. Because this waste was placed in the 2003 to 2004 timeframe, it is likely to be less decomposed (putrescible). Putrescible waste poses a greater potential to attract birds and emit odors than that posed by the older waste materials in Areas 1 and 2.

The above volume estimates do not account for the additional handling associated with temporary stockpiling or subsequent replacement of the overburden material, and therefore the actual volumes of waste being handled under the three excavation alternatives would be significantly greater than the amounts listed above.

Excavation of overburden and RIM would also create depressions in the landfill areas during the period of time required to remove the RIM and re-grade and cover the remaining landfill wastes. Precipitation that falls on the landfill while such depressions are open would potentially flow into and accumulate in the depressions. Any accumulation of precipitation[55] in depressions created

---

transferred at night, an at-grade rail crossing would still represent a significant safety issue for traffic on St. Charles Rock Road.

[55] Accumulation could be significant during a heavy rainstorm, as the maximum historical 24-hour rainfall for the St. Louis area ranges from a low of 3.7 inches in November to a high of 8.8 inches in August (NOAA, 2011).

during waste excavation could result in infiltration of precipitation runoff through the underlying waste materials, which in turn could result in leaching of VOCs or other soluble contaminants from the waste materials.

During construction, consideration would be given to minimizing the area of excavation that would be open and exposed to waste materials at any given time, though the ability to accomplish this for the "complete rad removal" and partial excavation alternatives may be limited. Application of daily soil cover or placement of tarps over areas of exposed waste at the end of each work day would be employed to reduce the potential for odor generation and infiltration of precipitation. Stormwater best management practices, including temporary diversion berms, would also be constructed above the open excavation areas to divert precipitation runoff and attempt to prevent the runoff from contacting uncovered waste materials. Precipitation that would contact uncovered waste materials would flow into the low point of the excavation and be pumped out of the excavation into temporary storage tanks using portable gas-driven pumps. Samples from each tank would be collected and sent to a laboratory for analysis. The stored water would be directly discharged on-site or treated and disposed off-site based on the analytical results.

7.2.3.2 Environmental Justice Considerations During Remedy Implementation

As discussed in Section 6.2.1.5.1, a screening level analysis did not identify any environmental justice concerns. EPA did identify a need for implementation of more traditional (non-electronic) communication methods to inform and ensure meaningful involvement of residents in the Terrisan Reste mobile home community.

7.2.3.3 Worker Protection

All of the remedial alternatives pose potentially increased cancer risks to workers involved with the remedy implementation, although the risks associated with the "compete rad removal" and partial excavation alternatives are higher than those associated with the ROD-selected remedy (Table 7-1). Workers involved with remedy implementation are assumed to be exposed to gamma radiation owing to their proximity to RIM. Carcinogenic risks to the reasonably maximally-exposed individual, determined to be a radiation technician, were projected to range from a high of 2.4×10^{-3} for the 1,000 partial excavation alternative to a low of 9.2×10^{-5} for the ROD-selected remedy (see Table 7-1 and Appendix H). The total effective dose equivalent (TEDE) to remediation workers are projected to be approximately 867 mrem/year for the 1,000 partial excavation alternative, 720 mrem/per year for the 52.9 partial excavation alternative, 405 mrem per year for the "complete rad removal" alternative, and 187 mrem/year for the ROD-selected remedy; however, the TEDEs associated with all of the alternatives are projected to be less than the OSHA and NRC standards of 5,000 mrem/year. Remediation workers would also be exposed to non-carcinogenic risks from exposure to chemicals within the waste materials. All of the alternatives are projected to result in hazard indices greater than 1.0 for worker exposures to chemical (non-radiological) constituents.

Potential risks to on-site workers are also associated with the projected incidence of industrial accidents, which were estimated to range from a high of 17.8 for the "complete rad removal" alternative to a low of 2.8 for the ROD-selected remedy (Table 7-1).

For all of the alternatives, workers would be instructed and trained in safe work practices, work practices at hazardous waste sites, work practices in extreme temperatures, vehicle and pedestrian safety, use and care of personal protective equipment and monitoring devices, and other measures to reduce worker exposures and the potential for accidents. Risks and doses to workers from exposure to RIM can be controlled by limiting exposure durations.

7.2.3.4 Environmental Impacts

No measurable long-term impacts to plants or animals in surrounding ecosystems are expected to occur from any of the alternatives. No wetlands are located within the on-site construction footprint of the alternatives and no endangered species were identified in the Site area. Excavating and re-grading Areas 1 and 2 and constructing new landfill covers over these areas would affect the wildlife and plant life on those portions of the landfill. Disturbance of the landfill surface would occur under all of the remedial alternatives and would destroy those portions of the habitats that currently exist on the surface of Areas 1 and 2, forcing wildlife to migrate to other areas. This disruption would be temporary and would last for the period of active construction[56]. Vegetative cover would be placed on the Site and the landfill would be allowed to return to an early-stage field ecosystem with periodic mowing and maintenance.

As discussed in the prior section, excavation of overburden and RIM could result in creation of depressions which could accumulate stormwater. Accumulation of stormwater in these depressions would increase infiltration and potential leaching and transport of chemicals or radionuclides, which could result in impacts to the underlying groundwater quality. Such impacts are expected to only be temporary because once regrading is completed, no further stormwater accumulation and infiltration would be expected to occur.

7.2.3.5 Time to Achieve Remedial Action Objectives (RAOs)

The RAOs would be achieved upon completion of construction, which is estimated to be finished within the following timeframes after notice to proceed with remedial design is issued (see also Table 7-1 and Appendix J). The ROD-selected remedy would achieve the RAOs in the shortest amount of time, while the "complete excavation alternative" would take the longest time to achieve RAOs.

- Approximately 2.7 years for the ROD-selected remedy,

[56] It should be noted that much of the vegetative cover was recently removed from Areas 1 and 2 as part of construction of the Non-Combustible Cover.

- Approximately 5.9 years for the 52.9 pCi/g partial excavation alternative, and
- Approximately 9 years for the 1,000 pCi/g partial excavation alternative, and
- Approximately 13.4 years for the “complete rad removal” alternative.

These estimated durations assume that remedial design for each alternative can be completed and approved within one year to 15 months of remedy approval and authorization to begin the RD phase, and that construction of the remedy is not fiscally constrained.

The short-term effectiveness of the alternatives would be assessed by monitoring performed during, at the completion of, and after construction. Monitoring performed during construction would include perimeter and work space air monitoring, as well as worker health and safety monitoring. Construction quality control monitoring would be performed as part of all of the remedial alternatives to document that remedy construction was completed in accordance with the design specifications.

For the “complete rad removal” and partial excavation alternatives, measurements, sampling and laboratory analyses would be performed to guide the excavation activities and verify that the RIM above the respective cleanup levels was removed. Because thorium-230 is a primary radionuclide of concern relative to the “complete rad removal” and partial excavation alternatives, significant reductions in efficiency and increased time may be required for RIM excavation, as compared with the ROD-selected remedy. Thorium-230 cannot be detected using field survey instruments, so excavation would have to be guided by collection and laboratory analyses of samples. In order to minimize the potential impacts on the excavation schedule, it is assumed that an on-site laboratory would be set up and operated to provide quick analyses of samples to guide excavation activities and initial confirmation that RIM to the specified cleanup level had been removed. A percentage of such samples would also be sent to an off-site laboratory for verification of the on-site laboratory results. Samples obtained for final confirmation that RIM has been removed from a particular area would also be subjected to off-site laboratory analyses. All of these activities would undoubtedly impact the rate of RIM excavation and the duration over which excavation areas need to remain open.

For the ROD-selected remedy and the partial excavation alternatives, measurements of gamma radiation levels and radon flux would be made on and around Areas 1 and 2 after construction is complete to provide for final quantification of the cover effectiveness.

All of the alternatives include long-term groundwater and landfill gas monitoring along the perimeter of Areas 1 and 2 and, if necessary, at off-site locations.

Because RIM and solid wastes would remain in Areas 1 and 2 under the ROD-selected remedy and the partial excavation alternatives, and solid wastes would remain in these areas under all of the alternatives, engineering measures and institutional controls intended to address the presence of solid wastes would be required for all of the alternatives. Engineering measures and institutional controls to address the presence of RIM would also be required for the ROD-selected remedy and partial excavation alternatives; however, these are the same types of measures that would be used to address the solid waste materials remaining in Areas 1 and 2 under the “complete rad removal” alternative, with certain enhancements to address the presence of RIM.

Unlike the ROD-selected remedy, the estimated schedules for construction of the “complete rad removal” and partial excavation alternatives are highly dependent upon the amount of expansion (the swell factor) the waste materials experience during excavation, handling and loading for shipment. Based on experience at the Mound Site, the Tulalip Landfill and other landfill waste excavation projects (see section 6.1.7.2), it is likely that the actual volume expansion swell factor could be greater than what has been assumed in this FFS, and unlikely that it would be less. To the extent that the swell factor is greater than what has been assumed during preparation of this FFS, the schedules for completion of construction – and consequently, the costs and risks associated with the “complete rad removal” and partial excavation alternatives – would increase. The swell factor does not apply to the ROD-selected remedy and therefore would not increase the costs and risks associated with that remedial alternative.

The projected construction schedule and the cost estimate for the “complete rad removal” and partial excavation alternatives are also highly dependent on the number of containers that could be loaded with RIM and shipped off-site per day. The schedules and cost estimates developed in this FFS for these alternatives are based on an assumption that a sufficient number of IM containers and rail cars can be made available, loaded, switched out and replaced every day. If the actual rate is less than the projected rates of RIM excavation used to develop the construction schedules, the time required to complete construction – and consequently, the costs and risks for the “complete rad removal” or partial excavation alternatives – would increase.

Similarly, the schedule, costs and risks for the “complete rad removal” and partial excavation alternatives are sensitive to the rates at which soil and RIM can be relocated on-site. These rates are a function of the capacity of the internal roads and road intersections, as well as the demands of the on-site truck traffic generated by the existing transfer station and asphalt plant operations. Since these estimates were based on an optimal number of trucks, it is possible that the number of off-road haul truck trips assumed for purposes of preparing this FFS may not be achievable; similarly, it is unlikely that the number assumed could be greater. Consequently, the actual duration required for construction of the “complete rad removal” and partial excavation alternatives could be greater than that assumed in this FFS, resulting in increased time to complete, costs and risks.

7.2.4 Implementability

This criterion addresses the technical and administrative implementability of each alternative and the availability of the various services and materials required to implement each alternative.

Installation of upgraded landfill covers to promote runoff and minimize infiltration, excavation and off-site disposal of waste materials, and implementation of institutional controls are all technically feasible, reliable, and established technologies that have been implemented and proven at other CERCLA landfill sites. Monitoring of landfill cover surfaces, landfill gas, radon, groundwater, and surface water are proven methods for demonstrating the long-term effectiveness of a covered landfill and are easily implemented.

All of the alternatives include re-grading and contouring the existing overburden and waste materials in Areas 1 and 2 in order to achieve final grades. Re-compaction of the re-graded materials will be required to minimize the potential for differential settlement over time that could affect the integrity of the landfill cover. Placement of additional fill material to achieve the final slope requirements and for construction of the landfill covers over Areas 1 and 2 may result in compaction of the existing waste materials, depending upon the nature, age, and amount of prior degradation of the materials. Long-term maintenance, including inspection and repair, is typically required to address the potential for differential settlement or surface erosion of the landfill cover over time and is anticipated to be part of all alternatives. The level of effort for inspection and repair of the cover surfaces over Areas 1 and 2 would be the same for all alternatives.

Monitoring of the Area 1 and 2 landfill cover surfaces, perimeter landfill gas monitoring, and groundwater and surface water quality monitoring, would be required for all of the alternatives in order to demonstrate the effectiveness of the remedy. Future groundwater monitoring activities could require acquisition and maintenance of access to off-site properties if off-site groundwater monitoring was required as part of the remedy. All of the monitoring activities are implementable.

The proximity of the landfill mass to the property boundaries and adjacent properties constrains the potential methods that can be utilized to re-grade Areas 1 and 2. Specifically, the lack of space along the margins of Areas 1 and 2 dictates that re-grading of these areas to achieve the desired slopes cannot be completed by placement of additional fill material alone. Relocation of a limited amount of existing waste materials would be necessary in some areas, and grading and contouring of existing waste would be required in other areas. Even so, the amount of waste relocation that may need to be performed for the ROD-selected remedy is still anticipated to be considerably less than the amount of overburden excavation and waste movement that would be required for the “complete rad removal” or partial excavation alternatives, as these alternatives entail removal and stockpiling of substantial amounts of overburden, removal of substantial amounts of RIM, and replacement of the overburden material.

Uncertainty exists concerning the ability to remove all of the RIM under the “complete rad removal” and partial excavation alternatives due to the depth of the RIM in some areas and the proximity of some of the RIM to other (OU-2) solid waste management units, including the North Quarry portion of the Bridgeton Landfill, closed construction and demolition waste landfill, and the inactive sanitary waste landfill.

Excavation of RIM would also present significant implementability concerns associated with the excavation and handling of contaminated materials, including:

- management of fugitive dust and potential odors;
- mitigation of bird hazards;
- management and treatment of stormwater exposed to RIM or other waste during excavation;
- management of RIM that fails the paint filter liquids test; and
- the identification, segregation, and disposal off-site of any hazardous wastes or regulated asbestos containing materials that may be encountered during RIM excavation.

These factors are discussed further in Section 6.

In addition, under the “complete rad removal” and partial excavation alternatives, directing and controlling the RIM excavation process using radiological scanning, sampling and laboratory analytical techniques would greatly impact (i.e., decrease) overburden and RIM excavation rates.

Implementability concerns specific to the off-site transport and disposal components of the “complete rad removal” and partial excavation alternatives include the considerations listed below. The ROD-selected remedy would not pose such implementability concerns because it does not involve the excavation and off-site disposal of waste.

- If a truck-to-rail transloading facility at an off-site rail spur location were to be used, a suitable location would have to be identified and a lease secured with the land/rail spur owner.

- If a rail spur were to be extended onto the West Lake Landfill property: (1) land located across St. Charles Rock Road would either need to be purchased or long-term leases would be needed with landowners, (2) it would be necessary to obtain state and local government, private landowner, facility occupant and community approval to construct a rail spur across private property located to the east of St. Charles Rock Road, across St. Charles Rock Road, and along the Site access roads which serve the existing solid waste transfer station and asphalt plant operations, and (3) the long-term lease of the asphalt plant would likely need to be renegotiated or otherwise acquired.

- Switching of railcars either at a truck-to-rail transloading facility spur or an on-site rail spur would need to be coordinated with the railroad company that would be hauling the rail cars to the off-site disposal facility. The capacity to switch rail cars could affect the rate at which RIM could be excavated and removed from the Site.

- If a rail spur could be extended onto the West Lake Landfill property, dropping off empty and picking up loaded railcars would likely be possible only during late nighttime due to the high traffic volume on St. Charles Rock Road during the day. The rail spur crossing at St. Charles Rock Road would need to meet appropriate state and local safety requirements.

- The EPA Region where the off-site disposal facility is located would need to be contacted every 60 days to obtain a compliance determination as to whether the disposal facility currently meets the criteria under the CERCLA Off-Site Rule. If, during RIM excavation, the contracted off-site disposal facility was found not to be in compliance for a period of time, excavation and transportation would need to cease until the facility became compliant, or RIM would need to be transported to another facility that EPA determined to be in compliance with all permit and regulatory requirements. Besides schedule delays, temporary stoppage of construction would present significant technical implementability concerns regarding open excavation areas.[57]

- If RIM were to be disposed at the Clean Harbors Deer Trail, CO facility, an application would have to be submitted to and accepted by the Rocky Mountain Low Level Radioactive Waste Compact.

Management and discharge of any leachate that may be collected or generated during implementation of any of the remedial actions would require coordination with the Metropolitan Sewer District (MSD) with respect to acceptance and conditions for discharge of leachate to the sewer system. Design for and discharge of stormwater will require coordination with the Earth City Flood Control District. Removal of soil containing radionuclides above unrestricted use levels that may still remain on the Crossroads Property, will require coordination with Crossroad Properties, LLC and AAA Trailer. A traffic control plan for and possibly improvements to the Site ingress and egress from St. Charles Rock Road may need to be developed and coordinated with the City of Bridgeton and/or the Missouri Department of Transportation

Because Areas 1 and 2 exist within a larger Site with other landfill areas, the following activities impact one or more of the alternatives and would require coordination with the Site owner and operator:

- Regrading of Areas 1 and 2, installation of an upgraded landfill cover, and design of stormwater management structures under any of the remedial alternatives would need to be integrated with the grading, landfill covers, and stormwater controls that currently exist or that may be constructed on the adjacent OU-2 landfill units;

- Use of Site areas outside of Areas 1 and 2 to stockpile cover materials in order to facilitate cover construction under all four remedial alternatives would need to be integrated with ongoing Site operations and/or implementation of remedial actions for OU-2;

- The flow of vehicles associated with remedy construction would need to be coordinated with the flow of vehicles associated with the on-site solid waste transfer station and asphalt plant operations;

---

[57] For example, if such an event of non-compliance were to occur and could not be resolved quickly, excavation at the Site might be required to halt temporarily, and existing excavations may need to be backfilled in order to minimize potential RIM exposures.

- Excavation of RIM under the "complete rad removal" and partial excavation alternatives would need to be coordinated with remedial actions to be performed for OU-2;

- Truck hauling of RIM off-site to a truck-to-rail transloading facility for the off-site disposal alternatives would need to be coordinated with vehicle activity associated with the existing Site operations;

- If a rail spur could be extended onto the Site for the off-site disposal alternatives, loading of railcars with RIM and switching of railcars would need to be coordinated with the Site owners and existing operations at the Site; and

- Truck delivery of rock, clay, and soil materials for cover construction over Areas 1 and 2 under all four remedial alternatives would need to be coordinated with vehicle traffic associated with the existing Site activities.

Specialized personnel, equipment, and materials are expected to be readily available to implement the cover systems, institutional controls, and monitoring components of the remedial alternatives. The implementability and potential costs for all of the remedial alternatives will be influenced by the availability and location of clean fill materials and/or off-site soil borrow sources at the time the selected alternative is implemented. Potential vendors of rock, clay and soil were contacted during the development of the FS and during preparation of the Remedial Design Work Plan for the ROD-selected remedy. These vendors indicated that rock, clay, and soil material were readily available from sources close to the Site. However, if these local sources become exhausted prior to or during remedy implementation, cover materials would have to be obtained from suppliers at greater distances from the Site.

Materials, equipment and personnel required for excavation of RIM and transport of RIM to an off-site disposal facility are readily available. Only a limited number of off-site disposal facilities exist that can accept excavated RIM from the West Lake Landfill. All of the facilities currently are anticipated to have sufficient available capacity to accept the estimated volumes of RIM from the Site; however, there is no assurance that sufficient capacity at one or more of these facilities would be available in the future to serve the "complete rad removal" or one of the partial excavation alternatives if such an alternative were to be selected by EPA. At this time, it is difficult to evaluate which disposal facilities that can currently accept wastes from the West Lake Landfill may be available in the future, or what their respective future capacities or waste acceptance criteria may be. The volumetric rate of acceptance for all off-site disposal facilities would also be a function of the availability of IM containers and the number of railcars that could be loaded at or near the Site, as well as the number of railcars that could be unloaded at or near the disposal facility. If a "complete rad removal" or partial excavation alternative were to be selected, the facilities identified in Section 3.2.3 and as further detailed in Appendix C are also permitted to (1) accept liquid wastes, should any stormwater accumulated in excavations during RIM excavation become contaminated and require disposal off-site, (2) accept mixed wastes, if mixed wastes are encountered during excavation, and (3) treat soil and/or debris that contains hazardous or mixed waste.

7.2.5 Cost

The final primary balancing criterion is cost. Table 6-1 presents a summary of the anticipated costs associated with each alternative. The highest costs are associated with the "complete rad removal" alternative, followed by the 1,000 pCi/g partial excavation alternative and the 52.9 pCi/g partial excavation alternative, with the lowest costs associated with the ROD-selected remedy as the second lowest (see listing below). Detailed information regarding the cost estimates for each alternative is presented in Appendix K.

- The ROD-selected remedy would result in the lowest overall estimated capital (design, construction and environmental monitoring during construction) costs of all of the remedial alternatives at $67 million, with estimated annual OM&M costs ranging from $167,000 to $326,000.

- Capital costs for construction of the 52.9 pCi/g partial excavation alternative are estimated to be $313 million with estimated annual operations, maintenance and monitoring costs of $167,000 to $326,000.

- Capital costs for construction of the 1,000 pCi/g partial excavation alternative are projected to be $361 million with estimated annual operations, maintenance and monitoring costs of $167,000 to $326,000.

- Implementation of the "complete rad removal" with off-site disposal alternative would result in incurrence of the highest total estimated capital cost at $616 million, with estimated annual operations, maintenance and monitoring costs of $167,000 to $326,000.

The cost estimates summarized above and provided elsewhere in this FFS are feasibility-level cost estimates; that is, they were developed to a level of accuracy such that the actual costs incurred to implement the alternatives are anticipated to be within a range bounded by 50% above and 30% below these estimates.

The ranges in values for the annual OM&M costs cited above result from variations in the specific activities that occur each year (*e.g.*, higher costs for years with additional environmental monitoring, years when landfill cover repairs may occur, and years when five-year reviews are conducted).

Based on a 7% discount rate, the 30-year present worth costs of the alternatives are estimated to be:

- $63 million for the ROD-selected remedy,

- $265 million for the 52.9 pCi/g partial excavation alternative,

- $275 million for the 1,000 pCi/g partial excavation alternative, and
- $421 million for the "complete rad removal" alternative.

Based on the Office of Management and Budget's current value (2016 value issued in December 2015) of 1.5% for the 30-year discount rate, the 30-year present worth costs of the alternatives are estimated to be:

- $70 million for the ROD-selected remedy,
- $305 million for the 52.9 pCi/g partial excavation alternative,
- $342 million for the 1,000 pCi/g partial excavation alternative, and
- $567 million for the "complete rad removal" alternative.

Finally, the total non-discounted costs over the same 30-year period are estimated to be:

- $72 million for the ROD-selected remedy,
- $318 million for the 52.9 pCi/g partial excavation alternative,
- $365 million for the 1,000 pCi/g partial excavation alternative, and
- $620 million for the "complete rad removal" alternative.

As discussed in Section 6.1.7.2, variable scope contingency factors were developed and applied to each of the major construction activities including excavation (55%), off-site disposal (15%), and landfill cover construction (10%). Scope contingency addresses unknown costs due to scope changes that may occur during RD and represents project risks associated with an incomplete design, because design concepts are not typically developed enough during preparation of an FS to identify all project components or quantities. This type of contingency represents costs unforeseeable at the time the FFS and conceptual design cost estimate were prepared, both of which are likely to become better known as the RD phase progresses.

The greatest source of uncertainty is associated with RIM excavation, and results from uncertainties associated with (1) the volume, configuration and composition of the RIM; (2) the volume and configuration of the overburden material; (3) excavation rates; (4) the material swell factors; (5) available areas for stockpiling overburden; (6) the nature and degree of nuisance factors (*e.g.*, odors, weather, stormwater management, bird control, etc.); and (7) the associated management techniques, and changes or additions to the construction and management procedures that may be requested or required by the regulatory agencies or other parties, among other factors. Among the alternatives, the greater the amount of RIM excavated, the greater the degree of uncertainty. Due to the limited number of off-site disposal facilities that could accept the waste materials, the greatest degree of uncertainty with the capital costs is associated with the off-site disposal component of the “complete rad removal” and partial excavation alternatives. There also are uncertainties regarding the specification and cost of the rock that would be used for the bio-intrusion layer included in the ROD-selected remedy and the partial excavation alternatives, as well as the source and unit costs for acquisition and delivery of the clay and soil to be used to construct the low permeability and vegetative layers of the final landfill covers over Areas 1 and 2 that are included in all of the remedial alternatives.

A 20% bid contingency was also included in the capital costs for all of the remedial alternatives to address unknowns that might occur after a construction contract is awarded. The ROD-selected remedy is not expected to have the potential for significant cost growth after construction begins because it is a demonstrated technology with fewer uncertainties in cost-determining factors. In contrast, the “complete rad removal” and partial excavation alternatives have the potential for significant cost growth due to the unknowns associated with excavation of the RIM, including, among other factors: (1) the configuration and volume of the RIM; (2) the swell resulting from RIM excavation; (3) the amount of overburden; (4) potential occurrences of hazardous wastes or RACM; and (5) actual production rates of excavation and disposal activities, especially under different weather conditions.

As an example, at OU-1 of the Mound CERCLA site in Miamisburg, OH, the remediation of landfilled contaminated soil/debris that contained radionuclides cost significantly more than anticipated. Review of available documents (ARC, 2009 and ARC, 2010) and discussions with regulatory agency representatives for this project indicate that one reason for the significant increase in costs was “variations with respect to waste location and waste type from those modeled by the project team in the original Remedial Action Work Plan were encountered during excavation” (ARC, 2009). Specific factors that resulted in the increased costs included:

- Uncertainty regarding the locations, extents, depths, configurations, volumes, types, and characteristics of the waste deposits;
- No data, or only limited characterization data, for the waste materials prior to initiation of the removal action;
- The presence of unanticipated and undocumented waste materials and waste types, including (but not limited to) mercury, PCBs, previously unidentified VOCs, Pu-239, and Am-241;
- The presence of a substantial amount of both mixed radioactive and hazardous wastes/debris and hazardous waste/debris, with both the hazardous wastes/debris and the mixed wastes requiring off-site incineration and chemical oxidation;
- The necessity of transporting materials to four different off-site disposal or waste processing facilities (rather than only one facility, as was anticipated during project planning) because of the variability in types of wastes encountered;

- The impacts of weather (heat, cold, rain, lightning) on implementability, employee productivity rates, equipment operation, and progress of the excavation activities;
- Excessive water ponding in trenches and limited operations during backfilling activities caused by severe precipitation; and
- Delayed and complicated backfill and soil cover compaction due to excessive precipitation and frozen soil.

Excavation of waste materials from OU-1 Areas 1 and 2 is likely to encounter many of the same complications encountered at the Mound OU-1 Landfill Area. In addition to the cost overrun issues listed above, experience with waste excavation at other landfill sites indicates that the following additional factors could also contribute to increased costs for the "complete rad removal" or partial excavation alternatives:

- Unanticipated variations in the volume-weight relationships for the wastes that could result in variability in costs charged on either a volumetric or weight-based unit price;
- Increased fuel and resultant transportation costs over time;
- Loss of the availability of one or more of the currently available off-site disposal facilities in the future;
- Potential increases in the off-site transportation and disposal pricing over time;
- Potential for encountering leachate containing hazardous substances that may require treatment;
- Potential for stormwater accumulation in depressions created by waste excavation and resultant potential for generation of contaminated stormwater requiring treatment; and
- Decreased availability and/or increased pricing for local fill material required to regrade Areas 1 and 2 to 5% slopes upon completion of the waste excavation activities.

The nature of the activities and the longer duration required for implementation of the "complete rad removal" and, to a lesser extent, partial excavation alternatives, significantly increases the potential for occurrence of cost increases over time.

7.3 Modifying Criteria

The two NCP modifying criteria are: (1) state acceptance; and (2) community acceptance. Comparison of the alternatives with respect to modifying criteria will be performed by EPA as part of the FFS review and decision process.

amsl = above mean sea level cpm = counts per minute

Notes: NA - Data were not collected or are otherwise not available.

X - Data support the presence of RIM in the indicated interval

'- Data do not indicate the presence of RIM at this location/interval

Notes: NDE = gamma log not deep enough. No Log = no log from RI investigation exists. * Indicates that result for one of the two isotopes was non-detect Final Q = final qualifier CSU[1] = combined standard uncertainty (+/- sigma for McLaren/Hart samples) CV = critical value

(highlighted) indicates that combined value is greater than the unrestricted use criteria established by EPA

J = The analyte was analyzed for, and was positively identified, but the associated numerical value may not be consistent with the amount actually present in the environmental sample.

J+ = Same as J qualification but with an indication of positive bias in the sample concentration.

U = The analyte was analyzed for and is not present above the level of the associated value. The associated numerical value indicates the approximate concentration necessary to detect the analyte in the sample.

For McLaren/Hart RI Soil Boring Data:

In calculated combined Ra and combined Th values, if of the the results was <MDA, one-half of the MDA was used in the calculation and the combined value was noted with an *. If both values were <MDA, combined results reported as "Non-detect".

In calculated combined U values, if one or two of the the results was <MDA, one-half of the MDA was used in the calculation and the combined value was noted with an *. If all three values were <MDA, combined results reported as "Non-detect".

Table 2-4: Area 2 Combined Radium, Thorium, and Uranium Results (RI Borings, A2 Additional Borings, and Cotter Borings)

Notes: NDE = gamma log not deep enough. No Log = no log from RI investigation exists. * Indicates that result for one of the two isotopes was non-detect Final Q = final qualifier CSU[1] = combined standard uncertainty (+/- sigma for McLaren/Hart samples) CV = critical value

(highlighted) indicates that combined value is greater than the unrestricted use criteria established by EPA

J = The analyte was analyzed for, and was positively identified, but the associated numerical value may not be consistent with the amount actually present in the environmental sample.

J+ = Same as J qualification but with an indication of positive bias in the sample concentration.

U = The analyte was analyzed for and is not present above the level of the associated value. The associated numerical value indicates the approximate concentration necessary to detect the analyte in the sample.

For McLaren/Hart RI Soil Boring Data:

- In calculated combined Ra and combined Th values, if of the the results was <MDA, one-half of the MDA was used in the calculation and the combined value was noted with an *. If both values were <MDA, combined results reported as "Non-detect".
- In calculated combined U values, if one or two of the the results was <MDA, one-half of the MDA was used in the calculation and the combined value was noted with an *. If all three values were <MDA, combined results reported as "Non-detect".

Table 2-5: Summary Statistics for Radium and Thorium Results - Areas 1 and 2

	Radium-226	Radium-228	Thorium-230	Thorium-232
Area 1				
Number of values	178	178	178	178
Median value	1.17	1.41	1.44	0.58
Average - single normally distributed population	81.3	2.38	547	7.77
Standard Deviation	510.5	2.96	2,851	47.28
Maximum value	4,926	31.8	25,825	515
95% UCL - single population	248	2.38	1,478	23.2
Weighted Bimodal Mean	81	1.7	550	7.8
Weighted Bimodal 95% UCL	890	5.2	1,900	46
Area 2				
Number of values	118	118	118	118
Median value	1.06	2.34	5.16	0.78
Average - single normally distributed population	152	2.34	1,706	10.5
Standard Deviation	572.8	4.23	7,148	33.6
Maximum value	3,720	29.1	57,300	240
95% UCL - single population	382	4.04	4,574	24
Weighted Bimodal Mean	150	2.4	1,500	11
Weighted Bimodal 95% UCL	340	82	4,000	29

All results except for number of values are in units of pCi/g.

Notes: No Log = no log from RI investigation exists. * Indicates that result for one of the two isotopes was non-detect Final Q = final qualifier CSU[1] = combined standard uncertainty (+/- sigma for McLaren/Hart samples) CV = critical value

(highlighted) indicates that combined value is greater than the unrestricted use criteria established by EPA

J = The analyte was analyzed for, and was positively identified, but the associated numerical value may not be consistent with the amount actually present in the environmental sample.

J+ = Same as J qualification but with an indication of positive bias in the sample concentration.

U = The analyte was analyzed for and is not present above the level of the associated value. The associated numerical value indicates the approximate concentration necessary to detect the analyte in the sample.

For McLaren/Hart RI Soil Boring Data:

- In calculated combined Ra and combined Th values, if of the the results was <MDA, one-half of the MDA was used in the calculation and the combined value was noted with an *. If both values were <MDA, combined results reported as "Non-detect".
- In calculated combined U values, if one or two of the the results was <MDA, one-half of the MDA was used in the calculation and the combined value was noted with an *. If all three values were <MDA, combined results reported as "Non-detect".

Table 2-9: Summary Comparison of Soil Sample Results to RCRA Toxicity Characteristic Regulatory Levels

EPA HW No.	Contaminant	Regulatory Level (mg/L)	x DAF of 20	Maximum Concentration in Soil (mg/kg)[1]	Location and Depth (ft)

D042	2,4,6-Trochlorophenol	2.0	40	ND	
D043	Vinyl chloride	0.2	4	ND	

Notes: [1]Bolded maximum concentrations indicate that the measured contaminant concentration is greater than the Regulatory Level times a Dilution-Attenuation Factor (DAF) of 20.

J - Estimated value, as result was below laboratory reporting limit.

Y - Estimated value, as all surrogate compounds were diluted beyond detection limits.

* Result is from EPA Method 8270. A result of 2,100 Y was obtained from the EPA Method 8260 analysis of this sample.

Notes:
According to EPA (2012b), about 0.4 pCi/L of Radon is normally found in outside air.
EPA Off-site air montioring results reported radon levels at its reference station (No. 5) of 0.11 to 1.45 with a median of 0.30 pCi/L.

Table 3-1: Preliminary Identification of Potential Chemical-Specific ARARs and TBC Criteria

Citation	Chemical	Medium	Requirement	Preliminary Determination	Remarks
Health and Environmental Protection Standards for Uranium and Thorium Mill Tailings (40 CFR 192), Subpart A, Standards for the Control of Residual Radioactive Material from Inactive Uranium Processing Sites	Radon-222	Air	The annual average release rate of radon-222 to the atmosphere applied over the entire surface of a disposal site should not exceed 20 pCi/m2-s, and the annual average concentration of radon-222 in air at or above any location outside the disposal site should not be increased by more than 0.5 pCi/L.	Not applicable but potentially relevant and appropriate	The West Lake Landfill OU-1 Site is not a designated Title I uranium mill tailings site; therefore, this requirement would not be applicable. The radiologically impacted materials at the Site are a small fraction of an overall matrix of municipal solid waste, debris and fill materials. Therefore, the waste materials at the Site are not similar to uranium mill tailings. These regulations are applicable to uncontrolled areas, whereas the current and future uses of Areas 1 and 2 are restricted. As these regulations address radon emissions, which is a concern for OU-1, they are considered potentially relevant and appropriate to the ROD-selected remedy and the partial excavation alternatives.
Health and Environmental Protection Standards for Uranium and Thorium Mill Tailings (40 CFR 192), Subpart A, Standards for the Control of Residual Radioactive Material from Inactive Uranium Processing Sites	Radium, Uranium, and trace metals	Ground-water	Establishes maximum concentration for groundwater protection. Maximum constituent concentration: Combined Ra_{226} and Ra_{228} — 5 pCi/L Combined U_{234} and U_{238} — 30 pCi/L Gross alpha (excluding radon & uranium) — 15 pCi/L Arsenic — 0.05 mg/L Barium — 1.0 mg/L Cadmium — 0.01 mg/L Chromium — 0.05 mg/L Lead — 0.05 mg/L Mercury — 0.002 mg/L Selenium — 0.01 mg/L Silver — 0.05 mg/L Nitrate (as N) — 10 mg/L Molybdenum — 0.1 mg/L	Not applicable but potentially relevant and appropriate	The West Lake Landfill OU-1 Site is not a designated Title I uranium mill tailings site; therefore, this requirement would not be applicable. As potential leaching of radionuclides and trace metals from the radiologically impacted materials at the Site is a possible issue of concern, these standards are potentially relevant and appropriate to the ROD-selected remedy and the partial excavation alternatives.

Table 3-1: Preliminary Identification of Potential Chemical-Specific ARARs and TBC Criteria

Citation	Chemical	Medium	Requirement	Preliminary Determination	Remarks
Health and Environmental Protection Standards for Uranium and Thorium Mill Tailings (40 CFR 192), Subpart B, Standards for Cleanup of Land and Buildings Contaminated with Residual Radioactive Materials from Inactive Uranium Processing Sites	Radium-226 (Radium-228)	Soil	Residual concentrations of radium-226 in soil at a designated uranium processing site should not exceed background by more than 5 pCi/g in the top 15 cm of soil or 15 pCi/g in each 15 cm layer below the top layer, averaged over an area of 100 m^2. (Similar limits are indirectly indicated for radium-228 in Subpart E, which addresses thorium by-product material.)	Neither applicable nor relevant and appropriate to Areas 1 & 2 Potentially relevant and appropriate for radiologically impacted soil on Buffer Zone/ Crossroad Property	The West Lake Landfill OU-1 Site is not a designated Title I uranium mill tailings site; therefore this requirement would not be applicable. The radiologically impacted materials at the Site are a small fraction of an overall matrix of municipal solid waste, debris and fill materials. Therefore, the waste materials at the Site are not similar to uranium mill tailings. These regulations are applicable to uncontrolled areas whereas current and future uses of Areas 1 and 2 are restricted. Consequently, these regulations are not relevant and appropriate to Areas 1 and 2. They are potentially relevant and appropriate for impacted soil on the Buffer Zone/ Crossroad Property.
Health and Environmental Protection Standards for Uranium and Thorium Mill Tailings (40 CFR 192), Subpart D, Standards for Management of Uranium Byproduct Materials Pursuant to Section 84 of the Atomic Energy Act of 1954, as amended; Subpart E, Standards for Management of Thorium Byproduct Materials Pursuant to Section 84 of the Atomic Energy Act of 1954, as amended	Radiation	Any	Processing operations during and prior to the end of the closure period at a facility managing uranium and thorium by-product materials should be conducted in a manner that provides reasonable assurance that the annual dose equiva-lent does not exceed 25 mrem to the whole body, 75 mrem to the thyroid, and 25 mrem to any other organ of any member of the public as a result of exposures to the planned discharge of radioactive material to the general environment (excluding radon-222, radon-220, and their decay products).	Neither applicable but potentially relevant and appropriate	The West Lake Landfill OU-1 Site is not a designated Title I uranium mill tailings site; therefore, this requirement would not be applicable. The radiologically impacted materials at the Site are a small fraction of an overall matrix of municipal solid waste, debris and fill materials. Therefore, the waste materials at the Site are not similar to uranium mill tailings. As alpha and gamma radiation is a potential exposure route for OU-1, these regaulations are considered to be potentially relevant and appropriate.
National Emissions Standards for Hazardous Air Pollutants (40 CFR 61), Subpart T, National Emissions Standards for Radon Emissions from disposal of Uranium Mill Tailings	Radon-222	Air	Radon-222 emissions to ambient air from uranium mill tailings piles that are no longer operational should not exceed 20 pCi/m^2-s.	Potentially relevant and appropriate	The West Lake Landfill OU-1 Site is not a designated uranium mill tailings site, so this requirement would not be applicable; however it could be considered relevant and appropriate because a portion of the waste materials at the Site do emit radon.

			Uranium (ug/L)	zero	30		
NRC Standards for Protection Against Ionizing Radiation (10 CFR 20 Subpart C), Maximum Permissible Exposure Limits	Radiation	Any	For persons inside a controlled area, the maximum permissible whole-body dose due to all external sources of radiation within a controlled area is limited to 5 rems/year or the sum of the deep-dose equivalent and the committed dose equivalent to any indvidual organ or tissue other than the lens of the eye being equal to 50 rems. The annual limits to the lens of the eye , to the skin of the whole body, and the skin of the extremities are a lends dose equivalent of 15 rems and a shallow-dose equivalent of 50 rem to the skin of the whole body or to the skin of any extremity. (Note: a controlled area is an area that requires control of access, occupancy, and working conditions for radiation protection purposes.)			Potentially relevant and appropriate	Because the site is not licensed by NRC, these requirements are not applicable. As these regulations address sources of ionizing radiation, they are potentially relevant and appropriate as they provide standards for protection from radiation for workers inside Areas 1 and 2 during any remedial actions that may be undertaken.
NRC Standards for Protection Against Ionizing Radiation (10 CFR 20 Subpart D), Maximum Permissible Exposure Limits	Radiation	Any	For persons outside a controlled area, the maximum permissible whole-body dose due to sources in or migrating from the controlled area is limited to 0.002 rem in any 1 hour, and 0.1 rem in any one hour. (Notes: a controlled area is an area that requires control of access, occupancy, and working conditions for radiation protection purposes; 0.5 rem = 500 mrem.)			Potentially relevant and appropriate	Because the site is not licensed by NRC, these requirements are not applicable. As these regulations address sources of ionizing radiation, they are potentially relevant and appropriate of workers and the public outside of Areas 1 and 2 during any remedial actions that may be taken.

Table 3-1: Preliminary Identification of Potential Chemical-Specific ARARs and TBC Criteria

Citation	Chemical	Medium	Requirement	Preliminary Determination	Remarks
NRC Standards for Protection Against Ionizing Radiation (10 CFR 20 Appendix B) Annual Liimits on Intake (ALIs) Derived Air Concentrations (DACs) Effluent Concentrations	Specific radionuclides (see table)	Air	The concentrations above natural background of radionuclides in air ouside a controlled area, averaged over any calendar quarter, should not exceed the following limits:	Potentially relevant and appropriate	Because the site is not licensed by NRC, these requirements are not applicable. These requirements would be potentially relevant and appropriate to protection of the public during implementation of any remedial action. Specifically, these regulations potentially may require perimeter monitoring to be undertaken during any activities that may expose or disturb the radiologically-impacted materials at the Site.

Isotope	Effluent Concentration Limit (uCi/mL) Air	Water
Actinium-227	1 x 10-15	5 x 10-9
Lead-210	6 x 10-13	1 x 10-8
Protactinium-231	8 x 10-15	6 x 10-9
Radium-226	9 x 10-13	6 x 10-8
Radium-228	2 x 10-12	6 x 10-8
Radon-222	1 x 10-8	NA
Thorium-230	3 x 10-14	1 x 10-7
Thorium-232	6 x 10-15	3 x 10-8
Uranium-234	5 x 10-14	3 x 10-7
Uranium-235	6 x 10-14	3 x 10-7
Uranium-238	6 x 10-14	3 x 10-7

NA = not applicable because radon-222 is a gas.

OSWER Directive No. 9200.4-25	Radium-226 Radium-228 Thorium-230 Throium-228	Soil	Clarifies EPA's position on the use of the soil cleanup criteria in 40 CFR Part 192 at CERCLA sites with radioactive contamination. In particular it clarifies the intent of 40 CFR Part 192 in setting remediation levels for subsurface soil, Also, Thorium-230 and Thorium-232 should be cleaned up to the same concentrations as their radium progeny (5 and 15 pCi/g).		Not an ARAR but potentially a TBC for the Buffer Zone/ Crossroad Property	As this is only guidance, it is not an ARAR. As 40 CFR 192 is considered to be potentially relevant and appropriate for the radiologically-impacted soil on the Buffer Zone/Crossroad Property, this guidance would be a TBC for alternatives that include excavation of soil from these properties.
			Radium 226 +228	5 pCi/g plus background		
			Thorium 230 +232	5 pCi/g plus background		

Table 3-2: Preliminary Identification of Potential Location-Specific ARARs and TBC Criteria

Citation	Location	Requirement	Preliminary Determination	Remarks
Archeological and Historic Preservation Act (54 USC 312508; PL 113-287; 128 Stat. 3256)	Land	Data recovery and preservation activities should be conducted if prehistoric, historical, and archaelogical data might be destroyed as a result of a federal, federally assisted, or federally licensed activity or program.	Potentially applicable	No destruction of such data is expected to result from remedial action. The Site has been considerably disturbed by past human activities and is therefore not expected to contain any such data. However, if these data were affected, *e.g.*, at any potential off-site borrow area, the requirement would be applicable.
Endangered Species Act, as amended [16 USC 1531-1544; 50 CFR Part 17]	Any	Federal agencies should ensure that any action authorized, funded, or carried out by the agency is not likely to jeopardize the continued existence of any threatened or endangered species or destroy or adversely modify any critical habitat.	Potentially applicable	No critical habitat has been identified in the affected area, and no adverse impacts to threatened or endangered species are expected to result from any remedial action. However, if such species were affected, the requirement would be applicable. An assessment of the potential for occurrences of threatened or endangered species was performed during the RI. No federal listed or proposed threatened and endangered species or their habitats were identified at or in the vicinity of the Site.
Missouri Wildlife Code (1989) (RSMo. 252.240; 3 CSR 10-4.111), Endangered Species	Any	Endangered species, i.e., those designated by the U.S. Department of the Interior and the Missouri Department of Conservation as threatened or endangered (see1978 Code, RSMo. 252.040), should not be pursued, taken, possessed, or killed.	Potentially applicable	No critical habitat has been identified in the affected area, and no adverse impacts to threatened or endangered species are expected to result from any remedial action. However, if such species were affected, the requirement would be applicable.
Floodplain Management [Executive Order 11988; 40 CFR 6.302(b)]	Floodplain	Federal agencies should avoid, to the maximum extent possible, any adverse impacts associated with direct and indirect development of a floodplain.	Potentially applicable	This requirement may be applicable to any remedial action for the Buffer Zone/Crossroad Property. Mitigative measures would be taken to minimize any adverse impacts.

Table 3-2: Preliminary Identification of Potential Location-Specific ARARs and TBC Criteria

Citation	Location	Requirement	Preliminary Determination	Remarks
Governor's Executive Order 82-19	Floodplain	Potential effects of actions taken in a floodplain should be evaluated to avoid adverse impacts.	Potentially applicable	This requirement may be applicable to any remedial action for the Buffer Zone/Crossroad Property. Mitigative measures would be taken to minimize any adverse impacts.
Clean Water Act (33 USC 1344); Disposal Sites Specifications(40 CFR 230), Dredged or Fill Material Discharges (Section 404 Program); Definitions, Exempt Activities Not Requiring Permits (40 CFR 232); State Program Regulations (40 CFR 233); General Regulatory Policies (33 CFR 320); Nationwide Permits (33 CFR 330)	Wetland	Dredge or fill material is not to be discharged into a wetland (as defined by the U.S. Army Corps of Engineers) without a permit.	Potentially applicable	This requirement could be applicable to any off-site borrow area if the location selected contains any wetlands or if the borrow activities could indirectly impact wetlands. No wetlands have been identified on-site.
Farmland Protection Policy Act (7 USC 4201 et seq.) Farmland Protection [7 CFR 658; 40 CFR 6.302(c)]	Farmland (prime, unique, or of state and local importance)	Federal agencies should take steps to ensure that federal actions do not cause U.S. farmland to be irreversibly converted to nonagricultural uses in cases in which other national interests do not override the importance of the protection of farmland or otherwise outweigh the benefits of maintaining farmland resources. Criteria developed by the U.S. Soil Conservation Service are to be used to identify and take into account the adverse effects of federal programs on farmland preservation. Federal agencies should consider alternative actions that could lessen adverse effects and should ensure that programs are compatible with state and local government and private programs and policies to protect farmland.	Potentailly applicable	This requirement would be applicable for any potential soil borrow area off-site. Mitigative measures and restoration activities would also be conducted at any off-site borrow area, as appropriate, to minimize any adverse impacts to farmland.

Table 3-2: Preliminary Identification of Potential Location-Specific ARARs and TBC Criteria

Citation	Location	Requirement	Preliminary Determination	Remarks
RCRA Subtitle D (40 CFR Part 258 Subpart B) and MDNR Solid Waste Regulations (10 CSR 80-3.010 (4)(B)(1))	Proximity of solid waste landfills to the end of runways used for turbojet aircraft	Requires new or existing municipal solid waste landfills or lateral expansions that are located within 10,000 ft of any airport runway end used by turbojet aircraft to demonstrate that the units are designed and operated so that the municipal solid waste landfill unit does not pose a bird hazard to aircraft.	Not applicable Potentially relevant and appropriate to the ROD-remedy and "complete rad removal" and partial excavation alternatives	As the OU-1 portion of the West Lake landfill closed in the 1970's, this requirement is not applicable to Areas 1 and 2. The ROD-remedy, "complete rad removal", and partial excavation alternatives include regrading of existing solid waste in Areas 1 and 2. This requirement may potentially be relevant and appropriate to these alternatives.
RCRA Subtitle D (40 CFR Part 258 Subpart B) and MDNR Solid Waste Regulations (10 CSR 80-3.010 (4)(B))	Landfill site selection	Sets forth criteria for site selection for new landfills and horizontal expansions of existing sanitary landfills and requirements for design and operation plans for sanitary landfills. Site selection criteria include (1) proximity to airport runways (see discussion above), floodplains, wetlands, seismic zones and faults, and unstable areas. Also sets out required demonstrations for liners placed near the depth of groudnwater.	Not applicable nor relevant and appropriate	No new landfills or horizontal expansion of existing landfills would be constructed under any of the remedial alternatives.
Missouri Guidance for Conducting and Reporting Detailed Geologic and Hydrogeologic Investigations at a Proposed Solid-Waste Disposal Area 10 CSR 80-2.015 Appendix 1	Landfill site selection	Provides general procedures for characterization of potential solid waste landfill sites	Not applicable nor relevant and appropriate	No new solid waste diposal areas would be proposed under any of the remedial alternatives.

Table 3-3: Preliminary Identification of Potential Action-Specific ARARs and TBC Criteria

Citation	Action	Medium	Requirement	Preliminary Determination	Remarks
Health and Environmental Protection Standards for Uranium and Thorium Mill Tailings (40 CFR 192), Subpart A, Standards for the Control of Residual Radioactive Materials from Inactive Uranium Processing Sites	Radioactive waste disposal		Control of residual radioactive materials at designated uranium processing or depository sites should be designed to be effective for at least 200 years and up to 1,000 years, to the extent reasonably achievable. In addition, the control should be designed such that releases of radon-222 from the residual radioactive material would not exceed an average rate of 20 pCi/m2-s or increase the annual average concentration in air outside the disposal site by more than 0.5 pCi/L. Because this standard applies to design, monitoring after disposal is not required to demonstrate compliance.	Not applicable but potentially relevant and appropriate in part for ROD-remedy and partial excavation alternatives	The West Lake Landfill OU-1 Site is not a designated Title I uranium mill tailings site; therefore, this requirement would not be applicable. These regulations are applicable to uncontrolled areas, whereas the current and future uses of Areas 1 and 2 are restricted. As OU-1 does contain radiologically-impacted materials, these requirements may potentially be relevant; however, the radiologically-impacted materials at the Site are a small fraction of an overall matrix of municipal solid waste, debris and fill materials. Although the waste materials are not similar to uranium tailings, the wastes do contain radium and thorium; therefore the longevity standard is potentially relevant and appropriate. As the radiologically-impacted materials do emit radon, the radon standard is potentially relevant and appropriate. For the ROD-remedy and partial excavation alternatives, radiologically-impacted materials will remain past the post-closure period for a solid waste landfill and longevity considerations should be factored into the cover design.
Health and Environmental Protection Standards for Uranium and Thorium Mill Tailings (40 CFR 192), Subpart D, Standards for Management of Uranium Byproduct Materials Pursuant to Section 84 of the U.S. Atomic Energy Act of 1954, as amended; Subpart E, Standards for Management of Thorium Byproduct Materials Pursuant to Section 84 of the U.S. Atomic Energy Act of 1954, as amended.	Radioactive waste disposal		Disposal areas for uranium and thorium by-product materials should be designed to be effective for at least 200 years and up to 1,000 years, to the extent reasonably achievable. In addition, the control should be designed so that releases of radon-222 and radon-220 from these materials (*i.e.* , excluding the cover) would not exceed an average of 20 pCi/m2-s. The standard applies to design, so monitoring for radon after installation of an appropriately designed cover is not required. (This requirement does not apply to any portion of the Site that contains residual surface and subsurface concentrations of radium-226 and radium-228 at or below those identified in Subparts B and E, respectively, which were described under potential chemical-specific ARARs and TBCs.)	Not applicable but potentially relevant and appropriate in part for the ROD-remedy and partial excavation alternatives	The West Lake Landfill OU-1 Site is not a designated Title I uranium mill tailings site. Therefore, this requirement would not be applicable. These regulations are applicable to uncontrolled areas whereas the current and future uses of Areas 1 and 2 are restricted. As OU-1 does contain radiologically impacted materials, these requirements may potentially be relevant; however, the radiologically-impacted materials at the Site are a small fraction of an overall matrix of municipal solid waste, debris and fill materials. Although the waste materials at West Lake Site are not similar to uranium mill tailings, the wastes do contain radium . and thorium; therefore the longevity standard is potentially relevant and appropriate. As the radiologically impacted materials will remain on-site beyond the 30-year post-closure period for a solid waste landfill, the 200/1000 year period, this standard is considered to be potentially relevant and appropriate.

Table 3-3: Preliminary Identification of Potential Action-Specific ARARs and TBC Criteria

Citation	Action	Medium	Requirement	Preliminary Determination	Remarks
Resource Conservation and Recovery Act (RCRA) Subtitle C (40 CFR 240 et seq.)	Hazardous waste management		Establishes standards for identification of and treatment, storage and disposal of hazardous wastes including hazardous wastes disposed in landfills. Standards for Identification of hazardous wastes (40 CFR 261) Standards for Generators of hazardous wastes (40 CFR 262) Standards for Transporters of hazardous wastes (40 CFR 263) Use and Management of Containers (40 CFR 264 Subpart I) Land Disposal Restrictions (40 CFR 264 Subpart N) Staging Piles (40 CFR 264.554)	Possibly applicable in the event that hazardous wastes or materials that potentially could be hazardous wastes are encountered during remedy implementation	The radiologically-impacted materials in Areas 1 and 2 do not meet the criteria for classification as hazardous wastes; however, other waste materials in Areas 1 or 2 may meet these criteria and as such these requirements may be applicable. The Subtitle D standards are considered to be the appropriate criteria for final cover design.
Solid Waste Disposal Act, as amended (42 USC 6901 et seq.); Criteria for Municipal Solid Waste Landfills (40 CFR 258), Subpart F, Closure and Post-Closure Care	Solid waste disposal		Criteria for closure of a landfill unit and post-closure care requirements are specified. Cover system design requirements at closure include (1) an infiltration layer constructed of a minimum of 18 in. of earthen material with a permeability less than or equal to the permeability of the bottom liner system or no greater than 1 x 10-5 cm/s, whichever is less, and (2) an erosion protectin layer of earthen material capable of supporting native plant growth; or equivalents approved by the director of an approved state program. Post-closure care requires maintenance of the integrity of the final cover system, the leachate collection system, ground-water monitoring, and gas monitoring for a period of 10 years or as necessary to protect human health and the envrionment. Management of the leachate may be terminated if the owner/ operator demonstrates that leachate no longer poses a threat to human health and the environment	Neither applicable nor relevant and appropriate	Neither applicable nor relevant and appropriate as solid waste landfills in Missouri are regulated by the Missouri solid waste regulations.
Missouri Radiation Regulations; Protection Against Ionizing Radiation (19 CSR 20-10.090), Disposal of Radioactive Wastes	Radioactive waste disposal		Radioactive waste material should not be disposed of by dumping or burial in soil, except at sites approved by and registered with the Missouri Department of Health; a permit should be obtained for holding and preparation of such material prior to disposal; and no releases to air or water should cause exposure of any person above the limits specified in 10-CSR 20-10.040.	Potentially applicable to the "complete rad removal" and partial excavation with off-site disposal alternatives	Certain of these requirements would be potentially applicable if one of the alternatives involving off-site disposal were to be implemented
Missouri Radiation Regulations; Protection Against Ionizing Radiation (19 CSR 20-10.070), Storage of Radioactive Materials	Radioactive waste storage		Radioactive materials should be stored in a manner that will not result in the exposure of any person, during routine access to a controlled area, in excess of the limits identified in 19 CSR 20-10.040 (see related discussion for contaminant-specific requirements); a facility used to store materials that may emit radioactive gases or airborne particulate matter should be vented to ensure that the concentration of such substances in air does not constitute a radiation hazard; and provisions should be made to minimize hazards to emergency workers in the event of a fire, earthquake, flood, or windstorm.	Potentially applicable	These requirements would be applicable to the temporary storage of radiologically-impacted soils that might be generated during any remedial action.

Table 3-3: Preliminary Identification of Potential Action-Specific ARARs and TBC Criteria

Citation	Action	Medium	Requirement	Preliminary Determination	Remarks
Missouri Solid Waste Rules (10 CSR 80), Chapter 3, Sanitary Landfills, 3.010(17), Cover	Solid waste disposal		The landfill should be covered to minimize fire hazard, infiltration of precipitation, odors and blowing litter; control gas venting and vectors; discourage scavenging; and provide a pleasing appearance. Final slope of the top shall be a minimum of 5%. No slopes shall ever exceed 33 1/3 % and slopes shall not exceed 25% without a detailed slope stability analysis. The final cover should be at least 2 ft of compacted clay with a permeability of 1 x 10^{-5} cm/sec or less overlain by 1 ft of soil capable of supporting vegetative growth.	Only applicable if Areas 1 or 2 are re-opened to accept additional solid wastes. Potentially relevant and appropriate for design of the final cover	These requirements are not applicable as they only apply to landfills in operation after 10-9-91. These requirements would be applicable to regrading of Areas 1 and 2 after removal of radiologically-impacted material under the "complete rad removal" and partial excavation alternatives. These regulations would also be applicable to the final slopes and cover design for Areas 1 and 2 under the ROD-selected remedy , "complete rad removal", and partial excavation alternatives except that the slopes would be a minimum of 2% (seee discussion in text).
Missouri Solid Waste Rules (10 CSR 80), Chapter 4, Demolition Landfills, 4.010(17), Cover	Solid waste disposal		The landfill should be covered to minimize fire hazard, infiltration of precipitation, odors and blowing litter; control gas venting and vectors; discourage scavenging; and provide a pleasing appearance. Final slope of the top shall be a minimum of 5%. No slopes shall ever exceed 33 1/3 % and slopes shall not exceed 25% without a detailed slope stability analysis. The final cover should be at least 1 ft of compacted clay with a permeability of 1 x 10^{-5} cm/sec or less overlain by 2 ft of soil capable of supporting vegetative growth.	Only applicable if Areas 1 or 2 are re-opened to accept additional solid wastes. Potentially relevant and appropriate for design of the final cover	These requirements are not applicable as they only apply to landfills in operation after 10-9-91. These requirements would be applicable to regrading of Areas 1 and 2 after removal of radiologically-impacted material under the "complete rad removal" and partial excavation alternatives. These regulations would also be applicable to the final slopes and cover design for Areas 1 and 2 under the ROD-selected remedy , "complete rad removal", and partial excavation alternatives except that the slopes would be a minimum of 2% (seee discussion in text).
Noise Control Act, as Amended; Noise Pollution and Abatement Act (42 USC 4901 et seq)	Construction activities		The public should be protected from noises that jeopardize human health or welfare.	Potentially applicable	These requirements would be applicable to any remedial action.
CERCLA Offsite Rule 40 CFR 300.440	Off-site disposal		Wastes can only be disposed at offsite facilities operating in compliance with applicable regulations as verified by EPA.	Applicable to off-site disposal	These requirements would be applicable to the "complete rad removal" and partial excavation with off-site disposal alternatives.
DOT and NRC regulations for shipment of radioactive materials 49 CFR Parts 171-180 and 10 CFR Part 71	Off-site disposal		Specifies requirements for shipment of radioactive materials including hazard communications, labeling, manifests, security, emergency response, and planning.	Applicable to off-site disposal	These requirements would be applicable to the "complete rad removal" and partial excavation with off-site disposal alternatives.
Offsite disposal Waste Acceptance Criteria	Off-site disposal		Lists the types of materials and activity levels of waste materials that can be accepted by off-site disposal facilities.	Applicable to off-site disposal	These requirements would be applicable to the "complete rad removal" and partial excavation with off-site disposal alternatives.
National Emissions Standards for Hazardous Air Pollutants - Asbestos 40 CFR Part 61	Asbestos management	Waste	Requirements for management of regulated asbestos containing materials (RACM)	Potentially applicable if RACM are encountered during remedy implementation	Standards for demolition and renovation may be applicable in the event that RACM is encountered during remedy implementation.
National Ambient Air Quality Standards	Radionuclides	Air	Air quality standards	Potentially applicable	Potential standards for air emissions during remedy

Table 3-3: Preliminary Identification of Potential Action-Specific ARARs and TBC Criteria

Citation	Action	Medium	Requirement	Preliminary Determination	Remarks
40 CFR 50	Radon and Particulates				implementation.
PCB Spill Cleanup Policy 40 CFR 761 Subpart G Cleanup Site Characterization Sampling for PCB Remediation Waste 40 CFR 761 Subpart N Sampling to Verify Completion of Self-Implementing Cleanup and On-Site Disposal of Bulk PCB Remediation Waste and Porous Surfaces 40 CFR 761 Subpart O Sampling Non-Porous Surfaces for Measurement-Based Use, Reuse and On-Site or Off-Site Disposal 40 CFR 761 Subpart P Sampling Non-Liquid, Non-Metal PCB Bulk Product Waste for Purposes of Characterization for PCB Disposal and Sampling PCB Remediation Waste Destined for Off-Site Disposal 40 CFR 761 Subpart R Double Wash/Rinse Method for Decontaminating Non-Porous Surfaces 40 CFR 761 Subpart S	PCB cleanup and management	Soil or waste	Requirements for cleanup of PCB wastes	Potentially applicable if PCBs are encountered during remedy implementation	Sets out procedures for cleanup of PCB wastes.
Missouri Storm Water Regulations 10 CSR 20-6.200		Storm-water	Requirements for control of stormwater runoff	Potentially applicable	Substantive requirements are potentially applicable for control of storm water runoff during and after remedy construction.
De Minimis Emissions Levels 10 CSR 10-6.020(3)(A)	PM-10 Non-methane organic compounds (NMOC)		Air quality standards	Potentially applicable	Potential standards for air emissions during remedy implementation.
Sampling Methods for Air Pollution Sources 10 CSR 10-6.030		Air	Stack emissions sampling procedures	Potentially applicable	Potentially applicable if a landfill gas flare is constructed and operated as part of the remedy.
Controlling Emissions During Episodes of High Air Pollution Potential 10 CSR 10-6.130		Air	Requirements for controlling emissions during air pollution events	Potentially applicable	Potentially could require shut down of remedy implementation construction operations during a purple or maroon air quality event.
Restriction of Particulate Matter to the Ambient Air Beyond the Premises of Origin 10 CSR-6.170	Particulate Matter	Air	Requirements for controlling emissions	Potentially applicable	Potentially applicable to the control of fugitive dust emissions during remedy construction activities.

Table 3-3: Preliminary Identification of Potential Action-Specific ARARs and TBC Criteria

Citation	Action	Medium	Requirement	Preliminary Determination	Remarks
Closure and Post-Closure Plan Laidlaw Waste Systems (Bridgeton), Inc. Sanitary Landfill, December 1996, Revised September 1997, Revised April 1998, Revised April 2016	Landfill cover		Sets out closure and post-closure procedures for the West Lake Landfill, in particluar, the final cover, grading and vegetation plan.	Potential TBC	Sets out the procedures to be used at the Landfill to comply with the MDNR Solid Waste Regulations. This document should be considered in the design and construction of any cover system or drainage improvements that may be constructed for Areas 1 and 2 or if aditional waste materials are placed in these areas as part of a remedial action. This docment will also need to be considered if any regrading and/or landfill cover improvements are implemented for Areas 1 or 2.

Table 6-1: Summary of Estimated Costs

DRAFT

Estimated Cost	No Action Alternative		ROD-Selected Remedy		"Complete Rad Removal" 7.9 pCi/g Excavation Alternative		Partial Excavation Alternatives: 52.9 pCi/g		Partial Excavation Alternatives: 1,000 pCi/g	
	i = 7%	*i = 1.5%*	*i = 7%*	*i = 1.5%*	*i = 7%*	*i = 1.5%*	*i = 7%*	*i = 1.5%*	*i = 7%*	*i = 1.5%*
Capital ($M)	0		67		616		313		361	
Operation, Maintenance, and Monitoring ($1,000/yr)	35 every 5 years		167 - 326		167 - 326		167 - 326		167 - 326	
30 year:										
Present Worth ($M)	0.1	0.2	64	70	420	566	265	305	275	342
Non-discounted Total ($M)	0.2	0.2	73	73	619	619	318	318	365	365
200 year:										
Present Worth ($M)	0.1	0.4	64	77	421	573	265	312	276	349
Non-discounted Total ($M)	1	1	102	102	649	649	348	348	395	395
1,000 year:										
Present Worth ($M)	0.1	0.5	64	78	421	573	265	312	276	350
Non-discounted Total ($M)	7	7	241	241	788	788	487	487	534	534

Note: These cost estimates are feasibility level cost estimates; that is they were developed to a level of accuracy such that the actual costs incurred to implement the alternatives should fall within a range bounded by 50% above and 30% below these estimates.

Table 6-2: Comparison of USEI Waste Acceptance Criteria to Projected OU-1 RIM Concentrations

DRAFT

"Complete Rad Removal" Alternative (removal of RIM to 7.9 pCi/g total Thorium or Radium)

USEI Category	WAC Criteria		OU-1 RIM Concentrations per Conveyance or Container					
	Maximum Concentration of Insitu Material	Sum of Concentrations of Parents and all Progeny	Activity Concentration (pCi/g)		Mass Concentration (ppm)		Series Activity, Assuming Equilibrium with Parent (pCi/g)	
Radionuclide			Area 1	Area 2	Area 1	Area 2	Area 1[a]	Area 2[a]
Unimportant Quantities of Source Material Uniformly Dispersed in Soil or Other Media								
Natural uranium in equilibrium with progeny[b]	<500 ppm Unat or 167 pCi ^{238}U/g	≤ 3,000 pCi/g	4.0	51.1	5.6	72.5	16 (3 dtrs)	204 (3 dtrs)
^{230}Th	0.1 ppm or ≤ 2,000 pCi/g	NC [c]	52	300	0.003	0.015	52 (0 dtrs)	300 (0 dtrs)
Natural thorium (^{232}Th + ^{228}Th)	<500 ppm or 110 pCi/g	≤ 2,000 pCi/g	3.9	8.6	17.9	39.0	39 (9 dtrs)	86 (9 dtrs)
Mixture of Thorium and Uranium	Sum of ratios ≤ 1	≤ 2,000 pCi/g	0.04	0.27	NA [d]	NA [d]	0.1	0.3[e]
Naturally Occurring Radioactive Material other than Uranium and Thorium Uniformly Dispersed in Soil or Other Media								
^{226}Ra w/ progeny in bulk form	500 pCi/g	≤ 4,500 pCi/g	33.4	129	0.00003	0.00013	200 (5 dtrs)	773 (5 dtrs)
^{210}Pb with ^{210}Bi and ^{210}Po	1,500 pCi/g	≤ 1,500 pCi/g	6.2	27.1	0.0000001	0.0000004	19 (2 dtrs)	81 (2 dtrs)

a () in this column indicate the number decays the parent atom undergoes before becoming a stable isotope.
b 238U used as surrogate for U nat. Assumes natural isotopic abundance of 238U, 235U and 234U.
c NC = Not calculated. Daughter activity accounted for in Radium-226 line item.
d NA = Not applicable, see activity concentration.
e Insitu activity in Area 2 may exceed WAC at times. Must control excavation and handling while monitoring outbound loads.

Table 6-3: Comparison of USEI Waste Acceptance Criteria to Projected OU-1 RIM Concentrations

DRAFT

Partial Excavation of Shallow RIM with Activities above 52.9 pCi/g total Thorium or Radium

USEI Category	WAC Criteria		OU-1 RIM Concentrations per Conveyance or Container					
	Maximum Concentration of Insitu Material	Sum of Concentrations of Parents and all Progeny	Activity Concentration (pCi/g)		Mass Concentration (ppm)		Series Activity, Assuming Equilibrium with Parent (pCi/g)	
Radionuclide			Area 1	Area 2	Area 1	Area 2	Area 1[a]	Area 2[a]
Unimportant Quantities of Source Material Uniformly Dispersed in Soil or Other Media								
Natural uranium in equilibrium with progeny[b]	<500 ppm Unat or 167 pCi ^{238}U/g	≤ 3,000 pCi/g	19	91	27	130	76 (3 dtrs)	363 (3 dtrs)
^{230}Th	0.1 ppm or ≤ 2,000 pCi/g	NC [c]	250	529	0.01	0.03	250 (0 dtrs)	529 (0 dtrs)
Natural thorium (^{232}Th + ^{228}Th)	<500 ppm or 110 pCi/g	≤ 2,000 pCi/g	18.5	15.2	84	69	185 (9 dtrs)	152 (9 dtrs)
Mixture of Thorium and Uranium	Sum of ratios ≤ 1	≤ 2,000 pCi/g	0.20	0.48	NA [d]	NA [d]	0.3	0.5[e]
Naturally Occurring Radioactive Material other than Uranium and Thorium Uniformly Dispersed in Soil or Other Media								
^{226}Ra w/ progeny in bulk form	500 pCi/g	≤ 4,500 pCi/g	157	229	0.00016	0.00023	939 (5 dtrs)	1373 (5 dtrs)
^{210}Pb with ^{210}Bi and ^{210}Po	1,500 pCi/g	≤ 1,500 pCi/g	29	48	0.0000004	0.0000006	87 (2 dtrs)	144 (2 dtrs)

a () in this column indicate the number decays the parent atom undergoes before becoming a stable isotope.
b 238U used as surrogate for U nat. Assumes natural isotopic abundance of 238U, 235U and 234U.
c NC = Not calculated. Daughter activity accounted for in Radium-226 line item.
d NA = Not applicable, see activity concentration.
e Insitu activity in Area 2 may exceed WAC at times. Must control excavation and handling while monitoring outbound loads.

Table 6-4: Comparison of USEI Waste Acceptance Criteria to Projected OU-1 RIM Concentrations

DRAFT

Partial Excavation of RIM with Activities above 1,000 pCi/g total Thorium or Radium

USEI Category Radionuclide	WAC Criteria: Maximum Concentration of Insitu Material	WAC Criteria: Sum of Concentrations of Parents and all Progeny	Activity Concentration (pCi/g): Area 1	Activity Concentration (pCi/g): Area 2	Mass Concentration (ppm): Area 1	Mass Concentration (ppm): Area 2	Series Activity, Assuming Equilibrium with Parent (pCi/g): Area 1[a]	Series Activity, Assuming Equilibrium with Parent (pCi/g): Area 2[a]

Table 7-1: Summary of Comparative Analysis of Alternatives DRAFT

Evaluation Criteria	No Action	ROD-Selected Remedy	52.9 Partial Excavation	1,000 Partial Excavation	"Complete Rad Removal"
THRESHOLD CRITERIA					
Overall Protection of Human Health and the Environment	Per the BRA, OU-1 does not currently pose unacceptable risks. Potential risks to a future groundskeeper may exceed EPA's acceptable risk range. Therefore, the No Action alternative is not protective.	All of the active remedial alternatives would be protective of human health and the environment. All remedial alternatives eliminate or reduce potential exposures to (1) external gamma radiation, (2) radon emissions, (3) inhalation or ingestion of contaminated soil or wastes, (4) dermal contact with contaminated soil or waste, and (5) dispersal of contaminants in fugitive dust. All of the remedial alternatives would reduce potential infiltration of precipitation into the waste and thereby reduce the potential for leaching to groundwater. All remedial alternatives include institutional controls to ensure that only land and resource uses that are consistent with the remedy and protective of human health and the environment are allowed in the future.			
Compliance with ARARs					
Compliance with Chemical-Specific ARARs	Chemical-specific ARARs are currently being met, however, continued compliance with these standards cannot be ensured without installation and maintenance of additional engineering controls and enforcement of institutional controls.	All of the remedial alternatives would comply with chemical-specific ARARs, including (1) UMTRCA standards for radon emissions, maximum concentrations for groundwater protection, and cleanup of contaminated land, as modified by the EPA OSWER Directives regarding use of these standards at Superfund sites (Buffer Zone and Crossroad Property); (2) radon NESHAP; (3) Nuclear Regulatory Commission (NRC) radiation protection standards, and (4) Missouri maximum contaminant levels (MCLs).			
Compliance with Location-Specific ARARs	Conditions associated with OU-1 comply with the location-specific ARARs	All of the remedial alternatives would meet the location-specific ARARs found in the Missouri solid waste regulations standards for landfills located within the 100-year floodplain or within 10,000 feet of an airport runway. Waste excavation under the complete and partial excavation alternatives and waste regrading activities under all of the alternatives would need to be performed in a manner that minimizes attractions for birds. Specifically, an avian management plan that incorporates the various techniques described in Section 4.3.6.2 of this FFS would need to be developed and approved by EPA and MDNR.			

Evaluation Criteria	No Action	ROD-Selected Remedy	52.9 Partial Excavation	1,000 Partial Excavation	"Complete Rad Removal"
Compliance with ARARs (cont.)					
Compliance with Action-Specific ARARs	No actions would be taken under this alternative and therefore, there are no action-specific ARARs.	Would meet action-specific ARARs, including the Missouri solid waste regulations closure and post-closure standards; the NRC radiation protection standards; the UMTRCA standards for longevity of disposal facilities; and the Missouri noise protection standards during implementation of a remedial action and closure of Areas 1 and 2.	Would meet action-specific ARARs, including the Missouri solid waste regulation closure and post-closure standards; the NRC radiation protection standards; the UMTRCA standards for longevity of disposal facilities; the Missouri noise protection standards during implementation of a remedial action and closure of Areas 1 and 2; DOT and NRC standards for shipment of radioactive wastes; and offsite disposal facility waste acceptance criteria.		
PRIMARY BALANCING CRITERIA					
Long-Term Effectiveness and Permanence					
Magnitude of residual risks	Projected long-term risks to a site groundskeeper exceed EPA's acceptable risk range.	All of the alternatives would result in projected long-term risks that far are below EPA's target risk range of 10^{-4} to 10^{-6}.			
Adequacy and reliability of controls	Not applicable as no controls would be implemented.	Engineering measures would be augmented and supported by existing and additional institutional controls which also have been used at numerous solid waste and NCP sites.			

Evaluation Criteria	No Action	ROD-Selected Remedy	52.9 Partial Excavation	1,000 Partial Excavation	"Complete Rad Removal"
Long-Term Effectiveness and Permanence (cont.)					
Climate Change and Tornado Impacts	Not applicable as no engineered controls would be implemented.	• Increased temperatures or decreased precipitation could damage the vegetation cover or dry out the low-permeability layer included in the landfill cover included as part of all of the alternatives. • Increased heavy precipitation could erode the vegetation layer and potentially the underlying low-permeability layer; however, the presence of the underlying rock/rubble layer is expected to prevent exposure of the underlying waste materials, except for the "complete rad removal" alternative, which does not include the rock/rubble layer. • None of the alternatives are expected to be impacted by flooding that may occur in the area because Areas 1 and 2 are not located in the floodplain.			
Impacts from a Subsurface Heating Event	The only impact that may occur from subsurface heating is a temporary, localized increase in radon emissions; however, the total emissions from the Site during such an event is projected to remain below the UMTRCA standard and radon NESHAP.				
Thermal Isolation Barrier (IB) interaction	Not applicable as no engineered controls would be implemented.	• No adverse impacts or unacceptable risks are expected to result if an SSR or SSE were to extend into in Area 1; therefore, regardless of the location or type of IB that may be installed, or even if no barrier is installed, no unacceptable risks are expected to occur. • Installation of an IB is not expected to impact the performance of any of the alternatives; however, implementation of any of the excavation alternatives could impact the integrity of or potentially destroy an IB.			
Environmental Justice	A screening level analysis did not identify any environmental justice concerns relative to the Site. However, EPA did identify a need to utilize more traditional communication methods (US Mail) to inform residents of the Terrisan Reste mobile home park.				
Reduction of Toxicity, Mobility or Volume through Treatment					
	Not applicable as no actions would be implemented.	• None of the alternatives include treatment technologies that would reduce the toxicity, mobility or volume of waste material through treatment as a primary component. Treatment technologies are generally not applicable to the site wastes due to the nature and overall large volume of wastes, combined with the fact that radionuclides are naturally occurring elements that cannot be fully neutralized or destroyed by treatment. • All of the alternatives include off-site treatment and disposal of hazardous wastes in accordance with the RCRA regulations if any such wastes are encountered during implementation of the remedy.			

Evaluation Criteria	No Action	ROD-Selected Remedy	52.9 Partial Excavation	1,000 Partial Excavation	"Complete Rad Removal"
Short-Term Effectiveness					
Protection of the community during any remedial action					
Potential radiological or chemical exposures	Not applicable as no engineered controls would be implemented.	None of the alternatives are expected to pose unacceptable risks to the general public during remedy implementation. Projected total carcinogenic risks are less than 1 x 10^{-7} and projected hazard indices for non-carcinogenic effects were less than 0.001 for all of the alternatives.			
Waste excavation volumes (yards)	Not applicable as no waste would be moved	126,000	501,000	825,000	1,572,000
Projected incidence of transportation-related accidents	Not applicable as no engineered controls would be implemented	0.61	10.6	16.6	34.9
Greenhouse gas emissions (tons)	Not applicable as no actions would be taken	19,000	43,000	53,000	83,000
Environmental Justice	A screening level analysis did not identify any environmental justice concerns relative to the Site; however, EPA did identify a need to utilize more traditional communication methods (US Mail) to inform residents of the Terrisan Reste mobile home park.				
Protection of workers					
Protection of workers during remedial actions	Not applicable as no actions would be taken	Remediation workers could be exposed to gamma radiation resulting in potential cancer risks above the upper bound of EPA's target risk range of 10^{-4} and also to non-carcinogenic risks with a hazard index greater than 1 during implementation of any of the remedial alternatives. None of the alternatives are expected to result in radiation doses (TEDEs) greater than the 5,000 mrem/yr limit established by OSHA and NRC.			
Carcinogenic Risks	Not applicable	9.23 x 10^{-5}	1.18 x 10^{-3}	2.38 x 10^{-3}	2.19 x 10^{-3}
TEDEs	Not applicable	187	720	867	405
Hazard indices	Not applicable	1.22	1.22	1.22	1.22
Industrial accident incidence	Not applicable	2.76	8.47	11.7	17.8
Time until RAOs are achieved					
Time until RAOs are achieved	No Action will not achieve RAOs.	RAOs would be achieved upon completion of construction. No potential threats would remain after implementation of any of the alternatives.			
Construction completion (years) including design)	Not applicable as no construction would be performed.	2.7	5.9	9	13.4

Evaluation Criteria	No Action	ROD-Selected Remedy	52.9 Partial Excavation	1,000 Partial Excavation	"Complete Rad Removal"
Implementability					
Technical Feasibility	Not applicable as no actions would be taken	All of the alternatives are constructible.			
Reliability of the technologies	Not applicable as no engineered controls would be implemented.	Landfill cover systems have been used extensively and with proper inspection and maintenance have been demonstrated to be reliable. Stormwater controls and environmental monitoring are commonly used techniques that have been demonstrated to be reliable.	• Excavation and offsite disposal is a common and reliable technology. • Landfill cover systems have been used extensively and with proper inspection and maintenance have been demonstrated to be reliable. • Stormwater controls and environmental monitoring are commonly used and demonstrated reliable techniques. • Per the FAA, the reliability of most bird mitigation technologies are questionable. • There is uncertainty regarding the actual volumes of RIM that would need to be removed and the volume of daily cover that would be added resulting in uncertainty the actual disposal volume. • The ability to remove deeper occurrences of RIM adjacent to other (OU-2) solid waste units is a technical difficulty with this alternative and might result in schedule delays. • Reductions in the number of IM containers or rail cars or the frequency of exchange of full and empty rail cars could impact the schedule for this alternative. • Excavation of RIM would also present significant implementability concerns associated with the excavation and handling of contaminated materials; management of fugitive dust and potential odors; mitigation of bird hazards; management and treatment of stormwater exposed to RIM during excavation; management of RIM that fails the paint filter liquids test; and the identification, segregation, and disposal offsite of any hazardous wastes or regulated asbestos containing materials that may be encountered during RIM excavation. • Excavation of RIM would also present significant implementability concerns associated with the excavation and handling of contaminated materials; management of fugitive dust and potential		

Evaluation Criteria	No Action	ROD-Selected Remedy	52.9 Partial Excavation	1,000 Partial Excavation	"Complete Rad Removal"
Implementability (cont.)					
Reliability of the technologies (cont.)			• odors; mitigation of bird hazards; management and treatment of stormwater exposed to RIM during excavation; management of RIM that fails the paint filter liquids test; and the identification, segregation, and disposal offsite of any hazardous wastes or regulated asbestos containing materials that may be encountered during RIM excavation.		
Ease of undertaking additional remedial actions	Not applicable as no actions would be taken under this alternative.	• The only future actions anticipated to be required for all of the alternatives are ongoing inspection, monitoring, maintenance and, if needed, repair of the final landfill covers. Each of these future actions can be easily implemented. • All of the alternatives include a provision for a contingent landfill gas control system in the event the monitoring of subsurface occurrences of landfill gas or radon indicates a need for such a system. Implementation of such a system is expected to be simple and straightforward and should not pose any difficulties			
Monitoring considerations	No monitoring would be performed.	Performance of all the alternatives can be monitored and potential risk of exposure in the event of failure of any of the alternatives would be low.			
Administrative Feasibility	Not applicable as no engineered controls or additional institutional controls would be implemented.	All of the alternatives could require: • coordination and permitting with MSD for disposal of leachate during construction; • access to Crossroad Property for investigation/removal of soil; • coordination with Earth City Flood Control District for design and operation of long-term stormwater management systems; and • preparation and approval of a traffic control plan for St. Charles Rock Road.			
Administrative Feasibility (cont.)			Alternatives that include off-site disposal would also require • Routine approval and verification of current acceptability for off-site disposal from EPA. • Use of the Clean Harbors facility for disposal would require approval by the Rocky Mountain Low Level Radioactive Waste Compact.		
Availability of Specialized Services and Materials	Not applicable as no engineered controls would be implemented.	Specialized personnel, equipment, and materials are readily available to implement the cover systems, institutional controls, and monitoring components of the remedial alternatives. The implementability and potential costs for all of the remedial alternatives will be influenced by the availability and location of clean fill materials and/or offsite soil borrow sources at the time the selected alternative is implemented.			

<table>
<tr><th>Evaluation Criteria</th><th>No Action</th><th>ROD-Selected Remedy</th><th>52.9 Partial Excavation</th><th>1,000 Partial Excavation</th><th>“Complete Rad Removal”</th></tr>
<tr><td colspan="6">Implementability (cont.)</td></tr>
<tr><td>Availability of Materials, Equipment, and Personnel</td><td>Not applicable as no engineered controls would be implemented.</td><td>Preliminary discussions with MSD indicate that it is willing and has sufficient capacity to accept leachate or stormwater that may be generated during construction. Alternatively, off-site disposal facilities are available to accept these materials if necessary</td><td colspan="3">• Materials, equipment and personnel required for excavation of the RIM and transport of RIM to an offsite disposal facility are readily available.
• Only a limited number of offsite disposal facilities exist that can accept excavated RIM from the West Lake Landfill. At this time, it is difficult to evaluate which disposal facilities that can currently accept wastes from the West Lake Landfill may be available in the future, or what their respective future capacities or waste acceptance criteria may be.
• The volumetric rate of acceptance for all offsite disposal facilities would also be a function of the availability of IM containers and the number of railcars that could be loaded at or near the Site, as well as the number of railcars that could be unloaded at or near the disposal facility.
• Preliminary discussions with MSD indicate that it is willing and has sufficient capacity to accept leachate or stormwater that may be generated during construction. Alternatively, off-site disposal facilities are available to accept these materials if necessary.</td></tr>
<tr><td>Availability of Technologies</td><td>Not applicable as no engineered controls would be implemented.</td><td>Technologies for this alternative are generally available and sufficiently demonstrated. No prospective technologies are anticipated as part of this alternative.</td><td colspan="3">Technologies included as part of these alternatives are generally available and sufficiently demonstrated. No prospective technologies are anticipated. Use of physical separation techniques could, if effective, reduce the overall cost of this alternative; however, the potential effectiveness, implementability, risks and cost of such techniques cannot be determined from available information. An on-site pilot-scale test would be necessary to make such determinations.</td></tr>

LEGEND

SPECIAL FLOOD HAZARD AREAS (SFHAs) SUBJECT TO INUNDATION BY THE 1% ANNUAL CHANCE FLOOD

The 1% annual chance flood (100-year flood), also known as the base flood, is the flood that has a 1% chance of being equaled or exceeded in any given year. The Special Flood Hazard Area is the area subject to flooding by the 1% annual chance flood. Areas of Special Flood Hazard include Zones A, AE, AH, AO, AR, A99, V, and VE. The Base Flood Elevation is the water-surface elevation of the 1% annual chance flood.

ZONE A	No Base Flood Elevations determined.
ZONE AE	Base Flood Elevations determined.
ZONE AH	Flood depths of 1 to 3 feet (usually areas of ponding); Base Flood Elevations determined.
ZONE AO	Flood depths of 1 to 3 feet (usually sheet flow on sloping terrain); average depths determined. For areas of alluvial fan flooding, velocities also determined.
ZONE AR	Special Flood Hazard Area formerly protected from the 1% annual chance flood by a flood control system that was subsequently decertified. Zone AR indicates that the former flood control system is being restored to provide protection from the 1% annual chance or greater flood.
ZONE A99	Area to be protected from 1% annual chance flood by a Federal flood protection system under construction; no Base Flood Elevations determined.
ZONE V	Coastal flood zone with velocity hazard (wave action); no Base Flood Elevations determined.
ZONE VE	Coastal flood zone with velocity hazard (wave action); Base Flood Elevations determined.

FLOODWAY AREAS IN ZONE AE

The floodway is the channel of a stream plus any adjacent floodplain areas that must be kept free of encroachment so that the 1% annual chance flood can be carried without substantial increases in flood heights.

OTHER FLOOD AREAS

ZONE X	Areas of 0.2% annual chance flood; areas of 1% annual chance flood with average depths of less than 1 foot or with drainage areas less than 1 square mile; and areas protected by levees from 1% annual chance flood.

OTHER AREAS

ZONE X	Areas determined to be outside the 0.2% annual chance floodplain.
ZONE D	Areas in which flood hazards are undetermined, but possible.

COASTAL BARRIER RESOURCES SYSTEM (CBRS) AREAS

OTHERWISE PROTECTED AREAS (OPAS)

CBRS areas and OPAs are normally located within or adjacent to Special Flood Hazard Areas.

	1% annual chance floodplain boundary
	0.2% annual chance floodplain boundary
	Floodway boundary
	Zone D boundary
	Boundary dividing Special Flood Hazard Areas of different Base Flood Elevations, flood depths, or flood velocities.
	CBRS and OPA boundary
	International, State, or County boundary
	Corporate, Extraterritorial Jurisdiction, or Urban Growth boundary
	Area Not Included boundary
	Military Reservation, Native American Lands boundary
513	Base Flood Elevation line and value; elevation in feet*
(EL 987)	Base Flood Elevation value where uniform within zone; elevation in feet*
	* Referenced to the North American Vertical Datum of 1988
A — A	Cross section line
23 ---- 23	Transect line
87°07'45", 32°22'30"	Geographic coordinates referenced to the North American Datum of 1983 (NAD 83)
$^{42}76^{000m}$E	1000-meter Universal Transverse Mercator grid values, zone 15
600000 FT	5000-foot grid ticks: Missouri State Plane coordinate system, east zone (FIPSZONE 2401), Transverse Mercator projection
DX5510 ×	Bench mark (see explanation in Notes to Users section of this FIRM panel)
● M1.5	River Mile

Figure 2-30

Chloride in Groundwater,
August 2012 Through November 2013

West Lake Landfill OU-1 Final Feasibility Study

EMSI Engineering Management Support, Inc.

GENERAL RESPONSE ACTION	REMEDIAL TECHNOLOGY	PROCESS OPTIONS	DESCRIPTION	IMPLEMENTABILITY SCREENING COMMENTS
No Action	See Figure 4-1 in FS (EMSI, 2006)			
Institutional Controls[1]	See Figure 4-1 in FS (EMSI, 2006)			
Monitoring	Long-term performance monitoring	Groundwater, surface water, sediment, landfill gas, and radon gas monitoring	Monitoring to evaluate site conditions over time and/or remedial action performance.	Potentially applicable.
	Short-term monitoring during construction	Perimeter environmental media air monitoring	Monitoring station contains low volume air sampler to collect airborne particulates and organic vapor samples for analysis of VOCs and radionuclide activity; continuous radon monitor; and radiation dosimeter. Data to be collected pre-, during, and post-remedial action.	Potentially applicable. Would be required during construction of any remedy to monitor doses, activities, and concentrations at the fenceline and areas where workers will frequent, to assure that non-remediation workers present in other portions of the landfill site are not exposed, and to assure that remediation workers are not exposed to unnecessary radiation exposure.
		Work zone monitoring	Site workers would participate in medical and dosimetry monitoring programs. Breathing zone samplers might be assigned to selected workers to evaluate intake of airborne particulates and radon. Equipment and workers leaving radiologically-controlled area will be surveyed and decontaminated, if necessary.	Potentially applicable. Would be required during construction of any remedy.
		Excavation guidance/ clearance monitoring	Use of walkover field radiological survey equipment and solids sampling to identify impacted materials above cleanup levels to guide excavation equipment. Final walkover radiological scans of exposed faces and base of excavated areas and sampling of soil/trash at base of excavation to document that RIM have been removed.	Potentially applicable. Would be required during construction of any remedy if RIM were to be relocated.
		Waste acceptance monitoring	If excavated RIM were to be disposed off-site, each load of material removed from the site would be scanned to ensure that the radiological Waste Acceptance Criteria of the facility where the RIM would disposed would be met.	Potentially applicable. Would be required if RIM is to be disposed off-site.
		Post cover construction radon flux monitoring	Use of Large Area Activated Charcoal Canisters (LAACCs) to measure radon flux of the cover surface after construction is complete.	Potentially applicable. Would be required during construction of any remedy if radionuclides remain under the cover.

[1] Indicates that General Response Action or remedial technology is component of presumptive remedy for CERCLA municipal landfill sites (USEPA, 1993)

[2] Treatment technology or remedial technology specified in Technology Reference Guide for Radioactively Contaminated Media, EPA 402-R-07-004, October 2007.

(hatched box) Technology and/or Process Option screened out on the basis of technical implementability.

Figure 4-1
Technical Implementability Screening of Remediation Technologies and Process Options
West Lake Landfill OU-1 Final Feasibility Study

EMSI Engineering Management Support, Inc.

GENERAL RESPONSE ACTION	REMEDIAL TECHNOLOGY	PROCESS OPTIONS	DESCRIPTION	IMPLEMENTABILITY SCREENING COMMENTS
Containment	See Figure 4-1 in FS (EMSI, 2006) for Surface Controls/Diversions, Surface Water/Sediment Control/Barriers, and Dust Controls			
	Capping and Covers[1,2]	Soil, clay, and vegetation; asphalt or concrete; synthetic membrane material; and multilayer, multimedia material	Capping can limit contaminant mobility and mitigate potential migration via air, surface water, and groundwater by attenuating radon emissions and controlling particulate resuspension, storm water run-on and runoff, and precipitation-enhanced percolation and leaching. These processes can be implemented with conventional equipment.	Potentially applicable.
	Land Encapsulation[2]	On-site: New Cell[2]	New cell would be constructed in area of the site outside geomorphic flood plain. Cell would consist of engineered liner and a final cover consistent with both MDNR solid waste regulations and UMTRCA requirements.	EPA requested that a new on-site cell be evaluated in the SFS (EMSI, 2011) but is not requiring its consideration in the FFS.
		Off-site Licensed Facility[2]	This option would involve incorporation of removed material at an existing acceptable permitted commercial disposal facility. Land based disposal can reduce the mobility of contaminated material and mitigate potential exposures and migration by controlling the contaminant source. In addition to engineering requirements, constraints include issues such as transportation routes and risks, costs for off-site disposal and regulatory community acceptance.	EPA has requested that this be evaluated as potentially applicable. Waste Acceptance Criteria of disposal facility must be met for all material prior to the material being transported. Wastes hauled offsite to an offsite licensed facility must be shipped in appropriate containers and USDOT requirements for shipping must be met.
	Cryogenic Barriers[2]	Subsurface Cryogenic Barrier[2]	Provides containment and reduces the mobility of radionuclide contaminants by freezing contaminated subsurface soils to create an ice barrier around a contaminated zone. Rows of freeze pipes are inserted in an array outside and beneath the contaminated zone and the array of pipes connected to a refrigeration plant. Coolants typically consist of salt water, propylene glycol or calcium chloride.	Soil moisture content of 14 to 18% is considered optimal. Thorough subsurface characterization including identification of all subsurface structures is needed for proper design. Because containment by other barrier methods such as slurry walls and grout curtains becomes more cost effective after 8 or 9 years of operation, cryogenic barriers might be more applicable to containment of short-lived radionuclides such as tritium. Large volume of RIM in several areas would need to be refrigerated and soils containing radionuclides are comingled with municipal solid waste and construction debris. Consequently, this option was eliminated from further consideration.

MATCH A				
Containment	Vertical Barriers[2]	Slurry Wall[2]	Mixture of soil and bentonite is used to construct a low conductivity wall that is typically keyed-into bedrock or an impermeable hydrostratigraphic layer. Wall is normally installed by introducing bentonite slurry into a trench as the trench is excavated to hydraulically shore the trench to prevent collapse. Soil from the excavation is mixed above ground with bentonite and the mixture is placed back into the trench, displacing the slurry.	Would be difficult to implement in landfill containing municipal solid waste and construction and demolition debris. Consequently, this option was eliminated from further consideration.
		Grout curtain[2]	Grout is injected into the natural formation in-situ to fill interstitial void spaces and significantly reduce the hydraulic conductivity of the soil, forming a vertical barrier to groundwater flow.	Only applicable to low permeable zones. Would be difficult to implement in landfill containing municipal solid waste and construction and demolition debris. Consequently, this option was eliminated from further consideration.
		Sheet Pile Cutoff Wall[2]	Sheet piling barriers are constructed by driving individual sections of interlocking steel sheets into the ground using impact or vibratory hammers to form an impermeable barrier. Joints between individual sheet piles can be filled with grout to provide a better seal.	Would be difficult to implement in landfill containing municipal solid waste and construction and demolition debris. Consequently, this option was eliminated from further consideration.
Physical/Chemical Treatment	Solidification/ Stabilization[2]	Cement Solidification/ Stabilization[2]	The cement solidification/stabilization process involves the addition of agents including Portland cement, gypsum and pozzolanic-based materials such as fly ash, blast furnace slag, kiln dust, and pumice with a waste to form a densified and hardened soil mass that limits the solubility or mobility of the waste constituents. It is conducted either in-situ by injecting a cement-based agent into the contaminated materials or ex-situ by excavating the materials, machine-mixing them with a cement-based agent, and depositing the solidified mass in a designated area. Is best suited to fine-grained soil with small pores.	Potentially applicable for use at an off-site licensed disposal facility if hazardous wastes are encountered that need to undergo solidification/stabilization or encapsulation at the off-site facility prior to disposal.
		Chemical Solidification/ Stabilization[2]	Similar to cement solidification/stabilization except agents include thermoplastic polymers, thermosetting polymers, and other proprietary additives. Is best suited to highly porous, coarse-grained, low-level radioactive waste in permeable matrices.	Potentially applicable for use at an off-site licensed disposal facility if hazardous wastes are encountered that need to undergo solidification/stabilization or encapsulation at the off-site facility prior to disposal.

MATCH B

GENERAL RESPONSE ACTION	REMEDIAL TECHNOLOGY	PROCESS OPTIONS	DESCRIPTION	IMPLEMENTABILITY SCREENING COMMENTS
Physical/Chemical Treatment	Chemical Separation[2] (screened out)	Solvent/Chemical Extraction[2] (screened out)	An ex-situ chemical separation technology that separates hazardous contaminants from soils, sludges, and sediments using solvent/chemical extraction to reduce the volume of waste that must be subsequently treated or disposed. Solvents that have been used to remove radionuclide contaminants include complexing agents such as EDTA; inorganic salts; organic solvents; and sulfuric, hydrochloric, and nitric mineral acids. When contaminants have been sufficiently extracted, solvent is separated from the soil and distilled or removed by precipitation. Distilled vapor consists of relatively pure solvent that is recycled into the extraction process. The liquid residue containing concentrated contaminants undergoes further treatment or disposal. If multiple radionuclides or metals are targeted for removal, multiple solvent extraction steps may be required using multiple solvents.	To be considered for potential removal of radionuclides from the soil component of the RIM, would require pilot-testing of a dry soil separation technology to remove comingled municipal solid waste and debris greater than 2.4 inches in diameter to obtain representative soil samples for bench- and pilot-testing. Since multiple radionuclides would be targeted for removal, multiple solvent extraction steps would be required using multiple solvents, each requiring treatability testing. Removal percentages cited in the literature for uranium, radium-226, and thorium-232 would not meet the criteria that would allow for unrestricted use. Consequently, this option was eliminated from further consideration.
	Physical Separation[2]	Dry Soil Separation[2]	Dry soil separation involves screening and sieving soils to separate finer fractions, such as silt and clay, from coarser fractions of the soil. Since contaminants tend to bind to the fine fraction of a soil, the purpose of solids separation processes is to concentrate the contaminants to a smaller volume of soil that would subsequently be treated or disposed. Large debris would be removed and rocks, concrete, and asphalt would be crushed before fixed, vibrating, or rotation (trommel) screening. The segmented gate technology uses conveyor belts and gamma radiation detectors to separate dry materials. Shredders may be employed prior to screening.	Data are not available to assess potential effectiveness, implementability or cost at this time. Full-scale pilot testing would be required using representative material from Areas 1 and/or 2 to assess the degree to which the radiologically-impacted soil fraction of RIM can be separated from the overall matrix of landfilled refuse, debris and fill materials, and unimpacted soil and quarry spoils. Potentially applicable for reducing the volume of RIM that needs to be addressed under the "complete rad removal" and partial excavtion alternatives if results of pilot-testing indicate that the separated non-soil fraction of RIM does not exhibit radionuclide concentrations exceeding the EPA - specified activity levels for the "complete rad removal" and partial excavation alternatives. It may be difficult to identify soil with a thorium-230 concentration that would allow for unrestricted use using gamma radiation detectors. Worker exposures, dust creation, and bird nuisance potential would increase.
		Soil Washing[2] (screened out)	A process in which water, with or without surfactants, is mixed with contaminated soil and debris to produce a slurry feed that is scrubbed to remove contaminated fine soil particles (silts and clays) from granular soil particles. Clean soil (sands and gravels) is returned to the excavation area, while remaining smaller volume of contaminated soil fines and process water are further treated and/or disposed.	Despite many bench- and pilot-scale tests, soil washing has not been fully demonstrated as a technology for reducing the volume of radionuclide-contaminated soil. Consequently, this option was eliminated from further consideration.

GENERAL RESPONSE ACTION	REMEDIAL TECHNOLOGY	PROCESS OPTIONS	DESCRIPTION	IMPLEMENTABILITY SCREENING COMMENTS
MATCH C	MATCH C			
Physical/Chemical Treatment	Physical Separation[2]	Flotation[2]	Radionuclide-contaminated soil is pretreated to remove coarse material and separated fine silt and clay soil particles are mixed with water to form a slurry. Flotation agent is added to the slurry. Small air bubbles passed upward through the slurry adhere to the floating particles, transport them to the surface, producing a foam containing the radionuclide-contaminated soil particles that is mechanically skimmed from the surface and further treated in a subsequent process to remove the radionuclides.	Flotation is most effective at separating soil particles in the very fine 0.0004 to 0.004 inch size range. For soils that include a wider range of particle sizes, flotation would need to be combined with other treatment processes. Has been employed extensively in the mining industry to segregate metal-containing fines, but has not been fully demonstrated for reducing the volume of radionuclide-contaminated soil. Consequently, this option was eliminated from further consideration.
	Virtrification[2]	In-situ Vitrification[2]	Vitrification involves heating contaminated media to extremely high temperatures, then cooling to form a dense, glassified solid mass, trapping and greatly reducing the mobility of radioactive contaminants. In-situ vitrification uses a square array of 4 graphite electrodes that allows a melt width of approximately 20 to 40 ft; the array is lowered progressively, as the melt grows, to the desired treatment depth. Offgas treatment may be required, depending on the amount/types of organics and metals that may volatilize.	Void volumes and percentages of metals, rubble, and combustible organics (e.g., methane in landfill gas) in contaminated media need to be considered - soils and waste containing greater than 55% inorganic debris and/or rubble are difficult to treat. Should not be used on contaminated soils with organic contents higher than 10%. Soils should have greater that 30% glass-forming materials (i.e., SiO2) to effectively immobilize radionuclides. RIM volume not expected to have greater than 30% glass-forming materials. Consequently, this option was eliminated from further consideration.
		Ex-situ Vitrification[2]	In the ex-situ vitrification configuration, waste is fed to a furnace (e.g., joule-process heating; plasma; electric arc; microwave; and coal-, gas-, or oil-fired cyclone furnace) on either a batch or continuous feed basis.	Not retained, see in-situ vitrification.
	Apatite/Phosphate Based Treatment	Mixing/Injection of crystalline minerals with wastes or groundwater	In an isomorphous mineral, such as apatite, certain ions or molecules can enter and be incorporated into the crystal-lattice of a mineral solid without causing any marked change in the crystal morphology or other physical properties of the mineral. Apatite or other phosphate-based materials or solutions would be added to the solid phase materials or to groundwater containing radionuclides in sufficient quantities and under appropriate geochemical conditions necessary to promote apatite crystallization, potentially resulting in incorporation of Site-related radionuclides such as thorium, radium and uranium into the apatite crystals. Incorporation of radionuclides into the crystalline matrix would reduce the potential for leaching of such radionuclides.	There is no demonstrated application of use of apatite and/or other phosphate-based materials for treatment to MSW. Uncertainty whether apatite solids or solutions could be delivered and homogeneously distributed within an overall heterogeneous matrix of MSW. Concerns about unintended consequences that could result from physical disturbance or modification of the geochemical conditions within the landfill from application of apatite based treatment technologies.

Figure 4-1
Technical Implementability Screening of Remediation Technologies and Process Options
West Lake Landfill OU-1 Final Feasibility Study

EMSI Engineering Management Support, Inc.

GENERAL RESPONSE ACTION	REMEDIAL TECHNOLOGY	PROCESS OPTIONS	DESCRIPTION	IMPLEMENTABILITY SCREENING COMMENTS
Biological Treatment	Phytoremediation[2]	Phytoextraction[2]	Phytoextraction is the uptake of contaminants by plant roots and the translocation/accumulation of contaminants in plant shoots and leaves. Plants are subsequently harvested from the growing area, dried, and disposed. Will produce harvested biomass residual waste that will require further treatment and/or disposal. Based on bench and field-testing, most promising candidates for phytoextraction are cesium and strontium.	Treatment technology is limited to shallow soils and sediments. RIM in Areas 1 and 2 is present at depths greater than 20 feet and is comingled with municipal solid waste and construction debris. Will not be effective year-round because of limited growing season. Little full-scale operating experience and technology not effective for removal of uranium and thorium radionuclides. Consequently, this option was eliminated from further consideration.
		Phytostabilization[2]	Phytostabilization is the production of chemical compounds by plants to immobilize contaminants at the interface of roots and soil.	Treatment technology is limited to shallow soils and sediments. RIM in Areas 1 and 2 is present at depths greater than 20 feet and is comingled with municipal solid waste and construction debris. Will not be effective year-round because of limited growing season. Little full-scale operating experience. Technology not effective for removal of uranium and thorium radionuclides. Consequently, this option was eliminated from further consideration.
Removal	Excavation	Backhoe, bulldozer, scraper and front-end loader	Excavation can limit contaminant mobility and mitigate potential exposures at the affected area by removing the contaminant source. This technology can be implemented with conventional equipment.	Potentially applicable.
	Physical Separation	Dry Soil Separation	Since most contaminants tend to bind to the fine fraction of soils either chemically or physically, process involves screening and sieving soils to separate finer (silt and clay) fractions from coarser (sands and gravels) fractions of the soil. Separating the finer fraction of the soil can concentrate the contaminants to a smaller volume.	Because RIM at the Site occurs in soil that is intermixed with and interspersed within the overall matrix of landfilled refuse, debris, fill materials, and soil and quarry spoils, prior to a dry soil separation process being employed, the interstitial soil materials would need to be separated from the other landfilled materials using additional solids separation processes. Solids separation processes can include hand picking for large bulky items and hazardous materials such as propane tanks; magnetic separation for ferrous metals and contaminants associated with ferrous metals; eddy current separation for non-ferrous metals (*e.g.*, inducing an electric current to separate aluminum cans from other recyclables); air classification for papers and plastics; and various fixed, vibrating, or rotating screens. Concern that moist soil containing RIM could continue to adhere to landfilled materials after solids separation process(es).

GENERAL RESPONSE ACTION	REMEDIAL TECHNOLOGY	PROCESS OPTIONS	DESCRIPTION	IMPLEMENTABILITY SCREENING COMMENTS
MATCH D	MATCH D			
Removal	Physical Separation	Rotating Screen - Trommel	Revolving cylindrical sieve (trommel) screens are commonly used during landfill mining and reclamation projects to separate materials by size, with the soil fraction passing through the screen. Metal conveyor flights on the inside surface of the screen direct the non-soil fraction to the discharge end of the rotating cylinder. Trommel screens are typically used downstream in series with a shear shredder to reduce volume fed to the trommel, break up pockets/clumps of organic and matted materials and soil, dislodge smaller materials that may be hidden in among larger materials, and pulverize materials such as brick and large chunks of concrete that contain rebar and to provide a stream of more uniformly-sized material such that fines and the soil fraction of the waste can be more easily separated.	Large landfilled objects such as white goods and steel beams need to be hand-picked from the waste stream prior to shear shredding. Would require full-scale pilot test at the Site during RD to assess whether the RIM soil can be separated from the overall matrix of landfilled refuse, debris, fill materials, and soil and quarry spoils. Non-soil MSW material (wire, rebar, plastics) can get jammed in the screen requiring personnel to enter the screen to remove the material, potentially increasing exposure to RIM. Concern that moist soil containing RIM could continue to adhere to landfilled materials after shear shredding and trommel screening. Therefore, potentially applicable to partial excavation alternatives; likely not applicable for complete rad removal alternative.
		Radiological Segregation/ Separation	Refinement of dry soil separation process using radiation detectors to further separate materials. Radionuclide-contaminated soil is first excavated and screened to remove large rocks and debris. Large rocks are crushed and placed with soil on a conveyor belt which carries the soil under radiation detectors that measure and record the level of radiation in the material. Radioactive batches of material on the conveyor belt are tracked and mechanically diverted through automated gates, which separate the soil into contaminated and clean segments.	Large debris needs to be removed before processing the soil and crushed rocks, concrete, or asphalt. Screening to size the feed material to a diameter of less than 0.5 inches is desirable; material greater than 1.5 inches cannot be processed without crushing. Optimal soil moisture content is between 5 and 15 percent. System is best suited to sort a dry matrix contaminated with no more than two radionuclides with different gamma energies that can be transported by conveyor belts. Since limited to gamma-emitting radionuclides; RIM with Th-230 restricts use. Therefore, potentially applicable to 1,000 pCi/gm criteria partial excavation alternative; likely not applicable for 52.9 pCi/gm criteria partial excavation and complete rad removal alternatives.
	Tranportation (hauling of waste material)	Truck	Includes off-road haul trucks that would move materials within a large construction or mining site; semi-trailer bottom-, end-, and side-dump trucks; standard dump; and transfer truck and pup vehicles for transporting loose material such as sand, gravel, asphalt, soil or waste materials on roads and highways.	Potentially applicable. If waste materials were to be transported to an off-site disposal facility, trucks can be used as the sole method of transportation to the facility, or alternatively to transfer materials to another transportation method such as rail. If hauled offsite, wastes with radionuclides must be placed in appropriate containers and USDOT requirements for shipping must be met.

GENERAL RESPONSE ACTION	REMEDIAL TECHNOLOGY	PROCESS OPTIONS	DESCRIPTION	IMPLEMENTABILITY SCREENING COMMENTS
MATCH E	MATCH E			
Removal	Tranportation (hauling of waste material)	Rail	Bulk waste material is placed directly into 90-100 ton gondola rail cars if a rail spur is extended on-site; or a truck-to-rail transloading operation is used. Truck-to-rail involves loading of rail cars at a non-shared dedicated rail spur or siding. For loading of bulk material, a back-on transloading ramp is located perpendicular to the rail cars and end dump trucks discharge material into the gondolas after backing onto the ramp. After filling, covers are bolted onto the gondolas to keep the bulk material in-place in route to a disposal facility. Alternatively, end-dump truck trailers can be lined with IP-1 DOT bags, filled with bulk waste material, the bags "zippered" shut, and the bags dumped into a gondola car at the transloading ramp. Another transloading operation involves loading bulk waste material into intermodal containers, hauling the containers on a flat-bed truck to the truck-to-rail transloading station, and stacking multiple intermodal containers on a flat railcar for rail transportation to the disposal facility.	Potentially applicable. Wastes hauled offsite to an offsite licensed facility must be shipped in appropriate containers and USDOT requirements for shipping must be met. Would require lease of nearby rail spur and a truck-to-rail transloading facility as spur does not exist on-site. Extension of a rail spur on-site would be difficult to implement. Number of rail cars per day would be constrained by the length of spur and railroad switching limitations.
	Diposal	Off-site Disposal in licensed facility	This option would involve incorporation of removed material at an existing acceptable permitted commercial disposal facility. Waste must meet the Waste Acceptance Criteria (WAC) of the facility before being transported from the Site.	Currently only four facilities in US that potentially could accept RIM from the Site. Distances to facilities range from 520 to 1,600 miles, likely requiring transportation by rail. Since there is no rail spur at the Site, RIM would need to be trucked from the Site to a truck-to-rail transloading operation set-up at a leased rail spur location for loading onto railcars. Rail transport would require a dedicated fleet of railcars, subject to the switching frequency of the railroad serving the leased rail spur, and a continuous flow of RIM from the Site to the rail spur.
	Storm Water Management	Implement Best Management Practices to route runon around working areas.	Involves use of diversion ditches, earthern berms, culverts, sumps, and pumps if necessary.	Potentially applicable.
		Implement Best Management Practices to minimize waste exposure to direct precipitation.	Involves use of selective excavation, staging, daily soil cover, and tarps.	Potentially applicable.

GENERAL RESPONSE ACTION	REMEDIAL TECHNOLOGY	PROCESS OPTIONS	DESCRIPTION	IMPLEMENTABILITY SCREENING COMMENTS
Removal	Storm Water Management	Enclose excavation within temporary structure to minimize waste exposure to direct precipitation (screened out)	Involves use of rigid-frame structure with fabric roofing that can be constructed over the excavation area and moved as work progresses. Maximum width of available structures is 200 feet, but reasonable max width is 140 feet. Length is added in 15-foot segments and is unlimited. Frame height can accommodate arm-height of heavy equipment. Building ends can be open or equipped with access doors. Ventilation can be provided to remove landfill emissions, engine exhaust, and ambient heat. Structure can be segmented such that it can be partially disassembled, lifted by crane to a new location, and reassembled. Foundation must be supported with piers or grade beam. Structures are designed for flat or uniform grade not to exceed 6% along length. Foundation width (side-to-side) must be level, or beam leg height must be adjusted so building does not lean.	Not practical because surface topography of landfills undulates and slope exceeds 6% in some areas. Considerable regrading would be needed to accommodate foundation, exposing organic waste to precipitation. Width of RIM in Areas 1 and 2 plus layback for overburden ranges from 250 to 1,050 feet. Thus, structure would need to be moved several times, overlapping excavated and backfilled areas every time. Even if the available structures could be partially disassembled, relocated, and reassembled, sufficient foundation beams and/or piers would be required to support the new locations. That would necessitate over-excavating soils and trash and/or installing foundation piers on 15-foot centers through base of landfills. Overall timeframe for remediation would be lengthened. Consequently, this option was eliminated from further consideration.
		Implement Best Management Practices to collect, detain, treat, and release runoff.	Involves use of sumps, pumps, pipelines, lined impoundments or temporary storage tanks, outlet structures to regulate discharge rate to design storm flow, and flow and water quality monitoring. If treatment is necessary, conventional processes such as gravity precipitation and/or filtration may be used and NPDES permit or discharge to a POTW would be necessary.	Potentially applicable.
Nuisance Control Technologies	Bird Nuisance Mitigation	Implement Best Management Practices	Involves use of selective excavation techniques to minimize exposure of in-place waste, temporarily staging excavated waste in as small an area as practical, daily cover of waste material with soil or tarp, and rapid recovering of exposed waste whenever practicable.	Particularly applicable to landfill regrading projects.

GENERAL RESPONSE ACTION	REMEDIAL TECHNOLOGY	PROCESS OPTIONS	DESCRIPTION	IMPLEMENTABILITY SCREENING COMMENTS
MATCH G	MATCH G			
Nuisance Control Technologies	Bird Nuisance Mitigation	Enclose excavation within temporary structure	Involves use of rigid-frame structure with fabric roofing that can be constructed over the excavation area and moved as work progresses. Maximum width of available structures is 200 feet, but reasonable max width is 140 feet. Length is added in 15-foot segments and is unlimited. Frame height can accommodate arm-height of heavy equipment. Building ends can be open or equipped with access doors, but if left open, birds will enter. Ventilation can be provided to remove landfill emissions, engine exhaust, and ambient heat. Structure can be segmented such that it can be partially disassembled, lifted by crane to a new location, and reassembled. Foundation must be supported with piers or grade beam. Structures are designed for flat or uniform grade not to exceed 6% along length. Foundation width (side-to-side) must be level, or beam leg height must be adjusted so building does not "lean".	Not practical because surface topography of landfills undulates and slope exceeds 6% in some areas. Considerable regrading would be needed to accommodate foundation, exposing organic waste to birds in the process. Width of RIM in Areas 1 and 2 plus layback for overburden ranges from 250 to 1,050 feet. Thus, structure would need to be moved several times, overlapping excavated and backfilled areas every time. Even if the available structures could be partially disassembled, relocated, and reassembled, sufficient foundation beams and/or piers would be required to support the new locations. That would necessitate over-excavating soils and trash and/or installing foundation piers on 15-foot centers through base of landfills. Overall timeframe for remediation would be lengthened. Consequently, this option was eliminated from further consideration.
		Erect wire or monofilament grids over exposed refuse	Involves use of stainless steel wire, monofilament, or Kevlar lines placed in parallel, or in spoke configurations to prevent bird access. Parallel spacings of between 10 and 50 feet should be effective for most birds near site. Lines must be placed above the maximum height of working equipment. Line length would depend on strength of the wire/filament used, poles and pole anchors, and available space for poles.	Potentially applicable. The size of open excavations may limit the constructability of wire or monofilament grids.
		Use of visual deterrents such as predator birds or effigies of predator birds	Involves use of predator birds and/or visual devices such as statues, flags, and kites of predator hawks, eagles, or owls as deterrents for birds.	Potentially applicable. Visual deterrents can be successful short-term, but not long term because birds habituate to the deterrent. Frequent relocation of predatory birds and predator effigies may help, but long-term effectiveness in not assured.
		Use of auditory "frightening" devices such as pyrotechnics, exploders, bird alarm calls, or sound generators.	Involves use of big "bang" devices such as pyrotechnics, cracker shells, racket bombs, screamer shells, whistle bombs, propane exploders, and recordings of bird distress calls. All can be successful short-term to frighten birds away, but over time, birds habituate to the deterrent.	Potentially applicable except for loud "bang" noises that will be a nuisance to nearby land owners, including the Airport Authority. Frequent repositioning and/or altering the timing of auditory activation may help, but long-term effectiveness in not assured.
		Use of EPA-registered chemical frightening agents or toxicants.	Involves use of EPA-registered gull toxicant DRC-1339 and/or Avitrol® . DRC-1339 is applied to bread baits and causes renal failure, killing birds within days of ingestion. Avitrol® is a chemical frightening agent that causes birds to fly erratically and emit distress calls, frightening unaffected birds. Affected birds typically die within 4 hours. Avitrol® has not been formally evaluated for dispersing gulls.	Not likely applicable because killing or disorienting birds does not address the concern about congregating birds within the flight path of aircraft. Consequently, this option was eliminated from further consideration.

MATCH H	MATCH H			
Nuisance Control Technologies	Fugitive Dust/Odor Control	Implement Best Management Practices	Involves use of selective excavation techniques to minimize exposure of in-place waste, temporarily staging excavated waste in as small an area as practical, daily cover of waste material with soil or tarp, and rapid recovering of exposed waste whenever practicable.	Particularly applicable to landfill regrading projects.
		Water spray/mist, foam, or other agents	Use of water mist/spray and/or foam agents to reduce dust and mask odors; including temporary misting systems on staged waste piles, water or foam spraying on excavation surfaces or staged waste, and water trucks for dust control on roads.	For exposed waste, water would have minimal effect on odor control, may freeze during cold season, and runoff may need to be collected if not absorbed by the waste. Foam would not present runoff concerns. Foam delivery equipment would need to be setup adjacent to excavations and staged waste areas.
		Enclose excavation within temporary structure (screened out)	Involves use of rigid-frame structure with fabric roofing that can be constructed over the excavation area and moved as work progresses. (see description above under Bird Nuisance Mitigation)	Not practical for the same reasons discussed above.
		Enclose waste sorting/loading within temporary structure	For the partial excavation and “complete rad removal” alternatives, excavated waste that would be staged and sorted prior to shipment off-site for disposal would be enclosed within a temporary tensioned fabric frame structure. Loading of trucks or intermodal containers for transport of RIM to the off-site disposal facility would also be performed in this structure. The structure would include a concrete floor working surface and include ventilation and emissions control facilities to reduce/eliminate fugitive dust and odor concerns associated with staged waste.	Temporary structure would require us of a large area (3-4 acres) of the West Lake Landfill site not within OU-1 and therefore use of and approval of the landowner. Structure would need to be on-site throughout the entire off-site shipping of RIM campaign. Significant lead time needed for procurement of structure and emissions control facilities, site preparation, and structure erection.

GENERAL RESPONSE ACTION	REMEDIAL TECHNOLOGY	PROCESS OPTIONS	EFFECTIVENESS	IMPLEMENTABILITY	COST	SCREENING COMMENTS
No Action	See Figure 4-2 in FS (EMSI, 2006)					
Institutional Controls	See Figure 4-2 in FS (EMSI, 2006)					
Monitoring	Long-term performance monitoring	Groundwater, surface water, sediment, landfill gas, and radon gas monitoring	Effective at determining whether there is any migration of contamination from soil or landfilled areas to groundwater, surface water, and sediment as well as verifying if any remedy is performing as required.	Easily implemented; resources are readily available.	Low capital and low to moderate O&M costs.	Would be implemented under monitoring program.
	Short-term monitoring during construction	Perimeter environmental media air monitoring	For airborne particulates, volatile organics, and radon, effective at documenting background conditions prior to, during, and after remedy implementation. Multiple monitoring stations may be required.	Easily implemented; resources are readily available.	Relatively high capital costs to establish power at monitoring station. Can be high O&M costs depending on parameters requiring analyses in off-site laboratory.	Would be implemented under monitoring program.
		Work zone monitoring	Effective at monitoring exposures of workers to radionuclides and contaminants that may be in airborne particulates.	Easily implemented using various portable, hand-held, passive and breathing zone monitoring devices and equipment. Worker participation in medical monitoring program may be required.	Low capital for dosimeter badges. Most other equipment can be rented.	Would be implemented under monitoring program.
		Excavation guidance/ clearance monitoring	For radionuclides and indirectly for volatile organics, effective for assessing presence of, location/extent, and relative concentration of waste materials. Provides real-time information for decisions during waste excavation projects. Monitoring for metals and semi-volatile organics would require analysis at off-site laboratory and delay excavation.	Easily implemented. Real-time monitoring and sampling equipment and supplies are readily available.	High capital costs for some portable radionuclide survey equipment and on-site laboratory, if needed. Low O&M costs.	Would be implemented under monitoring program.

GENERAL RESPONSE ACTION	REMEDIAL TECHNOLOGY	PROCESS OPTIONS	EFFECTIVENESS	IMPLEMENTABILITY	COST	SCREENING COMMENTS
		MATCH A				
	Short-term monitoring during construction	Waste acceptance monitoring	Effective at assessing whether a container of waste meets off-site disposal facility acceptance criteria before waste material is shipped off-site. Results of field monitoring devices may need to be verified with samples analyzed in off-site laboratory.	Easily implemented with standard, readily-available equipment. Will require profile sampling and preparation/signature of waste manifests prior to shipment.	Low capital and O&M costs (unless laboratory confirmation required).	Would be implemented under monitoring program.
		Post cover construction radon flux monitoring	Effective at measuring radon flux of the cover surface of tailings piles and landfills.	Easily implemented with Large Area Activated Charcoal Canisters (LAACCs).	No capital and low O&M. LAACCs are rented from the analytical laboratory.	Would be implemented under monitoring program.
Containment	See Figure 4-2 in FS (EMSI, 2006) for Surface Controls/Diversions, Surface Water/Sediment Control/Barriers, and Dust Controls					
	Capping and Covers[1,2]	Soil, clay, and vegetation; asphalt or concrete; synthetic membrane material; and multilayer, multimedia material	Caps and covers can effectively limit airborne emissions (including radon) and external gamma radiation, and they can also reduce precipitation-enhanced percolation and leaching.	Can be easily implemented with conventional equipment and procedures. Resources are readily available. Consideration must be given to settlement of filled materials in OU-1 after a cover is placed. Surface depressions must be filled-in.	Moderate to high capital costs, depending on type of cover. Low maintenance and monitoring costs.	Soil, clay and vegetation layer covers retained. Asphalt or concrete covers screened-out because of potential settlement concerns if a cover were to be placed over Areas 1 and 2. Synthetic membrane and multilayer/multimedia material covers screened out because they are inconsistent with the existing landfill cover requirements.
	Land Encapsulation[2]	Off-site Licensed Facility[2]	Can effectively remove the source of contamination to limit contaminant mobility and volume at the affected area and reduce related exposures.	Difficult to implement; potentially only three facilities in U.S. will accept wastes. Will require construction of an on-site rail spur or truck-to-railcar transfer facility. Will require transportation of radiologically-impacted materials by truck and railroad and the attendant risks.	High	Associated with Excavation and Transportation.

GENERAL RESPONSE ACTION	REMEDIAL TECHNOLOGY	PROCESS OPTIONS	EFFECTIVENESS	IMPLEMENTABILITY	COST	SCREENING COMMENTS
Physical/Chemical Treatment	Solidification/ Stabilization[2]	Cement Solidification/ Stabilization[2]	Effective at reducing mobility of hazardous and radioactive contaminants.	Cement solidification/stabilization is best suited to highly porous, coarse-grained, permeable soils. Would be difficult to implement in-situ because of the nature of the matrix of landfilled refuse, debris and fill materials, soil, and quarry spoils. Easily implemented ex-situ at permitted off-site disposal facility prior to disposal of hazardous or mixed wastes if hazardous wastes encountered during excavation of RIM in Areas 1 and 2.	Moderate capital costs.	Would only be relevant if hazardous wastes were encountered during surface regrading or excavation of RIM in Areas 1 and 2.
		Chemical Solidification/ Stabilization[2]	Effective at reducing mobility of hazardous and radioactive contaminants.	Chemical solidification/stabilization best suited to fine-grained soil with small pores. Macroencapsulation is used for immobilizing low-level radioactive and mixed debris waste with dimensions greater than or equal to 2.5 inches while microencapsulation used to solidify wastes with smaller particles. Would be difficult to implement in-situ because of the nature of the matrix of landfilled refuse, debris and fill materials, soil, and quarry spoils. Easily implemented ex-situ at permitted off-site disposal facility prior to disposal of hazardous or mixed wastes if hazardous wastes encountered during excavation of RIM in Areas 1 and 2.	Moderate capital costs.	Would only be relevant if hazardous wastes were encountered during surface regrading or excavation of RIM in Areas 1 and 2.

EMSI Engineering Management Support, Inc.

MATCH C

GENERAL RESPONSE ACTION	REMEDIAL TECHNOLOGY	PROCESS OPTIONS	EFFECTIVENESS	IMPLEMENTABILITY	COST	SCREENING COMMENTS
Physical/Chemical Treatment	Physical Separation[2]	Dry Soil Separation[2]	Could potentially be effective at reducing volume of RIM by separating the soil materials containing radionuclides from the overall matrix of landfilled refuse, debris and fill materials, and unimpacted soil and quarry spoils if full-scale pilot-testing indicates that radionuclide concentrations in samples of the non-soil fraction of RIM that is discharged from the screening process would allow for unrestricted use of the non-soil fraction. If soil materials containing radionuclides remain adhered to the segregated refuse because of moisture content or other reasons, a separation process would not be effective. The effectiveness and degree of separation that may be achieved is uncertain until pilot-testing results are obtained. RIM matrix may require drying to improve separation effectiveness.	Pilot-testing using representative material from Areas 1 and/or 2 would be needed to determine the site-specific implementability. Equipment is readily available. Shear shredding pretreatment step prior to separation screening would be required. In maintaining the separation screening equipment, workers would be exposed to increased radiation emitted by RIM that adheres to the screen. Inclusion of a solids separation step as part of a process used for excavation and disposal of the RIM could become a factor relative to the daily production rates and project duration. Use of separation equipment could extend the overall project schedule and increase the potential or amounts of stormwater accumulation, airborne (dust) emissions, and bird or other vector impacts due to a possible increase in the overall schedule.	High capital cost. High operating costs.	Full-scale pilot-testing using representative material from Areas 1 and/or 2 would need to be conducted as a pre-design study early in the Remedial Design schedule.
Removal	Excavation	Backhoe, bulldozer, scraper and front-end loader	Can effectively remove the source of contamination to limit contaminant mobility and volume at the affected area and reduce related exposures.	Can be implemented with conventional equipment and procedures, and resources are available. Consideration must be given to type and composition of material to be excavated and excavations at depths greater than 25 feet, as special excavation equipment may be required.	Cost dependent on material properties. Moderate if shallow. High if deep.	None.
	Physical Separation	Dry Soil Separation	Would potentially be effective at reducing volume of RIM if pilot testing shows that the activity of the separated non-soil MSW would be less than the activity criteria for the respective complete rad removal or partial excavation alternative.	Interstitial soil materials need to be separated from MSW using solids separation process (handpicking, magnetic and eddy current separation, air classification, screens).	Moderate to high capital costs, high operating costs.	Pilot testing of various methods needed during remedial design.

MATCH D

GENERAL RESPONSE ACTION	REMEDIAL TECHNOLOGY	PROCESS OPTIONS	EFFECTIVENESS	IMPLEMENTABILITY	COST	SCREENING COMMENTS
Removal	Physical Separation	Rotating Screen - Trommel	Would potentially be effective at reducing volume of RIM if pilot testing shows that the activity of the separated non-soil MSW would be less than the activity criteria for the respective complete rad removal or partial excavation alternative.	Shredding pretreatment needed prior to rotating screen to reduce size of larger materials. Materials such as rebar and plastics can jamb or clog rotating screen requiring workers to enter screen to remove, which would interrupt production. Full scale pilot testing using representative materials excavated from West Lake OU-1 required.	High capital and operating costs.	Air borne dust would be generated during shredding and screening activities if excavated materials are dry. Increased worker exposure when removing materials from clogged screen. Pilot testing needed during remedial design.
		Radiological Segregation/ Separation	Would potentially be effective at reducing volume of RIM if pilot testing shows that the activity of the separated non-soil MSW would be less than the activity criteria for the respective complete rad removal or partial excavation alternative. Effective for gamma emitting radionuclides only.	Materials greater than 1.5 inches would need to be hand-picked out, screened-out or crushed. Optimal soil moisture content of between 5 and 15% needed. Limited to analysis of 2 radionuclides at a time.	High capital and operating costs.	Likely not applicable for 7.9 pCi/g complete rad removal and 52.9 pCi/g partial excavation alternatives, may be applicable for 1,000 pCi/g partial excavation alternative. Pilot testing needed during remedial design.
	Transportation (hauling of waste material)	Truck	With the numerous types of trucks available, effective for hauling of waste materials over all types of terrain and distances.	Easily implemented. Can be mobilized quickly. Depending on the characteristics of the waste material, truck beds may require lining or the waste may need to be transported in special containers. Federal, State, and local laws limit weight that can be carried on roads (depending on type of truck and characteristics of road).	Relatively cost-effective, plenty of competition available. Truck hauling is typically the only option to haul materials short distances. Not cost-effective for hauling large volumes/weights of materials long distances.	Except for maybe the US Ecology - Michigan location, eliminated for hauling of radiologically-impacted materials to off-site disposal facilities because of long distances.

MATCH E (General Response Action) — MATCH E (Remedial Technology)

GENERAL RESPONSE ACTION	REMEDIAL TECHNOLOGY	PROCESS OPTIONS	EFFECTIVENESS	IMPLEMENTABILITY	COST	SCREENING COMMENTS
Removal	Transportation (hauling of waste material)	Rail	Effective for hauling of waste materials over long distances or heavy volumes locally.	Difficult to implement. Would require truck-to-rail transfer and lease of nearby rail spur or extension of a rail spur onto the Site. Construction of new spur on-site would require land purchase or lease and coordination with local agencies and the railroad. Rate of waste transport via rail would be dependent on length of rail spur, number of switches provided by the railroad per week, and availability of specialty railcars for waste transport.	Cost-effective for hauling large volumes/weights long distances.	None.
Removal	Disposal	Off-site disposal in a licensed facility	Can effectively remove the source of contamination to limit contaminant mobility and volume at the affected area and reduce related exposures.	Logistically more difficult to implement if a rail spur is not on-site. Will require construction of an on-site rail spur and crossing across St. Charles Rock Rd or a truck-to-rail transloading facility at a nearby rented rail spur. Depending on disposal facility selected, RIM may need to be staged and blending prior to loading into trucks or railcars.	High costs.	Risk of accidents associated with truck and rail transportation. Significant amount of greenhouse gases emitted during transportation to disposal facility.
Removal	Storm Water Management	Implement Best Management Practices to route runon around working areas.	Effective in the short-term and long-term.	Easily implementable. Relies on use of conventional construction equipment and materials.	Low capital and O&M cost.	Would be implemented as part of RA and O&M.
Removal	Storm Water Management	Implement Best Management Practices to minimize waste exposure to direct precipitation.	Would be effective during excavation if the RIM was being removed.	Easily implementable. Relies on use of conventional construction equipment and materials.	Moderate O&M cost.	Would be implemented as part of RA.
Removal	Storm Water Management	Implement Best Management Practices to collect, detain, treat, and release runoff.	Effective during excavation while the RIM is being removed.	Easily implementable. Relies on use of conventional construction equipment and materials.	Moderate capital and O&M cost.	Would be implemented as part of RA.

GENERAL RESPONSE ACTION	REMEDIAL TECHNOLOGY	PROCESS OPTIONS	EFFECTIVENESS	IMPLEMENTABILITY	COST	SCREENING COMMENTS
Nuisance Control Technologies	Bird Nuisance Mitigation	Implement Best Management Practices	Effective means to minimize waste exposure opportunity for birds.	Can be implemented as part of an excavation program.	Low-moderate cost, depending on size of waste area to be covered.	Potentually effective.
		Erect wire or monofilament grids over exposed refuse.	May be effective deterrent with adequate grid spacing and pole placement.	Can be implemented with parallel spacings of between 10 and 50 feet. Line height can be 10-15 feet above the starting grade for Areas 1 and 2 if scrapers are used to strip overburden. Line length depends on strength of the wire/filament used and available space for poles and pole anchors. Should be able to implement with conventional wire, poles, construction equipment, and labor.	Cost dependent on wire/monofilament used, grid spacing, and height. Moderate capital cost if parallel spacings >15 feet and pole height <15 feet.	More effective if combined with visual and/or auditory deterrents.
		Use of visual deterrents such as predator birds or effigies of predator birds	May be effective short-term in one position, but long-term (greater than several months) effectiveness will require frequent repositioning.	Can be implemented with commercially-available effigies of predator birds mounted on poles and/or onsite buildings.	Low capital and O&M cost.	More effective if combined with auditory deterrents and/or overhead wire grid.
		Use of auditory "frightening" devices such as pyrotechnics, screamer whistles, and bird distress calls.	May be effective short-term in one position, but long-term (greater than several months) effectiveness will require frequent repositioning and altering of timing of activation.	Can be implemented with commercially-available sound devices that can be mobilized to new locations.	Low capital and O&M cost.	More effective if combined with visual deterrents and/or overhead wire grid.
	Fugitive Dust/Odor Control	Implement Best Management Practices	Effective for minimizing dust on exposed surfaces, but little effect with respect to odor.	Easily implementable using conventional materials, but depending on construction schedule requirements, may be difficult to constantly move tarps to minimize exposed surfaces.	Low to moderate cost, depending on size of waste area to be covered.	Would be implemented in areas where MSD is exposed.

GENERAL RESPONSE ACTION	REMEDIAL TECHNOLOGY	PROCESS OPTIONS	EFFECTIVENESS	IMPLEMENTABILITY	COST	SCREENING COMMENTS
MATCH G	MATCH G					
Nuisance Control Technologies	Fugitive Dust/Odor Control	Water spray/mist, foam, or other agents	Water effective for fugitive dust, particularly on roads, little effectiveness for odor. Foam would be effective for minimizing dust and odor on excavated surfaces and staged waste.	Sprayed water or mist could runoff sloped excavation.	Water: low cost. Foam: moderate cost.	Foam covering of exposed waste in excavation and staged material would assist with bird mitigation. For alternatives where recently-filled materials from the North Quarry portion of the Bridgeton Landfill in the southeast area of Area 1 need to be excavated and stockpiled to access RIM, foaming of surfaces of open excavations and stockpiles might be desirable to address odors.
		Enclose waste sorting/ loading within temporary structure	Effective for addressing fugitive dust and odor associated with excavated RIM staged for off-site disposal, not effective for open excavations.	Easily implemented with standard construction equipment and personnel. Would require an approximate 4-acre open area on the West Lake Landfill Site that is not located on fill. Long lead time from placement of order to delivery on-site. Would require ventilation exhaust air treatment for odor control.	Very high capital and O&M costs.	Would eliminate precipitation on as well as odor to the public from excavated RIM staged for off-site disposal and eliminate bird nuisance concerns associated with staged RIM.

Re: West Lake Landfill Site, Declaration of Covenants and Restrictions

Dear David:

With this letter I enclose copies of the following documents:

1. Declaration of Covenants and Restrictions executed by West Lake Quarry and Material Company, recorded with the St. Louis County Recorder of Deeds on June 30, 1997 at Book 11208, Page 2499;

2. Declaration of Covenants and Restrictions executed by Rock Road Industries, Inc., recorded with the St. Louis County Recorder of Deeds on June 30, 19997 at Book 11208, Page 2508;

3. Declaration of Covenants and Restrictions executed by Laidlaw Waste Systems (Bridgeton) Inc., recorded with the St. Louis County Recorder of Deeds on June 30, 1997 at Book 11208, Page 2515.

By recording these Declarations of Covenants and Restrictions, future use of the area encompassed by the West Lake Superfund Site has been limited and cannot include residential use. To change such use, the Environmental Protection Agency, the Missouri Department of Natural Resources, and the owner of the affected premises would have to agree to such changes. Therefore, the West

212540.1

Lake Landfill Site Respondents believe that the only reasonable future use that should be considered for risk assessment purposes is a non-residential use.

Sincerely,

Michael D. Hockley

DECLARATION OF COVENANTS AND RESTRICTIONS

WEST LAKE QUARRY AND MATERIAL COMPANY

West Lake Quarry and Material Company, a Missouri corporation ("Declarant"), hereby (a) imposes the provisions of this Declaration upon the Premises (as defined below), (b) publishes and declares that the following terms, conditions, restrictions and obligations shall (i) affect and encumber the Premises, (ii) run with and be a burden upon and a benefit to the Premises, and (iii) be fully binding upon Declarant and all other persons or entities acquiring the Premises or any part thereof or interest therein whether by descent, devise, purchase or otherwise, and (c) declares that any person or entity, by the acceptance of title to the Premises or any part thereof or interest therein, shall thereby agree and covenant to abide by and be bound by the following terms, conditions, restrictions and obligations.

RECITALS

A. Declarant is the owner of certain real property (located in the City of Bridgeton, County of St. Louis, State of Missouri), legally described on Exhibit A, attached hereto and incorporated herein by this reference, which real property is herein referred to as the "Premises".

B. The Premises and nearly all real property in the immediate vicinity of the Premises have been used exclusively for more than 40 years for non-residential uses, primarily for commercial and industrial uses and in some cases, for agricultural uses.

C. Such uses have included, but have not been limited to, quarrying operations, demolition and sanitary landfill operations, asphalt and concrete batch plant operations, and vehicle maintenance, repair and body shop operations.

D. Such uses, and the character and nature of the land uses in the vicinity of the Premises, make the Premises unsuitable for any future residential use.

E. The United States Environmental Protection Agency ("EPA") has entered into an Administrative Order on Consent (the "Consent Order") with Cotter Corporation (N.S.L.), Laidlaw Waste Systems (Bridgeton) Inc., Rock Road Industries, Inc., and the United States Department of Energy.

F. The Consent Order, among other things, (i) provides for the investigation of the nature and extent of contamination and any threat to the public health, welfare, or the environment caused by the release or threatened release of hazardous substances at or from two isolated areas either on or in the vicinity of the Premises and which have been designated as Radiological Areas 1 and 2 in the Consent Order, and which contain low-level radioactive waste materials, and (ii) has been filed with the Regional Hearing Clerk, EPA, Region VII, 726 Minnesota Avenue, Kansas City, Kansas, Docket No. VII-93-F-0005.

G. Declarant desires to prohibit the present and future use of the Premises for any residential purpose in accordance with the terms and provisions of this Declaration.

DECLARATION

Declarant hereby states and declares as follows:

1. Neither the Premises, nor any portion thereof, shall be used now or hereafter for any residential purpose, or for any day care, preschool or other educational use.

2. This Declaration shall not unlawfully restrict and shall not be used to violate any federal law, rule, or regulation regarding the use of real estate, including, but not limited to, the Fair Housing Act.

3. No water well for drinking water use shall be installed on the Premises.

4. This Declaration shall be recorded in the office of the Recorder of Deeds for the County of St. Louis, State of Missouri.

5. Any deed or other instrument of conveyance for the Premises or any portion thereof shall be subject to this Declaration.

6. Each of EPA (or its successor), the Missouri Department of Natural Resources ("MDNR") (or its successor) and the owner of any portion of the Premises shall have the right to sue for and obtain an injunction, prohibitive or mandatory, to prevent the breach, or to enforce the observance, of this Declaration. This right shall be in addition to any other action available at law or in equity. The failure to enforce any covenant or restriction herein at the time of its violation shall not constitute a waiver of the right to do so later.

7. The provisions of this Declaration shall continue in full force and effect until the fiftieth anniversary of the date of this Declaration and thereafter for successive twenty-year periods unless, prior to the expiration of the then current term, a written notice of termination of this Declaration, executed by each of the then owners of the Premises and by authorized representatives of EPA (or its successor) and MDNR (or its successor), has been filed with the office of the Recorder of Deeds for St. Louis County, State of Missouri. A notice of termination of this Declaration may be filed at any time after the effective date of this Declaration, and the Declaration shall terminate on the date the notice of termination is filed with the Recorder of Deeds.

IN WITNESS WHEREOF, West Lake Quarry and Material Company has caused this instrument to be executed this 27th day of May, 1997.

DECLARATION OF COVENANTS AND RESTRICTIONS

ROCK ROAD INDUSTRIES, INC.

Rock Road Industries, Inc., a Missouri corporation ("Declarant"), hereby (a) imposes the provisions of this Declaration upon the Premises (as defined below), (b) publishes and declares that the following terms, conditions, restrictions and obligations shall (i) affect and encumber the Premises, (ii) run with and be a burden upon and a benefit to the Premises, and (iii) be fully binding upon Declarant and all other persons or entities acquiring the Premises or any part thereof or interest therein whether by descent, devise, purchase or otherwise, and (c) declares that any person or entity, by the acceptance of title to the Premises or any part thereof or interest therein, shall thereby agree and covenant to abide by and be bound by the following terms, conditions, restrictions and obligations.

RECITALS

A. Declarant is the owner of certain real property (located in the City of Bridgeton, County of St. Louis, State of Missouri), legally described on Exhibit A, attached hereto and incorporated herein by this reference, which real property is herein referred to as the "Premises".

B. The Premises and nearly all real property in the immediate vicinity of the Premises have been used exclusively for more than 40 years for non-residential uses, primarily for commercial and industrial uses and in some cases, for agricultural uses.

C. Such uses have included, but have not been limited to, quarrying operations, demolition and sanitary landfill operations, asphalt and concrete batch plant operations, and vehicle maintenance, repair and body shop operations.

D. Such uses, and the character and nature of the land uses in the vicinity of the Premises, make the Premises unsuitable for any future residential use.

E. The United States Environmental Protection Agency ("EPA") has entered into an Administrative Order on Consent (the "Consent Order") with Cotter Corporation (N.S.L.), Declarant, Laidlaw Waste Systems (Bridgeton) Inc., and the United States Department of Energy.

F. The Consent Order, among other things, (i) provides for the investigation of the nature and extent of contamination and any threat to the public health, welfare, or the environment caused by the release or threatened release of hazardous substances at or from two isolated areas either on or in the vicinity of the Premises and which have been designated as Radiological Areas 1 and 2 in the Consent Order, and which contain low-level radioactive waste materials, and (ii) has been filed with the Regional Hearing Clerk, EPA, Region VII, 726 Minnesota Avenue, Kansas City, Kansas, Docket No. VII-93-F-0005.

G. Declarant desires to prohibit the present and future use of the Premises for any residential purpose in accordance with the terms and provisions of this Declaration.

DECLARATION

Declarant hereby states and declares as follows:

1. Neither the Premises, nor any portion thereof, shall be used now or hereafter for any residential purpose, or for any day care, preschool or other educational use.

2. This Declaration shall not unlawfully restrict and shall not be used to violate any federal law, rule, or regulation regarding the use of real estate, including, but not limited to, the Fair Housing Act.

3. No water well for drinking water use shall be installed on the Premises.

4. This Declaration shall be recorded in the office of the Recorder of Deeds for the County of St. Louis, State of Missouri.

5. Any deed or other instrument of conveyance for the Premises or any portion thereof shall be subject to this Declaration.

6. Each of EPA (or its successor), the Missouri Department of Natural Resources ("MDNR") (or its successor) and the owner of any portion of the Premises shall have the right to sue for and obtain an injunction, prohibitive or mandatory, to prevent the breach, or to enforce the observance, of this Declaration. This right shall be in addition to any other action available at law or in equity. The failure to enforce any covenant or restriction herein at the time of its violation shall not constitute a waiver of the right to do so later.

7. The provisions of this Declaration shall continue in full force and effect until the fiftieth anniversary of the date of this Declaration and thereafter for successive twenty-year periods unless, prior to the expiration of the then current term, a written notice of termination of this Declaration, executed by each of the then owners of the Premises and by authorized representatives of EPA (or its successor) and MDNR (or its successor), has been filed with the office of the Recorder of Deeds for St. Louis County, State of Missouri. A notice of termination of this Declaration may be filed at any time after the effective date of this Declaration, and the Declaration shall terminate on the date the notice of termination is filed with the Recorder of Deeds.

IN WITNESS WHEREOF, Rock Road Industries, Inc. has caused this instrument to be executed this 27th day of May, 1997.

DECLARATION OF COVENANTS AND RESTRICTIONS
LAIDLAW WASTE SYSTEMS (BRIDGETON) INC.

Laidlaw Waste Systems (Bridgeton) Inc. f/k/a/ West Lake Landfill, Inc., a Missouri corporation ("Declarant"), hereby (a) imposes the provisions of this Declaration upon the Premises (as defined below), (b) publishes and declares that the following terms, conditions, restrictions and obligations shall (i) affect and encumber the Premises, (ii) run with and be a burden upon and a benefit to the Premises, and (iii) be fully binding upon Declarant and all persons or entities acquiring the Premises or any part thereof or interest therein whether by descent, devise, purchase or otherwise, and (c) declares that any person or entity, by the acceptance of title to the Premises or any part thereof or interest therein, shall thereby agree and covenant to abide by and be bound by the following terms, conditions, restrictions and obligations.

RECITALS

A. Declarant is the owner of certain real property (located in the City of Bridgeton, County of St. Louis, State of Missouri), legally described on Exhibit 1, attached hereto and incorporated herein by this reference, which real property is herein referred to as the "Premises".

B. The Premises and nearly all real property in the immediate vicinity of the Premises have been used exclusively for more than 40 years for non-residential uses, primarily for commercial and industrial uses and in some cases, for agricultural uses.

C. Such uses have included, but have not been limited to, quarrying operations, demolition and sanitary landfill operations, asphalt and concrete batch plant operations, and vehicle maintenance, repair and body shop operations.

D. Such uses, and the character and nature of the land uses in the vicinity of the Premises, make the Premises unsuitable for any future residential use.

E. The United States Environmental Protection Agency ("EPA") has entered into an Administrative Order on Consent (the "Consent Order") with Cotter Corporation (N.S.L.), Declarant, Rock Road Industries, Inc., and the United States Department of Energy.

F. The Consent Order, among other things, (i) provides for the investigation of the nature and extent of contamination and any threat to the public health, welfare, or the environment caused by the release or threatened release of hazardous substances at or from two isolated areas either on or in the vicinity of the Premises, which have been designated as Radiological Areas 1 and 2 in the Consent Order, and which contain low-level radioactive waste materials, and (ii) has been filed with the Regional Hearing Clerk, EPA, Region VII, 726 Minnesota Avenue, Kansas City, Kansas, Docket No. VII-93-F-0005.

G. The EPA and Declarant have entered into an additional Administrative Order on Consent, which has been filed with the Regional Hearing Clerk, EPA, Region VII, 726 Minnesota Avenue, Kansas City, Kansas, Docket No. VII-94-F-0025, to investigate the nature and extent of any potential contamination at the Premises (other than Radiological Areas 1 and 2) relating to the historical use of the Premises.

H. Declarant desires to prohibit the present and future use of the Premises for any residential purpose in accordance with the terms and provisions of this Declaration.

DECLARATION

Declarant hereby states and declares as follows:

1. Neither the Premises, nor any portion thereof, shall be used now or hereafter for any residential purpose, or for any day care, preschool, or other educational use.

2. This Declaration shall not unlawfully restrict and shall not be used to violate any federal law, rule, or regulation regarding the use of real estate, including, but not limited to, the Fair Housing Act.

3. No water well for drinking water use shall be installed on the Premises.

4. This Declaration shall be recorded in the office of the Recorder of Deeds for the County of St. Louis, State of Missouri.

5. Any deed or other instrument of conveyance for the Premises or any portion therefor shall be subject to this Declaration.

6. Each of EPA (or its successor), the Missouri Department of Natural Resources ("MDNR") (or its successor), and the owner of any portion of the Premises shall have the right to sue for and

obtain an injunction, prohibitive or mandatory, to prevent the breach, or to enforce the observance, of this Declaration. This right shall be in addition to any other action available at law or in equity. The failure to enforce any covenant or restriction herein at the time of its violation shall not constitute a waiver of the right to do so later.

7. The provisions of this Declaration shall continue in full force and effect until the fiftieth anniversary of the date of this Declaration and thereafter for successive twenty-year periods unless, prior to the expiration of the then current term, a written notice of termination of this Declaration, executed by each of the then owners of the Premises and by authorized representatives of EPA (or its successor) and MDNR (or its successor), has been filed with the office of the Recorder of Deeds for St. Louis County, State of Missouri. A notice of termination of this Declaration may be filed at any time after the effective date of this Declaration, and the Declaration shall terminate on the date the notice of termination is filed with the Recorder of Deeds.

IN WITNESS WHEREOF, Laidlaw Waste Systems (Bridgeton) Inc. has caused this instrument to be executed this 9th day of June, 1997.

LAIDLAW WASTE SYSTEMS
(BRIDGETON) INC.

By ______________________

ACKNOWLEDGMENT

STATE OF Arizona)
) SS.
COUNTY OF Maricopa)

On this 9th day of June, 1997, before me, a notary public, personally appeared Steven Helm, to me known, who, being by me duly sworn, did say that he is the Vice President of Laidlaw Waste Systems (Bridgeton) Inc., a Missouri corporation, and that said instrument was signed on behalf of said corporation by authority of its Board of Directors, and said person acknowledged said instrument to be the free act and deed of said corporation.

IN WITNESS WHEREOF, I have hereunto set my hand and affixed my official seal in the County and State aforesaid, the day and year first above written.

EXHIBIT "1"

Landfill Area

Tract 1

tract of land in part of Lots 1,2, and 3 of the Yosti Partition in U.S. Survey 131, part of Lots 20,21, and 22 of the St. Charles Ferry Company Tract in U.S. Survey 47 and 1934, part of U.S. Survey 131, and part of U.S. Survey 47 in Townships 46 and 47 North, Range 5 East of the 5th Principal Meridian, St. Louis County Missouri, described as follows:

Beginning at the intersection of the northwesterly line of U.S. Survey 131 and the southwesterly right of way line of Highway 40, also known as St. Charles Rock Road; thence South 43 degrees 53 minutes 31 seconds East, along said right of way line, a distance of 72.80 feet; thence South 51 degrees 12 minutes 40 seconds West, a distance of 277.46 feet; thence South 75 degrees 52 minutes 00 seconds West, a distance of 426.11 feet; thence North 50 degrees 18 minutes 12 seconds West, a distance of 205.86 feet; thence South 53 degrees 20 minutes 34 seconds West, a distance of 126.98 feet; thence South 39 degrees 22 minutes 26 seconds West, a distance of 463.83 feet; thence South 43 degrees 55 minutes 12 seconds East, a distance of 444.12 feet; thence South 2 degrees 03 minutes 23 seconds East, a distance of 332.12 feet; thence South 58 degrees 55 minutes 53 seconds West, a distance of 277.03 feet; thence around a curve to the left, having a radius of 450.00 feet and a chord bearing South 30 degrees 29 minutes 30 seconds West, a chord distance of 428.61 feet to a point of compound curve; thence around a curve to the left, having a radius of 150.00 feet and a chord bearing South 47 degrees) minutes 16 seconds East, a chord distance of 229.44 feet to its point of tangency; thence North 82 degrees 16 minutes 22 seconds East, a distance of 106.78 feet; thence South 7 degrees 43 minutes 38 seconds East, a distance of 65.61 feet; thence South 49 degrees 02 minutes 55 seconds East, a distance of 174.81 feet; thence South 56 degrees 34 minutes 13 seconds East, a distance of 296.04 feet; thence South 26 degrees 44 minutes 32 seconds West, a distance of 644.89 feet; thence South 51 degrees 56 minutes 32 seconds West, a distance of 311.60 feet to the centerline of St. Charles Rock Road; thence along said centerline the following courses and distances: North 61 degrees 07 minutes 11 seconds West, a distance of 739.36 feet; North 5 degrees 58 minutes 11 seconds West, a distance of 997.50 feet; North 11 degrees 22 minutes 11 seconds West, a distance of 477.70 feet; North 17 degrees 07 minutes 11 seconds West, a distance of 348.30 feet; North 31 degrees 34 minutes 11 seconds West, a distance of 349.50 feet; North 38 degrees 50 minutes 11 seconds West, a distance of 22.38 feet to the northwest line of Lot 20 of the St. Charles Ferry Company Tract; thence North 28 degrees 53 minutes 11 seconds East, along said Northwest line, a distance of 824.56 feet to the Northwest corner of said Lot 20; thence North 72 degrees 46 minutes 42 seconds West, along the North line of Lot 19 of the St. Charles Ferry Company Tract, a distance of 674.79 feet; thence North 47 degrees 43 minutes 02 seconds East, a distance of 1137.84 feet to the Southwesterly right of way line of Highway 40 also known as St. Charles Rock Road; thence along said right of way line the following courses and distances; thence South 75 degrees 56 minutes 31 seconds East, a distance of 260.00 feet; thence around a curve to the right, having a radius of 1825.08 feet and a chord bearing South 65 degrees 11 minutes 52 seconds East, a chord distance of 680.49 feet; thence

North 35 degrees 32 minutes 48 seconds East, a distance of 30.00 feet; thence around a curve to the right, having a radius of 1855.08 feet and a chord bearing South 49 degrees 10 minutes 22 seconds East, chord distance of 341.47 feet; thence South 43 degrees 53 minutes 31 seconds East, a distance of 47.91 feet; thence South 46 degress 06 minutes 29 seconds West, a distance of 15.00 feet; thence South 43 degrees 53 minutes 31 seconds East, a distance of 34.28 feet; thence South 55 degrees 55 minutes 28 seconds East, a distance of 95.94 feet; thence South 43 degrees 53 minutes 31 seconds East, a distance of 602.78 feet to the Point of Beginning and containing 111.80 Acres.

Tract 2

A tract of land in part of Lots 1,3, and 4 of the Yosti Partition in U.S. Survey 131, and part of U.S. Survey 131, in Townships 46 and 47 North, Range 5 East of the 5th Principal Meridian, St. Louis County, Missouri, described as follows:

Beginning at the most easterly corner of Lot 1 of the Yosti Partition in U.S. Survey 131, being a point in the centerline of Taussig Avenue; thence South 43 degrees 34 minutes 53 seconds East, along the northeasterly line of Lot 4 of the Yosti Partition, a distance of 99.92 feet; thence South 6 degrees 41 minutes 15 seconds West, a distance of 68.96 feet; thence South 23 degrees 21 minutes 55 seconds West, a distance of 154.73 feet; thence South 26 degrees 49 minutes 07 seconds East, a distance of 55.27 feet; thence South 14 degrees 32 minutes 36 seconds West, a distance of 143.63 feet; thence South 34 degrees 03 minutes 12 seconds West, a distance of 220.86 feet; thence North 55 degrees 41 minutes 34 seconds West, a distance of 127.00 feet; thence South 88 degrees 59 minutes 19 seconds West, a distance of 62.24 feet; thence South 54 degrees 43 minutes 18 seconds West, a distance of 240.50 feet; thence South 26 degrees 44 minutes 32 seconds West, a distance of 450.91 feet; thence South 8 degrees 25 minutes 49 seconds West, a distance of 224.01 feet; thence South 17 degrees 14 minutes 43 seconds East, a distance of 28.63 feet; thence South 47 degrees 09 minutes 44 seconds East, a distance of 61.27 feet; thence South 24 degrees 34 minutes 10 seconds East, a distance of 73.64 feet; thence South 0 degrees 07 minutes 21 seconds West, a distance of 107.37 feet to the northeasterly right of way line of the St. Charles Rock Road, 60 foot wide; thence South 61 degrees 07 minutes 11 seconds East, along said right of way line, a distance of 758.45 feet to the most southerly corner of Lot 4 of said Yosti Partition; thence North 39 degrees 17 minutes 12 seconds East, along the southeasterly line of said Lot 4, a distance of 1349.58 feet to the most easterly corner thereof; thence North 43 degrees 34 minutes 53 seconds West, along the northeasterly line of said lot 4, a distance of 779.68 feet to a point 50.00 feet southeasterly of the most southerly corner of a tract of land conveyed to John Guerra and wife by deed recorded in Book 1642 on Page 263; thence North 46 degrees 24 minutes 31 seconds East, parallel with the southeasterly line of said Guerra tract, a distance of 437.11 feet; thence North 43 degrees 34 minutes 53 seconds West, parallel with the northeasterly line of said Guerra tract, a distance of 486.26 feet to the centerline of Taussig Avenue; thence North 41 degrees 52 minutes 29 seconds East, along said centerline, a distance of 68.21 feet; thence North 47 degrees 48 minutes 29 seconds East, along said centerline, a distance of 340.00 feet; thence North 42 degrees 11 minutes 31 seconds West, a distance of 30.00 feet to the northwesterly right of way line of said Taussig Avenue; thence North 47 degrees 48 minutes

29 seconds East, along said right of way a distance of 312.95 feet; thence North 5 degrees 09 minutes 06 seconds West, continuing along said right of way, a distance of 57.50 feet to the southwesterly right of way of Highway 40, also known as St. Charles Rock Road; thence North 43 degrees 53 minutes 31 seconds West, along said southwesterly right of way line, a distance of 877.45 feet; thence South 51 degrees 12 minutes 40 seconds West, a distance of 1023.23 feet; thence South 25 degrees 58 minutes 41 seconds West, a distance of 181.33 feet, to the northeasterly line of Lot 1 of the Yosti Partition of U.S. Survey 131; thence South 43 degrees 34 minutes 53 seconds East, along said northeasterly line, a distance of 971.20 feet to the Point of Beginning.

Tract 3

A tract of land being part of Lots 1, 3, and 4 of the "Yosti Partition in U.S. Survey 131, townships 46 and 47 north, range 5 east of the Fifth Principal Meridian, St. Louis County, Missouri, more particularly described as follows:

Commencing at the intersection of the northwesterly line of U.S. Survey 131 and the southwesterly right of way line of Highway 40, also known as "St. Charles Rock Road;" thence South 37 degrees 11 minutes 39 seconds East, along said south right of way line, 209.98 feet; thence exiting said right of way line, South 57 degrees 54 minutes 32 seconds West, 1023.23 feet; thence South 32 degrees 40 minutes 33 seconds West, 181.33 feet to the northeasterly line of said lot 1; thence South 36 degrees 53 minutes 01 seconds East, along said northeasterly line of lot 1, a distance of 591.05 feet to the point of beginning of the tract described herein; thence continuing along the northeasterly line of said lot 1 and along the northeasterly line of said lot 4, South 36 degrees 53 minutes 01 seconds East, 480.07 feet; thence exiting said northeasterly line, South 13 degrees 23 minutes 07 seconds West, 68.96 feet; thence South 30 degrees 03 minutes 47 seconds West, 154.73 feet; thence South 20 degrees 07 minutes 14 seconds East, 55.27 feet; thence South 21 degrees 14 minutes 28 seconds West, 143.63 feet; thence South 40 degrees 45 minutes 05 seconds West, 220.86 feet; thence North 48 degrees 59 minutes 42 seconds West, 127.00 feet; thence North 84 degrees 18 minutes 49 seconds West, 62.24 feet; thence South 61 degrees 25 minutes 10 seconds West, 240.50 feet; thence South 33 degrees 26 minutes 24 seconds West, 450.91 feet; thence South 15 degrees 07 minutes 41 seconds West, 224.01 feet; thence South 10 degrees 32 minutes 51 seconds East, 28.63 feet; thence South 40 degrees 27 minutes 52 seconds East, 61.27 feet; thence South 17 degrees 52 minutes 18 seconds East, 73.64 feet; thence South 06 degrees 49 minutes 13 seconds West, 107.37 feet to the north right of way line of "Old St. Charles Rock Road;" thence North 54 degrees 25 minutes 19 seconds West, along said right of way line, 99.72 feet; thence North 34 degrees 48 minutes 53 seconds East, 100.00 feet; thence exiting said west line, North 54 degrees 25 minutes 19 seconds West, 120.00 feet; thence North 21 degrees 27 minutes 09 seconds East, 153.52 feet; thence North 00 degrees 02 minutes 46 seconds West, 37.43 feet; thence North 56 degrees 33 minutes 36 seconds West, 70.00 feet; thence North 33 degrees 26 minutes 24 seconds East, 624.89 feet; thence South 49 degrees 52 minutes 21 seconds East, 56.85 feet; thence North 67 degrees 30 minutes 55 seconds East, _6.05 feet; thence North 08 degrees 48 minutes 44 seconds East, 158.15 feet; thence South 59 degrees 03 minutes 26 seconds East, 82.21 feet; thence North 3_ degrees 28 minutes 55 seconds East, 321.44 feet; thence North 55 degrees 02 minutes 11 seconds West, 158.34 feet; thence North 01 degrees 10 minutes 17 seconds East, 342.38 feet to the point of beginning.

Excluding from the above tracts the real property sometimes referred to as Area 1 and Area 2, and more particularly described as follows:

AREA 1

A tract of land in part of U.S. Survey 131, Township 47 North, Range 5 East of the 5th Principal Meridian, St. Louis County, Missouri, described as follows:

Commencing at the intersection of the northwesterly line, of U.S. Survey 131 and the southwesterly right of way line of Highway 40, also known as St. Charles Rock Road; thence South 43 degrees 53 minutes 31 seconds East, along said right of way line, a distance of 729.68 feet; thence South 40 degrees 49 minutes 32 seconds West, a distance of 92.54 feet to the Point of Beginning of the following described tract; thence continuing South 40 degrees 49 minutes 32 seconds West, a distance of 288.61 feet; thence South 89 degrees 29 minutes 50 seconds West, a distance of 241.41 feet; thence North 79 degrees 05 minutes 44 seconds West, a distance of 390.43 feet; thence North 29 degrees 48 minutes 55 seconds East, a distance of 499.73 feet; thence North 84 degrees 45 minutes 59 seconds East, a distance of 248.68 feet; thence South 32 degrees 24 minutes 17 seconds East, a distance of 201.28 feet;thence South 56 degrees 18 minutes 22 seconds East, a distance of 251.78 feet to the Point of Beginning.

AREA 2

A tract of land in part of Lot 20, of the St. Charles Ferry Company Tract in U.S. Survey 47 and 1934 and in part of U.S. Survey 47 Township 47 North, Range 5 East of the 5th Principal Meridian, St. Louis County, Missouri, described as follows:

Commencing at the intersection of the centerline of St. Charles Rock Road and the northwesterly line of Lot 20 of the St. Charles Ferry Company Tract; thence North 28 degrees 53 minutes 11 seconds East, along said northwesterly line, a distance of 148.48 feet of the Point of Beginning of the following described tract; thence continuing North 28 degrees 53 minutes 11 seconds East, along said line, a distance of 676.08 feet to the northwest corner of said Lot 20; thence North 72 degrees 46 minutes 42 seconds West, along the northerly line of Lot 19 of the St. Charles Ferry Company tract, a distance of 674.79 feet;thence North 47 degrees 43 minutes 02 seconds East, a distance of 906.64 feet; thence South 64 degrees 46 minutes 52 seconds East, a distance of 389.58 feet; thence South 76 degrees 30 minutes 26 seconds East, a distance of 245.51 feet; thence South 60 degrees 07 minutes 01 seconds East, a distance of 283.36 feet; thence South 31 degrees 26 minutes 39 seconds West, a distance of 1136.42 feet; thence South 33 degrees 08 minutes 25 seconds West, a distance of 109.40 feet; thence South 34 degrees 54 minutes 38 seconds East, a distance of 149.81 feet; thence South 44 degrees 29 minutes 33 seconds West, a distance of 267.70 feet; thence North 78 degrees 25 minutes 41 seconds West, a distance of 241.02 feet; thence North 34 degrees 31 minutes 30 seconds West, a distance of 351.19 feet to the Point of Beginning.

SUPPLEMENTAL DECLARATION OF COVENANTS AND RESTRICTIONS

ROCK ROAD INDUSTRIES, INC.

Rock Road Industries, Inc., a Missouri corporation ("Declarant"), hereby (a) imposes the provisions of this Supplemental Declaration upon the Premises (as defined below), (b) publishes and declares that the following terms, conditions, restrictions and obligations shall (i) affect and encumber the Premises, (ii) run with and be a burden upon and a benefit to the Premises, and (iii) be fully binding upon Declarant and all other persons or entities acquiring the Premises or any part thereof or interest therein whether by descent, devise, purchase or otherwise, and (c) declares that any person or entity, by the acceptance of title to the Premises or any part thereof or interest therein, shall thereby agree and covenant to abide by and be bound by the following terms, conditions, restrictions and obligations.

RECITALS

A. Declarant is the owner of certain real property (located in the City of Bridgeton, County of St. Louis, State of Missouri), legally described on Exhibit A, attached hereto and incorporated herein by this reference, which real property is herein referred to as the "Premises".

B. The United States Environmental Protection Agency ("EPA") has entered into an Administrative Order on Consent (the "Consent Order") with Cotter Corporation (N.S.L.), Declarant, Laidlaw Waste Systems (Bridgeton) Inc., and the United States Department of Energy for a Remedial Investigation and Feasibility Study.

C. The Consent Order, among other things, (i) provides for the investigation of the nature and extent of contamination and any threat to the public health, welfare, or the environment caused by the release or threatened release of hazardous substances at or from two isolated areas either on or in the vicinity of the Premises and which have been designated as Radiological Areas 1 and 2 in the Consent Order, and which contain low-level radioactive waste materials (the "Environmental Condition"), and (ii) has been filed with the Regional Hearing Clerk, EPA, Region VII, 726 Minnesota Avenue, Kansas City, Kansas, Docket No. VII-93-F-0005.

D. The Premises is subject to a Declaration of Covenants and Restrictions dated May 27, 1997, which is recorded in Book 11208 Page 2507 in the St. Louis County Recorder of Deeds Office (the "May 1997 Declaration").

E. In addition to the restrictions contained in the May 1997 Declaration, Declarant desires to prohibit in perpetuity (i) the construction or placement upon the Premises of any building for any purpose, and (ii) the installation of underground utilities, pipes and/or excavation upon the Premises, except as set forth herein.

DECLARATION

Declarant hereby states and declares as follows:

1. No building of any kind or nature for any purpose shall be constructed or placed on the Premises, now or at any time in the future, in perpetuity. In addition, no underground utilities or pipes shall be installed at the Premises and no excavation work shall be performed on the Premises, now or at any time in the future, in perpetuity, except such utilities, pipes and/or excavation work, if any, which (a) are approved by EPA in connection with a plan selected by EPA to remediate the Environmental Condition and are performed in accordance with safety regulations applicable to such remedial plan or otherwise required by EPA as a condition of such approval, or (b) are any part of a landfill gas control, leachate collection, or surface water management system installed and operated pursuant to a plan approved by all

applicable Federal, State and/or local authorities exercising jurisdiction over inactive landfill conditions on the Premises or active or inactive landfill operations conducted adjacent to the Premises.

2. This Supplemental Declaration shall not unlawfully restrict and shall not be used to violate any Federal law, rule, or regulation regarding the use of real estate, including, but not limited to, the Fair Housing Act.

3. This Supplemental Declaration shall be recorded in the office of the Recorder of Deeds for the County of St. Louis, State of Missouri.

4. Any deed or other instrument of conveyance for the Premises or any portion thereof shall be subject to this Supplemental Declaration.

5. Each of EPA (or its successor), the Missouri Department of Natural Resources ("MDNR") (or its successor) and the owner of any portion of the Premises shall have the right to sue for and obtain an injunction, prohibitive or mandatory, to prevent the breach, or to enforce the observance, of this Supplemental Declaration. This right shall be in addition to any other action available at law or in equity. The failure to enforce any covenant or restriction herein at the time of its violation shall not constitute a waiver of the right to do so later.

6. The provisions of this Supplemental Declaration shall continue in full force and effect until the fiftieth anniversary of the date of this Supplemental Declaration and thereafter for successive twenty-year periods unless, prior to the expiration of the then current term, a written notice of termination of this Supplemental Declaration, executed by each of the then owners of the Premises and by authorized representatives of EPA (or its successor) and MDNR (or its successor), has been filed with the office of the Recorder of Deeds for St. Louis County, State of Missouri. A notice of termination of this Supplemental Declaration may be filed at any

time after the effective date of this Supplemental Declaration, and this Supplemental Declaration shall terminate on the date the notice of termination is filed with the Recorder of Deeds.

7. The May 1997 Declaration remains in full force and effect, and shall be deemed supplemented, but not amended, by this Supplemental Declaration.

IN WITNESS WHEREOF, Rock Road Industries, Inc. has caused this instrument to be executed this 16th day of January, 1998.

ROCK ROAD INDUSTRIES, INC., a Missouri corporation

By: ____________________
William E. Whitaker
President

ACKNOWLEDGEMENT

STATE OF MISSOURI)
) ss
County OF ST. LOUIS)

On this 16th day of January, 1998, before me, a notary public, personally appeared William E. Whitaker, to me known, who, being by me duly sworn, did say that he is the President of Rock Road Industries, Inc., a Missouri corporation, and that said instrument was signed on behalf of said corporation by authority of its Board of Directors, and said person acknowledged said instrument to be the free act and deed of said corporation.

IN WITNESS WHEREOF, I have hereunto set my hand and affixed my official seal in the County and State aforesaid, the day and year first above written.

Margaret G. Cusumano
Notary Public

My Commission Expires:

MARGARET G CUSUMANO
NOTARY PUBLIC STATE OF MISSOURI
ST. LOUIS COUNTY
MY COMMISSION EXP. NOV. 5,1998

EXHIBIT A

AREA 1

A tract of land in part of U.S. Survey 131, Township 47 North, Range 5 East of the 5th Principal Meridian, St. Louis County, Missouri, described as follows:

Commencing at the intersection of the northwesterly line, of U.S. Survey 131 and the southwesterly right of way line of Highway 40, also known as St. Charles Rock Road; thence South 43 degrees 53 minutes 31 seconds East, along said right of way line, a distance of 729.68 feet; thence South 40 degrees 49 minutes 32 seconds West, a distance of 92.54 feet to the Point of Beginning of the following described tract; thence continuing South 40 degrees 49 minutes 32 seconds West, a distance of 288.61 feet; thence South 89 degrees 29 minutes 50 seconds West, a distance of 241.41 feet; thence North 79 degrees 05 minutes 44 seconds West, a distance of 390.43 feet; thence North 29 degrees 48 minutes 55 seconds East, a distance of 499.73 feet; thence North 84 degrees 45 minutes 59 seconds East, a distance of 248.68 feet; thence South 32 degrees 24 minutes 17 seconds East, a distance of 201.28 feet; thence South 56 degrees 18 minutes 22 seconds East, a distance of 251.78 feet to the Point of Beginning.

AREA 2

A tract of land in part of Lot 20, of the St. Charles Ferry Company Tract in U.S. Survey 47 and 1934 and in part of U.S. Survey 47 Township 47 North, Range 5 East of the 5th Principal Meridian, St. Louis County, Missouri, described as follows:

Commencing at the intersection of the centerline of St. Charles Rock Road and the northwesterly line of Lot 20 of the St. Charles Ferry Company Tract; thence North 28 degrees 53 minutes 11 seconds East, along said northwesterly line, a distance of 148.48 feet of the Point of Beginning of the following described tract; thence continuing North 28 degrees 53 minutes 11 seconds East, along said line, a distance of 676.08 feet to the northwest corner of said Lot 20; thence North 72 degrees 46 minutes 42 seconds West, along the northerly line of Lot 19 of the St. Charles Ferry Company tract, a distance of 674.79 feet; thence North 47 degrees 43 minutes 02 seconds East, a distance of 906.64 feet; thence South 64 degrees 46 minutes 52 seconds East, a distance of 389.58 feet; thence South 76 degrees 30 minutes 26 seconds East, a distance of 245.51 feet; thence South 60 degrees 07 minutes 01 seconds East, a distance of 283.36 feet; thence South 31 degrees 26 minutes 39 seconds West, a distance of 1136.42 feet; thence South 33 degrees 08 minutes 25 seconds West, a distance of 109.40 feet; thence South 34 degrees 54 minutes 38 seconds East, a distance of 149.81 feet; thence South 44 degrees 29 minutes 33 seconds West, a distance of 267.70 feet; thence North 78 degrees 25 minutes 41 seconds West, a distance of 241.02 feet; thence North 34 degrees 31 minutes 30 seconds West, a distance of 351.19 feet to the Point of Beginning.

DECLARATION OF COVENANTS AND RESTRICTIONS

ROCK ROAD INDUSTRIES, INC.

Rock Road Industries, Inc., a Missouri corporation ("Declarant"), hereby (a) imposes the provisions of this Declaration upon the Premises (as defined below); (b) publishes and declares that the following terms, conditions, restrictions, and obligations shall (i) affect and encumber the Premises; (ii) run with and be a burden upon and a benefit to the Premises; and (iii) be fully binding upon Declarant and all other persons or entities acquiring the Premises or any part thereof or interest therein, whether by descent, devise, purchase or otherwise; and (c) declares that any person or entity, by the acceptance of title to the Premises or any part thereof or interest therein, shall thereby agree and covenant to abide by and be bound by the following terms, conditions, restrictions, and obligations.

RECITALS

A. Declarant is the owner of certain legal property, located in the City of Bridgeton, County of St. Louis, State of Missouri, legally described on **Exhibit A-1** and described by survey on **Exhibit A-2**, both of which are attached hereto and incorporated herein by this reference, which real property is herein referred to as "the Premises."

B. The Premises and nearly all real property in the immediate vicinity of the Premises have been used exclusively for more than forty (40) years for non-residential uses – primarily for commercial and industrial uses, but in some cases, for agricultural uses.

C. Such uses have included, but have not been limited to, quarrying operations, demolition and sanitary landfill operations, asphalt and concrete batch plant operations, trailer storage operations, and vehicle maintenance, repair, and body shop operations.

D. Such uses, and the nature and character of the land in the vicinity of the Premises, make the Premises unsuitable for any future residential use.

E. The United States Environmental Protection Agency ("EPA") has entered into an Administrative Order on Consent (the "Consent Order") with Cotter Corporation (N.S.L.), Declarant, Bridgeton Landfill, LLC (f/k/a Laidlaw Waste Systems (Bridgeton) Inc.), and the United States Department of Energy, dated March 3, 1993, as amended from time to time thereafter, and as is attached hereto as **Exhibit B**.

F. The Consent Order, among other things, provides for the investigation of the nature and extent of contamination and any threat to the public health, welfare, or the environment caused by the release or threatened release of hazardous substances at or from isolated areas either on or in the vicinity of the Premises.

G. Declarant desires to prohibit in perpetuity (i) the use of the Premises for residential purposes; (ii) the construction or placement upon the Premises of any building or habitable structure for any purpose; (iii) the use of the Premises for commercial and industrial purposes, including (but not limited to) use of the property as a storage yard; (iv) the installation of underground utilities, pipes and/or excavation upon the Premises, and (v) the installation on the Premises of water wells for drinking water use, except as set forth herein.

DECLARATION

Declarant hereby states and declares as follows:

1. Neither the Premises, nor any portion thereof, shall be used now or hereafter for any residential purpose, or for any day care, preschool, or any other educational use.

2. The Premises shall not be used for commercial or industrial purposes, now or at any time in the future, in perpetuity.

3. No building or habitable structure of any kind, and for any purpose, shall be constructed or placed upon the Premises, now or at any time in the future, in perpetuity.

4. The Premises shall not be used as a storage yard (whether temporarily or permanently), now or at any time in the future, in perpetuity.

5. No underground utilities or pipes shall be installed at, on, or under the Premises, and no excavation work shall be performed on the Premises, now or at any time in the future, in perpetuity, except for such utilities, pipes, and/or excavation work, if any, which are approved by EPA in connection with a plan selected by EPA to remediate hazardous substances on the Premises and that are performed in accordance with environmental and safety regulations applicable to such a remedial plan or are otherwise required by EPA as a condition of such approval.

6. No water wells for drinking water use shall be installed on the Premises.

7. This Declaration shall not unlawfully restrict and shall not be used to violate any federal law, rule, or regulation regarding the use of real estate, including, but not limited to, the Fair Housing Act.

8. This Declaration shall be recorded in the office of the Recorder of Deeds for the County of St. Louis, State of Missouri.

9. Any deed or other instrument of conveyance for the Premises or any portion thereof shall be subject to this Declaration.

10. Each of EPA (or its successor), the Missouri Department of Natural Resources ("MNDR") (or its successor), and the owner of any portion of the Premises shall have the right to sue for and obtain an injunction, prohibitive or mandatory, to prevent the breach, or to enforce the observance, of this Declaration. This right shall be in addition to any other action available

at law or in equity. The failure to enforce any covenant or restriction herein at the time of its violation shall not constitute a waiver of the right to do so later.

11. The provisions of this Declaration shall continue in full force and effect until the fiftieth (50^{th}) anniversary of the date of this Declaration and thereafter for successive twenty (20) year periods unless, prior to the expiration of the then-current term, a written notice of termination of this Declaration, executed by each of the then-owners of the Premises and by authorized representatives of EPA (or its successor) and MDNR (or its successor), has been filed with the office of the Recorder of Deeds for St. Louis County, State of Missouri. A notice of termination of this Declaration may be filed at any time after the effective date of this Declaration, and the Declaration shall terminate on the date the notice of termination is filed with the Recorder of Deeds.

[Signature Page Follows]

IN WITNESS WHEREOF, Rock Road Industries, Inc. has caused this instrument to be executed this 14th day of October, 2016.

ROCK ROAD INDUSTRIES INC.
A Missouri corporation

By: ______________________
Tim M. Benter, Vice President and Assistant Secretary

ACKNOWLEDGEMENT

STATE OF ARIZONA)

EXHIBIT A-1

Legal Description

Part of Lot 19 of St. Charles Ferry Co. Tracts in U.S. Surveys 47 and 1934 Township 47 North; Range 5 East of the Fifth Principal Meridian, St. Louis, MO being more particularly described as follows:

Beginning at a point of intersection of the Centerline of the Old St. Charles Rock Road with the Easterly line of Lot 19 of St. Charles Ferry Co. Tracts; thence North 35 degrees 35 minutes 03 seconds East along the easterly line of lot 19 a distance of 824.56 feet to the Northeast corner of said Lot 19; thence North 66 degrees 04 minutes 50 seconds West along the northerly line of lot 19 a distance of 150.00 feet; thence South 28 degrees 11 minutes 18 seconds West a distance of 781.79 feet to the aforementioned Center line of the Old St. Charles Rock Road; thence South 32 degrees 08 minutes 19 seconds East along said centerline a distance of 50.00 feet to the point of beginning and containing 1.78 acres.

Consent Order

[See attached]

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY
REGION VII
726 MINNESOTA AVENUE
KANSAS CITY, KANSAS 66101

IN THE MATTER OF: COTTER CORPORATION (N.S.L.), and LAIDLAW WASTE SYSTEMS (BRIDGETON), INC., and ROCK ROAD INDUSTRIES, INC., and UNITED STATES DEPARTMENT OF ENERGY, RESPONDENTS. Proceeding Under Sections 104, 122(a), and 122(d)(3) of the Comprehensive Environmental Response, Compensation, and Liability Act as amended 42 U.S.C §§ 9604, 9622(a), 9622(d)(3).	Docket No. VII-93-F-0005

ADMINISTRATIVE ORDER ON CONSENT
FOR REMEDIAL INVESTIGATION/FEASIBILITY STUDY

TABLE OF CONTENTS

I. INTRODUCTION

1. This Administrative Order on Consent ("Consent Order") is entered into voluntarily by the United States Environmental Protection Agency ("EPA"), Cotter Corporation (N.S.L.) ("Cotter"), Laidlaw Waste Systems (Bridgeton), Inc. ("Laidlaw"), Rock Road Industries, Inc. ("Rock Road"), and the United States Department of Energy ("DOE") (Cotter, Laidlaw, Rock Road, and DOE are collectively referred to herein as "Respondents"). This Consent Order concerns the preparation of, performance of, and reimbursement of all costs incurred by EPA in connection with a remedial investigation and feasibility study ("RI/FS") at the West Lake Landfill NPL Site located at Bridgeton, Missouri (hereinafter referred to as "West Lake" or "Site").

II. JURISDICTION

2. This Consent Order is issued pursuant to the authority vested in the President of the United States by Sections 104, 122(a), and 122(d)(3) of the Comprehensive Environmental Response, Compensation, and Liability Act, as amended, 42 U.S.C. §§ 9604, 9622(a), and 9622(d)(3) ("CERCLA"). This authority was delegated to the Administrator of EPA by Executive Order 12580 of January 23, 1987, 52 Fed. Reg. 2923, and was further delegated to EPA's Regional Administrators on September 13, 1987 by EPA Delegation No. 14-14-C. This authority has been redelegated by the Regional Administrator of EPA Region VII to the Director of the Waste Management Division of EPA Region VII by Delegation R7-14-14C dated May 16, 1988.

3. Respondents agree to undertake all actions required by the terms and conditions of this Consent Order. In any action by EPA or the United States to enforce the terms of this Consent Order, Respondents consent to and agree not to contest the authority or jurisdiction of EPA to issue or enforce this Consent Order, and agree not to contest the validity of this Consent Order or its terms.

III. PARTIES BOUND

4. This Consent Order shall apply to and be binding upon EPA and Respondents and their respective agents, successors, and assigns, and upon all persons, including contractors and consultants, acting under or on behalf of Respondents or EPA with regard to the Site. Respondents' participation in this Consent Order, however, shall not be construed as an admission of liability or of EPA's findings of fact or conclusions of law and determinations contained in this Consent Order. The signatories to this Consent Order certify that they are authorized to execute and legally bind the parties they represent to this Consent Order. No change in the ownership or corporate status of Respondents, or of the ownership of the Site, shall alter Respondents' responsibilities under this Consent Order.

5. Respondents shall provide a copy of this Consent Order to any subsequent owners or successors before all or substantially all of the stock or assets are transferred in a corporate acquisition. Respondents shall provide a copy of this Consent Order to all contractors, subcontractors, laboratories, and consultants which

are retained to conduct any work performed under this Consent Order within fourteen (14) days after the effective date hereof or the date of retaining their services, whichever is later. Respondents shall condition any such contracts upon satisfactory compliance with all applicable terms of this Consent Order. Notwithstanding the terms of any contract, each Respondent is responsible for compliance with this Consent Order and shall use its best efforts to ensure that its subsidiaries, employees, contractors, consultants, subcontractors, and agents comply with all applicable terms of this Consent Order.

IV. STATEMENT OF PURPOSE

6. In entering into this Consent Order, the objectives of EPA and Respondents are: (a) to determine the nature and extent of contamination and any threat to the public health, welfare, or the environment caused by the release or threatened release of hazardous substances, pollutants, or contaminants at or from Radiological Areas 1 and 2, as defined in Paragraph 12, herein, at the Site by conducting a remedial investigation; (b) to determine and evaluate alternatives for remedial action (if any) to prevent, mitigate, or otherwise respond to or remedy any release or threatened release of hazardous substances, pollutants, or contaminants at or from Radiological Areas 1 and 2 at the Site, by conducting a feasibility study; and (c) to recover all response and oversight costs incurred by EPA with respect to this Consent Order in accordance with the procedures set forth in Section XXII (Reimbursement of Response and Oversight Costs).

7. The activities conducted under this Consent Order are subject to approval by EPA and shall provide all appropriate and necessary information for the RI/FS, and for a Record of Decision ("ROD") that is consistent with CERCLA and the National Oil and Hazardous Substances Pollution Contingency Plan ("NCP"), 40 C.F.R. Part 300. The activities conducted under this Consent Order shall be conducted in compliance with all applicable EPA guidances, policies, and procedures, which EPA will identify in writing in advance. Activities conducted in compliance with this Consent Order shall be deemed in compliance with the NCP.

V. EPA'S FINDINGS OF FACT

EPA makes the following Findings of Fact (contained in Paragraphs 8-31), which Respondents do not admit:

8. The Landfill is comprised of approximately 200 acres located at 13570 St. Charles Rock Road, Bridgeton, St. Louis County, Missouri, and is approximately 4 miles west of St. Louis' Lambert Field International Airport, near the intersection of Highways I-70 and I-270. Limestone was quarried at the Landfill from 1939 to the present. Since 1962 portions of the quarried property have been used for landfilling municipal refuse, industrial solid and liquid wastes, and construction demolition debris.

9. In 1966, the Atomic Energy Commission ("AEC") sold 8,700 tons of leached barium sulfate, together with other radioactive residues, to Continental Mining and Milling Company ("Continental Mining"). The radioactive residues were generated as by-products

of uranium processing performed by the AEC's contractor. These processing residues were stored at the AEC's St. Louis Airport Storage Site ("SLAPSS").

10. Continental Mining removed the radioactive residues to its facility at 9200 Latty Avenue in Hazelwood, Missouri. Eventually, Cotter purchased the radioactive residues and shipped all but the 8,700 tons of leached barium sulfate to its processing facility in Colorado.

11. In 1973 approximately 8,700 tons of radioactively contaminated leached barium sulfate residues were mixed with approximately 39,000 tons of soil, and the entire amount was disposed of in Radiological Areas 1 and 2, which are described in Paragraph 12, at the Landfill. This material resulted from decontamination efforts undertaken by Cotter at 9200 Latty Avenue, St. Louis, Missouri, where the residues had been stored.

12. In 1978, an aerial survey sponsored by the Nuclear Regulatory Commission ("NRC") revealed two areas within the Landfill where gamma radiation levels indicated radioactive material had been deposited. In 1980-81, Radiation Management Corporation ("RMC") of Chicago, Illinois, performed a detailed radiological survey of the Landfill under contract to the NRC. This survey was performed to determine the extent of radiological contamination. This survey indicated that the radioactive contaminants were located in two areas of the Landfill. The northern area of radioactive contamination ("Radiological Area 2") is comprised of approximately 13 acres. The radioactive debris in

this area forms a layer 2 to 15 feet thick, with radioactive debris exposed on the surface of the Landfill and along the berm on the northwest face of the Landfill. The southern area of radioactive contamination ("Radiological Area 1") is comprised of approximately 3 acres with most of the contaminated soil buried under approximately 3 feet of soil and fill.

13. The RMC survey indicated that the radioactivity emanates from uranium-238 ("U-238") and uranium-235 ("U-235") series with thorium-230 ("Th-230") and radium-226 ("Ra-226"). The survey data indicate that the average Ra-226 concentration in the radioactive wastes is approximately 90 picocuries per gram ("pCi/g"), with the average Th-230 concentration estimated to be approximately 9,000 pCi/g. Since Ra-226 has been depleted with respect to its parent Th-230, Ra-226 activity will increase in time (for example, over the next 200 years, Ra-226 activity will increase ninefold over the present level).

14. In addition to RMC's radiological survey, the NRC through Oak Ridge Associated Universities ("ORAU") contracted with the University of Missouri-Columbia Department of Civil Engineering to describe the environmental characteristics of the Site, conduct an engineering evaluation, and propose possible remedial actions for dealing with the radioactive materials at the Site. In March of 1984 a radiological survey along a section of a berm bounding the Landfill was performed by ORAU.

15. Measurements of direct radiation levels and radionuclide concentrations in soil and the physical condition of the berm area

indicated that erosion was occurring and that there were elevated concentrations of Ra-226 and Th-230 at the base of the berm and extending into the adjacent field. A sample from the mound of soil at the base of the berm contained 185 pCi/g of Ra-226 and 6,270 pCi/g of Th-230. Samples collected in the adjacent field contained 4.29-4.47 pCi/g of Ra-226 and 132-178 pCi/g of Th-230. In May 1986, ORAU sampled water wells on and close to the Landfill to determine if radioactive contamination had migrated into the groundwater. The sampling consisted of 18 monitoring wells which are located in various locations around the Landfill and are screened in the shallow, intermediate, and deep parts of the aquifer. Two sampling rounds were evaluated. Round 1 occurred from December 11-15, 1985 and Round 2 from May 19-21, 1986. All samples were analyzed for priority pollutants listed under 40 C.F.R. Part 122, Appendix D. This list includes volatile organics, acid and base/neutral extractables, pesticides, polyclorinated biphenyls ("PCBs"), total phenols, total cyanide, and metals. Four wells sampled during Round 1 were also analyzed for gross alpha and beta radiation.

16. Chemical results indicated that samples from certain wells contained detectable levels of several constituents. Chemicals found during Round 1 included methylene chloride (2-83 micrograms per liter ("ug/l"), bis-2-ethyhexyl phthalate (4-477 ug/l), phenol (7-19 ug/l), total cyanide (1-6 ug/l), sodium (5-175 milligrams per liter), iron (20-14,380 ug/l), lead (13 ug/l), and zinc (2-1,240 ug/l). Trace amounts of several pesticides also were

detected such as lindane, chlordane, dieldrin, endrin, 4,4'DDD, 4,4' DDE, 4,4' DDT, and hexachlorobenzene. The four wells sampled for gross alpha and beta radiation during Round 1 contained values for gross alpha ranging from 2-270 picocuries per liter ("pCi/l") and values for gross beta ranging from 11-171 pCi/l. Round 2 chemical results indicated the presence of methylene chloride (6-10 ug/l), bis-2-ethyhexyl phthalate (10 ug/l), total cyanide (7 ug/l), zinc (2-2,000 ug/l), and arsenic (4-9 ug/l). Compounds such as antimony, nickel, and thallium also were found.

17. In May 1986, 32 wells at the Site were sampled and analyzed for gross alpha and beta by ORAU. Isotopic analyses were performed on many of the samples to determine radium levels. The radionuclide concentrations were found to be gross alpha (0.9-8.4 pCi/l), gross beta (1.9-22 pCi/l), Ra-226 (0.2-0.7 pCi/l), Ra-228 (0.2-5.8 pCi/l), U-total (1.6-25 pCi/l), Th-228 (0.2-1.7 pCi/l), Th-230 (0.1-12 pCi/l), and Th-232 (0.2-4.0 pCi/l). The concentrations for gross alpha, Ra-226, and Ra-228 are below the permissible maximum contaminant levels for community water systems set forth in 40 C.F.R. § 141.

18. Direct contact with, and air transport of, radiological contamination would primarily affect persons working in and around the Site. Surface water runoff from the Landfill primarily flows to a drainage ditch along the north side of the Landfill and the south side of St. Charles Rock Road. This ditch may occasionally be recharged by groundwater. This surface water either recharges the groundwater or discharges through a drainage ditch to the

Missouri River. A pond along this ditch is located on the north side of the Landfill and is known to contain fish. Surface water runoff to the south and southwest flows across relatively flat agricultural fields. This runoff joins the small intermittent ditches which traverse the area. Groundwater contamination could affect persons using groundwater downgradient of the Landfill before it discharges to the Missouri River.

19. In a report entitled "Hydrogeological Investigation, West Lake Landfill, Primary Phase Report" prepared by Burns & McDonnell in October 1986, it was stated that the predominant groundwater flow direction in the alluvial aquifer in the vicinity of the Site is northwestward toward the Missouri River. The water table generally slopes toward the Missouri River, although changes in gradient direction apparently occur at some times during the year in response to changes in the stage of the Missouri River. The alluvial aquifer consists of a continuous sequence of sand deposits with some gravel zones. The alluvium at shallow depths is primarily fine to medium sand, with only traces of gravel. The alluvium in the deeper part of the aquifer is coarser grained, consisting primarily of coarse sand and gravel.

20. Uranium, thorium, radium, protactinium, and actinium are all known human carcinogens. Methylene chloride and lead are both probable human carcinogens. Phenol is a suspected carcinogen and mutagen.

21. The following pesticides were detected in analyses of groundwater samples taken at the Site: gamma BH (Lindane),

chlordane, dieldrin, endrin, 4,4' DDD, 4,4' DDE, 4,4' DDT, and hexachlorobenzene. These highly-chlorinated pesticides are probable carcinogens. They are toxic to humans via ingestion and dermal contact. Some are reproductive toxins.

22. U-238, U-235, Th-230, and Ra-226, the pesticides identified in Paragraph 21, above, methylene chloride, phenol, and lead are hazardous substances as defined in CERCLA Section 101(14), 42 U.S.C. § 9601(14).

23. Pursuant to Section 105 of CERCLA, 42 U.S.C. § 9605, EPA placed the Site on the National Priorities List, set forth at 40 C.F.R. Part 300, Appendix B, by publication in the Federal Register on August 30, 1990, 55 Fed. Reg. 35502.

24. Cotter Corporation (N.S.L.) is a corporation organized and existing pursuant to the laws of the State of New Mexico.

25. Laidlaw Waste Systems (Bridgeton), Inc. is a corporation organized and existing pursuant to the laws of the State of Missouri.

26. Rock Road Industries, Inc. is a corporation organized and existing pursuant to the laws of the State of Missouri.

27. The United States Department of Energy is a department of the United States Government and is a successor to the Atomic Energy Commission.

28. Cotter, by contract, agreement, or otherwise arranged for the disposal, or arranged with a transporter for transport for disposal, hazardous substances owned or possessed by it at the Site.

29. At the time of disposal of hazardous substances at the Site, West Lake Landfill, Inc. (now known as Laidlaw Waste Systems (Bridgeton), Inc., and referred to herein as Laidlaw) was an owner or operator of the Site.

30. DOE, by contract, agreement, or otherwise arranged for the disposal, or arranged with a transporter for transport for disposal, hazardous substances owned or possessed by it at the Site.

31. Rock Road is a current owner of the Site.

VI. EPA'S CONCLUSIONS OF LAW AND DETERMINATIONS

EPA makes the following Conclusions of Law and Determinations, which Respondents do not admit:

32. The Site is a "facility" as defined in Section 101(9) of CERCLA, 42 U.S.C. § 9601(9).

33. There has been a "release" or threat of a release of a "hazardous substance" at the Site as defined in Section 101(22) and 101(14) of CERCLA, 42 U.S.C. §§ 9601(22) and 9601(14).

34. Respondents are each a "person" as defined in Section 101(21) of CERCLA, 42 U.S.C. § 9601(21).

35. Respondents are each a responsible party pursuant to Sections 104, 107, and 122 of CERCLA, 42 U.S.C. §§ 9604, 9607, and 9622.

36. The actions required by this Consent Order are necessary to protect the public health, welfare, or environment, are practicable and in the public interest, are consistent with CERCLA and the NCP, and will expedite effective remedial action and

minimize litigation, all in accordance with Sections 104 and 122 of CERCLA, 42 U.S.C. §§ 9604 and 9622.

VII. NOTICE TO THE STATE

37. By providing a copy of this Consent Order to the State of Missouri, EPA is notifying the State of Missouri that this Consent Order is being issued and that EPA is the lead agency for coordinating, overseeing, and enforcing the activities required hereunder.

VIII. WORK TO BE PERFORMED

38. All activities performed pursuant to this Consent Order (the "Work") shall be under the direction and supervision of qualified personnel. Within thirty (30) days of the effective date of this Consent Order, and before the Work outlined below begins, Respondents shall notify EPA in writing of the names, titles, and qualifications of the principal personnel, including contractors, subcontractors, consultants, and laboratories, to be used in carrying out the Work. The qualifications of the principal persons responsible for undertaking the Work for Respondents shall be subject to EPA's review, for verification that such persons meet minimum technical background and experience requirements. This Consent Order is contingent on Respondents' demonstration to EPA's satisfaction that Respondents are qualified to perform properly and promptly the actions set forth in this Consent Order. If EPA disapproves of the technical qualifications of any person, Respondents shall notify EPA of the identity and qualifications of a replacement within thirty (30) days of receipt of EPA's

disapproval. If EPA disapproves of the replacement, EPA reserves the right to terminate this Consent Order and to conduct the Work itself, to seek reimbursement from Respondents, and/or to seek any other appropriate relief as provided herein. During the course of the performance of the Work, Respondents shall notify EPA in writing of any changes or additions in the principal personnel used to carry out the Work, including their names, titles, and qualifications. EPA shall have the same right to approve changes and additions to principal personnel as it has hereunder regarding the initial notification.

39. Respondents shall conduct activities and submit deliverables as provided by this Consent Order and the attached RI/FS Statement of Work ("SOW"), which is incorporated herein by reference, and Section IV (Statement of Purpose). All such work shall be conducted in accordance with CERCLA, the NCP, and EPA guidance including, but not limited to, the "Interim Final Guidance for Conducting Remedial Investigations and Feasibility Studies under CERCLA" (OSWER Directive 9355.3-01), guidances referenced therein, and guidances referenced in the SOW, as may be amended or modified by EPA. The general activities that Respondents are required to perform are identified below. The tasks that Respondents must perform are described more fully in the SOW and guidances. The activities and deliverables identified below shall be developed as provided in the RI/FS Work Plan and Sampling and Analysis Plan, and shall be submitted to EPA as provided. All work performed under this Consent Order shall be in accordance with the

schedules herein, and in full accordance with the standards, specifications, and other requirements of the RI/FS Work Plan and Sampling and Analysis Plan, as approved by EPA, and as may be amended or modified by EPA.

a. **Task I - Scoping**. EPA determines the Site-specific objectives of the RI/FS and devises a general management approach for the Site, as stated in the attached SOW. Respondents shall conduct the remaining scoping activities as described in the SOW and referenced guidances. At the conclusion of the project planning phase, Respondents shall submit the following deliverables to EPA:

(1) RI/FS Work Plan. Within sixty (60) days of the effective date of this Consent Order, Respondents shall submit to EPA a complete RI/FS Work Plan in accordance with the SOW. If EPA disapproves of or requires revisions to the RI/FS Work Plan, in whole or in part, Respondents shall amend and submit to EPA a revised RI/FS Work Plan which is responsive to all of EPA's comments, within forty-five (45) days of receiving EPA's comments.

(2) Sampling and Analysis Plan. Within sixty (60) days of the effective date of this Consent Order, Respondents shall submit to EPA a Sampling and Analysis Plan in accordance with the schedule set forth in the EPA approved RI/FS Work Plan. This Sampling and Analysis Plan shall consist of a Field Sampling Plan ("FSP") and a Quality Assurance Project Plan ("QAPP") as described in the SOW and guidances. If EPA

disapproves of or requires revisions to the Sampling and Analysis Plan, in whole or in part, Respondents shall amend and submit to EPA a revised Sampling and Analysis Plan which is responsive to all of EPA's comments, within forty-five (45) days of receiving EPA's comments.

(3) Site Health and Safety Plan. Within sixty (60) days of the effective date of this Consent Order, Respondents shall submit to EPA a Site Health and Safety Plan.

b. **Task II - Community Relations**. EPA will prepare a Community Relations Plan, in accordance with EPA guidance and the NCP. Respondents shall provide information supporting EPA's community relations programs.

c. **Task III - Site Characterization**. Following EPA approval or modification of the RI/FS Work Plan and Sampling and Analysis Plan, Respondents shall implement the provisions of these Plans to characterize the Site. Respondents shall complete Site characterization in accordance with the schedule set forth in the EPA approved RI/FS Work Plan. Respondents shall provide EPA with validated analytical data generated pursuant to this Consent Order in a form showing the location, medium, and results. As used herein, "validated analytical data" refers to data that has been quality assured pursuant to the QAPP and the supporting empirical data, including instrument printouts, used to determine such quality assured data. Respondents shall require validation of all sampling results within sixty (60) days of receipt from the laboratory. This information shall be submitted to EPA with the subsequent monthly progress report as described in Section XIII (Progress Reports), herein. Within seven (7) days of completion of field activities, Respondents shall notify EPA in writing. During Site characterization, Respondents shall provide EPA with the following deliverables, as described in the SOW and RI/FS Work Plan:

(1) Technical Memorandum on Modeling of Site Characteristics. Where Respondents propose that modeling is appropriate, Respondents shall submit a technical memorandum on modeling of Site characteristics in accordance with the schedule set forth in the approved RI/FS Work Plan. If EPA disapproves of, or requires revisions to, the technical memorandum on modeling of Site characteristics, in whole or in part, Respondents shall amend and submit to EPA a revised technical memorandum on modeling of Site characteristics which is responsive to all of EPA's comments, within forty-five (45) days of receiving EPA's comments.

(2) Site Characterization Summary Report. Respondents shall submit a Site Characterization Summary Report to EPA in accordance with the schedule set forth in the approved RI/FS Work Plan.

(3) Remedial Investigation Report. Within sixty (60) days of receipt from EPA of the Baseline Risk Assessment described in Section IX (EPA's Baseline Risk Assessment), Respondents shall submit to EPA a Remedial Investigation Report consistent with the SOW, RI/FS Work Plan, and Sampling

and Analysis Plan. If EPA disapproves of or requires revisions to the Remedial Investigation Report, in whole or in part, Respondents shall amend and submit to EPA a revised Remedial Investigation Report which is responsive to all of EPA's comments, within forty-five (45) days of receiving EPA's comments.

d. **<u>Task IV - Treatability Studies</u>**. Respondents shall submit to EPA a memorandum analyzing whether treatability studies are needed based on the information developed during the conduct of the Remedial Investigation and the basis therefor. EPA will then determine whether Respondents shall conduct treatability studies and notify Respondents of its decision in writing. If required, major components of the treatability studies include determination of the need for and scope of studies, the design of the studies, and the completion of the studies as described in the SOW. During treatability studies, Respondents shall provide EPA with the following deliverables:

(1) <u>Identification of Candidate Technologies Memorandum</u>. This memorandum shall be submitted in accordance with the schedule set forth in the EPA approved RI/FS Work Plan. If EPA disapproves of, or requires revisions to, the technical memorandum identifying candidate technologies, in whole or in part, Respondents shall amend and submit to EPA a revised technical memorandum identifying candidate technologies which is responsive to all of EPA's comments within forty-five (45) days of receiving EPA's comments.

(2) <u>Treatability Testing Work Plan</u>. Respondents shall submit a Treatability Testing Work Plan or a proposed amendment to the RI/FS Work Plan, including a schedule, in accordance with the schedule set forth in the approved RI/FS Work Plan. If EPA disapproves of, or requires revisions to, the Treatability Testing Work Plan or the proposed amendment to the RI/FS Work Plan, in whole or in part, Respondents shall amend and submit to EPA a revised Treatability Testing Work Plan or proposed amendment to the RI/FS Work Plan, which is responsive to all of EPA's comments, within forty-five (45) days of receiving EPA's comments.

(3) <u>Treatability Study Sampling and Analysis Plan</u>. Upon the identification of the need for a separate or amended QAPP or FSP, Respondents shall submit a Treatability Study Sampling and Analysis Plan or a proposed amendment to the original QAPP or FSP, in accordance with the schedule set forth in the approved RI/FS Work Plan. If EPA disapproves of, or requires revisions to, the Treatability Study Sampling and Analysis Plan or the proposed amendment to the original QAPP or FSP, in whole or in part, Respondents shall amend and submit to EPA a revised Treatability Study Sampling and Analysis Plan or proposed amendment to the original QAPP or FSP, which is responsive to all of EPA's comments, within forty-five (45) days of receiving EPA's comments.

(4) <u>Treatability Study Site Health and Safety Plan</u>. Upon the identification of the need for a separate or amended

Health and Safety Plan, Respondents shall submit a Treatability Study Site Health and Safety Plan or a proposed amendment to the original Site Health and Safety Plan, in accordance with the schedule set forth in the approved RI/FS Work Plan.

(6) Treatability Study Evaluation Report. Respondents shall submit a Treatability Study Evaluation Report as provided in the SOW and RI/FS Work Plan in accordance with the schedule set forth in the approved RI/FS Work Plan. If EPA disapproves of, or requires revisions to, the Treatability Study Evaluation Report, in whole or in part, Respondents shall amend and submit to EPA a revised Treatability Study Evaluation Report which is responsive to all of EPA's comments within forty-five (45) days of receiving EPA's comments.

e. **Task V - Development and Screening of Remedial Alternatives**. Respondents shall develop an appropriate range of waste management options that will be evaluated through the development and screening of alternatives as provided in the SOW and RI/FS Work Plan. During the development and screening of alternatives, Respondents shall provide EPA with the following deliverables:

(1) Memorandum on Remedial Action Objectives. Within sixty (60) days of receipt of the Baseline Risk Assessment, Respondents shall submit a memorandum on remedial action objectives.

(2) Report on Development and Screening of Remedial Alternatives. Respondents shall submit a report summarizing the development and screening of remedial alternatives including an alternatives array document as described in the SOW in accordance with the schedule set forth in the approved RI/FS Work Plan.

f. **Task VI - Detailed Analysis of Remedial Alternatives**. Respondents shall conduct a detailed analysis of remedial alternatives as described in the SOW and RI/FS Work Plan. During the detailed analysis of alternatives, Respondents shall provide EPA with the following deliverables and presentation:

(1) Comparative Analysis Technical Memorandum and Presentation to EPA. Respondents shall submit a technical memorandum to EPA summarizing the results of the comparative analysis performed between the remedial alternatives in accordance with the schedule set forth in the approved RI/FS Work Plan. If EPA disapproves of, or requires revisions to, the comparative analysis technical memorandum, Respondents shall amend and submit to EPA a revised comparative analysis technical memorandum which is responsive to all of EPA's comments within forty-five (45) days of receiving EPA's comments. Upon EPA's request, Respondents shall make a presentation to EPA during which Respondents shall summarize the findings of the remedial investigation and remedial action objectives, and present the results of the nine criteria evaluation and comparative analysis as described in the SOW,

in accordance with the schedule set forth in the approved RI/FS Work Plan.

(2) Feasibility Study Report. Respondents shall submit a draft Feasibility Study Report which reflects the findings in the Baseline Risk Assessment in accordance with the schedule set forth in the approved RI/FS Work Plan. Respondents shall refer to Table 6-5 of the RI/FS Guidance for report content and format. If EPA disapproves of, or requires revisions to, the draft Feasibility Study Report, in whole or in part, Respondents shall amend and submit to EPA a revised Feasibility Study Report which is responsive to all of EPA's comments, within forty-five (45) days of receiving EPA's comments. The report, as amended, and the Administrative Record shall provide the basis for the Proposed Plan under CERCLA §§ 113(k) and 117(a), 42 U.S.C. §§ 6913(k) and 6917(a), by EPA and shall document the development and analysis of remedial alternatives.

40. For all deliverables, EPA will approve, disapprove, or return the deliverable to Respondents with comments or requests for modifications. In subsequent or resubmitted deliverables, Respondents shall respond to the specified deficiencies and address the information and comments from EPA. If EPA disapproves of a deliverable, EPA will state with specificity the grounds for disapproval.

41. Respondents shall not proceed further with any subsequent activities or tasks until receiving EPA approval for the following

deliverables: RI/FS Work Plan, Sampling and Analysis Plan, draft Remedial Investigation Report, Treatability Testing Work Plan, Treatability Study Sampling and Analysis Plan, and the draft Feasibility Study Report. While awaiting EPA approval on these deliverables, Respondents shall proceed with all other tasks and activities which may be conducted independently of these deliverables, in accordance with the schedule set forth in this Consent Order or the approved RI/FS Work Plan.

42. For all remaining deliverables not enumerated in the preceding Paragraph, Respondents may proceed with all subsequent tasks, activities and deliverables without awaiting EPA approval. If Respondents have not complied with an approved Work Plan or this Consent Order, or at any time EPA deems necessary to protect public health, welfare, or the environment, however, EPA reserves the right to disapprove Respondents' implementation of such tasks and may require that Respondents' cease the implementation of such tasks, either temporarily or permanently, at any point during the RI/FS.

43. In the event that Respondents amend or revise a report, plan, or other submittal upon receipt of EPA comments, if EPA subsequently disapproves of the revised submittal, or if subsequent submittals do not fully reflect EPA's directions for changes, EPA retains the right to seek stipulated or statutory penalties, perform its own studies, complete the RI/FS (or any portion of the RI/FS) pursuant to CERCLA and the NCP, and seek reimbursement from the Respondents for its costs and/or seek any other appropriate

relief. In the event EPA refuses to approve a deliverable unless Respondents change or modify it in a manner which Respondents deem inconsistent with Respondents' best professional judgment, Respondents reserve the right to seek Dispute Resolution in accordance with Section XIX (Dispute Resolutions) or pursue any other rights they may have.

44. In the event that EPA takes over some of the tasks but not the preparation of the RI/FS, Respondents shall incorporate and integrate information supplied by EPA into the final RI/FS report.

45. Neither the failure of EPA to expressly approve or disapprove of Respondents' submissions within a specified time period nor the absence of comments, shall be construed as approval by EPA. EPA will make it a goal to approve, disapprove, or comment on all deliverables within sixty (60) days of receipt of the deliverable.

IX. EPA'S BASELINE RISK ASSESSMENT

46. EPA will perform the Baseline Risk Assessment. Respondents shall support EPA in the effort by providing various information to EPA as outlined above. The major components of the Baseline Risk Assessment include contaminant identification, exposure assessment, toxicology assessment, and human health and ecological risk characterization.

47. EPA will provide, after review of Respondents' Site Characterization Summary, sufficient information concerning the baseline risks such that the Respondents can begin drafting the

Feasibility Study Report and the Memorandum on Remedial Action Objectives.

48. EPA will prepare a Baseline Risk Assessment report based on data collected by the Respondents during Site characterization. EPA will release the final report to the public at the same time it releases the final RI Report. Both reports will be put into the Administrative Record for the Site.

X. MODIFICATION OF THE RI/FS WORK PLAN

49. Respondents shall have the right to gather any additional data not specified or required under this Consent Order. If, at any time during the performance of the Work required under this Consent Order, Respondents identify a need for additional data to complete the Work which shall require a modification or extension of any part of the schedule, Respondents shall submit a memorandum to the EPA Project Coordinator explaining the need for and the nature of the requested modification or extension. If EPA does not approve or disapprove of the request for modification or extension within fourteen (14) days of receipt of the request, Respondents may proceed to gather such additional data and submit it to EPA for inclusion in the administrative record. However, any schedule modification or extension may be accomplished only in conformity with Section XXVII (Effective Date and Subsequent Modification) of this Consent Order.

50. In the event conditions posing an immediate threat to human health, welfare, or the environment become known to them, Respondents shall notify EPA and the State of Missouri no later

than twenty-four (24) hours of discovery. In the event of material unanticipated or changed circumstances at the Site, Respondents shall notify the EPA Project Coordinator by telephone within forty-eight (48) hours of discovery of such unanticipated or changed circumstances. In addition to the authorities in the NCP, in the event that EPA determines that the immediate threat or the material unanticipated or changed circumstances warrant changes in the RI/FS Work Plan, EPA may modify or amend the RI/FS Work Plan in writing accordingly. If Respondents dispute EPA's modifications or amendments to the RI/FS Work Plan, they shall submit such issue to Dispute Resolution pursuant to Section XIX. Otherwise, Respondents shall perform the RI/FS Work Plan as modified or amended.

51. EPA may determine that in addition to tasks defined in the initially approved RI/FS Work Plan, other additional work may be necessary to accomplish the objectives of the RI/FS as set forth in the SOW and the Statement of Purpose set forth in Section IV, herein. EPA may request that Respondents perform such other work in addition to the work required by the initially approved RI/FS Work Plan including any approved modifications if it determines that such actions are necessary for a complete RI/FS and is consistent with the Statement of Purpose set forth in Section IV, herein. Respondents shall confirm their willingness to perform the additional work in writing to EPA within seven (7) days of receipt of the EPA request or Respondents shall invoke Dispute Resolution. Subject to resolution of any dispute pursuant to the provisions of Section XIX (Dispute Resolution), Respondents shall implement the

additional tasks which EPA determines are necessary. The additional work shall be completed according to the standards, specifications, and schedules set forth or approved by EPA in a written modification to the RI/FS Work Plan. In the event Respondents do not agree to perform the additional work and the modification is not the subject of Dispute Resolution, EPA reserves the right to conduct the additional work itself, to seek reimbursement from Respondents, and/or to seek other appropriate relief.

XI. QUALITY ASSURANCE

52. Respondents shall assure that work performed, samples taken, and analyses conducted pursuant to this Consent Order conform to the requirements of the SOW, the QAPP, and all guidances identified herein. Respondents shall assure that field personnel used by Respondents are properly trained in the use of field equipment and in chain of custody procedures.

XII. FINAL RI/FS; PROPOSED PLAN; PUBLIC COMMENT; RECORD OF DECISION; ADMINISTRATIVE RECORD

53. EPA retains the responsibility for the release to the public of the RI/FS Reports. EPA retains responsibility for the preparation and release to the public of the Proposed Plan and ROD in accordance with CERCLA and the NCP.

54. EPA will determine the contents of the administrative record file for selection of the remedial action. Respondents will submit to EPA documents developed during the course of the RI/FS upon which selection of the response action may be based. Respondents shall provide copies of plans, task memoranda

(including documentation of field modifications, if any), recommendations for further action, quality assurance memoranda and audits, raw data, field notes, laboratory analytical reports, and other reports. To the extent not in EPA's possession at Region VII or in the possession of MDNR, Respondents must additionally submit copies of any previous studies in their possession or under their control conducted under state, local, or other federal authorities relating to selection of a response action for Radiological Areas 1 and 2, and copies of all written communications between Respondents and state, local, or other federal authorities concerning selection of a response action for Radiological Areas 1 and 2. At their discretion, Respondents may establish a community information repository at, or near, the Site to house a copy of the administrative record.

XIII. <u>PROGRESS REPORTS</u>

55. Respondents shall make presentations at and participate in meetings at the request of EPA during the initiation, conduct, and completion of the Work. In addition to discussion of the technical aspects of the Work, topics will include anticipated problems or new issues. Meetings will be scheduled at EPA's discretion. When practicable, EPA will give Respondents five (5) days advance written notice of any such meeting or presentation.

56. In addition to the deliverables set forth in this Consent Order, Respondents shall provide to EPA monthly progress reports by the 10th day of each following month. These progress reports shall include: (1) a description of the actions which have been taken to

comply with this Consent Order during that month; (2) all validated analytical data and all other validated data received by Respondents during that month; (3) a description of the work planned for the next two months with schedules relating such work to the overall project schedule; and (4) a description of all material problems encountered and any anticipated material problems, any actual or anticipated material delays, and solutions developed and implemented to address any actual or anticipated material problems or delays.

XIV. SAMPLING AND DATA ANALYSIS

57. All validated analytical data, including results of sampling, tests, modeling, or other data generated by Respondents or on Respondents' behalf, pursuant to the requirements of this Consent Order shall be submitted to EPA in the subsequent monthly progress report as described in Section XIII (Progress Reports) of this Consent Order. EPA will make available to Respondents validated data generated by EPA unless it is exempt from disclosure by any federal or state law or regulation.

58. Respondents orally will notify EPA at least fourteen (14) days prior to conducting significant field events as described in the SOW, RI/FS Work Plan, or Sampling and Analysis Plan. Upon EPA's request, Respondents shall allow EPA or its authorized representatives to take a reasonable number of split or duplicate samples of samples collected by Respondents in implementing this Consent Order.

59. Respondents may assert a business confidentiality claim covering part or all of the information submitted to EPA pursuant to the terms of this Consent Order to the extent permitted by and in accordance with Section 104(e)(7) of CERCLA, 42 U.S.C. § 9607(e)(7), and 40 C.F.R. § 2.203(b). This claim shall be asserted in the manner described by 40 C.F.R. § 2.203(b) and substantiated at the time the claim is made. Information determined to be confidential by EPA will be given the protection specified in 40 C.F.R. Part 2, Subpart B. If no such claim accompanies the information when it is submitted to EPA, it may be made available to the public without further notice to Respondents. Respondents agree not to assert confidentiality claims with respect to any data related to Site conditions, sampling, or monitoring.

60. By entering into this Consent Order, Respondents waive any objections to the validity of any data gathered, generated, or evaluated by EPA, the State of Missouri, or Respondents in the performance or oversight of the Work that has been verified according to the approved quality assurance/quality control ("QA/QC") procedures required by the Consent Order. If Respondents object to data relating to the Work, Respondents shall submit to EPA a report that identifies and explains its objections, describes the acceptable uses of the data, if any, and identifies any limitations to the use of the data. Such report must be submitted to EPA within fifteen (15) days of the monthly progress report containing the data.

61. To the extent practicable, EPA orally will notify Respondents at least five (5) days prior to conducting any independent field activities relating to the Site during the course of the performance of the Work. At Respondents' oral or written request, EPA will permit Respondents' representative to be present during any such activities and shall allow split or duplicate samples to be taken by Respondents of any samples collected by EPA relating to the Site. All samples taken by EPA will be taken, handled, and analyzed in accordance with the procedures specified in the FSP, to the extent applicable, and the QAPP. EPA will assure that field personnel used by EPA are properly trained in the use of field equipment, in chain of custody procedures, and as required by the Health and Safety Plan.

XV. ACCESS

62. Commencing upon the effective date of this Consent Order, Respondents agree to provide EPA and its representatives, including its contractors, access at all times to the Site and any other property to which access is required for the implementation of this Consent Order, to the extent access to the property is controlled by Respondents, for the purposes of conducting any activity related to this Consent Order including, but not limited to:

a. Monitoring the Work;

b. Verifying any data or information submitted to EPA;

c. Conducting investigations relating to contamination at or near the Site;

d. Obtaining samples;

e. Assessing the need for, planning, or implementing additional response actions at or near the Site;

f. Inspecting and copying records, operating logs, contracts, or other documents maintained or generated by Respondents or their agents; and

g. Assessing Respondents' compliance with this Consent Order.

63. Prior to entering the Site, EPA will provide, when practicable, Respondents' Project Coordinator with the credentials or other written notice of all EPA personnel and representatives authorized to enter the Site pursuant to this Section.

64. EPA and its representatives shall comply with the Site Health and Safety Plan while on Site.

65. To the extent that the Site or any other property to which access is required for the implementation of this Consent Order is owned or controlled by persons other than Respondents, Respondents shall use best efforts to secure from such persons access for Respondents, as well as for EPA and its representatives, including, but not limited to, its contractors, as necessary to effectuate this Consent Order. If any access required to complete the Work is not obtained within thirty (30) days of the effective date of this Consent Order, or within thirty (30) days of the date EPA notifies Respondents in writing that additional access beyond that previously secured is necessary, Respondents shall promptly notify EPA, and shall include in that notification a summary of the steps Respondents have taken to attempt to obtain access. EPA may, as it deems appropriate, assist Respondents in obtaining access.

Respondents shall reimburse EPA, in accordance with the procedures in Section XXII (Reimbursement of Response and Oversight Costs), for all costs incurred by EPA in obtaining access.

66. Notwithstanding any provision of this Consent Order, EPA retains all of its access authorities and rights, including enforcement authorities related thereto, under CERCLA, the Resource Conservation and Recovery Act, 42 U.S.C. §§ 6901-6992k, and any other applicable statutes or regulations.

XVI. PROJECT COORDINATORS

67. All documents and correspondence which must be submitted pursuant to this Consent Order shall be sent by certified mail, return receipt requested, by overnight delivery service, or hand-delivered to the following addressees or to any other addressees which Respondents and EPA designate in writing:

a. Documents to be submitted to EPA shall be sent in triplicate to:

Diana L. Newman
U.S. Environmental Protection Agency
Region VII
WSTM/SAFE
726 Minnesota Avenue
Kansas City, Kansas 66101

b. Documents to be submitted to Respondents should be sent to:

Jerome T. Wolf
Michael D. Hockley
Spencer Fane Britt & Browne
1400 Commerce Bank Building
1000 Walnut Street
Kansas City, Missouri 64106

with cc by mail to:

James F. Gunn
Sandra L. Oberkfell
The Stolar Partnership
911 Washington Avenue
St. Louis, Missouri 63101

Charlotte Neitzel
Holme Roberts & Owen
1700 Lincoln, Suite 4100
Denver, Colorado 80203

James W. Wagoner II
Director, Division of Offsite Programs
Office of Eastern Area Programs
Office of Environmental Restoration
U.S. Department of Energy
12800 Middlebrook Road
Germantown, Maryland 20874

Unless otherwise specified, any notices or submissions required by this Consent Order shall be deemed delivered on the date placed in the United States Mail, delivered to an overnight service, or hand-delivered. If response deadlines are triggered by receipt of a notice, then such notice, for purposes of calculating the affected deadline, shall be deemed received upon actual receipt.

68. On or before the effective date of this Consent Order, EPA and Respondents shall each designate their own Project Coordinator. Each Project Coordinator shall be responsible for overseeing the implementation of this Consent Order. To the maximum extent possible, communications between Respondents and EPA shall be directed between the Project Coordinators as specified in Section XVI (Project Coordinators), herein, by mail with copies to such other persons as EPA and Respondents may respectively designate. Communications include, but are not limited to, all

documents, reports, approvals, and other correspondence submitted under this Consent Order.

69. EPA and Respondents each have the right to change their respective Project Coordinator. The other party must be notified in writing at least ten (10) days prior to any such change.

70. EPA's Project Coordinator shall have the authority lawfully vested in a Remedial Project Manager ("RPM") and On-Scene Coordinator ("OSC") by the NCP. In addition, EPA's Project Coordinator shall have authority consistent with the NCP to halt any work required by this Consent Order and to take any necessary response action when EPA determines that conditions at the Site may present an immediate endangerment to public health or welfare or the environment. The absence of the EPA Project Coordinator from the Site shall not be cause for the stoppage or delay of work.

XVII. OTHER APPLICABLE LAWS

71. Respondents shall comply with all applicable laws when performing the activities pursuant to this Consent Order. No federal, state, or local permits are required for on-Site response actions conducted pursuant to CERCLA Sections 104, 121, or 122. The term "on-Site" means the areal extent of contamination and all suitable areas in very close proximity to the contamination necessary for implementation of activities pursuant to this Consent Order.

XVIII. RECORD PRESERVATION

72. One complete set of all records and documents in Respondents' possession that relate to this Consent Order shall be

preserved during the conduct of this Consent Order and for a minimum of six (6) years after commencement of construction of any remedial action. Respondents shall acquire and retain one complete copy of all non-privileged documents that relate to this Consent Order that are in the possession of their employees, agents, accountants, contractors, or attorneys. At the conclusion of this six (6) year period, Respondents shall notify EPA at least ninety (90) days prior to the destruction of any such records or documents, and, upon EPA's request, Respondents shall deliver any such records or documents to EPA.

XIX. DISPUTE RESOLUTION

73. The provisions of this Dispute Resolution section apply to all deliverables required by the Consent Order and all matters for which Dispute Resolution has been expressly provided. Any disputes concerning activities or deliverables required under this Consent Order for which Dispute Resolution is applicable shall be resolved as follows: If Respondents object to any EPA notice of disapproval or requirement made pursuant to this Consent Order, Respondents shall notify EPA's Project Coordinator in writing of their objections within fourteen (14) days of receipt of the disapproval notice or requirement. Respondents' written objections shall define the dispute, state the basis of Respondents' objections, and be sent certified mail, return receipt requested. EPA will, within fourteen (14) days of receipt of Respondents' objections, respond to Respondents in writing, specifically addressing the points raised by Respondents and identifying points

of agreement and disagreement. EPA and Respondents then have an additional fourteen (14) days to reach agreement.

74. If agreement is not reached within the fourteen (14) day period referenced above, Respondents and EPA will communicate their respective position in writing to the Division Director of EPA Region VII's Waste Management Division, who shall resolve the dispute and provide a written statement of his decision to Respondent. The Division Director's determination is EPA's final decision. Respondents shall proceed in accordance with EPA's final decision regarding the matter in dispute regardless of whether Respondents agree with the decision. If the Respondents do not agree to perform, or do not perform the work in accordance with EPA's final decision, EPA reserves the right in its sole discretion to conduct the work itself, to seek reimbursement from the Respondents, to seek enforcement of the decision, to seek stipulated penalties, and/or to seek any other appropriate relief. No action, decision, or directive made by EPA, including without limitation the Division Director of EPA Region VII's Waste Management Division pursuant to this Consent Order shall constitute a final agency action giving rise to any rights to judicial review prior to EPA's initiation of judicial action to compel Respondents' compliance with this Consent Order. Respondents reserve any rights that they may have to seek any appropriate relief to the extent available by applicable law.

75. Respondents are not relieved of their obligations to perform and conduct activities and submit deliverables on the

schedule set forth in the RI/FS Work Plan while a matter is pending in Dispute Resolution. The invocation of Dispute Resolution does not stay stipulated penalties under this Consent Order. If, however, Respondents prevail in the dispute, deadlines directly affected by the matters in dispute shall be extended for a period of time equal to the time taken to resolve the dispute under the procedures of this Section, plus reasonable time for remobilization, as determined by EPA.

XX. DELAY IN PERFORMANCE/STIPULATED PENALTIES

76. Respondents (excluding DOE) shall be liable for stipulated penalties in the amounts set forth in Paragraphs 77 and 78 to the EPA for failure to comply with the requirements of this Consent Order specified below, unless excused pursuant to Section XXI (Force Majeure). In the event that EPA determines that DOE has failed to comply with any provision which would otherwise give rise to stipulated penalties, DOE understands that this Consent Order, as it applies to DOE, will be deemed null and void, and the rights and protections afforded DOE under the Consent Order will be terminated. "Compliance" by Respondents shall include completion of the activities under this Consent Order or any work plan or other plan approved under this Consent Order identified below in accordance with all applicable requirements of law, this Consent Order, the SOW, and any plans or other documents approved by EPA pursuant to this Consent Order and within the specified time schedules established by and approved under this Consent Order.

77. If Respondents do not submit the deliverable items listed below by the deadlines stated in the SOW, or do not perform the tasks listed below in accordance with the schedules listed in the RI/FS Work Plan, the following stipulated penalties shall be payable per day by Respondents:

Penalty Per Violation Per Day	Period of Noncompliance
$ 500	1st through 7th day
$ 1,000	8th through 30th day
$ 2,500	31st day and beyond.

The penalties in this Paragraph shall apply to the following deliverable items:

a. The draft and any revised work plan.

b. The draft and any revised sampling and analysis plan.

c. The draft and any revised Remedial Investigation Report.

d. The draft and any revised Feasibility Study Report.

78. If Respondents do not submit the deliverable items listed below by the deadlines stated in the RI/FS Work Plan, or do not perform the tasks listed below in accordance with the schedules listed in the RI/FS Work Plan, the following stipulated penalties shall be payable per day by Respondents:

Penalty Per Violation Per Day	Period of Noncompliance
$ 250.00	1st through 7th day
$ 500.00	8th through 30th day
$ 1,000.00	31st day and beyond.

The penalties in this Paragraph shall apply to the following deliverable items as well as any other deliverables not specifically listed in this Section:

a. Site Health and Safety Plan.

b. Technical memorandum on modeling of Site characteristics.

c. Site Characterization Summary.

d. Evaluation of Need for Treatability Studies technical memorandum.

e. Treatability Study Site Health and Safety Plan.

f. Treatability Study Evaluation Report.

g. Technical memorandum entitled Refined Remedial Action Objectives.

h. Report entitled Development and Screening of Remedial Alternatives.

i. Comparative analysis technical memorandum.

j. Monthly progress reports.

79. Except as otherwise provided herein, all penalties shall begin to accrue on the day after complete performance is due or the day a violation occurs, and shall continue to accrue through the final day of the correction of the noncompliance or completion of the activity. Nothing herein shall prevent the simultaneous accrual of separate penalties for separate violations of this Consent Order. For violations not based on timeliness, stipulated penalties shall not begin to accrue until after Respondents have had the opportunity to revise the submission to respond to EPA's written comments. If any revised submission fails to respond to

EPA's comments and/or remedy the specified deficiencies and EPA deems such failure to constitute a violation, then EPA will provide Respondents with written notice of such violation. In such case, the stipulated penalties shall accrue from the date of receipt of such notice by Respondents.

80. Following EPA's determination that Respondents have failed to comply with a requirement of this Consent Order, EPA will provide Respondents with written notification of same and describe the noncompliance. This notice also will indicate the amount of penalties due and whether the penalties continue to accrue. Except for violations not based on timeliness, penalties shall accrue as provided in the preceding Paragraph regardless of whether EPA has notified the Respondents of a violation.

81. All penalties owed to the EPA under this Section shall be due and payable within thirty (30) days of the Respondents' receipt from EPA of a notification of noncompliance, unless Respondents invoke the Dispute Resolution procedures set forth in Section XIX (Dispute Resolution) of this Consent Order. Respondents shall pay interest on the unpaid balance, which shall begin to accrue at the end of the thirty (30) day period at the rate established by the Department of Treasury pursuant to 31 U.S.C. § 3717 and 4 C.F.R. § 102.13. Respondents shall further pay a handling charge of one percent (1%), to be assessed at the end of each thirty-day period, and a six percent (6%) per annum penalty charge, to be assessed if the penalty is not paid in full within ninety (90) days after it is due. All payments under this Section shall be paid by certified

check made payable to "EPA Hazardous Substance Superfund," shall be mailed to:

Mellon Bank
Attn: Superfund Accounting
EPA Region VII
(Comptroller Branch)
Post Office Box 360748M
Pittsburgh, PA 15251

82. Copies of check(s) paid pursuant to this Section, and any accompanying transmittal letter(s), shall be sent to EPA's Project Coordinator as set forth in Section XVI (Project Coordinators) of this Consent Order.

83. Neither the filing of a request to resolve a dispute nor the payment of penalties shall alter in any way Respondents' obligation to complete the performance required hereunder.

84. Respondents may dispute the applicability of stipulated penalties and EPA's right to the stated amount of penalties by invoking the Dispute Resolution procedures set forth in Section XIX (Dispute Resolution) of this Consent Order. Penalties shall accrue but need not be paid during the Dispute Resolution period.

85. If Respondents fail to pay stipulated penalties when due, EPA may institute proceedings to collect the penalties, as well as late charges and interest. Respondents shall pay interest on the unpaid balance, which shall begin to accrue at the end of the forty-five day period at the rate established pursuant to 31 U.S.C. § 3717 and 4 C.F.R. § 102.13. The stipulated penalties provisions do not prohibit, alter, or in any way limit EPA's ability to seek any other remedies or sanctions available by virtue of Respondents' violation of this Consent Order or of the statutes and regulations

upon which it is based. Provided, however, EPA will be precluded from seeking other judicial or administrative penalties for those violations specified in this Section unless Respondents fail to pay penalties assessed pursuant to this Section.

XXI. FORCE MAJEURE

86. Respondents shall perform the requirements of this Consent Order within the time limits set forth herein, unless the performance is prevented or delayed by events which constitute a force majeure or excusable delay. A force majeure or excusable delay is defined as any event arising from causes not foreseeable and beyond the reasonable control of Respondents, including its consultants and contractors, which could not be overcome by Respondents' best efforts and which delays or prevents performance by a date required by this Consent Order. Such events do not include unanticipated or increased costs of performance or changed economic circumstances. To the extent Respondents (excluding DOE pursuant to Paragraph 76 herein) are subject to stipulated penalties as a result of a delay caused by an act or omission of DOE, EPA, at its discretion, may consider such delay excusable for the purposes of assessment of stipulated penalties.

87. Respondents shall notify EPA orally within forty-eight (48) hours of when they first knew or should have known that a delay might occur. Within ten (10) business days thereafter, Respondents shall submit to EPA a written statement setting forth the reasons for the delay; the anticipated duration of the delay; all actions taken or to be taken to prevent or minimize the delay;

a schedule for implementation of any measures to be taken to mitigate the effect of the delay; and a statement as to whether, in the opinion of Respondents, such event may cause or contribute to an endangerment to public health, welfare, or the environment. Respondents shall adopt all reasonable measures to avoid and minimize the delay. Failure to comply with the notice provision of this Section shall constitute a waiver of Respondent's right to assert a force majeure or that the delay is excusable.

88. If EPA determines that the delay has been or will be caused by force majeure or that the delay is otherwise excusable, the time for performance for that element of work, and other tasks the completion of which is dependent upon that element of work, may be extended, upon EPA approval, for a period of equal to the delay resulting from such circumstances. All such modifications of the schedule caused by a force majeure or excusable delay shall be made in accordance with Section XXVII (Effective Date and Subsequent Modification) of this Consent Order. The schedule for those tasks which are not altered by these modifications remains unchanged unless altered in accordance with Section XXVII (Effective Date and Subsequent Modification). In the event EPA and Respondents cannot agree that any delay or failure has been or will be caused by a force majeure or that the delay is otherwise excusable, or if there is no agreement on the length of the extension, this dispute shall be resolved in accordance with the Dispute Resolution provisions of Section XIX (Dispute Resolution) of this Consent Order.

XXII. REIMBURSEMENT OF RESPONSE AND OVERSIGHT COSTS

89. Following the effective date of this Consent Order, EPA periodically will submit to the Respondents an accounting of all response costs including oversight costs incurred by EPA with respect to this Consent Order. Response costs may include, but are not limited to, costs incurred by EPA in overseeing Respondents' implementation of the requirements of this Consent Order and activities performed by EPA relating to the Consent Order and any costs incurred while assisting Respondents in obtaining access. Costs shall include all direct and indirect costs including, but not limited to, time and travel costs of EPA personnel and associated indirect costs, contractor costs, cooperative agreement costs, compliance monitoring, including the collection and analysis of split samples, inspection of activities required by this Consent Order, Site visits, discussions regarding disputes that may arise as a result of this Consent Order, review and approval or disapproval of reports, and costs of redoing any of Respondents' tasks. Any necessary summaries including, but not limited to, EPA's certified Agency Financial Management System summary data ("SPUR Reports"), or such other summary as certified by EPA, shall serve as a basis for payment demands.

90. Respondents (excluding DOE) shall, within sixty (60) days of receipt of each accounting, remit a certified or cashier's check for the amount of those costs. Interest shall accrue from the later of the date payment of a specified amount demanded in writing is due, or the date of the expenditure. The interest rate is the

rate of interest on investments for the Hazardous Substances Superfund in Section 107(a) of CERCLA, 42 U.S.C. § 9607(a).

91. All payments to EPA under this Section shall be made by certified or cashier's check made payable to "EPA Hazardous Substance Superfund" and shall include the Site name, the EPA Site identification number 514, and the EPA Docket Number assigned to this matter, and shall be remitted to:

Mellon Bank
Attn: Superfund Accounting
EPA Region VII
(Comptroller Branch)
Post Office Box 360748M
Pittsburgh, PA 15251

92. A copy of the check shall be sent simultaneously to the EPA Project Coordinator.

93. Respondents agree to limit any disputes concerning costs to accounting errors, the inclusion of costs outside the scope of this Consent Order, or costs that are inconsistent with the NCP. Respondents shall identify any contested costs and the basis of their objection. All undisputed costs shall be remitted in accordance with the time frame set forth above. Disputed costs shall be paid into an escrow account while the dispute is pending. Respondents bear the burden of establishing an EPA accounting error, the inclusion of costs outside the scope of this Consent Order, or costs inconsistent with the NCP.

XXIII. <u>RESERVATION OF RIGHTS</u>

94. Any requirement for the payment or obligation of funds by DOE established by the terms of this Consent Order shall be subject to the availability of funds appropriated for that purpose, and no

provision herein shall be interpreted to require the obligation or payment of funds in violation of the Anti-Deficiency Act, 31 U.S.C. § 1341.

95. EPA reserves the right to bring an action against the Respondents pursuant to Section 107 of CERCLA, 42 U.S.C. § 9607, for the recovery of all response costs including oversight costs incurred by EPA at the Site that are not reimbursed by the Respondents, any costs incurred in the event that EPA performs the RI/FS or any part thereof, and any future costs incurred by EPA in connection with response activities conducted under CERCLA at the Site. Respondents reserve all rights they may have to oppose and defend against such claims and actions and to assert any and all claims they may have against EPA or any person or government agency.

96. EPA reserves the right to bring an action against Respondents to enforce the requirements of this Consent Order, and to seek penalties and punitive damages pursuant to CERCLA.

97. Except as expressly provided in this Consent Order, each party reserves all rights and defenses it may have. Nothing in this Consent Order shall affect EPA's removal authority or EPA's response or enforcement authorities including, but not limited to, the right to seek injunctive relief, statutory penalties, and/or punitive damages. To the extent stipulated penalties apply to violations of a particular requirement of this Consent Order, however, EPA will not seek statutory penalties for such violations unless Respondents fail or refuse to pay stipulated penalties

assessed for such a violation. Respondents reserve any and all rights they may have to oppose and defend against such claims and actions and to assert any and all claims they may have against EPA or any person or government agency. Respondents reserve any rights they may have to bring any action otherwise available against any "person" as defined in Section 101(21) of CERCLA, 42 U.S.C. § 9601(21).

98. Following satisfaction of the requirements of this Consent Order, Respondents shall have resolved their liability to EPA for the work performed by Respondents pursuant to this Consent Order. Respondents are not released from liability, if any, for any response actions taken beyond the scope of this Consent Order regarding removals or activities arising pursuant to Section 121(c) of CERCLA, 42 U.S.C. § 9612(c).

XXIV. DISCLAIMER

99. By signing this Consent Order and taking actions under this Consent Order, Respondents do not admit EPA's Findings of Fact and Conclusions of Law. Furthermore, the participation of Respondents in this Consent Order shall not be considered an admission of liability and is not admissible in evidence against Respondents in any judicial or administrative proceeding other than a proceeding by the United States on behalf of EPA to enforce this Consent Order or a judgment relating to it. Each Respondent retains its rights to assert claims against the other Respondents and other potentially responsible parties at the Site. Respondents agree, however, not to contest the validity or terms of this

Consent Order or the procedures underlying or relating to it in any action brought by the United States on behalf of EPA to enforce its terms.

XXV. OTHER CLAIMS

100. In entering into this Consent Order, Respondents waive any right to seek reimbursement pursuant to Section 106(b) of CERCLA, 42 U.S.C. § 9606(b). Respondents also waive any right to present a claim under Section 111 or 112 of CERCLA, 42 U.S.C. §§ 9611 and 9612. This Consent Order does not constitute any decision on preauthorization of funds under Section 111(a)(2) of CERCLA, 42 U.S.C. § 9611(a)(2). Injuries or damages resulting from acts or omissions of the EPA, its agents, employees or other persons acting on its behalf on property owned or operated by Respondents shall be subject to the procedures of the Federal Tort Claims Act of 1949, as amended, 28 U.S.C. § 2671, et seq. (FTCA). Except for claims subject to the procedures of the FTCA, Respondents waive all other statutory and common law claims against EPA relating to or arising out of conduct of the RI/FS under this Consent Order.

101. Nothing in this Consent Order shall constitute or be construed as a release from any claim, cause of action, or demand in law or equity against any party not a signatory to this Consent Order for any liability it may have arising out of or relating in any way to the generation, storage, treatment, handling, transportation, releases or disposal of any hazardous substances, pollutants, or contaminants found at, taken to, or taken from the Site.

102. Respondents shall each bear their own costs and attorneys fees.

XXVI. FINANCIAL ASSURANCE AND INDEMNIFICATION

103. Within thirty (30) days of the effective date of this Consent Order, Respondents (excluding DOE) shall obtain a Letter of Credit in the amount of $1,050,000, naming EPA as the Beneficiary, and provide a copy of such letter to EPA within forty-five (45) days of the effective date of this Consent Order.

104. Respondents (excluding DOE) agree to indemnify and hold the EPA, its agents, and its employees harmless from any and all claims or causes of action arising from or on account of acts or omissions of Respondents, its employees, agents, servants, receivers, successors, or assignees, or any persons including, but not limited to, firms, corporations, subsidiaries and contractors in carrying out activities under this Consent Order. Except for contracts entered into by DOE, the United States Government or any agency or authorized representative thereof shall not be held as a party to any contract entered into by Respondents in carrying out activities under this Consent Order. Respondents shall be under no duty, however, to indemnify the EPA for claims or causes of action arising from or on account of negligent, willful, or intentional acts or omissions of the EPA, its officers, agents, employees or any other person acting on its behalf. Nothing herein is intended to or shall be construed as extending the liability of the EPA beyond that provided for under federal law.

XXVII. EFFECTIVE DATE AND SUBSEQUENT MODIFICATION

105. The effective date of this Consent Order shall be the date that it is signed by EPA.

106. This Consent Order may be amended by mutual agreement of EPA and Respondents. Amendments shall be in writing and shall be effective when signed by EPA.

107. No informal advice, guidance, suggestions, or comments by EPA regarding reports, plans, specifications, schedules and any other writing submitted by the Respondents will be construed as relieving the Respondents of its obligation to obtain such formal approval as may be required by this Consent Order. Any deliverables, plans, technical memoranda, reports (other than progress reports), specifications, schedules and attachments required by this Consent Order are, upon approval by EPA, incorporated into this Consent Order.

XXVIII. TERMINATION AND SATISFACTION

108. This Consent Order shall terminate when Respondents demonstrate in writing and certify to the satisfaction of EPA that all activities required under this Consent Order including any additional work, payment of response and oversight costs, and any stipulated penalties demanded by EPA have been performed and EPA has approved the certification. EPA will make it a goal to notify Respondents within sixty (60) days of receipt of such certification whether it has approved or disapproved the certification. In the event EPA disapproves the certification, it will specify in writing the reasons therefore. If EPA disapproves the certification or

fails to respond to the certification within sixty (60) days, Respondents may invoke the provisions of Section XIX (Dispute Resolution). This notice shall not, however, terminate Respondents' obligation to comply with Sections XVII (Other Applicable Laws), XVIII (Record Preservation), XXII (Reimbursement of Response and Oversight Costs), and XXIII (Reservation of Rights) of this Consent Order.

109. The certification shall be signed by a responsible official representing each Respondent. Each representative shall make the following attestation: "I certify that the information contained in or accompanying this certification is true, accurate, and complete." For purposes of this Consent Order, a responsible official is a corporate official who is in charge of a principal business function.

SUPPLEMENTAL AND PARTIALLY RESTATED DECLARATION OF COVENANTS AND RESTRICTIONS ROCK ROAD INDUSTRIES, INC. BRIDGETON LANDFILL, LLC

Rock Road Industries, Inc., a Missouri corporation ("Rock Road"), and Bridgeton Landfill, LLC, a Missouri corporation ("Bridgeton Landfill") (f/k/a Laidlaw Waste Systems (Bridgeton) Inc. and successor in interest to West Lake Quarry and Material Company, a Missouri corporation) (Rock Road and Bridgeton Landfill are collectively referred to hereinafter as "Declarants"), hereby (a) impose the provisions of this Supplemental and Partially Restated Declaration of Covenants and Restrictions (the "Supplemental Declaration") upon the Premises (as defined below); (b) publish and declare that the following terms, conditions, restrictions and obligations shall (i) affect and encumber the Premises; (ii) run with and be a burden upon and a benefit to the Premises, and (iii) be fully binding upon Declarants and all other persons or entities acquiring the Premises or any part thereof or interest therein, whether by descent, devise, purchase or otherwise; and (c) declare that any person or entity, by acceptance of title to the Premises or any part thereof or interest therein, shall thereby agree and covenant to abide by and be bound by the following terms, conditions, restrictions, and obligations.

RECITALS

A. Declarants are the owners of certain real property (located in the City of Bridgeton, County of St. Louis, State of Missouri), which is described more particularly on **Exhibit A**, attached hereto.

B. Certain portions of Declarants' real property are located within the areas legally described on **Exhibit B-1** and described by survey on **Exhibit B-2**, both of which are attached hereto and incorporated herein by this reference, as "OU Area 1" and "OU Area 2". The portions of Declarants' real property located within OU Area 1 and OU Area 2 shall be collectively referred to herein as the "Premises."

C. The United States Environmental Protection Agency ("EPA") has entered into an Administrative Order on Consent ("AOC") with Cotter Corporation (N.S.L.), Declarants and the United States Department of Energy, dated March 3, 1993, as amended from time to time thereafter, and as is attached hereto as **Exhibit C.**

D. The AOC, among other things, provides for the investigation of the nature and extent of contamination and any threat to the public health, welfare, or the environment caused by the release or threatened release of hazardous substances at or from the Premises.

E. The entire portion of the Premises owned by Rock Road is subject to a Declaration of Covenants and Restrictions filed by Rock Road dated May 27, 1997, which was recorded June 30, 1997 in Book 11208 Page 2507 in the St. Louis County Recorder of Deeds Office (the "Land Records"), and the entire portion of the Premises owned by Bridgeton Landfill is subject to a Declaration of Covenants and Restrictions filed by Bridgeton Landfill dated June 9, 1997, which was recorded June 30, 1997 in Book 11208 Page 2514 in the Land Records (collectively, the "1997 Declarations").

F. The 1997 Declarations restrict the Premises as follows: (i) neither the Premises, nor any part thereof, shall be used for any residential purpose, or for any day care, preschool or other educational use, and (ii) no water well for drinking water use shall be installed on the Premises.

G. The entire portion of the Premises owned by Rock Road is further subject to a Supplemental Declaration of Covenants and Restrictions filed by Rock Road dated

January 16, 1998, which was recorded January 20, 1998 in Book 11427 Page 1633 in the Land Records (the "1998 Declarations").

H. The 1998 Declarations restrict the portions of the Premises owned by Rock Road as follows: (i) no building of any kind or nature for any propose shall be constructed or placed on the portions of the Premises owned by Rock Road, now or at any time in the future, in perpetuity, and (ii) no underground utilities or pipes shall be installed at the portions of the Premises owned by Rock Road, and no excavation work shall be performed on the portions of the Premises owned by Rock Road, now or at any time in the future, in perpetuity, except such utilities, pipes, and/or excavation work, if any, which (a) are approved by EPA in connection with a plan selected by EPA to remediate hazardous substances on the Premises and that are performed in accordance with environmental and safety regulations applicable to such a remedial plan or are otherwise required by EPA as a condition of such approval; or (b) are a part of a landfill gas control, leachate collection, or surface water management system installed and operated pursuant to a plan approved by all applicable federal, state, or local authorities exercising jurisdiction over inactive landfill conditions on the portions of the Premises owned by Rock Road or active or inactive landfill operations conducted adjacent to the portions of the Premises owned by Rock Road.

I. All of the Premises in OU Area 1 and a portion of the Premises in OU Area 2 are further subject to a Negative Easement and Declaration of Restrictive Covenants Agreement, dated April 6, 2005, and which is recorded April 11, 2005 at Book 16465 Page 1141 in the Land Records (the "April 2005 Negative Easement").

J. The April 2005 Negative Easement restricts all of the Premises in OU Area 1 and the portion of the Premises in OU Area 2 as follows: there shall be no new or additional depositing or dumping of municipal waste, organic waste, and/or putrescible waste above, upon, on or under such portions of the Premises beginning as of August 1, 2005 and continuing in perpetuity, unless and until such time as the April 2005 Negative Easement is terminated or cancelled by the City of St. Louis, Missouri in accordance with the terms set forth in the April 2005 Negative Easement.

K. Declarants desire to subject the entirety of the Premises (i.e., all of OU Area 1 and OU Area 2) to the restrictions set forth in the 1998 Declarations and, for avoidance of confusion caused by the varying ownership of such parcels and the varying applicability of such restrictions, Declarants desire to restate or extend the restrictions set forth in the 1997 Restrictions and the 1998 Restrictions against the entirety of the Premises, as the case may be.

L. In addition to the restrictions contained in the 1997 Declaration, the 1998 Declaration and the April 2005 Negative Easement, Declarants desire to prohibit in perpetuity (i) the use of the Premises for commercial and industrial purposes, including (but not limited to) use of the Premises as a storage yard, and (ii) placement upon the Premises of water wells for agricultural purposes, except as set forth herein.

DECLARATION

Declarant hereby states and declares the following:

1. Neither the Premises, nor any portion thereof, shall be used now or hereafter for any residential purpose, or for any day care, preschool, or any other educational use.

2. No building or habitable structure of any kind or nature for any purpose shall be constructed or placed on the Premises, now or at any time in the future, in perpetuity.

3. No underground utilities or pipes shall be installed at, on or under the Premises and no excavation work shall be performed on the Premises, now or at any time in the future, in

perpetuity, except such utilities, pipes, and/or excavation work, if any, which (a) are approved by EPA in connection with a plan selected by EPA to remediate hazardous substances on the Premises and that are performed in accordance with environmental and safety regulations applicable to such a remedial plan or are otherwise required by EPA as a condition of such approval; or (b) are a part of a landfill gas control, leachate collection, or surface water management system installed and operated pursuant to a plan approved by all applicable federal, state, or local authorities exercising jurisdiction over inactive landfill conditions on the Premises or active or inactive landfill operations conducted adjacent to the Premises.

4. The Premises shall not be used for commercial or industrial purposes, now or at any time in the future, in perpetuity.

5. The Premises shall not be used as a storage yard (whether temporarily or permanently), now or at any time in the future, in perpetuity.

6. No water wells for drinking water or agricultural use shall be installed on the Premises.

7. This Supplemental Declaration shall not unlawfully restrict and shall not be used to violate any federal or state law, rule, or regulation regarding the use of real property, including (but not limited to) the Fair Housing Act.

8. This Supplemental Declaration shall be recorded in the Office of the Recorder of Deeds for the County of St. Louis, State of Missouri.

9. Any deed or other instrument of conveyance for the Premises or any portion thereof shall be subject to this Supplemental Declaration.

10. Each of EPA (or its successor), the Missouri Department of Natural Resources ("MDNR") (or its successor), and the owner of any portion of the Premises shall have the right to

sue for and obtain an injunction, prohibitive or mandatory, to prevent the breach, or to enforce the observance, of this Supplemental Declaration. This right shall be in addition to any other action available at law or in equity. The failure to enforce any covenant or restriction herein at the time of its violation shall not constitute a waiver of the right to do so at a later time.

11. The provisions of this Supplemental Declaration shall continue in full force and effect until the fiftieth (50th) anniversary of the date of this Supplemental Declaration and thereafter for successive twenty (20) year periods, unless, prior to the expiration of the then-current term, a written notice of termination of this Supplemental Declaration, executed by each of the then-owners of the Premises, authorized representatives of EPA (or its successor), and the MDNR (or its successor) has been filed with the Office of the Recorder of Deeds for St. Louis County, State of Missouri (the "Notice of Termination"). Any Notice of Termination not so executed shall not be valid and shall have no binding effect on the terms and conditions of this Supplemental Declaration. The Notice of Termination may be filed at any time after the Effective Date of this Supplemental Declaration, and this Supplemental Declaration shall terminate on the date that the Notice of Termination is filed with the Recorder of Deeds.

12. The 1997 Declaration, the 1998 Declaration and the April 2005 Negative Easement each remain in full force and effect, and each shall be deemed supplemented and where applicable restated, but not amended, by this Supplemental Declaration.

IN WITNESS WHEREOF, Rock Road Industries, Inc. and Bridgeton Landfill, LLC have caused this instrument to be executed this 4th day of October 2016.

EXHIBIT B-1

Legal Description of OU Area 1 and OU Area 2

OU Area 1:

A tract of land in part of U.S. Survey 131 in Township 47 North; Range 5 East of the Fifth Principal Meridian St. Louis, Mo. being more particularly described as follows:

Commencing at a point being the intersection of the Northwesterly line of U.S. Survey 131 with the Southwesterly right of way line at St. Charles Rock Road- (Highway 40); thence South 37 degrees 11 minutes 39 seconds East along said right of way line a distance of 228.33 feet to the point of beginning at the tract described herein; thence South 37 degrees 11 minutes 39 seconds East continuing along said right of way line a distance of 501.34 feet; thence South 47 degrees 31 minutes 24 seconds West a distance of 591.78 feet; thence South 31 degrees 22 minutes 15 seconds West a distance of 320.47 feet; thence South 47 degrees 08 minutes 46 seconds West a distance of 307.43 feet; thence North 36 degrees 53 minutes 01 seconds West a distance of 804.43 feet; thence North 38 degrees 16 minutes 06 seconds East a distance of 146.84 feet; thence North 64 degrees 14 minutes 08 seconds East a distance of 113.07 feet; thence North 60 degrees 07 minutes 22 seconds East a distance of 384.20 feet; thence North 49 degrees 33 minutes 57 seconds East a distance of 249.05 feet; thence North 56 degrees 17 minutes 00 seconds East a distance of 112.57 feet; thence North 59 degrees 38 minutes 15 seconds East a distance of 102.59 feet; thence North 86 degrees 35 minutes 54 seconds East a distance of 110.98 feet to the point of beginning and containing 18.51 acres.

OU Area 2:

A tract of land being part of lots 20 and 21 of St. Charles Ferry Co. Tracts in U.S. Survey 47 and 1934 and part of U.S. Survey 47 all in township 47 North Range 5 East of the Fifth Principal Meridian St. Louis County, Mo. being more particularly described as follows:

Commencing at a point being the intersection of the Southwesterly right of way line at St. Charles Rock Road with the dividing line between U.S. Survey 47 and U.S. Survey 131; thence North 37 degrees 11 minutes 39 seconds West along said right of way line a distance of 602.78 feet; thence North 49 degrees 13 minutes 36 seconds West continuing along said right of way line a distance of 95.94 feet; thence North 37 degrees 11 minutes 39 seconds West continuing along said right of way line a distance of 35.28 feet; thence North 52 degrees 48 minutes 21 seconds East continuing along said right of way line a distance of 15.00 feet; thence North 37 degrees 11 minutes 39 seconds West continuing along said right of way line a distance of 47.91 feet; thence along said right of way line being a curve to the left having a radius of 1855.08 feet a chord bearing North 41 degrees 02 minutes 55 seconds West a chord distance of 249.41 feet to the point of beginning of the tract described herein; thence South 43 degrees 20 minutes 33 seconds West a distance of 1042.77 feet; thence South 32 degrees 48 minutes 22 seconds East a distance of 327.69 feet; thence South 63 degrees 07 minutes 00 seconds West a distance of 752.42 seconds; thence South 55 degrees 39 minutes 27 seconds West a distance of 158.01 feet; thence South 67 degrees 24 minutes 36 seconds West a distance of 199.34 feet to the centerline of the Old St. Charles Rock Road; thence North 10 degrees 25 minutes 19 seconds West along said centerline a distance of 88.10 feet; thence North 24 degrees 52 minutes 19 seconds West continuing along said centerline a distance of 349.50 feet; thence North 32 degrees 08 minutes 19 seconds West continuing along said centerline a distance of 22.38 feet to the Northwesterly line of Lot 20 of St. Charles Ferry Co. Tracts; thence North 35 degrees 35 minutes 03 seconds East along said lot line a distance of 824.56 feet to the Northwest corner of lot 20; thence North 66 degrees 04 minutes 50 seconds West a distance of 674.79 feet; thence North 54 degrees 24 minutes 55 seconds East a distance of 1137.84 feet to the aforementioned Southwesterly right of way line of St. Charles Rock Road- (Highway 40); thence South 69 degrees 14 minutes 39 seconds East along said right of way line a distance of 260.00 feet; thence continuing along said right of way line being a curve to the right having a radius of 1825.08 feet a chord bearing South 58 degrees 29 minutes 59 seconds East a chord distance of 680.49 feet; thence North 42 degrees 14 minutes 40 seconds East continuing along said right of way line a distance of 30.00 feet; thence continuing along said right of way line being a curve to the right having a radius of 1855.08 feet a chord bearing South 46 degrees 19 minutes 46 seconds East a chord distance of 92.34 feet to the point of beginning and containing 41.88 acres.

Consent Order

[See Attached]

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY
REGION VII
726 MINNESOTA AVENUE
KANSAS CITY, KANSAS 66101

IN THE MATTER OF: COTTER CORPORATION (N.S.L.), and LAIDLAW WASTE SYSTEMS (BRIDGETON), INC., and ROCK ROAD INDUSTRIES, INC., and UNITED STATES DEPARTMENT OF ENERGY, RESPONDENTS. Proceeding Under Sections 104, 122(a), and 122(d)(3) of the Comprehensive Environmental Response, Compensation, and Liability Act as amended 42 U.S.C §§ 9604, 9622(a), 9622(d)(3).	Docket No. VII-93-F-0005

ADMINISTRATIVE ORDER ON CONSENT
FOR REMEDIAL INVESTIGATION/FEASIBILITY STUDY

TABLE OF CONTENTS

I. INTRODUCTION

1. This Administrative Order on Consent ("Consent Order") is entered into voluntarily by the United States Environmental Protection Agency ("EPA"), Cotter Corporation (N.S.L.) ("Cotter"), Laidlaw Waste Systems (Bridgeton), Inc. ("Laidlaw"), Rock Road Industries, Inc. ("Rock Road"), and the United States Department of Energy ("DOE") (Cotter, Laidlaw, Rock Road, and DOE are collectively referred to herein as "Respondents"). This Consent Order concerns the preparation of, performance of, and reimbursement of all costs incurred by EPA in connection with a remedial investigation and feasibility study ("RI/FS") at the West Lake Landfill NPL Site located at Bridgeton, Missouri (hereinafter referred to as "West Lake" or "Site").

II. JURISDICTION

2. This Consent Order is issued pursuant to the authority vested in the President of the United States by Sections 104, 122(a), and 122(d)(3) of the Comprehensive Environmental Response, Compensation, and Liability Act, as amended, 42 U.S.C. §§ 9604, 9622(a), and 9622(d)(3) ("CERCLA"). This authority was delegated to the Administrator of EPA by Executive Order 12580 of January 23, 1987, 52 Fed. Reg. 2923, and was further delegated to EPA's Regional Administrators on September 13, 1987 by EPA Delegation No. 14-14-C. This authority has been redelegated by the Regional Administrator of EPA Region VII to the Director of the Waste Management Division of EPA Region VII by Delegation R7-14-14C dated May 16, 1988.

3. Respondents agree to undertake all actions required by the terms and conditions of this Consent Order. In any action by EPA or the United States to enforce the terms of this Consent Order, Respondents consent to and agree not to contest the authority or jurisdiction of EPA to issue or enforce this Consent Order, and agree not to contest the validity of this Consent Order or its terms.

III. PARTIES BOUND

4. This Consent Order shall apply to and be binding upon EPA and Respondents and their respective agents, successors, and assigns, and upon all persons, including contractors and consultants, acting under or on behalf of Respondents or EPA with regard to the Site. Respondents' participation in this Consent Order, however, shall not be construed as an admission of liability or of EPA's findings of fact or conclusions of law and determinations contained in this Consent Order. The signatories to this Consent Order certify that they are authorized to execute and legally bind the parties they represent to this Consent Order. No change in the ownership or corporate status of Respondents, or of the ownership of the Site, shall alter Respondents' responsibilities under this Consent Order.

5. Respondents shall provide a copy of this Consent Order to any subsequent owners or successors before all or substantially all of the stock or assets are transferred in a corporate acquisition. Respondents shall provide a copy of this Consent Order to all contractors, subcontractors, laboratories, and consultants which

are retained to conduct any work performed under this Consent Order within fourteen (14) days after the effective date hereof or the date of retaining their services, whichever is later. Respondents shall condition any such contracts upon satisfactory compliance with all applicable terms of this Consent Order. Notwithstanding the terms of any contract, each Respondent is responsible for compliance with this Consent Order and shall use its best efforts to ensure that its subsidiaries, employees, contractors, consultants, subcontractors, and agents comply with all applicable terms of this Consent Order.

IV. STATEMENT OF PURPOSE

6. In entering into this Consent Order, the objectives of EPA and Respondents are: (a) to determine the nature and extent of contamination and any threat to the public health, welfare, or the environment caused by the release or threatened release of hazardous substances, pollutants, or contaminants at or from Radiological Areas 1 and 2, as defined in Paragraph 12, herein, at the Site by conducting a remedial investigation; (b) to determine and evaluate alternatives for remedial action (if any) to prevent, mitigate, or otherwise respond to or remedy any release or threatened release of hazardous substances, pollutants, or contaminants at or from Radiological Areas 1 and 2 at the Site, by conducting a feasibility study; and (c) to recover all response and oversight costs incurred by EPA with respect to this Consent Order in accordance with the procedures set forth in Section XXII (Reimbursement of Response and Oversight Costs).

7. The activities conducted under this Consent Order are subject to approval by EPA and shall provide all appropriate and necessary information for the RI/FS, and for a Record of Decision ("ROD") that is consistent with CERCLA and the National Oil and Hazardous Substances Pollution Contingency Plan ("NCP"), 40 C.F.R. Part 300. The activities conducted under this Consent Order shall be conducted in compliance with all applicable EPA guidances, policies, and procedures, which EPA will identify in writing in advance. Activities conducted in compliance with this Consent Order shall be deemed in compliance with the NCP.

V. EPA'S FINDINGS OF FACT

EPA makes the following Findings of Fact (contained in Paragraphs 8-31), which Respondents do not admit:

8. The Landfill is comprised of approximately 200 acres located at 13570 St. Charles Rock Road, Bridgeton, St. Louis County, Missouri, and is approximately 4 miles west of St. Louis' Lambert Field International Airport, near the intersection of Highways I-70 and I-270. Limestone was quarried at the Landfill from 1939 to the present. Since 1962 portions of the quarried property have been used for landfilling municipal refuse, industrial solid and liquid wastes, and construction demolition debris.

9. In 1966, the Atomic Energy Commission ("AEC") sold 8,700 tons of leached barium sulfate, together with other radioactive residues, to Continental Mining and Milling Company ("Continental Mining"). The radioactive residues were generated as by-products

of uranium processing performed by the AEC's contractor. These processing residues were stored at the AEC's St. Louis Airport Storage Site ("SLAPSS").

10. Continental Mining removed the radioactive residues to its facility at 9200 Latty Avenue in Hazelwood, Missouri. Eventually, Cotter purchased the radioactive residues and shipped all but the 8,700 tons of leached barium sulfate to its processing facility in Colorado.

11. In 1973 approximately 8,700 tons of radioactively contaminated leached barium sulfate residues were mixed with approximately 39,000 tons of soil, and the entire amount was disposed of in Radiological Areas 1 and 2, which are described in Paragraph 12, at the Landfill. This material resulted from decontamination efforts undertaken by Cotter at 9200 Latty Avenue, St. Louis, Missouri, where the residues had been stored.

12. In 1978, an aerial survey sponsored by the Nuclear Regulatory Commission ("NRC") revealed two areas within the Landfill where gamma radiation levels indicated radioactive material had been deposited. In 1980-81, Radiation Management Corporation ("RMC") of Chicago, Illinois, performed a detailed radiological survey of the Landfill under contract to the NRC. This survey was performed to determine the extent of radiological contamination. This survey indicated that the radioactive contaminants were located in two areas of the Landfill. The northern area of radioactive contamination ("Radiological Area 2") is comprised of approximately 13 acres. The radioactive debris in

this area forms a layer 2 to 15 feet thick, with radioactive debris exposed on the surface of the Landfill and along the berm on the northwest face of the Landfill. The southern area of radioactive contamination ("Radiological Area 1") is comprised of approximately 3 acres with most of the contaminated soil buried under approximately 3 feet of soil and fill.

13. The RMC survey indicated that the radioactivity emanates from uranium-238 ("U-238") and uranium-235 ("U-235") series with thorium-230 ("Th-230") and radium-226 ("Ra-226"). The survey data indicate that the average Ra-226 concentration in the radioactive wastes is approximately 90 picocuries per gram ("pCi/g"), with the average Th-230 concentration estimated to be approximately 9,000 pCi/g. Since Ra-226 has been depleted with respect to its parent Th-230, Ra-226 activity will increase in time (for example, over the next 200 years, Ra-226 activity will increase ninefold over the present level).

14. In addition to RMC's radiological survey, the NRC through Oak Ridge Associated Universities ("ORAU") contracted with the University of Missouri-Columbia Department of Civil Engineering to describe the environmental characteristics of the Site, conduct an engineering evaluation, and propose possible remedial actions for dealing with the radioactive materials at the Site. In March of 1984 a radiological survey along a section of a berm bounding the Landfill was performed by ORAU.

15. Measurements of direct radiation levels and radionuclide concentrations in soil and the physical condition of the berm area

indicated that erosion was occurring and that there were elevated concentrations of Ra-226 and Th-230 at the base of the berm and extending into the adjacent field. A sample from the mound of soil at the base of the berm contained 185 pCi/g of Ra-226 and 6,270 pCi/g of Th-230. Samples collected in the adjacent field contained 4.29-4.47 pCi/g of Ra-226 and 132-178 pCi/g of Th-230. In May 1986, ORAU sampled water wells on and close to the Landfill to determine if radioactive contamination had migrated into the groundwater. The sampling consisted of 18 monitoring wells which are located in various locations around the Landfill and are screened in the shallow, intermediate, and deep parts of the aquifer. Two sampling rounds were evaluated. Round 1 occurred from December 11-15, 1985 and Round 2 from May 19-21, 1986. All samples were analyzed for priority pollutants listed under 40 C.F.R. Part 122, Appendix D. This list includes volatile organics, acid and base/neutral extractables, pesticides, polyclorinated biphenyls ("PCBs"), total phenols, total cyanide, and metals. Four wells sampled during Round 1 were also analyzed for gross alpha and beta radiation.

16. Chemical results indicated that samples from certain wells contained detectable levels of several constituents. Chemicals found during Round 1 included methylene chloride (2-83 micrograms per liter ("ug/l"), bis-2-ethyhexyl phthalate (4-477 ug/l), phenol (7-19 ug/l), total cyanide (1-6 ug/l), sodium (5-175 milligrams per liter), iron (20-14,380 ug/l), lead (13 ug/l), and zinc (2-1,240 ug/l). Trace amounts of several pesticides also were

detected such as lindane, chlordane, dieldrin, endrin, 4,4'DDD, 4,4' DDE, 4,4' DDT, and hexachlorobenzene. The four wells sampled for gross alpha and beta radiation during Round 1 contained values for gross alpha ranging from 2-270 picocuries per liter ("pCi/l") and values for gross beta ranging from 11-171 pCi/l. Round 2 chemical results indicated the presence of methylene chloride (6-10 ug/l), bis-2-ethyhexyl phthalate (10 ug/l), total cyanide (7 ug/l), zinc (2-2,000 ug/l), and arsenic (4-9 ug/l). Compounds such as antimony, nickel, and thallium also were found.

17. In May 1986, 32 wells at the Site were sampled and analyzed for gross alpha and beta by ORAU. Isotopic analyses were performed on many of the samples to determine radium levels. The radionuclide concentrations were found to be gross alpha (0.9-8.4 pCi/l), gross beta (1.9-22 pCi/l), Ra-226 (0.2-0.7 pCi/l), Ra-228 (0.2-5.8 pCi/l), U-total (1.6-25 pCi/l), Th-228 (0.2-1.7 pCi/l), Th-230 (0.1-12 pCi/l), and Th-232 (0.2-4.0 pCi/l). The concentrations for gross alpha, Ra-226, and Ra-228 are below the permissible maximum contaminant levels for community water systems set forth in 40 C.F.R. § 141.

18. Direct contact with, and air transport of, radiological contamination would primarily affect persons working in and around the Site. Surface water runoff from the Landfill primarily flows to a drainage ditch along the north side of the Landfill and the south side of St. Charles Rock Road. This ditch may occasionally be recharged by groundwater. This surface water either recharges the groundwater or discharges through a drainage ditch to the

Missouri River. A pond along this ditch is located on the north side of the Landfill and is known to contain fish. Surface water runoff to the south and southwest flows across relatively flat agricultural fields. This runoff joins the small intermittent ditches which traverse the area. Groundwater contamination could affect persons using groundwater downgradient of the Landfill before it discharges to the Missouri River.

19. In a report entitled "Hydrogeological Investigation, West Lake Landfill, Primary Phase Report" prepared by Burns & McDonnell in October 1986, it was stated that the predominant groundwater flow direction in the alluvial aquifer in the vicinity of the Site is northwestward toward the Missouri River. The water table generally slopes toward the Missouri River, although changes in gradient direction apparently occur at some times during the year in response to changes in the stage of the Missouri River. The alluvial aquifer consists of a continuous sequence of sand deposits with some gravel zones. The alluvium at shallow depths is primarily fine to medium sand, with only traces of gravel. The alluvium in the deeper part of the aquifer is coarser grained, consisting primarily of coarse sand and gravel.

20. Uranium, thorium, radium, protactinium, and actinium are all known human carcinogens. Methylene chloride and lead are both probable human carcinogens. Phenol is a suspected carcinogen and mutagen.

21. The following pesticides were detected in analyses of groundwater samples taken at the Site: gamma BH (Lindane),

chlordane, dieldrin, endrin, 4,4' DDD, 4,4' DDE, 4,4' DDT, and hexachlorobenzene. These highly-chlorinated pesticides are probable carcinogens. They are toxic to humans via ingestion and dermal contact. Some are reproductive toxins.

22. U-238, U-235, Th-230, and Ra-226, the pesticides identified in Paragraph 21, above, methylene chloride, phenol, and lead are hazardous substances as defined in CERCLA Section 101(14), 42 U.S.C. § 9601(14).

23. Pursuant to Section 105 of CERCLA, 42 U.S.C. § 9605, EPA placed the Site on the National Priorities List, set forth at 40 C.F.R. Part 300, Appendix B, by publication in the Federal Register on August 30, 1990, 55 Fed. Reg. 35502.

24. Cotter Corporation (N.S.L.) is a corporation organized and existing pursuant to the laws of the State of New Mexico.

25. Laidlaw Waste Systems (Bridgeton), Inc. is a corporation organized and existing pursuant to the laws of the State of Missouri.

26. Rock Road Industries, Inc. is a corporation organized and existing pursuant to the laws of the State of Missouri.

27. The United States Department of Energy is a department of the United States Government and is a successor to the Atomic Energy Commission.

28. Cotter, by contract, agreement, or otherwise arranged for the disposal, or arranged with a transporter for transport for disposal, hazardous substances owned or possessed by it at the Site.

29. At the time of disposal of hazardous substances at the Site, West Lake Landfill, Inc. (now known as Laidlaw Waste Systems (Bridgeton), Inc., and referred to herein as Laidlaw) was an owner or operator of the Site.

30. DOE, by contract, agreement, or otherwise arranged for the disposal, or arranged with a transporter for transport for disposal, hazardous substances owned or possessed by it at the Site.

31. Rock Road is a current owner of the Site.

VI. EPA'S CONCLUSIONS OF LAW AND DETERMINATIONS

EPA makes the following Conclusions of Law and Determinations, which Respondents do not admit:

32. The Site is a "facility" as defined in Section 101(9) of CERCLA, 42 U.S.C. § 9601(9).

33. There has been a "release" or threat of a release of a "hazardous substance" at the Site as defined in Section 101(22) and 101(14) of CERCLA, 42 U.S.C. §§ 9601(22) and 9601(14).

34. Respondents are each a "person" as defined in Section 101(21) of CERCLA, 42 U.S.C. § 9601(21).

35. Respondents are each a responsible party pursuant to Sections 104, 107, and 122 of CERCLA, 42 U.S.C. §§ 9604, 9607, and 9622.

36. The actions required by this Consent Order are necessary to protect the public health, welfare, or environment, are practicable and in the public interest, are consistent with CERCLA and the NCP, and will expedite effective remedial action and

minimize litigation, all in accordance with Sections 104 and 122 of CERCLA, 42 U.S.C. §§ 9604 and 9622.

VII. NOTICE TO THE STATE

37. By providing a copy of this Consent Order to the State of Missouri, EPA is notifying the State of Missouri that this Consent Order is being issued and that EPA is the lead agency for coordinating, overseeing, and enforcing the activities required hereunder.

VIII. WORK TO BE PERFORMED

38. All activities performed pursuant to this Consent Order (the "Work") shall be under the direction and supervision of qualified personnel. Within thirty (30) days of the effective date of this Consent Order, and before the Work outlined below begins, Respondents shall notify EPA in writing of the names, titles, and qualifications of the principal personnel, including contractors, subcontractors, consultants, and laboratories, to be used in carrying out the Work. The qualifications of the principal persons responsible for undertaking the Work for Respondents shall be subject to EPA's review, for verification that such persons meet minimum technical background and experience requirements. This Consent Order is contingent on Respondents' demonstration to EPA's satisfaction that Respondents are qualified to perform properly and promptly the actions set forth in this Consent Order. If EPA disapproves of the technical qualifications of any person, Respondents shall notify EPA of the identity and qualifications of a replacement within thirty (30) days of receipt of EPA's

disapproval. If EPA disapproves of the replacement, EPA reserves the right to terminate this Consent Order and to conduct the Work itself, to seek reimbursement from Respondents, and/or to seek any other appropriate relief as provided herein. During the course of the performance of the Work, Respondents shall notify EPA in writing of any changes or additions in the principal personnel used to carry out the Work, including their names, titles, and qualifications. EPA shall have the same right to approve changes and additions to principal personnel as it has hereunder regarding the initial notification.

39. Respondents shall conduct activities and submit deliverables as provided by this Consent Order and the attached RI/FS Statement of Work ("SOW"), which is incorporated herein by reference, and Section IV (Statement of Purpose). All such work shall be conducted in accordance with CERCLA, the NCP, and EPA guidance including, but not limited to, the "Interim Final Guidance for Conducting Remedial Investigations and Feasibility Studies under CERCLA" (OSWER Directive 9355.3-01), guidances referenced therein, and guidances referenced in the SOW, as may be amended or modified by EPA. The general activities that Respondents are required to perform are identified below. The tasks that Respondents must perform are described more fully in the SOW and guidances. The activities and deliverables identified below shall be developed as provided in the RI/FS Work Plan and Sampling and Analysis Plan, and shall be submitted to EPA as provided. All work performed under this Consent Order shall be in accordance with the

schedules herein, and in full accordance with the standards, specifications, and other requirements of the RI/FS Work Plan and Sampling and Analysis Plan, as approved by EPA, and as may be amended or modified by EPA.

a. **Task I - Scoping**. EPA determines the Site-specific objectives of the RI/FS and devises a general management approach for the Site, as stated in the attached SOW. Respondents shall conduct the remaining scoping activities as described in the SOW and referenced guidances. At the conclusion of the project planning phase, Respondents shall submit the following deliverables to EPA:

(1) RI/FS Work Plan. Within sixty (60) days of the effective date of this Consent Order, Respondents shall submit to EPA a complete RI/FS Work Plan in accordance with the SOW. If EPA disapproves of or requires revisions to the RI/FS Work Plan, in whole or in part, Respondents shall amend and submit to EPA a revised RI/FS Work Plan which is responsive to all of EPA's comments, within forty-five (45) days of receiving EPA's comments.

(2) Sampling and Analysis Plan. Within sixty (60) days of the effective date of this Consent Order, Respondents shall submit to EPA a Sampling and Analysis Plan in accordance with the schedule set forth in the EPA approved RI/FS Work Plan. This Sampling and Analysis Plan shall consist of a Field Sampling Plan ("FSP") and a Quality Assurance Project Plan ("QAPP") as described in the SOW and guidances. If EPA

disapproves of or requires revisions to the Sampling and Analysis Plan, in whole or in part, Respondents shall amend and submit to EPA a revised Sampling and Analysis Plan which is responsive to all of EPA's comments, within forty-five (45) days of receiving EPA's comments.

(3) Site Health and Safety Plan. Within sixty (60) days of the effective date of this Consent Order, Respondents shall submit to EPA a Site Health and Safety Plan.

b. **Task II - Community Relations**. EPA will prepare a Community Relations Plan, in accordance with EPA guidance and the NCP. Respondents shall provide information supporting EPA's community relations programs.

c. **Task III - Site Characterization**. Following EPA approval or modification of the RI/FS Work Plan and Sampling and Analysis Plan, Respondents shall implement the provisions of these Plans to characterize the Site. Respondents shall complete Site characterization in accordance with the schedule set forth in the EPA approved RI/FS Work Plan. Respondents shall provide EPA with validated analytical data generated pursuant to this Consent Order in a form showing the location, medium, and results. As used herein, "validated analytical data" refers to data that has been quality assured pursuant to the QAPP and the supporting empirical data, including instrument printouts, used to determine such quality assured data. Respondents shall require validation of all sampling results within sixty (60) days of receipt from the laboratory. This information shall be submitted to EPA with the subsequent monthly progress report as described in Section XIII (Progress Reports), herein. Within seven (7) days of completion of field activities, Respondents shall notify EPA in writing. During Site characterization, Respondents shall provide EPA with the following deliverables, as described in the SOW and RI/FS Work Plan:

(1) Technical Memorandum on Modeling of Site Characteristics. Where Respondents propose that modeling is appropriate, Respondents shall submit a technical memorandum on modeling of Site characteristics in accordance with the schedule set forth in the approved RI/FS Work Plan. If EPA disapproves of, or requires revisions to, the technical memorandum on modeling of Site characteristics, in whole or in part, Respondents shall amend and submit to EPA a revised technical memorandum on modeling of Site characteristics which is responsive to all of EPA's comments, within forty-five (45) days of receiving EPA's comments.

(2) Site Characterization Summary Report. Respondents shall submit a Site Characterization Summary Report to EPA in accordance with the schedule set forth in the approved RI/FS Work Plan.

(3) Remedial Investigation Report. Within sixty (60) days of receipt from EPA of the Baseline Risk Assessment described in Section IX (EPA's Baseline Risk Assessment), Respondents shall submit to EPA a Remedial Investigation Report consistent with the SOW, RI/FS Work Plan, and Sampling

and Analysis Plan. If EPA disapproves of or requires revisions to the Remedial Investigation Report, in whole or in part, Respondents shall amend and submit to EPA a revised Remedial Investigation Report which is responsive to all of EPA's comments, within forty-five (45) days of receiving EPA's comments.

d. **<u>Task IV - Treatability Studies</u>**. Respondents shall submit to EPA a memorandum analyzing whether treatability studies are needed based on the information developed during the conduct of the Remedial Investigation and the basis therefor. EPA will then determine whether Respondents shall conduct treatability studies and notify Respondents of its decision in writing. If required, major components of the treatability studies include determination of the need for and scope of studies, the design of the studies, and the completion of the studies as described in the SOW. During treatability studies, Respondents shall provide EPA with the following deliverables:

(1) <u>Identification of Candidate Technologies Memorandum</u>. This memorandum shall be submitted in accordance with the schedule set forth in the EPA approved RI/FS Work Plan. If EPA disapproves of, or requires revisions to, the technical memorandum identifying candidate technologies, in whole or in part, Respondents shall amend and submit to EPA a revised technical memorandum identifying candidate technologies which is responsive to all of EPA's comments within forty-five (45) days of receiving EPA's comments.

(2) Treatability Testing Work Plan. Respondents shall submit a Treatability Testing Work Plan or a proposed amendment to the RI/FS Work Plan, including a schedule, in accordance with the schedule set forth in the approved RI/FS Work Plan. If EPA disapproves of, or requires revisions to, the Treatability Testing Work Plan or the proposed amendment to the RI/FS Work Plan, in whole or in part, Respondents shall amend and submit to EPA a revised Treatability Testing Work Plan or proposed amendment to the RI/FS Work Plan, which is responsive to all of EPA's comments, within forty-five (45) days of receiving EPA's comments.

(3) Treatability Study Sampling and Analysis Plan. Upon the identification of the need for a separate or amended QAPP or FSP, Respondents shall submit a Treatability Study Sampling and Analysis Plan or a proposed amendment to the original QAPP or FSP, in accordance with the schedule set forth in the approved RI/FS Work Plan. If EPA disapproves of, or requires revisions to, the Treatability Study Sampling and Analysis Plan or the proposed amendment to the original QAPP or FSP, in whole or in part, Respondents shall amend and submit to EPA a revised Treatability Study Sampling and Analysis Plan or proposed amendment to the original QAPP or FSP, which is responsive to all of EPA's comments, within forty-five (45) days of receiving EPA's comments.

(4) Treatability Study Site Health and Safety Plan. Upon the identification of the need for a separate or amended

Health and Safety Plan, Respondents shall submit a Treatability Study Site Health and Safety Plan or a proposed amendment to the original Site Health and Safety Plan, in accordance with the schedule set forth in the approved RI/FS Work Plan.

(6) Treatability Study Evaluation Report. Respondents shall submit a Treatability Study Evaluation Report as provided in the SOW and RI/FS Work Plan in accordance with the schedule set forth in the approved RI/FS Work Plan. If EPA disapproves of, or requires revisions to, the Treatability Study Evaluation Report, in whole or in part, Respondents shall amend and submit to EPA a revised Treatability Study Evaluation Report which is responsive to all of EPA's comments within forty-five (45) days of receiving EPA's comments.

e. **Task V - Development and Screening of Remedial Alternatives**. Respondents shall develop an appropriate range of waste management options that will be evaluated through the development and screening of alternatives as provided in the SOW and RI/FS Work Plan. During the development and screening of alternatives, Respondents shall provide EPA with the following deliverables:

(1) Memorandum on Remedial Action Objectives. Within sixty (60) days of receipt of the Baseline Risk Assessment, Respondents shall submit a memorandum on remedial action objectives.

(2) <u>Report on Development and Screening of Remedial Alternatives</u>. Respondents shall submit a report summarizing the development and screening of remedial alternatives including an alternatives array document as described in the SOW in accordance with the schedule set forth in the approved RI/FS Work Plan.

f. **<u>Task VI - Detailed Analysis of Remedial Alternatives</u>**. Respondents shall conduct a detailed analysis of remedial alternatives as described in the SOW and RI/FS Work Plan. During the detailed analysis of alternatives, Respondents shall provide EPA with the following deliverables and presentation:

(1) <u>Comparative Analysis Technical Memorandum and Presentation to EPA</u>. Respondents shall submit a technical memorandum to EPA summarizing the results of the comparative analysis performed between the remedial alternatives in accordance with the schedule set forth in the approved RI/FS Work Plan. If EPA disapproves of, or requires revisions to, the comparative analysis technical memorandum, Respondents shall amend and submit to EPA a revised comparative analysis technical memorandum which is responsive to all of EPA's comments within forty-five (45) days of receiving EPA's comments. Upon EPA's request, Respondents shall make a presentation to EPA during which Respondents shall summarize the findings of the remedial investigation and remedial action objectives, and present the results of the nine criteria evaluation and comparative analysis as described in the SOW,

in accordance with the schedule set forth in the approved RI/FS Work Plan.

(2) Feasibility Study Report. Respondents shall submit a draft Feasibility Study Report which reflects the findings in the Baseline Risk Assessment in accordance with the schedule set forth in the approved RI/FS Work Plan. Respondents shall refer to Table 6-5 of the RI/FS Guidance for report content and format. If EPA disapproves of, or requires revisions to, the draft Feasibility Study Report, in whole or in part, Respondents shall amend and submit to EPA a revised Feasibility Study Report which is responsive to all of EPA's comments, within forty-five (45) days of receiving EPA's comments. The report, as amended, and the Administrative Record shall provide the basis for the Proposed Plan under CERCLA §§ 113(k) and 117(a), 42 U.S.C. §§ 6913(k) and 6917(a), by EPA and shall document the development and analysis of remedial alternatives.

40. For all deliverables, EPA will approve, disapprove, or return the deliverable to Respondents with comments or requests for modifications. In subsequent or resubmitted deliverables, Respondents shall respond to the specified deficiencies and address the information and comments from EPA. If EPA disapproves of a deliverable, EPA will state with specificity the grounds for disapproval.

41. Respondents shall not proceed further with any subsequent activities or tasks until receiving EPA approval for the following

deliverables: RI/FS Work Plan, Sampling and Analysis Plan, draft Remedial Investigation Report, Treatability Testing Work Plan, Treatability Study Sampling and Analysis Plan, and the draft Feasibility Study Report. While awaiting EPA approval on these deliverables, Respondents shall proceed with all other tasks and activities which may be conducted independently of these deliverables, in accordance with the schedule set forth in this Consent Order or the approved RI/FS Work Plan.

42. For all remaining deliverables not enumerated in the preceding Paragraph, Respondents may proceed with all subsequent tasks, activities and deliverables without awaiting EPA approval. If Respondents have not complied with an approved Work Plan or this Consent Order, or at any time EPA deems necessary to protect public health, welfare, or the environment, however, EPA reserves the right to disapprove Respondents' implementation of such tasks and may require that Respondents' cease the implementation of such tasks, either temporarily or permanently, at any point during the RI/FS.

43. In the event that Respondents amend or revise a report, plan, or other submittal upon receipt of EPA comments, if EPA subsequently disapproves of the revised submittal, or if subsequent submittals do not fully reflect EPA's directions for changes, EPA retains the right to seek stipulated or statutory penalties, perform its own studies, complete the RI/FS (or any portion of the RI/FS) pursuant to CERCLA and the NCP, and seek reimbursement from the Respondents for its costs and/or seek any other appropriate

relief. In the event EPA refuses to approve a deliverable unless Respondents change or modify it in a manner which Respondents deem inconsistent with Respondents' best professional judgment, Respondents reserve the right to seek Dispute Resolution in accordance with Section XIX (Dispute Resolutions) or pursue any other rights they may have.

44. In the event that EPA takes over some of the tasks but not the preparation of the RI/FS, Respondents shall incorporate and integrate information supplied by EPA into the final RI/FS report.

45. Neither the failure of EPA to expressly approve or disapprove of Respondents' submissions within a specified time period nor the absence of comments, shall be construed as approval by EPA. EPA will make it a goal to approve, disapprove, or comment on all deliverables within sixty (60) days of receipt of the deliverable.

IX. EPA'S BASELINE RISK ASSESSMENT

46. EPA will perform the Baseline Risk Assessment. Respondents shall support EPA in the effort by providing various information to EPA as outlined above. The major components of the Baseline Risk Assessment include contaminant identification, exposure assessment, toxicology assessment, and human health and ecological risk characterization.

47. EPA will provide, after review of Respondents' Site Characterization Summary, sufficient information concerning the baseline risks such that the Respondents can begin drafting the

Feasibility Study Report and the Memorandum on Remedial Action Objectives.

48. EPA will prepare a Baseline Risk Assessment report based on data collected by the Respondents during Site characterization. EPA will release the final report to the public at the same time it releases the final RI Report. Both reports will be put into the Administrative Record for the Site.

X. MODIFICATION OF THE RI/FS WORK PLAN

49. Respondents shall have the right to gather any additional data not specified or required under this Consent Order. If, at any time during the performance of the Work required under this Consent Order, Respondents identify a need for additional data to complete the Work which shall require a modification or extension of any part of the schedule, Respondents shall submit a memorandum to the EPA Project Coordinator explaining the need for and the nature of the requested modification or extension. If EPA does not approve or disapprove of the request for modification or extension within fourteen (14) days of receipt of the request, Respondents may proceed to gather such additional data and submit it to EPA for inclusion in the administrative record. However, any schedule modification or extension may be accomplished only in conformity with Section XXVII (Effective Date and Subsequent Modification) of this Consent Order.

50. In the event conditions posing an immediate threat to human health, welfare, or the environment become known to them, Respondents shall notify EPA and the State of Missouri no later

than twenty-four (24) hours of discovery. In the event of material unanticipated or changed circumstances at the Site, Respondents shall notify the EPA Project Coordinator by telephone within forty-eight (48) hours of discovery of such unanticipated or changed circumstances. In addition to the authorities in the NCP, in the event that EPA determines that the immediate threat or the material unanticipated or changed circumstances warrant changes in the RI/FS Work Plan, EPA may modify or amend the RI/FS Work Plan in writing accordingly. If Respondents dispute EPA's modifications or amendments to the RI/FS Work Plan, they shall submit such issue to Dispute Resolution pursuant to Section XIX. Otherwise, Respondents shall perform the RI/FS Work Plan as modified or amended.

51. EPA may determine that in addition to tasks defined in the initially approved RI/FS Work Plan, other additional work may be necessary to accomplish the objectives of the RI/FS as set forth in the SOW and the Statement of Purpose set forth in Section IV, herein. EPA may request that Respondents perform such other work in addition to the work required by the initially approved RI/FS Work Plan including any approved modifications if it determines that such actions are necessary for a complete RI/FS and is consistent with the Statement of Purpose set forth in Section IV, herein. Respondents shall confirm their willingness to perform the additional work in writing to EPA within seven (7) days of receipt of the EPA request or Respondents shall invoke Dispute Resolution. Subject to resolution of any dispute pursuant to the provisions of Section XIX (Dispute Resolution), Respondents shall implement the

additional tasks which EPA determines are necessary. The additional work shall be completed according to the standards, specifications, and schedules set forth or approved by EPA in a written modification to the RI/FS Work Plan. In the event Respondents do not agree to perform the additional work and the modification is not the subject of Dispute Resolution, EPA reserves the right to conduct the additional work itself, to seek reimbursement from Respondents, and/or to seek other appropriate relief.

XI. QUALITY ASSURANCE

52. Respondents shall assure that work performed, samples taken, and analyses conducted pursuant to this Consent Order conform to the requirements of the SOW, the QAPP, and all guidances identified herein. Respondents shall assure that field personnel used by Respondents are properly trained in the use of field equipment and in chain of custody procedures.

XII. FINAL RI/FS; PROPOSED PLAN; PUBLIC COMMENT; RECORD OF DECISION; ADMINISTRATIVE RECORD

53. EPA retains the responsibility for the release to the public of the RI/FS Reports. EPA retains responsibility for the preparation and release to the public of the Proposed Plan and ROD in accordance with CERCLA and the NCP.

54. EPA will determine the contents of the administrative record file for selection of the remedial action. Respondents will submit to EPA documents developed during the course of the RI/FS upon which selection of the response action may be based. Respondents shall provide copies of plans, task memoranda

(including documentation of field modifications, if any), recommendations for further action, quality assurance memoranda and audits, raw data, field notes, laboratory analytical reports, and other reports. To the extent not in EPA's possession at Region VII or in the possession of MDNR, Respondents must additionally submit copies of any previous studies in their possession or under their control conducted under state, local, or other federal authorities relating to selection of a response action for Radiological Areas 1 and 2, and copies of all written communications between Respondents and state, local, or other federal authorities concerning selection of a response action for Radiological Areas 1 and 2. At their discretion, Respondents may establish a community information repository at, or near, the Site to house a copy of the administrative record.

XIII. PROGRESS REPORTS

55. Respondents shall make presentations at and participate in meetings at the request of EPA during the initiation, conduct, and completion of the Work. In addition to discussion of the technical aspects of the Work, topics will include anticipated problems or new issues. Meetings will be scheduled at EPA's discretion. When practicable, EPA will give Respondents five (5) days advance written notice of any such meeting or presentation.

56. In addition to the deliverables set forth in this Consent Order, Respondents shall provide to EPA monthly progress reports by the 10th day of each following month. These progress reports shall include: (1) a description of the actions which have been taken to

comply with this Consent Order during that month; (2) all validated analytical data and all other validated data received by Respondents during that month; (3) a description of the work planned for the next two months with schedules relating such work to the overall project schedule; and (4) a description of all material problems encountered and any anticipated material problems, any actual or anticipated material delays, and solutions developed and implemented to address any actual or anticipated material problems or delays.

XIV. SAMPLING AND DATA ANALYSIS

57. All validated analytical data, including results of sampling, tests, modeling, or other data generated by Respondents or on Respondents' behalf, pursuant to the requirements of this Consent Order shall be submitted to EPA in the subsequent monthly progress report as described in Section XIII (Progress Reports) of this Consent Order. EPA will make available to Respondents validated data generated by EPA unless it is exempt from disclosure by any federal or state law or regulation.

58. Respondents orally will notify EPA at least fourteen (14) days prior to conducting significant field events as described in the SOW, RI/FS Work Plan, or Sampling and Analysis Plan. Upon EPA's request, Respondents shall allow EPA or its authorized representatives to take a reasonable number of split or duplicate samples of samples collected by Respondents in implementing this Consent Order.

59. Respondents may assert a business confidentiality claim covering part or all of the information submitted to EPA pursuant to the terms of this Consent Order to the extent permitted by and in accordance with Section 104(e)(7) of CERCLA, 42 U.S.C. § 9607(e)(7), and 40 C.F.R. § 2.203(b). This claim shall be asserted in the manner described by 40 C.F.R. § 2.203(b) and substantiated at the time the claim is made. Information determined to be confidential by EPA will be given the protection specified in 40 C.F.R. Part 2, Subpart B. If no such claim accompanies the information when it is submitted to EPA, it may be made available to the public without further notice to Respondents. Respondents agree not to assert confidentiality claims with respect to any data related to Site conditions, sampling, or monitoring.

60. By entering into this Consent Order, Respondents waive any objections to the validity of any data gathered, generated, or evaluated by EPA, the State of Missouri, or Respondents in the performance or oversight of the Work that has been verified according to the approved quality assurance/quality control ("QA/QC") procedures required by the Consent Order. If Respondents object to data relating to the Work, Respondents shall submit to EPA a report that identifies and explains its objections, describes the acceptable uses of the data, if any, and identifies any limitations to the use of the data. Such report must be submitted to EPA within fifteen (15) days of the monthly progress report containing the data.

61. To the extent practicable, EPA orally will notify Respondents at least five (5) days prior to conducting any independent field activities relating to the Site during the course of the performance of the Work. At Respondents' oral or written request, EPA will permit Respondents' representative to be present during any such activities and shall allow split or duplicate samples to be taken by Respondents of any samples collected by EPA relating to the Site. All samples taken by EPA will be taken, handled, and analyzed in accordance with the procedures specified in the FSP, to the extent applicable, and the QAPP. EPA will assure that field personnel used by EPA are properly trained in the use of field equipment, in chain of custody procedures, and as required by the Health and Safety Plan.

XV. ACCESS

62. Commencing upon the effective date of this Consent Order, Respondents agree to provide EPA and its representatives, including its contractors, access at all times to the Site and any other property to which access is required for the implementation of this Consent Order, to the extent access to the property is controlled by Respondents, for the purposes of conducting any activity related to this Consent Order including, but not limited to:

a. Monitoring the Work;

b. Verifying any data or information submitted to EPA;

c. Conducting investigations relating to contamination at or near the Site;

d. Obtaining samples;

e. Assessing the need for, planning, or implementing additional response actions at or near the Site;

f. Inspecting and copying records, operating logs, contracts, or other documents maintained or generated by Respondents or their agents; and

g. Assessing Respondents' compliance with this Consent Order.

63. Prior to entering the Site, EPA will provide, when practicable, Respondents' Project Coordinator with the credentials or other written notice of all EPA personnel and representatives authorized to enter the Site pursuant to this Section.

64. EPA and its representatives shall comply with the Site Health and Safety Plan while on Site.

65. To the extent that the Site or any other property to which access is required for the implementation of this Consent Order is owned or controlled by persons other than Respondents, Respondents shall use best efforts to secure from such persons access for Respondents, as well as for EPA and its representatives, including, but not limited to, its contractors, as necessary to effectuate this Consent Order. If any access required to complete the Work is not obtained within thirty (30) days of the effective date of this Consent Order, or within thirty (30) days of the date EPA notifies Respondents in writing that additional access beyond that previously secured is necessary, Respondents shall promptly notify EPA, and shall include in that notification a summary of the steps Respondents have taken to attempt to obtain access. EPA may, as it deems appropriate, assist Respondents in obtaining access.

Respondents shall reimburse EPA, in accordance with the procedures in Section XXII (Reimbursement of Response and Oversight Costs), for all costs incurred by EPA in obtaining access.

66. Notwithstanding any provision of this Consent Order, EPA retains all of its access authorities and rights, including enforcement authorities related thereto, under CERCLA, the Resource Conservation and Recovery Act, 42 U.S.C. §§ 6901-6992k, and any other applicable statutes or regulations.

XVI. PROJECT COORDINATORS

67. All documents and correspondence which must be submitted pursuant to this Consent Order shall be sent by certified mail, return receipt requested, by overnight delivery service, or hand-delivered to the following addressees or to any other addressees which Respondents and EPA designate in writing:

a. Documents to be submitted to EPA shall be sent in triplicate to:

Diana L. Newman
U.S. Environmental Protection Agency
Region VII
WSTM/SAFE
726 Minnesota Avenue
Kansas City, Kansas 66101

b. Documents to be submitted to Respondents should be sent to:

Jerome T. Wolf
Michael D. Hockley
Spencer Fane Britt & Browne
1400 Commerce Bank Building
1000 Walnut Street
Kansas City, Missouri 64106

with cc by mail to:

James F. Gunn
Sandra L. Oberkfell
The Stolar Partnership
911 Washington Avenue
St. Louis, Missouri 63101

Charlotte Neitzel
Holme Roberts & Owen
1700 Lincoln, Suite 4100
Denver, Colorado 80203

James W. Wagoner II
Director, Division of Offsite Programs
Office of Eastern Area Programs
Office of Environmental Restoration
U.S. Department of Energy
12800 Middlebrook Road
Germantown, Maryland 20874

Unless otherwise specified, any notices or submissions required by this Consent Order shall be deemed delivered on the date placed in the United States Mail, delivered to an overnight service, or hand-delivered. If response deadlines are triggered by receipt of a notice, then such notice, for purposes of calculating the affected deadline, shall be deemed received upon actual receipt.

68. On or before the effective date of this Consent Order, EPA and Respondents shall each designate their own Project Coordinator. Each Project Coordinator shall be responsible for overseeing the implementation of this Consent Order. To the maximum extent possible, communications between Respondents and EPA shall be directed between the Project Coordinators as specified in Section XVI (Project Coordinators), herein, by mail with copies to such other persons as EPA and Respondents may respectively designate. Communications include, but are not limited to, all

documents, reports, approvals, and other correspondence submitted under this Consent Order.

69. EPA and Respondents each have the right to change their respective Project Coordinator. The other party must be notified in writing at least ten (10) days prior to any such change.

70. EPA's Project Coordinator shall have the authority lawfully vested in a Remedial Project Manager ("RPM") and On-Scene Coordinator ("OSC") by the NCP. In addition, EPA's Project Coordinator shall have authority consistent with the NCP to halt any work required by this Consent Order and to take any necessary response action when EPA determines that conditions at the Site may present an immediate endangerment to public health or welfare or the environment. The absence of the EPA Project Coordinator from the Site shall not be cause for the stoppage or delay of work.

XVII. OTHER APPLICABLE LAWS

71. Respondents shall comply with all applicable laws when performing the activities pursuant to this Consent Order. No federal, state, or local permits are required for on-Site response actions conducted pursuant to CERCLA Sections 104, 121, or 122. The term "on-Site" means the areal extent of contamination and all suitable areas in very close proximity to the contamination necessary for implementation of activities pursuant to this Consent Order.

XVIII. RECORD PRESERVATION

72. One complete set of all records and documents in Respondents' possession that relate to this Consent Order shall be

preserved during the conduct of this Consent Order and for a minimum of six (6) years after commencement of construction of any remedial action. Respondents shall acquire and retain one complete copy of all non-privileged documents that relate to this Consent Order that are in the possession of their employees, agents, accountants, contractors, or attorneys. At the conclusion of this six (6) year period, Respondents shall notify EPA at least ninety (90) days prior to the destruction of any such records or documents, and, upon EPA's request, Respondents shall deliver any such records or documents to EPA.

XIX. DISPUTE RESOLUTION

73. The provisions of this Dispute Resolution section apply to all deliverables required by the Consent Order and all matters for which Dispute Resolution has been expressly provided. Any disputes concerning activities or deliverables required under this Consent Order for which Dispute Resolution is applicable shall be resolved as follows: If Respondents object to any EPA notice of disapproval or requirement made pursuant to this Consent Order, Respondents shall notify EPA's Project Coordinator in writing of their objections within fourteen (14) days of receipt of the disapproval notice or requirement. Respondents' written objections shall define the dispute, state the basis of Respondents' objections, and be sent certified mail, return receipt requested. EPA will, within fourteen (14) days of receipt of Respondents' objections, respond to Respondents in writing, specifically addressing the points raised by Respondents and identifying points

of agreement and disagreement. EPA and Respondents then have an additional fourteen (14) days to reach agreement.

74. If agreement is not reached within the fourteen (14) day period referenced above, Respondents and EPA will communicate their respective position in writing to the Division Director of EPA Region VII's Waste Management Division, who shall resolve the dispute and provide a written statement of his decision to Respondent. The Division Director's determination is EPA's final decision. Respondents shall proceed in accordance with EPA's final decision regarding the matter in dispute regardless of whether Respondents agree with the decision. If the Respondents do not agree to perform, or do not perform the work in accordance with EPA's final decision, EPA reserves the right in its sole discretion to conduct the work itself, to seek reimbursement from the Respondents, to seek enforcement of the decision, to seek stipulated penalties, and/or to seek any other appropriate relief. No action, decision, or directive made by EPA, including without limitation the Division Director of EPA Region VII's Waste Management Division pursuant to this Consent Order shall constitute a final agency action giving rise to any rights to judicial review prior to EPA's initiation of judicial action to compel Respondents' compliance with this Consent Order. Respondents reserve any rights that they may have to seek any appropriate relief to the extent available by applicable law.

75. Respondents are not relieved of their obligations to perform and conduct activities and submit deliverables on the

schedule set forth in the RI/FS Work Plan while a matter is pending in Dispute Resolution. The invocation of Dispute Resolution does not stay stipulated penalties under this Consent Order. If, however, Respondents prevail in the dispute, deadlines directly affected by the matters in dispute shall be extended for a period of time equal to the time taken to resolve the dispute under the procedures of this Section, plus reasonable time for remobilization, as determined by EPA.

XX. DELAY IN PERFORMANCE/STIPULATED PENALTIES

76. Respondents (excluding DOE) shall be liable for stipulated penalties in the amounts set forth in Paragraphs 77 and 78 to the EPA for failure to comply with the requirements of this Consent Order specified below, unless excused pursuant to Section XXI (Force Majeure). In the event that EPA determines that DOE has failed to comply with any provision which would otherwise give rise to stipulated penalties, DOE understands that this Consent Order, as it applies to DOE, will be deemed null and void, and the rights and protections afforded DOE under the Consent Order will be terminated. "Compliance" by Respondents shall include completion of the activities under this Consent Order or any work plan or other plan approved under this Consent Order identified below in accordance with all applicable requirements of law, this Consent Order, the SOW, and any plans or other documents approved by EPA pursuant to this Consent Order and within the specified time schedules established by and approved under this Consent Order.

77. If Respondents do not submit the deliverable items listed below by the deadlines stated in the SOW, or do not perform the tasks listed below in accordance with the schedules listed in the RI/FS Work Plan, the following stipulated penalties shall be payable per day by Respondents:

Penalty Per Violation Per Day	Period of Noncompliance
$ 500	1st through 7th day
$ 1,000	8th through 30th day
$ 2,500	31st day and beyond.

The penalties in this Paragraph shall apply to the following deliverable items:

a. The draft and any revised work plan.

b. The draft and any revised sampling and analysis plan.

c. The draft and any revised Remedial Investigation Report.

d. The draft and any revised Feasibility Study Report.

78. If Respondents do not submit the deliverable items listed below by the deadlines stated in the RI/FS Work Plan, or do not perform the tasks listed below in accordance with the schedules listed in the RI/FS Work Plan, the following stipulated penalties shall be payable per day by Respondents:

Penalty Per Violation Per Day	Period of Noncompliance
$ 250.00	1st through 7th day
$ 500.00	8th through 30th day
$ 1,000.00	31st day and beyond.

The penalties in this Paragraph shall apply to the following deliverable items as well as any other deliverables not specifically listed in this Section:

a. Site Health and Safety Plan.

b. Technical memorandum on modeling of Site characteristics.

c. Site Characterization Summary.

d. Evaluation of Need for Treatability Studies technical memorandum.

e. Treatability Study Site Health and Safety Plan.

f. Treatability Study Evaluation Report.

g. Technical memorandum entitled Refined Remedial Action Objectives.

h. Report entitled Development and Screening of Remedial Alternatives.

i. Comparative analysis technical memorandum.

j. Monthly progress reports.

79. Except as otherwise provided herein, all penalties shall begin to accrue on the day after complete performance is due or the day a violation occurs, and shall continue to accrue through the final day of the correction of the noncompliance or completion of the activity. Nothing herein shall prevent the simultaneous accrual of separate penalties for separate violations of this Consent Order. For violations not based on timeliness, stipulated penalties shall not begin to accrue until after Respondents have had the opportunity to revise the submission to respond to EPA's written comments. If any revised submission fails to respond to

EPA's comments and/or remedy the specified deficiencies and EPA deems such failure to constitute a violation, then EPA will provide Respondents with written notice of such violation. In such case, the stipulated penalties shall accrue from the date of receipt of such notice by Respondents.

80. Following EPA's determination that Respondents have failed to comply with a requirement of this Consent Order, EPA will provide Respondents with written notification of same and describe the noncompliance. This notice also will indicate the amount of penalties due and whether the penalties continue to accrue. Except for violations not based on timeliness, penalties shall accrue as provided in the preceding Paragraph regardless of whether EPA has notified the Respondents of a violation.

81. All penalties owed to the EPA under this Section shall be due and payable within thirty (30) days of the Respondents' receipt from EPA of a notification of noncompliance, unless Respondents invoke the Dispute Resolution procedures set forth in Section XIX (Dispute Resolution) of this Consent Order. Respondents shall pay interest on the unpaid balance, which shall begin to accrue at the end of the thirty (30) day period at the rate established by the Department of Treasury pursuant to 31 U.S.C. § 3717 and 4 C.F.R. § 102.13. Respondents shall further pay a handling charge of one percent (1%), to be assessed at the end of each thirty-day period, and a six percent (6%) per annum penalty charge, to be assessed if the penalty is not paid in full within ninety (90) days after it is due. All payments under this Section shall be paid by certified

check made payable to "EPA Hazardous Substance Superfund," shall be mailed to:

Mellon Bank
Attn: Superfund Accounting
EPA Region VII
(Comptroller Branch)
Post Office Box 360748M
Pittsburgh, PA 15251

82. Copies of check(s) paid pursuant to this Section, and any accompanying transmittal letter(s), shall be sent to EPA's Project Coordinator as set forth in Section XVI (Project Coordinators) of this Consent Order.

83. Neither the filing of a request to resolve a dispute nor the payment of penalties shall alter in any way Respondents' obligation to complete the performance required hereunder.

84. Respondents may dispute the applicability of stipulated penalties and EPA's right to the stated amount of penalties by invoking the Dispute Resolution procedures set forth in Section XIX (Dispute Resolution) of this Consent Order. Penalties shall accrue but need not be paid during the Dispute Resolution period.

85. If Respondents fail to pay stipulated penalties when due, EPA may institute proceedings to collect the penalties, as well as late charges and interest. Respondents shall pay interest on the unpaid balance, which shall begin to accrue at the end of the forty-five day period at the rate established pursuant to 31 U.S.C. § 3717 and 4 C.F.R. § 102.13. The stipulated penalties provisions do not prohibit, alter, or in any way limit EPA's ability to seek any other remedies or sanctions available by virtue of Respondents' violation of this Consent Order or of the statutes and regulations

upon which it is based. Provided, however, EPA will be precluded from seeking other judicial or administrative penalties for those violations specified in this Section unless Respondents fail to pay penalties assessed pursuant to this Section.

XXI. FORCE MAJEURE

86. Respondents shall perform the requirements of this Consent Order within the time limits set forth herein, unless the performance is prevented or delayed by events which constitute a force majeure or excusable delay. A force majeure or excusable delay is defined as any event arising from causes not foreseeable and beyond the reasonable control of Respondents, including its consultants and contractors, which could not be overcome by Respondents' best efforts and which delays or prevents performance by a date required by this Consent Order. Such events do not include unanticipated or increased costs of performance or changed economic circumstances. To the extent Respondents (excluding DOE pursuant to Paragraph 76 herein) are subject to stipulated penalties as a result of a delay caused by an act or omission of DOE, EPA, at its discretion, may consider such delay excusable for the purposes of assessment of stipulated penalties.

87. Respondents shall notify EPA orally within forty-eight (48) hours of when they first knew or should have known that a delay might occur. Within ten (10) business days thereafter, Respondents shall submit to EPA a written statement setting forth the reasons for the delay; the anticipated duration of the delay; all actions taken or to be taken to prevent or minimize the delay;

a schedule for implementation of any measures to be taken to mitigate the effect of the delay; and a statement as to whether, in the opinion of Respondents, such event may cause or contribute to an endangerment to public health, welfare, or the environment. Respondents shall adopt all reasonable measures to avoid and minimize the delay. Failure to comply with the notice provision of this Section shall constitute a waiver of Respondent's right to assert a force majeure or that the delay is excusable.

88. If EPA determines that the delay has been or will be caused by force majeure or that the delay is otherwise excusable, the time for performance for that element of work, and other tasks the completion of which is dependent upon that element of work, may be extended, upon EPA approval, for a period of equal to the delay resulting from such circumstances. All such modifications of the schedule caused by a force majeure or excusable delay shall be made in accordance with Section XXVII (Effective Date and Subsequent Modification) of this Consent Order. The schedule for those tasks which are not altered by these modifications remains unchanged unless altered in accordance with Section XXVII (Effective Date and Subsequent Modification). In the event EPA and Respondents cannot agree that any delay or failure has been or will be caused by a force majeure or that the delay is otherwise excusable, or if there is no agreement on the length of the extension, this dispute shall be resolved in accordance with the Dispute Resolution provisions of Section XIX (Dispute Resolution) of this Consent Order.

XXII. REIMBURSEMENT OF RESPONSE AND OVERSIGHT COSTS

89. Following the effective date of this Consent Order, EPA periodically will submit to the Respondents an accounting of all response costs including oversight costs incurred by EPA with respect to this Consent Order. Response costs may include, but are not limited to, costs incurred by EPA in overseeing Respondents' implementation of the requirements of this Consent Order and activities performed by EPA relating to the Consent Order and any costs incurred while assisting Respondents in obtaining access. Costs shall include all direct and indirect costs including, but not limited to, time and travel costs of EPA personnel and associated indirect costs, contractor costs, cooperative agreement costs, compliance monitoring, including the collection and analysis of split samples, inspection of activities required by this Consent Order, Site visits, discussions regarding disputes that may arise as a result of this Consent Order, review and approval or disapproval of reports, and costs of redoing any of Respondents' tasks. Any necessary summaries including, but not limited to, EPA's certified Agency Financial Management System summary data ("SPUR Reports"), or such other summary as certified by EPA, shall serve as a basis for payment demands.

90. Respondents (excluding DOE) shall, within sixty (60) days of receipt of each accounting, remit a certified or cashier's check for the amount of those costs. Interest shall accrue from the later of the date payment of a specified amount demanded in writing is due, or the date of the expenditure. The interest rate is the

rate of interest on investments for the Hazardous Substances Superfund in Section 107(a) of CERCLA, 42 U.S.C. § 9607(a).

91. All payments to EPA under this Section shall be made by certified or cashier's check made payable to "EPA Hazardous Substance Superfund" and shall include the Site name, the EPA Site identification number 514, and the EPA Docket Number assigned to this matter, and shall be remitted to:

Mellon Bank
Attn: Superfund Accounting
EPA Region VII
(Comptroller Branch)
Post Office Box 360748M
Pittsburgh, PA 15251

92. A copy of the check shall be sent simultaneously to the EPA Project Coordinator.

93. Respondents agree to limit any disputes concerning costs to accounting errors, the inclusion of costs outside the scope of this Consent Order, or costs that are inconsistent with the NCP. Respondents shall identify any contested costs and the basis of their objection. All undisputed costs shall be remitted in accordance with the time frame set forth above. Disputed costs shall be paid into an escrow account while the dispute is pending. Respondents bear the burden of establishing an EPA accounting error, the inclusion of costs outside the scope of this Consent Order, or costs inconsistent with the NCP.

XXIII. RESERVATION OF RIGHTS

94. Any requirement for the payment or obligation of funds by DOE established by the terms of this Consent Order shall be subject to the availability of funds appropriated for that purpose, and no

provision herein shall be interpreted to require the obligation or payment of funds in violation of the Anti-Deficiency Act, 31 U.S.C. § 1341.

95. EPA reserves the right to bring an action against the Respondents pursuant to Section 107 of CERCLA, 42 U.S.C. § 9607, for the recovery of all response costs including oversight costs incurred by EPA at the Site that are not reimbursed by the Respondents, any costs incurred in the event that EPA performs the RI/FS or any part thereof, and any future costs incurred by EPA in connection with response activities conducted under CERCLA at the Site. Respondents reserve all rights they may have to oppose and defend against such claims and actions and to assert any and all claims they may have against EPA or any person or government agency.

96. EPA reserves the right to bring an action against Respondents to enforce the requirements of this Consent Order, and to seek penalties and punitive damages pursuant to CERCLA.

97. Except as expressly provided in this Consent Order, each party reserves all rights and defenses it may have. Nothing in this Consent Order shall affect EPA's removal authority or EPA's response or enforcement authorities including, but not limited to, the right to seek injunctive relief, statutory penalties, and/or punitive damages. To the extent stipulated penalties apply to violations of a particular requirement of this Consent Order, however, EPA will not seek statutory penalties for such violations unless Respondents fail or refuse to pay stipulated penalties

assessed for such a violation. Respondents reserve any and all rights they may have to oppose and defend against such claims and actions and to assert any and all claims they may have against EPA or any person or government agency. Respondents reserve any rights they may have to bring any action otherwise available against any "person" as defined in Section 101(21) of CERCLA, 42 U.S.C. § 9601(21).

98. Following satisfaction of the requirements of this Consent Order, Respondents shall have resolved their liability to EPA for the work performed by Respondents pursuant to this Consent Order. Respondents are not released from liability, if any, for any response actions taken beyond the scope of this Consent Order regarding removals or activities arising pursuant to Section 121(c) of CERCLA, 42 U.S.C. § 9612(c).

XXIV. DISCLAIMER

99. By signing this Consent Order and taking actions under this Consent Order, Respondents do not admit EPA's Findings of Fact and Conclusions of Law. Furthermore, the participation of Respondents in this Consent Order shall not be considered an admission of liability and is not admissible in evidence against Respondents in any judicial or administrative proceeding other than a proceeding by the United States on behalf of EPA to enforce this Consent Order or a judgment relating to it. Each Respondent retains its rights to assert claims against the other Respondents and other potentially responsible parties at the Site. Respondents agree, however, not to contest the validity or terms of this

Consent Order or the procedures underlying or relating to it in any action brought by the United States on behalf of EPA to enforce its terms.

XXV. OTHER CLAIMS

100. In entering into this Consent Order, Respondents waive any right to seek reimbursement pursuant to Section 106(b) of CERCLA, 42 U.S.C. § 9606(b). Respondents also waive any right to present a claim under Section 111 or 112 of CERCLA, 42 U.S.C. §§ 9611 and 9612. This Consent Order does not constitute any decision on preauthorization of funds under Section 111(a)(2) of CERCLA, 42 U.S.C. § 9611(a)(2). Injuries or damages resulting from acts or omissions of the EPA, its agents, employees or other persons acting on its behalf on property owned or operated by Respondents shall be subject to the procedures of the Federal Tort Claims Act of 1949, as amended, 28 U.S.C. § 2671, et seq. (FTCA). Except for claims subject to the procedures of the FTCA, Respondents waive all other statutory and common law claims against EPA relating to or arising out of conduct of the RI/FS under this Consent Order.

101. Nothing in this Consent Order shall constitute or be construed as a release from any claim, cause of action, or demand in law or equity against any party not a signatory to this Consent Order for any liability it may have arising out of or relating in any way to the generation, storage, treatment, handling, transportation, releases or disposal of any hazardous substances, pollutants, or contaminants found at, taken to, or taken from the Site.

102. Respondents shall each bear their own costs and attorneys fees.

XXVI. FINANCIAL ASSURANCE AND INDEMNIFICATION

103. Within thirty (30) days of the effective date of this Consent Order, Respondents (excluding DOE) shall obtain a Letter of Credit in the amount of $1,050,000, naming EPA as the Beneficiary, and provide a copy of such letter to EPA within forty-five (45) days of the effective date of this Consent Order.

104. Respondents (excluding DOE) agree to indemnify and hold the EPA, its agents, and its employees harmless from any and all claims or causes of action arising from or on account of acts or omissions of Respondents, its employees, agents, servants, receivers, successors, or assignees, or any persons including, but not limited to, firms, corporations, subsidiaries and contractors in carrying out activities under this Consent Order. Except for contracts entered into by DOE, the United States Government or any agency or authorized representative thereof shall not be held as a party to any contract entered into by Respondents in carrying out activities under this Consent Order. Respondents shall be under no duty, however, to indemnify the EPA for claims or causes of action arising from or on account of negligent, willful, or intentional acts or omissions of the EPA, its officers, agents, employees or any other person acting on its behalf. Nothing herein is intended to or shall be construed as extending the liability of the EPA beyond that provided for under federal law.

XXVII. EFFECTIVE DATE AND SUBSEQUENT MODIFICATION

105. The effective date of this Consent Order shall be the date that it is signed by EPA.

106. This Consent Order may be amended by mutual agreement of EPA and Respondents. Amendments shall be in writing and shall be effective when signed by EPA.

107. No informal advice, guidance, suggestions, or comments by EPA regarding reports, plans, specifications, schedules and any other writing submitted by the Respondents will be construed as relieving the Respondents of its obligation to obtain such formal approval as may be required by this Consent Order. Any deliverables, plans, technical memoranda, reports (other than progress reports), specifications, schedules and attachments required by this Consent Order are, upon approval by EPA, incorporated into this Consent Order.

XXVIII. TERMINATION AND SATISFACTION

108. This Consent Order shall terminate when Respondents demonstrate in writing and certify to the satisfaction of EPA that all activities required under this Consent Order including any additional work, payment of response and oversight costs, and any stipulated penalties demanded by EPA have been performed and EPA has approved the certification. EPA will make it a goal to notify Respondents within sixty (60) days of receipt of such certification whether it has approved or disapproved the certification. In the event EPA disapproves the certification, it will specify in writing the reasons therefore. If EPA disapproves the certification or

fails to respond to the certification within sixty (60) days, Respondents may invoke the provisions of Section XIX (Dispute Resolution). This notice shall not, however, terminate Respondents' obligation to comply with Sections XVII (Other Applicable Laws), XVIII (Record Preservation), XXII (Reimbursement of Response and Oversight Costs), and XXIII (Reservation of Rights) of this Consent Order.

109. The certification shall be signed by a responsible official representing each Respondent. Each representative shall make the following attestation: "I certify that the information contained in or accompanying this certification is true, accurate, and complete." For purposes of this Consent Order, a responsible official is a corporate official who is in charge of a principal business function.

NEGATIVE EASEMENT AND DECLARATION OF RESTRICTIVE COVENANTS AGREEMENT

THIS NEGATIVE EASEMENT AND DECLARATION OF RESTRICTIVE COVENANTS AGREEMENT, dated as of April 6, 2005 (the "**Agreement**"), is made and entered into by and among the grantors, whose names and addresses are listed below (collectively referred to herein as the "**Grantors**") and THE CITY OF ST. LOUIS, a municipal corporation of the State of Missouri, as the grantee ("**St. Louis**"), whose address is City Hall, Room 200, 1200 Market Street, St. Louis, Missouri 63103, acting by and through its Board of Estimate and Apportionment and its City Counselor.

GRANTORS' NAMES AND ADDRESSES:

Bridgeton Landfill LLC, a Delaware limited liability company
15880 N. Greenway-Hayden Loop, Ste.100
Scottsdale, AZ 85260

Rock Road Industries, Inc., a Missouri corporation
15880 N. Greenway-Hayden Loop, Ste.100
Scottsdale, AZ 85260

Bridgeton Transfer Station, LLC, a Delaware limited liability company
15880 N. Greenway-Hayden Loop, Ste.100
Scottsdale, AZ 85260

TIA 170270A-SC

WITNESSETH THAT:

WHEREAS, the Grantors are the fee simple owners of certain real property located in St. Louis County, Missouri that is more fully described in **EXHIBIT "A"**, which is attached hereto and incorporated herein (the "**Property**");

WHEREAS, St. Louis is the owner and operator of Lambert-St. Louis International Airport® ("**Airport**");

WHEREAS, St. Louis wishes to impose certain limitations and restrictions on the use and enjoyment of the Property in order to reduce or mitigate the potential harm to airport-related activities that could be caused by certain wildlife or birds on or from the Property. Such wildlife may include various species (birds, mammals, reptiles), including feral animals and domesticated animals not under control, that are associated with aircraft strike problems, are capable of causing structural damage to airport facilities, or act as attractants to other wildlife that pose a strike hazard to aircraft; and

WHEREAS, the Grantors and St. Louis recognize that the grant of a negative easement by Grantors to St. Louis, and the declaration of restrictive covenants by Grantors, will assist in reducing or mitigating the potential harm to airport-related activities that could be caused by said wildlife.

NOW, THEREFORE, stating their intention to be legally bound hereby and in consideration of the foregoing, and the promises, covenants, and agreements herein contained, and for other good and valuable consideration, including the sum of FOUR HUNDRED THOUSAND DOLLARS ($400,000.00) in hand paid by St. Louis to Grantors, the receipt and sufficiency of which are hereby acknowledged, Grantors do hereby grant and convey unto St. Louis, its successors in interest and assigns, a negative easement, as more particularly described below, upon, over, in, and to the Property.

The negative easement granted herein and described below shall constitute a binding servitude upon the Property. To that end, Grantors do hereby covenant on behalf of themselves and their heirs, successors in interest and assigns with St. Louis, its successors in interest and assigns, such covenants and provisions being deemed to run with the land as a binding servitude in perpetuity, as provided for below, to do and to refrain from doing upon the Property the following stipulations, which contribute to the public purpose in that they aid in the reduction or mitigation of said potential wildlife or bird hazards on or from the Property, and hereby declare and impose the following restrictions upon the use and enjoyment of the Property:

1. There shall be no new or additional depositing or dumping of municipal waste, organic waste, and/or putrescible waste (municipal waste, organic waste and putrescible waste hereinafter collectively referred to as "Putrescible Waste") above, upon, on, or under the Property beginning as of August 1, 2005 and continuing in perpetuity, unless and until such time as this Agreement is terminated or canceled by St. Louis in accordance with the terms set out in paragraph 4 below. The parties acknowledge and agree that the restriction described in the preceding sentence does not, and shall not, in any way prohibit solid waste transfer station activities or operations conducted on the

Transfer Station site as shown on the drawing attached hereto as Exhibit A (the "Site") as expanded to include any encroachments by solid waste transfer station buildings or improvement extending beyond the boundaries of the Site onto the Property at the time of the execution of this Agreement. For purposes of this Agreement, **"Putrescible Waste"** shall mean solid waste that contains organic matter capable of being decomposed by micro-organisms and of such a character and proportion as to be capable of attracting or providing food for birds. For purposes of this Agreement, **"Putrescible Waste"** shall not include solid waste that qualifies for disposal in a demolition landfill as defined in 10 CSR 8O-2.010(20).

2. At all times after the Effective Date (defined below), the Grantor shall comply with all applicable federal, state and local laws and regulations regarding proper landfill cover.

3. This Agreement shall become effective and binding on the date first written above upon the execution and delivery hereof by St. Louis and the Grantors (the **"Effective Date"**). This Agreement and any companion documents or instruments referred to herein may be executed in any number of counterparts, each of which shall be original, but all of which together shall constitute one document or instrument.

4. The term of this Agreement shall begin on the Effective Date and shall end only if and when St. Louis chooses in its sole and absolute discretion to abandon its negative easement granted herein by terminating or canceling this Agreement in writing and recording such writing with St. Louis County's Recorder of Deeds.

5. Except as provided for herein, Grantors reserve unto themselves all rights, privileges, powers, and immunities in and to the Property including, without limitation, the right of possession and the use and enjoyment of the Property.

6. Representatives and agents of St. Louis shall be permitted at reasonable times, which times shall be established in advance by St. Louis by three (3) days' written notice, to come upon the Property to inspect for violation of any of the promises, covenants, restrictions, or agreements herein (**"Inspections"**), except that if St. Louis has reasonable cause to believe that such violations are occurring or have occurred, St. Louis shall not be obligated to give said three (3) days' written notice or any other notice whatsoever to the Grantors. This right of Inspections is independent of any right-of-entry granted to the St. Louis under any separate agreement. Notwithstanding the foregoing, any representative or agent of St. Louis that comes upon the Property shall enter and exit the Property exclusively through the gate maintained by Grantors for such purpose and shall observe all customary formalities required by Grantors with respect to visitors including, but not limited to, immediately reporting their presence to Grantor's administrative personnel and signing in and signing out on appropriate security logs.

7. St. Louis shall promptly repair any damage it causes to the Property in the course of any Inspections, generally placing the Property and all points of entry in the same general condition as before the Inspections or entry, to the extent reasonably practical, ordinary wear and tear excepted, unless otherwise agreed to in writing by Grantors. All

Inspections, and all repairs to the Property arising from the Inspections, shall be at the sole cost of St. Louis. St. Louis and its representatives and agents shall use their best efforts to minimize damage to the Property and shall not substantially or materially disturb or interfere with the administration and/or operations of the Grantors when conducting its Inspections.

8. St. Louis, to the extent permitted by law, hereby agrees to indemnify, release and hold Grantors and their officers, employees, representatives and agents harmless from and against any and all losses, claims, judgments, actions, suits, cross-claims, counterclaims, third party actions, damages, liabilities, fines, penalties, including all reasonable costs for investigation and defense thereof (including, without limitation, attorneys' fees, court costs, expert fees and litigation expenses) and expenses in connection with loss of life, personal injury, bodily injury or damage to property, to the extent caused by or resulting from this Agreement (including activities conducted thereunder or relating thereto), the operations of the Airport in regard to aircraft bird strikes (provided that the Grantors are in compliance with the terms and provisions of this Agreement and the Right-Of-Entry Agreement dated April 6 2005 between St. Louis and the Grantors), the Inspections or the actions of St. Louis, its employees, contractors, representatives or agents in the course of the Inspections, except to the extent arising out of the negligence or intentional misconduct of the Grantors, or their officers, boards, commissions, employees, contractors, representatives, or agents. In case the Grantors or such other persons or entities shall be made a party to any action or proceeding commenced against St. Louis, to the extent provided in the preceding sentence, St. Louis shall protect and hold such parties harmless and pay all costs, expenses and reasonable attorneys' fees incurred or paid by such parties in connection with such action or proceeding. Grantors shall give to St. Louis reasonable notice of any such claims or actions. St. Louis shall use counsel reasonably acceptable to Grantors in carrying out their obligations hereunder. This indemnity provision shall survive the termination or cancellation of this Agreement, any and all sales or transfers of the Property or any portion thereof, or interest therein and shall be binding on St. Louis and its successors in interest and assigns and shall inure to the benefit of Grantors and their successors in interest and assigns.

9. In the event of a violation or default of any promise, covenant, restriction, stipulation, warranty, agreement, or provision (**"Provision"**) herein by either party, the non-defaulting party shall have all rights and remedies available in law or equity including, without limitation, the right to specific performance and injunctive relief, and the right to institute a suit to enjoin such violation. Notwithstanding the above sentence, Grantors hereby expressly stipulate and agree that Grantors and their heirs, successors in interest and assigns shall not have the right to terminate or cancel this Agreement under any circumstance whether with or without cause. In the event of any dispute regarding any Provision of this Agreement or the rights, obligations, and liabilities of the parties with regard to this Agreement, the prevailing party shall be entitled to recover from the non-prevailing party its reasonable attorneys' fees, court costs, and other litigation costs incurred in connection with such matter.

10. All notices, requests, information or other documents required or permitted hereunder or necessary or convenient in connection with this Agreement shall be in writing and shall be deemed duly given upon receipt if sent by certified mail or by overnight or express mail service, with a return receipt, postage prepaid, and addressed to the parties as set forth below. Notice shall be deemed received at the earlier of actual receipt or two (2) calendar days after deposit with one of the mail services described in this paragraph. Any party may change the person or address to which notices are to be sent to it by giving written notice of such change to the other party in the manner herein provided for giving notice.

11. No waiver of any breach of any Provision herein contained shall be deemed, or shall constitute, a waiver of any preceding or succeeding breach thereof of any Provision contained herein. No extension of time for performance of any obligation or act shall be deemed an extension of the time for performance of any other obligation or act. No waiver shall be binding unless executed in writing by the party granting the waiver.

12. The parties hereto covenant and warrant that they have the authority and power to enter into this Agreement, that this Agreement has been authorized by all necessary corporate and municipal actions, and that each party is authorized and empowered to consummate the transaction provided for herein. This Agreement constitutes a legal, binding, valid and enforceable obligation of the parties, and there are no claims or defenses, personal or otherwise, or offsets whatsoever to the enforceability or validity of this Agreement.

13. This Agreement constitutes the entire understanding between the parties hereto with respect to the subject matter hereof and supersedes all prior or contemporaneous agreements, whether verbal or written, between the parties in regard thereto. This Agreement shall not be altered or modified except by an agreement in writing signed by the authorized representatives of the parties hereto, which writing specifically shall refer to this Agreement. It is expressly understood by the parties hereto that the provisions of this Agreement shall in no way affect or impair the provisions or obligations of St. Louis or the Grantors in regard to any other existing, contemporaneous, or prior agreements between the parties.

14. The parties hereto affirm each has full knowledge of the Provisions and requirements contained in this Agreement. Each party hereto acknowledges that such party and its counsel, after negotiation and consultation, have reviewed and revised this

Agreement. As such, the Provisions of this Agreement shall be fairly construed, and the usual rule or construction, if applicable, to the effect that any ambiguities herein should be resolved against the drafting party, shall not be employed in the interpretation of this Agreement or any amendments modifications or exhibits thereto.

15. If for any reason one or more of the Provisions contained in this Agreement shall be held to be invalid, illegal, or unenforceable in any respect, such invalidity, illegality, or unenforceability shall not affect any other Provision of this Agreement and shall be construed as if such invalid, illegal, or unenforceable Provision never had been included in this Agreement, provided the invalidity of such Provision does not materially prejudice either St. Louis or the Grantors in their respective rights and obligations contained in the valid Provisions of this Agreement

16. When the consent, approval, waiver, or certification (**"Approval"**) of a party is required under the terms of this Agreement, such Approval must be in writing and signed by the party making the Approval. Whenever the Approval of St. Louis or the Director of Airports is required, the Approval must be from the Director of Airports or his/her authorized or designated representative. Whenever the Approval of the Grantors is required (individually or collectively), the Approval must be from all fee owners of the Property or any portion thereof or their authorized or designated representatives. St. Louis and the Grantors agree that an extension of time of performance may be made with the written mutual consent of St. Louis and Grantors. Whenever the approval of St. Louis, the Director of Airports or the Grantors is required or necessary herein, no such approval shall be unreasonably requested, withheld, conditioned, or delayed.

17. MISCELLANEOUS PROVISIONS:

A. Not An Agent: St. Louis and Grantors acknowledge and agree that nothing herein shall be interpreted or construed to mean that the parties hereto, or their respective officers, contractors, consultants, employees, representatives, or agents are employees or agents of the other party.

B. Dates and Non-Business Days: Whenever a number of days is referred to in this Agreement, days shall mean consecutive calendar days unless otherwise expressly provided. If the last day for giving of notice or for performance of any obligation or condition hereunder is a Saturday, Sunday or federal, state, or city holiday, then such last day shall be extended to the next succeeding business day thereafter. Whenever it is provided in this Agreement that days shall be counted, the first day to be counted shall be the day following the date on which the event causing the period to commence occurs.

C. Other Documents: St. Louis and Grantors agree that, at the request of the other, they will execute, acknowledge, certify, (if appropriate), and deliver whatever additional documents, affidavits, certifications, and records, and perform such other acts in good faith, as may be reasonably required in order to accomplish the intent and purposes of this Agreement.

D. <u>Gender and Number</u>: Whenever the sense of this Agreement so requires, the use of (i) the singular shall be deemed to include the plural, (ii) the masculine gender shall be deemed to include the feminine or neuter gender, and (iii) the neuter gender shall be deemed to include the masculine and feminine gender.

E. <u>Exhibits</u>: All exhibits described herein are fully incorporated into this Agreement by this reference as if fully set out herein. St. Louis and Grantors shall reasonably and in good faith finalize and attach all such exhibits to this Agreement, which may not have been in final form as of the Effective Date, or may require revisions. St. Louis hereby authorizes the Director of Airports to revise or approve said amendments or revisions to the exhibits on behalf of St. Louis.

F. <u>Compliance with Laws and Regulations</u>: This Agreement does not affect such other obligations as the Grantor may have under applicable federal, state, or local laws and regulations including, without limitation, 40 C.F.R 258.10.

TO HAVE AND TO HOLD unto St. Louis and unto its successors in interest and assigns forever. The Provisions of this Agreement and the parties' rights, commitments, and obligations within, shall be binding on the parties hereto, their respective heirs, successors in interest, and assigns. Every party acquiring or holding any interest or estate in any portion of the Property shall take or hold such interest or estate, or the security interest with respect thereto, with notice of this Agreement and of the Provisions of this Agreement. In accepting any interest or estate in, or any security interest with respect to any portion of the Property, such party shall be deemed to have assented to all of the Provisions hereof. The Provisions of this Agreement shall run with the land. To that end, this Agreement shall be deemed incorporated into all deeds and conveyances hereinafter made by Grantors and any heirs, successor in interest or assigns thereto. Grantors, for themselves, their heirs, successors in interest and assigns, hereby acknowledge, stipulate, and agree that the Provisions agreed to and the restrictions imposed, as aforesaid, shall be binding rights and privileges granted hereunder appertaining or belonging to St. Louis, its successors in interest and assigns, and shall continue as a servitude running in perpetuity with the Property, unless abandoned and terminated by St. Louis as provided for in paragraph 4 above.

[Signature pages to follow.]

IN WITNESS WHEREOF, the Grantors and St. Louis have entered into this Negative Easement and Declaration of Restrictive Covenants Agreement on the date first written above.

TRACT I
PROPERTY DESCRIPTION OF
ACTIVE LANDFILL MINUS TRANSFER STATION

A tract of land being part of U.S. Survey 131, all of Lots 1, 2, 3, and 4 of the Yosti Partition as recorded in Survey Record Book 3 Page 101 of the St. Louis City (former County) records, part of Lots 20 and 21 of the St. Charles Ferry Company tract as recorded in Plat Book 7 Pages 98 and 99 of the St. Louis City (former County) records, and being located in U.S. Surveys 131 and 1934, Townships 46 and 47 North, Range 5 East of the Fifth Principal Meridian, City of Bridgeton, St. Louis County, Missouri, and being more particularly described as follows:

Beginning at the most Westerly corner of Lot 3 of the Boundary Adjustment Plat of Lots 1 and 3 of West Lake Acres Plat Two, a subdivision according to the plat thereof recorded in Plat Book 348 Page 667 of the St. Louis County, Missouri Records; thence South 36 degrees 52 minutes 59 seconds East along the Southwesterly line of said Lot 3 and the Southwesterly line of Lot 4 of West Lake Acres Plat Two, a subdivision according to the plat thereof recorded in Plat Book 344 Page 261 of said records a distance of 486.26 feet to a point on the Northwesterly line of last said Lot 4; thence South 53 degrees 06 minutes 26 seconds West along said Northwesterly line 437.11 feet to a point on the Southwesterly line of last said Lot 4; thence South 36 degrees 52 minutes 59 seconds East along last said Southwesterly line 779.68 feet to a point on the Northwesterly line of Lot 13 of Foersters Subdivision, a subdivision according to the plat thereof recorded in Plat Book 10 Page 55 of the St. Louis City (former County) records, thence South 45 degrees 59 minutes 06 seconds West along said Northwesterly line of said Lot 13 and the Northwesterly line of Lot 12 of said Foersters Subdivision 1349.58 feet to the Northerly line of Old St. Charles Rock Road, 60 feet wide, also known as Boenker Lane; thence North 54 degrees 25 minutes 17 seconds West along said Northerly line 858.18 feet to a point on the centerline of Taussig Avenue, 40 feet wide (vacated); thence North 34 degrees 48 minutes 55 seconds East along said centerline 100.00 feet to a point on the Northeasterly line of a tract of land as conveyed to Laidlaw Waste Systems (Bridgeton), Inc. according to the instrument recorded in Book 11082 Page 319 of the St. Louis County Records; thence North 54 degrees 25 minutes 17 seconds West along said Northeasterly line 120.00 feet to a point on the Northwesterly line of above said Laidlaw Waste Systems (Bridgeton), Inc. tract; thence South 34 degrees 45 minutes 34 seconds West along said Northwesterly line 130.00 feet to a point on the centerline of above said Old St. Charles Rock Road (vacated); thence along said centerline the following courses and distances: North 54 degrees 25 minutes 17 seconds West 991.55 feet, North 00 degrees 43 minutes 42 seconds East 997.52 feet, North 04 degrees 40 minutes 18 seconds West 477.70 feet, North 10 degrees 25 minutes 18 seconds West 348.30 feet, North 24 degrees 52 minutes 18 seconds West 349.50 feet; thence North 32 degrees 08 minutes 18 seconds West 22.38 feet to a point on the Southeasterly line of a tract of land as conveyed to Rock Road Industries, Inc. according to the instrument recorded in Book 12868 Page 1159 of the St. Louis County Records; thence North 35 degrees 35 minutes 04 seconds East 824.56 feet to a point on the Southwesterly line of a tract of land as conveyed to Rock Road Industries, Inc. according to the instrument recorded in Book 8356 Page 1807 of said records, and being a point on the common line between U.S. Survey 47 and U.S Survey 1934, Township 47 North, Range 5 East; thence South 66 degrees 04 minutes 54 seconds East along said Southwesterly line and said common line 167.44 feet to a point on the Southwesterly line of said Rock Road Industries, Inc. tract; thence South 36 degrees 52 minutes 59 seconds East along last said Southwesterly line and the Southwesterly line of a tract of land as conveyed to West Lake Landfill, Inc. according to the instrument recorded in Book 5262 Page 311 of above said records, and departing above said common line South 36 degrees 52 minutes 59 seconds East 1221.43 feet to a point on the Southeasterly line of a tract of land as conveyed to above said West Lake Landfill, Inc. tract, and being a point on the common line between U.S. Survey 131 and U.S Survey 47, Township 47 North, Range 5 East; thence North 54 degrees 46 minutes 17 seconds East along said Southeasterly line and said common line 1188.94 feet to a point on the Southwesterly line of Highway 40, also known as St. Charles Rock Road, variable width; thence South 37 degrees 11 minutes 37 seconds East along said Southwesterly line 1087.25 feet; thence departing said Southwesterly line the following courses and distances: South 01 degrees 32 minutes 48 seconds West 57.51 feet, South 54 degrees 30 minutes 23 seconds West 312.95 feet and South 35 degrees 29 minutes 37 seconds East 30.00 feet to a point on the Northwesterly line of above said Lot 3 of the Boundary Adjustment Plat of Lots 1 and 3 of West Lake Acres Plat Two; thence South 54 degrees 30 minutes 23 seconds West along said Northwesterly line 340.00 feet and South 48 degrees 34 minutes 23 seconds West 68.21 feet to the POINT OF BEGINNING and containing 7,119,040 square feet or 163.43 acres more or less according to a survey by Stock & Associates Consulting Engineers, Inc. dated November 19, 2004, and most recently revised February 15, 2005.

AND EXCEPTING THEREFROM the following:

A tract of land being part of Lot 1 of the Yosti Partition as recorded in Survey Record Book 3 Page 101 of the St. Louis City (former County) Records and part of U.S. Survey 131 in Township 47 North, Range 5 East of the Fifth Principal Meridian, City of Bridgeton, St. Louis County, Missouri, and being the same property as described in Ordinance Number 03-26 approved by the City of Bridgeton on June 18, 2003, and being more particularly described as follows:

Commencing at a point on the Southwesterly line of Highway 40, also known as St. Charles Rock Road, variable width, with the intersection of the common line between U.S.

 BP16465/1156

Survey 131 and U.S. Survey 47, Township 47 North, Range 5 East; thence South 37 degrees 11 minutes 37 seconds West along said Southwesterly line 72.80 feet to the POINT OF BEGINNING of the herein described tract; thence continuing along said Southwesterly line South 37 degrees 11 minutes 37 seconds East 137.01 feet; thence departing said Southwesterly line the following courses and distances: South 57 degrees 54 minutes 34 seconds West 1023.24 feet, South 32 degrees 40 minutes 35 seconds West 181.33 feet, South 36 degrees 52 minutes 59 seconds East 771.12, South 53 degrees 07 minutes 01 seconds West 332.71 feet, North 10 degrees 28 minutes 16 seconds West 198.67 feet, North 20 degrees 00 minutes 51 seconds East 166.52 feet, North 30 degrees 50 minutes 21 seconds East 404.44 feet, North 04 degrees 38 minutes 30 seconds East 131.00 feet, North 37 degrees 13 minutes 19 seconds West 153.74 feet, and North 57 degrees 54 minutes 34 seconds East 1260.74 feet to the POINT OF BEGINNING and containing 347,048 square feet or 7.967 acres more or less according to a survey by Stock & Associates Consulting Engineers, Inc. dated November 19, 2004, and most recently revised February 15, 2005.

The above property (less exception) contains 6,771,992 square feet or 155.464 acres more or less according to a survey by Stock & Associates Consulting Engineers, Inc. dated November 19, 2004, most recently revised March 9, 2005 and on file with the City of St. Louis.

TRACT II

All of Lot 4 of West Lake Acres Plat II, according to the plat thereof recorded in Plat Book 344 Page 261 of the St. Louis County Records.

The above property is shown on as parcel 3 on a survey by Stock & Associates Consulting Engineers, Inc. dated November 19, 2004, most recently revised March 9, 2005 and on file with the City of St. Louis.

TRACT III

Part of Lots 12 and 13 of the "Foersters Subdivision" in U.S. Survey 131 in Township 46 North, Range 5 East of the Fifth Principal Meridian, St. Louis County, Missouri, said part being more particularly described as follows:

Beginning at the most southerly corner of Lot 4 of Yosti Partition, being the same as the most westerly corner of said Lot 12 of Foersters Subdivision; thence North 45 degrees 59 minutes 04 seconds East, along the northwesterly line of Lots 12 and 13 of Foersters Subdivision, being the same as the southeasterly line of Lot 4 of Yosti Partition, a distance of 1349.58 feet to a concrete monument which marks the most northerly corner of said Lot 13; thence South 36 degrees 53 minutes 01 seconds East, along the northeasterly line of said Lot 13, a distance of 151.17 feet to its intersection with a line which lies 150 feet southeasterly of and parallel to the northwesterly lines of said Lots 12 and 13 of the Foersters Subdivision; thence South 45 degrees 59 minutes 04 seconds West, along said parallel line, a distance of 1303.26 feet to the northerly right of way line of "Old St. Charles Rock Road"; thence North 54 degrees 25 minutes 19 seconds West, along said right of way line, a distance of 152.51 feet to the Point of Beginning.

The above property is shown on as parcel 4 on a survey by Stock & Associates Consulting Engineers, Inc. dated November 19, 2004, most recently revised March 9, 2005 and on file with the City of St. Louis.

TRACT IV

Lot 3 of the Boundary Adjustment Plat of Lots 1 and 3 of West Lake Acres Plat II, according to the plat thereof recorded in Plat Book 348 Page 657 of the St. Louis County Records.

The above property is shown on as parcel 6 on a survey by Stock & Associates Consulting Engineers, Inc. dated November 19, 2004, most recently revised March 9, 2005 and on file with the City of St. Louis.

TRACT V

All of Lot 5 of West Lake Acres Plat II, according to the plat thereof recorded in Plat Book 344 Page 261 of the St. Louis County Records.

The above property is shown on as parcel 7 on a survey by Stock & Associates Consulting Engineers, Inc. dated November 19, 2004, most recently revised March 9, 2005 and on file with the City of St. Louis.

TRACT VI

Lot 6 of West Lake Acres Plat II, according to the plat thereof recorded in Plat Book 344 Page 261 of the St. Louis County Records.

The above property is shown on as parcel 8 on a survey by Stock & Associates Consulting Engineers, Inc. dated November 19, 2004, most recently revised March 9, 2005 and on file with the City of St. Louis.

RECORD OF DECISION

For

Lambert-St. Louis International Airport
St. Louis, MO

September 30, 1998

The Federal Aviation Administration has approved Lambert-St. Louis International Airport's proposed airside and landside improvements, commonly known as Alternative W-1W. A Record of Decision (ROD) was signed on September 30, 1998, by FAA Central Region Administrator John E. Turner.

By October 14, 1998, official copies of the ROD may be viewed at the various locations (City Halls, Libraries, FAA and Lambert-St. Louis International Airport) identified in the September 30, 1998, press release *included at the end of this document.*

Record of Decision

Lambert-St. Louis International Airport

TABLE OF CONTENTS

TABLE OF CONTENTS

TABLE OF CONTENTS

APPENDICES

1. FAA DECISION

This Record of Decision (ROD) provides final Federal Aviation Administration (FAA) approval for the Federal actions for proposed improvements at Lambert-St. Louis International Airport (Lambert), including construction and operation of a new air carrier length runway (12W/30W). The Federal actions and associated airport development are described in detail in the Final Environmental Impact Statement, Lambert-St. Louis International Airport, dated December 1997 (FEIS). The Federal actions are considered in Section 3, Agency Actions, of this ROD. The FAA's decision is based on the information contained in the FEIS and all other applicable documents available to the FAA and considered by it, which constitute the administrative record.

This ROD is issued in accordance with the requirements of the Council on Environmental Quality (CEQ), 40 CFR 1505.2. The principal features include:

- A statement of the agency's decision;
- An identification of all the alternatives considered by the FAA in reaching its decision, with a specification of the alternative or alternatives that are considered to be environmentally preferable; and
- The means adopted (mitigation measures) to avoid or minimize environmental harm from the alternative selected.

Based on a review of the administrative record and the FEIS approved on December 19, 1997, it is the FAA’s final determination that the revised Airport Layout Plan (ALP) for proposed improvements to Lambert, including a new air carrier-length runway, specifically described in Sections 2, 4 and 5 of this ROD, and identified in the FEIS as the "FAA’s Preferred Alternative” (Alternative W-1W), is approved. This runway is designated, for planning purposes, as 12W/30W. In addition, the runway is approved as eligible for Federal financial assistance and construction.

These approvals of the ALP and eligibility for Federal funding constitute final approval. The FAA notes that the airport-project sponsor, the St. Louis Airport Authority (STLAA), has agreed to the various conditions of approval, in particular, the conditions requiring mitigation measures.

In reaching this determination, careful consideration has been given to: (a) the needs of Lambert as a part of the national air transportation system and the airport capacity/delay reduction needs through the year 2015; (b) the aviation safety and operational objectives of the project in the light of the various aeronautical factors and judgments presented and (c) the anticipated environmental impacts of the project.

The FAA has carefully considered all reasonable alternatives to the proposed action. Although the “No-Action Alternative” had fewer developmental and environmental impacts than the preferred alternative and was the “environmentally preferred alternative,” it failed to achieve the purposes and needs for this project. The other reasonable development alternative, Alternative S-1, was examined in detail by the FAA and found to provide capacity and delay reduction benefits slightly higher than Alternative W-1W, at higher costs and with greater environmental impacts. Alternative W-1W is more protective than Alternative S-1 of natural resources protected under *49 U.S.C. 47016(c),* park and historic resources protected under Section 303 of the Department of Transportation Act (DOT Section 303, also referred to as Section 4(f)) and Section 6(f) of the Land and Water Conservation Fund Act, and wetlands. For the reasons summarized in this ROD, and supported by detailed discussion in the FEIS, the FAA has determined that the agency’s preferred alternative, Alternative W-1W, is the only possible, prudent and practicable alternative.

A discussion of the leading factors considered by the FAA in reaching this decision follows.

2. BACKGROUND

Over the past decade, the FAA has worked closely with local and regional officials and with the STLAA aviation planning staff to investigate ways to accommodate the increasing passenger and operational activity demands at Lambert. As documented in Section 1.0, Introduction, of the FEIS, the present airport runway configuration, with two closely spaced parallel air carrier runways (12L/30R and 12R/30L), is currently responsible for significant airside delays, particularly during poor weather conditions. It is forecast that this configuration will be responsible for increasing such delays in the future.

The FAA has prepared an FEIS to identify the potential environmental effects associated with the construction and operation of proposed improvements to Lambert. The City of St. Louis, the owner and operator of Lambert, has completed a Master Plan Supplement (MPS) that proposes a comprehensive development program for the expansion of Lambert. The STLAA has submitted an ALP to the FAA for approval and requested from the FAA the Federal environmental approval necessary to proceed with the processing of an application for Federal funds.

AIRPORT DESCRIPTION

Lambert is located 12 miles northwest of the St. Louis central business district. The primary area served by Lambert includes nine counties and the City of St. Louis. This area is referred to as the St. Louis Metropolitan Statistical Area and encompasses approximately 5,340 square miles. Five counties and 24 percent of the service area's population is in Illinois, while four counties, the City of St. Louis, and 76 percent of the service area's population is in Missouri.

Currently, Lambert has two parallel air carrier runways: 12L/30R and 12R/30L. In addition, Lambert has two crosswind runways, Runways 6/24 and 17/35, and Runway 13/31, which is a converted taxiway that is only used for small aircraft in visual daytime conditions. Runway 13/31 will be converted back to a taxiway after the new Runway 12W/30W is operational.

Runway 12R/30L, Lambert's longest runway, is 11,018 feet long, and the parallel Runway 12L/30R is 9,003 feet long. Runways 12R/30L and 12L/30R are separated by 1,300 feet. The airport is reduced to one precision instrument approach during adverse weather conditions because of the minimal separation of the parallel runways.

LAMBERT’S ROLE

Lambert is the primary commercial air carrier airport in the region and is one of the nation's major hub airports. It has consistently been ranked among the top 20 (Airport Council International) most active airports nationally, and in 1996, it ranked 14th in terms of total passengers (enplaned and deplaned) and 8th in total aircraft operations. In 1996, Lambert was served by nine scheduled air carriers, six cargo carriers and six commuter airlines.

Lambert serves as the primary connecting hub for TransWorld Airlines (TWA). In 1996, TWA offered direct service to over 70 cities. Approximately 60 percent of the enplaning passengers at Lambert were connecting passengers.

AIRPORT MASTER PLANNING PROCESS

Lambert-St. Louis International Airport Master Plan

Between the years 1987 and 1993, the STLAA prepared a comprehensive master plan study, the “Lambert-St. Louis International Airport Master Plan” (LAMP). The study developed forecasts of aviation demand through the year 2010 and proposed an airport development plan to enable Lambert to meet future projected demand levels.

The LAMP study culminated with the identification of a preferred airport development plan called Alternative F-4. This alternative proposed to rebuild the entire airfield while the airport continued to operate. Alternative F-4 would have reconfigured and expanded the airfield by rotating the alignment of the airport’s main runway system clockwise approximately 10 degrees. This configuration involved the construction of new runways resulting in four parallel Runways (14R/32L, 14L/32R, 13R/31L, and 13L/31R) and the retention of existing crosswind Runway 6/24.

In 1993, a more detailed review of the F-4 concept was accomplished by the STLAA. This review indicated that the costs to construct the proposed F-4 plan would be significantly greater than originally anticipated. There were several problems with this Alternative’s “constructability” (e.g., ability to phase and construct the alternative while maintaining continuous 24-hour operations, ability to maintain the hub at Lambert, and ability to operate the terminal and existing runways during construction). In particular, rotation of the airfield and the staging of its development would severely affect the ability of Lambert to operate as a hub for several years. The STLAA determined that it would be prudent to re-examine the development options at Lambert.

Master Plan Supplement

In 1994, the STLAA undertook a review and update to the master planning process at Lambert. This study, called the Master Plan Supplement (previously identified as MPS), re-examined the needs of Lambert. It resulted in the recommended course of development proposed by the STLAA and considered in the FEIS.

Aviation Demand Forecasts

During the development of the MPS, the City of St. Louis developed, refined, and updated aviation activity forecasts for Lambert, which considered the development and growth trends in the region, the aviation growth trends regionally and nationally, and changes in the airline industry. Before facility requirements were determined, the STLAA submitted forecasts representing unconstrained conditions to the FAA for its review and approval. The FAA approved the forecasts representing unconstrained conditions during the development of the MPS. Subsequently, the FAA issued FAA Safety Notice N7110.157, "Wake Turbulence." The Safety Notice has the effect of reducing airport capacity due to the recategorization of certain aircraft types and a resulting increase in separation standards. Taking into consideration the recently published guidelines, the FAA recognized that the unconstrained forecasts for the No-Action Alternative might not be achievable, given the configuration of the current runways. Therefore, the forecasts for the 2015 No-Action Alternative were adjusted to represent a constrained condition.

The MPS revised forecasts indicate that in the year 2015, Lambert has the potential to accommodate approximately 632,000 aircraft operations with the selected action, as compared to 595,000 aircraft operations without the proposed improvements. The FAA's revised 2015 No-Action constrained forecast for Lambert was 532,000 operations. The forecasts used in the FEIS and the FAA's Terminal Area Forecasts (TAF) are within the same range. Although the TAF are slightly higher than the FEIS forecasts, the differences are within a range that FAA considers to be insignificant and within the range of acceptable aviation forecasting.

Facility Requirements and Alternatives Analysis

A facility requirements analysis was accomplished to identify the shortfalls of the existing airport and to identify development items that would enable Lambert to effectively solve the shortfalls and meet projected demand levels. The analysis examined major components of the airport, including runways, airspace, terminals and ground transportation. This evaluation confirmed that Lambert needed an east-west parallel runway system capable of accommodating simultaneous independent Instrument Flight Rules (IFR) approaches.

The MPS included a comprehensive re-evaluation of possible development options, including an analysis of the alternatives studied as part of the previous LAMP. It was determined that the use of a Precision Runway Monitor (PRM) would enable consideration of runway development alternatives, which were rejected in previous studies. PRM is a system comprised of a rapid update radar, an enhanced color graphic monitor, and software package which aids the air traffic controller in more accurately monitoring the position of aircraft on final approach to a runway. PRM is the primary tool that has allowed the FAA to approve simultaneous independent instrument approaches to parallel runways spaced as little as 3,000 feet apart (3,400 feet for straight-in approaches). The PRM allows sufficient runway separation to allow simultaneous independent IFR approaches during marginal visual and instrument meteorological conditions. The alternatives analysis process considered operational, financial and environmental factors. From an initial list of more than 40 development concepts, the STLAA selected the airport development alternative, designated Alternative W-1W, as its preferred alternative.

THE PROPOSED IMPROVEMENTS TO LAMBERT

The STLAA has proposed airside and landside improvements to Lambert to enable the airport to meet projected levels of activity. The City's preferred development alternative, known as W-1W, includes a new parallel runway (12W/30W), 9,000 feet long by 150 feet wide, located at the southwestern side of Lambert in the City of Bridgeton. This runway will be located parallel to and 4,100 feet from existing runway 12L/30R with a staggered threshold of approximately 12,100 feet. This runway has been proposed to improve airfield capacity during both visual meteorological conditions (VMC) and instrument meteorological conditions (IMC).

The two parallel runways at Lambert, which are 1,300 feet apart, are too close together to allow simultaneous independent approaches. With the proposed improvements, the weighted hourly capacity at Lambert will be increased. With the use of a PRM, the separation of the new runway from the existing runways will be of sufficient distance to allow the airport to accommodate simultaneous independent approaches during IMC. Lambert does not currently have this capability. This feature will allow Lambert to reduce delay times, improve adverse weather capabilities, enhance capacity, and continue to accommodate hubbing operations such as the system TWA is now using at Lambert.

Other associated actions include property acquisition, terminal expansion, roadway improvements, and relocation of several airport tenant operations. A summary of the major components of the development plan and the proposed phasing is provided in Section 5, Alternatives Analysis, of this ROD.

EIS PROCESS

On August 17, 1995**,** the FAA began the public phase of the environmental process involving STLAA site-specific development proposals, which included a new runway for Lambert, by announcing in the Federal Register (60 Fed. Reg. 42938) its intent to prepare an Environmental Impact Statement (EIS), and by requesting scoping comments. Scoping meetings were held with the general public and with Federal, state and local agencies on September 6 and 7, 1995. See FEIS Section 7.0, regarding public involvement, and FEIS Appendix J, for a summary of scoping comments.

On October 4, 1996**,** a Notice of Availability of the Draft Environmental Impact Statement (DEIS) was published in the Federal Register (61 Fed. Reg. 51939). Public comments were taken on the DEIS from the date of its release until January 17, 1997. A public hearing was held on October 28, 1996. Appendix V of the FEIS contains a summary of comments and responses on the DEIS, which were received from the public and government agencies during the hearing as well as through the mail.

The FEIS was approved by the FAA on December 19, 1997, and released to the public on December 22, 1997. The FEIS addressed areas of public concern by way of modifications to the DEIS text and specific responses to public comments.

Pursuant to 40 CFR 1506.10, the U.S. Environmental Protection Agency (EPA) published a notice of the availability of the approved FEIS in the Federal Register on January 2, 1998 (63 Fed. Reg. 75). According to CEQ regulations, the FAA was required to wait a minimum of 30 days after the notice of availability of the approved FEIS before issuing its ROD. That 30-day waiting period has passed.

Although the FAA did not solicit public comment on the FEIS, several public agencies, community groups, and citizens submitted written comments for agency consideration. The FAA has to the extent practicable considered all comments received on the FEIS. Appendices A, B, C, D, E and G of the ROD respond to substantive agency and public comments on the FEIS and any new significant issues that have arisen.

3. AGENCY ACTIONS

The Federal actions are:

1. The approval of revisions to the ALP for construction and operation of proposed Runway 12W/30W and associated improvements, listed in full in Section 3.4.3 of the FEIS;

2. The Federal environmental approval necessary to proceed with processing of an application for Federal funding for those development items qualifying under the former Airport and Airway Improvement Act of 1982, as amended and recodified at *49 U.S.C. 47101 et seq.*; and

3. The approval of associated safety actions.

The City of St. Louis may also submit an amendment to its passenger facility charge (PFC) application to the FAA in order to use such PFC revenues for eligible portions of the proposed project. Although future projects other than Runway 12W/30W are depicted on the ALP, the City of St. Louis is requesting final environmental approval only for the runway and associated projects assessed as part of Phase I through the year 2000 and Phase II (2002-2015) in the FEIS. It is recognized that other projects may require additional environmental analysis when ripe for decision at a later date and will only be conditionally approved by the FAA on the ALP at this time.

The U.S. Army Corps of Engineers (COE), a cooperating agency for the FEIS, will be responsible for permitting processes under Section 404 of the Clean Water Act and Section 10 of the Rivers and Harbors Act. In addition, the U.S. Air Force (USAF) and the U.S. Navy (Navy) will be preparing separate RODs, when appropriate, for the relocation of their facilities. The necessary approval actions required by the Federal Highway Administration (FHWA) are included in Section 8, Cooperating Agencies, of this ROD.

The necessary FAA determinations and approvals are summarized below:

a. Determination of project eligibility for Federal grant-in-aid funds (*49 U.S.C. Section 47101*, *et. seq.*) and PFC funds (*49 U.S.C. Section 40117*), for land acquisition and relocation (49 CFR Part 24), site preparation, runway, taxiway, runway safety area, and other airfield construction, terminal and related landside development, navigational and landing aids, roadway improvements and environmental mitigation.

b. Determination regarding air quality conformance of the proposed facility with applicable air quality standards under the Clean Air Act, as amended (*42 U.S.C.*

Section 7506, Section 176 (c) (1), and 40 CFR Part 93). (The FAA issued a Final General Conformity Determination and published a notice in the *St. Louis Post Dispatch* on June 29, 1998.)

c. Approvals for establishment of new instrument landing systems (ILS) and associated approach lighting systems and navigational aids, including use of a PRM, as appropriate, for the new runway, the existing runways, and the airport as a whole (*49 U.S.C. Section 44502 (a) (1)*).

d. Decisions to develop air traffic control and airspace management procedures to effect the safe and efficient movement of air traffic to and from the proposed new runway. This includes the development of a system for the routing of arriving and departing traffic and the design, establishment, and publication of standardized flight operating procedures, including instrument approach procedures and standard instrument departure procedures (*49 U.S.C. Section 40103 (b)*).

e. Determinations, through the aeronautical study process, under 14 CFR Part 77, regarding obstructions to navigable airspace (*49 U.S.C. Section 40103 (b) and 40113*).

f. Determinations under 14 CFR Part 157 as to whether the FAA objects to the airport development proposal from an airspace perspective, based upon aeronautical studies (*49 U.S.C. Section 40113 (a)*).

g. Determinations under the *49 U.S.C. Sections 47106 and 47107* pertaining to FAA funding of airport development (including approval of a revised ALP, *49 U.S.C. Section 47107 (a) (16)*), environmental approval (*42 U.S.C. Sections 4321-4347*, and *40 CFR Section 1500-1508*), and approvals under various executive orders discussed in the ROD.

h. A certification that the proposed facility is reasonably necessary for use in air commerce or for the national defense (*49 U.S.C. Section 44502 (b)*).

i. FAA review and approval of amended Airport Certification Manual (14 CFR Part 139).

j. FAA determination that there would be no undue burden (unusual circumstances) barring the sponsor from obtaining a Section 404 permit for the filling of wetlands.

k. FAA determination that there would be no undue burden (unusual circumstances) barring the sponsor from obtaining a National Pollutant Discharge Elimination System (NPDES) permit for stormwater and wastewater discharges.

4. PURPOSE AND NEED

The identification of a proposed action's purpose and need is the primary foundation for the identification of reasonable alternatives and the evaluation of the impacts of the development. In exercising its authority and in the public interest, the FAA considers assigning, maintaining and enhancing safety and security as its highest priority (*49 U.S.C. 40101(d)*). This is the FAA's first consideration in evaluating the purpose and need for any proposed airport improvements.

The *purpose* of the proposed action is to:

1. Enable Lambert to effectively and safely accommodate projected levels of aviation activity at an acceptable level of delay by:

   – Increasing airfield capacity.

   – Improving visual flight rules (VFR) capacity.

   – Allowing dual simultaneous independent IFR arrival operations.

   – Decreasing delays.

2. Enhance the National Airspace System (NAS) by:

   – Reducing delays nationwide.

   – Increasing airfield capacity.

3. Recognize the importance of the economic benefits provided by Lambert and allow the local communities and the region to continue to reap those economic benefits.

4. Facilitate the airline hub at St. Louis, which is vital to alleviating projected shortfalls in capacity at Lambert and in the NAS. This is interrelated with all of the above purposes for the proposed project.

The proposed action is *needed* because:

1. The existing airport is severely constrained and it is projected that the airport will be unable to adequately meet projected levels of demand without incurring unacceptable operational delays;

2. As an important component of the NAS, Lambert cannot be allowed to become a “bottleneck,” because it would have detrimental ripple effects throughout the airspace system; and

3. The airport serves an important function in providing economic benefits important to the airport sponsor and the region.

INCREASED AIRFIELD CAPACITY

The 9,000-foot length of Runway 12W/30W will accommodate the operation of most of the aircraft types currently operating and projected to operate at Lambert. Both ends of Runway 12W/30W will be equipped with an ILS. In addition, the PRM, which is to be installed for the existing airfield, will be used for the new runway.

The increased airfield capacity provided by Runway 12W/30W will substantially reduce the existing and projected average annual delay time per aircraft operation. These estimated decreases in delay time will result in annual savings in aircraft delay costs. Conversely, estimated aircraft taxiing distances and time will slightly increase aircraft operating costs as a result of Runway 12W/30W. Taken together, there will be an estimated net savings in aircraft delay costs and taxiing costs of close to $100 million in the year 2005 and approaching $300 million in the year 2015.

PASSENGER HUB EFFICIENCY

The continued use of Lambert as an effective major airline hub will be constrained if the airport facilities are not expanded to accommodate future demand. One key airside feature associated with other hub airports that is absent from Lambert is simultaneous independent IFR arrival capability (including marginal VFR). The lack of independent IFR arrival capability greatly impacts the ability of a hub airline in St. Louis to effectively meet projected demand. Without an improvement in IFR and marginal VFR operating capability, the reliability of services at Lambert will be increasingly burdened during the periods of the year when IFR and marginal VFR weather conditions occur (approximately 14 percent of the year). Without terminal and airfield expansion capabilities, it will be difficult for Lambert to continue as an effective hub airport. This lack of facilities and expansion capabilities will result in increased delay times, decreases in airport capacity, and increased costs to the airlines and the traveling public.

From a national perspective, it is in the interest of the FAA to maintain an airline hub at Lambert. The FAA believes that due to its central location in the U.S. and its local market, St. Louis is a natural hubbing location. St. Louis is the only place within hundreds of miles in any direction where there are both a very large air travel origination/destination market and airport capacity that can handle substantial hubbing activity. Keeping the traffic that now hubs at St. Louis flowing smoothly and efficiently is critical to the entire national aviation system.

MULTIPLE AIRPORT SYSTEMS

Shifting some of Lambert's operations to another airport to relieve existing and future forecast capacity problems has been debated and studied for several years. Recent studies have found that, even though there are nearby available facilities capable of handling commercial jet traffic, such as Scott Air Force Base/Mid-America Airport (Scott AFB/MAA), the overflow of commercial jet operations from Lambert to other airports in the region would not efficiently solve the capacity problem because most of the aviation activity is associated with airline hubbing. The lack of a sponsor for airport expansion in another political jurisdiction is a reality that the FAA is authorized to consider under CEQ regulations. Correspondence from St. Clair County, the operator of MAA (which is a joint-use facility with SCOTT AFB), indicates that St. Clair supports Lambert as the regional hub.

Use of multiple airports would complicate the hubbing issue, because an adequate level of peak-hour operations required to maintain hubbing operations at one location might not be obtainable if traffic were split between two airports. In this case, both airports would lose. In addition, a threshold of 10 to 12 million originating passengers is needed for a community to support a second commercial service airport. The St. Louis forecasts indicate that originating passengers for the St. Louis metropolitan area in the year 2015 would be approximately 8.7 million, below the threshold for a second commercial service airport.

The continued use of Lambert as a major airline hub is in question, unless expanded to accommodate future demand. St. Louis competes with other airline hubs that are being or have been expanded. Unless more operational capability is provided, Lambert's ability to compete will be limited.

ECONOMIC BENEFITS

Lambert plays an important role in supporting the economic goals of the St. Louis metropolitan region. Over the years, Lambert has evolved into one of the largest employment and income centers in the region. The proposed Runway 12W/30W project will strengthen Lambert as a major economic asset that serves as a vital link to the nation and world, as well as a significant employment and income center.

5. ALTERNATIVES ANALYSIS

In addition to the relevant environmental statutes, the FAA in its consideration of alternatives, has been mindful of its statutory charter to encourage the development of civil aeronautics and safety of air commerce in the United States (*49 U.S.C. 40104*). FAA has also considered the congressional policy declaration that airport construction and improvement projects that increase the capacity of facilities to accommodate passenger and cargo traffic be undertaken to the maximum feasible extent so that safety and efficiency increase and delays decrease (*49 U.S.C. 47101(a)(7)*).

While the FAA does not have the authority to control or direct the actions and decisions of the STLAA relative to planning for this project, it does have the authority to withhold project approval, including Federal funding and the other Federal actions discussed in this ROD. It was from this perspective that the various alternatives were considered in terms of evaluating and comparing their impacts to determine whether there was an alternative superior to that proposed by STLAA, or whether STLAA's proposal would cause impacts warranting disapproval of the Federal actions discussed in this ROD, including the withholding of Federal funds for the project.

The FAA identified numerous alternatives to the proposal (reference FEIS Section 3.2). During this exploration of alternatives, all reasonable alternatives were carefully examined, ranging from doing nothing to specific runway alignments at Lambert. After considering all reasonable alternatives, the FAA selected the construction of Runway 12W/30W and associated projects as the agency's preferred alternative in the FEIS. The FAA identified Alternative X-1, the No-Action Alternative, as the environmentally preferable alternative. Other alternatives were eliminated for a variety of reasons as discussed below.

The DEIS alternatives evaluation utilized a three-tiered evaluation process that concentrated on the purpose and need for the proposed project. The first tier evaluated whether the various alternatives met the purpose and need criteria established in Section 2.0 of the DEIS. Alternatives that satisfied these criteria were retained for evaluation under the second tier of analysis. The second tier evaluated the "constructability" (ability to phase and construct the alternative while maintaining continuous 24-hour operations, ability to maintain the hub at Lambert, and ability to operate the terminal and existing runways during construction), and the benefit/cost ratio (BCR) of the alternatives (BCR of less than "1" indicates costs outweigh economic benefits, greater than "1" indicates economic benefits outweigh costs). Alternatives that met these criteria were retained for evaluation under the third tier of analysis. The third tier evaluated multiple specific criteria relating to operational efficiency (taxi times, delay times), cost per passenger (lower costs vs. higher costs) and environmental impacts (noise, land use, social, etc.).

As part of Tier 3, the FAA analyzed the best representative alternatives from the remaining families of alternative runway alignments. The best representative selected for detailed analysis within each family was the best overall environmentally, particularly as to resources protected under special purpose environmental laws. This approach is consistent with guidance in CEQ's Forty Questions (Question 1), which provides that: "When there are potentially a very large number of alternatives, only a reasonable number of examples, covering the full spectrum of alternatives, must be analyzed and compared in the EIS. ... What constitutes a reasonable range of alternatives depends on the nature of the proposal and the facts in each case."

Alternatives that met the criteria under the third tier of analysis, were the best in their families and had the least overall environmental impact were retained for detailed analysis in subsequent sections of the DEIS. Table S.1 contains a summary of the tiered analysis used in the alternatives analysis for the DEIS (Appendix J of this ROD, FEIS Summary).

The alternatives explored in the FEIS include the following:

REASONABLE ALTERNATIVES EXAMINED AND ELIMINATED FROM DETAILED ANALYSIS

- Other modes of transportation, including surface transportation alternatives such as rail, bus and automobiles.

- Construct a new airport to replace Lambert.

- A multiple-airport system with a supplemental airport in addition to Lambert.

- Airfield alignment alternatives:
  North Airfield Alternatives: N-1, NE-1, NE-1a
  West Airfield Alternatives: W-1E, W-2
  South Airfield Alternatives: Modified S-1
  Canted Airfield Alternative: C-1

- Other on-airport alternatives:
  Bridgeton's Lambert 2020 Plan
  Hyland Plan
  Alternative runway lengths
  Existing facility with advanced navigational aids

These alternatives were rejected for the following reasons:

1. Other modes of transportation do not fulfill the main needs for improving Lambert. They do not meet local aviation needs, nor enhance the economic contribution of Lambert to the region, or strengthen Lambert's role in the NAS. Other modes, including automobiles, buses and rail, have a complementary role to air travel, not a replacement one. Further, the other modes do not provide the fast, flexible and efficient long-distance transportation needed by the public and provided by Lambert.

2. The construction of a new regional airport is not a viable solution to satisfy the projected capacity deficiency at Lambert in the foreseeable future due to time and cost requirements.

3. Although several other airports exist in the region, none--individually or collectively--can adequately accommodate the anticipated traffic from Lambert, fulfilling the need for the new runway. Multiple reasons are responsible: airline hubbing, lack of facilities at other airports, detrimental environmental impacts and airspace conflicts and constraints.

4. Although several on-airport runway alignment alternatives were considered, most were eliminated from detailed study. The FEIS examined in detail only those alternatives that provide for a similar magnitude of development and have the capability of providing simultaneous independent IFR arrival operations, which are considered critical to the operation of the airline hub. The airfield alignment alternatives and other on-airport alternatives not retained for detailed study were considered either: (a) to be infeasible and/or imprudent (in the case of alternatives not retained at Tiers 1 or 2), or (b) to present equivalent or greater impacts to parks and wetlands (in the case of alternatives not retained at Tier 3, the “best in family” comparison).

ALTERNATIVES CONSIDERED IN DETAIL

No-Action Alternative (X-1)

The No-Action Alternative would not accomplish the critical elements of the purpose and need that the selected alternative will provide. The No-Action Alternative (X-1) is depicted in Figure S.1 of the FEIS Summary (Appendix J of this ROD). Although the No-Action Alternative would be the least disruptive in terms of development impacts, it would not solve the capacity needs or delays existing at Lambert Airport, and thus would not achieve the purposes and needs for the proposed action. The No-Action Alternative would not provide capacity, delay reductions nor benefits to the community. In addition, the No-Action Alternative would not give Lambert the necessary operating flexibility provided by the selected alternative. To do nothing would, under some circumstances, actually exacerbate environmental conditions; for example, selection of the No-Action Alternative would worsen air quality as compared to the selected alternative. The environmental impacts associated with Alternative X-1 include increased air emissions and energy consumption due to added delay.

Alternative S-1

Alternative S-1 consists of the following developments, which would be initiated and/or completed by the year 2002:

- Land acquisition (approximately 1,332 acres) and associated relocation of homes and businesses.
- Construction of a new 9,000-foot parallel runway south of highway I-70. The new runway would be laterally separated by at least 5,500 feet from existing Runway 12L/30R. Although a PRM, for enhanced air traffic control of existing operations, has been installed at Lambert (projected commissioning scheduled for November 1998), Alternative S-1 would not require the use of a PRM.
- Construction of two new dual taxiway bridges across I-70.
- Construction of related taxiways, lighting, navigational aids, grading, drainage and utility relocations.
- Implementation of air traffic control procedures below 3,000 feet above ground level (AGL).
- Renovation and expansion of existing terminal facilities and associated aprons.
- Demolition of portions of the East Terminal Complex for Connector Taxiway construction.
- Relocation of airline support facilities.
- Implementation of mitigation measures and acquisition of permits.
- Improvements to I-70/Airport Terminal Interchange.

- Relocation of the Missouri Air National Guard (MoANG) and Navy/Marine Corps Reserve facilities.

- Realignment of McDonnell Boulevard, Lambert International Boulevard, and portions of the Metro Link light rail.

- Closure of numerous local roads between I-70 and what would become Lambert's new southern boundary.

Alternative S-1 also has one Phase II project that would be developed between the years 2002 and 2015:

- Construction of new landside terminal facilities, west of the existing terminal, possibly located at the current location of the MoANG and Navy/Marine Corps Reserve facilities. A portion of the terminal facilities may be located west of Runway 6/24.

The S-1 Alternative is depicted in Figure S.2 of the FEIS Summary (Appendix J of this ROD).

The S-1 concept was refined during the DEIS to ensure that the proposed parallel taxiways over I-70 would meet FAA design criteria. It was found that both pairs of taxiways would need to be shifted in order to meet FAA taxiway grade criteria of 1.5 percent. The shift in the east pair would require demolition of the East Terminal Complex and relocation of a portion of the Metro Link commuter rail system. The shift in the west pair from a perpendicular alignment to a slightly northwest diagonal alignment was also necessary to allow the taxiways to clear I-70 and meet FAA taxiway grade criteria.

Operational Considerations

Operationally, Alternative S-1 fulfills all of the first tier purpose and need review criteria, because it would allow dual simultaneous IFR arrival operations during IMC, improve VFR capacity at Lambert, help enhance the NAS, allow the passenger hub to remain at Lambert, and would be consistent with local planning and economic goals.

Of the reasonable alternatives retained for detailed evaluation, the FAA acknowledges that Alternative S-1 is superior from an operational standpoint. Alternative S-1 has a shorter stagger of runway threshold locations than Alternative W-1W. The absence of this stagger eliminates the double dependency of departures from the future center runway (existing Runway 12R/30L) with arrivals on the outboard runways (30R and 30W) in west flow conditions. Alternative S-1 would be more airfield-efficient and would reduce taxi times when compared to Alternative W-1W.

Financial Feasibility

A detailed analysis of the financial implications of each of the reasonable alternatives was prepared as part of the MPS. The results of this analysis indicate that for Alternative S-1, year 2015, the total savings in annual aircraft operating cost is calculated to be $329 million, cost per passenger is projected at $13, total construction cost is estimated to be $2.4 billion and the BCR is calculated to be 1.8. With a BCR of 1.8, the economic benefits of implementing this alternative are almost twice as great as the costs associated with its construction. However, the refined design of Alternative S-1, shifting the taxiways, would add approximately $75 to $100 million to the cost of Alternative S-1. This would bring the cost of Alternative S-1 up to approximately $2.5 billion and the per-passenger cost to over $13. The BCR would consequently be reduced to less than 1.8.

Environmental Impacts

Alternative S-1 would result in adverse environmental impacts including: the acquisition and displacement of established land uses, such as homes, schools, churches, and businesses; shifting aircraft noise exposure patterns over sensitive areas; impacting park and archaeological resources; requiring development in wetland and floodplain areas and potentially disrupting several hazardous materials sites.

Alternative S-1 would require the acquisition of approximately 4,528 households (relocating approximately 9,725 people), 210 businesses, 8 schools and 6 churches. The areas of acquisition would include the northern part of the City of St. Ann (displacing approximately 2,556 people), all of the City of Edmundson (approximately 1,107 people), two-thirds of the City of Woodson Terrace (2,640 people), the southwest part of the City of Berkeley (1,847 people), part of Bridgeton (406 people) and part of the City of St. John (1,169 people). Operations on the new south runway could increase aircraft noise levels at the University of Missouri-St. Louis campus to the southeast. Alternative S-1 would directly affect nine park and recreational areas (57 total acres), requiring replacement.

Alternative W-1W

Alternative W-1W consists of the following developments, which would be initiated and/or completed by the year 2002 (Phase I):

- Land acquisition (approximately 1,568 acres) and associated relocations of homes and businesses.

- Construction of a new runway complex parallel to and southwest of existing runways 12L/30R and 12R/30L. Runway 12W/30W would be 9,000 feet in length and 150 feet in width and would be capable of handling air carrier jet aircraft. The parallel runway would be laterally separated by 4,100 feet from existing Runway 12L/30R and would be south and west of existing Runway 6/24. A PRM, for enhanced air traffic control of existing operations, has been installed at Lambert (projected commissioning scheduled for November 1998). Alternative W-1W would require the use of a PRM.

- Construction of related taxiways, lighting, navigational aids, grading, drainage, and utility relocations.

- Implementation of air traffic control procedures below 3,000 feet AGL.

- Renovation and expansion of existing terminal facilities and associated aprons.

- Relocation of airline support facilities.

- Relocation of the MoANG and Navy/Marine Corps Reserve facilities.

- Realignment of Lindbergh Boulevard and construction of a roadway tunnel for those portions of Lindbergh Boulevard impacted by the construction of the new runway and the optional future extension of existing Runway 12R/30L.

- Realignment or relocation of roadways, including Natural Bridge Road, Bonfils Road, Fee Fee Road, Cypress Road, Gist Road, Lambert International Boulevard, Missouri Bottom Road and McDonnell Boulevard.

- Improvements to the I-70/Airport Terminal Interchange.

- Implementation of mitigation measures and acquisition of permits.

Alternative W-1W, Phase II projects that would be developed between the years 2002 and 2015 include the following:

- Construction of new landside terminal facilities (up to approximately 110 gates), west of the existing terminal, possibly located at the current location of the MoANG and Navy/Marine Corps Reserve facilities. A portion of the terminal facilities may be located west of Runway 6/24.

Phase III projects are beyond the 20-year planning period and are not specifically programmed for implementation. Possible projects that may be developed in Phase III, after the year 2015, include:

- Construction of a 2,500-foot extension to the northwest end of existing Runway 12R/30L.
- Additional construction of new west landside terminal facilities.
- Construction of a new airport access roadway from I-270 to the new west landside terminal complex.
- Demolition of the existing terminal complex and construction of new east airfield terminal concourses.

Alternative W-1W is depicted in Figure S.3 of the FEIS Summary (Appendix J of this ROD).

Operational Considerations

Operationally, Alternative W-1W fulfills all of the first tier purpose and need review criteria in the FEIS, because it would allow dual simultaneous IFR arrival operations, improve VFR capacity at Lambert, help enhance the NAS, allow the passenger hub to remain at Lambert and would be consistent with local planning and economic goals.

Financial Feasibility

The results of the MPS financial feasibility analysis indicate that for Alternative W-1W, in the year 2015, the total savings in annual aircraft operating cost is calculated to be $297 million, cost per passenger is projected at $10.50, total construction cost is estimated to be $2.2 billion, and the BCR is calculated to be 2.2. The BCR of 2.2 indicates that the economic benefits of implementing this alternative are more than twice as great as the costs associated with its construction. An independent benefit/cost analysis (BCA), conducted by FAA’s Systems and Policy Analysis Division (APO-200), determined that Alternative W-1W had a BCR of 2.6.

Environmental Impacts

The adverse environmental impacts that would result from Alternative W-1W include the acquisition and displacement of established land uses including homes, schools, churches and businesses; shifting aircraft noise exposure patterns over sensitive areas; impacting park, historic and archaeological resources; requiring development in wetland and floodplain areas and potential disruption of several hazardous materials sites.

Alternative W-1W would require the acquisition of approximately 2,324 households (relocating approximately 5,680 people), 75 businesses, 6 schools, 6 churches and one nursing home for airfield development and surface transportation improvements. The areas of acquisition would be in the City of Bridgeton (displacing approximately 5,404 people), and the City of St. Ann (displacing 276 people). Alternative W-1W would directly affect four park and recreational areas (26 total acres), requiring replacement. The 12W end of the proposed runway would also be located within 10,000 feet of an existing active landfill and would not be consistent with FAA's current runway siting guidelines without mitigation.

THE FAA'S SELECTED ALTERNATIVE (ALTERNATIVE W-1W)

The FAA finds that the selected alternative is preferred principally because it enhances capacity and reduces delay for Lambert and the total NAS. The FAA in this ROD approves the preferred alternative.

Alternative W-1W was selected rather than Alternative S-1 because it meets purpose and need and is environmentally superior to S-1. Alternative W-1W has fewer impacts on people to be relocated, and less severe impacts on resources protected under special purpose laws (e.g., parks, wetlands).

The FAA has made its required special purpose law determinations that there is no possible, prudent and practicable alternative to Alternative W-1W, based upon the following information (see also Appendix J of this ROD, Table S.1A, page S-9):

- Both development alternatives would have unavoidable impacts on resources protected under Section 303 of the Department of Transportation Act and Section 6(f) of the Land and Water Conservation Fund Act. There are no possible or prudent alternatives to the use of these resources. Alternative W-1W will use approximately half the park and recreational resources and acres that would be required for Alternative S-1.

- Both Alternatives W-1W and S-1 would have unavoidable wetland impacts due to the proximity of wetlands to the airport. Consequently, there are no practicable alternatives to filling of wetlands. Alternative W-1W has the least amount (acreage) of wetland impacts.

- There is no practicable alternative to the floodplain impacts of Alternative W-1W. Mitigation measures to minimize the floodplain impacts can be accomplished. The floodplain encroachment will not be considered significant.

The FAA has also considered that the preferred alternative proposed in the FEIS has withstood extensive public scrutiny throughout the public involvement process. The FAA recognizes that some segments of the community strongly oppose Alternative W-1W. Lambert has been conducting ongoing negotiations with the neighboring cities to resolve issues related to the impacts and mitigation proposed in the FEIS.

Because the FAA determined that Alternative W-1W is the least impacting alternative, overall, it selected Alternative W-1W as the preferred alternative. A comparative table summarizing Alternatives X-1, S-1 and W-1W is contained in Table S.2 of the FEIS Summary (Appendix J of this ROD).

However, a few key comparisons of impacts to the communities are:

	Alternative S-1	**Alternative W-1W**
Number of people to be relocated	9,725	5,680
Number of households to be relocated	4,528	2,324
Number of residential parcels to be acquired	2,902	1,937
Number of businesses to be relocated	210	75
Number of schools to be acquired	8	6
Number of churches to be acquired	6	6
Number of nursing homes to be acquired	0	1
Number of parks directly affected	9	4
Acreage of parks directly affected	57	26
Acreage of parks affected	10.8	9.7
Acreage of floodplains affected	51	57

Accordingly, having considered: (1) the policies set forth at *49 U.S.C. Sections 40104 and 47101*, (2) the ability of the alternatives to meet the purpose and need, and (3) the administrative record which concerns these development projects, the FAA hereby selects the W-1W development recommended in the FEIS.

The FAA's approval of these expansion and improvement projects in this ROD signifies that these projects meet FAA standards for agency approval discussed in Section 3 of this ROD. It does not, however, signify an FAA commitment to provide a specific level of financial support for these projects, which must await future decisions under the criteria prescribed by *49 U.S.C. 47115(d) and 49 U.S.C. 40117*.

6. MAJOR IMPACTS AND MITIGATION

In accordance with 40 CFR 1505.3, the FAA will take appropriate steps, through Federal funding grant assurances and conditions, PFC "use" approvals, airport layout plan approvals and contract plans and specifications to ensure that the following mitigation actions are implemented during project development. The FAA will monitor the implementation of these mitigation actions as necessary. The approvals contained in this ROD are specifically conditioned upon full implementation of these mitigation measures. These mitigation actions will be made the subject of a special condition included in future airport grants to the STLAA.

A detailed environmental analysis of the potential environmental impacts resulting from the construction and operation of the selected alternative was accomplished as part of the FEIS. Two study periods were examined, 2002 and 2015. The year 2002 is projected to be the first year that the new runway and associated development will be operational. The year 2015 is the outside planning period of the MPS and when most of the ALP's recommendations will be operational. Twenty-two different environmental impact categories were examined.

SUPPLEMENTAL TECHNICAL REPORTS

Supplemental technical reports have been prepared, published and distributed separately from the FEIS. These reports address the potential direct and indirect effects to resources protected under special Federal laws. The following lists each of these reports and the relevant Federal law:

- Section 303 and 6(f) Evaluation - *49 U.S.C. Sections 303* [Recodified from and commonly known as Section 4(f) of the Department of Transportation Act 1966]; and the Land and Water Conservation Fund Act;
- Section 106 Documentation associated with the Final Environmental Impact Statement - Section 106 of the National Historic Preservation Act of 1966; and
- Draft and Final General Conformity Determinations - Federal Clean Air Act and State of Missouri requirements.

IMPACTS AND MITIGATION

This section of the ROD includes a summary of the mitigation measures, discussed more fully in the FEIS, Section 6.3, for each environmental impact category.

The primary responsibility for implementation of the mitigation program rests with the STLAA. The FAA will have oversight responsibility and will condition grant agreements and/or PFC “use” approvals upon completion of the mitigation program by the City of St. Louis. Mitigation measures for those impact categories where mitigation measures are necessary to avoid or minimize significant environmental impacts, as well as identified or adopted monitoring and enforcement programs, are summarized below. The FAA finds that all practical means to avoid or minimize environmental harm have been adopted, through appropriate mitigation planning.

Noise and Compatible Land Use Impacts and Mitigation

Because of the effects of the introduction of quieter Stage 3 aircraft, noise levels are projected to decrease in future years. For this reason, even with the selected alternative, there will be a significant reduction in land area and population impacted by noise in the years 2002 and 2015 when compared to current conditions. For future year comparisons, Alternative W-1W will impact fewer people within the Day-Night Equivalent Sound Level (DNL) 65 dB contour than Alternative S-1, but more than Alternative X-1, in both 2002 and 2015. A review of the proposed roadway improvements and realignments for Alternative W-1W indicates that traffic noise impacts would be minimal. Noise impacts resulting from the proposed airport development will be mitigated through measures identified in Section 6.3.1 of the FEIS.

The noise mitigation program for the selected alternative consists of operational and land use control measures. The program was developed in a manner which is consistent with the previous and ongoing noise mitigation and abatement programs implemented by the STLAA. The main objective of this program is to mitigate noise impacts associated with the selected alternative’s aircraft operations by recommending appropriate measures consistent with the approved 1997 Part 150 Noise Compatibility Program Update. Although the mitigation program outlined below is designed to be consistent with the ongoing Lambert Part 150 process, the mitigation measures described below are associated with the specific impacts of Lambert’s proposed expansion. It is the obligation of the City of St. Louis to implement the mitigation for the expansion.

The land use mitigation program is based on the potential noise impacts identified through the comparison of the year 2002 No-Action and selected alternative noise contours. The year 2002 selected alternative noise contours were chosen for the mitigation program, because they are larger in size than the year 2015 noise contours. The mitigation program consists of:

Land Acquisition for Mitigation of Noise Impacts Due to Alternative W-1W

The STLAA will acquire all residential and residentially zoned areas located within the 70 DNL noise contour for the year 2002, as well as all mobile home parks within the 65 DNL noise contour. It is anticipated that any of these land uses not acquired through the STLAA's ongoing Part 150 acquisition program for the existing airport will be acquired through the acquisition program for the construction of Alternative W-1W.

Voluntary Noise Mitigation Program

The STLAA will offer a voluntary noise mitigation program to eligible homeowners (located in the 65 DNL noise contour for the year 2002). Each eligible homeowner within this area will be offered the choice of one of three options: sales assistance, sound insulation or easement purchase. In exchange for one of these three options, the airport will receive an avigation easement.

Noise Mitigation Assurance

This element of the noise mitigation program enables STLAA to concentrate the voluntary and land acquisition measures on the areas actually experiencing the annual average DNL noise levels predicted in the FEIS, Section 5.1, after the opening of the new west runway. Using a permanent noise monitoring system, STLAA will monitor and analyze the noise levels resulting from actual, normal operation of the new west runway. If that actual experience diverges from the contours projected, an adjustment will be made to the boundaries of the areas eligible for the mitigation programs. The STLAA will reassess the average-annual noise characteristics of Lambert approximately 18 months after the new runway opens.

Accommodate New Runway in the Permanent Noise Management System

The STLAA is in the process of installing a new permanent noise management (monitoring) system, which will assist in the management of the noise program and monitor the effectiveness of operational noise mitigation measures. The STLAA will add or relocate noise monitoring stations to monitor operations on Runway 12W/30W and associated flight tracks. Appropriate sites will be selected to provide data for monitoring of Runway 12W/30W to assist STLAA in re-assessing the boundaries of the mitigation programs.

Noise Abatement Departure Procedures

This voluntary procedure, already in use for existing runways, involves the reduction of thrust for departing air-carrier aircraft to reduce noise levels in sensitive areas. Once

Runway 12W/30W is commissioned (or operational), commercial jet airline departures will be requested to use the voluntary "Distant Noise Abatement Departure Procedure," as defined in FAA Advisory Circular 91-53A.

Social Impacts and Mitigation; Environmental Justice Impacts

Residential and business displacements are the principal social impacts associated with the selected alternative. The selected alternative will result in the acquisition and relocation of numerous residences and businesses. Other direct social impacts involve the relocation of community facilities such as schools and churches. A large degree of community disruption will be experienced in the City of Bridgeton due to the selected alternative. All acquisitions and relocations will comply with the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970. STLAA will develop a detailed plan for the relocation of all properties including residential, commercial, public, and nonprofit organizations. The program will be consistent with FAA Advisory Circular 150/5100-17, Land Acquisition and Relocation Assistance for Airport Improvement Program Assisted Projects.

Surface transportation patterns will be altered and temporarily disrupted with the selected alternative. Measures to mitigate surface transportation impacts are discussed in Section 6.3.13 of the FEIS and later in this Section of the ROD. The acquisition and relocation of residential and commercial properties will be required to accommodate the proposed surface transportation improvements associated with the selected alternative.

Acquisition of property will result in the loss of assessed valuation and, therefore, tax revenue to local taxing units through the year 2002. However, this loss should be offset between the years 2002 and 2015 by the development of commercial, industrial, office, and mixed land uses in or adjacent to the previously acquired areas. For that reason and because per capita tax revenues will likewise be maintained, formal mitigation actions for tax base impacts are not required. Implementation of the selected alternative will not result in disproportionately adverse impacts on minority or low-income populations. For example, the racial characteristics within the acquisition areas are approximately 95 percent white; 3 percent black; and less than 2 percent other races. Low-income persons make up approximately 1.5 percent of the total number of impacted persons. The measures to mitigate social impacts, discussed in Section 6.3.2 of the FEIS, are summarized below.

Acquisition and Relocation Program

This program will minimize the impacts of property acquisition and relocation on displaced residents, businesses and churches by providing services to educate, inform and respond to the needs of those affected, both individually and collectively. This program will also provide for the acquisition and relocation of public and private schools and other public facilities included within the development area for the selected alternative. This program will include measures to minimize the adverse effects associated with the displacement of these facilities.

Acquisitions and relocations will proceed in keeping with the following mitigation objectives:

- Comply with the Uniform Relocation Assistance and Real Property Acquisition Policies Act.

- Comply with the Missouri Airport Relocation Act, R.S. Mo. Section 305.600, *et seq.*

- Develop a detailed Relocation Plan that addresses the specific needs of relocated residents, such as access to employment, access to social services, residency in existing school districts, and access to commercial facilities.

- Educate residents about the Uniform Act and the STLAA's Relocation Plan by holding community meetings prior to the actual acquisition process.

- Work to maintain neighborhood relationships by providing comparable housing areas that can accommodate multiple households from acquisition areas.

- Coordinate with the St. Louis County Housing Authority, the Missouri Housing Development Corporation and the U.S. Department of Housing and Urban Development to provide access to housing assistance programs that meet the identified needs of displaced households.

- Provide information to the real estate industry on the project displacements and acquisition/relocation process. Communicate with real estate agents through the St. Louis Association of Realtors to facilitate access to the real estate market for needed replacement properties.

- Work closely with churches through the relocation process to determine facility needs based on net impact to church membership and to maintain church communities.

- Work with school districts and private schools to determine facility needs based on the net student enrollment impacts.

- Relocate acquired schools in existing enrollment areas to cause the least disruption to students.

Acquisitions related to construction will be completed before the opening of the new runway, estimated to be the year 2002. For those acquisitions not necessary for construction but for noise mitigation, the airport shall have made an offer for acquisition prior to the opening of the new runway, estimated to be the year 2002.

Induced Socioeconomic Impacts

Between 1998 and 2002, economic impacts of the airport expansion project and surface transportation improvements will be related primarily to construction employment, loss of market area population for certain retail developments, and the acquisition of commercial properties. The selected alternative will generate significantly greater construction employment than the No-Action Alternative. However, considering the long-term impacts of the airport, these short-term construction employment increases will not be significant. Loss of market area population will create isolated impacts for several retail establishments along Natural Bridge Road and Pear Tree Lane with the acquisition and relocation of commercial property. These localized impacts will not be significant when assessed from a regional perspective or for the local economy but could be significant to individual businesses, especially those businesses that depend on neighborhood patronage. Impacts to the local economy and the tax base will be short term, as anticipated induced growth and development resulting from airport expansion will replace initial tax base losses.

Since no adverse impacts are anticipated as a result of induced socioeconomic impacts, mitigation is not required.

Air Quality Impacts and Mitigation

Lambert is located in an area designated as moderate non-attainment for ozone and maintenance for carbon monoxide (CO). Based on recent monitoring data, the City of St. Louis may be redesignated by EPA as serious non-attainment for ozone. Air emissions from aircraft, motor vehicles, ground support equipment and adjacent roadway improvements associated with Lambert are expected to increase somewhat in the future as enplanements and aircraft operations increase. However, comparison of the Build and No-Build Alternative in 2002 shows that emissions resulting from the selected alternative are predicted to be lower, in nearly all cases, than emissions from the No-Build Alternative. Project-related emissions, including construction, do not exceed *de minimis* levels in 2002 for any pollutant (including nitrogen oxides, CO and volatile organic compounds (VOCs)). In spite of the increased airport capacity, emissions reductions result from decreased aircraft delay and queuing times attributable to the proposed improvements to Lambert. The only exception to this is the predicted increase in NO_X emissions over the No-Build condition some time between the years 2002 and 2015. However, this long-range (2015) estimate is beyond SIP forecasts and potentially imprecise due to likely changes in the future aircraft fleet and fuel combustion technology. These long-range estimates are subject to change, should only be used for planning or information purposes and are not appropriate for conformity determination. Notwithstanding the above, total emissions associated with Lambert are not expected to result in any violation of the National Ambient Air Quality Program (NAAQS), nor interfere with the goals of the State Implementation Plan (SIP).

Lambert-related emissions for aircraft and fueling are accounted for in the SIP through the year 2005. The action does not cause or contribute to a violation of the NAAQS. The project-related emissions are not regionally significant. Based on these findings, the FAA determined, in its Final General Conformity Determination, that the planned improvements to Lambert conform to the goals of the SIP and meet the requirements of the General Conformity Rule and the Clean Air Act.

Both EPA and MDNR reviewed the Draft General Conformity Determination developed for this project and determined that all of the relevant issues were addressed (see FEIS Appendix A, EPA letter dated November 7, 1997, and MDNR letter dated November 20, 1997). On June 29, 1998, the FAA published in the *St. Louis Post Dispatch* notice of its Final General Conformity Determination. Copies of the Final General Conformity Determination were provided to EPA and MDNR. In accordance with the Clean Air Act, and EPA General Conformity Regulations, the FAA has demonstrated that the selected alternative will conform with the Missouri SIP for achieving and maintaining the NAAQS for ozone and carbon monoxide, respectively.

As noted in this ROD, Section 11.C, after consultation with the Missouri Department of Natural Resources (MDNR) (the Governor's designated agency for air quality), the Governor of Missouri certified that there is a reasonable assurance that the project will meet all applicable air quality standards in accordance with Section 509(b)(7) of the Airport and Airway Improvement Act, recodified under *49 U.S.C. 47106(c)* (letter dated August 11, 1998, in Appendix I).

Further Studies and Ongoing and Planned Activities to Minimize Air Pollution

The FAA and STLAA have agreed to explore EPA's request to establish additional air quality monitors in the airport area. Also, the MPS identified certain terminal area improvement concepts that included roadway, parking structure, transit and terminal structure developments. These improvements have the potential to influence air quality for workers, passengers and visitors. However, the MPS did not provide design-specific details to enable the meaningful analysis of the carbon monoxide impacts of future terminal facilities. The FAA and STLAA have agreed that when terminal design progresses sufficiently, the STLAA will conduct a carbon monoxide hot-spot analysis for terminal expansion to ensure that the terminal structure is designed efficiently from an air-quality standpoint. The results of the terminal carbon monoxide hot-spot analysis will be submitted to EPA and MDNR.

While specific measures to mitigate for air-quality impacts were not required for the preferred alternative, some air-pollutant minimization efforts were considered reasonable and proposed by STLAA. Ongoing or planned STLAA air-quality minimization measures, contained in Section 6.3.3 of the FEIS, are summarized below:

- **Continued Membership in the St. Louis Regional Clean Cities Program:** The City of St. Louis, the owner and operator of Lambert, is a participating member of the St. Louis Regional Clean Cities Program, which is a partnership of public- and private-sector entities, who encourage voluntary emissions reductions through awareness, education and demonstration.

- **Conversion to Alternative, Cleaner Burning Fuels:** Lambert is using alternative, cleaner burning fuels in its maintenance vehicles. This program involves the retrofit or procurement of airport service vehicles capable of burning alternative fuel types, which emit fewer pollutants. An alternative fuel station will supply fuel for airport service vehicles. Construction of this facility is scheduled for 1998.

- **Use of Low Volatile Organic Compound (VOC) Traffic Coatings:** To limit both VOC and hazardous air pollution emissions, STLAA has switched to the use of coating materials for the airfield and roadway improvements, which emit extremely low levels of VOCs. These materials include paints and asphalt-seal coating.

- **Continued Compliance with the Stationary Source Operating Permit and Air Emission Source Survey:** STLAA has voluntarily chosen to limit its annual emissions below 100 tons per year for hazardous air pollutants. Lambert is placing a cap on the amount of fuel consumed at the East and West Power Plants.

Water Quality Impacts and Mitigation

Many of the routine operations that will occur at Lambert as a result of the selected alternative will affect the water quality of Coldwater Creek. Stormwater runoff from runways, taxiways, apron areas, storage areas, gates and surface transportation improvements has the potential to be contaminated. These areas may contain pollutants such as oil, grease, sediments and deicing agents that may require detention and/or treatment. In addition, effluent from oil/water separators or waste reduction activities on the airport may also contribute to degradation of water quality. As runoff from the above activities is subject to the requirements of the NPDES permit process, all future stormwater discharges will be required to comply with the permit-established pollutant limits.

As noted in Section 11.C of this ROD, after consultation with the MDNR (the Governor's designated agency for water quality), the Governor of Missouri certified that there is a reasonable assurance that the project will meet all applicable water quality standards in accordance with Section 509(b)(7) of the Airport and Airway Improvement Act, recodified under *49 U.S.C. 47106(c)* (letter dated August 11, 1998, in Appendix I).

The proposed airport improvements will result in an increase in potable water demand and wastewater generation. However, with the acquisition of additional land for airport development and noise compatibility, overall or net airport area water demand and wastewater generation will be less than the existing airport area demand. Proposed water quality mitigation measures are described in detail in Section 6.3.4 of the FEIS and summarized below:

- **Implement Glycol Deicing Master Plan System:** Airlines operating at Lambert currently use glycol fluids for the deicing of aircraft. This fluid has the potential to pass through the airport's drainage system into local surface waters. The airport is currently in the process of implementing a Glycol Deicing Master Plan, which centralizes the collection of deicing fluids for recycling and treatment. It is anticipated that this system will handle 90 percent of the storm events encountered during the deicing season. In addition, a central deicing facility for narrow body aircraft will be used when applicable for westbound departures from existing Runways 30R and 30L.

- **Implement Stormwater Management Options:** Lambert's NPDES permit regulates the discharge of stormwater to Coldwater Creek by imposing effluent limitation, monitoring and reporting obligations. The airport has undertaken voluntary management options to reduce pollutants entering the stormwater system. These include the use of potassium acetate and heated sand for runway/taxiway deicing, the use of remote aircraft deicing facilities and diversion and treatment of runoff containing deicing fluid to wastewater treatment plants. The STLAA will implement similar management options for the new runway and taxiways.

- **Create Stormwater Detention Areas For Attenuation of Stormwater Runoff:** Runoff from new impervious areas (associated with buildings, parking, apron, runway and roadway areas) will be directed to stormwater detention areas for peak discharge attenuation. These detention areas may consist of grassed swales, dry detention areas or underground vaults, which will allow stormwater to be detained prior to discharging to Coldwater, Cowmire or Maline Creeks.

- **Increase Airport Potable Water Storage and Pressure Capacity:** Potable water storage tank and booster pump capacity will be evaluated to ensure that adequate potable water and fire-protection supply and pressure requirements are met.

- **Review Wastewater Discharge Capacity:** The airport will be required to consult with the Metropolitan Sewer District (MSD) on future wastewater discharges to determine whether methods for increasing wastewater discharge capacity are needed.

- **Close Wastewater Lines in Acquisition Areas:** Existing wastewater lines will be removed or plugged prior to discharging to the MSD wastewater main lines. Otherwise, inflow of stormwater could occur through broken pipe joints and contribute to additional flow to the wastewater treatment plant. Closing abandoned lines will help offset future wastewater contributions from the airport expansion by reducing infiltration flows to the wastewater treatment plant.

With regard to normal airport operations, the airport sponsor, through its grant assurances with the FAA, commits to suitably operating and maintaining the airport and all facilities in a safe and serviceable condition and complying with all applicable Federal laws, regulations, executive orders and other mandatory requirements related to water quality.

Section 303 and Section 6(f) Impacts and Mitigation

The selected alternative will directly affect four park and recreation area Section 303 sites. Three of the sites adversely affected by the selected alternative are also protected under Section 6(f). The selected alternative, including the associated surface transportation improvements, also has the potential to directly and indirectly affect several historic and archaeological sites protected under Section 106 of the National Historic Preservation Act. These sites will be mitigated through a Section 106 Memorandum of Agreement (MOA) (Appendix H of this ROD). The project will also have indirect adverse impacts upon Section 303 and 6(f) sites. The selected alternative will not result in any incompatible park areas due to aircraft noise. In terms of avoidance alternatives, review of the tiered alternatives evaluation prepared in Section 3.0, Alternatives, of the FEIS, indicates that there are no prudent and feasible alternatives to the use of the Section 303 and 6(f) sites.

The FAA has coordinated with the public and agencies having jurisdiction over the affected sites to determine site significance and to develop mitigation measures necessary to meet Section 303 and 6(f) requirements. Generally, the entity responsible for conversion of the Section 6(f) parkland to other use is the local government entity where the Section 6(f) facilities are located, in this case, the City of Bridgeton. By letter dated January 16, 1997, the City of Bridgeton, through its counsel, has advised that it does not intend to initiate the 6(f) conversion process. A coordination meeting with the City of Bridgeton was held on April 18, 1997, with the mayor and key staff members to discuss Draft EIS comments relative to Section 303/6(f) issues, and to solicit input from the City of Bridgeton regarding future plans and goals for their parks and recreation program. Items listed in the City of Bridgeton's comprehensive plan were discussed regarding candidate mitigation options. The City of Bridgeton has stated that it will not initiate the Section 6(f) conversions for Lambert.

Since the FAA is issuing this ROD that approves the Federal actions needed to implement the selected alternative, the City of St. Louis and the STLAA will initiate condemnation proceedings and take possession of the parklands. The City of St. Louis and STLAA will then be responsible for the conversion of the 6(f) property as the owner of the parkland and local project sponsor. MDNR will be the authorized agency to document the adequacy of the replacement lands (see FEIS Appendix A, Department of Interior (DOI) letter commenting on FEIS.)

Measures to minimize harm to Section 303 and 6(f) resources are summarized in Section 6.3.5 of the FEIS. The Section 303 and 6(f) Evaluation, published separately, provides detailed information about the effects of the proposed improvements on Section 303 and 6(f) resources and describes the mitigation plans developed. The STLAA will provide mitigation that fulfills both the Section 303 and Section 6(f) requirements. Conceptual mitigation plans have been developed to minimize harm to the affected resources. The mitigation measures proposed in Section 6.3.5 of the FEIS are summarized below.

Develop and Replace Existing Parks and Associated Facilities

The selected alternative will directly affect three Section 6(f) properties, consisting of a portion of Oak Valley Park (approximately 5 acres), all of Freebourn Park (approximately 14 acres), and Cardinal Park (approximately 4 acres). The selected alternative will also affect one Section 303 resource, Bridgeton Memorial Park, which is approximately 3 acres in size.

Candidate replacement areas have been identified and are under consideration as mitigation for both Section 303 and Section 6(f) direct effects at Freebourn, Oak Valley and Cardinal parks. Definitive locations will be determined during final design of the project. Playgrounds, ballfields, ball courts and fitness and nature trails are some of the potential recreational opportunities that could be provided at each new site. Potential mitigation areas exceed an acre-for-acre replacement ratio to provide the opportunity for maximum flexibility in the actual types and locations of facilities. Because the STLAA has committed to exceeding an acre-for-acre replacement ratio as well as meeting fair-market value requirements, the proposed mitigation exceeds the minimum mitigation requirements and provides significant improvement to the recreational resources in the affected area.

The selected alternative will result in direct impacts to one Section 303 resource (Bridgeton Memorial Park), which is not a Section 6(f) resource. STLAA proposes to provide separate mitigation for the direct effects to this site. Candidate replacement property for this Section 303 resource, which is approximately 3 acres in size, would be located near other cemetery property close to the City of Bridgeton. In addition, the construction of a new neighborhood park in south Bridgeton, to supplement those facilities already in place, is also under consideration. This activity will commence when the Property Acquisition Program is implemented.

Expand and Enhance Existing Parks and Recreational Areas

Indirect effects associated with the selected alternative have been identified at four sites: O’Connor Park, Berry Hill Golf Course, Oak Valley Park and Carrollton Buffer Zone. As mitigation for these effects, enhanced vehicular access to these sites is under study. In addition, a new bicycle trail is being considered to link the City of Bridgeton’s recreation resources to the regional bicycle network. This link to the regional bicycle network would occur via the Missouri Highway 370 bridge leading to St. Charles and would directly connect with the Katy Trail. A bicycle facility is already provided on the bridge. Potential trailheads could be located at the Bridgeton Municipal Athletic Complex and the (proposed) expanded O’Connor Park/Carrollton Buffer Zone Park Complex. The proposed new bicycle trail would increase and replace lost patronage, enhance the area’s existing bicycling opportunities, provide a logical and accessible origin/destination point for trail users and be consistent with regional bicycle plans.

In addition to the proposed recreational bicycle trail, local roadway improvements associated with the selected alternative would provide the opportunity to integrate paved, striped bicycle lanes as a part of these roadway improvements. New bicycle lanes would enhance existing multi-modal transportation options, including linking community and neighborhood parks within the City of Bridgeton, as well as ultimately providing access to the regional trail network. Consultation with local and regional planning agencies has indicated that such improvements are consistent with long-range multi-modal plans for the area. The STLAA will assist in funding as appropriate. This activity will be scheduled concurrent with airport expansion.

Reasonably Equivalent Replacement Of Converted DOI Section 6(f) Lands

Mitigation for Section 6(f) impacts will consist of replacement of the converted Section 6(f) lands with land of equal or greater value and usefulness. At the time of conversion, appraisals will be conducted in accordance with the Uniform Appraisal Standards for Federal Land Acquisition (Interagency Land Acquisition Conference, 1992) to assure that fair market values of the replacement facilities will be at least equal to that of any converted Section 6(f) sites. This activity will commence when the Property Acquisition Program is implemented.

Historic, Architectural, and Archaeological Impacts and Mitigation

An evaluation of the potential impacts to historic and archaeological resources was accomplished in accordance with the requirements of Section 106 of the National Historic Preservation Act of 1966, as amended. The FAA has determined that the selected alternative will have an adverse effect on historic resources and may have an effect on archaeological resources eligible for listing in the National Register. The State Historic Preservation Officer (SHPO) has concurred in this determination.

The FEIS states that in the event artifacts are discovered during construction activities, construction in the area will be halted immediately in order to record the finding, determine its level of significance, and develop appropriate mitigation measures.

An MOA has been prepared stipulating measures to be implemented to avoid, reduce or mitigate the adverse effects from this project on historic properties. The Missouri SHPO, the Advisory Council on Historic Preservation (Advisory Council), the STLAA, and the City of Bridgeton have been consulted on the MOA and provided comments on the agreement document throughout its development (see FEIS Appendix N-1, November 18, 1997, letter from MDNR, and November 14, 1997, letter from City of Bridgeton). The FAA solicited final comments on the MOA from the consulting parties, including the City of Bridgeton.

The MOA, in compliance with Section 106 of the National Historic Preservation Act, has been signed by the FAA, STLAA and MDNR. The City of Bridgeton did not concur with the MOA and chose not to sign the agreement. The agreement was executed by the Council on May 29, 1998. As part of the FAA's comprehensive efforts to involve all appropriate commenters, the FAA will continue to work with the appropriate agencies. In reaching its conclusions relative to the National Historic Preservation Act, the FAA's findings are supported by the FEIS, and the Department of Transportation Section 303/Section 6(f) Evaluation. Execution of the MOA satisfies the FAA's Section 106 responsibilities for all actions associated with the selected alternative. The stipulations of the MOA are discussed in Section 6.3.6 of the FEIS. A final copy of the entire MOA is included in Appendix H of this ROD.

Memorandum of Agreement

Specifically, the stipulations within the MOA, summarized below, ensure that:

- The FAA will consult with the SHPO and the Council to seek ways to reduce or mitigate the adverse effects on the five (5) above ground historic properties within the undertaking's APE. These properties include the Bridgeton Inn, the Airport News Building, the Emmanuel Blum House, the Blum Store, and the De Hatre House.

- The FAA will prepare a preservation management plan, in consultation with the SHPO, that ensures the long-term protection of archaeological resources within the APE of the selected alternative which the FAA and the SHPO agree are considered eligible for listing on the National Register of Historic Places and that can be preserved in place.

- Those sites that the FAA and the SHPO agree are considered eligible for listing in the National Register of Historic Places and that cannot be preserved in place shall be treated in accordance with a data recovery plan.

- As the Village à Robert Cemetery (which is encompassed by the current Bridgeton Memorial Park Cemetery) cannot be preserved in place, it shall be treated in accordance with a data recovery plan.

The MOA also states that all human remains and funerary objects excavated during the data recovery will be reburied in a location where their subsequent disturbance is unlikely and in a manner as similar as possible to the manner in which they were originally interred. The location and method of reburial, and the memorialization and commemoration of the reburial site(s), will be made in consultation with descendants of individuals that were buried within the cemetery.

Biotic Communities Impacts

The selected alternative will impact upland and wetland communities. Although the project will reduce existing vegetation and small, fragmented areas of wildlife habitat, none of the affected areas are characterized by unique vegetative patterns. Development will impact biotic communities within the Cowmire Creek watershed, in addition to those of the Coldwater Creek watershed. The project will place aircraft at lower altitudes over the Missouri River floodplain, which may have the potential to disrupt feeding and nesting activities of birds in a flyway area. However, the anticipated impacts will be minimal and will not require mitigation.

Threatened and Endangered Species Impacts

Several Federally listed plant and animal species have historically occurred in the airport area. Based on information obtained and correspondence received, the expansion project for Lambert would not have an effect on Federal or state listed threatened and endangered species or areas designated as “critical habitat” by the U.S. Fish and Wildlife Service (FWS). In accordance with Section 7 of the Endangered Species Act, the FAA’s consulted with the FWS. The FWS concurred that Alternative W-1W will likely have no adverse effects on listed species or their habitats (letter dated September 1, 1994, in Appendix A of the FEIS). Therefore, mitigation measures are not required.

Wetlands Impacts and Mitigation

The airfield development and associated surface transportation improvements will result in impacts to existing wetlands. The various types of impacts will include loss of wetlands as a result of earthwork or construction, removal of existing vegetation and re-vegetation with grasses, or the clearing of trees and shrubs to ground level. Based on the conceptual plans used in the preparation of the FEIS, the selected alternative will impact approximately 9.7 acres. The majority of the wetlands that will be impacted have been previously disturbed and exhibit low habitat values. Their current status exhibits erosion, dumping, loss of canopy cover and extensive ditching.

Final design plans will be prepared in such a manner as to avoid, minimize and mitigate wetland impacts to the greatest extent practicable, as required by applicable rules and regulations. These plans will be developed during the permitting process and as construction plans are finalized. A formal jurisdictional wetland delineation with agencies having jurisdiction over this project will be conducted during the permitting process. Wetlands have been avoided to the extent practicable. Measures to mitigate wetland impacts have been developed, are contained in Section 6.3.7 of the FEIS and summarized below.

- **Enhance and Replace Existing Wetlands:** This program will mitigate for the removal of existing wetland areas by enhancing and/or replacing existing wetland areas. Enhancing and replacing existing wetland areas on-airport has been eliminated from further consideration because of the potential safety hazard associated with aircraft bird strikes. Off-site mitigation options that remain under consideration include: mitigation within the Coldwater Creek watershed, mitigation within the Cowmire Creek watershed or a combination.

- **Candidate Mitigation Sites:** Several candidate wetland mitigation sites have been examined; however, none have been formally designated for the Lambert wetland mitigation program at this time. Final mitigation requirements will be determined during the Section 404 permit application review process in consultation with the COE.

The wetland mitigation program will be initiated upon Section 404 permit approval. For any particular affected wetland area, the wetland mitigation (enhancement or replacement) will be completed prior to the removal of the existing wetland.

Floodplains Impacts and Mitigation

The project will result in additional development within the 100-year floodplain. Surface transportation improvements associated with the selected alternative will impact the 100-year floodplain as well. The project will impact approximately 22.3 acres for year 2002 and 35 acres for year 2015 in the Coldwater Creek floodplain. Therefore, this project will result in a floodplain encroachment. Mitigation will be developed to compensate for potential increased flooding caused by the proposed development. Mitigation measures to minimize the floodplain impacts will be accomplished so that the floodplain encroachment would not be considered significant. Floodplains have been avoided to the extent practicable, in light of greater impacts on protected resources in other impact categories. Measures to mitigate floodplain impacts, which are contained in Section 6.3.8 of the FEIS, are summarized here.

- **Limit Fill Within Floodplain Areas:** During design of the proposed runways and taxiways, the placement of fill within the floodplains adjacent to Coldwater Creek will be minimized. However, airport runways and taxiways must be designed to meet specific criteria related to runway profiles and cross slope. Some fill within the floodplain areas is unavoidable. Infield areas will be graded to reduce potential floodplain impacts.

- **Provide Stormwater Detention Areas:** To offset potential filling of shallow floodplain areas and construction of new impervious areas, detention storage volume may be provided to reduce peak discharges downstream, provide for floodplain storage compensation volume and avoid airport-induced increases of flood elevations upstream. The detention areas will be of shallow depth to minimize standing water in the ponds, thereby reducing attractiveness of the ponds to birds, which are a potential safety hazard to aircraft. Underground detention vaults may also be used. Detention areas will be constructed concurrently with the construction of new impervious areas.

Farmland Impacts

Development will not adversely impact any prime or unique farmlands or soil types as designated by the U.S. Department of Agriculture, Natural Resource Conservation Service. The areas have already been converted into urban uses, such as residential and commercial, and no longer retain their previous agricultural designation. Since there are no impacts anticipated, mitigation measures are not proposed.

Energy Supply and Natural Resources Impacts

Energy consumption at Lambert is expected to increase as activity increases. Aircraft and vehicle energy consumption estimates for the selected alternative are predicted to be less when compared to the No-Build Alternative. This reduction is a consequence of declining aircraft and vehicle fuel consumption resulting from shorter aircraft queuing times and moderate improvements to the roadway network surrounding Lambert. There are no known sources of mineral or energy resources in the Lambert area that will be impacted. Development of the selected alternative will not require the use of unusual materials or those that are in short supply in the Lambert area. Since there are no impacts anticipated, specific measures to mitigate energy consumption are not proposed.

Light Emissions Impacts and Mitigation

Areas sensitive to changes in light emissions are located in the vicinity of the proposed lighting systems. The proposed project will have the potential to create off-airport, light emission impacts. Through shielding and screening techniques, light emission impacts on surrounding residential areas will be minimized. Future light emission levels from airborne aircraft or aircraft operating on the ground are not anticipated to adversely impact surrounding residential areas. Proposed light emissions mitigation measures, described in Section 6.3.9 of the FEIS, include using light shields to direct light emissions away from residential or other sensitive areas. This measure will pertain primarily to the terminal area and roadway pole-mounted lighting.

Solid Waste Impacts and Mitigation

Alternative W-1W would increase the quantity of solid waste generated at the airport. This is primarily due to increased passenger flow and operations at the airport, increased airport tenant operations, and construction activity. Alternative W-1W would result in the generation of approximately 49,000 more cubic yards per year of solid waste as compared to the existing condition. However, this increase is not anticipated to adversely impact the area's solid waste handling practices or disposal facility capacity. Airport-generated solid waste levels comprise only a small percentage of the total waste produced in the metropolitan area, and existing solid waste disposal facilities have sufficient capacity to accommodate projected future solid waste generation levels.

While specific measures to mitigate for demolition-waste impacts were not required for the preferred alternative, some waste minimization efforts were considered reasonable and proposed by STLAA. These planned efforts to minimize demolition waste, contained in Section 6.3.10 of the FEIS, include the development and implementation of a construction recycling and salvage pilot program. This program will maximize recovery and reuse of construction materials, and reduce the waste entering landfills. Examples of the types of measures which may be considered in the pilot program are: conducting a salvage operation process to remove reusable building components and interior furnishings such as doors, windows, cabinets and plumbing fixtures and segregating building components and interior finishings by type and offering them for resale or reuse. The recycling and salvage management pilot program will be developed and approved prior to initiation of demolition and construction activities.

Several active landfills are located in the vicinity of Lambert. The Laidlaw Combined Sanitary and Demolition Landfill, at its closest point, is located approximately 9,166 feet west of the northwest end of proposed Runway 12W/30W. This is not consistent with FAA’s runway siting guideline of 10,000 feet, which was developed to protect aircraft from potential bird strikes. The new runway will be compatible with all area landfills in accordance with FAA Order 5200.5A, as described in detail in Section 6.3.10 of the FEIS. STLAA will attempt to develop an agreement with the operator of the landfill to implement one of the following options:

- Re-prioritize the landfill utilization plan so that the subject portion (i.e., that portion within the FAA’s 10,000-foot radius of incompatibility) of the landfill is utilized first;

- Require that STLAA be able to direct available fill that cannot be reasonably recycled from the construction projects to the subject portions of the landfill;

- Require that organic waste be capped in the landfill before the new runway is opened and that only clean fill (such as construction materials) be placed in the subject portions of the landfill once the runway is operational.

Should it not be practical to completely fill the subject landfill through the above measures, the STLAA will purchase an easement from the landfill operator which will provide the operator compensation for any lost revenue associated with the unused excess capacity. Any plan to convert or close the landfill must provide for a one-year bird-repelling program. Repelling efforts will begin 6 months before opening of the new runway and continue for a minimum of 6 months thereafter. The program will be in effect from dawn until dusk.

Coastal Barriers and Coastal Zone Management Program Impacts

The proposed improvements will not affect or involve the Coastal Zone Management Program or the Coastal Barriers Resources Act of 1982. Since there will be no impacts, mitigation measures have not been proposed.

Wild and Scenic Rivers Impacts

Review of the U.S. Department of the Interior's National Inventory of Wild and Scenic Rivers indicated that there are no designated "Wild and Scenic Rivers" within a 1,000-foot radius of Lambert. There will be no impact on any rivers designated as "Wild and Scenic"; therefore, mitigation measures are not warranted.

Construction Impacts and Mitigation

Construction impacts resulting from the airport development alternatives, including surface-transportation-related improvements, may include but are not limited to temporary impacts, such as soil erosion, increased air emissions, water quality degradation, noise disturbance and disrupted surface transportation patterns. These temporary impacts are short term in nature and can be minimized through the establishment and utilization of environmental controls and best management practices (BMPs).

To minimize construction impacts, environmental controls as specified in Advisory Circular 150/5370.10A will be included throughout the preparation of the plans and specifications for each of the proposed construction projects. These controls will be established to minimize the temporary air, water, noise, erosion, and light impacts typically associated with construction activities. STLAA will also incorporate all applicable State of Missouri and St. Louis County construction and environmental control provisions into the plans and specifications developed for all roadway and off-site airport-related improvements. Construction and environmental control measures will be developed as part of the preparation of plans and specifications for each airport development project and will be implemented with the initiation of demolition and construction activities.

Design, Art and Architecture Impacts

Design, art and architectural applications will be a consideration in the design and operation of the proposed improvements to the terminal facilities. Therefore, no mitigation measures are required.

Hazardous Materials Impacts and Mitigation

Several areas in the vicinity of Lambert have been reported to or have the potential to contain hazardous materials, hazardous wastes and/or petroleum products that have resulted in environmental contamination. Some of these sites have undergone preliminary investigations and will either be evaluated further, cleaned up or will require no further action by the responsible parties. Other sites have not been investigated. These sites have been identified and located so that they can be avoided or, if necessary, properly addressed during the planning and development of the proposed airport improvements. It is not expected that the project will involve any sites that are significantly impacted by hazardous materials, petroleum products or environmental contamination. Therefore mitigation measures *per se* are not required. However, BMPs developed as a means to minimize potential impacts are discussed in Section 6.3.12 of the FEIS. Examples of such BMPs include the following practices:

- **Assess and Remediate Contaminated Sites:** In accordance with state regulations, sites that are contaminated with hazardous materials will be fully assessed to determine the types and areas of the impacts. These sites will be cleaned up or other appropriate corrective measures will be undertaken.

- **Conduct Environmental Audits of Properties Prior to Acquisition:** The STLAA will conduct surveys of existing facilities requiring demolition to evaluate any potential involvement with asbestos, lead paint and/or other regulated materials. Site assessments will be included as part of the property acquisition process. Sites found to contain hazardous wastes, other regulated materials and/or environmental contamination will be properly addressed.

- **Develop/Implement Asbestos and Hazardous Materials Management Plan:** When materials containing asbestos or classified as hazardous are encountered during demolition, appropriate precautions will be followed. These include the employment of certified contractors trained and equipped to work under such conditions and the strict adherence to standards, practices and guidelines governing the handling and disposal of these materials.

Surface Transportation Impacts and Mitigation

Development will impact significant surface transportation facilities located in the airport vicinity. It will require the modification and/or realignment of several local and regional roadways to accommodate the proposed expansion of the airport.

It is estimated that after the year 2010, the additional aviation activity will result in increased associated surface traffic. Sections 5.22 and 6.3.13 of the FEIS provide a detailed analysis of the anticipated environmental impacts and mitigation measures associated specifically with the surface transportation improvements that would result from the proposed development.

Based on the assessment of surface transportation impacts detailed in Section 5.22 of the FEIS, there are no specific mitigation measures required for associated roadway improvements for the selected alternative. However, means to minimize impacts associated with the proposed roadway improvements, including construction of the Lindbergh Tunnel, are presented below.

- **Maintenance of Traffic Plan:** The Missouri Department of Transportation (MoDOT) will develop a staged implementation plan. This staging plan will identify what portions of the proposed roadway improvements will be constructed during each phase of the implementation plan, what the overall sequence of construction will be, and how traffic flow/access will be maintained during the construction phases. This staged construction plan will be coordinated with the appropriate county and city agencies prior to the beginning of construction. The maintenance of traffic plan will be developed during the preliminary engineering and final design of the improvements.

- **Roadway Improvement Safety Plan:** To mitigate the potential for vehicular accidents, fire and/or explosions occurring in the proposed

Lindbergh Tunnel, all applicable state and local fire codes will be adhered to during the design of the tunnel. The tunnel will also be designed to meet or exceed the current MoDOT lighting criteria/standards.

- **Visual Impacts from I-70/Airport Access Improvements:** Retaining walls will be incorporated into the construction design plans and implemented prior to the beginning of any roadway construction. The plans for retaining walls will be developed during the design phase of the I-70/Airport Interchange improvements and are dependent on specific requirements of MoDOT.

MITIGATION SUMMARY

The FAA has provided a comprehensive mitigation program, which establishes measures to mitigate the adverse effects of construction and operation of the proposed development. This program was developed to meet applicable Federal and state requirements and in consideration of local guidelines. The concerns and interests of the public and government agencies were also addressed. The mitigation program is described in Section 6.3, Mitigation, of the FEIS. A summary of the mitigation requirements for Alternative W-1W is contained in Table S.3 in Appendix J of this ROD.

Alternative mitigation measures considered in the FEIS are conditions of approval of the project in this ROD, and the project sponsor, the STLAA, has agreed to them. The FAA will monitor the implementation of these mitigation actions as necessary to assure they are carried out as project commitments. The FAA finds that these measures constitute all reasonable steps to minimize harm and all practicable means to avoid or minimize environmental harm from the selected alternative.

7. PUBLIC AND AGENCY INVOLVEMENT

From the outset, the concerns of the public have been considered. Both the STLAA and the FAA have been forthcoming with the communities about the project through extensive opportunities for public involvement. The interests of communities have been considered throughout the decision-making process regarding expansion at Lambert. This is shown in part by the information provided below.

Because of Lambert's impact on the surrounding communities, the FAA and the STLAA have conducted open public meetings to inform the public of the expansion plans. The FAA and the STLAA have received thousands of public comments throughout the EIS process. To the extent practicable, all of these comments have been reviewed to ensure that the needs and concerns of the public were considered and addressed. Based on the extensive opportunities for public participation, the FAA is satisfied that full consideration has been given to the public's views on airport expansion plans.

PUBLIC INVOLVEMENT PROCESS

Public involvement included the following:

- Three EIS scoping meetings were held on September 6 and 7, 1995.

- A scoping comment period extended from August 17 through September 21, 1995. A summary of the scoping comments is provided in Appendix J of the FEIS.

- A public workshop on the environmental process was held on June 11, 1996. There were 476 people in attendance. The meeting was advertised in the *St. Louis Post Dispatch* and other local newspapers. In addition, approximately 13,000 postcards were mailed to residents in the vicinity of the airport announcing the meeting and extending an invitation to the public to attend.

- The DEIS was distributed to local libraries, city halls and to principal commenting agencies. The DEIS was available for review from September 27, 1996, through January 17, 1997.

- The DEIS was available for more than the minimum 45 days required by CEQ regulations. The comment period for the DEIS opened on September 27, 1996. The initial comment period was extended twice, once in response to a request by the City of Bridgeton. The comment period on the DEIS closed on January 17, 1997.

- A public workshop/public hearing to receive comments on the DEIS was held on October 28, 1996, more than 30 days after the DEIS was released for review. Approximately 1,580 people attended.

- Over 15,000 comments were received from the public and agencies in response to the DEIS. The comments were reviewed and considered by the FAA in the preparation of the FEIS. All comments received were summarized and responded to in the FEIS (Appendices S, T, U, V, and W of the FEIS).

- The STLAA used a total of six newsletters to distribute information to approximately 13,000 airport neighbors and to provide information about commonly asked questions regarding airport expansion.

- The FEIS was distributed to local libraries, city halls and the principal commenters on the DEIS. The FEIS was available for review from December 22, 1997, through February 17, 1998.

The public involvement process for this project was documented in Section 7.0 of the FEIS. The list of recipients of the DEIS and FEIS is found in Section 8.2. DEIS and FEIS review locations are listed in Section 8.2.2.

Subsequent to the release of the FEIS and the end of the review period, a series of meetings was held prior to the ROD with certain interested organizations and citizens of local communities in the vicinity of Lambert. The purpose of these meetings was to allow these groups to air their concerns with the proposed expansion of Lambert and Alternative W-1W to FAA headquarters personnel.

ADDITIONAL MEETINGS

May 13, 1998

At the request of Senator Christopher Bond and Congressman Jim Talent, FAA Administrator Jane Garvey met in Washington, D.C., with citizens and representatives of organizations and local governments concerned with the proposed expansion of Lambert. Those meeting with the Administrator on May 13, 1998, were representatives of the Air Line Pilots Association (ALPA), National Air Traffic Controllers Association (NATCA), the City of Bridgeton, the City of St. Charles, St. Charles County, and Citizens Against Airport Noise (CAAN). Representatives from Congressman Talent's and Senator Bond's offices also attended.

ALPA, NATCA, the City of Bridgeton, St. Charles County, and CAAN gave presentations. The participants generally supported expansion at Lambert; however, they all oppose Alternative W-1W. Among the reasons given for opposing W-1W, ALPA and NATCA oppose W-1W based on the safety and capacity questions they raised. The represented communities oppose W-1W on the basis of noise concerns and general dissatisfaction with the adequacy of the FAA's EIS and hearing process. The impact to the City of Bridgeton would be a new runway in the city and impacts to approximately 2,324 households, 6 churches, 6 schools, 1 nursing home and 75 businesses. All support a real-time simulation study of Alternative W-1W.

The represented communities expressed a need to see that the STLAA and the FAA are concerned about noise and impacts to the historic district of St. Charles. The City of St. Charles believes that its historic district was ignored and that FAA did not hold a public hearing in St. Charles. St. Charles wants assurance that the EIS is accurate in its prediction of noise impacts. St. Charles desires an enforceable settlement agreement with STLAA if the FAA approves W-1W.

The attendees requested that they be given an opportunity to meet face-to-face with FAA personnel (program office and other specialists) to discuss their concerns, and that FAA authorize a real-time simulation study for the expansion project at Lambert.

The Administrator acknowledged that the meeting was helpful and raised important issues that the FAA would consider further. The Administrator stated that the FAA would take the time needed to study the issues raised.

June 9, 1998

As a follow-on to the FAA Administrator's meeting of May 13, 1998, representatives of ALPA and NATCA met in Washington, D.C., on June 9, 1998, with various FAA technical specialists and representatives of FAA's Headquarters and Regional Airports program offices. Also attending were representatives of Leigh Fisher Associates, the consultants to St. Louis on the MPS, who conducted the MPS capacity simulations. ALPA and NATCA wanted to present their concerns regarding the MPS, which they felt had not been considered during the planning and environmental processes.

ALPA and NATCA asserted that inaccurate assumptions and/or input data used for the MPS simulations resulted in an overstatement of benefits projected for the preferred Alternative W-1W and an understatement of benefits for the existing airfield. They also asserted that a real-time simulation study is needed to verify their opinion that: (1) it would be impossible to operate Alternative W-1W as proposed or (2) the capacity penalties required to make W-1W work would reduce the project benefit/cost ratio to a point where it would no longer be attractive to TWA. ALPA and NATCA submitted, and discussion was held on, a list of eighteen questions regarding simulation assumptions affecting the outcome of the MPS that they claim are incorrect or inappropriate.

FAA committed itself to carefully reviewing the ALPA and NATCA concerns. The ALPA and NATCA representatives expressed appreciation for the opportunity to discuss these matters with FAA headquarters personnel on a face-to-face basis.

June 16, 1998

As another follow-on to the FAA Administrator's meeting of May 13, 1998, representatives of ALPA, NATCA, the City of Bridgeton, the City of St. Charles, St. Charles County and CAAN met with the FAA Associate Administrator for Airports, Susan Kurland, on June 16, 1998, in Washington, D.C. Also in attendance were various FAA technical specialists and other representatives of FAA's Headquarters and Regional Airports program offices, and a representative from Congressman Talent's office.

For the most part, the presentations were a reiteration of the points brought up before in the meetings of May 13, 1998, and/or June 9, 1998, although in some cases in more detail. The parties either wanted to present their concerns regarding the MPS, which they felt had not been considered during the planning and environmental processes, or to express their general dissatisfaction with the adequacy of the FAA's EIS. They again expressed their opinion that a real-time simulation study is necessary to demonstrate that Alternative W-1W can be operated as proposed. The communities offered to provide the funding for the study.

The FAA reiterated its commitment to carefully review the concerns and issues raised.

July 20, 1998

In furthering the study of the issues, concerns and criticisms expressed during the above outlined meetings of May 13, June 9, and June 16, 1998, with FAA, the FAA's Acting Deputy Administrator, Monte Belger, gave the City of St. Louis the opportunity to meet with officials of FAA. That meeting was held in Washington, D.C., on July 20, 1998, with the St. Louis Director of Airports and his staff and consultants. In addition to the Acting Deputy Administrator, FAA was represented by the Associate Administrator for Regulation and Safety, the Associate Administrator for Airports and the Acting Associate Administrator for Air Traffic Services.

In addition to responding to a number of questions raised on certain safety aspects of Alternative W-1W, the City of St. Louis provided the FAA with a briefing, from its perspective, on several current issues before the FAA involving Alternative W-1W. As background, they provided a summary of the Lambert MPS planning process. They then provided comments on what they believed to be misleading allegations about Alternative W-1W. They also provided responses to questions raised by the FAA Flight Standards Office regarding the operation of Alternative W-1W, and responded as well to the 18 concerns raised by ALPA and NATCA in their June 9 meeting with FAA.

July 23, 1998

FAA Administrator, Jane Garvey; Acting Deputy Administrator, Monte Belger; Associate Administrator for Airports, Susan Kurland; and the Assistant Administrator of Government and Industry Affairs, Bradley Mims, attended a meeting at Congressman Richard Gephardt's office in Washington, D.C., on July 23, 1998, to discuss Lambert's proposed expansion.

Congressman Gephardt indicated that he had convened the meeting so that St. Louis public officials could make the case personally to the FAA Administrator in support of issuance of the ROD for the Alternative W-1W runway development project

St. Louis Mayor, Clarence Harmon, stressed that the Lambert expansion was the most critical project before the City of St. Louis in terms of the future economic viability of the city. Mr. Harold Gregory, representing the Let's Get On With Our Lives coalition, indicated his group has 1,100 petitions requesting a buyout and urged the Administrator to issue the ROD at the earliest possible time. Mr. Richard Fleming, President and CEO of the St. Louis Regional Commerce and Growth Association, told the FAA Administrator that each year of delay results in an estimated $400 million in business opportunities, 4,400 lost jobs, and $1.4 million in lost taxes. Ms. Norma Kaehler, Managing Director of TWA's Washington Government Affairs Office, indicated that TWA strongly supports the W-1W expansion plan. It is important to TWA from an operational viewpoint that the new runway proceed as soon as possible. Mr. Thomas Chapman, Southwest Airlines Government Affairs Director in Washington, paralleled TWA's comments. Lastly, the St. Louis Director of Airports, Leonard Griggs, stated that St. Louis believes that a real-time study of the planned runway operations is unnecessary and would cause a lengthy delay before the ROD could be issued. He reminded the group that Alternative W-1W has been coordinated with airline pilot and controller groups, and representatives of FAA's Flight Standard organization have been included in these past technical discussions. He urged the FAA Administrator to deny the pending request for a real-time study at St. Louis and to approve the ROD without delay.

8. COOPERATING AGENCIES

The environmental process involved the following cooperating agencies:

- U.S. Air Force - for environmental processing of relocation of the MoANG.
- U.S. Navy - for environmental processing of relocation of Naval and Marine Reserve Corps facilities.
- U.S. Army Corps of Engineers - for coordination of wetland impact and mitigation issues.
- Federal Highway Administration - for environmental processing of related roadway improvements.

A cooperating agency is an agency that has jurisdiction by law or special expertise regarding any environmental impact resulting from a proposed action or reasonable alternative. These agencies and the reasons for their inclusion in the process as cooperating agencies are described below.

U.S. AIR FORCE

The proposed expansion of Lambert involves the relocation and/or improvement of the MoANG, which falls under the jurisdiction of the USAF. To provide for additional terminal expansion, the Lambert development plan proposes to relocate the MoANG from its present location on the south side of the airfield to the northeast side of the airfield. The FEIS examined the potential environmental impacts associated with the relocation of the MoANG facilities and associated actions. This information will assist the USAF in meeting its specific environmental obligations.

The USAF has notified the FAA that it will prepare its own separate ROD at the appropriate time, once negotiations between the USAF and STLAA have progressed to the point that specific replacement facilities are identified and being finalized.

U.S. NAVY

The proposed expansion of Lambert involves the relocation and/or improvement of a Naval Reserve facility located on the south side of the airport. To provide for additional terminal expansion, the Lambert development plan proposes to relocate the Navy facility from its present location near the MoANG on the south side of the airfield to another site in the airport vicinity. The FEIS examined the potential environmental impacts associated with the relocation of the Navy facilities and associated actions. This information will assist the Navy in meeting its specific environmental obligations.

The Navy's ROD preparation would be similar to the USAF's in that it will be prepared at the appropriate time, once negotiations between the Navy and STLAA have progressed to the point that specific replacement facilities are identified and in the process of being finalized.

U.S. ARMY CORPS OF ENGINEERS

The proposed expansion of Lambert has the potential to impact wetlands, floodplains, and water quality--all under the jurisdiction of the COE. For that reason, the FEIS examined the potential environmental impacts to those resources and possible mitigation concepts. The involvement of the COE in conceptual mitigation planning at the EIS stage facilitates the subsequent preparation of permits, which may be required after the preparation of detailed design plans. The FEIS fulfills the National Environmental Policy Act (NEPA) requirements of the COE.

The COE will not need to prepare its own ROD for this project. It will approve a Section 404 permit application to be submitted by STLAA at the appropriate time after design plans are sufficiently finalized.

FEDERAL HIGHWAY ADMINISTRATION

The proposed expansion of Lambert involves the relocation and/or improvement of roadways under the jurisdiction of the FHWA. These roadways include improvements to portions of I-70 and relocation of a portion of Lindbergh Boulevard (U.S. 67) through a tunnel. The FEIS examined the potential environmental impacts associated with the modification of these and other local roadways. The FEIS fulfills the NEPA requirements of the FHWA.

The FHWA asked the FAA to include the following section in its ROD, which the FHWA will adopt regarding that agency's Federal actions.

Decisions Relative to Surface Transportation Actions

Airport development Alternative W-1W will impact significant surface transportation facilities located in the airport vicinity. Alternative W-1W will require the modification and/or realignment of several local and regional roadways to accommodate the proposed expansion of the airport. Section 5.22 of the FEIS provides a summary of the anticipated environmental impacts associated with surface transportation improvements that would result from the airport development alternative. This section of the EIS was designed to fulfill the NEPA requirements of both MoDOT and FHWA and addresses transportation impacts. Both MoDOT and FHWA assisted the FAA in the development of this section of FAA's FEIS. Only the incremental impacts of the roadway improvements are discussed in Section 5.22 of the FEIS, which is provided in a format consistent with the FHWA Technical Advisory T 6640.8A, "Guidance for Preparing and Processing Environmental and Section 303 Documents." The other portions of Section 5.0 of the FEIS address the cumulative impacts of the airport and roadway improvements. Measures to mitigate surface transportation impacts have been developed and are contained in Section 6.3.13 of the FEIS.

The proposed action is to expand Lambert-St. Louis International Airport, and Alternative W-1W was identified as the selected alternative to improve the airport. The selected alternative appears on Figures S-3 and 2.1 of the FEIS. Associated with that airport action are the following roadway location changes, along with an explanation of the proposed action and purpose/need for each of those changes:

Roadway	**Proposed Action**	**Purpose/Need**
Lindbergh Blvd (U.S. 67) [FEIS Figure 5.32]	Horizontal and vertical realign-ment through a tunnel 3,400' long by 6 lanes wide.	To accommodate new parallel runway and midfield terminal area, and to provide sufficient capacity to meet projected traffic demands.
Improvements to I-70/Airport Terminal Interchange and Terminal Area Roadway [FEIS Figure 5.31]	Improvements to I-70 in terminal area: improved system of access ramps and increased capacity along mainline. Re-alignment and expansion of on-airport terminal area roadway and ramp facilities, including parts of Lambert International Blvd., that provide access to terminal buildings and parking facilities.	To provide acceptable level of service by alleviating current congestion problems and accommodating future needs. To improve operational efficiency of the terminal area roadway system and provide added land area for proposed terminal expansion.
Natural Bridge Rd. (SR 115) [FEIS Figure 5.34]	Relocation of this road to the south, and relocate Natural Bridge-Lindbergh interchange immediately south of proposed Lindbergh tunnel.	To accommodate new parallel runway and midfield development and provide capacity to meet projected traffic demands.
McDonnell Blvd. [FEIS Figure 5.35]	Relocation of about 6,000 feet of Blvd., along I-70 right-of-way	To maximize the amount of land available for the relocation of the MoANG.
Missouri Bottom Rd. [FEIS Figure 5.38]	Relocation of the intersection of Missouri Bottom Rd. and Lindbergh Blvd.	To avoid conflict with the Lindbergh Blvd. north tunnel entrance/exit.
Local and neighbor-hood roadways [FEIS Figures 5.36 and 5.3.7]	Closure or relocation of numerous local and neighborhood roadways	To accommodate new parallel runway and midfield development. Acquisition of homes will make some roads no longer necessary.

Figure 5.29 of the FEIS provides a general location or description of area roadways that will be affected by Alternative W-1W. Figures 5.31 through 5.38 of the FEIS show individual roadway concepts, including the preferred alternative selected for each concept.

The final recommendation for the aviation-related preferred alternative selection, as well as the surface transportation-related preferred alternative selections, was accomplished through an assessment of the social, economic, engineering and environmental consequences of the alternatives, in combination with public involvement. After release of the DEIS, a public hearing was held on the airport improvements, and comments were grouped by category. Twenty-one comments were received relative to roadway improvements. Summaries of comments received on the DEIS and responses to those comments are located in Appendix V, number 27, of the FEIS.

Through the surface transportation alternatives screening process (described in Section 5.22.4 of the FEIS), it became apparent that the selected alternatives for each roadway had the least detrimental social, economic, engineering and environmental impacts. Additional discussion of the selected alternatives for roadway improvements appears in Section 5.22.4 of the FEIS. The selection of a preferred alternative to implement a solution for Lambert's capacity problems was completed in December 1997, with the concurrent release of the FEIS documentation. The FAA's FEIS review period ended on February 17, 1998.

While the aviation element of the overall project received strong opposition, the surface transportation alternatives received no strong public opposition. No notable concerns relative to surface transportation alternatives arose that would alter or prevent the selection of the preferred alignments.

Surface Transportation Alternatives Considered

A discussion of the process leading up to the selection of aviation-related facilities described in Alternative W-1W (including Runway 12W-30W) is provided in Section 5 of this ROD.

Per FHWA requirements, Transportation System Management (TSM) alternatives, such as High-Occupancy-Vehicle (HOV) lanes, park-and-ride lots, and employer-sponsored ridesharing programs, were examined. Public transit alternatives, such as bus systems and rail, were also considered. Based on the results of the evaluation process, it was concluded that the TSM strategy, and the transit strategy by themselves would not fulfill the safety and mobility goals of this project. As such, these two strategies were eliminated from this study for further evaluation as stand-alone solutions.

It has been concluded that the No-Build Alternative does not address the purpose and need of this project. However, it was the baseline alternative for the FEIS and is required by Federal law to be evaluated in concert with the other project alternatives.

The surface transportation alternative described below was found to be the only alternative to solve the safety and capacity problems associated with the selected aviation-related elements in Alternative W-1W.

The MPS identified surface transportation elements on the proposed ALP. However, the details provided on the ALP were conceptual in nature, requiring further refinement by the FAA, FHWA, MoDOT, STLAA and the FAA's FEIS consultant as part of the FEIS. This refinement consisted of traffic capacity analyses and development of alternative concepts that would more effectively meet roadway design standards and provide acceptable levels of service for surface vehicle traffic. Projected traffic volumes were developed based on traffic count data and methodologies provided by MoDOT. For each of the roadways discussed below that will be impacted by the new Runway 12W/30W, numerous alternatives were evaluated to determine the best solution to the surface transportation problems for that affected roadway area. In some instances, only one roadway concept is provided. This is primarily due to severe constraints imposed by the adjacent roadway system, the land uses, and the existing right-of-way.

The process leading to the selection of the preferred alternative for each of these roadway areas is summarized below and discussed in detail in the FEIS, Section 5.22.2.2 and in Appendix K, Roadway Concepts. Figure 5.29 in the FEIS depicts all the proposed roadway improvements associated with Alternative W-1W. Figures 5.31 through 5.38 in the FEIS show individual roadway concepts.

Lindbergh Boulevard (U.S. 67)

The implementation of new Runway 12W-30W will create a conflict with the existing alignment of Lindbergh Boulevard. Because Lindbergh Boulevard (U.S. 67) is a principal artery within St. Louis County, all of the alternatives developed and evaluated kept this roadway in service. Four alternatives for Lindbergh Boulevard were evaluated and are depicted in Figure 5.32 of the FEIS.

Alternative D, the preferred alternative, included the construction of a tunnel for Lindbergh Boulevard underneath the proposed Runway 12W-30W between the intersection of relocated Natural Bridge Road and relocated Missouri Bottom Road.

This alternative shifts the tunnel alignment approximately 200 to 300 feet to the west of the existing alignment of Lindbergh Boulevard.

Alternative D was selected because, among other reasons: (1) the horizontal alignment provides for a 60 mph design speed; (2) the vertical alignment provides for a 65 mph design speed; (3) the relocated Lindbergh Boulevard alignment would allow construction of the tunnel to occur while traffic was using the existing Lindbergh alignment. This alternative also offered the additional advantages of allowing the TWA training facility to remain at its present site and making 50 more acres available for future airport terminal expansion.

Improvements to I-70/Airport Terminal Interchange and Terminal Area Roadways

Improved capacity and access will be needed in the terminal area to provide an acceptable level of service. I-70 improvements include an improved system of access ramps and increased capacity along the mainline. These improvements are needed to provide an acceptable level of service by alleviating current congestion problems and to accommodate future needs. Re-alignment and expansion of terminal area roadways is required to improve operational efficiency and provide additional land area for terminal expansion. These improvements are depicted in Figure 5.31 of the FEIS.

Only one alternative, depicted in Figure 5.31 of the FEIS, was considered reasonable. This alternative involves the widening of I-70, adding ramps, reconstructing bridges, and reconstructing crossroads over I-70. In addition, this alternative involves improvements to the terminal access roadway system and reconstruction of the existing elevated Metro Link guideway.

This alternative was selected as the preferred alternative primarily based on its lesser right-of-way acquisition, fewer structures, lesser roadway length, and longer distances between successive ramps when compared to the other development concepts.

Natural Bridge Road (SR 115)

Because of the development of new Runway 12W-30W, Natural Bridge Road (SR 115) will require a relocation south with a new interchange to accommodate new parallel runway and midfield development.

Due to the need to maintain service on Natural Bridge Road and because of the high costs associated with some of the other alternatives, only one alternative was retained for the relocation of Natural Bridge Road. The relocation configuration is depicted in Figure 5.33 of the FEIS.

The major consideration of this proposed element involved alternatives for the new interchange that will be required at Lindbergh Boulevard and relocated Natural Bridge Road. Five alternative interchange configurations for Natural Bridge and Lindbergh Boulevard were evaluated and are depicted in Figure 5.34 of the FEIS.

Alternative E, which was selected as the preferred alternative, will be a partial cloverleaf interchange. The primary factors that led to the selection of this interchange configuration as the best type for this location are: (1) the available ramps to/from the north and (2) the need to maintain access between the Natural Bridge Road and Lindbergh Boulevard. There is a need to provide continuous traffic flow on Lindbergh Boulevard; therefore, the traffic signal on Lindbergh Boulevard was replaced with on/off ramps. To improve operations and safety for vehicles, other modifications are also provided.

McDonnell Boulevard

The proposed relocation of the MoANG will require relocation of McDonnell Boulevard east along the I-170 right-of-way and the reconfiguration of the intersection of I-170 and Airport Road.

Only one roadway alignment alternative, depicted in Figure 5.35 of the FEIS, was found to be reasonable and practicable for this roadway. McDonnell Boulevard will remain as a two-lane roadway from the end of the extended centerline of existing Runway 30R to the intersection of Airport Road. Internal roadways between existing McDonnell Boulevard and I-170 may be modified to meet the need of the MoANG.

The airport's future land use plans call for this area to be used by the MoANG. This alignment maximizes the efficient use of this land for the MoANG and other future airport-related developments.

Missouri Bottom Road

Relocation of the intersection of Missouri Bottom Road and Lindbergh Boulevard (approximately 1,800 feet north of its existing location) will be required to avoid conflict with the Lindbergh Boulevard north tunnel entrance/exit.

Only one alternative was considered reasonable for this improvement. It is depicted in Figure 5.38 of the FEIS. The development of the new Runway 12W-30W will require tunneling of Lindbergh Boulevard under the new runway. To safely maintain a connection between Missouri Bottom Road and Lindbergh Boulevard, the intersection of these roads will need to be relocated so that it will not conflict with the north tunnel entrance/exit. This alternative was selected as preferred because the shortest distance that will allow safe connection of this intersection is the 1,800 feet relocation to the north.

Local and Neighborhood Roadways

Closure or relocation of numerous local and neighborhood roadways will be needed to accommodate new parallel runway and midfield terminal development. Unnecessary roadways will also be removed.

Bonfils Drive - Bonfils Drive improvements that would be associated with Alternative W-1W include the realignment of Bonfils Drive from Gist Road to Natural Bridge Road. The two alternatives evaluated for this action are depicted in Figure 5.36 of the FEIS.

With Alternative B, the new roadway will be realigned so it will not travel through the proposed Runway Protection Zone (RPZ) of Runway 12W. The future road will be two lanes (approximately 4,700 feet long) and will serve as the local connector between Gist Road and Natural Bridge Road.

The primary consideration in evaluating the alternatives for this action were safety considerations involving the location and use of a public roadway within the active RPZ of future Runway 12W. FAA guidelines state that, whenever possible, roadways should be located outside the RPZ for the safety of the traveling public, as well as the safety of people and structures on the ground. For these reasons, Alternative B was selected as the preferred alternative for the relocation of Bonfils Drive.

Gist Road/Fee Fee Road - These two roadways are currently connected by a 90-degree intersection. Only one alternative runway alignment was found to be reasonable and practicable. Figure 5.37 of the FEIS depicts the preferred alternative for the Gist Road/Fee Fee Road improvements.

The proposed improvements will eliminate a portion of Fee Fee Road from Gist Road to relocated Natural Bridge Road (approximately 3,000 feet) and eliminate the existing T-intersection. The alignment of Gist Road in the vicinity of the existing Fee Fee Road intersection will be modified to provide a 300-foot turning radius. Gist Road will remain a two-lane facility. Because alternative north-south routes are available within proximity of Fee Fee Road (Lindbergh Boulevard and Bonfils Drive), the closure of Fee Fee Road in this area was determined to be the most reasonable and practicable alternative.

Summary of Proposed Roadway Development Plans for Alternative W-1W

All the above options were discussed at length during seven separate coordination meetings and six conference calls of the team overseeing the surface transportation projects. The team consisted of the cooperating agencies, FAA, FHWA and MoDOT, along with the airport sponsor, STLAA, and FAA's consultant, Greiner.

The individual roadway alternatives selected as the preferred, which make up the proposed development plan for each roadway area discussed above, are summarized as follows:

- Realignment of McDonnell Boulevard.
- Tunneling of Lindbergh Boulevard (Alternative D).
- Reconfiguration of the Lindbergh Boulevard/Natural Bridge Road Interchange (Alternative E).
- Improvements to the I-70/Airport Terminal Interchange.
- Realignment of Natural Bridge Road.
- Realignment of Bonfils Drive (Alternative B).
- Removal of approximately 3,000 feet of Fee Fee Road.
- Realignment of the intersection of Gist Road and Fee Fee Road.
- Terminal Area Roadway improvements.
- Relocation of portions of Gist Road and Fee Fee Road.
- Terminal area improvements and the relocation of Lambert International Boulevard.
- Realignment of Missouri Bottom Road.

Section 303 (Formerly Called Section 4(f)) and Section 6 Resources

There are no Section 303 (formerly called Section 4(f)) or Section 6(f) resources that will be impacted by the surface transportation elements of the overall project. The

Section 303/Section 6(f) impacts, associated with the aviation element, are discussed in Section 6 of this ROD.

Measures to Minimize Harm

All practicable measures to minimize harm have been incorporated into the decision for the selected alternative, W-1W, and its associated surface transportation elements.

The project will require approximately 24.2 acres of land for roadway right-of-way, consisting of 12 residential parcels, 7 commercial/industrial parcels, and 17 tax exempt parcels. These include six single-family residences, a 133-unit apartment complex, and the Drury Office Building. The proposed roadway improvements would not disproportionately impact low-income or minority groups. The acquisition and relocation program will be conducted in accordance with the Uniform Relocation Assistance and Real Properties Act of 1970, as amended in 1987 (*42 U.S.C. 4601*). A summary of the environmental impacts of surface transportation for Alternative W-1W follows:

Relocations	
Homes	6
Rental Units	133
Commercial Buildings	1
Population	276
Wetlands (acres)	1.8
Floodplains (acres)	2.3
Parks	0
Hazardous Material Sites	10

Section 6.3 of the FEIS provides further information regarding mitigation for surface transportation elements of Alternative W-1W. Efforts will be made to minimize disruption of communities and hardships on neighborhoods during construction of the roadway improvements through the development and implementation of a Maintenance of Traffic Plan and a Roadway Improvement Safety Plan.

Farmland impacts have been addressed. Because the area is zoned for urban uses and is fully developed, the criteria established in the Farmland Protection Policy Act do not apply and mitigation is not warranted.

Cultural resources have been addressed in accordance with regulations (36 CFR 800) implementing Section 106 of the National Historic Preservation Act (*16 U.S.C. 470*). The FAA determined that the surface transportation improvements may have an adverse effect on currently identified historic properties and additional, yet-to-be-identified historic properties. An MOA was required for the FEIS. The MOA was developed to specify measures to be implemented to avoid, reduce or mitigate any adverse effects. The MOA also details eligibility assessment and treatment measures for any additional archaeological and historic architectural resources that may be present in the undertaking's Area of Potential Effect (APE). The MOA was prepared in consultation with the Missouri SHPO and the Advisory Council on Historic Preservation and was executed by the Advisory Council on Historic Preservation on May 29, 1998. This satisfies the Section 106 responsibilities for all actions associated with the proposed surface transportation improvements. A final copy of the MOA is included in ROD Appendix H.

Due to the proximity of the alignment to residential areas, a carefully planned and executed drilling and blasting program will be implemented. The requirements of this blasting program will be governed by local, state and Federal regulations. This program can involve the following activities: pre-blast survey, vibration criteria, contractor's blasting plan, vibration monitoring during blasting, and post-blasting survey. This type of program has been successfully used on a large number of projects, including blasting in urban areas and along natural gas and electrical lines.

Motor vehicle emissions caused by the proposed action are estimated to be well below the *de minimis* levels requiring a determination to demonstrate conformity with the SIP. Emissions from all airport-related sources were evaluated in the Final General Conformity Determination, which FAA made available on June 19, 1998.

Job construction specifications will require erosion control measures to prevent sedimentation. MoDOT's Sediment and Erosion Control Plan, as approved by the MDNR, will be implemented to prevent pollution caused by construction activities. As described in detail in the FEIS, compliance with the provisions of the MDNR's stormwater regulations and the provisions of the NPDES permit will also minimize adverse water quality impacts.

MoDOT will implement BMPs for stormwater control and comply with MDNR stormwater regulations and the provisions of the NPDES, a general permit issued for road construction projects statewide.

Wetlands have been avoided to the extent practicable. The position of the selected alternatives have been chosen to minimize impacts to wetlands. The surface transportation elements associated with Alternative W-1W will require a structure across Coldwater Creek, the relocation of a culvert crossing for McDonnell Boulevard, and possible modifications to an existing ditch system. Final mitigation measures, if required, will be decided in coordination with the U.S. Army Corps of Engineers with the assistance of the U.S. Fish and Wildlife Service. Stormwater, NPDES and COE

Section 404 permits will be obtained prior to construction of any of the proposed roadway facilities. Mitigation measures addressing stormwater NPDES and COE Section 404 permits are discussed in Section 6.3 of the FEIS.

The proposed surface transportation improvements associated with Alternative W-1W will impact approximately 2.0 acres of Coldwater Creek floodplain and 0.3 acre of Cowmire Creek floodplain. Floodplain impacts have been reduced by holding right-of-way requirements to a minimum.

Wells found during construction will be sealed to prevent groundwater pollution from construction and from future road maintenance.

The project will not have adverse effects on any Federally listed endangered or threatened species.

Noise studies as detailed in the FEIS, dependent upon final design, indicate that traffic noise impacts will be minimal because: (1) noise-sensitive sites will be part of the relocation program associated with the airport alternative; (2) remaining noise-sensitive sites will experience traffic noise from another existing roadway; or (3) noise-sensitive sites will be impacted by aircraft noise. The mitigation of noise impacts all along the roadway project is unlikely. Consideration of noise barriers for residential properties adjacent to the highway project will be in accordance with the MoDOT policy on noise abatement. Mitigation of aircraft noise impacts is discussed in Section 6 of this ROD.

Ten sites (depicted in Figure 5.28 of the FEIS) potentially involving hazardous materials and/or environmental contamination, could be impacted by the surface transportation elements of Alternative W-1W. The preferred method of mitigation for hazardous waste sites is avoidance. The sites that cannot be avoided will require additional site inspection and characterization of material releases. It is not anticipated that remediation of potential contaminants will require substantial amounts of work. Sites requiring remediation will need to have a Remedial Action Plan developed with approval by the MDNR prior to implementation.

Monitoring or Enforcement Program

The proposed project will be subject to further review by Federal and state agencies and local units of government. Some permits will need to be obtained. This review and permit process will ensure that the included mitigation measures are implemented.

Comments on FEIS

The FEIS was approved for circulation on December 19, 1997, and was distributed to the agencies and individuals noted within the document on December 22, 1997. Those receiving a copy of the FEIS were provided 30 days to respond with comments. The Notice of Availability of the FEIS was published in the Federal Register on January 2, 1998. Only one letter, from Mr. Wilfred H. Adelt, mentioned the roadway projects. No other comments on the surface transportation projects were received on the FEIS.

Mr. Adelt suggested that the Lindbergh Boulevard tunnel will negatively impact the main thoroughfare between north and south St. Louis County. The response to that comment is as follows: The FAA has coordinated the proposed roadway changes, including the tunneling of Lindbergh Boulevard, with the FHWA and MoDOT. The environmental impacts of the roadway changes are contained in the FEIS Section 5.22. The proposed tunnel will not separate ties to neighborhoods, families or local businesses, or adversely affect community cohesion. The tunnel will be built to the appropriate level of service to accommodate the traffic needs of the roadway.

9. RELATED PLANNING ISSUES

Several commenting parties, principally ALPA and NATCA, maintain that Alternative W-1W will not provide the needed capacity at Lambert (Appendices C and G of this ROD). This belief is based in part on their view that the proposed operation of the expanded airport is unsafe and, therefore, cannot be operated as planned.

The major technical issues raised include:

- Safety

- Capacity
  - National Airspace System Capacity Benefits
  - Runway Stagger/Departure Dependency
  - PRM/No Transgression Zone (NTZ) Issue
  - Real Time Simulation
  - SIMMOD Input
  - Terminal Expansion
  - Benefit/Cost Analyses
  - ALPA/NATCA 18 points

SAFETY

Concerns have been expressed about safety issues and capacity/delay estimates developed during the MPS and EIS processes. In analyzing and comparing capacity and delay reduction benefits of various alternatives during the planning and environmental review processes, both the FAA and the City of St. Louis gave the highest priority to safety requirements in accordance with FAA's statutory mandate. Safety of operation is a prerequisite for operation and expansion of any airport. The FAA has rules (such as FAA Order 7110.65L, Air Traffic Control) and local air traffic control procedures, that govern the operation and interaction of aircraft in virtually any conceivable situation and combination of weather conditions. These rules include such things as in-trail, horizontal and vertical separations. The same rules applied by FAA's Air Traffic Division in operating existing airports are applied in airport planning to estimate the capacity and delay benefit of alternatives. The existing airport or any expanded airport will be operated safely in accordance with the rules established by FAA and applied by the Air Traffic Division.

The FAA has carefully considered all safety issues raised during the EIS process. Safety implications related to airfield layout are addressed by designing facilities in accordance with FAA design standards. The selected alternative, W-1W, is designed in accordance with Advisory Circular 150/5300-13. Alternative W-1W enhances safety because it reduces the project number of runway crossings with the existing airfield in 2015 from approximately 800 to 580 per day. See Appendix C of this ROD, response to Comment 8. See also Appendix G.

The selected alternative, W-1W, will use procedures that are already approved by FAA and used daily at airports throughout the United States. It was developed using FAA approved airport design standards for airfield layout.

CAPACITY

Estimates of capacity and delay are complex. The capacity and associated delay of a particular airport is influenced by a large number of variables, including the runway layout, taxiway system, terminal layout, gate utilization, weather variability, volume of demand, peaking characteristics of demand, airline operating strategies and fleet mix, to name a few. Estimating how well some future runway configuration will perform becomes a nearly impossible task, unless computer models are used to simulate the operation of the future airport. These models are very useful in analyzing different alternatives by changing one or two of the variables for comparative runs of the model and observing the differences in average annual delay that result. Such computer models have been used throughout this process.

The hourly capacity numbers for any specific set of circumstances produced as a result of this modeling are of far less importance than the relative magnitude of delay estimated. Any comparison or discussion of hourly capacity numbers for a specific case that does not include the associated delay results in an incomplete understanding of the operating efficiency of the case.

ALPA has stated that the runway stagger, which influences the dependence of departures from the existing Runway 30L on arrivals to the new Runway 30W, negates the advantage of the new runway. The FAA and the MPS consultant have always agreed that the departure dependence will exist. The condition was included in the modeling assumptions. The result is that the proposed expansion provides sufficient delay reduction to produce a very favorable benefit/cost ratio and acceptable projected delay levels through the planning period (the year 2015).

All of the inconsistencies in capacity/delay figures cited by ALPA have been derived from taking numbers from one study that used one set of assumptions and comparing them to another study that used different assumptions. Valid comparisons depend on use of the same assumptions and variables. Simulations for capacity and delay analysis are conducted by comparing each alternative with the existing airport and changing one variable at a time while keeping all the other variables constant.

Generally, capacity and delay estimates have more importance for comparative purposes than for any given absolute value.

The planning process for Lambert included capacity/delay analyses utilizing four different computer models: the FAA Runway Capacity Model, the FAA Annual Delay Model, SIMMOD and the National Airspace System Performance Analysis Capability (NASPAC) model. The assumptions and conditions used as input for these models were extensively discussed and coordinated with appropriate parties. In the case of the first three models, this included the Airfield and Airspace Working Group (AAWG). This group was comprised of representatives such as the St. Louis Air Traffic Control Tower (ATCT), ALPA, the airlines, Air Transport Association (ATA), and others. In the case of the National Airspace System Performance Analysis Capability (NASPAC) analysis, the FAA's William J. Hughes Technical Center (FAA Technical Center) performed the study, with input coordinated with FAA Airports Division and the St. Louis ATCT.

In the alternatives analysis stage of the master planning process, FAA's capacity and delay models were used to compare the relative operational efficiency of the various alternatives. The assumptions and results of this analysis are documented in Section 2 of the Master Plan Supplement Technical Compendium (MPSTC). Additionally, a sensitivity analysis was performed to assess the impact of changing circumstances that occurred during the planning process.

Once STLAA selected its preferred alternative, W-1W, different simulations were performed utilizing the more sophisticated SIMMOD computer model. The goals of the SIMMOD analysis were twofold: (1) to evaluate the most efficient means of operating the preferred airfield alternative, W-1W, reconfirming its overall operational benefits; and (2) to evaluate effects on aircraft delays and taxiing times of potential refinements to the operation and layout of Alternative W-1W. For these reasons, eighteen simulations were performed. The conditions and results of the model simulations are documented in Section 6 of the MPSTC.

The FAA Technical Center also performed capacity and delay simulation modeling to compare the preferred alternative (W-1W) to the existing airfield. This analysis utilized FAA's NASPAC computer model. Assumptions, conditions and results of this study are documented in a report published by the FAA Technical Center in June 1997, entitled "Evaluation of the Proposed Lambert-St. Louis Airport Expansion" and are discussed elsewhere in this section of the ROD.

Within each analysis, the alternatives being compared were subjected to the same sets of variables, which could affect the capacity/delay results of the study. This is necessary in order to draw valid comparisons between alternatives. Results of studies performed under different assumptions and circumstances do not provide for valid comparisons.

The proposed expansion does rely on the use of a PRM to allow dual simultaneous independent IFR approaches to the outboard runways. This procedure has been tested and approved by the FAA. Simultaneous IFR approaches to closely spaced parallel runways were subjected to real-time simulations prior to the FAA approving them. In addition, a PRM was installed and operated for over a year in Raleigh-Durham, North Carolina.

In summary, the proposed expansion at Lambert has been subjected to simulations using the FAA Runway Capacity Model, the Annual Delay Model, the SIMMOD model, and the NASPAC model. In each case, the proposed expansion has shown the potential to increase capacity and significantly reduce projected delays.

National Airspace System Capacity Benefits

The lack of airfield capacity at high-activity airports in the United States is a frequent cause of "bottlenecks" in the nation's aviation system. Lambert is identified as 1 of 23 existing delay-problem airports in the FAA's 1994 Aviation Capacity Enhancement Plan; therefore, the proposed project at the airport is crucial to the development of needed capacity for the NAS.

In 1997, the FAA Technical Center conducted a study of the proposed expansion of Lambert-St. Louis International Airport to determine the expected benefits of the proposed project to Lambert and the NAS. The study was initiated at the request of FAA Central Region Airports Division. A report documenting the methodology used and results of the study was published in June 1997.

The NASPAC Simulation Modeling System (SMS) was used to perform the task. The NASPAC SMS is a discrete event simulation model that tracks aircraft as they progress through the NAS and compete for Air Traffic Control (ATC) resources, e.g., airports, sectors, flow control restrictions and arrival and departure fixes. The NASPAC evaluates system performance based on the demand placed on resources modeled in the NAS and records statistics at the 50 busiest national airports and 8 associated airports.

The study used the model to calculate local and system-wide delays, with and without the new runway proposed for the airport. Monetary benefits of the new runway were calculated using the NASPAC Cost of Delay Module. The Cost of Delay Module calculates the passenger and operational delay cost based on actual cost reported by the airlines to the Department of Transportation's Office of Aviation Statistics. The results of the study indicate that the construction of the new runway would provide substantial monetary benefits to the airlines and the user community due to the abatement of operational and passenger delays locally and in the NAS.

Data were presented for operational delay, passenger delay and delay savings. Operational delay occurs whenever an aircraft has to compete for an ATC system resource. Passenger delay reflects the "ripple-effects" in the NAS and shows the lateness of a flight at the destination airport. The delay savings represent the difference in delay with or without the Lambert expansion project. The delay savings assumed that the current NAS stays essentially the same for the study period (2005 - 2015), with some new technologies introduced and some airspace procedures revised.

The new runway will reduce operational delay at Lambert by 63 percent in 2005, 65 percent in 2010 and 66 percent in 2015. NAS-wide, operational delay will be reduced by 5 percent in 2005, 8 percent in 2010 and 14 percent in 2015 with the implementation of the improvements at Lambert.

The new runway will also reduce passenger delay at Lambert by 55 percent in 2005, 52 percent in 2010 and 57 percent in 2015. NAS-wide, passenger delay will be reduced by 7 percent in 2005, 9 percent in 2010 and 18 percent in 2015.

Delay savings in monetary terms was also analyzed by the NASPAC model. The monetary savings indicated do not represent actual cash savings but an estimate of what could be saved by the airlines and passengers with the implementation of the Lambert expansion project. The benefits to the airlines were based on their direct cost as reported to the Department of Transportation. The passenger cost was assumed to be $45.50 per passenger hour, if they were reimbursed for lost time caused by delays in the system.

The estimated savings that could be realized by implementing the new runway at Lambert would result in significant operational and passenger delay savings both at Lambert and NAS-wide. In terms of cumulative operational delay savings during the study period (2005 - 2015), the model predicted a $1.9 billion savings at Lambert and a $5.1 billion savings NAS-wide. Likewise, cumulative passenger delay savings over the study period was predicted to be $1.4 billion at Lambert and $9.5 billion NAS-wide.

Runway Stagger/Departure Dependency

The selected alternative, W-1W, includes construction of one new parallel runway located 4,100 feet south of the existing north parallel runway (30R). The threshold of the proposed new runway is staggered approximately 12,200 feet to the west from the threshold of existing Runway 30R. This location, along with the location of the existing south parallel runway (30L), results in departures from either of the existing runways being dependent on arrivals to the new runway in IFR west flow conditions.

Critics of the W-1W plan claim this operation is unsafe and inefficient and, therefore, does not provide the capacity necessary to reduce delays as the MPS and FEIS suggest it will.

The stagger of Alternative W-1W increases safety because simultaneous arrivals will occur on runways separated by 4,100 feet instead of 3,400 feet. This is 600 feet more than the minimum lateral spacing of 3,400 feet allowed under PRM operations for straight-in approaches. The effects of the runway stagger and the dependency of departures have been thoroughly analyzed in the MPS. In addition, these issues have been addressed in the FEIS, in particular, see the responses to Comments 2-39, 2-64, 2-65, 2-137,2-142, 2-144 and 2-150 in Appendix V. The SIMMOD input and ALPA/NATCA 18 points are discussed below.

Precision Runway Monitor/No Transgression Zone Issue

This issue has both safety and capacity aspects. It also relates to the real-time simulation issue discussed below. The safety and capacity of operational procedures contemplated for use with Alternative W-1W has been the subject of numerous comments previously responded to in the FEIS. See FEIS response to Comment 1-50.

The Precision Runway Monitor (PRM) is a system comprised of a rapid update radar, an enhanced color graphic monitor and a software package, which aids the air traffic controller in more accurately monitoring the position of aircraft on final approach to a runway. As noted above, use of a PRM to allow dual simultaneous independent IFR approaches to closely spaced parallel runways has been subjected to real-time simulation and approved by the FAA. The FAA has certified PRM for use to provide simultaneous independent approaches with parallel runways separated by at least 3,000 feet (FAA Order 8260.39) (3,400 feet for straight-in approaches). PRM is the primary tool that has allowed the FAA to achieve this. The W-1W proposal for St. Louis includes outboard runways spaced 4,100 feet apart, and stipulates that a PRM would be required to provide independent approaches. Runways spaced 4,300 feet apart allow simultaneous independent approaches without a PRM.

One of the features of the PRM system is a digital map displayed on a computer terminal monitored by an air traffic controller. The digital map includes an area designated as the No Transgression Zone (NTZ). The NTZ is generally centered between the approach paths of the runways being monitored with the PRM. In the case of the Lambert expansion, the outboard runways are separated by 4,100 feet. The NTZ is 2,000 feet wide, centered between the runways. Therefore, the edge of the NTZ is

1,050 feet from the centerline of each outboard runway. Since the existing two parallel runways are 1,300 feet apart, the future center runway will be 250 feet inside the NTZ. The purpose of the NTZ is to assure proper horizontal separation between arrivals.

When operating the proposed expanded airport in IFR conditions in west flow, the plan envisions approaches to the outboard runways, existing 30R and the new runway 30W (which will be designated 30L after expansion), while allowing a departure on existing Runway 30L (which would be 30C after expansion). With the PRM in operation, this will result in the departure off existing Runway 30L (30C after expansion) entering the NTZ. With the current software design for the operation of PRM, the departure would generate an alarm notifying the controller monitoring the PRM that an aircraft has penetrated the NTZ.

Some commenters have expressed concerns that PRM has not been specifically tested with the approximately 12,200-foot stagger contemplated for Alternative W-1W or with simultaneous approaches to the outboard runways with departures from the center runway. Others comment that use of PRM with a staggered runway and departures on a center runway in the NTZ exceeds the parameters for PRM certification. The FAA has carefully considered whether use of the PRM is authorized in these circumstances. The Air Traffic Division and Flight Standards Division reviewed the plan for operation of Alternative W-1W and requirements under Air Traffic Control Handbook 7110.65 Chapters 3 and 5 and PRM procedures in FAA Order 8260.39 as they apply to that plan in detail. That review indicates that the planned operation of the runway configuration is authorized as explained below:

When operating in IFR conditions in west flow, aircraft will arrive on the outboard Runways 30W (which will be designated 30L after expansion) and 30R, while departing 30C. Departures from Runway 30C will be dependent on arrivals to both outboard runways. Before a departure is released from Runway 30C the air traffic controller will apply the provisions of FAA Order 7110.65L Paragraph 5-9-8 c.3, which defines conditions for termination of radar monitoring. Internal air traffic procedures will specify that when provisions of paragraph 5-9-8 c.3 have been applied, radar monitoring shall be terminated and no action will be required in response to any alarm that may be generated by aircraft departing runway 30C. The fact that a departure from the center runway (current 30L) is inside the NTZ is not relevant because radar monitoring will have been terminated for the approach, and PRM is not used to separate departures.

W-1W does not depend upon a change in the PRM software to deactivate alarms for departures to assure safety. The purpose of the NTZ is to enable controllers to detect loss of separation between simultaneous approaches. To conduct operations as planned, modification of the software may be required. If such a software modification is required it will be subject to appropriate testing not involving real-time simulation.

This review of the proposed procedures determined that they are authorized by current ATC guidance and consistent with procedures that would require real-time simulation, as discussed below, are necessary. This determination is documented in letters dated July 31, 1998, from the FAA Administrator, Jane Garvey, to Congressmen James Talent and Richard Gephardt (Appendix I of this ROD). The result of this review and documentation is to confirm that the proposed expanded runway configuration can be operated safely as planned and depicted in the MPS and the FEIS and that real-time simulation is not necessary to verify the safety of the procedures.

Real-Time Simulation

The request for real-time simulation was first submitted to the FAA in a letter dated December 29, 1997, from ALPA representative, Dean Adam, to John Turner, Central Region Administrator, FAA. In that letter, ALPA stated that real-time simulation was the only way to resolve capacity questions surrounding the W-1W proposal. Real-time simulation was subsequently requested to address claimed significant safety impacts and to confirm the operational assumptions in the MPS and FEIS, particularly in west flow. ALPA considers such a study essential to determine whether controllers can actually pair arrivals of aircraft having different approach speeds as simulated by computer modeling. ALPA also views testing as needed to address safe use of the NTZ for departures on the center runway.

Real-time simulation is the process by which computers, flight simulators, target generators and radar scopes, operated by real air traffic controllers and actual pilots, replicate actual flight operations in an air traffic control environment. The controllers are located in a radar lab (normally at the FAA Technical Center) while the pilots operate flight simulators at various locations throughout the country, many of which are leased from airline training departments.

The process begins with a definition of requirements. Next comes the design of the simulation, which involves the development of scenarios to reflect such variables as fleet mix, weather conditions, runway configuration and use, air traffic procedures, navigational aids, approach speeds and in-trail and lateral separation. Then the actual real-time simulation is completed. If further risk analysis is required, the data is sent to the FAA's Aeronautical Center for use in a computer simulation system. Analysis of the resulting data leads to a final report.

Real-time simulation has been used by FAA numerous times to test the viability of new procedures that have been developed for specific applications. Notably, the real-time simulation process has been used by FAA to test simultaneous independent parallel IFR approaches to closely spaced parallel runways using a PRM, when it was a new approach aid system. As a result of this and other analyses, FAA approved dual simultaneous independent IFR approaches to parallel runways spaced as close as 3,400 feet apart using PRM. Subsequently, FAA approved dual simultaneous independent IFR approaches to parallel runways spaced as close as 3,000 feet apart (3,400 feet for straight-in approaches) using PRM, with a 2½ degree offset of one of the approaches.

Real-time simulation was deemed unnecessary for this project because the procedures to be used with Alternative W-1W are authorized under existing procedures that are used daily at airports throughout the United States. Some commenters stated that real-time simulation would show that Alternative W-1W would not have the capacity claimed in comparison to other alternatives, particularly in west flow conditions. As new and untested procedures are not needed to support Alternative W-1W, real-time simulation would have no bearing on estimates of capacity and delay. While real-time simulation is a valuable tool in analyzing new and untested procedures and special situations, it is not a capacity tool. It does not provide capacity/delay numbers for comparison of alternatives.

SIMMOD Review

ALPA has commented throughout the environmental review process that various characteristics of Alternative W-1W were not properly reflected in the computer modeling and simulation analysis used by the airport's consultant and by the FAA in determining capacity. ALPA contends that incorrect information was used as input to the computer models, particularly the SIMMOD model. Others have commented that the SIMMOD capacity calculations overstate the capacity of Alternative W-1W and understate that of the existing airfield and Alternative NE-1a and that all alternatives should be evaluated using SIMMOD.

Some of the factors ALPA believes were incorrectly analyzed include the runway stagger, the dependency of departures from the center runway, the ground movements in front of the terminal, the arrival rates for the existing parallel runways, the arrival rates for the Dependent Converging Instrument Approach (DCIA) operation for the existing airfield, runway crossings and the effects of wake turbulence.

During the MPS, the City of St. Louis compared alternatives using the results of the FAA Airfield Capacity Model and the FAA Annual Delay Model. Numerous sensitivity analyses were performed throughout the planning and environmental review process using the capacity and delay models in order to determine what, if any, effect the suggested changes would have on the alternatives analysis. The latest of these analyses was conducted for the No-Action, S-1, NE-1a and three scenarios for W-1W in response to a list of 18 points that ALPA presented to FAA during a meeting on June 9, 1998 (Appendix C of this ROD).

After the capacity and delay models were used to make estimates that enabled the City of St. Louis to select its preferred alternative, Alternative W-1W, the SIMMOD was used to refine comparisons between Alternative W-1W and the No-Action Atlernative. Although FAA had already conducted one study that confirmed the results of the MPS SIMMOD analysis, to further address concerns about the adequacy of FAA's independent review, the FAA Technical Center reviewed the input files used by the consultant for the SIMMOD analysis, as well as the procedures used for modeling the runway crossings, departure dependencies and taxiway movements in front of the terminal.

The results of the FAA Technical Center review of the SIMMOD analysis of the proposed expansion are documented in an August 1998 report**.** The Technical Center established that the analysis was performed in conformance with the accepted standard practice and the results obtained are reasonable. The Technical Center's letter dated July 29, 1998, summarizing the results of this review, is documented in Appendix I of this ROD. As it is reasonable for the FAA to select Alternative W-1W based upon the comparison with other alternatives, it would not be useful to conduct additional SIMMOD analyses to refine other alternatives.

Terminal Expansion

One of the issues raised concerns the plan for expansion of the terminal facilities included in the overall expansion plan for Lambert.

The local press reported in May 1998, that TWA (the major hub operator at Lambert) was pressing the airport for immediate construction of a new 60-gate terminal. It was also reported that TWA was contemplating withdrawing its support of the W-1W plan, if the airline did not get its new terminal by the time the new runway was to open. This report stirred controversy, because the MPS and the FEIS envisioned development of new terminal facilities on a more gradual schedule.

The MPS and the FEIS documented terminal development to the west of the current terminal location, including a location west of Runway 06/24 (Figure S.3 in Appendix J of this ROD). The FEIS addresses impacts of terminal development relating to location (footprint) of new facilities and gates to accommodate the forecast aviation demand through 2015. It was estimated that 105 to 110 total gates would be necessary to accommodate the aviation demand in 2015. As part of the mitigation program in the FEIS, STLAA has agreed that when terminal design progresses sufficiently, the STLAA will conduct a carbon monoxide hot-spot analysis for terminal expansion to ensure that the terminal structure is designed efficiently from an air quality standpoint.

At the request of the FAA, the STLAA and TWA subsequently clarified the level and extent to which negotiations for new terminal facilities for TWA had progressed (see letters from STLAA and TWA in Appendix F of this ROD). Both parties reported that preliminary discussions had taken place, but that both STLAA and TWA were in full support of the expansion plan as developed in the MPS and documented in the FEIS.

An issue directly related to the terminal expansion plan that has been the subject of comments is the ground movement on Taxiway Delta in front of (and adjacent to) Concourse C. The current configuration of this taxiway in relationship to the terminal requires that aircraft using the gates on the north side of Concourse C push back into the taxiway. This restricts the efficient utilization of the taxiway.

This limitation was identified at the alternatives analysis stage in the MPS process. A number of possible solutions to the problem were explored with the participation of the AAWG. Some of those solutions were:

1. Remove a section of Concourse C near the main terminal to allow one-way taxi flow into the "back alley" between Concourses C and D, with opposite flow along the north side of Concourse C.

2. Move Runway 12R/30L 300 feet north of its present location to allow enough room to clear push backs from the terminal with a new parallel taxiway.

3. Reduce the width of Runway 12R/30L to 150 feet (presently 200 feet) to allow room to shift Taxiways Alfa and Delta 50 feet to the north.

4. Eliminate approximately 11 conventional gate positions on the north side of Concourse C, replacing them with 5 "power-in, power-out" gate positions to eliminate push backs into the taxiway--to be accomplished when terminal expansion to the west of the present terminal provides enough gates to compensate for the six-gate net loss required by the plan. This is the solution that was selected.

In summary, terminal development up to a total of 110 gates is covered in the FEIS. Terminal development west of the current terminal and some terminal development west of Runway 6/24 is documented in the FEIS. The proposed terminal areas are shown in green in Figure S.3 of the FEIS (Appendix J of this ROD). Impacts of the terminal facilities were considered for each of the 22 environmental categories examined in the FEIS and documented in the FEIS. The only additional analysis needed is a carbon monoxide hot-spot analysis unique to exact terminal design. Terminal development in excess of 110 total gates would need additional environmental review.

Benefit/Cost Analyses

Two separate benefit/cost analyses were prepared during the study process. The first was conducted by the MPS contractor for STLAA. A second independent BCA was conducted by the FAA.

Master Plan Supplement Benefit/Cost Analysis

Benefit/cost ratios (BCR) were computed in the MPS. Benefits included aircraft travel time and delay savings, while costs were calculated using construction costs to be incurred from 1996 to 2015. According to the analysis prepared by STLAA, the new runway at Lambert (Runway 12W/30W) would have a BCR of 2.2, indicating that its economic benefits are over two times greater than the project cost, and that it is economically preferable to not constructing the runway.

FAA's Independent Benefit/Cost Analysis

As a supplement to the analysis of the Lambert expansion plan (W-1W) for the FEIS, and in anticipation of a request for funding under the Airport Improvement Program (AIP), the FAA Airports Division requested the FAA's Systems and Policy Analysis Division (APO-200), Office of Aviation Policy and Plans, to conduct an independent BCA of the proposed plan.

In July 1997, the FAA performed and completed an independent BCA for Lambert. The analysis, performed by FAA's Systems and Policy Analysis Division, Office of Aviation Policy and Plans, compared Alternative W-1W with the No-Action Alternative. The methodology, assumptions and results of the analysis are documented in a report entitled "Benefit-Cost Analysis for Lambert-St. Louis International Airport Capacity Enhancement Project," dated July 31, 1997.

The results of the FAA analysis indicate that Alternative W-1W has a BCR of 2.6 compared to the No-Action Alternative, making it economically preferable to the No-Action Alternative.

The FAA report also includes a risk analysis, which calculates the effect of cost overruns, construction schedule slippage, traffic growth variations, and combinations of these variables. The risk analysis indicates that Alternative W-1W has a high probability of maintaining a BCR greater that 1.0 under a wide variety of scenarios.

In summary, regardless of whether one relies upon the BCR of 2.2 from the MPS or the FAA's BCR of 2.6, the BCR for Alternative W-1W is clearly advantageous.

Air Line Pilots Association/National Air Traffic Controllers Association 18 Points

ALPA and NATCA presented a written list of 18 concerns to FAA senior staff at a meeting on June 9, 1998, and submitted basically the same list when they met with the Associate Administrator for Airports on June 16, 1998.

In response to these concerns, the FAA Airports and Air Traffic staff met with STLAA and its consultant to determine the variables to examine in a "sensitivity" analysis. A sensitivity analysis is a process of reevaluation or recalculation of a previously completed analysis using one or more changed variables. The purpose of the sensitivity analysis is to see what effect the changed variables have on the results of the analysis, or how sensitive the results of the analysis are to the variables that are the subject of the sensitivity analysis. In this case, at the request of the FAA, STLAA and its consultant performed a sensitivity analysis to determine what effect the use of the variables suggested by ALPA and NATCA would have on the results of the capacity/delay analysis and the overall analysis of the alternatives. The results of the sensitivity analysis indicate that incorporation of the ALPA/NATCA data would make no significant difference in the capacity/delay and cost/benefit analysis relative comparison of the alternatives. The details of the sensitivity analysis are included in Appendix C of this ROD.

In recent comments, both ALPA and Bridgeton have misinterpreted FAA's use of different assumptions as proof that the assumptions and analyses in the MPS and the FEIS are incorrect. The sensitivity analysis was done with, among other assumptions, a lower arrival rate of 60 arrivals per hour instead of 72 per hour during VFR 1 conditions for the No-Action Alternative and Alternative W-1W. It also examined the effect of using outboard runways during VFR 1 and 2 conditions and west flow with Alternative W-1. These analyses were done to accommodate and address concerns about the validity and integrity of the process.

The operational assumptions used in the planning and EIS processes remain reasonable and valid. The arrival rate of 72 arrivals per hour includes ample time for voice communication between pilots and controllers and for clearances. The assumptions used in the MPS and the FEIS are consistent with operational efficiency. During good weather and west flow, it would be more efficent to use the new runway for departures and the existing runways for simultaneous independent arrivals than to sequence departures between gaps in simultaneous arrivals to the outboard runways given the demand for departures at Lambert.

10. ENVIRONMENTAL ISSUES RAISED ABOUT THE FEIS

During the 30-day review period, comments were received from the following in response to the FEIS:

Federal Agencies

- Department of Health and Human Services
- Department of the Interior
- Department of Transportation, Federal Transit Administration
- US Environmental Protection Agency

Local Agencies/Interest Groups

- City of Woodson Terrace
- St. Clair County Board
- St. Charles R-6 School District
- Office of the County Executive, St. Charles County
- City of Bridgeton
- City of St. Charles
- National Air Traffic Controllers Association
- Air Line Pilots Association
- People Building Community
- St. Charles County Citizens Against Aircraft Noise
- Bridgeton Air Defense

Interested Citizens

- 161 letters from interested citizens

Letters from the public echoed many of the comments received from the local governments and interest groups. Most of their comments were in the areas of noise, airport planning, alternatives and public involvement.

No substantive comments were received from the public on the following categories after the release of the FEIS: hazardous materials; water quality; historic, architectural and archaeological resources; biotic communities; endangered and threatened species; wetlands; farmlands; energy and natural resources; light emissions; solid waste impacts; construction impacts; cost considerations; environmental justice; surface transportation; floodplains; and design, art and architecture.

The FAA has carefully assessed and considered comment letters received on the FEIS in making its decision. Copies of these letters are available for inspection at the FAA Regional office. While not every comment in every letter has been addressed, Appendices A, B, C, D, E and G of this ROD provide detailed responses to comments on major issues raised by the principal commenting agencies and citizen groups. Airport planning issues raised in comments on the FEIS are summarized previously, in Section 9 of this ROD. The major environmental issues raised in comments on the FEIS are summarized below.

1. Flawed purpose statement includes dual simultaneous independent arrivals

Commenters contend that dual simultaneous independent arrivals are not a legitimate purpose and need.

The purpose and need statements contained in the FEIS present an accurate description of the purpose for the project and the reasons why the proposed Lambert action is needed. The FEIS, Section 2.0, Purpose and Need, identifies four major elements of the purpose of the proposed Federal action.

The first major element listed is associated with capacity and aircraft delay. One of the sub-items identified under capacity and delay is the development of a capability for dual simultaneous independent IFR arrival operations. This capability was identified as far back as the FAA's 1986 Capacity Enhancement Study, done by the FAA Technical Center. It was subsequently identified in the master planning process. Both the FAA and STLAA determined, based on the forecasts of aviation demand and analysis of existing airfield capacity, that a third parallel runway and a separation of at least 3,400 feet between the outboard parallel runways would have the greatest potential to reduce aircraft delays during adverse weather conditions. This capability was identified as a subordinate item under the general purpose of enhancing capacity and reducing delays, reflecting the operational importance of improving airport capacity during poor weather (IFR and VFR-3) conditions. This was the major capacity problem identified by the master planning process and confirmed by the FAA Technical Center's independent evaluation.

The City of Bridgeton commented both on the DEIS and on the FEIS that the FAA has unduly narrowed the purpose and need and skewed the analysis of alternatives by relying upon simultaneous instrument arrival capability as a factor. The inclusion of dual simultaneous independent IFR arrival operations at Lambert did not unduly narrow or restrict the consideration of alternatives.

It was reasonable to include simultaneous arrival capability during instrument meteorological conditions as a sub-element of the general purpose and need of enhancing capacity based on the 1986 and master planning studies. Simultaneous arrival capability did not skew the analysis of alternatives because it was one of seven project goals or factors weighed by FAA, along with reducing delay and enhancing capacity generally both at Lambert and in the NAS during visual meteorological conditions, consistency with local planning, and consistency with economic goals (FEIS, Section 3.2, p. 3-3-3-6). These factors, derived from the purpose and need section of the EIS (FEIS Section 2.0), are listed in Section 4 of this ROD. Subsequently, operational efficiency, financial and environmental concerns were considered in the decisionmaking process.

While independent arrival capability during IMC was dispositive in dismissing Alternative NE-1a in the DEIS, two other similar north airfield alternatives met this requirement and were retained for further consideration in Tier 2.

Even if simultaneous independent arrival capability in IMC was an overriding factor, the analysis of alternatives was not skewed because all but one of the eight development alternatives carried forward from the MPS met the criteria. In addition to Alternative W-1W, of the onsite airfield alternatives, Alternatives NE-1, N-1, C-1, W-1E, W-2 and S-1 met the simultaneous arrival capability criteria (FEIS, Table 3.7, p. 3-35). Alternative S-1, which had simultaneous independent arrival capability, was one of the reasonable alternatives evaluated fully throughout the EIS process. A recent NASA study indicates that additional runways, providing independent IFR capability, are one of the most promising strategies for improving capacity in the NAS (Pages 24-26 of the NASA study, attached to the City of Bridgeton's comments on the FEIS dated February 2, 1998). That the FAA and STLAA view independent arrival capability as important and the most plausible goal is not unreasonable because others might consider the lower levels of capacity and delay reduction of NE-1a tolerable.

The analysis of alternatives was also not skewed because the FAA has done supplemental analysis to assure that it did not elevate independent arrival capability over the larger project goals. In the DEIS, the FAA examined the FAA Runway Capacity Model and FAA Annual Delay Model results that estimated the capacity and delay associated with Alternative W-1W, and Alternative S-1, along with the other alternatives N-1, NE-1, NE-1a, C-1, W-1E, W-2 and the No-Action Alternative. This analysis indicated that Alternative W-1W provides greater capacity benefits than the No-Action Alternative. In response to comments on the DEIS, the FAA examined Alternative NE-1a in more detail in the FEIS (FEIS Section 3.3.4.1). Further examination in the FEIS indicates that Alternative NE-1a was not a reasonable alternative because it has substantially higher average annual delays, total annual delay and more runway crossings than the alternatives studied in detail in the EIS (MPS Section 3, Attachment D-2).

In response to further comments from the City of Bridgeton, ALPA and NATCA, that questioned the validity of the modeling assumptions used in the FEIS, the STLAA, with oversight from the FAA, conducted a sensitivity analysis in June 1998 that included Alternative NE-1a. This sensitivity analysis assumed, for the sake of argument, the truth of four different assumptions posited by these commenters. The sensitivity analysis indicated that Alternative W-1W increases capacity and reduces delays better than Alternative NE-1a and the No-Action Alternative. The commenters do not identify any alternative that provides capacity or delay reduction benefits comparable to or greater than Alternative W-1W but lacks simultaneous independent arrival capability.

This comment is very similar to prior comments on the DEIS. See responses to Comments 1-14, 1-21 and 1-49 in FEIS Appendix V.

2. FEIS flawed based on tiering process for screening alternatives

There were concerns that the FEIS and its alternatives analysis do not meet the requirements of NEPA, because the tiering process used by FAA to screen alternatives was flawed.

While some commenters believe that the FEIS is flawed, the FEIS is a comprehensive document that fully meets the spirit, intent and requirements of NEPA as well as other substantive statutes. The FAA prepared an evaluation of the proposed action through the EIS process as required by NEPA. The purpose of an EIS is to consider alternatives, present probable environmental impacts and examine possible mitigation to address the significant adverse environmental impacts of those alternatives. The FEIS identifies significant adverse environmental impacts for the preferred alternative and contains appropriate mitigation for those significant adverse environmental impacts.

The FAA solicited comments from interested parties, starting with the scoping process on the DEIS, and continuing throughout, so that it could correct any deficiencies in the documents and provide any additional analyses needed in the FEIS. As examples, because of comments received on the DEIS, the FAA supplemented its FEIS noise analysis with grid points outside the 65 DNL contour, and supplemented the air quality analysis to further describe issues of interest to EPA and MDNR.

The FAA worked closely with each jurisdictional agency to ensure that its concerns were adequately addressed in the FEIS. The EPA expressed satisfaction with the Draft General Conformity Determination, which demonstrated that the project meets the requirements of the Clean Air Act (EPA letter dated April 22, 1998, in Appendix A of this ROD). The DOI and MDNR commented on requirements of the Land and Water Conservation Fund Act and DOT Section 303 (also referred to as Section 4(f)) and had no outstanding issues remaining. Along with the FAA and the STLAA, the SHPO and Advisory Council on Historic Preservation signed an MOA (Appendix H of this ROD) that satisfies the requirements of the National Historic Preservation Act. The Corps of Engineers was consulted and had no objections to the proposed wetlands mitigation concept. These examples demonstrate that the FAA has fulfilled the procedural and substantive requirements of NEPA as well as other environmental statutes and requirements.

Regarding the FAA's tiering process and alternatives analysis, a full and comprehensive range of alternatives was explored by the FAA in the Federal EIS process. The EIS examined the alternatives of using a multiple airport system, using existing or proposed regional airports as a replacement or supplement to Lambert, development of a new airport, other modes of transportation and use of other runway configurations at Lambert.

The Council on Environmental Quality (CEQ) regulations require that reasonable alternatives be comprehensively considered and an explanation be provided as to why other alternatives were eliminated from detailed consideration. The FAA used a three-tiered analysis process, which the EPA acknowledged as meeting the requirements of NEPA, to determine the reasonable alternatives that were subject to detailed analysis. Alternatives that were not considered reasonable were not retained for detailed evaluation. In order to be carried through for detailed analysis, an alternative had to meet all the purposes and needs for the proposed action.

In its letter dated February 27, 1998, the EPA expressed concerns regarding the alternatives analysis in the FEIS. The FAA provided additional explanation to EPA in a letter dated April 9, 1998, and the EPA responded, in a letter dated April 22, 1998, that its remaining concerns had been resolved (Appendix A of this ROD contains these letters). In that letter, the EPA stated the following: "I believe it is important to note that while we may have expressed disagreements or requested clarification in the areas of air quality and noise impacts, our comments on the FEIS should not be viewed as questioning whether the FEIS met the spirit, intent, and requirements of NEPA in these two issue areas. Our comments concerning NEPA requirements were directed solely at the issue of the alternatives analysis contained in the FEIS, and particularly the role of economic factors in the screening process for the alternatives."

The tiered alternatives analysis presented a logical, objective means to screen all alternatives considered in the study. The tiered evaluation retained two reasonable alternatives, W-1W and S-1, for detailed evaluation, not just the sponsor's proposed action. In its letter of April 22, 1998, the EPA stated that the tiered screening analysis of alternatives, based on the particular purposes and needs identified for this project, represented an adequate screening of the alternatives consistent with the requirements of NEPA. In its response to FAA's clarification of the alternatives analysis, the EPA responded: "As we indicated in our earlier correspondence, our Agency supports the concept of screening a full range of alternatives against a project's purpose and needs to identify which alternatives are reasonable, and are carried forward for detailed analysis. We believe this approach meets the spirit, the intent, and the requirements of NEPA, provided that the process is conducted in a valid, legitimate manner. With the additional clarification provided in your letter of April 9, 1998, we better understand how FAA conducted the tiered alternatives screening, and believe that the analysis of alternatives, based on the particular purpose and needs identified for this project, represents an adequate screening of the alternatives consistent with the requirements of NEPA." Thus, the FAA's analysis of alternatives fulfills the requirements of NEPA.

These comments also do not raise entirely new issues, but are similar to comments previously raised on the DEIS. Tiering was discussed in the FEIS Appendix V, responses to Comments 2-74, 2-77, 2-78, 2-121, 2-131, 2-132, 2-133, and 2-134. The alternatives selection process was discussed in the FEIS responses to Comments 211, 2-15, 2-29, 2-58, 2-72 and 2-85.

In summary, the FEIS, including its alternatives analysis, is a comprehensive document that fully meets the spirit, intent and requirements of NEPA.

3. Use of Scott AFB/MAA

Citizens questioned why Mid-America Airport (MAA) could not be used as an alternative to supplement or replace Lambert.

The FAA believes that the effects of the future development of MAA on Lambert have been fully considered in the FEIS. The use of other airports, including MAA, as a hub or to supplement Lambert is not considered a viable alternative to the planned development of Lambert. At the present time, it appears that the capital investment required, the travel distance involved, and the impact on airline hub operations exceed the benefits derived. However, all airports in the St. Louis area were examined in the FEIS to determine their capability to handle commercial traffic.

In order to be carried through for detailed analysis, an alternative had to meet all the purposes and needs for the proposed action. Alternatives eliminated during Tier 1 of the analysis did not meet aviation-related project purposes and needs and were not considered reasonable. All off-site alternatives were found to be unreasonable alternatives in terms of the first tier of the analysis. In the EIS, we discussed specifically how the off-site alternatives, such as MAA, did not maintain a passenger hub at Lambert, a key component of the project need. If a proposed alternative could not enable Lambert to effectively function as a hub by safely accommodating projected levels of aviation activity at an acceptable level of delay, then it would serve no purpose to carry that alternative forward for detailed evaluation.

The lack of a sponsor for airport expansion in another political jurisdiction is a reality that the FAA is authorized to consider under CEQ regulations and the rule of reason. The FAA has received correspondence from St. Clair County, the operator of MAA (which is a joint-use facility with Scott AFB), that indicates it supports Lambert as the regional hub (FEIS Appendix A, pages A-20 and A-21). There has been no correspondence from St. Clair County or any other political entity in the region that indicates the desire to be the sponsor of such a hub airport.

Section 3.3.3 of the FEIS contains a thorough analysis of the MAA alternative. Also, comments on this alternative were received after release of the DEIS and FAA provided explanation of its elimination from consideration in FEIS Appendix V responses to Comments 2-3, 2-33, 2-45, 2-60 and 2-120.

4. Selection of Modified S-1 alternative

Some groups favored the Modified S-1 alternative, which was supported by ALPA, and believed FAA should select that alternative rather than Alternative W-1W.

An analysis contained in Section 3.3.4.3 of the FEIS details the environmental impacts associated with the Modified S-1 alternative. ALPA has proposed two versions of the Modified S-1 plan. It was estimated that the 1993 version would involve the purchase of nearly twice the number of homes, and the overall environmental impact would greatly exceed Alternative S-1. While the 1996 version would affect substantially fewer homes, simple review of the Modified S-1 plan reveals that it would so severely impact I-70 that the cost and construction difficulties make it unreasonable and also less desirable than Alternative S-1. As indicated in the FEIS analysis, this alternative would have significantly greater environmental impacts when compared to Alternative S-1. Therefore, after examination of the Modified S-1 alternative, the FAA eliminated it from further consideration, because there were no operational or cost advantages when compared to Alternative S-1.

These comments do not present significantly new issues. Similar comments were made on the DEIS. FAA previously provided responses to those comments (FEIS Appendix V responses to Comments 2-5, 2-27, 2-104, 2-140 and 2-155).

5. Selection of Alternative NE-1a

NATCA and other commenters suggested that FAA should select Alternative NE-1a as its preferred alternative. In comments provided on the DEIS, NATCA outlined numerous reasons why it believes that runways separated by 2,500 feet would meet Lambert's needs.

Although Alternative NE-1a provides only a 2,500-foot separation between the outboard runways, it was included and studied in detail in the MPS at the request of the airlines. One of the purposes of the proposed action is to increase IFR capacity, as well as VFR capacity. Alternative NE-1a was eliminated from detailed environmental analysis in the DEIS because it provides less than the 3,400-foot separation needed for simultaneous, independent arrivals in either IFR or VFR weather conditions.

In comments provided on the DEIS, NATCA outlined numerous reasons why it believed that runways separated by 2,500 feet would meet Lambert's needs. FAA's detailed responses to NATCA's comments are provided in responses to Comments 1-52, 2-157 and 2-158 in the FEIS Appendix V. Other FEIS Appendix V responses to comments that discuss Alternative NE-1a include Numbers 2-27, 2-40, 2-89, 2-90, 2-119, 2-126 and 2-139. In response to these comments, FAA conducted further analysis of NE-1a in the FEIS (FEIS Section 3.3.4.1). The analysis indicated that Alternative NE-1a increases the number of runway crossings over existing conditions, as well as over Alternative W-1W. Additionally, more significant interactions between arrivals and departures would be expected with NE-1a as compared to the other alternatives. Thus, the FAA did examine the alternative preferred by NATCA, NE-1a, but eliminated it from further consideration.

6. Selection of the Lambert 2020 alternative

The City of Bridgeton stated that the FAA should select the Lambert 2020 alternative, which was proposed by the City of Bridgeton.

The City of Bridgeton's Lambert 2020 Plan as submitted was very general in nature. However, the Lambert 2020 Plan is very similar to Alternative NE-1a, particularly as to runway location. The Lambert 2020 Plan calls for a third parallel runway in the same location as Alternative NE-1a. It does not meet the purpose and need, primarily because the runway spacing would only be 2,500 feet, which would not permit simultaneous, independent arrivals in poor weather conditions.

Section 3.3.4.5 of the FEIS provides further details regarding the elimination of this alternative. The Lambert 2020 plan was also previously discussed in FEIS Appendix V responses to Comments 2-24, 2-109 and 2-141.

7. EPA concerns with noise impact analysis and noise mitigation program

The EPA expressed concerns that the noise impact analysis and noise mitigation program, as described in the DEIS, werenot adequate. Those concerns were addressed in the FEIS, Appendix V, responses to Comments 3-77, 3-78, 3-79, 3-87 and 3-99.

The EPA was under the impression from the DEIS that the FAA deferred mitigation to a Part 150 study, which was not our intention. The FEIS states that mitigation for the EIS is separately required and not dependent upon a Part 150 study (Section 6.3.1 of the FEIS).

Regarding noise impacts, the FAA believes it provided a comprehensive analysis of noise impacts, including an analysis of the areas that will experience a 3-dB increase in the 60 to 65 DNL contour. Although it was not the type of analysis that the EPA expressed an interest in seeing, FAA believes that the extended analysis is within the framework of the Federal Interagency Committee on Noise (FICON) guidelines and public disclosure requirements under NEPA.

With respect to the EPA's suggestion for clarification of proposed mitigation, as stated in the FEIS, the FAA has determined that the mitigation programs will consist of: (1) for areas 70 DNL and higher, residential and residentially zoned areas will be acquired; and (2) for areas 65-70 DNL, a voluntary mitigation program (sound insulation or residential sales transaction assistance) will be offered for residences and community facilities, including schools, and mobile home parks will be acquired. For areas between 60-65 DNL, we have determined that mitigation measures are neither appropriate nor practical. We note also that the STLAA has an ongoing, FAA-approved FAR Part 150 Noise Compatibility Program, which already provides mitigation for existing and future noise impacts around the airport.

The FEIS noise mitigation program was explained to EPA staff, who concurred that it is sufficient. Therefore, the FAA believes its noise analysis and mitigation program adequately meet the spirit, intent and disclosure requirements of NEPA.

The development of Alternative W-1W will not reverse ongoing efforts to provide relief to residents impacted by existing airport noise. The airport is continuing with its Part 150 program, approved by the FAA in 1997, to address noise issues related to existing airport operations.

The STLAA is planning to install a new permanent noise monitoring and flight tracking system, intended to assist in the management of its noise program and monitor the effectiveness of operational noise mitigation measures, such as directing aircraft to turn over the Missouri River bottoms. Once a full year's noise and flight track data showing the actual noise levels and flight tracks resulting from the operation of the new west runway are available and have been analyzed, an adjustment will be made to the mitigation program, if appropriate.

8. Increases in noise and overflights in communities west of Lambert

Citizens in communities west of the airport, such as Bridgeton, St. Charles and Maryland Heights, question the noise analysis and believe there will be large increases of noise and overflights in their communities

The noise exposure analysis was prepared by Greiner and reviewed and approved by the FAA. Flight tracks were developed by Greiner under the direction of the FAA, utilizing information from FAA Air Traffic Control Specialists, analysis of Automated Radar Terminal System (ARTS) data and information gathered during field observations. The FAA's Integrated Noise Model (INM) was used to model dispersed flight tracks, which represent corridors of aircraft flight activity. Departure and arrival flight tracks used in the noise analysis represent average conditions, including both instrument and visual flight conditions. Flight tracks for Alternative W-1W were developed based on a 3-parallel runway configuration. The aircraft operations mix was developed through coordination with the FAA ATCT, airlines, the Missouri Air National Guard and other airport users. Information was also obtained from aircraft manufacturers regarding aircraft performance characteristics of existing and new generation aircraft. Projections of future operations were closely coordinated with the FAA and aircraft operators. Therefore, the noise exposure analysis and noise exposure maps contained in the FEIS are based on the most accurate information available regarding the current and predicted future operation of the airport. The flight paths projected do represent annual average conditions. We note, however, that flight paths may change from day to day because of wind, weather or other conditions.

Although noise measurements are not required for an FEIS, since the airport has had a permanent Noise Monitoring System, data collected by the Noise Monitoring System were used for the EIS. The purpose was to provide validation of, or adjustments to, the data base provided in the INM computer model. On-site noise measurements provided data to compare with that provided by the prediction model for the existing condition. Measured values were compared with the noise levels derived from the INM. On the basis of this comparison, it was concluded that the measured values of these sites were within reasonable conformance with values calculated by the computer program. No manual adjustments not already included in the computer model were required due to terrain or climatic variations. The INM noise analysis results correlated to within 1 dB of the actual monitored results (Section 4.2.4.2 of the FEIS).

Airplanes will fly over St. Charles or Maryland Heights. Departing flight tracks will not be concentrated over the central portions of the City of St. Charles. For the existing runways and the proposed new runway, departure corridors to the southwest would be over the Missouri River Bottoms. This would generally place aircraft over the Missouri River Bottoms, rather than over the City of St. Charles. Departure Track T46, as shown in Figure 5.7 of the FEIS, will be located over St. Charles. Tracks T47, T48 and T49 are also departing flight tracks from Runway 30W, which do not go over the City of St. Charles. As indicated in the FEIS Appendix F, Table F.21, of all the departures on Runway 30W, only 33 percent of general aviation and small and medium commercial jets will utilize Track T46. All large commercial jets and military jets, as well as 67 percent of general aviation and small and medium commercial jets departing from Runway 30W, will utilize Tracks T47, T48 and T49, which do not impact the City of St. Charles.

In summary, after Runway 12W/30W is operational, certain neighborhoods in St. Charles and other communities west of the airport will be overflown more directly and at shorter slant ranges than they are at present. Because of the effects of the introduction of quieter Stage 3 aircraft, noise levels are projected to decrease in future years. With the implementation of Alternative W-1W and the increased percentage of Stage 3 aircraft, the FEIS grid point analysis conducted for locations C01 through C06 in St. Charles indicates that noise levels at these locations will be well below the DNL 65 dB threshold. By the year 2002, aircraft noise levels will have decreased to below DNL 60 dB, with or without Runway 12W-30W.

Similar comments previously received on the DEIS regarding noise increases and flight tracks were addressed in responses to Comments 3-17, 3-86, 3-93, 3-102, 3-103, 3-107 and 29-62 in Appendix V of the FEIS.

9. Current noise levels in St. Charles

According to an independent noise study commissioned by the City of St. Charles and prepared by Engineering Dynamics International (EDI), St. Charles is currently experiencing high noise levels.

The current noise situation in St. Charles is not associated with the proposed Runway 12W/30W alternative. While some areas in St. Charles may currently experience noise levels between DNL 60 and 65 dB, they are not related to the proposed expansion, including Runway 12W/30W.

Section 4.2.4.2 of the FEIS contains a detailed analysis of the existing noise environment in the Lambert study area. Based on the information contained in this section, the St. Charles area is outside the DNL 65 dB contour area. This conclusion is supported by the results of both the St. Charles County Government study, prepared by EDI, and the FEIS. The EDI report was considered by the FAA in its preparation of the FEIS. In Appendix V of the FEIS, responses to Comments 3-43 and 3-54 address the findings of the EDI report.

10. Inappropriate use of 65 DNL as cutoff for noise impacts or mitigation

St. Charles citizens expressed the opinion that DNL 65 is not an appropriate cutoff for noise impacts or mitigation.

NEPA requires Federal agencies to evaluate the environmental consequences of a project's environmental impacts and to determine whether they are potentially significant. In some impact categories, that significance is determined by reliance upon certain thresholds or standards. In this case, the FAA used the 1.5 dB or greater increases in noise within the DNL 65 dB.

In 1979, Congress directed the FAA to adopt regulations to establish standard methodologies for measuring noise and guidelines for determining noise levels at which land uses are compatible with various levels of noise exposure (*49 U.S.C. 47502*). In 1981, the FAA issued 14 CFR Part 150. Under FAA guidelines, residential land uses are compatible with noise exposure levels below DNL 65 dB. The FAR Part 150 guidelines were established after years of extensive consideration by various agencies (i.e., EPA, HUD, FAA) of the impact of aircraft noise on people. FAA's policy decision regarding the selection of DNL 65 dB as the threshold of significant noise impact is based upon a variety of noise studies such as <u>Impact of Noise on People</u> (USDOT, May 1977) and <u>Guidelines for Considering Noise in Land Use Planning and Control</u> (Federal Interagency Committee on Urban Noise, June 1980). This study states that "a valid indicator of noise impact is the changing percentage of population associated with a given response category." The study indicates that at DNL 65 dB, 30 percent of the population rate noise as unacceptable, while 70 percent rate noise as acceptable. Use of the 65 DNL contour as the threshold of significance under FAA Orders 1050.1D and 5050.4A, which implement NEPA, is well established and has been judicially approved.

As discussed below, a DNL grid point analysis was done for certain noise-sensitive locations, including some residential areas in St. Charles. However, the FAA properly determined not to analyze alternative mitigation measures in areas surrounding the airport like St. Charles that would experience less than significant cumulative noise exposure levels as a result of the proposed action. The FICON report indicates that few mitigation measures are appropriate or practical in areas below DNL 65 dB. Noise abatement adjustments to flight procedures tend to be viewed as the most likely candidates for mitigating noise at lower levels, because they are within Federal control and do not involve changes in land use. However, this tool also has limitations. In order for a noise abatement flight procedure to be considered for analysis, there should be a reasonable expectation that a noise benefit of worthwhile magnitude would result and that implementation of the procedure is appropriate and practicable. Procedural changes usually involve moving noise around rather than eliminating it and may actually result in noise increases for some people, while reducing noise for others. It is generally expected that Federal priority will be given to mitigating noise at higher levels. It would not normally be a mitigating practice to increase the impacted population at higher noise levels in order to reduce increases at lower noise levels.

Recognizing that residents located outside the DNL 65 contour experience noise exposure, the FAA did examine noise at residential and other noise-sensitive facilities located in areas less than DNL 65. The noise impacts to St. Charles that can be expected with the implementation of Alternative W-1W are evaluated in Appendix Q of the FEIS. Table Q-1 in Appendix Q of the FEIS indicated that DNL levels will increase at three of the six grid points analyzed. However, in no instance was the DNL level in excess of DNL 60 dB with the proposed action. The table also indicates that the DNL level will decrease at three of the six grid point locations, again, with none of the locations experiencing DNL levels greater than DNL 60 dB with the proposed action. Therefore, residential land uses in St. Charles are compatible under Federal guidelines and no mitigation is required. No mitigation is warranted in St. Charles.

Comments on the DEIS stated that DNL 65 dB is not an appropriate standard for the examination of noise impacts or the establishment of the mitigation program for the Lambert expansion. The FAA explained this issue in the responses to Comments 3-10, 3-45, 3-56, 3-58, 3-67, 3-100, and 3-101 in Appendix V of the FEIS.

In summary, DNL is an appropriate noise metric and DNL 65 dB is an appropriate standard of significance. The FICON report states in Section 3 Airport Noise Policy Recommendations, “All Federal agencies have now adopted DNL as the metric for airport noise analysis in NEPA (EIS/EA) documents.”

11. Use of supplemental metrics for speech interference and sleep disturbance

Commenters requested that FAA should use supplemental metrics to determine speech interference and sleep disturbance impacts in St. Charles.

In keeping with the guidance provided by FICON, the use of supplemental metrics (such as single-event analysis) is best left to the discretion of individual agencies. At the onset of the study, and again later in the study after additional information was available, the FAA made a policy decision that the noise analysis in the FEIS would be based on DNL contour analyses. The FAA further found that the use of supplemental metrics to analyze noise conditions in the City of St. Charles was not necessary. However, in response to comments received on the DEIS, the FAA did prepare a DNL Grid Point analysis for several sites located within St. Charles County. The results of this analysis, contained in Appendix Q of the FEIS, indicate that DNL levels at each of the six modeled locations would be below DNL 60 dB for both the 2002 and 2015 study years.

<u>Time-Above Analysis</u> - The FAA's decision that a Time-above analysis is not needed in St. Charles is based upon the results of the DNL grid point analyses, which indicate that St. Charles will experience noise levels below DNL 60 dB. The time-above analysis has no standards or guidelines against which it can be compared, so it provides relatively limited information.

<u>Speech Interference and Sleep Deprivation</u> - As discussed above, supplemental noise analysis was done by evaluating noise impacts and noise-sensitive areas in St. Charles (FEIS Appendix Q). This analysis confirmed that the cumulative noise exposure levels will not exceed DNL 60 dB with the proposed action.

The FEIS does not include supplemental noise analysis concerning speech interference or sleep deprivation in St. Charles. <u>Impact of Noise on People</u> (USDOT May 1977) indicates that below DNL 65 dB less than 10 percent sentence interference occurs outdoors with normal voice level and 2 meters separation. Indoor interference does not begin to appear until the DNL 70 dB level is reached. At these levels of cumulative noise exposure, only 8 percent of the population experience sleep disruption at DNL 65 dB and only 1 percent at DNL 55 dB. At levels below DNL 60 dB, less than 2 percent sentence interference occurs outdoors with normal voice level and 2 meters separation. Based on these indicators, the FAA decided that the FEIS did not need to analyze potential speech interference or sleep deprivation impacts in areas surrounding Lambert that would be exposed to aviation noise at levels below DNL 60 dB.

With regard to the St. Charles historic river front district, in particular, the FAA did not analyze speech interference or sleep deprivation impacts for that area, because the INM grid analysis included in Appendix Q of the FEIS indicates that St. Charles will be below DNL 60 dB. The FICON report states in Section 3 Airport Noise Policy Recommendations, "...because public health and welfare effects below DNL 60 dB have not been well established, the FICON decided not to recommend evaluation of aviation noise impacts below DNL 60 dB." Since St. Charles is below DNL 60 dB with the proposed airport noise exposure, further evaluations of aviation noise impacts, such as speech interference and sleep deprivation effects, in St. Charles were not deemed necessary for the FEIS.

In addition, although not required, STLAA has committed to monitor noise for one year and to adjust the boundaries of the noise mitigation program in the unlikely event that actual noise levels exceed those predicted in the FEIS.

12. Unacceptable noise and vibration impacts in the St. Charles historic district, the Goldenrod Showboat and Frontier Park

Citizens of St. Charles believe that noise and vibration impacts will be unacceptable in the St. Charles historic district and two of its unique resources, the Goldenrod Showboat and Frontier Park.

The issues of noise exposure and vibrations on the City of St. Charles and its historic district have been thoroughly discussed throughout the FEIS (Sections 5.1 and 5.5). The effects of Alternative W-1W on the City of St. Charles, including noise and vibration impacts, are also documented in FEIS Appendix Q and FEIS Appendix V in numerous responses to comments, such as numbers 3-17, 3-43, 3-54, 3-56, 3-57, 3-58, 3-68, 36, 11-2, 11-6, 23-46, 23-47, 23-53, 23-54, 23-55, 23-56, 23-57, and 23-58.

The FAA uses 1.5 dB increases in the DNL 65 dB noise contour as the standard for evaluating the effects of increases in aircraft noise on historic properties used as residences and for outdoor music areas or amphitheaters, fulfilling the requirements of 36 CFR 800.9. This is based on FAA's land-use compatibility guidelines under 14 CFR Part 150. For other historic properties, the FAA considers whether noise or other impacts due to the proximity of the project substantially impair the activities, features, or attributes of the resource.

The historic properties in the City of St. Charles, including the Goldenrod Showboat, are not expected to be within the DNL 65 dB noise contour as a result of Alternative W-1W. The results of the FAA's noise analysis indicate that with the proposed W-1W improvements, cumulative aircraft noise levels will be below DNL 60 dB in the St. Charles historic district, including the Goldenrod Showboat and Frontier Park. DNL grid sites in St. Charles for future years 2002-2015 will range between DNL 48 and 58 dB (FEIS Appendix Q). Therefore, neither the Goldenrod Showboat, a national historic landmark used for performances, nor Frontier Park, used for festivals, will be significantly impacted by the project.

There are no impacts in St. Charles that require mitigation, and there will be no new substantial incompatible land uses as defined by FAR Part 150 guidelines. Impact of Noise on People (USDOT May 1977) indicates that at levels below DNL 60 dB, less than 2 percent sentence interference occurs outdoors with normal voice level and 2 meters separation. Indoor sentence interference will occur even less frequently as a result of the exterior-to-interior noise reduction provided by the Goldenrod Showboat. Aircraft noise levels of this magnitude will not have a significant impact on the many plays and events that occur on the Goldenrod Showboat or the festivals in Frontier Park.

One commenter noted that people occupy and care for many of the historic buildings. Under FAA noise compatibility guidelines, these buildings will continue to be compatible land uses appropriate for residential homes. Therefore, the proposed alternative will have no effect on historic properties within the City of St. Charles. The Missouri SHPO and the Advisory Council have concurred with the FAA on the area of potential effect, which encompassed land areas above DNL 65 dB.

To summarize, regarding noise impacts on historic properties in St. Charles, noise levels below DNL 60 dB are not considered significant. All land uses, including historic properties, are considered compatible with noise levels below DNL 60 dB. Given that noise levels in St. Charles are projected to be below DNL 60 dB with Runway 12W/30W in operation, it is unlikely that noise will significantly impact the daily lives of the citizenry of St. Charles, their carefully preserved national historic district, or the annual outdoor celebrations of their heritage. Therefore, the FAA has concluded that the new runway will not significantly affect the heart of St. Charles or its national historic district.

Regarding vibration impacts, generally, overflights by fixed-wing, subsonic aircraft do not generate vibration levels of the frequency or intensity to result in damage to structures. It has been found that exposure to normal weather conditions, such as thunder and wind, usually have more potential that could result in significant structural vibration than aircraft. Two recent studies that involved the measurement of vibration level resulting from aircraft operations upon sensitive historic structure concluded that aircraft operations do not result in significant structural vibration. Additional details regarding this comment are addressed in Section 5.1.6, Vibration Resulting from Aircraft Operations, in the FEIS.

13. Effect of Bridgeton's planning and zoning laws on airport expansion

The City of Bridgeton believes that the effects of its planning and zoning laws on the proposed Lambert expansion were not adequately considered by the FAA and STLAA.

In April 1996, the City of Bridgeton sued the City of St. Louis to block the proposed expansion plan. The lawsuit alleged that City of St. Louis officials were taking away Bridgeton's constitutional right to determine how its land is used, by expanding the airport onto land not zoned for airport use. The City of Bridgeton stated that Missouri law gives its residents control over airport expansion by allowing city officials to determine whether any land is zoned for airport use. The suit asserted that Missouri Revised Statutes, Section 305 prohibits the City of St. Louis from building an airport or landing field in any city in violation of zoning regulations. Since the proposed airport acquisition area in Bridgeton has not been zoned for airport use by the City of Bridgeton, the City of Bridgeton asserted that the proposed expansion plan cannot be built. The suit also claimed that the right of the City of Bridgeton to determine this zoning is guaranteed by the Missouri State Constitution and State statutes, and that as a Constitutional Charter City, Bridgeton is granted by the Missouri Constitution (Article VI, Section 19(a)) full authority to designate zoning within its borders.

The City of St. Louis moved to dismiss the lawsuit on the grounds that it was premature before the FAA issues its Record of Decision. On the merits, St. Louis maintained that the Missouri courts held in a previous suit of a similar nature, that upon balancing the needs of a community, i.e., a local city versus the needs of a metropolitan area for an airport, the needs of the metropolitan area are superseding.

The court dismissed the case, stating that until the FAA issues a ROD, no legal grounds exist to try the case. The outcome of the litigation does not affect the decisions of the FAA following completion of the FEIS. Whether the City of St. Louis is required to obtain a local permit is, in the circumstances, a matter of local law and is not relevant to the approval of the Federal actions pertaining to the expansion of Lambert. The FAA assumes that if the ordinances are finally determined to be applicable to the City of St. Louis, then the City of St. Louis will comply with them or will be exempted.

For the reasons discussed above, there may be little or no inconsistency with local plans. With regard to any restrictions on land acquisition by the City of St. Louis for essential aviation safety and aircraft operation purposes, the FAA notes that such planning policies may be of questionable applicability and legal validity, both under state and Federal law.

This issue was covered previously in the FEIS Sections 5.2.5.1 and 5.2.5.3 and in FEIS Appendix V responses to Comments 5-53, 6-23, and 6-24.

14. Effects of Alternative W-1W on the City of Bridgeton

The City of Bridgeton and its citizens commented that Alternative W-1W would destroy a large part of Bridgeton and there would be effects on the Bridgeton City Hall/Police Station complex.

The FAA acknowledges that Alternative W-1W will cause significant impacts to the City of Bridgeton including community disruption; displacement of residents; acquisition of community properties, parkland, historic properties, and community facilities; and changes to the local road network. Section 6.3 of the FEIS outlines specific measures to mitigate these impacts.

The FAA recognizes that people's lives will be adversely affected by the acquisition of their homes. The FAA will take all measures available to ensure that the STLAA minimizes the impacts as much as possible and to ensure that programs are implemented in a fair and equitable manner. The disruption of established neighborhoods and displacement of residents will be mitigated by ensuring that all property acquisitions and relocations are implemented according to the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970. The airport has committed to expediting and streamlining the acquisition process, after project approval, to minimize the amount of time residents will have to remain in neighborhoods where acquisition would be required. A relocation plan, developed in accordance with the Uniform Relocation Act, will be designed to minimize relocation impacts as much as possible. The relocation counselor assigned to each resident will provide advisory assistance to alleviate the stress associated with moving to a new location.

Because there will be a small area of new residential noncompatible land use in Bridgeton, the FEIS includes specific mitigation for the residential portion of Bridgeton that will be impacted by levels above DNL 65 dB (Section 6.3.1 and Figures 6.2 and 6.3 in the FEIS). Mitigation is not included for the portions of Bridgeton that will be impacted by noise levels below DNL 65 dB, because they are considered a compatible land use.

Section 5.3 of the FEIS discusses the acquisition of commercial properties in Bridgeton. All properties acquired will be entitled to fair market value, including commercial properties, and will be subject to the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970.

The realignment and/or closure of portions of the local roadway network will be minimized in order to reduce the impacts to the local communities. Those roadways that will be removed are associated with facilities within the acquisition areas. Other areas will be adequately served by the relocated roads. Prior to the construction of any proposed roadway improvements, MoDOT will develop a Maintenance of Traffic Plan designed to reduce impacts of roadway construction and maintain access during construction (Section 6.3.13 of the FEIS).

The effects on Bridgeton City Hall/Police Station complex were previously addressed in the FEIS Appendix V, responses to Comments 5-43, 29-46, 29-58 and 29-74. Alternative W-1W will not have a direct impact on the Bridgeton City Hall. The FEIS indicates that with the proposed action Bridgeton City Hall would be in the 70 DNL noise contour. Unless the existing structure includes noise attenuation of 25 dB, City Hall would be rendered incompatible in light of its governmental services and office uses, even without noise insulation measures. St. Louis will offer to provide any necessary soundproofing and is willing to work with Bridgeton to relocate City Hall, if necessary.

Parks and recreation facilities to be impacted by Alternative W-1W are described in Section 5.7 of the FEIS. The City of Bridgeton has been consulted regarding these impacts and the potential candidate mitigation sites. The proposed candidate mitigation sites are described in detail in the Section 303 and 6(f) Evaluation, which was released concurrently with the FEIS, and summarized in Section 6.3.5 of the FEIS.

The FAA has considered alternatives that avoid historic properties. As discussed in the Section 303 document, the FAA determined that due to environmental and social consequences, there was no prudent or feasible alternative to avoid the following historic properties in the City of Bridgeton: the Bridgeton Inn, the Airport News Building, the Emmanuel Blum House, the Blum Store, and the De Hatre House, which are eligible for inclusion in the National Register of Historic Places; and the Village à Robert Cemetery (which encompasses the current Bridgeton Memorial Park), which is eligible for inclusion in the National Register of Historic Places under National Register Criterion D. Therefore, there will be an adverse effect on these historic properties, pursuant to 36 CFR 800.9(b). Treatment measures for these adversely affected historic properties are included within the MOA for the selected alternative, W-1W. The MOA was signed by FAA, the SHPO, and the Advisory Council. The STLAA signed as a concurring party. The City of Bridgeton was invited to participate as a concurring party to the MOA, but it chose not to concur in the MOA. The Advisory Council executed the MOA on May 29, 1998. A copy of the MOA is included in Appendix H of this ROD.

15. People Building Community survey objections

People Building Community objects to a survey accomplished as part of the MPS, and referenced in the FEIS, which claims that the majority of residents want to be acquired. A detailed description of this survey, conducted in October 1995, by a subcontractor to the MPS consultant, is contained in Section 8 of the MPS. People Building Community wants FAA recognition of the results of the Peters Marketing Research Survey showing strong Bridgeton opposition to expansion. The FAA's responses to comments on the FEIS submitted by People Building Community are contained in Appendix A of this ROD.

The FAA did not rely on the results of the referenced survey to make its decision. Its existence was only mentioned in the FEIS for informational purposes. Its mention was not intended to minimize or dismiss the concerns of neighboring communities. While the conduct of social surveys might provide information of interest to area residents, the information would not alter or affect the conclusions of an EIS process. The purpose of the EIS was to analyze the potential environmental impacts of the proposed improvements upon the communities surrounding the airport. In some cases, there were no impacts to the communities. In others, there were even positive effects overall. Where there were significant adverse impacts, the EIS examined mitigation to lessen the adverse impacts. The FAA's EIS identified the anticipated impacts associated with the alternatives analyzed and outlined the proposed measures for mitigation for significant impacts associated with the Alternative W-1W.

It is recognized that the impact categories of principal concern to neighboring residents are noise and land acquisition. The social impacts resulting from the airport development would include the displacement of persons, homes, businesses, and community facilities. These would be mitigated by ensuring that all property acquisition and relocations be implemented according to the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970.

The FAA recognizes that the acquisition/relocation process can be a difficult and emotionally upsetting experience for homeowners. As part of its land acquisition programs, the STLAA offers advisory services to those being relocated. Part of that advisory service is to notify those relocatees of special programs being offered by different agencies. This includes first-time home buyer programs, loan information, and assistance in understanding the various documents.

The FAA has acknowledged throughout the EIS process that some segments of the community strongly oppose the proposed plan. The comments provided by agencies, associations, elected officials and individuals have been thoroughly evaluated by the FAA during the EIS process and have been carefully considered in the development of this ROD. This included the FAA's review of the results of the Peters Marketing Research Survey, which People Building Community requested the FAA to consider. This survey was conducted to determine how many Bridgeton residents feel about the airport expansion.

The FAA acknowledges that there are also residents in the area of the proposed expansion, including Bridgeton residents, who feel they have been held hostage by the expansion process. Given the length of time needed to prepare the planning studies on the proposed expansion, this is understandable. The STLAA has received approximately 250 letters from residents, who indicated that they either need or want to move from their residence because of different hardship situations (STLAA letter dated

July 9, 1998, in Appendix I). The STLAA has received inquiries from another 150 residents, who wish to have their property purchased and move on with their lives. Many of those citizens have also called the FAA's Regional Office over the last several months to express those same views to the FAA decisionmakers on the ROD. The Let's Get On With Our Lives group, which consists of over 1,200 people living in the area proposed for acquisition, has requested that the FAA make a final decision on the Lambert as quickly as possible so that they can relocate (Don Vandervort letter, dated July 9, 1998, in Appendix I).

The FAA has carefully assessed and considered both sides of the issue in making its decision. Fair consideration has been given to the interests of communities in or near the project location throughout the EIS process.

16. Bridgeton's non-concurrence in DOT Section 303/DOI Section 6(f) process

Bridgeton has notified the FAA that it cannot concur in the DOT Section 303/DOI Section 6(f) process, because it believes that the alternative selected did not safeguard park land and other resources warranting special protection. Bridgeton commented on this issue after release of the DEIS, and its position has not changed since that time. For FAA's responses to Bridgeton's comments on this issue, see FEIS Appendix V, numbers 2-78, 10-10, 10-26, 10-27 and 10-34.

FAA environmental documents must provide evidence that replacement of affected Section 6(f) lands to the satisfaction of the Secretary of the Interior will be accomplished. Through its grant agreements, the FAA will require STLAA to comply with mitigation provisions of the FEIS related to replacement of Section 303 and Section 6(f) lands.

As documented in the Section 303/Section 6(f) Evaluation and the FEIS Section 5.7, the FAA will require STLAA to provide the responsible jurisdiction with the funds necessary to replace the converted land. In this case, the City of Bridgeton is considered to be the project sponsor, or subgrantee. It is generally held that in the event the subgrantee is unable or unwilling to replace the converted property, the State becomes fully responsible for actual replacement. Since the City of Bridgeton has declined to participate in the process of selecting and securing replacement lands, responsibility for replacement falls upon the MDNR. If Bridgeton continues to decline to participate in the process, the FAA will require STLAA to provide the funds to the MDNR for replacement of converted lands, providing that conversions-in-use are approved.

On January 28, 1998, the Department of Interior provided its final comments on the FEIS, the Section 303/Section 6(f) Evaluation, and the Section 106 process. Appendix

A of the ROD contains the DOI letter and FAA's responses to those comments. The receipt of DOI's comments completes consultation under Sections 303/6(f).

17. Bridgeton's non-concurrence in MOA for historic/archaeological resources

The City of Bridgeton notified the FAA that it could not concur in the MOA for proposed improvements at Lambert, because the City did not agree with the selection of Alternative W-1W.

As discussed in Section 6 of this ROD, on May 29, 1998, the Advisory Council executed the MOA for the proposed improvements at Lambert (Appendix H of this ROD). Other signatories to the MOA are the FAA and the Missouri SHPO. The STLAA signed the MOA as a concurring party.

The MOA stipulates measures to be implemented to avoid, reduce, or mitigate the adverse effects from this project on historic properties. The SHPO, the Council, the STLAA, and the City of Bridgeton have been consulted on the MOA and provided comments on the agreement document throughout its development (FEIS Appendix N-1, November 18, 1997, letter from MDNR, and November 14, 1997, letter from City of Bridgeton). The FAA solicited final comments on the MOA from the consulting parties, including the City of Bridgeton. As noted above under response to Comment 14, the City of Bridgeton chose not to sign the agreement.

On June 10, 1998, the FAA notified the following parties that the MOA for the Section 106 process had been executed by the Advisory Council: Deputy SHPO at MDNR; DOI; MoDOT, STLAA, and Bridgeton. By entering into and having STLAA carry out the terms of the Agreement, FAA has fulfilled its responsibilities under Section 106 of the National Historic Preservation Act and the Advisory Council's regulations.

18. Analysis of special purpose laws

Compliance with special purpose laws (e.g., for wetlands, water quality, and floodplains) was raised in comments on the DEIS, which are addressed in the FEIS Appendix V response to Comment 2-78.

All of the development alternatives studied in detail have unavoidable impacts on resources protected under Section 303 of the Department of Transportation Act and Section 6(f) of the Land and Water Conservation Fund Act. There are no possible or prudent alternatives to the use of these resources. Of the development alternatives, Alternative W-1W would use approximately half the park and recreational resources and acres required for S-1.

All of the reasonable alternatives have unavoidable wetland impacts due to the proximity of wetlands to the airport. Consequently, there are no practicable alternatives to filling of wetlands. Of the development alternatives evaluated, Alternative W-1W would have the least amount (acreage) of wetland impacts. This information is displayed in Table S.1A of the FEIS (Appendix J of this ROD, page S-9).

Impacts of the project on water quality have been examined in Section 5.6 of the FEIS. See also response to Comment 9-6 in Appendix V of the FEIS. The MDNR also provided its assurance that state water quality standards would be met with the project (MDNR letter dated November 20, 1997, in Appendix A of the FEIS). On August 11, 1998, the Governor of the State of Missouri provided a letter to the FAA certifying that there is reasonable assurance that the proposed construction and operation of the expansion of Lambert will be located, designed, constructed and operated so as to comply with applicable water quality standards (Governor's letter dated August 11, 1998, in Appendix I of this ROD.)

Potential impacts on floodplains were thoroughly evaluated in the FEIS. There is no practicable alternative to the floodplain impacts of the proposed project. Mitigation measures to minimize the floodplain impacts can be accomplished for each alternative so that the floodplain encroachment would not be considered significant. The floodplain mitigation measures are described in the FEIS Section 6.3.8. See also response to Comment 25-4 in FEIS Appendix V.

19. Adequacy of air quality conformity determination

The City of Bridgeton believes the air quality conformity determination prepared by the FAA is inadequate.

Bridgeton's comments on air quality issues were addressed in the FEIS Appendix V responses to Comments 7-18, 7-19, and 7-31 and in the Final General Conformity Determination. Based on EPA, MDNR, and other comments on the DEIS, the FAA has revised and supplemented the air quality analysis in the FEIS and prepared a Draft and Final General Conformity Determination. These documents and supporting underlying material are available for public review. Both EPA and MDNR indicated that the Draft General Conformity Determination was adequate. The Governor has also certified a reasonable assurance that the project will be designed, built, and operated in conformance with applicable air quality standards (Appendix I of this ROD).

The FAA has been very diligent in addressing air quality concerns. In response to comments made by the City of Bridgeton on the DEIS, the FAA revised its air quality analysis to address the effects of FAA Safety Notice N7110.157, "Wake Turbulence," upon the operational assumptions for air quality emission inventories. This notice, which was issued during preparation of the DEIS, has the effect of reducing airport capacity due to recategorization of certain aircraft types and a resulting increase in separation standards. The Safety Notice results in potentially constraining the 2015 No-Action Alternative at approximately 532,000 operations a year instead of 595,000 as originally projected in the DEIS. The results of the revised analysis show that, with the exception of NOx emissions in 2015, the development alternatives improve air quality in the St. Louis area in comparison with the No-Action Alternative. This is largely the result of increased airfield operational efficiency and reduced delay periods (FEIS Section 5.5.6).

In consultation with the EPA and MDNR, the FAA prepared Draft and Final General Conformity Determinations to address emissions associated with Alternatives S-1 and W-1W, specifically focusing on NOx, CO and VOCs. In December 1997, the FAA issued its Draft General Conformity Determination, along with the FEIS. In June 1998, the FAA issued the Final General Conformity Determination. It was subsequently announced in the *St. Louis Post Dispatch*. By issuing this Final Determination, the FAA has fulfilled its affirmative responsibilities to assure conformity of proposed Federal actions under Section 176(c) of the Clean Air Act, as amended in 1990.

20. Concerns of EPA regarding FAA's air quality modeling assumptions in DEIS

The EPA had questions regarding the assumptions used by FAA in its air quality modeling assumptions in the DEIS.

Based upon the EPA comments received on the air quality analysis in the DEIS, the FAA revised and supplemented information in the FEIS. That information was summarized in the FEIS Section 5.5, and is included in Appendices A and M. The FEIS Appendix V contains responses to EPA's comments on the DEIS (Comments 7-18, 7-69, 7-72, 7-73, 7-81 and 7-85).

Regarding air quality modeling, while EPA agreed that there would be no significant air quality impacts associated with the proposed project, it stated that its conclusion was based on air modeling done by MDNR. The Emissions Dispersion Modeling System (EDMS) is the FAA's preferred model for performing air quality analysis on airports and was utilized in this case for developing project emission inventories for NEPA and general conformity purposes. The development alternative would reduce carbon monoxide (CO) emissions compared to the No-Action and the project so that the project was clearly *de minimis* for CO under general conformity requirements. Although no further analysis was necessary, in response to requests from EPA and MDNR the FAA also conducted a microscale dispersion analysis to address "CO hotspots." It was determined, with EPA's concurrence, that the CAL3QHC and ISCST3 models would be appropriate to conduct this dispersion analysis. Based on the entire assessment of air quality, including modeling, we concluded that there would be no significant impacts to air quality in the St. Louis area. The modeling conducted by MDNR provided independent, definitive, corroboration of the conclusion. The EPA and MDNR have agreed that inclusion in this ROD of the results of the modeling done by MDNR resolves the air quality concerns expressed in EPA's letter dated February 27, 1998.

As noted above, MDNR provided its assurance that state air quality standards would be met with the project (MDNR letter dated November 20, 1997, in Appendix A of FEIS). On August 11, 1998, the Governor of the State of Missouri provided a letter to the FAA certifying that there is reasonable assurance that the proposed construction and operation of the expansion of Lambert will be located, designed, constructed and operated so as to comply with applicable air quality standards (Governor's letter dated August 11, 1998, in Appendix I of this ROD.)

As discussed in number 19 above, on June 19, 1998, the FAA made its Final General Conformity Determination. A legal notice announcing the Final General Conformity Determination was published in the *St. Louis Post Dispatch* on June 29, 1998. By publishing this Final Determination, the FAA has fulfilled its responsibilities under Section 176(c) of the Federal Clean Air Act.

Therefore, the FAA believes that the analysis of air quality impact satisfies the requirements of NEPA, including public disclosure requirements, and other air quality statutes.

21. Length of FEIS review period

Citizens commented that thirty days to review the FEIS was too short and believed the FAA ignored their comments.

FAA carefully reviewed all comments made by the public and local, state, and Federal agencies during the EIS process. The DEIS was available for review and comment from September 27, 1996 through January 17, 1997. A public hearing, attended by over 1580 people, was held, affording each of them the opportunity to provide written or verbal comments to court reporters. The FAA then carefully reviewed over 15,000 letters received on the DEIS. The FAA aggregated these comments and concerns into 29 major categories for review and written response by qualified personnel. All suggestions were taken into consideration and changes were made to the FEIS where appropriate. In addition, the FEIS was revised in some instances to make it clearer and easier to read and understand. All letters, as categorized, were available for public review at Lambert and at the FAA Regional office in Kansas City, Missouri. All comments received, whether in the form of testimony given to the court reporters at the public hearing or in the form of letters, were summarized, and responses were provided in the FEIS Appendices S, T, U, and V. Appendix W contained a list of commenters. The FEIS Volumes 1, 2, and 3 were available at 21 city halls and 11 libraries.

The 30-day review period after release of the FEIS is not a public comment period, but rather a minimum period that a Federal agency must wait before issuing a Record of Decision. The FEIS review period is required by CEQ regulation to be no less than 30 days. The review period for this FEIS was approximately 58 days. Late filed comments were considered as practicable. Much of the material provided to the public in the FEIS was not new information, as it was simply clarification or enhancement and refinement of material already in the EIS or was in other documents available during review of the DEIS. CEQ regulations permit the FAA to summarize and respond to comments in the FEIS.

Appendices A and B of this ROD contain responses to comments received during the FAA's review or "waiting" period. Appendices C, D, E and G of this ROD contain responses to comments from ALPA, NATCA, Bridgeton Air Defense, the City of Bridgeton, the City of St. Charles, the St. Charles County Executive, and U.S. Congressman Talent. All comments received by the FAA were reviewed and considered during the decision-making process for this ROD.

22. Inappropriate public hearing format

Commenters stated that the public hearing format was inappropriate. They would have preferred a "town hall" format. Commenters indicated that the FAA failed to provide an adequate opportunity for public input in a "formal" public hearing; therefore, they concluded that fair consideration had not been given to the interests of the communities near the project location.

The FAA recognizes that the "town hall" format is the more traditional approach. However, the format the FAA chose to use was equally acceptable and appropriate. The FAA exceeded NEPA requirements, which do not require Federal agencies to conduct public hearings, when it held the public hearing for the proposed action at Lambert. Federal agencies have wide latitude to structure public hearings as appropriate to facilitate public input for consideration in the decision-making process.

The public hearing was also held to afford an opportunity for a public hearing "to consider the economic, social and environmental effects of the [project] and the [project's] consistency with the objectives of any planning that the community has carried out" (*49 U.S.C. 47106(c)(1)(A)(I)*). The City of St. Louis must certify that this opportunity was provided to qualify for eligibility to receive funds for major airport development projects under the FAA's Airport Improvement Program.

Title 49 U.S.C. 47106(c)(1)(A)(I) does not dictate the manner in which the hearing should be held. No case law requires that a "town hall" or any specific type of hearing take place. The public hearing held for the proposed project met and exceeded the statutory standard that opportunity be provided to consider the effects of the proposed action. The record demonstrates that such opportunity was provided in this case.

The public hearing was held near the airport during the hours of 3 p.m. to 8 p.m. on October 28, 1996. Approximately 1,580 people attended. It was held in an open meeting format. The public could interact with FAA personnel and FAA's consultants at numerous displays or stations, and react to hearing materials provided, presentations made, and the DEIS. Persons could leave written comments, provide oral comments to court reporters, or submit written comments to FAA up until January 17, 1997.

Citizens accessed the public hearing area from an entryway where they were given a proposed project information packet, which contained information about the public hearing format, how to make public comments and a copy of the FEIS Summary about the proposed project itself. Citizens then proceeded through a videotape area, which provided additional information about the proposed project.

In the large hearing room, FAA employees and government contractors, who were involved in the environmental study process, were present the entire time to answer questions and explain exhibits, which were provided to give further information about the proposed project. Government representatives were clearly identified by name tags and circulated through the hearing room to provide opportunity for face-to-face information exchange. All government representatives and contractors present responded to all information sought from them and answered all questions asked of them. This format allowed citizens to view the materials and absorb information at their own pace. Citizens were able to talk to government and contractor representatives directly to obtain meaningful information exchange. In addition, the format allowed citizens to confer among themselves or in small groups with government or contractor representatives in an open forum.

In the middle of the hearing room, all citizens were given opportunity to provide written comments on the proposed project or comments of other persons. In an adjacent area, four court reporters were available to record verbal comments. Citizens had the choice to comment in writing, or verbally to a court reporter. This hearing format provided meaningful, informed community input to this public project. The public was informed about potential economic, social and environmental impacts of the proposed project by government representatives through the information packet, information displays and exhibits and the face-to-face interaction and information exchange. The opportunity for public comment was afforded in an orderly and open manner. All citizens who wished to comment at the hearing were provided with the opportunity to do so.

The format of the public hearing was selected to allow the attendees to view the materials at their leisure and talk to study team members. In addition, the format allowed for the attendees to talk among themselves and study team members in an open forum. Citizens had the choice to comment in writing or verbally to a court reporter. These are the same choices that would have been available had the FAA used an alternate format.

All comments received were responded to in the FEIS. In this way, informed public comments generated by the public hearing process were communicated to the public and taken into account by decision-makers. The public hearing provided ample opportunity to consider the "economic, social and environmental effects" of the proposed project (*40 U.S.C. 47106(c)(1)(A)*).

For a review of FAA's responses to comments received specifically regarding the public hearing format, see FEIS Appendix V Comments 21-17, 21-26, 21-27, 23-17, and 23-23.

23. Potential conflict of interest for FAA contractor

St. Charles Executive Ortwerth believes that FAA's contractor had a conflict of interest, because data compiled by Greiner were used in the MPS, as well as the EIS, and because St. Louis paid Greiner.

Specifically the commenter argues that Greiner had a conflict of interest for the following reasons:

- Greiner could not assist the FAA in accomplishing an independent review of alternatives as the FAA claims in FEIS response to Comment 2-72 because in April 1995 Greiner prepared an environmental evaluation of alternatives and baseline environmental information for the MPS.

- The MPS indicates that Greiner prepared the environmental evaluation of alternatives. Greiner did not prepare the information for the EIS then provide it to St. Louis as claimed in response to Comment 23-39 of the FEIS because Greiner did the work in April 1995 and scoping for the EIS began in September 1995.

- Greiner was intimately involved in developing the justification for the project; there is no evidence to justify that the FAA conducted an independent review of alternative studies of the alternatives rejected; very little independent work has been generated that distinguishes the EIS from the MPS prepared by the City of St. Louis.

- Greiner was paid by the project sponsor.

Under 40 CFR 1506.5(c) if a Federal agency decides to select a consultant to prepare the EIS, the consultant must “execute a disclosure statement ... specifying that [it has] no financial or other interest in the outcome of the project. A consultant with a known conflict of interest “should be disqualified from preparing the EIS.” (CEQ 40 Questions, 46 Federal Register 18,026 18,031)

Whether there is a conflict of interest depends upon the definition of “financial or other interest” under 40 CFR 1506.5(c). In 1981, the CEQ interpreted the provision “broadly to cover any known benefits other than general enhancement of reputation.” (CEQ 40 Questions 46 Federal Register at 18,031). Even then, the CEQ instructed agencies that contractors may bid in competition with others for future work on a project if the contractor has “no promise of future work or other interest in the outcome of the project.” (40 Questions at 18,031). Subsequently, the CEQ clarified that, absent an agreement to perform construction on the proposed project or actual ownership of construction site, it is “doubtful that an inherent conflict of interest will exist” unless “the contract for the EIS preparer contains ... incentive clauses or guarantees of any future work on the project.” (Guidance Re: NEPA Regulations, 48 Federal Register 34,263 34,266, CEQ, 1983).

In this case, after a competitive bidding process, the FAA selected URS Greiner in November 1992 to prepare the EIS. Greiner’s contract was executed with STLAA in 1993.

In April 1995, the FAA requested that Greiner prepare preliminary environmental evaluations so that the FAA could begin to meet its responsibilities to evaluate other reasonable alternatives in preparation for the EIS. To assure consistency in the environmental analysis done as part of the ongoing Part 150, environmental and master planning studies, the FAA had Greiner submit this baseline environmental information and its environmental analysis of alternatives to St. Louis for use in its master planning and airport noise compatibility (14 CFR Part 150) studies. This practice was instituted several years ago as a practical matter to ensure consistency between the two processes. It arose, in part, as a result of a lawsuit filed by the City of Bridgeton, which challenged approval of the use of passenger facility charges for noise mitigation projects. The major issue was the adequacy of the environmental analysis, because the noise analysis done by the consultant that prepared the Part 150 study differed from that done by another consultant as part of a concurrent environmental study.

This practice does not constitute a conflict of interest. URS Greiner has executed the disclosure statement required under 40 CFR 1506.6(c) specifying that it has no financial or other interest in the outcome of the project. URS Greiner's only assignment at Lambert has been to assist the FAA in the EIS and at no time during the Lambert expansion process have they been involved in any other contract that could be construed to represent a conflict of interest. There have been no guarantees of future work or incentive clauses in the EIS contract.

While Greiner did prepare the environmental overview for the FAA, which was used as an appendix in the MPS, it did not participate in the STLAA's development of the airport facility needs or the selection of its preferred alternative for the project. Nor did Greiner's preparation of this factual information interfere with its ability to assist the FAA in using its judgment to independently review the range of primary and secondary alternatives to decide which to analyze in the FEIS. The FAA was actively participating in the MPS process at this point. This participation included independent operational analysis and input regarding the development and analysis of alternatives. Once the MPS was submitted to the FAA, as required, the FAA then independently reviewed and analyzed the development alternatives identified in the MPS as well as exploring other alternatives not identified in the MPS. These alternatives included different runway layouts, construction of a new airport facility as well as some publicly submitted alternatives. For a discussion on FAA involvement in the analysis of alternatives, see Section 3.0 of the FEIS.

Moreover, preparation of this information did not give Greiner any incentive to promote the Alternative W-1W over the No-Action Alternative. Providing information to St. Louis, at the FAA's direction, did not result in an enforceable promise, contract, or expectation of future work on the project or other interest in the outcome of the project so as to compromise the integrity of the NEPA process.

To the extent that FAA's practice could be perceived to give rise to a conflict, the FAA exercised a sufficient degree of supervision to cure any defect arising from the perceived conflict and preserve the objectivity and integrity of the NEPA process.

When an agency is integrally involved in the preparation of an EIS, that involvement diminishes the threat posed by any potential conflicts of interest because the agency then has the opportunity to direct the analysis and supplement areas it deems deficient. The record indicates that FAA exercised substantial supervision over the preparation of the EIS. Even after Greiner was hired, FAA continued to perform all management activities and only used Greiner's personnel for technical expertise or to supplement staff where there was insufficient manpower. FAA managers made all major decisions involved in the FEIS and Greiner's representatives reported to those managers, sometimes on a daily basis, to receive direction. Throughout the environmental process, approximately 90 percent of one FAA environmental program manager's work hours were dedicated solely to managing Greiner and its work products. Other FAA personnel, including airport planning specialists and air traffic controllers, reviewed and corrected Greiner work products, as needed. In addition, FAA prepared, without Greiner's assistance, those portions of the FEIS addressing airport planning and air traffic control issues, particularly responses to comments in FEIS Appendix V. The FAA independently and extensively reviewed all of Greiner's analyses, commented on Greiner's field data and written product, noted deficiencies in the data and analyses, gave direction to the work, and frequently required Greiner to gather more facts or perform supplemental analysis on aspects of the project. This degree of supervision exercised by the FAA protected the integrity and objectivity of the EIS.

Finally, with respect to the commenter's final point, the payment of Greiner by the City of St. Louis does not present a conflict of interest. Greiner was selected by the FAA to prepare the EIS using a common practice known as third-party contracting. Under this practice, the City of St. Louis entered into a contract with Greiner to fund work done on the EIS under the direction and supervision of the FAA. Approved by CEQ, third-party contracting is utilized by many Federal agencies during the preparation of an EIS (40 CFR 1506.5(c) and Forty Most Asked Questions No. 16). So long as the lead agency, or in certain cases the cooperating agency, selects the consulting firm to do the work, the project sponsor is permitted to pay the consultant. Once selected, the preparer's responsibility is to the lead agency to prepare an EIS that complies with NEPA. Third-party contracting is a voluntary practice that is ultimately beneficial to both the agency and the applicant. By paying for the preparation of the EIS, the applicant ensures that movement of its application will not be determined by the budgetary constraints of the agency it is dealing with. At the same time, the agency in question is able to focus its resources on analysis and evaluation rather than the preparation of the EIS.

In this case, the FAA selected Greiner to prepare the EIS. Greiner's responsibility was solely to the FAA to prepare an EIS that met NEPA regulations and FAA's NEPA procedures. As required by CEQ regulations, a memorandum of understanding (MOU) was executed between St. Louis and FAA setting out the procedures to be followed during the third-party contract process. Under the MOA, it was the FAA's responsibility to determine the scope of the EIS, evaluate all environmental data and analysis submitted by Greiner or St. Louis, and to revise or cause additional study and analysis to be performed as necessary.

In conclusion, none of the commenter's concerns have raised issues sufficient to show that the objectivity and integrity of the NEPA process has been compromised.

Greiner's actions were within the scope of its duties. It has properly disclosed that it had no interest, financial or otherwise, in the outcome of the project. The FAA independently evaluated the alternatives analysis and exercised supervision over Greiner's work.

This matter is also discussed in response to the City of St. Charles FEIS Comment FL0004, Comments 28 through 36 of this ROD.

24. <u>FAA realizes Lambert will not operate as planned and must prepare a revised or supplemental EIS</u>

According to commenters, the FAA has revealed that Lambert will not operate as planned and must withdraw and revise the FEIS or prepare a supplemental EIS to address the proposed new runway use. Specifically, ALPA, NATCA and the City of Bridgeton indicate that the FAA now plans to use the new Runway 12W/30W primarily for arrivals, instead of exclusively for departures in west flow during VFR 1 and 2 conditions (good weather) as analyzed in the MPS and the FEIS. As proof, the City of Bridgeton relies upon an excerpt from a preliminary draft memorandum prepared by Leigh Fisher Associates dated June 16, 1998. The memorandum states, in relevant part, "For W-1W, the Tower representatives recommended assuming no significant use of visuals to the close parallels (see response to Comment 7 below)." The commenters claim that this change in runway use would significantly impact communities southeast of the airport and requires a revised or supplemental EIS.

The commenters are correct that the environmental impacts in the FEIS, including the noise contours (or footprint), were predicated upon the assumption that the new runway would be used primarily, but not exclusively, for departures during good weather and in west flow. Thus, there would be some arrivals to the new runway. The FAA has not changed its plans for runway use. The statement in the Leigh Fisher Associates preliminary draft memorandum cannot be read in isolation, but rather in the broader context of the sensitivity analysis and related hypothetical assumption concerning arrival rates to which it relates. Appendix C of this ROD clarifies that although this assumption was made, it was only for purposes of modeling. The original assumptions in the MPS and FEIS remain valid. That the FAA elected to include a scenario that featured use of outboard runways during visual conditions and west flow (the "W-1W Outboards Case," see Appendix C, response to Comment 7), did not reflect an FAA realization, decision or intention to change the planned operation of new Runway 12W/30W.

This statement "For W-1W, the Tower representatives recommended assuming no significant use of visuals to the close parallels" is best understood in the context of the related comment from ALPA to which it also responds. As part of its 18 concerns, ALPA also commented that the MPS and FEIS incorrectly assumed that visuals to the existing closely spaced runways would be independent and arrive at a rate of 80 per hour and should have assumed a rate of 60 per hour instead. This change in assumption clearly would have the effect of increasing delays at the existing airport and under Alternative W-1W. By the referenced statement, the controllers at the June 15 meeting meant that, if the arrival rate during visual and west flow use of the closely spaced existing parallel runways was assumed to be only 60 aircraft per hour, then they agreed with ALPA that it should also be assumed that they would try to minimize delays by using the new runway more for arrivals than for departures. That is, to boost the arrival rate they would seek to use both outboard runways (the existing 30R and the new 30W) primarily for arrivals in west flow during VFR-1 and 2 conditions, instead of limiting its use to departures. The capacity studies done for the MPS estimated an arrival rate of 72 aircraft an hour, not 80 as asserted by ALPA.

Internal agency deliberations after the June 15, 1998, meeting and the preparation of this preliminary draft memorandum by St. Louis' consultant, including discussions with the Air Traffic Division of the Central Region, have confirmed that the FAA has not changed plans to operate Alternative W-1W. Those discussions have also confirmed that the assumptions used in the MPS and FEIS are reasonable and reflect the proposed operation of the airport. The results of the sensitivity analysis confirm that an arrival rate of 60 per hour is an unreasonable assumption. It results in delays greater than those currently experienced at the airport now. This issue is discussed in more detail in Appendix G, response to Comment 7.

11. THE AGENCY FINDINGS

In accordance with applicable law, the FAA makes the following determinations for this project, based upon the appropriate information and data contained in the FEIS and the administrative record.

A. The project is consistent with existing plans of public agencies for development of the area surrounding the airport (*49 U.S.C. 47106(a)(1)*).

The determination prescribed by this statutory provision is a precondition to agency approval of airport project funding applications. It has been the long-standing policy of the FAA to rely heavily upon actions of metropolitan planning organizations (MPOs) to satisfy the project consistency requirement of *49 U.S.C. 47106 (a) (1*) [see, e.g., *Suburban O'Hare Com'n* v. *Dole*, *787 F.2d 186, 199 (7th Cir., 1986)*]. Furthermore, both the legislative history and consistent agency interpretations of this statutory provision make it clear that reasonable, rather than absolute consistency with these plans is all that is required.

Under the provisions of both Federal and state law, the East-West Gateway Coordinating Council (EWGCC) has been designated as the MPO for the St. Louis metropolitan area and given primary responsibility for transportation planning in the region. On December 3, 1997, the EWGCC notified the FAA that it endorsed the EIS on the basis that it represented an accurate assessment of the related costs, operational feasibility, and community and environmental impacts. Furthermore, the EWGCC's board had voted to support Alternative W-1W (FEIS Section 5.2.5.3). Thus, Alternative W-1W is reasonably consistent with the plans of public agencies having broad geographic responsibilities in the area.

If the focus is limited to municipalities where land would be acquired for airport expansion, four of the five municipalities (St. Ann, Edmundson, Berkeley, and Hazelwood) have land-use policies for the acquisition areas consistent with W-1W. Alternative W-1W is not consistent with the zoning plans of the City of Bridgeton, but it is not clear that as a matter of state law, Bridgeton is authorized to enforce a zoning plan that is inconsistent with needed airport development.

The FAA finds that the project is reasonably consistent with the existing plans of public agencies authorized by the state in which the airport is located to plan for the development of the area surrounding the airport. The FAA is satisfied that it has fully complied with *49 U.S.C. 47106 (a)(1).*

With regard to this issue, however, the FAA has also reviewed the substantial documentation in the administrative record demonstrating that throughout the environmental process the STLAA has shown concern for the impact of the proposed development actions on surrounding communities. Moreover, the STLAA has attempted to ensure consistency of its project proposals with the planning efforts of neighboring communities. The administrative record for this ROD includes details of coordination between the STLAA and neighboring jurisdictions concerning local planning proposals, along with documents describing the public meetings, hearings, and other means by which public participation in project planning was accommodated. Further discussion of consistency of the proposed development projects with public agency planning is summarized in the FEIS Section 5.2.5.3.

The proposed Lambert expansion lies almost totally within the boundaries of the City of Bridgeton. The extent to which City of Bridgeton regulations apply to Lambert Airport development is unresolved. Meanwhile, the STLAA has offered to assist the City of Bridgeton in land-use planning activities, to address any issues relating to the proposed Lambert development.

The City of Bridgeton has engaged in land-use planning actions, which appear designed to limit airport expansion. Its local plans and ordinances establish zoning policies (a prohibition on use of lands acquired by public entities to be used for new commercial activities). These ordinances purport to restrict the use of some lands within Bridgeton's jurisdiction (e.g., for the new runway), needed by the STLAA in order to implement important safety and aircraft operation aspects of its preferred alternative.

In any event, it is not clear that the development actions proposed in the MPS would be subject to any of the plans and ordinances adopted by the City of Bridgeton. Thus there may be little or no inconsistency with local plans. Implementation of STLAA's preferred alternative would not be expected to result, after mitigation, in any significant increases of noise on land of these neighboring jurisdictions. With regard to any restrictions on land acquisition by STLAA for essential aviation safety and aircraft operation purposes, the FAA notes that such planning policies may be of questionable applicability and legal validity, both under state and Federal law.

In making its determination under *49 U.S.C. 47106 (a) (1)*, the FAA has considered the fact that local governments have been represented on the EWGCC and have participated as members of that organization in its decision to authorize the new runway project at Lambert (although some of these local governments may have disagreed, as individual EWGCC members, with that ultimate decision). The FAA has also recognized the fact that none of these jurisdictions has regulatory authority over airport operations, since long-established doctrines of Federal preemption preclude these communities from regulating aircraft operations conducted at Lambert.

Given the FAA determination in this ROD, under appropriate Federal law, that there is a compelling need for the proposed Lambert improvements, as documented in the FEIS, it is inappropriate for local communities to attempt to exercise local zoning control in a manner which would conflict with the domestic and international aviation requirements of this airport. If there were a conflict between Federal and local policies, the local policies must give way to the Federal policies, under the doctrine of Federal preemption.

B. The interest of the communities in or near where the project may be located was given fair consideration (*49 U.S.C. 47106(b)(2)*).

The determination prescribed by this statutory provision is a precondition to agency approval of airport development project funding applications. The regional planning process over the past decade and the environmental process for this project-specific EIS, which began in 1995 and extended to this point of decision, provided numerous opportunities for the expression of and response to issues put forward by communities in and near the project location. Nearby communities and their residents have had the opportunity to express their views during the DEIS public comment period, at a public hearing, as well as during the review period following public issuance of the FEIS. The FAA's consideration of these community views is set forth in FEIS Appendices J, U, and V and in Appendices A, B, C, D, E and G of this ROD.

Thus, the FAA has determined that throughout the environmental process, beginning at its earliest planning stages, fair consideration was given to the interest of communities in or near the project location.

C. The State of Missouri has certified in writing that there is reasonable assurance that the project will be located, designed, constructed and operated in compliance with applicable air and water quality standards (*49 U.S.C. Section 47106(c)(1)(B)*).

The determination prescribed by this statuary provision is a precondition to agency approval of airport development project funding applications involving a new runway. By letter dated August 11,1998, (Appendix I of this ROD), after consultation with the MDNR (the Governor’s designated agency for air and water quality), the Governor of Missouri, certified that there is a reasonable assurance that the project will meet all applicable air and water quality standards.

The FAA concludes that the airport project evaluated in the FEIS will be located, designed, constructed and operated so as to comply with applicable air and water quality standards.

D. Effect on Natural Resources (*49 U.S.C. Section 47106(c)(1)(C)*).

Under this statutory provision, after consultation with the Secretary of the Interior and the Administrator of the EPA, the FAA may approve funding of a new runway having a significant adverse effect on natural resources, only after determining that no possible and prudent alternative to the project exists and that every reasonable step has been taken to minimize the adverse effect.

As documented in the FEIS, FAA has consulted extensively with both Interior and EPA. For several natural resource impact categories with established significance levels, the FAA finds that, without implementation of the mitigation summarized in Section 6.3 of the FEIS, the selected alternative would have a significant adverse effect. However, given the inability of other alternatives discussed in the FEIS, to satisfy the purpose and needs of the project, we have concluded that no possible and prudent alternative exists to development of the proposed alternative. As discussed in Section 6 of this ROD, and documented throughout the FEIS and the administrative record, every reasonable step has been taken to minimize adverse environmental effects resulting from the project.

In order to consider further mitigation under NEPA, and to address any possible adverse environmental effects resulting from the projects approved in this ROD, the FAA has decided to condition such approval upon the mitigation measures described in Section 6.3 of the FEIS and in Section 6 of this ROD. This conditional approval will be enforced through a special condition included in future Federal airport grants and PFC "use" approvals to the STLAA.

The FAA has determined that all reasonable steps have been taken to minimize any adverse effects on natural resources through mitigation.

E. Appropriate action, including the adoption of zoning laws, has been or will be taken to the extent reasonable to restrict the use of land next to or near the airport to uses that are compatible with normal airport operations (*49 U.S.C. Section 47107(a)(10)*).

The sponsor assurance prescribed by this statutory provision is a precondition to agency approval of airport development project funding applications. In addition to the actions described in Section 11.A of this ROD, the STLAA has worked extensively with local jurisdictions to develop and implement plans and policies to ensure compatible land use in the airport vicinity.

FEIS Section 5.2 describes the current status of zoning and land use planning for lands near the airport. The Airport has an existing noise compatibility program, designed to either reduce noise at the source or mitigate the noise received by sensitive land uses in the airport vicinity. As explained in the FEIS Section 6.3.1, with planned mitigation, development of the project will not result in any increased significant impacts on non-compatible land uses.

The FAA requires satisfactory assurances, in writing, that appropriate action, including the adoption of zoning laws, has been or will be taken to restrict, to the extent reasonable, the use of land adjacent to or in the immediate vicinity of the airport to activities and purposes compatible with normal airport operations, including landing and takeoff of aircraft. Appendix I of the FEIS contains Lambert's land use compatibility assurance.

Based upon the administrative record for this ROD, the FAA has concluded that existing and planned noise reduction programs at Lambert provide for appropriate action to ensure compatible land use in the airport vicinity.

F. Clean Air Act, Section 176 (c) (1) Conformity Determination Regarding Lambert-St. Louis International Airport Master Plan Supplement Development Actions (*42 U.S.C. Section 7506(c)*).

The determination prescribed by this statutory provision is a precondition for Federal Agency support or approval of airport development actions which are projected to exceed the *de minimis* air emission levels prescribed at 40 CFR Section 93.153. The EPA regulations more generally governing the conformity determination process are found at 40 CFR Part 93, Subpart B.

In the 1997 FEIS, the FAA made a Draft General Conformity Determination on the Lambert MPS proposals (FEIS Sections 5.5.6 and 5.5.7). Pursuant to EPA regulations, the FAA announced the availability of the Draft General Conformity Determination in the *St. Louis Post Dispatch*, and provided notice to appropriate Federal, state and local public agencies. The agencies and the general public were invited to review and comment on the Draft General Conformity Determination. Comments received on the Draft General Conformity Determination and responses to those comments are presented in the Final General Conformity Determination. The FEIS Appendix A presents letters from the EPA (dated November 7, 1997) and MDNR (dated November 20, 1997). In their letters, these air quality agencies concurred with the conformity determination analysis conclusions for general conformity under the Clean Air Act. The Final General Conformity Determination was prepared and a notice of the FAA's determination was published in the *St. Louis Post Dispatch* on June 28, 1998. No comments or requests were received regarding the Final General Conformity Determination.

In order to achieve public disclosure and to address community concerns, the FEIS presented an analysis of air quality impacts utilizing the regulatory structure set forth in the EPA conformity regulations. The FEIS analysis (Section 5.5) demonstrates that the project would not cause or contribute to any new exceedances of air quality standards. As confirmed by the MDNR, the project conforms to the Missouri SIP.

Because projects at Lambert are governed by the moderate non-attainment designation for ozone and the maintenance area designation for carbon monoxide, the FAA needed to determine that the project will not cause or contribute to any new violations of the NAAQS in the project area or the metropolitan area. The FEIS and other supporting documentation provided the FAA the information needed to make that determination. The computer modeling predicted that the carbon monoxide NAAQS would not be exceeded in the future with or without the proposed improvements. The FEIS showed that the project will not increase the frequency or severity of any existing violations of any NAAQS and that the project will not delay timely attainment of the NAAQS or any required interim emission reduction in the project area.

Based upon the air quality information and discussion presented in the FEIS and its appendices, the Final General Conformity Determination, and upon supporting material in the administrative record, the FAA finds that the development actions will not cause or contribute to any air quality standards being exceeded and conform to the Missouri SIP and the NAAQS.

G. For this project, involving new construction which will directly affect wetlands, there is no practicable alternative to such construction. The proposed action includes all practicable measures to minimize harm to wetlands that may result from such use. (Executive Order 11990, as amended).

This executive order requires all Federal agencies to avoid providing assistance for new construction located in wetlands, unless there is no practicable alternative to such construction, and all practicable measures to minimize harm to wetlands are included in the action.

The FEIS, Section 5.11 documents that the preferred development alternative selected by the STLAA from the MPS will directly affect approximately 9.7 acres of wetlands. The FEIS alternatives analysis (FEIS Section 3.3) identifies no reasonable alternative to developing a new runway at Lambert. The FAA additionally concludes that there is no practicable alternative to constructing such a runway, resulting in these wetland impacts, given the purposes and needs documented in the FEIS, consideration of environmental and economic factors, and land-use issues.

The FEIS, Section 5.11 states that the S-1 development alternative of a 9,000-foot runway would result in impacts to more wetlands (10.8 acres) than would Alternative W-1W (9.7 acres). The FEIS demonstrates that these are low quality wetlands. Two of their significant functions, floodwater attenuation and floodwater storage, would be fully mitigated within the airport basin. Additionally wetland functions for these wetlands will be mitigated as part of the overall wetlands mitigation program.

Alternatives of staggering runway ends or relocating the entire runway are not practicable, because, among other reasons, they would increase delays, have additional detrimental environmental effects, require considerable additional cost and complicate air traffic control procedures. Considering these and other reasons described more fully in Section 3.0 of the FEIS, and taking into consideration cost, existing air traffic control and aviation technology and logistics, in light of the overall purpose of the runway project, the FAA finds that there is no practicable alternative to the wetland loss associated with the 9,000-foot runway.

As noted in the FEIS Section 5.11, the COE has worked with the FAA as a cooperating agency to ensure that all practicable measures will be taken to minimize harm to wetlands, impacted through development of the selected alternative. This will be accomplished by using BMPs during construction and developing a wetland compensatory mitigation site. Following issuance of this ROD, the COE, in consultation with the MDNR, will complete its processing of a Section 404 permit, required for the STLAA to proceed with development impacting wetlands. The project approvals in this ROD and this wetlands determination are expressly conditioned upon permit approval and conditions to be outlined by the COE, and upon the STLAA accomplishing the wetlands mitigation measures identified in the FEIS and any COE permit approval.

Although it is generally preferable to attempt to mitigate wetland loss through replacement wetlands in the same watershed, this is not the case where such replacement would create man-made wetlands in the vicinity of airport aircraft movement areas. FAA Advisory Circular 150/5300-33, dated May 1, 1997, states the FAA's opposition to wetland mitigation projects located within 10,000 feet of airports serving turbine-powered aircraft (such as Lambert), due to the safety hazard such wetlands present as attractants of wildlife, which significantly increase the risk of bird/aircraft strikes.

The safety standards set forth in this FAA policy statement are recommended for the operators of all public-use airports. Furthermore, for airport sponsors who are the recipients of Federal grant funding, adherence to safety standards set forth in FAA advisory circulars is a requirement of standard grant assurance #34, as acknowledged in paragraph 4-6.a. of Advisory Circular 150/5200-33.

This recent agency policy guidance supports the FEIS determination that the replacement wetlands for the Lambert development actions should not be located in the vicinity of the airport. Given the potential hazard associated with the creation of wildlife attractions within 10,000 feet of jet runways, the FAA and COE agreed that it is prudent to permit the STLAA to replace these impacted wetlands outside of the Lambert watershed.

As detailed in the FEIS Section 6.3.7, a wetland mitigation program has been developed to offset the impacts of the project and to recognize other long-term biological problems. The mitigation plan calls for replacing the filled wetlands. Several candidate wetland mitigation sites have been examined. Final mitigation requirements will be determined during the Section 404 permit application and review process in consultation with the COE.

H. For this project, involving a significant encroachment on a floodplain, there is no practicable alternative to the selected development of the preferred alternative. The proposed action conforms to all applicable state and/or local floodplain protection standards. (Executive Order 11988).

This executive order, together with applicable DOT and FAA orders, establish a policy to avoid supporting construction within a 100-year floodplain where practicable, and where avoidance is not practicable, to ensure that the construction design minimizes potential harm to or within the floodplain.

Section 5.12 of the FEIS explains that, without mitigation, construction and operation of the MPS preferred alternative could result in adverse floodplain impacts in the Coldwater Creek floodplain.

As outlined in the "Alternatives" discussion in Section 5 of this ROD, and in the FEIS, there is no practicable alternative to the selected alternative. Development of this alternative achieves the purposes and needs for the projects in the most cost-effective manner with the least impact on the surrounding land uses. As shown in the FEIS Section 6.3.8, a mitigation program has been designed, which will create a floodplain so that there would be no net loss of flood storage capacity or increased risk of loss of human life or property damage. This program has been designed to comply with applicable requirements of the permitting agencies, with whom the FAA and the STLAA have been coordinating, in order to ensure that the construction design minimizes potential harm to or within the floodplain. Each of these agencies have agreed with the mitigation plan in concept, and coordination will continue throughout the permitting process.

I. Relocation Assistance (*42 U.S.C. Section 4601 et seq.*).

These statutory provisions, imposed by Title II of the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970, require that state or local agencies, undertaking Federally-assisted projects which cause the involuntarily displacement of persons or businesses, must make relocation benefits available to those persons impacted.

As detailed in the FEIS Section 5.3, the selected development alternative will displace approximately 2,324 households, 75 businesses, and 6 schools, 6 churches, and one nursing home.

The FAA will require Lambert to provide fair and reasonable relocation payments and assistance payments pursuant to the provision of the Uniform Relocation Assistance and Real Property Acquisition Policies Act. Comparable decent, safe, and sanitary dwellings are available for occupancy on the open market.

J. For any use of lands with significant historic sites, there is no prudent and feasible alternative to using the land; the project includes all possible planning to minimize harm resulting from the use (*49 U.S.C. Section 303(c)*).

The FEIS Section 5.7 concluded that the MPS development actions would involve either the use or constructive use of resources protected by this statutory provision, more commonly referred to as "4(f)" resources. The selected alternative would directly affect four park and recreation area Section 303 sites and indirectly affect four sites. One of the sites, Oak Valley Park, would have both direct and indirect effects. Three of the sites are also protected under Section 6(f) of the Land and Water Conservation Fund Act of 1965 (*16 U.S.C. Section 460l-8(f)3*).

In terms of avoidance alternatives, review of the tiered alternatives evaluation prepared in Section 3.0 of the FEIS indicated that there are no prudent and feasible alternatives to the identified impacts to Section 303 and 6(f) sites. The FAA has coordinated with the public and agencies having jurisdiction over the impacted sites to determine site significance and to develop mitigation measures necessary to meet Section 303 and 6(f) requirements. The agencies involved in the coordination were the DOI, the MDNR, the Council, STLAA, and the City of Bridgeton.

A coordination meeting with the City of Bridgeton was held on April 18, 1997, with the mayor and key staff members to discuss Draft EIS comments relative to Section 303/6(f) issues, and to solicit input from the City of Bridgeton regarding future plans and goals for their parks and recreation program. Items listed in the City of Bridgeton’s comprehensive plan were discussed regarding candidate mitigation options. The City of Bridgeton has stated that it will not initiate the Section 6(f) conversions for Lambert. Measures to minimize harm to Sections 303 and 6(f) resources are summarized in Section 6.3.5 of the FEIS.

As discussed at FEIS Section 5.8, the FAA determined the project will impact five structures of historic significance. Assuming such "historical significance" and such "use," the referenced FEIS Section 5.8 demonstrates that there is no prudent or feasible alternative to any such use. Furthermore, based upon the planned mitigation (discussed at FEIS Section 6.3.6), the FAA concludes that there has been all possible planning to minimize any harm resulting from use of historic or archaeological resources.

The Missouri SHPO has been consulted concerning these determinations. Treatment measures for these adversely affected historic properties are included within the MOA for the selected alternative, W-1W. It stipulates measures to be implemented to avoid, reduce or mitigate the adverse effects this project will have on historic properties. The MOA was signed by the FAA, the Missouri SHPO, and the Advisory Council. The STLAA signed as a concurring party. The City of Bridgeton was invited to participate as a concurring party to the MOA, but it chose not to concur in the MOA. The Advisory Council executed the MOA on May 29, 1998. A copy of the MOA is included in Appendix H of this ROD.

K. There are no disproportionately high or adverse human health or environmental effects from the project on minority or low-income populations. (Executive Order 12898).

Environmental justice concerns were addressed in Section 5.3 of the FEIS, and it was concluded that no minority or low-income group would be disproportionately affected by displacements occurring as a result of the selected alternative. The FEIS contains a discussion of environmental justice issues relative to the selected alternative. It was concluded that the impacts from the proposed MPS improvements will not disproportionately affect minority or low-income communities.

L. The FAA has given this proposal the independent and objective evaluation required by the Council on Environmental Quality. (40 CFR 1506.5).

As the FEIS outlined, a lengthy process led to the ultimate identification of the selected alternative, disclosure of potential impacts and selection of appropriate mitigation measures. This process began with the FAA competitive selection of an independent EIS contractor, continuing throughout the preparation of the DEIS and FEIS, and culminating in this ROD. The FAA provided input, advice and expertise throughout the planning and technical analysis, along with administrative direction and legal review of the project. From its inception, the FAA has taken a strong leadership role in the environmental evaluation of this project and has maintained its objectivity.

12. APPROVALS AND FAA ORDER

FHWA APPROVAL

I have carefully considered the FHWA's goals and objectives in relation to the surface transportation aspects of the proposed MPS development actions discussed in the FEIS. After careful review of Section 5.22 of the FEIS and Section 8 of this ROD, I find the surface transportation projects described in this ROD meet the FHWA's NEPA requirements.

[signature]
FHWA Approving Official

9-30-98
Date

FAA APPROVAL AND ORDER

Having determined that the agency's preferred alternative, Alternative W-1W, is the only possible, prudent, and practicable alternative, the remaining decision is whether to approve or not approve the agency actions necessary for implementation of the project. Approval would signify that applicable Federal requirements relating to airport development planning have been met, and would permit the City of St. Louis to proceed with the proposed development and possibly receive Federal funding for eligible items. Not approving these actions would prevent the City of St. Louis from proceeding with Federally supported development in a timely way.

I have carefully considered the FAA's goals and objectives in relation to various aeronautical aspects of the proposed MPS development actions discussed in the FEIS. These include the purposes and needs to be served by the projects, the alternative means of achieving them, the environmental impacts of these alternatives, the mitigation necessary to preserve and enhance the environment, and the costs and benefits of achieving these purposes and needs in terms of effective and fiscally responsible expenditure of Federal funds. I have also considered comments received by the FAA on the social, environmental and economic impacts of the proposed actions.

Therefore, under the authority delegated to me by the Administrator of the FAA, I find that the projects in this ROD are reasonably supported and approved. For those projects I, therefore, direct that action be taken to carry out the agency actions discussed more fully in Section 3 of this ROD, including:

A. Approval under existing or future FAA criteria of project eligibility for Federal grant-in-aid funds and/or PFC, including the following elements:

1. Land Acquisition
2. Site Preparation
3. Runway, Taxiway, and Runway Safety Area Construction
4. Landside Developments, including Roadways
5. Certain Navigational Aids
6. Acquisition/relocation of MoANG and Navy/Marine Corps Reserve Facilities
7. Terminal Facility Improvements and New Terminal Facilities
8. Environmental Mitigation

B. Approval of a revised ALP, based on determinations through the aeronautical study process regarding obstructions to navigable airspace, and no FAA objection to the airport development proposal from an airspace perspective.

C. Approval for relocation and/or upgrade of various navigational aids.

D. The development of air traffic control and airspace management procedures to effect the safe and efficient movement of air traffic to and from the proposed new runway, including the development of a system for the routing of arriving and departing traffic and the design, establishment, and publication of standardized flight operating procedures, including instrument approach procedures and standard instrument departure procedures.

E. Review and subsequent approval of an amended Airport Certification Manual for Lambert-St. Louis International Airport (per 14 CFR Part 139).

Finally, based upon the administrative record of this project, I certify, as prescribed by 49 U.S.C. 44502 (b), that implementation of the proposed project is reasonably necessary for use in air commerce.

RIGHT OF APPEAL

This decision constitutes the Federal approval for the actions identified above and any subsequent actions approving a grant of Federal funds to the City of St. Louis. Today's action is taken pursuant to 49 U.S.C. Subtitle VII, Parts A and B, and constitutes a final order of the Administrator subject to review by the Courts of Appeals of the United States in accordance with the provisions of 49 U.S.C. Section 46110.

FAA ISSUES RECORD OF DECISION ON LAMBERT-ST. LOUIS INTERNATIONAL AIRPORT

The Federal Aviation Administration has approved Lambert-St. Louis International Airport's proposed airside and landside improvements, commonly known as Alternative W-1W. This Record of Decision (ROD) in favor of W-1W deems the improvements eligible for federal financial assistance and commits the airport operator to specific conditions including environmental mitigation measures. The ROD was signed today by FAA Central Region Administrator John E. Turner.

The approved alternative was selected from numerous proposals considered during the environmental process. A central feature of W-1W is a new staggered parallel runway configuration, suitable for use by air carriers, to be located on the southwest side of the airport in Bridgeton, Mo. The plan also includes property acquisition, terminal expansion, roadway improvements and relocation of several airport tenants.

The principal features of the ROD, which is based on a review of the administrative record, including the Final Environmental Impact Statement, include:

- A statement of the agency's decision;
- Identification of all alternatives considered by the FAA, including the environmentally preferable one, and
- Mitigation measures planned to prevent or minimize environmental harm.

The FAA issued its Final Environmental Impact Statement on Dec. 19, 1997, finding that the city of St. Louis's proposed alternative met the requirements of the National Environmental Policy Act (NEPA).

By Oct. 14, 1998, the ROD will be available for review at the following locations:

The City Halls of:

Bel Nor; Bel-Ridge; Berkeley; Bridgeton; Calverton Park; Cool Valley; Edmundson; Ferguson; Greendale; Hazelwood; Kinloch; Maryland Heights; Normandy; Northwoods; Pasadena Hills; Village of Pasadena Park; St. Ann; St. John; Woodson Terrace; St. Charles City; St. Charles County.

the U.S. Army,
the U.S. Environmental Protection Agency,
the U.S. Fish and Wildlife Service, and
the U.S. Department of Agriculture
to Address Aircraft-Wildlife Strikes

PURPOSE

The signatory agencies know the risks that aircraft-wildlife strikes pose to safe aviation.

This Memorandum of Agreement (MOA) acknowledges each signatory agency's respective missions. Through this MOA, the agencies establish procedures necessary to coordinate their missions to more effectively address existing and future environmental conditions contributing to aircraft-wildlife strikes throughout the United States. These efforts are intended to minimize wildlife risks to aviation and human safety, while protecting the Nation's valuable environmental resources.

BACKGROUND

Aircraft-wildlife strikes are the second leading causes of aviation-related fatalities. Globally, these strikes have killed over 400 people and destroyed more than 420 aircraft. While these extreme events are rare when compared to the millions of annual aircraft operations, the potential for catastrophic loss of human life resulting from one incident is substantial. The most recent accident demonstrating the grievous nature of these strikes occurred in September 1995, when a U.S. Air Force reconnaissance jet struck a flock of Canada geese during takeoff, killing all 24 people aboard.

The Federal Aviation Administration (FAA) and the United States Air Force (USAF) databases contain information on more than 54,000 United States civilian and military aircraft-wildlife strikes reported to them between 1990 and 1999[1]. During that decade, the FAA received reports indicating that aircraft-wildlife strikes, damaged 4,500 civilian U.S. aircraft (1,500 substantially), destroyed 19 aircraft, injured 91 people, and killed 6 people. Additionally, there were 216 incidents where birds struck two or more engines on civilian aircraft, with damage occurring to 26 percent of the 449 engines involved in these incidents. The FAA estimates that during the same decade, civilian U.S. aircraft sustained $4 billion worth of damages and associated losses and 4.7 million hours of aircraft downtime due to aircraft-wildlife strikes. For the same period,

---

[1] FAA estimates that the 28,150 aircraft-wildlife strike reports it received represent less than 20% of the actual number of strikes that occurred during the decade.

USAF planes colliding with wildlife resulted in 10 Class A Mishaps[2], 26 airmen deaths, and over $217 million in damages.

Approximately 97 percent of the reported civilian aircraft-wildlife strikes involved common, large-bodied birds or large flocks of small birds. Almost 70 percent of these events involved gulls, waterfowl, and raptors (Table 1).

About 90 percent of aircraft-wildlife strikes occur on or near airports, when aircraft are below altitudes of 2,000 feet. Aircraft-wildlife strikes at these elevations are especially dangerous because aircraft are moving at high speeds and are close to or on the ground. Aircrews are intently focused on complex take-off or landing procedures and monitoring the movements of other aircraft in the airport vicinity. Aircrew attention to these activities while at low altitudes often compromises their ability to successfully recover from unexpected collisions with wildlife and to deal with rapidly changing flight procedures. As a result, crews have minimal time and space to recover from aircraft-wildlife strikes.

Increasing bird and wildlife populations in urban and suburban areas near airports contribute to escalating aircraft-wildlife strike rates. FAA, USAF, and Wildlife Services (WS) experts expect the risks, frequencies, and potential severities of aircraft-wildlife strikes to increase during the next decade as the numbers of civilian and military aircraft operations grow to meet expanding transportation and military demands.

SECTION I.

SCOPE OF COOPERATION AND COORDINATION

Based on the preceding information and to achieve this MOA’s purpose, the signatory agencies:

A. Agree to strongly encourage their respective regional and local offices, as appropriate, to develop interagency coordination procedures necessary to effectively and efficiently implement this MOA. Local procedures should clarify time frames and other general coordination guidelines.

B. Agree that the term “airport” applies only to those facilities as defined in the attached glossary.

C. Agree that the three major activities of most concern include, but are not limited to:

1. airport siting and expansion;

[2] See glossary for the definition of a Class A Mishap and similar terms.

2. development of conservation/mitigation habitats or other land uses that could attract hazardous wildlife to airports or nearby areas; and

3. responses to known wildlife hazards or aircraft-wildlife strikes.

D. Agree that "hazardous wildlife" are those animals, identified to species and listed in FAA and USAF databases, that are most often involved in aircraft-wildlife strikes. Many of the species frequently inhabit areas on or near airports, cause structural damage to airport facilities, or attract other wildlife that pose an aircraft-wildlife strike hazard. Table 1 lists many of these species. It is included solely to provide information on identified wildlife species that have been involved in aircraft-wildlife strikes. It is not intended to represent the universe of species concerning the signatory agencies, since more than 50 percent of the aircraft-wildlife strikes reported to FAA or the USAF did not identify the species involved.

E. Agree to focus on habitats attractive to the species noted in Table 1, but the signatory agencies realize that it is imperative to recognize that wildlife hazard determinations discussed in Paragraph L of this section may involve other animals.

F. Agree that not all habitat types attract hazardous wildlife. The signatory agencies, during their consultative or decisionmaking activities, will inform regional and local land use authorities of this MOA's purpose. The signatory agencies will consider regional, local, and site-specific factors (e.g., geographic setting and/or ecological concerns) when conducting these activities and will work cooperatively with the authorities as they develop and implement local land use programs under their respective jurisdictions. The signatory agencies will encourage these stakeholders to develop land uses within the siting criteria noted in Section 1-3 of FAA Advisory Circular (AC) 150.5200-33 (Attachment A) that do not attract hazardous wildlife. Conversely, the agencies will promote the establishment of land uses attractive to hazardous wildlife outside those siting criteria. Exceptions to the above siting criteria, as described in Section 2.4.b of the AC, will be considered because they typically involve habitats that provide unique ecological functions or values (e.g., critical habitat for federally-listed endangered or threatened species, ground water recharge).

G. Agree that wetlands provide many important ecological functions and values, including fish and wildlife habitats; flood protection; shoreline erosion control; water quality improvement; and recreational, educational, and research opportunities. To protect jurisdictional wetlands, Section 404 of the Clean Water Act (CWA) establishes a program to regulate dredge and/or fill activities in these wetlands and navigable waters. In recognizing Section 404 requirements and the Clean Water Action Plan's goal to annually increase the Nation's net wetland acreage by 100,000 acres through 2005, the signatory agencies agree to resolve aircraft-wildlife conflicts. They will do so by avoiding and minimizing wetland impacts to the maximum extent practicable, and will work to compensate for all associated unavoidable wetland impacts. The agencies agree to work with landowners and communities to encourage and support wetland restoration or enhancement efforts that do not increase aircraft-wildlife strike potentials.

H. Agree that the: U.S. Army Corps of Engineers (ACOE) has expertise in protecting and managing jurisdictional wetlands and their associated wildlife; U.S. Environmental Protection Agency (EPA) has expertise in protecting environmental resources; and the U.S. Fish and Wildlife Service (USFWS) has expertise in protecting and managing wildlife and their habitats, including migratory birds and wetlands. Appropriate signatory agencies will cooperatively review proposals to develop or expand wetland mitigation sites, or wildlife refuges that may attract hazardous wildlife. When planning these sites or refuges, the signatory agencies will diligently consider the siting criteria and land use practice recommendations stated in FAA AC 150/5200-33. The agencies will make every effort to undertake actions that are consistent with those criteria and recommendations, but recognize that exceptions to the siting criteria may be appropriate (see Paragraph F of this section).

I. Agree to consult with airport proponents during initial airport planning efforts. As appropriate, the FAA or USAF will initiate signatory agency participation in these efforts. When evaluating proposals to build new civilian or military aviation facilities or to expand existing ones, the FAA or the USAF, will work with appropriate signatory agencies to diligently evaluate alternatives that may avoid adverse effects on wetlands, other aquatic resources, and Federal wildlife refuges. If these or other habitats support hazardous wildlife, and there is no practicable alternative location for the proposed aviation project, the appropriate signatory agencies, consistent with applicable laws, regulations, and policies, will develop mutually acceptable measures, to protect aviation safety and mitigate any unavoidable wildlife impacts.

J. Agree that a variety of other land uses (e.g., storm water management facilities, wastewater treatment systems, landfills, golf courses, parks, agricultural or aquacultural facilities, and landscapes) attract hazardous wildlife and are, therefore, normally incompatible with airports. Accordingly, new, federally-funded airport construction or airport expansion projects near habitats or other land uses that may attract hazardous wildlife must conform to the siting criteria established in the FAA Advisory Circular (AC) 150/5200-33, Section 1-3.

K. Agree to encourage and advise owners and/or operators of non-airport facilities that are known hazardous wildlife attractants (See Paragraph J) to follow the siting criteria in Section 1-3 of AC 150/5200-33. As appropriate, each signatory agency will inform proponents of these or other land uses about the land use’s potential to attract hazardous species to airport areas.

The signatory agencies will urge facility owners and/or operators about the critical need to consider the land uses' effects on aviation safety.

L. Agree that FAA, USAF, and WS personnel have the expertise necessary to determine the aircraft-wildlife strike potentials of various land uses. When there is disagreement among signatory agencies about a particular land use and its potential to attract hazardous wildlife, the FAA, USAF, or WS will prepare a wildlife hazard assessment. Then, the appropriate signatory agencies will meet at the local level to review the assessment. At a minimum, that assessment will:

1. identify each species causing the aviation hazard, its seasonal and daily populations, and the population's local movements;

2. discuss locations and features on and near the airport or land use attractive to hazardous wildlife; and

3. evaluate the extent of the wildlife hazard to aviation.

M. Agree to cooperate with the airport operator to develop a specific, wildlife hazard management plan for a given location, when a potential wildlife hazard is identified. The plan will meet applicable FAA, USAF, and other relevant requirements. In developing the plan, the appropriate agencies will use their expertise and attempt to integrate their respective programmatic responsibilities, while complying with existing laws, regulations, and policies. The plan should avoid adverse impacts to wildlife populations, wetlands, or other sensitive habitats to the maximum extent practical. Unavoidable impacts resulting from implementing the plan will be fully compensated pursuant to all applicable Federal laws, regulations, and policies.

N. Agree that whenever a significant aircraft-wildlife strike occurs or a potential for one is identified, any signatory agency may initiate actions with other appropriate signatory agencies to evaluate the situation and develop mutually acceptable solutions to reduce the identified strike probability. The agencies will work cooperatively, preferably at the local level, to determine the causes of the strike and what can and should be done at the airport or in its vicinity to reduce potential strikes involving that species.

O. Agree that information and analyses relating to mitigation that could cause or contribute to aircraft-wildlife strikes should, whenever possible, be included in documents prepared to satisfy the National Environmental Policy Act (NEPA). This should be done in coordination with appropriate signatory agencies to inform the public and Federal decision makers about important ecological factors that may affect aviation. This concurrent review of environmental issues will promote the streamlining of the NEPA review process.

P. Agree to cooperatively develop mutually acceptable and consistent guidance, manuals, or procedures addressing the management of habitats attractive to hazardous wildlife, when those habitats are or will be within the siting criteria noted in Section 1-3 of FAA AC 5200-33. As appropriate, the signatory agencies will also consult each other when they propose revisions to any regulations or guidance relevant to the purpose of this MOA, and agree to modify this MOA accordingly.

SECTION II.
GENERAL RULES AND INFORMATION

A. Development of this MOA fulfills the National Transportation Safety Board's recommendation of November 19, 1999, to form an inter-departmental task force to address aircraft-wildlife strike issues.

B. This MOA does not nullify any obligations of the signatory agencies to enter into separate MOAs with the USFWS addressing the conservation of migratory birds, as outlined in Executive Order 13186, *Responsibilities of Federal Agencies to Protect Migratory Birds*, dated January 10, 2001 (66 *Federal Register*, No. 11, pg. 3853).

C. This MOA in no way restricts a signatory agency's participation in similar activities or arrangements with other public or private agencies, organizations, or individuals.

D. This MOA does not alter or modify compliance with any Federal law, regulation or guidance (e.g., Clean Water Act; Endangered Species Act; Migratory Bird Treaty Act; National Environmental Policy Act; North American Wetlands Conservation Act; Safe Drinking Water Act; or the "no-net loss" policy for wetland protection). The signatory agencies will employ this MOA in concert with the Federal guidance addressing wetland mitigation banking dated March 6, 1995 (60 *Federal Register*, No. 43, pg. 12286).

E. The statutory provisions and regulations mentioned above contain legally binding requirements. However, this MOA does not substitute for those provisions or regulations, nor is it a regulation itself. This MOA does not impose legally binding requirements on the signatory agencies or any other party, and may not apply to a particular situation in certain circumstances. The signatory agencies retain the discretion to adopt approaches on a case-by-case basis that differ from this MOA when they determine it is appropriate to do so. Such decisions will be based on the facts of a particular case and applicable legal requirements. Therefore, interested parties are free to raise questions and objections about the substance of this MOA and the appropriateness of its application to a particular situation.

F. This MOA is based on evolving information and may be revised periodically without public notice. The signatory agencies welcome public comments on this MOA at any time and will consider those comments in any future revision of this MOA.

G. This MOA is intended to improve the internal management of the Executive Branch to address conflicts between aviation safety and wildlife. This MOA does not create any right, benefit, or trust responsibility, either substantively or procedurally. No party, by law or equity, may enforce this MOA against the United States, its agencies, its officers, or any person.

H. This MOA does not obligate any signatory agency to allocate or spend appropriations or enter into any contract or other obligations.

I. This MOA does not reduce or affect the authority of Federal, State, or local agencies regarding land uses under their respective purviews. When requested, the signatory agencies will provide technical expertise to agencies making decisions regarding land uses within the siting criteria in Section 1-3 of FAA AC 150/5200-33 to minimize or prevent attracting hazardous wildlife to airport areas.

J. Any signatory agency may request changes to this MOA by submitting a written request to any other signatory agency and subsequently obtaining the written concurrence of all signatory agencies.

K. Any signatory agency may terminate its participation in this MOA within 60 days of providing written notice to the other agencies. This MOA will remain in effect until all signatory agencies terminate their participation in it.

SECTION III. PRINCIPAL SIGNATORY AGENCY CONTACTS

The following list identifies contact offices for each signatory agency.

Federal Aviation Administration
Office Airport Safety and Standards
Airport Safety and
Compliance Branch (AAS-310)
800 Independence Ave., S.W.
Washington, D.C. 20591
V: 202-267-1799
F: 202-267-7546

U.S. Air Force
HQ AFSC/SEFW
9700 Ave., G. SE, Bldg. 24499
Kirtland AFB, NM 87117
V: 505-846-5679
F: 505-846-0684

U.S. Army
Directorate of Civil Works
Regulatory Branch (CECW-OR)
441 G St., N.W.
Washington, D.C. 20314
V: 202-761-4750
F: 202-761-4150

GLOSSARY

This glossary defines terms used in this MOA.

Airport. All USAF airfields or all public use airports in the FAA's National Plan of Integrated Airport Systems (NPIAS). Note: There are over 18,000 civil-use airports in the U.S., but only 3,344 of them are in the NPIAS and, therefore, under FAA's jurisdiction.

Aircraft-wildlife strike. An aircraft-wildlife strike is deemed to have occurred when:

1. a pilot reports that an aircraft struck 1 or more birds or other wildlife;
2. aircraft maintenance personnel identify aircraft damage as having been caused by an aircraft-wildlife strike;
3. personnel on the ground report seeing an aircraft strike 1 or more birds or other wildlife;
4. bird or other wildlife remains, whether in whole or in part, are found within 200 feet of a runway centerline, unless another reason for the animal's death is identified; or
5. the animal's presence on the airport had a significant, negative effect on a flight (i.e., aborted takeoff, aborted landing, high-speed emergency stop, aircraft left pavement area to avoid collision with animal)

(Source: *Wildlife Control Procedures Manual*, Technical Publication 11500E, 1994).

Aircraft-wildlife strike hazard. A potential for a damaging aircraft collision with wildlife on or near an airport (14 CFR 139.3).

Bird Sizes. Title 40, Code of Federal Regulations, Part 33.76 classifies birds according to weight:

small birds weigh less than 3 ounces (oz).
medium birds weigh more than 3 oz and less than 2.5 lbs.
large birds weigh greater than 2.5 lbs.

Civil aircraft damage classifications. The following damage descriptions are based on the *Manual on the International Civil Aviation Organization Bird Strike Information System*:

Minor: The aircraft is deemed airworthy upon completing simple repairs or replacing minor parts and an extensive inspection is not necessary.

Substantial: Damage or structural failure adversely affects an aircraft's structural integrity, performance, or flight characteristics. The damage normally requires major repairs or the replacement of the entire affected component. Bent fairings or cowlings; small dents; skin punctures; damage to wing tips, antenna, tires or brakes, or engine blade damage not requiring blade replacement are specifically excluded.

Destroyed: The damage sustained makes it inadvisable to restore the aircraft to an airworthy condition.

Significant Aircraft-Wildlife Strikes. A significant aircraft-wildlife strike is deemed to have occurred when any of the following applies:

1. a civilian, U.S. air carrier aircraft experiences a multiple aircraft-bird strike or engine ingestion;
2. a civilian, U.S. air carrier aircraft experiences a damaging collision with wildlife other than birds; or
3. a USAF aircraft experiences a Class A, B, or C mishap as described below:

    A. **Class A Mishap:** Occurs when at least one of the following applies:
        1. total mishap cost is $1,000,000 or more;
        2. a fatality or permanent total disability occurs; and/or
        3. an Air Force aircraft is destroyed.

    B. **Class B Mishap:** Occurs when at least one of the following applies:
        1. total mishap cost is $200,000 or more and less than $1,000,000; and/or
        2. a permanent partial disability occurs and/or 3 or more people are hospitalized;

    C. **Class C Mishap:** Occurs when at least one of the following applies:
        1. cost of reported damage is between $20,000 and $200,000;
        2. an injury causes a lost workday (i.e., duration of absence is at least 8 hours beyond the day or shift during which mishap occurred); and/or
        3. an occupational illness causing absence from work at any time.

Wetlands. An ecosystem requiring constant or recurrent, shallow inundation or saturation at or near the surface of the substrate. The minimum essential characteristics of a wetland are recurrent, sustained inundation or saturation at or near the surface and the presence of physical, chemical, and biological features indicating recurrent, sustained inundation, or saturation. Common diagnostic wetland features are hydric soils and hydrophytic vegetation. These features will be present, except where specific physiochemical, biotic, or anthropogenic factors have removed them or prevented their development.

(Source the 1987 Delineation Manual; 40 CFR 230.3(t)).

Wildlife. Any wild animal, including without limitation any wild mammal, bird, reptile, fish, amphibian, mollusk, crustacean, arthropod, coelenterate, or other invertebrate, including any part, product, egg, or offspring there of (50 CFR 10.12, *Taking, Possession, Transportation, Sale, Purchase, Barter, Exportation, and Importation of Wildlife and Plants*). As used in this MOA, "wildlife" includes feral animals and domestic animals while out of their owner's control (14 CFR 139.3, *Certification and Operations: Land Airports Serving CAB-Certificated Scheduled Air Carriers Operating Large Aircraft (Other Than Helicopters)*)

Table 1. Identified wildlife species, or groups, that were involved in two or more aircraft-wildlife strikes, that caused damage to one or more aircraft components, or that had an adverse effect on an aircraft's flight. Data are for 1990-1999 and involve only civilian, U.S. aircraft.

Birds	No. reported strikes
Gulls (all spp.)	874
Geese (primarily, Canada geese)	458
Hawks (primarily, Red-tailed hawks)	182
Ducks (primarily Mallards.)	166
Vultures (primarily, Turkey vulture)	142
Rock doves	122
Doves (primarily, mourning doves)	109
Blackbirds	81
European starlings	55
Sparrows	52
Egrets	41
Shore birds (primarily, Killdeer & Sandpipers)	40
Crows	31
Owls	24
Sandhill cranes	22
American kestrels	15
Great blue herons	15
Pelicans	14
Swallows	14
Eagles (Bald and Golden)	14
Ospreys	13
Ring-necked pheasants	11
Herons	11
Barn-owls	9
American robins	8
Meadowlarks	8
Buntings (snow)	7
Cormorants	6
Snow buntings	6
Brants	5
Terns (all spp.)	5
Great horned owls	5
Horned larks	4
Turkeys	4
Swans	3
Mockingbirds	3
Quails	3
Homing pigeons	3
Snowy owls	3
Anhingas	2

Birds	No. reported strikes
Ravens	2
Kites	2
Falcons	2
Peregrine falcons	2
Merlins	2
Grouse	2
Hungarian partridges	2
Spotted doves	2
Thrushes	2
Mynas	2
Finches	2
Total known birds	2,612

Mammals	No. reported strikes
Deer (primarily, White-tailed deer)	285
Coyotes	16
Dogs	10
Elk	6
Cattle	5
Bats	4
Horses	3
Pronghorn antelopes	3
Foxes	2
Raccoons	2
Rabbits	2
Moose	2
Total known mammals	340

Ring-billed gulls were the most commonly struck gulls. The U.S. ring-billed gull population increased steadily at about 6% annually from 1966-1988. Canada geese were involved in about 90% of the aircraft-goose strikes involving civilian, U.S. aircraft from 1990-1998. Resident (non-migratory) Canada goose populations increased annually at 13% from 1966-1998. Red-tailed hawks accounted for 90% of the identified aircraft-hawk strikes for the 10-year period. Red-tailed hawk populations increased annually at 3% from 1966 to 1998. Turkey vultures were involved in 93% of he identified aircraft-vulture strikes. The U.S. Turkey vulture populations increased at annually at 1% between 1966 and 1998. Deer, primarily white-tailed deer, have also adapted to urban and airport areas and their populations have increased dramatically. In the early 1900's, there were about 100,000 white-tailed deer in the U.S. Current estimates are that the U.S. population is about 24 million.

Advisory Circular

Subject: HAZARDOUS WILDLIFE ATTRACTANTS ON OR NEAR AIRPORTS

Date: 8/28/2007

Initiated by: AAS-300

AC No: 150/5200-33B

Change:

1. PURPOSE. This Advisory Circular (AC) provides guidance on certain land uses that have the potential to attract hazardous wildlife on or near public-use airports. It also discusses airport development projects (including airport construction, expansion, and renovation) affecting aircraft movement near hazardous wildlife attractants. Appendix 1 provides definitions of terms used in this AC.

2. APPLICABILITY. The Federal Aviation Administration (FAA) recommends that public-use airport operators implement the standards and practices contained in this AC. The holders of Airport Operating Certificates issued under Title 14, Code of Federal Regulations (CFR), Part 139, Certification of Airports, Subpart D (Part 139), may use the standards, practices, and recommendations contained in this AC to comply with the wildlife hazard management requirements of Part 139. Airports that have received Federal grant-in-aid assistance must use these standards. The FAA also recommends the guidance in this AC for land-use planners, operators of non-certificated airports, and developers of projects, facilities, and activities on or near airports.

3. CANCELLATION. This AC cancels AC 150/5200-33A, *Hazardous Wildlife Attractants on or near Airports*, dated July 27, 2004.

4. PRINCIPAL CHANGES. This AC contains the following major changes, which are marked with vertical bars in the margin:

a. Technical changes to paragraph references.

b. Wording on storm water detention ponds.

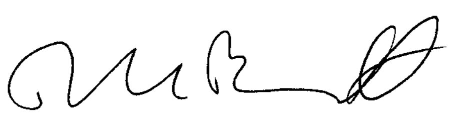
c. Deleted paragraph 4-3.b, *Additional Coordination.*

5. BACKGROUND. Information about the risks posed to aircraft by certain wildlife species has increased a great deal in recent years. Improved reporting, studies, documentation, and statistics clearly show that aircraft collisions with birds and other wildlife are a serious economic and public safety problem. While many species of wildlife can pose a threat to aircraft safety, they are not equally hazardous. Table 1 ranks the wildlife groups commonly involved in damaging strikes in the United States according to their relative hazard to aircraft. The ranking is based on the 47,212 records in the FAA National Wildlife Strike Database for the years 1990 through 2003. These hazard rankings, in conjunction with site-specific Wildlife Hazards Assessments (WHA), will help airport operators determine the relative abundance and use patterns of wildlife species and help focus hazardous wildlife management efforts on those species most likely to cause problems at an airport.

Most public-use airports have large tracts of open, undeveloped land that provide added margins of safety and noise mitigation. These areas can also present potential hazards to aviation if they encourage wildlife to enter an airport's approach or departure airspace or air operations area (AOA). Constructed or natural areas—such as poorly drained locations, detention/retention ponds, roosting habitats on buildings, landscaping, odor-causing rotting organic matter (putrescible waste) disposal operations, wastewater treatment plants, agricultural or aquaculture activities, surface mining, or wetlands—can provide wildlife with ideal locations for feeding, loafing, reproduction, and escape. Even small facilities, such as fast food restaurants, taxicab staging areas, rental car facilities, aircraft viewing areas, and public parks, can produce substantial attractions for hazardous wildlife.

During the past century, wildlife-aircraft strikes have resulted in the loss of hundreds of lives worldwide, as well as billions of dollars in aircraft damage. Hazardous wildlife attractants on and near airports can jeopardize future airport expansion, making proper community land-use planning essential. This AC provides airport operators and those parties with whom they cooperate with the guidance they need to assess and address potentially hazardous wildlife attractants when locating new facilities and implementing certain land-use practices on or near public-use airports.

6. MEMORANDUM OF AGREEMENT BETWEEN FEDERAL RESOURCE AGENCIES. The FAA, the U.S. Air Force, the U.S. Army Corps of Engineers, the U.S. Environmental Protection Agency, the U.S. Fish and Wildlife Service, and the U.S. Department of Agriculture - Wildlife Services signed a Memorandum of Agreement (MOA) in July 2003 to acknowledge their respective missions in protecting aviation from wildlife hazards. Through the MOA, the agencies established procedures necessary to coordinate their missions to address more effectively existing and future environmental conditions contributing to collisions between wildlife and aircraft (wildlife strikes) throughout the United States. These efforts are intended to minimize wildlife risks to aviation and human safety while protecting the Nation’s valuable environmental resources.



DAVID L. BENNETT
Director, Office of Airport Safety
and Standards

Table 1. Ranking of 25 species groups as to relative hazard to aircraft (1=most hazardous) based on three criteria (damage, major damage, and effect-on-flight), a composite ranking based on all three rankings, and a relative hazard score. Data were derived from the FAA National Wildlife Strike Database, January 1990–April 2003.[1]

Species group	Ranking by criteria: Damage[4]	Ranking by criteria: Major damage[5]	Ranking by criteria: Effect on flight[6]	Composite ranking[2]	Relative hazard score[3]
Deer	1	1	1	1	100
Vultures	2	2	2	2	64
Geese	3	3	6	3	55
Cormorants/pelicans	4	5	3	4	54
Cranes	7	6	4	5	47
Eagles	6	9	7	6	41
Ducks	5	8	10	7	39
Osprey	8	4	8	8	39
Turkey/pheasants	9	7	11	9	33
Herons	11	14	9	10	27
Hawks (buteos)	10	12	12	11	25
Gulls	12	11	13	12	24
Rock pigeon	13	10	14	13	23
Owls	14	13	20	14	23
H. lark/s. bunting	18	15	15	15	17
Crows/ravens	15	16	16	16	16
Coyote	16	19	5	17	14
Mourning dove	17	17	17	18	14
Shorebirds	19	21	18	19	10
Blackbirds/starling	20	22	19	20	10
American kestrel	21	18	21	21	9
Meadowlarks	22	20	22	22	7
Swallows	24	23	24	23	4
Sparrows	25	24	23	24	4
Nighthawks	23	25	25	25	1

[1] Excerpted from the *Special Report for the FAA, "Ranking the Hazard Level of Wildlife Species to Civil Aviation in the USA: Update #1, July 2, 2003".* Refer to this report for additional explanations of criteria and method of ranking.
[2] Relative rank of each species group was compared with every other group for the three variables, placing the species group with the greatest hazard rank for $\geq$ 2 of the 3 variables above the next highest ranked group, then proceeding down the list.
[3] Percentage values, from Tables 3 and 4 in Footnote 1 of the *Special Report*, for the three criteria were summed and scaled down from 100, with 100 as the score for the species group with the maximum summed values and the greatest potential hazard to aircraft.
[4] Aircraft incurred at least some damage (destroyed, substantial, minor, or unknown) from strike.
[5] Aircraft incurred damage or structural failure, which adversely affected the structure strength, performance, or flight characteristics, and which would normally require major repair or replacement of the affected component, or the damage sustained makes it inadvisable to restore aircraft to airworthy condition.
[6] Aborted takeoff, engine shutdown, precautionary landing, or other.

SECTION 1.

GENERAL SEPARATION CRITERIA FOR HAZARDOUS WILDLIFE ATTRACTANTS ON OR NEAR AIRPORTS.

1-1. INTRODUCTION. When considering proposed land uses, airport operators, local planners, and developers must take into account whether the proposed land uses, including new development projects, will increase wildlife hazards. Land-use practices that attract or sustain hazardous wildlife populations on or near airports can significantly increase the potential for wildlife strikes.

The FAA recommends the minimum separation criteria outlined below for land-use practices that attract hazardous wildlife to the vicinity of airports. Please note that FAA criteria include land uses that cause movement of hazardous wildlife onto, into, or across the airport's approach or departure airspace or air operations area (AOA). (See the discussion of the synergistic effects of surrounding land uses in Section 2-8 of this AC.)

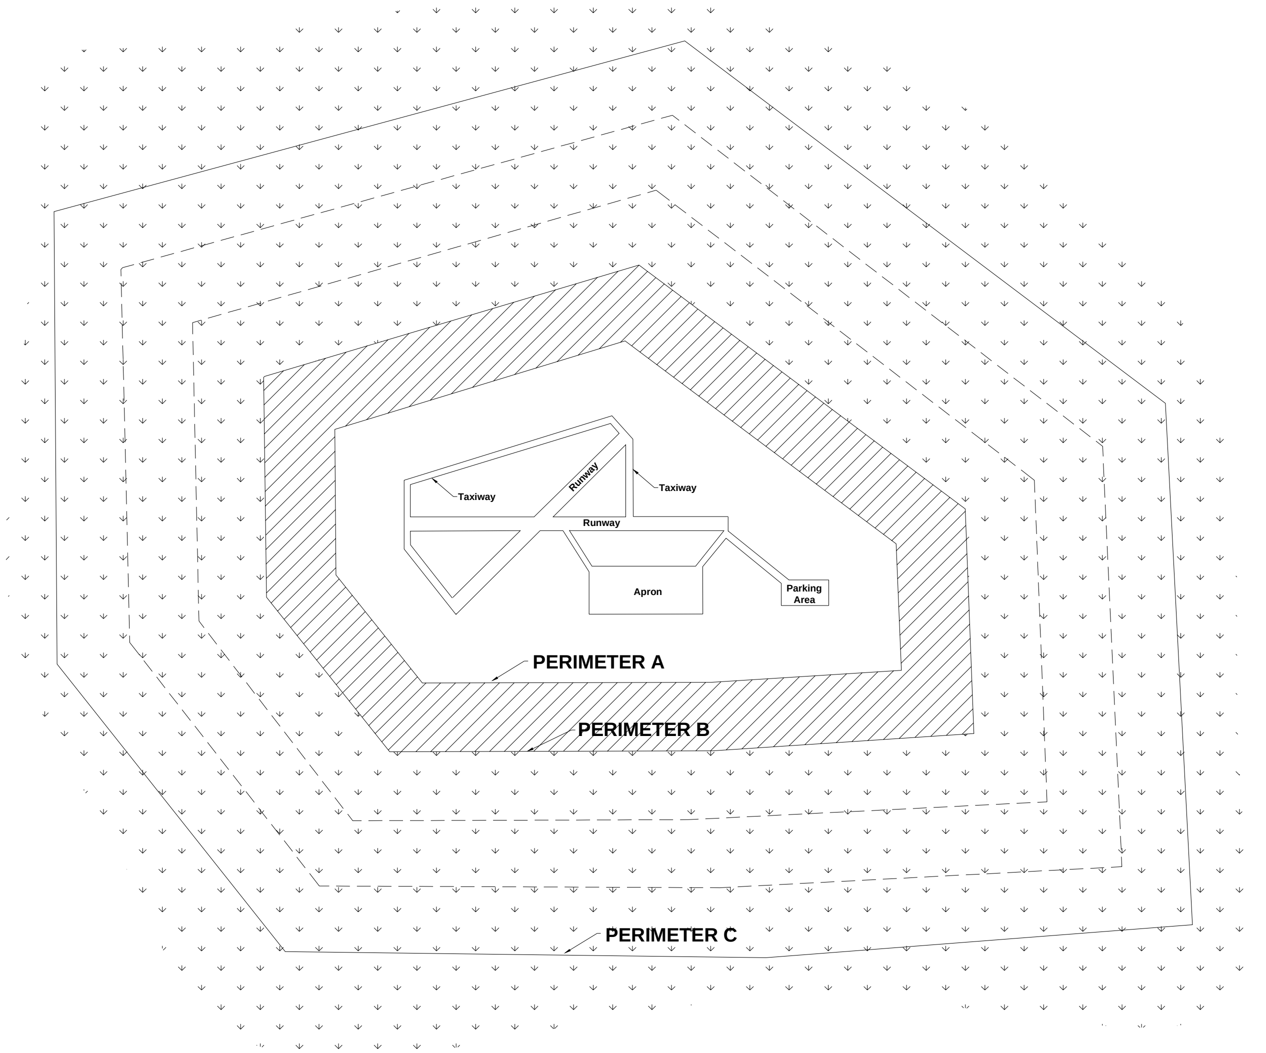
The basis for the separation criteria contained in this section can be found in existing FAA regulations. The separation distances are based on (1) flight patterns of piston-powered aircraft and turbine-powered aircraft, (2) the altitude at which most strikes happen (78 percent occur under 1,000 feet and 90 percent occur under 3,000 feet above ground level), and (3) National Transportation Safety Board (NTSB) recommendations.

1-2. AIRPORTS SERVING PISTON-POWERED AIRCRAFT. Airports that do not sell Jet-A fuel normally serve piston-powered aircraft. Notwithstanding more stringent requirements for specific land uses, the FAA recommends a separation distance of 5,000 feet at these airports for any of the hazardous wildlife attractants mentioned in Section 2 or for new airport development projects meant to accommodate aircraft movement. This distance is to be maintained between an airport's AOA and the hazardous wildlife attractant. Figure 1 depicts this separation distance measured from the nearest aircraft operations areas.

1-3. AIRPORTS SERVING TURBINE-POWERED AIRCRAFT. Airports selling Jet-A fuel normally serve turbine-powered aircraft. Notwithstanding more stringent requirements for specific land uses, the FAA recommends a separation distance of 10,000 feet at these airports for any of the hazardous wildlife attractants mentioned in Section 2 or for new airport development projects meant to accommodate aircraft movement. This distance is to be maintained between an airport's AOA and the hazardous wildlife attractant. Figure 1 depicts this separation distance from the nearest aircraft movement areas.

1-4. PROTECTION OF APPROACH, DEPARTURE, AND CIRCLING AIRSPACE. For all airports, the FAA recommends a distance of 5 statute miles between the farthest edge of the airport's AOA and the hazardous wildlife attractant if the attractant could cause hazardous wildlife movement into or across the approach or departure airspace.

Figure 1. Separation distances within which hazardous wildlife attractants should be avoided, eliminated, or mitigated.



PERIMETER A: For airports serving piston-powered aircraft, hazardous wildlife attractants must be 5,000 feet from the nearest air operations area.

PERIMETER B: For airports serving turbine-powered aircraft, hazardous wildlife attractants must be 10,000 feet from the nearest air operations area.

PERIMETER C: 5-mile range to protect approach, departure and circling airspace.

SECTION 2.

LAND-USE PRACTICES ON OR NEAR AIRPORTS THAT POTENTIALLY ATTRACT HAZARDOUS WILDLIFE.

2-1. GENERAL. The wildlife species and the size of the populations attracted to the airport environment vary considerably, depending on several factors, including land-use practices on or near the airport. This section discusses land-use practices having the potential to attract hazardous wildlife and threaten aviation safety. In addition to the specific considerations outlined below, airport operators should refer to *Wildlife Hazard Management at Airports,* prepared by FAA and U.S. Department of Agriculture (USDA) staff. (This manual is available in English, Spanish, and French. It can be viewed and downloaded free of charge from the FAA's wildlife hazard mitigation web site: http://wildlife-mitigation.tc.FAA.gov.). And, *Prevention and Control of Wildlife Damage,* compiled by the University of Nebraska Cooperative Extension Division. (This manual is available online in a periodically updated version at: ianrwww.unl.edu/wildlife/solutions/handbook/.)

2-2. WASTE DISPOSAL OPERATIONS. Municipal solid waste landfills (MSWLF) are known to attract large numbers of hazardous wildlife, particularly birds. Because of this, these operations, when located within the separations identified in the siting criteria in Sections 1-2 through 1-4, are considered incompatible with safe airport operations.

a. Siting for new municipal solid waste landfills subject to AIR 21. Section 503 of the Wendell H. Ford Aviation Investment and Reform Act for the 21st Century (Public Law 106-181) (AIR 21) prohibits the construction or establishment of a new MSWLF within 6 statute miles of certain public-use airports. Before these prohibitions apply, both the airport and the landfill must meet the very specific conditions described below. These restrictions do not apply to airports or landfills located within the state of Alaska.

The airport must (1) have received a Federal grant(s) under 49 U.S.C. § 47101, et. seq.; (2) be under control of a public agency; (3) serve some scheduled air carrier operations conducted in aircraft with less than 60 seats; and (4) have total annual enplanements consisting of at least 51 percent of scheduled air carrier enplanements conducted in aircraft with less than 60 passenger seats.
