TABLE OF CONTENTS

EXECUTIVE SUMMARY 1

1.0 INTRODUCTION 1

1.1 PURPOSE 1
1.2 ORGANIZATION 2

2.0 SITE CHARACTERIZATION 3

2.1 SITE OVERVIEW 3
2.2 FORMER WASTEWATER TREATMENT AND STORAGE 5
2.3 SOLID WASTE BASINS 6
2.4 LAND USE 6
2.5 BASIS FOR POTENTIAL HUMAN HEALTH CONCERN 7
2.6 SUMMARY OF SITE INVESTIGATIONS 7

3.0 EXPOSURE ASSESSMENT 9

3.1 SITE CONCEPTUAL MODEL 9
3.1.1 Primary Sources of Contamination 9
3.1.2 Transport in the Environment 10
3.1.3 Populations of Primary Concern 11
3.2 EXPOSURE PATHWAYS OF CHIEF CONCERN 13
3.2.1 Exposures to Soil 13
3.2.2 Exposures to Groundwater 15
3.2.3 Exposures to Sediment 16
3.2.4 Exposures to Surface Water 16
3.2.5 Exposures to Food Items 17
3.2.6 Summary of Exposure Pathways for Quantitative Assessment 18
3.3 DATA USED IN THIS ASSESSMENT 19
3.3.1 Calculation of Toxicity Equivalents 20
3.3.2 Polychlorinated Biphenyls 22
3.3.3 Fish Tissue Concentrations 22
3.3.4 Inorganics in Groundwater 23
3.4 SELECTION OF CHEMICALS OF POTENTIAL CONCERN 23
3.4.1 COPC Selection Process 23
3.4.2 Source of Risk-Based Screening Level Values 24
3.4.3 Evaluation of Beneficial Minerals 25
3.4.4 COPC Screening Results 25
3.5 QUANTIFICATION OF EXPOSURE 26
3.5.1 Basic Equations 26
3.5.2 Human Exposure Parameters 30
3.5.3 Exposure Areas 32
3.5.4 Exposure Point Concentrations 33
3.5.5 Relative Bioavailability of Dioxins and Metals in Soil 37

4.0 TOXICITY ASSESSMENT 38

4.1 TOXICITY OVERVIEW 38

4.2 HUMAN TOXICITY VALUES 40

5.0 RISK CHARACTERIZATION 52

5.1 RISK CHARACTERIZATION OF NON-CANCER EFFECTS 52
5.2 RISK CHARACTERIZATION OF CANCER EFFECTS 54
5.3 RISK CHARACTERIZATION RESULTS 56
5.3.1 Risks to Hypothetical Future Residents 56
5.3.2 Risks to Hypothetical Future Commercial/Industrial Workers 59
5.3.3 Risks to Hypothetical Future Construction Workers 60
5.3.4 Risks to Current and Hypothetical Recreational Visitors 61

6.0 UNCERTAINTY ASSESSMENT 66

6.1 UNCERTAINTIES IN EXPOSURE ASSESSMENT 66
6.1.1 Uncertainties in Exposure Pathways Not Evaluated 66
6.1.2 Uncertainties from Chemicals Not Evaluated 68
6.1.3 Uncertainties in Exposure Point Concentrations 69
6.1.4 Uncertainties in Human Exposure Parameters 71
6.1.5 Uncertainties in Chemical Absorption (RBA) 71
6.2 UNCERTAINTIES IN TOXICITY ASSESSMENT 72
6.3 UNCERTAINTIES IN RISK CHARACTERIZATION 74
6.3.1 Uncertainties Risk Estimates Based on Fish Consumption 74
6.3.2 Uncertainties Based on Background Concentrations 75

7.0 SUMMARY AND CONCLUSIONS 77

7.1 RISKS TO HYPOTHETICAL FUTURE RESIDENTS 77
7.2 RISKS TO HYPOTHETICAL FUTURE WORKERS 78
7.3 RISKS TO RECREATIONAL VISITORS AND TRIBAL FISHERS 79
7.3.1 Risks to Recreational Visitors 79
7.3.2 Risks to Tribal Fishers 80
7.3.3 Summary of Risks Associated with Recreational and Tribal Activities 80

5-10 Total Cancer Risks to Hypothetical Future Workers from Exposures to Groundwater

LIST OF ACRONYMS AND ABBREVIATIONS

95UCL	95% Upper Confidence Limit
ABS_d	Dermal Absorption Fraction
ABS_{GI}	Fraction absorbed in gastrointestinal tract
ADAF	Age-Dependent Adjustment Factor
Ah	Aromatic Hydrocarbon
AOC	Administrative Order on Consent
AT	Averaging Time
ATSDR	Agency for Toxic Substances and Disease Registry
BCF	Bioconcentration Factor
Bgs	Below Ground Surface
BOD	Biological Oxygen Demand
BW	Body Weight
C	Concentration
C_{air}	Concentration in Air
C_c	Concentration in Fish Carcass
C_f	Concentration in Fish Fillet
C_{soil}	Concentration in Soil
C_{wb}	Concentration in Whole Body Fish
CalEPA	California Environmental Protection Agency
CDD	Chlorinated Dibenzo-*p*-Dioxins
CDF	Chlorinated Dibenzo-*p*-Furans
CF_{soil}	Conversion Factor for Soil
CFR	Clark Fork River
COPC	Contaminant of Potential Concern
Cr(VI)	Hexavalent Chromium
Cr(III)	Trivalent Chromium
CSKT	Confederated Salish and Kootenai Tribes
CSM	Conceptual Site Model
CTE	Central Tendency Exposure
DAD	Dermal Absorbed Dose
DA_{event}	Absorbed dose per event
DAF	Dermal Adherence Factor
DI	Daily Intake
DI_L	Daily Intake, averaged over a lifetime
DL	Sample-specific Detection Limit
DRI	Daily Recommended Intake
EC	Exposure Concentration
ED	Exposure Duration
EF	Exposure Frequency
EPC	Exposure Point Concentration
EPD	Effective Predictive Domain
ET	Exposure Time
EU	Exposure Unit
EV	Event Frequency

FRN	Frenchtown
FSP	Field Sampling Plan
HDPT	High Density Pulp Tank
HEAST	Health Effects Assessment Summary Table
HHRA	Human Health Risk Assessment
HI	Hazard Index
HIF	Human Intake Factor
HIF_{ing}	Human Intake Factor for Ingestion
HIF_{derm}	Human Intake Factor for Dermal
HQ	Hazard Quotient
IR	Intake Rate
IRIS	Integrated Risk Information System
Kow	Octanol/water partition coefficient
LOAEL	Lowest Observed Adverse Effect Level
MCLG	Maximum Contaminant Level Goal
MDEQ	Montana Department of Environmental Quality
MDL	Method Detection Limit
MPDES	Montana Pollution Discharge Elimination System
MRL	Minimal Risk Level
MW	Molecular Weight
ND	Non-Detect
NOAEL	No Observed Adverse Effect Level
NPL	National Priorities List
NPP	North Polishing Pond
NTP	National Toxicology Program
OCC	Old Corrugated Container
OU	Operable Unit
PCB	Polychlorinated Biphenyl
PCDD	Polychlorinated Dibenzo-*p*-dioxin
PCDF	Polychlorinated Dibenzo-*p*-furan
PEF	Particulate Emission Factor
PPRTV	Provisional Peer Reviewed Toxicity Value
p-RfC	Provisional Reference Concentration
p-RfD	Provisional Reference Dose
PRP	Potentially Responsible Party
QAPP	Quality Assurance Project Plan
RBA	Relative Bioavailability
REL	Reference Exposure Level
RI	Remedial Investigation
RI/FS	Remedial Investigation/Feasibility Study
RIWP	Remedial Investigation Work Plan
RfC	Reference Concentration
RfD	Reference Dose
RfD_{ABS}	Absorbed Reference Dose
RME	Reasonable Maximum Exposure
RSL	Regional Screening Level

SA	Surface Area
SAB	Science Advisory Board
SB	Spoils Basin
SF	Slope Factor
SF_{ABS}	Absorbed Slope Factor
SI	Site Investigation
SL	Screening Level
STR	Saint Regis
STSC	Superfund Technical Support Center
SVOC	Semi-volatile Organic Compound
SWB	Solid Waste Basin
TCDD	2,3,7,8-Tetrachlorodibenzo-*p*-dioxin
TDS	Total Dissolved Solids
TEF	Toxicity Equivalence Factor
TEQ	Toxicity Equivalent
$TEQ_{(D/F)}$	Toxicity Equivalent for Dioxins and Furans
$TEQ_{(D/F/PCB)}$	Toxicity Equivalent for Dioxins, Furans and Coplanar Polychlorinated Biphenyls
$TEQ_{(PCB)}$	Toxicity Equivalent for Polychlorinated Biphenyls
TSB	Transformer Storage Building
TSS	Total Suspended Solids
TWA	Time Weighted Average
TWF	Time Weighting Factor
UR	Unit Risk
USEPA	United States Environmental Protection Agency
VOC	Volatile Organic Compound
W_c	Weight of Fish Carcass
W_f	Weight of Fish Fillet
WOE	Weight of Evidence
kg/day	Kilogram per day
kg/kg-day	Kilogram per kilogram per day
L/day	Liter per day
m^3/day	Cubic meter per day
m^3/kg	Cubic meter per kilogram
mg/day	Milligram per day
mg/kg	Milligram per kilogram
mg/kg-day	Milligram per kilogram per day
mg/m^3	Milligram per cubic meter
$\mu g/m^3$	Microgram per cubic meter

EXECUTIVE SUMMARY

ES-1 INTRODUCTION

This document is a baseline human health risk assessment (HHRA) for the Smurfit-Stone/Frenchtown Mill Site Operable Unit 3 (OU3) ("Site). The purpose of this document is to characterize the potential risks to humans, both now and in the future, from site-related contaminants that are present at the Site, assuming that no steps are taken to remediate the environment or to reduce human contact with contaminated environmental media.

ES-2 SITE DESCRIPTION

The Site is located in Missoula County, Montana within the Clark Fork River (CFR) drainage. The historic pulp mill operated at the Site from 1957 to 2010. Most areas of the Site have been idle since industrial activities ceased in 2010. OU3 includes the current open space that was formerly used as the wastewater treatment system (settling ponds, aeration basins, polishing ponds, solid waste basins, holding ponds, spoils basins, and infiltration basins) and parts of the CFR where hazardous substances from Site activities may have come to be located.

Mill operations (predominantly the pulping and bleaching processes) used or produced various hazardous chemicals on Site, including volatile and semi-volatile organic compounds (VOCs and SVOCs), and bleaching chemicals. The use of chlorine for the bleaching of pulp produces chlorinated organic compounds, including dioxins and furans. The historical use of OU3 for treatment and storage of wastewater and solid wastes represents the primary source of contamination of OU3 soils. Historical Mill operations consisting of boiler emissions may have also resulted in direct deposition of contaminants in OU3 surface soils. Fate and transport mechanisms may have resulted in contamination moving from soils to groundwater, or surface water and sediments of on-site creeks, ponds and the CFR. As described in further detail in NewFields (2020), the Mill also operated under a Montana Pollutant Discharge Elimination System (MPDES) permit that applied to the discharging of treated effluent to the CFR via permitted outfalls and infiltration to underlying groundwater. Previous site investigations have identified contaminants of potential concern (COPCs) at the Site to include dioxins/furans, heavy metals, polychlorinated biphenyls (PCBs), SVOCs, and VOCs. Exposures to these types of COPCs may cause a range of non-cancer and cancer effects in humans, so humans who reside in, work at, and/or visit the OU3 Site now or in the future could be at risk of adverse health effects if excessive exposure to contaminated environmental media were to occur.

ES-3 EXPOSURE ASSESSMENT

Exposure is the process by which humans come into contact with chemicals in the environment. In general, humans can be exposed to chemicals in a variety of environmental media (e.g., soil, water), and these exposures can occur through several pathways (e.g., ingestion, dermal contact, inhalation).

This HHRA evaluates the potential for unrestricted future use of OU3. As such, the following receptors and exposure pathways were selected for evaluation:

Receptor	Exposure Pathway
Hypothetical Future Resident	Incidental ingestion of and dermal contact to surface soil Ingestion of groundwater as drinking water
Hypothetical Future Commercial/Industrial Worker	Incidental ingestion of and dermal contact to surface soil Ingestion of groundwater as drinking water
Hypothetical Future Construction Worker	Incidental ingestion of and dermal contact to surface and subsurface soil Inhalation of soil particulates
Recreational Visitors	
Hiker	Incidental ingestion of and dermal contact to surface soil
Camper	Incidental ingestion of and dermal contact to surface soil Ingestion of surface water (as drinking water) Incidental ingestion of and dermal contact to surface water and sediment while swimming
Recreational Fisher	Incidental ingestion of and dermal contact to surface soil Incidental ingestion of and dermal contact to surface water and sediment while fishing Ingestion of fish

Receptor	Exposure Pathway
Tribal Fisher	Incidental ingestion of and dermal contact to surface soil Incidental ingestion of and dermal contact to surface water and sediment while fishing Ingestion of fish

COPCs are contaminants which exist in the environment at concentration levels that might be of potential health concern to humans and which are or might be derived, at least in part, from site-related sources. COPCs for OU3 media were selected using a conservative procedure that is expected to retain some contaminants that are actually of little or no concern, but which ensures that no contaminants of authentic concern will be overlooked. The COPCs identified for evaluation are summarized below:

COPC	Soil	Groundwater	Surface Water	Sediment	Fish
Dioxins/furans evaluated as toxicity equivalent ($TEQ_{D/F}$)	X	X			X
Coplanar polychlorinated biphenyls (PCBs) evaluated as toxicity equivalent (TEQ_{PCB})					X
Dioxins, furans and coplanar PCBs evaluated as toxicity equivalent ($TEQ_{D/F/PCB}$)					X
Total PCBs					X
Aroclor-1260		X			
Aluminum	X	X			
Antimony	X	X			
Arsenic	X	X	X	X	
Barium	X	X			
Beryllium		X			
Cadmium	X	X			
Chromium	X	X	X	X	
Cobalt	X	X			
Copper		X			
Iron	X	X			
Manganese	X	X			
Mercury	X				

Nickel		X			
Thallium	X	X			
Vanadium	X	X			
1,4-dichlorobenzene		X			
Benzene		X			
Chlorobenzene		X			

Human exposures to COPCs in environmental media at the Site were quantified using standard equations developed by the USEPA for use at Superfund sites. Exposure parameters that define the magnitude and frequency of exposure were selected from USEPA defaults or by application of professional judgment. Because there is normally a wide range of exposure levels that may occur in a population of exposed humans, parameters were selected to provide an estimate of exposures that are "average" or are near the upper end of the range. These two exposure estimates are referred to as Central Tendency Exposure (CTE) and Reasonable Maximum Exposure (RME), respectively. Exposure parameters selected for each exposure scenario are summarized in Section 3.5 (see Tables 3-23 to 3-29).

Exposure concentrations were estimated for defined exposure areas. An exposure area (also referred to as an exposure unit or exposure point) is an area where a receptor may be exposed to one or more environmental media. In general, receptors are assumed to move about at random within an exposure area. For this assessment, OU3 was evaluated based on randomized 20-acre grid exposure areas in the upland area and based on randomized 100-acre grid exposure areas in the floodplain (see Figures 3-4 and 3-5). Groundwater wells were evaluated individually. Surface water and sediment were evaluated by water body whereby the area in the CFR defined as the OU3 study area was evaluated as one exposure area. Since the true arithmetic mean concentration cannot be calculated with certainty from a limited number of measurements, the USEPA recommends that the 95 percent (%) upper confidence limit (95UCL) of the arithmetic mean at each exposure area be used as the exposure point concentration (EPC) when calculating exposure and risk at that location. EPCs were estimated differently for soil and groundwater based on the data available. For soils, UCLs could not be calculated. Multiple soil sample types were collected from the various exposure grids including 5-point composites collected over a biased area of a 1- to 3-meter radius and 20-point composites comprised of random grab samples collected across an entire exposure grid. The larger the number of grab samples used to create the composite sample, the lower the variability around the mean estimate. Additionally, the larger the area within the exposure area that a composite sample is based, the more representative of the mean exposure across the exposure area. A 20-point composite comprised of 20 grab samples collected across the whole of the exposure area grid provides a representative estimate of the mean. Whereas, a mean concentration derived based on a localized 5-point composite is more uncertain, and the variability around the mean could be much greater. Therefore, soil EPCs

were estimated as grid-specific weighted concentrations by assigning higher confidence in the concentration based on the 20-point composite than the 5-point composite (see Section 3.5.4). Particulate concentrations in air were estimated from soil concentrations and an assumed particulate emission factor (PEF) to account for soil disturbances at construction sites (inhalation of soil particulates was only quantified for a hypothetical future construction worker).

Groundwater EPCs were generated for each individual well. Data from all sampling years considered in the risk assessment were used in deriving well-specific EPCs. A 95UCL was calculated where at least four detected values were available, per USEPA guidance (USEPA 2015b). If this data requirement was not met, the EPC was set equal to the maximum detected value. CFR surface water and sediment EPCs for arsenic and chromium were derived using ProUCL to generate 95UCLs. Surface water EPCs for arsenic and chromium in the on-site creeks were based on the maximum detected concentrations.

Fish EPCs were based on wet weight concentrations estimated as 95UCLs by species and tissue type (fillet or whole body).

An accurate assessment of human exposure to ingested contaminants requires knowledge of the amount of contaminant absorbed from the gastrointestinal tract into the body from site media compared to the amount of absorption that occurred in the toxicity studies used to derive the toxicity factors. This ratio (amount absorbed from site media compared to the amount absorbed in toxicity tests) is referred to as Relative Bioavailability (RBA).

The oral RBA value for dioxins in soil is assumed to be 100% in accordance with USEPA (USEPA 2010b). This is considered to be a conservative assumption, because reports summarized by USEPA (2010b) indicate that absorption of dioxins from soils through the gastrointestinal tract is usually less than 50%.

In general, metals in soils exist in the form of mineral particles that are not completely solubilized in gastrointestinal fluids when ingested, while toxicity studies often utilize readily soluble forms of the test contaminant. Thus, oral RBA values for metals in soils are often less than 1.0. For arsenic, sufficient data are available to establish that oral RBA values in soil are generally less than 60% (USEPA 2012b). Thus, for the purposes of this HHRA, a RBA of 60% was applied for arsenic in OU3 soils. RBA data are much more limited or absent for other metals (except lead which was not identified as a COPC in this assessment). RBA values for all other metal COPCs were conservatively assumed to be 100%.

ES-4 TOXICITY ASSESSMENT

The objective of a toxicity assessment is to identify what adverse health effects a contaminant may cause, and how the emergence of these adverse effects depends on exposure level.

The toxicity assessment process is usually divided into two parts: the first characterizes and quantifies the non-cancer effects of the contaminant, while the second addresses the cancer effects of the contaminant. This two-part approach is employed because there are typically major differences in the time-course of action and the shape of the dose-response curve for cancer and non-cancer effects. The relationship between the dose of the contaminant administered or received and the incidence of adverse health effects in the exposed population forms the basis for a quantitative dose-response relationship. Toxicity values are derived based on such dose-response relationships (see tables 4-1 to 4-2).

ES-5 RISK CHARACTERIZATION

The potential for non-cancer effects is evaluated by comparing the estimated exposure concentration for a receptor over a specified time period to a reference threshold that represents the exposure below which it is unlikely for even sensitive populations to experience adverse health effects. This ratio of exposure to toxicity is called a Hazard Quotient (HQ). The sum of HQ values cross different exposure pathways is referred to as the hazard Index (HI). If the HQ or HI for a chemical is equal to or less than one, it is believed that there is no appreciable risk that non-cancer health effects will occur. If an HQ or HI exceeds one, there is some possibility that non-cancer effects may occur, although an HQ or HI above one does not indicate an effect will occur. However, the larger the value, the more likely it is that an adverse effect may occur. Because the assumption of dose additivity in the HI approach is most relevant to contaminants that induce an effect on the same target organ within a human body, target organ specific HI values were calculated in this HHRA for receptors and pathways where the total HI summed across COPCs >1E+00. The risk benchmark for non-cancer hazard based on target organ HIs was also HI >1E+00.

The excess risk of cancer from exposure to a chemical is described in terms of the probability that an exposed individual will develop cancer because of that exposure. Excess cancer risks are summed across all carcinogenic chemicals and all exposure pathways that contribute to exposure of an individual in a given population. The level of total cancer risk that is of concern is a matter of personal, community, and regulatory judgment. In general, the USEPA considers excess cancer risks that are below one in one million (1E-06) to be so small as to be negligible, and risks above one in ten thousand (1E-04) to be sufficiently large that some sort of remediation is desirable. Excess cancer risks that range between 1E-04 and 1E-06 are generally considered to be acceptable, although this is evaluated on a case by case basis. Furthermore, the MDEQ

allowable cancer risk level is 1E-05, which will be considered outside of this risk assessment as part of the risk management decisions associated with this Site.

Detailed calculations of exposure and risk from each COPC for each exposure scenario are presented in Appendix D and are summarized in Section 5.3. In brief, unacceptable risks (HI > 1E+00, cancer risk ≥ 1E-04) are predicted for hypothetical future residents and commercial/industrial workers who may be exposed to OU3 soils and groundwater. Non-cancer hazards and cancer risks for these receptors are primarily driven by consumption of OU3 groundwater as drinking water. The primary risk drivers in groundwater are arsenic and manganese, and to a lesser extent cobalt, iron, and chromium. Acceptable non-cancer hazards (HI ≤ 1E+00) to hypothetical future residents based on direct exposures to OU3 soils are predicted in most areas of OU3. However, unacceptable non-cancer hazards for a hypothetical future child resident are predicted in 27 of the exposure grids. HIs in these grids are driven by exposure via the incidental ingestion of surface soil. Target organ specific HIs only exceed 1E+00 in five of these exposure grids (grids 55, 58, 67, 68 and 74). The risk driver in grid 55 is manganese that contributes to potential nervous system effects. $TEQ_{D/F}$ is the risk driver in the other grids contributing to potential reproductive system effects. In grid 74, arsenic and thallium are also risk drivers that contribute to potential dermal effects. Unacceptable cancer risks are also predicted for the hypothetical future RME resident based on incidental ingestion of OU3 surface soils in upland exposure area grids 26, 42, 47, 48, 49, 50, 53, 54, 55, 56, 58, 59, 65, 67, 68, 71, 72, 74 and in floodplain exposure area grids 86, 88, 90, 91, 93, 94, 95, and 98. Unacceptable cancer risks for the hypothetical future CTE resident are only predicted in grid 48 (cancer risk = 1E-04). These predicted cancer risks from soil exposures to hypothetical future residents are primarily driven by assumed early lifetime exposures to chromium (evaluated as hexavalent chromium [Cr(VI)] accounting for a mutagenic mode of action). Acceptable non-cancer hazards and cancer risks are predicted for the hypothetical future commercial/industrial worker and construction worker populations based on direct contact exposures to OU3 soils.

Estimated non-cancer hazards and cancer risks to a current and/or hypothetical future hiker within OU3 are predicted to be acceptable (HI ≤ 1E+00, cancer risk < 1E-04) based on direct contact exposures with OU3 surface soils. Acceptable risks were predicted for direct contact exposures by current and/or hypothetical future campers to most OU3 soils, with the exception of surface soils in grid 74. The cancer risk predicted from exposures to OU3 soils in Grid 74 is 1E-04 for the RME scenario. This cancer risk is based on total risk from $TEQ_{D/F}$, arsenic, and chromium. However, the individual contaminant predicted cancer risks are all below 1E-04. Cancer risks predicted for campers from exposures to OU3 soils in all other grids are below 1E-04. Acceptable risks are predicted based on exposures by campers to surface waters and sediments in on-site creeks or in the CFR.

Unacceptable non-cancer hazards and cancer risks are predicted for both recreational and tribal fishers (HI > 1E+00, cancer risk ≥ 1E-04). These are attributed to consumption of fish collected from the CFR; acceptable non-cancer hazards and cancer risks are predicted for both recreational and tribal fishers based on exposures to floodplain soils and CFR surface water and sediment. Evaluation of exposures to dioxins/furans and PCBs in rainbow trout and northern pike revealed that levels of TEQ and total PCBs within the tissues of game fish in the CFR from within the OU3 study area may contribute to risks above a level of concern for fishers who consume these fish as a significant portion of their diet. Comparison of the risk estimates for TEQ suggest that coplanar PCBs are contributing most of the risk to TEQ. Cancer risks based on total PCBs are also ≥1E-04 for a RME tribal fisher consuming northern pike as fillets or whole body. Predicted non-cancer hazards and cancer risks to local fishers are likely lower than those estimated in this assessment based on potential cooking losses of dioxins/furans and PCBs. Evaluation of general cooking loss for dioxins and PCBs demonstrated that the predicted non-cancer hazards and cancer risks are reduced by comparison to the risk estimates based on no assumed cooking loss. However, unacceptable risks are still predicted based on the consumption of fish collected from the CFR even when accounting for cooking loss.

ES-6 UNCERTAINTY ASSESSMENT

Quantitative evaluation of the risks to humans from environmental contamination is frequently limited by uncertainty regarding a number of key data items, including concentration levels in the environment, the true level of human contact with contaminated media, and the true dose-response curves for non-cancer and cancer effects in humans. This uncertainty is usually addressed by making assumptions or estimates for uncertain parameters based on whatever limited data are available. Because of these assumptions and estimates, the results of risk calculations are themselves uncertain, and it is important for risk managers and the public to keep this in mind when interpreting the results of a risk assessment. However, the assumptions applied in this assessment are intended to be health-protective to account for this uncertainty. The cumulative effect of these assumptions can result in an evaluation with an overall conservativeness greater than the individual components. Thus, it is important to note that the risks presented in this assessment are more likely to be overestimated rather than underestimated.

A significant source of uncertainty for this risk assessment is the form of chromium present in Site media. Chromium was only evaluated as total chromium in Site samples. There is no information available to understand the ratio of Cr(VI) to trivalent chromium (Cr(III)) in Site media. In the absence of data based on oxidation state, the health protective approach used in this evaluation estimated risks based on the more toxic form, Cr(VI). Because there is no indication that historical Mill operations used or generated Cr(VI), evaluating chromium risks as being attributed to 100% exposure to Cr(VI) suggests that the estimated risks are overestimated.

Unacceptable risks associated with the recreational scenarios evaluated in this assessment are predicted for fishers consuming fish collected from the CFR within the OU3 study area. Risk estimates derived for the purposes of this assessment were based on conservative exposure assumptions including assuming that 100% of a fisher's diet was comprised of locally caught fish. This type of assumption likely overestimates actual risks associated with fish consumption, but nonetheless it is considered health protective consistent with USEPA Superfund guidance.

1.0 INTRODUCTION

1.1 Purpose

This document is a human health risk assessment (HHRA) for the Smurfit-Stone/Frenchtown Mill Operable Unit 3 (OU3) Site located in Montana. The purpose of this document is to evaluate potential risks to humans, both now and in the future, from Site-related chemicals that are present at the OU3 Site, assuming that no steps are taken to remediate the environment or to reduce human contact with contaminated environmental media.

The results of this assessment are intended to help inform risk managers and the public about current and potential future health risks to humans that may occur as a result of exposure to Site-related contaminants, and to help determine if there is a need for action to protect public health at the OU3 Site. Although the Site is not listed on the National Priorities List (NPL), a Remedial Investigation (RI) is being conducted by the Potentially Responsible Parties (PRPs)[1] in accordance with the Administrative Order on Consent (AOC) entered into with the United States Environmental Protection Agency (USEPA) in November 2015 (USEPA 2015a). The RI serves as the mechanism for collecting data to characterize Site conditions for the purposes of developing and evaluating remedial alternatives. The RI characterizes the nature and extent of contamination at a Site and estimates risks to human health and the environment posed by contaminants at the Site. The latter objective is achieved by conducting a baseline risk assessment during the RI process to characterize risks posed to human health or the environment by current environmental conditions at the Site. To meet this requirement and consistent with the Site-specific AOC, the USEPA has developed this HHRA to quantitatively describe the potential human health risks at the OU3 Site in the absence of remediation. The risk information generated by this evaluation based on USEPA's current understanding of the Site will be used in the Remedial Investigation/Feasibility Study (RI/FS) at the Site. This baseline risk assessment represents only one part of the human health evaluation being conducted under the RI/FS.

The methods used to evaluate risks in this assessment are consistent with current guidelines for human health risk assessment provided by the USEPA for use at Superfund sites (USEPA 1989; 1991a; 1991b; 1991c; 1992; 2002a,b; 2004; 2009; 2014a, 2014b). The evaluation presented herein is based on the current understanding of the Site given the information and data available at the time of development. This HHRA represents a dynamic document that may need to be revised and/or updated to address new information.

[1] International Paper Company, WestRock CP, LLC, and M2Green LLC as defined in the Administrative Order on Consent (AOC).

1.2 Organization

In addition to this introduction, this report is organized into the following sections:

Section 2 This section provides a description of the Site and a review of Site investigations that have been conducted to collect and characterize the environmental contamination at the Site.

Section 3 This section identifies human exposure scenarios of potential concern at the OU3 Site and describes the approach for identifying chemicals of potential concern (COPCs) for each exposure medium.

Section 4 This section includes the toxicity assessment and identifies potential non-cancer and cancer effects and toxicity values for the COPCs identified at the OU3 Site.

Section 5 This section summarizes estimated exposure and risk to humans from COPCs at the OU3 Site.

Section 6 This section summarizes the uncertainty analysis.

Section 7 This section summarizes the main conclusions based on the risk characterization.

Section 8 This section provides full citations for USEPA guidance documents, Site-related documents, and scientific publications referenced in this report.

All tables, figures, and appendices cited in the text are provided at the end of the report.

2.0 SITE CHARACTERIZATION

A detailed description of the Smurfit-Stone/Frenchtown Mill Site and its history is provided in the Remedial Investigation Work Plan (RIWP) report for the Site (NewFields 2015). Site information is also provided on USEPA's Superfund Page for the Site[2]. Pertinent information derived from these sources is summarized in brief in the following subsections.

2.1 Site Overview

The Smurfit-Stone/Frenchtown Mill Site is in Missoula County, Montana and is located 11 miles northwest of Missoula, Montana (Figure 2-1). The entire Site consists of three operable units and encompasses approximately 3,150 acres. The Site is located in the Clark Fork River (CFR) drainage. The CFR flows westward through the valley and north along the Site's western property boundary. The small tributaries O'Keefe Creek and Lavalle Creek flow through the southern end of the Site and drain into the CFR. A pulp mill operated at the Site from 1957 to 2010. Most areas of the Site have been idle since industrial activities at the Mill ceased in 2010. A detailed description of the Site and historical operation of the pulp mill is provided in the RIWP (NewFields 2015) and briefly summarized below.

The core industrial footprint of the Mill Site covers about 260 acres and includes the former mill, recycling plant, wood chipping area, and hog fuel area as well as various equipment storage areas. Over 900 acres of the Site consist of a series of unlined ponds used to store treated and untreated wastewater effluent from the Mill, as well as primary sludge recovered from untreated wastewater. Some ponds initially used to store wastewater were drained and used for the landfilling of solid wastes generated from the Mill. Most of the pulp was used to produce un-bleached linerboard, but about 6 percent of the total pulp produced from 1960-1999 was used to create white linerboard or sold as bleached pulp. The on-site production of chlorine, for the pulp bleaching process results in the formation of chlorinated dibenzo-*p*-dioxins (CDDs) and dibenzo-*p*-furans (CDFs) (USEPA 1990). During the production of pulp and paper, high usage of water and energy resulted in large amounts of wastewater, solid waste (e.g., treatment sludges, boiler ash, wood processing residuals, lime kiln grits, inert materials, and general refuse) and air emissions. The paper making process at the Site was designed to recover and recycle chemicals utilized in the washing and digesting processes. Stack emissions from recovery boilers, power boilers, and lime kilns were controlled and monitored, and releases to the atmosphere were subject to permit standards. The Mill included a wastewater treatment system that included a primary clarifier and settling ponds (primary treatment), sludge dewatering plant, aeration basins

[2] Smurfit-Stone Mill Frenchtown, Missoula, MT webpage: https://cumulis.epa.gov/supercpad/cursites/csitinfo.cfm?id=0802850

(secondary treatment), polishing ponds, a color removal plant (tertiary treatment), and a series of unlined holding ponds used to store treated effluent prior to discharge. When holding ponds were at capacity, treated wastewater was moved to infiltration basins and infiltrated to groundwater. Treated wastewaters discharged to the CFR was subject to Montana Pollution Discharge Elimination System (MPDES) permit standards (i.e., flow and ambient river temperature criteria). There are two main levees and several berms that were constructed using on-Site materials[3]. The CFR levee located west of the treated water holding ponds provides flood protection, and the inner levee provides a physical barrier between wastewater solids and treated water holding ponds.

The USEPA conducted an initial site investigation (SI) in 2011 to support evaluation of the Site for possible inclusion in the NPL (USEPA 2012a). This investigation was focused on the former wastewater treatment and storage area, O'Keefe Creek, and the CFR. The Smurfit-Stone/Frenchtown Mill Site was proposed to be added to the NPL on December 12, 2013. As noted above, the Site has not been added to the NPL. For assessment and management purposes, the USEPA, the Montana Department of Environmental Quality (MDEQ), and the PRPs agreed to divide the Site into three operable units (OUs) based on historic use and the nature of the potential environmental concerns, as follows (Figure 2-2):

> **OU1** encompasses about 1,200 acres of the Site. This area has been and continues to be used largely for agricultural purposes, including grasslands for cattle grazing and cropland irrigated for alfafa and grain crops.
>
> **OU2** encompasses approximately 255 acres of the Site and includes the former industrial area. This area includes the former buildings and process areas for the Mill.
>
> **OU3** encompasses approximately 1,700 acres of the Site and includes areas of the Site where solid and aqueous wastes were treated and stored. This area includes the former wastewater treatment system (settling ponds, aeration basins, polishing ponds, solid waste basins, holding ponds, spoils basins, and infiltration basins), the holding ponds areas within the 100-year floodplain, and parts of the CFR where hazardous substances from site activities may have come to be located.

Human health risks within OU1 were previously evaluated in 2017 (USEPA 2017). Human health risks within OU2 are being evaluated in a separate report. This assessment focuses on OU3 (i.e., the study area). OU3 includes the land outside of the 100-year floodplain where the

[3] This HHRA does not evaluate effects from hypothetical future flooding events. Berm stability has been evaluated in multiple investigations (NewFields 2018a, 2018b, 2019).

former wastewater treatment system was contained. This area will be referred to herein as the "upland" area. OU3 also includes the land within the 100-year floodplain up to and including the CFR. As defined in NewFields (2015), OU3 includes locations in the CFR where hazardous substances from Site activities have come to be located, if any. The full nature and extent to which hazardous substances from Site activities have come to be located in the CFR adjacent to and downstream of the Site has not been fully established and is outside of the scope of this risk assessment, but will be considered within the RI. For the purposes of this assessment, sampling conducted to date within the CFR adjacent to the Site and downstream of the Site is considered to represent potential areas where Site-related contamination may have deposited, and is hereafter defined as within the "study area" evaluated within this HHRA (Figure 2-3).

Within the AOC, OU3 is defined to include site-wide groundwater (USEPA 2015a). Groundwater beneath the Site is present in three primary hydrostatigraphic units (NewFields 2020):

- Unit 1 – water table aquifer below the Site, generally present to a depth of approximately 35 feet below ground surface (ft bgs). Most onsite monitoring wells are completed within Unit 1.
- Unit 2 – semi-confining layer generally present from 35 to 130 ft bgs. No monitoring or water supply wells have been completed in Unit 2, as this unit transmits relatively minor quantities of water compared to Units 1 and 3.
- Unit 3 – regional water supply aquifer generally present from 130 to 160 ft bgs. Several monitoring wells and all the industrial and domestic water supply wells on the Site are completed in Unit 3.

Since the USEPA is evaluating human health risks separately for each individual OU, each HHRA includes evaluation of groundwater collected from wells within the boundary for the OU being assessed. For the purposes of this assessment, groundwater data collected from wells within the OU3 land boundary were evaluated in this report. Groundwater data collected from wells within the land boundaries of the other OUs were evaluated in the respective HHRA reports.

2.2 Former Wastewater Treatment and Storage

Figure 2-4 (adapted from NewFields 2015) presents a schematic of the general wastewater treatment flow process that was followed during the last 13 years of operation (1997-2010). The wastewater treatment system was designed to allow for flexibility to route treated water to multiple areas when needed. As shown in Figure 2-4, the Mill maintained four permitted outfalls to the CFR. Treated wastewater discharged to the CFR through outfalls 1 through 3 was subject to permit conditions including ambient river temperature and flow. Outfall 4 was used for

discharging non-contact cooling water. The outlet at the North Polishing Pond (NPP) was the point of compliance for the wastewater treatment system.

2.3 Solid Waste Basins

The Mill utilized spoils basins (SBs) and solid waste basins (SWBs) in OU3 (Figure 2-4), as follows:

- SB19 & SB20 received dredged pond material (spoils) removed from the aeration basins and settling ponds (P5 and P8).
- SWBA received general refuse (paper, plastic, metal, wood, glass, and food).
- SWB6 received hog fuel ash and lime kiln grits.
- SWBCa and SWBCb received hog fuel, lime grits, and ragger wire.
- SWBF received asbestos containing materials.
- SWBG received Class III inert materials (wood, gravel, log yard wastes, bricks).

All solid waste basins listed above were closed and capped in 1993 except for SWBG which has an open and active permit to receive Class III inert materials. After 1993, all Class II solid wastes generated by the Mill were transported offsite for disposal.

2.4 Land Use

The OU3 Site is mostly open space consisting of upland and floodplain meadows, ponds, and wetlands. O'Keefe Creek enters the boundary of the Smurfit-Stone/Frenchtown Mill Site along the southern edge of OU2 as shown in Figure 2-2. O'Keefe Creek runs through portions of OU3 to the confluence with Lavalle Creek prior to discharging to the CFR. Lavalle Creek runs up through OU1 land on the southern end of the Site prior to the confluence with O'Keefe Creek. The CFR is used recreationally in the summer months (mainly between Memorial Day to Labor Day) for a variety of activities, including camping, hiking, and fishing. The CFR is a culturally significant fishery of the Confederated Salish and Kootenai Tribes (CSKT) of the Flathead Nation.

There are no current residential or commercial properties within OU3. Building within the floodplain is not preferred, but with proper design and conditions, residential development is allowable within the 100-year floodplain (Missoula County 2017). The PRPs have indicated that there is a restrictive covenant currently placed on the property that restricts future development to industrial/commercial activities. The agencies have not approved the use of such a restrictive covenant as an element of the final remedial action, nor does the restrictive covenant limit the agencies' analysis of risk or reasonably anticipated future use. Previous discussions have indicated the potential to develop areas within the 100-year floodplain of the CFR into natural

riparian woodlands or wet meadows with recreational features including trails, river access, golf course, and/or parks (NewFields 2015).

2.5 Basis for Potential Human Health Concern

Mill operations (predominantly the pulping and bleaching processes) used or produced various hazardous chemicals on site, including volatile and semi-volatile organic compounds (VOCs and SVOCs), and bleaching chemicals. The use of chlorine for the bleaching of pulp produces chlorinated organic compounds, including dioxins and furans. Treatment and storage of solid and aqueous wastes within OU3 may have resulted in contamination of surface soils and subsequent contamination of subsurface soils and groundwater, as well as possible contamination of sediments and surface water within the CFR and its tributaries that flow through the Site via fate and transport mechanisms discussed in further detail below. Previous site investigations have identified COPCs at the Site to include dioxins/furans[4], heavy metals, polychlorinated biphenyls (PCBs)[5], SVOCs, and VOCs. Exposures to these types of COPCs may cause a range of non-cancer and cancer effects in humans. Humans who reside in, work at, and/or visit the OU3 Site now or in the future could be at risk of adverse health effects if excessive exposure to contaminated environmental media were to occur.

2.6 Summary of Site Investigations

Numerous environmental studies and compliance monitoring events have been conducted at the Site in support of ongoing RI activities. In 2011, the USEPA conducted a site investigation (SI) to support evaluation of the Site for proposed NPL listing (USEPA 2012a)[6]. Following the 2011 SI, the PRPs for the Site commissioned the collection of environmental samples in April 2014 from areas that were not investigated by the USEPA in 2011. These data were evaluated within the RIWP (NewFields 2015) which also outlined sampling planned in 2015. Follow-up sampling was conducted in a series of sampling events in accordance with the USEPA approved RIWP and associated Field Sampling Plan (FSP) and Quality Assurance Project Plan (QAPP). Between 2014 and 2020, the following environmental investigations were conducted[7]:

[4] See USEPA Factsheet on dioxins/furans at the Site (USEPA 2021a).
[5] See USEPA Factsheet on PCBs at the Site (USEPA 2021b).
[6] As noted in Appendix A, data collected in 2011 were not considered in the HHRA due to deviations from the Quality Assurance Project Plan that occurred during sampling and analysis of those samples. Instead, USEPA used those data to inform the RI sampling.
[7] RIWP reports are available on the Smurfit-Stone Mill Frenchtown, Missoula, MT webpage: https://cumulis.epa.gov/supercpad/SiteProfiles/index.cfm?fuseaction=second.docdata&id=0802850

Sampling Date	Sample Type[8]	Reference
April 2014	Soil and groundwater sampling	RIWP (NewFields 2015)
November/December 2015	Soil, groundwater, sediment and surface water sampling	RIWP (NewFields 2015, 2016a)
May/June 2016	Groundwater sampling	RIWP Addendum 1 (NewFields 2016b)
August 2016	Soil sampling for PCBs at the HDPT foundation and TSB foundation areas	RIWP Addendum 2 (NewFields 2016c)
January and March 2017	Groundwater sampling	RIWP Addendum 3 (NewFields 2017a)
June, July, December 2017 and January 2018	Groundwater sampling	RIWP Addendum 4 (NewFields 2017b)
October 2017	Soil sampling	RIWP Addendum 7 (NewFields 2017c)
July 2018	Fish sampling	USEPA (2018a)
August 2018	Sediment, surface water, and biotic tissue sampling	RIWP Addendum 9 (NewFields 2018b)
June 2019	Fish sampling	USEPA (2019)
June 2019 and September/October 2019	Groundwater sampling	RIWP Addendum 8 (NewFields 2018a)
June and September 2020	Groundwater sampling	RIWP Addendum 10 (NewFields 2020)

[8] Soil samples collected from the Site represent bulk soils.

3.0 EXPOSURE ASSESSMENT

Exposure is the process by which humans come in to contact with chemicals in the environment. In general, humans can be exposed to chemicals in a variety of environmental media (e.g., soil, sediment, water, air, food), and these exposures can occur through several routes (e.g., ingestion, dermal contact, inhalation).

3.1 Site Conceptual Model

Figure 3-1 presents a Conceptual Site Model (CSM) for OU3 that summarizes USEPA's current understanding of how chemicals that have been released to the environment within OU3 might result in exposure of human receptors. This CSM is based on the most current understanding of expected land use now and in the future. The main features of this CSM are discussed below.

3.1.1 Primary Sources of Contamination

As noted above and as described in further detail in the RIWP, historic Mill operations included the creation of pulp, wood chipping, recycling of old corrugated container (OCC), burning of solid fuels in boilers, and paper making (NewFields 2015). Pulp and paper manufacturing involve a series of steps, each producing one or more characteristic wastes. NewFields (2020) provides a detailed description of the pulp making process at the Mill and the associated waste streams generated during operation. In brief, the chemical pulping process used at the Mill (the "Kraft process") used a sodium-based alkaline solution (white liquor), consisting of sodium hydroxide and sodium sulfide, to digest wood chips and produce pulp. Smaller amounts of sulfuric acid and aluminum sulfate were also used during the process. No metals besides aluminum were used in the paper making process, although pulp is made from raw materials (i.e., wood), and the concentrations of metals in the trees used to produce the pulp is unknown.

After producing the raw pulp, it was processed to remove impurities by chemically treating the pulp mixture to recover residual white liquor for reuse and remove heavy metals. Waste products such as excess sodium hydroxide and sodium sulfite were also removed. As noted above, a chlorine bleaching process was used to create white linerboard for about 6% of the pulp produced between 1960 and 1999 (NewFields 2020). The combination of chlorine and carbon can result in the formation of dioxins and furans under particular temperature and pressure conditions.

The historical use of OU3 for treatment and storage of wastewater and solid wastes represents the primary source of contamination of OU3 soils. Historical Mill operations consisting of boiler emissions may have also resulted in direct deposition of contaminants in OU3 surface soils.

Emissions from the recovery boilers, multi-fuel and power boilers, the lime kilns, and ambient air systems were controlled and monitored consistent with the Mill's Title V air quality operating permit issued by MDEQ (NewFields 2020; Permit OP 2589). The Title V permit covered the sources of air emissions at the historic Mill including the: Pulp, Chip Dock and Recycled Fiber Department, the Power, Recovery, and Recausticizing Department, the Paper Mill Department, the Environmental and Technical Department, and the Engineering and Maintenance Department.

As described in further detail in NewFields (2020), the Mill also operated under a MPDES permit that applied to the discharging of treated effluent to the CFR via permitted outfalls and infiltration to underlying groundwater. MPDES permits included limits based on biological oxygen demand (BOD), total suspended solids (TSS), total dissolved solids (TDS), and nutrient reduction (nitrogen and phosphorus). Limits on toxic pollutants were based on Section 307(a) of the Montana Water Quality Act pursuant to established water quality standards. During mill operations, wastewater in the ponds infiltrated into Unit 1. The accumulation of wastewater in the ponds resulted in seasonal groundwater mounding in Unit 1 that was most pronounced in the winter and early spring. Groundwater mounding in Unit 1 likely contributed to downward vertical hydraulic gradients from Unit 1 to Unit 3.

PCBs are not generally produced in the practice of wastewater chlorination in the paper industry (USEPA 1977). Generally speaking, potential sources of PCBs in the pulp and paper industry may include the use of printing inks containing PCBs, the recycling of carbonless copy paper (if manufactured from 1957 to 1971), use of PCB transformers and capacitors, and possible use of PCB-filled hydraulic or heat transfer systems, PCB-containing lubricants, paints, etc. (USEPA 1977). Specific to the Site, there is no available information to suggest significant use of process chemicals or inks containing PCBs. Site investigations have determined that PCBs were present in localized areas of OU2 associated with transformer storage (Transformer Storage Building [TSB]) and in the vicinity of the former High-Density Pulp Tank (HDPT). A removal action was taken in these areas in 2016 (NewFields 2018c).

3.1.2 Transport in the Environment

Solid wastes generated during mill operations or recovered from the aqueous waste stream were either burned for energy recovery (e.g. primary wastewater treatment plant solids) or were stored in solid waste disposal areas. Treated wastewater was stored in ponds designed to allow infiltration into soil and groundwater. Water that did not infiltrate was ultimately discharged into the CFR. Additionally, contaminants generated and/or released from historical Mill operations may migrate in the environment by several processes:

- Fine-grained soil particulates from contaminated soil and/or solid waste disposal areas may be released into air as a consequence either of wind erosion and/or human disturbances. The waste materials in the settling ponds were saturated due to precipitation and historic inundation which limited dust generation. Additionally, transport of contaminants emitted to the air from boiler emissions can result in direct deposition of chemicals in OU3 surface soils[9].

- Runoff (from rain or snowmelt) from surface soils and/or solid waste disposal areas may result in contamination of both surface water and sediments in the CFR and its tributaries (O'Keefe and Lavalle Creeks).

- Contaminants in soil may be dissolved by water (rain or snowmelt) and infiltrate into subsurface soils and downward into groundwater.

3.1.3 Populations of Primary Concern

Humans who are most likely to be exposed to Site-related contamination include the following:

Hypothetical Future Residents. There are no current residences at the OU3 Site. To be conservative and consistent with USEPA Superfund guidance, hypothetical future residential land use within OU3 is evaluated. The residential population is defined as individuals (children aged 0 to 6 years and adults) that inhabit residences within OU3.

Hypothetical Future Commercial/Industrial Workers. There are no current commercial/industrial buildings within OU3. Anticipated future land use within the OU3 upland area includes commercial/industrial activities. Consistent with the evaluation of potential hypothetical future residential land use within OU3, hypothetical future commercial/industrial land use within OU3 is also evaluated. The commercial/industrial worker population is defined as full-time employees (adults) working on-Site.

Hypothetical Future Construction Workers. In support of hypothetical future residential and/or commercial/industrial development within OU3, associated construction activities may occur. The construction worker population is defined as an adult who may be exposed during construction activities including soil excavation.

[9] USEPA published a Smurfit Stone Mill Site Air Deposition Fact Sheet (USEPA 2021c) that describes how USEPA has investigated impacts of aerial deposition and addresses potential environmental concerns. https://semspub.epa.gov/work/08/100010222.pdf

Recreational Visitors. As noted above, the OU3 Site is mostly open space consisting of upland and floodplain meadows, ponds, and wetlands. Aside from the access road in OU3, there are no well-defined hiking trails. However, the CFR is popular for recreation and a variety of different types of recreational visitors may encounter Site-related contamination while recreating in the study area. For this evaluation, it is assumed that hiking or camping may occur anywhere in OU3. It is also assumed that the CFR is used for wading, floating, boating and fishing. The lack of fish and stagnate nature of the on-Site ponds, and the presence of only smaller fish that are not typically targeted for human consumption within the smaller on-Site creeks (O'Keefe and Lavalle Creeks) limits similar activities in these water bodies. For the purposes of this assessment, three scenarios have been selected to serve as representative activities for a recreational visitor at the Site:

- Hiker: The hiker is selected to represent a typical soil exposure at the Site. The hiker population is assumed to include older children/adolescents (aged 6 to 16 years) or adults who pass across the Site while hiking in the area.

- Camper: The camper is selected to represent a receptor who may come into contact with multiple contaminated media (soil, surface water, sediment) while camping within the Site boundary. This population is assumed to include young children (0-6 years), older children/adolescents (aged 6 to 16 years), and adults.

- Recreational Fisher: The recreational fisher population represents children (0-6 years), older children (aged 6 to 16 years), and adults who may collect and consume fish from the CFR included within the OU3 study area.

Tribal Fishers. Pursuant to the Hellgate Treaty of 1855, the CSKT are a natural resources trustee of the CFR fishery and reserved themselves the right to fish within the CFR. Thus, the OU3 CSM includes tribal fishers as an additional population of concern. The tribal fisher population is defined as children (0-6 years), older children (aged 6 to 16 years), and adults that fish within the CFR.

USEPA recognizes that there may be other receptors who are exposed at the Site now or in the future that are not specifically captured within the populations described above. However, it is assumed that evaluation of the receptor populations described above is protective of other potential receptors who may be intermittently exposed to contaminated media at the OU3 site. For instance, it is assumed that exposures to hypothetical future commercial/industrial workers and construction workers will be higher than exposures to people working on maintenance of the levees and berms or trespassers.

3.2 Exposure Pathways of Chief Concern

Not all of the potential exposure pathways to these populations of receptors are likely to be of equal concern. First, in order to be of concern, an exposure pathway must be "complete". That is, there must be contact between a human receptor and a contaminated environmental medium. Exposure pathways that are not complete are indicated in Figure 3-1 by open boxes. For pathways that are complete, the relative importance of one to another is related to the amount of chemical taken into the body by each pathway. Exposure scenarios that are likely to result in the highest level of exposure are shown in Figure 3-1 by boxes containing a solid circle (●). Greatest attention is focused on quantification of exposure from these pathways in order to determine if the pathway contributes significant risk. Pathways that are complete, but which are judged to contribute only minor exposures in comparison to other pathways, are shown by boxes with an open circle (❍). Because of their minor contribution, these pathways are not evaluated quantitatively. Boxes with an "X" indicate exposure pathways that are likely to be complete, but for which data are insufficient to derive meaningful risk estimates.

The following sections present a more detailed description of these pathways and an analysis of their relative importance for human exposure.

3.2.1 Exposures to Soil

Exposures to Surface Soil

Incidental Ingestion of Soil

Even though few people intentionally ingest soil, anyone who has direct contact with contaminated surface soil may incidentally ingest small amounts that adhere to their hands during outdoor activities. Incidental ingestion of soil is often one of the most important routes of human exposure, so ingestion of surface soil is evaluated for all receptors. For this evaluation, surface soil is defined as the six-inch depth below ground surface (0-6" bgs).

Due to the nature of the work, construction workers may be exposed via direct contact to soils down to a depth of 10 feet. Construction workers who have direct contact with contaminated soils may get soils on their skin and incidentally ingest small amounts that adhere to their hands during construction activities. On this basis, incidental ingestion of surface and subsurface soils is considered a complete exposure pathway for hypothetical future construction workers.

Dermal Contact with Surface Soil

Humans who come into contact with contaminated soils may get some of the material on their skin. As such, dermal exposure to surface soil is considered a complete exposure pathway and is evaluated quantitatively for all receptors. For hypothetical future construction workers, it is assumed that dermal exposure to surface and subsurface soil is a complete exposure pathway and is evaluated quantitatively.

Inhalation of Airborne Soil Particulates

Whenever contaminated soils are exposed at the surface, fine-grained particles may become suspended in air by wind and/or human activity, and humans in the area could inhale those particles. In cases where the soil is disturbed only by wind or light human activity (e.g., walking/hiking), the amount of particulate material inhaled from air is generally quite small compared to the amount that is typically assumed for incidental ingestion. Therefore, inhalation of soil particulates generated by wind erosion or walking was considered a minor pathway for hypothetical future residents, commercial/industrial workers, and recreational visitors. Appendix B presents screening level calculations to support this designation.

When soil is disturbed by mechanical forces such as construction equipment, dust levels in air may be significant and intake of soil from inhalation of airborne dusts may become similar to or even higher than the ingestion pathway. Thus, inhalation of soil particulates generated through the use of construction equipment was evaluated quantitatively for hypothetical future construction workers.

Inhalation of Vapors Emitted from Surface Soils

Whenever contaminated soils are exposed at the surface, volatile chemicals may volatilize into the air and humans in the area could inhale those vapors. Soils in OU3 have not been analyzed for VOCs because no VOCs were detected in OU2 soils (where they were considered most likely to occur) (NewFields, 2016c). Volatilization of dioxins/furans in OU3 soils is generally not expected to be significant given the relatively low volatility of these chemicals and the absence of a continuous source. Also, the amount of vapor inhaled from air is generally quite small compared to the amount that is typically assumed for incidental ingestion. Therefore, inhalation of vapors emitted from surface soils was considered a minor pathway for all potential human receptors. Appendix B presents screening level calculations to support this designation.

3.2.2 Exposures to Groundwater

Groundwater is not currently used as a drinking water source in OU3. Therefore, current exposures to groundwater are not evaluated quantitatively. However, it is possible that groundwater within OU3 could be used within hypothetical future residences and/or commercial/industrial buildings. There are three primary pathways by which a hypothetical future resident or commercial worker may be exposed to groundwater as described below.

Ingestion of Drinking Water

Hypothetical future residents or commercial workers may ingest Site groundwater as drinking water.

Dermal Contact with Groundwater

If Site groundwater was used in residential homes in the future, dermal exposure by residents would primarily be the result of showering/bathing. If Site groundwater was used in commercial/industrial buildings in the future, dermal exposure by workers would primarily be the result of hand washing. Several VOCs were detected in groundwater from wells within the OU3 upland area. However, VOCs tend to volatilize from the skin (USEPA 2004). Metals and dioxins/furans have been detected in OU3 groundwater samples. USEPA guidance recommends against quantifying exposure and risk based on dermal contact with 2,3,7,8-TCDD in water because the molecular weight (MW) and octanol/water partition coefficient (Kow) are outside of the effective predictive domain (EPD) (USEPA 2004). Uptake of metals across the skin from contact with water is usually a minor exposure pathway due to the relatively low tendency of metals to cross the skin even when contact does occur. Furthermore, risk associated with dermal contact to metals in water is expected to be relatively small compared to the amount that is typically assumed for ingestion of drinking water. On this basis, dermal exposure to groundwater by hypothetical future residents and workers is considered a minor pathway in the CSM. Appendix B presents screening level calculations to support this designation. Thus, dermal exposure to contaminants in groundwater by hypothetical future residents and workers was considered a minor pathway and was not evaluated quantitatively in this assessment.

Inhalation of Vapors Released from Water

Volatile chemicals in water can be released to indoor air by two pathways: 1) vaporization to indoor air through standard indoor water uses, and 2) vapor intrusion in which vapors rise from the groundwater through the soil underlying a building foundation and get into the building through cracks in the foundation. Although these pathways may be complete at future residences

and/or commercial/industrial buildings within the OU3 Site, the chemicals detected at a high frequency in OU3 groundwater (dioxins/furans, metals) are not considered to be of sufficient volatility to expect significant exposures via these pathways. Therefore, these pathways were not evaluated quantitatively in this assessment.

3.2.3 Exposures to Sediment

Incidental Ingestion of Sediment

Tribal receptors and people recreating along/within the CFR included in the OU3 study area are unlikely to intentionally ingest sediment, but as described above for surface soil, anyone who has direct contact with contaminated sediments may incidentally ingest small amounts that adhere to their hands during recreational and tribal activities. Thus, incidental ingestion of CFR sediment is considered a complete exposure pathway for campers, recreational fishers, and tribal fishers.

Dermal Contact with Sediment

Campers, recreational fishers, and tribal fishers who come into contact with contaminated sediments may get some of the material on their skin during recreational activities. As such, dermal exposure to sediments is considered a complete exposure pathway for all recreational visitors and tribal fishers in the CFR.

3.2.4 Exposures to Surface Water

Ingestion of Surface Water as Drinking Water

Although it is assumed that people recreating in the OU3 study area generally bring potable drinking water and/or some form of a water filtration system, this assessment also considers exposure to people who may ingest drinking water drawn from the CFR or on-Site creeks without the benefit of filtration. Of the various types of receptors, it is assumed that campers would be most likely to do this. Thus, ingestion of surface water as drinking water was considered a complete exposure pathway for campers.

Incidental Ingestion of Surface Water

Campers, recreational fishers and tribal fishers may not intentionally ingest surface water, but may incidentally ingest small amounts while recreating. It is assumed that the camper represents the recreational visitor most likely to swim within the CFR. Therefore, it is assumed that a fisher (general and tribal) may incidentally ingest surface water while fishing and a camper may incidentally ingest surface water while swimming in the CFR.

Dermal Contact with Surface Water

Humans visiting the CFR for recreational or tribal purposes may have occasional dermal contact with surface water while fishing. Dermal contact with surface water is also a complete pathway for people swimming in the CFR. As noted above, it is assumed that the camper represents the recreational visitor most likely to swim within the CFR. Therefore, it is assumed that a fisher (general and tribal) may have occasional dermal contact with surface water while fishing and a camper will be exposed dermally while swimming in the CFR.

3.2.5 Exposures to Food Items

Ingestion of Homegrown Produce Items

Hypothetical future residential use within OU3 may include residential gardens used to grow vegetables or fruit in Site-impacted soils. Area residents who ingest home-grown produce may be exposed to certain contaminants that may be taken up by the vegetables or fruit. No data are available on the levels of contaminants that may be present in vegetation within OU3. Thus, this pathway cannot be evaluated quantitatively in this risk assessment without modeling uptake from soils into plants. Dioxins/furans and metals have been detected in OU3 soils. USEPA (1999) notes that most plants do not generally absorb dioxin. ATSDR (1998) notes that plants take up only very small amounts of CDDs by their roots and that most of the CDDs found on the parts of plants above the ground probably come from air and dust. Uptake of metals in plants varies for each metal and by metal form, and is strongly influenced by soil pH (USEPA 2013a). However, in general, the highest accumulation of metals in plants generally occurs in the roots whereby exposures to humans from most fruits and vegetables (except roots or green, leafy vegetables) are low (USEPA 2013a). In addition, exposure to dioxins and metals from ingestion of washed garden fruits or vegetables is likely to be a minor source of exposure compared with direct ingestion of soil. On this basis, ingestion of home grown produce by a hypothetical future resident was not evaluated quantitatively in this risk assessment. A qualitative evaluation of excluding this pathway from the risk characterization is discussed in the uncertainty assessment.

Ingestion of Fish from CFR

Fish that live in the CFR may take up contaminants from surface water, sediment, or food, leading to exposure of humans who eat locally-caught fish. The State of Montana currently has a consumption advisory in place to avoid eating all species collected from the CFR reach between from the Bitterroot River to the Flathead River (State of Montana 2021). Although this advisory is likely to limit the potential exposure by fishers to contaminants in the tissues of fish caught from locations in the CFR included in the study area, an advisory is not a regulation. As such, consumption of locally-caught fish is assumed to occur and this pathway is retained for quantitative evaluation in this assessment for both a recreational fisher and a tribal fisher. It is

assumed that both the recreational fisher and the tribal fisher primarily consume the fillets of fish collected from the CFR. However, information provided by the CSKT indicate that other parts of the fish (i.e., heads) are also used by tribal members in making soups. On this basis, ingestion of fish fillets is evaluated for both a recreational fisher and a tribal fisher, and ingestion of a whole fish is also evaluated for a tribal fisher.

3.2.6 Summary of Exposure Pathways for Quantitative Assessment

The receptor populations and exposure pathways evaluated quantitatively in this HHRA are summarized in the table below.

Receptor	Exposure Pathway
Hypothetical Future Resident	Incidental ingestion of and dermal contact to surface soil Ingestion of groundwater as drinking water
Hypothetical Future Commercial/Industrial Worker	Incidental ingestion of and dermal contact to surface soil Ingestion of groundwater as drinking water
Hypothetical Future Construction Worker	Incidental ingestion of and dermal contact to surface and subsurface soil Inhalation of soil particulates
Recreational Visitors	
Hiker	Incidental ingestion of and dermal contact to surface soil
Camper	Incidental ingestion of and dermal contact to surface soil Ingestion of surface water (as drinking water) Incidental ingestion of and dermal contact to surface water and sediment while swimming
Recreational Fisher	Incidental ingestion of and dermal contact to surface soil Incidental ingestion of and dermal contact to surface water and sediment while fishing Ingestion of fish
Tribal Fisher	Incidental ingestion of and dermal contact to surface soil Incidental ingestion of and dermal contact to surface water and sediment while fishing Ingestion of fish

3.3 Data Used in this Assessment

As noted in Section 2.6, a number of Site investigations have been conducted between 2014 and 2020 that have generated soil, groundwater, sediment, surface water and fish tissue data pertinent to evaluating human health risks within the OU3 Study Area. Not all available data are relevant for quantifying risks to potential human receptors; only those data relevant to evaluating the significant and complete exposure pathways identified in the CSM (Figure 3-1) were considered. All of the data used in this assessment have been validated, were collected in accordance with the Site-specific QAPP, and are considered appropriate for use in risk assessment. The data collected that are relevant to evaluating human health risks at the OU3 Site are summarized in Table 3-1 and include the following:

- Upland and floodplain surface soil (0-6 inches) collected in 2014, 2015, and 2017 from locations shown in Figures 3-4 and 3-5. Surface soil summary statistics are presented in Tables 3-2 and 3-3.
- Upland subsurface soil collected in 2014, 2015 and 2017 from locations shown in Figure 3-6. Only those samples collected down to 10 feet (the depth to which a construction worker may be exposed) were considered in this assessment. Subsurface soil summary statistics are presented in Table 3-4.
- Groundwater data collected between 2014 and 2020 from wells shown in Figure 3-2 (denoted by hydrostratigraphic unit). Groundwater summary statistics are presented in Table 3-5.
- Sediment and surface water data collected in 2015 and 2018 from the CFR at sampling locations adjacent to and downstream of the Site as shown in Figures 3-7 and 3-8. CFR bed sediment, flood fringe sediment, and surface water summary statistics are presented in Tables 3-6, 3-7, and 3-8 respectively.
- Sediment and surface water data collected in 2015 and 2018 from locations within O'Keefe and Lavalle Creeks within the current Site boundary as shown in Figures 3-7 and 3-9. O'Keefe sediment and surface water summary statistics are presented in Tables 3-9 and 3-10, respectively. Lavalle sediment and surface water summary statistics are presented in Tables 3-11 and 3-12, respectively.
- Rainbow trout and northern pike fillet and carcass tissues of fish caught in 2019 from reaches within the CFR adjacent to and downstream of the Site as shown in Figure 3-10 (Frenchtown [FRN] and St. Regis [STR] reaches). Summary statistics are presented in Table 3-13.

Consistent with the RI Work Plan Addendum 7, a randomized sampling grid design was used to collect 20-point composite surface soil samples in 2017 (NewFields 2017c). Older surface soil

data correspond to 5-point grab samples collected under a biased sampling strategy that targeted areas of most concern (NewFields 2015, 2016b). Subsurface soil samples were collected as vertical composites from varying depths down to 18 feet. Only those samples collected down to 10 feet (the depth to which a construction worker may be exposed) were considered in this assessment. Soil samples are based on the bulk fraction. As noted in Appendix A, data for rainbow trout and northern pike collected from the CFR in 2019 were used in this assessment to quantify human health risks associated with fish consumption. Rainbow trout and northern pike collected in 2018 are also considered in the uncertainty assessment (Section 6) consistent with USEPA (2020). More information on the sampling strategies that lead to the generation of the data used int this risk assessment is available in the individual RI Work Plan Addenda which are available on the Site webpage. Appendix A summarizes the data reduction procedures applied for the purposes of this specific assessment. All data used in this report are provided in Excel format in Appendix A for transparency and completeness. Other specific data considerations are outlined in brief below.

3.3.1 Calculation of Toxicity Equivalents

Because polychlorinated dibenzo-*p*-dioxin (PCDD) and furan (PCDF) congeners, and dioxin-like coplanar PCB congeners all act by the same mechanism as 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD), concentrations for the PCDD, PCDF, and coplanar PCB congeners were converted to a TCDD toxicity equivalent value (TEQ) by computing the sum across congeners of the product of congener-specific concentration and relative Toxicity Equivalence Factor (TEF) (USEPA 2013b):

$$TEQ = \Sigma (C_i \times TEF_i)$$

TEFs were based on USEPA (2010a) as shown in the following table.

Compound	TEF
Polychlorinated dibenzo-p-dioxins (PCDDs)	
2,3,7,8-TCDD	1
1,2,3,7,8-PeCDD	1
1,2,3,4,7,8-HxCDD	0.1
1,2,3,6,7,8-HxCDD	0.1
1,2,3,7,8,9-HxCDD	0.1
1,2,3,4,6,7,8-HpCDD	0.01
OCDD	0.0003

Compound	TEF
Polychlorinated dibenzofurans (PCDFs)	
2,3,7,8-TCDF	0.1
1,2,3,7,8-PeCDF	0.03
2,3,4,7,8-PeCDF	0.3
1,2,3,4,7,8-HxCDF	0.1
1,2,3,6,7,8-HxCDF	0.1
1,2,3,7,8,9-HxCDF	0.1
2,3,4,6,7,8-HxCDF	0.1
1,2,3,4,6,7,8-HpCDF	0.01
1,2,3,4,7,8,9-HpCDF	0.01
OCDF	0.0003
Polychlorinated biphenyls (PCBs)	
3,3',4,4'-TCB (77)	0.0001
3,4,4',5-TCB (81)	0.0003
3,3',4,4',5-PeCB (126)	0.1
3,3',4,4',5,5'-HxCB (169)	0.03
2,3,3',4,4'-PeCB (105)	0.00003
2,3,4,4',5-PeCB (114)	0.00003
2,3',4,4',5-PeCB (118)	0.00003
2',3,4,4',5-PeCB (123)	0.00003
2,3,3',4,4', 5 -HXCB (156)	0.00003
2,3,3',4,4',5'-HxCB (157)	0.00003
2,3',4,4',5,5'-HxCB (167)	0.00003
2,3,3',4,4',5,5'-HpCB (189)	0.00003

For this assessment, TEQ values in soil, groundwater, sediment and surface water were calculated based on data for the individual dioxin and furan congeners as described above ($TEQ_{D/F}$). The USEPA Scribe database for the Smurfit-Stone/Frenchtown Mill Site includes three alternative TEQ values that were computed based on evaluating non-detect (ND) concentrations as zero, at one-half the method detection limit (MDL) and at one-half the sample-specific detection limit (DL). Risk calculations included in this risk assessment were based on evaluating NDs at ½ DL. Evaluation of NDs at ½ DL when calculating TEQ is consistent with evaluations conducted at other USEPA sites in the region.

3.3.2 Polychlorinated Biphenyls

There are 209 distinct PCB congeners. PCBs generally occur as a mixture of congeners; the most common commercial mixtures are Aroclors. Abiotic samples collected within OU3 were analyzed for PCBs as Aroclor mixtures. This approach is useful because human health toxicity associated with exposures to most Aroclor mixtures has been evaluated, whereby toxicity values have been derived. The northern pike and rainbow trout fish tissue samples were analyzed for PCBs as the individual PCB congeners. This was done to provide information to risk managers that would be consistent with data used to generate the current fish advisory.

For fish tissues, total PCB concentrations were calculated as the sum across all PCB congeners for each sample. Similar to estimating TEQ concentrations, total PCB concentrations were calculated based on evaluating NDs at ½ DL (i.e., sample-specific detection limit), consistent with evaluations conducted at other USEPA sites in the region. Further, TEQ concentrations in fish tissues were calculated as $TEQ_{D/F}$ as well as toxicity equivalents for coplanar PCB congeners (TEQ_{PCB}) and as toxicity equivalents for dioxin, furan and coplanar PCB congeners ($TEQ_{D/F/PCB}$).

3.3.3 Fish Tissue Concentrations

Fish collected from the CFR were filleted in accordance with USEPA (2019) and fillet (skin and belly flap attached) and carcass (remainder) samples were submitted to the laboratory for analysis. For each tissue type, samples were composited (5 fish/composite where possible) and analyzed for dioxin, furan, and PCB congeners as summarized in USEPA (2020). The analysis focused on dioxins, furans, and PCBs based on a previous evaluation of risks from fish consumption (USEPA 2018b) and the current Montana Fish, Wildlife, and Parks (MFWP) fish advisory for the CFR (State of Montana 2021).

In addition to fillet concentrations, whole-body concentrations (C_{wb}) were estimated from the fillet and carcass samples as (Bevelhimer et al. 1997):

$$C_{wb} = \frac{\left(C_f \times W_f + C_c \times W_c\right)}{\left(W_f + W_c\right)}$$

where,

C_f	=	fillet concentration (µg/g)
W_f	=	fillet weight (g)
C_c	=	carcass concentration (µg/g)

W_c = carcass weight (g)

Wet-weight (e.g., as consumed) fish tissue concentrations were used in this assessment.

3.3.4 Inorganics in Groundwater

Groundwater samples were analyzed for both total recoverable and dissolved concentrations of inorganics. In general, filtered water data may underestimate actual exposure to humans if contaminants of concern are primarily associated with particulate matter and the pH of the human gastrointestinal environment is sufficiently low such that metals may dissociate from the bound particulate matter matrix. For risk assessment purposes, USEPA Region 8 evaluates exposures to groundwater assuming that the water is consumed without filtration. Thus, total recoverable metal concentrations were used to quantify risks in this assessment.

3.4 Selection of Chemicals of Potential Concern

COPCs are contaminants which exist in the environment at concentration levels that might be of potential health concern to humans and which are or might be derived, at least in part, from Site-related sources.

3.4.1 COPC Selection Process

The procedure used to identify COPCs for the evaluation of risks to human receptors from contaminated environmental media (soil and groundwater) is shown in Figure 3-3. It is important to note that this COPC selection procedure is intended to be conservative. That is, it is expected that some contaminants may be identified as COPCs that are actually of little or no concern to human health based on current USEPA guidelines, but that no contaminants of authentic concern will be overlooked.

In brief, the COPC selection procedure classifies each contaminant into one of three categories:

- COPC
- Not a COPC
- Source of Uncertainty

The process begins by determining if the contaminant has a risk-based screening level (SL) that can be used to evaluate potential risk. A risk-based SL is a concentration of a contaminant in a medium below which is believed to pose negligible health risk to a specified population of human receptors. For carcinogens, this is a concentration that corresponds to an added cancer

risk of 1E-06. For non-carcinogens, this is a concentration that corresponds to a Hazard Quotient (HQ) of 0.1.

If a risk-based SL is available, the next step is to evaluate the detection frequency. If a contaminant was detected in 5% or more of the Site samples, the maximum detected concentration for each contaminant in each medium is compared to the risk-based SL. If the maximum detected concentration exceeds the risk-based SL, the contaminant is identified as a COPC. If the maximum detected concentration does not exceed the risk-based SL, it may be concluded that the contaminant does not pose a significant risk to humans and may be excluded as a COPC.

If the contaminant was detected in fewer than 5% of the Site samples, or if the contaminant was not detected, then the detection limit is evaluated. If the detection limit is lower than the risk-based SL, then it is very unlikely that the contaminant will pose a significant risk to human health and may be excluded as a COPC. However, if the detection limit is above the risk-based SL, this is identified as a source of uncertainty because the detection limit was inadequate for detecting concentrations at the risk-based SL.

If a contaminant does not have a risk-based SL, this is identified as a source of uncertainty unless the contaminant is a beneficial nutrient and the expected average intake from Site media is similar to the range that is considered healthful.

In summary, a contaminant is identified as a COPC if the maximum detected concentration in the medium being evaluated (e.g., groundwater, soil, fish) exceeds an available risk-based SL.

To provide consistency in results reported across different areas of the OU3 site (i.e., upland and floodplain), all OU3 soil data evaluated for human health risks in this assessment were screened collectively. Thus, the maximum detected concentration across all OU3 soil samples was compared to the available RSL for each contaminant. Similarly, all OU3 groundwater data evaluated for human health risks in this assessment were screened collectively.

3.4.2 Source of Risk-Based Screening Level Values

Risk-based SLs used in this assessment were selected based on the human receptor identified in the CSM (Figure 3-1) who is expected to receive the highest exposure for each environmental medium. Risk-based SLs used in this assessment were derived from USEPA's Regional Screening Level (RSL) Tables (USEPA, 2021d)[10]. Soil and groundwater data were screened

[10] https://www.epa.gov/risk/regional-screening-levels-rsls (Tables last updated May 2021)

using the residential RSLs. USEPA's RSL Tables include generic SLs for a resident exposed to soil or drinking water calculated assuming default exposure parameters that represent Reasonable Maximum Exposure (RME) conditions for chronic exposures via the oral, dermal and inhalation pathways. Sediment, surface water and fish RSLs were calculated using the USEPA RSL Calculator assuming the exposure parameters for the recreational visitor exposure scenario expected to receive the highest exposure. For surface water, RSLs were calculated based on the camper scenario. For sediment, RSLs were calculated based on the tribal fisher scenario. Fish RSLs were also calculated based on exposure parameters assumed for the tribal fisher. Tables 3-14 and 3-15 present the exposure parameters assumed for each of these receptors. The SLs calculated based on these assumed exposures are shown in the COPC screening tables discussed below.

3.4.3 Evaluation of Beneficial Minerals

A number of metals are beneficial minerals, and a certain level of intake is required to maintain good health. This includes calcium, chromium (III), copper, iron, magnesium, manganese, molybdenum, potassium, selenium, sodium, and zinc. However, excess intake of these minerals may cause adverse effects. If a SL was available for such minerals in USEPA's RSL Tables, they were evaluated as described above. Because of their low toxicity (even at high doses), USEPA has not derived RSL values for some minerals, including calcium, magnesium, potassium, and sodium. These four essential nutrients were evaluated by calculating an effective SL as follows:

Effective SL (beneficial) = DRI / DI

Where:

DRI = Daily Recommended Intake (mg/day), derived from the Food and Nutrition Board (FNB 2013)

DI = Daily intake of Site medium (kg/day of soil; L/day of water)

3.4.4 COPC Screening Results

Tables 3-16 to 3-22 present the application of the COPC selection process to the OU3 soils, groundwater, sediment, surface water and fish data. The results are briefly summarized below.

Risk-based Screen

Maximum detected concentrations were higher than respective risk-based SLs (for contaminants detected in ≥5% of samples) in OU3 media for the following:

- $TEQ_{D/F}$, aluminum, antimony, arsenic, barium, cadmium, chromium, cobalt, iron, manganese, mercury, thallium, and vanadium in OU3 soils (Table 3-16).

- $TEQ_{D/F}$, Aroclor-1260, aluminum, antimony, arsenic, barium, beryllium, cadmium, chromium, cobalt, copper, iron, manganese, nickel, thallium, vanadium, 1,4-dichlorobenzene, benzene, and chlorobenzene in groundwater (Table 3-17).

Arsenic and chromium in CFR and creek sediments (Tables 3-18 and 3-19).

- Arsenic and chromium in CFR and creek surface waters (Tables 3-20 and 3-21).

- $TEQ_{D/F}$, TEQ_{PCB}, $TEQ_{D/F/PCB}$, and total PCBs in fish (Table 3-22).

3.5 Quantification of Exposure

3.5.1 Basic Equations

Ingestion Exposures

The amount of contaminant which is ingested by receptors exposed to Site media may be quantified using the following general equation:

$$DI = C \cdot (IR / BW) \cdot (EF \cdot ED / AT) \cdot RBA$$

where:

DI = Daily intake of contaminant (mg per kg of body weight per day).

C = Concentration of the contaminant in the contaminated environmental medium (soil, groundwater, surface water, sediment, fish tissue) to which the person is exposed. The units are mg/kg for soil/sediment, µg/L for water, and mg/kg-ww for fish.

IR = Intake rate of the contaminated environmental medium. The units are kg/day for soil/sediment and fish, and L/day for water.

BW = Body weight of the exposed person (kg).

EF = Exposure frequency (days/year). This describes how often a person is likely to be exposed to the contaminated medium over the course of a typical year.

ED = Exposure duration (years). This describes how long a person is likely to be exposed to the contaminated medium during their lifetime.

AT = Averaging time (days). This term specifies the length of time over which the average dose is calculated. For a chemical which causes non-cancer effects, the averaging time is equal to the exposure duration. For a chemical that causes cancer effects, the averaging time is 70 years.

RBA = Relative bioavailability.

Note that the factors EF, ED, and AT combine to yield a factor between zero and one. Values near 1.0 indicate that exposure is nearly continuous over the specified averaging period, while values near zero indicate that exposure occurs only rarely.

For mathematical convenience, the general equation for calculating dose can be written as:

$$DI = C \cdot HIF_{ing} \cdot RBA$$

where:

HIF_{ing} = Human Intake Factor. This term describes the average amount of an environmental medium contacted by the exposed person each day. The value of HIF is typically given by:

$$HIF_{ing} = (IR / BW) \cdot (EF \cdot ED / AT)$$

The units of HIF_{ing} are kg/kg-day for soil and L/kg-day for water.

When the same individual may be exposed beginning as a child and extending into adulthood, exposure was calculated as the time-weighted average (TWA) lifetime exposure for evaluating cancer risks as recommended in USEPA Guidance (USEPA 1989).

Dermal Exposures

The amount of a contaminant which is absorbed across the skin is referred to as the dermally absorbed dose (DAD). Procedures for estimation of the DAD as outlined in USEPA (2004) are used in this assessment and described below. Exposure is quantified using an equation of the following general form:

$$DAD = DA_{event} \cdot EF \cdot ED \cdot EV \cdot SA / (BW \cdot AT)$$

where:

DAD = Dermal absorbed dose (mg of contaminant per kg of body weight per day).

DA_{event} = Absorbed dose per event (mg of chemical per square centimeter of skin surface area per event). This is media-specific and is further described below.

EF = Exposure frequency (days/year). This describes how often a person is likely to be exposed to the contaminated medium over the course of a typical year.

ED = Exposure duration (years). This describes how long a person is likely to be exposed to the contaminated medium during their lifetime.

EV = Event frequency (events/day). This describes the number of times per day a person comes in contact with a contaminant in soil.

SA = Surface area (cm^2). This describes the amount of skin exposed to the contaminated media.

BW = Body weight of the exposed person (kg).

AT = Averaging time (days). This term specifies the length of time over which the average dose is calculated.

For contaminants in soil, DA_{event} is estimated as follows:

$$DA_{event} = C_{soil} \cdot CF_{soil} \cdot DAF \cdot ABS_d$$

where:

C_{soil} = Chemical contaminant in soil (mg of contaminant per kg of soil).

CF_{soil} = Conversion factor for soil (10^{-6} kg/mg).

DAF = Dermal adherence factor (mg of soil per square centimeter of skin surface area per event). This describes the amount of soil that adheres to the skin per unit of surface area.

ABS_d = Dermal absorption fraction (unitless). This value is contaminant-specific and represents the contribution of absorption of a chemical across a person's skin from soil to the systemic dose.

For mathematical convenience, the general equation for calculating DAD for soil exposures can be written as:

$$DAD = C_{soil} \cdot ABS_d \cdot HIF_{derm}$$

where:

$$HIF_{derm} = (SA \cdot DAF \cdot EF \cdot ED \cdot EV \cdot CF_{soil}) / (BW \cdot AT)$$

The units of HIF_{derm} are kg/kg-day for soil.

Inhalation Exposures

Inhalation exposures are evaluated in accordance with the inhalation dosimetry methodology presented in USEPA (2009). In accordance with this guidance, the human intake equation does not include an inhalation rate (m^3/day) or body weight because the amount of the chemical that reaches the target site is not a simple function of these factors. Instead, the interaction of the inhaled contaminant with the respiratory tract is affected by factors such as species-specific relationships of exposure concentrations to deposited/delivered doses and physiochemical characteristics of the inhaled contaminant (USEPA 2009). Therefore, the inhaled exposure concentration (EC) for chronic exposures is calculated as:

$$EC = C_{air} \cdot (ET \cdot EF \cdot ED / AT)$$

where:

EC = Exposure Concentration ($\mu g/m^3$). This is the time-weighted concentration based on the characteristics of the exposure scenario being evaluated.

C_{air} = Concentration of the chemical in air ($\mu g/m^3$) to which the person is exposed.

ET = Exposure time (hours/day). This describes how long a person is likely to be exposed to the contaminated medium over the course of a day.

EF = Exposure frequency (days/year). This describes how often a person is likely to be exposed to the contaminated medium over the course of a year.

ED = Exposure duration (years). This describes how long a person is likely to be exposed to the contaminated medium during their lifetime.

AT = Averaging time (hours). This term specifies the length of time over which the time-weighted average concentration is calculated.

For mathematical convenience, the general equation for exposure concentration can be written as:

$$EC = C_{air} \cdot TWF$$

where:

TWF = Time-Weighting Factor (unitless). The value of TWF is given by:

$$TWF = (ET \cdot EF \cdot ED / AT)$$

As described above, when the same individual may be exposed beginning as a child and extending into adulthood, exposure was calculated as the TWA lifetime exposure for evaluating cancer risks.

3.5.2 Human Exposure Parameters

For every exposure pathway of potential concern, it is expected that there will be differences between different individuals in the level of exposure at a specific location due to differences in intake rates, body weights, exposure frequencies, and exposure durations. Thus, there is normally

a wide range of average daily intakes between different members of an exposed population. Because of this, all daily intake calculations must specify what part of the range of doses is being estimated. Typically, attention is focused on intakes that are "average" or are otherwise near the central portion of the range, and on intakes that are near the upper end of the range (e.g., the 95th percentile). These two exposure estimates are referred to as Central Tendency Exposure (CTE) and RME, respectively.

Because one or more exposure parameters (e.g., intake rates, body weight, and EF) may change as a function of age, exposure calculations are often performed separately for children and adults. For evaluation of non-cancer effects, the child (0-6 years) represents the most sensitive receptor based on a higher assumed exposure than adults. In this case, evaluation of risks for non-cancer effects for the child resident, child camper, child recreational fisher, and child tribal fisher is considered protective of risks for non-cancer effects for the adolescent or adult. As noted above, exposures for evaluating excess cancer risks over a lifetime are calculated as the TWA exposure.

Tables 3-23 to 3-29 list the CTE and RME exposure parameters and resultant HIF values used in this assessment for each receptor population. Some of the values are based on USEPA default guidelines, while other values were informed by Site information or professional judgment. The footnotes in the tables provide the basis and rationale for each selected parameter. Some key assumptions are summarized below.

- Exposures to recreational visitors are quantified for the peak summer months. This is because these are the times when soils are expected to be exposed and people are most likely to be recreating given the climate and weather in this region.

- Soil ingestion rates for recreational visitors are based on the default soil ingestion rates assumed for residents.

- Exposed skin surface areas for dermal exposures to surface waters and sediments within the CFR assume the full body for the camper to account for potential swimming exposures. For the general recreational fisher and the tribal fisher, it is assumed that people will remain on the banks while fishing and only enter the water for significant amounts of time if wearing protective clothing such as waders and waterproof shoes/boots.

- The fish ingestion rate for the general recreational fisher is based on data presented in USEPA (2011) for freshwater recreational fish intake by consuming anglers. Such data are only available for some states. Data for North Dakota were used as being closest and most representative of the Site.

- For the tribal fisher, fish consumption rates were selected in accordance with the approach described in Appendix E

3.5.3 Exposure Areas

An exposure point (also referred to as an exposure unit or exposure area) is an area where a receptor may be exposed to one or more environmental media. In general, receptors are assumed to move about at random within an exposure area. Because the key attribute of an exposure point is the assumption of random exposure, exposure areas represent the entire area that a selected receptor may be exposed to over their entire exposure duration. Realistically, it is possible that any particular receptor does not move entirely at random within an exposure area but instead frequents certain locations more often than others. However, Superfund risk assessments do not seek to estimate risk to any one particular current receptor, but to a hypothetical population who may be exposed in any part of the exposure area.

Soil

For the purposes of this assessment, the OU3 upland area and the OU3 floodplain area were evaluated separately given the differences in historical land use, and the potential for differences in hypothetical future land use. As noted above, building within the floodplain is not preferred. Thus, sampling in the floodplain was conducted to support potential recreational exposures as opposed to potential residential scenarios. In both the upland and floodplain areas, exposure units (EUs) were defined as a geographic area of an assumed size identified based on random grid assignment. In concept, this assumes that a receptor is expected to contact all locations within a grid equally over their exposure duration (26 or 70 years).

The OU3 upland area was subdivided into 20-acre grids as shown in Figure 3-4. Each 20-acre area is assumed to represent the maximum area within which a hypothetical future resident or worker may be exposed at random over their entire exposure duration. Thus, each 20-acre grid represents an individual EU.

The OU3 floodplain area was subdivided into 100-acre grids as shown in Figure 3-5. Each 100-acre area is assumed to represent the maximum area within which a recreational visitor may be exposed at random over their entire exposure duration. Thus, each 100-acre grid represents an individual EU.

Although building in the floodplain will likely only occur under a special circumstance, evaluation of the hypothetical future residential and commercial development was evaluated

because the possibility is not ruled out. For each receptor, the soil EU was identified as the soil sampling grids noted above.

Groundwater

When groundwater is used for drinking water, exposure evaluation is often performed on a well-by-well basis. This is because wells in different areas and screened at different depths may draw water with differing levels of contamination. Thus, each well within OU3 (see Figure 3-2) was evaluated as a separate EU.

Fish

As noted previously, the OU3 Site includes the CFR where hazardous substances from Site activities may have come to be located. As defined for this assessment, the OU3 study area within the CFR includes the area adjacent to and downstream of the Site to the St. Regis sampling location shown in Figure 3-10. This stretch includes two fish sampling reaches: FRN and STR. The entire stretch of the CFR within the study area was evaluated as a single EU for evaluating exposures from fish consumption.

3.5.4 Exposure Point Concentrations

Based on the assumption of random exposure over an exposure area, risk from a contaminant within an exposure area is related to the arithmetic mean concentration of that contaminant averaged over the entire exposure area. An exposure point concentration (EPC) is a COPC-specific and media-specific concentration value used in the dose equation for each receptor and exposure pathway. The EPCs used in this assessment reflect Site-specific conditions and data as described below.

Soil

Surface soil data have been collected at this Site over the course of four years during three separate sampling events (2014, 2015 and 2017). Surface soil sampling conducted in 2014 and 2015 involved the collection of 5-point composites collected over a 1-square meter area (2014 sampling event) or over an area of 1 to 3-meter radius (2015 sampling event) following a biased sampling approach (sampling locations selected based on Site knowledge to identify areas of most concern). During the most recent sampling event in 2017, one 20-point composite surface soil sample was collected from those EUs within OU3 where data were lacking (i.e., fewer than two 5-point composite samples). The 20-point composite sample was comprised of 20 grab samples collected across the entire EU. This sampling approach is recommended by the USEPA

because it is designed to provide a representative sample of the average concentration in the exposure unit (ITRC 2012). The surface soil data available for each exposure area grid (see Figures 3-4 and 3-5) falls into one of the following categories:

a) One 20-point composite sample only
b) One 20-point composite plus one or more 5-point composites
c) One or more 5-point composites

Tables 3-30 and 3-31 summarize the available soil data by grid for the upland and floodplain areas, respectively.

As described in USEPA (1992), the USEPA recommends that a 95% upper confidence limit (95UCL) of the arithmetic mean at each EU be used as the EPC when calculating exposure and risk at that location. This is because the true arithmetic mean concentration cannot be calculated with certainty from a limited number of measurements. However, OU3 soil data are available based on unequally weighted samples which limits characterization of the EPC using a 95UCL. The larger the number of grab samples used to create the composite sample, the lower the variability around the mean estimate. Additionally, the larger the area within the EU that a composite sample is based, the more representative of the mean exposure across the entire EU. Therefore, if available, a 20-point composite comprised of grabs collected across the whole of the EU provides a representative estimate of the mean. Whereas, a mean derived based on a localized 5-point composite is more uncertain, and the variability around the mean could be much greater. Thus, for this assessment, the available data for each EU will be used to represent the best estimate of the mean for each of the data categories listed above as follows:

Category a. For EUs where a single 20-point composite sample is available, this concentration was used as the EPC, since this is the only data point available.

Category b. For EUs in Category b, the EPC was based on weighting the data by the number of grab samples collected. For example, if for a given contaminant, the concentration in a 5-point composite sample collected from an EU was 5 mg/kg and the concentration in a 20-point composite sample was 3 mg/kg, the EPC would be calculated as:

(5 mg/kg * 5) + (3 mg/kg * 20) / (20 + 5) = 3.4 mg/kg

This approach effectively places more confidence in the value of the 20-point composite because this sample provides an unbiased estimate of the mean concentration over the entire exposure area, while the 5-point composite samples represent only a small area of the exposure unit and may tend to be biased high. Data in some EUs include a 20-point

composite and more than one 5-point composite. In this case, the concentrations of the 5-point composites were averaged prior to calculating the weighted EPC.

Category c. For EUs where two or more 5-point composite samples are available and there is no 20-point composite, the average concentration was used as the EPC. If the 5-point composites were unbiased, use of the maximum value would normally be preferred to help ensure that the EPC does not underestimate the true mean. However, since all of the 5-point composites are likely to be biased high, a simple average of the values is likely to be adequately conservative, and use of the maximum value would likely result in a substantial overestimate of the true mean.

Within the center of the OU3 upland area (i.e., grids 50-66), a 30-point composite sample was collected from within a historically defined basin/pond (e.g., aeration basin II, settling pond 8) where previously collected data were lacking. This sampling was primarily conducted to support the ecological risk assessment for the Site, but these data also fill data gaps for EUs with little to no other data. Concentrations based on 30-point composite samples were used in calculating EPCs similar to data based on 20-point composite samples.

Grab samples were also collected from boreholes at depth in the subsurface. For evaluating exposures to hypothetical future construction workers, data for both surface and subsurface soils were combined into a single dataset. The same approach outlined above was followed for calculating grid-specific EPCs, except a grid-specific weighted concentration accounted for an additional sample result based on the average across subsurface samples if available.

Soil EPCs are presented in Tables 3-32 and 3-33.

Airborne Dust from Construction Activities

No Site-specific data are available on particulate levels in air generated during mechanical disturbances with construction equipment. In the absence of measured values, the concentration of contaminants in air that would occur during hypothetical future construction activities was estimated using the following equation:

$$C_{air} = C_{soil} / PEF$$

where:

C_{air} = concentration of contaminant in air (mg/m^3)
C_{soil} = concentration of contaminant in soil (mg/kg)
PEF = particulate emission factor (m^3 of air per kg of soil) for a construction scenario

As noted in Section 3.2.1, inhalation of soil particulates is only quantified for the hypothetical future construction worker scenario in this assessment. The PEF assumed for evaluating exposures related to construction activities is assumed to be 4.4E+08 m^3/kg. This value is consistent with the recommendation in USEPA (2002a) that accounts for the mass of dust emitted by traffic on unpaved roads during construction activities and the mass of dust emitted by wind erosion. USEPA (2002a) notes that the most significant contribution to inhalation of fugitive dust exposure by construction workers comes from disturbance of surface soil by traffic on unpaved roads. Thus, evaluation of this pathway is based on surface soils only.

Because inhalation toxicity values are based on an assumed continuous exposure over a specified exposure duration, when exposure is less than continuous, the value of the EC used to quantify risk is calculated from C_{air} as follows:

$$EC \text{ (non-cancer effects)} = C_{air} \cdot ET/24 \cdot EF/365$$
$$EC \text{ (cancer effects)} = C_{air} \cdot ET/24 \cdot EF/365 \cdot ED/70$$

where:

ET = exposure time (hrs/day)
EF = exposure frequency (days/yr)
ED = exposure duration (years)

Groundwater

As noted above, wells in OU3 were evaluated as individual EUs. The mathematical approach that is most appropriate for computing the 95UCL of a data set depends on a number of factors, including the number of data points available, the shape of the distribution of the values, and the degree of censoring (USEPA 2002b). Because of the complexity of this process, the USEPA Technical Support Center has developed a software application called ProUCL v5.0 (USEPA 2013a) to assist in the estimation of 95UCL values. ProUCL calculates 95UCLs for a data set using several different strategies and recommends which 95UCL is considered preferable based on the properties of the data set. As discussed in USEPA (2015b), a 95UCL can be calculated for data sets containing at least four detected values. If this data requirement was not met, the EPC was set equal to the maximum detected value. Table 3-34 presents the samples evaluated for each well. Data from all years were considered in deriving well-specific EPCs to account for temporal variability. All measured values for each COPC were provided to ProUCL for evaluation. The EPC was based on the 95UCL recommended by ProUCL. If the suggested 95UCL value from ProUCL exceeds the maximum detected concentration, the EPC was selected

consistent with SRC (2021). ProUCL output is included in Appendix C. Table 3-35 presents the groundwater EPCs.

Surface Water and Sediment

CFR surface water and sediment EPCs for arsenic and chromium were derived using ProUCL to generate 95UCLs. Surface water EPCs for arsenic and chromium in the on-site creeks were based on the maximum detected concentrations.

Fish

Exposures based on the consumption of fish were estimated separately for rainbow trout and northern pike, and separately for fillets and whole-body. For each of these categories, EPC values were based on a 95UCL generated using ProUCL. In cases where the recommended 95UCL exceeded the maximum detected concentration, the maximum value was used as the EPC. Table 3-36 presents the fish EPCs.

3.5.5 Relative Bioavailability of Dioxins and Metals in Soil

An accurate assessment of human exposure to ingested chemicals requires knowledge of the amount of chemical absorbed from the gastrointestinal tract into the body from Site media compared to the amount of absorption that occurred in the toxicity studies used to derive the toxicity factors. This ratio (amount absorbed from Site media compared to the amount absorbed in toxicity tests) is referred to as RBA.

The oral RBA value for dioxins in soil is assumed to be 100% in accordance with USEPA (USEPA 2010b). This is considered to be a conservative assumption, because reports summarized by USEPA (2010b) indicate that absorption of dioxins from soils through the gastrointestinal tract is usually less than 50%.

In general, metals in soils exist in the form of mineral particles that are not rapidly solubilized in gastrointestinal fluids when ingested, while toxicity studies often utilize readily soluble forms of the test contaminant. Thus, oral RBA values for metals in soils are often less than 1.0. For arsenic, sufficient data are available to establish that oral RBA values in soil are generally less than 60% (USEPA 2012b). Thus, for the purposes of this HHRA, a RBA of 60% was applied for arsenic in OU2 soils. RBA data are much more limited or absent for other metals (except lead which was not identified as a COPC in this assessment). RBA values for all other metal COPCs were conservatively assumed to be 100%.

4.0 TOXICITY ASSESSMENT

4.1 Toxicity Overview

The basic objective of a toxicity assessment is to identify what adverse health effects a chemical may cause, and how the appearance of these adverse effects depends on exposure level. In addition, the toxic effects of a chemical frequently depend on the route of exposure (oral, inhalation, dermal) and the duration of exposure (subchronic, chronic, or lifetime). Thus, a full description of the toxic effects of a chemical includes a listing of what adverse health effects the chemical may cause, and how the occurrence of these effects depends upon dose, route, and duration of exposure.

The toxicity assessment process is usually divided into two parts: the first characterizes and quantifies the non-cancer effects of the chemical, while the second addresses the cancer effects of the chemical. This two-part approach is employed because there are typically major differences in the time-course of action and the shape of the dose-response curve for cancer and non-cancer effects. The relationship between the dose of the chemical administered or received and the incidence of adverse health effects in the exposed population forms the basis for a quantitative dose-response relationship. Toxicity values (e.g, reference doses and slope factors) are derived based on such dose-response relationships.

4.1.1 Non-cancer Effects

Essentially all chemicals can cause adverse health effects if given at a high enough dose. However, when the dose is sufficiently low, typically adverse non-cancer effects are not observed. Thus, in characterizing the non-cancer effects of a chemical, the key parameter is the threshold dose at which an adverse effect first becomes evident. Doses below the threshold are considered to be safe, while doses above the threshold are likely to cause an effect.

The threshold dose is typically estimated from toxicological data (derived from studies of humans and/or animals) by finding the highest dose that does not produce an observable adverse effect, and the lowest dose which does produce an effect. These are referred to as the "No-observed-adverse-effect-level" (NOAEL) and the "Lowest-observed-adverse-effect-level" (LOAEL), respectively. The threshold is presumed to lie in the interval between the NOAEL and the LOAEL. However, in order to be conservative (health protective), non-cancer risk evaluations are not based directly on the threshold exposure level, but on a value referred to as the Reference Dose (RfD) for oral exposures or Reference Concentration (RfC) for inhalation exposures. The RfD and RfC are estimates (with uncertainty spanning perhaps an order of

magnitude) of a daily exposure to the human population (including sensitive subgroups) that is likely to be without an appreciable risk of deleterious effects during a lifetime.

The RfD and RfC values are derived from a NOAEL (or a LOAEL if a reliable NOAEL is not available) by dividing by an "uncertainty factor". If the data are from studies in humans, and if the observations are considered to be very reliable, the uncertainty factor may be as small as 1.0. However, the uncertainty factor is normally at least 10, and can be much higher if the data are limited. The effect of dividing the NOAEL or the LOAEL by an uncertainty factor is to ensure that the RfD or RfC is not higher than the threshold level for adverse effects. Thus, there is always a "margin of safety" built into an RfD and RfC values, and doses equal to or less than the RfD or RfC are nearly certain to be without any risk of adverse effect. Doses higher than the RfD or RfC may carry some risk, but because of the margin of safety, a dose above the RfD or RfC does not mean that an effect will necessarily occur.

Chronic oral RfDs and chronic inhalation RfCs are specifically developed to be protective for long-term exposure to that particular contaminant. Chronic RfDs and RfCs are generally used to evaluate the potential noncarcinogenic effects associated with exposure periods greater than 7 years (approximately 10 percent of a human lifetime). Subchronic oral RfDs and inhalation RfCs are specifically developed to be protective for short-term exposure to that particular contaminant. As a guideline for Superfund risk assessments, subchronic RfDs and RfCs are generally used to evaluate potential noncarcinogenic effects of exposure periods between two weeks and seven years.

4.1.2 Cancer Effects

For cancer effects, the toxicity assessment process has two components. The first is a qualitative evaluation of the weight of evidence (WOE) that the chemical does or does not cause cancer in humans. Previously, this evaluation was performed by the USEPA using the system summarized below:

WOE	Meaning	Description
A	Known human carcinogen	Sufficient evidence of cancer in humans.
B1	Probable human carcinogen	Suggestive evidence of cancer incidence in humans.
B2	Probable human carcinogen	Sufficient evidence of cancer in animals, but lack of data or insufficient data in humans.
C	Possible human carcinogen	Suggestive evidence of carcinogenicity in animals.
D	Cannot be evaluated	No evidence or inadequate evidence of cancer in animals or humans.
E	Not carcinogenic to humans	Strong evidence that it does not cause cancer in humans.

More recently, USEPA has developed a revised classification system for characterizing the weight of evidence for carcinogens (USEPA 2005a). However, this system has not yet been implemented for a number of chemicals, so the older classification scheme is retained for use in this assessment.

For chemicals which are classified in Group A, B1, B2, or C, the second part of the toxicity assessment is to describe the carcinogenic potency of the chemical. This is done by quantifying how the number of cancers observed in exposed animals or humans increases as the dose increases. Typically, it is assumed that the dose response curve for cancer has no threshold, arising from the origin and increasing linearly until high doses are reached. Thus, the most convenient descriptor of cancer potency is the slope of the dose-response curve at low doses (where the slope is still linear). This is referred to as the Slope Factor (SF), which has dimensions of risk of cancer per unit dose.

Estimating the cancer SF is often complicated by the fact that observable increases in cancer incidence usually occur only at relatively high doses, frequently in the part of the dose-response curve that is no longer linear. Thus, it is necessary to use mathematical models to extrapolate from the observed high dose data to the desired (but un-measurable) slope at low dose. In order to account for the uncertainty in this extrapolation process, USEPA typically chooses to employ the 95 percent upper confidence limit of the slope as the SF. That is, there is a 95 percent probability that the true cancer potency is lower than the value chosen for the SF. This approach ensures that there is a margin of safety in cancer as well as non-cancer risk estimates.

For inhalation exposures, cancer risk is characterized by an inhalation Unit Risk (UR) value. This value represents the upper-bound excess lifetime cancer risk estimated to result from continuous lifetime exposure to a chemical at a concentration of 1 µg/m^3 in air.

4.2 Human Toxicity Values

In 2003, USEPA's Superfund program revised its hierarchy of human health toxicity values into the following three-tiered approach:

1. USEPA's Integrated Risk Information System (IRIS)[11].

2. The Provisional Peer Reviewed Toxicity Values (PPRTVs) derived by USEPA's Superfund Health Risk Technical Support Center (STSC)[12].

[11] https://www.epa.gov/iris
[12] https://hhpprtv.ornl.gov/

3. Other toxicity values including additional USEPA and non-USEPA sources of toxicity information. Priority should be given to those sources of information that are the most current, the basis for which is transparent and publicly available, and which have been peer reviewed.

Table 4-1 presents the toxicity values used for evaluating human health risks associated with chronic exposures to COPCs at the OU3 Site. Because construction workers are assumed to be exposed for one year or less, the subchronic noncancer toxicity values presented in Table 4-2 were used to evaluate risks from soil exposures to hypothetical future construction workers at the OU3 Site. As seen in Table 4-2, chronic RfDs and RfCs were used if a subchronic value was not available. The basis of these toxicity values is discussed in further detail below.

Organics

Dioxin

Toxicity values developed for TCDD are used to evaluate the exposure to the mixture of dioxins, furans, and coplanar PCBs. In February 2012, USEPA released an IRIS RfD for TCDD of 7E-10 mg/kg-day (USEPA 2021e). This value is based on two epidemiological studies reporting reproductive effects in populations exposed to TCDD from an industrial accident. This RfD was derived based on an adjusted LOAEL of 20 pg/kg-day and an uncertainty factor of 30 (10 for extrapolation from a LOAEL to a NOAEL and 3 for human-to-human variability). The ATSDR minimal risk level (MRL) for intermediate duration oral exposure to TCDD of 2E-08 mg/kg-day was used as the subchronic RfD (ATSDR 1998).

There is no IRIS RfC, oral SF, or inhalation UR for TCDD. However, Tier 3 toxicity values are available from the California EPA (CalEPA). CalEPA recommends a chronic inhalation reference exposure level (REL) of 4.0E-08 mg/m^3 based on route-to-route extrapolation from a dietary study conducted in rats (OEHHA 2008). In addition to route extrapolation, an uncertainty factor of 100 (10 for interspecies extrapolation and 10 for intraspecies variability) was applied to the identified LOAEL of 0.01 µg/kg-day. The chronic RfC was used to evaluate non-cancer hazards for both chronic and subchronic exposures.

The oral SF and inhalation UR recommended by CalEPA for TCDD are 1.3E+05 $(mg/kg\text{-}day)^{-1}$ and 3.8E+01 $(\mu g/m^3)^{-1}$, respectively (OEHHA 2009). These values were derived based on an oncogenicity bioassay of TCDD in rats and mice conducted by the National Toxicology Program (NTP).

PCBs

There is no RfD or RfC available for evaluating non-cancer effects from exposures to Aroclor-1260.

The IRIS WOE characterizes PCBs as probable human carcinogens (based on sufficient evidence of carcinogenicity in animals) (USEPA 2021f). The cancer potency of PCB mixtures is assessed using the IRIS SF of 2 $(mg/kg\text{-}day)^{-1}$ for high risk PCBs. This value was used to calculate a high-risk inhalation UR of 5.7E-04 $(\mu g/m^3)^{-1}$by dividing by body weight over inhalation rate (70 kg / 20 m^3), and applying a conversion factor of 1,000 µg/mg.

1,4-Dichlorobenzene

There is no IRIS RfD for 1,4-dichlorobenzene. ATSDR has developed a toxicological profile for dichlorobenzenes (ATSDR 2006). This review derived a chronic oral MRL of 0.07 mg/kg-day for 1,4-dichlorobenzene based on liver and kidney effects in animals. This value was based on a point of departure derived by benchmark dose analysis using clinical chemistry parameters in dogs fed capsules of 1,4-dichlorobenzene daily for one year. The adjusted benchmark dose was divided by an uncertainty factor of 100 (10 for animal to human extrapolation and 10 for human variability) to derive the MRL.

There is an IRIS RfC of 8E-01 mg/m^3 for 1,4-dichlorobenzene (USEPA 2021g). This value is based on increased liver weights in male rats observed in a multigeneration reproductive inhalation study. An uncertainty factor of 100 (10 for human variability and 3 for interspecies differences) was applied to the NOAEL based human equivalent concentration.

There are no IRIS cancer toxicity values for 1,4-dichlorobenzene. However, an oral cancer SF of 5.4E-03 $(mg/kg\text{-}day)^{-1}$ and an inhalation UR of 1.1E-05 $(\mu g/m^3)^{-1}$ have been derived for 1,4-dichlorobenzene by CalEPA (OEHHA 2009). These values are derived from an NTP study in rats and mice that reported increased incidences of liver and kidney cancers, and leukemia following oral intubation for 103 weeks. The SF was calculated by extrapolating from a linearized multistage model, applying a scaling factor and then using a default animal to human body weight ratio. Route-to-route extrapolation was applied for calculated the UR value.

Benzene

There is an IRIS RfD for benzene of 4E-03 mg/kg-day. This value is based on immune system effects (decreased lymphocyte counts) in workers exposed to benzene by inhalation. The RfD was derived based on route-to-route extrapolation (USEPA 2021h). An uncertainty factor of 300

(3 for use of a minimal LOAEL, 10 for human variability, 3 for subchronic to chronic extrapolation, and 3 for database deficiencies) was applied to the benchmark modeled dose of 1.2 mg/kg-day. The IRIS RfC of 3E-02 mg/m^3 is based on the same occupational exposure study. The same uncertainty factor of 300 was applied to the benchmark modeled concentration of 8.2 mg/m^3.

The IRIS WOE characterizes benzene as a known human carcinogen (Category A). Human studies have demonstrated a causal association between exposure to benzene and acute nonlymphocytic leukemia (USEPA 2021h). Evidence also suggests a relationship between benzene exposure and other types of leukemia. Based on available studies on leukemia in workers exposed to benzene via inhalation, ranges were derived for both the oral cancer SF and the inhalation UR. The oral SF range of 1.5E-02 to 5.5E-02 $(mg/kg\text{-}day)^{-1}$ is based on route-to-route extrapolation from the inhalation UR range of 2.2E-06 to 7.8E-06 $(\mu g/m^3)^{-1}$. The USEPA RSLs are based on the SF of 5.5E-02 $(mg/kg\text{-}day)^{-1}$ and the UR of 7.8E-06 $(\mu g/m^3)^{-1}$. These are the cancer values that were used in this assessment.

Chlorobenzene

There is an IRIS RfD for chlorobenzene of 2E-02 mg/kg-day (USEPA 2021i). This value is based on a NOAEL of 27.25 mg/kg-day derived from a study of dogs given chlorobenzene orally by capsule for 13 weeks. Dogs experienced histopathological changes in their liver at the LOAEL of 54.5 mg/kg-day. The NOAEL was adjusted by an uncertainty factor of 1,000 (10 for interspecies extrapolation, 10 for human variability, and 10 for subchronic-to-chronic extrapolation).

There is no IRIS RfC for chlorobenzene. However, a PPRTV RfC (p-RfC) of 5E-02 mg/m^3 is available (USEPA 2006a). This value is based on kidney lesions among rats in a 2-generation study. The human equivalent concentration was adjusted by an uncertainty factor of 1000 (3 for interspecies extrapolation, 10 for human variability, 3 for database uncertainties, and 10 for subchronic-to-chronic extrapolation).

The IRIS WOE characterizes chlorobenzene as not classifiable as to human carcinogenicity due to inadequate data.

Inorganics

Inorganic COPCs were measured as total concentrations. However, within the environment, inorganic COPCs may exist in multiple forms or valence states. In general, inorganics exist primarily as salts within the environment. Therefore, toxicity values used in this assessment were

based on the salt forms when available. The basis of the toxicity values used in this assessment for inorganic COPCs is discussed in brief below.

Aluminum

IRIS does not report toxicity values for aluminum. However, a PPRTV RfD (p-RfD) of 1E+00 mg/kg-day and PPRTV RfC (p-RfC) of 5.0E-03 mg/m^3 have been derived based on evaluation of available toxicity data (USEPA 2006b). The p-RfD is based on a LOAEL of 100 mg/kg-day for minimal neurotoxicity in the offspring of mice adjusted by an uncertainty factor of 100 (3 for use of a minimal LOAEL, 10 for interspecies extrapolation, and 3 for human variability). The LOAEL was characterized as minimal because postweaning neurobehavioral test battery results indicated that performance deficits may be marginal. The same value of 1E+00 mg/kg-day is recommended for subchronic exposures based on the ATSDR intermediate duration oral MRL (ATSDR 2008). This MRL was derived based on a NOAEL of 26 mg/kg-day protective of neurological effects, neurodevelopmental effects, and delays in maturation. An uncertainty factor of 100 (10 for interspecies extrapolation and 10 for human variability) was applied to this NOAEL.

The p-RfC is based on a LOAEL of 4.6E+00 mg/m^3 for psychomotor and cognitive impairment for an 8-hour occupational exposure (USEPA 2006b). This LOAEL was adjusted for continuous exposure to a value of 1.6E+00 mg/m^3 and an uncertainty factor of 300 (10 for human variability, 10 for use of a LOAEL, and 3 for an incomplete database) was applied.

USEPA (2006b) determined that there was inadequate information to assess the carcinogenic potential of aluminum.

Antimony

Antimony concentrations in soil were reported based on total antimony. The IRIS RfD of 4.0E-04 mg/kg-day is based on a chronic drinking water study in rats using potassium antimony tartrate (USEPA 2021j). This value is based on a LOAEL of 0.35 mg/kg-day for effects on longevity, blood glucose and cholesterol levels adjusted by an uncertainty factor of 1,000. This value was adopted as the subchronic p-RfD (USEPA 2008a). In October 2019, the ATSDR released an updated evaluation of antimony that derived a chronic inhalation MRL of 3E-04 mg/m^3 based on induction of lung inflammation in female rates exposed to antimony trioxide (ATSDR 2019). This value was based on a benchmark modeled concentration lower confidence limit of 8E-03 mg/m^3 adjusted by an uncertainty factor of 30. This value was added to the USEPA RSL table in May 2020.

Arsenic

Arsenic is a naturally occurring element that is found in combination with either inorganic or organics substances to form many different compounds (ATSDR 2007a). Inorganic arsenic compounds are found in soils, sediments, and groundwater. These compounds occur either naturally or as a result of industrial use of arsenic. Organic arsenic compounds are found mainly in fish and shellfish. IRIS toxicity values for arsenic are based on the carcinogenic inorganic form.

The IRIS RfD of 3.0E-04 mg/kg-day for inorganic arsenic was derived based increased incidences of hyperpigmentation and keratosis in a Taiwanese population exposed to arsenic in drinking water (USEPA 2021k). This RfD is based on a LOAEL of 1.4E-02 mg/kg-day adjusted by an uncertainty factor of 3 (accounts for both the lack of data to preclude reproductive toxicity as a critical effect and to account for uncertainty in whether the NOAEL of the critical study accounts for all sensitive individuals). A subchronic RfD for inorganic arsenic is not available.

No IRIS RfC is available for inorganic arsenic, but a Tier 3 RfC is available from CalEPA. The CalEPA inhalation REL for inorganic arsenic of 1.5E-05 mg/kg-day is based on extrapolation from a chronic drinking water study in children (OEHHA 2008). The estimated LOAEL of 2.3E-04 mg/m^3 for decreased intellectual function and adverse effects on neurobehavioral development was adjusted by an uncertainty factor of 30 (3 for use of an estimated LOAEL and 10 for human variability). Due to the possibility of repeated exposure and the relatively slow clearance of arsenic compounds, CalEPA considers the 8-hour REL to be equivalent to the chronic REL.

The IRIS WOE characterizes inorganic arsenic as a known human carcinogen for both the oral and inhalation routes based on sufficient evidence from human data (USEPA 2021k). Increased lung cancer mortality was observed in multiple human populations exposed primarily through inhalation. Also, increased incidence of skin cancer and increased mortality from multiple internal organ cancers (liver, kidney, lung, and bladder) were observed in populations consuming drinking water high in inorganic arsenic. The oral SF for inorganic arsenic is 1.5E+00 (mg/kg-day)$^{-1}$. The inhalation unit risk for inorganic arsenic is 4.3E-03 (µg/m^3)$^{-1}$.

Barium

The IRIS RfD for barium of 2.0E-01 mg/kg-day is based on nephropathy observed in mice during a two-year drinking water study (USEPA 2021m). Dose response data from the critical study were modeled, and the lower benchmark dose for male mice associated with a benchmark response predicted to affect 5% of the population was used for derived the RfD. An uncertainty

factor of 300 (10 for interspecies extrapolation, 10 for human variability, and 3 for database deficiencies) was applied. The same value of 2.0E-01 mg/kg-day is recommended for subchronic exposures based on the ATSDR intermediate duration oral MRL (ATSDR 2007b). This MRL was derived based on a NOAEL of 65 mg/kg-day protective of kidney effects. An uncertainty factor of 100 (10 for interspecies extrapolation and 10 for human variability) was applied to this NOAEL.

No IRIS RfC is available for barium. The Health Effects Assessment Summary Table (HEAST) RfC of 5E-04 mg/m^3 is used to evaluated risks from inhalation exposures to barium (USEPA 2021n). This value is based on a NOAEL of 8.0E-01 mg/m^3 derived from a 4-month inhalation study in rats. An uncertainty factor of 1000 was applied (10 for interspecies extrapolation, 10 for human variability, and 10 for extrapolation from subchronic to chronic exposure). Based on the duration of the critical study, a subchronic RfC was also derived by applying an uncertainty factor of 100 (10 for interspecies extrapolation and 10 for human variability).

There are no cancer toxicity values available for barium.

Cadmium

The IRIS assessment for cadmium reports two RfD values, one for exposures to cadmium in water, and one for exposures to cadmium in food based on significant proteinuria observed in humans exposed orally to cadmium. The food RfD of 0.001 mg Cd/kg/day is used to evaluate oral exposures to soil. The ATSDR MRL of 5E-04 mg/kg-day for intermediate duration oral exposure was used as the subchronic RfD (ATSDR 2012a). No IRIS RfC is available, but a tier 3 RfC is available from ATSDR. A value of 1E-05 mg/m^3 is recommended as a chronic duration MRL (ATSDR 2012a). This value is based on environmental exposure studies that evaluated the urinary cadmium and renal response relationship in European cohorts (ATSDR 2012a). An intermediate duration inhalation MRL was not derived. The IRIS WOE characterizes cadmium as a probably human carcinogen (B1) by the inhalation pathway. The IRIS inhalation UR is 1.8E-03 $\mu g/m^3$. This value is based on a cohort study that demonstrated increased lung cancer risk among cadmium smelter workers (USEPA 2021o).

Chromium

Chromium can exist in the environment in several different forms, the most common being trivalent chromium (Cr(III)) and hexavalent chromium (Cr(VI)). Cr(III) is an essential nutrient and occurs naturally. Cr(VI) rarely occurs naturally, but is usually produced from anthropogenic sources (ATSDR 2012b). Cr(VI) has a higher toxic potency than Cr(III). For the purposes of this assessment, because data on chromium speciation at the Site are not available, a conservative,

health-protective assumption that all of the chromium detected at the Site is in the hexavalent form was applied. Uncertainties associated with this assumption are described under the uncertainty assessment.

An IRIS RfD, RfC and inhalation UR are available for Cr(VI). The IRIS RfD for Cr(VI) is 3.0E-03 mg/kg-day (USEPA 2021p). This value is based on an adjusted NOAEL of 2.5 mg/kg-day derived from a one-year drinking water study in rats. An uncertainty factor of 300 was applied (10 for interspecies extrapolation, 10 for human variability, and 3 to compensate for the less-than-lifetime exposure in the critical study), along with a modifying factor of 3 to account for uncertainties related to reports of gastrointestinal effects following drinking water exposures in a residential population in China. A value of 5E-03 mg/kg-day is recommended for subchronic exposures based on the ATSDR intermediate duration oral MRL (ATSDR 2012b). This MRL was derived based on hematological effects in male rats and female mice after exposure to sodium dichromate dihydrate in drinking water for 22 days. An average benchmark modeled dose of 5.2E-01 mg/kg-day was adjusted by an uncertainty factor of 100 (10 for interspecies extrapolation and 10 for human variability).

The IRIS RfC for Cr(VI) is 1.0E-04 mg/m^3 (USEPA 2021p). This value is based on the RfC derived for Cr(VI) particulates and was derived from a benchmark modeled concentration of 3.4E-02 mg/m^3 for increased lactate dehydrogenase in bronchioalveolar lavage fluid in rats exposed for up to 90 days. An uncertainty factor of 300 (3 for pharmcodynamic differences, 3 for less-than-lifetime exposure, and 10 for human variability). A value of 3.0E-04 mg/m^3 is recommended for subchronic exposures based on the ATSDR intermediate duration oral MRL (ATSDR 2012b). This MRL was derived based on the same study identified as the critical study for the derivation of the IRIS chronic RfC. The subchronic RfC was based on adjusting a benchmark dose concentration of 1E-02 mg/m^3 by an uncertainty factor of 30 (3 for interspecies extrapolation and 10 for human variability).

The IRIS WOE characterizes Cr(VI) as a known human carcinogen by the inhalation route of exposure. The IRIS assessment determined that the carcinogenic potential of Cr(VI) by the oral route could not be determined. No IRIS oral SF is available, but a Tier 3 oral SF is available from CalEPA. The CalEPA oral SF for Cr(VI) is 5.0E-01 $(mg/kg\text{-}day)^{-1}$ derived based on a dose-related increase of tumors of the small intestine in male mice (OEHHA 2011). The IRIS inhalation UR is 1.2E-02 $(\mu g/m^3)^{-1}$ (USEPA 2021h). However, consistent with the USEPA RSLs, an assumption that the ratio of Cr(VI) to Cr(III) is 1:6 is applied to result in an inhalation UR of 8.4E-02 $(\mu g/m^3)^{-1}$ (USEPA 2021a).

As noted in OEHHA (2011), the carcinogenic effects of Cr(VI) have been shown to be associated with a mutagenic mode of action. Consistent with USEPA (2005b), age-dependent

adjustment factors (ADAFs) were applied to the non-age dependent oral slope factor to account for differences in potency that may occur from exposure during early life (up to age 16). The ADAFs recommended in USEPA (2005b) were applied to the different age intervals as:

Age Interval (years)	ADAF
0 - < 2	10
2 - < 16	3
16 - 18	1

USEPA (2005b) further indicates that any grouping of ages in the exposure assessment will need to be integrated with the ADAF age groupings to derive age group-specific risk estimates. Tables 4-3 through 4-6 present the age group-specific exposure assumptions for the resident, camper, recreational fisher, and tribal fisher (i.e., young child receptors evaluated in this assessment), respectively.

Cobalt

IRIS does not report toxicity values for cobalt. However, chronic and subchronic p-RfD values of 3E-04 mg/kg-day and 3E-03 mg/kg-day, respectively, were derived using a LOAEL of 1 mg/kg-day for decreased iodine uptake in the thyroid and polycythemia in humans following a two-week exposure (USEPA 2008b). An uncertainty factor of 3,000 (10 for subchronic to chronic extrapolation, 10 for LOAEL to NOAEL extrapolation, 10 for human variability, and 3 for database deficiencies) was applied to the LOAEL for derivation of the chronic p-RfD. An uncertainty factor of 300 (10 for LOAEL to NOAEL extrapolation, 10 for human variability, and 3 for database deficiencies) was applied to the LOAEL for derivation of the subchronic p-RfD.

Chronic and subchronic p-RfC values of 6E-06 mg/m^3 and 2E-05 mg/m^3, respectively, were derived using an adjusted NOAEL of 1.9 µg/m^3 based on an occupational exposure study that reported respiratory effects in workers exposed to cobalt dust (USEPA 2008b). An uncertainty factor of 300 (3 for subchronic to chronic extrapolation, 10 for human variability, and 10 for database deficiencies) was applied to the NOAEL for derivation of the chronic p-RfC. An uncertainty factor of 100 (10 for human variability and 10 for database deficiencies) was applied to the NOAEL for derivation of the subchronic p-RfC.

The PPRTV WOE characterizes cobalt as likely to be carcinogenic to humans by the inhalation route (USEPA 2008b). This characterization is based on both limited evidence of carcinogenicity in humans (respiratory tumors following occupational exposures), and sufficient evidence of carcinogenicity in animals (alveolar/bronchiolar tumors in rats and mice, pheochromocytomas in

female rats, and hemangiosarcomas in male mice). No data were available to evaluate the carcinogenicity of cobalt by the oral route. The PPRTV inhalation UR is 9.0E-03 $(\mu g/m^3)^{-1}$.

Copper

IRIS does not report toxicity values for copper. USEPA's RSL tables include an RfD for copper of 4E-02 mg/kg-day attributed to the HEAST (USEPA 1987). This value is based on the HEAST maximum contaminant level goal (MCLG) of 1.3 mg/L. No other toxicity values are available for copper.

Iron

There is no IRIS RfD for iron. However, there is a PPRTV RfD for iron of 7.0E-01 mg/kg-day (USEPA 2006c). This value is based on adverse gastrointestinal effects in humans observed at a LOAEL of 60 mg/day following dietary exposures. The PPRTV RfD was based on an adjusted LOAEL calculated by adding the LOAEL for gastrointestinal effects to the estimated mean dietary intake of 11 mg/day and dividing by a reference body weight of 70 kg. This resulted in an adjusted LOAEL of 1 mg/kg-day which was used to derive the PPRTV RfD by applying an uncertainty factor of 1.5. This value is based on gastrointestinal toxicity, but is also protective against iron deficiency given that iron is an essential element for humans.

Manganese

Two oral RfD values are available for manganese, depending on exposure medium (food, nonfood). The IRIS RfD (1.4E-01 mg/kg-day) includes manganese from all sources, including diet (USEPA 2021q). This RfD is derived to be protective against central nervous system effects in humans following oral exposure, and is based on the upper range of total dietary intake (10 mg/day) as recommended in the 1989 Food and Nutrition Board National Research Council report. USEPA (2021q) notes that intakes above the RfD derived from the upper range of total dietary intake are not necessarily associated with toxicity. The USEPA RSL User's Guide recommends subtracting the dietary contribution when evaluating non-food exposures (e.g., drinking water or soil) to manganese, leading to an RfD of 7.1E-02 mg/kg-day for non-food media (USEPA 2021d). IRIS recommends using a modifying factor of 3 when calculating risks associated with non-food sources due to a number of uncertainties, leading to an RfD of 2.4E-02 mg/kg-day. This RfD is consistent with the RfD of 2.5E-02 mg/kg-day used in the recently derived MDEQ health-based guidance for manganese protective of the most sensitive population, formula-fed infants less than one year of age (MDEQ 2020). A subchronic RfD for manganese in non-food media is not available.

The IRIS RfC for manganese of 5.0E-05 mg/m^3 is based on a number of studies that indicated neurotoxicity associated with low-level occupational exposure to manganese (USEPA 2021q). This RfC was derived based on a LOAEL of 1.5E-01 mg/m^3 adjusted for continuous exposure. An uncertainty factor of 1,000 (10 for human variability, 10 for use of a LOAEL, and 10 for database limitations) was applied to derive the RfC. A separate subchronic RfC for manganese in non-food media is not available.

There are no cancer toxicity values for manganese.

Mercury

Mercury concentrations in soil were reported based on total mercury. There is no oral RfD for total mercury. Mercury exists primarily in salt forms within the environment. There is an IRIS RfD for mercuric chloride (and other mercury salts) of 3.0E-04 mg/kg-day (USEPA 2021r). This RfD was used to evaluate soil exposures in this assessment. An intermediate duration MRL of 2E-03 mg/kg-day is available for inorganic mercury (ATSDR 1999). There is no RfC available for mercuric chloride, but the California EPA offers a RfC for mercuric chloride that is based on a study of elemental mercury. The IRIS RfC for elemental mercury is 3E-04 mg/m^3 based on neurological effects observed in human occupational studies. This value is based on a LOAEL of 0.025 mg/m^3 adjusted for an 8-hour time weighted average exposure scenario and adjusted by an uncertainty factor of 30. This value is used to evaluate inhalation exposures to construction workers to mercury evaluated as mercuric chloride (and other mercury salts); this approach is consistent with the current recommendations within the USEPA RSL User's Guide (USEPA 2021d).

Nickel

The IRIS RfD for nickel soluble salts is 2E-02 mg/kg-day based on a chronic feeding study in rats (USEPA 2021s). The LOAEL for this study was 50 mg/kg-day for decreased body weights, higher heart-to-body weight ratios and lower liver-to-body weight ratios. The NOAEL of 5 mg/kg-day was adjusted by an uncertainty factor of 300 (10 for interspecies extrapolation, 10 for human variability, and 3 for database deficiencies).

There is no IRIS RfC available for nickel soluble salts. ATSDR has derived a chronic-duration MRL of 9E-05 mg/m^3 based on lung inflammation in rodents (ATSDR 2005). This MRL was derived by applying an uncertainty factor of 30 (3 for interspecies extrapolation and 10 for human variability) to the human equivalent concentration.

The carcinogenicity of nickel soluble salts has not been evaluated by IRIS. No oral SF is available. CalEPA has derived an inhalation UR of 2.6E-04 (µg/m^3) (OEHHA 2009). This value was derived from lung cancer data for an Ontario nickel refinery plant worker study.

Thallium

IRIS does not report toxicity values for thallium. However, IRIS does report a qualitative discussion on the limitations of deriving a RfD for thallium (USEPA 2021t). The available toxicity database for thallium contains oral studies that are generally of poor quality. For this same reason, a p-RfD has not been derived for thallium. However, recognizing the associated limitations, screening level p-RfD values were derived for chronic and subchronic exposures (USEPA 2012c). These RfD values are based on an approximated NOAEL of 4E-02 mg/kg-day protective of hair follicle atrophy in female rats following a 90-day gavage exposure to soluble thallium. An uncertainty factor of 3,000 (10 for interspecies extrapolation, 10 for human variability, 10 for database deficiencies, and 3 for extrapolation from subchronic to chronic exposure) was applied to derive a chronic screening p-RfD of 1.0E-05 mg/kg-day. An uncertainty factor of 1,000 (10 for interspecies extrapolation, 10 for human variability, and 10 for database deficiencies) was applied to derive a subchronic screening p-RfD of 4.0E-05 mg/kg-day.

There are no RfC or cancer toxicity values available for thallium.

Vanadium

An IRIS RfD of 9.0E-03 mg/kg-day is available for vanadium pentoxide (USEPA 2021u). This RfD is based on decreased hair cysteine observed in rats exposed to vanadium pentoxide in their diet for 2.5 years. The NOAEL for the critical study of 0.89 mg/kg-day was adjusted by an uncertainty factor of 100 (10 interspecies extrapolation and 10 human variability) to derive the RfD value. Consistent with the USEPA RSL User's Guide (USEPA 2021d), the molecular weight of the oxide ion was factored out to estimate an RfD for vanadium compounds of 5.0E-03 mg/kg-day. A separate subchronic RfD for vanadium is not available from IRIS. An ATSDR intermediate-duration MRL if 1E-02 mg/kg-day is available (ATSDR 2012c).

An IRIS RfC for vanadium is not available. ATSDR has derived a chronic inhalation MRL of 1.0E-04 mg/m^3 (ATSDR 2012c). This MRL is based on a two-year inhalation study in rats and mice that observed lung, larynx, and nasal effects at the lowest dose tested. The MRL was derived based on the benchmark modeled concentration for degeneration of epiglottis respiratory epithelium adjusted by an uncertainty factor of 30 (3 for interspecies extrapolation with dosimetric adjustment and 10 for human variability).

5.0 RISK CHARACTERIZATION

Risk characterization integrates the exposure assessment and the toxicity assessment to estimate non-cancer hazards and cancer risks for the receptor populations of concern at the OU3 Site. Non-cancer health hazards and cancer risks are characterized separately. Non-cancer hazards are evaluated by comparing an estimated exposure level or dose with a reference dose that is without appreciable risk of adverse health effects. Cancer risk is expressed as the probability that an individual will develop cancer over a lifetime as a result of exposure to a potential carcinogen. Risk characterization results are presented below by receptor.

5.1 Risk Characterization of Non-Cancer Effects

The potential for non-cancer effects is evaluated by comparing the estimated DI or EC for a receptor over a specified time period to a reference threshold that represents the exposure below which it is unlikely for even sensitive populations to experience adverse health effects (USEPA 1989). This ratio of exposure to toxicity is called a Hazard Quotient (HQ). When a receptor is exposed to a COPC by more than one route, or is exposed to more than one COPC, these values may be summed to yield a hazard Index (HI). If the HQ or HI value is equal to or less than one, it is believed that there is no appreciable risk that non-cancer health effects will occur. If an HQ or HI exceeds one, there is some possibility that non-cancer effects may occur, although an HQ or HI above one does not indicate an effect will definitely occur. This is because of the margin of safety inherent in the derivation of all toxicity values (see Section 4). However, the larger the HQ or HI value, the more likely it is that an adverse effect may occur.

The assumption of dose additivity in the HI approach is most relevant to contaminants that induce the same effect by the same mode of action. If an HI >1E+00 because of summing several HQs across pathways, then the contaminants can be segregated by effect and mode of action, and an HI can be calculated for each target organ group (USEPA, 1989). Target organ HIs were calculated in this HHRA for receptors and pathways where the HI >1E+00 if summed across COPCs within an exposure pathway, or across exposure pathways for a specific exposure scenario. The risk benchmark for non-cancer hazard based on target organ HIs was HI >1E+00.

5.1.1 Ingestion Exposures

For most contaminants, the potential for non-cancer effects is evaluated by comparing the estimated daily intake of the contaminant over a specific time period with the RfD for that contaminant derived for a similar exposure period, as follows (USEPA 1989):

$$HQ = DI / RfD$$

where:

DI = Daily Intake (mg/kg-day)
RfD = Reference Dose (mg/kg-day)

5.1.2 Dermal Exposures

For most contaminants, the potential for non-cancer effects following dermal exposure is evaluated by comparing the estimated absorbed dose of the contaminant over a specific time period with the absorbed RfD for that contaminant derived for a similar exposure period, as follows (USEPA 1989):

$$HQ = DAD / RfD_{ABS}$$

where:

DAD = Dermal absorbed dose (mg/kg-day)
RfD_{ABS} = Absorbed Reference Dose (mg/kg-day)
$RfD_{ABS} = RfD \cdot ABS_{GI}$

The ABS_{GI} term is unitless, chemical-specific and is applied to the available oral toxicity value to account for the absorption efficiency of an administered dose across the gastrointestinal tract and into the bloodstream.

5.1.3 Inhalation Exposures

For inhalation exposures, the potential for non-cancer effects is evaluated by comparing the time-weighted EC over a specific time period to the appropriate inhalation RfC for that contaminant, as follows (USEPA 2009):

$$HQ = EC / RfC$$

where:

EC = Exposure Concentration (mg/m^3)
RfC = Reference Concentration (mg/m^3)

As per the CSM (Figure 3-1), inhalation exposures were only evaluated for hypothetical future construction workers exposed to OU3 upland soils down to a depth of 10 feet during construction activities.

5.2 Risk Characterization of Cancer Effects

The excess risk of cancer from exposure to a contaminant is described in terms of the probability that an exposed individual will develop cancer because of that exposure. Excess cancer risks are summed across all carcinogenic contaminants and all exposure pathways that contribute to exposure of an individual in a given population. The level of total cancer risk that is of concern is a matter of personal, community, and regulatory judgment. In general, the USEPA considers excess cancer risks that are below 1E-06 to be so small as to be negligible, and risks above 1E-04 to be sufficiently large that some sort of remediation is desirable[13]. USEPA policy states that CERCLA actions are generally warranted when the baseline risk assessment indicates that a cumulative site risk to an individual using RME assumptions for either current or future land use is greater than the 1E-04 lifetime excess cancer risk end of the cancer risk range of 1E-04 to 1E-06 (USEPA 1991b). Excess cancer risks that range between 1E-04 and 1E-06 are generally considered to be within USEPA health guidelines (USEPA 1991b), although this is evaluated on a case by case basis, and USEPA may determine that risks lower than 1E-04 are not sufficiently protective and warrant remedial action. Furthermore, the MDEQ allowable cancer risk level is 1E-05, which will be considered as part of the risk management decisions associated with this Site[14]. Cancer risks for each chemical are calculated as described below.

5.2.1 Ingestion Exposures

The excess risk of cancer from ingestion exposure to a chemical is calculated as follows (USEPA 1989):

$$\text{Excess Cancer Risk} = 1 - \exp(-DI_L \cdot SF)$$

where:

DI_L = Daily Intake, averaged over a lifetime (mg/kg-day)

[13] Note that excess cancer risk can be expressed in several formats. A cancer risk expressed in a scientific notation format as 1E-06 is equivalent to 1 in 1,000,000 or 10^{-6}. Similarly, a cancer risk of 1E-04 is equivalent to 1 in 10,000or 10^{-4}. For the purposes of this document, all cancer risks are presented in a scientific notation format (*i.e.*, 1E-06).

[14] Montana DEQ-7 standards will be considered separately in the RI/FS.

SF = Slope Factor $(mg/kg\text{-}day)^{-1}$

In most cases (except when the product of $DI_L \cdot SF$ is larger than about 0.01), this equation may be approximated by the following:

Excess Cancer Risk = $DI_L \cdot SF$

When calculating cancer risks from ingesting fish, cooking loss is accounted for as:

Excess Cancer Risk = $DI_L \cdot 1\text{-}CL \cdot SF$

5.2.2 Dermal Exposures

The excess risk of cancer from dermal exposure to a contaminant is calculated as follows (USEPA 2004):

Excess Cancer Risk = $DAD_L \cdot SF_{ABS}$

where:

DAD_L = Dermal Absorbed Dose, averaged over a lifetime (mg/kg-day)
SF_{ABS} = Absorbed Slope Factor $(mg/kg\text{-}day)^{-1}$
$SF_{ABS} = SF / ABS_{GI}$

5.2.3 Inhalation Exposures

The excess risk of cancer from inhalation exposure is calculated based on inhalation UR values, as follows (USEPA 2009):

Excess Cancer Risk = $EC \cdot UR$

where:

EC = Exposure Concentration $(\mu g/m^3)$
UR = Unit Risk $(\mu g/m^3)^{-1}$

5.3 Risk Characterization Results

Detailed risk calculations are presented in Appendix D. Risk characterization results are presented in Section 5 tables as summarized below. Within the summary tables, non-cancer hazards that exceed the USEPA guidelines of non-cancer hazards ≤1E+00 and cancer risk < 1E-04 are bolded and shaded (orange). Cancer risk that exceeds MDEQs criteria of 1E-05 are also shaded (blue) for reference[15].

5.3.1 Risks to Hypothetical Future Residents

5.3.1.1 Risks from Exposures to COPCs in OU3 Soils

Table 5-1 summarizes the predicted non-cancer HIs and cancer risks for exposures to OU3 surface soils by a hypothetical future resident for each OU3 exposure unit grid. As shown, non-cancer HIs for a RME young child are > 1E+00 for grids 26, 36, 45, 47, 48, 49, 50, 53, 54, 55, 56, 58, 59, 64, 65, 67, 68, 72, 74, 86, 88, 90, 91, 93, 94, 95, and 98. These exceedances are driven by exposure via the incidental ingestion of surface soils within each grid. Total HI values in most of these grids range from 2E+00 to 4E+00, except for grid 74. Total HI for a RME young child in grid 74 is 1E+01. Grid 74 is also the only grid where total HI for a CTE young child also exceeds 1E+00 (HI=4E+00). Table 5-2 presents the COPC HQs for grid 74 which indicates that $TEQ_{D/F}$ is the primary risk driver with an associated HQ of 6E+00 for the RME young child scenario. Grid 74 includes the historic settling pond P17. As shown in Figure 2-4, this was the first settling pond in the process to receive effluent from the lime kiln and the multifuel boiler.

Target organ specific non-cancer hazards for the young child resident are shown by exposure grid in Appendix D. Of all of the grids where the HI for a RME young child exceeds 1E+00, target organ specific HIs based on incidental ingestion of surface soil exceed 1E+00 in grids 55, 58, 67, 68 and 74 as follows:

- Nervous system effects in grid 55: aluminum and manganese; manganese is the primary risk driver in soil within grid 55 (HQ = 1E+00) with aluminum as a minor risk contributor (HQ = 2E-01) that when combined, result in an HI > 1E+00.
- Dermal effects in grid 74: arsenic, thallium, and vanadium; arsenic and thallium are the primary risk drivers in soil within grid 74 (HQ = 1E+00 for each COPC) with vanadium as a minor risk contributor (HQ = 6E-02) that when combined, result in an HI > 1E+00.
- Reproductive effects in grids 58, 67, 68, and 74 are attributable to $TEQ_{D/F}$. The RME HQs for $TEQ_{D/F}$ in each of grids 58, 67 and 68 are equal to 2E+00 (note that the EPC for grid 67 was assumed for grid 68 where data were lacking); CTE HQs for $TEQ_{D/F}$ in these

[15] Montana DEQ's cancer risk criteria of 1E-05 will be considered within the Feasibility Study.

grids are all ≤ 1E+00. The HQs for $TEQ_{D/F}$ in grid 74 are 6E+00 and 2E+00 for the RME and CTE receptors, respectively.

As shown in Table 5-1, RME cancer risks are ≥ 1E-04 in upland exposure area grids 26, 42, 47, 48, 49, 50, 53, 54, 55, 56, 58, 59, 65, 67, 68, 71, 72, 74 and in floodplain exposure area grids 86, 88, 90, 91, 93, 94, 95, and 98. Unacceptable cancer risks for the CTE resident are only predicted in grid 48 (cancer risk = 1E-04). Table 5-3 presents the COPC cancer risks for grid 48; all other COPC specific cancer risks are shown in the Appendix D tables. As shown in these tables, the predicted excess cancer risks to a hypothetical future resident are primarily driven by early lifetime exposures to chromium via incidental ingestion of surface soils (evaluated as Cr(VI) accounting for a mutagenic mode of action).

5.3.1.2 Risks from Exposures to COPCs in OU3 Groundwater

Table 5-4 summarizes the predicted non-cancer HIs and cancer risks for the hypothetical future residential scenario for each OU3 groundwater well. As shown in this table and in Figure 5-1, non-cancer HIs exceed 1E+00 in every OU3 well evaluated for the RME child resident except SMW16d. Predicted HIs for the RME child resident range from 1E+00 (well SMW16d) to 1E+02 (well NFMW19). As shown in Table 5-4, HIs exceed 1E+00 in all but six OU3 wells for the CTE child resident. Predicted HIs for the CTE child resident range from 6E-01 (well SMW16d) to 5E+01 (well NFMW19). The primary groundwater risk drivers are arsenic and manganese, and to a lesser extent cobalt. Figures 5-2, 5-3, and 5-4 plot the HQs for arsenic, manganese, and cobalt, respectively. HQs also exceed 1E+00 for the RME resident for iron in three wells (HQ=2E+00 in wells NFMW9, and SMW19; HQ=3E+00 in NFMW19), and for chromium in one well (HQ=3E+00 in NFMW1s). Primary risk contributors in the well with the highest predicted non-cancer hazard, NFMW19, are cobalt (HQs of 6E+00 and 1E+01 for CTE and RME, respectively), iron (HQs of 1E+00 and 3E+00 for CTE and RME, respectively), and manganese (HQs of 4E=01 and 1E+02 for CTE and RME, respectively). Target organ specific non-cancer hazards are shown in Appendix D. Evaluation of HIs across all wells indicates that target organ specific non-cancer HIs exceed 1E+00 for nervous system effects, dermal effects, gastrointestinal effects, and thyroid effects in different wells. Individual groundwater COPCs that exert toxicity above the respective RfDs on these systems are (as shown in Tables 4-1 and 4-2):

- Nervous system effects: aluminum and manganese; manganese is the primary risk driver in OU3 groundwater with aluminum as a minor risk contributor. For every well where the nervous system HI > 1E+00, the manganese HQ > 1E+00 and the aluminum HQ ≤1E+00.
- Dermal effects: arsenic, thallium, and vanadium; arsenic is the primary risk driver in OU3 groundwater with thallium and vanadium as minor risk contributors. The arsenic HQs exceed 1E+00 in 17 wells for the RME receptor and in eight wells for the CTE

receptor; thallium and vanadium HQs are all below 1E+00. There are two wells (NFMW7 and SMW15) where the dermal HI > 1E+00, but the arsenic HQ ≤ 1E+00.

- Gastrointestinal effects: beryllium and iron; iron is the primary risk driver in OU3 groundwater with beryllium as a minor risk contributor. For the four wells where the gastrointestinal HI > 1E+00, the iron HQ > 1E+00 in three wells.
- Thyroid effects: cobalt. The cobalt HQ > 1E+00 for the RME receptor in six wells, and for the CTE receptor in three wells. The cobalt HQs are highest in well SMW15 (HQ=2E+01 for the CTE receptor; HQ=4E+01 for the RME receptor).

As shown in Table 5-4 and Figure 5-5, RME cancer risks are ≥ 1E-04 in all OU3 wells except NFMW12, SMW7, SMW16d, and SMW17d. CTE cancer risks are ≥ 1E-04 in wells NFMW1d, NFMW1s, NFMW9, NFMW10, NFMW22, NFMW23, SMW10, SMW11, SMW12, SMW16, SMW17, SMW18 and the waste water clarifier well. The primary risk drivers are arsenic and chromium.

5.3.1.3 Risks from Combined Exposures to OU3 COPCs

As outlined in the OU3 CSM (Figure 3-1), hypothetical future residents are assumed to be exposed to both surface soils and groundwater. Based on the results of the individual media presented above, non-cancer hazards to hypothetical future residents would primarily be driven by consuming OU3 groundwater as drinking water. Table 5-5 summarizes the combined non-cancer hazards associated with exposures to COPCs in OU3 soils and COPCs in groundwater within OU3 wells. There is no groundwater well within grid 74 where unacceptable non-cancer hazards were predicted for a child resident exposed to surface soil. Non-cancer HIs for the CTE and RME residents assumed to consume groundwater from well NFMW7 located in the nearby grid 73 were 2E+00 and 4E+00, respectively. Using these estimates, the combined exposure to soil within grid 74 results in HIs of 5E+00 and 1E+01 for the CTE and RME child resident, respectively.

As described above, unacceptable excess cancer risks (risk ≥1E-04) were predicted for the hypothetical future RME resident based on exposures to surface soils (in some, but not all exposure grids) and exposures to groundwater (in most, but not all OU3 wells) separately. As shown in Table 5-6, total cancer risks for exposures to both surface soil and groundwater predicted for the RME resident are all equal to or exceed 1E-04. Of note, acceptable excess cancer risks were predicted for the RME resident assumed to consume groundwater from well NFMW12 and for the RME resident assumed to be exposed via direct contact to surface soils in grid 40 (which includes well NFMW12). However, total risk based on exposures to both soil and groundwater in this grid equal 1E-04. Unacceptable excess cancer risks were also predicted for the CTE resident based on consumption of groundwater as drinking water in wells NFMW1,

NFMW9, NFMW10, NFMW22, NFMW23, SMW10, SMW11, SMW12, SMW16, SMW17, SMW18 and the wastewater clarifier well. However, acceptable excess cancer risks (risk < 1E-04) were predicted for the CTE resident based on direct contact exposures to OU3 surface soils. For the CTE resident, there are several total cancer risk estimates for combined exposure to soil and groundwater that equal or exceed 1E-04 where both the individual soil and groundwater predicted cancer risks were less than 1E-04 (denoted with an x in the table).

5.3.2 Risks to Hypothetical Future Commercial/Industrial Workers

5.3.2.1 Risks from Exposures to COPCs in OU3 Soils

Table 5-7 summarizes the predicted non-cancer HIs and cancer risks for exposures to OU3 surface soils by a hypothetical future commercial/industrial worker for each OU3 exposure unit grid. As shown, non-cancer HI's for hypothetical future commercial/industrial workers do not exceed 1E+00 in any exposure unit. Estimated excess cancer risks for hypothetical future commercial/industrial workers and hypothetical future construction workers are all below 1E-04 for all exposure units.

5.3.2.2 Risks from Exposures to COPCs in OU3 Groundwater

Table 5-8 summarizes the predicted non-cancer HIs and cancer risks for the hypothetical future commercial/industrial worker scenario for each OU3 groundwater well. As shown in this table and in Figure 5-6, non-cancer HIs exceed 1E+00 in 26 OU3 wells for the RME receptor and in 13 OU3 wells for the CTE receptor. Predicted HIs for the RME worker range from 3E-01 (well SMW16d) to 2E+01 (well NFMW19). Predicted HIs for the CTE worker range from 1E-01 (well SMW16d) to 1E+01 (well NFMW19). The primary groundwater risk drivers are arsenic and manganese. The HQ for cobalt also exceeds 1E+00 for both the RME and CTE workers in well SMW15 (RME HQ=9E+00 and CTE HQ=4E+00). Figures 5-7, 5-8 and 5-9 plot the HQs for arsenic, manganese, and cobalt, respectively.

Target organ specific non-cancer hazards are shown in Appendix D. Evaluation of HIs across all wells indicates that target organ specific non-cancer HIs exceed 1E+00 for nervous system effects, dermal effects, and thyroid effects in different wells. Individual groundwater COPCs that exert toxicity above the respective RfDs on these systems are (as shown in Tables 4-1 and 4-2):

- Nervous system effects: aluminum and manganese; manganese is the primary risk driver in OU3 groundwater with aluminum as a minor risk contributor. For every well where the nervous system HI > 1E+00, the manganese HQ > 1E+00 and the aluminum HQ ≤1E+00.

- Dermal effects: arsenic, thallium, and vanadium; arsenic is the primary risk driver in OU3 groundwater with thallium and vanadium as minor risk contributors. The dermal HI exceeds 1E+00 in 3 wells. In one of these wells, the arsenic HQ ≤ 1E+00.
- Thyroid effects: cobalt. There are two wells where the thyroid HI > 1E+00 based on the cobalt HQ > 1E+00.

As shown in Table 5-8 and Figure 5-10, RME cancer risks for hypothetical future commercial/industrial workers assumed to consume groundwater as drinking water are ≥ 1E-04 in OU3 wells NFMW1d, NFMW1s, NFMW9, NFMW10, NFMW23, SMW10, SMW11, SMW12, SMW14, SMW16, SMW17, and the wastewater clarifier well. Arsenic is the primary risk driver with additional contributions primarily from chromium. CTE cancer risks are < 1E-04 in all wells.

5.3.2.3 Risks from Combined Exposures to OU3 COPCs

As outlined in the OU3 CSM (Figure 3-1), hypothetical future commercial/industrial workers are assumed to be exposed to both surface soils and groundwater. Based on the results of the individual media presented above, non-cancer hazards to hypothetical future commercial/industrial workers would primarily be driven by consuming OU3 groundwater as drinking water. Table 5-9 summarizes the combined non-cancer hazards associated with exposures to COPCs in OU3 soils and COPCs in groundwater within OU3 wells.

As described above, acceptable excess cancer risks (risk <1E-04) were predicted for the hypothetical future commercial/industrial worker based on exposures to surface soils, while unacceptable excess cancer risks (risk ≥1E-04) were predicted for the RME receptor consuming groundwater as drinking water from twelve OU3 wells. As shown in Table 5-10, total cancer risks for exposures to both surface soil and groundwater predicted for the hypothetical future commercial/industrial worker are driven by risks attributed to the consumption of groundwater. The additional exposure to hypothetical future commercial/industrial workers from incidental ingestion of and dermal contact with surface soil does not appreciably increase the total risk when combined with exposure to COPCs in groundwater.

5.3.3 Risks to Hypothetical Future Construction Workers

Table 5-11 summarizes the non-cancer HIs and cancer risks for exposures to OU3 surface and subsurface soils by a hypothetical future construction worker scenario for each OU3 exposure unit grid. As shown, non-cancer HI's for hypothetical future construction workers do not exceed 1E+00 in any exposure unit. Estimated excess cancer risks for hypothetical future construction workers are below 1E-04 for all exposure units.

5.3.4 Risks to Current and Hypothetical Recreational Visitors

5.3.4.1 Risks to Hikers

Table 5-12 summarizes the non-cancer HIs and cancer risks for exposures to OU3 surface soils by a hiker for each OU3 exposure unit grid. As shown, non-cancer HIs for the hiker do not exceed 1E+00 in any exposure unit. Estimated excess cancer risks for hiker are below 1E-04 for all exposure units.

5.3.4.2 Risks to Campers

As outlined in the OU3 CSM (Figure 3-1), current and hypothetical future campers are assumed to be exposed to surface soil, surface water, and sediment within the OU3 study area. Estimated non-cancer hazards and cancer risks are discussed by media type first and then combined across exposure media.

Risks were estimated for a camper assuming exposure to surface soils across OU3. Table 5-13 summarizes the non-cancer HIs and cancer risks for exposures to OU3 surface soils by a camper for each OU3 exposure unit grid. As shown, non-cancer HIs for the child camper do not exceed 1E+00 in any exposure unit. Estimated excess cancer risks for a camper are below 1E-04 for all exposure units except grid 74 where the total cancer risk is estimated to be equal to 1E-04. As shown in Table 5-13, this risk is driven by exposure via the incidental ingestion of surface soils within this grid. Cancer risk by COPC for grid 74 is shown in Table 5-14.

Table 5-15 summarizes the estimated non-cancer hazards and cancer risks to a camper from exposure to surface water at the OU3 site. The camper was evaluated for potential risks associated with drinking surface water collected directly (unfiltered) from the on-site creeks (O'Keefe and Lavalle Creeks) or from the CFR as well as with incidental ingestion and dermal contact with the CFR surface water while swimming/tubing. As shown in Table 5-15, acceptable risks (non-cancer HI $\leq$ 1E+00 and cancer risks < 1E-04) are predicted for campers from such surface water exposures. Intentional ingestion of CFR surface waters as drinking water by a camper is estimated to result in cancer risks of 1E-05 and 4E-06 for the RME and CTE campers, respectively.

Similarly, the camper was evaluated for incidental ingestion of and dermal contact with CFR sediments while swimming/tubing. As shown in Table 5-15, acceptable risks (non-cancer HI $\leq$ 1E+00 and cancer risks < 1E-04) are predicted for campers from such sediment exposures.

A hypothetical camper who may drink from and swim in the CFR was also evaluated for a combined exposure to CFR surface water and sediments and floodplain surface soils. As shown in Table 5-15, acceptable risks (non-cancer HI ≤ 1E+00 and cancer risks < 1E-04) are predicted for campers from such a combined exposure scenario. The predicted cancer risks for a RME and CTE camper are 5E-05 and 2E-05, respectively. These risks are primarily contributed by consuming CFR surface water as drinking water and incidental ingestion of floodplain surface soils.

5.3.4.3 Risks to Recreational Fishers

As outlined in the OU3 CSM (Figure 3-1) and described in Section 3.1, the recreational fisher is assumed to include young children, older children/adolescents and adults who are exposed via incidental ingestion of and dermal contact to surface soils, surface water, and sediments while fishing along the banks of the CFR. The recreational fisher is also assumed to consume the fillets of fish collected from the CFR. Estimated non-cancer hazards and cancer risks are discussed by media type first and then combined across exposure media.

Risks were estimated for a recreational fisher assuming exposure to surface soils within the floodplain. Table 5-16 summarizes the non-cancer HIs and cancer risks for exposures to floodplain surface soils by a recreational fisher for each OU3 floodplain exposure unit grid. As shown, non-cancer HIs for the young child do not exceed 1E+00 and total cancer risks are all below 1E-04.

Table 5-17 summarizes the estimated non-cancer hazards and cancer risks to a recreational fisher from exposure to surface water and sediment while fishing along the banks of the CFR. As shown, acceptable risks (non-cancer HI ≤ 1E+00 and cancer risks < 1E-04) are predicted for recreational fishers from such exposures.

Recreational fishers were assumed to consume the fillets of fish caught from the CFR within the OU3 study area. As shown in Table 5-18, the predicted non-cancer HQs based on consumption of $TEQ_{D/F/PCB}$ in northern pike fillets are 8E+00 and 2E+00 for the RME and CTE recreational child fishers, respectively. The predicted non-cancer HQs based on consumption of $TEQ_{D/F/PCB}$ in rainbow trout fillets are 5E+00 and 1E+00 for the RME and CTE recreational child fishers, respectively. As shown in the table, coplanar PCB congeners are contributing the majority of the TEQ hazard as evidenced by HQs ≤ 1E+00 for $TEQ_{D/F.}$ If it is assumed that an RME recreational child fisher consumes 50% northern pike and 50% rainbow trout, the non-cancer HQ for $TEQ_{D/F/PCB}$ is 7E+00 (estimated by summing half of the risk calculated for northern pike and half of the risk calculated for rainbow trout).

Table 5-18 also presents the estimated excess cancer risk for a recreational fisher consuming northern pike or rainbow trout fillets. As shown, the predicted cancer risks based on consumption of $TEQ_{D/F/PCB}$ in northern pike fillets are 2E-04 and 3E-05 for the RME and CTE recreational fishers, respectively. The predicted cancer risks based on consumption of $TEQ_{D/F/PCB}$ in rainbow trout fillets are 1E-04 and 2E-05 for the RME and CTE recreational fishers, respectively. Coplanar PCBs contribute more to the TEQ risk than dioxins and furans. Cancer risks for $TEQ_{D/F}$ fall within USEPA's acceptable cancer risk range (risk = 3E-05 for the RME fisher). Non-cancer hazards and cancer risks for the RME recreational fisher for total PCBs are 5E-05 and 2E-05 for northern pike and rainbow trout fillets, respectively.

The non-cancer hazards and cancer risks based on fish consumption shown in Table 5-18 assume no loss in COPC concentrations during preparation and cooking of the fillets. USEPA (2000) notes that fish preparation and cooking procedures can modify the amount of contaminant ingested by fish consumers. USEPA (2000) indicates that contaminant losses from cooking can be significant for organics, such as dioxins and PCBs. Cooking loss is a function of many variables including cooking method, cooking duration, cooking temperature, preparation techniques, lipid content of fish, and fish species. For this risk characterization, assumed cooking losses for Total PCBs and TEQ were 30% and 54%, respectively. These assumptions were based on the Great Lakes fish data presented in USEPA (2000) that identified an average cooking loss for PCBs of 30%, and a median cooking loss of 54% for TCDD (ranged from 37 to 80%). The 30% (mean) loss for PCBs was based on multiple species, trimming the belly flap area for skin-on fillets. The 54% (median) loss for TCDD was based on multiple species, cooked, with a mixture of skin-on and skin-off. Cooking loss for fish is accounted for using the following equation:

$$HQ = DI \cdot 1\text{-}CL / RfD$$

where:

CL = cooking loss (as a fraction)

The risk results presented in Table 5-19 assumes general cooking loss for dioxins and PCBs. As shown, the non-cancer hazards and cancer risks are reduced by comparison to those shown in Table 5-18 reflecting a loss of contaminant residues in the fish tissue due to preparation and cooking processes. In this case, the non-cancer HQ for the RME child fisher consuming $TEQ_{D/F/PCB}$ in northern pike fillets is 4E+00. The corresponding cancer risk (1E-04) is at the upper end of USEPA's acceptable cancer risk range.

Cumulative non-cancer hazards and cancer risks for a general recreational fisher inclusive of risks from fish consumption are also shown in Table 5-17. As shown in the table and described above, unacceptable total risks are primarily associated with fish consumption.

5.3.4.4 Risks to Tribal Fishers

As outlined in the OU3 CSM (Figure 3-1) and described in Section 3.1, the tribal fisher is assumed to include young children, older children/adolescents, and adults who are exposed via incidental ingestion of and dermal contact to surface soils, surface water, and sediments while fishing along the banks of the CFR. The tribal fisher is also assumed to consume the fillets or whole body of fish collected from the CFR. Estimated non-cancer hazards and cancer risks are discussed by media type first and then combined across exposure media.

Risks were estimated for a tribal fisher assuming exposure to surface soils within the floodplain. Table 5-20 summarizes the non-cancer HIs and cancer risks for exposures to floodplain surface soils by a tribal fisher for each OU3 floodplain exposure unit grid. As shown, non-cancer HIs do not exceed 1E+00 and cancer risks are all below 1E-04. Predicted cancer risks for the RME tribal fisher from incidental ingestion of surface floodplain soils are within USEPA's acceptable cancer risk range (1E-06 to 1E-04). Cancer risks are primarily driven by the assumed early childhood exposures to chromium evaluated as Cr(VI).

Table 5-21 summarizes the estimated non-cancer hazards and cancer risks to a tribal fisher from exposure to surface water and sediment while fishing along the banks of the CFR. As shown, acceptable risks (non-cancer HI ≤ 1E+00 and cancer risks < 1E-04) are predicted for tribal fishers from such exposures.

It was assumed that tribal fishers sometimes consume just the fillets of fish caught from the CFR, but other times will consume other parts of the fish. Thus, risks associated with fish consumption by tribal receptors were estimated based on both measured fillet concentrations and calculated whole body concentrations (on a wet weight basis for both). As shown in Table 5-22, unacceptable risks are predicted for the tribal fisher consuming either fillets or whole-body fish regardless of species. In general, risks decrease in magnitude as follows: northern pike whole body > northern pike fillet > rainbow trout whole body > rainbow trout fillet. Non-cancer HQs exceed 1E+00 for all TEQ-based COPCs evaluated in this assessment ($TEQ_{D/F}$, TEQ_{PCB}, $TEQ_{D/F/PCB}$) for the RME tribal fisher, with the largest magnitude HQs associated with $TEQ_{D/F/PCB}$. Non-cancer HQs exceed 1E+00 for the CTE tribal fisher also, but not for all COPCs; HQs based on $TEQ_{D/F}$ are below 1E+00 for the CTE receptor. Predicted cancer risks exceed 1E-04 for the RME tribal fisher consuming fillets or whole body for both species. Cancer risks are greatest for the RME tribal fisher consuming whole body northern pike with predicted cancer

risks based on $TEQ_{D/F}$ of 1E-04 and based on each TEQ_{PCB} and $TEQ_{D/F/PCB}$ of 1E-03. Predicted cancer risks are estimated at 1E-04 for the CTE tribal fisher consuming whole body northern pike. These results suggest that the TEQ risks are primarily driven by coplanar PCBs. Cancer risks based on total PCBs are also ≥1E-04 for a RME tribal fisher consuming northern pike as fillets or whole body.

The non-cancer hazards and cancer risks based on fish consumption shown in Table 5-22 assume no loss in COPC concentrations during preparation and cooking of the fish. As noted above for the recreational fisher, it is expected that dioxin and PCB residues in fish tissue will be reduced due to preparation and cooking processes. The risk results presented in Table 5-23 assumes general cooking loss for dioxins and PCBs. As shown, the non-cancer hazards and cancer risks are reduced by comparison to those shown in Table 5-22. In this case, the non-cancer HQs for the RME fisher consuming $TEQ_{D/F/PCB}$ exceed 1E+00 for northern pike and rainbow trout, fillets and whole body. The non-cancer HQs for $TEQ_{D/F}$ based on consumption by the RME tribal fisher are > 1E+00 for whole-body northern pike only (HQs = 1E+00 for other fish tissues). The non-cancer HQs based on $TEQ_{D/F}$ remain lower than HQs based on TEQ_{PCB} or $TEQ_{D/F/PCB}$, again reflecting that coplanar PCBs appear to contribute the most to the associated non-cancer TEQ hazards. Cancer risks for the RME tribal fisher exceed 1E-04 for $TEQ_{D/F/PCB}$ and TEQ_{PCB} regardless of species or tissue type. Cancer risks assuming cooking loss are all less than 1E-04 for the CTE tribal fisher.

When evaluating cumulative non-cancer hazards and cancer risks for a tribal fisher, predicted HIs and cancer risks were evaluated based on the range of fish consumption risks. As shown in Table 5-21 and as described above, unacceptable cumulative risks for a tribal fisher are driven by the fish consumption pathway.

6.0 UNCERTAINTY ASSESSMENT

Quantitative evaluation of the risks to humans from environmental contamination is frequently limited by uncertainty regarding a number of key data items, including concentration levels in the environment, the true level of human contact with contaminated media, and the true dose-response curves for non-cancer and cancer effects in humans. This uncertainty is usually addressed by making assumptions or estimates for uncertain parameters based on whatever limited data are available. Because of these assumptions and estimates, the results of risk calculations are themselves uncertain, and it is important for risk managers and the public to keep this in mind when interpreting the results of a risk assessment.

6.1 Uncertainties in Exposure Assessment

6.1.1 Uncertainties in Exposure Pathways Not Evaluated

Omission of exposure pathways believed to be minor compared to one or more other pathways that were evaluated may result in a small underestimation of exposure and risk, but the magnitude of this underestimation is not expected to be significant.

Evaluation of risks by hypothetical future residents based on consumption of cultivated garden fruits and vegetables was not quantified in this assessment. USEPA (2007) notes that risks to humans from most metals when consuming fruits and vegetables (except roots or green, leafy vegetables) is low. Risks to hypothetical future residents were assessed assuming full-time residential exposure, and full-time residential soil exposures (assuming direct soil ingestion) are expected to be protective of consumption of home-grown produce. Based on this, it is concluded that omission of the home grown produce pathway is not likely to result in a significant underestimation of exposure and risk from dioxin/furan and metal contaminants in soil. Further, as shown in the Appendix D tables, unacceptable risks to a hypothetical future resident were primarily based on chromium. Data on plant uptake of chromium are limited, but ATSDR (2012b) noted that some data indicate that chromium has a low mobility for translocation from roots to above ground parts of plants. Because most of the uptake of chromium in plants is retained in the roots, it is possible that total risks from chromium reported in this HHRA are slightly underestimated when considering the potential for consumption of locally grown root vegetables. Similarly, other metals and dioxins/furans have also been shown to accumulate in roots, suggesting that total risks from other COPCs may also be underestimated. The magnitude of this underestimation associated with the consumption of root vegetables is likely small but would be dependent upon the uptake potential of plant species and the consumption rates by a human receptor.

This HHRA includes evaluation of the fish consumption pathway for both recreational and tribal fishers. For the purposes of this assessment, consumption of rainbow trout and northern pike were evaluated as representative species most likely to be caught and consumed. However, people collecting fish from the CFR for consumption may also catch and consume other species. In general, it is reasonable to assume that concentrations and subsequent risks from consumption of bottom dwelling fish (i.e., suckers) may be similar to or greater than those observed in trout and pike.

This HHRA evaluates risks to a tribal receptor who may fish from the portion of the CFR included within the OU3 study area. Risks were quantified for this exposure scenario to account for potential incidental ingestion of soil, sediment, and surface water while fishing in addition to fish consumption. However, it is recognized that a tribal receptor may also be exposed by other potential exposure pathways that were not evaluated in this HHRA including, but not limited to, consumption of wild game and wild plants, and non-consumptive uses of fish, wildlife, and plants. The exclusion of such non-consumptive pathways is not considered a significant source of uncertainty because such exposures are likely minor relative to the exposures associated with the incidental ingestion of soil/sediment and fish consumption. Site-related risks from consumption of terrestrial wildlife are also considered minor by comparison to incidental ingestion of site soils because it is assumed that the time spent on-site by a herbivorous large home range wild animal (i.e., deer, waterfowl) is limited in duration over a chronic exposure period. ATSDR (2012b) notes that there is no indication of biomagnification of chromium along the terrestrial food chain (soil-plant-animal). Such is not necessarily the case for CDD/CDFs which have been shown to bioaccumulate in fish-eating birds and to a lesser extent in terrestrial mammals (ATSDR 1998). Dioxins and furans demonstrate low water solubilities and high lipophilicity which means they have potential for bioconcentrating in aquatic organisms (ATSDR 1998). However, actual uptake by such organisms may be less than predicted due to the propensity for dioxins and furans to bind to suspended organic matter. Similarly, because dioxins and furans are expected to adsorb strongly to soil and are not very soluble in water, root uptake and translocation of CDD/CDFs to upper plant parts is generally considered minor (ATSDR 1998). Two specific exceptions identified in the literature are zucchini and pumpkin which have previously been found to translocate CDD/CDFs to the shoots and into the fruits (ATSDR 1998). Further, evidence suggests increased concentrations of CDD/CDFs in root vegetables, such as carrots, when grown in dioxin contaminated soils (ATSDR 1998). As noted above, such potential for accumulation of dioxins and metals in root vegetables suggests a possible underestimation in total risks when excluding the consumption of the roots of plants grown within the OU3 study area. Recognizing that contamination of plant foliage via atmospheric deposition is a more important contamination mechanism than uptake via roots, it is assumed that such exposure is generally limited by the washing of plants/produce prior to consumption. This assumption coupled with generally low soil/sediment-to-plant bioconcentration factors (BCFs) (with a few

exceptions), it is expected that risks based on quantitatively evaluated exposure scenarios (residential/occupational/recreational) are protective of the plant ingestion pathway.

6.1.2 Uncertainties from Chemicals Not Evaluated

As discussed above, quantitative risk estimates are derived only for COPCs. Contaminants that were measured in Site samples but excluded as a COPC may contribute a small amount of added risk, but the contribution is expected to be so small that this is not a source of significant uncertainty. The same is expected of contaminants that could not be evaluated as COPCs due to the lack of a risk-based screening level (no toxicity value), or contaminants qualified as not detected but whose sample-specific DL is greater than the available RSL. Although these contaminants are flagged as sources of uncertainty in the COPC screens, their relative contribution to the total risk is expected to be minor.

USEPA (2021b) discusses PCBs at the Site. As noted in USEPA (2021b), hundreds of samples have been collected across OU1, OU2, and OU3 and analyzed for PCBs. PCBs in OU3 soils and groundwater have been analyzed as Aroclor mixtures, but no data are available on PCB congeners in these media. Similarly, only a small number of surface water and sediment samples collected from the CFR were analyzed for PCBs as Aroclor mixtures. The Aroclor-based evaluations were consistent with the data quality objectives in the site-specific QAPP. This approach was considered adequate because the available historical information did not suggest any specific source of PCBs associated with the historical Mill operations. Once PCBs were determined to be present in localized areas of OU2 at concentrations above health protective SLs (based on a target HQ of 1 and a target cancer risk of 1E-04), additional samples were collected from those specific areas and analyzed for PCB congeners. Additional soil and groundwater samples were not collected from OU3 for analysis by PCB congeners because Aroclor concentrations in OU3 soils and groundwater did not similarly exceed USEPA health protective SLs. Aroclor concentrations reported in groundwater samples are flagged as a source of uncertainty given that the reported detection limits exceeded the risk-based SLs for a resident. However, this is not considered a significant source of uncertainty because concentrations similar to the DLs would result in risks from drinking groundwater in the low 1E-06 range and are not expected to substantially contribute to cumulative risk estimates. As reported in NewFields (2018c), approximately 155 cubic yards of material was removed from the localized areas within OU2. PCB congener data were reported for fish tissues evaluated for fish collected from the CFR. The USFWP fish advisory is based on dioxins, furans and PCBs. Evaluation of PCB congener data in fish tissues provides additional information to the USEPA and MDEQ about relative contributions of dioxins and furans versus coplanar PCBs to TEQ concentrations in fish.

6.1.3 Uncertainties in Exposure Point Concentrations

In all exposure calculations, the desired input parameter is the true mean concentration of a contaminant within a medium, averaged over the area where random exposure occurs. However, because the true mean cannot be calculated based on a limited set of measurements, the USEPA (1989, 1992) recommends that the exposure estimate be based on the 95UCL. The groundwater and fish EPCs were based on 95UCLs for the COPCs with enough detected data to support the development of the 95UCL. When data are plentiful and inter-sample variability is not large, the UCL may be only slightly higher than the mean of the data. However, when data are sparse and/or are highly variable, the 95UCL may be substantially greater than the mean of the available data.

When data are presented as summed values (i.e., TEQ and total PCBs), one-half the DL was used as a surrogate concentration for those specific congeners reported as non-detect. Use of one-half the DL assumes that there is equal probability that the actual concentration in the sample may be greater or less than the surrogate value. In general, the detection limits for non-detect results were low relative to detected concentrations. The uncertainty associated with the use of surrogate values for non-detect results was minimized by only including those contaminants that were determined to be present in a given medium.

95UCL values were not calculated for soil due to the mix of sample types and limited sample sizes. The compositing schemes applied to the soil collection efforts were developed to be representative of hypothetical future residential or occupational (the receptors with the highest assumed exposures) exposure units in the upland areas and representative of current and/or hypothetical future recreational exposure units in the floodplain areas. In cases where a 20-point composite or 30-point composite was collected over the entire exposure area, variability around the mean is characterized better than within a 5-point composite. Surface soils collected in 2017 were composited on a grid-by-grid basis, resulting in a single sample result for some exposure units. Without additional data it is uncertain if the use of a single 20-point or 30-point composite may overestimate or underestimate the true mean. In cases where additional data from localized samples (5-point composites collected over a small area, or grab samples) collected through biased sampling at areas identified as being of environmental concern, the weighted EPC is likely biased slightly high. If a soil grid was found to pose an unacceptable risk (i.e., grid 74 for hypothetical future residents), additional samples within that grid may be warranted within the RI/FS. This is because future changes in land use may result in higher density housing than was assumed for the soil sampling conducted on 20-acre grid areas. The composite sampling strategy reduces data variability and provides a reasonably unbiased estimate of mean contaminant concentrations in a specified decision unit (ITRC 2020). Thus, although evaluation based on the maximum spatial extent grid size increases uncertainty about hypothetical future exposure, this is

not considered a significant source of uncertainty for the specific scenarios evaluated within this assessment.

Exposures to hypothetical future construction workers via direct contact with subsurface soils were calculated based on available concentration data in both surface and subsurface soil samples consistent with the CSM. However, the weighting approach applied to calculate the soil EPCs inherently weights the concentrations associated with the available 20-point composite surface soil samples heaviest and the single vertical composite subsurface samples the least. This would represent a significant source of uncertainty if concentrations at depth were significantly higher than concentrations at the surface. This is not anticipated at this Site given that the expected fate and transport systems would have resulted primarily in surface deposition. Nonetheless, to evaluate this source of uncertainty further, the maximum detected concentrations within the subsurface soil samples were used to estimate non-cancer hazards and excess cancer risks to hypothetical future construction workers for this uncertainty assessment. The non-cancer HI calculated following this approach is less than 1E+00 and the cancer risk is less than 1E-06.

Soil concentration data for the OU3 Site are based on evaluation of bulk or coarse soil particles. It is generally expected that small particles (<150 µm, "fine fraction") are more likely to adhere to the hands (or other objects that may be mouthed) than coarse particles (2mm) and be subsequently ingested (USEPA 2016c). Studies of other sites have suggested enrichment of metal concentrations in the fine fraction (Beamer et al. 2012; Siciliano et al. 2009). This indicates that EPCs based on concentrations of COPCs in bulk samples collected at the Site may underestimate true exposure concentrations, but the magnitude of this underestimation is unknown.

Groundwater data for the wastewater clarifier well are limited to a single sample collected in 2019. There is high uncertainty as to whether or not the EPC used to evaluate groundwater exposures associated with this well underestimate or overestimate potential chronic exposures.

During the 2018 RI Addendum 9 sampling event, surface water and sediment samples were collected from a number of the on-Site ponds. As noted in Section 3, it is not anticipated that a person will be exposed in these ponds, so these data were not considered in the risk characterization. However, if these ponds were dried out in the future (during land development), the sediment concentration may represent contamination within the surface soil. Conceivably, the ponded areas may represent areas of increased concentrations due to sediment deposition to low-lying areas. For the purposes of this uncertainty assessment, the maximum detected pond sediment concentrations were compared to the residential soil SLs based on an HQ=0.1 or a cancer risk of 1E-06 similar to how soil data were used in the COPC selection process in Section 3.3. Residential and recreational risk estimates were calculated for those contaminants where the

maximum detected concentration exceeded the SL (the resident represents the most sensitive receptor) based on 95UCL values (calculated across all pond data). For assumed recreational land use, total HI was < 1E+00 and total cancer risk was < 1E-04. Total HI based on incidental ingestion of soil by a hypothetical future child resident was 3E+00, but all individual HQs were ≤1E+00 (see tables in Appendix D). Total cancer risk for an RME resident was at the upper end of USEPA's acceptable cancer risk range at 1E-04. This value was based primarily on assumed early childhood exposures to chromium evaluated as Cr(VI). As noted previously, the evaluation of chromium exposures presented in this assessment are conservative based on assuming the most toxic form of Cr(VI) and likely overestimate actual Site risks.

6.1.4 Uncertainties in Human Exposure Parameters

Accurate calculation of exposures requires accurate estimates of the level of human exposure that is occurring. However, many of the required exposure parameters are not known with certainty and must be estimated from limited data or knowledge. In general, when exposure data were limited or absent, the exposure parameters were chosen in a way that was intended to be conservative. Because of this, the values selected are thought to be more likely to overestimate than underestimate actual exposure and risk.

The risk estimates presented in Table 5-9 for a tribal fisher are based on the fish consumption rates from the Shoshone-Bannock Tribe (USEPA 2016a). As described in Appendix E, the USEPA considers these consumption rates to best represent inland tribes with limited access to abundant fisheries as expected within the stretch of the CFR included in the OU3 study area. However, in the absence of tribe-specific fish consumption data, it is uncertain how representative the Shoshone-Bannock fish consumption rates are for the CSKT. If similar fish consumption rates based on the Nez Perce Tribe (USEPA 2016b) were used instead (mean of 98.4 g/day and 95th percentile of 345 g/day), non-cancer hazards from consuming fish caught in the CFR exceed 1E+00 for both the CTE and RME tribal fisher with HQs as high as 2E+02 based on $TEQ_{D/F/PCB}$ in northern pike whole body as shown in Table 6-1. Using the higher ingestion rates correspond to increased excess cancer risk for the CTE and RME tribal fishers with all cancer risks exceeding 1E-04 for the RME tribal fisher (cancer risks ranging from 3E-04 up to 4E-03). Nearly all predicted cancer risk estimates exceed 1E-04 for the CTE tribal fisher also with the exception of $TEQ_{D/F}$ for both species and tissue types, and except for total PCBs in fillets.

6.1.5 Uncertainties in Chemical Absorption (RBA)

The risk from an ingested chemical depends on how much of the ingested chemical is absorbed from the gastrointestinal tract into the body. Currently available information suggests that RBA

of dioxin in soils can be expected to be less than 100%, but available estimates of soil dioxin RBA are not adequate to derive an alternative to assuming an RBA of 1.0. Similarly, data are not available to derive contaminant-specific RBA values for any of the metal COPCs except arsenic. Using an assumed RBA of 1.0 for these COPCs is likely to overestimate the true risk with the magnitude of the error depending on the true RBA value.

6.2 Uncertainties in Toxicity Assessment

Toxicity information for many chemicals is often limited. Consequently, there are varying degrees of uncertainty associated with toxicity values (i.e., oral SF, RfD, RfC, inhalation UR). For example, uncertainties can arise from the following sources:

- Extrapolation from animal studies to humans
- Extrapolation from high dose to low dose
- Extrapolation from continuous exposure to intermittent exposure
- Limited or inconsistent toxicity studies

In general, uncertainty in toxicity factors is one of the largest sources of uncertainty in risk estimates at a site. Because of the conservative methods USEPA uses in dealing with these uncertainties, it is much more likely that the uncertainty will result in an overestimation rather than an underestimation of risk (USEPA 2014b).

For TEQ, cancer risks were based on using the CalEPA toxicity criteria for TCDD. The CalEPA values assume that there is no level of exposure that is without risk. This assumes that TCDD induces cancer by way of a non-threshold linear dose-response relationship. The National Resource Council (NRC 2006) discussed the primary uncertainties with the toxicity values for dioxin and dioxin-like compounds and reported that the estimation of cancer risks at doses below the range of existing reliable data may result in an overestimation of risk, and that the relative concentrations of the congener mixture in the environment may change over an exposure period. Further, NRC (2006) and members of USEPA's Science Advisory Board (SAB) that reviewed USEPA's 2000 dioxin reassessment suggested that the assumption that TCDD carcinogenicity is consistent with a non-threshold linear dose-response is inconsistent with what is known about the mode of action of TCDD and other dioxins. That evaluation reported that TCDD acts as a cancer promoter and is not directly genotoxic. NRC (2006) noted that the lack of evidence of cancer-initiating activity by TCDD in animal studies further supports this observation. TCDD has been reported to produce toxic effects by binding with a receptor, called the aromatic hydrocarbon (Ah) receptor. This binding, in addition to ligand-receptor interactions and subsequent molecular events, results in a complex, multi-step process to produce dioxin toxicity (NRC 2006). Chemicals that act via a receptor-mediated process produce sublinear responses at low doses. In

previous evaluations of other receptor-mediated carcinogens, USEPA concluded that use of a nonlinear, low-dose model was appropriate for risk assessment. Although USEPA has not completed a cancer reassessment for dioxin, the Agency has established that the 2012 RfD for TCDD will be used to develop site-specific risk-based cleanup levels at Superfund sites. Dioxin cleanup levels based on the 2012 non-cancer RfD are expected to be within the cancer risk range currently used by USEPA's Superfund cleanup program (USEPA 2021e).

For chromium, non-cancer hazards and cancer risks were based on using toxicity values for the more potent form of chromium, Cr(VI). This is a health-protective approach, but likely overestimates actual chromium risks. Chromium was only evaluated as total chromium in Site samples. There is no indication that historical Mill operations used or generated Cr(VI), and there is no information available to understand the ratio of Cr(VI) to Cr(III) in Site soils or groundwater. Adding to this source of uncertainty, Cr(VI) is expected to readily reduce to Cr(III) in soil (USEPA 1998). On this basis, evaluating chromium risks as being attributed to 100% exposure to Cr(VI) is a significant source of uncertainty that suggests that the estimated cancer risks associated with chromium in this assessment are overestimated.

For manganese, toxicity data in humans generally agree that occupational exposures to manganese dust in the air results in central nervous system pathology. However, data on the neurotoxicity of orally ingested manganese at relatively low doses are less consistent, albeit suggestive (USEPA 2021q). Additionally, many variables including environmental factors and biological factors can influence manganese absorption. The IRIS oral RfD for manganese in water is particularly uncertain as it is based on an upper dietary intake rate of 10 mg/day, instead of quantitative information to indicate toxic levels of manganese in the diet of humans. A modifying factor of 3 is applied for evaluating exposures from drinking water adding to the conservativeness of the overall non-diet RfD. Because of the conservativeness of the oral RfD for manganese, it is likely that uncertainty associated with this toxicity value will result in an overestimation rather than an underestimation of risk for the general receptors of concern (USEPA 2021q). However, the RfD of 2.4E-02 mg/kg-day is consistent with the recently derived MDEQ public health goal for manganese in drinking water based on being protective of formula-fed infants (MDEQ 2020).

Where available, subchronic toxicity values were used to evaluate exposures to construction workers. These values were higher than the chronic toxicity values. Similar conclusions of no unacceptable risks to hypothetical future construction workers from exposures to OU3 soils were maintained when chronic toxicity values were used.

6.3 Uncertainties in Risk Characterization

Because risk estimates for a chemical are derived by combining uncertain estimates of exposure and toxicity (see above), the risk estimates for each chemical are more uncertain than either the exposure estimate or the toxicity estimate alone. The hazards and risks presented in this assessment are based on numerous and often conservative assumptions in an effort to be protective of human health. In the absence of definitive information, assumptions are used to ensure that actual site risks are not underestimated. The cumulative effect of these assumptions can result in an evaluation with an overall conservativeness greater than the individual components. Thus, it is important to note that the risks presented in this assessment are more likely to be overestimated rather than underestimated.

6.3.1 Uncertainties Risk Estimates Based on Fish Consumption

Risk estimates for fish consumption presented in this assessment assume that 100% of fish consumed by a fisher is comprised of locally caught fish. This is a conservative assumption that likely overestimates actual risks, particularly for a recreational fisher who likely consumes fish caught from the Site only occasionally. For a tribal fisher, this assumption may not be considered as conservative, but there is no information to determine the magnitude to which this assumption may overestimate risks. Currently, there is a fish advisory in place on the CFR within the OU3 study area that recommends against eating collected fish (State of Montana 2021). This may result in limiting fish consumption (and subsequent exposure), but it is unknown to what extent consumption is actually limited.

Risk estimates for fish consumption are based on fish collected during one sampling event. This presents uncertainty in temporal variability. As noted in Section 2.6, a similar fish sampling effort to that conducted in 2019 was also conducted in 2018. As described in USEPA (2019, 2020), these data were not used in the risk characterization due to sampling compliance issues. As noted in USEPA (2019), these issues included the lack of chain-of-custody (COC) forms and a lack of QC field samples. The lack of COC forms limits the Agency's ability to confirm the integrity of the fish tissue samples (during transmittal to and upon receipt at the laboratory) and the accuracy of sample identification numbers, collection times, etc. in the context of Superfund policies. Similarly, the lack of reliable field QC samples limits the USEPA's ability to verify that contamination of samples and/or cross-contamination between samples did not occur. Under the Superfund requirements to meet data quality, the 2018 fish cannot be quantitatively used as the basis of decision-making. However, USEPA does not consider the data criteria limitations of the 2018 fish to significantly impact the concentrations of contaminants within the fish tissues themselves. Therefore, USEPA considers these data useful for further characterizing the uncertainties in fish consumption risk estimates. Non-cancer hazards and cancer risks were

estimated following the same approach applied in Section 5 using EPCs derived based on the combined 2018 and 2019 dataset. Tables 6-2 and 6-3 summarize the results. As shown, combining the 2018 and 2019 fish tissue samples results in the same general risk conclusions as determined based on the 2019 dataset alone. However, the magnitude of the risk estimates is slightly lower based on the combined dataset.

6.3.2 Uncertainties Based on Background Concentrations

In order to incorporate feedback from USEPA Headquarters, be consistent with guidance, and increase transparency, this risk assessment will no longer use background concentrations as criteria for screening COPCs for targeted risk evaluation as was performed in the previous draft. High background concentrations that are either naturally occurring or attributable to non-Site related sources, such as other industrialized areas, may nevertheless contribute to collective risk at the Site and are thus appropriately included in the risk assessment. Although evaluation of background is an important consideration for risk management decisions, the risk assessment does not make remedial decisions but only documents risks associated with the site as consistent with USEPA guidance. USEPA will narrow the list of COPCs, considering background information, as the remedial investigation process continues.

The USEPA has developed a preferred approach for the consideration of background constituent concentrations of hazardous substances, pollutants, and contaminants in certain steps of the remedy selection process. USEPA does not require remedial action or further investigation of contaminants that are below background (non-site related) levels (USEPA 2002c). Quantitative evaluation of background contributions to risk estimates may be necessary when making risk management decisions. The purpose of the HHRA is to quantify potential Site-related risks to receptors within the currently defined study area. On this basis, risk estimates were generated based on the assumption that 100% of the detected contamination in Site samples is attributed to historical Mill operations. However, some of the estimated risk may be associated with COPC concentrations attributable to natural and/or anthropogenic non-point sources. Naturally occurring constituents are present in the environment in forms that have not been influenced by human activity. MDEQ (2005) notes that arsenic may occur naturally in Montana soils at levels above risk-based concentrations. Conversely, contaminants may also be present in the environment as a result of human activities not specifically related to the Site. Some contaminants detected in Site media may have both natural and non-Site related anthropogenic sources, in addition to contributions from historic Site activities. For instance, dioxins have multiple anthropogenic and natural point and non-point sources, making it difficult to evaluate whether concentrations at the Site are due to the bleaching process conducted as part of historical Mill operations, or other sources (e.g., forest fires, barrel trash burning, etc.).

Sources of background information relevant to OU3 include the MDEQ soil background studies on dioxins/furans and metals (MDEQ 2011, 2013), as well as available groundwater data collected from monitoring wells located upgradient from any potential Site contamination and upstream surface water, sediment and fish sampling within the CFR [16]. Evaluation of these data as part of ongoing RI activities may provide risk managers with a better understanding of the predicted risks presented in this assessment. For example, surface water and sediment concentrations of arsenic and chromium in the CFR within the OU3 study area generally fall within the range of arsenic and chromium concentrations measured in samples collected from locations within the CFR upstream of the Site[17].

[16] These data are included in the Scribe database for the Site.
[17] Based on a qualitative comparison of data collected as part of the RI that are included in the Site-specific Scribe database.

7.0 SUMMARY AND CONCLUSIONS

Multiple investigations performed at the Site have produced data for characterizing exposures to Site-related COPCs and associated risks to potential human receptors within OU3. This HHRA assesses potential risks to hypothetical future residents, commercial/industrial workers, and construction workers within the OU3 upland area based on current Site conditions. This HHRA also assesses potential risks to tribal fishers and recreational visitors including hikers, campers, and fishers within the upland and floodplain areas of OU3. Risk characterization used exposure data for OU3 soils and groundwater from wells within the OU3 boundary, as well as fish tissue data. Predicted risks were calculated as non-cancer hazards (HIs and HQs) and excess cancer risk. Risks were estimated above a level of concern for potential human receptors at the OU3 Site based primarily on ingestion of groundwater as drinking water and consumption of locally caught game fish as summarized below.

7.1 Risks to Hypothetical Future Residents

The evaluation in this HHRA predicts potential unacceptable risks to hypothetical future residents in OU3 from exposures to surface soils and groundwater. Non-cancer hazards for a hypothetical future child resident from incidental ingestion of surface soils are predicted to be > 1E+00 in 27 exposure area grids within OU3. The highest predicted HI for a child resident is within grid 74 (the area of former settling pond 17). The non-cancer HIs for exposures by CTE and RME child residents to soils within this area were 4E+00 and 1E+01, respectively. In this grid, the primary risk driver is $TEQ_{D/F}$ (HQs of 2E+00 and 6E+00 for the CTE and RME receptors, respectively). Dermal non-cancer effects associated with arsenic and thallium also correspond to a target organ HI > 1E+00 for the RME child resident within grid 74 (HI=2E+00). HQs for $TEQ_{D/F}$ also exceed 1E+00 in three other grids (grids 58, 67 and 68). The only other target organ HI that exceeds 1E+00 is based on nervous system effects within grid 55. The predicted target organ HI for a RME child in this grid is 2E+00 based primarily on incidental ingestion of manganese in surface soils. Unacceptable cancer risks for hypothetical future residents exposed to surface soils are also predicted in a number of OU3 soil exposure grids. The estimated cancer risks ≥ 1E-04 are primarily driven by risks associated with chromium when evaluated as Cr(VI). Cr(VI) represents the more toxic, and carcinogenic, form of chromium. Qualitative information suggests that chromium is more likely to exist within the environment as the less toxic trivalent form. Available data are for total chromium only, and there is no data on the ratio of Cr(VI) to Cr(III) in OU3 soils. However, there is no information to suggest that hexavalent chromium was used or produced as a waste product during historic Mill operations. On this basis, these cancer risks are likely overestimated. Further evaluation within the RI/FS regarding chromium forms that exist in OU3 soils and/or relative comparisons with background chromium concentrations will help to address this significant source of uncertainty.

Elevated levels of manganese and arsenic, and to a lesser extent cobalt, chromium, and iron, in groundwater may contribute to risks above a level of concern for hypothetical future residents who consume Site groundwater as drinking water. Non-cancer hazards for these COPCs exceeded USEPA's health guideline (HI≤1E+00) for the CTE resident in most wells and for the RME resident in all wells evaluated in this assessment. In addition to the potential for exposure to arsenic in groundwater to cause non-cancer effects in residential receptors, arsenic is also considered a known human carcinogen. The estimated cancer risks associated with drinking arsenic in groundwater for residential use exceeded 1E-04 for the RME resident in 23 wells, and in five wells for the CTE resident. Levels of arsenic in groundwater may contribute to excess cancer risks above USEPA's health guideline (cancer risk ≤ 1E-04). Chromium may also contribute to unacceptable excess cancer risks associated with the consumption of groundwater as drinking water. However, as noted above chromium was evaluated as Cr(VI) in this assessment which likely overestimates actual cancer risks as chromium is more likely to be present in the environment as the less toxic Cr(III).

7.2 Risks to Hypothetical Future Workers

Acceptable risks are predicted for exposures by hypothetical future commercial/industrial and/or construction workers from exposures to OU3 soils.

Elevated levels of manganese, and to a lesser extent arsenic and cobalt, in groundwater may contribute to risks above a level of concern for hypothetical future commercial/industrial workers who consume Site groundwater as drinking water. Predicted non-cancer HIs for these COPCs exceeded 1E+00 for the CTE worker in seven wells and for the RME worker in twenty wells. However, endpoint specific HIs were below a level of concern in six wells where the total HI exceeds 1E+00 for the RME worker. Levels of arsenic in groundwater may contribute to excess cancer risks above USEPA's health guideline (cancer risk ≤ 1E-04) for hypothetical future commercial/industrial workers at the OU3 Site. There are eleven wells where the estimated cancer risks associated with drinking arsenic in groundwater for commercial use exceeded 1E-04 for the RME worker. There is one well where the estimated cancer risk associated with drinking chromium in groundwater for commercial use exceeded 1E-04 for the RME worker.

Total risks (exposure to soil and groundwater) are driven by exposures to groundwater; risks from exposures to OU3 soils do not contribute significantly to total risk. There is one well (TW2R) where the non-cancer HI was equal to 1E+00, but when adding in the estimated non-cancer hazard from exposure to soil, the total HI > 1E+00. There is one well (NFMW22) where the cancer risk to a hypothetical future worker was estimated below 1E-04, but when adding in the estimated cancer risk from exposure to soil, the total cancer risk equals 1E-04.

7.3 Risks to Recreational Visitors and Tribal Fishers

7.3.1 Risks to Recreational Visitors

In this assessment it was assumed that a hiker may be exposed to surface soils across OU3. Acceptable risks were predicted for potential direct contact exposures (incidental ingestion and dermal contact) to OU3 surface soils while hiking (HI ≤ 1E+00, cancer risk < 1E-04).

In this assessment it was assumed that a camper may be exposed to surface soils while camping, but may also consume surface water from the CFR or on-site creeks as drinking water, and be exposed while recreating within the CFR to surface water and sediments. Acceptable risks were predicted for direct contact exposures by campers to most OU3 soils, with the exception of surface soils in grid 74. The cancer risk predicted from exposures to OU3 soils in Grid 74 is 1E-04 for the RME scenario. This cancer risk is based on total risk from $TEQ_{D/F}$, arsenic, and chromium. However, the individual contaminant predicted cancer risks are all below 1E-04. Cancer risks predicted for campers from exposures to OU3 soils in all other grids are below 1E-04. Acceptable risks are predicted based on exposures by campers to surface waters and sediments in on-site creeks or in the CFR.

In this assessment it was assumed that a recreational fisher may be exposed to surface soils in the OU3 floodplain and surface water and sediment in the CFR while fishing. Acceptable risks were predicted for such exposures while fishing (HI ≤ 1E+00, cancer risk < 1E-04). It was also assumed that a recreational fisher would consume the fillets of fish collected from the CFR. Unacceptable risks based on fish consumption were predicted for the recreational fisher. Levels of TEQ_{PCB}, $TEQ_{D/F/PCB}$, and total PCBs within the tissues of game fish in the CFR from within the OU3 study area may contribute to risks above a level of concern for fishers who consume these fish as a significant portion of their diet. Unacceptable non-cancer hazards and cancer risks are predicted based on the consumption of northern pike and rainbow trout collected from the CFR within the OU3 study area. Specifically, non-cancer hazards exceed 1E+00 and cancer risks are predicted to be ≥ 1E-04 for RME recreational fishers consuming northern pike or rainbow trout. Exceedances of USEPA's risk criteria for the recreational fisher are seen for TEQ_{PCB} and $TEQ_{D/F/PCB}$, but not for $TEQ_{D/F}$. This suggests that coplanar PCBs are contributing most of the risk to TEQ. Non-cancer hazards for a CTE child recreational fisher also exceed 1E+00 for TEQ_{PCB} and $TEQ_{D/F/PCB}$,in northern pike fillets. Non-cancer hazards for the CTE receptor are below 1E+00 for rainbow trout fillets. When cooking loss is assumed, non-cancer hazards and cancer risks are reduced, but HQs > 1E+00 are still observed for the RME child consuming TEQ_{PCB} and $TEQ_{D/F/PCB}$ in northern pike and rainbow trout fillets. Cancer risk is equal to 1E-04 for the RME child consuming $TEQ_{D/F/PCB}$ in northern pike fillets.

Total non-cancer HI and cancer risks summed across exposure pathways for recreational fishers are similar to the predicted HIs and cancer risks based on fish consumption. Consumption of locally caught fish represents the risk driver for a recreational fisher based on the scenario evaluated in this assessment.

7.3.2 Risks to Tribal Fishers

In this assessment it was assumed that a tribal fisher may be exposed to surface soils in the OU3 floodplain and surface water and sediment in the CFR while fishing. Acceptable non-cancer hazards and cancer risks are predicted for a tribal fisher from exposures to OU3 floodplain soils and/or CFR surface waters and sediments while fishing (HI ≤ 1E+00, cancer risk < 1E-04). However, similar to the recreational fisher, unacceptable non-cancer hazards and cancer risks are predicted for the tribal fisher based on the consumption of fish collected from the CFR within the OU3 study area. The highest HQs and cancer risk estimates are based on $TEQ_{D/F/PCB}$. Comparing the HQs and cancer risk estimates for $TEQ_{D/F}$ and TEQ_{PCB} indicates that coplanar PCBs are contributing the majority of risk. However, the non-cancer HQ for $TEQ_{D/F}$ is also above 1E+00 for the child RME tribal fisher when assuming no cooking loss. When cooking loss is assumed, the $TEQ_{D/F}$ HQ for the RME tribal fisher is predicted to be less than 1E+00 when consuming fillets only, or when consuming whole-body rainbow trout. The $TEQ_{D/F}$ HQ remains > 1E+00 for the tribal child consuming whole-body northern pike, even when cooking loss is assumed. Total non-cancer HI and cancer risks summed across exposure pathways for tribal fishers are similar to the predicted HIs and cancer risks based on fish consumption. Consumption of locally caught fish represents the risk driver for a tribal fisher based on the scenario evaluated in this assessment. Uncertainties associated with the amount of fish consumed by members of the CSKT was evaluated by assuming a higher fish ingestion rate as described in Section 6.3.1. Higher non-cancer hazards and cancer risks are predicted when assuming higher ingestion.

7.3.3 Summary of Risks Associated with Recreational and Tribal Activities

Acceptable risks were predicted for potential exposures by hikers and fishers to OU3 soils, CFR and on-site creek surface water, and CFR sediments. Acceptable risks were also predicted for campers with the exception of incidental ingestion exposure to surface soils in grid 74. The unacceptable risk predicted in grid 74 is based on the cumulative cancer risk summed across the predicted risk estimates for $TEQ_{D/F}$, arsenic and chromium. As discussed in the uncertainty assessment, a significant source of uncertainty in this risk estimate for chromium is associated with assuming that the concentration of total chromium measured in soils is 100% attributable to the more toxic hexavalent form of chromium. Chromium is more likely to exist primarily as the less toxic trivalent form in environmental media without a known source of hexavalent

chromium. There is also uncertainty in the cancer slope factor for TCDD which contributes to uncertainty in the cancer risk estimate for $TEQ_{D/F}$.

Unacceptable risks associated with the recreational and tribal scenarios evaluated in this assessment are predicted for fishers consuming fish collected from the CFR within the OU3 study area. Risk estimates derived for the purposes of this assessment were based on conservative exposure assumptions including assuming that 100% of a fisher's diet was comprised of locally caught fish. This type of assumption likely overestimates actual risks associated with fish consumption, but nonetheless it is considered health protective consistent with USEPA Superfund guidance.

TABLES

OU3 Smurfit-Stone/Frenchtown Mill Site
Human Health Risk Assessment

Table 3-1. OU3 Site Data Summary

Media	Sample Date	Sample Description	Analysis	Reference
Upland Surface Soil	April 2014	Surface (0-2.4 inches) soil samples were collected from 7 locations (n=7). Surface (0-6 inches) soil samples were collected from 13 locations (n=13). Samples were 5-point composites collected over a square meter area.	Aroclors (n=19), TAL metals (n=19), dioxins and furans (n=20).	NewFields 2015
	December 2015	Two surface (0-2 inches and 5-7 inches) soil samples were collected at 8 locations (n=16). Samples were 5-point composites collected over an area of 1 to 3-meter radius.	TAL metals and dioxins and furans.	NewFields 2015, 2016a
	October 2017	Composite surface (0-6 inches) soil samples were collected from 24 areas (n=24). Samples were 20-point composites collected over a 20-acre grid. 30-point composites were collected over the area of a historically defined basin/pond.	TAL metals, dioxins and furans and TOC.	NewFields 2017
Upland Subsurface Soil	April/May 2014	Subsurface soil samples were collected from 11 locations at varying depths from 1 to 10 feet (n=12). Samples were discrete samples.	Aroclors (n=10), TAL metals (n=10), dioxins and furans (n=12).	NewFields 2015
	December 2015	Subsurface soil samples were collected from 26 locations at varying depths from 0 to 12 feet (n=26). Samples were a vertical composite.	Aroclors (n=4), TAL metals (n=26), and dioxins and furans (n=26).	NewFields 2016a
	October 2017	Composite subsurface (24-30 inches) soil samples were collected from 14 area (n=14). Samples were discrete samples.	Dioxins and furans, TAL metals, and TOC.	NewFields 2017
Floodplain Surface Soil	April 2014	Surface (0-2.4 inches and 0-6 inches) soil samples were collected from 2 locations (n=2). Samples were 5-point composites collected over a square meter area.	Aroclors, TAL metals, dioxins and furans.	NewFields 2015
	December 2015	Surface (0-2 inches) soil samples were collected at 17 locations (n=17). Samples were 5-point composites collected over an area of 1 to 3-meter radius.	TAL metals, dioxins and furans and TOC.	NewFields 2015, 2016a
	October 2017	Composite surface (0-6 inches) soil samples were collected from 5 areas (n=5). Samples were 20-point composites collected over a 100-acre grid.	TAL metals, dioxins and furans and TOC.	NewFields 2017
Floodplain Subsurface Soil	April/May 2014	Subsurface soil samples were collected from 1 to 1.5 feet at 1 location and from 5.5 to 6 feet at 1 location (n=2). Samples were discrete samples.	Aroclors, TAL metals, and dioxins and furans.	NewFields 2015
	October 2017	Composite subsurface (24-30 inches) soil samples were collected from 6 areas (n=6). Samples were discrete samples. Samples were discrete samples.	Dioxins and furans, TAL metals, and TOC.	NewFields 2017
Groundwater	April 2014	Twenty shallow wells sampled (n=20).	Aroclors, total and dissolved TAL metals, dioxins and furans and miscellaneous parameters (e.g. DO, temperature, etc.).	NewFields 2015
	December 2015	Twenty-six shallow wells sampled (n=26). Eighteen of the wells sampled in 2014 were also sampled during this event.	Aroclors (n=2), total and dissolved TAL metals (n=26), dioxins and furans (n=26), SVOCs (n=8), VOCs (n=8), and miscellaneous parameters (e.g. DO, temperature, etc.; n=26).	NewFields 2015, 2016a
	June 2016	Twenty-three wells sampled (n=23). All of the wells were previoulsy sampled in 2015.	Aroclors (n=5), dissolved TAL metals (n=23), dioxins and furans (n=22), and miscellaneous parameters (e.g. DO, temperature, etc.; n=23).	NewFields 2016b
	January/March/June/ July/December 2017	Twenty-six shallow wells sampled (n=29). All of the wells were previously sampled at least once before in 2015 and 2016.	Aroclors (n=12), total and dissolved TAL metals (n=29), dioxins and furans (n=29), SVOCs (n=12), VOCs (n=12), and miscellaneous parameters (e.g. DO, temperature, etc.; n=29).	NewFields 2017a,b
	January/May/June/ December 2018	Same wells sampled previously.	Aroclors, total and dissolved TAL metals, dioxins and furans, SVOCs and VOCs, and miscellaneous parameters (e.g. DO, temperature, etc.).	NewFields 2017b
	June/September/ October 2019	Same wells sampled previously.	Aroclors, total and dissolved TAL metals, dioxins and furans, SVOCs and VOCs, and miscellaneous parameters (e.g. DO, temperature, etc.).	NewFields 2018a
	June/September 2020	Same wells sampled previously.	Aroclors, total and dissolved TAL metals, dioxins and furans, SVOCs and VOCs, and miscellaneous parameters (e.g. DO, temperature, etc.).	NewFields 2020a
Bed Sediment	November 2015	Bed sediment samples were collected from 6 locations within the CFR adjacent to and downstream of the Site.	Aroclors (n=2), TAL metals (n=6), dioxins and furans (n=6), SVOCs (n=2) and TOC (n=6).	NewFields 2015, 2016a
	August 2018	Sediment samples were collected from the CFR, O'Keefe Creek, Lavalle Creek and on-Site ponds.	Dioxins and furans, TAL metals, and TOC.	NewFields 2018b
Flood Fringe Sediment	December 2015	Flood fringe sediment samples were collected from 1 location within the site boundary and 2 locations downstream of the site (n=3).	TAL metals, dioxins and furans, and TOC.	NewFields 2015, 2016a
Surface Water	November 2015	Surface water was collected from three locations within the CFR adjacent to and downstream of the Site.	Aroclors (n=2), total and dissolved TAL metals (n=3), dioxins and furans (n=3), and SVOCs (n=2).	NewFields 2015, 2016a
	August 2018	Surface water samples were collected from the CFR, O'Keefe Creek, Lavalle Creek and on-Site ponds.	Dioxins and furans, total and dissolved TAL metals, and TOC.	NewFields 2018b
Fish	June 2019	Rainbow trout and northern pike collected from reaches within the Clark Fork River adjacent to and downstream of the Site. Separate fillet (skin-on; belly flap attached) and carcass samples were submitted for analysis.	Dioxin, furan and PCB congeners, as well as percent moisture and percent lipid.	USEPA 2019

TAL = target analyte list; TOC = total organic carbon; DO = dissolved oxygen; SVOC = semi-volatile organic compound; VOC = volatile organic compound; PCB = polychlorinated biphenyl.

Table 3-2. OU3 Upland Surface Soil (0-6 inches) Summary Statistics[a]

Contaminant		N Samples	N Detected	Detection Frequency (%)	Average Concentration[b]	Standard Deviation[b]	Maximum Detected Concentration	Average DL
TEQ	$TEQ_{D/F}$ (ND=0)	52	52	100	3.16E-05	1.08E-04	7.56E-04	--

TEQ = toxicity equivalent; $TEQ_{D/F}$ = toxicity equivalent for dioxins and furans; ND = non-detect; DL = sample-specific detection limit; PCB = polychlorinated biphenyl

[a]All concentrations reported in units of mg/kg.

[b]Non-detects evaluated at 1/2 the DL when calculating average and standard deviation.

TEQ = toxicity equivalent; $TEQ_{D/F}$ = toxicity equivalent for dioxins and furans; ND = non-detect; DL = sample-specific detection limit; PCB = polychlorinated biphenyl

[a]All concentrations reported in units of µg/L.

[b]Non-detects evaluated at 1/2 the DL when calculating average and standard deviation.

Table 3-13. Summary Statistics for Fish Collected from the Clark Fork River within the OU3 Study Area[a]

Fish Species	Tissue Type	Contaminant		N Samples[b]	N Detected	Detection Frequency (%)	Average Concentration[c]	Standard Deviation[c]	Maximum Detected Concentration
Northern Pike	Fillet	TEQ	$TEQ_{D/F}$ (ND=1/2 DL)	4	4	100	0.51	0.11	0.64
			TEQ_{PCB} (ND=1/2 DL)	4	4	100	1.87	1.47	3.69

		PCB	Total PCBs	8	8	100	29,403	3,458	34,760

TEQ = toxicity equivalence; $TEQ_{D/F}$ = toxicity equivalence for dioxins/furans; TEQ_{PCB} = toxicity equivalence for dioxin-like polychlorinated biphenyl congeners; $TEQ_{D/F/PCB}$ = toxicity equivalence for dioxins/furans/dioxin-like polychlorinated biphenyls; ND = non-detect; DL = sample-specific detection limit.

[a]Concentrations are reported in units of picograms per gram (pg/g) wet weight (ww).

[b]Number of composite samples analyzed for fish collected from the Frenchtown (FRN) and St. Regis (STR) reaches. For northern pike, four composite samples comprised of five fish each were available for the FRN reach, but no fish were collected from the STR reach. For rainbow trout, four composite samples comprised of five fish each were available for both the FRN and STR reaches.

[c]Non-detects were evaluated at 1/2 the DL.

[d]Whole-body concentrations were estimated based on fillet and carcass tissue concentrations as:
(fillet concentration x fillet weight + carcass concentration x carcass weight) / (fillet weight + carcass weight).

Table 3-14. Exposure Parameters for a Camper

Exposure Pathway	Exposure Parameter	Units	CTE		RME	
			Value	Source	Value	Source
General	Body weight as adult	kg	80	[1]	80	[1]
	Body weight as child	kg	15	[1]	15	[1]
	Exposure frequency	days/yr	32	[4, a]	48	[4, a]

Notes:

[a] Assumes exposure occurs over the course of 16 weeks (roughly Memorial Day to Labor Day) at a frequency of 2 day/week for a CTE visitor and 3 days/week for an RME visitor.

[b] Assumes a value similar to that of a resident.

[c] CTE value is assumed to be half that of the RME receptor.

[d] Assumes half the soil value.

[e] Weighted mean of consumer-only ingestion of drinking water (Table 3-1).

[f] For soil, surface area value for an adult assumes exposure to head, hands, forearms, and lower legs as an adult; also to feet for sediment. For soil and sediment, surface area value for a child assumes exposure to head, hands, forearms, lower legs and feet.

[g] Assumes full body exposure to while swimming.

Table 3-15. Exposure Parameters for a Tribal Fisher

Exposure Pathway	Exposure Parameter	Units	CTE		RME	
			Value	Source	Value	Source
General	Body weight as adult	kg	80	[2]	80	[2]

Notes:

[a] Table 8-1. Age-weighted average based on body weights of children 6-<11 years old and 11-<16 years old.

[b] Assumes exposure occurs over the course of 24 weeks (roughly April - September) at a frequency of 2 day/week for a CTE receptor and 4 days/week for an RME receptor.

[c] Accounts for an older child exposed from 6 to 16 years of age.

[d] Assumes a value similar to that of a resident.

[e] CTE value is assumed to be half that of the RME receptor.

[f] Assumes half the soil value.

[g] Based on the mean and upper confidence limit for estimated water ingestion while fishing (Table 3-93).

[h] Incidental ingestion from splashing or hand-to-face contact during fishing assumed to be 10% of the incidental ingestion rate while swimming assumed for the camper scenario.

[i] RME value based on 95th percentile NCI value and CTE value based on mean NCI value for Group 2 adult consuming fishers of the Shoshone-Bannock Tribes (Table S2).

[j] Child fish ingestion rates were estiamted by multiplying the adult ingestion rate by a ratio of child-to-adult estimated energy requirements (0.5).

[k] Weighted average surface areas (Tables 7-1 and 7-2) calculated assuming exposure to head, hands, and forearms. It is assumed that in general, people will remain on the banks while fishing and only e for significant amounts of time if wearing protective clothing such as waders and waterproof shoes/boots.

[l] Weighted average surface areas (Tables 7-1 and 7-2) calculated assuming exposure to head, hands, forearms, lower legs and feet. It is assumed that in general, children will remain on the banks while fi an adult wearing short-sleeves and shorts.

DF = Detection Frequency; TEQ = Toxicity Equivalence; TEQ_{DF} = toxicity equivalent for dioxins/furans; PCBs = Polychlorinated Biphenyls; ND = non-detect; MDL = method detection limit; EN = essential nutrient.

Bolded contaminants are those where the maximum detected concentration exceeds the respective risk-based SL.

[a]Concentrations in units of mg/kg. Includes both surface and subsurface soil.

[b]Risk-based concentrations are based on USEPA's generic residential soil RSL values (May 2021) using a target cancer risk of 1E-06 ("C" = cancer based value) or a target HQ of 0.1 ("NC" = non-cancer based value).

[c]Detection limts were evaluated for those chemicals with a detection frequency <5%.

DF = Detection Frequency; TEQ = Toxicity Equivalence; PCBs = Polychlorinated Biphenyls; ND = non-detect; DL = detection limit; EN = essential nutrient; MCL = maximum contaminant level

Bolded contaminants are those where the maximum detected concentration exceeds the respective risk-based SL.

[a]Concentrations in units of µg/L. Data from wells in Units 1 and 3 were used to generate these summary statistics.

[b]Risk-based SLs are based on generic residential tapwater RSL values using a target cancer risk of 1E-06 ("C" = cancer based value) or a target HQ of 0.1 ("NC" = non-cancer based value) (USEPA 2016). For essential nutrients, tolerable Upper Intake levels derived by the Food and Nutrition Information Center (FNIC) were used to derive a RBC assuming a water intake rate of 0.78 L/day for a child receptor (there is no Tolerable Upper Intake Level for Potassium, so a Dietary Reference Intake was used instead).

[c]Detection limts were evaluated for those chemicals with a detection frequency <5%.

[d]Excluded as a COPC for being an essential nutrient. This is identified as a source of uncertainty.

Table 3-18. OU3 Clark Fork River Sediments COPC Screen

Contaminant		DF (%)	Maximum Detected Concentration	Average DL	Risk-based SL[b]	COPC SELECTION STEPS				OU3 CFR SEDIMENT COPCs		
						Does chemical have an RBC?	Is chemical detected ≥5%?	Is Max Detect > RBC?	Detection Limit[c] Is DL > RBC?	COPC	Not a COPC	Source of Uncertainty

DL = sample-specific detection limit; RBC = risk-based concentration; COPC = contaminant of potential concern; COG = Council Grove; MIS = Missoula; LOL = Lolo; TEQ = toxicity equivalence; $TEQ_{D/F}$ = toxicity equivalence for dioxins and furans; TEQ_{PCB} = toxicity equivalence for dioxin-like polychlorinated biphenyl congeners; $TEQ_{D/F/P}$ = toxicity equivalence for dioxins, furans and dioxin-like polychlorinated biphenyl congeners; PCBs = polychlorinated biphenyls; ND = non-detect; NC = non-cancer; C = cancer.

Bolded contaminants are those where the maximum detected concentration exceeds the respective RBC.

[a]Concentrations in units of pg/g wet weight.

[b]Risk-based concentrations are based on values calcualted using USEPA's RSL calculator and assumed ingestion rates (43 g/day recreational fisher; 93 g/day tribal fisher) using a target cancer risk of 1E-06 ("C" = cancer based value) or a target HQ of 0.1 ("NC" = non-cancer based value).

Table 3-23. Exposure Parameters for a Hypothetical Future Resident and Calculated Human Intake Factors (HIFs)

Exposure Pathway	Exposure Input Parameter	Units	CTE		RME	
			Value	Source	Value	Source
General	Body Weight - adult	kg	80	[1]	80	[1]
	Body Weight - child	kg	15	[1]	15	[1]
	Exposure frequency	days/yr	256	[4, a]	350	[1]
	Exposure duration - adult	yr	9	[4, b]	20	[1]
	Exposure duration - child	yr	3	[4, b]	6	[1]
	Exposure duration (total)	yr	12	[4, b]	26	[1]
	Averaging Time, Cancer	yr	70	[2]	70	[2]
Incidental Ingestion of Soil	Ingestion rate - adult	mg/day	50	[3, c]	100	[1]
	Ingestion rate - child	mg/day	100	[3, c]	200	[1]
	Conversion Factor	kg/mg	1.00E-06		1.00E-06	
	HIF_{child} (noncancer)	**kg/kg-day**	**4.68E-06**		**1.28E-05**	
	HIF_{TWA} (cancer)	**kg/kg-day**	**2.57E-07**		**1.44E-06**	
Ingestion of Groundwater	Ingestion rate - adult	L/day	1.2	[4, d]	2.5	[1]
	Ingestion rate - child	L/day	0.45	[4, d]	0.78	[1]
	HIF_{child} (noncancer)	**L/kg-d**	**2.10E-02**		**4.99E-02**	
	HIF_{TWA} (cancer)	**L/kg-d**	**2.25E-03**		**1.28E-02**	
Dermal Exposure to Soil	Exposed Surface Area - adult	cm^2/event	6,032	[1]	6,032	[1]
	Exposed Surface Area - child	cm^2/event	2,373	[1]	2,373	[1]
	Adherence Factor - adult	mg/cm^2	0.01	[5]	0.07	[1]
	Adherence Factor - child	mg/cm^2	0.04	[5]	0.2	[1]
	Dermal Absorption Fraction (ABSd)	unitless	CS	[5]	CS	[5]
	Event Frequency	events/day	1	[5]	1	[5]
	Conversion Factor	kg/mg	1.00E-06		1.00E-06	
	HIF_{child} (noncancer)	**kg/kg-day**	**4.44E-06**		**3.03E-05**	
	HIF_{TWA} (cancer)	**kg/kg-day**	**2.58E-07**		**4.05E-06**	

RME = Reasonable Maximum Exposure; CTE = Central Tendency Exposure; CS = chemical-specific; HIF = human intake factor;
HIF_{child} = human intake factor for the young child; HIF_{TWA} = time weighted average human intake factor (assumes exposure over a lifetime from childhood into adulthood).

[4] USEPA 1991. OSWER Directive 9285.6-03.

[5] Professional judgment.

Notes:

[a] USEPA 1991 states that half of an individual's daily water intake is assumed to occur at work. Thus, the RME value is based on half of the default daily water intake is 2.5 L/day. This is consistent with the FAQs for OSWER Directive 9200.1-120.

[b] The CTE adherence factor is based on adherence factor for an RME adult resident (derived using the 50th percentile weighted AF for a high-end activity [gardening]).

[c] CTE ingestion rate assumed to be half that of the RME receptor.

Table 3-25. Exposure Parameters for a Hypothetical Future Construction Worker and Calculated Human Intake Factors (HIFs) and Time Weighting Factors (TWFs)

Exposure Pathway	Exposure Input Parameter	Units	CTE		RME	
			Value	Source	Value	Source

[5] MDEQ 2016. Development of Montana-Specific Default Soil Exposure Frequencies. June.

[6] Professional judgment.

Notes:

[a] CTE value assumed to be half that of the RME receptor.

[b] RME value is based on the default value for construction scenario (Exhibit 5-1) is based on the 95th percentile value for adult soil intake rates reported in a soil ingestion mass-balance study.

[c] Assumes the entire 8-hour workday is outdoors.

[d] Particle emission factor is based on the value recommended for off-site residents of a construction site. This value normalizese the mass of fugitive dust over 30 years but accounts for the mass of dust emited by traffic on unpaved roads during construction and the mass of dust emitted by wind erosion.

[e] Construction workers are assumed to wear a short-sleeved shirt, long pants, and shoes. Assumes that the exposed surface area is equal to the USEPA default for a worker based on assumed exposure to the head, hands and forearms.

[f] Exhibit 3-3; based on the 95th percentile value (0.3) AF for the RME receptor and the geometric mean value (0.1) AF for the CTE receptor.

Table 3-26. Exposure Parameters for a Hiker and Calculated Human Intake Factors (HIFs)

Exposure Pathway	Exposure Parameter	Units	CTE		RME	
			Value	Source	Value	Source
General	Body weight as adult	kg	80	[1, a]	80	[1, a]
	Body weight as older child	kg	44	[2]	44	[2]

Notes:

[a] Table 8-1. Age-weighted average based on body weights of children 6-<11 years old and 11-<16 years old.

[b] Assumes exposure occurs over the course of 16 weeks (roughly Memorial Day to Labor Day) at a frequency of 2 day/week for a CTE receptor and 4 days/week for an RME receptor.

[c] Accounts for an older child exposed from 6 to 16 years of age.

[d] Assumes a value similar to that of an adult resident.

[e] CTE value is assumed to be half that of the RME receptor.

[f] Assumes same surface area as a resident (head, hands, forearms, and lower legs for an adult; head, hands, forearms, lower legs, and feet for an older child).

[g] Weighted average surface area for an older child aged 6-16 years (Tables 7-1 and 7-2) assuming exposure to head, hands, forearms, and lower legs (similar to a resident).

Table 3-27. Exposure Parameters for a Camper and Calculated Human Intake Factors (HIFs)

Exposure Pathway	Exposure Parameter	Units	CTE		RME	
			Value	Source	Value	Source
General	Body weight as adult	kg	80	[1]	80	[1]
	Body weight as child	kg	15	[1]	15	[1]

[5] USEPA 2004. Risk Assessment Guidance for Superfund, Volume I: Human Health Evaluation Manual (Part E). Office of Solid Waste and Emergency Response. July.

Notes:

[a] Assumes exposure occurs over the course of 16 weeks (roughly Memorial Day to Labor Day) at a frequency of 2 day/week for a CTE visitor and 3 days/week for an RME visitor.

[b] Assumes a value similar to that of a resident.

[c] CTE value is assumed to be half that of the RME receptor.

[d] Assumes half the soil value.

[e] Weighted mean of consumer-only ingestion of drinking water (Table 3-1).

[f] For soil, surface area value for an adult assumes exposure to head, hands, forearms, and lower legs as an adult; also to feet for sediment. For soil and sediment, surface area value for a child assumes exposure to head, hands, forearms, lower legs and feet.

[g] Assumes full body exposure to while swimming.

Table 3-28. Exposure Parameters for a Recreational Fisher and Calculated Human Intake Factors (HIFs)

Exposure Pathway	Exposure Parameter	Units	CTE		RME	
			Value	Source	Value	Source

RME = Reasonable Maximum Exposure; CTE = Central Tendency Exposure; CS = chemical-specific; HIF = human intake factor;
HIF_{child} = human intake factor for the young child; HIF_{TWA} = time weighted average human intake factor (assumes exposure over a lifetime from childhood into adulthood).

Notes:

[a] Table 8-1. Age-weighted average based on body weights of children 6-<11 years old and 11-<16 years old.

[b] Assumes exposure occurs over the course of 24 weeks (roughly April - September) at a frequency of 2 day/week for a CTE receptor and 4 days/week for an RME receptor.

[c] Accounts for an older child exposed from 6 to 16 years of age.

[d] Assumes a value similar to that of a resident.

[e] CTE value is assumed to be half that of the RME receptor.

[f] Assumes half the soil value.

[g] Based on the mean and upper confidence limit for estimated water ingestion while fishing (Table 3-93).

[h] Incidental ingestion from splashing or hand-to-face contact during fishing assumed to be 10% of the incidental ingestion rate while swimming assumed for the camper scenario.

[i] Based on long-term average mean and 95th percentile ingestion rates presented in EFH Table 10-5 for freshwater recreational fish intake by consuming anglers in North Dakota (nearest state to Montan

[j] Child fish ingestion rates were estiamted by multiplying the adult ingestion rate by a ratio of child-to-adult estimated energy requirements (0.5).

[k] Weighted average surface areas (Tables 7-1 and 7-2) calculated assuming exposure to head, hands, and forearms. It is assumed that in general, people will remain on the banks while fishing and only en significant amounts of time if wearing protective clothing such as waders and waterproof shoes/boots.

[l] Weighted average surface areas (Tables 7-1 and 7-2) calculated assuming exposure to head, hands, forearms, lower legs and feet. It is assumed that in general, children will remain on the banks while fis adult wearing short-sleeves and shorts.

Key: I = IRIS; P = PPRTV; S = PPRTV Screening Level; G = USEPA RSL User's Guide; H = HEAST; C = CalEPA; A = ATSDR.

Notes:

[1] Absorbed Reference Doses for Dermal were derived using the Oral Reference Dose as follows: $RFD_{ABS} = RfD_o * ABS_{GI}$ (Equation 4.3 from USEPA 2004).

[2] Absorbed Cancer Slope Factors for Dermal were derived using the Oral Cancer Slope Factors as follows: $SF_{ABS} = SF_o / ABS_{GI}$ (Equation 4.2 from USEPA 2004).

[3] USEPA (2013) noted that the contribution of the inhalation pathway to total risk is well below 1%.

[4] Toxicity values are for hexavalent chromium [Cr(VI)].

[5] The oral RfD is based on the maximum contaminant level goal of 1.3 mg/L.

[6] The IRIS RfD (0.14 mg/kg-day) is adjusted by subtracting the dietary exposure (default assumption of 5 mg) and applying a modifying factor of 3.

[7] Based on factoring out the molecular weight of the oxide ion from the RfD for vanadium pentoxide.

Table 4-2. Sub-Chronic Human Health Toxicity Values for COPCs

Notes:

[a] Table 8-1. Age-weighted average for the following age ranges: 0 to <2 years old, 2 to <6 years old, 6 to <16 years old, and ≥16 years old.

[b] Averaging time expressed as days. Noncancer averaging time calculated by multiplying the exposure duration by 365 days/year. Cancer averaging time calculated by multiplying a 70 year lifetime for cancer effects by 365 days/year.

[c] Assumes CTE value is half of the RME value.

[d] Incidental ingestion from splashing or hand-to-face contact during fishing assumed to be 10% of the incidental ingestion rate while swimming assumed for the camper scenario.

[e] Based on the mean and upper confidence limit for estimated water ingestion while fishing (Table 3-93).

[f] Weighted average surface areas (Tables 7-1 and 7-2) calculated assuming exposure to head, hands, forearms, lower legs and feet. It is assumed that in general, children will remain on the banks while fishing with an adult wearing short-sleeves and shorts.

[g] Weighted average surface areas (Tables 7-1 and 7-2) calculated assuming exposure to head, hands, and forearms. It is assumed that in general, people will remain on the banks while fishing and only enter the water for significant amounts of time if wearing protective clothing such as waders and waterproof shoes/boots.

[h] Assumes adherence factor equal to the soil adherence factor for a resident (USEPA 2004, Exhibit 3-3).

HI = hazard index; CTE = central tendency estimate; RME = reasonable maximum exposure.
Non-cancer hazards are based on the young child (assumed protective of an adult).

[a]Orange highlight flags non-cancer hazards > 1E+00 and cancer risks ≥ 1E-04. Blue highlight flags cancer risks≥ 1E-05.

[b]Only subsurface depth intervals were sampled at this grid. No surface soil sample data are available. The EPC was derived from subsurface samples.

Table 5-2. Summary of Non-Cancer Hazards for Hypothetical Future Residents in Grid 74 from Incidental Ingestion of OU3 Upland Surface Soils

Grid	COPC	Non-Cancer Hazard Quotient		Non-Cancer Target System	Non-Cancer Hazard Quotient	
		CTE	RME		CTE	RME
74	Arsenic	4E-01	1E+00	Dermal	8E-01	2E+00
	Thallium	4E-01	1E+00			
	Vanadium	2E-02	6E-02			
	Iron	9E-02	2E-01	Gastrointestinal	9E-02	2E-01
	Mercury	3E-03	1E-02	Immune	3E-03	1E-02
	Barium	2E-02	5E-02	Kidney	5E-02	1E-01
	Cadmium	3E-02	8E-02			
	Aluminum	9E-02	2E-01	Nervous	5E-01	1E+00
	Manganese	5E-01	1E+00			
	$TEQ_{D/F}$	2E+00	6E+00	Reproduction	2E+00	6E+00
	Antimony	3E-02	8E-02	Systemic	3E-02	8E-02
	Cobalt	1E-01	3E-01	Thyroid	1E-01	3E-01
	Chromium	5E-02	1E-01			
	Total	4E+00	1E+01			

COPC = Contaminant of potential concern; CTE = central tendence estimate; RME = reasonable maximum exposure; $TEQ_{D/F}$ = toxicity equivalence for dioxins and furans.

Orange highlight flags non-cancer hazards > 1E+00.

Table 5-3. Cancer Risks for Hypothetical Future Residents from Exposure to OU3 Surface Soil in Grid 48

Grid	COPC	Risk	
		CTE	RME
48	$TEQ_{D/F}$	2E-06	9E-06
	Arsenic	3E-06	2E-05
	Chromium	1E-04	3E-04
	Total	1E-04	3E-04

COPC = contaminant of potential concern; $TEQ_{D/F}$ = toxicity equivalent for dioxins and furans; CTE = central tendency estimate; RME = reasonable maximum exposure.

Orange highlight flags cancer risks≥ 1E-04.
Blue highlight flags cancer risks ≥ 1E-05.

Chromium was evaluated as hexavalent chromium.

HI = hazard index; CTE = central tendency estimate; RME = reasonably maximum exposure.
Orange highlight flags cancer risks≥ 1E-04. Blue highlight flags cancer risks ≥ 1E-05.
"x" denotes where the cancer risk from exposure to groundwater only and the exposure to soil only were < 1E-04, but the total cancer risk ≥ 1E-04.

HI = hazard index; CTE = central tendency estimate; RME = reasonable maximum exposure.

[a]Orange highlight flags non-cancer hazards > 1E+00 and cancer risks≥ 1E-04. Blue highlight flags cancer risks≥ 1E-05.

[b]Only subsurface depth intervals were sampled at this grid. No surface soil sample data are available. The EPC was derived from subsurface samples.

CTE = central tendency estimate; RME = reasonably maximum exposure; As = arsenic; Co = cobalt; Fe = iron; Mn = manganese; Tl = thallium.

Orange highlight flags non-cancer hazards > 1E+00 and cancer risks≥ 1E-04. Blue highlight flags cancer risks ≥ 1E-05.

* = HQ for this individual COPC < 1E+00 or Cancer Risk for this individual COPC < 1E-04

HI = hazard index; CTE = central tendency estimate; RME = reasonably maximum exposure.
Orange highlight flags cancer risks≥ 1E-04. Blue highlight flags cancer risks ≥ 1E-05.
"x" denotes where the cancer risk from exposure to groundwater only and the exposure to soil only were < 1E-04, but the total cancer risk ≥ 1E-04.

HI = hazard index; CTE = central tendency estimate; RME = reasonable maximum exposure.

[a]Orange highlight flags non-cancer hazards > 1E+00 and cancer risks≥ 1E-04. Blue highlight flags cancer risks ≥ 1E-05.

HI = hazard index; CTE = central tendency estimate; RME = reasonable maximum exposure.

[a]Orange highlight flags non-cancer hazards > 1E+00 and cancer risks≥ 1E-04. Blue highlight flags cancer risks ≥ 1E-05.

[b]Only subsurface depth intervals were sampled at this grid. No surface soil sample data are available. The EPC was derived from subsurface samples.

HI = hazard index; CTE = central tendency estimate; RME = reasonable maximum exposure.
Non-cancer hazards are based on the young child (assumed protective of an adult).

[a]Orange highlight flags non-cancer hazards > 1E+00 and cancer risks≥ 1E-04. Blue highlight flags cancer risks ≥1E-05.

[b]Only subsurface depth intervals were sampled at this grid. No surface soil sample data are available. The EPC was derived from subsurface samples.

Table 5-14. Cancer Risks for a Camper from Exposure to OU3 Surface Soil in Grid 74

Grid	COPC	Risk	
		CTE	RME
74	$TEQ_{D/F}$	2E-05	5E-05
	Arsenic	2E-05	5E-05
	Chromium	6E-06	2E-05
	Total	4E-05	1E-04

COPC = contaminant of potential concern; $TEQ_{D/F}$ = toxicity equivalent for dioxins and furans; CTE = central tendency estimate; RME = reasonable maximum exposure.

Orange highlight flags cancer risks≥ 1E-04.
Blue highlight flags cancer risks ≥1E-05.

Chromium was evaluated as hexavalent chromium.

Table 5-15. Summary of Non-Cancer Hazards and Cancer Risks to Campers

Exposure Medium	Exposure Unit	Exposure Route	Non-cancer HI		Cancer Risk	
			CTE	RME	CTE	RME
Surface Water	On-site Creeks	Intentional Ingestion (as drinking water)	3E-02	8E-02	2E-06	7E-06

Combined Exposure - Surface water, Sediment, & Soil	CFR/Floodplain	Total	2E-01	8E-01	1E-05	5E-05
Fish Fillets[b]	CFR	Ingestion	2E+00	8E+00	3E-05	2E-04
Combined Exposure - Surface water, Sediment, Soil, & Fish	CFR/Floodplain	Total	3E+00	9E+00	4E-05	3E-04

HI = hazard index; CTE = central tendency estimate; RME = reasonable maximum exposure; CFR = Clark Fork River.

Orange highlight flags non-cancer hazards > 1E+00 and cancer risks≥ 1E-04. Blue highlight flags cancer risks ≥ 1E-05.

Non-cancer hazards shown are for the young child (assumed protective of an adolescent and an adult).

[a]Non-cancer HI and cancer risk shown in this table correspond to the maximum values estimated for the floodplain exposure unit grids.

[b]Non-cancer HI and cancer risk shown in this table correspond to the maximum values estimated for fish consumption (assumes no cooking loss).

Table 5-18. Non-Cancer Hazards and Cancer Risks for Ingestion of TEQ and Total PCBs in Fish by a Recreational Fisher

Panel A: Northern Pike Fillets

	Non-Cancer		Cancer	
	HQ		Risk	
COPC	CTE	RME	CTE	RME
$TEQ_{D/F}$	4E-01	1E+00	5E-06	3E-05
TEQ_{PCB}	2E+00	7E+00	3E-05	2E-04
$TEQ_{D/F/PCB}$	2E+00	8E+00	3E-05	2E-04
Total PCBs			8E-06	5E-05

Panel B: Rainbow Trout Fillets

	Non-Cancer		Cancer	
	HQ		Risk	
COPC	CTE	RME	CTE	RME
$TEQ_{D/F}$	4E-01	1E+00	5E-06	3E-05
TEQ_{PCB}	1E+00	4E+00	2E-05	1E-04
$TEQ_{D/F/PCB}$	1E+00	5E+00	2E-05	1E-04
Total PCBs			3E-06	2E-05

HI = hazard index; CTE = central tendency estimate; RME = reasonably maximum exposure; $TEQ_{D/F}$ = toxicity equivalence for dioxin and furan congeners; TEQ_{PCB} = toxicity equivalence for dioxin-like polychlorinated biphenyl congeners; $TEQ_{D/F/PCB}$ = toxicity equivalence for dioxin, furan and dioxin-like polychlorinated biphenyl congeners; PCB = polychlorinated biphenyls.

Assumes no loss in concentrations while prepping and/or cooking fish fillets.

TEQ and Total PCB concentrations are calculated evaluating non-detects at 1/2 the sample-specific detection limit.

Non-cancer hazards shown are for the young child (assumed protective of an adolescent and an adult).

Orange highlight flags non-cancer hazards > 1E+00 and cancer risks≥ 1E-04. Blue highlight flags cancer risks≥ 1E-05.

Table 5-19. Non-Cancer Hazards and Cancer Risks for Ingestion of TEQ and Total PCBs in Fish by a Recreational Fisher Accounting for Potential Cooking Loss

Panel A: Northern Pike Fillets

	Non-Cancer		Cancer	
	HI		Risk	
COPC	CTE	RME	CTE	RME
$TEQ_{D/F}$	2E-01	6E-01	2E-06	2E-05
TEQ_{PCB}	9E-01	3E+00	1E-05	9E-05
$TEQ_{D/F/PCB}$	1E+00	4E+00	1E-05	1E-04
Total PCBs			5E-06	4E-05

Panel B: Rainbow Trout Fillets

	Non-Cancer		Cancer	
	HI		Risk	
COPC	CTE	RME	CTE	RME
$TEQ_{D/F}$ (ND = 1/2 DL)	2E-01	6E-01	2E-06	2E-05
TEQ_{PCB} (ND = 1/2 DL)	5E-01	2E+00	7E-06	5E-05
$TEQ_{D/F/PCB}$ (ND = 1/2 DL)	7E-01	2E+00	9E-06	6E-05
Total PCBs			2E-06	1E-05

HI = hazard index; CTE = central tendency estimate; RME = reasonably maximum exposure; $TEQ_{D/F}$ = toxicity equivalence for dioxin and furan congeners; TEQ_{PCB} = toxicity equivalence for dioxin-like polychlorinated biphenyl congeners; $TEQ_{D/F/PCB}$ = toxicity equivalence for dioxin, furan and dioxin-like polychlorinated biphenyl congeners; PCB = polychlorinated biphenyls.

Assumes cooking loss of 54% for TEQ and 30% for PCBs.

TEQ and Total PCB concentrations are calculated evaluating non-detects at 1/2 the sample-specific detection limit.

Non-cancer hazards shown are for the young child (assumed protective of an adolescent and an adult).

Orange highlight flags non-cancer hazards > 1E+00 and cancer risks≥ 1E-04. Blue highlight flags cancer risks ≥ 1E-05.

Table 5-20. Risk Estimates for Tribal Fishers Exposed to OU3 Surface Soils within the Floodplain while Fishing[a]

Exposure Unit	Exposure Route	Non-cancer HI		Cancer Risk

Rainbow trout whole body fish	CFR	Ingestion[b]	4E+00	2E+01	6E-05	4E-04
Combined Exposure - Surface water, Sediment, Soil, & Fish	CFR/Floodplain	Total	4E+00 - 1E+01	2E+01 - 4E+01	6E-05 - 1E-04	5E-04 - 1E-03

HI = hazard index; CTE = central tendency estimate; RME = reasonable maximum exposure; CFR = Clark Fork River.

Orange highlight flags non-cancer hazards > 1E+00 and cancer risks ≥ 1E-04. Blue highlight flags cancer risks ≥ 1E-05.

Non-cancer hazards shown are for the young child (assumed protective of an adolescent and an adult).

[a]Non-cancer HI and cancer risk shown in this table correspond to the maximum values estimated for the floodplain exposure unit grids.

[b]Non-cancer HI and cancer risk shown in this table correspond to the maximum values assuming no cooking loss.

Table 5-22. Non-Cancer Hazards and Cancer Risks for Ingestion of TEQ and Total PCBs in Fish by a Tribal Fisher

Panel A: Northern Pike Fillets

	Non-Cancer		Cancer	
	HQ		Risk	
COPC	CTE	RME	CTE	RME
$TEQ_{D/F}$	7E-01	3E+00	9E-06	7E-05
TEQ_{PCB}	4E+00	2E+01	5E-05	4E-04
$TEQ_{D/F/PCB}$	4E+00	2E+01	6E-05	5E-04
Total PCBs			1E-05	1E-04

Panel B: Rainbow Trout Fillets

	Non-Cancer		Cancer	
	HQ		Risk	
COPC	CTE	RME	CTE	RME
$TEQ_{D/F}$	7E-01	3E+00	9E-06	7E-05
TEQ_{PCB}	2E+00	9E+00	3E-05	2E-04
$TEQ_{D/F/PCB}$	3E+00	1E+01	4E-05	3E-04
Total PCBs			5E-06	4E-05

Panel C: Northern Pike Whole-Body

	Non-Cancer		Cancer	
	HQ		Risk	
COPC	CTE	RME	CTE	RME
$TEQ_{D/F}$	1E+00	4E+00	1E-05	1E-04
TEQ_{PCB}	9E+00	4E+01	1E-04	1E-03
$TEQ_{D/F/PCB}$	1E+01	4E+01	1E-04	1E-03
Total PCBs			4E-05	3E-04

Panel D: Rainbow Trout Whole-Body

	Non-Cancer		Cancer	
	HQ		Risk	
COPC	CTE	RME	CTE	RME
$TEQ_{D/F}$	8E-01	3E+00	1E-05	8E-05
TEQ_{PCB}	3E+00	1E+01	4E-05	3E-04
$TEQ_{D/F/PCB}$	4E+00	2E+01	6E-05	4E-04
Total PCBs			7E-06	6E-05

HQ = hazard quotient; CTE = central tendency estimate; RME = reasonably maximum exposure; $TEQ_{D/F}$ = toxicity equivalence for dioxin and furan congeners; TEQ_{PCB} = toxicity equivalence for dioxin-like polychlorinated biphenyl congeners; $TEQ_{D/F/PCB}$ = toxicity equivalence for dioxin, furan and dioxin-like polychlorinated biphenyl congeners; PCB = polychlorinated biphenyls.

Assumes no loss in concentrations while prepping and/or cooking fish fillets.

TEQ and Total PCB concentrations are calculated evaluating non-detects at 1/2 the sample-specific detection limit.

Non-cancer hazards shown are for the young child (assumed protective of an adolescent and an adult).

Orange highlight flags non-cancer hazards > 1E+00 and cancer risks≥ 1E-04. Blue highlight flags cancer risks ≥1E-05.

Table 5-23. Non-Cancer Hazards and Cancer Risks for Ingestion of TEQ and Total PCBs in Fish by a Tribal Fisher Accounting for Potential Cooking Loss

Panel A: Northern Pike Fillets

	Non-Cancer		Cancer	
	HQ		Risk	
COPC	CTE	RME	CTE	RME
$TEQ_{D/F}$	3E-01	1E+00	4E-06	3E-05
TEQ_{PCB}	2E+00	7E+00	2E-05	2E-04
$TEQ_{D/F/PCB}$	2E+00	8E+00	3E-05	2E-04
Total PCBs			1E-05	8E-05

Panel B: Rainbow Trout Fillets

	Non-Cancer		Cancer	
	HQ		Risk	
COPC	CTE	RME	CTE	RME
$TEQ_{D/F}$	3E-01	1E+00	4E-06	3E-05
TEQ_{PCB}	1E+00	4E+00	1E-05	1E-04
$TEQ_{D/F/PCB}$	1E+00	5E+00	2E-05	1E-04
Total PCBs			4E-06	3E-05

Panel C: Northern Pike Whole-Body

	Non-Cancer		Cancer	
	HQ		Risk	
COPC	CTE	RME	CTE	RME
$TEQ_{D/F}$	5E-01	2E+00	6E-06	5E-05
TEQ_{PCB}	4E+00	2E+01	6E-05	5E-04
$TEQ_{D/F/PCB}$	5E+00	2E+01	6E-05	5E-04
Total PCBs			3E-05	2E-04

Panel D: Rainbow Trout Whole-Body

	Non-Cancer		Cancer	
	HQ		Risk	
COPC	CTE	RME	CTE	RME
$TEQ_{D/F}$	4E-01	1E+00	5E-06	4E-05
TEQ_{PCB}	1E+00	6E+00	2E-05	2E-04
$TEQ_{D/F/PCB}$	2E+00	8E+00	3E-05	2E-04
Total PCBs			5E-06	4E-05

HQ = hazard quotient; CTE = central tendency estimate; RME = reasonably maximum exposure; $TEQ_{D/F}$ = toxicity equivalence for dioxin and furan congeners; TEQ_{PCB} = toxicity equivalence for dioxin-like polychlorinated biphenyl congeners; $TEQ_{D/F/PCB}$ = toxicity equivalence for dioxin, furan and dioxin-like polychlorinated biphenyl congeners; PCB = polychlorinated biphenyls.

Assumes cooking loss of 54% for TEQ and 30% for PCBs.

TEQ and Total PCB concentrations are calculated evaluating non-detects at 1/2 the sample-specific detection limit.

Non-cancer hazards shown are for the young child (assumed protective of an adolescent and an adult).

Orange highlight flags non-cancer hazards > 1E+00 and cancer risks≥ 1E-04. Blue highlight flags cancer risks ≥ 1E-05.

Table 6-1. Non-Cancer Hazards and Cancer Risks for Ingestion of TEQ and Total PCBs in Fish by a Tribal Fisher Using Higher Ingestion Rates to Assess Uncertainties in Exposure Parameters

Panel A: Northern Pike Fillets

	Non-Cancer		Cancer	
	HI		Risk

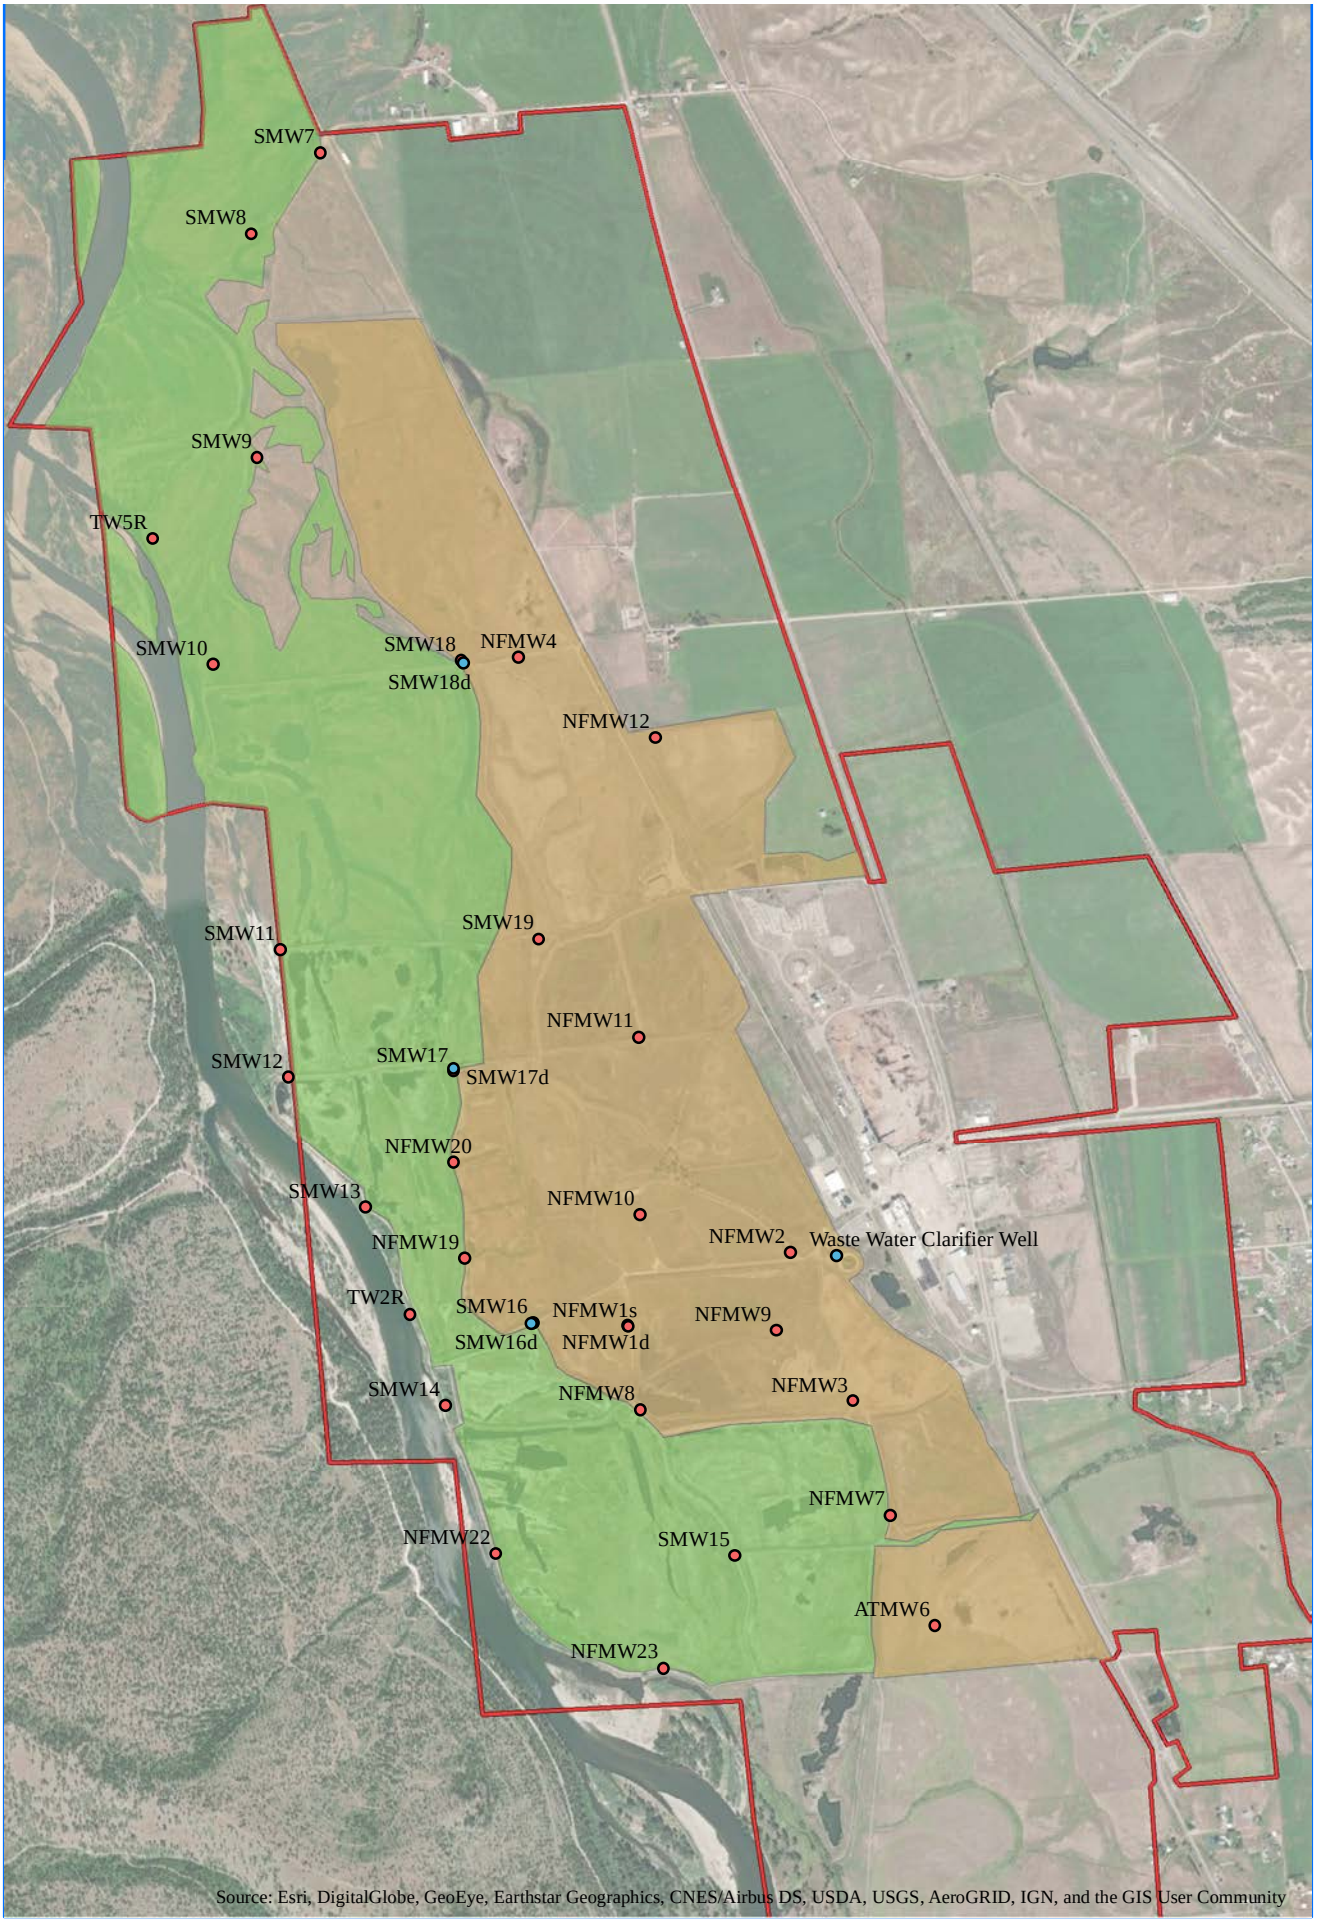
LEGEND



●	Pathway is complete and might be significant; quantitative evaluation.
❍	Pathway is complete, but is relatively minor; semi-quantitative evaluation.
X	Pathway is or may be complete, however, data are lacking. Qualitative evaluation only.
	Pathway is not complete; no evaluation required.

Notes

[1] Residents and workers represent hypothetical future exposure scenarios. Recreational visitors represent current and/or hypothetical future exposure scenarios. Fishers are only expected to be exposed within the floodplain while fishing within the CFR.

[2] Incidental ingestion of surface water within the CFR and on-Site creeks (O'Keefe and Lavalle Creeks) may occur while recreating. For this assessment, it is also assumed that the camper may ingest drinking water drawn from the CFR and on-Site creeks. It is not anticipated that humans will be exposed within on-Site ponds due to the nature of the ponds themselves (i.e., standing/stagnant water with algal growth).

APPENDIX A

OU3 DATA SUMMARY

Smurfit-Stone/Frenchtown Mill Site
OU3 Human Health Risk Assessment

1.0 INTRODUCTION

This appendix summarizes the data utilized in the Operable Unit 3 (OU3) human health risk assessment (HHRA). As described in the main text of this OU3 HHRA, soil, groundwater, sediment, surface water, and fish tissue samples were collected within OU3 as part of various Site investigations conducted between 2014 and 2020. All data were collected following United States Environmental Protection Agency (USEPA) approved sampling plans as part of ongoing remedial investigation (RI) activities. This appendix presents a brief overview of the available data used in the OU3 HHRA. Additional details on sampling and analysis can be found in the RI reports available on the Site webpage[1].

Data collected prior to 2014 to support the Preliminary Assessment/Site Investigation are not used in the HHRA due to deviations from the Quality Assurance Project Plan (QAPP) that occurred during sampling and analysis of those samples. Instead, USEPA used those data to inform the RI Work Plan (RIWP) and focused collection on those areas identified as having potentially elevated contamination. The sampling conducted as part of RI activities are more recent, were collected in accordance with the USEPA approved QAPP, and have been evaluated and determined to meet the needs of the risk assessment.

Data collected for the RIWP and associated Addenda have been uploaded to a USEPA Scribe database for the Smurfit-Stone/Frenchtown Mill Site. Data considered for use in the OU3 HHRA were based on a Scribe download conducted May 2021. Not all of the data in Scribe were utilized in the OU3 risk evaluation presented within the HHRA.

The available data downloaded from Scribe used in this HHRA were reduced as described below to produce the Site datasets utilized in the quantitative risk evaluations. Data used in the OU3 HHRA are provided as an electronic data file in Attachment A-1 to this appendix. Attachment A-1 includes separate tabs for each medium.

2.0 DATA SUMMARY

2.1 Soil

Soil samples were collected at locations throughout OU3 in April 2014, November/December 2015, and October 2017. In 2014/2015, surface soils were collected as localized 5-point composites over a 1 to 2-meter area. In 2017, 20-point composite samples were collected from

[1] Smurfit-Stone Mill Frenchtown, Missoula, MT webpage: https://cumulis.epa.gov/supercpad/cursites/csitinfo.cfm?id=0802850

square grid units in OU3. Samples were collected from 20-acre grid units in the OU3 upland area outside of the 100-year floodplain, and from 100-acre grid units in the OU3 Floodplain. In addition to the 20-point composite samples, 30-point composite surface soil samples were also collected from historic wastewater treatment basins within the OU3 upland area. Surface soil samples were collected from 0 to 2 inches and from 0 to 6 inches. Subsurface samples were collected as vertical composites from varying depths down to 18 feet. Only those samples collected down to 10 feet (the depth to which a construction worker may be exposed) were considered in the HHRA. All of the soil samples collected from the Site represent bulk soil. OU3 soil samples were analyzed for metals, dioxins/furans, and polychlorinated biphenyls (PCBs; as Aroclors). These data are briefly summarized in the main text. OU3 soil samples were not analyzed for semi-volatile organic compounds (SVOCs) and volatile organic compounds (VOCs) based on the low level of detection of these contaminants observed in OU2 soil samples. More details on the soil sampling efforts are available in the RI Work Plan Addenda available on the Site webpage.

2.2 Groundwater

Within the Scribe database, the location zone for all groundwater samples is entered as “OU3”. Based on the maps provided in the RI reports, the following groundwater wells have been identified for inclusion in OU3: ATMW6, NFMW1 to NFMW4, NFMW7 to NFMW12, NFMW19, NFMW20, NFMW22, NFMW 23, SMW7 to SMW19, TW2R, TW5R and the waste water clarifier well. Groundwater monitoring has been happening at the Site annually since April 2014. Samples were collected multiple times within a year starting in 2017. Data collected through 2020 were considered in the OU3 HHRA. The monitoring wells (those identified as “MW”) are located within the water table aquifer below the Site that is generally present to a depth of approximately 35 feet below ground surface (ft bgs) (referred to as hydrostratigraphic unit 1) (NewFields 2020). The water supply well (waste water clarifier well) and deep wells (SMW16d, SMW17d, SMW18d) are located within the regional water supply aquifer that is generally present from approximately 130 to 160 ft bgs (referred to as hydrostratigraphic unit 3) (NewFields 2020). Groundwater samples have been analyzed for total recoverable and dissolved metals, dioxins/furans, PCBs (as Aroclors), SVOCs and VOCs. Not all samples were analyzed for all contaminant classes. Various field parameters were also measured including pH, temperature, dissolved oxygen, oxidation reduction potential, specific conductance, alkalinity and anions.

2.3 Sediment

Sediment samples were collected in 2015 and 2018. In November 2015, bed sediment samples were collected from O’Keefe and Lavalle Creeks and within the CFR downstream and adjacent

to the Site. In December 2015, additional sediment sampling was conducted along the CFR from the flood fringe of the 100-year floodplain downstream of the Site. In August 2018, bed sediment samples were collected from on-Site ponds, O'Keefe and Lavalle Creeks, and from the CFR adjacent to and downstream of the Site. Sediment samples were analyzed for dioxins/furans and metals. Miscellaneous parameters (e.g., organic carbon, percent fines) were also measured. Six of the bed sediment samples collected in 2015 were also analyzed for PCBs (as Aroclors) and SVOCs.

2.4 Surface Water

Surface water samples were collected in November 2015 from Lavalle Creek and within the CFR downstream and adjacent to the Site at locations coincident with the bed sediment samples. One surface water sample was collected from Lavalle Creek and three surface water samples were collected from the CFR adjacent to or downstream of the Site and analyzed for dioxins/furans, metals (total and dissolved), and miscellaneous parameters (e.g., measures of water quality such as alkalinity and pH, as well as ions such as chloride and fluoride). Three of the four surface water samples were also analyzed for PCBs (as Aroclors) and SVOCs.

To evaluate potential impacts to the CFR during high flows, surface water samples were collected in May 2018 from the CFR adjacent to the Site and within historic ponds during a high flow event. Two samples were collected from the CFR adjacent to the Site and two samples were collected from Site pond areas (HP2POND and HP13APOND). Samples were analyzed for dioxins/furans, metals (total and dissolved), and miscellaneous parameters (e.g., measures of water quality such as alkalinity and pH, as well as ions such as chloride and fluoride).

In August 2018, surface water samples were collected from 12 on-Site ponds, O'Keefe and Lavalle Creeks, and within the CFR downstream and adjacent to the Site co-incident with bed sediment samples. Samples were analyzed for dioxins/furans, metals (total and dissolved), and miscellaneous parameters (e.g., measures of water quality such as alkalinity and pH, as well as ions such as chloride and fluoride).

2.5 Fish Tissue

In July 2018, USEPA in cooperation with MFWP collected northern pike (*Esox lucius*) and rainbow trout (*Oncorhynchus mykiss*) from the CFR and its tributaries (USEPA 2018, 2019a). Four composite fillet and four composite carcass northern pike samples were collected from the Frenchtown reach of the CFR adjacent to the site. Eight composite fillet and eight composite carcass rainbow trout samples were collected from reaches of the CFR downstream of the site. As noted in USEPA (2020), sampling compliance issues, including the lack of chain-of-custody

(COC) forms and a lack of QC field samples, prohibited the use of these data in the quantitative risk evaluation. These data were not evaluated quantitatively in the OU3 HHRA, but were considered in the uncertainty assessment in accordance with USEPA (2020).

In June 2019, USEPA with the support of multiple agencies and contractors, collected additional northern pike and rainbow trout samples from the CFR and its tributaries to address a data gap (USEPA 2019b). Four composite fillet and four composite carcass northern pike samples were collected from the Frenchtown reach of the CFR adjacent to the Site. Eight composite fillet and eight composite carcass rainbow trout samples were collected from reaches of the CFR adjacent to (Frenchtown reach) and downstream (St. Regis reach) of the Site.

All northern pike and rainbow trout samples from the 2018 and 2019 sampling events were analyzed for dioxins/furans, PCB congeners, % solids, and % lipids. All fish tissue concentration data used in the OU3 HHRA were based on wet weight concentrations.

3.0 DATA REDUCTION

3.1 Categorization as Surface Soil and Subsurface Soil

For the purposes of the HHRA, surface soil samples were classified as samples collected from a starting depth of either zero or one inch down to six inches below ground surface (bgs). Samples collected from at or below one-foot bgs were classified as subsurface soil samples. Subsurface data used in the OU3 HHRA were restricted to samples collected within the top 10 feet bgs.

3.2 Treatment of Field Duplicates

In accordance with the RI work plan (RIWP) QAPP, blind field duplicates (one for every twenty natural samples) were collected to provide quality assurance for field sampling. Two concentration results for a parent sample-duplicate pair were reduced to a single value for each contaminant as follows:

- If both the parent sample and the duplicate sample results were detected, the maximum detected concentration was retained and the result was flagged as a detect.

- If both the parent sample and the duplicate sample results were qualified as not detected, the maximum DL was retained and the result was flagged as a non-detect.

- If one result from the sample pair was detected, while the other was qualified as not detected, the detected concentration was retained and the result was flagged as a detect.

TEQ concentrations were calculated for each parent sample and field duplicate as described in Sections 3.6 below. For each sample pair, the results were reduced to a single value for each calculated result in accordance with the protocol presented above. Duplicate reduction was not done at the congener level.

3.3 Treatment of Multiple Analytical Results

Some soil samples collected within OU3 were analyzed using two extraction methods during VOC analysis: EPA 5035/5030B and EPA 5035 Low. This resulted in several samples having two results for each VOC in the Scribe database. These results were reduced to a single value for each contaminant as follows:

- If both the results were detected, the maximum detected concentration was retained and the result was flagged as a detect.

- If both results were qualified as not detected, the maximum DL was retained and the result was flagged as a non-detect.

- If one of the results was detected, while the other was qualified as not detected, the detected concentration was retained and the result was flagged as a detect.

TEQ concentrations were calculated for each parent sample and field duplicate as described in Section 3.6. For each sample pair, the results were reduced to a single value for each calculated result in accordance with the protocol presented above. Duplicate reduction was not done at the congener level.

Field duplicates were not collected during the 2018 and 2019 northern pike and rainbow trout sampling events. However, duplicate homogenate samples were created during sample processing to assess whether contamination occurred during sample processing (e.g., two carcass homogenate samples created from the same composite sample were submitted for analysis). Homogenate duplicate samples were not evaluated in the OU3 HHRA, but were considered during the data validation process.

3.4 Treatment of Non-detects

When calculating summary statistics, non-detects (NDs) were evaluated at ½ the sample-specific detection limit (DL). When inputting data to ProUCL for the purposes of calculating 95 percent

(%) upper confidence limit (95UCL) values, ND data were based on the DL (i.e., sample-specific detection limit).

Various detection limits were reported for Site data by laboratories and are defined slightly different by each laboratory that analyzed Site samples. Pace Analytical performed sample analyses for metals, PCBs (in abiotic media only), SVOCs and VOCs. For each sample result, Pace reported a "MDL" (method detection limit; adjusted for sample dilution) and "RDL/QL" (laboratory reporting limit/quantitation level). The MDL refers to the lowest concentration that can be detected by the laboratory with confidence that the analyte is present (i.e., not a false positive). The RDL/QL refers to the lowest concentration that can be reported with confidence in the accuracy and precision of the value. Concentrations below this limit can be detected, but the value should be considered estimated. The MDL reported by Pace was used as the DL for Site data. Dioxins/furans were analyzed by Frontier Analytical (Frontier) for all media except the northern pike and rainbow trout tissue samples. For Frontier, the reported MDL is the method detection limit under ideal conditions – not accounting for matrix interferences, dilution, etc. If an analyte is not detected in a sample, Frontier calculates a sample-specific detection limit and reports it as the RDL. The QL reported by Frontier is the lowest point of calibration on the instrument. This is analogous to the QL reported by Pace: analytes detected below this limit are present, but the reported value is estimated. The RDL reported by Frontier was used as the DL for Site data.

The northern pike and rainbow trout samples were analyzed for dioxins/furans and PCB congeners by ALS Environmental (ALS). For dioxins/furans a contract required quantitation limit (CRQL) and MDL were reported by ALS. MDLs were calculated for each analyte in each sample by measuring the height of the noise level for each quantitation ion for the associated labeled standard. The concentration equivalent to 2.5 times the height of the noise is then calculated using the appropriate response factor and the weight of the sample. The calculated concentration equals the MDL. For PCB congeners an estimated detection limit (EDL) was reported by ALS. The EDL is defined as the Estimated Detection Limit and based on the measured background noise for this target in this sample. The dioxin/furan MDL and PCB EDL reported by ALS was used as the DL for Site data.

3.5 Calculation Total PCB Concentrations

There are 209 PCB congeners. PCBs generally occur as a mixture of congeners. Aroclors are commercial mixtures of PCB congeners that contain many of the individual congeners in varying ratios. When Aroclors are released into the environment, the original congener composition of the PCB mixture changes due to differential fate and transport processes (USEPA 1996). Chemical analyses of environmental samples often report PCB concentrations in terms of the

Aroclor mixture(s) they most closely resemble. All PCB data for OU3 abiotic media were reported in concentrations of Aroclor mixtures.

Fish tissues were analyzed for PCB congeners. Total PCB concentrations were calculated by summing across all reported congeners. Not all 209 PCB congeners can be separated using the procedures described in the analytical method. Thus, in some cases two or more PCB congeners elute from the chromatographic column at the same time. To avoid double counting of PCB congeners that co-elute, data are only reported for coeluting pair/group.

3.6 Calculation of TEQ

Because dioxin and furan congeners and dioxin-like PCBs all act by the same mechanism as 2,3,7,8-TCDD, data for the dioxin and furan congeners and dioxin-like PCBs was converted to a TCDD TEQ by computing the sum across congeners of the product of congener-specific concentration and relative toxicity equivalence factor (TEF):

$$TEQ = \sum (Ci \times TEFi)$$

TEFs were based on USEPA (2010). In the site database, separate TEQ values were calculated for dioxins and furans ($TEQ_{D/F}$), DL-PCBs (TEQ_{PCB}), and dioxins, furans, and dioxin-like PCBs combined ($TEQ_{D/F/PCB}$). A TEQ concentration is flagged as ND only if no individual congener was detected in that sample. Exposure and risk estimates in the HHRA are based on evaluating TEQ assuming ND = ½ DL consistent with other regional risk assessments.

APPENDIX B

SCREENING LEVEL EVALUATIONS

Smurfit-Stone/Frenchtown Mill Site
OU3 Human Health Risk Assessment

1.0 INTRODUCTION

This appendix presents a screening level evaluation of those pathways identified as "minor" in the conceptual site model (CSM) for the Operable Unit 3 Site (OU3 Site) (see Figure 3-1 of the main document). These pathways include the following:

- Inhalation of soil particulates generated via wind erosion
- Inhalation of vapors released from surface soils
- Dermal contact with groundwater used in future residential and commercial buildings

As discussed in the main text of the human health risk assessment (HHRA) for the OU3 Site, ingestion is the primary pathway by which exposure to site media is expected to occur at the OU3 Site. In general, the above pathways are considered minor exposure pathways when compared to the ingestion pathway. This screening level evaluation considers the relative risks from exposure to a chemical from each of the pathways listed above compared to the relative risks from exposure of the same chemical via the ingestion pathway.

2.0 INHALATION OF CONTAMINANTS IN SOIL

As described in the main text of this HHRA, human receptors at the OU3 Site may be exposed to contaminated soil via inhalation of soil particulates suspended in air by wind disturbance or via inhalation of vapors in the air emitted from soil. This section evaluates the relative comparison between the ingestion pathway and the inhalation pathway for exposures to soil. The basic equations recommended by USEPA (1989; 2009) for evaluating exposures via ingestion and inhalation are described in brief below.

2.1 Ingestion Exposures

The daily ingested intake for chronic exposures is calculated as (USEPA 1989):

$$DI = C \cdot (IR / BW) \cdot (EF \cdot ED / AT)$$

where:

DI	=	Daily intake of chemical (mg per kg of body weight per day).
C	=	Concentration of the chemical in the contaminated environmental medium (soil, water) to which the person is exposed. The units are mg/kg for soil and µg/L for water.
IR	=	Intake rate of the contaminated environmental medium. The units are kg/day for soil and L/day for water.

BW = Body weight of the exposed person (kg).
EF = Exposure frequency (days/year).
ED = Exposure duration (years).
AT = Averaging time (days).

2.2 Inhalation Exposures

The inhaled exposure concentration (EC) for chronic exposures is calculated as (USEPA 2009):

$$EC = C_{air} \cdot (ET \cdot EF \cdot ED / AT)$$

where:

EC = Exposure Concentration ($\mu g/m^3$). This is the time-weighted concentration based on the characteristics of the exposure scenario being evaluated.
C_{air} = Concentration of the chemical in air ($\mu g/m^3$) to which the person is exposed.
ET = Exposure time (hours/day).
EF = Exposure frequency (days/year).
ED = Exposure duration (years).
AT = Averaging time (hours).

and

C_{air} = C_{soil} / PEF or VF

where:

C_{soil} = Concentration of the chemical in soil (mg/kg)
PEF = Particulate Emission Factor (m^3/kg)
VF = Volatilization Factor (m^3/kg)

To compare the relative contributions to exposure from the two pathways, non-cancer hazards and cancer risks were calculated as follows:

Non-cancer hazard quotients

HQ = DI / RfD (ingestion pathway)

HQ = EC / RfC (inhalation pathway)

Cancer risks

Risk = DI · SF (ingestion pathway)

Risk = EC · UR (inhalation pathway)

Based on the above equations, the relative magnitude of risks from inhalation exposures can be compared to risks from ingestion exposure by calculating the ratio as follows:

Ratio = Inhalation Risk / Ingestion Risk

Using the exposure parameters for a resident, cancer risks and non-cancer HQ values were calculated for 2,3,7,8-TCDD (herein referred to as dioxin) as an example, assuming an arbitrary soil concentration.

Media	Endpoint	Pathway	Ratio (Inhalation/Ingestion)
Soil	Cancer	Inhalation (particulates)	6E-05 (<0.01%)
		Inhalation (vapor)	4E-02 (4%)
	Non-cancer	Inhalation (particulates)	3E-06 (<0.001%)
		Inhalation (vapor)	2E-03 (0.2%)

As shown in the table above, risks from inhalation exposures are small compared to risks from ingestion exposures (<5%). These findings support designating the inhalation pathways for soil exposures as minor for the purposes of this assessment.

2.3 Dermal Contact with Water

As described in the main text of this HHRA, if groundwater were used in future residential buildings at the OU3 site, residents may be exposed while bathing/showering. The basic equations recommended by USEPA (1989; 2004) for evaluating exposures and risk via dermal contact are described in brief below.

Dermal Exposure

The dermally absorbed dose (DAD) is quantified using an equation of the following general form (USEPA 2004):

$$DAD = DA_{event} \cdot EF \cdot ED \cdot EV \cdot SA / (BW \cdot AT)$$

where:

DAD	=	Dermally absorbed dose (mg of chemical per kg of body weight per day).
DA_{event}	=	Absorbed dose per event (mg of chemical per square centimeter of skin surface area per event).
EF	=	Exposure frequency (days/year).
ED	=	Exposure duration (years).
EV	=	Event frequency (events/day).
SA	=	Surface area (cm^2).
BW	=	Body weight of the exposed person (kg).
AT	=	Averaging time (days).

Non-cancer hazard quotients

$HQ = DAD/RfD_{ABS}$ (dermal pathway; $RfD_{ABS}=RfD \cdot ABS_{GI}$)

Cancer Risk

$Risk = DAD \cdot SF_{ABS}$ (dermal pathway; $SF_{ABS} = SF/ABS_{GI}$)

Using the exposure parameters for a resident, dermal cancer risks and non-cancer HQ values were calculated for antimony as an example, assuming an arbitrary water concentration. The (dermal/ingestion) ratio between the non-cancer HQs for antimony is 8E-05 (0.01%). These findings support designating the dermal pathway for groundwater exposures to hypothetical future commercial workers as minor for the purposes of this assessment.

UCL Statistics for Data Sets with Non-Detects

User Selected Options	
Date/Time of Computation	ProUCL 5.15/10/2021 11:12:03 AM
From File	OU3 ProUCL Input 05.07.2021.xls
Full Precision	OFF
Confidence Coefficient	95%
Number of Bootstrap Operations	2000

1,4-Dichlorobenzene (nfmw10)

General Statistics

Total Number of Observations	9	Number of Distinct Observations	7
Number of Detects	0	Number of Non-Detects	9
Number of Distinct Detects	0	Number of Distinct Non-Detects	7

Warning: All observations are Non-Detects (NDs), therefore all statistics and estimates should also be NDs!

Specifically, sample mean, UCLs, UPLs, and other statistics are also NDs lying below the largest detection limit!

The Project Team may decide to use alternative site specific values to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable 1,4-Dichlorobenzene (nfmw10) was not processed!

1,4-Dichlorobenzene (nfmw11)

General Statistics

Total Number of Observations	2	Number of Distinct Observations	2
Number of Detects	0	Number of Non-Detects	2
Number of Distinct Detects	0	Number of Distinct Non-Detects	2

Warning: This data set only has 2 observations!

Data set is too small to compute reliable and meaningful statistics and estimates!

The data set for variable 1,4-Dichlorobenzene (nfmw11) was not processed!

It is suggested to collect at least 8 to 10 observations before using these statistical methods!

If possible, compute and collect Data Quality Objectives (DQO) based sample size and analytical results.

1,4-Dichlorobenzene (nfmw19)

General Statistics

Total Number of Observations	4	Number of Distinct Observations	2
Number of Detects	0	Number of Non-Detects	4
Number of Distinct Detects	0	Number of Distinct Non-Detects	2

Warning: All observations are Non-Detects (NDs), therefore all statistics and estimates should also be NDs!

Specifically, sample mean, UCLs, UPLs, and other statistics are also NDs lying below the largest detection limit!

The Project Team may decide to use alternative site specific values to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable 1,4-Dichlorobenzene (nfmw19) was not processed!

66												
67	**Note: Sample size is small (e.g., <10), if data are collected using ISM approach, you should use**											
68	**guidance provided in ITRC Tech Reg Guide on ISM (ITRC, 2012) to compute statistics of interest.**											
69	**For example, you may want to use Chebyshev UCL to estimate EPC (ITRC, 2012).**											
70	**Chebyshev UCL can be computed using the Nonparametric and All UCL Options of ProUCL 5.1**											
71												
72	**Normal GOF Test on Detects Only**											
73	Shapiro Wilk Test Statistic					0.971	**Shapiro Wilk GOF Test**					
74	5% Shapiro Wilk Critical Value					0.748	Detected Data appear Normal at 5% Significance Level					
75	Lilliefors Test Statistic					0.23	**Lilliefors GOF Test**					
76	5% Lilliefors Critical Value					0.375	Detected Data appear Normal at 5% Significance Level					
77	**Detected Data appear Normal at 5% Significance Level**											
78												
79	**Kaplan-Meier (KM) Statistics using Normal Critical Values and other Nonparametric UCLs**											
80	KM Mean					0.547	KM Standard Error of Mean					0.158
81	KM SD					0.34	95% KM (BCA) UCL					N/A
82	95% KM (t) UCL					0.855	95% KM (Percentile Bootstrap) UCL					N/A
83	95% KM (z) UCL					0.808	95% KM Bootstrap t UCL					N/A
84	90% KM Chebyshev UCL					1.022	95% KM Chebyshev UCL					1.237
85	97.5% KM Chebyshev UCL					1.536	99% KM Chebyshev UCL					2.122
86												
87	**Gamma GOF Tests on Detected Observations Only**											
88	A-D Test Statistic					0.296	**Anderson-Darling GOF Test**					
89	5% A-D Critical Value					0.657	Detected data appear Gamma Distributed at 5% Significance Level					
90	K-S Test Statistic					0.26	**Kolmogorov-Smirnov GOF**					
91	5% K-S Critical Value					0.394	Detected data appear Gamma Distributed at 5% Significance Level					
92	**Detected data appear Gamma Distributed at 5% Significance Level**											
93												
94	**Gamma Statistics on Detected Data Only**											
95	k hat (MLE)					17.52	k star (bias corrected MLE)					4.548
96	Theta hat (MLE)					0.0445	Theta star (bias corrected MLE)					0.172
97	nu hat (MLE)					140.2	nu star (bias corrected)					36.38
98	Mean (detects)					0.78						
99												
100	**Gamma ROS Statistics using Imputed Non-Detects**											
101	GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs											
102	GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)											
103	For such situations, GROS method may yield incorrect values of UCLs and BTVs											
104	This is especially true when the sample size is small.											
105	For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates											

106					Minimum	0.404					Mean	0.644

349												
350	**Note: Sample size is small (e.g., <10), if data are collected using ISM approach, you should use**											
351	**guidance provided in ITRC Tech Reg Guide on ISM (ITRC, 2012) to compute statistics of interest.**											
352	**For example, you may want to use Chebyshev UCL to estimate EPC (ITRC, 2012).**											
353	**Chebyshev UCL can be computed using the Nonparametric and All UCL Options of ProUCL 5.1**											
354												
355	**Normal GOF Test on Detects Only**											
356						Shapiro Wilk Test Statistic	0.982				**Shapiro Wilk GOF Test**	
357						5% Shapiro Wilk Critical Value	0.788				Detected Data appear Normal at 5% Significance Level	
358						Lilliefors Test Statistic	0.131				**Lilliefors GOF Test**	
359						5% Lilliefors Critical Value	0.325				Detected Data appear Normal at 5% Significance Level	
360	**Detected Data appear Normal at 5% Significance Level**											
361												
362	**Kaplan-Meier (KM) Statistics using Normal Critical Values and other Nonparametric UCLs**											
363						KM Mean	0.835				KM Standard Error of Mean	0.238
364						KM SD	0.647				95% KM (BCA) UCL	1.262
365						95% KM (t) UCL	1.277				95% KM (Percentile Bootstrap) UCL	1.228
366						95% KM (z) UCL	1.226				95% KM Bootstrap t UCL	1.257
367						90% KM Chebyshev UCL	1.548				95% KM Chebyshev UCL	1.872
368						97.5% KM Chebyshev UCL	2.321				99% KM Chebyshev UCL	3.202
369												

370	**Gamma GOF Tests on Detected Observations Only**											
371					A-D Test Statistic	0.153	**Anderson-Darling GOF Test**					
372					5% A-D Critical Value	0.701	Detected data appear Gamma Distributed at 5% Significance Level					
373					K-S Test Statistic	0.125	**Kolmogorov-Smirnov GOF**					
374					5% K-S Critical Value	0.334	Detected data appear Gamma Distributed at 5% Significance Level					
375	**Detected data appear Gamma Distributed at 5% Significance Level**											
376												
377	**Gamma Statistics on Detected Data Only**											
378					k hat (MLE)	3.473	k star (bias corrected MLE)	1.848				
379					Theta hat (MLE)	0.329	Theta star (bias corrected MLE)	0.619				
380					nu hat (MLE)	41.68	nu star (bias corrected)	22.17				
381					Mean (detects)	1.143						
382												
383	**Gamma ROS Statistics using Imputed Non-Detects**											
384	GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs											
385	GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)											
386	For such situations, GROS method may yield incorrect values of UCLs and BTVs											
387	This is especially true when the sample size is small.											
388	For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates											
389					Minimum	0.01	Mean	0.788				
390					Maximum	2.1	Median	0.65				
391					SD	0.733	CV	0.929

UCL Statistics for Data Sets with Non-Detects

User Selected Options	
Date/Time of Computation	ProUCL 5.15/7/2021 12:35:54 PM
From File	OU3 ProUCL Input 05.07.2021.xls
Full Precision	OFF
Confidence Coefficient	95%
Number of Bootstrap Operations	2000

Aroclor-1260 (atmw6)

General Statistics

Total Number of Observations	1	Number of Distinct Observations	1
Number of Detects	0	Number of Non-Detects	1
Number of Distinct Detects	0	Number of Distinct Non-Detects	1

Warning: This data set only has 1 observations!

Data set is too small to compute reliable and meaningful statistics and estimates!

The data set for variable Aroclor-1260 (atmw6) was not processed!

It is suggested to collect at least 8 to 10 observations before using these statistical methods!

If possible, compute and collect Data Quality Objectives (DQO) based sample size and analytical results.

Aroclor-1260 (nfmw10)

General Statistics

Total Number of Observations	7	Number of Distinct Observations	5
Number of Detects	0	Number of Non-Detects	7
Number of Distinct Detects	0	Number of Distinct Non-Detects	5

Warning: All observations are Non-Detects (NDs), therefore all statistics and estimates should also be NDs!

Specifically, sample mean, UCLs, UPLs, and other statistics are also NDs lying below the largest detection limit!

The Project Team may decide to use alternative site specific values to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable Aroclor-1260 (nfmw10) was not processed!

Aroclor-1260 (nfmw11)

General Statistics

Total Number of Observations	2	Number of Distinct Observations	2
Number of Detects	0	Number of Non-Detects	2
Number of Distinct Detects	0	Number of Distinct Non-Detects	2

Warning: This data set only has 2 observations!

Data set is too small to compute reliable and meaningful statistics and estimates!

The data set for variable Aroclor-1260 (nfmw11) was not processed!

It is suggested to collect at least 8 to 10 observations before using these statistical methods!

If possible, compute and collect Data Quality Objectives (DQO) based sample size and analytical results.

107					Skewness Detects	1.319					Kurtosis Detects	N/A
108					Mean of Logged Detects	-2.041					SD of Logged Detects	0.832
109												
110					**Warning: Data set has only 3 Detected Values.**							
111					**This is not enough to compute meaningful or reliable statistics and estimates.**							
112												
113												
114					**Note: Sample size is small (e.g., <10), if data are collected using ISM approach, you should use**							
115					**guidance provided in ITRC Tech Reg Guide on ISM (ITRC, 2012) to compute statistics of interest.**							
116					**For example, you may want to use Chebyshev UCL to estimate EPC (ITRC, 2012).**							
117					**Chebyshev UCL can be computed using the Nonparametric and All UCL Options of ProUCL 5.1**							
118												
119					**Normal GOF Test on Detects Only**							
120					Shapiro Wilk Test Statistic	0.919	**Shapiro Wilk GOF Test**					
121					5% Shapiro Wilk Critical Value	0.767	Detected Data appear Normal at 5% Significance Level					
122					Lilliefors Test Statistic	0.295	**Lilliefors GOF Test**					
123					5% Lilliefors Critical Value	0.425	Detected Data appear Normal at 5% Significance Level					
124					**Detected Data appear Normal at 5% Significance Level**							
125												
126					**Kaplan-Meier (KM) Statistics using Normal Critical Values and other Nonparametric UCLs**							
127					KM Mean	0.0777	KM Standard Error of Mean	0.0352				
128					KM SD	0.0863	95% KM (BCA) UCL	N/A				
129					95% KM (t) UCL	0.143	95% KM (Percentile Bootstrap) UCL	N/A				
130					95% KM (z) UCL	0.136	95% KM Bootstrap t UCL	N/A				
131					90% KM Chebyshev UCL	0.183	95% KM Chebyshev UCL	0.231				
132					97.5% KM Chebyshev UCL	0.298	99% KM Chebyshev UCL	0.428				
133												
134					**Gamma GOF Tests on Detected Observations Only**							
135					**Not Enough Data to Perform GOF Test**							
136												
137					**Gamma Statistics on Detected Data Only**							
138					k hat (MLE)	2.36	k star (bias corrected MLE)	N/A				
139					Theta hat (MLE)	0.0691	Theta star (bias corrected MLE)	N/A				
140					nu hat (MLE)	14.16	nu star (bias corrected)	N/A				
141					Mean (detects)	0.163						
142												
143					**Gamma ROS Statistics using Imputed Non-Detects**							
144					GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs							
145					GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)							
146					For such situations, GROS method may yield incorrect values of UCLs and BTVs							
147					This is especially true when the sample size is small.							
148					For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates							
149					Minimum	0.01	Mean	0.061				
150					Maximum	0.31	Median	0.01				
151					SD	0.101	CV	1.65				
152					k hat (MLE)	0.642	k star (bias corrected MLE)	0.502				
153					Theta hat (MLE)	0.0951	Theta star (bias corrected MLE)	0.122				
154					nu hat (MLE)	11.55	nu star (bias corrected)	9.034				
155					Adjusted Level of Significance (β)	0.0231						
156					Approximate Chi Square Value (9.03, α)	3.348	Adjusted Chi Square Value (9.03, β)	2.66

UCL Statistics for Data Sets with Non-Detects

User Selected Options	
Date/Time of Computation	ProUCL 5.15/10/2021 11:12:47 AM
From File	OU3 ProUCL Input 05.07.2021.xls
Full Precision	OFF
Confidence Coefficient	95%
Number of Bootstrap Operations	2000

Benzene (nfmw10)

General Statistics

Total Number of Observations	8	Number of Distinct Observations	6
Number of Detects	0	Number of Non-Detects	8
Number of Distinct Detects	0	Number of Distinct Non-Detects	6

Warning: All observations are Non-Detects (NDs), therefore all statistics and estimates should also be NDs!

Specifically, sample mean, UCLs, UPLs, and other statistics are also NDs lying below the largest detection limit!

The Project Team may decide to use alternative site specific values to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable Benzene (nfmw10) was not processed!

Benzene (nfmw11)

General Statistics

Total Number of Observations	2	Number of Distinct Observations	2
Number of Detects	0	Number of Non-Detects	2
Number of Distinct Detects	0	Number of Distinct Non-Detects	2

Warning: This data set only has 2 observations!

Data set is too small to compute reliable and meaningful statistics and estimates!

The data set for variable Benzene (nfmw11) was not processed!

It is suggested to collect at least 8 to 10 observations before using these statistical methods!

If possible, compute and collect Data Quality Objectives (DQO) based sample size and analytical results.

Benzene (nfmw19)

General Statistics

Total Number of Observations	4	Number of Distinct Observations	2
Number of Detects	0	Number of Non-Detects	4
Number of Distinct Detects	0	Number of Distinct Non-Detects	2

Warning: All observations are Non-Detects (NDs), therefore all statistics and estimates should also be NDs!

Specifically, sample mean, UCLs, UPLs, and other statistics are also NDs lying below the largest detection limit!

The Project Team may decide to use alternative site specific values to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable Benzene (nfmw19) was not processed!

UCL Statistics for Data Sets with Non-Detects

User Selected Options	
Date/Time of Computation	ProUCL 5.15/10/2021 11:13:20 AM
From File	OU3 ProUCL Input 05.07.2021.xls
Full Precision	OFF
Confidence Coefficient	95%
Number of Bootstrap Operations	2000

Chlorobenzene (nfmw10)

General Statistics

Total Number of Observations	8	Number of Distinct Observations	6
Number of Detects	0	Number of Non-Detects	8
Number of Distinct Detects	0	Number of Distinct Non-Detects	6

Warning: All observations are Non-Detects (NDs), therefore all statistics and estimates should also be NDs!

Specifically, sample mean, UCLs, UPLs, and other statistics are also NDs lying below the largest detection limit!

The Project Team may decide to use alternative site specific values to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable Chlorobenzene (nfmw10) was not processed!

Chlorobenzene (nfmw11)

General Statistics

Total Number of Observations	2	Number of Distinct Observations	2
Number of Detects	0	Number of Non-Detects	2
Number of Distinct Detects	0	Number of Distinct Non-Detects	2

Warning: This data set only has 2 observations!

Data set is too small to compute reliable and meaningful statistics and estimates!

The data set for variable Chlorobenzene (nfmw11) was not processed!

It is suggested to collect at least 8 to 10 observations before using these statistical methods!

If possible, compute and collect Data Quality Objectives (DQO) based sample size and analytical results.

Chlorobenzene (nfmw19)

General Statistics

Total Number of Observations	4	Number of Distinct Observations	2
Number of Detects	0	Number of Non-Detects	4
Number of Distinct Detects	0	Number of Distinct Non-Detects	2

Warning: All observations are Non-Detects (NDs), therefore all statistics and estimates should also be NDs!

Specifically, sample mean, UCLs, UPLs, and other statistics are also NDs lying below the largest detection limit!

The Project Team may decide to use alternative site specific values to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable Chlorobenzene (nfmw19) was not processed!

444	**Suggested UCL to Use**											
445					95% Student's-t UCL	104.2						
446												
447	Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.											
448	Recommendations are based upon data size, data distribution, and skewness.											
449	These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).											
450	However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

UCL Statistics for Data Sets with Non-Detects

User Selected Options	
Date/Time of Computation	ProUCL 5.15/7/2021 12:32:59 PM
From File	OU3 ProUCL Input 05.07.2021.xls
Full Precision	OFF
Confidence Coefficient	95%
Number of Bootstrap Operations	2000

TEQ-ND=1/2DL (atmw6)

General Statistics

Total Number of Observations	8	Number of Distinct Observations	8
		Number of Missing Observations	0
Minimum	1.0777E-6	Mean	1.8151E-6
Maximum	2.8130E-6	Median	1.7609E-6
SD	5.5618E-7	Std. Error of Mean	1.9664E-7
Coefficient of Variation	N/A	Skewness	0.742

Note: Sample size is small (e.g., <10), if data are collected using ISM approach, you should use guidance provided in ITRC Tech Reg Guide on ISM (ITRC, 2012) to compute statistics of interest. For example, you may want to use Chebyshev UCL to estimate EPC (ITRC, 2012). Chebyshev UCL can be computed using the Nonparametric and All UCL Options of ProUCL 5.1

Normal GOF Test

Shapiro Wilk Test Statistic	0.947	**Shapiro Wilk GOF Test**
5% Shapiro Wilk Critical Value	0.818	Data appear Normal at 5% Significance Level
Lilliefors Test Statistic	0.232	**Lilliefors GOF Test**
5% Lilliefors Critical Value	0.283	Data appear Normal at 5% Significance Level

Data appear Normal at 5% Significance Level

Assuming Normal Distribution

95% Normal UCL		**95% UCLs (Adjusted for Skewness)**	
95% Student's-t UCL	2.1877E-6	95% Adjusted-CLT UCL (Chen-1995)	2.1937E-6
		95% Modified-t UCL (Johnson-1978)	2.1963E-6

Gamma GOF Test

A-D Test Statistic	0.216	**Anderson-Darling Gamma GOF Test**
5% A-D Critical Value	0.715	Detected data appear Gamma Distributed at 5% Significance Level
K-S Test Statistic	0.193	**Kolmogorov-Smirnov Gamma GOF Test**
5% K-S Critical Value	0.294	Detected data appear Gamma Distributed at 5% Significance Level

Detected data appear Gamma Distributed at 5% Significance Level

Gamma Statistics

k hat (MLE)	12.64	k star (bias corrected MLE)	7.985
Theta hat (MLE)	1.4358E-7	Theta star (bias corrected MLE)	2.2732E-7

83	**Suggested UCL to Use**											
84	95% Student's-t UCL				2.19E-06							
85												
86	Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.											
87	Recommendations are based upon data size, data distribution, and skewness.											
88	These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).											
89	However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

UCL Statistics for Data Sets with Non-Detects

User Selected Options	
Date/Time of Computation	ProUCL 5.15/10/2021 10:37:12 AM
From File	OU3 ProUCL Input 05.07.2021.xls
Full Precision	OFF
Confidence Coefficient	95%
Number of Bootstrap Operations	2000

Aluminum (atmw6)

General Statistics

Total Number of Observations	9	Number of Distinct Observations	9
		Number of Missing Observations	0
Minimum	57	Mean	208
Maximum	480	Median	161
SD	156.6	Std. Error of Mean	52.21
Coefficient of Variation	0.753	Skewness	1.175

Note: Sample size is small (e.g., <10), if data are collected using ISM approach, you should use guidance provided in ITRC Tech Reg Guide on ISM (ITRC, 2012) to compute statistics of interest. For example, you may want to use Chebyshev UCL to estimate EPC (ITRC, 2012). Chebyshev UCL can be computed using the Nonparametric and All UCL Options of ProUCL 5.1

Normal GOF Test

Shapiro Wilk Test Statistic	0.82	**Shapiro Wilk GOF Test**
5% Shapiro Wilk Critical Value	0.829	Data Not Normal at 5% Significance Level
Lilliefors Test Statistic	0.247	**Lilliefors GOF Test**
5% Lilliefors Critical Value	0.274	Data appear Normal at 5% Significance Level

Data appear Approximate Normal at 5% Significance Level

Assuming Normal Distribution

95% Normal UCL		**95% UCLs (Adjusted for Skewness)**	
95% Student's-t UCL	305	95% Adjusted-CLT UCL (Chen-1995)	315.7
		95% Modified-t UCL (Johnson-1978)	308.5

Gamma GOF Test

A-D Test Statistic	0.358	**Anderson-Darling Gamma GOF Test**
5% A-D Critical Value	0.729	Detected data appear Gamma Distributed at 5% Significance Level
K-S Test Statistic	0.163	**Kolmogorov-Smirnov Gamma GOF Test**
5% K-S Critical Value	0.282	Detected data appear Gamma Distributed at 5% Significance Level

Detected data appear Gamma Distributed at 5% Significance Level

Gamma Statistics

k hat (MLE)	2.241	k star (bias corrected MLE)	1.568
Theta hat (MLE)	92.81	Theta star (bias corrected MLE)	132.6

85												
86	When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test											
87	When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL											
88												
89	Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.											
90	Recommendations are based upon data size, data distribution, and skewness.											
91	These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).											
92	However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

2021					Mean (detects)	85.56						
2022												
2023	**Gamma ROS Statistics using Imputed Non-Detects**											
2024	GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs											
2025	GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)											
2026	For such situations, GROS method may yield incorrect values of UCLs and BTVs											
2027	This is especially true when the sample size is small.											
2028	For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

UCL Statistics for Data Sets with Non-Detects

User Selected Options	
Date/Time of Computation	ProUCL 5.15/10/2021 10:40:46 AM
From File	OU3 ProUCL Input 05.07.2021.xls
Full Precision	OFF
Confidence Coefficient	95%
Number of Bootstrap Operations	2000

Antimony (atmw6)

General Statistics

Total Number of Observations	9	Number of Distinct Observations	9
Number of Detects	2	Number of Non-Detects	7
Number of Distinct Detects	2	Number of Distinct Non-Detects	7
Minimum Detect	0.26	Minimum Non-Detect	0.11
Maximum Detect	0.46	Maximum Non-Detect	0.38
Variance Detects	0.02	Percent Non-Detects	77.78%
Mean Detects	0.36	SD Detects	0.141
Median Detects	0.36	CV Detects	0.393
Skewness Detects	N/A	Kurtosis Detects	N/A
Mean of Logged Detects	-1.062	SD of Logged Detects	0.403

Warning: Data set has only 2 Detected Values.

This is not enough to compute meaningful or reliable statistics and estimates.

Note: Sample size is small (e.g., <10), if data are collected using ISM approach, you should use guidance provided in ITRC Tech Reg Guide on ISM (ITRC, 2012) to compute statistics of interest. For example, you may want to use Chebyshev UCL to estimate EPC (ITRC, 2012). Chebyshev UCL can be computed using the Nonparametric and All UCL Options of ProUCL 5.1

Normal GOF Test on Detects Only

150												
151	**Gamma ROS Statistics using Imputed Non-Detects**											
152	GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs											
153	GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)											
154	For such situations, GROS method may yield incorrect values of UCLs and BTVs											
155	This is especially true when the sample size is small.											
156	For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

3209					**Suggested UCL to Use**							
3210					95% KM (t) UCL	0.296					KM H-UCL	0.269
3211					95% KM (BCA) UCL	N/A						
3212					**Warning: One or more Recommended UCL(s) not available!**							
3213												
3214					Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.							
3215					Recommendations are based upon data size, data distribution, and skewness.							
3216					These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).							
3217					However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.							
3218												
3219												
3220	**Antimony (waste water clarifier well)**											
3221												
3222					**General Statistics**							
3223					Total Number of Observations	1					Number of Distinct Observations	1
3224											Number of Missing Observations	0

	A	B	C	D	E	F	G	H	I	J	K	L
3225					Minimum	0.82					Mean	0.82
3226					Maximum	0.82					Median	0.82
3227												
3228	Warning: This data set only has 1 observations!											
3229	Data set is too small to compute reliable and meaningful statistics and estimates!											
3230	The data set for variable Antimony (waste water clarifier well) was not processed!											
3231												
3232	It is suggested to collect at least 8 to 10 observations before using these statistical methods!											
3233	If possible, compute and collect Data Quality Objectives (DQO) based sample size and analytical results.

UCL Statistics for Data Sets with Non-Detects

User Selected Options	
Date/Time of Computation	ProUCL 5.15/10/2021 10:43:47 AM
From File	OU3 ProUCL Input 05.07.2021.xls
Full Precision	OFF
Confidence Coefficient	95%
Number of Bootstrap Operations	2000

Arsenic (atmw6)

General Statistics

Total Number of Observations	9	Number of Distinct Observations	9
		Number of Missing Observations	0
Minimum	3.8	Mean	6.544
Maximum	11.1	Median	6.3
SD	2.635	Std. Error of Mean	0.878
Coefficient of Variation	0.403	Skewness	0.866

Note: Sample size is small (e.g., <10), if data are collected using ISM approach, you should use guidance provided in ITRC Tech Reg Guide on ISM (ITRC, 2012) to compute statistics of interest. For example, you may want to use Chebyshev UCL to estimate EPC (ITRC, 2012). Chebyshev UCL can be computed using the Nonparametric and All UCL Options of ProUCL 5.1

Normal GOF Test

Shapiro Wilk Test Statistic	0.881	**Shapiro Wilk GOF Test**	
5% Shapiro Wilk Critical Value	0.829	Data appear Normal at 5% Significance Level	
Lilliefors Test Statistic	0.209	**Lilliefors GOF Test**	
5% Lilliefors Critical Value	0.274	Data appear Normal at 5% Significance Level	

Data appear Normal at 5% Significance Level

Assuming Normal Distribution

95% Normal UCL		**95% UCLs (Adjusted for Skewness)**	
95% Student's-t UCL	8.178	95% Adjusted-CLT UCL (Chen-1995)	8.26
		95% Modified-t UCL (Johnson-1978)	8.22

Gamma GOF Test

A-D Test Statistic	0.367	**Anderson-Darling Gamma GOF Test**	
5% A-D Critical Value	0.722	Detected data appear Gamma Distributed at 5% Significance Level	
K-S Test Statistic	0.162	**Kolmogorov-Smirnov Gamma GOF Test**	
5% K-S Critical Value	0.28	Detected data appear Gamma Distributed at 5% Significance Level	

Detected data appear Gamma Distributed at 5% Significance Level

UCL Statistics for Data Sets with Non-Detects

User Selected Options	
Date/Time of Computation	ProUCL 5.15/10/2021 10:46:53 AM
From File	OU3 ProUCL Input 05.07.2021.xls
Full Precision	OFF
Confidence Coefficient	95%
Number of Bootstrap Operations	2000

Barium (atmw6)

General Statistics

Total Number of Observations	9	Number of Distinct Observations	9
		Number of Missing Observations	0
Minimum	57.2	Mean	81.13
Maximum	113	Median	79.1
SD	16.46	Std. Error of Mean	5.487
Coefficient of Variation	0.203	Skewness	0.66

Note: Sample size is small (e.g., <10), if data are collected using ISM approach, you should use guidance provided in ITRC Tech Reg Guide on ISM (ITRC, 2012) to compute statistics of interest. For example, you may want to use Chebyshev UCL to estimate EPC (ITRC, 2012). Chebyshev UCL can be computed using the Nonparametric and All UCL Options of ProUCL 5.1

Normal GOF Test

Shapiro Wilk Test Statistic	0.971	**Shapiro Wilk GOF Test**
5% Shapiro Wilk Critical Value	0.829	Data appear Normal at 5% Significance Level
Lilliefors Test Statistic	0.125	**Lilliefors GOF Test**
5% Lilliefors Critical Value	0.274	Data appear Normal at 5% Significance Level

Data appear Normal at 5% Significance Level

Assuming Normal Distribution

95% Normal UCL		95% UCLs (Adjusted for Skewness)	
95% Student's-t UCL	91.34	95% Adjusted-CLT UCL (Chen-1995)	91.45
		95% Modified-t UCL (Johnson-1978)	91.54

Gamma GOF Test

A-D Test Statistic	0.152	**Anderson-Darling Gamma GOF Test**
5% A-D Critical Value	0.721	Detected data appear Gamma Distributed at 5% Significance Level
K-S Test Statistic	0.122	**Kolmogorov-Smirnov Gamma GOF Test**
5% K-S Critical Value	0.279	Detected data appear Gamma Distributed at 5% Significance Level

Detected data appear Gamma Distributed at 5% Significance Level

Gamma Statistics

k hat (MLE)	28.17	k star (bias corrected MLE)	18.85
Theta hat (MLE)	2.881	Theta star (bias corrected MLE)	4.304
nu hat (MLE)	507	nu star (bias corrected)	339.3
MLE Mean (bias corrected)	81.13	MLE Sd (bias corrected)	18.69
		Approximate Chi Square Value (0.05)	297.6
Adjusted Level of Significance	0.0231	Adjusted Chi Square Value	289.4

Assuming Gamma Distribution

95% Approximate Gamma UCL (use when n>=50))	92.5	95% Adjusted Gamma UCL (use when n<50)	95.13

UCL Statistics for Data Sets with Non-Detects

User Selected Options	
Date/Time of Computation	ProUCL 5.15/10/2021 11:10:39 AM
From File	OU3 ProUCL Input 05.07.2021.xls
Full Precision	OFF
Confidence Coefficient	95%
Number of Bootstrap Operations	2000

Beryllium (atmw6)

General Statistics

Total Number of Observations	8	Number of Distinct Observations	4
Number of Detects	0	Number of Non-Detects	8
Number of Distinct Detects	0	Number of Distinct Non-Detects	4

Warning: All observations are Non-Detects (NDs), therefore all statistics and estimates should also be NDs!

Specifically, sample mean, UCLs, UPLs, and other statistics are also NDs lying below the largest detection limit!

The Project Team may decide to use alternative site specific values to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable Beryllium (atmw6) was not processed!

Beryllium (nfmw10)

General Statistics

Total Number of Observations	7	Number of Distinct Observations	5
Number of Detects	1	Number of Non-Detects	6
Number of Distinct Detects	1	Number of Distinct Non-Detects	4

Warning: Only one distinct data value was detected! ProUCL (or any other software) should not be used on such a data set!

It is suggested to use alternative site specific values determined by the Project Team to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable Beryllium (nfmw10) was not processed!

Beryllium (nfmw11)

General Statistics

Total Number of Observations	7	Number of Distinct Observations	5
Number of Detects	0	Number of Non-Detects	7
Number of Distinct Detects	0	Number of Distinct Non-Detects	5

Warning: All observations are Non-Detects (NDs), therefore all statistics and estimates should also be NDs!

Specifically, sample mean, UCLs, UPLs, and other statistics are also NDs lying below the largest detection limit!

The Project Team may decide to use alternative site specific values to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable Beryllium (nfmw11) was not processed!

Beryllium (nfmw12)

UCL Statistics for Data Sets with Non-Detects

User Selected Options	
Date/Time of Computation	ProUCL 5.15/10/2021 10:48:55 AM
From File	OU3 ProUCL Input 05.07.2021.xls
Full Precision	OFF
Confidence Coefficient	95%
Number of Bootstrap Operations	2000

Cadmium (atmw6)

General Statistics

Total Number of Observations	9	Number of Distinct Observations	6
Number of Detects	3	Number of Non-Detects	6
Number of Distinct Detects	3	Number of Distinct Non-Detects	3
Minimum Detect	0.044	Minimum Non-Detect	0.03
Maximum Detect	0.074	Maximum Non-Detect	0.14
Variance Detects	2.8133E-4	Percent Non-Detects	66.67%
Mean Detects	0.0547	SD Detects	0.0168
Median Detects	0.046	CV Detects	0.307
Skewness Detects	1.704	Kurtosis Detects	N/A
Mean of Logged Detects	-2.935	SD of Logged Detects	0.288

Warning: Data set has only 3 Detected Values.

This is not enough to compute meaningful or reliable statistics and estimates.

Note: Sample size is small (e.g., <10), if data are collected using ISM approach, you should use

guidance provided in ITRC Tech Reg Guide on ISM (ITRC, 2012) to compute statistics of interest.

For example, you may want to use Chebyshev UCL to estimate EPC (ITRC, 2012).

Chebyshev UCL can be computed using the Nonparametric and All UCL Options of ProUCL 5.1

Normal GOF Test on Detects Only

Shapiro Wilk Test Statistic	0.8	**Shapiro Wilk GOF Test**	
5% Shapiro Wilk Critical Value	0.767	Detected Data appear Normal at 5% Significance Level	
Lilliefors Test Statistic	0.364	**Lilliefors GOF Test**	
5% Lilliefors Critical Value	0.425	Detected Data appear Normal at 5% Significance Level	

Detected Data appear Normal at 5% Significance Level

Kaplan-Meier (KM) Statistics using Normal Critical Values and other Nonparametric UCLs

KM Mean	0.0393	KM Standard Error of Mean	0.00632
KM SD	0.0146	95% KM (BCA) UCL	N/A
95% KM (t) UCL	0.051	95% KM (Percentile Bootstrap) UCL	N/A
95% KM (z) UCL	0.0496	95% KM Bootstrap t UCL	N/A
90% KM Chebyshev UCL	0.0582	95% KM Chebyshev UCL	0.0668
97.5% KM Chebyshev UCL	0.0787	99% KM Chebyshev UCL	0.102

Gamma GOF Tests on Detected Observations Only

Not Enough Data to Perform GOF Test

Gamma Statistics on Detected Data Only

k hat (MLE)	17.43	k star (bias corrected MLE)	N/A

53					Theta hat (MLE)	0.00314				Theta star (bias corrected MLE)		N/A
54					nu hat (MLE)	104.6				nu star (bias corrected)		N/A
55					Mean (detects)	0.0547						
56												
57					**Gamma ROS Statistics using Imputed Non-Detects**							
58					GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs							
59					GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)							
60					For such situations, GROS method may yield incorrect values of UCLs and BTVs							
61					This is especially true when the sample size is small.							
62					For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates							
63					Minimum	0.01				Mean		0.0266
64					Maximum	0.074				Median		0.0178
65					SD	0.0229				CV		0.858

302			Maximum Detect			0.16		Maximum Non-Detect				0.54
303			Variance Detects			0.00306		Percent Non-Detects				42.86%
304			Mean Detects			0.0775		SD Detects				0.0553
305			Median Detects			0.053		CV Detects				0.714
306			Skewness Detects			1.933		Kurtosis Detects				3.764
307			Mean of Logged Detects			-2.71		SD of Logged Detects				0.596
308												
309						Note: Sample size is small (e.g., <10), if data are collected using ISM approach, you should use						
310						guidance provided in ITRC Tech Reg Guide on ISM (ITRC, 2012) to compute statistics of interest.						
311						For example, you may want to use Chebyshev UCL to estimate EPC (ITRC, 2012).						
312						Chebyshev UCL can be computed using the Nonparametric and All UCL Options of ProUCL 5.1

340					Mean (detects)	0.0775						
341												
342	**Gamma ROS Statistics using Imputed Non-Detects**											
343	GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs											
344	GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)											
345	For such situations, GROS method may yield incorrect values of UCLs and BTVs											
346	This is especially true when the sample size is small.											
347	For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates											
348					Minimum	0.044			Mean	0.0705
