** Appendix B Cost Adjustment Factors

This appendix provides information on how to calculate and apply cost adjustment factors, including those for escalation, area cost, and health and safety productivity.

Escalation

Costs that have been derived from sources that are one year old or more should be updated or escalated to the base year. This can be done using the following equation:

$$C_b = C_o(F_b/F_o)$$

where C_b is the base year or current cost, C_o is the old cost, F_b is the base year or current index factor, and F_o is the index factor for the old cost.

Escalation indexes are available from both private and public sources. Most are published on a monthly or annual basis. An example index is Engineering News Record's (ENR) building cost index, which is based on a 20-city average of labor rates for bricklayers, carpenters, and iron workers plus material costs for structural steel, portland cement, and lumber using a certain number of labor hours and material quantity. Monthly factors for this index, from January 1978 to July 2000, are shown in Exhibit B-1. The index is also available at http://www.enr.com/cost/costbci.asp.

Area Cost Factors

Costs that are based on national averages or on geographic locations other than the site should be adjusted for location using area cost factors (ACFs). This can be done using the following equation:

$$C_s = C_o(F_s/F_o)$$

where C_s is the cost for the site location, C_o is the cost based on other location, F_s is the area cost factor for the site, and F_o is the area cost factor for other location.

ACFs are available from both private and public sources. Most are updated yearly for their publication. National and state averages for ACFs (current as of March 10, 2000), as maintained by the USACE for military construction use, are provided in Exhibit B-2 below, as an example. These factors are based on local construction costs of labor, material, and equipment, and other factors such as weather, climate, seismic, mobilization, overhead and profit, labor availability, and labor productivity. The most current ACFs can be downloaded through the USACE Cost Engineering Branch website at http://www.hq.usace.army.mil/cemp/e/es/pax/321/321.pdf.

Exhibit B-2 USACF Area Cost Fa	ctors as of March 10, 2	000

Mississippi	0.87	Wyoming	0.99
Missouri	0.97	Washington, D.C.	0.95
Montana	1.13	National Average	1.00

Health and Safety Productivity

Unless effects are already accounted for, factors that reflect decreased productivity due to required health and safety levels of protection should be applied to costs for labor and construction equipment used in a crew makeup. The levels of protection, which are determined based on the hazards to workers that might be present at a hazardous waste site, are classified as follows:

- ♦ Level A: Fully encapsulating vapor-tight suit with full-facepiece, self-contained breathing apparatus (SCBA) or supplied-air respirator.
- ◆ Level B: Totally encapsulating suit, not necessarily vapor-tight, with full-facepiece SCBA or supplied-air respirator.
- ♦ Level C: Chemical protective, full body suit with full-face, canister air-purifying respirator.
- ♦ Level D: Basic work uniform (i.e., coveralls, gloves, hardhat, boots, faceshield or goggles). Modified Level D adds a chemical protective, full body suit (i.e., Level C without respirator).

Factors associated with decreased productivity due to protective equipment and clothing as described above include restricted mobility, heat stress requiring break time, and time for safety meetings, suit-up, suit-down, decontamination, and air tank changes. All of these factors reduce crew production rates.

As an example, the productivity factors used by the USACE for Hazardous, Toxic, and Radioactive Waste (HTRW) projects are shown in Exhibits B-3 and B-4, for light and heavy work, respectively, as published in *Construction Cost Estimates* (USACE 1997). The factors in these exhibits are based on a productivity study conducted in 1994 and are applied to crew production rates in the Unit Price Book (UPB), which are based on "clean" site conditions, to develop adjusted rates based on the health and safety level of protection. The decreased production rate has an impact on cost by either increasing the time required to complete the activity or prompting the cost engineer to add crews.

As an approximate method (e.g., development of cost estimate during FS), the inverse of these factors can be applied to the unadjusted cost of an element to reflect decreased productivity for that item. This can be done using the following equation:

$$C_l = C_o(1/F_l)$$

where C_l is the cost for the assumed level of protection, C_o is the cost unadjusted for level of protection, and F_l is the productivity factor from Exhibit B-3 or B-4.

The productivity factors do not apply to material costs, treatment equipment costs, or other costs that do not include crew costs.

- Notes: 1. Standard Losses account for all time losses independent of temperature variations. They include safety meetings, instructions, donning / doffing PPE, decontamination, switching air supply / filters, monitoring delays, and cleanup.
 - 2. Scheduled / Heat Stress Breaks account for all paid rest periods per manday.
 - 3. Dexterity Losses are based on subjective opinions of the percentage that PPE slows down a normal worker because of factors such as discomfort, clumsiness, weight, and restricted breathing and communication. The number of minutes actually worked is reduced by the percentage representing the average response for that particular PPE level.
 - 4. Values for A, B, and C were derived by averaging the survey responses for each PPE level. Responses that varied greatly from the average were subject to omission at the author's discretion.
 - 5. Total Paid Time = 480 minutes
 - 6. 50 min delay on clean site = 10 min. safety meeting & instructions + 10 min. cleanup + 30 min. breaks

G = E / F T = Temperature Farenheit

8. Level A protection is used in extreme emergency situations only. Productivity factors for Level A should be used with caution because they were extrapolated from 2 data points.
